2-REGULARIZED NYQUIST CRITERION IN LINEAR CONTINUOUS-TIME PERIODIC SYSTEMS AND ITS IMPLEMENTATION*

JUN ZHOU† AND TOMOMICHI HAGIWARA†

Abstract. First, by using the 2-regularized determinant technique for Hilbert–Schmidt operators, the computation formula, infinite-product convergence, and analyticity of the 2-regularized determinant of the modified harmonic state operator in finite-dimensional linear continuous-time periodic (FDLCP) systems are derived in this paper. Second, based on these results, a 2-regularized Nyquist criterion is established for asymptotic stability analysis of a class of FDLCP systems for the first time. Third, a numeric implementation algorithm for the 2-regularized Nyquist criterion is also proposed via the staircase truncation on the harmonic transfer operator of the FDLCP system concerned. Finally, to illustrate the results of this paper, asymptotic stability of the lossy Mathieu differential equation is investigated.

Key words. continuous-time periodic system, Nyquist criterion, determinant of Hilbert–Schmidt operators, implementation, convergence

1. Introduction.

Stability analysis is a difficult topic in finite-dimensional linear continuous-time periodic (FDLCP) systems [3], [8], [14], [19], [27], which are encountered in many engineering applications. For instance, the flapping dynamics of helicopter rotors [7], [26] and rolling motion of ships in waves [1] can be related to FDLCP models. Other examples include robot arms moving along periodic trajectories and electromechanical oscillation in AC generators [22]. Different types of (closed-loop) stability of FDLCP systems are discussed via various methods in the literature. Absolute stability of FDLCP systems with nonlinearities satisfying integral quadratic constraints is dealt with in [16] and [28] by the cutting plane algorithm and the Hamiltonian approach, respectively, while input/output stability and Youla-style parameterization of stabilizing controllers are discussed in [6] via the graph representation theory. As for asymptotic stability analysis of FDLCP systems, the Floquet theorem [18] completes the task by testing the eigenvalues of its monodromy matrix that is hard to find. Asymptotic stability has also been examined by a Lyapunov method [4] and the harmonic analysis [31]. Perturbation methods to study stability in FDLCP systems can be found in [20]. Nyquist-type stability criteria have also been considered in the FDLCP cases; for example, two generalized Nyquist criteria are suggested in [15] and [26]. The former is an integral-operator-based Nyquist criterion, while the latter is given in terms of the Hill-determinant of the infinite-dimensional harmonic transfer operator of an FDLCP system. However, due to the infinite-dimensionality and various convergence issues in the Hill-determinant, the validity of the latter generalized Nyquist criterion [26] remains as an open problem in general situations. Similar comments also apply to the former criterion. As for integral-operator modeling of periodic systems, we refer the readers to [2] for a general idea.

A crucial observation for establishing Nyquist-type stability criteria in more general FDLCP systems is that the harmonic transfer operators of FDLCP systems are Hilbert–Schmidt operators under mild assumptions. Hence the validity of the 2-regularized determinant on the harmonic transfer operators [5] can be justified. It should be pointed out that the harmonic transfer operators do not belong to the trace class [9] in general so that the standard operator determinant cannot be validated. Thus, developing a Nyquist-type criterion based on the 2-regularized determinant technique provides us with a natural and much stronger tool in stability analysis in the FDLCP field. In connection with the usual determinant defined on trace class operators, it is worth mentioning that in sampled-data systems, which are periodic (but not included in FDLCP systems) if the signal behavior both at the sampling instants and intersamples is considered, a Nyquist criterion regarding internal stability has been recovered with the transfer operator defined via lifting technique [13] under the assumption that the transfer operator is a trace class operator.

In this paper, using the 2-regularized determinant on Hilbert–Schmidt operators, we first derive some interesting analytic properties of the 2-regularized determinant of what we call the modified harmonic state operator of an FDLCP system. These results have not been explicitly discussed in the literature to the authors' best knowledge and constitute a significant contribution to this study. Second, based on these properties, a 2-regularized Nyquist criterion is established for asymptotic stability of a class of FDLCP systems. This Nyquist criterion is necessary and sufficient, and makes it possible for us to investigate the closed-loop asymptotic stability via the open-loop FDLCP system and the 2-regularized determinant of the corresponding harmonic return difference operator, similar to what we do in the LTI (linear time-invariant) continuous-time case. In spite of the success that the criterion applies to a big class of practical FDLCP systems, however, it brings another problem. Namely, it is nontrivial to implement the criterion numerically because of the 2-regularized determinant on the infinite-dimensional harmonic return difference operator. To resolve the problem, the staircase truncation [30] is applied to the harmonic transfer operator. It is shown that under mild assumptions the truncation convergence can be ensured, and the 2-regularized Nyquist criterion can be implemented via only finite-dimensional computations to any degree of accuracy, and the truncation size can be estimated readily through simple computations.

The following is the outline of this paper. Section 2 gives preliminaries to FDLCP systems, their harmonic state operators and transfer operators, the Toeplitz transformation of periodic functions, and operator determinants. Properties about the 2-regularized determinants of the modified harmonic transfer operators are also derived. In section 3, the 2-regularized Nyquist criterion is established, while its implementation is considered via truncation in section 4. The lossy Mathieu equation is studied to illustrate the results in section 5. Proofs of lemmas, if any, are given in appendices.

In this paper, $\|\cdot\|$ denotes the Euclidean norm of a vector and the norm of a matrix induced by this norm. l_2 is the set of all infinite-dimensional vectors $\underline{x}$ such that $\|\underline{x}\|_{l_2}^2 := \sum_{-\infty}^{+\infty} \|[\underline{x}]_m\|^2 < \infty$, where $[\underline{x}]_m$ is the mth (vector) entry of $\underline{x}$. $\|\cdot\|_{l_2/l_2}$ is the l_2-induced norm. $L_2[0,h]$ is the linear space of all vector measurable functions x defined on $[0,h]$ such that $\|x(\cdot)\|_{L_2[0,h]} := [\int_0^h \|x(t)\|^2\,dt]^{1/2} < \infty$. $F(\cdot) \in L_2[0,h]$ means that F is an h-periodic matrix function, each element of which belongs to $L_2[0,h]$ when its domain is restricted to $[0,h]$. This expression is also used for other function sets defined over $[0,h]$. $\mathbf{C}$ is the field of all complex numbers, and $\mathbf{Z}$ is the ring of all integers.

2. Preliminaries to FDLCP systems and operator determinants. In this section we first review facts about FDLCP systems [29], and then the 2-regularized determinant [5] for Hilbert–Schmidt operators. In particular, we derive properties about the harmonic state operator of FDLCP systems in the 2-regularized determinant sense.

Consider the FDLCP system given by

$$G : \begin{cases} \dot{x} = A(t)x + B(t)u, \\ y = C(t)x, \end{cases} \tag{2.1}$$

where $A(t)$, $B(t)$, and $C(t)$ are h-periodically time-varying matrices. The transition matrix of (2.1) with the initial time t_0 is denoted by $\Phi(t, t_0)$. By the Floquet theorem [14], [18], if $A(t) \in L_2[0, h]$, then $\Phi(t, t_0)$ is continuous with respect to t and has a Floquet factorization $\Phi(t, t_0) = P(t, t_0)e^{Q(t-t_0)}$, where $P(t, t_0)$ is absolutely continuous in t, nonsingular and h-periodic in t and t_0, and Q is a constant matrix. Moreover, the system is asymptotically stable if and only if the eigenvalues of Q lie in the open left-half plane. Without loss of generality, we assume $t_0 = 0$.

Now we review the Toeplitz transformation of periodic functions. Expand $X(t) \in L_2[0, h]$ to its Fourier series $\sum_{m=-\infty}^{+\infty} X_m e^{jm\omega_h t}$ with $\omega_h := 2\pi/h$. The Toeplitz transformation on $X(t)$, denoted by $\mathcal{T}\{X(t)\}$, maps $X(t)$ onto a doubly infinite-dimensional block Toeplitz operator [26] (or block Laurent operator [10, p. 564]) of the form

$$\mathcal{T}\{X(t)\} := \begin{bmatrix} \ddots & \vdots & \vdots & \vdots & \iddots \\ \cdots & X_0 & X_{-1} & X_{-2} & \cdots \\ \cdots & X_1 & X_0 & X_{-1} & \cdots \\ \cdots & X_2 & X_1 & X_0 & \cdots \\ \iddots & \vdots & \vdots & \vdots & \ddots \end{bmatrix} =: \underline{X}. \tag{2.2}$$

We further define $\underline{A} := \mathcal{T}\{A(t)\}$, $\underline{B} := \mathcal{T}\{B(t)\}$, $\underline{C} := \mathcal{T}\{C(t)\}$, $\underline{P} := \mathcal{T}\{P(t, 0)\}$, $\underline{\hat{B}} := \mathcal{T}\{P^{-1}(t, 0)B(t)\}$, $\underline{\hat{C}} := \mathcal{T}\{C(t)P(t, 0)\}$, $\underline{Q} := \operatorname{diag}[\ldots, Q, Q, Q, \ldots]$, and

$$\underline{E}(s) := \operatorname{diag}[\ldots, \varphi_{-2}(s)I, \varphi_{-1}(s)I, \varphi_0(s)I, \varphi_1(s)I, \varphi_2(s)I, \ldots], \tag{2.3}$$

where $\varphi_m(s) := s + jm\omega_h, m \in \mathbf{Z}, s \in \mathbf{C}$. It follows that $\underline{E}(s) = \underline{E}(j0) + s\underline{I}$, where $\underline{I} := \mathcal{T}\{I\}$.

We need the following function sets to validate the Fourier analysis and Toeplitz transformation operations involved (see [29] and [32] for details) and simplify our statements.

$$L_{\mathrm{PCD}}[0, h] := \left\{ f(t) : \begin{matrix} f(t) \text{ is piecewise continuous and} \\ \text{differentiable at a.e. } t \in [0, h] \end{matrix} \right\},$$

$$L_{\mathrm{PCC}}[0, h] := \left\{ f(t) : \begin{matrix} f(t) \text{ is piecewise continuous and its Fourier series} \\ \text{expansion is convergent to } f(t_0) \text{ for a.e. } t_0 \in [0, h] \end{matrix} \right\},$$

$$L_{\mathrm{CAC}}[0, h] := \left\{ f(t) : \begin{matrix} f(t) \text{ is continuous and the Fourier series} \\ \text{expansion of } f(t) \text{ is absolutely convergent} \end{matrix} \right\} \subset L_{\mathrm{PCC}}[0, h].$$

Here PCD stands for piecewise continuous and differentiable, and PCC is short for piecewise continuous and convergent, while CAC is the abbreviation for continuous and absolutely convergent.

Now we state the similarity transformation formulas and eigenvalues of FDLCP systems in terms of the Toeplitz transformation of the system matrices and the Floquet factorization of the transition matrix [29], [31]. To facilitate the statements, let $l_E := \{\underline{x} \in l_2 : \underline{E}(j0)\underline{x} \in l_2\}$. Then, l_E is a proper subset of l_2 and dense in l_2 [29].

LEMMA 2.1. *In the* FDLCP *system* (2.1)*, assume that* $A(t) \in L_{\mathrm{PCD}}[0,h]$ *and* $B(t), C(t) \in L_{\mathrm{PCC}}[0,h]$*. Then,* l_E *is* $\underline{P}$*- and* $\underline{P}^{-1}$*-invariant. Also, the unbounded operators* $\underline{P}(\underline{E}(j0) - \underline{Q})\underline{P}^{-1}$ *and* $\underline{E}(j0) - \underline{A}$ *are densely defined on* l_2 *(or equivalently, well defined on the subset* $l_E \subset l_2$*) and coincide with each other:*

$$\underline{P}(\underline{E}(j0) - \underline{Q})\underline{P}^{-1} = \underline{E}(j0) - \underline{A}. \tag{2.4}$$

Moreover, it holds on the whole Hilbert space l_2 *that* $\hat{\underline{B}} = \underline{P}^{-1}\underline{B}$ *and* $\hat{\underline{C}} = \underline{C}\,\underline{P}$*.*

Furthermore, system (2.1) *is asymptotically stable if and only if the set* Λ *of all eigenvalues of* $\underline{Q} - \underline{E}(j0)$*, i.e.,* $\Lambda = \{\lambda(Q) + jm\omega_h : m \in \mathbf{Z}\}$*, lies in the open left-half plane. It is also true that* $\Lambda = \Lambda_A$ *where* Λ_A *is the set of all eigenvalues of* $\underline{A} - \underline{E}(j0)$*. In the above,* $\lambda(\cdot)$ *denotes the set of all eigenvalues of the matrix* $(\cdot)$*.*

Now we introduce the harmonic transfer operator [26] of system (2.1) given by

$$\underline{G}(s) := \underline{C}(\underline{E}(s) - \underline{A})^{-1}\underline{B} \tag{2.5}$$

in which $\underline{A} - \underline{E}(s)$ is called the harmonic state operator of system (2.1). In view of (2.4) in Lemma 2.1, $\underline{Q} - \underline{E}(s)$ is called the Floquet state operator of (2.1) to distinguish it from $\underline{A} - \underline{E}(s)$. When $\underline{E}^{-1}(s)$ exists, $\underline{I} - \underline{E}^{-1}(s)\underline{A}$ (respectively, $\underline{I} - \underline{E}^{-1}(s)\underline{Q}$) will be called the modified harmonic state operator (respectively, the modified Floquet state operator) of system (2.1).

Now we consider a domain $\Omega \subset \mathbf{C}$ and assume that $s \in \Omega$. Let us further give assumptions A1 and A2 about Ω to facilitate our statements.

A1 The domain Ω is closed and has a simple closed boundary, denoted by $\partial\Omega$, and thus is a simply connected domain on $\mathbf{C}$. Also, it holds that

$$|\mathrm{Im}(s)| < K_\Omega := \omega_h \quad (\forall s \in \Omega). \tag{2.6}$$

Furthermore, $\underline{E}(s) - \underline{Q}$ is an invertible mapping from l_E to l_2 for each $s \in \partial\Omega$.

A2 On the domain Ω, $\underline{E}(s)$ is an invertible mapping from l_E to l_2.

Note that the last assumption of A1 is satisfied if and only if $\partial\Omega$ contains no points in Λ, while A2 is satisfied if and only if Ω does not contain any points in $\Gamma := \{jm\omega_h : m \in \mathbf{Z}\}$. Hence, relation (2.4) tells us that

$$\underline{P}(\underline{E}(s) - \underline{Q})^{-1}\underline{P}^{-1} = (\underline{E}(s) - \underline{A})^{-1} \tag{2.7}$$

for all $s \in \Omega \setminus \Lambda$. That is, $\underline{E}(s) - \underline{A}$ is an invertible mapping from l_E to l_2 for each $s \in \Omega \setminus \Lambda$. (2.7) says that the harmonic transfer operator $\underline{G}(s)$ is well defined on l_2 for all $s \in \Omega\backslash\Lambda$. Lemma 2.2 gives basic facts about $\underline{G}(s)$ that play a key role in developing the Nyquist criterion.

LEMMA 2.2. *In the* FDLCP *system* (2.1)*, let* $A(t) \in L_{\mathrm{PCD}}[0,h]$ *and* $B(t), C(t) \in L_{\mathrm{PCC}}[0,h]$*. Assume that the domain* Ω *satisfies* A1*. Then for each* $s \in \Omega\backslash\Lambda$*,* $(\underline{E}(s) - \underline{Q})^{-1} \in \mathcal{C}_2(l_2)$*, and thus* $\underline{G}(s) \in \mathcal{C}_2(l_2)$*. Furthermore,* $\|\underline{G}(s)\|_2$ *has a uniform upper bound over* $s \in \partial\Omega$*.*

Now we introduce the 2-regularized determinant of Hilbert–Schmidt operators and derive some properties about the 2-regularized determinant of the modified harmonic transfer operators.

Let $\lambda_i(A)$ denote the ith eigenvalue of a linear compact operator $A : l_2 \to l_2$, and $s_i(A) := (\lambda_i(A^*A))^{1/2}$ be its ith singular value. For $p = 1$ and 2, the set of all compact operators $A : l_2 \to l_2$ satisfying $\|A\|_p := (\sum_i s_i(A)^p)^{1/p} < \infty$ is denoted by $\mathcal{C}_1(l_2)$ and $\mathcal{C}_2(l_2)$, respectively. In particular, the operators in $\mathcal{C}_1(l_2)$ are called trace class operators while those in $\mathcal{C}_2(l_2)$ are called Hilbert–Schmidt operators [5]. Clearly, $\mathcal{C}_1(l_2) \subset \mathcal{C}_2(l_2)$. For $A \in \mathcal{C}_1(l_2)$, the operator trace and determinant below are well defined in the sense that the infinite series and product converge

$$\mathrm{tr}(A) := \sum \lambda_i(A), \quad \det(I + A) := \prod (1 + \lambda_i(A)). \tag{2.8}$$

Note that for $A \in \mathcal{C}_2(l_2)$, $R_2(A) := (I + A)\exp\{-A\} - I \in \mathcal{C}_1(l_2)$. Thus, it is justified to define the determinant of $I + R_2(A)$ in the sense of (2.8), denoted by $\det_2(I+A) := \det(I+R_2(A))$, which is called the 2-regularized determinant of $I+A$. For our aim, assume that $B \in \mathcal{C}_2(l_2)$. Then

$$\det_2(I + A) = \prod [(1 + \lambda_i(A)) \exp(-\lambda_i(A))], \tag{2.9}$$

$$\det_2(I + A)\det_2(I + B) = \det_2[(I + A)(I + B)] \exp\{\mathrm{tr}(AB)\}. \tag{2.10}$$

By Proposition 1.3 of [9, p. 98], if $A \in \mathcal{C}_2(l_2)$ and B and C are bounded linear operators on l_2, then BAC belongs to $\mathcal{C}_2(l_2)$ and $\|BAC\|_2 \le \|B\|_{l_2/l_2}\|A\|_2\|C\|_{l_2/l_2}$. Moreover, Theorem 3.1 of [9, p. 43] says that AB and BA have the same nonzero eigenvalues with multiplicity taken into account, i.e., $\det_2(I + AB) = \det_2(I + BA)$.

When establishing a Nyquist-type criterion for FDLCP systems, one might be tempted to talk about some sort of determinant about the harmonic state operator $\underline{A} - \underline{E}(s)$ or the Floquet state operator $\underline{Q} - \underline{E}(s)$ as in the LTI continuous-time case. However, such a determinant notion for these unbounded operators is not readily available in the literature. The following lemma will be a key to get around the difficulty, in which the 2-regularized determinant of these operators premultiplied by $-\underline{E}^{-1}(s)$ (i.e., the modified harmonic and Floquet state operators) are considered.

LEMMA 2.3. *In the* FDLCP *system* (2.1)*, let* $A(t) \in L_{\mathrm{CAC}}[0, h] \cap L_{\mathrm{PCD}}[0, h]$. *Assume that the domain* Ω *satisfies* A1 *and* A2. *Then for each* $s \in \Omega$, $\underline{E}^{-1}(s) \in \mathcal{C}_2(l_2)$, *and thus* $\underline{E}^{-1}(s)\underline{A} \in \mathcal{C}_2(l_2)$, $\underline{E}^{-1}(s)\underline{Q} \in \mathcal{C}_2(l_2)$. *In particular,* $\|\underline{E}^{-1}(s)\|_2$ *has a uniform upper bound over* $s \in \Omega$. *Furthermore,*

$$\det_2[\underline{I} - \underline{E}^{-1}(s)\underline{A}] = g_A(s) \det_2[\underline{I} - \underline{E}^{-1}(s)\underline{Q}], \tag{2.11}$$

where the function $g_A(s)$ *does not vanish for each* $s \in \Omega$ *and is analytic over* Ω. *Also,* $\underline{I} - \underline{E}^{-1}(s)\underline{A}$ *is invertible for each* $s \in \Omega$, *and the inverse of* $\underline{I} - \underline{E}^{-1}(s)\underline{A}$ *is bounded on* l_2.

LEMMA 2.4. *Let* $\lambda_k(Q)$ *denote the* k*th eigenvalue of the* $n \times n$ *matrix* Q. *If the domain* Ω *satisfies* A1 *and* A2, *then the function*

$$\begin{aligned} f_Q(s) &:= \det_2[\underline{I} - \underline{E}^{-1}(s)\underline{Q}] \\ &= \prod_{k=1}^{n} \prod_{m=-\infty}^{\infty} \left(1 - \frac{\lambda_k(Q)}{s + jm\omega_h}\right) \exp\left\{\frac{\lambda_k(Q)}{s + jm\omega_h}\right\} \end{aligned} \tag{2.12}$$

is analytic on Ω, *which has a zero at each point* $\lambda_k(Q) - jm\omega_h$, $k = 1, 2, \ldots, n$, *and* $m \in \mathbf{Z}$ *(i.e., counted up to multiplicity), and has no other zeros on the complex plane.*

Remark 1. Lemma 2.4 says that the set of all zeros of $f_Q(s)$ is equal to the set Λ of all the eigenvalues of $\underline{Q} - \underline{E}(j0)$. This, together with Lemma 2.1, tells us that asymptotic stability of an FDLCP system can be reflected by the function $f_Q(s)$. This is the starting point of establishing a generalized Nyquist criterion via the 2-regularized determinant approach. To relate $f_Q(s)$ to its closed-loop counterpart via the 2-regularized determinant of the harmonic return differential operator will be the task in the following section, by which a Nyquist criterion of FDLCP systems will be derived in a similar fashion to the corresponding result in the LTI continuous-time systems.

In the following, $\partial\Omega$ will be chosen to form a Nyquist contour N_r, which needs to directly pass through the origin or to include the origin in the interior of the region enclosed by N_r (that is, to bypass the origin if there are any eigenvalues of $\underline{Q} - \underline{E}(j0)$ at the origin). However, such an Ω violates the assumption A2, since $0 \in \Gamma$. To surmount this problem, we introduce a shift factor $\rho > 0$ to s and replace assumption A2 by the following assumption.

A2′ On the domain Ω, $\underline{E}(s+\rho)(= \underline{E}(s) + \rho\,\underline{I})$ is an invertible mapping from l_E to l_2.

As we shall see later, assumption A2′ can in fact be essentially simplified to the condition $\rho > 0$ in our context due to the specific choice of the domain Ω given later. The introduction of such $\rho > 0$ is crucial only in the FDLCP setting exactly because $\underline{E}(s+\rho)$ is noninvertible at $s = 0$ if $\rho = 0$; this noninvertibility causes a problem when we try to deal with the 2-regularized determinant of $\underline{I} - \underline{E}^{-1}(s)\underline{A}$. It is easy to see that such a difficulty does not exist in the LTI continuous-time case since in that case $\det(sI - A)$ can be considered directly and s need not be inverted (recall the paragraph just before Lemma 2.3).

Remark 2. Once we introduce $\rho > 0$, we consider $\det_2[\underline{I} - \underline{E}^{-1}(s+\rho)(\underline{A}+\rho\underline{I})]$ and $\det_2[\underline{I} - \underline{E}^{-1}(s+\rho)(\underline{Q}+\rho\underline{I})]$ instead of similar relations in Lemmas 2.3 and 2.4. Hence, what we indeed employ in the subsequent arguments is the accordingly modified versions of Lemmas 2.3 and 2.4. Note that A1 is not affected by this shift factor. Thus, Lemma 2.3 still holds even if A2 is replaced by A2′, provided that $\underline{E}(s)$, $g_A(s)$, $\underline{A}$, and $\underline{Q}$ are also replaced by $\underline{E}(s+\rho)$, $g_{A+\rho I}(s+\rho)$, $\underline{A} + \rho\underline{I}$, and $\underline{Q} + \rho\underline{I}$, respectively. To facilitate the following descriptions, we will refer to this modified result as Lemma 2.3′. Similarly, Lemma 2.4 holds true when A2 is replaced by A2′ if $\underline{E}(s)$, $f_Q(s)$, $\underline{Q}$, $\lambda_k(Q)$, and $jm\omega_h$ are replaced by $\underline{E}(s+\rho)$, $f_{Q+\rho I}(s+\rho)$, $\underline{Q} + \rho\underline{I}$, $\lambda_k(Q+\rho I)$, and $\rho + jm\omega_h$, respectively. This modified result will be referred to as Lemma 2.4′. Moreover, it is obvious that the set of zeros of $f_{Q+\rho I}(s+\rho)$ equals that of the set of zeros of $f_Q(s)$. Clearly, these modified results can be validated even if condition (2.6) is removed from A1, because of the periodicity of $\underline{E}(s)$.

It is worth noticing that the introduction of the shift factor $\rho > 0$ does not cause any approximation effect at all on the stability analysis. This is because the invertibility of $\underline{I} - \underline{E}^{-1}(s+\rho)(\underline{A}+\rho\underline{I})$ is equivalent to that of $\underline{E}^{-1}(s+\rho)\{\underline{I} - \underline{E}^{-1}(s+\rho)(\underline{A}+\rho\underline{I})\} = \underline{E}(s) - \underline{A}$.

3. 2-Regularized Nyquist stability criterion. In this section, we develop a Nyquist criterion by the 2-regularized determinant for stability analysis of the closed-loop FDLCP system when an output feedback is introduced. In system (2.1), let $A(t)$, $B(t)$, $C(t) \in L_{\mathrm{CAC}}[0,h] \cap L_{\mathrm{PCD}}[0,h]$, and an h-periodically time-varying output feedback $u = -K(t)y + v$ is introduced. This leads to the closed-loop FDLCP system

described by

$$G_c : \begin{cases} \dot{x} = A_c(t)x + B(t)v, \\ y = C(t)x. \end{cases} \tag{3.1}$$

Here v is a new reference input and it is assumed that $K(t) \in L_{\mathrm{CAC}}[0,h] \cap L_{\mathrm{PCD}}[0,h]$. Clearly, $A_c(t) := A(t) - B(t)K(t)C(t) \in L_{\mathrm{CAC}}[0,h] \cap L_{\mathrm{PCD}}[0,h]$. These assumptions about $A(t), B(t), C(t)$, and $K(t)$ ensure that the Toeplitz transformation and Lemmas 2.1–2.4 (see also Remark 2) apply to both the open- and closed-loop FDLCP systems.

Now such a question emerges, In what way can one claim asymptotic stability of the closed-loop system G_c by observing the open-loop harmonic transfer operator?

3.1. 2-Regularized determinant relation between open- and closed-loop modified harmonic state operators. As known in the LTI case, one must obtain the relationship between the open- and closed-loop pole polynomials before claiming the Nyquist criterion. The aim of this subsection is to get a similar relationship in the FDLCP case, where Lemma 2.4 and Remark 2 suggest that $f_{Q+\rho I}(s+\rho) = \det_2[\underline{I} - \underline{E}^{-1}(s+\rho)(\underline{Q} + \rho\underline{I})]$, and the corresponding closed-loop counterpart plays the role of pole polynomials. To derive such a relationship, let us define $\underline{K} = \mathcal{T}\{K(t)\}$. Then it follows from Lemma 2.2 that for each $s \in \Omega\backslash\Lambda$, $\underline{K}\,\underline{G}(s)$ is well defined and belongs to $\mathcal{C}_2(l_2)$. Therefore, it makes sense to talk about the $\det_2$ of the return difference operator $\underline{I} + \underline{K}\,\underline{G}(s)$ for each $s \in \Omega\backslash\Lambda$. Noting that $\underline{E}(s+\rho)$ is invertible for all $s \in \Omega$ by A2′, we compute $\det_2$ of $\underline{I} + \underline{K}\,\underline{G}(s)$ as

$$\begin{aligned} \det_2[\underline{I} + \underline{K}\,\underline{G}(s)] &= \det_2[\underline{I} + (\underline{E}(s) - \underline{A})^{-1}\underline{B}\,\underline{K}\,\underline{C}] \\ &= \det_2[\underline{I} + (\underline{I} - \underline{E}^{-1}(s+\rho)(\underline{A} + \rho\underline{I}))^{-1}\underline{E}^{-1}(s+\rho)\underline{B}\,\underline{K}\,\underline{C}] \\ &= \det_2[(\underline{I} - \underline{E}^{-1}(s+\rho)(\underline{A} + \rho\underline{I}))^{-1}(\underline{I} - \underline{E}^{-1}(s+\rho)(\underline{A}_c + \rho\underline{I}))], \end{aligned} \tag{3.2}$$

where $\underline{A}_c := \underline{A} - \underline{B}\,\underline{K}\,\underline{C}$. Note that $\underline{A} - \underline{B}\,\underline{K}\,\underline{C} = \mathcal{T}\{A_c(t)\}$ holds since $B(t), K(t)$, and $C(t)$ belong to $L_{\mathrm{CAC}}[0,h]$ [17]. In (3.2), we used the facts that $(\underline{E}(s) - \underline{A})^{-1} \in \mathcal{C}_2(l_2)$ for each $s \in \Omega\backslash\Lambda$ and that $\underline{K}\,\underline{C}$ is bounded on l_2, where the first fact can be shown by (2.7) and Lemma 2.2.

Before we expand (3.2) via (2.10), we must show that the $\det_2$'s of $(\underline{I} - \underline{E}^{-1}(s+\rho)(\underline{A} + \rho\underline{I}))^{-1}$ and $\underline{I} - \underline{E}^{-1}(s+\rho)(\underline{A}_c + \rho\underline{I})$ are well defined for all $s \in \Omega \setminus \Lambda$. To this end, let us define the infinite-dimensional matrix $\underline{M}(s+\rho)$ such that for each $s \in \Omega\backslash\Lambda$, it holds that

$$(\underline{I} - \underline{E}^{-1}(s+\rho)(\underline{A} + \rho\underline{I}))(\underline{I} + \underline{M}(s+\rho)) = \underline{I}. \tag{3.3}$$

It follows easily that $\underline{M}(s+\rho)$ is indeed given by

$$\underline{M}(s+\rho) = \underline{E}^{-1}(s+\rho)(\underline{A} + \rho\underline{I})(\underline{I} - \underline{E}^{-1}(s+\rho)(\underline{A} + \rho\underline{I}))^{-1}.$$

Then the fact that $\underline{E}^{-1}(s+\rho) \in \mathcal{C}_2(l_2)$ and that $(\underline{A} + \rho\underline{I})(\underline{I} - \underline{E}^{-1}(s+\rho)(\underline{A} + \rho\underline{I}))^{-1}$ is bounded on l_2 (by Lemma 2.3) implies that $\underline{M}(s+\rho) \in \mathcal{C}_2(l_2)$. Similarly, for each $s \in \Omega$, $\underline{E}^{-1}(s+\rho)(\underline{A}_c + \rho\underline{I})$ and $\underline{E}^{-1}(s+\rho)(\underline{A} + \rho\underline{I})$ belong to $\mathcal{C}_2(l_2)$. Thus it makes sense to deal with the $\det_2$'s of $(\underline{I} - \underline{E}^{-1}(s+\rho)(\underline{A} + \rho\underline{I}))^{-1}$, $\underline{I} - \underline{E}^{-1}(s+\rho)(\underline{A}_c + \rho\underline{I})$, and $\underline{I} - \underline{E}^{-1}(s+\rho)(\underline{A} + \rho\underline{I})$ on $\Omega\backslash\Lambda$, separately.

Now taking the $\det_2$ on both sides of (3.3), we obtain

$$\begin{aligned} &\det_2[\underline{I} - \underline{E}^{-1}(s+\rho)(\underline{A} + \rho\underline{I})] \\ &\quad = \frac{\exp\{-\mathrm{tr}(\underline{E}^{-1}(s+\rho)(\underline{A} + \rho\underline{I})\underline{M}(s+\rho))\}}{\det_2[\underline{I} + \underline{M}(s+\rho)]}. \end{aligned} \tag{3.4}$$

Then expanding the $\det_2$ of (3.2) via (2.10) and using (3.4), we have

$$\begin{aligned}\det_2[\underline{I}+\underline{K}\,\underline{G}(s)] &= \det_2[(\underline{I}-\underline{E}^{-1}(s+\rho)(\underline{A}+\rho\underline{I}))^{-1}]\\ &\quad\times\det_2[\underline{I}-\underline{E}^{-1}(s+\rho)(\underline{A}_c+\rho\underline{I})]\\ &\quad\times\exp\{\mathrm{tr}(\underline{M}(s+\rho)\underline{E}^{-1}(s+\rho)(\underline{A}_c+\rho\underline{I}))\}\\ &= \exp\{\Delta(s+\rho)\}\frac{\det_2[\underline{I}-\underline{E}^{-1}(s+\rho)(\underline{A}_c+\rho\underline{I})]}{\det_2[\underline{I}-\underline{E}^{-1}(s+\rho)(\underline{A}+\rho\underline{I})]},\end{aligned}\tag{3.5}$$

where the scalar function $\Delta(s+\rho)$ is given by

$$\begin{aligned}\Delta(s+\rho) &:= \mathrm{tr}(\underline{M}(s+\rho)\underline{E}^{-1}(s+\rho)(\underline{A}_c+\rho\underline{I}))-\mathrm{tr}(\underline{M}(s+\rho)\underline{E}^{-1}(s+\rho)(\underline{A}+\rho\underline{I}))\\ &= -\mathrm{tr}(\underline{E}^{-1}(s+\rho)(\underline{A}+\rho\underline{I})(\underline{E}(s)-\underline{A})^{-1}\underline{B}\,\underline{K}\,\underline{C}).\end{aligned}\tag{3.6}$$

3.2. Nyquist contour and Nyquist locus. Before leading the above arguments to a Nyquist stability criterion, we need to describe in what way an appropriate Nyquist contour, i.e., $\partial\Omega$, should be taken and how the corresponding Nyquist locus should be plotted in the 2-regularized determinant sense.

First let us see how an appropriate Nyquist contour should be taken.

To this purpose, we mention some facts about the eigenvalues of $\underline{Q}-\underline{E}(j0)$ (or equivalently the operator $\underline{A}-\underline{E}(j0)$), which are given in Lemma 2.1. First, all the eigenvalues of $\underline{Q}-\underline{E}(j0)$ are located in a vertical strip region parallel to the imaginary axis; second, the eigenvalues distribution pattern in the horizontal strip

$$\mathbf{C}_F := \{s\in\mathbf{C} : -\omega_h/2 < \mathrm{Im}(s) \le \omega_h/2\},\tag{3.7}$$

which is called the fundamental strip [26], unfolds itself vertically to both $-j\infty$ and $j\infty$ with the period $j\omega_h$. In other words, if we can understand the eigenvalue distribution pattern in $\mathbf{C}_F$, then the whole eigenvalue structure of $\underline{Q}-\underline{E}(j0)$ is clarified. Based on this, a possible Nyquist contour would be the boundary of the right-half fundamental strip of $\mathbf{C}_F$, i.e., $\{s : \mathrm{Re}(s)\ge 0, s\in\mathbf{C}_F\}$. However, since $\underline{G}(s)$ is not well defined for $s\in\Lambda$, the actual Nyquist contour should avoid going through these points in Λ. Hence the Nyquist contour N_r shown in Figure 3.1 is taken. In Figure 3.1 the crosses ($\times$'s) denote possible eigenvalues of the open-loop operator $\underline{Q}-\underline{E}(j0)$ on the boundary of the right-hand half of $\mathbf{C}_F$. It should be stressed that the Nyquist contour N_r bypasses the eigenvalues of $\underline{Q}-\underline{E}(j0)$ on the imaginary axis with $-\omega_h/2 < \mathrm{Im}(\lambda) < \omega_h/2$, if any, from the left-hand side while other eigenvalues on the boundary of the right-half fundamental strip, if any, from the upper-side, via a semicircle with the radius r that is small enough. Thus, if $\underline{Q}-\underline{E}(j0)$ has eigenvalues on the imaginary axis such that $-\omega_h/2 < \mathrm{Im}(\lambda)\le\omega_h/2$, they are to be included in the interior of the region enclosed by N_r. Now let us assume that the right edge of N_r is far enough from the imaginary axis so that there are no eigenvalues of $\underline{Q}-\underline{E}(j0)$ on it, and finally, let us define the domain Ω as the union of the Nyquist contour N_r and the interior of the region enclosed by N_r. Then, it is obvious that Ω satisfies A1 and A2$'$ whenever $\rho > r \ge 0$ and $K_\Omega > \omega_h/2 + r$. Hence the arguments from (3.2) to (3.6) are validated for such a ρ.

Next let us see how the corresponding Nyquist locus can be plotted.

Now segment the Nyquist contour N_r given in Figure 3.1 into four pieces N_{ab}, N_{bc}, N_{cd}, and N_{da} in the obvious fashion and note the following observations. First, since $\det_2[\underline{I}+\underline{K}\underline{G}(s)]$ and $\Delta(s+\rho)$ are $j\omega_h$-periodic in the frequency domain, the plot of $\det_2[\underline{I}+\underline{K}\,\underline{G}(s)]\exp\{-\Delta(s+\rho)\}$ corresponding to N_{ab} will form a closed curve.

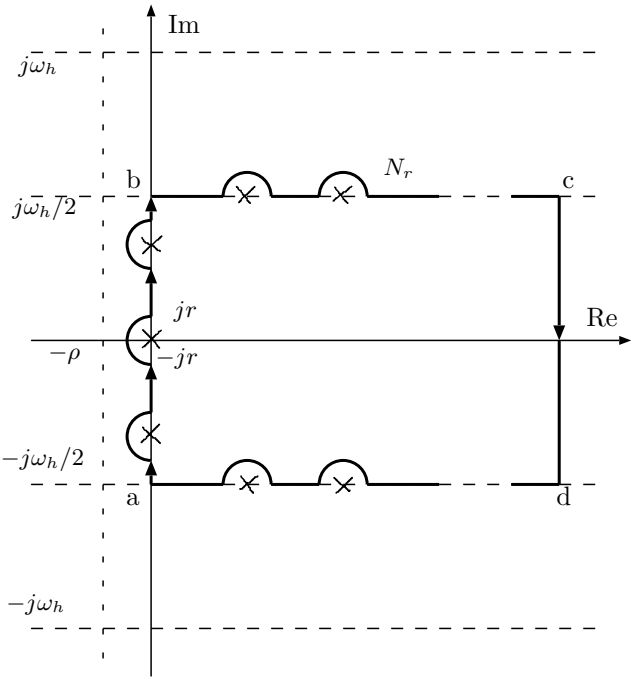

FIG. 3.1. *Nyquist contour* N_r.

Second, for each $s \in N_{bc}$, there is a corresponding complex number $\tilde{s} = s - j\omega_h \in N_{da}$ such that $\det_2[\underline{I} + \underline{K}\,\underline{G}(s)] \exp\{-\Delta(s+\rho)\} = \det_2[\underline{I} + \underline{K}\,\underline{G}(\tilde{s})] \exp\{-\Delta(\tilde{s}+\rho)\}$ due to the same periodicity. The only difference between the plot of $\det_2[\underline{I} + \underline{K}\,\underline{G}(s)] \exp\{-\Delta(s+\rho)\}$ corresponding to N_{bc} and that corresponding to N_{da} is that these two plots are drawn in just opposite directions. To facilitate the discussions, we assume that N_{bc} and N_{da} are taken in such a way that they bypass *closed-loop* eigenvalues, if any, in a similar fashion to what is done for *open-loop* eigenvalues. Clearly, this requirement on N_{bc} and N_{da} can always be satisfied, in principle, and brings no essential difficulty to validate the second assertion we just claimed while keeping A2′. Third, if $\mathrm{Re}(s)$ is made large enough for $s \in N_{cd}$ (i.e., the Nyquist contour N_r is extended to the right far enough so that it encloses all the unstable closed-loop eigenvalues on the fundamental strip), $\det_2[\underline{I} + \underline{K}\,\underline{G}(s)] \exp\{-\Delta(s+\rho)\} \to 1$ for each $s \in N_{cd}$. These facts indicate that the plot segment of $\det_2[\underline{I} + \underline{K}\,\underline{G}(s)] \exp\{-\Delta(s+\rho)\}$ corresponding to N_{bc}, N_{cd}, and N_{da} neither goes through the origin nor contributes to encirclements around the origin. In other words, to investigate the encirclements of $\det_2[\underline{I} + \underline{K}\,\underline{G}(s)] \exp\{-\Delta(s+\rho)\}$ around the origin on N_r, it is enough to see the plot of $\det_2[\underline{I} + \underline{K}\,\underline{G}(s)] \exp\{-\Delta(s+\rho)\}$ corresponding to N_{ab}. In view of this, the plot $\det_2[\underline{I} + \underline{K}\,\underline{G}(s)] \exp\{-\Delta(s+\rho)\} : N_{ab} \to \mathbf{C}$ is called the Nyquist locus of (2.1) when $s \in N_{ab}$ moves in the clockwise direction with respect to N_r.

3.3. 2-Regularized Nyquist stability criterion. On the basis of arguments in the two preceding subsections, we are ready to show the 2-regularized Nyquist criterion, which is the main result of this paper.

THEOREM 3.1. *Assume that* $A(t), B(t), C(t)$ *of the* FDLCP *system* (2.1) *and the feedback matrix* $K(t)$ *belong to* $L_{\mathrm{CAC}}[0,h] \cap L_{\mathrm{PCD}}[0,h]$. *Let* n_{us} *denote the number*

of the unstable eigenvalues of the open-loop Floquet state operator $\underline{Q} - \underline{E}(j0)$ *(or equivalently, the harmonic state operator* $\underline{A} - \underline{E}(j0)$*) in the fundamental strip* $\mathbf{C}_F$ *defined in* (3.7) *counted according to their multiplicity. Take an arbitrary positive number* ρ *and a sufficiently small number* r *according to the open-loop eigenvalue condition of* $\underline{Q} - \underline{E}(j0)$ *on the imaginary axis such that* $\rho > r \geq 0$*, and then consider the harmonic transfer operator* $\underline{G}(s)$ *and the scalar function* $\Delta(s+\rho)$ *defined in* (3.6)*. Then, the closed-loop system* G_c *is asymptotically stable if and only if the Nyquist locus,* $\det_2[\underline{I} + \underline{K}\,\underline{G}(s)] \exp\{-\Delta(s+\rho)\} : N_{ab} \to \mathbf{C}$*, vanishes nowhere on* N_{ab} *and encircles the origin* n_{us} *times in the counterclockwise sense.*

Proof. Under the given assumptions on the system matrices and the feedback gain matrix, Lemma 2.3′ stated in Remark 2 ensures a modified version of (2.11), which reads

$$\det_2[\underline{I} - \underline{E}^{-1}(s+\rho)(\underline{A} + \rho\underline{I})] = g_{A+\rho I}(s+\rho) \det_2[\underline{I} - \underline{E}^{-1}(s+\rho)(\underline{Q} + \rho\underline{I})]$$

for each $s \in \Omega$, where $g_{A+\rho I}(s+\rho)$ is analytic and vanishes nowhere on Ω. By applying Lemma 2.3′ to the closed-loop term $\det_2[\underline{I} - \underline{E}^{-1}(s+\rho)(\underline{A}_c + \rho\underline{I})]$, we readily obtain

$$\det_2[\underline{I} - \underline{E}^{-1}(s+\rho)(\underline{A}_c + \rho\underline{I})] = g_{A_c+\rho I}(s+\rho) \det_2[\underline{I} - \underline{E}^{-1}(s+\rho)(\underline{Q}_c + \rho\underline{I})]$$

for each $s \in \Omega$, where $g_{A_c+\rho I}(s+\rho)$ is analytic and vanishes nowhere on Ω. Here, $\underline{Q}_c := \mathcal{T}\{Q_c\}$ with Q_c being the constant matrix of the Floquet factorization of the transition matrix $\Phi_c(t, t_0)$ of the closed-loop FDLCP system (3.1). Thus, relation (3.5) can be rewritten as

$$\begin{aligned} &\det_2[\underline{I} + \underline{K}\,\underline{G}(s)] \exp\{-\Delta(s+\rho)\} \\ &\quad = \frac{g_{A_c+\rho I}(s+\rho) \det_2[\underline{I} - \underline{E}^{-1}(s+\rho)(\underline{Q}_c + \rho\underline{I})]}{g_{A+\rho I}(s+\rho) \det_2[\underline{I} - \underline{E}^{-1}(s+\rho)(\underline{Q} + \rho\underline{I})]}. \end{aligned} \tag{3.8}$$

Now we concentrate the attention on the right-hand side of (3.8). By Lemma 2.4′ stated in Remark 2, the right-hand side of (3.8) is just $g_{A_c+\rho I}(s+\rho) f_{Q_c+\rho I}(s+\rho) / g_{A+\rho I}(s+\rho) f_{Q+\rho I}(s+\rho) =: d(s)$, which is analytic on Ω except at the zeros of $f_{Q+\rho I}(s+\rho)$ contained in Ω. It is also clear that $d(s)$ is meromorphic by Theorem 15.12 of [24]. Apparently, by the definition of Ω, only finitely many zeros of $f_{Q_c+\rho I}(s+\rho)$ and $f_{Q+\rho I}(s+\rho)$ are contained in Ω, which in particular implies that (3.8) is not identically zero over Ω. These facts imply that the argument principle about complex functions applies to $d(s)$ if the right-hand side of (3.8) never vanishes at each $s \in \partial\Omega (= N_r)$ (this guarantees that there are no zeros of $f_{Q_c+\rho I}(s+\rho)$ located on N_r). Note by Remark 2 that the sets of zeros of $f_{Q+\rho I}(s+\rho)$ and $f_{Q_c+\rho I}(s+\rho)$ are actually independent of ρ and just the sets of the eigenvalues of the open- and closed-loop operators, $\underline{Q} - \underline{E}(j0)$ and $\underline{Q}_c - \underline{E}(j0)$, respectively. Furthermore, it follows readily that the right-hand side of (3.8) never vanishes on the segments N_{bc}, N_{cd}, and N_{da} of N_r because of the assumption that they do not go through the closed-loop eigenvalues. Hence, some straightforward discussions will lead to the desired assertions. □

Remark 3. It should be stressed that n_{us} indicates the number of unstable eigenvalues of $\underline{Q} - \underline{E}(j0)$ in the closed right-half portion of the fundamental strip. However, it is easy to see that n_{us} equals the number of the unstable eigenvalues of Q in the whole closed right-half plane.

3.4. Equivalent interpretation of Theorem 3.1. In this subsection we show that Theorem 3.1 can have a more explicit expression which will provide convenience for implementing Theorem 3.1. To this end, let us return to (3.2) and compute the

$\det_2$ of $\underline{I} + \underline{K}\,\underline{G}(s)$ again but after the harmonic transfer operator $\underline{G}(s)$ has been rewritten as $\underline{G}(s) = \hat{\underline{C}}(\underline{E}(s) - \underline{Q})^{-1}\hat{\underline{B}}$ by means of Lemma 2.1 and (2.7). That is, we compute

$$\det_2[\underline{I} + \underline{K}\,\underline{G}(s)] = \det_2[\underline{I} + \underline{K}\,\hat{\underline{C}}(\underline{E}(s) - \underline{Q})^{-1}\hat{\underline{B}}]. \tag{3.9}$$

It is not hard to see that all the arguments around (3.2)–(3.6) can be repeated on the operator $\underline{K}\,\hat{\underline{C}}(\underline{E}(s) - \underline{Q})^{-1}\hat{\underline{B}} \in \mathcal{C}_2(l_2)$. Then we can conclude that

$$\det_2[\underline{I} + \underline{K}\,\underline{G}(s)]\exp\{-\tilde{\Delta}(s+\rho)\} = \frac{\det_2[\underline{I} - \underline{E}^{-1}(s+\rho)(\underline{\tilde{A}}_c + \rho\underline{I})]}{\det_2[\underline{I} - \underline{E}^{-1}(s+\rho)(\underline{Q} + \rho\underline{I})]} \tag{3.10}$$

with $\underline{\tilde{A}}_c := \underline{Q} - \hat{\underline{B}}\,\underline{K}\,\hat{\underline{C}}$ and

$$\tilde{\Delta}(s+\rho) := -\mathrm{tr}(\underline{E}^{-1}(s+\rho)(\underline{Q} + \rho\underline{I})(\underline{E}(s) - \underline{Q})^{-1}\hat{\underline{B}}\,\underline{K}\,\hat{\underline{C}}). \tag{3.11}$$

Now we observe that $\underline{E}(j0) - \underline{\tilde{A}}_c = \underline{P}^{-1}(\underline{E}(j0) - \underline{A}_c)\underline{P}$, where the similarity transformation formula is used. This equation clearly says that every eigenvalue of $\underline{E}(j0) - \underline{\tilde{A}}_c$ is also an eigenvalue of $\underline{E}(j0) - \underline{A}_c$ and vice versa. This implies that one can test stability of the closed-loop system G_c by that of the closed-loop system $\tilde{G}_c : (\tilde{A}_c(t) := Q - \hat{B}(t)K(t)\hat{C}(t), \hat{B}(t), \hat{C}(t))$. Combining this fact with (3.10), we have the following corollary about Theorem 3.1.

COROLLARY 3.2. *Suppose all the assumptions of Theorem* 3.1 *hold. Take an arbitrary positive number* ρ *and a sufficiently small number* r *according to the open-loop eigenvalue condition of* $\underline{Q} - \underline{E}(j0)$ *on the imaginary axis such that* $\rho > r \geq 0$. *Consider the harmonic transfer operator* $\underline{G}(s)$ *and the scalar function* $\tilde{\Delta}(s+\rho)$ *given in* (3.11). *Then the closed-loop system* G_c *is asymptotically stable if and only if the modified Nyquist locus,* $\det_2[\underline{I} + \underline{K}\,\underline{G}(s)]\exp\{-\tilde{\Delta}(s+\rho)\} : N_{ab} \to \mathbf{C}$ *vanishes nowhere on* N_{ab} *and encircles the origin* n_{us} *times in the counterclockwise sense.*

The Nyquist locus in Theorem 3.1 is defined by $\det_2[\underline{I} + \underline{K}\,\underline{G}(s)]\exp\{-\Delta(s+\rho)\} : N_{ab} \to \mathbf{C}$, while that of Corollary 3.2 is defined by $\det_2[\underline{I} + \underline{K}\,\underline{G}(s)]\exp\{-\tilde{\Delta}(s+\rho)\} : N_{ab} \to \mathbf{C}$. That is, in Corollary 3.2 one only needs to compute $\tilde{\Delta}(s+\rho)$ instead of $\Delta(s+\rho)$. If we further compute $\det_2[\underline{I} + \underline{K}\,\underline{G}(s)]$ by the right-hand relation of (3.9), then the block-diagonal structures of $(\underline{E}(s) - \underline{Q})^{-1}$ and $\underline{E}^{-1}(s+\rho)(\underline{Q} + \rho\underline{I})(\underline{E}(s) - \underline{Q})^{-1}$ will bring us convenience in plotting the modified Nyquist locus $\det_2[\underline{I} + \underline{K}\,\underline{G}(s)]\exp\{-\tilde{\Delta}(s+\rho)\} : N_{ab} \to \mathbf{C}$ as we will see in the next section.

Remark 4. Note that only the "DC-part" of $\hat{B}(t)K(t)\hat{C}(t)$ contributes to $\tilde{\Delta}(s+\rho)$. In other words, if the "DC-part" of $\hat{B}(t)K(t)\hat{C}(t)$ is zero, then the exponential part on the left-hand side of (3.10) can be dropped. As a side note, we point out that $\Delta(s+\rho)$ does not equal $\tilde{\Delta}(s+\rho)$ since $\underline{P}$ and $\underline{E}^{-1}(s)$ do not commute, and $\det_2[\underline{I} - \underline{E}^{-1}(s)\underline{Q}] \neq \det_2[\underline{I} - \underline{E}^{-1}(s)\underline{A}]$ in general.

Remark 5. Since any periodically time-varying state matrix $A(t)$ can be rewritten in the form of $A_{\mathrm{const}} + \tilde{A}(t)$ with A_{const} being a constant matrix, stability of the FDLCP system with the state matrix $A(t)$, no matter this FDLCP system itself is open- or closed-loop, can be easily tested by recasting the stability problem as a closed-loop stability problem with $(A_{\mathrm{const}}, I, I) = (Q, I, I)$ being the open-loop system matrices and $-\tilde{A}(t)$ being (treated as) the feedback gain. This recasting technique means that Corollary 3.2 can be easily applied without computing the transition matrix of any FDLCP models. Having this recasting technique in mind, a finite-dimensional truncated implementation of the modified Nyquist criterion is developed in the following section.

4. Implementation of the 2-regularized Nyquist criterion. In the previous section, generalized Nyquist criteria were developed for asymptotic stability of FDLCP systems. Unfortunately, however, it is hard to implement them directly due to the infinite-dimensionality of the harmonic transfer operator and operators involved in the determinant and trace computations. In this section, we consider the implementation problem of the 2-regularized Nyquist criterion in Corollary 3.2 through the staircase truncations on $\underline{G}(s)$ and other infinite-dimensional operators involved, and then the closed-loop stability analysis is reduced to that of a finite-dimensional LTI continuous-time system in an asymptotic sense.

The staircase truncation is first proposed for the H_∞ norm computation in FDLCP systems [30]. It should be noted that although the same truncation is adopted, the convergence problem in the H_∞ norm computation and that in the Nyquist locus plotting are essentially different. More precisely, in the H_∞ norm case convergence is related to infinite summations, while in the Nyquist locus case of this paper convergence pertains to infinite products. This discrepancy alerts us that just sketching the convergence proof might mislead the reader in understanding the implementation algorithm, and thus we keep the arguments in their complete form. Another benefit to make the convergence arguments in this way is that the inequalities in the convergence arguments can explicitly provide us with estimation formulas of the truncation size, though we will not deal with the size estimation problem in the paper due to the space limitation.

For simplicity, the discussions are given for the case of $\underline{K} = \underline{I}$ throughout this section. This brings no loss of generality if we notice that one can always treat $\underline{K}\,\underline{C}$ as a single operator in the harmonic return difference operator $\underline{I} + \underline{K}\,\underline{G}(s)$.

4.1. Truncation description. In this subsection we describe the staircase truncation. Strictly speaking, the staircase truncation is two-step: first skew truncate $\underline{G}(s)$ to $\underline{G}_{[N]}(s)$, and then truncate $\underline{G}_{[N]}(s)$ in a staircase fashion to $\underline{G}_{[N,M]}(s)$. Namely, we take an integer $N \geq 1$ and approximate $\underline{G}(s) = \underline{\hat{C}}(\underline{E}(s) - \underline{Q})^{-1}\underline{\hat{B}}$ by

$$\underline{G}_{[N]}(s) = \underline{\hat{C}}_{[N]}(\underline{E}(s) - \underline{Q})^{-1}\underline{\hat{B}}_{[N]}, \tag{4.1}$$

where $\underline{\hat{B}}_{[N]} := \mathcal{T}\{\hat{B}_N(t)\}$. Here $\hat{B}_N(t) := \sum_{m=-N}^{N} \hat{B}_m e^{jm\omega_h t}$ with $\{\hat{B}_m\}$ being the Fourier coefficient sequence of $\hat{B}(t)$. Similarly, $\underline{\hat{C}}_{[N]}$ is constructed in terms of $\{\hat{C}_m\}$, which is the Fourier coefficient sequence of $\hat{C}(t)$. Only the skew truncation cannot reduce the $\det_2$ computation to a finite-dimensional one, and thus we introduce the staircase truncation on $\underline{G}(s)$ as follows:

$$\underline{G}_{[N,M]}(j\varphi) = \underline{\hat{C}}_{[N,M]}(\underline{E}_M(s) - \underline{Q}_M)^{-1}\underline{\hat{B}}_{[N,M]}. \tag{4.2}$$

Here, the infinite-dimensional matrix $\underline{\hat{B}}_{[N,M]} := \mathrm{diag}[\ldots, \hat{B}_{NM}, \hat{B}_{NM}, \hat{B}_{NM}, \ldots]$ is defined with

$$\hat{B}_{NM} = \underbrace{\begin{bmatrix} \hat{B}_0 & \cdots & \hat{B}_{-N} & & 0 \\ \vdots & \ddots & & \ddots & \\ \hat{B}_N & & \ddots & & \hat{B}_{-N} \\ & \ddots & & \ddots & \vdots \\ 0 & & \hat{B}_N & \cdots & \hat{B}_0 \end{bmatrix}}_{(2M+1)-\text{blocks}}, \tag{4.3}$$

where we assume $M \geq N+1$. The infinite-dimensional matrix $\underline{\hat{C}}_{[N,M]}$ is defined similarly to $\underline{\hat{B}}_{[N,M]}$ but in terms of the Fourier coefficients of $\hat{C}(t)$. Furthermore, the infinite-dimensional but block-diagonal operators $\underline{E}(s)$ and $\underline{Q}$ are partitioned into diagonal blocks accordingly. That is,

$$\begin{aligned}\underline{Q}_M &:= \operatorname{diag}[\ldots, Q_M, Q_M, Q_M, \ldots](=\underline{Q}),\\ \underline{E}_M(s) &:= \operatorname{diag}[\ldots, E_{M,-1}(s), E_{M0}(s), E_{M1}(s), \ldots](=\underline{E}(s))\end{aligned}$$

with $Q_M = \operatorname{diag}[Q, Q, \ldots, Q]$ being $(2M+1)\times(2M+1)$ and

$$E_{Mm}(s) = \operatorname{diag}[\varphi_{m(2M+1)-M}(s)I, \ldots, \varphi_{m(2M+1)}(s)I, \ldots, \varphi_{m(2M+1)+M}(s)I],$$

where $m \in \mathbf{Z}$.

4.2. Truncation convergence. To state the final result, we need to establish convergence lemmas associated with the staircase truncation on the harmonic transfer operator in the $\det_2$ and trace sense. In this subsection, we show relevant convergence lemmas for the suggested truncation treatment.

LEMMA 4.1. *Assume in the* FDLCP *system* (2.1) *that* $A(t) \in L_{\mathrm{PCD}}[0,h]$ *and* $B(t), C(t) \in L_{\mathrm{CAC}}[0,h]$, *and the domain* Ω *satisfies* A1. *Then for any* $\mu > 0$, *there exists an integer* $N_0(\mu) > 0$ *such that* $|\det_2[\underline{I} + \underline{G}_{[N]}(s)] - \det_2[\underline{I} + \underline{G}(s)]| < \mu$ $(\forall N \geq N_0(\mu), \forall s \in \partial\Omega)$.

On the basis of Lemma 4.1, to show the convergence that $\det_2[\underline{I} + \underline{G}_{[N,M]}(s)] \to \det_2[\underline{I} + \underline{G}(s)]$ as $N, M \to \infty$, it suffices to show that $\det_2[\underline{I} + \underline{G}_{[N,M]}(s)] \to \det_2[\underline{I} + \underline{G}_{[N]}(s)]$ as $M \to \infty$ for each fixed $N > 0$. This is answered by the following lemma.

LEMMA 4.2. *Assume in the* FDLCP *system* (2.1) *that* $A(t) \in L_{\mathrm{PCD}}[0,h]$ *and* $B(t), C(t) \in L_{\mathrm{CAC}}[0,h]$, *and the domain* Ω *satisfies* A1. *Then for any* $\mu > 0$ *and fixed* $N > 0$, *there exists an integer* $M_0(N,\mu) > 0$ *such that* $|\det_2[\underline{I} + \underline{G}_{[N,M]}(s)] - \det_2[\underline{I} + \underline{G}_{[N]}(s)]| < \mu$ $(\forall M \geq M_0(N,\mu), \forall s \in \partial\Omega)$.

Now we apply the staircase truncation on the infinite-dimensional matrix $\underline{\hat{B}}\,\underline{\hat{C}}$ as we do on $\underline{G}(s)$, and get the truncated version $\underline{\widehat{BC}}_{[N,M]}$, which is defined similarly to $\underline{\hat{B}}_{[N,M]}$ but in terms of the Fourier coefficients of $\hat{B}(t)\hat{C}(t)$. Based on this truncation, we further define

$$\begin{aligned}\tilde{\Delta}_{[N,M]}(s+\rho) &:= -\operatorname{tr}\big(\underline{E}^{-1}(s+\rho)(\underline{Q}+\rho\underline{I})(\underline{E}(s)-\underline{Q})^{-1}\underline{\widehat{BC}}_{[N,M]}\big)\\ &= -\sum_m \operatorname{tr}\big(\tilde{\Delta}_{m[N,M]}(s+\rho)\big),\end{aligned} \tag{4.4}$$

where $\underline{I}_M$ is defined similarly to $\underline{Q}_M$ but in terms of the identity matrix I and

$$\tilde{\Delta}_{m[N,M]}(s+\rho) := E_{Mm}^{-1}(s+\rho)(Q_M+\rho I_M)(E_{Mm}(s)-Q_M)^{-1}\widehat{BC}_{NM} \tag{4.5}$$

with $m \in \mathbf{Z}$ and I_M being the $(2M+1)\times(2M+1)$ blockwise identity. The matrix $\widehat{BC}_{NM}$ is defined similarly to $\hat{B}_{NM}$ but in terms of the Fourier coefficients of $\hat{B}(t)\hat{C}(t)$. Then by repeating arguments similar to those in the proofs of Lemmas 4.1 and 4.2, the following lemma can be shown.

LEMMA 4.3. *Assume in the* FDLCP *system* (2.1) *that* $A(t) \in L_{\mathrm{PCD}}[0,h]$ *and* $B(t), C(t) \in L_{\mathrm{CAC}}[0,h]$, *and the domain* Ω *satisfies* A1 *and* A2$'$. *Then for any* $\mu > 0$ *and fixed* $N > 0$, *there exist integers* $N_1(\mu) > 0$ *and* $M_1(N,\mu) > 0$ *such that* $|\tilde{\Delta}_{[N,M]}(s+\rho) - \tilde{\Delta}(s+\rho)| < \mu$ $(\forall N \geq N_1(\mu), M \geq M_1(N,\mu), \forall s \in \partial\Omega)$.

Combining Lemmas 4.1, 4.2, and 4.3, we can get a tight estimation of $\det_2[\underline{I}+\underline{G}(s)]\exp\{-\tilde{\Delta}(s+\rho)\}$ by $\det_2[\underline{I}+\underline{G}_{[N,M]}(s)]\exp\{-\tilde{\Delta}_{[N,M]}(s+\rho)\}$. Now we show that the latter can be reduced to finite-dimensional computations. Indeed, by definition, we have

$$\begin{aligned}&\det_2\big[\underline{I}+\underline{G}_{[N,M]}(s)\big]\exp\big\{-\tilde{\Delta}_{[N,M]}(s+\rho)\big\}\\&\quad=\prod_m\prod_k\big(1+\lambda_k\big(G_{m[N,M]}(s)\big)\big)\exp\big\{-\lambda_k\big(G_{m[N,M]}(s)\big)\big\}\\&\quad\quad\times\exp\Big\{-\sum_m\operatorname{tr}\big(\tilde{\Delta}_{m[N,M]}(s+\rho)\big)\Big\},\end{aligned}\tag{4.6}$$

where the finite-dimensional matrix $G_{m[N,M]}(s)$ is given by

$$G_{m[N,M]}(s):=\hat{C}_{NM}(E_{Mm}(s)-Q_M)^{-1}\hat{B}_{NM}\quad(m\in\mathbf{Z}).\tag{4.7}$$

LEMMA 4.4. *Assume in the* FDLCP *system* (2.1) *that* $A(t)\in L_{\mathrm{PCD}}[0,h]$ *and* $B(t),C(t)\in L_{\mathrm{CAC}}[0,h]$, *and the domain* Ω *satisfies* A1 *and* A2′. *Then for any fixed* N, *it holds uniformly over* $s\in\partial\Omega$ *that*

$$\begin{cases}\lim\limits_{M\to\infty}\prod\limits_{m\neq0}\prod\limits_k\big(1+\lambda_k\big(G_{m[N,M]}(s)\big)\big)\exp\big\{-\lambda_k\big(G_{m[N,M]}(s)\big)\big\}=1,\\ \lim\limits_{M\to\infty}\sum\limits_{m\neq0}\operatorname{tr}\big(\tilde{\Delta}_{m[N,M]}(s+\rho)\big)=0.\end{cases}\tag{4.8}$$

On the basis of Lemma 4.4 and (4.6), it follows readily that for any $\mu>0$ and fixed $N>0$, there exists an integer $M_2(N,\mu)$ such that $\forall M\geq M_2(N,\mu)$ and $\forall s\in\partial\Omega$

$$\begin{aligned}&\big|\det_2\big[\underline{I}+\underline{G}_{[N,M]}(s)\big]\exp\big\{-\tilde{\Delta}_{[N,M]}(s+\rho)\big\}\\&\quad-\det_2\big[I_M+G_{0[N,M]}(s)\big]\exp\big\{-\operatorname{tr}\big(\tilde{\Delta}_{0[N,M]}(s+\rho)\big)\big\}\big|<\mu.\end{aligned}\tag{4.9}$$

A complete proof for (4.9) is given in Appendix B to keep our mainstream discussions clear.

4.3. Finite-dimensional 2-regularized Nyquist criterion. Summarizing the above discussions, we are led immediately to the following theorem, which reduces the Nyquist criterion of Corollary 3.2 to a finite-dimensional one in an asymptotic sense.

THEOREM 4.5. *Suppose in the* FDLCP *system* (2.1) *that* $A(t)$, $B(t)$, $C(t)\in L_{\mathrm{CAC}}[0,h]\cap L_{\mathrm{PCD}}[0,h]$. *Let* n_{us} *denote the number of the unstable eigenvalues of the open-loop Floquet state operator* $\underline{Q}-\underline{E}(j0)$ *in the fundamental strip* $\mathbf{C}_F$ *defined in* (3.7). *Take an arbitrary positive number* ρ *and a sufficiently small number* r *according to the open-loop eigenvalue condition of* $\underline{Q}-\underline{E}(j0)$ *on the imaginary axis such that* $\rho>r\geq0$. *If* N *and* M *are large enough truncation parameters satisfying* $M\geq N+1$, *then the closed-loop system* G_c *is asymptotically stable if and only if the modified Nyquist locus,* $\det_2[I_M+G_{0[N,M]}(s)]\exp\{-\operatorname{tr}(\tilde{\Delta}_{0[N,M]}(s+\rho))\}:N_{ab}\to\mathbf{C}$, *vanishes nowhere on* N_{ab} *and encircles the origin* n_{us} *times in the counterclockwise sense.* $\tilde{\Delta}_{0[N,M]}(s+\rho)$ *and* $G_{0[N,M]}(s)$ *are defined in* (4.5) *and* (4.7), *respectively, with* $m=0$.

Remark 6. Recall the recasting treatment suggested in Remark 5, by which A_{const} can be taken in such a way that the "DC-part" of $\tilde{A}(t)$ is zero. It would be worth noting that $\operatorname{tr}(\tilde{\Delta}_{0[N,M]}(s+\rho))$ will be identically zero in such a recasting treatment, and thus the exponential part can be dropped in the (modified) Nyquist locus (see Remark 4).

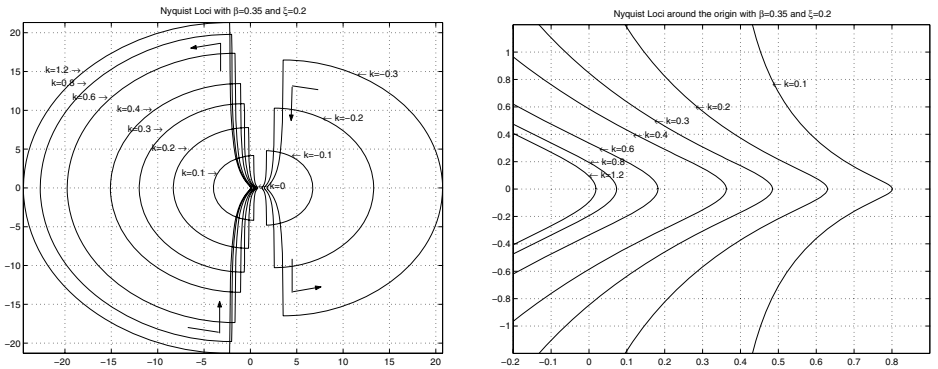
5. Numeric examples. Consider asymptotic stability of the lossy Mathieu equation by means of Theorem 4.5. The lossy Mathieu equation was frequently encountered in such studies as the rolling motion of ships [1], the flapping dynamics of the helicopter rotor blade [26], and the motion of a pendulum with a periodically excited support [12]. A comprehensive study about this differential equation can be found in [23] and [25]. It turns out to be one of the most widely studied FDLCP models in the literature, and hence using the lossy Mathieu equation as our numeric example is reasonable. More precisely, the lossy Mathieu equation is given by

$$\ddot{x}(t) + 2\xi\dot{x}(t) = [1 - 2\beta\cos\omega_h t]u(t), \quad \omega_h = 2 \quad (\text{i.e.}, h = \pi)$$

which leads to the state-space model

$$A(t) = \begin{bmatrix} 0 & 1 \\ 0 & -2\xi \end{bmatrix}, \quad B(t) = \begin{bmatrix} 0 \\ 1 - 2\beta\cos\omega_h t \end{bmatrix}, \quad C(t) = [1 \quad 0],$$

where the open-loop state matrix $A(t)$ is constant but the input matrix $B(t)$ is a π-periodic time-varying matrix, each entry of which is continuous and differentiable on $[0, h]$. In other words, in the open-loop system, $Q = A(t)$ and $P(t, 0) = I$. Now we introduce the output feedback $u(t) = -ky(t)$, where k is a scalar constant. This leads to a closed-loop FDLCP system with a π-periodic time-varying state matrix, and our problem is to test the closed-loop stability by Theorem 4.5.

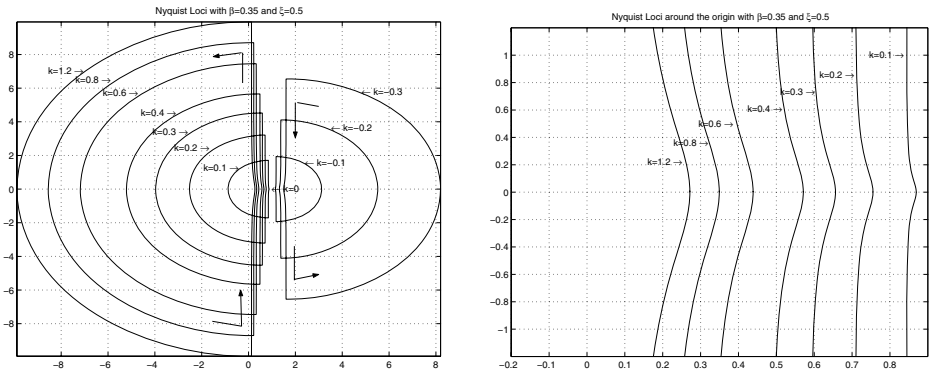


(a) Nyquist loci (b) Nyquist loci around the origin

FIG. 5.1. 2-*Regularized Nyquist loci with the output feedback gain* k *varying from* 1.2 *to* -0.3 *in the case of* $\beta = 0.35$ *and* $\xi = 0.2$ *(*$N_r = N_{0.05}$*, the arrows indicate the Nyquist locus direction).*

It is clear that the open-loop system has a zero eigenvalue. If we take a Nyquist contour as described in Figure 3.1, the corresponding region enclosed by this Nyquist contour has one unstable open-loop eigenvalue of the operator $\underline{Q} - \underline{E}(j0)$, assuming that $\xi > 0$. Note also that the Fourier series expansion of $B(t)$ has nonzero terms only up to the first harmonic wave. Since $P(t, 0) = I$, it follows that the skew truncation can be dispensed with, and only the staircase truncation on the corresponding (open-loop) harmonic transfer operator is enough. Figures 5.1 and 5.2 give the (modified) Nyquist loci under different parameters β, ξ while the output feedback gain k varies from 1.2 to -0.3. In the computations, the staircase truncation parameter $M = 10$, the shift factor $\rho = 0.1$, and the bypassing radius $r = 0.05$ are taken for simplicity. The computation results show that there are no numerically discernible differences among the Nyquist loci when larger M's are taken, for example, when $M = 20$.

From Figure 5.1, it can be asserted that in the case of $\beta = 0.35$ and $\xi = 0.2$, the closed-loop FDLCP system is stable when the feedback gain k is relatively small, while the closed-loop system slides to the stable/unstable boundary when the feedback gain k is overstrong (i.e., $k \geq 1.2$). However, in the case of $\beta = 0.35$ and $\xi = 0.5$, whose Nyquist loci are given in Figure 5.2, stability of the closed-loop FDLCP system has relatively strong robustness to the output feedback gain variation. From Figures 5.1 and 5.2, the Nyquist loci when positive feedback is applied, i.e., $k \leq 0$, tell us that the closed-loop FDLCP systems are unstable in both cases.



(a) Nyquist loci (b) Nyquist loci around the origin

FIG. 5.2. 2-*Regularized Nyquist loci with the output feedback gain* k *varying from* 1.2 *to* -0.3 *in the case of* $\beta = 0.35$ *and* $\xi = 0.5$ *(*$N_r = N_{0.05}$*, the arrows indicate the Nyquist locus direction).*

Finally, we observe that Nyquist loci under different bypassing radii r's can also reveal some structural features of the open-loop FDLCP systems. For example, in the case of $\beta = 0.5$, $\xi = 0.2$, and $k = 0.4$, Figure 5.3 gives the Nyquist loci with the bypassing radius being $r = 0.05$, 0.04, and 0.03, respectively. One can see that as $r \to 0$, the Nyquist locus goes to infinity on the portion corresponding to the bypassing semicircle. This clearly reflects the fact that the open-loop system has an unstable eigenvalue at the origin.

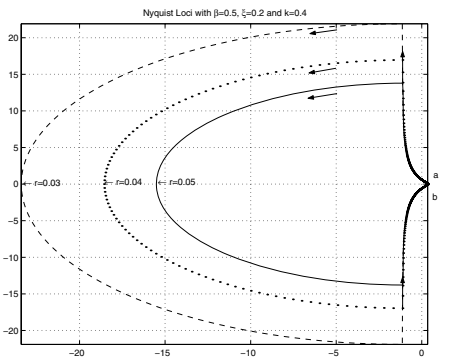


FIG. 5.3. 2-*Regularized Nyquist loci with different bypassing radii* r.

The stability results about the lossy Mathieu equation here coincide with those derived through the approximate modeling approach [31], which also gives necessary and sufficient stability conditions for FDLCP systems via the so-called harmonic

Lyapunov equation. Note that the lossy Mathieu equation may be reexpressed by a periodic differential equation similar to that of Exercise 1.5.6 of [12]. Hence, the stability assertion for Exercise 1.5.6 of [12] confirms that stability analysis through the Nyquist criterion upon the lossy Mathieu equation is effective.

6. Conclusion. In this paper, we established a generalized Nyquist criterion in FDLCP systems by means of the 2-regularized determinant related to the open-loop harmonic transfer operator. This work is inspired by the fact that the harmonic transfer operators of most practical FDLCP systems, which are defined via the Fourier series analysis of the system matrices, are Hilbert–Schmidt operators; that is, the use of the 2-regularized determinants can be validated for a large class of FDLCP systems, while the use of the usual determinant cannot. This criterion makes it possible to test the closed-loop asymptotic stability through open-loop analysis in a much more general FDLCP setting, compared to the Hill-determinant and trace class operator determinant techniques. The Hill-determinant defined on the harmonic transfer operator [26] is hard to validate in general. Moreover, by using the recasting technique suggested in Remark 5, the generalized Nyquist criterion can be applied to both open- and closed-loop FDLCP systems without involving the transition matrix and Floquet factorization computations, and thus can be implemented via finite-dimensional conditions in an asymptotic sense. In addition, it is clear that the 2-regularized Nyquist criterion applies to both SISO (single input/single output) and MIMO (multi input/multi output) cases. Observations (say by Theorem 7.4 of [11]) indicate that the Nyquist locus in the 2-regularized determinant sense is also continuous with regard to the periodically time-varying feedback gain $K(t)$, and thus can be utilized in robustness analysis. This is left as one of our subsequent research topics.

Appendix A. The function $f(n)$ of an integer n is defined by

$$f(n) = \begin{cases} 1, & n = 0, \\ |n|^{-1}, & n \neq 0. \end{cases}$$

Then we have $\sum_{n=N+1}^{\infty} f(n)^2 < \frac{1}{N} \quad (N \geq 1)$ and $\sum_{n=-\infty}^{\infty} f(n)^2 < 5$.

Appendix B.

Proof of Lemma 2.2. Under the assumptions on $A(t), B(t)$, and $C(t)$, the similarity transformation formulas of Lemma 2.1 apply. Thus the harmonic transfer operator can be rewritten as

$$\underline{G}(s) = \hat{\underline{C}}(\underline{E}(s) - \underline{Q})^{-1}\hat{\underline{B}} \tag{B.1}$$

for all $s \in \Omega\backslash\Lambda$. Here, $\hat{\underline{B}}$ and $\hat{\underline{C}}$ are bounded on l_2 by Corollary 2.2 of [9, p. 567]. Also, it is obvious that for each fixed $s \in \Omega\backslash\Lambda$, there exists a number $K(s) > 0$ such that

$$\|(\varphi_m(s)I - Q)^{-1}\| \leq K(s)f(m), \tag{B.2}$$

where f is defined in Appendix A. Noting the block-diagonal structure of $(\underline{E}(s)-\underline{Q})^{-1}$, it follows that $(\underline{E}(s) - \underline{Q})^{-1}$ is compact for $s \in \Omega\backslash\Lambda$. Since $\|(\underline{E}(s) - \underline{Q})^{-1}\|_2^2 = \sum_m \|(\varphi_m(s) - Q)^{-1}\|_2^2 \leq n\sum_m \|(\varphi_m(s) - Q)^{-1}\|^2$, (B.2) tells that $(\underline{E}(s) - \underline{Q})^{-1} \in \mathcal{C}_2(l_2)$ for each fixed $s \in \Omega\backslash\Lambda$. Noting that $\hat{\underline{B}}$ and $\hat{\underline{C}}$ are bounded on l_2, we obtain by (B.1) that $\underline{G}(s) \in \mathcal{C}_2(l_2)$ for each $s \in \Omega\backslash\Lambda$.

It remains to show that $\|\underline{G}(s)\|_2$ is uniformly bounded over $s \in \partial\Omega$. To this end, let us show that there exists a number $K > 0$ independent of s such that

$$\|(\varphi_m(s)I - Q)^{-1}\| \le Kf(m) \tag{B.3}$$

for all $s \in \partial\Omega$. To see this, we note that if $\|Q/z\| < 1$, then

$$\begin{aligned}\|(zI - Q)^{-1}\| &= \frac{1}{|z|}\left\|I - \frac{1}{z}Q + \frac{1}{z^2}Q^2 - \cdots\right\| \\ &\le \frac{1}{|z|}\left(\|I\| + \left\|\frac{1}{z}Q\right\| + \left\|\frac{1}{z^2}Q^2\right\| + \cdots\right) \le \frac{1}{|z| - \|Q\|}.\end{aligned}$$

Since $|\varphi_m(s)| > \|Q\|$ if $|m|\omega_h > |\mathrm{Im}(s)| + \|Q\|$, this inequality says if $|m|\omega_h > |\mathrm{Im}(s)| + \|Q\|$, then

$$\|(\varphi_m(s)I - Q)^{-1}\| \le (|\varphi_m(s)| - \|Q\|)^{-1}. \tag{B.4}$$

Thus it is clear by (2.6) that there exists an integer $m_0 > 0$ such that (B.4) holds for all integers $m \ge m_0$ and $s \in \partial\Omega$. Again from (2.6), there is $K_{m_0} > 0$ independent of s such that $\|(\varphi_m(s)I - Q)^{-1}\| \le K_{m_0} f(m)$ for all $m \ge m_0$ and $s \in \partial\Omega$. Furthermore, for each $s \in \partial\Omega$, $\varphi_m(s)$ is not an eigenvalue of Q by A1. Hence, from (2.6) there is $K'_{m_0} > 0$ such that for all $|m| < m_0$ and $s \in \partial\Omega$, $\|(\varphi_m(s)I - Q)^{-1}\| \le K'_{m_0} f(m)$. Taking $K = \max\{K_{m_0}, K'_{m_0}\}$, (B.3) follows for any $s \in \partial\Omega$. Thus it follows from Appendix A that for any $s \in \partial\Omega$, $\|(\underline{E}(s) - \underline{Q})^{-1}\|_2 \le [\sum_m nK^2 f(m)^2]^{1/2} < K'$ for some $K' > 0$ independent of $s \in \partial\Omega$. Finally, noting that $\underline{\hat{B}}$ and $\underline{\hat{C}}$ are bounded on l_2 and $\|\underline{\hat{C}}(\underline{E}(s) - \underline{Q})^{-1}\underline{\hat{B}}\|_2 \le \|\underline{\hat{C}}\|_{l_2/l_2}\|\underline{\hat{B}}\|_{l_2/l_2}\|(\underline{E}(s) - \underline{Q})^{-1}\|_2$, the uniform boundedness of $\|\underline{\hat{C}}(\underline{E}(s) - \underline{Q})^{-1}\underline{\hat{B}}\|_2$ over $\partial\Omega$ follows readily. □

Proof of Lemma 2.3. By the definition of $\varphi_m(s)$, if we write $s = x + jy$, then we obtain

$$|\varphi_m(s)^{-1}| = \frac{1}{\sqrt{x^2 + (y + m\omega_h)^2}} \le \begin{cases} (|y + m\omega_h|)^{-1} \le K_\varphi f(m) & (m \ne 0), \\ (\sqrt{x^2 + y^2})^{-1} \le K_\varphi f(m) & (m = 0) \end{cases} \tag{B.5}$$

for some $K_\varphi > 0$ independent of $s \in \Omega$, where A1 is used for $m \ne 0$ while A2 is used for $m = 0$. Furthermore, we observe from (B.5) that

$$\|\underline{E}^{-1}(s)\|_2 \le \left[\sum_m nK_\varphi^2 f(m)^2\right]^{1/2} \le K_E < \infty \tag{B.6}$$

for some $K_E > 0$ independent of $s \in \Omega$. The inequality (B.6) says that $\underline{E}^{-1}(s) \in \mathcal{C}_2(l_2)$ for each $s \in \Omega$. Since $\underline{A}$ and $\underline{Q}$ are bounded on l_2, $\underline{E}^{-1}(s)\underline{A}$ and $\underline{E}^{-1}(s)\underline{Q}$ belong to $\mathcal{C}_2(l_2)$ for each $s \in \Omega$.

To see (2.11), we note by Lemma 2.1 that $\underline{E}(s) - \underline{A} = \underline{P}(\underline{E}(s) - \underline{Q})\underline{P}^{-1}$, which implies

$$\underline{I} - \underline{E}^{-1}(s)\underline{A} = \underline{E}^{-1}(s)\underline{P}\,\underline{E}(s)(\underline{I} - \underline{E}^{-1}(s)\underline{Q})\underline{P}^{-1} \tag{B.7}$$

on the subset l_E of l_2. Furthermore, it is already known [29] on l_E that

$$\underline{\tilde{P}} = \underline{E}(s)\underline{P} - \underline{P}\,\underline{E}(s) \tag{B.8}$$

with $\underline{\tilde{P}} := \mathcal{T}\{\frac{d}{dt}P(t,0)\}$. Since l_E is $\underline{P}^{-1}$-invariant by Lemma 2.1, using (B.8) in (B.7) gives that on l_E

$$\begin{aligned}\underline{I} - \underline{E}^{-1}(s)\underline{A} &= (\underline{P} - \underline{E}^{-1}(s)\underline{\tilde{P}})(\underline{I} - \underline{E}^{-1}(s)\underline{Q})\underline{P}^{-1} \\ &= (\underline{I} - \underline{E}^{-1}(s)\underline{\tilde{P}}\,\underline{P}^{-1})(\underline{I} - \underline{P}\,\underline{E}^{-1}(s)\underline{Q}\underline{P}^{-1}). \qquad \text{(B.9)}\end{aligned}$$

Noting that all operators in (B.9) are bounded and l_E is dense in l_2, (B.9) is true on the whole l_2. On the other hand, it is straightforward to see that $\underline{E}^{-1}(s)\underline{\tilde{P}}\,\underline{P}^{-1}$ and $\underline{P}\,\underline{E}^{-1}(s)\underline{Q}\underline{P}^{-1}$ belong to $\mathcal{C}_2(l_2)$ since $\underline{E}^{-1}(s)$ does. These observations validate the following derivations:

$$\begin{aligned}\det_2[\underline{I} - \underline{E}^{-1}(s)\underline{A}] &= \det_2[\underline{I} - \underline{E}^{-1}(s)\underline{\tilde{P}}\,\underline{P}^{-1}]\det_2[\underline{I} - \underline{P}\,\underline{E}^{-1}(s)\underline{Q}\underline{P}^{-1}] \\ &\quad \times \exp\{-\mathrm{tr}(\underline{E}^{-1}(s)\underline{\tilde{P}}\,\underline{P}^{-1}\underline{P}\,\underline{E}^{-1}(s)\underline{Q}\underline{P}^{-1})\} \\ &= \det_2[\underline{I} - \underline{E}^{-1}(s)\underline{\tilde{P}}\,\underline{P}^{-1}]\det_2[\underline{I} - \underline{E}^{-1}(s)\underline{Q}] \\ &\quad \times \exp\{-\mathrm{tr}(\underline{E}^{-1}(s)\underline{\tilde{P}}\,\underline{E}^{-1}(s)\underline{Q}\underline{P}^{-1})\} \\ &=: g_A(s)\det_2[\underline{I} - \underline{E}^{-1}(s)\underline{Q}], \qquad \text{(B.10)}\end{aligned}$$

where $g_A(s) := \det_2[\underline{I} - \underline{E}^{-1}(s)\underline{\tilde{P}}\,\underline{P}^{-1}]\exp\{-\mathrm{tr}(\underline{E}^{-1}(s)\underline{\tilde{P}}\,\underline{E}^{-1}(s)\underline{Q}\underline{P}^{-1})\}$. Hence, the assertions regarding (2.11) will follow if it is shown that $g_A(s)$ does not vanish and is analytic over Ω.

We complete the task in two steps by showing that the two components of $g_A(s)$ vanish nowhere on Ω and are analytic in s over Ω.

Step 1. It is shown that $\det_2[\underline{I} - \underline{E}^{-1}(s)\underline{\tilde{P}}\,\underline{P}^{-1}]$ vanishes nowhere on Ω and is analytic in s over Ω. To see this, we note from (B.8) that on l_E,

$$\underline{I} - \underline{E}^{-1}(s)\underline{\tilde{P}}\,\underline{P}^{-1} = \underline{E}^{-1}(s)\underline{P}\,\underline{E}(s)\underline{P}^{-1}, \qquad \text{(B.11)}$$

which says that $\underline{I} - \underline{E}^{-1}(s)\underline{\tilde{P}}\,\underline{P}^{-1}$ is invertible on l_E for each $s \in \Omega$ since $\underline{E}(s)$ is invertible on l_E, and l_E is $\underline{P}$- and $\underline{P}^{-1}$-invariant (see Lemma 2.1). Since l_E is dense in l_2, this, in particular, implies that $\underline{I} - \underline{E}^{-1}(s)\underline{\tilde{P}}\,\underline{P}^{-1}$ has a dense range in l_2. Furthermore, one can claim that $\underline{I} - \underline{E}^{-1}(s)\underline{\tilde{P}}\,\underline{P}^{-1}$ is one-to-one on l_2 since $(\underline{I} - \underline{E}^{-1}(s)\underline{\tilde{P}}\,\underline{P}^{-1})\underline{x} = 0$ implies that $\underline{x} \in l_E$, and thus $\underline{x} = 0$ by the invertibility of $\underline{I} - \underline{E}^{-1}(s)\underline{\tilde{P}}\,\underline{P}^{-1}$ on l_E. On the basis of these facts, Theorem 2.7.6 of [21, p. 30] tells us that the operator $\underline{I} - \underline{E}^{-1}(s)\underline{\tilde{P}}\,\underline{P}^{-1}$ is actually invertible on the whole l_2. This, together with the invertibility of $\underline{I} - \underline{E}^{-1}(s)\underline{Q}$, implies by (B.9) that $\underline{I} - \underline{E}^{-1}(s)\underline{A}$ is invertible on l_2. On the other hand, Property 1.8(e) of [5, p. 17] ensures that $\det_2[\underline{I} - \underline{E}^{-1}(s)\underline{\tilde{P}}\,\underline{P}^{-1}] \neq 0$ on Ω.

To show that $\det_2[\underline{I} - \underline{E}^{-1}(s)\underline{\tilde{P}}\,\underline{P}^{-1}]$ is analytic in s over Ω, we need some preparations. To this end, let us approximate $\underline{\tilde{P}}$ and $\underline{P}^{-1}$ by $[\underline{\tilde{P}}]_N$ and $[\underline{P}^{-1}]_N$, respectively, as follows:

$$[\underline{\tilde{P}}]_N := \mathcal{T}\left\{\sum_{|m|\le N}\tilde{P}_m e^{jm\omega_h t}\right\}, \quad [\underline{P}^{-1}]_N := \mathcal{T}\left\{\sum_{|m|\le N}\check{P}_m e^{jm\omega_h t}\right\}.$$

Here $\{\tilde{P}_m\}$ and $\{\check{P}_m\}$ are the Fourier coefficients sequences of $\tilde{P}(t,0)$ and $P^{-1}(t,0)$, respectively. Now let us define the operators

$$\underline{K}(s) := -\underline{E}^{-1}(s)\underline{\tilde{P}}\,\underline{P}^{-1}, \quad \underline{K}_N(s) := -\underline{E}^{-1}(s)[\underline{\tilde{P}}]_N[\underline{P}^{-1}]_N.$$

Since $\underline{E}^{-1}(s) \in \mathcal{C}_2(l_2)$, it follows that $\underline{K}_N(s) \in \mathcal{C}_2(l_2)$ for each N and $s \in \Omega$. By the structure of the operators $\underline{\tilde{P}}$ and $\underline{P}^{-1}$ and (B.6), Proposition 1.3 of [9, p. 98] tells us that

$$\|\underline{K}(s)\|_2 \le \|\underline{E}^{-1}(s)\|_2 \|\underline{\tilde{P}}\|_{l_2/l_2} \|\underline{P}^{-1}\|_{l_2/l_2} \le K_1 < \infty, \tag{B.12}$$

$$\begin{aligned}\|\underline{K}_N(s)\|_2 &\le \|\underline{E}^{-1}(s)\|_2 \|[\underline{\tilde{P}}]_N\|_{l_2/l_2} \|[\underline{P}^{-1}]_N\|_{l_2/l_2} \le K_E \sum_{|m|\le N} \|\tilde{P}_m\| \sum_{|m|\le N} \|\check{P}_m\| \\ &\le K_E \sum_{m=-\infty}^{+\infty} \|\tilde{P}_m\| \sum_{m=-\infty}^{+\infty} \|\check{P}_m\| \le K_2 < \infty \end{aligned} \tag{B.13}$$

for some $K_1 > 0$ and $K_2 > 0$ independent of $s \in \Omega$ and N. This is because $\tilde{P}(t,0)$ and $P(t,0)$ belong to $L_{\mathrm{CAC}}[0,h]$ under the assumption about $A(t)$ [29], and thus $\sum_{m=-\infty}^{+\infty} \|\tilde{P}_m\| < \infty$ and $\sum_{m=-\infty}^{+\infty} \|\check{P}_m\| < \infty$. By A2 and the form of $\underline{E}(s)$, $\underline{K}_N(s)$ is analytic in s over Ω in the elementwise sense since each entry of $\underline{K}_N(s)$ is a finite sum due to the skew-strip structure of $[\underline{\tilde{P}}]_N$ and $[\underline{P}^{-1}]_N$. In the following, we say that $\underline{K}_N(s)$ is an analytic $\mathcal{C}_2(l_2)$-valued function in this sense.

Now we show that $\underline{K}(s) - \underline{K}_N(s) \to 0$ in the norm of $\mathcal{C}_2(l_2)$ uniformly over Ω as $N \to \infty$. To see this, we note that

$$\begin{aligned}\|\underline{K}(s) - \underline{K}_N(s)\|_2 &\le \|\underline{E}^{-1}(s)\|_2 \|\underline{\tilde{P}}\,\underline{P}^{-1} - [\underline{\tilde{P}}]_N [\underline{P}^{-1}]_N\|_{l_2/l_2} \\ &\le K_E \big(\|\underline{\tilde{P}} - [\underline{\tilde{P}}]_N\|_{l_2/l_2} \|\underline{P}^{-1}\|_{l_2/l_2} + \|[\underline{\tilde{P}}]_N\|_{l_2/l_2} \|\underline{P}^{-1} - [\underline{P}^{-1}]_N\|_{l_2/l_2} \big). \end{aligned} \tag{B.14}$$

On the other hand, by the structures of $\underline{\tilde{P}} - [\underline{\tilde{P}}]_N$ and $\underline{P}^{-1} - [\underline{P}^{-1}]_N$ and the facts that $\tilde{P}(t,0)$ and $P^{-1}(t,0)$ belong to $L_{\mathrm{CAC}}[0,h]$, it follows readily that $\|\underline{\tilde{P}} - [\underline{\tilde{P}}]_N\|_{l_2/l_2}$ and $\|\underline{P}^{-1} - [\underline{P}^{-1}]_N\|_{l_2/l_2}$ go to zero as $N \to \infty$. These facts, together with the fact that there is an upper bound for $\|[\underline{\tilde{P}}]_N\|_{l_2/l_2}$ independent of N, imply that $\|\underline{K}(s) - \underline{K}_N(s)\|_2 \to 0$ uniformly over Ω as $N \to \infty$. This ensures that $\underline{K}(s)$ is an analytic $\mathcal{C}_2(l_2)$-valued function, which leads us to the desired consequence.

Step 2. It is shown that $\exp\{-\mathrm{tr}(\underline{E}^{-1}(s)\underline{\tilde{P}}\,\underline{E}^{-1}(s)\underline{Q}\underline{P}^{-1})\}$ does not vanish and is analytic over $s \in \Omega$. By Property 1.3(c) of [5, p. 14] and Theorem 2.1 of [9, p. 111], we have

$$\begin{aligned}|\mathrm{tr}(\underline{E}^{-1}(s)\underline{\tilde{P}}\,\underline{E}^{-1}(s)\underline{Q}\underline{P}^{-1})| &\le \|\underline{E}^{-1}(s)\underline{\tilde{P}}\,\underline{E}^{-1}(s)\underline{Q}\underline{P}^{-1}\|_1 \\ &\le \|\underline{E}^{-1}(s)\|_2^2 \|\underline{\tilde{P}}\|_{l_2/l_2} \|\underline{Q}\underline{P}^{-1}\|_{l_2/l_2} \le K_E^2 \|\underline{\tilde{P}}\|_{l_2/l_2} \|\underline{Q}\underline{P}^{-1}\|_{l_2/l_2} \le K_3 < \infty \end{aligned}$$

for some $K_3 > 0$ independent of $s \in \Omega$ since $\underline{\tilde{P}}$, $\underline{Q}$, and $\underline{P}^{-1}$ are bounded on l_2. This inequality says clearly that $\exp\{-\mathrm{tr}(\underline{E}^{-1}(s)\underline{\tilde{P}}\,\underline{E}^{-1}(s)\underline{Q}\underline{P}^{-1})\}$ does not vanish on Ω.

To show that $\exp\{-\mathrm{tr}(\underline{E}^{-1}(s)\underline{\tilde{P}}\,\underline{E}^{-1}(s)\underline{Q}\underline{P}^{-1})\}$ is analytic over $s \in \Omega$, by Remark 10.3 of [24, p. 197], it is enough to show that $\mathrm{tr}(\underline{E}^{-1}(s)\underline{\tilde{P}}\,\underline{E}^{-1}(s)\underline{Q}\underline{P}^{-1}) =: t_A(s)$ is analytic over $s \in \Omega$. To this end, we further define the trace function

$$\mathrm{tr}(\underline{E}^{-1}(s)[\underline{\tilde{P}}]_N \underline{E}^{-1}(s)\underline{Q}[\underline{P}^{-1}]_N) =: t_N(s).$$

It should be pointed out that for each fixed N, $\underline{E}^{-1}(s)[\underline{\tilde{P}}]_N \underline{E}^{-1}(s)\underline{Q}[\underline{P}^{-1}]_N$ belongs to $\mathcal{C}_1(l_2)$ since $\underline{E}^{-1}(s) \in \mathcal{C}_2(l_2)$. Hence, $t_N(s)$ is well defined. Now we observe that

$$|t_A(s) - t_N(s)| \le |\mathrm{tr}(\underline{E}^{-1}(s)(\underline{\tilde{P}} - [\underline{\tilde{P}}]_N)\underline{E}^{-1}(s)\underline{Q}\underline{P}^{-1})|$$

$$
\begin{aligned}
&\quad + |\mathrm{tr}(\underline{E}^{-1}(s)[\underline{\tilde{P}}]_N\underline{E}^{-1}(s)\underline{Q}(\underline{P}^{-1}-[\underline{P}^{-1}]_N))|\\
&\le \|(\underline{E}^{-1}(s)(\underline{\tilde{P}}-[\underline{\tilde{P}}]_N)\underline{E}^{-1}(s)\underline{Q}\underline{P}^{-1})\|_1\\
&\quad + \|\underline{E}^{-1}(s)[\underline{\tilde{P}}]_N\underline{E}^{-1}(s)\underline{Q}(\underline{P}^{-1}-[\underline{P}^{-1}]_N)\|_1\\
&\le \|\underline{E}^{-1}(s)\|_2^2\|\underline{\tilde{P}}-[\underline{\tilde{P}}]_N\|_{l_2/l_2}\|\underline{Q}\underline{P}^{-1}\|_{l_2/l_2}\\
&\quad + \|\underline{E}^{-1}(s)\|_2^2\|[\underline{\tilde{P}}]_N\|_{l_2/l_2}\|\underline{Q}\|_{l_2/l_2}\|\underline{P}^{-1}-[\underline{P}^{-1}]_N\|_{l_2/l_2}.
\end{aligned}
$$

As seen in Step 1 that $\tilde{P}(t,0)$ and $P^{-1}(t,0)$ belong to $L_{\mathrm{CAC}}[0,h]$, it follows that $\|\underline{\tilde{P}}-[\underline{\tilde{P}}]_N\|_{l_2/l_2}$ and $\|\underline{P}^{-1}-[\underline{P}^{-1}]_N\|_{l_2/l_2}$ go to zero as $N\to\infty$. These facts, together with $\|\underline{E}^{-1}(s)\|_2^2\le K_E^2$ and the fact that $\|[\underline{\tilde{P}}]_N\|_{l_2/l_2}$ has an upper bound independent of N, imply that $|t_N(s)-t_A(s)|\to 0$ as $N\to\infty$ uniformly over $s\in\Omega$. This indicates that to complete the proof, it suffices to show that for each fixed N, the function $t_N(s)$ is analytic over $s\in\Omega$.

It is easy to see from the structure of $[\underline{\tilde{P}}]_N$ and $[\underline{P}^{-1}]_N$ that the blockwise (m,m)th entry on the diagonal of the operator $\underline{E}^{-1}(s)[\underline{\tilde{P}}]_N\underline{E}^{-1}(s)\underline{Q}[\underline{P}^{-1}]_N$ is

$$
\varphi_m^{-1}(s)[\tilde{P}_N,\dots,\tilde{P}_{-N}]\,\mathrm{diag}\big[\varphi_{m-N}^{-1}(s),\dots,\varphi_{m+N}^{-1}(s)\big]\begin{bmatrix}Q\check{P}_{-N}\\ \vdots\\ Q\check{P}_N\end{bmatrix}
$$

whose trace is denoted by $t_{Nm}(s)$. Obviously, $t_N(s)=\sum_{m=-\infty}^{\infty}t_{Nm}(s)$. It is straightforward to see that $t_{Nm}(s)$ is analytic over Ω, and

$$
|t_{Nm}(s)|\le nK_N|\varphi_m^{-1}(s)|\max\big\{|\varphi_{m-N}^{-1}(s)|,\dots,|\varphi_{m+N}^{-1}(s)|\big\},
$$

where $K_N=\|[\tilde{P}_N,\dots,\tilde{P}_{-N}]\|\dots\|[\check{P}_{-N}^TQ^T,\dots,\check{P}_N^TQ^T]\|$. Furthermore, by Appendix A and (B.5),

$$
\begin{aligned}
&\left|t_N(s)-\sum_{|m|\le M}t_{Nm}(s)\right|\le\sum_{|m|>M}|t_{Nm}(s)|\\
&\le nK_N\left[\sum_{|m|>M}|\varphi_m^{-1}(s)|^2\right]^{1/2}\left[\sum_{|m|>M}\big(\max\big\{|\varphi_{m-N}^{-1}(s)|,\dots,|\varphi_{m+N}^{-1}(s)|\big\}\big)^2\right]^{1/2}\\
&\le nK_N\left[\sum_{|m|>M}K_\varphi^2f^2(m)\right]^{1/2}\left[\sum_{m=-\infty}^{\infty}\big(\max\big\{|\varphi_{m-N}^{-1}(s)|,\dots,|\varphi_{m+N}^{-1}(s)|\big\}\big)^2\right]^{1/2}\\
&< nK_N\left[\frac{2K_\varphi^2}{M}\right]^{1/2}\left[(2N+1)K_\varphi^2f(0)^2+\sum_{|m|\ge1}K_\varphi^2f^2(m)\right]^{1/2}\\
&< nK_NK_\varphi^2\left[\frac{2}{M}\right]^{1/2}[(2N+1)+5]^{1/2}=:nK_N'\left[\frac{2}{M}\right]^{1/2}\to 0\quad(M\to\infty)
\end{aligned}
$$

since $K_N'<\infty$ for any fixed $N\ge1$. The above arguments say that $\sum_{|m|\le M}t_{Nm}(s)$ converges to $t_N(s)$ uniformly over $s\in\Omega$. Therefore, it follows that $t_N(s)$ is also analytic over $s\in\Omega$.

Finally, let us show the assertion that $(\underline{I}-\underline{E}^{-1}(s)\underline{A})^{-1}$ is bounded on l_2. To this end, we note by (B.8) that $\underline{E}^{-1}(s)\underline{P}^{-1}\underline{E}(s)=\underline{P}^{-1}+\underline{E}^{-1}(s)\underline{P}^{-1}\underline{\tilde{P}}\,\underline{P}^{-1}$ on l_E. Hence, $\underline{E}^{-1}(s)\underline{P}^{-1}\underline{E}(s)$ is bounded on l_E. Obviously, this implies that $\underline{P}\,\underline{E}^{-1}(s)\underline{P}^{-1}\underline{E}(s)$,

which is the inverse of $\underline{I}-\underline{E}^{-1}(s)\underline{\tilde{P}}\,\underline{P}^{-1}$ by (B.11), is bounded on l_E. Since l_E is dense in l_2, it follows that $(\underline{I}-\underline{E}^{-1}(s)\underline{\tilde{P}}\,\underline{P}^{-1})^{-1}$ is also bounded on l_2. On the other hand, by the block-diagonal structure of $(\underline{I}-\underline{E}^{-1}(s)\underline{Q})^{-1}$ and the assumption about Ω, it is straightforward to show that $(\underline{I}-\underline{E}^{-1}(s)\underline{Q})^{-1}$ is also bounded on l_2. Summarizing these facts leads to the desired assertion by (B.9). □

Proof of Lemma 2.4. The second equality of (2.12) follows from the 2-regularized determinant definition and the fact that $\underline{E}^{-1}(s)\underline{Q}$ has an eigenvalue at each point $\lambda_k(Q)/(s+jm\omega_h)$, $m\in\mathbf{Z}$.

To see the assertions about $f_Q(s)$, we consider only the case of $n=1$ without loss of generality. The arguments are given by means of the results in Chapter 15 of [24, pp. 298–303]. More precisely, let us define the function sequence $\{f_m(s)\}$ by

$$f_m(s) := \Big(1-\frac{\lambda(Q)}{s+jm\omega_h}\Big)\exp\Big\{\frac{\lambda(Q)}{s+jm\omega_h}\Big\} \quad (m\in\mathbf{Z}).$$

By A2, the function $f_m(s)$ is analytic on Ω and has a zero at $\lambda(Q)-jm\omega_h$. Note by (B.5) that $|\frac{\lambda(Q)}{s+jm\omega_h}|\le|\lambda(Q)|K_\varphi f(m)$ for any $m\in\mathbf{Z}$ and $s\in\Omega$. Hence, there exists a finite integer $m_0>1$ such that $|\frac{\lambda(Q)}{s+jm\omega_h}|\le 1\ \forall|m|\ge m_0$ and $\forall s\in\Omega$, which implies by Lemma 15.8 of [24, p. 301] that

$$|1-f_m(s)|\le\Big|\frac{\lambda(Q)}{s+jm\omega_h}\Big|^2\le|\lambda(Q)|^2K_\varphi^2f^2(m)\quad(\forall|m|\ge m_0\quad\forall s\in\Omega).$$

The above arguments tell us that

$$\sum_{|m|\ge m_0}|1-f_m(s)|\le\sum_{|m|\ge m_0}|\lambda(Q)|^2K_\varphi^2f^2(m)\le\frac{2}{m_0-1}K_\varphi^2|\lambda(Q)|^2 \tag{B.15}$$

by Appendix A, which implies that $\sum_m|1-f_m(s)|$ is uniformly convergent on Ω. Then it follows by the first conclusion of Theorem 15.6 of [24, p. 300] that $\prod_m f_m(s)$ converges uniformly on Ω, and thus the product $\prod_m f_m(s)$ is analytic on Ω. The zeros property is a direct result of the second conclusion of Theorem 15.6 of [24, p. 300]. □

Proof of Lemma 4.1. First let us show that $\det_2[\underline{I}+\underline{G}_{[N]}(s)]$ is well defined for each N. That is, we must show that $\underline{G}_{[N]}(s)\in\mathcal{C}_2(l_2)$ for each N and $s\in\partial\Omega$. To see this, we note by the assumptions about the system matrices that $\hat{B}(t)$ and $\hat{C}(t)$ belong to $L_{\mathrm{CAC}}[0,h]$ [29]. Furthermore, by the structures of the operators $\underline{\hat{B}}_{[N]}$ and $\underline{\hat{C}}_{[N]}$, it follows that

$$\begin{cases}\|\underline{\hat{B}}_{[N]}\|_{l_2/l_2}\le\displaystyle\sum_{|m|\le N}\|\hat{B}_m\|\le\sum_{m=-\infty}^{+\infty}\|\hat{B}_m\|\le K_B<\infty,\\ \|\underline{\hat{C}}_{[N]}\|_{l_2/l_2}\le K_C<\infty\end{cases} \tag{B.16}$$

for some $K_B>0$ and $K_C>0$ that are independent of N. These facts, together with the definition of $\underline{G}_{[N]}(s)$ and (B.3), imply that for any $s\in\partial\Omega$

$$\begin{aligned}\|\underline{G}_{[N]}(s)\|_2&\le\|\underline{\hat{B}}_{[N]}\|_{l_2/l_2}\|\underline{\hat{C}}_{[N]}\|_{l_2/l_2}\|(\underline{E}(s)-\underline{Q})^{-1}\|_2\\ &\le K_BK_C\Big[n\sum_m K^2f^2(m)\Big]^{1/2}<\sqrt{5n}K_BK_CK<\infty.\end{aligned} \tag{B.17}$$

Equation (B.17) gives that $\underline{G}_{[N]}(s)$ belongs to $\mathcal{C}_2(l_2)$ and $\|\underline{G}_{[N]}(s)\|_2$ has a uniform upper bound for all N and $s \in \partial\Omega$. Similarly we can show that $\underline{G}_{[N,M]}(s) \in \mathcal{C}_2(l_2)$ and $\|\underline{G}_{[N,M]}(s)\|_2$ has a uniform upper bound for all N, M, and $s \in \partial\Omega$.

Now we show the main assertion. It is known from Theorem 7.4 of [11, p. 69] that

$$\begin{aligned} &|\det_2[\underline{I} + \underline{G}(s)] - \det_2[\underline{I} + \underline{G}_{[N]}(s)]| \\ &\quad \le \|\underline{G}(s) - \underline{G}_{[N]}(s)\|_2 \exp\left\{\frac{1}{2}(\|\underline{G}(s)\|_2 + \|\underline{G}_{[N]}(s)\|_2 + 1)^2\right\}. \end{aligned} \tag{B.18}$$

Hence, the uniform boundedness of $\|\underline{G}_{[N]}(s)\|_2$ over N and $s \in \partial\Omega$ together with that of $\|\underline{G}(s)\|_2$ over $s \in \partial\Omega$ says that to show the main convergence, it suffices to show that $\|\underline{G}(s) - \underline{G}_{[N]}(s)\|_2 \to 0$ uniformly for all $s \in \partial\Omega$ as $N \to \infty$. To see this, we observe that

$$\begin{aligned} \|\underline{G}(s) - \underline{G}_{[N]}(s)\|_2 &\le \|\hat{\underline{C}} - \hat{\underline{C}}_{[N]}\|_{l_2/l_2}\|(\underline{E}(s) - \underline{Q})^{-1}\|_2\|\hat{\underline{B}}\|_{l_2/l_2} \\ &\quad + \|\hat{\underline{C}}_{[N]}\|_{l_2/l_2}\|(\underline{E}(s) - \underline{Q})^{-1}\|_2\|\hat{\underline{B}} - \hat{\underline{B}}_{[N]}\|_{l_2/l_2} \\ &< \sqrt{5n}KK_B\|\hat{\underline{C}} - \hat{\underline{C}}_{[N]}\|_{l_2/l_2} + \sqrt{5n}KK_C\|\hat{\underline{B}} - \hat{\underline{B}}_{[N]}\|_{l_2/l_2}, \end{aligned} \tag{B.19}$$

where (B.16) is used. Furthermore, by the skew structure of $\hat{\underline{C}} - \hat{\underline{C}}_{[N]}$, it follows that $\|\hat{\underline{C}} - \hat{\underline{C}}_{[N]}\|_{l_2/l_2} \le \sum_{|m|\ge N}\|\hat{C}_m\| \to 0$ as $(N \to \infty)$ since $\hat{C}(t) \in L_{\mathrm{CAC}}[0,h]$. Similarly, by $\hat{B}(t) \in L_{\mathrm{CAC}}[0,h]$ we have $\|\hat{\underline{B}} - \hat{\underline{B}}_{[N]}\|_{l_2/l_2} \to 0$ as $N \to \infty$. Using these facts in (B.19), the desired convergence follows. ∎

Proof of Lemma 4.2. From the proof of Lemma 4.1, we have $\underline{G}_{[N]}(s), \underline{G}_{[N,M]}(s) \in \mathcal{C}_2(l_2)$ for all N, M, and $s \in \partial\Omega$, and $\|\underline{G}_{[N]}(s)\|_2$ and $\|\underline{G}_{[N,M]}(s)\|_2$ are uniformly bounded from above over N, M, and $s \in \partial\Omega$. Therefore, an inequality similar to (B.18) between $\underline{G}_{[N]}(s)$ and $\underline{G}_{[N,M]}(s)$ can be claimed. This means that to show the result, it suffices to show that

$$\|\underline{G}_{[N,M]}(s) - \underline{G}_{[N]}(s)\|_2 \to 0 \quad \forall s \in \partial\Omega \quad (M \to \infty) \tag{B.20}$$

uniformly for each fixed $N > 0$. To this end, we focus the attention on the inequality

$$\begin{aligned} \|\underline{G}_{[N,M]}(s) - \underline{G}_{[N]}(s)\|_2 &\le \|\check{\underline{C}}_{[N,M]}(\underline{E}(s) - \underline{Q})^{-1}\|_2\|\hat{\underline{B}}_{[N,M]}\|_{l_2/l_2} \\ &\quad + \|\hat{\underline{C}}_{[N]}\|_{l_2/l_2}\|(\underline{E}(s) - \underline{Q})^{-1}\check{\underline{B}}_{[N,M]}\|_2, \end{aligned} \tag{B.21}$$

where $\check{\underline{B}}_{[N,M]} := \hat{\underline{B}}_{[N]} - \hat{\underline{B}}_{[N,M]}$. More explicitly, it is given by the infinite-dimensional matrix

$$\check{\underline{B}}_{[N,M]} := \begin{bmatrix} \ddots & \ddots & \ddots & & & & 0 \\ & \check{B}_{NMl} & 0 & \check{B}_{NMu} & & & \\ & & \check{B}_{NMl} & 0 & \check{B}_{NMu} & & \\ & & & \check{B}_{NMl} & 0 & \check{B}_{NMu} & \\ 0 & & & & \ddots & \ddots & \ddots \end{bmatrix}$$

with the entry matrices $\check{B}_{NMl}$ and $\check{B}_{NMu}$ given by

$$\check{B}_{NMl} = \underbrace{\begin{bmatrix} 0 & \hat{B}_N & \cdots & \hat{B}_1 \\ & \ddots & \ddots & \vdots \\ & & \ddots & \hat{B}_N \\ 0 & & & 0 \end{bmatrix}}_{(2M+1)}, \quad \check{B}_{NMu} = \underbrace{\begin{bmatrix} 0 & & & 0 \\ \hat{B}_{-N} & \ddots & & \\ \vdots & \ddots & \ddots & \\ \hat{B}_{-1} & \cdots & \hat{B}_{-N} & 0 \end{bmatrix}}_{(2M+1)}.$$

The matrix $\underline{\check{C}}_{[N,M]}$ is defined similarly but in terms of $\{\hat{C}_m\}_{m=-N}^{N}$.

Furthermore, by the structure of $\underline{\hat{B}}_{[N,M]}$, it is easy to see that $\|\underline{\hat{B}}_{[N,M]}\|_{l_2/l_2} \le \sum_{|m|\le N} \|\hat{B}_m\| \le \sum_{m=-\infty}^{+\infty} \|\hat{B}_m\| \le K_B < \infty$ as in (B.16). This, together with the fact that $\|\underline{\hat{C}}_{[N]}\|_{l_2/l_2} \le K_C$, implies that to complete the proof of (B.20) via (B.21), it remains to show that as $M \to \infty$

$$\|\underline{\check{C}}_{[N,M]}(\underline{E}(s) - \underline{Q})^{-1}\|_2 \to 0, \quad \|(\underline{E}(s) - \underline{Q})^{-1}\underline{\check{B}}_{[N,M]}\|_2 \to 0 \tag{B.22}$$

uniformly for $s \in \partial\Omega$. Now we show that the convergence of (B.22) is true. To see this, we note that

$$\begin{aligned} &\big\|(\underline{E}(s) - \underline{Q})^{-1}\underline{\check{B}}_{[N,M]}\big\|_2 \\ &\quad \le \big\|(\underline{E}(s) - \underline{Q})^{-1}\underline{\check{B}_l}_{[N,M]}\big\|_2 + \big\|(\underline{E}(s) - \underline{Q})^{-1}\underline{\check{B}_u}_{[N,M]}\big\|_2, \end{aligned} \tag{B.23}$$

where $\underline{\check{B}_l}_{[N,M]}$ and $\underline{\check{B}_u}_{[N,M]}$ are the lower and upper triangle portions of $\underline{\check{B}}_{[N,M]}$, respectively. Hence, by the structures of $\underline{E}_M(j\varphi)$, $\underline{Q}_M$, and $\underline{\check{B}_l}_{[N,M]}$ as well as the fact that the entries of $\check{B}_{NMl}$ are zero except its right-upper blocks, we have

$$\begin{aligned} \big\|(\underline{E}(s) - \underline{Q})^{-1}\underline{\check{B}_l}_{[N,M]}\big\|_2 &= \Big[\sum_m \big\|(E_{Mm}(s) - Q_M)^{-1}\check{B}_{NMl}\big\|_2^2\Big]^{1/2} \\ &\le \Big[\sum_m \big\|\partial_N\big((E_{Mm}(s) - Q_M)^{-1}\big)\big\|_2^2 \cdot \|\check{B}_{NMl}\|^2\Big]^{1/2}, \end{aligned} \tag{B.24}$$

where $\partial_N(\cdot)$ means taking out the first N block columns from $(\cdot)$. Moreover, by similar arguments to the above, it readily follows that $\|\check{B}_{NMl}\| \le K_B$ since $\check{B}_{NMl}$ is a submatrix of $\underline{\hat{B}}_{[N,M]}$. Hence, it is easy to see by (B.3) that under our standing assumption $M \ge N + 1$,

$$\begin{aligned} &\big\|(\underline{E}(s) - \underline{Q})^{-1}\underline{\check{B}_l}_{[N,M]}\big\|_2 \\ &\quad \le K_B\Big[\sum_m \sum_{k=0}^{N-1} n\|((s + j(m(2M+1) - M + k))I - Q)^{-1}\|_2^2\Big]^{1/2} \\ &\quad \le K_B\sqrt{n}\Big[\sum_m \sum_{k=0}^{N-1} K^2 f^2(m(2M+1) - M + k)\Big]^{1/2} \\ &\quad \le K_B\sqrt{n}\Big[NK^2 \sum_m \max_{k\in\{0,1,\ldots,N-1\}}\{f^2(m(2M+1) - M + k)\}\Big]^{1/2} \end{aligned}$$

$$\le KK_B\sqrt{nN}\Big[\sum_m f^2\Big(\min_{k\in\{0,1,\dots,N-1\}}\{|m(2M+1)-M+k|\}\Big)\Big]^{1/2}$$
$$< KK_B\sqrt{nN}\Big[\sum_m f^2(m(M+1))\Big]^{1/2}$$
$$= KK_B\sqrt{nN}\Big[\frac{1}{(M+1)^2}\sum_m f^2(m)\Big]^{1/2} \le \frac{KK_B\sqrt{5nN}}{M+1}. \tag{B.25}$$

Thus, for each fixed N and for any $\mu>0$, there exists an integer $M_0'(N,\mu)>0$ such that

$$\|\hat{\underline{C}}_{[N]}\|_{l_2/l_2}\big\|(\underline{E}(s)-\underline{Q})^{-1}\check{\underline{B}}_{l[N,M]}\big\|_2 < \frac{\mu}{4} \quad (\forall M\ge M_0'(N,\mu) \quad \forall s\in\partial\Omega). \tag{B.26}$$

The above arguments can be repeated on the second term of the right-hand side of (B.23). Hence, for the same $\mu>0$ and $M_0'(N,\mu)$, it is easy to see that

$$\|\hat{\underline{C}}_{[N]}\|_{l_2/l_2}\big\|(\underline{E}(s)-\underline{Q})^{-1}\check{\underline{B}}_{u[N,M]}\big\|_2 < \frac{\mu}{4} \quad (\forall M\ge M_0'(N,\mu) \quad \forall s\in\partial\Omega), \tag{B.27}$$

where we used the fact that $\|\check{B}_{NMl}\|$ and $\|\check{B}_{NMu}\|$ have the same upper bound. From (B.26) and (B.28), it follows that

$$\|\hat{\underline{C}}_{[N]}\|_{l_2/l_2}\big\|(\underline{E}(s)-\underline{Q})^{-1}\check{\underline{B}}_{[N,M]}\big\|_2 < \frac{\mu}{2} \quad (\forall M\ge M_0'(N,\mu) \quad \forall s\in\partial\Omega). \tag{B.28}$$

In a similar way, one can conclude that for each fixed N and any $\mu>0$, there exists an integer $M_0''(N,\mu)>0$ such that

$$\|\hat{\underline{B}}_{[N,M]}\|_{l/2l_2}\big\|\check{\underline{C}}_{[N,M]}(\underline{E}(s)-\underline{Q})^{-1}\big\|_2 < \frac{\mu}{2} \quad (\forall M\ge M_0''(N,\mu) \quad \forall s\in\partial\Omega). \tag{B.29}$$

Then, the desired convergence assertion follows from (B.21), (B.28), and (B.29) by taking $M_0(N,\mu)=\max\{M_0'(N,\mu),M_0''(N,\mu)\}$. □

Proof of Lemma 4.4. To see the first assertion of (4.8), we observe from (B.3) that

$$\|G_{m[N,M]}(s)\| \le \|\hat{C}_{NM}\|\cdot\|(E_{Mm}(s)-Q_M)^{-1}\|\cdot\|\hat{B}_{NM}\|$$
$$\le K\,\|\hat{C}_{NM}\|\cdot\|\hat{B}_{NM}\|\,\max\{f(m(2M+1)-M),\dots,$$
$$f(m(2M+1)),\dots,f(m(2M+1)+M)\}$$
$$< K\,\|\hat{C}_{NM}\|\cdot\|\hat{B}_{NM}\|\,f(|m|(M+1)) \le K\,K_B'K_C'\,f(|m|(M+1)) \tag{B.30}$$

for each $|m|\ge 1$. Here $\|\hat{C}_{NM}\|$ and $\|\hat{B}_{NM}\|$ have upper bounds independent of N and M (see similar arguments around (B.16)), denoted by K_B' and K_C'. Inequality (B.30) says that for each fixed N, there exists a large enough integer M_0 with $M_0\ge N+1$ such that $\|G_{m[N,M]}(s)\|<1$ for all $|m|\ge 1$, $M\ge M_0$, and $s\in\partial\Omega$. Thus, $|\lambda_k(G_{m[N,M]}(s))|<1$, from which Lemma 15.8 of [24] and (B.30) yield that

$$\sum_{m\ne 0}\sum_k |1-(1+\lambda_k(G_{m[N,M]}(s)))\exp\{-\lambda_k(G_{m[N,M]}(s))\}|$$
$$\le \sum_{m\ne 0}\sum_k [KK_B'K_C'f(|m|(M+1))]^2$$
$$= [KK_B'K_C']^2\frac{(2M+1)d_C}{(M+1)^2}\sum_{m\ne 0} f^2(m) < \frac{8d_C[KK_B'K_C']^2}{M+1}, \tag{B.31}$$

where d_C is the row dimension of the output matrix $C(t)$ of the FDLCP system (2.1).

On the other hand, it is straightforward to show by induction that

$$\left|\prod_k (1+a_k) - 1\right| \le \exp\left\{\sum_k |a_k|\right\} - 1, \tag{B.32}$$

where $a_k \in \mathbf{C}$. Since $\sum_{m\neq 0}\sum_k |1-(1+\lambda_k(G_{m[N,M]}(s)))\exp\{-\lambda_k(G_{m[N,M]}(s))\}| \to 0$ as $M\to\infty$ by (B.31), it follows from (B.32) that

$$\prod_{m\neq 0}\prod_k \big(1+\lambda_k\big(G_{m[N,M]}(s)\big)\big)\exp\big\{-\lambda_k\big(G_{m[N,M]}(s)\big)\big\} \to 1$$

uniformly with respect to s. This gives the first assertion.

To see the second assertion of (4.8), we observe

$$\begin{aligned}\|\tilde{\Delta}_{m[N,M]}(s+\rho)\| &\le \big\|E_{Mm}^{-1}(s+\rho)\big\|\,\|Q_M+\rho I_M\|\,\big\|(E_{Mm}(s)-Q_M)^{-1}\big\|\,\|\widehat{BC}_{NM}\| \\ &< KK_\varphi f^2(|m|(M+1))(\|Q\|+\rho)\|\widehat{BC}_{NM}\| \end{aligned}\tag{B.33}$$

for each $|m|\ge 1$. In the derivation of (B.33), we repeated some arguments similar to those in (B.30) and used the fact that $\|E_{Mm}^{-1}(s+\rho)\| \le K_\varphi f(|m|(2M+1)-M) < K_\varphi f(|m|(M+1))$. It is easy to see that under the given assumptions about the system matrices, $\|\widehat{BC}_{NM}\|$ has an upper bound independent of N and M, denoted by K_{BC}. Then it follows that

$$\begin{aligned}\left|\sum_{m\neq 0}\operatorname{tr}(\tilde{\Delta}_{m[N,M]}(s+\rho))\right| &\le \sum_{m\neq 0}(2M+1)n\|\tilde{\Delta}_{m[N,M]}(s+\rho)\| \\ &< \sum_{m\neq 0}(2M+1)nKK_\varphi K_{BC}f^2(|m|(M+1))(\|Q\|+\rho) \\ &< \frac{4(2M+1)nKK_\varphi K_{BC}(\|Q\|+\rho)}{(M+1)^2} \to 0 \quad (M\to\infty)\end{aligned}\tag{B.34}$$

which leads to the desired assertion. This completes the proof. □

Proof of (4.9). By the $\det_2$ definition and the block-diagonal structure of the infinite-dimensional matrix $\underline{G}_{[N,M]}(s)$, it is evident that

$$\begin{aligned}&\big|\det_2\big[\underline{I}+\underline{G}_{[N,M]}(s)\big]\exp\big\{-\tilde{\Delta}_{[N,M]}(s+\rho)\big\} \\ &\quad -\det_2\big[I_M+G_{0[N,M]}(s)\big]\exp\big\{-\operatorname{tr}\big(\tilde{\Delta}_{0[N,M]}(s+\rho)\big)\big\}\big| \\ &\le \big|\det_2\big[I_M+G_{0[N,M]}(s)\big]\exp\big\{-\operatorname{tr}\big(\tilde{\Delta}_{0[N,M]}(s+\rho)\big)\big\}\big| \\ &\quad\times\Bigg[\Bigg|\prod_{m\neq 0}\prod_k\big(1+\lambda_k\big(G_{0[N,M]}(s)\big)\big)\exp\big\{-\lambda_k\big(G_{0[N,M]}(s)\big)\big\}-1\Bigg| \\ &\quad\times\left|\exp\left\{-\sum_{m\neq 0}\operatorname{tr}\big(\tilde{\Delta}_{m[N,M]}(s+\rho)\big)\right\}\right| \\ &\quad+\left|\exp\left\{-\sum_{m\neq 0}\operatorname{tr}\big(\tilde{\Delta}_{m[N,M]}(s+\rho)\big)\right\}-1\right|\Bigg].\end{aligned}$$

This, together with Lemma 4.4, tells us that (4.9) follows if it is shown that $|\det_2[I_M+G_{0[N,M]}(s)]|$ and $|\operatorname{tr}(\tilde{\Delta}_{0[N,M]}(s+\rho))|$ are uniformly bounded over M and $s\in\partial\Omega$.

To see the uniform boundedness of $|\mathrm{tr}(\tilde{\Delta}_{0[N,M]}(s+\rho))|$, we observe by (4.5) that

$$\begin{aligned}
\big|\mathrm{tr}\big(\tilde{\Delta}_{0[N,M]}(s+\rho)\big)\big| &\le \big\|\tilde{\Delta}_{0[N,M]}(s+\rho)\big\|_1 \\
&\le \big\|E_{M0}^{-1}(s+\rho)(Q_M+\rho I_M)\big\|_2 \big\|(E_{M0}(s)-Q_M)^{-1}\widehat{\underline{BC}}_{[N,M]}\big\|_2 \\
&\le \big\|E_{M0}^{-1}(s+\rho)\big\|_2 \|Q_M+\rho I_M\| \cdot \big\|(E_{M0}(s)-Q_M)^{-1}\big\|_2 \big\|\widehat{\underline{BC}}_{[N,M]}\big\| \\
&\le (\|Q\|+\rho)\big\|\widehat{\underline{BC}}_{[N,M]}\big\| \sum_{|i|\le M} nK_\varphi^2 f^2(i) \sum_{|i|\le M} nK^2 f^2(i) \\
&< (5nKK_\varphi)^2(\|Q\|+\rho)\big\|\widehat{\underline{BC}}_{[N,M]}\big\|.
\end{aligned}$$

Hence, the desired uniform boundedness follows from the fact that $\|\widehat{\underline{BC}}_{[N,M]}\|$ has an upper bound independent of M.

To see the uniform boundedness of $|\det_2[I_M + G_{0[N,M]}(s)]|$, we need some preparations. By Theorem 7.4 of [11, p. 69], we have

$$\big|\det_2\big[I_M + G_{0[N,M]}(s)\big]\big| \le \exp\left\{\frac{1}{2}\big\|G_{0[N,M]}(s)\big\|_2\right\}$$

which implies that to see the uniform boundedness of $|\det_2[I_M+G_{0[N,M]}(s)]|$, it suffices to show that $\|G_{0[N,M]}(s)\|_2$ is uniformly bounded over M and $s \in \partial\Omega$. To see this, we note that $\hat{B}_{NM}$ and $\hat{C}_{NM}$ are submatrices of $\underline{\hat{B}}_{[N]}$ and $\underline{\hat{C}}_{[N]}$, respectively. Hence, we immediately have

$$\begin{aligned}
\big\|G_{0[N,M]}(s)\big\|_2 &\le \|\hat{C}_{NM}\| \cdot \big\|(E_{M0}(s)-Q_M)^{-1}\big\|_2 \cdot \|\hat{B}_{NM}\| \\
&\le K_C K_B \sum_{|i|\le M} nK^2 f^2(i) < 5nK^2 K_C K_B.
\end{aligned}$$

This completes the proof. □

GENERATING SERIES FOR INTERCONNECTED ANALYTIC NONLINEAR SYSTEMS*

W. STEVEN GRAY† AND YAQIN LI†

Abstract. Given two analytic nonlinear input-output systems represented as Fliess operators, four system interconnections are considered in a unified setting: the parallel connection, product connection, cascade connection, and feedback connection. In each case, the corresponding generating series is produced and conditions for the convergence of the corresponding Fliess operator are given. In the process, an existing notion of a *composition product* for formal power series has its set of known properties significantly expanded. In addition, the notion of a *feedback product* for formal power series is shown to be well defined in a broad context, and its basic properties are characterized.

1. Introduction. Let $X = \{x_0, x_1, \ldots, x_m\}$ denote an alphabet and X^* the set of all words over X (including the empty word $\emptyset$). A formal power series in X is any mapping of the form $X^* \to \mathbb{R}^\ell$, and the set of all such mappings will be denoted by $\mathbb{R}^\ell\langle\langle X\rangle\rangle$. For each $c \in \mathbb{R}^\ell\langle\langle X\rangle\rangle$, one can formally associate an m-input, ℓ-output operator F_c in the following manner. Let $p \geq 1$ and $a < b$ be given. For a measurable function $u : [a, b] \to \mathbb{R}^m$, define $\|u\|_p = \max\{\|u_i\|_p : \ 1 \leq i \leq m\}$, where $\|u_i\|_p$ is the usual L_p-norm for a measurable real-valued function, u_i, defined on $[a, b]$. Let $L_p^m[a, b]$ denote the set of all measurable functions defined on $[a, b]$ having a finite $\|\cdot\|_p$-norm and $B_p^m(R)[a, b] := \{u \in L_p^m[a, b] : \|u\|_p \leq R\}$. With $t_0, T \in \mathbb{R}$ fixed and $T > 0$, define recursively for each $\eta \in X^*$ the mapping $E_\eta : L_1^m[t_0, t_0 + T] \to \mathcal{C}[t_0, t_0 + T]$ by $E_\emptyset = 1$, and

$$E_{x_i\bar{\eta}}[u](t, t_0) = \int_{t_0}^{t} u_i(\tau) E_{\bar{\eta}}[u](\tau, t_0)\, d\tau,$$

where $x_i \in X$, $\bar{\eta} \in X^*$, and $u_0(t) \equiv 1$. The input-output operator corresponding to c is then

$$F_c[u](t) = \sum_{\eta \in X^*} (c, \eta)\, E_\eta[u](t, t_0),$$

which is referred to as a *Fliess operator*. All Volterra operators with analytic kernels, for example, are Fliess operators. In the classical literature, where these operators first appeared [7, 9, 10, 26], it is normally assumed that there exist real numbers $K, M > 0$ such that $|(c, \eta)| \leq KM^{|\eta|}|\eta|!$ for all $\eta \in X^*$, where $|z| = \max\{|z_1|, |z_2|, \ldots, |z_\ell|\}$ when $z \in \mathbb{R}^\ell$, and $|\eta|$ denotes the number of letters in η. This growth condition on the coefficients of c ensures that there exist positive real numbers R and T_0 such that, for all piecewise continuous u with $\|u\|_\infty \leq R$ and $T \leq T_0$, the series defining

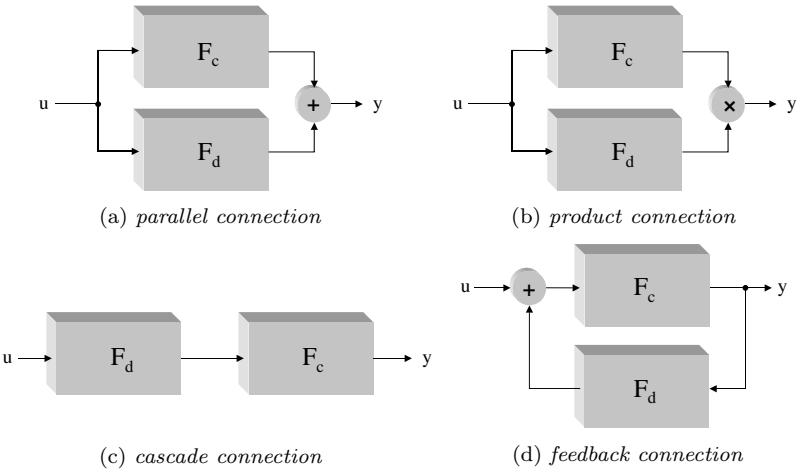

FIG. 1.1. *Elementary system interconnections.*

F_c converges uniformly and absolutely on $[t_0, t_0 + T]$. Therefore, a power series c is said to be *locally convergent* when its coefficients satisfy such a growth condition. The set of all locally convergent series in $\mathbb{R}^\ell\langle\langle X\rangle\rangle$ will be denoted by $\mathbb{R}^\ell_{LC}\langle\langle X\rangle\rangle$. More recently, it was shown in [13] that local convergence also implies that F_c constitutes a well-defined operator from $B^m_p(R)[t_0, t_0 + T]$ into $B^\ell_q(S)[t_0, t_0 + T]$ for sufficiently small $R, S, T > 0$, where the numbers $p, q \in [1, \infty]$ are conjugate exponents, i.e., $1/p + 1/q = 1$ with $(1, \infty)$ being a conjugate pair by convention.

In many applications, input-output systems are interconnected in a variety of ways. Given two Fliess operators F_c and F_d, where $c, d \in \mathbb{R}^\ell_{LC}\langle\langle X\rangle\rangle$, Figure 1.1 shows four elementary interconnections. The product connection is defined componentwise, and in the case of the feedback connection it is assumed that $\ell = m > 0$. The general goal of this paper is to describe in a unified manner the generating series for each elementary interconnection and conditions under which it is locally convergent. The clear antecedent to this work is that of Ferfera, who first described the generating series for such connections (implicitly in the case of feedback) and, in particular, introduced the composition product $c \circ d$ of two formal power series c and d [5, 6]. In each case, however, the local convergence of the new generating series or, equivalently, the convergence of the corresponding Fliess operator, was not explicitly addressed. It is trivial to show that the parallel connection of F_c and F_d always produces a locally convergent generating series when c and d are locally convergent. The same conclusion was later provided in [28] for the product connection via an analysis involving the shuffle product. In this paper, an analogous result is developed for the composition product by producing an explicit expression for one pair of growth constants, $K_{c\circ d}$ and $M_{c\circ d}$. In the process, the set of known properties of the composition product is significantly expanded. (An interesting parallel development has appeared in [3, 11] regarding a composition product for formal power series motivated by the composition of two analytic functions (see, e.g., [18]) rather than two Fliess (integral) operators. Its definition is quite distinct and not clearly related to the composition product described in this paper.)

The feedback connection is a fundamentally more difficult case to analyze. For example, when F_c is a linear operator, the formal solution to the feedback equation

$$y = F_c[u + F_d[y]] \tag{1}$$

is

$$y = F_c[u] + F_c \circ F_d \circ F_c[u] + \cdots.$$

It is not immediately clear that this series converges in any manner and, in particular, converges to another Fliess operator, say, $F_{c@d}$, for some $c@d \in \mathbb{R}^m_{LC}\langle\langle X \rangle\rangle$. When F_c is nonlinear, the problem is further complicated by the fact that operators of the form $I + F_d$, where I denotes the identity map, *never* have a Fliess operator representation. In this paper, the problem is circumvented by introducing a simple variation of the composition product so that an appropriate *feedback product*, $c@d$, is well defined, and $y = F_{c@d}[u]$ satisfies the feedback equation (1) in the sense that every analytic input u produces an analytic output y with (u, y) satisfying (1). In this case, $c@d$ is referred to as being *input-output locally convergent*, and explicit expressions are derived for one set of growth constants, K_{c_y} and M_{c_y}, for the series representation of the output function, c_y.

It should be stated that Ferfera's primary interest in [5, 6] was rational series and their corresponding bilinear realizations. In a state space setting, the issue of local convergence is rather straightforward. If c and d each have finite Lie rank, in addition to being locally convergent, then the mappings F_c and F_d each have a finite-dimensional analytic state space realization, and therefore so does each interconnected system (see [16, 21] for a basic treatment of nonlinear realization theory). The literature then provides that the corresponding generating series can be computed by successive Lie derivatives and, in particular, it must be locally convergent [26, Lemma 4.2]. (Additional analysis of interconnected state space systems using a chronological product together with Hall–Viennot bases appears in [17].) While the state space formalism is clearly dominant in modern control theory, other system descriptions like Volterra series [10, 16, 21] or input-output differential equations [28, 29, 30] are sometimes useful. In such settings, the convergence analysis of interconnected systems is a natural application for the main results of this paper. But even in a pure state space setting, as illustrated by Examples 3.2 and 4.11, knowledge of the growth constants for the generating series of a given interconnection permits one to compute a lower bound on any finite escape time. This is particularly useful in physical problems, like the one described in [12], as it provides computable limitations on the applicability of the underlying mathematical models.

The paper is organized as follows. In section 2 the composition product is introduced and developed independently of the system interconnection problem. First, its various fundamental properties are presented. Then, in preparation for the feedback analysis, it is shown that the composition product produces a contractive mapping on the set of all formal power series using a familiar ultrametric. In section 3, the three *nonrecursive* connections, parallel, product, and cascade, are analyzed primarily by applying results from section 2. In section 4 the feedback connection is considered. The main focus is on showing when the feedback product of two formal power series is well defined and in precisely what sense it is locally convergent.

2. The composition product. The composition product of two formal power series over an alphabet $X = \{x_0, x_1, \ldots, x_m\}$ is defined recursively in terms of the

shuffle product. The shuffle product of two words $\eta, \xi \in X^*$ is defined recursively by

$$\eta \sqcup\!\sqcup \xi = (x_j\eta') \sqcup\!\sqcup (x_k\xi') := x_j[\eta' \sqcup\!\sqcup \xi] + x_k[\eta \sqcup\!\sqcup \xi']$$

with $\emptyset \sqcup\!\sqcup \emptyset = \emptyset$ and $\xi \sqcup\!\sqcup \emptyset = \emptyset \sqcup\!\sqcup \xi = \xi$. It is easily verified that $\eta \sqcup\!\sqcup \xi$ is always a polynomial consisting of words each having length $|\eta|+|\xi|$. The definition is extended to any two series $c, d \in \mathbb{R}\langle\langle X\rangle\rangle$ by

$$c \sqcup\!\sqcup d = \sum_{\eta,\xi\in X^*} [(c,\eta)(d,\xi)]\, \eta \sqcup\!\sqcup \xi. \tag{2}$$

For a fixed $\nu \in X^*$, the coefficient $(\eta \sqcup\!\sqcup \xi, \nu) = 0$ if $|\eta| + |\xi| \neq |\nu|$. Hence, the infinite sum in (2) is well defined since the family of polynomials $\{\eta \sqcup\!\sqcup \xi : \eta, \xi \in X^*\}$ is locally finite [2]. In general, the shuffle product is commutative. It is also associative and distributes over addition. Thus, the vector space $\mathbb{R}\langle\langle X\rangle\rangle$ with the shuffle product forms a commutative $\mathbb{R}$-algebra, the so-called *shuffle algebra*, with multiplicative identity element $\emptyset$. The shuffle product on $\mathbb{R}^\ell\langle\langle X\rangle\rangle$ is defined componentwise, i.e., $(c \sqcup\!\sqcup d, \nu)_i = (c_i \sqcup\!\sqcup d_i, \nu)$ for $i = 1, 2, \ldots, \ell$.

For any $\eta \in X^*$ and $d \in \mathbb{R}^m\langle\langle X\rangle\rangle$, the *composition product* is defined recursively as

$$\eta \circ d = \begin{cases} \eta & : \ |\eta|_{x_i} = 0 \ \ \forall i \neq 0, \\ x_0^{n+1}[d_i \sqcup\!\sqcup (\eta' \circ d)] & : \ \eta = x_0^n x_i \eta', \ \ n \geq 0, \ \ i \neq 0, \end{cases}$$

where $|\eta|_{x_i}$ denotes the number of letters in η equivalent to x_i and $d_i : \xi \mapsto (d, \xi)_i$, the ith component of the coefficient (d, ξ). Consequently, if

$$\eta = x_0^{n_k} x_{i_k} x_0^{n_{k-1}} x_{i_{k-1}} \cdots x_0^{n_1} x_{i_1} x_0^{n_0}, \tag{3}$$

where $i_j \neq 0$ for $j = 1, \ldots, k$, then it follows that

$$\eta \circ d = x_0^{n_k+1}[d_{i_k} \sqcup\!\sqcup x_0^{n_{k-1}+1}[d_{i_{k-1}} \sqcup\!\sqcup \cdots x_0^{n_1+1}[d_{i_1} \sqcup\!\sqcup x_0^{n_0}] \cdots]].$$

Alternatively, for any $\eta \in X^*$, one can uniquely associate a set of right factors $\{\eta_0, \eta_1, \ldots, \eta_k\}$ by the iteration

$$\eta_{j+1} = x_0^{n_{j+1}} x_{i_{j+1}} \eta_j, \ \ \eta_0 = x_0^{n_0}, \ \ i_{j+1} \neq 0, \tag{4}$$

so that $\eta = \eta_k$ with $k = |\eta| - |\eta|_{x_0}$. In which case, $\eta \circ d = \eta_k \circ d$, where

$$\eta_{j+1} \circ d = x_0^{n_{j+1}+1}[d_{i_{j+1}} \sqcup\!\sqcup (\eta_j \circ d)]$$

and $\eta_0 \circ d = x_0^{n_0}$. The theorem below ensures that the composition product of two series described subsequently is well defined.

THEOREM 2.1. *Given a fixed $d \in \mathbb{R}^m\langle\langle X\rangle\rangle$, the family of series $\{\eta \circ d : \eta \in X^*\}$ is locally finite, and therefore summable.*

Proof. Given an arbitrary $\eta \in X^*$ expressed in the form (3), it follows directly that

$$\operatorname{ord}(\eta \circ d) = n_0 + k + \sum_{j=1}^{k} n_j + \operatorname{ord}(d_{i_j}) = |\eta| + \sum_{j=1}^{|\eta|-|\eta|_{x_0}} \operatorname{ord}(d_{i_j}), \tag{5}$$

where the *order* of c is defined as

$$\operatorname{ord}(c) = \begin{cases} \inf\{|\eta| : \eta \in \operatorname{supp}(c)\} & : \quad c \neq 0, \\ \infty & : \quad c = 0, \end{cases}$$

and $\operatorname{supp}(c) := \{\eta \in X^* : (c, \eta) \neq 0\}$ denotes the *support* of c. Hence, for any $\xi \in X^*$,

$$\begin{aligned} I_d(\xi) &:= \{\eta \in X^* : (\eta \circ d, \xi) \neq 0\} \\ &\subset \{\eta \in X^* : \operatorname{ord}(\eta \circ d) \leq |\xi|\} \\ &= \left\{ \eta \in X^* : |\eta| + \sum_{j=1}^{|\eta|-|\eta|_{x_0}} \operatorname{ord}(d_{i_j}) \leq |\xi| \right\}. \end{aligned}$$

Clearly this last set is finite, and thus $I_d(\xi)$ is finite for all $\xi \in X^*$. This fact implies summability. □

For any $c \in \mathbb{R}^\ell\langle\langle X \rangle\rangle$ and $d \in \mathbb{R}^m\langle\langle X \rangle\rangle$, the composition product is defined as

$$c \circ d = \sum_{\eta \in X^*} (c, \eta)\, \eta \circ d.$$

The summation can also be written using the set of all right factors as described by (4). Let X^i be the set of all words in X^* of length i. For each word $\eta \in X^i$, the jth right factor, η_j, has exactly j letters not equal to x_0. Therefore, given any $\nu \in X^*$,

$$(c \circ d, \nu) = \sum_{i=0}^{|\nu|} \sum_{j=0}^{i} \sum_{\eta_j \in X^i} (c, \eta_j)(\eta_j \circ d, \nu). \tag{6}$$

The third summation is understood to be the sum over the set of all possible jth right factors of words of length i. This set has a familiar combinatoric interpretation. A *composition* of a positive integer N is an ordered set of positive integers $\{a_1, a_2, \ldots, a_K\}$ such that $N = a_1 + a_2 + \cdots + a_K$. (For example, the integer 3 has the compositions $1+1+1$, $1+2$, $2+1$, and 3). For a given N and K, it is well known that there are $\mathcal{C}_K(N) = \binom{N-1}{K-1}$ possible compositions. Now each factor $\eta_j \in X^i$, when written in the form

$$\eta_j = x_0^{n_j} x_{i_j} x_0^{n_{j-1}} x_{i_{j-1}} \cdots\ x_0^{n_1} x_{i_1} x_0^{n_0},$$

maps to a unique composition of $i+1$ with $j+1$ elements:

$$i + 1 = (n_0 + 1) + (n_1 + 1) + \cdots + (n_j + 1).$$

Thus, there are exactly $\mathcal{C}_{j+1}(i+1)m^j = \binom{i}{j} m^j$ possible factors η_j in X^i, and the total number of terms in the summations of (6) is $((m+1)^{|\nu|+1} - 1)/m \approx (m+1)^{|\nu|}$. As will be seen shortly, this provides a conservative lower bound on the growth rate of the coefficients of $c \circ d$.

It is easily verified that the composition product is linear in its first argument, but not its second. A special exception are *linear series*. A series $c \in \mathbb{R}^\ell\langle\langle X \rangle\rangle$ is called linear if

$$\operatorname{supp}(c) \subseteq \{\eta \in X^* : \eta = x_0^{n_1} x_i x_0^{n_0},\ \ i \in \{1, 2, \ldots, m\},\ \ n_1, n_0 \geq 0\}.$$

It was shown in [5] that the composition product is associative and distributive from the right over the shuffle product. But in general it is neither commutative nor has an identity element. This lack of an identity element is precisely the reason the identity map I is not realizable as a Fliess operator. Other elementary properties concerning the composition product are summarized below.

LEMMA 2.2. *The following identities hold* ($\mathbb{1}$ *is a column vector with* m *ones*):

1. $0 \circ d = 0$ for all $d \in \mathbb{R}^m\langle\langle X\rangle\rangle$.
2. $c \circ 0 = c_0 := \sum_{n\geq 0}(c, x_0^n)\, x_0^n$. (*Therefore,* $c \circ 0 = 0$ *if and only if* $c_0 = 0$.)
3. $c_0 \circ d = c_0$ for all $d \in \mathbb{R}^m\langle\langle X\rangle\rangle$. (*In particular,* $1 \circ d = 1$.)
4. $c \circ \mathbb{1} = c_{\mathbb{1}} := \sum_{\eta\in X^*}(c, \eta)\, x_0^{|\eta|}$. (*Therefore,* $c \circ \mathbb{1} = c$ *if and only if* $c_0 = c$.)

The set $\mathbb{R}^m\langle\langle X\rangle\rangle$ forms a metric space under the ultrametric

$$\begin{aligned} \text{dist} \quad &: \quad \mathbb{R}^m\langle\langle X\rangle\rangle \times \mathbb{R}^m\langle\langle X\rangle\rangle \to \mathbb{R}^+ \cup \{0\}, \\ &: \quad (c, d) \mapsto \sigma^{\text{ord}(c-d)}, \end{aligned}$$

where $\sigma \in (0, 1)$ is arbitrary [2]. The following theorem states that the composition product on $\mathbb{R}^m\langle\langle X\rangle\rangle \times \mathbb{R}^m\langle\langle X\rangle\rangle$ is continuous in its left argument. (Right argument continuity will be addressed later.)

THEOREM 2.3. *Let* $\{c_i\}_{i\geq 1}$ *be a sequence in* $\mathbb{R}^m\langle\langle X\rangle\rangle$ *with* $\lim_{i\to\infty} c_i = c$. *Then* $\lim_{i\to\infty}(c_i \circ d) = c \circ d$ *for any* $d \in \mathbb{R}^m\langle\langle X\rangle\rangle$.

Proof. Define the sequence of nonnegative integers $k_i = \text{ord}(c_i - c)$ for $i \geq 1$. Since c is the limit of the sequence $\{c_i\}_{i\geq 1}$, the sequence $\{k_i\}_{i\geq 1}$ must have an increasing subsequence $\{k_{i_j}\}$. Now observe that

$$\text{dist}(c_i \circ d, c \circ d) = \sigma^{\text{ord}((c_i - c)\,\circ d)}$$

and

$$\begin{aligned} \text{ord}((c_{i_j} - c) \circ d) &= \text{ord}\left(\sum_{\eta\in\text{supp}(c_{i_j}-c)} (c_{i_j} - c, \eta)\ \eta \circ d\right) \\ &\geq \inf_{\eta\in\text{supp}(c_{i_j}-c)} \text{ord}(\eta \circ d) \\ &\geq \inf_{\eta\in\text{supp}(c_{i_j}-c)} |\eta| + (|\eta| - |\eta|_{x_0})\, \text{ord}(d) \\ &\geq k_{i_j}. \end{aligned}$$

Thus, $\text{dist}(c_{i_j} \circ d, c \circ d) \leq \sigma^{k_{i_j}}$ for all $j \geq 1$, and $\lim_{i\to\infty} c_i \circ d = c \circ d$. ∎

The ultrametric space $(\mathbb{R}^m\langle\langle X\rangle\rangle, \text{dist})$ is known to be complete [2]. Given a fixed $c \in \mathbb{R}^m\langle\langle X\rangle\rangle$, consider the mapping $\mathbb{R}^m\langle\langle X\rangle\rangle \to \mathbb{R}^m\langle\langle X\rangle\rangle : d \mapsto c \circ d$. The goal is to show that this mapping is always a contraction on $\mathbb{R}^m\langle\langle X\rangle\rangle$, i.e., that

$$\text{dist}(c \circ d, c \circ e) \leq \sigma\, \text{dist}(d, e) \quad \forall d, e \in \mathbb{R}^m\langle\langle X\rangle\rangle,$$

so that fixed point theorems can be applied in later analysis [14, 22, 23, 24]. Any $c \in \mathbb{R}^m\langle\langle X\rangle\rangle$ can be written unambiguously in the form

$$c = c_0 + c_1 + \cdots, \tag{7}$$

where $c_k \in \mathbb{R}^m\langle\langle X\rangle\rangle$ has the defining property that $\eta \in \text{supp}(c_k)$ only if $|\eta| - |\eta|_{x_0} = k$. Some of the series c_k may be the zero series. When $c_0 = 0$, c is referred to as being *homogeneous*. When $c_k = 0$ for $k = 0, 1, \ldots, l-1$ and $c_l \neq 0$, then c is called *homogeneous of order* l. In this setting consider the following lemma.

LEMMA 2.4. *For any* c_k *in* (7),

$$\text{dist}(c_k \circ d, c_k \circ e) \leq \sigma^k\, \text{dist}(d, e) \quad \forall d, e \in \mathbb{R}^m\langle\langle X\rangle\rangle.$$

Proof. The proof is by induction for the nontrivial case, where $c_k \neq 0$. First suppose $k = 0$. From the definition of the composition product it follows directly that $\eta \circ d = \eta$ for all $\eta \in \operatorname{supp}(c_0)$. Therefore,

$$c_0 \circ d = \sum_{\eta \in \operatorname{supp}(c_0)} (c_0, \eta)\, \eta \circ d = \sum_{\eta \in \operatorname{supp}(c_0)} (c_0, \eta)\, \eta = c_0,$$

and

$$\operatorname{dist}(c_0 \circ d, c_0 \circ e) = \operatorname{dist}(c_0, c_0) = 0 \leq \sigma^0 \operatorname{dist}(d, e).$$

Now fix any $k \geq 0$ and assume the claim is true for all $c_0, c_1, \ldots, c_k$. In particular, this implies that

$$\operatorname{ord}(c_k \circ d - c_k \circ e) \geq k + \operatorname{ord}(d - e). \tag{8}$$

For any $j \geq 0$, words in $\operatorname{supp}(c_j)$ have the form η_j as defined in (4). Observe then that

$$\begin{aligned}
c_{k+1} \circ d - c_{k+1} \circ e &= \sum_{\eta_{k+1} \in X^*} (c_{k+1}, \eta_{k+1})\, \eta_{k+1} \circ d - (c_{k+1}, \eta_{k+1})\, \eta_{k+1} \circ e \\
&= \sum_{\eta_k, \eta_{k+1} \in X^*} (c_{k+1}, \eta_{k+1}) \; \big[{x_0}^{n_{k+1}+1} [d_{i_{k+1}} \sqcup [\eta_k \circ d]] \\
&\qquad\qquad - {x_0}^{n_{k+1}+1} [e_{i_{k+1}} \sqcup [\eta_k \circ e]] \big] \\
&= \sum_{\eta_k, \eta_{k+1} \in X^*} (c_{k+1}, \eta_{k+1}) \; \big[{x_0}^{n_{k+1}+1} [d_{i_{k+1}} \sqcup [\eta_k \circ d]] \\
&\qquad\qquad - {x_0}^{n_{k+1}+1} [d_{i_{k+1}} \sqcup [\eta_k \circ e]] \\
&\qquad + {x_0}^{n_{k+1}+1} [d_{i_{k+1}} \sqcup [\eta_k \circ e]] - {x_0}^{n_{k+1}+1} [e_{i_{k+1}} \sqcup [\eta_k \circ e]] \big] \\
&= \sum_{\eta_k, \eta_{k+1} \in X^*} (c_{k+1}, \eta_{k+1}) \; \big[{x_0}^{n_{k+1}+1} [d_{i_{k+1}} \sqcup [\eta_k \circ d - \eta_k \circ e]] \\
&\qquad\qquad + {x_0}^{n_{k+1}+1} [(d_{i_{k+1}} - e_{i_{k+1}}) \sqcup [\eta_k \circ e]] \big] ,
\end{aligned}$$

using the fact that the shuffle product distributes over addition. Next, applying the identity (5) and the inequality (8) with $c_k = \eta_k$, it follows that

$$\begin{aligned}
\operatorname{ord}(c_{k+1} \circ d - c_{k+1} \circ e) &\geq \min \Big\{ \inf_{\eta_{k+1} \in \operatorname{supp}(c_{k+1})} n_{k+1} + 1 + \operatorname{ord}(d) + k + \operatorname{ord}(d - e), \\
&\qquad\qquad \inf_{\eta_{k+1} \in \operatorname{supp}(c_{k+1})} n_{k+1} + 1 + \operatorname{ord}(d - e) + |\eta_k| + k \operatorname{ord}(e) \Big\} \\
&\geq k + 1 + \operatorname{ord}(d - e),
\end{aligned}$$

and thus,

$$\operatorname{dist}(c_{k+1} \circ d, c_{k+1} \circ e) \leq \sigma^{k+1} \operatorname{dist}(d, e).$$

Hence, $\operatorname{dist}(c_k \circ d, c_k \circ e) \leq \sigma^k \operatorname{dist}(d, e)$ holds for any $k \geq 0$. ∎

Applying the above lemma leads to the following result.

LEMMA 2.5. *If $c \in \mathbb{R}^m\langle\langle X\rangle\rangle$, then for any series $c_0' \in \mathbb{R}^m\langle\langle X_0\rangle\rangle$,*

$$\operatorname{dist}((c_0' + c) \circ d, (c_0' + c) \circ e) = \operatorname{dist}(c \circ d, c \circ e) \ \ \forall d, e \in \mathbb{R}^m\langle\langle X\rangle\rangle. \tag{9}$$

(*Here X_0 denotes the single letter alphabet $\{x_0\}$.*) *If c is homogeneous of order $l \geq 1$ then*

$$\operatorname{dist}(c \circ d, c \circ e) \leq \sigma^l \operatorname{dist}(d, e) \ \ \forall d, e \in \mathbb{R}^m\langle\langle X\rangle\rangle. \tag{10}$$

Proof. The equality is proved first. Since the ultrametric dist is shift-invariant, observe that

$$\begin{aligned}\operatorname{dist}((c_0' + c) \circ d, (c_0' + c) \circ e) &= \operatorname{dist}(c_0' \circ d + c \circ d, c_0' \circ e + c \circ e) \\ &= \operatorname{dist}(c_0' + c \circ d, c_0' + c \circ e) \\ &= \operatorname{dist}(c \circ d, c \circ e).\end{aligned}$$

The inequality is proved next by first selecting any fixed $l \geq 1$ and showing inductively that it holds for any partial sum $\sum_{i=l}^{l+k} c_i$, where $k \geq 0$. When $k = 0$, Lemma 2.4 implies that

$$\operatorname{dist}(c_l \circ d, c_l \circ e) \leq \sigma^l \operatorname{dist}(d, e).$$

If the result is true for partial sums up to any fixed $k \geq 0$, then using the ultrametric property

$$\operatorname{dist}(d, e) \leq \max\{\operatorname{dist}(d, f), \operatorname{dist}(f, e)\} \ \ \forall d, e, f \in \mathbb{R}^m\langle\langle X\rangle\rangle,$$

it follows that

$$\begin{aligned}&\operatorname{dist}\left(\left(\sum_{i=l}^{l+k+1} c_i\right) \circ d, \left(\sum_{i=l}^{l+k+1} c_i\right) \circ e\right) \\ &= \operatorname{dist}\left(\left(\sum_{i=l}^{l+k} c_i\right) \circ d + c_{l+k+1} \circ d, \left(\sum_{i=l}^{l+k} c_i\right) \circ e + c_{l+k+1} \circ e\right) \\ &\leq \max\left\{\operatorname{dist}\left(\left(\sum_{i=l}^{l+k} c_i\right) \circ d + c_{l+k+1} \circ d, \left(\sum_{i=l}^{l+k} c_i\right) \circ d + c_{l+k+1} \circ e\right),\right. \\ &\qquad \left.\operatorname{dist}\left(\left(\sum_{i=l}^{l+k} c_i\right) \circ d + c_{l+k+1} \circ e, \left(\sum_{i=l}^{l+k} c_i\right) \circ e + c_{l+k+1} \circ e\right)\right\} \\ &= \max\left\{\operatorname{dist}(c_{l+k+1} \circ d, c_{l+k+1} \circ e), \operatorname{dist}\left(\left(\sum_{i=l}^{l+k} c_i\right) \circ d, \left(\sum_{i=l}^{l+k} c_i\right) \circ e\right)\right\} \\ &\leq \max\left\{\sigma^{l+k+1} \operatorname{dist}(d, e), \sigma^l \operatorname{dist}(d, e)\right\} \\ &\leq \sigma^l \operatorname{dist}(d, e).\end{aligned}$$

Hence, the result holds for all $k \geq 0$. Inequality (10) is proved by noting that $c = \lim_{k\to\infty} \sum_{i=l}^{l+k} c_i$ and using the left argument continuity of the composition product, proved in Theorem 2.3, and the continuity of the ultrametric. ∎

The main result regarding contractive mappings is below.

THEOREM 2.6. *For any $c \in \mathbb{R}^m\langle\langle X\rangle\rangle$, the mapping $d \mapsto c \circ d$ is a contraction on $\mathbb{R}^m\langle\langle X\rangle\rangle$.*

Proof. Choose any series $d, e \in \mathbb{R}^m\langle\langle X\rangle\rangle$. If c is homogeneous of order $l \geq 1$, then the result follows directly from (10). Otherwise, observe that, via (9),

$$\operatorname{dist}(c \circ d, c \circ e) = \operatorname{dist}\left(\left(\sum_{l=1}^{\infty} c_i\right) \circ d, \left(\sum_{l=1}^{\infty} c_i\right) \circ e\right) \leq \sigma \operatorname{dist}(d, e). \qquad \square$$

An immediate result of this theorem is the right argument continuity of the composition product.

THEOREM 2.7. *Let $\{d_i\}_{i\geq 1}$ be a sequence in $\mathbb{R}^m\langle\langle X\rangle\rangle$ with $\lim_{i\to\infty} d_i = d$. Then $\lim_{i\to\infty}(c \circ d_i) = c \circ d$ for all $c \in \mathbb{R}^m\langle\langle X\rangle\rangle$.*

Proof. Trivially,

$$\lim_{i\to\infty} \operatorname{dist}(c \circ d_i, c \circ d) \leq \sigma \lim_{i\to\infty} \operatorname{dist}(d_i, d) = 0. \qquad \square$$

The final property considered in this section is local convergence. If all the summands in the defining expression (6) are unity, i.e., c and d have no coefficient growth whatsoever, then earlier combinatoric analysis shows that $(c \circ d, \nu)$ grows at least at the rate $(m+1)^{|\nu|}$. Of course, in general, much faster growth rates are possible when c and d are simply locally convergent. The analysis begins by considering the local convergence of the shuffle product. It provides a point of reference and some important tools. The following theorem was proved in [28].

THEOREM 2.8. *Suppose $c, d \in \mathbb{R}^{\ell}_{LC}\langle\langle X\rangle\rangle$ with growth constants K_c, M_c and K_d, M_d, respectively. Then $c \sqcup\!\sqcup d \in \mathbb{R}^{\ell}_{LC}\langle\langle X\rangle\rangle$ with*

$$|(c \sqcup\!\sqcup d, \nu)| \leq K_c K_d M^{|\nu|}(|\nu|+1)! \ \ \forall \nu \in X^*, \tag{11}$$

where $M = \max\{M_c, M_d\}$.

Noting that $n + 1 \leq 2^n$ for all $n \geq 0$, (11) can be written more conventionally as

$$|(c \sqcup\!\sqcup d, \nu)| \leq K_c K_d (2M)^{|\nu|}|\nu|! \ \ \forall \nu \in X^*.$$

The specific goal here is to show that $c \circ d$ is also locally convergent, when the series c and d are locally convergent, and to produce an inequality analogous to (11). The following properties of the shuffle product are essential.

LEMMA 2.9 (see [28]). *For $c, d \in \mathbb{R}\langle\langle X\rangle\rangle$ and any $\nu \in X^*$,*

1. $$(c \sqcup\!\sqcup d, \nu) = \sum_{\xi,\bar{\xi}\in X^*} (c,\xi)(d,\bar{\xi})(\xi \sqcup\!\sqcup \bar{\xi}, \nu) = \sum_{i=0}^{|\nu|} \sum_{\substack{\xi\in X^i \\ \bar{\xi}\in X^{|\nu|-i}}} (c,\xi)(d,\bar{\xi})(\xi \sqcup\!\sqcup \bar{\xi}, \nu);$$

2. $$\sum_{\substack{\xi\in X^i \\ \bar{\xi}\in X^{|\nu|-i}}} (\xi \sqcup\!\sqcup \bar{\xi}, \nu) = \binom{|\nu|}{i}, \ \ 0 \leq i \leq |\nu|.$$

Now given any $\eta \in X^*$, the set of right factors $\{\eta_0, \eta_1, \ldots, \eta_k\}$ defined by (4) produces a corresponding family of real-valued functions:

$$S_{\eta_0}(n) = \frac{1}{|\eta_0|!}, \ \ n \geq 0,$$

$$S_{\eta_1}(n) = \frac{1}{(n)_{n_1+1}} S_{\eta_0}(n), \ \ 1 \leq |\eta_1| \leq n,$$

$$S_{\eta_j}(n) = \frac{1}{(n)_{n_j+1}} \sum_{i=0}^{n-|\eta_j|} S_{\eta_{j-1}}(n - (n_j+1) - i), \ \ j \leq |\eta_j| \leq n, \ \ 2 \leq j \leq k,$$

where $(n)_i = n!/(n-i)!$ denotes the falling factorial. The next two lemmas form the core of the local convergence proof for the composition product.

LEMMA 2.10. *Suppose $c \in \mathbb{R}^{\ell}_{LC}\langle\langle X\rangle\rangle$ and $d \in \mathbb{R}^{m}_{LC}\langle\langle X\rangle\rangle$ with growth constants K_c, M_c and K_d, M_d, respectively. Then*

$$|(c \circ d, \nu)| \leq K_c\, \psi_{|\nu|}(K_d)\, M^{|\nu|} |\nu|! \;\; \forall \nu \in X^*, \tag{12}$$

where $M = \max\{M_c, M_d\}$, and $\{\psi_n(K_d)\}_{n\geq 0}$ is the set of degree n polynomials in K_d,

$$\psi_n(K_d) = \sum_{i=0}^{n} \sum_{j=0}^{i} \sum_{\eta_j \in X^i} K_d^j\, S_{\eta_j}(n)\, |\eta_j|!, \;\; n \geq 0.$$

Proof. The proof has two main steps. It is first shown that for any integer $l > 0$ and any $\eta \in X^*$ with $|\eta| \leq l$ and right factors $\{\eta_0, \eta_1, \ldots, \eta_k\}$ as defined in (4),

$$|(\eta_j \circ d, \nu)| \leq K_d^j M_d^{-|\eta_j|} M_d^{|\nu|}\, |\nu|!\, S_{\eta_j}(|\nu|) \tag{13}$$

for all $0 \leq j \leq k$ and $|\eta_j| \leq |\nu| \leq l$. (Note that when $|\nu| < |\eta_j|$, the coefficients $(\eta_j \circ d, \nu) = 0$, and $S_{\eta_j}(|\nu|)$ is simply not defined.) This is shown by induction on j. The case $j = 0 < l$ is trivial. When $j = 1 \leq l$, the left-shift operator $x_0^{-(n_1+1)} := (x_0^{n_1+1})^{-1}$ is employed, where, in general, for any $\xi, \nu \in X^*$,

$$\xi^{-1}(\nu) = \begin{cases} \nu' & : \quad \nu = \xi\nu', \\ 0 & : \quad \text{otherwise.} \end{cases}$$

Observe the following for any ν with $|\eta_1| \leq |\nu| \leq l$ and containing the left factor $x_0^{n_1+1}$ (otherwise the claim is trivial):

$$\begin{aligned}
|(\eta_1 \circ d, \nu)| &= \left|(x_0^{n_1+1}(d_{i_1} \sqcup x_0^{n_0}), \nu)\right| \\
&= \left|\Big(d_{i_1} \sqcup x_0^{n_0}, \underbrace{x_0^{-(n_1+1)}(\nu)}_{\nu'}\Big)\right| \\
&= \left|\sum_{\xi \in X^{|\nu'|-n_0}} (d_{i_1}, \xi)(\xi \sqcup x_0^{n_0}, \nu')\right| \\
&\leq \sum_{\xi \in X^{|\nu'|-n_0}} (K_d M_d^{|\xi|} |\xi|!)\, (\xi \sqcup x_0^{n_0}, \nu') \quad (\text{since } 0 \leq |\xi| < l) \\
&\leq K_d M_d^{|\nu'|-n_0} (|\nu'| - n_0)! \binom{|\nu'|}{n_0} \\
&= K_d M_d^{-|\eta_1|} M_d^{|\nu|} |\nu|!\, S_{\eta_1}(|\nu|).
\end{aligned}$$

Now assume that the result holds up to some fixed j, where $1 \leq j \leq k-1$. Then in a similar fashion for $|\eta_{j+1}| \leq |\nu| \leq l$,

$$\begin{aligned}
|(\eta_{j+1} \circ d, \nu)| &= \left|\Big(d_{i_{j+1}} \sqcup (\eta_j \circ d), \underbrace{x_0^{-(n_{j+1}+1)}(\nu)}_{\nu'}\Big)\right| \\
&= \left|\sum_{i=0}^{|\nu'|} \sum_{\substack{\xi \in X^i \\ \bar{\xi} \in X^{|\nu'|-i}}} (d_{i_{j+1}}, \xi)(\eta_j \circ d, \bar{\xi})(\xi \sqcup \bar{\xi}, \nu')\right|.
\end{aligned}$$

Since $(\eta_j \circ d, \bar{\xi}) = 0$ for $|\bar{\xi}| < |\eta_j|$, it follows that, by using the coefficient bounds for d (because $0 \le |\xi| \le l - (j+1)$) and Lemma 2.9 (since $|\eta_j| \le |\bar{\xi}| < l - (n_{j+1}+1)$),

$$\begin{aligned}
|(\eta_{j+1} \circ d, \nu)| &\le \sum_{i=0}^{|\nu'|-|\eta_j|} \sum_{\substack{\xi \in X^i \\ \bar{\xi} \in X^{|\nu'|-i}}} (K_d M_d^{|\xi|} |\xi|!) \cdot \left(K_d^j M_d^{-|\eta_j|} M_d^{|\bar{\xi}|} |\bar{\xi}|!\, S_{\eta_j}(|\bar{\xi}|) \right) (\xi \sqcup\!\sqcup \bar{\xi}, \nu') \\
&= K_d^{j+1} M_d^{-|\eta_{j+1}|} M_d^{|\nu|} \sum_{i=0}^{|\nu'|-|\eta_j|} i!\, (|\nu'|-i)!\, S_{\eta_j}(|\nu'|-i) \binom{|\nu'|}{i} \\
&= K_d^{j+1} M_d^{-|\eta_{j+1}|} M_d^{|\nu|} |\nu|!\, \frac{1}{(|\nu|)_{n_{j+1}+1}} \sum_{i=0}^{|\nu'|-|\eta_j|} S_{\eta_j}(|\nu| - (n_{j+1}+1) - i) \\
&= K_d^{j+1} M_d^{-|\eta_{j+1}|} M_d^{|\nu|} |\nu|!\, S_{\eta_{j+1}}(|\nu|).
\end{aligned}$$

Hence, the claim is true for all $0 \le j \le k$.

In the second step of the proof, the claimed upper bound on $(c \circ d, \nu)$ is produced in terms of the polynomials $\psi_n(K_d)$. Since $\eta \in I_d(\nu)$ only if $|\eta| \le |\nu|$, using the inequality (13), it follows that

$$\begin{aligned}
|(c \circ d, \nu)| &= \left| \sum_{i=0}^{|\nu|} \sum_{j=0}^{i} \sum_{\eta_j \in X^i} (c, \eta_j)(\eta_j \circ d, \nu) \right| \\
&\le \sum_{i=0}^{|\nu|} \sum_{j=0}^{i} \sum_{\eta_j \in X^i} (K_c M^{|\eta_j|} |\eta_j|!) \cdot (K_d^j M^{-|\eta_j|} M^{|\nu|} |\nu|!\, S_{\eta_j}(|\nu|)) \\
&= K_c\, \psi_{|\nu|}(K_d)\, M^{|\nu|} |\nu|!. \qquad \square
\end{aligned}$$

LEMMA 2.11. *For each right factor η_j as defined in* (4) *of a given word $\eta \in X^*$, the following bounds apply:*

$$0 < S_{\eta_j}(n) \le \frac{(\alpha+1)^{n-|\eta_j|+j}}{\alpha^j |\eta_j|!}$$

for any $\alpha > 0$ and all $n \ge |\eta_j|$.

Proof. The proof is again by induction. The $j = 0$ case is trivial. When $j = 1$, observe that

$$\begin{aligned}
S_{\eta_1}(n) &= \frac{1}{(n)_{n_1+1} |\eta_0|!} \\
&\le \frac{1}{(|\eta_1|)_{n_1+1} |\eta_0|!}, \quad n \ge |\eta_1|, \\
&= \frac{1}{|\eta_1|!} \\
&\le \left(\frac{\alpha+1}{\alpha} \right) \frac{(\alpha+1)^{n-|\eta_1|}}{|\eta_1|!}, \quad n \ge |\eta_1|.
\end{aligned}$$

Now suppose the lemma is true up to some fixed $j \ge 1$. Then

$$S_{\eta_{j+1}}(n) = \frac{1}{(n)_{n_{j+1}+1}} \sum_{i=0}^{n-|\eta_{j+1}|} S_{\eta_j}(n - (n_{j+1}+1) - i)$$

$$\leq \frac{1}{(n)_{n_{j+1}+1}} \sum_{i=0}^{n-|\eta_{j+1}|} \frac{(\alpha+1)^{(n-(n_{j+1}+1)-i)-|\eta_j|+j}}{\alpha^j |\eta_j|!}$$

$$\leq \frac{(\alpha+1)^j}{\alpha^j |\eta_{j+1}|!} \sum_{i=0}^{n-|\eta_{j+1}|} (\alpha+1)^{n-|\eta_{j+1}|-i}, \quad n \geq |\eta_{j+1}|,$$

$$\leq \frac{(\alpha+1)^{n-|\eta_{j+1}|+j+1}}{\alpha^{j+1}|\eta_{j+1}|!}.$$

So the result holds for all $j \geq 0$. □

The main local convergence theorem for the composition product follows.

THEOREM 2.12. *Suppose $c \in \mathbb{R}^{\ell}_{LC}\langle\langle X\rangle\rangle$ and $d \in \mathbb{R}^{m}_{LC}\langle\langle X\rangle\rangle$ with growth constants K_c, M_c and K_d, M_d, respectively. Then $c \circ d \in \mathbb{R}^{\ell}_{LC}\langle\langle X\rangle\rangle$ with*

$$|(c \circ d, \nu)| \leq K_c((\phi(mK_d)+1)M)^{|\nu|}(|\nu|+1)! \ \ \forall \nu \in X^*,$$

where $\phi(x) := x/2 + \sqrt{x^2/4 + x}$ and $M = \max\{M_c, M_d\}$.

Proof. In light of Lemma 2.10, the goal is to show that $\psi_n(K_d) \leq (\phi(mK_d)+1)^n(n+1)$ for all $n \geq 0$. Observe that applying Lemma 2.11 gives, for any $\alpha > 0$,

$$\psi_n(K_d) \leq \sum_{i=0}^{n} \sum_{j=0}^{i} \sum_{\substack{\eta_j \in X^i \\ i \geq j}} K_d^j \frac{(\alpha+1)^{n-|\eta_j|+j}}{\alpha^j}$$

$$= (\alpha+1)^n \sum_{i=0}^{n} \sum_{j=0}^{i} \binom{i}{j} \left(\frac{mK_d}{\alpha}\right)^j \left(\frac{1}{\alpha+1}\right)^{i-j}$$

$$= (\alpha+1)^n \sum_{i=0}^{n} \beta^i,$$

where $\beta := mK_d/\alpha + 1/(\alpha+1)$. Setting $\beta = 1$ corresponds to letting $\alpha = \phi(mK_d)$, and the theorem is proved. (Note that $\phi(1) = \phi_g := (1+\sqrt{5})/2$, the golden ratio, and $\phi(mK_d) \approx mK_d$ when $mK_d \gg 1$.) □

Example 2.13. In some cases, the coefficient boundaries given in Theorem 2.12 are conservative; i.e., smaller growth constants might be produced by exploiting particular features of the series under consideration. For example, given linear series $c = \sum_{n\geq 0}(c, x_0^n x_1)x_0^n x_1$ and $d = \sum_{n\geq 0}(d, x_0^n x_1)x_0^n x_1$ in $\mathbb{R}_{LC}\langle\langle X\rangle\rangle$ with $X = \{x_0, x_1\}$, it can be shown directly that, by writing the composition product as a convolution sum and using the fact that $\sum_{k=0}^{n}\binom{n}{k}^{-1} < 3$ for any $n \geq 0$,

$$|(c \circ d, \nu)| < K_c K_d M^{|\nu|}|\nu|! \ \ \forall \nu \in X^*.$$

3. The nonrecursive connections. In this section the generating series are produced for the three nonrecursive interconnections, and their local convergence is characterized.

THEOREM 3.1. *If $c, d \in \mathbb{R}^{\ell}_{LC}\langle\langle X\rangle\rangle$, then each nonrecursive interconnected input-output system shown in* Figure 1.1(a)–(c) *has a Fliess operator representation generated by a locally convergent series as indicated:*

1. $F_c + F_d = F_{c+d}$;
2. $F_c \cdot F_d = F_{c \sqcup\!\sqcup d}$;
3. $F_c \circ F_d = F_{c \circ d}$, *where* $\ell = m$.

Proof.

1. Observe that

$$F_c[u](t) + F_d[u](t) = \sum_{\eta \in X^*} [(c,\eta) + (d,\eta)]\, E_\eta[u](t,t_0) = F_{c+d}[u](t).$$

Since c and d are locally convergent, define $M = \max\{M_c, M_d\}$. Then it follows that

$$|(c+d,\eta)| = |(c,\eta) + (d,\eta)| \leq (K_c + K_d) M^{|\eta|} |\eta|! \ \ \forall \eta \in X^*,$$

or $c + d$ is locally convergent.

2. In light of the componentwise definition of the product interconnection and the shuffle product, it can be assumed without loss of generality that $\ell = 1$. Therefore,

$$\begin{aligned} F_c[u](t) F_d[u](t) &= \sum_{\eta \in X^*} (c,\eta) E_\eta[u](t,t_0) \sum_{\xi \in X^*} (d,\xi) E_\xi[u](t,t_0) \\ &= \sum_{\eta,\xi \in X^*} (c,\eta)(d,\xi)\, E_{\eta \sqcup\!\sqcup \xi}[u](t,t_0) \\ &= F_{c \sqcup\!\sqcup d}[u](t). \end{aligned}$$

Local convergence of $c \sqcup\!\sqcup d$ is provided by Theorem 2.8.

3. It is first shown by induction that $F_\eta \circ F_d = F_{\eta \circ d}$ for any $\eta \in X^*$ and $d \in \mathbb{R}^m_{LC}\langle\langle X \rangle\rangle$. Choose any $\eta \in X^*$, and let $\{\eta_0, \eta_1, \ldots, \eta_k\}$ be the corresponding set of right factors defined in (4). Clearly,

$$(F_{\eta_0} \circ F_d[u])(t) = E_{\eta_0}[u](t,t_0) = F_{\eta_0}[u](t) = F_{\eta_0 \circ d}[u](t).$$

Now assume that

$$(F_{\eta_j} \circ F_d[u])(t) = F_{\eta_j \circ d}[u](t)$$

holds up to some fixed factor η_j. Then

$$\begin{aligned} (F_{\eta_{j+1}} \circ F_d[u])(t) &= E_{x_0^{n_{j+1}} x_{i_{j+1}} \eta_j}[F_d[u]](t,t_0) \\ &= \underbrace{\int_{t_0}^{t} \cdots \int_{t_0}^{\tau_2}}_{n_{j+1}+1 \text{ times}} F_{d_{i_{j+1}}}[u](\tau_1) E_{\eta_j}[F_d[u]](\tau_1,t_0)\, d\tau_1 \cdots d\tau_{n_{j+1}+1} \\ &= \underbrace{\int_{t_0}^{t} \cdots \int_{t_0}^{\tau_2}}_{n_{j+1}+1 \text{ times}} F_{d_{i_{j+1}} \sqcup\!\sqcup (\eta_j \circ d)}[u](\tau_1)\, d\tau_1 \cdots d\tau_{n_{j+1}+1} \\ &= F_{x_0^{n_{j+1}+1}[d_{i_{j+1}} \sqcup\!\sqcup (\eta_j \circ d)]}[u](t) \\ &= F_{\eta_{j+1} \circ d}[u](t). \end{aligned}$$

Thus, the claim holds for $\eta = \eta_{j+1}$ and, by induction, for $\eta = \eta_k$. Finally,

$$\begin{aligned} (F_c \circ F_d[u])(t) &= \sum_{\eta \in X^*} (c,\eta) E_\eta[F_d[u]](t,t_0) = \sum_{\eta \in X^*} (c,\eta) F_{\eta \circ d}[u](t) \\ &= \sum_{\eta \in X^*} (c,\eta) \left[\sum_{\nu \in X^*} (\eta \circ d, \nu) E_\nu[u](t,t_0) \right] \end{aligned}$$

$$
\begin{aligned}
&= \sum_{\nu\in X^*}\left[\sum_{\eta\in X^*}(c,\eta)(\eta\circ d,\nu)\right]E_\nu[u](t,t_0)\\
&= \sum_{\nu\in X^*}(c\circ d,\nu)\,E_\nu[u](t,t_0)\\
&= F_{c\circ d}[u](t).
\end{aligned}
$$

Local convergence of $c\circ d$ was proved in Theorem 2.12. □

Example 3.2. Let $X=\{x_0,x_1\}$, $c=\sum_{k\geq 0}K_cM_c^k k!\,x_1^k$, and $d=\sum_{k\geq 0}K_dM_d^k k!\,x_1^k$, where $K_c,M_c>0$ and $K_d,M_d>0$ are arbitrary growth constants. It is easily verified that the state space systems,

$$
\begin{aligned}
&\dot{z_c}=M_cz_c^2u_c,\quad z_c(0)=1, && \dot{z_d}=M_dz_d^2u_d,\quad z_d(0)=1,\\
&y_c=K_cz_c, && y_d=K_dz_d,
\end{aligned}
$$

realize the operators $F_c:u_c\mapsto y_c$ and $F_d:u_d\mapsto y_d$, respectively, for sufficiently small inputs and intervals of time. Letting $z=[z_c^T\ \ z_d^T]^T$, it follows directly that $F_{c\circ d}$ is realized by

$$\dot{z}=f(z)+g(z)u,\quad z(0)=[1\ \ 1]^T, \tag{14}$$

$$y=h(z), \tag{15}$$

where

$$f(z)=\begin{pmatrix}K_dM_cz_c^2z_d\\0\end{pmatrix},\quad g(z)=\begin{pmatrix}0\\M_dz_d^2\end{pmatrix},\quad h(z)=K_cz_c.$$

The first few coefficients of c, d, and $c\circ d$ are given in Table 3.1 along with the upper bounds on the coefficients of $c\circ d$ predicted by Theorem 2.12. Since these upper bounds hold for *any* series c and d with the given growth constants, they can be

TABLE 3.1

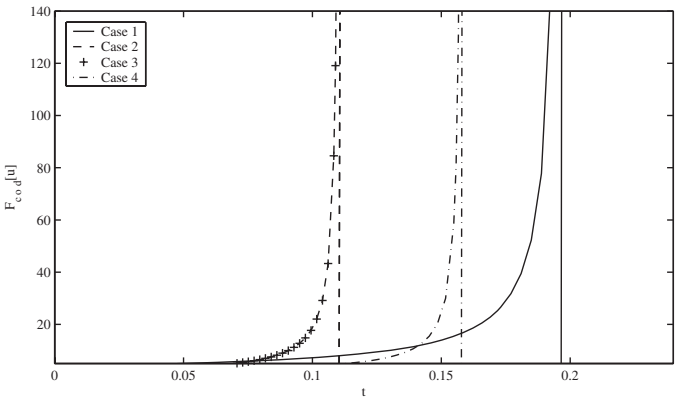

FIG. 3.1. *The output of $F_{c\circ d}[u]$ when $u(t) = \bar{u} = 1$ for Cases 1–4 of Table 3.2.*

conservative in specific cases. In [13] it is shown that given any series $c \in \mathbb{R}^{\ell}_{LC}\langle\langle X\rangle\rangle$, where $X = \{x_0, x_1, \ldots, x_m\}$ and $|(c,\nu)| \le K_c M_c^{|\nu|}\,|\nu|!$ for all $\nu \in X^*$, if

$$\max\{||u||_1, T\} \le \frac{1}{(m+1)^2 M_c},$$

then $F_c[u]$ converges absolutely and uniformly on $[0,T]$. The result still holds if one has the slightly more generous growth condition $|(c,\nu)| \le K_c M_c^{|\nu|}\,(|\nu|+1)!$. For a constant input $u(t) = \bar{u}$, where $|\bar{u}| \ge 1$, define

$$T_{\max} = \frac{1}{(m+1)^2 M_c |\bar{u}|}. \tag{16}$$

Then it follows from Theorem 2.12 that when $m = 1$, $F_{c\circ d}[\bar{u}]$ will always be well defined on at least the interval $[0, T_{\max})$, where

$$T_{\max} = \frac{1}{4M_{c\circ d}|\bar{u}|}$$

and $M_{c\circ d} = (\phi(K_d)+1)\max\{M_c, M_d\}$. Four specific cases are described in Table 3.2. Here each $T_{\max}$ is compared against the finite escape time, t_{esc}, of the state space system (14)–(15) with $u(t) = \bar{u} = 1$, which is determined numerically (see Figure 3.1). In each case, the value of $T_{\max} < t_{\text{esc}}$, but, as expected, $T_{\max}$ is conservative since the coefficient upper bounds for $c \circ d$ are conservative.

Example 3.3. The composition product provides an alternative interpretation of the symbolic calculus of Fliess [8, 10, 19]. Specifically, consider an input-output system represented by F_c with $c \in \mathbb{R}^{\ell}_{LC}\langle\langle X\rangle\rangle$. Any input u, which is analytic at $t = t_0$, can be represented near t_0 by a series $c_u \in \mathbb{R}^{m}_{LC}\langle\langle X_0\rangle\rangle$, i.e., $u = F_{c_u}[v]$ for

some locally convergent series $c_u = \sum_{k\geq 0}(c_u, x_0^k)\, x_0^k$ and all $\nu \in B_p^m(R)[t_0, t_0+T]$. In effect, c_u is the formal Laplace–Borel transform of the input u. (See [20] for more analysis of this example using the formal Laplace–Borel transform.) The analyticity of $y = F_c[u]$ follows from [28, Lemma 2.3.8], and therefore the formal Laplace–Borel transform of y, namely, c_y, can be related to c and c_u via

$$F_{c_y}[v] = y = F_c[F_{c_u}[v]] = F_{c\circ c_u}[v].$$

From [28, Corollary 2.2.4], it follows directly that $c_y = c \circ c_u$.

This last example motivates the following definition.

DEFINITION 3.4. *A series $c \in \mathbb{R}^\ell\langle\langle X\rangle\rangle$ is* input-output locally convergent *if for every $c_u \in \mathbb{R}^m_{LC}\langle\langle X_0\rangle\rangle$ it follows that $c \circ c_u \in \mathbb{R}^\ell_{LC}\langle\langle X_0\rangle\rangle$.*

It is immediate that every locally convergent series is input-output locally convergent, but the converse claim is only known to hold at present in certain special cases.

LEMMA 3.5. *Let $c \in \mathbb{R}^\ell\langle\langle X\rangle\rangle$ be an input-output locally convergent series with nonnegative coefficients. Then c is locally convergent.*

Proof. Set $c_u = \mathbb{1}$ and let K, M be the growth constants for the series $c \circ \mathbb{1}$. Then from Lemma 2.2, property 4,

$$|(c\circ\mathbb{1}, x_0^n)| = \max_i \sum_{\eta\in X^n} (c_i, \eta) \leq KM^n\, n!\ \ \forall n \geq 0.$$

Thus, $|(c,\eta)| = \max_i(c_i,\eta) \leq KM^n\, n!$ for all $n \geq 0$. ∎

LEMMA 3.6. *Let $c \in \mathbb{R}^\ell\langle\langle X\rangle\rangle$ be an input-output locally convergent linear series of the form $c = \sum_{j\geq 0}(c, x_0^j x_{i_j})\, x_0^j x_{i_j}$, where $i_j \in \{1,2,\ldots,m\}$ for all $j \geq 0$. Then c is locally convergent.*

Proof. Again set $c_u = \mathbb{1}$ and let K, M be the growth constants for the series $c \circ \mathbb{1}$. Then

$$|(c\circ\mathbb{1}, x_0^n)| = \max_i |(c_i, x_0^{n-1}x_{i_n})| \leq KM^n\, n!\ \ \forall n \geq 0,$$

and the conclusion follows. ∎

4. The feedback connection. Given any $c, d \in \mathbb{R}^m_{LC}\langle\langle X\rangle\rangle$, the general goal of this section is to determine when there exists a y which satisfies the feedback equation (1) and, in particular, when there exists a generating series e so that $y = F_e[u]$ for all admissible inputs u. In the latter case, the feedback equation becomes equivalent to

$$F_e[u] = F_c[u + F_{d\circ e}[u]], \tag{17}$$

and the *feedback product* of c and d is defined by $c@d = e$. It is assumed throughout that $m > 0$; otherwise the feedback connection is degenerate. An initial obstacle in this analysis is that F_e is required to be the composition of two operators, F_c and $I + F_{d\circ e}$, where the second operator is *never* realizable by a Fliess operator due to the direct feed term I. This does not prevent the composition from being a Fliess operator, but to compensate for the presence of this term a *modified* composition product is needed. Specifically, for any $\eta \in X^*$ and $d \in \mathbb{R}^m\langle\langle X\rangle\rangle$, define the modified composition product as

$$\eta \,\tilde{\circ}\, d = \begin{cases} \eta & : \ |\eta|_{x_i} = 0 \ \ \forall i \neq 0, \\ x_0^n x_i(\eta' \,\tilde{\circ}\, d) + x_0^{n+1}[d_i \sqcup\!\sqcup (\eta' \,\tilde{\circ}\, d)] & : \ \eta = x_0^n x_i \eta', \ \ n \geq 0, \ \ i \neq 0. \end{cases}$$

For $c \in \mathbb{R}^{\ell}\langle\langle X\rangle\rangle$ and $d \in \mathbb{R}^{m}\langle\langle X\rangle\rangle$, the definition is extended as

$$c \,\tilde{\circ}\, d = \sum_{\eta \in X^*} (c, \eta)\ \eta \,\tilde{\circ}\, d.$$

It can be verified in a manner completely analogous to the original composition product that the modified composition product is always well defined (summable), continuous in both arguments, and locally convergent when both c and d are. In particular, the following theorems are central to the analysis in this section.

THEOREM 4.1. *For any $c \in \mathbb{R}^{\ell}_{LC}\langle\langle X\rangle\rangle$ and $d \in \mathbb{R}^{m}_{LC}\langle\langle X\rangle\rangle$, it follows that*

$$F_{c \,\tilde{\circ}\, d}[u] = F_c[u + F_d[u]]$$

for all admissible u.

Proof. The result is verified simply by inserting the direct feed term into the proof of Theorem 3.1, part 3. ∎

THEOREM 4.2. *For any $c \in \mathbb{R}^{m}\langle\langle X\rangle\rangle$, the mapping $d \mapsto c \,\tilde{\circ}\, d$ is a contraction on $\mathbb{R}^{m}\langle\langle X\rangle\rangle$.*

Proof. This is also a minor variation of previous results concerning the composition product, in particular, Lemma 2.4, Lemma 2.5, and Theorem 2.6. The contraction coefficient, σ, is unaffected by the required modifications. ∎

The first main result of this section is given next.

THEOREM 4.3. *Let c, d be fixed series in $\mathbb{R}^{m}\langle\langle X\rangle\rangle$. Then the following propositions hold:*

1. *The mapping*

$$\begin{aligned} S &: \mathbb{R}^{m}\langle\langle X\rangle\rangle \to \mathbb{R}^{m}\langle\langle X\rangle\rangle \\ &: e_i \mapsto e_{i+1} = c \,\tilde{\circ}\, (d \circ e_i) \end{aligned} \tag{18}$$

has a unique fixed point in $\mathbb{R}^{m}\langle\langle X\rangle\rangle$, $c@d = \lim_{i\to\infty} e_i$, which is independent of e_0.

2. *If c, d, and $c@d$ are locally convergent, then $F_{c@d}$ satisfies the feedback equation* (17).

Proof.

1. The mapping S is a contraction since, by Theorems 2.6 and 4.2,

$$\operatorname{dist}(S(e_i), S(e_j)) \le \sigma \operatorname{dist}(d \circ e_i, d \circ e_j) \le \sigma^2 \operatorname{dist}(e_i, e_j).$$

Therefore, the mapping S has a unique fixed point, $c@d$, that is independent of e_0, i.e.,

$$c@d = c \,\tilde{\circ}\, (d \circ (c@d)). \tag{19}$$

2. From the stated assumptions concerning c, d, and $c@d$, it follows that

$$F_{c@d}[u] = F_{c \,\tilde{\circ}\, (d \circ (c@d))}[u] = F_c[u + F_d[F_{c@d}[u]]]$$

for any admissible u. ∎

The obvious question is whether $c@d$ is always locally convergent, or at least input-output locally convergent, when both c and d are locally convergent. The local convergence of c and d guarantees that the feedback system in Figure 1.1(d) is at least *well-posed* in the sense described in [1, 27] since F_c and F_d are well-defined causal analytic operators. That is, there exist sufficiently small $R, S, T > 0$ such that

for any $u \in B_p^m(R)[t_0, t_0+T]$, there exists a $y \in B_q^m(S)[t_0, t_0+T]$ which satisfies the feedback equation (1). But whether $y = F_{c@d}[u]$ on some ball of input functions of nonzero radius over a nonzero interval of time is not immediate. The following example shows that $\mathbb{R}^m_{LC}\langle\langle X\rangle\rangle$ is not a closed subset of $\mathbb{R}^m\langle\langle X\rangle\rangle$ in the ultrametric topology.

Example 4.4. Let $X = \{x_0, x_1\}$ and consider the following sequence of polynomials in $\mathbb{R}^m_{LC}\langle\langle X\rangle\rangle$:

$$e_i = x_1 + 2^2 2!\, x_1^2 + 3^3 3!\, x_1^3 + \cdots + i^i i!\, x_1^i, \quad i \geq 1.$$

Clearly, $e = \lim_{i\to\infty} e_i$ is not locally convergent.

A central issue is whether such an example can be produced by repeated compositions of a locally convergent series. It will be first shown that the answer to this question is *no*. Then the more general case described by (18) is examined. This leads to the main conclusion that the feedback product of two locally convergent series is always input-output locally convergent.

Observe first that if $e = c \circ e$, then it follows that e must have the form $e = \sum_{n\geq 0}(e, x_0^n)\, x_0^n$. Furthermore, since e appears on both sides of the expression $e = c \circ e$, it is possible by repeated substitution to express each coefficient (e, x_0^n) in terms of the coefficients $\{(c, \nu) : |\nu| \leq n\}$. For example, if $X = \{x_0, x_1\}$, the first few coefficients of e are

$$\begin{aligned}
(e,\emptyset) &= (c,\emptyset),\\
(e,x_0) &= (c,x_0) + (c,\emptyset)(c,x_1),\\
(e,x_0^2) &= (c,x_0^2) + (c,x_0)(c,x_1) + (c,\emptyset)(c,x_1)^2 + (c,\emptyset)(c,x_0x_1) + (c,\emptyset)(c,x_1x_0)\\
&\quad +(c,\emptyset)^2(c,x_1^2),\\
(e,x_0^3) &= (c,x_0^2)(c,x_1) + (c,x_0)(c,x_1)^2 + (c,\emptyset)(c,x_1)^3 + (c,\emptyset)(c,x_1)(c,x_0x_1)\\
&\quad +(c,\emptyset)(c,x_1)(c,x_1x_0) + (c,\emptyset)^2(c,x_1)(c,x_1^2) + (c,x_0)(c,x_0x_1)\\
&\quad +(c,\emptyset)(c,x_1)(c,x_0x_1) + 2(c,x_0)(c,x_1x_0) + 2(c,\emptyset)(c,x_1)(c,x_1x_0)\\
&\quad +3(c,\emptyset)(c,x_0)(c,x_1^2) + 3(c,\emptyset)^2(c,x_1)(c,x_1^2) + (c,x_0^3) + (c,\emptyset)(c,x_0^2x_1)\\
&\quad +(c,\emptyset)(c,x_0x_1x_0) + (c,\emptyset)^2(c,x_0x_1^2) + (c,\emptyset)(c,x_1x_0^2) + (c,\emptyset)^2(c,x_1x_0x_1)\\
&\quad +(c,\emptyset)^2(c,x_1^2x_0) + (c,\emptyset)^3(c,x_1^3)\\
&\ \ \vdots
\end{aligned}$$

If c is locally convergent with growth constants K_c, M_c, then

$$\begin{aligned}
|(e,\emptyset)| &\leq K_c,\\
|(e,x_0)| &\leq K_c(K_c+1)M_c,\\
|(e,x_0^2)| &\leq K_c\left(\frac{3}{2}K_c^2 + \frac{5}{2}K_c + 1\right) M_c^2\, 2!,\\
|(e,x_0^3)| &\leq K_c\left(\frac{5}{2}K_c^3 + \frac{35}{6}K_c^2 + \frac{13}{3}K_c + 1\right) M_c^3\, 3!\\
&\ \ \vdots
\end{aligned}$$

This suggests that a variation of inequality (12) is possible, namely, that

$$|(e, x_0^n)| \leq K_c\, \tilde{\psi}_n(K_c)\, M_c^n\, n! \ \ \forall n \geq 0,$$

TABLE 4.1
The first few polynomials $\tilde{S}_{\eta_j}(K_c, n)$ and $\tilde{\psi}_n(K_c)$ when $m = 1$.

	$x_1^2x_0$	$\tilde{S}_{x_0}(K_c,3)=1,\ \tilde{S}_{x_1x_0}(K_c,3)=\frac{1}{3}K_c+\frac{2}{3},$ $\tilde{S}_{x_1^2x_0}(K_c,3)=\frac{1}{6}$	
	x_1^3	$\tilde{S}_{\emptyset}(K_c,3)=1,\ \tilde{S}_{x_1}(K_c,3)=\frac{1}{2}K_c^2+K_c+1,$ $\tilde{S}_{x_1^2}(K_c,3)=\frac{1}{2}K_c+1,\ \tilde{S}_{x_1^3}(K_c,3)=\frac{1}{6}$	

where each $\tilde{\psi}_n(K_c)$ is a polynomial in K_c of degree n. The next lemma establishes the claim using a family of polynomials of the form

$$\tilde{\psi}_n(K_c)=\sum_{i=0}^{n}\sum_{j=0}^{i}\sum_{\eta_j\in X^i}K_c^j\tilde{S}_{\eta_j}(K_c,n)|\eta_j|!,\quad n\geq 0.$$

Given a fixed n, every word η_j in the innermost summation satisfies $j\leq|\eta_j|\leq n$ and has a corresponding set of right factors $\{\eta_0,\eta_1,\dots,\eta_j\}$. When $j>0$, each polynomial $\tilde{S}_{\eta_j}(K_c,n)$ is computed iteratively using its right factors and the previously computed polynomials $\{\tilde{\psi}_0(K_c),\tilde{\psi}_1(K_c),\dots,\tilde{\psi}_{n-1}(K_c)\}$:

$$\begin{aligned}
\tilde{S}_{\eta_0}(K_c,n)&=\frac{1}{|\eta_0|!},\quad 0\leq|\eta_0|\leq n,\\
\tilde{S}_{\eta_1}(K_c,n)&=\frac{1}{(n)_{n_1+1}}\,\tilde{\psi}_{n-|\eta_1|}(K_c)\,\tilde{S}_{\eta_0}(K_c,n),\quad 1\leq|\eta_1|\leq n,\\
\tilde{S}_{\eta_2}(K_c,n)&=\frac{1}{(n)_{n_2+1}}\sum_{i=0}^{n-|\eta_2|}\tilde{\psi}_i(K_c)\,\tilde{S}_{\eta_1}(K_c,n-(n_2+1)-i),\quad 2\leq|\eta_2|\leq n,\\
&\vdots\\
\tilde{S}_{\eta_j}(K_c,n)&=\frac{1}{(n)_{n_j+1}}\sum_{i=0}^{n-|\eta_j|}\tilde{\psi}_i(K_c)\,\tilde{S}_{\eta_{j-1}}(K_c,n-(n_j+1)-i),\quad 2\leq j\leq|\eta_j|\leq n.
\end{aligned}$$

See Table 4.1 for the case where $m=1$.

LEMMA 4.5. *Let $c \in \mathbb{R}^m_{LC}\langle\langle X\rangle\rangle$ with growth constants K_c, M_c, and $e \in \mathbb{R}^m\langle\langle X\rangle\rangle$ such that $e = c \circ e$. Then*

$$|(e, x_0^n)| \leq K_c\, \tilde{\psi}_n(K_c)\, M_c^n\, n!\ \ \forall n \geq 0. \tag{20}$$

Proof. The proof has some elements in common with that of Lemma 2.10, except here it is not assumed a priori that e is locally convergent. The basic approach employs *nested inductions*. The outer induction is on n. It is clear from the discussion above that the claim holds when $n = 0$ and $n = 1$ for $m = 1$. A similar calculation can be done for arbitrary $m \geq 1$. Now suppose (20) holds up to some fixed $n - 1 \geq 1$. Given any η_j, where $j \leq |\eta_j| \leq n$, it will first be shown by induction on j (the inner induction) that

$$|(\eta_j \circ e, x_0^n)| \leq K_c^j M_c^{-|\eta_j|} M_c^n\, n!\, \tilde{S}_{\eta_j}(K_c, n),\ \ 0 \leq j \leq n. \tag{21}$$

The $j = 0$ case is trivial. Suppose $j = 1$. Then $0 \leq n - |\eta_1| \leq n - 1$ and

$$\begin{aligned}
|(\eta_1 \circ e, x_0^n)| &= \left|\left(x_0^{n_1+1}(e_{i_1} \sqcup\!\sqcup x_0^{n_0}), x_0^n\right)\right| \\
&= \left|\left(e_{i_1} \sqcup\!\sqcup x_0^{n_0}, x_0^{n-(n_1+1)}\right)\right| \\
&= \left|\left(e_{i_1}, x_0^{n-|\eta_1|}\right)\left(x_0^{n-|\eta_1|} \sqcup\!\sqcup x_0^{n_0}, x_0^{n-(n_1+1)}\right)\right| \\
&\leq \left(K_c\, \tilde{\psi}_{n-|\eta_1|}(K_c)\, M_c^{n-|\eta_1|}(n - |\eta_1|)!\right)\binom{n-(n_1+1)}{n-|\eta_1|} \\
&= K_c M_c^{-|\eta_1|} M_c^n\, n!\, \tilde{S}_{\eta_1}(K_c, n).
\end{aligned}$$

Now assume that inequality (21) holds up to some fixed j, where $1 \leq j \leq n-1$. Then $0 \leq n - |\eta_{j+1}| \leq n - (j+1)$ and

$$\begin{aligned}
|(\eta_{j+1} \circ e, x_0^n)| &= \left|\left(e_{i_{j+1}} \sqcup\!\sqcup (\eta_j \circ e), x_0^{n-(n_{j+1}+1)}\right)\right| \\
&= \left|\sum_{i=0}^{n-(n_{j+1}+1)} \left(e_{i_{j+1}}, x_0^i\right)\left(\eta_j \circ e, x_0^{n-(n_{j+1}+1)-i}\right)\binom{n-(n_{j+1}+1)}{n-(n_{j+1}+1)-i}\right|.
\end{aligned}$$

Since $(\eta_j \circ e, x_0^{n-(n_{j+1}+1)-i}) = 0$ when $n - (n_{j+1}+1) - i < |\eta_j|$ or, equivalently, $i > n - |\eta_{j+1}|$, it follows that, using the coefficient bound (20) for e (because $0 \leq i \leq n-1$) and the bound (21) for $\eta_j \circ e$,

$$\begin{aligned}
|(\eta_{j+1} \circ e, x_0^n)| \leq & \sum_{i=0}^{n-|\eta_{j+1}|} \left(K_c \tilde{\psi}_i(K_c) M_c^i\, i!\right)\Big(K_c^j M_c^{-|\eta_j|} M_c^{n-(n_{j+1}+1)-i} \\
& \cdot (n-(n_{j+1}+1)-i)!\, \tilde{S}_{\eta_j}(K_c, n-(n_{j+1}+1)-i)\Big) \\
& \cdot \binom{n-(n_{j+1}+1)}{n-(n_{j+1}+1)-i} \\
= & K_c^{j+1} M_c^{-|\eta_{j+1}|} M_c^n\, n!\, \frac{1}{(n)_{n_{j+1}+1}} \\
& \cdot \sum_{i=0}^{n-|\eta_{j+1}|} \tilde{\psi}_i(K_c)\, \tilde{S}_{\eta_j}(K_c, n-(n_{j+1}+1)-i) \\
= & K_c^{j+1} M_c^{-|\eta_{j+1}|} M_c^n\, n!\, \tilde{S}_{\eta_{j+1}}(K_c, n).
\end{aligned}$$

Hence, the claim is true for all $0 \le j \le n$.

To complete the outer induction with respect to n, observe that

$$\begin{aligned}|(e, x_0^n)| = |(c \circ e, x_0^n)| &= \left| \sum_{i=0}^{n} \sum_{j=0}^{i} \sum_{\eta_j \in X^i} (c, \eta_j)(\eta_j \circ e, x_0^n) \right| \\ &\le \sum_{i=0}^{n} \sum_{j=0}^{i} \sum_{\eta_j \in X^i} \left(K_c M_c^{|\eta_j|} |\eta_j|! \right) \left(K_c^j M_c^{-|\eta_j|} M_c^n \, n! \, \tilde{S}_{\eta_j}(K_c, n) \right) \\ &= K_c \, \tilde{\psi}_n(K_c) \, M_c^n \, n!.\end{aligned}$$

Therefore, inequality (20) holds for all $n \ge 0$. ∎

The next lemma provides an upper bound on the growth of the sequence $\tilde{\psi}_n(K_c)$, $n \ge 0$, when K_c is fixed.

LEMMA 4.6. *For any $K_c \ge 1$, it follows that*

$$\tilde{\psi}_n(K_c) \le \phi_g (m K_c (2 + \phi_g) + 1)^n s_n \quad \forall n \ge 0, \tag{22}$$

where $s_0 = 1/\phi_g$, and s_n, $n \ge 1$, is an integer sequence equivalent to the binomial transform of the sequence of Catalan numbers, C_n, $n \ge 1$ (specifically, sequence A007317 *in* [25]).

Proof. The proof has two main parts. First, it is shown by a nested induction that, for any $\epsilon > 0$, there exists a sequence of positive real numbers, $\xi_n(\epsilon)$, such that

$$\tilde{\psi}_n(K_c) \le (m K_c (2 + \epsilon) + 1)^n \xi_n(\epsilon), \quad n \ge 0, \quad K_c \ge 1. \tag{23}$$

Then inequality (22) is produced for $n \ge 1$ by setting $\epsilon = \phi_g$ and showing that $\xi_n(\phi_g) = \phi_g s_n$ when $n \ge 1$. ($n = 0$ is a trivial special case.)

Let $\epsilon > 0$ and define two sequences of positive real numbers, $\xi_n(\epsilon)$ and $\Gamma_n(\epsilon)$, via the recurrence equations

$$\xi_{n+1}(\epsilon) = \xi_n(\epsilon) + \Gamma_{n+1}(\epsilon), \quad n \ge 0, \quad \xi_0 = 1, \quad \Gamma_1 = 1/\epsilon, \tag{24}$$

$$\Gamma_{n+1}(\epsilon) = \frac{1}{\epsilon} \left[\xi_n(\epsilon) + \sum_{i=1}^{n} \xi_i(\epsilon) \Gamma_{n-i+1}(\epsilon) \right], \quad n \ge 1. \tag{25}$$

By definition, $\Gamma_0 = 1$. In light of Table 4.1, inequality (23) clearly holds when $n = 0$ and $n = 1$ for $m = 1$ and $K_c \ge 1$. (It is easily verified to also hold when $m \ge 1$.) Now suppose the inequality holds up to some fixed $n - 1 \ge 1$. Given any word η_j, where $j \le |\eta_j| \le n$, an inner induction with respect to j will now show that

$$\tilde{S}_{\eta_j}(K_c, n) \le \frac{(m K_c (2 + \epsilon) + 1)^{n - |\eta_j|} \, (2 + \epsilon)^j \, \Gamma_{n - |\eta_j|}(\epsilon)}{|\eta_j|!}, \quad 0 \le j \le |\eta_j| \tag{26}$$

(cf. the proof of Lemma 2.11, where some of the computational details are similar). The $j = 0$ case is trivial. Suppose $j = 1$. Since $n - |\eta_1| < n$, it follows that

$$\begin{aligned}\tilde{S}_{\eta_1}(K_c, n) &= \frac{1}{(n)_{n_1+1}} \frac{\tilde{\psi}_{n-|\eta_1|}(K_c)}{|\eta_0|!} \\ &\le \frac{(m K_c (2 + \epsilon) + 1)^{n - |\eta_1|} \, \xi_{n-|\eta_1|}(\epsilon)}{|\eta_1|!} \\ &\le \frac{(m K_c (2 + \epsilon) + 1)^{n - |\eta_1|} \, (2 + \epsilon) \, \Gamma_{n-|\eta_1|}(\epsilon)}{|\eta_1|!}, \quad n \ge |\eta_1|.\end{aligned}$$

This last inequality employs the general properties for any $j \geq 0$ that $\xi_{n-|\eta_j|}(\epsilon) = \Gamma_{n-|\eta_j|}(\epsilon)$ when $n = |\eta_j|$ and

$$\sum_{i=0}^{n-|\eta_j|} \xi_i(\epsilon)\Gamma_{n-|\eta_j|-i}(\epsilon) = (2+\epsilon)\,\Gamma_{n-|\eta_j|}(\epsilon) \tag{27}$$

when $n > |\eta_j|$. Now suppose that inequality (26) holds up to some fixed $j \geq 1$. Then

$$\begin{aligned}
\tilde{S}_{\eta_{j+1}}(K_c, n) &= \frac{1}{(n)_{n_{j+1}+1}} \sum_{i=0}^{n-|\eta_{j+1}|} \tilde{\psi}_i(K_c)\, \tilde{S}_{\eta_j}(K_c, n-(n_{j+1}+1)-i) \\
&\leq \frac{1}{|\eta_{j+1}|!} \sum_{i=0}^{n-|\eta_{j+1}|} (mK_c(2+\epsilon)+1)^i \xi_i(\epsilon) \\
&\qquad \cdot \Big[(mK_c(2+\epsilon)+1)^{n-|\eta_{j+1}|-i}\,(2+\epsilon)^j\,\Gamma_{n-|\eta_{j+1}|-i}(\epsilon)\Big] \\
&= \frac{(mK_c(2+\epsilon)+1)^{n-|\eta_{j+1}|}(2+\epsilon)^j}{|\eta_{j+1}|!} \sum_{i=0}^{n-|\eta_{j+1}|} \xi_i(\epsilon)\Gamma_{n-|\eta_{j+1}|-i}(\epsilon) \\
&= \frac{(mK_c(2+\epsilon)+1)^{n-|\eta_{j+1}|}\,(2+\epsilon)^{j+1}\,\Gamma_{n-|\eta_{j+1}|}(\epsilon)}{|\eta_{j+1}|!}, \quad |\eta_j| < |\eta_{j+1}| \leq n,
\end{aligned}$$

where again identity (27) was used to derive the final equality above. Hence, inequality (26) holds for all $0 \leq j \leq |\eta_j|$. To complete the outer induction with respect to n, observe that

$$\begin{aligned}
\tilde{\psi}_{n+1}(K_c) &= \sum_{i=0}^{n+1} \sum_{j=0}^{i} \sum_{\eta_j \in X^i} K_c^j \tilde{S}_{\eta_j}(K_c, n+1)|\eta_j|! \\
&\leq \sum_{i=0}^{n+1} \sum_{j=0}^{i} \binom{i}{j} \left[\frac{(mK_c(2+\epsilon)+1)^{n+1-i}\,(mK_c(2+\epsilon))^j\,\Gamma_{n+1-i}(\epsilon)}{i!}\right] i! \\
&= (mK_c(2+\epsilon)+1)^{n+1} \sum_{i=0}^{n+1} \Gamma_{n+1-i}(\epsilon) \\
&= (mK_c(2+\epsilon)+1)^{n+1} \xi_{n+1}(\epsilon).
\end{aligned}$$

Thus, inequality (23) must hold for all $n \geq 0$.

Now consider setting $\epsilon = \phi_g$ in the system of equations (24)–(25). Eliminating by substitution the sequence $\Gamma_n(\phi_g)$ gives the recurrence relation

$$\xi_{n+1}(\phi_g) = \phi_g + \frac{1}{\phi_g} \sum_{i=1}^{n} \xi_i(\phi_g)\xi_{n-i+1}(\phi_g), \quad n \geq 1, \quad \xi_1(\phi_g) = \phi_g,$$

or, equivalently,

$$\left(\frac{\xi_{n+1}(\phi_g)}{\phi_g}\right) = 1 + \sum_{i=1}^{n} \left(\frac{\xi_i(\phi_g)}{\phi_g}\right)\left(\frac{\xi_{n-i+1}(\phi_g)}{\phi_g}\right), \quad n \geq 1, \quad \frac{\xi_1(\phi_g)}{\phi_g} = 1.$$

It is known that s_n satisfies the recurrence equation

$$s_{n+1} = 1 + \sum_{i=1}^{n} s_i s_{n-i+1}, \quad n \geq 1, \quad s_1 = 1 \tag{28}$$

(see [25] and the references therein). Hence, the conclusion that $\xi_n(\phi_g) = \phi_g s_n$, $n \geq 1$, is immediate. ∎

The recurrence equation (28) can be derived from the well-known recurrence relation for the Catalan numbers: $C_{n+1} = \sum_{i=0}^{n} C_i C_{n-i}$ with $C_0 = 1$ [4], which in turn is equivalent to Segner's recurrence formula given in the year 1758 as a solution to Euler's polygon division problem [31]. It is also worth noting that the sequence $t_n := \Gamma_n(\phi_g)/\phi_g$, $n \geq 1$, the increments of s_n, is sequence A002212 in [25]. The positive integer sequences C_n, s_n, and t_n each have a variety of combinatoric interpretations in graph theory and the theory of formal languages. Of particular interest to system theorists, for example, is the fact that C_n is equivalent to the number of ways to binary bracket the letters in a word of length $n+1$ [31, 32]. The asymptotic behavior of s_n,

$$s_n \sim \frac{1}{8}\sqrt{\frac{5}{\pi}}\,\frac{5^n}{n^{3/2}}$$

(see [15, sequence 124]), motivates the following central result concerning local convergence.

THEOREM 4.7. *If $c \in \mathbb{R}^m_{LC}\langle\langle X\rangle\rangle$ with growth constants K_c, M_c, and $e = c \circ e$, then $e \in \mathbb{R}^m_{LC}\langle\langle X_0\rangle\rangle$. Specifically, for any $K_c \geq 1$,*

$$|(e, x_0^n)| \leq K_c((mK_c(2+\phi_g)+1)5M_c)^n\ n!\ \ \forall n \geq 0. \tag{29}$$

Proof. The result is trivial when $n = 0$. When $n \geq 1$, it is first necessary to show by induction that $s_{n+1} < 5s_n$. The claim is clearly true when $n = 1$ or $n = 2$. Suppose it is known to hold up to some fixed integer $n+1 \geq 2$. Sequence s_n is known to satisfy another recurrence equation [15, 25]:

$$(n+2)s_{n+2} = (6n+4)s_{n+1} - 5ns_n.$$

Therefore,

$$s_{n+2} < [(6n+4)s_{n+1} - ns_{n+1}]/(n+2) < 5s_{n+1},$$

which proves the claim for all $n \geq 1$. Next, substituting the upper bound $\phi_g s_n \leq 5^n, n \geq 0$, into (22) gives

$$\tilde{\psi}_n(K_c) \leq ((mK_c(2+\phi_g)+1)5)^n\ \ \forall n \geq 0. \tag{30}$$

The theorem is finally proved by simply applying Lemma 4.5. ∎

In most cases the upper bound in (29) is quite conservative because the upper bound (30) is conservative. Figure 4.1 shows $\tilde{\psi}_n(K_c)$ (generated symbolically via MAPLE) and upper bound (30) versus n for various values of K_c.

The final step of the analysis is to use Theorem 4.7 to prove the input-output local convergence of the feedback product.

THEOREM 4.8. *If $c, d \in \mathbb{R}^m_{LC}\langle\langle X\rangle\rangle$, then c@d is input-output locally convergent. Specifically, when $K_c \geq 1$, then*

$$((c@d) \circ b, x_0^n) \leq K_c([mK_c(2+\phi_g)+1][\phi(m(K_b+K_d))+1]10M)^n\ n!$$

for any $b \in \mathbb{R}^m_{LC}\langle\langle X_0\rangle\rangle$ and where $M = \max\{M_b, M_c, M_d\}$.

Proof. Select any series $b \in \mathbb{R}^m_{LC}\langle\langle X_0\rangle\rangle$. It follows from (19) that

$$(c@d) \circ b = (c \,\tilde{\circ}\, (d \circ (c@d))) \circ b = c \circ (b+d) \circ ((c@d) \circ b).$$

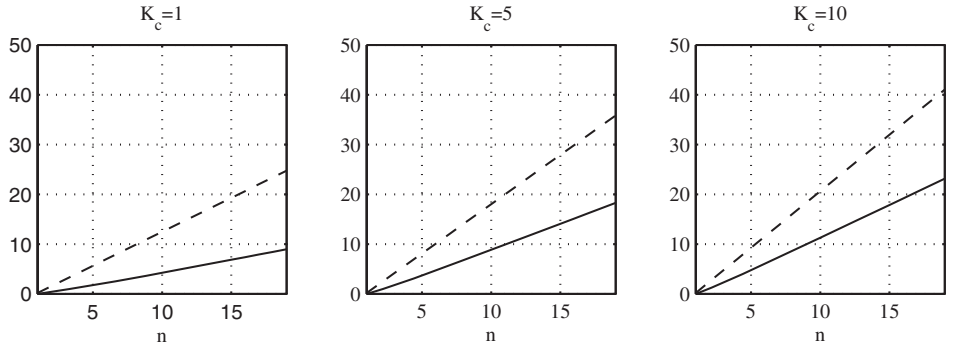

FIG. 4.1. *A plot of* $\log_{10}(\tilde{\psi}_n(K_c))$ (*solid lines*) *and the logarithm* (*base* 10) *of the upper bound in* (30) (*dashed lines*) *versus* n *for various values of* K_c.

Since b, c, and d are all locally convergent, so is the series $c \circ (b + d)$. Now apply Theorem 4.7, replacing c with $c \circ (b + d)$ and e with $(c@d) \circ b$. This implies that $(c@d) \circ b$ is always locally convergent, and therefore $c@d$ must be input-output locally convergent. To produce the given growth condition for the output series, note that

$$K_{c\circ(b+d)} = K_c \qquad M_{c\circ(b+d)} = 2(\phi(m(K_b + K_d)) + 1)M,$$

using Theorem 2.12 and the fact that $n + 1 \leq 2^n$ for all $n \geq 0$. Substituting these growth constants for K_c and M_c, respectively, in Theorem 4.7 produces the desired result. □

Example 4.9. Suppose c and d are linear series in $\mathbb{R}^m_{LC}\langle\langle X\rangle\rangle$. Then $c@d = \lim_{i\to\infty} e_i$, where

$$e_{i+1} = c \,\tilde{\circ}\, (d \circ e_i) = c + (c \circ d) \circ e_i.$$

Setting $e_0 = c$ gives

$$c@d = c + \sum_{k=1}^{\infty} (c \circ d)^{\circ k} \circ c,$$

where $c^{\circ k}$ denotes k copies of c composed $k - 1$ times. It is easily verified since $(c, \emptyset) = 0$ that $((c \circ d)^{\circ k}, \nu) = 0$ for all $k > |\nu|$. Hence,

$$(c@d, \nu) = (c, \nu) + \sum_{k=1}^{|\nu|-1} ((c \circ d)^{\circ k} \circ c, \nu).$$

Example 4.10. For any $c, d \in \mathbb{R}_{LC}\langle\langle X\rangle\rangle$, a self-excited feedback loop can be described by $F_{c@d}[0] = F_{(c@d)\circ 0}[u] = F_{(c@d)_0}[u]$ (cf. Lemma 2.2, property 2). In this case $(c@d)_0 = \lim_{i\to\infty} e_i$, where $e_{i+1} = (c \circ d) \circ e_i$. Using the $m = 0$ version of (16)

TABLE 4.2

x_1	K_cM_c	K_dM_d	K_cM_c
x_0^2	0	0	$K_c((K_dM_c)^2\ 2! + K_cK_dM_cM_d)$
x_0x_1	0	0	$K_cK_dM_c^2\ 2!$
x_1x_0	0	0	$K_cK_dM_c^2\ 2!$
x_1^2	$K_cM_c^2 2!$	$K_dM_d^2 2!$	$K_cM_c^2\ 2!$
x_0^3	0	0	$K_c((K_dM_c)^3\ 3! + K_c(K_dM_c)^2M_d\ 7 + K_c^2K_dM_cM_d^2\ 2!)$
$x_0^2x_1$	0	0	$K_c((K_dM_c)^2M_c\ 3! + K_cK_dM_c^2M_d\ 3)$
$x_0x_1x_0$	0	0	$K_c((K_dM_c)^2M_c\ 3! + K_cK_dM_c^2M_d\ 2!)$
$x_0x_1^2$	0	0	$K_cK_dM_c^3\ 3!$
$x_1x_0^2$	0	0	$K_c((K_dM_c)^2M_c\ 3! + K_cK_dM_c^2M_d\ 2!)$
$x_1x_0x_1$	0	0	$K_cK_dM_c^3\ 3!$
$x_1^2x_0$	0	0	$K_cK_dM_c^3\ 3!$
x_1^3	$K_cM_c^3 3!$	$K_dM_d^3 3!$	$K_cM_c^3\ 3!$

(since the closed-loop system has, in effect, no external input) and Theorem 4.7, $F_{(c@d)_0}[u]$ will converge at least on the interval $[0, T_{\max})$, where

$$T_{\max} = \frac{1}{M_{(c@d)_0}} = \frac{1}{(K_{c\circ d}(2+\phi_g)+1)5M_{c\circ d}}.$$

Of course, if the series $(c@d)_0$ can be computed explicitly, a potentially better estimate $T'_{\max} = 1/M'_{(c@d)_0}$ is possible. For example, when $c\circ d = 1+x_1$, it is easily verified that $(c@d)_0 = \sum_{k\geq 0} x_0^k$ so that $F_{c@d}[0](t) = e^t$ for $t \geq 0$. In this case, both $T_{\max} = 0.04331$ and $T'_{\max} = 1$ are very conservative. On the other hand, when $c \circ d = 1 + 2x_1 + 2x_1^2$, it follows that $(c@d)_0 = \sum_{k\geq 0}(k+1)!\, x_0^k$ and $F_{c@d}[0](t) = 1/(1-t)^2$ for $0 \leq t < 1$. Here $T_{\max} = 0.02428$ is less conservative and $T'_{\max} = 1$ is exact.

Example 4.11. Reconsider the state space systems in Example 3.2. The operator $F_{c@d}[u]$ then has the analytic state space realization

$$f(z) = \begin{pmatrix} K_dM_cz_c^2z_d \\ K_cM_dz_cz_d^2 \end{pmatrix}, \quad g(z) = \begin{pmatrix} M_cz_c^2 \\ 0 \end{pmatrix}, \quad h(z) = K_cz_c$$

near $z(0) = [1\ \ 1]^T$. The first few coefficients of $c@d$ are given in Table 4.2. Since $c@d$ is a nonnegative series in this case, local convergence and input-output local convergence are equivalent as a consequence of Lemma 3.5. Setting $u(t) = \bar{u} = 1$ is equivalent to letting $b = 1$ in Theorem 4.8. Therefore, using again the $m = 0$ version of (16) and the growth condition from Theorem 4.8, a lower bound on the finite escape time for this system is

$$T_{\max} = \frac{1}{M_{(c@d)\circ 1}} = \frac{1}{[K_c(2+\phi_g)+1][\phi(1+K_d)+1]10M}.$$

Four specific cases of $T_{\max}$ are given in Table 4.3 and compared against the numerically determined escape times. The conservativeness in these estimates is a consequence of *accumulated* conservativeness in various intermediate upper bounds, for example inequality (30), as compared to the cascade connection in Example 3.2.

TABLE 4.3
$T_{\max}$ and t_{esc} for specific examples of $(c@d)\circ 1$.

A CONNECTION BETWEEN THE MAXIMUM PRINCIPLE AND DYNAMIC PROGRAMMING FOR CONSTRAINED CONTROL PROBLEMS*

AURELIAN CERNEA† AND HÉLÈNE FRANKOWSKA‡

Abstract. We consider the Mayer optimal control problem with dynamics given by a nonconvex differential inclusion, whose trajectories are constrained to a closed set and obtain necessary optimality conditions in the form of the maximum principle together with a relation between the costate and the value function. This additional relation is applied in turn to show that the maximum principle is nondegenerate. We also provide a sufficient condition for the normality of the maximum principle.

To derive these results we use convex linearizations of differential inclusions and convex linearizations of constraints along optimal trajectories. Then duality theory of convex analysis is applied to derive necessary conditions for optimality. In this way we extend the known relations between the maximum principle and dynamic programming from the unconstrained problems to the constrained case.

Key words. differential inclusions, nondegenerate maximum principle, dynamic programming, generalized derivatives, state constraints, variational inclusions

1. Introduction.

Consider the following Mayer problem:

$$\text{minimize} \quad g(x(1)) \tag{1.1}$$

over the solutions to the differential inclusion

$$x'(t) \in F(t, x(t)) \quad \text{a.e. in } [0,1], \tag{1.2}$$

satisfying state constraints of the form

$$x(t) \in K \quad \forall\, t \in [0,1] \tag{1.3}$$

and end point constraints of the form

$$x(1) \in K_1, \tag{1.4}$$

$$x(0) = x_0, \tag{1.5}$$

‡CNRS, CREA, École Polytechnique, 1, rue Descartes, 75005 Paris, France (franko@shs.polytechnique.fr).

where $K, K_1 \subseteq \mathbf{R}^n$ are closed sets, $g(\cdot) : \mathbf{R}^n \to \mathbf{R}$ is a given function and $F(\cdot,\cdot) : [0,1] \times \mathbf{R}^n \rightsquigarrow \mathbf{R}^n$ is a given set-valued map and $x_0 \in K$. It is well known that the classical Bolza problem in control theory

$$\text{minimize} \quad \left\{ g(x(1)) + \int_0^1 L(t, x(t), x'(t))dt \mid x(\cdot) \text{ solves (1.2)–(1.5)} \right\}$$

is equivalent to the Mayer problem via a simple change of variables. This is the reason why we choose the apparently simpler problem (1.1)–(1.5), instead of a more general Bolza problem.

The value function associated to the problem (1.1)–(1.5) is defined by

(1.6)
$$V(t_0, y_0) = \inf\{g(x(1)) \mid \ x(\cdot) \text{ is a solution to (1.2)–(1.4) on } [t_0, 1],\ x(t_0) = y_0\},$$

with the convention $\inf \emptyset = +\infty$. The value function satisfies the dynamic programming principle. In particular, it is nondecreasing along trajectories to (1.2)–(1.4) and is constant along optimal trajectories. This property can be used to show that the value function is the only solution (in an appropriate sense) of an associated Hamilton–Jacobi–Bellman equation under state constraints (see, for instance, [19, 20]). Such solution is defined using subdifferentials of V. The aim of this paper is to study, using the dynamic programming principle, a sensitivity relation between necessary conditions for optimality and "gradients" of the value function.

Necessary optimality conditions for the problem (1.1)–(1.5) exist in the literature in the form of the maximum principle. When $F(t,x) = f(t,x,U)$ for some smooth enough f, i.e., when the differential inclusion (1.2) is replaced by the control system

$$x'(t) = f(t, x(t), u(t)), \ \ u(t) \in U \quad \text{a.e. in } [0,1],$$

this principle says that for every optimal trajectory/control pair $(\bar{x}, \bar{u})$ there exist $\lambda \in \{0,1\}$, a positive (scalar) Radon measure μ on $[0,1]$ and a μ-integrable function $\nu(\cdot) : [0,1] \to \mathbf{R}^n$, satisfying

$$\nu(t) \in N_K(\bar{x}(t)) \quad \mu - \text{a.e.},$$

(where $N_K(\bar{x}(t))$ denotes the normal cone to K at $\bar{x}(t)$) such that a solution $p(\cdot) : [0,1] \to \mathbf{R}^n$ to the adjoint system

$$-p'(t) = \frac{\partial f}{\partial x}(t, \bar{x}(t), \bar{u}(t))^* \left(p(t) + \int_{[0,t]} \nu(s) d\mu(s) \right),$$

$$-p(1) \in \lambda \nabla g(\bar{x}(1)) + \int_{[0,1]} \nu(s) d\mu(s) + N_{K_1}(\bar{x}(1)) \tag{1.7}$$

satisfies almost everywhere the maximum principle

$$\left\langle p(t) + \int_{[0,t]} \nu(s) d\mu(s), f(t, \bar{x}(t), \bar{u}(t)) \right\rangle = \max_{u \in U} \left\langle p(t) + \int_{[0,t]} \nu(s) d\mu(s), f(t, \bar{x}(t), u) \right\rangle$$

and $(\lambda, p, \mu) \neq 0$. When $\lambda = 0$, the above equalities are more related to constraint qualifications than to optimality and are sometimes called abnormal multiplier rule. When

$\bar{x}(0) \in \partial K$, then there exists a trivial choice of multipliers $0 \neq \zeta \in N_K(\bar{x}(0))$, $\nu = \zeta\delta_0$, $p = -\zeta$, $\lambda = 0$ which forces any feasible trajectory starting at $\bar{x}(0)$ to satisfy the maximum principle (here δ_0 denotes the unit measure concentrated at $\{0\}$.) In [1, 10, 13, 25, 29] the authors investigate the so-called nondegenerate maximum principle, but they still allow $\lambda = 0$. We would like to underline here that calmness of $V(0,\cdot)$ may be used to investigate normality of some maximum principles.

Let $D_x^+V(0,x_0)(\cdot)$ denote the upper directional derivative of $V(0,\cdot)$ at x_0 defined by

$$D_x^+V(0,x_0)(\theta) = \limsup_{s\to 0+,\theta'\to\theta,x_0+s\theta'\in K} \frac{V(0,x_0+s\theta') - V(0,x_0)}{s}.$$

From the results of this paper it follows in particular that if for all $t \in [0,1]$ the Clarke's tangent cones $C_K(\bar{x}(t))$ have nonempty interior, $C_{K_1}(\bar{x}(1)) \cap Int(C_K(\bar{x}(1))) \neq \emptyset$ and for some nonempty open convex subset $\mathcal{F} \subset C_K(\bar{x}(0))$ and $M > 0$

$$D_x^+V(0,\bar{x}(0))(\theta) \geq -M||\theta|| \ \ \forall\, \theta \in \mathcal{F},$$

then the maximum principle is nondegenerate in the sense that for $\psi(t) := \int_{[0,t]} \nu(s)d\mu(s)$ we have

$$\lambda + \sup_{t\in(0,1)} ||p(t) + \psi(t)|| \neq 0.$$

Moreover, if $\bar{x}(1) \in Int(K_1)$, then

$$\lambda + var(\psi,(0,1]) \neq 0,$$

where $var(\psi,(0,1])$ denotes the total variation of ψ on $(0,1]$. Both relations eliminate the above mentioned trivial multipliers for $\bar{x}(0) \in \partial K$. Actually we shall prove this result with a more general choice of tangents (see Corollary 3.7).

A sufficient condition, very similar to the Mangasarian–Fromowitz constraint qualification of mathematical programming, ensuring that $\lambda = 1$ is the existence of a solution w to the linearized along $(\bar{x},\bar{u})$ control system

$$w' = \frac{\partial f}{\partial x}(t,\bar{x}(t),\bar{u}(t))w + v(t), \quad v(t) \in T_{co(f(t,\bar{x}(t),U))}(\bar{x}'(t)), \tag{1.8}$$

satisfying

$$w(t) \in Int(C_K(\bar{x}(t))) \ \ \forall\, t \in [0,1],\ w(1) \in Int(C_{K_1}(\bar{x}(1))), \tag{1.9}$$

where $T_{co(f(t,\bar{x}(t),U))}(\bar{x}'(t))$ denotes the tangent cone of convex analysis to $co(f(t,\bar{x}(t),U))$ at $\bar{x}'(t)$. We shall provide such a condition even in the case of differential inclusions. This condition uses the trajectory/control pair $(\bar{x},\bar{u})$ and is not directly verifiable. Still it can be used to test for optimality a given trajectory/control pair. Furthermore, the cones $\{C_K(\bar{x}(t))\}_{t\in[0,1]}$ may be replaced by larger subsets satisfying Hypothesis 3.3 (see Example 2 in section 3).

In [28], in the context of nonsmooth control systems and smooth state constraints the authors proved that $\lambda = 1$ if an inward pointing condition (involving continuous selections from U) holds true on a neighborhood of the boundary of K and $K_1 = \mathbf{R}^n$. Here we get a similar result by asking a weaker (pointwise) inward pointing condition

just along the optimal trajectory (see Theorem 3.10). Namely we show that $\lambda = 1$ provided $\bar{x}(1) \in Int(K_1)$, for some $\eta > 0$ the signed distance

$$d(x) = \begin{cases} -dist(x, \partial K) & \forall\, x \in K \\ dist(x, \partial K) & \text{otherwise} \end{cases}$$

is of class $C^{1,1}_{loc}$ on $\partial K + \eta B$ and there exists $\rho > 0$ such that for almost all $t \in [0,1]$ with $\bar{x}(t) \in \partial K + \eta B$ we have $\min_{v \in F(t,\bar{x}(t))} \langle \nabla d(\bar{x}(t)), v \rangle \leq -\rho$.

We discuss next the sensitivity relation of the adjoint state $p(0)$ to the value function $V(0,\cdot)$. When there is no end point and state constraints, then $\lambda = 1$ and $\nu = 0$. If moreover $V(t,\cdot)$ is differentiable at $\bar{x}(t)$, then it is well known that

$$p(t) = -\frac{\partial V}{\partial x}(t, \bar{x}(t))$$

and this last relation can be used to get sufficient conditions for optimality (see [5]). Even when $K_1 = K = \mathbf{R}^n$, in general, $V(t,\cdot)$ is not differentiable. Still a relationship was obtained with the gradient of $V(t,\cdot)$ replaced by the superdifferential. Indeed, it was shown in [5, 16, 26, 36] that in addition the adjoint variable p is related to the value function in the following way:

$$-p(t) \in \partial_x^+ V(t, \bar{x}(t)) \;\; \forall\, t \in [0,1], \tag{1.10}$$

where $\partial_x^+ V(t, \bar{x}(t))$ denotes the superdifferential of $V(t,\cdot)$ at $\bar{x}(t)$ (see section 2 for the precise definition). A similar statement was previously obtained in [9] for control systems with $\partial_x^+ V(t, \bar{x}(t))$ replaced by Clarke's generalized gradient $\partial_x^C V(t, \bar{x}(t))$. We underline that, in general, $\partial_x^+ V(t, \bar{x}(t))$ is smaller than $\partial_x^C V(t, \bar{x}(t))$ and $\partial_x^+ V(t,x) = \frac{\partial V}{\partial x}(t,x)$ whenever $V(t,\cdot)$ is differentiable at x.

The aim of this paper is to derive a relation similar to (1.10) for the value function of the constrained problem (1.1)–(1.5) for $t = 0$. This extension is used in turn to investigate the nondegeneracy of the constrained maximum principle. Furthermore, we are dealing with a more general setting of nonconvex differential inclusions.

Necessary optimality conditions for systems given by differential inclusions in terms of adjoint inclusions associated to derivatives of the set-valued map F were obtained in [14, 15, 17, 27] for problems with endpoint constraints and in [6, 7] for problems under state constraints. We underline that such necessary optimality conditions, in general, are not equivalent to necessary conditions expressed in terms of generalized gradients of the Hamiltonian [1, 23, 33], the generalized Jacobians [34] or in terms of the limiting normal cones (sometimes called Euler–Lagrange necessary conditions) [35] (see [22] for several comparison results and examples). In [23] some necessary conditions involving a costate satisfying simultaneously the Euler–Lagrange and Hamiltonian conditions are proved for constrained convex valued differential inclusions. The maximum principle of the present paper is related to the Euler–Lagrange conditions, but we do not take limiting normals. Since the graph of $F(t,\cdot)$ is, in general, nonsmooth and we allow nonconvex values of F, our results are not contained in [23, 29]. In Example 1 provided in section 3 we show that a trajectory to an unconstrained system satisfies necessary conditions of [35], but in the same time does not fulfill our necessary conditions and so is not optimal. So in some situations our necessary conditions lead to a stronger discrimination between nonoptimal and optimal trajectories. Naturally there is a price to pay to have stronger necessary conditions. It consists in the assumption of existence of a "linearization" of F along

$(\bar{x}, \bar{x}')$ by closed convex processes, which are Lipschitz with respect to the state (see Hypothesis 3.2 in section 3). In the penalization approach to nonsmooth constrained problems based on variational principles (see, for instance, [1, 34, 35]) such assumption is not needed. When f is differentiable with respect to the state variable, the Jacobian of f (with respect to x) can be used to get a linearization. However, it is not the only instance when "linearizations" do exist. Example 1 concerns a nonsmooth control systems "linearized" by linear and convex processes; see also remarks following Hypothesis 3.2.

It is impossible in a short paper to provide the full overview, credits and bibliographies to the constrained maximum principle, because this topic was investigated by many authors since the early sixties. We refer to [23, 29, 33, 35] for extended discussions on the constrained maximum principle and further references and to [1, 10, 11, 25] for the Russian bibliography on the subject.

We derive a similar maximum principle for our problem (1.1)–(1.5) and also obtain a relation of $p(0)$ to $V(0, \cdot)$ (see Theorem 3.4). This relation implies in particular that $p(0) = 0$ whenever $\lambda = 0$. When $V(0, \cdot)$ exhibits some additional regularity (for instance, is Lipschitz on a neighborhood of $\bar{x}(0)$ in K), then

$$-p(0) \in \lambda \partial_x V(0, \bar{x}(0)), \tag{1.11}$$

where λ is the same as in (1.7) and $\partial_x V(0, \bar{x}(0))$ denotes a generalized supergradient of $V(0, \cdot)$ at $\bar{x}(0)$ defined by (2.5) in section 2. This supergradient is kind of regularized (in the terminology of [31]) superdifferential. When $V(0, \cdot)$ is locally Lipschitz around $\bar{x}(0) \in Int(K)$, $\partial_x V(0, \bar{x}(0))$ coincides with Clarke's generalized gradient of $V(0, \cdot)$ at $\bar{x}(0)$. In particular, for control systems, if there exists a solution to (1.8), (1.9), then $-p(0) \in \partial_x V(0, \bar{x}(0))$.

Even if (1.11) looks similar to (1.10), it is valid only at the initial point. In general, the relation (1.11) does not hold when $t \neq 0$ and needs a correction term involving measures (see Example 2 of section 3). In Theorem 3.11 (under some additional assumptions) we show how to correct $p(t)$ by an element $r(t)$ in order that

$$-r(t) - p(t) \in \partial_x V(t, \bar{x}(t)). \tag{1.12}$$

We also deduce few corollaries from our main theorem, Theorem 3.4. For instance, a nondegenerate maximum principle for (1.1)–(1.4) in the presence of initial point constraints $x(0) \in K_0$ for some closed set K_0 (Corollary 3.8), the sensitivity relation for the unconstrained case (Corollary 3.5) and a nondegenerate maximum principle which encompass calm problems (Corollary 3.7).

In the literature proofs of the maximum principle for systems under state constraints are based either on a penalization [1, 34, 35] or on an abstract multiplier rule [11, 21]. We proceed by using linearization of differential inclusion (1.2) along the optimal trajectory, as it was done in [15, 17], but then we also "linearize" constraints (along the optimal trajectory as well) and use the variational inclusions from [15] to get a Fermat type inequality. We derive next the maximum principle for "the linear problem" under conical constraints, that is a very simple application of separation theorems and convex duality results. Recently, variational inclusions under state constraints were obtained in [32] under additional assumptions on the boundary of constraints implying that the value function is Lipschitz. In [8] we used them to derive some preliminary results on this topic. In the present paper such Lipschitz regularity requirement is removed, an additional endpoint constraint is added and a new result on normality of the maximum principle is derived.

The paper is organized as follows. In section 2 we recall some notations and preliminary results to be used in what follows. In section 3 we present the main theorems of this paper. Section 4 is devoted to the study of polar of the set of continuous selections from a lower semicontinuous set-valued map and in section 5 we provide proofs of results of section 3.

2. Preliminaries. Denote by B the closed unit ball in $\mathbf{R}^n$. If $Q \subset \mathbf{R}^n$ we denote by $\overline{Q}$ its closure and by $co(Q)$ (resp. $\overline{co}(Q)$) the convex (resp. closed convex) hull of Q. We recall first the following definitions.

DEFINITION 2.1. *Let $K \subset \mathbf{R}^n$ be closed and $x \in K$.*

(i) the contingent cone *to K at x is defined by*

$$T_K(x) = \left\{ v \in \mathbf{R}^n | \quad \liminf_{s \to 0+} \frac{dist(x+sv, K)}{s} = 0 \right\}.$$

(ii) Clarke's tangent cone *to K at x is defined by*

$$C_K(x) = \left\{ v \in \mathbf{R}^n \mid \quad \lim_{s \to 0+, x' \to_K x} \frac{dist(x'+sv, K)}{s} = 0 \right\},$$

where $\to_K$ denotes the convergence in K.

Let Y be a real Banach space. Recall that a set $C \subset Y$ is called a cone if it is nonempty and for all $\lambda \geq 0$ and $v \in C$ we have $\lambda v \in C$. The negative polar cone of a set $Q \subset Y$ is defined by

$$Q^- = \{ y^* \in Y^* \mid \quad \langle y^*, y \rangle \leq 0 \quad \forall\, y \in Q \},$$

where Y^* denotes the dual of Y. The positive polar cone of Q is $Q^+ = -Q^-$. The negative polar of Clarke's tangent cone $N_K(x) := C_K(x)^-$ is also called the normal cone to the set K at $x \in K$.

Let $F : \mathbf{R}^n \rightsquigarrow \mathbf{R}^n$ be a set-valued map. It is called *Lipschitz* around $x_0 \in \mathbf{R}^n$ if there exist $\varepsilon > 0,\ L \geq 0$ such that for any $x,\ y \in x_0 + \varepsilon B$, $F(x) \subset F(y) + L||x-y||B$, where $||\cdot||$ denotes the Euclidean norm on $\mathbf{R}^n$. Define

$$graph(F) := \{ (x, y) \in \mathbf{R}^n \times \mathbf{R}^n \mid y \in F(x) \}.$$

DEFINITION 2.2. *Consider a set-valued map $F : \mathbf{R}^n \rightsquigarrow \mathbf{R}^n$, Lipschitz around x and let $y \in F(x)$. The adjacent derivative of F at (x, y) is the set-valued map $dF(x, y)$ from $\mathbf{R}^n$ into subsets of $\mathbf{R}^n$ defined by*

$$dF(x,y)w = \left\{ v \in \mathbf{R}^n \mid \quad \lim_{s \to 0+} dist\left(v, \frac{F(x+sw) - y}{s} \right) = 0 \right\}.$$

It is well known that $graph(dF(x, y))$ is equal to the adjacent tangent cone to $graph(F)$ at (x, y) (see [3]*).*

In this paper we use closed convex cones $\mathcal{A} \subset graph(dF(x, y))$. Each such convex cone defines a set-valued map $A : \mathbf{R}^n \rightsquigarrow \mathbf{R}^n$ by $v \in A(u)$ if and only if $(u, v) \in \mathcal{A}$.

DEFINITION 2.3. *Let $A : \mathbf{R}^n \rightsquigarrow \mathbf{R}^n$ be a set-valued map. A is called* closed *(resp.,* convex*) process if $graph(A)$ is a closed (resp., convex) cone. Its adjoint process $A^* : \mathbf{R}^n \rightsquigarrow \mathbf{R}^n$ is defined by*

$$A^*(p) = \{ q \in \mathbf{R}^n \mid \langle q, u \rangle \leq \langle p, v \rangle \ \ \forall\ (u, v) \in graph(A) \},$$

where $\langle \cdot, \cdot \rangle$ denotes the scalar product in $\mathbf{R}^n$.

Notice that if A is Lipschitz on $\mathbf{R}^n$ with a Lipschitz constant m, then $\sup_{q\in A^*(p)} \|q\| \leq m\|p\|$. For other properties of closed convex processes we refer to [3].

Consider an extended real function $\phi(\cdot) : \mathbf{R}^n \to \mathbf{R} \cup \{\pm\infty\}$. We say that it is *positively homogeneous* if $\phi(0) > -\infty$ and for every $\lambda > 0$, $\theta \in \mathbf{R}^n$ we have $\phi(\lambda\theta) = \lambda\phi(\theta)$. We would like to underline that this definition differs slightly from the one given in [31, pp. 5 and 87], where the authors require $\phi(0) < \infty$. We need to change this notion, since in this paper we deal with functions whose hypographs are cones, while definitions in [31] are adapted to functions whose epigraphs are cones.

Consider a subset $X \subset \mathbf{R}^n$ and an extended real function $h(\cdot) : X \to \mathbf{R} \cup \{\pm\infty\}$. The domain of $h(\cdot)$ is $dom(h) = \{x \in X \mid \ h(x) \in \mathbf{R}\}$. When $h(\cdot)$ is not differentiable, it is possible to define its gradient by taking weaker limits of differential quotients.

DEFINITION 2.4. *Let $x_0 \in dom(h)$. The* superdifferential *of h at x_0 is the closed convex set*

$$\partial^+ h(x_0) := \left\{ p \in \mathbf{R}^n \mid \limsup_{x \to_X x_0} \frac{h(x) - h(x_0) - \langle p, x - x_0\rangle}{||x - x_0||} \leq 0 \right\}.$$

The subdifferential *of h at x_0 is the closed convex set defined by $\partial^- h(x_0) = -\partial^+(-h)(x_0)$.*

When $x_0 \in Int(dom(h))$ and $h(\cdot)$ is Fréchet differentiable at x_0, then $\partial^+ h(x_0) = \{\nabla h(x_0)\}$.

DEFINITION 2.5. *The upper derivative of $h(\cdot)$ at $x_0 \in dom(h)$ in the direction θ is given by*

$$D^+ h(x_0)(\theta) = \limsup_{s\to 0+,\ \theta'\to\theta,\ x_0+s\theta'\in X} \frac{h(x_0 + s\theta') - h(x_0)}{s} \quad \forall\ \theta \in T_X(x_0)$$

and $D^+ h(x_0)(\theta) = -\infty$ for all $\theta \notin T_X(x_0)$.

Notice that $D^+ h(x_0)(\cdot)$ is upper semicontinuous and positively homogeneous. It is known that $\partial^+ h(x_0) = \{p \in \mathbf{R}^n \mid \langle p, \theta\rangle \geq D^+ h(x_0)(\theta)$ for all $\theta \in T_X(x_0)\}$; see [16, Lemma 2.7]. If X is convex and h is concave, then $\partial^+ h(x_0)$ is equal to the supergradient of convex analysis, i.e., $p \in \partial^+ h(x_0)$ if and only if $h(x) \leq h(x_0) + \langle p, x - x_0\rangle$ for all $x \in X$.

In the proof of the results in the next sections we use the following consequence of the separation theorem.

LEMMA 2.6. *Let $h(\cdot) : \mathbf{R}^n \to \mathbf{R} \cup \{+\infty\}$ be a positively homogeneous convex function and $C \subseteq \mathbf{R}^n$ be nonempty, convex, and such that for all $\lambda > 0$ and $v \in C$ we have $\lambda v \in C$. Assume that $dom(h) - C = \mathbf{R}^n$ and $h(c) \geq 0$ for all $c \in C$. Then there exists $q_0 \in C^+$ such that $\langle q_0, v\rangle \leq h(v)$ for all $v \in \mathbf{R}^n$.*

Proof. If $dom(h) = \emptyset$, then $h \equiv +\infty$ and the conclusion holds true with $q_0 = 0$. Assume next that $dom(h) \neq \emptyset$. Define $\mathbf{R}^*_- = \{r \in \mathbf{R} \mid r < 0\}$ and $Epi(h) = \{(u, v) \in \mathbf{R}^n \times \mathbf{R} \mid v \geq h(u)\}$. Since $Epi(h) \subset \mathbf{R}^n \times \mathbf{R}$ and $C \times \mathbf{R}^*_- \subset \mathbf{R}^n \times \mathbf{R}$ are convex sets and $(Epi(h)) \cap (C \times \mathbf{R}^*_-) = \emptyset$, there exists $(p, q) \in \mathbf{R}^n \times \mathbf{R}$, $(p, q) \neq 0$ such that

$$\langle p, u\rangle + qv \leq \langle p, c\rangle + qr \tag{2.1}$$

for any $(u, v) \in Epi(h)$ and any $(c, r) \in C \times \mathbf{R}^*_-$. Let $u_0 \in dom(h)$, $c_0 \in C$. If in (2.1) we take $u = \lambda_k u_0, v = \lambda_k h(u_0), r = r_k$ with $\lambda_k \to 0+$, $r_k \to 0-$ we deduce that $0 \leq \langle p, c\rangle$ for all $c \in C$. Hence $p \in C^+$. On the other hand, if in (2.1) we take $u = \lambda_k u_0$, $v = \lambda_k h(u_0) + \rho$, $c = \lambda_k c_0$, $r = r_k$ with $\rho \geq 0$, $\lambda_k \to 0+, r_k \to 0-$ we infer that $q\rho \leq 0$ for all $\rho \geq 0$. Thus $q \leq 0$. Let us assume for a moment that $q = 0$. Then from (2.1) we deduce that

$$p(u - c) \leq 0 \quad \forall\ u \in dom(h),\ c \in C. \tag{2.2}$$

Therefore, from (2.2) and our assumption it follows that $p = 0$, which leads to a contradiction with $(p, q) \neq 0$. Thus $q < 0$. From (2.1) we get

$$\left\langle \frac{p}{|q|}, u \right\rangle - h(u) \leq \left\langle \frac{p}{|q|}, \lambda_k c_0 \right\rangle - r_k \tag{2.3}$$

for any $u \in dom(h)$ and $\lambda_k \to 0+$, $r_k \to 0-$. Passing to the limit with $k \to \infty$ we find that $\langle \frac{p}{|q|}, u \rangle \leq h(u)$. It remains to set $q_0 = \frac{p}{|q|}$ and the lemma is proved. □

Results of the next sections use a lower version of the regular subderivative (see [31, p. 311]).

DEFINITION 2.7. *Let $X \subset \mathbf{R}^n$, $\phi : X \to \mathbf{R} \cup \{\pm\infty\}$ and $x \in dom(\phi)$. The regular superderivative is defined by $\hat{d}\phi(x)(u) = -\infty$ for all $u \notin C_X(x)$ and*

$$\hat{d}\phi(x)(u) = \lim_{\delta \to 0+} \left(\liminf_{x' \to_\phi x,\ s \to 0+} \sup_{u' \in u + \delta B, x' + su' \in X} \left[\frac{\phi(x' + su') - \phi(x')}{s} \right] \right) \ \forall\, u \in C_X(x), \tag{2.4}$$

where $\to_\phi$ denotes the $\phi-$attentive convergence introduced in [31, p. 301]. *This means that the lower limit is taken over all sequences $x_i \to x$, $s_i \to 0+$ such that $\phi(x_i) \to \phi(x)$.*

It follows from [31, pp. 311–313] that $\hat{d}\phi(x)(\cdot)$ is upper semicontinuous and positively homogeneous and if ϕ is locally upper semicontinuous at x, then $\hat{d}\phi(x)(\cdot)$ is concave. Thus, if in addition $dom(d\phi(x)) \neq \emptyset$, then $\hat{d}\phi(x)(\cdot)$ takes values in $[-\infty, +\infty)$ and $\hat{d}\phi(x)(0) = 0$.

When $x \in Int(X)$ and ϕ is locally Lipschitz at x, then Clarke's directional derivative is defined by

$$\phi^0(x)(u) = \limsup_{(x', s) \to (x, 0+)} \frac{\phi(x' + su) - \phi(x')}{s}, \quad u \in \mathbf{R}^n$$

and Clarke's generalized gradient is defined by

$$\partial^C \phi(x) := \{p \in \mathbf{R}^n \mid \quad \langle p, v \rangle \leq \phi^0(x)(v) \quad \forall\, v \in \mathbf{R}^n\}.$$

A generalized supergradient of ϕ at x that we shall use in this paper is defined using $\hat{d}\phi(x)(\cdot)$ by

$$\partial\phi(x) := \{p \in \mathbf{R}^n \mid \quad \langle p, v \rangle \geq \hat{d}\phi(x)(v) \quad \forall\, v \in C_X(x)\}. \tag{2.5}$$

By [31, Theorem 8.24, p. 317] if $\hat{d}\phi(x)(0) = 0$, then $\partial\phi(x) \neq \emptyset$. It is not difficult to show that if ϕ is locally Lipschitz on a neighborhood of $x \in Int(X)$, then $\partial\phi(x)$ coincides with Clarke's generalized gradient of ϕ at x.

Denote by I the interval $[0, 1]$, by $C(I)$ the space of all continuous functions $x(\cdot) : I \to \mathbf{R}^n$ and by $W^{1,p}(I)$ the space of all absolutely continuous functions $x(\cdot) : I \to \mathbf{R}^n$ such that $x'(\cdot) \in L^p(I)$, $p \geq 1$.

The space $NBV(I)$ (normalized bounded variations) is the space of functions f of bounded variation on I, which are continuous from the right on $(0, 1)$ and such that $f(0) = 0$. The norm of $f \in NBV(I)$ is the total variation of f on I denoted by $\|f\|_{TV}$.

Finally, by a solution of the differential inclusion

$$x'(t) \in F(t, x(t)) \tag{2.6}$$

we mean a function $x(\cdot) \in W^{1,1}(I)$ which satisfies (2.6) almost everywhere in I.

Remark. Let $f(\cdot,\cdot,\cdot) : I \times \mathbf{R}^n \times U \to \mathbf{R}^n$ be measurable in the first variable and continuous in the second and third variables. Set $F(t,x) := f(t,x,U)$. It is well known that if U is a complete separable metric space, then the set of solutions to the control system

$$x' = f(t,x,u(t)), \quad u(t) \in U, \quad u(\cdot) \text{ is measurable}$$

coincides with the set of solutions to the differential inclusion (2.6).

3. Main results. In this section we state several results announced in the introduction. Their proofs are provided in section 5.

Consider the Mayer problem (1.1)–(1.5). We assume the following hypotheses.

Hypothesis 3.1. (i) $F(\cdot,\cdot) : I \times \mathbf{R}^n \rightsquigarrow \mathbf{R}^n$ is a set-valued map with nonempty closed values.

(ii) $\forall\, x \in \mathbf{R}^n,\ F(\cdot,x)$ is measurable.

(iii) There exists $c > 0$ such that $\forall\, (t,x) \in I \times \mathbf{R}^n,\ F(t,x) \subset c(1 + ||x||)B$.

(iv) There exists $l(\cdot) \in L^1(I,\mathbf{R})$ such that $F(t,\cdot)$ is $l(t)$-Lipschitz.

(v) $g : \mathbf{R}^n \to \mathbf{R}$ is locally Lipschitz.

Consider a solution $\bar{x}(\cdot)$ to (1.2). We wish to "linearize" F and K along $\bar{x}(\cdot)$. Denote by $\overline{co}F$ the set-valued map, whose value at (t,x) is the closed convex hull of $F(t,x)$, $\overline{co}F(t,x)$. Below we denote by $d_x\, \overline{co}F(t,\bar{x}(t),\bar{x}'(t))v$ the adjacent derivative of $\overline{co}F(t,\cdot)$ at $(\bar{x}(t),\bar{x}'(t))$.

Hypothesis 3.2. There exists a family of closed convex processes $A(t,\cdot) : \mathbf{R}^n \rightsquigarrow \mathbf{R}^n$, $t \in I$, that satisfies

(i) $A(\cdot,v)$ is measurable $\forall\, v \in \mathbf{R}^n$.

(ii) $A(t,v) \subseteq d_x\, \overline{co}F(t,\bar{x}(t),\bar{x}'(t))v \ \ \forall\, v \in \mathbf{R}^n$, for a.e. $t \in I$.

(iii) For some $m \geq 0$, $A(t,\cdot)$ is m-Lipschitz on $\mathbf{R}^n$ for a.e. $t \in I$.

Notice that from (iii) it follows that for almost all $t \in I,\ A(t,\cdot)^*(0) = \{0\}$.

Remark.

(i) Assume that there exists a Carathéodory selection $f(t,x) \in F(t,x)$ such that for a.e. $t \in I$, $\bar{x}'(t) = f(t,\bar{x}(t))$ and $f(t,\cdot)$ is differentiable at $\bar{x}(t)$. If $||f'_x(\cdot,\bar{x}(\cdot))||_\infty < \infty$, then we may take $A(t,v) = f'_x(t,\bar{x}(t))v$ for all $v \in \mathbf{R}^n$.

(ii) If in Hypothesis 3.1 (iv) we have $l \in L^\infty(I)$ and $graph(\overline{co}F(t,\cdot))$ is sleek along $(\bar{x},\bar{x}')$ in the sense that $T_{graph(\overline{co}F(t,\cdot))}(\bar{x}(t),\bar{x}'(t)) = C_{graph(\overline{co}F(t,\cdot))}(\bar{x}(t),\bar{x}'(t))$ for almost all $t \in I$, then, by results of [3, Chapter 5], we may take

$$A(t,v) := d_x\, \overline{co}F(t,\bar{x}(t),\bar{x}'(t))v \quad \forall\, v \in \mathbf{R}^n.$$

Moreover, in this case $graph(A(t,\cdot))$ is equal to $C_{graph(\overline{co}F(t,\cdot))}(\bar{x}(t),\bar{x}'(t))$.

Example 1. Consider the nonsmooth control system

$$\begin{cases} x' = -|x| - 4y + u + v, & x(0) = 0 \\ y' = u, & y(0) = 0 \\ u,\ v \in [0,1] \end{cases}$$

and let $(\bar{x},\bar{y}) \equiv 0$.

As convex processes satisfying Hypothesis 3.2 one may take, for instance, linear process $A_\lambda(t,(w_1,w_2)) = (\lambda w_1 - 4w_2, 0)$ for any $\lambda \in [-1,1]$, or the convex process $A(t,(w_1,w_2)) = (|w_1| - 4w_2 + \mathbf{R}_+, 0)$.

Concerning the constraints K and K_1 we assume the following hypothesis.

Hypothesis 3.3. K and K_1 are closed subsets of $\mathbf{R}^n$, $Int(C_{K_1}(\bar{x}(1))) \neq \emptyset$ and there exists a lower semicontinuous set-valued map $G : I \rightsquigarrow \mathbf{R}^n$ such that for all $t \in I$, $G(t)$ is a closed convex cone with nonempty interior and for every $v \in Int(G(t))$ we can find $\varepsilon > 0$ such that for all $s \in [t-\varepsilon, t+\varepsilon] \cap I$, $\bar{x}(s) + [0,\varepsilon](v + \varepsilon B) \subset K$.

Remark. When for all $t \in I$, $Int(C_K(\bar{x}(t))) \neq \emptyset$, then we may set $G(t) = C_K(\bar{x}(t))$. Indeed by [2, Proposition 7.13], $v \in Int(C_K(\bar{x}(t)))$ if and only if there exists $\varepsilon > 0$ such that for all $x \in K \cap (\bar{x}(t) + \varepsilon B)$, $x + [0,\varepsilon](v + \varepsilon B) \subset K$. However, in general, there may exist sets $G(t)$ larger than Clarke's tangent cone and sets different from it; see Example 2.

Recall that V denotes the value function of problem (1.1)–(1.5) defined by (1.6). Let $D_x^+ V(0, \bar{x}(0))$, $\hat{d}_x V(0, \bar{x}(0))$ and $\partial_x V(0, \bar{x}(0))$ denote, respectively, the directional derivatives from Definitions 2.5 and 2.7, where we have set $X = K$ and the generalized supergradient of $V(0, \cdot)$ at $\bar{x}(0)$, defined by (2.5).

THEOREM 3.4. *Let $\bar{x}(\cdot)$ be an optimal solution to problem (1.1)–(1.5) and assume that Hypotheses 3.1, 3.2, and 3.3 hold true. Further assume that an upper semicontinuous concave positively homogeneous function $\varphi : \mathbf{R}^n \to \mathbf{R} \cup \{-\infty\}$ satisfies $Int(G(0)) \subset dom(\varphi)$ and $\varphi \leq D_x^+ V(0, \bar{x}(0))$.*

Then there exist $\lambda \in \{0, 1\}$, $\psi \in NBV(I)$ and an absolutely continuous function $p(\cdot) : I \to \mathbf{R}^n$ such that $\lambda + ||\psi||_{TV} \neq 0$ and p satisfies the adjoint inclusion

$$p'(t) \in A^*(t, -p(t) - \psi(t)) \quad \text{a.e. in } I, \tag{3.1}$$

the transversality condition

$$p(1) \in -\lambda \partial^C g(\bar{x}(1)) - \psi(1) - N_{K_1}(\bar{x}(1)), \tag{3.2}$$

the maximum principle

$$\langle p(t) + \psi(t), \bar{x}'(t) \rangle = \max_{v \in F(t, \bar{x}(t))} \langle p(t) + \psi(t), v \rangle \quad \text{a.e. in } I \tag{3.3}$$

and the sensitivity relation

$$-p(0) \in \lambda \partial^+ \varphi(0). \tag{3.4}$$

Furthermore,

$$\psi(0+) \in G(0)^-, \quad \psi(t) - \psi(t-) \in G(t)^-, \quad \psi(t) = \int_{[0,t]} \nu(s) d\mu(s) \quad \forall\, t \in (0, 1] \tag{3.5}$$

for a positive (scalar) Radon measure μ on I and a μ-measurable function $\nu(\cdot) : I \to \mathbf{R}^n$ satisfying

$$\nu(s) \in G(s)^- \cap B \quad \mu - a.e.$$

If $C_{K_1}(\bar{x}(1)) \cap Int(G(1)) \neq \emptyset$, then the following nondegeneracy condition holds true

$$\lambda + \sup_{t \in (0,1)} ||p(t) + \psi(t)|| \neq 0 \tag{3.6}$$

and if $\bar{x}(1) \in Int(K_1)$, then

$$\lambda + var(\psi, (0, 1]) \neq 0,$$

where $var(\psi, (0, 1])$ denotes the total variation of ψ on $(0, 1]$.

Moreover, $\lambda = 1$ if there exists a solution to the constrained differential inclusion

$$w' \in \overline{A(t,w) + T_{co(F(t,\bar{x}(t)))}(\bar{x}'(t))}, \quad w(1) \in Int(C_{K_1}(\bar{x}(1))), \quad w(t) \in Int(G(t)) \quad \forall\, t \in I.$$

In particular, if $V(0,\cdot)$ is locally upper semicontinuous at $\bar{x}(0)$ and $Int(G(0)) \subset dom(\hat{d}_x V(0,x_0))$, then (3.4) *may be replaced by*

$$-p(0) \in \lambda \partial_x V(0, \bar{x}(0)). \tag{3.4'}$$

Remark. Several remarks are in order.

(i) If $G(\cdot)$ satisfies Hypothesis 3.3, then for any closed convex cone with nonempty interior $Q \subset G(0)$, the set-valued map $\hat{G}$ defined by $\hat{G}(t) = G(t)$ for $t > 0$ and $\hat{G}(0) = Q$ also satisfies Hypothesis 3.3. This property will be used to prove Corollary 3.7.

(ii) If the subdifferential $\partial_x^- V(0,x_0)$ of $V(0,\cdot)$ at x_0 is nonempty, then any $\zeta \in \partial_x^- V(0,x_0)$ defines a function φ of Theorem 3.4 by $\varphi(\theta) = \langle \zeta, \theta \rangle$ for all $\theta \in G(0)$ and $\varphi(\theta) = -\infty$ otherwise. Then, for $\lambda = 1$, relation (3.4) implies $-p(0) \in \zeta + G(0)^+ \subset \partial_x^- V(0,x_0) + G(0)^+$, which can be seen as another sensitivity relation at points where $\partial_x^- V(0,x_0) \neq \emptyset$.

The subdifferentials of the value function were used in [19, 20] to define solutions to a Hamilton–Jacobi equation associated to the Mayer problem under state constraints.

(iii) The last statement (3.4′) holds true, in particular, when $V(0,\cdot)$ is Lipschitz on a neighborhood of $\bar{x}(0)$ in K and $Int(G(0)) \subset C_K(\bar{x}(0))$. In the case when $K_1 = \mathbf{R}^n$, the local Lipschitz continuity of $V(0,\cdot)$ can be deduced from the Lipschitz dependence of solutions to (1.2), (1.3) on the initial conditions. In [18] this issue was investigated for both smooth and nonsmooth sets of constraints K using the neighboring feasible trajectories theorem; see also [20] for the case of inequality constraints.

(iv) If in the above theorem we assume that $g(\cdot)$ is differentiable at $\bar{x}(1)$, then, by a very slight modification of the proof provided in section 5, inclusion (3.2) can be replaced by

$$p(1) \in -\lambda \nabla g(\bar{x}(1)) - \psi(1) - N_{K_1}(\bar{x}(1)).$$

Notice that, in general, $\{\nabla g(\bar{x}(1))\}$ may be not equal to $\partial^C g(\bar{x}(1))$; so this would lead to a stronger result.

(v) If $\bar{x}(\cdot)$ is optimal, then for all $t_0 \in I$, the restriction $\bar{x}|_{[t_0,1]}$ is optimal for the problem

$$\text{minimize} \quad g(x(1))$$

over the solutions to

$$x' \in F(t,x), \quad x(t_0) = \bar{x}(t_0), \quad x(t) \in K \quad \forall\, t \in [t_0,1], \quad x(1) \in K_1.$$

Thus the above theorem may be used to get the same conclusion on the time interval $[t_0,1]$ with a costate function $q(\cdot)$ and the inclusion

$$-q(t_0) \in \lambda \partial_x V(t_0, \bar{x}(t_0)).$$

Example 1 *(continuation).* Consider the unconstrained minimization problem

$$\text{minimize } x(1)$$

over solutions to the nonsmooth control system defined at the beginning of this section. We check that $(\bar{x}, \bar{y}) \equiv 0$ does not satisfy conclusions of Theorem 3.4 and so is not optimal. Indeed consider the convex process

$$A(t, (w_1, w_2)) = (w_1 - 4w_2, 0).$$

It satisfies Hypothesis 3.2. Then the adjoint system of Theorem 3.4 can be written as

$$\begin{cases} -p_1' = p_1, & p_1(1) = -1 \\ -p_2' = -4p_1, & p_2(1) = 0. \end{cases}$$

Then $p_1(t) = -e^{1-t},\ p_2(t) = 4e^{1-t} - 4$. Notice that

$$\max_{u,v\in[0,1]} \langle (p_1(t), p_2(t)), (u+v, u)\rangle = \max_{u\in[0,1]} (3e^{1-t} - 4)u.$$

When t is sufficiently small, this maximum is strictly positive. Consequently, $(\bar{x}, \bar{y}) \equiv 0$ does not verify the maximum principle of Theorem 3.4.

We show next that the result of [35] does not allow to eliminate the control $u \equiv 0$.

Indeed, set $F(x, y) = \bigcup_{u,v\in[0,1]}(-|x| - 4y + u + v, u)$ and let $N^L_{graph(F)}(0, 0, 0, 0)$ denote the limiting normal cone to $graph(F)$ at $(0, 0, 0, 0)$ (see, for instance, [33] for the definition of the limiting normal cone). It is not difficult to check that $\{(-1, 0, -1, 0), (1, 0, -1, 0)\} \subset N^L_{graph(F)}(0, 0, 0, 0)$. Let $p \equiv (-1, 0)$. Since $(0, 0) \in co\{(-1, 0), (1, 0)\}$, this p satisfies the necessary conditions of [35].

Example 2. Consider a two-dimensional control system

$$x' = u,\ y' = v + u - 1,\ \ (u, v) \in [-1, 1] \times [-1, 1],$$

the closed set of constraints

$$K = (\mathbf{R}_- \times \mathbf{R}_-) \cup (\mathbf{R}_+ \times \mathbf{R}),$$

and the Mayer problem

$$\text{minimize } -y(1)$$

over solutions to the above control system satisfying the state constraints $(x, y)(t) \in K$. Then, by a direct calculation, for all $(x_0, y_0) \in K$,

$$V(t, (x_0, y_0)) = \begin{cases} t - y_0 - 1 & \text{if } x_0 \geq 0 \text{ or } y_0 \leq x_0 \\ t - x_0 - 1 & \text{otherwise.} \end{cases}$$

Notice that $V(t, \cdot)$ is continuously differentiable on $\mathbf{R}^*_+ \times \mathbf{R}$, where $\mathbf{R}^*_+ = \mathbf{R}_+ \backslash \{0\}$. For the initial condition $x(0) = -1/2,\ y(0) = 0$ an optimal trajectory is given by

$$(\bar{x}(t), \bar{y}(t)) = \begin{cases} (t - 1/2, 0) & \text{if } t \leq 1/2 \\ \\ (t - 1/2, t - 1/2) & \text{if } t \geq 1/2. \end{cases}$$

Set

$$G(t) = \begin{cases} \mathbf{R} \times \mathbf{R}_- & \text{if } t < 1/2 \\ \{(x, y) \mid y \leq x,\ y \leq 0\} & \text{if } t = 1/2 \\ \mathbf{R} \times \mathbf{R} & \text{if } t > 1/2. \end{cases}$$

Then, for every $t_0 > 1/2$, $(0,1) = -\frac{\partial V}{\partial(x,y)}(t_0, \bar{x}(t_0))$. On the other hand, the optimal control $\bar{u}(\cdot)$ corresponding to $\bar{x}(\cdot)$ is equal to $(1,0)$ on $[0, \frac{1}{2}]$ and $G(t)^- = \mathbf{R}_+(0,1)$ for all $t \in [0, \frac{1}{2})$, $G(\frac{1}{2})^- = \{(x,y) \mid |x| \le y,\ x \le 0\}$ and $G(t)^- = \{0\}$ for all $t \in (\frac{1}{2}, 1]$. Let $\lambda,\ p,\ \psi$ be as in Theorem 3.4 for $A(t,\cdot) \equiv 0$ and $\varphi(\theta_1, \theta_2) = -\theta_1$ for $(\theta_1, \theta_2) \in \mathbf{R} \times \mathbf{R}_-$.

By (3.1) we have $p(\cdot) \equiv p(1)$ and, by (3.5), for some nonnegative nondecreasing function γ and all $t \in [0, 1/2)$, $\psi(t) = \gamma(t)(0,1)$. We also have $\psi(t) = \psi(\frac{1}{2})$ for all $t \in [\frac{1}{2}, 1]$ and

$$\psi\left(\frac{1}{2}\right) - \gamma\left(\frac{1}{2} -\right)(0,1) \in \{(x,y) \mid |x| \le y,\ x \le 0\}. \tag{3.7}$$

Define $w(t) = (0,-1) + (0,-1)t$. Then $w(\cdot)$ is a solution to the linearized along $(\bar{x}, \bar{u})$ control system and $w(t) \in Int(G(t))$ for all $t \in [0,1]$. Thus, by Theorem 3.4, $\lambda = 1$.

We first claim that $\psi(1) \neq 0$. Indeed otherwise, by (3.7), $\psi \equiv 0$ and $p = (0,1)$. But this contradicts the maximum principle (3.4) on $[0, \frac{1}{2})$.

Consequently, $\psi(1) \neq 0$ and for all $t_0 > 1/2$, $-p(t_0) = (0,1) + \psi(1) \neq \frac{\partial V}{\partial(x,y)}(t_0, \bar{x}(t_0))$. Hence for all $t \in (\frac{1}{2}, 1]$, $-p(t) \notin \partial_x V(t, \bar{x}(t))$.

To complete the study of this example we next show that the multipliers $p(\cdot),\ \psi(\cdot)$ are unique and $p(\cdot) \equiv (1,0)$,

$$\psi(s) = \begin{cases} 0 & s \in [0, \frac{1}{2}) \\ (-1,1) & s \in [\frac{1}{2}, 1], \end{cases}$$

while there are several choices for ν, μ. For instance, μ may be equal to the Lebesgue measure on $\Pi := [0,1] \backslash \{\frac{1}{2}\}$ and $\mu(\{\frac{1}{2}\}) = 1$ and $\nu(\cdot) = 0$ on $\Pi, \nu(\frac{1}{2}) = (-1,1)$. Another possible choice is the Dirac measure $\mu = \delta_{\frac{1}{2}}$ and any Borel measurable $\nu : [0,1] \to \mathbf{R}^2$ satisfying $\nu(\frac{1}{2}) = (-1,1)$.

We first compute ψ using the maximum principle. By (3.1) we have $p(\cdot) \equiv (0,1) - \psi(1)$ and, by (3.5), $\psi(t) = \psi(\frac{1}{2})$ for all $t \in [\frac{1}{2}, 1]$. Notice that (3.5) implies that for all $0 < t < \frac{1}{2}$ we have

$$p(t) + \psi(t) = (0,1) - \int_{(t, \frac{1}{2}]} \nu(s) d\mu(s) = (0,1) - \rho(t)(0,1) - (n_x, n_y)\mu\left(\left\{\frac{1}{2}\right\}\right) \tag{3.8}$$

for $\nu(s) = (\nu_1(s), \nu_2(s)) \in N_K(\bar{x}(s))$ μ-a.e. and $\nu_2(s) \ge 0$ μ-a.e., the nonincreasing function $\rho(t) := \int_{(t, \frac{1}{2})} \nu_2(s) d\mu(s) \ge 0$ and $(n_x, n_y) \in G(\frac{1}{2})^-$. Hence for a.e. $t \in [0, \frac{1}{2}]$,

$$\langle p(t) + \psi(t), (1,0) \rangle = -n_x \mu\left(\left\{\frac{1}{2}\right\}\right) = \max_{(u,v) \in [-1,1]^2} \langle p(t) + \psi(t), (u, u+v-1) \rangle . \tag{3.9}$$

Since ψ is right continuous on $(0, \frac{1}{2})$, (3.9) holds true for all $0 < t < \frac{1}{2}$. Then (3.8) and (3.9) together imply that for every $0 < t < \frac{1}{2}$, $1 - \int_{(t, \frac{1}{2}]} \nu_2(s) d\mu(s) = 1 - \rho(t) - n_y \mu(\{\frac{1}{2}\}) = 0$ and therefore

$$\rho(t) = 0 \ \ \& \ \ n_y \mu\left(\left\{\frac{1}{2}\right\}\right) = 1. \tag{3.10}$$

Set $\beta := n_x\mu(\{\frac{1}{2}\}) \leq 0$. Then $p(t) + \psi(t) = (-\beta, 0)$ and $\psi(t) = \psi(0+)\ \ \forall\, t \in (0, \frac{1}{2})$. By (3.5), $\psi(0+) \in \mathbf{R}_+(0,1)$. This implies that for some $\alpha \geq 0$ we have

$$\psi(s) = \begin{cases} 0 & s = 0 \\ \alpha(0,1) & s \in (0, \frac{1}{2}) \\ \alpha(0,1) + (\beta, 1) & s \in [\frac{1}{2}, 1]. \end{cases}$$

Notice that $p(\cdot) \equiv (0,1) - \psi(1)$ satisfies the maximum principle (3.3) with any choice of $\alpha \geq 0,\ \beta \leq 0$ and ψ defined as above. The next step is to show that (3.4) implies that $\alpha = 0$ and $\beta = -1$. Indeed, $-p(0) = \alpha(0,1) + (\beta, 1) - (0,1) = (\beta, \alpha) \in \partial\varphi(0)$ and $1 = \varphi(-1,0) \leq -\beta,\ -1 = \varphi(1,0) \leq \beta,\ 0 = \varphi(0,-1) \leq -\alpha$. Therefore $\beta = -1,\ \alpha = 0$. Finally, $p(\cdot) \equiv (0,1) - (-1,1) = (1,0)$.

Observe next that

$$-p(t) - \psi(t) = \begin{cases} (-1,0) & t \in [0, \frac{1}{2}) \\ (0,-1) & t \in [\frac{1}{2}, 1]. \end{cases}$$

Consider

$$\varphi_t(\theta) = \begin{cases} \langle (-1,0), \theta \rangle & t \in [0, \frac{1}{2}),\ \ \theta \in G(t) \\ \langle (0,-1), \theta \rangle & t \in [\frac{1}{2}, 1],\ \ \theta \in G(t) \\ -\infty & \text{otherwise.} \end{cases}$$

Then $\varphi_t \leq D_x^+ V(t, (\bar{x}(t), \bar{y}(t)))$ for all $t \in I$ and we obtained the inclusion $-p(t) - \psi(t) \in \partial^+ \varphi_t(0)$ for all $t \in I$.

The natural question arises: Should we expect, in general, such property along optimal trajectories for any choice of upper semicontinuous positively homogeneous concave function $\varphi_t \leq D_x^+ V(t, \bar{x}(t))$? We conjecture that without additional assumptions on constraints, this is false.

In the unconstrained case, however, by Remark (iv) right after Theorem 3.4, we have the inclusion $-p(t) \in \partial_x V(t, \bar{x}(t))$ for all $t \in I$ provided the costate is unique.

COROLLARY 3.5. *Let $\bar{x}(\cdot)$ be an optimal solution to problem* (1.1)–(1.5) *and assume that Hypotheses* 3.1, 3.2, *and* 3.3 *hold true and that $\bar{x}(I) \subset Int(K)$, $\bar{x}(1) \in Int(K_1)$. Then there exists an absolutely continuous function $p(\cdot) : I \to \mathbf{R}^n$ such that*

$$p'(t) \in A^*(t, -p(t)),\ \ \langle p(t), \bar{x}'(t) \rangle = \max_{v \in F(t, \bar{x}(t))} \langle p(t), v \rangle \quad \text{a.e. in } I,$$

$$p(1) \in -\partial^C g(\bar{x}(1)), \quad -p(0) \in \partial_x V(0, \bar{x}(0)).$$

If, in addition, $g(\cdot)$ is differentiable at $\bar{x}(1)$ and the solution to the adjoint inclusion

$$p'(t) \in A^*(t, -p(t)), \quad p(1) = -\nabla g(\bar{x}(1))$$

is unique, then for all $t \in I$, $-p(t) \in \partial_x V(t, \bar{x}(t))$.

When the value function is differentiable, we have a more precise statement than the one of Theorem 3.4.

THEOREM 3.6. *Let $\bar{x}(\cdot)$ be an optimal solution to problem* (1.1)–(1.5) *and assume that Hypotheses* 3.1, 3.2, *and* 3.3 *hold true. If $\bar{x}(0) \in Int(K)$ and $V(0, \cdot)$ is differentiable at $\bar{x}(0)$, then the same conclusions as in Theorem* 3.4 *hold true with* (3.4) *replaced by $p(0) = -\lambda \frac{\partial V}{\partial x}(0, \bar{x}(0))$.*

The next corollary implies that if $V(0,\cdot)$ has some directional derivatives bounded from below and $C_{K_1}(\bar{x}(1)) \cap Int(G(1)) \neq \emptyset$, then the maximum principle is nondegenerate.

COROLLARY 3.7. *Let $\bar{x}(\cdot)$ be an optimal solution to problem* (1.1)–(1.5). *Assume that Hypotheses* 3.1, 3.2, *and* 3.3 *are satisfied and that there exists a nonempty open convex set $\mathcal{F} \subset G(0)$ and $M > 0$ such that for all $\theta \in \mathcal{F}$*

$$D_x^+ V(0, \bar{x}(0))(\theta) \geq -M||\theta||. \tag{3.11}$$

Then we have the same conclusions as in Theorem 3.4 *with $G(0)$ replaced by $\overline{\mathbf{R}_+\mathcal{F}}$ and* (3.4) *replaced by*

$$-p(0) \in \lambda(MB + \mathcal{F}^+).$$

Proof. It is enough to set $\varphi(\theta) = -M||\theta||$ for all $\theta \in \overline{\mathbf{R}_+\mathcal{F}}$ and $\varphi(\theta) = -\infty$ otherwise and apply Theorem 3.4. □

Remark. Assume that our problem (1.1)–(1.5) is calm in the sense that

$$\liminf_{x \to_K \bar{x}(0)} \frac{V(0,x) - V(0,\bar{x}(0))}{||x - \bar{x}(0)||} > -\infty,$$

then (3.11) holds true for some $M > 0$ and all $\theta \in G(0)$.

Consider next the Mayer problem (1.1)–(1.4) with an initial constraint of the form

$$x(0) \in K_0, \tag{3.12}$$

where $K_0 \subset \mathbf{R}^n$ is a given closed set.

Then we have the following maximum principle for problem (1.1)–(1.4), (3.12) with state and both initial and endpoints constraints.

COROLLARY 3.8. *Let $\bar{x}(\cdot)$ be an optimal solution to problem* (1.1)–(1.4), (3.12) *and assume that Hypotheses* 3.1, 3.2, *and* 3.3 *are satisfied and $Int(C_{K_0}(\bar{x}(0))) \cap Int(G(0)) \neq \emptyset$. Then we have the same conclusions as in Theorem* 3.4 *with* (3.4) *replaced by*

$$p(0) \in \lambda(N_{K_0}(\bar{x}(0)) + G(0)^-). \tag{3.13}$$

Proof. Consider the set-valued map $\hat{G}(\cdot)$ defined by $\hat{G}(0) = C_{K_0}(\bar{x}(0)) \cap G(0)$ and $\hat{G}(t) = G(t)$ for all $t \in (0,1]$ and notice that $\hat{G}(\cdot)$ satisfies Hypothesis 3.3. It remains to apply Theorem 3.4 with $G(\cdot)$ replaced by $\hat{G}(\cdot)$ and with the mapping $\varphi(\cdot)$ defined by

$$\varphi(x) = \begin{cases} 0 & \text{if } x \in C_{K_0}(\bar{x}(0)) \cap G(0) \\ -\infty & \text{otherwise.} \end{cases}$$ □

Remark. In the case when we may take $G(t) \equiv \mathbf{R}^n$, if in the statement of Corollary 3.8 we define $q(t) := p(t) + \psi(0+)$, then we obtain the maximum principle with endpoint constraints from [15].

In what follows we show that when the boundary of K is smooth enough and a pointwise inward pointing assumption holds true along the optimal trajectory, then the maximum principle of Theorem 3.4 is normal, i.e., $\lambda = 1$ provided $\bar{x}(1) \in Int(K_1)$. A normal maximum principle (with a different adjoint inclusion and without assuming

Hypothesis 3.2) was derived in [28] in the context of nonsmooth control systems, smooth state constraints and $K_1 = \mathbf{R}^n$ under an inward pointing condition (involving continuous selections from U) imposed on a neighborhood of the boundary of K. We propose here a less restrictive inward pointing assumption.

Hypothesis 3.9. K is closed and

(i) $\exists\ \eta > 0$ such that the signed distance defined by

$$d(x) = \begin{cases} -dist(x, \partial K) & \forall\ x \in K \\ dist(x, \partial K) & \text{otherwise} \end{cases}$$

is of class $C^{1,1}_{loc}$ on $\partial K + \eta B$.

(ii) $\exists\ \rho > 0$ such that for almost all $t \in I$ with $\bar{x}(t) \in \partial K + \eta B$ we have

$$\min_{v \in F(t, \bar{x}(t))} \langle \nabla d(\bar{x}(t)), v \rangle \leq -\rho.$$

For all $x \in \partial K$ we denote by $n(x)$ the outward unit normal to K at x. Then $T_K(x) = (\mathbf{R}_+ n(x))^-$. Under Hypothesis 3.9, $n(x) = \nabla d(x)$ and therefore $n(\cdot)$ is locally Lipschitz on the boundary of K.

Remark. Assume that Hypothesis 3.1 holds true with l independent from time, that Hypothesis 3.9 (i) is satisfied and that there exists $\rho > 0$ such that for all $t \in I$ we have

$$\forall\ x \in \partial K, \quad \min_{v \in F(t,x)} \langle n(x), v \rangle \leq -\rho.$$

Then it is not difficult to show that Hypothesis 3.9 (ii) holds true with ρ replaced by $\rho/2$ and may be a different choice of a constant η. Furthermore, from results of [18] it follows that in this case the value function is locally Lipschitz on K.

THEOREM 3.10. *Let $\bar{x}(\cdot)$ be an optimal solution to problem* (1.1)–(1.5). *Assume that Hypotheses* 3.1, 3.2, *and* 3.9 *hold true and that $\bar{x}(1) \in Int(K_1)$. Then all conclusions of Theorem* 3.4 *are valid with $\lambda = 1$ and $G(t) = T_K(\bar{x}(t))$ for every $t \in I$.*

THEOREM 3.11. *In Theorem* 3.4 *assume that for all $t \in I$, $A(t, \cdot)$ is a linear operator and $A(t, \cdot)$ is $m(t)$-Lipschitz for some $m(\cdot) \in L^1(I)$. Then all the conclusions of Theorem* 3.4 *are valid.*

If there exists a solution to the constrained linear control system

$$w' = A(s, w) + v(s),\ v(s) \in T_{co(F(s, \bar{x}(s)))}(\bar{x}'(s)), \tag{3.14}$$

$$w(s) \in Int(G(s))\ \ \forall\ s \in [0, 1],\ w(1) \in Int(C_{K_1}(\bar{x}(1))) \tag{3.15}$$

and g is differentiable at $\bar{x}(1) \in Int(K_1)$, then $p(1) = -\nabla g(\bar{x}(1)) - \psi(1)$ and for every upper semicontinuous concave function $\varphi_t : \mathbf{R}^n \to \mathbf{R} \cup \{-\infty\}$ satisfying $Int(G(t)) \subset dom(\varphi_t)$ and $\varphi_t \leq D^+_x V(t, \bar{x}(t))$ there exist $\psi_t \in NBV([t, 1])$, a positive Radon measure μ_t, a selection $\nu_t(s) \in G(s)^- \cap B$ μ_t-a.e. such that for every $s \in (t, 1]$

$$\psi_t(s) = \int_{[t,s]} \nu_t(\tau) d\mu_t(\tau),\ \psi_t(s) - \psi_t(s-) \in G(s)^-,\ \psi_t(t+) \in G(t)^-$$

and the solution $r(\cdot) : [t, 1] \to \mathbf{R}^n$ to

$$r'(s) = A^*(s, -r(s) - \psi_t(s) + \psi(s)), \quad r(1) = \psi(1) - \psi_t(1)$$

satisfies

$$-r(t) - p(t) \in \partial^+ \varphi_t(0), \quad \langle r(s) + p(s) + \psi_t(s), \bar{x}'(s) \rangle$$
$$= \max_{v \in co(F(s,\bar{x}(s)))} \langle r(s) + p(s) + \psi_t(s), v \rangle \text{ a.e. in } [t,1].$$

Remark. The mapping r of the above theorem depends on t. That means for each $t > 0$ the costate $p(t)$ is corrected by a solution of the adjoint equation with a different function ψ_t in order $-r(t) - p(t) \in \partial^+ \varphi_t(0)$. Notice that if for all $s \geq t$, $\bar{x}(s) \in Int(K)$ and $\bar{x}(1) \in Int(K_1)$, then $\nu_t = 0$ and the above theorem implies that the solution q to

$$-q'(s) = A^*(s, q(s)), \quad q(1) = -\nabla g(\bar{x}(1))$$

satisfies $-q(t) \in \partial^+ \varphi_t(0)$.

On the other hand, slightly modifying the proof provided in section 5 we get $-q(s) \in \partial_x^+ V(s, \bar{x}(s))$ for all $s \in [t,1]$, which is a known relation of the costate to the value function derived in [5] for unconstrained problems.

4. Polar of the set of continuous selections. Recall that any function $f : [a,b] \to \mathbf{R}^n$ of bounded variation on $[a,b]$ has right and left limits $f(a+)$ and $f(b-)$ (see [12, p. 154]).

The space $NBV([a,b])$ (Normalized Bounded Variations) is the space of functions f of bounded variation on $[a,b]$, which are continuous from the right on (a,b) and such that $f(a) = 0$. The norm of $f \in NBV([a,b])$ is the total variation of f on $[a,b]$ denoted by $\|f\|_{TV}$. If $\beta \in C([a,b])^*$, then there exists a unique $f \in NBV([a,b])$ such that for all $\varphi \in C([a,b]), \beta(\varphi) = \int_a^b \varphi(s) df(s)$ (the Stieltjes integral) and $\|\beta\| = \|f\|_{TV}$ (see, for instance, [24, p. 113]). Conversely, every $f \in NBV([a,b])$ defines an element $\beta_f \in C([a,b])^*$ by setting $\langle \beta_f, \varphi \rangle = \int_a^b \varphi(s) df(s)$ for all $\varphi \in C([a,b])$.

Let $f \in NBV(I)$ and $\varphi \in W^{1,1}(I)$. We have the following integration by parts formula

$$\int_0^1 \varphi(s) df(s) = \langle f(1), \varphi(1) \rangle - \int_0^1 \langle f(s), \varphi'(s) \rangle ds.$$

Recall that any $g \in NBV(I)$ defines a regular finite countably additive measure on (I, Σ), where Σ denotes the σ-field of Borel subsets of I. We briefly recall the corresponding construction that will be used to prove Lemma 4.2 below.

Define $\bar{g}$ by $\bar{g} = g$ on $[0,1)$ and $\bar{g}(1) = 0$. For all $0 < c < d \leq 1$ set $\lambda_g((c,d]) = \bar{g}(d) - \bar{g}(c)$ and $\lambda_g([0,d])) = \bar{g}(d)$. By [12, pp. 141, 142] λ_g can be extended to a regular countably additive measure (again denoted) λ_g on Borel subsets of I such that $var(\lambda_g, (c,d]) = var(\bar{g}, (c,d])$ and $var(\lambda_g, [0,d]) = var(\bar{g}, [0,d])$, where var states for the variation. Define next the measure μ_g on Borel subsets of I by setting $\mu_g(\{0\}) = g(0+)$, $\mu_g(\{1\}) = g(1) - g(1-)$ and for every Borel subset A of $(0,1)$, $\mu_g(A) = \lambda_g(A)$. It is not difficult to verify that μ_g is a finite, countably additive and regular measure on I.

Notice that for every $0 < t < 1$,

$$\mu_g([0,t]) = \mu_g(\{0\}) + \lambda_g((0,t]) = g(0+) + \mu_g(\cup_{j \geq 1}((a_{j+1}, a_j])) = g(0+)$$
$$+ \bar{g}(t) - \bar{g}(0+) = g(t),$$

where $0 < \cdots < a_2 < a_1 = t$ and for all $0 < t < s < 1, \mu_g((t,s]) = g(s) - g(t)$. Furthermore,

$$\mu_g((t,1]) = \mu_g(\{1\}) + \lambda_g((t,1)) = g(1) - g(1-) + \mu_g(\cup_{j\geq 1}((a_j, a_{j+1}])),$$

where $t = a_1 < a_2 < \cdots < 1$. Thus, by countable additivity,

$$\mu_g((t,1]) = g(1) - g(1-) + g(1-) - g(t) = g(1) - g(t).$$

This and the definition of the Stieltjes integral imply that for every $w \in C(I)$,

$$\int_{[0,1]} w(s) d\mu_g(s) = \int_0^1 w(s) dg(s).$$

LEMMA 4.1. *Consider a lower semicontinuous set-valued map $G : I \rightsquigarrow \mathbf{R}^n$ such that for all $t \in I$, $G(t)$ is a closed convex cone. Assume that for all $t \in I$, $Int(G(t)) \neq \emptyset$ and let*

$$\mathcal{C} = \{w(\cdot) \in C(I) \mid \quad w(t) \in G(t) \quad \forall\, t \in I\}. \tag{4.1}$$

Then

$$Int(\mathcal{C}) = \{w(\cdot) \in C(I) \mid \quad w(t) \in Int(G(t)) \quad \forall\, t \in I\} \neq \emptyset.$$

Proof. Define the compact set $\mathcal{D} = \{t \in I \mid G(t) \neq \mathbf{R}^n\}$. If $\mathcal{D} = \emptyset$, then there is nothing to prove. Assume next that $\mathcal{D} \neq \emptyset$ and define $\Gamma(t) := \{p \in G(t)^- \mid ||p|| = 1\}$ for all $t \in \mathcal{D}$.

We claim that $\Gamma(\cdot)$ is upper semicontinuous on $\mathcal{D}$. Indeed, $\Gamma(\cdot)$ has nonempty compact images and is bounded, so it is enough to check that its graph is closed. Consider any $p_i \in \Gamma(t_i) \subset G(t_i)^-$, $p_i \to p$, $t_i \to_{\mathcal{D}} t_0$. Then $||p|| = 1$. Let $v \in G(t_0)$. By the lower semicontinuity of $G(\cdot)$ there exist $v_i \in G(t_i)$, $v_i \to v$. Hence $\langle p_i, v_i\rangle \leq 0$ and, taking the limit, we get $\langle p, v\rangle \leq 0$. Since $v \in G(t_0)$ is arbitrary, $p \in G(t_0)^-$ and our claim is proved.

Fix $\overline{\varepsilon} > 0$ and define for all $t \in \mathcal{D}$, $F_{\overline{\varepsilon}}(t) = \{v \in G(t) \mid \langle p, v\rangle \leq -\overline{\varepsilon} \ \ \forall\, p \in \Gamma(t)\}$. Since $Int(G(t)) \neq \emptyset$, also $F_{\overline{\varepsilon}}(t) \neq \emptyset\ \forall\ t \in \mathcal{D}$. Obviously, $F_{\overline{\varepsilon}}(\cdot)$ has closed convex images and is lower semicontinuous on $\mathcal{D}$. So by Michael's theorem there exists a continuous selection $\bar{f}(t) \in F_{\overline{\varepsilon}}(t) \subset Int(G(t))\ \forall\ t \in \mathcal{D}$. Let f be any continuous extension of $\bar{f}$ on the whole interval I. Then $f(t) \in Int(G(t))$ for all $t \in I$.

Consider any $g \in C(I)$ such that $||g||_\infty \leq \overline{\varepsilon}$. Then for any $t \in \mathcal{D}$ and $p \in \Gamma(t)$ $\langle p, f(t) + g(t)\rangle \leq -\overline{\varepsilon} + \overline{\varepsilon} = 0$, i.e., $f(t) + g(t) \in G(t)\ \ \forall\, t \in I$, implying that $Int(\mathcal{C}) \neq \emptyset$. Notice that if $\varphi \in Int(\mathcal{C})$, then for some $\varepsilon > 0$ and all $t \in I$, $B_\varepsilon(\varphi(t)) \subset G(t)$. Thus $Int(\mathcal{C}) \subset W := \{w(\cdot) \in C(I) \mid w(t) \in Int(G(t))\ \forall\ t \in I\}$. Next, fix any $\overline{\varphi} \in W$. Then, by the lower semicontinuity of $G(\cdot)$ and compactness of I, there exists $\varepsilon > 0$ such that for all $t \in I$, $\overline{\varphi}(t) + \varepsilon B \subset G(t)$. So, $\overline{\varphi} \in Int(\mathcal{C})$. ∎

In the next lemma we consider $NBV(I)$ as the dual of $C(I)$: with every $f \in NBV(I)$ we associate the functional $\beta_f \in C(I)^*$ defined by $\langle \beta_f, x\rangle = \int_0^1 x(s) df(s)$ (the Stieltjes integral).

LEMMA 4.2. *Consider a lower semicontinuous set-valued map $G : I \rightsquigarrow \mathbf{R}^n$ such that for all $t \in I$, $G(t)$ is a closed convex cone with nonempty interior. Let $\mathcal{C}$ be defined by* (4.1) *and $g \in NBV(I)$ be such that $g \in \mathcal{C}^-$. Then there exists a scalar*

positive Radon measure μ on I and a selection $\nu(s) \in G(s)^- \cap B$ $\mu - a.e.$ such that for every $t \in (0,1]$ $g(t) = \int_{[0,t]} \nu(s) d\mu(s)$, $g(t) - g(t-) \in G(t)^-$ and $g(0+) \in G(0)^-$.

Proof. Let μ_g be the regular countably additive finite measure on I associated to g by the construction recalled at the beginning of this section.

Define also for all $t > 0$, $f(t) = var(g, [0,t])$ (total variation of g on $[0,t]$) and set $f(0) = \|g(0+)\|$. Then $f \geq 0$ is increasing, right continuous on $[0,1)$ and has bounded variation. By the construction provided in [12, pp. 141–142], f defines a regular countably additive positive scalar measure μ on Borel subsets of $(0,1)$. Setting $\mu(\{0\}) = f(0)$, $\mu(\{1\}) = f(1)$ we obtain a Radon measure on I. Furthermore, since the total variation is additive, it follows from this construction that μ_g is μ-continuous. By the Radon–Nikodym theorem there exists a unique μ-integrable function ν such that $\int_E \nu(s) d\mu(s) = \mu_g(E)$ for every Borel set $E \subset I$. In particular, this yields $g(t) = \int_{[0,t]} \nu(s) d\mu(s)$ for all $0 < t \leq 1$. For every Borel subset $A \subset I$ denote by $v(\mu_g, A)$ the total variation of μ_g on A. It is not difficult to check that for every open set $\mathcal{O}$ in $[0,1]$ we have $\mu(\mathcal{O}) = v(\mu_g, \mathcal{O})$. Since μ_g and μ are regular also for every Borel subset $A \subset I$, $\mu(A) = v(\mu_g, A)$. □

Claim 1. $\nu(s) \in B$ μ-a.e. Define $\zeta : I \to B$ by $\zeta(s) = 0$ if $\nu(s) = 0$ and $\zeta(s) = \nu(s)/||\nu(s)||$ otherwise. Then for every Borel set $A \subset I$, $\int_A \zeta(s) d\mu_g(s) = \int_A \zeta(s)\nu(s) d\mu(s) = \int_A ||\nu(s)|| d\mu(s)$. Let A be the set of all $s \in I$ such that $||\nu(s)|| > 1$. If $\mu(A) > 0$ then from the last equality we get $\mu(A) < \int_A \zeta(s) d\mu_g(s) \leq v(\mu_g, A)$. The obtained contradiction proves our claim.

We next show that $\nu(s) \in G(s)^-$ *μ-a.e.* Even if it may be deduced from [30, Corollary 6A] we provide the proof of this inclusion for the sake of completeness.

Set $\Delta = \{t \in I \mid g(t) \neq g(t-)\}$. This set is at most countable.

Claim 2. Let $w_0 \in \mathbf{R}^n$ and $0 \leq t_1 < t_2 \leq 1$ be such that $w_0 \in G(s)$ for all $s \in [t_1, t_2]$ and $t_1 \notin \Delta$. We claim that $\langle g(t_2) - g(t_1), w_0 \rangle \leq 0$. Indeed, by Lemma 4.1, there exists a selection $\bar{w}(t) \in Int(G(t))$, $t \in I$. Then for every $\varepsilon > 0$, $\varepsilon \bar{w}(t) \in Int(G(t))$ $\forall\, t \in I$. For all $\delta > 0$ define $a_\delta := \max\{t_1 - \delta, 0\}$, $b_\delta = \min\{t_2 + \delta, 1\}$ and the function $w_\delta \in C(I)$ by

$$w_\delta(s) := \begin{cases} \frac{s - a_\delta}{\delta} w_0 + \frac{t_1 - s}{\delta} \varepsilon \bar{w}(s) & \text{if } s \in [a_\delta, t_1) \\ w_0 & \text{if } s \in [t_1, t_2] \\ \frac{b_\delta - s}{\delta} w_0 + \frac{s - t_2}{\delta} \varepsilon \bar{w}(s) & \text{if } s \in (t_2, b_\delta] \\ \varepsilon \bar{w}(s) & \text{otherwise.} \end{cases}$$

Then $\int_0^1 w_\delta(s) dg(s) \leq 0$ whenever $\delta > 0$ is sufficiently small. Notice that $\int_{t_1}^{t_2} w_0 dg(s) = \langle g(t_2) - g(t_1), w_0 \rangle$. On the other hand if $t_1 - \delta \geq 0$, then

$$\int_{t_1 - \delta}^{t_1} \frac{t_1 - \delta}{\delta} dg(s) = \frac{t_1 - \delta}{\delta} (g(t_1) - g(t_1 - \delta))$$

and, integrating by parts, we get

$$\int_{t_1 - \delta}^{t_1} \frac{s}{\delta} dg(s) = \frac{t_1}{\delta} g(t_1) - \frac{t_1 - \delta}{\delta} g(t_1 - \delta) - \frac{1}{\delta} \int_{t_1 - \delta}^{t_1} g(s) ds.$$

Finally, if $t_2 + \delta \leq 1$, then

$$\int_{(t_2, t_2 + \delta]} \frac{t_2 + \delta}{\delta} dg(s) = \frac{t_2 + \delta}{\delta} (g(t_2 + \delta) - g(t_2+)).$$

Integrating by parts we get

$$\int_{(t_2,t_2+\delta]} \frac{s}{\delta} dg(s) = \frac{t_2+\delta}{\delta} g(t_2+\delta) - \frac{t_2}{\delta} g(t_2+) - \frac{1}{\delta}\int_{t_2}^{t_2+\delta} g(s)ds.$$

Thus from the equality $g(t_2+) = g(t_2)$ we obtain

$$\int_{t_1-\delta}^{t_1} \frac{s+\delta-t_1}{\delta} dg(s) = g(t_1) - \frac{1}{\delta}\int_{t_1-\delta}^{t_1} g(s)ds,$$
$$\int_{(t_2,t_2+\delta]} \frac{\delta+t_2-s}{\delta} dg(s) = -g(t_2) + \frac{1}{\delta}\int_{t_2}^{t_2+\delta} g(s)ds.$$

Since $\lim_{s\to t_2+} g(s) = g(t_2)$, $\lim_{s\to t_1-} g(s) = g(t_1)$, from the inequality $\int_0^1 w_\delta(s)\, dg(s) \le 0$ we deduce that $\langle g(t_2) - g(t_1), w_0\rangle \le \varepsilon\|\bar{w}\|_\infty \|g\|_{TV}$. Passing to the limit when $\varepsilon \to 0+$, we end the proof of our claim.

To show that $\nu(s) \in G(s)^-$ μ-a.e it is enough to consider the case $\mu(I) \neq 0$. Let $\pi(s) \in G(s)$ be the projection of $\nu(s)$ on $G(s)$. Then π is μ-measurable and $||\pi(s)|| \le 1$ μ-a.e. Thus π is μ-integrable. Furthermore, $\pi(s) = 0$ if and only if $\nu(s) \in G(s)^-$. On the other hand, $\int_I \pi(s)d\mu_g(s) = \int_I \pi(s)\nu(s)d\mu(s) = \int_I ||\pi(s)||^2 d\mu(s)$. Hence if $\pi(s) \neq 0$ on a set of positive measure, then for some $\varepsilon > 0$, $\int_I \pi(s)d\mu_g(s) \ge 2\varepsilon$.

Let $\bar{w} \in Int(\mathcal{C})$. We may assume that $\|\bar{w}\|_\infty \le 1$. Let $\delta > 0$ be so that for all $s \in I$, $\bar{w}(s)+\delta B \subset G(s)$. Then $\pi(s)+\frac{\varepsilon}{\mu(I)}(\bar{w}(s)+\delta B) \subset G(s)$. Set $\zeta(s) := \pi(s)+\frac{\varepsilon}{\mu(I)}\bar{w}(s)$. Then $\int_I \zeta(s)d\mu_g(s) \ge \varepsilon$. Since ζ is μ-measurable, there exist μ-measurable functions $\zeta_i : I \to \mathbf{R}^n$ assuming only countable numbers of values and converging uniformly to ζ. Thus for all large i and all $s \in I$, $\zeta_i(s) \in Int(G(s))$. Consequently, for all large i, $\int_I \zeta_i(s)d\mu_g(s) > 0$. Fix i sufficiently large. Then for some $\alpha \in \mathbf{R}^n$ and a Borel set $A \subset I$, we have $\zeta_i(s) = \alpha$ for all $s \in A$ and $\alpha\mu_g(A) > 0$. Notice next that by the lower semicontinuity of $G(\cdot)$ and since $\alpha \in Int(G(s))$ for every $s \in A$ there exists an open set $\mathcal{O}_s \ni s$ such that $\alpha \in Int(G(s'))$ for all $s' \in \mathcal{O}_s$. Set $\mathcal{O}_2 := \bigcup_{s\in A} \mathcal{O}_s$. Since μ_g is regular, there exists an open (in I) set $\mathcal{O}_3 \supset A$ such $v(\mu_g, \mathcal{O}_3\backslash A) < \mu_g(A)/2$. Define the open set $\mathcal{O} := \mathcal{O}_2 \cap \mathcal{O}_3$.

Consequently, $\alpha\mu_g(\mathcal{O}) > \alpha\mu_g(A)/2 > 0$. Since $\mathcal{O}$ is at most a countable union of disjoint intervals $(t_1^i, t_2^i]$ and eventually an interval $[0, t_0]$ with $0 < t_1^i \notin \Delta$, $t_0 > 0$, either $\alpha\mu_g([0,t_0]) = \alpha g(t_0) > 0$ or there exist $0 < t_1 < t_2$ such that $\alpha\mu_g((t_1,t_2]) = \langle\alpha, g(t_2) - g(t_1)\rangle > 0$. In both cases we obtain a contradiction with Claim 2.

To prove jump conditions, observe that $G(t)^- \cap B = [0,1]\Gamma(t)$ for all $t \in \mathcal{D}$, where Γ and $\mathcal{D}$ are defined as in the proof of Lemma 4.1. Thus, by the proof of Lemma 4.1, $t \rightsquigarrow G(t)^- \cap B$ is upper semicontinuous on $\mathcal{D}$. Since $G(t)^- = \{0\}$ whenever $t \notin \mathcal{D}$, we deduce that the set-valued map $t \rightsquigarrow G(t)^- \cap B$ is upper semicontinuous on I. This implies that for all $\varepsilon > 0$ and for all small $t > 0$, $g(t) = \int_{[0,t]} \nu(s)d\mu(s) \in ((G(0)^- \cap B) + \varepsilon B)\mu([0,t])$. Taking the limit when $t \to 0+$ we get $g(0+) \in ((G(0)^- \cap B) + \varepsilon B)\lim_{t\to 0+}\mu([0,t])$. Since this inclusion is valid for all $\varepsilon > 0$ we deduce that $g(0+) \in G(0)^-$. Fix next any $0 < t \le 1$. Again, using the upper semicontinuity of $t \rightsquigarrow G(t)^- \cap B$, we obtain that for every $\varepsilon > 0$ and all $\tau < t$ sufficiently close to t we have $g(t) - g(\tau) = \int_{(\tau,t]} \nu(s)d\mu(s) \in ((G(t)^- \cap B) + \varepsilon B)\mu((\tau,t])$. Taking the limit, first when $\tau \to t-$ and then when $\varepsilon \to 0+$ we deduce that $g(t) - g(t-) \in G(t)^-$. The proof is complete.

5. Proofs of results of section 3. *Proof of Theorem* 3.4. Consider the set-valued map $B(\cdot,\cdot) : I \times \mathbf{R}^n \rightsquigarrow \mathbf{R}^n$ defined by

$$B(t,v) = \overline{A(t,v) + T_{co(F(t,\bar{x}(t)))}(\bar{x}'(t))}.$$

By [15] for almost all $t \in I$, $B(t,\cdot)$ is a closed convex process, Lipschitz with the same Lipschitz constant as $A(t,\cdot)$ and $B(t,v) \subseteq d_x\, \overline{co}F(t,\bar{x}(t),\bar{x}'(t))v$ for all $v \in \mathbf{R}^n$. Thus the family $\{B(t,\cdot)\}_{t\in I}$ satisfies Hypothesis 3.2. It was also proved in [15] that

$$\begin{aligned} (5.1)\qquad & r(t) \in B^*(t,q(t)) \text{ iff } r(t) \in A^*(t,q(t)),\ q(t) \in [T_{co(F(t,\bar{x}(t)))}(\bar{x}'(t))]^+ \\ & = [F(t,\bar{x}(t)) - \bar{x}'(t)]^+. \end{aligned}$$

Set

$$S := \{w(\cdot) \in W^{1,2}(I) \mid \quad w'(t) \in B(t,w(t)) \quad \text{a.e. in } I\},$$

$$(5.2)\qquad \mathcal{C} = \{w(\cdot) \in C(I) \mid w(t) \in G(t) \quad \forall\, t \in I\}, \quad \mathcal{C}_1 = \{w(\cdot) \in C(I) \mid w(1) \in C_{K_1}(\bar{x}(1))\}$$

$$\gamma(x(\cdot)) = (x(0),x(1)), \quad \gamma_1(x(\cdot)) = x(1) \quad \forall\, x(\cdot) \in C(I).$$

Denote by $\bar{S}$ the closure of S in $C(I)$. By Lemma 4.1, $Int(\mathcal{C}) \neq \emptyset$. It is also clear that $Int(\mathcal{C}_1) \neq \emptyset$. Furthermore, since $\mathcal{C}_1 = \gamma_1^{-1}(C_{K_1}(\bar{x}(1)))$, $\mathcal{C}_1^+ = (\gamma_1^{-1}(C_{K_1}(\bar{x}(1))))^+ = \gamma_1^*((C_{K_1}(\bar{x}(1)))^+)$ (see, for instance, [4]), we infer that for every $\beta_1 \in \mathcal{C}_1^-$ there exists $\eta \in N_{K_1}(\bar{x}(1))$ such that all $w \in C(I)$, $\langle \beta_1, w\rangle = \langle \eta, w(1)\rangle$.

If $Int(\mathcal{C}_1) \cap Int(\mathcal{C}) = \emptyset$, then, by the separation theorem, there exists $0 \neq \beta_1 \in \mathcal{C}_1^-$ satisfying $-\beta_1 \in \mathcal{C}^-$. Let $\eta \in N_{K_1}(\bar{x}(1))$ be such that all $w \in C(I)$, $\langle \beta_1, w\rangle = \langle \eta, w(1)\rangle$. By Lemma 4.2 it is enough then to set $\psi(1) = -\eta$, $\psi = 0$ on $[0,1)$, $\lambda = 0$ and $p \equiv 0$ to get the conclusion of Theorem 3.4 in this case.

We assume next that $Int(\mathcal{C}_1) \cap Int(\mathcal{C}) \neq \emptyset$. Then $Int(\mathcal{C}_1 \cap \mathcal{C}) = Int(\mathcal{C}_1) \cap Int(\mathcal{C})$ and therefore $(\mathcal{C} \cap \mathcal{C}_1)^- = \mathcal{C}^- + \mathcal{C}_1^-$ (see, for instance, [4]).

We have two cases.

Case 1. $\bar{S} \cap (Int(\mathcal{C} \cap \mathcal{C}_1)) = \emptyset$. Since $\bar{S}$ and $\mathcal{C} \cap \mathcal{C}_1$ are closed convex cones in $C(I)$ and $Int(\mathcal{C} \cap \mathcal{C}_1) \neq \emptyset$, they can be separated by a closed hyperplane passing through the origin, i.e., there exists $0 \neq \beta \in C(I)^*$ such that

$$(5.3)\qquad \langle \beta, b\rangle \leq 0 \leq \langle \beta, a\rangle \quad \forall\, a \in \bar{S},\ b \in \mathcal{C} \cap \mathcal{C}_1.$$

Thus $\beta \in \mathcal{C}^- + \mathcal{C}_1^-$. Consider $\beta_0 \in \mathcal{C}^-$ and $\beta_1 \in \mathcal{C}_1^-$ such that $\beta = \beta_0 + \beta_1$.

We claim that $\beta_0 \neq 0$. Indeed otherwise $\beta_1 \neq 0$ and $\beta_1 \in \bar{S}^+$. Let $0 \neq \eta \in N_{K_1}(\bar{x}(1))$ be such that for all $w \in C(I)$, $\langle \beta_1, w\rangle = \langle \eta, w(1)\rangle$. Notice that for every $w_1 \in C_{K_1}(\bar{x}(1))$ there exists $w \in S$ such that $w(1) = w_1$. Hence, by (5.3), for all $w_1 \in C_{K_1}(\bar{x}(1))$ we have $\langle \eta, w_1\rangle = 0$. The interior of $C_{K_1}(\bar{x}(1))$ being nonempty, this last equality yields $\eta = 0$. The obtained contradiction proves our claim.

Let $\psi \in NBV(I)$ be such that for all $w \in C(I)$, $\langle \beta_0, w\rangle = \int_0^1 w(s)d\psi(s)$. Then $\|\psi\|_{TV} \neq 0$. By Lemma 4.2 applied to β_0 for a positive Radon measure μ on I and a μ-measurable selection $\nu(t) \in G(t)^- \cap B$ μ-a.e., relations (3.5) hold true.

On the other hand, by (5.3), we have that $\beta \in S^+ \subset W^{1,2}(I)^*$. Set

$$D(x(\cdot)) = x'(\cdot) \quad \forall\, x(\cdot) \in W^{1,2}(I),$$

$$L = \{(x(\cdot), y(\cdot)) \in L^2(I) \times L^2(I) \mid \quad y(s) \in B(s, x(s)) \ \text{ a.e. in } I\}.$$

According to [15] one has

$$S^+ = (1 \times D)^*(L^+), \tag{5.4}$$

$$L^+ = \{(-r(\cdot), q(\cdot)) \in L^2(I) \times L^2(I) \mid \quad r(s) \in B^*(s, q(s)) \text{ a.e. in } I\}. \tag{5.5}$$

Therefore, there exists $(-r, q) \in L^+$ such that for any $x \in W^{1,2}(I)$

$$\langle \beta, x\rangle = \langle (1 \times D)^*(-r, q), x\rangle = \langle (-r, q), (x, x')\rangle.$$

Let $\eta \in N_{K_1}(\bar{x}(1))$ be such that for all $w \in C(I)$, $\langle \beta_1, w\rangle = \langle \eta, w(1)\rangle$. Hence for any $x(\cdot) \in W^{1,2}(I)$

$$\langle \eta, x(1)\rangle = -\int_0^1 r(t)x(t)dt + \int_0^1 q(t)x'(t)dt - \int_0^1 x(t)d\psi(t). \tag{5.6}$$

From (5.6), integrating by parts, we get

$$\int_0^1 \left[q(t) + \int_0^t r(s)ds + \psi(t)\right] x'(t)dt - \left\langle \int_0^1 r(s)ds, x(1)\right\rangle - \langle \psi(1), x(1)\rangle - \langle \eta, x(1)\rangle = 0.$$

The above holds true, in particular, for all $x(\cdot) \in W^{1,2}(I)$ with $x(1) = 0$. Thus, from the Dubois–Raymond lemma it follows that there exists $r_0 \in \mathbf{R}^n$ such that

$$q(t) + \int_0^t r(s)ds + \psi(t) = r_0 \ \text{ a.e. in } I. \tag{5.7}$$

Define $p(t) := \int_0^t r(s)ds - r_0$. We have $q(t) = -p(t) - \psi(t)$ a.e. and from (5.5) and (5.1) we obtain (3.1) and (3.3). Using (5.7) we deduce that for any $x \in W^{1,2}(I)$

$$0 = \left\langle -\int_0^1 r(t)dt, x(1)\right\rangle + \langle r_0, x(1) - x(0)\rangle - \langle \psi(1), x(1)\rangle - \langle \eta, x(1)\rangle.$$

Applying this relation to all $x(\cdot) \in W^{1,2}(I)$ with $x(1) = 0$, we get $r_0 = 0$, $p(0) = 0$ and therefore $-\int_0^1 r(t)dt - \psi(1) - \eta = 0$. Consequently, $-p(1) - \psi(1) = \eta \in N_{K_1}(\bar{x}(1))$ and (3.2), (3.4) are satisfied with $\lambda = 0$.

Case 2. $\bar{S} \cap (Int(\mathcal{C} \cap \mathcal{C}_1)) \neq \emptyset$. Then $Int(\mathcal{C} \cap \mathcal{C}_1) = Int(\mathcal{C}) \cap Int(\mathcal{C}_1)$ and also $S \cap (Int(\mathcal{C} \cap \mathcal{C}_1)) \neq \emptyset$. Since $\mathcal{C} \cap \mathcal{C}_1$ and $\bar{S}$ are closed convex cones in $C(I)$ and $\bar{S} \cap (Int(\mathcal{C} \cap \mathcal{C}_1)) \neq \emptyset$ we infer that

$$(\bar{S} \cap \mathcal{C} \cap \mathcal{C}_1)^+ = \bar{S}^+ + \mathcal{C}^+ + \mathcal{C}_1^+ \tag{5.8}$$

(see, for instance, [4]). Let $\theta \in \mathbf{R}^n$ and consider a solution w to the differential inclusion

$$w' \in B(t, w), \ \ w(0) = \theta. \tag{5.9}$$

From the variational inclusion (Theorem 3.4 in [15]) we know that for all $s_i \to 0+$, $\theta_i \to \theta$ there exist solutions $x_i(\cdot)$ to (1.2) with $x_i(0) = \bar{x}(0) + s_i\theta_i$ such that $\frac{x_i(\cdot) - \bar{x}(\cdot)}{s_i}$ converge uniformly to $w(\cdot)$.

Define $h(\cdot,\cdot) : \mathbf{R}^n \times \mathbf{R}^n \to \mathbf{R} \cup \{+\infty\}$ by

$$h(\theta, v) = g^0(\bar{x}(1))(v) - \varphi(\theta).$$

Set $\mathcal{E} = \gamma(\bar{S} \cap Int(\mathcal{C} \cap \mathcal{C}_1))$. We claim that

$$h(\theta, v) \geq 0 \quad \forall\, (\theta, v) \in \mathcal{E}. \tag{5.10}$$

We first show that

$$h(\theta, v) \geq 0 \quad \forall\, (\theta, v) \in \gamma(S \cap Int(\mathcal{C} \cap \mathcal{C}_1)). \tag{5.11}$$

For this aim fix $w \in S \cap Int(\mathcal{C} \cap \mathcal{C}_1)$. Then, by Lemma 4.1, $w(t) \in Int(G(t))$ for all $t \in I$. From Hypothesis 3.3, continuity of w and compactness of I we deduce that for some $\varepsilon > 0$ and all $t \in I$, $\bar{x}(t) + [0, \varepsilon](w(t) + \varepsilon B) \subset K$.

Let $s_i \to 0+$, $\theta_i \to w(0)$ be such that $\bar{x}(0) + s_i\theta_i \in K$ and

$$D_x^+ V(0, \bar{x}(0))(w(0)) = \limsup_{i \to \infty} \frac{V(0, \bar{x}(0) + s_i\theta_i) - V(0, \bar{x}(0))}{s_i}$$

and x_i be solutions to (1.2) starting at $\bar{x}(0) + s_i\theta_i$ and such that $\frac{x_i(\cdot) - \bar{x}(\cdot)}{s_i}$ converge uniformly to $w(\cdot)$.

Then, by the dynamic programming principle,

$$\varphi(w(0)) \leq D_x^+ V(0, \bar{x}(0))(w(0)) \leq \limsup_{i \to \infty} \frac{g(x_i(1)) - g(\bar{x}(1))}{s_i} \leq g^0(\bar{x}(1))(w(1)).$$

Consequently, $h(w(0), w(1)) \geq 0$.

Consider next $w \in \bar{S} \cap Int(\mathcal{C} \cap \mathcal{C}_1)$ and $w_j \in S$ such that $\lim_{j \to \infty} w_j = w$ in $C(I)$. Then for all large j, $w_j \in S \cap Int(\mathcal{C} \cap \mathcal{C}_1)$ and, by (5.11),

$$h(w_j(0), w_j(1)) \geq 0.$$

Since $w(0) \in Int(G(0)) \subset dom(\varphi)$ and φ is concave, φ is continuous at $w(0)$. Thus passing to the limit in the last inequality when $j \to \infty$, we deduce (5.10).

Let $\overline{w}(\cdot) \in S \cap (Int(\mathcal{C} \cap \mathcal{C}_1))$. By Lemma 4.1 $\overline{w}(0) \in Int(G(0))$ and so $dom(h) - \mathcal{E} = \mathbf{R}^n \times \mathbf{R}^n$. We apply Lemma 2.6 to deduce that there exists $(a, c) \in \mathcal{E}^+$ such that

$$h(\theta, v) \geq \langle (a, c), (\theta, v) \rangle \quad \forall\, (\theta, v) \in \mathbf{R}^n \times \mathbf{R}^n. \tag{5.12}$$

From (5.12) and the definition of $h(\cdot,\cdot)$ we get $g^0(\bar{x}(1))(v) - \langle c, v \rangle - \langle a, \theta \rangle \geq \varphi(\theta)$ for every $(\theta, v) \in \mathbf{R}^n \times \mathbf{R}^n$. If $\theta = 0$ we obtain

$$c \in \partial^C g(\bar{x}(1)). \tag{5.13}$$

Consequently, for any $\theta \in \mathbf{R}^n$ we have $\varphi(\theta) \leq \langle -a, \theta \rangle$ and therefore

$$-a \in \partial^+ \varphi(0). \tag{5.14}$$

Since for every $w \in \bar{S} \cap Int(\mathcal{C} \cap \mathcal{C}_1)$, $\langle (a, c), \gamma(w) \rangle \geq 0$ we get $\gamma^*(a, c) \in (\bar{S} \cap Int(\mathcal{C} \cap \mathcal{C}_1))^+ = (\bar{S} \cap \mathcal{C} \cap \mathcal{C}_1)^+$. Hence, by (5.8), for some $\beta_0 \in \mathcal{C}^-$, $\beta_1 \in \mathcal{C}_1^-$, $\gamma^*(a, c) + \beta_0 + \beta_1 \in \bar{S}^+$. Denote by S^+ the positive polar of S in $W^{1,2}(I)^*$. Then $\gamma^*(a, c) + \beta_0 + \beta_1 \in S^+$. From (5.4), (5.5) it follows that there exist $(-r, q) \in L^+$ such that

$$\langle \gamma^*(a, c), x \rangle + \langle \beta_0 + \beta_1, x \rangle = \langle (1 \times D)^*(-r, q), x \rangle \ \ \forall\, x \in W^{1,2}(I)$$

or, equivalently, for any $x \in W^{1,2}(I)$

(5.15)
$$\langle \eta, x(1)\rangle + \langle a, x(0)\rangle + \langle c, x(1)\rangle = -\int_0^1 r(t)x(t)dt + \int_0^1 q(t)x'(t)dt - \int_0^1 x(t)d\psi(t)$$

for some $\psi \in NBV(I)$, $\eta \in N_{K_1}(\bar{x}(1))$ satisfying $\langle \beta_0, y\rangle = \int_0^1 y(s)d\psi(s)$ for all $y \in C(I)$ and $\langle \beta_1, w\rangle = \langle \eta, w(1)\rangle$ for all $w \in C(I)$.

We take $x(\cdot) \in W^{1,2}(I)$ such that $x(0) = x(1) = 0$ and we show as in Case 1 that there exists $r_0 \in \mathbf{R}^n$ that verifies (5.7). Define $p(t) = \int_0^t r(s)ds - r_0$. Thus $q(t) = -p(t) - \psi(t)$ a.e. in I and from (5.5) and (5.1) we deduce (3.1) and (3.3). Using again (5.15) and integrating by parts we obtain that for any $x \in W^{1,2}(I)$

$$\langle \eta, x(1)\rangle + \langle a, x(0)\rangle + \langle c, x(1)\rangle = -\langle r_0, x(0)\rangle + \langle -p(1) - \psi(1), x(1)\rangle.$$

We take first $x \in W^{1,2}(I)$ with $x(0) = 0$ and we find that $c + \eta = -p(1) - \psi(1)$ and, by (5.13), (3.2) holds true with $\lambda = 1$. From Lemma 4.2 we deduce that ψ satisfies (3.5) for some ν and μ as in the conclusions of our theorem.

If we take $x \in W^{1,2}(I)$ with $x(1) = 0$, then we get $a = -r_0 = p(0)$ and (3.4) follows from (5.14) with $\lambda = 1$.

We next prove (3.6). We already know that $\lambda + \|\psi\|_{TV} \neq 0$. Assume for a moment that $\lambda = 0$ and

$$\sup_{t\in(0,1)} ||p(t) + \psi(t)|| = 0. \tag{5.16}$$

Then $\|\psi\|_{TV} \neq 0$. From (3.1) and Hypothesis 3.2 we get $p'(t) = 0$ a.e. in I and, by (3.4), $p(\cdot) \equiv 0$. Therefore, by (3.2), $-\psi(1) \in N_{K_1}(\bar{x}(1))$ and, by (5.16), $\psi(\cdot) \equiv 0$ on $(0,1)$. Thus $\psi(1-) = 0$ and, via (3.5), we have that $\psi(1) \in G(1)^-$. Hence $\langle \psi(1), v_1\rangle \leq 0$ for all $v_1 \in G(1)$ and $\langle \psi(1), -v_2\rangle \leq 0$ for all $v_2 \in C_{K_1}(\bar{x}(1))$. This implies that $\psi(1) \in (G(1) - C_{K_1}(\bar{x}(1)))^-$. On the other hand, assumption $C_{K_1}(\bar{x}(1)) \cap Int(G(1)) \neq \emptyset$ yields $G(1) - C_{K_1}(\bar{x}(1)) = \mathbf{R}^n$ and we infer that $\psi(1) = 0$. Hence $\sup_{t\in I}||\psi(t)|| = 0$. This yields $\|\psi\|_{TV} = 0$ and so we derive a contradiction and (3.6) follows.

We have to check that when $\bar{x}(1) \in Int(K_1)$,

$$\lambda + var(\psi, (0,1]) \neq 0. \tag{5.17}$$

Indeed, assume for a moment that $\lambda + var(\psi, (0,1]) = 0$. Then $\|\psi\|_{TV} \neq 0$. By (3.2), $p(1) = -\psi(1) = -\psi(0+)$ and for all $t \in (0,1], \psi(t) = \psi(0+)$. Setting $q(t) := p(t) + \psi(0+)$ we deduce from (3.1) that $q'(t) \in A^*(t, -q(t))$ a.e. in I and $q(1) = 0$. But, by Hypothesis 3.2, $\|q'(t)\| \leq m\|q(t)\|$ for a.e. $t \in I$. This and the Gronwall inequality imply that $q(\cdot) \equiv 0$. By (3.4), $p(0) = 0$ and therefore $\psi \equiv 0$ contradicting to $\|\psi\|_{TV} \neq 0$. Inequality (5.17) is proved.

Let us assume next that there exists a solution $w(\cdot) \in W^{1,1}(I)$ to

$$\begin{aligned} w' &\in \overline{A(t,w) + T_{co(F(t,\bar{x}(t)))}(\bar{x}'(t))}, \quad w(1) \in Int(C_{K_1}(\bar{x}(1))), \\ w(t) &\in Int(G(t)) \quad \forall\, t \in I. \end{aligned}$$

We already know that there exist λ, p, ψ as in the statement of our theorem. Assume for a moment that $\lambda = 0$ and set $\eta = -p(1) - \psi(1) \in N_{K_1}(\bar{x}(1))$. Then, by

(3.4), $p(0) = 0$ and $\int_0^1 w(s)d\psi(s) = \int_{[0,1]} w(s)\nu(s)d\mu(s)$. Hence for all $w \in \mathcal{C} \cap \mathcal{C}_1$, $\int_{[0,1]} w(s)d\psi(s) + \langle \eta, w(1)\rangle \leq 0$. On the other hand, by the very definition of the adjoint process, for every $w \in S$ we have $\int_0^1 (p'w + pw' + \psi w')(s)ds \leq 0$. Thus $\langle p(1), w(1)\rangle + \int_0^1 \psi(s)w'(s)ds \leq 0$. Integrating by parts we deduce that $\langle \eta, w(1)\rangle + \int_0^1 w(s)d\psi(s) \geq 0$. The above yields $S \cap (Int(\mathcal{C} \cap \mathcal{C}_1)) = \emptyset$.

To deduce that $\lambda = 1$ it remains to verify that $S \cap (Int(\mathcal{C} \cap \mathcal{C}_1)) \neq \emptyset$. For every $i \geq 1$ define the measurable set $E_i = \{s \in I \mid ||w'(s)|| \leq i\}$. Then the Lebesgue measures $\mu_l(I \backslash E_i)$ converge to zero and $\lim_{i\to\infty} \int_{I\backslash E_i} ||w'(s)||ds = 0$. Consider $v_i(\cdot) \in L^\infty(I)$ defined by $v_i(s) = w'(s)$ for all $s \in E_i$ and $v_i(s) = 0$ otherwise and set $y_i(t) = w(0) + \int_0^t v_i(s)ds$ for all $t \in I$. Then y_i converge uniformly to w. Furthermore, for almost all $s \in E_i$, $dist(y_i'(s), B(s, y_i(s))) \leq m||y_i(s) - w(s)||$ and for almost all $s \in I\backslash E_i$, $dist(y_i'(s), B(s, y_i(s))) \leq m||y_i(s)||$. By the Filippov theorem (see, for instance, [3, p. 401]) there exist $M > 0$ and $w_i \in W^{1,1}(I)$ such that $w_i'(s) \in B(s, w_i(s))$ a.e. in I and

$$||w_i - y_i||_\infty \leq \varepsilon_i := M(||y_i - w||_\infty + \mu_l(I\backslash E_i)), \quad ||w_i'(t) - y_i'(t)|| \leq m\varepsilon_i + m||y_i(t)|| \text{ a.e. in } I.$$

Then $w_i \in W^{1,\infty}(I)$ and the sequence w_i converge uniformly to w. Hence for all large i, $w_i \in S \cap (Int(\mathcal{C} \cap \mathcal{C}_1))$.

Proof of Theorem 3.6. The proof follows by exactly the same arguments as the ones in the proof of Theorem 3.4. The only change is that in Case 2 it can be directly proved that for any $w(\cdot) \in \mathcal{E}$

$$\left\langle \frac{\partial V}{\partial x}(0, \bar{x}(0)), w(0) \right\rangle \leq g^0(\bar{x}(1))(w(1))$$

and then we apply Lemma 2.6 to the convex function $h(\theta, v) = g^0(\bar{x}(1))(v) - \langle \frac{\partial V}{\partial x}(0, \bar{x}(0)), \theta\rangle$.

Proof of Theorem 3.10.

It is not restrictive to assume that $\rho < 1$. Notice that $d(\bar{x}(t)) \leq 0$ for all $t \in I$. Set $G(t) = T_K(\bar{x}(t))$. We claim that $G(\cdot)$ satisfies Hypothesis 3.3. Indeed for all $t \in I$ such that $\bar{x}(t) \in \partial K$,

$$G(t) = \{v \in \mathbf{R}^n \mid \langle n(\bar{x}(t)), v\rangle \leq 0\}$$

and

$$Int\ (G(t)) = \{v \in \mathbf{R}^n \mid \langle n(\bar{x}(t)), v\rangle < 0\}.$$

Furthermore, $G(t) = \mathbf{R}^n$ whenever $\bar{x}(t) \in Int(K)$. Since $n(\cdot)$ is locally Lipschitz on the boundary of K, the set-valued map $I \ni t \rightsquigarrow Int\ (G(t))$ is lower semicontinuous on I. Thus also $G(\cdot)$ is lower semicontinuous on I. If $\bar{x}(t) \in Int\ (K)$, then for all s sufficiently close to t, $\bar{x}(s) \in Int\ (K)$ and therefore for every $v \in \mathbf{R}^n$ there exists $\epsilon > 0$ such that for all $s \in [t - \epsilon, t + \epsilon] \cap I$, $\bar{x}(s) + [0, \epsilon](v + \epsilon B) \subset K$.

Assume next that $t \in I$ is so that $\bar{x}(t) \in \partial K$ and fix $v \in Int\ (G(t))$. Then $\langle n(\bar{x}(t)), v\rangle < 0$. Notice that the oriented distance is Lipschitz with the Lipschitz constant one on η-neighborhood of ∂K.

By the mean value theorem for all $(s, h) \in I \times \mathbf{R}_+$ sufficiently close to $(t, 0)$ there exist $\theta(s, h) \in [0, 1]$ such that

$$d(\bar{x}(s) + hv) = d(\bar{x}(s)) + h\langle \nabla d(\bar{x}(s) + \theta(s, h)hv), v\rangle \leq h\langle \nabla d(\bar{x}(s) + \theta(s, h)hv), v\rangle.$$

By Hypothesis 3.9 (i) there exist $\delta > 0$ such that for all $s \in [t-\delta, t+\delta] \cap I$, $h \in [0,\delta]$, $\langle \nabla d(\bar{x}(s) + \theta(s,h)hv), v\rangle \leq -\delta$. Therefore for all $v' \in v + \delta B$, $d(\bar{x}(s) + hv') \leq d(\bar{x}(s) + hv) + h|v' - v| \leq -h\delta + h\delta = 0$. Consequently, $\bar{x}(s) + [0,\delta](v + \delta B) \subset K$. This proves our claim.

By Theorem 3.4 it is enough to show that there exists a solution to

$$w' \in \overline{A(t,w) + T_{co(F(t,\bar{x}(t)))}(\bar{x}'(t))}, \quad w(t) \in Int(G(t)) \quad \forall\, t \in I.$$

From [3, Theorem 9.5.3] it follows that there exist $L > 0$ and a selection $\gamma(t,w) \in A(t,w)$ such that for all $w \in \mathbf{R}^n$, $\gamma(\cdot, w)$ is measurable, $\gamma(t,\cdot)$ is L-Lipschitz and $\gamma(t,0) = 0$ for all $t \in I$. Thus $|\gamma(t,w)| \leq L|w|$.

Define $\Gamma := \{t \in I \mid \bar{x}(t) \in \partial K + \eta B\}$. By the measurable selection theorem (see, for instance, [3]) there exists a measurable selection $\Gamma \ni s \to v(s) \in F(s, \bar{x}(s))$ such that $\langle \nabla d(\bar{x}(s)), v(s)\rangle \leq -\rho$ for almost all $s \in \Gamma$. We extend v on I by setting $v(s) = \bar{x}'(s)$ for all $s \notin \Gamma$.

Then $\mathbf{R}_+(v(s) - \bar{x}'(s)) \in T_{co(F(s,\bar{x}(s)))}(\bar{x}'(s))$. We prove that there exists a solution w to

$$w' \in \gamma(s,w) + \mathbf{R}_+(v(s) - \bar{x}'(s)) \tag{5.18}$$

such that $w(s) \in Int\ (G(s))$ for all $s \in I$.

If for all $s \in I$, $\bar{x}(s) \in Int(K)$, then any solution to $w' = \gamma(s,w)$ satisfies $w(s) \in Int\ (G(s))$. Assume next that $\bar{x}(I) \cap \partial K \neq \emptyset$ and set $s_0 = \inf\{s \in I \mid \bar{x}(s) \in \partial K\}$. Let $\bar{w}_0 \in Int\ (G(s_0))$ and consider the solution $\bar{w}$ to

$$w'(s) \in \gamma(s,w),\ s \in [0,s_0],\ \bar{w}(s_0) = \bar{w}_0.$$

Then $\bar{w}(s) \in Int\ (G(s))$ for all $s \in [0,s_0]$.

Denote by k a Lipschitz constant of $\nabla d(\bar{x}(\cdot))$ on $\{t \mid \bar{x}(t) \in \partial K + \eta B\}$ and set

$$M = \sup_{s\in I}\ \sup_{v\in F(s,\bar{x}(s))} ||v||, \quad \chi = max\left\{\frac{1}{\eta}, \frac{k+L+1}{\rho}\left(L + 2M\frac{k+L+1}{\rho}\right)\right\}, \quad \delta = \frac{1}{2M\chi}.$$

Then $\eta \geq 1/\chi$. We claim that it is enough to show that for any $s_0 \leq t_0 < 1$ such that $\bar{x}(t_0) \in \partial K$ and any $w_0 \in Int(G(t_0))$ there exist $t_1 \geq t_0 + \min\{1 - t_0, \delta\}$ and a solution to (5.18) defined on $[t_0, t_1]$ with $w(t_0) = w_0$ and $w(s) \in Int\ (G(s))$ for all $s \in [t_0, t_1]$ and either $t_1 = 1$ or $\bar{x}(t_1) \in \partial K$. Indeed if we prove this property, then we can extend $\bar{w}(\cdot)$ on the time interval $[s_0, 1]$ in a finite number of steps.

So fix $t_0 \geq s_0$ such that $\bar{x}(t_0) \in \partial K$ and $w_0 \in Int(G(t_0))$. Then $w_0 \neq 0$. Define

$$t_2 = \max\left\{s \in [t_0,1] \mid \bar{x}([t_0,s]) \subset \partial K + \frac{1}{2\chi}B\right\} > t_0.$$

Then either $t_2 = 1$ or $d(\bar{x}(t_2)) = -\frac{1}{2\chi}$. In this second case

$$-\frac{1}{2\chi} = d(\bar{x}(t_2)) = d(\bar{x}(t_0)) + \int_{t_0}^{t_2} \langle \nabla d(\bar{x}(s)), \bar{x}'(s)\rangle ds.$$

Thus $\frac{1}{2\chi} \leq M(t_2 - t_0)$ and so $t_2 - t_0 \geq 1/2M\chi = \delta$. Consider the solution w to

$$w' = \gamma(s,w) + \frac{k+L+1}{\rho}||w||(v(s) - \bar{x}'(s)), \quad w(t_0) = w_0$$

and set $\xi(s) = \nabla d(\bar{x}(s))$. Notice that $w(t_2) \neq 0$. Fix any $t \in [t_0, t_2]$ with $\bar{x}(t) \in \partial K$. We have to check that $w(t) \in Int\ (G(t))$. By the choice of $v(\cdot)$

$$\langle \xi(t), w(t)\rangle = \langle \xi(t_0), w_0\rangle + \int_{t_0}^{t} \langle \xi, w\rangle'(s)ds \leq \int_{t_0}^{t} ||\xi'(s)|| \cdot ||w(s)||ds + \int_{t_0}^{t} \langle \xi(s), w'(s)\rangle ds$$

$$\leq (k+L)\int_{t_0}^{t} ||w(s)||ds + \frac{k+L+1}{\rho}\int_{t_0}^{t} \langle \nabla d(\bar{x}(s)), v(s)\rangle ||w(s)||ds -$$

$$\frac{k+L+1}{\rho}\int_{t_0}^{t} d(\bar{x})'(s)||w(s)||ds \leq -\int_{t_0}^{t} ||w(s)||ds - \frac{k+L+1}{\rho}\int_{t_0}^{t} d(\bar{x})'(s)||w(s)||ds.$$

On the other hand, integrating by parts, we obtain

$$-\int_{t_0}^{t} d(\bar{x})'(s)||w(s)||ds = -d(\bar{x}(t))||w(t)|| + d(\bar{x}(t_0))||w(t_0)|| + \int_{t_0}^{t} d(\bar{x}(s))||w||'(s)ds$$

$$\leq \int_{t_0}^{t} |d(\bar{x}(s))| \cdot ||w'(s)||ds \leq \int_{t_0}^{t} \left(L + 2M\frac{k+L+1}{\rho}\right) |d(\bar{x}(s))| \cdot ||w(s)||ds.$$

Consequently,

$$-\frac{k+L+1}{\rho}\int_{t_0}^{t} d(\bar{x})'(s)||w(s)||ds \leq \chi \int_{t_0}^{t} |d(\bar{x}(s))| \cdot ||w(s)||ds \leq \frac{1}{2}\int_{t_0}^{t} ||w(s)||ds.$$

This implies that

$$\langle \xi(t), w(t)\rangle \leq -\int_{t_0}^{t} ||w(s)||ds + \frac{1}{2}\int_{t_0}^{t} ||w(s)||ds = -\frac{1}{2}\int_{t_0}^{t} ||w(s)||ds < 0.$$

So we defined $w(\cdot)$ on $[t_0, t_2]$ in such a way that $w(s) \in Int(G(s))$ for all $s \in [t_0, t_2]$. If $t_2 = 1$ or $\bar{x}(t_2) \in \partial K$, then $w(\cdot)$ is as required. Assume next that $t_2 < 1$ and $\bar{x}(t_2) \notin \partial K$. Set $w_2 = w(t_2)$. If for all $s > t_2$, $\bar{x}(s) \in Int(K)$, then w can be extended on $[t_2, 1]$ by the solution to $w' = \gamma(s, w),\ w(t_2) = w_2$. So we obtain a solution w to (5.18) satisfying $w(s) \in Int(G(s))$ for all $s \in [t_0, 1]$. It remains to consider the case when for some $t_2 < s \leq 1$, $\bar{x}(s) \in \partial K$. Define $t_1 = \min\{s > t_2 \mid \bar{x}(s) \in \partial K\}$ and let

$$t_3 = \max\left\{s \in [t_2, t_1] \mid\ |d(\bar{x}(\tau))| = \frac{1}{2\chi}\right\} < t_1.$$

Then for all $s \in [t_3, t_1]$, $|d(\bar{x}(s))| \leq \rho/4M$.

We extend $w(\cdot)$ to the time interval $[t_2, t_3]$ by the solution to $w' = \gamma(s, w),\ w(t_2) = w_2$. Then $w(s) \in Int\ (G(s))$ for all $s \in [t_2, t_3]$. Set $w_3 = w(t_3) \neq 0$ and extend w on the time interval $[t_3, t_1]$ by the solution to

$$w' = \gamma(s, w) + \frac{k+L+1}{\rho}||w||(v(s) - \bar{x}'(s)) + \frac{2||w_3||}{\rho(t_1 - t_3)}(v(s) - \bar{x}'(s)),\ w(t_3) = w_3.$$

Then $w(s) \in Int\ (G(s)) = \mathbf{R}^n$ for all $s \in [t_3, t_1)$. It remains to check that $w(t_1) \in Int(G(t_1))$.

As before, by the choice of $v(\cdot)$,

$$\langle \xi(t_1), w(t_1)\rangle \leq ||w_3|| + \int_{t_3}^{t_1} \langle \xi, w\rangle'(s)ds \leq ||w_3|| + \int_{t_3}^{t_1} k||w(s)||ds + \int_{t_3}^{t_1} \langle \xi(s), w'(s)\rangle ds$$

$$\leq ||w_3|| - \int_{t_3}^{t_1} ||w(s)||ds + \frac{2||w_3||}{\rho(t_1-t_3)} \int_{t_3}^{t_1} \langle \nabla d(\bar{x}(s)), v(s)\rangle ds - \frac{k+L+1}{\rho} \int_{t_3}^{t_1} d(\bar{x})'(s)||w(s)||ds$$

$$-\frac{2||w_3||}{\rho(t_1-t_3)} \int_{t_3}^{t_1} d(\bar{x})'(s)ds \leq -\int_{t_3}^{t_1} ||w(s)||ds + \frac{k+L+1}{\rho} \int_{t_3}^{t_1} d(\bar{x})(s)||w(s)||'ds - ||w_3|| \leq$$

$$-\int_{t_3}^{t_1} ||w(s)||ds + \chi \int_{t_3}^{t_1} |d(\bar{x}(s))| \cdot ||w(s)||ds - ||w_3|| + \frac{4M||w_3||}{\rho(t_1-t_3)} \int_{t_3}^{t_1} |d(\bar{x}(s))|ds \leq$$

$$-\frac{1}{2} \int_{t_3}^{t_1} ||w(s)||ds - ||w_3|| + ||w_3|| < 0.$$

This yields $w(t_1) \in Int(G(t_1))$. The proof is complete.

Proof of Theorem 3.11. In the difference with Theorem 3.4 we have $m(\cdot) \in L^1(I)$ instead of $L^\infty(I)$. For this reason instead of (5.4), (5.5) we use the integration by parts formula. The proof is very similar to the one of Theorem 3.4 so we only sketch it. Let $\mathcal{C}$, $\mathcal{C}_1$, γ have the same meaning as in the proof of Theorem 3.4 and set

$$S := \{w(\cdot) \in W^{1,1}(I) \mid \ w'(s) \in A(s, w(s)) + T_{co(F(s,\bar{x}(s)))}(\bar{x}'(s)) \text{ a.e. in } I\}.$$

Let $\bar{S}$ denote the closure of S in $C(I)$. By Lemma 4.1 $Int(\mathcal{C}) \neq \emptyset$. We only consider the case $Int(\mathcal{C}) \cap Int(\mathcal{C}_1) \cap \bar{S} \neq \emptyset$ since arguments used in the proof of Theorem 3.4 when $Int(\mathcal{C}_1) \cap Int(\mathcal{C}) = \emptyset$ and $Int(\mathcal{C} \cap \mathcal{C}_1) \cap \bar{S} = \emptyset$ correspond to $\lambda = 0$ and are of the same nature as in the proof of Theorem 3.4 via integration by parts arguments given below.

As in Case 2 of the proof of Theorem 3.4 we show that there exist $-a \in \partial^+\varphi(0)$, $c \in \partial^C g(\bar{x}(1))$, $\beta_0 \in \mathcal{C}^-$ and $\beta_1 \in \mathcal{C}_1^-$ such that $\gamma^*(a,c) + \beta_0 + \beta_1 \in S^+$. Let $\psi \in NBV(I)$ and $\eta \in N_{K_1}(\bar{x}(1))$ be such that for all $w \in C(I)$, $\langle \beta_0, w\rangle = \int_0^1 w(s)d\psi(s)$, $\langle \beta_1, w\rangle = \langle \eta, w(1)\rangle$.

By Lemma 4.2 there exist a positive Radon measure μ, a selection $\nu(s) \in N_K(\bar{x}(s)) \cap B$ μ-a.e. such that (3.5) holds true. Furthermore, for all $w \in S$

$$\langle \eta, w(1)\rangle + \langle a, w(0)\rangle + \langle c, w(1)\rangle + \int_0^1 w(t)d\psi(t) \geq 0.$$

Let p solve (3.1) with $p(1) = -c - \psi(1) - \eta$. From the last inequality, integrating by parts, we deduce that

$$\langle a, w(0)\rangle - \langle p(1), w(1)\rangle - \int_0^1 \langle \psi(t), w'(t)\rangle dt \geq 0 \ \ \forall\, w \in S. \tag{5.19}$$

Notice next that for every solution to $w' = A(s,w)$ on $[0,1]$ we have

$$0 = \int_0^1 (\langle p'(t), w(t)\rangle + \langle p(t) + \psi(t), w'(t)\rangle)dt = \langle p(1), w(1)\rangle - \langle p(0), w(0)\rangle + \int_0^1 \langle \psi(t), w'(t)\rangle dt.$$

This and (5.19) imply that for all $w(0) \in \mathbf{R}^n$, $\langle a - p(0), w(0)\rangle \geq 0$. So $a = p(0)$.

To prove (3.3) consider an integrable selection $v(t) \in T_{co(F(t,\bar{x}(t)))}(\bar{x}'(t))$ and let $w \in S$ be such that $w(0) = 0$ and $w'(t) = A(t, w(t)) + v(t)$ a.e. Then

$$\langle p(1), w(1)\rangle = \int_0^1 (\langle p'(t), w(t)\rangle + \langle p(t), w'(t)\rangle)dt.$$

Since p solves (3.1) with $p(1) = -c - \psi(1) - \eta$, from the last equality and (5.19) we deduce

$$\langle p(1), w(1)\rangle = -\int_0^1 \langle \psi(t), w'(t) - v(t)\rangle dt + \int_0^1 \langle p(t), v(t)\rangle dt \geq \langle p(1), w(1)\rangle + \int_0^1 \langle p(t) + \psi(t), v(t)\rangle dt.$$

Consequently, $0 \geq \int_0^1 \langle p(t) + \psi(t), v(t)\rangle dt$. Since $F(t, \bar{x}(t)) - \bar{x}'(t) \subset T_{co(F(t,\bar{x}(t)))}(\bar{x}'(t))$ and $v(t) \in T_{co(F(t,\bar{x}(t)))}(\bar{x}'(t))$ is an arbitrary integrable selection, we deduce (3.3) from the measurable selection theorem. Exactly the same arguments as those used in the proof of Theorem 3.4 imply that if $C_{K_1}(\bar{x}(1)) \cap Int(G(1)) \neq \emptyset$, then $\lambda + \sup_{t\in(0,1)} ||p(t) + \psi(t)|| \neq 0$ and if $\bar{x}(1) \in Int(K_1)$, then $\lambda + var(\psi, (0,1]) \neq 0$, and that $\lambda = 1$ if there exists a solution $\bar{w}(\cdot)$ to (3.14), (3.15).

To prove the last statement, notice that $\bar{w}(\cdot)$ solves the constrained linear control system (3.14), (3.15) also on the time interval $[t,1]$. If $\bar{x}(1) \in Int(K_1)$ and g is differentiable at $\bar{x}(1)$, then by Remark (iv) after Theorem 3.4, $p(1) = -\nabla g(\bar{x}(1)) - \psi(1)$.

From the already proved first statement of Theorem 3.11, replacing the time interval $[0,1]$ by $[t,1]$, we deduce that there exist ψ_t, μ_t, ν_t as in Theorem 3.11 such that a solution $q(\cdot)$ to the adjoint system

$$q' = A^*(s, -q - \psi_t), \quad q(1) = -\nabla g(\bar{x}(1)) - \psi_t(1)$$

satisfies $-q(t) \in \partial^+ \varphi_t(0)$ and $\langle q(s) + \psi_t(s), \bar{x}'(s)\rangle = \max_{v\in co(F(s,\bar{x}(s)))} \langle q(s) + \psi_t(s), v\rangle$ for almost all $s \in [t,1]$. Setting $r(s) = q(s) - p(s)$, we end the proof.

Acknowledgment. The authors are grateful to anonymous referees for constructive suggestions which helped to improve considerably the first version of this manuscript.

INPUT-TO-STATE STABILITY OF RATE-CONTROLLED BIOCHEMICAL NETWORKS*

MADALENA CHAVES†

Abstract. In this paper, the study of the class of biochemical systems known as zero deficiency networks is extended to the case of time-varying kinetic parameters. We show that the resulting class of nonlinear systems with inputs satisfies a notion of input-to-state stability uniformly over a set of parameters. In particular, the input-to-state stability estimates allow us to characterize the robustness of zero deficiency networks with respect to perturbations in the parameters as well as study their stability when the reaction rates are controlled by an independent process.

Key words. stability, robustness, biochemical networks

1. Introduction. A biochemical network consists of the interactions among a certain number of species, according to a set of specified reactions that induce a dynamics for the species' concentrations. The time evolution of the species' concentrations is usually modeled by a system of differential equations together with a family of parameters that characterize the reaction rates. These parameters may depend on various external factors and stimuli such as temperature, the concentration of ligands/substrates, or the concentration of an enzyme which may be regulated by an independent dynamics.

Thus biological systems may, in many cases, be viewed as cascades of biochemical networks, where the output of the ith level becomes the input to the $(i+1)$th level of the cascade. This is indeed the structure of many intracellular signal transduction pathways, which are central to biological processes. For example, the binding of a ligand to a cell receptor triggers a sequence of biochemical reactions [12] that ultimately lead to a cell response (such as contraction, motility, or proliferation).

Each level in the cascade may be studied independently as a system with inputs, and in particular we will focus on the input-to-state stability properties of such system. We are also interested in studying the effect of small parameter perturbations (which may be due, for instance, to variations in the room temperature or other experimental setup problems) on the steady-state response of the system. The notion of a parameter robust system should reflect the idea that these *small perturbations* should not greatly affect the qualitative response and guarantee that the output error will also be small. In addition, the input-to-state stability properties of a system provide a framework for the analysis of the stability and convergence of cascades of systems (see, for instance, [15, 2]).

A mathematical model for a certain family of biochemical networks, where the reactions satisfy the mass action kinetics principle, was introduced by Horn and Jackson in 1972 [9] and followed up by the work of Feinberg [6, 7, 8]. These authors

developed a rich and beautiful theory on these systems, also known in the literature as *zero deficiency networks*. This model accommodates a wide variety of significant biological systems, including many models for enzymatic mechanisms [14], a model for T-cell receptor signal transduction [13], and receptor–ligand interactions and G-protein coupled receptor activity in cyclic signaling pathways [3, 12, 19]. The models of receptor–ligand interaction are of interest for biomedical applications as well as for drug design: the concentration–response curves associated with some of the basic models [3, 12] may also be analyzed in the context of these zero deficiency networks [5].

The zero deficiency networks may be characterized in terms of a strongly connected graph and the corresponding irreducible matrix, while the mass action kinetics property leads to nonlinear systems with polynomial vector fields. These are the systems we consider in this paper: for these systems, which exhibit multiple steady states, the state space may be viewed as a (disjoint) union of invariant manifolds (which are parallel translates of a given subspace of $\mathbb{R}^n$) so that to each of these invariant manifolds corresponds a distinct (globally) asymptotically stable steady state. The idea of invariant sets of the state space and the existence of steady states, and how these are affected by the external inputs or perturbations will be central to our analysis.

Recently [17], this class of nonlinear systems was studied from a control theory point of view, and the stability and other properties for the system with no inputs were further analyzed. In [17] a formalism is developed for dealing with this type of systems and several results are established which will be frequently referred to in the present work.

We first introduce the class of systems to be studied and recall some basic results (section 2). The definition and characterization of the notion of uniformly semiglobal input-to-state stable systems as well as the statement of the main results are given in section 3. The input-to-state stability estimates are established and the main theorems are proved in sections 5 and 6. In section 4 we show the dependence of steady states of the system on its parameters: the unique steady state in each invariant manifold is an analytic function of the parameters. Section 7 summarizes the main contributions in this paper.

2. Some notation and previous results. Let $n \geq m$ be integers and let $x \in \mathbb{R}^n$. Introduce the *positive orthant*

$$\mathbb{R}^n_{>0} = \{(x_1, \ldots, x_n) \in \mathbb{R}^n : x_i > 0 \quad \forall\, i\}$$

and the *closed positive orthant*

$$\mathbb{R}^n_{\geq 0} = \{(x_1, \ldots, x_n) \in \mathbb{R}^n : x_i \geq 0 \quad \forall\, i\}.$$

Assume given two matrices $A = (a_{ij}) \in \mathbb{R}^{m\times m}_{\geq 0}$ and $B \in \mathbb{N}_0^{n\times m}$, where the columns of B are denoted by $b_1, \ldots, b_m$. In our model of biochemical reactions there are n distinct species whose concentrations are given by $x = (x_1, \ldots, x_n)'$ and m *complexes*, each complex denoting a set of reactants or products in a reaction. The complexes are represented by the column vectors $b_1, \ldots, b_m$ with $b_j = (b_{1j}, \ldots, b_{nj})'$ and $b_{lj} \neq 0$ if the species l appears in the complex j. The matrix $A = (a_{ij})$ is the matrix of the kinetic constants, and an entry $a_{ij} \neq 0$ means that complex i is being produced from complex j.

The model for biochemical reaction networks of the Horn–Jackson–Feinberg zero

deficiency type, with mass action kinetics, is as follows:

$$\dot{x} = f_A(x) := \sum_{i=1}^{m}\sum_{j=1}^{m} a_{ij} x_1^{b_{1j}} x_2^{b_{2j}} \cdots x_n^{b_{nj}} (b_i - b_j). \tag{2.1}$$

Since the vector $x \in \mathbb{R}^n$ represents the concentration of each species involved in the reactions, we will be interested only in those trajectories that evolve in the positive orthant. In fact, it is easy to see that the positive orthant $\mathbb{R}^n_{>0}$ is a forward-invariant set for the system (2.1) (see also section 5). We have the following assumptions on A and B.

(a) The matrix $B = (b_1, \ldots, b_m)$ has nonnegative integer entries; it has full column rank and none of its rows vanishes completely.

(b) The matrix $A = (a_{ij})$ has nonnegative entries (without loss of generality, we assume that its diagonal entries are zero, since the corresponding terms would be of the form $a_{ii} x_1^{b_{1i}} \cdots x_n^{b_{ni}} (b_i - b_i) \equiv 0$) and is assumed to be irreducible.

This last property is equivalent to saying that the incidence graph of A is strongly connected, and it describes the following property of the network: there is a chemical pathway connecting every pair of complexes, but the pathway leading from b_i to b_j may be different from the pathway leading from b_j back to b_i (in other words, each individual chemical reaction is not necessarily reversible). Another equivalent definition of irreducibility says that there is an integer k such that all the entries of the matrix $(A + I)^k$ are strictly positive (see [10]).

Example. The simplest model for the interaction of a cell surface receptor with a specific ligand is depicted as $R + L \leftrightharpoons C$. Here we have three species ($n = 3$): receptor (R), ligand (L), and receptor–ligand product (C). There are only two complexes ($m = 2$): $R + L$ and C. Let x_1, x_2, and x_3 denote the concentrations of R, L, and C, respectively. Then the two columns of matrix B are $b_1 = (1, 1, 0)'$ and $b_2 = (0, 0, 1)'$. The matrix A is of size 2 and its nonzero elements are a_{21} (the rate constant for $R + L \to C$) and a_{12} (the rate constant for $C \to R + L$). It is easy to see that $\dot{x}_1 = \dot{x}_2 = -\dot{x}_3 = -a_{21} x_1 x_2 + a_{12} x_3$. A network involving two distinct receptor conformations is shown in Figure 1.

Example. Another simple example is a dimer model, where the ligand binds to two receptors, according to the diagram $2R + L \leftrightharpoons R + C_1 \leftrightharpoons C_2$. In this case $n = 4$ and $m = 3$. Setting $x = (R, L, C_1, C_2)$, the matrix B consists of the vectors $b_1 = (2, 1, 0, 0)'$, $b_2 = (1, 0, 1, 0)'$, and $b_3 = (0, 0, 0, 1)'$. The nonnegative entries of the matrix A are a_{21}, a_{12}, a_{32}, and a_{23}. Again, it is easy to see that properties (a) and (b) are satisfied. At any given time, the concentration of receptors is given by the equation $\dot{R} = -a_{21} R^2 L - (a_{32} - a_{12}) R C_1 + a_{23} C_2$, and the concentration of ligand is given by $\dot{L} = -a_{21} R^2 L + a_{12} R C_1$. The concentrations of C_1 and C_2 are given by $\dot{C}_1 = -(a_{12} + a_{32}) R C_1 + a_{21} R^2 L + a_{23} C_2$ and $\dot{C}_2 = -a_{23} C_2 + a_{32} R C_1$, respectively.

In this paper, we wish to study system (2.1) when the parameters a_{ij} are allowed to be *time variant*. Values of the parameters should be such that, at each time instant, the matrix $A = (a_{ij})$ is irreducible, so we consider the set of irreducible $m \times m$ matrices whose entries are nonnegative:

$$\mathcal{A}_{\geq 0} = \left\{ A \in \mathbb{R}^{m \times m} : A \geq 0 \text{ and } (A + I)^k > 0 \text{ for some power } k \right\}$$

(the inequality $A \geq 0$ (resp., $A > 0$) means that every entry of the matrix on the left-hand side is nonnegative (resp., positive)). Let $|A|_{\text{ecl}}$ denote the matrix norm induced by the vector norm $|\cdot|$ (the Euclidean norm). Throughout this paper, we will

define an *input* $u(\cdot)$ to be a piecewise locally Lipschitz function, with a finite number of discontinuities, that is, there exist $\ell \in \mathbb{N}$ and numbers $0 = T_0 < T_1 < \cdots < T_\ell < T_{\ell+1} = \infty$ such that the function u is locally Lipschitz on each interval (T_{i-1}, T_i): for each $i = 1, \ldots, \ell+1$ and each compact interval $J \subset (T_{i-1}, T_i)$, there exists $\kappa > 0$ such that

$$|u(t) - u(s)| \leq \kappa |t - s| \quad \forall\, s, t \in J. \tag{2.2}$$

In addition, the mass action kinetics model may be generalized as in [17], so we will consider the system with inputs

$$\dot{x} = f(x, u) := \sum_{i=1}^{m} \sum_{j=1}^{m} u_{ij} \theta_1(x_1)^{b_{1j}} \theta_2(x_2)^{b_{2j}} \cdots \theta_n(x_n)^{b_{nj}} (b_i - b_j), \tag{2.3}$$

where the same assumptions on B hold and each map $\theta_i : \mathbb{R} \to [0, +\infty)$ has the following properties:

(c) θ_i is real analytic;
(d) $\theta_i(0) = 0$;
(e) $\int_0^1 |\ln \theta_i(r)|\, dr < \infty$;
(f) its restriction to $\mathbb{R}_{\geq 0}$ is strictly increasing and onto the set $[0, \sigma_i)$, where $0 < \sigma_i \leq +\infty$.

Before stating the last condition that the functions θ_i should satisfy, let us introduce the following vector functions:

$$\rho^{[n]}(x) = (\ln \theta_1(x_1), \ldots, \ln \theta_n(x_n))' \quad \text{and} \quad \exp^{[n]}(v) = (e^{v_1}, \ldots, e^{v_n})'$$

defined on $\mathbb{R}^n_{>0}$ and $\mathbb{R}^n$, respectively. (From now on, we will drop the superscript n of $\rho^{[n]}$ and $\exp^{[n]}$, since its value is usually clear from the context.)

Each θ_i (restricted to $\mathbb{R}_{>0}$) is onto the set $(0, \sigma_i)$, so each function $\rho_i = \ln \theta_i$ (for the restriction of θ_i to $\mathbb{R}_{>0}$) is onto $(-\infty, \bar{\rho}_i)$ with $\bar{\rho}_i = \ln \sigma_i$. Since θ_i (restricted to $\mathbb{R}_{\geq 0}$) is strictly increasing, ρ_i has an inverse function, which is onto $\mathbb{R}_{>0}$: $\rho_i^{-1} : (-\infty, \bar{\rho}_i) \to \mathbb{R}_{>0}$. Each function θ_i should also satisfy

(g) for any given constant p, $\lim_{t \to \ln \sigma_i} \int_a^t \rho_i^{-1}(s)\, ds - pt = +\infty$ for any $a < \ln \sigma_i$.

Note that, for any constant p, there exists $t_0 \in (-\infty, \bar{\rho}_i)$ such that $\rho_i^{-1}(s) > p + 1$ for all $s \geq t_0$. Therefore, when $\sigma_i = +\infty$, condition (g) always holds. The case of mass action kinetics corresponds to $\theta_i(r) = |r|\ \forall\, i$. Another example of interest is the case $\theta_i(r) = \frac{|r|}{k+|r|}$ with $k > 0$. Even though condition (g) will not be used explicitly in this paper, it is necessary to prove some auxiliary results such as Lemma IV.1 in [17], which will be used in section 4.

For the case of a constant matrix A, system (2.3) has been extensively studied. It takes the form

$$\dot{x} = f(x, A) := f_A(x), \tag{2.4}$$

and we next recall some results already established about this system, which are given in [6, 7, 8, 9] (for the particular case of mass action kinetics), and can also be found in [17] (for the general case).

For any two vectors $a, b \in \mathbb{R}^n$, let $\langle a, b \rangle$ denote their dot product. Define the *stoichiometric space*

$$\mathcal{D} = \text{ span } \{b_i - b_j : i, j = 1, \ldots, m\}$$

and also consider its orthogonal space

$$\mathcal{D}^{\perp} := \{v \in \mathbb{R}^n : \ \langle v, d\rangle = 0 \quad \forall\, d \in \mathcal{D}\}.$$

Then, for any $v \in \mathcal{D}^{\perp}$, notice that

$$\langle f_A, v\rangle = \sum_{i=1}^{m}\sum_{j=1}^{m} a_{ij} x_1^{b_{1j}} \cdots x_n^{b_{nj}} \ \langle (b_i - b_j), v\rangle \equiv 0 \tag{2.5}$$

by the definition of v. Hence $\langle x(t), v\rangle$ =constant= $\langle x(0), v\rangle$, and we have

$$\langle x(t) - x(0), v\rangle = 0 \quad \forall\, v \in \mathcal{D}^{\perp} \ \Leftrightarrow \ x(t) - x(0) \in \mathcal{D} \ \Leftrightarrow \ x(t) \in x(0) + \mathcal{D}.$$

Therefore, the parallel translates of the stoichiometric space, $p + \mathcal{D}$ with $p \in \mathbb{R}^n_{>0}$, define invariant manifolds for the system $\dot{x} = f_A(x)$. For each $p \in \mathbb{R}^n_{>0}$, we will define a *positive class* of system (2.4) to be

$$\mathcal{S} := (p + \mathcal{D}) \cap \mathbb{R}^n_{\geq 0} = \{p + d : d \in \mathcal{D}\} \cap \mathbb{R}^n_{\geq 0}.$$

(If $\mathcal{S} \subset \partial\mathbb{R}^n_{\geq 0}$, then we do not consider such $\mathcal{S}$ as a positive class. In this work, we are not concerned with trajectories that evolve on the boundary of the positive orthant.) Note that the positive classes do not depend on the matrix A, only on B.

The equilibria of system (2.4) may be divided into *boundary equilibria*, $E_0 = \{x \in \partial\mathbb{R}^n_{\geq 0} : \ f_A(x) = 0\}$, and *positive equilibria*, $E_{A,+} = \{x \in \mathbb{R}^n_{>0} : \ f_A(x) = 0\}$.

From [17, Proposition VI.3] we know that E_0 depends only on the matrix B and not on A (however, the elements in $E_{A,+}$ may depend on the matrix A). Throughout this paper we will assume that *no boundary equilibria exist in any positive class*, i.e.,

$$\mathcal{S} \cap E_0 = \emptyset \quad \text{for each positive class } \mathcal{S}. \tag{2.6}$$

Under these conditions we have the following result from [17] and also [6].

THEOREM 2.1. *Consider system* (2.4) *and assume that condition* (2.6) *holds. Then, for each positive class* $\mathcal{S}$ *there exists a (unique) state* $\bar{x} = \bar{x}_{\mathcal{S}} \in \mathbb{R}^n_{>0}$ *which is a globally asymptotically stable point relative to* $\mathcal{S}$*, i.e., for each* $x_0 \in \mathcal{S}$*, the solution of* $\dot{x} = f_A(x)$*,* $x(0) = x_0$*, is defined* $\forall\, t \geq 0$*, and* $x(t) \to \bar{x}$ *as* $t \to \infty$*, and* $\forall\, \varepsilon > 0$ *there exists* $\delta > 0$ *such that if* $|\bar{x} - x_0| < \delta$*, then* $|\bar{x} - x(t)| < \varepsilon$ $\forall\, t > 0$.

Throughout this paper, we will assume that the matrix B (which defines the complexes that form the network) is fixed. Each matrix $A \in \mathcal{A}_{\geq 0}$ characterizes a system of the form (2.4), and we will let $x(t, x_0, A)$ denote the solution of the differential equation $\dot{x} = f_A(x)$ at time t, when the initial condition is $x(0) = x_0 \in \mathbb{R}^n_{>0}$. Then, from Theorem 2.1, it follows that each trajectory $x(\cdot, x_0, A)$ converges to the positive equilibrium in the same class as x_0. So we define $\bar{x}(x_0, A)$ to be the unique equilibrium in the same class as x_0, and thus we may also write

$$E_{A,+} = \left\{\bar{x}(x_0, A) : x_0 \in \mathbb{R}^n_{>0}\right\}$$

and introduce the set of all such positive equilibrium points:

$$\mathcal{E} = \bigcup_{A \in \mathcal{A}_{\geq 0}} E_{A,+}.$$

In section 4 we will show that, as a map from $\mathbb{R}^n_{>0} \times \mathcal{A}_{\geq 0}$ to $\mathbb{R}^n$, $\bar{x}(\cdot, \cdot)$ is a real analytic function.

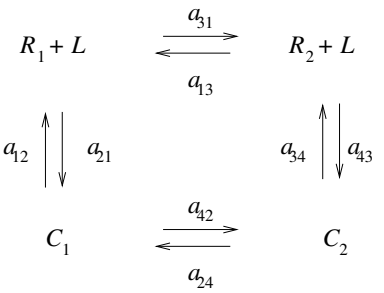

FIG. 1. *A receptor–ligand network.*

2.1. An example. As a motivation for our theoretical results, we will discuss a nominal example. The biochemical network depicted in Figure 1 is a basic model for receptor–ligand interactions at the cell surface [3, 12]. The ligand is denoted by L, two cell receptor conformations are denoted by R_1 and R_2, and the respective receptor–ligand complexes are denoted by C_1 and C_2. These constitute the $n = 5$ individual species, $X = (R_1, R_2, L, C_1, C_2)'$. There are $m = 4$ complexes, $R_1 + L$, C_1, $R_2 + L$, and C_2. This model may be characterized by the matrices

$$A = \begin{pmatrix} 0 & a_{12} & a_{13} & 0 \\ a_{21} & 0 & 0 & a_{24} \\ a_{31} & 0 & 0 & a_{34} \\ 0 & a_{42} & a_{43} & 0 \end{pmatrix}, \quad B = \begin{pmatrix} 1 & 0 & 0 & 0 \\ 0 & 0 & 1 & 0 \\ 1 & 0 & 1 & 0 \\ 0 & 1 & 0 & 0 \\ 0 & 0 & 0 & 1 \end{pmatrix},$$

where A is clearly irreducible. Under mass action kinetics, the dynamics of the system is

$$\begin{aligned} \dot{R}_1 &= -(a_{21} + a_{31})R_1L + a_{12}C_1 + a_{13}R_2L, \\ \dot{R}_2 &= -(a_{13} + a_{43})R_2L + a_{31}R_1L + a_{34}C_2, \\ \dot{L} &= -a_{21}R_1L - a_{43}R_2L + a_{12}C_1 + a_{34}C_2, \\ \dot{C}_1 &= -(a_{12} + a_{42})C_1 + a_{21}R_1L + a_{24}C_2, \\ \dot{C}_2 &= -(a_{34} + a_{24})C_2 + a_{42}C_1 + a_{43}R_2L. \end{aligned} \tag{2.7}$$

The stoichiometric space is given by

$$\begin{aligned} \mathcal{D} = &\ \operatorname{span}\{b_i - b_j : i, j = 1, \ldots, 4\} \\ = &\ \operatorname{span}\{(1, 0, 1, -1, 0)', (1, -1, 0, 0, 0)', (1, 0, 1, 0, -1)'\}, \end{aligned}$$

and the positive classes are thus characterized by a pair of positive constants (α_1, α_2),

$$L + C_1 + C_2 = \alpha_1, \quad R_1 + R_2 + C_1 + C_2 = \alpha_2,$$

and, incidentally, note that the classes reflect the conservation of the total amount of ligand and the total amount of cell receptors in the system. The boundary equilibria set is given by

$$E_0 = \{(r_1, r_2, 0, 0, 0)', (0, 0, l, 0, 0)' : \ r_1, r_2, l \in [0, +\infty)\},$$

and it is easy to see that each of these equilibrium points implies either $\alpha_1 = 0$ or $\alpha_2 = 0$, which do not define a positive class. Therefore, the "no boundary equilibria" assumption (2.6) holds.

In this receptor–ligand model, the kinetic parameters are assumed to be fixed. A rough numerical estimate of the effect of perturbations on the steady-states shows that, for a sufficiently large (and fixed) T,

$$|x(T, x_0, A) - x(T, x_0, A_0)| \lesssim 0.15\, |A - A_0|_{\text{ecl}}, \tag{2.8}$$

suggesting that the system is indeed parameter-robust and that, moreover, the error is not amplified. Figure 2 shows the effect on the trajectories of the system of random perturbations in the kinetic constants, while Figure 3 justifies estimate (2.8). In this figure, each point $\cdot$ corresponds to the mean square error at steady state for a given error in the kinetic constant ($|A - A_0|_{\text{ecl}}$). To obtain Figure 3, for each $p \in \{10, 20, 30, 40, 50, 60\}$, system (2.7) was simulated 20 times for the same fixed initial condition (x_0), with its kinetic constants randomly perturbed within $p\%$, i.e.,

$$a_{ij} = (1 + \tilde{p}_{ij})a^0_{ij} \quad \text{with} \quad \tilde{p}_{ij} \in [-p/100, p/100].$$

For each simulation, the norms $|A - A_0|_{\text{ecl}}$ and $|x(T, x_0, A) - x(T, x_0, A_0)|$, for a sufficiently large T, were computed, and a point $\cdot$ was plotted. An average of the values $|x(T, x_0, A) - x(T, x_0, A_0)|$ over intervals $|A - A_0|_{\text{ecl}} \in [d_0, d_1]$ of length 0.16 was also computed, resulting in the open squares ($\square$). The solid line represents the best linear fit to these average points with a slope of 0.05. Finally, notice that mostly all points are below the dash-dotted line, that is, they satisfy estimate (2.8).

For both figures, the initial condition was set to $x_0 = (7, 2, 15, 0.5, 0.5)'$ corresponding to a common situation where the amount of ligand is larger than the total amount of receptors, and there are practically no receptor–ligand complexes formed at the beginning of the reaction. The (ideal) values of the parameters were set to

$$A_0 = \begin{pmatrix} 0 & 0.25 & 0.8 & 0 \\ 2.7 & 0 & 0 & 0.45 \\ 0.9 & 0 & 0 & 0.25 \\ 0 & 0.55 & 2.5 & 0 \end{pmatrix}.$$

3. Input-to-state stability and robustness. We wish to study the system with inputs (2.3) and establish general estimates that reflect the stability result obtained numerically for the example in (2.8). To do this, we start by defining appropriate input-to-state stability notions. An important observation on the system is that positive classes are invariant not only under constant inputs but also under any time-variant input map with $u(t) \in \mathcal{A}_{\geq 0}\ \forall t$. This follows from the fact that the matrix B (and hence also the stoichiometric space and its orthogonal space $\mathcal{D}^{\perp}$) is fixed, and also from (2.5). Indeed, let $\mathcal{S}_{\bar{x}}$ be any class (recall that each class may be characterized by a positive equilibrium $\bar{x} \in \mathcal{E}$). Then, for each initial condition $x_0 \in \mathcal{S}_{\bar{x}}$ and input map $u(\cdot)$, the trajectory of system (2.3) evolves in this positive class for all times. Thus, any input-to-state stability estimates only need to hold in that class.

3.1. Definition of input-to-state stability in each invariant subspace. The input-to-state stability notion introduced in Definition 3.2 follows the ideas and the concept of input-to-state stability (ISS) first established in [15] (and see also the notion of input-output-to-state stability introduced in [11]). With the goal of analyzing positive systems, the main difference in our definition of ISS is the introduction of a condition on the completeness of the system with respect to positive states (i.e., those states with all coordinates in the strictly positive half-line). This condition

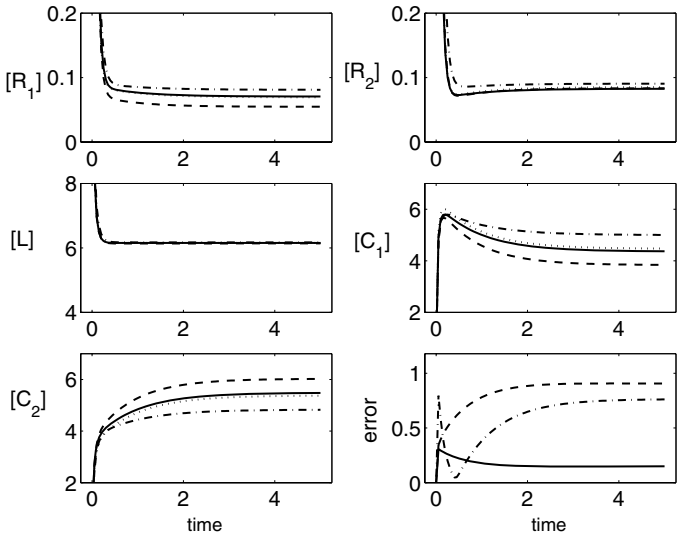

FIG. 2. *The dotted lines represent the trajectory of the system* $\dot{x} = f_{A_0}(x)$ *(*A_0 *as indicated in the text), while the solid, dashed, and dash-dotted lines represent the trajectories of* $\dot{x} = f_A(x)$ *with the entries of* A *randomly chosen within, respectively,* 10%, 20%, *and* 30% *of the (nonzero) entries of* A_0. *The error is computed as the norm* $|x(t, x_0, A_0) - x(t, x_0, A)|$.

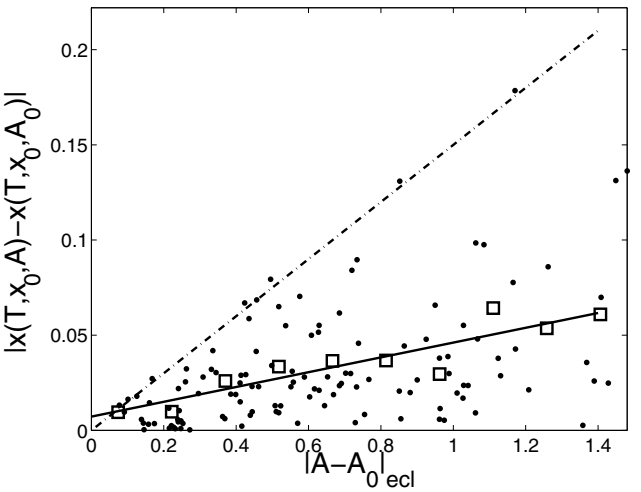

FIG. 3. *The error in the steady states due to random perturbations in the kinetic constants* A_0 *(see explanation in the text).*

plays an important part in the subsequent characterization of the ISS property in terms of an ISS-Lyapunov function: such a function need only be defined on $\mathbb{R}^n_{\geq 0}$ and differentiable on the strictly positive orthant, and it is not required to satisfy a decrease condition except at positive vectors, as stated in Definition 3.3 (in the original characterization, the ISS-Lyapunov function was defined in $\mathbb{R}^n$).

In addition, our notion of ISS is formulated as a *semiglobal* property, in the sense that the input-to-state estimates only hold while the trajectories remain in some preestablished compact set (see also [4]). And it is a *uniform* property, in the sense

that the same functions provide input-to-state estimates for all trajectories evolving in $\cup_{\bar{x}\in P}\mathcal{S}_{\bar{x}}$, where P is a compact subset of $\mathcal{E}$.

We first recall some standard notions that will be used in establishing estimates: a function $\alpha : \mathbb{R}_{\geq 0} \to \mathbb{R}_{\geq 0}$ is said to be of class $\mathcal{K}$ if it is continuous, strictly increasing, and $\alpha(0) = 0$. The function α is said to be of class $\mathcal{K}_\infty$ if it is of class $\mathcal{K}$ and in addition $\alpha(r) \to +\infty$ as $r \to +\infty$. A function $\beta : \mathbb{R}_{\geq 0} \times \mathbb{R}_{\geq 0} \to \mathbb{R}_{\geq 0}$ is said to be of class $\mathcal{KL}$ if, for each fixed t, $\beta(\cdot, t)$ is of class $\mathcal{K}$ and for each fixed r, $\beta(r, \cdot)$ is strictly decreasing with $\beta(r, t) \to 0$ as $t \to +\infty$.

For the following definitions, let the system $\dot{x} = f(x, u)$ evolve on a state space $\mathcal{X}$ which is an open subset of $\mathbb{R}^n$ containing $\mathbb{R}^n_{>0}$. Let $\mathbb{U}$ be a subset of $\mathcal{A}_{\geq 0}$, and let $A_0 \in \mathbb{U}$. For any $\bar{x}_0 \in \mathbb{R}^n_{>0}$, let $\mathcal{S}_{\bar{x}_0}$ represent any invariant set for the system $\dot{x} = f(x, u)$ (with $\bar{x}_0 \in \mathcal{S}_{\bar{x}_0}$). Let

$$\|u - A_0\| = \text{ess. sup}\,.\{|u(t) - A_0|_{\text{ecl}} : \ t \in [0, +\infty)\}.$$

DEFINITION 3.1. *A system $\dot{x} = f(x, u)$, with input-value set $\mathbb{U}$, is $\mathbb{R}^n_{>0}$-forward invariant if, for each initial state $x(0) \in \mathbb{R}^n_{>0}$ and each $\mathbb{U}$-valued input $u(\cdot)$, the corresponding maximal solution of $\dot{x} = f(x, u)$ as a differential equation in $\mathcal{X}$, which is defined on an interval $J_{x(0),u} = [0, t_{max})$, has values $x(t) \in \mathbb{R}^n_{>0}$ $\forall\, t \in J_{x(0),u}$. The system is $\mathbb{R}^n_{>0}$-forward complete if it is $\mathbb{R}^n_{>0}$-forward invariant and, for each $x(0) \in \mathbb{R}^n_{>0}$ and $\mathbb{U}$-valued input $u(\cdot)$, $J_{x(0),u} = [0, +\infty)$.*

DEFINITION 3.2. *A system $\dot{x} = f(x, u)$ is uniformly semiglobal input-to-state stable with input-value set $\mathbb{U}$ if*

(i) *the system is $\mathbb{R}^n_{>0}$-forward complete, and*

(ii) *for every compact set $P \subset \mathcal{E}$ and every compact set $F \subset \mathbb{R}^n_{\geq 0}$ containing P, there exist functions $\beta = \beta_{P,F}$ of class $\mathcal{KL}$ and $\varphi = \varphi_{P,F}$ of class $\mathcal{K}_\infty$ such that, for every $\bar{x}_0 \in P \cap E_{A_0,+}$ for some $A_0 \in \mathbb{U}$,*

$$|x(t) - \bar{x}_0| \leq \beta(|x_0 - \bar{x}_0|, t) + \varphi(\|u - A_0\|) \tag{3.1}$$

for each $\mathbb{U}$-valued input $u(\cdot)$ and every initial condition $x_0 \in F \cap \mathcal{S}_{\bar{x}_0}$[1] and $\forall\, t \geq 0$ such that $x(s) \in F$ $\forall\, s \in [0, t]$.

If the functions β, φ given in (ii) *may be chosen independently of the compact F, then the system is uniformly input-to-state stable with input-value set $\mathbb{U}$.*

DEFINITION 3.3. *A continuous function $V : \mathbb{R}^n_{\geq 0} \to \mathbb{R}_{\geq 0}$ is a uniformly semiglobal ISS-Lyapunov function for the system $\dot{x} = f(x, u)$ with input-value set $\mathbb{U}$ if*

(i) *the restriction of V to $\mathbb{R}^n_{>0}$ is continuously differentiable;*

(ii) *for every compact $P \subset \mathcal{E}$, there exist functions $\nu_1 = \nu_{1,P}, \nu_2 = \nu_{2,P} \in \mathcal{K}_\infty$, so that*

$$\nu_1(|x - \bar{x}_0|) \leq V(x) \leq \nu_2(|x - \bar{x}_0|)$$

for each $\bar{x}_0 \in P$ and $\forall\, x \in \mathbb{R}^n_{\geq 0}$;

(iii) *for every compact set $P \subset \mathcal{E}$ and every compact set $F \subset \mathbb{R}^n_{\geq 0}$ containing P, there exist functions $\alpha = \alpha_{P,F}, \gamma = \gamma_{P,F} \in \mathcal{K}_\infty$ such that, for every $\bar{x}_0 \in P \cap E_{A_0,+}$ for some $A_0 \in \mathbb{U}$,*

$$\nabla V(x)\ f(x, u) \leq -\alpha(|x - \bar{x}_0|) + \gamma(|u - A_0|)$$

for every $u \in \mathbb{U}$ and every $x \in F \cap \mathcal{S}_{\bar{x}_0} \cap \mathbb{R}^n_{>0}$.

[1] Since $P \subset F$, the intersection $F \cap \mathcal{S}_{\bar{x}_0}$ is nonempty, containing at least the point $\bar{x}_0$.

If the functions α, γ given in (iii) *may be chosen independently of the compact $F \subset \mathbb{R}^n_{\geq 0}$, then the function V is a uniformly ISS-Lyapunov function for the system.*

We next state without proof that the existence of an ISS-Lyapunov function implies that the system is input-to-state stable (in the sense of the previous definitions). The proof of the lemma is very similar to what is done in the case of the usual definition of an ISS system and follows closely the argument given in [18]. One should keep in mind that the Lyapunov function is differentiable only on the positive orthant, and that the trajectories evolve in invariant classes. (For a similar adaptation of the proof given in [18], see also [4].)

LEMMA 3.4. *Consider an $\mathbb{R}^n_{>0}$-forward complete system $\dot{x} = f(x,u)$ with input-value set $\mathbb{U}$. Suppose that there is a uniformly (semiglobal) ISS-Lyapunov function V for the system. Then, the system is uniformly (semiglobal) input-to-state stable with input-value set $\mathbb{U}$.*

3.2. Main results. As already mentioned, the work of Horn and Jackson, and Feinberg [6, 7, 8, 9] on zero deficiency biochemical networks considers only constant kinetic parameters. This is also the case in the recent work developed in [17, 4]. In other words, so far the focus has been on systems (2.3) with constant inputs, $u_{ij}(t) \equiv a_{ij}$. In this paper, our goal is to study the stability and robustness of zero deficiency networks under time-varying parameters. In order to establish our stability results a "lower bound" on the parameters will be assumed, that is, given any $\varepsilon > 0$, we consider the input-value set to be the following subset of $\mathcal{A}_{\geq 0}$:

$$\mathbb{U}_\varepsilon = \{A \in \mathcal{A}_{\geq 0} : \ a_{ij} \geq \varepsilon \text{ or } a_{ij} = 0\}. \tag{3.2}$$

Note, however, that no upper bound on the values of a_{ij} is required. In addition, recall that the input maps satisfy the regularity condition (2.2). So, we define

$$\mathcal{W} := \{w : [0,+\infty) \to \mathbb{U}_\varepsilon |\ w \text{ is a piecewise locally Lipschitz function}\}. \tag{3.3}$$

The main results state that, first, system (2.3) is uniformly semiglobal ISS, and second, if (2.3) is mass-conservative, then it is also uniformly ISS. The proofs of the theorems are presented in section 6: the ISS properties are established by showing that the system admits a uniformly (semiglobal) ISS-Lyapunov function (section 5.1).

THEOREM 3.5. *System* (2.3) *with the state space $\mathcal{X} = \mathbb{R}^n$, restricted to taking input maps $w \in \mathcal{W}$, is uniformly semiglobal ISS with input-value set $\mathbb{U}_\varepsilon$.*

THEOREM 3.6. *Suppose that system* (2.3) *with state space $\mathcal{X} = \mathbb{R}^n$ satisfies*

$$\exists v \in \mathbb{R}^n_{>0}, \quad v \cdot f(x,u) = 0 \quad \forall\, x \in \mathcal{X} \quad \forall\, u \in \mathcal{A}_{\geq 0}. \tag{3.4}$$

Then the system, when restricted to input maps $w \in \mathcal{W}$, is uniformly ISS with input-value set $\mathbb{U}_\varepsilon$.

We would like to point out that, in the particular case of the constant input $u(t) \equiv A_0$, Theorem 3.6 recovers the global stability result of Theorem 2.1 for mass-conservative systems. In fact, establishing that a given system is uniformly input-to-state stable with input-value set $\mathbb{U}_\varepsilon$ (appropriately chosen) provides an alternative proof of Theorem 2.1. Furthermore, in the case when the input consists of small perturbations around a desired value A_0, for instance, $u(t) = A_0 + \delta(t)$, uniform (global) ISS implies robustness of the system with respect to A_0. In other words, if $\|\delta\| \leq \delta_0$, then we expect the difference between the desired and perturbed steady states of the system to satisfy $|\bar{x} - \bar{x}_0| \lesssim \varphi(\|\delta\|) \leq \varphi(\delta_0)$ (see also the example discussed in section 2.1).

Remark. Condition (3.4) is satisfied by many biochemical systems; in particular, it is satisfied by mass-conservative systems, whose trajectories are a priori constrained to move in a compact subset of $\mathbb{R}^n_{\geq 0}$. A system of the form (2.3) is mass-conservative if and only if

$$v = \sum_{i=1}^{n-m+1} v_i \in \mathbb{R}^n_{>0},$$

where $\{v_1, \ldots, v_{n-m+1}\}$ is a basis of the space $\mathcal{D}^\perp$. Recall that, by definition of the invariant classes, for each v_i there exists a positive constant α_i such that $\langle v_i, x(t)\rangle = \alpha_i$, $\forall\, t \in J$. Then $\langle v, x(t)\rangle = \sum \alpha_i$ for every t, and in those cases where v has all coordinates positive, we immediately have that $x(t)$ evolves in a compact subset of $\mathbb{R}^n_{\geq 0}$ and hence a compact subset of the state space. The example discussed in section 2.1 is mass-conservative with $v = (1, 1, 1, 2, 2)'$.

Remark. One of the main assumptions in the model (2.3) is that, for all times t, the incidence graph of the matrix $u(t)$ is strongly connected or, equivalently, $u(t)$ is irreducible; hence the input u is only allowed to take values in $\mathcal{A}_{\geq 0}$. However, in some ways, the structure of the network may be modified, i.e., new reactions may be added and existing reactions may be removed, provided that *the irreducibility of the matrix $u(t)$ is not violated at any time t.* This is guaranteed by requiring that $u \in \mathbb{U}_\varepsilon$.

As discussed above, Theorems 3.6 and 3.5 hold for input maps that are piecewise locally Lipschitz. These include many of the typical biological inputs such as piecewise constant, periodic, or exponentially decaying signals.

Example. As mentioned in the introduction, changes in the temperature induce changes in the value of the reaction rate constants. These changes are given by the *Arrhenius law* [1]:

$$k = k(T) := F_a\, e^{-\frac{E_a}{RT}},$$

where $F_a > 0$ is the *frequency factor*, E_a is the *activation energy*, T is the temperature (in K), and R is the universal gas constant ($\approx$8.31 $\mathrm{J\,K^{-1}\,mol^{-1}}$). The values F_a and E_a are fixed for each reaction (e.g., for water formation, $\mathrm{OH{+}H_2} \xrightarrow{k} \mathrm{H_2O{+}H}$, $F_a = 8 \times 10^{10}$ $\mathrm{L\,mol^{-1}\,s^{-1}}$, and $E_a = 42 \times 10^3$ $\mathrm{J\,mol^{-1}}$). For most reactions $E_a > 0$, so that k increases with the temperature. Then we have (note that $4/c$ is a Lipschitz constant for the function $e^{-c/x}$)

$$|k(T_1) - k(T_0)| = F_a \left| e^{-\frac{E_a}{RT_1}} - e^{-\frac{E_a}{RT_0}} \right| \leq 4R \frac{F_a}{E_a} |T_1 - T_0|\,.$$

In general, changes in temperature will be reflected in the matrix of kinetic parameters as $\|u^{T_1} - u^{T_0}\| \leq c\,|T_1 - T_0|$ for some $c > 0$. Then, from Theorem 3.6, we expect that a change in temperature from T_0 to T_1 will lead to a deviation in the steady state of order $|\bar{x}_1 - \bar{x}_0| \lesssim \varphi(|T_1 - T_0|)$, where φ is some $\mathcal{K}_\infty$ function.

Example. Consider the model in Figure 1 and assume that the concentration of ligand is regulated from "outside." For instance, $L(t)$ may be experimentally designed to be a piecewise constant function, in order to measure the response of the system to different concentrations of ligand. Or L could be regulated by an independent network. In either case, we would have the following system:

$$\dot{x} = f(x, w), \tag{3.5}$$

where $x = (R_1, R_2, C_1, C_2)'$ and

$$w(t) = \begin{pmatrix} 0 & a_{12} & a_{13}L(t) & 0 \\ a_{21}L(t) & 0 & 0 & a_{24} \\ a_{31}L(t) & 0 & 0 & a_{34} \\ 0 & a_{42} & a_{43}L(t) & 0 \end{pmatrix}.$$

If L is determined by a dynamical system, say $\dot{z} = g(z)$, also of the form (2.1), then we know that $z(t) \to \bar{z}$ for some $\bar{z} \in \mathcal{E}$, and therefore $w(\cdot) \in \mathcal{W}$. An interesting problem for further analysis is whether the convergence of $L(t)$ to some $\bar{L}$ implies that the trajectory $x(t)$ will also converge to some $\bar{x} \in \mathcal{E}$. Another interesting question, which we leave for further research, is whether the cascade system $\dot{x} = f(x, z)$, $\dot{z} = g(z)$ is again input-to-state stable, in the manner developed in [15].

4. Dependence of the steady states on the kinetic parameters. A typical problem concerning cell receptor–ligand interactions, and many other biochemical reactions, is to determine the "dose-response" curves, that is, determine the final concentration of the products, $\bar{C}_1$ or $\bar{C}_2$, as a function of the initial concentration of ligand, L_0 (see [12, 19] and [5]). When translated into mathematical language, this problem involves the characterization of the multiple steady states of system (2.4) and their dependence on the matrix A and classes $\mathcal{S}_{x_0}$.

We recall that, for the case of constant inputs, say $u(t) \equiv A$, the system $\dot{x} = f(x, u)$ with initial condition $x(0) = x_0$ converges to the constant steady state $\bar{x}(x_0, A)$. In contrast, for a general input $u(\cdot)$ one certainly does not expect the system to converge to a constant steady state. However, one may still consider the map $\bar{x} : \mathbb{R}^n_{>0} \times \mathcal{A}_{\geq 0} \to \mathcal{E}$, where $\bar{x}(x_0, A)$ is defined as the unique positive steady state of the system $\dot{x} = f(x, A) = f_A(x)$ in the class $\mathcal{S}_{x_0}$. Then the following is true:

$$\bar{x}(x_0, u(t)) \in \mathcal{E} \quad \forall\, t.$$

We will show that $\bar{x}$ is in fact a real analytic function of x_0 and A. This will help us in the proof of the main results, namely, in section 5, to show that the system is $\mathbb{R}^n_{\geq 0}$-forward complete.

THEOREM 4.1. *Assume that the maps θ_i are real analytic functions. Then the map $\bar{x} : \mathbb{R}^n_{>0} \times \mathcal{A}_{\geq 0} \to \mathcal{E} \subset \mathbb{R}^n_{>0}$ given by $(x_0, A) \mapsto \bar{x}(x_0, A)$ is real analytic.*

To prove this theorem we will use the following alternative expression for f_A (see [17]):

$$f_A(x) = B\tilde{A}\theta_B(x), \tag{4.1}$$

where

$$\theta_B(x) = \begin{pmatrix} \theta_1(x_1)^{b_{11}}\theta_2(x_2)^{b_{21}} \cdots \theta_n(x_n)^{b_{n1}} \\ \theta_1(x_1)^{b_{12}}\theta_2(x_2)^{b_{22}} \cdots \theta_n(x_n)^{b_{n2}} \\ \vdots \\ \theta_1(x_1)^{b_{1m}}\theta_2(x_2)^{b_{2m}} \cdots \theta_n(x_n)^{b_{nm}} \end{pmatrix} = \exp[B'\rho(x)]$$

and

$$\tilde{A} = A + \begin{pmatrix} -\sum_{i=1}^m a_{i1} & 0 & \cdots & 0 \\ 0 & -\sum_{i=1}^m a_{i2} & \cdots & 0 \\ \vdots & \vdots & & \vdots \\ 0 & 0 & \cdots & -\sum_{i=1}^m a_{im} \end{pmatrix}.$$

(Recall that we assumed without loss of generality that all the diagonal entries of A are zero.) Now, given any matrix $G \in \mathbb{R}^{m\times m}$, with entries g_{ij}, define

$$\phi(G) = \left(1 + \sum_{i=1}^{m} g_{ii}^2\right)^{-1} \quad \text{and} \quad M_G = (\phi(G)G + I)^{m-1}.$$

By construction, the diagonal entries of $\phi(G)G+I$ are positive. Introduce the following subset of $\mathbb{R}^{m\times m}$:

$$\mathcal{G} = \{G \in \mathbb{R}^{m\times m} : M_G > 0 \text{ and } \bar{1}\, G = 0\},$$

where the inequality means that every entry of the matrix on the left-hand side is strictly positive, and $\bar{1}$ is the row vector $(1\ 1\cdots 1)$. The set $\mathcal{G}$ may be seen as an open subset of the $(m^2 - m)$-dimensional linear subspace $\{G : \bar{1}\, G = 0\}$ of $\mathbb{R}^{m\times m}$. Define $\mathcal{G}_{\geq 0}$ to be the set of all irreducible matrices which have $\bar{1}\, G = 0$, *nonnegative off-diagonal* entries and *arbitrary diagonal* entries. Note that

$$\mathcal{G}_{\geq 0} = \{G \in \mathcal{G} : G \text{ has nonnegative off-diagonal entries}\}.$$

Then to each matrix $A \in \mathcal{A}_{\geq 0}$, we associate a matrix $\tilde{A} \in \mathcal{G}_{\geq 0}$: clearly, $\bar{1}\tilde{A} = 0$ and so $\tilde{A} \in \mathcal{G}_{\geq 0}$.

For each $G \in \mathcal{G}$ observe that $\bar{1}M_G = \bar{1}(\phi(G)\, G + I)^{m-1} = \bar{1}$ because $\bar{1}\, G = 0$ and $\bar{1}(\phi(G)\, G + I) = \bar{1}$. So, any nonnegative eigenvector, $v \in \mathbb{R}^n_{\geq 0}$, of the matrix M_G must correspond to the eigenvalue $\mu = 1$ since

$$M_G v = \mu v \ \Rightarrow\ \bar{1}(M_G v) = \bar{1}(\mu v) \ \Leftrightarrow\ \bar{1}v = \mu \bar{1}v$$

and $\bar{1}v$ is a positive scalar (since $v \neq (0, \ldots, 0)'$ by the definition of eigenvector).

Since, by definition, M_G is irreducible and has all entries positive, by the Perron–Frobenius theorem we know that the spectral radius of M_G, $\sigma(M_G)$, is an eigenvalue of M_G of algebraic (and hence geometric) multiplicity one. Moreover, an eigenvector associated with $\sigma(M_G)$ can be chosen to have all entries strictly positive (this will be a Perron eigenvector of M_G, and any two such vectors are positive multiples of each other). But, as we have just seen, any positive eigenvector of M_G corresponds to the eigenvalue $\mu = 1$, so we have

$$\sigma(M_G) \equiv 1 \quad \forall\, G \in \mathcal{G}.$$

Define $v_{\text{P}} : \mathcal{G} \to \mathbb{R}^m_{>0}$ to be the map that assigns to each $G \in \mathcal{G}$ the unique Perron eigenvector of M_G, which has its first coordinate equal to 1,

$$v_{\text{P}} = \begin{pmatrix} 1 \\ w_{\text{P}} \end{pmatrix}$$

for some $w_{\text{P}} \in \mathbb{R}^{m-1}_{>0}$. Then the map v_{P} is a rational function on $\mathcal{G}$, as shown in the appendix.

Proof of Theorem 4.1. A function f, defined on an open set $\mathcal{V}$, is real analytic if it admits a power series expansion on a neighborhood of each point of $\mathcal{V}$. If, as in our case, the set $\mathcal{V}$ is not open, then the function f is still called real analytic if it admits an extension to a real analytic function on a neighborhood of $\mathcal{V}$ (see [16]). This is what we will show for the map $\bar{x}(\cdot, \cdot)$.

For each A consider the matrix $\tilde{A} \in \mathcal{G}_{\geq 0}$, constructed from A as indicated above. Then, from (A.1), $\ker \tilde{A} = \text{ span } \{v_{\text{P}}(\tilde{A})\}$. Because B has full column rank, it follows that each equilibrium $\bar{x} \in E_{A,+}$ is characterized by

$$\theta_B(\bar{x}) = c\, v_{\text{P}}(\tilde{A}) \quad \Leftrightarrow \quad B'\rho(\bar{x}) = \rho(c\, v_{\text{P}}(\tilde{A})), \tag{4.2}$$

where c is a positive constant.

Claim. For each A, the element $\bar{z}(A) \in \mathbb{R}^n_{>0}$ given by

$$\bar{z}(A) = \exp\big[B(B'B)^{-1}\rho(v_{\text{P}}(\tilde{A}))\big]$$

is an equilibrium point in $E_{A,+}$.

To prove the claim, note that B has full column rank, so $B'B$ is an invertible matrix and the formula gives $\rho(\bar{z}(A)) = B(B'B)^{-1}\rho(v_{\text{P}}(\tilde{A}))$ or, equivalently,

$$B'\rho(\bar{z}(A)) = B'B(B'B)^{-1}\rho(v_{\text{P}}(\tilde{A})) = \rho(v_{\text{P}}(\tilde{A})).$$

The claim is proved by letting $c = 1$ and $\bar{x} = \bar{z}(A)$ in (4.2).

Now, by Proposition A.1, the map v_{P} is a rational function on $\mathcal{G}$ and, furthermore, $v_{\text{P}}(G) \in \mathbb{R}^m_{>0}$. The functions $\exp(\cdot)$ and $\rho(\cdot)$ are analytic on $\mathbb{R}^n$ and $\mathbb{R}^n_{>0}$, respectively, so it follows that the map $\tilde{A} \mapsto A(\tilde{A}) \mapsto \bar{z}(A)$ from $\mathcal{G}_{\geq 0} \to \mathcal{E}$ is analytic because it admits an analytic extension to $\mathcal{G} \to \mathbb{R}^n_{>0}$. (Denote by $A(\tilde{A})$ the matrix which coincides with A on the off-diagonal entries and has zero in its diagonal.)

Next, from Lemma IV.1 (and proof of Theorem 2) in [17], there is a real analytic map $\varphi(q, w)$, defined on $\mathbb{R}^n_{>0} \times \mathbb{R}^n_{>0}$, such that, for each $q \in \mathbb{R}^n_{>0}$, $x = \varphi(q, \bar{z}(A))$ is the *unique positive equilibrium* of the system $\dot{x} = f_A(x)$ in the same class of q. Let $q = x_0$ and $w = \bar{z}(A)$. We may now conclude that the map $\mathbb{R}^n_{>0} \times \mathcal{G}_{\geq 0} \to \mathcal{E}$ given by

$$(x_0, \tilde{A}) \mapsto \varphi(x_0, \bar{z}(A))$$

is again analytic because it admits an analytic extension to $\mathbb{R}^n_{>0} \times \mathcal{G}$. Therefore,

$$\bar{x}(x_0, A) \equiv \varphi(x_0, \bar{z}(A))$$

is the unique element that belongs to both the class of x_0 and the equilibria set $E_{A,+}$, and we have just shown that the map $\bar{x} : \mathbb{R}^n_{>0} \times \mathcal{A}_{\geq 0} \to \mathcal{E}$ is real analytic. □

5. Existence and completeness of solutions. We now turn our attention to system (2.3) and will show that it is complete in the sense of Definition 3.1.

PROPOSITION 5.1. *Consider system* (2.3)*, with state space* $\mathcal{X} = \mathbb{R}^n$ *and input-value set* $\mathcal{A}_{\geq 0}$*. Then the system is* $\mathbb{R}^n_{>0}$*-forward invariant.*

Proof. Given an initial condition $x(0) = x_0 \in \mathbb{R}^n_{>0}$ and an $\mathcal{A}_{\geq 0}$-valued input $u(t)$, define $F(t, x) := f(x, u(t))$. The existence and uniqueness of a maximal solution to this initial-value problem follows from standard results (such as stated in [16]), by noticing that, for each fixed t, $F(t, x)$ is locally Lipschitz in x and, for each fixed x, it is locally integrable as a function of time. Forward invariance also follows from standard arguments based on the fact that, for $x \in \mathbb{R}^n_{\geq 0}$, if $x_k = 0$ for any k, then $F_k(t, x) \geq 0$. The actual proof is very similar to that of Proposition 3.13 in [4], so we will not reproduce it here. In that proposition, simply take $C = 0$ and replace "a_{ij}" by "u_{ij}" (we only use the fact that $u_{ij} \geq 0$). □

5.1. A Lyapunov function. In order to prove $\mathbb{R}^n_{>0}$-forward completeness of system (2.3), we will need to introduce our candidate ISS-Lyapunov function. Fix any point $\bar{x}$ in $\mathcal{E}$ and recall the notation $\rho_i = \ln \theta_i$. Define

$$V(x,\bar{x}) = \sum_{i=1}^{n} \int_{\bar{x}_i}^{x_i} (\,\rho_i(s) - \rho_i(\bar{x}_i)\,)\, ds. \tag{5.1}$$

This function is introduced and motivated in [17], where it is shown that V is always nonnegative and zero if and only if $x \equiv \bar{x}$. It is also easy to see that $V(x,\bar{x}) \to +\infty$ as $|x-\bar{x}| \to +\infty$. Also, the function V is *proper* in the following sense: for each compact set $P \subset \mathcal{E}$, one can show that there exist two class $\mathcal{K}_\infty$ functions $\nu_1 = \nu_{1,P}$, $\nu_2 = \nu_{2,P}$ such that

$$\nu_1(|x-\bar{x}|) \le V(x,\bar{x}) \le \nu_2(|x-\bar{x}|) \tag{5.2}$$

$\forall\, x \in \mathbb{R}^n_{\ge 0}$ and $\forall\, \bar{x} \in P$. For instance, we may take

$$\nu_1(r) = \inf\{V(x,\bar{x}) : |x-\bar{x}| \ge r,\ x \in \mathbb{R}^n_{\ge 0},\ \bar{x} \in P\}$$

and

$$\nu_2(r) = r + \max\{V(x,\bar{x}) : |x-\bar{x}| \le r,\ x \in \mathbb{R}^n_{\ge 0},\ \bar{x} \in P\}.$$

So, it is easy to see that V satisfies both properties (i) and (ii) of Definition 3.3. In the case of maps $\theta_i(r) = |r|$, the function has the form

$$V(x,\bar{x}) = \sum_{i=1}^{n} x_i\,(\ln x_i - \ln \bar{x}_i) + (\bar{x}_i - x_i). \tag{5.3}$$

Some more notation will be useful. For any $\bar{x} = (\bar{x}_1,\dots,\bar{x}_n)' \in \mathcal{E}$ and $\forall\, x \in \mathbb{R}^n_{>0}$ define

$$q_j(x,\bar{x}) = q_j := \langle b_j, \rho(x) - \rho(\bar{x})\rangle. \tag{5.4}$$

Introduce also the scalar function $\omega : \mathbb{R} \to \mathbb{R}_{\ge 0}$ given by

$$\omega(r) = e^r - 1 - r\,. \tag{5.5}$$

Furthermore, note that

$$\nabla_x V(x,\bar{x}) = \rho(x) - \rho(\bar{x}) = (\ln\theta_1(x_1) - \ln\theta_1(\bar{x}_1),\dots,\ln\theta_n(x_n) - \ln\theta_n(\bar{x}_n)),$$

$$\nabla_{\bar{x}} V(x,\bar{x}) = \left((\bar{x}_1 - x_1)\,\frac{\theta_1'(\bar{x}_1)}{\theta_1(\bar{x}_1)},\dots,(\bar{x}_n - x_n)\,\frac{\theta_n'(\bar{x}_n)}{\theta_n(\bar{x}_n)}\right).$$

Now, given any $A \in \mathcal{A}_{\ge 0}$ and any $\bar{x} \in E_{A,+}$, consider

$$\begin{aligned} \nabla V(x,\bar{x})\, f_A(x) &= \langle \rho(x) - \rho(\bar{x}), f_A(x)\rangle \\ &= \sum_{i=1}^{m}\sum_{j=1}^{m} a_{ij} e^{\langle b_j,\rho(\bar{x})\rangle} e^{q_j}(q_i - q_j) \\ &= -\sum_{i=1}^{m}\sum_{j=1}^{m} a_{ij} e^{\langle b_j,\rho(\bar{x})\rangle} e^{q_j}\omega(q_i - q_j) \\ &=: -W(x,\bar{x}). \end{aligned} \tag{5.6}$$

The third inequality holds because

$$\begin{aligned} e^{q_j}(q_i - q_j) &= e^{q_j}(q_i - q_j) - e^{q_j}(e^{q_i - q_j} - 1) + e^{q_j}(e^{q_i - q_j} - 1) \\ &= -e^{q_j}\omega(q_i - q_j) + (e^{q_i} - e^{q_j}) \end{aligned}$$

and

$$\begin{aligned} &\sum_{i=1}^{m}\sum_{j=1}^{m} a_{ij} e^{\langle b_j, \rho(\bar{x})\rangle}(e^{q_i} - e^{q_j}) \\ &= (e^{q_1}, \dots, e^{q_m})' A \theta_B(\bar{x}) - (e^{q_1}, \dots, e^{q_m})' \operatorname{diag}\left(\sum_i a_{i1}, \dots, \sum_i a_{im} \right) \theta_B(\bar{x}) \\ &= (e^{q_1}, \dots, e^{q_m})' \tilde{A} \theta_B(\bar{x}) = 0, \end{aligned} \tag{5.7}$$

since at steady state, recalling (4.1) and that B has full rank,

$$f(\bar{x}, A) = f_A(\bar{x}) = B\tilde{A}\theta_B(\bar{x}) = 0.$$

An important point to notice is that $-W(x, \bar{x})$ (hence $\nabla V(x, \bar{x}) f_A(x)$) is *always nonpositive*, because $\omega(r) \geq 0 \ \forall\, r$ (with $\omega(r) = 0$ if and only if $r = 0$).

To prove $\mathbb{R}^n_{>0}$-forward completeness, we consider the function $V(x(t), \bar{x}(x_0, u(t)))$ along a trajectory $x(\cdot, x_0, u(\cdot))$, which is the solution of (2.3), when the input is $u(\cdot)$ and the initial condition $x(0) = x_0$. For the next lemma recall that the maps θ_i are onto an interval of the form $[0, \sigma_i)$, where $0 < \sigma_i \leq +\infty$.

LEMMA 5.2. *Given any compact set $P \subset \mathcal{E}$, let $\ell_1, \ell_2 > 0$ be any numbers so that*

$$e^{\frac{1}{\ell_1}} < \frac{\sigma_i}{\theta_i(\bar{x}_i)} \quad \forall\, \bar{x} \in P, \quad \forall\, i = 1, \dots, n \tag{5.8}$$

and

$$\ell_2 \bar{x}_i > |\bar{x}_i - r_\pm| \quad \forall\, \bar{x} \in P, \quad \forall\, i = 1, \dots, n, \tag{5.9}$$

where the numbers $r_\pm$ are defined by the equations $\ln \theta_i(r_\pm) = \ln \theta_i(\bar{x}_i) \pm 1/\ell_1$.

Then

$$|\bar{x}_i - x_i| \leq \ell_1 V(x, \bar{x}) + \ell_2 \bar{x}_i$$

$\forall\, x \in \mathbb{R}^n_{\geq 0}$ and $\forall\, \bar{x} \in P$.

Remark. If $\theta_i(r) = |r| \ \forall\, i = 1, \dots, n$, then $r_\pm = e^{\pm \frac{1}{\ell_1}} \bar{x}_i$, and we may choose ℓ_1 and ℓ_2 independently of P: indeed, condition (5.8) becomes $e^{\frac{1}{\ell_1}} < \infty$ (satisfied by any $\ell_1 > 0$), and condition (5.9) becomes $\ell_2 > |1 - e^{\pm \frac{1}{\ell_1}}|$. For instance, we may pick $\ell_1 = 1$ and $\ell_2 = 2$.

Proof. Pick any compact set $P \subset \mathcal{E}$ and pick any numbers ℓ_1 and ℓ_2 according to (5.8) and (5.9). First, note that the definition of V implies (see (5.1))

$$\int_{\bar{x}_i}^{x_i} \rho_i(s) - \rho_i(\bar{x}_i)\, ds \leq V(x, \bar{x}), \quad i = 1, \dots, n$$

(recall that $\rho_i(s) = \ln \theta_i(s)$). Now fix any $i \in \{1, \dots, n\}$ and put $a = \bar{x}_i$. For $r \geq 0$, $a > 0$, define

$$h(r) = \ell_1 \int_a^r \rho_i(s) - \rho_i(a)\, ds - |a - r| + \ell_2 a.$$

We will show that $h(r) \geq 0 \; \forall \, r \geq 0$. The first derivative of h is piecewise continuous

$$\frac{dh}{dr} = \begin{cases} \ell_1(\rho_i(r) - \rho_i(a)) + 1 & \text{if } 0 \leq r < a, \\ \ell_1(\rho_i(r) - \rho_i(a)) - 1 & \text{if } r > a \end{cases}$$

and the second derivative is

$$\frac{d^2h}{dr^2} = \ell_1 \, \frac{\theta_i'(r)}{\theta_i(r)} > 0 \quad \text{for} \quad r \neq a,$$

where $\theta_i'(r) = d\theta_i/dr > 0$, because θ_i is strictly increasing. Each continuous piece of the derivative has a zero, at the points $r_\pm$,

$$\frac{dh}{dr} = 0 \quad \Leftrightarrow \quad \begin{cases} \rho_i(r_-) = -\frac{1}{\ell_1} + \rho_i(a) & \text{if } 0 < r < a, \\ \rho_i(r_+) = \frac{1}{\ell_1} + \rho_i(a) & \text{if } r > a. \end{cases}$$

Note that, because ρ_i is an increasing function, indeed $r_- < a$ and $r_+ > a$. In addition, from (5.8) it follows that both r_- and r_+ are well defined, since they belong to the domain of θ_i. Since the second derivative of h is always positive for $r \neq a$, h has local minima at the points $r = r_\pm$. By definition of ℓ_2, it follows that the value of h at $r_\pm$ is positive:

$$h(r_\pm) = \ell_1 \int_a^{r_\pm} \rho_i(s) - \rho_i(a) \, ds - |a - r_\pm| + \ell_2 a,$$

since the first term is positive by construction of V and the two other terms satisfy (5.9)

$$-|a - r_\pm| + \ell_2 a > 0.$$

To summarize,

$$\frac{dh}{dr} = \begin{cases} < 0, & 0 \leq r < r_-, \\ > 0, & r_- < r < a, \\ < 0, & a < r < r_+, \\ > 0, & r_+ < r \end{cases}$$

so that h decreases down to a local *positive* minimum at r_-, then increases up to $h(a) > 0$, and decreases again to another local *positive* minimum at r_+, and increases $\forall r > r_+$. Therefore,

$$h(r) > 0 \quad \forall \, r \in [0, +\infty).$$

This finishes the proof, since for each $a = \bar{x}_i$,

$$\begin{aligned} h(r) > 0 \quad \Leftrightarrow \quad |\bar{x}_i - x_i| &\leq \ell_1 \int_{\bar{x}_i}^{x_i} \rho_i(s) - \rho_i(\bar{x}_i) \, ds + \ell_2 \bar{x}_i \\ &\leq \ell_1 V(x, \bar{x}_i) + \ell_2 \bar{x}_i. \qquad \square \end{aligned}$$

5.2. Completeness.

PROPOSITION 5.3. *Consider system* (2.3) *with state space* $\mathcal{X} = \mathbb{R}^n$. *Then the system is* $\mathbb{R}^n_{>0}$*-forward complete, whenever the input map* $u(\cdot)$ *is in* $\mathcal{W}$.

Proof. Pick any input map $u(\cdot)$ in $\mathcal{W}$. Let $x(t)$ be the issuing solution of (2.3), with the initial condition $x(0) = x_0 \in \mathbb{R}^n_{>0}$, and let it be defined on the maximal interval

$[0,T)$. From Proposition 5.1, we already know that $x(t) := x(t, x_0, u(\cdot)) \in \mathbb{R}^n_{>0}\ \forall\, t$ in the interval $[0,T)$. Assuming that $T < +\infty$, we will show that $x(\cdot)$ evolves on a compact subset of $\mathcal{X}\ \forall\, t \in [0,T)$, which is a contradiction. To do this, we consider the function

$$g(t) = V(x(t), \bar{x}(x_0, u(t)))$$

whose derivative is

$$\begin{aligned}\dot{g}(t) &= \nabla_x V(x(t), \bar{x}(x_0,u(t)))\ \frac{d}{dt}[x(t)] + \nabla_{\bar{x}} V(x(t), \bar{x}(x_0,u(t)))\ \frac{d}{dt}[\bar{x}(x_0,u(t))] \\ &= \langle \rho(x) - \rho(\bar{x}), f(x,u)\rangle + \sum_{i=1}^{n} (\bar{x}_i - x_i)\ \dot{\bar{x}}_i\ \frac{\theta_i'(\bar{x}_i)}{\theta_i(\bar{x}_i)},\end{aligned}$$

where, for simplicity, we used $x \equiv x(t)$ and $\bar{x} \equiv \bar{x}(x_0,u(t))$, and $\dot{\bar{x}}_i := \frac{d}{dt}[\bar{x}_i(x_0,u(t))]$.

Now, for almost all $t \in [0,T)$, $u(t)$ takes values in a compact set. So there exist constants $\underline{c}, \overline{c} > 0$ such that

$$\underline{c} \le |\bar{x}_i(x_0,u(t))| \le \overline{c} \quad \text{for almost all}\ \ t \in [0,T).$$

By differentiability of $\bar{x}(\cdot,\cdot)$ (Theorem 4.1), and because u is piecewise locally Lipschitz with finitely many points of discontinuity, there exist positive constants κ and c_1 such that

$$\dot{\bar{x}}_i = \sum_{i,j=1}^{m} \frac{d\bar{x}_i}{du_{ij}} \frac{du_{ij}}{dt} \le \sum_{i,j=1}^{m} \kappa \left| \frac{d\bar{x}_i}{du_{ij}} \right| \le c_1 \quad \text{for almost all}\ \ t \in [0,T).$$

The function θ_i is positive and strictly increasing, so $\theta_i'(r)$ is also positive. Since $\bar{x}_i(\cdot,\cdot)$ takes values in a compact set, there exists $c_2 > 0$ such that

$$\frac{\theta_i'(\bar{x}_i)}{\theta_i(\bar{x}_i)} \le c_2 \quad \text{for almost all}\ \ t \in [0,T).$$

From (5.6), $\langle \rho(x) - \rho(\bar{x}(x_0,u)), f(x,u)\rangle \le 0\ \forall\, x \in \mathbb{R}^n_{>0},\ u \in \mathcal{A}_{\ge 0}$. Then, applying Lemma 5.2, with $P = [\underline{c}, \overline{c}]^n \cap \mathcal{E}$, to the second term on $\dot{g}$, we obtain

$$\dot{g} \le \sum_{i=1}^{n} |\dot{\bar{x}}_i|\ \ \frac{\theta_i'(\bar{x}_i)}{\theta_i(\bar{x}_i)} (\ell_1\, V(x,\bar{x}) + \ell_2 \bar{x}_i),$$

which implies

$$\dot{g}(t) \le \ell_1 c_1 c_2\, g(t) + \ell_2 c_1 c_2 \overline{c} \quad \text{for almost all}\ t \in [0,T).$$

Taking $c_3 = \ell_2 c_1 c_2 \overline{c}$ and $c_4 = \ell_1 c_1 c_2$ and applying Gronwall's lemma, yield

$$g(t) \le c_3 e^{c_4 T} \quad \forall\, t \in [0,T).$$

For the compact set $P = [\underline{c}, \overline{c}]^n \cap \mathcal{E}$, let $\nu_1 = \nu_{1,P}$ be the class $\mathcal{K}_\infty$ function such that $\nu_1(|x - \bar{x}|) \le V(x,\bar{x})\ \forall\, x \in \mathbb{R}^n_{\ge 0}$ and $\bar{x} \in P$. Thus,

$$\nu_1(|x(t) - \bar{x}(x_0,u(t))|) \le g(t) \quad \forall\, t \in [0,T)$$

and, therefore,

$$|x(t)| \le \overline{c} + \nu_1^{-1}\big(c_3 e^{c_4 T}\big)$$

implying that x evolves in a compact subset of the state space, which contradicts $T < +\infty$. ∎

6. ISS estimates. To establish the main results, we now show that the function V is a uniformly semiglobal ISS-Lyapunov function. In section 5.1 it was shown that V satisfies properties (i) and (ii) of Definition 3.3. We next show that it also satisfies property (iii).

For any $\bar{x} = (\bar{x}_1, \ldots, \bar{x}_n)' \in \mathcal{E}$ and any $x \in \mathbb{R}^n_{\geq 0}$ define

$$\pi_j(x, \bar{x}) = \pi_j := \left[\frac{\theta_1(x_1)}{\theta_1(\bar{x}_1)}\right]^{b_{1j}} \left[\frac{\theta_2(x_2)}{\theta_2(\bar{x}_2)}\right]^{b_{2j}} \cdots \left[\frac{\theta_n(x_n)}{\theta_n(\bar{x}_n)}\right]^{b_{nj}} \tag{6.1}$$

and observe that, if $x \in \mathbb{R}^n_{>0}$, from (5.4)

$$\pi_j = e^{q_j}.$$

Using this notation, define the function $\Psi : \mathbb{R}^n_{\geq 0} \times \mathcal{E} \to \mathbb{R}_{\geq 0}$,

$$\Psi(x, \bar{x}) := \sum_{i=1}^{m} \sum_{j=1}^{m} \left(e^{-\pi_i} - e^{-\pi_j}\right)^2,$$

which, from Lemma 3.8 in [4], satisfies

$$\Psi(x, \bar{x}) = 0 \quad \Leftrightarrow \quad x \in E_0 \cup E_{A,+}, \tag{6.2}$$

where E_0 is the set of boundary equilibria and $A \in \mathcal{A}_{\geq 0}$ is such that $\bar{x} \in E_{A,+}$. Recall the function W defined in (5.6): a useful estimate (see Lemma 3.10 in [4]) establishes that, for each fixed $\bar{x}$,

$$W(x, \bar{x}) \geq \frac{1}{2} \sum_{i=1}^{m} \sum_{j=1}^{m} a_{ij}\, e^{\langle b_j, \rho(\bar{x})\rangle} \left(e^{-\pi_i} - e^{-\pi_j}\right)^2 \quad \forall\, x \in \mathbb{R}^n_{>0}. \tag{6.3}$$

Moreover, since $x \in \mathbb{R}^n_{>0}$, it follows from (6.2) that the expression on the right-hand side is zero if and only if $x \equiv \bar{x}$.

Next, given any $A \in \mathcal{A}_{\geq 0}$, suppose that A_1 is a matrix with entries $a^1_{ij} = 1$ if $a_{ij} > 0$ and $a^1_{ij} = 0$ if $a_{ij} = 0$. Then, for expression (6.3), we can write

$$W(x, \bar{x}) \geq \frac{1}{2} \min_{a_{ij}>0}\{a_{ij}\} \min_j e^{\langle b_j, \rho(\bar{x})\rangle} \sum_{i=1}^{m} \sum_{j=1}^{m} a^1_{ij} \left(e^{-\pi_i} - e^{-\pi_j}\right)^2.$$

Since A_1 is irreducible, we may apply Lemma VIII.1 from [17] to conclude that there exists a positive constant $\kappa(A_1)$ such that

$$\sum_{i=1}^{m} \sum_{j=1}^{m} a^1_{ij} \left(e^{-\pi_i} - e^{-\pi_j}\right)^2 \geq \kappa(A_1) \sum_{i=1}^{m} \sum_{j=1}^{m} \left(e^{-\pi_i} - e^{-\pi_j}\right)^2.$$

Now, define the following subset of $\mathcal{A}_{\geq 0}$,

$$\mathcal{A}^1_{\geq 0} := \{A \in \mathcal{A}_{\geq 0} : \ a_{ij} = 1 \ \text{ or } \ a_{ij} = 0\},$$

and note that its cardinality is finite (in fact, the number of elements in $\mathcal{A}^1_{\geq 0}$ is equal to the number of distinct strongly connected graphs with m vertexes). Then let

$$\kappa_1 := \min\left\{\kappa(A) : \ A \in \mathcal{A}^1_{\geq 0}\right\}.$$

Additionally observe that, given any $\varepsilon > 0$,

$$A \in \mathbb{U}_\varepsilon \quad \text{satisfies} \quad \min_{a_{ij}>0}\{a_{ij}\} = \varepsilon$$

(where $\mathbb{U}_\varepsilon$ is the set defined in (3.2)).

From this discussion, it is easy to establish the following lemmas.

LEMMA 6.1. *For each compact $P \subset \mathcal{E}$ and each $\varepsilon > 0$, there exists a constant $c(P,\varepsilon)$ given by*

$$c(P,\varepsilon) = \frac{1}{2}\,\varepsilon\kappa_1 \min_{\bar{x}\in P} \min_j e^{\langle b_j, \rho(\bar{x})\rangle}$$

such that

$$W(x,\bar{x}) \geq c(P,\varepsilon)\,\Psi(x,\bar{x}) \tag{6.4}$$

$\forall\, x \in \mathbb{R}^n_{>0}$ and any element $\bar{x} \in P$.

LEMMA 6.2. *Let $P \subset \mathcal{E}$ be any compact set. Given any compact subset $F \subset \mathbb{R}^n_{\geq 0}$ containing the set P, there exists a class $\mathcal{K}_\infty$ function, $\alpha = \alpha_{P,F}$, such that*

$$\Psi(x,\bar{x}) \geq \alpha(|x-\bar{x}|)$$

$\forall\, \bar{x} \in P$, $x \in F \cap \mathcal{S}_{\bar{x}}$.

Proof. Pick any compact set $P \subset \mathcal{E}$. Let $F \subset \mathbb{R}^n_{\geq 0}$ be any compact set which contains P, and let R_0 be such that the closed ball $|x| \leq R_0$ contains the set F. Define $R = R_0 + \max_{\bar{x}\in P}\ \bar{x}$. Note that, for every $\bar{x} \in P$, the ball $|x-\bar{x}| \leq R$ also contains the set F. Consider the function $\mathbb{R}^n_{\geq 0} \to \mathbb{R}^n_{\geq 0}$ given by

$$\alpha(r) := \begin{cases} \frac{r}{r+1}\min\{\Psi(x,\bar{x}) :\ \bar{x}\in P, x \in \mathcal{S}_{\bar{x}}, r \leq |x-\bar{x}| \leq R\} & \forall\, 0 \leq r \leq R, \\ \alpha(R)\frac{r}{R} & \forall\, r > R. \end{cases}$$

As discussed above, for $x \in \mathcal{S}_{\bar{x}}$, $\Psi(x,\bar{x}) = 0$ if and only if $x = \bar{x}$. Since the minimum is taken over a compact set, the function α satisfies $\alpha(0) = 0$ and $\alpha(r) > 0$ for $r > 0$. Also clearly, for $R \leq r$, α is strictly increasing and satisfies $\alpha(r) \to +\infty$ as $r \to +\infty$. For $0 \leq r \leq R$, $\alpha(r)$ is also strictly increasing, as a product of a strictly increasing function and a nondecreasing function. By construction, $\Psi(x,\bar{x}) \geq \alpha(|x-\bar{x}|)$ for all $\bar{x} \in P$, $x \in F \cap \mathcal{S}_{\bar{x}}$. Finally, without loss of generality we may assume that α is continuous on $\mathbb{R}_{\geq 0}$ (otherwise, it is possible to construct a continuous $\tilde{\alpha}$, $\tilde{\alpha}(0) = 0$, with $\alpha(r) \geq \tilde{\alpha}(r)$, and $\tilde{\alpha}(r) \to +\infty$ as $r \to +\infty$). □

Pick any $\varepsilon > 0$ and consider the sets $\mathbb{U}_\varepsilon$ and $\mathcal{W}$ as defined in (3.2) and (3.3), respectively. For any point $\bar{x}_0 \in \mathcal{E}$, set $V_0(x) \equiv V(x,\bar{x}_0)$, where V is the function defined in (5.1). As in section 2, let $\mathcal{S}_{\bar{x}_0}$ be the class that contains $\bar{x}_0$.

PROPOSITION 6.3. *Given any compact sets $P \subset \mathcal{E}$ and $F \subset \mathbb{R}^n_{\geq 0}$ containing P, there exist class $\mathcal{K}_\infty$ functions $\alpha = \alpha_{P,F}$ and $\gamma = \gamma_{P,F}$ such that, for every $\bar{x}_0 \in P \cap E_{A_0,+}$ for some $A_0 \in \mathbb{U}_\varepsilon$,*

$$\nabla V_0(x)\ f(x,u) \leq -\alpha(|x-\bar{x}_0|) + \gamma(|u-A_0|_{\text{ecl}})$$

for every $u \in \mathbb{U}_\varepsilon$ and every $x \in F \cap \mathcal{S}_{\bar{x}_0} \cap \mathbb{R}^n_{>0}$.

Proof. Pick any compact sets $P \subset \mathcal{E}$ and $F \subset \mathbb{R}^n_{\geq 0}$ containing P. Let $c(P,\varepsilon)$ be the constant given by Lemma 6.1, and let $\tilde{\alpha} = \tilde{\alpha}_{P,F}$ be the $\mathcal{K}_\infty$ function given by

Lemma 6.2. Now, pick any $\bar{x}_0 \in P \cap E_{A_0,+}$ for some $A_0 = (a^0_{ij}) \in \mathbb{U}_\varepsilon$. Using the notation $q_i \equiv q_i(x, \bar{x}_0)$ (defined in (5.4)), we have

$$\begin{aligned}
\nabla V_0(x)\ f(x,u) &= \sum_{i=1}^m \sum_{j=1}^m u_{ij} e^{\langle b_j, \rho(\bar{x}_0)\rangle} e^{q_j}(q_i - q_j) \\
&= \sum_{i=1}^m \sum_{j=1}^m u_{ij} e^{\langle b_j, \rho(\bar{x}_0)\rangle} e^{q_j}(q_i - q_j - (e^{q_i - q_j} - 1)) \\
&\quad + \sum_{i=1}^m \sum_{j=1}^m u_{ij} e^{\langle b_j, \rho(\bar{x}_0)\rangle} e^{q_j}(e^{q_i - q_j} - 1) \\
&= -\sum_{i=1}^m \sum_{j=1}^m u_{ij} e^{\langle b_j, \rho(\bar{x}_0)\rangle} e^{q_j}\, \omega(q_i - q_j) \\
&\quad + \sum_{i=1}^m \sum_{j=1}^m (u_{ij} - a^0_{ij}) e^{\langle b_j, \rho(\bar{x}_0)\rangle}(e^{q_i} - e^{q_j}),
\end{aligned}$$

where $\omega(r)$ is the function defined in (5.5). The last equality is justified because $\omega(r) \geq 0\ \forall\, r \in \mathbb{R}$ and, by (5.7),

$$\sum_{i=1}^m \sum_{j=1}^m a^0_{ij} e^{\langle b_j, \rho(\bar{x}_0)\rangle}(e^{q_i} - e^{q_j}) = (e^{q_1}, \ldots, e^{q_m})' \tilde{A}_0 \theta_B(\bar{x}_0) = 0.$$

Applying Lemmas 6.1 and 6.2, there is a $\mathcal{K}_\infty$ function $\tilde{\alpha}$ such that

$$\begin{aligned}
\nabla V_0(x)\ f(x,u) \leq &-c(P,\varepsilon)\, \tilde{\alpha}(|x - \bar{x}_0|) \\
&+ |u - A_0|_{\text{ecl}} \sum_{i=1}^m \sum_{j=1}^m e^{\langle b_j, \rho(\bar{x}_0)\rangle}\, |e^{q_i} - e^{q_j}|\,.
\end{aligned}$$

Next, let

$$c_2(P,F) = (m^2 - m) \max_j \max_{\bar{x}_0 \in P} e^{\langle b_j, \rho(\bar{x}_0)\rangle} \max_j \max_{x \in F} e^{q_j}$$

and observe that

$$|u - A_0|_{\text{ecl}} \sum_{i=1}^m \sum_{j=1}^m e^{\langle b_j, \rho(\bar{x}_0)\rangle}\, |e^{q_i} - e^{q_j}| \leq 2\, c_2(P,F)\, |u - A_0|_{\text{ecl}}$$

$\forall\, x \in F$.

Finally, choose $\alpha = \alpha_{P,F}$ to be $\alpha(r) = c(P,\varepsilon)\tilde{\alpha}(r)$ and $\gamma = \gamma_{P,F}$ to be $\gamma(r) = 2\, c_2(P,F)\, r$. □

6.1. Proof of Theorem 3.5. Let $\varepsilon > 0$ be any constant and consider the input-value set $\mathbb{U}_\varepsilon$ defined in (3.2) and the set $\mathcal{W}$ defined in (3.3). Proposition 5.3 shows that system (2.3) is $\mathbb{R}^n_{>0}$-forward complete with respect to input maps in $\mathcal{W}$.

Choose any compact sets $P \subset \mathcal{E}$ and $F \subset \mathbb{R}^n_{\geq 0}$ with $P \subset F$. Pick any element $\bar{x}_0 \in P$ and any matrix $A_0 \in \mathbb{U}_\varepsilon$ so that $\bar{x}_0 = \bar{x}(x_0, A_0)$ for some $x_0 \in F \cap \mathbb{R}^n_{>0}$.[2] Using

[2] If no such A_0 exists, that is, if $P \cap E_{A_0,+} = \emptyset\ \forall\, A_0 \in \mathbb{U}_\varepsilon$, then there is nothing to prove, because the statement of Definition 3.2 is vacuous. But if A_0 exists, then x_0 always exists, for instance, $\bar{x}_0$.

this element $\bar{x}_0$, construct the function $V_0(x) := V(x, \bar{x}_0)$. This function V_0 satisfies properties (i) and (ii) of Definition 3.3 and Proposition 6.3 establishes property (iii). Hence V_0 is a uniformly semiglobal ISS-Lyapunov function for system (2.3).

By Lemma 3.4, it follows that system (2.3) is uniformly semiglobal ISS with the input-value set $\mathbb{U}_\varepsilon$, as we wanted to show.

6.2. Proof of Theorem 3.6. Let $\varepsilon > 0$ be any constant and consider the input value set $\mathbb{U}_\varepsilon$ defined in (3.2) and the set $\mathcal{W}$ defined in (3.3). Proposition 5.3 shows that system (2.3) is $\mathbb{R}^n_{>0}$-forward complete with respect to input maps in $\mathcal{W}$. Assume that system (2.3) is mass conservative, i.e., there exists $v = (v_1, \ldots, v_n)' \in \mathbb{R}^n_{>0}$ so that $\langle v, f(x,u)\rangle = 0$ for every $x \in \mathbb{R}^n$ and every $u \in \mathbb{U}_\varepsilon$.

Choose any compact subset $P \subset \mathcal{E}$ and put

$$F(P) := \text{ closure } \big\{q \in \mathbb{R}^n_{>0} : \ \bar{x}(q, A) \in P \text{ for some } A \in \mathbb{U}_\varepsilon\big\}.$$

Then $F(P)$ is a compact subset of $\mathbb{R}^n_{\geq 0}$ because it is closed and also bounded, since

$$q \in F(P) \ \Rightarrow \ \exists\, \bar{x} \in P \ \text{ such that } \ v_i q_i \leq \langle v, q\rangle = \langle v, \bar{x}\rangle \ \Rightarrow \ q_i \leq \frac{1}{v_i}|v||\bar{x}| \leq \overline{c}\,\frac{|v|}{v_i}$$

$\forall\, i$, where $\overline{c} = \max\{|\bar{x}| : \ \bar{x} \in P\}$. Moreover, given any $\bar{x} \in P$, $F(P)$ contains the whole class $\mathcal{S}_{\bar{x}}$.

Now, pick any element $\bar{x}_0 \in P$ and any matrix $A_0 \in \mathbb{U}_\varepsilon$ so that $\bar{x}_0 = \bar{x}(x_0, A_0)$ for some $x_0 \in F(P) \cap \mathbb{R}^n_{>0}$.[2] Using this element $\bar{x}_0$, construct the function $V_0(x) := V(x, \bar{x}_0)$. This function V_0 satisfies properties (i) and (ii) of Definition 3.3. Moreover, the two $\mathcal{K}_\infty$ functions provided by Proposition 6.3 depend only on P:

$$\alpha = \alpha_{P,F(P)} \equiv \alpha_P \quad \text{ and } \quad \gamma = \gamma_{P,F(P)} \equiv \gamma_P.$$

So, V_0 is in fact a uniformly ISS-Lyapunov function for system (2.3).

By Lemma 3.4, it follows that system (2.3) (when constrained to take input maps in $\mathcal{W}$) is uniformly ISS with the input-value set $\mathbb{U}_\varepsilon$.

7. Conclusions. We have extended the analysis of zero deficiency biochemical networks to the case where the kinetic parameters associated with each reaction rate are assumed to be time-varying inputs. We have shown that these rate controlled biochemical systems are input-to-state stable with respect to an appropriate input set. Thus one may analyze the stability of the biochemical network when the reaction rates are controlled by some independent process; for instance, some reactions may be inhibited or activated through enzymatic activity. Also as a consequence of the ISS property, we conclude that such systems of biochemical networks are robust with respect to small perturbations in the kinetic parameters such as temperature fluctuations.

By definition, the zero deficiency biochemical networks are assumed to be closed systems in the sense that there are no inflows or outflows (such as additive inputs). While the systems we have studied also do not allow any inflows or outflows, we have nevertheless incorporated outside effects, in the form of "multiplicative" inputs, by allowing an independent system to control the reaction rates.

Appendix. The Perron eigenvector $\mathbf{v_P}$. By a *rational function everywhere defined on* $\mathcal{G}$ we mean a function $\psi : \mathcal{G} \to \mathbb{R}^m$ for which every coordinate is a quotient $\psi_i = p_{\text{num}} p_{\text{den}}^{-1}$ of two polynomial functions (on the entries of G) $p_{\text{num}}, p_{\text{den}} : \mathbb{R}^{m\times m} \to \mathbb{R}$ such that $p_{\text{den}}(G) \neq 0\ \forall\, G \in \mathcal{G}$.

PROPOSITION A.1. *The map v_P is a rational function on $\mathcal{G}$.*

Proof. For each $G \in \mathcal{G}$, by an abuse of notation, we write $v_{\rm P}$ for $v_{\rm P}(G)$. We will also drop the subscript and we let $M = M_G$ for simplicity. We have $Mv_{\rm P} = \sigma(M)v_{\rm P} \Leftrightarrow (M-I)v_{\rm P} = 0$. The matrix $M-I$ has rank $m-1$ because $\sigma(M) = 1$ is a simple root of the characteristic polynomial of M. Put $M - I = (N_1\ N)$, where N_1 is the first column of $M-I$ and N is the remaining $m \times (m-1)$ matrix, and notice that

$$(N_1\ N)\begin{pmatrix} 1 \\ w_{\rm P} \end{pmatrix} = 0 \ \Leftrightarrow\ Nw_{\rm P} = -N_1.$$

Claim. The matrix N has full rank.

Suppose the claim is false. Then there exists an element u in the kernel of N, and one can write $N(w_{\rm P} + u) = -N_1$. But if this is true, then it also holds that

$$(M-I)\begin{pmatrix} 1 \\ w_{\rm P} + u \end{pmatrix} = 0$$

which implies $w_{\rm P} + u = w_{\rm P}$, because $v_{\rm P}$ is in fact the unique vector with first coordinate equal to 1 in the kernel of $M-I$. So $u \equiv 0$, which proves the claim.

It follows that $\det(N'N) \neq 0$ for every G, and applying the Moore–Penrose pseudo-inverse of N yields

$$v_{\rm P} = \begin{pmatrix} 1 \\ w_{\rm P} \end{pmatrix} = \begin{pmatrix} 1 \\ -(N'N)^{-1}N'N_1 \end{pmatrix},$$

where N and N_1 are defined from $M = M_G$, as above. This shows that $v_{\rm P}$ is a rational function on $\mathcal{G}$. ∎

For every $G \in \mathcal{G}$, the Perron eigenvector of M_G, $v_{\rm P}$, is also an eigenvector of the matrix G, corresponding to the 0 eigenvalue, and has multiplicity 1. This fact follows from two observations.

1. $\ker(G) \neq \emptyset$, so $\exists v \in \mathbb{R}^m \setminus \{0\}$ such that $Gv = 0$.

This is because $\bar{1}G = 0$, which means that the rows of G are linearly dependent and thus have rank $G \leq m-1$.

2. Any v such that $Gv = 0$ satisfies $v \in$ span $\{v_{\rm P}\}$.

This follows from

$$(\phi(G)\,G + I)v = v \Rightarrow (\phi(G)\,G + I)^{m-1}v = M_G\,v = v,$$

and hence $v \in$ span $\{v_{\rm P}\}$, since $\sigma(M_G) = 1$ is an eigenvalue of M_G, of multiplicity 1.

Therefore, the kernel of G has dimension 1 and is given by

$$\ker(G) = \text{ span}\,\{v_{\rm P}(G)\}. \tag{A.1}$$

AN OPTIMAL OPTICAL FLOW*

KAZUFUMI ITO†

Abstract. The problem of determining optical flow for the image registration problem is discussed. Feedback solutions are proposed, and it is shown that they are optimal for certain optimal control formulations of the problem. Well-posedness of the proposed feedback solutions is analyzed, and numerical findings are presented.

Key words. optical flow, feedback solution

DOI. 10.1137/S0363012904433444

1. Introduction.

In this paper we discuss the image registration problem [8, 4]. Let $I(t,x) \geq 0$ denote the brightness of an image defined on $[0,T] \times \Omega$, where Ω is a bounded domain in R^d, $d = 2, 3$, with sufficiently smooth boundary. Consider the optical flow equation

$$\frac{\partial}{\partial t} I + V \cdot \nabla I = 0, \quad I(0) = I_0, \tag{1.1}$$

where $\nabla I = \mathrm{grad}_x I$ is the gradient of I with respect to $x \in R^d$. Let I_1 be a target image at T. The problem is to find a vector field $V = V(t,x)$ such that $I(T) = I_1$. From this optical flow V, information about the spatial arrangement of an object and its rate of change ought to be determined. Assuming that objects represented in the image are flat surfaces, that illumination is uniform, and that reflectance varies smoothly and has no spatial discontinuities, the image brightness of an object point remains constant in the images when the object moves [8]. That is, the total derivative of I vanishes, which results in (1.1). Optical flow is often a convenient and useful image motion representation, and there has been increasing literature using this approach (e.g., [8, 2, 1, 15, 4]) during the last decade.

In this paper we propose a method to construct such a vector field V, and we test and analyze the proposed methods. We follow the optimal control formulation in [4]: find V that minimizes

$$J(I,V) = \int_0^\tau \int_\Omega \left[\frac{\alpha(|\nabla I(t)|)}{q} |V(t)|^q + \frac{\beta(|\nabla I(t)|)}{p} |I(t) - I_1|^p \right] dxdt \tag{1.2}$$

subject to (1.1), where $\frac{1}{p} + \frac{1}{q} = 1$ and nonnegative functions α, β are chosen appropriately. In order to obtain a smoother vector field $V(t) = V(t,x)$ (say, in $H^1(\Omega)$), for $\delta > 0$ we also consider the following regularized optimal control formulation:

$$\begin{aligned} \min \frac{1}{2} \int_0^\tau \big[&((I - \delta\,\Delta)^{-1}(|I(t) - I_1|^{p-1}\mathrm{sign}(I(t) - I_1)\nabla I), \\ &|I - I_1|^{p-1}\mathrm{sign}(I(t) - I_1)\nabla I)_{L^2(\Omega)} + (|V|^2_{L^2(\Omega)} + \delta\,|\nabla V|^2_{L^2(\Omega)})\big]\, dt, \end{aligned} \tag{1.3}$$

subject to (1.1), where Δ is the Laplace operator.

In [4] an iterative algorithm based on the Lagrange multiplier method is developed for determining the optimal vector field $V(t)$ that minimizes the cost functional, and it is tested numerically. In this paper (section 1.1) the feedback solution for (1.2) in the following forms is derived:

$$V(t,x) = \frac{1}{T-t}\,(I(t)-I_1)\Phi(|\nabla I(t)|)\,\nabla I(t) \tag{1.4}$$

and

$$V(t,x) = |I(t)-I_1|^{p-1}\mathrm{sign}(I(t)-I_1)\,\Phi(|\nabla I(t)|)\,\nabla I(t). \tag{1.5}$$

Let

$$\Psi(s) = \Phi(s)\,s^2, \quad s \in R^+,$$

and assume $\Psi : R^+ \to R^+$ is Lipschitz with $\Psi(0) = 0$. The resulting closed loop equations for I are thus given by

$$I_t + \frac{1}{T-t}\,(I(t)-I_1)\Psi(|\nabla I(t)|) = 0, \quad I(0) = I_0, \tag{1.6}$$

and

$$I_t + |I(t)-I_1|^{p-1}\mathrm{sign}(I(t)-I_1)\Psi(|\nabla I(t)|) = 0, \quad I(0) = I_0, \tag{1.7}$$

respectively. For example, we use in our testing

$$\Psi(s) = \frac{s}{\max(c,s)}, \quad \Phi(s) = \frac{1}{s\max(c,s)}$$

for some $c > 0$. If we let $\Phi(s) = \frac{1}{s}$, then (1.4)–(1.5) reduces to the geometrical motion [11, 13]

$$I_t + \frac{1}{T-t}\,(I(t)-I_1)|\nabla I(t)| = 0, \quad I(0) = I_0,$$

and

$$I_t + |I(t)-I_1|^{p-1}\mathrm{sign}(I(t)-I_1)\,|\nabla I(t)| = 0, \quad I(0) = I_0.$$

The corresponding optimal feedback law (section 1.2) for (1.3) is given by

$$V(t,x) = (I-\delta\,\Delta)^{-1}(\mathrm{sign}(I(t)-I_1)|I(t)-I_1|^{p-1}\nabla I(t)), \tag{1.8}$$

where Δ is the Laplace operator. If $\delta = 0$, then (1.8) reduces to a specific case of (1.5). Because of the nonlocal operation $(I-\delta\,\Delta)^{-1}$ for determining the vector field V at a given time t, the evaluation of (1.8) costs more in terms of its implementation compared to that for (1.5).

The proposed algorithms are of the feedback form; i.e., the vector field V is determined along with the reformed image I by integrating (1.1) with (1.5) or (1.8) in time. Thus it is an alternative to the iterative methods discussed in [8, 4] and references therein. If we solve for $X(t) = X(t;x)$ at each $x \in \Omega$,

$$\frac{d}{dt}X(t) = V(t,X(t)), \quad X(0) = x, \tag{1.9}$$

then $M(x) = X(T;x)$ defines a mapping such that $I_1(x) = I_0(M(x))$ if $I_1 = I(T)$.

In [1, 15] the (stationary optical flow) optimization of the form

$$E(h) = \int_\Omega [|I_0(x - h(x)) - I_1(x)|^2 + C\,\mathrm{trace}(\nabla h\, D(\nabla I_0)\, \nabla h)]\, dx$$

over maps $h : R^2 \to R^2$ with an appropriate matrix weight D is analyzed, and the iterative schemes for finding the optimal map ($M(x) = x - h(x)$) are developed and tested. We also refer to [2] for the alternative approaches and performance comparisons. Finally, we note that our algorithm does not require us to take the derivatives of the images I_0 and I_1 directly.

The following is the key property of the proposed algorithms. Suppose I is a Lipschitz solution of (1.6). By multiplying (1.6) by $I(t) - I_1$ and integrating in x over Ω, we obtain

$$\frac{d}{dt}\frac{1}{2}\int_\Omega |I(t) - I_1|^2\, dx + \int_\Omega \frac{1}{T-t}\, |I(t) - I_1|^2 \Psi(|\nabla I(t)|)\, dx = 0.$$

Thus, $t \to |I(t) - I_1|_{L^2(\Omega)}$ is decreasing and

$$\liminf_{t \to T} \int_\Omega |I(t) - I_1|^2 \Psi(|\nabla I(t)|)\, dx = 0.$$

Moreover, if $\Psi(|\nabla I(t,x)|) \geq \omega > 0$ a.e. in $(0,T) \times \Omega$, then

$$|I(t) - I_1|_{L^2} \leq \left(\frac{T-t}{T}\right)^\omega |I_0 - I_1|_{L^2}$$

and thus $I(T) = I_1$. Similarly, for (1.7),

$$\frac{d}{dt}\frac{1}{2}\int_\Omega |I(t) - I_1|^2\, dx + \int_\Omega |I(t) - I_1|^p \Psi(|\nabla I(t)|)\, dx = 0.$$

If $\Psi(|\nabla I(t,x)|) \geq \omega > 0$ a.e. in $(0,T) \times \Omega$ and $1 \leq p < 2$, then $|I(t) - I_1|_{L^2} = 0$ in a finite time, say $\tau > 0$. Then, we scale the time by $\frac{T}{\tau}$ to obtain $I(T) = I_1$. Similar results also hold for (1.3) and (1.8) (see section 1.2).

Remark 1. Note that any C^1 solution to (1.1) satisfies

$$\max_{x \in \Omega} I(t,x) = \max_{x \in \Omega} I_0(x)$$

for all $t \geq 0$. Thus, in order to have $I(T) = I_1$, it is necessary to have

$$\max_{x \in \Omega} I_0(x) = \max_{x \in \Omega} I_1(x).$$

Otherwise, $\Psi(|\nabla I(t,x)|) \to 0$ as $t \to \infty$ on a subset of Ω, and thus $I(t)$ does not converge to I_1 in a finite time. However, it is observed numerically that $I(t)$ converges to $\min(I_1, \max(I_0))$.

Remark 2. From the above estimate problem, (1.2) as well as (1.3) is the exit problem with $T = \tau$, and the exit time is given by

$$\tau = \inf\left\{t : \int_\Omega |\nabla I(t)|\, |I(t) - I_1|\, dx = 0\right\}.$$

That is, it is possible that it is terminated with a nontrivial subdomain $\tilde{\Omega}$ such that $|\nabla I(\tau, x)| = 0$ and $I(\tau, x) = \max_{x \in \Omega} I(\tau, x) =$ a constant on $\tilde{\Omega}$.

Remark 3. It should be noted that our problem is closely related to the so-called Monge–Kantorovich mass transport problem in the form described in [3]: find a vector field V that minimizes

$$\int_0^T \int_\Omega \rho(t,x)\,|V(t,x)|^2\,dxdt$$

subject to

$$\rho_t + \nabla\cdot(\rho\,V) = 0,$$

$$\rho(0,x) = \rho_0(x), \quad \text{and} \quad \rho(T,x) = \rho_1(x).$$

In [3] an iterative method based on the augmented Lagrangian method is developed for this optimal control problem. It is of interest here to construct a feedback solution to the problem.

Through our numerical testing we observed the following:

- Algorithms (1.5) in general are very efficient, using the numerical integrations outlined in section 2, and work very well for short-range motion including expansion and redistribution. However, for long-range motion we observed cases with a nontrivial subdomain $\tilde{\Omega}$ such that $|\nabla I(\tau,x)| = 0,\ x \in \tilde{\Omega}$.
- Algorithms (1.8) cost more in general but produce smoother motion representations. Also, they work well for long-range motion including large transport. Throughout our numerical tests we did not observe the constant subdomain cases (see Remark 2). However, the convergence of this algorithm is slower in general compared to that for (1.5).

These observations are not surprising because the level-set equation (1.6) works well for the front propagation but may result in a constant subdomain for algorithm (1.5). Because of the nonlocal operation of (1.8), constant regions are prevented, but τ can be ∞ for algorithm (1.8). In conclusion, algorithms (1.5) and (1.8) should be used in the combined manner such that (1.8) is first employed to capture the long-range motions and (1.5) is then used for faster convergence and an accurate representation for the localized motions. This combination is implemented for our numerical tests and is quite effective.

An outline of the paper is as follows. In section 2 we describe numerical integration methods we used to implement the proposed algorithms (1.5) as well as (1.8) and present our numerical tests and findings. In section 3 we present the well-posedness of the proposed algorithm. We conclude the section with the optimality of (1.5) and analysis for the regularized version (1.8).

1.1. Optimality. The feedback solution (1.5) is optimal in the following sense. Consider the optimal control problem

$$\min \quad \int_0^\tau \int_\Omega \left[\frac{\alpha(|\nabla I(t)|)}{q}\,|V(t)|^q + \frac{\beta(|\nabla I(t)|)}{p}|I(t) - I_1|^p \right] dxdt$$

subject to (1.1), where $\frac{1}{p} + \frac{1}{q} = 1$ and $\tau \geq 0$ is the exit time defined by

$$\tau = \inf\left\{ t : \int_\Omega \beta(|\nabla I|)\,|I(t) - I_1|^p = 0 \right\}.$$

Nonnegative functions $\alpha,\ \beta$ should be chosen so that

$$\frac{\beta(s)}{s} = \left(\frac{\alpha(s)}{s}\right)^{1-p}$$

and $\beta = \Psi$, where Ψ appears in (1.6)–(1.7). For example, we have the specific cases

$$\alpha(s) = 1, \quad \beta(s) = s^p, \quad \text{and} \quad \alpha(s) = \beta(s) = s.$$

In our experiments we used

$$\beta(s) = \Psi(s) = \frac{s}{\max(c, s)} = \begin{cases} \dfrac{s}{c} & \text{if } s \le c, \\ \\ 1 & \text{if } s \ge c \end{cases}$$

for some $c > 0$, and the corresponding α is given by

$$\alpha(s) = \begin{cases} c^{q-1} s & \text{if } s \le c, \\ \\ s^q & \text{if } s \ge c. \end{cases}$$

First, we claim that $\mathcal{V}(I) = \frac{1}{2} \int_\Omega |I(x) - I_1(x)|^2$ satisfies the formal Hamilton–Jacobi equation

$$\min_V \int_\Omega \left[-(\mathcal{V}_I, V \cdot \nabla I) + \frac{\alpha(|\nabla I|)}{q} |V|^q + \frac{\beta(|\nabla I|)}{p} |I - I_1|^p \right] dx = 0, \tag{1.10}$$

where $(\mathcal{V}_I, \phi) = (I - I_1, \phi)$. In fact, without loss of generality we let $V = c \frac{\nabla I}{|\nabla I|}$ for almost every x in Ω. Then

$$J = -(\mathcal{V}_I, V \cdot \nabla I) + \frac{\alpha(|\nabla I|)}{q} |V|^q = -c|\nabla I| \, (I - I_1) + \frac{\alpha(|\nabla I|)}{q} |c|^q \tag{1.11}$$

is minimized when

$$c = (|\nabla I| \alpha^{-1}(|\nabla I|)|I - I_1|)^{\frac{1}{q-1}} \operatorname{sign}(I - I_1)$$

and

$$\min \quad J = -\frac{1}{p} |\nabla I|^p \alpha^{-\frac{1}{q-1}}(|\nabla I|)|I - I_1|^p$$

for almost every x in Ω. Since $\frac{1}{q-1} = p - 1$, if we let

$$\Psi(s) = \beta(s) = s^p \alpha(s)^{1-p} \quad \text{and} \quad \Phi(s) = s^{p-2} \alpha(s)^{1-p},$$

then the feedback form

$$V = V(I) = |I - I_1|^{p-1} \operatorname{sign}(I - I_1) \Phi(|\nabla I|) \, \nabla I$$

as defined by (1.5) attains the minimum in (1.11), and $\mathcal{V}$ satisfies (1.10).

Next, we argue the optimality. Let $W \in W^{1\infty}((0, \tau) \times \Omega)$. Then (1.1) has a unique solution $I \in W^{1,\infty}((0, \tau))$; e.g., see [4]. We assume that τ is an exit time. Since $V = V(I)$ as above minimizes J a.e. in Ω, thus

$$\begin{aligned} \frac{d}{dt} \mathcal{V}(I(t)) &= -(I - I_1, W \cdot \nabla I) \\ &= \int_\Omega - \left[\frac{\alpha(|\nabla I|)}{q} |W|^q + \frac{\beta(|\nabla I|)}{p} |I - I_1|^p - \delta(W, V(I)) \right] dx, \end{aligned}$$

where $\delta(\hat{W}, V(I)) > 0$ if $\hat{W} \in R^d$ and $\delta(\hat{W}, V(I)) = 0$ if $\hat{W} = V(I)$. Hence we have

$$\int_0^\tau \int_\Omega \left[\frac{\alpha(|\nabla I|)}{q} |W|^q + \frac{\beta(|\nabla I|)}{p} |I - I_1|^p \right] dxdt$$

$$= \int_\Omega \frac{1}{2} |I_0 - I_1|^2 \, dx + \int_0^\tau \int_\Omega \delta(W, V(I)) \, dxdt.$$

Therefore (1.5) is optimal.

1.2. Regularization. In this section we discuss the regularized versions of (1.3) and (1.8). First, we can show that $\mathcal{V}(I) = \frac{1}{p} \int_\Omega |I(x) - I_1(x)|^p$ satisfies the (formal) Hamilton–Jacobi equation

(1.12)
$$\min_V \int_\Omega \Big[-(\mathcal{V}_I, V \cdot \nabla I) + \frac{1}{2} (|V|^2 + \delta |\nabla V|^2)$$
$$+ \frac{1}{2} ((I - \delta \Delta)^{-1} (|I - I_1|^{p-1} \text{sign}(I(t) - I_1) \nabla I), |I - I_1|^{p-1} \text{sign}(I(t) - I_1) \nabla I) \Big] \, dx = 0,$$

where $(\mathcal{V}_I, \phi) = (|I - I_1|^{p-1} \text{sign}(I - I_1), \phi)$. In fact, it is easy to see that

$$V = (I - \delta \Delta)^{-1} (\text{sign}(I - I_1) |I - I_1|^{p-1} \nabla I)$$

attains the minimum (0) of the quadratic form in (1.12). Thus, the corresponding optimal feedback law is given by (1.8), and its optimality can be argued using exactly the same arguments as in section 1.1.

In general we consider

$$V(t, x) = G(|I(t) - I_1|^{p-1} \text{sign}(I(t) - I_1) \nabla I(t)), \tag{1.13}$$

where

$$G : L^2(\Omega)^d \to L^2(\Omega)^d \quad \text{is a bounded, positive operator.}$$

For example,

$$GV = k_0 V(x) + \int_\Omega k(|x - y|) V(y) \, dy,$$

with a smoothing kernel $k \geq 0$ and $k_0 \geq 0$. For (1.8) we have

$$G = (I - \epsilon \Delta)^{-1}.$$

Suppose that I is a Lipschitz solution of (1.1) with (1.13). Then

$$\frac{d}{dt} \frac{1}{p} \int_\Omega |I(t) - I_1|^p \, dx + (G(|I - I_1|^{p-1} \text{sign}(I - I_1) \nabla I), |I - I_1|^{p-1} \text{sign}(I - I_1) \nabla I) = 0.$$

Thus, $t \to |I - I_1|_{L^p}$ is decreasing. Moreover, if $(GV, V)_{L^2} \geq \gamma |V|^2_{L^2}$ for some $\gamma > 0$, then

$$\frac{d}{dt} \frac{1}{p} \int_\Omega |I(t) - I_1|^p \, dx + \int_\Omega \gamma |I(t) - I_1|^{2p-2} |\nabla I|^2 \, dx \leq 0.$$

Hence, if $|\nabla I(t)|^2 \geq \omega > 0$ a.e. and $1 \leq p < 2$, then $|I(t) - I_1|_{L^p} = 0$ in a finite time $\tau > 0$.

2. Numerical integration and testing. In this section we discuss the numerical integration of the proposed methods and present testing results. We use the Gudnov-type scheme (see, e.g., [12, 16]) for the Hamilton–Jacobi equation on a fixed Cartesian grid with uniform mesh-size h of the square $\Omega = (0,1) \times (0,1)$, and time step-size $\Delta t > 0$ (satisfying the CFL condition); i.e.,

$$0 = \frac{I^{k+1} - I^k}{\Delta t} + c_k$$
$$\begin{cases} \Psi\left(\sqrt{[\max((D_x^-)_{i,j}I^k, -(D_x^+)_{i,j}I^k, 0)]^2 + [\max((D_y^-)_{i,j}I^k, -(D_y^+)_{i,j}I^k, 0)]^2}\right) \\ \qquad \text{for } \ c_k > 0, \\ \Psi\left(\sqrt{[\min((D_x^-)_{i,j}I^k, -(D_x^+)_{i,j}I^k, 0)]^2 + [\min((D_y^-)_{i,j}I^k, -(D_y^+)_{i,j}I^k, 0)]^2}\right) \\ \qquad \text{for } \ c_k < 0 \end{cases}$$

with

$$c_k = |I^k - I_1|^{p-1}(I^k - I_1).$$

If we use the first order backward and forward difference

$$(D_x^-)_{i,j}I = \frac{I_{i,j} - I_{i-1,j}}{h}, \quad (D_x^+)_{i,j}I = \frac{I_{i+1,j} - I_{i,j}}{h},$$

$$(D_y^-)_{i,j}I = \frac{I_{i,j} - I_{i,j-1}}{h}, \quad (D_y^+)_{i,j}I = \frac{I_{i,j+1} - I_{i,j}}{h},$$

then this is a monotone scheme, and its convergence can be argued, for example, as in [7, 12].

We use the third order WENO (weighted essential nonoscillatory) scheme [10] to evaluate the forward and backward differences $(D_x^-)_{i,j}I^k$, $(D_x^+)_{i,j}I^k$ and $(D_y^-)_{i,j}I^k$, $(D_y^+)_{i,j}I^k$. It is advantageous to use the higher order scheme to obtain accurate spatial discretization and reduce the CFL number requirement for the time step-size Δt. We refer to [11] and references therein for further discussion on approximation methods for the Hamilton–Jacobi equation. For the implementation of (1.1) with (1.8) we use the upwinding method based on WENO differences.

2.1. Test results. In our calculations we use (1.5) and (1.7) with $p = \frac{5}{4}$ and

$$\Psi(|\nabla I|) = \frac{|\nabla I|}{\max(c, |\nabla I|)},$$

where $c > 0$ is appropriately chosen (we choose $c = 0.5$ in our computations). Let $\Omega = (0,1) \times (0,1)$ and set $h = 0.01$.

Example 1. The first example [4] is

$$I(t) = \begin{cases} \frac{2}{3}(x+y) - \frac{1}{3}\,t & \text{if } x + y \geq 1, \\ \frac{1}{3}(x+y) + \frac{1}{3} - \frac{1}{3}\,t & \text{if } x + y \leq 1, \end{cases}$$

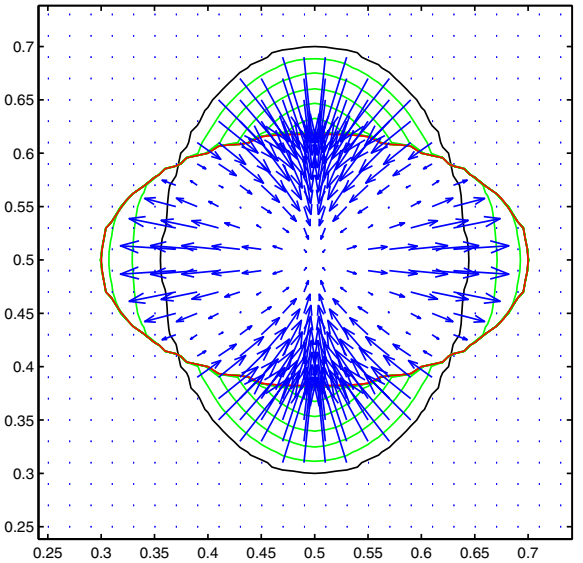

FIG. 1. *Evolution of deforming images from I_0 to I_1, using algorithm* (1.5).

and $I_0 = I(0)$ and $I_1 = I(1)$. In this example the constant field

$$V_0 = \begin{cases} \left(\frac{1}{2}, \frac{1}{2}\right) & \text{if } x + y > 1, \\ (1,1) & \text{if } x + y \le 1 \end{cases}$$

is a solution to problem (1.1). Our algorithm (1.5) with $c \le \frac{\sqrt{2}}{3}$ produces a solution

$$V(t,x) = c(t) \begin{cases} \left(\frac{1}{2}, \frac{1}{2}\right) & \text{if } x + y > 1, \\ (1,1) & \text{if } x + y \le 1, \end{cases}$$

with

$$c(t) = \frac{9}{2}\left(\left(\frac{1}{3}\right)^{\frac{3}{4}} - \frac{3}{4}t\right)^{\frac{1}{3}}.$$

Example 2. This example is a redistribution of image I_0 defined on an ellipse to image I_1 defined on a rotated and resized ellipse:

$$I_0 = \max(0, .041 - 2(x - .5)^2 - (y - .5)^2),$$

$$I_1 = \max(0, .041 - (x - .5)^2 - 3(y - .4)^2).$$

We compare the resulting motions using algorithms (1.5) and (1.8). In Figure 1 we show level curves $\{x \in \Omega : I(t,x) = .001\}$ at uniform time units and the net motion by arrows. The net motion is defined by $M(x) - x \in R^2$ on the support of

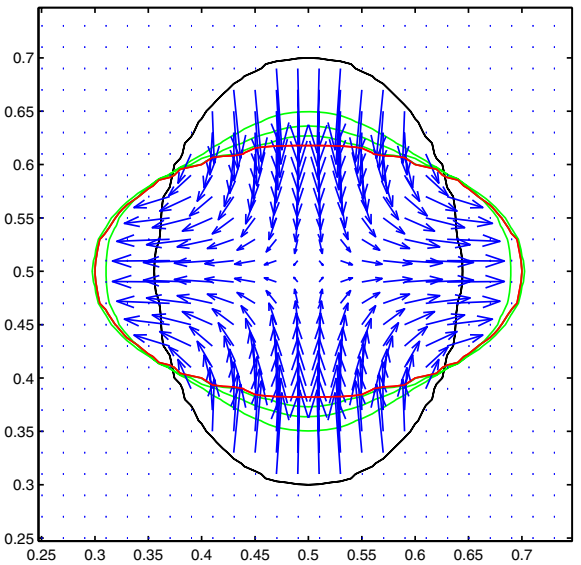

FIG. 2. *Evolution of deforming images from* I_0 *to* I_1*, using algorithm* (1.8).

I_0. The actual trajectory $X(t;x)$ from (1.9) is an oriented curved arc. In Figure 2 the corresponding results for algorithm (1.8) are shown. Algorithm (1.8) is actually terminated by algorithm (1.5) as described in introduction. Algorithm (1.8) results in a smoother motion representation.

For the remaining examples we used the combined algorithms as described in the introduction, i.e., algorithm (1.8) terminated by algorithm (1.5).

Example 3. This example is the same as in Example 2, with noise in I_1. We add i.i.d. (independently and identically distributed) noise uniformly distributed on $.041\,(-.1,.1)$ to I_1 at each pixel. We apply prefilter I_1 by $(I - 1.e^{-4}\,\Delta)^{-1}\,I_1$. It is observed that the final $I(\tau)$ deformed image from I_0 is much smoother that the target prefiltered noisy image I_1 due to the smooth vector field $V(\cdot,x) \in H^2(\Omega)$. Effects of noise can be noticed in Figure 3 compared to Figure 2 (noise-free) but the algorithm performs very well with large noise in the data.

Example 4. This example is for the transport and the redistribution of an image I_0 defined on an ellipse to I_1 defined on a circle:

$$I_0 = \max(0, .041 - 2(x-.5)^2 - (y-.5)^2),$$

$$I_1 = \max(0, .041 - 4(x-.6)^2 - 4(y-.4)^2).$$

The resulting level curves $\{x \in \Omega : I(t,x) = .001\}$ at uniform time units and the net motion by arrows are shown in Figure 4.

Example 5. This example is for the disjointly supported image I_0:

$$I_0 = \max(0, .041 - 4(x-.6)^2 - 4(y-.4)^2, .041 - 4(x-.4)^2 - 4(y-.6)^2)$$

merging into the connected image I_1 as $I_1 = I_0$ in Example 2. In Figure 5 the two disjointed level-sets $\{x \in \Omega : I(t,x) = .005\}$ merge into the center of I_1. The support of $I(t,x)$ remains disconnected under algorithm (1.8) and attached by the algorithm (1.5) phase.

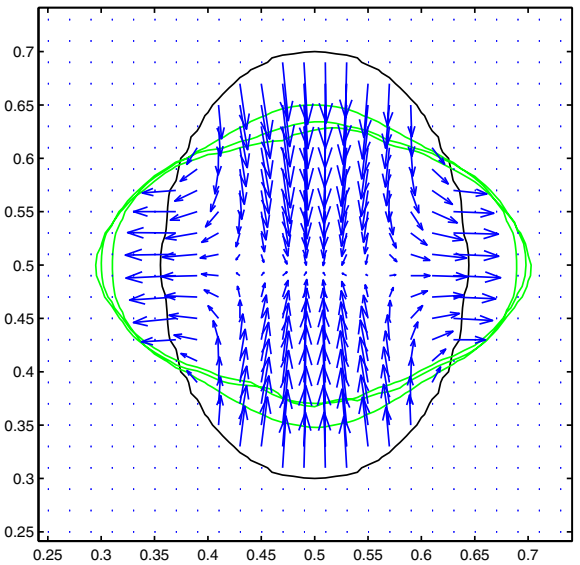

FIG. 3. *Evolution of deforming images from I_0 to I_1, with noise.*

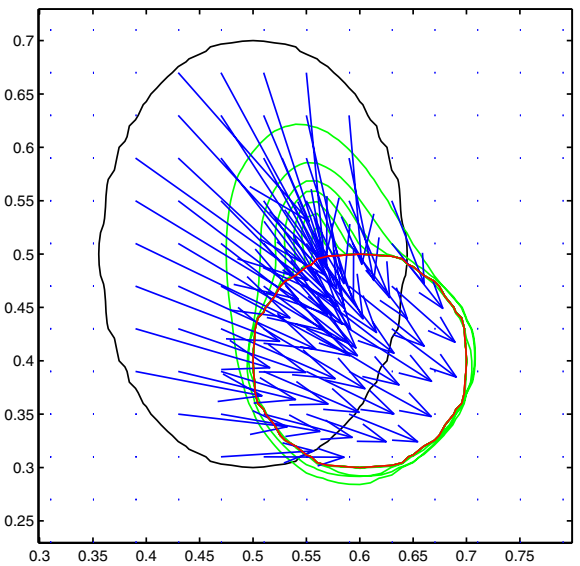

FIG. 4. *Evolution of deforming images from I_0 to I_1, for Example* 4.

Example 6. We tested our algorithm against a consecutive frame of the Yosemite fly-through image sequences by Lynn Quann at SRI. The sequence is generated by taking an aerial image of Yosemite valley and texture mapping it onto a depth map of the valley. It is a benchmark for optimal flow methods. The interest of this test is that one can give a quantitative evaluation of optimal flow methods; for example, the web page http://www.cs.brown.edu/people/black/ contains the files with ground truth flow fields and hints on how the errors should be computed. We have 256×256

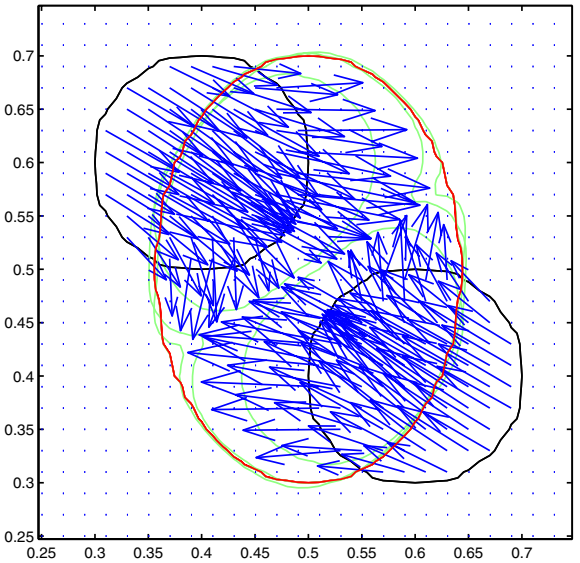

FIG. 5. *Evolution of deforming images from I_0 to I_1 with geometrical change.*

TABLE 1
Comparison between results reported in [2, 1] *with* 100% *density and our result.*

Technique	Average Error	Standard Deviation
Horn and Schunck (original)	31.69°	31.18°
Horn and Schunck (modified)	9.78°	16.19°
Nagel	10.22°	16.51°
Anandan (unthresholded)	13.36°	15.64°
Uras et al. (unthresholded)	8.94°	15.61°

Alvarez et al.	5.53°	7.40°
Our method	9.24°	10.77°

pixels, and we select $\Delta x = 1$ and normalize the images so that the maximum intensity is one. The sequence of images used for our testings and the resulting net motion are shown in Figure 6. The correct flow field and the estimated flow field are plotted on the top of each other for comparison.

The angular error is calculated in the same way as in [2] using

$$Error = \arccos\left(\frac{u_c u_e + v_c v_e + 1}{\sqrt{(u_c^2 + v_c^2 + 1)(u_e^2 + v_e^2 + 1)}}\right),$$

where (u_c, v_c) denotes the correct flow and (u_e, v_e) is the estimated flow. Our method performs better than the other methods except the one in [1] (see Table 1). As you can see from Figure 6, the majority of errors happen in the cloud region. We have the angular error 4.36° with standard deviation 3.86° if we exclude the cloud region.

3. Well-posedness. In this section we show the well-posedness of the proposed algorithm (1.5). A similar analysis can be done for algorithm (1.8) without much modification. For the clarity of our discussions we assume $\Omega = (0, 1)^d$, and we discuss the periodic boundary condition for I throughout this section. First we consider the

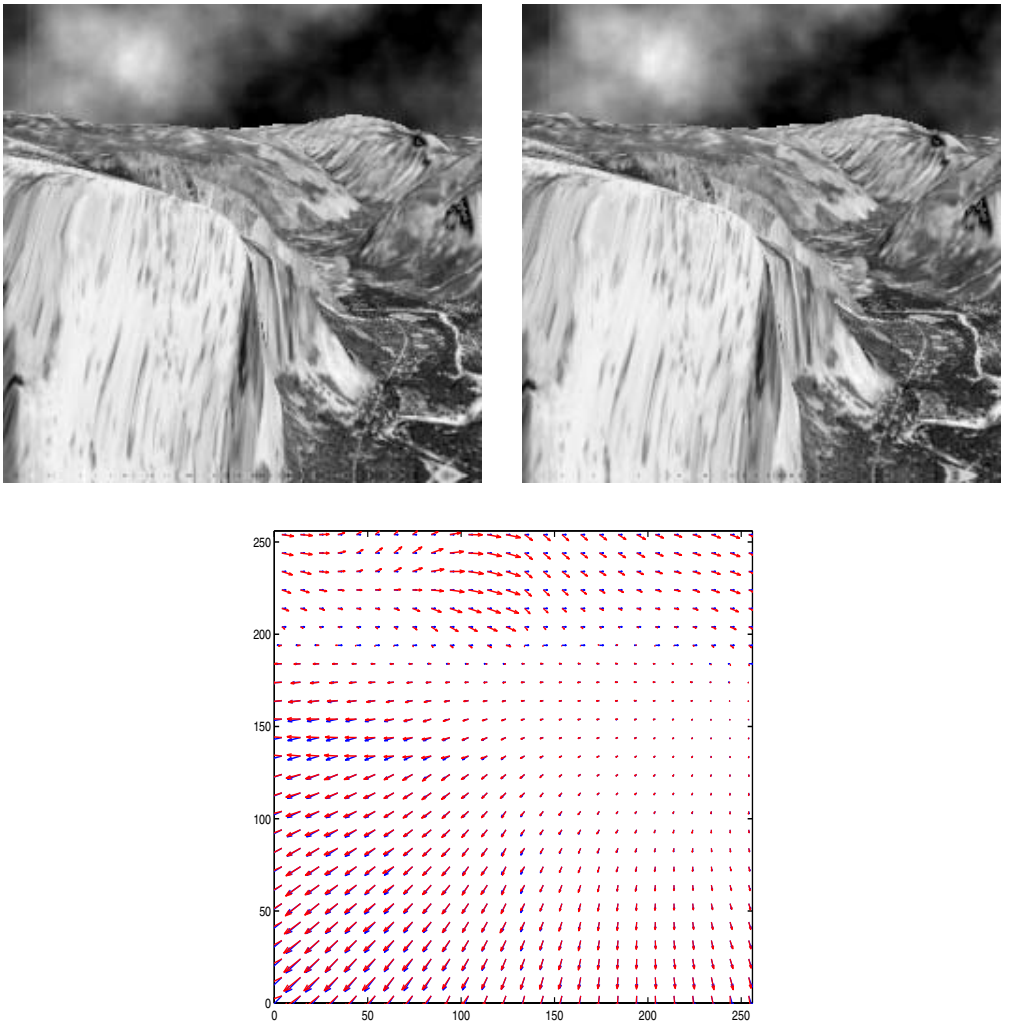

FIG. 6. *Yosemite fly-through images and optical flow.*

regularized problem

$$I_t + \phi(I - I_1)\psi(|\nabla I|) = \epsilon\,\Delta I, \quad I(0) = I_0, \tag{3.1}$$

where $\epsilon > 0$, $\phi : R \to R$ is a monotone increasing bounded Lipschitz function with $\phi(0) = 0$, and $\psi : R^+ \to R^+$ is a Lipschitz continuous function with $\psi(0) = 0$.

Let

$$X = \{I \in H^1(\Omega) : I \text{ is } \Omega \text{ periodic}\},$$

$$V = \{I \in H^2(\Omega) : I,\ \nabla I \text{ are } \Omega \text{ periodic}\}.$$

It can be proved (e.g., see [9]) that A on X defined by

$$AI = -\epsilon\Delta I + \phi(I - I_1)\psi(|\nabla I|)$$

satisfies

$$(AI_1 - AI_2, I_1 - I_2)_X \geq \frac{\epsilon}{2}|I_1 - I_2|_V^2 - \omega\,|I_1 - I_2|_X^2$$

for some $\omega > 0$ and $A : V \to V^* = L^2(\Omega)$ maximum [14], where X is the pivoting space. Note that for $I \in V$

$$\nabla[\phi(I - I_1)\psi(|\nabla I|)] = \phi'(I - I_1)\,(J - \bar{J})\psi(|J|) + \phi(I - I_1)\psi'(|J|)\frac{J}{|J|}\cdot\nabla J, \tag{3.2}$$

where $J = \nabla I$ and $\bar{J} = \nabla I_1$. Thus,

$$|\phi(I(\cdot) - I_1)\psi(|\nabla I(\cdot)|)|_{L^2(0,T;X)} \leq M\,|I(\cdot)|_{L^2(0,T;V)}$$

for some M. It follows from [14] that there exists a unique solution $I(\cdot)$ to (3.1) in $H^1(0,T;X) \cap L^2(0,T;H^3(\Omega)) \cap C(0,T;H^2(\Omega))$.

Let $q \geq 2$. Multiplying (3.1) by $|I|^{q-2}I$ and integrating in x over Ω, we obtain

$$\frac{d}{dt}\int_\Omega |I|^q\,dx + \int_\Omega [q\,|I|^{q-2}I\phi(I - I_1)\psi(|\nabla I|) + q(q-1)\epsilon\,|I|^{q-2}|\nabla I|^2]\,dx = 0.$$

Since $|\phi(I - I_1)\psi(|\nabla I|)| \leq \gamma\,|\nabla I|$ for some γ in Ω, thus

$$\frac{d}{dt}\int_\Omega |I|^q\,dx \leq \int_\Omega \frac{q\gamma^2}{4(q-1)\epsilon}|I|^q\,dx.$$

Hence

$$|I(t)|_{L^q(\Omega)} \leq e^{\frac{\gamma^2}{4(q-1)\epsilon}t}\,|I(0)|_{L^q(\Omega)}.$$

By letting $q \to \infty$, we obtain

$$|I(t)|_{L^\infty(\Omega)} \leq |I(0)|_{L^\infty(\Omega)}. \tag{3.3}$$

Note that, from (3.2), $J = \nabla I$ satisfies

$$J_t + \phi'(I - I_1)\,(J - \bar{J}) + \phi(I - I_1)\psi'(|J|)\frac{J}{|J|}\cdot\nabla J = \epsilon\,\Delta J. \tag{3.4}$$

Let $q \geq 2$. Multiplying (3.4) by $q\,|J|^{q-2}J$ and integrating over Ω, we obtain

$$\frac{d}{dt}\int_\Omega |J|^q\,dx + \int_\Omega [q\,|J|^{q-2}(E_1 + E_2)\cdot J\,dx - q\epsilon\,|J|^{q-2}(J\cdot\Delta J)]\,dx = 0,$$

where

$$E_1 = \phi'(I - I_1)\,(J - \bar{J})\psi(|J|),$$

$$E_2 = \phi(I - I_1)\psi'(|J|)\frac{J}{|J|}\cdot\nabla J.$$

By Green's theorem,

$$-\int_\Omega |J|^{q-2}(J\cdot\Delta J)\,dx = \int_\Omega \left[|J|^{q-2}|\nabla J|^2 + \frac{q-2}{2}\,|J|^{q-4}|\nabla|J|^2|^2\right]dx = 0.$$

Let $|\psi'| \le c_1$ and $0 \le \phi' \le c_2$. Note that

$$|J|^{q-2}J \cdot E_2 \le \frac{c_1}{2}|J|^{q-2}|\nabla|J|^2| \le \epsilon\,\frac{q-2}{2}\,|J|^{q-4}|\nabla|J|^2|^2 + \frac{c_1^2}{4\epsilon(q-2)}|J|^q$$

and

$$|J|^{q-2}J \cdot E_1 = \phi'(|J|^q - |J|^{q-2}J \cdot \bar{J})\psi(|J|) \le c_1c_2|\bar{J}|_\infty|J|^q.$$

Hence we have

$$\frac{d}{dt}\int_\Omega |J|^q\,dx \le \int_\Omega q\left(c_1c_2|\bar{J}|_\infty + \frac{c_1^2}{4\epsilon(q-2)}\right)|J|^q\,dx$$

and thus

$$|J(t)|_{L^\infty(\Omega)} \le e^{c_1c_2|\bar{J}|_\infty t}|J(0)|_{L^\infty(\Omega)}. \tag{3.5}$$

Similarly, for $\dot{I} = \frac{dI}{dt}$ we have

$$\dot{I}_t + \phi'(I - I_1)\,\dot{I}\psi(|J|) + \phi(I - I_1)\psi'(|J|)\frac{J}{|J|} \cdot \nabla\dot{I} = \epsilon\,\Delta\dot{I},$$

assuming $I_0 \in V$. By using the same arguments as above, it can be shown that

$$|\dot{I}(t)|_{L^\infty(\Omega)} \le |\dot{I}(0)|_{L^\infty(\Omega)}. \tag{3.6}$$

From estimate (3.2) it is not necessary to assume that ϕ is bounded. Moreover, in the above it is implicitly assumed that $\psi'(|J|)\frac{J}{|J|}$ is a.e. defined. For the case $\psi(|J|) = |J|$ it is not necessary that such a derivative exists. Thus, we consider a family of regularizations $\psi_\delta(|J|) = \sqrt{\delta^2 + |J|^2} - \delta$ for $\delta > 0$. It can be shown that the estimates (3.3), (3.5), and (3.6) hold uniformly in $\delta > 0$. Let $\{I_\delta\}$ be the corresponding solution to (3.1) with $\psi = \psi_\delta$ and a fixed $\epsilon > 0$. Then $\{I_\delta\}$ is bounded in $W^{1,\infty}((0,T)\times\Omega)\cap L^2(0,T;V)$. Hence it has a weak star–weak convergent subsequence to the limit $I \in W^{1,\infty}((0,T)\times\Omega)\cap L^2(0,T;V)$ as $\delta \to 0^+$, and I is the unique solution to (3.1).

Now we prove that a family of functions $\{I^\epsilon\}$, which are the solution to (3.1) for $\epsilon > 0$, has a convergent subsequence to the limit $I \in W^{1,\infty}((0,T)\times\Omega)$ as $\epsilon \to 0^+$ and that I is a viscosity solution [6, 5] to

$$I_t + \phi(I - I_1)\psi(|\nabla I|) = 0, \quad I(0) = I_0. \tag{3.7}$$

That is, for all $\zeta \in C^1((0,T)\times\Omega)$ if $V - \zeta$ attains a local maximum at $(t_0, x_0) \in (0,T)\times\Omega$, then

$$\zeta_t + \phi(I - I_1)\psi(|\nabla\zeta|) \le 0 \quad \text{at } (t_0, x_0), \tag{3.8a}$$

and if $V - \zeta$ attains a local minimum at $(t_0, x_0) \in (0,T)\times\Omega$, then

$$\zeta_t + \phi(I - I_1)\psi(|\nabla\zeta|) \ge 0 \quad \text{at } (t_0, x_0). \tag{3.8b}$$

First, we note that from (3.3), (3.5)–(3.6)

$$|I^\epsilon|_{W^{1,\infty}((0,T)\times\Omega)} \quad \text{is bounded uniformly in } \epsilon > 0.$$

Thus there exists a subsequence of I^ϵ (denoted by the same symbol) that converges to $I \in W^{1,\infty}((0,T)\times\Omega)$, where the convergence is uniform in $(0,T)\times\Omega$. Next, it can be shown (see, e.g., [9]) that for all $\zeta \in C^2((0,T)\times\Omega)$ if $I^\epsilon - \zeta$ attains a local maximum (minimum, respectively) at $(t_0,x_0)\in R^n$, then

$$\zeta_t + \phi(I^\epsilon - I_1)\psi(|\nabla\zeta|) - \epsilon\,\Delta\zeta \le 0 \quad (\ge 0, \text{ respectively}) \tag{3.9}$$

at (t_0,x_0). We prove (3.8a) first for $\zeta \in C^2((0,T)\times\Omega)$. Assume that for $\zeta \in C^2((0,T)\times\Omega)$ $V^\epsilon - \zeta$ has a local maximum at $x_0\in\Omega$. We can choose $\xi \in C^\infty((0,T)\times\Omega)$ such that $\nabla\xi(t_0,x_0)=0$ and $I^\epsilon-(\zeta-\xi)$ has a strict local maximum at (t_0,x_0). For $\epsilon>0$ sufficiently small, $I^\epsilon-(\zeta-\xi)$ has a local maximum at some $(t_\epsilon,x_\epsilon)\in(0,T)\times\Omega$ and $(t_\epsilon,x_\epsilon)\to(t_0,x_0)$ as $\epsilon\to 0^+$. From (3.9),

$$\zeta_t + \phi(I^\epsilon - I_1)\psi(|\nabla\zeta|) - \epsilon\,\Delta\zeta \le 0$$

at (t_ϵ,x_ϵ). We conclude (3.8a), since $I^\epsilon(t_\epsilon,x_\epsilon)\to I(t_0,x_0)$, $\nabla\zeta(t_\epsilon,x_\epsilon)-\nabla\xi(t_\epsilon,x_\epsilon)\to\nabla\zeta(t_0,x_0)-\nabla\xi(t_0,x_0)=\nabla\zeta_x(t_0,x_0)$, and $\epsilon\,\Delta(\zeta-\xi)_{xx}(t_\epsilon,x_\epsilon)\to 0$ as $\epsilon\to 0$. For $\zeta\in C^1((0,T)\times\Omega)$ exactly the same argument is applied to the convergent sequence $\zeta_n\in C^2((0,T)\times\Omega)$ to ζ in $C^1((0,T)\times\Omega)$ to prove (3.8a).

The uniqueness of the viscosity solution to (3.7) is established in [6, 5].

THEOREM. *Assume that $\phi: R\to R$ is a monotone increasing Lipschitz function with $\phi(0)=0$, and that $\psi: R^+\to R^+$ is a Lipschitz continuous function with $\psi(0)=0$. Equation* (3.7) *has a unique viscosity solution $I\in W^{1,\infty}((0,T)\times\Omega)$, provided that $I_0, I_1\in W^{1,\infty}(\Omega)$.*

OPTIMIZATION PROBLEMS FOR CURVED MECHANICAL STRUCTURES*

VIOREL ARNĂUTU†, JÜRGEN SPREKELS‡, AND DAN TIBA‡§

Abstract. We study optimal design problems for three-dimensional curved rods and for shells under minimal regularity assumptions for the geometry. The results that we establish concern the existence of optimal shapes and the sensitivity analysis. We also compute some numerical examples for the optimization of curved rods. The models used have been investigated in our previous works [A. Ignat, J. Sprekels, and D. Tiba, *Math. Methods Appl. Sci.*, 25 (2002), pp. 835–854], [J. Sprekels and D. Tiba, *Adv. Math. Sci. Appl.*, 12 (2002), pp. 175–190]. A complete study of Kirchhoff–Love arches and of related minimization questions has been performed in [A. Ignat, J. Sprekels, and D. Tiba, *SIAM J. Control Optim.*, 40 (2001), pp. 1107–1133].

Key words. shells and curved rods, minimal regularity, optimal design

1. Introduction.

The scientific literature concerning the modeling of curved mechanical structures currently offers a variety of mathematical models for the study of the deformation of such elastic bodies under the impact of various types of internal or external forces and tractions. We refer just to the monographs of Ciarlet [11], Trabucho and Viaño [19], and Antman [2], where very rich material can be found for investigations in this direction.

It is a natural question now to develop a research program concerning the optimization of such objects, including numerical experiments. It should be mentioned that there exist several works of interest discussing such problems, including Chenais and Rousselet [10], Rousselet [16], Myslinski, Piekarski, and Rousselet [14], Sprekels and Tiba [17], and Ignat, Sprekels, and Tiba [12].

In this article, we attempt an analysis of general optimization problems associated with curved rods and shells. The generality of our setting is related to the consideration of a general performance index, of general constraints on the geometry, the relaxation of the regularity assumptions, and the implementation of some numerical experiments. In particular, we are assuming just C^2-regularity, instead of the usual C^3-hypotheses from literature. For shells, we obtain this by using the generalized Naghdi-type model introduced in Sprekels and Tiba [18]. For rods, this is achieved by replacing the classical Frenet frame with a new general algebraic construction that will be introduced in section 2. Other variants of local coordinates systems associated with three-dimensional (3D) curves under low regularity conditions may be found in Cartan [7] (the Darboux frame) or in Ignat, Sprekels, and Tiba [13], from which we

take the linear model used here. It consists of a system of nine ODEs with null boundary conditions, written in the weak form, which corresponds to the clamped rods case. Other boundary conditions may also be considered. Comparing with the regularity assumptions from the modeling process, we see that the optimization hypotheses are minimal. Let us also mention that both models use the Timoshenko assumption and allow for shear and Poisson effects (i.e., the deformation of the cross section). They generalize the classical Naghdi model for shells, Ciarlet [11], and the model studied by Arunakirinathar and Reddy [3] and Chapelle [8] for curved rods.

Our approach allows us to minimize within the class of curved rods of a prescribed length, which is a natural condition in applications. The prescribed length is also preserved by the variations employed here, according to section 4. We also show how to avoid certain degenerate cases: rods of zero length or with multiple points (see (2.15) below).

Also note that, besides the fact that we have general constraints on the geometry, in certain important examples the parametrization used here allows us to reexpress them in a convex way. The optimization problems considered in this paper are nonconvex, but the convexity of the constraint set is very helpful in the numerical experiments.

The plan of the paper is as follows. We start with the theoretical discussion of optimization problems for curved rods. In section 2, we indicate the necessary preliminaries and the formulation of the problem. In section 3, we prove the existence of the solution (while uniqueness is not valid, in general), and in section 4 we perform a sensitivity study.

A similar program is carried out in sections 5, 6, and 7, in connection with the study of optimal shell configurations. Our basic assumption is that the geometry of the shell can be described by the graph of some mapping in $C^2(\bar{o})$, where $o \subset \mathbb{R}^2$ is a bounded Lipschitz domain; that is, the use of local charts is avoided. While this setting still allows for many applications, it is also helpful as it reduces the complexity of the problem and of the notation.

We underline that, in order to prove the existence of optimal shapes, coercivity inequalities of Korn type, which are uniform with respect to the geometry, have to be established (in sections 3 and 6). In particular, in the case of shells the extension property in Lipschitz domains plays an essential role (see Adams [1]).

In the last section, we present some numerical experiments for optimization problems for 3D curved rods. We underline that it is rather difficult to construct academic examples for geometric optimization problems in three dimensions that also allow a mechanical interpretation. Their computational complexity is quite large, and it seems that here such 3D examples are solved for the first time in the scientific literature. Moreover, the fact that the computed optimal solution has a clear physical interpretation in some of the examples provides a strong validation of the model and of the optimization and approximation methods used here. The numerical treatment of the optimization of shells (which is not considered here) requires very special numerical approximation methods.

2. Description of the curved rods problem. Let $\bar{\theta} = (\theta_1, \theta_2, \theta_3) \in C^k[0, L]^3$, $k \in \mathbb{N}$, be a 3D Jordan curve of length $L > 0$, and let $\bar{t} = (t_1, t_2, t_3) \in C^{k-1}[0, L]^3$ be its tangent vector. We shall always assume that $\bar{\theta}$ originates in the origin of the coordinates system and that it is parametrized with respect to its arc length; i.e., $|\bar{t}(x_3)|_{\mathbb{R}^3} = 1 \; \forall \, x_3 \in [0, L]$.

Then, alternatively, we may consider $\varphi \in C^{k-1}[0, L]$ and $\psi \in C^{k-1}[0, L]$ to be

some spherical coordinates of a unit vector given by $(\sin\varphi\cos\psi, \sin\varphi\sin\psi, \cos\varphi) \in C^{k-1}[0,L]$, which we denote again by $\bar{t}(x_3) = \bar{t}(\varphi(x_3), \psi(x_3))$. The corresponding 3D curve, depending on φ, ψ, is obtained by

$$\bar{\theta}(x_3) = \int_0^{x_3} \bar{t}(\tau)\, d\tau\,, \quad x_3 \in [0,L]\,. \tag{2.1}$$

The arbitrary mappings φ, ψ will play the role of the minimization parameters (controls) in the optimization problems to be studied in sections 3 and 4. Further conditions, called constraints, may be imposed on them later.

Notice that although the polar coordinates may not be uniquely determined in certain cases, relation (2.1) with arbitrary φ, ψ generates a rich class of 3D regular curves having C^k-regularity, which is enough for optimization applications. Later, we will have $k = 2$.

One advantage of the form (2.1) is that the curve is automatically parametrized with respect to its arc length, and that a local frame may be defined by purely algebraic means,

$$\bar{n} = (\cos\varphi\cos\psi\,,\ \cos\varphi\sin\psi\,,\ -\sin\varphi)\,, \tag{2.2}$$

$$\bar{b} = (-\sin\psi\,,\ \cos\psi\,,\ 0)\,, \tag{2.3}$$

in all points of the curve.

We denote by A the orthogonal matrix having the columns $\bar{t}, \bar{n}, \bar{b}$. The geometric meaning of this construction is that we perform a rotation of the global axis system, corresponding to the angles φ and ψ and indicated by A, i.e., $\bar{t} = A(1,0,0)^T$, $\bar{n} = A(0,1,0)^T$, $\bar{b} = A(0,0,1)^T$.

Remark 2.1. It is possible to apply (2.1)–(2.3) to absolutely continuous regular (i.e., with nonzero tangent) curves, after a reparametrization with respect to the arc length. Although we employ the same notation, the vectors $\bar{n}$, $\bar{b}$ are different, in general, from the normal and binormal vectors of the classical Frenet frame obtained under stronger regularity assumptions; see Bloch [5]. Other useful variants of local frames under low smoothness hypotheses may be found in Cartan [7], and Ignat, Sprekels, and Tiba [13].

We introduce the open set (which may be compared with a horizontal "cylinder" of nonconstant thickness)

$$\Omega = \bigcup_{x_3 \in]0,L[} \Big(\omega(x_3) \times \{x_3\}\Big) \subset \mathbb{R}^3, \tag{2.4}$$

where the cross section $\omega(x_3) \subset \mathbb{R}^2$, $x_3 \in [0,L]$, is a bounded, but not necessarily simply connected, domain such that $\omega(x_3) \supset \omega$, with an open set $\omega \subset \mathbb{R}^2$ satisfying the symmetry relations

$$0 = \int_\omega x_1\, dx_1\, dx_2 = \int_\omega x_2\, dx_1\, dx_2 = \int_\omega x_1\, x_2\, dx_1\, dx_2\,. \tag{2.5}$$

The curved rod $\tilde{\Omega}$ associated with $\bar{\theta}$ is obtained by the one-to-one nonlinear geometrical transformation $F : \Omega \to \tilde{\Omega}$,

$$\begin{aligned} &(x_1, x_2, x_3) = \bar{x} \in \Omega \mapsto F\bar{x} = \tilde{x} = (\tilde{x}_1, \tilde{x}_2, \tilde{x}_3) \\ &= \bar{\theta}(x_3) + x_1\, \bar{n}(x_3) + x_2\, \bar{b}(x_3) \in \tilde{\Omega} \quad \forall\, \bar{x} \in \Omega\,, \\ &\text{where } \tilde{\Omega} = \{\tilde{x} = F\,\bar{x}\,;\, \bar{x} \in \Omega\}\,. \end{aligned} \tag{2.6}$$

The fact that F is one-to-one follows from (2.10), (2.11) below. In the scientific literature (Trabucho and Viaño [19]), $\tilde{\Omega}$ is also called a "tube," in view of the possible presence of holes in $\omega(\,\cdot\,)$. In what follows, we will always assume that $\varphi, \psi \in C^1[0, L]$, i.e., $k = 2$. Then we get

$$\left\langle \bar{t}(x_3)\,,\, \bar{t}'(x_3) \right\rangle_{\mathbb{R}^3} = \left\langle \bar{n}(x_3)\,,\, \bar{n}'(x_3) \right\rangle_{\mathbb{R}^3} = \left\langle \bar{b}(x_3)\,,\, \bar{b}'(x_3) \right\rangle_{\mathbb{R}^3} = 0\,, \tag{2.7}$$

where $\langle \cdot\,,\, \cdot \rangle_{\mathbb{R}^3}$ denotes the Euclidean inner product in $\mathbb{R}^3$. This yields the "equations of motion" of the considered local frame:

$$\begin{aligned} \bar{t}'(x_3) &= a(x_3)\,\bar{b}(x_3) \,+\, \beta(x_3)\,\bar{n}(x_3)\,, \\ \bar{b}'(x_3) &= -\,a(x_3)\,\bar{t}(x_3) \,+\, c(x_3)\,\bar{n}(x_3)\,, \\ \bar{n}'(x_3) &= -\,\beta(x_3)\,\bar{t}(x_3) \,+\, c(x_3)\,\bar{b}(x_3)\,, \end{aligned} \tag{2.8}$$

with $a\,,\, \beta\,,\, c \in C[0, L]$ expressing the curvature and torsion properties of the curved rod.

The Jacobian of F at $\bar{x} \in \Omega$, denoted by $J(\bar{x}) = D\,F(\bar{x})$, is given by

$$J(\bar{x}) \,=\, \begin{bmatrix} n_1(x_3) & b_1(x_3) & t_1(x_3) \,+\, x_1\,n_1'(x_3) \,+\, x_2\,b_1'(x_3) \\ n_2(x_3) & b_2(x_3) & t_2(x_3) \,+\, x_1\,n_2'(x_3) \,+\, x_2\,b_2'(x_3) \\ n_3(x_3) & b_3(x_3) & t_3(x_3) \,+\, x_1\,n_3'(x_3) \,+\, x_2\,b_3'(x_3) \end{bmatrix}\,. \tag{2.9}$$

By (2.8), (2.9), we have

$$\det J(\bar{x}) \,=\, 1 \,-\, \beta(x_3)\,x_1 \,-\, a(x_3)\,x_2 \quad \forall\, \bar{x} \,\in\, \bar{\Omega}\,. \tag{2.10}$$

Remark 2.2. Relations (2.7)–(2.10) require the existence of second-order derivatives for $\bar{\theta}$ (or of first-order derivatives for $\varphi\,,\, \psi$). The results proved in the next sections show that these assumptions, together with the continuity property for the derivatives, are also sufficient. The same is true for the case of shells; see sections 5–7. For the modeling process, various ways to relax the geometric regularity assumptions have been proposed by Blouza [6], Ignat, Sprekels, and Tiba [13], and Sprekels and Tiba [18].

Usually, in the scientific literature a stronger regularity is required for the parametrization of rods or shells. In the case of the curved rods, the key point in our approach is the use of special local bases as in (2.1)–(2.3) or as in Ignat, Sprekels, and Tiba [13].

If $\omega(x_3)\,,\, x_3 \in [0, L]$, is contained in a sufficiently small disk in $\mathbb{R}^2$, then we may assume that

$$\det J(\bar{x}) \,\geq\, c \,>\, 0 \quad \forall\, \bar{x} \,\in\, \bar{\Omega}\,, \tag{2.11}$$

which justifies the introduction of the curved rod $\tilde{\Omega}$ via the geometric transformation F in (2.6); see Ciarlet [11, Thm. 3.1-1].

We assume that the rod is clamped at both ends, and that it is subjected to body forces $\tilde{f} \in L^2(\tilde{\Omega})^3$ (weight, electromagnetic field, etc.), as well as to surface tractions $\tilde{g} \in L^2(\tilde{\Sigma})^3$ on the lateral surface $\tilde{\Sigma}$ of the rod. On the "inside" lateral face of $\tilde{\Omega}$ (i.e., corresponding to possible holes), we take $\tilde{g} \equiv 0$.

Denote by $\bar{y} : \tilde{\Omega} \to \mathbb{R}^3$ the corresponding displacement of each point $\tilde{x} \in \tilde{\Omega}$. In Ignat, Sprekels, and Tiba [13], the general geometrical assumption that

$$\bar{y}(\tilde{x}) \,=\, \bar{\tau}(x_3) \,+\, x_1\,\bar{N}(x_3) \,+\, x_2\,\bar{B}(x_3) \quad \forall\, \tilde{x} \,\in\, \tilde{\Omega}\,, \tag{2.12}$$

with $\bar{x} = (x_1\,,\, x_2\,,\, x_3) = F^{-1}(\tilde{x})$ and $\bar{\tau}\,,\, \bar{N}\,,\, \bar{B} \in H_0^1(0,L)$ being unknown functions, has been imposed. This is a special case of the so-called *polynomial approximation* of the displacement; see Trabucho and Viaño [19]. Then, the following boundary value problem is obtained from the elasticity problem, where we also introduce the notation $\mathbf{b}_i, i = 1,3$, for later use:

$$
\begin{aligned}
(2.13)\quad & \mathcal{B}(\bar{y},\bar{v}) \,=\, \tilde{\lambda}\,\mathbf{b}_1(\bar{y},\bar{v}) \,+\, \tilde{\mu}\,\mathbf{b}_2(\bar{y},\bar{v}) \,+\, 2\,\tilde{\mu}\,\mathbf{b}_3(\bar{y},\bar{v}) \\
&= \tilde{\lambda} \int_{\Omega} \sum_{i,j=1}^{3} \Bigg[N_i(x_3)\,h_{1i}(\bar{x}) + B_i(x_3)\,h_{2i}(\bar{x}) \\
&\quad + \Big(\tau_i'(x_3) + x_1\,N_i'(x_3) + x_2\,B_i'(x_3)\Big) h_{3i}(\bar{x}) \Bigg] \Bigg[M_j(x_3)\,h_{1j}(\bar{x}) \\
&\quad + D_j(x_3)\,h_{2j}(\bar{x}) + \Big(\mu_j'(x_3) + x_1\,M_j'(x_3) + x_2\,D_j'(x_3)\Big)\,h_{3j}(\bar{x}) \Bigg] \Big|\det J(\bar{x})\Big|\,d\bar{x} \\
&\quad + \tilde{\mu} \int_{\Omega} \sum_{i<j} \Bigg[N_i(x_3)\,h_{1j}(\bar{x}) + B_i(x_3)\,h_{2j}(\bar{x}) + \Big(\tau_i'(x_3) + x_1\,N_i'(x_3) \\
&\qquad + x_2\,B_i'(x_3)\Big)\,h_{3j}(\bar{x}) + N_j(x_3)\,h_{1i}(\bar{x}) + B_j(x_3)\,h_{2i}(\bar{x}) \\
&\quad + \Big(\tau_j'(x_3) + x_1\,N_j'(x_3) + x_2\,B_j'(x_3)\Big)\,h_{3i}(\bar{x}) \Bigg] \Bigg[M_i(x_3)\,h_{1j}(\bar{x}) + D_i(x_3)\,h_{2j}(\bar{x}) \\
&\quad + \Big(\mu_i'(x_3) + x_1\,M_i'(x_3) + x_2\,D_i'(x_3)\Big)\,h_{3j}(\bar{x}) + M_j(x_3)\,h_{1i}(\bar{x}) + D_j(x_3)\,h_{2i}(\bar{x}) \\
&\quad + \Big(\mu_j'(x_3) + x_1\,M_j'(x_3) + x_2\,D_j'(x_3)\Big)\,h_{3i}(\bar{x}) \Bigg] \Big|\det J(\bar{x})\Big|\,d\bar{x} \\
&\quad + 2\,\tilde{\mu} \int_{\Omega} \sum_{i=1}^{3} \Bigg[N_i(x_3)\,h_{1i}(\bar{x}) + B_i(x_3)\,h_{2i}(\bar{x}) + \Big(\tau_i'(x_3) + x_1\,N_i'(x_3) \\
&\qquad + x_2\,B_i'(x_3)\Big)\,h_{3i}(\bar{x}) \Bigg] \Bigg[M_i(x_3)\,h_{1i}(\bar{x}) + D_i(x_3)\,h_{2i}(\bar{x}) \\
&\quad + \Big(\mu_i'(x_3) + x_1\,M_i'(x_3) + x_2\,D_i'(x_3)\Big)\,h_{3i}(\bar{x}) \Bigg] \Big|\det J(\bar{x})\Big|\,d\bar{x} \\
&= \sum_{l=1}^{3} \int_{\Omega} f_l(\bar{x}) \Big(\mu_l(x_3) + x_1\,M_l(x_3) + x_2\,D_l(x_3)\Big)\,|\det J(\bar{x})|\,d\bar{x} \\
&\quad + \sum_{i,j=1}^{3} \sum_{l=1}^{3} \int_{\partial\Omega} g_l(\bar{x}) \Big(\mu_l(x_3) + x_1\,M_l(x_3) + x_2\,D_l(x_3)\Big) |\det J(\bar{x})| \\
&\qquad \times \sqrt{\nu_i(\bar{x})\,g^{ij}(\bar{x})\,\nu_j(\bar{x})}\,d\tau\,.
\end{aligned}
$$

Above, $\tilde{\lambda} \geq 0\,,\, \tilde{\mu} > 0$ are the Lamé coefficients of the material; we have the matrices $(h_{ij}(\bar{x})) = J(\bar{x})^{-1}$, $(g^{ij}(\bar{x})) = (g_{ij}(\bar{x}))^{-1}$, and $(g_{ij}(\bar{x})) = J(\bar{x})^T\,J(\bar{x})$; and $\bar{\mu}\,,\, \bar{M}\,,\, \bar{D} \in H_0^1(0,L)^3$ are arbitrary test functions with $\bar{v}(\bar{x}) = \bar{\mu}(x_3) + x_1\,\bar{M}(x_3) + x_2\,\bar{D}(x_3)$. Further details, and the proof of the coercivity of the bilinear functional $\mathcal{B}(\,\cdot\,,\,\cdot\,)$:

$H_0^1(0,L)^9 \times H_0^1(0,L)^9 \to \mathbb{R}$ given by (2.13), may be found in Ignat, Sprekels, and Tiba [13], where different local bases are used. This yields the existence and the uniqueness of the solution $\bar{y}$ of (2.13) in $H_0^1(0,L)^9$. Equation (2.13) is derived via (2.12) from the usual displacement approach to curved rods (see Trabucho and Viaño [19, Chap. I]):

$$\sum_{i,j=1}^{3} \int\limits_{\tilde{\Omega}} \sigma_{ij}(\bar{u})\, e_{ij}(\bar{v})\, d\tilde{x} \;=\; \sum_{l=1}^{3} \left[\int\limits_{\tilde{\Omega}} \tilde{f}_l\, \bar{v}_l\, d\tilde{x} \;+\; \int\limits_{\tilde{\Sigma}} \tilde{g}_l\, \bar{v}_l\, d\tilde{\tau} \right]$$

$$\forall\, \bar{v} \in \Big\{ \bar{w} \in H^1(\tilde{\Omega})\,;\, \bar{w} \,=\, 0 \text{ on } F(\omega(0) \,\times\, \{0\}) \,\cup\, F(\omega(L) \,\times\, \{L\}) \Big\}$$

with the constitutive law (the stress/strain relation) of linearized elasticity (also known as Hooke's law),

$$\sigma(\bar{u}) \;=\; (\sigma_{ij}(\bar{u}))_{i,j=\overline{1,3}} \;=\; \big(\tilde{\lambda}\, e_{pp}(\bar{u})\, \delta_{ij} \;+\; 2\,\tilde{\mu}\, e_{ij}(\bar{u})\big)_{i,j=\overline{1,3}}\,.$$

In what follows, we shall suppose that $\omega(x_3) = \omega\, \forall\, x_3 \in [0,L]$, with ω satisfying (2.5).

For given $\tilde{f}$, $\tilde{g}$, a general shape optimization problem associated with (2.13) is

$$\text{(P)} \qquad \min_{\varphi,\psi} \Big\{ \Pi(\varphi,\psi) \;=\; j\Big(\bar{\theta}(\varphi,\psi)\,,\, \bar{y}(\varphi,\psi)\Big) \;=\; j(\bar{\theta},\bar{y}) \Big\}\,,$$

subject to $\bar{\theta} \in \mathcal{K}$, where $\mathcal{K} \subset C^2[0,L]^3$ is a closed bounded subset, and $\bar{y} = (\bar{\tau}, \bar{N}, \bar{B}) \in H_0^1(0,L)^9$ is obtained as the solution of (2.13). The condition $\bar{\theta} \in \mathcal{K}$ represents the natural way to impose restrictions on the geometry of the rod in (P). It gives an implicit constraint on $\varphi, \psi \in C^1[0,L]$. We assume that the mappings $j : C^2[0,L]^3 \times H_0^1(0,L)^9 \to \mathbb{R}$ and $\Pi : C^1[0,L]^2 \to \mathbb{R}$ satisfy some regularity properties, to be imposed later. An important example for a cost functional j is the quadratic case. For instance, if

$$j(\bar{\theta},\bar{y}) \;=\; |\tau_1|^2_{H_0^1(0,L)} \;+\; |\tau_2|^2_{H_0^1(0,L)} \;+\; |\tau_3|^2_{H_0^1(0,L)}\,, \tag{2.14}$$

then (P) aims at finding the shape of the curved rod that minimizes the displacement of the line of centroids under prescribed forces and tractions. This is a natural safety requirement in many applications.

Concerning the constraints to which the curved rod may be submitted, we underline that our formalism automatically ensures a prescribed length $L > 0$. This eliminates possible trivial cases, such as a constant $\bar{\theta}$ in $[0,L]$, and is also important from the optimization point of view, since otherwise the cost may depend on L. A simple sufficient condition under which $\bar{\theta}$ has no multiple points (i.e., there are no values $x_3^1, x_3^2 \in [0,L]$, $x_3^1 \neq x_3^2$, such that $\bar{\theta}(x_3^1) = \bar{\theta}(x_3^2)$) is

$$0 \;\le\; \varphi(x_3) \;\le\; \frac{\pi}{2} \;-\; \varepsilon\,, \quad x_3 \;\in\; [0,L]\,, \tag{2.15}$$

with $\varepsilon > 0$ small. This is due to the fact that (2.1) gives $\theta_3'(x_3) = t_3(x_3) = \cos\varphi(x_3) > 0$ in $[0,L]$; i.e., θ_3 is a strictly increasing function in $[0,L]$. Similar other conditions may easily be formulated in accordance with the desired applications. They may be used, for instance, in problems concerning the optimization of strings, where the periodicity condition (for θ_1, θ_2)

$$\int\limits_0^L t_1\, dx_3 \;=\; \int\limits_0^L t_2\, dx_3 \;=\; 0 \tag{2.16}$$

is also important.

Notice that relations (2.14), (2.15) correspond to convex optimization problems, while relation (2.16) is nonlinear in φ, ψ and, consequently, the corresponding set $\mathcal{K}$ is nonconvex. Relation (2.11) should also be included in the definition of $\mathcal{K}$.

Remark 2.3. A very simple variant of representation of the unit tangent vector is $\bar{t} = (u_1, u_2, \sqrt{1 - u_1^2 - u_2^2})$, but this already assumes a prescribed sign for t_3 and requires the more restrictive hypothesis

$$u_1^2 + u_2^2 \leq 1 - \varepsilon$$

for the differentiability of the local frame. However, under this representation relation (2.16) becomes linear, which may be useful in some applications.

3. Existence of optimal curved rods. We prove the following continuous dependence result.

THEOREM 3.1. *Assume that* $\varphi_n \to \varphi$, $\psi_n \to \psi$, *strongly in* $C^1[0, L]$. *If* $\bar{y}_n$, $\check{y}$ *denote the solutions to* (2.13) *associated with* (φ_n, ψ_n) *and* (φ, ψ), *respectively, then*

$$\bar{y}_n \to \check{y} \quad \text{strongly in } H_0^1(0, L)^9. \tag{3.1}$$

Proof. Clearly,

$$\begin{aligned} \bar{t}_n &= (\cos\psi_n \sin\varphi_n, \sin\psi_n \sin\varphi_n, \cos\varphi_n) \\ &\to \bar{t} = (\cos\psi \sin\varphi, \sin\psi \sin\varphi, \cos\varphi) \end{aligned} \tag{3.2}$$

in $C^1[0, L]^3$. Then, (2.1) shows that $\bar{\theta}_n \to \bar{\theta}$ in $C^2[0, L]^3$. By (2.2), (2.3), and with obvious notation, we get that $\bar{n}_n \to \bar{n}$ and $\bar{b}_n \to \bar{b}$ in $C^1[0, L]^3$.

From (2.8) it is easy to infer that

$$a_n = \langle \bar{t}_n', \bar{b}_n \rangle_{\mathbb{R}^3} \to a = \langle \bar{t}', \bar{b} \rangle_{\mathbb{R}^3} \quad \text{strongly in } C[0, L]. \tag{3.3}$$

We also have $\beta_n \to \beta$ and $c_n \to c$ in $C[0, L]$.

Relation (2.10) shows that

$$\det J_n(\bar{x}) \to \det J(\bar{x}) \quad \text{in } C(\bar{\Omega}), \tag{3.4}$$

and from (2.11) we infer that $\{\det J_n(\bar{x})\}$ is bounded from below by some positive constant.

Moreover, (2.9) implies that $J_n(\bar{x}) \to J(\bar{x})$ in $C(\bar{\Omega})^9$ and, likewise, that $J_n^{-1}(\bar{x}) \to J^{-1}(\bar{x})$, by (3.4) and the above observations. In particular, we have

$$h_{ij}^n(\bar{x}) \to h_{ij}(\bar{x}) \quad \text{in } C(\bar{\Omega}) \quad \forall\, i, j = \overline{1, 3}. \tag{3.5}$$

Let $\mathcal{B}_n$ denote the bilinear functional (2.13) with the coefficients h_{ij}^n, $\det J_n$.

LEMMA 3.2. *There are* $c_1 > 0$, $c_2 > 0$ *such that*

$$\mathcal{B}_n(\bar{y}, \bar{y}) \geq c_1 |\bar{y}|^2_{H_0^1(0,L)^9} - c_2 |\bar{y}|^2_{L^2(0,L)^9} \tag{3.6}$$

for any $\bar{y} \in H_0^1(0, L)^9$ *and any* $n \in \mathbb{N}$.

Proof. By (3.4) and (2.11), we have

$$\mathcal{B}_n(\bar{y},\bar{y}) \geq \tilde{\mu}\, c \int\limits_\Omega \sum_{i<j} \Bigg[N_i\, h^n_{1j} + B_i\, h^n_{2j} + \Big(\tau_i' + x_1\, N_i' + x_2\, B_i'\Big)\, h^n_{3j} + N_j\, h^n_{1i} + B_j\, h^n_{2i} + \Big(\tau_j' + x_1\, N_j' + x_2\, B_j'\Big)\, h^n_{3i} \Bigg]^2 d\bar{x} + 2\,\tilde{\mu}\, c \int\limits_\Omega \sum_{i=1}^{3} \Bigg[N_i\, h^n_{1i} + B_i\, h^n_{2i} + \Big(\tau_i' + x_1\, N_i' + x_2 B_i'\Big)\, h^n_{3i} \Bigg]^2 d\bar{x}\,.$$

From the uniform boundedness of the coefficients due to (3.5), and using standard binomial inequalities, we find that

$$\frac{1}{\tilde{\mu}\, c}\, \mathcal{B}_n(\bar{y},\bar{y}) \geq \frac{1}{2} \int\limits_\Omega \sum_{i<j} \Bigg[\Big(\tau_i' + x_1\, N_i' + x_2\, B_i'\Big)\, h^n_{3j} + \Big(\tau_j' + x_1\, N_j' + x_2\, B_j'\Big)\, h^n_{3i} \Bigg]^2 d\bar{x} + \int\limits_\Omega \sum_{i=1}^{3} \Bigg[\Big(\tau_i' + x_1\, N_i' + x_2\, B_i'\Big)\, h^n_{3i} \Bigg]^2 d\bar{x} \;-\; \tilde{c}|\bar{y}|^2_{L^2(0,L)^9}\,.$$

We use the following algebraic identity:

$$\begin{aligned} &\frac{1}{2}\Bigg[\Big(z_1\, h^n_{32} + z_2\, h^n_{31}\Big)^2 + \Big(z_2\, h^n_{33} + z_3\, h^n_{32}\Big)^2 + \Big(z_1\, h^n_{33} + z_3\, h^n_{31}\Big)^2 \Bigg] \\ &\quad + \frac{3}{2}\Bigg[z_1^2 (h^n_{31})^2 + z_2^2 (h^n_{32})^2 + z_3^2 (h^n_{33})^2 \Bigg] \\ &= \frac{1}{2}\Big(z_1^2 + z_2^2 + z_3^2\Big)\Bigg[(h^n_{31})^2 + (h^n_{32})^2 + (h^n_{33})^2 \Bigg] + \frac{1}{2}\Big(z_1\, h^n_{31} + z_2\, h^n_{32}\Big)^2 \\ &\quad + \frac{1}{2}\Big(z_1\, h^n_{31} + z_3\, h^n_{33}\Big)^2 + \frac{1}{2}\Big(z_2\, h^n_{32} + z_3\, h^n_{33}\Big)^2, \end{aligned}$$

with $z_i := \tau_i' + x_1\, N_i' + x_2\, B_i'$, $i = \overline{1,3}$. It follows that

$$\frac{1}{\tilde{\mu}\, c}\mathcal{B}_n(\bar{y},\bar{y}) \;\geq\; \frac{1}{4} \int\limits_\Omega \sum_{i=1}^{3} \Big(\tau_i' + x_1\, N_i' + x_2\, B_i'\Big)^2 \sum_{i=1}^{3} (h^n_{3i})^2\, d\bar{x} - \tilde{c}\,|\bar{y}|^2_{L^2(0,L)^9}\,. \tag{3.7}$$

A direct calculus allows us to find h^n_{ij} and to check that, for some $k > 0$,

$$\sum_{i=1}^{3} (h^n_{3i})^2 \;=\; \Big[\det J_n\Big]^{-2} \sum_{i=1}^{3} (t^n_i)^2 \;=\; \Big[\det J_n\Big]^{-2} \;\geq\; k \;>\; 0 \tag{3.8}$$

since $|\bar{t}_n|_{\mathbb{R}^3} = 1$.

Relations (3.7), (3.8) give

$$\frac{1}{\tilde{\mu}\, c}\mathcal{B}_n(\bar{y},\bar{y}) \;\geq\; \frac{k}{4} \int\limits_\Omega \sum_{i=1}^{3} \Big(\tau_i' + x_1\, N_i' + x_2\, B_i'\Big)^2 d\bar{x} \;-\; \tilde{c}\,|\bar{y}|^2_{L^2(0,L)^9}\,.$$

Performing the computations in the right-hand side and integrating with respect to x_1, x_2, we obtain the inequality (3.6) by means of (2.5). ∎

Proof of Theorem 3.1 *(continued).* We use a contradiction argument to show that the functionals $\mathcal{B}_n$ are uniformly coercive. We assume that there is a sequence $\varepsilon_n \to 0$ and a sequence $\tilde{y}_n \in H_0^1(0,L)^9$, $|\tilde{y}_n|_{H_0^1(0,L)^9} = 1$, such that

$$0 \le \mathcal{B}_n(\tilde{y}_n, \tilde{y}_n) \le \varepsilon_n |\tilde{y}_n|^2_{H_0^1(0,L)^9}. \tag{3.9}$$

Let $\hat{y}$ be the weak limit of $\tilde{y}_n$ in $H_0^1(0,L)^9$, which may be supposed to exist.

We give a detailed computation for the last integral in the definition of $\mathcal{B}_n(\tilde{y}_n, \tilde{y}_n)$:

$$\begin{aligned}
I_n &= 2\,\tilde{\mu} \int_\Omega \sum_{i=1}^{3} \left[\tilde{N}_i^n\, h_{1i}^n + \tilde{B}_i^n\, h_{2i}^n + \left(\tilde{\tau}_i^{n'} + x_1\, \tilde{N}_i^{n'} + x_2\, \tilde{B}_i^{n'} \right) h_{3i}^n \right]^2 \det J^n \, d\bar{x} \\
&= 2\,\tilde{\mu} \int_\Omega \sum_{i=1}^{3} \left[\tilde{N}_i^n\, h_{1i} + \tilde{B}_i^n\, h_{2i} + \left(\tilde{\tau}_i^{n'} + x_1\, \tilde{N}_i^{n'} + x_2\, \tilde{B}_i^{n'} \right) h_{3i} \right]^2 \det J \, d\bar{x} \\
&\quad + 2\,\tilde{\mu} \int_\Omega \sum_{i=1}^{3} \left[\tilde{N}_i^n \left(h_{1i}^n \sqrt{\det J^n} - h_{1i} \sqrt{\det J} \right) + \tilde{B}_i^n \left(h_{2i}^n \sqrt{\det J^n} - h_{2i} \sqrt{\det J} \right) \right. \\
&\qquad \left. + \left(\tilde{\tau}_i^{n'} + x_1\, \tilde{N}_i^{n'} + x_2\, \tilde{B}_i^{n'} \right) \left(h_{3i}^n \sqrt{\det J^n} - h_{3i} \sqrt{\det J} \right) \right] \\
&\quad \times \left[\tilde{N}_i^n \left(h_{1i}^n \sqrt{\det J^n} + h_{1i} \sqrt{\det J} \right) + \tilde{B}_i^n \left(h_{2i}^n \sqrt{\det J^n} + h_{2i} \sqrt{\det J} \right) \right. \\
&\qquad \left. + \left(\tilde{\tau}_i^{n'} + x_1\, \tilde{N}_i^{n'} + x_2\, \tilde{B}_i^{n'} \right) \left(h_{3i}^n \sqrt{\det J^n} + h_{3i} \sqrt{\det J} \right) \right] d\bar{x}\,.
\end{aligned}$$

Here, $\tilde{y}_n = (\tilde{\tau}_n, \tilde{N}_n, \tilde{B}_n)$ belongs to the unit ball in $H_0^1(0,L)^9$. The uniform convergence of the coefficients (see (3.4), (3.5)) shows that the last integral converges to zero. The weak lower semicontinuity of quadratic forms gives

$$\begin{aligned}
\liminf_{n\to\infty} I_n &= \liminf_{n\to\infty}\ 2\tilde{\mu} \int_\Omega \sum_{i=1}^{3} \left[\tilde{N}_i^n\, h_{1i} + \tilde{B}_i^n\, h_{2i} + \left(\tilde{\tau}_i^{n'} + x_1\, \tilde{N}_i^{n'} + x_2\, \tilde{B}_i^{n'} \right) h_{3i} \right]^2 \\
&\qquad \times \det J d\bar{x} \\
&\ge 2\,\tilde{\mu} \int_\Omega \sum_{i=1}^{3} \left[\hat{N}_i\, h_{1i} + \hat{B}_i\, h_{2i} + \left(\hat{\tau}_i' + x_1\, \hat{N}_i' + x_2\, \hat{B}_i' \right) h_{3i} \right]^2 \det J \, d\bar{x}\,,
\end{aligned}$$

where $(\hat{\tau}\,,\, \hat{N}\,,\, \hat{B}) \in H_0^1(0,L)^9$ is the detailed notation of $\hat{y}$.

Computing the other terms in a similar way, we get

$$\begin{aligned}
\liminf_{n\to\infty} \mathcal{B}_n(\tilde{y}_n, \tilde{y}_n) \ge 2\,\tilde{\mu} \int_\Omega \sum_{i=1}^{3} \Bigg[& \hat{N}_i\, h_{1i} + \hat{B}_i\, h_{2i} \\
& + \left(\hat{\tau}_i' + x_1\, \hat{N}_i' + x_2\, \hat{B}_i' \right) h_{3i} \Bigg]^2 \det J \, d\bar{x}
\end{aligned} \tag{3.10}$$

$$
\begin{aligned}
&+\tilde{\lambda}\int_\Omega \sum_{i,j=1}^{3}\left[\hat{N}_i\,h_{1i}+\hat{B}_i\,h_{2i}+\left(\hat{\tau}_i'+x_1\,\hat{N}_i'+x_2\,\hat{B}_i'\right)h_{3i}\right]\\
&\quad\times\left[\hat{N}_j\,h_{1j}+\hat{B}_j\,h_{2j}+\left(\hat{\tau}_j'+x_1\,\hat{N}_j'+x_2\,\hat{B}_j'\right)h_{3j}\right]\det J\,d\bar{x}\\
&+\tilde{\mu}\int_\Omega \sum_{i<j}\left[\hat{N}_i\,h_{1j}+\hat{B}_i\,h_{2j}+\left(\hat{\tau}_i'+x_1\,\hat{N}_i'+x_2\,\hat{B}_i'\right)h_{3j}\right.\\
&\quad\left.+\hat{N}_j\,h_{1i}+\hat{B}_j\,h_{2i}+\left(\hat{\tau}_j'+x_1\,\hat{N}_j'+x_2\,\hat{B}_j'\right)h_{3i}\right]^2\det J\,d\bar{x}\\
&=\mathcal{B}(\hat{y},\hat{y})\,.
\end{aligned}
$$

By assumption (3.9) and by (3.10), we have $\mathcal{B}(\hat{y},\hat{y})=0$.

It is known that such a relation yields $\hat{y}=0$ (see, for instance, Lemma 2.3 in [13]).

We again use inequality (3.9) with Lemma 3.2:

$$
\varepsilon_n\;\geq\;\mathcal{B}_n(\tilde{y}_n,\tilde{y}_n)\;\geq\;c_1\;-\;c_2|\tilde{y}_n|^2_{L^2(0,L)^9}\,, \tag{3.11}
$$

since $|\tilde{y}_n|_{H_0^1(0,L)^9}=1$.

Notice that $\tilde{y}_n\to\hat{y}=0$ strongly in $L^2(0,L)^9$, by the above argument. Then, combining (3.10) and (3.11), we obtain the contradiction $0\geq c_1$. We conclude that there is some $\delta>0$ such that, $\forall\ n\geq 1$,

$$
\mathcal{B}_n(\bar{y},\bar{y})\;\geq\;\delta|\bar{y}|^2_{H_0^1(0,L)^9}\quad\forall\ \bar{y}\;\in\;H_0^1(0,L)^9\,. \tag{3.12}
$$

Let us fix $\bar{v}=\bar{y}_n$ in the state equations (2.13) corresponding to $\mathcal{B}_n(\,\cdot\,,\,\cdot\,)$. Taking (3.12) into account, we immediately obtain that $\{\bar{y}_n\}$ is bounded in $H_0^1(0,L)^9$. We may take a subsequence such that $\bar{y}_n\to\check{y}$ weakly in $H_0^1(0,L)^9$. Due to the uniform convergence of the coefficients h_{ij}^n, $\det J_n$, g_n^{ij}, one may pass to the limit in (2.13) and see that $\check{y}$ is indeed the solution to (2.13) associated with $(\varphi\,,\,\psi)$.

The last step of the proof is to show that the convergence is valid in the strong topology of $H_0^1(0,L)^9$. We subtract the equations corresponding to (τ^n,N^n,B^n) (resp., $(\check{\tau},\check{N},\check{B})$), we intercalate advantageous terms, and, finally, we take test functions of the form $(\tau^n,N^n,B^n)-(\check{\tau},\check{N},\check{B})\in H_0^1(0,L)^9$. We write in detail just the simplest term:

$$
\begin{aligned}
&2\,\tilde{\mu}\int_\Omega\sum_{i=1}^{3}\left[N_i^n\,h_{1i}^n+B_1^n\,h_{2i}^n+\left(\tau_i^{n'}+x_1\,N_i^{n'}+x_2\,B_i^{n'}\right)h_{3i}^n\right]\\
&\times\left[(N_i^n-\check{N}_i)\,h_{1i}^n+(B_i^n-\check{B}_i)\,h_{2i}^n+\left(\tau_i^{n'}-\check{\tau}_i'+x_1(N_i^{n'}-\check{N}_i')+x_2(B_i^{n'}-\check{B}_i')\right)h_{3i}^n\right]\\
&\qquad\times\det J^n\,d\bar{x}-2\,\tilde{\mu}\int_\Omega\sum_{i=1}^{3}\left[\check{N}_i\,h_{1i}+\check{B}_i\,h_{2i}+\left(\check{\tau}_i'+x_1\,\check{N}_i'+x_2\,\check{B}_i'\right)h_{3i}\right]\\
&\times\left[(N_i^n-\check{N}_i)h_{1i}+(B_i^n-\check{B}_i)\,h_{2i}+\left(\tau_i^{n'}-\check{\tau}_i'+x_1(N_i^{n'}-\check{N}_i')+x_2(B_i^{n'}-\check{B}_i)'\right)h_{3i}\right]
\end{aligned}
$$

$$\times \det J\, d\bar{x} = 2\,\tilde{\mu} \int_\Omega \sum_{i=1}^{3} \Big[(N_i^n - \check{N}_i)\, h_{1i} + (B_i^n - \check{B}_i)\, h_{2i}$$

$$+ \Big(\tau_i^{n'} - \check{\tau}_i' + x_1 (N_i^{n'} - \check{N}_i') + x_2 (B_i^{n'} - \check{B}_i') \Big)\, h_{3i} \Big]^2 \det J\, d\bar{x}$$

$$+ 2\,\tilde{\mu} \int_\Omega \sum_{i=1}^{3} \times \Big[N_i^n\, h_{1i} + B_i^n\, h_{2i} + \Big(\tau_i^{n'} + x_1\, N_i^{n'} + x_2\, B_i^{n'} \Big)\, h_{3i} \Big]$$

$$\times \Big[(N_i^n - \check{N}_i)(h_{1i}^n - h_{1i}) + (B_i^n - \check{B}_i)(h_{2i}^n - h_{2i}) + \Big(\tau_i^{n'} - \check{\tau}_i' + x_1 (N_i^{n'} - \check{N}_i')$$

$$+ x_2 (B_i^{n'} - \check{B}_i') \Big) (h_{3i}^n - h_{3i}) \Big] \det J\, d\bar{x}$$

$$+ 2\,\tilde{\mu} \int_\Omega \sum_{i=1}^{3} \Big[N_i^n\, h_{1i} + B_i^n\, h_{2i} + \Big(\tau_i^{n'} + x_1\, N_i^{n'} + x_2\, B_i^{n'} \Big)\, h_{3i} \Big]$$

$$\times \Big[(N_i^n - \check{N}_i)\, h_{1i}^n + (B_i^n - \check{B}_i)\, h_{2i}^n + \Big(\tau_i^{n'} - \check{\tau}_i^{n'} + x_1 (N_i^{n'} - \check{N}_i') + x_2 (B_i^{n'} - \check{B}_i') \Big)\, h_{3i}^n \Big]$$

$$\times \Big[\det J^n - \det J \Big]\, d\bar{x}$$

$$+ 2\,\tilde{\mu} \int_\Omega \sum_{i=1}^{3} \Big[N_i^n (h_{1i}^n - h_{1i}) + B_i^n (h_{2i}^n - h_{2i}) + \Big(\tau_i^{n'} + x_1\, N_i^{n'} + x_2\, B_i^{n'} \Big) (h_{3i}^n - h_{3i}) \Big]$$

$$\times \Big[(N_i^n - \check{N}_i) h_{1i}^n + (B_i^n - \check{B}_i) h_{2i}^n$$

$$+ \Big(\tau_i^{n'} - \check{\tau}_i' + x_1 (N_i^{n'} - \check{N}_i') + x_2 (B_i^{n'} - \check{B}_i') \Big) h_{3i}^n \Big] \det J^n\, d\bar{\tau}.$$

All the terms above, except the first one after the equality sign (the quadratic one), converge to zero due to the weak convergence of (τ^n, N^n, B^n) and to the uniform convergence of the coefficients. Similar computations may be performed for all the integrals in the variational equations, and we conclude that

$$\lim_{n \to \infty} \mathcal{B}(\bar{y}_n - \check{y}\,,\, \bar{y}_n - \check{y}) \;=\; 0\,. \tag{3.13}$$

By (3.12), (3.13) the proof is finished. □

COROLLARY 3.3. *If $\mathcal{K} \subset C^2[0,L]^3$ is generated by a compact in $C^1[0,L]^3$ subset of $\{\varphi, \psi\}$ and $j : C^2(0,L)^3 \times H_0^1(0,L)^9 \to \mathbb{R}$ is lower semicontinuous, then the shape optimization problem* (P) *admits at least one optimal curved rod solution in $\mathcal{K}$.*

Example 3.4 The functional (2.14) satisfies the above conditions, and the constraint (2.15), supplemented by boundedness conditions on ψ and φ', ψ', provides a simple case when Corollary 3.3 may be applied.

4. Sensitivity analysis of curved rods. We first study some differentiability properties of the mapping $(\varphi, \psi) \in C^1[0,L]^2 \mapsto \bar{y} \in H_0^1(0,L)^9$, with $\bar{y}$ being the solution of (2.13) corresponding to (φ, ψ). We consider $(\varphi_\lambda, \psi_\lambda) = (\varphi + \lambda\,\gamma\,,\, \psi +$

$\lambda\,\xi) \in C^1[0,1]^2$, $\lambda \in \mathbb{R}_+$, to be some variation around (φ,ψ), and we denote by $\bar{y}_\lambda = (\bar{\tau}_\lambda, \bar{N}_\lambda, \bar{B}_\lambda) \in H^1_0(0,L)^9$ the corresponding solution of (2.13). Similarly, we denote by $\bar{t}_\lambda, \bar{\theta}_\lambda, \bar{n}_\lambda, \bar{b}_\lambda, a_\lambda, \beta_\lambda, c_\lambda, J_\lambda, h^\lambda_{ij}, g^{ij}_\lambda$ all the quantities defined in section 2, starting from $(\varphi_\lambda, \psi_\lambda)$. Notice that, by our construction, the perturbed curved rod $\bar{\theta}_\lambda$ still has length L and is parametrized with respect to its arc length, i.e., $|\bar{t}_\lambda|_{\mathbb{R}^3} = 1$.

It is elementary, though tedious, to check that all the below listed limits (computed in the indicated "range" spaces) and operators exist and satisfy the indicated properties:

$$\lim_{\lambda\to 0} \frac{\bar{t}_\lambda - \bar{t}}{\lambda} = \tilde{t}(\gamma,\xi)\,,\ \tilde{t} : C^1[0,L]^2 \to C^1[0,L]^3\,, \tag{4.1}$$

$$\lim_{\lambda\to 0} \frac{\bar{\theta}_\lambda - \bar{\theta}}{\lambda} = \tilde{\theta}(\gamma,\xi)\,,\ \tilde{\theta} : C^1[0,L]^2 \to C^2[0,L]^3\,, \tag{4.2}$$

$$\lim_{\lambda\to 0} \frac{\bar{n}_\lambda - \bar{n}}{\lambda} = \tilde{n}(\gamma,\xi)\,,\ \tilde{n} : C^1[0,L]^2 \to C^1[0,L]^3\,, \tag{4.3}$$

$$\lim_{\lambda\to 0} \frac{\bar{b}_\lambda - \bar{b}}{\lambda} = \tilde{b}(\gamma,\xi)\,,\ \tilde{b} : C^1[0,L]^2 \to C^1[0,L]^3\,, \tag{4.4}$$

$$\lim_{\lambda\to 0} \frac{a_\lambda - a}{\lambda} = \tilde{a}(\gamma,\xi)\,,\ \tilde{a} : C^1[0,L]^2 \to C[0,L]\,, \tag{4.5}$$

$$\lim_{\lambda\to 0} \frac{\beta_\lambda - \beta}{\lambda} = \tilde{\beta}(\gamma,\xi)\,,\ \tilde{\beta} : C^1[0,L]^2 \to C[0,L]\,, \tag{4.6}$$

$$\lim_{\lambda\to 0} \frac{c_\lambda - c}{\lambda} = \tilde{c}(\gamma,\xi)\,,\ \tilde{c} : C^1[0,L]^2 \to C[0,L]\,, \tag{4.7}$$

$$\lim_{\lambda\to 0} \frac{\det J_\lambda - \det J}{\lambda} = \tilde{\mathcal{D}}(\gamma,\xi)\,,\ \tilde{\mathcal{D}} : C^1[0,L]^2 \to C(\bar{\Omega})\,, \tag{4.8}$$

$$\lim_{\lambda\to 0} \frac{J_\lambda - J}{\lambda} = \tilde{J}(\gamma,\xi)\,,\ \tilde{J} : C^1[0,L]^2 \to C(\bar{\Omega})^9\,, \tag{4.9}$$

$$\lim_{\lambda\to 0} \frac{J_\lambda^{-1} - J^{-1}}{\lambda} = \tilde{I}(\gamma,\xi)\,,\ \tilde{I} : C^1[0,L]^2 \to C(\bar{\Omega})^9\,, \tag{4.10}$$

$$\lim_{\lambda\to 0} \frac{h^\lambda_{ij} - h_{ij}}{\lambda} = \tilde{h}_{ij}(\gamma,\xi)\,,\ \tilde{h}_{ij} : C^1[0,L]^2 \to C(\bar{\Omega})\,, \tag{4.11}$$

$$\lim_{\lambda\to 0} \frac{g^{ij}_\lambda - g^{ij}}{\lambda} = \tilde{g}^{ij}(\gamma,\xi)\,,\ \tilde{g}^{ij} : C^1[0,L]^2 \to C(\bar{\Omega})\,. \tag{4.12}$$

All the operators $\tilde{t}, \tilde{\theta}, \tilde{n}, \tilde{b}, \tilde{a}, \tilde{\beta}, \tilde{c}, \tilde{\mathcal{D}}, \tilde{J}, \tilde{I}, \tilde{h}_{ij}, \tilde{g}^{ij}$ are linear and bounded in the indicated spaces. For instance, relation (4.1) reads in full detail as

$$\lim_{\lambda\to 0} \lambda^{-1} \Big[\Big(\sin\varphi_\lambda\,\cos\psi_\lambda,\, \sin\varphi_\lambda\,\sin\psi_\lambda,\, \cos\varphi_\lambda\Big) - \Big(\sin\varphi\,\cos\psi,\, \sin\varphi\,\sin\psi,\, \cos\varphi\Big)\Big]$$
$$= \Big(\gamma\,\cos\varphi\,\cos\psi\,-\,\xi\,\sin\varphi\,\sin\psi\,,\,\gamma\,\cos\varphi\,\sin\psi\,+\,\xi\,\sin\varphi\,\cos\psi\,,\,-\gamma\,\sin\varphi\Big)\,.$$

It is valid in $C^1[0,L]^3$; i.e., a similar relation may be written with respect to the derivatives of the above vector functions in $[0,L]$. The linear operator $\tilde{t} : C^1[0,L]^2 \to C^1[0,L]^3$, associated with $\varphi, \psi \in C^1[0,L]$, is

$$\tilde{t}(\gamma,\xi) = \begin{bmatrix} \cos\varphi\,\cos\psi & -\sin\varphi\,\sin\psi \\ \cos\varphi\,\sin\psi & \sin\varphi\,\cos\psi \\ -\sin\varphi & 0 \end{bmatrix} \begin{bmatrix} \gamma \\ \xi \end{bmatrix} \quad \forall\ (\gamma,\xi) \in C^1[0,L]^2\,.$$

By Theorem 3.1, we also have that

$$\bar{y}_\lambda \to \bar{y} \text{ strongly in } H_0^1(0,L)^9\,. \tag{4.13}$$

In order to prove the differentiability properties of $\bar{y}_\lambda$, we subtract the equations for $\bar{y}_\lambda$, $\bar{y}$, divide by λ, and intercalate advantageous terms. Later, we shall also fix test functions of the form $\lambda^{-1}(\bar{y}_\lambda - \bar{y}) \in H_0^1(0,L)^9$.

In the right-hand side of (2.13), it is possible to pass to the limit,

$$\begin{aligned}
&\lim_{\lambda\to 0}\Bigg\{\sum_{l=1}^{3}\int_\Omega f_l(\bar{x})\Big(\mu_l(x_3)+x_1\,M_l(x_3)+x_2\,D_l(x_3)\Big)\frac{\det J_\lambda-\det J}{\lambda}\,d\bar{x}\\
&\quad+\sum_{i,j=1}^{3}\sum_{l=1}^{3}\int_{\partial\Omega} g_l(\bar{x})\Big(\mu_l(x_3)+x_1\,M_l(x_3)+\,x_2\,D_l(x_3)\Big)\\
&\quad\times\frac{\det J_\lambda\sqrt{\nu_i(\bar{x})\,g_\lambda^{ij}\,\nu_j(\bar{x})}-\det J\sqrt{\nu_i(\bar{x})g^{ij}\nu_j(\bar{x})}}{\lambda}\,d\tau\Bigg\}\\
&=\sum_{l=1}^{3}\int_\Omega f_l(\bar{x})\Big(\mu_l(x_3)+x_1\,M_l(x_3)+x_2\,D_l(x_3)\Big)\,\tilde{\mathcal{D}}(\gamma,\xi)\,d\bar{x}\\
&\quad+\sum_{i,j=1}^{3}\sum_{l=1}^{3}\int_{\partial\Omega} g_l(\bar{x})\Big(\mu_l(x_3)+x_1\,M_l(x_3)+x_2\,D_l(x_3)\Big)\Bigg[\tilde{\mathcal{D}}(\gamma,\xi)\sqrt{\nu_i\,g^{ij}\,\nu_j}\\
&\qquad+\det J\frac{\nu_i\,\tilde{g}^{ij}(\gamma,\xi)\nu_j}{2\sqrt{\nu_i\,g^{ij}\,\nu_j}}\Bigg]\,d\tau\,.
\end{aligned}\tag{4.14}$$

We also write the corresponding transformation of the simplest term (i.e., of $\mathbf{b}_3(\,\cdot\,,\,\cdot\,)$) in $\mathcal{B}_\lambda(\,\cdot\,,\,\cdot\,)$, the bilinear functional (2.13) obtained from $(\varphi_\lambda,\psi_\lambda)$:

$$\begin{aligned}
&\frac{1}{\lambda}\Bigg\{2\,\tilde{\mu}\int_\Omega\sum_{i=1}^{3}\Big[N_i^\lambda\,h_{1i}^\lambda+B_i^\lambda\,h_{2i}^\lambda+\Big(\tau_i^{\lambda'}+x_1\,N_i^{\lambda'}+x_2\,B_i^{\lambda'}\Big)\,h_{3i}^\lambda\Big]\\
&\quad\times\Big[M_i\,h_{1i}^\lambda+D_i\,h_{2i}^\lambda+\Big(\mu_i'+x_1\,M_i'+x_2\,d_i'\Big)\,h_{3i}^\lambda\Big]\,\det J_\lambda\,d\bar{x}\\
&\quad-2\,\tilde{\mu}\int_\Omega\sum_{i=1}^{3}\Big[N_i\,h_{1i}+B_i\,h_{2i}+\Big(\tau_i'+x_1\,N_i'+x_2\,B_i'\Big)\,h_{3i}\Big]\\
&\quad\times\Big[M_i\,h_{1i}+D_i\,h_{2i}+\Big(\mu_i'+x_1\,M_i'+x_2\,D_i'\Big)\,h_{3i}\Big]\,\det J\,d\bar{x}\Bigg\}\\
&=2\,\tilde{\mu}\int_\Omega\sum_{i=1}^{3}\Bigg[\frac{N_i^\lambda-N_i}{\lambda}\,h_{1i}+\frac{B_i^\lambda-B_i}{\lambda}h_{2i}\\
&\qquad+\Bigg(\frac{\tau_i^{\lambda'}-\tau_i'}{\lambda}+x_1\frac{N_i^{\lambda'}-N_i'}{\lambda}+x_2\frac{B_i^{\lambda'}-B_{(i'}}{\lambda}\Bigg)\,h_{3i}\Bigg]\\
&\quad\times\Big[M_i\,h_{1i}+D_i\,h_{2i}+\Big(\mu_i'+x_1\,M_i'+x_2\,D_i'\Big)\,h_{3i}\Big]\,\det J\,d\bar{x}
\end{aligned}\tag{4.15}$$

$$
\begin{aligned}
&+2\,\tilde{\mu}\int\limits_{\Omega}\sum_{i=1}^{3}\left[N_i^{\lambda}\,h_{1i}+B_i^{\lambda}\,h_{2i}+\left(\tau_i^{\lambda'}+x_1\,N_i^{\lambda'}+x_2\,B_i^{\lambda'}\right)h_{3i}\right]\\
&\times\left[M_i\frac{h_{1i}^{\lambda}-h_{1i}}{\lambda}+D_i\frac{h_{2i}^{\lambda}-h_{2i}}{\lambda}+\left(\mu_i'+x_1\,M_i'+x_2\,D_i'\right)\frac{h_{3i}^{\lambda}-h_{3i}}{\lambda}\right]\det J\,d\bar{x}\\
&+2\,\tilde{\mu}\int\limits_{\Omega}\sum_{i=1}^{3}\left[N_i^{\lambda}\frac{h_{1i}^{\lambda}\,\det J_{\lambda}-h_{1i}\,\det J}{\lambda}+B_i^{\lambda}\frac{h_{2i}^{\lambda}\,\det J_{\lambda}-h_{2i}\,\det J}{\lambda}\right.\\
&\qquad\left.+\left(\tau_i^{\lambda'}+x_1\,N_i^{\lambda'}+x_2\,B_i^{\lambda'}\right)\frac{h_{3i}^{\lambda}\,\det J_{\lambda}-h_{3i}\,\det J}{\lambda}\right]\\
&\qquad\times\left[M_i\,h_{1i}^{\lambda}+D_i\,h_{2i}^{\lambda}+\left(\mu_i'+x_1\,M_i'+x_2\,D_i'\right)h_{3i}^{\lambda}\right]d\bar{x}\,.
\end{aligned}
$$

The terms $\mathbf{b}_1(\,\cdot\,,\,\cdot\,)$ and $\mathbf{b}_2(\,\cdot\,,\,\cdot\,)$ appearing in (2.13) (after replacing φ and ψ by $\varphi_\lambda\,,\,\psi_\lambda$) can be handled exactly as in (4.15). By summing up (4.14) and (4.15) (including the terms obtained from $\mathbf{b}_1$ and $\mathbf{b}_2$), we get the relation

$$
\mathcal{B}\left(\frac{\bar{y}_\lambda-\bar{y}}{\lambda}\,,\,\bar{v}\right)\,=\,Z_\lambda(\bar{v}) \tag{4.16}
$$

for any test function $\bar{v}\,=\,(\bar{\mu},\bar{M},\bar{D})\,\in\,H_0^1(0,L)^9$, and with some linear bounded operator $Z_\lambda : H_0^1(0,L)^9\to\mathbb{R}$ for any $\lambda\in\mathbb{R}_+$. More precisely, we have

$$
\begin{aligned}
Z_\lambda(\bar{v})\,=\,&\sum_{l=1}^{3}\int\limits_{\Omega}f_l(\bar{x})\Big(\mu_l(x_3)\,+\,x_1\,M_l(x_3)\,+\,x_2\,D_l(x_3)\Big)\,\tilde{\mathcal{D}}(\gamma,\xi)\,d\bar{x}\\
&+\,\sum_{i,j=1}^{3}\sum_{l=1}^{3}\int\limits_{\partial\Omega}g_l(\bar{x})\Big(\mu_l(x_3)\,+\,x_1\,M_l(x_3)\,+\,x_2\,D_l(x_3)\Big)\,\Bigg[\tilde{\mathcal{D}}(\gamma,\xi)\sqrt{\nu_i\,g^{ij}\,\nu_j}\\
&+\,\det J\,\frac{\nu_i\,\tilde{g}^{ij}(\gamma,\xi)\,\nu_j}{2\sqrt{\nu_i\,g^{ij}\,\nu_j}}\Bigg]\,d\tau\,+\,2\,\tilde{\mu}\int\limits_{\Omega}\sum_{i=1}^{3}\Bigg[N_i^{\lambda}\,h_{1i}\,+\,B_i^{\lambda}\,h_{2i}\,+\,\Big(\tau_i^{\lambda'}\,+\,x_1\,N_i^{\lambda'}\\
&+\,x_2\,B_i^{\lambda'}\Big)\,h_{3i}\Bigg]\,\Bigg[M_i\,\frac{h_{1i}^{\lambda}\,-\,h_{1i}}{\lambda}\,+\,D_i\,\frac{h_{2i}^{\lambda}\,-\,h_{2i}}{\lambda}\,+\,(\mu_i'\,+\,x_1\,M_i'\\
&+\,x_2\,D_i')\frac{h_{3i}^{\lambda}\,-\,h_{3i}}{\lambda}\Bigg]\,\det J\,d\bar{x}\,+\,2\,\tilde{\mu}\int\limits_{\Omega}\sum_{i=1}^{3}\Bigg[N_i^{\lambda}\,\frac{h_{1i}^{\lambda}\,\det J_{\lambda}\,-\,h_{1i}\,\det J}{\lambda}\\
&+\,B_i^{\lambda}\,\frac{h_{2i}^{\lambda}\,\det J_{\lambda}\,-\,h_{2i}\,\det J}{\lambda}\,+\,\Big(\tau_i^{\lambda}\,+\,x_1\,N_i^{\lambda'}\\
&+\,x_2\,B_i^{\lambda'}\Big)\,\frac{h_{3i}^{\lambda}\,\det J_{\lambda}\,-\,h_{3i}\,\det J}{\lambda}\Bigg]\,\Big[M_i\,h_{1i}^{\lambda}\,+\,D_i\,h_{2i}^{\lambda}\,+\,(\mu_i'\,+\,x_1\,M_i'\\
&+\,x_2\,D_i')\,h_{3i}^{\lambda}\Big]\,d\bar{x}\,+\,\hat{Z}_\lambda(\bar{v})\,.
\end{aligned}
$$

The operator $\hat{Z}_\lambda : H_0^1(0,L)^9\to\mathbb{R}$ is obtained from the terms $\mathbf{b}_1(\,\cdot\,,\,\cdot\,)$ and $\mathbf{b}_2(\,\cdot\,,\,\cdot\,)$ as explained after (4.15). We do not write it explicitly to save space. The relations

(4.14), (4.15) show that the following estimate is valid:

$$|Z_\lambda(\bar v)| \;\le\; C|\bar v|_{H_0^1(0,L)^9} \tag{4.17}$$

with some constant independent of $\lambda > 0$. Here, we use the differentiability properties of the coefficients, given in (4.1)–(4.12), and the convergence of $\bar y_\lambda$, according to (4.13).

By fixing $\bar v = \lambda^{-1}(\bar y_\lambda - \bar y)$, relations (4.16) and (4.17) show that $\{\frac{\bar y_\lambda - \bar y}{\lambda}\}$ is bounded in $H_0^1(0,L)^9$ for $\lambda > 0$, by the coercivity of $\mathcal{B}$. We may take a weakly convergent subsequence

$$\frac{\bar y_\lambda - \bar y}{\lambda} \to \hat y\,, \quad \text{weakly in } H_0^1(0,L)^9\,. \tag{4.18}$$

As in the previous section, one may see that the convergence is valid in the strong topology of $H_0^1(0,L)^9$. The equation in variations has the form

$$\mathcal{B}(\hat y, \bar v) \;=\; Z(\bar v) \quad \forall\ \bar v \;\in\; H_0^1(0,L)^9\,, \tag{4.19}$$

with $Z(\bar v) = \lim_{\lambda\to 0} Z_\lambda(\bar v)$, which exists by the above discussion. Z depends linearly and boundedly on $(\gamma,\xi) \in C^1[0,L]^2$.

Note that (4.19) has a unique solution $\hat y \in H_0^1(0,L)^9$. We have proved the following result.

PROPOSITION 4.1. *The mapping $(\varphi,\psi) \in C^1[0,L]^2 \mapsto \bar y \in H_0^1(0,L)^9$ is Gâteaux differentiable, and the derivative $\hat y$ satisfies* (4.19).

We introduce now the so-called adjoint system, with unknowns $\bar T = (\bar R, \bar P, \bar Q) \in H_0^1(0,L)^9$ and defined by

$$\mathcal{B}(\bar T, \bar v) \;=\; \nabla_2\, j(\bar\theta, \bar y)(\bar v) \quad \forall\ \bar v \;\in\; H_0^1(0,L)^9\,. \tag{4.20}$$

In (4.20), we assume that $j : C^2[0,L]^3 \times H_0^1(0,L)^9 \to \mathbb{R}$ is Fréchet differentiable and that $\nabla_2 j$ denotes the second component of ∇j or, equivalently, the partial Fréchet differential with respect to $\bar y$. The existence and uniqueness of a solution $\bar T \in H_0^1(0,L)^9$ to (4.20) is obvious, due to the coercivity and boundedness of $\mathcal{B}(\,\cdot\,,\,\cdot\,)$.

PROPOSITION 4.2. *If j is Fréchet differentiable, then the directional derivative of the cost functional* Π *in problem* (P) *at the point $(\varphi,\psi) \in C^1[0,L]^2$ and in the direction $(\gamma,\xi) \in C^1[0,L]^2$ is given by*

$$\begin{aligned}
&\nabla\Pi(\varphi,\psi)\,(\gamma,\xi)\\
&= \nabla_1 j(\bar\theta,\bar y)\,\tilde\theta(\gamma,\xi) + \sum_{l=1}^{3}\int_\Omega f_l(\bar x)\Big(R_l(x_3) + x_1\,P_l(x_3) + x_2\,Q_l(x_3)\Big)\,\tilde{\mathcal{D}}(\gamma,\xi)\,d\bar x\\
&\quad + \sum_{i,j=1}^{3}\sum_{l=1}^{3}\int_{\partial\Omega} g_l(\bar x)\Big(R_l(x_3) + x_1\,P_l(x_3) + x_2\,Q_l(x_3)\Big)\,\tilde{\mathcal{D}}(\gamma,\xi)\sqrt{\nu_i\,g^{ij}\nu_j}\,d\tau\\
&\quad + \sum_{i,j=1}^{3}\sum_{l=1}^{3}\int_{\partial\Omega} g_l(\bar x)\Big(R_l(x_3) + x_1\,P_l(x_3) + x_2\,Q_l(x_3)\Big)\\
&\qquad \times \det J\,\frac{1}{\sqrt{\nu_i\,g^{ij}\nu_j}}\,\nu_i\tilde g^{ij}(\gamma,\xi)\nu_j\,d\tau\\
&\quad - 2\,\tilde\mu\int_\Omega \sum_{i=1}^{3}\Big[N_i\,h_{1i} + B_i\,h_{2i} + \Big(\tau_i' + x_1\,N_i' + x_2\,B_i'\Big)\,h_{3i}\Big]
\end{aligned}$$

$$\times\left[P_i\,\tilde h_{1i}(\gamma,\xi)+Q_i\,\tilde h_{2i}(\gamma,\xi)+\Big(R_i'+x_1\,P_i'+x_2\,Q_i'\Big)\,\tilde h_{3i}(\gamma,\xi)\right]\,\det J\,d\bar x$$

$$-2\,\tilde\mu\int\limits_\Omega\sum_{i=1}^3\left[N_i\,\tilde h_{1i}(\gamma,\xi)+B_i\,\tilde h_{2i}(\gamma,\xi)+\Big(\tau_i'+x_1\,N_i'+x_2\,B_i'\Big)\,\tilde h_{3i}(\gamma,\xi)\right]$$

$$\times\left[P_i\,h_{1i}+Q_i\,h_{2i}+\Big(R_i'+x_1\,P_i'+x_2\,Q_i'\Big)\,h_{3i}\right]\,\det J\,d\bar x$$

$$-2\,\tilde\mu\int\limits_\Omega\sum_{i=1}^3\left[N_i\,h_{1i}+B_i\,h_{2i}+\Big(\tau_i'+x_1\,N_i'+x_2\,B_i'\Big)\,h_{3i}\right]$$

$$\times\left[P_i\,h_{1i}+Q_i\,h_{2i}+\Big(R_i'+x_1\,P_i'+x_2\,Q_i'\Big)\,h_{3i}\right]\tilde{\mathcal D}(\gamma,\xi)\,d\bar x$$

$$-\tilde\lambda\int\limits_\Omega\sum_{i,j=1}^3\left[N_i\,h_{1i}+B_i\,h_{2i}+\Big(\tau_i'+x_1\,N_i'+x_2\,B_i'\Big)\,h_{3i}\right]$$

$$\times\left[P_j\,\tilde h_{1j}(\gamma,\xi)+Q_j\,\tilde h_{2j}(\gamma,\xi)+\Big(R_j'+x_1\,P_j'+x_2\,Q_j'\Big)\,\tilde h_{3j}(\gamma,\xi)\right]\,\det J\,d\bar x$$

$$-\tilde\lambda\int\limits_\Omega\sum_{i,j=1}^3\left[N_i\,\tilde h_{1i}(\gamma,\xi)+B_i\,\tilde h_{2i}(\gamma,\xi)+\Big(\tau_i'+x_1\,N_i'+x_2\,B_i'\Big)\,\tilde h_{3i}(\gamma,\xi)\right]$$

$$\times\left[P_j\,h_{1j}+Q_j\,h_{2j}+\Big(R_j'+x_1\,P_j'+x_2\,Q_j'\Big)\,h_{3j}\right]\,\det J\,d\bar x$$

$$-\tilde\lambda\int\limits_\Omega\sum_{i,j=1}^3\left[N_i\,h_{1i}+B_i\,h_{2i}+\Big(\tau_i'+x_1\,N_i'+x_2\,B_i'\Big)\,h_{3i}\right]$$

$$\times\left[P_j\,h_{1j}+Q_j\,h_{2j}+\Big(R_j'+x_1\,P_j'+x_2\,Q_j'\Big)\,h_{3j}\right]\tilde{\mathcal D}(\gamma,\xi)\,d\bar x$$

$$-\tilde\mu\int\limits_\Omega\sum_{i<j}\left[N_i\,h_{1j}+B_i\,h_{2j}+\Big(\tau_i'+x_1\,N_i'+x_2\,B_i'\Big)\,h_{3j}+N_j\,h_{1i}+B_j\,h_{2i}\right.$$

$$\left.+\Big(\tau_j'+x_1\,N_j'+x_2\,B_j'\Big)\,h_{3i}\right]$$

$$\times\left[P_i\,\tilde h_{1j}(\gamma,\xi)+\,Q_i\,\tilde h_{2j}(\gamma,\xi)+\Big(R_i'+x_1\,P_i'+x_2\,Q_i'\Big)\,\tilde h_{3j}(\gamma,\xi)+P_j\,\tilde h_{1i}(\gamma,\xi)\right.$$

$$\left.+Q_j\,\tilde h_{2i}(\gamma,\xi)+\Big(R_j'+x_1\,P_j'+x_2\,Q_j'\Big)\,\tilde h_{3i}(\gamma,\xi)\right]\,\det J\,d\bar x$$

$$-\tilde\mu\int\limits_\Omega\sum_{i<j}\left[N_i\,\tilde h_{1j}(\gamma,\xi)+B_i\,\tilde h_{2j}(\gamma,\xi)+\Big(\tau_i'+x_1\,N_i'+x_2\,B_i'\Big)\,\tilde h_{3j}(\gamma,\xi)\right.$$

$$
\begin{aligned}
&+ N_j\,\tilde h_{1i}(\gamma,\xi) + B_j\,\tilde h_{2i}(\gamma,\xi) + \Big(\tau_j' + x_1\,N_j' + x_2\,B_j'\Big)\,\tilde h_{3i}(\gamma,\xi)\Big]\\
&\times\Big[P_i\,h_{1j} + Q_i\,h_{2j} + \Big(R_i' + x_1\,P_i' + x_2\,Q_i'\Big)\,h_{3j} + P_j\,h_{1i} + Q_j\,h_{2i}\\
&\quad + \Big(R_j' + x_1\,P_j' + x_2\,Q_j'\Big)\,h_{3i}\Big]\,\det J\,d\bar x\\
-\tilde\mu\int_\Omega \sum_{i<j}\Big[&N_i\,h_{1j} + B_i\,h_{2j} + \Big(\tau_i' + x_1\,N_i' + x_2\,B_i'\Big)\,h_{3j}\\
&+ N_j\,h_{1i} + B_j\,h_{2i} + \Big(\tau_j' + x_1\,N_j' + x_2\,B_j'\Big)\,h_{3i}\Big]\\
&\times\Big[P_i\,h_{1j} + Q_i\,h_{2j} + \Big(R_i' + x_1\,P_i' + x_2\,Q_i'\Big)\,h_{3j} + P_j\,h_{1i} + Q_j\,h_{2i}\\
&\quad + \Big(R_j' + x_1\,P_j' + x_2\,Q_j'\Big)\,h_{3i}\Big]\,\tilde{\mathcal{D}}(\gamma,\xi)\,d\bar x\,.
\end{aligned}
\tag{4.21}
$$

Remark 4.3. In order to compute (4.21), from (φ,ψ) and $(\gamma,\xi)\in C^1[0,L]^2$, one has to compute $\bar\theta\in C^2[0,L]^3$ by (2.1), $\bar y=(\bar\tau,\bar N,\bar B)\in H_0^1(0,L)^9$ by (2.13), $\bar T=(\bar R,\bar P,\bar Q)\in H_0^1(0,L)^9$ by (2.20), and use (4.1)–(4.12), where γ, ξ enter effectively. See the explicit form of $\tilde t(\gamma,\xi)$ given after (4.12). Writing all the operators in (4.1)–(4.12) explicitly, and replacing them in (4.21), would give the "full" expression for $\nabla\Pi(\varepsilon,\psi)(\gamma,\xi)$, which we do not write down to save space. Since spaces of continuous functions are taken into account, it is not advantageous to rewrite (4.21) by using adjoint operators.

Note also that the above argument holds if φ,ψ,γ,ξ are only piecewise continuously differentiable. This is important for the numerical experiments in section 8.

Remark 4.4. Assuming that the cross section of the rod is not constant, one may study optimization problems with respect to the cross section as well, under appropriate regularity conditions.

Let $\mathcal{C}=\{(\varphi,\psi)\in C^1[0,L]^2\,;\,\bar\theta(\varphi,\psi)\in\mathcal{K}\}$ and $u_0=(\varphi_0,\psi_0)\in\mathcal{C}$ be arbitrarily fixed. We denote by

$$
T(\mathcal{C};u_0)=\Big\{u\in C^1[0,L]^2\,;\,u=\lim_{n\to\infty}\lambda_n(u_n-u_0)\,,\ \lambda_n\ge 0\,,\ u_n\in\mathcal{C}\,,\ \text{and } u_n\to u_0\Big\}
$$

the cone of tangents to $\mathcal{C}$ at u_0 (see Barbu and Precupanu [4]). It is known that if $\mathcal{C}$ is convex (see examples (2.15), (2.16) and Remark 2.3), then $T(\mathcal{C};u_0)=\overline{\bigcup_{\lambda>0}\lambda(\mathcal{C}-u_0)}$.

COROLLARY 4.5. *Assume that $u^*=(\varphi^*,\psi^*)$ is a (local) optimum point for* (P). *Then the following statements are valid:*

(i) *If* Π *is Fréchet differentiable on* $C^1[0,L]^2$, *then*

$$
\nabla\Pi(\varphi^*,\psi^*)(\gamma,\xi)\ge 0\quad\forall\,(\gamma,\xi)\,\in\,T(\mathcal{C};u^*)\,.
$$

(ii) *If* $\mathcal{C}$ *is convex, then the directional derivative of* Π *satisfies*

$$
\nabla\Pi(\varphi^*,\psi^*)(\gamma,\xi)\ge 0\quad\forall\,(\gamma,\xi)\,\in\,\mathcal{C}-u^*\,.
$$

Remark 4.6. Corollary 4.5 gives the standard first-order optimality conditions for problem (P) (see Tröltzsch [20]). Relations (4.21), (4.20), etc., indicate the explicit calculation of the directional derivative of the cost functional and will be used in the last section in the numerical experiments.

5. Formulation of the shell optimization problem. Let $o \subset \mathbb{R}^2$ denote a bounded domain, not necessarily simply connected, with Lipschitz boundary ∂o. Define

$$\Omega \,=\, o \times]-\varepsilon\,,\,\varepsilon[\subset \mathbb{R}^3$$

for some "small" $\varepsilon > 0$. We denote by $(x_1, x_2) \in o$ and $x_3 \in]-\varepsilon, \varepsilon[$, $\bar{x} = (x_1, x_2, x_3) \in \Omega$ the independent variables.

Let $p : o \to \mathbb{R}$ be a $C^2(\bar{o})$ mapping, whose graph represents the middle surface $\mathcal{S}$ of a shell. We introduce the geometrical transformation

$$F \,:\, \Omega \,\to\, \mathbb{R}^3\,,$$

$$F(\bar{x}) \,=\, \bar{\pi}(x_1, x_2) \,+\, x_3\, \bar{n}(x_1, x_2)\,, \tag{5.1}$$

with $\bar{\pi} = (\pi_1, \pi_2, \pi_3) = (x_1, x_2, p(x_1, x_2))$, and with $\bar{n} = (n_1, n_2, n_3)$ denoting the normal vector to $\mathcal{S}$ in the point $\bar{\pi}(x_1, x_2)$. Since the tangent vectors $\frac{\partial \bar{\pi}}{\partial x_1} = (1, 0, p_1)$ and $\frac{\partial \bar{\pi}}{\partial x_2} = (0, 1, p_2)$, with $p_1 = \frac{\partial p}{\partial x_1}$ and $p_2 = \frac{\partial p}{\partial x_2}$, are always linearly independent, we may take $\bar{n}$ as the normalization of $\frac{\partial \bar{\pi}}{\partial x_1} \wedge \frac{\partial \bar{\pi}}{\partial x_2}$, that is,

$$\bar{n} \,=\, \frac{1}{\sqrt{1 + p_1^2 + p_2^2}}(-p_1, -p_2, 1)\,. \tag{5.2}$$

Assume that $\partial o = \bar{\gamma}_0 \cup \bar{\gamma}_1$, with $\gamma_0\,,\, \gamma_1$ being nonoverlapping open parts of ∂o such that $\mathrm{meas}\,(\gamma_0) > 0$, and let $\Gamma_0 := \gamma_0 \times]-\varepsilon, \varepsilon[$, $\Gamma_1 := \partial\Omega \setminus \Gamma_0$. We introduce the notation

$$\hat{\Omega} := F(\Omega)\,, \quad \hat{\Gamma}_0 := F(\Gamma_0)\,, \quad \hat{\Gamma}_1 := F(\Gamma_1)\,.$$

We argue later (see (5.9)) that F is a homeomorphism for small ε, and the open set $\hat{\Omega}$ will represent a shell. We assume that body forces $\hat{f} \in L^2(\hat{\Omega})^3$ and surface tractions $\hat{g} \in L^2(\hat{\Gamma}_1)^3$ act on the shell. Our main mechanical assumption is that the corresponding displacement $\hat{u} \in V(\hat{\Omega}) = \{\hat{v} \in H^1(\hat{\Omega})^3\,;\, \hat{v}|_{\hat{\Gamma}_0} = 0\}$ has the form

$$\hat{u}(\hat{x}) \,=\, \bar{u}(x_1, x_2) \,+\, x_3\, \bar{r}(x_1, x_2)\,, \quad x \,\in\, \hat{\Omega}\,. \tag{5.3}$$

Here, $\bar{x} = (x_1, x_2, x_3) = F^{-1}(\hat{x}) \,\in\, \Omega$ and $\bar{u} = (u_1, u_2, u_3)\,,\, \bar{r} = (r_1, r_2, r_3)$ belong to the Hilbert space

$$V(o) \,=\, \{\bar{v} \,=\, (v_1, v_2, v_3) \,\in\, H^1(o)^3\,;\, \bar{v}|_{\gamma_0} \,=\, 0\}\,, \tag{5.4}$$

equipped with the norm

$$|\bar{v}|_{V(o)} := \int_o \left(|\nabla v_1|^2 + |\nabla v_2|^2 + |\nabla v_3|^2\right) dx_1 dx_2\,.$$

If we denote by $\tilde{V}(\hat{\Omega})$ the subspace of $V(\hat{\Omega})$ defined by (5.3), (5.4), we can see that $\tilde{V}(\hat{\Omega})$ can simply be identified with $V(o) \times V(o)$, and we shall do this repeatedly later in this paper.

Clearly, $\bar{u}$ represents the displacement of the middle surface $\mathcal{S}$ of the shell, while $\bar{r}$ is the modification of the points along the normal $\bar{n}(x_1, x_2)$, assumed to remain on a line. The form (5.3) allows for both dilation and contraction of the elastic material; it is a generalization of the classical Naghdi model (see Ciarlet [11] and Blouza [6]).

The Jacobian $J = D\,F$ of F is given by

$$J(\bar{x}) = \begin{bmatrix} 1 + x_3 \dfrac{\partial n_1}{\partial x_1} & x_3 \dfrac{\partial n_1}{\partial x_2} & n_1 \\ x_3 \dfrac{\partial n_2}{\partial x_1} & 1 + x_3 \dfrac{\partial n_2}{\partial x_2} & n_2 \\ p_1 + x_3 \dfrac{\partial n_3}{\partial x_1} & p_2 + x_3 \dfrac{\partial n_3}{\partial x_2} & n_3 \end{bmatrix}. \tag{5.5}$$

As $|\bar{n}|^2_{\mathbb{R}^3} = 1$, we get $\langle \bar{n}\,,\, \frac{\partial \bar{n}}{\partial x_i} \rangle_{\mathbb{R}^3} = 0\,,\ i = 1, 2$, which shows that $\frac{\partial \bar{n}}{\partial x_i}$ can be generated by $\frac{\partial \bar{\pi}}{\partial x_1}$ and $\frac{\partial \bar{\pi}}{\partial x_2}$. We get the relations

$$\frac{\partial \bar{n}}{\partial x_1}(x_1, x_2) = \frac{\partial n_1}{\partial x_1}\frac{\partial \bar{\pi}}{\partial x_1} + \frac{\partial n_2}{\partial x_1}\frac{\partial \bar{\pi}}{\partial x_2}\,, \tag{5.6}$$

$$\frac{\partial \bar{n}}{\partial x_2}(x_1, x_2) = \frac{\partial n_1}{\partial x_2}\frac{\partial \bar{\pi}}{\partial x_1} + \frac{\partial n_2}{\partial x_1}\frac{\partial \bar{\pi}}{\partial x_2}\,, \tag{5.7}$$

which are special cases of the equations of motion of the local frame on the surface $\mathcal{S}$; see Cartan [7]. The coefficients $\frac{\partial n_i}{\partial x_\alpha}\,,\ i = \overline{1,3}\,,\ \alpha = 1, 2$, are related to the curvatures of $\mathcal{S}$.

Equalities (5.5)–(5.7) yield

$$\det J(\bar{x}) = \left[1 + x_3\left(\frac{\partial n_1}{\partial x_1} + \frac{\partial n_2}{\partial x_2}\right) + x_3^2\left(\frac{\partial n_1}{\partial x_1}\frac{\partial n_2}{\partial x_2} - \frac{\partial n_1}{\partial x_2}\frac{\partial n_2}{\partial x_1}\right)\right] \times \sqrt{1 + p_1^2 + p_2^2}\,. \tag{5.8}$$

Since $p \in C^2(\bar{o})$, for "small" $\varepsilon > 0$ we get that

$$\det J(\bar{x}) \geq c > 0 \quad \forall\, \bar{x} \in \Omega\,. \tag{5.9}$$

Let us notice that (5.9) justifies the definition of the shell $\hat{\Omega}$ via the transformation F; see Ciarlet [11, Thm. 3.1-1].

We denote the elements of $J(\bar{x})^{-1}$ by

$$J(\bar{x}) = (h_{ij}(\bar{x}))_{i,j=\overline{1,3}}\,. \tag{5.10}$$

In Sprekels and Tiba [18], the following generalized Naghdi model is obtained:

$$\begin{aligned} &\mathcal{B}\left((\bar{u}, \bar{r})\,,\, (\bar{\mu}, \bar{\rho})\right) \\ &= \tilde{\lambda} \int_\Omega \left\{ \sum_{i=1}^{3} \left[\left(\frac{\partial u_i}{\partial x_1} + x_3 \frac{\partial r_i}{\partial x_1} \right) h_{1i} + \left(\frac{\partial u_i}{\partial x_2} + x_3 \frac{\partial r_i}{\partial x_2} \right) h_{2i} + r_i\, h_{3i} \right] \right\} \\ &\times \left\{ \sum_{j=1}^{3} \left[\left(\frac{\partial \mu_j}{\partial x_1} + x_3 \frac{\partial \rho_j}{\partial x_1} \right) h_{1j} + \left(\frac{\partial \mu_j}{\partial x_2} + x_3 \frac{\partial \rho_j}{\partial x_2} \right) h_{2j} + \rho_j\, h_{3j} \right] \right\} |\det J(\bar{x})|\, d\bar{x} \end{aligned}$$

$$
\begin{aligned}
&+2\,\tilde{\mu}\int_{\Omega}\sum_{i=1}^{3}\left[\left(\frac{\partial u_i}{\partial x_1}+x_3\frac{\partial r_i}{\partial x_1}\right)h_{1i}+\left(\frac{\partial u_i}{\partial x_2}+x_3\frac{\partial r_i}{\partial x_2}\right)h_{2i}+r_i\,h_{3i}\right]\\
&\times\left[\left(\frac{\partial \mu_i}{\partial x_1}+x_3\frac{\partial \rho_i}{\partial x_1}\right)h_{1i}+\left(\frac{\partial \mu_i}{\partial x_2}+x_3\frac{\partial \rho_i}{\partial x_2}\right)h_{2i}+\rho_i\,h_{3i}\right]|\det J(\bar{x})|\,d\bar{x}\\
&+\tilde{\mu}\int_{\Omega}\sum_{1\le i<j\le 3}\left[\left(\frac{\partial u_i}{\partial x_1}+x_3\frac{\partial r_i}{\partial x_1}\right)h_{1j}+\left(\frac{\partial u_i}{\partial x_2}+x_3\frac{\partial r_i}{\partial x_2}\right)h_{2j}+r_i\,h_{3j}\right.\\
&\left.+\left(\frac{\partial u_j}{\partial x_1}+x_3\frac{\partial r_j}{\partial x_1}\right)h_{1i}+\left(\frac{\partial u_j}{\partial x_2}+x_3\frac{\partial r_j}{\partial x_2}\right)h_{2i}+r_j\,h_{3i}\right]\\
&\times\left[\left(\frac{\partial \mu_i}{\partial x_1}+x_3\frac{\partial \rho_i}{\partial x_1}\right)h_{1j}+\left(\frac{\partial \mu_i}{\partial x_2}+x_3\frac{\partial \rho_i}{\partial x_2}\right)h_{2j}+\rho_i\,h_{3j}\right.\\
&\left.+\left(\frac{\partial \mu_j}{\partial x_1}+x_3\frac{\partial \rho_j}{\partial x_1}\right)h_{1i}+\left(\frac{\partial \mu_j}{\partial x_2}+x_3\frac{\partial \rho_j}{\partial x_2}\right)h_{2i}+r_j\,h_{3i}\right]|\det J(\bar{x}|\,d\bar{x}\\
&=\int_{\Omega}\sum_{l=1}^{3}f_l(\mu_l+x_3\,\rho_l)\,|\det J(\bar{x})|\,d\bar{x}+\int_{\Gamma_1}\sum_{l=1}^{3}\sum_{i,j=1}^{3}g_l(\mu_l+x_3\,\rho_l)\,|\det J(\bar{x})|\\
&\times\sqrt{\nu_i(\bar{x})\,g^{ij}(\bar{x})\,\nu_j(\bar{x})}\,d\tau\quad\forall\ (\bar{\mu},\bar{\rho})\ \in\ V(o)^2\,. \qquad (5.11)
\end{aligned}
$$

Here, $\bar{f}(\bar{x})=\hat{f}(F\bar{x})$, $\bar{g}(\bar{x})=\hat{g}(F\bar{x})$, $\bar{x}\in\Omega$, we use the assumed form (5.3) of the displacement, and $\bar{\mu}\in V(o)$, $\bar{\rho}\in V(o)$ are arbitrary test functions. The coefficients g^{ij} are obtained by

$$
\Big(g^{ij}(\bar{x})\Big)_{i,j=\overline{1,3}}\ =\ J(\bar{x})^{-1}\Big[J(\bar{x})^{T}\Big]^{-1}\,, \qquad (5.12)
$$

and $(\nu_i(\bar{x}))_{i=\overline{1,3}}$ is the unit outside normal to Γ_1 at $\bar{x}\in\Gamma_1$.

The coercivity of $\mathcal{B}$ on $V(o)\times V(o)$ was proved by Sprekels and Tiba [18] for ε small enough. This gives the existence and the uniqueness of the solution $(\bar{u},\bar{r})\in V(o)\times V(o)$ to (5.11).

For given $\bar{f}$ and $\bar{g}$ (defined in a sufficiently large ball in $\mathbb{R}^3$), we consider the following general shape optimization problem associated with (5.11):

$$
\min_{p}\ \left\{\Pi(p)\ =\ j\Big(\bar{y}(x_1,x_2)\,,\,p(x_1,x_2)\Big)\right\} \qquad (\mathrm{P}')
$$

with $\bar{y}(x_1,x_2)=(\bar{u}(x_1,x_2),\bar{r}(x_1,x_2))\in V(o)^2$ given by (2.11), and subject to the "control" constraint $p\in\mathcal{K}\subset C^2(\bar{o})$, closed and bounded. Notice that (5.9) should be included in the definition of $\mathcal{K}$. The mapping $j:V(o)^2\times C^2(o)\to\mathbb{R}$ satisfies certain regularity properties to be described later. One classical example is the quadratic case

$$
2j(\bar{y},p)\ =\ |u_1|^2_{V(o)}\ +\ |u_2|^2_{V(o)}\ +\ |u_3|^2_{V(o)}\,. \qquad (5.13)
$$

Then (P′) aims at finding the shape of the shell (the surface $\mathcal{S}$) that minimizes the displacement of the middle surface under prescribed body forces and tractions.

Concerning the constraints to which the shell itself may be submitted and which are abstractly written as $p \in \mathcal{K}$, there is a large variety of examples. We just list

$$0 \le p(x_1, x_2) \quad \forall\, (x_1, x_2) \in o \tag{5.14}$$

(pointwise constraints),

$$\int_o p(x_1, x_2)\, dx_1\, dx_2 \ge c \tag{5.15}$$

(integral constraints). A special integral constraint is to prescribe limits for the area of $\mathcal{S}$:

$$\int_o \sqrt{1 + p_1^2 + p_2^2} \ge \beta\,. \tag{5.16}$$

Although all the examples (5.13)–(5.16) have a convex nature, the shape optimization problem (P′) is strongly nonconvex, since the dependence $p \mapsto \bar{y}$ is nonlinear. (P′) is a control-into-coefficients problem.

6. Existence of optimal shells. First we prove the following continuous dependence result.

THEOREM 6.1. *Assume that* $p_n : \bar{o} \to \mathbb{R}$ *and* $p_n \to p$ *in* $C^2(\bar{o})$. *If* $\bar{y}_n = (\bar{u}_n, \bar{r}_n)$ *and* $\bar{y} = (\bar{u}, \bar{r})$ *are the solutions of* (5.11) *corresponding to* p_n, p, *then* $\bar{y}_n \to \bar{y}$ *strongly in* $V(o)^2$ *for sufficiently small* $\varepsilon > 0$.

Relations (5.1), (5.2), (5.5), and (5.8) give (with obvious notation)

$$\bar{n}_n \to \bar{n} \quad \text{in } C^1(\bar{o})^3\,, \tag{6.1}$$

$$F_n = \bar{\pi}_n + x_3\, \bar{n}_n \to F = \bar{\pi} + x_3\, \bar{n} \quad \text{in } C^1(\bar{\Omega})^3\,, \tag{6.2}$$

$$J_n \to J \quad \text{in } C(\bar{\Omega})^9\,, \tag{6.3}$$

$$\det J_n \to \det J \quad \text{in } C(\bar{\Omega})\,. \tag{6.4}$$

Notice that

$$J(\bar{x}) = \begin{bmatrix} 1 & 0 & n_1 \\ 0 & 1 & n_2 \\ p_1 & p_2 & n_3 \end{bmatrix} \begin{bmatrix} 1 + x_3 \frac{\partial n_1}{\partial x_1} & x_3 \frac{\partial n_1}{\partial x_2} & 0 \\ x_3 \frac{\partial n_2}{\partial x_1} & 1 + x_3 \frac{\partial n_2}{\partial x_2} & 0 \\ 0 & 0 & 1 \end{bmatrix} = S\,R =: S(I + x_3\, M) \tag{6.5}$$

(new matrix notation).

Similarly, we have

$$J_n = S_n\, R_n = S_n(I + x_3\, M_n)\,. \tag{6.6}$$

A simple calculus gives

$$S_n^{-1} = \frac{1}{\sqrt{1 + (p_1^n)^2 + (p_2^n)^2}} \begin{bmatrix} n_3^n - n_2^n\, p_2^n & n_1^n\, p_2^n & -n_1^n \\ n_2^n\, p_1^n & n_3^n - n_1^n\, p_1^n & -n_2^n \\ -p_1^n & -p_2^n & 1 \end{bmatrix}$$

$$\longrightarrow \frac{1}{\sqrt{1 + p_1^2 + p_2^2}} \begin{bmatrix} n_3 - n_2\, p_2 & n_1\, p_2 & -n_1 \\ n_2\, p_1 & n_3 - n_1\, p_1 & -n_2 \\ -p_1 & -p_2 & 1 \end{bmatrix} = S^{-1}\,,$$

strongly in $C^1(\bar{o})$. Moreover,

$$R_n^{-1} = (I + x_3 M_n)^{-1} = I - x_3 M_n + x_3^2 M_n^2 - x_3^3 M_n^3 + \dots \tag{6.7}$$

for ε small. Clearly, we have

$$M_n = \begin{bmatrix} \dfrac{\partial n_1^n}{\partial x_1} & \dfrac{\partial n_1^n}{\partial x_2} & 0 \\ \dfrac{\partial n_2^n}{\partial x_1} & \dfrac{\partial n_2^n}{\partial x_2} & 0 \\ 0 & 0 & 0 \end{bmatrix} \longrightarrow M = \begin{bmatrix} \dfrac{\partial n_1}{\partial x_1} & \dfrac{\partial n_1}{\partial x_2} & 0 \\ \dfrac{\partial n_2}{\partial x_1} & \dfrac{\partial n_2}{\partial x_2} & 0 \\ 0 & 0 & 0 \end{bmatrix} \tag{6.8}$$

in $C(\bar{o})$. Relations (6.7) and (6.8) show (by a passage to the limit in the infinite sum, $n \to \infty$) that $R_n^{-1} \to R^{-1}$ in $C(\bar{\Omega})^9$ for ε small.

Then, (6.6) and the above argument give

$$J_n^{-1} \longrightarrow J^{-1} \quad \text{in } C(\bar{\Omega})^9 \,. \tag{6.9}$$

In particular, we have that

$$h_{ij}^n(\bar{x}) \longrightarrow h_{ij}(\bar{x}) \quad \text{in } C(\bar{\Omega}) \quad \forall\, i,j = \overline{1,3}\,, \tag{6.10}$$

$$g_n^{ij}(\bar{x}) \longrightarrow g^{ij}(\bar{x}) \quad \text{in } C(\bar{\Omega}) \quad \forall\, i,j = \overline{1,3}\,, \tag{6.11}$$

according to (5.10), (5.12), (6.3), and (6.4).

Let $\mathcal{B}_n$ denote the bilinear form $\mathcal{B}$ from (5.11) with coefficients h_{ij}^n, $\det J_n$. We show that it has a coercivity constant independent of $n \in \mathbb{N}$ for $\varepsilon > 0$ small enough (again independently of n).

Proposition 6.2. *Assume that $\mathcal{K}$ is bounded in $C^2(\bar{o})$ and that $\varepsilon < \varepsilon(\mathcal{K})$ and $\delta \ll \varepsilon$ are given positive numbers. There are $c = c(\mathcal{K}) > 0$ and $m = m(\mathcal{K}) > 0$ such that*

$$\mathcal{B}_p(\hat{u},\hat{u}) \geq c\Big[\varepsilon|\bar{u}|^2_{V(o)} + \varepsilon^3|\bar{r}|^2_{V(o)}\Big] - \frac{m}{\delta}\Big[|\bar{r}|^2_{L^2(o)^3} + |\bar{u}|^2_{L^2(o)^3}\Big] \tag{6.12}$$

for any $p \in \mathcal{K}$ and any $\hat{u} \in H^1(\hat{\Omega})^3$ given by (5.3).

The constant $\varepsilon(\mathcal{K}) > 0$ depends on $c_i > 0$, $i = 1,2$, defined below in (6.23) and in Lemma 6.3. It should be small enough such that (5.8) is fulfilled, which is possible due to the boundedness of $\mathcal{K}$ in $C^2(\bar{o})$. The precise significance of $\varepsilon(\mathcal{K})\,,\ c(\mathcal{K})\,,\ m(\mathcal{K})$ is indicated in the proof.

The notation $\mathcal{B}_p(\,\cdot\,,\,\cdot\,)$ signifies the bilinear functional (5.11) associated with some $p \in \mathcal{K}$. We prove Proposition 6.2 only for the case $\bar{u}, \bar{r} \in H_0^1(o)^3 = V(o)$, in order to avoid more technical arguments related to the extension of $\hat{u}$ to $H_0^1(\mathbb{R})^3$.

Proof. We consider the mapping $\bar{w} \in H^1(\Omega)^3$, given by

$$\bar{w}(x_1,x_2,x_3) = \bar{u}(x_1,x_2) + x_3\,\bar{r}(x_1,x_2)\,, \tag{6.13}$$

such that $\hat{u}(\hat{x}) = \bar{w}(F^{-1}\hat{x})\,,\ \hat{x} \in \hat{\Omega}\,,\ \bar{x} = F^{-1}\hat{x} \in \Omega$. We denote

$$S^+ = [\varepsilon\,,\,\varepsilon+\delta] \times \bar{o}\,, \quad S^- = [-\varepsilon-\delta\,,\,-\varepsilon] \times \bar{o}\,. \tag{6.14}$$

We extend $\bar{w}$ to $\Omega \cup S^+ \cup S^-$ by $\tilde{w}|_\Omega = \bar{w}$, and

$$\tilde{w}(\bar{x}) \;=\; \delta^{-1}\{[(\varepsilon+\delta)-x_3]\,\bar{u}(x_1,x_2)+\varepsilon\,(\varepsilon+\delta-x_3)\,\bar{r}(x_1,x_2)\} \tag{6.15}$$

for $\bar{x} \in S^+$,

$$\tilde{w}(\bar{x}) \;=\; \delta^{-1}\,\{(\varepsilon+\delta+x_3)\,\bar{u}(x_1,x_2)-\varepsilon\,(\varepsilon+\delta+x_3)\,\bar{r}(x_1,x_2)\} \tag{6.16}$$

for $\bar{x} \in S^-$.

Then, we may extend $\tilde{w}$ by 0 to $\mathbb{R}^3$ as $\bar{u}, \bar{r} \in H_0^1(o)^3$. In the general case of a partially clamped shell, one has to use an extension procedure around $o \subset \mathbb{R}^2$, too (for instance, the Calderon extension (Adams [1]), since ∂o is assumed Lipschitzian).

We may assume that F_p, i.e., the transformation (5.1) associated with any $p \in \mathcal{K}$, is still one-to-one on $\Omega \cup S^+ \cup S^-$, since $\varepsilon+\delta$ is "small" and $\mathcal{K}$ is bounded (see (5.8)). We denote

$$\Sigma_p^+ \;:=\; F_p(S^+)\,, \qquad \Sigma_p^- \;:=\; F_p(S^-)\,. \tag{6.17}$$

Above, the index $p \in \mathcal{K}$ puts into evidence the dependence on p of the geometrical transformation and of the sets. We introduce the extension of $\hat{u} \in H^1(\hat{\Omega}_p)^3$ by

$$\tilde{u}(\hat{x}) \;=\; \tilde{w}\Big(F_p^{-1}(\hat{x})\Big)\,. \tag{6.18}$$

Clearly, it holds that $\tilde{u} \in H_0^1(\hat{\Omega}_p \cup \Sigma_p^+ \cup \Sigma_p^-)$.

As $\mathcal{K}$ is bounded in $C^2(\bar{o})$, there is a ball O in $\mathbb{R}^3$ such that $O \supset \hat{\Omega}_p \cup \Sigma_p^+ \cup \Sigma_p^-$ for any $p \in \mathcal{K}$. We may extend $\tilde{u}$ by 0 to O so that $\tilde{u} \in H_0^1(O)$. We have

$$\mathcal{B}_p(\hat{u},\hat{u}) + \tilde{\mu} \int\limits_{\Sigma_p^+\cup\Sigma_p^-} \sum_{i,j=1}^{3} \Big|\hat{e}_{ij}(\tilde{u})\Big|^2\,d\hat{x} \;\geq\; \tilde{\mu} \int\limits_{O} \sum_{i,j=1}^{3} \Big|\hat{e}_{ij}(\tilde{u})\Big|^2\,d\hat{x}$$

since $\tilde{\lambda} \geq 0\,,\ \tilde{\mu} \geq 0$. Korn's inequality, applied to the last integral, gives that

$$\begin{aligned} \mathcal{B}_p(\hat{u},\hat{u}) &\geq c|\tilde{u}|^2_{H_0^1(O)} \;-\; \tilde{\mu} \int\limits_{\Sigma_p^+\cup\Sigma_p^-} \sum_{i,j=1}^{3} \Big|\hat{e}_{ij}(\tilde{u})\Big|^2\,d\hat{x} \\ &\geq c|\tilde{u}|^2_{H^1(\hat{\Omega}_p)} \;-\; \tilde{\mu} \int\limits_{\Sigma_p^+\cup\Sigma_p^-} \sum_{i,j=1}^{3} \Big|\hat{e}_{ij}(\tilde{u})\Big|^2\,d\hat{x}\,, \end{aligned} \tag{6.19}$$

with $c > 0$ being independent of $p \in \mathcal{K}$.

We have to estimate the last term in (6.19). To this end, we compute

$$\begin{aligned} \int\limits_{\Sigma_p^+\cup\Sigma_p^-} \left|\frac{\partial \tilde{u}_i}{\partial \hat{x}_j}\right|^2 d\hat{x} \;&=\; \int\limits_{\Sigma_p^+\cup\Sigma_p^-} \Big\langle \Big(\frac{\partial \tilde{w}_i}{\partial x_1}\,(\bar{x}(\hat{x}))\,, \\ &\qquad \frac{\partial \tilde{w}_i}{\partial x_2}\,(\bar{x}(\hat{x}))\,,\, \frac{\partial \tilde{w}_i}{\partial x_3}\,(\bar{x}(\hat{x}))\Big)\,,\, \big(d^p_{1j}(\hat{x})\,,\, d^p_{2j}(\hat{x})\,,\, d^p_{3j}(\hat{x})\big)\Big\rangle^2_{\mathbb{R}^3}\, d\hat{x} \\ &=\; \int\limits_{S^+\cup S^-} \Big\langle \Big(\frac{\partial \tilde{w}_i}{\partial x_1}\,,\, \frac{\partial \tilde{w}_i}{\partial x_2}\,,\, \frac{\partial \tilde{w}_i}{\partial x_3}\Big)\,,\, \big(h^p_{1j}\,,\, h^p_{2j}\,,\, h^p_{3j}\big)\Big\rangle^2_{\mathbb{R}^3} \,|\det J_p| d\bar{x}\,, \end{aligned}$$

where $(d_{ij}^p)_{i,j=\overline{1,3}} := D\,F_p^{-1}(\hat{x})$, $(h_{ij}^p)_{i,j=\overline{1,3}} := J_p^{-1}(\bar{x})$, and where we have performed a standard change of variables in the integral (see Sprekels and Tiba [18] for a detailed calculation). Notice that the extension of h_{ij}^p to $S^+ \cup S^-$ is obvious by (5.5).

As $\{\det J_p\}$, $\{h_{ij}^p\}$ are bounded for $p \in \mathcal{K}$, we have to estimate the gradient of $\tilde{w}$ in $L^2(S^+ \cup S^-)$. We compute it in S^+, for example:

$$\frac{\partial \tilde{w}}{\partial x_\alpha} \,=\, \delta^{-1}\left[(\varepsilon+\delta-x_3)\frac{\partial \bar{u}}{\partial x_\alpha} + \varepsilon\,(\varepsilon+\delta-x_3)\frac{\partial \bar{r}}{\partial x_\alpha}\right], \quad \alpha \,=\, 1,2\,, \tag{6.20}$$

$$\frac{\partial \tilde{w}}{\partial x_3} \,=\, -\,\delta^{-1}(\bar{u}+\varepsilon\,\bar{r})\,. \tag{6.21}$$

Thus, we get

$$\left|\frac{\partial \tilde{w}}{\partial x_3}\right|_{L^2(S^+\cup S^-)^3} \le \sqrt{2}\delta^{-\frac{1}{2}}|\bar{u}|_{L^2(\omega)^3} + \sqrt{2}\varepsilon\,\delta^{-\frac{1}{2}}|\bar{r}|_{L^2(\omega)^3}\,.$$

For $\alpha = 1,2$, we have

$$\left|\frac{\partial \tilde{w}}{\partial x_\alpha}\right|_{L^2(S^+\cup S^-)^3} \le \frac{\sqrt{2}}{\sqrt{3}}\,\delta^{\frac{1}{2}}\left|\frac{\partial \bar{u}}{\partial x_\alpha}\right|_{L^2(o)^3} + \frac{\sqrt{2}}{\sqrt{3}}\,\varepsilon\,\delta^{\frac{1}{2}}\left|\frac{\partial \bar{r}}{\partial x_\alpha}\right|_{L^2(o)^3}\,. \tag{6.22}$$

Consequently, we can find some $c_1 > 0$, independent of $p \in \mathcal{K}$, such that

$$\begin{aligned}\mathcal{B}_p(\hat{u},\hat{u}) &\ge c|\hat{u}|^2_{H^1(\hat{\Omega}_p)}\\ &\quad - c_1\left[\delta|\bar{u}|^2_{V(o)} + \varepsilon^2\,\delta|\bar{r}|^2_{V(o)} + \delta^{-1}|\bar{u}|^2_{L^2(o)^3} + \varepsilon^2\,\delta^{-1}|\bar{r}|^2_{L^2(o)^3}\right].\end{aligned} \tag{6.23}$$

Lemma 6.3. *If $\hat{\Omega}_p = F_p(\Omega)$, there are $c_2 > 0$, $c_3 \in \mathbb{R}$, independent of $p \in \mathcal{K}$, such that*

$$\begin{aligned}|\hat{u}|^2_{H^1(\hat{\Omega}_p)} &\ge c_2\Big[\varepsilon|\bar{u}|^2_{V(o)} + \varepsilon^3|\bar{r}|^2_{V(o)}\Big]\\ &\quad - c_3\,\varepsilon|\bar{r}|^2_{L^2(o)^3}\,, \quad \forall\ \hat{u}(\hat{x}) \,=\, \bar{w}(F_p^{-1}\hat{x}) \,\in\, H^1(\Omega_p)\,,\end{aligned}$$

for $\varepsilon \le \varepsilon_0$ and with $\varepsilon_0 > 0$ independent of $p \in \mathcal{K}$.

Proof. The proof of this lemma is quite technical, and we quote Sprekels and Tiba [18, sect. 3] in this respect. It is possible to check that all the constants appearing there may be chosen independently of $p \in \mathcal{K}$. We indicate here just a precise quantitative argument that replaces the qualitative proof of Lemma 3.3 in Sprekels and Tiba [18], in order to preserve the control of the constants. We have

$$\begin{aligned}|\hat{u}|^2_{H^1(\hat{\Omega}_p)} = \int_\Omega \sum_{i,j=1}^3 \Bigg[&\left(\frac{\partial u_i}{\partial x_1} + x_3\frac{\partial r_i}{\partial x_1}\right) h_{1j}^p(\bar{x}) + \left(\frac{\partial u_i}{\partial x_2} + x_3\frac{\partial r_i}{\partial x_2}\right) h_{2j}^p(\bar{x})\\ &+ r_i(\bar{x})\,h_{3j}^p(\bar{x})\Bigg]^2 |\det J_p(\bar{x})|\,d\bar{x}\,,\end{aligned} \tag{6.24}$$

after the change of variables via $F_p : \Omega \to \hat{\Omega}_p$.

We define the quadratic form

$$Q_p(\bar u,\bar r)=2\,\varepsilon\int\limits_o\sum_{i,j=1}^{3}\left(\frac{\partial u_i}{\partial x_1}\,h_{1j}^{p,0}+\frac{\partial u_i}{\partial x_2}\,h_{2j}^{p,0}+r_1\,h_{3j}^{p,0}\right)^2\sqrt{1+p_1^2+p_2^2}\;dx_1\,dx_2$$

$$+\frac{2\,\varepsilon^3}{3}\int\limits_o\sum_{i,j=1}^{3}\left(\frac{\partial r_i}{\partial x_1}\,h_{1j}^{p,0}+\frac{\partial r_i}{\partial x_2}\,h_{2j}^{p,0}\right)^2\sqrt{1+p_1^2+p_2^2}\;dx_1\,dx_2\,, \tag{6.25}$$

and we estimate it first. Here, $(h_{ij}^{p,0})$ are the elements of the matrix S_p^{-1} (see (6.5), (6.6)); that is, they constitute an approximation of (h_{ij}^{p}). Taking into account the structure of S_p^{-1}, we get

$$\frac{\partial r_i}{\partial x_1}=\frac{p_1}{\sqrt{1+p_1^2+p_2^2}}\left(\frac{\partial r_i}{\partial x_1}\,h_{13}^{p,0}+\frac{\partial r_i}{\partial x_2}\,h_{23}^{p,0}\right)$$

$$+\frac{1}{\sqrt{1+p_1^2+p_2^2}}\left(\frac{\partial r_i}{\partial x_1}\,h_{11}^{p,0}+\frac{\partial r_i}{\partial x_2}\,h_{21}^{p,0}\right)\,, \tag{6.26}$$

and similarly for $\frac{\partial r_i}{\partial x_2}$, $\frac{\partial u_i}{\partial x_\alpha}$, $i=\overline{1,3}$, $\alpha=1,2$.

Then, simple algebraic manipulations in (6.25), (6.26), involving the triangle inequality (and the fact that the coefficients of the parentheses in the right-hand side of (6.26) are less than one), put into evidence a constant, independent of $p\in\mathcal{K}$, such that

$$Q_p(\bar u,\bar r)\;\geq\;c\Big(\varepsilon|\bar u|^2_{V(o)}+\varepsilon^3|\bar r|^2_{V(o)}-\varepsilon|\bar r|^2_{L^2(o)^3}\Big)\,,\quad c\;>\;0\,. \tag{6.27}$$

Taking the difference between (6.24) and (6.25), estimates similar to those of Sprekels and Tiba [18, sect. 3] show that it will be dominated by the right-hand side in (6.27) for ε small. This ends the proof of Lemma 6.3. □

Combining this difference with (6.23), we get (6.12), for $\delta\ll\varepsilon$, and the proof of Proposition 6.2 is finished. □

PROPOSITION 6.4. *Let $\tilde{\mathcal{K}}\subset\mathcal{K}$ be a compact subset. There are $\hat\varepsilon>0$ such that for $\varepsilon<\hat\varepsilon$ there is $c_\varepsilon>0$, independent of $p\in\tilde{\mathcal{K}}$, and*

$$\mathcal{B}_p(\hat u,\hat u)\;\geq\;c_\varepsilon\Big[|\bar u|^2_{V(o)}\;+\;|\bar r|^2_{V(o)}\Big]\,,\quad \hat u(\hat x)\;=\;\bar w(F_p^{-1}(\hat x))\;\in\;H^1(\hat\Omega_p) \tag{6.28}$$

for any $p\in\tilde{\mathcal{K}}$.

Proof. We fix $\hat\varepsilon$ and $\varepsilon<\hat\varepsilon$, $\delta\ll\varepsilon$, such that (6.12) is valid.

Assume that (6.28) is false; i.e., there is no $c_\varepsilon>0$ with the indicated property. Therefore, for any $a>0$, there is $p_a\in\mathcal{K}$ and $\bar u_a$, $\bar r_a$, $\hat u_a(\hat x)=\bar w_a(F_{p_a}^{-1}(\hat x))$ such that

$$0\;\leq\;\mathcal{B}_{p_a}(\hat u_a,\hat u_a)\;\leq\;a\Big[|\bar u_a|^2_{V(o)}\;+\;|\bar r_a|^2_{V(o)}\Big]\,. \tag{6.29}$$

In (6.29), we can assume that $|(\bar u_a,\bar r_a)|_{V(o)^2}=1$, and, consequently, that $\mathcal{B}_{p_a}(\hat u_a,\hat u_a)\to 0$ for $a\to 0$. Moreover, we can suppose that $\bar u_a\to\hat u$, $\bar r_a\to\hat r$, both weakly in $V(o)$, and $p_a\to\hat p\in\tilde{\mathcal{K}}$ strongly in $C^2(\bar o)$, due to the compactness of $\tilde{\mathcal{K}}$. In particular, we get $h_{ij}^a\to\hat h_{ij}$ strongly in $C(\bar\Omega)$, where $(h_{ij}^a)_{i,j=1,3}=J_{p_a}^{-1}$, $(\hat h_{ij})_{i,j=\overline{1,3}}=J_{\hat p}^{-1}$.

It is simple to see, due to the uniform convergence of the coefficients h_{ij}^a, that

$$\mathcal{B}_{p_a}(\hat u_a,\hat u_a)\;-\;\mathcal{B}_{\hat p}(\hat u_a,\hat u_a)\;\to\;0 \tag{6.30}$$

(see (5.11)). The weak lower semicontinuity in $H^1(o)^3 \times H^1(o)^3$ of $\mathcal{B}_{\hat{p}}(\,\cdot\,,\,\cdot\,)$ and (6.29), (6.30) show that

$$0 \geq \liminf_{a\to 0} \mathcal{B}_{p_a}(\hat{u}_a, \hat{u}_a) = \liminf_{a\to 0} \mathcal{B}_{\hat{p}}(\hat{u}_a, \hat{u}_a) \geq \mathcal{B}_{\hat{p}}\Big((\hat{u}\,,\,\hat{r})\,;\,(\hat{u}\,,\,\hat{r})\Big) \geq 0\,. \tag{6.31}$$

Clearly, (6.31) shows that $\mathcal{B}_{\hat{p}}((\hat{u}\,,\,\hat{r})\,;\,(\hat{u}\,,\,\hat{r})) = 0$, and the coercivity of $\mathcal{B}_{\hat{p}}$ gives $\hat{u} = 0\,,\ \hat{r} = 0$, according to Sprekels and Tiba [18]. We conclude that $\bar{u}_a \to 0\,,\ \bar{r}_a \to 0$, both weakly in $V(o)$ and strongly in $L^2(o)^3$.

We combine (6.29) and (6.12) to obtain that

$$\begin{aligned} a &\geq c\Big[\varepsilon|\bar{u}_a|^2_{V(o)} + \varepsilon^2|\bar{r}_a|^2_{V(o)}\Big] - \frac{m}{\delta}\Big[|\bar{r}_a|^2_{L^2(o)^3} + |\bar{u}_a|^2_{L^2(o)^3}\Big] \\ &\geq c\,\varepsilon^3 - \frac{m}{\delta}\Big[|\bar{r}_a|^2_{L^2(o)^3} + |\bar{u}_a|^2_{L^2(o)^3}\Big]\,. \end{aligned}$$

Taking $a \to 0$, we get the contradiction

$$0 \geq c\,\varepsilon^3,$$

which ends the proof. □

Proof of Theorem 6.1. We note that the assumptions of Proposition 6.4 are fulfilled and that (6.28) is valid for $\{p_n\}$, for any $n \in \mathbb{N}$. Then, if we fix $(\bar{\mu}, \bar{\rho}) = \bar{y}_n = (\bar{u}_n, \bar{r}_n)$ in (5.11) with $p = p_n$, we get immediately that $\{\bar{y}_n\}$ is bounded in $V(o)^2$. We may assume that $\bar{u}_n \to \bar{u}\,,\ \bar{r}_n \to \bar{r}$, both weakly in $V(o)$, on a subsequence. Due to the uniform convergence of the coefficients, one may pass to the limit in (5.11) and see that $\bar{y} = (\bar{u}, \bar{r})$ is indeed the solution of (5.11) associated with p. As the solution of (5.11) is unique, $\bar{y}$ is the weak limit of the whole sequence.

Now, we have to show that the convergence is valid in the strong topology of $V(o)^2$. We subtract the equations corresponding to $\bar{y}_n\,,\ \bar{y}$; we intercalate advantageous terms (see the last step in the proof of Theorem 3.1) and; finally, we take test functions of the form $\bar{y}_n - \bar{y} \in V(o)^2$. As the difference of the corresponding right-hand sides converges to 0 (by the above weak convergence property), a detailed calculus gives that

$$\lim_{n\to\infty} \mathcal{B}_p(\bar{y}_n - \bar{y},\, \bar{y}_n - \bar{y}) = 0\,. \tag{6.32}$$

By (6.28), (6.32), the proof is finished. □

Corollary 6.5. *If $\mathcal{K} \subset C^2(\bar{o})$ is compact and $j : V(o)^2 \times C^2(\bar{o}) \to R$ is lower semicontinuous, then the shape optimization problem* (P′) *admits at least one optimal solution $p \in \mathcal{K}$.*

7. Sensitivity analysis for shells. We investigate some differentiability properties of the mapping $p \in C^2(\bar{o}) \mapsto \bar{y} \in V(o)^2$ defined by (5.11). We consider $p + \lambda\,q\,,\ \lambda \in \mathbb{R}_+$, and $q \in C^2(\bar{o})$, a small perturbation of $p \in C^2(\bar{o})$, and we denote by $\bar{y}_\lambda = (\bar{u}^\lambda, \bar{r}^\lambda) \in V(o)^2$ the corresponding solution of (5.11). Similarly, we denote by $\bar{n}_\lambda \in C^1(\bar{o})^3\,,\ F_\lambda \in C^1(\bar{\Omega})^3\,,\ J_\lambda \in C(\bar{\Omega})^9\,,\ h^\lambda_{ij} \in C(\bar{\Omega})\,,\ g^{ij}_\lambda \in C(\bar{\Omega})\,,\ \mathcal{B}_\lambda$, etc., all the quantities defined in section 5, starting from $p_\lambda = p + \lambda\,q$. We shall simply write $\mathcal{B}$ for $\mathcal{B}_p$.

It is elementary, though tedious, to check that the below listed limits and linear and bounded operators exist in the indicated spaces:

$$\lim_{\lambda\to 0} \frac{\bar{n}_\lambda - \bar{n}}{\lambda} = \tilde{n}(q)\,,\ \tilde{n} : C^2(\bar{o}) \to C^1(\bar{o})^3\,, \tag{7.1}$$

$$\lim_{\lambda\to 0}\frac{J_\lambda - J}{\lambda} = \tilde J(q)\,,\ \tilde J\,:\,C^2(\bar o)\,\to C(\bar\Omega)^9\,, \tag{7.2}$$

$$\lim_{\lambda\to 0}\frac{J_\lambda^{-1} - J^{-1}}{\lambda} = \tilde I(q)\,,\ \tilde I\,:\,C^2(\bar o)\,\to C(\bar\Omega)^9\,, \tag{7.3}$$

$$\lim_{\lambda\to 0}\frac{h_{ij}^\lambda - h_{ij}}{\lambda} = \tilde h_{ij}(q)\,,\ \tilde h_{ij}\,:\,C^2(\bar o)\,\to C(\bar\Omega)\,, \tag{7.4}$$

$$\lim_{\lambda\to 0}\frac{\det J_\lambda - \det J}{\lambda} = \mathcal{D}(q)\,,\ \mathcal{D}\,:\,C^2(\bar o)\,\to C(\bar\Omega)\,, \tag{7.5}$$

$$\lim_{\lambda\to 0}\frac{g_\lambda^{ij} - g^{ij}}{\lambda} \,=\, \tilde g^{ij}(q)\,,\ \tilde g^{ij}\,:\,C^2(\bar o)\,\to C(\bar\Omega)\,. \tag{7.6}$$

By Theorem 6.1, we also know that

$$\bar y_\lambda \,\longrightarrow\, \bar y \quad \text{strongly in } V(o)^2\,. \tag{7.7}$$

Now, we subtract the equations for $\bar y_\lambda$ and for $\bar y$, we divide by λ, and we prove that it is possible to take $\lambda\to 0$. In the right-hand side, we have

$$\begin{aligned}
&\lim_{\lambda\to 0}\left\{\int_\Omega\sum_{l=1}^3 f_l(\mu_l + x_3\,\rho_l)\frac{\det J_\lambda - \det J}{\lambda}\,d\bar x\right.\\
&\left.+\int_{\Gamma_1}\sum_{l=1}^3\sum_{i,j=1}^3 g_l(\mu_l + x_3\,\rho_l)\frac{\det J_\lambda\sqrt{\nu_i\,g_\lambda^{ij}\,\nu_j} - \det J\sqrt{\nu_i\,g^{ij}\,\nu_j}}{\lambda}\,d\tau\right\}\\
&=\sum_{l=1}^3\int_\Omega f_l(\mu_l + x_3\,\rho_l)\mathcal{D}(q)\,d\bar x\\
&\quad+\sum_{l=1}^3\sum_{i,j=1}^3\int_{\Gamma_1} g_l(\mu_l + x_3\,\rho_l)\left[\mathcal{D}(q)\sqrt{\nu_i\,g^{ij}\,\nu_j} + \det J\frac{\nu_i\,\tilde g^{ij}(q)\,\nu_j}{2\sqrt{\nu_i\,g^{ij}\,\nu_j}}\right]d\tau\,.
\end{aligned} \tag{7.8}$$

Here $\bar v = (\bar\mu,\bar\rho)\in V(o)^2$ is an arbitrary test function.

As the computation of $\frac{1}{\lambda}[\mathcal{B}_\lambda - \mathcal{B}]$ is quite lengthy, we write in detail just the terms from the bilinear functionals associated with the coefficient $2\,\tilde\mu$, namely,

$$\begin{aligned}
&\frac{1}{\lambda}\left\{\int_\Omega\sum_{i=1}^3\left[\left(\frac{\partial u_i^\lambda}{\partial x_1} + x_3\,\frac{\partial r_i^\lambda}{\partial x_1}\right)h_{1i}^\lambda + \left(\frac{\partial u_i^\lambda}{\partial x_2} + x_3\,\frac{\partial r_i^\lambda}{\partial x_2}\right)h_{2i}^\lambda + r_i^\lambda\,h_{3i}^\lambda\right]\right.\\
&\times\left[\left(\frac{\partial \mu_i}{\partial x_1} + x_3\,\frac{\partial \rho_i}{\partial x_1}\right)h_{1i}^\lambda + \left(\frac{\partial \mu_i}{\partial x_2} + x_3\,\frac{\partial \rho_i}{\partial x_2}\right)h_{2i}^\lambda + \rho_i\,h_{3i}^\lambda\right]|\det J_\lambda|d\bar x\\
&-\int_\Omega\left[\left(\frac{\partial u_i}{\partial x_1} + x_3\frac{\partial r_i}{\partial x_1}\right)h_{1i} + \left(\frac{\partial u_i}{\partial x_2} + x_3\frac{\partial r_i}{\partial x_2}\right)h_{2i} + r_i h_{3i}\right]\\
&\left.\times\left[\left(\frac{\partial \mu_i}{\partial x_1} + x_3\frac{\partial \rho_i}{\partial x_1}\right)h_{1i} + \left(\frac{\partial \mu_i}{\partial x_2} + x_3\frac{\partial \rho_i}{\partial x_2}\right)h_{2i} + \rho_i h_{3i}\right]|\det J|d\bar x\right\}\\
&=\int_\Omega\sum_{i=1}^3\left[\left(\frac{\partial\frac{u_i^\lambda - u_i}{\lambda}}{\partial x_1} + x_3\frac{\partial\frac{r_i^\lambda - r_i}{\lambda}}{\partial x_1}\right)h_{1i} + \left(\frac{\partial\frac{u_i^\lambda - u_i}{\lambda}}{\partial x_2} + x_3\frac{\partial\frac{r_i^\lambda - r_i}{\lambda}}{\partial x_2}\right)h_{2i} + \frac{r_i^\lambda - r_i}{\lambda}h_{3i}\right]
\end{aligned}$$

$$
\begin{aligned}
&\times\left[\left(\frac{\partial\mu_i}{\partial x_1}+x_3\frac{\partial\rho_i}{\partial x_1}\right)h_{1i}+\left(\frac{\partial\mu_i}{\partial x_2}+x_3\frac{\partial\rho_i}{\partial x_2}\right)h_{2i}+\rho_i h_{3i}\right]|\det J|d\bar{x}\\
&+\int_\Omega\sum_{i=1}^{3}\left[\left(\frac{\partial u_i^\lambda}{\partial x_1}+x_3\frac{\partial r_i^\lambda}{\partial x_1}\right)\frac{h_{1i}^\lambda\det J_\lambda-h_{1i}\det J}{\lambda}\right.\\
&\left.+\left(\frac{\partial u_i^\lambda}{\partial x_2}+x_3\frac{\partial r_i^\lambda}{\partial x_2}\right)\frac{h_{2i}^\lambda\det J_\lambda-h_{2i}\det J}{\lambda}+r_i^\lambda\frac{h_{3i}^\lambda\det J_\lambda-h_{3i}\det J}{\lambda}\right]\\
&\times\left[\left(\frac{\partial\mu_i}{\partial x_1}+x_3\frac{\partial\rho_i}{\partial x_1}\right)h_{1i}^\lambda+\left(\frac{\partial\mu_i}{\partial x_2}+x_3\frac{\partial\rho_i}{\partial x_2}\right)h_{2i}^\lambda+\rho_i h_{3i}^\lambda\right]d\bar{x}\\
&+\int_\Omega\sum_{i=1}^{3}\left[\left(\frac{\partial u_i^\lambda}{\partial x_1}+x_3\frac{\partial r_i^\lambda}{\partial x_1}\right)h_{1i}+\left(\frac{\partial u_i^\lambda}{\partial x_2}+x_3\frac{\partial r_i^\lambda}{\partial x_2}\right)h_{2i}+r_i^\lambda h_{3i}\right]\\
&\times\left[\left(\frac{\partial\mu_i}{\partial x_1}+x_3\frac{\partial\rho_i}{\partial x_1}\right)\frac{h_{1i}^\lambda-h_{1i}}{\lambda}+\left(\frac{\partial\mu_i}{\partial x_2}+x_3\frac{\partial\rho_i}{\partial x_2}\right)\frac{h_{2i}^\lambda-h_{2i}}{\lambda}+\rho_i\frac{h_{3i}^\lambda-h_{3i}}{\lambda}\right]|\det J|d\bar{x}\,.
\end{aligned}
\tag{7.9}
$$

According to (7.4), (7.5), and (6.10) the last two integrals are of the form $Z_\lambda(\bar{y}_\lambda\,,\,\bar{v})$, and there is a constant independent of $\lambda>0$ such that the bilinear forms Z_λ satisfy

$$
|Z_\lambda(\bar{y}_\lambda\,,\,\bar{v}|\le C|\bar{y}_\lambda|_{V(o)^2}|\bar{v}|_{V(o)^2}\,. \tag{7.10}
$$

Applying the same technique to all of the terms of $\mathcal{B}_\lambda-\mathcal{B}$, (7.8)–(7.10) give

$$
\mathcal{B}\Big(\frac{\bar{y}_\lambda-\bar{y}}{\lambda}\,,\,\bar{v}\Big)\;=\;\tilde{Z}_\lambda(\bar{y}_\lambda,\bar{v})\quad\forall\;\bar{v}\in V(o)^2\,, \tag{7.11}
$$

where $\tilde{Z}_\lambda$ is obtained by adding together all the terms from (7.8)–(7.10).

By fixing $\bar{v}=\frac{\bar{y}_\lambda-\bar{y}}{\lambda}$ in (7.11), and taking into account (7.10) and (7.7), we see that $\{\frac{\bar{y}_\lambda-\bar{y}}{\lambda}\}$ is bounded in $V(o)^2$, due to Proposition 6.4. We may take a weakly convergent subsequence,

$$
\frac{\bar{y}_\lambda-\bar{y}}{\lambda}\to\hat{y}\quad\text{weakly in}\quad V(o)^2\,, \tag{7.12}
$$

and we can pass to the limit in (7.11). The obtained equation in variations has the form

$$
\mathcal{B}(\hat{y},\bar{v})=Z(\bar{v})\quad\forall\;\bar{v}\in V(o)^2\,, \tag{7.13}
$$

where $Z(\bar{v})=\lim_{\lambda\to0}\tilde{Z}_\lambda(\bar{y}_\lambda,\,\bar{v})$ and $Z:V(o)^2\to\mathbb{R}$ is a linear bounded functional. Notice that (7.13) has a unique solution $\hat{y}\in V(o)^2$, due to (6.28). We thus have proved the following proposition.

PROPOSITION 7.1. *The mapping $p\in C^2(\bar{o})\mapsto\bar{y}\in V(o)^2$ given by* (5.11) *is Gâteaux differentiable, and the directional derivative $\hat{y}$ satisfies* (7.13).

We introduce now the so-called adjoint system with unknowns $\bar{s}=(\bar{a}\,,\,\bar{b})\in V(o)^2$,

$$
\mathcal{B}(\bar{s}\,,\,\bar{v})\;=\;\nabla_1 j(\bar{y}\,,\,p)(\bar{v})\;\;\forall\;\bar{v}\in V(o)^2\,. \tag{7.14}
$$

The existence and the uniqueness of the solution to (7.14) are clear due to the properties of $\mathcal{B}$. We have assumed that j is Fréchet differentiable on $V(o)^2\times C^2(\bar{o})$, and $\nabla_1 j$, $\nabla_2 j$ denote the partial differentials with respect to $\bar{y}\,,\,p$.

PROPOSITION 7.2. *If j is Fréchet differentiable, then the directional derivative of the cost functional Π in problem (P′), at the point $p \in C^2(\bar{o})$ and in the direction $q \in C^2(\bar{o})$, is given by*

$$\nabla\Pi(p)q \;=\; \nabla_2 j(\bar{y}\,, p)q + Z(\bar{s})\,. \tag{7.15}$$

Proof.

$$\lim_{\lambda\to 0} \frac{\Pi(p+\lambda q) - \Pi(p)}{\lambda} \;=\; \nabla_2 j(\bar{y}\,, p)q + \nabla_1 j(\bar{y}\,, p)\hat{y}\,,$$

by the chain rule and Proposition 7.1. Moreover, by (7.14), (7.13), we have

$$\nabla_1 j(\bar{y}\,, p)\hat{y} \;=\; \mathcal{B}(\bar{s}\,, \hat{y}) \;=\; \mathcal{B}(\hat{y}\,, \bar{s}) \;=\; Z(\bar{s})\,. \qquad \square$$

Remark 7.3. In order to compute (7.15) from $p\,,\ q \in C^2(\bar{o})$, one has to compute $\bar{y}$ by (5.11), $\bar{s}$ by (7.14), and Z by (7.13). The computation of Z is standard (see (7.9), (7.8)) but tedious, and we do not detail it here.

COROLLARY 7.4. *Assume that p^* is a (local) optimal shape for (P′), that $\bar{y}^*$ is the associated deformation, and that all the above assumptions are fulfilled. Then*

(i) *If $\mathcal{K} \subset C^2(\bar{o})$ is convex, we have*

$$\nabla_2 j(\bar{y}^*\,, p^*)q + Z(\bar{s}) \geq 0 \quad \forall\ q \in \mathcal{K} - p^*\,.$$

(ii) *If $\mathcal{K}$ is not convex, we have*

$$\nabla_2 j(\bar{y}^*\,, p^*)q + Z(\bar{s}) \geq 0 \quad \forall\ q \in T(\mathcal{K}\,, p^*)\,.$$

Remark 7.5. Corollary 7.4 gives the standard optimality conditions for problem (P′). The directional derivative obtained in Proposition 7.2 may be used, in principle, in the numerical computations, as in the case of the curved rods. However, the coercivity properties of the bilinear functional $\mathcal{B}_p$ are valid just for small thickness ε, and the coercivity constant depends in a very bad manner, namely like ε^3 (see Proposition 6.2 or Sprekels and Tiba [18]). This shows that instabilities (the locking problem) may appear in the numerical experiments and special numerical schemes are to be used. The interested reader may consult Chenais and Paumier [9] and Pitkäranta and Leino [15] for a discussion on the approximation of the state equation (5.11).

8. Numerical experiments. In the papers of Ignat, Sprekels, and Tiba [12], [13], many numerical examples concerning the deformation of 3D curved rods and the optimization of planar arches are reported. Here, we concentrate on the problem discussed in sections 2–4. Namely, we assume that a certain field of forces acting on "any possible curved rod" is given (see (8.4)–(8.7) below), and we search for the geometry which produces the minimum value for some cost functional. The cost considered in the examples is related to various components of the deformation $\bar{\tau}$ of the line of centroids of the curved rod. The "locking phenomenon," specific to numerical computations involving thin structures (see [9], [15]), is avoided in our experiments by allowing the thickness of the curved rod to be "larger" than the division that we consider for the interval $[0, L]\,,\ L = 4\pi\sqrt{2}$. Namely, we have divided the interval $[0, L]$ into 100 equal parts and we have taken the cross section of the curved rod to always be given by a disk with radius $R = 0.3$. For the integrals over the cross section, the usual change of variables to polar coordinates leads to the integration over the

rectangle $[0,R]\times[0,2\pi]$, which allows the use of simple numerical integration formulae corresponding to the discrete grids. We have divided it into 8, respectively, 80, parts and we have used Simpson's iterative formula.

In general, as initial iteration to the optimization algorithm, we have considered the spiral, lying on the cylinder $x_1^2+x_2^2=1$, given by

$$\varphi^0(x_3)=\frac{\pi}{4}\,,\quad \psi^0(x_3)=\frac{\pi}{2}+\frac{x_3}{\sqrt{2}}\,,\quad x_3\in[0,L]\,. \tag{8.1}$$

A simple calculus shows that the rod parametrization corresponding to (8.1) is

$$\bar\theta(x_3)=\left(\cos\frac{x_3}{\sqrt{2}}\,,\ \sin\frac{x_3}{\sqrt{2}}\,,\ \frac{x_3}{\sqrt{2}}\right),\quad x_3\in[0,L]\,. \tag{8.2}$$

Deformations for this example of a curved rod, under the action of various body forces, have been computed in Ignat, Sprekels, and Tiba [13]. The Lamé constants taken into account are $\lambda=50\,,\ \mu=100$. The solution of the state system (2.13) in the Sobolev space $H_0^1(0,L)^9$ is approximated by linear splines from V_h^9, where $h=10^{-2}L$ is the division norm of $[0,L]$, and where

$$V_h=\{v_h\in C[0,L]\,;\ v_h(0)=v_h(L)=0\,,\ v_h \text{ is piecewise linear in } [0,L]\}\,. \tag{8.3}$$

The same matrix governs the discrete equations for both (2.13) and the adjoint system (4.20). We underline that finding the matrix (which has to be recomputed in each optimization iteration) is the most time-consuming step of the algorithm. This is due to the 3D character of the objects that we are studying. The model (2.13) provides a dimension reduction up to ODEs, and this is reflected in that the coefficients involve the computation of many integrals over the cross section. One can compute the gradient of the cost functional and use projected gradient methods for the optimization of the geometry of the 3D rods, as explained in section 4. We have used the Uzawa algorithm combined with the Armijo line search rule for the minimization of the cost.

A first class of examples is obtained when the force $\bar f=(0,0,f_3)$ with the variants

$$f_3(x_3)=\begin{cases} 10, & x_3\in\left[0,\ \dfrac{L}{2}\right],\\[2ex] -10, & x_3\in\left]\dfrac{L}{2}\,,L\right],\end{cases} \tag{8.4}$$

$$f_3(x_3)\equiv 10\quad\text{in }\ [0,L]\,, \tag{8.5}$$

$$f_3(x_3)=\begin{cases} 10, & x_3\in\left[0,\ \dfrac{L}{2}\right],\\[2ex] 0, & x_3\in\left]\dfrac{L}{2},\ L\right],\end{cases} \tag{8.6}$$

$$f_3(x_3)=\begin{cases} 0, & x_3\in\left[0,\ \dfrac{L}{2}\right],\\[2ex] 10, & x_3\in\left]\dfrac{L}{2},\ L\right].\end{cases} \tag{8.7}$$

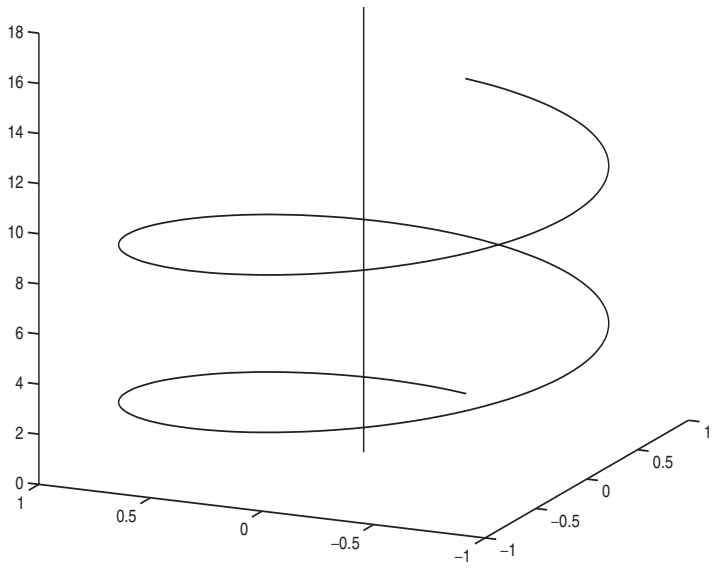

FIG. 1.

The control problem has the cost functional $\Pi = \frac{1}{2}|\tau_i|^2_{L^2(0,L)}$ with $i = 2, 3$ (compare with (2.14)) and state equation (2.13) with various $\bar{f}$ chosen as above. We have also imposed the constraint (2.15), with $\varepsilon = \frac{\pi}{8}$, to avoid the appearance of self-intersecting curves. We have neglected (2.11), but it may be checked a posteriori that $\det J \neq 0$.

In all the cases (8.4)–(8.7), the vertical column, which corresponds to $\varphi \equiv 0$, was the geometric solution of the given problem. Indeed, the vertical column is the most resistant structure with respect to vertical forces as in (8.4)–(8.7). In this case also, the lateral displacements τ_1 , τ_2 are several orders of magnitude smaller than the vertical displacement.

Figure 1 shows the initial and the final geometries, obtained in one or two iterations. In Figures 2–5, the values of τ_3 (in the final iteration) are shown, and one can see their dependence on the forces (8.4)–(8.7), respectively.

The fact that these examples have a clear physical interpretation provides a validation of the model and of the approximation and optimization procedures that we are using.

In another set of numerical tests, we have considered $\bar{f} = 10\bar{b}$ (recall (2.3)). Again the initial iteration was given by (8.1) (or (8.2)) or by the following perturbation of it,

$$\varphi^0(x_3) = \begin{cases} \dfrac{\pi}{4} + 0,1, & x_3 \in \left[0, \dfrac{L}{2}\right], \\ \dfrac{\pi}{4} - 0,1, & x_3 \in \left]\dfrac{L}{2}, L\right], \end{cases} \tag{8.8}$$

and the objective functional was the same as above.

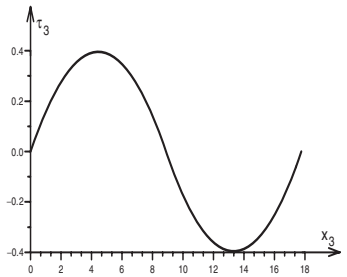

FIG. 2.

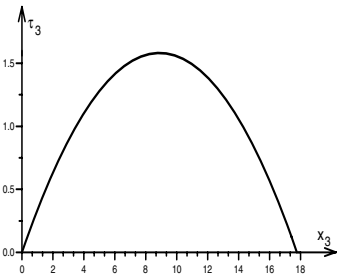

FIG. 3.

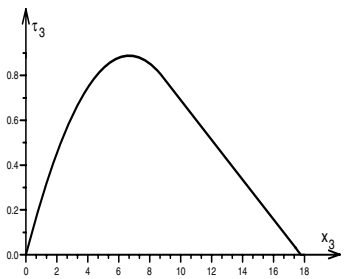

FIG. 4.

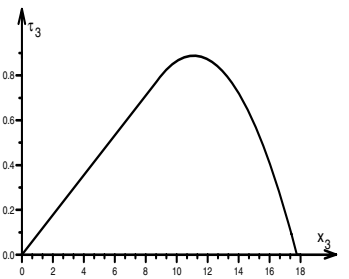

FIG. 5.

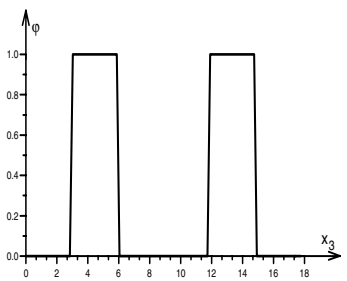

FIG. 6.

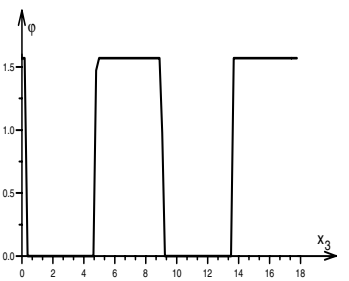

FIG. 7.

Notice that, under our parametrization, it is very simple to change the initial iteration, which is an important advantage in nonconvex optimization problems. The main property of this choice of $\bar{f}$ is that it always acts in the horizontal plane, although in various directions. It is also very easy to construct, under our approach. For the constraints, we have taken $\varepsilon = 0$ in (2.15). This allows horizontal curves as well, but self-intersections may appear (which indeed was the case). That is, in this set of experiments (2.11) is violated. In the examples that we have computed, a clear decrease in the cost was observed and the tendency was to produce a horizontal curve as the solution. Although self-intersections are present, horizontal curves will deform just in the horizontal plane under the action of $\bar{f} = 10\bar{b}$. That is, a mechanical interpretation is still possible (and due to this, it was necessary to allow $\varepsilon = 0$ in (2.15)).

An interesting feature of this type of experiment was that the optimal φ has a bang-bang structure. Figures 6 and 7 show this for when the initial iteration was given by (8.8) and (8.1), respectively.

In general, one experiment took between two and three hours, on a powerful Compaq GS80 workstation.

Acknowledgment. The authors thank both referees for their suggestions which led to an improvement of the presentation.

ON THE ROBUSTNESS OF $\mathcal{KL}$-STABILITY FOR DIFFERENCE INCLUSIONS: SMOOTH DISCRETE-TIME LYAPUNOV FUNCTIONS*

CHRISTOPHER M. KELLETT† AND ANDREW R. TEEL‡

Abstract. We consider stability with respect to two measures of a difference inclusion, i.e., of a discrete-time dynamical system with the push-forward map being set-valued. We demonstrate that robust stability is equivalent to the existence of a smooth Lyapunov function and that, in fact, a continuous Lyapunov function implies robust stability. We also present a sufficient condition for robust stability that is independent of a Lyapunov function. Toward this end, we develop several new results on the behavior of solutions of difference inclusions. In addition, we provide a novel result for generating a smooth function from one that is merely upper semicontinuous.

Key words. difference inclusions, stability with respect to two measures, Lyapunov functions, robustness, smoothing upper-semicontinuous functions

1. Introduction.

The close connection between robustness of stability properties for differential equations and the existence of Lyapunov functions has been implicit in the literature since the result of Kurzweil [13]. In particular, Kurzweil exploited the inherent robustness of asymptotic stability of the origin for differential equations defined by a continuous right-hand side in order to demonstrate the existence of a smooth Lyapunov function. Since Kurzweil, robustness of the assumed stability property has played a key role in deriving Lyapunov functions. Results on the existence of Lyapunov functions for asymptotically stable closed sets became available in the 1960s in the works of Hoppensteadt [7] and Wilson [23]. These results were extended by Lin, Sontag, and Wang [15] to consider asymptotic stability of closed sets for locally Lipschitz differential equations subject to disturbances. Recently, Clarke, Ledyaev, and Stern [4] demonstrated the existence of a smooth Lyapunov function for upper-semicontinuous differential inclusions with an asymptotically stable origin.

Rather than considering differential inclusions, we will consider the difference inclusion

$$x^+ \in F(x), \quad x \in \mathcal{G}, \tag{1.1}$$

where $\mathcal{G} \subseteq \mathbb{R}^n$ is open. Difference inclusions are a natural way to consider difference equations subject to disturbances or controlled difference equations. One may consider a set-valued map as

$$x^+ \in F(x) := f(x, \mathcal{V}),$$

where $\mathcal{V}$ is a set of disturbances or the admissible control set. We use $\phi \in \mathcal{S}(x)$ to denote a solution of the difference inclusion (1.1) from initial condition $x \in \mathcal{G}$, i.e., a

function satisfying $\phi(0,x) = x$ and

$$\phi(k+1,x) \in F(\phi(k,x)) \quad \forall k \in \mathbb{Z}_{\geq 0}.$$

Whereas in the continuous-time case a solution was an absolutely continuous function, in the discrete-time case solutions are sequences of points. Solutions are defined for all $k \in \mathbb{Z}_{\geq 0}$ when $F(\cdot)$ maps $\mathcal{G}$ to subsets of $\mathcal{G}$, which is the discrete-time counterpart to forward completeness for continuous-time systems.

In the 1970s, Lakshmikantham and Salvadori [14] demonstrated a locally Lipschitz Lyapunov function for a differential equation under the assumption of stability with respect to two measures, a concept first introduced by Movchan [17]. Stability with respect to two measures can be seen to cover uniform global or local asymptotic stability of a point, prescribed motion, or closed set. In fact, Teel and Praly [22, Proposition 1] (following [15, Proposition 2.5]) demonstrated that $\mathcal{KL}$-stability with respect to two measures is equivalent to uniform stability and global boundedness coupled with uniform global attractivity (both properties being defined in an appropriate two-measure sense). In Proposition 2.2 we show that this property carries over to the discrete-time case.

A smooth Lyapunov function for output stability, a special case of stability with respect to two measures where one of the measures is the norm of the output function, was presented by Sontag and Wang [20, Theorem 2]. Teel and Praly [22] extended these results to consider the existence of a smooth Lyapunov function under the assumption of $\mathcal{KL}$-stability with respect to two measures for differential inclusions. It is this last result by Teel and Praly [22, Theorem 1] that we propose to develop in the discrete-time case, namely, the equivalence of robustness of $\mathcal{KL}$-stability with respect to two measures for a difference inclusion and the existence of a smooth Lyapunov function. This is the result of Theorem 2.7.

In Theorem 2.8 we present a result stating that when the set-valued map defining the difference inclusion (1.1) is compact and nonempty, a continuous Lyapunov function is sufficient to demonstrate robustness. This result has important implications in robustness analysis. The authors used this fact in [11, Theorem 14] to demonstrate robustness for a (discontinuous) difference equation. Frequently, in model predictive control, a continuous Lyapunov function is assumed (see Mayne et al. [16]) which guarantees robustness of stability. Recently, Grimm et al. [6] presented several examples where model predictive control is nonrobust. Intuitively, these results follow from the lack of a continuous Lyapunov function.

A question of great interest over many years is the so-called converse Lyapunov question, namely, what stability requirements guarantee the existence of a Lyapunov function? We see from Theorem 2.7 that, for $\mathcal{KL}$-stability with respect to two measures, this question is reduced to that of finding sufficient conditions for robustness. The result of Theorem 2.10 states that if the difference inclusion $x^+ \in F(x)$ is $\mathcal{KL}$-stable, the set-valued map $F(x)$ is nonempty and compact for each $x \in \mathcal{G}$, and $F(\cdot)$ is continuous, then the $\mathcal{KL}$-stability is robust. In [9] and [10], other sufficient conditions were presented for robustness of $\mathcal{KL}$-stability. For example, $\mathcal{KL}$-stability is robust when using a single measurement function that is a proper indicator function for a compact attractor. Each of these sufficient conditions then allows us to state a converse Lyapunov theorem.

Previous converse Lyapunov theorems for discrete-time systems appeared in books by Agarwal [1, Theorem 5.12.5] and Stuart and Humphries [21, Theorem 1.7.6], where uniform global asymptotic stability of the origin or a compact attractor for a locally

Lipschitz single-valued mapping yields a locally Lipschitz Lyapunov function. Nešić, Teel, and Kokotović [18] demonstrated the equivalence of uniform global asymptotic stability of the origin for a difference equation (with no regularity) and the existence of a Lyapunov function (with no regularity).

Jiang and Wang [8, Theorem 1] showed that uniform global asymptotic stability to a closed set $\mathcal{A}$ for a difference equation with disturbances is equivalent to the existence of a smooth Lyapunov function under the assumption that the difference equation is continuous. The assumption of continuity on the difference equation (and compactness of the set of allowable disturbances) gives rise to a continuous set-valued map. This result can then be seen to be a special case of Theorem 2.7 and Theorem 2.10 with $\omega_1(\cdot) = \omega_2(\cdot) = |\cdot|_{\mathcal{A}}$, where $|x|_{\mathcal{A}} := \inf_{a\in\mathcal{A}} |x - a|$.

The authors [11] demonstrated that global asymptotic stability of a point for an upper-semicontinuous difference inclusion implied the existence of a smooth Lyapunov function. This result follows from the results presented here and in [10] (see also [9]).

We will require two sets of technical results, heretofore unknown in the literature. In section 5 we develop results pertaining to difference inclusions which parallel those found in the work of Filippov [5] for differential inclusions. Specifically, we prove results on closeness of solutions under perturbations (Lemmas 5.1 and 5.2) as well as on uniform convergence of sequences of solutions (Lemma 5.3). The second novel technical result involves smoothing nonsmooth functions on a given open domain. As in much previous work (e.g., [13], [15], [22], and [23]), we first construct a Lyapunov function satisfying the desired decrease condition, but with a rather weak regularity property, and then apply a smoothing result to obtain the smooth Lyapunov function without destroying the decrease property. In the past, these smoothing results applied to continuous functions. In section 3, we present a novel smoothing theorem which obtains a smooth function from one that is upper semicontinuous.

2. Smooth Lyapunov functions and robustness. We now turn to precise statements of our results. Recall that a function $\alpha : \mathbb{R}_{\geq 0} \to \mathbb{R}_{\geq 0}$ is of class-$\mathcal{K}$ if it is continuous, zero at zero, and strictly increasing. A function is of class-$\mathcal{K}_\infty$ if, in addition to being class-$\mathcal{K}$, it is unbounded. A function $\beta : \mathbb{R}_{\geq 0} \times \mathbb{R}_{\geq 0} \to \mathbb{R}_{\geq 0}$ is said to belong to class-$\mathcal{KL}$ if, for each $t \geq 0$, $\beta(\cdot, t)$ is of class-$\mathcal{K}$ and, for each $s \geq 0$, $\beta(s, \cdot)$ is nonincreasing and $\lim_{t\to\infty} \beta(s, t) = 0$.

DEFINITION 2.1. *Let $\omega_i : \mathcal{G} \to \mathbb{R}_{\geq 0}$, $i = 1, 2$, be continuous functions. Let $F(\cdot)$ be a set-valued map from $\mathcal{G}$ to subsets of $\mathcal{G}$. We say that the difference inclusion $x^+ \in F(x)$ is $\mathcal{KL}$-stable with respect to (ω_1, ω_2) on $\mathcal{G}$ if there exists a function $\beta \in \mathcal{KL}$ such that for every initial condition $x \in \mathcal{G}$ all solutions $\phi \in \mathcal{S}(x)$ satisfy*

$$\omega_1(\phi(k, x)) \leq \beta(\omega_2(x), k) \quad \forall k \in \mathbb{Z}_{\geq 0}. \tag{2.1}$$

Note that appropriate choices for the measurement functions $\omega_1(\cdot)$ and $\omega_2(\cdot)$ as well as the domain $\mathcal{G}$ allow us to recover several classical stability notions. For instance, global asymptotic stability of the origin (for a given difference inclusion evolving in $\mathbb{R}^n$) corresponds to taking $\mathcal{G} = \mathbb{R}^n$ and the measurement functions $\omega_1(x) = \omega_2(x) = |x|$ for all $x \in \mathbb{R}^n$. Other stability notions, such as local asymptotic stability or partial state stability, can be covered by appropriately choosing the domain and measurement functions.

Lin et al. [15, Proposition 2.5] demonstrated that $\mathcal{KL}$-stability with respect to $(|\cdot|_{\mathcal{A}}, |\cdot|_{\mathcal{A}})$ (where $\mathcal{A}$ is a closed set) is equivalent to uniform stability and uniform attractivity of the set $\mathcal{A}$ (i.e., $\mathcal{KL}$-stability is equivalent to uniform global asymptotic stability of the set $\mathcal{A}$). Teel and Praly [22, Proposition1] extended this result to the

consideration of the general two-measure case; that is, $\mathcal{KL}$-stability with respect to two measures is equivalent to uniform stability and global boundedness coupled with uniform global attractivity, where these properties are defined in an appropriate two-measure sense. This result also holds in the discrete time. The details are similar to the continuous-time result and may be found in [9].

PROPOSITION 2.2. *Let $\omega_i : \mathcal{G} \to \mathbb{R}_{\geq 0}$, $i = 1, 2$, be continuous and let $F(\cdot)$ be a set-valued map from $\mathcal{G}$ to subsets of $\mathcal{G}$. The following are equivalent:*

1. *The difference inclusion $x^+ \in F(x)$ is $\mathcal{KL}$-stable with respect to (ω_1, ω_2) on $\mathcal{G}$.*
2. *The following hold:*
   (a) *(Uniform stability and global boundedness): There exists a function $\gamma \in \mathcal{K}_\infty$ such that, for each $x \in \mathcal{G}$, all solutions $\phi \in \mathcal{S}(x)$ satisfy*

$$\omega_1(\phi(k, x)) \leq \gamma(\omega_2(x)) \quad \forall k \in \mathbb{Z}_{\geq 0}.$$

   (b) *(Uniform global attractivity): For each $r, \varepsilon > 0$, there exists $K(r, \varepsilon) > 0$ such that, for each $x \in \mathcal{G}$, all solutions $\phi \in \mathcal{S}(x)$ satisfy*

$$\omega_2(x) \leq r, \quad k \geq \mathbb{Z}_{\geq K} \quad \Longrightarrow \quad \omega_1(\phi(k, x)) \leq \varepsilon.$$

For a continuous function $\sigma : \mathcal{G} \to \mathbb{R}_{\geq 0}$ we define the σ-perturbation of $F(\cdot)$ as

$$F_\sigma(x) := \left\{ v \in \mathbb{R}^n : v \in \{\eta\} + \sigma(\eta)\overline{\mathcal{B}}, \eta \in F\left(x + \sigma(x)\overline{\mathcal{B}}\right) \right\}. \tag{2.2}$$

We denote the solution set of the difference inclusion $x^+ \in F_\sigma(x)$ starting from an initial condition $x \in \mathcal{G}$ by $\mathcal{S}_\sigma(x)$. We will use $\mathcal{B}$ (or $\overline{\mathcal{B}}$) to denote the open (or closed) unit ball in $\mathbb{R}^n$. For two sets $\mathcal{O}_1$ and $\mathcal{O}_2$, we denote the intersection of $\mathcal{O}_1$ and the complement of $\mathcal{O}_2$ by $\mathcal{O}_1 \backslash \mathcal{O}_2$.

The following set will be used in what follows:

$$\mathcal{A} := \left\{ \xi \in \mathcal{G} : \sup_{k \in \mathbb{Z}_{\geq 0}, \phi \in \mathcal{S}(\xi)} \omega_1(\phi(k, \xi)) = 0 \right\}. \tag{2.3}$$

In most cases the set $\mathcal{A}$ will be nonempty, but we observe that this is not necessary for the following results to hold. When $\mathcal{A}$ is empty, we define $|x|_{\mathcal{A}} = \inf_{a \in \mathcal{A}} |x - a|$ to be infinite.

For stability with respect to (ω, ω) ($\omega : \mathcal{G} \to \mathbb{R}_{\geq 0}$ continuous) the closed set $\mathcal{A}$ is

$$\mathcal{A} := \{ x \in \mathcal{G} : \omega(x) = 0 \}.$$

This follows from the previous definition (2.3) by examining the $\mathcal{KL}$-estimate defining stability. Specifically, if

$$\omega(\phi(k, x)) \leq \beta(\omega(x), k) \quad \forall x \in \mathcal{G},\ \phi \in \mathcal{S}(x),\ k \in \mathbb{Z}_{\geq 0},$$

then, for $\xi \in \mathcal{G}$, $\omega(\xi) = 0$ if and only if $\sup_{k \in \mathbb{Z}_{\geq 0}, \phi \in \mathcal{S}(\xi)} \omega(\phi(k, \xi)) = 0$.

Our robustness definition is defined relative to the above σ-perturbation.

DEFINITION 2.3. *Let $F(\cdot)$ be a set-valued map from $\mathcal{G}$ to subsets of $\mathcal{G}$. We say that the difference inclusion $x^+ \in F(x)$ is robustly $\mathcal{KL}$-stable with respect to (ω_1, ω_2) on $\mathcal{G}$ if there exists a continuous function $\sigma : \mathcal{G} \to \mathbb{R}_{\geq 0}$ such that*

1. *for all $x \in \mathcal{G}$, $\{x\} + \sigma(x)\overline{\mathcal{B}} \subset \mathcal{G}$;*
2. *for all $x \in \mathcal{G} \backslash \mathcal{A}$, $\sigma(x) > 0$;*

3.

$$\mathcal{A} = \mathcal{A}_\sigma := \left\{ \xi \in \mathcal{G} : \sup_{k \in \mathbb{Z}_{\geq 0},\ \phi \in \mathcal{S}_\sigma(\xi)} \omega_1(\phi(k,\xi)) = 0 \right\}; \quad \text{and} \tag{2.4}$$

4. *the difference inclusion $x^+ \in F_\sigma(x)$ is $\mathcal{KL}$-stable with respect to (ω_1, ω_2) on $\mathcal{G}$.*

In what follows, we denote the exponential function by e.

DEFINITION 2.4. *A function $V : \mathcal{G} \to \mathbb{R}_{\geq 0}$ is said to be a Lyapunov function with respect to (ω_1, ω_2) on $\mathcal{G}$ for the difference inclusion $x^+ \in F(x)$ if there exist $\alpha_1, \alpha_2 \in \mathcal{K}_\infty$ such that for all $x \in \mathcal{G}$,*

$$\alpha_1(\omega_1(x)) \leq V(x) \leq \alpha_2(\omega_2(x)), \tag{2.5}$$

$$\sup_{f \in F(x)} V(f) \leq V(x)e^{-1}, \quad \text{and} \tag{2.6}$$

$$V(x) = 0 \iff x \in \mathcal{A}. \tag{2.7}$$

We claim that the above decrease condition (2.6) can be stated as

$$\sup_{f \in F(x)} V(f) \leq V(x) - \alpha(V(x)) \quad \forall x \in \mathcal{G}, \tag{2.8}$$

where $\alpha : \mathbb{R}_{\geq 0} \to \mathbb{R}_{\geq 0}$ is continuous and positive definite. However, we prefer (2.6) because of the symmetry with the continuous time decrease condition

$$\sup_{\omega \in F(x)} \langle \nabla V(x), \omega \rangle \leq -V(x),$$

which yields an exponential decrease of the Lyapunov function along trajectories. The following claim is proved in section 8.

CLAIM 1. *Suppose we are given functions $V : \mathcal{G} \to \mathbb{R}_{\geq 0}$, $\alpha : \mathbb{R}_{\geq 0} \to \mathbb{R}_{\geq 0}$, and $\alpha_1, \alpha_2 \in \mathcal{K}_\infty$ satisfying* (2.5), (2.7), *and* (2.8). *Then there exist $W : \mathcal{G} \to \mathbb{R}_{\geq 0}$ and functions $\hat{\alpha}_1$, $\hat{\alpha}_2 \in \mathcal{K}_\infty$ such that for all $x \in \mathcal{G}$*

$$\hat{\alpha}_1(\omega_1(x)) \leq W(x) \leq \hat{\alpha}_2(\omega_2(x)), \tag{2.9}$$

$$\sup_{f \in F(x)} W(f) \leq e^{-1} W(x), \quad \text{and} \tag{2.10}$$

$$W(x) = 0 \iff x \in \mathcal{A}. \tag{2.11}$$

Prior to stating our first result we require two definitions related to set-valued maps.

DEFINITION 2.5. *The set-valued map $F(\cdot)$ is said to be upper semicontinuous on (the open set) $\mathcal{O}$ if for each $x \in \mathcal{O}$ and $\varepsilon > 0$ there exists $\delta > 0$ such that, for all $\xi \in \mathcal{O}$ satisfying $|x - \xi| < \delta$, we have $F(\xi) \subseteq F(x) + \varepsilon \mathcal{B}$.*

We point out that the concept of upper semicontinuity for a set-valued map is not the same as that for extended real-valued functions. In fact, for $f : \mathbb{R}^n \to \mathbb{R}^n$, the set-valued map $x \mapsto \{f(x)\}$ is upper semicontinuous if and only if $x \mapsto f(x)$ is continuous.

DEFINITION 2.6. *We say that the set-valued map $F(\cdot)$ satisfies the basic conditions on $\mathcal{G}$ if $F(\cdot)$ is upper semicontinuous on $\mathcal{G}$ and, for each $x \in \mathcal{G}$, $F(x)$ is nonempty and compact.*

In continuous time the "basic conditions" also require convexity of $F(x)$ for each $x \in \mathcal{G}$. This is necessary to guarantee solutions of the differential inclusion $\dot{x} \in F(x)$ (see [5]). Obviously, solutions to the difference inclusion $x^+ \in F(x)$ will exist so long as $F(x)$ is nonempty.

With all the necessary definitions in hand, we may state under what conditions robust stability is equivalent to the existence of a Lyapunov function. The following is the discrete-time analogue of [22, Theorem 1] and is proved in section 6.

THEOREM 2.7. *Let $F(\cdot)$ mapping $\mathcal{G}$ to subsets of $\mathcal{G}$ satisfy the basic conditions on $\mathcal{G}$. Then, for the difference inclusion $x^+ \in F(x)$, there exists a smooth Lyapunov function with respect to (ω_1, ω_2) on $\mathcal{G}$ if and only if the inclusion is robustly $\mathcal{KL}$-stable with respect to (ω_1, ω_2) on $\mathcal{G}$.*

Remark 1. We note that (2.4) and (2.7) were not required in the corresponding definitions of robustness and a Lyapunov function in [22]. The addition of (2.4) to the definition of robustness significantly simplifies the proof. In order to maintain the equivalence of robustness and the existence of a Lyapunov function, one would then expect that an extra property is required of $V(\cdot)$. This property is (2.7). This is not unreasonable as, in the case of a single measure, we see that the upper and lower bounds (2.5) actually imply (2.7). □

It is possible to weaken the conditions of Theorem 2.7 and still maintain the necessity. This means that, in order to demonstrate robustness, it is only necessary to exhibit a continuous Lyapunov function (rather than a smooth one). Furthermore, note that we can drop the regularity requirement on the set-valued map. This allows application of the theorem, for example, to the consideration of discontinuous difference equations.

THEOREM 2.8. *Let $F(\cdot)$ mapping $\mathcal{G}$ to subsets of $\mathcal{G}$ be compact and nonempty, and suppose we have a continuous Lyapunov function. Then $x^+ \in F(x)$ is robustly $\mathcal{KL}$-stable with respect to (ω_1, ω_2) on $\mathcal{G}$.*

Since Lyapunov functions can sometimes be difficult to find, we would like a sufficient condition for robustness that is independent of having a Lyapunov function. Intuitively, if the set-valued map $F(\cdot)$ of (1.1) is sufficiently regular, robustness should follow since small perturbations will lead to small deviations. In fact, continuity of $F(\cdot)$ outside of the set $\mathcal{A}$ is sufficient.

DEFINITION 2.9. *We say the set-valued map $F(\cdot)$ is continuous on (the open set) $\mathcal{O}$ if, in addition to being upper semicontinuous on $\mathcal{O}$, for each $x \in \mathcal{O}$ and $\varepsilon > 0$ there exists $\delta > 0$ such that, for $z \in \mathcal{O}$ satisfying $|z - x| < \delta$, we have $F(x) \subseteq F(z) + \varepsilon\mathcal{B}$.*

The following theorem is the discrete-time counterpart of [22, Theorem 2] and is proved in section 7.

THEOREM 2.10. *Let $F(\cdot)$ be a set-valued map from $\mathcal{G}$ to subsets of $\mathcal{G}$ satisfying the basic conditions on $\mathcal{G}$ and continuous on an open set containing $\mathcal{G}\backslash\mathcal{A}$. Under these conditions, if $x^+ \in F(x)$ is $\mathcal{KL}$-stable with respect to (ω_1, ω_2) on $\mathcal{G}$, then the inclusion is robustly $\mathcal{KL}$-stable with respect to (ω_1, ω_2) on $\mathcal{G}$.*

3. Smoothing functions. Frequently one wishes to prove that certain assumptions such as asymptotic stability of a set or asymptotic controllability to a set imply the existence of a function satisfying certain boundedness and decrease properties, as well as a given regularity property. Typically, one constructs a function which satisfies all the given properties (i.e., boundedness and decrease properties) excepting the desired regularity property. One may then take the additional step of "smoothing" the constructed function without destroying the boundedness or decrease properties. Such techniques were first used by Kurzweil [13] and Wilson [23]. Throughout this

section, we take $\mathcal{O}$ to be an open set.

We will smooth nonsmooth functions via an integration which involves a change of variables. We will require the following assumption on the function we wish to smooth.

ASSUMPTION 1. *The function $V : \mathcal{O} \to \mathbb{R}_{\geq 0}$ is such that*

1. *$V(\cdot)$ is upper semicontinuous and locally bounded on $\mathcal{O}$,*
2. *$V(x) > 0$ implies that there exists $\delta > 0$ such that $|z-x| < \delta$ implies $V(z) > 0$.*

Define

$$\mathcal{A} := \{x \in \mathcal{O} : V(x) = 0\}. \tag{3.1}$$

We observe that, under the above assumption on $V(\cdot)$, the set $\mathcal{O}\backslash\mathcal{A}$ is open. Note that we need not assume that $\mathcal{A}$ is nonempty.

We will also require an assumption on the "smoothing perturbation."

ASSUMPTION 2. *The smooth function $\sigma : \mathcal{O}\backslash\mathcal{A} \to \mathbb{R}_{>0}$ satisfies the following:*

1. *for each $x^* \in \mathcal{A}$ and $\varepsilon > 0$ there exists $\delta > 0$ such that*

$$x \in \mathcal{O}\backslash\mathcal{A}\ , \quad |x - x^*| \leq \delta \qquad \Longrightarrow \qquad \sigma(x) \leq \varepsilon, \tag{3.2}$$

2.

$$x \in \mathcal{O}\backslash\mathcal{A} \qquad \Longrightarrow \qquad \{x\} + \sigma(x)\overline{\mathcal{B}} \subset \mathcal{O}. \tag{3.3}$$

Item 1 implies that the function $\sigma(\cdot)$ can be continuously extended to the set $\mathcal{A}$ by defining it to be identically zero on $\mathcal{A}$. For the case where $\mathcal{A}$ is empty, item 1 is trivially satisfied.

We define $V_s : \mathcal{O} \to \mathbb{R}_{\geq 0}$ as

$$\begin{aligned} V_s(x) &:= 0, && x \in \mathcal{A}, \\ V_s(x) &:= \int V(x + \sigma(x)\xi)\psi(\xi)\, d\xi, && x \in \mathcal{O}\backslash\mathcal{A}, \end{aligned} \tag{3.4}$$

where $\psi : \mathbb{R}^n \to [0, 1]$ is smooth, vanishes on $\mathbb{R}^n\backslash\overline{\mathcal{B}}$, and satisfies $\int \psi(\xi)d\xi = 1$.

The following theorem is a generalization of [11, Theorem 20], where the smoothing was carried out on $\mathbb{R}^n\backslash\{0\}$.

THEOREM 3.1. *Under Assumptions* 1 *and* 2*, the function $V_s : \mathcal{O} \to \mathbb{R}_{\geq 0}$ defined by* (3.4) *is well defined, continuous on $\mathcal{O}$, and smooth on $\mathcal{O}\backslash\mathcal{A}$.*

Proof. The properties of $\sigma(\cdot)$ and $\psi(\cdot)$ and the upper semicontinuity of $V(\cdot)$ guarantee that the (Lebesgue) integral in (3.4) is well defined.

Continuity at $\mathcal{A}$. Since $V_s(x) \equiv 0$ for $x \in \mathcal{A}$, the function is clearly continuous in the interior of $\mathcal{A}$. It remains to check continuity at the boundary of $\mathcal{A}$. Let x^* belong to the boundary of $\mathcal{A}$ so that $V_s(x^*) = 0$. Let $\varepsilon > 0$ be given. Since $V(\cdot)$ is upper semicontinuous, there exists $\delta_2 > 0$ such that $V(z) \leq \varepsilon$ for all $z \in \mathcal{O}$ satisfying $|z-x^*| \leq \delta_2$. Since (3.2) holds, there exists $\delta > 0$ such that $\{x\}+\sigma(x)\overline{\mathcal{B}} \subseteq \{x^*\}+\delta_2\overline{\mathcal{B}}$ for all $|x-x^*| \leq \delta$. Consequently, with the fact that $\int \psi(\xi)d\xi = 1$, if $|x-x^*| \leq \delta$ and $x \in \mathcal{O}\backslash\mathcal{A}$, then

$$V_s(x) = \int V(x + \sigma(x)\xi)\psi(\xi)d\xi \leq \sup_{z \in \{x^*\}+\delta_2\overline{\mathcal{B}}} V(z) \leq \varepsilon;$$

i.e., $V_s(x)$ is continuous for x in the boundary of $\mathcal{A}$.

Finally, if we can establish that V_s is smooth on $\mathcal{O}\backslash\mathcal{A}$, then it will be continuous on $\mathcal{O}$.

Smoothness on $\mathcal{O}\backslash\mathcal{A}$. For each $x \in \mathcal{O}\backslash\mathcal{A}$, we perform a change of variables under the integration with $z = x + \sigma(x)\xi$ so that

$$V_s(x) = \sigma(x)^{-n} \int V(z)\psi(\sigma(x)^{-1}(z-x))\, dz.$$

For notational purposes, we define $h(x,z) := \psi(\sigma(x)^{-1}(z-x))$ so that, for each $x \in \mathcal{O}\backslash\mathcal{A}$,

$$V_s(x) = \sigma(x)^{-n} \int V(z)h(x,z)\, dz.$$

For $x, z \in \mathcal{O}\backslash\mathcal{A}$ such that $|z-x| > \sigma(x)$ we note that $h(x,z)$ and all of its higher order partial derivatives with respect to x vanish. From this, (3.4), and the fact that $\psi(\cdot)$ and $\sigma(\cdot)$ are smooth (the latter on $\mathcal{O}\backslash\mathcal{A}$) it follows that each of these partial derivatives is continuous in x uniformly in z.

Because of the properties of $\sigma(\cdot)$, to establish smoothness of $V_s(\cdot)$ on $\mathcal{O}\backslash\mathcal{A}$ it is enough to establish smoothness of

$$W_s(x) := \int V(z)h(x,z)\, dz.$$

We note that, using the mean value theorem, for each $x \in \mathcal{O}\backslash\mathcal{A}$, $\varepsilon > 0$, and $v \in \mathbb{R}^n$, there exists $\lambda \in [0,1]$ such that

$$\begin{aligned}\frac{W_s(x+\varepsilon v) - W_s(x)}{\varepsilon} &= \int V(z)\frac{h(x+\varepsilon v, z) - h(x,z)}{\varepsilon}\, dz \\ &= \int V(z)\langle \nabla h(x+\varepsilon\lambda v, z), v\rangle\, dz \\ &= r(x,\varepsilon,v) + \int V(z)\langle \nabla h(x,z), v\rangle\, dz,\end{aligned}$$

where $r(x,\varepsilon,v) := \int V(z)\langle \nabla h(x+\varepsilon\lambda v, z) - \nabla h(x,z), v\rangle dz$.

Using that $V(\cdot)$ is locally bounded on $\mathcal{O}$, (3.3), the fact that $\nabla h(x,z) = 0$ when $|z-x| > \sigma(x)$, and the continuity of $\nabla h(\cdot,z)$, which is uniform in z, for each $\rho > 0$ and $M > 0$ there exists $\varepsilon^* > 0$ such that if $\varepsilon \in (0,\varepsilon^*]$ and $|v| \le M$, then $|r(x,\varepsilon,v)| \le \rho$. It follows that $W_s(\cdot)$ is (Fréchet) differentiable (hence continuous) and

$$\langle \nabla W_s(x), v\rangle = \int V(z)\langle \nabla h(x,z), v\rangle\, dz.$$

Repeating this argument for higher order derivatives, we conclude that $W_s(\cdot)$ is smooth on $\mathcal{O}\backslash\mathcal{A}$. □

The following lemma can be applied to the function $V_s(\cdot)$ obtained from Theorem 3.1 in order to obtain a function that is smooth on the entire domain $\mathcal{O}$. The lemma appeared as [22, Lemma 17], which derives from [15, Lemma 4.3] and [13, Theorem 6].

LEMMA 3.2. *Let $\mathcal{A} \subset \mathcal{O}$ be a closed set, and assume that $V_s : \mathcal{O} \to \mathbb{R}_{\ge 0}$ is continuous, the restriction of V_s to $\mathcal{O}\backslash\mathcal{A}$ is smooth, $V_s(x) = 0$ for all $x \in \mathcal{A}$, and $V_s(x) > 0$ for all $x \in \mathcal{O}\backslash\mathcal{A}$. Then there exists a strictly convex function $\rho \in \mathcal{K}_\infty$, smooth on $(0,\infty)$, such that $V := \rho \circ V_s$ is smooth on $\mathcal{O}$.*

Frequently, to construct the function $\sigma(\cdot)$ used in the integral smoothing of Theorem 3.1, we will first specify a constraint which $\sigma(\cdot)$ must satisfy and then take a smaller smooth function.

LEMMA 3.3. *Given a function $\sigma_2 : \mathcal{O} \to \mathbb{R}_{>0}$ bounded away from zero on compact subsets of $\mathcal{O}$ there exists a smooth function $\sigma_1 : \mathcal{O} \to \mathbb{R}_{>0}$, also bounded away from zero on compact subsets of $\mathcal{O}$, such that, for all $x \in \mathcal{O}$, $\sigma_1(x) \leq \sigma_2(x)$.*

Proof. We let $\{\mathcal{U}_i\}_{i=1}^{\infty}$ be a locally finite open cover of $\mathcal{O}$ with $\overline{\mathcal{U}}_i$ a compact subset of $\mathcal{O}$ and let $\{\kappa_i\}_{i=1}^{\infty}$ be a smooth partition of unity on $\mathcal{O}$ subordinate to $\{\mathcal{U}_i\}$. Define $\varepsilon_i := \inf_{\xi \in \mathcal{U}_i} \sigma_2(\xi)$,

$$\sigma_1(x) := \sum_{i=1}^{\infty} \kappa_i(x)\varepsilon_i,$$

and, for each $x \in \mathcal{O}$, $\mathcal{I}_x := \{j : x \in \mathcal{U}_j\}$. The set $\mathcal{I}_x$ is finite for each $x \in \mathcal{O}$. We also note that

$$\max_{j \in \mathcal{I}_x} \varepsilon_j = \max_{j \in \mathcal{I}_x} \inf_{\xi \in \mathcal{U}_j} \sigma_2(\xi) \leq \sigma_2(x).$$

Since $\overline{\mathcal{U}}_i$ is a compact subset of $\mathcal{O}$ for each i and $\sigma_2(\cdot)$ is bounded away from zero on compact subsets of $\mathcal{O}$, we have $\varepsilon_i > 0$ for each i. Thus $\sigma_1(x) > 0$ for all $x \in \mathcal{O}$. Also,

$$\sigma_1(x) \leq \max_{j \in \mathcal{I}_x} \varepsilon_j \leq \sigma_2(x).$$

Finally, σ_1 is smooth on $\mathcal{O}$, inheriting this property from the κ_i. ∎

4. Set-valued maps. Prior to stating our novel results for difference inclusions, we require certain facts from set-valued analysis. Our primary sources for set-valued analysis include the books by Aubin and Cellina [2], Aubin and Frankowska [3], Filippov [5], and Kisielewicz [12].

Given a set-valued map $F(\cdot)$ from an open set $\mathcal{O} \subset \mathbb{R}^n$ to subsets of $\mathbb{R}^n$, we define the mapping of a compact set M by

$$F(M) := \bigcup_{\xi \in M} F(\xi).$$

We also define the composition of two set-valued maps $F(\cdot)$ and $G(\cdot)$ to be

$$F(G(x)) := \bigcup_{w \in G(x)} F(w),$$

and we denote the n-times composition of $F(\cdot)$ with itself by $F^n(\cdot)$ (e.g., $F(F(x)) = F^2(x)$).

The following is well known. See, for example, [12, Proposition 2.3].

CLAIM 2. *Let $F(\cdot)$ be an upper-semicontinuous set-valued map from $\mathcal{O}$ to subsets of $\mathbb{R}^n$, let $M \subset \mathcal{O}$ be compact, and let $F(x)$ be compact for all $x \in \mathcal{O}$. Then the set $F(M)$ is compact.*

For $\delta \geq 0$, we define the δ-perturbation of the set-valued map $F(\cdot)$ by

$$F_\delta(x) := F\left(\{x\} + \delta\overline{\mathcal{B}}\right) + \delta\overline{\mathcal{B}}$$

and the δ-inflation of a set M by

$$M_\delta := M + \delta\overline{\mathcal{B}}.$$

The following claim, which is not difficult to prove, extends the concept of upper semicontinuity to the consideration of compact sets rather than merely points.

CLAIM 3. *Let $F(\cdot)$ be an upper-semicontinuous set-valued map from $\mathcal{O}$ to subsets of $\mathbb{R}^n$ and let $M \subset \mathcal{O}$ be compact. Then for every $\varepsilon > 0$ there exists $\delta > 0$ such that*

$$F_\delta(M_\delta) \subseteq F(M) + \varepsilon\overline{\mathcal{B}} \ .$$

CLAIM 4. *Let $F(\cdot)$ be an upper-semicontinuous set-valued map from $\mathcal{O}$ to subsets of $\mathbb{R}^n$. Let $k \in \mathbb{Z}_{>0}$, $i \in \{1, 2, \ldots, k\}$, and S_i compact subsets of $\mathcal{O}$. Then there exist $\rho \in \mathcal{K}_\infty$ and $c > 0$ such that for every $\delta \in (0, c]$*

$$F_\delta(S_{i_\delta}) \subseteq F(S_i) + \rho(\delta)\overline{\mathcal{B}}.$$

Proof. For a particular S_i, let $\varepsilon > 0$. Then, from the result of Claim 3, there exists $\delta_i > 0$ such that $F_{\delta_i}(S_{i_\delta}) \subseteq F(S_i) + \varepsilon\overline{\mathcal{B}}$. For fixed $\varepsilon > 0$, let $\bar{\delta}_i(\varepsilon)$ be the supremum of all applicable $\delta_i(\varepsilon)$. Therefore,

$$F_{\bar{\delta}_i(\varepsilon)}(S_{i_{\bar{\delta}_i(\varepsilon)}}) \subseteq F(S_i) + \varepsilon\overline{\mathcal{B}}.$$

We note that $\bar{\delta}_i(\varepsilon)$ is positive and nondecreasing, but not necessarily continuous. Choose $\alpha_i \in \mathcal{K}$ such that $\alpha_i(r) \leq k\bar{\delta}_i(r)$ for all $r \in \mathbb{R}_{\geq 0}$ with $k \in (0, 1)$. Let $c_i := \lim_{r\to\infty} \alpha_i(r)$ and $\rho_i(r) := \alpha_i^{-1}(r)$ for all $r \in [0, c_i)$. Then ρ_i is continuous, zero at zero, strictly increasing, and is defined on $[0, c_i)$. Given $\delta_i < c_i$, let $\varepsilon = \rho_i(\delta_i)$. Then $\delta_i < \bar{\delta}_i(\varepsilon)$ and

$$F_{\delta_i}(S_{i_\delta}) \subseteq F(S_i) + \rho_i(\delta_i)\overline{\mathcal{B}}.$$

Let $c^* := \min_{i\in\{1,\ldots,k\}}\{c_i\}$ and, for each $r \in [0, c^*)$, let $\hat{\rho}(r) := \max_{i\in\{1,\ldots,k\}} \rho_i(r)$. Then, for each $i \in \{1, 2, \ldots, k\}$, $F_\delta(S_{i_\delta}) \subseteq F(S_i) + \hat{\rho}(\delta)\overline{\mathcal{B}}$ for all $\delta \in (0, c^*)$. Finally, let $\rho \in \mathcal{K}_\infty$ be such that $\rho(r) \geq \hat{\rho}(r)$ for all $r \in [0, \frac{1}{2}c^*]$. Therefore, with $c := \frac{1}{2}c^*$,

$$F_\delta(S_{i_\delta}) \subseteq F(S_i) + \rho(\delta)\overline{\mathcal{B}} \quad \forall \delta \in (0, c]. \qquad \square$$

CLAIM 5. *Suppose $F(\cdot)$ is an upper-semicontinuous set-valued map from $\mathcal{O}$ to subsets of $\mathbb{R}^n$ and that, for each $x \in \mathcal{O}$, $F(x)$ is nonempty and compact. Let M be a compact set in $\mathcal{O}$ and $K \in \mathbb{Z}_{>0}$. Assume $F^k(M) \subset \mathcal{O}$ for all $k \in \{1, \ldots, K\}$. Then there exist $\tilde{\rho} \in \mathcal{K}_\infty$ and $\tilde{c} > 0$ such that, for every $\delta \in (0, \tilde{c}]$ and $k \in \{1, \ldots, K\}$,*

$$F_\delta^k(M_\delta) \subseteq F^k(M) + \tilde{\rho}(\delta)\overline{\mathcal{B}}.$$

Proof. Define the compact sets $S_0 := M$, $S_1 := F(M), \ldots, S_k := F^k(M)$. Let $\rho \in \mathcal{K}_\infty$ and $c > 0$ come from Claim 4. Without loss of generality, assume $\rho(s) \geq s$ for all $s \in \mathbb{R}_{\geq 0}$. Let $\tilde{c} > 0$ be such that $\rho^{k-1}(\tilde{c}) < c$ and define $\tilde{\rho}(r) := \rho^k(r)$ for all $r \in [0, c)$ (where $\rho^k(\cdot)$ is the k-times composition of $\rho(\cdot)$ with itself). From Claim 4 we may write

$$F_\delta(M_\delta) = F_\delta(S_0 + \delta\overline{\mathcal{B}}) \subseteq F(M) + \rho(\delta)\overline{\mathcal{B}}.$$

Since $\delta < \tilde{c}$, we have that $\rho(\delta) < c$.

Assume the result holds for $k-1$; i.e., $F_\delta^{k-1}(M_\delta) \subseteq F^{k-1}(M) + \rho^{k-1}(\delta)\overline{\mathcal{B}}$. Noting that $\delta \leq \rho^{k-1}(\delta) < c$ we may write

$$\begin{aligned} F_\delta^k(M_\delta) &= F_\delta\left(F_\delta^{k-1}(M_\delta)\right) \ \subseteq \ F_\delta\left(F^{k-1}(M) + \rho^{k-1}(\delta)\overline{\mathcal{B}}\right) \\ &\subseteq F_{\rho^{k-1}(\delta)}\left(F^{k-1}(M) + \rho^{k-1}(\delta)\overline{\mathcal{B}}\right) \ \subseteq \ F^k(M) + \rho^k(\delta)\overline{\mathcal{B}} \\ &= F^k(M) + \tilde{\rho}(\delta)\overline{\mathcal{B}}, \end{aligned}$$

where the final subset is obtained by appealing to Claim 4. □

We will need to apply the lemmas in the following section to the difference inclusion defined by $x^+ \in F_\sigma(x)$ with $F_\sigma(\cdot)$ as in (2.2). To do this, we need to know that $F_\sigma(\cdot)$ satisfies the basic conditions.

CLAIM 6. *If $F(\cdot)$ is a set-valued map from $\mathcal{G}$ to subsets of $\mathcal{G}$ satisfying the basic conditions on $\mathcal{G}$, and $\sigma : \mathcal{G} \to \mathbb{R}_{\geq 0}$ satisfies item 1 of Definition 2.3, then $F_\sigma(\cdot)$ satisfies the basic conditions on $\mathcal{G}$.*

Proof. That $F_\sigma(x)$ is nonempty follows from $F(x)$ nonempty. Similarly, $F_\sigma(x)$ being compact follows from $F(x)$ compact, the compactness of the closed unit ball, $F(\cdot)$ upper semicontinuous, and the fact that upper-semicontinuous maps send compacts to compacts (see Claim 2).

Appealing to Claim 3 with $M := \{x\} + \sigma(x)\overline{\mathcal{B}}$ and any $\varepsilon > 0$ there exists $\delta > 0$ such that $F(M_\delta) = F\left(\{x\} + (\sigma(x) + \delta)\overline{\mathcal{B}}\right) \subseteq F\left(\{x\} + \sigma(x)\overline{\mathcal{B}}\right) + \varepsilon\overline{\mathcal{B}}$. Let $\varepsilon_\sigma = \frac{\delta}{2} > 0$. Then, since $\sigma(\cdot)$ is continuous, there exists $\delta_\sigma \in (0, \frac{\delta}{2}]$ such that if $|x - z| < \delta_\sigma$, then $|\sigma(x) - \sigma(z)| < \varepsilon_\sigma = \frac{\delta}{2}$. Therefore, $\{z\} + \sigma(z)\overline{\mathcal{B}} \subseteq \{x\} + (\sigma(x) + \delta)\overline{\mathcal{B}}$ and

$$F\left(\{z\} + \sigma(z)\overline{\mathcal{B}}\right) \subseteq F\left(\{x\} + \sigma(x)\overline{\mathcal{B}}\right) + \varepsilon\overline{\mathcal{B}};$$

i.e., $F_\sigma(\cdot)$ is upper semicontinuous on $\mathcal{G}$. □

5. Difference inclusions. In this section we present three new results for difference inclusions which will be necessary for the proofs of the results presented in section 2.

The first result makes use of a perturbed difference inclusion. Let $F(\cdot)$ map an open set $\mathcal{O} \subset \mathbb{R}^n$ to subsets of $\mathbb{R}^n$, let $\delta \geq 0$, and consider

$$x^+ \in F_\delta(x) := F(x + \delta\overline{\mathcal{B}}) + \delta\overline{\mathcal{B}}, \quad x \in \mathcal{O}. \tag{5.1}$$

We denote the solution set of (5.1) from the point $x \in \mathbb{R}^n$ by $\mathcal{S}_\delta(x)$. This result is similar to a result on closeness of solutions for differential inclusions (see, for example, [5, section 8, Corollary 2]).

LEMMA 5.1. *Let $\mathcal{O}$ be open, $\omega : \mathcal{O} \to \mathbb{R}_{\geq 0}$ be continuous, and $F(\cdot)$ map $\mathcal{O}$ to subsets of $\mathbb{R}^n$ satisfy the basic conditions on $\mathcal{O}$. Let the triple (K, ε, M) be such that $K \in \mathbb{Z}_{>0}$, $\varepsilon > 0$, $M \subset \mathcal{O}$ compact, and $F^k(M) \subset \mathcal{O}$ for all $k \in \{1, \ldots, K\}$. Under these conditions, there exists $\delta > 0$ such that for every $x \in M_\delta$*

1. *every solution $\psi \in \mathcal{S}_\delta(x)$ satisfies $\psi(k, x) \in \mathcal{O}$ for $k \in \{0, \ldots, K\}$, and*
2. *for every $\psi \in \mathcal{S}_\delta(x)$ there exists $\bar{x} \in M$ and $\phi \in \mathcal{S}(x)$ such that for all $k \in \{0, \ldots, K\}$ we have*

$$|\omega(\psi(k, x)) - \omega(\phi(k, \bar{x}))| \leq \varepsilon. \tag{5.2}$$

Proof. The first item follows from Claim 5 and the fact that $F^k(M)$ is compact for each $k \in \mathbb{Z}_{>0}$.

If the second item is not true, then no matter how small we pick δ, there is an initial condition in M_δ and a solution to $x^+ \in F_\delta(x)$ starting at this initial condition such that, no matter which initial condition in M and solution of $x^+ \in F(x)$ we pick, the condition (5.2) is violated for some $k \in \{0, \ldots, K\}$. In particular, there exist sequences $x_i \in M_{1/i}$ and $\psi_i \in \mathcal{S}_{1/i}(x_i)$ such that, no matter which initial condition in M and solution of $x^+ \in F(x)$ we pick, the condition (5.2) is violated for some $k \in \{0, \ldots, K\}$. The sequence x_i has a subsequence, which we will not relabel, converging to a point $f_0^* \in M$. Associated with this subsequence is a sequence of

points $\psi_i(1, x_i) \in F_{1/i}(x_i)$. This sequence has a converging subsequence and, from the upper semicontinuity of F and compactness of $F(f_0^*)$, its accumulation point, denoted f_1^*, belongs to $F(f_0^*)$. Continuing in this way we get a sequence of initial conditions $x_i \in M_{1/i}$ and a sequence of solutions $\psi_i \in \mathcal{S}_{1/i}(x_i)$ such that $x_i \to f_0^* \in M$ and $\psi_i(k, x_i) \to f_k^* \in F(f_{k-1}^*)$. Now with the solution $\phi \in \mathcal{S}(f_0^*)$ given by $\phi(k, f_0^*) = f_k^* \in F(\phi(k-1, f_0^*))$ for all $k \in \{1, \dots, K\}$, and using the continuity of ω, condition (5.2) holds for all i sufficiently large. This is a contradiction and thus proves the lemma. ∎

We will require the following lemma on closeness of solutions for difference inclusions defined by continuous set-valued maps.

LEMMA 5.2. *Suppose $F(\cdot)$ is a set-valued map from $\mathcal{O}$ to subsets of $\mathbb{R}^n$ continuous on an open set $\mathcal{O}_1 \subseteq \mathcal{O}$ and that, for each $x \in \mathcal{O}$, $F(x)$ is compact and nonempty. Furthermore, suppose $\omega : \mathcal{O} \to \mathbb{R}_{\geq 0}$ is continuous. For each triple (K, ε, x_0) such that $K \in \mathbb{Z}_{>0}$, $\varepsilon > 0$, and $x_0 \in \mathcal{O}$, and for each solution $\phi \in \mathcal{S}(x_0)$ such that $\phi(k, x_0) \in \mathcal{O}_1$ for all $k \in \{0, \dots, K\}$ there exists a $\delta > 0$ such that, for every $x \in \{x_0\} + \delta\overline{\mathcal{B}}$, there exists a solution $\psi \in \mathcal{S}(x)$ such that, for all $k \in \{0, \dots, K+1\}$,*

$$|\omega(\phi(k, x_0)) - \omega(\psi(k, x))| \leq \varepsilon.$$

Proof. Define the compact set

$$\mathcal{C} := \{\phi(k, x_0)\} \subset \mathcal{O}_1 \subseteq \mathcal{O} \quad \forall k \in \{0, \dots, K\}.$$

For the given $\varepsilon > 0$, since $\omega(\cdot)$ is continuous, there exists $\delta_\omega > 0$ such that $r \in \mathcal{C}$ and $|s - r| \leq \delta_\omega$ imply $|\omega(s) - \omega(r)| \leq \varepsilon$. Without loss of generality, we also impose $\delta_\omega \leq \varepsilon$ and $\mathcal{C} + \delta_\omega\overline{\mathcal{B}} \subset \mathcal{O}_1$.

From the continuity of $F(\cdot)$ at $\phi(K, x_0)$, there exists $\delta_K \in (0, \delta_\omega]$ such that for all $z \in \mathcal{O}$ satisfying $|z - \phi(K, x_0)| \leq \delta_K$ we have $F(\phi(K, x_0)) \subseteq F(z) + \delta_\omega\overline{\mathcal{B}}$. Similarly, from the continuity of $F(\cdot)$ at $\phi(K-1, x_0)$, there exists $\delta_{K-1} \in (0, \delta_\omega]$ such that for all $z \in \mathcal{O}$ satisfying $|z - \phi(K-1, x_0)| \leq \delta_{K-1}$ we have $F(\phi(K-1, x_0)) \subseteq F(z) + \delta_K\overline{\mathcal{B}}$. We repeat this procedure until we reach the initial point x_0. From the previous step we will have a $\delta_1 \in (0, \delta_\omega]$. Then, from the continuity of $F(\cdot)$ at x_0, there exists a $\delta_0 \in (0, \delta_\omega]$ such that, for all $z \in \mathcal{O}$,

$$|z - x_0| \leq \delta_0 \quad \Longrightarrow \quad F(x_0) \subseteq F(z) + \delta_1\overline{\mathcal{B}}. \tag{5.3}$$

From (5.3), for any $x \in \{x_0\} + \delta_0\overline{\mathcal{B}}$ there exists a point $\psi(1, x) \in F(x)$ such that

$$|\phi(1, x_0) - \psi(1, x)| \leq \delta_1. \tag{5.4}$$

This follows from (5.3) since $|x - x_0| \leq \delta_0$, so that $\phi(1, x_0) \in F(x_0) \subseteq F(x) + \delta_1\overline{\mathcal{B}}$.

Since (5.4) holds, we see that there exists a point $\psi(2, x) \in F(\psi(1, x))$ such that

$$|\phi(2, x_0) - \psi(2, x)| \leq \delta_2.$$

This follows from (5.4) since $\phi(2, x_0) \in F(\phi(1, x_0)) \subseteq F(\psi(1, x)) + \delta_2\overline{\mathcal{B}}$. That is, for the point $\phi(2, x_0)$, there exists an element in $F(\psi(1, x))$ (which we have called $\psi(2, x)$) that is no more than δ_2 away from $\phi(2, x_0)$.

We can repeat this procedure at each step until we get to $\phi(K+1, x_0)$.

Since, for each $\ell \in \{0, \dots, K\}$, we imposed $\delta_\ell \leq \delta_\omega$ we see that, with $\psi \in \mathcal{S}(x)$ constructed as above,

$$|\omega(\phi(k, x_0)) - \omega(\psi(k, x))| \leq \varepsilon \quad \forall k \in \{0, \dots, K+1\}. \qquad \blacksquare$$

We present a lemma regarding sequences of solutions. This lemma is similar to the continuous-time results found in [22, Lemmas 4 and 5], which derived from [5, section 7, Theorem 3].

LEMMA 5.3. *Let $F(\cdot)$ mapping $\mathcal{O}$ to subsets of $\mathbb{R}^n$ satisfy the basic conditions on $\mathcal{O}$. Let $x \in \mathcal{O}$ be given and suppose that all solutions $\phi \in \mathcal{S}(x)$ are defined and belong to $\mathcal{O}$ for all $k \geq 0$. Then each sequence $\{\phi_n\}_{n=1}^{\infty}$ of solutions in $\mathcal{S}(x)$ has a subsequence converging to a function $\phi \in \mathcal{S}(x)$ and the convergence is uniform on each finite time interval.*

Proof. From Claim 2 we know that for each $k \in \mathbb{Z}_{\geq 0}$ the set $F^k(x)$ is a compact set. Since for all n and k, $\phi_n(k,x) \in F^k(x)$, it follows that $\{\phi_n\}_{n=1}^{\infty}$ has a converging subsequence $\{\phi_{1m}\}_{m=1}^{\infty}$ such that $\phi_{1m}(1,x) \to f_1^* =: \phi(1,x)$. Similarly, $\{\phi_{1m}\}_{m=1}^{\infty}$ has a converging subsequence $\{\phi_{2m}\}_{m=1}^{\infty}$ such that $\phi_{2m}(2,x) \to f_2^* =: \phi(2,x)$, and so on. In this way, we construct a subsequence which converges to a solution $\phi \in \mathcal{S}(x)$, and, for a finite time interval, this convergence is uniform. ∎

6. Proof of Theorem 2.7. We demonstrate that robust $\mathcal{KL}$-stability is a necessary and sufficient condition for the existence of a smooth Lyapunov function with respect to (ω_1, ω_2).

6.1. Sufficiency. One of the most useful lemmas regarding comparison functions is frequently referred to as Sontag's lemma on $\mathcal{KL}$-estimates [19, Proposition 7]. This lemma allows us to view asymptotic stability as exponential stability via a suitable nonlinear scaling. The following lemma is a slight refinement of Sontag's original lemma wherein we specify the required regularity property of one of the $\mathcal{K}_\infty$ functions.

LEMMA 6.1. *For each $\beta \in \mathcal{KL}$ and $\lambda > 0$, there exist $\alpha_1, \alpha_2 \in \mathcal{K}_\infty$ such that $\alpha_1(\cdot)$ is Lipschitz on its domain, continuously differentiable on $(0,\infty)$, $\alpha_1(s) \leq s\alpha_1'(s)$ for all $s > 0$, and $\alpha_1(\beta(s,t)) \leq \alpha_2(s)e^{-\lambda t}$ for all $(s,t) \in \mathbb{R}_{\geq 0} \times \mathbb{R}_{\geq 0}$.*

6.1.1. Bounds. Given $\beta_\sigma \in \mathcal{KL}$ from the assumption of $\mathcal{KL}$-stability with respect to (ω_1, ω_2) for $x^+ \in F_\sigma(x)$, Lemma 6.1 yields $\hat{\alpha}_1, \hat{\alpha}_2 \in \mathcal{K}_\infty$ such that

$$\hat{\alpha}_1\left(\beta_\sigma(s,k)\right) \leq \hat{\alpha}_2(s)e^{-2k} \quad \forall k \in \mathbb{Z}_{\geq 0},\ \forall s \geq 0. \tag{6.1}$$

For each $x \in \mathcal{G}$ we define the function $V_1 : \mathcal{G} \to \mathbb{R}_{\geq 0}$ by

$$V_1(x) := \sup_{k \in \mathbb{Z}_{\geq 0}, \phi \in \mathcal{S}_\sigma(x)} \hat{\alpha}_1(\omega_1(\phi(k,x)))e^k. \tag{6.2}$$

We claim that

$$V_1(x) = 0 \quad \Longleftrightarrow \quad x \in \mathcal{A}_\sigma = \mathcal{A}. \tag{6.3}$$

To see this, note that if $x \in \mathcal{A}_\sigma$, then, by definition (2.4), $V_1(x) = 0$. Furthermore, $V_1(x) = 0$ implies that

$$0 = \sup_{k \in \mathbb{Z}_{\geq 0}, \phi \in \mathcal{S}_\sigma(x)} \hat{\alpha}_1(\omega_1(\phi(k,x))),$$

and, since $\hat{\alpha}_1 \in \mathcal{K}_\infty$, $x \in \mathcal{A}_\sigma = \mathcal{A}$.

It is easy to see that, for all $x \in \mathcal{G}$,

$$V_1(x) \geq \sup_{\phi \in \mathcal{S}_\sigma(x)} \hat{\alpha}_1(\omega_1(\phi(0,x)))e^0 = \hat{\alpha}_1(\omega_1(x)), \quad \text{and} \tag{6.4}$$

$$V_1(x) \leq \sup_{k\in\mathbb{Z}_{\geq 0}} \hat{\alpha}_1(\beta_\sigma(\omega_2(x),k))e^k$$
$$\leq \sup_{k\in\mathbb{Z}_{\geq 0}} \hat{\alpha}_2(\omega_2(x))e^{-k} = \hat{\alpha}_2(\omega_2(x)). \tag{6.5}$$

For each $x \in \mathcal{G}$ and $\phi \in \mathcal{S}_\sigma(x)$ we may write

$$\begin{aligned} V_1(\phi(j,x)) &= \sup_{k\in\mathbb{Z}_{\geq 0},\ \psi\in\mathcal{S}_\sigma(\phi(j,x))} \hat{\alpha}_1\left(\omega_1(\psi(k,\phi(j,x)))\right)e^k \\ &\leq \sup_{k\in\mathbb{Z}_{\geq j},\ \psi\in\mathcal{S}_\sigma(x)} \hat{\alpha}_1(\omega_1(\psi(k,x)))e^{k-j} \\ &\leq \sup_{k\in\mathbb{Z}_{\geq 0},\ \psi\in\mathcal{S}_\sigma(x)} \hat{\alpha}_1(\omega_1(\psi(k,x)))e^k e^{-j} \\ &= V_1(x)e^{-j}\ . \end{aligned}$$

We note that $w \in F_\sigma(x)$ implies the existence of $\phi \in \mathcal{S}_\sigma(x)$ such that $\phi(1,x) = w$. Therefore, we may write

$$\sup_{f\in F_\sigma(x)} V_1(f) \leq e^{-1}V_1(x) \quad \forall x \in \mathcal{G}. \tag{6.6}$$

6.1.2. Smoothing V_1. We proceed to smooth the function $V_1(\cdot)$ without destroying the nature of the upper and lower bounds (6.4) and (6.5) and the decrease condition (6.6). To do this, we will appeal to Theorem 3.1, which requires Assumptions 1 and 2 and uses a set $\mathcal{A}$ defined in (3.1) that, as a consequence of (6.3), is the same as the set $\mathcal{A}$ of (2.3). Assumption 1 requires that $V_1(\cdot)$ be upper semicontinuous and that if $V_1(x) > 0$, then $V_1(z) > 0$ for z near x.

$V_1(\cdot)$ is upper semicontinuous: We first show that for each $x \in \mathcal{G}\backslash\mathcal{A}$ there exists a solution such that the supremum defining $V_1(\cdot)$ is attained for some solution and over a finite time interval.

Claim 7. *Let $x \in \mathcal{G}$ be such that $V_1(x) > 0$. Define*

$$K(x) := -\left\lfloor \ln\left(\frac{V_1(x)}{\hat{\alpha}_2(\omega_2(x))}\right)\right\rfloor + 1. \tag{6.7}$$

Then there exists $\hat{\phi} \in \mathcal{S}_\sigma(x)$ such that, for every $\kappa \geq K(x)$,

$$V_1(x) = \max_{k\in\{0,\ldots,\kappa\}} \hat{\alpha}_1\left(\omega_1(\hat{\phi}(k,x))\right)e^k. \tag{6.8}$$

Proof. It is obvious that

$$\sup_{k\in\{0,\ldots,\kappa\},\phi\in\mathcal{S}_\sigma(x)} \hat{\alpha}_1\left(\omega_1(\phi(k,x))\right)e^k \leq V_1(x). \tag{6.9}$$

We note that, for all $x \in \mathcal{G}\backslash\mathcal{A}$,

$$e^{-\kappa} \leq e^{-K(x)} \leq \frac{V_1(x)}{\hat{\alpha}_2(\omega_2(x))}e^{-1}.$$

Therefore, with (2.1) and (6.1), we may write

$$\begin{aligned} V_1(x) &= \max\left\{ \sup_{k\in\{0,\dots,\kappa\},\phi\in\mathcal{S}_\sigma(x)} \hat{\alpha}_1\left(\omega_1(\phi(k,x))\right)e^k, \right. \\ &\qquad\qquad \left. \sup_{k\in\mathbb{Z}_{\geq\kappa},\phi\in\mathcal{S}_\sigma(x)} \hat{\alpha}_1\left(\omega_1(\phi(k,x))\right)e^k \right\} \\ &\leq \max\left\{ \sup_{k\in\{0,\dots,\kappa\},\phi\in\mathcal{S}_\sigma(x)} \hat{\alpha}_1\left(\omega_1(\phi(k,x))\right)e^k, \quad \hat{\alpha}_2(\omega_2(x))e^{-\kappa} \right\} \\ &\leq \max\left\{ \sup_{k\in\{0,\dots,\kappa\},\phi\in\mathcal{S}_\sigma(x)} \hat{\alpha}_1\left(\omega_1(\phi(k,x))\right)e^k, \quad V_1(x)e^{-1} \right\}, \end{aligned}$$

which, together with (6.9), implies

$$\begin{aligned} V_1(x) &= \sup_{k\in\{0,\dots,\kappa\},\phi\in\mathcal{S}_\sigma(x)} \hat{\alpha}_1\left(\omega_1(\phi(k,x))\right)e^k \\ &= \sup_{\phi\in\mathcal{S}_\sigma(x)} \max_{k\in\{0,\dots,\kappa\}} \hat{\alpha}_1\left(\omega_1(\phi(k,x))\right)e^k, \end{aligned}$$

where we can pass to the "max" since the supremum is taken over a finite number of elements. Now let $\{\phi_\ell\}_{\ell=1}^\infty$ be a maximizing sequence of solutions in $\mathcal{S}_\sigma(x)$; i.e.,

$$V_1(x) = \lim_{\ell\to\infty} \max_{k\in\{0,\dots,\kappa\}} \hat{\alpha}_1\left(\omega_1(\phi_\ell(k,x))\right)e^k.$$

Since $F_\sigma(\cdot)$ satisfies the basic conditions (see Claim 6), we may appeal to Lemma 5.3 to see that a subsequence of $\{\phi_\ell(\cdot,x)\}_{\ell=1}^\infty$ converges uniformly on $\{0,\dots,\kappa\}$ to some solution $\hat{\phi}\in\mathcal{S}_\sigma(x)$. Since the functions $\hat{\alpha}_1(\cdot)$ and $\omega_1(\cdot)$ are continuous, we may write

$$V_1(x) = \max_{k\in\{0,\dots,\kappa\}} \hat{\alpha}_1\left(\omega_1(\hat{\phi}(k,x))\right)e^k. \qquad \square$$

We now prove that $V_1(\cdot)$ is upper semicontinuous. In order to obtain a contradiction, suppose that there exist $x\in\mathcal{G}$ and a sequence $\{x_\ell\}_{\ell=1}^\infty$ of points in $\mathcal{G}$ converging to $x\in\mathcal{G}$ such that

$$\limsup_{\ell\to\infty} V_1(x_\ell) > V_1(x) \geq 0.$$

Without loss of generality, for all ℓ and some $\eta>0$

$$V_1(x_\ell) \geq \eta. \tag{6.10}$$

Define $\kappa := \sup_\ell K(x_\ell)$. From (6.10), the continuity of $\hat{\alpha}_2\circ\omega_2(\cdot)$, and the definition of $K(\cdot)$ in (6.7), we see that $\kappa<\infty$. Let $\hat{\phi}\in\mathcal{S}_\sigma(x_\ell)$ come from Claim 7 so that

$$V_1(x_\ell) = \max_{k\in\{0,\dots,\kappa\}} \hat{\alpha}_1\left(\omega_1(\hat{\phi}(k,x_\ell))\right)e^k.$$

Let $\varepsilon>0$. Since $F_\sigma(\cdot)$ satisfies the basic conditions, we appeal to Lemma 5.1 with the triple (κ,ε,x) and the continuity of $\hat{\alpha}_1\circ\omega_1(\cdot)$ to assert the existence of ℓ_ε so that, for all $\ell\geq\ell_\varepsilon$, there exists $\psi_\ell\in\mathcal{S}_\sigma(x)$ such that

$$\begin{aligned} V_1(x_\ell) = \max_{k\in\{0,\dots,\kappa\}} \hat{\alpha}_1\left(\omega_1(\hat{\phi}(k,x_\ell))\right)e^k &\leq \varepsilon + \max_{k\in\{0,\dots,\kappa\}} \hat{\alpha}_1\left(\omega_1(\psi_\ell(k,x))\right)e^k \\ &\leq \varepsilon + V_1(x). \end{aligned}$$

This implies $\limsup_{\ell\to\infty} V_1(x_\ell) \leq V_1(x)$, which is a contradiction. In addition, it also establishes continuity of $V_1(\cdot)$ at each point $x \in \{\xi \in \mathcal{G} : V_1(\xi) = 0\}$ since, for each such x, we may write

$$0 \leq \limsup_{z\to x} V_1(z) \leq V_1(x) = 0.$$

Next we establish item 1 of Assumption 1.

CLAIM 8. *If $V_1(x) > 0$, then there exists $\delta > 0$ such that $|z - x| < \delta$ implies $V_1(z) > 0$.*

With this claim, we see that the set $\mathcal{G}\backslash\mathcal{A}$ is open.

Proof. If $x \in \mathcal{G}\backslash\mathcal{A}$ is such that $\omega_1(x) > 0$, then the result follows from the continuity of $\omega_1(\cdot)$, the lower bound (6.4), and the fact that $\hat{\alpha}_1 \in \mathcal{K}_\infty$. So we just need to consider points $x \in \mathcal{G}\backslash\mathcal{A}$ such that $\omega_1(x) = 0$. We first assert that

$$\sup_{f\in F(x)} V_1(f) > 0. \tag{6.11}$$

If this were not the case, then with the lower bound (6.4) and the fact that $\hat{\alpha}_1 \in \mathcal{K}_\infty$ we would have $\max_{f\in F(x)} \omega_1(f) = 0$. Furthermore, with the decrease condition (6.6) and $F(x) \subseteq F_\sigma(x)$ we would have, for all $f \in F(x)$,

$$\sup_{g\in F(f)} V_1(g) \leq e^{-1} V_1(f) = 0.$$

Iterating and using the condition $\omega_1(x) = 0$, we would have

$$\sup_{k\in\mathbb{Z}_{\geq 0}, \phi\in\mathcal{S}(x)} \omega_1(\phi(k, x)) = 0;$$

i.e., $x \in \mathcal{A}$, which is a contradiction.

We also have, according to the definition of robust $\mathcal{KL}$ stability, $\sigma(x) > 0$ for $x \in \mathcal{G}\backslash\mathcal{A}$. Using the continuity of $\sigma(\cdot)$, there exists $\delta > 0$ such that $\delta \leq \min_{q\in\delta\overline{\mathcal{B}}} \sigma(x + q)$. It follows that

$$0 \in \bigcap_{z\in\delta\overline{\mathcal{B}}} \{z\} + \sigma(x + z)\overline{\mathcal{B}}$$

and thus, for any $z \in \delta\overline{\mathcal{B}}$, we see that $F(x) \subseteq F(x + z + \sigma(x + z)\overline{\mathcal{B}})$. Now, using (6.6) and (6.11), we have, for $z \in \delta\overline{\mathcal{B}}$,

$$e^{-1} V_1(x + z) \geq \sup_{f\in F_\sigma(x+z)} V_1(f) \geq \sup_{f\in F(x)} V_1(f) > 0,$$

which establishes the claim. ∎

Finally, we need to construct a function $\sigma_2 : \mathcal{G}\backslash\mathcal{A} \to \mathbb{R}_{>0}$ satisfying Assumption 2 and such that the smooth function $V(\cdot)$ of Theorem 3.1 retains bounds like (6.4) and (6.5) and the decrease condition (6.6).

Construction of σ_2:

CLAIM 9. *There exists a smooth function $\sigma_1 : \mathcal{G}\backslash\mathcal{A} \to \mathbb{R}_{>0}$ such that, for all $x \in \mathcal{G}\backslash\mathcal{A}$,*

$$\sigma_1(x) \leq \sigma(x), \qquad \textit{and} \tag{6.12}$$

$$\sup_{f\in F_{\sigma_1}(x), f\in\mathcal{G}\backslash\mathcal{A}} V_1(f) \leq e^{-1} \inf_{z\in\sigma_1(x)\overline{\mathcal{B}}} V_1(x + z)\ . \tag{6.13}$$

Proof. We define a function $\sigma_1 : \mathcal{G}\backslash\mathcal{A} \to \mathbb{R}_{>0}$ by associating to each $x \in \mathcal{G}\backslash\mathcal{A}$ one-half the supremum over all values $\tilde{\sigma}_1$ satisfying

$$2\tilde{\sigma}_1 \leq \min_{q \in \tilde{\sigma}_1 \overline{\mathcal{B}}} \sigma(x+q). \tag{6.14}$$

The existence of $\sigma_1(\cdot)$ follows from continuity of $\sigma(\cdot)$ and the fact that $\sigma(x) > 0$ for all $x \in \mathcal{G}\backslash\mathcal{A}$. These properties for $\sigma(\cdot)$ also guarantee that $\sigma_1(\cdot)$ is bounded away from zero on compact subsets of $\mathcal{G}\backslash\mathcal{A}$.

It follows from (6.14) that

$$\sigma_1(x) \leq \sigma(x) \quad \forall x \in \mathcal{G}\backslash\mathcal{A}, \tag{6.15}$$

i.e., (6.12) holds. We further see that

$$\sigma_1(x)\overline{\mathcal{B}} \subseteq \bigcap_{z \in \sigma_1(x)\overline{\mathcal{B}}} \{z\} + \sigma(x+z)\overline{\mathcal{B}},$$

so that

$$F(x + \sigma_1(x)\overline{\mathcal{B}}) \subseteq \bigcap_{z \in \sigma_1(x)\overline{\mathcal{B}}} F(x + z + \sigma(x+z)\overline{\mathcal{B}}). \tag{6.16}$$

With the definition of $F_\sigma(\cdot)$, (6.15), and (6.16) we see that, for any $z \in \sigma_1(x)\overline{\mathcal{B}}$,

$$F_{\sigma_1}(x) \subseteq F_\sigma(x+z). \tag{6.17}$$

From the decrease condition (6.6), we have

$$e^{-1}V_1(x+z) \geq \sup_{f \in F_\sigma(x+z)} V_1(f).$$

Taking the infimum on both sides and appealing to (6.17) we have

$$\inf_{z \in \sigma_1(x)\overline{\mathcal{B}}} e^{-1}V_1(x+z) \geq \inf_{z \in \sigma_1(x)\overline{\mathcal{B}}} \left[\sup_{f \in F_{\sigma(x+z)}(x+z)} V_1(f) \right] \geq \sup_{f \in F_{\sigma_1(x)}(x)} V_1(f).$$

It is clear that this inequality and (6.15) hold for any function smaller than $\sigma_1(\cdot)$, and so we can smooth $\sigma_1(\cdot)$ using Lemma 3.3 to prove the claim. ∎

Let the function $\sigma_a : \mathcal{G}\backslash\mathcal{A} \to \mathbb{R}_{\geq 0}$ be given by

$$\sigma_a(x) := \min\left\{1, \frac{1}{2}\sup\left\{\eta \ : \ |z-x| \leq \eta \ \Rightarrow \ |\omega_2(z) - \omega_2(x)| \leq \frac{1}{2}\omega_2(x)\right\}\right\} \tag{6.18}$$

and the function $\sigma_b : \mathcal{G}\backslash\mathcal{A} \to \mathbb{R}_{\geq 0}$ be given by

$$\sigma_b(x) := \min\left\{1, \frac{1}{2}\sup\left\{\eta \ : \ V_1(x + \eta\overline{\mathcal{B}}) \geq \hat{\alpha}_1\left(\frac{1}{2}\omega_1(x)\right)\right\}\right\}. \tag{6.19}$$

We then define, for each $x \in \mathcal{G}\backslash\mathcal{A}$,

$$\bar{\sigma}_2(x) := \min\{\sigma_a(x), \sigma_b(x), \sigma_1(x), |x|_{\mathcal{A}}\}. \tag{6.20}$$

Before proceeding, we demonstrate that the function $\bar{\sigma}_2(\cdot)$ is bounded away from zero on compact subsets of $\mathcal{G}\backslash\mathcal{A}$. Since $\sigma_1(\cdot)$ and $|\cdot|_{\mathcal{A}}$ are continuous and positive on $\mathcal{G}\backslash\mathcal{A}$, we need to establish this property only for $\sigma_a(\cdot)$ and $\sigma_b(\cdot)$.

We first note that $\omega_2(x) > 0$ for $x \in \mathcal{G}\backslash\mathcal{A}$. Suppose not. If $x \notin \mathcal{A}$, then there exists a solution $\phi \in \mathcal{S}_\sigma(x)$ and a time $k \in \mathbb{Z}_{\geq 0}$ such that $\omega_1(\phi(k,x)) > 0$. However, from the stability estimate we see that $0 < \omega_1(\phi(k,x)) \leq \beta_\sigma(\omega_2(x), 0) = 0$, which is a contradiction.

First we demonstrate that $\sigma_a(\cdot)$ is bounded away from zero on compact subsets of $\mathcal{G}\backslash\mathcal{A}$. Suppose not. Then there exists a compact set $D \subset \mathcal{G}\backslash\mathcal{A}$, a sequence $\{x_i\}_{i=1}^{\infty}$ in D, and a sequence $z_i \in \{x_i\} + \sigma_a(x_i)\overline{\mathcal{B}} \subset \{x_i\} + \frac{1}{i}\overline{\mathcal{B}}$ such that

$$|\omega_2(z_i) - \omega_2(x_i)| > \frac{1}{2}\omega_2(x_i). \tag{6.21}$$

The sequence x_i has an accumulation point $x^* \in D$. Now, since $x^* \in D$, we have $\omega_2(x^*) > 0$. Since $\omega_2(\cdot)$ is continuous we have, as $i \to \infty$, $|\omega_2(z_i) - \omega_2(x_i)| \to 0$ while $\frac{1}{2}\omega_2(x_i) \to \frac{1}{2}\omega_2(x^*) > 0$. This contradicts (6.21).

Next we demonstrate that $\sigma_b(\cdot)$ is bounded away from zero on compact subsets of $\mathcal{G}\backslash\mathcal{A}$. Suppose not. Then there exist a compact set $D \subset \mathcal{G}\backslash\mathcal{A}$, a sequence $x_i \in D$, and a sequence z_i with $|x_i - z_i| \leq 1/i$ such that

$$V_1(z_i) < \hat{\alpha}_1\left(\frac{1}{2}\omega_1(x_i)\right). \tag{6.22}$$

The sequence x_i has an accumulation point $x^* \in D$. Henceforth we use x_i to denote the converging subsequence, and z_i the associated subsequence. Suppose $\omega_1(x^*) > 0$. Using the continuity of $\omega_1(\cdot)$, there exists i^* such that $\omega_1(z_i) \geq \frac{1}{2}\omega_1(x_i)$ for all $i \geq i^*$ and thus

$$V_1(z_i) \geq \hat{\alpha}_1\left(\omega_1(z_i)\right) \geq \hat{\alpha}_1\left(\frac{1}{2}\omega_1(x_i)\right),$$

which contradicts (6.22).

Alternatively, suppose $\omega_1(x^*) = 0$. We make the following claim.

Claim 10. *There exists $c > 0$ such that*

$$V_1(x^* + \sigma_1(x^*)\overline{\mathcal{B}}) \geq c. \tag{6.23}$$

Proof. Suppose not. Then, for all $c > 0$

$$\inf_{z \in \sigma_1(x^*)\overline{\mathcal{B}}} V_1(x^* + z) < c.$$

We note that this implies that if $f \in F(x^*)$, then $f \in \mathcal{A}$. Suppose not. Then, since $x^* \in D \subset \mathcal{G}\backslash\mathcal{A}$, (6.13) implies that $\sup_{f \in F(x^*)} V_1(f) = 0$. However, appealing to (6.3), we see that $V_1(f) = 0$ if and only if $f \in \mathcal{A}$.

From (6.6), we see that if $f \in \mathcal{A}$, then

$$\sup_{f_1 \in F(f)} V_1(f_1) \leq \sup_{f_1 \in F_\sigma(f)} V_1(f_1) \leq e^{-1} V_1(f) = 0.$$

In other words, any solution starting from a point $f \in F(x^*)$ is such that $V_1(\cdot)$ remains identically zero and, from (6.4), we see that $\omega_1(\cdot)$ also remains identically

zero. Furthermore, with $\omega_1(x^*) = 0$, it follows that any solution starting at x^* is such that $\omega_1(\cdot)$ remains identically zero so that $x^* \in \mathcal{A}$, which contradicts $x^* \in \mathcal{G}\backslash\mathcal{A}$. ∎

For sufficiently large i we have $z_i \in \{x^*\} + \sigma_1(x^*)\overline{\mathcal{B}}$ and, since $\omega_1(x^*) = 0$, we have $\hat{\alpha}_1\left(\frac{1}{2}\omega_1(x_i)\right) \leq c$ so that, with (6.23),

$$V(z_i) \geq \hat{\alpha}_1\left(\frac{1}{2}\omega_1(x_i)\right),$$

which contradicts (6.22).

Let the function $\sigma_2 : \mathcal{G}\backslash\mathcal{A} \to \mathbb{R}_{>0}$ come from the application of Lemma 3.3 to the function $\bar{\sigma}_2(\cdot)$ defined in (6.20) so that $\sigma_2(\cdot)$ is smooth and positive on $\mathcal{G}\backslash\mathcal{A}$. We see that $\sigma_2(\cdot)$ is such that, for a sequence of points $x_i \in \mathcal{G}\backslash\mathcal{A}$ such that $x_i \to x^* \in \mathcal{A}$, we have $\sigma_2(x_i) \to 0$, since $\sigma_2(x) \leq |x|_{\mathcal{A}}$. We also note that $x \in \mathcal{G}\backslash\mathcal{A}$ implies $\{x\} + \sigma_2(x)\overline{\mathcal{B}} \subset \mathcal{G}$. This follows from the fact that $x \in \mathcal{G}\backslash\mathcal{A}$ implies $\{x\} + \sigma_1(x)\overline{\mathcal{B}} \subset \mathcal{G}$ (which stems from the fact that $\sigma_2(x) \leq \sigma_1(x) \leq \sigma(x)$ and the definition of robust $\mathcal{KL}$ stability). Consequently, $\sigma_2(\cdot)$ satisfies Assumption 2.

Let $\psi : \mathbb{R}^n \to \mathbb{R}_{\geq 0}$ be smooth, vanish outside $\mathbb{R}^n\backslash\overline{\mathcal{B}}$, and satisfy $\int \psi(\xi)d\xi = 1$. For $x \in \mathcal{G}\backslash\mathcal{A}$ we define

$$V_s(x) := \int V_1(x + \sigma_2(x)\xi)\psi(\xi)\, d\xi.$$

For $x \in \mathcal{A}$ we let $V_s(x) = 0$. That $V_s(\cdot)$ is smooth on $\mathcal{G}\backslash\mathcal{A}$ and continuous on $\mathcal{G}$ follows from Theorem 3.1.

Using (6.18) and $\sigma_2(x) \leq \sigma_a(x)$ for all $x \in \mathcal{G}\backslash\mathcal{A}$, we see that

$$V_s(x) \leq \max_{z \in \{x\} + \sigma_2(x)\overline{\mathcal{B}}} \hat{\alpha}_2(\omega_2(z)) \leq \hat{\alpha}_2\left(\frac{3}{2}\omega_2(x)\right).$$

From (6.19) and $\sigma_2(x) \leq \sigma_b(x)$ for all $x \in \mathcal{G}\backslash\mathcal{A}$, we have

$$V_s(x) \geq \hat{\alpha}_1\left(\frac{1}{2}\omega_1(x)\right).$$

We now check that an appropriate decrease condition holds for $V_s(\cdot)$. Suppose $x \notin \mathcal{A}$ and $f \in F(x)$ is such that $f \in \mathcal{A}$. Then it is obvious that $V_s(f) \leq e^{-1}V_s(x)$. If $x \in \mathcal{A}$, by definition of $\mathcal{A}$ this implies that $f \in \mathcal{A}$ for all $f \in F(x)$. Therefore, $V_s(f) = 0 = e^{-1}V_s(x)$. It remains to check the decrease condition for $x, f \notin \mathcal{A}$.

Making use of (6.6), the result of Claim 9, and the fact that $\sigma_2(\cdot) \leq \sigma_1(\cdot)$, we may write

$$\begin{aligned}
\max_{f \in F(x)} V_s(f) &= \max_{f \in F(x)} \int V_1(f + \sigma_2(f)\xi)\psi(\xi)\, d\xi \;\leq\; \int \max_{f \in F_{\sigma_2}(x)} V_1(f)\psi(\xi)\, d\xi \\
&\leq e^{-1} \int \min_{z \in \sigma_2(x)\overline{\mathcal{B}}} V_1(x + z)\psi(\xi)\, d\xi \;\leq\; e^{-1} \int V_1(x + \sigma_2(x)\xi)\psi(\xi)\, d\xi \\
&= e^{-1}V_s(x). \qquad (6.24)
\end{aligned}$$

Let $\rho \in \mathcal{K}_\infty$ come from Lemma 3.2 and define $V(x) := \rho \circ V_s(x)$. Then we may write

$$\begin{aligned}
V(x) &\leq \rho \circ \hat{\alpha}_2\left(\frac{3}{2}\omega_2(x)\right) =: \alpha_2(\omega_2(x)), \qquad \text{and} \\
V(x) &\geq \rho \circ \hat{\alpha}_1\left(\frac{1}{2}\omega_1(x)\right) =: \alpha_1(\omega_1(x)).
\end{aligned}$$

Since $\rho \in \mathcal{K}_\infty$ is convex, $\rho(e^{-1}s) \leq e^{-1}\rho(s)$ for all $s \in \mathbb{R}_{\geq 0}$. Consequently, following (6.24), we may write

$$\begin{aligned}\max_{f\in F(x)} V(f) &= \rho\left(\max_{f\in F(x)} V_s(f)\right) \leq \rho(V_s(x)e^{-1}) \leq \rho(V_s(x))e^{-1} \\ &= V(x)e^{-1}. \qquad \square\end{aligned}$$

6.2. Necessity. We note that in order to demonstrate that robust $\mathcal{KL}$-stability follows from a smooth Lyapunov function, we actually only make use of a continuous Lyapunov function. Furthermore, the upper semicontinuity of the set-valued map $F(\cdot)$ is not used. This, then, is the result of Theorem 2.8 as well as the necessity of Theorem 2.7

We assume we have a continuous function $V : \mathcal{G} \to \mathbb{R}_{\geq 0}$ and functions $\alpha_1, \alpha_2 \in \mathcal{K}_\infty$ such that, for every $x \in \mathcal{G}$,

$$\alpha_1(\omega_1(x)) \leq V(x) \leq \alpha_2(\omega_2(x)), \tag{6.25}$$

$$\max_{f\in F(x)} V(f) \leq e^{-1}V(x), \tag{6.26}$$

and $V(x) = 0$ if and only if $x \in \mathcal{A}$. Since $V(\cdot)$ is continuous on $\mathcal{G}$ and bounded away from zero on compact subsets of $\mathcal{G}\backslash\mathcal{A}$, we see that $\mathcal{G}\backslash\mathcal{A}$ is open.

Let $\varepsilon > 0$ satisfy $(1+\varepsilon)^2 e^{-1} < 1$. Since $V(\cdot)$ is continuous, for each $x \in \mathcal{G}\backslash\mathcal{A}$ there exists $\tilde{\delta}_1 > 0$ such that for all $\xi \in \mathcal{G}$

$$|x - \xi| \leq \tilde{\delta}_1 \quad \Longrightarrow \quad |V(x) - V(\xi)| \leq \varepsilon V(x). \tag{6.27}$$

For each $x \in \mathcal{G}\backslash\mathcal{A}$ let $\delta_1(x)$ be one-half the supremum over all $\tilde{\delta}_1 \leq 1$ such that (6.27) holds and, for $x \in \mathcal{A}$, let $\delta_1(x) = 0$. Then $\delta_1(\cdot)$ is bounded away from zero on compact subsets of $\mathcal{G}\backslash\mathcal{A}$. Suppose not. Then there exists a compact set $D \subset \mathcal{G}\backslash\mathcal{A}$, a sequence of points $x_i \in D$, and an accumulation point $x^* \in D$ such that $\delta_1(x_i) \to 0$ as $x_i \to x^*$ and

$$|V(z_i) - V(x_i)| > \varepsilon V(x_i), \tag{6.28}$$

where $z_i \in \{x_i\} + \delta(x_i)\overline{\mathcal{B}}$. Since $\delta(x_i) \to 0$ we may pick a subsequence (which we do not relabel) such that $\delta(x_i) < \frac{1}{i}$, which implies that $|z_i - x_i| \leq \frac{1}{i}$. Since $x^* \in D$, $V(x^*) > 0$. With the continuity of $V(\cdot)$, as $i \to \infty$, $|V(z_i) - V(x_i)| \to 0$ while

$$V(x_i) \to V(x^*) > 0,$$

which contradicts (6.28).

For every $x \in \mathcal{G}$ let $\delta_2(x)$ be the supremum over all $\hat{\delta} \leq 1$ such that $\{x\} + 2\hat{\delta}\overline{\mathcal{B}} \subset \mathcal{G}$. Since $\mathcal{G}$ is open, $\hat{\delta}$ always exists and satisfies $\hat{\delta} > 0$. Moreover $\delta_2(\cdot)$ is bounded away from zero on compact subsets of $\mathcal{G}$. Suppose not. Then there exists $D \subset \mathcal{G}$ compact and a sequence $\{x_i\}_{i=1}^\infty$ such that $x_i \in D$ and the sequence has an accumulation point $x^* \in D$ such that $\delta_2(x_i) \to 0$, and for each i there exists $z_i \in \{x_i\} + \frac{1}{2}\delta_2(x_i)\overline{\mathcal{B}}$ so that $z_i \notin \mathcal{G}$. We pick a subsequence (without relabeling) such that $\delta(x_i) < \frac{1}{2i}$. Since $\mathcal{G}$ is open and $D \subset \mathcal{G}$ is compact, x^* is in the interior of $\mathcal{G}$, and consequently, for i sufficiently large, $\{x^*\} + \frac{1}{i}\overline{\mathcal{B}} \subset \mathcal{G}$. Therefore, again for i sufficiently large, we see that

$$z_i \in \{x_i\} + \frac{1}{2i}\overline{\mathcal{B}} \subset \{x^*\} + \frac{1}{i}\overline{\mathcal{B}},$$

which is a contradiction.

For each $x \in \mathcal{G}$ we define

$$\delta(x) := \min\{\delta_1(x), \delta_2(x), |x|_{\mathcal{A}}\}$$

and note that $x \in \mathcal{A}$ implies $\delta(x) = 0$. That $\delta(\cdot)$ is bounded away from zero on compact subsets of $\mathcal{G}\backslash\mathcal{A}$ follows from the fact that $\delta_2(x)$ is bounded away from zero on compact subsets of $\mathcal{G}$ and that $\delta_1(x)$ and $|x|_{\mathcal{A}}$ are bounded away from zero on compact subsets of $\mathcal{G}\backslash\mathcal{A}$.

Let the function $\sigma : \mathcal{G} \to \mathbb{R}_{\geq 0}$ come from the application of Lemma 3.3 to the function $\delta(\cdot)$ on $\mathcal{G}\backslash\mathcal{A}$ and define $\sigma(x) = 0$ for $x \in \mathcal{A}$. The restriction of $\sigma(\cdot)$ to $\mathcal{G}\backslash\mathcal{A}$ is smooth and, for all $x \in \mathcal{G}\backslash\mathcal{A}$, $\sigma(x) > 0$, satisfying item 2 in Definition 2.3. Since $\delta(x) \leq |x|_{\mathcal{A}}$ for all $x \in \mathcal{G}$, it follows that $\sigma(\cdot)$ is continuous on $\mathcal{G}$. Since $\delta(x) \leq \delta_2(x)$, $\{x\} + \sigma(x)\overline{\mathcal{B}} \subset \mathcal{G}$ for all $x \in \mathcal{G}$, satisfying item 1 of Definition 2.3. It remains to check items 3 and 4 of Definition 2.3.

Since $\sigma(x) \leq \delta_1(x)$ for all $x \in \mathcal{G}\backslash\mathcal{A}$, we may write

$$V(\xi + \sigma(\xi)\overline{\mathcal{B}}) \leq (1+\varepsilon)V(\xi)\ . \tag{6.29}$$

Then, using the definition of $F_\sigma(x)$ in (2.2), the bound (6.29), the decrease (6.26), and (6.27) we may write, for $x \in \mathcal{G}\backslash\mathcal{A}$,

$$\begin{aligned}\max_{\substack{f\in F_\sigma(x)\\ f\in\mathcal{G}\backslash\mathcal{A}}} V(f) \;&\leq\; (1+\varepsilon) \max_{\substack{f\in F(x+\sigma(x)\overline{\mathcal{B}})\\ f\in\mathcal{G}\backslash\mathcal{A}}} V(f) \;\leq\; (1+\varepsilon)e^{-1} \max_{z\in\{x\}+\sigma(x)\overline{\mathcal{B}}} V(z)\\ &\leq\; (1+\varepsilon)^2 e^{-1} V(x). \qquad (6.30)\end{aligned}$$

We can see that (6.30) holds for all $x \in \mathcal{G}$ by considering the two remaining cases. First, suppose $x \in \mathcal{A}$; then, by the definition of $\mathcal{A}$ and the fact that $\sigma(x) = 0$ for $x \in \mathcal{A}$, $f \in \mathcal{A}$, (6.30) is trivially satisfied. Second, suppose $x \notin \mathcal{A}$ and $f \in \mathcal{A}$, then (6.30) is again satisfied since $0 \leq (1+\varepsilon)^2 e^{-1} V(x)$. Let $\lambda := (1+\varepsilon)^2 e^{-1} < 1$. From (6.30), we see that, for any $x \in \mathcal{G}$ and $\phi \in \mathcal{S}_\sigma(x)$, we may write

$$V(\phi(k,x)) \leq \lambda^k V(x) \quad \forall k \in \mathbb{Z}_{\geq 0}.$$

If $x \in \mathcal{A}$, then $V(x) = 0$ and, using (6.25), we may write, for any $\phi \in \mathcal{S}_\sigma(x)$,

$$\alpha_1(\omega_1(\phi(k,x))) \leq V(\phi(k,x)) \leq V(x)\lambda^k = 0 \quad \forall k \in \mathbb{Z}_{\geq 0},$$

which implies that $x \in \mathcal{A}_\sigma$; i.e.,

$$\sup_{k\in\mathbb{Z}_{\geq 0}, \phi\in\mathcal{S}_\sigma(x)} \omega_1(\phi(k,x)) = 0 \quad \forall x \in \mathcal{A}.$$

Furthermore, if $x \in \mathcal{A}_\sigma$, then $x \in \mathcal{A}$ as a consequence of $\mathcal{S}(x) \subseteq \mathcal{S}_\sigma(x)$. Consequently, $\mathcal{A} = \mathcal{A}_\sigma$ and item 3 of Definition 2.3 is satisfied.

Now, using the upper and lower $\mathcal{K}_\infty$ bounds (6.25) on the Lyapunov function we may write, for all $x \in \mathcal{G}$, $\phi \in \mathcal{S}(x)$, and $k \in \mathbb{Z}_{\geq 0}$,

$$\alpha_1(\omega_1(\phi(k,x))) \leq V(\phi(k,x)) \leq \lambda^k V(x) \leq \lambda^k \alpha_2(\omega_2(x)).$$

Inverting $\alpha_1(\cdot)$ we obtain

$$\omega_1(\phi(k,x)) \leq \alpha_1^{-1}\left(\alpha_2(\omega_2(x))\lambda^k\right) =: \beta_\sigma(\omega_2(x), k);$$

i.e., $x^+ \in F_\sigma(x)$ is $\mathcal{KL}$-stable with respect to (ω_1, ω_2) on $\mathcal{G}$, satisfying item 4 of Definition 2.3. Therefore $x^+ \in F(x)$ is robustly $\mathcal{KL}$-stable with respect to (ω_1, ω_2) on $\mathcal{G}$. ∎

7. Proof of Theorem 2.10. If we can demonstrate that there exists a continuous Lyapunov function, the result of Theorem 2.8 yields that the $\mathcal{KL}$-stability is robust. Toward this end, we will define a (Lyapunov) function that is similar to (6.2), with the only difference being that the solution set under consideration in (6.2) is for the perturbed difference inclusion $x^+ \in F_\sigma(x)$. Here, however, we are not assuming robust $\mathcal{KL}$-stability. Rather, we are assuming $\mathcal{KL}$-stability of $x^+ \in F(x)$ and continuity of $F(\cdot)$ on $\mathcal{G}\backslash\mathcal{A}$.

In particular, we apply Lemma 6.1, with $\lambda = 2$, to the function $\beta \in \mathcal{KL}$ defining the stability estimate in order to obtain functions $\alpha_1, \alpha_2 \in \mathcal{K}_\infty$ such that $\alpha_1(\beta(s,k)) \leq \alpha_2(s)e^{-2k}$ for all $(s,k) \in \mathbb{R}_{\geq 0} \times \mathbb{R}_{\geq 0}$. We define our Lyapunov function as

$$V(x) := \sup_{k \in \mathbb{Z}_{\geq 0}, \phi \in \mathcal{S}(x)} \alpha_1(\omega_1(\phi(k,x)))e^k \quad \forall x \in \mathcal{G}. \tag{7.1}$$

We can then obtain appropriate upper and lower bounds, the required decrease condition, upper semicontinuity of $V(\cdot)$ on $\mathcal{G}$, and continuity of $V(\cdot)$ on $\mathcal{A}$ by following the proof given in section 6.1. We note that the result of Claim 7 also holds. Therefore, in order to appeal to Theorem 2.8 it remains to show that $V(\cdot)$ as defined by (7.1) is lower semicontinuous on $\mathcal{G}\backslash\mathcal{A}$.

Lower semicontinuity of $V(\cdot)$ on $\mathcal{G}\backslash\mathcal{A}$: Let $x \in \mathcal{G}\backslash\mathcal{A}$. Appealing to Claim 7, there exists $\hat{\phi} \in \mathcal{S}(x)$ and $K(x) \in \mathbb{Z}_{\geq 0}$ such that

$$V(x) = \max_{k \in \{0,\ldots,K(x)\}} \alpha_1\left(\omega_1(\hat{\phi}(k,x))\right)e^k.$$

Let $\kappa \in \{0,\ldots,K(x)-1\}$ be the smallest integer such that $\hat{\phi}(\kappa+1,x) \in \mathcal{A}$ or, if $\hat{\phi}(k,x) \in \mathcal{G}\backslash\mathcal{A}$ for all $k \in \{0,\ldots,K(x)\}$, let $\kappa = K(x)$. We see that

$$\max_{k \in \{0,\ldots,K(x)\}} \alpha_1\left(\omega_1(\hat{\phi}(k,x))\right)e^k = \max_{k \in \{0,\ldots,\kappa\}} \alpha_1\left(\omega_1(\hat{\phi}(k,x))\right)e^k$$

since, if $K(x) \neq \kappa$, then $\hat{\phi}(k,x) \in \mathcal{A}$ for $k \in \{\kappa,\ldots,K(x)\}$, which implies that, for those k, $\omega_1(\hat{\phi}(k,x)) = 0$.

Since $F(\cdot)$ is continuous on $\mathcal{G}\backslash\mathcal{A}$ and since $\hat{\phi}(k,x) \in \mathcal{G}\backslash\mathcal{A}$ for all $k \in \{0,\ldots,\kappa\}$, given any $\varepsilon > 0$, Lemma 5.2 yields a $\delta > 0$ such that, for any $\bar{x} \in \{x\} + \delta\overline{\mathcal{B}}$, there exists a solution $\psi \in \mathcal{S}(\bar{x})$ such that we may write

$$\begin{aligned}
V(x) &= \max_{k \in \{0,\ldots,\kappa\}} \alpha_1\left(\omega_1(\hat{\phi}(k,x))\right)e^k \\
&\leq \max_{k \in \{0,\ldots,\kappa\}} \alpha_1\left(\omega_1(\psi(k,\bar{x}))\right)e^k \\
&\quad + \max_{k \in \{0,\ldots,\kappa\}} \left|\alpha_1\left(\omega_1(\hat{\phi}(k,x))\right) - \alpha_1\left(\omega_1(\psi(k,\bar{x}))\right)\right|e^k \\
&\leq \sup_{k \in \mathbb{Z}_{\geq 0}} \alpha_1\left(\omega_1(\psi(k,\bar{x}))\right)e^k + \varepsilon \\
&\leq V(\bar{x}) + \varepsilon.
\end{aligned}$$

Therefore, $V(\cdot)$ is lower semicontinuous at x; i.e., $\liminf_{z \to x} V(z) \geq V(x)$. ∎

8. Proof of Claim 1. In order to simplify the presentation, we define

$$V^+(x) := \sup_{f \in F(x)} V(f) \quad \forall x \in \mathcal{G}.$$

We will use W_1^+ and W^+ for the same purpose.

Let $g \in \mathcal{K}_\infty$ be such that $g'(\cdot)$ is nondecreasing, $g'(s) \geq 1$ for all $s \geq 0$, and such that there exists $\gamma \in \mathcal{K}_\infty$ such that

$$\alpha(s)\,(\exp(g(s)) - 1) \geq \gamma(s) \quad \forall s \geq 0.$$

We define $\rho(s) := \exp(g(s)) - 1$ and note that

$$\rho'(s) = (\rho(s) + 1)\, g'(s) \geq \rho(s)\ .$$

The equality shows that $\rho'(\cdot)$ is nondecreasing, so that, by the mean value theorem,

$$\rho(V^+(x)) - \rho(V(x)) \leq \rho'(V^+(x))[V^+(x) - V(x)] \quad \forall x \in \mathcal{G}.$$

For all $x \in \mathcal{G}$ we define $W_1(x) := \rho(V(x))$. It is obvious that $W_1(x) = 0$ if and only if $x \in \mathcal{A}$. For all $s \geq 0$ let $\mu(s) := \frac{1}{2}\min\left\{s, \gamma \circ \rho^{-1}(s)\right\}$ so that $\mu \in \mathcal{K}_\infty$. With this definition we observe that $(\mathrm{Id} - \mu) \in \mathcal{K}_\infty$. Now, for every $x \in \mathcal{G}$ either $\rho(V^+(x)) \leq \frac{1}{2}\rho(V(x))$ or $\rho(V^+(x)) \geq \frac{1}{2}\rho(V(x))$. In the first case

$$W_1^+(x) := \rho(V^+(x)) \leq \frac{1}{2}\rho(V(x)) = \frac{1}{2}W_1(x) \leq W_1(x) - \mu(W_1(x)), \tag{8.1}$$

while, in the latter case, we may write

$$\begin{aligned} W_1^+(x) - W_1(x) &= \rho(V^+(x)) - \rho(V(x)) \leq \rho'(V^+(x))\left[V^+(x) - V(x)\right] \\ &\leq -\rho'(V^+(x))\alpha(V(x)) \leq -\rho(V^+(x))\alpha(V(x)) \\ &\leq -\frac{1}{2}\rho(V(x))\alpha(V(x)) \leq -\frac{1}{2}\gamma(V(x)) \\ &= -\frac{1}{2}\gamma \circ \rho^{-1}(W_1(x)) \leq -\mu(W_1(x))\ . \end{aligned} \tag{8.2}$$

Combining (8.1) and (8.2) we have $W_1^+(x) \leq W_1(x) - \mu(W_1(x))$ for all $x \in \mathcal{G}$.

We require the following lemma, which appeared as [9, Lemma 2.4].

LEMMA 8.1. *If $\ell > 1$ and $\varphi \in \mathcal{K}_\infty$ satisfies $(\varphi - \mathrm{Id}) \in \mathcal{K}_\infty$, then there exists $\tilde{\alpha} \in \mathcal{K}_\infty$ such that $\tilde{\alpha} \circ \varphi(s) = \ell\tilde{\alpha}(s)$ for all $s \geq 0$.*

Define $\varphi \in \mathcal{K}_\infty$ as $\varphi(s) := (\mathrm{Id} - \mu)^{-1}(s)$ for all $s \geq 0$. We note that $\varphi(\cdot)$ is well defined by virtue of $(\mathrm{Id} - \mu) \in \mathcal{K}_\infty$. From the definition of $\varphi(\cdot)$ we see that, for all $s \geq 0$, $s - \varphi^{-1}(s) = \mu(s)$ or, equivalently, $\varphi(s) - s = \mu \circ \varphi(s)$. Therefore, $(\varphi - \mathrm{Id}) \in \mathcal{K}_\infty$. Let $\ell = e^1 > 1$ and let $\tilde{\alpha} \in \mathcal{K}_\infty$ come from Lemma 8.1. For all $x \in \mathcal{G}$ we define $W(x) := \tilde{\alpha}(W_1(x))$. We may then write

$$\begin{aligned} W^+(x) &= \tilde{\alpha}(W_1^+(x)) \leq \tilde{\alpha}\left(W_1(x) - \mu(W_1(x))\right) \\ &= \tilde{\alpha}(\varphi^{-1}(W_1(x))) = e^{-1}\tilde{\alpha}(W_1(x)) = e^{-1}W(x) \quad \forall x \in \mathcal{G}. \end{aligned}$$

Finally, we define the functions $\hat{\alpha}_1, \hat{\alpha}_2 \in \mathcal{K}_\infty$ by $\hat{\alpha}_1 := \tilde{\alpha} \circ \rho \circ \alpha_1$ and $\hat{\alpha}_2 := \tilde{\alpha} \circ \rho \circ \alpha_2$ so that (2.9) holds. ∎

STATIONARY FILTER FOR CONTINUOUS-TIME MARKOVIAN JUMP LINEAR SYSTEMS*

MARCELO D. FRAGOSO† AND NEI C. S. ROCHA‡

Abstract. We derive a stationary filter for the best linear mean square filter (BLMSF) of continuous-time Markovian jump linear systems (MJLS). It amounts here to obtain the convergence of the error covariance matrix of the BLMSF to a stationary value under the assumption of mean square stability of the MJLS and ergodicity of the associated Markov chain θ_t. It is shown that there exists a unique solution for the stationary Riccati filter equation, and this solution is the limit of the error covariance matrix of the BLMSF. The advantage of this scheme is that it is easy to implement since the filter gain can be performed offline, leading to a linear time-invariant filter.

Key words. Kalman filter, Riccati equation, jump systems, Markov parameters

1. Introduction.

Markovian jump linear systems (MJLS) have been the subject of extensive research over the last few years, and the associated literature is now fairly extensive (see, e.g., [2], [4], [5], [10], [11], [12], [13], [16], [17], [18], [19], [20], [21], [22], [23], [24], [25], [26], [27], [28], [29], [30], [35], [36], [43], [44], [50], and references therein). Since its inception, this class of models has an intimate connection with systems which are vulnerable to abrupt changes in their structure, which includes, for instance, safety-critical and high-integrity systems (e.g., aircraft, chemical plants, nuclear power station, robotic manipulator systems, large scale flexible structures for space stations such as antenna, solar arrays, etc.). This, in turn, has led to applications in a variety of fields (see, e.g., [3], [12], [21], [22], [33], [34], [39], [42], [44], [1], [48], [49], [51], and references therein), which illustrate the breadth of possibilities of applications of MJLS. For instance, it is said in [48] that the results achieved by MJLS, when applied to the synthesis problem of wing deployment of an uncrewed air vehicle, were quite encouraging.

Filtering theory has been widely celebrated as a great achievement in stochastic systems theory and is of fundamental importance in application. The appearance of seminal papers such as [8], [9], [32], [40], and [53] gave an enormous impetus to the theory. Although the theoretical machinery available to deal with nonlinear estimation problems is by now rather considerable (see, e.g., [37] for an overview of the classical results and [15] for a nice introduction), there are yet many challenging questions in this area. One of these is the fact that the description of the optimal nonlinear filter can rarely be given in terms of a closed finite system of stochastic differential equations, i.e., the so-called finite filters; the exceptions are, for instance, the classical

Kalman filter, those described in [52], and Benes' class. More recently, the concept of estimation algebra, proposed initially in [7], has been used to enlarge this class in [55]. Unfortunately, this is what happens with the optimal nonlinear filter for our MJLS model (see, e.g., [45]). In view of this, the best linear mean square filter (BLMSF) for our MJLS model has been derived in [30]. This filter provides some of the desirable features of the Kalman filter.

With some simplifications in the MJLS model, finite filters have been derived. For instance, with the simplification that the observation process is not fed by the state, in [2] a finite filter is derived. Another finite-dimensional related paper is [53], but here the variable to be estimated is just the Markov chain (the state variable is assumed accessible). In the nonlinear setting, this problem has been studied in [56] for a small noise observation scenario, without requiring knowledge of the generator of the Markov chain, and asymptotic optimality is proved. See also, e.g., [19], [20], [23], [24], [51], and references therein, for some recent related results. For the case in which the associated Markov chain is assumed to be accessible, i.e., the operation mode is known for every $t \geq 0$, H_∞ filtering and the robust Kalman filtering for uncertain MJLS (including the time-lag case) has been studied, for instance, in [17], [18], [41], and [47].

In this paper, we make a further foray into the problem of linear estimation for the class of MJLS. The BLMSF derived in [30] is a function of the error covariance matrix whose dynamics is governed by two matrix differential equations: one associated with the second moment of the state variable and the other associated with the second moment of the estimator. Our aim here is to work out a certain matrix Riccati differential equation for the error covariance matrix of the BLMSF and show that the unique solution of this matrix Riccati differential equation converges to the unique solution of an algebraic Riccati equation, under the hypotheses of mean square stability of the system and ergodicity of the Markovian process θ_t. In the spirit of the Kalman filter theory, when using the algebraic Riccati equation, instead of the differential Riccati equation, for the BLMSF, we call this filter the stationary BLMSF. In addition to interest in its own right, it is a well-known fact that stationary filters have, *prima facie*, the desirable advantage of being easier to implement. Finally, the discrete-time counterpart of our problem was already contemplated in [13] and has inspired our work.

A brief outline of the content of this paper is as follows. In section 2, we fix the notation and recall a few notions and facts which can be found in [14]. The MJLS model is described in section 3. A Riccati-like differential equation for the BLMSF is derived in section 4. Finally, an asymptotic analysis is carried out in section 5.

2. Notation and preliminaries. We shall denote by $\mathbb{R}^n$ the n-dimensional Euclidean space and by $\mathbb{B}(\mathbb{R}^n, \mathbb{R}^m)$ the normed bounded linear space of all $m \times n$ matrices with $\mathbb{B}(\mathbb{R}^n) := \mathbb{B}(\mathbb{R}^n, \mathbb{R}^n)$. For $L \in \mathbb{B}(\mathbb{R}^n)$, L' will indicate the transpose of L. As usual, $L \geq 0\,(L > 0)$ will mean that the symmetric matrix $L \in \mathbb{B}(\mathbb{R}^n)$ is positive semidefinite (positive definite), respectively. In addition, we set $\mathbb{B}(\mathbb{R}^n)^+ := \{L \in \mathbb{B}(\mathbb{R}^n); L = L' \geq 0\}$. We use $\mathbb{R}^+$ to denote the interval $[0, \infty)$, and by $L \otimes K \in \mathbb{B}(\mathbb{R}^{sn}, \mathbb{R}^{rm})$ we mean the Kronecker product for any $L \in \mathbb{B}(\mathbb{R}^s, \mathbb{R}^r)$ and $K \in \mathbb{B}(\mathbb{R}^n, \mathbb{R}^m)$. We recall also that for $L \in \mathbb{B}(\mathbb{R}^n)$ and $K \in \mathbb{B}(\mathbb{R}^m)$ the Kronecker sum is defined as $L \oplus K := L \otimes I_m + I_n \otimes K \in \mathbb{B}(\mathbb{R}^{nm})$ (see, e.g., [6]). For $D_i \in \mathbb{B}(\mathbb{R}^n)$, $i = 1, \ldots, N$, $\mathrm{diag}(D_i)$ stands for an $Nn \times Nn$ matrix, where the matrices D_i are put together corner-to-corner diagonally, with all the other entries being zero, and $1_{\{\cdot\}}$ for the Dirac measure. In addition, we denote by $\mathrm{Re}\{\lambda_i(\mathcal{T})\}$ the real part of the eigenvalue

$\lambda_i(\mathcal{T})$ of the operator $\mathcal{T}$ and write generically $\mathrm{Re}\{\lambda(\mathcal{T})\} < 0$ if all its eigenvalues have real part less than zero. Furthermore, $\mathbb{H}^{n,m}$ represents the linear space composed of all sequences of N matrices $V = (V_1, \ldots, V_N)$ with $V_i \in \mathbb{B}(\mathbb{R}^n, \mathbb{R}^m)$, for $i = 1, \ldots, N$, and, for simplicity, we define $\mathbb{H}^n := \mathbb{H}^{n,n}$. Also, we shall define $\mathbb{H}^{n+} := \{V = (V_1, \ldots, V_N);$ $V_i \geq 0$ for $i = 1, \ldots, N\}$. Finally, we shall write, for $V = (V_1, \ldots, V_N) \in \mathbb{H}^n$ and $S = (S_1, \ldots, S_N) \in \mathbb{H}^n$, that $V \geq S$ if $V - S = (V_1 - S_1, \ldots, V_N - S_N) \in \mathbb{H}^{n^+}$, and that $V > S$ if $V_i - S_i > 0$ for $i = 1, \ldots, N$.

As usual, we define $\mathcal{H} := L_2(\Omega, \mathcal{F}, \mathbb{P})$, the Hilbert space of all square integrable r.v.'s in the probability space $(\Omega, \mathcal{F}, \mathbb{P})$, equipped with the inner product $\langle x, y\rangle = Ex'y$. Convergence here will be in the *quadratic mean* (q.m.) sense, i.e., a sequence $\{x(n)\}$ converges to x if $\|x(n) - x\|_2 \to 0$. We define also $\mathcal{H}_0 = \{x \in \mathcal{H} | Ex = 0\}$, the closed subspace of all centered r.v.'s of $\mathcal{H}$ and therefore a Hilbert space. In addition, $x \in \mathcal{H}$ and $y \in \mathcal{H}$ are said to be *orthogonal* (from now on $x \perp y$) if $\langle x, y\rangle = 0$.

For any stochastic process $y(t) \in \mathcal{H}_0$, we define $\mathcal{H}_t^y := \mathcal{L}\{y(s),\ 0 \leq s \leq t\}$, the space of all linear combinations $\sum_i \alpha_i y(t_i)$, where $t_i < t$ and q.m. limits of these combinations (a closed subspace) such that $\mathcal{H}_s^y \subset \mathcal{H}_t^y \subset \mathcal{H}^y := \mathcal{H}_\infty^y$ for $s \leq t$. We recall that if $\{y(t)\}$ is q.m. continuous, then $\mathcal{H}^y$ is a separable Hilbert space, and as a fundamental property of a Hilbert space, any $z \in \mathcal{H}_0$ has a unique decomposition (cf. [14, p. 45]), $z = \hat{z} + \tilde{z}$, where $\hat{z} = \mathfrak{P}_t^y z \in \mathcal{H}_t^y$ and $\tilde{z} \perp \mathcal{H}_t^y$, where $\mathfrak{P}_t^y$ denotes the *projection operator* which projects each element of $\mathcal{H}_0$ onto $\mathcal{H}_t^y$. Moreover, we have the following properties (cf. [14, p. 45]): (i) $\|z - \mathfrak{P}_t^y z\| = \min_{y \in \mathcal{H}_t^y} \|z - y\|$, and therefore $\hat{z} = \mathfrak{P}_t^y z$ is the linear minimum mean square error estimator of z given $\mathcal{H}_t^y$, i.e., the best linear estimator is the projection of z onto $\mathcal{H}_t^y$; (ii) $\tilde{z} = z - \hat{z} \perp \mathcal{H}_t^y$.

3. The model. Let $(\Omega, \mathcal{F}, \{\mathcal{F}_t\}_{t \in \mathbb{R}^+}, \mathbb{P})$ be a stochastic basis (a complete probability space, carrying its natural filtration $\{\mathcal{F}_t\}_{t \in \mathbb{R}^+}$) on which all the processes in this work are defined. Let us consider the class of hybrid dynamical systems modeled by the following MJLS:

$$dx(t) = A_{\theta_t} x(t) dt + C_{\theta_t} dw_0(t), \quad x(0) = x, \quad t \in \mathbb{R}^+, \tag{3.1}$$

$$dy(t) = H_{\theta_t} x(t) dt + G_{\theta_t} dw(t), \quad y(0) = 0, \tag{3.2}$$

where $\{x(t)\}$ denotes the state vector in $\mathbb{R}^n$ (*signal process*), and $\{y(t)\}$ denotes the output process in $\mathbb{R}^m$, which generates the observational information that is available at time t, i.e., $\mathcal{H}_t^y$. Furthermore, we assume the following:

(A1) $\theta = \{(\theta_t,\ \mathcal{F}_t),\ t \in \mathbb{R}^+\}$ is a nonobserved homogeneous Markov process with right continuous trajectories and taking values on the finite set $\mathcal{S} := \{1, 2, \ldots, N\}$. We assume the following:

$$P(\theta_{t+h} = j \mid \theta_t = i) = \begin{cases} \lambda_{ij} h + o(h), & i \neq j, \\ 1 + \lambda_{ii} h + o(h), & i = j, \end{cases}$$

where $\Lambda := [(\lambda_{ij})]$ is the stationary $N \times N$ transition rate matrix of $\{\theta_t\}$ with $\lambda_{ij} > 0$, $i \neq j$, and $\lambda_i = -\lambda_{ii} = \sum_{j\,:\,j \neq i} \lambda_{ij} < \infty$, i.e., the process is supposed to be conservative (see, e.g., [38]). In addition, defining $p_{ij}(t) = P(\theta_{t+s} = j \mid \theta_s = i)$ and $p_i(t) = P(\theta_t = i)$ for $i, j = 1, \ldots, N$ and denoting $\mathbf{P}(t) := [p_{ij}(t)]$ and $\mathbf{p}(t) := (p_1(t), \ldots, p_N(t))'$, it is well known, under the hypothesis of the homogeneity of the process $\theta = \{(\theta_t,\ \mathcal{F}_t),\ t \in \mathbb{R}^+\}$, that $\frac{d}{dt}\mathbf{P}(t) = \mathbf{P}(t)\Lambda$, $\mathbf{P}(0) = I$, and $\frac{d}{dt}\mathbf{p}(t) = \Lambda'\mathbf{p}(t)$. Moreover, we assume that $\{(\theta_t, \mathcal{F}_t), t \in \mathbb{R}^+\}$ has initial distribution $\{v(i); i = 1, \ldots, N\}$.

(A2) $\mathcal{W}_0 = \{(w_0(t), \mathcal{F}_t),\ t \in \mathbb{R}^+\}$ and $\mathcal{W} = \{(w(t), \mathcal{F}_t),\ t \in \mathbb{R}^+\}$ are statistically mutually independent Wiener processes in $\mathbb{R}^r$ and $\mathbb{R}^p$, respectively.

(A3) $x1_{\{\theta_0=i\}}$, $i = 1, \dots, N$, are second order *r.v.*'s with $E[x1_{\{\theta_0=i\}}] = \mu_i$ and $E[xx'1_{\{\theta_0=i\}}] = V_i$.

(A4) $x(0)$ and $\{\theta_t\}$ are independent of $\{w_0(t)\}$ and $\{w(t)\}$.

(A5) $G_iG_i' > 0$ for $i = 1, \dots, N$.

In addition, notice that A_{θ_t}, C_{θ_t}, H_{θ_t}, and G_{θ_t} are random matrices such that, for $\theta_t = i$, $i \in \mathcal{S}$, they assume the values $A_i \in \mathbb{B}(\mathbb{R}^n)$, $C_i \in \mathbb{B}(\mathbb{R}^r, \mathbb{R}^n)$, $H_i \in \mathbb{B}(\mathbb{R}^n, \mathbb{R}^m)$, and $G_i \in \mathbb{B}(\mathbb{R}^p, \mathbb{R}^m)$, respectively.

4. The Riccati differential equation (RDE). In order to derive the stationary filter for (3.1)–(3.2), we need first to work out a Riccati differential equation for the main result concerning the best linear mean square filter obtained in [30]. First, define $z_i(t) := x(t)1_{\{\theta_t=i\}} \in \mathbb{R}^n$, $z(t) := (z_1(t)', \dots, z_N(t)')' \in \mathbb{R}^{Nn}$, $\hat{z}_i(t) := \mathfrak{P}_t^y z_i(t)$, $\hat{z}(t) := (\hat{z}_1(t)', \dots, \hat{z}_N(t)')'$, $\tilde{z}_i(t) := z_i(t) - \hat{z}_i(t)$, $\tilde{z}(t) := (\tilde{z}_1(t)', \dots, \tilde{z}_N(t)')' = z(t) - \hat{z}(t)$, and $\mathcal{P}(t) := E[\tilde{z}(t)\tilde{z}(t)']$. Furthermore, $Z(t) := \operatorname{diag}(Z_i(t))$ with $Z_i(t) := E[z_i(t)z_i(t)'] \in \mathbb{B}(\mathbb{R}^n)$, $\mathcal{Z}_t := (Z_1(t), \dots, Z_N(t)) \in \mathbb{H}^n$, and $\hat{Z}(t) := E[\widehat{z}(t)\widehat{z}(t)']$. With these definitions, we clearly have $x(t) = \sum_{i=1}^N z_i(t)$, $\hat{x}(t) := \mathfrak{P}_t^y x(t) = \sum_{i=1}^N \hat{z}_i(t)$, and $\tilde{x}(t) = x(t) - \hat{x}(t) = \sum_{i=1}^N [z_i(t) - \hat{z}_i(t)] = \sum_{i=1}^N \tilde{z}_i(t)$.

In addition, we shall be using the notation

$$\mathcal{A} := \Lambda' \otimes I_n + \operatorname{diag}(A_i) \quad \in \quad \mathbb{B}(\mathbb{R}^{Nn}), \tag{4.1}$$

$$H := [H_1, \dots, H_N] \quad \in \quad \mathbb{B}\big(\mathbb{R}^{Nn}, \mathbb{R}^m\big), \tag{4.2}$$

$$G_t^p := [\sqrt{p_1(t)}G_1, \dots, \sqrt{p_N(t)}G_N] \quad \in \quad \mathbb{B}\big(\mathbb{R}^{Np}, \mathbb{R}^m\big) \tag{4.3}$$

so that

$$0 < G_t^p G_t^{p\prime} = \sum_{j=1}^N G_j G_j' p_j(t) \in \mathbb{B}(\mathbb{R}^m).$$

Define also the innovations process $\{\nu(t)\}$ as

$$\nu(t) := y(t) - \int_0^t \hat{m}(s)\, ds,$$

where $\hat{m}(t) = \mathfrak{P}_t^y[H_{\theta_t}x(t)] = \sum_{i=1}^N H_i\hat{z}_i(t)$, or

$$d\nu(t) = dy(t) - H\hat{z}(t)\, dt.$$

THEOREM 4.1. *For system* (3.1)–(3.2)*, the best linear mean square estimator* $\hat{x}(t)$ *is given by the following filter:*

$$\hat{x}(t) = \sum_{i=1}^N \hat{z}_i(t),$$

where

$$d\widehat{z}(t) = \mathcal{A}\widehat{z}(t)\, dt + \mathcal{P}(t)H'(G_t^pG_t^{p\prime})^{-1}d\nu(t), \tag{4.4}$$

$$\widehat{z}(0) = \mu := (\mu_1', \dots, \mu_N')', \tag{4.5}$$

with

$$\mathcal{P}(t) := Z(t) - \hat{Z}(t) \in \mathbb{B}(\mathbb{R}^{Nn})^+,$$

where

$$\dot{Z}_i(t) = A_i Z_i(t) + Z_i(t)A_i' + \sum_{j=1}^{N} Z_j(t)\lambda_{ji} + C_i C_i' p_i(t), \tag{4.6}$$

$$Z_i(0) = V_i \geq 0, \quad i = 1, \ldots, N, \tag{4.7}$$

and

$$\begin{aligned}\dot{\hat{Z}}(t) = {} & \overline{\mathcal{A}}\hat{Z}(t) + \hat{Z}(t)\overline{\mathcal{A}}' + \hat{Z}(t)H'(G_t^p G_t^{p\prime})^{-1}H\hat{Z}(t) \\ & + Z(t)H'(G_t^p G_t^{p\prime})^{-1}HZ(t)\end{aligned} \tag{4.8}$$

with $\hat{Z}(0) = \mu\mu'$, *and*

$$\overline{\mathcal{A}} = \mathcal{A} - Z(t)H'(G_t^p G_t^{p\prime})^{-1}H. \tag{4.9}$$

Proof. See Theorem 4.1 in [30]. □

Notice that in (4.4) the term $\mathcal{P}(t)$ is obtained as the difference of two terms $(Z(t) - \hat{Z}(t))$ which are derived via (4.6) and (4.8). Our first step then is to obtain a Riccati differential equation for $\mathcal{P}(t)$ as follows.

LEMMA 4.2. *$\mathcal{P}(t)$ satisfies the following matrix Riccati differential equation:*

$$\begin{aligned}\dot{\mathcal{P}}(t) &= \mathcal{A}\mathcal{P}(t) + \mathcal{P}(t)\mathcal{A}' - \mathcal{P}(t)H'(G_t^p G_t^{p\prime})^{-1}H\mathcal{P}(t) + \mathcal{C}_t\mathcal{C}_t' + \mathcal{V}(\mathcal{Z}_t), \\ \mathcal{P}(0) &= \mathcal{P}_0 \geq 0,\end{aligned} \tag{4.10}$$

with $\mathcal{C}_t := \operatorname{diag}(\sqrt{p_i(t)}C_i)$, $\mathcal{Z}_t := (Z_1(t), \ldots, Z_N(t))$, *where* $Z_i(t)$ *is solution of* (4.6), *and* $\mathcal{V}(\mathcal{Z}_t)$ *is defined by*

$$\begin{aligned}\mathcal{V}(\mathcal{Z}_t) := {} & \begin{bmatrix} \sum_{j=1}^N Z_j(t)\lambda_{j1} & \cdots & 0 \\ \vdots & \ddots & \vdots \\ 0 & \cdots & \sum_{j=1}^N Z_j(t)\lambda_{jN} \end{bmatrix} \\ & - (\Lambda' \otimes I_n)Z(t) - Z(t)(\Lambda' \otimes I_n)'.\end{aligned} \tag{4.11}$$

Moreover, $\mathcal{V}(\mathcal{Z}_t) \geq 0$ *and is a linear operator.*

Proof. Let us first prove that $\mathcal{V}(.)$ is a linear operator and $\mathcal{V}(\mathcal{Z}_t) \geq 0$. For any $\mathcal{Q} = (Q_1, \ldots, Q_N) \in \mathbb{H}^{n+}$, $\mathcal{R} = (R_1, \ldots, R_N) \in \mathbb{H}^{n+}$, α and $\beta \in \mathbb{R}$, it is straightforward to show that $\mathcal{V}(\alpha\mathcal{Q} + \beta\mathcal{R}) = \alpha\mathcal{V}(\mathcal{Q}) + \beta\mathcal{V}(\mathcal{R})$. Now, defining $d\mathcal{D}_t = \left[x(t)'d(1_{\{\theta_t=1\}}) \cdots x(t)'d(1_{\{\theta_t=N\}})\right]' \in \mathbb{R}^{Nn}$, one can show that $E[d\mathcal{D}_t d\mathcal{D}_t'] = \mathcal{V}(\mathcal{Z}_t)\,dt$, by using Lemma 4.3 in [29]. Then, for any constant vector $v \in \mathbb{R}^{Nn}$,

$$\begin{aligned}v'\mathcal{V}(\mathcal{Z}_t)v\,dt &= v'E\left[d\mathcal{D}_t d\mathcal{D}_t'\right]v \\ &= E\left[\left\|d\mathcal{D}_t'v\right\|^2\right] \\ &\geq 0\end{aligned}$$

and therefore $\mathcal{V}(\mathcal{Z}_t) \geq 0$. Now, by the definition of $Z(t)$, we have

$$\begin{aligned}\dot{Z}(t) = {} & [\operatorname{diag}(A_i)]Z(t) + Z(t)[\operatorname{diag}(A_i)]' + \mathcal{C}_t\mathcal{C}_t' \\ & + \begin{bmatrix} \sum_{j=1}^N Z_j(t)\lambda_{j1} & \cdots & 0 \\ \vdots & \ddots & \vdots \\ 0 & \cdots & \sum_{j=1}^N Z_j(t)\lambda_{jN}, \end{bmatrix},\end{aligned}$$

and bearing in mind the definition of $\mathcal{V}(\mathcal{Z}_t)$ and $\mathcal{A}$, we have

$$\dot{Z}(t) = \mathcal{A}Z(t) + Z(t)\mathcal{A}' + \mathcal{C}_t\mathcal{C}_t' + \mathcal{V}(\mathcal{Z}_t).$$

Now from (4.8) and (4.9), we have

$$\dot{\hat{Z}}(t) = \mathcal{A}\hat{Z}(t) + \hat{Z}(t)\mathcal{A}' + \big[Z(t) - \hat{Z}(t)\big]H'(G_t^pG_t^{p\prime})^{-1}H\big[Z(t) - \hat{Z}(t)\big].$$

Finally, bearing in mind that $\mathcal{P}(t) = Z(t) - \hat{Z}(t)$, we get

$$\dot{\mathcal{P}}(t) = \mathcal{A}\mathcal{P}(t) + \mathcal{P}(t)\mathcal{A}' - \mathcal{P}(t)H'(G_t^pG_t^{p\prime})^{-1}H\mathcal{P}(t) + \mathcal{C}_t\mathcal{C}_t' + \mathcal{V}(\mathcal{Z}_t),$$

which proves the lemma. □

In the next section we shall use the following definition of mean square stability.

DEFINITION 4.3. *A linear system with a Markovian jump parameter is mean square stable (MSS) if for any initial condition x_0 and initial distribution $\{v(i), i = 1, \dots, N\}$, there exist $q \in \mathbb{R}^n$ and $Q \in \mathbb{B}(\mathbb{R}^n)^+$ independent of x_0 such that*

(a) $\|E[x(t)] - q\| \longrightarrow 0$ *as* $t \longrightarrow \infty$;

(b) $\|E[x(t)x(t)'] - Q\| \longrightarrow 0$ *as* $t \longrightarrow \infty$.

Finally, we shall also need the following notation. Define the operators φ and $\hat{\varphi}$ in the following way: for $V = (V_1, \dots, V_N) \in \mathbb{H}^{n,m}$, with $V_i = (v_{i1}, \dots, v_{in})$, $v_{ij} \in \mathbb{R}^m$,

$$\varphi(V_i) = \begin{bmatrix} v_{i1} \\ \vdots \\ v_{in} \end{bmatrix} \in \mathbb{R}^{mn} \quad \text{and} \quad \hat{\varphi}(V) = \begin{bmatrix} \varphi(V_1) \\ \vdots \\ \varphi(V_N) \end{bmatrix} \in \mathbb{R}^{Nmn}.$$

Furthermore, for $v_i := \varphi(V_i)$ and $\mathfrak{V} := \hat{\varphi}(V)$, $i = 1, \dots, N$, we define

$$\hat{\varphi}^{-1}\begin{bmatrix} v_1 \\ \vdots \\ v_N \end{bmatrix} := \begin{bmatrix} \hat{\varphi}_1^{-1}(\mathfrak{V}) & \cdots & \hat{\varphi}_N^{-1}(\mathfrak{V}) \end{bmatrix} = \begin{bmatrix} \varphi^{-1}(v_1) & \cdots & \varphi^{-1}(v_N) \end{bmatrix}.$$

That is, φ is a mapping that stacks up the columns of a matrix from left to right and makes a long vector out of the matrix.

5. Asymptotic analysis of the RDE. In this section, we obtain our main result concerning the asymptotic behavior of the matrix Riccati differential equation (4.10). We shall show that, under the assumption of ergodicity of the process $\{\theta_t\}$ and of mean square stability of (3.1), the unique solution of the matrix Riccati differential equation (4.10) converges to the unique solution of an algebraic Riccati equation.

The main result reads as follows.

THEOREM 5.1. *Assume that system* (3.1) *is MSS, according to Definition* 4.3*, and $\{\theta_t\}$ is ergodic. Then for any $\mathcal{Z}_0 = (Z_1(0), \dots, Z_N(0)) \in \mathbb{H}^n$, with $Z_i(0) \geq 0$, $i = 1, \dots, N$, and $\mathcal{P}_0 \geq 0$ we have that $\mathcal{P}(t) \to \mathcal{P}$ exponentially fast with $\mathcal{P}$ the unique positive semidefinite solution of the algebraic Riccati equation (ARE):*

$$\mathcal{A}\mathcal{P} + \mathcal{P}\mathcal{A}' - \mathcal{P}H'(\mathcal{G}\mathcal{G}')^{-1}H\mathcal{P} + \mathcal{C}\mathcal{C}' + \mathcal{V}(\mathcal{Q}) = 0, \tag{5.1}$$

where $\mathcal{A} - \mathcal{P}H'(\mathcal{G}\mathcal{G}')^{-1}H$ *is a stable matrix,*

$$\mathcal{C} := \operatorname{diag}(\sqrt{\pi_i}C_i), \qquad \mathcal{G} := [\sqrt{\pi_1}G_1 \cdots \sqrt{\pi_N}G_N],$$

with $\{\pi_i; i = 1, \ldots, N\}$ *the limit distribution of* θ_t, $\mathcal{Q} := (Q_1, \ldots, Q_N)$, *with* Q_i *the limit of* $Z_i(t)$, *in the sense that* $\|Z_i(t) - Q_i\| \to 0$ *as* $t \to \infty$, *where* $Q_i = \hat{\varphi}_i^{-1}(-\mathcal{F}^{-1}\hat{\varphi}(\mathcal{R}_1, \ldots, \mathcal{R}_N))$ *with* $\mathcal{F} := \Lambda' \otimes I_{n^2} + \operatorname{diag}(A_i \oplus A_i)$ *and* $\mathcal{R}_i = C_i C_i' \pi_i$.

Proof. The idea of the proof runs as follows. First, notice that from Lemma 5.1 in [31], (4.10) has a unique positive semidefinite solution. We have to prove then, existence and uniqueness of a positive semidefinite solution, $\mathcal{P}$, for the algebraic Riccati equation (5.1). Now, proving that $\mathcal{P}(t) \to \mathcal{P}$ is tantamount to proving that there exist lower and upper bound functions $P_\star(t)$ and $P^\star(t)$ for $\mathcal{P}(t)$, i.e., $P_\star(t) \leq \mathcal{P}(t) \leq P^\star(t)$, and these functions squeeze asymptotically $\mathcal{P}(t)$ to $\mathcal{P}$.

From Proposition 5.7 of [29], if system (3.1) is MSS, then $\operatorname{Re}(\lambda(\mathcal{F})) < 0$, where $\mathcal{F} = \Lambda' \otimes I_{n^2} + \operatorname{diag}(A_i \oplus A_i)$. But from Proposition 4.3 of [29], if $\operatorname{Re}(\lambda(\mathcal{F})) < 0$, then $\operatorname{Re}(\lambda(\mathcal{A})) < 0$. Therefore, we conclude that matrix $\mathcal{A}$ in (4.10) is stable. Now, from Theorem 4.1 in [31] (see also Theorem 4.1 in [54]), it follows that there exists a unique positive semidefinite solution $\mathcal{P}$ to (5.1) and, furthermore, $\mathcal{A} - \mathcal{P}H'(\mathcal{G}\mathcal{G}')^{-1}H$ is stable.

Now, from Proposition 5.6 of [29], under the assumption of mean square stability of system (3.1), $\|Z_i(t) - Q_i\| \to 0$ as $t \to \infty$, where $Q_i = \hat{\varphi}_i^{-1}(-\mathcal{F}^{-1}\hat{\varphi}(\mathcal{R}_1, \ldots, \mathcal{R}_N))$ with $\mathcal{R}_i = C_i C_i' \pi_i$. In addition, notice that $\mathcal{V}(\mathcal{Z}_t) = \mathcal{V}(Z_1(t), \ldots, Z_N(t)) \to \mathcal{V}(Q_1, \ldots, Q_N) = \mathcal{V}(\mathcal{Q})$ as $t \to \infty$, with $\mathcal{V}(\mathcal{Z}_t)$ defined by (4.11), since $\mathcal{V}(\mathcal{Z}_t)$ is a linear bounded operator.

Finally, from Lemmas 6.1 and 6.4 in the appendix, there exist matrices $P_\star(t)$ and $P^\star(t)$ such that

$$P_\star(t) \leq \mathcal{P}(t) \leq P^\star(t)$$

and

$$\lim_{t\to\infty} P_\star(t) = \lim_{t\to\infty} P^\star(t) = \mathcal{P}$$

exponentially fast and, consequently, we have $\lim_{t\to\infty} \mathcal{P}(t) = \mathcal{P}$, which completes the proof. □

REMARK 1. *Bearing in mind that for the case in which there is no jump* ($N = 1$) *we have that* $\mathcal{V}(\mathcal{Q}) = 0$, *it is not difficult to show that in this case our filter reduces to the Kalman filter.*

REMARK 2. *Some preliminary simulations for the discrete-time case can be found in* [13]. *This includes some comparison with the IMM algorithm* (*the interacting multiple model algorithm*) *derived in* [4]. *However, for a better assessment of the full potentialities of our filter in applications, exhaustive simulations of adequate examples, and comparison with other approximation of the infinite-dimensional filter is required. For instance, it would be interesting to carry out exhaustive simulations in order to compare the nonstationary filter with the stationary one, and a certain PEM filter* (*polymorphic estimator filter*), *which can be found in* [51].

6. Appendix. We assume here the hypothesis of Theorem 5.1. In addition, we assume the results regarding existence and uniqueness of a positive semidefinite solution, $\mathcal{P}$, for the algebraic Riccati equation (5.1), including the fact that $\mathcal{A} - \mathcal{P}H'(\mathcal{G}\mathcal{G}')^{-1}H$ is stable.

In order to prove the following results we shall rewrite the matrix Riccati equation (4.10) in a more convenient way. Defining $T_t := \mathcal{P}(t)H'K_t^{-1}$ and $K_t := G_t^p G_t^{p\prime}$, (4.10) is given by

$$\dot{\mathcal{P}}(t) = (\mathcal{A} - T_t H)\,\mathcal{P}(t) + \mathcal{P}(t)\,(\mathcal{A} - T_t H)' + T_t K_t T_t' + \mathcal{C}_t\mathcal{C}_t' + \mathcal{V}(\mathcal{Z}_t),$$
$$\mathcal{P}(0) = E\big[\tilde{z}_0\tilde{z}_0'\big] \geq 0.$$

In addition, since the Markovian process $\{\theta_t\}$ is ergodic by the assumption, there exist limit probabilities $\{\pi_i;\ i = 1,\dots,N\}$, which do not depend upon the initial distribution, with $\sum_{i=1}^N \pi_i = 1$, satisfying the following inequalities:

$$\max_i |p_{ij}(t) - \pi_j| \leq \alpha e^{-\beta t} \quad \text{and} \quad \max_i |p_j(t) - \pi_j| \leq \alpha e^{-\beta t}$$

for some positive constants α and β; therefore, $p_{ij}(t) \to \pi_j$ and $p_j(t) \to \pi_j$, exponentially fast, as $t \to \infty$. Thus,

$$G_t^p = \Big[\sqrt{p_1(t)}G_1, \dots, \sqrt{p_N(t)}G_N\Big] \to [\sqrt{\pi_1}G_1, \dots, \sqrt{\pi_N}G_N] = \mathcal{G}$$

and

$$\mathcal{C}_t = \operatorname{diag}(\sqrt{p_i(t)}C_i) \to \operatorname{diag}(\sqrt{\pi_i}C_i) = \mathcal{C}.$$

So, as $t \to \infty$, we have $G_t^p G_t^{p\prime} \to \mathcal{G}\mathcal{G}'$ and $\mathcal{C}_t\mathcal{C}_t' + \mathcal{V}(\mathcal{Z}_t) \to \mathcal{C}\mathcal{C}' + \mathcal{V}(\mathcal{Q})$ exponentially fast.

LEMMA 6.1. *Let $P^\star(t)$ be the solution of the matrix differential equation given by*

$$\dot{P}^\star(t) = \mathfrak{A}P^\star(t) + P^\star(t)\mathfrak{A}' + T_\infty K_t T_\infty' + \mathcal{C}_t\mathcal{C}_t' + \mathcal{V}(\mathcal{Z}_t), \tag{6.1}$$
$$P^\star(0) = \mathcal{P}(0) = E\big[\tilde{z}_0\tilde{z}_0'\big] \geq 0,$$

where $\mathfrak{A} := \mathcal{A} - T_\infty H$, $T_\infty := \mathcal{P}H'K^{-1}$ with $\mathcal{P}$ a solution of (5.1), and $K := \mathcal{G}\mathcal{G}'$ with $\mathcal{G} := [\sqrt{\pi_1}G_1, \dots, \sqrt{\pi_N}G_N]$. Then $P^\star(t) \geq \mathcal{P}(t)$ for any $t \in [0,\infty)$ and $\lim_{t\to\infty} P^\star(t) = \mathcal{P}$.

Proof. Define $\tilde{P}^\star(t) := P^\star(t) - \mathcal{P}(t)$. Then

$$\dot{\tilde{P}}^\star(t) = \mathfrak{A}\tilde{P}^\star(t) + \tilde{P}^\star(t)\mathfrak{A}' + (T_t - T_\infty)\,K_t\,(T_t - T_\infty)', \tag{6.2}$$
$$\tilde{P}^\star(0) = 0.$$

Let $\Phi^\star(t,s)$ be the transition matrix associated with $\mathfrak{A}$, i.e., $\Phi^\star(t,s) = e^{\mathfrak{A}(t-s)}$. Then, the solution of (6.2) is given by

$$\tilde{P}^\star(t) = \int_0^t \Phi^\star(t,s)\,(T_s - T_\infty)\,K_s\,(T_s - T_\infty)'\,\Phi^\star(t,s)'\,ds.$$

Since $K_t > 0$ for all $t \in [0,\infty)$, we have $\tilde{P}^\star(t) \geq 0$ and, consequently, $P^\star(t) \geq \mathcal{P}(t)$. Now, let us consider the solution of (6.1). Defining $\mathcal{W}(t) := T_\infty K_t T_\infty' + \mathcal{C}_t\mathcal{C}_t' + \mathcal{V}(\mathcal{Z}_t)$, we get from (6.1)

$$P^\star(t) = \Phi^\star(t,0)\mathcal{P}(0)\Phi^\star(t,0)' + \int_0^t \Phi^\star(t,s)\mathcal{W}(s)\Phi^\star(t,s)'\,ds. \tag{6.3}$$

Since $\mathfrak{A}$ is stable, $\Phi^\star(t,0) = e^{\mathfrak{A}t} \to 0$ as $t \to \infty$. Defining

$$\mathcal{I}(t) := \int_0^t \Phi^\star(t,s)\mathcal{W}(s)\Phi^\star(t,s)'\,ds,$$

it is clear that $\lim_{t\to\infty} P^\star(t)$ exists if and only if $\lim_{t\to\infty}\mathcal{I}(t)$ exists. Now we shall show that this limit does exist. First observe that

$$\begin{aligned}\frac{\partial}{\partial s}\left[\Phi^\star(t,s)\mathcal{W}(s)\Phi^\star(t,s)'\right] &= -\mathfrak{A}\Phi^\star(t,s)\mathcal{W}(s)\Phi^\star(t,s)' \\ &\quad + \Phi^\star(t,s)\dot{\mathcal{W}}(s)\Phi^\star(t,s)' \\ &\quad - \Phi^\star(t,s)\mathcal{W}(s)\Phi^\star(t,s)'\mathfrak{A}'.\end{aligned} \tag{6.4}$$

Integrating both sides of (6.4), we have

$$\mathfrak{A}\mathcal{I}(t) + \mathcal{I}(t)\mathfrak{A}' = \Phi^\star(t,0)\mathcal{W}(0)\Phi^\star(t,0)' + \int_0^t \Phi^\star(t,s)\dot{\mathcal{W}}(s)\Phi^\star(t,s)'\,ds - \mathcal{W}(t). \tag{6.5}$$

Since $\Phi^\star(t,0)\to 0$ and $\mathcal{W}(t)\to T_\infty K T_\infty' + \mathcal{C}\mathcal{C}' + \mathcal{V}(\mathcal{Q})$ as $t\to\infty$, it follows that $\lim_{t\to\infty}\mathcal{I}(t)$ exists if and only if $\lim_{t\to\infty}\int_0^t \Phi^\star(t,s)\mathcal{W}(s)\Phi^\star(t,s)'\,ds$ exists. To show that this limit does exist, first observe that

$$\begin{aligned}\left\|\int_0^t e^{\mathfrak{A}(t-s)}\dot{\mathcal{W}}(s)e^{\mathfrak{A}'(t-s)}\,ds\right\| &\le \mu^2\int_0^t e^{-2\alpha(t-s)}\|\dot{\mathcal{W}}(s)\|\,ds \\ &\le \mu^2\int_0^\infty e^{-2\alpha(t-s)}\|\dot{\mathcal{W}}(s)\|ds.\end{aligned}$$

Define $f(t) := e^{-2\alpha t}$ and $g(t) := \|\dot{\mathcal{W}}(t)\|$. Then

$$\begin{aligned}\left\|\int_0^t e^{\mathfrak{A}(t-s)}\dot{\mathcal{W}}(s)e^{\mathfrak{A}'(t-s)}\,ds\right\| &\le \mu^2\int_0^\infty f(t-s)g(s)\,ds, \\ &= \mu^2(f*g)(t),\end{aligned}$$

where $(f*g)(t)$ stands for the convolution of f and g.

Clearly $f(t)\in L_1(\mathbb{R}^+)$. Let us now show that $g(t)\in L_1(\mathbb{R}^+)$,

$$\|\dot{\mathcal{W}}(t)\| \le \|T_\infty\|^2\left\|\frac{d}{dt}K_t\right\| + \left\|\frac{d}{dt}\left[\mathcal{C}_t\mathcal{C}_t'\right]\right\| + \left\|\frac{d}{dt}\mathcal{V}(\mathcal{Z}_t)\right\|.$$

We are going to show that $\|\frac{d}{dt}K_t\|$, $\|\frac{d}{dt}[\mathcal{C}_t\mathcal{C}_t']\|$, and $\|\frac{d}{dt}\mathcal{V}(\mathcal{Z}_t)\|$ belong to $L_1(\mathbb{R}^+)$, and, consequently, $\|\frac{d}{dt}\mathcal{W}(t)\|\in L_1(\mathbb{R}^+)$.

It is straightforward to show that $|\dot{p}_j(t)|\le \max_j|p_j(t)-\pi_j|\sum_{i=1}^N|\lambda_{ij}|$, and since $\max_j|p_j(t)-\pi_j|\le \alpha e^{-\beta t}$ for some constants $\alpha>0$ and $\beta>0$, we have that $|\dot{p}_j(t)|\in L_1(\mathbb{R}^+)$.

Now $\|\frac{d}{dt}K_t\| \le \sum_{j=1}^N \|G_jG_j'\||\dot{p}_j(t)|$ and $\|\frac{d}{dt}(\mathcal{C}_t\mathcal{C}_t')\| = \|\mathrm{diag}(C_iC_i'\dot{p}_i(t))\| \le \|\mathrm{diag}(\|C_iC_i'\||\dot{p}_i(t)|)\| = \max_{1\le i\le N}\{\|C_iC_i'\||\dot{p}_i(t)|\}$, so $\|\frac{d}{dt}K_t\|\in L_1(\mathbb{R}^+)$ and $\|\frac{d}{dt}(\mathcal{C}_t\mathcal{C}_t')\|\in L_1(\mathbb{R}^+)$. As for $\|\frac{d}{dt}\mathcal{V}(\mathcal{Z}_t)\|$, we have

$$\begin{aligned}\left\|\frac{d}{dt}\mathcal{V}(\mathcal{Z}_t)\right\| &\le \left\|\mathrm{diag}\left(\sum_{l=1}^N \dot{Z}_l(t)\lambda_{li}\right)\right\| + \|(\Lambda'\otimes I_n)\mathrm{diag}(\dot{Z}_i(t))\| \\ &\quad + \|\mathrm{diag}(\dot{Z}_i(t))(\Lambda'\otimes I_n)'\| \\ &\le \left\|\mathrm{diag}\left(\sum_{l=1}^N \|\dot{Z}_l(t)\|\,|\lambda_{li}|\right)\right\| + 2\,\|(\Lambda'\otimes I_n)\|\,\|\mathrm{diag}(\|\dot{Z}_i(t)\|)\| \\ &\le \max_i\left\{\sum_{l=1}^N \|\dot{Z}_l(t)\|\,|\lambda_{li}|\right\} + 2\,\|(\Lambda'\otimes I_n)\|\max_i\{\|\dot{Z}_i(t)\|\}.\end{aligned}$$

Define $|\lambda|_{\max} := \max_{i,j}\{|\lambda_{ij}|\}$. Then $\|\frac{d}{dt}\mathcal{V}(\mathcal{Z}_t)\| \leq \gamma \max_i\{\|\dot{Z}_i(t)\|\}$ with $\gamma := N|\lambda|_{\max} + 2\|(\Lambda' \otimes I_n)\| > 0$. So, it suffices to prove that $\|Z_i(t)\| \in L_1(\mathbb{R}^+)$ to have that $\|\frac{d}{dt}\mathcal{V}(\mathcal{Z}_t)\| \in L_1(\mathbb{R}^+)$.

But from Proposition 5.7 in [29], we have

$$\hat{\varphi}(\dot{\mathcal{Z}}_t) = \mathcal{F}\hat{\varphi}(\mathcal{Z}_t) + \hat{\varphi}(R(t)), \tag{6.6}$$

where $R(t) := [R_1(t), \ldots, R_N(t)]$ with $R_i(t) := C_i C_i' p_i(t)$. Now taking the derivative on both sides of (6.6), we have

$$\frac{d}{dt}\hat{\varphi}(\dot{\mathcal{Z}}_t) = \mathcal{F}\hat{\varphi}(\dot{\mathcal{Z}}_t) + \hat{\varphi}(\dot{R}(t)).$$

Now define $u(t) := \hat{\varphi}(\dot{\mathcal{Z}}_t)$, so

$$\dot{u}(t) = \mathcal{F}u(t) + \hat{\varphi}(\dot{R}(t)),$$

whose solution is

$$u(t) = e^{\mathcal{F}t}u(0) + \int_0^t e^{\mathcal{F}(t-s)}\hat{\varphi}(\dot{R}(s))\, ds.$$

Thus

$$\begin{aligned}\|u(t)\| &\leq \|e^{\mathcal{F}t}\|\,\|u(0)\| + \int_0^t \|e^{\mathcal{F}(t-s)}\|\|\hat{\varphi}(\dot{R}(s))\|\, ds \\ &\leq \|e^{\mathcal{F}t}\|\,\|u(0)\| + \int_0^\infty \|e^{\mathcal{F}(t-s)}\|\|\hat{\varphi}(\dot{R}(s))\|\, ds.\end{aligned}$$

Since $\mathcal{F}$ is stable, we have $\|e^{\mathcal{F}t}\| \leq \alpha_1 e^{-\beta_1 t}$ with $\alpha_1 > 0$ and $\beta_1 > 0$. Also, $\|\hat{\varphi}(\dot{R}(t))\| \in L_1(\mathbb{R}^+)$, because $\|\hat{\varphi}(\dot{R}(t))\| = (\sum_{i=1}^N k_i(\dot{p}_i(t))^2)^{\frac{1}{2}} \leq \max_j |\dot{p}_i(t)|(\sum_{i=1}^N k_i)^{\frac{1}{2}}$ for some constants $k_i > 0$. Therefore,

$$\|u(t)\| \leq \alpha_1\,\|u(0)\|\, e^{-\beta_1 t} + \alpha_1 \int_0^\infty e^{-\beta_1(t-s)}\|\hat{\varphi}(\dot{R}(s))\|\, ds. \tag{6.7}$$

Defining $h_1(t) := e^{-\beta_1 t} \in L_1(\mathbb{R}^+)$ and $h_2(t) := \|\hat{\varphi}(\dot{R}(t))\| \in L_1(\mathbb{R}^+)$ and bearing in mind that the integral on the right-hand side of (6.7) is $(h_1 * h_2)(t) \in L_1(\mathbb{R}^+)$ (cf. [46, Theorem 8.14, p. 170]) we show that $\|\hat{\varphi}[\dot{Z}_1(t), \ldots, \dot{Z}_N(t)]\| \in L_1(\mathbb{R}^+)$. Finally, we have $\|\dot{Z}_i(t)\| \in L_1(\mathbb{R}^+)$, for all i, and $\max_i\{\|\dot{Z}_i(t)\|\} \in L_1(\mathbb{R}^+)$ and, consequently, $\|\frac{d}{dt}\mathcal{V}(\mathcal{Z}_t)\| \in L_1(\mathbb{R}^+)$, which proves that $\|\frac{d}{dt}\mathcal{W}(t)\| \in L_1(\mathbb{R}^+)$.

Now, since $f(t) \in L_1(\mathbb{R}^+)$ and $g(t) \in L_1(\mathbb{R}^+)$, we have that $(f * g)(t) \in L_1(\mathbb{R}^+)$ (cf. [46, Theorem 8.14, p. 170]), and so

$$\lim_{t\to\infty}\left\|\int_0^t e^{\mathfrak{A}(t-s)}\dot{\mathcal{W}}(s)e^{\mathfrak{A}'(t-s)}\, ds\right\| = 0,$$

that is,

$$\int_0^t e^{\mathfrak{A}(t-s)}\dot{\mathcal{W}}(s)e^{\mathfrak{A}'(t-s)}\, ds \to 0 \text{ as } t \to \infty$$

which proves that $\lim_{t\to\infty}\mathcal{I}(t)$ exists. Defining $\lim_{t\to\infty}\mathcal{I}(t) = \lim_{t\to\infty}P^\star(t) := \overline{P}^\star$ and taking limits on both sides of (6.5), we obtain

$$\mathfrak{A}\overline{P}^\star + \overline{P}^\star\mathfrak{A}' = \lim_{t\to\infty}\int_0^t e^{\mathfrak{A}(t-s)}\dot{\mathcal{W}}(s)e^{\mathfrak{A}'(t-s)}ds - \left[T_\infty K T_\infty' + \mathcal{C}\mathcal{C}' + \mathcal{V}(\mathcal{Q})\right]. \tag{6.8}$$

Finally, (6.8) becomes

$$(\mathcal{A} - T_\infty H)\,\overline{P}^\star + \overline{P}^\star\,(\mathcal{A} - T_\infty H)' + T_\infty K T_\infty' + \mathcal{C}\mathcal{C}' + \mathcal{V}(\mathcal{Q}) = 0. \tag{6.9}$$

Notice that $\mathcal{P}$ is also a solution of (6.9) because, replacing $\overline{P}^\star$ by $\mathcal{P}$ in (6.9), and taking into account that $T_\infty = \mathcal{P}H'K^{-1}$, we have

$$\mathcal{A}\mathcal{P} + \mathcal{P}\mathcal{A}' - \mathcal{P}H'\left(\mathcal{G}\mathcal{G}'\right)^{-1} H\mathcal{P} + \mathcal{C}\mathcal{C}' + \mathcal{V}(\mathcal{Q}) = 0,$$

which is (5.1).

Since $\mathcal{A} - T_\infty H$ is stable, the algebraic Riccati equation (6.9) admits a unique solution. Therefore, we must have $\overline{P}^\star = \mathcal{P}$. In short, we have $\lim_{t\to\infty} P^\star(t) = \mathcal{P}$ and $P^\star(t) \geq \mathcal{P}(t)$. □

LEMMA 6.2. *Let $Z_i(t)$ and $\overline{Z_i}(t)$ be solutions of matrix differential equations given, respectively, by*

$$\begin{aligned} \dot{Z}_i(t) &= A_i Z_i(t) + Z_i(t)A_i' + \sum_{j=1}^{N} Z_j(t)\lambda_{ji} + C_i C_i' p_i(t), \\ Z_i(0) &= V_i \geq 0 \end{aligned} \tag{6.10}$$

and

$$\begin{aligned} \dot{\bar{Z}}_i(t) &= A_i \bar{Z}_i(t) + \bar{Z}_i(t)A_i' + \sum_{j=1}^{N} \bar{Z}_j(t)\lambda_{ji} + C_i C_i' \alpha_i(t), \\ \bar{Z}_i(0) &= V_i \geq 0, \end{aligned} \tag{6.11}$$

where $\alpha_i(t) = \inf_{s\in[0,\infty)}\{p_i(t+s)\}$. *Then, for all $t > 0$, we have $Z_i(t) \geq \bar{Z}_i(t)$.*

Proof. First observe that $p_i(t) \geq \alpha_i(t)$ and that for $0 \leq s \leq t$, $\alpha_i(t) \geq \alpha_i(s)$, i.e., $\alpha_i(t)$ is a nondecreasing function of t. Moreover, $\alpha_i(t) \to \pi_i$ exponentially fast, as $t \to \infty$, because $p_i(t) \to \pi_i$ exponentially fast. Next, from Lemma 4.1 in [29], under positive semidefinite initial conditions, (6.10) and (6.11) admit positive semidefinite solution for all t, which can be obtained by successive approximations. Then $Z_i(t) \geq 0$ and $\bar{Z}_i(t) \geq 0$ for all t.

To see this, notice that (6.11) can be rewritten as

$$\begin{aligned} \dot{\bar{Z}}_i(t) &= \left(A_i + \frac{1}{2}\lambda_{ii} I\right)\bar{Z}_i(t) + \bar{Z}_i(t)\left(A_i + \frac{1}{2}\lambda_{ii} I\right)' \\ &\quad + \sum_{j=1,\ j\neq i}^{N} \bar{Z}_j(t)\lambda_{ji} + C_i C_i' \alpha_i(t), \\ \bar{Z}_i(0) &= V_i \geq 0. \end{aligned}$$

Now let $\overline{\Phi}_i(t,s)$ be the transition matrix associated with $A_i + \frac{1}{2}\lambda_{ii} I$, i.e., $\overline{\Phi}_i(t,s) = e^{(A_i + \frac{1}{2}\lambda_{ii} I)(t-s)}$. Then the solution $\bar{Z}_i(t)$ will be given by

$$\begin{aligned} \bar{Z}_i(t) &= \overline{\Phi}_i(t,0) V_i \overline{\Phi}_i'(t,0) \\ &\quad + \int_0^t \overline{\Phi}_i(t,s)\left[\sum_{j=1,\ j\neq i}^{N} \bar{Z}_j(s)\lambda_{ji} + C_i C_i' \alpha_i(s)\right]\overline{\Phi}_i'(t,s)\,ds. \end{aligned}$$

Since $\alpha_i(t) \geq 0$ for all t, and since $\bar{Z}_j(t)\lambda_{ji} \geq 0$ for all t and $i \neq j$, we have that

$$\sum_{j=1,\ j\neq i}^{N} \bar{Z}_j(u)\lambda_{ji} + C_i C_i' \alpha_i(u) \geq 0 \quad \text{for all } u \geq 0.$$

We shall now show that $Z_i(t) \geq \bar{Z}_i(t)$. (6.10) can be rewritten as

$$\begin{aligned}\dot{Z}_i(t) &= \left(A_i + \frac{1}{2}\lambda_{ii}I\right) Z_i(t) + Z_i(t)\left(A_i + \frac{1}{2}\lambda_{ii}I\right)' \\ &\quad + \sum_{j=1,\ j\neq i}^{N} Z_j(t)\lambda_{ji} + C_iC_i'p_i(t), \\ Z_i(0) &= V_i \geq 0.\end{aligned}$$

Define $R_i(t) := Z_i(t) - \bar{Z}_i(t)$. Then, we get

$$\begin{aligned}\dot{R}_i(t) &= \left(A_i + \frac{1}{2}\lambda_{ii}I\right) R_i(t) + R_i(t)\left(A_i + \frac{1}{2}\lambda_{ii}I\right)' \\ &\quad + \sum_{j=1,\ j\neq i}^{N} R_j(t)\lambda_{ji} + C_iC_i'\left[p_i(t) - \alpha_i(t)\right], \\ R_i(0) &= 0.\end{aligned}$$

Since $C_iC_i'[p_i(t) - \alpha_i(t)] \geq 0$, because $p_i(t) \geq \alpha_i(t)$ for all t, the solution $R_i(t)$ is obtained in the same way as we did for the solution of $\bar{Z}_i(t)$ and possesses the same properties as those of $\bar{Z}_i(t)$. So, $R_i(t) \geq 0$, which proves that $Z_i(t) \geq \bar{Z}_i(t)$, completing the proof of lemma. □

LEMMA 6.3. *Let $\mathcal{Z}_t = (Z_1(t), \ldots, Z_N(t)) \in \mathbb{H}^{n+}$, and let $\overline{\mathcal{Z}}_t = (\bar{Z}_1(t), \ldots, \bar{Z}_N(t)) \in \mathbb{H}^{n+}$. Then $\mathcal{V}(\mathcal{Z}_t) \geq \mathcal{V}(\overline{\mathcal{Z}}_t)$ for all $t \geq 0$, where $\mathcal{V}(\mathcal{Z}_t)$ is defined by* (4.11).

Proof. We have shown that $\mathcal{V}(\mathcal{Z}_t)$ is a linear operator and that $\mathcal{V}(\mathcal{Z}_t) \geq 0$ for all $\mathcal{Z}_t = (Z_1(t), \ldots, Z_N(t)) \in \mathbb{H}^{n+}$. From the previous lemma, $\mathcal{Z}_t - \overline{\mathcal{Z}}_t \geq 0$. Then, $0 \leq \mathcal{V}(\mathcal{Z}_t - \overline{\mathcal{Z}}_t) = \mathcal{V}(\mathcal{Z}_t) - \mathcal{V}(\overline{\mathcal{Z}}_t)$, which is equivalent to saying that $\mathcal{V}(\mathcal{Z}_t) \geq \mathcal{V}(\overline{\mathcal{Z}}_t)$, completing the proof. □

LEMMA 6.4. *Let $P_\star(t)$ be the solution of the Riccati differential equation given by*

$$\begin{aligned}\dot{P}_\star(t) &= (\mathcal{A} - T_\star(t)H)\, P_\star(t) + P_\star(t)\,(\mathcal{A} - T_\star(t)H)' \\ &\quad + T_\star(t)\bar{K}_tT_\star'(t) + \bar{C}_t\bar{C}_t' + \mathcal{V}(\overline{\mathcal{Z}}_t), \\ P_\star(0) &= 0,\end{aligned} \tag{6.12}$$

where $T_\star(t) := P_\star(t)H'\bar{K}_t^{-1}$, $\bar{K}_t := \bar{G}_t\bar{G}_t'$, $\bar{G}_t := [\sqrt{\alpha_1(t)}G_1 \ldots \sqrt{\alpha_N(t)}G_N]$, $\bar{C}_t := \operatorname{diag}(\sqrt{\alpha_i(t)}C_i)$, $\mathcal{V}(\overline{\mathcal{Z}}_t)$ is the linear operator defined by (4.11) *applied to $\overline{\mathcal{Z}}_t = (\bar{Z}_1(t), \ldots, \bar{Z}_N(t))$, the solution of the matrix differential equation given by* (6.11)*, and $\alpha_i(t) = \inf_{s\in[0,\infty)}\{p_i(t+s)\}$. Then, for $0 \leq s \leq t$, $P_\star(s) \leq P_\star(t)$. In addition, $P_\star(t) \leq \mathcal{P}(t)$ for all $t \in [0,\infty)$ and $\lim_{t\to\infty} P_\star(t) = \mathcal{P}$, where $\mathcal{P}$ is the solution of* (5.1).

Proof. First, observe that, for all t, $\mathcal{C}_t\mathcal{C}_t' \geq \bar{C}_t\bar{C}_t' \geq 0$ and $K_t \geq \bar{K}_t \geq 0$. Also from the previous lemma, $\mathcal{V}(\mathcal{Z}_t) \geq \mathcal{V}(\overline{\mathcal{Z}}_t) \geq 0$. In addition, from the exponential speed of convergence of $\alpha_i(t)$ to π_i, we have that $\bar{C}_t\bar{C}_t' \to \mathcal{C}\mathcal{C}'$, $\mathcal{V}(\overline{\mathcal{Z}}_t) \to \mathcal{V}(\mathcal{Q})$, and $\bar{K}_t \to K = \mathcal{G}\mathcal{G}'$ exponentially fast as $t \to \infty$.

Also, for $0 \leq s \leq t$, $P_\star(s) \leq P_\star(t)$, from Lemma 5.2 in [54].

Let us now prove that $P_\star(t) \leq \mathcal{P}(t)$ for all $t \in [0,\infty)$. In order to do that we rewrite (6.13) in the following way:

$$\begin{aligned}\dot{P}_\star(t) &= (\mathcal{A} - T_tH)\, P_\star(t) + P_\star(t)\,(\mathcal{A} - T_tH)' \\ &\quad + \bar{C}_t\bar{C}_t' + \mathcal{V}(\overline{\mathcal{Z}}_t) + T_t\bar{K}_tT_t' - (T_t - T_\star(t))\,\bar{K}_t\,(T_t - T_\star(t))'.\end{aligned}$$

Defining $\tilde{P}_\star(t) := \mathcal{P}(t) - P_\star(t)$, we have

$$\begin{aligned}\dot{\tilde{P}}_\star(t) &= (\mathcal{A} - T_t H)\,\tilde{P}_\star(t) + \tilde{P}_\star(t)\,(\mathcal{A} - T_t H)' \\ &\quad + T_t\left[K_t - \bar{K}_t\right] T_t' + \left[\mathcal{C}_t\mathcal{C}_t' - \bar{C}_t\bar{C}_t'\right] + \left[\mathcal{V}(\mathcal{Z}_t) - \mathcal{V}(\overline{\mathcal{Z}}_t)\right] \\ &\quad + (T_t - T_\star(t))\,\bar{K}_t\,(T_t - T_\star(t))', \\ \tilde{P}_\star(0) &= \mathcal{P}(0) \geq 0.\end{aligned}$$

Let $\Phi(t,s)$ be the transition matrix associated with $\mathcal{A} - T_t H$. Then

$$\begin{aligned}\tilde{P}_\star(t) &= \Phi(t,0)\mathcal{P}(0)\Phi'(t,0) \\ &\quad + \int_0^t \Phi(t,s)\left\{T_s\left[K_s - \bar{K}_s\right] T_s' + \left[\mathcal{C}_s\mathcal{C}_s' - \bar{C}_s\bar{C}_s'\right] + \left[\mathcal{V}(\mathcal{Z}_s) - \mathcal{V}(\overline{\mathcal{Z}}_s)\right]\right. \\ &\quad \left. + (T_s - T_\star(s))\,\bar{K}_s\,(T_s - T_\star(s))'\right\}\Phi'(t,s)ds.\end{aligned}$$

Since $\mathcal{P}(0) \geq 0$, $K_t - \bar{K}_t \geq 0$, $\mathcal{C}_t\mathcal{C}_t' - \bar{C}_t\bar{C}_t' \geq 0$, $\mathcal{V}(\mathcal{Z}_t) - \mathcal{V}(\overline{\mathcal{Z}}_t) \geq 0$, and $(T_t - T_\star(t))\bar{K}_t(T_t - T_\star(t))' \geq 0$ because $\bar{K}_t \geq 0$ for all $t \geq 0$, we have $\tilde{P}_\star(t) \geq 0$, which proves that $\mathcal{P}(t) \geq P_\star(t)$.

Now, since $P_\star(t)$ is a nondecreasing function of t and is bounded above by $\mathcal{P}$, because $P_\star(t) \leq \mathcal{P}(t) \leq P^\star(t)$ and $\lim_{t\to\infty} P^\star(t) = \mathcal{P}$, we have that $\lim_{t\to\infty} P_\star(t)$ exists. So, there exists a matrix $\overline{P}_\star$, such that $P_\star(t) \to \overline{P}_\star$ as $t \to \infty$. Now, due to the monotonicity and convergence of $P_\star(t)$, it is a classical result that $\dot{P}_\star(t) \to 0$ as $t \to \infty$. Therefore, $\overline{P}_\star$ is the solution of the algebraic Riccati equation given by

$$\left(\mathcal{A} - \overline{T}_\star H\right)\overline{P}_\star + \overline{P}_\star\left(\mathcal{A} - \overline{T}_\star H\right)' + \overline{T}_\star K \overline{T}_\star' + \mathcal{C}\mathcal{C}' + \mathcal{V}(\mathcal{Q}) = 0,$$

where $\overline{T}_\star = \overline{P}_\star H'(\mathcal{G}\mathcal{G}')^{-1}$. But the above equation can be rewritten as

$$\mathcal{A}\overline{P}_\star + \overline{P}_\star\mathcal{A}' - \overline{P}_\star H'\left(\mathcal{G}\mathcal{G}'\right)^{-1} H\overline{P}_\star + \mathcal{C}\mathcal{C}' + \mathcal{V}(\mathcal{Q}) = 0. \tag{6.13}$$

Since (6.13) is equivalent to (5.1), we have, from the unicity of solution of (5.1), $\overline{P}_\star = \mathcal{P}$. Therefore, $\lim_{t\to\infty} P_\star(t) = \mathcal{P}$. □

A SYMBOLIC APPROACH TO PERFORMANCE ANALYSIS OF QUANTIZED FEEDBACK SYSTEMS: THE SCALAR CASE*

FABIO FAGNANI† AND SANDRO ZAMPIERI‡

Abstract. When dealing with the control of a large number of interacting systems, the fact that the flow of information has to be limited becomes an essential feature of the control design. The first consequence of the limited information flow constraint is that the signals that the controllers and the systems exchange have to be quantized. Though quantization has already been extensively considered in the control literature, its analysis from the point of view of the information flow demand has been considered only recently.

Limiting the information flow between a plant and a controller will necessarily lead to a performance degradation of the feedback loop, and we expect a trade-off between the achievable performance and the amount of information exchange allowed in the loop.

Most of the success of modern digital communication theory in the last 50 years is due to the contributions of information theory, which proposed a symbolically based analysis of the communication channel performance. The same goal is much more difficult to reach in digital control theory.

This paper proposes an attempt toward this direction. The main contribution of this paper is to provide a complete analysis of the trade-off between performance and information flow in the simple case of the stabilization of a scalar linear system by means of a memoryless quantized feedback map.

Key words. stability, stabilization, communication constraint, quantized feedback, chaotic control, symbolic dynamics, Markov chains, entropy

1. Introduction.

Stabilization by quantized feedback controllers has been widely investigated in the last few years (see [2, 3, 6, 7, 9, 16, 20, 21, 22, 23, 25, 26] and references therein). There are two different situations in which quantization appears to be a central feature in the control design. The first is related to control systems in which either the sensor's or the actuator's limitations impose the condition that their measures or their commands can take a limited number of different values. In this case, the number of quantization levels provides a measure of the sensor or of the actuator complexity. Another situation in which quantization plays an important role is when plants and controllers exchange information through digital communication channels with a limited capacity. In this last case, the measures and the commands need to be quantized before being communicated and the number of quantization levels is strictly related to the information flow between the components of the control system and so to the capacity required to transmit the control information.

Two different approaches have been proposed in the literature for solving the control problem with a quantized feedback. The first approach considers memoryless feedback quantizers. In particular in [6] there is a first mathematical analysis of control systems with uniform quantized feedback, while in [26, 2] a first bound of the number of quantization intervals needed to stabilize a linear system is proposed. In

[7] logarithmic quantizers are shown to yield the Lyapunov stability. In [9] a chaos-based quantized controller was proposed and a first comparison between uniform, logarithmic, and chaotic quantized feedback controllers was presented in the scalar case. In [23] performance of uniform quantized feedback controllers is analyzed for general linear systems.

The second approach considers quantized feedback controllers with an internal state. In particular [3] proposes a stabilization technique in which the quantizer is scaled according to the state growth. In [25] this technique is used to show the relation between the degree of instability of the system to be controlled and the number of quantization levels of the feedback quantizer. The same relation was found independently in [20] in a different context.

In general the analysis of memoryless quantized feedback controllers is difficult, while the results become quite neat for quantized feedback controllers with infinite memory. Notice that, while it is reasonable to allow a memory structure on sensors and actuators when designing control systems under communication constraint [25, 20], in situations in which quantization is due to the poor quality of sensors or actuators, only the memoryless quantized feedback controller becomes a reasonable model.

This paper considers memoryless quantized controllers for which, as we mentioned, a mathematical analysis is more complicated. The relation between controller complexity and controller performance is investigated by using theoretical information and combinatorial techniques. One of the main contributions of this paper is to show that the controller performance has to be described by two conflicting parameters, one evaluating the steady state and the other evaluating the transient of the controlled system. Roughly speaking we proved that, for a fixed controller complexity, a good steady state implies a bad transient and vice versa.

More precisely, in this paper we consider the stabilization problem for discrete time linear systems with a one-dimensional state, namely, a system described by the equation

$$x_{t+1} = ax_t + u_t.$$

While in the classical control setting this stabilization problem is completely trivial and there is little to be said, in the memoryless quantized feedback setting nontrivial issues already come up in this simple situation. In this setup, a memoryless quantized feedback is a control law $u_t = k(x_t)$, where $k(\cdot)$ is a quantized (i.e., piecewise constant) map. Let N be the number of distinct values which $k(\cdot)$ is allowed to take. The number N will provide a measure of the information flow in the feedback loop. In the literature referenced above several different quantized stabilizing strategies have been proposed in this context. Moreover in [2, 26] the minimum value of N (as a function of $|a|$) has been found, ensuring the existence of a memoryless quantized controller yielding stability (but not convergence) of the system.

The aim of this paper is to compare different quantized control strategies proposed in the literature in terms of complexity and performance and to establish a number of results showing fundamental limitations of quantized control. To be more precise about performance, notice first that, if the original system is unstable, a state feedback with finitely many quantization intervals can only yield so-called practical stabilization, namely, the convergence of any initial state belonging to a bigger bounded region I into another smaller target region of the state space J. The ratio C between the measure of the starting region and the target region is called contraction, and it provides a description of the steady state properties of the closed loop system.

Beyond C, the expected time T needed to shrink the state of the plant from the starting set to the target set will measure the transient controller performance. Notice that these two parameters represent a particular way of evaluating the steady state and the transient performance of the controller. There are other possible choices. For instance, it is possible to evaluate the transient by means of a quadratic-like index. Some preliminary investigations show that the techniques proposed in this paper can also be applied in this setup and yield similar trade-off results.

We will evaluate the relations between the parameters N, C, T, and a in a series of different stabilization strategies. In all cases we will see that, for fixed a, as C grows, either N has to grow or T has to grow. However, different strategies exhibit different growth rates of the two parameters N and T. In all cases an increasing value of $|a|$ either requires an increase in N or yields a degradation of C and T. These results extend the relations between N and $|a|$ proposed in [2, 26] and complete the analysis started in [9], where, however, the parameter T was interpreted as the sup norm of the entrance time and where a stronger notion of stability was considered. The relations between the parameters N, C, T pointed out in the examples are in accordance with some fundamental bounds which are proved in the second part of the paper, proving in this way the optimality of the proposed quantized controller synthesis techniques.

Now we present an outline of the contents of this paper and of our main results. In section 2, we present all basic definitions and notation. In particular we introduce the concepts of stability and almost stability, and we state precisely the problems we want to solve. Moreover, we introduce some basic tools from the ergodic theory of piecewise affine maps. Using these we show that the expected entrance time T is always finite if we have almost stability.

Section 3 is devoted to the introduction and the discussion of a general stabilization strategy based on nesting an initial given quantized stabilizer.

Section 4 is devoted to the analysis of some examples. We show that, by nesting the quantized deadbeat controller in a suitable way, we can obtain a variety of different quantized stabilizers, which can be analyzed in terms of the parameters N and T as functions of a and C. There are three particularly significant cases. The first is the quantized deadbeat control which is obtained by using uniform quantized feedback. In this case N grows linearly in C and $|a|$ and T tend to the constant 1. The second is the logarithmic quantized feedback strategy. In this case, instead, both N and T grow logarithmically in C. The latter is the chaotic quantized feedback strategy. In this last case only almost stability can be achieved and N tends to the constant $\lceil |a| \rceil$ while T grows linearly in C. Notice that the first and the last strategies present dual characteristics of N and T as functions of C. It is interesting to observe that, if we take any linear feedback $u_t = kx_t$, with $k \in \mathbb{R}$, such that the linear closed loop system $x_{t+1} = (a+k)x_t$ is asymptotically stable, then the expected entrance time T of this controlled system is such that $T/\log C$ tends to a constant which is a decreasing function of $|a + k|$. Hence the logarithmic regime corresponds to the performance which can be obtained through the allocation of the eigenvalue inside the unit circle and the absolute value of this eigenvalue determines the logarithmic rate.

In section 5, we obtain universal bounds relating T, N, and C for fixed $|a|$. The main results are presented in Theorems 3 and 4 and Corollaries 3 and 2. All these results, except Theorem 4, need the assumption $|a| > 2$. Corollary 3 says two things: First, in order to obtain expected entrance time T growing at most logarithmically with respect to C, we need a number of quantization intervals N growing at least logarithmically with respect to C. Second, if we use a number of quantization intervals

N growing at most logarithmically with respect to C, we obtain expected entrance times T growing at least logarithmically with respect to C. Moreover, the corollary furnishes a quantitative trade-off between the two ratios $T/\log C$ and $N/\log C$ which turns out to be interesting if related to the previous comment on the logarithmic regime which can be obtained in the linear feedback case. Another consequence of the results presented in this section is that the chaos-based stabilization strategy is somehow optimal since its performance cannot be improved without paying this with a greater information flow. Finally, Theorem 5 shows that any stabilization strategy yielding stability has the ratio $N/\log C$ bounded from below.

To prove the results in section 5 we need to use the tools of combinatorial analysis of the symbolic dynamics associated with piecewise affine maps. This is developed in section 6, which contains the deeper mathematical result of this paper, which is Theorem 6. This theorem provides a new bound on the number of the paths on a graph with possibly infinite uncountable edges, when this graph has some specific properties. This theorem is very general and has potential applications in other situations such as the analysis of quantized feedback systems when the state is multidimensional [10].

We conclude this introduction with a few remarks to emphasize the reasons why we limited our analysis to scalar state space systems. From an application viewpoint, these may be seen as a relatively uninteresting family of systems to be considered. However, this simple case already contains all the interesting issues of the coupling between control and information and mathematically leads to nontrivial problems. The completeness of the results obtained in this paper, because of the simplified setup we choose, will provide the guidelines for future investigations on more general situations (see [10]). Observe finally that first order systems can be considered as simplified models of more general systems and that one important case in which control under communication constraint is relevant is just when many simple systems have to be controlled by a unique centralized controller.

Notation. We present here some notation which will be used in this paper. If A and B are two sets, then $A \setminus B := \{a \in A : a \notin B\}$. Given a map $f : A \to B$ and $B_1 \subseteq B$ we define

$$f^{-1}(B_1) := \{a \in A : f(a) \in B_1\}.$$

The symbol $A^{\mathbb{N}}$ denotes the set of all sequences taking values on the set A, while the symbol A^* denotes the set of all finite words over the alphabet A. The symbol $\#A$ denotes the cardinality of A.

The symbol $\mathbb{R}_+$ denotes the set of all positive real numbers. If $a \in \mathbb{R}_+$, then $\lceil a \rceil$ means the minimum integer greater than or equal to a, and $\log a$ is the natural logarithm of a. Given $a, b \in \mathbb{R}$, $a \wedge b$ and $a \vee b$ denote the minimum and the maximum between a and b, respectively. Given $K \subseteq \mathbb{R}$, $\overline{K}$ denotes the closure of K, while ∂K denotes the boundary set of K.

Let I be an interval in $\mathbb{R}$. Given any function $f : I \to \mathbb{R}$ we define

$$\text{supp } (f) := \{x \in I : f(x) \neq 0\}.$$

For any $J \subseteq I$ we denote by $\mathbf{1}_J$ the function defined on I which is 1 in J and 0 on $I \setminus J$, and it is called the indicator function of J. With the symbol $L^1(I)$ we mean the set of absolutely integrable functions which is a normed space with the norm

$$||f||_1 := \int_I |f(x)|dx \qquad \forall f \in L^1(I).$$

If $\mathcal{P} : L^1(I) \to L^1(I)$ is a linear continuous operator, then the symbol $||\mathcal{P}||_1$ denotes the induced norm of $\mathcal{P}$. The symbol $L^\infty(I)$ means the set of bounded functions on I which is a normed space as well. A function $f \in L^1(I)$ such that $f(x) \geq 0$ for all $x \in I$ and such that $||f||_1 = 1$ is called a density function on I. It induces a probability measure on I which will be denoted by $\mathbb{P}_f$, while the symbol $\mathbb{E}_f$ will denote the expected value with respect to $\mathbb{P}_f$. The probability measure and the expected value with respect to a uniform Lebesgue measure on I will be simply denoted by the symbols $\mathbb{P}$ and $\mathbb{E}$, respectively.

2. Problem statement. Consider the following discrete-time, one-dimensional linear model:

$$x_{t+1} = ax_t + u_t, \tag{1}$$

where $a \in \mathbb{R}$. Most of the paper is devoted to the stabilization problem, and so it is assumed that $|a| > 1$. Some results, however, hold true also for stable systems and so for $|a| \leq 1$.

Let $k : \mathbb{R} \to \mathbb{R}$ be a piecewise constant function with only finitely many discontinuities. If we use k as a static feedback in system (1), namely, we let $u_t = k(x_t)$, we obtain the closed loop system

$$x_{t+1} = \Gamma(x_t), \tag{2}$$

where $\Gamma(x) := ax + k(x)$ is a piecewise affine map with a fixed slope a. Autonomous systems such as (2) in which Γ is piecewise affine can exhibit very wild behavior. Their dynamical properties were extensively studied in the past [15, 18, 5, 24].

Remark. In fact, the definition we gave is not precise if we do not define what happens at the boundary points of the intervals. We assume there is a finite family of disjoint open intervals I_h such that $D := \cup_h I_h$ is dense in $\mathbb{R}$ and that $k(x) = u_h$ for every $x \in I_h$. In this way the associated closed loop map is defined as a map

$$\Gamma : D \to \mathbb{R}, \tag{3}$$

$$\Gamma(x) = ax + u_h \quad \text{if } x \in I_h.$$

In order to consider iterations of Γ we need to restrict the domain by considering

$$\Omega = \bigcap_{n=0}^{\infty} \Gamma^{-n}(D). \tag{4}$$

It is clear that $\Gamma(\Omega) \subseteq \Omega$. Notice that $\mathbb{R} \setminus \Omega$ is a countable subset of $\mathbb{R}$, and since most of the questions considered in this paper are related to mean properties, it will be sufficient to consider Γ as a map defined on Ω, disregarding all the orbits which will eventually get to a discontinuity point.

However, in those situations in which it is necessary to understand how the dynamics is defined at the boundaries, it is necessary to define the dynamics of Γ on all $\mathbb{R}$. This is done by considering, for any $x_0 \in \mathbb{R}$, the left and right limits of $\Gamma(x)$ for $x \to x_0$ denoted by $\Gamma(x_0-)$ and $\Gamma(x_0+)$, and by defining the enlarged set of orbits as

$$X_\Gamma = \big\{(x_t) \in \mathbb{R}^{\mathbb{N}} \mid x_{t+1} = \Gamma(x_t+) \text{ or } x_{t+1} = \Gamma(x_t+) \quad \forall t \in \mathbb{N}\big\}. \tag{5}$$

The subset $X_\Gamma \cap \Omega^{\mathbb{N}}$ consists of the orbits of Γ on Ω, and it is in bijection with Ω through the initial condition.

It is obvious that, by using quantized feedback controllers, only a "practical stability" can be obtained as detailed in the following definitions.

DEFINITION (invariance and almost invariance). *Given a closed interval I, we say that I is Γ-invariant if every orbit (x_t) of Γ with $x_0 \in I$ is such that $x_t \in I$ for every t. It is almost Γ-invariant if the assertion above is true for almost every initial condition x_0 with respect to the Lebesgue measure. When an interval I is invariant or almost invariant we will use in any case the notation $\Gamma : I \to I$.*

DEFINITION (stability and almost stability). *Given two closed intervals $J \subseteq I$, we say that Γ is (I, J)-stable if I and J are invariant by Γ and if for every orbit (x_t) of Γ with $x_0 \in I$, there exists an integer $t \geq 0$ such that $x_t \in J$. We say that Γ is almost (I, J)-stable if I and J are almost invariant and the convergence to J as defined above occurs for almost all initial conditions in the orbit $x_0 \in I$ with respect to the Lebesgue measure. A quantized feedback map $k : \mathbb{R} \to \mathbb{R}$ is said to be (almost) (I, J)-stabilizing if the corresponding closed loop map Γ is (almost) (I, J)-stable.*

Remark. With regard to almost invariance and almost stability, it is sufficient to work with Γ on the set Ω as defined in (4). The concepts of invariance and stability also depend on the dynamics on boundary points, and so the orbits have to be considered as defined in (5).

Assume that Γ is almost (I, J)-stable. The first entrance time function

$$T_{(I,J)} : I \cap \Omega \to \mathbb{N} \cup \{+\infty\}$$

is defined by

$$T_{(I,J)}(x) = \inf \left\{ n \in \mathbb{N} \mid \Gamma^n x \in J \right\} = \sum_{n=1}^{\infty} \mathbf{1}_{I \setminus J}(\Gamma^n x). \tag{6}$$

We put $T_{(I,J)}(x) := +\infty$ if $\Gamma^t x \notin J$ for all t. Notice that the map $T_{(I,J)}$ is always finite exactly when we have stability, while it is almost surely finite when we have almost stability.

Remark. Notice that, if we want to extend the function $T_{(I,J)}$ to all I, we cannot use definition (6). Indeed, there is a possible ambiguity for orbits touching discontinuity points since, given $x \in I$, there can be infinitely many orbits having x as an initial condition and, therefore, $\Gamma^n x$ is not uniquely defined. In this case definition (6) should be replaced as follows: we say that $T_{(I,J)}(x) = n$ if every orbit $(x_t) \in X_\Gamma$ such that $x_0 = x$ is such that $x_t \in J$ for any $t \geq n$, and if there exists an orbit $(x_t) \in X_\Gamma$ such that $x_0 = x$ and such that $x_{n-1} \notin J$.

The expected value of the entrance time with respect to a density function f on I is given by

$$\mathbb{E}_f(T_{(I,J)}) = \int_I T_{(I,J)}(x) f(x) dx.$$

It is clear that

$$\mathbb{E}_f(T_{(I,J)}) = \int_I \left[\sum_{n=1}^{\infty} \mathbf{1}_{I \setminus J}(\Gamma^n x) f(x) \right] dx = \sum_{n=1}^{\infty} n \mathbb{P}_f[T_{(I,J)} = n] = \sum_{n=0}^{\infty} \mathbb{P}_f[T_{(I,J)} > n].$$

In what follows, for any given (almost) (I, J)-stabilizing quantized feedback k yielding an (almost) (I, J)-stable piecewise affine closed loop map Γ, we will use the symbol $\mathbf{T}(k)$ or $\mathbf{T}(\Gamma)$ to denote the relative expected entrance time $\mathbf{E}(T_{(I,J)})$ with respect

to the uniform density function on I. Notice that this quantity depends only on the restriction of Γ to $I \setminus J$, and so we can assume that Γ is defined only on $I \setminus J$. For this reason the right parameter measuring the information flow will be the number of quantization intervals in $I \setminus J$, which will be denoted by the symbol $\mathbf{N}(k)$ or $\mathbf{N}(\Gamma)$. Finally the ratio between the length of I and the length of J will be called the contraction rate and will be denoted by $C(k)$ or $C(\Gamma)$.

The performance analysis of the quantized stabilization consists of determining, for a given $C > 1$, $N \in \mathbb{N}$, and $T > 0$, whether there exists or not a (almost) stabilizing quantized feedback k such that $C(k) = C$, $\mathbf{N}(k) = N$, and $\mathbf{T}(k) = T$, or, in other words, estimating the set

$$\mathcal{A} := \{(C, N, T) \ : \ \text{there exists } k \text{ such that } C(k) = C, \quad \mathbf{N}(k) = N, \quad \mathbf{T}(k) = T\}.$$

Remark. The analysis proposed in this paper can be extended to a family of more general performance measures. Let

$$V : I \to \mathbb{R}$$

be such that $0 \leq V(x) \leq 1$ for every $x \in I$, and $V(x) = 0$ for every $x \in J$. Another measure of the transient properties of the closed loop system is the following number:

$$\mathbb{E}\left(\sum_{n=0}^{\infty} V(\Gamma^n x)\right).$$

It is clear that, if $V(x) = \mathbf{1}_{I\setminus J}(x)$, then the previous cost coincides with the expected entrance time in J. If $V(x)$ is a general continuous function, then for any $\alpha \in [0, 1]$ we have that

$$\alpha \mathbf{1}_{I\setminus J(\alpha)}(x) \leq V(x) \leq \mathbf{1}_{I\setminus J}(x),$$

where $J(\alpha) := \{x \in I \ : \ V(x) \leq \alpha\}$. This fact implies that

$$\alpha \mathbb{E}(T_{J(\alpha)}) \leq \mathbb{E}\left(\sum_{n=0}^{\infty} V(\Gamma^n x)\right) \leq \mathbb{E}(T_{(I,J)}).$$

This shows that the dependence of this generalized performance index and of the expected entrance time on the parameters $C(\Gamma)$ and $\mathbf{N}(\Gamma)$ will be similar.

2.1. The Perron–Frobenius operator for piecewise affine maps. In this subsection we recall some standard results on the ergodic theory of piecewise affine maps, and we will present a first preliminary result asserting that the expected entrance time is always finite for almost (I, J)-stable piecewise affine maps.

Let $\Gamma : I \to I$ be a piecewise affine map with a fixed slope a and assume here that $|a| > 1$. It is a standard fact that Γ induces a linear transformation

$$\mathcal{P}_\Gamma : L^1(I) \to L^1(I)$$

called the Perron–Frobenius operator associated with Γ which is uniquely defined by the following duality relation:

$$\int_I (g \circ \Gamma)(x) f(x) dx = \int_I g(x)(\mathcal{P}_\Gamma f)(x) dx \tag{7}$$

for all $g \in L^\infty(I), f \in L^1(I)$. It can be shown that the operator $\mathcal{P}_\Gamma$ is bounded with $||\mathcal{P}_\Gamma||_1 \leq 1$, and it maps probability densities onto probability densities. An important interpretation of $\mathcal{P}_\Gamma$ is as follows. If we have a continuous random variable X defined on I whose density is f, then the density of the transformed random variable $X \circ \Gamma$ is $\mathcal{P}_\Gamma f$. A final important property of the Perron–Frobenius operator $\mathcal{P}_\Gamma$ is that $\mathcal{P}_{\Gamma^n} = \mathcal{P}_\Gamma^n$.

The relevance of the Perron–Frobenius operator in our investigations is due to the fact that

$$\mathbb{P}_f\big[T_{(I,J)} > n\big] = \int_{I\setminus J} \mathcal{P}_\Gamma^n f(x)dx,$$

which follows by iterating (7) and by taking $g(x) = \mathbf{1}_{I\setminus J}(x)$. This shows that the asymptotics of this operator and so its spectral properties will be relevant for our purposes.

We have the following result.

LEMMA 1. *Let Γ be almost (I, J)-stable. If $h(x) \in L^1(I)$ is an invariant density of $\mathcal{P}_\Gamma$, then*

$$\text{supp } h \subseteq J.$$

Proof. First we show that, since J is invariant by Γ, the fact that supp $f \subseteq J$ implies that supp $\mathcal{P}_\Gamma^k f \subseteq J$. Indeed, if $K \subseteq I \setminus J$, then $\Gamma^{-1}(K) \subseteq I \setminus J$, and so

$$\int_K (\mathcal{P}_\Gamma f)(x)dx = \int_{\Gamma^{-1}(K)} f(x)dx = 0.$$

We show now that, if h is invariant by $\mathcal{P}_\Gamma$, then $h\mathbf{1}_J$ and $h\mathbf{1}_{I\setminus J}$ are also invariant by $\mathcal{P}_\Gamma$. Indeed for any $g \in L^\infty(I), f \in L^1(I)$ we have that

$$\begin{aligned}\int_I g(x)(\mathcal{P}_\Gamma h\mathbf{1}_J)(x)dx &= \int_J g(x)(\mathcal{P}_\Gamma h\mathbf{1}_J)(x)dx = \int_J g(x)(\mathcal{P}_\Gamma h)(x)dx \\ &= \int_I g(x)\mathbf{1}_J(x)(\mathcal{P}_\Gamma h)(x)dx = \int_I g(x)(h\mathbf{1}_J)(x)dx,\end{aligned}$$

where in the first equality we used the fact that supp $h\mathbf{1}_J \subseteq J$. This shows that $h\mathbf{1}_J$ is invariant. Since both h and $h\mathbf{1}_J$ are invariant, so is $h\mathbf{1}_{I\setminus J}$, as well.

Finally, if we assume by contradiction that there exists a nonzero invariant density of $\mathcal{P}_\Gamma$ not supported inside J, then for the above considerations, there also exists a nonzero invariant density supported inside $I \setminus J$. Let us call it h_0. We can find $\delta > 0$ and a subset $K \subseteq I \setminus J$ of nonzero Lebesgue measure such that $h_0(x) > \delta$ for every $x \in K$. Consequently, $h_0 - \delta\mathbf{1}_K$ is a nonnegative function. Therefore, $\mathcal{P}_\Gamma^n(h_0 - \delta\mathbf{1}_K) = h_0 - \mathcal{P}_\Gamma^n(\delta\mathbf{1}_K)$ is also nonnegative for all $n \geq 0$. Since h_0 is 0 on J, it follows that $\mathcal{P}_\Gamma^n\mathbf{1}_K$ is 0 on J for every n. This implies that

$$\int_{\Gamma^{-n}(J)} \mathbf{1}_K(x)dx = \int_J (\mathcal{P}_\Gamma^n\mathbf{1}_K)(x)dx = 0,$$

which implies that $K \cap \Gamma^{-n}(J)$ has zero Lebesgue measure for all $n \geq 0$, which contradicts the almost (I, J)-stability of Γ. ∎

To obtain a good characterization of the spectral properties of $\mathcal{P}_\Gamma$ we need to restrict the type of densities to be considered. Let $\mathrm{BV}(I) \subseteq L^1(I)$ be the subspace of $L^1(I)$ constituted by the bounded variation functions on the interval I. More precisely, if we define the variation of a function f as

$$\bigvee f := \sup\left\{\sum_{i=1}^{n-1} |f(x_{i+1}) - f(x_i)| \; x_i \in I, \quad x_1 < x_2 < \cdots < x_n\right\},$$

then

$$\mathrm{BV}(I) := \Big\{f : I \to \mathbb{R} : \bigvee f < \infty\Big\}.$$

Now equip the space $\mathrm{BV}(I)$ with a new norm

$$|||f||| := \bigvee f + ||f||_1.$$

It is a classical fact that $\mathcal{P}_\Gamma(\mathrm{BV}(I)) \subseteq \mathrm{BV}(I)$ and that $\mathcal{P}_\Gamma|_{\mathrm{BV}(I)}$ is bounded with respect to the norm $|||\cdot|||$. Using the Lasota–Yorke inequality [15] and the spectral theorem of Ionescu-Tulcea and Marinescu [12], the following facts can be shown to hold true.

(i) Let σ_1 be the set of eigenvalues of modulus 1 of $\mathcal{P}_\Gamma$ seen as an operator on $L^1(I)$. Then this set is a finite multiplicative group. Moreover, each of these eigenvalues has a finite dimensional eigenspace contained in $\mathrm{BV}(I)$.

(ii) The Perron–Frobenius operator $\mathcal{P}_\Gamma$ on $\mathrm{BV}(I)$ admits the following decomposition:

$$\mathcal{P}_\Gamma = \sum_{\lambda\in\sigma_1} \lambda Q_\lambda + R, \tag{8}$$

where Q_λ are finite rank operators on $\mathrm{BV}(I)$, and R is a bounded operator on $\mathrm{BV}(I)$ such that

(a) $Q_\lambda \circ R = R \circ Q_\lambda = 0$ for all $\lambda \in \sigma_1$;
(b) $Q_\lambda \circ Q_{\lambda'} = 0$ for all $\lambda, \lambda' \in \sigma_1$ such that $\lambda \neq \lambda'$;
(c) $Q_\lambda \circ Q_\lambda = Q_\lambda$ for all $\lambda \in \sigma_1$;
(d) $|||R^n||| \leq c\gamma^n$ for all $n \in \mathbb{N}$, where c is a positive constant and $0 < \gamma < 1$.

An important consequence of the above results is that the spectrum of $\mathcal{P}_\Gamma$ in $\mathrm{BV}(I)$ is composed of a finite set of eigenvalues on the unit circle (with finite dimensional eigenspaces) and of another part contained in a disk of radius strictly smaller than 1.

We now state and prove the main result of this section.

PROPOSITION 1. *Let Γ be an almost (I, J)-stable piecewise affine map. Then, there exists a constant $K > 0$ such that*

$$\mathbb{E}_f(T_{(I,J)}) \leq K|||f|||$$

for every probability density $f \in \mathrm{BV}(I)$.

Proof. Notice preliminarily that there exists $\nu \in \mathbb{N}$ such that $\lambda^\nu = 1$ for every $\lambda \in \sigma_1$. This implies that

$$\mathcal{P}_\Gamma^\nu = \sum_{\lambda\in\sigma_1} Q_\lambda + R^\nu.$$

This implies that for any density $f \in \mathrm{BV}(I)$ we have that $Q_\lambda f$ is invariant by $\mathcal{P}_\Gamma^\nu$. Since $\mathcal{P}_\Gamma^\nu$ is the Perron–Frobenius operator for the map Γ^ν which is almost (I,J)-stable, then, by Lemma 1, we have that supp $Q_\lambda f \subseteq J$. Using this fact and formula (8), we obtain

$$\mathbb{P}_f[T_{(I,J)} > n] = \int_{I\setminus J} (\mathcal{P}_\Gamma^n f)(x)dx = \int_{I\setminus J} (R^n f)(x)dx \le c\gamma^n |||f|||$$

and hence

$$\mathbb{E}_f(T_{(I,J)}) = \sum_{n=0}^{+\infty} \mathbb{P}_f[T_{(I,J)} > n] \le \frac{c}{1-\gamma}|||f|||. \qquad \square$$

3. Nested quantized feedback strategies. Consider the linear discrete time system (1), where $|a| > 1$, and consider two intervals $J \subseteq I$. We want to stabilize it through a quantized state feedback, i.e., we want to find a quantized feedback map k such that the closed loop system (2) drives (almost) any initial state $x_0 \in I$ into a state evolution which, after a transient, enters the interval J. Several solutions to this problem can be proposed. In fact, we will show that, starting from a base quantized feedback, it is possible to construct a family of quantized feedbacks by iterating the base one.

More precisely, suppose that we have found an (I,J)-stabilizing quantized feedback $k_1(x)$ and a (J,K)-stabilizing quantized feedback $k_2(x)$. Then it is clear that the quantized feedback

$$k(x) = \begin{cases} k_1(x) & \text{if } x \in I \setminus J, \\ k_2(x) & \text{if } x \in J \setminus K \end{cases} \tag{9}$$

will be (I,K)-stabilizing. The analogous conclusion is less straightforward in case we start from almost stabilizing quantized feedbacks. In what follows we will show that this is indeed the case, namely, if $k_1(x)$ is almost (I,J)-stabilizing and $k_2(x)$ is almost (J,K)-stabilizing, then $k(x)$ is almost (I,K)-stabilizing.

Let $\Gamma : I \to I$ be an almost (I,J)-stable piecewise affine map with a fixed slope a such that $|a| > 1$, and let $\mathcal{P}_\Gamma$ be the Perron–Frobenius operator associated with Γ. From any density function $f \in L^1(I)$ it is possible to define a probability measure μ on J as the image of the measure $\mathbb{P}_f$ through the map

$$\psi(x) := \Gamma^{T_{(I,J)}(x)}(x),$$

where $T_{(I,J)}(x)$ is the first entrance time function of Γ. More precisely, if $A \subseteq J$ is a measurable set, then

$$\mu(A) := \mathbb{P}_f\big[\psi^{-1}(A)\big]. \tag{10}$$

The following result gives important information on the measure μ.

PROPOSITION 2. *For any density $f \in L^1(I)$, the measure μ defined in* (10) *is absolutely continuous with respect to the Lebesgue measure and its corresponding density h is given by*

$$h = \mathbf{1}_J f + \sum_{j=1}^{+\infty} \mathbf{1}_J \mathcal{P}_\Gamma\big(\mathbf{1}_{I\setminus J}\mathcal{P}_\Gamma^{j-1} f\big). \tag{11}$$

Moreover, there exists a constant $H > 0$ only depending on Γ such that

$$|||h||| \le H|||f||| \quad \forall f \in \mathrm{BV}(I).$$

Proof. Let $A \subseteq J$ be a measurable set. Then

$$\begin{aligned}\mu(A) = \mathbb{P}_f[\psi^{-1}(A)] &= \sum_{j=0}^{+\infty} \mathbb{P}_f\big[\psi^{-1}(A) \cap \{T_{(I,J)}(x) = j\}\big] \\ &= \sum_{j=0}^{+\infty} \mathbb{P}_f\big[\Gamma^{-j}(A) \cap \{T_{(I,J)}(x) = j\}\big] \\ &= \mathbb{P}_f[A] + \sum_{j=1}^{+\infty} \mathbb{P}_f\big[\Gamma^{-j}(A) \cap \Gamma^{-j+1}(I \setminus J)\big].\end{aligned} \tag{12}$$

Notice that

$$\begin{aligned}\mathbb{P}_f\big[\Gamma^{-j}(A) \cap \Gamma^{-j+1}(I \setminus J)\big] &= \int_I \mathbf{1}_{\Gamma^{-j}(A)}(x)\mathbf{1}_{\Gamma^{-j+1}(I\setminus J)}(x)f(x)dx \\ &= \int_I \mathbf{1}_{\Gamma^{-1}(A)}(x)\Big[\mathbf{1}_{I\setminus J}(x)\mathcal{P}_\Gamma^{j-1}f(x)\Big]dx \\ &= \int_A \mathcal{P}_\Gamma\big(\mathbf{1}_{I\setminus J}\mathcal{P}_\Gamma^{j-1}f\big)(x)dx = \int_A h_j(x)dx,\end{aligned}$$

where $h_j(x) := \mathbf{1}_J(x)\mathcal{P}_\Gamma(\mathbf{1}_{I\setminus J}\mathcal{P}_\Gamma^{j-1}f)(x)$. Using this relation in (12) and the fact that $h_j(x)$ are nonnegative we obtain, by Fatou's lemma, that

$$\mu(A) = \mathbb{P}_f[A] + \sum_{j=1}^{+\infty}\int_A h_j(x)dx = \int_A \left[\mathbf{1}_J(x)f(x) + \sum_{j=1}^{+\infty} h_j(x)\right]dx,$$

which shows that the series $\sum_{j=1}^{+\infty} h_j(x)$ converges in the L^1 sense. Hence, the function h, defined in (11), is in L^1 and μ is absolutely continuous with respect to the Lebesgue measure with density h.

We now show that there is also a convergence in the norm $|||\cdot|||$ if $f \in \mathrm{BV}(I)$. First notice that, by the Yorke inequality [15, Formula (6.1.12)], for all $g \in \mathrm{BV}(I)$ we have

$$\bigvee(g\mathbf{1}_J) \le 2\bigvee g + \frac{2}{|I|}||g||_1,$$

which implies that

$$|||g\mathbf{1}_J||| \le 2\bigvee g + \left(1 + \frac{2}{|I|}\right)||g||_1 \le \left(2 + \frac{2}{|I|}\right)|||g|||.$$

Using the previous inequality we can argue that

$$|||\mathbf{1}_J\mathcal{P}_\Gamma(\mathbf{1}_{I\setminus J}\mathcal{P}_\Gamma^{j-1}f)||| \le \left(2 + \frac{2}{|I|}\right)|||\mathcal{P}_\Gamma||| \cdot |||\mathbf{1}_{I\setminus J}\mathcal{P}_\Gamma^{j-1}f|||. \tag{13}$$

Using the spectral decomposition for $\mathcal{P}_\Gamma$ we can estimate this last term as

$$|||\mathbf{1}_{I\setminus J}\mathcal{P}_\Gamma^{j-1}f\,||| = |||R^{j-1}f||| \le c\gamma^{j-1}|||f|||, \tag{14}$$

where we used the same arguments used in Proposition 1. Putting together estimates (13) and (14), we finally obtain that sum (11) indeed converges in the norm $|||\cdot|||$ and, moreover, we have that

$$\left|\left|\left|\sum_{j=1}^{+\infty} \mathbf{1}_J \mathcal{P}_\Gamma\left(\mathbf{1}_{I\setminus J}\mathcal{P}_\Gamma^{j-1} f\right)\right|\right|\right| \leq \left(2+\frac{2}{|I|}\right)\frac{|||\mathcal{P}_\Gamma|||c}{1-\gamma}|||f|||\,,$$

which yields the thesis. □

From the previous proposition and from Proposition 1 we can argue that the composed quantized feedback $k(x)$ defined in (9) is always almost (I,K)-stabilizing. The previous result can also be used to obtain an estimate of the expected entrance time $\mathbf{T}(k)$. Let $T_{(I,J)}(x)$ for k_1, and let $T_{(J,K)}(x)$ be the first entrance time function for k_2. It is clear that the first entrance time function $T_{(I,K)}(x)$ of the quantized feedback k is given by

$$T_{(I,K)}(x) = T_{(I,J)}(x) + T_{(J,K)}\left(\Gamma_1^{T_{(I,J)}(x)}(x)\right).$$

This implies that

$$\begin{aligned}\mathbb{E}_f(T) &= \int_J T_{(I,J)}(x)f(x)dx + \int_J T_{(J,K)}\left(\Gamma_1^{T_{(I,J)}(x)}(x)\right)f(x)dx\\ &= \mathbb{E}_f(T_{(I,J)}) + \mathbb{E}_h(T_{(J,K)}),\end{aligned}$$

where h is the probability density on J obtained form f as shown in the previous proposition.

This shows a way to estimate the expected entrance time of $k(x)$. As far as the number of quantization intervals is concerned, it is clear that we have simply that $\mathbf{N}(k) = \mathbf{N}(k_1) + \mathbf{N}(k_2)$. Finally, the contraction rate of the overall quantized feedback is the product of the contraction rates of the component quantized feedbacks, i.e., $C(k) = C(k_1)C(k_2)$.

The previous considerations can be used to obtain a class of (almost) stabilizing quantized feedbacks starting from one. Indeed, assume that $k(x)$ is an (almost) (I,J)-stabilizing quantized feedback with contraction rate $C(k) = C$, $\mathbf{N}(k)$ quantization intervals, and expected entrance time $\mathbf{T}(k)$. Let

$$F(x) := \frac{x}{C} + \beta$$

be an affine map such that $J = F(I)$. It is clear that the quantized feedback

$$F \circ k \circ F^{-1} \;:\; F(I) \to F(I)$$

is (almost) $(F(I), F^2(I))$-stabilizing. Observe that the corresponding closed loop map is $F \circ \Gamma \circ F^{-1}$. The same construction can be iterated, obtaining for every $i = 0, 1, \ldots, \tau - 1$ the quantized feedback $F^i \circ k \circ F^{-i}$ which is (almost) $(F^i(I), F^{i+1}(I))$-stabilizing. The quantized feedback defined by

$$k^{(\tau)}(x) := F^i \circ k \circ F^{-i}(x) \quad \text{if} \quad x \in F^i(I) \setminus F^{i+1}(I)$$

will be (almost) $(I, F^\tau(I))$-stabilizing with the contraction rate $C(k^{(\tau)}) = C(k)^\tau$ and $\mathbf{N}(k^{(\tau)}) = \tau\mathbf{N}(k)$ quantization intervals. As far as the expected entrance time $\mathbf{T}(k^{(\tau)})$

is concerned, it is difficult in general to estimate its dependence on the number τ of iterations.

Consider the map

$$\Psi : I \to I : x \mapsto F^{-1} \circ \Gamma^{T_{(I,J)}(x)}(x), \tag{15}$$

where $T_{(I,J)}(x)$ is the first entrance time function for k. It follows from Proposition 2 that Ψ transforms absolutely continuous measures into themselves so that also in this case we can consider the associated Perron–Frobenius operator

$$\mathcal{P}_\Psi : L^1(I) \to L^1(I).$$

It is easy to see that

$$\mathcal{P}_\Psi f = C^{-1}(h \circ F),$$

where h is the density which is obtained from f as shown in (11).

It is clear from the previous considerations that

$$\mathbf{T}\big(k^{(\tau)}\big) = \sum_{i=0}^{\tau-1} \mathbb{E}_{\mathcal{P}_\Psi^i f}\big(T_{(I,J)}\big), \tag{16}$$

where f is the uniform probability density on I. From Propositions 2 and 1 we obtain

$$\mathbf{T}\big(k^{(\tau)}\big) \le \sum_{i=0}^{\tau-1} K|||\mathcal{P}_\Psi^i f||| \le \sum_{i=0}^{\tau-1} K H^i |||f||| \le \frac{K}{H-1} H^\tau |||f|||. \tag{17}$$

This is not a very good estimate, since we expect that in many situations the growth should be linear in τ. For instance, if the uniform density on I is invariant, then we have that $\mathbf{T}(k^{(\tau)}) = \tau \mathbf{T}(k)$. In this case from a triple $(C, N, T) \in \mathcal{A}$ we can obtain a sequence of triples $(C^\tau, \tau N, \tau T) \in \mathcal{A}$ for all $\tau \in \mathbb{N}$. This method will be used in the following subsections to obtain three specific quantized feedback strategies.

In general we cannot guarantee that Ψ will possess invariant probability densities, and it seems to be very difficult to obtain estimates which are better than (17). Notice that indeed Ψ is also a piecewise affine map but in general with an infinite number of continuity intervals. For this type of maps the theory is quite weak: invariant probability densities are not guaranteed to exist, and we may lose the spectral structure of the corresponding Perron–Frobenius operator we had in the finite case (see [4] for more details). There is, however, a case in which things go smooth, namely, when $T(x)$ is bounded. In this case Ψ is an expanding piecewise affine map with only a finite number of continuity intervals, and in this case invariant densities do exist and the Perron–Frobenius operator $\mathcal{P}_\Psi$ admits the usual spectral decomposition (8). In this case we have the following result.

PROPOSITION 3. *Assume that $T(x)$ is bounded. Then, there exist a probability density $\overline{f}$ and a bounded sequence $\{a_\tau\}$ such that*

$$\mathbf{T}\big(k^{(\tau)}\big) = \tau \mathbb{E}_{\overline{f}}(T) + a_\tau. \tag{18}$$

Proof. Let f be the uniform probability density on I. Moreover, let $\nu \in \mathbb{N}$ be such that $\lambda^\nu = 1$ for every $\lambda \in \sigma_1$, and let $Q = \sum_\lambda Q_\lambda$. Observe that for all $j \in \mathbb{N}$

we have $Q\mathcal{P}_\Psi^j = \mathcal{P}_\Psi^j - R^j$ and that $Q\mathcal{P}_\Psi^\nu = Q$. This implies that if we decompose $j = l\nu + r$, with $l \in \mathbb{N}$ and $r \in \{0, \dots, \nu - 1\}$, we have that

$$\mathcal{P}_\Psi^j = Q\mathcal{P}_\Psi^r + R^j.$$

Define

$$\overline{f} = Q\left(\frac{1}{\nu}\sum_{j=0}^{\nu-1}\mathcal{P}_\Psi^j f\right).$$

Then, if $\tau - 1 = l\nu + r$, we have that

$$\begin{aligned}\sum_{j=0}^{\tau-1}\mathcal{P}_\Psi^j f - \tau\overline{f} &= lQ\left(\sum_{j=0}^{\nu-1}\mathcal{P}_\Psi^j f\right) + Q\left(\sum_{j=0}^{r}\mathcal{P}_\Psi^j f\right) + \sum_{j=0}^{\tau-1}R^j f - \tau\overline{f}\\ &= (l\nu - \tau)\overline{f} + Q\left(\sum_{j=0}^{r}\mathcal{P}_\Psi^j f\right) + \sum_{j=0}^{\tau-1}R^j f.\end{aligned}$$

Notice that

$$\begin{aligned}\left|\left|\left|(l\nu - \tau)\overline{f} + Q\left(\sum_{j=0}^{r}\mathcal{P}_\Psi^j f\right) + \sum_{j=0}^{\tau-1}R^j f\right|\right|\right| &\le \nu|||\overline{f}|||\\ + |||Q|||\left(\sum_{j=0}^{\nu-1}|||\mathcal{P}_\Psi^j|||\right)|||f||| &+ \frac{C}{1-\gamma}|||f|||\end{aligned}$$

is bounded in τ. Observe finally that

$$\begin{aligned}|\mathbf{T}(k^{(\tau)}) - \tau\mathbb{E}_{\overline{f}}(T)| &= \left|\int_I T(x)\left(\sum_{j=0}^{\tau-1}\mathcal{P}_\Psi^j f(x) - \tau\overline{f}(x)\right)dx\right|\\ &\le \int_I T(x)\left|\sum_{j=0}^{\tau-1}\mathcal{P}_\Psi^j f(x) - \tau\overline{f}(x)\right|dx.\end{aligned}$$

The result now follows by applying Proposition 1. □

This has the following consequence. If the triple (C, N, T) is in $\mathcal{A}$ and corresponds to a situation in which the entrance time function is bounded, then we can obtain a sequence of triples $(C^\tau, \tau N, \tau\overline{T} + a_\tau) \in \mathcal{A}$ for all $\tau \in \mathbb{N}$, where $\overline{T}$ is the expected entrance time with respect to a suitable probability density, and $\{a_\tau\}$ is a bounded sequence.

4. Three stabilizing quantized feedback strategies. The method presented in the previous section will be used in the following subsections to obtain three specific quantized feedback strategies. In what follows we assume for simplicity that $I = [-1, 1]$ and $J = [\epsilon, \epsilon]$ with $\epsilon \le 1$, and so we have that $C = 1/\epsilon$. In this section we will simply write $C, \mathbf{N}, \mathbf{T}$ dropping the explicit dependence from k. All probabilistic considerations in this section will be carried on with respect to the uniform probability on I.

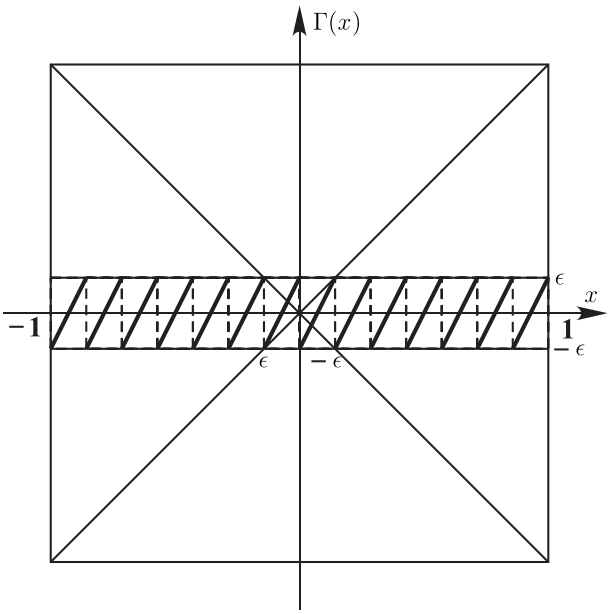

FIG. 1. *The map* Γ *associated with the quantized feedback defined in* (19).

4.1. Deadbeat quantized feedback strategy. The first strategy, which has been analyzed in detail by Delchamps in [6], consists of approximating the one-step deadbeat controller $k(x) := -ax$ by its quantized version, i.e., by a uniform quantized function $k(x)$ such that $-ax - \epsilon \le k(x) \le -ax + \epsilon$. One possibility is to take

$$k(x) := -(2h+1)\epsilon \quad \text{for} \quad h\frac{2\epsilon}{a} < x \le (h+1)\frac{2\epsilon}{a}, \tag{19}$$

which yields the closed loop map $\Gamma(x)$ illustrated in Figure 1.

This controller drives any state belonging to I into J in one step. In this case we have that

$$\mathbf{N} = 2\left\lceil |a|\frac{C-1}{2} \right\rceil \sim |a|C$$

and that

$$\mathbf{T} = \sum_{n=1}^{\infty} \mathbb{P}[T_J \ge n] = \mathbb{P}[T_J \ge 1] = 1 - \mathbb{P}[J] = 1 - 1/C,$$

where $f(C) \sim g(C)$ means that $f(C)/g(C)$ tends to 1 as $C \to \infty$.

Using the nesting strategy presented above we can construct a τ-step deadbeat quantized feedback simply iterating the one-step deadbeat quantized feedback. We only need to pay attention to the fact that the uniform density in I is invariant with respect to the map Ψ defined in (15). This happens if $|a|(C-1)/2$ is an integer. Assume that this is the case, and denote it by n. We obtain a triple contraction rate, quantization intervals, and expected entrance time equal to

$$\left(\frac{2n+|a|}{|a|}, 2n, \frac{2n}{2n+|a|}\right) \in \mathcal{A}.$$

Using the strategy presented above, we can iterate the construction τ times, obtaining in this way a sequence of triples

$$\left(\left(\frac{2n+|a|}{|a|}\right)^{\tau}, 2\tau n, \tau\frac{2n}{2n+|a|}\right) \in \mathcal{A}, \qquad n,\tau \in \mathbb{N},$$

which provides a family of quantized feedbacks parameterized by the two integers τ and n. We are mainly interested in understanding what asymptotic behavior can be obtained of $\mathbf{N}$ and $\mathbf{T}$ as $C \to \infty$. To this aim observe that

$$\frac{\mathbf{N}/|a|}{\mathbf{T}C^{1/\mathbf{T}}} = \left(\frac{2n+|a|}{|a|}\right)^{-\frac{|a|}{2n}} \in [1/e, 1].$$

Making the change of variable

$$C = \left(\frac{2n+|a|}{|a|}\right)^{\tau}, \qquad n = \frac{|a|}{2}\big(C^{\frac{1}{\tau}} - 1\big), \tag{20}$$

we obtain

$$\begin{aligned} \mathbf{N}/|a| &= \tau\big(C^{\frac{1}{\tau}} - 1\big), \\ \mathbf{T} &= \tau\big(1 - C^{-\frac{1}{\tau}}\big), \end{aligned}$$

where τ is any function of C that by (20) can be chosen arbitrarily subject to the fact that $\tau(C)/\log C$ is bounded from above. If in particular τ is fixed, we obtain

$$\begin{aligned} \mathbf{N}/|a| &\sim \tau C^{\frac{1}{\tau}}, \\ \mathbf{T} &\sim \tau. \end{aligned}$$

If instead we think of τ as a possible function of C, we can distinguish two different patterns of behavior: the case when $\tau(C)/\log C \to 0$ and the case when $\tau(C) \sim K\log C$. In the first case we have that

$$\mathbf{N}/|a| \sim \mathbf{T}C^{1/\mathbf{T}}, \tag{21}$$

and moreover $\mathbf{N}/\log C \to \infty$, namely, we have a superlogarithmic growth of the number of quantization intervals, while the expected entrance time has a sublogarithmic growth $\mathbf{T}/\log C \to 0$. In the second situation when $\tau(C) \sim K\log C$ we have that both $\mathbf{N}$ and $\mathbf{T}$ grow logarithmically in C. More precisely, we have that

$$\begin{aligned} \mathbf{N}/|a| &\sim K\big(e^{1/K} - 1\big)\log C, \\ \mathbf{T} &\sim K\big(1 - e^{-1/K}\big)\log C. \end{aligned} \tag{22}$$

4.2. Logarithmic quantized feedback strategy. The second strategy is based on the quantized feedback (we assume $a > 0$, the case $a < 0$ being completely analogous)

$$k(x) = \begin{cases} -a+1 & \text{if } \epsilon \le x \le 1, \\ +a-1 & \text{if } -1 \le x \le -\epsilon, \end{cases} \tag{23}$$

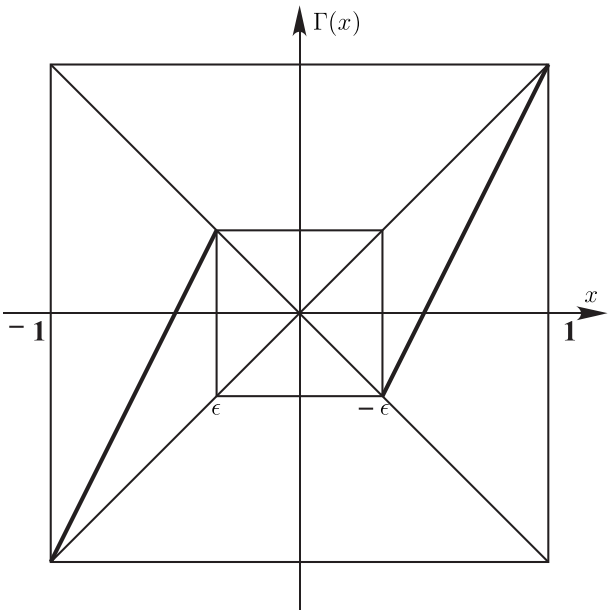

FIG. 2. *The map* Γ *associated with the quantized feedback defined in* (23).

where

$$\epsilon = \frac{a-1}{a+1}.$$

In this way we obtain an almost (I, J)-stabilizing quantized feedback, where $I = [-1, 1]$ and $J = [-\epsilon, \epsilon]$. The graph of closed loop map $\Gamma(x)$ is illustrated in Figure 2.

In this case we have a contraction rate $1/\epsilon$ and two quantization intervals. The expected entrance time can be found by noticing that

$$\Gamma^{-n}(I \setminus J) = [-1, -\epsilon_n] \cup [\epsilon_n, 1],$$

where $\epsilon_n = 1 - 2/(a+1)a^n$, which implies that the expected entrance time is

$$\sum_{n=0}^{\infty} \mathbb{P}[T_{(I,J)} > n] = \sum_{n=0}^{\infty} \mathbb{P}[\Gamma^{-n}(I \setminus J)] = \frac{2}{a+1} \sum_{n=0}^{\infty} a^{-n} = \frac{2a}{a^2-1}.$$

In general, when we do not restrict to positive a, we obtain a triple contraction rate, quantization intervals, the expected entrance time equal to

$$\left(\frac{|a|-1}{|a|+1}, 2, \frac{2|a|}{|a|^2-1} \right) \in \mathcal{A}.$$

Using the strategy presented above, we can iterate the construction τ times. In this case it is less obvious to show that the Lebesgue measure is invariant with respect to the map Ψ defined from Γ as in (15). To show this, observe preliminarily that if we assume that $\Gamma(x) = x$ for all $x \in J$, then

$$\lim_{n\to\infty} \Gamma^n(x) = \Gamma^{T_{(I,J)}(x)}(x) \qquad \text{for almost all } x \in I,$$

which implies that $\Gamma^n(x)$ converges to $\Gamma^{T_{(I,J)}(x)}(x)$ in distribution. Observe moreover that if the density function f_n of the random variable $\Gamma^n(x)$ is of the form

$$f_n(a) = \begin{cases} \alpha_n & \text{if } a \in J, \\ \beta_n & \text{if } a \in I \setminus J, \end{cases}$$

then also f_{n+1} has the same structure with $\alpha_{n+1} = 2\beta_n/|a| + \alpha_n$, and $\beta_{n+1} = \beta_n/|a|$. This implies that

$$\lim_{n\to\infty} f_n(a) = \begin{cases} 1/\epsilon & \text{if } a \in I_1, \\ 0 & \text{if } a \in I_0 \setminus I_1 \end{cases}$$

from which we can argue that the Lebesgue measure is invariant with respect to the map Ψ.

These facts allow us to obtain a sequence of triples

$$\left(\left(\frac{|a|+1}{|a|-1} \right)^\tau, 2\tau, \frac{2|a|}{|a|^2-1}\tau \right) \in \mathcal{A}, \qquad \tau \in \mathbb{N}.$$

Making the change of variable

$$C = \left(\frac{|a|+1}{|a|-1} \right)^\tau, \qquad \tau = \frac{\log C}{\log(|a|+1) - \log(|a|-1)},$$

we obtain

$$\mathbf{N}/|a| = \frac{2}{|a|} \; \frac{\log C}{\log(|a|+1) - \log(|a|-1)},$$

$$\mathbf{T} = \frac{2|a|}{|a|^2-1} \; \frac{\log C}{\log(|a|+1) - \log(|a|-1)}.$$

These expressions motivate the fact that this quantized feedback is called a logarithmic quantizer. The strategy obtained in this way coincides with the one proposed in [7, 9] which yields a Lyapunov stability.

4.3. Chaotic quantized feedback strategy. In [9] another possible quantized feedback yielding almost stability has been proposed. This control strategy exploits the chaotic behavior of the state evolution inside $I = [-1, 1]$ produced by the feedback map

$$k_0(x) := -(2h+1) \quad \text{for} \quad \frac{2}{a}h < x \le \frac{2}{a}(h+1), \tag{24}$$

when we have that $|a| \ge 2$. In this way we have that, for almost every initial condition x_0, the state evolution x_t is maintained inside the interval I and is dense in this interval. For this reason x_t will visit the interval $J = [-\epsilon, \epsilon]$. Therefore, if we modify this feedback map in J as follows:

$$k(x) = \begin{cases} k_0(x) & \text{if } x \in I \setminus J, \\ k_1(x) & \text{if } x \in J, \end{cases} \tag{25}$$

where $k_1(x)$ is any quantized feedback making J invariant (take for instance $k_1(x) = \epsilon k_0(x/\epsilon)$), we obtain that the state will move chaotically inside I until it enters the

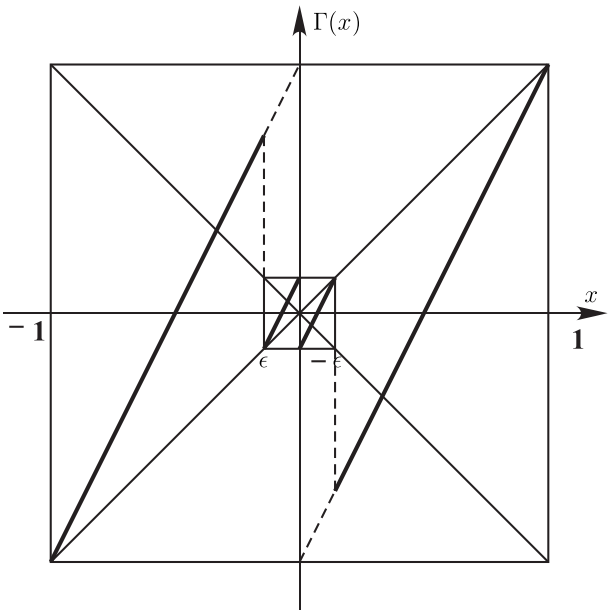

FIG. 3. *The map* Γ *associated with the quantized feedback defined in* (25).

interval J, and there it will be entrapped. In this way we obtain a feedback map requiring

$$\mathbf{N} = \lceil |a| \rceil$$

quantization intervals. The closed loop map $\Gamma(x)$ is shown in Figure 3 in the case $a = 2$.

In this case the evaluation of the expected entrance time can be done using Markov chain techniques. Assume that $\epsilon = 2^{-n}$. It is clear that, for evaluating the expected entrance time, we can refer to the system with feedback $k_0(x)$. Define the sets $I_i := [-i2^{-n}, -(i-1)2^{-n}] \cup [(i-1)2^{-n}, i2^{-n}]$, $i = 1, \ldots, 2^n$. In this way we have that $J = I_1$. Assuming that the initial state x_0 is uniformly distributed in I, we can argue that

$$\mathbb{P}[x_0 \in I_i] = 2^{-n}.$$

The initial distribution is described by the row vector

$$\pi := 2^{-n} \begin{bmatrix} 1 & 1 & \cdots & 1 & 1 \end{bmatrix} \in \mathbb{R}^{1 \times 2^n}.$$

Assuming that the iterated state x_t is uniformly distributed in each quantization interval I_i, the structure of the closed loop map $\Gamma_0(x) = ax + k_0(x)$ ensures also that the updated state $x_{t+1} = \Gamma_0(x_t)$ will be uniformly distributed in each quantization interval. Moreover, we have that

$$\mathbb{P}[x_{t+1} \in I_j | x_t \in I_i] = \Pi_{ij},$$

where Π_{ij} is the i,j-element of the matrix

$$\Pi = \frac{1}{2}\begin{bmatrix} 0 & 0 & 0 & 0 & \cdots & 0 & 0 & 1 & 1 \\ 0 & 0 & 0 & 0 & \cdots & 1 & 1 & 0 & 0 \\ \vdots & \vdots & \vdots & \vdots & \ddots & \vdots & \vdots & \vdots & \vdots \\ 0 & 0 & 1 & 1 & \cdots & 0 & 0 & 0 & 0 \\ 1 & 1 & 0 & 0 & \cdots & 0 & 0 & 0 & 0 \\ 1 & 1 & 0 & 0 & \cdots & 0 & 0 & 0 & 0 \\ 0 & 0 & 1 & 1 & \cdots & 0 & 0 & 0 & 0 \\ \vdots & \vdots & \vdots & \vdots & \ddots & \vdots & \vdots & \vdots & \vdots \\ 0 & 0 & 0 & 0 & \cdots & 1 & 1 & 0 & 0 \\ 0 & 0 & 0 & 0 & \cdots & 0 & 0 & 1 & 1 \end{bmatrix} \in \mathbb{R}^{2^n \times 2^n}.$$

Then (see [13]) the expected first entrance time in the state 1 is given by the formula

$$\mathbf{T} = \mathbb{E}\big(T_{(I,J)}\big) = \frac{d}{dz} w(z)_{|z=1},$$

where

$$w(z) := \frac{\pi\Pi(z)e_1}{e_1^T\Pi(z)e_1}$$

and where $\Pi(z) := \sum_{n\geq 0} \Pi^n z^n$ and $e_1 := [1\ 0\ \cdots\ 0]^T$. Since $\pi\Pi = \pi$, then

$$\pi\Pi(z) := \frac{1}{1-z}\pi.$$

It can be seen that

$$e_1^T\Pi(z)e_1 = 1 + 2^{-n}\frac{z^n}{1-z},$$

obtaining in this way

$$w(z) = \frac{1}{z^n + (1-z)2^n}$$

and

$$\mathbf{T} = \frac{d}{dz} w(z)_{|z=1} = 2^n - n.$$

In this way we obtained the triple

$$(2^n, 2, 2^n - n) \in \mathcal{A}.$$

Using the strategy presented above we can iterate this construction τ times. It can be shown that in this case also the Lebesgue measure is invariant with respect to the closed map Ψ defined from Γ as in (15). To show this we use the same kind of reasoning used in the previous subsection. Again, by defining Γ in such a way that $\Gamma(x) = x$ for all $x \in J$, we have that the random variable $\Gamma^n(x)$ converges to $\Gamma^{T_{(I,J)}(x)}(x)$ in distribution. Observe moreover that if the density function f_n of the random variable $\Gamma^n(x)$ is constant in each quantization interval I_i, then it can be

shown that f_{n+1} has also the same property. This implies that the limit density will also be a function which is constant in each set I_i and particularly in J. From this we can argue that the Lebesgue measure is invariant with respect to the map Ψ. These facts allow us to obtain a sequence of triples

$$(2^{\tau n}, \tau 2, \tau 2^n - \tau n) \in \mathcal{A}, \qquad n, \tau \in \mathbb{N}.$$

The previous reasoning can be extended to any situation in which $|a|$ is an integer. In this case we can obtain the sequence of triples

$$(|a|^{\tau n}, \tau |a|, \tau |a|^n - \tau n) \in \mathcal{A}, \qquad n, \tau \in \mathbb{N},$$

which provides a family of quantized feedbacks parameterized by the two integers τ, n. We are mainly interested in understanding what asymptotic behavior can be obtained for $\mathbf{N}$ and $\mathbf{T}$ as $C \to \infty$. To this aim observe that

$$\frac{\mathbf{T}}{\frac{\mathbf{N}}{|a|} C^{\frac{|a|}{\mathbf{N}}}} = 1 - \frac{n}{|a|^n} \in \left[1 - \frac{1}{e \log |a|}, 1\right].$$

Making the change of variable

$$C = |a|^{\tau n}, \qquad n = \frac{\log C}{\tau \log |a|}, \tag{26}$$

we obtain that

$$\begin{aligned} \mathbf{N}/|a| &= \tau, \\ \mathbf{T} &= \tau C^{\frac{1}{\tau}} - \frac{\log C}{\log |a|}, \end{aligned}$$

where τ is any function of C that, by (26), can be chosen arbitrarily subject to the fact that $\tau(C)/\log C$ is bounded from above. If in particular τ is fixed, we obtain

$$\begin{aligned} \mathbf{N}/|a| &= \tau, \\ \mathbf{T} &\sim \tau C^{\frac{1}{\tau}}. \end{aligned}$$

If instead we think of τ as a possible function of C, we can distinguish the case when $\tau(C)/\log C \to 0$ and the case when $\tau(C) \sim K \log C$. In the first case we have that

$$\mathbf{T} \sim \frac{\mathbf{N}}{|a|} C^{\frac{|a|}{\mathbf{N}}}, \tag{27}$$

and moreover $\mathbf{N}/\log C \to 0$, namely, a sublogarithmic growth of the number of quantization intervals, while the expected entrance time has a superlogarithmic growth $\mathbf{T}/\log C \to \infty$. In the second situation when $\tau(C) \sim K \log C$ we have that both $\mathbf{N}$ and $\mathbf{T}$ grow logarithmically in C. More precisely, we have that

$$\begin{aligned} \mathbf{N}/|a| &= K \log C, \\ \mathbf{T} &= \left(K e^{1/K} - \frac{1}{\log |a|}\right) \log C. \end{aligned} \tag{28}$$

Chaotic stabilizers can also be considered for nonintegers slopes a. Some preliminary results in this case have been obtained in [9]. In [8] the following more refined result is proved.

THEOREM 1. *Let a be such that $|a| > 2$, $I = [-1, 1]$, and $J = [-\epsilon, \epsilon]$, where $0 < \epsilon < 1$. There exists an almost (I, J)-stabilizing quantized feedback $k : I \to \mathbb{R}$ such that*

$$\mathbf{N} = \lceil |a| \rceil + 1,$$
$$\mathbf{T} \leq KC,$$

where K is a positive constant only depending on a.

Remark. The following table summarizes the properties of the different quantized feedback strategies.

	$\mathbf{N}/\lvert a\rvert$	$\mathbf{T}$
τ-step deadbeat quantizer	$\tau C^{\frac{1}{\tau}}$	τ
Logarithmic quantizer	$\frac{2}{\lvert a\rvert} \frac{\log C}{\log(\lvert a\rvert - 1) - \log(\lvert a\rvert + 1)}$	$\frac{2\lvert a\rvert}{\lvert a\rvert^2 - 1} \frac{\log C}{\log(\lvert a\rvert - 1) - \log(\lvert a\rvert + 1)}$
τ-step chaotic quantizer	τ	$\tau C^{\frac{1}{\tau}}$

This table highlights the relations between the parameters $|a|$, N, C, and T. In all cases it is possible to see that the steady state performance parameter C and transient performance parameter T are conflicting; namely, for fixed $|a|$ and N, an increasing value of C implies an increasing value of T and vice versa. Moreover, both the performance parameters are improved when N is increased and are worsened when $|a|$ is increased. A qualitative description of the relations between the parameters $|a|$, N, C, and T is given in Figure 4.

This suggests that looking for the stabilizing quantized feedback with minimal quantization intervals is a rather naive approach to the quantized control problem. Indeed, in case we do not consider the transient performance described by the parameter T, the optimal strategy would be clearly the chaos-based one. However, this provides only a partial view of the problem, since in fact the different strategies provide closed loop systems with different trade-off relations between the performance parameters T and C.

5. Bounds of the performance of a quantized feedback system. In this section we will present some general bounds involving the parameters $C(\Gamma)$, $\mathbf{N}(\Gamma)$, and $\mathbf{T}(\Gamma)$. These will be obtained by means of a symbolic representation of the dynamical system and using basic combinatorial arguments.

5.1. Symbolic descriptions of the dynamical system. Let $\Gamma : I \to I$ be a piecewise affine map with a fixed slope a. Let $J \subseteq I$ be another almost invariant

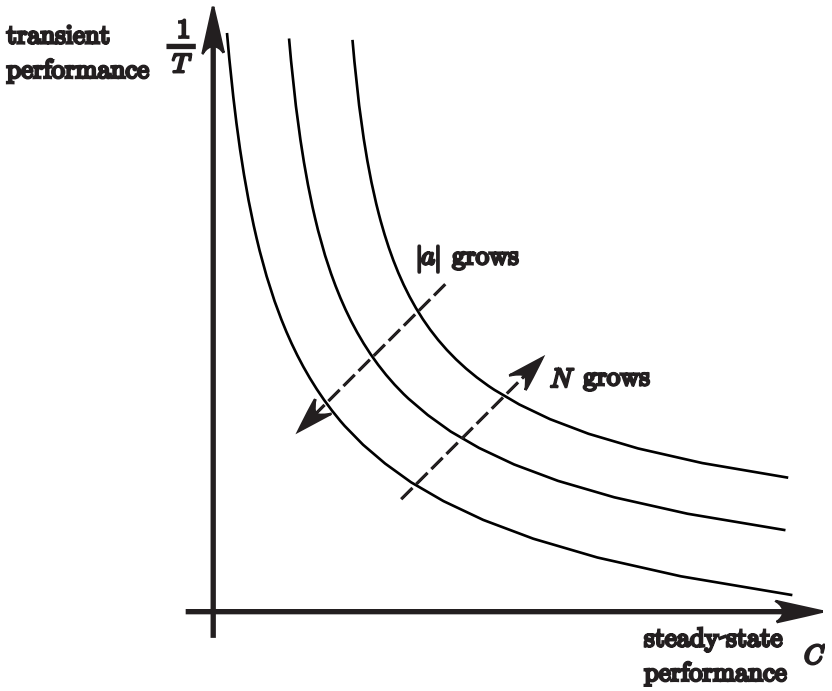

FIG. 4. *The qualitative relations between the parameters $|a|$, N, C, and T. The parameter C describes the steady state performance, the parameter $1/T$ describes the transient performance, the curves describe the trade-off between these two parameters for fixed N and $|a|$. Different curves refer to different values of N and $|a|$.*

interval. We can write

$$J = \overline{J_1 \cup J_2 \cup \cdots \cup J_M}, \qquad I = \overline{I_1 \cup I_2 \cup \cdots \cup I_N} \cup J,$$

where the I_h's and the J_l's are disjoint open intervals on which Γ is affine. In what follows, we will use the shorthand notation $C = C(\Gamma)$, $\mathbf{N} = \mathbf{N}(\Gamma)$, and $\mathbf{T} = \mathbf{T}(\Gamma)$. In this section, we will always consider Γ defined on the set Ω as defined in (4). Define the finite sets

$$\mathcal{I} = \{I_1, I_2, \ldots, I_{\mathbf{N}}\}, \quad \mathcal{J} = \{J_1, J_2, \ldots, J_M\},$$

and define a map $\psi : \Omega \to (\mathcal{I} \cup \mathcal{J})^{\mathbb{N}}$ by

$$\psi(x)_n = \omega_n \ \text{ if } \ \Gamma^n(x) \in \omega_n \,. \tag{29}$$

Notice that the above map is well defined by the way in which Ω has been defined. Consider the language $\Sigma_*(\Gamma)$ over the alphabet $\mathcal{I} \cup \mathcal{J}$ which is the subset of $(\mathcal{I} \cup \mathcal{J})^*$ consisting of all the finite words appearing in the infinite sequences in the range of ψ. If $|a| > 1$, then Γ locally expands and, as a consequence, the map ψ is injective. Indeed, it follows from (29) that $x \in \omega_0 \cap \cdots \cap \Gamma^{-n}\omega_n$ for every n. On the other hand it follows from the simple bound (33) that the length of this interval goes to 0 for $n \to +\infty$, which yields injectivity. This implies that all the dynamical and statistical properties of the map Γ can be read out from the language $\Sigma_*(\Gamma)$. Notice, for further use, the following properties of simple verification.

1. $\omega_0\omega_1\cdots\omega_n \in \Sigma_*(\Gamma)$ if and only if $\omega_0 \cap \Gamma^{-1}\omega_1 \cap \cdots \cap \Gamma^{-n}\omega_n \neq \emptyset$.
2. For all $\omega_0\omega_1\cdots\omega_n \in \Sigma_*(\Gamma)$ the map Γ^{n+1} is affine on the interval $\omega_0 \cap \Gamma^{-1}\omega_1 \cap \cdots \cap \Gamma^{-n}\omega_n$.
3. If $\omega_0\omega_1\cdots\omega_n$ and $\nu_0\nu_1\cdots\nu_m$ are in $\Sigma_*(\Gamma)$ and none of the two happens to be the initial subword of the other, then the two intervals $\omega_0 \cap \Gamma^{-1}\omega_1 \cap \cdots \cap \Gamma^{-n}\omega_n$ and $\nu_0 \cap \Gamma^{-1}\nu_1 \cap \cdots \cap \Gamma^{-m}\nu_m$ are disjoint.

As we mentioned above, language $\Sigma_*(\Gamma)$ contains all the dynamical and statistical properties of the map Γ. In particular this is true for the expected entrance time. Indeed, as the following lemma shows, the expected entrance time can be estimated by knowing how the number of words in $\Sigma_*(\Gamma)$ grows with respect to their length. More precisely, denote by γ_n the number of distinct words in sublanguage $\Sigma_*(\Gamma) \cap \mathcal{I}^*$ of length n, i.e.,

$$\gamma_n := \#\big\{\omega_0\omega_1\cdots\omega_{n-2}\omega_{n-1} \in \Sigma_*(\Gamma) \cap \mathcal{I}^*\big\}. \tag{30}$$

Then we have the following result.

LEMMA 2. *Given any $n \in \mathbb{N}$ we have that*

$$\mathbb{P}\big[T_{(I,J)} = n\big] \leq \mathbb{P}[J]\frac{\gamma_n}{|a|^n}, \tag{31}$$

$$\mathbb{P}\big[T_{(I,J)} \geq n\big] \geq \mathbb{P}[I \setminus J] - \mathbb{P}[J]\sum_{k=1}^{n-1}\frac{\gamma_k}{|a|^k}. \tag{32}$$

Proof. As mentioned above, the family of intervals of the form

$$\omega_0 \cap \Gamma^{-1}(\omega_1) \cap \cdots \cap \Gamma^{-(n-1)}(\omega_{n-1}) \cap \Gamma^{-n}(\omega_n), \qquad \omega_0, \ldots, \omega_{n-1} \in \mathcal{I}, \omega_n \in \mathcal{J}$$

constitutes a partition of the set of points of I which end inside J in exactly n steps. Moreover, since Γ^n is affine on each of these intervals, it follows that

$$\mathbb{P}\big[\omega_0 \cap \Gamma^{-1}(\omega_1) \cap \cdots \cap \Gamma^{-(n-1)}(\omega_{n-1}) \cap \Gamma^{-n}(\omega_n)\big] \leq \frac{\mathbb{P}[J]}{|a|^n}. \tag{33}$$

Therefore, if we let

$$\tilde{\gamma}_n := \#\{\omega_0\omega_1\cdots\omega_{n-2}\omega_{n-1} \in \Sigma_*(\Gamma) \mid \omega_0\omega_1\cdots\omega_{n-2}\omega_{n-1} \in \mathcal{I}^* \text{ and } \omega_{n-1} \in \mathcal{J}\}\ ,$$

we can argue that

$$\mathbb{P}[T_{(I,J)} = n] \leq \mathbb{P}[J]\frac{\tilde{\gamma}_{n+1}}{|a|^n} \leq \mathbb{P}[J]\frac{\gamma_n}{|a|^n}\ ,$$

where we used the fact that for all $n \geq 1$ we have that $\tilde{\gamma}_{n+1} \leq \gamma_n$.

We prove now the second assertion by induction on n. The assertion is trivial for $n = 1$. Assume by induction that the assertion holds for n, and let us prove it for $n + 1$. We can now write

$$\begin{aligned}\mathbb{P}\big[T_{(I,J)} \geq n+1\big] &= \mathbb{P}\big[T_{(I,J)} \geq n\big] - \mathbb{P}\big[T_{(I,J)} = n\big] \geq \mathbb{P}\big[T_{(I,J)} \geq n\big] - \mathbb{P}[J]\frac{\gamma_n}{|a|^n} \\ &\geq \mathbb{P}[I \setminus J] - \mathbb{P}[J]\sum_{k=1}^{n-1}\frac{\gamma_k}{|a|^k} - \mathbb{P}[J]\frac{\gamma_n}{|a|^n} \\ &= \mathbb{P}[I \setminus J] - \mathbb{P}[J]\sum_{k=1}^{n}\frac{\gamma_k}{|a|^k}. \qquad \square\end{aligned}$$

Notice that $\mathbb{P}[J] = C^{-1}$. This implies that formula (32) can be rewritten as

$$\mathbb{P}\big[T_{(I,J)} \geq n\big] \geq 1 - C^{-1} - C^{-1} \sum_{k=1}^{n-1} \frac{\gamma_k}{|a|^k} \tag{34}$$

from which we can argue that for any arbitrarily fixed $\overline{n} \in \mathbb{N}$ we have that

$$\begin{aligned} \mathbf{T} &= \mathbb{E}\big(T_{(I,J)}\big) \\ &= \sum_{n=1}^{+\infty} \mathbb{P}\big[T_{(I,J)} \geq n\big] \geq \sum_{n=1}^{\overline{n}} \mathbb{P}[T_{(I,J)} \geq n] \geq \overline{n}(1 - C^{-1}) - C^{-1} \sum_{n=1}^{\overline{n}} \sum_{k=1}^{n-1} \frac{\gamma_k}{|a|^k}. \end{aligned} \tag{35}$$

If we can establish upper bounds on γ_k, through (35), we can thus achieve lower bounds on $\mathbf{T}$. The following theorem provides the most relevant contribution of this paper, since it presents a bound on the growth of γ_k depending on the number of quantization intervals $\mathbf{N}$. The proof of this theorem is very long, and it will be presented in the last section.

THEOREM 2. *Assume that $|a| > 2$. Then*

$$\frac{\gamma_k}{|a|^k} \leq 2 \left[\sum_{s=1}^{r \wedge k} \binom{k-1}{s-1} \binom{r}{s} \left(\frac{s}{r}\right)^s \right] \left(\frac{\mathbf{N}M}{k \wedge \frac{\mathbf{N}M}{e}} \right)^{k \wedge \frac{\mathbf{N}M}{e}} \qquad \forall k \geq 1, \tag{36}$$

where $r \in \{1, \ldots, \mathbf{N}\}$ is independent of k, but may depend on the specific system, while M depends only on $|a|$.

Remark. In symbolic dynamics [17] the set $\overline{\Psi(\Omega)}$ (where the closure is to be intended in the product topology of $(\mathcal{I} \cup \mathcal{J})^{\mathbb{N}}$) is called shift. It can be shown that its topological entropy is $\log |a|$. As a consequence, for every $\epsilon > 0$, there exists $M_\epsilon > 0$ such that

$$\gamma_k \leq M_\epsilon (|a| + \epsilon)^k. \tag{37}$$

This type of estimate is of no use for our purposes for two reasons: first because the geometric growth rate $|a| + \epsilon$ causes a too quick growth in the double summation in (35), making impossible any useful estimate, and second because it is not clear how explicitly M_ϵ depends on the map Γ. In fact, estimate (36) is uniform with respect to all the possible piecewise affine maps having slope a and $\mathbf{N}$ quantization intervals. Notice, moreover, that for large k ($k \geq \max\{\mathbf{N}, \mathbf{N}/Me\}$), (36) can be written as

$$\gamma_k \leq (\overline{M}k)^{\mathbf{N}} |a|^k,$$

where $\overline{M}$ is a suitable constant depending only on a. This is clearly a much better estimate than (37).

Using Theorem 2 we obtain a lower bound estimate on $\mathbf{T}$.

COROLLARY 1. *For any $\overline{n} \in \mathbb{N}$ we have that*

$$\mathbf{T} \geq \overline{n}\big(1 - C^{-1}\big) - 2C^{-1} \left[\sum_{s=1}^{r \wedge \overline{n}-1} \binom{\overline{n}}{s+1} \binom{r}{s} \left(\frac{s}{r}\right)^s \right] \left(\frac{\mathbf{N}M}{\overline{n} - 1 \wedge \frac{\mathbf{N}M}{e}} \right)^{\overline{n}-1 \wedge \frac{\mathbf{N}M}{e}}. \tag{38}$$

Proof. From Theorem 2 we can argue that

$$
\begin{aligned}
(39)\qquad \sum_{k=1}^{n-1}\frac{\gamma_k}{|a|^k} &\le 2\sum_{k=1}^{n-1}\sum_{s=1}^{r\wedge k}\binom{k-1}{s-1}\binom{r}{s}\left(\frac{s}{r}\right)^s\left(\frac{\mathbf{N}M}{k\wedge\frac{\mathbf{N}M}{e}}\right)^{k\wedge\frac{\mathbf{N}M}{e}}\\
&= 2\sum_{s=1}^{r\wedge n-1}\sum_{k=s}^{n-1}\binom{k-1}{s-1}\binom{r}{s}\left(\frac{s}{r}\right)^s\left(\frac{\mathbf{N}M}{k\wedge\frac{\mathbf{N}M}{e}}\right)^{k\wedge\frac{\mathbf{N}M}{e}}\\
&\le 2\sum_{s=1}^{r\wedge n-1}\binom{r}{s}\left(\frac{s}{r}\right)^s\max_{k=s}^{n-1}\left\{\left(\frac{\mathbf{N}M}{k\wedge\frac{\mathbf{N}M}{e}}\right)^{k\wedge\frac{\mathbf{N}M}{e}}\right\}\sum_{k=s}^{n-1}\binom{k-1}{s-1}\\
&= 2\left[\sum_{s=1}^{r\wedge n-1}\binom{n-1}{s}\binom{r}{s}\left(\frac{s}{r}\right)^s\right]\left(\frac{\mathbf{N}M}{n-1\wedge\frac{\mathbf{N}M}{e}}\right)^{n-1\wedge\frac{\mathbf{N}M}{e}},
\end{aligned}
$$

where we used identity (88) and bound (93) of the appendix.

From (39) we can further obtain

$$
\begin{aligned}
\sum_{n=1}^{\overline{n}}\sum_{k=1}^{n-1}\frac{\gamma_k}{|a|^k} &\le 2\sum_{n=1}^{\overline{n}}\sum_{s=1}^{r\wedge n-1}\binom{n-1}{s}\binom{r}{s}\left(\frac{s}{r}\right)^s\left(\frac{\mathbf{N}M}{n-1\wedge\frac{\mathbf{N}M}{e}}\right)^{n-1\wedge\frac{\mathbf{N}M}{e}}\\
&= 2\sum_{s=1}^{r\wedge\overline{n}-1}\sum_{n=s+1}^{\overline{n}}\binom{n-1}{s}\binom{r}{s}\left(\frac{s}{r}\right)^s\left(\frac{\mathbf{N}M}{n-1\wedge\frac{\mathbf{N}M}{e}}\right)^{n-1\wedge\frac{\mathbf{N}M}{e}}\\
&\le 2\sum_{s=1}^{r\wedge\overline{n}-1}\binom{r}{s}\left(\frac{s}{r}\right)^s\max_{n=s+1}^{\overline{n}}\left\{\left(\frac{\mathbf{N}M}{n-1\wedge\frac{\mathbf{N}M}{e}}\right)^{n-1\wedge\frac{\mathbf{N}M}{e}}\right\}\\
&\quad\times\sum_{n=s+1}^{\overline{n}}\binom{n-1}{s}\\
&= 2\left[\sum_{s=1}^{r\wedge\overline{n}-1}\binom{\overline{n}}{s+1}\binom{r}{s}\left(\frac{s}{r}\right)^s\right]\left(\frac{\mathbf{N}M}{\overline{n}-1\wedge\frac{\mathbf{N}M}{e}}\right)^{\overline{n}-1\wedge\frac{\mathbf{N}M}{e}},
\end{aligned}
$$

where again we used identity (88) and bound (93). From this (38) follows by a simple substitution. □

In the following subsections we will exploit the previous result to obtain bounds describing the trade-off between the number of quantization intervals $\mathbf{N}$ and the expected entrance time $\mathbf{T}$ for a given almost (I, J)-stable piecewise affine map Γ with the contraction rate C. Three situations will be distinguished. First, we will consider the regime when $\mathbf{N}/\log C$ is sufficiently small. It contains the case when $\mathbf{N}/\log C \to 0$, namely, the regime of sublogarithmic growth of $\mathbf{N}$ in C. The corresponding expected entrance time $\mathbf{T}$ will exhibit a superlogarithmic growth in C. The second case considered will be a sort of a dual of the first one, since we will assume that $\mathbf{T}/\log C$ is sufficiently small. It contains the case when $\mathbf{T}/\log C \to 0$, namely, the regime of sublogarithmic growth of $\mathbf{T}$ in C. This time the corresponding number of quantization intervals $\mathbf{N}$ will exhibit a superlogarithmic growth in C. From these two cases

we will then be able to study in detail a third situation, the logarithmic regime, which is when both $\mathbf{N}$ and $\mathbf{T}$ exhibit a logarithmic growth. In this case, we will establish quantitative bounds relating the ratios $\mathbf{N}/\log C$ and $\mathbf{T}/\log C$.

5.2. The regime of sublogarithmic growth of N in C. In this subsection we will assume that $\mathbf{N}/\log C$ is small enough. In this case it is convenient to proceed the estimates in (38) as follows:

$$\sum_{s=1}^{r\wedge\overline{n}-1}\binom{\overline{n}}{s+1}\binom{r}{s}\left(\frac{s}{r}\right)^s \le \sum_{s=0}^{r\wedge\overline{n}-1}\binom{\overline{n}}{s+1}\binom{r}{s} = \binom{\overline{n}+r}{r+1} = \frac{\overline{n}}{r+1}\binom{\overline{n}+r}{r}$$

$$\le \frac{1}{\sqrt{\pi}}\frac{\overline{n}}{r+1}\left(1+\frac{\overline{n}}{r}\right)^r e^r \le \overline{n}\left(1+\frac{\overline{n}}{\mathbf{N}}\right)^{\mathbf{N}} e^{\mathbf{N}},$$

where we used bound (91), the fact that $\frac{2}{(r+1)\sqrt{\pi}} \le 1$ and that $\left(1+\frac{\overline{n}}{r}\right)^r e^r$ is an increasing function in r. We obtain in this way

$$\mathbf{T} \ge \overline{n}\left[1 - C^{-1} - \left(1+\frac{\overline{n}}{\mathbf{N}}\right)^{\mathbf{N}} A^{\mathbf{N}} C^{-1}\right], \tag{40}$$

where $A := e^{\left(\frac{M}{e}+1\right)}$. We are now ready to prove the following result.

THEOREM 3. *There exist $K_1 > 0$, $\beta_1 > 0$, and $C_1 > 1$ such that*

$$C \ge C_1 \quad \text{and} \quad \frac{\mathbf{N}}{\log C} \le \beta_1 \implies \mathbf{T} \ge K_1 \mathbf{N} C^{1/\mathbf{N}}. \tag{41}$$

Proof. If in (40) we choose $\overline{n} = \lceil D\mathbf{N}C^{1/\mathbf{N}}\rceil$ for some constant $D > 0$ which will be fixed later, we have that

$$\frac{\mathbf{T}}{\mathbf{N}C^{1/\mathbf{N}}} \ge \frac{\lceil D\mathbf{N}C^{1/\mathbf{N}}\rceil}{\mathbf{N}C^{1/\mathbf{N}}}\left[1 - C^{-1} - \left(1+\frac{\lceil D\mathbf{N}C^{1/\mathbf{N}}\rceil}{\mathbf{N}}\right)^{\mathbf{N}} A^{\mathbf{N}} C^{-1}\right] \tag{42}$$

$$\ge D\left[1 - C^{-1} - \left(1+\frac{D\mathbf{N}C^{1/\mathbf{N}}+\mathbf{N}}{\mathbf{N}}\right)^{\mathbf{N}} A^{\mathbf{N}} C^{-1}\right]$$

$$= D\left[1 - C^{-1} - \left(2C^{-1/\mathbf{N}} + D\right)^{\mathbf{N}} A^{\mathbf{N}}\right].$$

Assume now that $\mathbf{N} \le \beta \log C$ for some β which will be chosen later. This implies that

$$(2C^{-1/\mathbf{N}} + D)A \le (2e^{-1/\beta} + D)A.$$

By choosing β and D small enough, we obtain that $(2e^{-1/\beta}+D)A \le 1/2$. Let β_1 and D_1 be possible solutions of the this inequality. In this situation, we can argue that

$$\frac{\mathbf{T}}{\mathbf{N}C^{1/\mathbf{N}}} \ge D_1[1 - C^{-1} - (1/2)^{\mathbf{N}}] \ge D_1[1/2 - C^{-1}],$$

and so there exist $C_1 > 1$ and $K_1 > 0$ such that (41) holds true. ∎

Theorem 3 will be important for later results on the logarithmic regime. Notice, moreover, that the bound established in Theorem 3 resembles relation (27) between the expected entrance time and the number of quantization intervals that can be obtained when using the nested chaotic scheme proposed in subsection 4.3. However, there is a difference and in fact the bound provided by Theorem 3 is not tight in this case. Consider for simplicity the case in which $\tau = 1$, so that we have a simple chaotic quantized feedback. In this case we have $\mathbf{N} = \lceil |a| \rceil$ quantization intervals and this, by Theorem 3, yields the bound

$$\mathbf{T} \geq K_1 C^{1/\lceil |a| \rceil}.$$

However, this is not a good bound since we expect in this case that $\mathbf{T} \sim C$. In fact, this bound can be improved in this particular case by using Proposition 5 that is a modification of Theorem 2 in which r is fixed equal to 1.

COROLLARY 2. *There exist $K_1 > 0$ and $C_1 > 1$ such that*

$$C \geq C_1 \quad \text{and} \quad \mathbf{N} = \lceil |a| \rceil \implies \mathbf{T} \geq K_1 C.$$

Proof. By Proposition 5 we can argue that

$$\frac{\gamma_k}{|a|^k} \leq 2 \left(\frac{\mathbf{N}M}{k \wedge \frac{\mathbf{N}M}{e}} \right)^{k \wedge \frac{\mathbf{N}M}{e}} \leq 2e^{\frac{\mathbf{N}M}{e}} = 2e^{\frac{\lceil |a| \rceil M}{e}}.$$

Let $A := e^{\frac{\lceil |a| \rceil M}{e}}$. Then, by (35) this implies that

$$\mathbf{T} \geq \overline{n}\big(1 - C^{-1}\big) - C^{-1} 2 \binom{\overline{n}}{2} A = \overline{n}\big[1 - C^{-1} - C^{-1}(\overline{n} - 1)A\big].$$

Let $\overline{n} = \lceil DC \rceil$ for some constant $D > 0$ which will be fixed later. We have that

$$\frac{\mathbf{T}}{C} \geq D \left[1 - C^{-1} - (\lceil DC \rceil - 1) AC^{-1}\right] \geq D \left[1 - C^{-1} - DA\right],$$

and this implies the thesis. ∎

5.3. The regime of sublogarithmic growth of T in C. In this subsection, we will assume instead that $\mathbf{T}/\log C$ is small enough. In this case, it is convenient to proceed the estimates in (38) as follows:

$$\begin{aligned}
\sum_{s=1}^{r \wedge \overline{n}-1} \binom{\overline{n}}{s+1} \binom{r}{s} \left(\frac{s}{r}\right)^s &\leq \frac{1}{\sqrt{\pi}} \sum_{s=1}^{\overline{n}-1} \binom{\overline{n}}{s+1} \left(1 + \frac{r-s}{s}\right)^s e^s \left(\frac{s}{r}\right)^s \\
&= \frac{1}{\sqrt{\pi}} \sum_{s=1}^{\overline{n}-1} \binom{\overline{n}}{s+1} e^s \leq \frac{1}{\sqrt{\pi}} \sum_{s=0}^{\overline{n}} \binom{\overline{n}}{s} e^{s-1} \\
&= \tfrac{1}{\sqrt{e\pi}} (1+e)^{\overline{n}},
\end{aligned}$$

where again we used bound (91). We thus obtain

$$\mathbf{T} \geq \overline{n}\big(1 - C^{-1}\big) - C^{-1} \frac{2}{\sqrt{e\pi}} (1+e)^{\overline{n}} \left(\frac{\mathbf{N}M}{\overline{n} - 1 \wedge \frac{\mathbf{N}M}{e}} \right)^{\overline{n} - 1 \wedge \frac{\mathbf{N}M}{e}} \tag{43}$$

$$\geq \overline{n}\big(1-C^{-1}\big) - C^{-1}A^{\overline{n}-1}\left(\frac{\mathbf{N}M}{\overline{n}-1\wedge\frac{\mathbf{N}M}{e}}\right)^{\overline{n}-1\wedge\frac{\mathbf{N}M}{e}},$$

where $A := \frac{2(1+e)^2}{e\sqrt{\pi}}$, and where the last inequality holds if $\overline{n} \geq 2$. We are now ready to prove the following result.

THEOREM 4. *There exist $K_2 > 0$, $\gamma_2 > 0$, and $C_2 > 1$ such that*

$$C \geq C_2 \quad \text{and} \quad \frac{\lceil \mathbf{T} \rceil}{\log C} \leq \gamma_2 \implies \mathbf{N} \geq K_2 \lceil \mathbf{T} \rceil C^{\frac{1}{\lceil \mathbf{T} \rceil}}. \tag{44}$$

Proof. We first show that we can find $C' > 1$ and $\gamma > 0$ such that

$$C \geq C' \quad \text{and} \quad \frac{\lceil \mathbf{T} \rceil}{\log C} \leq \gamma \implies \lceil \mathbf{T} \rceil \leq \frac{\mathbf{N}M}{e}. \tag{45}$$

Assume by contradiction that $\lceil \mathbf{T} \rceil > \mathbf{N}M/e$. Then, choosing $\overline{n} := \lceil \mathbf{T} \rceil + 1$, it follows from (35) and (43) that

$$\mathbf{T} \geq (\lceil \mathbf{T} \rceil + 1)\big(1-C^{-1}\big) - C^{-1}A^{\lceil \mathbf{T} \rceil}e^{\frac{\mathbf{N}M}{e}} \geq (\lceil \mathbf{T} \rceil + 1)\big(1-C^{-1}\big) - C^{-1}\,(eA)^{\lceil \mathbf{T} \rceil}, \tag{46}$$

which implies that

$$\begin{aligned} 0 &\geq C(\lceil \mathbf{T} \rceil - \mathbf{T} + 1) - (eA)^{\lceil \mathbf{T} \rceil} - \lceil \mathbf{T} \rceil - 1 \\ &\geq C - (eA)^{\lceil \mathbf{T} \rceil} - \lceil \mathbf{T} \rceil - 1 \\ &\geq C - (eA)^{\gamma \log C} - \gamma \log C - 1 = C - C^{\gamma \log eA} - \gamma \log C - 1. \end{aligned} \tag{47}$$

If we choose $\gamma < (\log eA)^{-1}$, it is clear that there exists $C' > 1$ such that

$$C - C^{\gamma \log eA} - \gamma \log C - 1 > 0$$

for all $C \geq C'$. For such values of C (47) cannot hold. Hence (45) must hold.

Assume now that (45) holds true and choose again $\overline{n} := \lceil \mathbf{T} \rceil + 1$ in (43). Then we obtain

$$\mathbf{T} \geq (\lceil \mathbf{T} \rceil + 1)\big(1-C^{-1}\big) - \left(\frac{\mathbf{N}MA}{\lceil \mathbf{T} \rceil}\right)^{\lceil \mathbf{T} \rceil} C^{-1}. \tag{48}$$

Solving with respect to $\mathbf{N}$, we obtain

$$\begin{aligned} \mathbf{N} &\geq \frac{\lceil \mathbf{T} \rceil}{AM}[C(\lceil \mathbf{T} \rceil - \mathbf{T} + 1) - \lceil \mathbf{T} \rceil - 1]^{1/\lceil \mathbf{T} \rceil} \geq \frac{\lceil \mathbf{T} \rceil}{AM}[C - \lceil \mathbf{T} \rceil - 1]^{1/\lceil \mathbf{T} \rceil} \\ &\geq \frac{\lceil \mathbf{T} \rceil}{AM}[C - \gamma \log C - 1]^{1/\lceil \mathbf{T} \rceil}\ . \end{aligned} \tag{49}$$

Observe finally that

$$\lim_{C\to\infty} \frac{C - \gamma \log C - 1}{C} = 1,$$

which implies that for any $\epsilon > 0$ there exists $C'' > 0$ such that $C - \gamma \log C - 1 > (1-\epsilon)C$ for all $C > C''$. From this we can argue that

$$\mathbf{N} \geq \frac{\lceil \mathbf{T} \rceil}{AM}[(1-\epsilon)C]^{1/\lceil \mathbf{T} \rceil} \geq \frac{1-\epsilon}{AM}\lceil \mathbf{T} \rceil C^{1/\lceil \mathbf{T} \rceil}.$$

By letting $K_2 := \frac{1-\epsilon}{AM}$, $C_2 := C' \vee C''$, and $\gamma_2 := \gamma$, we have thus proved the thesis. □

Also in this case it is interesting to compare the bound provided by the previous theorem with relation (21) between the number of quantization intervals and the expected entrance time that can be obtained when using the nested strategy proposed in subsection 4.1. In this case this comparison shows that, up to a multiplication by a constant, the bound is tight.

5.4. The logarithmic regime. We have the following direct consequence of previous theorems.

COROLLARY 3. *There exist $C_0 > 1$ and two functions $F, G : \mathbb{R}_+ \to \mathbb{R}_+$ which are decreasing and converging to 0 at $+\infty$ such that for all $C > C_0$ we have that*

$$\frac{\mathbf{N}}{\log C} \geq F\left(\frac{\lceil \mathbf{T} \rceil}{\log C}\right) \quad \text{and} \quad \frac{\lceil \mathbf{T} \rceil}{\log C} \geq G\left(\frac{\mathbf{N}}{\log C}\right). \tag{50}$$

Proof. Notice first that the function $f :]0,1] \to \mathbb{R} : x \mapsto xe^{1/x}$ is strictly decreasing, and its image is $[e, +\infty)$. Let $C_0 := C_1 \vee C_2$, where C_1, C_2 are the constants introduced, respectively, in Theorems 3 and 4. Define the function

$$F(x) = \begin{cases} 1 \wedge \beta_1 & \text{if } 0 \leq x \leq K_1 f(1 \wedge \beta_1), \\ f^{-1}(x/K_1) & \text{if } x > K_1 f(1 \wedge \beta_1), \end{cases}$$

where K_1 and β_1 are the constants provided by Theorem 3. This function is decreasing such that $F(+\infty) = 0$. We want to show that if $C > C_0$, then

$$\frac{\mathbf{N}}{\log C} \geq F\left(\frac{\lceil \mathbf{T} \rceil}{\log C}\right).$$

If $\mathbf{N}/\log C > 1 \wedge \beta_1$, then

$$\frac{\mathbf{N}}{\log C} > \max_{x \in \mathbb{R}_+} F(x) \geq F\left(\frac{\lceil \mathbf{T} \rceil}{\log C}\right).$$

If instead $\mathbf{N}/\log C \leq 1 \wedge \beta_1$, then by Theorem 3 we can argue that

$$\frac{\mathbf{T}}{\log C} \geq K_1 \frac{\mathbf{N}}{\log C} C^{1/\mathbf{N}} = K_1 f\left(\frac{\lceil \mathbf{N} \rceil}{\log C}\right),$$

which implies that

$$\frac{\mathbf{N}}{\log C} \geq f^{-1}\left(\frac{\mathbf{T}}{K_1 \log C}\right) = F\left(\frac{\mathbf{T}}{\log C}\right).$$

In the same way it can be shown that

$$\frac{\lceil \mathbf{T} \rceil}{\log C} \geq G\left(\frac{\mathbf{N}}{\log C}\right),$$

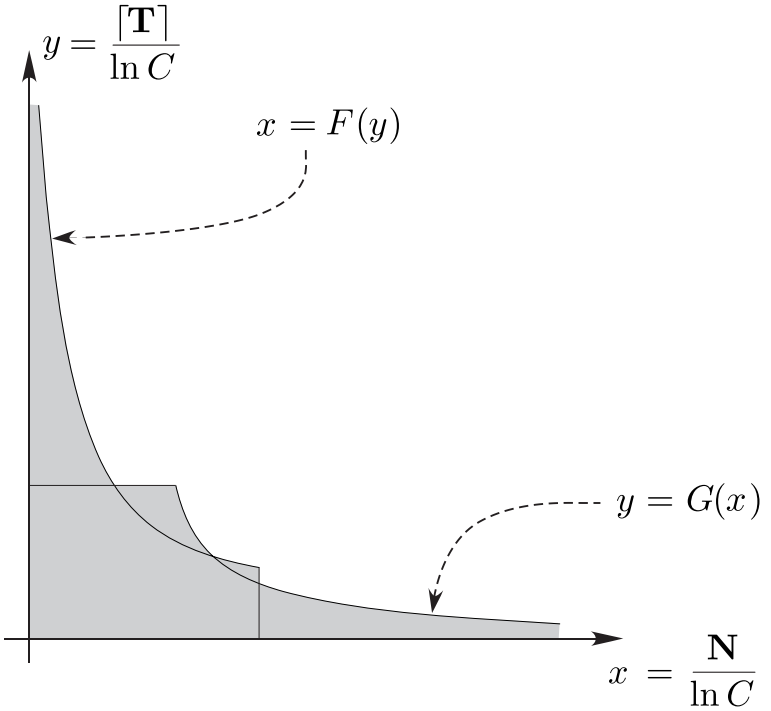

FIG. 5. *The grey region in this figure represents the set in which the pairs* $(\mathbf{N}/\log C, \mathbf{T}/\log C)$ *cannot belong.*

where

$$G(x) = \begin{cases} 1 \wedge \gamma_2 & \text{if } 0 \le x \le K_2 f(1 \wedge \beta_1), \\ f^{-1}(x/K_2) & \text{if } x > K_2 f(1 \wedge \gamma_2), \end{cases}$$

where K_2 and γ_2 are the constants provided by Theorem 4. □

Remark. The constraint provided by the previous corollary is illustrated in Figure 5 which shows explicitly the region in which the pairs $(\mathbf{N}/\log C, \mathbf{T}/\log C)$ cannot belong. Observe moreover that the functions $F(x)$ and $G(x)$ in the previous corollary which determine the boundary of this region tend to 0 as the function $f(x) = xe^{1/x}$. This is in agreement with the behavior of the logarithmic regime exhibited in the nesting of both deadbeat quantized feedbacks and chaotic quantized feedbacks (see (22) and (28)). This implies that, up to multiplicative constants, our bounds appear to be quite tight and that the examples presented in section 4 cannot be improved much.

5.5. The case when $|a| \le 2$. All previous results have been obtained under the assumption $|a| > 2$. In fact, part of the results presented in this subsection can be extended to the case $|a| \le 2$. Indeed, in this case, using the second part of Theorem 6, we obtain the estimate

$$\frac{\gamma_k}{2^k} \le \left[\sum_{s=1}^{r \wedge k} \binom{k+s-1}{2s-1} \binom{r}{s} \left(\frac{s}{r}\right)^s \right] \left(\frac{\mathbf{N}M}{k \wedge \frac{\mathbf{N}M}{e}} \right)^{k \wedge \frac{\mathbf{N}M}{e}}.$$

By similar arguments used to deal with the case $|a| > 2$, we obtain

$$\mathbf{T} \geq \overline{n}(1 - C^{-1}) - C^{-1} 2 \left[\sum_{s=1}^{r \wedge \overline{n}-1} \binom{\overline{n}+s}{2s+1} \binom{r}{s} \left(\frac{s}{r}\right)^s \right] \times \left(\frac{\mathbf{N}M}{\overline{n} - 1 \wedge \frac{\mathbf{N}M}{e}} \right)^{\overline{n}-1 \wedge \frac{\mathbf{N}M}{e}} \left(\frac{2}{|a|} \right)^{\overline{n}-1}$$

for all $\overline{n} \in \mathbb{N}$. Observing that

$$\sum_{s=1}^{r \wedge \overline{n}-1} \binom{\overline{n}+s}{2s+1} \binom{r}{s} \left(\frac{s}{r}\right)^s \leq \frac{1}{\sqrt{\pi}} \sum_{s=1}^{\overline{n}-1} \binom{2\overline{n}-1}{2s+1} e^s \leq \frac{1}{\sqrt{\pi}} \sum_{s=1}^{\overline{n}-1} \binom{2\overline{n}-1}{2s+1} e^{2s+1} \leq \frac{1}{\sqrt{\pi}} (1+e)^{2\overline{n}-1},$$

we thus obtain

$$\mathbf{T} \geq \overline{n}(1 - C^{-1}) - C^{-1} \frac{2}{\sqrt{\pi}} (1+e)^{2\overline{n}-1} \left(\frac{\mathbf{N}M}{\overline{n} - 1 \wedge \frac{\mathbf{N}M}{e}} \right)^{\overline{n}-1 \wedge \frac{\mathbf{N}M}{e}} \left(\frac{2}{|a|} \right)^{\overline{n}-1}$$

$$\geq \overline{n}(1 - C^{-1}) - C^{-1} A^{\overline{n}-1} \left(\frac{\mathbf{N}M}{\overline{n} - 1 \wedge \frac{\mathbf{N}M}{e}} \right)^{\overline{n}-1 \wedge \frac{\mathbf{N}M}{e}},$$

where $A := \frac{4(1+e)^3}{|a|\sqrt{\pi}}$ and where the last inequality holds if $\overline{n} \geq 2$. The previous inequality looks exactly like (43). This immediately implies that Theorem 4 also holds true for $|a| \leq 2$. We can instead only recover a part of Corollary 3: (50) remains true for small values of γ, as it is easy to see from the proof we gave.

5.6. Stabilizing quantized feedbacks. In this section, we will show that quantized control strategies yielding stability or even almost stability, but with only a countable subset of points never entering inside J, require a number of quantization intervals which grows at least logarithmically in C. The result is based on Theorem 7 which is given in the last section.

THEOREM 5. *If Γ is almost (I, J)-stable and if the set of points in I never entering inside J is at most countable, then there exists $\beta > 0$, only depending on a such that*

$$\mathbf{N} / \log C \geq \beta$$

for all $C > 1$.

Proof. Using (87) we can argue that

$$\sum_{k=1}^{n-1} \frac{\gamma_k}{|a|^k} \leq e^{\frac{\mathbf{N}}{e}} \sum_{k=0}^{+\infty} \binom{k + 2\mathbf{N} - 1}{2\mathbf{N} - 1} \left(\frac{2}{|a|} \right)^k = \frac{e^{\frac{\mathbf{N}}{e}}}{\left(1 - \frac{2}{|a|}\right)^{2\mathbf{N}}} = \left(\frac{e^{1/e}|a|^2}{(|a|-1)^2} \right)^{\mathbf{N}}.$$

By letting $A := \frac{e^{1/e}|a|^2}{(|a|-1)^2}$, from (34) we can argue that

$$\mathbb{P}\big[T_{(I,J)} \geq n\big] \geq 1 - C^{-1} - A^{\mathbf{N}} C^{-1} \geq 1 - C^{-1}(1+A)^{\mathbf{N}}. \tag{51}$$

Since Γ is almost stable, by Proposition 1 we have that $\mathbb{E}(T_{(I,J)}) < +\infty$, which implies that

$$\lim_{n\to\infty} \mathbb{P}\big[T_{(I,J)} \geq n\big] = 0.$$

From this and (51) we can argue that $1 - C^{-1}(1+A)^{\mathbf{N}} \leq 0$, which implies that

$$\mathbf{N} \geq \frac{\log C}{\log(1+A)}. \qquad \square$$

6. Estimation of paths in a class of weighted graphs. For proving our main result, namely Theorem 2, we introduce a class of weighted graphs and propose a method for bounding the number of paths on this graphs. In the last section, we will show how this bound can be used for proving Theorem 2. We use this strategy which considers this graph abstraction because the general result we are going to prove is useful to deal with more general situations, such as quantized controller with memory or the case in which the state of the system is multidimensional (see [10]).

Consider a direct graph $\mathcal{G}$ on a vertex set $\mathcal{X}$ (which is not necessarily finite or countable). For any choice of $\mathcal{X}_1, \dots, \mathcal{X}_k \subset \mathcal{X}$ we define $\mathcal{F}_k[\mathbf{x}_1 \in \mathcal{X}_1, \dots, \mathbf{x}_k \in \mathcal{X}_k]$ to be the set of paths $\mathbf{x}_1 \cdots \mathbf{x}_k \in \mathcal{X}^*$ on the graph $\mathcal{G}$ such that $\mathbf{x}_1 \in \mathcal{X}_1, \dots, \mathbf{x}_k \in \mathcal{X}_k$.

Assume the graph $\mathcal{G}$ has the following structure. We assume there exist a finite partition

$$\mathcal{X} = \mathcal{X}_1 \cup \mathcal{X}_2 \cup \cdots \cup \mathcal{X}_{\mathbf{N}},$$

a subset $\mathcal{X}_P \subseteq \mathcal{X}$, and a function $q : \mathcal{X} \to]0,1[$ with the following properties.

(A) There exist numbers $q_1, \dots, q_{\mathbf{N}} \in]0,1[$ such that

$$\begin{aligned} q(\mathbf{x}) &\leq q_i \quad \forall \mathbf{x} \in \mathcal{X}_i, \\ q(\mathbf{x}) &= q_i \quad \forall \mathbf{x} \in \mathcal{X}_{P,i} := \mathcal{X}_P \cap \mathcal{X}_i. \end{aligned}$$

(B) There exist positive numbers D_1 and α_1 such that, for every $\mathbf{x}' \in \mathcal{X}$, $\mathcal{X}'' \subseteq \mathcal{X}$, and $k \geq 2$,

$$\#\mathcal{F}_k[\mathbf{x}_1 = \mathbf{x}', \mathbf{x}_2, \dots, \mathbf{x}_{k-1} \in \mathcal{X}, \mathbf{x}_k \in \mathcal{X}''] \leq D_1 \frac{q(\mathbf{x}')}{\inf_{\mathbf{x}'' \in \mathcal{X}''} q(\mathbf{x}'')} \alpha_1^{k-2}.$$

(C) There exist positive numbers D_2 and α_2 such that, for every $\mathbf{x}' \in \mathcal{X}$, $i \in \{1, \dots, \mathbf{N}\}$, and $k \geq 2$,

$$\#\mathcal{F}_k[\mathbf{x}_1 = \mathbf{x}', \mathbf{x}_2, \dots, \mathbf{x}_{k-1} \in \mathcal{X} \setminus \mathcal{X}_P, \mathbf{x}_k \in \mathcal{X}_i] \leq D_2 \alpha_2^{k-2}.$$

Then, if we define

$$\gamma_{k,h} = \sup_{\mathbf{x}' \in \mathcal{X}_{P,h}} \#\mathcal{F}_k[\mathbf{x}_1 = \mathbf{x}', \mathbf{x}_2, \dots, \mathbf{x}_k \in \mathcal{X}], \qquad h = 1, \dots, \mathbf{N},$$

$$\gamma_k = \sum_{h=1}^{\mathbf{N}} \gamma_{k,h}, \tag{52}$$

we have the following result.

THEOREM 6. *We have the following bounds.*

(1) *If* $\alpha_1 > \alpha_2$, *then*

$$\frac{\gamma_k}{\alpha_1^k} \leq 2\left[\sum_{s=1}^{r\wedge k}\binom{k-1}{s-1}\binom{r}{s}\left(\frac{s}{r}\right)^s\right]\left(\frac{\mathbf{N}M}{k\wedge\frac{\mathbf{N}M}{e}}\right)^{k\wedge\frac{\mathbf{N}M}{e}} \qquad \forall k\geq 1. \tag{53}$$

(2) *If* $\alpha_1 \leq \alpha_2$, *then*

$$\frac{\gamma_k}{\alpha_2^k} \leq \left[\sum_{s=1}^{r\wedge k}\binom{k+s-1}{2s-1}\binom{r}{s}\left(\frac{s}{r}\right)^s\right]\left(\frac{\mathbf{N}M}{k\wedge\frac{\mathbf{N}M}{e}}\right)^{k\wedge\frac{\mathbf{N}M}{e}} \qquad \forall k\geq 1. \tag{54}$$

The constant $r \in \{1,\dots,\mathbf{N}\}$ *is independent of* k, *but may depend on the specific graph, while* M *depends only on the constants* $D_1, D_2, \alpha_1, \alpha_2$.

The proof of the previous theorem is quite lengthy. For this reason we prefer to divide it into various steps.

Remark. As specified in the previous theorem M depends only on the constants D_1, D_2, α_1, and α_2, and r depends on the specific graph. These conditions can be exchanged and the same bounds can be shown to hold true in which instead r depends only on the constants D_1, D_2, α_1, and α_2, and M depends on the specific graph. However, this exchange makes the bounds useless in general. Only in the specific situation considered in Proposition 5 does this point of view yield some advantages.

6.1. The proof of Theorem 6: Hierarchies of paths. Assume with no loss of generality that the subsets $\mathcal{X}_1, \mathcal{X}_2, \dots, \mathcal{X}_{\mathbf{N}}$ are ordered in such a way that

$$q_1 \geq q_2 \geq \cdots \geq q_{\mathbf{N}}.$$

For any choice of integers

$$0 = N_0 < N_1 < \cdots < N_{r-1} < N_r = \mathbf{N},$$

we can partition $\mathcal{X}_P$ into the subfamilies

$$\begin{aligned}\mathcal{X}_P^1 :&= \{\mathcal{X}_{P,N_0+1},\dots,\mathcal{X}_{P,N_1}\},\ \ \mathcal{X}_P^2 := \{\mathcal{X}_{P,N_1+1},\dots,\mathcal{X}_{P,N_2}\},\dots,\\ \mathcal{X}_P^r :&= \{\mathcal{X}_{P,N_{r-1}+1},\dots,\mathcal{X}_{P,N_r}\}\end{aligned} \tag{55}$$

and consider, moreover,

$$\begin{aligned}\mathcal{X}_P^{l+} &:= \bigcup_{j=l}^{r}\mathcal{X}_P^j,\\ \mathcal{X}^l &:= (\mathcal{X}\setminus\mathcal{X}_P)\cup\mathcal{X}_P^l,\\ \mathcal{X}^{l+} &:= (\mathcal{X}\setminus\mathcal{X}_P)\cup\mathcal{X}_P^{l+}.\end{aligned}$$

For each $k\in\mathbb{N}$, $h = 1,\dots,\mathbf{N}$, and $l = 1,\dots,r,r+1$ define

$$\gamma_{k,h,l} := \sup_{\mathbf{x}'\in\mathcal{X}_{P,h}} \#\mathcal{F}_k[\mathbf{x}_1 = \mathbf{x}', \mathbf{x}_2,\dots,\mathbf{x}_k \in \mathcal{X}^{l+}].$$

From these definitions it follows that $\mathcal{X}_P^{1+} = \mathcal{X}_P$, $\mathcal{X}^{1+} = \mathcal{X}$, and $\mathcal{X}^{(r+1)+} := \mathcal{X}\setminus\mathcal{X}_P$. This implies that $\gamma_{k,h,1} = \gamma_{k,h}$.

We present now two bounds on $\gamma_{k,h,l}$ which will be used in what follows. The first bound is based on the decomposition of the paths in $\mathcal{F}_k[\mathbf{x}_1 = \mathbf{x}', \mathbf{x}_2, \dots, \mathbf{x}_k \in \mathcal{X}^{l+}]$ according to the last exit from $\mathcal{X}_P^l$ among the indices $j = 2, \dots, k$

$$\mathcal{F}_k\big[\mathbf{x}_1 = \mathbf{x}', \mathbf{x}_2, \dots, \mathbf{x}_k \in \mathcal{X}^{l+}\big] =$$
$$\left\{ \bigcup_{j=2}^{k} \bigcup_{s=N_{l-1}+1}^{N_l} \mathcal{F}_k\big[\mathbf{x}_1 = \mathbf{x}', \mathbf{x}_2, \dots, \mathbf{x}_{j-1} \in \mathcal{X}^{l+}, \mathbf{x}_j \in \mathcal{X}_{P,s}, \mathbf{x}_{j+1}, \dots, \mathbf{x}_k \in \mathcal{X}^{(l+1)+}\big] \right\}$$
$$\times \bigcup \mathcal{F}_k\big[\mathbf{x}_1 = \mathbf{x}', \mathbf{x}_2, \dots, \mathbf{x}_k \in \mathcal{X}^{(l+1)+}\big].$$

Applying property (B) it follows that, for all $l = 1, \dots, r$,

$$\begin{aligned} \gamma_{k,h,l} \le & \sum_{j=2}^{k} \sum_{s=N_{l-1}+1}^{N_l} \sup_{\mathbf{x}' \in \mathcal{X}_{P,h}} \#\mathcal{F}_j\big[\mathbf{x}_1 = \mathbf{x}', \mathbf{x}_2, \dots, \mathbf{x}_{j-1} \in \mathcal{X}^{l+}, \mathbf{x}_j \in \mathcal{X}_{P,s}\big] \\ & \times \sup_{\mathbf{x}'' \in \mathcal{X}_{P,s}} \#\mathcal{F}_{k-j+1}\big[\mathbf{x}_j = \mathbf{x}'', \mathbf{x}_{j+1}, \dots, \mathbf{x}_k \in \mathcal{X}^{(l+1)+}\big] \\ & + \sup_{\mathbf{x}' \in \mathcal{X}_{P,h}} \#\mathcal{F}_k\big[\mathbf{x}_1 = \mathbf{x}', \mathbf{x}_2, \dots, \mathbf{x}_k \in \mathcal{X}^{(l+1)+}\big] \\ \le & \sum_{j=2}^{k} \sum_{s=N_{l-1}+1}^{N_l} D_1 \frac{q_h}{q_s} \alpha_1^{j-2} \gamma_{k-j+1,s,l+1} + \gamma_{k,h,l+1}. \end{aligned} \tag{56}$$

The second bound is based on the decomposition of the paths in $\mathcal{F}_k[\mathbf{x}_1 = \mathbf{x}', \mathbf{x}_2, \dots, \mathbf{x}_k \in \mathcal{X}^{l+}]$ according to the first entrance in $\mathcal{X}_P^{l+}$ among the indices $j = 2, \dots, k$:

$$\mathcal{F}_k\big[\mathbf{x}_1 = \mathbf{x}', \mathbf{x}_2, \dots, \mathbf{x}_k \in \mathcal{X}^{l+}\big] =$$
$$\left\{ \bigcup_{j=2}^{k} \bigcup_{s=N_{l-1}+1}^{\mathbf{N}} \mathcal{F}_k\big[\mathbf{x}_1 = \mathbf{x}', \mathbf{x}_2, \dots, \mathbf{x}_{j-1} \in \mathcal{X} \setminus \mathcal{X}_P, \mathbf{x}_j \in \mathcal{X}_{P,s}, \mathbf{x}_{j+1}, \dots, \mathbf{x}_k \in \mathcal{X}^{l+}\big] \right\}$$
$$\times \bigcup \mathcal{F}_k\big[\mathbf{x}_1 = \mathbf{x}', \mathbf{x}_2, \dots, \mathbf{x}_k \in \mathcal{X} \setminus \mathcal{X}_P\big].$$

Applying property (C) it follows that

$$\begin{aligned} \gamma_{k,h,l} \le & \sum_{j=2}^{k} \sum_{s=N_{l-1}+1}^{\mathbf{N}} \sup_{\mathbf{x}' \in \mathcal{X}_{P,h}} \mathcal{F}_j\big[\mathbf{x}_1 = \mathbf{x}', \mathbf{x}_2, \dots, \mathbf{x}_{j-1} \in \mathcal{X} \setminus \mathcal{X}_P, \mathbf{x}_j \in \mathcal{X}_{P,s}\big] \\ & \times \sup_{\mathbf{x}'' \in \mathcal{X}_{P,s}} \mathcal{F}_{k-j+1}\big[\mathbf{x}_j = \mathbf{x}'', \mathbf{x}_{j+1}, \dots, \mathbf{x}_k \in \mathcal{X}^{l+}\big] \\ & + \sup_{\mathbf{x}' \in \mathcal{X}_{P,h}} \mathcal{F}_k\big[\mathbf{x}_1 = \mathbf{x}', \mathbf{x}_2, \dots, \mathbf{x}_k \in \mathcal{X} \setminus \mathcal{X}_P\big] \\ \le & \sum_{j=2}^{k} \sum_{s=N_{l-1}+1}^{\mathbf{N}} D_2 \alpha_2^{j-2} \gamma_{k-j+1,s,l} + D_2 \alpha_2^{k-1}. \end{aligned} \tag{57}$$

Notice that the previous bound holds true for $l = 1, \dots, r, r+1$.

Define

$$\delta_{k,l} := \sum_{h=N_{l-1}+1}^{\mathbf{N}} \gamma_{k,h,l}, \quad \tilde{\delta}_{k,l} := \sum_{h=N_{l-2}+1}^{N_{l-1}} \gamma_{k,h,l} \qquad l = 1, \dots, r, r+1,$$

which imply that $\delta_{k,r+1} = 0$ for all $k \in \mathbb{N}$. Observe that from (56) we can argue that

$$\begin{aligned}\delta_{k,l} &\le \sum_{h=N_{l-1}+1}^{\mathbf{N}} \left(\sum_{j=2}^{k} \sum_{s=N_{l-1}+1}^{N_l} D_1 \frac{q_h}{q_s} \alpha_1^{j-2} \gamma_{k-j+1,s,l+1} + \gamma_{k,h,l+1} \right) \\ &\le \sum_{j=2}^{k} D_1 \frac{\sum_{h=N_{l-1}+1}^{\mathbf{N}} q_h}{q_{N_l}} \alpha_1^{j-2} \sum_{s=N_{l-1}+1}^{N_l} \gamma_{k-j+1,s,l+1} + \sum_{h=N_{l-1}+1}^{N_l} \gamma_{k,h,l+1} \\ &\quad + \sum_{h=N_l+1}^{\mathbf{N}} \gamma_{k,h,l+1} \le D_1 \beta_l \sum_{j=2}^{k} \alpha_1^{j-2} \tilde{\delta}_{k-j+1,l+1} + \tilde{\delta}_{k,l+1} + \delta_{k,l+1} \\ &= D_1 \beta_l \sum_{j=0}^{k-2} \alpha_1^{j} \tilde{\delta}_{k-j-1,l+1} + \tilde{\delta}_{k,l+1} + \delta_{k,l+1} \ ,\end{aligned}$$

where we define

$$\beta_l := \frac{\sum_{h=N_{l-1}+1}^{\mathbf{N}} q_h}{q_{N_l}}. \tag{58}$$

On the other hand (57) implies that

$$\tilde{\delta}_{k,l} \le D_2 (N_{l-1} - N_{l-2}) \left(\sum_{j=2}^{k} \alpha_2^{j-2} \delta_{k-j+1,l} + \alpha_2^{k-1} \right),$$

which using the convention

$$\delta_{0,l} = 1, \qquad l = 1, \ldots, r, r+1,$$

is equivalent to

$$\tilde{\delta}_{k,l} \le D_2 \Delta N_{l-1} \sum_{j=2}^{k+1} \alpha_2^{j-2} \delta_{k-j+1,l} = D_2 \Delta N_{l-1} \sum_{j=0}^{k-1} \alpha_2^{j} \delta_{k-j-1,l},$$

where we defined $\Delta N_l := N_l - N_{l-1}$.

Summarizing we have the following two inequalities holding for $k \ge 1$:

$$\begin{aligned}\delta_{k,l} &\le D_1 \beta_l \sum_{j=0}^{k-2} \alpha_1^{j} \tilde{\delta}_{k-j-1,l+1} + \tilde{\delta}_{k,l+1} + \delta_{k,l+1}, \qquad l = 1, \ldots, r, \\ \tilde{\delta}_{k,l} &\le D_2 \Delta N_{l-1} \sum_{j=0}^{k-1} \alpha_2^{j} \delta_{k-j-1,l}, \qquad l = 1, \ldots, r, r+1.\end{aligned} \tag{59}$$

Now define the sequences $\eta_{k,l}, \tilde{\eta}_{k,l}$ for $k = 0, 1, 2, \ldots$ and $l = 1, \ldots, r, r+1$ by letting $\eta_{k,r+1} = \delta_{k,r+1} = 0$ for $k = 0, 1, \ldots$, and satisfying, for every $k \ge 0$, the following recursive relations:

$$\begin{aligned}\eta_{k,l} &= D_1 \beta_l \sum_{j=0}^{k-2} \alpha_1^{j} \tilde{\eta}_{k-j-1,l+1} + \tilde{\eta}_{k,l+1} + \eta_{k,l+1}, \\ \tilde{\eta}_{k,l} &= D_2 \Delta N_{l-1} \sum_{j=0}^{k-1} \alpha_2^{j} \eta_{k-j-1,l}.\end{aligned} \tag{60}$$

Notice that from the above recursive relations it follows that $\eta_{0,l} = 1$ for every l. This implies in particular that $\delta_{k,l} \leq \eta_{k,l}$ for every k and l. In what follows we will estimate $\eta_{k,l}$ by using the zeta transforms formalism.

Let

$$\eta_l(z) := \sum_{k=0}^{+\infty} \eta_{k,l} z^k, \quad \tilde{\eta}_l(z) := \sum_{k=0}^{+\infty} \tilde{\eta}_{k,l} z^k.$$

Then by some standard manipulations from (60) we obtain

$$\begin{aligned} \eta_l(z) &= D_1 \beta_l \frac{z}{1-\alpha_1 z} \tilde{\eta}_{l+1}(z) + \tilde{\eta}_{l+1}(z) + \eta_{l+1}(z), \\ \tilde{\eta}_l(z) &= D_2 \Delta N_{l-1} \frac{z}{1-\alpha_2 z} \eta_l(z), \end{aligned} \tag{61}$$

which yields

$$\eta_l(z) = \left\{ \left[D_1 \beta_l \frac{z}{1-\alpha_1 z} + 1 \right] D_2 \Delta N_l \frac{z}{1-\alpha_2 z} + 1 \right\} \eta_{l+1}(z).$$

By iterating this formula we obtain

$$\eta_1(z) = \prod_{l=1}^{r} \left\{ \left[D_1 \beta_l \frac{z}{1-\alpha_1 z} + 1 \right] D_2 \Delta N_l \frac{z}{1-\alpha_2 z} + 1 \right\}, \tag{62}$$

where we used the fact that $\eta_{r+1}(z) = 1$.

6.2. The proof of Theorem 6: Combinatorial bounds. We now want to estimate the coefficients $\eta_{k,1}$ of $\eta_1(z)$. We recall that $\gamma_k = \delta_{k,1} \leq \eta_{k,1}$. In order to obtain such bounds we will first need to work out some combinatorics.

Bounds on the coefficients of elementary symmetric polynomials. Consider the following polynomial in the indeterminates x and y:

$$p(x,y) := \prod_{l=1}^{r} \left\{ \left[\beta_l x + 1 \right] \alpha_l y + 1 \right\} = \sum_{s=0}^{r} \sum_{\sigma=0}^{s} \bar{p}_{\sigma,s} x^\sigma y^s. \tag{63}$$

The aim of this part of the section is to determine bounds on the coefficients $\bar{p}_{\sigma,s}$ if we assume that

$$\sum_{l=0}^{r} \alpha_l \leq \alpha, \qquad \sum_{l=0}^{r} \beta_l \leq \beta.$$

Consider preliminarily the polynomial

$$\prod_{l=1}^{r} \{\alpha_l y + 1\} = \sum_{s=0}^{r} p_s^r(\alpha_1, \ldots, \alpha_r) y^s. \tag{64}$$

The polynomials $p_s^r(\alpha_1, \ldots, \alpha_r)$ are called elementary symmetric polynomials [11], and they can be expressed by the formula

$$p_s^r(\alpha_1, \ldots, \alpha_r) = \sum_{1 \leq l_1 < \cdots l_s \leq r} \prod_{j=1}^{s} \alpha_{l_j}.$$

We have the following first elementary result.

LEMMA 3. *Assume that* $\sum_{l=0}^{r} \alpha_l \leq \alpha$. *Then*

$$p_s^r(\alpha_1, \ldots, \alpha_r) \leq \binom{r}{s} \left(\frac{\alpha}{r}\right)^s. \tag{65}$$

Proof. We will actually prove that bound (65) holds true, and it is attained when $\alpha_i = \alpha/r$ for all $i = 1, \ldots, r$. For $r = 2$ it can be proven directly. For the general case, it is sufficient to notice that

$$\begin{aligned}
&p_s^r(\alpha_1, \alpha_2, \ldots, \alpha_r) \\
&= p_s^{r-2}(\alpha_3, \ldots, \alpha_r) + p_1^2(\alpha_1, \alpha_2) p_{s-1}^{r-2}(\alpha_3, \ldots, \alpha_r) + p_2^2(\alpha_1, \alpha_2) p_{s-2}^{r-2}(\alpha_3, \ldots, \alpha_r) \\
&\leq p_s^{r-2}(\alpha_3, \ldots, \alpha_r) + p_1^2\left(\tfrac{\alpha_1+\alpha_2}{2}, \tfrac{\alpha_1+\alpha_2}{2}\right) p_{s-1}^{r-2}(\alpha_3, \ldots, \alpha_r) \\
&\quad + p_2^2\left(\tfrac{\alpha_1+\alpha_2}{2}, \tfrac{\alpha_1+\alpha_2}{2}\right) p_{s-2}^{r-2}(\alpha_3, \ldots, \alpha_r) \\
&= p_s^r\left(\tfrac{\alpha_1+\alpha_2}{2}, \tfrac{\alpha_1+\alpha_2}{2}, \alpha_3, \ldots, \alpha_r\right). \qquad \square
\end{aligned}$$

We come back to the problem of finding bounds on the coefficients $\bar{p}_{\sigma,s}$ of polynomial (63).

LEMMA 4. *For every* $1 \leq s \leq r$ *and* $0 \leq \sigma \leq s$, *the following bound holds:*

$$\bar{p}_{\sigma,s} \leq \binom{s}{\sigma} \left(\frac{\beta}{s}\right)^\sigma \binom{r}{s} \left(\frac{\alpha}{r}\right)^s. \tag{66}$$

Proof. Observe first that

$$p(x, y) = \prod_{l=1}^{r} \left\{[\beta_l x + 1]\alpha_l y + 1\right\} = \sum_{s=0}^{r} p_s^r\big(\alpha_1(1 + \beta_1 x), \ldots, \alpha_r(1 + \beta_r x)\big) y^s.$$

Moreover, we have that

$$\begin{aligned}
p_s^r\big(\alpha_1(1 + \beta_1 x), \ldots, \alpha_r(1 + \beta_r x)\big) &= \sum_{1 \leq l_1 < \cdots l_s \leq r} \prod_{j=1}^{s} \alpha_{l_j} \prod_{j=1}^{s} (1 + \beta_{l_j} x) \\
&= \sum_{1 \leq l_1 < \cdots l_s \leq r} \prod_{j=1}^{s} \alpha_{l_j} \sum_{\sigma=0}^{s} p_\sigma^s(\beta_{l_1}, \ldots, \beta_{l_s}) x^\sigma,
\end{aligned}$$

from which we can argue that, using Lemma 3,

$$\begin{aligned}
\bar{p}_{\sigma,s} &= \sum_{1 \leq l_1 < \cdots l_s \leq r} p_\sigma^s(\beta_{l_1}, \ldots, \beta_{l_s}) \prod_{j=1}^{s} \alpha_{l_j} \leq \binom{s}{\sigma} \left(\frac{\beta}{s}\right)^\sigma \sum_{1 \leq l_1 < \cdots l_s \leq r} \prod_{j=1}^{s} \alpha_{l_j} \\
&= \binom{s}{\sigma} \left(\frac{\beta}{s}\right)^\sigma p_s^r(\alpha_1, \ldots, \alpha_r) \leq \binom{s}{\sigma} \left(\frac{\beta}{s}\right)^\sigma \binom{r}{s} \left(\frac{\alpha}{r}\right)^s. \qquad \square
\end{aligned}$$

To apply the result provided by the previous lemma to our problem, we need to have bounds on $\sum_{l=1}^{r} \Delta N_l$ and $\sum_{l=1}^{r} \beta_l$. While it is evident that

$$\sum_{l=1}^{r} \Delta N_l = \mathbf{N},$$

it is less clear how to bound the other sum. This will depend indeed on the way the subfamilies $\mathcal{X}_P^i$ are selected. It follows from (58) that

$$\beta_l = \sum_{k=0}^{r-l} \frac{\sum_{h=N_{l+k-1}+1}^{N_{l+k}} q_h}{q_l} \leq \sum_{k=0}^{r-l} \Delta N_{l+k} \frac{q_{N_{l+k-1}+1}}{q_{N_l}} = \frac{q_{N_{l-1}+1}}{q_{N_l}} \sum_{k=0}^{r-l} \Delta N_{l+k} \frac{q_{N_{l+k-1}+1}}{q_{N_{l-1}+1}}. \tag{67}$$

Choose inductively the numbers N_l as follows:

$$N_l = \max \left\{ k \geq N_{l-1} + 1 \mid q_k \geq \frac{1}{2} q_{N_{l-1}+1} \right\}. \tag{68}$$

In this way we have that

$$\frac{q_{N_{l-1}+1}}{q_{N_l}} \leq 2, \qquad \frac{q_{N_{l+k-1}+1}}{q_{N_{l-1}+1}} \leq 2^{-k}.$$

Inserting in (67), we thus obtain

$$\beta_l \leq 2 \sum_{k=0}^{r-l} \Delta N_{l+k} 2^{-k} \quad \forall l = 1, \ldots, r, \tag{69}$$

which implies that

$$\sum_{l=1}^{r} \beta_l \leq 2 \sum_{l=1}^{r} \sum_{k=0}^{r-l} \Delta N_{l+k} 2^{-k} = 2 \sum_{k=0}^{r-1} \left(\sum_{l=1}^{r-k} \Delta N_{l+k} \right) 2^{-k} \leq 2\mathbf{N} \sum_{k=0}^{r-1} 2^{-k} \leq 4\mathbf{N}.$$

Hence it follows from Lemma 3 that in our case the coefficients $\bar{p}_{\sigma,s}$ can be bounded as

$$\bar{p}_{\sigma,s} \leq \binom{r}{s} \binom{s}{\sigma} \left(\frac{\mathbf{N} D_2}{r} \right)^s \left(\frac{4\mathbf{N} D_1}{s} \right)^\sigma. \tag{70}$$

Bounds on the coefficients of the power series. Define the coefficients $a_k^{\sigma,s}$ by

$$\left(\frac{1}{1-\alpha_1 z} \right)^\sigma \left(\frac{1}{1-\alpha_2 z} \right)^s = \sum_{k=0}^{+\infty} a_k^{\sigma,s} z^k. \tag{71}$$

The aim of this part of the section is to determine bounds on the coefficients $a_k^{\sigma,s}$. Simple combinatorial manipulation shows that

$$a_k^{\sigma,0} = \binom{k+\sigma-1}{\sigma-1} \alpha_1^k \quad \forall \sigma \geq 1 \quad \forall k \geq 0. \tag{72}$$

In general we have the bound given by the following lemma.

LEMMA 5. *Assume that $\alpha_1 > \alpha_2$. Then, for every $s \geq 0$, $\sigma \geq 1$, and $k \geq 0$, we have*

$$0 \leq a_k^{\sigma,s} \leq \left(\frac{\alpha_1}{\alpha_1 - \alpha_2} \right)^s a_k^{\sigma,0}.$$

Proof. We start by proving that

$$a_k^{\sigma,1} \le \frac{\alpha_1}{\alpha_1-\alpha_2} a_k^{\sigma,0}$$

by induction on k. It is trivial if $k=0$. Assume it to be true for $k-1$ (with $k \ge 1$), and let us prove it for k. Then

$$a_k^{\sigma,1} = \sum_{h=0}^{k} a_h^{\sigma,0}\alpha_2^{k-h} = \sum_{h=0}^{k} \binom{h+\sigma-1}{\sigma-1} \alpha_1^h \alpha_2^{k-h}$$

$$= \sum_{h=0}^{k-1} \binom{h+\sigma-1}{\sigma-1} \alpha_1^h \alpha_2^{k-h} + \binom{k+\sigma-1}{\sigma-1} \alpha_1^k = \alpha_2 a_{k-1}^{\sigma,1} + \binom{k+\sigma-1}{\sigma-1} \alpha_1^k.$$

Using the induction we obtain

$$a_k^{\sigma,1} \le \frac{\alpha_2\alpha_1}{\alpha_1-\alpha_2} a_{k-1}^{\sigma,0} + \binom{k+\sigma-1}{\sigma-1} \alpha_1^k = \left[\frac{\alpha_2}{\alpha_1-\alpha_2} \binom{k+\sigma-2}{\sigma-1}\right.$$

$$\left. + \binom{k+\sigma-1}{\sigma-1}\right] \alpha_1^k = \left[\frac{\alpha_2}{\alpha_1-\alpha_2} \frac{k}{k+\sigma-1} + 1\right] \binom{k+\sigma-1}{\sigma-1} \alpha_1^k$$

$$\le \left[\frac{\alpha_2}{\alpha_1-\alpha_2} + 1\right] \binom{k+\sigma-1}{\sigma-1} \alpha_1^k = \frac{\alpha_1}{\alpha_1-\alpha_2} a_k^{\sigma,0}.$$

Finally assume that the assertion of the lemma holds true for $s-1$. Then

$$a_k^{\sigma,s} = \sum_{h=0}^{k} a_h^{\sigma,s-1}\alpha_2^{k-h} \le \left(\frac{\alpha_1}{\alpha_1-\alpha_2}\right)^{s-1} \sum_{h=0}^{k} a_h^{\sigma,0}\alpha_2^{k-h} = \left(\frac{\alpha_1}{\alpha_1-\alpha_2}\right)^{s-1} a_h^{\sigma,1}$$

$$\le \left(\frac{\alpha_1}{\alpha_1-\alpha_2}\right)^{s} a_h^{\sigma,0}. \qquad \square$$

6.3. The proof of Theorem 6: The final step. We now want to use the estimates obtained above for bounding the coefficients $\eta_{k,1}$.

From (62) we can argue that

(73)

$$\eta_1(z) = \sum_{s=0}^{r}\sum_{\sigma=0}^{s} \bar{p}_{\sigma,s} \left(\frac{1}{1-\alpha_1 z}\right)^{\sigma} \left(\frac{1}{1-\alpha_2 z}\right)^{s} z^{\sigma+s} = \sum_{s=0}^{r}\sum_{\sigma=0}^{s} \bar{p}_{\sigma,s} \sum_{h=0}^{+\infty} a_h^{\sigma,s} z^{h+\sigma+s}$$

$$= \sum_{s=0}^{r}\sum_{\sigma=0}^{s}\sum_{k=\sigma+s}^{+\infty} \bar{p}_{\sigma,s} a_{k-\sigma-s}^{\sigma,s} z^k = \sum_{k=0}^{+\infty}\sum_{s=0}^{r\wedge k}\sum_{\sigma=0}^{s\wedge k-s} \bar{p}_{\sigma,s} a_{k-\sigma-s}^{\sigma,s} z^k,$$

where $\bar{p}_{\sigma,s}$ was defined in (63) and $a_k^{\sigma,s}$ in (71). Hence we have

$$\eta_{k,1} = \sum_{s=0}^{r\wedge k}\sum_{\sigma=0}^{s\wedge k-s} \bar{p}_{\sigma,s} a_{k-\sigma-s}^{\sigma,s}.$$

Decompose $\eta_{k,1}$ as follows:

$$\eta_{k,1} = \eta'_{k,1} + \eta''_{k,1},$$

where

$$\eta'_{k,1} = \sum_{s=1}^{r\wedge k} \sum_{\sigma=1}^{s\wedge k-s} \bar{p}_{\sigma,s} a^{\sigma,s}_{k-\sigma-s}, \qquad \eta''_{k,1} = \sum_{s=0}^{r\wedge k} \bar{p}_{0,s} a^{0,s}_{k-s}. \tag{74}$$

Assume now that $\alpha_1 > \alpha_2$, and fix

$$M := \frac{8D_1}{\alpha_1} \vee \frac{2D_2}{\alpha_1 - \alpha_2} \vee \frac{D_2}{\alpha_2}. \tag{75}$$

Inserting bounds of Lemmas 4 and 5, we now obtain

$$\begin{aligned}
\frac{\eta'_{k,1}}{\alpha_1^k} &= \sum_{s=1}^{r\wedge k} \sum_{\sigma=1}^{s\wedge k-s} \bar{p}_{\sigma,s} \frac{a^{\sigma,s}_{k-\sigma-s}}{\alpha_1^k} \\
&\leq \sum_{s=1}^{r\wedge k} \sum_{\sigma=1}^{s\wedge k-s} \binom{s}{\sigma}\binom{r}{s}\left(\frac{4\mathbf{N}D_1}{s}\right)^{\sigma}\left(\frac{\mathbf{N}D_2}{r}\right)^{s}\left(\frac{\alpha_1}{\alpha_1-\alpha_2}\right)^{s}\binom{k-s-1}{\sigma-1}\frac{\alpha_1^{k-\sigma-s}}{\alpha_1^k} \\
&\leq \sum_{s=1}^{r\wedge k} \sum_{\sigma=1}^{s\wedge k-s} \binom{r}{s}\binom{s}{\sigma}\left(\frac{s}{r}\right)^{s}\left(\frac{\mathbf{N}M}{2s}\right)^{s+\sigma}\binom{k-s-1}{\sigma-1} \\
&\leq \left[\sum_{s=1}^{r\wedge k}\binom{r}{s}\left(\frac{s}{r}\right)^{s}\sum_{\sigma=1}^{s\wedge k-s}\binom{s}{\sigma}\binom{k-s-1}{\sigma-1}\right] \max_{s=1}^{r\wedge k}\max_{\sigma=0}^{s\wedge k-s}\left\{\left(\frac{\mathbf{N}M}{2s}\right)^{s+\sigma}\right\}.
\end{aligned}$$

Observe that

$$\max_{\sigma=0}^{s\wedge k-s}\left\{\left(\frac{\mathbf{N}M}{2s}\right)^{s+\sigma}\right\} = \left(\frac{\mathbf{N}M}{2s}\right)^{s} \bigvee \left(\frac{\mathbf{N}M}{2s}\right)^{2s\wedge k}$$

and that by (93),

$$\max_{s=1}^{r\wedge k}\left\{\left(\frac{\mathbf{N}M}{2s}\right)^{s}\right\} \leq \left(\frac{\mathbf{N}M/2}{k\wedge\frac{\mathbf{N}M}{2e}}\right)^{k\wedge\frac{\mathbf{N}M}{2e}} \quad \max_{s=1}^{r\wedge k}\left\{\left(\frac{\mathbf{N}M}{2s}\right)^{2\left(s\wedge\frac{k}{2}\right)}\right\} \leq \left(\frac{\mathbf{N}M}{k\wedge\frac{\mathbf{N}M}{e}}\right)^{k\wedge\frac{\mathbf{N}M}{e}},$$

which implies

$$\max_{s=1}^{r\wedge k},\ \max_{\sigma=0}^{s\wedge k-s}\left\{\left(\frac{\mathbf{N}M}{2s}\right)^{s+\sigma}\right\} \leq \left(\frac{\mathbf{N}M}{k\wedge\frac{\mathbf{N}M}{e}}\right)^{k\wedge\frac{\mathbf{N}M}{e}}.$$

From this fact and using the combinatorial identity (89), we obtain

$$\frac{\eta'_{k,1}}{\alpha_1^k} \leq \left[\sum_{s=1}^{r\wedge k}\binom{k-1}{s-1}\binom{r}{s}\left(\frac{s}{r}\right)^{s}\right]\left(\frac{\mathbf{N}M}{k\wedge\frac{\mathbf{N}M}{e}}\right)^{k\wedge\frac{\mathbf{N}M}{e}}. \tag{76}$$

On the other hand, assuming $k \geq 1$, similar computations show that

$$\frac{\eta''_{k,1}}{\alpha_1^k} = \sum_{s=1}^{r\wedge k} \bar{p}_{0,s} \frac{a_{k-s}^{0,s}}{\alpha_1^k} = \left[\sum_{s=1}^{r\wedge k} \binom{r}{s} \left(\frac{\mathbf{N}D_2}{r}\right)^s \binom{k-1}{s-1} \alpha_2^{-s}\right] \frac{\alpha_2^k}{\alpha_1^k}$$

$$\leq \left[\sum_{s=1}^{r\wedge k} \binom{r}{s} \left(\frac{\mathbf{N}M}{r}\right)^s \binom{k-1}{s-1}\right]$$

$$\leq \left[\sum_{s=1}^{r\wedge k} \binom{k-1}{s-1} \binom{r}{s} \left(\frac{s}{r}\right)^s\right] \max_{1\leq s\leq r\wedge k} \left\{\left(\frac{\mathbf{N}M}{s}\right)^s\right\},$$

which yields

$$\frac{\eta''_{k,1}}{\alpha_1^k} \leq \left[\sum_{s=1}^{r\wedge k} \binom{k-1}{s-1} \binom{r}{s} \left(\frac{s}{r}\right)^s\right] \left(\frac{\mathbf{N}M}{k \wedge \frac{\mathbf{N}M}{e}}\right)^{k\wedge \frac{\mathbf{N}M}{e}}. \tag{77}$$

Putting together (76) and (77), we obtain the final bound

$$\frac{\gamma_k}{\alpha_1^k} \leq \frac{\eta_{k,1}}{\alpha_1^k} \leq 2\left[\sum_{s=1}^{r\wedge k} \binom{k-1}{s-1} \binom{r}{s} \left(\frac{s}{r}\right)^s\right] \left(\frac{\mathbf{N}M}{k \wedge \frac{\mathbf{N}M}{e}}\right)^{k\wedge \frac{\mathbf{N}M}{e}},$$

which proves Theorem 6 in the case when $\alpha_1 > \alpha_2$. Observe that M depends only on the parameters α_1, α_2, D_1, and D_2.

In the case when $\alpha_2 \geq \alpha_1$, we replace the estimate in Lemma 5 with

$$0 \leq a_k^{\sigma,s} \leq \binom{k+s+\sigma-1}{s+\sigma-1} \alpha_2^k \quad \forall s+\sigma \geq 1 \quad \forall k \geq 0 \tag{78}$$

and fix

$$M = \frac{8D_1}{\alpha_2} \vee \frac{2D_2}{\alpha_2}.$$

Similar computations show that, for $k \geq 1$, we can estimate

$$\frac{\gamma_k}{\alpha_2^k} \leq \frac{\eta_{k,1}}{\alpha_2^k} \leq \left[\sum_{s=1}^{r\wedge k} \sum_{\sigma=0}^{s\wedge k-s} \binom{r}{s} \binom{s}{\sigma} \left(\frac{\mathbf{N}M}{2r}\right)^s \left(\frac{\mathbf{N}M}{2s}\right)^\sigma \binom{k-1}{s+\sigma-1}\right] \tag{79}$$

$$\leq \left[\sum_{s=1}^{r\wedge k} \binom{k+s-1}{2s-1} \binom{r}{s} \left(\frac{s}{r}\right)^s\right] \left(\frac{\mathbf{N}M}{k \wedge \frac{\mathbf{N}M}{e}}\right)^{k\wedge \frac{\mathbf{N}M}{e}}.$$

The proof of Theorem 6 is now complete. □

7. Proof of Theorem 2. The aim of this section is to obtain a representation of the language $\Sigma_*(\Gamma)$ by a finite state automaton or equivalently by a graph. This will be called a Markov representation of the language. Then we will show that this representation satisfies conditions (A), (B), and (C) of the previous section, and so we will be in a position to apply the estimates proposed there.

7.1. The Markov representation. Assume $\Gamma : I \to I$ is any piecewise affine map. The graph representation of the language $\Sigma_*(\Gamma)$ can be constructed as follows. We define as the set of vertices the set $\mathcal{V} := \Sigma_*(\Gamma)$ and as set of edges $\mathcal{E}$ the set given by

$$(\omega_0\omega_1\cdots\omega_{n-1} \to \omega_0\omega_1\cdots\omega_{n-1}\omega_n) \in \mathcal{E} \iff \omega_0\omega_1\cdots\omega_{n-1}\omega_n \in \Sigma_*(\Gamma). \tag{80}$$

Moreover, we introduce the following labeling $\xi : \mathcal{E} \to \mathcal{I} \cup \mathcal{J}$ on the edges:

$$\xi(\omega_0\omega_1\cdots\omega_{n-1} \to \omega_0\omega_1\cdots\omega_{n-1}\omega_n) = \omega_n.$$

Notice that $\Sigma_*(\Gamma)$ coincides with the set of all the labeled words associated with the finite paths on the graph starting from the empty word ϵ. This representation of $\Sigma_*(\Gamma)$ will be called a *Markov representation*. This can be simplified by considering an equivalence relation on the vertices. With each finite word $\omega_0\omega_1\cdots\omega_n \in \Sigma_*(\Gamma)$ we associate its *symbolic future*

$$\mathrm{fut}_\Sigma(\omega_0\omega_1\cdots\omega_n) = \big\{\overline{\omega}_0\overline{\omega}_1\cdots\overline{\omega}_k \mid \overline{\omega}_0 = \omega_n \text{ and } \omega_0\omega_1\cdots\omega_n\overline{\omega}_1\cdots\overline{\omega}_k \in \Sigma_*(\Gamma)\big\},$$

which is a subset of $\Sigma_*(\Gamma)$. More roughly, the symbolic future of a word $\omega_0\omega_1\cdots\omega_n$ is the set of words whose concatenation with $\omega_0\omega_1\cdots\omega_n$ is in $\Sigma_*(\Gamma)$.

Consider also the *geometric future* which is

$$\mathrm{fut}(\omega_0\omega_1\cdots\omega_n) = \Gamma^n(\omega_0 \cap \Gamma^{-1}\omega_1 \cap \ldots \cap \Gamma^{-n}\omega_n).$$

The following result is in [5].

PROPOSITION 4. *Let $\omega_0\omega_1\cdots\omega_n$ and $\nu_0\nu_1\cdots\nu_m$ be two words in $\Sigma_*(\Gamma)$. Then*

$$\mathrm{fut}(\omega_0\omega_1\cdots\omega_n) = \mathrm{fut}(\nu_0\nu_1\cdots\nu_m) \iff \mathrm{fut}_\Sigma(\omega_0\omega_1\cdots\omega_n) = \mathrm{fut}_\Sigma(\nu_0\nu_1\cdots\nu_m). \tag{81}$$

Now define $\overline{\mathcal{X}}$ to be the quotient of the set $\Sigma_*(\Gamma)$ by the equivalence relation

$$\omega'_0\cdots\omega'_n \equiv \omega''_0\cdots\omega''_m \Leftrightarrow \mathrm{fut}_\Sigma(\omega'_0\cdots\omega'_n) = \mathrm{fut}_\Sigma(\omega''_0\cdots\omega''_m). \tag{82}$$

The elements of $\overline{\mathcal{X}}$ will be called *states* and will be denoted by the symbol $\mathbf{x}$. The symbol $\langle\omega_0\omega_1\cdots\omega_n\rangle$ represents the state consisting of the equivalent class which contains the word $\omega_0\omega_1\cdots\omega_n$. States representable by words of length 1 will be called *principal states*. The equivalence relation defining $\overline{\mathcal{X}}$ ensures that any state $\mathbf{x} \in \overline{\mathcal{X}}$ has a well-defined geometric future $\mathrm{fut}(\mathbf{x})$. In fact, the geometric future $\mathrm{fut}(\mathbf{x})$ uniquely determines the state $\mathbf{x}$. Edges and labels can be naturally redefined on $\overline{\mathcal{X}}$ to obtain a new labeled graph denoted by $\overline{\mathcal{G}}$ which is still a Markov representation of $\Sigma_*(\Gamma)$ and so, with the property that the labeled sequences associated with the finite paths on $\overline{\mathcal{G}}$, starting from empty word, corresponds to all the possible sequences in $\Sigma_*(\Gamma)$.

Notice that there is an edge connecting a state $\mathbf{x}'$ to another state $\mathbf{x}''$ labeled with ω if and only if $\mathrm{fut}(\mathbf{x}'') = \Gamma(\mathrm{fut}(\mathbf{x}')) \cap \omega$. This shows that the Markov representation $\overline{\mathcal{G}}$ has the property that the terminal state of any edge is determined by its initial state and by its label. This means that $\overline{\mathcal{G}}$ is a deterministic automaton. This implies in particular that there is a one to one correspondence between paths $\mathbf{x}_1\mathbf{x}_2\cdots\mathbf{x}_k$ on the graph $\overline{\mathcal{G}}$ starting from a principal state and words in $\Sigma_*(\Gamma)$. In order to count the number of words in $\Sigma_*(\Gamma)$ of length k, it will thus be equivalent to count the paths in $\overline{\mathcal{G}}$ of the same length k.

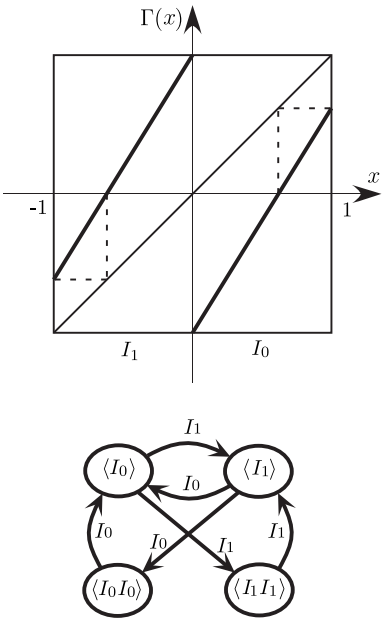

FIG. 6. *The map* Γ *of Example* 1 *and the graph* $\overline{\mathcal{G}}$ *describing the language associated with its dynamics.*

Example 1. We provide here a simple example which should clarify the concepts introduced so far. Consider the piecewise affine map $\Gamma : [-1,1] \to [-1,1]$ defined as follows:

$$\Gamma(x) := \begin{cases} ax+1 & \text{if } -1 < x < 0, \\ ax-1 & \text{if } 0 < x < 1, \end{cases}$$

where $a = \frac{1+\sqrt{5}}{2}$. The map $\Gamma(x)$ is shown in Figure 6. Let $I_0 :=]-1,0[$, and let $I_1 :=]0,1[$. For this particular choice of a we have that the set of states is finite:

$$\overline{\mathcal{X}} = \big\{\langle I_0\rangle, \langle I_1\rangle, \langle I_0 I_0\rangle, \langle I_1 I_1\rangle\big\}.$$

The graph $\overline{\mathcal{G}}$ is shown in Figure 6.

7.2. Properties of the Markov representation. Assume $\Gamma : I \to I$ is a piecewise affine map and that $J \subseteq I$ is another invariant interval as in the setting of section. We now want to show that the just introduced Markov representation restricted to $\Sigma_*(\Gamma) \cap \mathcal{I}^*$ (we are using the notation established in section 5.1) satisfies properties (A), (B), and (C) introduced in the previous section. To this aim we define

$$\mathcal{X}_P := \big\{\langle I_1\rangle, \langle I_2\rangle, \dots, \langle I_{\mathbf{N}}\rangle\big\},$$
$$\mathcal{X}_i := \big\{\langle \omega_0\omega_1\cdots\omega_k I_i\rangle \in \overline{\mathcal{X}} |\ \omega_0\omega_1\cdots\omega_k \in \Sigma_*(\Gamma)\cap\mathcal{I}^*\big\} = \big\{\mathbf{x}\in\overline{\mathcal{X}} \mid \mathrm{fut}(\mathbf{x}) \subseteq I_i\big\},$$
$$\mathcal{X} := \bigcup_{i=1}^{\mathbf{N}} \mathcal{X}_i = \big\{\mathbf{x}\in\overline{\mathcal{X}} \mid \mathrm{fut}(\mathbf{x}) \subseteq I\setminus J\big\},$$
$$q : \mathcal{X} \to]0,1[: \mathbf{x} \mapsto q(\mathbf{x}) := \mathbb{P}\big[\mathrm{fut}(\mathbf{x})\big],$$

and the graph $\mathcal{G}$ which coincides with the graph $\overline{\mathcal{G}}$ restricted to the set of states $\mathcal{X}$.

By taking $q_i = \mathbb{P}[I_i]$, we have that property (A) holds true. The next two lemmas will show that properties (B) and (C) also hold true with $\alpha_1 = |a|$, $\alpha_2 = 2$, $D_1 = |a|$, and $D_2 = 1$.

LEMMA 6. *Let $\mathbf{x}' \in \mathcal{X}$, $\mathcal{X}'' \subseteq \mathcal{X}$, and let $k \geq 2$. Then*

$$\#\mathcal{F}_k\big[\mathbf{x}_1 = \mathbf{x}', \mathbf{x}_2, \dots, \mathbf{x}_{k-1} \in \mathcal{X}, \mathbf{x}_k \in \mathcal{X}''\big] \leq \frac{\mathbb{P}\big[\mathrm{fut}(\mathbf{x}')\big]}{\inf_{\mathbf{x}'' \in \mathcal{X}''} \mathbb{P}\big[\mathrm{fut}(\mathbf{x}'')\big]} |a|^{k-1}.$$

Proof. Notice that the intervals of the form

$$\mathrm{fut}(\mathbf{x}') \cap \Gamma^{-1}\mathrm{fut}(\mathbf{x}_2) \cap \cdots \cap \Gamma^{-(k-2)}\mathrm{fut}(\mathbf{x}_{k-1}) \cap \Gamma^{-(k-1)}\mathrm{fut}(\mathbf{x}_k), \qquad \mathbf{x}_2, \dots, \mathbf{x}_k \in \mathcal{X},$$

constitute a family of disjoint subsets of $\mathrm{fut}(\mathbf{x}')$. This shows that

$$\begin{aligned}\mathbb{P}[\mathrm{fut}(\mathbf{x}')] \geq \sum_{\substack{\mathbf{x}_2, \dots, \mathbf{x}_{k-1} \in \mathcal{X} \\ \mathbf{x}_k \in \mathcal{X}''}} & \mathbb{P}\big[\mathrm{fut}(\mathbf{x}') \cap \Gamma^{-1}\mathrm{fut}(\mathbf{x}_2) \cap \cdots \\ & \cap \Gamma^{-(k-2)}\mathrm{fut}(\mathbf{x}_{k-1}) \cap \Gamma^{-(k-1)}\mathrm{fut}(\mathbf{x}_k)\big].\end{aligned}$$

Notice, moreover, that Γ^{k-1} is affine on each of these intervals and that

$$\Gamma^{k-1}\big(\mathrm{fut}(\mathbf{x}') \cap \Gamma^{-1}\mathrm{fut}(\mathbf{x}_2) \cap \cdots \cap \Gamma^{-(k-2)}\mathrm{fut}(\mathbf{x}_{k-1}) \cap \Gamma^{-(k-1)}\mathrm{fut}(\mathbf{x}_k)\big) = \mathrm{fut}(\mathbf{x}_k).$$

This implies that

$$\begin{aligned}&\mathbb{P}\big[\mathrm{fut}(\mathbf{x}') \cap \Gamma^{-1}\mathrm{fut}(\mathbf{x}_2) \cap \cdots \cap \Gamma^{-(k-2)}\mathrm{fut}(\mathbf{x}_{k-1}) \cap \Gamma^{-(k-1)}\mathrm{fut}(\mathbf{x}_k)\big] \\ &\quad \geq \frac{\inf_{\mathbf{x}'' \in \mathcal{X}''} \mathbb{P}[\mathrm{fut}(\mathbf{x}'')]}{|a|^{k-1}}\end{aligned}$$

if $\mathbf{x}'\mathbf{x}_2 \cdots \mathbf{x}_{k-1}\mathbf{x}_k \in \mathcal{F}_k[\mathbf{x}_1 = \mathbf{x}', \mathbf{x}_2, \dots, \mathbf{x}_{k-1} \in \mathcal{X}, \mathbf{x}_k \in \mathcal{X}'']$, and it is 0 otherwise. This yields the result. ∎

LEMMA 7. *Let $\mathbf{x}' \in \mathcal{X}$, and let $i = 1, \dots, \mathbf{N}$. Then*

$$\#\mathcal{F}_k[\mathbf{x}_1 = \mathbf{x}', \mathbf{x}_2, \dots, \mathbf{x}_{k-1} \in \mathcal{X} \setminus \mathcal{X}_P, \mathbf{x}_k \in \mathcal{X}_i] \leq 2^{k-2}.$$

Proof. As mentioned above, there is an edge connecting a state $\mathbf{x}'$ to another state $\mathbf{x}''$ with label ω if and only if $\mathrm{fut}(\mathbf{x}'') = \Gamma(\mathrm{fut}(\mathbf{x}')) \cap \omega$. Since the map Γ is affine on $\mathrm{fut}(\mathbf{x}')$, $\Gamma(\mathrm{fut}(\mathbf{x}'))$ is an interval, and so at most two followers of a state can be nonprincipal. The result follows by applying this argument. ∎

It follows from Lemmas 6 and 7 that the graph $\mathcal{G}$ satisfies properties (A), (B), and (C), and hence Theorem 6 holds true in this case. Notice that this yields Theorem 2, since γ_k defined in (30) coincides with γ_k defined in (30). Indeed, in this case we have that

$$\gamma_{k,h} = \#\mathcal{F}_k[\mathbf{x}_1 = \langle I_h \rangle, \mathbf{x}_2, \dots, \mathbf{x}_k \in \mathcal{X}],$$

so that $\gamma_k = \sum_h \gamma_{k,h}$ coincides with the number of paths of length k in the graph $\overline{\mathcal{G}}$, starting from a principal state and always remaining in $\mathcal{X}$. This, by the previous discussion, corresponds to the number of distinct subwords in $\Sigma_*(\Gamma) \cap \mathcal{I}^*$ of length k.

7.3. Estimation of the number of paths in the chaotic case. As mentioned in the remark after Theorem 6, in bound (53) we can fix r instead of the constant M. More precisely, instead of fixing the contraction factor equal to $1/2$ in (68) we can choose any $\delta \in]0,1[$. In this case, instead of (70), we obtain

$$\bar{p}_{\sigma,s} \leq \binom{r}{s}\binom{s}{\sigma}\left(\frac{\mathbf{N}D_2}{r}\right)^s\left(\frac{\mathbf{N}D_1}{s\delta(1-\delta)}\right)^\sigma. \tag{83}$$

In the case $\alpha_1 > \alpha_2$, the only consequence on the subsequent computations is that the factor $\frac{1}{\delta(1-\delta)}$ will enter in definition (75) of M. On the other hand, the number r also depends on the contraction factor δ. An important situation in which it is possible to take advantage of this degree of freedom is the following.

If we fix $\delta := q_{\mathbf{N}}/q_1 \wedge 1/2$, then $r = 1$, and in this way we obtain a simplified bound on γ_k in which, however, the constant M is a decreasing function of δ. In order to obtain an effective bound we need to have a bound from above on M, and so a bound from below on $q_{\mathbf{N}}/q_1$. In the context of piecewise affine maps this means that we need to have a bound from below on $\delta = \mathbb{P}[I_{\mathbf{N}}]/\mathbb{P}[I_1]$. An interesting situation in which this is possible is when $\mathbf{N} = \lceil |a| \rceil$, namely, for the chaotic quantized stabilizers.

PROPOSITION 5. *Let $|a| > 2$, and let $\mathbf{N} = \lceil |a| \rceil$. There exist constants $C_1 > 1$ and $M > 0$, depending only on $|a|$ such that if $C > C_1$, then*

$$\frac{\gamma_k}{|a|^k} \leq 2\left(\frac{\mathbf{N}M}{k \wedge \frac{\mathbf{N}M}{e}}\right)^{k \wedge \frac{\mathbf{N}M}{e}} \qquad \forall k \geq 1. \tag{84}$$

Proof. For the arguments presented above, we need only to prove that there exist constants $\delta_1 > 0$ and $C_1 > 1$, depending only on $|a|$ such that

$$C \geq C_1 \;\Rightarrow\; \frac{\mathbb{P}[I_{\mathbf{N}}]}{\mathbb{P}[I_1]} \geq \delta_1.$$

First notice that $1 \geq \mathbb{P}[\Gamma(I_1)] \geq |a|\,\mathbb{P}[I_1]$, from which we can argue that $\mathbb{P}[I_1] \leq 1/|a|$. Moreover,

$$\mathbb{P}[I_{\mathbf{N}}] = 1 - \mathbb{P}[J] - \sum_{h=1}^{\mathbf{N}-1}\mathbb{P}[I_h] \geq 1 - C^{-1} - (\mathbf{N}-1)\mathbb{P}[I_1] \geq 1 - C^{-1} - \frac{\lceil |a| \rceil - 1}{|a|},$$

and hence

$$\frac{\mathbb{P}[I_{\mathbf{N}}]}{\mathbb{P}[I_1]} \geq \frac{\mathbb{P}[I_{\mathbf{N}}]}{1/|a|} \geq |a| - |a|C^{-1} - \lceil |a| \rceil + 1 \overset{C\to\infty}{\longrightarrow} |a| - \lceil |a| \rceil + 1 > 0.$$

This proves the result. □

7.4. Estimation of the number of paths in the stable case. In this section, we will propose a bound on γ_k which holds true when Γ is (I,J)-stable or when Γ is almost (I,J)-stable but with only a countable subset of points in I never entering inside J. To obtain this bound we need the following lemma.

LEMMA 8. *Assume that there exists a state $\mathbf{x} \in \mathcal{X}$ such that there exist two distinct paths in the graph $\mathcal{G}$ both starting and ending in $\mathbf{x}$ and not passing by $\mathbf{x}$ in any intermediate step (simple loops through $\mathbf{x}$). Then there is an uncountable set of points in I never entering inside J.*

Proof. The proof is based on a general argument on the symbolic description of a one-dimensional expansive map as Γ which consists in constructing a sort of inverse of the map ψ defined in (29); see [5].

Given any loop $\nu = \mathbf{x}\mathbf{x}_1 \cdots \mathbf{x}_{k-1}\mathbf{x}$ in $\mathcal{G}$, if we consider the open interval

$$K_\nu = \mathrm{fut}(\mathbf{x}) \cap \Gamma^{-1}(\mathrm{fut}(\mathbf{x}_1)) \cap \cdots \cap \Gamma^{-(k-1)}(\mathrm{fut}(\mathbf{x}_{k-1})) \cap \Gamma^{-k}(\mathrm{fut}(\mathbf{x}))\,,$$

we have that Γ^k is affine on K_ν, and $\Gamma^k(K_\nu) = \mathrm{fut}(\mathbf{x})$. In particular it follows that

$$\mathbb{P}[K_\nu] = \mathbb{P}[\mathrm{fut}(\mathbf{x})]|a|^{-k}. \tag{85}$$

We now set some notation: if $\nu_1 = \mathbf{x}\mathbf{x}_1^1 \cdots \mathbf{x}_{k_1-1}^1\mathbf{x}$ and $\nu_2 = \mathbf{x}\mathbf{x}_1^2 \cdots \mathbf{x}_{k_2-1}^2\mathbf{x}$ are two loops through $\mathbf{x}$, we define the concatenation of ν_1 and ν_2 as the new loop

$$\nu = \nu_1 \wedge \nu_2 = \mathbf{x}\mathbf{x}_1^1 \cdots \mathbf{x}_{k_1-1}^1\mathbf{x}\mathbf{x}_1^2 \cdots \mathbf{x}_{k_2-1}^2\mathbf{x}.$$

Assume that there are two distinct simple loops ν_1 and ν_2 of length k_1 and k_2, respectively, through $\mathbf{x}$. The corresponding open intervals K_1 and K_2 as defined above are then disjoint. Define now a map $\Upsilon : \{1,2\}^{\mathbb{N}} \to I$ in the following way: given a sequence $(a_n) \in \{1,2\}^{\mathbb{N}}$, consider the set

$$\overline{K}_{a_1} \cap \Gamma^{-k_{a_1}}\left(\overline{K}_{a_2}\right) \cap \Gamma^{-k_{a_1}-k_{a_2}}\left(\overline{K}_{a_3}\right) \cap \cdots = \bigcap_{n=1}^{+\infty} \Gamma^{-\sum_{j=1}^{n-1} k_{a_j}}\left(\overline{K}_{a_n}\right). \tag{86}$$

Since

$$\bigcap_{n=1}^{q} \Gamma^{-\sum_{j=1}^{n-1} k_{a_j}}\left(\overline{K}_{a_n}\right)$$

is simply the closure of the open interval K associated with the loop $\nu_{a_1} \wedge \nu_{a_2} \wedge \cdots \wedge \nu_{a_q}$, it follows that it is nonempty and that, by (85), its size decreases by a factor

$$|a|^{-\sum_{j=1}^{n-1} k_{a_j}}.$$

Hence this implies that the set in (86) consists of exactly one point x. We then put $\Upsilon((a_n)) = x$. Call $\Delta = \Upsilon(\{1,2\}^{\mathbb{N}})$. A standard argument of symbolic dynamics of one-dimensional maps now show that there exists $\Delta_1 \subseteq \Delta$, at most countable, such that the counterimage set $\Upsilon^{-1}(x)$ is a singleton for every $x \in \Delta \backslash \Delta_1$. Indeed, it follows by the definition that the only points x which have more than one counterimage (and in fact exactly two) are those in the union of boundaries of the intervals

$$\bigcap_{n=1}^{q} \Gamma^{-\sum_{j=1}^{n-1} k_{a_j}}\left(\overline{K}_{a_n}\right),$$

namely, those in the subset

$$\Delta_1 = \bigcup_{q=1}^{+\infty} \bigcup_{a_1,\ldots a_q} \partial\left(\bigcap_{n=1}^{q} \Gamma^{-\sum_{j=1}^{n-1} k_{a_j}}\left(\overline{K}_{a_n}\right)\right),$$

which is clearly at most countable. Finally, the subset of points in Δ which will never enter inside Δ_1,

$$\Delta_2 = \bigcap_{k=0}^{+\infty} \Gamma^{-k}(\Delta \setminus \Delta_1),$$

is clearly uncountable.

We claim that no point in Δ_2 will ever enter inside J. Notice first that, by construction, $\Delta_2 \subseteq \Omega$. Now take $x \in \Delta_2$, and let $(a_n) \in \{1,2\}^{\mathbb{N}}$ be such that $\Upsilon(a_n) = x$. Then

$$\Gamma^{k_{a_1}}(\Upsilon(a_n)) = \Upsilon(\tilde{a}_n),$$

where $(\tilde{a}_n)$ is a sequence defined by $\tilde{a}_n = a_{n+1}$ for all $n \in \mathbb{N}$. This implies in particular that $\Gamma^{k_{a_1}}(x) \in \Delta_2$ by the way Δ_2 has been defined. Hence we have that for every $x \in \Delta_2$ either $\Gamma^{k_1}(x)$ or $\Gamma^{k_2}(x)$ is also in Δ_2. If, by contradiction, n_0 exists such that $\Gamma^n x \in J$ for every $n \geq n_0$, we could find for sure $n_1 \geq n_0$ such that $y = \Gamma^{n_1} x \in \Delta_2 \cap J$. Since $\Delta_2 \subseteq K_1 \cup K_2$ it would follow that $y \in \partial K_1 \cup \partial K_2$, which is absurd by the way Δ_2 has been defined. □

THEOREM 7. *Assume that Γ is almost (I,J)-stable with an at most countable subset of points in I never entering inside J. Then*

$$\frac{\gamma_k}{2^k} \leq \binom{k + 2\mathbf{N} - 1}{2\mathbf{N} - 1} e^{\frac{\mathbf{N}}{e}} \qquad \forall k \geq 1. \tag{87}$$

Proof. Decompose the set $\mathcal{X}_P$ into maximal subfamilies $\mathcal{X}_P^1, \mathcal{X}_P^2, \ldots, \mathcal{X}_P^m$ in such a way that two principal states belong to the same family if and only if there exists a loop in $\mathcal{G}$ connecting them. Also we can assume the families are ordered in such a way that if there exists a path from $\mathbf{x}_1 \in \mathcal{X}_P^i$ to $\mathbf{x}_2 \in \mathcal{X}_P^j$, then $i \leq j$. Let N_i be the cardinality of $\mathcal{X}_P^i$. We thus have $\mathbf{N} = \sum_{i=1}^m N_i$.

Given now any path ν of length k inside the graph $\mathcal{G}$ starting from a principal state, we can always split it as

$$\nu = \nu_1 \mu_1 \nu_2 \mu_2 \cdots \nu_m \mu_m,$$

where ν_i is a path connecting two principal states in $\mathcal{X}_P^i$, while ν_i is a path only consisting of nonprincipal states. Assume ν_i has length k_i^1 and that μ_i has length k_i^2. We thus have

$$k = \sum_{i=1}^m k_i^1 + \sum_{i=1}^m k_i^2.$$

The number of ways we can split k in the sum above is equal to

$$\binom{k + 2m - 1}{2m - 1}.$$

Once the numbers k_i^1 and k_i^2 have been fixed, we notice that the path ν_i can be chosen in N_i distinct ways corresponding to the ways we can choose the initial principal state. This follows from the fact that from any principal state in $\mathcal{X}_P^i$ there is exactly one path reaching another element in $\mathcal{X}_P^i$ because otherwise there would be two distinct

simple loops in $\mathcal{G}$ contradicting the result in Lemma 8. Notice that using the fact that $\sum_{i=1}^{m} N_i = \mathbf{N}$, by Lemma 3, the number of ways we can choose the family of paths $\nu_1, \nu_1, \ldots, \nu_m$ is bounded from above by

$$\prod_{i=1}^{m} N_i \leq \left(\frac{\mathbf{N}}{m}\right)^m \leq e^{\frac{\mathbf{N}}{e}}.$$

Once all the paths ν_i have been chosen, the remaining paths μ_i can be chosen in at most $2^{k_i^2}$ distinct ways. Hence the number of ways we can choose the family of paths $\mu_1, \mu_1, \ldots, \mu_m$ is bounded from above by 2^k. We thus have the thesis. □

8. Conclusions. In this paper, some stabilizing quantized feedback strategies are proposed and their different properties in terms of performance and communication requirements are compared. These strategies are based on nesting one base quantized feedback. The performance, defined as the expected time needed to get from a big initial state set into a smaller target state set, is analyzed by using the concept of the Perron–Frobenius operator associated with a nonlinear transformation.

The second part of the paper is devoted to the search of general bounds which could highlight the trade-off existing between performance and information flow required by a quantized control technique. This investigation is based on a symbolic representation of the closed loop nonlinear system. In this way the system is described by a Markov chain with possibly infinite states. Counting the paths on the graph which represents the Markov chain, it is possible to obtain bounds on the performance which yield to some interesting trade-off relations. This method is based on a technical result which is expressed in terms of general Markov chains and its proof, though quite long, is based on basic combinatorial relations.

It is our hope that, as information theory has been a successful symbolic technique to treat digital communication, a symbolic technique will be the right tool to deal with digital control as well. In fact, although this paper deals only with the static control of linear scalar systems, the symbolic method proposed here seems to be very promising for treating more general situations. In [10] the same method is applied for treating both the case in which a memory structure is allowed on the controller and the case in which the system is multidimensional. We hope that this method will be useful to solve other questions which remain open. In our opinion the most important ones are the following.

1. In most of the contributions on control with communication constraint proposed in the literature it is assumed that the channels are digital with a finite rate but are noiseless. In the future investigations it will be important to allow the presence of errors in the data exchange between the plant and the controller.
2. In our opinion more attention has to be devoted to the control problem with communication constraint in those situations in which there are more interacting agents to be controlled to achieve a joint control objective. In this case the communication constraint have to be imposed on the data which are exchanged by the differently located agents.
3. In this paper, we have been able to analyze the performance of some simple quantized feedback strategies. It remains to obtain an algorithm able to provide an approximate performance evaluation for any given specific quantized feedback. In our opinion a promising method could be based on the approximation of the Perron–Frobenius operator by a finite state Markov chain

which is connected with the so-called Ulam conjecture (see [19] and references therein).

Appendix: Some useful elementary combinatorics. In the paper, we use some elementary properties of the binomials. The first one is

$$\sum_{j=0}^{m} \binom{l+j}{j} = \binom{m+l+1}{m}, \tag{88}$$

which follows by iterating the elementary identity

$$\binom{m+l+1}{m} = \binom{m+l}{m} + \binom{m+l}{m-1}.$$

Another useful formula follows by comparing the binomial coefficients of the term z^k in the polynomial identity

$$(1+z)^{n_1}\left(1+z^{-1}\right)^{n_2} = (1+z)^{n_1+n_2} z^{-n_2},$$

which yields

$$\sum_{j=0}^{(n_1-k)\wedge n_2} \binom{n_1}{k+j}\binom{n_2}{j} = \binom{n_1+n_2}{k+n_2}. \tag{89}$$

Another useful formula is given by the following series of inequalities which holds true for all $n, m \geq 1$ [1, p. 113]:

$$\begin{aligned}\binom{n+m}{m} &\leq \sqrt{\frac{1}{2\pi}\left(\frac{1}{n}+\frac{1}{m}\right)}\left(1+\frac{n}{m}\right)^m\left(1+\frac{m}{n}\right)^n \\ &\leq \sqrt{\frac{1}{2\pi}\left(\frac{1}{n}+\frac{1}{m}\right)}\left(1+\frac{n}{m}\right)^m e^m \leq \sqrt{\frac{1}{2\pi}\left(\frac{1}{n}+\frac{1}{m}\right)}e^{n+m}.\end{aligned} \tag{90}$$

From (90) we can argue that for all $n \geq 0$ and $m \geq 1$,

$$\binom{n+m}{m} \leq \frac{1}{\sqrt{\pi}}\left(1+\frac{n}{m}\right)^m e^m. \tag{91}$$

Finally consider the function

$$f(x) := \left(\frac{A}{x}\right)^{Bx}.$$

This is a unimodal function having a unique maximum in $x_M = \frac{A}{e}$. This implies that for all $\bar{x} > 0$, we have

$$\max_{0<x\leq\bar{x}} f(x) = f(\bar{x} \wedge x_M) = \left(\frac{A}{\bar{x} \wedge \frac{A}{e}}\right)^{B\left(\bar{x}\wedge\frac{A}{e}\right)}. \tag{92}$$

Observe, moreover, that for all $\hat{x} > 0$, we have

$$\left(\frac{A}{x}\right)^{B(x\wedge\hat{x})} \leq \left(\frac{A}{x\wedge\hat{x}}\right)^{B(x\wedge\hat{x})},$$

which implies that

$$\max_{0<x\le\bar{x}}\left(\frac{A}{x}\right)^{B(x\wedge\hat{x})} \le \max_{0<x\le\bar{x}}\left(\frac{A}{x\wedge\hat{x}}\right)^{B(x\wedge\hat{x})} = \max_{0<x\le\bar{x}\wedge\hat{x}} f(x) = \left(\frac{A}{\bar{x}\wedge\hat{x}\wedge\frac{A}{e}}\right)^{B(\bar{x}\wedge\hat{x}\wedge\frac{A}{e})}. \tag{93}$$

FAITHFUL REPRESENTATIONS FOR CONVEX HAMILTON–JACOBI EQUATIONS*

FRANCO RAMPAZZO†

Abstract. When a Hamiltonian $H = H(t, x, p)$ is convex in the adjoint variable p, the corresponding Hamilton–Jacobi equation

$$u_t + H(t, x, u_x) = 0 \tag{0.1}$$

is known to be the Bellman equation of a suitable optimal control problem. Of course, the latter is not unique, so it is interesting to select a *good* optimal control problem among those representing (0.1). We call such a representation *faithful* if (i) it involves a dynamics which is locally Lipschitz continuous in the state variable—so that a unique trajectory corresponds to any given control and initial point—and (ii) *the Lagrangian displays the same regularity as H in the x variable.* The main result of the present paper establishes the existence of faithful representations for a large class of Hamiltonians, including those for which the standard comparison theorems (of viscosity solution theory) are valid. Moreover, our investigation includes t-measurable Hamiltonians as well.

If a faithful control-theoretical representation does exist (and (0.1) enjoys uniqueness properties), one can infer sharp regularity results for the solution of (0.1) just by studying the regularity of the value function of the associated optimal control problem. A further application consists of a simple interpretation of the front propagation phenomenon in terms of optimal trajectories of the underlying minimum problem.

1. Introduction.

1.1. Some notation and conventions. We shall call *modulus* any increasing, continuous function $\omega : [0, +\infty[\to [0, +\infty[$ such that $\omega[0] = 0$. A *local modulus* will be a continuous map $\omega : [0, +\infty[\times [0, +\infty[\to [0, +\infty[$ that is increasing in the first variable and is a modulus in the second variable. The closed ball of $\mathbb{R}^n$ of radius $R \geq 0$ will be denoted by $\mathbf{B}_R$, and $\mathbf{B}$ will stand in place of $\mathbf{B}_1$. For each map $\varphi : \mathbb{R}^n \to \mathbb{R} \cup +\infty$, the domain of φ, i.e., the subset of those $v \in \mathbb{R}^n$ such that $\varphi(v) < +\infty$, will be denoted by $\mathrm{dom}(\varphi(\cdot))$. For any map $H : [0, T] \times \mathbb{R}^n \times \mathbb{R}^n \to \mathbb{R}$, H^* will denote the conjugate map with respect to the third variable; that is, we shall set

$$H^*(t, x, v) \doteq \sup_{p \in \mathbb{R}^n} \{p \cdot v - H(t, x, p)\}$$

for all $(t, x, v) \in [0, T] \times \mathbb{R}^n \times \mathbb{R}^n$.

If $w = w(y_1, \ldots, y_q)$ is a map of many (possibly vector-valued) variables, for any $i = 1, \ldots, q$ we shall use w_{y_i} to denote the gradient with respect to the y_i variable. It will be clear by the context whether this has to be intended in the sense of viscosity solution theory.

1.2. Statement of the problem. For every $(t,x) \in [0,T] \times \mathbb{R}^n$ let us consider the Bolza optimal control problem

$$(\mathcal{P}_{t,x}) \qquad \begin{array}{ll} \text{minimize} & \int_t^T l(s,y(s),a(s))ds + g(y(T)), \\ & \dot{y}(s) = f(s,y(s),a(s)), \\ & y(t) = x, \end{array}$$

where the controls $a(\cdot)$ (are measurable maps on $[t,T]$ and) take values in some subset A of a Euclidean vector space and the *Lagrangian-dynamics* pair (l,f) verify suitable hypotheses which will be made precise later. The function g will be assumed continuous, even though weaker assumptions could be considered (see Remark 2.1 below).

The Bellman–Cauchy problem corresponding to the family of optimal control problems $\{\mathcal{P}_{t,x},\ (t,x) \in [0,T] \times \mathbb{R}^n\}$ is defined as the Hamilton–Jacobi equation

$$u_t + H(t,x,u_x) = 0 \qquad \text{in }]0,T[\times \mathbb{R}^n \tag{1.1}$$

with the initial condition

$$u(0,x) = g(x) \qquad \forall x \in \mathbb{R}^n, \tag{1.2}$$

where

$$H(t,x,p) \doteq \sup_{a \in A} \{p \cdot f(t,x,a) - l(t,x,a)\}. \tag{1.3}$$

As is well known, the connection between the Bolza problems $(\mathcal{P}_{t,x})$ and the initial value problem (1.1)–(1.2) relies on the fact that if $V(t,x)$ is the value function of $(\mathcal{P}_{t,x})$, that is,

$$V(t,x) = \inf_{a(\cdot)} \int_t^T l(s,y(s),a(s))ds + g(y(T)), \tag{1.4}$$

then the map $u(t,x) = V(T-t,x)$ is a solution (e.g., viscosity [BCD] or minmax [Su] solution) of (1.1)–(1.2). Notice, in particular, that the Hamiltonian is convex in the gradient variable.

Let us consider the converse question. Suppose the Cauchy problem (1.1)–(1.2) is given, with only the information that H is convex in the gradient variable (plus other technical conditions which guarantee existence and uniqueness of *solutions* to (1.1)–(1.2)). Then it is natural to wonder whether (1.1)–(1.2) is the Bellman–Cauchy problem of a family $\{\mathcal{P}_{t,x},\ (t,x) \in [0,T] \times \mathbb{R}^n\}$ of optimal control problems. This means that one looks for a triple (A,f,l) such that (1.3) is verified. Such a triple will be called a (*control theoretical*) *representation of* H.

It is easily seen that if a representation of H exists, then infinitely many others exist.[1] So, we may consider a further question, namely, that of choosing a representation verifying some given properties.

[1] For instance, the map $H(p) = |p|$ is the Hamiltonian corresponding to the trivial optimal control problem

$$\begin{array}{ll} \text{minimize} & \int_t^T (1 - |a(s)|)ds, \\ & \dot{y}(s) = a(s), \qquad a(s) \in [-1,1], \\ & y(t) = x. \end{array}$$

On the other hand, for every pair $(h(\cdot),k(\cdot))$ of positive maps, $H(p) = |p|$ is also the Hamiltonian of

Indeed, this is our aim, which, loosely speaking, consists of finding representations that allow both *uniqueness of trajectories of* f (for any given control) and *a Lagrangian with the same* x*-regularity* as the given Hamiltonian.

In order to define the problem let us begin by stating properties (A1)–(A3) below, which are the properties we wish to be satisfied by a family of optimal control problems. They will imply certain conditions on H, which have to be considered as sort of *minimal assumptions* for our problem.

Given a family $\{\mathcal{P}_{t,x},\ (t,x) \in [0,T] \times \mathbb{R}^n\}$ of Bolza optimal control problems, we shall consider the following hypotheses on the triple (A, f, l):

(A1) *There exists a constant* Q *such that*

$$|f(t,0,a,)|, |l(t,0,a)| \le Q$$

for all $t \in [0,T]$ *and* $a \in A$.

(A2) *The maps* f *and* l *are continuous from* $[0,T] \times \mathbb{R}^n \times A$ *into* $\mathbb{R}^n$ *and* $\mathbb{R}$, *respectively, and for every* $R > 0$ *there exists a nonnegative number* E_R *such that*

$$|f(t,x,a) - f(t,y,a)| \le E_R|x-y|, \tag{1.5}$$

$$|l(t,x,a) - l(t,y,a)| \le \nu[R, |x-y|] \tag{1.6}$$

for all $(t,x,a), (t,y,a) \in [0,T] \times \mathbf{B}_R \times A$, *where* ν *is a suitable local modulus.*

(A3) *There is* $C > 0$ *such that*

$$|f(t,x,a)| \le C(1+|x|)$$

for all $(t,x,a) \in [0,T] \times \mathbb{R}^n \times A$.

From a control theoretical viewpoint these are rather standard hypotheses for the triple (A, f, l). In turn, it is straightforward to verify that they imply the following properties for the Hamiltonian H defined in (1.3):

(H1) *For any* $(t,x) \in [0,T] \times \mathbb{R}^n$, *the map* $q \mapsto H(t,x,q)$ *is convex from* $\mathbb{R}^n$ *into* $\mathbb{R}$.

(H2) *There exist local moduli* ω_1, ω_2, *and* ω_3 *such that for any* $R > 0$, *one has*

$$|H(t,x,p) - H(t,y,p)| \le \omega_1[R, |x-y|(1+|p|)] \tag{1.7}$$

and

$$|H(t,x,p) - H(s,x,p)| \le |p|\omega_2[R, |t-s|] + \omega_3[R, |t-s|] \tag{1.8}$$

for all $x, y \in \mathbf{B}_R$, $p \in \mathbb{R}^n$, *and* $t, s \in [0,T]$.

(H3) *There exists a constant* C *such that*

$$|H(t,x,p) - H(t,x,q)| \le C(1+|x|)|p-q| \tag{1.9}$$

for all $(t,x) \in [0,T] \times \mathbb{R}^n$ *and* $p, q \in \mathbb{R}^n$.

(H4) *For every* $R > 0$, *there exists a nonnegative number* N_R *such that*

$$|H^*(t,x,v)| \le N_R$$

for all $(t,x) \in [0,T] \times \mathbf{B}_R$ *and* $v \in \mathrm{dom}(H^*(t,x,\cdot))$.

---

the (much more involved) optimal control problem

$$\begin{array}{ll} \text{minimize} & \int_t^T \frac{h(y(s))}{a^2(s)}\,ds, \\ & \dot{y}(s) = \frac{a(s)k(y(s))}{1+|a(s)|k(y(s))} \cdot \frac{1-a^2(s)}{1+a^2(s)}, \qquad a(s) \in \mathbb{R}, \\ & y(t) = x. \end{array}$$

1.3. Aim. Assumptions (H1)–(H4), beyond being *necessary* for (A1)–(A3) (see Remark 2.2), are in fact verified with

$$\omega_1[R,s] = E_R(s + \nu[R,s]).$$

That is, the local modulus of continuity (in x) of H turns out to coincide—up to a sum with a linear mapping and a multiplication by a positive number, both depending on the radius R—with the local modulus of l. We say that H *inherits the same continuity (in x) from l.*

For a given Hamiltonian H verifying (H1)–(H4), we wish to find a representation (A, f, l) such that f *is locally Lipschitz continuous in x*—so that uniqueness of trajectories is guaranteed—and l *has the same kind of continuity (in x) as H.*

To be more precise, this means that we are looking for a triple (A, f, l) verifying (A1)–(A3) *with*

$$\nu[R,s] = P_R(s + \omega_1[R,s])$$

for suitable coefficients $P_R(\geq 0)$.

Remark 1.1. Up to now, the major contribution to the representation's issue for convex Hamiltonians could be found in Ishii [Is2]. As a matter of fact, in [Is2] representations were provided such that both f and l turn out to have a modulus of continuity equal to $(\omega_1)^{\frac{1}{2}}$ (while the control set turns out to be infinite-dimensional). This implies, for instance, that even in the quite regular case when $\omega_1[R,s] = L \cdot s$, f and l turn out to be just $\frac{1}{2}$-Holder continuous in x. In particular, the Lagrangian is *less regular* than the Hamiltonian, and the Cauchy problems for the control vector field f in general admit multiple solutions (for each control). On the contrary, in such a situation our result implies that both the dynamics f and the Lagrangian l are locally Lipschitz continuous in the state variable.

Remark 1.2. Problems with no convexity were investigated, e.g., by Ishii in [Is3] and by Evans and Souganidis in [ES]. Both papers aimed toward a representation of the solution in terms of an (Elliot–Kalton) upper or lower value of a suitable differential game. The dynamics of Ishii's representation involves infinite-dimensional control sets for the opponents in the game and displays a sort of Lipschitz continuity on compact sets. Instead the Lagrangian is just continuous. On the other hand, in [ES] Hamiltonians as well as initial data are restricted to Lipschitz continuous, bounded, functions. When referred to the case with convexity these results are weaker than ours. However, a comparison actually does not make sense because of the greater generality of the problems treated in [Is3] and [ES]. As a matter of fact, the lack of convexity could well be a serious drawback in the attempt to give a representation with a Lagrangian *as regular (in x)* as the Hamiltonians—apart from the Lipschitz bounded case treated in [ES].

1.4. Main results and an outline of the paper. The main contribution of this paper—see Theorems 2.1 and 2.2 below—consists of accomplishing *the twofold program of finding a locally Lipschitz continuous dynamics f and a Lagrangian l that preserves the same kind of continuity (in x) of the Hamiltonian.* Moreover, the control set A in our representation turns out to be particularly simple, namely, the unit ball of $\mathbb{R}^n$. Lastly (see section 6) we can prove extensions of these results to Hamiltonians measurably dependent on t.

As a first consequence of such results, many statements in the literature that have been proved for a Hamiltonian displaying an explicit control-theoretical form

as in (1.3) can now be updated by considering Hamiltonians H that merely verify (H1)–(H4) (and, for some specific purposes, a further technical hypothesis (H5)). Furthermore, some results concerning the solution of the Cauchy problem (1.1) can be sharpened by means of the control-theoretical representation we are providing. For instance, this is the case of the regularity of the solution to (1.1), which is addressed in section 5. Finally, already known results may be interpreted as facts concerning the optimal trajectories of the underlying optimal control problem, as it happens for the phenomenon of front propagation (see section 5).

As for the proof of the main result, let us remark that it is based essentially on the following arguments. First, in Theorem 3.2 below we establish (by means of an argument based on Kakutani's fixed point theorem) that under hypotheses (H1)–(H4) the multifunction that maps (t,x) into $F(t,x) \doteq \mathrm{dom}(H^*(t,x,\cdot))$ is *locally Lipschitz continuous* in x (and an analogous fact holds in the case of Hamiltonians measurable in t). Theorem 3.3 yields a global version of this result. Observe that the presence of the local modulus ω_1 in (H2) would suggest an (at most) ω_1-regularity for this multifunction rather than the local Lipschitz continuity actually obtained by means of our results. Secondly, we exploit a parameterization theorem for convex multifunctions proved in [O] (see also [Lo]). According to this theorem, if $F(t,x)$ is a convex multifunction satisfying suitable regularity assumptions, then there exists a map $f : [0,T] \times \mathbb{R}^n \times \mathbf{B} \to \mathbb{R}^n$ displaying an akin regularity and verifying $F(t,x) = f(t,x,\mathbf{B})$ for all (t,x). Finally, by (H4) one proves that l displays the same kind of continuity (in x) as H.

The outline of the paper is as follows. In section 2 we state the main result (Theorem 2.1) and a version of it involving global regularity. In section 3 we establish that the multivalued map $(t,x) \mapsto \mathrm{dom}(H^*(t,x,\cdot))$ is (continuous and) locally Lipschitz continuous in x. Subsequently, a global version of this result is proven as well. In section 4 we conclude the proof of the main result by exploiting the parameterization theorem for multifunctions mentioned above. Section 5 is devoted to applications to regularity questions and to a control theoretical interpretation of the front propagation phenomenon. Finally, in section 6, we extend the results of the previous sections to the case when H is just measurable in the variable t.

2. The main result. In the next theorem we shall also consider the following hypothesis on the Hamiltonian H.

(H5) *For every $R > 0$ there exists $K_R > 0$ such that for every $(t,x) \in [0,T] \times \mathbf{B}_R$ and every $v \in \mathrm{dom}(H^*(t,x,\cdot))$, one has*

$$\mathrm{argmax}_p\{p \cdot v - H(t,x,p)\} \cap B_{K_R} \neq \emptyset.$$

Here $\mathrm{argmax}_p\{p \cdot v - H(t,x,p)\}$ denotes the set of values of p where the map $p \mapsto p \cdot v - H(t,x,p)$ attains its maximum.

THEOREM 2.1. *Let us consider a Hamiltonian H verifying hypotheses* (H1)–(H4). *Then there exist a dynamics $f = f(t,x,a)$ satisfying* (A1)–(A3) *and a continuous Lagrangian $l = l(t,x,a)$, with the control set A coinciding with the unit ball $\mathbf{B}$, such that*

$$H(t,x,p) = \sup_{a \in \mathbf{B}} \{p \cdot f(t,x,a) - l(t,x,a)\} \qquad \forall (t,x,p) \in [0,T] \times \mathbb{R}^n \times \mathbb{R}^n. \tag{2.1}$$

Furthermore, if hypothesis (H5) *is in force as well, then* (A2) *turns out to be satisfied with $\nu[R,s] \doteq \omega_1[R,(1+K_R)s] + D_R s$ for suitable coefficients D_R.*

Remark 2.1. As we have already pointed out in the introduction, the main point of Theorem 2.1 consists of the fact that, on one hand, f *turns out to be locally Lipschitz continuous* (in x), even in the case when H is *not* locally Lipschitz continuous (in x), and, on the other hand, l turns out to *inherit* the regularity (in x) of H. Finally, the control set A turns out to be quite simple, namely, it coincides with the unit ball of $\mathbb{R}^n$.

The following theorem is a global version of the previous one.

THEOREM 2.2. *Let H verify* (H1)–(H5)*, where we assume that ω_1 is a modulus (i.e., it is independent of R) and there exists a constant K such that $K_R = K$ for all $R \geq 0$. Then there exist a dynamics f and a Lagrangian l such that*

$$H(t,x,p) = \sup_{a \in \mathbf{B}} \{p \cdot f(t,x,a) - l(t,x,a)\} \qquad \forall (t,x,p) \in [0,T] \times \mathbb{R}^n \times \mathbb{R}^n \tag{2.2}$$

holds true, and (A1)–(A3) *are satisfied, with the control set A coinciding with the unit ball $\mathbf{B}$, E_R independent of R, and, for all $R \geq 0$, $\nu[R,s] = \nu(s) = \omega_1[(1+K)s + Ds]$ for a suitable $D \geq 0$.*

Remark 2.2 (*on hypotheses* (H1)–(H4)). Assumptions (H1)–(H4) are *necessary* if we look for a representation (A,f,l) verifying (A1)–(A3). Moreover, they guarantee the (existence and) uniqueness of a viscosity solution to the Cauchy problem (1.1)–(1.2) (see, e.g., [CL]).

Let us observe that by assuming (H3) we are confining our investigation to Hamiltonians which are (convex and) *Lipschitz continuous in the adjoint variable* (not necessarily uniformly with respect to x). Moreover, (H4) prescribes the boundedness of the conjugate map H^*, locally with respect to (t,x). This is motivated by the fact that, on one hand, we are looking for control-theoretical representations (f,l,A) of H such that both the sets $f(t,x,A)$ and $l(t,x,A)$ are bounded, not necessarily uniformly with respect to t and x. And, on the other hand, the sets $f(t,x,A)$ and $l(t,x,A)$ finally will coincide with $\mathrm{dom}(H^*(t,x,\cdot))$ and $(H^*(t,x,\mathbb{R}^n))\backslash\{\infty\}$, respectively. As a matter of fact, we regard this paper as a first step of a wider program which shall allow for more general conditions on H. These should include superlinearity in the adjoint variable, which in turn would force one to look for representations with noncompact (possibly unbounded) control sets.

Finally, let us notice that assumption (H2) is quite standard for comparison (and hence uniqueness) results for a viscosity solution of (1.1); see, e.g., [BCD] and [Ba]. (However, let us remark that there are boundary value problems for which (H2) is no longer sufficient to guarantee uniqueness of the solution. In this case, a faithful representation of the Hamiltonian could be still exploited in order to provide a representation of *all* solutions of the boundary value problem, as, e.g., in [So], where the Hamiltonian is a control-theoretical one.)

Remark 2.3 (*on hypothesis* (H5)). Let us point out that, unlike hypotheses (H1)–(H4), hypothesis (H5) is not necessary for the existence of a representation (A,f,l) verifying (A1)–(A3), i.e., for the theses of Theorems 2.1 and 2.2 to hold true. For instance, let us consider the Hamiltonian

$$\tilde{H}(x,p) = (1+p^2)^{\frac{1}{2}} - 1 - \psi(x),$$

where ψ is just a continuous function. It is straightforward to verify that this Hamiltonian satisfies hypotheses (H1)–(H4), but *it does not satisfy hypothesis* (H5). On the other hand, it is easy to check that *the triple*

$$(\tilde{A}, \tilde{f}, \tilde{l}) = ([-1,1], a, 1 - (1-a^2)^{\frac{1}{2}} + \psi(x))$$

is a representation of H verifying (A1)–(A3), that is,

$$\tilde{H}(x,p) = \sup_{a\in[-1,1]} \{p\cdot a - \tilde{l}(x,a)\}.$$

At present we are unable to foresee how (H5) could be weakened, so we leave this question as an open problem.

Remark 2.4. Let us just mention that the representation question can also be addressed by considering only calculus of variations problems (see, e.g., [L] and also [G]) at the cost of allowing the *extended* Lagrangian H^*. Of course there is an intimate relation between the two approaches: roughly speaking, in the control-theoretical approach one is looking for a dynamics-Lagrangian pair so that, in particular, the *forbidden* velocities, that is, those mapped to $+\infty$ by H^*, are not contained in the dynamics.

3. The map $(t,x)\mapsto \mathbf{dom}(H^*(t,x,\cdot))$. In this section we prove that the (convex) multifunction $F(t,x)\doteq \mathrm{dom}(H^*(t,x,\cdot))$ is Lipschitz continuous in x. As a matter of fact, the proofs of Theorems 2.1 and 2.2, given in the next section, will be based essentially on the Lipschitz continuity of F and on the application of a parameterization theorem for convex-valued multifunctions; see Theorem 4.1 below.

Let us consider the set-valued map

$$(t,x)\mapsto F(t,x)\doteq \mathrm{dom}(H^*(t,x,\cdot)),$$

which is defined on $[0,T]\times\mathbb{R}^n$.

LEMMA 3.1. *The set-valued map F has nonempty, convex, compact values.*

Proof. Since for every $(t,x)\in[0,T]\times\mathbb{R}^n$ the map $v\mapsto H^*(t,x,v)$ is convex, proper (i.e., not everywhere equal to $+\infty$), lower semicontinuous, and bounded on its domain, $F(t,x)$ is a nonempty, convex, closed subset of $\mathbb{R}^n$(see, e.g., [RW]). Moreover, hypothesis (H3) implies that $F(t,x)\subset B_{C(1+|x|)}$ for every $(t,x)\in[0,T]\times\mathbb{R}^n$. Hence, for every $(t,x)\in[0,T]\times\mathbb{R}^n$, $F(t,x)$ is a compact convex subset of $\mathbb{R}^n$.

Throughout this paper the Hausdorff distance between two nonempty, compact subsets $A,B\subset\mathbb{R}^n$ will be denoted by $\delta(A,B)$; that is, we set

$$\delta(A,B)\doteq \max\left\{\max_{a\in A} d(a,B),\ \max_{b\in B} d(b,A)\right\}.$$

Let us recall that δ is a metric on the class $\mathcal{K}$ of nonempty, compact subsets of $\mathbb{R}^n$. In what follows, a multivalued map F with compact values from $[0,T]\times\mathbb{R}^n$ into $\mathbb{R}^n$ is said to be Lipschitz continuous (resp., continuous) if it is Lipschitz continuous (resp., continuous) when considered as a (univalued) map from $\mathbb{R}^n$ into the set $\mathcal{K}$ endowed with the metric δ. Actually, for maps with compact values, these definitions are equivalent to the usual ones (see [AC]).

F is said to be locally Lipschitz continuous if it is Lipschitz continuous on compact subsets of $[0,T]\times\mathbb{R}^n$.

THEOREM 3.2. *Let us assume hypotheses* (H1)–(H4). *Then, the set-valued map $x\mapsto F(t,x)$ is locally Lipschitz continuous in x, uniformly in t. That is, for every $R>0$, there exists a number $M_R\geq 0$ such that*

$$\delta(F(t,x),F(t,y))\leq M_R|x-y| \tag{3.1}$$

for all $x,y\in\mathbf{B}_R$ and $t\in[0,T]$.

Moreover, for every $R > 0$, there exists a number $\tilde{M}_R \geq 0$ such that

$$\delta(F(t,x), F(s,x)) \leq \tilde{M}_R \omega_2[R, |t-s|] \tag{3.2}$$

for every $x \in \mathbf{B}_R$ and $t, s \in [0,T]$. In particular, for each $x \in \mathbb{R}^n$, $t \mapsto F(t,x)$ is continuous.

In order to prove Theorem 2.2 we also need the following version of the previous result, which involves the global Lipschitz continuity of the map $x \mapsto F(t,x)$.

THEOREM 3.3. *Let us assume that hypotheses* (H1)–(H5) *are verified with both the local modulus ω_1 and the parameter K_R being in fact independent of R (that is, ω_1 is a modulus, and there exists a constant K such that $K_R = K$ for all $R \geq 0$.) Then, the set-valued map $x \mapsto F(t,x)$ is Lipschitz continuous in x, uniformly in t, that is,* (3.1) *holds true, and there exists a constant M such that $M_R = M$ for all R.*

Finally, let us state a simple property of the map H^* that will be used to prove both the regularity of the Lagrangian l and the global issue stated in Theorem 3.3.

PROPOSITION 3.4. *Assume hypotheses* (H1)–(H5)*, and fix $R > 0$. Then, for all $t \in [0,T]$, $x, y \in \mathbf{B}_R$, and $v \in F(t,x)$, $w \in F(t,y)$, one has*

$$|H^*(t,x,v) - H^*(t,y,w)| \leq \omega_1[R, (1+K_R)|x-y|] + K_R|v-w|.$$

Moreover, for all $t, s \in [0,T]$, $x \in \mathbf{B}_R$, and $v \in F(t,x)$, $w \in F(s,x)$, one has

$$|H^*(t,x,v) - H^*(s,x,w)| \leq \omega_2[R, K_R|t-s|] + \omega_3[R, |t-s|] + K_R|v-w|.$$

Proof of Theorem 3.2. Let us prove (3.1). Assume by contradiction that there exist sequences (x_n), (y_n) in $\mathbf{B}_R$ such that $x_n \neq y_n$ for every n and

$$\lim_{n\to\infty} \frac{\delta(F(t,x_n), F(t,y_n))}{|x_n - y_n|} = +\infty. \tag{3.3}$$

Up to the identification of the sequence (x_n, y_n) with a suitable subsequence, condition (3.3) yields either the existence of a selection $v_n \in F(t,x_n) \backslash F(t,y_n)$ verifying

$$\lim_{n\to\infty} \frac{d(v_n, F(t,y_n))}{|x_n - y_n|} = +\infty \tag{3.4}$$

or the existence of a selection $v_n' \in F(t,y_n) \backslash F(t,x_n)$ verifying

$$\lim_{n\to\infty} \frac{d(v_n', F(t,x_n))}{|x_n - y_n|} = +\infty. \tag{3.5}$$

Suppose that (3.4) is actually verified ((3.5) implying perfectly symmetric considerations). Then, for any selection $w_n \in F(t,y_n)$, one has

$$\lim_{n\to\infty} \frac{|v_n - w_n|}{|x_n - y_n|} = +\infty. \tag{3.6}$$

Setting

$$p_n \doteq \frac{v_n - w_n}{|v_n - w_n||x_n - y_n|},$$

one obtains

$$\begin{aligned}\omega_1[R,|x_n-y_n|(1+|p_n|)] &= \omega_1[R,|x_n-y_n|+1]\\ &\geq H(t,x_n,p_n)-H(t,y_n,p_n)\\ &\geq p_n\cdot v_n - H^*(t,x_n,v_n)\\ &\quad - \max_{w\in\mathrm{dom}(H^*(t,y_n,\cdot))}\{p_n\cdot w - H^*(t,y_n,w)\}.\end{aligned} \tag{3.7}$$

In order to achieve a contradiction, let us choose w_n to be a fixed point of the map

$$\eta_n(w)\doteq \mathrm{argmax}\left\{\frac{(v_n-w)\cdot\xi}{|x_n-y_n||v_n-w|}-H^*(t,y_n,\xi),\quad \xi\in\mathrm{dom}(H^*(t,y_n,\cdot))\right\}.$$

In view of Lemma 3.5 (where one sets $\varphi = H^*(t,y_n,\cdot)$ and $r=|x_n-y_n|$), such a point does exist. Hence one has

$$\frac{(v_n-w_n)\cdot w_n}{|x_n-y_n||v_n-w_n|}-H^*(t,y_n,w_n)\geq \frac{(v_n-w_n)\cdot\xi}{|x_n-y_n||v_n-w_n|}-H^*(t,y_n,\xi) \tag{3.8}$$

for all $\xi\in\mathrm{dom}(H^*(t,y_n,\cdot))$. By (3.7)–(3.8) and hypothesis (H4) one obtains

$$\begin{aligned}&\omega_1[R,2R+1]\geq\omega_1[R,|x_n-y_n|+1]\\ &\geq p_n\cdot(v_n-w_n)-H^*(t,x_n,v_n)+H^*(t,y_n,w_n)\geq p_n\cdot(v_n-w_n)-2N_R,\end{aligned} \tag{3.9}$$

which is a contradiction, for the right-hand side tends to $+\infty$ while the left-hand side is bounded.

In order to prove (3.2) one has to exploit the same arguments with suitable adjustments: more precisely, one has to replace the sequences x_n, y_n with sequences $t_n, s_n\in[0,T]$, and the v_n and w_n must belong to $F(t_n,x)$ and $F(s_n,x)$, respectively. Moreover, the quantities $|x_n-y_n|$ have to be replaced with $\omega_2[R,|t_n-s_n|]$. In particular, one has

$$\lim_{n\to\infty}\frac{v_n-w_n}{\omega_2[R,|t_n-s_n|]}=+\infty$$

instead of (3.6). Setting

$$p_n\doteq\frac{v_n-w_n}{|v_n-w_n|\omega_2[R,|t_n-s_n|]}$$

one can conclude by arguing as in the first part.

Proof of Theorem 3.3. If ω_1 and K do not depend on R, in order to prove global Lipschitz continuity let us argue as in the previous proof until estimate (3.9), except for the fact that now (x_n) and (y_n) lie in $\mathbb{R}^n$. In particular, the last inequality of (3.9) is no longer valid. Yet, it is not restrictive to assume that $|x_n-y_n|\leq\frac{1}{2K}$. Hence, in view of Proposition 3.4—where we take ω_1 and K independent of R—one has

$$|H^*(t,y_n,w_n)-H^*(t,x_n,v_n)|\leq\omega_1\left[\frac{1+K}{2K}\right]+K|v_n-w_n|.$$

Hence

$$\omega_1\left[\frac{1}{2K}+1\right]\geq\frac{|v_n-w_n|}{|x_n-y_n|}-\omega_1\left[\frac{1+K}{2K}\right]-K|v_n-w_n|. \tag{3.10}$$

Now, if $|v_n - w_n|$ is bounded, we contradict (3.6). If, on the contrary, (a subsequence of) $|v_n - w_n|$ tends to infinity, by the previous estimate we have

$$\omega_1\left[\frac{1}{2K}+1\right] \geq -\omega_1\left[\frac{1+K}{2K}\right] + K|v_n - w_n|, \tag{3.11}$$

which is a contradiction, in that the left-hand side is bounded while the right-hand side diverges. □

Proof of Proposition 3.4. Let p_v be an element of $\operatorname{argmax}_p\{p \cdot v - H(t,x,p)\}$. In view of hypothesis (H5) we can choose p_v such that the inequality $|p_v| \leq K_R$ is verified. Hence,

$$\begin{aligned} H^*(t,x,v) - H^*(t,y,w) &\leq p_v v - H(t,x,p_v) - p_v w + H(t,y,p_v) \\ &\leq K_R|v-w| + \omega_1[R,(1+K_R)|x-y|]. \end{aligned}$$

In an analogous way one obtains the same estimate for $H^*(t,y,w) - H^*(t,x,v)$, so the first inequality is proved. The proof of the estimate in the t-variable is akin, so we omit it. □

LEMMA 3.5. *Let $r > 0$ and let $\varphi : \mathbb{R}^n \to \mathbb{R} \cup \{+\infty\}$ be a convex, lower semicontinuous, proper map such that* $\operatorname{dom}(\varphi)$ *is compact. Let $v \in \mathbb{R}^n \backslash \operatorname{dom}(\varphi)$ and let us consider the set-valued map $\eta : \operatorname{dom}(\varphi) \to \mathcal{P}(\operatorname{dom}(\varphi))$ defined by*

$$\eta(w) \doteq \operatorname{argmax}\left\{\frac{(v-w)\cdot\xi}{r|v-w|} - \varphi(\xi), \quad \xi \in \operatorname{dom}(\varphi)\right\}.$$

Then η has a fixed point, that is, there exists $\bar{w} \in \operatorname{dom}(\varphi)$ such that $\bar{w} \in \eta(\bar{w})$.

Proof. The map η has compact convex values. Moreover, since φ is continuous on its domain, η is upper semicontinuous (and is defined on a compact convex subset of $\mathbb{R}^n$). Then the lemma follows from Kakutani's fixed point theorem (see, e.g., [AC]). □

4. Proofs of Theorems 2.1 and 2.2. To prove Theorems 2.1 and 2.2 we are going to exploit the parameterization result for convex multifunctions proved in [O] (see also [Lo]). This result involves measurability in t, which will be useful in section 6 in order to address the case with t-measurable Hamiltonians. In particular *t-measurable moduli* will be utilized. We call *t-measurable modulus* every map $w : [0,T] \times [0,*\infty[\to [0,*\infty[$ such that for every $r \in [0,*\infty[$ the map $t \mapsto w[t,r]$ is measurable and for every $t \in [0,1]$ the map $r \mapsto w[t,r]$ is a modulus. Similarly, a *local t-measurable modulus* will be a map $w : [0,*\infty[\times [0,T] \times [0,*\infty[\to [0,*\infty[$, increasing in the first variable and such that for every $R \in [0,*\infty[$ the map $(t,r) \mapsto w[R,t,r]$ is a t-measurable modulus.

Let us recall that a multifunction $\mathcal{M} : [0,T] \to \mathbb{R}^n$ is called *measurable* if for every open subset $V \subset \mathbb{R}^n$ the preimage

$$\mathcal{M}^{-1}(V) \doteq \{t \in [0,T] \,:\, \mathcal{M}(t) \cap V \neq \emptyset\}$$

is a measurable subset of $[0,T]$).

Let us consider a multivalued map $F : [0,T] \times \mathbb{R}^n \to \mathbb{R}^n$ verifying the following hypotheses.

Hypotheses (H_F):

(a) for every $(t,x) \in [0,T] \times \mathbb{R}^n$, $F(t,x)$ is a nonempty, compact, convex subset of $\mathbb{R}^n$;

(b) for every $x \in \mathbb{R}^n$ the multifunction $t \mapsto F(\cdot, x)$ is measurable;

(c) there exists a t-measurable local modulus w such that for every $R > 0$ and for almost every $t \in [0, T]$ one has

$$\delta(F(t,x), F(t,y)) \leq w[R, t, |x-y|] \tag{4.1}$$

for all $x, y \in \mathbf{B}_R$.

THEOREM 4.1 (see [O], Thm. 1). *Let F verify hypotheses* (H_F)*, and let us set*

$$M(t,x) \doteq \max\{1, |v| \ : \ v \in F(t,x)\}.$$

Then there exists a function $f : [0,T] \times \mathbb{R}^n \times \mathbf{B}$ such that

(i) *$F(t,x) = f(t,x,\mathbf{B})$ for all $x \in \mathbb{R}^n$ and for a.e. $t \in [0,T]$;*

(ii) *$f(\cdot, x, u)$ is measurable for every $(x,u) \in \mathbb{R}^n \times \mathbf{B}$;*

(iii) *there exists $N \geq 0$ such that for all $R > 0$ one has*

$$|f(t,x,u) - f(t,y,v)| \leq N(w[R,t,|x-y|] + M(t,x)|u-v|)$$

for all $x, y \in \mathbf{B}_R$ and for a.e. $t \in [0,T]$.

Moreover, if F and w are continuous, then f is continuous as well.

Remark 4.1. Actually, this theorem was proved (in [O]) under a hypothesis of uniform continuity, which means that in fact the map w is a t-measurable modulus. However, it is easy to verify (by direct inspection of the original proof) that the local statement of the present version can be proved by just replacing moduli with local moduli.

Proofs of Theorems 2.1 *and* 2.2. By Theorem 3.2 the multifunction $F(t,x) = \mathrm{dom}(H^*(t,x,\cdot))$ is continuous and agrees with the hypotheses of Theorem 4.1, with $w[R,t,r] \doteq M_R \cdot r$. Hence there exists a vector field f which verifies (A2) with $A = \mathbf{B}$ and such that $F(t,x) = f(t,x,\mathbf{B})$ for all x and a.e. $t \in [0,T]$.

Setting

$$l(t,x,a) \doteq H^*(t,x,f(t,x,a)) \qquad \forall (t,x,a) \in [0,T] \times \mathbb{R}^n \times \mathbf{B},$$

we get (2.1). Moreover, if hypothesis (H5) is in force, Proposition 3.4 and Theorem 4.1 imply the last part of the thesis. Notice that, since $A = \mathbf{B}$ is compact, (A1) is verified as well. Finally, let us prove that f satisfies the linear growth condition (A3). Indeed (H3) implies

$$|H(t,x,p)| \leq C(1+|x|)|p| + |H(t,x,0)| \tag{4.2}$$

for every $(t,x,p) \in [0,T] \times \mathbb{R}^n \times \mathbb{R}^n$. For any $(t,x,a) \in [0,T] \times \mathbb{R}^n \times \mathbf{B}$ and $\lambda > 0$ let us take $p = \lambda f(t,x,a)$, thus obtaining

$$\begin{aligned} \lambda f^2(t,x,a) - l(t,x,a) &\leq |H(t,x,\lambda f(t,x,a))| \\ &\leq \lambda C(1+|x|)|f(t,x,a)| + |H(t,x,0)|. \end{aligned} \tag{4.3}$$

If $f(t,x,a) = 0$, we are done. Otherwise, by dividing both members in (4.3) by $\lambda |f(t,x,a)|$ and letting λ go to $+\infty$ one obtains

$$|f(t,x,a)| \leq C(1+|x|).$$

In view of Theorem 3.3, Theorem 2.2 can be proved in a similar way. □

5. Some applications. Let us present two simple instances on how the representation results proved in the previous sections can be exploited both to sharpen and to interpret some facts concerning (1.1).

5.1. Regularity of the solutions of (1.1)–(1.2). The first issue concerns the regularity of the solutions to (1.1)–(1.2), which, in view of the representation results in section 2 (and of the uniqueness of the solution), is nothing but the regularity of the corresponding value function.

Let us begin by briefly recalling some well-known facts concerning the value function of an optimal control problem. Besides (A1)–(A3), let us assume the following hypothesis on the final cost g:

(A4) The map g is continuous, that is, it verifies

$$|g(x) - g(y)| \le \nu_g[R, |x-y|]$$

for all $x, y \in \mathbb{R}^n$ and a suitable local modulus ν_g.

Let us consider the value function $V = V(t,x)$ defined in (1.4) and the connected Hamiltonian

$$H(t,x,p) \doteq \sup_{a\in A} \{p \cdot f(t,x,a) - l(t,x,a)\}. \tag{5.1}$$

THEOREM 5.1. *Let us assume hypotheses* (A1)–(A4). *Then the map* $u(t,x) \doteq V(T-t,x)$ *is continuous on* $[0,T]\times\mathbb{R}^n$, *and, for any* $R>0$, *there exists a coefficient* $L_R \ge 0$ *such that*

$$\begin{aligned} |u(t,x) - u(t,y)| &\le L_R\,(|x-y| + \nu[R,|x-y|] + \nu_g[L_R R, L_R|x-y|]),\\ |u(t,x) - u(s,x)| &\le L_R\,(|t-s| + \nu[R,L_R|s-t|] + \nu_g[L_R R, L_R|t-s|]) \end{aligned}$$

for all $(t,x),(t,y),(s,x) \in [0,T]\times \mathbf{B}_R$. *Moreover,* u *is the unique viscosity solution of the Cauchy problem* (1.1)–(1.2).

We omit the proof of the regularity of V (and hence of u), which is standard and based essentially on Gronwall's lemma. For the uniqueness result see, e.g., [CL, Thm. VI.I]

As a corollary of Theorems 2.1 and 5.1 we obtain the following regularity result.

THEOREM 5.2. *Assume hypotheses* (H1)–(H5) *and let the initial datum* g *satisfy* (A4). *Then, for any* $R>0$ *there exists a coefficient* $C_R \ge 0$ *such that the solution* $u(t,x)$ *of* (1.1)–(1.2) *verifies*

$$\begin{aligned} |u(t,x) - u(t,y)| &\le C_R\big(|x-y| + \omega_1[R,|x-y|] + \nu_g[C_R R, C_R|x-y|]\big),\\ |u(t,x) - u(s,x)| &\le C_R\,(|t-s| + \omega_1[R,C_R|s-t|] + \nu_g[C_R R, C_R|t-s|]) \end{aligned}$$

for all $(t,x),(t,y) \in [0,T]\times\mathbf{B}_R$.

Example. Roughly speaking, this theorem shows that the solution *preserves* the (x-)continuity of both the Hamiltonian H and the datum g. For instance, if $\omega_1(\eta) \doteq |\eta|^\alpha$, $\alpha \le 1$, and g is β-Holder continuous, then the solution u turns out to be γ-Holder continuous, with $\gamma = \min\{\alpha,\beta\}$. As an example, consider the Cauchy problem in $[0,T]\times\mathbb{R}$:

$$u_t + \tilde H(x,u_x) = 0, \qquad u(0,x) = 0, \tag{5.2}$$

where

$$\tilde H(x,p) = |x\cdot p| - |x|^{\frac12}.$$

It is straightforward to check that the map

$$v(t,x) = 2|x|^{\frac{1}{2}}(1 - e^{-\frac{t}{2}}) \tag{5.3}$$

is a viscosity solution of (5.2), and well-known uniqueness results imply that no other solutions do exist. Since

$$|H(x,p) - H(y,p)| \leq |x-y|(1+|p|) + [|x-y|(1+|p|)]^{\frac{1}{2}}$$

and $g = 0$, Theorem 5.2 establishes that for any $R > 0$ and for all $(t,x),(t,y) \in [0,T] \times \mathbf{B}_R$ the solution of 5.2 satisfies

$$|v(t,x) - v(y,t)| \leq C_R(|x-y| + |x-y|^{\frac{1}{2}})$$

for a suitable positive number C_R. On the other hand, by the explicit expression (5.3) we know that this indeed is the case, with $C_R = 2$, for every R.

Let us note that neither the available results based on direct PDE methods nor the application of the representation provided in [Is2] would yield such sharpness in the regularity estimates. Indeed, on one hand, PDE arguments are mainly concerned with local Lipschitz continuity (see, e.g., [Ba], [CL], [Le]). On the other hand, the results in [Is2], when applied to the present example, give at most[2] $\frac{1}{4}$-Holder regularity for the solution (see Remark 1.1).

Example. An even more elementary but significative example is provided by the transport equation

$$u_t + u_x \cdot f(x) - l(x) = 0, \qquad u(0,x) = g(x),$$

where we assume that $f(x)$ and $l(x)$ verify (A2)–(A3) and g is continuous. Denoting the solution at time s of the Cauchy problem

$$\dot{y} = f(y), \qquad y(0) = x,$$

by $y(x,s)$ one can straightforwardly check that

$$u(t,x) = g(y(x,-t)) + \int_0^t l(y(x,-s))ds$$

is the unique viscosity solution of this problem. Moreover, in view of Remark 2.2, the involved Hamiltonian verifies hypotheses (H1)–(H5), with $\omega_1[R,s] = E_R s + \nu[R,s]$. So, comparing the actual regularity of u with the one which can be deduced by Theorem 5.2, we see that the latter is as sharp as possible.

Remark 5.1. As observed in the introduction, since Theorems 2.1 and 2.2 concern just the Hamiltonian H, results for different boundary value problems could be obtained as well. Similarly, the case where the datum g is no longer continuous, possibly equal to $+\infty$—which includes optimal control problems with endpoint constraints—also could be treated (by exploiting the notion of semicontinuous solution; see, e.g., [BJ91] and [Fr]).

[2]We use the expression "at most" because the fact remains that in general no uniqueness of trajectories—for a given control—would be guaranteed.

5.2. Front propagation. A second issue where a representation result can be applied concerns the phenomenon of front propagation. Let us begin with a definition. Let $\mathcal{G}$ be a class of real continuous functions on $\mathbb{R}^n$.

DEFINITION 5.3. *We say that the pair* $(H, \mathcal{G})$ *verifies the* front propagation property *if*

(i) *for every* g *belonging to* $\mathcal{G}$ *the Cauchy problem*

$$\begin{aligned} u_t + H(t, x, u_x) &= 0 \qquad \text{in }]0, T[\times \mathbb{R}^n, \\ u(0, x) &= g(x) \qquad \forall x \in \mathbb{R}^n \end{aligned}$$

has a unique (viscosity) solution, say u_g*;*

(ii) *if* $k \in \mathbb{R}$ *and* $g, \tilde{g} \in \mathcal{G}$ *are such that*

$$\begin{aligned} \Lambda_g^k(0) &\doteq \{x \in \mathbb{R}^n \,:\, g(x) < k\} = \{x \in \mathbb{R}^n \,:\, \tilde{g}(x) < k\} \doteq \Lambda_{\tilde{g}}^k(0), \\ \Gamma_g^k(0) &\doteq \{x \in \mathbb{R}^n \,:\, g(x) = k\} = \{x \in \mathbb{R}^n \,:\, \tilde{g}(x) = k\} \doteq \Gamma_{\tilde{g}}^k(0), \end{aligned}$$

then

$$\begin{aligned} \Lambda_g^k(t) &\doteq \{x \in \mathbb{R}^n \,:\, u_g(t, x) < k\} = \{x \in \mathbb{R}^n \,:\, u_{\tilde{g}}(t, x) < k\} \doteq \Lambda_{\tilde{g}}^k(t), \\ \Gamma_g^k(t) &\doteq \{x \in \mathbb{R}^n \,:\, u_g(t, x) = k\} = \{x \in \mathbb{R}^n \,:\, u_{\tilde{g}}(t, x) = k\} \doteq \Gamma_{\tilde{g}}^k(t) \end{aligned}$$

for every $t \in [0, T]$.

In other words, this condition states that the propagations of the k-level and the k-sublevel sets depend only on the k-sublevel set and the k-level set of the initial data. It is straightforward to check that property (ii) holds true for all k as soon as it is valid for one particular value of k. As is well known, a crucial role is played by the following homogeneity assumption:

(H-hom) For each $\lambda \geq 0$ one has

$$H(t, x, \lambda p) = \lambda H(t, x, p) \tag{5.4}$$

for all $(t, x, p) \in [0, T] \times \mathbb{R}^n \times \mathbb{R}^n$.

In fact, if the Hamiltonian H verifies hypotheses (H1)–(H3) *and* (H-hom) and $\mathcal{G}$ is the set of uniformly continuous functions, then the pair $(H, \mathcal{G})$ has the front propagation property (see, e.g., [BSS]). Thanks to the representation results of the previous sections—which can be applied here, for (H-hom) implies (H4) and (H5)—we can now give a simple control-theoretical explanation to this phenomenon, with $\mathcal{G}$ equal to the set of (not necessarily uniformly) continuous maps.

Remark 5.2. A control-theoretical interpretation of the front propagation phenomenon is nothing new: indeed it was originally proposed in [ES]. However, though the Hamiltonian is allowed to be nonconvex, the regularity assumptions therein assumed are much stronger than those considered here. In particular, they include the *global Lipschitz continuity of* H *in* (x, p), which in a representation like (1.3) means that f has to be *bounded*; see, for instance, assumption (1.1) in [So] in the context of front propagation along normal directions.

In section 6 we shall show that the front propagation property is still valid for Hamiltonians measurable in the variable t.

THEOREM 5.4. *Let us assume* (H1)–(H3)*, and let* $\mathcal{G} \doteq C(\mathbb{R}^n)$*. Then the following are equivalent:*

(i) H *verifies* (H-hom)*;*

(ii) *there exists a representation* (A, f, l) *of* H *satisfying* (A1)–(A3)*, with* l *equal to zero;*

(iii) *for every* $(t, x) \in [0, T] \times \mathbb{R}^n$*, the conjugate map* $v \mapsto H^*(t, x, v)$ *is constant equal to zero on its domain.*

Moreover, they imply the following:

(iv) *for all* $R > 0$ *the local modulus* $\omega_1[R, \cdot]$ *is in fact a linear mapping;*

(v) *the pair* $(H, \mathcal{G})$ *verifies the front propagation property.*

Proof. Since H is convex, the equivalence of (i) and (iii) is straightforward. Moreover, let us observe that (iii) trivially implies hypotheses (H4) and (H5), so Theorem 2.1 applies. Hence (ii) follows from (iii), since l was defined by $l(t, x, a) = H^*(t, x, f(t, x, a))$. The fact that (ii) implies (iii) and (iv) is straightforward as well.

Let us prove that (ii) implies (v). Assume by contradiction that there exist initial data g and $\tilde{g}$, both belonging to $\mathcal{G}$, and a point $(t, x) \in]0, T] \times \mathbb{R}^n$ such that $\Lambda_g^0(0) = \Lambda_{\tilde{g}}^0(0)$, $\Gamma_g^0(0) = \Gamma_{\tilde{g}}^0(0)$, while the corresponding solutions of (5.4) verify $u_g(t, x) = 0$, $u_{\tilde{g}}(t, x) \neq 0$. Let us recall that $u_g(t, x) = V_g(T - t, x)$ and $u_{\tilde{g}}(t, x) = V_{\tilde{g}}(T - t, x)$, where the value functions V_g and $V_{\tilde{g}}$ are defined as follows:

$$V_g(T - t, x) \doteq \inf g(y(T)), \quad \dot{y}(s) = f(s, y(s), a(s)), \quad y(T - t) = x,$$
$$V_{\tilde{g}}(T - t, x) \doteq \inf \tilde{g}(y(T)), \quad \dot{y}(s) = f(s, y(s), a(s)), \quad y(T - t) = x.$$

Let $\hat{a}$ be an optimal control for the datum g, which means

$$V_g(T - t, x) = g(\hat{y}(T)),$$
$$\dot{\hat{y}}(s) = f(s, \hat{y}(s), a(s)), \qquad y(T - t) = x.$$

(This control exists, for $f(s, y, \mathbf{B}) = \mathrm{dom} H^*(t, x, \cdot)$ is convex for every (s, y). However this is not crucial, for one could as well consider an ϵ-optimal control.) Now $0 = V_g(T - t, x) = g(\hat{y}(T))$, which implies $\tilde{g}(\hat{y}(T)) = 0$. Hence it cannot happen that $V_{\tilde{g}}(T - t, x) = u_{\tilde{g}}(t, x) > 0$, for one would get $\tilde{g}(\hat{y}(T)) = 0 < V_{\tilde{g}}(T - t, x)$. In a similar way, the case when $u_{\tilde{g}}(t, x) < 0$ produces a contradiction. Finally, with the same arguments one proves that it cannot happen that $u_g(t, x) > 0$ while $u_{\tilde{g}}(t, x) < 0$. □

6. *t*-measurable Hamiltonians. The results presented in the previous sections may be extended, substantially in their full strength, to the case where the Hamiltonian H is measurable in the variable t. The aim of this section is to present the corresponding statements and to point out some needed changes in the assumptions and in the proofs.

6.1. The value function and the Bellman equation. Aiming toward representations of t-measurable Hamiltonians, we have to consider optimal control problems where the data f and l are measurable in t. Accordingly, let us replace assumptions (A1)–(A3) with the following ones:

(A1′) *There exists a constant* Q *such that*

$$|f(t, 0, a)|, |l(t, 0, a)| \leq Q$$

for almost all $t \in [0, T]$ *and* $a \in A$.

(A2′) *The maps* f *and* l *are continuous in* (x, a) *from* $[0, T] \times \mathbb{R}^n \times A$ *into* $\mathbb{R}^n$ *and* $\mathbb{R}$*, respectively, and verify conditions*

$$|f(t, x, a) - f(t, y, a)| \leq E_R |x - y|, \tag{6.1}$$
$$|l(t, x, a) - l(t, y, a)| \leq \nu[R, |x - y|] \tag{6.2}$$

for all $(t,x,a),(t,y,a)\in[0,T]\times\mathbf{B}_R\times A$, *where* ν *is a suitable local modulus.*

(A3′) *There is* $C>0$ *such that*

$$f(t,x,a)\le C(1+|x|)$$

for all $(x,a)\in[0,T]\times\mathbb{R}^n\times A$ *and almost every* $t\in[0,T]$.

PROPOSITION 6.1. *The regularity results stated in Theorem* 5.1 *are still valid under the weaker hypotheses* (A1′), (A2′), (A3′), *and* (A4).

The proof of this proposition does not present substantial new difficulties with respect to the case where the data are continuous.

A *uniqueness result* analogous to the one stated in Theorem 5.1 holds true for t-measurable Hamiltonians as well, but some care is needed. To begin with, we cannot exploit the classical notion of viscosity solution, for the Hamiltonian H in (5.1) is now merely measurable in the t-variable. A suitable notion of solution for this case was introduced by Ishii in [Is2]. Successively, Lions and Perthame [LP87] provided three equivalent versions of this notion (see also [BJ87]). Recently (see [BR]) density results have been proved for this concept of solution. For the sake of self-consistency, let us recall the notion of subsolution, in one of the versions provided in [LP87].

DEFINITION 6.2. *A continuous map* $u:[0,T]\times\mathbb{R}^n$ *is a* viscosity subsolution *of* (1.1) *at* $(t_0,x_0)\in[0,T]\times\mathbb{R}^n$ *if for every* C^1 *map* ϕ *defined in a neighborhood of* (t_0,x_0) *and* $b\in L^1(0,T)$ *such that* (t_0,x_0) *is a local maximum for*

$$u(t,x)+\int_0^t b(s)ds-\phi(x)$$

one has

$$\lim_{\delta\downarrow 0^+}\operatorname*{ess\,inf}_{|t-t_0|<\delta}\inf\{H(t,x,s,p)-b(t):|x-x_0|\le\delta,|p-\nabla\phi(x_0)|\le\delta,|s-u(t_0,x_0)|\le\delta\}\le 0.$$

The definition of *viscosity supersolution* is perfectly symmetric, and a map is a *viscosity solution* if it is both a subsolution and a supersolution.

Again, it is not difficult to prove that the map $u(t,x)\doteq V(T-t,x)$ is a viscosity solution of the Cauchy problem (1.1)–(1.2).

6.2. A representation theorem for t-measurable Hamiltonians. In order to state a representation result for t-measurable Hamiltonians we shall assume suitable hypotheses. It turns out that we have to make only the obvious change due to the lack of continuity in t. Precisely we shall consider those hypotheses, which we label (H1′)–(H5′), respectively, that are obtained from (H1)–(H5) by replacing $[0,T]$ with any full-measure subset. (Of course, condition (1.8), which would imply continuity in t, is no longer assumed.)

In the new framework, the representation Theorems 2.1 and 2.2 assume the following forms, respectively.

THEOREM 6.3. *Let us consider a Hamiltonian* H *verifying hypotheses* (H1′)–(H4′). *Then there exist a dynamics* $f=f(t,x,a)$ *satisfying* (A1′)–(A3′) *and a Lagrangian* $l=l(t,x,a)$ *(continuous in* (x,a) *for almost every* $t\in[0,T]$*), with the control set* A *coinciding with the unit ball* $\mathbf{B}$, *such that*

$$H(t,x,p)=\sup_{a\in\mathbf{B}}\{p\cdot f(t,x,a)-l(t,x,a)\}\tag{6.3}$$

for almost all $t \in [0,T]$ *and for all* $(x,p) \in \mathbb{R}^n \times \mathbb{R}^n$. *Furthermore, if hypothesis* (H5′) *is in force as well, then* l *verifies* (A2′), *with* $\nu[R,s] \doteq \omega_1[R,(1+K_R)s] + D_R s$, *for suitable coefficients* D_R.

THEOREM 6.4. *Let* H *verify* (H1′)–(H5′), *with* ω_1 *being a modulus (i.e., independent of* R*) and the numbers* K_R *being equal to a constant* K *for all* R. *Then there exist a dynamics* f *and a Lagrangian* l *such that*

$$H(t,x,p) = \sup_{a \in \mathbf{B}} \{p \cdot f(t,x,a) - l(t,x,a)\} \tag{6.4}$$

holds true for almost all $t \in [0,T]$ *and for all* $(x,p) \in \mathbb{R}^n \times \mathbb{R}^n$, *conditions* (A1′)–(A3′) *are satisfied, and, moreover, the control set* A *coincides with the unit ball* $\mathbf{B}$. *Furthermore,* E_R *turns out to be independent of* R, *and* $\nu(s) = \omega_1[(1+K)s + Ds]$ *for a suitable* $D \geq 0$.

Proofs of Theorems 6.3 *and* 6.4. In view of Theorem 4.1, once we have proved that for every x the map $t \mapsto F(t,x) = \mathrm{dom} H^*(t,x,\cdot)$ is measurable (see definition in section 5) we are done. Indeed the parts of Theorems 3.2 and 3.3 concerning the variable x remain unchanged.

To prove that the map $t \mapsto F(t,x)$ is measurable we need some sharper result from set-valued analysis. Let us fix $x \in \mathbb{R}^n$. Then (see, e.g., [RW]) by the measurability of $t \mapsto H(t,x,p)$, the measurability of $t \mapsto H^*(t,x,v)$ follows, for each $v \in \mathbb{R}^n$.

Moreover, the multivalued map

$$t \mapsto \mathrm{epi}[H^*(t,x,\cdot)] \doteq \{(u,r) \in \mathbb{R}^n \times \mathbb{R} \,:\, r \geq H^*(t,x,u)\}$$

turns out to have a Castaing representation (u_n, r_n) (see, e.g., [RW]).

Hence (u_n) is a Castaing representation of the map $t \mapsto F(t,x)$, which therefore turns out to be measurable (see, e.g., [RW]). □

6.3. Regularity of solutions for *t*-measurable Hamiltonians. By the previous considerations it turns out that Theorem 5.2 on the regularity of solutions is still valid for t-measurable Hamiltonians verifying hypotheses (H1′)–(H5′) (plus some extra condition such that the uniqueness of the solution is guaranteed). Let us point out that the latter can be achieved either according to [Is1] (e.g., by imposing hypothesis (A6) therein) or by following the approach in [BR], which relies on the approximability of H by continuous Hamiltonians.

6.4. Front propagation for *t*-measurable Hamiltonians. Thanks to the representation provided by Theorem 6.3, the front propagation phenomenon can be studied for t-measurable Hamiltonians as well, as soon as the latter verify (H1′)–(H3′). For this purpose let us consider the following weakened version of assumption (H-hom):

(H′-hom) For each $\lambda \geq 0$ one has

$$H(t,x,\lambda p) = \lambda H(t,x,p) \tag{6.5}$$

for all $(t,x,p) \in [0,T] \backslash \mathcal{N} \times \mathbb{R}^n \times \mathbb{R}^n$ where $\mathcal{N}$ has measure zero.

With an unchanged proof with respect to Theorem 5.4, one obtains the following result.

THEOREM 6.5. *Let us assume* (H1′)–(H3′), *and let* $\mathcal{G} \doteq C(\mathbb{R}^n)$. *Then the following are equivalent:*

(i) H *verifies* (H′-hom);

(ii) *there exists a representation* (f, l) *of* H *satisfying* (A1′)–(A3′)*, with* l *equal to zero in* $[0,T]\backslash\mathcal{N}\times\mathbb{R}^n\times\mathbf{B}$*, for a suitable subset* $\mathcal{N}$ *of measure zero;*

(iii) *there is a zero measure subset* $\mathcal{N}$ *such that, for every* $(t,x)\in[0,T]\backslash\mathcal{N}\times\mathbb{R}^n$*, the conjugate map* $v\mapsto H^*(t,x,v)$ *is constant equal to zero on its domain.*

Moreover, each of them implies the following two conditions:

(iv) *for all* $R>0$ *the modulus* $\omega_1[R,\cdot]$ *is in fact a linear mapping;*

(v) *the pair* $(H,\mathcal{G})$ *verifies the front propagation property.*

Acknowledgment. The author is indebted to Michel Valadier, who suggested an argument related to the measurability issue in Theorems 6.3 and 6.4.

LOW-ORDER CONTROLLABILITY AND KINEMATIC REDUCTIONS FOR AFFINE CONNECTION CONTROL SYSTEMS*

FRANCESCO BULLO† AND ANDREW D. LEWIS‡

Abstract. Controllability and kinematic modeling notions are investigated for a class of mechanical control systems. First, low-order controllability results are given for the class of mechanical control systems. Second, a precise connection is made between those mechanical systems which are dynamic (i.e., have forces as inputs) and those which are kinematic (i.e., have velocities as inputs). Interestingly and surprisingly, these two subjects are characterized and linked by a certain intrinsic vector-valued quadratic form that can be associated to an affine connection control system.

Key words. affine connection control systems, controllability, mechanics, driftless systems

1. Introduction.

The determination of useful necessary and sufficient conditions for local controllability of nonlinear systems remains an open problem, although significant progress has been made [2, 4, 19, 20, 34, 36]. In this paper, we investigate local controllability for a class of nonlinear systems with a rich geometric structure, namely, affine connection control systems. For these systems, we provide first-order (in the sense that the conditions involve first derivatives of the system data) local controllability conditions. The results use a certain intrinsic vector-valued quadratic form. The use of vector-valued quadratic forms in control theory has been noticed in the context of optimal control (which has, of course, a relationship with controllability) by Agrachev [3], and they have been utilized explicitly for providing conditions for local controllability by Basto-Gonçalves [6] and Hirschorn and Lewis [21]. Other uses of vector-valued quadratic forms in control are outlined in [10]. The controllability conditions we provide in section 4 bear a strong resemblance to the more general conditions of Hirschorn and Lewis [21], but we are able to provide more detail in this case because of the additional structure of the class of systems under consideration.

Affine connection control systems are a slight generalization of a class of mechanical control systems, namely, those which are Lagrangian with kinetic energy Lagrangian, and possibly with nonholonomic constraints. An initial systematic investigation of the local controllability properties of this class of systems was undertaken by Lewis and Murray [27].

The conditions for local accessibility in this work are characterized geometrically by the same authors [28] by utilizing the characterization of the so-called symmetric product provided by Lewis [24]. However, the sufficient conditions for local controllability provided by Lewis and Murray, following Sussmann [36], are not entirely

satisfactory. One of the reasons for this is that these conditions are not feedback-invariant. The consequences of the lack of feedback invariance can be seen even in very simple examples, where a system can fail the sufficient condition test but still be controllable. This points out the need to better understand local controllability, and one way to do this is to obtain conditions which are not dependent on a choice of basis for the input distribution. It is this that we do in this paper, at least for systems whose controllability can be determined by brackets of low order.

A second objective of this paper is to characterize affine connection control systems in terms of equivalent lower-dimensional kinematic (or driftless) systems. The interest in low-complexity representations of affine connection control systems can be related to numerous previous efforts, including work on hybrid models for motion control systems [9], motion description languages [30], consistent control abstractions [32], hierarchical steering algorithms [31], and maneuver automata [18]. The key advantage of a low-complexity or reduced-order representation is the subsequent simplification of various control problems, including planning, stabilization, and optimal control.

In section 5, we introduce and characterize the notion of kinematic reductions as a reduced-order modeling technique adapted to affine connection control systems. This novel concept extends and unifies previous results by Lewis [25] and Bullo and Lynch [13]; see also the motivating work [5, 29, 15]. A kinematic model for an affine connection control system is one such that every controlled trajectory for the kinematic model can be realized as a trajectory, with a possible reparameterization, of the full affine connection control system with some appropriate control. We also introduce and characterize the notion of maximally reducible affine connection control systems. For such systems, every trajectory of the affine connection control system, starting from initial velocities in the input distribution, can be implemented as a controlled trajectory of a maximal kinematic reduction. Some open problems concerning inverse kinematics and sufficient conditions for controllability are presented by Cortés, Martínez, and Bullo [16].

As a third contribution of this paper, the existence of, and the controllability properties of, kinematic reductions are related to the low-order controllability properties of the corresponding affine connection control system. Interestingly, all these concepts are characterized in terms of the vector-valued quadratic form mentioned above. Insightful relationships are established and presented in Figure 5.4. We illustrate our results with some example systems. For instance, it appears that numerous (but not all) interesting mechanical devices satisfying the low-order sufficient controllability condition are also kinematically controllable. This is surprising because the concept of kinematic controllability is not a priori related to the conditions for low-order controllability. We refer to [12] for a catalog of examples.

One of the byproducts of the intrinsic formulation of the controllability and kinematic reduction results we give is that they provide a fairly complete characterization of what can be done. The incompleteness of the characterizations we give results from a possible degeneracy of the vector-valued quadratic forms. Here, one will generally have to go to higher-order conditions for controllability. Sometimes it is possible to give results using quadratic forms, even in degenerate cases, and this is being explored in a paper by Tyner and Lewis [39], currently in preparation.

Let us briefly describe the layout of the paper. We begin in section 2 with a general discussion of affine connection control systems, giving clear statements of the results of Lewis and Murray [27]. Background on vector-valued quadratic forms is presented in section 3, along with the construction of a vector-valued quadratic form that can

be associated with an affine connection control system. Our controllability results are motivated, stated, and proved in section 4. Similarly, our kinematic reductions are discussed in section 5. In this section are also presented a couple of physical examples, and a discussion of the relationships between low-order controllability and kinematic reductions.

2. Affine connection control systems. The basic differential geometric notation we use is that of [1]. When it is convenient to do so, we shall use the summation convention where summation over repeated indices is implied. For a vector bundle $\pi\colon E \to Q$, 0_q will denote the zero vector in the fiber E_q. Objects will be assumed real analytic (which we simply call "analytic") unless otherwise stated. We denote by $\Gamma(E)$ the set of analytic sections of the vector bundle $\pi\colon E \to Q$. Thus, in particular, $\Gamma(TQ)$ is the set of analytic vector fields on a manifold Q. The set of analytic functions on a manifold Q we denote by $\mathcal{F}(Q)$. We will assume the reader is familiar with affine differential geometry to the extent that it is used in [27]. An excellent reference is [22]. Affine connection control systems represent a class of mechanical control systems. We shall not devote any space to the physics involved in this representation, but refer to [27] for a few words along these lines. These issues are addressed also in the books [8, 11].

We begin with the essential definitions for affine connection control systems and provide definitions for what Lewis and Murray call "configuration controllability." Then we give the results of those authors which provide a launching point for what we do in the present paper. We provide fairly strong statements of the results of Lewis and Murray—stronger in fact than the original statements. All that we say, however, is readily implicit in the calculations of their original work.

2.1. Basic definitions. In this paper, an *affine connection control system* is a 5-tuple $\Sigma = (Q, \nabla, \mathsf{D}, \mathscr{Y}, U)$, where

1. Q is an analytic, finite-dimensional, manifold,
2. ∇ is an analytic affine connection on Q,
3. D is a constant-rank analytic distribution on Q having the property that ∇ restricts to D (i.e., $\nabla_X Y \in \Gamma(\mathsf{D})$ for all $Y \in \Gamma(\mathsf{D})$ and for all $X \in \Gamma(TQ)$),
4. $\mathscr{Y} = \{Y_1, \dots, Y_m\}$ is a collection of analytic vector fields on Q taking values in D, and
5. $U \subset \mathbb{R}^m$.

The distribution D will not concern us much here, and we allow it in order to correctly model systems with nonholonomic constraints [26]. The essential geometry of our results is captured by thinking of $\mathsf{D} = TQ$. We will frequently be interested only in 4-tuples $(Q, \nabla, \mathsf{D}, \mathscr{Y})$ satisfying the above conditions. Let us therefore agree to call this an *affine connection precontrol system*. This notion will be useful in discussions of properties of affine connection control systems that are independent of the control set U.

Associated with an affine connection control system $\Sigma = (Q, \nabla, \mathsf{D}, \mathscr{Y}, U)$ is the set of second-order control equations

$$\nabla_{\gamma'(t)}\gamma'(t) = \sum_{a=1}^{m} u^a(t) Y_a(\gamma(t)) \tag{2.1}$$

on Q. Thus a *controlled trajectory* for Σ is taken to be a pair (γ, u), where

1. $\gamma\colon I \to Q$ and $u\colon I \to U$ are both defined on the same interval $I \subset \mathbb{R}$,
2. u is locally integrable,

3. $\gamma'(t) \in \mathsf{D}_{\gamma(t)}$ for a.e. $t \in I$, and
4. (γ, u) together satisfy (2.1).

We denote by $\operatorname{conv}(U)$ and $\operatorname{aff}(U)$ the convex hull and affine hull, respectively, of $U \subset \mathbb{R}^m$. Thus $\operatorname{conv}(U)$ is the smallest convex set in $\mathbb{R}^m$ containing U, and $\operatorname{aff}(U)$ is the smallest affine subspace (i.e., shifted subspace) containing U. The control set U is *proper* (resp., *almost proper*) if $0 \in \operatorname{int}(\operatorname{conv}(U))$ (resp., if $\operatorname{aff}(U) = \mathbb{R}^m$ and $0 \in \operatorname{conv}(U)$). (One may verify that for a control-affine system the property of the control set being almost proper is exactly that which ensures that the Lie algebra rank condition is equivalent to the reachable set having nonempty interior.) We denote by Y the input distribution, so that

$$\mathsf{Y}_q = \operatorname{span}_{\mathbb{R}}\{Y_1(q), \dots, Y_m(q)\}.$$

More generally if $\mathscr{V} \subset \Gamma(TQ)$, then we denote by V the distribution generated by the vector fields $\mathscr{V}$: $\mathsf{V}_q = \operatorname{span}_{\mathbb{R}}\{X(q) |\ X \in \mathscr{V}\}$. We also denote by $\Gamma(\mathsf{V})$ the set of analytic vector fields taking values in V. We make no a priori assumptions on the constancy of the rank of any of the distributions we encounter, including the input distribution Y.

Remark 1. Our allowing a distribution to have variable rank has consequences for the choice of generators. Let us make some comments on this. Consider a family $\mathscr{Y}$ of analytic vector fields, letting Y be the distribution generated as above. Then $\Gamma(\mathsf{Y})$ is a submodule of $\Gamma(TQ)$. If Y has constant rank, then it is true that the vector fields $\mathscr{Y}$ generate this submodule. This is essentially due to a theorem of Swan [38]. However, if the rank of Y is *not* constant (more precisely, locally constant), then it can be the case that the vector fields $\mathscr{Y}$ are *not* generators for $\Gamma(\mathsf{Y})$. However, we shall always require that our families of vector fields have the property that they are generators for the submodule of sections of the induced distribution. Locally, and in the analytic setting, this can be done without loss of generality, due to the Noetherian property of the ring of analytic functions.

Let us clearly state our controllability definitions. First we provide notation for the reachable sets. For $T > 0$ and $q_0 \in Q$, let

$$\mathcal{R}^{\Sigma}_{TQ}(q_0, T) = \{\gamma'(T) |\ (\gamma, u) \text{ is a controlled trajectory on } [0, T] \text{ with } \gamma'(0) = 0_{q_0}\}$$

and let $\mathcal{R}^{\Sigma}_{TQ}(q_0, \leq T) = \bigcup_{0 \leq t \leq T} \mathcal{R}^{\Sigma}_{TQ}(q_0, t)$. These are therefore reachable *states* in TQ starting from zero initial velocity at the configuration q_0. We also consider the reachable configurations, which we denote by

$$\mathcal{R}^{\Sigma}_{Q}(q_0, T) = \tau_Q(\mathcal{R}^{\Sigma}_{TQ}(q_0, T)), \qquad \mathcal{R}^{\Sigma}_{Q}(q_0, \leq T) = \tau_Q(\mathcal{R}^{\Sigma}_{TQ}(q_0, \leq T)),$$

where $\tau_Q \colon TQ \to Q$ is the tangent bundle projection. Note that since D is invariant under ∇ and since the input vector fields are D-valued, solutions of (2.1) with initial conditions in D remain in D. In the following definition, $\operatorname{int}_{\mathsf{D}}(\cdot)$ means the interior in the relative topology on $\mathsf{D} \subset TQ$.

DEFINITION 2.1. *Let $\Sigma = (Q, \nabla, \mathsf{D}, \mathscr{Y}, U)$ be an affine connection control system and let $q_0 \in Q$.*

(i) *$(Q, \nabla, \mathsf{D}, \mathscr{Y})$ is* accessible *from q_0 if, for every almost proper control set, there exists $T > 0$ such that $\operatorname{int}_{\mathsf{D}}(\mathcal{R}^{\Sigma}_{TQ}(q_0, \leq t)) \neq \emptyset$ for $t \in (0, T]$.*

(ii) *$(Q, \nabla, \mathsf{D}, \mathscr{Y})$ is* configuration accessible *from q_0 if, for every almost proper control set, there exists $T > 0$ such that $\operatorname{int}(\mathcal{R}^{\Sigma}_{Q}(q_0, \leq t)) \neq \emptyset$ for $t \in (0, T]$.*

(iii) *Σ is* small-time locally controllable (STLC) *from q_0 if there exists $T > 0$ such that $0_{q_0} \in \operatorname{int}_{\mathsf{D}}(\mathcal{R}^{\Sigma}_{TQ}(q_0, \leq t)) \neq \emptyset$ for $t \in (0, T]$.*

(a) $(Q, \nabla, \mathsf{D}, \mathscr{Y})$ *is* properly small-time locally controllable (properly STLC) *from* q_0 *if* Σ *is STLC from* q_0 *for every proper control set* U.

(b) $(Q, \nabla, \mathsf{D}, \mathscr{Y})$ *is* small-time locally uncontrollable (STLUC) *from* q_0 *if* Σ *is not STLC from* q_0 *for any compact control set* U.

(iv) Σ *is* small-time locally configuration controllable (STLCC) *from* q_0 *if there exists* $T > 0$ *such that* $0_{q_0} \in \operatorname{int}(\mathcal{R}^{\Sigma}_{Q}(q_0, \leq t)) \neq \emptyset$ *for* $t \in (0, T]$.

(a) $(Q, \nabla, \mathsf{D}, \mathscr{Y})$ *is* properly small-time locally configuration controllable (properly STLCC) *from* q_0 *if* Σ *is STLCC from* q_0 *for every proper control set* U.

(b) $(Q, \nabla, \mathsf{D}, \mathscr{Y})$ *is* small-time locally configuration uncontrollable (STLCUC) *from* q_0 *if* Σ *is not STLCC from* q_0 *for any compact control set* U.

Remark 2.

1. Note that we are careful in these definitions to distinguish between those notions of controllability that depend only on the geometry of the affine connection precontrol system $(Q, \nabla, \mathsf{D}, \mathscr{Y})$ and those that also depend on the character of the control set U. Hirschorn and Lewis [21] illustrate various situations where the exact nature of the control set must be accounted for in the controllability analysis. For this reason we try to be careful about the exact manner in which the control set is considered.

2. A consequence of the classical theory of accessibility [37] is that for an affine connection precontrol system $(Q, \nabla, \mathsf{D}, \mathscr{Y})$, the reachable sets for $(Q, \nabla, \mathsf{D}, \mathscr{Y}, U)$ have nonempty interior for *all* almost proper control sets if and only if the reachable sets have nonempty interior for *some* almost proper control set.

3. It is clear that STLC implies STLCC and that STLCUC implies STLUC. The converse implications are generally false. What's more, even the relationships between STLCC and STLC *on the reachable set* are not completely understood at this time.

2.2. Review of existing results. Let us briefly review the results of [27]. These results rely on the *symmetric product* defined by the affine connection ∇ by $\langle X : Y \rangle = \nabla_X Y + \nabla_X Y$. First let us provide a description of the set of points accessible from the zero vector 0_q in the tangent space T_qQ. We let $\Sigma = (Q, \nabla, \mathsf{D}, \mathscr{Y}, U)$ be an affine connection control system. As above, we denote by Y the distribution generated by the vector fields $\mathscr{Y}$, and we now define a sequence $\mathsf{Sym}^{(k)}(\mathsf{Y})$, $k \in \mathbb{N}$, of distributions by

$$\begin{aligned}
&\mathsf{Sym}^{(1)}(\mathsf{Y})_q = \mathsf{Y}_q + \operatorname{span}_{\mathbb{R}}\{\langle Y_a : Y_b \rangle |\ a, b \in \{1, \dots, m\}\},\\
&\mathsf{Sym}^{(k)}(\mathsf{Y})_q = \mathsf{Sym}^{(k-1)}(\mathsf{Y})_q\\
&\quad + \operatorname{span}_{\mathbb{R}}\{\langle Y_a : Y_b \rangle |\ Y_a \in \Gamma(\mathsf{Sym}^{(k_1)}(\mathsf{Y})),\ Y_b \in \Gamma(\mathsf{Sym}^{(k_2)}(\mathsf{Y})),\ k_1 + k_2 = k - 1\}.
\end{aligned}$$

The smallest distribution containing these distributions we denote by $\mathsf{Sym}^{(\infty)}(\mathsf{Y})$, and we note that $\langle X : Y \rangle \in \Gamma(\mathsf{Sym}^{(\infty)}(\mathsf{Y}))$ for each $X, Y \in \Gamma(\mathsf{Sym}^{(\infty)}(\mathsf{Y}))$. The integrable distribution generated by $\mathsf{Sym}^{(\infty)}(\mathsf{Y})$ we denote by $\mathsf{Lie}^{(\infty)}(\mathsf{Sym}^{(\infty)}(\mathsf{Y}))$. Since this distribution is integrable, through each point $q_0 \in Q$ there is an immersed maximal integral manifold Λ_{q_0} with the property that $T_q\Lambda_{q_0} = \mathsf{Lie}^{(\infty)}(\mathsf{Sym}^{(\infty)}(\mathsf{Y}))_q$ for each $q \in \Lambda_{q_0}$. Note that since we are only thinking of local controllability, we may shrink Q so that Λ_{q_0} is an embedded submanifold, and thus $T_q\Lambda_{q_0}$ has its usual definition.

With this notation, we have the following theorem which describes the reachable set from $0_{q_0} \in TQ$. Note that the description we provide here is a little more complete

than that originally given by Lewis and Murray, but what we state here is certainly implicit in the original paper.

THEOREM 2.2. *Let $\Sigma = (Q, \nabla, \mathsf{D}, \mathscr{Y}, U)$ be an affine connection control system with U almost proper. Let Λ_{q_0} be the maximal integral manifold of $\mathsf{Lie}^{(\infty)}(\mathsf{Sym}^{(\infty)}(\mathsf{Y}))$ through $q_0 \in Q$, which we assume without loss of generality to be an embedded submanifold of Q. Let $\mathsf{S}(\mathsf{Y}, q_0)$ be the vector bundle over Λ_{q_0} whose fiber at $q \in \Lambda_{q_0}$ is $\mathsf{Sym}^{(\infty)}(\mathsf{Y})_q$. We have the following statements.*

(i) *There exists $T > 0$ such that for each $t \in (0, T]$, $\mathcal{R}^{\Sigma}_{TQ}(q_0, \leq t)$ is contained in $\mathsf{S}(\mathsf{Y}, q_0)$ and contains a nonempty open subset of $\mathsf{S}(\mathsf{Y}, q_0)$.*

(ii) *In particular, there exists $T > 0$ such that for each $t \in (0, T]$, $\mathcal{R}^{\Sigma}_{Q}(q_0, \leq t)$ is contained in Λ_{q_0} and contains a nonempty open subset of Λ_{q_0}.*

Theorem 2.2 obviously leads to the following corollary.

COROLLARY 2.3. *An affine connection precontrol system $(Q, \nabla, \mathsf{D}, \mathscr{Y})$*

(i) *is accessible from q_0 if and only if $\mathsf{Sym}^{(\infty)}(\mathsf{Y})_{q_0} = \mathsf{D}_{q_0}$, and*

(ii) *is configuration accessible from q_0 if and only if $\mathsf{Lie}^{(\infty)}(\mathsf{Sym}^{(\infty)}(\mathsf{Y}))_{q_0} = T_{q_0}Q$.*

Now we turn to local configuration controllability. Let $P(\mathscr{Y})$ denote the set of iterated symmetric products of vector fields in $\mathscr{Y}$. A product $P_0 \in P(\mathscr{Y})$ is *bad* when it is composed of an even number of each of the vector fields from $\mathscr{Y}$ and is otherwise *good*. The *degree* of $P_0 \in P(\mathscr{Y})$ is the total number of vector fields from $\mathscr{Y}$ which participate in P_0, counting multiplicities. Thus, for example, $\langle Y_a : \langle Y_b : Y_b \rangle \rangle$ is good and of degree 3, and $\langle \langle Y_a : Y_b \rangle : \langle Y_a : Y_b \rangle \rangle$ is bad and of degree 4. Let S_m be the symmetric group on m symbols. For $P_0 \in P(\mathscr{Y})$ and $\sigma \in S_m$, let $\sigma(P_0) \in P(\mathscr{Y})$ be obtained by permuting the occurrences of the vector fields from $\mathscr{Y}$ by σ. For example, if $P_0 = \langle Y_a : \langle Y_b : Y_c \rangle \rangle$ and if $\sigma = \left(\begin{smallmatrix} 1 & 2 & 3 \\ 2 & 3 & 1 \end{smallmatrix}\right)$, then $\sigma(P_0) = \langle Y_b : \langle Y_c : Y_a \rangle \rangle$. With this notation, we have the following definition.

DEFINITION 2.4. An affine connection precontrol system $(Q, \nabla, \mathsf{D}, \mathscr{Y})$ *satisfies the good/bad hypothesis at q_0* if, for each bad symmetric product $P_0 \in P(\mathscr{Y})$, there exist good symmetric products $P_1, \ldots, P_k \in P(\mathscr{Y})$ of degree strictly less than P_0 and such that

$$\sum_{\sigma \in S_m} \sigma(P_0)(q_0) = \sum_{j=1}^{k} c_j P_j(q_0)$$

for some $c_1, \ldots, c_k \in \mathbb{R}$.

The following result of Lewis and Murray [27] is derived from a result of Sussmann [36]. Again, we provide a somewhat more thorough statement of the result than is given in [27].

THEOREM 2.5. *Let $\Sigma = (Q, \nabla, \mathsf{D}, \mathscr{Y}, U)$ be an affine connection control system with U proper, and let $q_0 \in Q$. If $(Q, \nabla, \mathsf{D}, \mathscr{Y})$ satisfies the good/bad hypothesis at $q_0 \in Q$, then there exists $T > 0$ such that for each $t \in (0, T]$ the set $\mathcal{R}^{\Sigma}_{TQ}(q_0, \leq t)$ contains a neighborhood of 0_{q_0} in the vector bundle $\mathsf{S}(\mathscr{Y}, q_0)$ over Λ_{q_0}.*

The result essentially says that when the good/bad hypothesis is satisfied, the system is locally controllable when restricted to its reachable set. In particular, we have the following corollary.

COROLLARY 2.6. *Let $\Sigma = (Q, \nabla, \mathsf{D}, \mathscr{Y}, U)$ be an affine connection control system with U proper and such that the precontrol system $(Q, \nabla, \mathsf{D}, \mathscr{Y})$ satisfies the good/bad hypotheses at $q_0 \in Q$. Then*

(i) *Σ is locally controllable at q_0 if it is locally accessible at q_0, and*

(ii) Σ *is locally configuration controllable at* q_0 *if it is locally configuration accessible at* q_0.

The above results all follow from a detailed analysis of the Lie algebra of vector fields associated with the control system (2.1) when it is thought of as a control-affine system with state manifold TQ. The results reflect the fact that, when evaluated at zero velocity points, this Lie algebra structure simplifies enormously. We shall exploit this further when we prove our main results in section 4. We remark that the structure of the Lie algebra at points of nonzero velocity is not currently well understood.

3. Vector-valued quadratic forms. In our controllability analysis we are led to investigate symmetric bilinear maps $B\colon V \times V \to W$ from a finite-dimensional $\mathbb{R}$-vector space V into a finite-dimensional $\mathbb{R}$-vector space W. In this section we first look at such objects in general, and then we construct a specific such object associated to an affine connection control system. Some other control theoretic problems where vector-valued quadratic forms arise are given by Bullo et al. [10].

3.1. Basic definitions and properties. Let V and W be finite-dimensional $\mathbb{R}$-vector spaces and let $\Sigma_2(V;W)$ denote the set of symmetric $\mathbb{R}$-bilinear maps from $V \times V$ to W. For $B \in \Sigma_2(V;W)$, we define $Q_B\colon V \to W$ by $Q_B(v) = B(v,v)$. For $\lambda \in W^*$, we define $\lambda B\colon V \times V \to \mathbb{R}$ by $\lambda B(v_1, v_2) = \langle \lambda; B(v_1, v_2)\rangle$.

DEFINITION 3.1. *Let* $B \in \Sigma_2(V;W)$.

(i) B *is* definite *if there exists* $\lambda \in W^*$ *such that* λB *is positive-definite.*

(ii) B *is* essentially indefinite *if, for each* $\lambda \in W^*$, λB *is either*

(a) *zero or*

(b) *neither positive nor negative-semidefinite.*

The following properties of symmetric bilinear maps will be important for us. The proof follows more or less directly from the definitions.

LEMMA 3.2. *Let* V *and* W *be finite-dimensional* $\mathbb{R}$*-vector spaces with* $B \in \Sigma_2(V;W)$. *Suppose that* $V \neq \{0\}$. *The following statements hold:*

(i) *if* $W = \{0\}$, *then* B *is essentially indefinite;*

(ii) *if* $W \neq \{0\}$, *then* B *is essentially indefinite if and only if*

$$0 \in \mathrm{int}_{\mathrm{aff}(\mathrm{image}(Q_B))}(\mathrm{conv}(\mathrm{image}(Q_B)));$$

(iii) *if* $W \neq \{0\}$, *then* B *is definite if and only if there exists a hyperplane* P *through* $0 \in W$ *such that*

(a) $\mathrm{image}(Q_B)$ *lies on one side of* P *and*

(b) $\mathrm{image}(Q_B) \cap P = \{0\}$.

The matter of deciding whether a vector-valued quadratic form is essentially indefinite is known to be NP-complete, at least in the case when $\dim(W) > 1$.[1]

The following result gives some properties of $\mathbb{R}$-valued quadratic forms that will be useful in our discussion. We refer to Hirschorn and Lewis [21] for a proof.

LEMMA 3.3. *Let* V *be a finite-dimensional* $\mathbb{R}$*-vector space and let* $B \in \Sigma_2(V;\mathbb{R})$. *For a basis* $\mathscr{V} = \{v_1, \ldots, v_n\}$ *for* V, *let* $[B]_{\mathscr{V}}$ *be the* $n \times n$ *matrix representation of* B. *The following statements are equivalent:*

(i) *there exists a basis* $\mathscr{V}$ *for* V *for which the sum of the diagonal entries in the matrix* $[B]_{\mathscr{V}}$ *is zero;*

(ii) *there exists a basis* $\mathscr{V}$ *for* V *for which the diagonal entries in the matrix* $[B]_{\mathscr{V}}$ *are all zero;*

(iii) B *is essentially indefinite.*

[1] This was pointed out to the authors by a reviewer for [10].

3.2. Vector-valued quadratic forms and affine connection control systems. Let $\Sigma = (Q, \nabla, \mathsf{D}, \mathscr{Y}, U)$ be an affine connection control system and let $q \in Q$. If $S_q \subset T_qQ$ is a subspace, then we define $B_{\mathsf{Y}_q}(S_q)\colon \mathsf{Y}_q \times \mathsf{Y}_q \to T_qQ/S_q$ as the T_qQ/S_q-valued symmetric, bilinear mapping on Y_q given by

$$B_{\mathsf{Y}_q}(S_q)(v_1, v_2) = \pi_{S_q}(\langle V_1 : V_2\rangle(q)), \tag{3.1}$$

where V_1 and V_2 are vector fields extending $v_1, v_2 \in \mathsf{Y}_q$, and where $\pi_{S_q}\colon T_qQ \to T_qQ/S_q$ is the canonical projection. Note that $B_{\mathsf{Y}_q}(S_q)$ is not necessarily well-defined.

LEMMA 3.4. *If $\mathsf{Y}_q \subset S_q$, then $B_{\mathsf{Y}_q}(S_q)$ is well-defined.*

Proof. We need to show that the definition in (3.1) does not depend on the extensions V_1 and V_2 of v_1 and v_2. This will follow if $\pi_{S_q}(\langle V_1 : V_2\rangle(q))$ depends only on the values of V_1 and V_2 at q, and not on their derivatives. Let $\phi_1, \phi_2 \in \mathcal{F}(Q)$ and compute

$$\langle \phi_1 V_1 : \phi_2 V_2\rangle = \phi_1\phi_2\langle V_1 : V_2\rangle + \phi_1(\mathscr{L}_{V_1}\phi_2)V_2 + \phi_2(\mathscr{L}_{V_2}\phi_1)V_1.$$

Thus $\pi_{S_q}(\langle \phi_1 V_1 : \phi_2 V_2\rangle(q)) = \phi_1(q)\phi_2(q)\pi_{S_q}(\langle V_1 : V_2\rangle(q))$, showing that $\pi_{S_q}(\langle V_1 : V_2\rangle(q))$ does not depend on the derivatives of V_1 and V_2 at q, and so the result follows. ∎

Remark 3. Note that $(T_qQ/S_q)^* \simeq \operatorname{ann}(S_q)$. Therefore, the definition of $\lambda B_{\mathsf{Y}_q}(S_q)$, $\lambda \in (T_qQ/S_q)^*$ is concrete in that one needs to worry about objects in the quotient.

If Y has constant rank, then one can define a TQ/Y-valued quadratic form B_{Y} globally by

$$B_{\mathsf{Y}}(V_1, V_2) = \pi_{\mathsf{Y}}(\langle V_1 : V_2\rangle)$$

for $V_1, V_2 \in \Gamma(\mathsf{Y})$, where $\pi_{\mathsf{Y}}\colon TQ \to TQ/\mathsf{Y}$ is the projection.

4. Controllability results. In this section we undertake the formulation and discussion of novel controllability results. Our objective is to obtain controllability conditions that are independent of the basis for the input distribution Y. We achieve this by means of controllability tests that do not entail good/bad conditions but rather are expressed in terms of properties of a vector-valued quadratic form. Before we state the results we need some preliminary constructions.

4.1. Constructions concerning vanishing input vector fields. We let $\Sigma = (Q, \nabla, \mathsf{D}, \mathscr{Y}, U)$ be an analytic affine connection control system and we let $q_0 \in Q$. One of the generalizations we wish to allow is the case when q_0 may not be a regular point for the distribution Y generated by $\mathscr{Y}$. In this case the vector fields $\mathscr{Y}$ cannot be linearly independent at q_0. It may also happen that even if q_0 *is* a regular point for Y, the vector fields may still not be linearly independent. For example, if one wishes to globally define a control system for which the input distribution Y has constant rank but is not trivial, then one will necessarily have to choose more input vector fields than $\operatorname{rank}(\mathsf{Y})$, implying that the input vector fields will never be linearly independent. It will be convenient to organize the vector fields in $\mathscr{Y}$ in a manner consistent with these possibilities. The following result gives a useful way of doing this.

LEMMA 4.1. *Let $(Q, \nabla, \mathsf{D}, \mathscr{Y} = \{Y_1, \ldots, Y_m\})$ be an analytic affine connection precontrol system with $q_0 \in Q$. There exists $\boldsymbol{T} \in GL(m; \mathbb{R})$ with the property that if $\tilde{Y}_a = T_a^b Y_a$, $a \in \{1, \ldots, m\}$, then*

(i) *$\{\tilde{Y}_1(q_0), \ldots, \tilde{Y}_k(q_0)\}$ form a basis for Y_{q_0} and*

(ii) *the vector fields $\tilde{Y}_{k+1}, \ldots, \tilde{Y}_m$ vanish at q_0.*

Proof. We let $k = \dim(\mathsf{Y}_{q_0})$. Since $\mathscr{Y}$ generates Y, we may find $\boldsymbol{R} \in GL(m;\mathbb{R})$ with the property that if $X_a = R_a^b Y_b$, $a \in \{1,\dots,m\}$, then $\{X_1(q_0),\dots,X_k(q_0)\}$ form a basis for Y_{q_0}. Now let $L_{q_0}\colon \mathbb{R}^m \to \mathsf{Y}_{q_0}$ be defined by $L_{q_0}(\boldsymbol{u}) = \sum_{a=1}^m u^a X_a(q_0)$. Let $\boldsymbol{u}_{k+1},\dots,\boldsymbol{u}_m \in \mathbb{R}^m$ be a basis for $\ker(L_{q_0})$ and define $\boldsymbol{S} \in GL(m;\mathbb{R})$ by

$$\boldsymbol{S} = \left[\ \boldsymbol{e}_1 \ \middle|\ \cdots \ \middle|\ \boldsymbol{e}_k \ \middle|\ \boldsymbol{u}_{k+1} \ \middle|\ \cdots \ \middle|\ \boldsymbol{u}_m \ \right].$$

It is then clear that if we take $\tilde{Y}_a = S_a^b X_b$, $a \in \{1,\dots,m\}$, then $\{\tilde{Y}_1(q_0),\dots,\tilde{Y}_k(q_0)\}$ form a basis for Y_{q_0}, and that $\tilde{Y}_{k+1},\dots,\tilde{Y}_m$ vanish at q_0. Now we take $\boldsymbol{T} = \boldsymbol{R}\boldsymbol{S}$. ∎

Remark 4.

1. If the vector fields $\mathscr{Y}$ are linearly independent at q_0, then one may take $\boldsymbol{T} = \boldsymbol{I}_m$ in the lemma.

2. Suppose that we have a control set U for $(Q,\nabla,\mathsf{D},\mathscr{Y})$. If we take $\boldsymbol{T} \in GL(m;\mathbb{R})$ and $\tilde{\mathscr{Y}} = \{\tilde{Y}_1,\dots,\tilde{Y}_m\}$ as in the lemma, and if we define $\tilde{U} = \{\boldsymbol{T}^{-1}\boldsymbol{u} \mid\ \boldsymbol{u} \in U\}$, this gives an affine connection control system $\tilde{\Sigma} = (Q,\nabla,\mathsf{D},\tilde{\mathscr{Y}},\tilde{U})$. Clearly the controlled trajectories for $\Sigma = (Q,\nabla,\mathsf{D},\mathscr{Y},U)$ and $\tilde{\Sigma}$ agree, so we can without loss of generality assume that the input vector fields for an affine connection control system satisfy conditions (i) and (ii) of the lemma. Input vector fields satisfying these conditions at q_0 will be said to be *adapted at* q_0.

Let $X, Y \in \Gamma(Q)$. If $X(q_0) = 0_{q_0}$, then the expression $\langle X : Y\rangle(q_0)$ may be verified (in coordinates, for example) to depend only on the value of Y at q_0. That is to say, we may define a linear map $\mathrm{sym}_X\colon T_{q_0}Q \to T_{q_0}Q$ by $v \mapsto \langle X : V\rangle(q_0)$, where V is any extension of $v \in T_{q_0}Q$. If $\mathscr{Y}$ is adapted at q_0, then we denote by $Z_{q_0}(\mathscr{Y})$ the set of linear maps sym_{Y_a}, $a \in \{k+1,\dots,m\}$, where $k = \dim(\mathsf{Y}_{q_0})$. For an $\mathbb{R}$-vector space W, an arbitrary subset $\mathscr{L}$ of linear transformations of W, and a subspace $S \subset W$, we denote by $\langle \mathscr{L}, S\rangle$ the smallest subspace of W containing S and which is an invariant subspace for each of the linear maps from $\mathscr{L}$. One readily verifies that $\langle \mathscr{L}, S\rangle$ is generated by vectors of the form

$$L_1 \circ \cdots \circ L_{k-1}(v), \qquad L_1,\dots,L_{k-1} \in \mathscr{L},\ v \in S,\ k \in \mathbb{N}. \tag{4.1}$$

We will be interested in subspaces of the form $\langle Z_{q_0}(\mathscr{Y}), S_{q_0}\rangle$, where S_{q_0} is a subspace of $T_{q_0}Q$. In order for such constructions to make sense (in that they are independent of the choice of adapted family of vector fields) the subspace S_{q_0} should have some properties.

LEMMA 4.2. *Let $\Sigma = (Q,\nabla,\mathsf{D},\mathscr{Y},U)$ and $\tilde{\Sigma} = (Q,\nabla,\mathsf{D},\tilde{\mathscr{Y}},\tilde{U})$ be affine connection control systems satisfying*

(i) $\mathsf{Y} = \tilde{\mathsf{Y}}$ *and*

(ii) $\mathscr{Y}$ *and* $\tilde{\mathscr{Y}}$ *are adapted at* q_0.

Then $\langle Z_{q_0}(\tilde{\mathscr{Y}}), S_{q_0}\rangle = \langle Z_{q_0}(\mathscr{Y}), S_{q_0}\rangle$ for any subspace S_{q_0} containing Y_{q_0}.

Proof. We write $\mathscr{Y} = \{Y_1,\dots,Y_m\}$ and $\tilde{\mathscr{Y}} = \{\tilde{Y}_1,\dots,\tilde{Y}_{\tilde{m}}\}$. Since $\mathsf{Y} = \tilde{\mathsf{Y}}$, we must have

$$\tilde{Y}_\alpha = \sum_{a=1}^m \Lambda_\alpha^a Y_a, \qquad \alpha \in \{1,\dots,\tilde{m}\},$$

for functions $\Lambda_\alpha^a\colon Q \to \mathbb{R}$, $a \in \{1,\dots,m\}$, $\alpha \in \{1,\dots,\tilde{m}\}$. (Here we make use of the assumption stated in Remark 1.) Assume that $\dim(\mathsf{Y}_{q_0}) = k$ so that both $\{Y_1(q_0),\dots,Y_k(q_0)\}$ and $\tilde{Y}_1(q_0),\dots,\tilde{Y}_k(q_0)\}$ are bases for Y_{q_0} and so that $Y_{k+1},\dots,Y_m$

and $\tilde{Y}_{k+1}, \dots, \tilde{Y}_{\tilde{m}}$ all vanish at q_0. Note that $\langle Z_{q_0}(\mathscr{Y}), S_{q_0}\rangle$ is generated by those tangent vectors at q_0 of the form

$$\mathrm{sym}_{Y_{a_{\ell-1}}} \circ \cdots \circ \mathrm{sym}_{Y_{a_1}}(v), \qquad a_1, \dots, a_{\ell-1} \in \{k+1, \dots, m\},\ \ell \in \mathbb{N},\ v \in S_{q_0}.$$

We will show by induction on ℓ that each of these generators lies in $\langle Z_{q_0}(\tilde{\mathscr{Y}}), S_{q_0}\rangle$. This is clearly true for $\ell = 1$, so suppose it true for $\ell = j$ and let $a_j \in \{k+1, \dots, m\}$. Then for any $V \in \Gamma(TQ)$, we have

$$\langle Y_{a_j} : V\rangle = \langle \Lambda^\alpha_{a_j}(\tilde{Y}_\alpha) : V\rangle = \Lambda^\alpha_a \langle \tilde{Y}_\alpha : V\rangle + \sum_{\alpha=1}^{\tilde{m}} (\mathscr{L}_V \Lambda^\alpha_{a_j})\tilde{Y}_\alpha,$$

from which we ascertain that

$$\mathrm{sym}_{Y_{a_j}} = \sum_{\alpha=k+1}^{\tilde{m}} \Lambda^\alpha_{a_j}(q_0)\mathrm{sym}_{\tilde{Y}_\alpha} + \sum_{\alpha=1}^{k} \tilde{Y}_\alpha(q_0) \otimes \boldsymbol{d}^\alpha_{a_j}(q_0),$$

since $\Lambda^\alpha_a(q_0) = 0$ for $\alpha \in \{1, \dots, k\}$ and $a \in \{k+1, \dots, m\}$. Therefore, by the induction hypothesis, we conclude that

$$\mathrm{sym}_{Y_{a_j}} \circ \mathrm{sym}_{Y_{a_{j-1}}} \circ \cdots \circ \mathrm{sym}_{Y_{a_1}}(v) \in \langle Z_{q_0}(\tilde{\mathscr{Y}}), S_{q_0}\rangle.$$

This shows that $\langle Z_{q_0}(\mathscr{Y}), S_{q_0}\rangle \subset \langle Z_{q_0}(\tilde{\mathscr{Y}}), S_{q_0}\rangle$. The opposite inclusion follows as above, but swapping $\mathscr{Y}$ and $\tilde{\mathscr{Y}}$. □

The preceding result shows the invariance of the definition of a subspace on the choice of adapted generators for Y. The next result gives the same conclusion for a vector-valued quadratic form.

LEMMA 4.3. *Let $\Sigma = (Q, \nabla, \mathsf{D}, \mathscr{Y}, U)$ and $\tilde{\Sigma} = (Q, \nabla, \mathsf{D}, \tilde{\mathscr{Y}}, \tilde{U})$ be affine connection control systems satisfying*

(i) $\mathsf{Y} = \tilde{\mathsf{Y}}$ *and*

(ii) $\mathscr{Y}$ *and* $\tilde{\mathscr{Y}}$ *are adapted at* q_0.

If $S_{q_0} \subset T_{q_0}Q$ is a subspace containing Y_{q_0}, then $B_{\tilde{\mathsf{Y}}_{q_0}}(S_{q_0}) = B_{\mathsf{Y}_{q_0}}(S_{q_0})$.

Proof. As in the proof of Lemma 4.2 we have

$$\tilde{Y}_\alpha = \sum_{a=1}^{m} \Lambda^a_\alpha Y_a, \qquad \alpha \in \{1, \dots, \tilde{m}\},$$

for functions $\Lambda^a_\alpha \colon Q \to \mathbb{R}$, $a \in \{1, \dots, m\}$, $\alpha \in \{1, \dots, \tilde{m}\}$. We then compute

$$\langle Y_a : Y_b\rangle = \Lambda^\alpha_a \Lambda^\beta_b \langle \tilde{Y}_\alpha : \tilde{Y}_\beta\rangle + \sum_{\alpha,\beta=1}^{\tilde{m}} \Lambda^\beta_b (\mathscr{L}_{\tilde{Y}_\beta} \Lambda^\alpha_a)\tilde{Y}_\alpha + \sum_{\alpha,\beta=1}^{\tilde{m}} \Lambda^\alpha_a (\mathscr{L}_{\tilde{Y}_\alpha} \Lambda^\beta_b)\tilde{Y}_\beta + \Lambda^\alpha_a \Lambda^\beta_b S^\delta(\tilde{Y}_\alpha, \tilde{Y}_\beta)\tilde{Y}_\delta.$$

The lemma follows directly from this formula since the terms in $\Gamma(\mathsf{Y})$ will go to zero when projected by $\pi_{S_{q_0}}$ since $\mathsf{Y}_{q_0} \subset S_{q_0}$. □

4.2. Main results. Our main results may now be stated. Let us first state a sufficient condition for controllability.

THEOREM 4.4. *Let $(Q, \nabla, \mathsf{D}, \mathscr{Y})$ be an analytic affine connection precontrol system, and suppose that $\mathscr{Y}$ is adapted at $q_0 \in Q$. Suppose that*

(i) $\mathsf{Sym}^{(\infty)}(\mathsf{Y})_{q_0} = \langle Z_{q_0}(\mathscr{Y}), \mathsf{Sym}^{(2)}(\mathsf{Y})\rangle$, *and*

(ii) $B_{\mathsf{Y}_{q_0}}(\langle Z_{q_0}(\mathscr{Y}), \mathsf{Y}_{q_0}\rangle)$ *is essentially indefinite.*

Then $(Q, \nabla, \mathsf{D}, \mathscr{Y})$ is properly STLC from q_0 if it is accessible from q_0, and is properly STLCC from q_0 if it is configuration accessible from q_0.

Proof. The proof essentially follows from Theorem 2.5. However, the extension to allow singular points for the input distribution Y does not follow directly from Theorem 2.5 but requires some manipulations with the variational cone, which we will not go into here. The idea, in essence, is that if an input vector field vanishes at the reference point, then directions generated by symmetric products using these vector fields come "for free." Since these symmetric products are simply applications of a linear map, this explains the presence of the invariant subspace characterizations of the tangent space to the reachable set. We refer to [21, Lemma 7.2] for the details behind this, noting that the discussion in that paper builds on concepts presented in [36, 7]. A consequence of these discussions, once they are specialized to our setting, is the following result.

LEMMA 4.5. *Let $(Q, \nabla, \mathsf{D}, \mathscr{Y} = \{Y_1, \dots, Y_m\})$ be an analytic affine connection precontrol system for which $\mathscr{Y}$ is adapted at $q_0 \in Q$. Assume the following:*

(i) $\mathsf{Sym}^{(\infty)}(\mathsf{Y}) = \langle Z_{q_0}(\mathscr{Y}), \mathsf{Sym}^{(2)}(\mathsf{Y})_{q_0}\rangle$*;*

(ii) *there exist $\tilde{m} \geq m$ and a full-rank matrix $\boldsymbol{T} \in \mathbb{R}^{m\times\tilde{m}}$ such that if $\tilde{Y}_\alpha = T^a_\alpha Y_\alpha$, then*

$$\sum_{a=1}^{\tilde{m}} \langle \tilde{Y}_\alpha : \tilde{Y}_\alpha\rangle(q_0) \in \langle Z_{q_0}(\mathscr{Y}), \mathsf{Y}_{q_0}\rangle.$$

Then $(Q, \nabla, \mathsf{D}, \mathscr{Y})$ is properly STLC from q_0 if it is accessible from q_0 and is properly STLCC from q_0 if it is configuration accessible from q_0.

We shall show that if the hypotheses of Theorem 4.4 are satisfied at q_0, then the hypotheses of Lemma 4.5 are satisfied for some possibly different collection of input vector fields. From this the conclusion of Theorem 4.4 will follow.

For brevity let us denote $S_{q_0} = \langle Z_{q_0}(\mathscr{Y}), \mathsf{Y}_{q_0}\rangle$ and $B = B_{\mathsf{Y}_{q_0}}(S_{q_0})$. First we need to find an appropriate collection of input vector fields. Choose $v_1, \dots, v_\ell \in \mathsf{Y}_{q_0}$ such that $0_{q_0} + S_{q_0} \in \mathsf{Sym}^{(\infty)}(\mathsf{Y})_{q_0}/S_{q_0}$ lies in the interior of the convex hull of the vectors $B(v_1, v_1), \dots, B(v_\ell, v_\ell)$. That this is possible is guaranteed by the hypotheses of Theorem 4.4 and by Lemma 3.2. If necessary, add vectors $v_{\ell+1}, \dots, v_{\tilde{k}}$ such that the vectors $v_1, \dots, v_{\tilde{k}}$ span Y_{q_0}. It now follows that the vectors $B(v_1, v_1), \dots, B(v_{\tilde{k}}, v_{\tilde{k}})$ contain $0_{q_0} + S_{q_0} \in \mathsf{Sym}^{(\infty)}(\mathsf{Y})_{q_0}/S_{q_0}$ in the interior of their convex hull. Thus the vectors $v_1, \dots, v_{\tilde{k}}$ may be rescaled by strictly positive constants (for simplicity, let us denote the rescaled vectors also by $v_1, \dots, v_{\tilde{k}}$) so that

$$\sum_{\alpha=1}^{\tilde{k}} B(v_\alpha, v_\alpha) = 0_{q_0} + S_{q_0} \in \mathsf{Sym}^{(\infty)}(\mathsf{Y})_{q_0}/S_{q_0}. \tag{4.2}$$

It is now possible to define vector fields $\tilde{\mathscr{Y}} = \{\tilde{Y}_1, \dots, \tilde{Y}_{\tilde{m}}\}$ such that, if $\dim(\mathsf{Y}_{q_0}) = k$, then

1. $\tilde{Y}_{\tilde{k}+a} = Y_{k+a}$, $a \in \{1, \dots, m-k\}$, and
2. $\tilde{Y}_\alpha = \sum_{a=1}^{k} \tilde{T}^a_\alpha Y_a$, $\alpha \in \{1, \dots, \tilde{k}\}$, for a full-rank matrix $\tilde{\boldsymbol{T}} \in \mathbb{R}^{k\times\tilde{k}}$.

Clearly this then implies the existence of a full-rank matrix $\boldsymbol{T} \in \mathbb{R}^{m \times \tilde{m}}$ such that $\tilde{Y}_\alpha = T^a_\alpha Y_a$, $\alpha \in \{1, \dots, \tilde{m}\}$. From (4.2) it immediately follows that $(Q, \nabla, \mathsf{D}, \mathscr{Y})$ satisfies the hypotheses of Lemma 4.5, and so Theorem 4.4 follows. □

Remark 5. Our use of the vector fields $Z_{q_0}(\mathscr{Y})$ from $\mathscr{Y}$ that vanish at q_0 is similar in spirit to how the vanishing of the drift vector appears in the work of Sussmann [36] and Bianchini and Stefani [7]. The idea is that brackets generated by such vanishing vector fields can be achieved "for free," without invoking bad brackets.

A necessary condition for controllability is the following.

THEOREM 4.6. *Let $(Q, \nabla, \mathsf{D}, \mathscr{Y})$ be an analytic affine connection precontrol system for which $\mathscr{Y}$ is adapted at $q_0 \in Q$. Suppose that*

(i) *q_0 is a regular point for Y and*

(ii) *$B_{\mathsf{Y}_{q_0}}(\mathsf{Y}_{q_0})$ is definite.*

Then $(Q, \nabla, \mathsf{D}, \mathscr{Y})$ is STLCUC from q_0.

Proof. We work locally. Therefore, we may assume the vector fields $\{Y_1, \dots, Y_m\}$ are linearly independent in a neighborhood of q_0. First we show that the system is not STLC from q_0 using calculations of Hirschorn and Lewis [21]. We will not provide here a self-contained justification for all of our computations, since they take considerable space, but we refer to the paper [21]. The calculation uses the Chen–Fliess–Sussmann series [14, 17, 35]. For an analytic control-affine system

$$\xi'(t) = f_0(\xi(t)) + \sum_{a=1}^{m} u_a(t) f_a(\xi(t)), \qquad \xi(t) \in M,$$

on a manifold M with a compact control set, and for an analytic function ϕ, the Chen–Fliess–Sussmann series gives the following formula for the value of ϕ along a controlled trajectory (ξ, u):

$$\phi(\xi(t)) = \sum_J U_J(t) f_J \phi(\xi(0)).$$

The sum is over multi-indices $J = (a_1, \dots, a_k)$ in $\{0, 1, \dots, m\}$,

$$U_J(t) = \int_0^t u_{a_k}(t_k) \int_0^{t_k} u_{a_{k-1}}(t_{k-1}) \cdots \int_0^{t_2} u_{a_1}(t_1)\, \mathrm{d}t_1 \dots \mathrm{d}t_{k-1}\, \mathrm{d}t_k$$

and

$$f_J \phi = f_{a_1} f_{a_2} \cdots f_{a_k} \phi.$$

We adopt the convention that $u_0 = 1$. We also regard an affine connection control system as a control-affine system in the usual manner by taking f_0 to be the geodesic spray for ∇ and $f_1, \dots, f_m$ to be the vertical lifts of $Y_1, \dots, Y_m$ [27].

The function we evaluate is defined as follows. We let λ be an analytic covector field defined in a neighborhood of q_0 with the following properties:

1. λ annihilates the distribution Y;
2. $\lambda(q_0) B_{\mathsf{Y}_{q_0}} | \mathsf{Y}_{q_0}$ is negative-definite.

By a linear input transformation one can ensure that the input vector fields diagonalize $\lambda(q_0) B_{\mathsf{Y}_{q_0}}$ with the diagonal entries being -1. We assume this input transformation to have been made. We then define a function $\phi_\lambda \colon TQ \to \mathbb{R}$ by $\phi_\lambda(v_q) = \lambda(q) \cdot v_q$, and we also define

$$\Phi^+_\lambda = \{v_q \in TQ |\ \phi_\lambda(v_q) > 0\}, \quad \Phi^-_\lambda = \{v_q \in TQ |\ \phi_\lambda(v_q) < 0\}.$$

Note that in any neighborhood V of 0_{q_0} in TQ, the sets $V \cap \Phi_\lambda^-$ and $V \cap \Phi_\lambda^+$ will be nonempty, since ϕ_λ is linear on the fibers of TQ. Therefore, we can show that $(Q, \nabla, \mathsf{D}, \mathscr{Y})$ is STLUC from q_0 by showing that ϕ_λ has constant sign along any controlled trajectory. One may directly verify that ϕ_λ has the following properties:

1. $f_a\phi_\lambda$, $a \in \{1, \dots, m\}$, is zero in a neighborhood of 0_{q_0};
2. $\mathrm{ad}_{f_0}^k f_a \phi_\lambda(0_{q_0}) = 0$, $a \in \{1, \dots, m\}$, $k \in \mathbb{N}$;
3. $[f_a, [f_0, f_a]]\phi_\lambda(0_{q_0}) = -1$, $a \in \{1, \dots, m\}$ (this and the next fact use the formula $[f_a, [f_0, f_b]] = \mathrm{verlift}(\langle Y_a : Y_b \rangle)$, $a, b \in \{1, , \dots, m\}$);
4. $[f_a, [f_0, f_b]]\phi_\lambda(0_{q_0}) = 0$, $a, b \in \{1, \dots, m\}$, $a \neq b$.

For an input $u \colon [0, T] \to U$, let us define

$$\|u\|_{2,t} = \max\Big\{\Big(\int_0^t |u_a(t)|^2\Big)^{1/2} \Big| \ a \in \{1, \dots, m\}\Big\}.$$

The calculations of Hirschorn and Lewis [21] now immediately give the following inequality for $\phi_\lambda(\gamma'(t))$ along a controlled trajectory (γ, u) for an affine connection control system like that under consideration here:

$$\phi_\lambda(\gamma'(t)) \geq \frac{1}{2}(\|u\|_{2,t})^2 - |E(t)|.$$

According to the analysis in Hirschorn and Lewis, the map $t \mapsto E(t)$ satisfies the bound $|E(t)| \leq tE_0(\|u\|_{2,t})^2$ for some $E_0 > 0$. For t sufficiently small, this shows that $\phi_\lambda(\gamma'(t))$ has constant sign. This shows that $(Q, \nabla, \mathsf{D}, \mathscr{Y})$ is STLCUC from q_0.

Now let us show that our above constructions also preclude the system from being locally *configuration* controllable. Choose a coordinate chart (V, χ) for Q around q_0 with the following properties: (1) $\chi(q_0) = \mathbf{0}$ and (2) $\mathrm{d}q^n(q_0) = \lambda(q_0)$. Let us define a function ψ_λ on the coordinate domain V by $\psi_\lambda(q) = q^n$ such that the sets

$$\Psi_\lambda^+ = \{q \in Q| \ \psi_\lambda(q) > 0\}, \quad \Psi_\lambda^- = \{q \in Q| \ \psi_\lambda(q) < 0\}$$

each intersect any neighborhood of $q_0 \in Q$. Along any nontrivial trajectory $t \mapsto \gamma(t)$ we have

$$\frac{\mathrm{d}\psi_\lambda(\gamma(t))}{\mathrm{d}t}\Big|_{t=0} = \mathrm{d}\psi_\lambda(\gamma'(0)) = \phi_\lambda(\gamma'(0)) < 0.$$

Since $\psi_\lambda(q_0) = 0$, this means that, for sufficiently small t, $\psi_\lambda(\gamma(t)) < 0$, and this shows that the points in Ψ_λ^+ are not reachable in small time, and so Σ is not locally configuration controllable. □

Remark 6. The spirit of the preceding proof is that of the single-input necessary condition appearing as Proposition 6.3 in the paper by Sussmann [35]. However, the modifications to the multi-input case by Hirschorn and Lewis [21] require some care.

Let us provide an example that nicely illustrates Theorems 4.4 and 4.6. This example is a slight modification of an example in [33].

Example 1. We take $Q = \mathbb{R}^2$ with (x, y) the usual Cartesian coordinates. We choose the affine connection on $\mathbb{R}^2$ with all vanishing Christoffel symbols except for $\Gamma_{xx}^y = x$. We choose the single-input vector field $Y = \frac{\partial}{\partial x}$. We also take $\mathsf{D} = TQ$. One then readily computes

$$\langle Y : Y \rangle = 2x\frac{\partial}{\partial y}, \qquad \langle Y : \langle Y : Y \rangle\rangle = 2\frac{\partial}{\partial y}.$$

We consider two cases.

1. $q_0 = (0, y)$, $y \in \mathbb{R}$: We readily see that $B_{\mathsf{Y}_{q_0}}(\langle Z_{q_0}(\mathscr{Y}), \mathsf{Y}_{q_0}\rangle)$ is identically zero, and so essentially indefinite. We also have $\mathtt{Sym}^{(2)}(\mathsf{Y})_{q_0} = T_{q_0}Q$. Therefore, Theorem 4.4 shows that $(Q, \nabla, \mathbf{D}, \{Y\})$ is properly STLC from q_0.

2. $q_0 \neq (0, y)$, $y \in \mathbb{R}$: Here we use $\mathrm{span}_{\mathbb{R}}\{\frac{\partial}{\partial y}\}$ as a model for $T_{q_0}Q/\mathsf{Y}_{q_0}$. Thus both Y_{q_0} and $T_{q_0}Q/\mathsf{Y}_{q_0}$ are one-dimensional, and so $B_{\mathsf{Y}_{q_0}}(\mathsf{Y}_{q_0})$ is essentially a quadratic function on $\mathbb{R}$. This quadratic function is then exactly $\xi \mapsto 2x\xi^2$. This function is definite, so Theorem 4.6 implies that the system is STLCUC from q_0.

Thus this example has the rather degenerate feature of being controllable on the y-axis but being uncontrollable at every point in a neighborhood of the y-axis. Note that this example is also a counterexample to a single-input result of one of the authors [23]. There it was stated that a single-input affine connection control system is STLCC if and only if the dimension of the configuration space is one. We see here that this is false. However, what is true is that a single-input affine connection control system is STLCC at all points in an *open subset* of configuration space if and only if the configuration space has dimension one.

5. Reductions of affine connection control systems. The controllability results of section 4 turn out to apply to a great many examples. That is to say, many interesting physical examples may be shown to be controllable or uncontrollable using these results. What is not obvious is that many of these systems are describable, in some sense, by a driftless system. This effectively simplifies the system, making certain control design tasks, especially motion planning, considerably simpler. In this section we introduce the framework for discussing these simplifications.

The objective in this section is then to relate second-order systems to first-order systems. In order to do this, one must be aware that the allowable inputs for the two classes of systems cannot be the same. For example, a trajectory for a first-order system using a discontinuous input will be continuous in configuration, but not in velocity. These velocity discontinuities are not allowed for second-order systems with bounded inputs. Therefore, we need to fix a set of inputs to use in each case, and they need to differ, essentially, by one integration. To be specific, we let $\mathscr{U}_{\mathrm{kin}}$ be the collection of locally absolutely continuous controls, and we let $\mathscr{U}_{\mathrm{dyn}}$ be the collection of locally integrable controls. The former will be used for first-order systems and the latter for second-order systems. In all cases, we allow controls to be defined on an arbitrary interval $I \subset \mathbb{R}$.

5.1. Kinematic reductions. In this section, in order to emphasize the difference between the two kinds of systems we are comparing, we shall denote an affine connection control system by $\Sigma_{\mathrm{dyn}} = (Q, \nabla, \mathbf{D}, \mathscr{Y}, \mathbb{R}^m)$. A *driftless system* is a triple $\Sigma_{\mathrm{kin}} = (Q, \mathscr{X} = \{X_1, \dots, X_{\tilde{m}}\}, U \subset \mathbb{R}^{\tilde{m}})$. The associated control system is then

$$\gamma'(t) = \sum_{\alpha=1}^{\tilde{m}} \tilde{u}^\alpha(t) X_\alpha(\gamma(t)), \tag{5.1}$$

so that a *controlled trajectory* is a pair $(\gamma, \tilde{u})$, where

1. $\gamma\colon I \to Q$ and $\tilde{u}\colon I \to U$ are both defined on the same interval $I \subset \mathbb{R}$,
2. $\tilde{u} \in \mathscr{U}_{\mathrm{kin}}$, and
3. $(\gamma, \tilde{u})$ together satisfy (5.1).

A driftless system $(Q, \mathscr{X}, U)$ is *STLC from* q_0 if the set of points reachable from q_0 contains q_0 in its interior, and a pair $(Q, \mathscr{X})$ is *properly STLC from* q_0 if $(Q, \mathscr{X}, U)$ is STLC from q_0 for every proper U. With our underlying assumption of analyticity, it is well known that $(Q, \mathscr{X})$ is properly STLC from q_0 if and only if $\mathtt{Lie}^{(\infty)}(\mathsf{X})_{q_0} = T_{q_0}Q$.

First we define what we mean by a kinematic reduction.

DEFINITION 5.1. *Let* $\Sigma_{\text{dyn}} = (Q, \nabla, \mathsf{D}, \mathscr{Y} = \{Y_1, \dots, Y_m\}, \mathbb{R}^m)$ *be an affine connection control system with* Y *having constant rank. A driftless system* $\Sigma_{\text{kin}} = (Q, \mathscr{X} = \{X_1, \dots, X_{\tilde{m}}\}, \mathbb{R}^{\tilde{m}})$ *is a* kinematic reduction *of* Σ_{dyn} *if*

(i) X *is a constant-rank subbundle of* D *and*

(ii) *for every controlled trajectory* (γ, u_{kin}) *for* Σ_{kin} *with* $u_{\text{kin}} \in \mathscr{U}_{\text{kin}}$*, there exists* $u_{\text{dyn}} \in \mathscr{U}_{\text{dyn}}$ *such that* (γ, u_{dyn}) *is a controlled trajectory for* Σ_{dyn}.

The rank *of the kinematic reduction* Σ_{kin} *is the rank of* X.

Thus kinematic reductions are driftless systems whose controlled trajectories, at least for controls in $\mathscr{U}_{\text{kin}}$, can be followed by controlled trajectories of Σ_{dyn}. Let us characterize kinematic reductions. To do so, recall that with our constant-rank assumptions, given an affine connection ∇ and a family of vector fields $\mathscr{Y} = \{Y_1, \dots, Y_m\}$ on Q, we may globally define B_{Y} as at the end of section 3.2. This also allows us to define a map $Q_{B_{\mathsf{Y}}} \colon \Gamma(TQ) \to \Gamma(TQ/\mathsf{Y})$ by $Q_{B_{\mathsf{Y}}}(X)(q) = B_{\mathsf{Y}}(q)(X(q), X(q))$. With this notation, we have the following result.

THEOREM 5.2. *Let* $\Sigma_{\text{dyn}} = (Q, \nabla, \mathsf{D}, \mathscr{Y}, \mathbb{R}^m)$ *be an affine connection control system with* Y *of constant rank and let* $\Sigma_{\text{kin}} = (Q, \mathscr{X}, \mathbb{R}^{\tilde{m}})$ *be a driftless system with* X *of constant rank. The following statements are equivalent:*

(i) Σ_{kin} *is a kinematic reduction of* Σ_{dyn}*;*

(ii) $\mathsf{Sym}^{(1)}(\mathsf{X}) \subset \mathsf{Y}$*;*

(iii) $\mathsf{X} \subset \mathsf{Y}$ *and* $Q_{B_{\mathsf{Y}}}|\mathsf{X} = 0$.

Proof. (i) $\Longrightarrow$ (ii) Let $X \in \Gamma(\mathsf{X})$ such that $X = \phi^\alpha X_\alpha$ for some $\phi^1, \dots, \phi^{\tilde{m}} \in \mathcal{F}(Q)$. For $q \in Q$, define controls $\tilde{u}_1, \tilde{u}_2 \in \mathscr{U}_{\text{kin}}$ by $\tilde{u}_1 = (\phi^1(q), \dots, \phi^{\tilde{m}}(q))$ and $\tilde{u}_2 = (1+t)\tilde{u}_1$. Let $(\gamma_1, \tilde{u}_1)$ and $(\gamma_2, \tilde{u}_2)$ be the corresponding controlled trajectories of Σ_{kin} satisfying $\gamma_1(0) = \gamma_2(0) = q$. Thus $\gamma_i'(t) = \sum_{\alpha=1}^{\tilde{m}} \tilde{u}_i^\alpha(t) X_\alpha(\gamma_i(t))$, $i \in \{1, 2\}$. We compute

$$\begin{aligned}\nabla_{\gamma_1'(t)}\gamma_1'(t) &= \sum_{\alpha,\beta=1}^{\tilde{m}} \nabla_{\tilde{u}_1^\alpha(t) X_\alpha(\gamma_1(t))} \tilde{u}_1^\beta(t) X_\beta(\gamma_1(t)) \\ &= \sum_{\alpha,\beta=1}^{m} \tilde{u}_1^\alpha(t)\tilde{u}_1^\beta(t) \nabla_{X_\alpha(\gamma_1(t))} X_\beta(\gamma_1(t)) + \dot{\tilde{u}}_1^\beta(t) X_\beta(\gamma_1(t)).\end{aligned}$$

Evaluating this at $t = 0$ gives

$$\nabla_{\gamma_1'(t)}\gamma_1'(t)\big|_{t=0} = \sum_{\alpha,\beta=1}^{\tilde{m}} \tilde{u}_1^\alpha(0)\tilde{u}_1^\beta(0) \nabla_{X_\alpha} X_\beta(q) + \dot{\tilde{u}}_1^\beta(0) X_\beta(q) = \nabla_X X(q).$$

Similarly, for γ_2 we have

$$\nabla_{\gamma_2'(t)}\gamma_2'(t)\big|_{t=0} = \nabla_X X(q) + X(q).$$

Therefore, since Σ_{kin} is a kinematic reduction of Σ_{dyn}, we have $\nabla_X X(q), \nabla_X X(q) + X(q) \in \mathsf{Y}_q$, or simply $X, \nabla_X X \in \Gamma(\mathsf{Y})$ since the above constructions can be performed for all $X \in \Gamma(\mathsf{X})$ and $q \in Q$. Therefore, for $X, Y \in \Gamma(\mathsf{X})$ we have the polarization identity,

$$\langle X : Y \rangle = \frac{1}{2}\big(\langle X + Y : X + Y \rangle - \langle X : X \rangle - \langle Y : Y \rangle\big) \in \Gamma(\mathsf{Y}), \tag{5.2}$$

which gives (ii).

(ii) $\Longrightarrow$ (iii) From the definition of B_{Y} we readily see that $Q_{B_{\mathsf{Y}}}|\mathsf{X} = 0$ exactly means that $\langle X : X\rangle = 2\nabla_X X \in \Gamma(\mathsf{Y})$ for each $X \in \Gamma(\mathsf{X})$. From this observation, the current implication follows easily by employing the formula for $\langle X : Y\rangle$ in (5.2).

(iii) $\Longrightarrow$ (i) As in the preceding step, we see that the condition $Q_{B_{\mathsf{Y}}}|\mathsf{X} = 0$ is equivalent to asserting that $\nabla_X X \in \Gamma(\mathsf{Y})$ for each $X \in \Gamma(\mathsf{X})$. By (5.2) this implies that $\langle X_\alpha : X_\beta\rangle \in \Gamma(\mathsf{Y})$ for $\alpha, \beta \in \{1, \dots, \tilde{m}\}$. Let $u_{\text{kin}} \in \mathscr{U}_{\text{kin}}$ and let (γ, u_{kin}) be the corresponding controlled trajectory for Σ_{kin}. We then have

$$\nabla_{\gamma'(t)}\gamma'(t) = u^\alpha_{\text{kin}}(t)u^\beta_{\text{kin}}(t)\nabla_{X_\alpha(\gamma(t))}X_\beta(\gamma(t)) + \dot{u}^\alpha_{\text{kin}}(t)X_\alpha(\gamma(t)).$$

We note that

$$u^\alpha_{\text{kin}}(t)u^\beta_{\text{kin}}(t)\nabla_{X_\alpha(\gamma(t))}X_\beta(\gamma(t)) = \frac{1}{2}u^\alpha_{\text{kin}}(t)u^\beta_{\text{kin}}(t)\langle X_\alpha(\gamma(t)) : X_\beta(\gamma(t))\rangle.$$

Since $X_\alpha, \langle X_\alpha : X_\beta\rangle \in \Gamma(\mathsf{Y})$ it now follows that $\nabla_{\gamma'(t)}\gamma'(t) \in \mathsf{Y}_{\gamma(t)}$, implying that there exists a control $u_{\text{dyn}} \in \mathscr{U}_{\text{dyn}}$ such that (γ, u_{dyn}) is a controlled trajectory for Σ_{dyn}. □

Of particular interest are kinematic reductions of rank one: $(Q, \{X_1\}, \mathbb{R})$. In this case, any vector field of the form $X = \phi X_1$, where $\phi \in \mathcal{F}(Q)$ is nowhere vanishing, is called a *decoupling vector field*. From Theorem 5.2 we have the following description of a decoupling vector field.

COROLLARY 5.3. *A vector field X is a decoupling vector field for $\Sigma_{\text{dyn}} = (Q, \nabla, \mathsf{D}, \mathscr{Y}, \mathbb{R}^m)$ if and only if $X, \nabla_X X \in \Gamma(\mathsf{Y})$.*

It is the notion of a decoupling vector field that was initially presented by Bullo and Lynch [13], and which is generalized by our idea of a kinematic reduction.

Remark 7. While in general, even when a kinematic reduction exists, it will not be easy to find, it turns out that in practice many examples exhibit kinematic reductions in a more or less obvious way. We shall see this in the examples below. Note that condition (iii) of Theorem 5.2 provides a set of algebraic equations that can, in principle, be solved to identify decoupling vector fields. This was discussed by Bullo and Lynch [13].

Next, let us consider affine connection control systems endowed with multiple kinematic reductions. It is interesting to characterize when the concatenation of controlled trajectories of the kinematic reductions gives rise to a controlled trajectory for the affine connection control system. Given two curves γ_1 and γ_2 on Q, let $\gamma_1 * \gamma_2$ be their concatenation. The following lemma follows immediately from the definition of a kinematic reduction.

LEMMA 5.4. *Consider an affine connection control system $\Sigma_{\text{dyn}} = (Q, \nabla, \mathsf{D}, \mathscr{Y}, \mathbb{R}^m)$ with two kinematic reductions $\Sigma_{\text{kin},1} = (Q, \mathscr{X}_1, \mathbb{R}^{m_1})$ and $\Sigma_{\text{kin},2} = (Q, \mathscr{X}_2, \mathbb{R}^{m_2})$. For $i \in \{1, 2\}$, let $(\gamma_i, u_{\text{kin},i})$ be a controlled trajectory for $\Sigma_{\text{kin,i}}$ defined on the interval $[0, T_i]$ with $u_{\text{kin},i} \in \mathscr{U}_{\text{kin}}$. There exists a control $u_{\text{dyn}} \in \mathscr{U}_{\text{dyn}}$ such that $(\gamma_1 * \gamma_2, u_{\text{dyn}})$ is a controlled trajectory for Σ_{dyn} if and only if $\gamma_1'(T_1) = \gamma_2'(0)$.*

Motivated by this result we make the following definition.

DEFINITION 5.5. *An affine connection control system $\Sigma_{\text{dyn}} = (Q, \nabla, \mathsf{D}, \mathscr{Y}, \mathbb{R}^m)$ is* kinematically controllable from $q_0 \in Q$ (KC from $q_0 \in Q$) *if there exists a finite collection*

$$\Sigma_{\text{kin},1} = (Q, \mathscr{X}_1, \mathbb{R}^{m_1}), \dots, \Sigma_{\text{kin},k} = (Q, \mathscr{X}_k, \mathbb{R}^{m_k})$$

of kinematic reductions for Σ_{dyn} such that $(Q, \mathscr{X}_1 \cup \cdots \cup \mathscr{X}_k)$ is properly STLC from q_0.

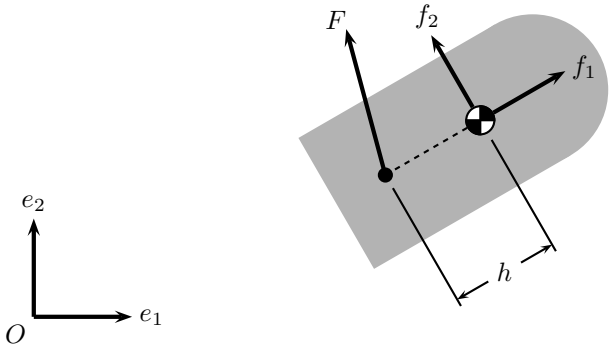

FIG. 5.1. *Planar rigid body with thruster.*

Remark 8.

1. For analytic systems, the condition that $(Q, \mathscr{X}_1 \cup \cdots \cup \mathscr{X}_k)$ be properly STLC from q_0 is equivalent to the condition that $\mathsf{Lie}^{(\infty)}(\mathsf{X}_1 + \cdots + \mathsf{X}_k)_{q_0} = T_{q_0}Q$, where $\mathsf{X}_1 + \cdots + \mathsf{X}_k$ denotes the fiberwise sum of the distributions $\mathsf{X}_1, \ldots, \mathsf{X}_k$.

2. If an affine connection control system $\Sigma_{\text{dyn}} = (Q, \nabla, \mathsf{D}, \mathscr{Y}, \mathbb{R}^m)$ is kinematically controllable from q_0, then it is STLCC from q_0. This fact is proved in Proposition 5.10 below, and we refer to section 5.3 for a discussion of the relationships between the various notions of controllability introduced in this paper.

3. Suppose the affine connection control system $\Sigma_{\text{dyn}} = (Q, \nabla, \mathsf{D}, \mathscr{Y}, \mathbb{R}^m)$ is kinematically controllable from all $q \in Q$. A standard control problem is to find a controlled trajectory connecting two given configurations $q_1, q_2 \in Q$, starting and ending with zero velocity. Lemma 5.4 says that this can be done for Σ_{dyn} by concatenating integral curves of decoupling vector fields where each segment is reparameterized to start and end at zero velocity. This is the viewpoint of Bullo and Lynch [13].

Example 2. We consider a planar rigid body with a variable-direction thruster as shown in Figure 5.1. The system has configuration manifold $SE(2)$. We use coordinates (x, y, θ) defined as follows. Let $\{e_1, e_2\}$ be an orthonormal frame in E^2 fixed at $O \in E^2$, and let $\{f_1, f_2\}$ be a body orthonormal frame attached to the center of mass and with the property that the vector f_1 points in the direction of the line connecting the center of mass with the point of application of the force (see Figure 5.1). Then (x, y) denote the position of the center of mass with respect to O, and θ is defined so that $f_1 = R(\theta)e_1$ with $R(\theta)$ the matrix giving a positive rotation by θ in E^2. With respect to these coordinates, the kinetic energy of the system is determined by the Riemannian metric

$$g = m\mathrm{d}x \otimes \mathrm{d}x + m\mathrm{d}y \otimes \mathrm{d}y + J\mathrm{d}\theta \otimes \mathrm{d}\theta,$$

where m is the mass of the body, and J is its inertia about the center of mass. Since the coefficients of this Riemannian metric are independent of the coordinates, the Christoffel symbols for the corresponding Levi-Civita affine connection are zero. As shown by Lewis and Murray [27], Newton's law with the force F as shown in Figure 5.1 is equivalent to (2.1) if the affine connection ∇ is the Levi-Civita connection associated with g and if the vector fields $\{Y_1, Y_2\}$ are chosen as follows:

$$Y_1 = \frac{\cos\theta}{m}\frac{\partial}{\partial x} + \frac{\sin\theta}{m}\frac{\partial}{\partial y}, \qquad Y_2 = -\frac{\sin\theta}{m}\frac{\partial}{\partial x} + \frac{\cos\theta}{m}\frac{\partial}{\partial y} - \frac{h}{J}\frac{\partial}{\partial\theta}.$$

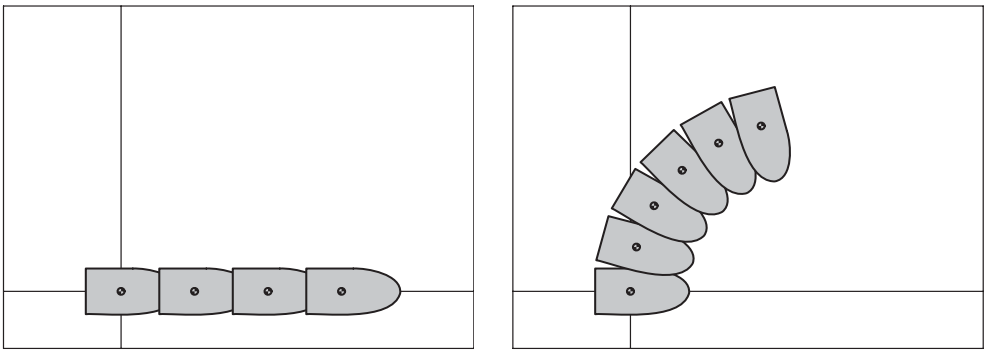

FIG. 5.2. *Decoupling motions for the planar rigid body: X_1 on the left and X_2 on the right.*

The system is unconstrained so we take $\mathsf{D} = TQ$.

We claim that the vector fields $X_1 = mY_1$ and $X_2 = mY_2$ are decoupling vector fields. Clearly, they are sections of Y. We also compute

$$\nabla_{X_1} X_1 = 0, \quad \nabla_{X_2} X_2 = \frac{mh\cos\theta}{J}\frac{\partial}{\partial x} + \frac{mh\sin\theta}{J}\frac{\partial}{\partial y}.$$

Therefore $\nabla_{X_1} X_1, \nabla_{X_2} X_2 \in \Gamma(\mathsf{Y})$, showing that X_1 and X_2 are indeed decoupling vector fields.

Let us explore the implications of the existence of these decoupling vector fields. Since X_1 and X_2 are decoupling vector fields, we may follow their integral curves. In Figure 5.2 we show motions of the body along sample integral curves of X_1 and X_2. In actuality, one can follow not only the integral curves of the decoupling vector fields but also any reparameterization of these vector fields. With this in mind, one has the following possible methodology for moving the body around in the plane:

1. Given $q_1, q_2 \in Q$, find a concatenation of the integral curves of X_1 and X_2 that connects q_1 with q_2. (This is possible since $\mathsf{Lie}^{(\infty)}(\mathsf{X}) = TQ$.)
2. Reparameterize each segment of the preceding concatenated curve so that each segment has zero initial and final velocity.
3. Because of Lemma 5.4, the resulting reparameterized curve can be followed by controlled trajectories of Σ_{dyn}.

This method for motion planning is explained in detail in [11, Chapter 13].

5.2. Maximally reducible systems. If $\Sigma_{\text{kin}} = (Q, \mathscr{X} = \{X_1, \dots, X_{\tilde{m}}\}, \mathbb{R}^{\tilde{m}})$ is a kinematic reduction of $\Sigma_{\text{dyn}} = (Q, \nabla, \mathsf{D}, \mathscr{Y} = \{Y_1, \dots, Y_m\}, \mathbb{R}^m)$, then, by definition, any controlled trajectory of Σ_{kin} may be followed by a controlled trajectory of Σ_{dyn}. In this section we wish to consider the possibility of the converse statement. The following definition, and the attendant Theorem 5.7 below, are due to Lewis [25].

DEFINITION 5.6. *An affine connection control system $\Sigma_{\text{dyn}} = (Q, \nabla, \mathsf{D}, \mathscr{Y} = \{Y_1, \dots, Y_m\}, \mathbb{R}^m)$ with Y of constant rank is* maximally reducible *to $\Sigma_{\text{kin}} = (Q, \mathscr{X} = \{X_1, \dots, X_{\tilde{m}}\}, \mathbb{R}^{\tilde{m}})$ if Σ_{kin} is a kinematic reduction of Σ_{dyn} and if for every controlled trajectory (γ, u_{dyn}) for Σ_{dyn} satisfying $\gamma'(0) \in \mathsf{X}_{\gamma(0)}$, there exists a control $u_{\text{kin}} \in \mathscr{U}_{\text{kin}}$ such that (γ, u_{kin}) is a controlled trajectory for Σ_{kin}.*

Before we proceed to characterize maximally reducible systems, let us illustrate that a system may not be maximally reducible to a given kinematic reduction.

Example 3 (Example 2 cont'd). We claim that the affine connection control system corresponding to the planar rigid body with a thruster is not maximally re-

ducible to either of the kinematic reductions $\Sigma_{\text{kin},1} = (Q, \mathscr{X}_1 = \{X_1\}, \mathbb{R})$ or $\Sigma_{\text{kin},2} = (Q, \mathscr{X}_2 = \{X_2\}, \mathbb{R})$ exhibited in Example 2. We shall exhibit this explicitly for $\Sigma_{\text{kin},1}$ and leave the other case to the reader.

Consider the control $t \mapsto u(t) = (0,1) \in \mathscr{U}_{\text{dyn}}$, along with the initial condition $\gamma'(0) = ((0,0,0),(1,0,0)) \in TQ$. We have $\gamma'(0) \in \mathsf{X}_{1,\gamma(0)}$, where X_1 is the distribution generated by the vector field X_1. If Σ_{dyn} is to be maximally reducible to $\Sigma_{\text{kin},1}$, then we should have $\gamma'(t) \in \mathsf{X}_{1,\gamma(t)}$ for each $t > 0$. To show that this is not the case, consider the governing equations for the system with the given control:

$$\ddot{x} = -\frac{\sin\theta}{m}, \quad \ddot{y} = \frac{\cos\theta}{m}, \quad \ddot{\theta} = -\frac{h}{J}.$$

Clearly the solution to this ordinary differential equation is not a reparameterization of the integral curve for X_1 through $\gamma(0)$ since the latter is given by $t \mapsto (t,0,0)$. Thus it cannot be that $\gamma'(t) \in \mathsf{X}_{1,\gamma(t)}$ for each $t > 0$.

Now let us establish when an affine connection control system is in fact maximally reducible to *some* driftless system. Note that in the statement of the following theorem, the driftless systems to which Σ_{dyn} is maximally reducible are characterized sharply.

THEOREM 5.7. *An affine connection control system* $\Sigma_{\text{dyn}} = (Q, \nabla, \mathsf{D}, \mathscr{Y} = \{Y_1, \dots, Y_m\}, \mathbb{R}^m)$, *with* Y *of constant rank, is maximally reducible to* $\Sigma_{\text{kin}} = (Q, \mathscr{X} = \{X_1, \dots, X_{\tilde{m}}\}, \mathbb{R}^{\tilde{m}})$ *if and only if the following two conditions hold:*

(i) $\mathsf{X} = \mathsf{Y}$;

(ii) $\mathsf{Sym}^{(\infty)}(\mathsf{Y}) = \mathsf{Y}$.

Proof. In the proof it is convenient to understand that the second-order system (2.1) on Q is equivalent to the first-order system on TQ given

$$\Upsilon'(t) = Z(\Upsilon(t)) + \sum_{a=1}^{m} u^a(t)\text{verlift}(Y_a)(\Upsilon(t)) \tag{5.3}$$

for a curve Υ on TQ, where Z is the geodesic spray for ∇ and $\text{verlift}(Y_a) \in \Gamma(TTQ)$ denotes the vertical lift of Y_a. This is discussed in Lewis and Murray [27]. Further, one may easily verify that a vector field X is a section of a distribution D if and only if $\text{verlift}(X)$ is tangent to $\mathsf{D} \subset TQ$. Also, Lewis [24] shows that condition (ii) is equivalent to the assertion that Y be geodesically invariant, by which we mean that geodesics $\gamma\colon I \to Q$ satisfying $\gamma'(t_0) \in \mathsf{Y}_{\gamma(t_0)}$ for some $t_0 \in I$ satisfy $\gamma'(t) \in \mathsf{Y}_{\gamma(t)}$ for all $t \in I$. Clearly, geodesic invariance of Y is equivalent to Y being an invariant submanifold for Z.

First suppose that Σ_{dyn} is maximally reducible to a driftless system Σ_{kin}. Let $\gamma\colon [0,T] \to Q$ be a geodesic so that $(\gamma', 0)$ is a controlled trajectory for Σ_{dyn}. If we ask that $\gamma'(0) \in \mathsf{X}$, then Definition 5.6 implies that there exists $u_{\text{kin}} \in \mathscr{U}_{\text{kin}}$ such that (γ, u_{kin}) is a controlled trajectory of Σ_{kin}. Indeed, u_{kin} is defined by

$$\gamma'(t) = \sum_{\alpha=1}^{\tilde{m}} u^\alpha_{\text{kin}}(t) X_\alpha(\gamma(t))$$

and so is smooth. Further, this implies that X is geodesically invariant. The remainder of this part of the proof will be directed towards showing that $\mathsf{X} = \mathsf{Y}$.

Let $\boldsymbol{e}_a$ be the ath standard basis vector for $\mathbb{R}^m$ and let $u_a\colon [0,T] \to \mathbb{R}^m$ be the control defined by $u_a(t) = \boldsymbol{e}_a$. Let $\Upsilon\colon [0,T] \to TQ$ be an integral curve for the

vector field $Z + \text{verlift}(Y_a)$, so that (Υ, u_a) satisfies (5.3). By Definition 5.6, Υ must be tangent to X. Since X is geodesically invariant, Z is tangent to X, and therefore $\text{verlift}(Y_a)$ must be tangent to X. This implies that $\mathsf{Y} \subset \mathsf{X}$.

To show that $\mathsf{X} \subset \mathsf{Y}$ we employ the following lemma.

LEMMA 5.8. *If a distribution D is geodesically invariant for an affine connection ∇, then for each $q \in Q$ and each $X \in \mathsf{D}_q$ there exist $T > 0$ and a smooth curve $\gamma\colon [0,T] \to Q$ with the following properties:*

(i) $\gamma'(t) \in \mathsf{D}_{\gamma(t)}$ *for* $t \in (0,T]$;

(ii) $\nabla_{\gamma'(0)}\gamma'(0) = X$.

Proof. Let (U, χ) be a normal coordinate chart [22, Proposition 8.4] with $\chi(q) = \mathbf{0}$. In such a chart the Christoffel symbols for ∇ satisfy $\Gamma^i_{jk}(\mathbf{0}) + \Gamma^i_{kj}(\mathbf{0}) = 0$, $i, j, k \in \{1, \dots, n\}$. Let $\tilde{T} > 0$ be small if necessary and let $\tilde{\gamma}\colon [0, \tilde{T}] \to Q$ be the geodesic satisfying $\tilde{\gamma}'(0) = X$. Let us denote the local representative of $\tilde{\gamma}$ in our normal coordinate chart by $t \mapsto (\tilde{q}^1(t), \dots, \tilde{q}^n(t))$. We must then have $\ddot{\tilde{q}}^i(0) = 0$, $i \in \{1, \dots, n\}$, since $\tilde{\gamma}$ is a geodesic and we are using normal coordinates. Since D is geodesically invariant, $\tilde{\gamma}'(t) \in \mathsf{D}_{\tilde{\gamma}(t)}$ for $t \in (0, \tilde{T}]$. Now define $\tau\colon [0, \tilde{T}] \to [0, \frac{1}{2}\tilde{T}^2]$ by $\tau(t) = \frac{1}{2}t^2$. Let $T = \frac{1}{2}\tilde{T}^2$, define $\gamma\colon [0,T] \to Q$ by $\gamma = \tilde{\gamma} \circ \tau$, and denote by $t \mapsto (q^1(t), \dots, q^n(t))$ the local representative of γ. Then we have

$$\dot{q}^i(t) = \frac{2t\dot{\tilde{q}}^i(t)}{T}, \qquad i \in \{1, \dots, n\},$$
$$\ddot{q}^i(0) = \dot{\tilde{q}}^i(0), \qquad i \in \{1, \dots, n\}.$$

Since $\tilde{\gamma}'(0) = X$ the result follows, and the proof of the lemma is complete. ∎

Now let $q \in Q$ and $X \in \mathsf{X}_q$. Choose a curve $\gamma\colon [0,T] \to Q$ as in the lemma. Define a smooth map $u_{\text{kin}}\colon [0,T] \to \mathbb{R}^{\tilde{m}}$ by asking that it satisfy

$$\gamma'(t) = \sum_{\alpha=1}^{\tilde{m}} u^\alpha_{\text{kin}}(t) X_\alpha(\gamma(t)).$$

Then (γ, u_{kin}) is a controlled trajectory for Σ_{kin}. Therefore, by Definition 5.6, there exists a map $u_{\text{dyn}}\colon [0,T] \to \mathbb{R}^m$ such that $(\gamma', u_{\text{dyn}})$ is a controlled trajectory for $(TQ, \mathscr{X}_{\Sigma_{\text{dyn}}}, \mathbb{R}^m)$. Indeed, since γ' is smooth, u_{dyn} will also be smooth. Furthermore, we have

$$X = \nabla_{\gamma'(0)}\gamma'(0) = \sum_{a=1}^{m} u^a_{\text{dyn}}(0) Y_a(\gamma(0)).$$

This shows that $\mathsf{X} \subset \mathsf{Y}$, which completes the proof of the "only if" part of the theorem.

Now suppose that parts (i) and (ii) of the theorem hold. Let us work locally, so we may as well assume that the vector fields $\{Y_1, \dots, Y_m\}$ and $\{X_1, \dots, X_{\tilde{m}}\}$ are linearly independent (and so $\tilde{m} = m$). First, part (ii) implies that Y is an invariant submanifold for the system $(TQ, \mathscr{X}_{\Sigma_{\text{dyn}}}, \mathbb{R}^m)$, since $\text{verlift}(Y_a)$, $a \in \{1, \dots, m\}$, is tangent to Y. If $(\Upsilon, u_{\text{dyn}})$ is a controlled trajectory of $(TQ, \mathscr{X}_{\Sigma_{\text{dyn}}}, \mathbb{R}^m)$, then $\Upsilon\colon [0,T] \to TQ$ is absolutely continuous, and so $\gamma \triangleq \tau_Q \circ \Upsilon$ is also absolutely continuous. In fact, $\Upsilon = \gamma'$, and so not only is γ absolutely continuous but γ' is also absolutely continuous. If we further suppose that $\gamma'(0) \in \mathsf{Y}_{\gamma(0)}$, then $\gamma'(t) \in \mathsf{Y}_{\gamma(t)}$ for $t \in [0,T]$. We may then define $u_{\text{kin}}\colon [0,T] \to \mathbb{R}^{\tilde{m}}$ by $\gamma'(t) = u^\alpha_{\text{kin}}(t) X_\alpha(\gamma(t))$, which uniquely defines u_{kin} since $(TQ, \mathscr{X}_{\Sigma_{\text{dyn}}}, \mathbb{R}^m)$ leaves Y, and hence X, invariant. It is clear that u_{kin} is absolutely continuous.

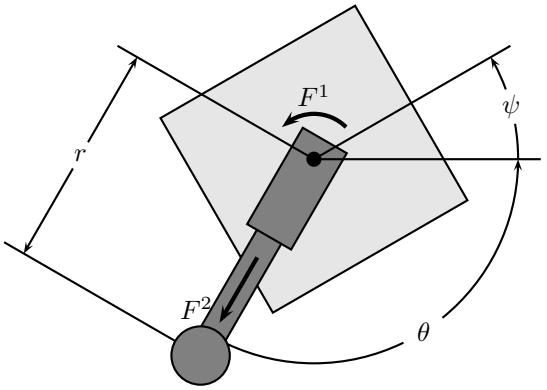

FIG. 5.3. *The robotic leg.*

Finally, let (γ, u_{kin}) be a controlled trajectory for Σ_{kin}. Thus γ' is absolutely continuous. Since Y, and therefore X, are geodesically invariant, $\nabla_{\gamma'(t)}\gamma'(t) \in \mathsf{Y}_{\gamma(t)}$ for $t \in [0,T]$. Thus we may write

$$\nabla_{\gamma'(t)}\gamma'(t) = \sum_{a=1}^{m} u^a_{\text{dyn}}(t) Y_a(\gamma(t)),$$

which defines $u_{\text{dyn}} \colon [0,T] \to \mathbb{R}^m$. It is clear that u is locally integrable, and this completes the proof. □

Remark 9. Note that all driftless systems to which a given affine connection control system $\Sigma_{\text{dyn}} = (Q, \nabla, \mathsf{D}, \mathscr{Y} = \{Y_1, \dots, Y_m\}, \mathbb{R}^m)$ is maximally reducible are essentially the same, by which we mean that for two such driftless systems, $\Sigma_{\text{kin}} = (Q, \mathscr{X} = \{X_1, \dots, X_m\}, \mathbb{R}^m)$ and $\tilde{\Sigma}_{\text{kin}} = (Q, \tilde{\mathscr{X}} = \{\tilde{X}_1, \dots, \tilde{X}_{\tilde{m}}\}, \mathbb{R}^{\tilde{m}})$, we have $\mathsf{X} = \tilde{\mathsf{X}}$. Thus, without loss of generality, we may take $(Q, \{Y_1, \dots, Y_m\}, \mathbb{R}^m)$ as the system to which Σ_{dyn} is maximally reducible. For this reason, it makes sense to simply say that Σ_{dyn} is *maximally reducible* if it is maximally reducible to *some* driftless system.

Let us give an example of a system that is maximally reducible.

Example 4. We consider the robotic leg system depicted in Figure 5.3. The configuration space for the system is $Q = \mathbb{R}_+ \times \mathbb{S}^1 \times \mathbb{S}^1$, and the coordinates we use are (r, θ, ψ), as indicated in Figure 5.3. The Riemannian metric for the system is

$$g = m(\mathrm{d}r \otimes \mathrm{d}r + r^2 \mathrm{d}\theta \otimes \mathrm{d}\theta) + J\mathrm{d}\psi \otimes \mathrm{d}\psi,$$

where m is the mass of the particle on the end of the extensible massless leg, and J is the moment of inertia of the base rigid body about the pivot point. The nonzero Christoffel symbols for the associated affine connection are $\Gamma^r_{\theta\theta} = -r$ and $\Gamma^\theta_{r\theta} = \Gamma^\theta_{\theta r} = \frac{1}{r}$. Lewis and Murray [27] show that if we define Y_1 and Y_2 by

$$Y_1 = \frac{1}{mr^2}\frac{\partial}{\partial\theta} - \frac{1}{J}\frac{\partial}{\partial\psi}, \quad Y_2 = \frac{1}{m}\frac{\partial}{\partial r},$$

then the equations of motion for the system are of the form (2.1), where ∇ is the Levi-Civita connection associated with g. There are no constraints on the system, so we take $\mathsf{D} = TQ$.

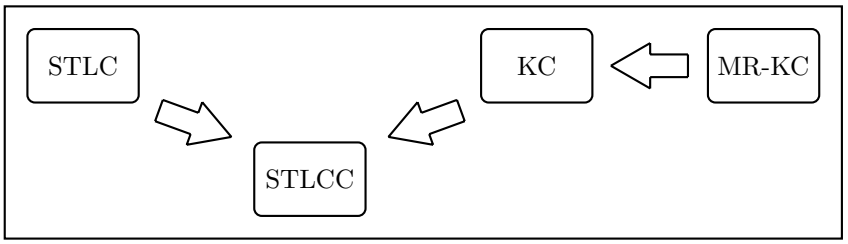

FIG. 5.4. *Relationships between various forms of controllability for affine connection control systems.*

One readily computes

$$\langle Y_1 : Y_1 \rangle = -\frac{2}{m^2 r^3} \frac{\partial}{\partial r}, \quad \langle Y_1 : Y_2 \rangle = 0, \qquad \langle Y_2 : Y_2 \rangle = 0.$$

This shows that Y is geodesically invariant. Thus the corresponding affine connection control system Σ_{dyn} is maximally reducible to $(Q, \{Y_1, Y_2\}, \mathbb{R}^2)$.

Since $\mathtt{Sym}^{(\infty)}(\mathsf{Y}) = \mathsf{Y}$ for an affine connection control system that is maximally reducible to a driftless system, by Remark 8(2) such an affine connection control system, if analytic, is STLCC from $q \in Q$ if and only if $\mathtt{Lie}^{(\infty)}(\mathsf{Y})_q = T_q Q$. Thus we make the following definition.

DEFINITION 5.9. *A maximally reducible affine connection control system* $\Sigma_{\text{dyn}} = (Q, \nabla, \mathsf{D}, \mathscr{Y}, \mathbb{R}^m)$ *is* maximally reducibly kinematically controllable from $q_0 \in Q$ (MR-KC from q_0) *if* $(Q, \mathscr{Y})$ *is properly STLC from* q_0.

5.3. Relationships to controllability. The appearance in Theorem 5.2 of the vector-valued quadratic form B_{Y} raises questions about how the notion of kinematic reductions is related to the low-order controllability results of section 4. In this section we describe the proper relationships. In [12] counterexamples are provided to show that one cannot generally improve on the relationships presented here.

Let $\Sigma_{\text{dyn}} = (Q, \nabla, \mathsf{D}, \mathscr{Y}, \mathbb{R}^m)$ be an affine connection control system. First let us list the various types of controllability we have at hand for Σ_{dyn} from a point $q_0 \in Q$:

1. small-time local controllability (STLC);
2. small-time local configuration controllability (STLCC);
3. kinematic controllability (KC);
4. maximal reducible kinematic controllability (MR-KC).

The relationships between these concepts are demonstrated in Figure 5.4. Let us show that these implications do indeed hold.

PROPOSITION 5.10. *For an analytic affine connection control system* $\Sigma_{\text{dyn}} = (Q, \nabla, \mathsf{D}, \mathscr{Y}, \mathbb{R}^m)$ *and for* $q_0 \in Q$, *the implications of Figure* 5.4 *hold.*

Proof. The implications STLC $\Longrightarrow$ STLCC and MR-KC $\Longrightarrow$ KC follow directly from the definitions of the various notions of controllability involved. Thus we need only show that KC $\Longrightarrow$ STLCC. We let

$$\Sigma_{\text{kin},1} = (Q, \mathscr{X}_1, \mathbb{R}^{m_1}), \ldots, \Sigma_{\text{kin},k} = (Q, \mathscr{X}_k, \mathbb{R}^{m_k})$$

be a collection of kinematic reductions for which $\mathtt{Lie}^{(\infty)}(\mathsf{X}_1 + \cdots + \mathsf{X}_k)_{q_0} = T_{q_0} Q$, where $\mathsf{X}_1 + \cdots + \mathsf{X}_k$ denotes the fiberwise sum of the distributions $\mathsf{X}_1, \ldots, \mathsf{X}_k$. Let $\mathscr{X} = \mathscr{X}_1 \cup \cdots \cup \mathscr{X}_k$. Note that since $\mathsf{X}_i \subset \mathsf{Y}$, Σ_{dyn} is STLCC from q_0 if $(Q, \nabla, \mathsf{D}, \mathscr{X})$

is properly STLCC from q_0. Select vector fields $X_{a_1}, \dots, X_{a_\ell}$ from the family $\mathscr{X}$ such that $\{X_{a_1}(q_0), \dots, X_{a_\ell}(q_0)\}$ is a basis for X_{q_0}. For brevity, let us denote by $B \in \Sigma_2(\mathsf{Y}_{q_0}; T_{q_0}Q/\mathsf{Y}_{q_0})$ the vector-valued quadratic form $B_{\mathsf{Y}}(q_0)$. By Theorem 5.2 we know that $Q_B|\mathsf{X}_{i,q_0} = 0$, $i \in \{1, \dots, k\}$. It therefore follows that for each $\lambda \in \operatorname{ann}(\mathsf{Y}_{q_0})$, $\lambda B(X_{a_j}(q_0), X_{a_j}(q_0)) = 0$, $j \in \{1, \dots, \ell\}$. From Lemma 3.3 this means that λB is essentially indefinite, and since this holds for every $\lambda \in \operatorname{ann}(\mathsf{Y}_{q_0})$, B is itself essentially indefinite. Therefore, by Theorem 4.4, $(Q, \nabla, \mathsf{D}, \mathscr{X})$ is properly STLCC if $\mathsf{Lie}^{(\infty)}(\mathsf{X})_{q_0} = T_{q_0}Q$. The result now follows directly. □

Remark 10. Note that all implications in Figure 5.4 are local. There are implications for global notions of controllability that follow from the local notions, but we do not consider this in a systematic way, as the understanding of global controllability of affine connection control systems is, as yet, poor.

A SMALL-GAIN THEORY FOR LIMIT CYCLES OF SYSTEMS ON LURÉ FORM*

ULF T. JÖNSSON† AND ALEXANDRE MEGRETSKI‡

Abstract. Local exponential stability and local robustness for limit cycle solutions of ordinary differential equations can be verified using the characteristic multipliers. These well-known results are here generalized to a class of infinite-dimensional systems. Stability and robustness are now verified using certain invertibility conditions on the linear equations that are obtained when the system is linearized along the limit cycle. The new criterion reduces to the classical condition on the characteristic multipliers when we consider a finite-dimensional system which is perturbed by a bounded but possibly infinite-dimensional operator. The computation of a robustness margin, i.e., a bound on the maximally allowed perturbation, is also considered.

Key words. limit cycles, uncertain system, robustness

1. Introduction.

Autonomous oscillations appear frequently in physical systems [4]. Such oscillations may appear naturally as in population dynamics and the motion of the planets or through intentional engineering design such as in electronic and mechanical oscillators. The system models used to generate such periodic solutions are often based on finite-dimensional ordinary differential equations (ODE). The robustness of these mathematical models is an important topic of investigation. For example, if a population model predicts an oscillatory solution, will there remain a nearby oscillation if unmodeled species are taken into account? Similarly, will an electronic oscillator function in the presence of stray capacitances and other unmodeled dynamics?

There is rich literature treating stability and robustness of periodic solutions of autonomous ODE. Stability and perturbation results were obtained early in [11, 2] and are discussed in many books on ODE theory and periodic systems; see, e.g., [3, 6, 4, 17]. These stability and robustness criteria are stated as a condition on the characteristic multipliers corresponding to the variational system which is obtained when the system is linearized around the nominal periodic solution. By using an extension of the implicit function theorem it is possible to determine bounds on the allowed perturbation [10, 4]. An extension of the stability results to infinite-dimensional systems has been obtained in [12]; see also [4]. Here we consider the above questions for systems consisting of a feedback interconnection of a linear time invariant (LTI) transfer function with a nonlinear function. No assumption is made on the dimension of the transfer function. This class of systems appear frequently in control applications under the name of the Luré system. Our main results are stated as invertibility conditions for certain linear operators corresponding to the variational system that

appear when the system is linearized along the periodic trajectory. This allows us to obtain robustness results that can be verified using techniques from robust control.

There are to our knowledge only a few results on robustness of oscillations in autonomous systems. A recent contribution by Georgiou and Smith considers robustness of a one-dimensional relaxation oscillator consisting of a relay hysteresis and an integrator [5]. By using the gap metric topology and suitably chosen function spaces they can prove that there remains an oscillatory solution (not necessarily periodic) as long as the perturbation of the integrator is sufficiently small in the gap topology. Varigonda extended the result to a new case in [14]. Yakubovich gave sector conditions for oscillatory solutions of a class of nonlinear systems in [15]. In [13], Stokes consider functional differential equations perturbed by an operator that vanish asymptotically as time tends to infinity.

The results obtained in this paper are different from the above in both the assumptions on the system and the obtained results. We consider a class of continuously differentiable systems and provide conditions which guarantee existence of an exponentially stable periodic solution for a general class of perturbations.

2. Problem formulation. We consider the following class of infinite-dimensional systems:

$$y(t) = \int_{-\infty}^{t} h(t-\tau,\theta)\varphi(y(\tau),\theta)\,d\tau, \tag{2.1}$$

where the impulse response function $h(t,\theta)$ and the nonlinearity $\varphi(y,\theta)$ are C^1 with respect to both arguments. We will state the exact assumptions on these functions below, but for now it is enough to think of the system as a feedback interconnection of an exponentially stable LTI plant and a memoryless nonlinearity. The system is called *nominal* when $\theta = 0$ and we assume the nominal system has a nontrivial isolated T_0-periodic solution $y_0(t) = y_0(t+T_0)\ \forall t$. Such solutions are called *limit cycles*. The case when $h(t,\theta)$ is finite-dimensional when $\theta = 0$ and infinite-dimensional for $\theta \neq 0$ is particularly interesting in applications because system design and system modeling are often done based on finite-dimensional approximations. The theory developed in this paper allows the systems analyst to rigorously verify that a modeled or designed limit cycle will also appear in the true infinite-dimensional system. The parameter θ should be viewed as a scaling of a class of infinite-dimensional perturbations. A typical case is illustrated in Figure 2.1, where S_0 denotes a finite-dimensional system with a periodic solution, Δ is a perturbation described by some norm bound, and θ scales the perturbation. In the next section we make some further connections to the standard models of robust control.

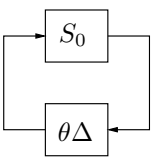

FIG. 2.1. *S_0 is a low-dimensional nominal system with limit cycle solution and $\theta\Delta$ is an infinite-dimensional but bounded perturbation. We derive conditions on S_0 that ensure existence of a stable limit cycle when θ is bounded away from zero.*

We also note that the classical model

$$\dot{x}(t) = f(x(t),\theta), \tag{2.2}$$

where f is C^1, a special case of system (2.1). Indeed, (2.2) can be written as $\dot{x} = Ax + \varphi(x,\theta)$, where A is stable and $\varphi(x,\theta) = f(x,\theta) - Ax$. Hence, the system can be represented as in (2.1) with $y = x$ and $h(t,\theta) = e^{At}\nu(t)$, where $\nu(t)$ is the unit step function. We assume that when $\theta = 0$, then (2.2) has a nontrivial T_0-periodic solution x_0. Conditions for existence and exponential stability of limit cycles are in the classical literature derived using the linearization of (2.2) along the nominal periodic solution

$$\dot{v} = f'_x(x_0(t),0)v.$$

This system cannot be asymptotically stable since $v(t) = f(x_0(t),0)$ is a nontrivial solution. This means that the monodromic matrix defined as $\Phi(T_0,0)$, where

$$\frac{d}{dt}\Phi(t,0) = f'_x(x_0(t),0)\Phi(t,0), \quad \Phi(0,0) = I,$$

has at least one eigenvalue at 1. The eigenvalues of $\Phi(T_0,0)$ are called the *characteristic multipliers* of $f'_x(x_0(t),0)$. We have thus seen that one characteristic multiplier must be 1. It can be proven that if $\lambda = 1$ is a simple characteristic multiplier of $f'_x(x_0(t),0)$, then for all sufficiently small θ there exists a periodic solution x_θ with period T_θ, which both are C^1 functions with respect to θ. Moreover, if all other characteristic multipliers are strictly inside the unit disc, then x_θ is locally exponentially stable. Proofs and exact formulations of these results can be found in [4, 3].

In this paper we extend the classical results to systems of the form (2.1). The development bears some similarities with the classical finite-dimensional theory. There will be, just as in the finite-dimensional case, a neutrally stable mode in the linearization of the dynamics (2.1) along the periodic solution. The classical results were derived using the implicit function theorem in a suitably chosen coordinate system, where the coordinate corresponding to the neutrally stable mode of the linearized dynamics can be removed. Here we use similar ideas in an operator setting. To prove exponential stability we use the concept *stability defect*, which allows us to move the neutrally stable mode into the unstable region, and then the implicit function theorem can be used. To prove structural robustness we use a version of the implicit function theorem that only require right invertibility of the linearized dynamics and thus overcome the problem with the neutrally stable mode.

2.1. Notation and assumptions. For a large part of this paper we consider a version of system (2.1) where the period time is normalized to 1. It is then natural to consider as solution space the set of continuous 1-periodic functions equipped with the norm $\|v\|_{C(1)} = \sup_{t\in[0,1]}|v(t)|$, which here is denoted by $C(1)$. For computational reasons we will state many of our results in terms of operators defined on $\mathbf{L}_2(1)$, the space of locally square integrable 1-periodic functions with the norm $\|v\|^2_{\mathbf{L}_2(1)} = \int_0^1 |v(t)|^2\,dt$. All our main results can, due to this choice of function space, be verified using methods from linear quadratic optimization.

The exponentially weighted $\mathbf{L}_2$ space ($\alpha > 0$)

$$\mathbf{L}_{2\alpha}[0,\infty) = \left\{ e(t) \in \mathbf{L}_2[0,\infty) : \int_0^\infty e^{2\alpha t}|e(t)|^2\,dt < \infty \right\} \tag{2.3}$$

will be used to define and prove exponential stability. The norm on the usual $\mathbf{L}_2[0,\infty)$ space is denoted as $\|\cdot\|$ while the norm on $\mathbf{L}_{2\alpha}[0,\infty)$ is denoted and defined as $\|v\|_\alpha = (\int_0^\infty e^{2\alpha t}|v(t)|^2\,dt)^{1/2}$. The spatial norm will always be the Euclidean norm

$|v| = (\sum_{i=1}^n v_i^2)^{1/2}$. At several places we consider the space $C(1) \times \mathbf{R}$ with the norm $\|(v,T)\|_{C(1)\times\mathbf{R}} = (\|v\|_{C(1)}^2 + |T|^2)^{1/2}$. Similarly, $\mathbf{L}_2(1) \times \mathbf{R}$ is equipped with the norm $\|(v,T)\|_{\mathbf{L}_2(1)\times\mathbf{R}} = (\|v\|_{\mathbf{L}_2(1)}^2 + |T|^2)^{1/2}$.

We also use that the characteristic multipliers (the Floquet multiplier) of a periodic matrix $A(t) = A(t+T_0)$ are the eigenvalues of the monodromy matrix $\Phi(T_0, 0)$, where

$$\frac{d}{dt}\Phi(t,0) = A(t)\Phi(t,0), \quad \Phi(0,0) = I.$$

The impulse response function in (2.1) is assumed to be a strictly proper exponentially stable system with the decay rate α.

DEFINITION 2.1 (strictly proper exponentially stable system (SPES)). *The impulse response function $h : \boldsymbol{R}^+ \to \boldsymbol{R}^p$ is exponentially stable if there exists $\epsilon > 0$ such that $e^{\epsilon t}h(t) \in \boldsymbol{L}_1[0,\infty)$. It is exponentially stable with the decay rate α if $e^{\alpha t}h(t) \in \boldsymbol{L}_1[0,\infty)$. We further say that h is a strictly proper exponentially stable system if additionally the differential of h has the form*

$$dh(t) = \dot{h}_c(t)\,dt + \sum_{k=0}^{\infty} h_k \delta(t - t_k)\,dt,$$

where $\delta(\cdot)$ denotes the Dirac impulse, $0 = t_0 < t_1 < t_2 \cdots$, and

$$e^{\epsilon t}\dot{h}_c \in \boldsymbol{L}_1[0,\infty), \quad \sum_{k=0}^{\infty} e^{\epsilon t_k}|h_k| < \infty$$

for some $\epsilon > 0$. If h is SPES, then the system output $y(t) = \int_{-\infty}^t h(t-\tau)v(\tau)\,d\tau$ belongs to $C(1)$ for $v \in C(1)$ and is differentiable with

$$\begin{aligned}\dot{y}(t) &= h(0)v(t) + \int_{-\infty}^t dh(t-\tau)v(\tau) \\ &= h(0)v(t) + \int_{-\infty}^t \dot{h}_c(t-\tau)v(\tau)\,d\tau + \sum_{k=0}^{\infty} h_k v(t-t_k),\end{aligned}$$

which also belongs to $C(1)$. As the norm on the convolution operators defined by h and dh we use

$$\begin{aligned}\|h\|_1 &= \int_0^\infty |h(t)|\,dt, \\ \|dh\|_1 &= \int_0^\infty |\dot{h}_c(t)| + \sum_{k=0}^{\infty} |h_k|.\end{aligned} \tag{2.4}$$

If h is SPES with the decay rate α, then the Laplace transforms $H(s)$ and $sH(s)$ are (i) *analytic in* $\operatorname{Re} s > -\alpha$, (ii) *continuous on* $-\alpha + i\boldsymbol{R}$, *and* (iii) *bounded such that for* $\operatorname{Re} s \geq -\alpha$ *we have* $\max(|sH(s,\theta)|, |H(s,\theta)|) \leq b$ *for some number b.*

REMARK 1. *The norms in* (2.4) *provide bounds on the induced norm of the convolution operators defined by h and dh in all applications of the paper. Sometimes we use the spaces $\boldsymbol{L}_2[0,\infty)$ and $\boldsymbol{L}_2(1)$ and then better estimates on the induced norm can be obtained for systems involving convolution with h.*

The results of the following lemma will be used in the paper.

LEMMA 2.2. *Suppose h is a strictly proper exponentially stable system. Then*
(a) $\|tdh(t)\|_1 < \infty$,
(b) $h(t)$ *is a bounded function which converges to zero with exponential rate, i.e.,* $|h(t)| \le ce^{-\epsilon t}$ *for some* $c, \epsilon > 0$,
(c) *if the decay rate is* α, *then* $e^{\alpha t}h(t) \in \boldsymbol{L}_2[0, \infty)$.

We let $\mathcal{L}(V_1, V_2)$ denote the vector space of bounded linear operators that map a normed vector space V_1 into another normed vector space V_2. The induced norm of $F \in \mathcal{L}(V_1, V_2)$ is denoted by $\|F\|_{V_1 \to V_2}$ unless $V_1 = V_2 = \mathbf{L}_2$ in which case we use the simplified notation $\|F\|$.

Next follows some terminology from nonlinear functional analysis; see, for example, [1] for further reference. Let V_1, V_2, V_3 be normed vector spaces and let $U_1 \subset V_1$, $U_2 \subset V_2$ be open subsets. A nonlinear operator $F : U_1 \to V_3$ is said to be continuously differentiable (C^1) if there exists a continuous operator $F' : U_1 \to \mathcal{L}(V_1, V_3)$ such that

$$\lim_{u \to u_0} \frac{\|F(u) - F(u_0) - F'(u_0)(u - u_0)\|_{V_3}}{\|u - u_0\|_{V_1}} = 0 \tag{2.5}$$

for each $u_0 \in U_1$. The derivative F' is called the Fréchet derivative. If F is a C^1 function of two variables, i.e., $F : U_1 \times U_2 \to V_3$, then the partial derivatives are denoted by $F'_{u_i} : U_1 \times U_2 \to \mathcal{L}(V_i, V_3)$ for $i = 1, 2$.

The kernel and the image of a linear operator $L \in \mathcal{L}(V, V)$ are defined as $\operatorname{Ker} L = \{v \in V : Lv = 0\}$ and $\operatorname{Im} L = \{Lv : v \in V\}$. The codimension of $\operatorname{Im} L$ is the dimension of the quotient space $V/\operatorname{Im} L$. An operator $L \in \mathcal{L}(V, V)$ is called a Fredholm operator if $\operatorname{Ker} L$ and the codimension of $\operatorname{Im} L$ both are finite-dimensional.

2.2. Summary of problem formulation. We consider system (2.1) under the following assumption.

Assumption 1. For system (2.1) we assume that
(i) the impulse response function $h(t, \theta)$ and the nonlinearity $\varphi(y, \theta)$ are defined for all θ on an open interval I_θ, which contains 0;
(ii) φ is continuously differentiable with respect to both arguments;
(iii) h is continuously differentiable with respect to θ and SPES with the decay rate α for every $\theta \in I_\theta$;
(iv) there exists a T_0-periodic solution y_0 of (2.1) for the case when $\theta = 0$.

In order to define exponential stability of systems of the form (2.1) we consider a system without perturbation. An absolutely continuous function $y_0(t)$ is called a T-periodic solution of the system equation if $y_0(t) = y_0(t + T)$ $\forall t$ and

$$y_0(t) = \int_{-\infty}^{t} h(t - \tau)\varphi(y_0(\tau))\, d\tau \quad \forall t. \tag{2.6}$$

To introduce the notion of local exponential stability of a given T-periodic solution $y_0(t)$, we consider the *non-steady-state* version of (2.6), defined as

$$y(t) = f(t) + \int_{0}^{t} h(t - \tau)\varphi(y(\tau))\, d\tau, \quad t \ge 0. \tag{2.7}$$

In (2.7), $f(\cdot)$ represents initial conditions and external disturbances. The choice

$$f_0(t) = \int_{-\infty}^{0} h(t - \tau)\varphi(y_0(\tau))\, d\tau \tag{2.8}$$

gives the T-periodic solution $y_0(t)$, since (2.7) has a unique solution for any locally integrable function $f(\cdot)$.

By exponential stability of the solution y_0 we will mean that for all f *close* to f_0 the solution y of (2.7) will *converge exponentially* to y_0.

DEFINITION 2.3. *The T-periodic solution y_0 is said to be* locally exponentially stable *if there exist $\alpha > 0$, $\delta > 0$, and $c > 0$ such that for any f satisfying the condition*

$$|f(t) - f_0(t)| \le \delta \quad \forall t \ge 0; \tag{2.9}$$

the corresponding solution y of (2.7) *satisfies the inequality*

$$\int_0^\infty e^{2\alpha t}|y(t) - y_0(t+d)|^2\,dt + |d|^2 \le c\int_0^\infty e^{2\alpha t}|f(t) - f_0(t)|^2\,dt \tag{2.10}$$

for some $d \in \boldsymbol{R}$.

The presence of the *phase shift* parameter d in (2.10) is necessary. It can be shown that with d fixed at $d = 0$, no nonequilibrium solution y_0 of (2.6) satisfies (2.10).

The following problem is considered in the paper.

PROBLEM 1. *Given Assumption* 1*, derive a sufficient condition for the existence of an open interval $\mathcal{I}_\theta \subset I_\theta$ around the origin with the property that for each $\theta \in \mathcal{I}_\theta$, there exists a unique exponentially stable periodic solution $y(t,\theta)$ of* (2.1) *with period $T(\theta)$ and with the property that $y(t,\theta)$ and $T(\theta)$ are C^1 in θ with $y(t,0) = y_0(t)$ and $T(0) = T_0$.*

REMARK 2. *We often use the notation $y_\theta(t) := y(t,\theta)$ and $T_\theta := T(\theta)$ for brevity.*

We will also derive a numerical procedure to verify a bound on θ for which there exists an exponentially stable periodic solution of (2.1) with orbit and period time within a given prespecified tolerance of the nominal solution. To do this we will normalize the nominal period time by the transformation $t/T_0 \to t$, which gives the nominal dynamics

$$y_0(t) = \int_{-\infty}^t T_0 h(T_0(t-\tau),0)\varphi(y_0(\tau),0)\,d\tau.$$

Hence, by redefining $T_0 h(T_0 t, 0) \to h(t,0)$ we can assume $T_0 = 1$. A general T-periodic solution of (2.1) can thus be written as

$$y(t) = \int_{-\infty}^t Th(T(t-\tau),\theta)\varphi(y(\tau),\theta)\,d\tau, \tag{2.11}$$

where y is the trajectory with period normalized to 1 and T is the period time. For the normalized dynamics in (2.11) we use an equivalent formulation of Assumption 1.

Assumption 2. For system (2.11) we assume (i)–(iii) in Assumption 1 together with

(iv′) there exists a 1-periodic solution y of (2.11) for the case when $\theta = 0$ and $T = 1$.

An advantage with the model class (2.11) is that we separate the orbit from the period time so the problem is to determine the existence of a pair (y_θ, T_θ) corresponding to each θ.

PROBLEM 2 (robustness margin). *Assume $(y_0, 1) \in C(1) \times \boldsymbol{R}$ is a nominal solution to* (2.11) *and let $\mathcal{Z} = \{(y,T) \in C(1) \times \boldsymbol{R} : \|y - y_0\|^2_{C(1)} + |T-1|^2 \le r_0^2\}$. A* robustness margin *is a bound $\overline{\theta} > 0$ such that for each $|\theta| \le \overline{\theta}$, there exists a unique exponentially stable solution $(y_\theta, T_\theta) \in \mathcal{Z}$ to* (2.11) *(here we assume $[-\overline{\theta}, \overline{\theta}] \subset I_\theta$).*

3. Main results. Our first result provides a solution to Problem 1 for the case when the nominal system is finite-dimensional.

THEOREM 3.1. *Suppose Assumption* 1 *holds and consider the system in* (2.1) *when* $h(t,0) = Ce^{At}B\nu(t)$, *where* $\nu(\cdot)$ *is the unit step function and* $\operatorname{Re}\lambda(\mathrm{A}) < -\alpha$. *If the characteristic multipliers of* $A_{cl}(t) = A + B\varphi_y'(y_0(t),0)C$ *can be sorted as*

$$1 = \lambda_1 > |\lambda_2| \geq |\lambda_3| \geq \cdots \geq |\lambda_n| \quad \textit{and} \quad \alpha < -\frac{\log|\lambda_2|}{T_0},$$

then for all sufficiently small θ *there exists a unique (modulo time translation) exponentially stable limit cycle solution* $y(t,\theta)$ *to* (2.1) *with period* $T(\theta)$ *and with the property that* $y(t,\theta)$ *and* $T(\theta)$ *are* C^1 *in* θ *with* $y(t,0) = y_0(t)$ *and* $T(0) = T_0$. *Moreover, the exponential decay rate in* (2.10) *can be chosen to be* α.

The proof of Theorem 3.1 and most other results in this section are collected in the appendix. The proof builds on results presented in sections 3.1–3.4.

We consider two examples. The first shows that the classical finite-dimensional result is completely recovered by Theorem 3.1 and the second treats an uncertainty model from robust control.

EXAMPLE 1. *System* (2.2) *can equivalently be written in the form* (2.1) *with* $y = x$, $\varphi(y,\theta) = f(y,\theta) - Ay$, *and* $h(t,\theta) = e^{At}\nu(t)$, *where* $\nu(\cdot)$ *is the unit step function and* A *is any Hurwitz matrix. Hence, since* $A_{cl}(t) = A + B\varphi_y'(y_0(t),0)C = f_x'(y_0(t),0)$, *it follows that the condition on the characteristic multipliers in Theorem* 3.1 *is the same as the classical criterion discussed in* [3, 4]. *Theorem* 3.1 *hence gives an extended interpretation of the well-known finite-dimensional perturbation result.*

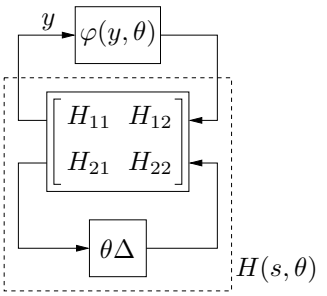

FIG. 3.1. *Block diagram corresponding to the perturbed system in* (2.1).

EXAMPLE 2. *In order to understand how our model class in* (2.1) *relates to standard uncertain system models from robust control we consider the block diagram in Figure* 3.1. *The transfer function*

$$H(s) = \begin{bmatrix} H_{11}(s) & H_{12}(s) \\ H_{21}(s) & H_{22}(s) \end{bmatrix} \in \boldsymbol{RH}_\infty$$

is assumed to be exponentially stable with the decay rate α, *i.e., the poles belong to the half space* $\operatorname{Re} s < -\alpha$. *This system corresponds to* (2.1) *with*[1] $h(t,\theta) = \mathcal{L}^{-1}(H(s,\theta))$, *where*

$$H(s,\theta) = H_{11}(s) + \theta H_{12}(s)\Delta(s)(I - \theta H_{22}(s)\Delta(s))^{-1}H_{21}(s). \tag{3.1}$$

[1]Here $\mathcal{L}$ denotes the Laplace transform.

The following result is a corollary to Theorem 3.1.

COROLLARY 3.2. *Assume*

(i) $H(s,\theta)$ *in* (3.1) *is SPES with the decay rate* α *for* $\theta \in I_\theta$,
(ii) φ *is* C^1 *with respect to both arguments,*
(iii) *for* $\theta = 0$ *the system has a nontrivial* T_0*-periodic solution* y_0,
(iv) $H_{11}(s) = C_1(sI - A_1)^{-1}B_1$, *where* $\mathrm{Re}\lambda(A_1) < -\alpha$ *and the characteristic multipliers of* $A_{cl}(t) = A_1 + B_1\varphi_y'(y_0(t),0)C_1$ *can be sorted as*

$$1 = \lambda_1 > |\lambda_2| \geq |\lambda_3| \geq \cdots \geq |\lambda_n| \quad \textit{and} \quad \alpha < -\frac{\log|\lambda_2|}{T_0}.$$

Then there exists a unique (modulo time translation) exponentially stable limit cycle solution for all sufficiently small θ. *Moreover, the exponential decay rate in* (2.10) *can be chosen to be* α *and the same continuity property as in Theorem* 3.1 *holds.*

We will next present a solution of Problem 2. At the same time we will touch upon some of the ideas behind the proof of Theorem 3.1. We will discuss the existence of solution and exponential stability separately and then combine them into our main small-gain theorem in section 3.3. We finally consider the case when the nominal system is finite-dimensional in section 3.4. This is where we derive the condition on the characteristic multipliers that is used to prove Theorem 3.1.

3.1. Existence of solution. To prove the existence of a periodic solution to the perturbed system we consider the system equation in the normalized time (2.11). This equation involves well-defined function spaces and the existence of solution is proven using an implicit function theorem that only requires right invertibility of the partial derivative with respect to the trajectory. To obtain a robustness bound we need to estimate the region in which the right inverse exists and for this we use Lemma 3.3. The robustness result in Lemma 3.4 is proven using Lemma 5.2 in the appendix, which is our basic result on local existence of solution.

First introduce the Banach spaces

$$X_y = C(1), \quad X_T = \mathbf{R}, \quad X_z = X_y \times X_T,$$

the open set $X_\theta = I_\theta$, and the operator $F : X_z \times X_\theta \to X_y$, which for each $z = (y,T)$ is defined as

$$F(z,\theta)(t) = y(t) - \int_{-\infty}^{t} Th(T(t-\tau),\theta)\varphi(y(\tau),\theta)\,d\tau. \tag{3.2}$$

By Assumption 2, we have $F(z_0,0) = 0$ for $z_0 = (y_0,1)$. To solve Problem 2 we need to show that for all $|\theta| \leq \overline{\theta}$ there exists a pair $z_\theta = (y_\theta, T_\theta) \in \mathcal{Z}$ such that

$$F(z_\theta,\theta) = 0. \tag{3.3}$$

This equation simply states that z_θ is a solution of (2.11). An important part of the proof of Theorem 3.1 is to use an implicit function theorem stated in the appendix. It shows that if $F_z'(z_0,0)$ has a bounded right inverse, then there exists a solution z_θ to (3.3) for all θ in some neighborhood of $\theta = 0$. To estimate the size of this neighborhood and to ensure that $z_\theta \in \mathcal{Z}$ we need to explore more structure of the operator equation (3.3). We proceed formally and differentiate the equality in (3.3), which gives

$$\frac{dz}{d\theta} = -F_z'(z(\theta),\theta)^\dagger F_\theta'(z(\theta),\theta), \tag{3.4}$$

where $F_z'(z(\theta),\theta)^\dagger$ denotes the right inverse. To evaluate the right inverse for an arbitrary solution (z_θ,θ) we use the following lemma.

LEMMA 3.3. *Let V_1, V_2 be Banach spaces and assume $H_0 \in \mathcal{L}(V_1,V_2)$ has a right inverse $G_0 \in \mathcal{L}(V_2,V_1)$. Then for each $\Delta \in \mathcal{L}(V_1,V_2)$ with $\|\Delta\|_{V_1\to V_2} < 1/\|G_0\|_{V_2\to V_1}$, there exists $G \in \mathcal{L}(V_2,V_1)$ such that $(H_0+\Delta)G = I$. One possible choice for this right inverse is*

$$G = G_0(I+\Delta G_0)^{-1}.$$

Proof. Since $H_0G_0 = I$, it follows that $(H_0+\Delta)G_0(I+\Delta G_0)^{-1} = I$. The right inverse $G = G_0(I+\Delta G_0)^{-1}$ is bounded with

$$\|G\|_{V_2\to V_1} \le \frac{\|G_0\|_{V_2\to V_1}}{1-\|\Delta\|_{V_1\to V_2}\cdot\|G_0\|_{V_2\to V_1}}. \qquad \square$$

Hence, if we let $\bar\Delta(z,\theta) = F_z'(z,\theta) - F_z'(z_0,0)$, then (3.4) becomes

$$\frac{dz}{d\theta} = -F_z'(z_0,0)^\dagger(I-\bar\Delta(z(\theta),\theta)F_z'(z_0,0)^\dagger)^{-1}F_\theta'(z(\theta),\theta) \tag{3.5}$$

which is well defined when

$$\sup_{z\in\mathcal{Z},|\theta|\le\bar\theta}\|\bar\Delta(z,\theta)\|_{X_z\to X_y}\cdot\|F_z'(z_0,0)^\dagger\|_{X_y\to X_z} < 1.$$

This small-gain condition will generally give rise to conservative estimates. It is our experience that better estimates can be obtained by extending the operators to the corresponding $\mathbf{L}_2$-spaces on which norm bounds can be computed efficiently:

$$\begin{array}{lll} \widetilde F_\theta' : \mathcal{Z}\times I_\theta \to \mathcal{L}(\tilde X_\theta,\tilde X_y), & & \tilde X_\theta = \mathbf{R}, \\ \widetilde F_z' : \mathcal{Z}\times I_\theta \to \mathcal{L}(\tilde X_z,\tilde X_y), & \text{where} & \tilde X_y = \mathbf{L}_2(1), \quad \tilde X_T = \mathbf{R}, \\ \widetilde\Delta : \mathcal{Z}\times I_\theta \to \mathcal{L}(\tilde X_z,\tilde X_y), & & \tilde X_z = \tilde X_y \times \tilde X_T. \end{array} \tag{3.6}$$

It is easy to show that we have the block representations

$$\begin{aligned} \widetilde F_z'(z,\theta) &= \begin{bmatrix}\widetilde F_y'(z,\theta) & \widetilde F_T'(z,\theta)\end{bmatrix} = \begin{bmatrix} I - L^s(z,\theta) & y_1(z,\theta)\end{bmatrix}, \\ \widetilde\Delta(z,\theta) &= \begin{bmatrix}\widetilde\Delta_1(z,\theta) & \widetilde\Delta_2(z,\theta)\end{bmatrix} = \begin{bmatrix} L^s(z_0,0) - L^s(z,\theta) & y_1(z,\theta) - y_1(z_0,0)\end{bmatrix}, \end{aligned} \tag{3.7}$$

where

$$\begin{aligned} (L^s(z,\theta)v)(t) &= \int_{-\infty}^t Th(T(t-\tau),\theta)\varphi_y'(y(\tau),\theta)v(\tau)\,d\tau, \\ (y_1(z,\theta))(t) &= \int_{-\infty}^t h(T(t-\tau),\theta)\varphi(y(\tau),\theta)\,d\tau \\ &\quad + \int_{-\infty}^t T(t-\tau)\,dh(T(t-\tau),\theta)\varphi(y(\tau),\theta). \end{aligned} \tag{3.8}$$

The operator $\bar\Delta : [\bar\Delta_1 \quad \bar\Delta_2] : \mathcal{Z}\times I_\theta \to \mathcal{L}(X_y,X_z)$ is defined in exactly the same way as $\widetilde\Delta$ but on a different function space. We have the following lemma.

LEMMA 3.4. *Suppose Assumption 2 holds and let* $\widetilde{F}'_z(z,\theta)$ *and* $\widetilde{\Delta}(z,\theta)$ *be defined as in* (3.6)–(3.8). *If*

(i) $\widetilde{F}'_z(z_0,0)$ *has a bounded right inverse denoted* $\widetilde{F}'_z(z_0,0)^\dagger$,

(ii) $\sup_{z\in\mathcal{Z},|\theta|\le\overline{\theta}} \|\widetilde{\Delta}(z,\theta)\|_{\tilde{X}_z\to\tilde{X}_y} \cdot \|\widetilde{F}'_z(z_0,0)^\dagger\|_{\tilde{X}_y\to\tilde{X}_z} < 1$,

(iii) $\sup_{z\in\mathcal{Z},|\theta|\le\overline{\theta}} \|\widetilde{F}'_z(z_0,0)^\dagger(I-\widetilde{\Delta}(z,\theta)\widetilde{F}'_z(z_0,0)^\dagger)^{-1}\widetilde{F}_\theta(z,\theta)\|_{\tilde{X}_\theta\to X_z} < \frac{r_0}{\overline{\theta}}$,

then there exists a unique (modulo time translation) solution $z_\theta = (y_\theta, T_\theta) \in \mathcal{Z}$ *to* (2.11) *for all* $|\theta| \le \overline{\theta}$.

3.2. Exponential stability. To prove exponential stability we consider a linearization of the nonsteady state dynamics in (2.7). The linearized model does not have a stable inverse due to a neutrally stable mode which is identified in Proposition 3.5. In order to prove convergence we remove the effect of the neutrally stable mode by compensating with a term corresponding to the phase delay. This leads us to define the notion stability defect in Definition 3.6. The main stability result in Theorem 3.7 is proven in the appendix.

We derive a sufficient condition for exponential stability by using the standard implicit function theorem. In order to obtain an appropriate topology on which Frechét derivatives can be defined we introduce the vector space $V = \{v : v \in \mathbf{L}_{2\alpha}[0,\infty) \cap \mathbf{L}_\infty[0,\infty)\}$ with the norm $\|v\|_V = \max(\|v\|_\alpha, \|v\|_\infty)$. The first norm is used to define the exponential decay while it is the second that allow us to compute the derivative. We let $\mathcal{X}_y = V$, $\mathcal{X}_d = \mathbf{R}$, and $\mathcal{X}_z = \mathcal{X}_y \times \mathcal{X}_d$ and consider the operator $\Psi : \mathcal{X}_z \times \mathcal{X}_y \to \mathcal{X}_y$, which for each pair $z = (\delta y, d) \in \mathcal{X}_z$ and $\delta f \in \mathcal{X}_y$ is defined as

$$(\Psi((\delta y,d),\delta f))(t) = y_0(t+d) + \delta y(t) - \int_0^t h(t-\tau)\varphi(y_0(\tau+d)+\delta y(\tau))\,d\tau - f_0(t) - \delta f(t), \tag{3.9}$$

where y_0 is a T-periodic solution of (2.7) and f_0 is defined in (2.8). Note that the equation $\Psi(z,\delta f) = 0$ is equivalent to (2.7) with $f(t) = f_0(t) + \delta f(t)$ and $y(t) = y_0(t+d)+\delta y(t)$. In particular, we know from (2.6) that $\Psi(0,0) = 0$. We need to show that for any δf in some neighborhood of 0 there exists a unique pair $z = (\delta y, d) \in \mathcal{X}_z$ such that $\Psi((\delta y,d),\delta f) = 0$ and such that the bound (2.10) holds. The first condition follows from the implicit function theorem if we can prove that the Frechét derivative with respect to the first argument, $\Psi'_z(0,0)$, has a bounded inverse. To prove that each such triplet $(\delta y, d, \delta f)$ satisfies the exponential decay condition in (2.10) we use the extension of the derivative to $\mathbf{L}_{2\alpha}$-space. With $\widetilde{\mathcal{X}}_y = \mathbf{L}_{2\alpha}[0,\infty)$, $\widetilde{\mathcal{X}}_d = \mathbf{R}$, and $\widetilde{\mathcal{X}}_z = \widetilde{\mathcal{X}}_y \times \widetilde{\mathcal{X}}_d$ the extension $\widetilde{\Psi}'_z(0,0) \in \mathcal{L}(\widetilde{\mathcal{X}}_z, \widetilde{\mathcal{X}}_y)$ is defined as

$$\widetilde{\Psi}'_z(0,0) = \begin{bmatrix}\widetilde{\Psi}'_y(0,0) & \widetilde{\Psi}'_d(0,0)\end{bmatrix} = \begin{bmatrix} I - L & e\end{bmatrix}, \tag{3.10}$$

where $L \in \mathcal{L}(\mathbf{L}_{2\alpha}, \mathbf{L}_{2\alpha})$ and $e \in \mathcal{L}(\mathbf{R}, \mathbf{L}_{2\alpha})$ are defined as

$$(Lv)(t) = \int_0^t h(t-\tau)\varphi'(y_0(\tau))v(\tau)\,d\tau \tag{3.11}$$

and

$$e(t) = \int_{-\infty}^0 h(t-\tau)\varphi'(y_0(\tau))\dot{y}_0(\tau)\,d\tau. \tag{3.12}$$

In the proof of Theorem 3.7 we shall show that (3.10) is the correct derivative by using Proposition 3.5 and that $e \in \mathbf{L}_{2\alpha}[0,\infty)$. The proof also shows that if $\widetilde{\Psi}'_z(0,0)$ has a bounded inverse, then the exponential decay condition in (2.10) holds and, moreover, that the original operator $\Psi'_z(0,0)$ has a bounded inverse (which proves the existence of $(\delta y, d)$).

The operator $I - L$ does not have a bounded inverse which follows from the next lemma.

PROPOSITION 3.5. *If $y_0 \neq$ const is a T-periodic solution of* (2.6) *and L and e are defined as in* (3.11)–(3.12)*, then $\dot{y}_0 \in (I-L)^{-1}e$.*

Proof. Let us differentiate $y_0(t)$ in (2.6). This gives

$$\begin{aligned}\dot{y}_0(t) &= \frac{d}{dt}\int_{-\infty}^{t} h(t-\tau)\varphi(y_0(\tau))\,d\tau \\ &= h(0)\varphi(y_0(t)) + \int_{-\infty}^{t} dh(t-\tau)\varphi(y_0(\tau)) \\ &= h(0)\varphi(y_0(t)) + \lim_{T\to-\infty}[-h(t-\tau)\varphi(y_0(\tau))]_T^t + \int_{-\infty}^{t} h(t-\tau)\varphi'(y_0(\tau))\dot{y}_0(\tau)\,d\tau \\ &= e(t) + \int_0^t h(t-\tau)\varphi'(y_0(\tau))\dot{y}_0(\tau)\,d\tau,\end{aligned}$$

where we used that $\lim_{T\to-\infty} h(t-T)\varphi(y_0(T)) = 0$ since h is exponentially stable and continuous, see Lemma 2.2. ∎

From this result it follows that $e \notin \operatorname{Im}(I-L)$ and one expects that (3.10) has a bounded inverse if $(I-L)$ has codimension 1. To make this precise we introduce the notion of α-defect of the operator L.

DEFINITION 3.6. *Let $L \in \mathcal{L}(\mathcal{X},\mathcal{X})$ be a bounded operator on a Banach space $\mathcal{X}$. Suppose that $I-L$ is a Fredholm operator with* $\operatorname{Ker}(I-L) = 0$*. Then the* stability defect *$def(L)$ is defined as the codimension of the subspace*

$$\mathcal{X}_L = \{(I-L)u : u \in \mathcal{X}\} \subset \mathcal{X}.$$

For $L \in \mathcal{L}(\tilde{X}_y, \tilde{X}_y)$ in (3.11) *the stability defect is called* α-defect*, denoted by $def_\alpha(L)$, due to the underlying space $\widetilde{\mathcal{X}}_y = \boldsymbol{L}_{2\alpha}[0,\infty)$.*

THEOREM 3.7. *The T-periodic solution y_0 of* (2.6) *is exponentially stable if $def_\alpha(L) = 1$ for L defined in* (3.11).

It will be convenient in computations to work with operators defined on $\mathbf{L}_2$ instead of $\mathbf{L}_{2\alpha}$. If $e^{\alpha t}h(t) \in \mathbf{L}_1[0,\infty)$, then the next lemma shows that the α-defect can be computed on $\mathbf{L}_2$ by using the operator $L_\alpha : \mathbf{L}_2[0,\infty) \to \mathbf{L}_2[0,\infty)$ defined by

$$(L_\alpha v)(t) = \int_0^t h_\alpha(t-\tau)\varphi'(y_0(\tau))v(\tau)\,d\tau, \tag{3.13}$$

where $h_\alpha(t) = e^{\alpha t}h(t)$.

LEMMA 3.8. *With $L : \boldsymbol{L}_{2\alpha} \to \boldsymbol{L}_{2\alpha}$ and $L_\alpha : \boldsymbol{L}_2 \to \boldsymbol{L}_2$ defined in* (3.11) *and* (3.13)*, respectively, we have $def_\alpha(L) = def(L_\alpha)$.*

Proof. The proof is easy and is given in [8]. ∎

3.3. A small-gain theorem. We will next combine the results in sections 3.1 and 3.2 to obtain a solution of Problem 2. First we derive a condition for exponential stability of all solutions $z_\theta = (y_\theta, T_\theta) \in \mathcal{Z}$ of (2.11) by proving that all possible

linearizations have α-defect 1. This is done in Lemma 3.9 which is a zero exclusion principle that is valid because the stability defect is robust to small perturbations.

Since we will do all computations in $\mathbf{L}_2$-space this leads us to consider the operators $L_\alpha : \mathcal{Z} \times I_\theta \to \mathcal{L}(\mathbf{L}_2, \mathbf{L}_2)$ defined by

$$(L_\alpha(z,\theta)v)(t) = \int_0^t Th_\alpha(T(t-\tau),\theta)\varphi_y'(y(\tau),\theta)v(\tau)\,d\tau, \tag{3.14}$$

where $h_\alpha(t,\theta) = e^{\alpha t}h(t,\theta)$. The nominal operator $L_\alpha^0 = L_\alpha(z_0,0)$ (where $z_0 = (y_0,1)$) is in our applications easy to work with. If $\mathrm{def}_\alpha(L) = 1$, then $\mathrm{Im}\,(I-L)$ is a closed subspace and it follows by the Banach inverse theorem that there exists $c > 0$ such that

$$\|(I - L_\alpha^0)v\| \geq c\|v\| \qquad \forall v \in \mathbf{L}_2. \tag{3.15}$$

We will use this bound in the next lemma, which shows that the α-defect is robust to perturbations of the system.

LEMMA 3.9. *Suppose Assumption* 2 *holds. Let* $L_\alpha : \mathcal{Z} \times I_\theta \to \mathcal{L}(\boldsymbol{L}_2, \boldsymbol{L}_2)$ *be defined as in* (3.14) *and let* $L_\alpha^0 = L_\alpha(z_0,0)$ *and* $\Delta L_\alpha(z,\theta) = L_\alpha(z,\theta) - L_\alpha^0$. *If*

(i) $def(L_\alpha^0) = 1$,

(ii) *there exists* $0 < \varepsilon < c$ *such that*

$$\sup_{z\in\mathcal{Z},|\theta|\leq\bar\theta} \|\Delta L_\alpha(z,\theta)\| \leq c - \varepsilon,$$

where $c > 0$ *satisfies* (3.15),

then $def(L_\alpha(z,\theta)) = 1$ *for all* $z \in \mathcal{Z}$ *and* $|\theta| \leq \bar\theta$. *In particular, every* 1*-periodic solution* $(y,T) \in \mathcal{Z}$ *of* (2.11) *is exponentially stable.*

The next theorem, which solves Problem 2, follows from Lemmas 3.4 and 3.9.

THEOREM 3.10. *Suppose Assumption* 2 *holds and let* $\widetilde{F}_z'(z,\theta)$ *and* $\widetilde{\Delta}(z,\theta)$ *be defined as in* (3.6)–(3.8). *Further let* $L_\alpha(z,\theta)$ *be defined as in* (3.14) *and define* $L_\alpha^0 = L_\alpha(z_0,0)$ *and* $\Delta L_\alpha(z,\theta) = L_\alpha(z,\theta) - L_\alpha^0$. *If*

(i) $\widetilde{F}_z'(z_0,0)$ *has a bounded right inverse denoted by* $\widetilde{F}_z'(z_0,0)^\dagger$,

(ii) $\sup_{z\in\mathcal{Z},|\theta|\leq\bar\theta} \|\widetilde{\Delta}(z,\theta)\|_{\tilde X_z\to\tilde X_y} \cdot \|\widetilde{F}_z'(z_0,0)^\dagger\|_{\tilde X_y\to\tilde X_z} < 1$,

(iii) $\sup_{z\in\mathcal{Z},|\theta|\leq\bar\theta} \|\widetilde{F}_z'(z_0,0)^\dagger(I - \widetilde{\Delta}(z,\theta)\widetilde{F}_z'(z_0,0)^\dagger)^{-1}\widetilde{F}_\theta(z,\theta)\|_{\tilde X_\theta\to X_z} < \frac{r_0}{\bar\theta}$,

(iv) $def(L_\alpha^0) = 1$,

(v) *there exists* $0 < \varepsilon < c$ *such that*

$$\sup_{z\in\mathcal{Z},|\theta|\leq\bar\theta} \|\Delta L_\alpha(z,\theta)\| \leq c - \varepsilon, \tag{3.16}$$

where $c > 0$ *satisfies* (3.15),

then there exists a unique (modulo time translation) exponentially stable solution $(y_\theta, T_\theta) \in \mathcal{Z}$ *to* (2.11) *for all* $\theta \in [-\bar\theta, \bar\theta]$.

3.4. Estimation of norms. We here consider the case when the nominal system in (2.11) is finite-dimensional. This means that $h(t,0) = Ce^{At}B\nu(t)$, where A is Hurwitz and $\nu(t)$ is the unit step function. In this case all conditions in Theorem 3.10 can be verified numerically. We show how right invertibility and the condition on the stability defect can be proven in the finite-dimensional case in Propositions 3.12 and 3.14, respectively. These two results are the foundation for the proof of Theorem 3.1. We also discuss how to estimate some of the relevant norms in Theorem 3.10.

3.4.1. Right invertibility of $\widetilde{F}'_{z}(z_0, 0)$. We first derive a state-space realization of the operator $\widetilde{F}'_z(z_0, 0) : (v, \delta T) \mapsto w$ in (3.6)–(3.8).

LEMMA 3.11. *Let $h(t, 0) = Ce^{At}B\nu(t)$. Then the Frechét derivative*

$$\widetilde{F}'_z(z_0, 0) = \begin{bmatrix} I - L^s(z_0, 0) & y_1(z_0, 0) \end{bmatrix},$$

where

$$(L^s(z_0, 0)v)(t) = \int_{-\infty}^{t} h(t - \tau, 0)\varphi'_y(y_0(\tau), 0)v(\tau)\, d\tau,$$
$$(y_1(z_0, 0))(t) = \int_{-\infty}^{t} h(t - \tau, 0)\varphi(y_0(\tau), 0)\, d\tau + \int_{-\infty}^{t} (t - \tau)\, dh(t - \tau, 0)\varphi(y_0(\tau), 0)$$

has the state space realization $\widetilde{F}'_z(z_0, 0) : (v, \delta T) \mapsto w$ defined by

$$\dot{x} = Ax + B\varphi'_y(y_0, 0)v + \dot{x}_0\delta T, \quad x(1) = x(0), \quad w = v - Cx, \tag{3.17}$$

where $\dot{x}_0(t) = Ax_0(t) + B\varphi(y_0(t), 0)$ is the nominal 1-periodic state trajectory.

Proof. It is straightforward to see that $L^s(z_0, 0) : v \mapsto w_1$ has the state space realization

$$\dot{x}_1 = Ax_1 + B\varphi'_y(y_0, 0)v, \quad x_1(1) = x_1(0), \quad w = v - Cx_1.$$

In order to obtain a state-space realization for $y_1(z_0, 0)$ we notice that

$$\begin{aligned}(y_1(z_0, 0))(t) &= C\int_{-\infty}^{t} (I + (t - \tau)A)e^{A(t-\tau)}B\varphi(y_0(\tau))\, d\tau \\ &= C\int_{-\infty}^{t} e^{A(t-\tau)}\left(\frac{d}{d\tau}\int_{-\infty}^{\tau} e^{A(\tau-s)}B\varphi(y_o(s))\, ds\right) d\tau.\end{aligned}$$

Hence $y_1(z_0, 0) : \delta T \to w_2$ has the state-space realization

$$\dot{x}_2 = Ax_2 + \dot{x}_0\delta T, \quad x_2(1) = x_2(0), \quad w_2 = Cx_2.$$

If we let $x = x_1 + x_2$, then we obtain the state-space realization in (3.17). ∎

The next proposition shows that the right invertibility condition (i) in Theorem 3.10 follows from the classical finite-dimensional condition on the characteristic multipliers of the system matrix for the linearized dynamics $A_{cl}(t) = A + B\varphi'_y(y_0(t), 0)C$. Note that one characteristic multiplier must be equal to 1 since $\frac{d}{dt}\dot{x}_0(t) = A_{cl}(t)\dot{x}_0(t)$, which implies that $\dot{x}_0(0) = \Phi_{cl}(1, 0)\dot{x}_0(0)$ due to the periodicity of $\dot{x}_0$.

PROPOSITION 3.12. *Consider the operator $\widetilde{F}'_z(z_0, 0)$ defined in (3.6)–(3.8) in the finite-dimensional case when $h(t, 0) = Ce^{At}B\nu(t)$, where A is Hurwitz. If $n-1$ of the characteristic multipliers of $A_{cl}(t) = A + B\varphi'_y(y_0(t), 0)C$ are different from 1, then $\widetilde{F}'_z(z_0, 0)$ has a bounded right inverse. One possible right inverse is $\widetilde{F}'_z(z_0, 0)^\dagger : w \mapsto (v, \delta T)$ defined by*

$$\begin{aligned}\dot{x} &= (A + B\varphi'_y(y_0, 0)C)x + B\varphi'_y(y_0, 0)w + \dot{x}_0 kx(0), \quad x(1) = x(0), \\ (v, \delta T) &= (w + Cx, kx(0)),\end{aligned} \tag{3.18}$$

where the row vector k must be chosen such that $1 \notin \operatorname{eig}(\Phi_{cl}(1,0) + \dot{x}_0(0)k)$, e.g., $k = \dot{x}_0(0)^T$. Here $\Phi_{cl}(t,0)$ is the transition matrix corresponding to A_{cl}.

Proof. The operator $\widetilde{F}'_z(z_0,0)$ can be represented by the state-space realization in (3.17). We proceed formally and construct a candidate right inverse by using $v = w + Cx$ in the first equation of (3.17) and $\delta T = kx(0)$. This gives rise to a map $w \mapsto (v, \delta T)$ defined by (3.18). In order for this to be well defined on $\mathbf{L}_2(1)$ it is necessary that the following equation have a solution for all $w \in \mathbf{L}_2(1)$:

$$x(0) = (\Phi_{cl}(1,0) + \dot{x}_0(0)k)x(0) + \int_0^1 \Phi_{cl}(1,\tau)B\varphi'_y(y_0(\tau),0)w(\tau)\,d\tau,$$

where we used that $\int_0^1 \Phi_{cl}(1,\tau)\dot{x}_0(\tau)\,d\tau kx(0) = \dot{x}_0(0)kx(0)$. Since $\operatorname{span}\{\dot{x}_0(0)\} = \operatorname{Ker}(I - \Phi_{cl}(1,0))$ it follows that there exists a vector k such that $I - \Phi_{cl}(1,0) - \dot{x}_0(0)k$ is invertible. Indeed, one possible choice is $k = \dot{x}_0(0)^T$. It is now easy to see that when the initial condition of (3.18) is the same as that of (3.17) then the composition of (3.17) with (3.18) is the identity operator. This proves the existence of a right inverse. ∎

3.4.2. Verification of condition (iii) in Theorem 3.10. To verify condition (iii) in Theorem 3.10 we exploit the structure of the operators. It follows from (3.18) in Proposition 3.12 that the nominal right inverse will have the block structure

$$\widetilde{F}'_z(z_0,0)^\dagger = \begin{bmatrix} 1 + G_1 \\ G_2 \end{bmatrix}. \tag{3.19}$$

Indeed, if we assume $k = \dot{x}_0(0)$, then the initial condition of (3.18) must be

$$x(0) = (I - \Phi_{cl}(1,0) - kk^T)^{-1} \int_0^1 \Phi_{cl}(1,\tau)B_{cl}(\tau)w(\tau)\,d\tau.$$

If we let

$$g_1(t,\tau) = \begin{cases} (\Gamma(t)\Phi_{cl}(1,t) + C)\Phi_{cl}(t,\tau)B_{cl}(\tau), & t > \tau, \\ \Gamma(t)\Phi_{cl}(1,\tau)B_{cl}(\tau), & t < \tau, \end{cases}$$
$$g_2(t,\tau) = k(I - \Phi_{cl}(1,0) - kk^T)^{-1}\Phi_{cl}(t,\tau)B_{cl}(\tau),$$

where $B_{cl}(t) = B\varphi'_y(y_0(t),0)$ and $\Gamma(t) = C(\Phi_{cl}(t,0) + \dot{x}_0(t)k)(I - \Phi_{cl}(1,0) - kk^T)^{-1}$, then we have the representation

$$(\widetilde{F}'_z(z_0,0)^\dagger w)(t) = (w(t) + (g_1 * w)(t), (g_2 * w)(1))$$

which corresponds to the block structure in (3.19). Here

$$(g_i * w)(t) = \int_0^1 g_i(t,\tau)w(\tau)\,d\tau, \quad i = 1,2. \tag{3.20}$$

We will also use the strictly proper part defined by

$$(G_{sp}w)(t) = ((g_1 * w)(t), (g_2 * w)(1)). \tag{3.21}$$

We have the following result.

PROPOSITION 3.13. *Define*[2]

$$\widetilde{\gamma}_1 = \|\widetilde{F}'_z(z_0,0)^\dagger\|_{\tilde{X}_y\to\tilde{X}_z}, \qquad \widetilde{\gamma}_2 = \|G_{sp}\|_{\tilde{X}_y\to X_z},$$
$$\widetilde{\gamma}_\Delta = \sup_{z\in\mathcal{Z},|\theta|\le\overline{\theta}} \|\widetilde{\Delta}(z,\theta)\|_{\tilde{X}_z\to\tilde{X}_y},$$
$$\gamma_{\Delta_1} = \sup_{z\in\mathcal{Z},|\theta|\le\overline{\theta}} \|\bar{\Delta}_1(z,\theta)\|_{X_y\to X_y}, \quad \gamma_{\Delta_2} = \sup_{z\in\mathcal{Z},|\theta|\le\overline{\theta}} \|\bar{\Delta}_2(z,\theta)\|_{X_T\to X_y},$$
$$\widetilde{\gamma}_\theta = \sup_{z\in\mathcal{Z},|\theta|\le\overline{\theta}} \|\widetilde{F}'_\theta(z,\theta)\|_{\tilde{X}_\theta\to\tilde{X}_y}, \quad \gamma_\theta = \sup_{z\in\mathcal{Z},|\theta|\le\overline{\theta}} \|F'_\theta(z,\theta)\|_{X_\theta\to X_y}.$$

A sufficient condition for (iii) *in Theorem* 3.10 *is*

$$\left(\frac{(\gamma_{\Delta_1}^2+\gamma_{\Delta_2}^2)^{1/2}}{1-\gamma_{\Delta_1}}+1\right)\frac{\widetilde{\gamma}_2\cdot\widetilde{\gamma}_\theta}{1-\widetilde{\gamma}_\Delta\cdot\widetilde{\gamma}_1}+\frac{\gamma_\theta}{1-\gamma_{\Delta_1}}<\frac{r_0}{\overline{\theta}}. \tag{3.22}$$

Proof. We start to derive a bound on the norm for fixed $z\in\mathcal{Z}$ and $\theta\in I_\theta$. We will use the block representations

$$\widetilde{F}'^{\,\dagger}_{z_0} := \widetilde{F}'_z(z_0,0)^\dagger = \begin{bmatrix}1+G_1\\ G_2\end{bmatrix}, \quad G_{sp}=\begin{bmatrix}G_1\\ G_2\end{bmatrix}, \quad \widetilde{\Delta}=[\widetilde{\Delta}_1 \quad \widetilde{\Delta}_2],$$

where G_1 and G_2 are defined in terms of the convolutions (3.20) and $\widetilde{\Delta}$ is defined as in (3.7). We have

$$\begin{aligned}\widetilde{F}'^{\,\dagger}_{z_0}(I+\widetilde{\Delta}\,\widetilde{F}'^{\,\dagger}_{z_0})^{-1} &= \begin{bmatrix}(I+\widetilde{\Delta}_1)^{-1}\\ 0\end{bmatrix} - (I+\widetilde{\Delta}_1)^{-1}\begin{bmatrix}\widetilde{\Delta}_1 & \widetilde{\Delta}_2\\ 0 & 0\end{bmatrix} G_{sp}(I+\widetilde{\Delta}\,\widetilde{F}'^{\,\dagger}_{z_0})^{-1}\\ &\quad + G_{sp}(I+\widetilde{\Delta}\,\widetilde{F}'^{\,\dagger}_{z_0})^{-1}\end{aligned} \tag{3.23}$$

which follows since by the identity $A^{-1}-B^{-1}=B^{-1}(B-A)A^{-1}$ we have

$$\begin{aligned}(I+\widetilde{\Delta}\,\widetilde{F}'^{\,\dagger}_{z_0})^{-1}-(I+\widetilde{\Delta}_1)^{-1} &= -(I+\widetilde{\Delta}_1)^{-1}(\widetilde{\Delta}_1G_1+\widetilde{\Delta}_2G_2)(I+\widetilde{\Delta}\,\widetilde{F}'^{\,\dagger}_{z_0})^{-1}\\ &= -(I+\widetilde{\Delta}_1)^{-1}\widetilde{\Delta}G_{sp}(I+\widetilde{\Delta}\,\widetilde{F}'^{\,\dagger}_{z_0})^{-1}.\end{aligned}$$

From (3.23) we get

$$\begin{aligned}\|\widetilde{F}'^{\,\dagger}_{z_0}(I+\widetilde{\Delta}\,\widetilde{F}'^{\,\dagger}_{z_0})^{-1}\widetilde{F}'_\theta\|_{\tilde{X}_\theta\to X_z} &\le \frac{\|F'_\theta\|_{X_\theta\to X_y}}{1-\|\bar{\Delta}_1\|_{X_y\to X_y}}\\ &\quad+\left(\frac{(\|\bar{\Delta}_1\|^2_{X_y\to X_y}+\|\bar{\Delta}_2\|^2_{X_\theta\to X_y})^{1/2}}{1-\|\bar{\Delta}_1\|_{X_y\to X_y}}+1\right)\frac{\|G_{sp}\|_{\tilde{X}_y\to X_z}\|\widetilde{F}'_\theta\|_{\tilde{X}_\theta\to\tilde{X}_y}}{1-\|\widetilde{\Delta}\|_{\tilde{X}_z\to\tilde{X}_y}\|\widetilde{F}'^{\dagger_{z_0}}\|_{\tilde{X}_y\to\tilde{X}_z}}.\end{aligned} \tag{3.24}$$

Note that some induced norms are over the original X-spaces ($C(1)$), others are over the $\tilde{X}$-spaces ($\mathbf{L}_2(1)$), and some are from $\tilde{X}$-space to X-space. If we optimize over $z\in\mathcal{Z}$ and $|\theta|\le\overline{\theta}$, we see from (3.24) that (3.22) is sufficient for (iii) in Theorem 3.10. ∎

The computation of $\widetilde{\gamma}_\Delta$-$\widetilde{\gamma}_\theta$ in Proposition 3.13 depends very much on the uncertainty structure and must be treated on a case-by-case basis. For $\widetilde{\gamma}_1$ and $\widetilde{\gamma}_2$ it is possible to derive systematic algorithms for computing bounds on these parameters.

[2]Recall that the operators $\bar{\Delta}$ and $\widetilde{\Delta}$ are both defined as in (3.6)–(3.8), but on different spaces.

3.4.3. Computation of $\widetilde{\gamma}_1$. For a given choice of k we compute

$$\widetilde{\gamma}_1 = \|\widetilde{F}_z'(z_0,0)^\dagger\|_{\tilde{X}_y\to\tilde{X}_z} = \|\widetilde{F}_z'(z_0,0)^\dagger\|_{\mathbf{L}_2(1)\to\mathbf{L}_2(1)\times\mathbf{R}}$$

by solving the optimization problem

$$\widetilde{\gamma}_1^2 = \inf\gamma^2 \quad \text{subject to} \quad J(x,w,\gamma)\le 0 \quad \forall (x,w)\in\mathcal{L}, \tag{3.25}$$

where

$$J(x,w,\gamma) = |kx(0)|^2 + \int_0^1 (|w+Cx|^2 - \gamma^2|w|^2)\,dt$$
$$\mathcal{L} = \{(x,w)\in\mathbf{L}_2(1) : \dot{x}(t) = A_{cl}(t)x(t) + B_{cl}(t)w(t) + \dot{x}_0(t)kx(0),\ x(1) = x(0)\}$$

and $A_{cl}(t) = A + B\varphi_y'(y_0(t),0)C$ and $B_{cl}(t) = B\varphi_y'(y_0(t),0)$. We obtain an upper bound by using LQ optimal control techniques. If we let $Q_0 = k^Tk$, $Q = C^TC$, $S = C^T$, $R = (1-\gamma^2)I$, then γ is an upper bound on the optimization problem (3.25), i.e., $\gamma > \|\widetilde{F}_z'(z_0,0)^\dagger\|_{\tilde{X}_y\to\tilde{X}_z}$ if and only if there exists $\epsilon > 0$ such that

$$\sup_{(x,w)\in\mathcal{L}} x(0)^TQ_0x(0) + \int_0^1 (x^TQx + 2x^TSw + w^TRw)\,dt \le -\epsilon|x(0)|^2. \tag{3.26}$$

Necessary and sufficient conditions for this condition to hold can be obtained from the Pontryagin maximum principle. The full details are given in [8].

3.4.4. Computation of $\widetilde{\gamma}_2$. In the linear systems theory the $\mathbf{H}_2$-norm can be used to estimate the $\|\cdot\|_{\mathbf{L}_2\to\mathbf{L}_\infty}$ norm of a transfer function. We will here estimate the corresponding norm for the strictly proper operator G_{sp} in (3.21). By the convolution formula in (3.21) and the definition of $\tilde{X}_y$ and X_z, we get

$$\|G_{sp}w\|_{X_z} = \|G_{sp}w\|_{C(1)\times\mathbf{R}} \le (\|G_1\|^2_{\mathbf{L}_2(1)\to C(1)} + \|G_2\|^2_{\mathbf{L}_2(1)\to\mathbf{R}})^{1/2}\|w\|_{\mathbf{L}_2(1)},$$

where

$$\|G_1\|^2_{\mathbf{L}_2(1)\to C(1)} := \max_{t\in[0,1]}\int_0^1 |g_1(t,s)|^2\,ds,$$
$$\|G_2\|^2_{\mathbf{L}_2(1)\to\mathbf{R}} := \int_0^1 |g_2(1,s)|^2\,ds.$$

Hence, we get the bound

$$\widetilde{\gamma}_2 = \|G_{sp}\|_{\tilde{X}_y\to X_z} = \|G_{sp}\|_{\mathbf{L}_2(1)\to C(1)\times\mathbf{R}} \le (\|G_1\|^2_{\mathbf{L}_2(1)\to C(1)} + \|G_2\|^2_{\mathbf{L}_2(1)\to\mathbf{R}})^{1/2}. \tag{3.27}$$

3.4.5. Verification of the α-defect. We will next derive a condition for the α-defect to be 1 in the finite-dimensional case.

PROPOSITION 3.14. *Consider the operator L defined in* (3.11) *in the finite-dimensional case when $h(t) = Ce^{At}B\nu(t)$, where* $\mathrm{Re}\lambda(A) < -\alpha$. *If the characteristic multipliers of $A_{cl}(t) = A + B\varphi'(y_0(t))C$ can be sorted as*

$$1 = \lambda_1 > |\lambda_2| \ge |\lambda_3| \ge \cdots \ge |\lambda_n|,$$

then $def_\alpha(L) = 1$ *for* $\alpha \in (0, -\frac{\log|\lambda_2|}{T})$.

We next discuss how to verify conditions (iv) and (v) in Theorem 3.10. For condition (iv) we introduce $L^0 \in \mathcal{L}(\mathbf{L}_2, \mathbf{L}_2)$ defined by

$$(L^0 v)(t) = \int_0^t h(t-\tau, 0)\varphi'(y(\tau), 0)v(\tau)\, d\tau.$$

If $h(t,0) = Ce^{At}B\nu(t)$, then $\mathrm{def}_\alpha(L^0) = 1$ if the condition in Proposition 3.14 holds, which by Lemma 3.8 implies $\mathrm{def}\,(L^0_\alpha) = 1$.

To verify condition (v) in Theorem 3.10 we need to derive a bound $c > 0$ (as large as possible) such that (3.15) holds, i.e.,

$$\|(I - L^0_\alpha)v\| \geq c\|v\| \quad \forall v \in \mathbf{L}_2[0,\infty), \tag{3.28}$$

where $L^0_\alpha = L_\alpha(z_0, 0)$ is defined as in (3.14) with $h_\alpha(t,0) = Ce^{(A+\alpha I)t}B\nu(t)$. The condition (3.28) holds if there exists $\epsilon > 0$ such that

$$\int_0^\infty (x^T C^T C x - 2x^T C^T v + (1-c^2)v^T v)\, dt \geq \epsilon(\|x\|^2 + \|v\|^2) \tag{3.29}$$

for all $(x,v) \in \{(x,v) \in \mathbf{L}_2[0,\infty) : \dot{x}(t) = (A+\alpha I)x(t) + B_{cl}(t)v(t),\ x(0) = 0\}$, where $B_{cl}(t) = B\varphi'(y_0(t), 0)$. Several equivalent conditions for the last inequality to hold are given in [16].

4. Numerical example. We consider the Wien bridge oscillator in Figure 4.1. The model is adopted from [9]. If we let $x_1 = v_{C_1}$ and $x_2 = v_{C_2}$, the voltages over C_1

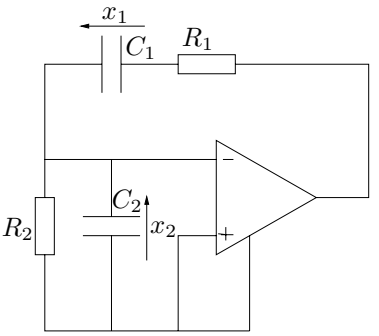

FIG. 4.1. *The Wien bridge oscillator.*

and C_2 be the state variables, then the system equation becomes

$$\dot{x}_1 = \frac{1}{C_1 R_1}(-x_1 + x_2 - \varphi(x_2)),$$
$$\dot{x}_2 = -\frac{1}{C_2 R_1}(-x_1 + x_2 - \varphi(x_2)) - \frac{1}{C_2 R_2}x_2,$$

where $\varphi(\cdot)$ is the model of the operational amplifier. With the values $C_1 = C_2 = 1$, $R_1 = R_2 = 1/6.32$, and

$$\varphi(y) = 3.234y - 2.195y^3 + 0.666y^5$$

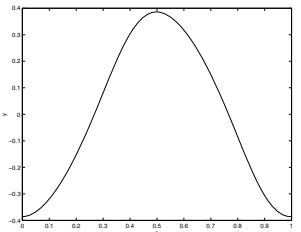

FIG. 4.2. *A period of the* 1*-periodic solution to the Wien bridge oscillator. Only the output* $y = x_2$ *is shown.*

we obtain the 1-periodic solution in Figure 4.2. The nominal system can be written as

$$y(t) = \int_{-\infty}^{t} h(t-\tau)\varphi(y(\tau))\,d\tau,$$

where $h(t) = Ce^{At}B\nu(t)$. Here $\nu(\cdot)$ is the unit step function and

$$A = \frac{1}{6.32}\begin{bmatrix} -1 & 1 \\ 1 & -2 \end{bmatrix}, \quad B = \frac{1}{6.32}\begin{bmatrix} -1 \\ 1 \end{bmatrix}, \quad C = [0 \quad 1].$$

We will investigate robustness to additive uncertainties of the form

$$H(s,\theta) = H(s) + \theta\Delta(s),$$

where $H(s) = C(sI - A)^{-1}B$ and $\Delta(s)$ is a stable transfer function. For $r_0 = 0.01$ we will show that $\bar{\theta} = 0.0007$ is a robustness margin. We let the exponential decay parameter be $\alpha = 0.7$. We assume

$$\sup_{|T-1|\le r_0} \|\Delta(s/T)\|_{C(1)\to C(1)} \le 1, \qquad \sup_{|T-1|\le r_0} \|(s/T)\Delta'(s/T)\|_{C(1)\to C(1)} \le 1,$$
$$\sup_{|T-1|\le r_0} \|\Delta((s-\alpha)/T)\|_{\mathbf{H}_\infty} \le 1, \qquad \sup_{|T-1|\le r_0} \|((s-\alpha)/T)\Delta'((s-\alpha)/T)\|_{\mathbf{H}_\infty} \le 1.$$

We start to verify conditions (i)–(iii) in Theorem 3.10. The characteristic multipliers of $A_{cl} = A + B\varphi'(y_0(t))C$ are 1 and 0.24, which by Proposition 3.12 implies that $\widetilde{F}'_z(z_0, 0)$ has a bounded right inverse. It also motivates the choice of α since $\alpha = 0.7 < -\log|\lambda_2|/T_0 = 1.43$.

We next need to compute bounds on the norms in Proposition 3.13.

- We obtain the bound $\widetilde{\gamma}_1 = \|\widetilde{F}'_z(z_0,0)^\dagger\|_{\tilde{X}_y\to\tilde{X}_z} \le 9.0$ by verifying (3.26).
- The bound $\widetilde{\gamma}_2 = \|G_{sp}\|_{\tilde{X}_y\to X_z} \le 17.0$ is obtained using (3.27).
- $\widetilde{\gamma}_\theta = \sup_{z\in\mathcal{Z},\ |\theta|\le\bar{\theta}} \|\widetilde{F}'_\theta(z,\theta)\|_{\tilde{X}_\theta\to\tilde{X}_y} \le \sup_{\|y-y_0\|_{C(1)}\le r_0} \|\varphi(y)\|_{\mathbf{L}_2(1)} \approx 0.6032.$
- $\gamma_\theta = \sup_{z\in\mathcal{Z},\ |\theta|\le\bar{\theta}} \|F'_\theta(z,\theta)\|_{X_\theta\to X_y} \le \sup_{\|y-y_0\|_{C(1)}\le r_0} \|\varphi(y)\|_{C(1)} \approx 1.072.$

The norm of the operator $\widetilde{\Delta}$ requires more work. This operator can be represented as ($z = (y, T)$)

$$\begin{aligned}\widetilde{\Delta}(z,\theta)(v,\delta T) &= \widetilde{\Delta}_1(y,T,\theta)v + \widetilde{\Delta}_2(y,T,\theta)\delta T \\ &= [H(s/T,\theta)\varphi'(y) - H(s)\varphi'(y_0)]v \\ &\quad + [(s/T)H'(s/T,\theta)\varphi(y) - sH'(s)\varphi(y_0)]\delta T.\end{aligned}$$

For each $z=(y,T)\in\mathcal{Z}$ and $|\theta|\le\bar\theta$ we use the bounds

(4.1)
$$\begin{aligned}\|\widetilde\Delta_1(z,\theta)\|_{\mathbf{L}_2(1)\to\mathbf{L}_2(1)} &\le \|H(s/T)-H(s)\|_{\mathbf{H}_\infty}\cdot\|\varphi'(y)\|_{C(1)}\\ &\quad+\|H(s)\|_{\mathbf{H}_\infty}\cdot\|\varphi'(y)-\varphi'(y_0)\|_{C(1)}+\bar\theta\|\varphi'(y)\|_{C(1)}=:N_1(z),\\ \|\widetilde\Delta_2(z,\theta)\|_{\mathbf{R}\to\mathbf{L}_2(1)} &\le \|(s/T)H'(s/T)-sH'(s)\|_{\mathbf{H}_\infty}\cdot\|\varphi(y)\|_{\mathbf{L}_2(1)}\\ &\quad+\|sH'(s)\|_{\mathbf{H}_\infty}\cdot\|\varphi(y)-\varphi(y_0)\|_{\mathbf{L}_2(1)}+\bar\theta\|\varphi(y)\|_{\mathbf{L}_2(1)}=:N_2(z).\end{aligned}$$

Hence using (4.1) we get

$$\begin{aligned}\widetilde\gamma_\Delta &= \sup_{z\in\mathcal{Z},|\theta|\le\bar\theta}\|\widetilde\Delta(z,\theta)\|_{\tilde X_z\to\tilde X_y}=\sup_{z\in\mathcal{Z},|\theta|\le\bar\theta}\|\widetilde\Delta(z,\theta)\|_{\mathbf{L}_2(1)\times\mathbf{R}\to\mathbf{L}_2(1)}\\ &\le \sup_{z\in\mathcal{Z},|\theta|\le\bar\theta}\sqrt{\|\widetilde\Delta_1(z,\theta)\|^2_{\mathbf{L}_2(1)\to\mathbf{L}_2(1)}+\|\widetilde\Delta_2(z,\theta)\|^2_{\mathbf{R}\to\mathbf{L}_2(1)}}\\ &\le \sup_{z\in\mathcal{Z}}\sqrt{N_1(z)^2+N_2(z)^2}\le 0.0194,\end{aligned}$$

where the last inequality was obtained numerically.

To obtain the remaining norms we use convolution representations of $\bar\Delta_1$ and $\bar\Delta_2$. If we let $h_{\bar\Delta(z,\theta)}(t,s)$ be the convolution kernel corresponding to the operator $H(s/T,\theta)\varphi'(y(t))-H(s,0)\varphi'(y_0(t))$ defined on $C(1)$ and $g_{\bar\Delta(z,\theta)}(t)$ correspond to the function $sH'(s,0)\varphi(y_0)-(s/T)H'(s/T,\theta)\varphi(y)\in C(1)$, then we can write ($z=(y,T)$)

$$\begin{aligned}(\bar\Delta_1(z,\theta)v)(t)&=\int_0^1 h_{\bar\Delta(z,\theta)}(t,s)v(s)\,ds,\\ (\bar\Delta_2(z,\theta)\delta T)(t)&=g_{\bar\Delta(z,\theta)}(t)\delta T.\end{aligned}$$

Note that

$$h_{\bar\Delta(z,\theta)}(t,s)=h_z(t,s)-h_{z_0}(t,s)+\theta\delta_T(t,s)\varphi'(y(s)),$$

where $\delta_T(t,s)$ is the weighting function corresponding to $\Delta(s/T)$ and

$$h_z(t,s)=\begin{cases}TC(I-e^{AT})^{-1}e^{AT(t-s)}B\varphi'(y(s)), & t>s,\\ TC(I-e^{AT})^{-1}e^{AT}e^{AT(t-s)}B\varphi'(y(s)), & t<s.\end{cases}$$

Similarly, we have

$$g_{\bar\Delta(z,\theta)}(t)=\int_0^1\left(g_z(t,s)-g_{z_0}(t,s)+\theta\hat\delta_T(t,s)\varphi(y(s))\right)ds,$$

where $\hat\delta_T(t,s)$ is the weighting function corresponding to $(s/T)\Delta(s/T)$ and

$$g_z(t)=\begin{cases}T\tilde C(I-e^{\tilde AT})^{-1}e^{\tilde AT(t-s)}\tilde B\varphi'(y(s)), & t>s,\\ T\tilde C(I-e^{\tilde AT})^{-1}e^{\tilde AT}e^{\tilde AT(t-s)}\tilde B\varphi'(y(s)), & t<s\end{cases}$$

and

$$\tilde A=\begin{bmatrix}A & I\\ 0 & A\end{bmatrix},\quad \tilde B=\begin{bmatrix}0\\ B\end{bmatrix},\quad \tilde C=-[CA\quad C].$$

We get

$$\gamma_{\Delta_1} = \sup_{z\in\mathcal{Z}} \sup_{|\theta|\le\bar\theta} \|\bar\Delta_1(z,\theta)\|_{C(1)\to C(1)} = \sup_{z\in\mathcal{Z}} \sup_{|\theta|\le\bar\theta} \|h_{\bar\Delta(z,\theta)}\|_1 \le 0.0226$$

and similarly

$$\gamma_{\Delta_2} = \sup_{z\in\mathcal{Z}} \sup_{|\theta|\le\bar\theta} \|\bar\Delta_2(z,\theta)\|_{\mathbf{R}\to C(1)} = \sup_{z\in\mathcal{Z}} \sup_{|\theta|\le\bar\theta} \|g_{\bar\Delta(z,\theta)}\|_{C(1)} \le 0.0053.$$

Hence, we have

$$\widetilde\gamma_\Delta \cdot \widetilde\gamma_1 = \sup_{z\in\mathcal{Z},|\theta|\le\bar\theta} \|\widetilde\Delta(z,\theta)\|_{\tilde X_z\to\tilde X_y} \cdot \|\widetilde F_z'(z_0,0)^\dagger\|_{\tilde X_y\to\tilde X_z} = 0.0194\cdot 9 = 0.175 < 1,$$

which verifies condition (ii). For condition (iii) we use (3.22) in Proposition 3.13. We have

$$\left(\left(\frac{(\gamma_{\Delta_1}^2+\gamma_{\Delta_2}^2)^{1/2}}{1-\gamma_{\Delta_1}}+1\right)\frac{\widetilde\gamma_2\cdot\widetilde\gamma_\theta}{1-\widetilde\gamma_\Delta\cdot\widetilde\gamma_1}+\frac{\gamma_\theta}{1-\gamma_{\Delta_1}}\right)\frac{\bar\theta}{r_0}\approx 0.9667.$$

It remains to verify the exponential stability conditions (iv)–(v) in Theorem 3.10. Condition (iv) follows from Proposition 3.14 since $\lambda_2 = 0.24$. Next we compute a bound on $c > 0$ such that (3.28) holds. A bound can be obtained by verifying (3.29) using [16], which results in the bound $c = 0.0735$. In order to verify (3.16) we use that

$$\Delta L_\alpha(z,\theta) = H((s-\alpha)/T)\circ\varphi'(y) - H(s-\alpha)\circ\varphi'(y_0) + \theta\Delta((s-\alpha)/T)\varphi'(y).$$

We get the bound

$$\begin{aligned}\sup_{z\in\mathcal{Z},\,|\theta|\le\bar\theta}\|\Delta L_\alpha(z,\theta)\| &\le \sup_{|T-1|\le r_0}\|H((s-\alpha)/T)-H(s-\alpha)\|_{\mathbf{H}_\infty}\sup_{\|y-y_0\|_{C(1)}\le r_0}\|\varphi'(y)\|_{C(1)}\\ &\quad+\|H(s-\alpha)\|_{\mathbf{H}_\infty}\sup_{\|y-y_0\|_{C(1)}\le r_0}\|\varphi'(y)-\varphi'(y_0)\|_{C(1)}+\bar\theta\sup_{\|y-y_0\|_{C(1)}\le r_0}\|\varphi'(y)\|_{C(1)}\\ &= 0.0210 \le c = 0.074,\end{aligned}$$

which proves that condition (v) in Theorem 3.10 is true. We have thus shown that $\bar\theta = 0.0007$ is a robustness margin when $r_0 = 0.01$. The question is whether this bound is conservative. We simulated the system with $\Delta(s) = \frac{10}{s+10}$. For $\hat\theta = 0.001$ we get a perturbation $\hat r = (\|y-y_0\|_{C(1)}^2 + |T-1|^2)^{1/2} \approx 0.01$. Hence, the gap between the true robustness margin and the estimated is not at larger than $\hat\theta/\bar\theta \approx 1.4$. Table 1 shows the results of several numerical experiments.

5. Concluding remarks. We have proven that a well-known condition for robustness of limit cycles of finite-dimensional systems is also valid when the system is perturbed by a sufficiently small dynamic perturbation. We also showed how bounds on a robustness margin can be estimated using a number of small-gain conditions.

The robustness conditions in this paper are to a large extent formulated as invertibility conditions on operators defined in $\mathbf{L}_2$ spaces. An existence result and a perturbation bound as in Lemma 3.4 are easier to derive in the Banach space $C(1)$. However, the resulting conditions gave much more conservative bounds for our numerical example in section 4. It is in particular the small-gain condition

TABLE 1

Results of numerical examples. $\overline{\theta}$ is the bound computed using our results and $\hat{\theta}$ is obtained by simulating with $\Delta(s) = 10/(s+10)$. The gap $\hat{\theta}/\overline{\theta}$ is an upper bound on how conservative our bound possibly can be.

r_0	$r_0/(\|y_0\|^2_{C(1)}+1)^{1/2}$	$\overline{\theta}$	$\frac{\overline{\theta}}{\|H\|_{\mathbf{H}_\infty}}$	$\hat{\theta}$	$\frac{\hat{\theta}}{\|H\|_{\mathbf{H}_\infty}}$	$\hat{\theta}/\overline{\theta}$

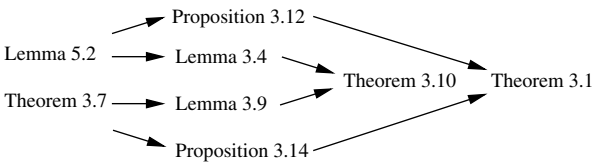
$\sup_{z\in\mathcal{Z},|\theta|\le\overline{\theta}} \|\widetilde{\Delta}(z,\theta)\|_{\tilde{X}_z\to\tilde{X}_y} \cdot \|\widetilde{F}'_z(z_0,0)^\dagger\|_{\tilde{X}_y\to\tilde{X}_z} < 1$ that is much less conservative and also easier to verify in $\mathbf{L}_2(1)$.

The problem of computing robust stability bounds for limit cycles is an important and challenging problem that is still in its infancy. The results provided in this paper are valid for a fairly large class of systems that appear frequently in applications. By using a minimum of structure in the problem we obtain a set of small gain conditions that can be used to estimate a robustness margin. The verification of the small gain conditions are involved and it is desirable to find conditions that can be verified with less effort.

Appendix: Proofs. We here collect several of the proofs in the paper. We start to state a version of the implicit function theorem suitable for our purposes. We then provide proofs for our main results using the following sequence of implications:



Here Lemma 5.2 gives a sufficient condition for existence of a periodic solution locally. The upper implications are results on the existence of a periodic solution and the lower implications are results on exponential stability. Next follows the implicit function theorem, which is used to prove Lemmas 5.2 and 3.4.

THEOREM 5.1. *Let V_1, V_2, V_3 be Banach spaces and suppose $F : U_1 \times U_2 \to V_3$ is C^1, where $U_1 \subset V_1$ and $U_2 \subset V_2$ are open. Assume $F(u_{10}, u_{20}) = 0$ for some $u_{10} \in U_1$ and $u_{20} \in U_2$. If $F'_{u_1}(u_{10}, u_{20})$ has a bounded right inverse, then there exists a neighborhood U_{20} of u_{20} and a C^1 function $E : U_{20} \to U_1$ such that*

$$F(E(u_2), u_2) = 0$$

for all $u_2 \in U_{20}$. To estimate the size of U_{20} assume G_0 is a bounded right inverse of $H_0 = D_{u_1}F(u_{10}, u_{20})$ and

$$\begin{aligned} B^1_{r_1}(u_{10}) &= \{u_1 : \|u_1 - u_{10}\| \le r_1\} \subset U_1, \\ B^2_{r_2}(u_{20}) &= \{u_2 : \|u_2 - u_{20}\| \le r_2\} \subset U_2, \\ B_r(u_0) &= B^1_{r_1}(u_{10}) \times B^2_{r_2}(u_{20}) \subset U_1 \times U_2 \end{aligned}$$

are such that

$$L_r = \sup_{u\in B_r(u_0)} \|F'_{u_1}(u) - F'_{u_1}(u_0)\|,$$
$$L_{r_1} = \sup_{u_1\in B^1_{r_1}(u_{10})} \|F'_{u_1}(u_1, u_{20}) - F'_{u_1}(u_{10}, u_{20})\|,$$
$$L_{r_2} = \sup_{u\in B_r(u_0)} \|F'_{u_2}(u)\|$$

satisfy

$$L_r\|G_0\| < 1, \tag{5.1}$$
$$\frac{L_{r_2}\|G_0\|}{1 - L_{r_1}\|G_0\|} r_2 \le r_1. \tag{5.2}$$

Then we can use $U_{20} = B^2_{r_2}(u_{20})$ *and* $E(u_2) \in B^1_{r_1}(u_{10})$ *for all* $u_2 \in B^2_{r_2}(u_{20})$.

Proof. We only sketch on a proof. The easiest way to prove the first part of the theorem is to use the standard implicit function theorem. Let $\hat{U}_k = U_k - u_{k0}$, $k = 1, 2$, and $\hat{F} : \hat{U}_1 \times \hat{U}_2 \to V_3$ be defined as

$$\hat{F}(\hat{u}_1, \hat{u}_2) = F(u_{10} + G_0\hat{u}_1, u_{20} + \hat{u}_2).$$

We have $\hat{F}(0, 0) = 0$ and $\hat{F}'_{\hat{u}_1}(0, 0) = I$. Hence, it follows from the standard implicit function theorem that there exists a neighborhood $\hat{U}_{20}$ of 0 and a unique C^1 function $\hat{E} : \hat{U}_{20} \to \hat{U}_1$ such that $\hat{F}(\hat{E}(\hat{u}_2), \hat{u}_2) = 0$ for all $\hat{u}_2 \in \hat{U}_{20}$; see, e.g., [1]. The first claim of the theorem follows by using $U_{20} = \hat{U}_{20} + u_{20}$ and $E(u_2) = u_{10} + G_0\hat{E}(u_2 - u_{20})$.

It remains to verify that the estimate $U_{20} = B^2_{r_2}(u_{20})$ is valid. The following sketch of this part also provides the idea behind a more constructive way of proving the theorem. We continue to use the translated variables and the ˆ notation, e.g., $\hat{B}^1_{r_1}(0) = \{\hat{u}_1 : \|\hat{u}_1\| \le r_1\} = B_{r_1}(u_{10}) - u_{10}$ but now with $\hat{F}(\hat{u}_1, \hat{u}_2) = F(u_{10} + \hat{u}_1, u_{20} + \hat{u}_2)$. The idea is to consider the fixed point iteration

$$x_{k+1} = L(x_k, \hat{u}_2) := G_0(\hat{F}'_{\hat{u}_1}(0, 0)x_k - \hat{F}(x_k, \hat{u}_2)).$$

If we can prove the existence of a fixed point $x = \hat{E}(\hat{u}_2)$, then this implies that $\hat{F}(\hat{E}(\hat{u}_2), \hat{u}_2) = 0$. We use the following inequalities.

(i) For any pairs $(x_2, \hat{u}_2) \in \hat{B}_r(0)$, $(x_1, \hat{u}_2) \in \hat{B}_r(0)$ we have

$$\|L(x_2, \hat{u}_2) - L(x_1, \hat{u}_2)\| \le L_r\|G_0\| \cdot \|x_2 - x_1\| < \|x_2 - x_1\|,$$

where the second inequality follows from (5.1).

(ii) For all $(x, \hat{u}_2) \in \hat{B}_r(0)$ we have

$$\begin{aligned}\|L(x, \hat{u}_2)\| &\le \|G_0\| \cdot \|\hat{F}'_{\hat{u}_1}(0, 0)x - \hat{F}(x, 0)\| + \|G_0\| \cdot \|\hat{F}(x, \hat{u}_2) - \hat{F}(x, 0)\| \\ &\le \|G_0\|(L_{r_1}\|x\| + L_{r_2}\|\hat{u}_2\|) \le \|G_0\|(L_{r_1}r_1 + L_{r_2}r_2) \le r_1,\end{aligned}$$

where the last inequality follows from (5.2).

These two inequalities show that $L(\cdot, \hat{u}_2)$ is a contraction on $\hat{B}^1_{r_1}(0)$ for each $\hat{u}_2 \in \hat{B}_{r_2}(0)$, which proves the existence of the function $\hat{E}(\cdot)$ on $\hat{B}^2_{r_2}(0)$. The C^1 property of $\hat{E}(\cdot)$ on $\hat{B}^2_{r_2}(0)$ can be proven fairly easily. ∎

Lemma 5.2 on the existence of a solution. Recall the notation $\tilde{X}_y = \mathbf{L}_2(1)$ and $\tilde{X}_z = \mathbf{L}_2(1) \times \mathbf{R}$. We have the following lemma.

LEMMA 5.2. *Suppose Assumption* 2 *holds and let* $z_0 = (y_0, 1)$. *If the operator* $\widetilde{F}'_z(z_0, 0) \in \mathcal{L}(\tilde{X}_z, \tilde{X}_y)$ *defined by*

$$(\widetilde{F}'_z(z_0,0)(v,\delta T))(t) = ((I - L^s)v)(t) - y_1^0(t)\delta T,$$

$$(L^s v)(t) = \int_{-\infty}^{t} h(t-\tau,0)\varphi'_y(y_0(\tau),0)v(\tau)\,d\tau,$$

$$y_1^0(t) = \int_{-\infty}^{t} h(t-\tau,0)\varphi(y(\tau),0)\,d\tau + \int_{-\infty}^{t} (t-\tau)\,dh((t-\tau),0)\varphi(y(\tau),0)$$

has a bounded right inverse, then for each sufficiently small $\theta \in \boldsymbol{R}$ *there exists* $y_\theta \in C(1)$ *and* $T_\theta > 0$ *that satisfies* (2.11). *The perturbed solution* $y_\theta = y(\theta)$, $T_\theta = T(\theta)$ *are* C^1 *functions of* θ *such that* $y(0) = y_0$ *and* $T(0) = 1$. *The perturbed solution is unique modulo phase delays (time translation).*

Proof. Let $F : X_z \times X_\theta \to X_y$ be defined as in (3.2). By assumption we have $F(z_0, 0) = 0$. The following conclusion follows from Theorem 5.1 with $V_1 = U_1 = X_z = C(1) \times \mathbf{R}$, $V_2 = X_\theta = \mathbf{R}$, $U_2 = I_\theta$, and $V_3 = X_y = C(1)$: if $F'_z(z_0, 0)$ has a bounded right inverse, then there exists a $z_\theta = (y_\theta, T_\theta) \in X_z$ satisfying $F(z_\theta, \theta) = 0$ for all $\theta \in (-\theta_0, \theta_0)$, where $\theta_0 > 0$ is some sufficiently small number. In other words, there exists a periodic solution of (2.11) for all sufficiently small θ. The C^1 condition on z_θ also follows from Theorem 5.1.

The Fréchet derivative of F with respect to its first argument at $(z_0, 0)$ is defined as

$$(F'_z(z_0,0)(v,\delta T))(t) = v(t) - \int_{-\infty}^{t} h(t-\tau,0)\varphi'_y(y_0(\tau),0)v(\tau)\,d\tau - y_1^0(t)\delta T.$$

We will show that the existence of a bounded right inverse to $\widetilde{F}'_z(z_0, 0)$ implies the existence of a bounded right inverse to $F'_z(z_0, 0)$, which proves Lemma 5.2. Note that these operators are defined in exactly the same way but on different spaces.

For notational convenience, we let

$$H^s := \widetilde{F}'_z(z_0,0) = \begin{bmatrix} I - L^s & y_1^0 \end{bmatrix} \in \mathcal{L}(\mathbf{L}_2(1) \times \mathbf{R}, \mathbf{L}_2(1)).$$

We have the topological inclusion $C(1) \hookrightarrow L_2(1)$ since $\|v\|_{\mathbf{L}_2(1)} \le \|v\|_{C(1)}$ for all $v \in C(1)$. This shows that the restriction $H^s|_{C(1)\times\mathbf{R}} = F'_z(z_0, 0)$. By assumption, there exists a right inverse of H^s, i.e., a bounded linear operator $G^s : \mathbf{L}_2(1) \to \mathbf{L}_2(1) \times \mathbf{R}$ such that

$$(H^s G^s)w = w \qquad \forall w \in \mathbf{L}_2(1).$$

We will show that $G = G^s|_{C(1)}$ is a bounded right inverse of $H^s|_{C(1)\times\mathbf{R}}$. Let $w \in C(1)$; then

$$w = (H^s \circ G)w = H^s(G_1 w, G_2 w) = (I - L^s)G_1 w + y_1^0 G_2 w,$$

which shows that $G_1 w = w + L^s G_1 w - y_1^0 G_2 w \in C(1)$. To prove boundedness we start with the second component. We have

$$\begin{aligned} \|G_2\|_{C(1)\to\mathbf{R}} &= \sup\{|G_2 w| : \|w\|_{C(1)} \le 1,\ w \in C(1)\} \\ &\le \sup\{|G_2 w| : \|w\|_{\mathbf{L}_2(1)} \le 1,\ w \in C(1)\} \\ &\le \sup\{|G_2^s w| : \|w\|_{\mathbf{L}_2(1)} \le 1,\ w \in \mathbf{L}_2(1)\} = \|G_2^s\|_{\mathbf{L}_2(1)\to\mathbf{R}}. \end{aligned}$$

For the first component we use

$$\begin{aligned}\|G_1 w\|_{C(1)} &= \|w + L^s G_1 w - y_1 G_2 w\|_{C(1)} \\ &\le \|w\|_{C(1)} + \|L^s\|_{\mathbf{L}_2(1)\to C(1)} \cdot \|G_1^s\|_{\mathbf{L}_2(1)\to\mathbf{L}_2(1)}\|w\|_{\mathbf{L}_2(1)} \\ &\quad + \|y_1^0\|_{C(1)} \cdot \|G_2\|_{C(1)\to\mathbf{R}}\|w\|_{C(1)} \\ &\le (1 + \|L^s\|_{\mathbf{L}_2(1)\to C(1)} \cdot \|G_1^s\|_{\mathbf{L}_2(1)\to\mathbf{L}_2(1)} + \|y_1^0\|_{C(1)}\cdot\|G_2^s\|_{\mathbf{L}_2(1)\to\mathbf{R}})\|w\|_{C(1)}.\end{aligned}$$

Note that $\|L^s\|_{\mathbf{L}_2(1)\to C(1)}$ is finite because we have (here $H = \mathcal{L}h$, $\mathcal{L}$ denotes the Laplace transform, H_n denotes the nth row of H, and $\hat{w}_k$ is the kth Fourier coefficient of w)

$$\begin{aligned}\Big|\int_{-\infty}^{t} h(t-\tau)w(\tau)\,d\tau\Big| &= \Big|\sum_{k=-\infty}^{\infty} H(i2\pi k)\hat{w}_k e^{-i2\pi kt}\Big| \le \sum_{k=-\infty}^{\infty}\sum_{n=1}^{p}\Big|H_n(i2\pi k)\hat{w}_k\Big| \\ &\le \sum_{n=1}^{p}\Big(\sum_{k=-\infty}^{\infty}|H_n(i2\pi k)|^2\Big)^{1/2}\Big(\sum_{k=-\infty}^{\infty}|\hat{w}_k|^2\Big)^{1/2} \le \Big(\sum_{n=1}^{p}\|H_n\|_2\Big)\|w\|_{\mathbf{L}_2(1)},\end{aligned}$$

where $\|H_n\|_2^2 = \sum_{k=-\infty}^{\infty}|H_n(i2\pi k)|^2 < \infty$, which follows since the SPES property of h can be used to show that $|H_n(i2\pi k)| \le \text{const}/k$ for all $n = 1, \dots, p$. Hence,

$$\|L^s\|_{\mathbf{L}_2(1)\to C(1)} \le \Big(\sum_{n=1}^{p}\|H_n\|_2\Big)\cdot\|\varphi_y'(y_0,0)\|_{C(1)}.$$

We have thus shown that $F_z'(z_0,0)$ has a bounded right inverse $F_z'(z_0,0)^\dagger = \widetilde{F}_z'(z_0,0)^\dagger|_{X_y}$, which, as we pointed out earlier, proves the existence.

Next we discuss the uniqueness. First notice that for each choice of right inverse the proof of Theorem 5.1 results in a unique solution that we can write as $u_1 = E_{G_0}(u_2)$. The solution is thus only unique modulo the particular choice of right inverse. To understand the implication for the perturbed solution we consider (for arbitrary θ)

$$F_z'(z_\theta,0) = [I - L^s(z_\theta,\theta) \quad y_1(z_\theta,\theta)] \in \mathcal{L}(C(1)\times\mathbf{R}, C(1)),$$

where $L^s(z_\theta,\theta)$ and $y_1(z_\theta,\theta)$ are defined as in (3.8). We will next show that

$$\operatorname{Ker} F_z'(z_\theta,\theta) = (\dot{y}_\theta, 0)$$

whenever the operator has a right inverse. This follows since, for any time translation d,

$$y_\theta(t+d) = \int_{-\infty}^{t} h(t-\tau,\theta)\varphi(y_\theta(\tau+d),\theta)\,d\tau.$$

Differentiation with respect to d at $d = 0$ gives

$$\dot{y}_\theta(t) = \int_{-\infty}^{t} h(t-\tau,\theta)\varphi_y'(y_\theta(\tau),\theta)\dot{y}_\theta(\tau)\,d\tau = (L^s(z_\theta,\theta)\dot{y}_\theta)(t).$$

This shows that $\dot{y}_\theta$ is an eigenfunction of $L^s(z_\theta,\theta)$ corresponding to the eigenvalue 1. We obtain the following necessary (and sufficient) condition for $F_z'(z_\theta,\theta)$ to have a

bounded right inverse:

(i) 1 is a simple eigenvalue of $L^s(z_\theta,\theta)$, which implies that $\operatorname{Im}(I-L^s)$ has codimension 1 since $L^s(z_\theta,\theta)$ is a compact operator;

(ii) $y_1 \notin \operatorname{Im}(I-L^s)$.

Hence, under the assumption of the theorem $\operatorname{Ker} F'_z(z_0,0) = (\dot y_0, 0)$. The implication is that the degree of freedom in the choice of the right inverse corresponds to the time translation of the nominal periodic solution. The limit cycle is a one-dimensional manifold whenever the right inverse exists and this implies that our perturbed solution $z_\theta = (y_\theta, T_\theta)$ is unique modulo time translation. A region of uniqueness can be proven using similar Lipschitz properties as was used in the proof of Theorem 5.1. □

Proof of Lemma 3.4. We start by repeating some of the discussions in section 3.1. Let $F : X_z \times X_\theta \to X_y$ be defined as in (3.2). A solution $z(\theta) = (y(\theta), T(\theta))$ to

$$F(z(\theta),\theta) = 0 \tag{5.3}$$

corresponds to a 1-periodic solution of (2.11). Differentiation of (5.3) gives

$$F'_z(z(\theta),\theta)\frac{dz}{d\theta} = -F'_\theta(z(\theta),\theta).$$

Now consider the operator $\widetilde F'_z : \mathcal{Z} \times I_\theta \to \mathcal{L}(\tilde X_z \times \tilde X_\theta, \tilde X_y)$ defined in (3.6)–(3.8). We note that the restriction of $\widetilde F'_z$ to $X_z \times X_\theta$ satisfies $\widetilde F'_z(z(\theta),\theta)|_{X_z} = F'_z(z(\theta),\theta)$. By assumption $\widetilde F'_z(z_0,0)$ has a bounded right inverse $\widetilde F'_z(z_0,0)^\dagger$, which by the proof of Lemma 5.2 implies that $\widetilde F'_z(z_0,0)|_{X_z} = F'_z(z_0,0)$ also has a bounded right inverse. In view of Lemma 3.3, the continuity of $F'_z(z,\theta)$ with respect to its arguments, and the continuity of the perturbed solution $z(\theta)$, it follows that for sufficiently small θ there exists a right inverse $F'_z(z(\theta),\theta)^\dagger$ such that

$$\frac{dz}{d\theta} = -F'_z(z(\theta),\theta)^\dagger F'_\theta(z(\theta),\theta). \tag{5.4}$$

In order to find a bound on θ for which this expression is valid we use Lemma 3.3. This leads to expression (3.5), which can be formulated equally well using the extensions of the operators to $\mathbf{L}_2(1)$ space. We can thus write

$$\frac{dz}{d\theta} = -\widetilde F'_z(z_0,0)^\dagger (I - \widetilde\Delta(z(\theta),\theta)\widetilde F'_z(z_0,0)^\dagger)^{-1}\widetilde F'_\theta(z(\theta),\theta). \tag{5.5}$$

Let Θ be the set of $\theta \in [-\bar\theta,\bar\theta]$ such that there exists a solution $z(\theta) \in \mathcal{Z}$ to (5.3). We use a homotopic argument based on the following observations to prove $\Theta = [-\bar\theta,\bar\theta]$:

(a) $0 \in \Theta$ since $z(0) = z_0 \in \mathcal{Z}$;

(b) if $[0,\theta] \in \Theta$, then (similarly with $[-\theta,0] \in \Theta$)

$$\begin{aligned}\|z(\theta) - z_0\|_{X_z} &\le \left\| \int_0^\theta \widetilde F'_z(z_0,0)^\dagger (I - \widetilde\Delta(z(\sigma),\sigma)\widetilde F'_z(z_0,0)^\dagger)^{-1}\widetilde F'_\theta(z(\sigma),\sigma)\,d\sigma \right\|_{X_z}\\ &\le \bar\theta \cdot \sup_{z\in\mathcal{Z},\ |\theta|\le\bar\theta} \|\widetilde F'_z(z_0,0)^\dagger (I - \widetilde\Delta(z,\theta)\widetilde F'_z(z_0,0)^\dagger)^{-1}\widetilde F'_\theta(z(\theta),\theta)\|_{\tilde X_\theta \to X_z} < r_0;\end{aligned}$$

(c) Θ is open as a subset of $[-\bar\theta,\bar\theta]$ since for any $\theta\in\Theta$ we have $\|\widetilde\Delta(z(\theta),\theta)\|_{\tilde X_z \to \tilde X_y} < 1/\|\widetilde F'_z(z_0,0)\|_{\tilde X_y \to \tilde X_z}$ by condition (ii). Then $\widetilde F'_z(z(\theta),\theta)$ is right invertible by Lemma 3.3, which by Lemma 5.2 implies the existence of a solution of (5.3) in

a neighborhood of θ. An explicit lower bound on this interval can be obtained since all derivatives are uniformly bounded in $[-\bar{\theta}, \bar{\theta}]$ and $\mathcal{Z}$. Indeed, we can use the second part of the implicit function theorem in Theorem 5.1 to derive a uniform bound on the neighborhood.[3]

Conclusions (a) and (c) imply that the set of θ such that there is a solution $z(\theta) \in \mathcal{Z}$ is nonempty and open as a subset of the interval $[-\bar{\theta}, \bar{\theta}]$ and (b) shows that it must be the full interval. Note that on the domain $[-\bar{\theta}, \bar{\theta}]$ the solution of (5.5) is unique and thus z_θ is unique modulo the choice of right inverse $\tilde{F}'_z(z_0, 0)^\dagger$. By the proof of Lemma 5.2 this corresponds to a degree of freedom due to the time translation. ∎

Proof of Theorem 3.7. We will use the standard implicit function theorem to prove this result. The Frechét derivative of (3.9) is

$$(\Psi'_z(0,0)(v, \delta d))(t) = \dot{y}_0(t)\delta d + v(t) - \int_0^t h(t-\tau)\varphi'(y_0(\tau))(\dot{y}_0(\tau)\delta d + v(\tau))\, d\tau.$$

To prove that $\Psi'_z(0,0)$ has a bounded inverse we need to show that there exists $c > 0$ such that for each $w \in V$ the equation

$$\dot{y}_0(t)\delta d + v(t) - \int_0^t h(t-\tau)\varphi'(y_0(\tau))(\dot{y}_0(\tau)\delta d + v(\tau))\, d\tau = w(t) \tag{5.6}$$

has a unique solution, which is bounded as $\|v\|_V^2 + |\delta d|^2 \le c\|w\|_V^2$. Let us restrict attention to solutions in $\mathbf{L}_{2\alpha}$ for a while. From the definition of L in (3.11) and from the proof of Proposition 3.5 it follows that system (5.6) (now extended to $\mathbf{L}_{2\alpha}$) can be rewritten as

$$(I - L)v + e\delta d = w, \tag{5.7}$$

where

$$e(t) = \int_{-\infty}^0 h(t-\tau)\varphi'(y_0(\tau))\dot{y}_0(\tau)\, d\tau = \dot{y}_0(t) - \int_0^t h(t-\tau)\varphi'(y_0(\tau))\dot{y}_0(\tau)\, d\tau \in \mathbf{L}_{2\alpha}[0,\infty).$$

The conclusion $e(t) \in \mathbf{L}_{2\alpha}[0,\infty)$ follows since h is exponentially stable with the decay rate α. Indeed, we have

$$e^{\alpha t}e(t) = \int_0^\infty e^{-\alpha s}e^{\alpha(t+s)}h(t+s)\varphi'(y_0(-s))\dot{y}_0(-s)\, ds.$$

This implies

$$\begin{aligned}\|e\|_\alpha^2 &\le \int_0^\infty \int_0^\infty e^{-\alpha s_1}e^{-\alpha s_2}\, ds_1\, ds_2 \|e^{\alpha t}h(t)\|^2 \cdot \|\varphi'(y_0)\dot{y}_0\|_\infty^2 \\ &\le \frac{1}{\alpha^2}\|e^{\alpha t}h(t)\|^2 \cdot \|\varphi'(y_0)\dot{y}_0\|_\infty^2,\end{aligned}$$

which proves the claim since $\|e^{\alpha t}h(t)\|$ is bounded by Lemma 2.2(c).

By assumption $\mathrm{def}_\alpha(L) = 1$, which implies that $V_1 = \mathrm{Im}\,(I - L)$ has codimension 1. We thus have a direct sum decomposition $\mathbf{L}_{2\alpha}[0,\infty) = V_1 \oplus V_1^\perp$, where $V_1^\perp$ is one-dimensional. The following properties will be used.

[3]The implicit function theorem can be directly used to estimate a robustness margin using computations in $C(1)$. However, this generally leads to conservative bounds.

(i) $(I-L):\mathbf{L}_{2\alpha}[0,\infty)\to V_1$ has a bounded inverse, i.e., there exists $\gamma>0$ such that $\|(I-L)^{-1}|_{V_1}\|\le\gamma$, which follows since when the domain of the inverse is restricted to V_1, the (closed) image of $(I-L)$, then the inverse is bounded by the Banach inverse theorem since $\operatorname{Ker}(I-L)=0$.

(ii) $(I-P_{V_1})e\neq 0$, where P_{V_1} is the orthogonal projection onto V_1. This follows from Proposition 3.5 since $(I-L)^{-1}e\notin\mathbf{L}_{2\alpha}$.

From (5.7) we obtain $(I-P_{V_1})e\delta d=(I-P_{V_1})w$, which has a unique solution by (ii) above. This gives the bound

$$|\delta d|\le c_1\|w\|_V,\quad c_1=1/\|(I-P_{V_1})e\|_V.$$

With this δd, we have $(I-L)v=w-e\delta d\in V_1$, which has a unique solution by (i) above. Moreover, we immediately get the norm bound

$$\|v\|_\alpha\le\gamma\|w-e\delta d\|_\alpha\le\gamma(\|w\|_\alpha+|\delta d|\cdot\|e\|_\alpha)\le\gamma(1+c_1\|e\|_\alpha)\|w\|_V.$$

However, we need a bound in terms of the norm $\|\cdot\|_V$. A $\|\cdot\|_\infty$ bound is obtained from the following derivation:

$$\begin{aligned}\|v\|_\infty&=\|Lv+w-e\delta d\|_\infty\le\|L\|_{\mathbf{L}_{2\alpha}\to\mathbf{L}_\infty}\cdot\|v\|_\alpha+\|w\|_\infty+c_1\|e\|_\infty\cdot\|w\|_V\\&\le(\|L\|_{\mathbf{L}_{2\alpha}\to\mathbf{L}_\infty}\gamma(1+c_1\|e\|_\alpha)+c_1\|e\|_\infty+1)\|w\|_V,\end{aligned}$$

where the norm $\|L\|_{\mathbf{L}_{2\alpha}\to\mathbf{L}_\infty}$ is bounded since h is SPES, see Lemma 3 in [7] for a related proof. Hence, we have $\|v\|_V\le c_2\|w\|_V$, where

$$c_2=\max(\gamma(1+c_1\|e\|_\alpha),\|L\|_{\mathbf{L}_{2\alpha}\to\mathbf{L}_\infty}\gamma(1+c_1\|e\|_\alpha)+c_1\|e\|_\infty+1).$$

This together with the previous bound on $|\delta d|$ shows that $\Psi_z'(0,0)$ has a bounded inverse. In fact, we have shown $\Psi_z'(0,0)^{-1}:\mathcal{X}_y\to\mathcal{X}_z$ satisfies $\|\Psi_z'(0,0)^{-1}\|_{\mathcal{X}_y\to\mathcal{X}_z}\le c$, where $c=(c_1^2+c_2^2)^{1/2}$.

Boundedness of $\Psi_z'(0,0)^{-1}$ implies by the implicit function theorem that there exists an open set $V_0\subset\mathcal{X}_y$ containing 0 and a C^1 function $E:V_0\to\mathcal{X}_z$ such that $\Psi(E(\delta f),\delta f)=0$ for all $\delta f\in V_0$. It is no restriction to assume that V_0 is convex since otherwise we can consider a ball $\{v\in V:\|v\|_V\le\eta\}\subset V_0$. We further have

$$E'(\delta f)=-\Psi_z'(E(\delta f),\delta f)^{-1}\Psi_{\delta f}'(E(\delta f),\delta f)=\Psi_z'(E(\delta f),\delta f)^{-1}.$$

We obtain the following bound in the $\widetilde{\mathcal{X}}_z=\mathbf{L}_{2\alpha}\times\mathbf{R}$-space:

$$\begin{aligned}\|\delta y\|_\alpha^2+|\delta d|^2&=\|E_1(\delta f)\|_\alpha^2+|E_2(\delta f)|^2=\|E(\delta f)-E(0)\|_{\mathbf{L}_{2\alpha}\times\mathbf{R}}^2\\&=\Big\|\int_0^1E'(s\delta f)\cdot\delta f\,ds\Big\|_{\mathbf{L}_{2\alpha}\times\mathbf{R}}^2\\&\le\sup_{s\in[0,1]}\|E'(s\delta f)\|_{\mathbf{L}_{2\alpha}\to\mathbf{L}_{2\alpha}\times\mathbf{R}}^2\|\delta f\|_\alpha^2\\&\le\sup_{v\in V_0}\|E'(v)\|_{\mathbf{L}_{2\alpha}\to\mathbf{L}_{2\alpha}\times\mathbf{R}}^2\|\delta f\|_\alpha^2\\&=\sup_{v\in V_0}\|\widetilde{\Psi}_z'(E(\delta f),\delta f)^{-1}\|_{\mathbf{L}_{2\alpha}\to\mathbf{L}_{2\alpha}\times\mathbf{R}}^2\|\delta f\|_\alpha^2\end{aligned}$$

for all $\delta f\in V_0$. Here $\widetilde{\Psi}_z'\in\mathcal{L}(\tilde{X}_z,\tilde{X}_y)$ is the extension of Ψ_z' to $\mathbf{L}_{2\alpha}$. Since Ψ is C^1 it follows that for any $\epsilon>0$ we get the bound

$$\|\delta y\|_\alpha^2+|d|^2\le c(\epsilon)^2\|\delta f\|_\alpha^2$$

by choosing V_0 small enough, where

$$c(\epsilon)^2 = \widetilde{c}_1^2 + \gamma^2(1+\widetilde{c}_1\|e\|_\alpha)^2 + \epsilon, \quad \widetilde{c}_1 = 1/\|(I-P_{V_1})e\|_\alpha.$$

This proves the exponential stability inequality in (2.10). □

Proof of Lemma 3.9. According to Theorem 3.7 we need to show that $L = L^0 + \Delta L$ has α-defect 1. We have

$$\begin{aligned}\|(I - L_\alpha^0 - \Delta L_\alpha)v\| &\geq \|(I-L_\alpha^0)v\| - \|\Delta L_\alpha v\| \\ &\geq (c - \|\Delta L_\alpha\|)\|v\| \geq \varepsilon\|v\|,\end{aligned}$$

where the last inequality follows from (3.16). Hence, we have shown that $\operatorname{Ker}(I - L_\alpha^0 - \Delta L_\alpha) = 0$ for all $\|\Delta L_\alpha\| \leq c - \epsilon$. The proof follows if we in addition prove that $\operatorname{codim}\operatorname{Im}(I - L_\alpha^0 - \Delta L_\alpha) = 1$. Since the codimension of $\operatorname{Im}(I - L_\alpha^0)$ is 1 it follows that we can find $v_1 \in \mathbf{L}_2[0,\infty)$ with $\|v_1\| = 1$ and $v_1 \perp \operatorname{Im}(I - L_\alpha^0)$. If we define $H : \mathbf{L}_2[0,\infty) \times \mathbf{R} \to \mathbf{L}_2[0,\infty)$ by

$$H(v,t_1) = (I - L_\alpha^0)v + ct_1v_1,$$

then H is a bijection and it follows from the Banach inverse theorem that it has a bounded inverse. Since

$$\|(I - L_\alpha^0)v + ct_1v_1\| \geq c(\|v\|^2 + |t_1|^2)^{1/2}$$

we have $\|H^{-1}\| \leq c^{-1}$. With $\Delta H(v,t_1) = -\Delta L_\alpha v$ we see that $H + \Delta H = H(I + H^{-1}\Delta H)$ is invertible since $\|H^{-1}\Delta H\| \leq 1 - \epsilon/c < 1$. It follows that $\operatorname{codim}\operatorname{Im}(I - L_\alpha^0 - \Delta L_\alpha) = 1$. □

Proof of Proposition 3.14. From Lemma 3.8 it follows that we can equivalently consider the operator L_α on $\mathbf{L}_2$ when deciding the stability defect. We will show

(i) $\operatorname{Ker}(I - L_\alpha) = 0$,

(ii) $\operatorname{codim}\operatorname{Im}(I - L_\alpha) = 1$.

Conditions (i) and (ii) show that L_α is a Fredholm operator with index 1. From Banach's isomorphism theorem it follows that $I - L_\alpha$ is nonsingular. This proves the theorem.

To prove (i) we assume that there exists nonzero $v \in \mathbf{L}_2$ such that $(I - L_\alpha)v = 0$. In the state-space domain this means that

$$\dot{x} = (A + \alpha I)x + B\varphi'(y_0(t))v, \quad x(0) = 0, \quad 0 = v - Cx$$

which implies that $v = Cx$ and $\dot{x} = (A + \alpha I + B\varphi'(y_0(t))C)x$, $x(0) = 0$. This contradicts the assumption that v is nonzero. Hence, $\operatorname{Ker}(I - L_\alpha) = 0$.

To prove (ii) we use $(\operatorname{Im}(I - L_\alpha))^\perp = \operatorname{Ker}(I - L_\alpha)^*$. One possible state-space representation of the adjoint system $v \mapsto w = (I - L_\alpha^*)v$ is

$$\begin{aligned}\dot{x} &= -(A + \alpha I)^T x + C^T v, \ x(\infty) = 0, \\ w &= v + \varphi'(y_0(t))^T B^T x.\end{aligned}$$

Any $v \in \operatorname{Ker}(I - L_\alpha^*)$ must satisfy $v = -\varphi'(y_0(t))^T B^T x$, where

$$\dot{x} = -(A + \alpha + B\varphi'(y_0(t))C)^T x, \quad x(\infty) = 0. \tag{5.8}$$

A result by Lyapunov shows that there exists a time-periodic coordinate transformation that turns system (5.8) into a linear system with constant coefficients; see, e.g., [4]. It is no restriction to assume the new coordinates are chosen such that

$$\begin{bmatrix} \dot{z}_1 \\ \dot{z}_2 \end{bmatrix} = \begin{bmatrix} -\alpha & 0 \\ 0 & A_2 \end{bmatrix} \begin{bmatrix} z_1 \\ z_2 \end{bmatrix}, \qquad \begin{bmatrix} z_1(\infty) \\ z_2(\infty) \end{bmatrix} = 0,$$

where $A_2 \in \mathrm{C}^{(n-1)\times(n-1)}$ has all its characteristic multipliers outside the unit disc since $-\alpha T - \log|\lambda_2| > 0$. If the coordinates are related as

$$x(t) = [P_1(t) \quad P_2(t)], \begin{bmatrix} z_1(t) \\ z_2(t) \end{bmatrix},$$

where $P(t) = [P_1(t) \quad P_2(t)]$ is invertible and T is periodic, then we see that

$$\operatorname{Ker}(I - L_\alpha)^* = \{v(t) = -\varphi'(y_0(t))^T B^T P_1(t) e^{-\alpha t} z_1(0) : z_1(0) \in \mathbf{R}\}.$$

This is a one-dimensional space. Hence, we have shown that $\operatorname{Ker}(I - L_\alpha) = 0$ and $\operatorname{codim} \operatorname{Im}(I - L_\alpha) = 1$. This implies $\operatorname{def}(L_\alpha) = 1$, which by Lemma 3.8 implies $\operatorname{def}_\alpha(L) = 1$. □

Proof of Theorem 3.1. First note that the characteristic multipliers do not change if we normalize the nominal period time to $T_0 = 1$ in (2.1). Existence of a solution in a neighborhood of $\theta = 0$ follows from Lemma 5.2 if $\widetilde{F}'_z(z_0, 0)$ has a bounded right inverse. From Proposition 3.12, we see that this is the case since $n - 1$ of the characteristic multipliers are different from 1.

To prove exponential stability we consider the operator L in (3.11), which becomes

$$(L(\theta)v)(t) = \int_0^t T(\theta) h(T(\theta)(t-\tau), \theta) \varphi'_y(y_\theta(\tau), \theta) v(\tau)\, d\tau.$$

It follows from Proposition 3.14 that $L(0)$ has the α-defect 1. The same arguments that we used to prove Lemma 3.9 shows that the α-defect remains constant for sufficiently small θ since $L(\theta)$ depends continuously on θ. Hence, $\operatorname{def}_\alpha(L(\theta)) = 1$ for sufficiently small θ, which by Theorem 3.7 proves exponential stability. □

MINIMAX OPTIMAL CONTROL*

R. B. VINTER†

Abstract. This paper provides a framework for deriving necessary conditions, in the form of a maximum principle, for minimax optimal control problems. The distinguishing feature of these problems is that the data depends on a vector α of unknown parameters, and "optimality" is defined on a worst case basis, as α ranges over the parameter set $\mathcal{A}$. The centerpiece, a minimax maximum principle, is a set of optimality conditions for such problems. Here, the parameter set $\mathcal{A}$ is taken to be an arbitrary compact metric space and the hypotheses imposed on the dynamics and endpoint constraints are of an unrestrictive nature. The minimax maximum principle captures as special cases necessary conditions for optimal control problems with minimax costs, for problems involving "semi-infinite" endpoint constraints, and also a maximum principle for state constrained optimal control problems.

Key words. optimal control, minimax problems, nonsmooth analysis, robust control

1. Introduction.

The purpose of this paper is to derive, in a unified fashion, necessary conditions of optimality for optimal control problems involving an unknown vector parameter. In these problems, "optimality" is typically defined in terms of worst case performance, i.e., the cost of a particular control strategy is that associated with the strategy and a system response corresponding to the least favorable value of the unknown parameter, and constraints are required to be satisfied for all values of the unknown parameter.

Fix a compact metric space $(\mathcal{A}, \rho_{\mathcal{A}}(.,.))$. Take functions $f : [0,1] \times R^n \times R^m \times \mathcal{A} \to R^n$ and $g : R^n \times \mathcal{A} \to R$, a vector $x_0 \in R^n$, a time dependent set $\Omega(t) \subset R^m$, $0 \le t \le 1$, and a family of closed sets $\{C(\alpha) \subset R^n \mid \alpha \in \mathcal{A}\}$.

A *control function* is a measurable function $u : [0,1] \to R^m$ satisfying $u(t) \in \Omega(t)$ *a.e.* The set of control functions is written $\mathcal{U}$. A *process* $(u, \{x(.;\alpha) \mid \alpha \in \mathcal{A}\})$ comprises a control function u and a family $\{x(.;\alpha) \in W^{1,1}([0,1]; R^n) \mid \alpha \in \mathcal{A}\}$ of arcs satisfying, for each $\alpha \in \mathcal{A}$,

$$\begin{cases} \dot{x}(t;\alpha) = f(t, x(t;\alpha), u(t), \alpha) \quad a.e. \\ x(0;\alpha) = x_0. \end{cases}$$

The process is termed *feasible* if the $x(.;\alpha)$s satisfy the terminal constraints

$$x(1;\alpha) \in C(\alpha) \quad \text{for all } \alpha \in \mathcal{A}.$$

The optimization problem of interest in this paper, which will be referred to as the

†Department of Electrical and Electronic Engineering, Imperial College of Science Technology and Medicine, Exhibition Road, London SW7 2BT, UK (r.vinter@imperial.ac.uk).

general minimax optimal control problem, is as follows:

$$(\mathrm{P})\quad \left\{\begin{array}{l} \text{Minimize } \max_{\alpha\in\mathcal{A}} g(x(1;\alpha),\alpha) \\ \qquad \text{over measurable functions } u:[0,1]\to R^m \text{ such that} \\ u(t)\in\Omega(t) \quad \textit{a.e. } t\in[0,1] \\ \qquad \text{and arcs } \{x(.;\alpha):[0,1]\to R^n \mid \alpha\in\mathcal{A}\} \text{ such that, for each } \alpha\in\mathcal{A}, \\ \dot{x}(t;\alpha)=f(t,x(t;\alpha),u(t),\alpha) \quad \textit{a.e. } t\in[0,1], \\ x(0;\alpha)=x_0 \quad \text{and} \quad x(1;\alpha)\in C(\alpha). \end{array}\right.$$

Briefly stated, the problem is to minimize $\sup_{\alpha\in\mathcal{A}} g(x(1;\alpha),\alpha)$ over feasible processes $(u,\{x(.;\alpha)\mid\alpha\in\mathcal{A}\})$.

A feasible process $(\bar{u},\{\bar{x}(.;\alpha)\mid\alpha\in\mathcal{A}\})$ is said to be a strong local minimizer when there exists $\epsilon>0$ such that

$$\sup_{\alpha\in\mathcal{A}} g(x(1;\alpha),\alpha) \;\geq\; \sup_{\alpha\in\mathcal{A}} g(\bar{x}(1;\alpha),\alpha)$$

for all feasible processes $(u,\{x(.;\alpha),\alpha\in\mathcal{A}\})$ such that

$$\|x(.;\alpha)-\bar{x}(.;\alpha)\|_C\leq\epsilon \quad \text{for all } \alpha\in\mathcal{A}\,.$$

The implications of our necessary conditions for various special cases of interest will also be investigated.

Our framework permits the set $\mathcal{A}$ of unknown parameter values to be an arbitrary compact metric space. It therefore covers minimax optimal control problems in which components of α comprise unknown gain values lying within specified bounds, magnitudes of step disturbances, etc., important cases that would be excluded by the requirement that $\mathcal{A}$ be a finite set.

The presence of, possibly, an infinite number of elements in $\mathcal{A}$ is the principal source of difficulty in the derivation of necessary conditions for minimax optimal control problems. In case $\mathcal{A}$ is a finite set $\{\alpha_1,\alpha_2,\ldots,\alpha_N\}$, the minimax optimal control problems studied here can be reformulated as standard optimal control problems, for which necessary conditions are already known. (See section 2.)

We comment on related earlier research. The most extensively studied minimax optimal control problems are zero sum differential games, in which a minimizer is chosen from a class of closed loop controls, appropriately defined, and the parameter set $\mathcal{A}$, from which a "worst case" element is selected, comprises open loop control functions of an opposing player [1], [4]. The fact that differential games are posed over closed loop controls gives them a quite different character to the problems studied here, in which the choice variables are open loop controls. Analysis of solutions to differential games is almost exclusively of a global nature, centering on the relationship between the value of the differential game and the solutions to the Hamilton–Jacobi equation; variants on the pontryagin maximum principle, such as featured in this paper, have a limited role in the analysis of optimal feedback strategies.

Versions of the open loop minimax optimal control problem were previously investigated by Warga, in the context of "relaxed and hyper-relaxed adverse controls." Warga adopts a broader framework than ours, in which the parameter set can include open control functions of an opposing player as well as finite dimensional vector parameters. Furthermore, he addresses questions of existence of solutions to minimax optimal control problems and appropriate relaxation schemes as well as local optimality conditions. Our minimax maximum principle, involving a Hamiltonian averaged

with respect to some measure, is implicit in the necessary conditions in ([11], Chapters IX and X). Warga's necessary conditions apply only in cases when the endpoint constraint sets are closed, convex sets with nonempty interiors and for smooth dynamics. The necessary conditions of this paper are proved by quite different methods and under significantly weaker hypotheses (for the minimax problems here considered). Furthermore, we give new insights into the limits of validity of the kinds of necessary conditions investigated here, by presenting some counterexamples where they no longer apply. Optimality conditions akin to those of section 2 below are featured also in [2], but only in the elementary case when the parameter set is a finite set and the endpoint constraint is specified by a functional inequality. The role of measures to estimate "gradients" of max functions is evident in the early Russian optimal control literature [5] and is widely exploited in nonsmooth analysis, for example, in applications of nonsmooth analysis to derive optimality conditions for state constrained optimal control problems [3].

Another point of contact with earlier work is semi-infinite programming. This is a branch of nonlinear programming that aims to provide efficient computational methods for optimization problems, in which constraints must be satisfied for a continuum of values of some parameter α. (See [8].) Minimax optimal control problems can be reformulated, by introduction of additional variables, as semi-infinite programming problems over function spaces with dynamic constraints.

One possible approach to the computation of solutions to a minimax optimal control problem is to approximate it by a (finite-dimensional) semi-infinite programming problem by means of time discretization and to apply semi-infinite programming algorithms. The emphasis in this paper is on structural properties of solutions to minimax optimal control problems. But the necessary conditions of optimality we provide may ultimately find application in convergence analysis of algorithms for minimax optimal control, based on semi-infinite programming or other approaches.

We allow nonsmooth data and express necessary conditions in terms of "limiting subdifferentials" and other constructs of nonsmooth analysis. We stress, however, that it is the unrestrictive nature of the conditions that we place on the parameter set $\mathcal{A}$, "$\mathcal{A}$ is an arbitrary compact metric space," which is the most significant feature of our analysis. The main optimality conditions supplied here (the maximum principle for the general minimax optimal control problem of section 3 and the implications explored in section 5) are new, even when specialized to the smooth case.

Finally, some notation. Throughout, $|\,.\,|$ denotes the Euclidean norm. We write B for the closed unit ball in Euclidean space. $B_{\mathcal{A}}(\alpha, \epsilon)$ denotes the set $\{\alpha' \in \mathcal{A} \mid \rho_{\mathcal{A}}(\alpha, \alpha') \leq \epsilon\}$.

$W^{1,1}([0,1]; R^n)$ is the space of absolutely continuous R^n-valued functions on $[0,1]$. Take a compact metric space A. $C(A)$ denotes the space of continuous real valued functions on A. We write $||.||_C$ for the supremum norm on this space. $C^*(A)$ denotes the topological dual of $C(A)$ with the norm topology. We use the fact that elements in $C^*(A)$ can be identified with the space of Radon measures on the Borel subsets of A. The dual norm of an element $\mu \in C^*(A)$ is written $||\mu||_{T.V.}$, a choice of notation that reflects the fact that the dual norm of μ coincides with the total variation of the Radon measure that represents μ.

The graph of a multifunction $D : A \rightsquigarrow R^k$ is denoted by $Gr\,D$,

$$Gr\,D \;:=\; \{(a,d) \in A \times R^k \,|\, d \in D(a)\}\,.$$

For a given set $E \subset R^d$, $d_E(.)$ denotes the Euclidean distance function

$$d_E(z) \;:=\; inf_{e \in E}|z - e|.$$

The *limiting normal cone* to a given closed set $C \subset R^k$ at $x \in R^k$ is the set

$$N_C(x) := \big\{\xi \in R^n \mid \exists\, \xi_i \to \xi, x_i \overset{C}{\to} x \text{ and } \{M_i\} \subset R^+ \\ \text{such that, for each } i,\ \xi_i \cdot (x - x_i) \le M_i |x - x_i|^2\ \forall\, x \in C\big\}.$$

Here "$x_i \overset{C}{\to} x$" means "$x_i \to x$ and $x_i \in C$ for all i." Note that $N_C(x) = \emptyset$, in the case $x \notin C$.

Take a function $f : R^n \to R \cup \{+\infty\}$ and a point $x \in dom\, f$. Here, $dom\, f$ is taken to be the set

$$dom\, f = \{y \in R^n \mid f(y) < +\infty\}.$$

The epigraph set of f is the set

$$epi\, f := \{(x, \alpha) \in R^n \times R \mid \alpha \ge f(x)\}.$$

The *limiting subdifferential* $\partial f(x)$ of $f : R^n \to R \cup \{+\infty\}$ at a point $x \in dom\, f$ is the set

$$\partial f(x) := \big\{\eta \mid (\eta, -1) \in N_{\mathrm{epi} f}(x, f(x))\big\}.$$

The partial limiting subdifferential $\partial_x f(x, y)$ of an extended valued function f of two variables x and y is the limiting subdifferential of $x \to f(x, y)$ for fixed y.

$N_C(x)$ and $\partial f(x)$ are widely used constructs from nonsmooth analysis in optimal control, that generalize classical notions of the set of outward normal vectors to a set with smooth boundary and of the gradient of a continuously differentiable function. They are also referred to as the normal cone and the subdifferential, respectively. For a review of their properties (and historical comments), see, for example, [7], [9], [10].

2. The finite parameter set case. Necessary conditions for minimax problems involving an arbitrary compact metric space parameter set $\mathcal{A}$ will be derived by approximating $\mathcal{A}$ by a finite set $\mathcal{A}_N$, by establishing properties of approximate minimizers for problems involving A_N, and passage to the limit. Necessary conditions for problems with finite parameter sets have an important intermediate role then in the proof of more general necessary conditions. This is one reason for attending to the finite parameter set case at this early stage. But studying this special case also gives insights into the necessary conditions we should expect to be valid in more general circumstances.

We shall invoke the following hypotheses on the data for the general minimax optimal control problem, in which $(\bar{u}, \{\bar{x}(.; \alpha) \mid \alpha \in \mathcal{A}\})$ is the strong local minimizer under consideration. For some $\delta > 0$,

(H1) The function $f(., x, ., \alpha)$ is $\mathcal{L} \times \mathcal{B}^m$ measurable for each $(x, \alpha) \in R^n \times \mathcal{A}$. ($\mathcal{L}$ denotes the Lebesgue subsets of $[0, 1]$ and $\mathcal{B}^m$ denotes the Borel subsets of R^m.) $t \rightsquigarrow \Omega(t)$ has a Borel measurable graph.

(H2) There exists a Borel measurable function $k_f : [0, 1] \times R^m$ such that $t \to k_f(t, \bar{u}(t))$ is integrable and, for each $\alpha \in \mathcal{A}$,

$$|f(t, x, u, \alpha) - f(t, x', u, \alpha)| \le k_f(t, u)|x - x'|$$

for all $x, x' \in \bar{x}(t; \alpha) + \delta B$, $u \in \Omega(t)$, *a.e.* $t \in [0, 1]$.

(H3) The function $g(.,\alpha)$ is Lipschitz continuous on $\bar{x}(1;\alpha)+\delta B$ for all $\alpha\in\mathcal{A}$.
Define the Hamiltonian

$$H(t,x,p,u,\alpha) := p\cdot f(t,x,u,\alpha).$$

PROPOSITION 2.1. *Let $(\bar{u},\{\bar{x}(.;\alpha)\mid\alpha\in\mathcal{A}\})$ be a strong local minimizer for the general minimax optimal control problem* (P). *Assume that $\mathcal{A}$ is a finite set and that, for some $\delta>0$, hypotheses* (H1)–(H3) *are satisfied.*

Then

$$\int H(t,\bar{x}(t;\alpha),\bar{u}(t),p(t;\alpha),\alpha)\ \Lambda(d\alpha)$$
$$= \max_{u\in\Omega(t)} \int H(t,\bar{x}(t;\alpha),u,p(t;\alpha),\alpha)\ \Lambda(d\alpha). \qquad a.e.\ t\in[0,1],$$

for some Radon probability measure $\Lambda\in C^*(\mathcal{A})$ and some family of arcs $\{p(.;\alpha)\in W^{1,1}([0,1];R^n)\mid\alpha\in\mathcal{A}\}$ such that, for Λ – a.e. $\alpha\in\mathcal{A}$,

$$\begin{aligned} -\dot{p}(t;\alpha) &\in co\,\partial_x H(t,\bar{x}(t;\alpha),\bar{u}(t),p(t;\alpha),\alpha) \quad a.e.,\\ -p(1;\alpha) &\in \bigcup_{0\le r\le 1}\{rG_0(\bar{x}(1;\alpha),\alpha)+(1-r)N(\bar{x}(1;\alpha),\alpha)\} \end{aligned} \tag{2.1}$$

and

$$supp\,\Lambda \subset \{\alpha\mid either\ G_0(\bar{x}(1;\alpha),\alpha)\neq\emptyset\ or\ N(\bar{x}(1;\alpha),\alpha)\neq\emptyset\}.$$

Here,

$$G_0(x,\alpha) := \begin{cases}\partial_x g(x,\alpha) & \text{if } g(x,\alpha)=max_{\alpha'\in\mathcal{A}}\ g(x,\alpha')\\ \emptyset & \text{otherwise}\end{cases}$$

and

$$N(x,\alpha) := \{\xi\in N_{C(\alpha)}(x)\,|\,|\xi|=1\}.$$

In condition (2.1), we allow the possibilities that (for some values of α) $G_0(x,\alpha)=\emptyset$ or $N(x,\alpha)=\emptyset$. If $G_0(x,\alpha)=\emptyset$, then $rG_0(x,\alpha)$ is defined only if $r=0$; in this case $rG_0(x,\alpha):=\{0\}$. If $N(x,\alpha)=\emptyset$, then $(1-r)N(x,\alpha)$ is defined only if $r=1$; in this case $(1-r)N(x,\alpha):=\{0\}$. Thus (2.1) implies that if $\Lambda(\{\alpha\})>0$, then the parameter α is "active" in either the endpoint constraint or in the objective, in the sense that

$$g(\bar{x}(1,\alpha),\alpha)=\max_{\alpha'\in\mathcal{A}} g(\bar{x}(1,\alpha'),\alpha') \quad\text{or}\quad \bar{x}(1:\alpha)\in bdy\,C(\alpha)\,.$$

($bdy\,C(\alpha)$ denotes the "boundary of the set $C(\alpha)$.")

Proof of Proposition 2.1. List the elements in the finite set $\mathcal{A}$ as

$$\mathcal{A}=\{\alpha_1,\alpha_2,\ldots,\alpha_N\}.$$

Denote by $\bar{x}=col\,\{\bar{x}(.;\alpha_1),\bar{x}(.;\alpha_2),\ldots,\bar{x}(.;\alpha_N)\}$ the collection of state trajectories corresponding to $\bar{u}$. Then $(\bar{u},\bar{x})$ is a strong local minimizer for the standard optimal control problem

$$(\tilde{\mathrm{P}})\begin{cases}\text{Minimize } \tilde{g}(x(1)) \text{ over } u(.) \text{ satisfying}\\ \dot{x}(t)=\tilde{f}(t,x(t),u(t)) \quad a.e.\ t\in[0,1],\\ x(0)=\tilde{x}_0,\\ x(1)\in\tilde{C},\\ u(t)\in\Omega(t) \quad a.e.\ t\in[0,1]\,,\end{cases}$$

in which the $N \times n$ dimensional state vector is partitioned as

$$\begin{aligned} x &= col\ \{x_1, x_2, \ldots, x_N\}, \\ \tilde{f}(t,x,u) &= col\ \{f(t,x_i,u,\alpha_i)\}_{i=1}^N, \\ \tilde{C} &= C(\alpha_1) \times C(\alpha_2) \times \cdots \times C(\alpha_N), \\ \tilde{x}_0 &= col\,\{x_0, x_0, \ldots, x_0\}, \\ \tilde{g}(x) &= \max_i\ g(x(.;\alpha_i),\alpha_i). \end{aligned}$$

Under the stated hypotheses, we deduce from the nonsmooth maximum principle (see, for example, [10], Theorem 6.2.1)), with the help of the max rule ([10], Theorem 5.5.2) to evaluate the limiting subdifferential of the cost function $\tilde{g}$, the following information. There exist numbers $\lambda_1, \ldots, \lambda_N \geq 0$, arcs $q(.;\alpha_i) \in W^{1,1}$, and elements $\xi_i \in N_{C(\alpha_i)}(x(1;\alpha_i))$, $i = 1, 2, \ldots, N$, such that

$$\text{(i)} \sum_{i=1}^N H(t, \bar{x}(t;\alpha_i), \bar{u}(t), q(t;\alpha_i), \alpha_i) = \max_{u \in \Omega(t)}\ \sum_{i=1}^N H(t, \bar{x}(t;\alpha_i), u, q(t;\alpha_i), \alpha_i) \quad a.e.$$

$$\text{(ii)} \sum_{i=1}^N (\lambda_i + |\xi_i|)\ =\ 1$$

and, for each i,

$$\text{(iii)} -\dot{q}(t;\alpha_i)\ \in\ \text{co}\,\partial_x H(t, \bar{x}(t;\alpha_i), \bar{u}(t), q(t;\alpha_i), \alpha_i) \quad a.e.,$$

$$\text{(iv)} -q(1;\alpha_i)\ \in\ \lambda_i \partial_x g(\bar{x}(t;\alpha_i),\alpha_i) + \xi_i,$$

$$\text{(v)} \lambda_i = 0 \quad \text{if} \quad g(\bar{x}(1;\alpha_i),\alpha_i) < \max_j\ g(\bar{x}(1;\alpha_j),\alpha_j).$$

Define Λ to be the discrete probability measure

$$\Lambda = \sum_{i=1}^N (\lambda_i + |\xi_i|)\ \delta_{\alpha_i},$$

in which δ_{α_i} denotes the unit measure concentrated at $\alpha = \alpha_i$. If $\alpha \in supp\ \{\Lambda\}$, in which case $\alpha = \alpha_i$ for some i such that $(\lambda_i + |\xi_i|) > 0$, define

$$p(t;\alpha_i) = \frac{1}{\lambda_i + |\xi_i|}\ q(t;\alpha_i).$$

If $\alpha \notin supp\ \{\Lambda\}$, choose the $W^{1,1}$ function $p(.;\alpha)$ arbitrarily.
All the assertions of the proposition can be confirmed for this choice of Λ and $\{p(.;\alpha) \mid \alpha \in \mathcal{A}\}$.

Note, in particular, that, if $\alpha_i \in supp\ \{\Lambda\}$, then

$$-p(1;\alpha_i) \in r_i \partial_x g(\bar{x}(1;\alpha_i),\alpha_i) + (1 - r_i)\{\xi \in N_{C(\alpha_i)}(\bar{x}(1;\alpha_i)) \mid |\xi| = 1\}.$$

Here, r_i, $0 \leq r_i \leq 1$, is the number

$$r_i = \frac{\lambda_i}{\lambda_i + |\xi_i|}.$$

We also observe that, for each $t \in [0,1]$ and $u \in \Omega(t)$,

$$\sum_{i=1}^{N} H(t, \bar{x}(t;\alpha_i), u, q(t;\alpha_i), \alpha_i) = \int_{\mathcal{A}} H(t, \bar{x}(t;\alpha), u, p(t;\alpha), \alpha)\ \Lambda(d\alpha),$$

i.e., the maximization of the "averaged" Hamiltonian condition is satisfied. Finally, note that for Λ – *a.e.* $\alpha \in \mathcal{A}$,

$$-\dot{p}(t;\alpha)\ \in\ \operatorname{co} \partial_x H(t, \bar{x}(t;\alpha), \bar{u}(t), p(t;\alpha), \alpha),$$

by positive homogeneity. □

3. A maximum principle for the general minimax optimal control problem. This section provides necessary conditions of optimality for the general minimax optimal control problem (P) of section 1, when the parameter set $\mathcal{A}$ is an arbitrary compact metric space.

Take $(\bar{u}, \{\bar{x}(.;\alpha) \,|\, \alpha \in \mathcal{A}\})$ to be the local minimizer for problem (P) of interest. For $\alpha \in \mathcal{A}$, define the set

$$\begin{aligned} Q_0(\alpha) := \big\{ p(.;\alpha) \in W^{1,1} \mid & -\dot{p}(t;\alpha)\ \in\ \operatorname{co} \partial_x H(t, \bar{x}(t;\alpha), \bar{u}(t), p(t;\alpha), \alpha) \quad \textit{a.e.} \\ & \text{and } -p(1;\alpha) \in \cup_{r\in[0,1]} \left(rG_0(\bar{x}(1;\alpha),\alpha) + (1-r)N(\bar{x}(1;\alpha),\alpha)\right), \end{aligned}$$

in which, for $\epsilon \in [0,1]$,

$$G_\epsilon(x,\alpha) := \begin{cases} \partial_x g(x,\alpha) & \text{if } g(x,\alpha) \geq \max_{\alpha' \in \mathcal{A}}\ g(x,\alpha') - \epsilon \\ \emptyset & \text{otherwise} \end{cases} \tag{3.1}$$

and

$$N(x,\alpha) := \big\{ \xi \in N_{C(\alpha)}(x) \mid |\xi| = 1 \big\}. \tag{3.2}$$

(Only $G_{\epsilon=0}(x,0)$ is involved in the definition of $Q_0(\alpha)$. $G_\epsilon(x,\alpha)$, with $\epsilon > 0$, is required for later analysis.)

The assertions of Proposition 2.1 can be expressed in terms of the set $Q_0(\alpha)$ as follows. If $(\bar{u}, \{\bar{x}(.;\alpha) \mid \alpha \in \mathcal{A}\})$ is a strong local minimizer and $\mathcal{A}$ is a finite set, then

$$\begin{aligned} &\int_{\mathcal{A}} H(t, \bar{x}(t;\alpha), \bar{u}(t), p(t;\alpha), \alpha)\ \Lambda(d\alpha) = \\ &\qquad \max_{u\in\Omega(t)} \int_{\mathcal{A}} H(t, \bar{x}(t;\alpha), u, p(t;\alpha), \alpha)\ \Lambda(d\alpha) \quad \textit{a.e. } t \in [0,1] \end{aligned}$$

for some Radon probability measure $\Lambda \in C^*(\mathcal{A})$ and family of arcs $\{p(.;\alpha) \mid \alpha \in \mathcal{A}\}$ such that

$$p(.;\alpha) \in Q_0(\alpha) \ \text{ for } \Lambda - \textit{a.e. } \alpha \in \mathcal{A}.$$

(Note that $Q_0(\alpha)$ may be empty unless α is "active" in the sense of our earlier remarks.) Unfortunately, the above optimality condition no longer remains valid in general, when we allow $\mathcal{A}$ to be an arbitrary compact metric space. Confirmation is provided by the counter examples of section 5. Indeed, standard variational techniques break down when $\mathcal{A}$ is an infinite set, because the multifunction

$$Q_0(.)\ :\ \mathcal{A} \to \{\text{subsets of } W^{1,1}\}$$

may lack the requisite convexity and closure properties for limit taking. To derive necessary conditions in this more general context, we need to replace $Q_0(\alpha)$ with a larger set, better matched to the limit taking operations involved.

Let $(\bar{u}, \{\bar{x}(.;\alpha) \mid \alpha \in \mathcal{A}\})$ be the process of interest. We embed $Q_0(.)$ in a family of multifunctions $\{Q_\epsilon(.) | \epsilon \geq 0\}$ defined as follows. For any $\epsilon \geq 0$ and $\alpha \in \mathcal{A}$ we define

$$Q_\epsilon(\alpha) := \big\{p(.;\alpha) \in W^{1,1} \mid \text{conditions (a) and (b) below are satisfied}\big\}$$

in which

(a)

$$-\dot{p}(t;\alpha) \in \bigcup_{x \in \bar{x}(t;\alpha)+\epsilon B} \operatorname{co} \partial_x H(t, x, \bar{u}(t), p(t;\alpha), \alpha) \quad a.e.$$

(b)

$$-p(1;\alpha) \in \bigcup_{x \in \bar{x}(1;\alpha)+\epsilon B} \bigcup_{r \in [0,1]} (rG_\epsilon(x,\alpha) + (1-r)N(x,\alpha))$$

The sets $G_\epsilon(x,\alpha)$ and $N(x,\alpha)$ appearing in these conditions were defined in (3.1) and (3.2).

The defining properties of the "costate" arcs $p(.;\alpha)$ will now include the condition

$$p(.;\alpha) \ \in \ \overline{Q}_0(\alpha),$$

where

$$\overline{Q}_0(\alpha) := \bigcap_{\epsilon>0} \overline{co} \left(\bigcup_{\alpha' \in B_{\mathcal{A}}(\alpha,\epsilon)} Q_\epsilon(\alpha') \right). \tag{3.3}$$

Here $\overline{co}$ denotes "convex closure" with respect to the strong $W^{1,1}$ topology. Note that the right side is a subset of $W^{1,1}([0,1]; R^n)$. This relationship involves a multifunction that is obtained from the multifunction $\alpha \rightsquigarrow Q_0(\alpha)$ by enlarging its graph. The enlargement is carried out in such a manner that the new multifunction has closed graph and convex values.

In certain cases, notably when the data is smooth and the right endpoint constraints are absent,

$$Q_0(\alpha) \ = \ \overline{Q}_0(\alpha).$$

But in many cases of interest, $Q_0(\alpha)$ is a strict subset of its "closed, convexified" counterpart. We discuss these points in section 5.

We now come to the main result of this paper, namely a maximum principle for the general minimax optimal control problem. Here, as usual, the Hamiltonian is

$$H(t,x,p,u,\alpha) := p \cdot f(t,x,u,\alpha).$$

The following hypotheses will be invoked, in which $(\bar{u}, \{\bar{x}(.;\alpha) \mid \alpha \in \mathcal{A}\})$ is the strong local minimizer for (P) of interest. For some $\delta > 0$,

(S1) The function $f(.,x,.,.)$ is $\mathcal{L} \times \mathcal{B}^m \times \mathcal{B}_{\mathcal{A}}$ measurable for each $x \in R^n$. ($\mathcal{B}_{\mathcal{A}}$ denotes the Borel subsets of $\mathcal{A}$.) $t \rightsquigarrow \Omega(t)$ has a Borel measurable graph.

(S2) There exists $k_f \in L^1$ and $c_f > 0$ such that

$$|f(t,x,u,\alpha) - f(t,x',u,\alpha)| \le k_f(t)|x - x'| \quad \text{and} \quad |f(t,x,u,\alpha)| \le c_f$$

for all $x, x' \in \bar{x}(t;\alpha) + \delta B$, $u \in \Omega(t)$ and $\alpha \in \mathcal{A}$, *a.e.* $t \in [0,1]$.

(S3) g is continuous and there exists $k_g > 0$ such that

$$|g(x,\alpha) - g(x',\alpha)| \le k_g|x - x'|$$

for all $x, x' \in \bar{x}(1;\alpha) + \delta B$ and $\alpha \in \mathcal{A}$.

(S4) There exists $\theta : [0,+\infty) \to [0,+\infty)$ such that $\lim_{s\downarrow 0} \theta(s) = 0$ and, for all $\alpha, \alpha' \in \mathcal{A}$,

$$\int_0^1 \sup_{x\in\bar{x}(t)+\delta B,\ u\in\Omega(t)} |f(t,x,u,\alpha) - f(t,x,u,\alpha')|\ dt \le \theta(\rho_{\mathcal{A}}(\alpha,\alpha')).$$

(S5) $\alpha \to d_{C(\alpha)}(x)$ is continuous on $\mathcal{A}$ for each $x \in R^n$.

In the following theorem, $\mathcal{A}$ is an arbitrary compact metric space.

THEOREM 3.1. *Let* $(\bar{u}, \{\bar{x}(.;\alpha) \mid \alpha \in \mathcal{A}\})$ *be a strong local minimizer for* (P). *Assume that, for some* $\delta > 0$, *Hypotheses* (S1)–(S5) *are satisfied.*

Then

$$\int H(t,\bar{x}(t;\alpha),\bar{u}(t),p(t;\alpha),\alpha)\ \Lambda(d\alpha)$$

$$= \max_{u\in\Omega(t)} \int H(t,\bar{x}(t;\alpha),u,p(t;\alpha),\alpha)\ \Lambda(d\alpha) \quad \textit{a.e. } t \in [0,1], \tag{3.4}$$

for some Radon probability measure $\Lambda \in C^*(\mathcal{A})$ *and family of arcs* $\{p(.;\alpha) \in W^{1,1} \mid \alpha \in \mathcal{A}\}$ *such that, for* Λ – *a.e.* $\alpha \in \mathcal{A}$,

$$p(.;\alpha)\ \in\ \overline{Q}_0(\alpha). \tag{3.5}$$

(Recall the definition of $\overline{Q}_0(\alpha)$ *in* (3.3).*)*

Note that the right side of (3.5) may be empty for certain values of α. The set is nonempty, however, on a set of full Λ measure.

Implicit in the optimality conditions is the assertion that the integrals in the maximization of the Hamiltonian condition (3.4) are well-defined, i.e., the function $\alpha \to H(t,\bar{x}(t;\alpha),u,p(t;\alpha),\alpha)$ is Λ-integrable for each $u \in \Omega(t)$, *a.e.* $t \in [0,1]$.

We might expect that necessary conditions of optimality are valid for a hybrid form of the minimax optimal control problem, in which the parameter set $\mathcal{A}$ separates into the union of a "discrete" and a "continuous" set, and which specializes to a version of Proposition 2.1 (valid under the stronger hypotheses of Theorem 3.1) and Theorem 3.1 in the extreme cases "$\mathcal{A}$ is purely discrete" and "$\mathcal{A}$ is purely continuous." The following theorem supplies such conditions. We explore some consequences in section 5.

THEOREM 3.2. *Let* $(\bar{u}, \{\bar{x}(.;\alpha) \mid \alpha \in \mathcal{A}\})$ *be a strong local minimizer for the general minimax optimal control problem* (P). *Assume that Hypotheses* (S1)–(S5) *are satisfied. Assume, furthermore, we can partition the compact metric space* $\mathcal{A}$ *into disjoint sets*

$$\mathcal{A} = \mathcal{A}^{(1)} \cup \mathcal{A}^{(2)},$$

in which $\mathcal{A}^{(1)}$ *is a compact metric space and* $\mathcal{A}^{(2)}$ *is a finite set.*

Then

$$\int H(t,\bar{x}(t;\alpha),\bar{u}(t),p(t;\alpha),\alpha)\ \Lambda(d\alpha)$$
$$= \max_{u\in\Omega(t)} \int H(t,\bar{x}(t;\alpha),u,p(t;\alpha),\alpha)\ \Lambda(d\alpha) \quad \textit{a.e. } t\in[0,1]$$

for some Radon probability measure $\Lambda \in C^*(\mathcal{A})$ *and family of arcs* $\{p(.;\alpha)\in W^{1,1} \mid \alpha\in\mathcal{A}\}$ *such that*

$$p(.;\alpha)\ \in\ \overline{Q}_0(\alpha) \quad \textit{for } \Lambda-\textit{a.e. } \alpha\in\mathcal{A}^{(1)}$$

and

$$p(.;\alpha)\ \in\ Q_0(\alpha) \quad \textit{for } \Lambda-\textit{a.e. } \alpha\in\mathcal{A}^{(2)}.$$

We conclude this section by stating a version of the foregoing theorems covering problems in which the endpoint constraints take the form of a finite collection of functional inequality constraints, namely problems for which each $C(\alpha)$ has the representation

$$C(\alpha)\ =\ \{x\in R^n \mid \psi(x,\alpha)\le 0\}, \tag{3.6}$$

for some function $\psi : R^n\times\mathcal{A}\to R^r$. The inequalities are interpreted in a "componentwise" sense. It will be assumed that, for some $\delta>0$, ψ satisfies the following hypothesis:

(H) ψ is continuous and there exist k_ψ such that

$$|\psi(x,\alpha)-\psi(x',\alpha)|\le k_\psi|x-x'| \text{ for all } x,x'\in\bar{x}(1;\alpha)+\delta B,\ \alpha\in\mathcal{A}.$$

Minor modifications to the proof of Theorems 3.1 and 3.2 yield the following optimality condition for problems involving endpoint functional inequality constraints:

THEOREM 3.3. *Let* $(\bar{u},\{\bar{x}(.;\alpha)\mid\alpha\in\mathcal{A}\})$ *be a strong local minimizer for* (P). *Assume that the endpoint constraint sets* $\{C(\alpha)\mid\alpha\in\mathcal{A}\}$ *take the form of a collection of functional inequality constraints* (3.6) *which satisfy Hypothesis* (H). *Then*

$$\int H(t,\bar{x}(t;\alpha),\bar{u}(t),p(t;\alpha),\alpha)\ \Lambda(d\alpha)$$
$$= \max_{u\in\Omega(t)} \int H(t,\bar{x}(t;\alpha),u,p(t;\alpha),\alpha)\ \Lambda(d\alpha) \quad \textit{a.e. } t\in[0,1],$$

for some Radon probability measure $\Lambda\in C^*(\mathcal{A})$ *and family of arcs* $\{p(.;\alpha)\in W^{1,1}\mid\alpha\in\mathcal{A}\}$ *such that,*

(a) *if* $\mathcal{A}$ *is a finite set and Hypotheses* (H1)–(H3) *are satisfied, then*

$$p(.;\alpha)\ \in\ Q_0^\psi(\alpha) \quad \textit{for } \Lambda-\textit{a.e. } \alpha\in\mathcal{A}.$$

(b) *if* $\mathcal{A}$ *is a compact metric space and Hypotheses* (S1)–(S4) *are satisfied, then*

$$p(.;\alpha)\in\bigcap_{\epsilon>0}\overline{co}\left(\bigcup_{\alpha'\in B_{\mathcal{A}}(\alpha,\epsilon)} Q_\epsilon^\psi(\alpha')\right) \quad \textit{for } \Lambda-\textit{a.e. } \alpha\in\mathcal{A}.$$

(c) *if Hypotheses* (S1)–(S4) *are satisfied and we can partition* $\mathcal{A} \subset R^k$ *into disjoint sets* $\mathcal{A} = \mathcal{A}^{(1)} \cup \mathcal{A}^{(2)}$, *in which* $\mathcal{A}^{(1)}$ *is a compact metric space and* $\mathcal{A}^{(2)}$ *is a finite set, then*

$$p(.;\alpha) \in \bigcap_{\epsilon>0} \overline{co}\left(\bigcup_{\alpha' \in B_{\mathcal{A}}(\alpha,\epsilon)} Q_\epsilon^\psi(\alpha') \right) \quad \text{for } \Lambda - \text{a.e. } \alpha \in \mathcal{A}^{(1)} \tag{3.7}$$

and

$$p(.;\alpha) \in Q_0^\psi(\alpha) \quad \text{for } \Lambda - \text{a.e. } \alpha \in \mathcal{A}^{(2)}.$$

In the above optimality conditions the set $Q_\epsilon^\psi(\alpha)$, $\epsilon \geq 0$, shares the defining relationships of $Q_\epsilon(\alpha)$ (see (3.3)) in all respects except that the set $N(x,\alpha)$ in condition (b), namely

$$N(x,\alpha) = \{\xi \in N_{C(\alpha)}(x) \mid |\xi| = 1\},$$

is replaced by the set

$$N^\psi(x,\alpha) := \left\{ \sum_j \lambda_j \nabla_x \psi_j(x,\alpha) \mid (\lambda_1,\ldots,\lambda_r) \in \mathcal{S}(r) \text{ such that } \lambda_i = 0 \text{ if } \psi_i(x,\alpha) < 0 \right\}.$$

in which

$$\mathcal{S}(r) := \left\{ \lambda \in R^r \mid \lambda_i \geq 0,\ i = 0,\ldots,r \text{ and } \sum_{i=0}^r \lambda_i = 1 \right\}.$$

It is a straightforward matter to derive variants on Theorem 3.3. We could, for example, assume that the endpoint constraint sets $C(\alpha)$ take the form $\{x \mid \psi(x,\alpha) \leq 0\}$ for $\alpha \in \mathcal{A}^{(2)}$ and are arbitrary closed sets for $\alpha \in \mathcal{A}^{(1)}$. In this case the necessary conditions will incorporate transversality conditions from both Theorems 3.2 and 3.3.

4. Discussion. Theorem 3.1 captures only a coarse version of Proposition 2.1 when specialized to the finite set case. This is because Proposition 2.1 asserts the existence of costate arcs in the sets $Q_0(\alpha)$, $\alpha \in \mathcal{A}$, with respect to which an "averaged" maximum principle is valid. On the other hand, Theorem 3.1 asserts the existence of costates with this property, chosen from the larger sets $\overline{Q}_0(\alpha)$, obtained by convexifying the values of $\alpha \to Q_0(\alpha)$ and closing its graph, in some sense. Minimax maximum principles involving $\overline{Q}_0(\alpha)$ provide significantly less information about minimizers than those involving $Q_0(\alpha)$. For further elucidation of this point, consider the case of (P) when the endpoint constraint sets are

$$C(\alpha) = \{x \mid \psi(x,\alpha) = 0\} \quad \text{for all } \alpha \in \mathcal{A}.$$

Here $\psi : R^n \times \mathcal{A} \to R$ is a given function. Assume that, for some fixed $\bar{\alpha}$, $g(.,\bar{\alpha})$, $\psi(.,\bar{\alpha})$ and $f(t,.,u,\bar{\alpha})$ are smooth functions and that $(\bar{u}, \{\bar{x}(.;\alpha) \mid \alpha \in \mathcal{A}\})$ is a feasible process for which

(A): $g_x(\bar{x}(1;\bar{\alpha}),\bar{\alpha})$ and $\psi_x(\bar{x}(1;\bar{\alpha}),\bar{\alpha})$ are linearly independent.

Let n be the vector of unit length

$$n = \frac{\psi_x(\bar{x}(1;\bar{\alpha}),\bar{\alpha})}{|\psi_x(\bar{x}(1;\bar{\alpha}),\bar{\alpha})|}.$$

Then we easily calculate that

$$Q_0(\bar\alpha) \;=\; \Big\{p(.;\bar\alpha)\in W^{1,1} \;|\; -\dot p(t;\bar\alpha)=H_x \text{ and } -p(1;\bar\alpha)\in co\{g_x,+n\}\cup co\{g_x,-n\}\Big\}$$

while $\overline{Q}_0(\bar\alpha)$ contains the subset

$$\Big\{p(.;\bar\alpha)\in W^{1,1} \;|\; -\dot p(.;\bar\alpha)=H_x \text{ and } -p(.;\bar\alpha)\in \text{co}\{g_x,+n,-n\}\Big\}. \tag{4.1}$$

Here g_x is evaluated at $\bar x(1;\bar\alpha)$.

Notice that the element $p(.;\bar\alpha)\equiv 0$ lies in the set (4.1), since $-\dot p(t;\bar\alpha)=H_x$ is a linear differential equation and $0\in\text{co}\{g_x,+n,-n\}$. This means that the optimality conditions of Theorem 3.1 are satisfied by any feasible process $(\bar u,\{\bar x(.;\alpha)\,|\,\alpha\in\mathcal{A}\})$ with the trivial choice of multipliers

$$\Lambda=\delta_{\{\bar\alpha\}} \text{ and } p(.;\alpha)\equiv 0 \quad \text{ for all } \alpha\in\mathcal{A}.$$

Theorem 3.1 therefore conveys no useful information about minimizers in this case. By contrast, we have

$$(p(.;\bar\alpha)\equiv 0) \;\notin\; Q_0(\bar\alpha)$$

since, under the hypothesis (A), $0\notin\text{co}\{g_x,+n\}\cup\text{co}\{g_x,-n\}$; thus the optimality conditions of Theorem 3.1 are not, in this case, automatically satisfied by any feasible process $(u,\{x(.;\alpha)\mid\alpha\in\mathcal{A}\})$.

On the other hand, consider a modification of the above special case, in which the former equality endpoint constraints are replaced by inequality constraints

$$C(\alpha)=\{x\mid\psi(x,\alpha)\le 0\}$$

and assume that

$$\psi(\bar x(1;\bar\alpha),\bar\alpha) \;=\; 0.$$

Then, under unrestrictive hypotheses,

$$\begin{aligned} Q_0(\bar\alpha)&=\overline{Q}_0(\bar\alpha)\\ &=\Big\{p(.;\bar\alpha)\in W^{1,1}\;|\;-\dot p(.;\bar\alpha)=H_x \text{ and } -p(1;\bar\alpha)\in\text{co}\{\nabla g,n\}\Big\}.\end{aligned}$$

Here, there is no loss of information in passing from $Q_0(\bar\alpha)$ to $\overline{Q}_0(\alpha)$.

These observations highlight the fact that the maximum principle for minimax optimal control problems with parameter set a general compact metric space, Theorem 3.1, will find primary application in situations where the endpoint constraints (if they are present) take the form of functional inequality constraints and their generalizations. Theorem 3.1 is not well-suited to problems with endpoint equality constraints.[1] It is therefore of interest to know whether Theorem 3.1 can be refined,

[1] Of course it can be argued that minimax problems of this nature are, broadly speaking, artificial: often such problems will have no minimizers because of the absence of feasible processes, i.e., control functions whose corresponding state trajectories satisfy the equality endpoint constraints for *all* values of the parameter α. Nontrivial maximum principles covering those few cases of interest involving equality endpoint constraints (e.g., cases where the equality constraints involve only those aspects of the dynamics which do not depend on α) can be developed along the lines of Theorem 3.2.

to provide necessary conditions for problems with parameter set a general compact metric space, in which $Q_0(\alpha)$ replaces $\overline{Q}_0(\alpha)$.

We now study two examples, the purpose of which is to demonstrate that this is not possible, in the absence of additional hypotheses.

EXAMPLE 4.1. *Consider the problem*

$$\begin{cases} \textit{Minimize } \sup_{\alpha\in[-1,+1]} -|x(1)-\alpha| \textit{ over } u(.) \textit{ such that} \\ \dot{x}(t) = u(t) \quad \textit{a.e. } t \in [0,1], \\ x(0) = 0, \\ u(t) \in [-1,+1] \quad \textit{a.e. } t \in [0,1]\,. \end{cases}$$

This is an example of the general minimax problem in which the parameter set is the interval $\mathcal{A} = [-1,1]$. *The cost function depends on* α, *but the dynamics do not. We denote processes* (u,x), *since all state trajectories corresponding to a given control function* u *coincide. Clearly,* $(\bar{u} \equiv 0,\ \bar{x} \equiv 0)$ *is a minimizer.*

Suppose that the assertions of Proposition 2.1 *were valid here. Then there would exist a probability measure* Λ *with support in*

$$\left\{\alpha \mid -|\bar{x}(1)-\alpha| = max_{\alpha'\in[-1,+1]}\left(-|\bar{x}(1)-\alpha'|\right)\right\} = \{0\}, \tag{4.2}$$

and a family of costate arcs $\{p(.;\alpha)\,|\,\alpha\in\mathcal{A}\}$ *such that* $p(.;\alpha)\in Q_0(\alpha)$ *for* Λ – *a.e.* $\alpha\in\mathcal{A}$ *and* (3.3) *is satisfied. But* (4.2) *implies that*

$$\Lambda = \delta_{\{0\}}.$$

Thus, supp $\{\Lambda\} = \{0\}$ *and the only relevant value of* α *is* $\alpha = 0$. *We calculate*

$$\begin{aligned} Q_0(\alpha=0) &= \left\{p\in W^{1,1} \mid -\dot{p} = 0,\ \ -p(1)\in\{-1\}\cup\{+1\}\right\} \\ &= \{p\equiv -1\}\cup\{p\equiv +1\}. \end{aligned}$$

We have then, for each $t\in[0,1]$,

$$\int_{\mathcal{A}} H(t,\bar{x}(t),u,p(t;\alpha),\alpha)\ \Lambda(d\alpha) = \begin{cases} +u & \text{if } p(.;\alpha=0)\equiv +1 \\ -u & \text{if } p(.;\alpha=0)\equiv -1, \end{cases}$$

for any $u\in[-1,+1]$ *and any family of costate arcs* $\{p(.;\alpha)\mid\alpha\in\mathcal{A}\}$ *such that* $p(.;\alpha)\in Q_0(\alpha)$ *for* Λ – *a.e.* $\alpha\in\mathcal{A}$.

We see that $u\to\int_{\mathcal{A}} H(t,\bar{x}(t),u,p(t),\alpha)\ \Lambda(d\alpha)$ *cannot be maximized at* $u=\bar{u}(t)$ *for a.e.* $t\in[0,1]$. *This shows that the assertions of Theorem* 3.1 *may fail to be true, if* $\mathcal{A}$ *is allowed to be an infinite set. On the other hand,*

$$\{p(.;\alpha=0)\equiv 0\}\ \in\ \overline{Q}_0(\alpha=0)$$

and so the maximization of the Hamiltonian condition is satisfied with Λ *taken to be the unit measure concentrated at* $\alpha=0$ *and with* $\{p(.;\alpha)|\alpha\in\mathcal{A}\}$ *an arbitrary collection of* $W^{1,1}$ *functions such that* $p(.;\alpha=0)\equiv 0$.

Example 4.1 involves nonsmooth data. The following more elaborate example illustrates that we cannot replace $p(\alpha)\in\overline{Q}_0(\alpha)$ by $p(\alpha)\in Q_0(\alpha)$, even for problems with smooth data.

EXAMPLE 4.2. *Consider the following example of the minimax optimal control problem, in which the state $x = (x_1, x_2)$ is a 2-vector and the control u is scalar:*

$$(\mathrm{P})\ \begin{cases} \textit{Minimize } \max_{\alpha\in\mathcal{A}} g(x(1;\alpha),\alpha) \\ \quad \textit{over } (u, \{x(.;\alpha) \mid \alpha\in\mathcal{A}\}) \textit{ satisfying} \\ \dot{x}(t;\alpha) = f(t, x(t;\alpha), u(t), \alpha) \quad \textit{a.e.,} \\ u(t)\in\Omega \quad \textit{a.e.,} \\ x(0;\alpha) = x_0 \quad \textit{and} \quad x(1;\alpha)\in C(\alpha). \end{cases}$$

Here, $x_0 = col\,(0;0)$, $\Omega = [-1,+1]$,

$$\mathcal{A} = \left[\frac{1}{3}, \frac{2}{3}\right] \cup \{1\},$$

and, for each $\alpha \in [\frac{1}{3}, \frac{2}{3}] \cup \{1\}$, $f = col(f_1, f_2)$ is the function

$$f_1(t,x,u,\alpha) = \begin{cases} u & \textit{if } 0\le t\le\alpha \\ 0 & \textit{if } \alpha < t \le 1 \end{cases}$$

$$f_2(t,x,u,\alpha) = \begin{cases} -u^2 & \textit{if } \frac{1}{3}\le t\le\frac{2}{3} \\ 0 & \textit{otherwise,} \end{cases}$$

$$g(x,\alpha) = \begin{cases} x_2 & \textit{if } \alpha = 1 \\ -1 & \textit{if } \alpha\in[\frac{1}{3},\frac{2}{3}] \end{cases}$$

and

$$C(\alpha) = \begin{cases} \{0\}\times R & \textit{if } \alpha\in[\frac{1}{3},\frac{2}{3}] \\ R\times R & \textit{if } \alpha = 1. \end{cases}$$

Noting the interpretation of this example provided below, we easily check that ($\bar{u}\equiv 0$, $\{\bar{x}(.;\alpha)\equiv(0,0)\,|\,\alpha\in\mathcal{A}\}$) is a minimizer. Suppose that

$$\int_{\mathcal{A}} H(t,\bar{x}(t;\alpha),\bar{u}(t),p(t;\alpha),\alpha)\ \Lambda(d\alpha)$$
$$= \max_u \int_{\mathcal{A}} H(t,\bar{x}(t;\alpha),u,p(t;\alpha),\alpha)\ \Lambda(d\alpha) \quad \textit{a.e. } t\in[0,1]$$

is satisfied for some probability measure Λ and family of arcs $\{p(.:\alpha)\}$ such that

$$p(.;\alpha)\in Q_0(\alpha) \qquad \Lambda - a.e. \quad \alpha\in\mathcal{A}.$$

Partition the adjoint arcs $p(.;\alpha) = (p_1(.;\alpha), p_2(.;\alpha))$. Then for Λ – a.e. $\alpha\in[\frac{1}{3},\frac{2}{3}]$

$$\begin{array}{ll} -\dot{p}_1(.;\alpha)\equiv 0, & -\dot{p}_2(.;\alpha)\equiv 0 \\ -p_1(1;\alpha) = m(\alpha), & -p_2(1;\alpha) = 0 \end{array}$$

in which $m(\alpha)$ is a Borel measurable function such that

$$m(\alpha) = -1 \textit{ or } +1 \quad \textit{for all } \alpha\in\left[\frac{1}{3},\frac{2}{3}\right].$$

Also

$$-\dot{p}_1(.:\alpha=1)\equiv 0,\ -p_1(1;\alpha=1) = 0$$
$$-\dot{p}_2(.:\alpha=1)\equiv 0,\ -p_2(1;\alpha=1) = +1.$$

Writing $a \vee b := max\{a, b\}$, *we deduce from the maximization of the Hamiltonian condition that*

$$u \to \int_{[\frac{1}{3} \vee t, \frac{2}{3}]} m(\alpha)\ \Lambda(d\alpha)u + u^2 \chi_{[\frac{1}{3},\ \frac{2}{3}]}(t)\Lambda(\{1\})$$

is maximized over $[-1, +1]$ *at* $u = 0$ *a.e.* $t \in [0, 1]$. *Here* χ_D *denotes the indicator function of the set* D. *It follows that, for a.e.* $t \in [0, 1]$,

$$\int_{[\frac{1}{3} \vee t, \frac{2}{3}]} m(\alpha)\ \Lambda(d\alpha)\ =\ 0 \tag{4.3}$$

and $\Lambda(\{1\}) = 0$. *But* (4.3) *implies*

$$\int_{[\frac{1}{3}, \frac{2}{3}]} m(\alpha)\ \Lambda(d\alpha) = 0$$

and

$$\int_{[t, \frac{2}{3}]} m(\alpha)\ \Lambda(d\alpha) = 0$$

for all $t \in F$, *where* F *is some countable dense subset of* $[\frac{1}{3}, \frac{2}{3}]$. *But since sets of the form* $[\frac{1}{3}, \frac{2}{3}]$ *and* $[t, \frac{2}{3}]$ *(for* $t \in F$*) generate the Borel subsets of* $[\frac{1}{3}, \frac{2}{3}]$, *we see that*

$$\int_B m(\alpha)\ \Lambda(d\alpha) = 0 \tag{4.4}$$

for all Borel sets $B \in \mathcal{A}$. *Let* $\mathcal{A}^{\pm} = \{\alpha \mid m(\alpha) = \pm 1\}$. *Since* $\mathcal{A}^- \cup \mathcal{A}^+ = \mathcal{A}$ *and* $||\Lambda||_{T.V.} = 1$, *either* $\Lambda(\mathcal{A}^+) > 0$ *or* $\Lambda(\mathcal{A}^-) > 0$. *Without loss of generality assume the former. Then*

$$\int_B m(\alpha)\ \Lambda(d\alpha) = \int_B\ \Lambda(d\alpha)\ =\ \Lambda(\mathcal{A}^+)\ > 0,$$

when we select $B = \mathcal{A}^+$. *This contradicts* (4.4). *It follows that a version of the minimax maximum principle is not valid for this problem, in which*

$$p(.; \alpha) \in Q_0(\alpha) \quad \textit{for } \Lambda - a.e.\ \ \alpha \in \mathcal{A}.$$

The preceding example originates in an optimal control problem with pathwise equality constraints

$$(\tilde{\mathrm{P}}) \begin{cases} & \text{Minimize} \quad -\int_{\frac{1}{3}}^{\frac{2}{3}} |u(t)|^2\ dt \\ \text{s.t.} & \dot{x}(t) = u(t), \quad a.e.\ t \in [0, 1], \\ & x(0) = 0, \\ & x(t) = 0 \quad \text{for } \frac{1}{3} \le t \le \frac{2}{3}, \\ & u(t) \in R, \quad a.e.\ t \in [0, 1]. \end{cases}$$

which has been reformulated as an example of the general minimax optimal control problem (P). The fact that we cannot derive a maximum principle involving the set $Q_0(\alpha)$ in the above example reflects the fact that measure multipliers can be used

in necessary conditions for problems with pathwise *equality* constraints only in very special circumstances.

Notice that the assertions of Theorem 3.1 are consistent with Example 4.2. In this example

$$Q_0(\alpha) \;=\; \big\{(p_1(.;\alpha)\equiv 0, p_2(.;\alpha)) \mid p_2(.;\alpha)\equiv m(\alpha)\big\},$$

for Λ – a.e. $\alpha \in [\frac{1}{3}, \frac{2}{3}]$, where $m(.)$ is some Borel measurable function such that

$$m(\alpha) \;\in\; \{-1\}\cup\{+1\} \quad \Lambda - a.e.$$

These sets are too small for the maximization condition on the "averaged" Hamiltonian to hold (for any choice of $m(.)$). On the other hand, for Λ – a.e. $\alpha \in [\frac{1}{3}, \frac{2}{3}]$,

$$\overline{Q}_0(\alpha) \;=\; \big\{(p_1(.;\alpha)\equiv 0, p_2(.;\alpha)) \mid p_2(.;\alpha)\equiv \tilde{m}(\alpha)\big\}$$

in which $\tilde{m}(.)$ is some Borel measurable function such that

$$\tilde{m}(\alpha) \;\in\; [-1,+1] \quad \Lambda - a.e.$$

The maximization condition does hold (in a trivial sense), with respect to $(p_1(.;\alpha), p_2(.;\alpha))$s chosen from this larger set; we can take $(p_1(.;\alpha), p_2(.;\alpha)) \equiv (0,0)$ Λ – *a.e.*

5. Special cases. In this section, we examine implications of the minimax maximum principle for a number of special cases of interest. Utmost generality is not a goal here; indeed, we often focus on smooth versions of the optimality conditions, when the nonsmooth version could easily be derived, better to reveal their essential character. Throughout, $\mathcal{A}$ is an arbitrary compact metric space.

Consider first the *minimax optimal control problem with no right endpoint constraints*,

$$\text{(P1)}\quad \begin{cases} \text{Minimize } \max_{\alpha\in\mathcal{A}} g(x(.;\alpha),\alpha) \\ \qquad \text{over measurable functions } u:[0,1]\to R^m \text{ such that} \\ u(t)\in\Omega(t), \quad a.e.\ t\in[0,1] \\ \qquad \text{and arcs } \{x(.;\alpha):[0,1]\to R^n \mid \alpha\in\mathcal{A}\} \text{ such that, for each } \alpha\in\mathcal{A}, \\ \dot{x}(t;\alpha) = f(t,x(t;\alpha),u(t),\alpha) \quad a.e.\ t\in[0,1], \\ x(0;\alpha) = x_0. \end{cases}$$

The data for (P1) comprises a compact metric space $\mathcal{A}$, functions $g: R^n\times\mathcal{A}\to R$, $f:[0,1]\times R^n\times R^m\times\mathcal{A}\to R^n$, a vector $x_0\in R^n$, and a time dependent set $\Omega(t)\subset R^m$, $0\le t\le 1$.

General necessary conditions for (P1) follow directly from Theorem 3.1. We state the conditions merely in the special case when the data are smooth.

PROPOSITION 5.1. *Let $(\bar{u}, \{\bar{x}(.;\alpha) \mid \alpha\in\mathcal{A}\})$ be a strong local minimizer for* (P1). *Assume that, for some $\delta>0$, the Hypotheses* (S1), (S2), *and* (S4) *of section* 3 *are satisfied. Assume, furthermore, that*

(a) *g is continuous, $g(.,\alpha)$ is differentiable for each $\alpha\in\mathcal{A}$ and g_x is continuous.*

(b) *$f(t,.,u,\alpha)$ is continuously differentiable on a neighborhood of $\bar{x}(t;\alpha)$ for all $u\in\Omega(t)$ and $\alpha\in\mathcal{A}$, a.e. $t\in[0,1]$, and $\alpha\to f_x(t,x,u,\alpha)$ is uniformly continuous with respect to $(t,x,u)\in\{(t',x',u')\in[0,1]\times R^n\times R^m \mid u'\in\Omega(t')\}$.*

Then

$$\int H(t,\bar{x}(t;\alpha),\bar{u}(t),p(t;\alpha),\alpha)\ \Lambda(d\alpha)$$
$$= \max_{u\in\Omega(t)} \int H(t,\bar{x}(t;\alpha),u,p(t;\alpha),\alpha)\ \Lambda(d\alpha) \quad a.e.$$

for some Radon probability measure $\Lambda \in C^*(\mathcal{A})$ *and some family of arcs* $\{p(.;\alpha) \in W^{1,1}([0,1];R^n) \mid \alpha \in \mathcal{A}\}$ *such that*

$$supp\ \{\Lambda\} \subset \left\{\alpha \in \mathcal{A} \mid g(\bar{x}(1;\alpha),\alpha) = \max_{\alpha'\in\mathcal{A}}\ g(\bar{x}(1;\alpha'),\alpha')\right\}$$

and, for Λ *– a.e.* $\alpha \in \mathcal{A}$,

(i) $-\dot{p}(t;\alpha) = f_x^T(t,\bar{x}(t;\alpha),\bar{u}(t),\alpha)\,p(t;\alpha) \quad a.e.$

(ii) $-p(1;\alpha) = g_x(\bar{x}(1;\alpha),\alpha).$

Proof. Everything follows from Thm. 3.1, when we note that, if a function $\phi : R^n \to R$ is continuously differentiable on a neighborhood of a point $\bar{x}$, then $\partial\phi(\bar{x}) = \{\phi_x(\bar{x})\}$ and, under the stated hypotheses,

$$\overline{Q}_0(\alpha) = \begin{cases} \left\{p' \in W^{1,1} \mid -\dot{p}' = f_x^T p',\ -p'(1) = g_x(\bar{x}(1;\alpha),\alpha)\right\} \\ \qquad\qquad \text{if } g(\bar{x}(1;\alpha)) = \max_{\alpha'\in\mathcal{A}} g(\bar{x}(1;\alpha'),\alpha') \\ \emptyset \qquad\qquad \text{otherwise.} \end{cases} \quad \square$$

Consider next the *optimal control problem with robust feasibility constraints*:

$$\text{(P2)} \begin{cases} \text{Minimize } g(x(1;\alpha^*)) \\ \quad \text{over measurable functions } u:[0,1]\to R^m \text{ such that} \\ u(t) \in \Omega(t), \quad a.e.\ t \in [0,1] \\ \quad \text{and arcs } \{x(.;\alpha):[0,1]\to R^n \mid \alpha\in\mathcal{A}\} \text{ such that, for each } \alpha\in\mathcal{A}, \\ \dot{x}(t;\alpha) = f(t,x(t;\alpha),u(t),\alpha) \quad a.e.\ t\in[0,1], \\ x(0;\alpha) = x_0 \quad \text{and} \quad \psi(x(1;\alpha)) \le 0. \end{cases}$$

The data for (P2) comprises a set $\mathcal{A} \subset R^k$, a point $\alpha^* \in \mathcal{A}$, functions $g : R^n \to R$ and $f : [0,1] \times R^n \times R^m \times \mathcal{A} \to R^n$ and $\psi : R^n \to R^{r'}$, a vector $x_0 \in R^n$ and a time dependent set $\Omega(t) \subset R^m$, $0 \le t \le 1$. The endpoint functional inequality terminal constraint is interpreted in the usual "componentwise" manner.

This is a formulation of optimal control problems involving an unknown parameter α, in which α is expected to take its nominal value α^*. Here, it is appropriate to choose a control to minimize the cost based on the system response for $\alpha = \alpha^*$. But our choice of control is restricted by the requirement that, even if α deviates from α^*, constraints on state variables must not be violated. Here, we regard values of α different from α^* as due to system degradation or failure, and "$\psi(x(1;\alpha)) \le 0$ for all $\alpha \in \mathcal{A}$" is the requirement that operational constraints (on displacements, velocities, pressures, etc.) are satisfied, even in the event of breakdown.

For simplicity, we assume that the data are smooth and that there is a single endpoint constraint ($r' = 1$).

PROPOSITION 5.2. *Let* $(\bar{u}, \{\bar{x}(.;\alpha) \mid \alpha \in \mathcal{A}\})$ *be a strong local minimizer for* (P2). *Assume that, for some* $\delta > 0$, *Hypotheses* (S1), (S2), *and* (S4) *are satisfied. Assume, furthermore, that* $r' = 1$ *and*

(a) g *and* ψ *are continuously differentiable on* $\bar{x}(1;\alpha^*) + \delta B$.

(b) *$f(t,.,u,\alpha)$ is continuously differentiable on a neighborhood of $\bar{x}(t;\alpha)$ for all $u \in \Omega(t)$ and $\alpha \in \mathcal{A}$, a.e. $t \in [0,1]$, and $\alpha \to f_x(t,x,u,\alpha)$ is uniformly continuous with respect to $(t,x,u) \in \{(t',x',u') \in [0,1] \times R^n \times R^m \mid u' \in \Omega(t')\}$.*

Then

$$\int H(t,\bar{x}(t;\alpha),\bar{u}(t),p(t;\alpha),\alpha)\ \Lambda(d\alpha)\ = \max_{u\in\Omega(t)} \int H(t,\bar{x}(t;\alpha),u,p(t;\alpha),\alpha)\ \Lambda(d\alpha) \quad \text{a.e. } t \in [0,1]$$

for some family of arcs $\{p(.;\alpha) \in W^{1,1}([0,1];R^n)\}$, a number $r \in [0,1]$ and a Radon probability measure $\Lambda \in C^*(\mathcal{A})$ such that

$$\text{supp } \{\Lambda\} \subset \big(\{\alpha^*\} \cup \big\{\alpha \in \mathcal{A} \mid \psi(\bar{x}(1;\alpha)) = 0\big\}\big),$$

and, for Λ – a.e. $\alpha \in \mathcal{A}$,

(i) $-\dot{p}(t;\alpha) = f_x^T(t,\bar{x}(t;\alpha),\bar{u}(t),\alpha)\, p(.;\alpha) \quad$ *a.e. $t \in [0,1]$,*

(ii) $-p(1;\alpha) = \begin{cases} \psi_x(\bar{x}(1;\alpha)) & \text{if } \alpha \neq \alpha^* \\ rg_x(\bar{x}(1;\alpha)) + (1-r)\psi_x(\bar{x}(1;\alpha)) & \text{if } \alpha = \alpha^* \end{cases}.$

Proof. It might appear that the simplest way to prove Proposition 6.2 would be to reformulate (P2) as a special case of the general minimax optimal control problem (P), in such a manner that $(\bar{u}, \{\bar{x}(.;\alpha) \mid \alpha \in \mathcal{A}\})$ remains a minimizer, by setting

$$g(x,\alpha) := \begin{cases} g(x) & \text{if } \alpha = \alpha^* \\ -K & \text{if } \alpha \neq \alpha^* \end{cases}$$

and

$$C(\alpha) := \{x \mid \psi(x) \leq 0\} \quad \text{for all } \alpha.$$

Here, K is a positive number such that, for some $\delta' > 0$,

$$\inf\big\{g(x) \mid x \in \bar{x}(1;\alpha) + \delta' B,\ \alpha \in \mathcal{A}\big\}\ >\ -K.$$

This is not helpful, however, since $\alpha \to g(x,\alpha)$ violates the continuity hypothesis (S3) for application of Theorem 3.1. Instead, we take a point $b \notin \mathcal{A}$ and associate with (P2) a general minimax problem with extended parameter set $\tilde{\mathcal{A}} := \mathcal{A} \cup \{b\}$, in which $g(x,\alpha)$ is the function

$$g(x,\alpha) := \begin{cases} g(x) & \text{if } \alpha = b \\ -K & \text{if } \alpha \in \mathcal{A} \end{cases}$$

and in which f is the extension of the function f of (P2), to allow for α's in $\mathcal{A} \cup \{b\}$,

$$f(t,x,u,\alpha = b) := f(t,x,u,\alpha^*).$$

The hypotheses are satisfied for the application of Theorem 3.2, with reference to the process $(\bar{u}, \{\bar{x}(.;\alpha) \mid \alpha \in \mathcal{A}\})$, when we partition the extended parameter set as

$$\tilde{\mathcal{A}} = \big(\mathcal{A}^1 := \mathcal{A}\big)\ \cup\ \big(\mathcal{A}^2 := \{b\}\big).$$

Straightforward calculations yield the following information: for $\alpha \in \mathcal{A}$

$$\overline{Q}_0(\alpha) \;=\; \begin{cases} \{q(.) \mid -\dot{q}(t) = f_x^T(t, \bar{x}(t;\alpha), \bar{u}(t), \alpha)q(t), \\ \qquad -q(1) = \psi_x(\bar{x}(1;\alpha))\} & \text{if } \psi(\bar{x}(1;\alpha)) = 0 \\ \emptyset & \text{if } \psi(\bar{x}(1;\alpha)) < 0 \end{cases}$$

and

$$Q_0(\alpha = b) \;=\; \{q(.) \mid -\dot{q}(t) = f_x^T(t, \bar{x}(t;\alpha^*), \bar{u}(t), \alpha^*)q(t), \;\; -q(1) = g_x(\bar{x}(1;\alpha^*))\}\,.$$

We deduce the existence of a Radon probability measure $\mu \subset C^*(\mathcal{A} \cup \{b\})$ and arcs $\{q(.;\alpha) \mid \alpha \in \mathcal{A}\} \cup \{q(.;b)\}$ such that, for μ – *a.e.* $\alpha \in \mathcal{A}$,

$$-\dot{q}(t;\alpha) \;=\; f_x^T(t, \bar{x}(t;\alpha), \bar{u}(t), \alpha)q(t;\alpha), \;\; -q(1;\alpha) \;=\; \psi_x(\bar{x}(1;\alpha)),$$

if $\alpha \in \mathcal{A}$ and

$$-\dot{q}(t;b) \;=\; f_x^T(t, \bar{x}(t;\alpha^*), \bar{u}(t), \alpha^*)q(t;b), \;\; -q(1;b) \;=\; g_x(\bar{x}(1;\alpha^*)).$$

Furthermore, $u \to \mathcal{H}(t,u)$ is maximized over $u \in \Omega(t)$ at $u = \bar{u}(t)$ for *a.e.* $t \in [0,1]$, where

$$\mathcal{H}(t,u) = \int_{\mathcal{A}\cup\{b\}} q(t;\alpha) \cdot f(t, \bar{x}(t;\alpha), u, \alpha)\; \mu(d\alpha)$$

and

$$supp\,\{\mu\} \;\subset\; \{\alpha \in \mathcal{A} \,|\, \psi(\bar{x}(1;\alpha)) = 0\} \cup \{b\}.$$

Now choose

$$r \;=\; \begin{cases} \frac{\mu(\{b\})}{\mu(\{b\})+\mu(\{\alpha^*\})} & \text{if } \mu(b) > 0 \\ 0 & \text{otherwise,} \end{cases}$$

$$p(.;\alpha) := \begin{cases} q(.;\alpha) & \text{for } \;\alpha \neq \alpha^* \\ rq(.;b) + (1-r)q(.;\alpha^*) & \text{for } \;\alpha = \alpha^*. \end{cases}$$

Choose also the Radon measure $\Lambda \in C^*(\mathcal{A})$,

$$\Lambda(E) := \begin{cases} \mu(\{b\}) + \mu(E) & \text{if } \;\alpha^* \in E \\ \mu(E) & \text{if } \;\alpha^* \notin E \end{cases}$$

for any Borel subset E of $\mathcal{A}$. Notice that $||\Lambda||_{T.V.} = ||\mu||_{T.V.} = 1$, so Λ is a probability measure. Clearly

$$supp\,\{\Lambda\} \;\subset\; \{\alpha^*\} \cup \{\alpha \in \mathcal{A} \,|\, \psi(\bar{x}(1;\alpha)) = 0\}\,.$$

We have

$$\begin{aligned}
\mathcal{H}(t,u) &= \left(\int_{\{b\}} + \int_{\{\alpha^*\}} + \int_{\mathcal{A}\setminus\{\alpha^*\}}\right) q(t;\alpha)\cdot f(t,\bar{x}(t;\alpha),u,\alpha)\ \mu(d\alpha)\\
&= \big(\mu(\{b\})q(t;b) + \mu(\{\alpha^*\})q(t;\alpha)\big)\cdot f(t,\bar{x}(t;\alpha^*),u,\alpha^*)\\
&\quad + \int_{\mathcal{A}\setminus\{\alpha^*\}} q(t;\alpha)\cdot f(t,\bar{x}(t;\alpha),u,\alpha)\ \mu(d\alpha)\\
&= \big(\mu(\{b\}) + \mu(\{\alpha^*\})\big)\big(rq(t;b) + (1-r)q(t;\alpha^*)\big)\cdot f(t,\bar{x}(t;\alpha^*),u,\alpha^*)\\
&\quad + \int_{\mathcal{A}\setminus\{\alpha^*\}} q(t;\alpha)\cdot f(t,x(t;\alpha),u,\alpha)\ \mu(d\alpha)\\
&= \Lambda(\{\alpha^*\})p(t;\alpha^*)\cdot f(t,\bar{x}(t;\alpha^*),u,\alpha^*) + \int_{\mathcal{A}\setminus\{\alpha^*\}} p(t;\alpha)\cdot f(t,\bar{x}(t;\alpha),u,\alpha)\ \Lambda(d\alpha)\\
&= \int p(t;\alpha)\cdot f(t,\bar{x}(t;\alpha),u,\alpha)\ \Lambda(d\alpha).
\end{aligned}$$

It follows that

$$\begin{aligned}
-\dot{p}(t;\alpha) &= f_x^T p(t;\alpha)\\
-p(1;\alpha) &= \psi_x(\bar{x}(1;\alpha))
\end{aligned}$$

for $\alpha \neq \alpha^*$. Also, by homogeneity,

$$\begin{aligned}
-\dot{p}(t;\alpha) &= f_x^T p(t;\alpha)\\
-p(1;\alpha) &= rg_x(\bar{x}(1;\alpha)) + (1-r)\psi_x(\bar{x}(1;\alpha))
\end{aligned}$$

for $\alpha = \alpha^*$. The proof is complete. □

Consider finally the *state constrained optimal control problem*,

$$\text{(P3)}\quad \begin{cases} \text{Minimize } g(x(1)) \text{ over measurable functions } u:[0,1]\to R^n \text{ such that}\\ \dot{x}(t) = f(t,x(t),u(t)) \quad \textit{a.e. } t\in[0,1],\\ x(0) = x_0 \quad \text{and} \quad x(1)\in C,\\ u(t)\in\Omega(t) \quad \textit{a.e. } t\in[0,1],\\ h(t,x(t)) \le 0 \qquad t\in[0,1]. \end{cases}$$

This is a "parameter-free" version of (P) (the function f no longer depends on α), to which has been appended an endpoint constraint and a pathwise state constraint

$$h(t,x(t)) \ \le\ 0 \quad \text{for all } t\in[0,1].$$

Here, $C\subset R^n$ is a given set and $h:[0,1]\times R^n\to R$ is a given function. This standard optimal control problem with state constraints would appear to have little relevance to minimax optimal control. The connection is this; (P3) can be interpreted as a minimax type optimal control problem to which the analytical tools of this paper are applicable. This is demonstrated below.

Thus, studying the state constrained optimal control problem in the present context establishes links between minimax optimal control and other well-established areas of optimal control. It also makes clear that the task of deriving necessary conditions of optimality for minimax problems is a challenging one, since it is at least as difficult as deriving necessary conditions for state constrained optimal control problems.

PROPOSITION 5.3. *Let $(\bar{u},\bar{x})$ be a strong local minimizer for* (P3). *Assume that for some $\delta>0$, the following hypotheses are satisfied.*

(a) *$f(.,x,.)$ is $\mathcal{L}\times\mathcal{B}$ measurable for each $x\in R^n$. $t\rightsquigarrow\Omega(t)$ has Borel measurable graph.*

(b) *There exist $k_f(t)\in L^1$ and $c_f>0$ such that*

$$|f(t,x,u)-f(t,x',u)|\le k_f(t)|x-x'| \quad \textit{and} \quad |f(t,x,u)|\le c_f$$

for all $x,x'\in\bar{x}(t)+\delta B$ and $u\in U(t)$, a.e. $t\in[0,1]$. Furthermore, $f(t,.,u)$ is continuously differentiable on a neighborhood of $\bar{x}(t)$ for all $u\in\Omega(t)$ a.e. $t\in[0,1]$.

(c) *g is continuously differentiable on $\bar{x}(1)+\delta B$.*

(d) *h is continuously differentiable.*

Then there exists an arc $p\in W^{1,1}([0,1];R^n)$, $\lambda\ge 0$, and a Radon measure $\mu\in C^*([0,1])$ such that

(i) $\lambda+\|\mu\|_{T.V.}+|p(1)|\neq 0$

(ii) $-\dot{p}=f_x^T(t,\bar{x}(t),\bar{u}(t))\ldots\Big(p(t)+\int_{[0,t)}h_x(s,\bar{x}(s))\mu(ds)\Big)$ *a.e.,*

(iii) $-(p(1)+\int_{[0,1]}h_x(s,\bar{x}(s))\mu(ds))\in\lambda g_x(\bar{x}(1))+N_C(\bar{x}(1))$

(iv) $\text{supp }\{\mu\}\subset\{t\mid h(t,\bar{x}(t))=0\}$

and

$$u\to\Big(p(t)+\int_{[0,t)}h_x(s,\bar{x}(s))\ \mu(ds)\Big)\cdot f(t,\bar{x}(t),u)$$

is maximized over $u\in\Omega(t)$ at $u=\bar{u}(t)$, a.e. $t\in[0,1]$.

We see that the minimax maximum principle can be used to obtain the maximum principle for state constrained problems with a general right endpoint constraint (cf. [10]).

Proof. We reformulate (P3) as a general minimax problem with parameter set $\mathcal{A}=[0,1]\cup\{2\}$. For all $\alpha\in[0,1]$ set

$$f(t,x,u,\alpha):=\begin{cases} f(t,x,u) & \text{for } 0\le t\le\alpha,\\ 0 & \text{for } t>\alpha\end{cases}$$

$$g(x,\alpha):=-K,$$

$$C(\alpha)=\{x\mid h(\alpha,x)\le 0\}.$$

Here, $-K$ is a number strictly less than $g(\bar{x}(1))$. Also set

$$f(t,x,u,\alpha=2):=f(t,x,u)$$

$$g(x,\alpha=2):=g(x),$$

$$C(\alpha=2)=C.$$

Clearly $(\bar{u},\{\bar{x}(.;\alpha)\mid\alpha\in\mathcal{A}\})$ is a strong local minimizer for the general minimax optimal control problem, with these identifications of the data, when

$$\bar{x}(t;\alpha)=\begin{cases}\bar{x}(t) & \text{for } 0\le t\le\alpha,\\ \bar{x}(\alpha) & \text{for } t>\alpha\end{cases}$$

for $\alpha\in[0,1]$ and

$$\bar{x}(.;\alpha=2)\equiv\bar{x}(.).$$

Now apply Theorem 3.3. (See also succeeding comments regarding the nature of the endpoint constraints.) Let $\{p(.;\alpha)\,|\,\alpha\in[0,1]\}$ and $p(.;\alpha=2)$ be the "costate arcs" for this problem and let $\Lambda\subset C^*([0,1]\cup\{2\})$ be the Radon probability measure whose existence is asserted in the theorem. Define $\mu'\subset C^*([0,1])$ to be the restriction of Λ to $[0,1]$. Then

$$||\mu'||_{T.V.}\ \leq\ 1.$$

We have, for $0\leq\alpha\leq 1$,

$$\begin{aligned}-\dot{p}(t;\alpha)\ &=\ \begin{cases} f_x^T(t,\bar{x}(t),\bar{u}(t))p(t;\alpha) & \text{for}\ \ 0\leq t\leq\alpha,\\ 0 & \text{for}\ \ t>\alpha,\end{cases}\\ -p(\alpha;\alpha)\ &=\ h_x(\alpha,\bar{x}(\alpha))\end{aligned}$$

and

$$\begin{aligned}-\dot{p}(t;\alpha=2)\ &=\ f_x^T(t,\bar{x}(t),\bar{u}(t))p(t;\alpha=2),\\ -p(1;\alpha=2)\ &\in\ \lambda g_x(\bar{x}(1))+(1-\lambda)\{\xi\in N_C(\bar{x}(1))\,|\,|\xi|=1\}.\end{aligned}$$

Furthermore, $\bar{u}(t)$ maximizes

$$u\to\left((1-\|\mu'\|_{T.V.})p(t;\alpha=2)+\int_{[t,1]}p(t;\alpha)\ \mu'(d\alpha)\right)\cdot f(t,\bar{x}(t),u)$$

over $u\in\Omega(t)$, *a.e.* $t\in[0,1]$, and

$$supp\ \{\mu'\}\subset\{\alpha\in[0,1]\mid h(\alpha,\bar{x}(\alpha))=0\}.$$

Let $\Phi(t,s)$ be the fundamental matrix for the linear equation $\dot{z}(t)=-f_x^T(t,\bar{x}(t),\bar{u}(t))z(t)$, i.e., for any $s\in[0,1]$, $\Phi(.,s)$ solves $\frac{d}{dt}\Phi(t,s)=-f_x^T(t,\bar{x}(t),\bar{u}(t))\Phi(t,s)$ for $0\leq t\leq 1$ and $\Phi(s,s)=I$.

Suppose $\|\mu'\|_{T.V.}<1$. Define

$$\mu:=\frac{1}{1-\|\mu'\|_{T.V.}}\mu'.$$

Then,

$$u\to\left(p(t)+\int_{[0,t)}h_x(s,\bar{x}(s))\ \mu(ds)\right)\cdot f(t,\bar{x}(t),u)$$

is maximized over $u\in\Omega(t)$ at $u=\bar{u}(t)$, *a.e.* $t\in[0,1]$, where

$$p(t):=p(t;\alpha=2)+\int_{[t,1]}p(t;\alpha)\ \mu(d\alpha)-\int_{[0,t)}h_x(\alpha,\bar{x}(\alpha))\ \mu(d\alpha).$$

We deduce from the differential equations for $p(.;\alpha=2)$ and $p(.;\alpha)$, $\alpha\in[0,1]$, that p satisfies

$$\begin{aligned}p(t)=&-\Phi(t,1)[\lambda g_x(\bar{x}(1))+(1-\lambda)\xi]\\ &-\int_{[t,1]}\Phi(t,\alpha)h_x(\alpha,\bar{x}(\alpha))\ \mu(d\alpha)-\int_{[0,t)}h_x(\alpha,\bar{x}(\alpha))\ \mu(d\alpha)\quad\text{for all } t\in[0,1]\,,\end{aligned}$$

for some $\xi \in \{\xi' \in N_C(\bar{x}(1)) \,|\, |\xi'| = 1\}$. It can be deduced from this relationship that $p(.)$ is an absolutely continuous function which satisfies

$$-\dot{p}(t) = f_x^T(t, \bar{x}(t), \bar{u}(t)) \left(p(t) + \int_{[0,t)} h_x(\alpha, \bar{x}(\alpha))\ \mu(d\alpha) \right) \quad a.e.\ t \in [0,1]$$

$$- \left(p(1) + \int_{[0,1]} h_x(\alpha, \bar{x}(\alpha))\ \mu(d\alpha) \right) = \lambda g_x(\bar{x}(1)) + (1-\lambda)\xi$$

$$\in \lambda g_x(\bar{x}(1)) + N_C(\bar{x}(1)).$$

Notice that if $\|\mu'\|_{T.V.} = 0$ and $\lambda = 0$, then $|p(1)| = |\xi| = 1$. Thus, the multiplier nondegeneracy condition is satisfied. We have confirmed the assertions of the proposition in the case $\|\mu'\|_{T.V.} < 1$.

It remains then to consider the case when $\|\mu'\|_{T.V.} = 1$. Set $\mu = \mu'$. Now condition (iv) in the theorem statement is valid with

$$p(t) = \int_{[t,1]} p(t;\alpha)\ \mu(d\alpha) - \int_{[0,t)} h_x(\alpha, \bar{x}(\alpha))\ \mu(d\alpha).$$

It can be deduced that p satisfies

$$-\dot{p}(t) = f_x^T(t, \bar{x}(t)\bar{u}(t)) \left(p(t) + \int_{[0,t)} h_x(\alpha, \bar{x}(\alpha))\ \mu(d\alpha) \right) \ a.e.\ t \in [0,1]$$

$$- \left(p(1) + \int_{[0,1]} h_x(\alpha, \bar{x}(\alpha))\ \mu(d\alpha) \right) = 0.$$

But

$$0 \in \lambda g_x(\bar{x}(1)) + N_C(\bar{x}(1)),$$

when $\lambda = 0$. The assertions of the proposition have been confirmed in this case too, and the proof is complete. □

6. Proofs of Theorems 3.1–3.3. Our analysis will require some properties of measures, summarized in the following proposition.

PROPOSITION 6.1. *Take a compact metric space $\mathcal{A}$, a sequence $\{\mu_i\}$ of nonnegative Radon measures in $C^*(\mathcal{A})$, a sequence $\{D_i : \mathcal{A} \to R^n\}$ of multifunctions and a sequence of Borel measurable functions $\{\gamma_i : \mathcal{A} \to R^n\}$. Take also a measure $\mu \in C^*(\mathcal{A})$ and a multifunction $D : \mathcal{A} \to R^n$. Assume that Gr D is compact,*

(6.1) $$D(\alpha) \text{ is convex for each } \alpha \in \mathcal{A},$$

$$\limsup_{i \to \infty} \ Gr\ D_i \subset Gr\ D,$$

$$\gamma_i(\alpha) \in D_i(\alpha) \qquad \mu_i \text{ – a.e. } \alpha \in \mathcal{A} \quad \text{for } \ i = 1, 2, \ldots$$

and

$$\mu_i \to \mu \qquad \text{weakly}^*.$$

Define $\eta_i \in C^*(\mathcal{A}; R^n)$ according to

$$\eta_i(d\alpha) = \gamma_i(\alpha)\mu_i(d\alpha) \qquad i = 1, 2, \ldots.$$

Then,

(i) *Along a subsequence,*

$$\eta_i \to \eta \qquad \textit{weakly}^*$$

for some $\eta \in C^*(\mathcal{A}; R^k)$ *and some Borel measurable function* γ *such that*

$$\eta(d\alpha) = \gamma(\alpha)\mu(d\alpha),$$

and

$$\gamma(\alpha) \in D(\alpha) \qquad \mu - a.e.$$

(ii) *Suppose* $\mathcal{A}$ *is expressible as a union of disjoint sets*

$$\mathcal{A} = \mathcal{A}^{(1)} \cup \mathcal{A}^{(2)}$$

in which $\mathcal{A}^{(1)}$ *is compact metric space and* $\mathcal{A}^{(2)}$ *is finite. Then the assertions of part* (i) *remain valid when the hypothesis* (6.1) *is replaced by*

$$D(\alpha) \textit{ is convex for each } \alpha \in \mathcal{A}^{(1)}.$$

Proof. The proof, which is similar to that of ([10], Proposition 9.2.1), is omitted. □

6.1. Proof of Theorem 3.1. We observe at the outset that we can, without loss of generality, replace (S2) and (S3) by stronger (global) hypotheses in which $\delta = +\infty$, that is, we can require the stated conditions in (S2) to hold for all $x, x' \in R^n$, not merely in $x, x' \in \bar{x}(t) + \delta B$; likewise for (S3). This can always be arranged by replacing f and g by their "localizations" $(t, x, u, \alpha) \to f(t, tr_{\bar{x}(t),\delta}(x), u, \alpha)$ and $(t, x, u, \alpha) \to g(t, tr_{\bar{x}(t),\delta}(x), \alpha)$, in which $tr_{y,\delta}(x)$ is the truncation function

$$tr_{y,\delta}(x) = \begin{cases} x & \text{if } |x - y| < \delta \\ y + \delta(x - y)/|x - y| & \text{if } |x - y| \geq \delta \end{cases}.$$

The property that $\bar{x}$ is a strong local minimizer is preserved under this modification of the data. It is a consequence of the hypotheses, strengthened in this way that to each $u \in \mathcal{U}$ and $\alpha \in \mathcal{A}$, there corresponds a unique state trajectory (on $[0, 1]$ with initial state x_0). This we write $x(.; \alpha, u)$.

The following lemma brings together some useful facts, regarding the dependence of the state trajectories on controls and parameters.

Let $\Delta : R^n \times R^n \to R$ denote the Ekeland metric on $\mathcal{U}$,

$$\Delta(u_1, u_2) := meas\{t \mid u_1(t) \neq u_2(t)\}.$$

LEMMA 6.1. *For any* $\delta > 0$, *a finite subset* $\widetilde{\mathcal{A}} \subset \mathcal{A}$ *and* $\rho > 0$ *can be chosen such that*

(i)

$$\sup_{u \in \mathcal{U}} \sup_{\alpha \in \mathcal{A}} \inf_{\alpha' \in \widetilde{A}} \|x(.; \alpha, u) - x(.; \alpha', u)\|_C < \delta$$

(ii)

$$\sup_{\alpha \in \mathcal{A}} \left\{ \|x(.; \alpha, u) - x(.; \alpha, u')\|_C \mid u, u' \in \mathcal{U},\ \Delta(u, u') < \rho \right\} < \delta.$$

These assertions are straightforward consequences of Filippov's existence theorem. (See, e.g., [10], Theorem 2.4.3.)

Take a sequence $\epsilon_i \downarrow 0$. For each i define $J_i : \mathcal{U} \to R$

$$J_i(u) := \max_{\alpha \in \mathcal{A}} \Big\{ \Big(g(x(1;\alpha,u),\alpha) - \max_{\alpha' \in \mathcal{A}} \; g(\bar{x}(1;\alpha'),\alpha') + \epsilon_i^2 \Big) \vee d_{C(\alpha)}(x(1;\alpha,u)) \Big\}.$$

Notice that $J_i(u) \geq 0$ for all $u \in \mathcal{U}$ and $J_i(\bar{u}) = \epsilon_i^2$. It follows that $\bar{u}$ is an ϵ_i^2-minimizer for the functional J_i on $\mathcal{U}$.

For each i, J_i is continuous with respect to the Δ-metric topology. We deduce from Ekeland's theorem the existence of a control function v_i, for each i, such that

$$\Delta(v_i, \bar{u}) \leq \epsilon_i$$

and

$$J_i(v_i) + \epsilon_i \Delta(v_i, v_i) \; = \; \min_{u \in \mathcal{U}} \Big\{ J_i(u) + \epsilon_i \Delta(v_i, u) \Big\}.$$

We have

$$J_i(v_i) > 0 \quad \text{for all } i \text{ sufficiently large,}$$

since $(\bar{u}, \{\bar{x}(.;\alpha) \,|\, \alpha \in \mathcal{A}\})$ is a strong local minimizer for (P) and by Lemma 6.1 (ii). Fix i. For any finite subset $\widetilde{\mathcal{A}} \subset \mathcal{A}$, which will be chosen presently, consider the functional

(6.2)

$$J_i^{\widetilde{\mathcal{A}}}(u) := \max_{\alpha \in \widetilde{\mathcal{A}}} \Big\{ \Big(g(x(1;\alpha,u),\alpha) - \max_{\alpha' \in \mathcal{A}} \; g(\bar{x}(1;\alpha'),\alpha') + \epsilon_i^2 \Big) \vee d_{C(\alpha)}(x(1;\alpha,u)) \Big\}.$$

Take $\rho > 0$. According to Lemma 6.1, the finite subset $\tilde{\mathcal{A}}$ can be chosen such that

$$J_i^{\widetilde{\mathcal{A}}}(u) \; \geq \; J_i(u) - \rho^2 \quad \text{for all } u \in \mathcal{U}.$$

Since v_i is a minimizer for $u \to J_i(u) + \epsilon_i \Delta(v_i, u)$ over $\mathcal{U}$, it follows that v_i is a ρ^2-minimizer for $u \to J_i^{\widetilde{A}}(u) + \epsilon_i \Delta(v_i, u)$ over $\mathcal{U}$. A second application of Ekeland's theorem then yields a control function $u_i \in \mathcal{U}$ such that

$$\Delta(v_i, u_i) \leq \rho$$

and

$$J_i^{\widetilde{\mathcal{A}}}(u_i) + \epsilon_i \Delta(v_i, u_i) + \rho \Delta(u_i, u_i) \; = \; \min_{u \in \mathcal{U}} \Big\{ J_i^{\widetilde{\mathcal{A}}}(u) + \epsilon_i \Delta(v_i, u) + \rho \Delta(u_i, u) \Big\}.$$

By adding extra elements to the finite subset $\widetilde{A}$ and reducing ρ if necessary, we can make the number $|J_i^{\widetilde{A}}(u_i) - J_i(v_i)|$ arbitrary small. (See Lemma 6.1.) Since $J_i(v_i) > 0$, we can arrange that

$$J_i^{\widetilde{\mathcal{A}}}(u_i) > 0.$$

Write $\mathcal{A}^i$ in place of $\widetilde{\mathcal{A}}$ and ρ_i in place of ρ, to emphasize their dependence on i.

We can carry out the above analysis for $i = 1, 2, \ldots$. By adding extra elements to each $\mathcal{A}^i$ and reducing each ρ_i, if necessary, we can arrange, also, that $\{\mathcal{A}^i\}$ is an increasing sequence and $\rho_i \downarrow 0$.

For clarity, we summarize relevant properties of the above constructs: for some sequences $\epsilon_i \downarrow 0$ and $\rho_i \downarrow 0$, sequences $\{u_i\}$ and $\{v_i\}$ in $\mathcal{U}$ and an increasing sequence of finite subsets $\{\mathcal{A}^i\}$ of $\mathcal{A}$, we have

(i) $J_i^{\mathcal{A}^i}(u_i) + \epsilon_i\Delta(v_i,u_i) + \rho_i\Delta(u_i,u_i)$
$= \min_{u\in\mathcal{U}}\left\{J_i^{\mathcal{A}^i}(u) + \epsilon_i\Delta(v_i,u) + \rho_i\Delta(u_i,u)\right\}$ for all i,

(ii) $J_i^{\mathcal{A}^i}(u_i) > 0$ for all i,

(iii) $\Delta(v_i,\bar{u}) \to 0$ and $\Delta(u_i,\bar{u}) \to 0$ as $i \to \infty$.

For each i, list the elements in $\mathcal{A}^i$,

$$\mathcal{A} = \{\alpha_1, \ldots, \alpha_{K_i}\}$$

and write $\{x_i(.;\alpha) \,|\, \alpha \in \mathcal{A}\}$ for the state trajectories corresponding to u_i. Define

$$m_i(t,u) := \begin{cases} 0 & \text{if } u = v_i(t), \\ 1 & \text{otherwise,} \end{cases} \quad \text{and} \quad n_i(t,u) := \begin{cases} 0 & \text{if } u = u_i(t), \\ 1 & \text{otherwise.} \end{cases}$$

With the help of these functions, we can express the minimizing property (i) of the u_i's in control theoretic terms, as follows. For each i, $(u_i, \{x_i(.;\alpha_k) \mid k = 1, \ldots, K_i\})$ is a minimizer for the optimal control problem

$$(\mathrm{P}_i)\begin{cases} \text{Minimize } \max_{k=1,\ldots,K_i}\Big\{\big(g(x(1;\alpha_k),\alpha_k) \\ \qquad\qquad - \max_{\alpha\in\mathcal{A}}\ g(\bar{x}(1;\alpha),\alpha) + \epsilon_i^2\big) \vee d_{C(\alpha_k)}(x(1;\alpha_k))\Big\} \\ \qquad\qquad + \epsilon_i \int_0^1 m_i(t,u(t))\,dt + \rho_i \int_0^1 n_i(t,u(t))\,dt \\ \text{over measurable functions } u \text{ and arcs } \{x(.;\alpha_1), \ldots, x(.;\alpha_{K_i})\} \text{ such that} \\ u(t) \in \Omega(t), \quad \textit{a.e. } t \in [0,1] \\ \text{and, for } k = 1, \ldots, K_i, \\ \dot{x}(t;\alpha_k) = f(t, x(t;\alpha_k), u(t), \alpha_k), \quad \textit{a.e. } t \in [0,1], \\ x(0;\alpha_k)(0) = x_0. \end{cases}$$

Since $u_i \to \bar{u}$ and $v_i \to \bar{u}$ with respect to the Δ-metric, we know that

$$\sup_{\alpha\in\mathcal{A}} \|\bar{x}(.;\alpha) - x(.;\alpha,u_i)\|_C \ \to\ 0 \qquad \text{as} \quad i \to \infty.$$

Take an infinite sequence of control functions $\{\hat{u}_j\} \in \mathcal{U}$ whose first element is $\bar{u}$. Using similar reasoning to that employed in the proof of Proposition 2.1 (note the crucial role of property (ii) above, to ensure multiplier nondegeneracy), we can deduce the following information from the nonsmooth maximum principle (see, e.g., [10], Theorem 6.2.1). For each i sufficiently large, there exist nonnegative numbers $\lambda_1^i, \ldots, \lambda_{K_i}^i$ such that

$$\sum_{k=1}^{K_i} \lambda_k^i = 1,$$

and a sequence $\epsilon_i' \downarrow 0$ with the following properties. Define the discrete probability measure

$$\Lambda_i = \sum_{k=1}^{K_i} \lambda_k^i \delta_{\alpha_k^i}.$$

Then, for each i sufficiently large and Λ_i – *a.e.* $\alpha \in \mathcal{A}$, there exists a costate arc $p_i(.;\alpha)$

satisfying

$$\text{(i)} -\dot{p}_i(t;\alpha) \in \operatorname{co} \partial_x H(t, \bar{x}(t) + \epsilon_i' B, \bar{u}(t), p_i(t;\alpha), \alpha)$$

$$\text{(ii)} -p_i(1;\alpha) \in \overline{co} \bigcup_{x \in \bar{x}(1;\alpha) + \epsilon_i' B} \bigcup_{r \in [0,1]} \left(r G_{\epsilon_i'}(x,\alpha) + (1-r) N(x,\alpha) \right)$$

where $G_{\epsilon'}(\alpha, x) =$

$$\begin{cases} \partial_x g(x,\alpha) & \text{if } g(x,\alpha) \geq \max_{\alpha' \in \mathcal{A}} g(x,\alpha') - \epsilon' \\ \emptyset & \text{otherwise} \end{cases}$$

and $N(x,\alpha) = \left\{ \xi \in N_{C(\alpha)}(x) \,|\, |\xi| = 1 \right\}$

$$\text{(iii)} \int_{\mathcal{A}} \int_0^1 p_i(t;\alpha) \cdot [f(t, \bar{x}(t;\alpha), \hat{u}_j(t), \alpha) - f(t, \bar{x}(t;\alpha), \bar{u}(t), \alpha)] \, dt \, \Lambda_i(d\alpha) \leq \epsilon_i'$$

for $j = 1, 2, \ldots$.

By extracting a subsequence, we can arrange that

$$\Lambda_i \to \Lambda \qquad \text{weakly}^* \qquad \text{as} \quad i \to \infty$$

for some Radon probability measure Λ on the Borel sets of $\mathcal{A}$.

Fix an integer N. We now apply the first part of Proposition 6.1, in which we identify μ with Λ, μ_i with the Λ_i, and take

$$D_i(\alpha) := \{(\xi_1, \ldots, \xi_N) \in R^N \,|\, \exists\, p(.;\alpha) \in Q_{\epsilon_i'}(\alpha) \text{ s.t. } \xi_j = w_j(p(.;\alpha), \alpha) \text{ for } j = 1, 2, \ldots, N\},$$

$i = 1, 2, \ldots$, and

(6.3)
$$D(\alpha) := \{(\xi_1, \ldots, \xi_N) \mid \exists\, p(.;\alpha) \in \overline{Q}_0(\alpha) \text{ s.t. } \xi_j = w_j(p(.;\alpha), \alpha),\ j = 1, 2, \ldots, N\}.$$

Here,

$$w_j(p(.), \alpha) := \int_0^1 p(t) \cdot [f(t, \bar{x}(t,\alpha), \hat{u}_j(t), \alpha) - f(t, \bar{x}(t,\alpha), \bar{u}(t), \alpha)] \, dt.$$

We deduce that

$$\int_{\mathcal{A}} \int_0^1 q_N(t,\alpha) \cdot [f(t, \bar{x}(t,\alpha), \hat{u}_j(t), \alpha) - f(t, \bar{x}(t,\alpha), \bar{u}(t), \alpha)] \, dt \, \Lambda(d\alpha) \leq 0 \tag{6.4}$$

for $j = 1, 2, \ldots, N$, in which $\{q_N(.;\alpha) \in W^{1,1} \,|\, \alpha \in \mathcal{A}\}$ is some family of arcs such that, for Λ – *a.e.* $\alpha \in \mathcal{A}$,

$$q_N(.;\alpha) \in \overline{Q}_0(\alpha).$$

For each N, we can regard $\alpha \to q_N(.;\alpha)$ as a representative of an equivalence class of Λ – *a.e.* equal elements in the Hilbert space

$$\mathcal{X} := L^2_\Lambda(\mathcal{A}; L^2([0,1]; R^n))$$

with the inner product

$$(p,q)_\Lambda = \int_{\mathcal{A}} \int_0^1 p(t;\alpha) \cdot q(t;\alpha) \, dt \, \Lambda(d\alpha).$$

The sequence $\{\alpha \to q_N(.;\alpha)\}_{N=1}^{\infty}$ is norm bounded and therefore has a weak limit, which we write $\{\alpha \to p(.;\alpha)\}$. But

$$\{d \in \mathcal{X} \mid d(\alpha) \in \overline{Q}_0(\alpha),\ \Lambda - a.e. \quad \alpha \in \mathcal{A}\}$$

is a strongly closed subset of $\mathcal{X}$. Since it is convex, it is also weakly closed. It follows that

$$p(.;\alpha) \in \overline{Q}_0(\alpha) \quad \Lambda - a.e.\ \alpha \in \mathcal{A}.$$

By weak convergence, we deduce from (6.4) that

$$\int \int_0^1 p(t;\alpha) \cdot [f(t, \bar{x}(t;\alpha), \hat{u}_j(t), \alpha) - f(t, \bar{x}(t;\alpha), \bar{u}(t), \alpha)]\ dt\ \Lambda(d\alpha) \leq 0 \tag{6.5}$$

for $j = 1, 2, \ldots$.

In view of the Castaing representation theorem (see, e.g., [10], Theorem 2.2.7), we can choose a subset $T \subset (0,1)$ of full measure and also the sequence of controls functions above, $\{\hat{u}_j\}$, to satisfy

$$\overline{\bigcup_j \int_{\mathcal{A}} p(t;\alpha) \cdot f(t, \bar{x}(t;\alpha), \hat{u}_j(t), \alpha)\Lambda(d\alpha)} \ \supset\ \int_{\mathcal{A}} p(t;\alpha) \cdot f(t, \bar{x}(t;\alpha), \Omega(t), \alpha)\Lambda(d\alpha) \tag{6.6}$$

for all $t \in T$. We can arrange that (6.5) remains valid when the countable set $\hat{u}_j(.)$ is replaced by another countable set comprising all concatenations of a finite number of segments of the original $\hat{u}_j$'s, with junction points belonging to a countable dense subset S of $[0,1]$.

Define T' to be the set of full measure, comprising points in T which are also Lebesgue points for

$$s \to \int p(s;\alpha)[f(s, \bar{x}(s,\alpha), \hat{u}_j(s), \alpha) - f(s, \bar{x}(s,\alpha), \bar{u}(s), \alpha)]\ \Lambda(d\alpha) \tag{6.7}$$

for all j. Take any $t \in T'$, $w \in \Omega(t)$ and $\beta > 0$, Then, in view of (6.6), there exists j such that

$$\int_{\mathcal{A}} p(t;\alpha) \cdot f(t, \bar{x}(t), \hat{u}_j(t), \alpha)\Lambda(d\alpha)\ \geq\ \int_{\mathcal{A}} p(t;\alpha) \cdot f(t, \bar{x}(t;\alpha), w, \alpha)\Lambda(d\alpha) - \beta. \tag{6.8}$$

Choose a sequence of intervals $\{[s_i, t_i]\}$, containing t and with endpoints in the set S and such that $s_i \to t$ and $t_i \to t$. Now let $v_i \in \{\hat{u}_j\}_{j=1}^{\infty}$ for $i = 1, 2, \ldots$, where

$$v_i := \begin{cases} \hat{u}_j(t) & \text{if } \ t \in [s_i, t_i], \\ \bar{u}(t) & \text{otherwise.} \end{cases}$$

Changing the order of integration, inserting $\hat{u}_j = v_i$ in (6.5) and dividing across by $|t_i - s_i|$ gives

$$\frac{1}{|t_i - s_i|} \int_{s_i}^{t_i} \int p(s;\alpha) \cdot [f(s, \bar{x}(s;\alpha), \hat{u}_j(s), \alpha) - f(s, \bar{x}(s;\alpha), \bar{u}(s), \alpha)]\ \Lambda(d\alpha)\ dt \leq 0$$

for each i. Since t is a Lebesgue point of the mapping (6.7), it follows that

$$\int p(t;\alpha)\cdot[f(t,\bar{x}(t;\alpha),\hat{u}_j(t),\alpha)-f(t,\bar{x}(t;\alpha),\bar{u}(t),\alpha)]\ \Lambda(d\alpha)\leq 0.$$

We conclude from (6.8) that

$$\int p(t;\alpha)\cdot[f(s,\bar{x}(t;\alpha),w,\alpha)-f(t,\bar{x}(t;\alpha),\bar{u}(t),\alpha)]\ \Lambda(d\alpha)\leq \beta.$$

But $\beta>0$ is arbitrary. So

$$\int p(t;\alpha)\cdot[f(t,\bar{x}(t;\alpha),w,\alpha)-f(t,\bar{x}(t;\alpha),\bar{u}(t),\alpha)]\ \Lambda(d\alpha)\leq 0.$$

Since the above inequality holds for any $t'\in T'$, a set of full measure, and any $w\in\Omega(t)$, the maximization of the Hamiltonian condition is confirmed. The proof is complete.

6.2. Proof of Theorem 3.2. The assertions of Theorem 3.1 are expressed in terms of selectors $p(.;\alpha)$ of the multifunction

$$\alpha\rightarrow\overline{Q}_0(\alpha)$$

in order to guarantee that $D(.)$, given by (6.3), has closed graph and convex values, and thereby to justify application of part (i) of Proposition 6.1.

In the case when $\mathcal{A}$ can be decomposed into disjoint sets $\mathcal{A}=A^{(1)}\cup A^{(2)}$ in which $A^{(2)}$ is finite, essentially the same analysis leads to optimality conditions involving a selector $p(.;\alpha)$ of the multifunction

$$\alpha\rightarrow\begin{cases}\overline{Q}_0(\alpha) & \text{if } \alpha\in A^{(1)},\\ Q_0(\alpha) & \text{if } \alpha\in A^{(2)}.\end{cases}\tag{6.9}$$

We do, however, now have to use part (ii) of Proposition 6.1 to justify (6.4), for some selector $p_N(.;\alpha)$ of the multifunction (6.9).

Also, to justify (6.5) (for some selector $p_N(.;\alpha)$ of (6.9)), we must use the facts that, if $A^{(2)}=\{b_1,\ldots,b_m\}$, then an element in

$$\mathcal{X}=L^2_\Lambda(\mathcal{A};L^2([0,1];R^n))$$

can be represented by an element in

$$\mathcal{X}'=L^2_\Lambda(\mathcal{A}^{(1)};L^2([0,1];R^n))\times L^2([0,1];R^n)^m,$$

and the weak topology on $\mathcal{X}$ is compatible with the weak product topology on $\mathcal{X}'$. It follows that, for the sequence $\{\alpha\rightarrow p_N(.;\alpha)\}_{N=1}^{\infty}$ constructed at the end of the proof of Theorem 3.1, we can arrange by subsequence extraction, that the limiting $p(.;\alpha)$ satisfies $p(.;\alpha)\in Q_0(\alpha)$ for $\Lambda-$ *a.e.* $\alpha\in A^{(2)}$.

6.3. Proof of Theorem 3.3. The proof the minimax maximum principle for problems with functional inequality endpoint constraints is along similar, but simpler, lines to that of Example 4.1. The main difference is that, for each i, we replace the cost function $J_i^{\tilde{A}}(u)$ (see (6.2)) of the earlier analysis by

$$\begin{aligned}\tilde{J}_i^{\tilde{A}}(u)\ :=\ \max_{\alpha\in\tilde{A}}\Big\{&\Big(g(x(1;\alpha,u),\alpha)-\max_{\alpha'\in\mathcal{A}}\ g(\bar{x}(1;\alpha'),\alpha')\Big)\\ &\vee\psi^1(\bar{x}(1;\alpha,u),\alpha,)\vee\cdots\vee\psi^r(\bar{x}(1;\alpha),\alpha)\Big\}.\end{aligned}\tag{6.10}$$

The proof is completed by examining properties of minimizers of perturbations of these cost functions and passage to the limit as before.

Acknowledgment. The assistance of the reviewers in improving earlier versions of this paper is gratefully acknowledged.

A CANONICAL FORM FOR THE INCLUSION PRINCIPLE OF DYNAMIC SYSTEMS*

DELIN CHU† AND DRAGOSLAV D. ŠILJAK‡

Abstract. The inclusion principle provides a mathematical framework for comparing behavior of dynamic systems having different dimensions. Our main objective is to derive a canonical form for larger systems (expansions) that are obtained by expanding smaller systems (contractions). The form offers full freedom in selecting appropriate matrices for the expansion-contraction process. We will broaden the form to include feedback and propose an explicit characterization of contractible control laws subject to overlapping information structure constraints.

Key words. inclusion principle, expansion, contraction, canonical form, decentralized control

1. Introduction. The inclusion principle for dynamic systems [1], which was developed in the 1980s, is now a well-established mathematical framework for comparing systems having different dimensions (for a self-contained presentation of the early results, see [2]). In particular, the principle has been established as a useful tool in formulation of control laws for systems with overlapping information structure constraints [3, 4, 5, 6, 7, 8, 9, 10]. In the past decade, the research on the inclusion principle has been focused on providing a wide variety of conditions for expansion and contraction of continuous, discrete-time, and stochastic dynamic systems [11, 12, 13, 14, 15, 16, 17, 18, 19, 20], which helped resolve both theoretical aspects and practical benefits of the principle in control designs.

Expansion, being an intersection of aggregation [21] and restriction [1, 2, 3], raises a question: What system properties are retained after the expansion-contraction process has been completed [22]? Much progress has been made in identifying the conditions that ensure the invariancy of controllability, observability, and stabilizability in the expanded systems [23, 24, 25].

A central issue in the framework of overlapping decentralized control has been the problem of contractibility of feedback control laws [2, 3, 4, 5, 6, 7, 8, 9, 10, 11, 12, 13, 14, 15, 16, 17, 18, 19, 20]. When a system contains overlapping subsystems, it is natural to add the locally available overlapping states to decentralized control in order to improve the performance of the overall system. This fact gives rise to the control design under overlapping information structure constraints, which is handled by expanding the systems into a larger space where the overlapping subsystems appear as disjoint. As a result of the expansion, overlapping decentralized control in the expanded space can be chosen by standard methods which are available for disjoint subsystems. After the selection is made, the expanded control law is contracted to the original space for implementation. While flexibility of the inclusion principle has been

greatly improved by the new conditions guiding the expansion-contraction process [10, 11, 12, 13, 14, 15, 16, 17, 18, 19, 20], the contractibility problem has not been satisfactorily resolved. A failure of a condition to provide the required contractibility of a control law is often hard to interpret; one is not sure if the choice of condition or selection of control law is inappropriate, or if contractibility is not possible due to an inherent structure of the system.

Our objective in this paper is to derive a canonical form for the inclusion principle in the spirit of canonical forms for linear dynamical systems [26, 27, 28, 29, 30]. By providing an explicit characterization of expanded systems, the form, as expected, simplifies the study of invariant properties in the expansion-contraction process. The proposed form involves expansion of inputs, outputs, and feedback control laws, thus broadening in an essential way the scope of the canonical form derived previously for state expansion only [1, 2]. A by-product of this fact is a complete resolution of the contractibility problem of expanded control laws for both static and dynamic controllers, which has a special significance in formulations of decentralized control for complex systems under overlapping information structure constraints.

The present paper is organized as follows: In section 2 the inclusion and contractibility of dynamic systems are formulated. Canonical forms for the inclusion principle are established in section 3. In section 4, a problem related to overlapping decentralized control is solved. Next the contractibility of dynamic controllers is discussed in section 5. Finally, in section 6, we offer a few concluding remarks.

2. Inclusion and contractibility. Consider a pair of linear time-invariant systems

$$\mathbf{S}: \quad \begin{cases} \dot{x} = Ax + Bu, \\ y = Cx \end{cases} \tag{2.1}$$

and

$$\tilde{\mathbf{S}}: \quad \begin{cases} \dot{\tilde{x}} = \tilde{A}\tilde{x} + \tilde{B}\tilde{u}, \\ \tilde{y} = \tilde{C}\tilde{x}, \end{cases} \tag{2.2}$$

where $x(t) \in \mathbf{R}^n$, $u(t) \in \mathbf{R}^m$, $y(t) \in \mathbf{R}^l$ are the state, input, and output of system $\mathbf{S}$ at time $t \geq 0$, and $\tilde{x}(t) \in \mathbf{R}^{\tilde{n}}$, $\tilde{u}(t) \in \mathbf{R}^{\tilde{m}}$, $\tilde{y}(t) \in \mathbf{R}^{\tilde{l}}$ are those of $\tilde{\mathbf{S}}$, and $A \in \mathbf{R}^{n\times n}$, $B \in \mathbf{R}^{n\times m}$, $C \in \mathbf{R}^{l\times n}$, $\tilde{A} \in \mathbf{R}^{\tilde{n}\times\tilde{n}}$, $\tilde{B} \in \mathbf{R}^{\tilde{n}\times\tilde{m}}$, $\tilde{C} \in \mathbf{R}^{\tilde{l}\times\tilde{n}}$ are constant matrices. Suppose

$$n \leq \tilde{n}, \quad m \leq \tilde{m}, \quad l \leq \tilde{l},$$

that is, $\mathbf{S}$ is smaller than $\tilde{\mathbf{S}}$. Denote by $x(t; x_0, u)$ and $y[x(t)]$ the state behavior and the corresponding output of system $\mathbf{S}$ for a fixed input $u(t)$ and for an initial state $x(0) = x_0$, respectively. Similar notation $\tilde{x}(t; \tilde{x}_0, \tilde{u})$ and $\tilde{y}[\tilde{x}(t)]$ are used for the state behavior and output of system $\tilde{\mathbf{S}}$.

Let us link systems $\mathbf{S}$ and $\tilde{\mathbf{S}}$ through the following transformations:

$$V: \mathbf{R}^n \longrightarrow \mathbf{R}^{\tilde{n}}, \quad L: \mathbf{R}^m \longrightarrow \mathbf{R}^{\tilde{m}}, \quad T: \mathbf{R}^l \longrightarrow \mathbf{R}^{\tilde{l}}, \tag{2.3}$$

where

$$\operatorname{rank}(V) = n, \quad \operatorname{rank}(L) = m, \quad \operatorname{rank}(T) = l. \tag{2.4}$$

Denote the unique pseudoinverses of V, L, and T by V^+, L^+, and T^+, respectively, and recall the definition of the inclusion principle [1, 2].

DEFINITION 2.1. *The system* $\tilde{\mathbf{S}}$ *includes the system* $\mathbf{S}$*, that is,* $\mathbf{S}$ *is included by* $\tilde{\mathbf{S}}$*, if there exists a triplet* (V, L, T) *satisfying* (2.3) *and* (2.4) *such that, for any initial state* x_0 *and any fixed* $u(t)$ *of system S, the choice*

$$\tilde{x}_0 = Vx_0, \quad \tilde{u}(t) = Lu(t) \quad \forall t \geq 0 \tag{2.5}$$

of the initial state $\tilde{x}_0$ *and input* $\tilde{u}(t)$ *of the system* $\tilde{\mathrm{S}}$ *implies*

$$x(t; x_0, u) = V^+\tilde{x}(t; \tilde{x}_0, \tilde{u}), \quad y[x(t)] = T^+\tilde{y}[\tilde{x}(t)] \quad \forall t \geq 0. \tag{2.6}$$

If the system $\tilde{\mathbf{S}}$ *includes the system* $\mathbf{S}$*, then system* $\tilde{\mathbf{S}}$ *is said to be an expansion of the system* $\mathbf{S}$ *and system* $\mathbf{S}$ *is a contraction of system* $\tilde{\mathbf{S}}$*.*

The inclusion principle has been used to expand overlapping decentralized control laws into a larger space, where they appear disjoint, design disjoint laws by known methods, and *contract* them to the original space for implementation (see, e.g., [2]). The central issue in the expansion-contraction process is the problem of contractibility defined as follows [1, 4].

DEFINITION 2.2. *The control law*

$$\tilde{u} = -\tilde{K}\tilde{x} + \tilde{v}$$

given for system $\tilde{\mathbf{S}}$ *is contractible to the control law*

$$u = -Kx + v$$

for implementation in system $\mathbf{S}$ *if one of the following two statements holds:*

(a) *The choice*

$$\tilde{x}_0 = Vx_0, \quad \tilde{u}(t) = Lu(t)$$

implies

$$x(t; x_0, u) = V^+\tilde{x}(t; \tilde{x}_0, \tilde{u}), \quad LKx(t; x_0, u) = \tilde{K}\tilde{x}(t; \tilde{x}_0, \tilde{u}) \tag{2.7}$$

for all $t \geq 0$*, any initial state* x_0*, and any fixed input* $u(t)$ *of system* $\mathbf{S}$*.*

(b) *The choice*

$$\tilde{x}_0 = Vx_0, \quad u = L^+\tilde{u}$$

implies

$$x(t; x_0, u) = V^+\tilde{x}(t; \tilde{x}_0, \tilde{u}), \quad Kx(t; x_0, u) = L^+\tilde{K}\tilde{x}(t; \tilde{x}_0, \tilde{u}) \tag{2.8}$$

for all $t \geq 0$*, any initial state* x_0 *of system* $\mathbf{S}$*, and any fixed input* $\tilde{u}$ *of system* $\tilde{\mathbf{S}}$*.*

It should be pointed out that both conditions in (a) and (b) above ensure that the closed-loop system

$$\dot{\tilde{x}} = (\tilde{A} + \tilde{B}\tilde{K})\tilde{x} + \tilde{B}\tilde{v}$$

includes the closed-loop system

$$\dot{x} = (A + BK)x + Bv.$$

This property plays an important role in the application of the inclusion principle to overlapping decentralized control.

For the expansion-contraction and contractibility between systems $\mathbf{S}$ and $\tilde{\mathbf{S}}$, the conditions are provided in the following theorem [4].

THEOREM 2.3. *Given systems* $\mathbf{S}$ *and* $\tilde{\mathbf{S}}$*, and transformations* V*,* L*, and* T *satisfying* (2.3) *and* (2.4)*.*

(i) *System* $\tilde{\mathbf{S}}$ *is an expansion of system* $\mathbf{S}$ *if and only if for all* $i = 1, 2, \ldots, \tilde{n}$

$$\begin{cases} V^+(\tilde{A} - VAV^+)^i V = 0, \\ V^+(\tilde{A} - VAV^+)^{i-1}(\tilde{B}L - VB) = 0, \\ (T^+\tilde{C} - CV^+)(\tilde{A} - VAV^+)^{i-1}V = 0, \\ (T^+\tilde{C} - CV^+)(\tilde{A} - VAV^+)^{i-1}(\tilde{B}L - VB) = 0. \end{cases} \tag{2.9}$$

(ii) *The control law* $-\tilde{K}\tilde{x}$ *is contractible to the control law* $-Kx$ *if and only if either*

$$\begin{cases} V^+(\tilde{A} - VAV^+)^i V = 0, \\ V^+(\tilde{A} - VAV^+)^{i-1}(\tilde{B}L - VB) = 0, \quad i = 1, 2, \ldots, \tilde{n}, \\ (LKV^+ - \tilde{K})\tilde{A}^{i-1}\begin{bmatrix} V & \tilde{B}L \end{bmatrix} = 0 \end{cases} \tag{2.10}$$

or

$$\begin{cases} V^+(\tilde{A} - VAV^+)^i V = 0, \\ V^+(\tilde{A} - VAV^+)^{i-1}(\tilde{B} - VBL^+) = 0, \quad i = 1, 2, \ldots, \tilde{n}, \\ (KV^+ - L^+\tilde{K})\tilde{A}^{i-1}\begin{bmatrix} V & \tilde{B} \end{bmatrix} = 0. \end{cases} \tag{2.11}$$

In applications, the inclusion principle relies heavily on the proper choice of expanded matrices $\tilde{A}$, $\tilde{B}$, $\tilde{C}$, and $\tilde{K}$ which are restricted by the expandability and contractibility conditions of Theorem 2.3. In a variety of situations, the conditions have been hard to use since there are no simple rules for their interpretation, nor systematic procedures for utilizing the conditions in the computation of expanded matrices. For this reason, there are a few standard choices [2, 3, 4, 5, 6, 7, 8, 9, 10, 11, 12, 13, 14, 15, 16, 17, 18, 19, 20] that have been repeatedly used in applications, while the full freedom offered by the conditions has remained unexplored. Recently, to broaden the scope of applications of the inclusion principle, new expansion-contraction conditions have been proposed, which involve additional flexibility provided by the choice of complementary matrices [14, 15, 16, 17, 18]. Even in this case, the conditions involve an intricate relationship between powers of matrices that obscures the full flexibility of the proposed choice.

In the next section we will establish a canonical form for the inclusion principle of dynamic system $\mathbf{S}$. The canonical form parameterizes explicitly all expansion-contraction matrices in the general setting of transformations V, L, T. Therefore, full freedom of the inclusion principle is readily available for control design.

3. Canonical form. Motivated by the difficulties in characterizing expansion matrices, we propose to derive a canonical form for the inclusion principle. The form resolves the difficulties by providing an explicit parameterization of the expanded system within the framework of expansion-contraction process. To show this, we need the following two lemmas [31, 32].

LEMMA 3.1. *Given* $\mathcal{A} \in \mathbf{R}^{n\times n}, \mathcal{B} \in \mathbf{R}^{n\times m}, \mathcal{C} \in \mathbf{R}^{l\times n}$*, and* $\mathcal{D} \in \mathbf{R}^{l\times m}$*.*

(i)

$$\max_{s\in\mathbf{C}} \operatorname{rank} \begin{bmatrix} sI - \mathcal{A} & \mathcal{B} \\ \mathcal{C} & \mathcal{D} \end{bmatrix} = n$$

if and only if

$$\mathcal{D} = 0$$

and

$$\max_{s\in\mathbf{C}} \operatorname{rank} \begin{bmatrix} sI - \mathcal{A} & \mathcal{B} \\ \mathcal{C} & 0 \end{bmatrix} = n.$$

(ii) *Assume that* $(\mathcal{A}, \mathcal{B})$ *is controllable, i.e.,*

$$\operatorname{rank} \begin{bmatrix} sI - \mathcal{A} & \mathcal{B} \end{bmatrix} = n \quad \forall s \in \mathbf{C}.$$

Then

$$\max_{s\in\mathbf{C}} \operatorname{rank} \begin{bmatrix} sI - \mathcal{A} & \mathcal{B} \\ \mathcal{C} & 0 \end{bmatrix} = n$$

if and only if

$$\mathcal{C} = 0.$$

LEMMA 3.2. *Given* $\mathcal{A} \in \mathbf{R}^{n\times n}, \mathcal{B} \in \mathbf{R}^{n\times m}, \mathcal{C} \in \mathbf{R}^{l\times n}$. *Then*

$$\mathcal{C}\mathcal{A}^i\mathcal{B} = 0 \quad \text{for } i = 0, 1, \ldots, n-1$$

if and only if

$$\max_{s\in\mathbf{C}} \operatorname{rank} \begin{bmatrix} sI - \mathcal{A} & \mathcal{B} \\ \mathcal{C} & 0 \end{bmatrix} = n.$$

Proof. From the Kalman decomposition of a linear time-invariant system [26], there exists nonsingular matrix $\mathcal{X} \in \mathbf{R}^{n\times n}$ such that

$$\mathcal{X}\mathcal{A}\mathcal{X}^{-1} = \begin{bmatrix} \mathcal{A}_{11} & \mathcal{A}_{12} \\ 0 & \mathcal{A}_{22} \end{bmatrix} \begin{matrix} \}\tau_1 \\ \}n-\tau_1 \end{matrix}, \quad \mathcal{X}\mathcal{B} = \begin{bmatrix} \mathcal{B}_1 \\ 0 \end{bmatrix} \begin{matrix} \}\tau_1 \\ \}n-\tau_1 \end{matrix}, \quad \mathcal{C}\mathcal{X}^{-1} = \begin{bmatrix} \overset{\tau_1}{\mathcal{C}_1} & \overset{n-\tau_1}{\mathcal{C}_2} \end{bmatrix},$$

where $(\mathcal{A}_{11}, \mathcal{B}_1)$ is controllable, which implies

$$\operatorname{rank} \begin{bmatrix} \mathcal{B}_1 & \mathcal{A}_{11}\mathcal{B}_1 & \cdots & \mathcal{A}_{11}^{\tau_1-1}\mathcal{B}_1 \end{bmatrix} = \tau_1. \tag{3.1}$$

Since

$$\begin{aligned} \operatorname{rank} \begin{bmatrix} \mathcal{C}\mathcal{B} & \mathcal{C}\mathcal{A}\mathcal{B} & \cdots & \mathcal{C}\mathcal{A}^{n-1}\mathcal{B} \end{bmatrix} &= \operatorname{rank}(\mathcal{C}_1 \begin{bmatrix} \mathcal{B}_1 & \mathcal{A}_{11}\mathcal{B}_1 & \cdots & \mathcal{A}_{11}^{n-1}\mathcal{B}_1 \end{bmatrix}) \\ &= \operatorname{rank}(\mathcal{C}_1 \begin{bmatrix} \mathcal{B}_1 & \mathcal{A}_{11}\mathcal{B}_1 & \cdots & \mathcal{A}_{11}^{\tau_1-1}\mathcal{B}_1 \end{bmatrix}), \end{aligned}$$

so, the property (3.1) gives that $\mathcal{C}\mathcal{A}^i\mathcal{B} = 0$ for all $i = 0, 1, \ldots, n-1$ if and only if $\mathcal{C}_1 = 0$.

On the other hand,

$$\begin{aligned} \max_{s\in\mathbf{C}} \operatorname{rank} \begin{bmatrix} sI - \mathcal{A} & \mathcal{B} \\ \mathcal{C} & 0 \end{bmatrix} &= (n - \tau_1) + \max_{s\in\mathbf{C}} \operatorname{rank} \begin{bmatrix} sI - \mathcal{A}_{11} & \mathcal{B}_1 \\ \mathcal{C}_1 & 0 \end{bmatrix} \\ &= n + \left(\max_{s\in\mathbf{C}} \operatorname{rank} \begin{bmatrix} sI - \mathcal{A}_{11} & \mathcal{B}_1 \\ \mathcal{C}_1 & 0 \end{bmatrix} - \tau_1 \right); \end{aligned}$$

thus, we have by using Lemma 3.1 that $\max_{s\in\mathbf{C}} \operatorname{rank} \begin{bmatrix} sI-\mathcal{C}^{-}\mathcal{A} & \mathcal{B} \\ 0 & \end{bmatrix} = n$ if and only if $\mathcal{C}_1 = 0$. Hence, Lemma 3.2 follows. □

Now we are ready to present a canonical form for the expansion-contraction triplet $(\tilde{A}, \tilde{B}, \tilde{C})$ under the inclusion principle as follows.

THEOREM 3.3. *Given systems* $\mathbf{S}$ *and* $\tilde{\mathbf{S}}$*, and transformations* V*,* L*,* T *satisfying* (2.3) *and* (2.4)*, let the QR factorizations of* V*,* L*, and* T *be given by*

$$
\begin{cases}
\begin{bmatrix} \mathcal{U} & U \end{bmatrix}^T V = \begin{bmatrix} V_{11} \\ 0 \end{bmatrix} \begin{matrix} \}n \\ \}\tilde{n}-n \end{matrix}, \quad \mathcal{U} \in \mathbf{R}^{\tilde{n}\times n}, \quad U \in \mathbf{R}^{\tilde{n}\times(\tilde{n}-n)}, \\
\begin{bmatrix} \mathcal{P} & P \end{bmatrix}^T L = \begin{bmatrix} L_{11} \\ 0 \end{bmatrix} \begin{matrix} \}m \\ \}\tilde{m}-m \end{matrix}, \quad \mathcal{P} \in \mathbf{R}^{\tilde{m}\times m}, \quad P \in \mathbf{R}^{\tilde{m}\times(\tilde{m}-m)}, \\
\begin{bmatrix} \mathcal{S} & S \end{bmatrix}^T T = \begin{bmatrix} T_{11} \\ 0 \end{bmatrix} \begin{matrix} \}l \\ \}\tilde{l}-l \end{matrix}, \quad \mathcal{S} \in \mathbf{R}^{\tilde{l}\times l}, \quad S \in \mathbf{R}^{\tilde{l}\times(\tilde{l}-l)},
\end{cases} \tag{3.2}
$$

where $\begin{bmatrix} \mathcal{U} & U \end{bmatrix}$, $\begin{bmatrix} \mathcal{P} & P \end{bmatrix}$, *and* $\begin{bmatrix} \mathcal{S} & S \end{bmatrix}$ *are orthogonal, and* V_{11}*,* L_{11}*, and* T_{11} *are nonsingular. Then, system* $\tilde{\mathbf{S}}$ *is an expansion of the system* $\mathbf{S}$ *if and only if*

$$
\begin{cases}
\tilde{A} = \begin{bmatrix} V & UW \end{bmatrix} \begin{bmatrix} A & 0 & \tilde{A}_{13} \\ \tilde{A}_{21} & \tilde{A}_{22} & \tilde{A}_{23} \\ 0 & 0 & \tilde{A}_{33} \end{bmatrix} \begin{bmatrix} V^+ \\ (UW)^T \end{bmatrix}, \\
\tilde{B} = \begin{bmatrix} V & UW \end{bmatrix} \begin{bmatrix} B & \tilde{B}_{12} \\ \tilde{B}_{21} & \tilde{B}_{22} \\ 0 & \tilde{B}_{32} \end{bmatrix} \begin{bmatrix} L^+ \\ P^T \end{bmatrix}, \\
\tilde{C} = \begin{bmatrix} T & S \end{bmatrix} \begin{bmatrix} C & 0 & \tilde{C}_{13} \\ \tilde{C}_{21} & \tilde{C}_{22} & \tilde{C}_{23} \end{bmatrix} \begin{bmatrix} V^+ \\ (UW)^T \end{bmatrix},
\end{cases} \tag{3.3}
$$

where $W \in \mathbf{R}^{(\tilde{n}-n)\times(\tilde{n}-n)}$ *is an arbitrary orthogonal matrix,* μ *is an arbitrary integer between* 0 *and* $\tilde{n}-n$*, and* $\tilde{A}_{13} \in \mathbf{R}^{n\times(\tilde{n}-n-\mu)}$*,* $\tilde{A}_{21} \in \mathbf{R}^{\mu\times n}$*,* $\tilde{A}_{22} \in \mathbf{R}^{\mu\times\mu}$*,* $\tilde{A}_{23} \in \mathbf{R}^{\mu\times(\tilde{n}-n-\mu)}$*,* $\tilde{A}_{33} \in \mathbf{R}^{(\tilde{n}-n-\mu)\times(\tilde{n}-n-\mu)}$*,* $\tilde{B}_{12} \in \mathbf{R}^{n\times(\tilde{m}-m)}$*,* $\tilde{B}_{21} \in \mathbf{R}^{\mu\times m}$*,* $\tilde{B}_{22} \in \mathbf{R}^{\mu\times(\tilde{m}-m)}$*,* $\tilde{B}_{32} \in \mathbf{R}^{(\tilde{n}-n-\mu)\times(\tilde{m}-m)}$*,* $\tilde{C}_{13} \in \mathbf{R}^{l\times(\tilde{n}-n-\mu)}$*,* $\tilde{C}_{21} \in \mathbf{R}^{(\tilde{l}-l)\times n}$*,* $\tilde{C}_{22} \in \mathbf{R}^{(\tilde{l}-l)\times\mu}$*, and* $\tilde{C}_{23} \in \mathbf{R}^{(\tilde{l}-l)\times(\tilde{n}-n-\mu)}$ *are constant matrices with arbitrary elements.*

Proof. It is easy to see that

$$
V^+ = \begin{bmatrix} V_{11}^{-1} & 0 \end{bmatrix} \begin{bmatrix} \mathcal{U} & U \end{bmatrix}^T, \quad L^+ = \begin{bmatrix} L_{11}^{-1} & 0 \end{bmatrix} \begin{bmatrix} \mathcal{P} & P \end{bmatrix}^T, \quad T^+ = \begin{bmatrix} T_{11}^{-1} & 0 \end{bmatrix} \begin{bmatrix} \mathcal{S} & S \end{bmatrix}^T.
$$

In the following we prove the necessity first and then sufficiency.

Necessity. For any $\tilde{A} \in \mathbf{R}^{\tilde{n}\times\tilde{n}}$, $\tilde{B} \in \mathbf{R}^{\tilde{n}\times\tilde{m}}$ and $\tilde{C} \in \mathbf{R}^{\tilde{l}\times\tilde{n}}$, define

$$
\begin{cases}
\begin{bmatrix} \mathcal{U} & U \end{bmatrix}^T \tilde{A} \begin{bmatrix} \mathcal{U} & U \end{bmatrix} = \begin{matrix} \quad n & \tilde{n}-n \\ \end{matrix} \\ \quad \begin{bmatrix} \hat{A}_{11} & \hat{A}_{12} \\ \hat{A}_{21} & \hat{A}_{22} \end{bmatrix} \begin{matrix} \}n \\ \}\tilde{n}-n \end{matrix}, \\
\begin{bmatrix} \mathcal{U} & U \end{bmatrix}^T \tilde{B} \begin{bmatrix} \mathcal{P} & P \end{bmatrix} = \begin{matrix} \quad m & \tilde{m}-m \\ \end{matrix} \\ \quad \begin{bmatrix} \hat{B}_{11} & \hat{B}_{12} \\ \hat{B}_{21} & \hat{B}_{22} \end{bmatrix} \begin{matrix} \}n \\ \}\tilde{n}-n \end{matrix}, \\
\begin{bmatrix} \mathcal{S} & S \end{bmatrix}^T \tilde{C} \begin{bmatrix} \mathcal{U} & U \end{bmatrix} = \begin{matrix} \quad n & \tilde{n}-n \\ \end{matrix} \\ \quad \begin{bmatrix} \hat{C}_{11} & \hat{C}_{12} \\ \hat{C}_{21} & \hat{C}_{22} \end{bmatrix} \begin{matrix} \}l \\ \}\tilde{l}-l \end{matrix}.
\end{cases} \tag{3.4}
$$

Let the system $\tilde{\mathbf{S}}$ be an expansion of the system $\mathbf{S}$. By Theorem 2.3 and Lemma 3.2, we have that

$$\max_{s\in\mathbf{C}} \operatorname{rank} \begin{bmatrix} sI-\tilde{A}+VAV^{+} & (\tilde{A}-VAV^{+})V & \tilde{B}L-VB \\ V^{+} & 0 & 0 \end{bmatrix} = \tilde{n},$$

$$\max_{s\in\mathbf{C}} \operatorname{rank} \begin{bmatrix} sI-\tilde{A}+VAV^{+} & V & \tilde{B}L-VB \\ T^{+}\tilde{C}-CV^{+} & 0 & 0 \end{bmatrix} = \tilde{n},$$

which gives

$$\max_{s\in\mathbf{C}} \operatorname{rank} \begin{bmatrix} sI-\tilde{A} & \tilde{A}V-VA & \tilde{B}L-VB \\ V^{+} & 0 & 0 \end{bmatrix} = \max_{s\in\mathbf{C}} \operatorname{rank} \begin{bmatrix} sI-\tilde{A} & V & \tilde{B}L \\ T^{+}\tilde{C}-CV^{+} & 0 & 0 \end{bmatrix} = \tilde{n}.$$

Hence, by using (3.4) we get

$$\max_{s\in\mathbf{C}} \operatorname{rank} \begin{bmatrix} sI-\hat{A}_{11} & -\hat{A}_{12} & \hat{A}_{11}V_{11}-V_{11}A & \hat{B}_{11}L_{11}-V_{11}B \\ -\hat{A}_{21} & sI-\hat{A}_{22} & \hat{A}_{21}V_{11} & \hat{B}_{21}L_{11} \\ V_{11}^{-1} & 0 & 0 & 0 \end{bmatrix}$$

$$= \max_{s\in\mathbf{C}} \operatorname{rank} \begin{bmatrix} sI-\hat{A}_{11} & -\hat{A}_{12} & V_{11} & \hat{B}_{11}L_{11} \\ -\hat{A}_{21} & sI-\hat{A}_{22} & 0 & \hat{B}_{21}L_{11} \\ T_{11}^{-1}\hat{C}_{11}-CV_{11}^{-1} & T_{11}^{-1}\hat{C}_{12} & 0 & 0 \end{bmatrix} = \tilde{n},$$

that is,

$$\max_{s\in\mathbf{C}} \operatorname{rank} \begin{bmatrix} sI-\hat{A}_{22} & \hat{A}_{21}V_{11} & \hat{B}_{21}L_{11} \\ -\hat{A}_{12} & \hat{A}_{11}V_{11}-V_{11}A & \hat{B}_{11}L_{11}-V_{11}B \end{bmatrix}$$

$$= \max_{s\in\mathbf{C}} \operatorname{rank} \begin{bmatrix} sI-\hat{A}_{22} & -\hat{A}_{21} & \hat{B}_{21}L_{11} \\ T_{11}^{-1}\hat{C}_{12} & T_{11}^{-1}\hat{C}_{11}-CV_{11}^{-1} & 0 \end{bmatrix} = \tilde{n}-n,$$

which, by means of Lemma 3.1, is equivalent to

$$\begin{bmatrix} \hat{A}_{11}V_{11}-V_{11}A & \hat{B}_{11}L_{11}-V_{11}B \end{bmatrix} = 0, \quad T_{11}^{-1}\hat{C}_{11}-CV_{11}^{-1} = 0$$

and

$$\max_{s\in\mathbf{C}} \operatorname{rank} \begin{bmatrix} sI-\hat{A}_{22} & \hat{A}_{21} & \hat{B}_{21} \\ \hat{A}_{12} & 0 & 0 \end{bmatrix} = \max_{s\in\mathbf{C}} \operatorname{rank} \begin{bmatrix} sI-\hat{A}_{22} & \hat{A}_{21} & \hat{B}_{21} \\ \hat{C}_{12} & 0 & 0 \end{bmatrix} = \tilde{n}-n$$

or, equivalently,

$$\hat{A}_{11} = V_{11}AV_{11}^{-1}, \quad \hat{B}_{11} = V_{11}BR_{11}^{-1}, \quad \hat{C}_{11} = T_{11}CV_{11}^{-1}, \tag{3.5}$$

and

$$\max_{s\in\mathbf{C}} \operatorname{rank} \begin{bmatrix} sI-\hat{A}_{22} & \hat{A}_{21} & \hat{B}_{21} \\ \hat{A}_{12} & 0 & 0 \\ \hat{C}_{12} & 0 & 0 \end{bmatrix} = \tilde{n}-n. \tag{3.6}$$

Now we only need to characterize $\hat{A}_{22}$, $\hat{A}_{21}$, $\hat{A}_{12}$, $\hat{B}_{21}$, and $\hat{C}_{12}$ in (3.6). It is well known [33] that there is an orthogonal matrix $W \in \mathbf{R}^{(\tilde{n}-n)\times(\tilde{n}-n)}$ and an integer μ between 0 and $\tilde{n}-n$ such that

$$\text{(3.7)}\qquad \begin{cases} \begin{matrix} & \mu & \tilde{n}-n-\mu & \\ W^T\hat{A}_{22}W = & \left[\begin{matrix} \tilde{A}_{22} & \tilde{A}_{23} \\ 0 & \tilde{A}_{33} \end{matrix}\right] & \begin{matrix} \}\mu \\ \}\tilde{n}-n-\mu \end{matrix} \end{matrix}, \\ \begin{matrix} & n & m & \\ W^T\left[\hat{A}_{21}V_{11} \mid \hat{B}_{21}L_{11}\right] = & \left[\begin{matrix} \tilde{A}_{21} & \tilde{B}_{21} \\ 0 & 0 \end{matrix}\right] & \begin{matrix} \}\mu \\ \}\tilde{n}-n-\mu \end{matrix} \end{matrix}, \\ (\tilde{A}_{22}, \left[\tilde{A}_{21} \quad \tilde{B}_{21}\right]) \text{ is controllable.} \end{cases}$$

Set

$$\left[\frac{\hat{A}_{12}}{\hat{C}_{12}}\right] W = \begin{matrix} & \mu & \tilde{n}-n-\mu & \\ & \left[\begin{matrix} \tilde{A}_{12} & V_{11}\tilde{A}_{13} \\ \tilde{C}_{12} & T_{11}\tilde{C}_{13} \end{matrix}\right] & \begin{matrix} \}n \\ \}l \end{matrix} \end{matrix}.$$

Then, (3.6) and Lemma 3.1 imply

$$\tilde{A}_{12} = 0, \quad \tilde{C}_{12} = 0,$$

that is,

$$\text{(3.8)}\qquad \left[\frac{\hat{A}_{12}}{\hat{C}_{12}}\right] W = \left[\frac{0 \quad V_{11}\tilde{A}_{13}}{0 \quad T_{11}\tilde{C}_{13}}\right].$$

Hence, (3.3) follows directly from a simple calculation using (3.4), (3.5), (3.7), and (3.8).

Sufficiency. Let (3.3) hold for an arbitrary orthogonal matrix $W \in \mathbf{R}^{(\tilde{n}-n)\times(\tilde{n}-n)}$, an arbitrary integer μ between 0 and $\tilde{n}-n$, and arbitrary matrices $\tilde{A}_{13} \in \mathbf{R}^{n\times(\tilde{n}-n-\mu)}$, $\tilde{A}_{21} \in \mathbf{R}^{\mu\times n}$, $\tilde{A}_{22} \in \mathbf{R}^{\mu\times\mu}$, $\tilde{A}_{23} \in \mathbf{R}^{\mu\times(\tilde{n}-n-\mu)}$, $\tilde{A}_{33} \in \mathbf{R}^{(\tilde{n}-n-\mu)\times(\tilde{n}-n-\mu)}$, $\tilde{B}_{12} \in \mathbf{R}^{n\times(\tilde{m}-m)}$, $\tilde{B}_{21} \in \mathbf{R}^{\mu\times m}$, $\tilde{B}_{22} \in \mathbf{R}^{\mu\times(\tilde{m}-m)}$, $\tilde{B}_{32} \in \mathbf{R}^{(\tilde{n}-n-\mu)\times(\tilde{m}-m)}$, $\tilde{C}_{13} \in \mathbf{R}^{l\times(\tilde{n}-n-\mu)}$, $\tilde{C}_{21} \in \mathbf{R}^{(\tilde{l}-l)\times n}$, $\tilde{C}_{22} \in \mathbf{R}^{(\tilde{l}-l)\times\mu}$, and $\tilde{C}_{23} \in \mathbf{R}^{(\tilde{l}-l)\times(\tilde{n}-n-\mu)}$. A direct calculation yields that

$$\begin{aligned} &\max_{s\in\mathbf{C}} \operatorname{rank} \begin{bmatrix} sI-\tilde{A} & \tilde{A}V-VA & \tilde{B}L-VB \\ V^+ & 0 & 0 \end{bmatrix} \\ &\quad = \max_{s\in\mathbf{C}} \operatorname{rank} \begin{bmatrix} sI-A & 0 & -\tilde{A}_{13} & 0 & 0 \\ -\tilde{A}_{21} & sI-\tilde{A}_{22} & -\tilde{A}_{23} & \tilde{A}_{21} & \tilde{B}_{21} \\ 0 & 0 & sI-\tilde{A}_{33} & 0 & 0 \\ I & 0 & 0 & 0 & 0 \end{bmatrix} \\ &\quad = n+\mu+(\tilde{n}-n-\mu) = \tilde{n} \end{aligned}$$

and

$$\begin{aligned} &\max_{s\in\mathbf{C}} \operatorname{rank} \begin{bmatrix} sI-\tilde{A} & V & \tilde{B}L \\ T^+\tilde{C}-CV^+ & 0 & 0 \end{bmatrix} \\ &\quad = \max_{s\in\mathbf{C}} \operatorname{rank} \begin{bmatrix} sI-A & 0 & -\tilde{A}_{13} & I & 0 \\ -\tilde{A}_{21} & sI-\tilde{A}_{22} & -\tilde{A}_{23} & 0 & \tilde{B}_{21} \\ 0 & 0 & sI-\tilde{A}_{33} & 0 & 0 \\ 0 & 0 & \tilde{C}_{13} & 0 & 0 \end{bmatrix} \\ &\quad = n+\mu+(\tilde{n}-n-\mu) = \tilde{n}. \end{aligned}$$

Consequently, we obtain that

$$\max_{s\in\mathbf{C}} \operatorname{rank}\begin{bmatrix} sI-\tilde{A}+VAV^{+} & (\tilde{A}-VAV^{+})V & \tilde{B}L-VB \\ V^{+} & 0 & 0 \end{bmatrix}$$
$$= \max_{s\in\mathbf{C}} \operatorname{rank}\begin{bmatrix} sI-\tilde{A}+VAV^{+} & V & \tilde{B}L-VB \\ T^{+}\tilde{C}-CV^{+} & 0 & 0 \end{bmatrix} = \tilde{n}.$$

Therefore, by Theorem 2.3 and Lemma 3.2 the system $\tilde{\mathbf{S}}$ is an expansion of the system $\mathbf{S}$. □

Since the expansion process underlying the above canonical form (3.3) involves the inputs and outputs, it includes the canonical form obtained in [1] (see also [2]).

Remark 1. Let

$$M=\tilde{A}-VAV^{+},\quad N=\tilde{B}-VBL^{+},\quad G=\tilde{C}-TCV^{+}.$$

Matrices M, N, G defined above are complementary matrices [1, 15]. Obviously, using the same notation as in Theorem 3.3, we conclude that system $\tilde{\mathbf{S}}$ is an expansion of $\mathbf{S}$ if and only if

$$\begin{cases} M=\begin{bmatrix} V & UW \end{bmatrix}\begin{bmatrix} 0 & 0 & \tilde{A}_{13} \\ \tilde{A}_{21} & \tilde{A}_{22} & \tilde{A}_{23} \\ 0 & 0 & \tilde{A}_{33} \end{bmatrix}\begin{bmatrix} V^{+} \\ (UW)^{T} \end{bmatrix}, \\ N=\begin{bmatrix} V & UW \end{bmatrix}\begin{bmatrix} 0 & \tilde{B}_{12} \\ \tilde{B}_{21} & \tilde{B}_{22} \\ 0 & \tilde{B}_{32} \end{bmatrix}\begin{bmatrix} L^{+} \\ P^{T} \end{bmatrix}, \\ G=\begin{bmatrix} T & S \end{bmatrix}\begin{bmatrix} 0 & 0 & \tilde{C}_{13} \\ \tilde{C}_{21} & \tilde{C}_{22} & \tilde{C}_{23} \end{bmatrix}\begin{bmatrix} V^{+} \\ (UW)^{T} \end{bmatrix}, \end{cases}$$

that is, Theorem 3.3 established a canonical form for complementary matrices as well.

Remark 2. In the case that matrices V, L, and T are defined as

$$V=\begin{bmatrix} I_{n_1} & 0 & 0 \\ 0 & I_{n_2} & 0 \\ 0 & I_{n_2} & 0 \\ 0 & 0 & I_{n_3} \end{bmatrix},\quad L=\begin{bmatrix} I_{m_1} & 0 & 0 \\ 0 & I_{m_2} & 0 \\ 0 & I_{m_2} & 0 \\ 0 & 0 & I_{m_3} \end{bmatrix},\quad T=\begin{bmatrix} I_{l_1} & 0 & 0 \\ 0 & I_{l_2} & 0 \\ 0 & I_{l_2} & 0 \\ 0 & 0 & I_{l_3} \end{bmatrix} \tag{3.9}$$

with

$$n_1+n_2+n_3=n,\quad m_1+m_2+m_3=m,\quad l_1+l_2+l_3=l,$$

$$n_1+2n_2+n_3=\tilde{n},\quad m_1+2m_2+m_3=\tilde{m},\quad l_1+2l_2+l_3=\tilde{l},$$

two classes of complementary matrices have been identified in [14, 15] such that system $\tilde{\mathbf{S}}$ includes system $\mathbf{S}$; see (3.30) and (3.31) in [15]. These classes can be obtained by choosing $\tilde{A}$, $\tilde{B}$, $\tilde{C}$ in (3.3) as follows:

$$\begin{cases} \tilde{A}=\begin{bmatrix} V & U \end{bmatrix}\begin{bmatrix} A & 0 \\ X_{21} & X_{22} \end{bmatrix}\begin{bmatrix} V^{+} \\ U^{T} \end{bmatrix}, \\ \tilde{B}=\begin{bmatrix} V & U \end{bmatrix}\begin{bmatrix} B & Y_{12} \\ Y_{21} & Y_{22} \end{bmatrix}\begin{bmatrix} L^{+} \\ P^{T} \end{bmatrix}, \\ \tilde{C}=\begin{bmatrix} T & S \end{bmatrix}\begin{bmatrix} C & 0 \\ Z_{21} & Z_{22} \end{bmatrix}\begin{bmatrix} V^{+} \\ U^{T} \end{bmatrix}, \end{cases} \quad \text{or} \quad \begin{cases} \tilde{A}=\begin{bmatrix} V & U \end{bmatrix}\begin{bmatrix} A & X_{12} \\ 0 & X_{22} \end{bmatrix}\begin{bmatrix} V^{+} \\ U^{T} \end{bmatrix}, \\ \tilde{B}=\begin{bmatrix} V & U \end{bmatrix}\begin{bmatrix} B & Y_{12} \\ 0 & Y_{22} \end{bmatrix}\begin{bmatrix} L^{+} \\ P^{T} \end{bmatrix}, \\ \tilde{C}=\begin{bmatrix} T & S \end{bmatrix}\begin{bmatrix} C & Z_{12} \\ Z_{21} & Z_{22} \end{bmatrix}\begin{bmatrix} V^{+} \\ U^{T} \end{bmatrix}. \end{cases}$$

Remark 3. The two special cases of aggregation and restriction, which have been used extensively in the existing literature, can now by easily characterized by the canonical form of Theorem 3.3.

- System $\mathbf{S}$ is an aggregation of system $\tilde{\mathbf{S}}$ if and only if

$$\begin{cases} \tilde{A} = \begin{bmatrix} V & U \end{bmatrix} \begin{bmatrix} A & X_{12} \\ 0 & X_{22} \end{bmatrix} \begin{bmatrix} V^+ \\ U^T \end{bmatrix}, \\ \tilde{B} = \begin{bmatrix} V & U \end{bmatrix} \begin{bmatrix} B & Y_{12} \\ 0 & Y_{22} \end{bmatrix} \begin{bmatrix} L^+ \\ P^T \end{bmatrix}, \\ \tilde{C} = \begin{bmatrix} T & S \end{bmatrix} \begin{bmatrix} C & Z_{12} \\ 0 & Z_{22} \end{bmatrix} \begin{bmatrix} V^+ \\ U^T \end{bmatrix}. \end{cases}$$

- System $\mathbf{S}$ is a restriction of system $\tilde{\mathbf{S}}$ if and only if

$$\begin{cases} \tilde{A} = \begin{bmatrix} V & U \end{bmatrix} \begin{bmatrix} A & 0 \\ X_{21} & X_{22} \end{bmatrix} \begin{bmatrix} V^+ \\ U^T \end{bmatrix}, \\ \tilde{B} = \begin{bmatrix} V & U \end{bmatrix} \begin{bmatrix} B & 0 \\ Y_{21} & Y_{22} \end{bmatrix} \begin{bmatrix} L^+ \\ P^T \end{bmatrix}, \\ \tilde{C} = \begin{bmatrix} T & S \end{bmatrix} \begin{bmatrix} C & 0 \\ Z_{21} & Z_{22} \end{bmatrix} \begin{bmatrix} V^+ \\ U^T \end{bmatrix}. \end{cases}$$

When the underlying space of an expansion is used to design control with information structure constraints, then problems arise with control laws when they have to be contracted for implementation in the original space. The explicit contractibility conditions are provided by the following control law canonical form.

THEOREM 3.4. *Given systems* $\mathbf{S}$ *and* $\tilde{\mathbf{S}}$*, and transformations* V*,* L*,* T *satisfying* (2.3) *and* (2.4)*, the control law*

$$\tilde{u} = -\tilde{K}\tilde{x}$$

for system $\tilde{\mathbf{S}}$ *is contractible to the control law*

$$u = -Kx$$

for system $\mathbf{S}$ *if and only if one of the following two statements holds:*

(a) *Matrices* $\tilde{A}$ *and* $\tilde{B}$ *of system* $\tilde{\mathbf{S}}$ *are given by* (3.3) *and*

$$\tilde{K} = \begin{bmatrix} L & P \end{bmatrix} \begin{bmatrix} K & 0 & \tilde{K}_{13} \\ 0 & 0 & \tilde{K}_{23} \end{bmatrix} \begin{bmatrix} V^+ \\ (UW)^T \end{bmatrix}, \tag{3.10}$$

where W *is orthogonal and is the same as that in* (3.3)*, and matrices* $\tilde{K}_{13} \in \mathbf{R}^{m\times(\tilde{n}-n-\mu)}$ *and* $\tilde{K}_{23} \in \mathbf{R}^{(\tilde{m}-m)\times(\tilde{n}-n-\mu)}$ *have arbitrary elements.*

(b) *Matrices* $\tilde{A}$ *and* $\tilde{B}$ *of system* $\tilde{\mathbf{S}}$ *are given by* (3.3) *with*

$$\tilde{B}_{12} = 0, \quad \tilde{B}_{32} = 0$$

and

$$\tilde{K} = \begin{bmatrix} L & P \end{bmatrix} \begin{bmatrix} K & 0 & \tilde{K}_{13} \\ \tilde{K}_{21} & \tilde{K}_{22} & \tilde{K}_{23} \end{bmatrix} \begin{bmatrix} V^+ \\ (UW)^T \end{bmatrix}, \tag{3.11}$$

where W is orthogonal and is the same as that in (3.3)*, and matrices* $\tilde{K}_{13} \in \mathbf{R}^{m\times(\tilde{n}-n-\mu)}$ *and* $\begin{bmatrix}\tilde{K}_{21} & \tilde{K}_{22} & \tilde{K}_{23}\end{bmatrix} \in \mathbf{R}^{(\tilde{m}-m)\times\tilde{n}}$ *have arbitrary elements.*

Proof. The proof is similar to that of Theorem 3.3 and hence is omitted. □

A corollary to Theorems 3.3 and 3.4, which delineates an important class of contractible control laws [17], is now automatic.

COROLLARY 3.5. *Given a system* $\mathbf{S}$ *and transformations* V, L, T *satisfying* (2.3) *and* (2.4)*, if matrices* $\tilde{A}$ *and* $\tilde{B}$ *are given by* (3.3) *with* $\mu = 0$*, then any control law* $\tilde{u} = -\tilde{K}\tilde{x}$ *for system* $\tilde{\mathbf{S}}$ *is contractible to the control law* $u = -Kx$ *with* $K = L^{+}\tilde{K}V$ *for system* $\mathbf{S}$*.*

Remark 4. The definition in [15, 16] for the contractibility is different from that given in [4, 17, 19]. In [15, 16] it is defined that the control law $\tilde{u} = -\tilde{K}\tilde{x}$ for the expanded system $\tilde{\mathbf{S}}$ is contractible to the control law $u = -Kx$ for system $\mathbf{S}$ if the choice $\tilde{x}_0 = Vx_0$ and $\tilde{u} = Lu$ implies

$$Kx(t; x_0, u) = L^{+}\tilde{K}\tilde{x}(t; \tilde{x}_0, \tilde{u})$$

for any $t \geq 0$, any initial state x_0, and any fixed input u of system $\mathbf{S}$. If such a definition is used, then we can show that the control law $\tilde{u} = -\tilde{K}\tilde{x}$ for the expanded system $\tilde{\mathbf{S}}$ is contractible to the control law $u = -Kx$ for system $\mathbf{S}$ if and only if matrices $\tilde{A}$ and $\tilde{B}$ of system $\tilde{\mathbf{S}}$ are given by (3.3) and $\tilde{K}$ is given by (3.11).

It was observed in [15] that our ability to use generalized (system) decompositions depends crucially not only on the choice of the transformation matrices V, R, and T, but also on the selection of the expansion-contraction matrices $\tilde{A}$, $\tilde{B}$, $\tilde{C}$, and $\tilde{K}$ of expanded system $\tilde{\mathbf{S}}$. All previous results enable such selection only partially because of the usage of the forms of matrices $\tilde{A}$, $\tilde{B}$, $\tilde{C}$, and $\tilde{K}$ in system $\tilde{\mathbf{S}}$ corresponding only with some particular cases. Theorems 3.3 and 3.4 have established a canonical form for the inclusion principle of dynamic system $\mathbf{S}$, which explicitly parameterizes all admissible expansion-contraction matrices $\tilde{A}$, $\tilde{B}$, $\tilde{C}$, and $\tilde{K}$ in system $\tilde{\mathbf{S}}$ and thus provides full freedom under the inclusion principle. Therefore, the significance of Theorems 3.3 and 3.4 is obvious. We hasten to add, however, that in choosing suitable expansions in applications of the inclusion principle, the role of complementary matrices [16] is indispensable.

An important issue in the expansion-contraction process has been the conditions under which structural properties of expansions and contractions, such as controllability, observability, and stabilizability, remain invariant in the process. This issue has been raised in [22, 23, 24] regarding controllability and observability, and general conditions for their invariance have been formulated in [25]. To provide a comprehensive relationship between expansions and contractions using the present canonical forms, let us state the following definitions [34].

DEFINITION 3.6. *Given a system* $\mathbf{S}$*. The sets of the uncontrollable modes, the unobservable modes, and the invariant zeros of system* $\mathbf{S}$ *are defined, respectively, by*

$$\Sigma_c(A, B) := \{\lambda \in \mathbf{C} : \ \operatorname{rank}[\lambda I - A \quad B] < n\},$$

$$\Sigma_o(C, A) := \left\{\lambda \in \mathbf{C} : \ \operatorname{rank}\begin{bmatrix}\lambda I - A \\ C\end{bmatrix} < n\right\},$$

and

$$\Sigma_z(C, A, B) := \left\{\lambda \in \mathbf{C} : \ \operatorname{rank}\begin{bmatrix}\lambda I - A & B \\ C & 0\end{bmatrix} < \max_{s\in\mathbf{C}} \operatorname{rank}\begin{bmatrix}sI - A & B \\ C & 0\end{bmatrix}\right\}.$$

DEFINITION 3.7. *Given $A \in \mathbf{R}^{n\times n}, B \in \mathbf{R}^{n\times m}$, let X be a nonsingular matrix such that $(X^{-1}AX, X^{-1}B)$ is in its controllability canonical form, i.e.,*

$$\begin{cases} & \begin{matrix} \mu & n-\mu \end{matrix} \\ X^{-1}AX = \begin{bmatrix} A_{11} & A_{12} \\ 0 & A_{22} \end{bmatrix} & \begin{matrix} \}\mu \\ \}n-\mu \end{matrix}, \quad X^{-1}B = \begin{bmatrix} B_1 \\ 0 \end{bmatrix} \begin{matrix} \}\mu \\ \}n-\mu \end{matrix}, \\ (A_{11}, B_1) \text{ is controllable.} \end{cases}$$

Then the controllability subspace $\mathcal{C}(A,B)$ of (A,B) is defined as

$$\mathcal{C}(A,B) = \text{Range}\left(X\begin{bmatrix} I_\mu \\ 0 \end{bmatrix}\right).$$

The desired result relating stability, controllability, observability, detectability, and stability of the invariant zeros is provided by the following.

THEOREM 3.8. *Given a system $\mathbf{S}$ and transformations V, L, and T satisfying (2.3) and (2.4), assume $n < \tilde{n}$, $m < \tilde{m}$, and $l < \tilde{l}$. Let $\bar{\mathbf{C}}^+$ denote the closed right half complex plane. Then, there exist matrices $\tilde{A}$, $\tilde{B}$, and $\tilde{C}$ such that the following properties hold simultaneously:*

(3.12) *System $\tilde{\mathbf{S}}$ is an expansion of system $\mathbf{S}$,*

(3.13) $\sigma(A) \subset \sigma(\tilde{A}), \quad \sigma(\tilde{A}) \cap \bar{\mathbf{C}}^+ = \sigma(A) \cap \bar{\mathbf{C}}^+,$

(3.14) $\Sigma_c(\tilde{A}, \tilde{B}) = \Sigma_c(A,B),$

(3.15) $\Sigma_o(\tilde{C}, \tilde{A}) = \Sigma_0(C,A),$

(3.16) $\Sigma_z(C,A,B) \subset \Sigma_z(\tilde{C}, \tilde{A}, \tilde{B}), \quad \Sigma_z(\tilde{C}, \tilde{A}, \tilde{B}) \cap \bar{\mathbf{C}}^+ = \Sigma_z(C,A,B) \cap \bar{\mathbf{C}}^+.$

Hence, stability, controllability, stabilizability, observability, detectability, and the stability of the invariant zeros can be transmitted simultaneously from system $\mathbf{S}$ to system $\tilde{\mathbf{S}}$ under the inclusion principle.

Proof. Let U, P, and Q be the same as those in Theorem 3.3. Take $\mu = 0$ in (3.3) and define

$$\begin{cases} \tilde{A} = \begin{bmatrix} V & U \end{bmatrix} \begin{bmatrix} A & 0 \\ 0 & \mathcal{A} \end{bmatrix} \begin{bmatrix} V^+ \\ U^T \end{bmatrix}, \\ \tilde{B} = \begin{bmatrix} V & U \end{bmatrix} \begin{bmatrix} B & 0 \\ 0 & \mathcal{B} \end{bmatrix} \begin{bmatrix} L^+ \\ P^T \end{bmatrix}, \\ \tilde{C} = \begin{bmatrix} T & S \end{bmatrix} \begin{bmatrix} C & 0 \\ 0 & \mathcal{C} \end{bmatrix} \begin{bmatrix} V^+ \\ U^T \end{bmatrix}, \end{cases}$$

where

$$\mathcal{A} = \begin{bmatrix} \lambda_1 & & & \\ & \lambda_2 & & \\ & & \ddots & \\ & & & \lambda_{\tilde{n}-n} \end{bmatrix}, \quad \mathcal{B} = \begin{bmatrix} b_1 & 0 \\ b_2 & 0 \\ \vdots & 0 \\ b_{\tilde{n}-n} & 0 \end{bmatrix}, \quad \mathcal{C} = \begin{bmatrix} c_1 & c_2 & \cdots & c_{\tilde{n}-n} \\ 0 & 0 & \cdots & 0 \end{bmatrix}$$

and

$$\lambda_1 < \lambda_2 < \cdots < \lambda_{\tilde{n}-n} < 0, \quad b_1 c_1 > 0, \quad b_2 c_2 > 0, \ldots, b_{\tilde{n}-n} c_{\tilde{n}-n} > 0.$$

It is easy to see that

$$\sigma(\mathcal{A}) \subset \mathbf{C}/\bar{\mathbf{C}}^{+}, \quad \Sigma_c(\mathcal{A},\mathcal{B}) = \Sigma_o(\mathcal{C},\mathcal{A}) = \emptyset, \quad \Sigma_z(\mathcal{C},\mathcal{A},\mathcal{B}) \subset \mathbf{C}/\bar{\mathbf{C}}^{+}. \tag{3.17}$$

For $\tilde{A}$, $\tilde{B}$, and $\tilde{C}$ above, Theorem 3.3 implies that system $\tilde{\mathbf{S}}$ is an expansion of system $\mathbf{S}$, the property (3.13) is obvious, and properties (3.14), (3.15), and (3.16) follow directly from (3.17) and the following facts:

$$\begin{cases} \sigma(\tilde{A}) = \sigma(A) \cup \sigma(\mathcal{A}), & \Sigma_c(\tilde{A},\tilde{B}) = \Sigma_c(A,B) \cup \Sigma_c(\mathcal{A},\mathcal{B}), \\ \Sigma_o(\tilde{C},\tilde{A}) = \Sigma(C,A) \cup \Sigma(\mathcal{C},\mathcal{A}), & \Sigma_z(\tilde{C},\tilde{A},\tilde{B}) = \Sigma_z(C,A,B) \cup \Sigma_z(\mathcal{C},\mathcal{A},\mathcal{B}). \end{cases} \quad \square$$

Remark 5. The result in [22] states that when using well-known particular forms of aggregations and restrictions, controllability or observability of the original system carries over to the expanded system, but not both. This result has been shown to be false in [24], which is confirmed by Theorem 3.8. However, it is obvious from Theorem 3.3 that the result of [22] is true when $\tilde{m} = m$ and $\tilde{l} = l$.

4. Overlapping decentralized control. A wide variety of applications of the expansion-contraction concept relies on decentralized control with overlapping information structure constraints. When a plant is composed of interconnected subsystems that share common parts, decentralized control laws, which utilize the state variables of the overlapping parts, are superior to disjoint decentralized control laws. This has been the case in the platooning of vehicles on highways and in the air where state variables are shared between adjacent vehicles [4, 9, 10, 35, 36]. Similarly, in electric power systems tie-line information is used to control each individual power area by decentralized control [2, 3, 7]. Another example is a plant which is overlapped by two controllers for reliability enhancement. The controllers either simultaneously stabilize the plant or individually, whenever one of them has failed [2, 37].

Assume that the system $\mathbf{S}$ is composed of two overlapping subsystems and is represented by the matrices

$$\begin{cases} A = \begin{array}{c} \begin{matrix} n_1 & & n_2 & & n_3 \end{matrix} \\ \left[\begin{array}{c|c|c} A_{11} & A_{12} & A_{13} \\ \hline A_{21} & A_{22} & A_{23} \\ \hline A_{31} & A_{32} & A_{33} \end{array}\right] \end{array} \begin{matrix} \}n_1 \\ \\ \}n_2 \\ \\ \}n_3 \end{matrix}, \\ B = \begin{array}{c} \begin{matrix} m_1 & & m_2 & & m_3 \end{matrix} \\ \left[\begin{array}{c|c|c} B_{11} & B_{12} & B_{13} \\ \hline B_{21} & B_{22} & B_{23} \\ \hline B_{31} & B_{32} & B_{33} \end{array}\right] \end{array} \begin{matrix} \}n_1 \\ \\ \}n_2 \\ \\ \}n_3 \end{matrix}, \\ C = \begin{array}{c} \begin{matrix} n_1 & & n_2 & & n_3 \end{matrix} \\ \left[\begin{array}{c|c|c} C_{11} & C_{12} & C_{13} \\ \hline C_{21} & C_{22} & C_{23} \\ \hline C_{31} & C_{32} & C_{33} \end{array}\right] \end{array} \begin{matrix} \}l_1 \\ \\ \}l_2 \\ \\ \}l_3 \end{matrix}, \end{cases} \tag{4.1}$$

where the lines delineate the subsystems. Using standard linear transformations

defined by matrices (3.9), we obtain the expanded matrices as

$$
(4.2)\qquad
\begin{cases}
\tilde{A} = \begin{array}{c} \begin{matrix} n_1 & n_2 & | & n_2 & n_3 \end{matrix} \\ \left[\begin{array}{cc|cc} \tilde{A}_{11} & \tilde{A}_{12} & \tilde{A}_{13} & \tilde{A}_{14} \\ \tilde{A}_{21} & \tilde{A}_{22} & \tilde{A}_{23} & \tilde{A}_{24} \\ \hline \tilde{A}_{31} & \tilde{A}_{32} & \tilde{A}_{33} & \tilde{A}_{34} \\ \tilde{A}_{41} & \tilde{A}_{42} & \tilde{A}_{43} & \tilde{A}_{44} \end{array}\right] \end{array} \begin{matrix} \}n_1 \\ \}n_2 \\ \\ \}n_2 \\ \}n_3 \end{matrix}, \\
\tilde{B} = \begin{array}{c} \begin{matrix} m_1 & m_2 & | & m_2 & m_3 \end{matrix} \\ \left[\begin{array}{cc|cc} \tilde{B}_{11} & \tilde{B}_{12} & \tilde{B}_{13} & \tilde{B}_{14} \\ \tilde{B}_{21} & \tilde{B}_{22} & \tilde{B}_{23} & \tilde{B}_{24} \\ \hline \tilde{B}_{31} & \tilde{B}_{32} & \tilde{B}_{33} & \tilde{B}_{34} \\ \tilde{B}_{41} & \tilde{B}_{42} & \tilde{B}_{43} & \tilde{B}_{44} \end{array}\right] \end{array} \begin{matrix} \}n_1 \\ \}n_2 \\ \} \\ n_2 \\ \}n_3 \end{matrix}, \\
\tilde{C} = \begin{array}{c} \begin{matrix} n_1 & n_2 & | & n_2 & n_3 \end{matrix} \\ \left[\begin{array}{cc|cc} \tilde{C}_{11} & \tilde{C}_{12} & \tilde{C}_{13} & \tilde{C}_{14} \\ \tilde{C}_{21} & \tilde{C}_{22} & \tilde{C}_{23} & \tilde{C}_{24} \\ \hline \tilde{C}_{31} & \tilde{C}_{32} & \tilde{C}_{33} & \tilde{C}_{34} \\ \tilde{C}_{41} & \tilde{C}_{42} & \tilde{C}_{43} & \tilde{C}_{44} \end{array}\right] \end{array} \begin{matrix} \}l_1 \\ \}l_2 \\ \\ \}l_2 \\ \}l_3 \end{matrix},
\end{cases}
$$

where the overlapping subsystems appear as disjoint.

An interesting idea was recently proposed in [15, 16] to use complementary matrices in order to make the interconnection (off-diagonal) block matrices as sparse as possible, thus enhancing decentralized control strategies for stabilization of the overall system. Note that V, L, and T are given by (3.9), so, the matrices V^+, L^+, T^+, U, P, and S in Theorem 3.3 are given by

$$
V^+ = \begin{bmatrix} I_{n_1} & 0 & 0 & 0 \\ 0 & I_{n_2}/2 & I_{n_2}/2 & 0 \\ 0 & 0 & 0 & I_{n_3} \end{bmatrix}, \quad L^+ = \begin{bmatrix} I_{m_1} & 0 & 0 & 0 \\ 0 & I_{m_2}/2 & I_{m_2}/2 & 0 \\ 0 & 0 & 0 & I_{m_3} \end{bmatrix},
$$

$$
T^+ = \begin{bmatrix} I_{l_1} & 0 & 0 & 0 \\ 0 & I_{l_2}/2 & I_{l_2}/2 & 0 \\ 0 & 0 & 0 & I_{l_3} \end{bmatrix}
$$

and

$$
U = \begin{bmatrix} 0_{n_1 \times n_2} \\ I_{n_2}/\sqrt{2} \\ -I_{n_2}/\sqrt{2} \\ 0_{n_3 \times n_2} \end{bmatrix}, \quad P = \begin{bmatrix} 0_{m_1 \times m_2} \\ I_{m_2}/\sqrt{2} \\ -I_{m_2}/\sqrt{2} \\ 0_{m_3 \times m_2} \end{bmatrix}, \quad S = \begin{bmatrix} 0_{l_1 \times l_2} \\ I_{l_2}/\sqrt{2} \\ -I_{l_2}/\sqrt{2} \\ 0_{l_3 \times l_2} \end{bmatrix}.
$$

From Theorem 3.3 we have that all expansion matrices $\tilde{A}$, $\tilde{B}$, and $\tilde{C}$ of system $\mathbf{S}$ are of the forms

(4.3)

$$
\tilde{A} = \begin{bmatrix} I_{n_1} & 0 & 0 & 0 \\ 0 & I_{n_2} & 0 & W/\sqrt{2} \\ 0 & I_{n_2} & 0 & -W/\sqrt{2} \\ 0 & 0 & I_{n_3} & 0 \end{bmatrix} \begin{bmatrix} A_{11} & A_{12} & A_{13} & 0 & X_{15} \\ A_{21} & A_{22} & A_{23} & 0 & X_{25} \\ A_{31} & A_{32} & A_{33} & 0 & X_{35} \\ X_{41} & X_{42} & X_{43} & X_{44} & X_{45} \\ 0 & 0 & 0 & 0 & X_{55} \end{bmatrix} \begin{bmatrix} I_{n_1} & 0 & 0 & 0 \\ 0 & I_{n_2}/2 & I_{n_2}/2 & 0 \\ 0 & 0 & 0 & I_{n_3} \\ 0 & W^T/\sqrt{2} & -W^T/\sqrt{2} & 0 \end{bmatrix},
$$

$$\tilde{B} = \begin{bmatrix} I_{n_1} & 0 & 0 & 0 \\ 0 & I_{n_2} & 0 & W/\sqrt{2} \\ 0 & I_{n_2} & 0 & -W/\sqrt{2} \\ 0 & 0 & I_{n_3} & 0 \end{bmatrix} \begin{bmatrix} B_{11} & B_{12} & B_{13} & Y_{14} \\ B_{21} & B_{22} & B_{23} & Y_{24} \\ B_{31} & B_{32} & B_{33} & Y_{34} \\ Y_{41} & Y_{42} & Y_{43} & Y_{44} \\ 0 & 0 & 0 & Y_{54} \end{bmatrix} \begin{bmatrix} I_{m_1} & 0 & 0 & 0 \\ 0 & I_{m_2}/2 & I_{m_2}/2 & 0 \\ 0 & 0 & 0 & I_{m_3} \\ 0 & I_{m_2}/\sqrt{2} & -I_{m_2}/\sqrt{2} & 0 \end{bmatrix},$$

$$\tilde{C} = \begin{bmatrix} I_{l_1} & 0 & 0 & 0 \\ 0 & I_{l_2} & 0 & I_{l_2}/\sqrt{2} \\ 0 & I_{l_2} & 0 & -I_{l_2}/\sqrt{2} \\ 0 & 0 & I_{l_3} & 0 \end{bmatrix} \begin{bmatrix} C_{11} & C_{12} & C_{13} & 0 & Z_{15} \\ C_{21} & C_{22} & C_{23} & 0 & Z_{25} \\ C_{31} & C_{32} & C_{33} & 0 & Z_{35} \\ Z_{41} & Z_{42} & Z_{43} & Z_{44} & Z_{45} \end{bmatrix} \begin{bmatrix} I_{n_1} & 0 & 0 & 0 \\ 0 & I_{n_2}/2 & I_{n_2}/2 & 0 \\ 0 & 0 & 0 & I_{n_3} \\ 0 & W^T/\sqrt{2} & -W^T/\sqrt{2} & 0 \end{bmatrix},$$

where $W \in \mathbf{R}^{n_2 \times n_2}$ is orthogonal, X_{44}, X_{55}, X_{i5} $(i = 1, \ldots, 4)$, Y_{j4} and Z_{4j} $(j = 1, \ldots, 5)$, X_{4k}, and Y_{4k} and Z_{k5} $(k = 1, 2, 3)$ are arbitrary matrices with appropriate dimensions, and in particular $X_{44} \in \mathbf{R}^{\mu \times \mu}$, $X_{55} \in \mathbf{R}^{(n_2-\mu)\times(n_2-\mu)}$, μ is an integer between 0 and n_2. Thus, by a direct computation using (4.3) we obtain

$$\tilde{A}_{14} = A_{13}, \quad \tilde{A}_{41} = A_{31}, \quad \tilde{B}_{14} = B_{13}, \quad \tilde{B}_{41} = B_{31}, \quad \tilde{C}_{14} = C_{13}, \quad \tilde{C}_{41} = C_{13}.$$

Consequently, system $\tilde{\mathbf{S}}$ is maximally sparsified if and only if

$$\begin{cases} \tilde{A}_{31} = 0,\ \tilde{A}_{32} = 0,\ \tilde{A}_{42} = 0,\ \tilde{A}_{23} = 0,\ \tilde{A}_{24} = 0,\ \tilde{A}_{13} = 0, \\ \tilde{B}_{31} = 0,\ \tilde{B}_{32} = 0,\ \tilde{B}_{42} = 0,\ \tilde{B}_{23} = 0,\ \tilde{B}_{24} = 0,\ \tilde{B}_{13} = 0, \\ \tilde{C}_{31} = 0,\ \tilde{C}_{32} = 0,\ \tilde{C}_{42} = 0,\ \tilde{C}_{23} = 0,\ \tilde{C}_{24} = 0,\ \tilde{C}_{13} = 0. \end{cases} \tag{4.4}$$

Now, the following problem is of interest.

Problem 1. Under what conditions does there exist an expansion $\tilde{\mathbf{S}}$ of system $\mathbf{S}$ having matrices (4.4)?

It has been mentioned in [15] that in some situation Problem 1 is solvable, but no solvability conditions have been stated; Problem 1 cannot be solved simply by setting $\tilde{A} := VAV^+$, $\tilde{B} := VBL^+$, and $\tilde{C} := TCV^+$, because

$$\begin{cases} VAV^+ = \left[\begin{array}{cc|c|cc} A_{11} & A_{12}/2 & & A_{12}/2 & A_{13} \\ A_{21} & A_{22}/2 & & A_{22}/2 & A_{23} \\ \hline\hline A_{21} & A_{22}/2 & & A_{22}/2 & A_{23} \\ A_{31} & A_{32}/2 & & A_{32}/2 & A_{33} \end{array}\right], \\ VBL^+ = \left[\begin{array}{cc|c|cc} B_{11} & B_{12}/2 & & B_{12}/2 & B_{13} \\ B_{21} & B_{22}/2 & & B_{22}/2 & B_{23} \\ \hline\hline B_{21} & B_{22}/2 & & B_{22}/2 & B_{23} \\ B_{31} & B_{32}/2 & & B_{32}/2 & B_{33} \end{array}\right], \\ TCV^+ = \left[\begin{array}{cc|c|cc} C_{11} & C_{12}/2 & & C_{12}/2 & C_{13} \\ C_{21} & C_{22}/2 & & C_{22}/2 & C_{23} \\ \hline\hline C_{21} & C_{22}/2 & & C_{22}/2 & C_{23} \\ C_{31} & C_{32}/2 & & C_{32}/2 & C_{33} \end{array}\right]; \end{cases}$$

in fact, there are no *general* algorithms for producing such systems. We provide these conditions by the following.

THEOREM 4.1. *Let the triplet* (A, B, C) *of system* $\mathbf{S}$ *be as in* (4.1) *and let matrices* V, L, *and* T *be those of* (3.9). *Then, there exists an expansion* $\tilde{\mathbf{S}}$ *of system* $\mathbf{S}$ *such*

that (4.4) *holds if and only if*

$$\mathcal{C}(A_{22}, \begin{bmatrix} A_{21} & -A_{23} & B_{21} & -B_{23} \end{bmatrix}) \subset \ker \left(\begin{bmatrix} A_{12} \\ -A_{32} \\ C_{12} \\ -C_{32} \end{bmatrix} \right). \tag{4.5}$$

Furthermore, in the case that condition (4.5) *is true, triplet* $(\tilde{A}, \tilde{B}, \tilde{C})$ *of the expanded system* $\tilde{\mathbf{S}}$ *is given by*

$$\begin{cases} \tilde{A} = \left[\begin{array}{ccc|cc} A_{11} & A_{12} & | & 0 & A_{13} \\ 2A_{21} & A_{22} & | & 0 & 0 \\ \hline 0 & 0 & | & A_{22} & 2A_{23} \\ A_{31} & 0 & | & A_{32} & A_{33} \end{array}\right], \\ \tilde{B} = \left[\begin{array}{ccc|cc} B_{11} & B_{12} & | & 0 & B_{13} \\ 2B_{21} & B_{22} & | & 0 & 0 \\ \hline 0 & 0 & | & B_{22} & 2B_{23} \\ B_{31} & 0 & | & B_{32} & B_{33} \end{array}\right], \\ \tilde{C} = \left[\begin{array}{ccc|cc} C_{11} & C_{12} & | & 0 & C_{13} \\ 2C_{21} & C_{22} & | & 0 & 0 \\ \hline 0 & 0 & | & C_{22} & 2C_{23} \\ C_{31} & 0 & | & C_{32} & C_{33} \end{array}\right]. \end{cases} \tag{4.6}$$

Proof. Since (4.3) holds, hence $\tilde{A}$, $\tilde{B}$, and $\tilde{C}$ satisfy (4.4) if and only if

$$\begin{cases} \begin{bmatrix} 0 & I_{n_2} & 0 & -W/\sqrt{2} \end{bmatrix} \begin{bmatrix} A_{11} & A_{12} & A_{13} & 0 & X_{15} \\ A_{21} & A_{22} & A_{23} & 0 & X_{25} \\ A_{31} & A_{32} & A_{33} & 0 & X_{35} \\ X_{41} & X_{42} & X_{43} & X_{44} & X_{45} \\ 0 & 0 & 0 & 0 & X_{55} \end{bmatrix} \begin{bmatrix} I_{n_1} & 0 \\ 0 & I_{n_2}/2 \\ 0 & 0 \\ 0 & W^T/\sqrt{2} \end{bmatrix} = 0, \\ \begin{bmatrix} 0 & 0 & I_{n_3} & 0 \end{bmatrix} \begin{bmatrix} A_{11} & A_{12} & A_{13} & 0 & X_{15} \\ A_{21} & A_{22} & A_{23} & 0 & X_{25} \\ A_{31} & A_{32} & A_{33} & 0 & X_{35} \\ X_{41} & X_{42} & X_{43} & X_{44} & X_{45} \\ 0 & 0 & 0 & 0 & X_{55} \end{bmatrix} \begin{bmatrix} 0 \\ I_{n_2}/2 \\ 0 \\ W^T/\sqrt{2} \end{bmatrix} = 0, \\ \begin{bmatrix} 0 & I_{n_2} & 0 & W/\sqrt{2} \end{bmatrix} \begin{bmatrix} A_{11} & A_{12} & A_{13} & 0 & X_{15} \\ A_{21} & A_{22} & A_{23} & 0 & X_{25} \\ A_{31} & A_{32} & A_{33} & 0 & X_{35} \\ X_{41} & X_{42} & X_{43} & X_{44} & X_{45} \\ 0 & 0 & 0 & 0 & X_{55} \end{bmatrix} \begin{bmatrix} 0 & 0 \\ I_{n_2}/2 & 0 \\ 0 & I_{n_3} \\ -W^T/\sqrt{2} & 0 \end{bmatrix} = 0, \\ \begin{bmatrix} I_{n_1} & 0 & 0 & 0 \end{bmatrix} \begin{bmatrix} A_{11} & A_{12} & A_{13} & 0 & X_{15} \\ A_{21} & A_{22} & A_{23} & 0 & X_{25} \\ A_{31} & A_{32} & A_{33} & 0 & X_{35} \\ X_{41} & X_{42} & X_{43} & X_{44} & X_{45} \\ 0 & 0 & 0 & 0 & X_{55} \end{bmatrix} \begin{bmatrix} 0 \\ I_{n_2}/2 \\ 0 \\ -W^T/\sqrt{2} \end{bmatrix} = 0, \end{cases}$$

$$\begin{cases} \begin{bmatrix} 0 & I & 0 & -W/\sqrt{2} \end{bmatrix} \begin{bmatrix} B_{11} & B_{12} & B_{13} & Y_{14} \\ B_{21} & B_{22} & B_{23} & Y_{24} \\ B_{31} & B_{32} & B_{33} & Y_{34} \\ Y_{41} & Y_{42} & Y_{43} & Y_{44} \\ 0 & 0 & 0 & Y_{54} \end{bmatrix} \begin{bmatrix} I & 0 \\ 0 & I/2 \\ 0 & 0 \\ 0 & I/\sqrt{2} \end{bmatrix} = 0, \\ \begin{bmatrix} 0 & 0 & I & 0 \end{bmatrix} \begin{bmatrix} B_{11} & B_{12} & B_{13} & Y_{14} \\ B_{21} & B_{22} & B_{23} & Y_{24} \\ B_{31} & B_{32} & B_{33} & Y_{34} \\ Y_{41} & Y_{42} & Y_{43} & Y_{44} \\ 0 & 0 & 0 & Y_{54} \end{bmatrix} \begin{bmatrix} 0 \\ I/2 \\ 0 \\ I/\sqrt{2} \end{bmatrix} = 0, \\ \begin{bmatrix} 0 & I & 0 & W/\sqrt{2} \end{bmatrix} \begin{bmatrix} B_{11} & B_{12} & B_{13} & Y_{14} \\ B_{21} & B_{22} & B_{23} & Y_{24} \\ B_{31} & B_{32} & B_{33} & Y_{34} \\ Y_{41} & Y_{42} & Y_{43} & Y_{44} \\ 0 & 0 & 0 & Y_{54} \end{bmatrix} \begin{bmatrix} 0 & 0 \\ I/2 & 0 \\ 0 & I \\ -I/\sqrt{2} & 0 \end{bmatrix} = 0, \\ \begin{bmatrix} I & 0 & 0 & 0 \end{bmatrix} \begin{bmatrix} B_{11} & B_{12} & B_{13} & Y_{14} \\ B_{21} & B_{22} & B_{23} & Y_{24} \\ B_{31} & B_{32} & B_{33} & Y_{34} \\ Y_{41} & Y_{42} & Y_{43} & Y_{44} \\ 0 & 0 & 0 & Y_{54} \end{bmatrix} \begin{bmatrix} 0 \\ I/2 \\ 0 \\ -I/\sqrt{2} \end{bmatrix} = 0, \end{cases}$$

and

$$\begin{cases} \begin{bmatrix} 0 & I & 0 & -I/\sqrt{2} \end{bmatrix} \begin{bmatrix} C_{11} & C_{12} & C_{13} & 0 & Z_{15} \\ C_{21} & C_{22} & C_{23} & 0 & Z_{25} \\ C_{31} & C_{32} & C_{33} & 0 & Z_{35} \\ Z_{41} & Z_{42} & Z_{43} & Z_{44} & Z_{45} \end{bmatrix} \begin{bmatrix} I & 0 \\ 0 & I/2 \\ 0 & 0 \\ 0 & W^T/\sqrt{2} \end{bmatrix} = 0, \\ \begin{bmatrix} 0 & 0 & I & 0 \end{bmatrix} \begin{bmatrix} C_{11} & C_{12} & C_{13} & 0 & Z_{15} \\ C_{21} & C_{22} & C_{23} & 0 & Z_{25} \\ C_{31} & C_{32} & C_{33} & 0 & Z_{35} \\ Z_{41} & Z_{42} & Z_{43} & Z_{44} & Z_{45} \end{bmatrix} \begin{bmatrix} 0 \\ I/2 \\ 0 \\ W^T/\sqrt{2} \end{bmatrix} = 0, \\ \begin{bmatrix} 0 & I & 0 & I/\sqrt{2} \end{bmatrix} \begin{bmatrix} C_{11} & C_{12} & C_{13} & 0 & Z_{15} \\ C_{21} & C_{22} & C_{23} & 0 & Z_{25} \\ C_{31} & C_{32} & C_{33} & 0 & Z_{35} \\ Z_{41} & Z_{42} & Z_{43} & Z_{44} & Z_{45} \end{bmatrix} \begin{bmatrix} 0 & 0 \\ I/2 & 0 \\ 0 & I \\ -W^T/\sqrt{2} & 0 \end{bmatrix} = 0, \\ \begin{bmatrix} I & 0 & 0 & 0 \end{bmatrix} \begin{bmatrix} C_{11} & C_{12} & C_{13} & 0 & Z_{15} \\ C_{21} & C_{22} & C_{23} & 0 & Z_{25} \\ C_{31} & C_{32} & C_{33} & 0 & Z_{35} \\ Z_{41} & Z_{42} & Z_{43} & Z_{44} & Z_{45} \end{bmatrix} \begin{bmatrix} 0 \\ I/2 \\ 0 \\ -W^T/\sqrt{2} \end{bmatrix} = 0. \end{cases}$$

Thus, a simple calculation yields that there exists a triplet $(\tilde{A}, \tilde{B}, \tilde{C})$ of the form (4.3) such that (4.4) holds if and only if

$$\text{(4.7)} \qquad \begin{cases} A_{22} = W \begin{bmatrix} X_{44} & X_{45} \\ 0 & X_{55} \end{bmatrix} W^T, \\ \begin{bmatrix} A_{21} & -A_{23} & B_{21} & -B_{23} \end{bmatrix} = W \begin{bmatrix} X_{41} & X_{43} & Y_{41} & Y_{43} \\ 0 & 0 & 0 & 0 \end{bmatrix} / \sqrt{2} \end{cases}$$

and

$$\begin{bmatrix} A_{12} \\ -A_{32} \\ C_{12} \\ -C_{32} \end{bmatrix} = \sqrt{2} \begin{bmatrix} 0 & X_{15} \\ 0 & X_{35} \\ 0 & Z_{15} \\ 0 & Z_{35} \end{bmatrix} W^T, \tag{4.8}$$

which is equivalent to condition (4.5).

Conversely, if condition (4.5) holds, then in (4.3) we can choose an orthogonal matrix W such that

$$(W^T A_{22} W, W^T \sqrt{2} \begin{bmatrix} A_{21} & -A_{23} & B_{21} & -B_{23} \end{bmatrix})$$

is in the controllability staircase form (4.7) [33] of $(A_{22}, \sqrt{2} \begin{bmatrix} A_{21} & -A_{23} & B_{21} & -B_{23} \end{bmatrix})$, let μ be the dimension of its controllability subspace, and define

$$\begin{bmatrix} X_{44} & X_{45} \\ 0 & X_{55} \end{bmatrix}, \quad \begin{bmatrix} X_{41} & X_{43} & Y_{41} & Y_{43} \end{bmatrix}, \quad \text{and} \quad \begin{bmatrix} X_{15} \\ X_{35} \\ Z_{15} \\ Z_{35} \end{bmatrix}$$

by equations (4.7) and (4.8) with $X_{44} \in \mathbf{R}^{\mu \times \mu}$ and $X_{55} \in \mathbf{R}^{(n_2-\mu)\times(n_2-\mu)}$. Now $(X_{44}, [X_{41} \quad X_{43} \quad Y_{41} \quad Y_{43}])$ is controllable. In addition, define

$$\begin{cases} X_{25} = 0, \quad X_{42} = 0, \quad Y_{24} = 0, \quad Y_{42} = 0, \quad Z_{25} = 0, \quad Z_{42} = 0, \\ Y_{14} = B_{12}/\sqrt{2}, \quad Y_{34} = -B_{32}/\sqrt{2}, \quad Z_{41} = \sqrt{2}C_{21}, \quad Z_{43} = -\sqrt{2}C_{23}, \\ \begin{bmatrix} Y_{44} \\ Y_{54} \end{bmatrix} = W^T B_{22}, \quad \begin{bmatrix} Z_{44} & Z_{45} \end{bmatrix} = C_{22} W. \end{cases} \tag{4.9}$$

Then (4.6) follows. □

Condition (4.5) can be verified easily using the well-known controllability staircase form of linear systems (see, e.g., [33]). Theorem 4.1 defines a numerically stable method for solving Problem 1.

5. Contractibility of dynamic controllers. Now, by capitalizing on the canonical form for state feedback laws, we want to present explicit solvability conditions for contractibility of dynamic controllers. They are exhaustive and include the sufficient conditions obtained in [17, 18].

Let us consider a dynamic controller for system **S**:

$$\mathbf{C}: \quad \begin{cases} \dot{w} = Fw + Gu + Jy, \ w(0) = w_0, \\ u = Kw + Hy + v, \end{cases} \tag{5.1}$$

where $w \in \mathbf{R}^\tau$, $u \in \mathbf{R}^m$, and $y \in \mathbf{R}^l$ are the state, input, and output of **C**. An expansion $\tilde{\mathbf{C}}$ of controller **C** is defined as

$$\tilde{\mathbf{C}}: \quad \begin{cases} \dot{\tilde{w}} = \tilde{F}\tilde{w} + \tilde{G}\tilde{u} + \tilde{J}\tilde{y}, \ \tilde{w}(0) = \tilde{w}_0, \\ \tilde{u} = \tilde{K}w + \tilde{H}y + \tilde{v}, \end{cases} \tag{5.2}$$

where $\tilde{w} \in \mathbf{R}^{\tilde{\tau}}$, $\tilde{u} \in \mathbf{R}^{\tilde{m}}$, and $\tilde{y} \in \mathbf{R}^{\tilde{l}}$. We recall the following [18].

DEFINITION 5.1. *The controller* $\tilde{\mathbf{C}}$ *for system* $\tilde{\mathbf{S}}$ *is contractible to the controller* **C** *for system* **S** *if there exist matrices* V, L, T, D, *and* E *satisfying* (2.3) *and* (2.4) *and*

$$\operatorname{rank}(E) = \tau, \quad \operatorname{rank}(D) = m \tag{5.3}$$

such that one of the following two statements holds:

(a) *For any initial states x_0 and w_0 and any input u, the choice*

$$\tilde{x}_0 = Vx_0, \quad \tilde{w}_0 = Ew_0, \quad \tilde{u} = Lu$$

implies that

$$\begin{cases} x(t;x_0,u) = V^+\tilde{x}(t;\tilde{x}_0,\tilde{u}), \quad y[x(t)] = T^+\tilde{y}[\tilde{x}(t)], \\ w(t;w_0,u) = E^+\tilde{w}(t;\tilde{w}_0,\tilde{u}), \quad D(Kw+Hy) = \tilde{K}\tilde{w}+\tilde{H}\tilde{y} \quad \forall t \geq 0. \end{cases}$$

(b) *For any initial states x_0 and w_0 and any input u, the choice*

$$\tilde{x}_0 = Vx_0, \quad \tilde{w}_0 = Ew_0, \quad u = L^+\tilde{u}$$

implies that

$$\begin{cases} x(t;x_0,u) = V^+\tilde{x}(t;\tilde{x}_0,\tilde{u}), \quad y[x(t)] = T^+\tilde{y}[\tilde{x}(t)], \\ w(t;w_0,u) = E^+\tilde{w}(t;\tilde{w}_0,\tilde{u}), \quad Kw+Hy = D^+(\tilde{K}\tilde{w}+\tilde{H}\tilde{y}) \quad \forall t \geq 0. \end{cases}$$

We shall now give an explicit characterization of contractibility of controller $\tilde{\mathbf{C}}$ by the following.

THEOREM 5.2. *Given system $\mathbf{S}$ and transformation matrices V, L, T, D, and E satisfying* (2.3), (2.4), *and* (5.3), *let the QR factorizations of V, L, and T be given by* (3.2). *Furthermore, let the QR factorizations of matrices D and E be given by*

$$(5.4) \quad \begin{cases} \begin{bmatrix} \mathcal{X} & X \end{bmatrix}^T D = \begin{bmatrix} D_{11} \\ 0 \end{bmatrix} \begin{matrix} \}m \\ \}\tilde{m}-m \end{matrix}, \quad \mathcal{X} \in \mathbf{R}^{\tilde{m}\times m}, \quad X \in \mathbf{R}^{\tilde{m}\times(\tilde{m}-m)}, \\ \begin{bmatrix} \mathcal{Y} & Y \end{bmatrix}^T E = \begin{bmatrix} E_{11} \\ 0 \end{bmatrix} \begin{matrix} \}\tau \\ \}\tilde{\tau}-\tau \end{matrix}, \quad \mathcal{Y} \in \mathbf{R}^{\tilde{\tau}\times\tau}, \quad Y \in \mathbf{R}^{\tilde{\tau}\times(\tilde{\tau}-\tau)}, \end{cases}$$

where $\begin{bmatrix} \mathcal{X} & X \end{bmatrix}$ and $\begin{bmatrix} \mathcal{Y} & Y \end{bmatrix}$ are orthogonal, and D_{11} and E_{11} are nonsingular. Then, the controller $\tilde{\mathbf{C}}$ for system $\tilde{\mathbf{S}}$ is contractible to the controller $\mathbf{C}$ for system $\mathbf{S}$ if one of the following four statements holds:

(a) *Matrices $\tilde{A}$, $\tilde{B}$, and $\tilde{C}$ of system $\tilde{\mathbf{S}}$ are given by* (3.3) *and furthermore, $\tilde{F}$, $\tilde{G}$, $\tilde{J}$, $\tilde{K}$, and $\tilde{H}$ are given by*

$$(5.5) \quad \begin{cases} \tilde{F} = \begin{bmatrix} E & YZ \end{bmatrix} \begin{bmatrix} F & 0 & \tilde{F}_{13} \\ \tilde{F}_{21} & \tilde{F}_{22} & \tilde{F}_{23} \\ 0 & 0 & \tilde{F}_{33} \end{bmatrix} \begin{bmatrix} E^+ \\ (YZ)^T \end{bmatrix}, \\ \tilde{G} = \begin{bmatrix} E & YZ \end{bmatrix} \begin{bmatrix} G & \tilde{G}_{12} \\ \tilde{G}_{21} & \tilde{G}_{22} \\ 0 & \tilde{G}_{32} \end{bmatrix} \begin{bmatrix} L^+ \\ P^T \end{bmatrix}, \\ \tilde{J} = \begin{bmatrix} E & YZ \end{bmatrix} \begin{bmatrix} J & 0 \\ \tilde{J}_{21} & \tilde{J}_{22} \\ 0 & 0 \end{bmatrix} \begin{bmatrix} T^+ \\ S^T \end{bmatrix}, \\ \tilde{K} = \begin{bmatrix} D & X \end{bmatrix} \begin{bmatrix} K & 0 & \tilde{K}_{13} \\ 0 & 0 & \tilde{K}_{23} \end{bmatrix} \begin{bmatrix} E^+ \\ (YZ)^T \end{bmatrix}, \\ \tilde{H} = \begin{bmatrix} D & X \end{bmatrix} \begin{bmatrix} H & 0 \\ 0 & 0 \end{bmatrix} \begin{bmatrix} T^+ \\ S^T \end{bmatrix}. \end{cases}$$

(b) *Matrices* $\tilde{A}$, $\tilde{B}$, *and* $\tilde{C}$ *of system* $\tilde{\mathbf{S}}$ *are given by* (3.3) *with* $\tilde{C}_{21} = 0$ *and* $\tilde{C}_{22} = 0$. *Furthermore,* $\tilde{F}$, $\tilde{G}$, $\tilde{J}$, $\tilde{K}$, *and* $\tilde{H}$ *are given by*

Proof. Theorem 5.2 can be proved using Definitions 5.1(a) and (b) directly, hence its proof is omitted. □

Similarly, as in Remarks 2 and 3, if in Theorem 5.2, we take $\nu = 0$ or $\nu = \tilde{\tau} - \tau$, then we can obtain some particular solvability conditions for contractibility of dynamic controllers, which contain the results of [17, 18] as special cases.

6. Conclusions. A canonical form for expanded systems is proposed in the inclusion principle for dynamic systems. The main benefits of the form are as follows:

1. In Theorems 3.3 and 3.4 we have established canonical forms for expansion-contraction matrices $\tilde{A}$, $\tilde{B}$, $\tilde{C}$, and $\tilde{K}$, which provide an explicit parameterization of all expansion-contraction matrices. As a result, the full freedom in selecting the expansion-contraction matrices can be exploited in system analysis and design.
2. Theorem 3.8 provides a simple way to determine if stability, stabilizability, controllability, detectability, observability, and the stability of the invariant zeros carry over from a system $\mathbf{S}$ to its expansion $\tilde{\mathbf{S}}$.
3. In Theorem 4.1, we solved Problem 1, which is central to overlapping decentralized control and which has not been solved in full generality by existing methods.
4. By Theorem 5.2 we broaden the class of dynamic controllers which are contractible for implementation in the original system.

It is hoped that the proposed canonical form will simplify not only design of overlapping decentralized control, but also design of reduced-order controllers [6, 23], where the laws can be generated in the smaller space and then expanded for implementation in the original system.

THE SUBOPTIMAL NEHARI PROBLEM FOR WELL-POSED LINEAR SYSTEMS*

RUTH F. CURTAIN† AND MARK R. OPMEER†

Abstract. We solve the suboptimal Nehari problem for a transfer function that has a state-space realization as a system-stable (input, output and input-output stable) well-posed linear system. We obtain an explicit solution in terms of the state-space parameters.

Key words. infinite-dimensional linear systems, J-spectral factorizations, well-posed linear systems, stability, Hankel operators, Lyapunov equations, Nehari problem

AMS subject classifications. 41A30, 47B35, 47N70, 93B28

DOI. 10.1137/S036301290444318X

1. Introduction.

The solution to the optimal Nehari problem is well known. The vector-valued case was solved by Page [22] (see also Nikol'skiĭ [20] and Peller [23]):

$$\inf_{\mathbf{K}(-s)\in\mathbf{H}_\infty(\mathcal{L}(U,Y))} \| \mathbf{G}+\mathbf{K} \|_\infty = \| H_{\mathbf{G}} \|,$$

where $\mathbf{G} \in \mathbf{L}_\infty(\mathcal{L}(U,Y))$, U, Y are separable Hilbert spaces, and $H_{\mathbf{G}}$ is the Hankel operator associated with the symbol $\mathbf{G}$. The suboptimal problem is to find for any $\sigma > \| H_{\mathbf{G}} \|$ all solutions $\mathbf{K}(-s) \in \mathbf{H}_\infty(\mathcal{L}(U,Y))$ to

$$\| \mathbf{G}+\mathbf{K} \|_\infty \le \sigma.$$

The suboptimal Nehari problem for functions on the disc has been solved in Kheifets [18] (see also Peller [23]), but for control applications we require explicit solutions in terms of state-space parameters of the continuous-time system as we explain below.

A crucial step in many control problems is solving the suboptimal Nehari problem for the stable case: $\mathbf{G} \in \mathbf{H}_\infty(\mathcal{L}(U,Y))$. In Salamon [26] it was shown that any $\mathbf{G} \in \mathbf{H}_\infty(\mathcal{L}(U,Y))$ has a system-stable well-posed realization; i.e., there exists a state space Z and (in general unbounded) operators A, B, C, where A is the infinitesimal generator of a strongly continuous semigroup on the separable Hilbert space Z and the following stability assumptions are satisfied:

$$C(sI-A)^{-1}z \in \mathbf{H}_2(Y), \quad B^*(sI-A^*)^{-1}z \in \mathbf{H}_2(U) \quad \forall z \in Z. \tag{1.1}$$

$\mathbf{G}$ is the transfer function of the well-posed linear system in the sense that

$$\mathbf{G}(s)-\mathbf{G}(\alpha) = (\alpha-s)C(sI-A)^{-1}(\alpha I-A)^{-1}B$$

for all α and s in some open right half-plane. Conversely, every system-stable well-posed linear system has a transfer function in $\mathbf{H}_\infty(\mathcal{L}(U,Y))$. Usually in control applications not $\mathbf{G}$, but A, B, and C are given, and one wants a solution $\mathbf{K}$ in terms of these state-space parameters.

Recently, it has been shown in Curtain and Sasane [9] that if $\rho(A) \cap i\mathbb{R} \neq \emptyset$, the Nehari problem for a system-stable well-posed linear system can be reduced to solving the Nehari problem for its reciprocal system which has bounded B and C operators. (The reciprocal approach to well-posed linear systems was introduced in Curtain [10] and [11].) Since problems with bounded B and C operators are technically simpler, we first consider the special case of bounded input and output operators. The next step is to use this special case to solve the general case.

Our approach to solving the suboptimal Nehari problem is to obtain solutions $\mathbf{K}$ via the J-spectral factorization problem of finding $\mathbf{X}$ such that

$$\mathbf{P}^*(i\omega)J_\sigma\mathbf{P}(i\omega) = \mathbf{X}(i\omega)J_1\mathbf{X}(i\omega)^* \quad \text{for almost all} \quad \omega \in \mathbb{R}, \tag{1.2}$$

where

$$\mathbf{P}(s) := \begin{bmatrix} I_Y & \mathbf{G}(s) \\ 0 & I_U \end{bmatrix} \quad \text{and} \quad J_\sigma := \begin{bmatrix} I_Y & 0 \\ 0 & -\sigma^2 I_U \end{bmatrix}.$$

The candidate solution for $\mathbf{X}$ involves the solutions of the Lyapunov equations

$$AL_1 + L_1A^* = -BB^*, \quad A^*L_2 + L_2A = -C^*C. \tag{1.3}$$

The smallest bounded nonnegative solutions are L_B, L_C, the controllability and observability gramians of the system $\Sigma(A, B, C, 0)$, respectively. These are not necessarily the only bounded nonnegative solutions. Once it is shown that $\mathbf{X}$ is indeed a solution to (1.2), the rest of the proof is relatively straightforward and one obtains a solution in terms of the known system parameters A, B, C, L_1, L_2, and σ.

There have been several versions of this approach in the literature; all but one (Curtain and Oostveen [6]) assume that A is the generator of an exponentially stable C_0-semigroup. We mention Curtain and Zwart [4], Glover, Curtain, and Partington [14], Ran [24], Curtain and Ran [2], Foias and Tannenbaum [13], Curtain and Zwart [3], and Curtain and Ichikawa [5], who all treat the problem under the assumption that A is the generator of an exponentially stable C_0-semigroup and varying additional assumptions.

For exponentially stable systems one can, since $i\mathbb{R} \subset \rho(A)$, verify directly that (1.2) holds for all $\omega \in \mathbb{R}$. However, there exist many systems with a stable transfer function for which A does not generate an *exponentially* stable C_0-semigroup. This motivated Curtain and Oostveen [6] to consider the class of system-stable systems satisfying (1.1) with bounded B and C and finite-dimensional U and Y. Now assumptions (1.1) provide no information about the spectrum of A and so it is not possible to verify (1.2) by a direct calculation. Unfortunately, this point was overlooked in [6]. We give an example of a system-stable system for which the candidate solution $\mathbf{X}$ does not satisfy (1.2) for a certain pair of solutions L_1, L_2 to the Lyapunov equations (1.3). This does not show that the claim in [6] is incorrect, since the claim in [6] is made only for the smallest solutions L_B and L_C. However, this counterexample does show that there is a gap in the proof in [6]. An easy remedy is to make an additional assumption on the spectrum of A, e.g., assume that $\sigma(A) \cap i\mathbb{R}$ has measure zero or that $\mathbb{C}_0^+ \subset \rho(A)$. Our major contribution is to show that if U and Y are finite-dimensional, then these assumptions are unnecessary. This new result has consequences for the recent paper by Ball, Mikkola, and Sasane [1] on the Nehari–Takagi problem, which is a generalization of the suboptimal Nehari problem. Using a J-spectral factorization approach, they solve the suboptimal Nehari–Takagi problem

for finite-dimensional U and Y under our assumptions (1.1) plus an assumption on the spectrum of A. Our result shows that the latter assumption is redundant.

Summarizing, under the assumptions (1.1), for any $\sigma > r^{1/2}(L_1L_2)$ (here $r(T)$ is the spectral radius of the operator T) we give an explicit formula for a spectral factor $\mathbf{X}$ satisfying (1.2) in terms of the system parameters A, B, C, L_1, and L_2 under either of the following additional assumptions:

A1. $\sigma(A) \cap i\mathbb{R}$ has measure zero.

A2. U and Y are finite-dimensional, and L_1 and L_2 are chosen to be the controllability and observability gramians L_B and L_C, respectively.

This leads to our second main result: a solution of the suboptimal Nehari problem in terms of the system parameters A, B, C, L_1, L_2, and σ under either of the above assumptions A1 or A2.

Our last main result is the extension of this result to the class of system-stable well-posed linear systems satisfying the assumption $\rho(A) \cap i\mathbb{R} \neq \emptyset$ and either assumption A1 or A2. We remark that in the well-posed case the standard formulas for the solution need not be well-defined, but we obtain alternative explicit formulas in terms of the reciprocal system as in Curtain and Sasane [9].

The paper is written to be as self-contained as possible. In section 2, we summarize relevant known results on state linear systems and in section 3 we prove some interesting new ones. Section 4 contains results on Riccati equations in terms of the concepts of input and output stability and stabilizability. In addition, we study two interesting Riccati equations connected to the Nehari problem. In section 5 we give an example of a system-stable system for which the candidate solution $\mathbf{X}$ does not satisfy (1.2) for a certain pair of solutions L_1, L_2 of the Lyapunov equations. However, we show that in the case that $L_1 = L_B$ and $L_2 = L_C$, we can always construct a spectral factor of (1.2). We collect several of its properties that enable us to obtain a solution of the suboptimal Nehari problem in section 6. In section 7, we obtain a parametrization of a family of solutions to the suboptimal Nehari problem for a system-stable state linear system. Finally, in section 8 we recall the concepts of system-stable well-posed linear systems and their reciprocals from [11]. Using the reciprocal approach from [9] we extend our results to obtain an explicit solution of the suboptimal Nehari problem for the class of system-stable well-posed linear systems under the assumption that $\rho(A) \cap i\mathbb{R} \neq \emptyset$ and either of the assumptions A1 or A2.

An interesting open question is whether our conclusions also hold if in assumption A2 we allow U and Y to be infinite-dimensional. The existence of frequency domain solutions is also known for this case (see Kheifets [18] or Peller [23]).

2. State linear systems: Known results. First we recall several known results for systems with bounded input and output operators. A is the generator of a strongly continuous semigroup $T(\cdot)$ on a separable Hilbert space Z, $B \in \mathcal{L}(U, Z), C \in \mathcal{L}(Z, Y), D \in \mathcal{L}(U, Y)$ with U, Y separable Hilbert spaces. Following the terminology in Curtain and Zwart [4] we call $\Sigma(A, B, C, D)$ a *state linear system*. We now define the transfer function and the characteristic function of a state linear system.

DEFINITION 2.1. *The transfer function* $\mathbf{G}$ *is defined as follows:* $\mathbf{G} - D$ *equals the Laplace transform of* $CT(t)B$ *on some right half-plane. We define the characteristic function* $\mathfrak{G}$ *for all* $s \in \rho(A)$ *by* $\mathfrak{G} = D + C(sI - A)^{-1}B$.

Remark 2.2. For s in some right half-plane we have $\mathbf{G} = \mathfrak{G}$, but they may differ outside this region. For a counterexample see Curtain and Zwart [4, Example 4.3.8]. A more detailed discussion is given in Zwart [33].

We introduce a stability concept that is weaker than exponential stability but

stronger than input-output stability. We will show that this is the right stability concept for the Nehari problem.

DEFINITION 2.3. *The state linear system* $\Sigma(A,B,C,D)$ *is* system-stable *if*

- *it is* input stable*: there exists a constant* $\beta > 0$ *such that for all* $u \in \mathbf{L}_2(0,\infty;U)$, $\| \int_0^\infty T(t)Bu(t)\,\mathrm{d}t\|^2 \le \beta \int_0^\infty \|u(t)\|^2\,\mathrm{d}t$*;*
- *it is* output stable*: there exists a constant* $\gamma > 0$ *such that for all* $z \in Z$, $\int_0^\infty \|CT(t)z\|^2\,\mathrm{d}t \le \gamma\|z\|^2$*;*
- *it is* input-output stable*: the transfer function* $\mathbf{G} \in \mathbf{H}_\infty(\mathcal{L}(U,Y))$.

Remark 2.4. We note that other authors may require the additional assumption that the semigroup be uniformly bounded for $t > 0$ for system stability (see Staffans [30] or Mikkola [19, Definition 6.1.1]). The essential difference in our definition is that we have made no stability assumptions on A and so it can have spectrum in the right half-plane $\mathbb{C}_0^+$.

DEFINITION 2.5. *The output map* $\mathcal{C} : Z \to \mathbf{L}_2(0,\infty;Y)$ *of an output stable state linear system* $\Sigma(A,B,C,D)$ *is defined by* $(\mathcal{C}z)(t) := CT(t)z$. *The input map* $\mathcal{B} : \mathbf{L}_2(0,\infty;U) \to Z$ *of an input stable state linear system is defined by*

$$\mathcal{B}u := \int_0^\infty T(s)Bu(s)\,ds.$$

The input and output stability properties are related to the existence of solutions to Lyapunov equations (see Grabowski [15] and Hansen and Weiss [16]).

LEMMA 2.6. *The state linear system* $\Sigma(A,B,C,D)$ *is* input stable *if and only if the following controllability Lyapunov equation has a bounded nonnegative solution* $L \in \mathcal{L}(Z)$:

$$ALz + LA^*z = -BB^*z \quad \forall\ z \in D(A^*). \tag{2.1}$$

In this case, the controllability gramian $L_B := \mathcal{B}\mathcal{B}^*$ *is the smallest bounded nonnegative solution of* (2.1) *and* $L_B^{1/2}T(t)^*z \to 0$ *as* $t \to \infty$ *for all* $z \in Z$.

The state linear system $\Sigma(A,B,C,D)$ *is* output stable *if and only if the following observability Lyapunov equation has a bounded nonnegative solution* $L \in \mathcal{L}(Z)$:

$$A^*Lz + LAz = -C^*Cz \quad \forall\ z \in D(A). \tag{2.2}$$

In this case, the observability gramian $L_C := \mathcal{C}^*\mathcal{C}$ *is the smallest bounded nonnegative solution of* (2.2) *and* $L_C^{1/2}T(t)z \to 0$ *as* $t \to \infty$ *for all* $z \in Z$.

The Hankel operator of a system is a fundamental concept.

DEFINITION 2.7. *For* $\mathbf{G} \in \mathbf{L}_\infty((-i\infty,i\infty);\mathcal{L}(U,Y))$ *we define the* Hankel operator with symbol $\mathbf{G}$ *as the operator* $H_{\mathbf{G}}$*:* $\mathbf{H}_2(U) \to \mathbf{H}_2(Y)$ *given by*

$$H_{\mathbf{G}}f = \Pi(\Lambda_{\mathbf{G}}f_-) \quad \textit{for} \quad f \in \mathbf{H}_2(U), \tag{2.3}$$

where $\Lambda_{\mathbf{G}}$ *is the multiplication map on* $\mathbf{L}_2((-i\infty,i\infty);U)$ *induced by* $\mathbf{G}$, Π *is the orthogonal projection from* $\mathbf{L}_2((-i\infty,i\infty);U)$ *onto* $\mathbf{H}_2(U)$, *and* $f_-(s) := f(-s)$.

Given $h \in \mathbf{L}_1^{\mathrm{loc}}([0,\infty);\mathcal{L}(U,Y))$, *we define the (time-domain)* Hankel operator Γ_h associated with h *for* $u \in \mathbf{L}_2^{\mathrm{loc}}([0,\infty);U)$ *with compact support by*

$$(\Gamma_h)(t) := \int_0^\infty h(t+\tau)u(\tau)d\tau. \tag{2.4}$$

There is a nice relationship between the time-domain and frequency-domain Hankel operators.

LEMMA 2.8. *Suppose that $\Sigma(A,B,C,0)$ is a system-stable system with impulse response $h(t)=CT(t)B$ and transfer function $\mathbf{G}$.*

1. *$\Gamma_h=\mathcal{CB}$ and it is isomorphic to $H_{\mathbf{G}}$ via*

$$\widehat{(\Gamma_h u)}(i\omega)=(H_{\mathbf{G}}\hat{u})(i\omega) \quad \text{for} \quad u\in \mathbf{L}_2([0,\infty);U). \tag{2.5}$$

Moreover,

$$\| H_{\mathbf{G}} \|=\| \Gamma_h \|= r^{\frac{1}{2}}(L_BL_C), \tag{2.6}$$

where r denotes the spectral radius and L_B, L_C are the controllability and observability gramians, respectively, of $\Sigma(A,B,C,0)$.

2. *If $\sigma > r^{\frac{1}{2}}(L_1L_2)$, where L_1, L_2 are arbitrary bounded nonnegative solutions of the Lyapunov equations (2.1), (2.2), respectively, then $N_\sigma := (I-\frac{1}{\sigma^2}L_1L_2)^{-1}\in \mathcal{L}(Z)$. Moreover, $W=N_\sigma L_1$ is nonnegative.*

Proof. 1. See Oostveen [21, Lemma 7.1.5].

2. Now $\sigma^2 > r(L_1L_2)$ implies that the spectral radius of $\frac{1}{\sigma^2}L_1L_2$ is less than 1 and so $I-\frac{1}{\sigma^2}L_1L_2$ is boundedly invertible. Noting that $L_1\geq 0$, the following shows that $W\geq 0$:

$$W=\left(I-\frac{1}{\sigma^2}L_1L_2\right)^{-1}L_1 = L_1^{1/2}\left(I-\frac{1}{\sigma^2}L_1^{1/2}L_2L_1^{1/2}\right)^{-1}L_1^{1/2}. \qquad \square$$

3. State linear systems: Some new results. In this section we develop several new results for state linear systems that we use in what follows, many of which are interesting in their own right.

First we examine the properties of the various concepts of stability from Definition 2.3 more closely.

LEMMA 3.1. *If $\Sigma(A,B,C,D)$ is output stable with observability gramian L_C, then for all $u\in \mathbf{L}_2^{\mathrm{loc}}(\mathbb{R};U)$ with compact support*

$$L_C^{1/2}\int_{-\infty}^{t} T(t-s)Bu(s)\,ds \to 0 \quad \text{as} \quad t\to\infty.$$

Proof. Let $\tau>0$ be such that $u(t)=0$ for $t>\tau$. Then

$$\begin{aligned} L_C^{1/2}\int_{-\infty}^{t} T(t-s)Bu(s)\,ds &= L_C^{1/2}\int_{-\infty}^{\tau} T(t-\tau)T(\tau-s)Bu(s)\,ds \\ &= L_C^{1/2}T(t-\tau)z(\tau), \end{aligned}$$

where $z(\tau)=\int_{-\infty}^{\tau}T(\tau-s)Bu(s)\,ds$ is independent of t. Lemma 2.6 now gives the result. $\square$

We recall that the output of a state linear system $\Sigma(A,B,C,D)$ with locally square integrable inputs u with support bounded to the left is defined by

$$y(t)=\int_{-\infty}^{t} CT(t-s)Bu(s)\,ds + Du(t). \tag{3.1}$$

Output stability does not imply input-output stability, but we do have the following partial result.

LEMMA 3.2. *If $\Sigma(A,B,C,D)$ is output stable, then for inputs $u\in \mathbf{L}_2^{\mathrm{loc}}(\mathbb{R};U)$ with compact support, the output given by (3.1) is in $\mathbf{L}_2(\mathbb{R};Y)$.*

Proof. Since u is square integrable we can assume without loss of generality that $D = 0$. Since u has compact support, there exists a $\tau > 0$ such that $u(t) = 0$ for $t > \tau$. We calculate the output $y(t)$ for $t > \tau$ as

$$\begin{aligned} y(t) &= \int_{-\infty}^{\tau} CT(t-\tau)T(\tau-s)Bu(s)\,ds \\ &= CT(t-\tau)\int_{-\infty}^{\tau} T(\tau-s)Bu(s)\,ds = CT(t-\tau)z(\tau), \end{aligned}$$

where

$$z(\tau) := \int_{-\infty}^{\tau} T(\tau-s)Bu(s)\,ds.$$

Since $\Sigma(A,B,C,D)$ is output stable we have

$$\begin{aligned} \int_{\tau}^{\infty} \| y(t) \|^2 \, dt &= \int_{0}^{\infty} \| CT(t)z(\tau) \|^2 \, dt \\ &\leq \text{const.} \| z(\tau) \|^2 < \infty. \end{aligned}$$

Since the output of a state linear system is always locally square integrable and the output has support bounded to the left by causality we have

$$\int_{-\infty}^{\infty} \| y(t) \|^2 \, dt = \int_{-\infty}^{\tau} \| y(t) \|^2 \, dt + \int_{\tau}^{\infty} \| y(t) \|^2 \, dt < \infty. \qquad \square$$

We next examine the connection between the transfer function and the characteristic function of a state linear system.

DEFINITION 3.3. *For an output stable state linear system we define* $\widehat{\mathcal{C}} : Z \to \mathbf{H}_2(Y)$ *by* $\widehat{\mathcal{C}}z := \widehat{\mathcal{C}z}$.

For an input stable state linear system we define $\widehat{\mathcal{B}}$ *for* $u \in U, z \in Z, s \in \mathbb{C}_0^+$ *by* $\langle \widehat{\mathcal{B}}(s)u, z\rangle := \langle u, \widehat{\mathcal{B}^*z}(\bar{s})\rangle$.

The following lemma shows that input or output stability ensures that the characteristic function and the transfer function are equal on the set where they are both defined. Parts of this lemma were shown for well-posed linear systems in [11, Lemma 2.3].

LEMMA 3.4.

1. *If the state linear system* $\Sigma(A,B,C,D)$ *is output stable, then*

$$\mathbf{G}(s) = D + \widehat{\mathcal{C}}(s)B \quad \forall s \in \mathbb{C}_0^+, \tag{3.2}$$

$$\mathbf{G}(s) = D + C(sI-A)^{-1}B = \mathfrak{G}(s) \quad \forall s \in \mathbb{C}_0^+ \cap \rho(A). \tag{3.3}$$

   Moreover, for all $u \in U$ *we have that* $(\mathbf{G} - D)u \in \mathbf{H}_2(Y)$.

2. *If the state linear system* $\Sigma(A,B,C,D)$ *is input stable, then* (3.3) *holds and*

$$\mathbf{G}(s) = D + C\widehat{\mathcal{B}}(s) \quad \forall s \in \mathbb{C}_0^+. \tag{3.4}$$

   Moreover, for all $u \in U, y \in Y$ *we have that* $\langle (\mathbf{G} - D)u, y\rangle \in \mathbf{H}_2$.

Proof. 1. Taking Laplace transforms of $CT(\cdot)z$, we obtain $C(sI-A)^{-1}z = \widehat{\mathcal{C}}(s)z$ and $\mathbf{G}(s) = \widehat{\mathcal{C}}(s)B + D$ for s in some right half-plane (see [4, Lemma 2.1.11]). Now since Σ is output stable, $\hat{\mathcal{C}}z \in \mathbf{H}_2(Y)$ for all $z \in Z$ and so $\widehat{\mathcal{C}}$ is holomorphic in $\mathbb{C}_0^+$ and

(3.2) holds. Again using that $\widehat{\mathcal{C}}$ is holomorphic on $\mathbb{C}_0^+$, the equality $\widehat{\mathcal{C}}(s)(sI-A)=C$ for s in some right half-plane extends to $\mathbb{C}_0^+$. Thus for $s\in\mathbb{C}_0^+\cap\rho(A)$ we have

$$\hat{\mathcal{C}}(s)(sI-A)(sI-A)^{-1}B=C(sI-A)^{-1}B,$$

which proves (3.3).

2. Similarly, input stability implies that $V(s)z\in\mathbf{H}_2(U)$ for $z\in Z$, where $V(s)z:=B^*(sI-A^*)^{-1}z$ on some right half-plane. Then $\langle u,V(\bar{s})z\rangle=\langle\widehat{\mathcal{B}}(s)u,z\rangle$ for all $z\in Z,u\in U$. So for all s in some right half-plane we have

$$\langle(sI-A)^{-1}Bu,z\rangle=\langle\widehat{\mathcal{B}}(s)u,z\rangle, \tag{3.5}$$

and letting $z=C^*x$, we obtain $\mathbf{G}=C\widehat{\mathcal{B}}+D$ on some right half-plane. Using that $\widehat{\mathcal{B}}$ is holomorphic, we obtain (3.4). To show (3.3) choose $z\in D(A^*)$, let $x=(\bar{s}I-A^*)z$, and substitute in (3.5) to obtain for s in some right half-plane

$$\langle Bu,x\rangle=\langle(sI-A)\widehat{\mathcal{B}}(s)u,x\rangle.$$

This extends to $s\in\mathbb{C}_0^+$ since $\widehat{\mathcal{B}}$ is holomorphic and to all $x\in Z$ by continuity. Thus

$$(sI-A)\widehat{\mathcal{B}}(s)=B\quad\forall\ s\in\mathbb{C}_0^+, \tag{3.6}$$

which proves (3.3). □

It turns out that the existence of boundary functions of $\mathbf{H}_2$ functions is crucial in our later proofs. We recall some basic results from [25]. Let $\omega\in\mathbb{R}$ and consider for $\alpha>0$ the cone

$$\Gamma_\alpha=\{s\in\mathbb{C}_0^+:|\mathrm{Im}(s)-\omega|<\alpha\ \mathrm{Re}(s)\}.$$

If $f\in\mathbf{H}_2(H)$, where H is a separable Hilbert space, then for almost all $\omega\in\mathbb{R}$ and all $\alpha>0$ the limit

$$\lim_{s\to i\omega,s\in\Gamma_\alpha}f(s)$$

exists. Such a limit is called a *nontangential limit*, and it associates with an $\mathbf{H}_2(H)$ function a function in $\mathbf{L}_2(i\mathbb{R},H)$ (see [25, Theorems 4.6.B and 4.8.B]).

It is well known that if U and Y are finite-dimensional and for all $u\in U$ we have $\mathbf{G}u\in\mathbf{H}_2(Y)$, then $\mathbf{G}\in\mathbf{H}_2(\mathcal{L}(U,Y))$. Hence we obtain an almost everywhere defined *boundary function* $\mathbf{G}:i\mathbb{R}\to\mathcal{L}(U,Y)$.

In the case where U and Y are infinite-dimensional we do have that for all $u\in U$ the function $\mathbf{G}(\cdot)u$ has a boundary function in $\mathbf{L}_2(i\mathbb{R};Y)$. However, in general there does not exist an almost everywhere defined function $F:i\mathbb{R}\to\mathcal{L}(U,Y)$ such that $F(i\omega)u$ equals this boundary function (see Mikkola [19, Example 3.3.6] for a counterexample).

If $\Sigma(A,B,C,D)$ is input or output stable and $\sigma(A)\cap i\mathbb{R}$ has measure zero, then $\mathbf{G}(s)=\mathfrak{G}(s)$ on $\mathbb{C}_0^+\cap\rho(A)$ by Lemma 3.4 and since $\mathfrak{G}(s)\to\mathfrak{G}(i\omega)$ as $s\to i\omega$ by continuity of the map $s\mapsto(sI-A)^{-1}$, we have $\mathbf{G}(s)\to\mathfrak{G}(i\omega)$. So if $\Sigma(A,B,C,D)$ is input or output stable and $\sigma(A)\cap i\mathbb{R}$ has measure zero, then $\mathbf{G}$ has an almost everywhere defined operator-valued boundary function. From the above we obtain the following.

LEMMA 3.5. *Let $\Sigma(A,B,C,D)$ be input or output stable and assume that either $\sigma(A)\cap i\mathbb{R}$ has measure zero or U and Y are finite-dimensional. Then there exists an*

almost everywhere defined function $\mathbf{G}_0 : i\mathbb{R} \to \mathcal{L}(U,Y)$ *such that for almost all* $\omega \in \mathbb{R}$ *and all nontangential paths we have*

$$\mathbf{G}_0(i\omega) = \lim_{s \to i\omega} \mathbf{G}(s).$$

Moreover, if $i\omega \in \rho(A)$, *then* $\mathbf{G}_0(i\omega) = \mathfrak{G}(i\omega)$.

Proof. This follows from the paragraphs preceding the lemma. ∎

We prove the following lemma that will be useful later.

LEMMA 3.6. *Let* $f : \mathbb{C}_0^+ \to \mathcal{L}(U,Y)$ *be such that for every* $u \in U$ *we have* $f(\cdot)u \in \mathbf{H}_2(Y)$. *Assume there exists a function* $f_0 \in \mathbf{L}_\infty(i\mathbb{R}; \mathcal{L}(U,Y))$ *such that for all* $u \in U$ *there exists a set* $\mathcal{N}_u$ *of measure zero such that for all* $\omega \in \mathbb{R} - \mathcal{N}_u$ *and all nontangential paths we have*

$$f_0(i\omega)u = \lim_{s \to i\omega} f(s)u.$$

Then $f \in \mathbf{H}_\infty(\mathcal{L}(U,Y))$.

Proof. Since $f(\cdot)u \in \mathbf{H}_2(Y)$ we have the Poisson representation [25, Theorem 4.8.A]

$$f(a+ib)u = \frac{1}{\pi} \int_{\mathbb{R}} \frac{b f_0(i\omega)u}{(t-a)^2 + b^2}\, dt,$$

so we have (using that the Poisson kernel has integral one)

$$\|f(a+ib)u\| \le \frac{1}{\pi} \int_{\mathbb{R}} \|f_0(i\omega)u\| \frac{b}{(t-a)^2+b^2}\, dt \le \operatorname*{ess\,sup}_{t \in \mathbb{R}} \|f_0(it)\|\ \|u\|.$$

This shows that

$$\sup_{s \in \mathbb{C}_0^+} \|f(s)\| \le \operatorname*{ess\,sup}_{t \in \mathbb{R}} \|f_0(it)\|$$

and since f is holomorphic we have $f \in \mathbf{H}_\infty(\mathcal{L}(U,Y))$. ∎

LEMMA 3.7. *Let* $\Sigma(A,B,C,D)$ *be output stable and assume that either* $\sigma(A) \cap i\mathbb{R}$ *has measure zero or* U *and* Y *are finite-dimensional. Then for inputs with compact support we have for almost all* $\omega \in \mathbb{R}$

$$\hat{y}(i\omega) = \mathbf{G}(i\omega)\hat{u}(i\omega). \tag{3.7}$$

Proof. We first prove the statement for the case that u is zero for negative time. Now on some right half-plane we have

$$\hat{y}(s) = \mathbf{G}(s)\hat{u}(s). \tag{3.8}$$

Since $\hat{y} \in \mathbf{H}_2(Y)$ by Lemma 3.2 (and causality) and $\mathbf{G}$ is holomorphic on $\mathbb{C}_0^+$ by Lemma 3.4 this extends to $\mathbb{C}_0^+$. By Lemma 3.5 we have $\mathbf{G}(s) \to \mathbf{G}(i\omega)$ in the operator norm as $s \to i\omega$. Since $\hat{u} \in \mathbf{H}_2(U)$ and $\hat{y} \in \mathbf{H}_2(Y)$, they converge to their boundary functions as $s \to i\omega$ so we obtain (3.7). The general case follows by applying the above to the function $\underline{u}(t) := u(t-\tau)$ with output $\underline{y}(t) := y(t-\tau)$, where y is the output corresponding to u and τ is chosen such that $\underline{u}$ is zero for negative time. ∎

In the proof of Lemma 3.8 we need to study systems defined on the positive time axis only and with a given initial state. We summarize some known results for this

type of system. For an input $u \in \mathbf{L}_2^{\mathrm{loc}}(0,\infty;U)$ and initial state $x_0 \in X$ the state $x(t) \in X$ at time $t \geq 0$ is defined by

$$x(t) = T(t)x_0 + \int_0^t T(t-s)Bu(s)\,ds.$$

If u is continuously differentiable and $x_0 \in D(A)$, then x as defined above is differentiable and satisfies

$$\dot{x}(t) = Ax(t) + Bu(t), \quad x(0) = x_0.$$

The output of the state linear system is defined by

$$y(t) = Cx(t) + Du(t).$$

A state linear system is well-posed in the sense that for all $t > 0$ there exists a $K > 0$ such that for all $u \in \mathbf{L}_2^{\mathrm{loc}}(0,\infty;U)$ and all $x_0 \in X$

$$\|x(t)\|^2 + \int_0^t \|y(s)\|^2\,ds \leq K\left(\|x_0\|^2 + \int_0^t \|u(s)\|^2\,ds\right);$$

i.e., the map from the initial state and the input restricted to $(0,t)$ to the state at time t and the output restricted to $(0,t)$ is continuous from $X \times L^2(0,t;U)$ to $X \times L^2(0,t;Y)$.

LEMMA 3.8. *Let $\Sigma(A,B,C,0)$ be output stable with observability gramian L_C and let $u_i \in \mathbf{L}_2^{\mathrm{loc}}(\mathbb{R};U)$ be an input with compact support. Denote by y_i the output of $\Sigma(A,B,C,0)$ with input u_i given by* (3.1) *and by y_i^{LC} the output of $\Sigma(A,B,B^*L_C,0)$ with input u_i given by the corresponding* (3.1). *Then we have the following*:

$$\int_{-\infty}^{\infty} \langle y_1(t), y_2(t)\rangle\,dt = \int_{-\infty}^{\infty} \langle u_1(t), y_2^{LC}(t)\rangle\,dt + \int_{-\infty}^{\infty} \langle y_1^{LC}(t), u_2(t)\rangle\,dt. \tag{3.9}$$

Proof. We first note that the integrals in (3.9) are well defined since $y_i \in \mathbf{L}_2(\mathbb{R};Y)$ by Lemma 3.2 and the u_i have compact support. Set $z_i(t) = \int_{-\infty}^t T(t-s)Bu_i(s)\,ds$ for $i = 1,2$. If u_i is continuously differentiable, then $z_i(t)$ is differentiable and

$$\begin{aligned}
&\frac{d}{dt}\langle z_1(t), L_C z_2(t)\rangle \\
&= \langle Az_1(t) + Bu_1(t), L_C z_2(t)\rangle + \langle L_C z_1(t), Az_2(t) + Bu_2(t)\rangle \\
&= \langle Bu_1(t), L_C z_2(t)\rangle + \langle L_C z_1(t), Bu_2(t)\rangle - \langle Cz_1(t), Cz_2(t)\rangle,
\end{aligned}$$

where we have used (2.2). On integrating the above we obtain

$$\langle z_1(t), L_C z_2(t)\rangle \tag{3.10}$$

$$= \int_{-\infty}^t \langle u_1(s), B^*L_C z_2(s)\rangle\,ds + \int_{-\infty}^t \langle B^*L_C z_1(s), u_2(s)\rangle\,ds - \int_{-\infty}^t \langle Cz_1(s), Cz_2(s)\rangle\,ds. \tag{3.11}$$

$$= \int_{-\infty}^t \langle u_1(s), y_2^{LC}(s)\rangle\,ds + \int_{-\infty}^t \langle y_1^{LC}(s), u_2(s)\rangle\,ds - \int_{-\infty}^t \langle y_1(s), y_2(s)\rangle\,ds. \tag{3.12}$$

From Lemma 3.1 we conclude that the left-hand side of (3.12) converges to zero as $t \to \infty$. This proves (3.9) for the case of continuously differentiable inputs, and the general case follows by the following approximation argument. Let $u_i \in \mathbf{L}_2^{\mathrm{loc}}(\mathbb{R};U)$ be inputs with compact support and let $u_i^n \in \mathbf{L}_2^{\mathrm{loc}}(\mathbb{R};U)$ be continuously differentiable inputs with compact support that converge to u_i in $\mathbf{L}_2(\mathbb{R};U)$. Let τ be such that u_i and u_i^n are equal to zero on (τ,∞), and assume that u_i and u_i^n are zero on $(-\infty,0)$. By the well-posedness there exists a $K(\tau)$ such that

$$\int_{-\infty}^{\tau} \|y_i(s)-y_i^n(s)\|^2\,ds \le K(\tau)\int_{-\infty}^{\tau} \|u_i(s)-u_i^n(s)\|^2\,ds$$

and hence

$$\int_{-\infty}^{\tau} \|y_i(s)-y_i^n(s)\|^2\,ds \to 0 \ \text{ as } \ n\to\infty.$$

For $z_i^n(\tau) := \int_{-\infty}^{\tau} T(\tau-s)Bu_i(s)\,ds$ we have

$$\int_{\tau}^{\infty} \|y_i(s)-y_i^n(s)\|^2\,ds = \int_0^{\infty} \|CT(s)\left(z_i(\tau)-z_i^n(\tau)\right)\|^2\,ds.$$

Since $\Sigma(A,B,C,0)$ is output stable, there exists a $\gamma>0$ such that

$$\int_{\tau}^{\infty} \|y_i(s)-y_i^n(s)\|^2\,ds \le \gamma\ \|z_i(\tau)-z_i^n(\tau)\|^2,$$

and by the well-posedness there exists a $K(\tau)$ such that

$$\|z_i(\tau)-z_i^n(\tau)\|^2 \le K(\tau)\int_{-\infty}^{\tau} \|u_i(s)-u_i^n(s)\|^2\,ds.$$

Hence

$$\int_{\tau}^{\infty} \|y_i(s)-y_i^n(s)\|^2\,ds \to 0 \ \text{ as } \ n\to\infty.$$

So we have $y_i^n \to y_i$ in $\mathbf{L}_2(\mathbb{R};Y)$. By the compact support of the inputs u_i and u_i^n we need only $y_i^{n,LC} \to y_i^{LC}$ in $\mathbf{L}_2(-\infty,\tau;Y)$ to establish (3.9). This convergence follows from the well-posedness as above. Using this (3.9) follows. The case that u_i is not zero on $(-\infty,0)$ can be reduced to the case that this is the case by a time-shift as in the proof of Lemma 3.7. ∎

We also need to study anticausal outputs of state linear systems. The anticausal output of the state linear system $\Sigma(A,B,C,D)$ for an input $u \in \mathbf{L}_2^{\mathrm{loc}}(\mathbb{R};U)$ with support bounded to the right is defined as

$$y^a(t) := \int_t^{\infty} CT(s-t)Bu(s)\,ds + Du(t). \tag{3.13}$$

We have the following analogue of Lemma 3.2.

LEMMA 3.9. *If $\Sigma(A,B,C,D)$ is output stable, then for inputs $u \in \mathbf{L}_2^{\mathrm{loc}}(\mathbb{R};U)$ with compact support, the anticausal output given by* (3.13) *is in $\mathbf{L}_2(\mathbb{R};Y)$.*

Proof. The proof is as in the proof of Lemma 3.2. ∎

We have the following analogue of Lemma 3.7.

LEMMA 3.10. *Let $\Sigma(A,B,C,D)$ be output stable and assume that either $\sigma(A)\cap i\mathbb{R}$ has measure zero or U and Y are finite-dimensional. Then for inputs with compact support we have for almost all $\omega\in\mathbb{R}$*

$$\hat{y}^a(i\omega)=\mathbf{G}(-i\omega)\hat{u}(i\omega), \tag{3.14}$$

where y^a is the anticausal output of $\Sigma(A,B,C,D)$ defined by (3.13).

Proof. This follows as in the proof of Lemma 3.7, but now by first assuming u to be zero for positive time and using the Hardy space $\mathbf{H}_2$ over the left half-plane. Details are as follows. We first prove the statement for the case that u is zero for positive time. Now on some left half-plane we have

$$\hat{y}^a(s)=\mathbf{G}(-s)\hat{u}(s). \tag{3.15}$$

Since $\hat{y}^a\in\mathbf{H}_2(\mathbb{C}_0^-;Y)$ by Lemma 3.9 (and anticausality) and $\mathbf{G}$ is holomorphic on $\mathbb{C}_0^+$ by Lemma 3.4 this extends to $\mathbb{C}_0^-$. By Lemma 3.5 we have $\mathbf{G}(s)\to\mathbf{G}(i\omega)$ in the operator norm as $s\to i\omega$. Since $\hat{u}\in\mathbf{H}_2(\mathbb{C}_0^-;U)$ and $\hat{y}^a\in\mathbf{H}_2(\mathbb{C}_0^-;Y)$, they converge to their boundary functions as $s\to i\omega$ so we obtain (3.14). The general case follows by applying the above to the function $\underline{u}(t):=u(t+\tau)$ with output $\underline{y}^a(t):=y^a(t+\tau)$, where y is the output corresponding to u and τ is chosen such that $\underline{u}$ is zero for positive time. ∎

The next result is a consequence of Lemma 3.8.

LEMMA 3.11. *Let $\Sigma(A,B,C,0)$ be input and output stable with observability gramian L_C and let $u_i\in\mathbf{L}_2^{\mathrm{loc}}(\mathbb{R};U)$ be an input with compact support. Denote by y_i the output of $\Sigma(A,B,C,0)$ with input u_i given by* (3.1) *and by y_i^a the anticausal output of $\Sigma(A^*,L_CB,B^*,0)$ with input u_i given by the corresponding* (3.13). *Then we have $y_i^a\in\mathbf{L}_2(\mathbb{R};U)$ and the following:*

$$\int_{-\infty}^{\infty}\langle y_1(t),y_2(t)\rangle\,dt=\int_{-\infty}^{\infty}\langle y_1^a(t),u_2(t)\rangle\,dt+\int_{-\infty}^{\infty}\langle u_1(t),y_2^a(t)\rangle\,dt. \tag{3.16}$$

Proof. Since $\Sigma(A,B,C,0)$ is input stable the system $\Sigma(A^*,L_CB,B^*,0)$ is output stable. Lemma 3.9 then implies that $y_i^a\in\mathbf{L}_2(\mathbb{R};U)$. Equation (3.16) follows from (3.9) by an application of Fubini's theorem and a change of variables. ∎

LEMMA 3.12. *If $\Sigma(A,B,C,0)$ is input and output stable with the observability gramian L_C, then*

$$\begin{aligned}&\langle L_CBu,\widehat{\mathcal{B}}(s)u\rangle+\langle\widehat{\mathcal{B}}(s)u,L_CBu\rangle\\&=\|\,\mathbf{G}(s)u\,\|^2+2\mathrm{Re}\;s\;\|L_C^{1/2}\widehat{\mathcal{B}}(s)u\|^2\quad\forall\;s\in\mathbb{C}_0^+,u\in U.\end{aligned} \tag{3.17}$$

Proof. We obtain a straightforward frequency domain identity from the Lyapunov equation (2.2):

$$(\bar{s}I-A^*)L_C+L_C(sI-A)=C^*C+2\mathrm{Re}\;s\;L_C.$$

This leads to the following identity on some right half-plane:

$$\begin{aligned}&B^*L_C(sI-A)^{-1}B+B^*(\bar{s}I-A^*)^{-1}L_CB\\&=B^*(\bar{s}I-A^*)^{-1}C^*C(sI-A)^{-1}B+2\mathrm{Re}\;sB^*(\bar{s}I-A)^{-1}L_C(sI-A)^{-1}B.\end{aligned}$$

From this we obtain (3.17) for s in some right half-plane using Lemma 3.4. From the input stability of $\Sigma(A,B,C,D)$ we obtain that $\widehat{\mathcal{B}}$ and $\mathbf{G}$ are holomorphic on $\mathbb{C}_0^+$.

From the appendix (Corollaries 9.1 and 9.4) it follows that all terms in (3.17) are real-analytic on $\mathbb{C}_0^+$. By the identity theorem for real-analytic functions we obtain (3.17) for $s \in \mathbb{C}_0^+$. ∎

The next lemma is the main result of this section.

LEMMA 3.13. *Let $\Sigma(A,B,C,0)$ be input and output stable with the observability gramian L_C and assume that either $\sigma(A) \cap i\mathbb{R}$ has measure zero or U and Y are finite-dimensional. Then for almost all $\omega \in \mathbb{R}$, all $u \in U$, and all nontangential paths*

$$\lim_{s \to i\omega} \text{Re } s \parallel L_C^{1/2} \widehat{\mathcal{B}}(s)u \parallel^2 = 0. \tag{3.18}$$

Proof. Let u_i be locally square integrable with compact support. Let y_i denote the output of $\Sigma(A,B,C,0)$ for input u_i from (3.1) and let y_i^a denote the anticausal output of $\Sigma(A^*, L_C B, B^*, 0)$ for input u_i from the corresponding (3.13). By Fourier transforming (3.16) we obtain

$$\int_{-\infty}^{\infty} \langle \hat{y}_1(i\omega), \hat{y}_2(i\omega) \rangle \, d\omega = \int_{-\infty}^{\infty} \langle \hat{y}_1^a(i\omega), \hat{u}_2(i\omega) \rangle \, d\omega + \int_{-\infty}^{\infty} \langle \hat{u}_1(i\omega), \hat{y}_2^a(i\omega) \rangle \, d\omega.$$

From Lemmas 3.7 and 3.10 we obtain

$$\int_{-\infty}^{\infty} \langle \mathbf{G}(i\omega)\hat{u}_1(i\omega), \mathbf{G}(i\omega)\hat{u}_2(i\omega) \rangle \, d\omega$$
$$= \int_{-\infty}^{\infty} \langle \mathbf{G}^{LC}(-i\omega)\hat{u}_1(i\omega), \hat{u}_2(i\omega) \rangle \, d\omega + \int_{-\infty}^{\infty} \langle \hat{u}_1(i\omega), \mathbf{G}^{LC}(-i\omega)\hat{u}_2(i\omega) \rangle \, d\omega,$$

where $\mathbf{G}^{LC}$ is the transfer function of the system $\Sigma(A^*, L_C B, B^*, 0)$. Letting $u_i(t) = f(t)v$, where f is a scalar function with compact support and $v \in U$, we obtain

$$\int_{-\infty}^{\infty} |\hat{f}(i\omega)|^2 \left(\langle \mathbf{G}^{LC}(-i\omega)v, v \rangle + \langle v, \mathbf{G}^{LC}(-i\omega)v \rangle - \|\mathbf{G}(i\omega)v\|^2 \right) d\omega = 0. \tag{3.19}$$

From (3.17) we obtain using $\mathbf{G}^{LC}(s) = \widehat{\mathcal{B}}(\bar{s})^* L_C B$ that for all $s \in \mathbb{C}_0^+$

$$\langle \mathbf{G}^{LC}(\bar{s})v, v \rangle + \langle v, \mathbf{G}^{LC}(\bar{s})v \rangle - \|\mathbf{G}(s)v\|^2 = 2\text{Re } s \, \|L_C^{1/2} \widehat{\mathcal{B}}(s)v\|^2 \geq 0.$$

Taking nontangential limits (which exist for all three terms on the left-hand side) we obtain for almost all $\omega \in \mathbb{R}$

$$\langle \mathbf{G}^{LC}(-i\omega)v, v \rangle + \langle v, \mathbf{G}^{LC}(-i\omega)v \rangle - \|\mathbf{G}(i\omega)v\|^2 \geq 0. \tag{3.20}$$

Combining (3.19) and (3.20) we obtain for almost all $\omega \in \mathbb{R}$

$$|\hat{f}(i\omega)|^2 \left(\langle \mathbf{G}^{LC}(-i\omega)v, v \rangle + \langle v, \mathbf{G}^{LC}(-i\omega)v \rangle - \|\mathbf{G}(i\omega)v\|^2 \right) = 0.$$

Now let $f : \mathbb{R} \to \mathbb{C}$ be a function that has compact support and such that $\hat{f}(i\omega) \neq 0$ for almost all $\omega \in \mathbb{R}$ (for example, the function equal to 1 on [0,1] and zero elsewhere). Then we obtain for all $v \in U$ and almost all $\omega \in \mathbb{R}$

$$\langle \mathbf{G}^{LC}(-i\omega)v, v \rangle + \langle v, \mathbf{G}^{LC}(-i\omega)v \rangle - \|\mathbf{G}(i\omega)v\|^2 = 0,$$

and comparing the above with (3.17) proves (3.18). ∎

It is an interesting open question whether Lemma 3.13 is true for infinite-dimensional U and Y without the spectrum assumption.

We need the following property of the system $\Sigma(A, B, B^*L_C, 0)$ shown in Weiss and Weiss [31, Theorem 11.1] (see also Oostveen [21, Lemma 4.2.6]).

LEMMA 3.14. *If $\Sigma(A, B, C, D)$ is output stable and input-output stable with observability gramian L_C, then $\Sigma(A, -, B^*L_C, -)$ is output stable.*

By duality we obtain the following.

COROLLARY 3.15. *If $\Sigma(A, B, C, D)$ is input stable and input-output stable with controllability gramian L_B, then $\Sigma(A, L_BC^*, -, -)$ is input stable.*

Lemma 3.13 has an easy corollary.

COROLLARY 3.16. *Let $\Sigma(A, B, C, 0)$ be a system-stable state linear system and assume that either $\sigma(A) \cap i\mathbb{R}$ has measure zero or U and Y are finite-dimensional. Denote by $\widehat{\mathcal{B}}_{LB}(\bar{s})^*$ and $\widehat{\mathcal{C}}_{LC}(s)$ the holomorphic extensions to $\mathbb{C}_0^+$ of $CL_B(sI - A^*)^{-1}$ and $B^*L_C(sI - A)^{-1}$, respectively. Then for almost all $\omega \in \mathbb{R}$, all $u \in U$, and all nontangential paths*

$$\lim_{s \to i\omega} \text{Re } s \parallel L_C^{1/2} \widehat{\mathcal{B}}_{LB}(s)u \parallel^2 = 0, \tag{3.21}$$

$$\lim_{s \to i\omega} \text{Re } s \parallel L_B^{1/2} \widehat{\mathcal{C}}(\bar{s})^* y \parallel^2 = 0, \tag{3.22}$$

$$\lim_{s \to i\omega} \text{Re } s \parallel L_B^{1/2} \widehat{\mathcal{C}}_{LC}(\bar{s})^* y \parallel^2 = 0. \tag{3.23}$$

Proof. Equation (3.21) follows from Lemma 3.13, since by Lemma 3.15, $\Sigma(A, L_BC^*, C, 0)$ is input stable and output stable and has observability gramian L_C. Equation (3.22) is the dual of (3.18), and (3.23) is the dual of (3.21). □

4. Riccati equations. In this section we obtain some new results on stabilizability and Riccati equations for state linear systems that we will need in what follows. First we introduce concepts of stabilizability from Curtain [10] that are refinements of the definitions introduced in Curtain and Oostveen [7].

DEFINITION 4.1. $\Sigma(A, B, C, D)$ *is* output stabilizable *if there exists an $F \in \mathcal{L}(Z, U)$ such that $\Sigma(A + BF, B, [C; F], 0)$ is output stable.* $\Sigma(A, B, C, D)$ *is* input stabilizable *if there exists an $L \in \mathcal{L}(Y, Z)$ such that $\Sigma(A + LC, [B, L], C, 0)$ is input stable.*

The following are extensions of the results in Curtain and Oostveen [7]. In fact, they are special cases of analogous results for the very large class of well-posed linear systems in Mikkola [19]. Since the proofs there are not so accessible, we give simple proofs here.

THEOREM 4.2. *If the state linear system $\Sigma(A, B, C, 0)$ is output stabilizable, then there exists a smallest bounded nonnegative solution of the control Riccati equation for $z \in D(A)$:*

$$A^*Qz + QAz + C^*Cz - QBB^*Qz = 0. \tag{4.1}$$

Moreover, for any bounded nonnegative solution, $\Sigma(A_Q, B, [C; -B^*Q], 0)$ is output stable, where $A_Q = A - BB^*Q$. If, in addition, $\Sigma(A, B, C, 0)$ is input stabilizable, then it is system-stable. If $\Sigma(A, B, C, 0)$ is input stabilizable, then there exists a smallest bounded nonnegative solution to the filter Riccati equation for $z \in D(A^*)$:

$$APz + PA^*z - PC^*CPz + BB^*z = 0. \tag{4.2}$$

Moreover, for any bounded nonnegative solution, $\Sigma(A_P, [B, -PC^*], C, 0)$ *is input stable, where* $A_P = A - PC^*C$. *If, in addition,* $\Sigma(A, B, C, 0)$ *is output stabilizable, then it is system-stable.*

Proof. The existence of a smallest bounded nonnegative solution to the Riccati equation has been shown in Curtain and Oostveen [7]. In fact, it follows from [4, Theorem 6.2.4], since output stabilizability implies optimizability. Next we note that the output stability of $\Sigma(A_Q, B, [C; -B^*Q], 0)$ follows from the following equivalent formulation of the Riccati equation:

$$A_Q^*Qz + QA_Qz + QBB^*Qz + C^*Cz = 0 \quad \text{for} \quad z \in D(A). \tag{4.3}$$

This is the observability Lyapunov equation for $\Sigma(A_Q, B, [C; -B^*Q], 0)$, and Lemma 2.6 shows that it is output stable.

Next we observe that the input stabilizability guarantees the existence of a solution P to the dual filter Riccati equation (4.2). This in turn shows that the solutions to the Lyapunov equations of the system $\Sigma(A_Q, B, [C; -B^*Q], 0)$ are Q and $P(I+QP)^{-1}$ (we use the dual version of Lemma 9.4.10 in [4]). So this system is input stable (see Lemma 2.6). So, from Theorem 3.4, we can write the transfer function $[\mathbf{N}; \mathbf{M}]$ of the closed-loop system on $\mathbb{C}_0^+$ in two ways:

$$[\mathbf{N}; \mathbf{M}] - [0; I] = \widehat{\mathcal{C}}_Q B = [C; -B^*Q]\widehat{\mathcal{B}}_Q,$$

where $\widehat{\mathcal{C}}_Q z$ is the Laplace transform of $[C; -B^*Q]T_Q(t)z$, $\langle \widehat{\mathcal{B}}_Q u, z\rangle$ is the Laplace transform of $\langle T_Q(t)Bu, z\rangle$ for all $z \in Z$ and $u \in U$, and T_Q is the semigroup generated by A_Q. We use this latter version of $[\mathbf{N}; \mathbf{M}]$ to compute for $s \in \mathbb{C}_0^+$

$$\begin{aligned}&[\mathbf{N}(s); \mathbf{M}(s)]^*[\mathbf{N}(s); \mathbf{M}(s)] \\ &= \widehat{\mathcal{B}}_Q^*(s)[C^*C + QBB^*Q]\widehat{\mathcal{B}}_Q(s) + I - \widehat{\mathcal{B}}_Q^*(s)QB - B^*Q\widehat{\mathcal{B}}_Q(s).\end{aligned} \tag{4.4}$$

We then use the formulation (4.3) of the Riccati equation to obtain

$$C^*C + QBB^*Q = A_Q^*Q + QA_Q = (sI - A_Q)^*Q + Q(sI - A_Q) - 2\mathrm{Re}\ s\ Q.$$

We substitute this into (4.4) and use the equality (3.6) applied to the closed-loop system $\Sigma(A_Q, B, [C; -B^*Q], 0)$,

$$(s - A_Q)\widehat{\mathcal{B}}_Q(s) = B \quad \text{for} \quad s \in \mathbb{C}_0^+,$$

to obtain

$$[\mathbf{N}(s); \mathbf{M}(s)]^*[\mathbf{N}(s); \mathbf{M}(s)] = I - 2\mathrm{Re}\ s\ \widehat{\mathcal{B}}_Q^*(s)Q\widehat{\mathcal{B}}_Q(s). \tag{4.5}$$

This shows that $[\mathbf{N}(s); \mathbf{M}(s)]^*[\mathbf{N}(s); \mathbf{M}(s)] \leq I$ for all $s \in \mathbb{C}_0^+$. Thus $[\mathbf{N}; \mathbf{M}] \in \mathbf{H}_\infty(\mathcal{L}(U, Y \oplus U))$. ∎

We proceed to deduce some interesting properties of the spectrum of the closed-loop generators A_Q and A_P on the right half-plane.

LEMMA 4.3. *Suppose that the state linear system* $\Sigma(A, B, C, 0)$ *is input and output stabilizable. Then for any bounded nonnegative solutions* Q, P *to the Riccati equations* (4.1), (4.2)*, respectively, the closed-loop generators have the following properties:*

1. *The closed-loop operators* $A_Q = A - BB^*Q$ *and* $A_P = A - PC^*C$ *have the same spectrum and*

$$(I + PQ)A_Qz = A_P(I + PQ)z \quad \textit{for} \quad z \in D(A). \tag{4.6}$$

2. *Let Q_1, Q_2 be two bounded nonnegative solutions of* (4.1). *Then* $\sigma(A_{Q_1}) = \sigma(A_{Q_2})$.
3. *The spectra of the closed-loop generators A_Q and A_P in the closed right half-plane are contained in the spectrum of A.*

Proof. 1. First we prove (4.6). As in Curtain and Zwart [4, Lemma 4.1.24] we have

$$Q : D(A) \to D(A^*), \qquad P : D(A^*) \to D(A).$$

So using (4.3) we obtain for $z \in D(A)$

$$\begin{aligned}
&(I + PQ)A_Q z \\
&= A_Q z - P(A_Q^* Qz + QB^*BQ + CC)z \\
&= (A - PC^*C)z - BB^*Qz - PA^*Qz \\
&= A_P z - P(A_P^* + C^*CP)Qz - BB^*Qz \\
&= A_P z + (A_P P + BB^*)Qz - BBQz \ \text{ from (4.2)} \\
&= A_P(I + PQ)z.
\end{aligned}$$

Since P, Q are bounded nonnegative operators, $(I + PQ)$ is boundedly invertible and $\sigma(A_Q) = \sigma(A_P)$.

2. From part 1 it follows that $\sigma(A_{Q_1}) = \sigma(A_P) = \sigma(A_{Q_2})$.

3. Suppose that $\lambda \in \overline{\mathbb{C}_0^+}$ is in the point spectrum of A_Q; i.e., $A_Q x = \lambda x$ for some nonzero $x \in D(A)$. Then from (4.3) we obtain

$$\begin{aligned}
2\ \mathrm{Re}\lambda\langle Qx, x\rangle &= \langle A_Q x, Qx\rangle + \langle Qx, A_Q x\rangle \\
&= -\|B^*Qx\|^2 - \|Cx\|^2.
\end{aligned}$$

Since $Q \geq 0$ and $\mathrm{Re}\ \lambda \geq 0$ we must have $B^*Qx = 0 = Cx$, which implies that $\lambda x = A_Q x = Ax$. So λ is in the point spectrum of A. Suppose now that $\mu \in \overline{\mathbb{C}_0^+}$ is in the residual spectrum of A_Q. Then by (4.6) $\bar{\mu}$ is in $P\sigma(A_Q^*) = P\sigma(A_P^*)$ and so there exists a $y \in D(A^*)$ such that $A_P^* y = \overline{\mu} y$. Now (4.2) can be reformulated as

$$A_P Pz + PA_P^* z = -PC^*CPz - BB^*z, \tag{4.7}$$

and substituting $z = y$ and taking the inner product with y gives

$$\begin{aligned}
2\ \mathrm{Re}\mu\langle Py, y\rangle &= \langle A_P^* y, Py\rangle + \langle Py, A_P^* y\rangle \\
&= -\|B^*y\|^2 - \|CPy\|^2.
\end{aligned}$$

Since $\mathrm{Re}\ \mu \geq 0$ and $P \geq 0$, we must have $CPy = 0 = B^*y$, which implies that $\overline{\mu} y = A_P^* y = A^* y$ and so $\mu \in \sigma(A)$. Suppose now that $\lambda \in \overline{\mathbb{C}_0^+}$ is in the continuous spectrum of A_Q. Then there exists a sequence $x_n \in D(A)$ with $\|x_n\| = 1$ and $\|A_Q x_n - \lambda x_n\| \to 0$ as $n \to \infty$. Substituting in (4.3) we obtain

$$\begin{aligned}
&\langle A_Q x_n - \lambda x_n, Qx_n\rangle + \langle Qx_n, A_Q x_n - \lambda x_n\rangle \\
&= -\|B^*Qx_n\|^2 - \|Cx_n\|^2 - 2\ \mathrm{Re}\lambda\langle Qx_n, x_n\rangle.
\end{aligned}$$

Since $Q \geq 0$ and $\mathrm{Re}\ \lambda \geq 0$, we deduce that $\|B^*Qx_n\|^2 \leq 2\|Q\|\ \|x_n\|\ \|A_Q x_n - \lambda x_n\| \to 0$ as $n \to \infty$. Thus

$$\|Ax_n - \lambda x_n\| \leq \|A_Q x_n - \lambda x_n\| + \|BB^*Qx_n\| \to 0$$

as $n \to \infty$. So λ is in the approximate point spectrum of A. The above shows that $\rho(A_Q) \cap \overline{\mathbb{C}_0^+} \subset \rho(A) \cap \overline{\mathbb{C}_0^+}$. Since by part 1 we have $\rho(A_Q) = \rho(A_P)$ this proves the assertion. ∎

In [6] it was discovered that two interesting Riccati equations play a role in the solution to the Nehari problem.

THEOREM 4.4. *Let $\Sigma(A, B, C, 0)$ be input and output stable and let L_1, L_2 be arbitrary bounded nonnegative solutions to the Lyapunov equations* (2.1), (2.2)*, respectively. Let $\sigma > r^{\frac{1}{2}}(L_1L_2)$ and define $N_\sigma := (I - \sigma^{-2}L_1L_2)^{-1}$. Then*

1. *$W := N_\sigma L_1$ is a bounded nonnegative solution of the following Riccati equation for $z \in D(A^*)$:*

$$WA^*z + AWz - \sigma^{-2}WC^*CWz + N_\sigma BB^*N_\sigma^*z = 0; \tag{4.8}$$

2. *$X := L_2N_\sigma$ is a bounded nonnegative solution of the following Riccati equation for $z \in D(A)$:*

$$A^*Xz + XAz - \sigma^{-2}XBB^*Xz + N_\sigma^*C^*CN_\sigma z = 0; \tag{4.9}$$

3. *the closed-loop systems $\Sigma(A_W, [N_\sigma B; WC^*], C)$ and $\Sigma(A_X, B, [CN_\sigma; B^*X])$ are system-stable, where $A_W = A - \sigma^{-2}WC^*C$ and $A_X = A - \sigma^{-2}BB^*X$;*
4. *$\sigma(A_X) \cap \mathbb{C}_0^+ \subset \sigma(A) \cap \mathbb{C}_0^+$ and $\sigma(A_X) \cap i\mathbb{R} \subset \sigma(A) \cap i\mathbb{R}$ and the closed-loop generators are related by $A_X = N_\sigma^{-1}A_WN_\sigma$.*

Proof. 1. and 2. The proofs of Lemmas 4.1.24 and 8.3.2 in [4] show that $L_1D(A^*) \subset D(A)$, $L_2D(A) \subset D(A^*)$, $N_\sigma D(A) \subset D(A)$, and $N_\sigma^*D(A^*) \subset D(A^*)$. Thus $WD(A^*) \subset D(A)$ and $XD(A) \subset D(A^*)$. That W satisfies (4.8) and X satisfies (4.9) can be readily verified algebraically.

3. The conclusions about the stability of the closed-loop systems then follow from Theorem 4.2, noting that $\Sigma(A, 1/\sigma B, CN_\sigma)$ is input stable and output stabilizable (with $F = -1/\sigma B^*X$) and that $\Sigma(A, N_\sigma B, 1/\sigma C)$ is output stable and input stabilizable (with $L = -1/\sigma WC^*$).

4. Theorem 4.3 shows that $\sigma(A_X) \cap \mathbb{C}_0^+ \subset \sigma(A) \cap \mathbb{C}_0^+$ and $\sigma(A_X) \cap i\mathbb{R} \subset \sigma(A) \cap i\mathbb{R}$. To relate A_X and A_W consider

$$\begin{aligned} A_XN_\sigma^{-1} &= A(I - \sigma^{-2}L_1L_2) - \sigma^{-2}BB^*L_2 \\ &= A - \sigma^{-2}(AL_1 + BB^*)L_2 \\ &= A + \sigma^{-2}L_1A^*L_2 \\ &= A - \sigma^{-2}L_1(L_2A + C^*C) \\ &= (I - \sigma^{-2}L_1L_2)A - \sigma^{-2}L_1C^*C \\ &= N_\sigma^{-1}A_W. \end{aligned}$$ ∎

5. The spectral factor. As in [4] and [6] we shall approach the solution of the Nehari problem for the input and output stable state linear system $\Sigma(A, B, C, 0)$ with transfer function $\mathbf{G}$ by solving the following J-spectral factorization problem: find $\mathbf{X}$ such that

$$\mathbf{P}(i\omega)^*J_\sigma\mathbf{P}(i\omega) = \mathbf{X}(i\omega)J_1\mathbf{X}(i\omega)^* \quad \text{for almost all} \quad \omega \in \mathbb{R}, \tag{5.1}$$

where

$$\mathbf{P}(s) = \begin{bmatrix} I_Y & \mathbf{G}(s) \\ 0 & I_U \end{bmatrix} \quad \text{and} \quad J_\sigma = \begin{bmatrix} I_Y & 0 \\ 0 & -\sigma^2 I_U \end{bmatrix}.$$

Here we introduce the candidate solution and give some properties. Let L_1 and L_2 be arbitrary bounded nonnegative solutions of the controllability and observability Lyapunov equations, respectively. For $\sigma > r^{\frac{1}{2}}(L_1L_2)$ we define $N_\sigma = (I-\sigma^{-2}L_1L_2)^{-1}$ and we introduce the state linear system

$$\Sigma\left(A, \sigma^{-2}N_\sigma \begin{pmatrix} L_1C^* & -\sigma B \end{pmatrix}, \begin{bmatrix} C \\ B^*L_2 \end{bmatrix}, \begin{bmatrix} I_Y & 0 \\ 0 & \sigma I_U \end{bmatrix}\right). \tag{5.2}$$

We denote the characteristic function of the state linear system (5.2) by $\mathfrak{X}$ and its transfer function by $\mathbf{X}$ and we prove the following lemma.

LEMMA 5.1. *Let*

$$\mathfrak{P}(s) = \begin{bmatrix} I_Y & \mathfrak{G}(s) \\ 0 & I_U \end{bmatrix}.$$

Then $\mathfrak{R}(s) = \mathfrak{P}(s)^* J_\sigma \mathfrak{P}(s) - \mathfrak{X}(s) J_1 \mathfrak{X}(s)^*$ *satisfies the following for* $s \in \rho(A)$*:*

$$\begin{aligned}
\mathfrak{R}(s)_{11} &= -2\sigma^{-2}\mathrm{Re}\ sC(sI-A)^{-1}N_\sigma L_1(sI-A)^{-*}C^*, \\
\mathfrak{R}(s)_{12} &= -2\sigma^{-2}\mathrm{Re}\ sC(sI-A)^{-1}N_\sigma L_1(sI-A)^{-*}L_2B, \\
\mathfrak{R}(s)_{21} &= \mathfrak{R}(s)_{12}^*, \\
\mathfrak{R}(s)_{22} &= -2\mathrm{Re}\ sB^*(sI-A)^{-*}L_2(sI-A)^{-1}B \\
&\qquad -2\sigma^{-2}\mathrm{Re}\ sB^*L_2(sI-A)^{-1}N_\sigma L_1(sI-A)^{-*}L_2B.
\end{aligned}$$

Proof. We only prove the formula for $\mathfrak{R}(s)_{11}$; the proof for the other components is similar. We have on some right half-plane

$$\begin{aligned}
\mathfrak{R}(s)_{11} &= I - \mathfrak{X}_{11}(s)\mathfrak{X}_{11}(s)^* + \mathfrak{X}_{12}(s)\mathfrak{X}_{12}(s)^* \\
&= -\sigma^{-4}C(sI-A)^{-1}WC^*CW(sI-A)^{-*}C^* \\
&\quad +\sigma^{-2}C(sI-A)^{-1}N_\sigma BB^*N_\sigma^*(sI-A)^{-*}C^* \\
&\quad -\sigma^{-2}C(sI-A)^{-1}WC^* - \sigma^{-2}CW(sI-A)^{-*}C \\
&= \sigma^{-2}C(sI-A)^{-1}\left(-\sigma^{-2}WC^*CW + N_\sigma BB^*N_\sigma^*\right)(sI-A)^{-*}C^* \\
&\quad -\sigma^{-2}C(sI-A)^{-1}WC^* - \sigma^{-2}CW(sI-A)^{-*}C.
\end{aligned}$$

Using (4.8) we obtain

$$\begin{aligned}
\mathfrak{R}(s)_{11} &= \sigma^{-2}C(sI-A)^{-1}\left(-WA^* - AW\right)(sI-A)^{-*}C^* \\
&\quad -\sigma^{-2}C(sI-A)^{-1}WC^* - \sigma^{-2}CW(sI-A)^{-*}C \\
&= \sigma^{-2}C(sI-A)^{-1}\left(W(sI-A)^* + (sI-A)W - 2\mathrm{Re}\ s\ W\right)(sI-A)^{-*}C^* \\
&\quad -\sigma^{-2}C(sI-A)^{-1}WC^* - \sigma^{-2}CW(sI-A)^{-*}C \\
&= -2\sigma^{-2}\mathrm{Re}\ s\ C(sI-A)^{-1}N_\sigma L_1(sI-A)^{-*}C^*. \qquad \square
\end{aligned}$$

It is clear from the above that if $\sigma(A) \cap i\mathbb{R}$ has measure zero and L_1, L_2 are an arbitrary pair of solutions to the Lyapunov equations, then $\mathfrak{X}$ is a solution to (5.1). If, in addition, (5.2) is input or output stable, then it follows from Lemma 3.5 that $\mathbf{X}$ is a solution to (5.1). The following example shows that in general $\mathbf{X}$ need not provide a spectral factor.

Example 5.2. We consider an example from Curtain and Sasane [8] (see also Sasane [28]). The transfer function $\mathbf{G}_0(s) = \frac{1}{\sqrt{s^2+1}}$ was shown to have a realization

$\Sigma(A, B, B^*, 0)$ on the state space $\ell_2(\mathbb{Z})$, where $A \in \mathcal{L}(\ell_2(\mathbb{Z}))$ and $B \in \ell_2(\mathbb{Z})$ are given by

$$A_{i,i+1} = -1/2,\ A_{i+1,i} = 1/2,\ A_{i,j} = 0 \ \text{ otherwise},$$
$$B_0 = 1,\ B_i = 0 \ \text{ otherwise}.$$

The spectrum of A is purely continuous and equals $[-i, i]$. The closed-loop system $\Sigma(A - BB^*, B, B^*, 0)$ is system-stable with the transfer function $\mathbf{G}(s) = \frac{1}{1+\sqrt{s^2+1}}$. It is continuous on the imaginary axis and it satisfies

$$\mathbf{G}(i\omega) + \mathbf{G}(i\omega)^* = 2\mathbf{G}(i\omega)^*\mathbf{G}(i\omega) \ \text{ for } \ |\omega| > 1, \tag{5.3}$$

$$\mathbf{G}(i\omega) = \mathbf{G}(i\omega)^* = \frac{1}{1+\sqrt{1-\omega^2}} \ \text{ for } \ |\omega| < 1. \tag{5.4}$$

The Lyapunov equations have solutions $L_1 = L_2 = 1/2\ I$, but note that it is known from [28] that these are not the observability or controllability gramians. The advantage of using these solutions is that the calculations are simple. In this specific case the state linear system (5.2) is

$$\Sigma\left(A - BB^*, \sigma^{-2}N_\sigma \begin{bmatrix} B/2 & -\sigma B \end{bmatrix}, \begin{bmatrix} B^* \\ B^*/2 \end{bmatrix}, \begin{bmatrix} 1 & 0 \\ 0 & \sigma \end{bmatrix}\right).$$

An easy calculation shows that for $s \in \rho(A - BB^*) = \rho(A) = \mathbb{C} - [-1, 1]$ we have

$$\mathfrak{X}(s) = \begin{bmatrix} 1 & 0 \\ 0 & \sigma \end{bmatrix} + \alpha \begin{bmatrix} 2 & -4\sigma \\ 1 & -2\sigma \end{bmatrix} \mathfrak{G}(s),$$

where $\alpha = \frac{1}{4\sigma^2-1}$. This, together with the stability properties of the state linear systems and Lemma 3.5, shows that we have for almost all $\omega \in \mathbb{R}$

$$\mathbf{X}(i\omega) = \begin{bmatrix} 1 & 0 \\ 0 & \sigma \end{bmatrix} + \alpha \begin{bmatrix} 2 & -4\sigma \\ 1 & -2\sigma \end{bmatrix} \mathbf{G}(i\omega).$$

It is now easily shown using (5.3) that (5.1) holds for $|\omega| > 1$ and using (5.4) that (5.1) does not hold for $|\omega| < 1$.

If we choose the smallest bounded nonnegative solutions to the Lyapunov equations we obtain stronger properties of the candidate spectral factor.

LEMMA 5.3. *If $\Sigma(A, B, C, 0)$ is output and input-output stable and $L_2 = L_C$, the observability gramian of the system $\Sigma(A, B, C, 0)$, then (5.2) is output stable.*

Proof. This follows from Lemma 3.14. ∎

LEMMA 5.4. *If $\Sigma(A, B, C, 0)$ is system-stable and either $\sigma(A) \cap i\mathbb{R}$ has measure zero or U and Y are finite-dimensional, and $L_1 = L_B$ and $L_2 = L_C$, where L_B, L_C are the controllability and observability gramians of the system $\Sigma(A, B, C, 0)$, respectively, then $\mathbf{X}$ satisfies (5.1).*

Proof. It follows from Lemma 5.1 that on some right half-plane

$$\left\langle \mathfrak{R}(s) \begin{bmatrix} y \\ u \end{bmatrix}, \begin{bmatrix} y \\ u \end{bmatrix} \right\rangle = -\frac{2}{\sigma^2} \mathrm{Re}\ s \left(\|\alpha(s)y + \beta(s)u\|^2 + \sigma^2 \|\gamma(s)u\|^2 \right), \tag{5.5}$$

where $\mathfrak{R}$ is as in Lemma 5.1 and

$$\alpha(s) = M_\sigma L_B^{1/2}(sI - A)^{-*}C^*, \quad \beta(s) = M_\sigma L_B^{1/2}(sI - A)^{-*}L_C B,$$
$$\gamma(s) = L_C^{1/2}(sI - A)^{-1}B, \qquad M_\sigma = (I - \frac{1}{\sigma^2} L_B^{1/2} L_C L_B^{1/2})^{-1/2}.$$

From the stability properties we can replace α, β, and γ in (5.5) by their holomorphic extensions (Lemmas 3.4 and 3.14). Then as in Lemma 3.12, using the real-analyticity property, it follows that the resulting equalities hold on $\mathbb{C}_0^+$.

Using Lemma 3.13 and Corollary 3.16 we see that the right-hand side of (5.5) converges to zero as $\operatorname{Re} s \to 0$ (here α, β, and γ are replaced by their holomorphic extensions). From this we obtain the J-spectral factorization (5.1). □

In the remainder of this section we collect some properties of the spectral factor described by (5.2) and of its inverse system

$$\Sigma\left(A, \sigma^{-2}\begin{bmatrix} -L_1C^* & B \end{bmatrix}, \begin{bmatrix} C \\ \sigma^{-1}B^*L_2 \end{bmatrix} N_\sigma, \begin{bmatrix} I_Y & 0 \\ 0 & \sigma^{-1}I_U \end{bmatrix}\right). \tag{5.6}$$

We denote the characteristic function of the state linear system (5.6) by $\mathfrak{V}$ and its transfer function by $\mathbf{V}$. It is the inverse of $\mathfrak{X}$ in the following sense.

LEMMA 5.5. *Assume that $\Sigma(A, B, C, 0)$ is input and output stable. Then for $s \in \rho(A)$ we have $\mathfrak{V}(s)\mathfrak{X}(s) = I = \mathfrak{X}(s)\mathfrak{V}(s)$.*

Proof. This follows from a straightforward calculation. □

LEMMA 5.6. *Assume that $\Sigma(A, B, C, 0)$ is system-stable and that $L_1 = L_B$, the controllability gramian of the system $\Sigma(A, B, C, 0)$. Then (5.6) is input stable.*

Proof. This follows from Corollary 3.15. □

LEMMA 5.7. *Assume that $\Sigma(A, B, C, 0)$ is system-stable and that $L_1 = L_B$ and $L_2 = L_C$, the controllability and observability gramians of the system $\Sigma(A, B, C, 0)$, respectively. Then $\mathbf{V}(s)\mathbf{X}(s) = I = \mathbf{X}(s)\mathbf{V}(s)$ for all $s \in \mathbb{C}_0^+$.*

Proof. From Lemmas 3.4, 5.3, 5.5, and 5.6 we have $\mathbf{V}(s)\mathbf{X}(s) = I = \mathbf{X}(s)\mathbf{V}(s)$ for all $s \in \mathbb{C}_0^+ \cap \rho(A)$. From Lemmas 5.3 and 5.6 both $\mathbf{X}$ and $\mathbf{V}$ are holomorphic on $\mathbb{C}_0^+$ and so the equality extends to this domain. □

LEMMA 5.8. *Assume that $\Sigma(A, B, C, 0)$ is system-stable and that $L_1 = L_B$ and $L_2 = L_C$, the controllability and observability gramians of the system $\Sigma(A, B, C, 0)$, respectively. If either $\sigma(A) \cap i\mathbb{R}$ has measure zero or U and Y are finite-dimensional, then $\mathbf{V}(i\omega)\mathbf{X}(i\omega) = I = \mathbf{X}(i\omega)\mathbf{V}(i\omega)$ for almost all $\omega \in \mathbb{R}$.*

Proof. This follows from Lemmas 5.3, 5.6, 5.7, and 3.5. □

The (2,2) component of $\mathfrak{V}$ plays a special role in what follows, and we need the following extra properties.

LEMMA 5.9. *Assume that $\Sigma(A, B, C, 0)$ is input and output stable. Then the system $\Sigma(A, \sigma^{-2}B, \sigma^{-1}B^*X, \sigma^{-1}I)$ is input stable, and its characteristic function $\mathfrak{V}_{22}(s)$ is invertible for $s \in \rho(A) \cap \rho(A_X)$. Its inverse is the characteristic function of the system-stable state linear system*

$$\Sigma(A_X, B, -\sigma^{-1}B^*X, \sigma I), \quad \text{with} \quad X = L_2N_\sigma. \tag{5.7}$$

Moreover, the transfer function $\mathbf{V}_{22}(s)$ is invertible for $s \in \mathbb{C}_0^+$, and its inverse is the transfer function of (5.7).

Proof. The input stability follows from that of $\Sigma(A, B, C, 0)$. The invertibility of the characteristic function $\mathfrak{V}_{22}$ is a simple calculation, and the stability property of (5.7) follows from Theorem 4.4. The invertibility of the transfer function follows as in Lemma 5.7. □

LEMMA 5.10. *Assume that $\Sigma(A, B, C, 0)$ is input and output stable and that either $\sigma(A) \cap i\mathbb{R}$ has measure zero or U and Y are finite-dimensional. Then the boundary function of $\mathbf{V}_{22}$ is almost everywhere invertible, and its inverse is the boundary function of the transfer function of (5.7).*

Proof. This follows from Lemmas 5.9 and 3.5. □

Dual results for $\mathfrak{X}_{11}(s)$ can be proved similarly.

COROLLARY 5.11. *Assume that $\Sigma(A,B,C,0)$ is input and output stable. Then the system $\Sigma(A,\sigma^{-2}WC^*,C,I)$ is output stable, and its characteristic function $\mathfrak{X}_{11}(s)$ is invertible for $s\in\rho(A)\cap\rho(A_W)$. Its inverse is the characteristic function of the system-stable state linear system*

$$\Sigma(A_W,-\sigma^{-2}WC^*,C,I),\quad \textit{with}\ \ W=N_\sigma L_1. \tag{5.8}$$

Moreover, the transfer function $\mathbf{X}_{11}(s)$ is invertible for $s\in\mathbb{C}_0^+$, and its inverse is the transfer function of (5.8).

COROLLARY 5.12. *Assume that $\Sigma(A,B,C,0)$ is input and output stable and that either $\sigma(A)\cap i\mathbb{R}$ has measure zero or U and Y are finite-dimensional. Then the boundary function of $\mathbf{X}_{11}$ is almost everywhere invertible, and its inverse is the boundary function of the transfer function of* (5.8).

6. The central solution. We introduce the following state linear system

$$\Sigma(A_W^*,L_2B,-\sigma^{-2}CW,0), \tag{6.1}$$

where W is as in Theorem 4.4. We denote its characteristic function by $\mathfrak{Z}$ and its transfer function by $\mathbf{Z}$. The candidate solution to the Nehari problem is given by $\mathbf{K}_c(-s)=\mathbf{Z}(s)$. The state linear system (6.1) has the following properties.

LEMMA 6.1. *If $\Sigma(A,B,C,0)$ is input and output stable, then the following hold:*

1. *The state linear system* (6.1) *is output stable.*
2. *The characteristic functions of the state linear system* (6.1) *and of the state linear system $\Sigma(A_X^*,-\sigma^{-2}XB,CL_1,0)$ coincide.*
3. *The state linear system $\Sigma(A_X^*,-\sigma^{-2}XB,CL_1,0)$ is input stable.*
4. *For $s\in\rho(A^*)\cap\rho(A_W^*)$ we have $\mathfrak{Z}(s)=\mathfrak{V}_{21}(\bar{s})^*\mathfrak{V}_{22}^{-1}(\bar{s})^*$.*

Proof. 1. This follows from Theorem 4.4, part 3.

2. This is an easy calculation using Theorem 4.4, part 4.
3. This follows from Theorem 4.4, part 3.
4. This is a simple calculation. □

The above shows that we have one realization of $\mathbf{Z}$ that is output stable and another that is input stable. We now show that $\mathbf{Z}$ is in $\mathbf{H}_\infty$ under the assumption A1.

THEOREM 6.2. *If $\Sigma(A,B,C,0)$ is system-stable and $\sigma(A)\cap i\mathbb{R}$ has measure zero, then $\mathbf{Z}\in\mathbf{H}_\infty(\mathcal{L}(U,Y))$ and with $\mathbf{K}_c(-s)=\mathbf{Z}(s)$ we have*

$$\|\mathbf{G}+\mathbf{K}_c\|_\infty\le\sigma.$$

Proof. It follows from Lemma 6.1, part 4, and Theorem 4.4, part 4, that for almost all $\omega\in\mathbb{R}$ we have

$$\mathfrak{K}_c(i\omega)=\mathfrak{V}_{21}(i\omega)^*\mathfrak{V}_{22}(i\omega)^{-*}. \tag{6.2}$$

From Lemma 5.1 we see that for almost all $\omega\in\mathbb{R}$ we have

$$\mathfrak{P}(i\omega)^*J_\sigma\mathfrak{P}(i\omega)=\mathfrak{X}(i\omega)J_1\mathfrak{X}(i\omega)^*. \tag{6.3}$$

From (6.2) we obtain for almost all $\omega\in\mathbb{R}$

$$\begin{bmatrix}\mathfrak{G}(i\omega)+\mathfrak{K}_c(i\omega)\\ I\end{bmatrix}=\mathfrak{P}(i\omega)\mathfrak{V}(i\omega)^*\begin{bmatrix}0\\ \mathfrak{V}_{22}(i\omega)^{-*}\end{bmatrix}.$$

So

$$
\begin{aligned}
&(\mathfrak{G}(i\omega)+\mathfrak{K}_c(i\omega))^*(\mathfrak{G}(\mathrm{i}\omega)+\mathfrak{K}_{\mathfrak{c}}(\mathrm{i}\omega))-\sigma^2 I\\
&=\begin{bmatrix}\mathfrak{G}(\mathrm{i}\omega)+\mathfrak{K}_{\mathfrak{c}}(\mathrm{i}\omega)\\ I\end{bmatrix}^* J_\sigma \begin{bmatrix}\mathfrak{G}(\mathrm{i}\omega)+\mathfrak{K}_{\mathfrak{c}}(\mathrm{i}\omega)\\ I\end{bmatrix}\\
&=\begin{bmatrix}0\\ \mathfrak{V}_{22}(i\omega)^{-*}\end{bmatrix}^* \mathfrak{V}(i\omega)\mathfrak{P}(i\omega)^* J_\sigma \mathfrak{P}(i\omega)\mathfrak{V}(i\omega)^* \begin{bmatrix}0\\ \mathfrak{V}_{22}(i\omega)^{-*}\end{bmatrix}\\
&=\begin{bmatrix}0\\ \mathfrak{V}_{22}(i\omega)^{-*}\end{bmatrix}^* \begin{bmatrix}I & 0\\ 0 & -I\end{bmatrix} \begin{bmatrix}0\\ \mathfrak{V}_{22}(i\omega)^{-*}\end{bmatrix}, \qquad (6.4)
\end{aligned}
$$

where in the last step we have used the spectral factorization (6.3). The above shows that

$$\|\mathfrak{G}(i\omega)+\mathfrak{K}_c(i\omega)\|^2-\sigma^2=-\|\mathfrak{V}_{22}(i\omega)^{-*}\|^2,$$

and so for almost all $\omega\in\mathbb{R}$

$$\|\mathfrak{G}(i\omega)+\mathfrak{K}_c(i\omega)\|\le\sigma,$$

which implies that $\mathfrak{G}+\mathfrak{K}_c\in\mathbf{L}_\infty(i\mathbb{R};\mathcal{L}(U,Y))$. Since $\mathbf{G}\in\mathbf{H}_\infty(\mathcal{L}(U,Y))$ and by Lemma 3.5 $\mathfrak{G}$ coincides almost everywhere with the boundary function of $\mathbf{G}$ on the imaginary axis, we have $\mathfrak{G}\in\mathbf{L}_\infty(i\mathbb{R};\mathcal{L}(U,Y))$ and thus $\mathfrak{K}_c\in\mathbf{L}_\infty(i\mathbb{R};\mathcal{L}(U,Y))$. From this it follows that $\mathfrak{Z}\in\mathbf{L}_\infty(i\mathbb{R};\mathcal{L}(U,Y))$. This, together with the output stability of the state linear system (6.1) from Lemma 6.1 using Lemmas 3.5 and 3.6, shows that $\mathbf{Z}\in\mathbf{H}_\infty(\mathcal{L}(U,Y))$. Thus with $\mathbf{K}_c(-s)=\mathbf{Z}(s)$ we obtain $\|\mathbf{G}+\mathbf{K}_c\|_\infty\le\sigma$. ∎

Our main result in this section is to show that under assumption A2, $\mathbf{Z}\in\mathbf{H}_\infty$ and $\mathbf{K}_c$ solves the suboptimal Nehari problem.

THEOREM 6.3. *Assume that $\Sigma(A,B,C,0)$ is system-stable and that $L_1=L_B$ and $L_2=L_C$, the controllability and observability gramians of the system $\Sigma(A,B,C,0)$, respectively, and that U and Y are finite-dimensional. Then $\mathbf{Z}\in\mathbf{H}_\infty(\mathcal{L}(U,Y))$ and with $\mathbf{K}_c(-s)=\mathbf{Z}(s)$ we have*

$$\|\mathbf{G}+\mathbf{K}_c\|_\infty\le\sigma.$$

Proof. The idea is to follow the lines of the proof of Theorem 6.2, replacing the characteristic functions by their corresponding transfer functions. So all we need to show is that the following two key properties hold for almost all $\omega\in\mathbb{R}$:

$$\mathbf{Z}(i\omega)=\mathbf{V}_{21}(-i\omega)^*\mathbf{V}_{22}^{-1}(-i\omega)^*, \qquad (6.5)$$

$$\mathbf{P}(i\omega)^*J_\sigma\mathbf{P}(i\omega)=\mathbf{X}(i\omega)J_1\mathbf{X}(i\omega)^*. \qquad (6.6)$$

Since (6.6) has already been shown in Lemma 5.4, it remains to show only (6.5). By Lemma 6.1, part 4, on some right half-plane we have $\mathbf{Z}(s)=\mathbf{V}_{21}(\bar{s})^*\mathbf{V}_{22}^{-1}(\bar{s})^*$. Using Lemma 6.1, part 1, Lemma 5.6, and Lemma 5.9 this equality holds on $\mathbb{C}_0^+$ (all functions are holomorphic on $\mathbb{C}_0^+$). Lemmas 3.5 and 5.10 now give (6.5). ∎

Under assumption A2 we can show that $\mathbf{Z}$ has a realization as a system-stable state linear system.

COROLLARY 6.4. *Assume that $\Sigma(A,B,C,0)$ is system-stable and that $L_1=L_B$ and $L_2=L_C$, the controllability and observability gramians of the system $\Sigma(A,B,C,0)$,*

respectively, and that U and Y are finite-dimensional. Then $\Sigma(A_W^*, L_2B, -\sigma^{-2}CW, 0)$ and $\Sigma(A_X^*, -\sigma^{-2}XB, CL_1, 0)$ are system-stable state linear systems.

Proof. We have already shown in Lemma 6.1 and Theorem 6.3 that $\Sigma(A_W^*, L_CB, -\sigma^{-2}CW, 0)$ is output and input-output stable. The input stability follows from the identity

$$B^*L_C(sI - A_W)^{-1} = B^*L_C(sI - A)^{-1} - \sigma^{-2}B^*L_C(sI - A_W)^{-1}WC^*C(sI - A)^{-1}$$

and the fact $B^*L_C(sI-A)^{-1}z \in \mathbf{H}_2(Y)$ (Lemma 3.14), that $B^*L_C(sI-A_W)^{-1}WC^* \in \mathbf{H}_\infty(\mathcal{L}(Y,U))$ (the input-output stability shown earlier), and that $C(sI - A)^{-1}z \in \mathbf{H}_2(Y)$ for all $z \in Z$. The proof for the other realization is similar. ∎

7. Parametrization of solutions. First we give a parameterization of a family of solutions to the Nehari problem in terms of the transfer function of (5.6) and an $\mathbf{H}_\infty$ parameter under assumption A2.

THEOREM 7.1. *Let $\Sigma(A, B, C, 0)$ be system-stable with transfer function $\mathbf{G}$ and let L_B and L_C be the controllability and observability gramians, respectively. Assume that U and Y are finite-dimensional. For $\sigma > r^{\frac{1}{2}}(L_BL_C)$ define*

$$\begin{bmatrix} \mathbf{R}_1(s) \\ \mathbf{R}_2(s) \end{bmatrix} = \mathbf{V}(\bar{s})^* \begin{bmatrix} \mathbf{Q}(-s) \\ I_U \end{bmatrix}, \tag{7.1}$$

where $\mathbf{Q}(-s) \in \mathbf{H}_\infty(\mathcal{L}(U,Y))$. If $\|\mathbf{Q}\|_\infty \le 1$, then $\mathbf{K}(-s) = \mathbf{R}_1(s)\mathbf{R}_2(s)^{-1} \in \mathbf{H}_\infty(\mathcal{L}(U,Y))$ and satisfies

$$\|\mathbf{K} + \mathbf{G}\|_\infty \le \sigma.$$

We prove this in a series of lemmas.

LEMMA 7.2. *Under the assumptions of Theorem 7.1 we have the following. For all $s \in \mathbb{C}_0^+$ and almost all $s \in i\mathbb{R}$ we have $\|\mathbf{V}_{12}(s)\mathbf{V}_{22}^{-1}(s)\| < 1$.*

Proof. Consider the state linear system $\Sigma(A, \sigma^{-1}B, CN_\sigma, 0)$, and denote its transfer function by $\mathbf{E}$. The control Riccati equation (4.1) corresponding to this system is precisely (4.9). From the proof of Theorem 4.2, specifically by (4.5), we have $\|[\mathbf{N}; \mathbf{M}]\|_\infty \le 1$, where $[\mathbf{N}; \mathbf{M}]$ is the transfer function of the closed-loop system $\Sigma(A_X, \sigma^{-1}B, [CN_\sigma, -\sigma^{-1}B^*X], [0; I])$. It is easily calculated that $\mathbf{V}_{12}(s)\mathbf{V}_{22}^{-1}(s) = \mathbf{N}(s)$. It also easily seen that $\mathbf{N}(s) = \mathbf{E}(s)\mathbf{M}(s)$ on some right half-plane. By stability this extends to the right half-plane and by taking nontangential limits to almost everywhere on the imaginary axis.

From the above inequality we obtain for almost all $\omega \in \mathbb{R}$ that $\|\mathbf{N}(i\omega)\| \le 1$. We show that, in fact, strict inequality holds. Suppose, on the contrary, that $\|\mathbf{N}(i\omega_0)\| = 1$. Then there would exist a sequence u_n with norm one such that $\|\mathbf{N}(i\omega_0)u_n\| \to 1$. From the above $\mathbf{H}_\infty$ bound we conclude that $\|\mathbf{M}(i\omega_0)u_n\| \to 0$. Since for almost all $\omega \in \mathbb{R}$ we have $\mathbf{N}(i\omega) = \mathbf{E}(i\omega)\mathbf{M}(i\omega)$, we obtain $\|\mathbf{N}(i\omega_0)u_n\| \to 0$. This gives the desired contradiction.

We now extend this inequality to $s \in \mathbb{C}_0^+$. From the above we know that $\|\mathbf{V}_{12}\mathbf{V}_{22}^{-1}\|_\infty = \|\mathbf{N}\|_\infty \le 1$. Suppose that there exists a point $s_0 \in \mathbb{C}_0^+$ such that $\|\mathbf{V}_{12}(s_0)\mathbf{V}_{22}^{-1}(s_0)\| = 1$. Then $\|\mathbf{V}_{12}(s)\mathbf{V}_{22}^{-1}(s)\|$ has a maximum in $\mathbb{C}_0^+$ and is therefore constant by the maximum modulus principle; see, e.g., [17, Theorem 3.13.1, p. 100]. This implies that $\|\mathbf{V}_{12}(s)\mathbf{V}_{22}^{-1}(s)\| = 1$ for all $s \in \mathbb{C}_0^+$. But then the boundary function would have norm one almost everywhere, and we have shown that this is not true. ∎

The next lemma ensures that $\mathbf{K}$ is well defined.

LEMMA 7.3. *Under the assumptions of Theorem* 7.1, $\mathbf{R}_2(s)$ *is invertible for all* $s \in \mathbb{C}_0^+$ *and almost all* $s \in i\mathbb{R}$.

Proof. Define $\mathbf{P}(s) := \mathbf{Q}(-\bar{s})^*$. Then $\mathbf{P} \in \mathbf{H}_\infty(\mathcal{L}(U,Y))$, and $\|\mathbf{P}\|_\infty \le 1$. Next, using Lemma 7.2 we obtain $\|\mathbf{P}(s)\mathbf{V}_{12}(s)\mathbf{V}_{22}^{-1}(s)\| < 1$. From this we see that $(I + \mathbf{P}(s)\mathbf{V}_{12}(s)\mathbf{V}_{22}^{-1}(s))^{-1} = \mathbf{V}_{22}(s)(\mathbf{V}_{22}(s) + \mathbf{P}(s)\mathbf{V}_{12}(s))^{-1}$ exists. Hence $\mathbf{T} := (\mathbf{V}_{22} + \mathbf{P}\mathbf{V}_{12})^{-1}$ exists. Since we have $\mathbf{R}_2(s)^{-1} = \mathbf{T}(\bar{s})^*$ we have that $\mathbf{R}_2(s)^{-1}$ exists. ∎

Next we prove Theorem 7.1 under the assumption $\|\mathbf{Q}\|_\infty < 1$.

LEMMA 7.4. *Theorem* 7.1 *is true for all* $\mathbf{Q}(-s) \in \mathbf{H}_\infty(\mathcal{L}(U,Y))$ *with* $\|\mathbf{Q}\|_\infty < 1$.

Proof. We show that $\mathbf{R}_2^{-1} \in \mathbf{H}_\infty(\mathcal{L}(U))$. This follows as the proof of Lemma 7.3 using that $\mathbf{H}_\infty$ is a Banach algebra: from $\|\mathbf{P}\mathbf{V}_{12}\mathbf{V}_{22}^{-1}\|_\infty < 1$ we conclude that $(I + \mathbf{P}\mathbf{V}_{12}\mathbf{V}_{22}^{-1})^{-1} \in \mathbf{H}_\infty$, and using that $\mathbf{V}_{22}^{-1} \in \mathbf{H}_\infty$ by Lemma 5.9 it follows that $\mathbf{R}_2^{-1} \in \mathbf{H}_\infty(\mathcal{L}(U))$.

$\mathbf{K}(-s) := \mathbf{R}_1(s)\mathbf{R}_2(s)^{-1}$ defines an $\mathbf{L}_\infty$ function which satisfies $\|\mathbf{G} + \mathbf{K}\|_\infty \le \sigma$. The proof is similar to that of Theorem 6.2.

Last we show that $\mathbf{K}(-s) \in \mathbf{H}_\infty(\mathcal{L}(U,Y))$.

Since for all $s \in \mathbb{C}_0^+$ we have $\mathbf{V}(s)\mathbf{X}(s) = I$, we obtain

$$\mathbf{X}_{11}(s)\mathbf{V}_{11}(s) + \mathbf{X}_{12}(s)\mathbf{V}_{21}(s) = I$$

and

$$\mathbf{X}_{11}(s)\mathbf{V}_{12}(s) + \mathbf{X}_{12}(s)\mathbf{V}_{22}(s) = 0,$$

from which we obtain

$$\mathbf{V}_{11}(s) = \mathbf{X}_{11}(s)^{-1} + \mathbf{V}_{12}(s)\mathbf{V}_{22}(s)^{-1}\mathbf{V}_{21}(s).$$

So

$$\begin{aligned}
\mathbf{R}_1(s) &= \mathbf{V}_{21}(\bar{s})^* + \mathbf{V}_{11}(\bar{s})^*\mathbf{Q}(-s) \\
&= \mathbf{X}_{11}(\bar{s})^{-*}\mathbf{Q}(-s) + \mathbf{V}_{21}(\bar{s})^*(I + \mathbf{V}_{22}(\bar{s})^{-*}\mathbf{V}_{12}(\bar{s})^*\mathbf{Q}(-s)) \\
&= \mathbf{X}_{11}(\bar{s})^{-*}\mathbf{Q}(-s) + \mathbf{V}_{21}(\bar{s})^*\mathbf{V}_{22}(\bar{s})^{-*}\mathbf{R}_2(s) \\
&= \mathbf{X}_{11}(\bar{s})^{-*}\mathbf{Q}(-s) + \mathbf{K}_c(-s)\mathbf{R}_2(s),
\end{aligned}$$

and so

$$\mathbf{K}(-s) = \mathbf{X}_{11}(\bar{s})^{-*}\mathbf{Q}(-s)\mathbf{R}_2(s)^{-1} + \mathbf{K}_c(-s).$$

Now $\mathbf{K}_c(-s) \in \mathbf{H}_\infty$ by Theorem 6.3, $\mathbf{X}_{11}^{-1} \in \mathbf{H}_\infty$ by Corollary 5.11, $\mathbf{R}_2(s)^{-1} \in \mathbf{H}_\infty$ as we proved above, and $\mathbf{Q}(-s) \in \mathbf{H}_\infty$ is given. So $\mathbf{K}(-s) \in \mathbf{H}_\infty(U,Y)$. ∎

The proof for the case $\|\mathbf{Q}\|_\infty \le 1$ follows the approach in [1].

LEMMA 7.5. *Theorem* 7.1 *is true for all* $\mathbf{Q}(-s) \in \mathbf{H}_\infty(\mathcal{L}(U,Y))$ *with* $\|\mathbf{Q}\|_\infty \le 1$.

Proof. We first note that $\mathbf{H}_\infty$ is weak-$*$ closed in $\mathbf{L}_\infty$. In the case of the unit disc and the unit circle instead of the right half-plane and the imaginary axis, this follows as in [27, p. 197]. The case we consider follows, using a Möbius transform.

Next we note that if a bounded sequence F_n in $\mathbf{L}_\infty$ converges pointwise to $F \in \mathbf{L}_\infty$, then F_n converges to F in the weak-$*$ topology. In the case of the unit disc and the unit circle instead of the right half-plane and the imaginary axis, this follows as in [1, Proposition 2.3]. The case we consider follows, using a Möbius transformation.

Using these two results, we prove the lemma. For $t \in (0,1)$ define $\mathbf{Q}_t := t\mathbf{Q}$. Then $\|\mathbf{Q}_t\| \le t < 1$. Define $\mathbf{K}_t$ in terms of $\mathbf{Q}_t$. Then by Lemma 7.4 we have $\mathbf{K}_t \in \mathbf{H}_\infty$. If $t \to 1$, then for almost all $\omega \in \mathbb{R}$ we have $\mathbf{K}_t(i\omega) \to \mathbf{K}(i\omega)$. Since $\mathbf{K}_t$ is bounded in norm by $\|\mathbf{G}\|_\infty + \sigma$, the limit function (which is well defined by Corollary 7.3) is in $\mathbf{L}_\infty$. By the above this implies that $\mathbf{K}_t$ converges to $\mathbf{K}$ in the weak-$*$ topology. Since $\mathbf{H}_\infty$ is closed in the weak-$*$ topology and $\mathbf{K}_t \in \mathbf{H}_\infty$, we obtain $\mathbf{K} \in \mathbf{H}_\infty$. □

Remark 7.6. It is clear from the results in the previous section and from the proof of Theorem 7.1 that the conclusions also hold under assumption A1: $\sigma(A) \cap i\mathbb{R}$ has measure zero. In this case L_B and L_C can be replaced by arbitrary bounded nonnegative solutions of the Lyapunov equations, and the assumption that U and Y should be finite-dimensional is redundant.

8. Well-posed linear systems and reciprocals. In this section we solve the suboptimal Nehari problem via the reciprocal system as in Curtain and Sasane [9].

First we briefly review the definitions of a well-posed linear system (see Weiss [32], Staffans [29]). Given an $\mathcal{L}(U,Y)$-valued function $\mathbf{G}$ that is holomorphic and uniformly bounded on some right half-plane, there exist operators A, B, C such that

• A is the infinitesimal generator of a strongly continuous semigroup $T(\cdot)$ on a separable Hilbert space Z;

• $C \in \mathcal{L}(D(A), Y)$ is an admissible observation operator with respect to $T(\cdot)$; i.e., given $\tau > 0$, there exists a $\gamma > 0$ such that

$$\int_0^\tau \|CT(t)z\|^2 \,\mathrm{d}t \le \gamma \|z\|^2 \quad \forall\ z \in D(A);$$

• $B^* \in \mathcal{L}(D(A^*), U)$, and B is an admissible control operator for $T(\cdot)$; i.e., for any $\tau > 0$, there exists a $\beta > 0$ such that for all $u \in \mathbf{L}_2(0,\tau;U)$

$$\left\| \int_0^\tau T(t-s)Bu(s)\,\mathrm{d}s \right\|^2 \le \beta \int_0^\tau \|u(t)\|^2 \,\mathrm{d}t;$$

• The operators A, B, C should be such that

$$\mathbf{G}(s) - \mathbf{G}(\alpha) = (\alpha - s)C(sI - A)^{-1}(\alpha I - A)^{-1}B \tag{8.1}$$

for any α, s larger than the growth bound of the semigroup T.

A triple A, B, C that satisfies the above conditions is called a *realization* of the function $\mathbf{G}$. Such a realization is not unique. A well-posed linear system is specified by operators A, B, C and a transfer function $\mathbf{G}$ that satisfy the above conditions.

The expression (8.1) is defined for all $s \in \rho(A)$, and as in section 2 to avoid confusion, we call this the *characteristic function* and denote it by $\mathfrak{G}$. If the admissibility definitions can be extended to $\tau = \infty$, then the term *infinite-time admissible* is used. Well-posed linear systems form a nice generalization of state linear systems, and the concepts of infinite-time admissibility are the natural extensions of input and output stability in Definition 2.3, and we shall use the terms input and output stability. In Grabowski [15] and Hansen and Weiss [16] it is shown that Lemma 2.6 generalizes perfectly to well-posed linear systems and in Curtain [11] that Lemma 3.4 also applies to well-posed linear systems. We call Σ a *system-stable well-posed linear system* if it is input stable and output stable and $\mathbf{G} \in \mathbf{H}_\infty(\mathcal{L}(U,Y))$.

The concept of a reciprocal system was introduced in [10].

Definition 8.1. *Suppose that the well-posed linear system Σ with generating operators A, B, C and transfer function $\mathbf{G}$ is such that $0 \in \rho(A)$. Its* reciprocal system *is the state linear system $\Sigma(A^{-1}, A^{-1}B, -CA^{-1}, \mathfrak{G}(0))$.*

The justification for this definition is the nice relationship between the well-posed linear system and its reciprocal system shown in [11, Lemma 3.2].

THEOREM 8.2. *Suppose that A, B, C are the generating operators of a well-posed linear system Σ with transfer function $\mathbf{G}$ and zero is in the resolvent set of A. Denote the characteristic function of its reciprocal system by $\mathfrak{G}_r$ and the transfer function of its reciprocal system by $\mathbf{G}_r$. Then the following hold:*

1. *$\mathfrak{G}(s) = \mathfrak{G}_r(\frac{1}{s})$ whenever s is in the resolvent set of A.*
2. *Σ is output stable if and only if its reciprocal system is output stable. If they are output stable, then their observability gramians are identical.*
3. *Σ is input stable if and only if its reciprocal system is input stable. If they are input stable, then their controllability gramians are identical.*
4. *The well-posed linear system is system-stable if and only if its reciprocal system is system-stable. In this case, we have $\mathbf{G}(s) = \mathbf{G}_r(\frac{1}{s})$ for $s \in \mathbb{C}_0^+$.*

The advantages of working with the reciprocal system are that all its generating operators are bounded and the close connections with the original well-posed linear system give us the following result.

THEOREM 8.3. *Let Σ be a system-stable well-posed linear system with generating operators A, B, C and transfer function $\mathbf{G}$ and assume that $0 \in \rho(A)$. Let $\mathbf{G}_r$ denote the transfer function of its reciprocal system $\Sigma(A^{-1}, A^{-1}B, -CA^{-1}, \mathfrak{G}(0))$. Then $\mathbf{K}(-s) \in \mathbf{H}_\infty(\mathcal{L}(U,Y))$ satisfies*

$$\| \mathbf{G} + \mathbf{K} \| \leq \sigma$$

if and only if $\mathbf{K}_r(-s) \in \mathbf{H}_\infty(\mathcal{L}(U,Y))$ satisfies

$$\| \mathbf{G}_r - \mathfrak{G}(0) + \mathbf{K}_r \| \leq \sigma, \tag{8.2}$$

where $\mathbf{K}(s) = \mathbf{K}_r(\frac{1}{s}) - \mathfrak{G}(0)$ for all $s \in \mathbb{C}_0^+$ and almost all $s \in i\mathbb{R}$.

Proof. From Theorem 8.2, part 4, we have $\mathbf{G}(s) = \mathbf{G}_-(\frac{1}{s})$ for $s \in \mathbb{C}_0^+$ and by input-output stability this extends to almost everywhere on $i\mathbb{R}$. So for all $s \in \mathbb{C}_0^+$ and almost all $s \in i\mathbb{R}$ we have

$$\mathbf{K}(-s) + \mathbf{G}(s) = \mathbf{K}_r\left(-\frac{1}{s}\right) + \left[\mathbf{G}_r\left(\frac{1}{s}\right) - \mathfrak{G}(0)\right].$$

Thus

$$\begin{aligned}\sup_{\mathbb{C}_0^+} \| \mathbf{K}(-s) + \mathbf{G}(s) \| &= \sup_{\mathbb{C}_0^+} \left\| \mathbf{K}_r\left(-\frac{1}{s}\right) + \mathbf{G}_r\left(\frac{1}{s}\right) - \mathfrak{G}(0) \right\| \\ &= \sup_{\mathbb{C}_0^+} \| \mathbf{K}_r(-s) + \mathbf{G}_r(s) - \mathfrak{G}(0) \|,\end{aligned}$$

which proves the claim. ∎

Remark 8.4. 1. Since $\mathbf{G}_r(\frac{1}{s}) - \mathfrak{G}(0)$ is the transfer function of the system-stable state linear system $\Sigma(A^{-1}, A^{-1}B, -CA^{-1}, 0)$, the results on state linear systems in this article generalize to well-posed linear systems in an obvious way. Note that the formulas that we so obtain are not the same as for the case of state linear systems but are in terms of the generating operators of the reciprocal system. The analogous formulas for the well-posed linear system need not be well defined.

2. Finally, we remark that the assumption in Theorem 8.3 that $0 \in \rho(A)$ can be relaxed. The arguments in this section can be adapted to the alternative assumption

that $i\omega \in \rho(A)$ for some real ω. Denoting $A_\omega = A - i\omega I$, we introduce the ω-reciprocal systems $\Sigma(A_\omega^{-1}, A_\omega^{-1}, -CA_\omega^{-1}, \mathbf{G}(i\omega))$ with transfer function $\mathbf{G}_r^\omega$. Noting that $\mathbf{G}(s + i\omega) = \mathbf{G}_r^\omega(\frac{1}{s})$, we can obtain connections between the Nehari problem for Σ and this new reciprocal system. By proving our results on state linear systems in discrete time and using the Cayley transform, one can even obtain Theorem 8.3 without any assumption on the spectrum.

9. Appendix. In this appendix we study real-analytic functions on a complex Banach space E following Dieudonné [12]. A function $f : \Omega \subset \mathbb{R}^2 \to E$ with Ω open is called real-analytic if at every point $\omega \in \Omega$ there exist vectors $c_{i,j} \in E$ such that

$$f(x, y) = \sum_{i,j \in \mathbb{N}^2} c_{i,j}(x - \omega_1)^i (y - \omega_2)^j$$

for all points (x, y) in a neighborhood of ω, the series converging absolutely in this neighborhood.

Consider a holomorphic function $h : \Omega \subset \mathbb{C} \to E$. It follows from Goursat's theorem [12, section 9.10, Problem 1] that at every point h can be expanded in an absolutely convergent power series in the complex variable z. Define $h_{\mathbb{R}} : \Omega \subset \mathbb{R}^2 \to E$ by $h_{\mathbb{R}}(x, y) := h(x + iy)$. It is easily seen that $h_{\mathbb{R}}$ is real-analytic: the series expansion in x and y follows from the series expansion in $x+iy$. We further note that if $g : \Omega \to \mathbb{C}$ is real-analytic, then so is $\bar{g}$.

COROLLARY 9.1. *Using the notation and assumptions of Lemma* 3.12*, we have that* $(x, y) \mapsto \langle \widehat{\mathcal{B}}(x + iy)u, L_C Bu\rangle$ *and* $(x, y) \mapsto \langle L_C Bu, \widehat{\mathcal{B}}(x + iy)u\rangle$ *are real-analytic on the right half-plane.*

Proof. With $h(s) = g(s) = \langle \widehat{\mathcal{B}}(s)u, L_C Bu\rangle$ this follows from the above discussion. ∎

We have the following characterization of real-analyticity.

LEMMA 9.2. *$f : \Omega \subset \mathbb{R}^2 \to E$ is real-analytic if and only if there exists an open set $\Omega_{\mathbb{C}} \subset \mathbb{C}^2$ such that $\Omega_{\mathbb{C}} \cap \mathbb{R}^2 = \Omega$ and a holomorphic function $f_{\mathbb{C}} : \Omega_{\mathbb{C}} \to E$ such that $f_{\mathbb{C}}|_\Omega = f$.*

Proof. This follows from [12, subsection 9.4.5, p. 209] and Goursat's theorem [12, section 9.10, Problem 1]. ∎

THEOREM 9.3. *If $f, g : \Omega \to H$ are real-analytic, then $\langle f, g\rangle$ is real-analytic.*

Proof. Since f is real-analytic, there exists a holomorphic function $f_{\mathbb{C}}$ of which f is the restriction. Since $\bar{g}$ is real-analytic, there exists a holomorphic function $\bar{g}_{\mathbb{C}}$ of which $\bar{g}$ is the restriction. We thus have that $(f_{\mathbb{C}}, \bar{g}_{\mathbb{C}})$ is holomorphic. We define a bilinear function by $B(h_1, h_2) = \langle h_1, \bar{h}_2\rangle$. Since the composition of holomorphic functions is holomorphic (and a bilinear function is holomorphic), we have that if h_1 and h_2 are holomorphic, then $B(h_1, h_2)$ is. We thus have that $\langle f_{\mathbb{C}}, \overline{\bar{g}_{\mathbb{C}}}\rangle$ is holomorphic. Restricted to Ω, this function equals $\langle f, g\rangle$. This shows that $\langle f, g\rangle$ is real-analytic. ∎

The above theorem in particular shows that the squared norm of a real-analytic function is real-analytic, which implies that the squared norm of a holomorphic function is real-analytic. This gives the following corollary.

COROLLARY 9.4. *Using the notation and assumptions of Lemma* 3.12*, we have that* $(x, y) \mapsto \|\mathbf{G}(x + iy)u\|^2$ *and* $(x, y) \mapsto 2x\ \|L_C^{1/2}\widehat{\mathcal{B}}(x + iy)u\|^2$ *are real-analytic.*

We quote the following identity theorem for real-analytic functions. This is used in Lemmas 3.12 and 5.4 with A the right half-plane and U some right half-plane.

LEMMA 9.5. *Let $A \subset \mathbb{R}^2$ be an open connected set, and let f and g be two real-analytic functions in A with values in E. If there is a nonempty open subset U of A such that $f(x) = g(x)$ in U, then $f(x) = g(x)$ for every $x \in A$.*

Proof. This follows from [12, subsection 9.4.2, p. 208]. ∎

Acknowledgments. The authors are grateful to Hans Zwart for lively discussions on Lemma 3.4, to Kalle Mikkola and Amol Sasane for their useful comments, and to Erik Thomas for a discussion on real-analytic functions. We are very grateful to the two anonymous reviewers for their painstaking work in reviewing our manuscript. Their efforts have improved this paper considerably.

SOLUTION OF FILTERING PROBLEM WITH NONLINEAR OBSERVATIONS*

STEPHEN S.-T. YAU† AND SHING-TUNG YAU‡

Abstract. For all known finite-dimensional filters, one always needs the conditon that the observation terms are degree one polynomial. On the other hand, in many practical examples, e.g., tracking problem, the observation terms may be nonlinear. Our new method in this paper can treat filtering problems with nonlinear observation terms in the first time, which includes Kalman–Bucy filter as a special case.

Key words. filtering problem, nonlinear observations, real time computation, DMZ equation, Kolmogorov equation

1. Introduction.

In 1961, Kalman–Bucy first established the finite-dimensional filters for linear filtering system with Gaussian initial distribution. In the sixties and early seventies, the basic approach to nonlinear filtering theory was via the "innovations method" originally proposed by Kailath and subsequently rigorously developed by Fujisaki, Kallianpur, and Kunita in 1972 [10]. As pointed out by Mitter [13], the difficulty with this approach is that the innovations process is not, in general, explicitly computable. In view of this weakness, Brockett [2] and Mitter [13] proposed, independently, the idea of using estimation algebras to construct finite-dimensional nonlinear filters. The idea is to imitate the Wei–Norman approach of using the Lie algebraic method to solve the DMZ equation, which the unnormalized conditional probability of the state must satisfy. Perhaps the most important merit of the Lie algebra approach is the following. As long as the estimation algebra is finite dimensional, not only the finite-dimensional filter can be constructed explicitly, but also the filter so constructed is universal in the sense of Chaleyat–Maurel and Michel [4]. In [23], [17], and [20] Yau proves that the number of sufficient statistics in the Lie algebra method, which is required in the computation of conditional probability density, is linear in n, where n is the dimension of the state space. Recently, Stephen Yau [17] and Tam, Wong, and Yau [14], [16], [5], [21], [20], and [6] have completely classified all finite-dimensional estimation algebras of maximal rank. In particular, they have proved that all the observation terms $h_i(x)$, $1 \leq i \leq m$ must be degree one polynomials.

However, in the Wei–Norman approach, one has to know explicitly the basis as vector space of the estimation algebra in order to reduce the DMZ equation to a finite system of ordinary differential equations, Kolmogorov equation, and several first-order linear partial differential equations. Classically, one knows the explicit

basis for the estimation algebra only in the case that it has maximal rank. Typically people assume that the linear system is controllable and observable. Recently, a new direct method was introduced to study the linear filtering and exact filtering systems with arbitrary initial condition for which f, g and h in (2.1) are independent of time (cf. [22], [23], [19], [18]). This approach offers several advantages. It is easy and the derivation no longer needs controllability and observability. Thus, the algorithm is universal for any linear filtering system. Furthermore, it eliminates the necessity of integrating n first-order linear partial differential equations, as was the case in the Lie algebra method. Finally, the number of sufficient statistics required to compute the conditional probability density of the state in this direct method is n. In all the direct methods in [22], [23], [18], and [19] they need to assume that all the observation terms $h_i(x)$, $1 \leq i \leq m$, are degree one polynomials.

In [26], we have proved the existence and decay estimates of the solution to the DMZ equation under the assumption that $f(x)$ and $h(x)$ in (2.1) have linear growth. In this paper, we use the theory developed in [26] to show that the real time computation of the DMZ equation can be reduced to numerical solution of Kolmogorov equation if $f(x)$ and $h(x)$ have linear growth. Similar results under a much stronger assumption that $f(x)$ and $h(x)$ are bounded functions were treated by various authors including Bensoussan, Glowinski, and Rascanu [1], Elliott and Glowinski [8], Florchinger and LeGland [9], Mikulevicious and Rozovskii [12]. Unlike our results, however, their results cannot cover Kalman–Bucy filters. Theorem 4.2 of this paper says that if the drifts ($f(x)$) are affine and the observation terms ($h(x)$) are nonlinear with linear growths, then the Kolmogorov equation can be solved in real time.

For all known finite-dimensional filters, one always needs the condition that the observation terms are degree one polynomial. On the other hand, in many practical examples, e.g., tracking problem, the observation terms may be nonlinear. Our new method in this paper can treat filtering problems with nonlinear observation terms in the first time, which includes Kalman–Bucy filter as a special case.

This paper is organized as follows. In section 2 we shall set up the notations and recall the basic filtering problem. In section 3, we shall show that real time computation of the DMZ equation can be reduced to off time computation of the Kolmogorov equation. An explicit algorithm of such a reduction is provided. In the appendix, we give a rigorous proof that the solution of our algorithm converges to the solution of the DMZ equation in pointwise and L^2 sense. In section 4, we show that if the drifts are linear and the observation terms are nonlinear with linear growths, then the Kolmogorov equation can be solved in real time via a system of ODEs. Consequently, the nonlinear filtering problem with linear drifts and nonlinear observations with linear growth can be solved in real time and memoryless manner. In section 5, we give a conclusion of this paper.

2. Basic filtering problem. The filtering problem considered here is based on the following signal observation model in Itô form:

$$\begin{cases} dx(t) = f(x(t))dt + g(x(t))dv(t) & x(0) = x_0 \\ dy(t) = h(x(t))dt + dw(t) & y(0) = 0 \end{cases} \tag{2.1}$$

in which x, v, y and w are, respectively, $\mathbb{R}^n, \mathbb{R}^p, \mathbb{R}^m$, and $\mathbb{R}^m$ valued processes and v and w independent, standard Brownian processes. We further assume that $n = p$; f, g, and h are vector-valued, orthogonal matrix-valued and vector-valued C^∞ smooth functions. We shall refer to $x(t)$ as the state and $y(t)$ as the observation at time t.

Let $\rho(t,x)$ denote the conditional probability density of the state given the observation $\{y(s) : 0 \le s \le t\}$. It is well known that $\rho(t,x)$ is given by normalizing a function $\sigma(t,x)$ that satisfies the following DMZ equation in Fisk–Stratonovich form:

$$\begin{cases} d\sigma(t,x) = L_0\sigma(t,x)dt + \sum_{i=1}^{m} L_i\sigma(t,x)dy_i(t) \\ \sigma(0,x) = \sigma_0(x), \end{cases} \tag{2.2}$$

where

$$L_0 = \frac{1}{2}\sum_{i=1}^{n}\frac{\partial^2}{\partial x_i^2} - \sum_{i=1}^{n} f_i(x)\frac{\partial}{\partial x_i} - \sum_{i=1}^{n}\frac{\partial f_i}{\partial x_i}(x) - \frac{1}{2}\sum_{i=1}^{m} h_i^2(x),$$

and for $i = 1, \dots, m$, L_i is the zero-degree differential operator of multiplication by h_i and σ_0 is the probability density of the initial point x_0.

Davis introduced a new unnormalized density

$$u(t,x) = \exp\left(-\sum_{i=1}^{m} h_i(x)y_i(t)\right)\sigma(t,x). \tag{2.3}$$

He reduced (2.2) to the following time-varying partial differential equation which is called the robust DMZ-equation:

$$\begin{cases} \dfrac{\partial u}{\partial t}(t,x) = L_0u(t,x) + \sum_{i=1}^{m} y_i(t)[L_0, L_i]u(t,x) \\ \qquad\qquad + \dfrac{1}{2}\sum_{i,j=1}^{m} y_i(t)y_j(t)[[L_0, L_i], L_j]u(t,x) \\ u(0,x) = \sigma_0(x), \end{cases} \tag{2.4}$$

where $[\cdot\ ,\ \cdot]$ is the Lie bracket as described in [14]. It is easy to show [24] that (2.4) is equivalent to the following time-varying partial differential equation:

$$\begin{cases} \dfrac{\partial u}{\partial t}(t,x) = \dfrac{1}{2}\sum_{i=1}^{n}\dfrac{\partial^2 u}{\partial x_i^2}(t,x) + \sum_{i=1}^{n}\left(-f_i(x) + \sum_{j=1}^{m} y_j(t)\dfrac{\partial h_j}{\partial x_i}(x)\right)\dfrac{\partial u}{\partial x_i}(t,x) \\ \qquad - \left[\sum_{i=1}^{n}\dfrac{\partial f_i}{\partial x_i}(x) + \dfrac{1}{2}\sum_{i=1}^{m} h_i^2(x) - \dfrac{1}{2}\sum_{i=1}^{m} y_i(t)\Delta h_i(x)\right. \\ \qquad \left. + \sum_{i=1}^{m}\sum_{j=1}^{n} y_i(t)f_j(x)\dfrac{\partial h_i}{\partial x_j}(x) - \dfrac{1}{2}\sum_{i,j=1}^{m}\sum_{k=1}^{n} y_i(t)y_j(t)\dfrac{\partial h_i}{\partial x_k}(x)\dfrac{\partial h_j}{\partial x_k}(x)\right]u(t,x) \\ u(0,x) = \sigma_0(x). \end{cases} \tag{2.5}$$

In this paper we shall solve the filtering problem in the case $f_i(x)$, $1 \le i \le n$, are degree one polynomials and $h_j(x)$, $1 \le j \le m$, may be nonlinear with linear growth, i.e., $|h_j(x)| \le C(1 + |x|)$ for some constant C.

3. Reduction from robust DMZ equation to Kolmogorov equation. The fundamental problem of nonlinear filtering theory is how to solve the robust DMZ

equation (2.5) in real time and memoryless manner. In this section, we shall describe our algorithm which achieves this goal for a large class of filtering system with arbitrary initial distribution by reducing it to solve Kolmogorov equation. Our algorithm is based on the following proposition.

PROPOSITION 3.1. *For any τ_1, τ_2 with $\tau_1 < \tau_2$, $\widetilde{u}(t,x)$ satisfies the following Kolmogorov equation:*

(3.1)
$$\frac{\partial \widetilde{u}}{\partial t}(t,x) = \frac{1}{2}\Delta\widetilde{u}(t,x) - \sum_{i=1}^{n} f_i(x)\frac{\partial \widetilde{u}}{\partial x_i}(t,x) - \left(\sum_{i=1}^{n}\frac{\partial f_i}{\partial x_i}(x) + \frac{1}{2}\sum_{i=1}^{m} h_i^2(x)\right)\widetilde{u}(t,x)$$

for $\tau_1 \le t \le \tau_2$ if and only if

$$u(t,x) = e^{-\sum_{i=1}^{m} y_i(\tau_1)h_i(x)}\widetilde{u}(t,x)$$

satisfies the robust DMZ equation with observation being freezed at $y(\tau_1)$,

$$\begin{aligned}\frac{\partial u}{\partial t}(t,x) = {} & \frac{1}{2}\Delta u(t,x) + \sum_{i=1}^{n}\left(-f_i(x) + \sum_{j=1}^{m} y_j(\tau_1)\frac{\partial h_j}{\partial x_i}(x)\right)\frac{\partial u}{\partial x_i}(t,x) \\ & -\Bigg(\sum_{i=1}^{n}\frac{\partial f_i}{\partial x_i}(x) + \frac{1}{2}\sum_{i=1}^{m} h_i^2(x) - \frac{1}{2}\sum_{i=1}^{m} y_i(\tau_1)\Delta h_i(x) \\ & \quad + \sum_{i=1}^{m}\sum_{j=1}^{n} y_i(\tau_1) f_j(x)\frac{\partial h_i}{\partial x_j}(x) \\ & \quad - \frac{1}{2}\sum_{k=1}^{n}\sum_{i,j=1}^{m} y_i(\tau_1)y_j(\tau_1)\frac{\partial h_i}{\partial x_k}(x)\frac{\partial h_j}{\partial x_k}(x)\Bigg)u(t,x). \qquad (3.2)\end{aligned}$$

Proof. It is straightforward to show that

$$\begin{aligned} & e^{\sum_{i=1}^{m} y_i(\tau_1)h_i(x)}\Bigg[-\frac{\partial}{\partial t} + \frac{1}{2}\Delta + \sum_{i=1}^{n}\left(-f_i(x) + \sum_{j=1}^{m} y_j(\tau_1)\frac{\partial h_j}{\partial x_i}\right)\frac{\partial}{\partial x_i} \\ & \quad -\Bigg(\sum_{i=1}^{n}\frac{\partial f_i}{\partial x_i}(x) + \frac{1}{2}\sum_{i=1}^{m} h_i^2(x) - \frac{1}{2}\sum_{i=1}^{m} y_i(\tau_1)\Delta h_i(x) \\ & \quad\quad + \sum_{i=1}^{m}\sum_{j=1}^{n} y_i(\tau_1) f_j(x)\frac{\partial h_i}{\partial x_j}(x) \\ & \quad\quad - \frac{1}{2}\sum_{k=1}^{n}\sum_{i,j=1}^{m} y_i(\tau_1)y_j(\tau_1)\frac{\partial h_i}{\partial x_k}\frac{\partial h_j}{\partial x_k}\Bigg)\Bigg]u(t,x) \\ & = -\frac{\partial \widetilde{u}}{\partial t}(t,x) + \frac{1}{2}\Delta\widetilde{u}(t,x) - \sum_{i=1}^{n} f_i(x)\frac{\partial \widetilde{u}}{\partial x_i}(t,x) \\ & \quad -\left(\sum_{i=1}^{n}\frac{\partial f_i}{\partial x_i}(x) + \frac{1}{2}\sum_{i=1}^{m} h_i^2(x)\right)\widetilde{u}(t,x). \qquad (3.3)\end{aligned}$$

Proposition (3.1) follows immediately from (3.3). □

We remark that (3.2) is obtained from the robust DMZ equation by freezing the observation $y(t)$ to $y(\tau_1)$. Based on Proposition (3.1), we shall formulate our algorithm to solve the robust DMZ equation and we shall show in Appendices A and B that the solution of our algorithm approximates the solution of the robust DMZ equation very well in both pointwise and L^2-sense.

Suppose that $u(t,x)$ is the solution of the robust DMZ equation and we want to compute $u(\tau,x)$. Let $\mathcal{P}_k = \{0 = \tau_0 < \tau_1 < \tau_2 < \cdots < \tau_k = \tau\}$ be a partition of $[0,\tau]$. Let $u_i(t,x)$ be a solution of the following partial differential equation for $\tau_{i-1} \le t \le \tau_i$:

$$
\begin{cases}
\dfrac{\partial u_i}{\partial t}(t,x) = \dfrac{1}{2}\Delta u_i(t,x) + \displaystyle\sum_{\ell=1}^{n}\left(-f_\ell(x) + \sum_{j=1}^{m} y_j(\tau_{i-1})\frac{\partial h_j}{\partial x_\ell}(x)\right)\frac{\partial u_i}{\partial x_\ell}(t,x) \\
\qquad\qquad -\left(\displaystyle\sum_{\ell=1}^{n}\frac{\partial f_\ell}{\partial x_\ell}(x) + \frac{1}{2}\sum_{\ell=1}^{m} h_\ell^2(x) - \frac{1}{2}\sum_{j=1}^{m} y_j(\tau_{i-1})\Delta h_j(x)\right. \\
\qquad\qquad +\displaystyle\sum_{j=1}^{m}\sum_{\ell=1}^{n} y_j(\tau_{i-1}) f_\ell(x)\frac{\partial h_j}{\partial x_\ell}(x) \\
\qquad\qquad \left. -\dfrac{1}{2}\displaystyle\sum_{p=1}^{n}\sum_{j,\ell=1}^{m} y_j(\tau_{i-1}) y_\ell(\tau_{i-1})\frac{\partial h_j}{\partial x_p}(x)\frac{\partial h_\ell}{\partial x_p}(x)\right) u_i(t,x) \\
u_i(\tau_{i-1},x) = u_{i-1}(\tau_{i-1},x).
\end{cases} \tag{3.4}
$$

Define the norm of the partition $\mathcal{P}_k$ by $|\mathcal{P}_k| = \sup_{1\le i\le k}\{|\tau_i - \tau_{i-1}|\}$. In Appendices A and B, we shall show that in both pointwise and L^2 sense

$$
u(\tau,x) = \lim_{|\mathcal{P}_k|\to 0} u_k(\tau,x). \tag{3.5}
$$

Therefore it remains to describe an algorithm to compute $u_k(\tau_k,x)$. By Proposition 3.1, $u_1(\tau_1,x)$ can be computed by $\widetilde{u}_1(\tau_1,x)$ where $\widetilde{u}_1(t,x)$ for $0 \le t \le \tau_1$ satisfies the following Kolmogorov equation:

$$
\begin{cases}
\dfrac{\partial \widetilde{u}_1}{\partial t}(t,x) = \dfrac{1}{2}\Delta\widetilde{u}_1(t,x) - \displaystyle\sum_{j=1}^{n} f_j(x)\frac{\partial \widetilde{u}_1}{\partial x_j}(x) - \left(\sum_{j=1}^{n}\frac{\partial f_j}{\partial x_j}(x) + \frac{1}{2}\sum_{i=1}^{m} h_j^2(x)\right)\widetilde{u}_1(t,x) \\
\widetilde{u}_1(0,x) = \sigma_0(x)e^{\sum_{j=0}^{m} y_j(0)h_j(x)} = \sigma_0(x).
\end{cases} \tag{3.6}
$$

In fact, by the uniqueness solution of the Kolmogorov equation, we have

$$
u_1(t,x) = \widetilde{u}_1(t,x), \qquad 0 \le t \le \tau_1. \tag{3.7}
$$

In general, Proposition 3.1 tells us that for $i \ge 2$, $u_i(\tau_i,x)$ can be computed by $\widetilde{u}_i(\tau_i,x)$, where $\widetilde{u}_i(t,x)$ for $\tau_{i-1} \le t \le \tau_i$ satisfies the following Kolmogorov equation:

$$
\begin{cases}
\dfrac{\partial \widetilde{u}_i}{\partial t}(t,x) = \dfrac{1}{2}\Delta\widetilde{u}_i(t,x) - \displaystyle\sum_{j=1}^{n} f_j(x)\frac{\partial \widetilde{u}_i}{\partial x_j}(t,x) - \left(\sum_{j=1}^{n}\frac{\partial f_j}{\partial x_j}(x) + \frac{1}{2}\sum_{j=1}^{m} h_j^2(x)\right)\widetilde{u}_i(t,x) \\
\widetilde{u}_i(\tau_{i-1},x) = e^{\sum_{j=1}^{m}(y_j(\tau_{i-1}) - y_j(\tau_{i-2}))h_j(x)}\,\widetilde{u}_{i-1}(\tau_{i-1},x),
\end{cases} \tag{3.8}
$$

where the last initial condition comes from

$$\begin{aligned}\widetilde{u}_i(\tau_{i-1},x) &= u_i(\tau_{i-1},x)e^{\sum_{j=1}^{m} y_j(\tau_{i-1})h_j(x)} = u_{i-1}(\tau_{i-1},x)e^{\sum_{j=1}^{m} y_j(\tau_{i-1})h_j(x)}\\ &= e^{\sum_{j=1}^{m}(y_j(\tau_{i-1})-y_j(\tau_{i-2}))h_j(x)}\widetilde{u}_{i-1}(\tau_{i-1},x).\end{aligned}$$

In fact, we have

$$u_i(\tau_i,x) = e^{-\sum_{j=1}^{m} y_j(\tau_{i-1})h_j(x)}\widetilde{u}_i(\tau_i,x). \tag{3.9}$$

In view of (2.3), (3.5), and (3.9), we have the following theorem.

THEOREM 3.2. *The unnormalized density σ can be computed via solution $\widetilde{u}$ of the Kolmogorov equation* (3.8). *More specifically,*

$$\sigma(\tau,x) = \lim_{|\mathcal{P}_k|\to 0}\widetilde{u}_k(\tau_k,x) \tag{3.10}$$

Proof.

$$\begin{aligned}\sigma(\tau,x) &= u(\tau,x)\exp\left(\sum_{i=1}^{m} h_i(x)y_i(\tau)\right) && \text{by (2.3)}\\ &= \lim_{|\mathcal{P}_k|\to 0} u_k(\tau,x)\exp\left(\sum_{i=1}^{m} h_i(x)y_i(\tau)\right), && \text{by (3.5)}\end{aligned}$$

where $\mathcal{P}_k = \{0=\tau_0<\tau_1<\cdots<\tau_k=\tau\}$.

In view of (3.9), we have

$$\begin{aligned}\sigma(\tau,x) &= \lim_{|\mathcal{P}_k|\to 0} e^{-\sum_{i=1}^{m} y_j(\tau_{k-1})h_j(x)}\widetilde{u}_k(\tau,x)e^{\sum_{i=1}^{m} h_i(x)y_i(\tau)}\\ &= \lim_{|\mathcal{P}_k|\to 0}\widetilde{u}_k(\tau,x). \qquad \square\end{aligned}$$

Observe that in our algorithm at step i (Lemma B.2), we only need the observation at time τ_{i-1} and τ_{i-2}. We do not need any other previous observation data. Observe also that the Kolmogorov equation (3.8) is uniform for all time steps and it depends on observation $y(t)$ only via initial condition.

4. Filtering problem with nonlinear observations. Consider the filtering system (2.1) with affine drift,

$$f_i(x) = \sum_{j=1}^{n}\ell_{ij}x_j + \ell_i, \qquad 1\le i\le n, \tag{4.1}$$

where ℓ_{ij}, ℓ_i are constants, and nonlinear observation

$$\sum_{i=1}^{m} h_i^2(x) = \sum_{i,j=1}^{n} q_{ij}x_ix_j + \sum_{i=1}^{n} q_ix_i + q_0, \tag{4.2}$$

where $q_{ij} = q_{ji}$, q_i, q_0 are constants.

We first remark that if $h_i(x)$, $1 \le i \le m$, are nonlinear observation with linear growths as follows:

$$h_i^2(x) \le m(1 + |x|^2), \qquad 1 \le i \le m-1, \tag{4.3}$$

where M is a constant, and

$$h_m^2(x) = (m-1)M(1+|x|^2) - \sum_{i=1}^{m-1} h_i^2(x), \tag{4.4}$$

then condition (4.2) is satisfied. The purpose of this section is to prove the following theorem.

THEOREM 4.1. *The unnormalized density of the filtering system* (2.1) *with affine drift* (4.1), *nonlinear observation* (4.2), *and Gaussian initial distribution can be computed in real time in a memoryless way.*

In view of Theorem 3.2, in order to solve the nonlinear filtering problem with conditions (4.1), (4.2) it suffices to solve the following Kolmogorov equation in real time. For $\tau_1 \le t \le \tau_2$,

$$\begin{cases} \dfrac{\partial \widetilde{u}}{\partial t}(t,x) = \dfrac{1}{2}\Delta \widetilde{u}(t,x) - \displaystyle\sum_{j=1}^{n} f_j(x)\frac{\partial \widetilde{u}}{\partial x_j}(t,x) - \left(\sum_{j=1}^{n}\frac{\partial f_j}{\partial x_j}(x) + \frac{1}{2}\sum_{j=1}^{m} h_j^2(x)\right)\widetilde{u}(t,x) \\ \widetilde{u}(0,x) = \phi(x). \end{cases} \tag{4.5}$$

It is well known that any $\phi(x)$ is well approximated by finite linear combination of Gaussians of the form $\alpha_1 G_1 + \cdots + \alpha_p G_p$, where α_is are real numbers and G_is are Gaussian distributions. Let $\widetilde{u}_i$ be the solution of (4.5) with initial distribution G_i. Since (4.5) is a linear partial differential equation, it follows that the solution of (4.5) is of the form $\alpha_1\widetilde{u}_1 + \cdots + \alpha_p\widetilde{u}_p$. Therefore it remains to solve (4.5) with Gaussian initial distribution. Theorem 4.2 gives an explicit solution of (4.5) with linear drift (4.1), nonlinear observation (4.2), and Gaussian initial distribution in terms of solutions of ODEs.

THEOREM 4.2. *Consider the filtering system* (2.1) *with linear drift* (4.1), *nonlinear observation* (4.2), *and Kolmogorov equation. For* $\tau_1 \le t \le \tau_2$,

$$\begin{cases} \dfrac{\partial \widetilde{u}}{\partial t}(t,x) = \dfrac{1}{2}\Delta \widetilde{u}(t,x) - \displaystyle\sum_{j=1}^{n} f_j(x)\frac{\partial \widetilde{u}}{\partial x_j}(t,x) - \left(\sum_{j=1}^{n}\frac{\partial f_j}{\partial x_j}(x) + \frac{1}{2}\sum_{j=1}^{m} h_j^2(x)\right)\widetilde{u}(t,x) \\ \widetilde{u}(\tau_1,x) = \exp[x^T A(\tau_1)x + B^T(\tau_1)x + C(\tau_1)], \end{cases} \tag{4.6}$$

where $A(\tau_1) = (A_{ij}(\tau_1))$ *is a* $n \times n$ *matrix,* $B^T(\tau_1) = (B_1(\tau_1), \ldots, B_n(\tau_1))$, $x^T = (x_1, \ldots, x_n)$ *are* $1 \times n$ *matrix and* $C(\tau_1)$ *is a scalar. Then the solution of* (4.6) *is of the following form:*

$$\widetilde{u}(t,x) = \exp(x^T A x + B^T x + C), \tag{4.7}$$

where $A = A^T = (A_{ij}(t))$ *is a* $n \times n$ *matrix valued function of* t, $B^T = (B_1(t), \ldots, B_n(t))$ *is a* $1 \times n$ *matrix valued function of* t, *and* $C(t)$ *is a scalar function of* t.

Moreover, $A(t)$, $B^T(t)$, and $C(t)$ satisfy the following system of nonlinear ODEs*:*

$$\begin{cases} \dfrac{dA}{dt}(t) = 2A^2(t) - A(t)L - L^T A(t) - \dfrac{1}{2}Q \\ A(t)|_{t=\tau_1} = A(\tau_1) \end{cases} \tag{4.8}$$

$$\begin{cases} \dfrac{dB^T}{dt}(t) = 2B^T(t)A(t) - B^T(t)L - 2\ell^T A(t) - \dfrac{1}{2}q \\ B^T(t)|_{t=\tau_1} = B^T(\tau_1) \end{cases} \tag{4.9}$$

$$\begin{cases} \dfrac{dC}{dt}(t) = tr\, A(t) + \dfrac{1}{2}B^T(t)B(t) - \ell^T B(t) - \dfrac{1}{2}q_0 - tr\, L \\ C(t)|_{t=\tau_1} = C(\tau_1), \end{cases} \tag{4.10}$$

where $L = (\ell_{ij})$, $Q = (q_{ij})$, $1 \le i, j \le n$, $\ell^T = (\ell_1, \dots, \ell_n)$, $q^T = (q_1, \dots, q_n)$ as in (4.1) *and* (4.2).

Proof. Differentiating (4.7) with respect to t and x, respectively, we get the following equations:

$$\begin{aligned} \frac{\partial \widetilde{u}}{\partial t} &= \left(x^T \frac{dA}{dt} x + \frac{dB^T}{dt} x + \frac{dC}{dt} \right) \widetilde{u} \\ \nabla \widetilde{u} &= [(A + A^T)x + B] e^{x^T Ax + B^T x + C} \\ \Delta \widetilde{u} &= \{ 2trA + [(A + A^T)x + B]^T [(A + A^T)x + B] \} e^{x^T Ax + B^T x + C} \\ &= [x^T (AA^T + A^T A + 2A^2)x + 2B^T (A + A^T)x + 2trA + B^T B]\widetilde{u} \\ \sum_{j=1}^{n} f_j(x) \frac{\partial \widetilde{u}}{\partial x_j} &= (Lx + \ell)^T \nabla \widetilde{u} \\ &= [x^T (A^T + A)Lx + (B^T L + \ell^T A + \ell^T A^T)x + \ell^T B]\widetilde{u}, \end{aligned} \tag{4.11}$$

where $L = (\ell_{ij}), \ell^T = (\ell_1, \dots, \ell_n)$

$$\left(\sum_{j=1}^{m} \frac{\partial f_j}{\partial x_j}(x) + \frac{1}{2} \sum_{j=1}^{m} h_j^2(x) \right) \widetilde{u}(t,x) = \left(\frac{1}{2} x^T Q x + \frac{1}{2} q^T x + \frac{1}{2} q_0 + trL \right) \widetilde{u}(t,x),$$

where $Q = (q_{ij}), q^T = (q_1, \dots, q_n)$.

Therefore the R.H.S. of (4.6) is given by

$$\begin{aligned} &\frac{1}{2}\Delta \widetilde{u}(t,x) - \sum_{j=1}^{n} f_j(x) \frac{\partial \widetilde{u}}{\partial x_j}(t,x) - \left(\sum_{j=1}^{n} \frac{\partial f_j}{\partial x_j}(x) + \frac{1}{2} \sum_{j=1}^{m} h_j^2(x) \right) \widetilde{u}(t,x) \\ &= \left[x^T \left(\frac{1}{2} AA^T + \frac{1}{2} A^T A + A^2 \right) x + B^T (A + A^T)x + trA + \frac{1}{2} B^T B \right] \widetilde{u} \\ &\quad - [x^T (A^T + A)Lx + (B^T L + \ell^T A + \ell^T A^T)x + \ell^T B]\widetilde{u} \\ &\quad - \left(\frac{1}{2} x^T Q x + \frac{1}{2} q^T x + \frac{1}{2} q_0 + trL \right) \widetilde{u}(t,x) \\ &= \left[x^T \left(\frac{1}{2} AA^T + \frac{1}{2} A^T A + A^2 - A^T L - AL - \frac{1}{2} Q \right) x + (B^T A + B^T A^T - B^T L \right. \\ &\quad \left. - \ell^T A - \ell^T A^T - \frac{1}{2} q^T)x + trA + \frac{1}{2} B^T B - \ell^T B - \frac{1}{2} q_0 - trL \right] \widetilde{u}. \end{aligned} \tag{4.12}$$

By comparing (4.11) and (4.12), we get (4.8), (4.9), and (4.10), which are necessary and sufficient conditions for (4.7) to be a solution of (4.6). □

5. Conclusion. All the known finite dimensional filters require observation terms linear in nature. In this paper we have solved the nonlinear filtering problem with linear drift and nonlinear observations in real time and memoryless manner. We first show that the solution of the DMZ equation can be obtained by solving the Kolmogorov equation. We also show that the Kolmogorov equation can be solved via solutions of systems of ODEs if the summation of observations is a quadratic polynomial (cf. (4.2)).

Appendix A: Pointwise Convergence of (3.5). By changing variables from x_i to $\sqrt{2}x_i$ and by letting

$$\overline{u}(t,x) = u\left(t, \frac{x}{\sqrt{2}}\right), \tag{A.1}$$

we get

$$\begin{aligned}
\frac{\partial \overline{u}}{\partial t}(t,x) &= \frac{\partial u}{\partial t}\left(t, \frac{x}{\sqrt{2}}\right),\\
\frac{\partial \overline{u}}{\partial x_i}(t,x) &= \frac{1}{\sqrt{2}}\frac{\partial u}{\partial x_i}\left(t, \frac{x}{\sqrt{2}}\right),\\
\frac{\partial^2 \overline{u}}{\partial x_i^2}(t,x) &= \frac{1}{2}\frac{\partial^2 u}{\partial x_i^2}\left(t, \frac{x}{\sqrt{2}}\right).
\end{aligned}$$

Hence the robust DMZ equation becomes

$$\frac{\partial\, \overline{u}}{\partial t}(t,x) = \Delta \overline{u}(t,x) + \sum_{i=1}^{m} \overline{f}_i(t,x)\frac{\partial\, \overline{u}}{\partial x_i}(t,x) - \overline{V}(t,x)\overline{u}(t,x), \tag{A.2}$$

where

$$\overline{f}_i(t,x) = \sqrt{2}\left[- f_i\left(\frac{x}{\sqrt{2}}\right) + \sum_{j=1}^{m} y_j(t)\frac{\partial h_j}{\partial x_i}\left(\frac{x}{\sqrt{2}}\right)\right] \tag{A.3}$$

$$\begin{aligned}
\overline{V}(t,x) = {} & \sum_{i=1}^{n}\frac{\partial f_i}{\partial x_i}\left(\frac{x}{\sqrt{2}}\right) + \frac{1}{2}\sum_{i=1}^{m} h_i^2\left(\frac{x}{\sqrt{2}}\right) - \sum_{i=1}^{m} y_i(t)\Delta h_i\left(\frac{x}{\sqrt{2}}\right)\\
& + \sum_{i=1}^{m}\sum_{j=1}^{n} y_i(t) f_j\left(\frac{x}{\sqrt{2}}\right)\frac{\partial h_i}{\partial x_j}\left(\frac{x}{\sqrt{2}}\right)\\
& - \frac{1}{2}\sum_{i,j=1}^{m}\sum_{k=1}^{n} y_i(t) y_j(t)\frac{\partial h_i}{\partial x_k}\left(\frac{x}{\sqrt{2}}\right)\frac{\partial h_j}{\partial x_k}\left(\frac{x}{\sqrt{2}}\right).
\end{aligned} \tag{A.4}$$

For any $\tau > 0$, we shall consider the following parabolic equations on $[0,\tau] \times \mathbb{R}^n$.

$$\begin{cases}
\dfrac{\partial\, \overline{u}}{\partial t}(t,x) = \Delta \overline{u}(t,x) + \displaystyle\sum_{i=1}^{n} \overline{f}_i(t,x)\frac{\partial\, \overline{u}}{\partial x_i}(t,x) - \overline{V}(t,x)\overline{u}(t,x)\\
\overline{u}(0,x) = \overline{\psi}(x)
\end{cases} \tag{A.5}$$

$$\text{(A.6)}\qquad \begin{cases} \dfrac{\partial \widetilde{u}}{\partial t}(t,x) = \Delta \widetilde{u}(t,x) + \displaystyle\sum_{i=1}^{n} \widetilde{f}_i(0,x)\frac{\partial \widetilde{u}}{\partial x_i}(t,x) - \widetilde{V}(0,x)\widetilde{u}(t,x) \\ \widetilde{u}(0,x) = \widetilde{\psi}(x), \end{cases}$$

where $\widetilde{f}_i(0,x) := \overline{f}_i(0,x)$ and $\widetilde{V}(0,x) := \overline{V}(0,x)$ are obtained from $\overline{f}_i(t,x)$ and $\overline{V}(t,x)$ by freezing the time variable at 0. For simplicity, we shall assume that the first, second, and third derivatives of $h(x)$ are bounded.

The goal of this appendix is to prove that if $\widetilde{\psi}(x)$ is close to $\overline{\psi}(x)$ uniformly in x, then $\widetilde{u}(\tau,x)$ is close to $\overline{u}(\tau,x)$ uniformly in x. From (A.5) and (A.6), we deduce that

(A.7)

$$\begin{aligned} \frac{\partial(\overline{u}-\widetilde{u})}{\partial t}(t,x) &= \Delta(\overline{u}-\widetilde{u})(t,x) + \sum_{i=1}^{n} \overline{f}_i(t,x)\frac{\partial(\overline{u}-\widetilde{u})}{\partial x_i}(t,x) - \overline{V}(t,x)(\overline{u}-\widetilde{u})(t,x) \\ &\quad + \sum_{i=1}^{n} (\overline{f}_i(t,x) - \widetilde{f}_i(0,x))\frac{\partial \widetilde{u}}{\partial x_i}(t,x) - (\overline{V}(t,x) - \widetilde{V}(0,x))\widetilde{u}(t,x) \\ &= (\Delta - \overline{V}(t,x))(\overline{u}-\widetilde{u})(t,x) + \sum_{i=1}^{n} \overline{f}_i(t,x)\frac{\partial(\overline{u}-\widetilde{u})}{\partial x_i}(t,x) + G_\tau(t,x), \end{aligned}$$

where

$$\text{(A.8)}\qquad G_\tau(t,x) = \sum_{i=1}^{n} (\overline{f}_i(t,x) - \widetilde{f}_i(0,x))\frac{\partial \widetilde{u}}{\partial x_i}(t,x) - (\overline{V}(t,x) - \widetilde{V}(0,x))\widetilde{u}(t,x).$$

LEMMA A.1. *There exists a nonnegative function $\alpha(t,x,y)$ such that*

$$\text{(A.9)}\qquad \begin{cases} \dfrac{\partial \alpha}{\partial t}(t,x,y) = \Delta_x \alpha(t,x,y) - \displaystyle\sum_{i=1}^{n} \overline{f}_i(\tau - t, x)\frac{\partial \alpha}{\partial x_i}(t,x,y) \\ \qquad\qquad - \left[\overline{V}(\tau - t, x) + \displaystyle\sum_{i=1}^{n} \frac{\partial \overline{f}_i}{\partial x_i}(\tau - t, x)\right]\alpha(t,x,y) \\ \alpha(0,x,y) = \delta_y(x), \qquad \int_x \alpha(0,x,y)dx = 1, \end{cases}$$

where $\int_x$ denotes the integration with respect to x variable.

Proof. Let $\beta_n(x,y)$ be a sequence of Gaussian with

$$\text{(A.10)}\qquad \int_x \beta_n(x,y)dx = 1 \quad \text{and} \quad \lim_{n\to\infty} \beta_n(x,y) = \delta_y(x).$$

In view of [26], there exists a solution $\alpha_n(t,x,y)$ with initial condition $\alpha_n(0,x,y) = \beta_n(x,y)$. By maximal principle, $\alpha(t,x,y) \geq 0$ for all $t \geq 0$. We shall take $\alpha(t,x,y) = \lim_{n\to\infty} \alpha_n(t,x,y)$. □

THEOREM A.2. *Let $w(t,x) = \overline{u}(t,x) - \widetilde{u}(t,x)$, where $\overline{u}$ and $\widetilde{u}$ are the solutions of the parabolic equations* (A.5) *and* (A.6)*, respectively. Let $\alpha(t,x,y)$ be the nonnegative function in* Lemma A.1. *Then*

$$w(\tau,y) = \int_x \alpha(\tau,x,y)w(0,x)dx + \int_0^\tau \int_x \alpha(t,x,y)G_\tau(t,x)dx,$$

where $G_\tau(t,x)$ is given in (A.8).

Proof.

$$\text{(A.11)}\quad \int_0^\tau \frac{d}{dt}\int_x \alpha(\tau-t,x,y)w(t,x)dx = -\int_0^\tau\int_x \frac{\partial\alpha}{\partial t}(\tau-t,x,y)w(t,x)dx + \int_0^\tau\int_x \alpha(\tau-t,x,y)\frac{\partial w}{\partial t}(t,x)dx$$

$$\text{L.H.S. of (A.11)} = w(\tau,y) - \int_x \alpha(\tau,x,y)w(0,x)dx$$

$$\begin{aligned}\text{R.H.S. of (A.11)} &= -\int_0^\tau\int_x \Delta_x\alpha(\tau-t,x,y)w(t,x)dx \\ &\quad + \int_0^\tau\int_x \sum_{i=1}^n \overline{f}_i(t,x)\frac{\partial\alpha}{\partial x_i}(\tau-t,x,y)w(t,x)dx \\ &\quad + \int_0^\tau\int_x \left[\overline{V}(t,x) + \sum_{i=1}^n \frac{\partial\overline{f}_i}{\partial x_i}(t,x)\right]\alpha(\tau-t,x,y)w(t,x)dx \\ &\quad + \int_0^\tau\int_x \alpha(\tau-t,x,y)\frac{\partial w}{\partial t}(t,x)dx \\ &= \int_0^\tau\int_x \alpha(\tau-t,x,y)\left[\frac{\partial w}{\partial t}(t,x) - \Delta w(t,x) - \sum_{i=1}^n \overline{f}_i(t,x)\frac{\partial w}{\partial x_i}(t,x)\right. \\ &\qquad\qquad \left. + \overline{V}(t,x)w(t,x)\right]dx \\ &= \int_0^\tau\int_x \alpha(\tau-t,x,y)G_\tau(t,x)dx. \qquad \text{by (A.7)}\end{aligned}$$

In the above computation, we have used the fact proved in [26] that $\alpha(t,x,y)$ has Gaussian decay in x. □

PROPOSITION A.3. *Let $\alpha(t,x,y)$ be the nonnegative function in* Lemma A.1. *Suppose that $\overline{V}(t,x) \geq -c_1$ for some positive constant c_1. Then*

$$\text{(A.12)}\qquad \int_x \alpha(\tau,x,y)dx \leq e^{c_1\tau}.$$

Proof.

$$\begin{aligned}e^{c_1t}\frac{d}{dt}\left(e^{-c_1t}\int_x \alpha(t,x,y)dx\right) &= -c_1\int_x \alpha(t,x,y)dx + \int_x \frac{\partial\alpha}{\partial t}(t,x,y)dx \\ &= -c_1\int_x \alpha(t,x,y)dx + \int_x \Delta_x\alpha(t,x,y)dx - \int_x\sum_{i=1}^n \overline{f}_i(\tau-t,x)\frac{\partial\alpha}{\partial x_i}(t,x,y)dx \\ &\quad - \int_x \left[\overline{V}(\tau-t,x) + \sum_{i=1}^n \frac{\partial\overline{f}_i}{\partial x_i}(\tau-t,x)\right]\alpha(t,x,y)dx \\ &= -c_1\int_x \alpha(t,x,y)dx - \int_x \overline{V}(\tau-t,x)\alpha(t,x,y)dx \\ &= -\int_x [\overline{V}(\tau-t,x)+c_1]\alpha(t,x,y)dx \leq 0.\end{aligned}$$

It follows that $e^{-c_1 t}\int_x \alpha(t,x,y)dx$ is a decreasing function of t and (A.12) follows. □

THEOREM A.4. *With the assumption of* Proposition A.3, *let* $w(t,x) = \overline{u}(t,x) - \widetilde{u}(t,x)$, *where* $\overline{u}$ *and* $\widetilde{u}$ *are the solutions of the parabolic equations* (A.5) *and* (A.6), *respectively. If* τ *is small and* $w(0,x)$ *is small uniformly in* τ, *then* $w(\tau,x)$ *is small uniformly in* x. *More precisely, we have*

$$\sup_{y\in\mathbb{R}^n}|w(\tau,y)| \le e^{c_1\tau}\sup_{x\in\mathbb{R}^n}|w(0,x)| + \tau e^{c_1\tau}\sup_{\substack{x\in\mathbb{R}^n\\ 0\le t\le\tau}}|G_\tau(t,x)|, \tag{A.13}$$

where $G_\tau(t,x)$ *is given in* (A.8).

Proof. In view of (A.3), (A.4), and (A.8), we have

$$\begin{aligned}
G_\tau(t,x) &= \sum_{i=1}^n (\overline{f}_i(t,x) - \widetilde{f}_i(0,x))\frac{\partial\widetilde{u}}{\partial x_i}(t,x) - (\overline{V}(t,x) - \widetilde{V}(0,x))\widetilde{u}(t,x)\\
&= \sum_{i=1}^n \sqrt{2}\sum_{j=1}^m (y_j(t) - y_j(0))\frac{\partial h_j}{\partial x_i}\left(\frac{x}{\sqrt{2}}\right)\frac{\partial\widetilde{u}}{\partial x_i}(t,x)\\
&\quad + \Bigg[-\sum_{i=1}^m (y_i(t) - y_i(0))\Delta h_i\left(\frac{x}{\sqrt{2}}\right) + \sum_{i=1}^m\sum_{j=1}^n (y_i(t) - y_i(0))f_j\left(\frac{x}{\sqrt{2}}\right)\frac{\partial h_i}{\partial x_j}\left(\frac{x}{\sqrt{2}}\right)\\
&\qquad -\frac{1}{2}\sum_{i,j=1}^m\sum_{k=1}^n (y_i(t)y_j(t) - y_i(0)y_j(0))\frac{\partial h_i}{\partial x_k}\left(\frac{x}{\sqrt{2}}\right)\frac{\partial h_j}{\partial x_k}\left(\frac{x}{\sqrt{2}}\right)\Bigg]\widetilde{u}(t,x).
\end{aligned}$$

Therefore if τ is small, then $G_\tau(t,x)$ is uniformly small in x for $0 \le t \le \tau$, because both $\widetilde{u}(t,x)$ and $\frac{\partial\widetilde{u}}{\partial x_i}(t,x)$ have Gaussian decay by [26]. The estimate (A.13) follows readily from Theorem A.2. □

Now we consider the global situation. For a fixed $T > 0$, we want to find the solution $\overline{u}(t,x)$ of the following parabolic equation on $[0,T]\times\mathbb{R}^n$:

$$\begin{cases} \dfrac{\partial\,\overline{u}}{\partial t}(t,x) = \Delta\overline{u}(t,x) + \displaystyle\sum_{j=1}^n \overline{f}_j(t,x)\frac{\partial\,\overline{u}}{\partial x_j}(t,x) - \overline{V}(t,x)\overline{u}(t,x)\\ \overline{u}(0,x) = \overline{\psi}(x). \end{cases} \tag{A.14}$$

Let $\{0 < \tau_1 < \tau_2 < \cdots < \tau_k = T\}$ be a partition of $[0,T]$. Let $\widetilde{u}_i(t,x)$ be the solution of the following parabolic equation on $[\tau_{i-1},\tau_i]\times\mathbb{R}^n$:

$$\begin{cases} \dfrac{\partial\widetilde{u}_i}{\partial t}(t,x) = \Delta\widetilde{u}_i(t,x) + \displaystyle\sum_{j=1}^n \widetilde{f}_j(\tau_{i-1},x)\frac{\partial\widetilde{u}_i}{\partial x_j}(t,x) - \widetilde{V}(\tau_{i-1},x)\widetilde{u}_i(t,x)\\ \widetilde{u}_i(\tau_{i-1},x) = \widetilde{u}_{i-1}(\tau_{i-1},x), \end{cases} \tag{A.15}$$

where $\widetilde{u}_1(0,x) = \overline{\psi}(x)$; $\widetilde{f}_j(\tau_{i-1},x)$ and $\widetilde{V}(\tau_{i-1},x)$ are functions independent of t and equal to $\overline{f}_j(\tau_{i-1},x)$ and $\overline{V}(\tau_{i-1},x)$, respectively.

LEMMA A.5. *Fix* T, *let* $G_{\tau_i}(t,x) = \sum_{j=1}^n(\overline{f}_j(t,x) - \widetilde{f}_j(\tau_{i-1},x))\frac{\partial\widetilde{u}_i}{\partial x_j}(t,x) - (\overline{V}(t,x) - \widetilde{V}(\tau_{i-1},x))\widetilde{u}_i(t,x)$. *For any given* $\epsilon > 0$, *we can choose* k *sufficiently large so that*

$$\sup_{1\le i\le n}\ \sup_{\tau_{i-1}\le t\le\tau_i}\ \sup_{x\in\mathbb{R}^n}|G_{\tau_i}(t,x)| \le \epsilon.$$

Proof. This follows from the proof of Theorem A.4. □

We are now ready to prove the main theorem in this appendix.

THEOREM A.6. *Let* $\overline{u}(t,x)$ *and* $\widetilde{u}_k(t,x)$ *be the solutions of* (A.14) *and* (A.15), *respectively. For any* $\epsilon > 0$, *let* k *be sufficiently large so that* Lemma A.5 *holds. Then*

$$|\overline{u}(T,x) - \widetilde{u}_k(T,x)| \le \epsilon T e^{c_1 T},$$

where c_1 *is the constant in* Proposition A.3.

Proof. In view of $\widetilde{u}_1(0,x) = \overline{\psi}(x) = \overline{u}(0,x)$ and Theorem A.4, we have

$$|\overline{u}(\tau_{1,x}) - \widetilde{u}_1(\tau_{1,x})| \le \tau_1 e^{c_1\tau_1} \sup_{\substack{x\in\mathbb{R}^n \\ 0\le t\le\tau_1}} |G_{\tau_1}(t,x)|.$$

By Theorem A.4 and induction, we have

$$\begin{aligned}
|\overline{u}(\tau_{2,x}) - \widetilde{u}_2(\tau_{2,x})| &\le \tau_1 e^{c_1\tau_1} e^{c_1(\tau_2-\tau_1)} \sup_{\substack{x\in\mathbb{R}^n \\ 0\le t\le\tau_1}} |G_{\tau_1}(t,x)| \\
&\quad + (\tau_2-\tau_1) e^{c_1(\tau_2-\tau_1)} \sup_{\substack{x\in\mathbb{R}^n \\ \tau_1\le t\le\tau_2}} |G_{\tau_2}(t,x)| \\
|\overline{u}(\tau_{k,x}) - \widetilde{u}_k(\tau_{k,x})| &\le \tau_1 e^{c_1\tau_k} \sup_{\substack{x\in\mathbb{R}^n \\ 0\le t\le\tau_1}} |G_{\tau_1}(t,x)| + (\tau_2-\tau_1) e^{c_1(\tau_k-\tau_1)} \sup_{\substack{x\in\mathbb{R}^n \\ \tau_1\le t\le\tau_2}} G_{\tau_2}(t,x)| \\
&\quad + \cdots + (\tau_i - \tau_{i-1}) e^{c_1(\tau_k-\tau_{i-1})} \sup_{\substack{x\in\mathbb{R}^n \\ \tau_{i-1}\le t\le\tau_i}} |G_{\tau_i}(t,x)| \\
&\quad + \cdots + (\tau_k - \tau_{k-1}) e^{c_1(\tau_k-\tau_{k-1})} \sup_{\substack{x\in\mathbb{R}^n \\ \tau_{k-1}\le t\le\tau_k}} |G_{\tau_k}(t,x)| \\
&\le \epsilon[\tau_1 e^{c_1\tau_k} + (\tau_2-\tau_1) e^{c_1(\tau_k-\tau_1)} + \cdots + (\tau_i - \tau_{i-1}) e^{c_1(\tau_k-\tau_{i-1})} \\
&\quad + \cdots + (\tau_k - \tau_{k-1}) e^{c_1(\tau_k-\tau_{k-1})}] \\
&\le \epsilon[\tau_1 + (\tau_2-\tau_1) + \cdots + (\tau_i - \tau_{i-1}) + \cdots + (\tau_n - \tau_{n-1})] e^{c_1 T} \\
&= \epsilon T e^{c_1 T}. \qquad \square
\end{aligned}$$

THEOREM A.7. *Fix* $T > 0$, *let* $\mathcal{P}_n = \{0 < \tau_1 < \tau_2 < \cdots < \tau_k = T\}$ *be a partition of* $[0,T]$. *Let* $\overline{u}(t,x)$ *be the solution of the following parabolic equation on* $[0,T]\times\mathcal{R}^n$:

$$\begin{cases} \dfrac{\partial \overline{u}}{\partial t}(t,x) = \Delta\overline{u}(t,x) + \displaystyle\sum_{j=1}^n \overline{f}_j(t,x)\frac{\partial \overline{u}}{\partial x_j}(t,x) - \overline{V}(t,x)\overline{u}(t,x) \\ \overline{u}(0,x) = \psi(x). \end{cases}$$

Let $\overline{u}_i(t,x)$ *be the solution of the following parabolic equation on* $[\tau_{i-1},\tau_i]\times\mathcal{R}^n$:

$$\begin{cases} \dfrac{\partial \widetilde{u}_i}{\partial t}(t,x) = \Delta\widetilde{u}_i(t,x) + \displaystyle\sum_{j=1}^n \widetilde{f}_j(\tau_{i-1},x)\frac{\partial \widetilde{u}_i}{\partial x_j}(t,x) - \widetilde{V}(\tau_{i-1},x)\widetilde{u}_i(t,x) \\ \widetilde{u}_i(\tau_{i-1},x) = \widetilde{u}_{i-1}(\tau_{i-1},x), \end{cases}$$

where $\widetilde{u}_i(0,x) = \psi(x)$ *and* $\widetilde{f}_j(\tau_{i-1},x) = \overline{f}_j(\tau_{i-1},x)$, $\widetilde{V}(\tau_{i-1},x) = \overline{V}(\tau_{i-1},x)$ *are obtained from* $\overline{f}_j(t,x)$ *and* $\overline{V}(t,x)$ *by freezing time variable at* τ_{i-1}. *Then*

$$\overline{u}(\tau,x) = \lim_{|\mathcal{P}_k|\to 0} \widetilde{u}_k(\tau_k,x) \text{ uniformly in } x.$$

Appendix B: L^2 Convergence of (3.5). In Appendix A we have shown that the solution $\widetilde{u}(t,x)$ of (A.6) is uniformly close to the solution $\overline{u}(t,x)$ of (A.5) for $0 \le t \le T$ if $\widetilde{\psi}(x) = \widetilde{u}(0,x)$ is uniformly close to $\overline{\psi}(x) = \overline{u}(0,x)$. In this section, we shall show that $\widetilde{u}(t,x)$ is also close to $\overline{u}(t,x)$ in L^2-sense, if $\overline{\psi}(x)$ is close to $\widetilde{\psi}(x)$ in L^2 sense. We first recall the following lemma.

LEMMA B.1. *If* $\frac{d\alpha}{dt}(t) \le c\alpha(t)+\beta(t)$, *where* c *is a constant, then* $e^{-ct}\alpha(t)-\alpha(0) \le \int_0^t e^{-cs}\beta(s)ds$.

Let $\overline{f}_{2R}$, $\widetilde{f}_{2R}$, $\overline{V}_{2R}$, and $\widetilde{V}_{2R}$ be the functions obtained by multiplying $\overline{f}, \widetilde{f}, \overline{V}$, and $\widetilde{V}$, respectively, by a cut off function σ which is equal to one in the ball of radius $R \ge 1$ and equal to zero outside a ball of radius $2R$. We can choose σ such that

$$|\nabla\sigma(x)| \le \frac{4}{1+|x|} \text{ and } |\Delta\sigma(x)| \le \frac{4}{1+|x|^2}. \tag{B.1}$$

Consider the following equations:

$$\frac{\partial \overline{u}_{2R}}{\partial t} = \Delta\overline{u}_{2R} + \sum_{i=1}^{n} (\overline{f}_{2R})_i \frac{\partial \overline{u}_{2R}}{\partial x_i} - \overline{V}_{2R}\overline{u}_{2R} \tag{B.2}$$

$$\frac{\partial \widetilde{u}_{2R}}{\partial t} = \Delta\widetilde{u}_{2R} + \sum_{i=1}^{n} (\widetilde{f}_{2R})_i \frac{\partial \widetilde{u}_{2R}}{\partial x_i} - \widetilde{V}_{2R}\widetilde{u}_{2R} \tag{B.3}$$

in the ball B_{2R} of radius $2R$ with the Neumann condition, where $(f_{2R})_i$ and $(\widetilde{f}_{2R})_i$ denote the ith components of f_{2R} and $\widetilde{f}_{2R}$, respectively. Let $\overline{\psi}_{2R}(x) = \overline{\psi}(x)\sigma(x)$ and $\widetilde{\psi}_{2R}(x) = \widetilde{\psi}(x)\sigma(x)$ to be the initial conditions of (B.2) and (B.3), respectively. Then (B.2) and (B.3) have unique solutions, respectively, for $t \in [0,\infty)$ with Neumann condition on $\partial B_{2R} \times (0,T]$.

LEMMA B.2. *Assume that* (4.1)–(4.3) *hold and the first, second, and third derivatives of* $h_i(x)$ *are bounded. Let* $\widetilde{c}$ *and* δ *be positive constants such that* $\widetilde{\widetilde{c}} := \widetilde{c}+\delta < \frac{5}{254}$. *Choose* τ *and* ϵ *suitably small with* $\tau+\epsilon < \delta$. *Then the following conclusions hold for any* $0 \le t \le \tau$ *for both* $\rho\epsilon\{\overline{\rho},\widetilde{\rho}\}$, $u \in \{\overline{u},\widetilde{u}\}$, *and where* $\overline{\rho}(t,x) = \frac{\widetilde{c}(1+|x|^2)}{t+\epsilon}$, $\widetilde{\rho}(t,x) = \frac{\widetilde{\widetilde{c}}(1+|x|^2)}{t+\epsilon}$:

(i) $$\int_{\{t\}\times B_{2R}} e^{\overline{\rho}}\overline{u}_{2R}^2 \le \int_{\{0\}\times B_{2R}} e^{\overline{\rho}}\overline{u}_{2R}^2$$

(ii) $$\int_{\{t\}\times B_{2R}} e^{\overline{\rho}}|\nabla\overline{u}_{2R}|^2 \le \int_{\{0\}\times B_{2R}} e^{\overline{\rho}}|\nabla\overline{u}_{2R}|^2 + \int_0^t \int_{B_{2R}} e^{\overline{\rho}(s,x)}|\overline{u}_{2R}(s,x)|^2$$

(iii) $$\int_{\{t\}\times B_{2R}} e^{\overline{\rho}}|\Delta\overline{u}_{2R}|^2 \le \int_{\{0\}\times B_{2R}} e^{\overline{\rho}}|\Delta\overline{u}_{2R}|^2$$

$$+O\bigg(\int_{[0,t]\times B_{2R}} e^{\overline{\rho}}|\nabla\overline{\rho}|^2|\overline{f}_{2R}|^2|\nabla\overline{u}_{2R}|^2+\int_{[0,t]\times B_{2R}} e^{\overline{\rho}}|\nabla\overline{f}_{2R}|^2|\nabla\overline{u}_{2R}|^2$$
$$+\int_{[0,t]\times B_{2R}} e^{\overline{\rho}}|\overline{f}_{2R}||\nabla\overline{u}_{2R}|^2|\Delta\overline{f}_{2R}|+\int_{[0,t]\times B_{2R}} e^{\overline{\rho}}|\overline{f}_{2R}|^4|\nabla\overline{u}_{2R}|^2$$
$$+\int_{[0,t]\times B_{2R}} e^{\overline{\rho}}|\nabla(\overline{V}_{2R}\overline{u}_{2R})|^2+\int_{[0,t]\times B_{2R}} e^{\overline{\rho}}|\nabla\overline{u}_{2R}|^2\left(\sum_{i=1}^n\frac{\partial(\overline{f}_{2R})_i}{\partial x_i}\right)^2\bigg).$$

Moreover, the following inequalities hold for both $\{\overline{\rho},\overline{f},\overline{V}\}$, *or* $\{\overline{\rho},\widetilde{f},\widetilde{V}\}$ *or* $\{\widetilde{\rho},\overline{f},\overline{V}\}$ *or* $\{\widetilde{\rho},\widetilde{f},\widetilde{V}\}$ *if* δ *is small enough,*

(iv) $$\frac{\partial\overline{\rho}}{\partial t}+2|\nabla\overline{\rho}|^2-\sum_{i=1}^n\overline{f}_i\frac{\partial\overline{\rho}}{\partial x_i}-\sum_{i=1}^n\frac{\partial\overline{f}_i}{\partial x_i}-2\overline{V}\le 0.$$

Proof. (i), (ii), and (iii) follow from Lemma 1.3 of [26] by setting $\epsilon_1=\frac{1}{5}$ in that lemma. In equality (iv), it follows from

$$\frac{\partial\widetilde{\rho}}{\partial t}+2|\nabla\widetilde{\rho}|^2-\sum_{i=1}^n\overline{f}_i\frac{\partial\widetilde{\rho}}{\partial x_i}-\sum_{i=1}^n\frac{\partial\overline{f}_i}{\partial x_i}-2\overline{V}$$
$$\le\left[\frac{-\,\widetilde{\widetilde{c}}\,(1-8\,\widetilde{\widetilde{c}})}{(t+\epsilon)^2}+\frac{2c\,\widetilde{\widetilde{c}}}{t+\epsilon}+(n+2)c\right](1+|x|)^2$$

as $1-8\,\widetilde{\widetilde{c}}\ge 0$. □

PROPOSITION B.3. *Consider the parabolic differential equations* (A.5) *and* (A.6). *Let* ϕ *be any smooth function defined on* $\mathbb{R}^n$ *with compact support contained in a domain* Ω. *Let* $\overline{\rho}$ *be any smooth function on* $\mathbb{R}_+\times\mathbb{R}^n$ *satisfying*

$$\frac{\partial\overline{\rho}}{\partial t}+2|\nabla\overline{\rho}|^2-\sum_{i=1}^n\overline{f}_i\frac{\partial\overline{\rho}}{\partial x_i}-\sum_{i=1}^n\frac{\partial\overline{f}_i}{\partial x_i}-2\overline{V}\le 0. \tag{B.4}$$

Then

$$\frac{d}{dt}\int_{\{t\}\times\Omega}\phi^2e^{\overline{\rho}}(\overline{u}-\widetilde{u})^2\le\int_{\{t\}\times\Omega}\phi^2e^{\overline{\rho}}(\overline{u}-\widetilde{u})^2+10\int_{\{t\}\times\Omega}e^{\overline{\rho}}(\overline{u}-\widetilde{u})^2|\nabla\phi|^2$$
$$+4\int_{\{t\}\times\Omega}e^{\overline{\rho}}\bigg|\sum_{i=1}^n\overline{f}_i\frac{\partial\phi}{\partial x_i}\bigg|^2(\overline{u}-\widetilde{u})^2+4\int_{\{t\}\times\Omega}e^{\overline{\rho}}\phi^2\bigg|\sum_{i=1}^n(\overline{f}_i-\widetilde{f}_i)\frac{\partial\overline{\rho}}{\partial x_i}\bigg|^2\widetilde{u}^2$$
$$+2\int_{\{t\}\times\Omega}e^{\overline{\rho}}\phi^2\widetilde{u}|\overline{f}-\widetilde{f}|^2+4\int_{\{t\}\times\Omega}e^{\overline{\rho}}\phi^2\widetilde{u}^2|\overline{V}-\widetilde{V}|^2$$
$$+2\int_{\{t\}\times\Omega}e^{\overline{\rho}}\phi^2|\overline{f}-\widetilde{f}|^2\widetilde{u}^2+4\int_{\{t\}\times\Omega}e^{\overline{\rho}}\phi^2\widetilde{u}^2\bigg|\sum_{i=1}^n\bigg(\frac{\partial\overline{f}_i}{\partial x_i}-\frac{\partial\widetilde{f}_i}{\partial x_i}\bigg)\bigg|^2. \tag{B.5}$$

Proof. From (A.5) and (A.6), we deduce that

$$\frac{\partial(\overline{u}-\widetilde{u})}{\partial t}=\Delta(\overline{u}-\widetilde{u})+\sum_{i=1}^n f_i\frac{\partial(\overline{u}-\widetilde{u})}{\partial x_i}-V(u-\widetilde{u})+\sum_{i=1}^n(\overline{f}_i-\widetilde{f}_i)\frac{\partial\widetilde{u}}{\partial x_i}-(\overline{V}-\widetilde{V})\widetilde{u}. \tag{B.6}$$

Then using (B.6) and integrating by part, we obtain

$$\begin{aligned}\frac{d}{dt}\int_{\{t\}\times\Omega}\phi^2(\overline{u}-\widetilde{u})^2e^{\overline{\rho}} \le &\int_{\{t\}\times\Omega}e^{\overline{\rho}}\phi^2(\overline{u}-\widetilde{u})^2\left(\frac{\partial\overline{\rho}}{\partial t}+2|\nabla\overline{\rho}|^2-\sum_{i=1}^n\overline{f}_i\overline{\rho}_i-\sum_{i=1}^n\frac{\partial\overline{f}_i}{\partial x_i}-2\overline{V}\right)\\ &-\frac{1}{2}\int_{\{t\}\times\Omega}e^{\overline{\rho}}\phi^2|\nabla(\overline{u}-\widetilde{u})|^2+8\int_{\{t\}\times\Omega}e^{\overline{\rho}}(\overline{u}-\widetilde{u})^2|\nabla\phi|^2\\ &-2\int_{\{t\}\times\Omega}\phi e^{\overline{\rho}}\left(\sum_{i=1}^n\overline{f}_i\phi_i\right)(\overline{u}-\widetilde{u})^2-4\int_{\{t\}\times\Omega}e^{\overline{\rho}}\phi\left[\sum_{i=1}^n(\overline{f}_i-\widetilde{f}_i)\phi_i\right]\widetilde{u}(\overline{u}-\widetilde{u})\\ &-2\int_{\{t\}\times\Omega}e^{\overline{\rho}}\phi^2\sum_{i=1}^n(\overline{f}_i-\widetilde{f}_i)\frac{\partial\overline{\rho}}{\partial x_i}\widetilde{u}(\overline{u}-\widetilde{u})+2\int_{\{t\}\times\Omega}e^{\overline{\rho}}\phi^2\widetilde{u}^2|f-\widetilde{f}|^2\\ &-2\int_{\{t\}\times\Omega}e^{\overline{\rho}}\phi^2(\overline{u}-\widetilde{u})\widetilde{u}\sum_{i=1}^n\left(\frac{\partial\overline{f}_i}{\partial x_i}-\frac{\partial\widetilde{f}_i}{\partial x_i}\right)-2\int_{\{t\}\times\Omega}e^{\overline{\rho}}\phi^2(\overline{u}-\widetilde{u})\widetilde{u}(\overline{V}-\widetilde{V}).\end{aligned}\tag{B.7}$$

In view of (B.4), (B.7) implies that

$$\begin{aligned}\frac{d}{dt}\int_{\{t\}\times\Omega}\phi^2e^{\overline{\rho}}(\overline{u}-\widetilde{u})^2 \le\ & 8\int_{\{t\}\times\Omega}e^{\overline{\rho}}(\overline{u}-\widetilde{u})^2|\nabla\phi|^2+4\int_{\{t\}\times\Omega}e^{\overline{\rho}}(\overline{u}-\widetilde{u})^2\left|\sum_{i-1}^n\overline{f}_i\frac{\partial\phi}{\partial x_i}\right|^2\\ &+\frac{1}{4}\int_{\{t\}\times\Omega}e^{\overline{\rho}}\phi^2(\overline{u}-\widetilde{u})^2+\frac{1}{4}\int_{\{t\}\times\Omega}e^{\overline{\rho}}\phi^2(\overline{u}-\widetilde{u})^2\\ &+4\int_{\{t\}\times\Omega}e^{\overline{\rho}}\phi^2\left|\sum_{i=1}^n(\overline{f}_i-\widetilde{f}_i)\frac{\partial\overline{\rho}}{\partial x_i}\right|^2\widetilde{u}^2+2\int_{\{t\}\times\Omega}e^{\overline{\rho}}\phi^2\widetilde{u}^2|\overline{f}-\widetilde{f}|^2\\ &+\frac{1}{4}\int_{\{t\}\times\Omega}e^{\overline{\rho}}\phi^2(\overline{u}-\widetilde{u})^2+4\int_{\{t\}\times\Omega}e^{\overline{\rho}}\phi^2\widetilde{u}^2|\overline{V}-\widetilde{V}|^2\\ &+4\left[\frac{1}{2}\int_{\{t\}\times\Omega}e^{\overline{\rho}}(\overline{u}-\widetilde{u})^2|\nabla\phi|^2+\frac{1}{2}\int_{\{t\}\times\Omega}e^{\overline{\rho}}\phi^2|\overline{f}-\widetilde{f}|^2\widetilde{u}^2\right]\\ &+2\left[\frac{1}{8}\int_{\{t\}\times\Omega}e^{\overline{\rho}}\phi^2(\overline{u}-\widetilde{u})^2+2\int_{\{t\}\times\Omega}e^{\overline{\rho}}\phi^2\widetilde{u}^2\left|\sum_{i=1}^n\left(\frac{\partial\overline{f}_i}{\partial x_i}-\frac{\partial\widetilde{f}_i}{\partial x_i}\right)\right|^2\right].\end{aligned}$$

Inequality (B.5) follows immediately. □

The following theorem states that when τ is sufficiently small and $\overline{\psi}(x)$ close to $\widetilde{\psi}(x)$ in L^2-sense, then the solution $\widetilde{u}(t,x)$ of (A.6) approximates the solution $\overline{u}(t,x)$ of (A.5) well in L^2-sense.

THEOREM B.4. *Consider the parabolic differential equation* (A.5) *and* (A.6). *Assume that* (4.1)–(4.3) *hold and the first, second, and third derivatives of* $h_i(x)$ *are bounded. Let* $\widetilde{c}$ *and* δ *be positive constants such that* $\widetilde{\widetilde{c}}:=\widetilde{c}+\delta<\frac{5}{254}$. *Let*

$$\overline{\rho}(t,x)=\frac{\widetilde{c}(1+|x|^2)}{t+\epsilon},\qquad \widetilde{\rho}(t,x)=\frac{\widetilde{\widetilde{c}}\ (1+|x|^2)}{t+\epsilon}.$$

Suppose that

$$\int_{\mathbb{R}^n}e^{\overline{\rho}(0,x)}(|\overline{\psi}(x)|^2+|\nabla\widetilde{\psi}(x)|^2+|\Delta\overline{\psi}(x)|^2)<\infty$$
$$\int_{\mathbb{R}^n}e^{\overline{\rho}(0,x)}(|\widetilde{\psi}(x)|^2+|\nabla\widetilde{\psi}(x)|^2+|\Delta\widetilde{\psi}(x)|^2)<\infty.$$

Choose τ and ϵ suitably small so that $\tau+\epsilon<\delta$ and the conclusions of Lemma B.2 *hold. Suppose that for $0\le t\le\tau$,*

$$|\overline{f}(t,x)-\widetilde{f}(t,x)|\le\widetilde{\epsilon}_1 c(1+|x|) \tag{B.8}$$

$$\left|\sum_{i=1}^n\left(\frac{\partial\overline{f}_i}{\partial x_i}(t,x)-\frac{\partial\widetilde{f}_i}{\partial x_i}(t,x)\right)\right|\le\widetilde{\epsilon}_1 c \tag{B.9}$$

$$|\overline{V}(t,x)-\widetilde{V}(t,x)|\le\widetilde{\epsilon}_1 c(1+|x|^2) \tag{B.10}$$

$$\int_{\mathbb{R}^n} e^{\overline{\rho}(0,x)}|\overline{\psi}(x)-\widetilde{\psi}(x)|^2\le\widetilde{\epsilon}_2. \tag{B.11}$$

Then

$$\begin{aligned}\int_{\{t\}\times\mathbb{R}^n} e^{\overline{\rho}}(\overline{u}-\widetilde{u})^2 &\le\widetilde{\epsilon}_2 e^t+16\widetilde{\epsilon}_1^2c^2\widetilde{c}^2\frac{t}{\epsilon(t+\epsilon)}e^t d_1+24t\widetilde{\epsilon}_1^2c^2e^t d_1\\ &\le\widetilde{\epsilon}_2e^\tau+\widetilde{\epsilon}_1^2\tau e^\tau c_1,\end{aligned}$$

where $d_1=\int_{\mathbb{R}^n}e^{\overline{\rho}(0,x)}(\widetilde{\psi}(x))^2$, $c_1=\frac{16c^2\widetilde{c}^2d_1}{\epsilon^2}+24c^2d_1$, and c is a constant for linear growth of $\nabla\overline{V}$ and $\nabla\widetilde{V}$, i.e., $|\nabla\overline{V}(t,x)|\le c(1+|x|)$, and $|\nabla\widetilde{V}(t,x)|\le c(1+|x|)$.

Proof. Let $R_0\ge1$ and $B_{R_0}^c=\{x\in\mathbb{R}^n:|x|>R_0\}$ and

$$\phi(x)=\begin{cases}1 & \text{for } |x|\le R_0\\ \frac{\log R-\log|x|}{\log R-\log R_0} & \text{for } R_0\le|x|\le R=2R_0\\ 0 & \text{for } |x|\ge R=2R_0.\end{cases}$$

Let Ω be defined as B_R in Proposition B.3. In view of Lemma B.1 and (B.5), we have

$$\begin{aligned}&e^{-t}\int_{\{t\}\times\Omega}\phi^2e^{\overline{\rho}}(\overline{u}-\widetilde{u})^2-\int_{\{0\}\times\Omega}\phi^2e^{\overline{\rho}}(\overline{u}-\widetilde{u})^2\\ &\le10\int_0^t e^{-s}\int_{\{s\}\times\Omega}e^{\overline{\rho}}(\overline{u}-\widetilde{u})^2|\nabla\phi|^2+4\int_0^t e^{-s}\int_{\{s\}\times\Omega}e^{\rho}\left|\sum_{i=1}^n\overline{f}_i\frac{\partial\phi}{\partial x_i}\right|^2(\overline{u}-\widetilde{u})^2\\ &+4\int_0^t e^{-s}\int_{\{s\}\times\Omega}e^{\overline{\rho}}\phi^2\left|\sum_{i=1}^n(\overline{f}_i-\widetilde{f}_i)\frac{\partial\rho}{\partial x_i}\right|^2\widetilde{u}^2+2\int_0^t e^{-s}\int_{\{s\}\times\Omega}e^{\overline{\rho}}\phi^2\widetilde{u}^2|\overline{f}-\widetilde{f}|^2\\ &+4\int_0^t e^{-s}\int_{\{s\}\times\Omega}e^{\overline{\rho}}\phi^2\widetilde{u}^2|\overline{V}-\widetilde{V}|^2+2\int_0^t e^{-s}\int_{\{s\}\times\Omega}e^{\overline{\rho}}\phi^2|\overline{f}-\widetilde{f}|^2\widetilde{u}^2\\ &+4\int_0^t e^{-s}\int_{\{s\}\times\Omega}e^{\overline{\rho}}\phi^2\widetilde{u}^2\left|\sum_{i=1}^n\left(\frac{\partial\overline{f}_i}{\partial x_i}-\frac{\partial\widetilde{f}_i}{\partial x_i}\right)\right|^2\\ &\le\frac{10e^{\overline{\rho}(0,R)}}{R_0^2(\log R-\log R_0)^2}\int_0^t e^{-s}\int_{\{s\}\times(B_{R_0}^C\cap B_R)}(\overline{u}-\widetilde{u})^2\\ &+\frac{4c^2(1+R)^2e^{\overline{\rho}(4R)}}{R_0^2(\log R-\log R_0)^2}\int_0^t e^{-s}\int_{\{s\}\times(B_{R_0}^c\cap B_R)}(\overline{u}-\widetilde{u})^2\end{aligned}$$

$$
\begin{aligned}
&+4\int_0^t e^{-s}\int_{\{s\}\times\Omega} e^{\overline{\rho}}\phi^2\left|\sum_{i=1}^n(\overline{f}_i-\widetilde{f}_i)\frac{\partial\overline{\rho}}{\partial x_i}\right|^2\widetilde{u}^2\\
&+4\int_0^t e^{-s}\int_{\{s\}\times\Omega} e^{\overline{\rho}}\phi^2\widetilde{u}^2|\overline{f}-\widetilde{f}|^2+4\int_0^t e^{-s}\int_{\{s\}\times\Omega} e^{\overline{\rho}}\phi^2\widetilde{u}^2|\overline{V}-\widetilde{V}|^2\\
&+4\int_0^t e^{-s}\int_{\{s\}\times\Omega} e^{\overline{\rho}}\phi^2\widetilde{u}^2\left|\sum_{i=1}^n\left(\frac{\partial\overline{f}_i}{\partial x_i}-\frac{\partial\widetilde{f}_i}{\partial x_i}\right)\right|^2. \qquad \text{(B.12)}
\end{aligned}
$$

Observe that (B.11) implies

$$
e^t\int_{\{0\}\times B_R} e^{\overline{\rho}}(\overline{u}-\widetilde{u})^2\le\widetilde{\epsilon}_2 e^t. \qquad \text{(B.13)}
$$

By Corollary 4.1 of [26], u and $\widetilde{u}$ decay like Gaussian in x variables. So we shall assume

$$
\max_{x\in\mathbb{R}^n}(|u|,|\widetilde{u}|)\le D_1e^{-D_2|x|^2}\text{ for }t\text{ small}, \qquad \text{(B.14)}
$$

for some $D_1,D_2>0$. In view of the proof of Corollary 4.1 of [26], we can take $D_2\ge\frac{4\widetilde{c}}{\epsilon}+1$ for sufficiently small t

$$
\begin{aligned}
&\frac{[10+4c^2(1+R)^2]e^{\overline{\rho}(0,R)}}{R_0^2(\log R-\log R_0)^2}\int_0^t e^{-s}\int_{\{s\}\times(B^c_{R_0}\cap B_R)}(\overline{u}-\widetilde{u})^2\\
&\le\frac{4[10+4c^2(1+R)^2]te^{\overline{\rho}(0,R)}}{R_0^2(\log R-\log R_0)^2}\int_{B^c_{R_0}\cap B_r}D_1e^{-D_2|x|^2}\\
&\le\frac{4D_1[10+4c^2(1+R)^2]te^{\overline{\rho}(0,R)}}{R_0^2(\log R-\log R_0)^2}\omega_0R^ne^{-D_2R_0^2}\\
&=\frac{4\omega_0D_1R^n[10+4c^2(1+R)^2]t}{R_0^2(\log R-\log R_0)^2}\exp\left(\frac{\overline{c}}{\epsilon}+\left(\frac{4\overline{c}}{\epsilon}-D_2\right)R_0^2\right)\\
&\le\frac{4\omega_0D_1R^n[10+4c^2(1+R)^2]t}{R_0^2(\log R-\log R_0)^2}\exp\left(-R_0^2+\frac{\overline{c}}{\epsilon}\right), \qquad \text{(B.15)}
\end{aligned}
$$

where ω_0 is the volume of the unit ball in $\mathbb{R}^n$. Recall that $|\nabla\overline{\rho}|^2=\frac{4\overline{c}^2|x|^2}{(t+\epsilon)^2}$. Hence (B.8) implies

$$
\begin{aligned}
&4\int_0^t e^{-s}\int_{\{s\}\times\Omega} e^{\overline{\rho}}\phi^2\left|\sum_{i=1}^n(\overline{f}_i-\widetilde{f}_i)\frac{\partial\overline{\rho}}{\partial x_i}\right|^2\widetilde{u}^2\\
&\le 4\int_0^t\int_{\{s\}\times\Omega} e^{\overline{\rho}}\phi^2|\overline{f}-\widetilde{f}|^2|\nabla\rho|^2\widetilde{u}^2\\
&\le 4\int_0^t\int_{\{s\}\times\Omega}\widetilde{\epsilon}_1^2c^2(1+|x|)^2\frac{4\overline{c}^2|x|^2}{(s+\epsilon)^2}e^{\overline{\rho}}\widetilde{u}^2\\
&\le 16\widetilde{\epsilon}_1^2c^2\widetilde{c}^2\int_0^t\frac{1}{(s+\epsilon)^2}\int_{\{s\}\times B_R}e^{\widetilde{\rho}}\widetilde{u}^2. \qquad \text{(B.16)}
\end{aligned}
$$

Similarly, we can prove that

$$4\int_0^t e^{-s}\int_{\{s\}\times\Omega} e^{\overline{\rho}}\phi^2\widetilde{u}^{\,2}|\overline{f}-\widetilde{f}|^2 \le 16\widetilde{\epsilon}_1^2c^2\int_0^t\int_{\{s\}\times B_R} e^{\widetilde{\rho}}\widetilde{u}^2 \tag{B.17}$$

$$4\int_0^t e^{-s}\int_{\{s\}\times\Omega} e^{\overline{\rho}}\phi^2\widetilde{u}^{\,2}|\overline{V}-\widetilde{V}|^2 \le 4\widetilde{\epsilon}_1^2c^2\int_0^t\int_{\{s\}\times B_R} e^{\widetilde{\rho}}\widetilde{u}^2 \tag{B.18}$$

$$4\int_0^t e^{-s}\int_{\{s\}\times\Omega} e^{\overline{\rho}}\phi^2\widetilde{u}^2\left|\sum_{i=1}^n\left(\frac{\partial\overline{f}_i}{\partial x_i}-\frac{\partial\widetilde{f}_i}{\partial x_i}\right)\right|^2 \le 4\widetilde{\epsilon}_1^2c^2\int_0^t\int_{\{s\}\times B_R} e^{\overline{\rho}}\widetilde{u}^2. \tag{B.19}$$

Hence (B.12)–(B.18) and Lemma B.2 imply that

$$\begin{aligned}
&\int_{\{t\}\times B_{R_0}} e^{\overline{\rho}}(\overline{u}-\widetilde{u})^2\\
&\quad\le \widetilde{\epsilon}_2e^t+\frac{4te^t\omega_0R^nD_1[10+4c^2(1+R)^2]}{R_0^2(\log R-\log R_0)^2}\exp\left(-R_0^2+\frac{\overline{c}}{\epsilon}\right)\\
&\quad+16e^t\widetilde{\epsilon}_1^2c^2\widetilde{c}^2\int_0^t\frac{1}{(s+\epsilon)^2}\int_{\{s\}\times B_R} e^{\widetilde{\rho}}\widetilde{u}^2+16e^t\widetilde{\epsilon}_1^2c^2\int_0^t\int_{\{s\}\times B_R} e^{\widetilde{\rho}}\widetilde{u}^2\\
&\quad+4e^t\widetilde{\epsilon}_1^2c^2\int_0^t\int_{\{s\}\times B_R} e^{\widetilde{\rho}}\widetilde{u}^2+4\widetilde{\epsilon}_1^2c^2e^t\int_0^t\int_{\{s\}\times B_R} e^{\widetilde{\rho}}\widetilde{u}^2\\
&\quad\le \widetilde{\epsilon}_2e^t+\frac{4te^t\omega_0D_1R^n[10+4c^2(1+R)^2]}{R_0^2(\log R-\log R_0)^2}\exp\left(-R_0+\frac{\overline{c}}{\epsilon}\right)\\
&\quad+16e^t\widetilde{\epsilon}_1^2c^2\widetilde{c}^2\int_0^t\frac{1}{(s+\epsilon)^2}\int_{\{0\}\times B_R} e^{\widetilde{\rho}}\widetilde{u}^2\\
&\quad+24e^t\widetilde{\epsilon}_1^2c^2\int_0^t\int_{\{0\}\times B_R} e^{\widetilde{\rho}}\widetilde{u}^2\\
&\quad\le \widetilde{\epsilon}_2e^t+\frac{16e^t\widetilde{\epsilon}_1^2c^2\widetilde{c}^{\,2}d_1t}{\epsilon(t+\epsilon)}+24te^t\widetilde{\epsilon}_1^2c^2d_1\\
&\quad+\frac{4te^t\omega_0D_1R^n[10+4c^2(1+R)^2]}{R_0^2(\log R-\log R_0)^2}\exp\left(-R_0^2+\frac{\overline{c}}{\epsilon}\right).
\end{aligned}\tag{B.20}$$

Let $R=2R_0$ go to infinity in (5.20), we obtain the estimate in the statement of Theorem B.4. □

Now we are ready to consider the global situation. For a fixed $T>0$, we want to find the solution $\overline{u}(t,x)$ of (A.5).

THEOREM B.5. *Let $\overline{u}(t,x)$ and $\widetilde{u}_i(t,x)$ be the solutions of* (A.14) *and* (A.15)*, respectively. For $\widetilde{\epsilon}_1>0$, let $|\mathcal{P}_k|=\sup_i\{|t_i-t_{i-1}|\}$ be sufficiently small so that the following estimates hold:*

$$|\overline{f}(t,x)-\widetilde{f}(\tau_{i-1},x)|\le\widetilde{\epsilon}_1c(1+|x|),\ \text{for}\ \ \tau_{i-1}\le t\le\tau_i, \tag{B.21}$$

$$\left|\sum_{j=1}^n\left(\frac{\partial\overline{f}_j}{\partial x_j}(t,x)-\frac{\partial\widetilde{f}_j}{\partial x_j}(\tau_{i-1},x)\right)\right|\le\widetilde{\epsilon}_1c \tag{B.22}$$

$$\left|\overline{V}(t,x)-\widetilde{V}(\tau_{i-1},x)\right|\le\widetilde{\epsilon}_1c(1+|x|^2). \tag{B.23}$$

Then

$$\int_{\mathbb{R}^n} e^{\overline{\rho}(T,x)}(\overline{u}(T,x)-\widetilde{u}_k(T,x))^2\le\widetilde{\epsilon}_1^2c_1k|\mathcal{P}_k|e^T\le\widetilde{\epsilon}_1^2c_1c_2(T),$$

where $\overline{\rho}(t,x) = \frac{\widetilde{c}(1+|x|^2)}{t+\epsilon}$ *so that the conclusion of* Theorem B.4 *holds,* c_1 *is the constant in* Theorem B.4*, and* $c_2(T)$ *is a constant that depends only on* T*.*

Proof. In view of $\widetilde{u}_1(0,x) = \psi(x) = \overline{u}(0,x)$ and Theorem B.4, we have

$$\int_{\{\tau_1\}\times\mathbb{R}^n} e^{\overline{\rho}}(\overline{u}-\widetilde{u})^2 \le \widetilde{\epsilon}_1^2 \tau_1 e^{\tau_1} c_1$$

$$\int_{\{\tau_2\}\times\mathbb{R}^n} e^{\overline{\rho}}(\overline{u}-\widetilde{u})^2 \le \widetilde{\epsilon}_1^2 c_1[\tau_1 e^{\tau_2} + (\tau_2-\tau_1)e^{\tau_2-\tau_1}].$$

By Theorem B.4 and induction, we have

$$\begin{aligned}\int_{\{\tau_k\}\times\mathbb{R}^n} e^{\overline{\rho}}(\overline{u}-\widetilde{u})^2 &= \widetilde{\epsilon}_1^2 c_1[\tau_1 e^{\tau_k} + (\tau_2-\tau_1)e^{\tau_k-\tau_1} + (\tau_3-\tau_2)e^{\tau_k-\tau_2} \\ &\qquad + \cdots + (\tau_k-\tau_{k-1})e^{\tau_k-\tau_{k-1}}] \\ &\le \widetilde{\epsilon}_1^2 c_1 k|\mathcal{P}_k|e^T \\ &\le \widetilde{\epsilon}_1^2 c_1 c_2(T). \qquad \square\end{aligned}$$

As a consequence of Theorem B.5, we have the following L^2-convergent theorem.

THEOREM B.6. *Fix* $T > 0$*, let* $\mathcal{P}_k = \{0 < \tau_1 < \tau_2 < \cdots < \tau_k = T\}$ *be a partition of* $[0,T]$*. Let* $\overline{u}(t,x)$ *be the solution of* (A.14) *on* $[0,T]\times\mathbb{R}^n$*. Let* $\widetilde{u}_i(t,x)$ *be the solution of* (A.15) *on* $[\tau_{i-1},\tau_i]\times\mathbb{R}^n$*. Let* $\overline{\rho}(t,x) = \frac{\widetilde{c}(1+|x|^2)}{t+\epsilon}$ *so that the conclusion of* Theorem B.5 *holds. Then*

$$\lim_{|\mathcal{P}_k|\to 0}\int_{\{T\}\times\mathbb{R}^n} \overline{\rho}(\overline{u}-\widetilde{u}_k)^2 = 0.$$

Acknowledgments. We gratefully acknowledge the referees for their careful reading of our paper and some useful suggestions of improving our presentation.

LINEAR COMPLEMENTARITY SYSTEMS: ZENO STATES*

JINGLAI SHEN† AND JONG-SHI PANG†

Abstract. A linear complementarity system (LCS) is a hybrid dynamical system defined by a linear time-invariant ordinary differential equation coupled with a finite-dimensional linear complementarity problem (LCP). The present paper is the first of several papers whose goal is to study some fundamental issues associated with an LCS. Specifically, this paper addresses the issue of Zeno states and the related issue of finite number of mode switches in such a system. The cornerstone of our study is an expansion of a solution trajectory to the LCS near a given state in terms of an observability degree of the state. On the basis of this expansion and an inductive argument, we establish that an LCS satisfying the P-property has no strongly Zeno states. We next extend the analysis for such an LCS to a broader class of problems and provide sufficient conditions for a given state to be weakly non-Zeno. While related mode-switch results have been proved by Brunovsky and Sussmann for more general hybrid systems, our analysis exploits the special structure of the LCS and yields new results for the latter that are of independent interest and complement those by these two and other authors.

Key words. linear complementarity systems, Zeno states, P-matrix, complementarity problem

1. Introduction.

A linear complementarity system (LCS) is a special dynamical system defined by an linear ordinary differential equation (ODE) involving an algebraic variable that is required to be a solution of a standard linear complementarity problem (LCP) [11]. While being a special instance of a differential variational inequality, which has recently been studied in great depth in [23], the LCS has itself received an extensive treatment in two excellent Ph.D. theses [5, 13] and in related articles [3, 8, 9, 15, 16, 17]. In addition, the LCS belongs to the broad framework of a hybrid system [18, 20, 30, 34, 35, 36, 26, 28], which is defined by a finite number of smooth ODEs, called *modes*, with transitions between the modes occurring along a state trajectory. Examples of dynamical systems in which the complementarity paradigm has played a prominent role include nonsmooth mechanical systems [2, 24] in general and multibody dynamics simulation under frictional contacts in particular [1, 21, 29, 31, 32], as well as switched electrical networks and switched control systems, e.g., relay systems and variable structure systems [6, 7, 14, 19, 38]. In addition, linear-quadratic dynamic Nash games with linear dynamics and control constraints naturally lead to LCSs with special boundary conditions. For an excellent state-of-the-art review of complementarity systems and their applications in engineering and economics, we refer to the excellent recent article by Schumacher [27].

The LCS occupies a fundamental role in the study of nonsmooth dynamical systems because it is arguably the simplest of such systems. Though seemingly simple, the analysis of the LCS in general is complicated by impulsive and multimodal behavior of its solutions. In the references cited above, such as in the two theses [5, 13],

the study of the LCS has employed many concepts and results from (constrained) linear systems theory; in particular, the concept of system passivity [37] has played a major role. In contrast to this system-theoretic approach, we feel that a better understanding of the LCS as a basic mathematical model can be achieved by considering the simplest, albeit nontrivial, instance of such a system. Motivated by this contrasting "mathematical programming" approach, we are led to consider an LCS satisfying the "P-property," i.e., where the underlying finite-dimensional LCP has a unique solution for all constant vectors. An immediate consequence of this property is that the LCS is globally equivalent to an ODE with a piecewise linear, thus Lipschitz continuous, right-hand side (which albeit is only implicitly defined). While this is a great simplification, the piecewise linear nature of the right-hand side renders the LCS a nonsmooth system and leads to many important system-theoretic and control issues that require careful study. Several of these topics are the main concern of this and accompanying papers. Extending the class of LCSs with the P-property, we will also consider a broader class of systems and study their (non-)Zeno states.

The organization of the rest of the paper is as follows. In section 2, we formally define the LCS, review some basic results of the LCP, and introduce two new LCP concepts that are useful for our study. Section 3 addresses the question of whether there can be infinitely many mode transitions in any finite time, i.e., the *Zeno behavior* of the LCS. Formal algebraic definitions of (non-)Zeno states and of mode switches that are tailored to the LCS are presented. An expansion based technique is developed to prove non-Zenoness, which is applicable to an LCS with the P-property. Extended Zeno results are presented in section 4. A special bimodal system is considered in section 5. The paper ends with some concluding remarks in the sixth and last section.

2. Preliminary discussion. Defined by a tuple of four matrices, $A \in \Re^{n\times n}$, $B \in \Re^{n\times m}$, $C \in \Re^{m\times n}$, and $D \in \Re^{m\times m}$, and a vector $x^0 \in \Re^n$, the goal of the LCS is to find trajectories $x(t) \in \Re^n$ and $u(t) \in \Re^m$ satisfying

$$\begin{aligned} \dot{x} &= Ax + Bu, \\ 0 \le u \perp Cx + Du &\ge 0, \\ x(0) &= x^0, \end{aligned} \tag{1}$$

where $\dot{x} \equiv \frac{dx}{dt}$ denotes the time derivative of the trajectory $x(t)$ and $a \perp b$ means that the two vectors a and b are orthogonal, i.e., $a^T b = 0$. While it is in general possible for the above differential and complementarity conditions to hold only at almost all times t, in the present paper, the conditions that we will impose on the tuple (A, B, C, D) will ensure that the x-trajectory is continuously differentiable and the u-trajectory is well defined (albeit not necessarily continuous) on the time interval of interest.

It is clear that LCP theory has a major role to play in the study of the LCS. For this reason, we summarize in the next subsection some of the essential concepts from this theory that are relevant to the developments in this paper. Details of this review can be found in the monograph [11], and the results therein will be used freely. Two new LCP concepts are introduced in subsection 2.2.

2.1. LCP background. Formally, given a vector $q \in \Re^m$ and a matrix $M \in \Re^{m\times m}$, the aim of the LCP (q, M) is to find a vector $u \in \Re^m$ such that

$$0 \le u \perp w \equiv q + Mu \ge 0.$$

The solution set of this problem is denoted by $\mathrm{SOL}(q, M)$. Among all matrix classes in LCP theory, the most fundamental one is that of the P-matrices. Specifically, M

is a P-matrix if all its principal minors are positive. This is the class of matrices that will be the starting point in our study of the LCS (1). It is well known that M is a P-matrix if and only if $\mathrm{SOL}(q, M)$ is a singleton for all $q \in \Re^m$; moreover, the unique element of $\mathrm{SOL}(q, M)$, which we denote $u(q)$, is a piecewise linear function of $q \in \Re^m$. This implies in particular that $u(q)$ is (globally) Lipschitz continuous and directionally differentiable. The directional derivative, denoted $u'(q; dq)$, of the solution function $u(q)$ along the direction dq can be expressed as the unique solution of a certain mixed LCP. Specifically, define three fundamental index sets associated with $u(q)$:

$$\begin{aligned}
\alpha &\equiv \{\, i \,:\, u(q)_i > 0 = (\, q + Mu(q)\,)_i \,\}, \\
\beta &\equiv \{\, i \,:\, u(q)_i = 0 = (\, q + Mu(q)\,)_i \,\}, \\
\gamma &\equiv \{\, i \,:\, u(q)_i = 0 < (\, q + Mu(q)\,)_i \,\}.
\end{aligned}$$

It follows that $u'(q; dq)$ is the unique solution $\widehat{u}$ of the mixed LCP:

$$\begin{aligned}
0 &= (\, dq + M\widehat{u}\,)_\alpha, \\
0 \le \widehat{u}_\beta \perp (\, dq + M\widehat{u}\,)_\beta &\ge 0, \\
0 &= \widehat{u}_\gamma.
\end{aligned}$$

The solution set $\mathrm{SOL}(q, M)$ of an LCP is in general the union of finitely many polyhedra, each called a *piece* of this set. Indeed, we have

$$\mathrm{SOL}(q, M) = \bigcup_\alpha \left\{ u \in \Re^m : \begin{array}{ll} (\, q + Mu\,)_\alpha = 0, & u_\alpha \ge 0 \\ (\, q + Mu\,)_{\bar\alpha} \ge 0, & u_{\bar\alpha} = 0 \end{array} \right\},$$

where the union ranges over all subsets α of $\{1, \ldots, m\}$. The case where $\mathrm{SOL}(q, M)$ is convex for all $q \in \Re^m$ is particularly important. This case is characterized by the column sufficiency property of the matrix M. Specifically, a matrix M is *column sufficient* if $u \circ Mu \le 0 \Rightarrow u \circ Mu = 0$, where $\circ$ denotes the Hadamard product of two vectors. It is easy to see that the property of column sufficiency is inherited by the principal submatrices of M and also by the principal pivot transforms of M. That is, if M is column sufficient, then so is the principal submatrix $M_{\alpha\alpha}$ for all $\alpha \subseteq \{1, \ldots, m\}$; moreover, if $M_{\alpha\alpha}$ is nonsingular, then the matrix below, called the α-principal pivot transform of M,

$$\begin{bmatrix} (\, M_{\alpha\alpha}\,)^{-1} & -(\, M_{\alpha\alpha}\,)^{-1} M_{\alpha\bar\alpha} \\ M_{\bar\alpha\alpha}(\, M_{\alpha\alpha}\,)^{-1} & M_{\bar\alpha\bar\alpha} - M_{\bar\alpha\alpha}(\, M_{\alpha\alpha}\,)^{-1} M_{\alpha\bar\alpha} \end{bmatrix}, \tag{2}$$

is also column sufficient, where $\bar\alpha$ is the complement of α in $\{1, \ldots, m\}$. If M is column sufficient, then

$$\mathrm{SOL}(q, M) \equiv \left\{ u \in \Re^m : \begin{array}{ll} (\, q + Mu\,)_\alpha = 0, & u_\alpha \ge 0 \\ (\, q + Mu\,)_{\bar\alpha} \ge 0, & u_{\bar\alpha} = 0 \end{array} \right\},$$

where α is the set consisting of all indices i for which there exists a solution $u \in \mathrm{SOL}(q, M)$ with $u_i > 0$.

Another known property of the LCP that we need is the "semistability" of its solutions sets. Specifically, by [12, Proposition 5.5.5, Corollary 5.5.9], it follows that

for any matrix $M \in \Re^{m\times m}$ and every vector $q \in \Re^m$, there exist positive scalars c and ε such that

$$\| q' - q \| \leq \varepsilon \Rightarrow \mathrm{SOL}(q', M) \subseteq \mathrm{SOL}(q, M) + c \| q - q' \| \mathcal{B},$$

where $\mathcal{B}$ is the (closed) unit ball in $\Re^m$.

2.2. New LCP concepts. While we are unable to directly deal with the entire class of LCSs with a column sufficient matrix D, such matrices provide the motivation to introduce two new LCP concepts to be used later. The first new LCP concept is a broadening of the class of column sufficient matrices that addresses the convexity of the solution sets of the homogeneous problems only.

DEFINITION 1. *The matrix $M \in \Re^{m\times m}$ is said to be* weakly column sufficient *if for every triple of index sets (α, β, γ) that partition $\{1, \ldots, m\}$, the set of vectors $u \in \Re^m$ satisfying*

$$\begin{aligned} (Mu)_\alpha &= 0, \\ 0 \leq u_\beta \perp (Mu)_\beta &\geq 0, \\ u_\gamma &= 0 \end{aligned} \tag{3}$$

is convex, or equivalently, is polyhedral. □

We leave it to the reader to verify that the convexity of the solution set of (3) is equivalent to its polyhedrality. Besides the class of column sufficient matrices which must be weakly column sufficient, a "nondegenerate matrix," i.e., one whose principal minors are all nonzero, is also weakly column sufficient; indeed if M is nondegenerate, then the only solution to the system (3) is the zero vector. The following result summarizes several properties of weak column sufficiency.

PROPOSITION 2. *Let $M \in \Re^{m\times m}$ be weakly column sufficient. The following statements are valid:*

(a) *For every subset $\tilde{\alpha}$ of $\{1, \ldots, m\}$, the principal submatrix $M_{\tilde{\alpha}\tilde{\alpha}}$ is weakly column sufficient.*

(b) *For every subset $\tilde{\alpha}$ of $\{1, \ldots, m\}$ such that $M_{\tilde{\alpha}\tilde{\alpha}}$ is nonsingular, the $\tilde{\alpha}$-principal pivot transform (2) of M is weakly column sufficient.*

(c) *The solution set of the homogeneous LCP $(0, M)$ is polyhedral; in fact,*

$$SOL(0, M) \equiv \left\{ u \in \Re^m : \begin{array}{ll} (Mu)_\alpha = 0, & u_\alpha \geq 0 \\ (Mu)_{\bar{\alpha}} \geq 0, & u_{\bar{\alpha}} = 0 \end{array} \right\},$$

where α is the set consisting of all indices i for which there exists $u \in SOL(0, M)$ such that $u_i > 0$ and $\bar{\alpha}$ is the complement of α.

Proof. Let α', β', and γ' be three index sets partitioning the subset $\tilde{\alpha}$. A vector $u_{\tilde{\alpha}}$ satisfies the system

$$\begin{aligned} (M_{\tilde{\alpha}\tilde{\alpha}} u_{\tilde{\alpha}})_{\alpha'} &= 0, \\ 0 \leq u_{\beta'} \perp (M_{\tilde{\alpha}\tilde{\alpha}} u_{\tilde{\alpha}})_{\beta'} &\geq 0, \\ u_{\gamma'} &= 0 \end{aligned}$$

if and only if the vector $u \equiv (u_{\tilde{\alpha}}, 0)$ satisfies the system (3) with $(\alpha, \beta, \gamma) = (\alpha', \beta', \gamma' \cup \hat{\alpha})$, where $\hat{\alpha}$ is the complement of $\tilde{\alpha}$ in $\{1, \ldots, m\}$. Consequently, part (a) holds. To

prove (b), let $\widetilde{M}$ be the $\tilde{\alpha}$-principal pivot transform (2) of M. Let α', β', and γ' be three index sets partitioning the set $\{1, \ldots, m\}$. Consider the system

$$\begin{aligned} (\widetilde{M}\widetilde{u})_{\alpha'} &= 0, \\ 0 \leq \widetilde{u}_{\beta'} &\perp (\widetilde{M}\widetilde{u})_{\beta'} \geq 0, \\ \widetilde{u}_{\gamma'} &= 0. \end{aligned} \tag{4}$$

Let $\widetilde{w} \equiv \widetilde{M}\widetilde{u}$. By pivoting on $(M_{\tilde{\alpha}\tilde{\alpha}})^{-1}$ in $\widetilde{M}$, we can recover the original system $w = Mu$, where the variables u and w are related to $\widetilde{u}$ and $\widetilde{w}$ via the identities:

$$w \equiv \begin{pmatrix} w_{\tilde{\alpha}} \\ w_{\hat{\alpha}} \end{pmatrix}, \quad u \equiv \begin{pmatrix} u_{\tilde{\alpha}} \\ u_{\hat{\alpha}} \end{pmatrix},$$

$$\widetilde{w} = \begin{pmatrix} u_{\tilde{\alpha}} \\ w_{\hat{\alpha}} \end{pmatrix}, \quad \widetilde{u} = \begin{pmatrix} w_{\tilde{\alpha}} \\ u_{\hat{\alpha}} \end{pmatrix}.$$

Therefore, system (4) is equivalent to system (3) for some suitable triple (α, β, γ) that partitions $\{1, \ldots, m\}$. From this equivalence, the convexity of the solution set of the former system can be easily proved. This establishes (b). To prove (c), we note that the LCP $(0, M)$ is just the system (3) with $\beta = \{1, \ldots, m\}$. Hence the polyhedrality of $\mathrm{SOL}(0, M)$ follows from the weak column sufficiency of M. The representation of $\mathrm{SOL}(0, M)$ can be proved in the same way as in the case of a column sufficient matrix; see the proof in [11, Theorem 3.5.8] for details. □

To introduce the second new LCP concept, we note that if $q \neq 0$, then for every solution u of the LCP (q, M), there must exist at least one index i such that $u_i > 0$ or $w_i \equiv (q + Mu)_i > 0$. Define two sets of "identifiable indices":

$$\begin{aligned} \mathcal{I}_u &\equiv \{\, i : u_i > 0 \quad \forall\, u \in \mathrm{SOL}(q, M) \,\}, \\ \mathcal{I}_w &\equiv \{\, i : (q + Mu)_i > 0 \quad \forall\, u \in \mathrm{SOL}(q, M) \,\}, \end{aligned}$$

one, or both, of which may be empty in general.

DEFINITION 3. *The LCP (q, M), where $q \neq 0$, is* identifiable *if the following two conditions hold:*

(a) *$\mathcal{I}_u \cup \mathcal{I}_w \neq \emptyset$, and*

(b) *the principal submatrix $M_{\mathcal{I}_u \mathcal{I}_u}$ is nonsingular if $\mathcal{I}_u \neq \emptyset$. (By convention, this condition is vacuously true if $\mathcal{I}_u$ is empty.)* □

If the LCP (q, M), where $q \neq 0$, has a unique solution u, then the LCP is identifiable if $M_{\alpha\alpha}$ is nonsingular, where α is the (possibly empty) support of u. The following lemma asserts a positivity property of the "identifiable variables" of an LCP.

PROPOSITION 4. *For any pair (q, M) with $q \neq 0$, there exists a scalar $\sigma > 0$ such that $u_i \geq \sigma$ and $(q + Mu)_j \geq \sigma$ for all $u \in \mathrm{SOL}(q, M)$ and all $i \in \mathcal{I}_u$ and $j \in \mathcal{I}_w$.*

Proof. We prove the claim only for the u-variable. For each $i \in \mathcal{I}_u$, consider the optimization problem

$$\begin{aligned} \text{minimize} \quad & u_i \\ \text{subject to} \quad & u \in \mathrm{SOL}(q, M). \end{aligned}$$

Since the feasible set of this problem is the union of finitely many polyhedra and its objective function is linear and positive (hence bounded below) on this set, it follows from linear programming theory that the above problem attains a finite minimum objective value which must be positive. The desired claim follows readily. □

2.3. Back to the LCS. Returning to the LCS (1), assume that D is a P-matrix. In this case, (1) is equivalent to the ODE

$$\dot{x} = Ax + Bu(Cx), \quad x(0) = x^0, \tag{5}$$

where the right-hand side $Ax+Bu(Cx)$ is a piecewise linear function of x. (Note that $u(0) = 0$.) As such, (1) has a unique solution trajectory $(x(t), u(t))$ defined on $[0, \infty)$ with $x(t)$ being continuously differentiable and $u(t) \equiv u(Cx(t))$ being continuous. In contrast to the above representation (5) which involves the implicit function $u(Cx)$, the right-hand side of the LCS (1) can be represented explicitly using the complementarity cones associated with the matrix D. Specifically, for each index subset δ of $\{1, \ldots, m\}$ with complement $\bar{\delta}$, define the polyhedral cone

$$\mathcal{C}_\delta \equiv \left\{ q \in \Re^m : E_\delta \begin{pmatrix} q_\delta \\ q_{\bar{\delta}} \end{pmatrix} \geq 0 \right\}, \tag{6}$$

where

$$E_\delta \equiv \begin{bmatrix} -(D_{\delta\delta})^{-1} & 0 \\ -D_{\bar{\delta}\delta}(D_{\delta\delta})^{-1} & I \end{bmatrix} \in \Re^{m \times m}.$$

Since D is a P-matrix, it is clear that E_δ is well defined and nonsingular. Defining the matrix

$$K_\delta \equiv \begin{bmatrix} -(D_{\delta\delta})^{-1} & 0 \\ 0 & 0 \end{bmatrix},$$

we have $u(Cx) = K_\delta Cx$, provided that $Cx \in \mathcal{C}_\delta$. Consequently, the ODE (5) can be written equivalently as

$$\dot{x} = (A + BK_\delta C)x \quad \text{if } E_\delta Cx \geq 0,$$

whose right-hand side is now in an *explicit*, piecewise linear form.

Consider next the case where D is not a P-matrix but the submatrix $D_{\alpha\alpha}$ is nonsingular for some subset α of $\{1, \ldots, m\}$. We can define a system that is equivalent to (1) by "pivoting" on $D_{\alpha\alpha}$ as done for a standard LCP [11], i.e., by solving for the variable u_α in the equation

$$w_\alpha = C_{\alpha\cdot}x + D_{\alpha\alpha}u_\alpha + D_{\alpha\bar{\alpha}}u_{\bar{\alpha}}$$

in terms of the other variables w_α, x, and $u_{\bar{\alpha}}$, where $\bar{\alpha}$ is the complement of α in $\{1, \ldots, m\}$, and then substituting the resulting expression for u_α into the other conditions in (1). The equivalent LCS, which we call the *α-principal transform* of (1), is

$$\begin{aligned} \dot{x} &= \widetilde{A}x + \widetilde{B}\widetilde{u}, \\ 0 \leq \widetilde{u} &\perp \widetilde{C}x + \widetilde{D}\widetilde{u} \geq 0, \\ x(0) &= x^0, \end{aligned} \tag{7}$$

where $\tilde{u} = (w_\alpha, u_{\bar{\alpha}})$ and

$$
\begin{aligned}
\widetilde{A} &\equiv A - B_{\cdot\alpha}(\,D_{\alpha\alpha}\,)^{-1}C_{\alpha\cdot},\\
\widetilde{B} &\equiv \begin{bmatrix} B_{\cdot\alpha}(\,D_{\alpha\alpha}\,)^{-1} & B_{\cdot\bar{\alpha}} - B_{\cdot\alpha}(\,D_{\alpha\alpha}\,)^{-1}D_{\alpha\bar{\alpha}} \end{bmatrix},\\
\widetilde{C} &\equiv \begin{bmatrix} -(\,D_{\alpha\alpha}\,)^{-1}C_{\alpha\cdot} \\ C_{\bar{\alpha}\cdot} - D_{\bar{\alpha}\alpha}(\,D_{\alpha\alpha}\,)^{-1}C_{\alpha\cdot} \end{bmatrix},\\
\widetilde{D} &\equiv \begin{bmatrix} (\,D_{\alpha\alpha}\,)^{-1} & -(\,D_{\alpha\alpha}\,)^{-1}D_{\alpha\bar{\alpha}} \\ D_{\bar{\alpha}\alpha}(\,D_{\alpha\alpha}\,)^{-1} & D_{\bar{\alpha}\bar{\alpha}} - D_{\bar{\alpha}\alpha}(\,D_{\alpha\alpha}\,)^{-1}D_{\alpha\bar{\alpha}} \end{bmatrix}.
\end{aligned} \tag{8}
$$

We call the tuple $(\widetilde{A}, \widetilde{B}, \widetilde{C}, \widetilde{D})$ the *α-principal transform* of (A, B, C, D). Of particular importance in the subsequent analysis is the following principal subsystem of this transform:

$$
\begin{aligned}
\dot{x} &= \widetilde{A}x + [\,B_{\cdot\bar{\alpha}} - B_{\cdot\alpha}(\,D_{\alpha\alpha}\,)^{-1}D_{\alpha\bar{\alpha}}\,]u_{\bar{\alpha}},\\
0 \le u_{\bar{\alpha}} &\perp [\,C_{\bar{\alpha}\cdot} - D_{\bar{\alpha}\alpha}(\,D_{\alpha\alpha}\,)^{-1}C_{\alpha\cdot}\,]x + [\,D_{\bar{\alpha}\bar{\alpha}} - D_{\bar{\alpha}\alpha}(\,D_{\alpha\alpha}\,)^{-1}D_{\alpha\bar{\alpha}}\,]u_{\bar{\alpha}} \ge 0.
\end{aligned} \tag{9}
$$

To illustrate the role of the latter subsystem, suppose that at some state $x(t_*) = x^*$, the corresponding algebraic vector $u(t_*) = u^*$ is a strongly regular solution [25] of the LCP (Cx^*, D). This means that the submatrix $D_{\alpha_*\alpha_*}$ is nonsingular and the Schur complement $D_{\beta_*\beta_*} - D_{\beta_*\alpha_*}(D_{\alpha_*\alpha_*})^{-1}D_{\alpha_*\beta_*}$ is a P-matrix, where

$$
\begin{aligned}
\alpha_* &\equiv \{\, i \,:\, u_i^* > 0 = (\,Cx^* + Du^*\,)_i \,\},\\
\beta_* &\equiv \{\, i \,:\, u_i^* = 0 = (\,Cx^* + Du^*\,)_i \,\},\\
\gamma_* &\equiv \{\, i \,:\, u_i^* = 0 < (\,Cx^* + Du^*\,)_i \,\}.
\end{aligned}
$$

If the solution trajectory $(x(t), u(t))$ is continuous near t_*, it then follows that for all t sufficiently near t_*, $(Cx(t) + Du(t))_i > 0$ for all $i \in \gamma_*$ and $u_i(t) > 0$ for all $i \in \alpha_*$. This implies that $u_i(t) = 0$ for all $i \in \gamma_*$ and $(Cx(t) + Du(t))_i = 0$ for all $i \in \alpha_*$. Hence, locally for t near t_*, the trajectory $(x(t), u(t))$ must satisfy the following mixed LCS obtained by fixing some variables at zero:

$$
\begin{aligned}
\dot{x} &= Ax + Bu,\\
0 &= (\,Cx + Du\,)_i \quad \forall\, i \in \alpha_*,\\
0 \le u_i &\perp (\,Cx + Du\,)_i \ge 0 \quad \forall\, i \in \beta_*,\\
0 &= u_i \quad \forall\, i \in \gamma_*.
\end{aligned} \tag{10}
$$

Since $D_{\alpha_*\alpha_*}$ is nonsingular, we can carry out the pivot operation as described above and deduce that (10) is equivalent to, for all t sufficiently near t_*,

$$
\begin{aligned}
\dot{x} &= \overline{A}x + \overline{B}u_\beta,\\
0 \le u_\beta &\perp \overline{C}x + \overline{D}u_\beta \ge 0,
\end{aligned} \tag{11}
$$

where

$$
\begin{aligned}
\overline{A} &\equiv A - B_{\cdot\alpha_*}(\,D_{\alpha_*\alpha_*}\,)^{-1}C_{\alpha_*}, & \overline{B} &\equiv B_{\cdot\beta_*} - B_{\cdot\alpha_*}(\,D_{\alpha_*\alpha_*}\,)^{-1}D_{\alpha_*\beta_*},\\
\overline{C} &\equiv C_{\beta_*\cdot} - D_{\beta_*\alpha_*}(\,D_{\alpha_*\alpha_*}\,)^{-1}C_{\alpha_*}, & \overline{D} &\equiv D_{\beta_*\beta_*} - D_{\beta\alpha_*}(\,D_{\alpha_*\alpha_*}\,)^{-1}D_{\alpha_*\beta_*}.
\end{aligned}
$$

The resulting LCS (11) has the P-property. We summarize this reduction in the following result, which we will later use to deduce an important consequence of the state x^*; see Corollary 15. For further discussion of the above reduction process, see [23, section 5.2].

PROPOSITION 5. *Let $(x(t), u(t))$ be a solution trajectory of the LCS (1) that is continuous near a time t_*. If $u(t_*)$ is a strongly regular solution of the LCP $(Cx(t_*), D)$, then $(x(t), u(t))$ must satisfy the reduced system (11) locally near t_*.* □

Finally, for any nonsingular constant matrix P, we can consider the change of variables $\bar{x} \equiv Px$ and obtain an LCS in the $\bar{x}$-variable that is equivalent to the original (1). This equivalent LCS is

$$\begin{aligned} \dot{\bar{x}} &= PAP^{-1}\bar{x} + PBu, \\ 0 \le u \perp CP^{-1}\bar{x} + Du &\ge 0, \\ \bar{x}(0) &= Px^0. \end{aligned}$$

Particularly useful for us later (see the proof of Lemma 12) is the transformation so that the pair (PAP^{-1}, CP^{-1}) is of a particular form satisfying a favorable observability condition.

3. Zeno states of an LCS. In what follows, we define two types of Zeno states of a general LCS; see Definition 6. Generally speaking, the presence of a Zeno state in a hybrid system could have an adverse effect on the numerical simulation of a solution trajectory to the system. This issue, which is closely tied to mode switches, has been dealt with extensively in the literature; see, e.g., [4, 9, 19, 33, 38]. In particular, for hybrid systems described by ODEs with piecewise real analytic right-hand sides, the results by Brunovsky [4] and Sussmann [33] show that there is a finite number of mode switches (defined in the sense in the cited references). While the latter results are in principle applicable to the LCS with the P-property, their treatment does not reveal the important complementarity nature of the LCS. (See [5, 9] for some special Zeno results for the LCS where the D matrix is positive definite or satisfies a passifiability assumption.) Because of the fundamental role of the LCS in hybrid system theory, it is useful to have a simplified approach that exploits the characteristics of the LCS. Most importantly, the Zeno concepts defined below are of a refined, algebraic nature that takes into account possible degeneracy of the solutions to the complementarity conditions. Analytically, our proofs of the main Zeno results, Theorems 9 and 21, are based on a local expansion of a solution trajectory to the LCS (Lemma 14) which is a new result by itself and enables us to study systems failing the P-property. Furthermore, this expansion reveals a local property of a solution trajectory of (1) in terms of an "observability degree" of a given state relative to the pair (C, A).

As is well known, an LCS is a special linear hybrid system with finitely many "modes," where a mode is a linear differential algebraic equation (LDAE) defined by a pair of disjoint index sets $(\alpha, \bar{\alpha})$ whose union is the index set $\{1, \ldots, m\}$; specifically, such an LDAE is as follows:

$$\begin{aligned} \dot{x} &= Ax + Bu, \\ 0 &= (\, Cx + Du \,)_\alpha, \\ 0 &= u_{\bar{\alpha}}. \end{aligned} \tag{12}$$

Every solution trajectory of the LCS (1) must satisfy, at every time instant, the above LDAE for a certain pair $(\alpha, \bar{\alpha})$ that is dependent on the time. Conversely, if $(x(t), u(t))$

is a solution trajectory satisfying the latter LDAE, then $(x(t), u(t))$ satisfies the LCS (1) if $(Cx(t) + Du(t))_{\bar{\alpha}} \geq 0$ and $u(t)_{\alpha} \geq 0$. In general, it is possible for a solution trajectory $(x(t), u(t))$ of the LCS (1) to satisfy at any given time t the LDAE (12) for multiple pairs of index sets, due to degeneracy of the complementarity conditions. For every such trajectory, at each time t_* that is neither the initial nor the terminal time, there exist (i) an infinite sequence of times $\{t_k^-\}$ converging to t_* from the left and a pair $(\alpha_-, \bar{\alpha}_-)$ of index sets partitioning $\{1, \ldots, m\}$ such that $(x(t_k^-), u(t_k^-))$ satisfies the LDAE (12) corresponding to $(\alpha_-, \bar{\alpha}_-)$ for all k, and (ii) an infinite sequence of times $\{t_k^+\}$ converging to t_* from the right and a pair $(\alpha_+, \bar{\alpha}_+)$ of partitioning index sets such that $(x(t_k^+), u(t_k^+))$ satisfies the LDAE (12) corresponding to $(\alpha_+, \bar{\alpha}_+)$ for all k. An intuitive definition of a *mode switch* at time t_* is that the two pairs of index sets $(\alpha_-, \bar{\alpha}_-)$ and $(\alpha_+, \bar{\alpha}_+)$ are not equal. Roughly speaking, a *Zeno state* of an LCS is a state near which there are infinitely many modes switches.

We now formalize the above informal discussion by defining "weak" and "strong" Zeno states of a solution trajectory $(x(t), u(t))$ of the LCS (1). Both are local properties of a state. The strong Zeno concept is more refined than the weak Zeno concept and is defined in terms of the index sets

$$\begin{aligned}
\alpha(t) &\equiv \{\, i \,:\, u_i(t) \,>\, 0 \,=\, (\, Cx(t) + Du(t)\,)_i \,\}, \\
\beta(t) &\equiv \{\, i \,:\, u_i(t) \,=\, 0 \,=\, (\, Cx(t) + Du(t)\,)_i \,\}, \\
\gamma(t) &\equiv \{\, i \,:\, u_i(t) \,=\, 0 \,<\, (\, Cx(t) + Du(t)\,)_i \,\};
\end{aligned}$$

in contrast, the weak Zeno concept relaxes the strong concept by restricting to the two combined sets $\alpha(t) \cup \beta(t)$ and $\gamma(t) \cup \beta(t)$. The two concepts coincide if $u(t)$ is a nondegenerate solution of the LCP $(Cx(t), D)$ for all t near t_*, in which case, the degenerate set $\beta(t)$ is empty for all such t.

DEFINITION 6. *Let $(x(t), u(t))$ be a solution trajectory of* (1) *and let $x(t_*) = x^*$. We say that x^* is*

(a) strongly left non-Zeno relative to $(x(t), u(t))$ *if a scalar $\varepsilon_- > 0$ and a triple of index sets $(\alpha_-, \beta_-, \gamma_-)$ exist such that $(\alpha(t), \beta(t), \gamma(t)) = (\alpha_-, \beta_-, \gamma_-)$ for every $t \in [t_* - \varepsilon_-, t_*)$;*

(b) strongly right non-Zeno relative to $(x(t), u(t))$ *if a scalar $\varepsilon_+ > 0$ and a triple $(\alpha_+, \beta_+, \gamma_+)$ of index sets exist such that $(\alpha(t), \beta(t), \gamma(t)) = (\alpha_+, \beta_+, \gamma_+)$ for every $t \in (t_*, t_* + \varepsilon_+]$;*

(c) weakly left non-Zeno relative to $(x(t), u(t))$ *if a scalar $\varepsilon_- > 0$ and a pair of index sets α_- and $\bar{\alpha}_-$ partitioning $\{1, \ldots, m\}$ exist such that $(x(t), u(t))$ satisfies the LDAE* (12) *corresponding to $(\alpha_-, \bar{\alpha}_-)$ for all $t \in [\, t_* - \varepsilon_-, t_*\,)$;*

(d) weakly right non-Zeno relative to $(x(t), u(t))$ *if a scalar $\varepsilon_+ > 0$ and a pair of index sets α_+ and $\bar{\alpha}_+$ partitioning $\{1, \ldots, m\}$ exist such that $(x(t), u(t))$ satisfies the LDAE* (12) *corresponding to $(\alpha_+, \bar{\alpha}_+)$ for all $t \in (t_*, t_* + \varepsilon_+]$.*

The state $x^* \equiv x(t_*)$ is said to be left (right) Zeno of the first (second) kind relative to the trajectory $(x(t), u(t))$ *if it is* not *strongly (weakly) left (right) non-Zeno relative to the same trajectory. When x^* is strongly (weakly) left* and *right non-Zero, then we say that x^* is strongly (weakly) non-Zeno; when x^* is either left* or *right Zeno of the first (second) kind, then we say that x^* is Zeno of the first (second) kind. When the trajectory is clear from the context, we will omit the phrase "relative to the trajectory."* □

Definition 6 is applicable to both the initial and the terminal states of an LCS. Specifically, if x^* is the initial state x^0 of the LCS (1), then we are interested only in the right (non-)Zeno property of x^*; similarly, if x^* is the terminal state $x(T)$ of the LCS

(1) at a prescribed terminal time $T > 0$, then we are interested only in the left (non-) Zeno property of x^*. It is clear that the strongly (left or right) non-Zeno properties must imply the respective weakly (left or right) non-Zeno properties. Nevertheless, the converse is clearly not always true. In essence, the left Zeno properties of a state refer to its reachability from the left, and the right Zeno properties refer to the continuation from the state. Obviously, these properties have important numerical implications when the LCS is solved by a time-stepping method. For instance, the numerical methods discussed in [30] for solving ODEs with discontinuous right-hand sides are based on the presumed absence of Zeno states. Further discussion of such numerical matters is beyond the scope of this paper.

An important remark should be made for Definition 6: namely, this definition pertains to the two trajectories $x(t)$ and $u(t)$ jointly. This is distinct from the treatment in [4, 33] which is applicable to the implicit formulation (5) of the LCS in which the algebraic variable u is eliminated and treated only implicitly. It is not a straightforward task to directly apply the results in these cited references to analyze the Zeno properties of the LCS as described in Definition 6, where the u-trajectory plays a prominent role. In many realistic applications of the LCS (such as in contact mechanics), the role of the algebraic variable u is as important as the differential variable x; thus, an explicit treatment of the former, as emphasized herein, is warranted.

Zeno states are closely tied to mode switches, which we formally define next. For simplicity, we present the definition below only for a time that is neither the initial nor the terminal time of a trajectory. The triple of index sets $(\alpha(t), \beta(t), \gamma(t))$ in this definition are the fundamental index sets associated with the pair $(x(t), u(t))$.

DEFINITION 7. *Let $(x(t), u(t))$ be a solution trajectory of* (1) *and let t_* be an intermediate time of this trajectory. We say that t_* is a*

(a) switch time of the first kind *relative to $(x(t), u(t))$ if there exist two triples of index sets, $(\alpha_-, \beta_-, \gamma_-)$ and $(\alpha_+, \beta_+, \gamma_+)$, and two infinite sequences of times, $\{t_k^-\}$ and $\{t_k^+\}$, the former converging to t_* from the left and the latter converging to t_* from the right, such that, for all k,*

$$(\alpha(t_k^-), \beta(t_k^-), \gamma(t_k^-)) = (\alpha_-, \beta_-, \gamma_-) \neq (\alpha_+, \beta_+, \gamma_+) = (\alpha(t_k^+), \beta(t_k^+), \gamma(t_k^+));$$

(b) switch time of the second kind *relative to $(x(t), u(t))$ if there exist two infinite sequences of times, $\{t_k^-\}$ and $\{t_k^+\}$, the former converging to t_* from the left and the latter converging to t_* from the right, such that for* no *pair of index sets $(\alpha, \bar{\alpha}_-)$ partitioning $\{1, \ldots, m\}$, $(x(t_k^-), u(t_k^-))$ and $(x(t_k^+), u(t_k^+))$ both satisfy the LDAE* (12) *for all k.* □

The following result shows that the absence of Zeno states in a finite time of interval provides a sufficient condition for the finite number of switch times in the interval.

PROPOSITION 8. *Let $(x(t), u(t))$ be a solution trajectory of the LCS* (1) *defined on an open interval containing $[0, T]$. If the trajectory has no Zeno states of the first (second) kind, then there is a finite number of switch times of the first (second) kind relative to $(x(t), u(t))$ in $[0, T]$.*

Proof. We prove the result for the "second" kind only. If $(x(t), u(t))$ contains no Zeno states of the second kind, then for every $t \in [0, T]$, there exist a right neighborhood $\mathcal{N}_t^+ \equiv (t, t + \varepsilon_t)$ and a left neighborhood $\mathcal{N}_t^- \equiv (t - \varepsilon_t, t)$ of t, for some scalar $\varepsilon_t > 0$, and two pairs of index sets, $(\alpha_t^+, \bar{\alpha}_t^+)$ and $(\alpha_t^-, \bar{\alpha}_t^-)$, both partitioning $\{1, \ldots, m\}$, such that for all $t' \in \mathcal{N}_t^+$, the pair $(x(t'), u(t'))$ satisfies the LDAE (12) corresponding to $(\alpha_t^+, \bar{\alpha}_t^+)$, and that for all $t' \in \mathcal{N}_t^-$, the pair $(x(t'), u(t'))$ satisfies

the LDAE (12) corresponding to $(\alpha_t^-, \bar{\alpha}_t^-)$. The family

$$\{ (t - \varepsilon_t, t + \varepsilon_t) : t \in [0, T] \}$$

constitutes an open covering of the compact interval $[0, T]$. Hence there exists a finite sequence $\{t_0, t_1, \ldots, t_\ell\} \subset [0, T]$ such that

$$[0, T] \subset \bigcup_{i=0}^{\ell} [t_i - \varepsilon_{t_i}, t_i + \varepsilon_{t_i}].$$

By refining the partition on the right-hand side, we may assume without loss of generality that there exist a finite sequence of times $0 = t_0' < t_1' < \cdots < t_k' < t_{k+1}' = T$ and a corresponding sequence of index sets α_i of $\{1, \ldots, m\}$ with respective complements $\bar{\alpha}_i$ such that $(x(t), u(t))$ satisfies (12) corresponding to $(\alpha_i, \bar{\alpha}_i)$ for all $t \in (t_i', t_{i+1}')$, $i = 0, 1, \ldots, k$. Consequently, the only possible switch times of the second type in the interval $[0, T]$ are the times t_i' for $i = 0, 1, \ldots, k+1$. □

3.1. The P-matrix case. The following is the main Zeno result for an LCS with the P-property.

THEOREM 9. *If D is a P-matrix, then all states of the LCS* (1) *must be strongly non-Zeno.*

The proof of the above theorem is accomplished via several lemmas. The first such lemma, which is a global and time-invariant version of Proposition 5.3 in [26], gives a decay rate for a Lipschitz continuous system.

LEMMA 10. *Let $\dot{x} = f(x)$, $x(0) = x^0$ be a dynamical system on $\Re^n$, where $f(x)$ is globally Lipschitz continuous in x with Lipschitz constant $L \geq 0$. If $x = 0$ is an equilibrium of the system, i.e., $f(0) = 0$, then*

$$\| x^0 \|_2 \, e^{-Lt} \leq \| x(t) \|_2 \leq \|x^0\|_2 \, e^{Lt} \quad \forall \, t \geq 0.$$

The main proof of Theorem 9 is divided into two parts, depending on whether a state x^* in question is observable or unobservable with respect to the pair (C, A). The concept of observability is well known for a linear time-invariant system $\dot{x} = Ax + Bu$ and $y = Cx + Du$ and is briefly reviewed here. A state $x \in \Re^n$ is *unobservable* with respect to (C, A) if $Ce^{At}x \equiv 0$ for all t; otherwise it is called *observable* with respect to (C, A). Without confusion, we usually simply call a state observable/unobservable. The set of all unobservable states is a subspace of $\Re^n$, called the *unobservable subspace* of the pair (C, A). An equivalent condition for a state x being observable is that $CA^k x \neq 0$ for some $0 \leq k \leq n-1$. The linear system is *observable* if $x = 0$ is the only unobservable state. In such the case, we call (C, A) an observable pair.

The next lemma asserts that the LCS (1) with the P-property is trivial if the initial state x^0 is unobservable.

LEMMA 11. *Let D be a P-matrix. If x^0 is unobservable, then the unique solution trajectory of* (1) *is $(x(t), u(t)) = (e^{At}x^0, 0)$ for all $t \geq 0$. In this case, we have $\beta(t) = \{1, \ldots, m\}$ for all $t \geq 0$; hence, all states $x(t)$ are strongly non-Zeno.*

Proof. This follows easily from the uniqueness of the solution trajectory and the fact that $Ce^{At}x^0 = 0$ for all $t \geq 0$. □

Lemma 11 suggests that we may assume without loss of generality that x^0 is observable. The next lemma asserts that in this case, all states on the trajectory $x(t)$ are observable.

LEMMA 12. *Let D be a P-matrix. If $x^0 = x(0)$ is observable, then so is $x(t)$ for all $t \geq 0$.*

Proof. Lemma 10 is applicable to the implicit form (5) of the LCS. It follows that $\|x(t)\| \geq \|x^0\| e^{-Lt}$ for some constant $L \geq 0$. Since x^0 is observable, it is not zero. Hence $x(t) \neq 0$ for all $t \geq 0$. Consequently, we may assume without loss of generality that (C, A) is an unobservable pair. Let $\overline{O}(C, A)$ denote the unobservable subspace whose dimension is n_2 with $1 \leq n_2 \leq n$. According to linear system theory [10, p. 203], there exists a nonsingular matrix $P \in \Re^{n \times n}$ such that the change of variables $\bar{x} = Px$ transforms the original linear system (1) into the observable canonical form

$$\dot{\bar{x}} = \begin{pmatrix} \dot{\bar{x}}_o \\ \dot{\bar{x}}_{uo} \end{pmatrix} = \begin{bmatrix} \bar{A}_o & 0 \\ \bar{A}_{21} & \bar{A}_{uo} \end{bmatrix} \begin{pmatrix} \bar{x}_o \\ \bar{x}_{uo} \end{pmatrix} + \begin{bmatrix} \bar{B}_o \\ \bar{B}_{uo} \end{bmatrix} u,$$

$$Cx = \begin{bmatrix} \bar{C}_o & 0 \end{bmatrix} \begin{pmatrix} \bar{x}_o \\ \bar{x}_{uo} \end{pmatrix} = \bar{C}_o \bar{x}_o,$$

and $(\bar{C}_o, \bar{A}_o)$ is an observable pair, $\bar{x} \equiv \left(\begin{smallmatrix} \bar{x}_o \\ \bar{x}_{uo} \end{smallmatrix}\right)$ is the transformed state, $\bar{x}_o \in \Re^{n-n_2}$ and $\bar{x}_{uo} \in \Re^{n_2}$ correspond to the observable part and unobservable part of $\bar{x}$, respectively. Hence, the LCS (1) can be decomposed into the observable dynamics

$$\begin{aligned} \dot{\bar{x}}_o &= \bar{A}_o \bar{x}_o + \bar{B}_o u, \\ 0 \leq u &\perp \bar{C}_o \bar{x}_o + Du \geq 0, \end{aligned} \tag{13}$$

and the unobservable dynamics

$$\dot{\bar{x}}_{uo} = \bar{A}_{21} \bar{x}_o + \bar{A}_{uo} \bar{x}_{uo} + \bar{B}_{uo} u. \tag{14}$$

Moreover, any unobservable state $\widehat{x} \in \overline{O}(C, A)$ is transformed to the following form under the above transformation:

$$P\widehat{x} = \begin{pmatrix} 0 \\ \bar{x}_{uo} \end{pmatrix}.$$

This means that the observable part of an original unobservable state must be zero and the observable part of an original observable state must not be zero. Since (13) remains an LCS with the P-property, and since $\bar{x}_o(0) \neq 0$ because $x(0)$ is observable, it follows that $\bar{x}_o(t) \neq 0$ for all $t \geq 0$, which means that $x(t)$ must be observable. ∎

A noteworthy remark is that Lemma 12 can be proved using the reverse-time argument.[1] Letting $(x^r(t), u^r(t)) \equiv (x(-t), u(-t))$ for all $t \geq 0$, one easily sees that the pair $(x^r(t), u^r(t))$ satisfies a reverse-time LCS for all $t \geq 0$:

$$\begin{aligned} \dot{x}^r(t) &= -Ax^r(t) - Bu^r(t), \\ 0 \leq u^r(t) &\perp Cx^r(t) + Du^r(t) \geq 0. \end{aligned}$$

Hence, the reverse-time LCS $(-A, -B, C, D)$ preserves the P-property and its solution pair is unique as well. Suppose $x(0)$ is observable but $x(t)$ is not at some $t \geq 0$. Then using the reverse-time LCS and Lemma 11, $x(0) = e^{-At} x(t)$, which is unobservable as well. However, the decomposition of the LCS into the observable dynamics (13)

[1] We thank an anonymous reviewer for bringing this remark to our attention.

and the unobservable dynamics (14) in Lemma 12 has its own interest. Therefore, we present it for this purpose.

Combining the above two lemmas, we have therefore proved Theorem 9 for the unobservable states. We formally state this conclusion in the following corollary, which requires no proof.

COROLLARY 13. *Any unobservable state of an LCS with the P-property is strongly non-Zeno.* □

We next turn our attention to the observable states. The cornerstone of the treatment of these states is an expansion of the solution trajectory near any given time t_*. We will make use of the (unique) solution $u(\pm CA^k x)$ of the LCPs $(\pm CA^k x, D)$. In general, except for the fact that both are nonnegative, the two vectors $u^{k+}(x) \equiv u(CA^k x^*)$ and $u^{k-}(x) \equiv u(-CA^k x^*)$ have very little to do with each other. Since D is a P-matrix, we can speak of the directional derivative of the solution function $u'(q; dq)$ of the LCP (q, D) at the vectors $q \equiv \pm CA^k x$ along the directions $dq \equiv \pm(CA^{k+1}x + CBu^{k\pm}(x))$. Specifically, we will use the following directional derivatives:

$$u'(CA^k x; CA^{k+1}x + CBu^{k+}(x)) = \lim_{\tau \downarrow 0} \frac{u(CA^k x + \tau(CA^{k+1}x + CBu^{k+}(x))) - u(CA^k x)}{\tau},$$

$$u'(CA^k x; -(CA^{k+1}x + CBu^{k+}(x))) = \lim_{\tau \downarrow 0} \frac{u(CA^k x - \tau(CA^{k+1}x + CBu^{k+}(x))) - u(CA^k x)}{\tau},$$

$$u'(-CA^k x; CA^{k+1}x - CBu^{k-}(x)) = \lim_{\tau \downarrow 0} \frac{u(-CA^k x + \tau(CA^{k+1}x - CBu^{k+}(x))) - u(-CA^k x)}{\tau}.$$

The reason for distinguishing these derivatives will be evident from the next result. In this result, we use the standard notation $o(f(t))$ to mean a function such that $\lim_{0 \neq t \to 0} \frac{o(f(t))}{t} = 0$; the notation $O(f(t))$ also has the standard meaning.

LEMMA 14. *Let D be a P-matrix. Let $x^* = x(t_*)$ be an arbitrary state of the solution trajectory $(x(t), u(t))$ such that $CA^j x^* = 0$ for all $j = 0, 1, \ldots, k-1$ for some integer $k \geq 0$. The following two statements hold:*

(a) *For all $t > t_*$,*

$$x(t) = \sum_{j=0}^{k+2} \frac{(t - t_*)^j}{j!} A^j x^* + \frac{(t - t_*)^{k+1}}{(k+1)!} Bu(CA^k x^*) + \frac{(t - t_*)^{k+2}}{(k+2)!} Bu'(CA^k x^*; CA^{k+1}x^* + CBu(CA^k x^*)) + o(|t - t_*|^{k+2}),$$

$$u(t) = \frac{(t - t_*)^k}{k!} u(CA^k x^*) + \frac{(t - t_*)^{k+1}}{(k+1)!} u'(CA^k x^*; CA^{k+1}x^* + CBu(CA^k x^*)) + o(|t - t_*|^{k+1}).$$

(b) *For all* $t < t_*$,

$$x(t) = \sum_{j=0}^{k+2} \frac{(t-t_*)^j}{j!} A^j x^* + \frac{(t-t_*)^{k+1}}{(k+1)!} Bu(CA^k x^*) + \frac{(t-t_*)^{k+2}}{(k+2)!} Bu'(CA^k x^*; -CA^{k+1}x^* - CBu(CA^k x^*)) + o(|t-t_*|^{k+2}),$$

$$u(t) = \frac{(t-t_*)^k}{k!} u(CA^k x^*) + \frac{|t-t_*|^{k+1}}{(k+1)!} u'(CA^k x^*; -CA^{k+1}x^* - CBu(CA^k x^*)) + o(|t-t_*|^{k+1})$$

if k *is even; and if* k *is odd,*

$$x(t) = \sum_{j=0}^{k+2} \frac{(t-t_*)^j}{j!} A^j x^* - \frac{(t-t_*)^{k+1}}{(k+1)!} Bu(-CA^k x^*) + \frac{(t-t_*)^{k+2}}{(k+2)!} Bu'(-CA^k x^*; CA^{k+1}x^* - CBu(-CA^k x^*)) + o(|t-t_*|^{k+2}),$$

$$u(t) = \frac{|t-t_*|^k}{k!} u(-CA^k x^*) + \frac{(t-t_*)^{k+1}}{(k+1)!} u'(-CA^k x^*; CA^{k+1}x^* - CBu(-CA^k x^*)) + o(|t-t_*|^{k+1}).$$

Proof. Define

$$z(t) = x(t) - \sum_{j=0}^{k} (t-t_*)^j \frac{A^j x^*}{j!}. \tag{15}$$

Hence, $z(t_*) = 0$ and $z(t)$ satisfies

$$\dot{z}(t) = Az(t) + \frac{(t-t_*)^k}{k!} A^{k+1}x^* + Bu(t), \tag{16}$$

where $u(t)$ satisfies

$$0 \le u(t) \perp Cz(t) + \frac{(t-t_*)^k}{k!} CA^k x^* + Du(t) \ge 0. \tag{17}$$

Since D is a P-matrix, it follows that there exists a constant $\eta > 0$ such that for all t,

$$\| u(t) \| \le \eta [\, \| z(t) \| + |t-t_*|^k \,].$$

By (16), we deduce the existence of positive constants λ and μ such that for all $t < t_*$,

$$\| z(t) \| \le \lambda (t_* - t)^{k+1} + \mu \int_t^{t_*} \| z(s) \| \, ds.$$

Thus by Gronwall–Bellman inequality, we obtain, for some constant $\mu' > 0$,

$$\begin{aligned} \| z(t) \| &\le \lambda (t_* - t)^{k+1} + \lambda \mu \int_t^{t_*} (t_* - \tau)^{k+1} e^{\mu(t_* - \tau)} d\tau \\ &\le \lambda (t_* - t)^{k+1} + \mu' (t_* - t)^{k+2} \end{aligned}$$

for all $t < t_*$ sufficiently near t_*. A similar bound can be derived for $\|z(t)\|$ for all $t > t_*$ sufficiently near t_*. Consequently, we deduce the existence of a scalar $\lambda' > 0$ such that for all t near t_*,

$$\| z(t) \| \leq \lambda' | t - t_* |^{k+1}. \tag{18}$$

Suppose that k is odd. For all $t < t_*$, (17) implies

$$0 \leq v(t) \perp k! C \frac{z(t)}{| t - t_* |^k} - CA^k x^* + Dv(t) \geq 0, \tag{19}$$

where $v(t) \equiv k!u(t)/|t - t_*|^k$. Since D is a P-matrix, it follows from the Lipschitz continuity of the solutions to the LCP (q, D) that, for some constant $L > 0$, we have

$$\| v(t) - u(-CA^k x^*) \| \leq L \frac{\| z(t) \|}{| t - t_* |^k}$$

or equivalently

$$\left\| u(t) - \frac{| t - t_* |^k}{k!} u(-CA^k x^*) \right\| \leq L k! \| z(t) \| \quad \forall t < t_* \text{ sufficiently near } t_*. \tag{20}$$

For k odd and for $t < t_*$, we can write (16) as

$$\begin{aligned} \dot{z}(t) &= Az(t) + \frac{(t - t_*)^k}{k!}[A^{k+1}x^* - Bu(-CA^k x^*)] + B\left[u(t) - \frac{| t - t_* |^k}{k!} u(-CA^k x^*)\right] \\ &= \frac{(t - t_*)^k}{k!}[A^{k+1}x^* - Bu(-CA^k x^*)] + B\left[u(t) - \frac{| t - t_* |^k}{k!} u(-CA^k x^*)\right] \\ &\quad + O(|t - t_*|^{k+1}), \end{aligned}$$

where the last inequality is due to (18). Integrating the above and using (20) and (18), we deduce

$$z(t) = z(t_*) + \int_{t_*}^{t} \dot{z}(s)\, ds = \frac{(t - t_*)^{k+1}}{(k+1)!} [A^{k+1}x^* - Bu(-CA^k x^*)] + O(|t - t_*|^{k+2})$$

for all $t < t_*$ sufficiently near t_*. Substituting into (19), we obtain

$$0 \leq v(t) \perp \frac{t_* - t}{k+1} C[A^{k+1}x^* - Bu(-CA^k x^*)] + O(|t - t_*|^2) - CA^k x^* + Dv(t) \geq 0.$$

Hence, we deduce

$$v(t) = u(-CA^k x^*) + \frac{t_* - t}{k+1} u'(-CA^k x^*; CA^{k+1}x^* - CBu(-CA^k x^*)) + o(|t - t_*|),$$

which yields

$$\begin{aligned} u(t) = \frac{| t - t_* |^k}{k!} u(-CA^k x^*) + \frac{(t_* - t)^{k+1}}{(k+1)!} u'(-CA^k x^*; CA^{k+1}x^* - CBu(-CA^k x^*)) \\ + o(|t - t_*|^{k+1}). \end{aligned}$$

Substituting this into (16), we deduce

$$\dot{z}(t) = Az(t) + \frac{(t-t_*)^k}{k!}\,[\,A^{k+1}x^* - Bu(-CA^kx^*)\,] + \frac{(t-t_*)^{k+1}}{(k+1)!}\,Bu'(-CA^kx^*; CA^{k+1}x^* - CBu(-CA^kx^*)) + o(|t-t_*|^{k+1}).$$

Integrating the above equation and recalling $x(t) = z(t) + \sum_{j=0}^{k}(t-t_*)^j A^j x^*/j!$, we obtain the desired expansion for $x(t)$ when k is odd and $t < t_*$.

Next, assume that k is even and consider $t < t_*$ sufficiently near t_*. In this case, instead of (19), we have

$$0 \le v(t) \perp k!\,C\,\frac{z(t)}{(t-t_*)^k} + CA^kx^* + Dv(t) \ge 0;$$

moreover, (20) is replaced by

$$\left\| u(t) - \frac{(t-t_*)^k}{k!}\,u(CA^kx^*) \right\| \le L\,k!\,\|\,z(t)\,\| \quad \forall\, t < t_* \text{ sufficiently near } t_*.$$

Proceeding as above, we obtain from (16)

$$\dot{z}(t) = \frac{(t-t_*)^k}{k!}\,[\,A^{k+1}x^* + Bu(CA^kx^*)\,] + B\left[u(t) - \frac{(t-t_*)^k}{k!}\,u(CA^kx^*)\right] + O(|t-t_*|^{k+1}).$$

At this point, we can repeat the above proof and obtain the desired expansion for $(x(t), u(t))$ in this case where k is even. Finally, the proof for statement (a) is similar and therefore omitted. □

On the basis of Lemma 14, we can complete the proof of Theorem 9 by defining the *observability degree* of an observable state x with respect to the pair (C, A), which is defined as the first nonnegative integer k such that $CA^kx \neq 0$.

Proof of Theorem 9. We use induction on m, the dimension of the input variable u. The case $m = 0$ is trivial. Inductively, assume that the theorem is valid for an integer $m \ge 0$. Consider the LCS (1) where the algebraic variable u is of dimension $m+1 \ge 1$. Let $x^* = x(t_*)$ be an arbitrary state. We first prove that x^* is strongly right non-Zeno. By the above arguments, we may assume without loss of generality that x^* is observable. Let $k \ge 0$ be the observability degree of x^*; thus $Cx^* = \cdots = CA^{k-1}x^* = 0$ and $CA^kx^* \neq 0$. The expansion in part (a) of Lemma 14 holds for the trajectory $(x(t), u(t))$ in a small interval $[t_*, t_* + \varepsilon_+]$ for some $\varepsilon_+ > 0$. Since $CA^kx^* \neq 0$, there must exist an index i such that either $u_i(CA^kx^*) > 0$ or $[CA^kx^* + Du(CA^kx^*)]_i > 0$. By part (a) of Lemma 14, this implies that if $u_i(CA^kx^*) > 0$ for some index i, then $u_i(t) > 0$ for all $t > t_*$ sufficiently near t_*, which implies, by complementarity, that $[Cx(t) + Du(t)]_i = 0$ for all such t. Hence, we can solve for $u_i(t)$ from this equation, obtaining

$$u_i(t) = d_{ii}^{-1}\left[C_{i\cdot}x(t) + \sum_{j\neq i} d_{ij}\,u_j(t)\right],$$

which we can then substitute into the remaining conditions in (1). This substitution

results in an LCS:

$$\begin{aligned} \dot{x}(t) &= \widehat{A}x(t) + \widehat{B}\widehat{u}(t), \\ 0 \leq \widehat{u}(t) &\perp \widehat{C}x(t) + \widehat{D}\widehat{u}(t), \\ x(t_*) &= x^*, \end{aligned} \tag{21}$$

where the matrix $\widehat{D}$ is the Schur complement of the diagonal entry d_{ii} in D and the algebraic variable $\widehat{u}$ is of dimension m, which is one less than that of the original variable u. The original trajectory $(x(t), u(t))$ with the variable u_i removed must satisfy (21) in a small interval $(t_*, t_* + \varepsilon'_+]$ for some $\varepsilon'_+ > 0$. Since $\widehat{D}$ remains a P-matrix, by the induction hypothesis, there exist an index set $(\alpha'_+, \beta'_+, \gamma'_+)$ such that $(\widehat{\alpha}(t), \widehat{\beta}(t), \widehat{\gamma}(t)) = (\alpha'_+, \beta'_+, \gamma'_+)$ for all $t > t_*$ sufficiently near t_*, where $(\widehat{\alpha}(t), \widehat{\beta}(t), \widehat{\gamma}(t))$ are the three fundamental index sets associated with the solution trajectory $(x(t), \widehat{u}(t))$. Clearly, we have $(\alpha(t), \beta(t), \gamma(t)) = (\alpha'_+ \cup \{i\}, \beta'_+, \gamma'_+)$ for all $t > t_*$ sufficiently near t_*.

Next, consider the case where $[CA^k x^* + Du(CA^k x^*)]_i > 0$ for some index i. We then have

$$[\, Cx(t) + Du(t)\,]_i = \frac{(\,t - t_*\,)^k}{k\,!}\,[\, CA^k x^* + Du(CA^k x^*)\,]_i + o(|t - t_*|^{k+1}),$$

which implies that $[\, Cx(t) + Du(t)\,]_i > 0$, and thus $u_i(t) = 0$ by complementarity for all $t > t_*$ sufficiently near t_*. Setting this variable equal to zero and dropping the ith column of B and D and the ith row of C and D, we obtain a principal linear complementarity subsystem of (1) that is satisfied by the trajectory $(x(t), u(t))$ for all $t > t_*$ sufficiently near t_*. The induction hypothesis can be applied to the resulting subsystem whose algebraic variable is of one less dimension than that of the original u. Finally, we can apply part (b) of Lemma 14 to deal with $t < t_*$ and employ similar reductions to complete the inductive proof. □

4. Extended Zeno results. Theorem 9 can be easily extended to the mixed LCS

$$\begin{aligned} \dot{x} &= Ax + B^1 u^1 + B^2 u^2, \\ 0 &= C^1 x + D^{11} u^1 + D^{12} u^2, \\ 0 \leq u^2 &\perp C^2 x + D^{21} u^1 + D^{22} u^2 \geq 0, \\ x(0) &= x^0, \end{aligned}$$

provided that the matrix D^{11} is nonsingular and the Schur complement

$$D^{22} - D^{21}(\,D^{11}\,)^{-1} D^{12}$$

is a P-matrix. Instead of presenting the details of this easy extension, we consider a local version of the extension that pertains to an LCS with a "strongly regular" state but which is not of the P-type. Specifically, we call x^* a *strongly regular state* of the LCS (1) if the LCP (Cx^*, D) has a strongly regular solution. The following corollary of Theorem 9 shows that any such state must be strongly non-Zeno. For simplicity, we treat the case where x^* is neither an initial nor a terminal state of a solution trajectory.

COROLLARY 15. *Any strongly regular state of the LCS* (1) *is strongly non-Zeno relative to a continuous solution trajectory of the system. In fact, if* $(x(t), u(t))$ *is such a trajectory defined on an open interval containing* t_* *and if the LCP* $(Cx(t_*), D)$ *has a strongly regular solution, then* $(x(t), u(t))$ *is the unique continuous solution trajectory passing through* $x^* \equiv x(t_*)$ *for all* t *sufficiently near* t_**, and* x^* *is strongly non-Zeno relative to this trajectory.*

Proof. We first establish the uniqueness of $(x(t), u(t))$. Suppose that $(\widetilde{x}(t), \widetilde{u}(t))$ is another continuous solution trajectory of (1) passing through x^* and defined on the same interval as $(x(t), u(t))$. By the strong regularity of u^*, a neighborhood $\mathcal{V}$ of Cx^*, a neighborhood $\mathcal{U}$ of u^*, and a Lipschitz continuous function $\widehat{u} : \mathcal{V} \to \mathcal{U}$ exist such that for every $q \in \mathcal{V}$, $\widehat{u}(q)$ is the unique solution of the LCP (q, D) in $\mathcal{U}$. Since $(x(t), u(t))$ and $(\widetilde{x}(t), \widetilde{u}(t))$ are both continuous near t_*, it follows that for all t sufficiently near t_*, $(Cx(t), u(t))$ and $(C\widetilde{x}(t), \widetilde{u}(t))$ both belongs to $\mathcal{V} \times \mathcal{U}$. Hence we have $u(t) = \widehat{u}(Cx(t))$ and $\widetilde{u}(t) = \widehat{u}(C\widetilde{x}(t))$. Moreover, a constant $L > 0$ exists such that for all t sufficiently near t_*, we have

$$\|u(t) - \widehat{u}(t)\| \le L \, \|x(t) - \widehat{x}(t)\|. \tag{22}$$

Since

$$\frac{d\,(x(t) - \widehat{x}(t))}{dt} = A(x(t) - \widehat{x}(t)) + B(u(t) - \widehat{u}(t)),$$

(22) implies that the right-hand side is a Lipschitz function of $x(t) - \widehat{x}(t)$. Since $x(t_*) = \widehat{x}(t_*) = x^*$, it follows that the two trajectories $x(t)$ and $\widehat{x}(t)$, and thus the two trajectories, $u(t)$ and $\widehat{u}(t)$, must coincide in a sufficiently small open interval containing t_*. The uniqueness of $(x(t), u(t))$ therefore follows.

By Proposition 5, it follows that for all t sufficiently near t_*, the trajectory $(x(t), u(t))$ must satisfy the reduced system (11). Since $\overline{D}$, being the Schur complement of $D_{\alpha_*\alpha_*}$ in a principal submatrix of D, remains a P-matrix, it follows that $x(t_*)$ is a strongly non-Zeno state of (11) relative to the trajectory $(x(t), u_{\beta_*}(t))$. Therefore, a scalar $\varepsilon > 0$ and two triples of index sets $(\alpha_{0+}, \beta_{0+}, \gamma_{0+})$ and $(\alpha_{0-}, \beta_{0-}, \gamma_{0-})$ exist such that

$$\left.\begin{aligned} \alpha_0(t) &\equiv \{i \in \beta_* : u_i(t) > 0 = (\,\overline{C}x(t) + \overline{D}u_{\beta_*}(t)\,)_i\} = \alpha_{0+} \\ \beta_0(t) &\equiv \{i \in \beta_* : u_i(t) = 0 = (\,\overline{C}x(t) + \overline{D}u_{\beta_*}(t)\,)_i\} = \beta_{0+} \\ \gamma_0(t) &\equiv \{i \in \beta_* : u_i(t) = 0 < (\,\overline{C}x(t) + \overline{D}u_{\beta_*}(t)\,)_i\} = \gamma_{0+} \end{aligned}\right\} \quad \forall\, t \in (t_*, t_* + \varepsilon]$$

and

$$\left.\begin{aligned} \alpha_0(t) &= \alpha_{0-} \\ \beta_0(t) &= \beta_{0-} \\ \gamma_0(t) &= \gamma_{0-} \end{aligned}\right\} \quad \forall\, t \in [\,t_* - \varepsilon, t_*\,).$$

Since $0 < u_{\alpha_*}(t) = -(D_{\alpha_*\alpha_*})^{-1}(C_{\alpha_*}.x(t) + D_{\alpha_*\beta_*}u_{\beta_*}(t))$ and $0 = u_{\gamma_*}(t)$, it follows that

$$\overline{C}x(t) + \overline{D}u_{\beta_*}(t) = (\,Cx(t) + Du(t)\,)_{\beta_*}$$

for all t sufficiently near t_*. Consequently,

$$\left.\begin{aligned} \alpha(t) &= \alpha_* \cup \alpha_{0+} \\ \beta(t) &= \beta_{0+} \\ \gamma(t) &= \gamma_* \cup \gamma_{0+} \end{aligned}\right\} \quad \forall\, t \in (\,t_*, t_* + \varepsilon\,]$$

and

$$\left.\begin{array}{l}\alpha(t) = \alpha_* \cup \alpha_{0-} \\ \beta(t) = \beta_{0-} \\ \gamma(t) = \gamma_* \cup \gamma_{0-}\end{array}\right\} \quad \forall\, t \in [\, t_* - \varepsilon, t_* \,).$$

This shows that x^* is a strongly non-Zeno state of (1). □

One important consequence of the P-property is that the u-trajectory must necessarily be unique. In what follows, we present an extended treatment of the Zeno issue for an LCS with nonunique u-trajectories. Specifically, we make several alternative assumptions on the tuple (A, B, C, D), the first of which ensures the existence and uniqueness of a continuously differentiable solution trajectory $x(t)$ corresponding to various subsystems of (1).

(A) For every $x \in \Re^n$ and every triple of index sets (α, β, γ) partitioning $\{1, \ldots, m\}$ with $\beta \neq \emptyset$, the mixed LCP

$$\begin{aligned} 0 &= [\, Cx + Du \,]_\alpha, \\ 0 \leq u_\beta \perp [\, Cx + Du \,]_\beta &\geq 0, \\ 0 &= u_\gamma \end{aligned} \tag{23}$$

has a solution $u \in \Re^m$; moreover, $Bu^1 = Bu^2$ for any two such solutions u^1 and u^2.

The fundamental role of the above assumption is described in the following result.

Proposition 16. *Under assumption* (A)*, for every triple of index sets* (α, β, γ) *partitioning* $\{1, \ldots, m\}$ *with* $\beta \neq \emptyset$*, the system*

$$\begin{aligned} \dot{x} &= Ax + Bu, \\ 0 &= [\, Cx + Du \,]_\alpha, \\ 0 \leq u_\beta \perp [\, Cx + Du \,]_\beta &\geq 0, \\ 0 &= u_\gamma, \\ x(0) &= x^0 \end{aligned} \tag{24}$$

has a unique solution trajectory $x(t)$ *for all* $t \in [0, T]$ *for any* $T > 0$*; moreover,* $x(t)$ *is continuously differentiable on its domain.*

Proof. Let $\mathcal{S}(x) \subset \Re^m$ denote the solution set of (23). As a multifunction, the map $\mathcal{S} : x \mapsto \mathcal{S}(x)$ is a polyhedral multifunction; i.e., its graph is the union of finitely many polyhedra. Under assumption (A), the mapping

$$\widehat{B} \,:\, x \in \Re^n \,\mapsto\, B\mathcal{S}(x)$$

is a single-valued function whose graph is the union of finitely many polyhedra. As such, by a result due originally to Gowda (see [12, Exercise 5.6.14]), it follows that $\widehat{B}$ is a (globally) Lipschitz continuous function on $\Re^n$. In terms of this mapping, the system (24) can be equivalently stated as

$$\dot{x} = Ax + \widehat{B}(x), \quad x(0) = x^0.$$

Since the right-hand side of the ODE is Lipschitz continuous, the existence and uniqueness and the continuous differentiability of a solution trajectory $x(t)$ follows from classical ODE theory. □

Before proceeding further, we make several remarks about Proposition 16 and assumption (A). First, if one is interested in the existence of a unique x-trajectory to the single LCS (1), then it suffices to assume that $B\mathrm{SOL}(Cx, D)$ is a singleton for all $x \in \Re^n$. Second, while the x-trajectory is necessarily unique in the proposition, no such uniqueness is asserted for the u-trajectory; no continuity of the u-trajectory is asserted either. This is a significant departure from the P-property under which the u-trajectory exists and is both unique and continuous. Nevertheless, it can be shown that in the case where C has full row rank, assumption (A) implies that D must be a P-matrix. Hence, condition (A) is most interesting when C is deficient in row rank. A class of triples (B, C, D) satisfying assumption (A) with D being non-P is presented in section 5. It should be noted that condition (A) is different from the passifiability property of the triple (B, C, D) used in [5]; the latter property, along with a minimality assumption on (A, B, C, D), yields the existence and uniqueness of a continuous x-trajectory and an $\mathcal{L}_2$ u-trajectory of the LCS (1). Examples of the class of triples (B, C, D) from section 5 can easily be constructed which fail the passifiability condition; conversely, any triple $(B, C, 0)$ with CB symmetric positive definite is passifiable but fails condition (A).

Another difference between assumption (A) and the P-matrix assumption is that (A) does not imply any apparent determinant properties of the principal matrix

$$\begin{bmatrix} D_{\alpha\alpha} & D_{\alpha\beta} \\ D_{\beta\alpha} & D_{\beta\beta} \end{bmatrix};$$

in particular, it could be singular. Assumption (A) does imply

$$\left.\begin{array}{c} 0 = (Du)_\alpha \\ 0 \le u_\beta \perp (Du)_\beta \ge 0 \\ 0 = u_\gamma \end{array}\right\} \Rightarrow Bu = 0,$$

and is implied by the following more restrictive condition:

$$u \circ Du \le 0 \Rightarrow Bu = 0.$$

For our purpose, the following invariance properties of assumption (A) are important for the extension of the previous inductive argument to an LCS not satisfying the P-property.

PROPOSITION 17. *Suppose that (B, C, D) satisfies condition* (A). *The same condition holds for the following triples of index sets:*

(a) $(B_{\cdot\tilde{\alpha}}, C_{\tilde{\alpha}\cdot}, D_{\tilde{\alpha}\tilde{\alpha}})$ *for every subset* $\tilde{\alpha} \subseteq \{1, \ldots, m\}$;

(b) *the triple* $(\widetilde{B}, \widetilde{C}, \widetilde{D})$ *associated with the* $\tilde{\alpha}$*-principal transform* (7) *of* (B, C, D) *for every subset* $\tilde{\alpha} \subseteq \{1, \ldots, m\}$ *such that* $D_{\tilde{\alpha}\tilde{\alpha}}$ *is nonsingular;*

(c) (PB, CP^{-1}, D) *for every nonsingular matrix* P.

Proof. Let α', β', and γ' be any three index sets partitioning $\tilde{\alpha}$, with $\beta' \neq \emptyset$. Let $x \in \Re^n$ be arbitrary. We need to show that the system

$$\begin{aligned} 0 &= [Cx + Du]_{\alpha'}, \\ 0 \le u_{\beta'} &\perp [Cx + Du]_{\beta'} \ge 0, \\ 0 &= u_{\gamma'} \end{aligned}$$

has a solution $u_{\tilde{\alpha}}$. Moreover, if $u^1_{\tilde{\alpha}}$ and $u^2_{\tilde{\alpha}}$ are any two such solutions, we must have $B_{\cdot\tilde{\alpha}}u^1_{\tilde{\alpha}} = B_{\cdot\tilde{\alpha}}u^2_{\tilde{\alpha}}$. But this is clear from condition (A) with the choice of $(\alpha, \beta, \gamma) = (\alpha', \beta', \gamma' \cup (\{1, \ldots, m\} \backslash \tilde{\alpha}))$. To prove (b), let $(\alpha', \beta', \gamma')$ be a triple of index sets partitioning $\{1, \ldots, m\}$ with $\beta' \neq \emptyset$ and consider the system

$$\begin{aligned} 0 &= [\,\widetilde{C}x + \widetilde{D}\widetilde{u}\,]_{\alpha'}, \\ 0 \leq \widetilde{u}_{\beta'} &\perp [\,\widetilde{C}x + \widetilde{D}\widetilde{u}\,]_{\beta'} \geq 0, \\ 0 &= \widetilde{u}_{\gamma'}. \end{aligned} \tag{25}$$

Letting $\widetilde{w} \equiv \widetilde{C}x + \widetilde{D}\widetilde{u}$ and "pivoting" on $(D_{\tilde{\alpha}\tilde{\alpha}})^{-1}$, we obtain $w \equiv Cx + Du$, where the relation between the pairs (w, u) and $(\widetilde{w}, \widetilde{u})$ is as follows:

$$\begin{aligned} w &\equiv \begin{pmatrix} w_{\tilde{\alpha}} \\ \\ w_{\bar{\alpha}} \end{pmatrix}, \quad u \equiv \begin{pmatrix} u_{\tilde{\alpha}} \\ \\ u_{\bar{\alpha}} \end{pmatrix}, \\ \widetilde{w} &= \begin{pmatrix} u_{\tilde{\alpha}} \\ \\ w_{\bar{\alpha}} \end{pmatrix}, \quad \widetilde{u} = \begin{pmatrix} w_{\tilde{\alpha}} \\ \\ u_{\bar{\alpha}} \end{pmatrix}, \end{aligned} \tag{26}$$

where $\bar{\alpha}$ is the complement of $\tilde{\alpha}$ in $\{1, \ldots, m\}$. Therefore, system (25) is equivalent to system (23) for some suitable triple (α, β, γ) that is derived from $(\alpha', \beta', \gamma')$. Therefore, the existence of a solution to (25) follows from condition (A) on the original triple (B, C, D). Suppose that $\widetilde{u}^1$ and $\widetilde{u}^2$ are any two solutions satisfying (25). Corresponding to $\widetilde{u}^i$, for $i = 1, 2$, let $\widetilde{w}^i \equiv \widetilde{C}x + \widetilde{D}\widetilde{u}^i$ and (w^i, u^i) be defined accordingly. It follows that $Bu^1 = Bu^2$. We have

$$\begin{aligned} \widetilde{B}\widetilde{u}^i &= B_{\cdot\tilde{\alpha}}(\,D_{\tilde{\alpha}\tilde{\alpha}}\,)^{-1}\widetilde{u}^i_{\tilde{\alpha}} + [\,B_{\cdot\bar{\alpha}} - B_{\cdot\alpha}(\,D_{\tilde{\alpha}\tilde{\alpha}}\,)^{-1}D_{\tilde{\alpha}\bar{\alpha}}\,]\widetilde{u}^i_{\bar{\alpha}} \\ &= B_{\cdot\tilde{\alpha}}(\,D_{\tilde{\alpha}\tilde{\alpha}}\,)^{-1}w^i_{\tilde{\alpha}} + [\,B_{\cdot\bar{\alpha}} - B_{\cdot\tilde{\alpha}}(\,D_{\tilde{\alpha}\tilde{\alpha}}\,)^{-1}D_{\tilde{\alpha}\bar{\alpha}}\,]u^i_{\bar{\alpha}} \\ &= B_{\cdot\tilde{\alpha}}(\,D_{\tilde{\alpha}\tilde{\alpha}}\,)^{-1}[\,Cx + Du^i\,]_{\tilde{\alpha}} + [\,B_{\cdot\bar{\alpha}} - B_{\cdot\tilde{\alpha}}(\,D_{\tilde{\alpha}\tilde{\alpha}}\,)^{-1}D_{\tilde{\alpha}\bar{\alpha}}\,]u^i_{\bar{\alpha}} \\ &= B_{\cdot\tilde{\alpha}}(\,D_{\tilde{\alpha}\tilde{\alpha}}\,)^{-1}C_{\tilde{\alpha}\cdot}x + Bu^i; \end{aligned}$$

hence, $\widetilde{B}\widetilde{u}^1 = \widetilde{B}\widetilde{u}^2$. This proves (b). Finally (c) is obvious. ∎

To motivate the following discussion, consider an unobservable state $x^* = x(t_*)$. In this case, $(x(t), u(t)) = (e^{A(t-t_*)}x^*, 0)$ is trivially an admissible solution trajectory to (1) for $t > t_*$. Moreover, under assumption (A), the trajectory $x(t) = e^{A(t-t_*)}x^*$ is unique for $t > t_*$. Nevertheless, if D is not an R_0-matrix, i.e., if the homogeneous LCP $(0, D)$ has a nonzero solution, then it is very difficult, if not impossible, to ascertain the Zeno properties of $(x(t), u(t))$ jointly. The reason is very simple: the LCP $(0, D)$, which must be satisfied by the u-trajectory in this case, is totally unaffected by the x-trajectory. Consequently, if one expects an unobservable state x^* to be (right) non-Zeno, one must restrict oneself to the class of matrices D for which the LCP $(0, D)$ has a polyhedral solution set; this is the principal motivation to introduce the class of weakly column sufficient matrices (Definition 1).

The following result extends the key expansion Lemma 14 and is applicable to an arbitrary tuple (A, B, C, D) satisfying condition (A).

LEMMA 18. *Suppose that (A, B, C, D) satisfy condition* (A). *Let $x^* = x(t_*)$ be a given state of the solution trajectory $(x(t), u(t))$ such that $CA^j x^* = 0$ for all $j = 0, 1, \ldots, k-1$ for some integer $k \geq 0$. The following two statements hold:*

(a) *For each $t > t_*$ sufficiently near t_*, there exists $u^{t+} \in \mathrm{SOL}(CA^k x^*, D)$ such that*

$$x(t) = \sum_{j=0}^{k+1} \frac{(t-t_*)^j}{j!} A^j x^* + \frac{(t-t_*)^{k+1}}{(k+1)!} B u^{t+} + O(|t-t_*|^{k+2}),$$

$$u(t) = \frac{(t-t_*)^k}{k!} u^{t+} + O(|t-t_*|^{k+1}).$$

(b) *If k is even, then for each $t < t_*$ sufficiently near t_*, there exists $u^{t+} \in \mathrm{SOL}(CA^k x^*, D)$ such that the expansion in part* (a) *remains valid. If k is odd, then for each $t < t_*$, there exists $u^{t-} \in \mathrm{SOL}(-CA^k x^*, D)$ such that*

$$x(t) = \sum_{j=0}^{k+1} \frac{(t-t_*)^j}{j!} A^j x^* - \frac{(t-t_*)^{k+1}}{(k+1)!} B u^{t-} + O(|t-t_*|^{k+2}),$$

$$u(t) = \frac{|t-t_*|^k}{k!} u^{t-} + O(|t-t_*|^{k+1}).$$

Proof. We prove only statement (a). Proceeding as in the proof of Lemma 14, we define $z(t)$ by (15) and note that (16) and (17) must hold. By the same result due of Gowda that we used in the proof of Proposition 16, we can deduce the existence of a constant $\eta > 0$ such that

$$\| Bu(t) \| \leq \eta [\| z(t) \| + | t - t_* |^k]$$

for all t. Consequently, it follows that (18) holds. The vector $v(t) \equiv k!u(t)/|t-t_*|^k$ satisfies, for all $t > t_*$,

$$0 \leq v(t) \perp k! C \frac{z(t)}{| t - t_* |^k} + CA^k x^* + Dv(t) \geq 0.$$

Since $\|z(t)\|$ is of order $|t-t_*|^{k+1}$, by the semistability of the LCP $(CA^k x^*, D)$, it follows that for every $t > t_*$ sufficiently near t_*, there exists $u^{t+} \in \mathrm{SOL}(CA^k x^*, D)$ such that $\|v(t) - u^{t+}\|$ is of order $O(|t-t_*|)$. The expansion for $u(t)$ in part (a) thus follows readily. Substituting this expansion into the differential equation

$$\dot{z}(t) = Az(t) + \frac{(t-t_*)^k}{k!} A^{k+1} x^* + Bu(t)$$

$$= Az(t) + \frac{(t-t_*)^k}{k!} [A^{k+1} x^* + Bu^{t+}] + O(| t - t_* |^{k+1})$$

using the fact that Bu^{t+} is independent of t (because $B\mathrm{SOL}(CA^k x^*, D)$ is a singleton), and integrating, we can deduce the desired expansion for $x(t)$. The details are not repeated. □

On the basis of the concept of an identifiable LCP, we introduce the following.

Definition 19. *A state x^* is said to be* identifiable *with respect to the triple (A, C, D) if, for each subset α of $\{1, \ldots, m\}$, if x^* is observable with degree k with respect to the pair $(C_{\alpha\cdot}, A)$, then the LCPs $(\pm C_{\alpha\cdot} A^k x^*, D_{\alpha\alpha})$ are identifiable. The state x^* is said to be* totally identifiable *with respect to the tuple (A, B, C, D) if x^* is*

identifiable with respect to all triples $(\widehat{A}, \widehat{C}, \widehat{D})$*, where*

$$\widehat{A} \equiv A - B_{\cdot\alpha}(\, D_{\alpha\alpha}\,)^{-1} C_{\alpha\cdot},$$

$$\widehat{C} \equiv C_{\bar{\alpha}\cdot} - D_{\bar{\alpha}\alpha}(\, D_{\alpha\alpha}\,)^{-1} C_{\alpha\cdot},$$

$$\widehat{D} \equiv D_{\bar{\alpha}\bar{\alpha}} - D_{\bar{\alpha}\alpha}(\, D_{\alpha\alpha}\,)^{-1} D_{\alpha\bar{\alpha}},$$

and α*, with complement* $\bar{\alpha}$*, ranges over all subsets of* $\{1, \ldots, m\}$ *for which* $D_{\alpha\alpha}$ *is nonsingular.* □

The next lemma asserts that the above identifiability property is inherited by the principal (sub)transforms of a given tuple.

LEMMA 20. *Suppose that* x^* *is totally identifiable with respect to* (A, B, C, D)*. Then* x^* *is also totally identifiable with respect to the following tuples:*

(a) $(A, B_{\cdot\alpha}, C_{\alpha\cdot}, D_{\alpha\alpha})$ *for all subsets* α *of* $\{1, \ldots, m\}$*;*

(b) *the principal subtuples* $(\widehat{A}, \widehat{B}, \widehat{C}, \widehat{D})$ *associated with all legitimate principal pivot transforms of* (A, B, C, D)*, where*

$$\widehat{A} \equiv A - B_{\cdot\alpha}(\, D_{\alpha\alpha}\,)^{-1} C_{\alpha\cdot}, \qquad \widehat{B} \equiv B_{\cdot\bar{\alpha}} - B_{\cdot\alpha}(\, D_{\alpha\alpha}\,)^{-1} D_{\alpha\bar{\alpha}},$$

$$\widehat{C} \equiv C_{\bar{\alpha}\cdot} - D_{\bar{\alpha}\alpha}(\, D_{\alpha\alpha}\,)^{-1} C_{\alpha\cdot}, \quad \widehat{D} \equiv D_{\bar{\alpha}\bar{\alpha}} - D_{\bar{\alpha}\alpha}(\, D_{\alpha\alpha}\,)^{-1} D_{\alpha\bar{\alpha}},$$

and α*, with complement* $\bar{\alpha}$*, ranges over all subsets of* $\{1, \ldots, m\}$ *for which* $D_{\alpha\alpha}$ *is nonsingular.*

Moreover, Px^* *is totally identifiable with respect to the triple* $(PAP^{-1}, PB, CP^{-1}, D)$ *for any nonsingular matrix* P*.*

Proof. Statement (a) is obvious. The validity of statement (b) is based on the observation that a tuple $(\widehat{\widehat{A}}, \widehat{\widehat{C}}, \widehat{\widehat{D}})$, where

$$\widehat{\widehat{A}} \equiv \widehat{A} - \widehat{B}_{\cdot\hat{\alpha}}(\, \widehat{D}_{\hat{\alpha}\hat{\alpha}}\,)^{-1} \widehat{C}_{\hat{\alpha}\cdot},$$

$$\widehat{\widehat{C}} \equiv \widehat{C}_{\bar{\hat{\alpha}}\cdot} - D_{\bar{\hat{\alpha}}\hat{\alpha}}(\, D_{\hat{\alpha}\hat{\alpha}}\,)^{-1} \widehat{C}_{\hat{\alpha}\cdot},$$

$$\widehat{\widehat{D}} \equiv \widehat{D}_{\bar{\hat{\alpha}}\bar{\hat{\alpha}}} - \widehat{D}_{\bar{\hat{\alpha}}\hat{\alpha}}(\, \widehat{D}_{\hat{\alpha}\hat{\alpha}}\,)^{-1} D_{\hat{\alpha}\bar{\hat{\alpha}}},$$

and $\hat{\alpha}$, with complement $\bar{\hat{\alpha}}$, is a subset of $\bar{\alpha}$ for which $\widehat{D}_{\hat{\alpha}\hat{\alpha}}$ is nonsingular, can be shown to be a principal subtuple associated with the $(\alpha \cup \hat{\alpha})$-principal pivot transform of (A, B, C, D). Hence (b) holds. The last assertion follows easily from the identity $CP^{-1}(PAP^{-1})^k = CA^kP^{-1}$. □

Our extended Zeno result for an LCS without the P-property is the following. The statement of the theorem assumes that x^* is neither the initial nor the terminal state of the solution trajectory so that we do not need to pay attention to the one-sidedness of these special states.

THEOREM 21. *Let* D *be a weakly column sufficient matrix. Suppose that condition* (A) *holds for the tuple* (A, B, C, D)*. The following two statements hold for any state* $x^* = x(t_*)$ *and any u-trajectory:*

(a) *If* x^* *is unobservable with respect to* (C, A)*, then* x^* *is weakly non-Zeno.*

(b) *If* x^* *is totally identifiable with respect to the tuple* (A, B, C, D)*, then* x^* *is weakly non-Zeno.*

Proof. We follow the proof of Theorem 9. Suppose that the initial state x^0 is unobservable with respect to (C, A). In this case, the unique x-trajectory is $x(t) = e^{At}x^0$

and we have $Cx(t) = 0$ for all t. Hence $u(t) \in \mathrm{SOL}(0, D)$ for all t. The weak column sufficiency of D then completes the proof. So we assume that x^0 is observable. The proof of Lemma 12 shows that all subsequent states are observable. This establishes part (a). We use induction on m to prove that if x^* is totally identifiable with respect to (A, B, C, D), then x^* is weakly right non-Zeno; the proof of weakly left non-Zenoness is similar and therefore omitted. Since the LCP $(CA^k x^*, D)$ is identifiable, where k is the observability degree of x^* with respect to the pair (C, A), either one of the two index sets $\mathcal{I}_u$ or $\mathcal{I}_w$ is nonempty. Without loss of generality, assume that the former is so. By Proposition 4, there exists a scalar $\sigma > 0$ such that $u_i \geq \sigma$ for all $u \in \mathrm{SOL}(CA^k x^*, D)$ and all $i \in \mathcal{I}_u$. Consequently, by the expansion of $u(t)$ near t_* as described in part (a) of Lemma 18 it follows that $u_i(t) > 0$ for all $i \in \mathcal{I}_u$ and all $t > t_*$ sufficiently near t_*. Moreover, $D_{\mathcal{I}_u \mathcal{I}_u}$ is nonsingular by the identifiability assumption. Consequently, the trajectory $(x(t), u(t))$ must satisfy the principal subtransform (9) with $\alpha \equiv \mathcal{I}_u$ for all $t > t_*$ sufficiently near t_*. The induction hypothesis then completes the proof. □

5. A special bimodal system. As an illustration of another application of the expansion Lemma 18, we consider a special bimodal system which has $D \equiv ff^T$, $B \equiv bf^T$, and $C \equiv fc^T$ for some m-vector f and n-vectors b and c. To avoid trivialities, we assume that f has no zero components. It is easy to see that condition (A) holds for the triple $(B, C, D) \equiv (bf^T, fc^T, ff^T)$. Notice that the LCS (1) with this triple remains an MIMO (multiple input, multiple output) system; nevertheless, it is a bimodal system because of the lemma below.

LEMMA 22. *The LCP*

$$0 \leq u \perp fc^T x + ff^T u \geq 0$$

has a solution for all $x \in \Re^n$; moreover, for any such solution u, $f^T u = 0$ if $fc^T x \geq 0$, and $c^T x + f^T u = 0$ otherwise. Consequently,

$$\mathrm{SOL}(fc^T x, ff^T) = \begin{cases} \{\, u \geq 0 : f^T u = 0 \,\} & \text{if } fc^T x \geq 0, \\ \{\, u \geq 0 : c^T x + f^T u = 0 \,\} & \text{otherwise.} \end{cases}$$

Proof. If $fc^T x \geq 0$, then $u = 0$ is a solution of the LCP. Since $f^T u$ is a constant on the solution set of this LCP, it follows that $f^T u = 0$ for all such solutions in this case. If $fc^T x \not\geq 0$, then $f^T u \neq 0$ for all solutions of the LCP. For any such solution u, we have

$$0 = (f^T u)(c^T x) + (f^T u)^2,$$

which yields $c^T x + f^T u = 0$ as claimed. The representation of $\mathrm{SOL}(fc^T x, ff^T)$ is easy to establish. □

In view of the above lemma, it follows that the LCS (1) is of the following bimodal kind:

$$\dot{x} = \begin{cases} Ax & \text{if } fc^T x \geq 0, \\ (A - bc^T)x & \text{otherwise.} \end{cases}$$

Since $f \neq 0$, it is clear that x^* is an observable state of the pair (C, A) if and only if the scalar $c^T A^k x^* \neq 0$ for some integer $k \geq 0$. If $c^T x^* = \cdots = c^T A^{k-1} x^* = 0 \neq c^T A^k x^*$, Lemma 18 implies that, for $t > t_*$,

$$c^T x(t) = \frac{(t - t_*)^k}{k!} c^T A^k x^* + O(|t - t_*|^{k+1}).$$

Since $c^T A^k x^*$ is a nonzero scalar, it follows that $c^T x(t)$ is nonzero and of one sign for all $t > t_*$ sufficiently near t_*. Since f is a constant vector, it follows that either $fc^T x(t) \geq 0$ for all $t > t_*$ sufficiently near t_*, which implies $f^T u(t) = 0$ for all $u(t) \in \mathrm{SOL}(fc^T x(t), ff^T)$, or $c^T x(t) + f^T u(t) = 0$ for all such t. In the latter case, it follows that x^* is a weakly right non-Zeno state with respect to the trajectory $(x(t), u(t))$. In the former case, f must be either a positive or a negative vector depending on whether $c^T A^k x^* > 0$ or $c^T A^k x^* < 0$; in either case, we must have $u(t) = 0$ for all $t > t_*$ sufficiently near t_* because $f^T u(t) = 0$ and $u(t) \geq 0$. This is enough to show that x^* is a weakly right non-Zeno state. A similar argument will establish that x^* is also a weakly left non-Zeno state. We have, therefore, proved the following result for an observable state. The proof of the result for an unobservable state is the same as before and is not repeated.

THEOREM 23. *Let $(B, C, D) \equiv (bf^T, fc^T, ff^T)$, where f has no zero component. The LCS* (1) *has no Zeno states of the second kind.* □

6. Concluding remarks. In this paper, via a basic expansion of the solution trajectory near a given time, we have shown that an LCS with the P-property has no Zeno states of the first kind, that the totally identifiable states of an LCS with the weakly column sufficient property are weakly non-Zeno, and that a certain bimodal LCS has no Zeno states of the second kind. Subsequently to the completion to this work, we have extended the results in several directions, in particular, to a special LCS of the "positive semidefinite plus" type [12] and to a strongly regular nonlinear complementarity system [22]. An interesting extension that we have *not* yet resolved is the case where $D = 0$ and CB is positive definite (but not symmetric). Such an LCS is not necessarily passifiable. Lastly, in the paper [22], we use the results established herein to study the "local observability" of an LCS.

Acknowledgments. The authors wish to thank Professor Hans Schumacher and Dr. Kanat Çamlibel for extensive discussion on the topic of this paper and for sharing their invaluable insights that contribute to our understanding of the LCS. They are also grateful to the associate editor, the referees, and David Stewart, who have made a number of constructive comments that have helped to improve the presentation of the paper.

OPTIMAL CONTROL OF OBSTACLE FOR QUASI-LINEAR ELLIPTIC VARIATIONAL BILATERAL PROBLEMS*

QIHONG CHEN†, DELIN CHU‡, AND ROGER C. E. TAN‡

Abstract. This paper is concerned with an optimal control problem for quasi-linear elliptic variational inequality in which the bilateral obstacles are the control. The cost functional of this optimal control problem is of Lagrange type in which the pth power of Laplacian of the control appears. This feature leads to the fact that it is hard to derive the optimality system for the underlying problem. In this paper, the optimality system is established by utilizing the special structure of the approximate optimality system including the monotonicity of the leading differential operator.

Key words. obstacle optimal control, quasi-linear elliptic equations, bilateral variational inequality, optimality system

1. Introduction.

The variational inequalities and related optimal control problems have been studied extensively in the literature; see [1, 2, 3, 4, 5, 6, 7, 8, 9, 10, 11, 12, 13, 14, 15, 16, 18, 19, 20, 23, 24, 25, 26, 27, 28, 29, 30] and the reference therein. Recently, various control problems for bilateral variational inequalities have been considered in [7, 14, 15, 16]. When the governing system is an obstacle variational inequality, the obstacle can also be regarded as the control. Such a case is referred to as an obstacle optimal control problem. To the best of our knowledge, such a problem was first studied in [1]. For the homogeneous case, an optimal obstacle control problem for an elliptic variational inequality is considered there. By virtue of the properties of the superharmonic functions, the existence and uniqueness as well as characterizations of the optimal pair are established in [1]. To study the obstacle optimal control problem for more general systems, an indirect obstacle control model is suggested in [11, 12, 13]. Motivated by [1] and [11], the regularity of the obstacle control problem has been investigated in [25] and [26]. The work in [1] has been extended by adding a nonzero source term to the right-hand side of the state equation and it has been found in [2] that such an extension is not trivial.

In this paper, we consider an obstacle optimal control problem for the quasi-linear case. The main feature of our problem is that the state satisfies a quasi-linear elliptic bilateral variational inequality and the input control is the pair of upper and lower obstacles, as stated as follows:

$$\begin{cases} \varphi \le y \le \psi, \\ -\mathrm{div} A(x, \nabla y)(y - \varphi) \le 0, \\ -\mathrm{div} A(x, \nabla y)(y - \psi) \le 0, \end{cases} \tag{1.1}$$

where $A(x,\cdot)$ is nonlinear.

In practice, there are many real physical or geometrical problems related to obstacle variational inequalities (cf. [28]). Except for some ideal cases, the governing equations are usually quasi-linear or nonlinear. A typical example is that in the study of non-Newtonian fluids [17]

$$A(\nabla y) = |\nabla y|^{p-2}\nabla y.$$

Another example is that in the study of a minimal surface with obstacle [23, 28]

$$A(\nabla y) = (1+|\nabla y|^2)^{-\frac{1}{2}}\nabla y.$$

Similar cases occur in evolutionary problems. We found that the techniques developed in [1, 2] do not work when $A(x,\cdot)$ is nonlinear. Hence, from both theoretical and practical points of view, it is necessary to study the case with $A(x,\cdot)$ nonlinear.

Suppose $\Omega \subset \mathcal{R}^n$ is a bounded domain with a $C^{1,1}$ boundary $\partial\Omega$. Let $z_d \in L^2(\Omega)$ be a given target profile. For any $\varphi, \psi \in W_0^{1,p}(\Omega)$, we define

$$K(\varphi,\psi) = \{z \in W_0^{1,p}(\Omega) | \varphi \le z \le \psi \quad \text{a.e. } x \in \Omega\}$$

and consider a weak formulation of quasi-linear elliptic bilateral obstacle problem (1.1):

$$\begin{cases} y \in K(\varphi,\psi), \\ \displaystyle\int_\Omega A(x,\nabla y)\cdot\nabla(z-y)dx \ge 0 \qquad \forall z \in K(\varphi,\psi), \end{cases} \tag{1.2}$$

where

$$A(x,\eta) = (a_1(x,\eta),\dots,a_n(x,\eta)). \tag{1.3}$$

Given $\varphi,\psi \in W_0^{1,p}(\Omega)$, under some further mild assumptions on $A(x,\eta)$ (see (H_1) and (H_2) below), the variational inequality (1.2) is uniquely solvable [22]. We will denote the unique solution of (1.2) corresponding to (φ,ψ) by $y = T(\varphi,\psi)$.

Let

$$W = W^{2,p}(\Omega) \cap W_0^{1,p}(\Omega)$$

and

$$U_{ad} = \{(\varphi,\psi) \in W \times W | \varphi \le \psi \quad \text{a.e. } \Omega\}.$$

We seek a pair of $(\bar\varphi,\bar\psi) \in U_{ad}$ so that the corresponding state $\bar y = T(\bar\varphi,\bar\psi)$ is close to the desired target profile z_d and the norm of $(\bar\varphi,\bar\psi)$ is not too large in $W \times W$. Consequently, we take our objective functional as

$$J(\varphi,\psi) = \int_\Omega \left\{ \frac{1}{2}(T(\varphi,\psi)-z_d)^2 + \frac{1}{p}[|\Delta\varphi|^p + |\Delta\psi|^p] \right\} dx, \tag{1.4}$$

which we try to minimize. More precisely, in this paper we study the following optimal control problem.

Problem (P). Find a pair of control $(\bar\varphi,\bar\psi) \in U_{ad}$ such that

$$J(\bar\varphi,\bar\psi) = \inf_{U_{ad}} J(\varphi,\psi). \tag{1.5}$$

One may also consider the case in which state constraints are presented. We will treat the problem with state constraints in a separate paper.

Related to Problem (P), we make the following two assumptions on $A(x,\eta)$ in (1.3):

(H_1) For any $\eta=(\eta_1,\dots,\eta_n)\in\mathcal{R}^n$, $a_j(\cdot,\eta)$ is a measurable function on Ω with $a_j(\cdot,0)=0$ and for any $x\in\Omega$, $a_j(x,\cdot)$ belongs to $C^1(\mathcal{R}^n)$, $j=1,\dots,n$.

(H_2) For any $p\geq 2$, $x\in\Omega$, and all $\xi,\eta\in\mathcal{R}^n$

$$\sum_{i,j=1}^{n}\frac{\partial a_j}{\partial\eta_i}(x,\eta)\xi_i\xi_j\geq\Lambda_1(k+|\eta|)^{p-2}|\xi|^2,$$

$$\sum_{i,j=1}^{n}\left|\frac{\partial a_j}{\partial\eta_i}(x,\eta)\right|\leq\Lambda_2|\eta|^{p-2},$$

where $k\in(0,1]$, and Λ_1 and Λ_2 are some positive constants.

The following lemma is an immediate consequence of assumptions (H_1) and (H_2).

LEMMA 1 (cf. [10]). *Under assumptions* (H_1)–(H_2), *there are positive constants* k_1 *and* k_2 *depending only on* n, Λ_1, *and* Λ_2 *such that for any* $x\in\Omega$, $\eta=(\eta_1,\dots,\eta_n)\in\mathcal{R}^n$, *and* $\eta'=(\eta_1',\dots,\eta_n')\in\mathcal{R}^n$

(a)

$$\sum_{j=1}^{n}(a_j(x,\eta)-a_j(x,\eta'))(\eta_j-\eta_j')\geq k_1|\eta-\eta'|^p.$$

(b)

$$\sum_{j=1}^{n}|a_j(x,\eta)|\leq k_2|\eta|^{p-1}.$$

In Problem (P) the cost functional is of Lagrange-type in which the Laplacian of the control (obstacle) appears. Such a term provides certain compactness of the control. As a direct result, the existence of the optimal control is almost routine. Consequently, the following existence theorem for Problem (P) can be obtained by some standard ideas with some suitable variational inequality techniques.

THEOREM 2. *Under assumptions* (H_1) and (H_2), *there exists an optimal solution* $(\bar\varphi,\bar\psi)$ *to Problem* (P).

In this paper, our main purpose is to establish the optimality system for Problem (P). In general, when the penalty on control is stronger (in the current case, the second derivative appears in the cost functional), the proof on the existence of optimal control becomes easier because of the stronger convergence property in the minimizing sequence. However, at the same time, the derivation of necessary conditions will become harder, since the corresponding duality relation has to be established in a bigger space. In addition, when the state equation is a variational inequality, one has to prove the convergence of the approximate adjoint equation, which is difficult since the approximate adjoint equation is defined in a very weak sense, and then some measure term will occur in the limit. As far as the optimality system is concerned, it is incomplete as long as the measure which intervenes in the adjoint equation has not been precisely described. To derive the optimality system for Problem (P), we have adopted the $W^{2,p}$ framework, which, however, causes some further difficulties due to

the lack of weak continuity of the leading differential operator in the approximate optimality systems. We have overcome the encountered difficulties by making full use of the special structure of the approximate optimality systems, including the monotonicity of the leading differential operator.

The rest of the paper is organized as follows. In section 2 some necessary support results are derived by studying an approximate optimal control problem. Then in section 3 the optimality system for Problem (P) is established, in which the support of the measure (mentioned above) has been well described. Finally, some conclusions are given in section 4.

2. An approximate problem and its convergence property. In this section we derive some necessary support results by studying an approximate problem related to Problem (P).

Let $\epsilon > 0$ and $(\varphi, \psi) \in U_{ad}$. We consider the following quasi-linear elliptic equation:

$$\begin{cases} -\mathrm{div} A(x, \nabla y) + \dfrac{1}{\epsilon}[\beta(y-\varphi) + \gamma(y-\psi)] = 0 \quad \text{in } \Omega, \\ y|_{\partial\Omega} = 0, \end{cases} \tag{2.1}$$

where

$$\beta(r) = \begin{cases} 0, & r > 0, \\ -r^2, & -\dfrac{1}{2} \le r \le 0, \\ r + \dfrac{1}{4}, & r < -\dfrac{1}{2}, \end{cases}$$

and

$$\gamma(r) = \begin{cases} 0, & r < 0, \\ r^2, & 0 \le r \le \dfrac{1}{2}, \\ r - \dfrac{1}{4}, & r > \dfrac{1}{2}. \end{cases}$$

As $\beta(\cdot)$ and $\gamma(\cdot)$ are nondecreasing, it is known that the above equation is uniquely solvable and the solution will be denoted by $y^\epsilon = T^\epsilon(\varphi, \psi)$.

The following lemma gives the Gâteaux-derivative of the operator T^ϵ.

LEMMA 3. *Let $(\xi, \zeta) \in U_{ad}$. Then we have*

$$\frac{T^\epsilon(\varphi + t\xi, \psi + t\zeta) - T^\epsilon(\varphi, \psi)}{t} \xrightarrow{w} w^\epsilon \quad \textit{in } W_0^{1,p}(\Omega) \qquad (t \to 0^+), \tag{2.2}$$

where w^ϵ satisfies

$$\begin{cases} -\mathrm{div}\left(\dfrac{\partial A}{\partial \eta}(x, \nabla y^\epsilon)\nabla w^\epsilon\right) + \dfrac{1}{\epsilon}[\beta'(y^\epsilon - \varphi) + \gamma'(y^\epsilon - \psi)]w^\epsilon \\ \quad = \dfrac{1}{\epsilon}[\beta'(y^\epsilon - \varphi)\xi + \gamma'(y^\epsilon - \psi)\zeta] \quad \textit{in } \Omega, \\ w^\epsilon|_{\partial\Omega} = 0 \end{cases} \tag{2.3}$$

with $y^\epsilon = T^\epsilon(\varphi, \psi)$.

Proof. First note that for any $t > 0$ and (φ, ψ), $(\xi, \zeta) \in U_{ad}$, we always get $(\varphi + t\xi, \psi + t\zeta) \in U_{ad}$.

The rest of the proof of Lemma 3 is similar to that of [10, Theorem 3.1] and is omitted here. □

Let $(\bar{\varphi}, \bar{\psi})$ be an optimal solution to Problem (P) and let $\bar{y} = T(\bar{\varphi}, \bar{\psi})$.

For any $\epsilon > 0$, we define

$$J^\epsilon(\varphi, \psi) = \int_\Omega \left\{ \frac{1}{2}(T^\epsilon(\varphi, \psi) - z_d)^2 + \frac{1}{p}[|\Delta\varphi|^p + |\Delta\psi|^p + |\varphi - \bar{\varphi}|^p + |\psi - \bar{\psi}|^p] \right\} dx$$

and investigate the following approximate optimal control problem.

Problem (P^ϵ). Find a pair of control $(\varphi^\epsilon, \psi^\epsilon) \in U_{ad}$ such that

$$J^\epsilon(\varphi^\epsilon, \psi^\epsilon) = \inf_{U_{ad}} J^\epsilon(\varphi, \psi).$$

Similar to Theorem 2, we can prove the existence for the approximate optimal control problem (P^ϵ).

THEOREM 4. *Problem* (P^ϵ) *has (at least) an optimal solution.*

In the following we derive the optimality system for Problem (P^ϵ).

THEOREM 5. *Assume* $(\varphi^\epsilon, \psi^\epsilon)$ *is an optimal solution to Problem* (P^ϵ) *and* $y^\epsilon = T^\epsilon(\varphi^\epsilon, \psi^\epsilon)$. *Then, there exists* $p^\epsilon \in H_0^1(\Omega)$ *such that the following optimality system is satisfied:*

$$\begin{cases} -\mathrm{div} A(x, \nabla y^\epsilon) + \dfrac{1}{\epsilon}[\beta(y^\epsilon - \varphi^\epsilon) + \gamma(y^\epsilon - \psi^\epsilon)] = 0 \quad \text{in } \Omega, \\ y^\epsilon|_{\partial\Omega} = 0, \end{cases} \tag{2.4}$$

$$\begin{cases} -\mathrm{div}\left(\dfrac{\partial A}{\partial \eta}(x, \nabla y^\epsilon)^T \nabla p^\epsilon\right) + \dfrac{1}{\epsilon}[\beta'(y^\epsilon - \varphi^\epsilon) + \gamma'(y^\epsilon - \psi^\epsilon)]p^\epsilon = y^\epsilon - z_d \quad \text{in } \Omega, \\ p^\epsilon|_{\partial\Omega} = 0, \end{cases} \tag{2.5}$$

and

$$\begin{aligned} &\int_\Omega \left[\frac{1}{\epsilon}\beta'(y^\epsilon - \varphi^\epsilon)p^\epsilon + |\varphi^\epsilon - \bar{\varphi}|^{p-2}(\varphi^\epsilon - \bar{\varphi})\right](\varphi - \varphi^\epsilon)dx \\ &\quad + \int_\Omega \left[\frac{1}{\epsilon}\gamma'(y^\epsilon - \psi^\epsilon)p^\epsilon + |\psi^\epsilon - \bar{\psi}|^{p-2}(\psi^\epsilon - \bar{\psi})\right](\psi - \psi^\epsilon)dx \\ &\quad + \int_\Omega [|\Delta\varphi^\epsilon|^{p-2}\Delta\varphi^\epsilon\Delta(\varphi - \varphi^\epsilon) + |\Delta\psi^\epsilon|^{p-2}\Delta\psi^\epsilon\Delta(\psi - \psi^\epsilon)]dx \\ &\quad \geq 0 \qquad \forall (\varphi, \psi) \in U_{ad}. \end{aligned} \tag{2.6}$$

Proof. As $(\varphi^\epsilon, \psi^\epsilon)$ is a solution to Problem (P^ϵ), we have

$$\forall (\varphi, \psi) \in U_{ad}, \qquad \liminf_{t \to 0^+} \frac{J^\epsilon(\varphi^\epsilon + t(\varphi - \varphi^\epsilon), \psi^\epsilon + t(\psi - \psi^\epsilon)) - J^\epsilon(\varphi^\epsilon, \psi^\epsilon)}{t} \geq 0.$$

This gives

$$\begin{aligned} &\int_\Omega [w^\epsilon(y^\epsilon - z_d) + |\Delta\varphi^\epsilon|^{p-2}\Delta\varphi^\epsilon\Delta(\varphi - \varphi^\epsilon) + |\Delta\psi|^{p-2}\Delta\psi^\epsilon\Delta(\psi - \psi^\epsilon)]dx \\ &\quad + \int_\Omega [|\varphi^\epsilon - \bar{\varphi}|^{p-2}(\varphi^\epsilon - \bar{\varphi})(\varphi - \varphi^\epsilon) + |\psi^\epsilon - \bar{\psi}|^{p-2}(\psi^\epsilon - \bar{\psi})(\psi - \psi^\epsilon)]dx \geq 0, \end{aligned} \tag{2.7}$$

where $w^\epsilon \in H_0^1(\Omega)$ satisfies

$$\begin{cases} -\mathrm{div}\left(\dfrac{\partial A}{\partial \eta}(x, \nabla y^\epsilon)\nabla w^\epsilon\right) + \dfrac{1}{\epsilon}[\beta'(y^\epsilon - \varphi^\epsilon) + \gamma'(y^\epsilon - \psi^\epsilon)]w^\epsilon \\ \quad = \dfrac{1}{\epsilon}[\beta'(y^\epsilon - \varphi^\epsilon)(\varphi - \varphi^\epsilon) + \gamma'(y^\epsilon - \psi^\epsilon)(\psi - \psi^\epsilon)] \quad \text{in } \Omega, \\ w^\epsilon|_{\partial\Omega} = 0. \end{cases}$$

Let p^ϵ be the solution of linear equation (2.5); then we obtain

$$\begin{aligned} &\int_\Omega w^\epsilon(y^\epsilon - z_d)dx \\ &\quad = \int_\Omega \left\{\nabla w^\epsilon \cdot \frac{\partial A}{\partial \eta}(x, \nabla y^\epsilon)^T \nabla p^\epsilon + \frac{1}{\epsilon}[\beta'(y^\epsilon - \varphi^\epsilon) + \gamma'(y^\epsilon - \psi^\epsilon)]p^\epsilon w^\epsilon\right\}dx \\ &\quad = \int_\Omega \frac{1}{\epsilon}[\beta'(y^\epsilon - \varphi^\epsilon)(\varphi - \varphi^\epsilon) + \gamma'(y^\epsilon - \psi^\epsilon)(\psi - \psi^\epsilon)]p^\epsilon dx. \end{aligned}$$

This leads to (2.6). □

Remark 1. Using the so-called monotonicity inequality (cf. [21])

$$(|A|^{p-2}A - |B|^{p-2}B) \cdot (A - B) \geq 0 \qquad (A, B \in \mathcal{R}^n)$$

we can deduce from (2.6) that

$$\begin{aligned} &\int_\Omega \left[\frac{1}{\epsilon}\beta'(y^\epsilon - \varphi^\epsilon)p^\epsilon + |\varphi^\epsilon - \bar\varphi|^{p-2}(\varphi^\epsilon - \bar\varphi)\right](\varphi - \varphi^\epsilon)dx \\ &\quad + \int_\Omega \left[\frac{1}{\epsilon}\gamma'(y^\epsilon - \psi^\epsilon)p^\epsilon + |\psi^\epsilon - \bar\psi|^{p-2}(\psi^\epsilon - \bar\psi)\right](\psi - \psi^\epsilon)dx \\ &\quad + \int_\Omega [|\Delta\varphi|^{p-2}\Delta\varphi\Delta(\varphi - \varphi^\epsilon) + |\Delta\psi|^{p-2}\Delta\psi\Delta(\psi - \psi^\epsilon)]dx \\ &\quad \geq 0 \qquad \forall (\varphi, \psi) \in U_{ad}. \end{aligned} \tag{2.8}$$

Remark 2. Inequality (2.6) implies

$$\begin{aligned} &\int_\Omega \left[\frac{1}{\epsilon}\beta'(y^\epsilon - \varphi^\epsilon)p^\epsilon + |\varphi^\epsilon - \bar\varphi|^{p-2}(\varphi^\epsilon - \bar\varphi)\right]wdx \\ &\quad + \int_\Omega \left[\frac{1}{\epsilon}\gamma'(y^\epsilon - \psi^\epsilon)p^\epsilon + |\psi^\epsilon - \bar\psi|^{p-2}(\psi^\epsilon - \bar\psi)\right]wdx \\ &\quad + \int_\Omega [|\Delta\varphi^\epsilon|^{p-2}\Delta\varphi^\epsilon + |\Delta\psi^\epsilon|^{p-2}\Delta\psi^\epsilon]\Delta wdx = 0 \qquad \forall w \in W. \end{aligned} \tag{2.9}$$

The above two remarks will play an important role in deriving the optimality system for the original Problem (P).

Next we consider the convergence of solution of the approximate problem—Problem (P^ϵ) as ϵ goes to 0^+.

LEMMA 6. *Assume* $y^\epsilon = T^\epsilon(\varphi^\epsilon, \psi^\epsilon)$. *Then*

$$\int_\Omega A(x, \nabla y^\epsilon) \cdot \nabla y^\epsilon dx \leq \int_\Omega A(x, \nabla y^\epsilon) \cdot \nabla z dx \qquad \forall z \in K(\varphi^\epsilon, \psi^\epsilon).$$

Proof. From the approximate equation (2.1), we have

$$\int_\Omega A(x,\nabla y^\epsilon)\cdot\nabla u dx+\frac{1}{\epsilon}\int_\Omega[\beta(y^\epsilon-\varphi^\epsilon)+\gamma(y^\epsilon-\psi^\epsilon)]udx=0 \qquad \forall u\in W_0^{1,p}(\Omega). \tag{2.10}$$

For any $z\in K(\varphi^\epsilon,\psi^\epsilon)$, substituting $u=y^\epsilon-z$ in (2.10), we obtain

$$\int_\Omega A(x,\nabla y^\epsilon)\cdot\nabla(y^\epsilon-z)dx+\frac{1}{\epsilon}\int_\Omega[\beta(y^\epsilon-\varphi^\epsilon)+\gamma(y^\epsilon-\psi^\epsilon)](y^\epsilon-z)dx=0. \tag{2.11}$$

Note that $\beta(y^\epsilon(x)-\varphi^\epsilon(x))$ differs from 0 only when $y^\epsilon(x)<\varphi^\epsilon(x)$, and $\gamma(y^\epsilon(x)-\psi^\epsilon(x))$ differs from 0 only when $y^\epsilon(x)>\psi^\epsilon(x)$. In any case we have, for any $z\in K(\varphi^\epsilon,\psi^\epsilon)$,

$$[\beta(y^\epsilon-\varphi^\epsilon)+\gamma(y^\epsilon-\psi^\epsilon)](y^\epsilon-z)\geq 0 \quad \text{a.e. in } \Omega.$$

Thus, we get

$$\int_\Omega A(x,\nabla y^\epsilon)\cdot\nabla(y^\epsilon-z)dx\leq 0 \qquad \forall z\in K(\varphi^\epsilon,\psi^\epsilon). \qquad \square$$

THEOREM 7. *Let $(\bar\varphi,\bar\psi)$ be an optimal solution to Problem* (P) *and $(\varphi^\epsilon,\psi^\epsilon)$ any optimal solution to Problem* (P^ϵ) *for any $\epsilon>0$. Then for $p>n$,*

$$\begin{aligned}
(\varphi^\epsilon,\psi^\epsilon)&\xrightarrow{w}(\bar\varphi,\bar\psi) && \text{in } W^{2,p}(\Omega)\times W^{2,p}(\Omega),\\
(\varphi^\epsilon,\psi^\epsilon)&\xrightarrow{s}(\bar\varphi,\bar\psi) && \text{in } W_0^{1,p}(\Omega)\times W_0^{1,p}(\Omega),\\
y^\epsilon=T^\epsilon(\varphi^\epsilon,\psi^\epsilon)&\xrightarrow{s}y=T(\bar\varphi,\bar\psi) && \text{in } W_0^{1,p}(\Omega),
\end{aligned} \tag{2.12}$$

and

$$\lim_{\epsilon\to 0^+}J^\epsilon(\varphi^\epsilon,\psi^\epsilon)=J(\bar\varphi,\bar\psi). \tag{2.13}$$

Proof. First, we note that

$$\frac{1}{p}\int_\Omega(|\Delta\varphi^\epsilon|^p+|\Delta\psi^\epsilon|^p)dx\leq J^\epsilon(\varphi^\epsilon,\psi^\epsilon)\leq J^\epsilon(0,0)=\frac{1}{2}\int_\Omega|z_d|^2dx+\frac{1}{p}\int_\Omega(|\bar\varphi|^p+|\bar\psi|^p)dx.$$

Thus $(\Delta\varphi^\epsilon,\Delta\psi^\epsilon)$ is bounded in $W^{2,p}(\Omega)\times W^{2,p}(\Omega)$. We may assume, extracting some subsequence if necessary,

$$\begin{aligned}
(\varphi^\epsilon,\psi^\epsilon)&\xrightarrow{w}(\varphi,\psi) \quad \text{in } W^{2,p}(\Omega)\times W^{2,p}(\Omega),\\
(\varphi^\epsilon,\psi^\epsilon)&\xrightarrow{s}(\varphi,\psi) \quad \text{in } W_0^{1,p}(\Omega)\times W_0^{1,p}(\Omega).
\end{aligned}$$

Applying Lemmas 1 and 6 and Hölder's inequality we get

$$\begin{aligned}
k_1\int_\Omega|\nabla y^\epsilon|^p dx&\leq\int_\Omega A(x,\nabla y^\epsilon)\cdot\nabla y^\epsilon dx\\
&\leq\int_\Omega A(x,\nabla y^\epsilon)\cdot\nabla\varphi^\epsilon dx\\
&\leq k_2\|\nabla y^\epsilon\|_p^{p-1}\|\nabla\varphi^\epsilon\|_p.
\end{aligned}$$

This implies that y^ϵ is bounded in $W_0^{1,p}(\Omega)$. Hence, for some subsequence, we have

$$y^\epsilon \xrightarrow{w} y \quad \text{in } W_0^{1,p}(\Omega),$$
$$y^\epsilon \xrightarrow{s} y \quad \text{in } L^p(\Omega).$$

Moreover, from Lemma 1(b), we can deduce that

$$\|A(x, \nabla y^\epsilon)\|_{p'} \le C. \tag{2.14}$$

For any $\eta \in W_0^{1,p}(\Omega)$, it follows from (2.10) that

$$\int_\Omega [\beta(y^\epsilon - \varphi^\epsilon) + \gamma(y^\epsilon - \psi^\epsilon)]\eta dx = -\epsilon \int_\Omega A(x, \nabla y^\epsilon) \cdot \nabla \eta dx \to 0$$

because the integral on the right-hand side is bounded. Then, by Lebesgue's dominated convergence theorem, we have

$$\int_\Omega [\beta(y - \varphi) + \gamma(y - \psi)]\eta dx = 0.$$

This implies that

$$\beta(y - \varphi) + \gamma(y - \psi) = 0 \quad \text{a.e. in } \Omega$$

due to the arbitrariness of η. By the definition of $\beta(\cdot)$ and $\gamma(\cdot)$, we have

$$\varphi(x) \le y(x) \le \psi(x) \quad \text{a.e. in } \Omega,$$

i.e., $y \in K(\varphi, \psi)$.

We further claim that y^ϵ strongly converges to y in $W_0^{1,p}(\Omega)$. In fact, let $v^\epsilon = \inf(\sup(y, \varphi^\epsilon), \psi^\epsilon)$; then $v^\epsilon \in K(\varphi^\epsilon, \psi^\epsilon)$ and v^ϵ strongly converges to y in $W_0^{1,p}(\Omega)$. By Lemma 6, we have

$$\int_\Omega A(x, \nabla y^\epsilon) \cdot \nabla y^\epsilon dx \le \int_\Omega A(x, \nabla y^\epsilon) \cdot \nabla v^\epsilon dx. \tag{2.15}$$

From Lemma 1, (2.14), and (2.15), we can further deduce that

$$\begin{aligned} 0 &\le k_1 \int_\Omega |\nabla(y^\epsilon - y)|^p dx \\ &\le \int_\Omega (A(x, \nabla y^\epsilon) - A(x, \nabla y)) \cdot (\nabla y^\epsilon - \nabla y) dx \\ &\le \int_\Omega A(x, \nabla y^\epsilon) \cdot (\nabla v^\epsilon - \nabla y) dx - \int_\Omega A(x, \nabla y) \cdot (\nabla y^\epsilon - \nabla y) dx \to 0. \end{aligned}$$

Therefore,

$$\nabla y^\epsilon \xrightarrow{s} \nabla y \quad \text{in } L^p(\Omega) \tag{2.16}$$

and by (H_1)

$$A(x, \nabla y^\epsilon) \to A(x, \nabla y) \quad \text{a.e. in } \Omega. \tag{2.17}$$

By (2.14) and (2.17), we conclude that

$$A(x,\nabla y^\epsilon) \overset{w}{\rightharpoonup} A(x,\nabla y) \quad \text{in } L^{p'}(\Omega). \tag{2.18}$$

It remains to prove $y = T(\varphi,\psi)$. For every $z \in K(\varphi,\psi)$, let $z^\epsilon = \inf(\sup(z,\varphi^\epsilon),\psi^\epsilon)$; then $z^\epsilon \in K(\varphi^\epsilon,\psi^\epsilon)$ and z^ϵ strongly converges to z in $W_0^{1,p}(\Omega)$. Again by Lemma 6, we have

$$\int_\Omega A(x,\nabla y^\epsilon)\cdot\nabla y^\epsilon dx \le \int_\Omega A(x,\nabla y^\epsilon)\cdot\nabla z^\epsilon dx. \tag{2.19}$$

Then, with (2.16) and (2.18), we may pass to the limit in (2.19) and get

$$\int_\Omega A(x,\nabla y)\cdot\nabla y dx \le \int_\Omega A(x,\nabla y)\cdot\nabla z dx. \tag{2.20}$$

This gives $\int_\Omega A(x,\nabla y)\cdot\nabla(z-y)dx \ge 0$ for every $z \in K(\varphi,\psi)$ and, therefore, $y = T(\varphi,\psi)$.

As U_{ad} is closed, then $(\varphi,\psi) \in U_{ad}$. Using the weak lower semicontinuity of the L^p-norm, we obtain

$$\begin{aligned} J(\varphi,\psi) + \frac{1}{p}[\|\varphi-\bar\varphi\|_p^p + \|\psi-\bar\psi\|_p^p] &\le \liminf_{\epsilon\to 0^+} J^\epsilon(\varphi^\epsilon,\psi^\epsilon) \\ &\le \limsup_{\epsilon\to 0^+} J^\epsilon(\varphi^\epsilon,\psi^\epsilon) \\ &\le \lim_{\epsilon\to 0^+} J^\epsilon(\bar\varphi,\bar\psi) = J(\bar\varphi,\bar\psi) \\ &\le J(\varphi,\psi). \end{aligned} \tag{2.21}$$

This yields $\|\varphi-\bar\varphi\|_p^p + \|\psi-\bar\psi\|_p^p \le 0$; so $\varphi = \bar\varphi$, $\psi = \bar\psi$, and hence $y = \bar y = T(\bar\varphi,\bar\psi)$. In addition, we see that

$$\lim_{\epsilon\to 0^+} J^\epsilon(\varphi^\epsilon,\psi^\epsilon) = J(\bar\varphi,\bar\psi). \tag{2.22}$$

Finally, the uniqueness of the limit point implies the convergence of the whole sequence of $(\varphi^\epsilon,\psi^\epsilon)$ and the whole sequence of y^ϵ as well. □

3. Optimality system for Problem (P). Now, we are in a position to establish the optimality system for the original Problem (P).

THEOREM 8. *Assume* (H_1) *and* (H_2). *Let* $(\bar y,\bar\varphi,\bar\psi)$ *be an optimal triple to Problem* (P). *Then there exist* $\bar p \in H_0^1(\Omega)$ *and* $\bar\mu \in H^{-1}(\Omega)\cap\mathcal{M}(\bar\Omega)$ *satisfying*

$$\begin{cases} -\operatorname{div}\left(\dfrac{\partial A}{\partial\eta}(x,\nabla\bar y)^T\nabla\bar p\right) + \bar\mu = \bar y - z_d & \text{in } \Omega, \\ \bar p|_{\partial\Omega} = 0, \end{cases} \tag{3.1}$$

and

$$\operatorname{supp}\bar\mu \subset \{x\in\Omega|\quad \bar y(x) = \bar\varphi(x) \quad \text{or} \quad \bar y(x) = \bar\psi(x)\} \qquad \left(\text{as } p > \frac{n}{2}\right) \tag{3.2}$$

such that

$$\Delta(|\Delta\bar\varphi|^{p-2}\Delta\bar\varphi + |\Delta\bar\psi|^{p-2}\Delta\bar\psi) + \bar\mu = 0 \qquad \text{in } \Omega, \tag{3.3}$$

where $\mathcal{M}(\bar{\Omega})$ is the set of all regular signed measures on $\bar{\Omega}$.

Proof. First consider the approximate problems (P^ϵ) related to $(\bar{y}, \bar{\varphi}, \bar{\psi})$. Let $(y^\epsilon, \varphi^\epsilon, \psi^\epsilon)$ be any optimal triple to Problem (P^ϵ). Then, by Theorem 5, the optimality condition (2.6) followed by (2.8) and (2.9) holds for some $p^\epsilon \in H_0^1(\Omega)$ satisfying (2.5) or equivalently that, for any $u \in H_0^1(\Omega)$,

(3.4)
$$\int_\Omega \nabla u^T \frac{\partial A}{\partial \eta}(x, \nabla y^\epsilon)^T \nabla p^\epsilon dx + \int_\Omega \frac{1}{\epsilon}[\beta'(y^\epsilon - \varphi^\epsilon) + \gamma'(y^\epsilon - \psi^\epsilon)]p^\epsilon u dx = \int_\Omega (y^\epsilon - z_d) u dx.$$

We put $u = p^\epsilon$ in (3.4) to obtain

(3.5)
$$\int_\Omega (\nabla p^\epsilon)^T \frac{\partial A}{\partial \eta} \nabla p^\epsilon dx + \int_\Omega \frac{1}{\epsilon}[\beta'(y^\epsilon - \varphi^\epsilon) + \gamma'(y^\epsilon - \psi^\epsilon)](p^\epsilon)^2 dx = \int_\Omega (y^\epsilon - z_d) p^\epsilon dx.$$

By (H_2), we get

$$\Lambda_1 \int_\Omega (k + |\nabla y^\epsilon|)^{p-2} |\nabla p^\epsilon|^2 dx + \int_\Omega \frac{1}{\epsilon}[\beta'(y^\epsilon - \varphi^\epsilon) + \gamma'(y^\epsilon - \psi^\epsilon)](p^\epsilon)^2 dx \le C\|p^\epsilon\|_2.$$

Then

$$\|p^\epsilon\|_{H_0^1(\Omega)} \le C,$$

where C is independent of ϵ. This implies that, for some subsequence,

$$p^\epsilon \overset{w}{\rightharpoonup} \bar{p} \quad \text{in } H_0^1(\Omega). \tag{3.6}$$

Denote

$$\mu_\varphi^\epsilon = \frac{1}{\epsilon}\beta'(y^\epsilon - \varphi^\epsilon)p^\epsilon, \quad \mu_\psi^\epsilon = \frac{1}{\epsilon}\gamma'(y^\epsilon - \psi^\epsilon)p^\epsilon; \quad \mu^\epsilon = \mu_\varphi^\epsilon + \mu_\psi^\epsilon.$$

From (3.4) we get

$$\begin{aligned} \left|\int_\Omega \mu^\epsilon u dx\right| &\le \left|\int_\Omega (y^\epsilon - z_d) u dx\right| + \left|\int_\Omega \nabla u^T \left(\frac{\partial A}{\partial \eta}\right)^T \nabla p^\epsilon dx\right| \\ &\le C\|u\|_{H_0^1(\Omega)} \qquad \forall u \in H_0^1(\Omega), \end{aligned} \tag{3.7}$$

i.e.,

$$\|\mu^\epsilon\|_{H^{-1}(\Omega)} \le C,$$

where C is independent of ϵ.

Furthermore, let $S_\tau(r) \in C^1(\mathcal{R})(\tau > 0)$ be a family of smooth approximations to *sign* r, satisfying the following:

$$S_\tau'(r) \ge 0 \qquad \forall r \in \mathcal{R}$$

and

$$S_\tau(r) = \begin{cases} 1 & \text{if } r > \tau, \\ 0 & \text{if } r = 0, \\ -1 & \text{if } r < -\tau. \end{cases}$$

Putting $u = S_\tau(p^\epsilon)$ in (3.4), we get

$$\int_\Omega S'_\tau(p^\epsilon)(\nabla p^\epsilon)^T \frac{\partial A}{\partial \eta} \nabla p^\epsilon dx + \int_\Omega \mu^\epsilon S_\tau(p^\epsilon) dx = \int_\Omega (y^\epsilon - z_d) S_\tau(p^\epsilon) dx.$$

This gives

$$\int_\Omega \mu^\epsilon S_\tau(p^\epsilon) dx \le C.$$

Letting $\tau \to 0^+$, we have

$$\|\mu^\epsilon\|_{L^1(\Omega)} \, (= \|\mu^\epsilon_\varphi\|_{L^1(\Omega)} + \|\mu^\epsilon_\psi\|_{L^1(\Omega)}) \le C.$$

Thus, extracting some subsequence if necessary, we may let

$$\begin{aligned} \mu^\epsilon_\varphi &\overset{w}{\rightharpoonup} \bar{\mu}_\varphi \quad \text{in } \mathcal{M}(\bar{\Omega}), \\ \mu^\epsilon_\psi &\overset{w}{\rightharpoonup} \bar{\mu}_\psi \quad \text{in } \mathcal{M}(\bar{\Omega}), \\ \mu^\epsilon &\overset{w}{\rightharpoonup} \bar{\mu} \quad \text{in } H^{-1}(\Omega) \cap \mathcal{M}(\bar{\Omega}), \end{aligned} \tag{3.8}$$

with $\bar{\mu} = \bar{\mu}_\varphi + \bar{\mu}_\psi$.

Passing to the limit in (2.8), we get

$$\begin{aligned} &\langle \bar{\mu}_\varphi, \varphi - \bar{\varphi} \rangle + \langle \bar{\mu}_\psi, \psi - \bar{\psi} \rangle \\ &\quad + \int_\Omega [|\Delta\varphi|^{p-2}\Delta\varphi\Delta(\varphi - \bar{\varphi}) + |\Delta\psi|^{p-2}\Delta\psi\Delta(\psi - \bar{\psi})] dx \\ &\quad \ge 0 \qquad \forall (\varphi, \psi) \in U_{ad} \end{aligned} \tag{3.9}$$

and consequently

$$\begin{aligned} &\langle \bar{\mu}, w \rangle + \int_\Omega [|\Delta(\bar{\varphi} + w)|^{p-2}\Delta(\bar{\varphi} + w) + |\Delta(\bar{\psi} + w)|^{p-2}\Delta(\bar{\psi} + w)]\Delta w dx \\ &\quad \ge 0 \qquad \forall w \in W. \end{aligned} \tag{3.10}$$

Noting that

$$\||\Delta\varphi^\epsilon|^{p-2}\Delta\varphi^\epsilon + |\Delta\psi^\epsilon|^{p-2}\Delta\psi^\epsilon\|_{p'} \le \|\Delta\varphi^\epsilon\|_p^{p-1} + \|\Delta\psi^\epsilon\|_p^{p-1} \le C$$

we may assume that, for some subsequence,

$$|\Delta\varphi^\epsilon|^{p-2}\Delta\varphi^\epsilon + |\Delta\psi^\epsilon|^{p-2}\Delta\psi^\epsilon \overset{w}{\rightharpoonup} F \quad \text{in } L^{p'}(\Omega).$$

Taking the limit in (2.9), we obtain

$$\langle \bar{\mu}, w \rangle + \int_\Omega F \Delta w dx = 0 \qquad \forall w \in W. \tag{3.11}$$

To prove (3.3), we need only to clarify that

$$F = |\Delta\bar{\varphi}|^{p-2}\Delta\bar{\varphi} + |\Delta\bar{\psi}|^{p-2}\Delta\bar{\psi}. \tag{3.12}$$

Combining (3.10) and (3.11), we have

$$\int_\Omega F\Delta w dx \le \int_\Omega [|\Delta(\bar{\varphi} + w)|^{p-2}\Delta(\bar{\varphi} + w) + |\Delta(\bar{\psi} + w)|^{p-2}\Delta(\bar{\psi} + w)]\Delta w dx \quad \forall w \in W. \tag{3.13}$$

For any given $\chi \in W$, choosing $w = \delta\chi$ ($\delta > 0$) in (3.13), then dividing it by δ and sending $\delta \to 0^+$, we get

$$\int_\Omega F\Delta\chi dx \le \int_\Omega [|\Delta\bar{\varphi}|^{p-2}\Delta\bar{\varphi} + |\Delta\bar{\psi}|^{p-2}\Delta\bar{\psi}]\Delta\chi dx. \tag{3.14}$$

On the other hand, choosing $w = \delta\chi$ ($\delta < 0$) in (3.13), then dividing it by δ and sending $\delta \to 0^-$, we get

$$\int_\Omega F\Delta\chi dx \ge \int_\Omega [|\Delta\bar{\varphi}|^{p-2}\Delta\bar{\varphi} + |\Delta\bar{\psi}|^{p-2}\Delta\bar{\psi}]\Delta\chi dx. \tag{3.15}$$

Thus, (3.12) follows.

To verify that $\bar{p}$ satisfies (3.1), it suffices to show that for any $u \in H_0^1(\Omega)$

$$\int_\Omega \nabla u^T \frac{\partial A}{\partial \eta}(x, \nabla y^\epsilon)^T \nabla p^\epsilon dx \to \int_\Omega \nabla u^T \frac{\partial A}{\partial \eta}(x, \nabla \bar{y})^T \nabla \bar{p} dx \quad (\epsilon \to 0^+). \tag{3.16}$$

Obviously,

$$\begin{aligned} &\int_\Omega \nabla u^T \left(\frac{\partial A}{\partial \eta}(x, \nabla y^\epsilon)^T \nabla p^\epsilon - \frac{\partial A}{\partial \eta}(x, \nabla \bar{y})^T \nabla \bar{p} \right) dx \\ &= \int_\Omega \nabla u^T \left(\frac{\partial A}{\partial \eta}(x, \nabla y^\epsilon)^T - \frac{\partial A}{\partial \eta}(x, \nabla \bar{y})^T \right) \nabla p^\epsilon dx \\ &\quad + \int_\Omega \nabla u^T \frac{\partial A}{\partial \eta}(x, \nabla \bar{y})^T (\nabla p^\epsilon - \nabla \bar{p}) dx. \end{aligned} \tag{3.17}$$

From (3.6), we get

$$\int_\Omega \nabla u^T \frac{\partial A}{\partial \eta}(x, \nabla \bar{y})^T (\nabla p^\epsilon - \nabla \bar{p}) dx \to 0 \qquad (\epsilon \to 0^+). \tag{3.18}$$

By (H_2), we know that $\sum_{i,j=1}^n \frac{\partial a_j}{\partial \eta_i}(x, \eta)$ is bounded. Then by Lebesgue's dominated convergence theorem

$$\int_\Omega \left| \nabla u^T \left(\frac{\partial A}{\partial \eta}(x, \nabla y^\epsilon)^T - \frac{\partial A}{\partial \eta}(x, \nabla \bar{y})^T \right) \right|^2 dx \to 0 \qquad (\epsilon \to 0^+). \tag{3.19}$$

Thus, using Hölder's inequality, we have

$$\begin{aligned} &\left| \int_\Omega \nabla u^T \left(\frac{\partial A}{\partial \eta}(x, \nabla y^\epsilon)^T - \frac{\partial A}{\partial \eta}(x, \nabla \bar{y})^T \right) \nabla p^\epsilon dx \right| \\ &\le \left(\int_\Omega \left| \nabla u^T \left(\frac{\partial A}{\partial \eta}(x, \nabla y^\epsilon)^T - \frac{\partial A}{\partial \eta}(x, \nabla \bar{y})^T \right) \right|^2 dx \right)^{1/2} \left(\int_\Omega |\nabla p^\epsilon|^2 dx \right)^{1/2} \\ &\to 0 \quad (\epsilon \to 0^+). \end{aligned} \tag{3.20}$$

Hence, in view of (3.17), (3.18), and (3.20), (3.16) holds.

Finally, we prove (3.2), which is understood as the following: for any $\chi \in C(\bar{\Omega})$ with $\operatorname{supp}\chi \subset \Omega' = \{x \in \Omega |\ \bar{\varphi}(x) < \bar{y}(x) < \bar{\psi}(x)\}$,

$$\langle \bar{\mu}, \chi \rangle_{\mathcal{M}(\bar{\Omega}), C(\bar{\Omega})} = 0. \tag{3.21}$$

In fact, for $p > \frac{n}{2}$, the $W^{2,p}$-bounded subset is relatively compact in $C^{\alpha}(\bar{\Omega})$ for some $\alpha \in (0,1)$. Then, for any $\chi \in C(\bar{\Omega})$ with supp $\chi \subset \Omega'$, the uniform convergence of the approximate optimal triple of control and state (cf. Theorem 7), combined with the compactness of supp χ, ensures that, for some $\epsilon_0 > 0$,

$$\varphi^{\epsilon}(x) < y^{\epsilon}(x) < \psi^{\epsilon}(x) \qquad \forall x \in \operatorname{supp} \chi, \qquad 0 < \epsilon < \epsilon_0,$$

which yields

$$\begin{aligned} \langle \bar{\mu}, \chi \rangle_{\mathcal{M}(\bar{\Omega}), C(\bar{\Omega})} &= \lim_{\epsilon \to 0^+} \int_{\Omega} \frac{1}{\epsilon} [\beta'(y^{\epsilon} - \varphi^{\epsilon}) + \gamma'(y^{\epsilon} - \psi^{\epsilon})] p^{\epsilon} \chi dx \\ &= \lim_{\epsilon \to 0^+} \int_{\operatorname{supp}\ \chi} \frac{1}{\epsilon} [\beta'(y^{\epsilon} - \varphi^{\epsilon}) + \gamma'(y^{\epsilon} - \psi^{\epsilon})] p^{\epsilon} \chi dx \\ &= 0. \end{aligned}$$

Thus, (3.2) holds.

Similarly, we can further prove that

$$\operatorname{supp}\ \bar{\mu}_{\varphi} \subset \{x \in \Omega | \quad \bar{y}(x) = \bar{\varphi}(x)\}$$

and

$$\operatorname{supp}\ \bar{\mu}_{\psi} \subset \{x \in \Omega | \quad \bar{y}(x) = \bar{\psi}(x)\}.$$

The proof is complete. □

4. Conclusions. In this paper we have studied the obstacle optimal control problem—Problem (P). The main contribution of the present work is Theorem 8, in which the optimality system for Problem (P) is obtained.

The present paper basically treated the problem without state constraints. One may consider the case in which state constraints are presented. However, different techniques are needed for solving the problem with different state constraints. Hence, the obstacle optimal control problem with state constraints are worthy of further investigation.

Acknowledgment. The authors are grateful to the anonymous referees for their invaluable comments and suggestions.

STATE AND MODE ESTIMATION FOR DISCRETE-TIME JUMP MARKOV SYSTEMS*

ROBERT J. ELLIOTT†, FRANCOIS DUFOUR‡, AND W. P. MALCOLM§

Abstract. In this article we compute new state and mode estimation algorithms for discrete-time Gauss–Markov models whose parameter sets switch according to a known Markov law. An important feature of our algorithms is that they are based upon the exact filter dynamics computed in [R. J. Elliott, F. Dufour, and D. Sworder, *IEEE Trans. Automat. Control*, 41 (1996), pp. 1807–1810].

The fundamental and well-known obstacle in estimation of jump Markov systems is managing the geometrically growing history of candidate hypotheses. In our scheme, we address this issue by proposing an extension of an idea due to Viterbi. Our scheme maintains a fixed number of candidate paths in a history, each identified by an optimal subset of estimated mode probabilities.

We compute finite-dimensional suboptimal filters and smoothers, which estimate the hidden state process and the mode probability. Our smoothers are based upon a duality between forward and backward dynamics. Further, our smoothing algorithms are general and can be configured into the standard forms of fixed point, fixed lag, and fixed interval smoothers. A computer simulation is included to demonstrate performance.

Key words. reference probability, jump Markov systems, hybrid dynamics, Viterbi algorithm, filtering, smoothing

1. Introduction.

In this article the reference probability method is used to compute state and mode estimation schemes for a discrete-time stochastic hybrid dynamical system.

Gauss–Markov jump linear systems arise quite naturally in many practical settings, for example, tracking a maneuvering object observed through radar. Here, no single set of dynamics will encapsulate all classes of motion, so one is led naturally to a hybrid collection of dynamics as a basic model. The estimation task for such models is significantly complicated by the need to jointly estimate a hidden state variable and the current model in effect. Currently, many of the standard techniques to solve this problem are ad hoc and not based upon the exact hybrid filter dynamics, which were presented in [5]. In contrast to this situation, our new filters and smoothers for Gauss–Markov jump linear systems are developed from the exact hybrid dynamics. Using a general result (see Lemma 2 in section 3), we propose a new suboptimal algorithm which provides an exact hypothesis management scheme, circumventing geometric growth in algorithmic complexity. Our approach is based, in part, upon approximating probability densities by finite Gaussian mixtures and is justified by the basic results given in [15].

In a simulation study, a comparison is given between the single extended Kalman filter (EKF), the IMM, and our algorithm. We also compute a general smoothing

algorithm for discrete-time hybrid dynamical system. To compute this algorithm, we exploit a duality between forward and backward (dual) dynamics. An interesting feature of our smoother is that it provides a new degree of freedom, that is, the product decomposition of the smoother density is approximated by mutually independent Gaussian mixtures, where the chosen accuracy of "the past" (influencing the smoother density) is independent of the chosen accuracy of "the future" (influencing the smoother density).

This paper is organized as follows. In section 2 we define the hybrid system dynamics and the reference probability measure. In section 3, we compute an exact filter for a hybrid dynamical system. Here, we suppose that our filter probability densities can be represented as finite Gaussian mixtures. This leads to a suboptimal filter whose memory requirements are fixed in time. Identities are given for the filter conditional mean estimate of the state and the filter conditional mean estimate of the corresponding state error covariance. In section 4 we compute an exact smoother for a hybrid system. In this section, we again suppose that certain functions can be represented as Gaussian mixtures. By using the same techniques as in section 3, we compute a suboptimal smoothing algorithm whose memory requirements are fixed in time. Identities are given for the smoother conditional mean estimate of the state and the smoother conditional mean estimate of the corresponding state error covariance. Finally, in section 5, we present a simulation study comparing the IMM and the extended Kalman filter to the new filter presented in section 3.

2. Dynamics and reference probability. Initially we suppose that all processes are defined on a fixed probability space $(\Omega, \mathcal{F}, P)$. For the class of jump Markov systems considered, we will require three sets of dynamics. These are the Markov chain dynamics for the process whose value determines the model parameters, the indirectly observed state process, and the observation process.

2.1. Markov chain dynamics. To model parameter switching we consider a time homogeneous discrete-time discrete-state Markov chain Z. If the cardinality of the state space is m, it is convenient, without loss of generality, to identify the state space of Z with an orthonormal basis indicator functions, which we denote by $\mathcal{L}$, that is,

$$\mathcal{L} = \{\mathbf{e}_1, \mathbf{e}_2, \ldots, \mathbf{e}_m\} = \left\{ \begin{bmatrix} 1 \\ 0 \\ \vdots \\ 0 \end{bmatrix}, \begin{bmatrix} 0 \\ 1 \\ \vdots \\ 0 \end{bmatrix}, \ldots, \begin{bmatrix} 0 \\ 0 \\ \vdots \\ 1 \end{bmatrix} \right\} \subseteq \mathbb{R}^m. \tag{2.1}$$

The dynamics for the process Z may be written as

$$Z_k = \Pi Z_{k-1} + L_k \in \mathbb{R}^m. \tag{2.2}$$

Here, $\Pi = [\pi_{(j,i)}]_{\substack{1 \le j \le m \\ 1 \le i \le m}}$ is the transition matrix of Z, with elements

$$\pi_{(j,i)} \triangleq P(Z_k = \boldsymbol{e}_j \mid Z_{k-1} = \boldsymbol{e}_i) \tag{2.3}$$

for all $k \in \mathbb{N}$. The process L is a $(P, \sigma\{Z\})$-martingale increment, and we suppose $E[Z_0] = p_0$.

2.2. State process dynamics. We suppose that the indirectly observed state vector $x \in \mathbb{R}^n$ has dynamics

$$x_k = \sum_{j=1}^{m} \langle Z_k, \boldsymbol{e}_j \rangle A_j x_{k-1} + \sum_{j=1}^{m} \langle Z_k, \boldsymbol{e}_j \rangle B_j w_k. \tag{2.4}$$

Here w is a vector-valued Gaussian process with $w \sim N(0, \boldsymbol{I}_n)$. A_j and B_j are $n \times n$ matrices and, for each $j \in \{1, 2, \ldots, m\}$, are nonsingular. This condition can be relaxed [9].

2.3. Observation process dynamics. Consider a vector-valued observation process with values in $\mathbb{R}^d$ and dynamics

$$y_k = \sum_{j=1}^{m} \langle Z_k, \boldsymbol{e}_j \rangle C_j x_k + \sum_{j=1}^{m} \langle Z_k, \boldsymbol{e}_j \rangle D_j v_k. \tag{2.5}$$

Here v is a vector-valued Gaussian process with $v \sim N(0, \boldsymbol{I}_d)$. We suppose the matrices $D_j \in \mathbb{R}^{d \times d}$, for each $j \in \{1, 2, \ldots, m\}$, are nonsingular. The systems we shall consider in this article are described by the dynamics (2.2), (2.4), and (2.5). The three stochastic processes Z, x, and y are mutually statistically independent. Taken together, these dynamics form a triply stochastic system, with random inputs due to the processes Z, x, and y. For example, if the Markov chain Z is in the state $\boldsymbol{e}_j$, then the dynamical model with state x and observation y is defined by the parameters set $\{A_j, B_j, C_j, D_j\}$.

Remark 1. At the cost of more complicated notation, we could consider observations of the form

$$y_k = \sum_{j=1}^{m} \langle Z_k, \boldsymbol{e}_j \rangle \big(C_j x_k + H_j\big) + \sum_{j=1}^{m} \langle Z_k, \boldsymbol{e}_j \rangle D_j v_k. \tag{2.6}$$

This formulation includes scenarios where the Markov chain Z is observed directly. However, in this article we restrict our attention to cases where $H_j = 0$ for all $j \in \{1, 2, \ldots, m\}$. We define our filtrations as follows:

$$\mathbb{F}_k = \{\mathcal{F}_\ell\}_{0 \le \ell \le k}, \quad \text{where} \quad \mathcal{F}_k = \sigma\{x_\ell, 0 \le \ell \le k\}, \tag{2.7}$$

$$\mathbb{Z}_k = \{\mathcal{Z}_\ell\}_{0 \le \ell \le k}, \quad \text{where} \quad \mathcal{Z}_k = \sigma\{Z_\ell, 0 \le \ell \le k\}, \tag{2.8}$$

$$\mathbb{Y}_k = \{\mathcal{Y}_\ell\}_{0 \le \ell \le k}, \quad \text{where} \quad \mathcal{Y}_k = \sigma\{y_\ell, 0 \le \ell \le k\}, \tag{2.9}$$

$$\mathbb{G}_k = \{\mathcal{G}_\ell\}_{0 \le \ell \le k}, \quad \text{where} \quad \mathcal{G}_k = \sigma\{Z_\ell, x_\ell, y_\ell, 0 \le \ell \le k\}. \tag{2.10}$$

2.4. Reference probability. The dynamics given in (2.2), (2.4), and (2.5) are each defined on a measurable space $(\Omega, \mathcal{F})$ under a measure P. However, consider a new measure $P^\dagger$, under which the dynamics for the processes Z, x, and y are, respectively,

$$P^\dagger \quad \begin{cases} Z_k & = \Pi Z_{k-1} + L_k, \\ x_k & \text{are i.i.d. and } N(0, \boldsymbol{I}_n), \\ y_k & \text{are i.i.d. and } N(0, \boldsymbol{I}_d). \end{cases} \tag{2.11}$$

Notation. The symbol $\Phi(\cdot)$ will be used to denote the zero mean normal density on $\mathbb{R}^d$:

$$\Phi(\xi) = (2\pi)^{-d/2} \exp\bigl(-\tfrac{1}{2}\xi'\xi\bigr). \tag{2.12}$$

Similarly we shall also use the symbol $\Psi(\cdot)$ to denote a standardized Gaussian density. The space dimension on which these densities are defined will be clear by context. To avoid cumbersome notation with matrices, we sometimes denote the inverse of a matrix A by $\mathrm{inv}(A)$. Further, we denote the space of all $m \times n$ matrices by $\mathbb{M}^{m\times n}$. To compute the filter dynamics we now define the measure P by setting the restriction of its Radon–Nikodým derivative to $\mathcal{G}_k$ to

$$\Lambda_{0,k} \triangleq \frac{dP}{dP^\dagger}|_{\mathcal{G}_k} = \prod_{\ell=0}^{k} \lambda_\ell, \tag{2.13}$$

where

$$\lambda_\ell = \sum_{j=1}^{m} \langle Z_\ell, \boldsymbol{e}_j\rangle \frac{\Phi\bigl(D_j^{-1}(y_\ell - C_j x_\ell)\bigr)}{|D_j|\Phi(y_\ell)} \times \frac{\Psi\bigl(B_j^{-1}(x_\ell - A_j x_{\ell-1})\bigr)}{|B_j|\Psi(x_\ell)}.$$

The existence of P follows from the Kolmogorov extension theorem (see [16, Theorem 4, p. 166]). We quote the following form of Bayes' theorem (see [8]).

THEOREM 1. *Suppose $\gamma = \{\gamma_\ell, 0 \le \ell \le k\}$ is an integrable $\mathcal{G}$-adapted process. Then*

$$E[\gamma_k|\mathcal{Y}_k] = \frac{E^\dagger[\Lambda_{0,k}\gamma_k|\mathcal{Y}_k]}{E^\dagger[\Lambda_{0,k}|\mathcal{Y}_k]}. \tag{2.14}$$

As in [9] we can then show the following.

LEMMA 1. *Under the measure P, the dynamics for the Markov process Z are unchanged and x and y have dynamics given by* (2.4) *and* (2.5)*, respectively.*

3. Hybrid filter dynamics.

3.1. Exact filter dynamics. The following lemma is critical in what follows.

LEMMA 2. *Suppose the random vector $\xi \in \mathbb{R}^n$ is normally distributed with $\xi \sim N(\mu, \Sigma)$. Further, suppose A is any matrix in $\mathbb{M}^{m\times n}$, y is a vector in $\mathbb{R}^n$, and the matrix $B \in \mathbb{M}^{m\times m}$ is nonsingular. With $p(\xi)$ denoting the Gaussian density function for ξ, the following identity holds:*

$$\begin{aligned}
&\int_{\mathbb{R}^n} \Psi\bigl(B^{-1}(y - A\xi)\bigr)p(\xi)d\xi \\
&\quad = (2\pi)^{-n/2} E\bigl[\exp\bigl\{-\tfrac{1}{2}(y - A\xi)'\,\mathrm{inv}(BB')(y - A\xi)\bigr\}\bigr] \\
&\quad = (2\pi)^{-n/2}|B||BB' + A\Sigma A'|^{-\frac{1}{2}} \exp\bigl\{-\tfrac{1}{2}(y - A\mu)'(BB' + A\Sigma A')^{-1}(y - A\mu)\bigr\}. \qquad (3.1)
\end{aligned}$$

A proof of Lemma 2 is given in [6]. To compute a filter jointly estimating the density of the state vector x and the state of the chain Z, consider the expectation

$$E[\langle Z_k, \boldsymbol{e}_j\rangle f(x_k)|\mathcal{Y}_k] = \frac{E^\dagger[\Lambda_{0,k}\langle Z_k, \boldsymbol{e}_j\rangle f(x_k)|\mathcal{Y}_k]}{E^\dagger[\Lambda_{0,k}|\mathcal{Y}_k]}. \tag{3.2}$$

Here the function $f(\cdot)$ is an arbitrary bounded measurable real-valued test function. Write the numerator as

$$\sigma(\langle Z_k, \boldsymbol{e}_j\rangle f(x_k)) \triangleq E^\dagger[\Lambda_{0,k}\langle Z_k, \boldsymbol{e}_j\rangle f(x_k)|\mathcal{Y}_k]. \tag{3.3}$$

Suppose we choose the test function $f(x) = 1$. Then

$$\sum_{j=1}^m \sigma(\langle Z_k, \boldsymbol{e}_j\rangle) = \sigma\bigg(\sum_{j=1}^m \langle Z_k, \boldsymbol{e}_j\rangle\bigg) = \sigma(1) = E^\dagger[\Lambda_{0,k}|\mathcal{Y}_k]. \tag{3.4}$$

Therefore, if the numerator (3.3) can be evaluated for any such f and all j, the denominator of (3.2) can be found. For each $j \in \{1, 2, \ldots, m\}$, the quantity $\sigma\big(\langle Z_k, \boldsymbol{e}_j\rangle f(x_k)\big)$, defined at (3.3), is a continuous linear functional on the space of continuous functions and so defines a unique measure (see [14, Theorem 2.14, p. 40]). Further, suppose that there exists a corresponding unique, unnormalized density function $q_k^j(x)$ such that

$$\sigma(\langle Z_k, \boldsymbol{e}_j\rangle f(x_k)) \triangleq \int_{\mathbb{R}^n} f(\eta) q_k^j(\eta) d\eta. \tag{3.5}$$

Then the normalized conditional density is

$$P(x \in dx, Z_k = \boldsymbol{e}_j|\mathcal{Y}_k) = \frac{q_k^j(x)dx}{\int_{\mathbb{R}^n} q_k^j(\xi)d\xi}. \tag{3.6}$$

THEOREM 2. *The unnormalized probability density $q_k^j(x)$ satisfies the following integral-equation recursion:*

$$q_k^j(x) = \frac{\Phi\big(D_j^{-1}(y_k - C_j x)\big)}{\Phi(y_k)|D_j||B_j|} \sum_{r=1}^m \pi_{(j,r)} \int_{\mathbb{R}^n} \Psi\big(B_j^{-1}(x - A_j\xi)\big) q_{k-1}^r(\xi) d\xi. \tag{3.7}$$

Proof. Recalling the definition at (3.5), note that

$$\begin{aligned}
\int_{\mathbb{R}^n} f(\eta) q_k^j(\eta) d\eta &= \sigma\big(\langle Z_k, \boldsymbol{e}_j\rangle f(x_k)\big) \\
&= E^\dagger[\Lambda_{0,k}\langle Z_k, \boldsymbol{e}_j\rangle f(x_k)|\mathcal{Y}_k] \\
&= E^\dagger[\lambda_k \Lambda_{0,k-1}\langle Z_k, \boldsymbol{e}_j\rangle f(x_k)|\mathcal{Y}_k] \\
&= E^\dagger\bigg[\Lambda_{0,k-1}\langle Z_k, \boldsymbol{e}_j\rangle \frac{\Phi\big(D_j^{-1}(y_k - C_j x_k)\big)}{|D_j|\Phi(y_k)} \\
&\quad \times \frac{\Psi\big(B_j^{-1}(x_k - A_j x_{k-1})\big)}{|B_j|\Psi(x_k)} f(x_k)|\mathcal{Y}_k\bigg] \\
&= \frac{1}{\Phi(y_k)|D_j||B_j|} E^\dagger\bigg[\Lambda_{0,k-1}\langle \Pi Z_{k-1} + L_k, \boldsymbol{e}_j\rangle \\
&\quad \times \Phi\big(D_j^{-1}(y_k - C_j x_k)\big) \frac{\Psi\big(B_j^{-1}(x_k - A_j x_{k-1})\big)}{\Psi(x_k)} f(x_k)|\mathcal{Y}_k\bigg] \\
&= \frac{1}{\Phi(y_k)|D_j||B_j|} \sum_{r=1}^m \pi_{(j,r)} E^\dagger\bigg[\Lambda_{k-1}\langle Z_{k-1}, \boldsymbol{e}_r\rangle \\
&\quad \times \Phi\big(D_j^{-1}(y_k - C_j x_k)\big) \frac{\Psi\big(B_j^{-1}(x_k - A_j x_{k-1})\big)}{\Psi(x_k)} f(x_k)|\mathcal{Y}_{k-1}\bigg].
\end{aligned} \tag{3.8}$$

The final equality follows because under $P^\dagger$, the y_k are independent and $N(0, I_d)$. Further, since the expectations here are with respect to the measure $P^\dagger$, under which the random variables Z_k, x_k, y_k, and x_{k-1} are (mutually) independent, the expected value with respect to x_k is obtained by multiplying by the density $\Psi(x_k)$ and integrating; that is, with

$$
\begin{aligned}
H(x_{k-1};\Theta) &\triangleq \int_{\mathbb{R}^n} \left\{ \Phi\big(D_j^{-1}(y_k - C_j\eta)\big) \frac{\Psi\big(B_j^{-1}(\eta - A_j x_{k-1})\big)}{\Psi(\eta)} f(\eta) \right\} \Psi(\eta) d\eta \\
&= \int_{\mathbb{R}^n} \Phi\big(D_j^{-1}(y_k - C_j\eta)\big) \Psi\big(B_j^{-1}(\eta - A_j x_{k-1})\big) f(\eta) d\eta.
\end{aligned} \tag{3.9}
$$

Then

$$
\begin{aligned}
\int_{\mathbb{R}^n} f(\eta) q_k^j(\eta) d\eta &= \frac{1}{\Phi(y_k)|D_j||B_j|} \sum_{r=1}^m \pi_{(j,r)} E^\dagger[\Lambda_{k-1} \langle Z_{k-1}, \boldsymbol{e}_r \rangle H(x_{k-1};\Theta) | \mathcal{Y}_{k-1}] \\
&= \frac{1}{\Phi(y_k)|D_j||B_j|} \sum_{r=1}^m \pi_{(j,r)} \int_{\mathbb{R}^n} H(\xi;\Theta) q_{k-1}^r(\xi) d\xi \\
&= \frac{1}{\Phi(y_k)|D_j||B_j|} \sum_{r=1}^m \pi_{(j,r)} \int_{\mathbb{R}^n} \int_{\mathbb{R}^n} \Phi\big(D_j^{-1}(y_k - C_j\eta)\big) \\
&\quad \times \Psi\big(B_j^{-1}(\eta - A_j\xi)\big) q_{k-1}^r(\xi) f(\eta) d\eta d\xi.
\end{aligned} \tag{3.10}
$$

Finally, as (3.10) holds for any suitable test function f, it follows that

$$
q_k^j(x) = \frac{\Phi\big(D_j^{-1}(y_k - C_j x)\big)}{\Phi(y_k)|D_j||B_j|} \sum_{r=1}^m \pi_{(j,r)} \int_{\mathbb{R}^n} \Psi\big(B_j^{-1}(x - A_j\xi)\big) q_{k-1}^r(\xi) d\xi. \qquad \square \tag{3.11}
$$

The recursion given in (3.11) is an exact filter; it is expressed as a density which is in general infinite-dimensional. However, Gaussian densities are determined by their mean and variance. In what follows we will consider a finite Gaussian mixture representation of $q_{k-1}^r(x)$. The use of Gaussian sums is justified because any density can be approximated by the sum of Gaussian densities (see [15]). Further, the noise in the state and the observation processes is assumed to be Gaussian. In turn, this implies that sums of Gaussian densities are introduced. For example, if the initial state is known exactly, the conditional state at the next time is described by a sum of Gaussian densities, and the number of terms in the sum increases at each time step by a factor equal to the number of states in the chain.

We can then compute the integrals in (3.11) by using Lemma 2.

Suppose $\Sigma_\alpha, \Sigma_\mu \in \mathbb{M}^{n\times n}$ are covariance matrices and $x, \alpha, \mu \in \mathbb{R}^n$. The following identity will be useful in what follows:

$$
\begin{aligned}
&\exp\Big\{-\tfrac{1}{2}(x-\alpha)'\Sigma_\alpha(x-\alpha)\Big\} \exp\Big\{-\tfrac{1}{2}(x-\mu)'\Sigma_\mu(x-\mu)\Big\} \\
&\quad = \exp\Big\{-\tfrac{1}{2}\Big(\alpha'\Sigma_\alpha\alpha + \mu'\Sigma_\mu\mu\Big)\Big\} \exp\Big\{\tfrac{1}{2}\Big(\Sigma_\alpha\alpha + \Sigma_\mu\mu\Big)' \operatorname{inv}(\Sigma_\alpha + \Sigma_\mu)\Big(\Sigma_\alpha\alpha + \Sigma_\mu\mu\Big)\Big\} \\
&\qquad \times \exp\Big\{-\tfrac{1}{2}\Big(x - \operatorname{inv}(\Sigma_\alpha + \Sigma_\mu)(\Sigma_\alpha\alpha + \Sigma_\mu\mu)\Big)' (\Sigma_\alpha + \Sigma_\mu) \\
&\qquad\quad \times \Big(x - \operatorname{inv}(\Sigma_\alpha + \Sigma_\mu)(\Sigma_\alpha\alpha + \Sigma_\mu\mu)\Big)\Big\}.
\end{aligned} \tag{3.12}
$$

THEOREM 3. *Suppose the unnormalized probability density $q^r_{k-1}(\xi)$ (as it appears under the integral in* (3.11)*) can be written as a finite weighted Gaussian mixture with $M^q \in \mathbb{N}$ components. That is, for $k \in \{1, 2, \dots\}$, we suppose*

$$q^r_{k-1}(\xi) = \sum_{s=1}^{M^q} p^{r,s}_{k-1} \frac{1}{(2\pi)^{n/2}|\Sigma^{r,s}_{k-1|k-1}|^{\frac{1}{2}}} \times \exp\Big\{-\tfrac{1}{2}(\xi - \alpha^{r,s}_{k-1|k-1})' \operatorname{inv}(\Sigma^{r,s}_{k-1|k-1})(\xi - \alpha^{r,s}_{k-1|k-1})\Big\}. \tag{3.13}$$

Here $\Sigma^{r,s}_{k-1|k-1} \in \mathbb{M}^{n\times n}$ and $\alpha^{r,s}_{k-1|k-1} \in \mathbb{R}^n$, are both $\mathcal{Y}_{k-1}$-measurable functions for all pairs $(r, s) \in \{1, 2, \dots, m\} \times \{1, 2, \dots, M^q\}$. Using the Gaussian mixture (3.13)*, the recursion for the optimal unnormalized density process has the form*

$$q^j_k(x) \triangleq \frac{1}{(2\pi)^{(d+n)/2}\Phi(y_k)} \sum_{r=1}^{m}\sum_{s=1}^{M^q} K^q_{k,k-1}(j, r, s) \times \exp\Big\{-\tfrac{1}{2}\Big(x - \operatorname{inv}(\sigma^{j,r,s}_{k-1})\delta^{j,r,s}_{k,k-1}\Big)' \sigma^{j,r,s}_{k-1}\Big(x - \operatorname{inv}(\sigma^{j,r,s}_{k-1})\delta^{j,r,s}_{k,k-1}\Big)\Big\}. \tag{3.14}$$

The means of the exponential densities in (3.14) *are computed by the update equations*

$$\operatorname{inv}(\sigma^{j,r,s}_{k-1})\delta^{j,r,s}_{k,k-1} = A_r\alpha^{r,s}_{k-1|k-1} + \overline{\Sigma}^{j,r,s}_{k-1|k-1}C_r' \operatorname{inv}\Big(C_r\overline{\Sigma}^{j,r,s}_{k-1|k-1}C_r' + D_rD_r'\Big)\big(y_k - C_rA_r\alpha^{r,s}_{k-1|k-1}\big). \tag{3.15}$$

Here

$$\overline{\Sigma}^{j,r,s}_{k-1|k-1} \triangleq B_jB_j' + A_j\Sigma^{r,s}_{k-1|k-1}A_j' \in \mathbb{R}^{n\times n}, \tag{3.16}$$

$$\widetilde{u}^{j,r,s}_{k-1|k-1} \triangleq A_j\alpha^{r,s}_{k-1|k-1} \in \mathbb{R}^n, \tag{3.17}$$

$$\sigma^{j,r,s}_{k-1} \triangleq C_r' \operatorname{inv}(D_rD_r')C_r + \operatorname{inv}(\overline{\Sigma}^{j,r,s}_{k-1|k-1}), \tag{3.18}$$

$$\delta^{j,r,s}_{k,k-1} \triangleq \operatorname{inv}(\overline{\Sigma}^{j,r,s}_{k-1|k-1})\widetilde{u}^{j,r,s}_{k-1|k-1} + C_r' \operatorname{inv}(D_rD_r')y_k, \tag{3.19}$$

$$K^q_{k,k-1}(j, r, s) \triangleq \frac{\pi_{(j,r)}p^{r,s}_{k-1}}{|\overline{\Sigma}^{j,r,s}_{k-1|k-1}|^{\frac{1}{2}}|D_j|} \exp\Big\{\tfrac{1}{2}(\delta^{j,r,s}_{k,k-1})' \operatorname{inv}(\sigma^{j,r,s}_{k-1})\delta^{j,r,s}_{k,k-1}\Big\} \times \exp\Big\{-\tfrac{1}{2}\big[y_k' \operatorname{inv}(D_rD_r')y_k + (\widetilde{u}^{j,r,s}_{k-1|k-1})' \operatorname{inv}(\overline{\Sigma}^{j,r,s}_{k-1|k-1})\widetilde{u}^{j,r,s}_{k-1|k-1}\big]\Big\} \tag{3.20}$$

(Note that the square matrices $\overline{\Sigma}^{j,r,s}_{k-1|k-1}$ and $\sigma^{j,r,s}_{k-1}$ are symmetric.)

Proof. To prove Theorem 3, we apply the identity given in Lemma 2 to the recursion at (3.7). In the first application, we eliminate the integral in (3.7). Using the finite-mixture representation (3.13), we write the recursion (3.7) for the function $q^j(x)$ as

$$q^j_k(x) = \frac{\Phi\big(D_j^{-1}(y_k - C_jx)\big)}{\Phi(y_k)|D_j||B_j|} \sum_{r=1}^{m} \pi_{(j,r)} \Bigg\{\sum_{s=1}^{M^q} p^{r,s}_{k-1} \Bigg[\int_{\mathbb{R}^n} \Psi\big(B_j^{-1}(x - A_j\xi)\big) \times \frac{1}{(2\pi)^{n/2}|\Sigma^{r,s}_{k-1|k-1}|^{\frac{1}{2}}} \exp\Big\{-\tfrac{1}{2}\Big(\xi - \alpha^{r,s}_{k-1|k-1}\Big)' \times \operatorname{inv}(\Sigma^{r,s}_{k-1|k-1})\Big(\xi - \alpha^{r,s}_{k-1|k-1}\Big)\Big\} d\xi\Bigg]\Bigg\}. \tag{3.21}$$

Recalling Lemma 2, we see that

(3.22)
$$\begin{aligned}
&\int_{\mathbb{R}^n} \Psi\big(B_j^{-1}(x - A_j\xi)\big) \frac{1}{(2\pi)^{n/2}|\Sigma^{r,s}_{k-1|k-1}|^{\frac{1}{2}}} \\
&\qquad \times \exp\big\{-\tfrac{1}{2}\big(\xi - \alpha^{r,s}_{k-1|k-1}\big)' \operatorname{inv}\big(\Sigma^{r,s}_{k-1|k-1}\big)\big(\xi - \alpha^{r,s}_{k-1|k-1}\big)\big\} d\xi \\
&\quad = \frac{1}{(2\pi)^{n/2}} |B_j| |B_jB_j' + A_j\Sigma^{r,s}_{k-1|k-1}A_j'|^{-\frac{1}{2}} \\
&\qquad \times \exp\big\{-\tfrac{1}{2}\big(x - A_j\alpha^{r,s}_{k-1|k-1}\big)'\big(B_jB_j' + A_j\Sigma^{r,s}_{k-1|k-1}A_j'\big)^{-1}\big(x - A_j\alpha^{r,s}_{k-1|k-1}\big)\big\}.
\end{aligned}$$

Using this calculation and the definitions for the quantities $\overline{\Sigma}^{j,r,s}_{k-1|k-1}$ and $\widetilde{u}^{j,r,s}_{k-1|k-1}$, we can write

$$\begin{aligned}
q_k^j(x) = \sum_{r=1}^{m}\sum_{s=1}^{M^q} &\frac{\pi_{(j,r)}p^{r,s}_{k-1}}{(2\pi)^{n/2}|\overline{\Sigma}^{j,r,s}_{k-1|k-1}|^{\frac{1}{2}}\Phi(y_k)|D_j|}\Phi\big(D_j^{-1}(y_k - C_jx)\big) \\
&\times \exp\Big\{-\tfrac{1}{2}\Big(x - \widetilde{u}^{j,r,s}_{k-1|k-1}\Big)' \operatorname{inv}(\overline{\Sigma}^{j,r,s}_{k-1|k-1})\Big(x - \widetilde{u}^{j,r,s}_{k-1|k-1}\Big)\Big\}.
\end{aligned} \tag{3.23}$$

The products of exponential functions in this equation can be simplified with the identity (3.12), resulting in

$$\begin{aligned}
q_k^j(x) = \frac{1}{(2\pi)^{(d+n)/2}\Phi(y_k)} \sum_{r=1}^{m}\sum_{s=1}^{M^q} &\frac{\pi_{(j,r)}p^{r,s}_{k-1}}{|\overline{\Sigma}^{j,r,s}_{k-1|k-1}|^{\frac{1}{2}}|D_j|} \exp\Big\{\tfrac{1}{2}(\delta^{j,r,s}_{k,k-1})' \operatorname{inv}(\sigma^{j,r,s}_{k-1})\delta^{j,r,s}_{k,k-1}\Big\} \\
&\times \exp\Big\{-\tfrac{1}{2}\Big[y_k' \operatorname{inv}(D_rD_r')y_k + (\widetilde{u}^{j,r,s}_{k-1|k-1})' \operatorname{inv}(\overline{\Sigma}^{j,r,s}_{k-1|k-1})\widetilde{u}^{j,r,s}_{k-1|k-1}\Big]\Big\} \\
&\times \exp\Big\{-\tfrac{1}{2}\Big(x - \operatorname{inv}(\sigma^{j,r,s}_{k-1})\delta^{j,r,s}_{k}\Big)' \sigma^{j,r,s}_{k-1}\Big(x - \operatorname{inv}(\sigma^{j,r,s}_{k-1})\delta^{j,r,s}_{k}\Big)\Big\}.
\end{aligned} \tag{3.24}$$

Finally, (3.15) is computed by the matrix inversion lemma. □

Remark 2. It is interesting to note the similarity of Theorem 3 to the Kalman filter. The mean update equation given by (3.15) is precisely the Kalman filter state update equation with Kalman gain $\overline{\Sigma}^{j,r,s}_{k-1|k-1}C_r' \operatorname{inv}(C_r\overline{\Sigma}^{j,r,s}_{k-1|k-1}C_r' + D_rD_r')$.

COROLLARY 1. *The estimated conditional mode probability for model j is given by*

$$p_k^j \triangleq P(Z_k = \boldsymbol{e}_j|\mathcal{Y}_k) = \frac{\int_{\mathbb{R}^n} q_k^j(\xi)d\xi}{\sum_{\ell=1}^m \int_{\mathbb{R}^n} q_k^\ell(\xi)d\xi} = \frac{q_k^j}{\sum_{\ell=1}^m q_k^\ell}. \tag{3.25}$$

Here the estimated unnormalized mode probability q_k^j is computed by the double summation

$$q_k^j = \frac{1}{(2\pi)^{d/2}\Phi(y_k)} \sum_{r=1}^{m}\sum_{s=1}^{M^q} \zeta^q_{k,k-1}(j,r,s), \tag{3.26}$$

where

$$\zeta^q_{k,k-1}(j,r,s) \triangleq K^q_{k,k-1}(j,r,s)|\sigma^{j,r,s}_{k-1}|^{-\frac{1}{2}}. \tag{3.27}$$

Proof. The proof of Corollary 1 is immediate.

$$
\begin{aligned}
q_k^j &\triangleq \int_{\mathbb{R}^n} q_k^j(\xi)d\xi \\
&= \frac{1}{(2\pi)^{(d+n)/2}\Phi(y_k)} \sum_{r=1}^{m}\sum_{s=1}^{M^q} K_{k,k-1}^q(j,r,s) \\
&\quad \times \int_{\mathbb{R}^n} \exp\Big\{-\tfrac{1}{2}\Big(\xi - \mathrm{inv}(\sigma_{k-1}^{j,r,s})\delta_{k,k-1}^{j,r,s}\Big)' \sigma_{k-1}^{j,r,s}\Big(\xi - \mathrm{inv}(\sigma_{k-1}^{j,r,s})\delta_{k,k-1}^{j,r,s}\Big)\Big\}d\xi \\
&= \frac{1}{(2\pi)^{d/2}\Phi(y_k)} \sum_{r=1}^{m}\sum_{s=1}^{M^q} K_{k,k-1}^q(j,r,s)|\sigma_{k-1}^{j,r,s}|^{-\frac{1}{2}}. \qquad \square
\end{aligned} \tag{3.28}
$$

Remark 3. The scalar-valued quantities $\zeta_{k,k-1}^q(j,r,s)$ are all nonnegative weights. These quantities form the double sum (3.26), whose value is the estimated mode probability q_k^j. In what follows, we shall exploit the form of (3.27) to fix the memory requirements of our suboptimal filters. Note that if $\sigma_{k-1}^{j,r,s}$ is relatively large, then $|\sigma_{k-1}^{j,r,s}|^{-\frac{1}{2}}$ makes a small contribution to (3.26). That is, larger (error) covariances give smaller weights in the sum (3.26). Accordingly, a subset of the terms $\zeta_{k,k-1}^q(j,r,s)$ will be identified from the set of all such $m \times M^q$ quantities. The elements of this subset will be identified through their relative magnitudes, as the most substantial contributors to the sum (3.26) and therefore the quantity q_k^j. Ultimately, this subset of quantities will be used to identify, at every time k, the most significant components of the Gaussian mixture for the density $q_k(x)$.

3.2. Suboptimal filter dynamics. In this section we develop a suboptimal recursive filter by extending an idea due to Viterbi [18]. The motivation to develop a suboptimal filter is immediate from the dynamics of the unnormalized density (3.14). Suppose at time $k = 1$, these dynamics involve $m \times M^q$ densities. Then the next time, $k = 2$, these dynamics require $m \times m \times M^q$ densities. It is clear that the demand on memory requirements is exponential in time, with the number of densities required at time k being $m^k \times M^q$. What we wish to do is to circumvent this growth by identifying a subset of candidate mixture densities, from which we construct a suboptimal density with fixed (in-time) memory requirements.

3.2.1. Hypothesis management. Write

$$
\Gamma^q \triangleq \{1,2,\ldots,m\} \times \big\{1,2,\ldots,M^q\big\}, \tag{3.29}
$$

$$
\widetilde{S}_{k,k-1}^q(j,r,s) \triangleq \big\{\zeta_{k,k-1}^q(j,r,s)\big\}_{(r,s)\in\Gamma^q}. \tag{3.30}
$$

To remove the growth in memory requirements, we propose to identify, at each time k, the M^q-best candidate densities for each suboptimal density $q_k^j(x)$, using the corresponding estimated mode probabilities. The key to this idea is to identify M^q optimal densities, that is, the M^q components in the Gaussian mixture, through their corresponding set of estimated mode probabilities q^j, $j \in \{1,2,\ldots,m\}$.

Since the estimated mode probabilities, given by (3.26), are formed by a summation over nonnegative quantities, we can identify the M^q largest contributors to this sum and then use the corresponding indexes to identify the M^q-best Gaussian

densities. This maximization procedure is as follows:

$$\zeta^q_{k,k-1}(j, r^*_{k,1}, s^*_{k,1}) \triangleq \max_{(r,s)\,\in\,\Gamma^q} \widetilde{S}^q_{k,k-1}(j, r, s), \tag{3.31}$$

$$\zeta^q_{k,k-1}(j, r^*_{k,2}, s^*_{k,2}) \triangleq \max_{(r,s)\,\in\,\Gamma^q\setminus(r^*_{k,1}, s^*_{k,1})} \widetilde{S}^q_{k,k-1}(j, r, s), \tag{3.32}$$

$$\vdots \qquad\qquad \vdots$$

$$\zeta^q_{k,k-1}(j, r^*_{k,M^q}, s^*_{k,M^q}) \triangleq \max_{(r,s)\,\in\,\Gamma^q\setminus\{(r^*_{k,1}, s^*_{k,1}),\ldots,(r^*_{k,M^q-1}, s^*_{k,M^q-1})\}} \widetilde{S}^q_{k,k-1}(j, r, s). \tag{3.33}$$

Note that we are not directly interested in the quantities $\zeta^q_{k,k-1}(j, r^*_{k,\ell}, s^*_{k,\ell})$, but rather in the indexes that locate these quantities. The optimal index set, for the density of model j, is

$$\mathcal{I}^j_k \triangleq \big\{(r^*_{k,1}, s^*_{k,1}), (r^*_{k,2}, s^*_{k,2}), \ldots, (r^*_{k,M^q}, s^*_{k,M^q})\big\}. \tag{3.34}$$

Using these indexes, we approximate the suboptimal unnormalized density, of order M^q, corresponding to the density $q^j_k(x)$ as

(3.35)

$$q^j_k(x) \triangleq \frac{1}{(2\pi)^{(d+n)/2}\Phi(y_k)} \sum_{\ell=1}^{M^q} K^q_{k,k-1}(j, r^*_{k,\ell}, s^*_{k,\ell})$$
$$\times \exp\Big\{-\tfrac{1}{2}\Big(x - \operatorname{inv}(\sigma^{j,r^*_{k,\ell},s^*_{k,\ell}}_{k-1})\delta^{j,r^*_{k,\ell},s^*_{k,\ell}}_{k,k-1}\Big)' \sigma^{j,r^*_{k,\ell},s^*_{k,\ell}}_{k-1} \Big(x - \operatorname{inv}(\sigma^{j,r^*_{k,\ell},s^*_{k,\ell}}_{k-1})\delta^{j,r^*_{k,\ell},s^*_{k,\ell}}_{k,k-1}\Big)\Big\}.$$

Further, by Corollary 1, the unnormalized mode probability corresponding to the expectation $E[Z_k = \boldsymbol{e}_j|\mathcal{Y}_k]$ is approximated by

$$q^j_k \triangleq \frac{1}{(2\pi)^{d/2}\Phi(y_k)} \sum_{\ell=1}^{M^q} \zeta^q_{k,k-1}(j, r^*_{k,\ell}, s^*_{k,\ell}). \tag{3.36}$$

To normalize the function $q^j_k(x)$, we need the sum of all terms $\{q^1_k, \ldots, q^m_k\}$ and so write

$$\varphi_{k|k} \triangleq \sum_{j=1}^{m} q^j_k. \tag{3.37}$$

3.2.2. Filter state statistics. Densities such as $q^j_k(x)$ provide all the information available. However, what is often required in state estimation (filtering) is an expression for the state estimate of x_k at time k given $\mathcal{Y}_k$, that is,

$$\widehat{x}_{k|k} \triangleq E\big[x_k|\mathcal{Y}_k\big]. \tag{3.38}$$

PROPOSITION 1. *The suboptimal state estimate $\widehat{x}_{k|k}$, for a Gaussian mixture of order M^q, has the representation*

$$\widehat{x}_{k|k} = \frac{1}{(2\pi)^{d/2}\Phi(y_k)\varphi_{k|k}} \sum_{j=1}^{m}\sum_{\ell=1}^{M^q} \frac{K^q_{k,k-1}(j, r^*_{k,\ell}, s^*_{k,\ell})}{|\sigma^{j,r^*_{k,\ell},s^*_{k,\ell}}_{k-1}|^{\frac{1}{2}}}$$
$$\times\Big[A_{r^*_{k,\ell}}\alpha^{r^*_{k,\ell},s^*_{k,\ell}}_{k-1|k-1} + \overline{\Sigma}^{j,r^*_{k,\ell},s^*_{k,\ell}}_{k-1|k-1} C'_{r^*_{k,\ell}} \operatorname{inv}\Big(D_{r^*_{k,\ell}} D'_{r^*_{k,\ell}} + C_{r^*_{k,\ell}} \overline{\Sigma}^{j,r,s}_{k-1|k-1} C'_{r^*_{k,\ell}}\Big)$$
$$\times\big(y_k - C_{r^*_{k,\ell}} A_{r^*_{k,\ell}} \alpha^{r^*_{k,\ell},s^*_{k,\ell}}_{k-1|k-1}\big)\Big]. \tag{3.39}$$

Here

$$\varphi_{k|k} = \frac{1}{(2\pi)^{d/2}\Phi(y_k)} \sum_{j=1}^{m} \sum_{\ell=1}^{M^q} K^q_{k,k-1}(j, r^*_{k,\ell}, s^*_{k,\ell}) |\sigma^{j,r^*_{k,\ell},s^*_{k,\ell}}_{k-1}|^{-\frac{1}{2}}. \tag{3.40}$$

Proof.

$$\begin{aligned}
E\big[x_k|\mathcal{Y}_k\big] &= \frac{1}{\varphi_{k|k}} \int_{\mathbb{R}^n} \xi \Big[\sum_{j=1}^{m} q^j_k(\xi)\Big] d\xi \\
&= \frac{1}{\varphi_{k|k}} \sum_{j=1}^{m} \Big[\int_{\mathbb{R}^n} \xi\, q^j_k(\xi) d\xi\Big] \\
&= \frac{1}{\varphi_{k|k}} \sum_{j=1}^{m} \int_{\mathbb{R}^n} \xi \Bigg[\frac{1}{(2\pi)^{(d+n)/2}\Phi(y_k)} \sum_{\ell=1}^{M^q} K^q_{k,k-1}(j, r^*_{k,\ell}, s^*_{k,\ell}) \\
&\qquad \times \exp\Big\{-\tfrac{1}{2}\Big(\xi - \mathrm{inv}(\sigma^{j,r^*_{k,\ell},s^*_{k,\ell}}_{k-1})\delta^{j,r^*_{k,\ell},s^*_{k,\ell}}_{k,k-1}\Big)' \sigma^{j,r^*_{k,\ell},s^*_{k,\ell}}_{k-1} \\
&\qquad\qquad \times \Big(\xi - \mathrm{inv}(\sigma^{j,r^*_{k,\ell},s^*_{k,\ell}}_{k-1})\delta^{j,r^*_{k,\ell},s^*_{k,\ell}}_{k,k-1}\Big)\Big\}\Bigg] d\xi \\
&= \frac{1}{(2\pi)^{(d+n)/2}\Phi(y_k)\varphi_{k|k}} \sum_{j=1}^{m} \sum_{\ell=1}^{M^q} K^q_{k,k-1}(j, r^*_{k,\ell}, s^*_{k,\ell}) \\
&\qquad \times \int_{\mathbb{R}^n} \xi \Bigg[\exp\Big\{-\tfrac{1}{2}\Big(\xi - \mathrm{inv}(\sigma^{j,r^*_{k,\ell},s^*_{k,\ell}}_{k-1})\delta^{j,r^*_{k,\ell},s^*_{k,\ell}}_{k,k-1}\Big)' \sigma^{j,r^*_{k,\ell},s^*_{k,\ell}}_{k-1} \\
&\qquad\qquad \times \Big(\xi - \mathrm{inv}(\sigma^{j,r^*_{k,\ell},s^*_{k,\ell}}_{k-1})\delta^{j,r^*_{k,\ell},s^*_{k,\ell}}_{k,k-1}\Big)\Big\}\Bigg] d\xi \\
&= \frac{1}{(2\pi)^{d/2}\Phi(y_k)\varphi_{k|k}} \sum_{j=1}^{m} \sum_{\ell=1}^{M^q} \frac{K^q_{k,k-1}(j, r^*_{k,\ell}, s^*_{k,\ell})}{|\sigma^{j,r^*_{k,\ell},s^*_{k,\ell}}_{k-1}|^{\frac{1}{2}}} \mathrm{inv}(\sigma^{j,r^*_{k,\ell},s^*_{k,\ell}}_{k-1})\delta^{j,r^*_{k,\ell},s^*_{k,\ell}}_{k,k-1}.
\end{aligned} \tag{3.41}$$

The proof is completed by applying the matrix inversion lemma to the term $\mathrm{inv}(\sigma^{j,r^*_{k,\ell},s^*_{k,\ell}}_{k-1})\delta^{j,r^*_{k,\ell},s^*_{k,\ell}}_{k,k-1}$. □

It is also of practical interest to have a relation for the corresponding error covariance, that is,

$$\begin{aligned}
\Sigma_{k|k} &\triangleq E\big[(x_k - \widehat{x}_{k|k})(x - \widehat{x}_{k|k})'|\mathcal{Y}_k\big] \\
&= \frac{1}{\varphi_{k|k}} \int_{\mathbb{R}^n} (\xi - \widehat{x}_{k|k})(\xi - \widehat{x}_{k|k})' \left(\sum_{j=1}^{m} q^j_k(\xi)\right) d\xi = \widehat{\Sigma}_{k|k}, \text{ say.}
\end{aligned} \tag{3.42}$$

PROPOSITION 2. *The filter state error covariance $\widehat{\Sigma}_{k|k}$, for a Gaussian mixture of order M^q, has the following representation:*

$$\begin{aligned}
\widehat{\Sigma}_{k|k} = \frac{1}{(2\pi)^{d/2}\Phi(y_k)\varphi_{k|k}} \sum_{j=1}^{m} \sum_{\ell=1}^{M^q} \frac{K^q_{k,k-1}(j, r^*_{k,\ell}, s^*_{k,\ell})}{|\sigma^{j,r^*_{k,\ell},s^*_{k,\ell}}_{k-1}|^{\frac{1}{2}}} \Big[\mathrm{inv}(\sigma^{j,r^*_{k,\ell},s^*_{k,\ell}}_{k-1}) \\
+ \Big(\mathrm{inv}(\sigma^{j,r^*_{k,\ell},s^*_{k,\ell}}_{k-1})\delta^{j,r^*_{k,\ell},s^*_{k,\ell}}_{k,k-1} - \widehat{x}_{k|k}\Big)\Big(\mathrm{inv}(\sigma^{j,r^*_{k,\ell},s^*_{k,\ell}}_{k-1})\delta^{j,r^*_{k,\ell},s^*_{k,\ell}}_{k,k-1} - \widehat{x}_{k|k}\Big)'\Big].
\end{aligned} \tag{3.43}$$

Proof. Recalling the approximate unnormalized density (3.35), we see that

$$\begin{aligned}\widehat{\Sigma}_{k|k} &= \frac{1}{(2\pi)^{(d+n)/2}\Phi(y_k)\varphi_{k|k}} \sum_{j=1}^{m}\sum_{\ell=1}^{M^q} K^q_{k,k-1}(j, r^*_{k,\ell}, s^*_{k,\ell}) \int_{\mathbb{R}^n} \big(\xi - \widehat{x}_{k|k}\big)\big(\xi - \widehat{x}_{k|k}\big)' \\ &\quad \times \Bigg[\exp\Big\{ -\tfrac{1}{2}\Big(\xi - \mathrm{inv}(\sigma_{k-1}^{j,r^*_{k,\ell},s^*_{k,\ell}})\delta_{k,k-1}^{j,r^*_{k,\ell},s^*_{k,\ell}}\Big)' \sigma_{k-1}^{j,r^*_{k,\ell},s^*_{k,\ell}} \\ &\qquad \times \Big(\xi - \mathrm{inv}(\sigma_{k-1}^{j,r^*_{k,\ell},s^*_{k,\ell}})\delta_{k,k-1}^{j,r^*_{k,\ell},s^*_{k,\ell}}\Big)\Big\}\Bigg] d\xi \\ &= \frac{1}{(2\pi)^{d/2}\Phi(y_k)\varphi_{k|k}} \sum_{j=1}^{m}\sum_{\ell=1}^{M^q} \frac{K^q_{k,k-1}(j, r^*_{k,\ell}, s^*_{k,\ell})}{|\sigma_{k-1}^{j,r^*_{k,\ell},s^*_{k,\ell}}|^{\frac{1}{2}}} \int_{\mathbb{R}^n} \big(\xi - \widehat{x}_{k|k}\big)\big(\xi - \widehat{x}_{k|k}\big)' \\ &\quad \times \Bigg[\frac{|\sigma_{k-1}^{j,r^*_{k,\ell},s^*_{k,\ell}}|^{\frac{1}{2}}}{(2\pi)^{n/2}} \exp\Big\{ -\tfrac{1}{2}\Big(\xi - \mathrm{inv}(\sigma_{k-1}^{j,r^*_{k,\ell},s^*_{k,\ell}})\delta_{k,k-1}^{j,r^*_{k,\ell},s^*_{k,\ell}}\Big)' \sigma_{k-1}^{j,r^*_{k,\ell},s^*_{k,\ell}} \\ &\qquad \times \Big(\xi - \mathrm{inv}(\sigma_{k-1}^{j,r^*_{k,\ell},s^*_{k,\ell}})\delta_{k,k-1}^{j,r^*_{k,\ell},s^*_{k,\ell}}\Big)\Big\}\Bigg] d\xi. \end{aligned} \tag{3.44}$$

Writing

$$\big(\xi - \widehat{x}_{k|k}\big) = \Big(\xi - \mathrm{inv}(\sigma_{k-1}^{j,r^*_{k,\ell},s^*_{k,\ell}})\delta_{k,k-1}^{j,r^*_{k,\ell},s^*_{k,\ell}} + \mathrm{inv}(\sigma_{k-1}^{j,r^*_{k,\ell},s^*_{k,\ell}})\delta_{k,k-1}^{j,r^*_{k,\ell},s^*_{k,\ell}} - \widehat{x}_{k|k}\Big), \tag{3.45}$$

(3.43) is the sum of the integrals

(3.46)
$$\begin{aligned}&\frac{|\sigma_{k-1}^{j,r^*_{k,\ell},s^*_{k,\ell}}|^{\frac{1}{2}}}{(2\pi)^{n/2}} \int_{\mathbb{R}^n} \Big(\xi - \mathrm{inv}(\sigma_{k-1}^{j,r^*_{k,\ell},s^*_{k,\ell}})\delta_{k,k-1}^{j,r^*_{k,\ell},s^*_{k,\ell}}\Big)\Big(\xi - \mathrm{inv}(\sigma_{k-1}^{j,r^*_{k,\ell},s^*_{k,\ell}})\delta_{k,k-1}^{j,r^*_{k,\ell},s^*_{k,\ell}}\Big)' \\ &\quad \times \exp\Big\{ -\tfrac{1}{2}\Big(\xi - \mathrm{inv}(\sigma_{k-1}^{j,r^*_{k,\ell},s^*_{k,\ell}})\delta_{k,k-1}^{j,r^*_{k,\ell},s^*_{k,\ell}}\Big)' \sigma_{k-1}^{j,r^*_{k,\ell},s^*_{k,\ell}} \\ &\qquad \times \Big(\xi - \mathrm{inv}(\sigma_{k-1}^{j,r^*_{k,\ell},s^*_{k,\ell}})\delta_{k,k-1}^{j,r^*_{k,\ell},s^*_{k,\ell}}\Big)\Big\} d\xi = \mathrm{inv}\big(\sigma_{k-1}^{j,r^*_{k,\ell},s^*_{k,\ell}}\big), \end{aligned}$$

(3.47)
$$\begin{aligned}&\frac{|\sigma_{k-1}^{j,r^*_{k,\ell},s^*_{k,\ell}}|^{\frac{1}{2}}}{(2\pi)^{n/2}} \int_{\mathbb{R}^n} \Big(\xi - \mathrm{inv}(\sigma_{k-1}^{j,r^*_{k,\ell},s^*_{k,\ell}})\delta_{k,k-1}^{j,r^*_{k,\ell},s^*_{k,\ell}}\Big) \\ &\quad \times \exp\Big\{ -\tfrac{1}{2}\Big(\xi - \mathrm{inv}(\sigma_{k-1}^{j,r^*_{k,\ell},s^*_{k,\ell}})\delta_{k,k-1}^{j,r^*_{k,\ell},s^*_{k,\ell}}\Big)' \sigma_{k-1}^{j,r^*_{k,\ell},s^*_{k,\ell}} \\ &\qquad \times \Big(\xi - \mathrm{inv}(\sigma_{k-1}^{j,r^*_{k,\ell},s^*_{k,\ell}})\delta_{k,k-1}^{j,r^*_{k,\ell},s^*_{k,\ell}}\Big)\Big\} d\xi (\mathrm{inv}(\sigma_{k-1}^{j,r^*_{k,\ell},s^*_{k,\ell}})\delta_{k,k-1}^{j,r^*_{k,\ell},s^*_{k,\ell}} - \widehat{x}_{k|k})' = 0, \end{aligned}$$

(3.48)
$$\begin{aligned}&\frac{|\sigma_{k-1}^{j,r^*_{k,\ell},s^*_{k,\ell}}|^{\frac{1}{2}}}{(2\pi)^{n/2}} \Big(\mathrm{inv}(\sigma_{k-1}^{j,r^*_{k,\ell},s^*_{k,\ell}})\delta_{k,k-1}^{j,r^*_{k,\ell},s^*_{k,\ell}} - \widehat{x}_{k|k}\Big)' \int_{\mathbb{R}^n} \Big(\xi - \mathrm{inv}(\sigma_{k-1}^{j,r^*_{k,\ell},s^*_{k,\ell}})\delta_{k,k-1}^{j,r^*_{k,\ell},s^*_{k,\ell}}\Big) \\ &\quad \times \exp\Big\{ -\tfrac{1}{2}\Big(\xi - \mathrm{inv}(\sigma_{k-1}^{j,r^*_{k,\ell},s^*_{k,\ell}})\delta_{k,k-1}^{j,r^*_{k,\ell},s^*_{k,\ell}}\Big)' \sigma_{k-1}^{j,r^*_{k,\ell},s^*_{k,\ell}} \\ &\qquad \times \Big(\xi - \mathrm{inv}(\sigma_{k-1}^{j,r^*_{k,\ell},s^*_{k,\ell}})\delta_{k,k-1}^{j,r^*_{k,\ell},s^*_{k,\ell}}\Big)\Big\} d\xi = 0, \end{aligned}$$

and

(3.49)
$$\begin{aligned}
&\frac{|\sigma_{k-1}^{j,r_{k,\ell}^*,s_{k,\ell}^*}|^{\frac{1}{2}}}{(2\pi)^{n/2}}\Big(\operatorname{inv}(\sigma_{k-1}^{j,r_{k,\ell}^*,s_{k,\ell}^*})\delta_{k,k-1}^{j,r_{k,\ell}^*,s_{k,\ell}^*}-\widehat{x}_{k|k}\Big)\Big(\operatorname{inv}(\sigma_{k-1}^{j,r_{k,\ell}^*,s_{k,\ell}^*})\delta_{k,k-1}^{j,r_{k,\ell}^*,s_{k,\ell}^*}-\widehat{x}_{k|k}\Big)'\\
&\quad\times\int_{\mathbb{R}^n}\exp\Big\{-\tfrac{1}{2}\Big(\xi-\operatorname{inv}(\sigma_{k-1}^{j,r_{k,\ell}^*,s_{k,\ell}^*})\delta_{k,k-1}^{j,r_{k,\ell}^*,s_{k,\ell}^*}\Big)'\sigma_{k-1}^{j,r_{k,\ell}^*,s_{k,\ell}^*}\\
&\qquad\qquad\times\Big(\xi-\operatorname{inv}(\sigma_{k-1}^{j,r_{k,\ell}^*,s_{k,\ell}^*})\delta_{k,k-1}^{j,r_{k,\ell}^*,s_{k,\ell}^*}\Big)\Big\}d\xi\\
&\quad=\Big(\operatorname{inv}(\sigma_{k-1}^{j,r_{k,\ell}^*,s_{k,\ell}^*})\delta_{k,k-1}^{j,r_{k,\ell}^*,s_{k,\ell}^*}-\widehat{x}_{k|k}\Big)\Big(\operatorname{inv}(\sigma_{k-1}^{j,r_{k,\ell}^*,s_{k,\ell}^*})\delta_{k,k-1}^{j,r_{k,\ell}^*,s_{k,\ell}^*}-\widehat{x}_{k|k}\Big)'.
\end{aligned}$$

Finally, combining the above calculations the result follows. □

Remark 4. It is interesting to note that (3.43) is essentially in the form of an additive decomposition of two components, that is, a weighted sum of the two terms $\operatorname{inv}(\sigma_{k-1}^{j,r_{k,\ell}^*,s_{k,\ell}^*})$ and $(\operatorname{inv}(\sigma_{k-1}^{j,r_{k,\ell}^*,s_{k,\ell}^*})\delta_{k,k-1}^{j,r_{k,\ell}^*,s_{k,\ell}^*}-\widehat{x}_{k|k})(\operatorname{inv}(\sigma_{k-1}^{j,r_{k,\ell}^*,s_{k,\ell}^*})\delta_{k,k-1}^{j,r_{k,\ell}^*,s_{k,\ell}^*}-\widehat{x}_{k|k})'$. This suggests that the estimation error arises from two sources: the approximation by a finite mixture and the standard error in the estimate of x. The matrix $\operatorname{inv}(\sigma_{k-1}^{j,r_{k,\ell}^*,s_{k,\ell}^*})$ is related, for example, to the covariance $\Sigma_{k-1|k-1}^{r,s}$, which contributes to component s, in the finite mixture representation of the rth unnormalized density (recall (3.13)). The matrix $(\operatorname{inv}(\sigma_{k-1}^{j,r_{k,\ell}^*,s_{k,\ell}^*})\delta_{k,k-1}^{j,r_{k,\ell}^*,s_{k,\ell}^*}-\widehat{x}_{k|k})(\operatorname{inv}(\sigma_{k-1}^{j,r_{k,\ell}^*,s_{k,\ell}^*})\delta_{k,k-1}^{j,r_{k,\ell}^*,s_{k,\ell}^*}-\widehat{x}_{k|k})'$, however, computes the error covariance between the state estimate $\widehat{x}_{k|k}$ and the approximate mean of the state x. This decomposition could provide another method to determine the appropriate number of components for the Gaussian mixtures.

4. Hybrid smoother dynamics. Smoothing is a term used for a form of off-line estimation where one has information (from the observation process) beyond the current time. Suppose one has a set of observations generated by the dynamics (2.5), for example, $\{y_1, y_2, \dots, y_T\}$ and we wish to estimate

$$E\big[x_\ell|\mathcal{Y}_{0,T}\big], \qquad 0\le\ell\le T. \tag{4.1}$$

Currently, all smoothing schemes for Gauss–Markov jump linear systems are ad hoc and are not based upon the exact hybrid filter dynamics; for example, see [3] and [4].

To compute smoothers, we exploit a duality between the forward function $q_k^j(x)$ which evolves forward in time and a related function $v_k^j(x)$ which evolves backward in time (see [12] and [10]). To construct our smoothing algorithm, we compute a finite memory time-reversed recursion for the functions $v_k^j(x)$. A suboptimal v is then defined using an extension of the idea of Viterbi, by replacing a summation with a maximization.

4.1. Exact smoother dynamics. Recalling the form of Bayes' rule (2.14), we note that

$$E\big[\langle Z_k,\boldsymbol{e}_j\rangle f(x_k)|\mathcal{Y}_{0,T}\big]=\frac{E^\dagger\big[\Lambda_{0,T}\langle Z_k,\boldsymbol{e}_j\rangle f(x_k)|\mathcal{Y}_{0,T}\big]}{E^\dagger\big[\Lambda_{0,T}|\mathcal{Y}_T\big]}. \tag{4.2}$$

Write

$$\widetilde{\mathcal{F}}_k\triangleq\sigma\big\{x_\ell,Z_\ell,0\le\ell\le k\big\}. \tag{4.3}$$

For reasons identical to those given in section 3.1, we need consider only the numerator in the quotient of (4.2):

(4.4)
$$\begin{aligned} E^\dagger\big[\Lambda_{0,T}\langle Z_k, \boldsymbol{e}_j\rangle f(x_k)|\mathcal{Y}_{0,T}\big] &= E^\dagger\big[\Lambda_{0,k}\Lambda_{k+1,T}\langle Z_k, \boldsymbol{e}_j\rangle f(x_k)|\mathcal{Y}_{0,T}\big] \\ &= E^\dagger\Big[E^\dagger\big[\Lambda_{0,k}\Lambda_{k+1,T}\langle Z_k, \boldsymbol{e}_j\rangle f(x_k)|\widetilde{\mathcal{F}}_k \vee \mathcal{Y}_{0,T}\big]|\mathcal{Y}_{0,T}\Big] \\ &= E^\dagger\Big[\Lambda_{0,k}\langle Z_k, \boldsymbol{e}_j\rangle f(x_k) E^\dagger\big[\Lambda_{k+1,T}|\widetilde{\mathcal{F}}_k \vee \mathcal{Y}_{0,T}\big]|\mathcal{Y}_{0,T}\Big]. \end{aligned}$$

As our processes are Markov,

$$E^\dagger\big[\Lambda_{k+1|T}|\widetilde{\mathcal{F}}_k \vee \mathcal{Y}_{0,T}\big] = E^\dagger\big[\Lambda_{k+1|T}|Z_k, x_k, \mathcal{Y}_{0,T}\big]. \tag{4.5}$$

Write

$$v_k^j(x) \triangleq E^\dagger\big[\Lambda_{k+1,T}|Z_k = \boldsymbol{e}_j, x_k = x, \mathcal{Y}_{0,T}\big]. \tag{4.6}$$

Then, as in [13],

$$E^\dagger\big[\Lambda_{0,k}\langle Z_k, \boldsymbol{e}_j\rangle f(x_k) v_k^j(x_k)|\mathcal{Y}_{0,T}\big] = \int_{\mathbb{R}^n}\Big\{q_k^j(\xi)v_k^j(\xi)\Big\}f(\xi)d\xi. \tag{4.7}$$

We now compute a backward recursion for the function $v_k^j(x)$, similar in form to the forward recursion for the function $q_k^j(x)$, given in (3.7).

THEOREM 4. *The unnormalized function $v_k^j(x)$ satisfies the backward recursion*

(4.8)
$$v_k^j(x) = \sum_{r=1}^m \frac{\pi_{(r,j)}}{|D_r||B_r|\Phi(y_{k+1})}\int_{\mathbb{R}^n}\Phi\big(D_r^{-1}(y_{k+1} - C_r\xi)\big)\Psi(B_r^{-1}(\xi - A_r x))v_{k+1}^r(\xi)d\xi.$$

Proof. From definition (4.6), we again use repeated conditioning to write

(4.9)
$$\begin{aligned} v_k^j(x) &= E^\dagger[\Lambda_{k+1,T}|Z_k = \boldsymbol{e}_j, x_k = x, \mathcal{Y}_{0,T}\big] \\ &= E^\dagger[\lambda_{k+1}E^\dagger[\Lambda_{k+2,T}|Z_{k+1}, x_{k+1}, Z_k = \boldsymbol{e}_j, x_k = x, \mathcal{Y}_{0,T}]| \\ &\qquad Z_k = \boldsymbol{e}_j, x_k = x, \mathcal{Y}_{0,T}] \\ &= \sum_{r=1}^m E^\dagger[\lambda_{k+1}\langle Z_{k+1}, \boldsymbol{e}_r\rangle E^\dagger\big[\Lambda_{k+2,T}|Z_{k+1} = \boldsymbol{e}_r, x_{k+1}, Z_k = \boldsymbol{e}_j, x_k = x, \mathcal{Y}_{0,T}]| \\ &\qquad Z_k = \boldsymbol{e}_j, x_k = x, \mathcal{Y}_{0,T}] \\ &= \sum_{r=1}^m E^\dagger[\lambda_{k+1}\langle Z_{k+1}, \boldsymbol{e}_r\rangle E^\dagger\big[\Lambda_{k+2,T}|Z_{k+1} = \boldsymbol{e}_r, x_{k+1}, \mathcal{Y}_{0,T}]| \\ &\qquad Z_k = \boldsymbol{e}_j, x_k = x, \mathcal{Y}_{0,T}] \end{aligned}$$

(since Z is a Markov chain, and under $P^\dagger$ the process x is i.i.d.)

$$\begin{aligned} &= \sum_{r=1}^m E^\dagger\Big[\langle Z_{k+1}, \boldsymbol{e}_r\rangle \frac{\Phi\big(D_r^{-1}(y_{k+1} - C_r x_{k+1})\big)}{|D_r|\Phi(y_{k+1})}\frac{\Psi\big(B_r^{-1}(x_{k+1} - A_r x_k)\big)}{|B_r|\Psi(x_{k+1})}v_{k+1}^r(x_{k+1})| \\ &\qquad\qquad Z_k = \boldsymbol{e}_j, x_k = x, \mathcal{Y}_{0,T}\Big] \\ &= \sum_{r=1}^m \frac{\pi_{(r,j)}}{|D_r||B_r|\Phi(y_{k+1})}\int_{\mathbb{R}^n}\Phi\big(D_r^{-1}(y_{k+1} - C_r\xi)\big)\Psi(B_r^{-1}(\xi - A_r x))v_{k+1}^r(\xi)d\xi. \end{aligned}$$

∎

THEOREM 5. *Suppose the unnormalized function $v_{k+1}^r(\xi)$ (as it appears under the integral in (4.8)) may be approximated as a finite weighted Gaussian mixture with $M^v \in \mathbb{N}$ components. That is, suppose*

(4.10)
$$v_{k+1}^r(\xi) = \sum_{s=1}^{M^v} \rho_{k+1}^{r,s} \frac{1}{(2\pi)^{n/2}|\Sigma_{k+1|T}^{r,s}|^{\frac{1}{2}}} \exp\Big\{-\tfrac{1}{2}\big(\xi - \alpha_{k+1|T}^{r,s}\big)' \operatorname{inv}\big(\Sigma_{k+1|T}^{r,s}\big)\big(\xi - \alpha_{k+1|T}^{r,s}\big)\Big\}.$$

Here $\Sigma_{k+1|T}^{r,s} \in \mathbb{M}^{n\times n}$ and $\alpha_{k+1|T}^{r,s} \in \mathbb{R}^n$ are both $\mathcal{Y}_{k+1,T}$-measurable functions for all pairs $(r,s) \in \{1,2,\dots,m\} \times \{1,2,\dots,M^v\}$. Using the Gaussian mixture (4.10), the recursion for $v_k^j(x)$, at times $k \in \{1,2,\dots,T-1\}$, has the form

$$\begin{aligned} v_k^j(x) \triangleq{}& \frac{1}{(2\pi)^{(n+d)/2}\Phi(y_{k+1})} \sum_{r=1}^{m}\sum_{s=1}^{M^v} K_{k+1,T}^v(j,r,s) \\ &\times \exp\Big\{-\tfrac{1}{2}\Big(x - \operatorname{inv}(S_{k+1|T}^{r,s})\tau_{k+1|T}^{r,s}\Big)' S_{k+1,T}^{r,s}\Big(x - \operatorname{inv}(S_{k+1|T}^{r,s})\tau_{k+1|T}^{r,s}\Big)\Big\}. \end{aligned} \tag{4.11}$$

At the final time T for all $j \in \{1,2,\dots,m\}$,

$$v_T^j(x) \triangleq 1. \tag{4.12}$$

Here

$$\begin{aligned} K_{k+1,T}^v(j,r,s) \triangleq{}& \frac{\pi_{(r,j)}\rho_{k+1}^{r,s}}{|D_r||B_r||\widetilde{\Sigma}_{k+1|T}^{r,s}|^{\frac{1}{2}}\Big|\gamma_r + \operatorname{inv}(\Sigma_{k+1|T}^{r,s})\Big|^{\frac{1}{2}}} \\ &\times \exp\Big\{-\tfrac{1}{2}\Big((\alpha_{k+1|T}^{r,s})' \operatorname{inv}(\Sigma_{k+1|T}^{r,s})\Big[I - \widetilde{\Sigma}_{k+1|T}^{r,s}\operatorname{inv}(\Sigma_{k+1|T}^{r,s})\Big]\alpha_{k+1|T}^{r,s}\Big\} \\ &\times \exp\Big\{-\tfrac{1}{2}y_{k+1}'\operatorname{inv}(D_rD_r')yk + 1\Big\} \\ &\times \exp\Big\{-\tfrac{1}{2}\Big(\widetilde{\Sigma}_{k+1|T}^{r,s}\operatorname{inv}(\Sigma_{k+1|T}^{r,s})\alpha_{k+1|T}^{r,s}\Big)' \operatorname{inv}(\widetilde{\Sigma}_{k+1|T}^{r,s}) \\ &\times \Big(\widetilde{\Sigma}_{k+1|T}^{r,s}\operatorname{inv}\big(\Sigma_{k+1|T}^{r,s}\big)\alpha_{k+1|T}^{r,s}\Big)\Big\} \\ &\times \exp\Big\{\tfrac{1}{2}\Big(C_r\operatorname{inv}(D_rD_r')y_{k+1}\operatorname{inv}(\Sigma_{k+1|T}^{r,s})\alpha_{k+1|T}^{r,s}\Big)' \\ &\times \operatorname{inv}\big(\widetilde{\Sigma}_{k+1|T}^{r,s}\big)\Big(C_r\operatorname{inv}(D_rD_r')y_{k+1} + \operatorname{inv}(\Sigma_{k+1|T}^{r,s})\alpha_{k+1|T}^{r,s}\Big)\Big\} \\ &\times \exp\Big\{\tfrac{1}{2}(\tau_{k+1|T}^{r,s})'\operatorname{inv}(S_{k+1|T}^{r,s})\tau_{k+1|T}^{r,s}\Big\} \in \mathbb{R}, \end{aligned} \tag{4.13}$$

$$S_{k+1|T}^{r,s} \triangleq A_r'\operatorname{inv}(B_rB_r')A_r - A_r'\operatorname{inv}(B_rB_r')\widetilde{\Sigma}_{k+1|T}^{r,s}\operatorname{inv}(B_rB_r')A_r \in \mathbb{R}^{n\times n}, \tag{4.14}$$

$$\begin{aligned} \tau_{k+1|T}^{r,s} \triangleq{}& A_r'\operatorname{inv}(B_rB_r')\widetilde{\Sigma}_{k+1|T}^{r,s} \\ &\times \big(C_r'\operatorname{inv}(D_rD_r')y_{k+1} + \operatorname{inv}(\Sigma_{k+1|T}^{r,s})\alpha_{k+1|T}^{r,s}\big) \in \mathbb{R}^n, \end{aligned} \tag{4.15}$$

$$\gamma_r \triangleq \operatorname{inv}(B_rB_r') + C_r'\operatorname{inv}(D_rD_r')C_r \in \mathbb{R}^{n\times n}, \tag{4.16}$$

$$\mu_{k+1}^r \triangleq C_r'\operatorname{inv}(D_rD_r')y_{k+1} + \operatorname{inv}(B_rB_r')A_rx \in \mathbb{R}^n, \tag{4.17}$$

$$\widetilde{\Sigma}_{k+1|T}^{r,s} \triangleq \operatorname{inv}\big(\gamma_r^{-1} + \Sigma_{k+1|T}^{r,s}\big) \in \mathbb{R}^{n\times n}. \tag{4.18}$$

(Note that the square matrices γ^r and $\widetilde{\Sigma}_{k+1|T}^{r,s}$ are symmetric.)

Proof. To prove Theorem 5, we first evaluate the integral in the recursion (4.8).

To complete the proof, the result of this calculation is written as a weighted sum of Gaussian densities.

Write

$$v_k^j(x) = \sum_{r=1}^{m} \frac{\pi_{(r,j)}}{|D_r||B_r|\Phi(y_{k+1})} I_a, \tag{4.19}$$

where

$$I_a \triangleq \int_{\mathbb{R}^n} \Phi\big(D_r^{-1}(y_{k+1} - C_r\xi)\big)\Psi(B_r^{-1}(\xi - A_r x))v_{k+1}^r(\xi)d\xi. \tag{4.20}$$

Completing the square of the exponentials in I_a, we see that

$$\begin{aligned} I_a = {} & \frac{1}{(2\pi)^{(n+d)/2}} \exp\Big\{\tfrac{1}{2}(\mu_{k+1}^r)' \operatorname{inv}(\gamma^r)\mu_{k+1}^r\Big\} \exp\Big\{-\tfrac{1}{2}y_{k+1}' \operatorname{inv}(D_r D_r')y_{k+1}\Big\} \\ & \times \exp\Big\{-\tfrac{1}{2}x' A_r' \operatorname{inv}(B_r B_r')A_r x\Big\} I_b. \end{aligned} \tag{4.21}$$

Here

$$I_b = \int_{\mathbb{R}^n} \exp\Big\{-\tfrac{1}{2}\big(\xi - \operatorname{inv}(\gamma^r)\mu_{k+1}^r\big)'\gamma_r\big(\xi - \operatorname{inv}(\gamma^r)\mu_{k+1}^r\big)\Big\} v_{k+1}^r(\xi)d\xi, \tag{4.22}$$

$$\gamma_r \triangleq C_r' \operatorname{inv}(D_r D_r')C_r + \operatorname{inv}(B_r B_r'), \tag{4.23}$$

$$\mu_{k+1}^r \triangleq C_r' \operatorname{inv}(D_r D_r')y_{k+1} + \operatorname{inv}(B_r B_r')A_r x. \tag{4.24}$$

Since $v_{k+1}^r(\xi)$ is a Gaussian mixture, the integrand of I_b is a product of Gaussian densities and can be evaluated with directly, that is,

$$\begin{aligned} I_b = {} & \sum_{s=1}^{M^v} \rho_{k+1}^{r,s} \int_{\mathbb{R}^n} \exp\Big\{-\tfrac{1}{2}\big(\xi - \operatorname{inv}(\gamma^r)\mu_{k+1}^r\big)'\gamma_r\big(\xi - \operatorname{inv}(\gamma^r)\mu_{k+1}^r\big)\Big\} \\ & \times \frac{1}{(2\pi)^{n/2}|\Sigma_{k+1|T}^{r,s}|^{\frac{1}{2}}} \exp\Big\{-\tfrac{1}{2}\big(\xi - \alpha_{k+1|T}^{r,s}\big)' \operatorname{inv}(\Sigma_{k+1|T}^{r,s})\big(\xi - \alpha_{k+1|T}^{r,s}\big)\Big\} d\xi \\ = {} & \sum_{s=1}^{M^v} \rho_{k+1}^{r,s} \Bigg[\frac{\big|\operatorname{inv}\big(\gamma^r + \operatorname{inv}(\Sigma_{k+1|T}^{r,s})\big)\big|^{\frac{1}{2}}}{\big|\Sigma_{k+1|T}^{r,s}\big|^{\frac{1}{2}}} \exp\big\{-\tfrac{1}{2}(\mu_{k+1}^r)' \operatorname{inv}(\gamma^r)\mu_{k+1}^r\big\} \\ & \times \exp\Big\{-\tfrac{1}{2}(\alpha_{k+1|T}^{r,s})' \operatorname{inv}(\Sigma_{k+1|T}^{r,s})\alpha_{k+1|T}^{r,s}\Big\} \\ & \times \exp\Big\{\tfrac{1}{2}\big(\mu_{k+1}^r + \operatorname{inv}\big(\Sigma_{k+1|T}^{r,s}\big)\alpha_{k+1|T}^{r,s}\big)' \operatorname{inv}\big(\gamma^r + \operatorname{inv}(\Sigma_{k+1|T}^{r,s})\big) \\ & \times \big(\mu_{k+1}^r + \operatorname{inv}(\Sigma_{k+1|T}^{r,s})\alpha_{k+1|T}^{r,s}\big)\Big\}\Bigg]. \end{aligned} \tag{4.25}$$

Recalling (4.19) and the terms I_a and I_b, we see that

$$
\begin{aligned}
v_k^j(x) = {} & \frac{1}{(2\pi)^{(d+n)/2}\,\Phi(y_{k+1})} \sum_{r=1}^{m}\sum_{s=1}^{M^v} \frac{\pi_{(r,j)}\rho_{k+1}^{r,s}\big|\big(\gamma^r + \operatorname{inv}(\Sigma_{k+1|T}^{r,s})\big)\big|^{\frac{1}{2}}}{|D_r||B_r||\Sigma_{k+1|T}^{r,s}|^{\frac{1}{2}}} \\
& \times \exp\Big\{-\tfrac{1}{2}x' A_r' \operatorname{inv}(B_r B_r') A_r x\Big\} \exp\Big\{-\tfrac{1}{2} y_{k+1}' \operatorname{inv}(D_r D_r') y_{k+1}\Big\} \\
& \times \exp\Big\{-\tfrac{1}{2}(\alpha_{k+1|T}^{r,s})' \operatorname{inv}(\Sigma_{k+1|T}^{r,s})\alpha_{k+1|T}^{r,s}\Big\} \\
& \times \exp\Big\{\tfrac{1}{2}(\alpha_{k+1|T}^{r,s})' \operatorname{inv}(\Sigma_{k+1|T}^{r,s})\widetilde{\Sigma}_{k+1|T}^{r,s}\Sigma_{k+1|T}^{r,s}\alpha_{k+1|T}^{r,s}\Big\} \\
& \times \exp\Big\{\tfrac{1}{2}\Big[(\mu_{k+1}^r)'\widetilde{\Sigma}_{k+1|T}^{r,s}\mu_{k+1}^r + (\mu_{k+1}^r)'\widetilde{\Sigma}_{k+1|T}^{r,s} \operatorname{inv}(\Sigma_{k+1|T}^{r,s})\alpha_{k+1|T}^{r,s} \\
& + (\alpha_{k+1|T}^{r,s})' \operatorname{inv}(\Sigma_{k+1|T}^{r,s})\widetilde{\Sigma}_{k+1|T}^{r,s}\mu_{k+1}^r\Big]\Big\}. \qquad (4.26)
\end{aligned}
$$

Consequently

$$
\begin{aligned}
v_k^j(x) = {} & \frac{1}{(2\pi)^{(d+n)/2}\Phi(y_{k+1})} \sum_{r=1}^{m}\sum_{s=1}^{M^v} \frac{\pi_{(r,j)}\rho_{k+1}^{r,s}\big|\operatorname{inv}\big(\gamma^r + \operatorname{inv}(\Sigma_{k+1|T}^{r,s})\big)\big|^{\frac{1}{2}}}{|D_r||B_r||\Sigma_{k+1|T}^{r,s}|^{\frac{1}{2}}} \\
& \times \exp\Big\{-\tfrac{1}{2}\big(\alpha_{k+1|T}^{r,s}\big)' \operatorname{inv}(\Sigma_{k+1|T}^{r,s})\big[I - \widetilde{\Sigma}_{k+1|T}^{r,s} \operatorname{inv}(\Sigma_{k+1|T}^{r,s})\big]\alpha_{k+1|T}^{r,s}\Big\} \\
& \times \exp\Big\{-\tfrac{1}{2} y_{k+1}' \operatorname{inv}(D_r D_r') y_{k+1}\Big\} \exp\Big\{-\tfrac{1}{2}\big(\widetilde{\Sigma}_{k+1|T}^{r,s} \operatorname{inv}(\Sigma_{k+1|T}^{r,s})\alpha_{k+1|T}^{r,s}\big)' \\
& \times \operatorname{inv}(\widetilde{\Sigma}_{k+1|T}^{r,s})\big(\widetilde{\Sigma}_{k+1|T}^{r,s} \operatorname{inv}(\Sigma_{k+1|T}^{r,s})\alpha_{k+1|T}^{r,s}\big)\Big\} \\
& \times \exp\Big\{\tfrac{1}{2}\big(C_r \operatorname{inv}(D_r D_r') y_{k+1} + \operatorname{inv}(\Sigma_{k+1|T}^{r,s})\alpha_{k+1|T}^{r,s}\big)' \\
& \times \operatorname{inv}(\widetilde{\Sigma}_{k+1|T}^{r,s})\big(C_r \operatorname{inv}(D_r D_r') y_{k+1} + \operatorname{inv}(\Sigma_{k+1|T}^{r,s})\alpha_{k+1|T}^{r,s}\big)\Big\} \\
& \times \exp\Big\{\tfrac{1}{2}(\tau_{k+1|T}^{r,s})' \operatorname{inv}(S_{k+1|T}^{r,s})\tau_{k+1|T}^{r,s}\Big\} \\
& \times \exp\Big\{-\tfrac{1}{2}\Big(x - \operatorname{inv}(S_{k+1|T}^{r,s})\tau_{k+1|T}^{r,s}\Big)' S_{k+1|T}^{r,s}\Big(x - \operatorname{inv}(S_{k+1|T}^{r,s})\tau_{k+1|T}^{r,s}\Big)\Big\}. \qquad (4.27)
\end{aligned}
$$

□

COROLLARY 2. *Write*

$$
v_k^j \triangleq \int_{\mathbb{R}^n} v_k^j(\xi)\,d\xi. \qquad (4.28)
$$

The scalar-valued quantity v_k^j is computed by the double sum

$$
v_k^j = \frac{1}{(2\pi)^{d/2}\Phi(y_{k+1})} \sum_{r=1}^{m}\sum_{s=1}^{M^v} \vartheta_{k+1,T}^v(j,r,s). \qquad (4.29)
$$

Here

$$
\vartheta_{k+1,T}^v(j,r,s) \triangleq K_{k+1,T}^v(j,r,s)|S_{k+1|T}^{r,s}|^{-\frac{1}{2}}. \qquad (4.30)
$$

The proof of Corollary 2 is immediate.

4.2. Suboptimal smoother dynamics.

4.2.1. Hypothesis management. Write

$$\Gamma^v \triangleq \{1,2,\dots,m\} \times \{1,2,\dots,M^v\}, \tag{4.31}$$

$$\widetilde{S}^v_{k+1,T}(j,r,s) \triangleq \big\{\vartheta^v_{k+1,T}(j,r,s)\big\}_{(r,s)\,\in\,\Gamma^v}. \tag{4.32}$$

As before, we propose, at each time k, to identify the M^v-best candidate functions (components in the Gaussian mixture) for each function $v^j_k(x)$. This maximization procedure is as follows:

$$\vartheta^v_{k+1,T}(j,r^*_1,s^*_1) \triangleq \max_{(r,s)\,\in\,\Gamma^v} \widetilde{S}^v_{k+1,T}(j,r,s), \tag{4.33}$$

$$\vartheta^v_{k+1,T}(j,r^*_2,s^*_2) \triangleq \max_{(r,s)\,\in\,\Gamma^v\setminus(r^*_1,s^*_1)} \widetilde{S}^v_{k+1,T}(j,r,s), \tag{4.34}$$

$$\vdots \qquad\qquad \vdots$$

$$\vartheta^v_{k+1,T}(j,r^*_{M^v},s^*_{M^v}) \triangleq \max_{(r,s)\,\in\,\Gamma^v\setminus\{(r^*_1,s^*_1),\dots,(r^*_{M^v-1},s^*_{M^v-1})\}} \widetilde{S}^v_{k+1,T}(j,r,s). \tag{4.35}$$

The optimal index set, for function $v^j_k(x)$, is

$$\mathcal{I}_k(j) \triangleq \big\{(r^*_{k,1},s^*_{k,1}),(r^*_{k,2},s^*_{k,2}),\dots,(r^*_{k,M^v},s^*_{k,M^v})\big\}. \tag{4.36}$$

Using these indexes, the order M^v equation for $v^j_k(x)$, whose memory requirements are fixed in time, has the form

$$\begin{aligned} v^j_k(x) \triangleq{}& \frac{1}{(2\pi)^{(d+n)/2}\Phi(y_{k+1})} \sum_{\ell=1}^{M^v} K^v_{k+1,T}(j,r^*_{k+1,\ell},s^*_{k+1,\ell}) \\ &\times \exp\Big\{-\tfrac{1}{2}\Big(x-\operatorname{inv}(S^{r^*_{k+1,\ell},s^*_{k+1,\ell}}_{k+1|T})\tau^{r^*_{k+1,\ell},s^*_{k+1,\ell}}_{k+1|T}\Big)' S^{r^*_{k+1,\ell},s^*_{k+1,\ell}}_{k+1,T} \\ &\times\Big(x-\operatorname{inv}(S^{r^*_{k+1,\ell},s^*_{k+1,\ell}}_{k+1|T})\tau^{r^*_{k+1,\ell},s^*_{k+1,\ell}}_{k+1|T}\Big)\Big\}. \end{aligned} \tag{4.37}$$

4.2.2. Smoother state statistics. Write, for the smoother density normalization constant,

$$\varphi_{k|T} \triangleq \sum_{j=1}^{m}\Big(\int_{\mathbb{R}^n}\big[q^j_k(\xi)v^j_k(\xi)\big]d\xi\Big). \tag{4.38}$$

Combining the functions $q^j_k(x)$ and $v^j_k(x)$, we see that the fixed interval smoothed estimate of state may be written as

$$\begin{aligned} \widehat{x}_{k|T} \triangleq E\big[x_t \mid \mathcal{Y}_{0,T}\big] &= \frac{\int_{\mathbb{R}^n}\xi\Big[\sum_{j=1}^m q^j_k(\xi)v^j_k(\xi)\Big]d\xi}{\int_{\mathbb{R}^n}\Big[\sum_{j=1}^m q^j_k(\xi)v^j_k(\xi)\Big]d\xi} \\ &= \frac{1}{\varphi_{k|T}}\int_{\mathbb{R}^n}\xi\left[\sum_{j=1}^m q^j_k(\xi)v^j_k(\xi)\right]d\xi \\ &= \frac{1}{\varphi_{k|T}}\sum_{j=1}^m\left[\int_{\mathbb{R}^n}\xi\Big[q^j_k(\xi)v^j_k(\xi)\Big]d\xi\right]. \end{aligned} \tag{4.39}$$

Since the functions $q_k(x)$ and $v_k(x)$ are each weighted Gaussian mixtures, the integrals in (4.39) can be evaluated exactly.

PROPOSITION 3. *The smoothed state estimate $\widehat{x}_{k|T}$, for Gaussian mixtures with orders M^q and M^v, has the following representation:*

$$\begin{aligned}
\widehat{x}_{k|T} = \frac{1}{\varphi_{k|T}} \sum_{j=1}^{m} \sum_{\ell=1}^{M^q} \sum_{i=1}^{M^v} \Bigg[& K^v_{k,k-1}(j, r^*_{k,l}, s^*_{k,\ell}) K^v_{k+1,T}(j, r^*_{k,i}, s^*_{k,i}) \\
& \times \left| \operatorname{inv}\left(\sigma_{k-1}^{r^*_{k,\ell}, s^*_{k,\ell}} + S_{k+1|T}^{r^*_{k+1,\ell}, s^*_{k+1,\ell}}\right) \right|^{\frac{1}{2}} \exp\left\{ \tfrac{1}{2} \left(\sigma_k^{r^*_{k,\ell}, s^*_{k,\ell}} + \tau_{k+1|T}^{r^*_{k+1,i} s^*_{k+1,i}} \right)' \right. \\
& \times \operatorname{inv}\left(\sigma_{k-1}^{r^*_{k,\ell}, s^*_{k,\ell}} + S_{k+1|T}^{r^*_{k+1,\ell}, s^*_{k+1,\ell}}\right) \left(\delta_k^{r^*_{k,\ell}, s^*_{k,\ell}} + \tau_{k+1|T}^{r^*_{k+1,i}, s^*_{k+1,i}} \right) \Bigg\} \\
& \times \exp\Big\{ -\tfrac{1}{2} \Big[(\tau_{k+1|T}^{r^*_{k+1,\ell}, s^*_{k+1,\ell}})' \operatorname{inv}(S_{k+1|T}^{r^*_{k+1,\ell}, s^*_{k+1,\ell}}) \tau_{k+1|T}^{r^*_{k+1,i}, s^*_{k+1,i}} + (\delta_k^{r^*_{k,\ell}, s^*_{k,\ell}})' \\
& \times \operatorname{inv}(\sigma_{k-1}^{r^*_{k,\ell}, s^*_{k,\ell}}) \delta_k^{r^*_{k,\ell}, s^*_{k,\ell}} \Big] \Big\} \\
& \times \operatorname{inv}\Big(\sigma_{k-1}^{r^*_{k,\ell}, s^*_{k,\ell}} + S_{k+1|T}^{r^*_{k+1,\ell}, s^*_{k+1,\ell}}\Big) \Big(\delta_k^{r^*_{k,\ell}, s^*_{k,\ell}} + \tau_{k+1|T}^{r^*_{k+1,i}, s^*_{k+1,i}} \Big) \Bigg]. \qquad (4.40)
\end{aligned}$$

Here

$$\begin{aligned}
\varphi_{k|T} = \sum_{j=1}^{m} \sum_{\ell=1}^{M^q} \sum_{i=1}^{M^v} \Bigg[& K^q_{k,k-1}(j, r^*_{k,\ell}, s^*_{k,\ell}) K^v_{k+1,T}(j, r^*_{k,i}, s^*_{k,i}) \\
& \times \exp\left\{ \tfrac{1}{2} \left(\delta_k^{r^*_{k,\ell}, s^*_{k,\ell}} + \tau_{k+1|T}^{r^*_{k+1,i}, s^*_{k+1,i}} \right) \operatorname{inv}\left(\sigma_{k-1}^{r^*_{k,\ell}, s^*_{k,\ell}} + S_{k+1|T}^{r^*_{k+1,\ell}, s^*_{k+1,\ell}} \right) \right. \\
& \times \left(\delta_k^{r^*_{k,\ell}, s^*_{k,\ell}} + \tau_{k+1|T}^{r^*_{k+1,i}, s^*_{k+1,i}} \right) \Big\} \exp\Big\{ -\tfrac{1}{2} \Big[\left(\tau_{k+1|T}^{r^*_{k+1,i}, s^*_{k+1,i}} \right)' \operatorname{inv}\left(S_{k+1|T}^{r^*_{k+1,\ell}, s^*_{k+1,\ell}} \right) \\
& \times \tau_{k+1|T}^{r^*_{k+1,i}, s^*_{k+1,i}} + \left(\delta_k^{r^*_{k,\ell}, s^*_{k,\ell}} \right)' \operatorname{inv}\left(\sigma_{k-1}^{r^*_{k,\ell}, s^*_{k,\ell}} \right) \delta_k^{r^*_{k,i}, s^*_{k,i}} \Big] \Big\} \\
& \times \left| \operatorname{inv}\left(\sigma_{k-1}^{r^*_{k,\ell}, s^*_{k,\ell}} + S_{k+1|T}^{r^*_{k+1,\ell}, s^*_{k+1,\ell}} \right) \right|^{\frac{1}{2}} \Bigg] \in \mathbb{R}. \qquad (4.41)
\end{aligned}$$

Proof.

$$\begin{aligned}
\widehat{x}_{k|T} &= \frac{1}{\varphi_{k|T}} \sum_{j=1}^{m} \left[\int_{\mathbb{R}^n} \xi \left[q_k^j(\xi) v_k^j(\xi) \right] d\xi \right] \\
&= \frac{1}{\varphi_{k|T}} \sum_{j=1}^{m} \Bigg[\int_{\mathbb{R}^n} \xi \Bigg(\frac{1}{(2\pi)^{(d+n)/2} \Phi(y_k)} \sum_{\ell=1}^{M^q} K^q_{k,k-1}(j, r^*_{k,\ell}, s^*_{k,\ell}) \\
&\quad \times \exp\left\{ -\tfrac{1}{2} \left(\xi - \operatorname{inv}(\sigma_{k-1}^{r^*_{k,\ell}, s^*_{k,\ell}}) \delta_k^{r^*_{k,\ell}, s^*_{k,\ell}} \right)' \sigma_{k-1}^{r^*_{k,\ell}, s^*_{k,\ell}} \right. \\
&\quad \times \left. \left(\xi - \operatorname{inv}(\sigma_{k-1}^{r^*_{k,\ell}, s^*_{k,\ell}}) \delta_k^{r^*_{k,\ell}, s^*_{k,\ell}} \right) \right\} \Bigg) \\
&\quad \times \Bigg(\frac{1}{(2\pi)^{(d+n)/2} \Phi(y_{k+1})} \sum_{i=1}^{M^v} K^v_{k+1,T}(j, r^*_{k,i}, s^*_{k,i}) \\
&\quad \times \exp\left\{ -\tfrac{1}{2} \left(\xi - \operatorname{inv}(S_{k+1|T}^{r^*_{k+1,\ell}, s^*_{k+1,\ell}}) \tau_{k+1|T}^{r^*_{k+1,\ell}, s^*_{k+1,\ell}} \right)' \right.
\end{aligned}$$

$$
\begin{aligned}
&\times S_{k+1,T}^{r^*_{k+1,\ell},s^*_{k+1,\ell}}\Big(\xi-\operatorname{inv}(S_{k+1|T}^{r^*_{k+1,\ell},s^*_{k+1,\ell}})\tau_{k+1|T}^{r^*_{k+1,\ell},s^*_{k+1,\ell}}\Big)\Big\}\Big)d\xi\Big]\\
&=\frac{1}{(2\pi)^{(d+n)}\Phi(y_k)\Phi(y_{k+1})\varphi_{k|T}}\sum_{j=1}^{m}\sum_{\ell=1}^{M^q}\sum_{i=1}^{M^v}\Big[K^q_{k,k-1}(j,r^*_{k,\ell},s^*_{k,\ell})\\

&\times\operatorname{inv}\Big(\sigma_{k-1}^{r^*_{k,\ell},s^*_{k,\ell}}+S_{k+1|T}^{r^*_{k+1,\ell},s^*_{k+1,\ell}}\Big)\Big(\delta_k^{r^*_{k,\ell},s^*_{k,\ell}}+\tau_{k+1|T}^{r^*_{k+1,i},s^*_{k+1,i}}\Big)\Big].\qquad\square
\end{aligned}
\tag{4.42}
$$

Remark 5. It is interesting to note that in the formulation of the smoother defined by (4.42), the integers M^q and M^v are mutually independent. This feature suggests that one is afforded an extra degree of freedom; that is, the practitioner can explicitly impose a desired accuracy in the contribution of the past (choice of M^q) and the contribution of the future (choice of M^v).

The smoother error covariance is defined as

$$
\begin{aligned}
\Sigma_{k|T}&\triangleq E\big[\big(x_k-\widehat{x}_{k|T}\big)\big(x_k-\widehat{x}_{k|T}\big)'|\mathcal{Y}_T\big]\\
&=\frac{1}{\varphi_{k|T}}\int_{\mathbb{R}^n}(\xi-\widehat{x}_{k|T})(\xi-\widehat{x}_{k|T})'\Bigg[\Bigg(\frac{1}{(2\pi)^{(d+n)/2}\Phi(y_k)}\sum_{\ell=1}^{M^q}K^q_{k,k-1}(j,r^*_{k,\ell},s^*_{k,\ell})\\
&\times\exp\Big\{-\tfrac{1}{2}\Big(\xi-\operatorname{inv}(\sigma_{k-1}^{r^*_{k,\ell},s^*_{k,\ell}})\delta_k^{r^*_{k,\ell},s^*_{k,\ell}}\Big)'\sigma_{k-1}^{r^*_{k,\ell},s^*_{k,\ell}}\Big(\xi-\operatorname{inv}(\sigma_{k-1}^{r^*_{k,\ell},s^*_{k,\ell}})\delta_k^{r^*_{k,\ell},s^*_{k,\ell}}\Big)\Big\}\Bigg)\\
&\times\Bigg(\frac{1}{(2\pi)^{(d+n)/2}\Phi(y_{k+1})}\sum_{i=1}^{M^v}K^v_{k+1,T}(j,r^*_{k,i},s^*_{k,i})\\
&\times\exp\Big\{-\tfrac{1}{2}\Big(\xi-\operatorname{inv}(S_{k+1|T}^{r^*_{k+1,\ell},s^*_{k+1,\ell}})\tau_{k+1|T}^{r^*_{k+1,\ell},s^*_{k+1,\ell}}\Big)'\\
&\times S_{k+1,T}^{r^*_{k+1,\ell},s^*_{k+1,\ell}}\Big(\xi-\operatorname{inv}(S_{k+1|T}^{r^*_{k+1,\ell},s^*_{k+1,\ell}})\tau_{k+1|T}^{r^*_{k+1,\ell},s^*_{k+1,\ell}}\Big)\Big\}\Bigg)\Bigg]d\xi=\widehat{\Sigma}_{k|T}.
\end{aligned}
\tag{4.43}
$$

PROPOSITION 4. *The smoother state error covariance $\widehat{\Sigma}_{k|T}$, for Gaussian mixtures with orders M^q and M^v, has the following representation:*

$$
\begin{aligned}
\widehat{\Sigma}_{k|T} = \frac{1}{\varphi_{k|T}} \sum_{j=1}^{m} \sum_{\ell=1}^{M^q} \sum_{i=1}^{M^v} & \\
& \times \Bigg[K^q_{k,k-1}(j, r^*_{k,\ell}, s^*_{k,\ell}) K^v_{k+1,T}(j, r^*_{k,i}, s^*_{k,i}) \Big| \operatorname{inv}\Big(\sigma_{k-1}^{r^*_{k,\ell}, s^*_{k,\ell}} + S_{k+1|T}^{r^*_{k+1,\ell}, s^*_{k+1,\ell}} \Big) \Big|^{\frac{1}{2}} \\
& \times \exp\Big\{ \tfrac{1}{2} \Big(\big(\tau_{k+1|T}^{r^*_{k+1,i}, s^*_{k+1,i}} \big)' \operatorname{inv}\big(S_{k+1|T}^{r^*_{k+1,\ell}, s^*_{k+1,\ell}} \big) \tau_{k+1|T}^{r^*_{k+1,i}, s^*_{k+1,i}} \\
& \times \big(\delta_k^{r^*_{k,\ell}, s^*_{k,\ell}} \big)' \operatorname{inv}\big(\sigma_{k-1}^{r^*_{k,\ell}, s^*_{k,\ell}} \big) \delta_k^{r^*_{k,\ell}, s^*_{k,\ell}} \Big) \Big\} \\
& \times \Big[\operatorname{inv}\Big(\sigma_{k-1}^{r^*_{k,\ell}, s^*_{k,\ell}} + S_{k+1|T}^{r^*_{k+1,\ell}, s^*_{k+1,\ell}} \Big) \\
& + \Big(\operatorname{inv}\big(\sigma_{k-1}^{r^*_{k,\ell}, s^*_{k,\ell}} + S_{k+1|T}^{r^*_{k+1,\ell}, s^*_{k+1,\ell}} \big) \big(\delta_k^{r^*_{k,\ell}, s^*_{k,\ell}} + \tau_{k+1|T}^{r^*_{k+1,i}, s^*_{k+1,i}} \big) - \widehat{x}_{k|T} \Big) \\
& \times \Big(\operatorname{inv}\big(\sigma_{k-1}^{r^*_{k,\ell}, s^*_{k,\ell}} + S_{k+1|T}^{r^*_{k+1,\ell}, s^*_{k+1,\ell}} \big) \big(\delta_k^{r^*_{k,\ell}, s^*_{k,\ell}} + \tau_{k+1|T}^{r^*_{k+1,i}, s^*_{k+1,i}} \big) - \widehat{x}_{k|T} \Big)' \Big] \Bigg].
\end{aligned} \tag{4.44}
$$

The proof of Proposition 4 is similar to the proof of Proposition 2, and so it is omitted.

5. Example. In this section we illustrate the performance of the new hybrid filter state estimator presented in section 3.2.2. Two scenarios are considered. In the first example, the Markov chain transition matrix is fixed and simulations are computed for five different values of signal-to-noise ratio (SNR). In the second example, we consider two different transition matrices. For each of our examples, comparisons are provided against the IMM algorithm (with standard Kalman filters). All the examples consider the same scalar-valued state process x and we set $m = 3$. Further, the order of the Gaussian mixtures is fixed at $M^q = 5$. For our first example, we set

$$
H_1 \triangleq \big\{ A_{H_1} = 1, B_{H_1} = 0.05, C_{H_1} = 1 \big\}, \tag{5.1}
$$

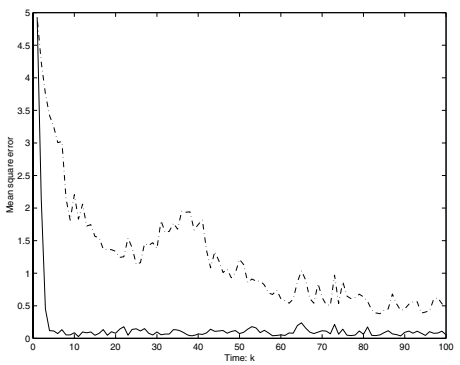
$$
H_2 \triangleq \big\{ A_{H_2} = 0.9, B_{H_2} = 0.01, C_{H_2} = 2 \big\}, \tag{5.2}
$$

$$
H_3 \triangleq \big\{ A_{H_3} = 1.1, B_{H_3} = 0.1, C_{H_3} = 1.5 \big\} \tag{5.3}
$$

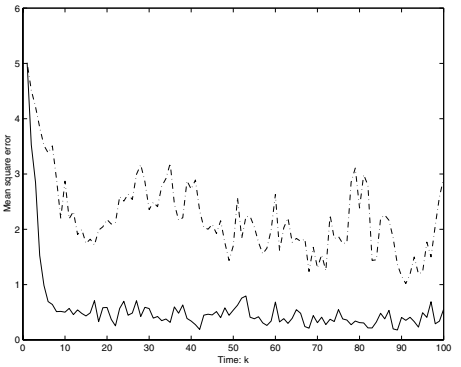
and

$$
\Pi \triangleq \begin{bmatrix} 0.8 & 0.2 & 0.2 \\ 0.1 & 0.6 & 0.2 \\ 0.1 & 0.2 & 0.6 \end{bmatrix}. \tag{5.4}
$$

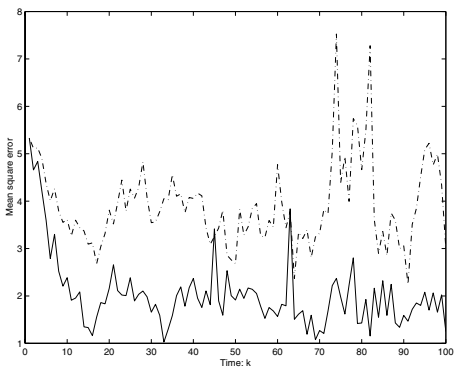
The initial state x_0 is a Gaussian random variable, with mean 10 and covariance 10. Each of the five Figures 5.1(a)–(e) shows simulations at different levels of SNR, which was varied only through the noise gain on the state dynamics; that is, SNR Case 1 $\big\{ D_{H_1} = 0.5, D_{H_2} = 0.25, D_{H_3} = 0.5 \big\}$, SNR Case 2 $\big\{ D_{H_1} = 1, D_{H_2} = 0.5, D_{H_3} = 1 \big\}$, SNR Case 3 $\big\{ D_{H_1} = 2, D_{H_2} = 1, D_{H_3} = 2 \big\}$, SNR Case 4 $\big\{ D_{H_1} = 4, D_{H_2} = 2, D_{H_3} = 4 \big\}$, SNR Case 5 $\big\{ D_{H_1} = 8, D_{H_2} = 4, D_{H_3} = 8 \big\}$. For these five scenarios, Monte Carlo simulations were computed, consisting of 100 trials and discrete time indexed from $k = 1$ to $k = 100$. The corresponding mean square errors for the IMM and the new hybrid filter are given in Figures 5.1(a)–(e).



(a) Case 1



(b) Case 2



(c) Case 3

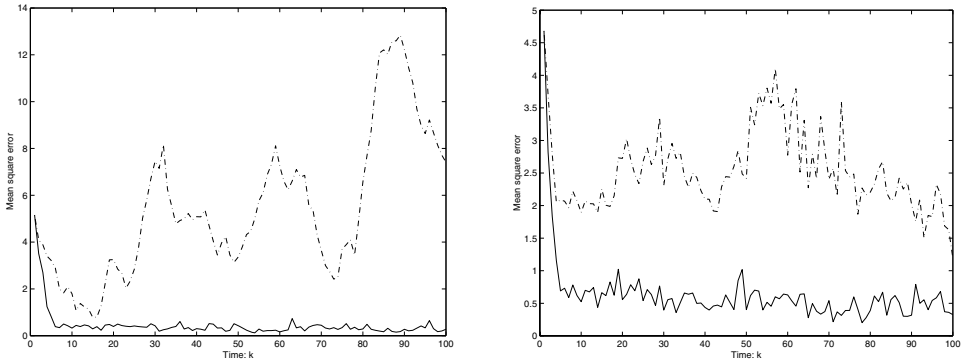
(e) Case 5

FIG. 5.1. *SNR performance of the IMM (dash-dotted line) and the new hybrid filter (solid line) with* $M^q = 5$.



(a) Case 6 (b) Case 7

FIG. 5.2. *Fast and slow switching Markov chain comparison of the IMM (dash-dotted line) and the new hybrid filter (solid line) with* $M^q = 5$.

In our second example, two different values of the parameter Π were considered, with

$$\text{(5.5)} \quad \Pi \text{ Case 6} \qquad \Pi \triangleq \begin{bmatrix} 0.8 & 0.1 & 0.1 \\ 0.1 & 0.8 & 0.1 \\ 0.1 & 0.1 & 0.8 \end{bmatrix}, \qquad \Pi \text{ Case 7} \qquad \Pi \triangleq \begin{bmatrix} 0.4 & 0.3 & 0.3 \\ 0.3 & 0.4 & 0.3 \\ 0.3 & 0.3 & 0.4 \end{bmatrix}.$$

In this example, the same model parameters from the first example were used, that is, H_1, H_2, and H_3, with the state noise gains set at $\{D_{H_1} = 1, D_{H_2} = 0.5, D_{H_3} = 1\}$. In all these cases, the new hybrid filter significantly outperforms the IMM. In Cases 4 and 5 (see Figures 5.1(d) and (e)), when the SNR is very low the performances of these two algorithms are comparable. For the Cases 1 to 3, when the SNR is standard or high, the suboptimal filter is more efficient than the IMM (see Figures 5.1(a)–(c)). The same conclusion can be made when the Markov chain Z jumps slowly or rapidly (see Cases 6 and 7 and Figures 5.2(a) and (b)).

ASYMPTOTIC STABILIZABILITY BY STATIONARY FEEDBACK OF THE TWO-DIMENSIONAL EULER EQUATION: THE MULTICONNECTED CASE*

OLIVIER GLASS†

Abstract. We construct a feedback law which allows us to asymptotically stabilize the Euler system for incompressible inviscid fluids in two dimensions, in the case of a multiconnected bounded domain, by means of a control localized on a part of the boundary that meets every connected component of the boundary. This generalizes a result of Coron [*SIAM J. Control Optim.*, 37 (1999), pp. 1874–1896] concerning simply connected domains.

Key words. incompressible inviscid fluids, stabilization by feedback control

1. Introduction.

1.1. Statement of the problem. In this paper, we are concerned with the null asymptotic stabilization by means of a stationary feedback of the Euler system for inviscid incompressible fluids in two space dimensions, namely, the following system:

$$\begin{cases} \partial_t v(t,x) + (v(t,x).\nabla)v(t,x) + \nabla p(t,x) = 0 \text{ for } (t,x) \text{ in } [0,T^*) \times \Omega, \\ \operatorname{div} v(t,x) = 0 \text{ for } (t,x) \text{ in } [0,T^*) \times \Omega. \end{cases} \tag{1.1}$$

In the above equation, t is the time (the problem under consideration is formulated for $T^* = +\infty$), and x is the position in the domain Ω. The function $v : [0,T^*) \times \Omega \to \mathbb{R}^2$ is the velocity field and $p : [0,T^*) \times \Omega \to \mathbb{R}$ is the pressure. The domain Ω is two-dimensional (2-D), bounded, regular and nonsimply connected (let us agree that the boundary $\partial\Omega$ is decomposed into $\partial\Omega = \Gamma_0 \cup \cdots \cup \Gamma_g$, where the components Γ_i are nonempty, connected, and disjoint).

The initial-boundary problem for equation (1.1) has been studied by Yudovich (see [10]). Given initial data

$$v_{|t=0} = v_0 \text{ in } \Omega, \tag{1.2}$$

where $v_0 : \overline{\Omega} \to \mathbb{R}^2$ is a divergence-free vector field, and appropriate boundary conditions, the system is well-posed. The boundary conditions can be taken as the following data:

- the normal component of the velocity $v(t,x) \cdot n(x)$ on the whole boundary $\partial\Omega$ for any time ($n(x)$ is the unit outward normal on $\partial\Omega$), which has to satisfy

$$\int_{\partial\Omega} v(t,x) \cdot n(x) dx = 0 \quad \forall t \in [0,T^*),$$

†Laboratoire Jacques-Louis Lions, Université Pierre et Marie Curie, Boîte courrier 187, 75252 Paris Cedex 05, France (glass@ann.jussieu.fr).

- the vorticity $\omega(t,x) := \operatorname{curl} v(t,x)$ at the points of $\partial\Omega$ which, moved by the velocity flow, enter inside Ω, namely, the points in

$$\Sigma^-_{T^*} := \{(t,x) \in [0,T^*) \times \partial\Omega \ / \ v(t,x) \cdot n(x) < 0\}\,.$$

Let us emphasize that certain compatibility conditions between the solution and the boundary data must be taken into account in order to obtain a solution with suitable regularity.

In this paper, the boundary conditions (or a part of them) will be considered as a control (that is, a parameter to be determined, that we choose to influence the system). More precisely, we fix Σ an open part of the boundary; the part Σ of the boundary is the zone where we can choose the boundary conditions, whereas $\partial\Omega \setminus \Sigma$ represents a wall that cannot be crossed. In other words, we will consider the Euler system with

- the constraint

$$v(t,x) \cdot n(x) = 0 \quad \text{on } [0,T^*) \times (\partial\Omega\backslash\Sigma); \tag{1.3}$$

that is, the fluid cannot enter or quit the domain through $\partial\Omega\backslash\Sigma$ (it must slip on it),

- the boundary condition on $[0,T^*) \times \Sigma$, which is the control to be chosen.

In this setting, the problem of controllability (i.e., to steer a prescribed initial state v_0 to a prescribed final state v_1 in an arbitrary time by choosing a relevant control) was answered affirmatively by Coron in [2], under the necessary condition that Σ meets each connected component of the boundary.

Here we are interested in the problem of asymptotic stabilizability of the equilibrium $v \equiv 0$ by means of a stationary feedback. In other words, we want to find a continuous function f of the state $\mathcal{S}(t)$ of the system at time t such that if the control $\mathcal{C}(t)$ is given at each time by $\mathcal{C}(t) = f(\mathcal{S}(t))$, then the resulting closed system makes 0 globally asymptotically stable in the sense that

- any solution defined on $[0,T^*) \times \overline{\Omega}$ with $T^* < +\infty$ can be extended for $t \geq T^*$;
- for any neighborhood $\mathcal{U}$ of 0, one can find another neighborhood $\mathcal{V}$ of 0 such that any solution of the closed system beginning in $\mathcal{V}$ is in $\mathcal{U}$ for any $t \geq 0$;
- any solution tends to 0 as $t \to +\infty$.

The above-mentioned problem was solved by Coron in the case of a simply connected domain; see [4].

Remark 1. As was already the case in the controllability problem, the condition that Σ meets any connected component of the boundary is a necessary condition to solve the problem. For instance, the vorticity around any "uncontrolled" connected component just slips on it and cannot be "modified." Another obstruction is the Kelvin law which states that the velocity circulation around any uncontrolled connected component of the boundary is constant. Throughout this paper, we will suppose that Σ meets every connected component of the boundary.

1.2. Mathematical setting. We have to specify which data will be the state of the system, and also the precise structure of the control. A natural state to consider would be the whole velocity field $v(t,\cdot)$ in $\overline{\Omega}$, but if we chose $\mathcal{S}$ this way, then (as we will consider solutions that are continuous up to the boundary) it would completely determine the choice of the control (since the boundary conditions described above would be given by the normal component of the trace of v on $[0,T^*) \times \Sigma$ and by the trace of $\operatorname{curl} v$ on $\Sigma^-_{T^*}$).

To avoid such a problem, as suggested in [3], we shall consider the following data as the state of the system:

$$\mathcal{S}(t) = (\omega(t,\cdot), \lambda_1(t), \dots, \lambda_g(t)), \tag{1.4}$$

where $\omega(t,\cdot) : \overline{\Omega} \to \mathbb{R}$ is the vorticity field (which is scalar in two dimensions), that is,

$$\omega(t,x) := \operatorname{curl} v(t,x),$$

and where λ_i, for $i = 1, \dots, g$, is the velocity circulation around the component Γ_i of $\partial\Omega$, that is,

$$\lambda_i(t) := \int_{\Gamma_i} v(t,x) \cdot \vec{\tau}(x) dx.$$

Here $\vec{\tau}(x)$ is the unit tangent vector field on $\partial\Omega$, chosen so that $(\vec{\tau}, n)$ should be direct. (Let us remark that consequently $\vec{\tau}$ endows the curve Γ_i with an orientation that is positive if the curve is an inner component of $\partial\Omega$ and negative in the case of the outer component.)

Remark 2. Of course, only g circulations of v around Γ_i are needed among $(g+1)$ available, since the sum of all these circulations is related to ω by Green's formula.

Once given the state $\mathcal{S}(t)$ and $v(t,x) \cdot n(x)$ on Σ (which is a part of the control, say $\mathcal{C}_1$), one can reconstruct $v(t,\cdot)$ in $\overline{\Omega}$, for each $t \in [0, T^*)$, by means of the following system:

$$\begin{cases} \operatorname{curl} v(t,\cdot) = \omega(t,\cdot) \quad \text{in } \Omega, \\ \operatorname{div} v(t,\cdot) = 0 \quad \text{in } \Omega, \\ v(t,\cdot) \cdot n(\cdot) = \mathcal{C}_1(t) \quad \text{on } \Sigma, \\ v(t,\cdot) \cdot n(\cdot) = 0 \quad \text{on } \partial\Omega \setminus \Sigma, \\ \displaystyle\int_{\Gamma_i} v(t,x).\vec{\tau}(x) dx = \lambda_i(t) \quad \text{for } i = 1, \dots, g. \end{cases} \tag{1.5}$$

The Euler equation can be written in terms of the state $\mathcal{S}(t)$: as is well known, the vorticity in two dimensions satisfies

$$\partial_t \omega + (v \cdot \nabla)\omega = 0 \quad \text{in } (0, T^*) \times \Omega, \tag{1.6}$$

or, equivalently,

$$\partial_t \omega + \operatorname{div}(\omega v) = 0 \quad \text{in } (0, T^*) \times \Omega, \tag{1.7}$$

and the velocity circulations satisfy

$$\lambda_i(t) - \lambda_i(0) = \int_0^t \int_{\Gamma_i} v(s,x) \cdot n(x) \omega(s,x) dx ds. \tag{1.8}$$

One easily sees that the group composed of (1.5), (1.7), and (1.8) is equivalent to (1.1).

We still need to specify the exact structure of the control that we use. The first part of the control is the normal component of the velocity on Σ, which we call $\mathcal{C}_1$. We must stipulate the other part of the control, which concerns the entering vorticity.

Since $\omega(t,\cdot)$ is now a part of the state, it seems inappropriate to consider ω on $\Sigma^-_{T^*}$ as the second part of the control (as will be specified below, $\omega(t,\cdot)$ is continuous

up to the boundary in our problem). Thus a natural control to consider would be the following:

$$\mathcal{C}(t) = \begin{cases} v(t,x)\cdot n(x) & \text{on } \Sigma, \\ \partial_t \omega(t,x) & \text{on } \Sigma^-, \end{cases} \tag{1.9}$$

with Σ^- given by

$$\Sigma^- := \{x \in \partial\Omega \ / \ v(t,x)\cdot n(x) < 0\}. \tag{1.10}$$

(To simplify the notation, we omit the dependence of Σ^- on t and $\mathcal{C}_1$—besides, essentially, Σ^- will be constant in what follows.)

Let us point out that the control described in (1.9) was the one used in [4]. However, for technical reasons that will be explained in section 2.1, we will have to consider the following control of *mixed type*:

$$\mathcal{C}(t) = (\mathcal{C}_1(t), \mathcal{C}_2(t), \mathcal{C}_3(t)), \tag{1.11}$$

with

$$\mathcal{C}_1 = v(t,x)\cdot n(x) \quad \text{on } \Sigma, \tag{1.12}$$

$$\mathcal{C}_2 = \partial_t \omega_1(t,x) \quad \text{on } \Sigma^-, \tag{1.13}$$

$$\mathcal{C}_3 = \omega_2(t,x) \quad \text{on } \Sigma^-, \tag{1.14}$$

and the boundary condition for the entering vorticity obtained as

$$\omega(t,x) = \omega_1(t,x) + \omega_2(t,x) \quad \text{on } \Sigma^-. \tag{1.15}$$

In other words, the entering vorticity ω is the sum of two terms: ω_1, whose time derivative we control, and ω_2, which we control directly.

Remark 3. Let us remark that this choice of the form of the control is important. Indeed, even the stabilizability by means of a simpler feedback law of the form $\partial_t \mathcal{C} = f(\mathcal{S})$ does not necessarily imply the stabilizability by means of a feedback law of the form $\mathcal{C} = f(\mathcal{S})$. See, for instance, [5] in the context of finite-dimensional systems.

We can now be more specific about the problem under study.

Definition 1.1. *Given a feedback law*

$$(\mathcal{C}_1, \mathcal{C}_2, \mathcal{C}_3) = (\mathcal{C}_1(\mathcal{S}), \mathcal{C}_2(\mathcal{S}), \mathcal{C}_3(\mathcal{S})),$$

1. *we shall call "the closed-loop system," with $\mathcal{S}$ as the unknown, the system* (1.5), (1.7), (1.8), *with boundary conditions given by* (1.12)–(1.15);
2. *we shall call $\mathcal{S} = (\omega, \lambda_1, \dots, \lambda_g)$ a solution of the closed-loop system if*
   - *$\mathcal{S} \in C^0([0,T^*) \times \overline{\Omega}; \mathbb{R}) \times C^0([0,T^*), \mathbb{R})^g$ (for some $T^* > 0$);*
   - *$v(t,\cdot)$ being for each $t \in [0,T^*)$ the unique solution (in the sense of distributions in Ω) of* (1.5), *the functions $(\lambda_i)_{i=1,\dots,g}$ satisfy* (1.8) *for all $t \in [0,T^*)$, and ω satisfies* (1.7) *in the sense of distributions in $(0,T^*) \times \Omega$ and* (1.13)–(1.15) *in the sense of distributions on the open manifold*

$$\Big\{(t,x) \in (0,T^*) \times \Sigma, \ \mathcal{C}_1[\mathcal{S}(t)](x) < 0\Big\};$$

3. *we call "maximal" any solution that cannot be extended over its maximal time T^*.*

The purpose of this paper is to establish the following result.

THEOREM 1.2. *If Σ meets every connected component of the boundary, one can find three continuous functions $\mathcal{C}_1$, $\mathcal{C}_2$, and $\mathcal{C}_3$ defined on $C^0(\overline{\Omega};\mathbb{R}) \times \mathbb{R}^g$ and with values in $C^0(\Sigma;\mathbb{R})$, $C^0(\Sigma^-;\mathbb{R})$, and $C^0(\Sigma^-;\mathbb{R})$, respectively, such that the following properties are fulfilled:*

P1. *For any $(\omega_0, \lambda_1^0, \dots, \lambda_g^0) \in C^0(\overline{\Omega};\mathbb{R}) \times \mathbb{R}^g$, the closed-loop system with initial condition*

$$\mathcal{S}(0) = (\omega_0, \lambda_1^0, \dots \lambda_g^0) \tag{1.16}$$

has a global in time solution, and any local in time solution can be extended to $T^* = +\infty$ (in other words, any maximal solution is global).

P2. *For any $\varepsilon > 0$, there exists $\eta > 0$ such that if*

$$\max(\|\omega_0\|_{L^\infty(\Omega)}, |\lambda_1^0|, \dots, |\lambda_g^0|) < \eta,$$

then one has

$$\max(\|\omega(t,\cdot)\|_{L^\infty(\Omega)}, |\lambda_1(t)|, \dots, |\lambda_g(t)|) \le \varepsilon,$$

for all $t \ge 0$ and any global in time solution of the closed-loop system satisfying (1.16).

P3. *Any global in time solution of the closed-loop system satisfies*

$$\max(\|\omega(t,\cdot)\|_{L^\infty(\Omega)}, |\lambda_1(t)|, \dots, |\lambda_g(t)|) \to 0 \text{ as } t \to +\infty.$$

We will describe in section 2 the feedback law $(\mathcal{C}_1(\mathcal{S}), \mathcal{C}_2(\mathcal{S}), \mathcal{C}_3(\mathcal{S}))$ which involves Theorem 1.2. The precise result expressed in terms of this feedback law is given in section 2.5.

1.3. A related problem concerning the stationary equation. As pointed out in [3], the problem of asymptotic stabilizability by stationary feedback is connected with a problem concerning the stationary equation. Indeed, Brockett established a necessary condition for a finite-dimensional control system to be stabilizable; see [1].

THEOREM 1.3 (see Brockett [1]). *A necessary condition for the control system $\dot{x} = f(x,u)$ to be locally asymptotically stabilizable at the equilibrium point x_0 (satisfying $f(x_0,0) = 0$) by a stationary feedback is that the image by f of any neighborhood of $(x_0,0)$ is a neighborhood of 0.*

The corresponding statement of this necessary condition in the infinite-dimensional system considered here is precisely what is proved in [6], that is, the existence of solutions for the stationary problem with a small force term (and by scaling arguments, with any force term). Hence, the study in [6] can be viewed as a preliminary step before this one. As we will see in section 2, some tools developed in [6] are essential in the construction here. For more details, see [3], [4], and [6].

1.4. Structure of the paper. In the next section, we begin by giving the main ideas concerning the construction of the feedback law that yields Theorem 1.2, then we detail this construction (which is rather involved), and finally we state our precise result (Theorem 2.4), which takes the stated form of the feedback law into account and clearly involves Theorem 1.2.

In section 3, we fix the notation and give preliminary elementary statements, which are classical for the construction of global in time solutions to the Euler system

in two dimensions. At the end of this section, a proposition that is central in the proof is stated.

Sections 4 and 5 prove the existence of local in time solutions of the closed-loop system defined with the control law introduced in section 2. This is done in two steps. In section 4, we construct a certain operator $\mathcal{F}$. Then section 5 proves by Schauder's fixed point theorem that the operator $\mathcal{F}$ has fixed points, which actually give local in time solutions to the closed-loop system.

Section 6 finishes the proof of Theorem 2.4, by proving that maximal solutions of the closed-loop system are global and satisfy the asymptotic stability properties P2 and P3 described in Theorem 1.2.

Finally, we put in the appendix the proofs of the most technical lemmas.

2. Description of the feedback.

2.1. Basic ideas. The most important feature of the 2-D Euler equation is a straightforward consequence of (1.6) (or (1.7)), precisely the following:

(2.1) the vorticity ω follows the flow of the velocity v.

A direct consequence of this fact is that, to perform P3 in Theorem 1.2, a global solution of the closed-loop has to satisfy

(2.2) the flow of the velocity v makes any point in $\overline{\Omega}$ go out of the domain

(except perhaps for configurations with important zones of null vorticity from the beginning, but this situation is essentially nongeneric).

To get (2.2), we examine the Hodge decomposition of the velocity, which in non-simply connected domains takes the following form (as usual, $\nabla^\perp := (-\partial_{x^2}, \partial_{x^1})$):

$$v(t,x) = \nabla\phi(t,x) + \nabla^\perp\psi(t,x) + \sum_{k=1}^{g} \mu_i(t)\nabla^\perp\tau_i, \tag{2.3}$$

where $\tau_i \in C^\infty(\overline{\Omega};\mathbb{R})$, $i \in \{1,\dots,g\}$, is the solution of the system

$$\begin{cases} \Delta\tau_i = 0 & \text{in } \Omega, \\ \tau_i = 1 & \text{on } \Gamma_i, \\ \tau_i = 0 & \text{on } \partial\Omega\backslash\Gamma_i, \end{cases} \tag{2.4}$$

and where the different terms satisfy, for each t,

$$\begin{cases} \Delta\phi(t,x) = 0 & \text{in } \Omega, \\ \partial_n\phi(t,x) = v(t,x)\cdot n(x) & \text{on } \partial\Omega, \end{cases} \tag{2.5}$$

$$\begin{cases} \Delta\psi(t,x) = \operatorname{curl} v(t,x) & \text{in } \Omega, \\ \psi(t,x) = 0 & \text{on } \partial\Omega, \end{cases} \tag{2.6}$$

$$\lambda_i(t) = -\sum_{j=1}^{g} \mu_j(t)\left(\int_\Omega \nabla\tau_i\cdot\nabla\tau_j\right) - \int_\Omega \omega(t,x)\tau_i(x)dx \quad \forall\, i \in \{1,\dots,g\}. \tag{2.7}$$

The family $\nabla^\perp\tau_i$ being clearly linearly independent, the matrix $(\int_\Omega \nabla\tau_i.\nabla\tau_j)_{i,j=1,\dots,n}$ is invertible.

Now to obtain (2.2), it seems rather arduous to rely on the last two terms in (2.3), because μ_j and $\nabla^\perp\psi$ are fixed at the beginning by the state and then slowly evolve

according to the flow of v itself. On the contrary, the $\nabla\phi$ part is directly obtained from the control. Hence a natural idea, which is also present in [2], [4], and [6], is to fix the $v \cdot n$ part of the control so that the $\nabla\phi$ part in (2.3) should prevail over the other two in such a way that (2.2) is satisfied.

As in [4], this program is fulfilled by finding a function $\theta : \overline{\Omega} \to \mathbb{R}$ such that

$$\begin{cases} \Delta\theta = 0 \quad \text{in } \Omega, \\ \partial_n\theta = 0 \quad \text{on } \partial\Omega \setminus \Sigma, \\ |\nabla\theta(x)| > 0 \quad \text{in } \overline{\Omega}. \end{cases} \tag{2.8}$$

Indeed, given such a function θ, one can hope that the control

$$\mathcal{C}_1 = f(\omega, \lambda_1, \dots, \lambda_g)\partial_n\theta \tag{2.9}$$

with $f(\omega, \lambda_1, \dots, \lambda_g)$ an adequate nonnegative function, which should be large when $(\omega, \lambda_1, \dots, \lambda_g)$ is large, will satisfy the requirements.

Once this part of the control is imposed, the idea is to choose the vorticity part of the control in the form

$$\partial_t\omega = -K(\omega, \lambda_1, \dots, \lambda_g)\omega \quad \text{in } \Sigma^-,$$

where $K(\omega, \lambda_1, \dots, \lambda_g)$ is an appropriate positive function. In this way, one can hope that the vorticity inside the domain will gradually be replaced by a smaller one.

However, there remain two issues:

- This might not be sufficient to get rid of the velocity circulations. The natural idea to diminish these circulations is to inject additional vorticity through $\Sigma^- \cap \Gamma_i$, as motivated by (1.8). This can raise a problem, because this injected vorticity could influence the other λ_j. In order to avoid this, we make this vorticity leave the domain through Γ_0.
- Because of (2.1), at a point of $\partial\Sigma^-$ where v is *pointing inside* Σ^-, there must be compatibility conditions on the control in vorticity so that the solution will have proper regularity. The reason for this is that, on one side of this point in $\partial\Omega$, the vorticity is determined by the control, whereas on the other side, it is determined by the incoming flow along the uncontrolled part of the boundary (see the points A in figures below). This is the main reason we must consider a control in the form (1.11)–(1.15): the continuity of the entering vorticity at this point is ensured by the $\mathcal{C}_3$-part of the control.
  Moreover, it will be technically simpler if these points in $\partial\Sigma^-$ where v is pointing inside Σ^- do not depend on the state. In fact, it can be expected that by choosing f in (2.9) properly, these points will be exactly those for which $\nabla\theta$ is pointing inside Σ^-.

Remark 4. It would seem natural to require the function θ to satisfy, besides (2.8),

(2.10)
at any point of $\partial\gamma^-$, $\nabla\theta$ is pointing outside γ^-, where $\gamma^- = \{x \in \Sigma \ / \ \partial_n\theta(x) < 0\}$.

In the case of a simply connected domain, this is possible; see [4]. But this is no longer possible in the case of a nonsimply connected domain, since this would result in a null index of the vector field $\nabla\theta$ around the outer component of the boundary

and in positive indices of $\nabla\theta$ around inner components, which would be inconsistent with (2.8).

Now that we have sketched the main ideas, we can construct a function θ satisfying (2.8); other conditions are required, either for technical reasons or to address the above-mentioned issues. The feedback law, which relies on θ, is constructed subsequently.

2.2. The function θ. The function θ that we introduce here has been used to prove the existence of solutions for the stationary problem; see section 1.3 and reference [6]. Precisely, we have the following result.

PROPOSITION 2.1 (see [6, Prop. 1]). *Consider Ω a nonempty, bounded, connected and regular domain in $\mathbb{R}^2$, assumed to be not simply connected. Denote $\Gamma_0, \dots, \Gamma_g$ the connected components of its boundary. Let n be the unit outward normal on $\partial\Omega$. Consider Σ an open part of $\partial\Omega$, which meets each connected component of $\partial\Omega$. Then there exists a function $\tilde{\theta} \in C^\infty(\overline{\Omega};\mathbb{R})$ that satisfies the following conditions:*

$$\Delta\tilde{\theta} = 0 \quad \text{in } \Omega, \tag{2.11}$$

$$\partial_n\tilde{\theta} = 0 \quad \text{on } \partial\Omega\backslash\Sigma, \tag{2.12}$$

$$|\nabla\tilde{\theta}(x)| > 0 \quad \text{for any } x \text{ in } \overline{\Omega}, \tag{2.13}$$

$$\text{for } \gamma^+(\tilde{\theta}) := \{x \in \partial\Omega \ / \ \partial_n\tilde{\theta} > 0\} \quad \text{and} \quad \gamma^-(\tilde{\theta}) := \{x \in \partial\Omega \ / \ \partial_n\tilde{\theta} < 0\}, \tag{2.14}$$
$$\text{one has: } \overline{\gamma^+(\tilde{\theta})} \cap \overline{\gamma^-(\tilde{\theta})} = \emptyset,$$

$$\gamma^+(\tilde{\theta}) \text{ and } \gamma^-(\tilde{\theta}) \text{ are unions of a finite number of intervals of } \partial\Omega \text{ with disjoint closures,} \tag{2.15}$$

$$\text{there exist } g \text{ points } \tilde{M}_1, \dots, \tilde{M}_g \text{ in } \gamma^-(\tilde{\theta}) \cap \Gamma_0, \text{ sent respectively on } \gamma^+(\tilde{\theta}) \cap \Gamma_1, \dots, \gamma^+(\tilde{\theta}) \cap \Gamma_g \text{ by the flow of } \nabla\tilde{\theta}, \tag{2.16}$$
$$\text{with the trajectories not touching } \partial\Omega\backslash[\gamma^+(\tilde{\theta}) \cup \gamma^-(\tilde{\theta})].$$

To describe properties of the flow, it is more convenient to work in a domain that is invariant by the flow. To that end, we consider $R > 0$ such that $\overline{\Omega} \subset B_R$ and introduce an operator π that extends continuous (resp., C^1) vector fields defined on Ω to continuous (resp., C^1) and compactly supported vector fields on B_R; see a more precise definition of π in section 3.1.

We have the following technical refinement of Proposition 2.1.

COROLLARY 2.2. *One can add the following requirement on $\tilde{\theta}$ (call $\tilde{\Phi}$ the flow of $\pi(\nabla\tilde{\theta})$):*

$$\text{given any point } E \text{ in } \partial\gamma^+(\tilde{\theta}) \text{ such that } \nabla\tilde{\theta}(E) \text{ is pointing outside } \gamma^+(\tilde{\theta}), \tag{2.17}$$
$$\text{then for } t > 0,\ \tilde{\Phi}(t,0,E) \text{ does not meet another point in } \partial\gamma^+(\tilde{\theta}) \text{ pointing outside } \gamma^+(\tilde{\theta}) \text{ before leaving } \overline{\Omega}.$$

The proof of this corollary is postponed to the appendix.

In fact, the function θ used in this paper is given by $-\tilde{\theta}$; hence θ satisfies (2.11), (2.12), (2.13), (2.14), and (2.15). However, (2.16) must be replaced by

$$\text{there exist } g \text{ points } M_1, \dots, M_g \text{ in } \gamma^-(\theta) \cap \Gamma_1, \dots, \gamma^-(\theta) \cap \Gamma_g, \text{ sent respectively on } \gamma^+(\theta) \cap \Gamma_0 \text{ by } \Phi, \text{ with the trajectories not touching } \partial\Omega\backslash[\gamma^+(\theta) \cup \gamma^-(\theta)] \tag{2.18}$$

(here Φ is the flow of $\pi(\nabla\theta)$, and we define $\gamma^+(\theta) := \gamma^-(\tilde{\theta})$ and $\gamma^-(\theta) := \gamma^+(\tilde{\theta})$), and (2.17) must be replaced by

(2.19) given any point A in $\partial\gamma^-(\theta)$ such that $\nabla\theta(A)$ is pointing inside $\gamma^-(\theta)$, $\Phi(t,0,A)$ has not met another point in $\partial\gamma^-(\theta)$ at which $\nabla\theta$ is pointing inside $\gamma^-(\theta)$ for $t<0$ such that $\Phi([t,0],0,E)\subset\overline{\Omega}$.

A representation of what $\nabla\theta$ may look like is given in Figure 2.1 below. The dotted lines represent some flow lines of $\nabla\theta$.

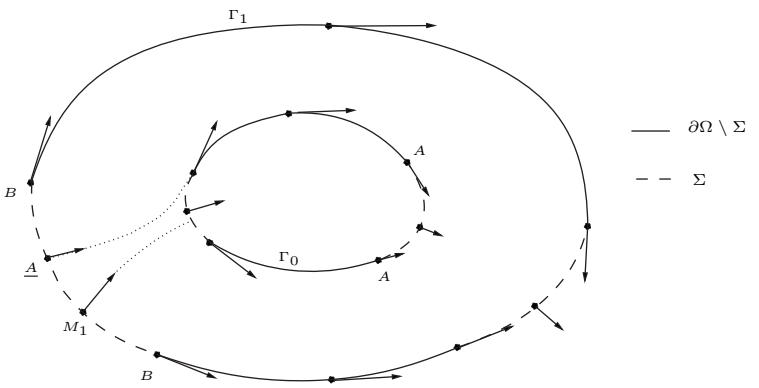

FIG. 2.1. *A representation of* $\nabla\theta$.

2.3. Some constructions relying on θ. We denote

$$\gamma^+ = \gamma^+(\theta) = \left\{x\in\partial\Omega \;\Big/\; \partial_n\theta(x) > 0\right\} \text{ and } \gamma^- = \gamma^-(\theta) = \left\{x\in\partial\Omega \;\Big/\; \partial_n\theta(x) < 0\right\}.$$

We also introduce

$$V(\theta) = \max_{\overline{\Omega}}\theta - \min_{\overline{\Omega}}\theta. \tag{2.20}$$

As in [6] we call A the points in $\partial\gamma^-$ on which $\nabla\theta$ is pointing *inside* γ^- and B the points in $\partial\gamma^-$ on which $\nabla\theta$ is pointing *outside* γ^-. In what follows, we denote by $\mathcal{A}$, $\mathcal{B}$, and $\mathcal{M}$ the sets of A, B, and M_i points, respectively.

For each $A\in\mathcal{A}$, we introduce γ_A as the component of $\partial\Omega\setminus(\overline{\gamma^-}\cup\overline{\gamma^+})$ whose closure contains A (and the same for B). We also consider the points $\underline{A}$ defined as

$$\underline{A} := \Phi(t'_A,0,A), \text{ where } t'_A := \min\left\{t\le 0 \;/\; \Phi([t,0],0,A)\subset\overline{\Omega}\right\}. \tag{2.21}$$

Using (2.19), one sees that $\underline{A}\in\gamma^-(\theta)\cup\mathcal{B}$.

Given θ, we shall introduce some functions on $\overline{\gamma^-}$, called Γ_A and Λ_i, defined for each $A\in\mathcal{A}$ and each $M_i\in\mathcal{M}$, respectively, and supported in a neighborhood of this point in $\overline{\gamma^-}$. Precisely, given $A\in\mathcal{A}$, call $\mathcal{V}_A$ a closed neighborhood of A in $\overline{\gamma^-}$, small enough that it contains neither any M_i point, nor any other point of $\mathcal{A}$, nor any $\underline{A}$ or

B point. Then define a function $\Gamma_A \in C^\infty(\overline{\gamma^-};\mathbb{R})$ satisfying

$$\begin{cases} -1 \leq \Gamma_A \leq 1, \\ \mathrm{Supp}(\Gamma_A) \subset \mathcal{V}_A, \\ \Gamma_A \equiv 1 \quad \text{in a neighborhood of } A, \\ \int_{\mathcal{V}_A} \Gamma_A(x) \nabla\theta(x) \cdot n(x) dx = 0. \end{cases} \tag{2.22}$$

Now, given an $M_i \in \mathcal{M}$, call $\mathcal{V}_{M_i}$ a closed neighborhood of M_i in $\gamma^- \cap \Gamma_i$, small enough that it contains neither any $\underline{A}$ point nor points of $\partial\gamma^-$, and such that all $\mathcal{V}_{M_i}$ are sent by Φ to $\gamma^+(\theta) \cap \Gamma_0$, with the trajectories not touching $\partial\Omega \backslash (\overline{\gamma^+} \cup \overline{\gamma^-})$ (as made possible by (2.18) and Gronwall's lemma; see Lemma 3.4 in section 3.3 below). Then define $\Lambda_i \in C^\infty(\overline{\gamma^-};\mathbb{R})$ satisfying

$$\begin{cases} \Lambda_i \leq 0, \\ \mathrm{Supp}(\Lambda_i) \subset \mathcal{V}_{M_i}, \\ \int_{\mathcal{V}_{M_i}} \Lambda_i(x) \nabla\theta(x) \cdot n(x) dx = 1. \end{cases} \tag{2.23}$$

Note that the last condition can be easily obtained since $\nabla\theta(x) \cdot n(x)$ is negative on $\mathcal{V}_{M_i}$.

We reduce if necessary the supports of Γ_A and Λ_i in order to obtain

$$\begin{array}{l} \mathrm{Supp}(\Gamma_A) \cap \mathrm{Supp}(\Lambda_i) = \emptyset \quad \text{for any } A \in \mathcal{A} \text{ and any } i = 1, \dots, g, \\ \mathrm{Supp}(\Gamma_A) \cap \mathrm{Supp}(\Gamma_{A'}) = \emptyset \quad \text{for any } A, A' \in \mathcal{A} \text{ such that } A \neq A'. \end{array} \tag{2.24}$$

To make the notation lighter, we write

$$\mathrm{Supp}(\Lambda) := \bigcup_{i=1}^{g} \mathrm{Supp}(\Lambda_i),$$
$$\mathrm{Supp}(\Gamma) := \bigcup_{A \in \mathcal{A}} \mathrm{Supp}(\Gamma_A).$$

Also, we introduce

$$\begin{aligned} &\|\Lambda\|_\infty := \max_{i=1}^{g} \|\Lambda_i\|_\infty, \\ &\mathcal{T}(\Gamma) = \sum_{A \in \mathcal{A}} \int_{\gamma^-} |\Gamma_A(x) \nabla\theta(x) \cdot n(x)| dx. \end{aligned} \tag{2.25}$$

We denote by ℓ a strict minimizer of the distance between the connected components of $\gamma^+ \cup \gamma^-$ and of the distances between the various $\mathrm{Supp}(\Gamma_A)$ with $A \in \mathcal{A}$, $\mathrm{Supp}(\Lambda_i)$ with $i \in \{1, \dots, g\}$, and points $B \in \mathcal{B}$.

The requirements on the supports are summarized in Figure 2.2 (where the arrows represent $\nabla\theta$).

2.4. The feedback law. Let us now describe the feedback law that we use. It is given by the following rule:

- If $(\omega(t), \lambda_1(t), \dots, \lambda_g(t)) = 0$, then fix

$$v \cdot n = \mathcal{C}_1 := 0 \text{ on } \Sigma. \tag{2.26}$$

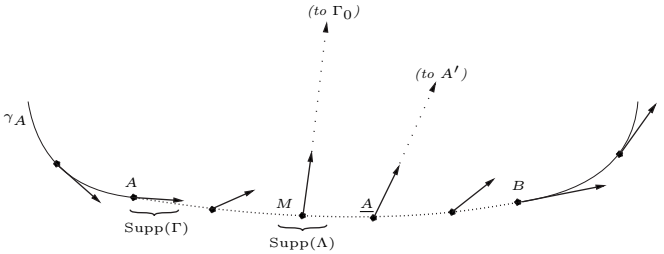

FIG. 2.2. *A representation of* $\Sigma^- \cap \Gamma_i$.

- If $(\omega(t), \lambda_1(t), \dots, \lambda_g(t)) \neq 0$, then fix

(2.27)
$$\begin{cases} v \cdot n = \mathcal{C}_1 := K \max(\|\omega(t,\cdot)\|_{L^\infty(\Omega)}, |\lambda_1(t)|, \dots, |\lambda_g(t)|) \nabla\theta(x) \cdot n(x) \text{ on } \Sigma, \\ \omega = \omega_1 + \omega_2 \text{ on } \gamma^-, \end{cases}$$

where ω_1 and ω_2 are given by

(2.28)
$$\begin{cases} \partial_t \omega_1 &= \mathcal{C}_2 := -M \max(\|\omega(t,\cdot)\|_{L^\infty(\Omega)}, |\lambda_1(t)|, \dots, |\lambda_g(t)|)\omega_1 \text{ on } \gamma^-, \\ \omega_2 &= \mathcal{C}_3 := \sum_{A\in\mathcal{A}} \omega(t,A)\Gamma_A(x) - \sum_{i=1}^g \lambda_i(t)\Lambda_i(x) \text{ on } \gamma^-. \end{cases}$$

Consequently, we will have $\Sigma^- = \gamma^-$ except in the case $(\omega(t), \lambda_1(t), \dots, \lambda_g(t)) = 0$.

Remark that ω_1 is a function of the state since

$$\omega_1(t,\cdot) = \omega(t,\cdot) - \sum_{A\in\mathcal{A}} \omega(t,A)\Gamma_A(\cdot) + \sum_{i=1}^g \lambda_i(t)\Lambda_i(\cdot) \text{ on } \gamma^-.$$

The constants K and M are to be chosen large enough, as will be seen more precisely later.

Remark 5. Let us remark that, as the vorticity functions ω considered here are in the class $C^0([0,T)\times\overline{\Omega})$, the functions $t \mapsto \omega(t,A)$ are well-defined and continuous. Consequently, the feedback law is equivalent (in a distributional sense) to

$$\begin{aligned} \partial_t\omega(t,x) = &- M \max(\|\omega(t,\cdot)\|_{L^\infty(\Omega)}, |\lambda_1(t)|, \dots, |\lambda_g(t)|) \\ &\times \left[\omega(t,x) - \sum_{A\in\mathcal{A}} \omega(t,A)\Gamma_A(x) + \sum_{i=1}^g \lambda_i(t)\Lambda_i(x)\right] \\ &+ \sum_{A\in\mathcal{A}} \partial_t\omega(t,A)\Gamma_A(x) - \sum_{i=1}^g \left(\frac{d}{dt}\lambda_i(t)\right)\Lambda_i(x), \end{aligned} \tag{2.29}$$

where $\partial_t\omega(t,A)$ and $\frac{d}{dt}\lambda_i(t)$ can be recovered, in a formal sense for the first one, from the state thanks to (1.7)–(1.8).

2.5. The result. We rewrite the definition of the solutions of the system with the above described feedback.

DEFINITION 2.3. *A function* $(\omega, \lambda_1, \dots, \lambda_g)$ *in* $C^0([0,T^*)\times\overline{\Omega};\mathbb{R})\times C^0([0,T^*);\mathbb{R})^g$ *is a solution of the closed-loop system with the feedback law of section* 2.4 *if and only if it satisfies*

- *the relation* (1.8) *for all* $t \in [0,T^*)$ *and the equation* (1.7) *in the sense of distributions, where* v *is defined for each* t *by* (1.5)*, with* $\mathcal{C}_1$ *fixed by* (2.27)*,*
- *that on the domain* $\{t \in [0,T^*) \ / \ (\omega(t,\cdot),\lambda_1(t),\dots,\lambda_g(t)) \not\equiv 0\} \times \gamma^-$ *(which is an open bidimensional manifold), the function*

$$\omega_1(t,x) = \omega(t,x) - \sum_{A\in\mathcal{A}} \omega(t,A)\Gamma_A(x) + \sum_{i=1}^{g} \lambda_i(t)\Lambda_i(x)$$

satisfies (2.28) *in a distributional sense.*

The following theorem is the main result of the paper; it clearly involves Theorem 1.2.

THEOREM 2.4. *If the constant* K *is large enough, and* M *is large enough depending on* K*, then for any initial condition* $(\omega_0,\lambda_1^0,\dots,\lambda_g^0)$ *in* $C^0(\overline{\Omega};\mathbb{R}) \times \mathbb{R}^g$*, there are solutions in* $C^0([0,T^*)\times\overline{\Omega};\mathbb{R}) \times C^0([0,T^*);\mathbb{R})^g$ *of the closed-loop system (for some* $T^*>0$*) satisfying*

$$(\omega,\lambda_1,\dots,\lambda_g)_{|t=0} = (\omega_0,\lambda_1^0,\dots,\lambda_g^0). \tag{2.30}$$

Moreover, any maximal solution is global and satisfies, for some $\mathcal{K}>0$ *depending only on* Ω *and* Σ *(and on the functions* θ*,* Γ_A*, and* Λ_i *constructed on* (Ω,Σ)*),*

$$\max(\|\omega(t,\cdot)\|_{L^\infty(\Omega)},|\lambda_1(t)|,\dots,|\lambda_g(t)|) \leq \mathcal{K}\max(\|\omega_0\|_{L^\infty(\Omega)},|\lambda_1^0|,\dots,|\lambda_g^0|) \quad \forall\ t\geq 0, \tag{2.31}$$

$$\max(\|\omega(t,\cdot)\|_{L^\infty(\Omega)},|\lambda_1(t)|,\dots,|\lambda_g(t)|) \to 0 \quad \text{as } t\to+\infty. \tag{2.32}$$

3. Notation and prerequisites.

3.1. Notation. We essentially keep the notation of [4]. The velocity field will now be designated by y. We write $\Omega_T := [0,T]\times\overline{\Omega}$ and $\Sigma_T := [0,T]\times\partial\Omega$. In that context we write $pr_1(t,x)=t$ and $pr_2(t,x)=x$.

For X a nonempty compact subset of $\mathbb{R}^n$ and f a continuous function $X\to\mathbb{R}$, we introduce $\Xi_X[f]$ as the following function $\mathbb{R}^{+*}\to\mathbb{R}^{+*}\cup\{+\infty\}$:

$$\Xi_X[f](\varepsilon) := \sup\left\{\eta>0 \ / \ \forall x,x'\in X,\ |x-x'|\leq\eta \Rightarrow |f(x)-f(x')|\leq\varepsilon\right\}; \tag{3.1}$$

for $x\in X$ we introduce $\Xi_X^x[f]$ as

$$\Xi_X^x[f](\varepsilon) := \sup\left\{\eta>0 \ / \ \forall x'\in X,\ |x-x'|\leq\eta \Rightarrow |f(x)-f(x')|\leq\varepsilon\right\}. \tag{3.2}$$

These two functions are clearly related to the modulus of continuity of f.

Given K a compact set in $\mathbb{R}^2$ and f a continuous function $K\to\mathbb{R}^2$, we introduce the *log-Lipschitz* norm

$$q_K(f) := \|f\|_\infty + \sup\left\{\frac{|f(x)-f(x')|}{r(|x-x'|)},\ (x,x')\in K^2,\ x\neq x'\right\}, \tag{3.3}$$

where $r(s)=s-s\ln(s)$ in $(0,1)$ and $r(s)=s$ in $[1,+\infty)$.

We call log-Lipschitz the functions for which $q_K(f)<+\infty$, and denote by $\mathcal{LL}(K)$ their space, which we endow with the norm described in (3.3). We denote by $\mathcal{L}ip(K)$ the space of Lipschitz functions on K.

In the notation of a functional space, an index 0 refers to functions with compact support.

Let R be a positive real number, large enough so that $\overline{\Omega}$ is included in the open 0-centered ball with radius R, denoted by B_R.

We consider a linear continuous extension operator $\pi : C^0(\overline{\Omega}) \to C^0_0(B_R)$, which maps any $\mathcal{LL}(\overline{\Omega})$ function to an $\mathcal{LL}_0(B_R)$ function, and any $C^1(\overline{\Omega})$ function to a $C^1_0(B_R)$ function. We fix c_π a constant such that

$$\|\pi(f)\|_{C^0(\overline{B_R})} \le c_\pi \|f\|_{C^0(\overline{\Omega})}, \qquad \|\pi(f)\|_{\mathcal{LL}(\overline{B_R})} \le c_\pi \|f\|_{\mathcal{LL}(\overline{\Omega})}, \quad \text{and} \quad \|\pi(f)\|_{C^1(\overline{B_R})} \le c_\pi \|f\|_{C^1(\overline{\Omega})}. \tag{3.4}$$

Frequently, we write (ω, λ_i) for $(\omega, \lambda_1, \dots, \lambda_g)$. Also, using the canonical isomorphism $C^0([0,T^*) \times \overline{\Omega}; \mathbb{R}) \cong C^0([0,T^*); C^0(\overline{\Omega}; \mathbb{R}))$, we often write $\omega(t)$ for $\omega(t,\cdot)$ and $y(t)$ for $y(t,\cdot)$. In the same way, $\|\omega(\cdot)\|_{L^\infty(\Omega)}$ denotes the function

$$t \mapsto \operatorname*{ess\,sup}_{x\in\Omega} |\omega(t,x)|.$$

3.2. The Wolibner–Yudovich theorem. In this section, we introduce a classical tool to deal with flows of vector fields which do not satisfy the Lipschitz condition (in fact, the existence is the Peano theorem, and the uniqueness is the Osgood theorem). One has the following theorem.

THEOREM 3.1 (Wolibner–Yudovich theorem). *Consider $T > 0$ and a vector field $y \in L^\infty([0,T]; C^0_0(B_R; \mathbb{R}^2))$ such that for some constant C*

$$q_{\overline{B_R}}(y(t)) \le C \ \text{ a.e. in } [0,T]. \tag{3.5}$$

Then there exists a unique map $\Phi^y \in C^0([0,T]\times[0,T]\times B_R; B_R)$, $(t,s,x) \mapsto \Phi^y(t,s,x)$, which is a flow of y, i.e., a function that satisfies

$$\Phi^y(t,s,x) = x + \int_s^t y(\tau, \Phi^y(\tau,s,x))d\tau \quad \forall (t,s,x) \in [0,T]\times[0,T]\times B_R. \tag{3.6}$$

Moreover, there are two positive constants C_{WY} and δ_{WY} depending only on (R,T,C) such that for any $(s,s',t,t',x,x') \in [0,T]^4 \times {B_R}^2$, one has

$$|\Phi^y(t,s,x) - \Phi^y(t',s',x')| \le C_{WY}(|s-s'|^{\delta_{WY}} + |t-t'|^{\delta_{WY}} + |x-x'|^{\delta_{WY}}). \tag{3.7}$$

For a proof of this theorem, we refer to Wolibner [9], Yudovich [11, Lemma 6.3], or Kato [7].

Estimates such as (3.5) can easily be established by using the following theorem.

THEOREM 3.2 (Wolibner). *Consider $\omega \in C^0(\overline{\Omega}; \mathbb{R})$, $\lambda_1, \dots, \lambda_g \in \mathbb{R}$. Then the function y defined in $C^0(\overline{\Omega}; \mathbb{R}^2)$ by*

$$\begin{cases} \operatorname{curl} y(x) = \omega(x) \quad \text{in } \Omega, \\ \operatorname{div} y(x) = 0 \quad \text{in } \Omega, \\ y(x)\cdot n(x) = 0 \quad \text{on } \partial\Omega, \\ \displaystyle\int_{\Gamma_i} y(x)\cdot \vec{\tau}(x)dx = \lambda_i \quad \text{for } i = 1, \dots g, \end{cases} \tag{3.8}$$

satisfies the estimate

$$\|y\|_{\mathcal{LL}(\overline{\Omega})} \le C_{\mathcal{LL}} \max\left(\|\omega\|_{C^0}, |\lambda_1|, \dots, |\lambda_g|\right). \tag{3.9}$$

We refer, for instance, to [7, Lemma 1.4] or [9].

3.3. Elementary tools. Here we recall two elementary Gronwall inequalities.

LEMMA 3.3. *Consider two vector fields $y_1 \in L^\infty([0,T];\mathcal{L}ip_0(B_R;\mathbb{R}^2))$ and $y_2 \in L^\infty([0,T];\mathcal{L}\mathcal{L}_0(B_R;\mathbb{R}^2))$ and their corresponding flows Φ_1 and Φ_2 (obtained with the Cauchy–Lipschitz theorem for the first and with the Wolibner–Yudovich theorem for the latter). Then one has, for all $t \in [0,T]$,*

(3.10)
$$\|\Phi_1(t,0,\cdot) - \Phi_2(t,0,\cdot)\|_{L^\infty(B_R)} \leq \exp\left(\int_0^t \|y_1(\tau)\|_{\mathcal{L}ip(B_R)} d\tau\right) \|y_1 - y_2\|_{L^1([0,t],L^\infty(B_R))}.$$

LEMMA 3.4. *Consider $y \in L^\infty([0,T],\mathcal{L}ip_0(B_R;\mathbb{R}^2))$ and its flow Φ^y. One has, for all $(t,x,x') \in [0,T]\times B_R^2$,*

$$|\Phi^y(t,0,x) - \Phi^y(t,0,x')| \leq \exp\left(\int_0^t \|y(\tau)\|_{\mathcal{L}ip(B_R)} d\tau\right) |x - x'|. \tag{3.11}$$

These are very classical and elementary statements.

3.4. A proposition concerning flows under the feedback law. We begin with a remark.

Remark 6. The flow Φ of $\pi(\nabla\theta)$ satisfies the following properties:

(i) for x in $\mathcal{B}\cup\gamma^-(\theta)$ and for any $t\in(0,T]$, $\exists \nu>0$ s.t. $\Phi([t-\nu,t],t,x)\subset \mathbb{R}^2\backslash\overline{\Omega}$;
(ii) for x in $\gamma^-(\theta)$ and for any $t\in[0,T)$, $\exists\nu>0$ s.t. $\Phi([t,t+\nu],t,x)\subset\Omega$;
(iii) for any $B\in\mathcal{B}$ and for any $t\in[0,T)$, $\exists\nu>0$ s.t. $\Phi([t,t+\nu],t,B)\subset\gamma_B$;
(iv) for any $A\in\mathcal{A}$, for any $t\in[0,T)$, and for $\tau<t$ s.t. $(t-\tau)\|\nabla\theta\|_\infty\leq \ell/2$, one has $\Phi(\tau,t,A)\in\gamma_A$;
(v) for any $A\in\mathcal{A}$, for any $t\in(0,T]$, and for $\tau>t$ s.t. $(\tau-t)\|\nabla\theta\|_\infty\leq\ell/2$, one has $\Phi(\tau,t,A)\in\Omega$;
(vi) for all $M_i\in\mathcal{M}$, one has $\Phi(t,0,M_i)\notin\partial\Omega\backslash[\overline{\gamma^+}\cup\overline{\gamma^-}]$ for $t>0$ s.t. $\Phi([0,t],0,M_i)\subset\overline{\Omega}$; that is, the trajectories of M_i do not touch the set $\partial\Omega\backslash[\overline{\gamma^+}\cup\overline{\gamma^-}]$ before leaving the domain.

These properties are easy to prove using the form of $\nabla\theta$, the uniqueness of the flow, and the definition of ℓ.

The idea of the following proposition is to prove that if one imposes a control of the form (2.27) with K large enough, some of the properties in Proposition 2.1 and Remark 6 are also true for the flow of the resulting velocity y.

PROPOSITION 3.5. *There exist $\kappa>0$ and $\overline{K}:=\overline{K}(\theta)>0$ such that, for any $K\geq\overline{K}$, any $T>0$, any $(\omega,\lambda_i)\in C^0(\Omega_T;\mathbb{R})\times C^0([0,T];\mathbb{R}^g)$, and any $\alpha\in C^0([0,T],\mathbb{R}^+)$ positive satisfying*

$$\alpha(t)\geq\max\left(|\lambda_1(t)|,\dots,|\lambda_g(t)|,\|\omega(t)\|_\infty\right), \tag{3.12}$$

the solution $y\in C^0(\Omega_T;\mathbb{R}^2)$ of

$$\begin{cases} \operatorname{curl} y(t,x)=\omega(t,x) \quad \text{for } (t,x)\in\Omega_T,\\ \operatorname{div} y(t,x)=0 \quad \text{for } (t,x)\in\Omega_T,\\ y(t,x)\cdot n(x)=K\alpha(t)\nabla\theta(x)\cdot n(x) \quad \text{for } (t,x)\in\Sigma_T,\\ \displaystyle\int_{\Gamma_i} y(t,x)\cdot\vec{\tau}(x)dx=\lambda_i(t) \quad \text{for } t\in[0,T] \text{ and } i\in\{1,\dots,g\} \end{cases} \tag{3.13}$$

satisfies

$$y(t,x)\cdot\nabla\theta(x)\geq\kappa K\alpha(t) \text{ in } \Omega_T, \tag{3.14}$$

and, Φ^y *being the flow of* $\pi(y)$ *in* B_R,

for any point x *in* $\mathcal{B} \cup \gamma^-(\theta)$ *and for any* $t \in (0,T)$,

$$\exists \nu > 0 \text{ such that } \Phi^y([t-\nu,t),t,x) \subset \mathbb{R}^2 \backslash \overline{\Omega}, \tag{3.15}$$

$$\exists \nu > 0 \text{ such that } \Phi^y((t,t+\nu],t,x) \subset \Omega \cup [\partial\Omega \backslash (\overline{\gamma^-} \cup \overline{\gamma^+})], \tag{3.16}$$

$$\text{for any } x \in \mathrm{Supp}(\Lambda) \text{ and for any } t \in [0,T], \text{ one has } \Phi^y(\tau,t,x) \notin \bigcup_{i=1}^{g} (\Gamma_i \cap \overline{\gamma^+}) \text{ for } \tau \in (t,T] \text{ such that } \Phi^y([t,\tau],t,x) \subset \overline{\Omega}, \tag{3.17}$$

(3.18)
$$\text{for any } A \in \mathcal{A} \text{ and for any } t \in (0,T], \text{ one has } \Phi^y(\tau,t,A) \in \gamma_A \text{ for } \tau \in [0,t) \text{ such that } c_\pi(K\|\nabla\theta\|_\infty + C_{\mathcal{LL}}) \left(\int_\tau^t \alpha(s)ds \right) \leq \ell/2,$$

(3.19)
$$\text{for any } A \in \mathcal{A} \text{ and for any } t \in [0,T), \text{ one has } \Phi^y(\tau,t,A) \in \Omega \text{ for } \tau \in (t,T] \text{ such that } c_\pi(K\|\nabla\theta\|_\infty + C_{\mathcal{LL}}) \left(\int_t^\tau \alpha(s)ds \right) \leq \ell/2,$$

$$\text{for any } A \in \mathcal{A} \text{ and for any } t \in [0,T], \text{ one has } \Phi^y(\tau,t,A) \notin \mathrm{Supp}(\Gamma) \cup \mathrm{Supp}(\Lambda) \text{ for } \tau \in [0,t) \text{ such that } \Phi^y([\tau,t],t,A) \subset \overline{\Omega}. \tag{3.20}$$

Of course, the previous flow has to be understood in the Wolibner–Yudovich sense.

The proof of Proposition 3.5 is delayed to the appendix.

Remark 7. Let us remark that, as a consequence of (3.14), the points A and B defined for $\nabla\theta$ are still valid for the velocity y described in (3.13); that is, for all t in $[0,T]$, $y(t,A)$ (resp., $y(t,B)$) is tangent to $\partial\Omega$ and pointing inside (resp., outside) γ^- (for $K \geq \overline{K}$, provided $\alpha(t) > 0$).

In what follows, we will systematically suppose $K \geq \overline{K}$.

4. Construction of the operator $\mathcal{F}$. In this section, we construct an operator $\mathcal{F} = (F, G_1, \ldots, G_g)$, whose fixed points give local in time solutions to the closed-loop system. Roughly speaking, $F[\omega,\lambda_i]$ is the solution of an initial-boundary problem, which is approximately the closed-loop system described above, where (1.7) is replaced by the following *linear* equation:

$$\partial_t F[\omega,\lambda_i] + \mathrm{div}(y_{\omega,\lambda_i} F[\omega,\lambda_i]) = 0 \quad \text{in } (0,T^*) \times \Omega,$$

where y_{ω,λ_i} is the solution of (1.5) corresponding to (ω,λ_i). Then G_i corresponds approximately to the solution of (1.8).

4.1. The domain X. First let us define the space X on which $\mathcal{F}$ is to be defined. The operator $\mathcal{F}$ is split into $\mathcal{F} = (F, G_i)$, with $F : X \to C^0([0,T] \times \overline{\Omega}; \mathbb{R})$

and $G_i : X \to C^0([0,T];\mathbb{R})$ for $i \in \{1,\dots,g\}$. We introduce

$$
\begin{aligned}
(4.1)\quad X := \Big\{ & (\omega,\lambda_i) \in C^0([0,T]\times\overline{\Omega};\mathbb{R}) \times \left[C^0([0,T];\mathbb{R})\right]^g \ \Big/ \\
& \text{(a)} \quad \omega(0,\cdot) = \omega_0, \\
& \text{(b)} \quad \|\omega(t,\cdot)\|_\infty \leq \mathcal{N}_{\omega_0,\lambda_i^0} \quad \text{for } t\in[0,T], \\
& \text{(c)} \quad \lambda_i(0) = \lambda_i^0 \quad \text{for } i = 1\dots g, \\
& \text{(d)} \quad \left\| \frac{\partial\omega}{\partial t} \right\|_{L_t^\infty(H_x^{-1})} \leq \kappa_1 \max\left(\|\omega_0\|_\infty, |\lambda_1^0|,\dots,|\lambda_g^0|\right)^2, \\
& \text{(e)} \quad |\lambda_i(t)| \leq \mathcal{M}_{\omega_0,\lambda_i^0} \quad \text{for } t\in[0,T], \\
& \text{(f)} \quad \left|\frac{d\lambda_i}{dt^-}\right|(t) \leq \kappa_2 \max\left(\|\omega_0\|_\infty, |\lambda_1^0|,\dots,|\lambda_g^0|\right)^2, \\
& \text{(g)} \quad \forall A\in\mathcal{A},\ \forall\varepsilon\in(0,1),\ \Xi_{[0,T]}[\omega(A,\cdot)](\varepsilon) \geq \tfrac{1}{c}\left(\Xi_{\gamma_A}[\omega_0](\varepsilon)\right)^{\frac{1}{\delta}}, \\
& \text{(h)} \quad \forall\varepsilon\in(0,1),\ \Xi_{[0,T]}[\|\omega(\cdot)\|_{L^\infty(\Omega)}](\varepsilon) \geq \tfrac{1}{c}\min\left[\left(\Xi_{\overline{\Omega}}[\omega_0](\varepsilon)\right)^{\frac{1}{\delta}}, \varepsilon\right]\Big\},
\end{aligned}
$$

where the constant c depends on Ω, θ, T, and (ω_0,λ_i^0) and will be chosen large enough later. The other constants are fixed as follows:

$$
(4.2)\qquad \mathcal{N}_{\omega_0,\lambda_i^0} := \left[3 + |\Omega| + \frac{V(\theta)}{\kappa}\mathcal{T}(\Gamma)\right](1+\|\Lambda\|_\infty)\max(|\lambda_1^0|,\dots,|\lambda_g^0|,\|\omega_0\|_\infty),
$$

$$
(4.3)\qquad \mathcal{M}_{\omega_0,\lambda_i^0} := \left[2 + |\Omega| + \frac{V(\theta)}{\kappa}\mathcal{T}(\Gamma)\right]\max(|\lambda_1^0|,\dots,|\lambda_g^0|,\|\omega_0\|_\infty),
$$

and δ is defined with reference to section 3.2 as

$$
(4.4)\qquad \delta := \delta_{WY}(R,T,c_\pi(C_{\mathcal{LL}} + K\|\nabla\theta\|_{\mathcal{LL}(\overline{\Omega})})\mathcal{N}_{\omega_0,\lambda_i^0}).
$$

The constants κ_1 and κ_2 depend on the domain and on the choice of θ, Λ, and Γ but not on T:

$$
(4.5)\qquad \kappa_1 := 2|\Omega|^{\frac{1}{2}}(C_{\mathcal{LL}} + K\|\nabla\theta\|_{L^\infty(\Omega)})\left[3 + |\Omega| + \frac{V(\theta)}{\kappa}\mathcal{T}(\Gamma)\right]^2(1+\|\Lambda\|_\infty)^2,
$$

$$
(4.6)\qquad \kappa_2 := |\Sigma|K\|\nabla\theta\|_{L^\infty(\Omega)}\left[3 + |\Omega| + \frac{V(\theta)}{\kappa}\mathcal{T}(\Gamma)\right]^2(1+\|\Lambda\|_\infty)^2.
$$

In (4.2)–(4.6), $|\Omega|$ stands for the Lebesgue measure of Ω and $|\Sigma|$ for the length of Σ, κ is the constant in (3.14), $V(\theta)$ is defined in (2.20), $\mathcal{T}(\Gamma)$ and $\|\Lambda\|_\infty$ are defined in (2.25), c_π is defined in (3.4), and $C_{\mathcal{LL}}$ is introduced in (3.9).

The time T is chosen in the following way:

- if $\max(|\lambda_1^0|,\dots,|\lambda_g^0|,\|\omega_0\|_\infty) = 0$, then 0 is a clear solution of the system and we pass (throughout sections 4 and 5 we will suppose $(\omega_0,\lambda_i^0) \neq (0,0)$);
- if $\|\omega_0\|_\infty = 0$, but $|\lambda_k^0| > 0$ for some $k\in\{1,\dots,g\}$, we fix

$$
(4.7)\qquad \underline{T} := \frac{|\lambda_k^0|}{2\kappa_2\max\left(\|\omega_0\|_\infty,|\lambda_1^0|,\dots,|\lambda_g^0|\right)^2};
$$

- if $\|\omega_0\|_\infty \neq 0$, then we fix

$$
(4.8)\qquad \underline{T} := \frac{\|\omega_0\|_\infty}{2\kappa_1\max\left(\|\omega_0\|_\infty,|\lambda_1^0|,\dots,|\lambda_g^0|\right)^2}.
$$

Finally, we define T as

$$T := \min\left(\frac{\ell}{4c_\pi(C_{\mathcal{LL}} + K\|\nabla\theta\|_\infty)\mathcal{N}_{\omega_0,\lambda_i^0}}, \underline{T}\right). \tag{4.9}$$

It is quite clear that X is convex, closed, and nonempty (since, for example, it contains the constant function $t \mapsto (\omega_0, \lambda_i^0)$).

Let us finish this paragraph with a remark concerning the choice of T.

Remark 8. Let us remark that T allows us to have the following properties:

- for any $A \in \mathcal{A}$ and any $(\omega, \lambda_i) \in X$, if one puts y as in (3.13) (with α satisfying (3.12)), then for any $t \in [0,T]$ one has $\Phi^y([0,t],t,A) \subset \overline{\gamma_A}$ (this is a consequence of the first part in the minimum in (4.9), using (3.18));
- for any $(\omega, \lambda_i) \in X$, one has as a consequence of the definition of $\underline{T}$ and of points (d) and (f) in (4.1), that
  - if $\underline{T}$ is defined by (4.7), then for all $t \in [0,T]$,

$$|\lambda_k(t)| \geq \frac{|\lambda_k^0|}{2} > 0, \tag{4.10}$$

  - if $\underline{T}$ is defined by (4.8), then for all $t \in [0,T]$,

$$\|\omega(t,\cdot)\|_\infty \geq \kappa_3^{-1}\frac{\|\omega_0\|_{H^{-1}(\Omega)}}{2} > 0, \tag{4.11}$$

    where κ_3 is some constant such that $\|\cdot\|_{H^{-1}(\Omega)} \leq \kappa_3\|\cdot\|_{L^\infty(\Omega)}$.

4.2. The operator F. Let us now describe the operator F. Consider $(\omega, \lambda_i) \in X$. First, we associate with (ω, λ_i) the function $\alpha_{\omega,\lambda_i} \in C^0([0,T], \mathbb{R}^{+*})$ by

$$\alpha_{\omega,\lambda_i}(t) := \max\left(|\lambda_1(t)|, \ldots, |\lambda_g(t)|, \|\omega(t)\|_\infty\right). \tag{4.12}$$

Then, we can associate the following vector field $y_{\omega,\lambda_i} \in C^0(\Omega_T, \mathbb{R}^2)$ as the solution of

$$\begin{cases} \operatorname{curl} y_{\omega,\lambda_i}(t,x) = \omega(t,x) \quad \text{for } (t,x) \in \Omega_T, \\ \operatorname{div} y_{\omega,\lambda_i}(t,x) = 0 \quad \text{for } (t,x) \in \Omega_T, \\ y_{\omega,\lambda_i}(t,x)\cdot n(x) = K\alpha_{\omega,\lambda_i}(t)\nabla\theta(x)\cdot n(x) \quad \text{for } (t,x) \in \Sigma_T, \\ \displaystyle\int_{\Gamma_i} y_{\omega,\lambda_i}(t,x)\cdot\vec{\tau}(x)dx = \lambda_i(t) \quad \text{for } t \in [0,T], \quad i = 1,\ldots,g, \end{cases} \tag{4.13}$$

where $K \geq \overline{K}(\theta)$. Then we extend this vector field to $[0,T]\times B_R$ by

$$\tilde{y}_{\omega,\lambda_i}(t,\cdot) = \pi[y_{\omega,\lambda_i}(t,\cdot)]. \tag{4.14}$$

By the Wolibner–Yudovich theorem (see section 3.2), this vector field yields a flow $\Phi^{\omega,\lambda_i} : [0,T]\times[0,T]\times B_R \to B_R$, i.e., a solution of (3.6). Now, given this flow, we can introduce the following two functions on $[0,T]\times\overline{\Omega}$ (which, roughly speaking, represent, respectively, the time and location of entrance in the domain of the point located at x at time t, when following the flow):

$$s_{\omega,\lambda_i}(t,x) := \max\left\{\tau \in [0,t],\ \Phi^{\omega,\lambda_i}(\tau,t,x) \in \overline{\gamma^-}\right\}, \tag{4.15}$$

$$a_{\omega,\lambda_i}(t,x) := \Phi^{\omega,\lambda_i}(s_{\omega,\lambda_i}(t,x),t,x), \tag{4.16}$$

with the convention that when $\{\tau \in [0,t],\ \Phi^{\omega,\lambda_i}(\tau,t,x) \in \overline{\gamma^-}\} = \emptyset$, then

$$s_{\omega,\lambda_i}(t,x) := 0,$$

and correspondingly

$$a_{\omega,\lambda_i}(t,x) := \Phi^{\omega,\lambda_i}(0,t,x).$$

Note that in all cases, one has $a_{\omega,\lambda_i}(t,x) \in \overline{\Omega}$. Note that the function s_{ω,λ_i} is not necessarily continuous (contrary to what happened in the simply connected case; see [4, equations (3.36)–(3.37)]).

Now we can define $F[\omega,\lambda_i](t,x)$ for $(t,x) \in \Omega_T$. In that order, we distinguish four cases, corresponding to different situations for $a_{\omega,\lambda_i}(t,x)$. In what follows, the constant M (which appears in (2.28)) is to be chosen large enough later.

Case α: $a_{\omega,\lambda_i}(t,x) \in \Omega \cup (\partial\Omega \backslash \overline{\gamma^-})$. This case is possible only if $s_{\omega,\lambda_i}(t,x) = 0$. In that case, we fix

$$F[\omega,\lambda_i](t,x) := \omega_0(a_{\omega,\lambda_i}(t,x)). \tag{4.17}$$

Case β: $a_{\omega,\lambda_i}(t,x) \in \overline{\gamma^-} \backslash [\mathrm{Supp}(\Gamma) \cup \mathrm{Supp}(\Lambda)]$. In that case, we fix

$$F[\omega,\lambda_i](t,x) := \omega_0(a_{\omega,\lambda_i}(t,x)) \exp\left(-M \int_0^{s_{\omega,\lambda_i}(t,x)} \alpha_{\omega,\lambda_i}(\tau) d\tau\right). \tag{4.18}$$

Case γ: $a_{\omega,\lambda_i}(t,x) \in \mathrm{Supp}(\Gamma_A)$ for some $A \in \mathcal{A}$. In that case, we fix

$$\begin{aligned} F[\omega,\lambda_i](t,x) := {} & \Big[\omega_0(a_{\omega,\lambda_i}(t,x)) - \omega_0(A)\Gamma_A(a_{\omega,\lambda_i}(t,x))\Big] \exp\left(-M \int_0^{s_{\omega,\lambda_i}(t,x)} \alpha_{\omega,\lambda_i}(\tau) d\tau\right) \\ & + \omega_0(\Phi^{\omega,\lambda_i}(0, s_{\omega,\lambda_i}(t,x), A))\Gamma_A(a_{\omega,\lambda_i}(t,x)). \end{aligned} \tag{4.19}$$

Case δ: $a_{\omega,\lambda_i}(t,x) \in \mathrm{Supp}(\Lambda_k)$ for some $k \in \{1,\dots,g\}$. In that case, we fix

$$\begin{aligned} F[\omega,\lambda_i](t,x) := {} & \Big[\omega_0(a_{\omega,\lambda_i}(t,x)) + \lambda_k^0 \Lambda_k(a_{\omega,\lambda_i}(t,x))\Big] \exp\left(-M \int_0^{s_{\omega,\lambda_i}(t,x)} \alpha_{\omega,\lambda_i}(\tau) d\tau\right) \\ & - \lambda_k(s_{\omega,\lambda_i}(t,x))\Lambda_k(a_{\omega,\lambda_i}(t,x)). \end{aligned} \tag{4.20}$$

Another way to express this is that $F[\omega,\lambda_i]$ is given by

$$\begin{aligned} F[\omega,\lambda_i](t,x) = {} & \left[\omega_0(a_{\omega,\lambda_i}(t,x)) - \sum_{A\in\mathcal{A}} \omega_0(A)\Gamma_A(a_{\omega,\lambda_i}(t,x)) + \sum_{k=1}^{g} \lambda_k^0 \Lambda_k(a_{\omega,\lambda_i}(t,x))\right] \\ & \times \exp\left(-M \int_0^{s_{\omega,\lambda_i}(t,x)} \alpha_{\omega,\lambda_i}(\tau) d\tau\right) \\ & + \sum_{A\in\mathcal{A}} \omega_0(\Phi^{\omega,\lambda_i}(0, s_{\omega,\lambda_i}(t,x), A))\Gamma_A(a_{\omega,\lambda_i}(t,x)) \\ & - \sum_{k=1}^{g} \lambda_k(s_{\omega,\lambda_i}(t,x))\Lambda_k(a_{\omega,\lambda_i}(t,x)) \end{aligned} \tag{4.21}$$

with at most one nonnull term in each summation.

We also define on $[0,T]\times\overline{\gamma^-}$

(4.22)
$$\begin{cases} \omega^\sharp(t,x) := \left[\omega_0(x) - \displaystyle\sum_{A\in\mathcal{A}} \omega_0(A)\Gamma_A(x) + \sum_{k=1}^{g} \lambda_k^0\Lambda_k(x)\right] \exp\left(-M\displaystyle\int_0^t \alpha_{\omega,\lambda_i}(\tau)d\tau\right), \\ \omega^\flat(t,x) := \displaystyle\sum_{A\in\mathcal{A}} \omega_0(\Phi^{\omega,\lambda_i}(0,t,A))\Gamma_A(x), \\ \omega^\natural(t,x) := -\displaystyle\sum_{k=1}^{g} \lambda_k(t)\Lambda_k(x). \end{cases}$$

Finally, let us call $\tilde{F}$ the same operator as F, with Λ_k replaced by 0 for each $k\in\{1,\dots,g\}$; that is, $\tilde{F}$ is constant along the flow of Φ^{ω,λ_i}, and on $\overline{\gamma^-}$, one has

$$\tilde{F}[\omega,\lambda_i](t,x) := \left[\omega_0(x) - \sum_{A\in\mathcal{A}} \omega_0(A)\Gamma_A(x)\right] \exp\left(-M\int_0^t \alpha_{\omega,\lambda_i}(\tau)d\tau\right) + \sum_{A\in\mathcal{A}} \omega_0(\Phi^{\omega,\lambda_i}(0,t,A))\Gamma_A(x). \tag{4.23}$$

4.3. The operators G_i. Define the function $\mathcal{T}_{\omega_0,\lambda_i^0}:\mathbb{R}\to\mathbb{R}$ as

$$\begin{cases} \mathcal{T}_{\omega_0,\lambda_i^0}(x) = x \quad \text{in } [-\mathcal{M}_{\omega_0,\lambda_i^0}, \mathcal{M}_{\omega_0,\lambda_i^0}], \\ \mathcal{T}_{\omega_0,\lambda_i^0}(x) = \mathcal{M}_{\omega_0,\lambda_i^0} \quad \text{in } [\mathcal{M}_{\omega_0,\lambda_i^0}, +\infty), \\ \mathcal{T}_{\omega_0,\lambda_i^0}(x) = -\mathcal{M}_{\omega_0,\lambda_i^0} \quad \text{in } (-\infty, -\mathcal{M}_{\omega_0,\lambda_i^0}]. \end{cases} \tag{4.24}$$

Let us now introduce the operators G_k, $k=1,\dots,g$. We define $G_k(\omega,\lambda_1,\dots,\lambda_g)\in C^0([0,T],\mathbb{R})$ by

(4.25)
$$G_k(\omega,\lambda_1,\dots,\lambda_g)(t) := \mathcal{T}_{\omega_0,\lambda_i^0}\left[\lambda_k^0 + \int_0^t\int_{\Gamma_k} y_{\omega,\lambda_i}(s,x)\cdot n(x)F[\omega,\lambda_i](s,x)dsdx\right].$$

5. Proof that $\mathcal{F}$ admits a fixed point. In this section, we prove that the operator $\mathcal{F} := (F, G_1,\dots,G_g)$ that we have just constructed admits a fixed point. This is done by using the Leray–Schauder fixed point theorem. Accordingly, we have to prove three properties:

- $\mathcal{F}(X)\subset X$;
- $\mathcal{F}(X)$ is compact in X for the C^0 topology;
- $\mathcal{F}$ is continuous for the C^0 topology.

We prove this in three distinct subsections.

5.1. $\mathcal{F}(X)\subset X$. The first point to prove is that, for $(\omega,\lambda_i)\in X$, $F[\omega,\lambda_i]$ is a continuous function of (t,x). Fixing $(t,x)\in[0,T]\times\overline{\Omega}$, let us prove that $F[\omega,\lambda_i]$ is continuous at the point (t,x). Again, we distinguish the four cases α, β, γ, and δ, corresponding respectively to the case when $a_{\omega,\lambda_i}(t,x)\in\Omega\cup(\partial\Omega\backslash\overline{\gamma^-})$, $a_{\omega,\lambda_i}(t,x)\in\overline{\gamma^-}\backslash[\mathrm{Supp}(\Gamma)\cup\mathrm{Supp}(\Lambda)]$, $a_{\omega,\lambda_i}(t,x)\in\mathrm{Supp}(\Gamma)$, and $a_{\omega,\lambda_i}(t,x)\in\mathrm{Supp}(\Lambda)$.

Case α: $a_{\omega,\lambda_i}(t,x)\in\Omega\cup(\partial\Omega\backslash\overline{\gamma^-})$. Therefore, $s_{\omega,\lambda_i}(t,x)=0$. By the continuity of the flow Φ^{ω,λ_i}, there exists a neighborhood of (t,x) on which $\Phi^{\omega,\lambda_i}(0,t',x')\in$

$\Omega \cup (\partial\Omega \backslash \overline{\gamma^-})$. Then the continuity of $F[\omega, \lambda_i]$ at the point (t, x) comes directly from the continuities of the flow and of ω_0, and from (4.17).

Case β: $a_{\omega,\lambda_i}(t,x) \in \overline{\gamma^-} \backslash [\mathrm{Supp}(\Gamma) \cup \mathrm{Supp}(\Lambda)]$. In this case, using (3.15) and the continuity of the flow, one sees that s_{ω,λ_i} is continuous at the neighborhood of (t, x). To be more precise the following hold:

– s_{ω,λ_i} is always upper semicontinuous, as follows from the continuity of the flow. Indeed, consider $s > s_{\omega,\lambda_i}(t,x)$; the trajectory

$$\Phi^{\omega,\lambda_i}(\tau, t, x) \quad \text{for } \tau \in [s, t]$$

does not touch $\overline{\gamma^-}$. Consequently, for (t', x') close enough to (t, x), the corresponding trajectory

$$\Phi^{\omega,\lambda_i}(\tau, t', x') \quad \text{for } \tau \in [s, t']$$

does not touch $\overline{\gamma^-}$ either. This leads to

$$\overline{\lim_{(t',x')\to(t,x)}} s_{\omega,\lambda_i}(t', x') \leq s_{\omega,\lambda_i}(t, x). \tag{5.1}$$

– s_{ω,λ_i} is lower semicontinuous in this neighborhood, as a consequence of (3.15). Indeed, for $s \in [s_{\omega,\lambda_i}(t,x) - \nu, s_{\omega,\lambda_i}(t,x))$, one has $\Phi^{\omega,\lambda_i}(s, t, x) \in B_R \backslash \overline{\Omega}$. Now using the continuity of the flow, this gives

$$\underline{\lim_{(t',x')\to(t,x)}} s_{\omega,\lambda_i}(t', x') \geq s_{\omega,\lambda_i}(t, x). \tag{5.2}$$

Then again, once we have obtained the continuity of s_{ω,λ_i}, the continuity of $F[\omega, \lambda_i]$ at the point (t, x) comes from the continuities of the flow and of ω_0, and from (4.21).

(Cases α and β are the only ones that arise in the simply connected case; see [4, Lemma 3.3].)

Case γ: $a_{\omega,\lambda_i}(t,x) \in \mathrm{Supp}(\Gamma_A)$ for some $A \in \mathcal{A}$. In this case, $s_{\omega,\lambda_i}(t,x)$ can be discontinuous, but only in the case where $a_{\omega,\lambda_i}(t,x) = A$, for the same reason as in case β. Indeed, when $a_{\omega,\lambda_i}(t,x) \neq A$, (3.15) is still valid, so the same argument stands true. So we suppose from now on that $a_{\omega,\lambda_i}(t,x) = A$. Consider (t', x') in a neighborhood of (t, x). We distinguish some subcases according to the locus of $a_{\omega,\lambda_i}(t', x')$.

- *Cases β' and δ':* $a_{\omega,\lambda_i}(t', x') \in \overline{\gamma^-} \setminus \mathrm{Supp}(\Gamma_A)$ (including $a_{\omega,\lambda_i}(t', x') \in \mathrm{Supp}(\Gamma_{A'})$ for some $A' \in \mathcal{A} \setminus \{A\}$). These cases cannot happen if the neighborhood around (t, x) is chosen small enough (this is a clear consequence of the continuity of the flow).
- *Case γ':* $a_{\omega,\lambda_i}(t', x') \in \mathrm{Supp}(\Gamma_A)$ (including A). Let us prove that in this case $a_{\omega,\lambda_i}(t', x')$ is close to $a_{\omega,\lambda_i}(t, x) = A$ and that $s_{\omega,\lambda_i}(t', x')$ is close to $s_{\omega,\lambda_i}(t, x)$ in the following sense: take a sequence (t'_n, x'_n) in the region of points in Case γ', converging to (t, x); then one has the corresponding convergences

$$a_{\omega,\lambda_i}(t'_n, x'_n) \to a_{\omega,\lambda_i}(t, x) \quad \text{and} \quad s_{\omega,\lambda_i}(t'_n, x'_n) \to s_{\omega,\lambda_i}(t, x) \quad \text{as } n \to +\infty.$$

  Indeed,
  * given $\varepsilon > 0$, one has for n large enough $s_{\omega,\lambda_i}(t'_n, x'_n) \geq s_{\omega,\lambda_i}(t, x) - \varepsilon$. If not, for some subsequence of (t'_n, x'_n) (that we still call (t'_n, x'_n)), one has $s_{\omega,\lambda_i}(t'_n, x'_n) \to \overline{s}$, with

$$\overline{s} \leq s_{\omega,\lambda_i}(t, x) - \varepsilon.$$

By continuity of the flow, $\Phi^{\omega,\lambda_i}(s_{\omega,\lambda_i}(t'_n,x'_n),t'_n,x'_n)$ converges to $\Phi^{\omega,\lambda_i}(\overline{s},t,x)$ as $n\to+\infty$. But as $\overline{s}\le s_{\omega,\lambda_i}(t,x)-\varepsilon$ and using (3.18), one must have $\Phi^{\omega,\lambda_i}(\overline{s},t,x)\in\gamma_A$, which contradicts the fact that it is a limit point of a sequence in $\overline{\gamma^-}$.

* we argue in the same way to get $s_{\omega,\lambda_i}(t'_n,x'_n)\le s_{\omega,\lambda_i}(t,x)+\varepsilon$. If this does not happen, one finds a subsequence of (t'_n,x'_n) for which $s_{\omega,\lambda_i}(t'_n,x'_n)$ converges to $\overline{s}\ge s_{\omega,\lambda_i}(t,x)+\varepsilon$. This yields a contradiction with the continuity of the flow and (3.19).

Now, using the continuity of the flow and the convergence of $s_{\omega,\lambda_i}(t'_n,x'_n)$, one gets the continuity of $a_{\omega,\lambda_i}(t'_n,x'_n)$.

It follows from the choice of T—see in particular Remark 8—that

$$F^{\omega,\lambda_i}(t,A)=\omega_0(\Phi^{\omega,\lambda_i}(0,t,A))$$

and hence that $t\mapsto F^{\omega,\lambda_i}(t,A)$ is continuous. Now, using the continuity of Γ_A, we get a neighborhood of (t,x) in which the points in the Case γ' satisfy

$$|F^{\omega,\lambda_i}(t',x')-F^{\omega,\lambda_i}(t,x)|<\epsilon.$$

- *Case* α': $a_{\omega,\lambda_i}(t',x')\in\Omega\cup(\partial\Omega\backslash\overline{\gamma^-})$. Then one has

$$F[\omega,\lambda_i](t',x')=\omega_0(\Phi^{\omega,\lambda_i}[0,t',x']).$$

But by (4.19) we also have

$$F[\omega,\lambda_i](t,x)=\omega_0\left(\Phi^{\omega,\lambda_i}[0,s_{\omega,\lambda_i}(t,x),a_{\omega,\lambda_i}(t,x)]\right)=\omega_0(\Phi^{\omega,\lambda_i}[0,t,x]).$$

(Remember $a_{\omega,\lambda_i}(t,x)=A$.) Then again, using only the continuity of the flow and the continuity of ω_0, we get that $F[\omega,\lambda_i](t,x')$ can be made arbitrarily close to $F[\omega,\lambda_i](t,x)$ if we restrict x' to a small neighborhood of x of points in Case α'.

Case δ: $a_{\omega,\lambda_i}(t,x)\in\mathrm{Supp}(\Lambda_k)$ for some $k\in\{1,\dots,g\}$. This is again, as in Case β, a situation where s_{ω,λ_i} is continuous at the neighborhood of (t,x). Then the continuity in this case is a consequence of the continuities of the flow, of ω_0 and λ_k, and of (4.21).

From the continuity of $F(\omega,\lambda_i)$ and (4.25), we get that the functions $G_k(\omega,\lambda_1,\dots,\lambda_g)$ are time continuous.

Once this is proved, we have to check that the points (a) to (h) in the definition of X are satisfied by $\mathcal{F}(\omega,\lambda_i)$ for $(\omega,\lambda_i)\in X$.

(a) That $F(\omega,\lambda_i)(0,\cdot)=\omega_0$ is a clear consequence of the construction of F.

(c) We have also $G_i(0)=\lambda_i^0$ for $i=1,\dots,g$, as a direct consequence of (4.3), (4.24), and (4.25).

(b) Let us check that for all $(t,x)\in[0,T]\times\overline{\Omega}$ one has $|F[\omega,\lambda_i](t,x)|\le\mathcal{N}_{\omega_0,\lambda_i^0}$ by separating the four cases. Let us therefore consider (t,x) which achieves the maximum of $|F[\omega,\lambda_i](t,x)|$.

Case α: Suppose $a_{\omega,\lambda_i}(t,x)\in\Omega\cup(\partial\Omega\backslash\overline{\gamma^-})$. Then one has

$$|F[\omega,\lambda_i](t,x)|=|\omega_0(a_{\omega,\lambda_i}(t,x))|\le\|\omega_0\|_\infty.$$

Case β: Suppose $a_{\omega,\lambda_i}(t,x)\in\overline{\gamma^-}\backslash[\mathrm{Supp}(\Gamma)\cup\mathrm{Supp}(\Lambda)]$. Then one has

$$\begin{aligned}|F[\omega,\lambda_i](t,x)|&=|\omega_0(a_{\omega,\lambda_i}(t,x))|\exp\left(-M\int_0^{s_{\omega,\lambda_i}(t,x)}\alpha_{\omega,\lambda_i}(\tau)d\tau\right)\\&\le\|\omega_0\|_\infty.\end{aligned}$$

Case γ: Suppose $a_{\omega,\lambda_i}(t,x) \in \mathrm{Supp}(\Gamma_A)$ for some $A \in \mathcal{A}$. It is a consequence of (3.20) (or Remark 8) that

$$|F[\omega,\lambda_i](t,A)| \leq \|\omega_0\|_\infty.$$

Then one has, using (2.22) and (4.19),

$$\begin{aligned}|F[\omega,\lambda_i](t,x)| &= |\omega^\sharp(s_{\omega,\lambda_i}(t,x),a_{\omega,\lambda_i}(t,x)) + \omega^\flat(s_{\omega,\lambda_i}(t,x),a_{\omega,\lambda_i}(t,x))| \\ &\leq 3\|\omega_0\|_\infty \leq \mathcal{N}_{\omega_0,\lambda_i^0}.\end{aligned}$$

Case δ: Suppose $a_{\omega,\lambda_i}(t,x) \in \mathrm{Supp}(\Lambda_k)$ for some $k \in \{1,\dots,g\}$. As $F[\omega,\lambda_i](t,x)$ is transported by the flow inside Ω, it suffices to prove that for $(t,x) \in [0,T] \times \mathrm{Supp}(\Lambda_k)$ one has

$$\begin{aligned}&|\omega^\sharp(t,x) + \omega^\natural(t,x)| \\ &\qquad \leq \left[3 + |\Omega| + \frac{V(\theta)}{\kappa}\mathcal{T}(\Gamma)\right](1+\|\Lambda\|_\infty)\max(|\lambda_1^0|,\dots,|\lambda_g^0|,\|\omega_0\|_\infty).\end{aligned}$$

Of course, one has

$$|\omega^\sharp(t,x)| \leq \|\omega_0\|_\infty + \|\Lambda\|_\infty|\lambda_k^0| \quad \text{on } [0,T]\times\mathrm{Supp}(\Lambda_k).$$

Now, using point (e), one gets, for $(t,x) \in [0,T]\times\mathrm{Supp}(\Lambda_k)$,

$$\begin{aligned}|\omega^\natural(t,x)| &\leq |\lambda_k(t)|\|\Lambda\|_\infty \\ &\leq \left[2 + |\Omega| + \frac{V(\theta)}{\kappa}\mathcal{T}(\Gamma)\right]\|\Lambda\|_\infty\max(|\lambda_1^0|,\dots,|\lambda_g^0|,\|\omega_0\|_\infty).\end{aligned}$$

Hence, one still gets the estimate (b) for $F(\omega,\lambda_i)$.

(e) That the functions G_i satisfy the constraint (e) is a direct consequence of (4.3) and (4.24).

(f) Point (f) is obtained as a consequence of (4.25). Consider $k \in \{1,\dots,g\}$ and $t \in (0,T]$. Then either t is a left accumulation of points where

$$\left|\lambda_k^0 + \int_0^t \int_{\Gamma_k} y_{\omega,\lambda_i}(t,x)\cdot n(x) F[\omega,\lambda_i](t,x)dx\right| \geq \mathcal{M}_{\omega_0,\lambda_i^0},$$

and in that case

$$\frac{dG_k(\omega,\lambda_i)}{dt^-} = 0,$$

or it is not, and one can write

$$\begin{aligned}\frac{dG_k(\omega,\lambda_i)}{dt^-} &= \int_{\Gamma_k} y_{\omega,\lambda_i}(t,x)\cdot n(x)F[\omega,\lambda_i](t,x)dx \\ &= K\int_{\Gamma_k}\alpha_{\omega,\lambda_i}(t)\nabla\theta(x)\cdot n(x)F[\omega,\lambda_i](t,x)dx.\end{aligned}$$

Using the fact that $(\omega,\lambda_i) \in X$ and consequently satisfies points (b) and (e), we get that

$$\|\alpha_{\omega,\lambda_i}(t)\nabla\theta(x)\cdot n(x)\|_{C^0([0,T]\times\partial\Omega)} \leq \mathcal{N}_{\omega_0,\lambda_i^0}\|\nabla\theta\|_\infty.$$

Using the fact that $F[\omega,\lambda_i]$ satisfies the estimate (b), this leads to

$$\left|\frac{dG_k(\omega,\lambda_i)}{dt^-}\right|(t) \le \kappa_2 \max\left(\|\omega_0\|_\infty, |\lambda_1^0|,\dots,|\lambda_g^0|\right)^2.$$

(d) Define

$$\check{y}_{\omega,\lambda_i} = y_{\omega,\lambda_i} - K\alpha_{\omega,\lambda_i}\nabla\theta.$$

Using (3.9) and (b) and (e) in (4.1), one gets

$$\|\check{y}_{\omega,\lambda_i}\|_{L^\infty([0,T];\mathcal{LL}(\Omega))} \le C_{\mathcal{LL}} \max(\mathcal{M}_{\omega_0,\lambda_i^0},\mathcal{N}_{\omega_0,\lambda_i^0}) = C_{\mathcal{LL}}\mathcal{N}_{\omega_0,\lambda_i^0}.$$

It follows that one has

$$\text{(5.3)}\qquad \begin{cases} \|y_{\omega,\lambda_i}\|_{L^\infty([0,T]\times\Omega)} \le C_{\mathcal{LL}}\mathcal{N}_{\omega_0,\lambda_i^0} + K\mathcal{N}_{\omega_0,\lambda_i^0}\|\nabla\theta\|_\infty, \\ \|y_{\omega,\lambda_i}\|_{L^\infty([0,T];\mathcal{LL}(\overline{\Omega}))} \le C_{\mathcal{LL}}\mathcal{N}_{\omega_0,\lambda_i^0} + K\mathcal{N}_{\omega_0,\lambda_i^0}\|\nabla\theta\|_{\mathcal{LL}}. \end{cases}$$

Moreover, we have from point (b) that

$$\max_{t\in[0,T]} \|F[\omega,\lambda_i](t,\cdot)\|_{L^\infty(\Omega)} \le \mathcal{N}_{\omega_0,\lambda_i^0}.$$

Consequently one gets

$$\|y_{\omega,\lambda_i}F[\omega,\lambda_i]\|_{L^\infty([0,T],L^\infty(\Omega))} \le (C_{\mathcal{LL}} + K\|\nabla\theta\|_\infty)\mathcal{N}^2_{\omega_0,\lambda_i^0}.$$

But it follows from the construction that $F[\omega,\lambda_i]$ satisfies

$$\partial_t F[\omega,\lambda_i] + \operatorname{div}(y_{\omega,\lambda_i}F[\omega,\lambda_i]) = 0 \text{ in } \mathcal{D}'((0,T)\times\Omega).$$

This leads to the fact that $F[\omega,\lambda_i]$ satisfies constraint (d).

(g) This point follows from (3.7), (3.18), and (4.19). Indeed, one has, for any $A\in\mathcal{A}$ and any $(t,t')\in[0,T]^2$,

$$F[\omega,\lambda_i](t,A) - F[\omega,\lambda_i](t',A) = \omega_0(\Phi^{\omega,\lambda_i}(0,t,A)) - \omega_0(\Phi^{\omega,\lambda_i}(0,t',A)),$$

with $\Phi^{\omega,\lambda_i}(0,t',A)$ and $\Phi^{\omega,\lambda_i}(0,t,A)$ in $\overline{\gamma_A}$. Hence, so that

$$|F[\omega,\lambda_i](t,A) - F[\omega,\lambda_i](t',A)| \le \varepsilon,$$

it is sufficient that $|\Phi^{\omega,\lambda_i}(0,t,A) - \Phi^{\omega,\lambda_i}(0,t',A)| \le \Xi_{\overline{\gamma_A}}[\omega_0](\varepsilon)$. Using (3.7) and (5.3), one sees that it is sufficient that

$$|t-t'| \le \left[\frac{\Xi_{\overline{\gamma_A}}[\omega_0](\varepsilon)}{C_{WY}(R,T,c_\pi\mathcal{N}_{\omega_0,\lambda_i^0}[C_{\mathcal{LL}}+K\|\nabla\theta\|_{\mathcal{LL}}])}\right]^{\frac{1}{\delta}}.$$

(h) We write $\hat{\omega} := F(\omega,\lambda_i)$. We divide the proof that $\hat{\omega}$ satisfies point (h) into two steps. First we estimate $\hat{t}-t$ so that

$$\text{(5.4)}\qquad \|\hat{\omega}(t,\cdot)\|_\infty - \|\hat{\omega}(\hat{t},\cdot)\|_\infty \le \varepsilon \quad \text{for } \hat{t} > t,$$

and then we estimate $\hat{t}-t$ so that

$$\text{(5.5)}\qquad \|\hat{\omega}(t,\cdot)\|_\infty - \|\hat{\omega}(\hat{t},\cdot)\|_\infty \ge -\varepsilon \quad \text{for } \hat{t} > t.$$

In what follows, we suppose $\hat{t} > t$.

- *Sufficient condition for* (5.4). First, we state a lemma.
LEMMA 5.1. *There exist* $\rho > 0$ *and* $\overline{\eta} > 0$ *such that for any* $\eta \in (0, \overline{\eta})$ *and any* $\overline{x} \in \overline{\Omega}$, *there is some* $\tilde{x} \in \Omega$ *such that*

$$d(\tilde{x}, \overline{x}) \leq \eta \quad \textit{and} \quad d(\tilde{x}, \partial\Omega) \geq \rho\eta.$$

Proof of Lemma 5.1. We introduce $\mathcal{V}$, a tubular neighborhood of $\partial\Omega$ in $\mathbb{R}^2$. It is easy to see that the following procedure, which associates a point $\tilde{x}$ to any $\overline{x}$, allows us to find relevant ρ and $\overline{\eta}$:
  - for $\overline{x}$ in $\mathcal{V} \cap \overline{\Omega}$, we pick a point $\tilde{x}$ in the direction of the inner normal to $\partial\Omega$,
  - for $\overline{x}$ in $\overline{\Omega} \backslash \mathcal{V}$, we pick $\tilde{x} = \overline{x}$.

The details are left to the reader.
We go back to the sufficient condition for (5.4). Let us consider $t \in [0, T)$. We introduce $\overline{x} \in \overline{\Omega}$ such that

$$|\hat{\omega}(t, \overline{x})| = \|\hat{\omega}(t, \cdot)\|_{\infty}.$$

We have two possible situations.
  - *First situation:* $d(\overline{x}, \overline{\gamma^+}) \geq \ell/4$. Then, considering (4.9), (5.3), the fact that $\hat{\omega}$ is constant along the flow of y_{ω,λ_i}, and the fact that a point following the flow of y_{ω,λ_i} can leave the domain only through $\overline{\gamma^+}$, one deduces that for $\hat{t} \in (t, T]$

$$\|\hat{\omega}(\hat{t})\|_{C^0(\overline{\Omega})} \geq |\hat{\omega}(\hat{t}, \Phi^{\omega,\lambda_i}(\hat{t}, t, \overline{x}))| = |\hat{\omega}(t, \overline{x})| = \|\hat{\omega}(t)\|_{C^0(\overline{\Omega})},$$

    which is stronger than (5.4).
  - *Second situation:* $d(\overline{x}, \overline{\gamma^+}) \leq \ell/4$, and hence, considering the definition of ℓ, one has

$$d(\overline{x}, \overline{\gamma^-}) \geq 3\ell/4.$$

    Considering (4.9) and (5.3), one deduces that

$$\Phi^{\omega,\lambda_i}(s, t, x) \in \overline{\Omega} \backslash \overline{\gamma^-} \quad \forall s \in [0, T] \text{ and any } x \in \overline{\Omega} \text{ such that } d(x, \overline{x}) < \ell/2. \tag{5.6}$$

    Moreover, using the fact that $\hat{\omega}$ is constant along the flow of y_{ω,λ_i} and the fact that a point following the flow of y_{ω,λ_i} cannot leave the domain except through $\overline{\gamma^+}$, we see that in order to have (5.4), it is sufficient that

$$|t - \hat{t}| \leq d(\tilde{x}, \overline{\gamma^+}) / \|y_{\omega,\lambda_i}\|_{L^\infty(\Omega_T)},$$

    where $\tilde{x} \in \Omega$ is some point satisfying

$$|\hat{\omega}(t, \tilde{x}) - \hat{\omega}(t, \overline{x})| \leq \varepsilon. \tag{5.7}$$

    Using (5.6), one sees that to get (5.7), it is sufficient to have

$$d(x, \overline{x}) < \ell/2 \text{ and } |\Phi^{\omega,\lambda_i}(0, t, \tilde{x}) - \Phi^{\omega,\lambda_i}(0, t, \overline{x})| \leq \Xi_{\overline{\Omega}}[\omega_0](\varepsilon),$$

and hence, using (3.7), that

$$|\tilde{x}-\overline{x}| \le \min\left\{ \left(\frac{\Xi_{\overline{\Omega}}[\omega_0](\varepsilon)}{C_{WY}(R,T,c_\pi(C_{\mathcal{LL}}+K\|\nabla\theta\|_{\mathcal{LL}})\mathcal{N}_{\omega_0,\lambda_i^0})} \right)^{\frac{1}{\delta}}, \ell/4 \right\}.$$

It follows from Lemma 5.1 that one can find such a point $\tilde{x}$ satisfying (5.7) such that

$$d(\tilde{x},\overline{\gamma^+}) \ge m \min\Big(\big(\Xi_{\overline{\Omega}}[\omega_0](\varepsilon)\big)^{\frac{1}{\delta}}, 1\Big)$$

for some $m>0$ independent from ε. So, using (5.3), one deduces that in order to have $\|\hat{\omega}(t,\cdot)\|_\infty - \|\hat{\omega}(\hat{t},\cdot)\|_\infty \ge -\varepsilon$ (given $\varepsilon\in(0,1)$), it is sufficient that

$$|t-\hat{t}| \le \frac{1}{c}\min\Big\{ \big(\Xi_{\overline{\Omega}}[\omega_0](\varepsilon)\big)^{\frac{1}{\delta}}, \varepsilon\Big\}$$

for some $c>0$ large enough depending on (ω_0,λ_i^0), on the domain, and on K and on θ, but not on (ω,λ_i) or on ε.

- *Sufficient condition for* (5.5). Let us prove that in order for (5.5) to happen, it is sufficient that

$$\|\hat{\omega}_{|\gamma^-}(s)\|_\infty - \|\hat{\omega}_{|\gamma^-}(t)\|_\infty \le \varepsilon \quad \forall\ s\in[t,\hat{t}]. \tag{5.8}$$

Indeed, let us consider $\hat{x}\in\overline{\Omega}$ such that

$$|\hat{\omega}(\hat{t},\hat{x})| = \|\hat{\omega}(\hat{t},\cdot)\|_\infty.$$

– If $\Phi^{\omega,\lambda_i}([t,\hat{t}],\hat{t},\hat{x})$ meets $\overline{\gamma^-}$, then clearly, using again the fact that $\hat{\omega}$ is constant along the flow of y_{ω,λ_i}, one deduces that

$$\|\hat{\omega}(\hat{t})\|_\infty \le \sup_{s\in[t,\hat{t}]} \|\hat{\omega}_{|\gamma^-}(s)\|_\infty,$$

and hence

$$\begin{aligned}\|\hat{\omega}(\hat{t})\|_\infty - \|\hat{\omega}(t)\|_\infty &\le \sup_{s\in[t,\hat{t}]} \|\hat{\omega}_{|\gamma^-}(s)\|_\infty - \|\hat{\omega}(t)\|_\infty \\ &\le \sup_{s\in[t,\hat{t}]} \|\hat{\omega}_{|\gamma^-}(s)\|_\infty - \|\hat{\omega}_{|\gamma^-}(t)\|_\infty.\end{aligned}$$

– Otherwise, it is quite clear that

$$\|\hat{\omega}(\hat{t})\|_\infty = |\hat{\omega}(\hat{t},\hat{x})| = |\hat{\omega}(t,\Phi^{\omega,\lambda_i}(t,\hat{t},\hat{x}))| \le \|\hat{\omega}(t)\|_{C^0(\overline{\Omega})},$$

which is stronger than (5.5).

Now, using (2.22) and the decomposition (4.22) of $F[\omega,\lambda_i]$, one gets on $(0,T)\times\gamma^-$,

$$\|\omega^\flat(t)-\omega^\flat(\hat{t})\|_\infty \le \max_{A\in\mathcal{A}} |\omega_0(\Phi^{\omega,\lambda_i}(0,t,A)) - \omega_0(\Phi^{\omega,\lambda_i}(0,\hat{t},A))|, \tag{5.9}$$

and

$$\frac{\partial}{\partial t}\left(\omega^\natural+\omega^\sharp\right)=-\sum_{k=1}^{g}\Lambda_k(x)\frac{d}{dt}\lambda_k(t)-M\alpha_{\omega,\lambda_i}(t) \tag{5.10}$$
$$\times\left[\omega_0(x)-\sum_{A\in\mathcal{A}}\omega_0(A)\Gamma_A(x)+\sum_{k=1}^{g}\lambda_k^0\Lambda_k(x)\right]\exp\left(-M\int_0^t\alpha_{\omega,\lambda_i}(\tau)d\tau\right).$$

In order to have (5.8), it is sufficient that

$$\|\omega^\flat(t)-\omega^\flat(\hat{t})\|_\infty\leq\varepsilon/2\quad\text{and}\quad\|\omega^\natural(t)+\omega^\sharp(t)-\omega^\natural(\hat{t})+\omega^\sharp(\hat{t})\|_\infty\leq\varepsilon/2$$

and hence, using points (b), (e), and (f) in the definition of X and (3.18), (5.9), and (5.10), that

$$|t-\hat{t}|\leq\frac{1}{c}\min(\varepsilon,\Xi_{\overline{\Omega}}[\omega_0](\varepsilon))$$

for some c large enough depending on ω_0 and λ_i^0, but not on ε, $\hat{t}$, or (ω,λ_i). So in all cases, in order to get (5.4) and (5.5), it is sufficient to have

$$|t-\hat{t}|\leq\frac{1}{c}\min\left(\varepsilon,\Xi_{\overline{\Omega}}[\omega_0](\varepsilon)\right)$$

for proper c, which allows us to conclude.

This ends the proof that $\mathcal{F}(X)\subset X$. □

5.2. $\mathcal{F}(X)$ is compact in $C^0([0,T]\times\overline{\Omega};\mathbb{R})\times[C^0([0,T];\mathbb{R})]^g$. Consider a sequence $(\omega_n,\lambda_i^n)_{n\geq1}$ in X. Let us prove that one can extract a converging subsequence from $\mathcal{F}(\omega_n,\lambda_i^n)$ in $C^0([0,T]\times\overline{\Omega};\mathbb{R})\times\left[C^0([0,T];\mathbb{R})\right]^g$. We will have to extract subsequences from $(\omega_n,\lambda_i^n)_{n\geq1}$ several times to get the convergence and, in order to avoid too heavy notation, we will continue to write those subsequences (ω_n,λ_i^n) (instead of $(\omega_{\varphi(n)},\lambda_i^{\varphi(n)})$, for instance). Moreover, we put an index n to objects constructed in section 4.2, corresponding to (ω_n,λ_i^n): each (ω_n,λ_i^n) yields a function α_n by (4.12) and then a vector field y_{ω_n,λ_i^n} on $[0,T]\times\overline{\Omega}$ by (4.13), which in turn yields a vector field $\tilde{y}_{\omega_n,\lambda_i^n}$ by (4.14). To these $\tilde{y}_{\omega_n,\lambda_i^n}$ one can associate a flow Φ_n by (3.6).

Using (3.9), (4.1), and (4.13), one easily gets that for some $C>0$,

$$q_{\overline{\Omega}}(y_{\omega_n,\lambda_i^n}(t,\cdot)-K\alpha_n(t)\nabla\theta(\cdot))\leq C\quad\forall t\in[0,T],\ \forall n\geq1,$$

and hence, using (4.1) again, the regularity of the function $\nabla\theta$, and (3.4), that for some $C'>0$,

$$q_{\overline{B_R}}(\tilde{y}_{\omega_n,\lambda_i^n}(t,\cdot))\leq C'\quad\forall t\in[0,T],\ \forall n\geq1.$$

Therefore, it follows from the Wolibner–Yudovich (see (3.7)) and Ascoli–Arzela theorems that Φ_n is relatively compact in $C^0([0,T]\times[0,T]\times B_R;B_R)$, say

$$\Phi_n\longrightarrow\overline{\Phi}\quad\text{in } C^0([0,T]\times[0,T]\times B_R;B_R). \tag{5.11}$$

We now have to prove

$$F(\omega_n,\lambda_i^n)\longrightarrow\overline{F}\quad\text{in } C^0([0,T]\times\overline{\Omega})\text{ as } n\to+\infty \tag{5.12}$$

for a certain $\overline{F}$ in $C^0([0,T]\times\overline{\Omega};\mathbb{R})$. To that end, let us first prove that one can get some compactness on the sequence $F(\omega_n,\lambda_i^n)$ on the boundary, precisely

$$F(\omega_n,\lambda_i^n)_{|[0,T]\times\overline{\gamma^-}} \longrightarrow \overline{\omega} \text{ uniformly on } [0,T]\times\overline{\gamma^-} \text{ as } n\to+\infty, \tag{5.13}$$

for some $\overline{\omega}$ in $C^0([0,T]\times\overline{\gamma^-};\mathbb{R})$.

For this, let us decompose $F(\omega_n,\lambda_i^n)_{|[0,T]\times\overline{\gamma^-}}$ into

$$F(\omega_n,\lambda_i^n)=\omega_n^\flat+\omega_n^\sharp+\omega_n^\natural \quad \text{on } [0,T]\times\overline{\gamma^-},$$

as described in (4.22). Then we prove (5.13) in several steps.

- First, it follows from points (b) and (g) in the definition of X and the Ascoli–Arzela theorem that one can extract subsequences s.t.

$$\omega_n^\flat \longrightarrow \overline{\omega}^\flat:=\sum_{A\in\mathcal{A}}\overline{\omega}(\cdot,A)\Gamma_A(\cdot) \quad \text{uniformly on } [0,T]\times\overline{\gamma^-} \text{ as } n\to+\infty. \tag{5.14}$$

- From the Ascoli–Arzela theorem and points (b) and (e) in the definition of X, one deduces that the sequence of functions $\Upsilon_n : t\mapsto M\int_0^t\alpha_n(\tau)d\tau$ is relatively compact in $C^0([0,T];\mathbb{R}^+)$ and hence, up to a subsequence, one has

$$\omega_n^\sharp \longrightarrow \overline{\omega}^\sharp:=\left[\omega_0(\cdot)-\sum_{A\in\mathcal{A}}\omega_0(A)\Gamma_A(\cdot)+\sum_{i=1}^g\lambda_i^0\Lambda_i(\cdot)\right]\exp(-\overline{\Upsilon}), \tag{5.15}$$
$$\text{uniformly on } [0,T]\times\overline{\gamma^-} \text{ as } n\to+\infty.$$

- Extracting again a subsequence if necessary, one can get from points (e) and (f) in the definition of X that $\lambda_i^n\to\overline{\lambda_i}$ in $C^0([0,T],\mathbb{R})$. Consequently one gets

$$\omega_n^\natural \longrightarrow \overline{\omega}^\natural:=\sum_{i=1}^g\Lambda_i(\cdot)\Big[-\overline{\lambda_i}\Big] \quad \text{uniformly on } [0,T]\times\overline{\gamma^-} \text{ as } n\to+\infty. \tag{5.16}$$

We get (5.13) from (5.14), (5.15), and (5.16).

Furthermore, using point (h) and the Ascoli–Arzela theorem one can extract a converging subsequence from $\|\omega_n(\cdot)\|_{L^\infty(\Omega)}$:

$$\|\omega_n(t)\|_{L^\infty(\Omega)}\longrightarrow\overline{N}(t) \text{ uniformly on } [0,T].$$

This yields, as $n\to+\infty$,

$$\begin{aligned}\alpha_n(t):=\max(|\lambda_1^n(t)|,\dots,|\lambda_g^n(t)|,\|\omega_n(t)\|_\infty)\\ \longrightarrow\overline{\alpha}(t):=\max(|\overline{\lambda}_1(t)|,\dots,|\overline{\lambda}_g(t)|,\overline{N}(t)) \text{ in } C^0([0,T];\mathbb{R}^+).\end{aligned} \tag{5.17}$$

Let us prove that this implies that $\overline{\Phi}$ satisfies the conclusions of Proposition 3.5. We proceed exactly as for [4, equation (3.57)ff]. Let us recall the argument. Define

$$\check{y}_{\omega_n,\lambda_i^n}:=y_{\omega_n,\lambda_i^n}-K\alpha_n(t)\nabla\theta.$$

Hence $\check{y}_{\omega_n,\lambda_i^n}$ satisfies (3.8) for (ω_n,λ_i^n). From (4.1) and usual elliptic estimates concerning (3.8), one deduces that, for any $r\in(2,+\infty)$,

$$\check{y}_{\omega_n,\lambda_i^n} \text{ is bounded in } C^0([0,T],W^{1,r}(\Omega;\mathbb{R}^2)),$$
$$\frac{\partial}{\partial t}\check{y}_{\omega_n,\lambda_i^n} \text{ is bounded in } L^\infty([0,T],H^{-1}(\Omega;\mathbb{R}^2)).$$

Using [8, Appendix C, Lemma C1] with $X=W^{1,r}(\Omega;\mathbb{R}^2)$ and $Y=H^{-1}(\Omega;\mathbb{R}^2)$, one deduces that $\check{y}_{\omega_n,\lambda_i^n}$ is relatively compact in $C^0([0,T],W^{1,r}(\Omega;\mathbb{R}^2)-w)$ and hence, using the Rellich–Kondrakov theorem, relatively compact in $C(\Omega_T)$. Hence using (5.17), the sequence y_{ω_n,λ_i^n} is itself relatively compact in $C(\Omega_T)$.

Hence, up to a subsequence, one has

$$y_{\omega_n,\lambda_i^n}\longrightarrow \overline{Y} \quad \text{in } C^0(\Omega_T;\mathbb{R}^2).$$

As in [4, equation (3.60)], we get that $\overline{\Phi}=\Phi^{\pi(\overline{Y})}$: this is a consequence of the definition of the flow and of the dominated convergence theorem.

Now let us observe that $\overline{Y}$ satisfies the assumptions of Proposition 3.5. This is a consequence of the fact that the sequence (ω_n,λ_i^n) satisfies them and of the fact that

$$\|\operatorname{curl}\overline{Y}\|_\infty \le \liminf_{n\to+\infty}\|\omega_n\|_\infty.$$

Note that by (5.17) and by (4.10)–(4.11), one has $\overline{\alpha}>0$.

Let us now show that, together with (5.11), this yields a convergence for $F(\omega_n,\lambda_i^n)$ in $[0,T]\times\overline{\Omega}$. The flow $\overline{\Phi}$ yields functions $\overline{s}$ and $\overline{a}$ as for (4.16) with Φ^{ω,λ_i} replaced by $\overline{\Phi}$. Then one can define $\overline{F}$ by

$$\overline{F}(t,x):=\overline{\omega}(\overline{s},\overline{a}), \tag{5.18}$$

where we extend the definition of $\overline{\omega}$ on $\{0\}\times\overline{\Omega}$ by ω_0. Note that in this setting, the function $\overline{\omega}$ is well-defined and continuous in $(\{0\}\times\overline{\Omega})\cup([0,T]\times\overline{\gamma^-})$.

We have determined the potential limit $\overline{F}$; it remains to prove (5.12). Toward this end, let us prove the following equivalent assertion (by using a compactness argument):

(5.19)
$$\forall\varepsilon>0 \text{ and } \forall(t,x)\in[0,T]\times\overline{\Omega},\exists N\in\mathbb{N} \text{ and } \exists\mathcal{V} \text{ a vicinity of } (t,x) \text{ in } [0,T]\times\overline{\Omega}$$
$$\text{such that } \forall n\ge N, \text{ one has } \|F(\omega_n,\lambda_i^n)-\overline{F}\|_{C^0(\mathcal{V})}\le\varepsilon.$$

To prove (5.19), we fix $\varepsilon>0$ and $(t,x)\in[0,T]\times\overline{\Omega}$, and discuss them relative to the location of $\overline{a}(t,x)$.

Case α: $\overline{a}(t,x)$ in $\Omega\cup(\partial\Omega\backslash\overline{\gamma^-})$. Then, by continuity of $\overline{\Phi}$, one has, for any (t',x') in a neighborhood $\mathcal{V}_1$ of (t,x) in $[0,T]\times\overline{\Omega}$, that $\overline{a}(t',x')\in\Omega\cup(\partial\Omega\backslash\overline{\gamma^-})$. Then by (5.11) we get that for n large enough, $a_n(t',x')\in\Omega\cup(\partial\Omega\backslash\overline{\gamma^-})$ for $(t',x')\in\mathcal{V}_1$. So on $\mathcal{V}_1$, for such n, the expression of $F(\omega_n,\lambda_i^n)$ is $\omega_0(\Phi_n(t,0,x))$. So enlarging N and reducing $\mathcal{V}_1$ if necessary, using (5.18), we get the conclusion of (5.19) in this case.

Cases β and δ: $\overline{a}(t,x)$ in $\overline{\gamma^-}\backslash\operatorname{Supp}(\Gamma)$. In this case—remember that $\overline{\Phi}$ satisfies the conclusions of Proposition 3.5—one can show that (5.1)–(5.2) is true for $\overline{s}$, exactly as in Case β in section 5.1. Hence, $(\overline{s},\overline{a})$ is continuous in a neighborhood of (t,x). Let us distinguish two subcases.

– *Subcase* (i): Suppose $\overline{s}(t,x) > 0$. In some neighborhood $\mathcal{V}_1$ of (t,x) in $[0,T] \times \overline{\Omega}$, one has $\overline{s}(t',x') > 0$. We introduce a neighborhood $\mathcal{W}$ of $(\overline{s}(t,x), \overline{a}(t,x))$ in $[0,T] \times (\overline{\gamma^-} \setminus \mathrm{Supp}(\Gamma))$, small enough that on it,

$$|\overline{\omega}(\tau,y) - \overline{\omega}(\overline{s}(t,x), \overline{a}(t,x))| \leq \varepsilon/2$$

(and $\tilde{\mathcal{W}}$ containing $\mathcal{W}$ in which this is valid with ε). Reducing $\mathcal{V}_1$ if necessary, we have

$$(\overline{s}(t',x'), \overline{a}(t',x')) \in \mathcal{W}$$

for (t',x') in $\mathcal{V}_1$. Using (3.15)–(3.16) and (5.11), one gets that for N large enough, one has

$$(s_n(t',x'), a_n(t',x')) \in \tilde{\mathcal{W}}$$

for (t',x') in $\mathcal{V}_1$, which yields the conclusion of (5.19).

– *Subcase* (ii): Suppose $\overline{s}(t,x) = 0$. Let us call $\mathcal{W}$ a vicinity of $(0, \overline{a}(t,x))$ in $(\{0\} \times \overline{\Omega}) \cup ([0,T] \times \overline{\gamma^-})$ such that for (τ,y) in $\mathcal{W}$ one has $|\overline{\omega}(\tau,y) - \overline{\omega}(0, \overline{a}(t,x))| \leq \varepsilon/2$. For (t',x') in a certain neighborhood $\mathcal{V}$ of (t,x) in $[0,T] \times \overline{\Omega}$ and N large enough, we have, for all $n \geq N$, either $s_n(t',x') \in pr_1(\mathcal{W})$ or $a_n(t',x') \in pr_2(\mathcal{W})$, because otherwise, we could find a subsequence for which $\Phi_n(\cdot,t',x')$ meets $\overline{\gamma^-} \setminus pr_2(\mathcal{W})$ for any n, which would be in contradiction with (5.11). With (5.13), this yields again the conclusion of (5.19).

Case γ: $\overline{a}(t,x)$ in $\mathrm{Supp}(\Gamma_A)$ for some $A \in \mathcal{A}$. We divide again into subcases:

– *Subcase* (i): Suppose $\overline{a}(t,x) \neq A$. Then one can reproduce the proof of the previous Cases β and δ if we take care that $\mathcal{W}$ stays at positive distance from $[0,T] \times \{A\}$.

– *Subcase* (ii): Suppose $\overline{a}(t,x) = A$ and $\overline{s}(t,x) > 0$. Note that in this case, $\overline{F}(t,x) = \omega_0(\overline{\Phi}(0,t,x))$ (thanks to (4.19) and (5.14)–(5.16)).
We fix $\mathcal{W}_1$ as an open vicinity of $(\overline{s}(t,x), \overline{a}(t,x))$ in $[0,T] \times \overline{\gamma^-}$ and $\mathcal{W}_2$ as an open vicinity of $(0, \overline{\Phi}(0,t,x))$ in $\{0\} \times \overline{\Omega}$, small enough such that, on both $\mathcal{W}_1$ and $\mathcal{W}_2$, we have $|\overline{\omega}(t',x') - \overline{\omega}(0, \overline{a}(t,x))| \leq \varepsilon/2$. Reduce them so that they are disjoint (this is possible thanks to (3.18)). Let us prove that for (t',x') in some neighborhood of (t,x) and for n large enough, we have

$$(s_n(t',x'), a_n(t',x')) \in \mathcal{W}_1 \cup \mathcal{W}_2. \tag{5.20}$$

If not, we would have an increasing sequence of integers $\varphi(n)$ and a sequence of points (t'_n, x'_n) converging to (t,x), for which

$$(s_{\varphi(n)}(t'_n,x'_n), a_{\varphi(n)}(t'_n,x'_n)) \notin \mathcal{W}_1 \cup \mathcal{W}_2.$$

By compactness of $[0,T] \times \overline{\Omega}$, one would have, up to a subsequence,

$$(s_{\varphi(n)}(t'_n,x'_n), a_{\varphi(n)}(t'_n,x'_n)) \to (\hat{s},\hat{a}) \notin \mathcal{W}_1 \cup \mathcal{W}_2.$$

This would be in contradiction with $(t'_n,x'_n) \to (t,x)$ and (5.11):

– Suppose indeed that $\hat{s} > 0$. By continuity of $\overline{\Phi}$ one has

$$\overline{\Phi}(s_{\varphi(n)}(t'_n, x'_n), t'_n, x'_n) \to \overline{\Phi}(\hat{s}, t, x) \quad \text{as } n \to +\infty.$$

This involves $\hat{s} = \overline{s}$, because for $\tau \neq s$, we have $\overline{\Phi}(\tau, t, x) \notin \overline{\gamma}$. Consequently, we have $\hat{a} \in \overline{\gamma^-} \backslash pr_2(\mathcal{W}_1)$. But the trajectory from x to $\overline{\Phi}(0, t, x)$ has no such point, so this is impossible.

– Suppose now that $\hat{s} = 0$. Then by (5.11) one should have

$$a_{\varphi(n)}(t'_n, x'_n) \sim \overline{\Phi}(0, t'_n, x'_n) \to \overline{\Phi}(0, t, x)$$

and hence $(\hat{s}, \hat{a}) \in \mathcal{W}_2$.

Now (5.20) gives again the conclusion in (5.19).

– *Subcase* (iii): Suppose $\overline{a}(t, x) = A$ and $\overline{s}(t, x) = 0$. Again, we have $\overline{F}(t, x) = \omega_0(\overline{\Phi}(0, t, x))$. We fix $\mathcal{W}$ as a vicinity of $(0, A)$ in $(\{0\} \times \overline{\Omega}) \cup ([0, T] \times \overline{\gamma^-})$ on which again $|\overline{\omega}(t', x') - \overline{\omega}(0, \overline{a}(t, x))| \leq \varepsilon/2$ occurs. Then again, as in Subcase (ii) one can see that, for (t', x') in a small neighborhood of (t, x) and n large enough, one has

$$(s_n(t', x'), a_n(t', x')) \in \mathcal{W},$$

which leads to the conclusion.

So in all cases (5.19) is obtained; thus we get (5.12), and then the relative compactness of the sequence $G_i(\omega_n, \lambda_1^n, \ldots, \lambda_g^n)$ follows. This concludes this section.

5.3. $\mathcal{F}$ is continuous for the $C^0([0,T] \times \overline{\Omega}; \mathbb{R}) \times [C^0([0,T]; \mathbb{R})]^g$ topology. Using the previous section; we see that it is enough to prove that if $(\omega_n, \lambda_i^n) \to (\overline{\omega}, \overline{\lambda}_i)$ for the C^0 topology, then $F[\omega_n, \lambda_i^n] \to F(\overline{\omega}, \overline{\lambda})$ pointwise. This is essentially the same argument as in the previous section; we do not repeat it. Now, as the convergence of $F(\omega_n, \lambda_i^n)$ is established, obtaining the convergence of $G_k(\omega_n, \lambda_i^n)$, $k = 1, \ldots, g$, is straightforward.

5.4. Conclusion. Hence we get by the Leray–Schauder fixed point theorem a fixed point $(\omega^*, \lambda_i^*) \in X$ of the operator $\mathcal{F}$ described in section 4.2.

It follows from the construction that on $[0, T] \times \Omega$, one has

$$\partial_t F(\omega^*, \lambda_i^*) + \operatorname{div}(y_{\omega^*, \lambda_i^*} F(\omega^*, \lambda_i^*)) = 0 \tag{5.21}$$

and

$$F(\omega^*, \lambda_i^*)_{|t=0} = \omega_0. \tag{5.22}$$

Let us assume for the moment that the following lemma is proven.

LEMMA 5.2. *If M has been chosen large enough (depending on Ω, Σ, θ, and K), then for any $k \in \{1, \ldots, g\}$ and all $t \in [0, T]$,*

$$\left| \lambda_k^0 + \int_0^t \int_{\Gamma_k} y_{\omega^*, \lambda_i^*}(\sigma, x).n(x) \omega^*(\sigma, x) dx d\sigma \right| \leq \mathcal{M}_{\omega_0, \lambda_i^0}. \tag{5.23}$$

If (5.23) is true, then by (1.8) one has

$$\lambda_k^* = G_k(\omega^*, \lambda_1^*, \ldots, \lambda_g^*)(t) = \lambda_k^0 + \int_0^t \int_{\Gamma_k} y_{\omega^*, \lambda_i^*}(\sigma, x).n(x) \omega^*(\sigma, x) dx d\sigma. \tag{5.24}$$

Hence $(\omega^*, \lambda_1^*, \dots, \lambda_g^*)$ satisfies (1.6)–(1.8). Moreover, this fixed point satisfies the initial conditions (2.30). That $F(\omega^*, \lambda_i^*)$ satisfies the boundary condition (2.27)–(2.28) is a clear consequence of the construction of $\mathcal{F}$. So it remains only to prove Lemma 5.2.

Proof of Lemma 5.2. In the proof of Lemma 5.2, we will not use the specific form of T (in particular, Remark 8). This will be useful in section 6. Denote $y^* := y_{\omega^*,\lambda_i^*}$, $\alpha^* := \alpha_{\omega^*,\lambda_i^*}$, and $\Phi^* := \Phi^{\omega^*,\lambda_i^*}$. For any $k \in \{1, \dots, g\}$, we have (using (2.22), (2.23), and (4.22))

$$\begin{aligned}
&\int_0^t \int_{\Gamma_k} y^*(\sigma,x).n(x)F[\omega^*,\lambda_i^*](\sigma,x)dxd\sigma \\
&\quad = K\int_0^t \int_{\Gamma_k} \alpha^*(\sigma)\nabla\theta(x).n(x)\omega^*(\sigma,x)dxd\sigma \\
&\quad = K\int_0^t \alpha^*(\sigma)\left[-\lambda_k^*(\sigma) + \int_{\Gamma_k\cap\gamma^-} \nabla\theta(x).n(x)\omega^{*\sharp}(x)\right. \\
&\quad \left. + \int_{\Gamma_k\cap\gamma^+} \nabla\theta(x).n(x)\omega^*(\sigma,x)\right]dxd\sigma \\
&\quad = -K\int_0^t \alpha^*(\sigma)\lambda_k^*(\sigma)dxd\sigma \\
&\quad +K\int_0^t \alpha^*(\sigma)\int_{\Gamma_k\cap\gamma^-} \nabla\theta(x).n(x)\left[\omega_0(x) + \lambda_k^0\Lambda_k(x)\right] \\
&\quad \cdot \exp\left(-M\int_0^\sigma \alpha^*(\tau)d\tau\right)dxd\sigma \\
&\quad +K\int_0^t \int_{\Gamma_k\cap\gamma^+} \alpha^*(\sigma)\nabla\theta(x).n(x)\omega^*(\sigma,x)dxd\sigma. \qquad (5.25)
\end{aligned}$$

Put

$$\mathcal{C}_0 = -\int_{\gamma^-} \nabla\theta(x).n(x)\left|\omega_0(x) + \sum_{i=1}^g \lambda_i^0\Lambda_i(x)\right|dx \qquad (5.26)$$

and

$$\mathcal{C}_1 = \int_{\gamma^-} |\nabla\theta(x).n(x)|dx. \qquad (5.27)$$

We will show that (5.23) is valid provided M is large enough (in terms of Ω, Σ, θ, and K) to satisfy

$$\frac{K\mathcal{C}_0}{M} < \frac{\max(|\lambda_1^0|, \dots, |\lambda_g^0|, \|\omega_0\|_\infty)}{4} \quad \text{and} \quad \frac{K(2\mathcal{C}_1 + \mathcal{T}(\Gamma))}{M} < \frac{1}{4}, \qquad (5.28)$$

which we suppose from now on. In fact, the most problematic term in (5.25) is the last one. To estimate λ_k^*, we thus introduce the following function:

$$h(t) = K\int_0^t \int_{\bigcup_{k=1}^g (\Gamma_k\cap\gamma^+)} \alpha^*(\sigma)\nabla\theta(x)\cdot n(x)|\omega^*(\sigma,x)|dxd\sigma.$$

In order to estimate $h(t)$, let us consider $\tilde{\omega} := \tilde{F}[\omega^*, \lambda_i^*]$. As y^* satisfies the assumptions of Proposition 3.5, one easily sees (using (3.17)) that $\tilde{\omega} = \omega^*$ on $[0,T] \times \cup_{k=1}^{g}(\Gamma_k \cap \gamma^+)$. Also, by (4.23), one has

$$\tilde{\omega}(t,x) = \left(\omega_0(x) - \sum_{A\in\mathcal{A}} \omega_0(A)\Gamma_A(x)\right) \exp\left(-M\int_0^t \alpha^*(\tau)d\tau\right) + \sum_{A\in\mathcal{A}} \omega^*(t,A)\Gamma_A(x) \quad \text{on } [0,T]\times\overline{\gamma^-}. \tag{5.29}$$

But as $\tilde{\omega}$ satisfies

$$\partial_t\tilde{\omega} + \operatorname{div}(y^*\tilde{\omega}) = 0,$$

one deduces that

$$\frac{d}{dt}\left(\int_\Omega |\tilde{\omega}|\right)(t) = -\int_{\partial\Omega}(y^*\cdot n)|\tilde{\omega}|(t) = -K\int_{\partial\Omega}\alpha^*(t)\nabla\theta(x)\cdot n(x)|\tilde{\omega}|(t,x)dx.$$

Consequently, one gets

$$\begin{aligned} h(t) &\le K\int_0^t\int_{\gamma^+}\alpha^*(\sigma)\nabla\theta(x)\cdot n(x)|\tilde{\omega}(\sigma,x)|d\sigma dx \\ &\le \int_\Omega|\tilde{\omega}(0,\cdot)| - K\int_0^t\int_{\gamma^-}\alpha^*(\sigma)\nabla\theta(x)\cdot n(x)|\tilde{\omega}(\sigma,x)|d\sigma dx. \end{aligned}$$

Using (5.29), one gets

$$\begin{aligned} h(t) \le \int_\Omega|\omega(0,\cdot)| + 2K\mathcal{C}_1\|\omega_0\|_\infty\int_0^t\alpha^*(\sigma)\exp\left(-M\int_0^\sigma\alpha^*(\tau)d\tau\right)d\sigma \\ - K\sum_{A\in\mathcal{A}}\int_0^t\int_{\gamma^-}\alpha^*(\sigma)\nabla\theta(x)\cdot n(x)|\omega^*(\sigma,A)\Gamma_A(x)|d\sigma dx, \end{aligned}$$

and hence

$$h(t) \le \int_\Omega|\omega(0,\cdot)| + 2K\frac{\mathcal{C}_1\|\omega_0\|_\infty}{M} + K\mathcal{T}(\Gamma)\max_{A\in\mathcal{A}}\int_0^t\alpha^*(\sigma)|\omega^*(\sigma,A)|d\sigma. \tag{5.30}$$

Let us now concentrate on the last term. For $A\in\mathcal{A}$ and $\sigma\in[0,T]$, let us define

$$\begin{aligned} &\mathfrak{s}(\sigma,A) := \min\left\{t\in[0,\sigma] \;\middle/\; \Phi^*([t,\sigma],\sigma,A)\subset\overline{\Omega}\right\}, \\ &\mathfrak{a}(\sigma,A) := \Phi^*(\mathfrak{s}(\sigma,A),\sigma,A). \end{aligned} \tag{5.31}$$

Using (3.20), (2.28), and the fact that ω^* is constant along the flow, one deduces that for any $A\in\mathcal{A}$ and any σ, one has

$$\omega(\sigma,A) = \omega_0(\mathfrak{a}(\sigma,A))\exp\left(-M\int_0^{\mathfrak{s}(\sigma,A)}\alpha^*(\tau)d\tau\right). \tag{5.32}$$

To estimate the last term in (5.30), we fix $A\in\mathcal{A}$.

- If t is such that

$$\int_0^t \alpha^*(\sigma)d\sigma \leq \frac{V(\theta)}{\kappa K}, \tag{5.33}$$

then using (5.32), one easily gets

$$\int_0^t \alpha^*(\sigma)|\omega(\sigma, A)|d\sigma \leq \frac{V(\theta)}{\kappa K}\|\omega_0\|_\infty.$$

(When considering a time T with the specific form (4.9), one could prove that on such a time interval we always have (5.33).)

- If not, call ξ the (unique) time for which

$$\int_0^\xi \alpha^*(\sigma)d\sigma = \frac{V(\theta)}{\kappa K}.$$

Let us prove that for $\sigma > \xi$, one has

$$\int_{\mathfrak{s}(\sigma,A)}^\sigma \alpha^*(\tau)d\tau \leq \frac{V(\theta)}{\kappa K}\left(= \int_0^\xi \alpha^*(\tau)d\tau\right). \tag{5.34}$$

This results from the fact that if one defines

$$\mu(t) = \theta(\Phi^*[t, \mathfrak{s}(\sigma, A), A]),$$

then one has (in the classical sense) for any $t \in [\mathfrak{s}(\sigma, A), \sigma]$

$$\begin{aligned}\frac{d\mu}{dt} &= y^*(t, \Phi^*[t, \mathfrak{s}(t, A), A]) \cdot \nabla\theta(\Phi^*[t, \mathfrak{s}(t, A), A]) \\ &\geq \kappa K \alpha^*(t).\end{aligned}$$

Integrating this inequality between $\mathfrak{s}(\sigma, A)$ and σ yields (5.34). In particular, as a consequence of (5.34), one gets that for $\sigma > \xi$, one has $\mathfrak{s}(\sigma, A) > 0$. Consequently, using (5.32),

$$\begin{aligned}\int_0^t \alpha^*(\sigma)|\omega(\sigma, A)|d\sigma &= \int_0^\xi \alpha^*(\sigma)|\omega(\sigma, A)|d\sigma + \int_\xi^t \alpha^*(\sigma)|\omega(\sigma, A)|d\sigma \\ &\leq \frac{V(\theta)}{\kappa K}\|\omega_0\|_\infty \\ &\quad + \int_\xi^t \alpha^*(\sigma)\|\omega_0\|_\infty \exp\left(-M\int_0^{\mathfrak{s}(\sigma,A)} \alpha^*(\tau)d\tau\right)d\sigma.\end{aligned}$$

Now using (5.34), one gets

$$\begin{aligned}\int_0^{\mathfrak{s}(\sigma,A)} \alpha^*(\tau)d\tau &= \int_0^\sigma \alpha^*(\tau)d\tau - \int_{\mathfrak{s}(\sigma,A)}^\sigma \alpha^*(\tau)d\tau \\ &\geq \int_0^\sigma \alpha^*(\tau)d\tau - \int_0^\xi \alpha^*(\tau)d\tau.\end{aligned}$$

Hence,

$$\int_\xi^t \alpha^*(\sigma)\|\omega_0\|_\infty \exp\left(-M\int_0^{\mathfrak{s}(\sigma,A)}\alpha^*(\tau)d\tau\right)d\sigma \\ \leq \int_\xi^t \alpha^*(\sigma)\|\omega_0\|_\infty \exp\left(-M\int_\xi^{\sigma}\alpha^*(\tau)d\tau\right)d\sigma \leq \frac{\|\omega_0\|_\infty}{M}.$$

Finally, in all cases we get

$$h(t) \leq \int_\Omega |\omega_0| + \left(\frac{2K\mathcal{C}_1}{M} + \mathcal{T}(\Gamma)\left[\frac{V(\theta)}{\kappa}+\frac{K}{M}\right]\right)\|\omega_0\|_\infty.$$

Let us go back to λ_k^*. At times t for which (5.23) is valid in $[0,t]$ (this is at least the case for times in a neighborhood of 0), one has (5.24) and consequently, one gets

$$|\lambda_k^*(t)| \leq |\lambda_k^0| + h(t) + K\int_0^t\left[-\alpha^*(s)\lambda_k^*(s) + \mathcal{C}_0\alpha^*(s)\exp\left(-M\int_0^s\alpha^*(\tau)d\tau\right)\right]ds \\ \leq |\lambda_k^0| + \int_\Omega|\omega(0,\cdot)| + \frac{V(\theta)\mathcal{T}(\Gamma)}{\kappa}\|\omega_0\|_\infty + K\frac{(2\mathcal{C}_1+\mathcal{T}(\Gamma))\|\omega_0\|_\infty+\mathcal{C}_0}{M} \\ -K\int_0^t\alpha^*(s)\lambda_k^*(s)ds.$$

Hence, with $\alpha^*(t)\geq 0$, we get

$$|\lambda_k^*(t)| \leq |\lambda_k^0| + \int_\Omega|\omega(0,\cdot)| + \frac{V(\theta)\mathcal{T}(\Gamma)}{\kappa}\|\omega_0\|_\infty \\ + K\frac{(2\mathcal{C}_1+\mathcal{T}(\Gamma))\|\omega_0\|_\infty+\mathcal{C}_0}{M}. \tag{5.35}$$

Using (5.28), one gets

$$|\lambda_k(t)| < \left(\frac{3}{2}+|\Omega|+\frac{V(\theta)\mathcal{T}(\Gamma)}{\kappa}\right)\max(|\lambda_1^0|,\dots,|\lambda_g^0|,\|\omega_0\|_\infty) \\ < \mathcal{M}_{\omega_0,\lambda_i^0}. \tag{5.36}$$

Hence (5.23) propagates during the whole time interval $[0,T]$.

So at this point, we have proven that for any (ω_0,λ_i^0), there exists a local solution of the closed-loop system.

6. End of the proof. To finish the proof, we still have to establish two propositions:

- any maximal solution of the closed-loop system is global,
- for any global solution of the closed-loop system, 0 is asymptotically stable.

6.1. Maximal solutions are global solutions. Consider a maximal solution (ω,λ_i) of the closed-loop system, say it is defined on $[0,T^*)$, with T^* maximal. Let us prove that $T^*=+\infty$. Toward this end, let us suppose by contradiction that $T^*<+\infty$, and prove that

$$(\omega(t),\lambda_i(t)) \longrightarrow (\omega(T^*),\lambda_i(T^*)) \text{ as } t\to T^{*-} \tag{6.1}$$

in $C^0(\overline{\Omega};\mathbb{R})\times\mathbb{R}^g$. Using again the local existence result, this yields a contradiction. This is done as in [4, Proposition 3.4]. We first establish the following lemma.

LEMMA 6.1. *Let $T>0$ and let $(\omega,\lambda_i)\in C^0([0,T]\times\overline{\Omega})\times C^0([0,T])^g$ be a solution of the closed-loop system. Then one has for $(t,x)\in\Omega_T$ and any $s\in[0,t]$*

$$\omega(t,x)=\omega(s_{\omega,\lambda_i}(t,x),a_{\omega,\lambda_i}(t,x)), \tag{6.2}$$

and for any t in $[0,T]$, one has

$$\begin{aligned}\max(\|\omega(t)\|_\infty,|\lambda_1|(t),\dots,|\lambda_g|(t))\\ \le\left(3+|\Omega|+\frac{V(\theta)\mathcal{T}(\Gamma)}{\kappa}\right)(1+\|\Lambda\|_\infty)\max(\|\omega_0\|_\infty,|\lambda_1^0|,\dots,|\lambda_g^0|).\end{aligned} \tag{6.3}$$

Proof of Lemma 6.1. First, such a solution satisfies

$$\partial_t\omega+\operatorname{div}(y_{\omega,\lambda_i}\omega)=0.$$

A classical regularization argument shows that ω is constant along the flow of y_{ω,λ_i}, which yields (6.2).

We suppose that $(\omega(t),\lambda_1(t),\dots,\lambda_g(t))$ does not vanish. If it does, then using the definition of the feedback and the fact that the vorticity is constant along the flow, $(\omega(t),\lambda_1(t),\dots,\lambda_g(t))$ stays null. From now on, we work on the initial interval where $(\omega(t),\lambda_1(t),\dots,\lambda_g(t))$ is not zero.

Now, the "λ_i" part in (6.3) can be reproduced from what was already done in (5.36), because we did not use the particular form of T but only (2.27)–(2.28), the fact that the vorticity follows the flow, and the fact that the velocity satisfies Proposition 3.5.

It remains to prove the "ω" part of (6.3). Having proved the estimate on the λ_i, this is done as for point (b) in the proof of $\mathcal{F}(X)\subset X$ (see section 5.1), except that now the estimate

$$|\omega(\cdot,A)|\le\|\omega_0\|_\infty\quad\text{for any } A\in\mathcal{A}$$

comes now from (5.32) (and not from the choice of T).

Having proved Lemma 6.1, we get Hölder estimates on the flow from (3.7), which can consequently be extended on $[0,T^*]$, and then we get (6.1) approximately as for the continuity of $F(\omega,\lambda_i)$ in section 5.1 (we omit the details). Hence, using again the local existence theorem, we find a contradiction to $T^*<+\infty$.

6.2. 0 is asymptotically stable. Now that we have proved (6.3), it remains to prove (2.32). We consider again a global solution (ω,λ_i) of the closed-loop system; let us show that $\|(\omega,\lambda_i)(t)\|_\infty\to0$ as $t\to+\infty$.

We suppose that $(\omega(t,\cdot),\lambda_i(t))$ never vanishes. If it does vanish for some $T>0$, it follows from (2.26) and from the fact that the vorticity is constant along the flow of y_{ω,λ_i} that (ω,λ_i) is null in the neighborhood in time of $+\infty$; hence the result is valid.

This is done in several steps. First, we prove that $\omega(t,\cdot)\to0$ on the entering zone γ^- and in a second step that this convergence holds in the rest of the domain. The convergence to zero of $\lambda_1,\dots,\lambda_g$ is proved in the same step.

Again, we denote

$$\alpha(t):=\max\left(|\lambda_1(t)|,\dots,|\lambda_g(t)|,\|\omega(t)\|_\infty\right).$$

We first prove the following lemma.

LEMMA 6.2. *Let $(\omega, \lambda_i) \in C^0([0,+\infty) \times \overline{\Omega}) \times C^0([0,+\infty))^g$ be a global solution of the closed-loop system. Then it satisfies*

$$\|\omega(t)\|_{C^0(\gamma^- \setminus [\mathrm{Supp}(\Lambda) \cup \mathrm{Supp}(\Gamma)])} \longrightarrow 0 \text{ as } t \to +\infty. \tag{6.4}$$

Proof of Lemma 6.2. Consider $x \in \gamma^- \setminus (\mathrm{Supp}(\Gamma) \cup \mathrm{Supp}(\Lambda))$. If $\omega(t_0, x) = 0$ for some time t_0, then it follows from (2.28) that $\omega(t, x) = 0$ for all t. Let us suppose that $\omega_0(x) \neq 0$. Then it follows from (2.28) that on $\gamma^- \setminus [\mathrm{Supp}(\Lambda) \cup \mathrm{Supp}(\Gamma)]$,

$$\partial_t |\omega(t,x)| \leq -M |\omega(t,x)|^2;$$

hence

$$|\omega(t,x)| \leq \frac{|\omega_0(x)|}{1 + M|\omega_0(x)|t},$$

and hence $\omega(t,x) \to 0$ as $t \to +\infty$. One sees that the estimate is uniform and hence that (6.4) holds.

Now, we have the following lemma.

LEMMA 6.3. *Let $(\omega, \lambda_i) \in C^0([0,+\infty) \times \overline{\Omega}) \times C^0([0,+\infty))^g$ be a global solution of the closed-loop system. Then it satisfies*

$$\|\omega(t)\|_{C^0(\mathrm{Supp}(\Gamma))} \longrightarrow 0 \text{ as } t \to +\infty. \tag{6.5}$$

Proof of Lemma 6.3. Let us first prove that for any $A \in \mathcal{A}$, one has

$$\omega(t, A) \longrightarrow 0 \text{ as } t \to +\infty. \tag{6.6}$$

It follows from (3.20) that

$$\Phi^{\omega, \lambda_i}(\mathfrak{s}(t,A), t, A) \notin \mathrm{Supp}(\Gamma) \cup \mathrm{Supp}(\Lambda),$$

with $\mathfrak{s}(t,A)$ given by (5.31). Now, we fix $\varepsilon > 0$ and let t_0 be a time such that for $t \geq t_0$, one has

$$\|\omega(t)\|_{C^0(\overline{\gamma^- \setminus [\mathrm{Supp}(\Lambda) \cup \mathrm{Supp}(\Gamma)]})} \leq \varepsilon.$$

Then if t_1 is such that $|\omega(t_1, A)| > \varepsilon$, one deduces that $\mathfrak{s}(t_1, A) \leq t_0$. Hence, using $\Phi^{\omega,\lambda_i}(s, t_1, A) \in \overline{\Omega}$ for $t_0 \leq s \leq t_1$ and the fact that the vorticity is constant along the flow, one gets

$$\|\omega(s)\|_{C^0(\overline{\Omega})} \geq \varepsilon \text{ for } t_0 \leq s \leq t_1.$$

But (3.14) implies that, in the classical sense,

$$\frac{d}{ds}\left[\theta(\Phi^{\omega,\lambda_i}(s, t_0, x))\right] = y_{\omega,\lambda_i}(s, \Phi^{\omega,\lambda_i}(s,t_0,x)) \cdot \nabla\theta(\Phi^{\omega,\lambda_i}(s,t_0,x)) \geq \kappa K \alpha(s) \geq \kappa K \varepsilon. \tag{6.7}$$

With the boundedness of θ in $\overline{\Omega}$, one sees that $|t_1 - t_0|$ must be bounded, which gives (6.6).

Now, consider $x \in \mathrm{Supp}(\Gamma_A)$ for a certain $A \in \mathcal{A}$ and t large enough. Then, (6.5) follows from the fact, due to (2.28), that for $t \in [0,T]$ and $x \in \mathrm{Supp}(\Gamma_A)$, one has

$$\omega(t,x) = (\omega_0(x) - \omega_0(A)\Gamma_A(x)) \exp\left(-M\int_0^t \alpha(\tau)d\tau\right) + \omega(t,A)\Gamma_A(x). \tag{6.8}$$

Indeed, given any $\varepsilon > 0$, for t_0 large enough, one has $|\omega_2(s,x)| \leq \varepsilon$ on $\mathrm{Supp}(\Gamma_A)$ for any $s \geq t_0$ (with the notation of ω_1 and ω_2 in (2.27)). One gets for any $s \geq t_0$ that

$$|\alpha(s)| \geq K \max(0, |\omega_1(s,x)| - |\omega_2(s,x)|) \geq K \max(0, |\omega_1(s,x)| - \varepsilon).$$

Then

- if $|\omega_1(t,x)| \leq 2\varepsilon$, then, because ω_1 has the form

$$\omega_1(s,x) = \left(\omega_0(x) - \sum_{A\in\mathcal{A}} \omega_0(A)\Gamma_A(x)\right) \exp\left(-M\int_0^s \alpha(\tau)d\tau\right),$$

  this inequality stays valid for $s \geq t$, or
- if $|\omega_1(t,x)| \geq 2\varepsilon$, then for $s \geq t$ such that this is still valid, one has $|\alpha(s)| \geq \varepsilon$; then with (6.8), one sees that $|\omega_1(s,x)|$ decreases until it reaches the previous situation.

Then, we establish the following lemma.

LEMMA 6.4. *Let $(\omega, \lambda_i) \in C^0([0,+\infty) \times \overline{\Omega}) \times C^0([0,+\infty))^g$ be a global solution of the closed-loop system. Then it satisfies*

$$\|\omega(t)\|_{C^0(\gamma^+\cap\Gamma_k)} \longrightarrow 0 \text{ as } t \to +\infty \quad \forall k = 1, \ldots, g. \tag{6.9}$$

Proof of Lemma 6.4. The limit (6.9) follows from (3.17), (6.2), and Lemmas 6.2 and 6.3. Indeed, we introduce t_0 such that for $t \geq t_0$, one has $|\omega(t,\cdot)| \leq \varepsilon$ on $\overline{\gamma^-} \setminus \mathrm{Supp}(\Lambda)$. Suppose that we could find, for times arbitrarily large, some points in $\cup_{i=1}^g (\overline{\gamma}^+ \cap \Gamma_k)$ for which $|\omega(t,x)| > \varepsilon$ and hence, by (3.17), such that $s_{\omega,\lambda_i}(t,x) \leq t_0$. This contradicts (6.7) and the boundedness of θ in $\overline{\Omega}$.

Now, we have the following lemma.

LEMMA 6.5. *Let $(\omega, \lambda_i) \in C^0([0,+\infty) \times \overline{\Omega}) \times C^0([0,+\infty))^g$ be a global solution of the closed-loop system. Then it satisfies*

$$\|\omega(t)\|_{C^0(\mathrm{Supp}(\Lambda))} \longrightarrow 0 \text{ as } t \to +\infty. \tag{6.10}$$

Proof of Lemma 6.5. Fix $k \in \{1, \ldots, g\}$. It follows from (1.8), (2.22), (2.23), (2.27), and (2.28) that λ_k satisfies

$$\begin{aligned}\frac{d}{dt}\lambda_k(t) = -K\alpha(t)\lambda_k(t) + K\alpha(t)\int_{\Gamma_k\cap\gamma^-} \nabla\theta(x)\cdot n(x)\omega_1(t,x)dx \\ + K\alpha(t)\int_{\Gamma_k\cap\gamma^+} \nabla\theta(x)\cdot n(x)\omega(t,x)dx.\end{aligned} \tag{6.11}$$

But ω_1 converges uniformly to 0 (this is proved exactly as Lemma 6.2), and by Lemma 6.4, the second integral in (6.11) converges to 0 (remember that $\alpha(t)$ is bounded thanks to (6.3)). Hence, given $\varepsilon > 0$, there exists t_0 such that for $t \geq t_0$,

$$\left|\int_{\Gamma_k\cap\gamma^-} \nabla\theta(x)\cdot n(x)\omega_1(t,x)dx\right| + \left|\int_{\Gamma_k\cap\gamma^+} \nabla\theta(x)\cdot n(x)\omega(t,x)dx\right| \leq \varepsilon.$$

Consequently, for $t \geq t_0$, if $\lambda_k(t) \geq 2\varepsilon$, using $|\lambda_k(t)| \leq \alpha(t)$, one gets

$$\frac{d}{dt}\lambda_k(t) \leq -\varepsilon K \lambda_k(t),$$

and if $\lambda_k(t) \leq -2\varepsilon$, one gets

$$\frac{d}{dt}\lambda_k(t) \geq -\varepsilon K \lambda_k(t).$$

This yields

$$\lambda_i(t) \longrightarrow 0 \text{ as } t \to +\infty \text{ for } i = 1, \ldots, g. \tag{6.12}$$

Then having proved (6.12), (6.10) follows from the same procedure as the one at the end of Lemma 6.3.

These lemmas allow us to establish the following proposition.

PROPOSITION 6.6. *Let $(\omega, \lambda_i) \in C^0([0,+\infty) \times \overline{\Omega}) \times C^0([0,+\infty))^g$ be a global solution of the closed-loop system. Then it satisfies*

$$\max(\|\omega(t)\|_{C^0(\overline{\Omega})}, |\lambda_1(t)|, \ldots, |\lambda_g(t)|) \longrightarrow 0 \text{ as } t \to +\infty. \tag{6.13}$$

Proof of Proposition 6.6. The $\lambda_i(t)$-part is precisely (6.12). For the ω-part, consider $\tau(\varepsilon)$ such that for $t \geq \tau(\varepsilon)$, one has

$$\|\omega_{|(\gamma^+ \cup \gamma^-)}(t,\cdot)\|_{L^\infty} \leq \varepsilon \quad \text{and} \quad |\lambda_i(t)| \leq \varepsilon \quad \forall i = 1, \ldots, g.$$

Suppose that for any $\tilde{\tau}$, one can find $t \geq \tilde{\tau}$ for which $\|\omega(t,\cdot)\|_{C^0(\overline{\Omega})} > \varepsilon$. Then there is some $x \in \overline{\Omega}$ for which $|\omega(t,x)| > \varepsilon$, and hence by (6.2) one has $s_{\omega,\lambda_i}(t,x) \leq \tau(\varepsilon)$ and hence $\alpha(t) \geq \varepsilon$ on $[\tau(\varepsilon), t]$. Consequently, there exists $x_0 \in \overline{\Omega}$ such that $|\omega(\tau(\varepsilon), x_0)| > \varepsilon$ and for which

$$\Phi^{\omega,\lambda_i}([\tau(\varepsilon), t], \tau(\varepsilon), x_0) \subset \overline{\Omega}.$$

With (6.7), this contradicts the fact that θ is bounded in $\overline{\Omega}$.

7. Appendix.

7.1. Proof of Corollary 2.2. We reduce Σ a little in order to keep some kind of margin. Introduce $\tilde{\theta}$ as in Proposition 2.1. We describe a procedure that allows us to slightly modify $\tilde{\theta}$ to get rid of problematic points "E," while preserving (2.11)–(2.16). The idea is the following: consider an E point as in (2.17); by $\tilde{\Phi}$ it is first transported along $\partial\Omega \backslash (\overline{\gamma^+(\tilde{\theta})} \cup \overline{\gamma^-(\tilde{\theta})})$ (remember (2.12) and (2.13)); call γ_E the corresponding connected component of $\partial\Omega \backslash (\overline{\gamma^+(\tilde{\theta})} \cup \overline{\gamma^-(\tilde{\theta})})$. Consider t_E the biggest positive time for which $\tilde{\Phi}((0,t),0,E) \subset \gamma_E$. There are two cases:

- If $\tilde{\Phi}(t_E, 0, E) \in \overline{\gamma^+(\tilde{\theta})}$, it is clear from (2.12)–(2.13) that this point is in $\partial\gamma^+(\tilde{\theta})$, pointing inside $\gamma^+(\tilde{\theta})$. And consequently for t just after t_E, one has $\tilde{\Phi}(t,0,E) \in B_R \backslash \overline{\Omega}$, so the E point under consideration satisfies (2.17).
- If $\tilde{\Phi}(t_E, 0, E) \in \overline{\gamma^-(\tilde{\theta})}$, we consider the following time t'_E:

$$t'_E = \sup\left\{ t \in (t_E, +\infty),\ \tilde{\Phi}((t_E, t), 0, E) \in \Omega \right\}.$$

It is indeed quite clear that for times $t > t_E$ with $t - t_E$ small, $\tilde{\Phi}(t, 0, E) \in \Omega$, and it follows from $|\nabla\tilde{\theta}|(x) > 0$ in $\overline{\Omega}$ that the preceding set is bounded from above. Then $\tilde{\Phi}(t'_E, 0, E) \in \overline{\gamma^+(\tilde{\theta})}$ (for it cannot be in $\partial\Omega\backslash(\overline{\gamma^-(\tilde{\theta})} \cup \overline{\gamma^+(\tilde{\theta})})$ because of the uniqueness of the flow and it cannot be in $\overline{\gamma^-(\tilde{\theta})}$ because points in $\overline{\gamma^-(\tilde{\theta})}$ come from $(B_R\backslash\overline{\Omega}) \cup \partial\Omega$ by the flow of $\nabla\theta$).
If $\tilde{\Phi}(t'_E, 0, E) \in \gamma^+(\tilde{\theta})$, then (2.17) is valid for this E; we now suppose that $E_2 := \tilde{\Phi}(t'_E, 0, E) \in \partial\gamma^+(\tilde{\theta})$.
We consider a small connected neighborhood $\mathcal{U}$ of E_2 in $\partial\Omega$; thanks to the margin we kept on Σ, one can require $\mathcal{U} \subset \Sigma$. We also consider a point $F \in \gamma^+(\tilde{\theta})$ and $\mathcal{V}_F$ a small connected neighborhood of F in $\gamma^+(\tilde{\theta})$, not touching $\partial\gamma^+(\tilde{\theta})$ or $\mathcal{U}$.
We introduce a function on $\partial\Omega$, say ψ, supported in $\mathcal{U} \cup \mathcal{V}_F$, nonnegative in $\mathcal{U}$, nonpositive in $\mathcal{V}_F$, and such that

$$\int_{\partial\Omega} \psi = 0 \quad \text{and} \quad \psi(E_2) = 1.$$

Then we define $\hat{\theta} \in C^\infty(\Omega; \mathbb{R})$ by

$$\left\{ \begin{array}{l} \Delta\hat{\theta} = 0 \quad \text{in } \Omega, \\ \partial_n\hat{\theta} = \psi \quad \text{on } \partial\Omega, \\ \int_\Omega \hat{\theta} = 0. \end{array} \right. \tag{7.1}$$

Using elliptic estimates and Lemma 3.3, one sees that $\tilde{\theta} + \varepsilon\hat{\theta}$ still satisfies (2.11)–(2.16) for $\varepsilon > 0$ small enough. Let us particularly emphasize that, for $\varepsilon > 0$ small enough, one has $\partial_n(\tilde{\theta} + \varepsilon\hat{\theta}) > 0$ on $\mathcal{V}_F$. The E considered now satisfies (2.17). The procedure has not added an E point, but it has slightly moved the frontier of $\gamma^+(\tilde{\theta})$: introduce

$$\gamma^+(\tilde{\theta} + \varepsilon\hat{\theta}) := \{x \in \partial\Omega \ / \ \partial_n(\tilde{\theta} + \varepsilon\hat{\theta}) > 0\}.$$

Then $E_2 \in \gamma^+(\tilde{\theta} + \varepsilon\hat{\theta})$, and the new frontier of γ^+ is now given by

$$\partial\gamma^+(\tilde{\theta} + \varepsilon\hat{\theta}) = \partial\gamma^+(\tilde{\theta}) \cup \{E_3\} \setminus \{E_2\},$$

where E_3 is the point in $\partial\mathcal{U}$ that does not belong to $\gamma^+(\tilde{\theta})$.
Now if E_2 satisfied (2.17), then E_3 also does for ε small enough: we have two cases:

- $\nabla\tilde{\theta}$ is pointing inside $\gamma^+(\tilde{\theta})$ at E_2. This case is in fact not possible because of the definition of E_2 and t'_E: points in $\partial\gamma^+(\tilde{\theta})$ at which $\nabla\tilde{\theta}$ is pointing inside $\gamma^+(\tilde{\theta})$ come from $\partial\Omega$ when following the flow.
- $\nabla\tilde{\theta}$ is pointing outside $\gamma^+(\tilde{\theta})$ at E_2. Then using (2.13), one sees that the trajectory of E_2 under the flow of $\nabla\tilde{\theta}$ follows the connected component of E_2 in $\partial\Omega\backslash[\gamma^+(\tilde{\theta}) \cup \gamma^-(\tilde{\theta})]$. In particular, this trajectory meets E_3. But for ε small enough, the trajectories under the flow of $\nabla(\tilde{\theta} + \varepsilon\hat{\theta})$ are almost the same as the ones in the flow of $\nabla\tilde{\theta}$ (as seen by Lemma 3.3 and elliptic estimates). This yields the conclusion.

So one can get rid of problematic points one after another.

7.2. Proof of Proposition 3.5.

- *Proof of* (3.14). Introduce $\hat{y}$ as the solution of

$$\begin{cases} \operatorname{curl} \hat{y}(t,x) = \omega(t,x) \quad \text{for } (t,x) \in \Omega_T, \\ \operatorname{div} \hat{y}(t,x) = 0 \quad \text{for } (t,x) \in \Omega_T, \\ \hat{y}(t,x) \cdot n(x) = 0 \quad \text{for } (t,x) \in \Sigma_T, \\ \displaystyle\int_{\Gamma_i} \hat{y}(t,x) \cdot \vec{\tau}(x) dx = \lambda_i(t) \quad \text{for } t \in [0,T], \text{ for } i = 1, \dots, g. \end{cases}$$

Of course, one has $y = \hat{y} + K\alpha(t)\nabla\theta(x)$. Now (3.9) involves

$$\|\hat{y}(t)\|_{L^\infty(\Omega)} \leq C_{\mathcal{LL}} \max\left(|\lambda_1(t)|, \dots, |\lambda_g(t)|, \|\omega(t)\|_\infty\right) \ \forall t \in [0,T].$$

(The constant $C_{\mathcal{LL}}$ does not depend on t.) Hence

$$y(t,x) \cdot \nabla\theta(x) \geq K\alpha(t)|\nabla\theta(x)|^2 - C_{\mathcal{LL}}\|\nabla\theta\|_\infty \alpha(t). \tag{7.2}$$

Equation (2.13) and the compactness of $\overline{\Omega}$ allow us to introduce

$$\underline{m} := \min_{x \in \overline{\Omega}} |\nabla\theta(x)| > 0.$$

One easily deduces from (7.2) that (3.14) holds if $\overline{K} \geq 2C_{\mathcal{LL}}\|\nabla\theta\|_\infty / \underline{m}^2$ and $\kappa = \underline{m}^2/2$ (which we suppose in what follows).

- *Proof of* (3.17). Property (3.17) will essentially follow from Gronwall's inequality (3.11), from (2.13), and from (2.16).
We extend the definition of α and (ω, λ^i) for times $t \geq T$ by $\alpha(T)$ and $(\omega, \lambda^i)(T)$, respectively.
We write $\Theta^\alpha(t,x) := K\alpha(t)\theta(x)$. We consider Φ, Φ^y, and Φ^α the respective flows of $\pi(\nabla\theta)$, $\pi(y(t,x))$, and $\pi(\nabla\Theta^\alpha(t,x))$.
First, by a compactness argument and using (2.13), one sees that there exist $T_\theta > 0$ and $d_\theta > 0$ such that

$$\forall x \in \overline{\Omega}, \ \exists t \in [0, T_\theta] \text{ such that } \operatorname{dist}(\Phi(t,0,x), \overline{\Omega}) \geq d_\theta.$$

It suffices, for instance, to observe that

$$\frac{d}{dt}\theta(\Phi(t,0,x)) = |\nabla\theta(\Phi(t,0,x))|^2$$

if x and t are such that $\Phi(t,0,x) \in \overline{\Omega}$, and to use (2.13) and the boundedness of θ on $\overline{\Omega}$.
Hence

$$\forall x \in \overline{\Omega}, \ \exists \mathcal{T}(x) \text{ such that } \int_0^{\mathcal{T}(x)} K\alpha(\tau)d\tau \leq T_\theta \text{ and such that } \operatorname{dist}(\Phi^\alpha(\mathcal{T}(x),0,x), \overline{\Omega}) \geq d_\theta.$$

Now by Lemma 3.3 one has

$$|\Phi^y(t,0,x) - \Phi^\alpha(t,0,x)| \leq \exp\left(K\|\pi(\nabla\theta)\|_{\mathcal{L}ip} \int_0^t \alpha(\tau)d\tau\right) \|\pi(\hat{y})\|_{L^1([0,T],L^\infty(B_R))}.$$

Consequently, one sees that for $x \in \overline{\Omega}$ and t such that $0 \le t \le \mathcal{T}(x)$,

$$\begin{aligned}|\Phi^y(t,0,x) - \Phi^\alpha(t,0,x)| &\le \exp(T_\theta \|\pi(\nabla\theta)\|_{\mathcal{L}ip(B_R)}) \|\hat{y}\|_{L^1([0,t],L^\infty_x)} \\ &\le C_{\mathcal{L}\mathcal{L}} \exp(T_\theta \|\pi(\nabla\theta)\|_{\mathcal{L}ip(B_R)}) \|(\omega,\lambda_i)\|_{L^1([0,t],L^\infty_x)}.\end{aligned}$$

Now one deduces from (3.12) that for $0 \le t \le \mathcal{T}(x)$,

$$\|(\omega,\lambda_i)\|_{L^1([0,t],L^\infty_x)} \le \int_0^t \alpha(\tau)d\tau \le \frac{T_\theta}{K}.$$

This yields

$$|\Phi^y(t,0,x) - \Phi^\alpha(t,0,x)| \le \frac{C_{\mathcal{L}\mathcal{L}} \exp(T_\theta \|\pi(\nabla\theta)\|_{\mathcal{L}ip(B_R)}) T_\theta}{K}. \tag{7.3}$$

Consequently, if K is large enough (in terms of only θ), one has

$$\begin{aligned}\forall x \in \overline{\Omega},\ \exists \mathcal{T}(x) \text{ such that } &\int_0^{\mathcal{T}(x)} K\alpha(\tau)d\tau \le T_\theta \\ &\text{and such that } \operatorname{dist}(\Phi^y(\mathcal{T}(x),0,x),\overline{\Omega}) \ge d_\theta/2,\end{aligned}$$

with (7.3) valid between times 0 and $\mathcal{T}(x)$. With (2.18), this gives (3.17) for K large enough.

- *Proof of* (3.18). This is due to the uniqueness of the flow: on $\overline{\gamma_A}$, $y(s,x)$ is of the form $\lambda(s,x)\vec{\tau}(x)$, the sign of $\lambda(s,x)$ being constant in such a way that the direction of $y(s,A)$ is pointing inside γ^- (indeed, thanks to (3.13) and (3.14), $y(s,x)$ has the same direction as $\nabla\theta(x)$ on $\partial\Omega$). So one finds a local in time backward solution of (3.6) inside γ_A. This solution does not go outside γ_A for times $\tau \in [0,t)$ if $t-\tau$ is small enough so that

$$c_\pi(K\|\nabla\theta\|_\infty + C_{\mathcal{L}\mathcal{L}}) \left(\int_\tau^t \alpha(s)ds\right) \le \ell/2, \tag{7.4}$$

because the velocity is estimated by

$$\begin{aligned}|\pi[y](s,x)| &\le \|\pi[\hat{y}](s,\cdot)\|_{L^\infty(B_R)} + K\alpha(s)\|\pi[\nabla\theta]\|_{L^\infty(B_R)} \\ &\le c_\pi(C_{\mathcal{L}\mathcal{L}} + K\|\nabla\theta\|_\infty)\alpha(s)\end{aligned} \tag{7.5}$$

and because of the definition of ℓ.

- *Proof of* (3.15)–(3.16). This is mutatis mutandis [4, Lemma 3.3]. Let us treat separately the points in γ^- and the B points.
  - Let us consider (3.16) for a point $B \in \mathcal{B}$. Using again (3.13) and (3.14), one sees that, as for $s \in [0,T]$, $y(s,B)$ is tangent to $\partial\Omega$ and by (3.14) pointing outside γ^-, there is a solution for the flow starting from B and that stays inside $\partial\Omega\backslash(\overline{\gamma^-} \cup \overline{\gamma^-})$ at least for small times. So the uniqueness of the flow gives (3.16).
  - Consider $x \in \gamma^-$. Let us use the coordinates in the reference frame given by $(\vec{\tau}(x), n(x))$. Then using (3.9) and (3.13), we see that for any $\varepsilon > 0$, one finds some neighborhood $\mathcal{U}$ of (t,x) in $(0,T] \times B_R$ for which one has for any $(\tilde{t},\tilde{x})$ in $\mathcal{U}$,

$$|\{\pi[y](\tilde{t},\tilde{x}) - K\alpha(\tilde{t})\pi[\nabla\theta](\tilde{x})\} \cdot n(x)| \le \varepsilon.$$

(And the left-hand side is null when $\tilde{x}$ is on γ^-.) Hence for suitable ε and $\mathcal{U}$ the second coordinate of $y(\tilde{t},\tilde{x})$ is positive in a neighborhood of (t,x) in $[0,T]\times B_R$. Using (3.6), one deduces (3.15) and (3.16) except for B points.

Before dealing with (3.15) for points $B\in\mathcal{B}$, let us make (3.15) more precise for points in γ^-. We consider $\tau<t$ sufficiently close to t for (7.4) to hold. Consider $\underline{s}$ the smallest time $s\in[\tau,t]$ such that $\Phi^y((s,t),t,E)\subset B_R\backslash\overline{\Omega}$, and let us suppose $\underline{s}>\tau$. One can estimate the velocity by (7.5) and consequently in our case, one has $\Phi^y(\underline{s},t,x)\notin\overline{\gamma^+}$. Certainly, one also has that $\Phi^y(\underline{s},t,x)\notin\Omega\cup\gamma^-\cup\mathcal{B}$ because of (3.16) that we just proved for points in $\gamma^-\cup\mathcal{B}$. This point can thus only be in $\partial\Omega\backslash(\overline{\gamma^+}\cup\gamma^-\cup\mathcal{B})$ (unless it is in $B_R\backslash\overline{\Omega}$). Hence it must lie in γ_B for the other components are too far because of (7.4). But by uniqueness of the flow, this is not possible. Consequently one has, for any $s\in[\tau,t]$ with τ satisfying (7.4),

$$\Phi^y(s,t,x)\in B_R\backslash\overline{\Omega}. \tag{7.6}$$

– Now, let us deal with (3.15) for B points. We see, using Remark 6(i) and the same procedure as for the proof of (3.17), that for some ν, one has $\Phi^y(t-\nu,t,B)\in B_R\backslash\overline{\Omega}$. Now we claim that, at least if ν has been chosen small enough, $\Phi^y(s,t,B)\in B_R\backslash\overline{\Omega}$ for any s in $[t-\nu,t)$. Indeed, when considering a sequence of points x_n in γ^- converging to B, by continuity of the flow we have that $\Phi^y(s,t,x_n)$ is converging to $\Phi^y(s,t,B)$. Using (7.6), one gets that $\Phi^y(s,t,B)\notin\Omega$ for $s\in[t-\nu,t)$. But $\Phi^y(s,t,B)$ cannot belong to γ^- by (3.15), which is already established for points in γ^-; nor can it belong to γ_B by uniqueness of the flow (and the other components of $\partial\Omega\backslash(\gamma^+\cup\gamma^-)$ are too far by the choice of ν). Hence, one must have $\Phi^y(s,t,B)\in B_R\backslash\overline{\Omega}$.

- *Proof of* (3.19). This is a consequence of the continuity of the flow. Suppose indeed by contradiction that for some ω, $(\lambda_i)_{i=1,\dots,g}$, and α, one has (3.19) not satisfied by an A point. Then for some $\tau>t$, $\Phi^y(\tau,t,A)\in B_R\backslash\overline{\Omega}$ (note indeed that this point cannot be in $\overline{\gamma_A}$ by uniqueness of the flow or in other components of $\partial\Omega\backslash(\gamma^+\cup\gamma^-)$ by the choice of τ (which is not too far from t), and if this point is in γ^-, we conclude by (3.15) that there indeed exists a point $\Phi^y(\tau-\nu,t,A)$ in $B_R\backslash\overline{\Omega}$). We look at the trajectories starting from x in γ^- close to A. By (3.16) they are inside Ω for small time and, in fact, by the same argument as previously, in Ω as long as $\tau-t$ is small enough so that

$$c_\pi(K\|\nabla\theta\|_\infty+C_{\mathcal{LL}})\left(\int_t^\tau\alpha(s)ds\right)\leq\ell/2.$$

  So our assumption would be in contradiction with the continuity of the flow.
- *Proof of* (3.20). This follows again from the procedure of the proof of (3.17) and the choices of $\mathrm{Supp}(\Gamma_A)$ and $\mathrm{Supp}(\Lambda_i)$ (which are at positive distance from $\underline{A}$).

Acknowledgment. The author thanks the anonymous referees for their useful comments on a first version of this paper.

CHARACTERISTIC FREQUENCIES, POLYNOMIAL-EXPONENTIAL TRAJECTORIES, AND LINEAR EXACT MODELING WITH MULTIDIMENSIONAL BEHAVIORS*

EVA ZERZ†

Abstract. The characteristic frequencies of a linear, shift-invariant multidimensional behavior correspond to its nonzero exponential trajectories. The set of polynomial-exponential trajectories belonging to a fixed characteristic frequency of a behavior is investigated: A test is derived for determining whether this space is finite-dimensional, and if so, a basis is constructed. If it is infinite-dimensional, one considers only the polynomial-exponential trajectories up to a certain degree of the polynomial part, and a characterization is given of the asymptotic growth of the dimensions of these spaces as the degree bound tends to infinity. A dual problem is concerned with linear exact modeling, that is, the construction of the so-called most powerful unfalsified model (MPUM): Given a finite set of polynomial-exponential trajectories, the goal is to construct a behavior that contains the data and as little else as possible.

Key words. multidimensional systems, linear PDE with constant coefficients, behavioral approach, polynomial ideals and modules

Introduction. The study of multidimensional, linear, shift-invariant behaviors (i.e., the solution spaces of linear systems of partial differential or difference equations with constant coefficients) using commutative algebra originated some 15 years ago in the seminal paper [9]. Since then, the theory has been advanced by several authors. In [13], the notion of a characteristic point (or frequency) of a multidimensional behavior was introduced. The present paper continues this line of research. In particular, the subset of a behavior consisting of all polynomial-exponential trajectories belonging to a fixed characteristic frequency will be studied. After some preliminaries, the question whether this set is finite-dimensional as a vector space will be addressed in section 1.1. If it is, a vector space basis can be constructed as described in section 1.2. In section 1.3, we determine the asymptotic behavior of the dimensions of the spaces of polynomial-exponential solutions belonging to a fixed characteristic frequency as the degree of the polynomial part grows.

In the second part of the paper, we study the problem of linear exact modeling within the multidimensional setting. Suppose that one observes a finite number of polynomial-exponential signals. The goal is to find a model for these data, that is, a behavior that contains the given trajectories, or in other words, a model that is unfalsified by the observations. Of course, the problem can always be solved by making this behavior large enough. However, the more solutions a model admits, the less it explains. This leads to the requirement that the model should be as powerful as possible, that is, it should not admit more solutions than necessary. In other words, we are looking for the most powerful unfalsified model (MPUM) that has been studied for one-dimensional behaviors in [1]. A preliminary version of the present paper can

be found in [15], where the computer algebraic implementation is described in more detail, and some geometric interpretations are given.

1. Characteristic frequencies and polynomial-exponential trajectories. We deal exclusively with linear and shift-invariant behaviors. For the sake of brevity, we focus on behaviors given by differential (rather than difference) equations, and we study only their smooth solutions, although the case of distributional solutions, and the discrete counterpart, can be treated analogously.

Let $\mathcal{A} := \mathcal{C}^\infty(\mathbb{R}^n)$ denote the space of complex-valued smooth functions defined on $\mathbb{R}^n$, and let $\mathcal{D} := \mathbb{C}[s_1, \dots, s_n]$ be the polynomial ring, in n variables, with complex coefficients. Let $R \in \mathcal{D}^{g\times q}$ be a polynomial matrix. Then

$$\mathcal{B} := \{w \in \mathcal{A}^q \mid R(\partial)w := R(\partial_1, \dots, \partial_n)w = 0\}$$

is the smooth solution space of a linear system of partial differential equations with constant coefficients. Such a set $\mathcal{B}$ will be called a *behavior* throughout this paper. If R has full column rank (by the rank of a polynomial matrix R, its generic rank is meant, i.e., its rank as a matrix over the field of rational functions $\mathbb{C}(s_1, \dots, s_n)$), then $\mathcal{B}$ is called *autonomous*. This means that the system does not contain free variables, that is, none of the components w_j of w is unconstrained by the system law $R(\partial)w = 0$. More precisely, none of the projections $\pi_j : \mathcal{B} \to \mathcal{A}$, $w \mapsto w_j$ is surjective. Algebraically speaking, autonomy is also equivalent to the fact that $P := \mathcal{D}^{1\times q}/\mathcal{D}^{1\times g}R$ is a torsion module, that is, for all $p \in P$ there exists $0 \neq d \in \mathcal{D}$ such that $dp = 0$ (indeed, we even have $dP = 0$ for some $0 \neq d \in \mathcal{D}$, that is, P has a nonzero annihilator).

Let a behavior $\mathcal{B}$ be given. An n-tuple of complex numbers, $\lambda \in \mathbb{C}^n$, is called a *characteristic frequency* (or characteristic point or pole point [13]) of $\mathcal{B}$ if there exists $0 \neq c \in \mathbb{C}^q$ such that

$$w := c\exp_\lambda \tag{1.1}$$

belongs to $\mathcal{B}$, where the scalar function $\exp_\lambda$ is defined by

$$\exp_\lambda(t) := \exp(t_1\lambda_1 + \cdots + t_n\lambda_n) \qquad \text{for } t \in \mathbb{R}^n.$$

The function w from (1.1) is called an *exponential trajectory with frequency vector* λ. Thus λ is a characteristic frequency of $\mathcal{B}$ if and only if the system contains a nonzero exponential trajectory with frequency vector λ.

The formula

$$R(\partial)c\exp_\lambda = R(\lambda)c\exp_\lambda$$

is easy to verify. It shows that w from (1.1) belongs to $\mathcal{B}$ if and only if $R(\lambda)c = 0$. This observation leads to the following lemma [13].

LEMMA 1. *The vector $\lambda \in \mathbb{C}^n$ is a characteristic frequency of $\mathcal{B}$ if and only if $R(\lambda) \in \mathbb{C}^{g\times q}$ does not have full column rank.*

Thus, λ is a characteristic frequency of $\mathcal{B}$ if and only if $\operatorname{rank}(R(\lambda)) < q$, that is, if and only if λ is common zero of all the $q \times q$ minors of $R \in \mathcal{D}^{g\times q}$. Therefore, the set V of all characteristic frequencies of $\mathcal{B}$ is an algebraic variety in $\mathbb{C}^n$, called the characteristic variety of $\mathcal{B}$ in [13]. If the rank of R is less than q, then all its minors of order q are (identically) zero, and then $V = \mathbb{C}^n$, that is, every λ is a characteristic frequency of $\mathcal{B}$. On the other hand, if the rank of R equals q, that is, if $\mathcal{B}$ is autonomous, then V is a proper subset of $\mathbb{C}^n$.

As is well known from the one-dimensional case ($n = 1$), i.e., ordinary differential equations, it is not sufficient to consider exponential trajectories alone. We have to admit polynomial-exponential solutions.

For this, we define the space of *polynomial-exponential functions* $\mathcal{A}_{pe}$ as the subspace of $\mathcal{A} = \mathcal{C}^\infty(\mathbb{R}^n)$ containing all finite sums of functions of the form

$$a := b \exp_\lambda,$$

where $b \in \mathbb{C}[t_1, \ldots, t_n]$ is a polynomial and $\lambda \in \mathbb{C}^n$. Just like $\mathcal{A}$ itself, the space $\mathcal{A}_{pe}$ is a module over $\mathbb{C}[\partial_1, \ldots, \partial_n]$. Moreover, we have [13]

$$\mathfrak{M}(\mathcal{B} \cap \mathcal{A}_{pe}^q) = \mathfrak{M}(\mathcal{B}),$$

where

$$\mathfrak{M}(B) := \{r \in \mathcal{D}^{1\times q} \mid r(\partial)w = 0 \text{ for all } w \in B\}$$

for an arbitrary set $B \subseteq \mathcal{A}^q$. In particular, $\mathcal{B}$ is uniquely determined by $\mathcal{B}_{pe} := \mathcal{B} \cap \mathcal{A}_{pe}^q$. Indeed, $\mathcal{B}_{pe}$ is dense in $\mathcal{B}$ [7], with respect to the standard $\mathcal{C}^\infty$-topology, that is, the topology of uniform convergence of all derivatives on compact sets. This fact is also referred to as the Malgrange approximation theorem, e.g., in [11]. If $\mathcal{B}$ is finite-dimensional (as a complex vector space) [2, 8, 10, 11, 12], then

$$\mathcal{B}_{pe} = \mathcal{B}.$$

This is true, for example, for every autonomous one-dimensional ($n = 1$) behavior, because the solution space of a homogeneous system of linear constant-coefficient ordinary differential equations is finite-dimensional. In dimensions $n \geq 2$, however, an autonomous system is not necessarily finite-dimensional (take for instance $n = 2$, and $R = s_1$; then $\mathcal{B}$ consists of all smooth functions of t_2). On the other hand, a finite-dimensional behavior is always autonomous.

One calls $\mathcal{B}_{pe}$ the set of *polynomial-exponential trajectories of* $\mathcal{B}$. Below, we will investigate the polynomial-exponential trajectories of $\mathcal{B}$ with respect to a fixed frequency vector.

For this, let $\lambda \in \mathbb{C}^n$. Via the affine change of variables

$$\tilde{R}(s) := R(s + \lambda)$$

we obtain $\tilde{\mathcal{B}} := \{w \in \mathcal{A}^q \mid \tilde{R}(\partial)w = 0\}$. There is a bijective relation between the polynomial-exponential solutions with frequency vector λ to $R(\partial)w = 0$ and the polynomial solutions to $\tilde{R}(\partial)w = 0$, which is given by

$$p \in \tilde{\mathcal{B}} \Leftrightarrow p \exp_\lambda \in \mathcal{B} \tag{1.2}$$

for $p \in \mathbb{C}[t_1, \ldots, t_n]^q$. This can be seen by comparing the formulas

$$(\partial + \lambda)^\mu t^\nu = \sum_\rho \binom{\mu}{\rho} (\partial^\rho t^\nu) \lambda^{\mu-\rho}$$

and

$$\partial^\mu t^\nu \exp_\lambda(t) = \sum_\rho \binom{\mu}{\rho} (\partial^\rho t^\nu)(\partial^{\mu-\rho} \exp_\lambda(t)) = \exp_\lambda(t) \sum_\rho \binom{\mu}{\rho} (\partial^\rho t^\nu) \lambda^{\mu-\rho},$$

which hold for all $\mu, \nu \in \mathbb{N}^n$, where the summation runs over all $\rho \in \mathbb{N}^n$ with $\rho_i \leq \mu_i$ for all $1 \leq i \leq n$, and the usual multi-index notation is used, e.g., $t^\nu := t_1^{\nu_1} \cdots t_n^{\nu_n}$, $\binom{\mu}{\rho} := \binom{\mu_1}{\rho_1} \cdots \binom{\mu_n}{\rho_n}$, etc. Thus

$$\exp_\lambda(t)(\partial + \lambda)^\mu t^\nu = \partial^\mu t^\nu \exp_\lambda(t).$$

By taking linear combinations, this shows that

$$\exp_\lambda(t) R(\partial + \lambda) p(t) = R(\partial) p(t) \exp_\lambda(t)$$

for any $R \in \mathcal{D}^{g \times q}$ and any $p \in \mathbb{C}[t_1, \ldots, t_n]^q$. Therefore, omitting the argument t,

$$R(\partial + \lambda)p = 0 \Leftrightarrow R(\partial) p \exp_\lambda = 0,$$

which is precisely the equivalence from (1.2).

Therefore we may assume, without loss of generality, that the characteristic frequency under consideration lies at the origin, and we write again R and $\mathcal{B}$ instead of $\tilde{R}$ and $\tilde{\mathcal{B}}$, respectively. For the remainder of this section, let $R \in \mathcal{D}^{g \times q}$ be a given polynomial matrix, and let $\mathcal{B} = \{w \in \mathcal{A}^q \mid R(\partial)w = 0\}$ be the corresponding behavior. We will investigate the polynomial-exponential trajectories of $\mathcal{B}$ with frequency vector zero. In other words, we are interested in the polynomial solutions to $R(\partial)w = 0$. Define

$$\mathfrak{P} := \{p \in \mathbb{C}[t_1, \ldots, t_n]^q \mid R(\partial)p = 0\}$$

and for any integer $d \geq 0$,

$$\mathfrak{P}_d := \{p \in \mathbb{C}[t_1, \ldots, t_n]^q \mid R(\partial)p = 0 \text{ and } \deg(p) \leq d - 1\}.$$

Here $\deg(p) := \max_{1 \leq j \leq q} \deg(p_j)$, where $\deg(\cdot)$ denotes the total degree of a nonzero polynomial, and $\deg(0) := -1$. Clearly,

$$\{0\} = \mathfrak{P}_0 \subseteq \mathfrak{P}_1 \subseteq \mathfrak{P}_2 \subseteq \cdots \subseteq \mathfrak{P}. \tag{1.3}$$

We have

$$\mathfrak{P} = \mathcal{B} \cap \mathbb{C}[t_1, \ldots, t_n]^q = \bigcup_{d=0}^{\infty} \mathfrak{P}_d$$

and

$$\mathfrak{P}_d = \{w \in \mathcal{A}^q \mid R(\partial)w = 0 \text{ and } \partial^\mu w = 0 \text{ for all } \mu \in \mathbb{N}^n \text{ with } |\mu| = d\},$$

where $|\mu| := \mu_1 + \cdots + \mu_n$. Here we use that w is a polynomial of degree less than d if and only if all its derivatives of order d vanish.

Let $M := \mathcal{D}^{1 \times g} R \subseteq \mathcal{D}^{1 \times q}$ be the polynomial module generated by the rows of R. According to [9], we have

$$M = \mathfrak{M}(\mathcal{B}) = \{r \in \mathcal{D}^{1 \times q} \mid r(\partial)w = 0 \text{ for all } w \in \mathcal{B}\}.$$

Conversely, we write

$$\mathcal{B} = \mathfrak{B}(M) := \{w \in \mathcal{A}^q \mid r(\partial)w = 0 \text{ for all } r \in M\}.$$

Due to the injective cogenerator property of $\mathcal{A}$ [9], the maps $\mathfrak{M}$ and $\mathfrak{B}$ are inclusion-reversing bijections between the set of behaviors in $\mathcal{A}^q$ and the set of submodules of $\mathcal{D}^{1\times q}$, and they are inverse to each other. Moreover, we note for later use that

$$\mathfrak{B}(M_1 \cap M_2) = \mathfrak{B}(M_1) + \mathfrak{B}(M_2). \tag{1.4}$$

Using these maps, we have

$$\mathfrak{M}(\mathfrak{P}_d) = M + I^d\mathcal{D}^{1\times q} \quad \text{and} \quad \mathfrak{P}_d = \mathfrak{B}(M + I^d\mathcal{D}^{1\times q}),$$

where $I := \langle s_1, \dots, s_n\rangle$ is the ideal in $\mathcal{D}$ generated by $s_1, \dots, s_n$, and the ideal I^d consists of all products of d elements of I, that is, it is generated by the monomials s^μ, where $\mu \in \mathbb{N}^n$ satisfies $|\mu| = d$. Finally,

$$I^d\mathcal{D}^{1\times q} := I^d \times \cdots \times I^d \subseteq \mathcal{D}^{1\times q}$$

is the module of all polynomial row vectors whose entries belong to I^d.

Each $\mathfrak{P}_d$ is a finite-dimensional complex vector space, and thus autonomous. We have [8, 10, 12]

$$\dim_{\mathbb{C}} \mathfrak{P}_d = \dim_{\mathbb{C}} \mathcal{D}^{1\times q}/\mathfrak{M}(\mathfrak{P}_d) = \dim_{\mathbb{C}} \mathcal{D}^{1\times q}/(M + I^d\mathcal{D}^{1\times q}). \tag{1.5}$$

Let

$$h_d := \dim_{\mathbb{C}} \mathfrak{P}_{d+1}/\mathfrak{P}_d. \tag{1.6}$$

In what follows, we will

1. decide whether $\mathfrak{P}$ is finite-dimensional as a complex vector space (this is true if and only if the sequence (1.3) becomes stationary, or, equivalently, $h_d = 0$ for large enough d);
2. construct a basis of $\mathfrak{P}_d$ (in the case where $\mathfrak{P}$ is finite-dimensional, this yields a basis of $\mathfrak{P}$ itself);
3. determine the behavior of h_d as d tends to infinity.

1.1. Deciding whether $\mathfrak{P}$ is finite-dimensional. Let $M = \mathcal{D}^{1\times g}R \subseteq \mathcal{D}^{1\times q}$, $I = \langle s_1, \dots, s_n\rangle$, and

$$(M : I) = \{r \in \mathcal{D}^{1\times q} \mid rI \subseteq M\}.$$

Since $\mathcal{D} = I^0 \supseteq I = I^1 \supseteq I^2 \supseteq \cdots$, we have

$$M \subseteq (M : I) \subseteq (M : I^2) \subseteq (M : I^3) \subseteq \cdots. \tag{1.7}$$

The *saturation* of M by I is defined by [4, 6, 12]

$$N := (M : I^\infty) := \bigcup_{d=0}^{\infty} (M : I^d).$$

Due to the Noetherian property of $\mathcal{D}$, the sequence (1.7) must become stationary, that is, there exists an integer $l \geq 0$ such that

$$(M : I^\infty) = (M : I^l).$$

The module N, being a submodule of $\mathcal{D}^{1\times q}$, possesses a representation $N = \mathcal{D}^{1\times h}S$ for some $S \in \mathcal{D}^{h\times q}$. The calculation of such a matrix S is implemented, e.g., in the computer algebra system SINGULAR [5]. Since $M \subseteq N$, we have $R = XS$ for some $\mathcal{D}$-matrix X. This implies that $\operatorname{rank}(R) \le \operatorname{rank}(S)$. Indeed, the rows of R and the rows of S generate the same $\mathbb{C}(s_1, \dots, s_n)$-vector space, and thus, the ranks of R and S coincide. Still, it may happen that $\operatorname{rank}(R(0)) < \operatorname{rank}(S(0))$. The inclusion $M \subseteq N$ also implies that $\mathfrak{B}(N) = \{w \in \mathcal{A}^q \mid S(\partial)w = 0\} \subseteq \mathfrak{B}(M) = \mathcal{B}$. The following theorem can be found in [12], for the special case of M being an ideal ($q = 1$). However, the version given below holds for arbitrary q.

THEOREM 1. *The following are equivalent:*

1. $\mathfrak{P}$ *is finite-dimensional over* $\mathbb{C}$*;*
2. $\mathfrak{B}(N)$ *contains no nonzero polynomial trajectories;*
3. *zero is not a characteristic frequency of* $\mathfrak{B}(N)$*;*
4. $\operatorname{rank}(S(0)) = q$.

Moreover, if these equivalent assertions are true, then $\mathcal{B}$ *is autonomous.*

Proof. The equivalence of assertions 3 and 4 is a consequence of Lemma 1. The implication "2 $\Rightarrow$ 3" follows trivially from the definition of a characteristic frequency. Conversely, suppose that $\mathfrak{B}(N)$ contains a nonzero polynomial vector, say $S(\partial)p = 0$, where $p(t) = \sum_{|\nu|<d} \frac{1}{\nu!} p_\nu t^\nu$ for some $d \in \mathbb{N}$, $p_\nu \in \mathbb{C}^q$. (The factors $\nu! := \nu_1! \cdots \nu_n!$ are extracted from the coefficient vectors for notational convenience.) Let d be chosen as small as possible, that is, there exists μ such that $|\mu| = d - 1$ and $p_\mu \neq 0$. Then $c := \partial^\mu p = p_\mu$ and hence $0 \neq c \in \mathbb{C}^q$. On the other hand, $S(\partial)c = S(\partial)\partial^\mu p = \partial^\mu S(\partial)p = 0$, that is, $c \in \mathfrak{B}(N)$, showing that zero is a characteristic frequency of $\mathfrak{B}(N)$.

Thus, assertions 2–4 are equivalent, and it remains to show their equivalence with the first assertion. For this, let $\mu \in \mathbb{N}^n$. Using the injective cogenerator property of $\mathcal{A}$ [9], one can show that $\partial^\mu\mathcal{B} := \{\partial^\mu w \mid w \in \mathcal{B}\}$ is again a behavior, and that

$$\mathfrak{M}(\partial^\mu\mathcal{B}) = (\mathfrak{M}(\mathcal{B}) : s^\mu) := \{r \in \mathcal{D}^{1\times q} \mid rs^\mu \in \mathfrak{M}(\mathcal{B})\}.$$

Hence, with $M = \mathfrak{M}(\mathcal{B})$, we have $\partial^\mu\mathcal{B} = \mathfrak{B}(M : s^\mu)$ and thus

$$\mathfrak{B}(M : I^d) = \mathfrak{B}\Big(\bigcap_{|\mu|=d} (M : s^\mu)\Big) = \sum_{|\mu|=d} \mathfrak{B}(M : s^\mu) = \sum_{|\mu|=d} \partial^\mu\mathcal{B},$$

where the relation (1.4) was used for the second equality. The set $\mathfrak{P}$ is infinite-dimensional if and only if there exist polynomial elements of $\mathcal{B}$ of arbitrarily high degree. This means that for all d, the behavior $\sum_{|\mu|=d} \partial^\mu\mathcal{B}$ possesses nonzero polynomial elements, and hence, similarly as shown in the first part of the proof, it also possesses nonzero constant solutions, that is, zero is a characteristic frequency of $\mathfrak{B}(M : I^d)$ for all d. Still equivalently, zero is a characteristic frequency of $\mathfrak{B}(M : I^\infty) = \mathfrak{B}(N)$.

The final statement follows from the fact that if $\operatorname{rank}(S(0)) = q$, then the rank of S, and hence of R, must be q. ∎

The set $\mathfrak{P}$ is finite-dimensional if and only if there exists an upper bound for the degree of any polynomial trajectory. This means that $h_d = 0$ for large enough d. Let d^* be the smallest integer such that $h_{d^*} = 0$, that is,

$$\mathfrak{P}_{d^*} = \mathfrak{P}_{d^*+1}.$$

Then $d^* - 1$ is the maximal degree of any polynomial solution to $R(\partial)w = 0$. This is due to the fact that the first equality in (1.3) will already yield stationarity, as shown in the subsequent lemma.

LEMMA 2. *If* $\mathfrak{P}_d = \mathfrak{P}_{d+1}$, *then*

$$\mathfrak{P}_d = \mathfrak{P}_{d+l} \quad \textit{for all } l \geq 0.$$

Thus $\mathfrak{P} = \mathfrak{P}_{d^*}$, *where* d^* *is the smallest integer with* $\mathfrak{P}_{d^*} = \mathfrak{P}_{d^*+1}$.

Proof. It suffices to show that $\mathfrak{P}_{d+2} \subseteq \mathfrak{P}_{d+1}$. We have

$$\mathfrak{P}_d = \mathfrak{B}(M + I^d\mathcal{D}^{1\times q}).$$

Hence the assumption $\mathfrak{P}_{d+1} \subseteq \mathfrak{P}_d$ is equivalent to

$$M + I^d\mathcal{D}^{1\times q} \subseteq M + I^{d+1}\mathcal{D}^{1\times q}$$

or

$$I^d\mathcal{D}^{1\times q} \subseteq M + I^{d+1}\mathcal{D}^{1\times q}.$$

From the last inclusion, it is easy to conclude that

$$I^{d+1}\mathcal{D}^{1\times q} \subseteq M + I^{d+2}\mathcal{D}^{1\times q}$$

and hence one obtains the desired result, by adding M, and by applying the inclusion-reversing map $\mathfrak{B}$. □

Example. Consider

$$R = \begin{bmatrix} s_1(s_2+1) & 0 \\ 0 & s_3 \\ (s_2+1)(s_3+1) & s_1 \end{bmatrix},$$

whose behavior has zero as a characteristic frequency, because $\operatorname{rank}(R(0)) = 1$. Using SINGULAR, it turns out that $N = M$. Hence we may choose $S = R$ and we may conclude that $\mathfrak{P}$ is not finite-dimensional. However, if we add an additional row and consider

$$\hat{R} = \begin{bmatrix} s_1(s_2+1) & 0 \\ 0 & s_3 \\ (s_2+1)(s_3+1) & s_1 \\ 0 & s_2^2 \end{bmatrix},$$

then the resulting behavior still has the characteristic frequency zero, but SINGULAR returns

$$\hat{S} = \begin{bmatrix} s_1(s_2+1) & 0 \\ 0 & 1 \\ (s_2+1)(s_3+1) & 0 \end{bmatrix},$$

and hence $\operatorname{rank}(\hat{S}(0)) = 2$, that is, $\hat{\mathfrak{P}}$ is finite-dimensional. In fact, $\dim_{\mathbb{C}} \hat{\mathfrak{P}} = 4$, and $\hat{\mathfrak{P}}_2 \neq \hat{\mathfrak{P}}_3 = \hat{\mathfrak{P}}_4$, that is, $d^* = 3$ and thus the largest degree of a polynomial solution to $\hat{R}(\partial)w = 0$ equals 2.

1.2. Computing a basis of $\mathfrak{P}_d$. A basis of $\mathfrak{P}_d$ can be computed in various ways, e.g., see [10, 12]. Here, we use the method described in [8]. For this, let $\delta := \dim_{\mathbb{C}} \mathfrak{P}_d$. Then $\mathfrak{P}_d$ possesses a representation

$$\mathfrak{P}_d = \{w \mid \exists x_0 \in \mathbb{C}^\delta : w(t) = C \exp(t_1 A_1 + \cdots + t_n A_n) x_0 \text{ for all } t \in \mathbb{R}^n\},$$

where $A_i \in \mathbb{C}^{\delta\times\delta}$ are nilpotent, pairwise commuting matrices, and $C \in \mathbb{C}^{q\times\delta}$. Thus, the columns of $C \exp(t_1 A_1 + \cdots + t_n A_n)$ are a basis of $\mathfrak{P}_d$.

The matrices A_i and C can be constructed as follows [8]:

Let

$$M^{(d)} := \mathfrak{M}(\mathfrak{P}_d) = M + I^d \mathcal{D}^{1\times q}.$$

According to (1.5), $P^{(d)} := \mathcal{D}^{1\times q}/M^{(d)}$ has dimension δ as a $\mathbb{C}$-vector space, and a concrete $\mathbb{C}$-basis $\{b_1, \ldots, b_\delta\}$ of $P^{(d)}$ can be found, e.g., using Gröbner bases. Thus there is a $\mathbb{C}$-vector space isomorphism $\mathbb{C}^\delta \cong P^{(d)}$, $e_k \leftrightarrow b_k$, where e_k is the kth natural basis vector of $\mathbb{C}^\delta$. Using this isomorphism, the multiplication by s_i in $P^{(d)}$ yields matrices $F_i \in \mathbb{C}^{\delta\times\delta}$, which are pairwise commuting (because $s_i s_j = s_j s_i$ in $P^{(d)}$) and nilpotent (because $s_i^d P^{(d)} = 0$ for all i). Let $A_i := F_i^T$ and let $C \in \mathbb{C}^{q\times\delta}$ be the matrix obtained from expressing each $[e_j] \in P^{(d)}$, where e_j is the jth natural basis vector of $\mathcal{D}^{1\times q}$, in terms of the basis elements of $P^{(d)}$ according to

$$[e_j] = \sum_{k=1}^{\delta} C_{jk} b_k.$$

This construction method works for any finite-dimensional behavior $\mathcal{B}$, not only for the behaviors of the form $\mathfrak{P}_d$. For instance, consider a one-dimensional and scalar system ($n = q = 1$), say $r(\frac{\mathrm{d}}{\mathrm{d}t})w = 0$ for $r = s^\delta + \alpha_{\delta-1}s^{\delta-1} + \cdots + \alpha_1 s + \alpha_0$. The procedure from above yields (choosing $b_1 = [1], \ldots, b_\delta = [s^{\delta-1}]$)

$$A = \begin{bmatrix} 0 & 1 & & \\ \vdots & & \ddots & \\ 0 & & & 1 \\ -\alpha_0 & \cdots & \cdots & -\alpha_{\delta-1} \end{bmatrix} \quad \text{and} \quad C = \begin{bmatrix} 1 & 0 & \cdots & 0 \end{bmatrix},$$

which is the so-called observability form. Similarly, one obtains the observer form by a suitable choice of the basis elements b_k. Note that the matrix A in this example is not in general nilpotent. This is because $\mathcal{B} = \{w \in \mathcal{A} \mid r(\frac{\mathrm{d}}{\mathrm{d}t})w = 0\}$ is finite-dimensional, but does not have the form $\mathfrak{P}_d$. For this $\mathcal{B}$, we have

$$\mathfrak{P}_d = \left\{ w \in \mathcal{A} \middle| r\left(\frac{\mathrm{d}}{\mathrm{d}t}\right) w = 0, \frac{\mathrm{d}^d}{\mathrm{d}t^d} w = 0 \right\} = \left\{ w \in \mathcal{A} \middle| \frac{\mathrm{d}^e}{\mathrm{d}t^e} w = 0 \right\},$$

where $e = \min\{d, \min\{k \mid \alpha_k \neq 0\}\}$, that is, s^e is the greatest common divisor of r and s^d. Thus, the only one-dimensional and scalar case that fits into the situation outlined above is $r = s^e$ and then all $\alpha_k = 0$ and hence we obtain a nilpotent matrix A.

In section 2, we will discuss another realization of a finite-dimensional behavior that is dual to the given one in a certain sense, and that corresponds to the controllability/controller forms in the one-dimensional scalar case.

Example. Let us return to $\hat{R}$ from the previous example. We have $d^* = 3$ and $\hat{\mathfrak{P}} = \hat{\mathfrak{P}}_3 = \{w \in \mathcal{A}^2 \mid Q(\partial)w = 0\}$, where

$$Q := \begin{bmatrix} s_3 & 0 \\ 0 & s_3 \\ s_2^2 & 0 \\ 0 & s_2^2 \\ s_1 & 0 \\ s_2 + 1 & s_1 \end{bmatrix}. \tag{1.8}$$

This matrix has been obtained by computing a Gröbner basis of $M^{(3)} = \mathcal{D}^{1\times 4}\hat{R} + I^3\mathcal{D}^{1\times 2} = \mathcal{D}^{1\times 6}Q$. Here, $\delta = 4$. As a basis of $P^{(3)} = \mathcal{D}^{1\times 2}/M^{(3)}$, we choose $b_1 = [e_1]$, $b_2 = [e_2]$, $b_3 = [s_2e_1]$, $b_4 = [s_2e_2]$. Then

$$A_1 = \begin{bmatrix} 0 & 0 & 0 & 0 \\ -1 & 0 & -1 & 0 \\ 0 & 0 & 0 & 0 \\ 0 & 0 & -1 & 0 \end{bmatrix}, \qquad A_2 = \begin{bmatrix} 0 & 0 & 1 & 0 \\ 0 & 0 & 0 & 1 \\ 0 & 0 & 0 & 0 \\ 0 & 0 & 0 & 0 \end{bmatrix}, \qquad A_3 = 0$$

and

$$C = \begin{bmatrix} 1 & 0 & 0 & 0 \\ 0 & 1 & 0 & 0 \end{bmatrix}.$$

Thus all polynomial solutions to $\hat{R}(\partial)w = 0$ have the form

$$w(t) = C\exp(t_1A_1 + t_2A_2 + t_3A_3)x_0 = \begin{bmatrix} c_1 + c_3t_2 \\ c_2 - (c_1 + c_3)t_1 + c_4t_2 - c_3t_1t_2 \end{bmatrix}, \tag{1.9}$$

where $x_0 = [c_1, c_2, c_3, c_4]^T \in \mathbb{C}^4$.

1.3. Asymptotic behavior of the numbers h_d. Consider the function $h : \mathbb{N} \to \mathbb{N}$, $d \mapsto h_d$, where h_d is defined in (1.6). As above, let $I = \langle s_1, \dots, s_n\rangle$. The set $\mathcal{D} \setminus I$ consists of all polynomials with a nonvanishing constant term, and thus, it is multiplicatively closed. The *localization* [4, 6] of $\mathcal{D}$ at I is defined by

$$\mathcal{D}_0 := \left\{ \frac{f}{g} \mid f \in \mathcal{D}, g \in \mathcal{D} \setminus I \right\}.$$

We identify $\mathcal{D}$ with a subring of $\mathcal{D}_0$ via $f = \frac{f}{1}$. Similarly, for $M = \mathcal{D}^{1\times g}R \subseteq \mathcal{D}^{1\times q}$, we define the localization of M at I as

$$M_0 := \left\{ \frac{f}{g} \mid f \in M, g \in \mathcal{D} \setminus I \right\}$$

and we identify M with a submodule of M_0. The (Krull) *dimension* [4, 6] of M_0 is an integer between -1 and n. The case $\dim(M_0) = -1$ corresponds to $\operatorname{rank}(R(0)) = q$, that is, to zero not being a characteristic frequency of $\mathcal{B}$. Then we have $\mathfrak{P}_d = \{0\}$ for all d, and the function h is identically zero. If we exclude this special case in the following theorem, we have $0 \le \dim(M_0) \le n$. Note that $\dim(M_0) = n$ holds if and only if $\mathcal{B}$ is not autonomous. The dimension can be computed by means of computer algebra systems such as SINGULAR.

THEOREM 2. *If* $\operatorname{rank}(R(0)) = q$, *then the function* h *is identically zero. Let* $\operatorname{rank}(R(0)) < q$. *Then the function* h *agrees, for large* d, *with a polynomial of degree* $\dim(M_0) - 1$, *where* M_0 *is the localization of* M *at* I, *and* $\dim(\cdot)$ *denotes the Krull dimension.*

Proof. Let $\mathcal{D}_0$ be the localization of $\mathcal{D}$ at I. Then $M_0 = \mathcal{D}_0^{1\times g}R \subseteq \mathcal{D}_0^{1\times q}$ and $\dim(M_0) = \dim(P_0)$, where $P_0 := \mathcal{D}_0^{1\times q}/M_0$. Since $\mathcal{D}_0$ is a local ring with maximal ideal $I_0 := \mathcal{D}_0 I$, it follows from the theory of the Hilbert–Samuel function [4, 6] that

$$\dim_{\mathbb{C}} P_0/I_0^d P_0$$

coincides, for large d, with a polynomial of degree $\dim(M_0)$. We have

$$P_0/I_0^d P_0 \cong \mathcal{D}_0^{1\times q}/M_0 + I_0^d \mathcal{D}_0^{1\times q} \cong \mathcal{D}^{1\times q}/M + I^d\mathcal{D}^{1\times q}. \tag{1.10}$$

The first isomorphism is straightforward, and can be directly verified by checking that the mapping

$$\begin{aligned} \mathcal{D}_0^{1\times q}/M_0 + I_0^d\mathcal{D}_0^{1\times q} &\to \mathcal{D}_0^{1\times q}/M_0/I_0^d\big(\mathcal{D}_0^{1\times q}/M_0\big), \\ r_0 + M_0 + I_0^d\mathcal{D}_0^{1\times q} &\mapsto \big(r_0 + M_0\big) + I_0^d\big(\mathcal{D}_0^{1\times q}/M_0\big) \end{aligned}$$

has the desired properties. The second isomorphism is more interesting. In [3], it is proven for zero-dimensional ideals. The generalization to the module case is easy, but it is given here for the sake of completeness. Consider the homomorphism

$$\varphi : \mathcal{D}^{1\times q} \to \mathcal{D}_0^{1\times q}/M_0 + I_0^d\mathcal{D}_0^{1\times q}, \qquad r \mapsto \varphi(r) := \tfrac{r}{1} + M_0 + I_0^d\mathcal{D}_0^{1\times q}.$$

It is clear that $r \in M + I^d\mathcal{D}^{1\times q}$ implies $\varphi(r) = 0$, and hence we have

$$M + I^d\mathcal{D}^{1\times q} \subseteq \ker(\varphi).$$

In order to establish the second isomorphism in (1.10), it suffices, in view of the homomorphism theorem, to show the converse inclusion, and the surjectivity of φ. Both facts follow from the following observation: For each $g \in \mathcal{D}\setminus I$ there exists $h \in \mathcal{D}$ such that $(1-hg)e_j \in I^d\mathcal{D}^{1\times q}$ for all $1 \le j \le q$, where e_j denotes the jth natural basis vector of $\mathcal{D}^{1\times q}$. To see this, note that $g_0 := 1 - \frac{g}{g(0)} \in I$, where $g(0) \in \mathbb{C}$ is the nonzero constant term of $g \notin I$. Then $h := \frac{1}{g(0)}(1 + g_0 + \cdots + g_0^{d-1})$ yields $hg = \frac{1}{g(0)}(1 + g_0 + \cdots + g_0^{d-1})g(0)(1-g_0) = 1 - g_0^d$. Thus $1 - hg = g_0^d \in I^d$, and therefore $(1-hg)e_j \in I^d\mathcal{D}^{1\times q}$ for all j. In other words, $e_j \equiv hge_j$ modulo $I^d\mathcal{D}^{1\times q}$.

Now let $r \in \ker(\varphi)$. Then $\frac{r}{1} = \frac{f}{g}$ for some $g \in \mathcal{D}\setminus I$ and some $f = gr \in M + I^d\mathcal{D}^{1\times q}$. Let $h \in \mathcal{D}$ be as constructed above. Then we have $hgr = hf \in M + I^d\mathcal{D}^{1\times q}$, and on the other hand,

$$hgr = \sum r_j hge_j \equiv \sum r_j e_j = r \text{ modulo } M + I^d\mathcal{D}^{1\times q}.$$

This implies that $r \in M + I^d\mathcal{D}^{1\times q}$. The surjectivity of φ is proven similarly.

Combining (1.10) with the dimension formula (1.5), one obtains that

$$\dim_{\mathbb{C}} \mathfrak{P}_d = \dim_{\mathbb{C}} \mathcal{D}^{1\times q}/M + I^d\mathcal{D}^{1\times q} = \dim_{\mathbb{C}} P_0/I_0^d P_0$$

is equal, for large d, to a polynomial of degree $\delta := \dim(M_0)$, say,

$$\dim_{\mathbb{C}} \mathfrak{P}_d = \alpha_\delta d^\delta + \sum_{k=0}^{\delta-1} \alpha_k d^k$$

for suitable coefficients α_k, and large enough d. Then

$$h_d = \dim_{\mathbb{C}} \mathfrak{P}_{d+1} - \dim_{\mathbb{C}} \mathfrak{P}_d = \alpha_\delta\big((d+1)^\delta - d^\delta\big) + \sum_{k=0}^{\delta-1} \alpha_k\big((d+1)^k - d^k\big)$$
$$= \alpha_\delta \delta d^{\delta-1} + \sum_{k=0}^{\delta-2} \beta_k d^k$$

for some coefficients β_k. It follows that h_d is a polynomial of degree $\dim(M_0) - 1$, for large d. □

If M is homogeneous, then the polynomial from Theorem 2 coincides with the *Hilbert polynomial* [4, 6] of M. For an interpretation of the Hilbert polynomial in the context of multidimensional behaviors, see [14].

As a consequence of the proof of Theorem 2, the function $\dim_{\mathbb{C}} \mathfrak{P}_d$ itself agrees, for large d, with a polynomial of degree $\dim(M_0)$. The connection between Theorems 1 and 2 is given by the fact that $\operatorname{rank}(S(0)) = q$ is equivalent to $\dim(M_0) \leq 0$, and $\operatorname{rank}(R(0)) < \operatorname{rank}(S(0)) = q$ is equivalent to $\dim(M_0) = 0$.

Example. Let us return to the matrix R from the previous example. We have already seen that $\mathfrak{P}$ is not finite-dimensional. Indeed, the numbers $\dim_{\mathbb{C}} \mathfrak{P}_d$ satisfy

$$\dim_{\mathbb{C}} \mathfrak{P}_d = 2d - 1$$

for all $d \geq 1$ and thus $h_d = 2$ for large enough d, a polynomial of degree 0. Note that the module $M = \mathcal{D}^{1\times 3}R$ has Krull dimension 2, but M_0, its localization at zero, has Krull dimension 1.

2. Polynomial-exponential trajectories and the MPUM. Let

$$p \in \mathbb{C}[t_1, \ldots, t_n]^q$$

be a vector of polynomials. In this section, we construct the smallest behavior $\mathcal{B}$ that contains p. This behavior will be called the *most powerful unfalsified model* (MPUM) of p [1]. For this, we write

$$p(t) = \sum_{\nu \in \mathbb{N}^n, |\nu| < d} \frac{1}{\nu!} p_\nu t^\nu, \qquad p_\nu \in \mathbb{C}^q,$$

where $\nu! = \nu_1! \cdots \nu_n!$, and we assume, without loss of generality, that d is chosen as small as possible. We have

$$\partial^\mu p = 0 \quad \text{for all } \mu \in \mathbb{N}^n \text{ with } |\mu| = d.$$

Consider the module $P := \mathcal{D}/I^d$. As a $\mathbb{C}$-vector space, P is generated by $[s^\nu]$, where $\nu \in \mathbb{N}^n$ is such that $|\nu| < d$. Thus the underlying vector space of P isomorphic to $\mathbb{C}^\delta$, where $\delta := |\{\nu \in \mathbb{N}^n \mid |\nu| < d\}|$. A simple combinatorial argument shows that

$$\delta = \binom{n+d-1}{n}.$$

The multiplication by s_i in P yields a linear transformation in $\mathbb{C}^\delta$ which we may identify with a matrix F_i after fixing a basis of $\mathbb{C}^\delta$. The easiest way to do this is to enumerate the elements of $\{\nu \in \mathbb{N}^n \mid |\nu| < d\} =: \{\nu_1, \ldots, \nu_\delta\}$, e.g., in lexicographical order, and to identify the element $[s^{\nu_k}]$ of P with the kth natural basis vector

of $\mathbb{C}^\delta$. The matrices obtained this way are pairwise commuting and nilpotent. This construction is a special case of the procedure described in section 1.2, but note that we put $A_i := F_i$ here (without transposition).

THEOREM 3. *The MPUM of p is given by*

$$\begin{aligned}\mathcal{B} &= \{w \in \mathcal{A}^q \mid \exists x \in \mathcal{A}^\delta : \partial_i x = A_i x \text{ for } 1 \le i \le n \text{ and } w = Cx\} \\ &= \{w \in \mathcal{A}^q \mid \exists x_0 \in \mathbb{C}^\delta : w(t) = C\exp(t_1A_1 + \cdots + t_nA_n)x_0 \text{ for all } t \in \mathbb{R}^n\},\end{aligned}$$

where C is the $q \times \delta$ matrix obtained from putting the coefficient vector p_{ν_k} into the kth column of C. In particular, the MPUM is finite-dimensional over $\mathbb{C}$, and hence autonomous.

This construction of the MPUM is similar to the one given in [1] for the case $n = 1$. The second equality in Theorem 3 is well known [2, 8, 10, 11, 12].

Proof. We show that $\mathcal{B}$ from above is really the MPUM of p. Note that

$$\xi(t) := \begin{bmatrix} \frac{1}{\nu_1!}t^{\nu_1} \\ \vdots \\ \frac{1}{\nu_\delta!}t^{\nu_\delta} \end{bmatrix}$$

satisfies $\partial_i\xi = A_i\xi$ for all i, and thus $p = C\xi \in \mathcal{B}$. Moreover, $\xi_\nu := \partial^\nu\xi$ also satisfies $\partial_i\xi_\nu = A_i\xi_\nu$ and we get $\partial^\nu p = C\xi_\nu \in \mathcal{B}$ for all $\nu \in \mathbb{N}^n$. Thus the given polynomial vector p and all its derivatives belong to $\mathcal{B}$. On the other hand, we have

$$\mathcal{B} = \{w \in \mathcal{A}^q \mid \exists x_0 \in \mathbb{C}^\delta : w(t) = C\exp(t_1A_1 + \cdots + t_nA_n)x_0 \text{ for all } t \in \mathbb{R}^n\}.$$

Since $\{\xi_\nu(0) \mid \nu \in \mathbb{N}^n, |\nu| < d\}$, where $\xi_0 = \xi$, is the set of all natural basis vectors of $\mathbb{C}^\delta$, we conclude that $\{C\xi_\nu \mid \nu \in \mathbb{N}^n, |\nu| < d\}$ is a generating set of $\mathcal{B}$. Therefore, $\mathcal{B}$ is the linear span of the given polynomial vector p and its derivatives, and thus it is the smallest behavior containing p. ∎

In the one-dimensional and scalar case, say, $p(t) = \alpha_{\delta-1}t^{\delta-1} + \cdots + \alpha_1 t + \alpha_0$, this yields

$$A = \begin{bmatrix} 0 & \cdots & 0 & 0 \\ 1 & & & \vdots \\ & \ddots & & \vdots \\ & & 1 & 0 \end{bmatrix} \quad \text{and} \quad C = \begin{bmatrix} \alpha_0 & \cdots & k!\alpha_k & \cdots & (\delta-1)!\alpha_{\delta-1} \end{bmatrix}$$

and then $C\exp(tA) = (p(t), p'(t), \ldots, p^{(\delta-1)}(t))$, in particular, $C\exp(tA)e_1 = p(t)$. This form is reminiscent of the controllability form. The controller form analogue is obtained similarly (by choosing another enumeration of the basis).

Example. Consider the polynomial vector from (1.9) as an element of $\mathbb{C}[t_1, t_2]^2$. Then $d = 3$ and $\delta = 6$. We have

$$A_1 = \begin{bmatrix} 0&0&0&0&0&0 \\ 0&0&0&0&0&0 \\ 0&0&0&0&0&0 \\ 1&0&0&0&0&0 \\ 0&1&0&0&0&0 \\ 0&0&0&1&0&0 \end{bmatrix}, \qquad A_2 = \begin{bmatrix} 0&0&0&0&0&0 \\ 1&0&0&0&0&0 \\ 0&1&0&0&0&0 \\ 0&0&0&0&0&0 \\ 0&0&0&1&0&0 \\ 0&0&0&0&0&0 \end{bmatrix}$$

and

$$C = \begin{bmatrix} c_1 & c_3 & 0 & 0 & 0 & 0 \\ c_2 & c_4 & 0 & -(c_1+c_3) & -c_3 & 0 \end{bmatrix}.$$

Hence

$$w(t) = \begin{bmatrix} c_1 + c_3 t_2 & c_3 & 0 & 0 & 0 & 0 \\ c_2 + c_4 t_2 - (c_1+c_3)t_1 - c_3 t_1 t_2 & c_4 - c_3 t_1 & 0 & -c_1 - c_3 - c_3 t_2 & -c_3 & 0 \end{bmatrix} x_0.$$

A kernel representation of the MPUM, that is, a matrix $\hat{Q}$ such that $w \in \mathcal{B}$ if and only if $\hat{Q}(\partial)w = 0$, is given by

$$\hat{Q} := \begin{bmatrix} s_2^2 & 0 \\ 0 & s_2^2 \\ s_1 & 0 \\ s_2 + 1 & s_1 \end{bmatrix}.$$

This corresponds to the last four rows of Q from (1.8). The first two rows of Q say that the solution does not depend on t_3; they would also be present in $\hat{Q}$ if we had worked over $\mathbb{C}[t_1, t_2, t_3]$. Note that the vector space dimension of the MPUM equals 4, and thus it is strictly smaller than $\delta = 6$. This shows that the "realization" of the MPUM constructed in Theorem 3 is not minimal, in general.

The minimality of MPUM realizations, and the reduction of a given realization to minimality, are discussed below, where we derive a generalization of the Kalman observability decomposition. Note that this is the key ingredient to keeping the computational effort moderate: The construction of A_i, C is quite cheap, since it consists in putting ones and zeros into the correct entries of each A_i, and in putting the given coefficient vectors of p into the correct positions of C, respectively, and thus, it is more or less a matter of bookkeeping. The computational cost becomes relevant, however, when we want to calculate $C \exp(t_1 A_1 + \cdots + t_n A_n)$ for the explicit description of the MPUM trajectories, or if we wish to construct a kernel representation of the MPUM (using the fundamental principle [9] for eliminating the latent variable x). Clearly, these operations are sensitive with respect to the size of the matrices A_i.

For this, let $A_i \in \mathbb{C}^{\delta \times \delta}$, $1 \le i \le n$, be pairwise commuting matrices, and let $C \in \mathbb{C}^{q \times \delta}$. Consider $\mathcal{B} = \{w \in \mathcal{A}^q \mid \exists x \in \mathcal{A}^\delta : \partial_i x = A_i x \text{ for } 1 \le i \le n \text{ and } w = Cx\}$. We call $(A_1, \ldots, A_n, C)$ a *realization* of $\mathcal{B}$ of size δ, and a realization is said to be *minimal* if there exists no realization of $\mathcal{B}$ of strictly smaller size. A realization $(A_1, \ldots, A_n, C)$ is called *observable* if

$$\mathcal{O}(A_1, \ldots, A_n, C) := \bigcap_{\mu \in \mathbb{N}^n} \ker(C A_1^{\mu_1} \cdots A_n^{\mu_n}) = \{0\}.$$

Observability means that x is uniquely determined by w with $w = Cx$ and $\partial_i x = A_i x$ for all i. This follows from $(\partial^\mu w)(0) = C A^\mu x_0$, where $A^\mu := A_1^{\mu_1} \cdots A_n^{\mu_n}$. Thus x_0, and hence x, is uniquely determined by w if and only if the realization is observable.

THEOREM 4. *A realization $(A_1, \ldots, A_n, C)$ of $\mathcal{B}$ is minimal if and only if it is observable. Given $(A_1, \ldots, A_n, C)$, there exists a nonsingular matrix $T \in \mathbb{C}^{\delta \times \delta}$ such that*

$$T A_i T^{-1} = \begin{bmatrix} A_i^1 & 0 \\ * & * \end{bmatrix} \quad \text{and} \quad C T^{-1} = \begin{bmatrix} C^1 & 0 \end{bmatrix},$$

where $(A_1^1, \ldots, A_n^1, C^1)$ is observable, and thus a minimal realization of $\mathcal{B}$.

Proof. Let $(A_1, \dots, A_n, C)$ be given. Let $\mathcal{K} := \mathcal{K}(A_1, \dots, A_n, C)$ be the subspace of $\mathbb{C}^{1\times\delta}$ spanned by the rows of the matrices CA^μ, where $\mu \in \mathbb{N}^n$ and $A^\mu = A_1^{\mu_1} \cdots A_n^{\mu_n}$. Note that it suffices to consider $0 \le \mu_i \le \delta - 1$. Let $r := \dim(\mathcal{K})$ and let $T_1 \in \mathbb{C}^{r\times\delta}$ be a matrix whose rows are a basis of $\mathcal{K}$. Choose T_2 such that $T^T = \left[T_1^T, T_2^T\right]$ is square and nonsingular. Since $\mathcal{K}$ is invariant under right multiplication by any A_i, that is, $x \in \mathcal{K}$ implies $xA_i \in \mathcal{K}$, we have $T_1 A_i = A_i^1 T_1$ for some $A_i^1 \in \mathbb{C}^{r\times r}$, and thus

$$TA_iT^{-1} = \begin{bmatrix} A_i^1 & 0 \\ * & * \end{bmatrix}.$$

Similarly, since the rows of C are contained in $\mathcal{K}$, we have $C = C^1 T_1$ for some $C^1 \in \mathbb{C}^{q\times r}$ and thus $CT^{-1} = [C^1, 0]$. The matrices A_i^1 are pairwise commuting, and $(A_1^1, \dots, A_n^1, C^1)$ is a realization of $\mathcal{B}$ of size $r = \delta - \dim(\mathcal{O}(A_1, \dots, A_n, C))$. Thus, a nonobservable realization can be reduced in size. Moreover, we have $\dim(\mathcal{K}) = \dim(\mathcal{K}(A_1^1, \dots, A_n^1, C^1))$ and thus $\mathcal{O}(A_1^1, \dots, A_n^1, C^1) = \{0\}$.

It remains to be shown that if $(A_1, \dots, A_n, C)$ is not minimal, then it does not satisfy $\mathcal{O}(A_1, \dots, A_n, C) = \{0\}$. Let $(\tilde{A}_1, \dots, \tilde{A}_n, \tilde{C})$ be a realization of $\mathcal{B}$ of strictly smaller size $\tilde{\delta} < \delta$. By considering $(\partial^\mu w)(0)$ for $w \in \mathcal{B}$ and $\mu \in \mathbb{N}^n$, we obtain that for every $x_0 \in \mathbb{C}^\delta$, there exists $\tilde{x}_0 \in \mathbb{C}^{\tilde{\delta}}$ such that $CA^\mu x_0 = \tilde{C}\tilde{A}^\mu \tilde{x}_0$ for all $\mu \in \mathbb{N}^n$. This implies that $\dim(\mathcal{K}) \le \dim(\tilde{\mathcal{K}})$, where $\mathcal{K}$ is as above and $\tilde{\mathcal{K}} = \mathcal{K}(\tilde{A}_1, \dots, \tilde{A}_n, \tilde{C})$, and thus $\dim(\mathcal{O}(A_1, \dots, A_n, C)) = \delta - \dim(\mathcal{K}) \ge \delta - \tilde{\delta} > 0$. ∎

Example. Returning to the example from above, a suitable transformation matrix is given by

$$T = \left[\begin{array}{cccccc} c_1 & c_3 & 0 & 0 & 0 & 0 \\ c_2 & c_4 & 0 & -(c_1+c_3) & -c_3 & 0 \\ c_3 & 0 & 0 & 0 & 0 & 0 \\ c_4 & 0 & 0 & -c_3 & 0 & 0 \\ \hline 0 & 0 & 1 & 0 & 0 & 0 \\ 0 & 0 & 0 & 0 & 0 & 1 \end{array}\right],$$

where the horizontal line denotes the partition between T_1 and T_2, and where we assume $c_3 \neq 0$. Then the new realization of the MPUM takes the form

$$A_1^1 = \begin{bmatrix} 0 & 0 & 0 & 0 \\ -1 & 0 & -1 & 0 \\ 0 & 0 & 0 & 0 \\ 0 & 0 & -1 & 0 \end{bmatrix}, \qquad A_2^1 = \begin{bmatrix} 0 & 0 & 1 & 0 \\ 0 & 0 & 0 & 1 \\ 0 & 0 & 0 & 0 \\ 0 & 0 & 0 & 0 \end{bmatrix}, \qquad C^1 = \begin{bmatrix} 1 & 0 & 0 & 0 \\ 0 & 1 & 0 & 0 \end{bmatrix}$$

which is minimal, and happens to coincide with the system that generated (1.9) in the first place.

Finally, it remains to generalize the result of Theorem 3 to the case where we have more than one given polynomial trajectory, and to the case where the data trajectories are polynomial-exponential rather than purely polynomial. We do this in three steps.

First, let $p_1, \dots, p_N \in \mathbb{C}[t_1, \dots, t_n]^q$ be given. Let $\mathcal{B}_l$ be the MPUM of p_l for $l = 1, \dots, N$. Then the MPUM of $D = \{p_1, \dots, p_N\}$ is given by

$$\mathcal{B} = \mathcal{B}_1 + \cdots + \mathcal{B}_N.$$

Moreover, if

$$\mathcal{B}_l = \left\{w \in \mathcal{A}^q \mid \exists x_l \in \mathcal{A}^{\delta_l} : \partial_i x_l = A_{il} x_l \text{ for } 1 \le i \le n \text{ and } w = C_l x_l\right\},$$

then

$$\mathcal{B} = \{w \in \mathcal{A}^q \mid \exists x \in \mathcal{A}^\delta : \partial_i x = A_i x \text{ for } 1 \le i \le n \text{ and } w = Cx\},$$

where $\delta := \delta_1 + \cdots + \delta_N$ and

$$A_i := \operatorname{diag}(A_{i1}, \ldots, A_{iN}) \quad \text{and} \quad C := \begin{bmatrix} C_1 & \ldots & C_N \end{bmatrix}. \tag{2.1}$$

Second, the equivalence (1.2) enables translating these results to the case where $p_1, \ldots, p_N$ are polynomial-exponential rather than purely polynomial. Let

$$\tilde{\mathcal{B}} = \{w \in \mathcal{A}^q \mid \exists x \in \mathcal{A}^\delta : \partial_i x = A_i x \text{ for } 1 \le i \le n \text{ and } w = Cx\}$$

be the MPUM of p. Then

$$\mathcal{B} = \{w \in \mathcal{A}^q \mid \exists x \in \mathcal{A}^\delta : \partial_i x = \lambda_i x + A_i x \text{ for } 1 \le i \le n \text{ and } w = Cx\}$$

is the MPUM of $p \exp_\lambda$.

Finally, let $D = \{p_1 \exp_{\lambda^{(1)}}, \ldots, p_N \exp_{\lambda^{(N)}}\}$ be given. Let

$$\mathcal{B}_l = \{w \in \mathcal{A}^q \mid \exists x_l \in \mathcal{A}^{\delta_l} : \partial_i x_l = \lambda_i^{(l)} x_l + A_{il} x_l \text{ for } 1 \le i \le n \text{ and } w = C_l x_l\}$$

be the MPUM of $p_l \exp_{\lambda^{(l)}}$. Then

$$\mathcal{B} = \{w \in \mathcal{A}^q \mid \exists x \in \mathcal{A}^\delta : \partial_i x = \Lambda_i x + A_i x \text{ for } 1 \le i \le n \text{ and } w = Cx\}$$

is the MPUM of D, where $\delta = \delta_1 + \cdots + \delta_N$,

$$\Lambda_i := \operatorname{diag}\left(\lambda_i^{(1)} I_{\delta_1}, \ldots, \lambda_i^{(N)} I_{\delta_N}\right),$$

and A_i and C are as in (2.1). Using Theorem 4, the resulting realization of the MPUM can be reduced to a minimal one.

Conclusion. The characteristic frequencies of a behavior correspond to its nonzero exponential trajectories. Similarly as with ordinary differential equations, it does not suffice to consider purely exponential solutions, one has to take polynomial-exponential functions into account. Since a fixed characteristic frequency can be shifted to the origin without loss of generality, the problem can be reduced to finding polynomial solutions. We have seen how to decide whether the polynomial solution set of a given system of PDE is finite-dimensional. If yes, we can construct a basis. In the general case, we can only construct a basis of the space of polynomial solutions up to a certain total degree d, and we can make a statement about the dimensions of these spaces as d tends to infinity. Finally, we have constructed the MPUM for the case of a single observed trajectory of polynomial type. This result has been generalized to the case where we have any finite number of polynomial-exponential trajectories. We have shown that the resulting realization of the MPUM is minimal if and only if it is observable, and we have described a method for reducing a given realization to a minimal one, which is analogous to the Kalman observability decomposition.

Acknowledgments. The author would like to thank Prof. Wilhelm Plesken and Prof. Gerhard Pfister for useful suggestions.

A UNIFIED APPROACH FOR STOCHASTIC AND MEAN SQUARE STABILITY OF CONTINUOUS-TIME LINEAR SYSTEMS WITH MARKOVIAN JUMPING PARAMETERS AND ADDITIVE DISTURBANCES*

MARCELO D. FRAGOSO† AND OSWALDO L. V. COSTA‡

Abstract. Necessary and sufficient conditions for stochastic stability (SS) and mean square stability (MSS) of continuous-time linear systems subject to Markovian jumps in the parameters and additive disturbances are established. We consider two scenarios regarding the additive disturbances: one in which the system is driven by a Wiener process, and one characterized by functions in $L_2^m(\Omega, \mathcal{F}, \mathbb{P})$, which is the usual scenario for the H_∞ approach. The Markov process is assumed to take values in an infinite countable set $\mathcal{S}$. It is shown that SS is equivalent to the spectrum of an augmented matrix lying in the open left half plane, to the existence of a solution for a certain Lyapunov equation, and implies (is equivalent for $\mathcal{S}$ finite) asymptotic wide sense stationarity (AWSS). It is also shown that SS is equivalent to the state $x(t)$ belonging to $L_2^n(\Omega, \mathcal{F}, \mathbb{P})$ whenever the disturbances are in $L_2^m(\Omega, \mathcal{F}, \mathbb{P})$. For the case in which $\mathcal{S}$ is finite, SS and MSS are equivalent, and the Lyapunov equation can be written down in two equivalent forms with each one providing an easier-to-check sufficient condition.

Key words. stochastic stability, mean square stability, jump parameter, continuous-time linear systems, Markov chain

1. Introduction.

In recent years, there has been a steadily rising level of activity with linear systems which are subject to abrupt changes in their structures. Most of the literature considers the case in which the abrupt changes are modeled by a Markov chain, namely, linear systems with Markovian jump parameters (LSMJP). These changes arise quite often in practice and may be due, for instance, to component and/or interconnection failures, *inter alia*. This is to be found, for instance, in robotic manipulator systems, aircraft control systems, large scale flexible structures for space stations (such as antenna, solar arrays, etc.), and flexible manufacturing systems, on which an actuator or a sensor failure is a quite common occurrence. Without any intention of being exhaustive here, we mention [4], [5], [6], [7], [8], [11], [12], [13], [14], [15], [17], [18], [19], [20], [21], [22], [23], [24], [25], [26], [27], [28], [29], [30], [34], [35], [37], [38], [39], [40], [41], [42], [43], [46], [49], and the references therein, as a small sample of works dealing with different aspects of LSMJP problems.

Although mean square and almost sure stability for linear stochastic systems with random parameter perturbation have a long and successful history, the interest in

getting easy-to-check conditions for special structures continues unabated. Among the techniques used, we mention the one which relies on martingale methods and the idea of projecting onto the unit sphere or the projective space to compute the asymptotic exponential growth rate (the Lyapunov exponent) and the one using the Lyapunov function approach. For the class $\dot{x}(t) = (A + P(t))x(t)$, where $P(t)$ is a matrix whose elements belong to a particular class of stochastic processes (either ergodic processes or a Markov jump, stationary, etc.), or $\dot{x}(t) = A(p(t))x(t)$, with $p(t)$ a white noise or an ergodic processes, the readers are referred, for instance, to [3], [16], and [31] (and the many references therein). Stability questions for LSMJP (the case in which $p(t)$ is a Markov chain) have given rise to a significant number of papers dealing with this subject (see, for instance, [4], [8], [11], [12], [13], [18], [19], [22], [23], [24], [26], [27], [34], [35], [37], [38], [39], [40], [43], [46], [49], and the references therein). See also [14] for a historical account on the discrete-time case. It is important to stress that most of these papers consider the case in which the Markov process takes values in a finite state space. This assumption has important consequences and, in particular, it is a well-known fact that mean square stability is equivalent to stochastic stability. For the case in which the state space of the Markov chain is *infinite countable*, these concepts are no longer equivalent (for examples, see [12] or [14] for the discrete-time case and [26] for the continuous-time scenario). In addition, they consider the real case.

In [37] and [40], necessary and sufficient conditions for mean square stability (MSS) were obtained for the homogeneous continuous-time noise-free real case. A common feature in these papers is that the MSS criteria is expressed as the maximal real part of a certain matrix being less than zero, and in fact this number was shown to be the mean square Lyapunov exponent of the system. In [37], the sample path Lyapunov exponent λ and the p-moment Lyapunov exponent $g(p)$ for a real homogeneous LSMJP is studied for the case of a stationary, ergodic Markov chain. Using extensions of results in [1], in conjunction with ideas developed in [2], relations between λ and $g(p)$ are derived. In addition, under a certain assumption which guarantees that the operation mode has the so-called property S, an exact expression for the mean square Lyapunov exponent is obtained. The result for $g(2)$ is given in terms of the maximal real part of a matrix representation of a certain linear operator (the matrix is not exhibited explicitly). The result closest to ours is that obtained in [40], using a technique completely different from that used here.

In [35] necessary and sufficient conditions for MSS of the discrete-time noise-free case were obtained in terms of the existence of a solution of a Lyapunov equation. The continuous-time counterpart of this result is derived in [24] (see also [43]), including a study on the relationship among various moment and sample path stability. In the time varying case with state dependent additive Wiener disturbance, exponential stability in mean square (ESMS) for the zero solution of the system are studied in [19] and [39]. In [19], after deriving a certain Itô-type formula, the authors show equivalence results for ESMS, including a Lyapunov-type equation. After discussing some properties of the solution for the nonlinear general case, it is given in [39] a sufficient condition for the pth moment exponential stability based on the Lyapunov-type result and sufficient condition for pth moment exponential stability to imply almost sure exponential stability, using essentially the idea of Lyapunov exponent. The author uses also the so-called M-matrices theory (in fact, nonsingular M-matrices) to derive sufficient conditions for the pth moment and almost sure exponential stability. In fact it has to be checked if, for $0 < p < 2$, a certain matrix $\mathcal{A}(p)$ is a nonsingular M-matrix. All these papers consider the real case with the Markov process taking values in a finite set.

Almost sure stability for Markovian jump linear systems (MJLS) is examined, for instance, in [11], [18], [22], [23], [38], [40], and [41] (see also [39] for almost sure exponential stability). A historical account on earlier works can be found in [22]. Some important issues regarding MSS for the case in which the state space of the Markov chain is infinite countable can be found in [12], [25], [26], and [27].

Asymptotic stability in distribution for LSMJP has been studied in [4] and [49]. This seems an adequate notion to adopt when, for instance, degeneracy of the noise is allowed. In [4], asymptotic stability in distribution for the semilinear stochastic differential equation with Markov jump parameters is discussed. Using the interesting concept of asymptotic flatness in the pth mean, the authors derive sufficient conditions for stability in distribution by assuming MSS of the autonomous systems and the rather interesting condition $dk_0^2 < 1/\Omega_p$, with d denoting the system dimension, k_0 being a certain Lipschitz condition for the diffusion matrix σ, and $\Omega_p = \max\{\Omega_{p_1}, \ldots, \Omega_{p_N}\}$, with Ω_{p_i} denoting the largest eigenvalue of the matrix P_i, which satisfies a certain Lyapunov equation. In [49], asymptotic stability in the distribution for a class of nonlinear diffusion with a Markov jump is derived. Sufficient conditions are established, provided certain properties of the solution are satisfied (called properties (P1) and (P2)). In addition, sufficient conditions for the mentioned properties in terms of Lyapunov functions are also exhibited. In order to make their result more applicable, the authors also derive sufficient conditions in terms of the M-matrix.

This paper deals with stochastic and mean square stability for continuous-time LSMJP with the Markov process taking values in an *infinite countable set* $\mathcal{S}$ in a unified way. This makes an important difference with respect to the previous papers and, in particular, we have that, unlike the finite-dimensional case, stochastic stability (SS) and MSS are not equivalent (see [26]). In this case, it is SS, as defined in the paper, that is equivalent to the spectrum of a certain matrix lying in the open left half plane. This equivalence does not hold anymore for MSS. In the *finite case* our paper provides, based on *an easily computable criterion* (the spectrum of a matrix), a unified result for SS, MSS, and asymptotic wide sense stationarity (AWSS) in Theorem 5.6 (necessary and sufficient conditions for the three scenarios considered in the paper). It extends and encompasses the results in [28].

A well-known feature of the class of LSMJP is that the state $x(t)$ is not Markov. The primary hindrance here then is related to the kind of analytical tools for handling the problem of getting easy-to-check stability criteria. A distinctive feature of our approach is that it can be used, also in a unified way, for continuous and discrete-time case, since it does not rely on a specific Itô type of result. It relies rather on the fact that the augmented state $(x(t), \theta(t))$ is Markov, and, therefore, an operator theoretical approach is possible, provided we can connect, in a suitable way, $x(t)$ with measurable functions of $(x(t), \theta(t))$. Briefly, the idea behind our approach is as follows: we know that $x(t)$ in (3.2) (also (3.3) and (3.4)) is not Markov, but $(x(t), \theta(t))$ is Markov. Therefore, if we work with the measurable function of $(x(t), \theta(t))$, i.e., $f(x(t), \theta(t))$, we can then think in tools such as infinitesimal generator, which allows us to think about the dynamics. The following question then arises: is it possible to bypass the non-Markovian property of $x(t)$ using $f(x(t), \theta(t))$? It comes up, bearing in mind that $x(t) = \sum_{i \in \mathcal{S}} x(t) 1_{\{\theta_t = i\}}$ and $x(t)x(t)^* = \sum_{i \in \mathcal{S}} x(t)x(t)^* 1_{\{\theta_t = i\}}$, that a natural answer to the above question is to work with $x(t)1_{\{\theta_t = i\}}$ and $x(t)x(t)^* 1_{\{\theta_t = i\}}$, since in this case we can think about differential equations for the moments (first and second moment) in terms of the operators defined in section 4. This approach was used in [11], which is, to some extent, the discrete-time version of this paper, and we believe that it may be useful elsewhere. In addition, since operator theory is the technical

underpinning of the paper, it has the advantage of being suitable for treating the general complex and infinite-dimensional (due to the fact that $\mathcal{S}$ is infinite countable) setting.

We deal with two scenarios regarding additive disturbances: the one in which the disturbances are characterized via a Wiener process, and the one characterized by any function in $L_2^m(\Omega, \mathcal{F}, \mathbb{P})$. It is shown that SS is equivalent to the real part of the spectrum of an augmented matrix being less than zero, or to the existence of a solution of a Lyapunov equation, or that the state $x(t) \in L_2^n(\Omega, \mathcal{F}, \mathbb{P})$ for $L_2^m(\Omega, \mathcal{F}, \mathbb{P})$-disturbances, and implies (is equivalent for $\mathcal{S}$ finite) AWSS stability. It is also shown that these equivalence relations hold even for the case in which only real initial conditions are considered. The first criterion (based on the eigenvalues) translates clearly the intuitive idea that unstable modes of operation do not necessarily compromise the global stability of the system. In fact it can be shown that the stability of all modes of operation is neither necessary nor sufficient for the global stability of the system (see, e.g., [34]). The eigenvalue criterion shows clearly the connection between SS and the probability of visits to the unstable modes. A cursory examination of the augmented matrix reveals that a balance between the modes and the transition probability matrix is essential for SS. For the case of one mode operation (no jumps in the parameters) our criteria reconcile to a well-known stability results for continuous-time linear systems. When the state space of the Markov process $\mathcal{S}$ is finite, MSS and SS are equivalent, and the Lyapunov equation can be written in two equivalent forms with each of these forms providing easier-to-check sufficient conditions. These results, we believe, provide a flexible theory which gives a rather complete and unified picture of SS and MSS for LSMJP.

Finally, it is noteworthy here that, besides the interest in its own right, matrices with complex coefficients are also interesting from an application point of view. As pointed out in [32] and [7], in several engineering applications, as in communication application of signals systems, whirling shafts, vibrational systems, etc., complex coefficients come into play. In [32] some systems with complex coefficients that naturally arise in mechanics and signal processing are presented, motivating the study of equations with complex coefficients and illustrating more general situations such as satellite and cosmic vehicles control. We refer to these papers and the references therein for further examples and results on systems with complex coefficients.

An outline of the content of this paper is as follows. In section 2 we provide the bare essentials of notational conventions and some preliminaries. The model and problem statement are described in section 3. Stochastic and mean square stability for the homogeneous case (including Lyapunov equations) is treated in section 4. For the case in which the $\mathcal{S}$ is finite it is proved that the Lyapunov equation can be written down in two equivalent forms with each one providing an easier-to-check sufficient condition. Section 5 accounts the case with additive disturbances. It embodies two kinds of analysis: one for the $L_2^m(\Omega, \mathcal{F}, \mathbb{P})$-disturbances and one for the linear jump-diffusion case. For all the cases, it is shown that SS is equivalent to the spectrum of an augmented matrix lying in the open left half plane, and to the existence of a solution for a certain Lyapunov equation, and implies (is equivalent for $\mathcal{S}$ finite) AWSS. In the appendix we present the proof of some auxiliary results.

2. Notation and preliminaries. For $\mathbb{X}$ and $\mathbb{Y}$ complex Banach spaces we set $\mathbb{B}(\mathbb{X}, \mathbb{Y})$ for the Banach space of all bounded linear operators of $\mathbb{X}$ into $\mathbb{Y}$, with the uniform induced norm represented by $\|.\|$. For simplicity we shall set $\mathbb{B}(\mathbb{X}) := \mathbb{B}(\mathbb{X}, \mathbb{X})$. For $T \in \mathbb{B}(\mathbb{X})$ we denote by $\sigma(T)$ the spectrum of T. If $\mathbb{X}$ is a Hilbert space, then

$\langle .;. \rangle$ will stand for the inner product, and for $\mathcal{T} \in \mathbb{B}(\mathbb{X})$, $\mathcal{T}^\star$ will indicate the adjoint operator of $\mathcal{T}$. As usual, $\mathcal{T} \geq 0$ ($\mathcal{T} > 0$) will mean that the operator $\mathcal{T} \in \mathbb{B}(\mathbb{X})$ is positive semidefinite (positive definite), respectively. In particular, we shall denote by $\mathbb{C}^n$ the n-dimensional complex Euclidean spaces and by $\mathbb{B}(\mathbb{C}^n, \mathbb{C}^m)$ the normed bounded linear space of all $m \times n$ complex matrices with $\mathbb{B}(\mathbb{C}^n) := \mathbb{B}(\mathbb{C}^n, \mathbb{C}^n)$ and $\mathbb{B}(\mathbb{C}^n)^+ := \{L \in \mathbb{B}(\mathbb{C}^n); L = L^* \geq 0\}$. In this case, the superscripts $-$, $\prime$, and $*$ will denote complex conjugate, transpose, and conjugate transpose, respectively. Either the uniform induced norm in $\mathbb{B}(\mathbb{C}^n)$ or the standard Euclidean norm in $\mathbb{C}^n$ is represented by $\|.\|$. We also use $\mathbb{R}^+$ to denote the interval $[0, \infty)$. Unless otherwise stated, we define $\mathcal{S} := \{1, 2, \dots\}$. For $D_i \in \mathbb{B}(\mathbb{C}^n)$, $i \in \mathcal{S}$, $\mathrm{diag}(D_i)$ is an infinity square matrix where the matrices D_i are put together corner-to-corner diagonally with all other entries being zero. We refer to I_ℓ as the $\ell \times \ell$ identity matrix and to $L_2^n(\mathbb{R}^+)$ as the space of functions $f : [0, \infty) \to \mathbb{C}^n$ such that each component $f^i(.)$ is in the standard L_2 $(\mathbb{R}^+)$ space of Lebesgue square integrable functions. Similarly, $L_2^n(\Omega, \mathcal{F}, \mathbb{P})$ is the space of square integrable stochastic process. $E[.]$ denotes the mathematical expectation, and we set for a second order random variable $x(t)$, $\|x(t)\|_2^2 := E[\|x(t)\|^2]$, and for $x = \{x(t); t \in \mathbb{R}^+\} \in L_2^n(\Omega, \mathcal{F}, \mathbb{P})$, $\|x\|_2^2 := \int_0^\infty E[\|x(t)\|^2]dt$. We denote by $\mathbb{R}_e\{\lambda\}$ the real part of a complex number λ. We recall that (see Theorem 1.1.2 of [48]) a linear operator $\mathcal{L}$ on a Banach space $\mathbb{X}$ is the infinitesimal generator of a uniformly continuous semigroup $\phi_{\mathcal{L}}(t)$ if and only if $\mathcal{L} \in \mathbb{B}(\mathbb{X})$. Furthermore, in this case $\phi_{\mathcal{L}}(t) = e^{\mathcal{L}t}(.)$, which is defined as

$$e^{\mathcal{L}t}(.) := \sum_{n=0}^{\infty} \frac{1}{n!} \mathcal{L}^n(.) t^n \in \mathbb{B}(\mathbb{X}). \tag{2.1}$$

We set

$$\mathbb{R}_e\{\lambda(\mathcal{L})\} := \sup\{\mathbb{R}_e\{\lambda\}; \lambda \in \sigma(\mathcal{L})\}.$$

We recall that the trace operator $\mathrm{tr}(.) : \mathbb{B}(\mathbb{C}^n) \to \mathbb{C}$ is a linear functional with the following properties: (i) $\mathrm{tr}(KL) = \mathrm{tr}(LK)$; (ii) for any $M, P \in \mathbb{B}(\mathbb{C}^n)^+$ with $P > 0$, we have

$$\Big(\min_{i=1,\dots,n} \lambda_i(P)\Big)\mathrm{tr}(M) \leq \mathrm{tr}(MP) \leq \Big(\max_{i=1,\dots,n} \lambda_i(P)\Big)\mathrm{tr}(M). \tag{2.2}$$

We shall denote by ℓ_1^n, ℓ_2^n, $\ell_{\sup}^n$, respectively, the sets made up of all infinite sequences of complex vectors $x = (x_1, x_2, \dots)$, $x_i \in \mathbb{C}^n$, such that $\sum_{i=1}^\infty \|x_i\| < \infty$, $\sum_{i=1}^\infty \|x_i\|^2 < \infty$, and $\sup\{\|x_i\|, i = 1, 2, \dots\} < \infty$. We denote the usual norms $\|.\|_1$, $\|.\|_2$, $\|.\|_{\sup}$ in ℓ_1^n, ℓ_2^n, and $\ell_{\sup}^n$, respectively, by $\|x\|_1 = \sum_{i=1}^\infty \|x_i\|$, $\|x\|_2 = (\sum_{i=1}^\infty \|x_i\|^2)^{\frac{1}{2}}$, and $\|x\|_{\sup} = \sup\{\|x_i\|, i = 1, 2, \dots\}$. We have that $(\ell_1^n, \|.\|_1)$, $(\ell_2^n, \|.\|_2)$, $(\ell_{\sup}^n, \|.\|_{\sup})$ are Banach spaces and, in fact, $(\ell_2^n, \|.\|_2)$ is a Hilbert space equipped with the usual inner product $\langle x; y \rangle := \sum_{i=1}^\infty x_i^* y_i$ (see [47]).

Set $\mathbb{H}_1^{n,m}$ (respectively, $\mathbb{H}_2^{n,m}$, $\mathbb{H}_{\sup}^{n,m}$), the linear space made up of all sequence of complex matrices $V = (V_1, V_2, \dots)$ with $V_i \in \mathbb{B}(\mathbb{C}^n, \mathbb{C}^m)$ such that $\sum_{i=1}^\infty \|V_i\| < \infty$ ($\sum_{i=1}^\infty \mathrm{tr}(V_i^* V_i) < \infty$, $\sup\{\|V_i\|; i = 1, 2, \dots\} < \infty$). For simplicity, set $\mathbb{H}_\iota^n := \mathbb{H}_\iota^{n,n}$, $\iota = 1, 2, \sup$. For $V = (V_1, \dots) \in \mathbb{H}_\iota^{n,m}$, we consider the following norms $\|.\|_\iota$ in $\mathbb{H}_\iota^{n,m}$,

$\iota = 1, 2, \sup$:

$$\|V\|_1 := \sum_{i=1}^{\infty} \|V_i\|, \tag{2.3}$$

$$\|V\|_2 := \left(\sum_{i=1}^{\infty} \operatorname{tr}(V_i^* V_i) \right)^{1/2}, \tag{2.4}$$

$$\|V\|_{\sup} := \sup\{\|V_i\|; i = 1, 2, \dots\}. \tag{2.5}$$

It is easy to verify that $(\mathbb{H}_\iota^{n,m}, \|.\|_\iota)$ and $(\ell_\iota^{nm}, \|.\|_\iota)$, $\iota = 1, 2, \sup$, are uniformly homeomorphic. Therefore, $(\mathbb{H}_\iota^{n,m}, \|.\|_\iota)$ are Banach spaces and, in fact, $(\mathbb{H}^{n,m}, \|.\|_2)$ is a Hilbert space, with the inner product given, for $S = (S_1, \dots)$ and $V = (V_1, \dots)$ in $\mathbb{H}_2^{n,m}$, by

$$\langle V; S \rangle = \sum_{i \in \mathcal{S}} \operatorname{tr}(V_i^* S_i). \tag{2.6}$$

For $V = (V_1, \dots) \in \mathbb{H}_\iota^{n,m}$ we shall write $V^* = (V_1^*, \dots) \in \mathbb{H}_\iota^{m,n}$ and say that $V \in \mathbb{H}_\iota^n$ is Hermitian if $V = V^*$. We define $\mathbb{H}_\iota^{n*} := \{V = (V_1, \dots) \in \mathbb{H}_\iota^n; V_i = V_i^*, i = 1, \dots\}$ and $\mathbb{H}_\iota^{n+} := \{V = (V_1, \dots) \in \mathbb{H}_\iota^{n*}; V_i \geq 0, i = 1, \dots\}$ and shall write, for $V = (V_1, \dots) \in \mathbb{H}_\iota^n$ and $S = (S_1, \dots) \in \mathbb{H}_\iota^n$, that $V \geq S$ if $V - S = (V_1 - S_1, \dots) \in \mathbb{H}_\iota^{n+}$, and that $V > S$ if $V_i - S_i > 0$ for $i \in \mathcal{S}$. Finally we say that $V = (V_1, \dots) \in \widetilde{\mathbb{H}}_{\sup}^{n+}$ if $V \in \mathbb{H}_{\sup}^{n+}$ and for some $\alpha > 0$, $V_i \geq \alpha I_n$ for each $i \in \mathcal{S}$.

For the case in which $\mathcal{S} = \{1, \dots, N\}$ norms (2.3), (2.4), (2.5) are equivalent, since the underline spaces are finite-dimensional. For notational simplicity we just write in this case $\mathbb{H}^n$ instead of $\mathbb{H}_\iota^n$.

Define now the operators φ and $\hat{\varphi}$ in the following way: for $\iota = 1, 2, \sup$, $V = (V_1, \dots) \in \mathbb{H}_\iota^{n,m}$, with $V_i = (v_{i1} \dots v_{in}) \in \mathbb{B}(\mathbb{C}^n, \mathbb{C}^m)$, $v_{ij} \in \mathbb{C}^m$,

$$\varphi(V_i) := \begin{bmatrix} v_{i1} \\ \cdot \\ \cdot \\ \cdot \\ v_{in} \end{bmatrix} \in \mathbb{C}^{mn} \qquad \text{and} \qquad \hat{\varphi}(V) := \begin{bmatrix} \varphi(V_1) \\ \cdot \\ \cdot \\ \cdot \end{bmatrix} \in \ell_\iota^{mn}.$$

Furthermore, for $v = (v_1, \dots) \in \ell_\iota^{nm}$, $v_i \in \mathbb{C}^{mn}$, we define $V_i \in \mathbb{B}(\mathbb{C}^n, \mathbb{C}^m)$ such that $V_i := \varphi^{-1}(v_i)$, and $V = (V_1, \dots) \in \mathbb{H}_\iota^{n,m}$, as

$$V := \hat{\varphi}^{-1} \left(\begin{bmatrix} v_1 \\ \cdot \\ \cdot \\ \cdot \end{bmatrix} \right) := \left[\hat{\varphi}_1^{-1}(v), \dots \right] = \left[\varphi^{-1}(v_1), \dots \right].$$

REMARK 2.1. *Notice that the mapping φ stacks up the column of the matrix from left to right and makes a long vector out of the matrix. Furthermore, it can be shown, through the mapping $\hat{\varphi}$, that $(\mathbb{H}_2^{n,m}, \|.\|_2)$ and $(\ell_2^{mn}, \|.\|_2)$ are isometrically isomorphic spaces (if $V \in \mathbb{H}_2^{n,m}$, then $\|V\|_2 = \|\hat{\varphi}(V)\|_2$).*

With the Kronecker product $L \otimes K \in \mathbb{B}(\mathbb{C}^{sn}, \mathbb{C}^{rm})$ defined in the usual way for any $L \in \mathbb{B}(\mathbb{C}^s, \mathbb{C}^r)$ and $K \in \mathbb{B}(\mathbb{C}^n, \mathbb{C}^m)$, the following properties hold (see, e.g., [9]):

$$\text{(i)} \quad (L \otimes K)^* = L^* \otimes K^* \qquad \text{and} \qquad \text{(ii)} \quad \varphi(LKH) = (H' \otimes L)\varphi(K). \tag{2.7}$$

Recall also that for $L \in \mathbb{B}(\mathbb{C}^n)$ and $K \in \mathbb{B}(\mathbb{C}^m)$ the Kronecker sum is defined as

$$L \oplus K := L \otimes I_m + I_n \otimes K \in \mathbb{B}(\mathbb{C}^{nm}).$$

The proof of the next result can be found in [13].

LEMMA 2.1. *For any $H \in \mathbb{H}_\iota^n$ there exist $H^i \in \mathbb{H}_\iota^{n+}$, $i = 1, 2, 3, 4$, such that*

$$H = (H^1 - H^2) + \sqrt{-1}(H^3 - H^4). \tag{2.8}$$

The next result follows immediately from section 4.2 of [48].

PROPOSITION 2.2. *Let $\mathbb{X}$ be a Banach space. Let $\mathcal{L} \in \mathbb{B}(\mathbb{X})$ be the infinitesimal generator of the uniformly continuous semigroup $\phi_{\mathcal{L}}(t) : \mathbb{X} \to \mathbb{X}$. The following assertions are equivalent:*

(i) $\mathbb{R}_e\{\lambda(\mathcal{L})\} < 0$.

(ii) *There are constants $k > 0, b > 0$ such that*

$$\|\phi_{\mathcal{L}}(t)\| \leq k e^{-bt} \quad \text{for all} \quad t \geq 0.$$

(iii) $\int_0^\infty \|\phi_{\mathcal{L}}(t)x\| dt < \infty$ *for every $x \in \mathbb{X}$.*

If X is finite-dimensional, then (iii) *can be replaced by*

(iii′) $\|\phi_{\mathcal{L}}(t)x\| \to 0$ *as $t \to \infty$ for every $x \in \mathbb{X}$.*

We recall from (2.1) that under the conditions of Proposition 2.2, $\phi_{\mathcal{L}}(t) = e^{\mathcal{L}t}$. From the decomposition of square matrices into positive semidefinite matrices as in Lemma 2.1 and Proposition 2.2 we have the following result.

PROPOSITION 2.3. *Let $\mathcal{L} \in \mathbb{B}(\mathbb{H}_1^n)$ be the infinitesimal generator of the uniformly continuous semigroup $e^{\mathcal{L}t} : \mathbb{H}_1^n \to \mathbb{H}_1^n$. The following assertions are equivalent.*

(i) $\mathbb{R}_e\{\lambda(\mathcal{L})\} < 0$.

(ii) *There are constants $k > 0, b > 0$ such that*

$$\|e^{\mathcal{L}t}\| \leq k e^{-bt} \quad \text{for all} \quad t \geq 0.$$

(iii) $\int_0^\infty \|e^{\mathcal{L}t}(V)\| dt < \infty$ *for every $V \in \mathbb{H}_1^{n+}$.*

For the finite-dimensional case (iii) *can be replaced by*

(iii′) $\|e^{\mathcal{L}t}(V)\| \to 0$ *as $t \to \infty$ for every $V \in \mathbb{H}^{n+}$.*

Proof. See the appendix for the proof. □

The next proposition, adapted from [48], will be useful in deriving some stability results.

PROPOSITION 2.4. *Let $\mathcal{A} \in \mathbb{B}(\ell_1^{n^2})$ and $\{f(t); t \in \mathbb{R}^+\}$ be a continuous function in $\ell_1^{n^2}$ such that $\lim_{t\to\infty} f(t) = f_0$. Consider*

$$\dot{y}(t) = \mathcal{A}y(t) + f(t). \tag{2.9}$$

If $\mathbb{R}_e\{\lambda(\mathcal{A})\} < 0$, then for any initial condition $y(0) = y_0 \in \ell_1^{n^2}$,

$$\lim_{t\to\infty} y(t) = -\mathcal{A}^{-1} f_0.$$

3. The models and problem statement. Let $(\Omega, \mathcal{F}, \mathbb{P})$ be a complete probability space equipped with a filtration $\{\mathcal{F}_t, t \in \mathbb{R}^+\}$ satisfying the usual hypothesis, that is, a right continuous filtration augmented by all null sets in the $\mathbb{P}$-completion of $\mathcal{F}$, and carrying the following statistically mutually independent objects:

(0.1) An m-dimensional Wiener process $W = \{(w(t), \mathcal{F}_t), t \in \mathbb{R}^+\}$ with an incremental covariance operator $R dt$.

(0.2) A homogeneous Markov process $\theta = \{(\theta_t, \mathcal{F}_t), t \in \mathbb{R}^+\}$ with right continuous trajectories and taking values on the set $\mathcal{S}$. We assume also that

$$P(\theta_{t+h} = j | \theta_t = i) = \begin{cases} \lambda_{ij} h + o(h), & i \neq j, \\ 1 + \lambda_{ii} h + o(h), & i = j, \end{cases} \tag{3.1}$$

where $[(\lambda_{ij})]$ is the stationary infinite-dimensional transition rate matrix of $\{\theta\}$ with $0 \leq \lambda_{ij}$, $i \neq j$, and $0 \leq \lambda_i := -\lambda_{ii} = \sum_{\{j:\ j \neq i\}} \lambda_{ij} \leq \varrho$ for all $i \in \mathcal{S}$, i.e., the process is supposed to be conservative (see, e.g., [36]). The notation $o(h)$ denotes an infinitesimal of higher order than h, i.e., $\lim_{h \downarrow 0} \frac{o(h)}{h} = 0$. We define $p_{ij}(t) := \mathbb{P}(\theta_{t+s} = j | \theta_s = i)$, $i, j \in \mathcal{S}$, and denote $p_i(t) := \mathbb{P}(\theta_t = i)$ for any $i \in \mathcal{S}$. Notice that, in this setting, $P_t := (p_1(t), \dots)'$ satisfies the Kolmogorov forward differential equation $dP_t/dt = \Lambda P_t$; $P_0 = P, t \in \mathbb{R}^+$, where $\Lambda := [(\lambda_{ij})]'$. In addition, we assume that $\{(\theta_t, \mathcal{F}_t), t \in \mathbb{R}^+\}$ has initial distribution $\{v(i); i \in \mathcal{S}\}$.

(0.3) A random variable $x_0 \colon \Omega \to \mathbb{C}^n$ with $E[\|x_0\|^2] < \infty$.

We assume that the filtration $\mathcal{F}_t$ contains the filtration generated by (0.1)–(0.3), i.e., the natural filtration of $\{(x_0, w(s), \theta(s))\}$.

We deal with three types of linear systems with Markovian jump parameters. First, in order to bring to bear some basic results in its more general form and put SS in a unified basis, we consider the homogeneous system

$$\dot{x}(t) = A(\theta_t) x(t), \quad x(0) = x_0, \quad \theta_0 = v, \quad t \in \mathbb{R}^+. \tag{3.2}$$

We next consider the class of dynamical systems modeled by the following stochastic differential equation:

$$\dot{x}(t) = A(\theta_t) x(t) + B(\theta_t) w(t), \quad x(0) = x_0, \quad \theta_0 = v, \quad t \in \mathbb{R}^+, \tag{3.3}$$

where the additive disturbance, $w(.)$, is modeled by

(0.1b) $\{w(t); t \in \mathbb{R}^+\}$ is any $L_2^m(\Omega, \mathcal{F}, \mathbb{P})$-function,

which is the usual scenario for the H_∞ approach. In addition, in order to reflect the types of additive disturbances encountered in the specialized literature in detail, we shall consider also the class of dynamical systems modeled by the following Itô stochastic differential equation:

$$dx(t) = A(\theta_t) x(t) dt + B(\theta_t) dw(t), \quad x(0) = x_0, \quad \theta_0 = v, \quad t \in \mathbb{R}^+, \tag{3.4}$$

where we require, in addition to (0.1)–(0.3), that

(0.4) $\theta = \{(\theta_t, \mathcal{F}_t), t \in \mathbb{R}^+\}$ is an irreducible positive Harris recurrent Markov process with initial distribution $\{v(i); i \in \mathcal{S}\}$. We recall that, in this setting, it is a standard result of the Markov chain theory (see [42]) that there exist limiting probabilities $\{\pi_i;\ i \in \mathcal{S}\}$ which do not depend on the initial distribution with $\{\sum_{i=1}^{\infty} \pi_i = 1\}$ and satisfy

$$\lim_{t \to \infty} \sup_{j \in \mathcal{S}} \{ \mid p_j(t) - \pi_j \mid \} = 0. \tag{3.5}$$

Furthermore, $A(.)$ and $B(.)$ are such that $A(\theta_t) = A_j$ and $B(\theta_t) = B_j$ for $\theta_t = j$, $j \in \mathcal{S}$, with A_j, B_j, $j \in \mathcal{S}$, being constant matrices in $\mathbb{B}(\mathbb{C}^n)$ and $\mathbb{B}(\mathbb{C}^m, \mathbb{C}^n)$, respectively. It

is assumed that $A := (A_1, \dots) \in \mathbb{H}_{\sup}^n$ and $B := (B_1, \dots) \in \mathbb{H}_{\sup}^{m,n}$ for the case (0.1b), and $B \in \mathbb{H}_2^{m,n}$ for the case (0.1). In addition, define for $t \in \mathbb{R}^+$

$$q(t) := E(x(t)) \ \in \ \mathbb{C}^n, \tag{3.6}$$

$$\mathcal{Q}(\tau, t) := E(x(t+\tau)x(t)^*) \ \in \ \mathbb{B}(\mathbb{C}^n), \tag{3.7}$$

$$Q(t) := \mathcal{Q}(0, t) \ \in \ \mathbb{B}(\mathbb{C}^n)^+ \tag{3.8}$$

and

$$q_i(t) := E(x(t)1_{\{\theta_t = i\}}) \ \in \ \mathbb{C}^n, \tag{3.9}$$

$$Q_i(t) := E(x(t)x(t)^* 1_{\{\theta_t = i\}}) \ \in \ \mathbb{B}(\mathbb{C}^n)^+, \tag{3.10}$$

$$\mathcal{Q}_i(s, t) := E(x(t+s)x(t)^* 1_{\{\theta_{t+s} = i\}}) \ \in \ \mathbb{B}(\mathbb{C}^n), \tag{3.11}$$

where $1_{\{.\}}$ stands for the Dirac measure. Set also

$$\hat{q}(t) := \begin{bmatrix} q_1(t) \\ \vdots \end{bmatrix},$$

$$\hat{Q}(t) := (Q_1(t), \dots),$$

$$\hat{\mathcal{Q}}(s, t) := (\mathcal{Q}_1(s, t), \dots).$$

Since

$$\|\hat{Q}(t)\|_1 = \sum_{i=1}^{\infty} \|Q_i(t)\| \le \sum_{i=1}^{\infty} E[\|x(t)\|^2 1_{\{\theta_t = i\}}] = E[\|x(t)\|^2], \tag{3.12}$$

it follows that $\hat{Q}(t) \in \mathbb{H}_1^{n+}$. Similarly we have that $\hat{q}(t) \in \ell_1^n$ and $\hat{\mathcal{Q}}(s, t) \in \mathbb{H}_1^n$.

Preserving the terminology, often used in the literature for MJLS, we define the following.

DEFINITION 3.1. *A linear system with a Markovian jump parameter is stochastically stable if for arbitrary initial conditions x_0 and an arbitrary initial distribution v we have*

$$\int_0^{\infty} \|x(t)\|^2 dt < \infty.$$

DEFINITION 3.2. *A linear system with a Markovian jump parameter is mean square stable if there exist $q \in \mathbb{C}^n$ and $Q \in \mathbb{B}(\mathbb{C}^n)^+$ such that for arbitrary initial conditions x_0 and arbitrary initial distribution v we have*

(a) $\|q(t) - q\| \to 0$ *as* $t \to \infty$,

(b) $\|Q(t) - Q\| \to 0$ *as* $t \to \infty$.

DEFINITION 3.3. *A linear system with a Markovian jump parameter is asymptotically wide sense stationary if there exist $q \in \mathbb{C}^n$ and $\mathcal{Q}(\tau) \in \mathbb{B}(\mathbb{C}^n)^+$ such that for arbitrary initial conditions x_0 and an arbitrary initial distribution v we have*

(a) $\|q(t) - q\| \to 0$ *as* $t \to \infty$,

(b) $\|\mathcal{Q}(\tau, t) - \mathcal{Q}(\tau)\| \to 0$ *as* $t \to \infty$.

REMARK 3.1. *In the case of systems* (3.3), (3.4), *we assume also that q, Q, and $\mathcal{Q}(\tau)$ are independent of $w(t)$.*

4. SS for the homogeneous case. In this section necessary and sufficient conditions for SS of the homogeneous case are established. It is required that either the sum of the real part of all the elements in the spectrum of an augmented infinite dimensional matrix is less than zero or that there exists a unique solution of a Lyapunov equation. Moreover, it is shown that for real matrices $A(i)$, the system is stochastically stable for the complex state space if and only if the system is stochastically stable for the real state space. For the case in which $\mathcal{S}$ is finite, more specific results can be obtained and, in particular, it is proved that the Lyapunov equation can be written down in two equivalent forms with each one providing an easier-to-check sufficient condition. In this case it is well known that SS and MSS are equivalent concepts (see, for instance, [24]).

We begin by providing part of the basic common notational machinery, definitions, and some important basic results, necessary for the analysis of the situations described in section 3 which resort here, in part, to the methods of operator theory.

4.1. Main operators and auxiliary results. We consider first the homogeneous equation (3.2), restated here for convenience:

$$dx(t) = A(\theta_t)x(t)dt, \quad x(t_0) = x_0, \quad \theta_{t_0} = v, \quad t \in \mathbb{R}^+. \tag{4.1}$$

In addition, let T_n denote the nth jump time of the Markov process $\{\theta_t; t \geq 0\}$ and define $\Upsilon := \{\omega \in \Omega; T_n(\omega) \to \infty\}$. For each realization of the Markov process $\{\theta_t; t \geq 0\}$ in Υ we have that $\{A(\theta_t); t \geq 0\}$ are matrix-valued functions on $\mathbb{R}^+$ of the class PC (piecewise continuous, see [10, p. 411]) and, therefore, according to [10, p. 11], there exists aunique continuous solution $\Phi(., t_0)$ from $\mathbb{R}^+$ to $\mathbb{B}(\mathbb{C}^n)$ of the homogeneous linear matrix differential equation

$$\frac{\partial \Phi(t, t_0)}{\partial t} = A(\theta_t)\Phi(t, t_0), \qquad \Phi(t_0, t_0) = I$$

for almost all $t \in \mathbb{R}^+$. Moreover, the solution of (4.1) is given by

$$x(t) = \Phi(t, t_0)x_0. \tag{4.2}$$

In what follows we shall be using the following notation:

$$\begin{array}{l} F := \Lambda' \otimes I_n + \operatorname{diag}(A_i); \quad V := \Lambda' \otimes I_{n^2}; \quad G := \operatorname{diag}(I_n \oplus A_i); \\ H := \operatorname{diag}(\bar{A}_i \oplus A_i); \quad \mathcal{A} := V + H; \quad \mathcal{B} := V + G. \end{array} \tag{4.3}$$

We define also the following linear operators:

$$\begin{array}{ll} \mathcal{E}(.) = (\mathcal{E}_1(.), \dots); & \mathcal{F}(.) = (\mathcal{F}_1(.), \dots); \\ \mathcal{L}(.) = (\mathcal{L}_1(.), \dots); & \mathcal{T}(.) = (\mathcal{T}_1(.), \dots); \end{array} \tag{4.4}$$

where for $P = (P_1, \dots) \in \mathbb{H}_1^n$, $V = (V_1, \dots) \in \mathbb{H}_{\sup}^n$, and $i \in \mathcal{S}$,

$$\begin{aligned} \mathcal{E}_i(P) &:= \sum_{j=1}^{\infty} \lambda_{ji} P_j, \\ \mathcal{F}_i(P) &:= A_i P_i + \sum_{j=1}^{\infty} \lambda_{ji} P_j, \\ \mathcal{L}_i(P) &:= A_i P_i + P_i A_i^* + \sum_{j=1}^{\infty} \lambda_{ji} P_j, \\ \mathcal{T}_i(V) &:= A_i^* V_i + V_i A_i + \sum_{j=1}^{\infty} \lambda_{ji} V_j. \end{aligned} \tag{4.5}$$

We now have the following auxiliary results.

LEMMA 4.1. *For $\mathcal{E}$, $\mathcal{L}$, $\mathcal{T}$, and $\mathcal{F}$ defined as in* (4.4) *and* (4.5), *we have that*

(a) $\mathcal{E} \in \mathbb{B}(\mathbb{H}_1^n)$, $\mathcal{L} \in \mathbb{B}(\mathbb{H}_1^n)$, *and* $\mathcal{F} \in \mathbb{B}(\mathbb{H}_1^n)$;

(b) $\mathcal{T} \in \mathbb{B}(\mathbb{H}_{\sup}^n)$;

(c) *for any* $Q = (Q_1, \dots) \in \mathbb{H}_1^n$, $\mathcal{L}(Q)^* = \mathcal{L}(Q^*)$;

(d) $Q \in \mathbb{H}_1^{n+}$ *implies* $e^{\mathcal{L}t}(Q) \in \mathbb{H}_1^{n+}$ *for any* $t \in \mathbb{R}^+$.

Items (c) *and* (d) *also hold replacing* $\mathbb{H}_1^n$ *by* $\mathbb{H}_{\sup}^n$ *and* $\mathcal{L}$ *by* $\mathcal{T}$.

Proof. See the appendix for the proof. □

LEMMA 4.2. *Let f(t) be $\mathcal{F}_t$-measurable and assume that* $E(f(t)1_{\{\theta_t=i\}}) := f_i(t)$ *exists. Then*

$$E(f(t)d(1_{\{\theta_t=i\}})) = \sum_{j=1}^{\infty} \lambda_{ji} f_j(t)dt + o(dt).$$

Proof. See the appendix for the proof. □

PROPOSITION 4.3. *There exist constants $c_1 > 0$ and $c_2 > 0$ such that for any $H = (H_1, \dots) \in \mathbb{H}_1^n$, $c_1\|\hat{\varphi}(H)\|_1 \le \|H\|_1 \le c_2\|\hat{\varphi}(H)\|_1$.*

Proof. See the appendix for the proof. □

The next proposition provides differential equations to compute the first and second moments of the state variable of (3.2).

PROPOSITION 4.4. *For $t \in \mathbb{R}^+$, we have for* (3.2) *that*

(a) $\dot{\hat{q}}(t) = F\hat{q}(t)$,

(b) $\dot{\hat{Q}}(t) = \mathcal{L}(\hat{Q}(t))$.

Proof. The proof relies essentially on (3.2), Lemma 4.2, and (3.9)–(3.10). See [28] for details. □

The following result is germane to our approach.

PROPOSITION 4.5. *For F, $\mathcal{A}$, $\mathcal{B}$ defined as in* (4.3) *we have that* $F \in \mathbb{B}(\ell_1^n)$, $\mathcal{A} \in \mathbb{B}(\ell_1^{n^2})$, $\mathcal{B} \in \mathbb{B}(\ell_1^{n^2})$, *and* $\mathcal{A}^* \in \mathbb{B}(\ell_{\sup}^{n^2})$. *Moreover, for any* $Q \in \mathbb{H}_1^n$, $\mathcal{Q} \in \mathbb{H}_1^n$, *and* $V \in \mathbb{H}_{\sup}^n$ *we have*

(a) $\hat{\varphi}(\mathcal{L}(Q)) = \mathcal{A}\hat{\varphi}(Q)$;

(b) $\hat{\varphi}(\mathcal{T}(V)) = \mathcal{A}^*\hat{\varphi}(V)$;

(c) $\hat{\varphi}(\mathcal{F}(\mathcal{Q})) = \mathcal{B}\hat{\varphi}(\mathcal{Q})$.

Proof. See the appendix for the proof. □

We need also the following auxiliary results.

LEMMA 4.6. *Let $\mathcal{A} \in \mathbb{B}(\ell_1^{n^2})$, as defined in* (4.3), *and consider the homogeneous system $\dot{y}(t) = \mathcal{A}y(t)$, $t \in \mathbb{R}^+$, with the initial condition $y(0) = \hat{\varphi}(Q)$, $Q \in \mathbb{H}_1^{n+}$. Then*

(a) $y(t) = \hat{\varphi}(e^{\mathcal{L}t}(Q))$,

(b) $\hat{\varphi}^{-1}(y(t)) \in \mathbb{H}_1^{n+}$ *and consequently* ${\hat{\varphi}_j}^{-1}(y(t)) \in \mathbb{B}(\mathbb{C}^n)^+, j \in \mathcal{S}$.

The result also holds replacing $\ell_1^{n^2}$, $\mathbb{H}_1^{n+}$, $\mathcal{A}$, and $\mathcal{L}$ by $\ell_{\sup}^{n^2}$, $\mathbb{H}_{\sup}^{n+}$, $\mathcal{A}^*$, and $\mathcal{T}$, respectively.

Proof. See the appendix for the proof. □

LEMMA 4.7. *For any second order random variable z taking values in $\mathbb{C}^n$ and $t, \tau \in \mathbb{R}^+$, $t \ge \tau$,*

$$\|\Phi(t,\tau)z\|_2^2 \le n\|e^{\mathcal{L}(t-\tau)}\|\|z\|_2^2. \tag{4.6}$$

Proof. See the appendix for the proof. □

PROPOSITION 4.8. *If $\mathbb{R}_e\{\lambda(\mathcal{A})\} < 0$, then $\mathbb{R}_e\{\lambda(F)\} < 0$.*

Proof. See the appendix for the proof. □

REMARK 4.1. *It is not difficult to see that* $\mathbb{R}_e\{\lambda(F)\} < 0$ *does not imply* $\mathbb{R}_e\{\lambda(\mathcal{A})\} < 0$. *Indeed, consider, for instance,* $n = 1, \mathcal{S} = \{1, 2\}$, $\lambda_{11} = \lambda_{22} = -1$, $A_1 = \frac{1}{2}$, *and* $A_2 = -5$. *It is then a straightforward exercise to show that*

$$\lambda_1(F) = \frac{-6.5 - \sqrt{34.25}}{2} < 0, \quad \lambda_2(F) = \frac{-6.5 + \sqrt{34.25}}{2} < 0$$

and that

$$\lambda_1(\mathcal{A}) = \frac{-11 + \sqrt{125}}{2} > 0, \quad \lambda_2(\mathcal{A}) = \frac{-11 - \sqrt{125}}{2} < 0.$$

4.2. SS results. Our main SS results will follow from the next propositions. The next result shows a SS result in the spirit of the classical linear case. It shows that SS is equivalent to the spectrum of an augmented matrix, $\mathcal{A}$, lying in the open left half plane.

PROPOSITION 4.9. *The following affirmatives are equivalent:*

(i) *System* (3.2) *is stochastically stable according to Definition* 3.1.
(ii) $\mathbb{R}_e\{\lambda(\mathcal{L})\} < 0$.
(iii) $\mathbb{R}_e\{\lambda(\mathcal{A})\} < 0$.

Proof. From Proposition 4.4(b) we have that $\dot{\hat{Q}}(t) = \mathcal{L}(\hat{Q}(t))$. Therefore, from (3.12),

$$\int_0^\infty \|e^{\mathcal{L}t}(\hat{Q}(0))\|_1 dt = \int_0^\infty \|\hat{Q}(t)\|_1 dt \le \int_0^\infty E(\|x(t)\|^2) dt \tag{4.7}$$

for any initial condition x_0 and initial distribution v. Suppose (i) holds, so that $\int_0^\infty E(\|x(t)\|^2)dt < \infty$ for any initial condition x_0 and initial distribution v. Consider any $H = (H_1, \dots) \in \mathbb{H}_1^{n+}$. By taking an initial condition x_0 and v such that $Q_i(0) = H_i$, it follows from (4.7) that for any $H = (H_1, \dots) \in \mathbb{H}_1^{n+}$, $\int_0^\infty \|e^{\mathcal{L}t}(H)\|_1 dt < \infty$, which implies, from Proposition 2.3, that (ii) holds. From Propositions 2.2 and 4.4(b) it is immediate that if (ii) holds, then (i) holds. The equivalence between (ii) and (iii) follows from Propositions 4.3, 4.5, and 2.2, Lemma 4.6, and the fact that for any $y \in \ell_1^{n^2}$,

$$\int_0^\infty \|e^{\mathcal{A}t}y\|_1 dt = \int_0^\infty \|\hat{\varphi}(e^{\mathcal{L}t}(\hat{\varphi}^{-1}(y)))\|_1 dt \le \frac{1}{c_1}\int_0^\infty \|e^{\mathcal{L}t}(\hat{\varphi}^{-1}(y)\|_1 dt,$$

and similarly, for any $H \in \mathbb{H}_1^n$, $\int_0^\infty \|e^{\mathcal{L}t}(H)\|_1 dt \le c_2 \int_0^\infty \|e^{\mathcal{A}t}(\hat{\varphi}(H))\|_1 dt$. □

PROPOSITION 4.10. *If system* (3.2) *is stochastically stable according to Definition* 3.1, *then for every* $S = (S_1, \dots) \in \widetilde{\mathbb{H}}_{\sup}^{n+}$, *there exists a unique* $G = (G_1, \dots) \in \widetilde{\mathbb{H}}_{\sup}^{n+}$ *such that*

$$\mathcal{T}(G) + S = 0. \tag{4.8}$$

Proof. See Theorem 8 in [27]. □

PROPOSITION 4.11. *If there exists* $G = (G_1, \dots) \in \widetilde{\mathbb{H}}_{\sup}^{n+}$ *such that* (4.8) *is satisfied for some* $S = (S_1, \dots) \in \widetilde{\mathbb{H}}_{\sup}^{n+}$, *then system* (3.2) *is stochastically stable according to Definition* 3.1.

Proof. See Theorem 7 in [27]. □

PROPOSITION 4.12. *If* $\mathbb{R}_e\{\lambda(\mathcal{A})\} < 0$, *then system* (3.2) *is mean square stable according to Definition* 3.2 *with* $q = 0$ *and* $Q = 0$.

Proof. First notice that since $\mathbb{R}_e\{\lambda(\mathcal{A})\} < 0$, we have from Proposition 4.8 that $\mathbb{R}_e\{\lambda(F)\} < 0$. Thus, from Propositions 4.4(a) and 2.2 it follows that $\hat{q}(t) \to 0$ as $t \to \infty$, and since $q(t) = \sum_{i=1}^{\infty} q_i(t)$ we have that $q(t) \to 0$ as $t \to \infty$. Now, from Propositions 4.4(b) and 4.5(b) we have $\hat{\varphi}(\hat{Q}(t)) = \mathcal{A}\hat{\varphi}(\hat{Q}(t))$. If we now define $y(t) := \hat{\varphi}(\hat{Q}(t))$, we get $\dot{y}(t) = \mathcal{A}y(t)$. Now by Proposition 2.2, it follows that $\hat{\varphi}(\hat{Q}(t)) \to 0$ as $t \to \infty$. By noting that $Q(t) = \sum_{i=1}^{\infty} Q_i(t)$ it follows that $Q(t) \to 0$ as $t \to \infty$. ∎

In order to show that our setup encompasses the real case, we consider now the situation in which the initial condition x_0 in (4.1) is real, as in Definition 2.1 of [24] stated below.

DEFINITION 4.13 (see [24]). *System* (3.2) *is stochastically stable for the real state space case if for any* $x_0 \in \mathbb{R}^n$ *and any probability distribution* v *for* θ_0,

$$\int_0^{\infty} E(\|x(t)\|^2)dt < \infty. \tag{4.9}$$

Notice that in Definition 4.13, we consider only real initial conditions for x_0. We next show that in fact Definitions 3.1 and 4.13 are equivalent.

PROPOSITION 4.14. *System* (3.2) *is stochastically stable for the real state space case as in Definition* 4.13 *if and only if it is stochastically stable according to Definition* 3.1.

Proof. Clearly if system (3.2) is stochastically stable according to Definition 3.1, it is stochastically stable for the real state space case as in Definition 4.13. Suppose now that system (3.2) is stochastically stable for the real state space case as in Definition 4.13. For any $H \in \mathbb{H}^{n+}$, define $\mathbb{I}(H) \in \mathbb{H}_1^{n+}$ as follows:

$$\mathbb{I}(H) := (\|H_1\|I_n, \|H_2\|I_n, \dots).$$

Clearly $H \le \mathbb{I}(H)$. We consider real initial conditions x_0 and v such that $Q_i(0) = \|H_i\|I_n$ so that $\hat{Q}(0) = \mathbb{I}(H)$ (for instance, x_0 and θ_0 are independent of $E(x_0x_0^*) = \|H\|_1 I_n$ and $v(i) = \frac{\|H_i\|}{\|H\|_1}$). Let $x_H(t)$ denote the trajectory for this initial condition. From Lemma 4.1, we have that for all $t \in \mathbb{R}^+$,

$$\mathbf{0} \le e^{\mathcal{L}t}(H) \le e^{\mathcal{L}t}(\mathbb{I}(H)). \tag{4.10}$$

From (3.12) and (4.10),

$$\int_0^{\infty} \|e^{\mathcal{L}t}(H)\|_1 dt \le \int_0^{\infty} \|e^{\mathcal{L}t}(\mathbb{I}(H))\|_1 dt \le \int_0^{\infty} E(\|x_H(t)\|^2)dt < \infty$$

for all $H \in \mathbb{H}_1^{n+}$, and thus from Propositions 2.3 and 4.9, system (3.2) is stochastically stable according to Definition 3.1. ∎

4.3. The case in which $\mathcal{S}$ is finite. We consider in this subsection the case in which $\mathcal{S} = \{1, \dots, N\}$ so that more specific results can be obtained. The first result reads as follows.

LEMMA 4.15. *$\mathcal{T}^\star = \mathcal{L}$, i.e., $\mathcal{T}$ is the adjoint operator of $\mathcal{L}$ in the Hilbert space* $(\mathbb{H}^n, \|.\|_2)$.

Proof. This can be proved easily. ∎

REMARK 4.2. *From Proposition* 4.5 *and Lemma* 4.15 *it is easy to verify that the following assertions are equivalent:*

(i) $\mathbb{R}_e\{\lambda(\mathcal{A})\} < 0$.

(ii) $\mathbb{R}_e\{\lambda(\mathcal{L})\} < 0$.
(iii) $\mathbb{R}_e\{\lambda(\mathcal{A}^*)\} < 0$.
(iv) $\mathbb{R}_e\{\lambda(\mathcal{T})\} < 0$.

The next result shows that MSS implies that $\mathbb{R}_e\{\lambda(\mathcal{A})\} < 0$.

PROPOSITION 4.16. *If system* (3.2) *is mean square stable according to Definition* 3.2(b) *with* $Q = 0$, *then* $\mathbb{R}_e\{\lambda(\mathcal{A})\} < 0$.

Proof. We have that $Q(t) = \sum_{i=1}^{N} Q_i(t)$ and from Proposition 4.4(b) and Proposition 4.5(a) $\hat{\varphi}(\dot{\hat{Q}}(t)) = \mathcal{A}\hat{\varphi}(\hat{Q}(t))$. Therefore, $\hat{\varphi}(\hat{Q}(t)) = e^{\mathcal{A}t}\hat{\varphi}(\hat{Q}(0))$ and

$$Q(t) = \sum_{i=1}^{N} \hat{\varphi}_i^{-1}(e^{\mathcal{A}t}\hat{\varphi}(\hat{Q}(0))).$$

Now, by hypothesis, $Q(t) \to 0$ as $t \to \infty$ for any $Q(0) = E(x_0 x_0^*)$ and the initial distribution $v(\imath) = 1$. Furthermore, from Lemma 4.6(b) we have that $\hat{\varphi}_j^{-1}(e^{\mathcal{A}t}\hat{\varphi}(\hat{Q}(0))) \geq 0$ for all $j = 1, \ldots, N$, which shows that $e^{\mathcal{A}t}\hat{\varphi}(\hat{Q}(0)) \to 0$ as $t \to \infty$. Moreover, bearing in mind that for any $H_i \in \mathbb{H}^{n+}$, $i = 1, \ldots, N$, we can show by straightforward arguments that there are second order random variables x_i such that $E(x_i x_i^*) = H_i$, we have that $e^{\mathcal{A}t}\hat{\varphi}(H_1, \ldots, H_N) \to 0$ as $t \to \infty$ and from Proposition 2.3 (for finite-dimensional spaces), $\mathbb{R}_e\{\lambda(\mathcal{A})\} < 0$. □

The next result captures an MSS result in the spirit of the classical linear case. It shows that MSS stability is equivalent to the spectrum of an augmented matrix, $\mathcal{A}$, lying in the open left half plane.

THEOREM 4.17. *System* (3.2) *is mean square stable according to Definition* 3.2 *if and only if* $\mathbb{R}_e\{\lambda(\mathcal{A})\} < 0$.

Proof. The proof follows from Propositions 4.12 and 4.16. □

The next examples, borrowed from [41], illustrate how sometimes the switching between operation modes can play tricks with our intuition. They show that system (3.2) carries a great deal of subtlety which distinguishes it from the linear case and provides us with a very rich structure. The need to combine the transition probability of the Markov chain with the eigenvalues of the matrices A_i in order to get an adequate criterion for MSS is portrayed by matrix $\mathcal{A}$.

EXAMPLE 4.1 (each mode is unstable but overall system is stable). *Consider the model*

$$A_1 = \begin{bmatrix} \frac{1}{2} & -1 \\ 0 & -2 \end{bmatrix}, \quad A_2 = \begin{bmatrix} -2 & -1 \\ 0 & \frac{1}{2} \end{bmatrix}, \quad \Lambda = \begin{bmatrix} -\beta & \beta \\ \beta & -\beta \end{bmatrix}.$$

Therefore, each mode is unstable. We have that depending on the value of β *the overall system will be mean square stable. For* $0 < \beta \leq 1.33$ *we have that for some* i, $\mathbb{R}_e\{\lambda_i(\mathcal{A})\} > 0$, *and thus the system is not mean square stable. But for* $\beta > 1.34$, *we get that* $\mathbb{R}_e\{\lambda(\mathcal{A})\} < 0$, *and the system is mean square stable. This shows that as the number of jumps per unit time increases, the effect of switching between the unstable modes makes the overall system mean square stable.*

EXAMPLE 4.2 (each mode is stable but overall system is unstable). *Consider now the model*

$$A_1 = \begin{bmatrix} -1 & 10 \\ 0 & -1 \end{bmatrix}, \quad A_2 = \begin{bmatrix} -1 & 0 \\ 10 & -1 \end{bmatrix}, \quad \Lambda = \begin{bmatrix} -\beta & \beta \\ \beta & -\beta \end{bmatrix}.$$

Therefore, each mode is stable. We have that depending on the value of β *the overall system will be mean square unstable in the mean square sense. For* $0 < \beta \leq 0.04$ *we*

have that $\mathbb{R}_e\{\lambda(\mathcal{A})\} < 0$*, and the system is mean square stable. But for* $\beta > 0.05$*, we get that for some* i*,* $\mathbb{R}_e\{\lambda_i(\mathcal{A})\} > 0$*, and thus the system is not mean square stable. This shows that as the number of jumps per unit time increases, the effect of switching between the stable modes makes the overall system mean square unstable.*

More specific results can also be obtained from Proposition 4.10, as follows.

PROPOSITION 4.18. *If* $\mathbb{R}_e\{\lambda(\mathcal{A})\} < 0$*, then for every* $S = (S_1, \ldots, S_N) \in \mathbb{H}^n$*, there exists a unique* $G = (G_1, \ldots, G_N) \in \mathbb{H}^n$ *such that*

$$\mathcal{L}(G) + S = 0. \tag{4.11}$$

Moreover,

(a) $G_i = -\hat{\varphi}_i^{-1}(\mathcal{A}^{-1}\hat{\varphi}(S))$*;*
(b) $\hat{\varphi}(G) = \int_0^\infty e^{\mathcal{A}t}\hat{\varphi}(S)dt$*;*
(c) $S \in \mathbb{H}^*$ *if and only if* $G \in \mathbb{H}^*$*;*
(d) $S \in \mathbb{H}^+$ *implies* $G \in \mathbb{H}^+$*;*
(e) $S \in \tilde{\mathbb{H}}^+$ *implies* $G \in \tilde{\mathbb{H}}^+$*.*

These results also hold replacing $\mathcal{L}$ *by* $\mathcal{T}$*.*

Proof. (a) From Proposition 4.5(a), we have that $\hat{\varphi}(\mathcal{L}(G_1, \ldots, G_N)) = \mathcal{A}\hat{\varphi}(G_1, \ldots, G_N)$, and, therefore, (4.11) is equivalent to

$$\mathcal{A}\hat{\varphi}(G_1, \ldots, G_N) = -\hat{\varphi}(S_1, \ldots, S_N). \tag{4.12}$$

The expression for G_i follows immediately from the assumption on $\mathcal{A}$ and the definition of $\hat{\varphi}$. Assume now that there exists $\bar{G} = (\bar{G}_1, \ldots, \bar{G}_N) \in \mathbb{H}^n$ such that $\mathcal{L}_i(\bar{G}) + S_i = 0$. Then, bearing in mind (4.12), we have $\mathcal{A}\hat{\varphi}(\bar{G} - G) = 0$, or $\hat{\varphi}(\bar{G} - G) = 0$, which implies that $\bar{G} - G = 0$ and the uniqueness follows.

(b) Item (b) follows from (4.12) bearing in mind that $\mathbb{R}_e\{\lambda(\mathcal{A})\} < 0$, Proposition 2.2, and that $\mathcal{A}\phi_{\mathcal{A}}(t) = d/dt(\phi_{\mathcal{A}}(t))$.

(c) From (4.8) and Lemma 4.1(c) we have that $\mathcal{L}(G^*) + S^* = 0$, and the result follows from the fact that $\mathcal{L}(G^* - G) + (S^* - S) = 0$.

(d,e) Items (d) and (e) are a consequence of $e^{\mathcal{A}t}\hat{\varphi}(Q) = \hat{\varphi}(e^{\mathcal{L}t}(Q))$, bearing in mind Lemma 4.1. □

We next present equivalent forms of the Lyapunov equation and the Lyapunov inequality. The next result shows that the dual representation ($\mathcal{L}$ instead of $\mathcal{T}$) of (4.8) also implies MSS.

THEOREM 4.19. *The following assertions are equivalent to MSS of system* (3.2)*:*

(a) $\mathbb{R}_e\{\lambda(\mathcal{A})\} < 0$*.*
(b) *For some* $G_j > 0 \in \mathbb{B}(\mathbb{C}^n)$*,* $j \in \mathcal{S}$*, we have* $\mathcal{L}_i(G) < 0,\ i \in \mathcal{S}$*.*
(c) *For any* $S_i > 0 \in \mathbb{B}(\mathbb{C}^n)$*,* $i \in \mathcal{S}$*, there is a unique* $G = (G_1, \ldots, G_N)$*,* $G_i > 0 \in \mathbb{B}(\mathbb{C}^n)$*,* $i \in \mathcal{S}$*, such that* $\mathcal{L}_i(G) + S_i = 0,\ i \in \mathcal{S}$*. Moreover,*

$$G_i = \hat{\varphi}_i^{-1}(-\mathcal{A}^{-1}\hat{\varphi}(S_1, \ldots, S_N)), \quad i \in \mathcal{S}.$$

Proof. Clearly (c) implies (b). Suppose that (b) holds. We consider the homogeneous system

$$\dot{y}(t) = \mathcal{A}^* y(t), \quad t \in \mathbb{R}^+, \qquad y(0) \in \hat{\varphi}(\mathbb{H}^{n+}), \tag{4.13}$$

where

$$\hat{\varphi}(\mathbb{H}^{n+}) = \{y \in \mathbb{C}^{Nn^2}; y = \hat{\varphi}(Q), Q \in \mathbb{H}^{n+}\}.$$

From Proposition 4.5, we have that

$$\hat{\varphi}_j^{-1}(\dot{y}(t)) = \mathcal{T}_j(\hat{\varphi}_1^{-1}(y(t)), \ldots, \hat{\varphi}_N^{-1}(y(t))) \ , \quad j \in \mathcal{S} \tag{4.14}$$

with $\hat{\varphi}_j^{-1}(y(0)) \in \mathbb{B}(\mathbb{C}^n)^+$. It follows from Lemma 4.6 that $\hat{\varphi}_j^{-1}(y(t)) \in \mathbb{B}(\mathbb{C}^n)^+$ for all $j \in \mathcal{S}$ and all $t \in \mathbb{R}^+$, and thus $y(t) \in \hat{\varphi}(\mathbb{H}^{n+}),\ t \in \mathbb{R}^+$. Define now the function $\phi : \hat{\varphi}(\mathbb{H}^{n+}) \to \mathbb{R}$ as

$$\phi_j(y) := \mathrm{tr}(\hat{\varphi}_j^{-1}(y)G_j) = \mathrm{tr}(G_j^{1/2}\hat{\varphi}_j^{-1}(y)G_j^{1/2}) \geq 0, \quad j \in \mathcal{S},$$
$$\phi(y) := \sum_{j=1}^{N} \phi_j(y) \geq 0.$$

In order to prove that ϕ is a Lyapunov function for the system (4.13) we do need to show that

(i) $\phi(y) \to \infty$ whenever $\|y\| \to \infty$ and $y \in \hat{\varphi}(\mathbb{H}^{n+})$;
(ii) $\phi(0) = 0$;
(iii) $\phi(y) > 0$ for all $y \neq 0 \in \hat{\varphi}(\mathbb{H}^{n+})$;
(iv) ϕ is continuous; and
(v) $\dot{\phi}(y(t)) < 0$ whenever $y(t) \neq 0 \in \hat{\varphi}(\mathbb{H}^{n+})$.

Now, for $y \in \hat{\varphi}(\mathbb{H}^{n+})$ let $\lambda_{ij}(y) \geq 0$ denote the ith eigenvalue of $\hat{\varphi}_j^{-1}(y)$ and $\lambda_i(G_j) > 0$ the ith eigenvalue of G_j. Define

$$c_o := \min_{1 \leq i \leq n \ 1 \leq j \leq N} \ \lambda_i(G_j) > 0$$

(since $G_j > 0$) and

$$c_1 := \max_{1 \leq i \leq n \ 1 \leq j \leq N} \lambda_i(G_j) > 0.$$

From (2.2(ii)) we have that

$$c_0 \left(\sum_{j=1}^{N} \sum_{i=1}^{n} \lambda_{ji}(y) \right) \leq \phi(y) \leq c_1 \left(\sum_{j=1}^{N} \sum_{i=1}^{n} \lambda_{ji}(y) \right). \tag{4.15}$$

Note that

$$\|y\|^2 = \mathrm{tr}(yy^*) = \sum_{j=1}^{N} \mathrm{tr}((\hat{\varphi}_j^{-1}(y))^2) = \sum_{j=1}^{N} \sum_{i=1}^{n} (\lambda_{ji}(y))^2,$$

and bearing in mind the positiveness of $\lambda_{ji}(y)$ we get that $\|y\| \to \infty$ if and only if

$$\sum_{j=1}^{N} \sum_{i=1}^{n} (\lambda_{ji}(y)) \to \infty,$$

and $y = 0$ if and only if $\lambda_{ji} = 0$, $i = 1, \ldots, n$, $j \in \mathcal{S}$. Thus, from these results and (4.15) we get (i)–(iii). Since continuity of ϕ is easily verified, it only remains to show (v). Now, from the definition of ϕ, (4.14), and Lemmas 4.1 and 4.15, we have

$$\begin{aligned}
\dot{\phi}(y(t)) &= \sum_{j=1}^{N} \dot{\phi}_j(y(t)) = \sum_{j=1}^{N} \mathrm{tr}\left(\hat{\varphi}_j^{-1}(\dot{y}(t))G_j\right) \\
&= \sum_{j=1}^{N} \mathrm{tr}\big(\mathcal{T}_j(\hat{\varphi}_1^{-1}(y(t)), \ldots, \hat{\varphi}_N^{-1}(y(t)))G_j\big) \\
&= \langle \mathcal{T}(\hat{\varphi}_1^{-1}(y(t)), \ldots, \hat{\varphi}_N^{-1}(y(t)))^*; G\rangle = \langle \mathcal{T}\big((\hat{\varphi}^{-1}(y(t)))^*\big); G\rangle \\
&= \langle \hat{\varphi}^{-1}(y(t))^*; \mathcal{L}(G)\rangle < 0
\end{aligned}$$

whenever $y(t) \neq 0 \in \hat{\varphi}(\mathbb{H}^{n+})$. Therefore, we have shown that (4.13) is asymptotically stable (cf. [33]) and thus $\|\exp(\mathcal{A}^* t)y\| \to 0$ as $t \to \infty$ for all $y \in \hat{\varphi}(\mathbb{H}^{n+})$ which yields from Proposition 2.3 that $\mathbb{R}_e(\lambda(\mathcal{A}^*)) = \mathbb{R}_e(\lambda(\mathcal{A})) < 0$.

Finally, from Proposition 4.18 we have that (a) implies (c) and from Theorem 4.17 that (a) is equivalent to MSS. □

REMARK 4.3. *The above theorem also holds if we replace $\mathcal{L}$ by $\mathcal{T}$.*

REMARK 4.4. *Note that for the case in which the coefficients are all real, the Lyapunov operator $\mathcal{L}$ works on a Hilbert space of dimension $\frac{Nn(n+1)}{2}$ rather than Nn^2, the dimension of the matrix $\mathcal{A}$. This information can then be used to write the Lyapunov operator $\mathcal{L}$ as a square matrix of dimension $\frac{Nn(n+1)}{2}$. Once this is done, it would be more advantageous to check if $\mathbb{R}_e\{\lambda(\mathcal{L})\} < 0$ by looking at the eigenvalues of this reduced order matrix.*

We show now that from Theorem 4.19 we can derive some *easier-to-check conditions* for MSS of (3.2).

COROLLARY 4.20. *Conditions* (i) *and* (ii) *below are equivalent:*

(i) $\exists\ \alpha_j > 0$, $j \in \mathcal{S}$, *such that* $\alpha_i \lambda_{max}(A_i + A_i^*) + \sum_{i=1}^N \lambda_{ij}\alpha_j < 0$;
(ii) $\exists\ \alpha_j > 0$, $j \in \mathcal{S}$, *such that* $\alpha_i \lambda_{max}(A_i + A_i^*) + \sum_{i=1}^N \lambda_{ji}\alpha_j < 0$;

where $\lambda_{max}(\mathcal{T}) := \max\{\lambda : \lambda$ is an eigenvalue of the operator $\mathcal{T}\}$. Moreover, if one of the above conditions is satisfied, then system (3.2) *is mean square stable.*

Proof. Consider the homogeneous scalar system

$$\dot{\tilde{x}}(t) = \tilde{a}(\theta_t)\tilde{x}(t), \quad t \in \mathbb{R}^+, \tag{4.16}$$

where $\tilde{a}_i := \frac{1}{2}\lambda_{max}(A_i + A_i^*)$, $i \in \mathcal{S}$. Then by applying Theorem 4.19 (bearing in mind Remark 4.3) to system (4.16) we obtain that conditions (i) and (ii) are equivalent. Suppose now that condition (i) is satisfied and set $G_j = \alpha_j I_n > 0$, $j \in \mathcal{S}$. Since

$$\begin{aligned} A_i^* G_i + G_i A_i + \sum_{i=1}^N \lambda_{ij} G_j &= \alpha_i (A_i + A_i^*) + \sum_{i=1}^N \lambda_{ij}\alpha_j I_n \\ &\leq \left(\alpha_i \lambda_{max}(A_i + A_i^*) + \sum_{i=1}^N \lambda_{ij}\alpha_j \right) I_n \ < \ 0, \end{aligned}$$

we get from Theorem 4.19(a) that system (3.2) is mean square stable. □

COROLLARY 4.21. *If for some real number $\delta_i > 0$, $i \in \mathcal{S}$, one of the following conditions is satisfied:*

(1) $\lambda_{max}[A_i + A_i^* + \frac{1}{\delta_i}(\sum_{\{j:\ j \neq i\}} \lambda_{ij}\delta_j) I_n] < -\lambda_{ii}$,
(2) $\lambda_{max}[A_i + A_i^* + \frac{1}{\delta_i}(\sum_{\{j:\ j \neq i\}} \lambda_{ji}\delta_j) I_n] < -\lambda_{ii}$,

then system (3.2) *is mean square stable. Moreover, these conditions are weaker than those in Corollary* 4.20.

Proof. Suppose that condition (1) is satisfied and set $G_i = \delta_i I_n > 0$, $j \in \mathcal{S}$. Then,

following the arguments of the previous corollary we have

$$A_i^*G_i + G_iA_i + \sum_{i=1}^{N}\lambda_{ij}G_j = \delta_i(A_i + A_i^*) + \sum_{i=1}^{N}\lambda_{ij}\delta_j I_n$$
$$= \delta_i\left[A_i + A_i^* + \frac{1}{\delta_i}\sum_{\{j:\ j\neq i\}}\lambda_{ij}\delta_j I_n + \lambda_{ii}I_n\right]$$
$$\leq \delta_i\left[\lambda_{max}\left(A_i + A_i^* + \frac{1}{\delta_i}\sum_{\{j:\ j\neq i\}}\lambda_{ij}\delta_j I_n\right)I_n + \lambda_{ii}I_n\right] < 0$$

and, therefore, system (3.2) is mean square stable. The proof for condition (2) is similar. Now note that if the conditions of Corollary 4.20 are satisfied and defining $|\lambda|_{max}(\mathcal{T}) := \max\{|\lambda|{:}\lambda \text{ is an eigenvalue of the operator } \mathcal{T}\}$, then from condition (i) we get

$$\lambda_{max}\left[A_i + A_i^* + \frac{1}{\delta_i}\left(\sum_{\{j:\ j\neq i\}}\lambda_{ij}\delta_j\right)I_n\right] \leq |\lambda|_{max}\left[A_i + A_i^* + \frac{1}{\delta_i}\left(\sum_{\{j:\ j\neq i\}}\lambda_{ij}\delta_j\right)I_n\right]$$
$$= \left\|A_i + A_i^* + \frac{1}{\delta_i}\left(\sum_{\{j:\ j\neq i\}}\lambda_{ij}\delta_j\right)I_n\right\|$$
$$\leq \|A_i + A_i^*\| + \frac{1}{\delta_i}\sum_{\{j:\ j\neq i\}}\lambda_{ij}\delta_j$$
$$= \lambda_{max}(A_i + A_i^*) + \frac{1}{\delta_i}\sum_{\{j:\ j\neq i\}}\lambda_{ij}\delta_j < -\lambda_{ii},$$

which implies that condition (1) above is satisfied. Similarly we can show that condition (ii) of Corollary 4.20 implies condition (2) above. □

5. The $L_2^m(\Omega, \mathcal{F}, \mathbb{P})$ and jump diffusion case. We consider in this section two scenarios regarding the additive disturbance: the one as in (3.3), characterized by functions in $L_2^m(\Omega, \mathcal{F}, \mathbb{P})$, and that in (3.4), a jump diffusion, where the noise is characterized via a Wiener process. For both cases, under suitable conditions, it is shown that SS implies (is equivalent for $\mathcal{S}$ finite) to AWSS. In addition, it is shown that the state $x(t) \in L_2^n(\Omega, \mathcal{F}, \mathbb{P})$ for $L_2^m(\Omega, \mathcal{F}, \mathbb{P})$-disturbances.

5.1. The $L_2^m(\Omega, \mathcal{F}, \mathbb{P})$ disturbance case. We consider in this subsection the class of dynamical systems modeled by the stochastic equation

$$\dot{x}(t) = A(\theta_t)x(t) + B(\theta_t)w(t), \quad x(0) = x, \quad \theta_0 = v, \quad t \in \mathbb{R}^+, \tag{5.1}$$

where the additive disturbance $\{w(t); t \in \mathbb{R}^+\}$ is any $L_2^m(\Omega, \mathcal{F}, \mathbb{P})$-function. The equation above is restated here just for the sake of convenience. We need the following result.

LEMMA 5.1. *Let $\{w(t); t \in \mathbb{R}^+\} \in L_2^m(\Omega, \mathcal{F}, \mathbb{P})$ and define, for $\lambda > 0$,*

$$\chi(t) = \int_0^t e^{-\lambda(t-\tau)}\|w(\tau)\|_2 d\tau. \tag{5.2}$$

Then $\chi(t) \to 0$ *as* $t \to \infty$.

Proof. See the appendix for the proof. ∎

We shall prove the following result.

THEOREM 5.2. *The following assertions are equivalent:*

1. $\mathbb{R}_e\{\lambda(\mathcal{A})\} < 0$.
2. $\{x(t); t \in \mathbb{R}^+\} \in L_2^n(\Omega, \mathcal{F}, \mathbb{P})$ *for every* $\{w(t); t \in \mathbb{R}^+\} \in L_2^m(\Omega, \mathcal{F}, \mathbb{P})$ *and initial conditions* x_0 *and* v.

Moreover, if (1) *or* (2) *is satisfied, then the following condition is satisfied.*

3. $\lim_{t\to\infty} E(x(t+s)^* x(t)) = 0$ *for every* $s \geq 0$, $\{w(t); t \in \mathbb{R}^+\} \in L_2^m(\Omega, \mathcal{F}, \mathbb{P})$ *and initial conditions* x_0 *and* v.

Proof. (1 ⇒ 2): First notice that over the set Υ, we have from (5.1) and Theorem 2.1.70 of [10, p. 17] that

$$x(t) = \Phi(t,0)x(0) + \int_0^t \Phi(t,\tau)B(\theta_\tau)w(\tau)d\tau. \tag{5.3}$$

By the triangular inequality and recalling that $\mathbb{P}(\Upsilon) = 1$, it follows from (5.3) that

$$\|x(t)\|_2 = \|\Phi(t,0)x(0)\|_2 + \int_0^t \|\Phi(t,\tau)B(\theta_\tau)w(\tau)\|_2 d\tau. \tag{5.4}$$

From (4.6),

$$\|\Phi(t,0)x(0)\|_2^2 \leq n\|e^{\mathcal{L}t}\|\|x(0)\|_2^2. \tag{5.5}$$

From (4.6) again, with $z = B(\theta_\tau)w(\tau)$, we have

$$\begin{aligned} \|\Phi(t,\tau)B(\theta_\tau)w(\tau)\|_2^2 &\leq n\|e^{\mathcal{L}(t-\tau)}\|\|B(\theta_\tau)w(\tau)\|_2^2 \\ &\leq n\|B\|_{\sup}^2\|e^{\mathcal{L}(t-\tau)}\|\|w(\tau)\|_2^2. \end{aligned} \tag{5.6}$$

From Proposition 4.9 and the hypothesis that $\mathbb{R}_e\{\lambda(\mathcal{A})\} < 0$, it follows that $\mathbb{R}_e\{\lambda(\mathcal{L})\} < 0$, and thus there exist constants $\lambda > 0$ and $\mu > 0$ such that

$$\|e^{\mathcal{L}t}\| \leq \mu e^{-2\lambda t}. \tag{5.7}$$

From (5.4), (5.5), (5.6), and (5.7) we have, for some $a > 0$,

$$\|x(t)\|_2 \leq a\left(e^{-\lambda t}\|x(0)\|_2 + \int_0^t e^{-\lambda(t-\tau)}\|w(\tau)\|_2 d\tau\right). \tag{5.8}$$

Consider $\chi(t)$ as in (5.2). If we define

$$f(t) = \begin{cases} e^{-\lambda t}, & t \geq 0, \\ 0, & t < 0, \end{cases}$$

$$g(t) = \begin{cases} \|w(t)\|_2, & t \geq 0, \\ 0, & t < 0, \end{cases}$$

we have that χ can be written as the convolution (denoted here by $*$) of f and g, that is, $\chi(t) = (f * g)(t)$. Since $f \in L_1(\mathbb{R}^+)$ and $g \in L_2(\mathbb{R}^+)$, it follows that the convolution $f * g \in L_2(\mathbb{R}^+)$ and, moreover, for some $b > 0$,

$$\int_0^\infty \chi(t)^2 dt \leq b^2 \int_0^\infty f(t)dt \int_0^\infty g(t)^2 dt = \frac{b^2}{\lambda}\|w\|_2^2 \tag{5.9}$$

(cf. [45]). Taking (5.8) into square, we get

$$\|x(t)\|_2^2 \leq 2a^2(e^{-2\lambda t}\,\|x(0)\|_2^2 + \chi(t)^2) \tag{5.10}$$

and from (5.9) and (5.10) it follows that for some $c > 0$,

$$\|x\|_2^2 = \int_0^\infty \|x(t)\|_2^2 dt \leq c(\|x(0)\|_2^2 + \|w\|_2^2)$$

showing the desired result.

$(2 \Rightarrow 1)$: Take $w(t) = 0$ for all $t \in \mathbb{R}^+$. It follows from the hypothesis that for any initial condition x_0 and initial distribution v, $\|x\|_2^2 < \infty$, that is,

$$\|x\|_2^2 = \int_0^\infty \|x(t)\|_2^2 dt < \infty.$$

Thus system (3.2) is stochastically stable as in Definition 3.1, and the result follows from Proposition 4.9.

$(1 \Rightarrow 3)$: From Lemma 5.1 and (5.10) it follows that $E(\|x(t)\|^2) \to 0$ as $t \to \infty$. The result follows since

$$|\,E(x(t+s)^* x(t))\,| \leq E(\|x(t+s)\|\|x(t)\|) \leq (E(\|x(t+s)\|^2)E(\|x(t)\|^2))^{1/2} \to 0$$

as $t \to \infty$. □

5.2. The jump diffusion case. In this subsection we deal with MSS issues for the class of systems described in section 3 by (3.4), i.e.,

$$dx(t) = A(\theta_t)x(t)dt + B(\theta_t)dw(t), \quad x(0) = x_0, \quad \theta_0 \text{ with distribution } v, \quad t \in \mathbb{R}^+,$$

under assumptions (0.1)–(0.4). We recall that in this case we assume that $B \in \mathbb{H}_2^{m,n}$.

Let $\hat{R}(t) := (R_1(t), \dots) \in \mathbb{H}_1^{n+}$ with $R_i(t) := B_i R B_i^* p_i(t) \in \mathbb{B}(\mathbb{C}^n)$, where $p_i(t) = \mathbb{P}(\theta_t = i)$. The next proposition provides differential equations to compute the first and second moments of the state variable and can be easily proved using a suitable version of Itô's rule in conjunction with Lemma 4.2.

PROPOSITION 5.3. *For $t \in \mathbb{R}^+$ we have*

(a) $\dot{\hat{q}}(t) = F\hat{q}(t)$,

(b) $\dot{\hat{Q}}(t) = \mathcal{L}(\hat{Q}(t)) + \hat{R}(t)$,

(c) $\dot{\hat{\mathcal{Q}}}(s,t) = \mathcal{F}(\hat{\mathcal{Q}}(s,t))$.

PROPOSITION 5.4. *If $\mathbb{R}_e\{\lambda(\mathcal{A})\} < 0$, then system (3.4) is mean square stable according to Definition 3.2 and asymptotically wide sense stationary according to Definition 3.3, with $q = 0$ and*

$$Q = \sum_{i=1}^{\infty} \hat{\varphi}_i^{-1}(-\mathcal{A}^{-1}\hat{\varphi}(\mathcal{R})), \tag{5.11}$$

$$\mathcal{Q}(s) = \sum_{i=1}^{\infty} \hat{\varphi}_i^{-1}(e^{\mathcal{B}s}\mathcal{A}^{-1}\hat{\varphi}(\mathcal{R})), \tag{5.12}$$

where $\mathcal{R} = (\mathcal{R}_1, \dots) \in \mathbb{H}_1^{n+}$, $\mathcal{R}_i := \bar{R}_i \pi_i$, and $\bar{R}_i := B_i R B_i^*$; $i \in \mathcal{S}$.

Proof. First notice that since $\mathbb{R}_e\{\lambda(\mathcal{A})\} < 0$, we have from Proposition 4.8 that $\mathbb{R}_e\{\lambda(F)\} < 0$. Thus, from Propositions 4.4(a) and 2.3 it follows that $\hat{q}(t) \to 0$ as

$t \to \infty$, and since $q(t) = \sum_{i=1}^{\infty} q_i(t)$ we have that $q(t) \to 0$ as $t \to \infty$. Now, from Propositions 5.3(b) and 4.5(a) we have

$$\hat{\varphi}(\dot{\hat{Q}}(t)) = \mathcal{A}\hat{\varphi}(\hat{Q}(t)) + \hat{\varphi}(\hat{R}(t)).$$

If we now define $y(t) := \hat{\varphi}(\hat{Q}(t))$ and $f(t) := \hat{\varphi}(\hat{R}(t))$, we get

$$\dot{y}(t) = \mathcal{A}y(t) + f(t).$$

From the forward differential equation to the Markov chain (section 3), bearing in mind the definition of $\hat{R}(t)$, it follows that $f(t)$ is continuous. Furthermore, recalling that θ has limiting probabilities $\{\pi_i;\ i \in \mathcal{S}\}$ satisfying expression (3.5), we get

$$\|\hat{R}(t) - \mathcal{R}\|_1 = \sum_{i=1}^{\infty} \|R_i(t) - \mathcal{R}_i\| \le \|R\| \|B\|_2^2 \sup_{j \in \mathcal{S}} \{ \mid p_j(t) - \pi_j \mid \}$$

and thus $\lim_{t\to\infty} \hat{R}(t) = \mathcal{R}$ in $\mathbb{H}_1^n$. Now by Proposition 2.4, it follows that $\hat{\varphi}(\hat{Q}(t)) \to -\mathcal{A}^{-1}\hat{\varphi}(\mathcal{R})$ as $t \to \infty$. By noting that $Q(t) = \sum_{i=1}^{\infty} Q_i(t)$ it follows that $Q(t) \to Q$ as $t \to \infty$, with Q as in (5.11). From Propositions 4.5(c) and 5.3(c) we have that $\dot{\hat{\varphi}}(\hat{\mathcal{Q}}(s,t)) = \mathcal{B}\hat{\varphi}(\hat{\mathcal{Q}}(s,t))$ and, therefore, $\hat{\varphi}(\hat{\mathcal{Q}}(s,t)) = e^{\mathcal{B}s}(\hat{\mathcal{Q}}(0,t))$. Moreover, as seen above, we have $\hat{\varphi}(\hat{Q}(t)) \to \mathcal{A}^{-1}\hat{\varphi}(\mathcal{R})$ as $t \to \infty$. It follows that $\hat{\varphi}(\hat{\mathcal{Q}}(s,t)) \to e^{\mathcal{B}s}\mathcal{A}^{-1}\hat{\varphi}(\mathcal{R})$ as $t \to \infty$ and since $\mathcal{Q}(s,t) = \sum_{i=1}^{\infty} \mathcal{Q}_i(s,t)$, we have $\mathcal{Q}(t,s) \to \sum_{i=1}^{\infty} \hat{\varphi}_i^{-1}(e^{\mathcal{B}s}\mathcal{A}^{-1}\hat{\varphi}(\mathcal{R})) = \mathcal{Q}(s)$. □

REMARK 5.1. *It is a consequence of Proposition* 5.4 *that the* L_2^m*-result of Theorem* 5.2 *does not apply for the Wiener disturbance setting.*

For the case in which $\mathcal{S} = \{1, \ldots, N\}$ we have the following result.

PROPOSITION 5.5. *The following affirmatives are equivalent:*

(a) $\mathbb{R}_e\{\lambda(\mathcal{A})\} < 0$.

(b) *System* (3.4) *is mean square stable according to Definition* 3.2(b).

(c) *System* (3.4) *is asymptotically wide sense stationary according to Definition* 3.3.

Proof. From Proposition 5.4 we have that (a) implies (b) and (c). In addition, it is obvious that AWSS implies MSS. It remains to prove that (b) implies (a). First, we have $Q(t) = \sum_{i=1}^{N} Q_i(t)$ and from Propositions 4.4(b) and 4.5(a) $\hat{\varphi}(\dot{\hat{Q}}(t)) = \mathcal{A}\hat{\varphi}(\hat{Q}(t)) + \hat{\varphi}(\hat{R}(t))$. Therefore, $\hat{\varphi}(\hat{Q}(t)) = e^{\mathcal{A}t}\hat{\varphi}(\hat{Q}(0)) + \int_0^t e^{\mathcal{A}(t-s)}\hat{\varphi}(\hat{R}(s))ds$ and

$$Q(t) = \sum_{i=1}^{N} \hat{\varphi}_i^{-1}(e^{\mathcal{A}t}\hat{\varphi}(\hat{Q}(0))) + \sum_{i=1}^{N} \hat{\varphi}_i^{-1}\left(\int_0^t e^{\mathcal{A}(t-s)}\hat{\varphi}(\hat{R}(s))ds\right). \tag{5.13}$$

Now, by hypothesis, there exists $Q \in \mathbb{H}^{n+}$ (which depends only on R) such that $Q(t) \to Q$ as $t \to \infty$ for any $Q(0) = E(x_0 x_0^*)$ and Q does not depend on x_0. Furthermore, notice that for $x_0 = 0$ we have that the second term on the right-hand side of (5.13) converges to Q as $t \to \infty$ and thus the first term goes to zero, for any x_0 and v. The remaining of the proof follows the proof of Proposition 4.16. □

Finally, we conclude with the following unifying result.

THEOREM 5.6. *Consider the following assertions:*

(a) $\mathbb{R}_e\{\lambda(\mathcal{A})\} < 0$.

(b) *There exists* $G \in \widetilde{\mathbb{H}}_{\sup}^{n+}$ *such that* (4.8) *is satisfied for some* $S \in \widetilde{\mathbb{H}}_{\sup}^{n+}$.

(c) *System* (3.2) *is stochastically stable according to Definition* 3.1.

(d) *System* (3.2) *is stochastically stable for the real state space case according to Definition* 4.13.
(e) *System* (3.3) *is stochastically stable according to Definition* 3.1.
(f) *System* (3.2) *is mean square stable according to Definition* 3.2.
(g) *System* (3.2) *is mean square stable according to Definition* 3.2(b).
(h) *System* (3.4) *is mean square stable according to Definition* 3.2.
(i) *System* (3.4) *is mean square stable according to Definition* 3.2(b).
(j) *System* (3.4) *is asymptotically wide sense stationary according to Definition* 3.3.
(k) *System* (3.3) *is mean square stable according to Definition* 3.2.
(l) *System* (3.3) *is mean square stable according to Definition* 3.2(b).
(m) *System* (3.3) *is asymptotically wide sense stationary according to Definition* 3.3.

The affirmatives (a), (b), (c), (d), (e) *are equivalent and any of them implies affirmatives* (f), (g), (h), (i), (j), (k), (l), (m). *Moreover, if* $\mathcal{S}$ *is finite, then all affirmatives are equivalent.*

Proof. It follows, essentially, from Propositions 4.9, 4.10, 4.11, 4.12, 4.14, 4.16, 5.4, 5.5 and Theorem 5.2. □

Appendix. In this section we present the proof of some auxiliary results.

Proof of Proposition 2.3. Suppose $\int_0^\infty \|e^{\mathcal{L}t}(V)\|_1 dt < \infty$ for every $V \in \mathbb{H}_1^{n+}$. From the decomposition (2.8), for any $H \in \mathbb{H}_1^n$ we can find $H^i \in \mathbb{H}_1^{n+}$, $i = 1, 2, 3, 4$, such that $H = (H^1 - H^2) + \sqrt{-1}(H^3 - H^4)$. From linearity of the semigroup $e^{\mathcal{L}t}$, we have

$$\int_0^\infty \|e^{\mathcal{L}t}(H)\|_1 dt \le \sum_{i=1}^4 \int_0^\infty \|e^{\mathcal{L}t}(H^i)\|_1 dt < \infty,$$

showing the desired result. □

Proof of Lemma 4.1. For (a), consider $P = (P_1, \dots) \in \mathcal{H}_1^n$. Then

$$\begin{aligned}\|\mathcal{L}_i(P)\| &= \left\| A_i P_i + P_i A_i^* + \sum_{j=1}^\infty \lambda_{ji} P_j \right\| \\ &\le 2\|A\|_{\sup}\|P_i\| + \sum_{j=1}^\infty \mid \lambda_{ji} \mid \|P_j\|.\end{aligned}$$

Taking the sum over i and recalling that $0 \le \lambda_j \le \varrho$, we get

$$\begin{aligned}\sum_{i=1}^\infty \|\mathcal{L}_i(P)\| &\le 2\|A\|_{\sup} \sum_{i=1}^\infty \|P_i\| + \sum_{j=1}^\infty \sum_{i=1}^\infty \mid \lambda_{ji} \mid \|P_j\| \\ &\le 2\|A\|_{\sup}\|P\|_1 + 2\sum_{j=1}^\infty \lambda_j \|P_j\| \\ &\le 2\|A\|_{\sup}\|P\|_1 + 2\varrho \sum_{j=1}^\infty \|P_j\| \\ &= 2\|P\|_1(\|A\|_{\sup} + \varrho),\end{aligned}$$

showing the desired result. The proof for $\mathcal{E}$ and $\mathcal{F}$ follows the same steps and will be omitted.

For (b), it follows that for any $P = (P_1, \dots) \in \mathbb{H}^n_{\sup}$,

$$\begin{aligned}\|\mathcal{T}_i(P)\| &= \left\| A_i^* P_i + P_i A_i + \sum_{j=1}^{\infty} \lambda_{ij} P_j \right\| \\ &\le 2\|A\|_{\sup}\|P\|_{\sup} + \|P\|_{\sup} \sum_{j=1}^{\infty} |\lambda_{ji}| \\ &= 2\|P\|_{\sup}(\|A\|_{\sup} + \lambda_i) \le 2\|P\|_{\sup}(\|A\|_{\sup} + \varrho),\end{aligned}$$

showing the desired result.

Part (c) follows from the definition of $\mathcal{L}(.)$. To prove (d) it suffices to prove that $Y_i(t) \in \mathbb{B}(\mathbb{C}^n)^+$ for $i \in \mathcal{S}$ and any $t \in \mathbb{R}^+$, where $Y(t) := (Y_1(t), \dots)$, with $Y(0) = Q$ and $t \in \mathbb{R}^+$, satisfies $\dot{Y}(t) = \mathcal{L}(Y(t))$ or $\dot{Y}_i(t) = \mathcal{L}_i(Y(t))$. From (4.5) and defining $\tilde{A}_i = A_i + \frac{1}{2}\lambda_{ii} I$, we have

$$\dot{Y}_i(t) = \tilde{A}_i Y_i(t) + Y_i(t)\tilde{A}_i^* + \sum_{\{j \ne i\}} \lambda_{ji} Y_j(t).$$

Furthermore,

$$Y_i(t) = e^{\tilde{A}_i t} Q_i e^{\tilde{A}_i^* t} + \int_0^t e^{\tilde{A}_i\ (t-s)} \left(\sum_{\{j \ne i\}} \lambda_{ji} Y_j(s) \right) e^{\tilde{A}_i^*(t-s)} ds.$$

Now, it is a *fait accompli* that the above equation has a unique integrable solution $Y_i(t)$ that can be found by successive approximations as follows. Consider the sequence $\{Y_i^k(t) : k = 0, 1, \dots, t \in \mathbb{R}^+\}$ for $i \in \mathcal{S}$ obtained recursively as

$$\begin{aligned} Y_i^{(k+1)}(t) &= e^{\tilde{A}_i t} Q_i e^{\tilde{A}_i^* t} + \int_0^t e^{\tilde{A}_i\ (t-s)} \left(\sum_{\{j \ne i\}} \lambda_{ji} Y_j^k(s) \right) e^{\tilde{A}_i^*(t-s)} ds, \\ Y_i^0(t) &= 0, \quad i \in \mathcal{S}. \end{aligned}$$

Bearing in mind that $\lambda_{ij} \ge 0$ for $i \ne j$, $i \in \mathcal{S}$, it is a routine exercise to show that $Y_i^{(k+1)}(t) \ge Y_i^{(k)}(t) \ge 0$ for $k = 0, 1, \dots$ and any $t \in \mathbb{R}^+$. Inspired in [29], we prove that, for $i \in \mathcal{S}$, $\|Y_i^{(k)}(t)\| \le \ell_i(t)$ for every $k = 0, 1, \dots$ and any $t \in \mathbb{R}^+$, where

$$\begin{aligned} \dot{\ell}_i(t) &= 2\|\tilde{A}_i\|\ell_i(t) + \sum_{\{j \ne i\}} \lambda_{ji} \|\ell_j(t)\|, \\ \ell_i(0) &= \|Y_i(0)\|. \end{aligned}$$

This is carried out by induction as follows. First notice that the assertion above is obviously true for $k = 0$. Assuming now that it holds for some k, i.e., $\|Y_i^{(k)}(t)\| \le \ell_i(t)$ for $i \in \mathcal{S}$ and any $t \in \mathbb{R}^+$, we have

$$\begin{aligned} \ell_i(t) &= e^{2\|\tilde{A}_i\| t} \ell_i(0) + \int_0^t e^{2\|\tilde{A}_i\|(t-s)} \left(\sum_{\{j \ne i\}} \lambda_{ji} \|\ell_j(s)\| \right) ds \\ &\ge \left\| e^{\tilde{A}_i t} Q_i e^{\tilde{A}_i^* t} + \int_0^t e^{\tilde{A}_i\ (t-s)} \left(\sum_{\{j \ne i\}} \lambda_{ji} Y_j^k \right) e^{\tilde{A}_i^*(t-s)} ds \right\| \\ &= \|Y_i^{(k+1)}(t)\|, \end{aligned}$$

and the assertion follows. Finally, using the differential equation for the approximating sequence, we get that $\lim_{k\to\infty} Y_i^{(k)}(t) = Y_i(t) \geq 0$ for $i \in \mathcal{S}$ and any $t \in \mathbb{R}^+$, i.e., $Y_i(t) \in \mathbb{B}(\mathbb{C}^n)^+$ for $i \in \mathcal{S}$ and any $t \in \mathbb{R}^+$, and part (d) follows. □

Proof of Lemma 4.2. Bearing in mind that $d(1_{\{\theta_t=i\}}) := 1_{\{\theta_{t+dt}=i\}} - 1_{\{\theta_t=i\}}$, we have

$$\begin{aligned} E(f(t)d(1_{\{\theta_t=i\}})) &= E(f(t)1_{\{\theta_{t+dt}=i\}}) - E(f(t)1_{\{\theta_t=i\}}) \\ &= \sum_{j=1}^{\infty} E(E(f(t)1_{\{\theta_{t+dt}=i\}}1_{\{\theta_t=j\}})|\mathcal{F}_t) - E(f(t)1_{\{\theta_t=i\}}) \\ &= \sum_{j=1}^{\infty} \mathbb{P}(\theta_{t+dt}=i|\theta_t=j)f_j(t) - f_i(t) \\ &= \sum_{j=1}^{\infty} \lambda_{ji} f_j(t)dt \ + \ o(dt). \end{aligned}$$ □

Proof of Proposition 4.3. We show now that for some constants $c_1 > 0$ and $c_2 > 0$ we have, for any $H_i \in \mathbb{B}(\mathbb{C}^n)$, that $c_1\|\varphi(H_i)\| \leq \|H_i\| \leq c_2\|\varphi(H_i)\|$. Since all norms in finite-dimensional spaces are equivalent (see [44]), for any $H = (H_1, \dots) \in \mathbb{H}_1^n$, $c_1\|\hat{\varphi}(H)\|_1 \leq \|H\|_1 \leq c_2\|\hat{\varphi}(H)\|_1$. □

Proof of Proposition 4.5. The proof follows from the definition of $\hat{\varphi}$ in section 2, in conjunction with Proposition 4.3 and the results given by (2.7), bearing in mind the definition of the operators $\mathcal{F}$, $\mathcal{L}$, and $\mathcal{T}$ in (4.4)–(4.5). □

Proof of Lemma 4.6. (a) We begin by noticing that the solution of the above differential equation is given by $y(t) = e^{\mathcal{A}t}y(0)$. Then

$$y(t) = e^{\mathcal{A}t}\hat{\varphi}(Q) = \sum_{n=0}^{\infty} \frac{1}{n!}\mathcal{A}^n\hat{\varphi}(Q)t^n = \sum_{n=0}^{\infty} \frac{1}{n!}\hat{\varphi}(\mathcal{L}^n(Q))t^n = \hat{\varphi}(e^{\mathcal{L}t}(Q)),$$

where the third equality follows from Proposition 4.5(a). Part (b) follows from Lemma 4.1 and the definitions of $\hat{\varphi}$ and ${\hat{\varphi}_j}^{-1}$. □

Proof of Lemma 4.7. Consider (4.1) with initial time $t_0 = \tau$ and initial condition $x(t_0) = z$. It follows from (4.2) that over the set Υ,

$$x(t) = \Phi(t, \tau)z.$$

Recalling that $\mathbb{P}(\Upsilon) = 1$, $Q_i(t) = E(x(t)x(t)^* 1_{\{\theta_t=i\}})$, $Q_i(\tau) = E(zz^* 1_{\{\theta_\tau=i\}})$, it follows that

$$\begin{aligned} \|x(t)\|_2^2 = \|\Phi(t,\tau)z\|_2^2 &= \sum_{i=1}^{\infty} \mathrm{tr}(Q_i(t)) \\ &\leq n\sum_{i=1}^{\infty} \|Q_i(t)\| = n\|\hat{Q}(t)\|_1. \end{aligned} \tag{5.14}$$

From Proposition 4.4(b),

$$\hat{Q}(t) = e^{\mathcal{L}(t-\tau)}\hat{Q}(\tau). \tag{5.15}$$

Substituting (5.15) into (5.14) leads to

$$\begin{aligned} \|\Phi(t,\tau)z\|_2^2 &\leq n\|e^{\mathcal{L}(t-\tau)}\hat{Q}(\tau)\| \\ &\leq n\|e^{\mathcal{L}(t-\tau)}\|\|\hat{Q}(\tau)\|_1. \end{aligned} \tag{5.16}$$

The result follows from (5.16) after noticing that

$$\|\hat{Q}(\tau)\|_1 = \sum_{i=1}^{\infty} \|Q_i(\tau)\| \leq \sum_{i=1}^{\infty} \mathrm{tr}(Q_i(\tau)) = \|z\|_2^2. \qquad \square \tag{5.17}$$

Proof of Proposition 4.8. Since $\mathbb{R}_e\{\lambda(\mathcal{A})\} < 0$ it follows from Propositions 2.3 and 4.9 that $\|e^{\mathcal{L}t}\| \leq \mu e^{-bt}$ for some $\mu > 0, b > 0$. For the homogeneous systems

$$\dot{x}(t) = A(\theta_t)x(t), \qquad t \in \mathbb{R}^+,$$

we have from Proposition 4.4(b) and (3.12) that

$$\begin{aligned} E(\|x(t)\|^2) &= \sum_{j=1}^{\infty} \mathrm{tr}(E(x(t)x(t)^* 1_{\{\theta_t = j\}})) \\ &= \sum_{j=1}^{\infty} \mathrm{tr}(Q_j(t)) \leq n \sum_{j=1}^{\infty} \|Q_j(t)\| = n\|\hat{Q}(t)\|_1 \\ &= \|e^{\mathcal{L}t}(\hat{Q}(0))\|_1 \leq n\mu e^{-bt}\|\hat{Q}(0)\|_1 \leq n\mu e^{-bt} E(\|x(0)\|^2) \end{aligned}$$

and from Proposition 4.4(a)

$$\begin{aligned} \|e^{Ft}\hat{q}(0)\|_1 = \|\hat{q}(t)\|_1 = \sum_{j=1}^{\infty} \|q_j(t)\| &\leq \sum_{j=1}^{\infty} E(\|x(t)\| 1_{\{\theta_t = j\}}) = E(\|x(t)\|) \\ &\leq (E(\|x(t)\|^2))^{1/2} \leq (n\mu)^{1/2} e^{-\frac{b}{2}t} (E(\|x(0)\|^2))^{1/2}. \end{aligned} \tag{5.18}$$

From Proposition 2.2 and (5.18) we get $\mathbb{R}_e\{\lambda(F)\} < 0$. $\square$

Proof of Lemma 5.1. The proof follows the same arguments as in [48, pp. 119–120]. Given any $\epsilon > 0$ consider $t_\epsilon > 0$ such that $\int_{t_\epsilon}^{\infty} \|w(\tau)\|_2^2 d\tau \leq \epsilon^2$. Then for $t > t_\epsilon$,

$$\chi(t) = e^{-\lambda(t-t_\epsilon)} \int_0^{t_\epsilon} e^{-\lambda(t_\epsilon - \tau)} \|w(\tau)\|_2 d\tau + \int_{t_\epsilon}^{t} e^{-\lambda(t-\tau)} \|w(\tau)\|_2 d\tau. \tag{5.19}$$

We have from the Schwarz inequality that

$$\left(\int_0^{t_\epsilon} e^{-\lambda(t_\epsilon - \tau)} \|w(\tau)\|_2 d\tau \right)^2 \leq \int_0^{t_\epsilon} e^{-2\lambda(t_\epsilon - \tau)} d\tau \int_0^{t_\epsilon} \|w(\tau)\|_2^2 d\tau \leq \frac{1}{2\lambda} \|w\|_2^2 \tag{5.20}$$

and

$$\left(\int_{t_\epsilon}^{t} e^{-\lambda(t-\tau)} \|w(\tau)\|_2 d\tau \right)^2 \leq \int_{t_\epsilon}^{t} e^{-2\lambda(t-\tau)} d\tau \int_{t_\epsilon}^{\infty} \|w(\tau)\|_2^2 d\tau \leq \frac{1}{2\lambda} \epsilon^2. \tag{5.21}$$

Taking the limit as $t \to \infty$ in (5.19), and from (5.20) and (5.21) we obtain that $0 \leq \lim_{t\to\infty} \chi(t) \leq \frac{\epsilon}{(2\lambda)^{1/2}}$, showing the desired result. $\square$

CHARACTERIZATION OF GRADIENT CONTROL SYSTEMS*

JORGE CORTÉS†, ARJAN VAN DER SCHAFT‡, AND PETER E. CROUCH§

Abstract. Given a general nonlinear affine control system with outputs and a torsion-free affine connection defined on its state space, we investigate the gradient realization problem: we give necessary and sufficient conditions under which the control system can be written as a gradient control system corresponding to some pseudo-Riemannian metric whose Levi-Civita connection is equal to the given affine connection. The results rely on a suitable notion of compatibility of the system with respect to the given affine connection, and on the output behavior of the prolonged system and the gradient extension. The symmetric product associated with an affine connection plays a key role throughout the discussion.

Key words. gradient control systems, symmetric product, prolongation and gradient extension of a nonlinear system, externally equivalent systems

1. Introduction.

A physically motivated class of nonlinear systems are *gradient control systems*; see [4, 5, 10, 22, 23, 25, 26, 27] and the references quoted therein. These systems are described in the following way: they are nonlinear affine control systems, which are endowed with a pseudo-Riemannian metric on the state-space manifold. The drift vector field of the system is the gradient vector field associated with an internal potential function with respect to the pseudo-Riemannian metric, and the input vector fields are the gradient vector fields associated with the output functions of the system. Examples of gradient control systems include nonlinear electrical RLC networks, and dissipative systems where the inertial effects are neglected. In the case of RL or RC networks, the pseudo-Riemannian metric is positive-definite, and thus is a usual Riemannian metric, while for general RLC networks the metric is indefinite. We refer to [4, 5, 10, 25, 26] for more background on the modeling of nonlinear networks as gradient systems.

Another relevant class of nonlinear systems is the family formed by the *Hamiltonian control systems*; see [13]. In this case, the state-space manifold is equipped with a symplectic form. The drift vector field and the input vector fields are the Hamiltonian vector fields associated, respectively, to an internal energy function and the output functions of the system with respect to the symplectic form. Hamiltonian equations are of central importance in the modeling of physical systems as they are the starting point to describe the dynamics of a very large class of phenomena, including mechanical, electrical, and electromagnetic systems.

Apart from their physical and engineering importance, gradient and Hamiltonian systems also possess very peculiar mathematical properties. For instance, an observable and controllable linear input-state-output system is a Hamiltonian control system [6] (respectively, a gradient control system [27]) if and only if its impulse response matrix $W(t)$ satisfies $W(t) = -W^T(-t)$ (respectively, $W(t) = W^T(t)$). Although they are typically not amenable to linearization techniques, their rich geometric structure makes it possible to combine powerful tools from nonlinear control theory, differential geometry, and classical mechanics in the study of a variety of problems including stability and stabilization, input-output decoupling, structural synthesis, and interconnection.

Their theoretical and practical relevance, together with their meaningful geometric properties and the wide range of results available for them, make the classes of Hamiltonian and gradient systems *distinct* within the family of nonlinear affine control systems. This explains the interest in identifying those systems that can be written as either Hamiltonian or gradient. This *characterization problem* is motivated by the realization problem in systems theory and the inverse problem in mechanics. The realization problem addresses the question of when the input-output map of a system can be realized as the external behavior of a Hamiltonian (respectively, gradient) input-output system. The inverse problem, which has a longstanding history in mathematical physics, poses the question of when a second-order differential equation can be realized as the Euler–Lagrange equations corresponding to certain Lagrangian function. For further reference on these problems, the reader is referred to [11, 15, 20, 21].

In [12, 13], necessary and sufficient conditions were given under which a minimal nonlinear affine control system with an equal number of inputs and outputs is a Hamiltonian control system with respect to some symplectic structure, which turned out to be unique. A different but somehow related problem is considered in [24]: assuming the state space of the nonlinear affine control system is already endowed with a symplectic form, conditions are derived that guarantee that a feedback transformation exists making Hamiltonian the drift vector field of the transformed control system. As we discuss below, there are a number of key differences in the treatment of the characterization problem for the Hamiltonian and the gradient cases, which make the latter more involved. A fundamental observation is that, while every input-state-output system admits a natural extension to a Hamiltonian system living on the cotangent bundle of its state space, the construction of a gradient extension on the cotangent bundle relies on the selection of a torsion-free affine connection on the state space. This is why our starting point in the gradient setting is the selection of an *appropriate* torsion-free affine connection. This appropriateness is defined in terms of a novel *compatibility condition* of the given nonlinear system with the selected affine connection, guaranteeing an appropriate choice of the latter one. The compatibility condition is expressed as a relation of the symmetric products of the drift vector field and the input vector fields with the output functions of the system. As a further remark, the role played in the Hamiltonian setting by the Lie bracket and the Hamiltonian vector fields is taken here by the symmetric product associated with the given affine connection and the gradient vector fields.

The question solved by the main result of this paper (cf. Theorem 5.4) is the following: given a torsion-free affine connection which is compatible with the nonlinear control system, find necessary and sufficient conditions under which the system is gradient with respect to a pseudo-Riemannian metric whose Levi-Civita connection is the given affine connection. The question that still remains to be addressed in order

to solve the full characterization problem for gradient control systems is the following: given a nonlinear control system, when does an affine connection exist such that these necessary and sufficient conditions are satisfied?

The paper is organized as follows. In section 2 we present the class of nonlinear systems considered throughout the paper. We also introduce the notions of prolongation and gradient extension of a nonlinear system. The observability properties of these systems, studied in section 3, together with the concept of (weakly) externally equivalent systems, introduced in section 4, turn out to be key in establishing Theorem 5.4. In section 5, we introduce the important notion of compatibility between a nonlinear system and a given affine connection. At this point, we are ready to state and prove the main result of the paper, namely, the characterization of when a general nonlinear control system is gradient. This characterization can be roughly described as follows: under certain technical conditions, a nonlinear affine control system is gradient if and only if its prolongation and its gradient extension *behave* similarly (i.e., have the same input-output behavior). In section 6 we investigate the uniqueness (up to isometry) of gradient realizations with the same input-output behavior and we give an alternative proof of a result in [1, 2]. We present our conclusions in section 7. Finally, an appendix in section 8 contains a simplifying result concerning the checkability of the compatibility condition for a nonlinear affine control system.

2. Setting. Let M be an n-dimensional (real-)analytic manifold. We will denote by TM, T^*M the tangent and cotangent bundles of M, by $\mathfrak{X}(M)$ the set of analytic vector fields on M, by $\Omega^1(M)$ the set of analytic one-forms on M, and by $C^\omega(M)$ the set of analytic functions on M. Consider a nonlinear control system Σ with state space M, affine in the inputs, and with an equal number of inputs and outputs,

$$\Sigma : \begin{cases} \dot{x} = g_0(x) + \displaystyle\sum_{j=1}^{m} u_j g_j(x)\,, \\ y_j = V_j(x)\,, \quad j = 1, \dots, m\,, \end{cases} \tag{2.1}$$

where $x \in M$, $x(0) = x_0$, and $u = (u_1, \dots, u_m) \in U \subset \mathbb{R}^m$. The vector fields $g_0, g_1, \dots, g_m$ on M are assumed to be complete and $V_1, \dots, V_m$ are real-valued functions on M. The set U is the control space, which for simplicity is assumed to be an open subset of $\mathbb{R}^m$, containing 0. The function $t \mapsto u(t) = (u_1(t), \dots, u_m(t))$, which we will commonly denote as $u(\cdot)$, belongs to a certain class of functions of time, denoted by $\mathcal{U}$, called the *admissible controls*. For our purposes, we may restrict the admissible controls to be the piecewise constant right continuous functions.

An important subclass of the family of nonlinear systems (2.1) is formed by the Hamiltonian control systems; see [13]. Here, we will instead focus our attention on the family of gradient control systems. Let $\mathcal{G}$ be a pseudo-Riemannian metric on M, i.e., a nondegenerate symmetric (0,2)-tensor on M (not necessarily positive-definite); see [7]. Consider the "musical" isomorphisms associated with $\mathcal{G}$, $\flat_{\mathcal{G}} : \mathfrak{X}(M) \to \Omega^1(M)$, $\sharp_{\mathcal{G}} : \Omega^1(M) \to \mathfrak{X}(M)$ defined by

$$\flat_{\mathcal{G}}(X)(Y) = \mathcal{G}(X, Y)\,, \quad \sharp_{\mathcal{G}}(\mu) = \flat_{\mathcal{G}}^{-1}(\mu)\,,$$

where $X, Y \in \mathfrak{X}(M)$ and $\mu \in \Omega^1(M)$. The *gradient vector field* associated with a function $V \in C^\omega(M)$ is given by $\operatorname{grad}_{\mathcal{G}} V = \sharp_{\mathcal{G}}(dV)$. Reciprocally, a vector field $X \in \mathfrak{X}(M)$ is said to be *locally gradient* if the one-form $\flat_{\mathcal{G}}(X)$ is closed. By Poincaré's lemma, this is equivalent to saying that there exists a locally defined function $V \in C^\omega(M)$ such that $\flat_{\mathcal{G}}(X) = dV$. If this equality holds globally, X is called *gradient* and

will be denoted by $X = \operatorname{grad}_{\mathcal{G}} V$. Throughout the paper, we will drop the subindex when the pseudo-Riemannian metric used in the computation of the gradient vector field is clear from the context. If we fix coordinates $(x^1, \dots, x^n)$ on M, then the pseudo-Riemannian metric can be locally expressed as $\mathcal{G} = \mathcal{G}_{ab} dx^a \otimes dx^b$, where $(\mathcal{G}_{ab} = \mathcal{G}(\frac{\partial}{\partial x^a}, \frac{\partial}{\partial x^b}))$ is a symmetric matrix. The musical isomorphisms are then given by $\flat_{\mathcal{G}} = \mathcal{G}_{ab} dx^a \otimes dx^b$, $\sharp_{\mathcal{G}} = \mathcal{G}^{ab} \frac{\partial}{\partial x^a} \otimes \frac{\partial}{\partial x^b}$, where $(\mathcal{G}^{ab})$ is the inverse matrix of $(\mathcal{G}_{ab})$. Finally, the gradient vector field associated with V reads

$$\operatorname{grad}_{\mathcal{G}} V = \mathcal{G}^{ab} \frac{\partial V}{\partial x^b} \frac{\partial}{\partial x^a}.$$

Now, assume that the state space M in (2.1) is a pseudo-Riemannian manifold, $(M, \mathcal{G})$. Furthermore, assume that the drift vector field g_0 is locally gradient and the input vector fields g_j, $j = 1, \dots, m$, are gradient with respect to the functions $V_1, \dots, V_m$, i.e., $g_j = \operatorname{grad}_{\mathcal{G}} V_j$, $j = 1, \dots, m$. Then, the resulting system

$$\Sigma : \begin{cases} \dot{x} = g_0(x) + \sum_{j=1}^{m} u_j(t) \operatorname{grad}_{\mathcal{G}} V_j(x), \\ y_j = V_j(x), \quad j = 1, \dots, m, \end{cases} \tag{2.2}$$

is called a *locally gradient control system on* M. If the drift g_0 is a gradient vector field, then the system is called a *gradient control system on* M.

Given an affine connection on M, our objective is to characterize when a nonlinear system of the form (2.1) is a locally gradient control system (2.2), i.e., find necessary and sufficient conditions for the existence of a pseudo-Riemannian metric $\mathcal{G}$ on the state space M whose Levi-Civita connection is the given affine connection such that the system (2.1) equals system (2.2). These conditions will be given in terms of the output behavior of the so-called prolonged system and the gradient extension of Σ, which we describe next.

2.1. The prolongation of a nonlinear system. Given an initial state $x(0) = x_0$, take a coordinate neighborhood of M containing x_0. Let $t \in [0, T] \mapsto x(t)$ be the solution of (2.1) corresponding to the input function $t \in [0, T] \mapsto u(t) = (u_1(t), \dots, u_m(t))$ and the initial state $x(0) = x_0$, such that $x(t)$ remains within the selected coordinate neighborhood. Denote the resulting output by $t \in [0, T] \mapsto y(t) = (y_1(t), \dots, y_m(t))$, with $y_j(t) = V_j(x(t))$. Then the *variational system* along the input-state-output trajectory $t \in [0, T] \mapsto (x(t), u(t), y(t))$ is given by the following time-varying system:

$$\begin{aligned} \dot{v}(t) &= \frac{\partial g_0}{\partial x}(x(t))v(t) + \sum_{j=1}^{m} u_j(t) \frac{\partial g_j}{\partial x}(x(t))v(t) + \sum_{j=1}^{m} u_j^p g_j(x(t)), \\ y_j^p(t) &= \frac{\partial V_j}{\partial x}(x(t))v(t), \quad j = 1, \dots, m, \end{aligned} \tag{2.3}$$

where $v(0) = v_0 \in \mathbb{R}^n$, and $u^p = (u_1^p, \dots, u_m^p)$, $y^p = (y_1^p, \dots, y_m^p)$ denote the inputs and the outputs of the variational system. The reasoning behind the term "variational" comes from the following fact: let $(x(t, \epsilon), u(t, \epsilon), y(t, \epsilon))$, $t \in [0, T]$, be a family of input-state-output trajectories of (2.1) parameterized by $\epsilon \in (-\delta, \delta)$, with $x(t, 0) = x(t)$, $u(t, 0) = u(t)$, and $y(t, 0) = y(t)$, $t \in [0, T]$. Then, the infinitesimal variations

$$v(t) = \frac{\partial x}{\partial \epsilon}(t, 0), \quad u^p(t) = \frac{\partial u}{\partial \epsilon}(t, 0), \quad y^p(t) = \frac{\partial y}{\partial \epsilon}(t, 0)$$

satisfy (2.3). Additionally, if the initial state is the same for the whole family of trajectories, $x(0,\epsilon) = x_0$, then the variational state $v(0)$ at time 0 is necessarily 0.

The *prolongation or prolonged system* of (2.1) corresponds to considering together the original system (2.1) and the variational system

$$\begin{aligned} \dot{x} &= g_0(x) + \sum_{j=1}^{m} u_j g_j(x), \\ \dot{v}(t) &= \frac{\partial g_0}{\partial x}(x(t))v(t) + \sum_{j=1}^{m} u_j(t)\frac{\partial g_j}{\partial x}(x(t))v(t) + \sum_{j=1}^{m} u_j^p g_j(x(t))\,, \\ y_j &= V_j(x)\,, \quad y_j^p(t) = \frac{\partial V_j}{\partial x}(x(t))\,v(t)\,, \quad j = 1,\dots,m, \end{aligned} \tag{2.4}$$

with inputs u_j, u_j^p, outputs y_j, y_j^p, and state (x, v). To state a coordinate-free definition of the prolonged system (2.4) on the whole tangent space TM, we need to introduce the notions of vertical and complete lifts of functions and vector fields. We do this following [28]. Given a function V on M, the *complete lift* of V to TM, $V^{\mathrm{C}} : TM \to \mathbb{R}$, is defined by $V^{\mathrm{C}}(v) = \langle dV, v\rangle$. In the induced local coordinates on TM, $(x^1,\dots,x^n,v^1,\dots,v^n)$, this reads

$$V^{\mathrm{C}}(x,v) = \sum_{a=1}^{n} \frac{\partial V}{\partial x^a}(x)\, v_a\,.$$

The *vertical lift* of V to TM, $V^{\mathrm{V}} : TM \to \mathbb{R}$, is defined by $V^{\mathrm{V}} = V \circ \tau_M$, where τ_M denotes the tangent bundle projection. Given a vector field X on M, the *complete lift* of X to TM, $X^{\mathrm{C}} \in \mathfrak{X}(TM)$, is defined as the unique vector field verifying $X^{\mathrm{C}}(f^{\mathrm{C}}) = (Xf)^{\mathrm{C}}$ for any $f \in C^\omega(M)$. Alternatively, if $\Phi_t : M \to M$, $t \in [0,\epsilon)$, denotes the flow of X, then we can define X^{C} as the vector field whose flow is given by $(\Phi_t)_* : TM \to TM$. In local coordinates,

$$X^{\mathrm{C}}(x,v) = \sum_{a=1}^{n} X_a(x)\frac{\partial}{\partial x^a} + \sum_{a,b=1}^{n} \frac{\partial X_a}{\partial x^b}(x)v^b\frac{\partial}{\partial v^a}\,. \tag{2.5}$$

The *vertical lift* of X to TM, $X^{\mathrm{V}} \in \mathfrak{X}(TM)$, is the unique vector field such that $X^{\mathrm{V}}(f^{\mathrm{C}}) = (Xf)^{\mathrm{V}}$ for any $f \in C^\omega(M)$. In local coordinates,

$$X^{\mathrm{V}}(x,v) = \sum_{a=1}^{n} X_a(x)\frac{\partial}{\partial v^a}\,. \tag{2.6}$$

The following definition provides an intrinsic way of pasting together the system (2.1) with the variational systems associated with its input-state-output trajectories.

DEFINITION 2.1. *The prolonged system Σ^p of a nonlinear system Σ of the form* (2.1) *is defined by*

$$\Sigma^p : \begin{cases} \dot{x}_p = g_0^{\mathrm{C}}(x_p) + \displaystyle\sum_{j=1}^{m} u_j(t) g_j^{\mathrm{C}}(x_p) + \sum_{j=1}^{m} u_j^p(t) g_j^{\mathrm{V}}(x_p), \\ y_j = V_j^{\mathrm{V}}(x_p)\,, \quad y_j^p = V_j^{\mathrm{C}}(x_p)\,, \quad j = 1,\dots,m\,, \end{cases} \tag{2.7}$$

where $x_p = (x,v) \in TM$ and $x_p(0) = (x_0, v_0)$.

One can easily check that in the induced tangent bundle coordinates, the local expression of the system (2.7) is precisely (2.4).

Remark 2.2. In the same way as we have presented above, one can also introduce the notions of adjoint variational system and Hamiltonian extension of the nonlinear system (2.1). These notions play a key role in the characterization of when a general system admits a Hamiltonian description; see [13].

2.2. The gradient extension of a nonlinear system. When dealing with the Hamiltonian extension of a nonlinear system, one relies on the fact that the cotangent bundle is endowed with a canonical symplectic structure. However, this is not the case when treating gradient systems, since a canonical pseudo-Riemannian structure on the cotangent bundle does not exist. In order to define the gradient extension of a nonlinear system of the form (2.1), we will first select a torsion-free affine connection ∇ on M, and then consider its Riemannian extension to T^*M (cf. [19]).

Let us briefly present some basic notions on affine connections and Riemannian geometry. An *affine connection* [16] on a manifold M is defined as an assignment

$$\begin{aligned} \nabla : \mathfrak{X}(M) \times \mathfrak{X}(M) &\longrightarrow \mathfrak{X}(M), \\ (X, Y) &\longmapsto \nabla_X Y \end{aligned}$$

which is $\mathbb{R}$-bilinear and satisfies $\nabla_{fX} Y = f \nabla_X Y$ and $\nabla_X (fY) = f \nabla_X Y + X(f) Y$ for any X, $Y \in \mathfrak{X}(M)$, $f \in C^\omega(M)$. This implies that $\nabla_X Y(x)$ depends only on $X(x)$ and the value of Y along a curve which is tangent to X at x. Let $c : t \in [t_0, t_1] \mapsto c(t) = (x^1(t), \dots, x^n(t)) \in M$ be a curve on M and W a vector field along c, i.e., a map $W \colon [t_0, t_1] \to TM$ such that $\tau_M(W(t)) = c(t)$ for all $t \in [a, b]$. Let V be a vector field that satisfies $V(c(t)) = W(t)$. The *covariant derivative of* W *along* c is defined by

$$\frac{DW(t)}{dt} = \nabla_{\dot{c}(t)} W(t) = \nabla_{\dot{c}(t)} V(x)\big|_{x=c(t)}.$$

This definition makes sense because of the defining properties of the affine connection. Now, we may take $W(t) = \dot{c}(t)$ and set up $\nabla_{\dot{c}(t)} \dot{c}(t) = 0$. This equation is called the *geodesic equation*, and its solutions are termed the *geodesics* of ∇. In local coordinates, this condition can be expressed as $\ddot{x}^a + \Gamma^a_{bc}(x) \dot{x}^b \dot{x}^c = 0$, $1 \le a \le n$, where the $\Gamma^a_{bc}(x)$ are the *Christoffel symbols* of the affine connection, defined by

$$\nabla_{\frac{\partial}{\partial x^b}} \frac{\partial}{\partial x^c} = \Gamma^a_{bc}(x) \frac{\partial}{\partial x^a} \,.$$

The vector field S on TM describing the geodesic equation is called the *geodesic spray* associated with the affine connection ∇. In local coordinates,

$$S = v^a \frac{\partial}{\partial x^a} - \Gamma^a_{bc}(x) v^b v^c \frac{\partial}{\partial v^a} \,.$$

Therefore, the integral curves of the geodesic spray S are the solutions of the geodesic equation. The torsion tensor of an affine connection is defined by

$$\begin{aligned} T : \mathfrak{X}(M) \times \mathfrak{X}(M) &\longrightarrow \mathfrak{X}(M), \\ (X, Y) &\longmapsto \nabla_X Y - \nabla_Y X - [X, Y] \,. \end{aligned}$$

Locally, we have

$$T\left(\frac{\partial}{\partial x^a}, \frac{\partial}{\partial x^b} \right) = \left(\Gamma^c_{ab} - \Gamma^c_{ba} \right) \frac{\partial}{\partial x^c} \,.$$

An affine connection is *torsion-free* if T is identically zero. Given an affine connection, the *symmetric product* [18] of two vector fields $X, Y \in \mathfrak{X}(M)$ is defined by the operation

$$\langle X : Y \rangle = \nabla_X Y + \nabla_Y X \,.$$

The geometric meaning of the symmetric product is the following [17]: a distribution $\mathcal{D}$ on M is geodesically invariant (meaning that each geodesic of ∇ whose initial velocity is in $\mathcal{D}$ has all its velocities in $\mathcal{D}$) if and only if $\langle X : Y \rangle \in \mathcal{D}$ for all X, $Y \in \mathcal{D}$. The symmetric product plays a crucial role within the so-called affine connection formalism for mechanical control systems in the study of a variety of aspects such as controllability, series expansions, motion planning, and optimal control [7]. Note that if the affine connection ∇ is torsion-free, then $\nabla_X Y = \frac{1}{2}(\langle X : Y \rangle + [X, Y])$ for all $X, Y \in \mathfrak{X}(M)$, i.e., there is a one-to-one correspondence between the covariant derivative and the symmetric product.

Associated with the metric $\mathcal{G}$ there is a natural affine connection called the *Levi-Civita* connection. The Levi-Civita connection $\nabla^{\mathcal{G}}$ is determined by the formula

$$\begin{aligned} 2\,\mathcal{G}(\nabla^{\mathcal{G}}_X Y, Z) = {} & X(\mathcal{G}(Y,Z)) + Y(\mathcal{G}(Z,X)) - Z(\mathcal{G}(X,Y)) \\ & + \mathcal{G}(Y,[Z,X]) - \mathcal{G}(X,[Y,Z]) + \mathcal{G}(Z,[X,Y])\,, \quad X,Y,Z \in \mathfrak{X}(M)\,. \end{aligned}$$

One can compute the Christoffel symbols of $\nabla^{\mathcal{G}}$ to be

$$\Gamma^a_{bc} = \frac{1}{2}\mathcal{G}^{ad}\left(\frac{\partial \mathcal{G}_{db}}{\partial x^c} + \frac{\partial \mathcal{G}_{dc}}{\partial x^b} - \frac{\partial \mathcal{G}_{bc}}{\partial x^d}\right). \tag{2.8}$$

The Levi-Civita connection is torsion-free, that is, $T(X, Y) = 0$ for any X, $Y \in \mathfrak{X}(M)$.

Therefore, a pseudo-Riemannian metric on M defines a unique affine torsion-free connection on M. The converse is, however, not true. Also, note that given an affine torsion-free connection which is the Levi-Civita connection corresponding to some pseudo-Riemannian metric, then there exist many more metrics that give rise to the same affine connection. For instance, any constant metric on the Euclidean space gives rise to the affine connection with Christoffel symbols $\Gamma^a_{bc} = 0$, $1 \le a, b, c \le n$.

Given a pseudo-Riemannian metric $\mathcal{G}$ on M, we can define the so-called Beltrami bracket [10, 22] of functions on M,

$$\{f : g\}_{\mathcal{G}} = \mathcal{G}(\mathrm{grad}_{\mathcal{G}}\, f, \mathrm{grad}_{\mathcal{G}}\, g)\,, \quad f, g \in C^\omega(M)\,.$$

In local coordinates, one has the expression

$$\{f : g\}_{\mathcal{G}} = \frac{\partial f}{\partial x^a}\mathcal{G}^{ab}\frac{\partial g}{\partial x^b}\,.$$

It is interesting to note that the mapping

$$\mathrm{grad}_{\mathcal{G}} : (C^\omega(M), \{\cdot : \cdot\}_{\mathcal{G}}) \to (\mathfrak{X}(M), \langle \cdot : \cdot \rangle_{\nabla^{\mathcal{G}}})$$

is a homomorphism of symmetric algebras, i.e., $\mathrm{grad}_{\mathcal{G}}\{f : g\}_{\mathcal{G}} = \langle \mathrm{grad}_{\mathcal{G}}\, f : \mathrm{grad}_{\mathcal{G}}\, g \rangle_{\nabla^{\mathcal{G}}}$ for all $f, g \in C^\omega(M)$.

Remark 2.3. The latter observation is the gradient analogue of the following fact in the Hamiltonian setting: consider the mapping $(C^\omega(M), \{\cdot, \cdot\}) \to (\mathfrak{X}(M), [\cdot, \cdot])$ (where $\{\cdot, \cdot\}$ denotes the Poisson bracket and $[\cdot, \cdot]$ denotes the Lie bracket) associating to each function f its Hamiltonian vector field X_f. Then this mapping is a homomorphism of Lie algebras, i.e., $X_{\{f,g\}} = [X_f, X_g]$.

Let us now turn our discussion to the cotangent bundle of M. First, we introduce the construction that associates to each vector field X on M a function V^X on T^*M, defined by $V^X(p) = \langle p, X\rangle$. In the induced local coordinates $(x^1, \dots, x^n, p_1, \dots, p_n)$ on T^*M, this reads $V^X(x,p) = \sum_{a=1}^n p_a X_a(x)$. The *complete lift* of X to T^*M, $X^{\mathrm{C}} \in \mathfrak{X}(T^*M)$, is defined as the Hamiltonian vector field (with respect to the canonical symplectic form on T^*M) associated with the function V^X. In local coordinates,

$$X^{\mathrm{C}}(x,p) = \sum_{a=1}^n X_a \frac{\partial}{\partial x^a} - \sum_{a,b=1}^n \frac{\partial X_b}{\partial x^a}(x) p_b \frac{\partial}{\partial p_a}.$$

The notion of *vertical lift* of a function V on M to a function V^{V} on T^*M is given by $V^{\mathrm{V}} = V \circ \pi_M$, where π_M is the cotangent bundle projection. An object which will play a key role in the subsequent discussion is the *Riemannian extension* [19, 28] of a torsion-free affine connection. Let ∇ be a torsion-free affine connection on M. Then, ∇ defines a pseudo-Riemannian metric on T^*M, denoted $\mathcal{G}^\nabla$, as the unique (0,2)-tensor on T^*M which satisfies

$$\mathcal{G}^\nabla(X^{\mathrm{C}}, Y^{\mathrm{C}}) = -V^{\langle X:Y\rangle}\,.$$

The fact that this single equality completely determines the Riemannian extension $\mathcal{G}^\nabla$ is a consequence of the result in Proposition 4.2 in [28, Chapter VII], which asserts that any $(0,s)$-tensor field on T^*M is univocally defined by its action on the complete lifts of vector fields of M. The matrix representations of the musical isomorphisms defined by $\mathcal{G}^\nabla$ in local coordinates are given by

$$\flat_{\mathcal{G}^\nabla} \equiv \begin{pmatrix} -2p_c\Gamma^c_{ab} & I_n \\ I_n & 0 \end{pmatrix}, \quad \sharp_{\mathcal{G}^\nabla} \equiv \begin{pmatrix} 0 & I_n \\ I_n & 2p_c\Gamma^c_{ab} \end{pmatrix}. \tag{2.9}$$

As for the gradient vector fields associated with the functions V^X, $V^{\mathrm{V}} \in C^\omega(T^*M)$, $X \in \mathfrak{X}(M)$, $V \in C^\omega(M)$, one has the local expressions

$$\operatorname{grad}_{\mathcal{G}^\nabla} V^X = X^a \frac{\partial}{\partial x^a} + p_a \left(\frac{\partial X^a}{\partial x^b} + 2\Gamma^a_{bc} X^c \right) \frac{\partial}{\partial p_b}, \quad \operatorname{grad}_{\mathcal{G}^\nabla} V^{\mathrm{V}} = \frac{\partial V}{\partial x^a} \frac{\partial}{\partial p_a}. \tag{2.10}$$

Given a metric $\mathcal{G}$ on M, one can also verify that the pseudo-Riemannian metric on T^*M defined by $\mathcal{G}^{\nabla^{\mathcal{G}}}$ corresponds to the pullback by $\sharp_{\mathcal{G}}$ of the complete lift $\mathcal{G}^{\mathrm{C}}$ to TM of $\mathcal{G}$, i.e., $\mathcal{G}^{\nabla^{\mathcal{G}}} = \sharp^*_{\mathcal{G}}(\mathcal{G}^{\mathrm{C}})$ (see [28]).

Definition 2.4. *The gradient extension Σ^e of a nonlinear system Σ of the form* (2.1) *with respect to a torsion-free affine connection ∇ on M is given by*

$$\Sigma^e : \begin{cases} \dot{x}_e = \operatorname{grad}_{\mathcal{G}^\nabla} V^{g_0}(x_e) + \sum_{j=1}^m u_j(t) \operatorname{grad}_{\mathcal{G}^\nabla} V^{g_j}(x_e) + \sum_{j=1}^m u^e_j(t) \operatorname{grad}_{\mathcal{G}^\nabla} V^{\mathrm{V}}_j(x_e), \\ y_j = V^{\mathrm{V}}_j(x_e), \quad y^e_j = V^{g_j}(x_e), \quad j = 1, \dots, m, \end{cases} \tag{2.11}$$

where $x_e = (x,p) \in T^*M$, $x_e(0) = (x_0, p_0)$, $u = (u_1, \dots, u_m) \in U \subset \mathbb{R}^m$, and $u^e = (u^e_1, \dots, u^e_m) \in \mathbb{R}^m$.

Remark 2.5. Note that the gradient extension Σ^e is itself a gradient control system.

3. Observability of the prolongation and the gradient extension. In this section, we investigate the observability properties of the prolonged system and the gradient extension of a nonlinear system. Roughly speaking, the observability properties of a given system determine to what extent one can *observe* the actual state of the system from its input-output behavior, i.e., to what extent the knowledge of the input-output response allows us to infer things about the evolution of the state. This study will later be key in establishing the characterization of when a nonlinear control system can be written as a gradient control system.

We start by briefly reviewing some notions such as distinguishable points and local observability. Let $\mathcal{Y}$ denote the space of absolutely continuous functions defined on $\mathbb{R}_+ = [0, +\infty)$ with values in $\mathbb{R}^m$. For a nonlinear system of the form (2.1), the *input-output map* $\mathcal{R}_\Sigma : M \times \mathcal{U} \to \mathcal{Y}$, $\mathcal{R}_\Sigma(x_0, u(\cdot)) = y(\cdot)$ is defined by assigning to each initial condition $x_0 \in M$ and any admissible control $u \in \mathcal{U}$ the output of the system

$$y(\cdot) = (V_1(x(\cdot, x_0, u(\cdot))), \ldots, V_m(x(t, x_0, u(\cdot)))),$$

where $x(\cdot, x_0, u(\cdot))$ denotes the solution of $\dot{x}(t) = g_0(x(t)) + \sum_{j=1}^m u_j(t) g_j(x(t))$ starting at x_0. Now, two points x_1, $x_2 \in M$ are said to be *indistinguishable*, $x_1 \sim x_2$, if $\mathcal{R}_\Sigma(x_1, u(\cdot)) = \mathcal{R}_\Sigma(x_2, u(\cdot))$ for any $u(\cdot) \in \mathcal{U}$.

DEFINITION 3.1. *A system Σ is* observable *if for any x_1, $x_2 \in M$, one has that $x_1 \sim x_2 \Rightarrow x_1 = x_2$. Alternatively, for any $x_1 \neq x_2$, there exists an admissible control such that the output functions resulting from the initial conditions $x(0) = x_1$, respectively, $x(0) = x_2$, are different. The system is* locally observable *at x_0 if there exists a neighborhood $\mathcal{N}$ of x_0 such that this holds for points in $\mathcal{N}$.*

Denote by $\mathcal{H}$ the $\mathbb{R}$-linear space in $C^\omega(M)$ spanned by the functions of the form $\mathcal{L}_{X_1}\mathcal{L}_{X_2}\cdots\mathcal{L}_{X_s}V_j$, with $\{X_r\}_{r=1}^s \subset \{g_i \mid i = 0, 1, \ldots, m\}$, and $j \in \{1, \ldots, m\}$. Alternatively, we may take X_r to be arbitrary elements of the accessibility algebra corresponding to the vector fields $g_0, g_1, \ldots, g_m$. $\mathcal{H}$ is called the *observation space* of Σ. It follows from the analyticity assumption that the system is observable if and only if $\mathcal{H}$ distinguishes points in M, i.e., for every x_1, $x_2 \in M$ with $x_1 \neq x_2$, there exists $V \in \mathcal{H}$ such that $V(x_1) \neq V(x_2)$; cf. [14].

PROPOSITION 3.2 (see [13]). *Consider a nonlinear system Σ of the form (2.1), with observation space $\mathcal{H}$. Then, the observation space $\mathcal{H}^p$ of the prolongation Σ^p is given by $\mathcal{H}^p = \mathcal{H}^{\mathrm{C}} + \mathcal{H}^{\mathrm{V}}$, where $\mathcal{H}^{\mathrm{C}} = \{V^{\mathrm{C}} \mid V \in \mathcal{H}\}$ and $\mathcal{H}^{\mathrm{V}} = \{V^{\mathrm{V}} \mid V \in \mathcal{H}\}$.*

The following corollary is a modified statement of Corollary 3.3 in [13].

COROLLARY 3.3. *Assume the codistribution $d\mathcal{H}$ is of constant rank. Then the system Σ is (locally) observable if and only if its prolongation is (locally) observable.*

Proof. Following [14], Σ is locally observable if and only if $\mathrm{rk}(d\mathcal{H}) = \dim M$. In addition, the codistribution $d\mathcal{H}$ on M has constant rank if and only if the codistribution $d\mathcal{H}^p$ on TM has constant rank. Therefore, $\mathrm{rk}(d\mathcal{H}) = \dim M$ if and only if $\mathrm{rk}(d\mathcal{H}^p) = \dim TM$ if and only if Σ^p is locally observable. The statement regarding observability is proved as in Corollary 3.3 in [13]. ∎

Let us turn our attention to the observability properties of the gradient extension of a nonlinear system of the form (2.1). The following lemma will be most helpful.

LEMMA 3.4. *Let ∇ be a torsion-free affine connection on a manifold M, and let $\mathcal{G}^\nabla$ denote its Riemannian extension to T^*M. Then, for any vector fields X, $Y \in \mathfrak{X}(M)$, and any functions f, $g \in C^\omega(M)$, the following identities hold:*

(i) $(\mathrm{grad}_{\mathcal{G}^\nabla} V^X)(V^Y) = \{V^X : V^Y\}_{\mathcal{G}^\nabla} = V^{\langle X:Y\rangle} = -\mathcal{G}^\nabla(X^{\mathrm{C}}, Y^{\mathrm{C}})$;

(ii) $(\mathrm{grad}_{\mathcal{G}^\nabla} V^X)(f^{\mathrm{V}}) = (\mathrm{grad}_{\mathcal{G}^\nabla} f^{\mathrm{V}})(V^X) = \{V^X : f^{\mathrm{V}}\}_{\mathcal{G}^\nabla} = X(f)^{\mathrm{V}}$;

(iii) $(\mathrm{grad}_{\mathcal{G}^\nabla} f^{\mathrm{V}})(g^{\mathrm{V}}) = \{f^{\mathrm{V}} : g^{\mathrm{V}}\}_{\mathcal{G}^\nabla} = 0$.

Proof. The first equality in (i) is the definition of the Beltrami bracket associated with $\mathcal{G}^\nabla$. For the second one, we resort to the local expressions in (2.9) to compute

$$\begin{aligned}\{V^X : V^Y\}_{\mathcal{G}^\nabla} &= \left(p_a \frac{\partial X^a}{\partial x^b}, X^b\right) \begin{pmatrix} 0 & I \\ I & 2p_e\Gamma^e_{cd} \end{pmatrix} \left(p_a \frac{\partial Y^a}{\partial x^b}, Y^b\right)^T \\ &= p_a \left(\frac{\partial X^a}{\partial x^b} Y^b + \frac{\partial Y^a}{\partial x^b} X^b + 2\Gamma^a_{bc} X^b Y^c\right) = V^{\langle X:Y\rangle}\,.\end{aligned}$$

The third equality corresponds to the definition of $\mathcal{G}^\nabla$. The first and second equalities in (ii) follow again by definition. As for the third one, note that

$$\operatorname{grad}_{\mathcal{G}^\nabla} f^{\mathrm{V}}(V^X) = \frac{\partial f}{\partial x^a}\frac{\partial}{\partial p_a}\left(p_b X^b\right) = \frac{\partial f}{\partial x^a} X^a = X(f)^{\mathrm{V}}.$$

Finally, the equalities in (iii) are straightforward. ∎

Denote by S_0 the $\mathbb{R}$-linear space in $\mathfrak{X}(M)$ spanned by the vector fields of the form $\langle X_1 : \langle X_2 : \langle \cdots : \langle X_s : g_j\rangle\rangle \cdots \rangle\rangle$, with $\{X_r\}_{r=1}^s \subset \{g_i \mid i = 0, 1, \ldots, m\}$ and $j \in \{1, \ldots, m\}$. Alternatively, one can define S_0 as the smallest subspace of $\mathfrak{X}(M)$ such that (i) $g_1, \ldots, g_m \in S_0$ and (ii) if $X \in S_0$, then $\langle g_i : X\rangle \in S_0$ for all $i = 0, 1, \ldots, m$. We denote by $\mathcal{S}_0$ the distribution on M generated by the space S_0,

$$\mathcal{S}_0(x) = \operatorname{span}\{X(x) \mid X \in S_0\}\,, \quad x \in M\,. \tag{3.1}$$

PROPOSITION 3.5. *Consider a nonlinear system Σ of the form (2.1), with observation space $\mathcal{H}$. Let ∇ be a torsion-free affine connection on M. Then, the observation space $\mathcal{H}^e$ of the gradient extension Σ^e is given by $\mathcal{H}^e = V^{\mathcal{S}_0} + (\mathcal{H} + \mathfrak{h})^{\mathrm{V}}$, where $V^{\mathcal{S}_0} = \{V^X \mid X \in \mathcal{S}_0\}$ and $\mathfrak{h}$ is spanned by $\mathcal{L}_{X_1}\mathcal{L}_{X_2}\cdots\mathcal{L}_{X_s}\mathcal{L}_X V_j$, with X_r, $r = 1, \ldots, s$, equal to g_i, $i = 0, 1, \ldots, m$, $X \in \mathcal{S}_0$, and $j = 1, \ldots, m$.*

Proof. The observation space of the gradient extension of Σ is spanned by

$$\mathcal{L}_{X_1}\mathcal{L}_{X_2}\cdots\mathcal{L}_{X_s} V_j^{\mathrm{V}}\,, \quad \mathcal{L}_{X_1}\mathcal{L}_{X_2}\cdots\mathcal{L}_{X_s} V^{g_j}\,,$$

where X_r, $r = 1, \ldots, s$, is equal to $\operatorname{grad}_{\mathcal{G}^\nabla} V^{g_i}$, $\operatorname{grad}_{\mathcal{G}^\nabla} V_j^{\mathrm{V}}$, $i = 0, 1, \ldots, m$, $j = 1, \ldots, m$. Now, using Lemma 3.4, we have that

$$\begin{aligned} &\mathcal{L}_{\operatorname{grad}_{\mathcal{G}^\nabla} V^{g_i}} V_j^{\mathrm{V}} = (\mathcal{L}_{g_i} V_j)^{\mathrm{V}}\,, && \mathcal{L}_{\operatorname{grad}_{\mathcal{G}^\nabla} V^{g_i}} V^{g_j} = V^{\langle g_i : g_j\rangle}\,, \\ &\mathcal{L}_{\operatorname{grad}_{\mathcal{G}^\nabla} V_j^{\mathrm{V}}} V_k^{\mathrm{V}} = 0\,, && \mathcal{L}_{\operatorname{grad}_{\mathcal{G}^\nabla} V_j^{\mathrm{V}}} V^{g_k} = (\mathcal{L}_{g_k} V_j)^{\mathrm{V}}\,, \end{aligned}$$

with $i = 0, 1, \ldots, m$ and $j, k = 1, \ldots, m$. Considering the next step of Lie derivatives yields

$$\begin{aligned} &\mathcal{L}_{\operatorname{grad}_{\mathcal{G}^\nabla} V^{g_h}} V^{\langle g_i : g_j\rangle} = V^{\langle g_h : \langle g_i : g_j\rangle\rangle}\,, && \mathcal{L}_{\operatorname{grad}_{\mathcal{G}^\nabla} V^{g_h}} (\mathcal{L}_{g_i} V_j)^{\mathrm{V}} = (\mathcal{L}_{g_h}\mathcal{L}_{g_i} V_j)^{\mathrm{V}}\,, \\ &\mathcal{L}_{\operatorname{grad}_{\mathcal{G}^\nabla} V_k^{\mathrm{V}}} V^{\langle g_i : g_j\rangle} = \left(\mathcal{L}_{\langle g_i : g_j\rangle} V_k\right)^{\mathrm{V}}\,, && \mathcal{L}_{\operatorname{grad}_{\mathcal{G}^\nabla} V_k^{\mathrm{V}}} (\mathcal{L}_{g_i} V_j)^{\mathrm{V}} = 0\,, \end{aligned}$$

with $h = 0, 1, \ldots, m$. Further iterating this process, we get to the desired result. ∎

COROLLARY 3.6. *Consider a nonlinear system Σ of the form (2.1), with observation space $\mathcal{H}$. Assume the codistribution $d\mathcal{H}$ is of constant rank. Let ∇ be a torsion-free affine connection on M and further assume that the distribution $\mathcal{S}_0$ is full-rank. Then, that Σ is (locally) observable implies that Σ^e is (locally) observable.*

Proof. Since the codistribution $d\mathcal{H}$ has constant rank, Σ is locally observable if and only if $\dim d\mathcal{H}(x) = \dim M$. Since $\mathcal{S}_0$ is full-rank, it is clear that Σ locally

observable implies that $\mathcal{H}^e$ has constant maximal rank, and therefore Σ^e is locally observable. With respect to observability, let (x_1, p_1), $(x_2, p_2) \in T^*M$, and assume that $V^e(x_1, p_1) = V^e(x_2, p_2)$ for all $V^e \in \mathcal{H}^e$. Since $\mathcal{H}^{\mathrm{v}} \subset \mathcal{H}^e$, this yields $V(x_1) = V(x_2)$ for any $V \in \mathcal{H}$. So, under observability of Σ, we conclude that $x_1 = x_2 = x$. Then, we have that $V^X(x, p_1) = V^X(x, p_2)$ for all $X \in S_0$, which finally implies that $p_1 = p_2$. □

4. Externally equivalent systems. In this section we introduce the notion of (weakly) externally equivalent systems, which will be instrumental in the statement of the main result in section 5. Consider two nonlinear systems $\alpha = 1, 2$, of the form

$$\Sigma^\alpha : \begin{cases} \dot{x}^\alpha = g_0^\alpha(x^\alpha) + \displaystyle\sum_{j=1}^{m} u_j g_j^\alpha(x^\alpha), \quad x^\alpha \in M^\alpha, \\ y_j = V_j^\alpha(x^\alpha), \quad j = 1, \dots, m, \ u = (u_1, \dots, u_m) \in U \subset \mathbb{R}^m. \end{cases}$$

Denote by $\mathcal{H}^\alpha$, $\alpha = 1, 2$, the associated observation spaces. Take a function $H^1 \in \mathcal{H}^1$, $H^1 = \mathcal{L}_{X_1} \cdots \mathcal{L}_{X_s} V_j^1$, with $X_r = g_{i_r}^1$, $i_r \in \{0, 1, \dots, m\}$, $r = 1, \dots, s$, and $j \in \{1, \dots, m\}$. Consider the function in $\mathcal{H}^2$ defined by $H^2 = \mathcal{L}_{Y_1} \cdots \mathcal{L}_{Y_s} V_j^2$, with $Y_r = g_{i_r}^2$, $r = 1, \dots, s$. Then we say that H^1 and H^2 formally *correspond* to each other. This notion is useful in defining the concept of *weakly externally equivalent* systems.

DEFINITION 4.1. *The systems Σ^1 and Σ^2 are weakly externally equivalent if and only if for all $x^1 \in M^1$, there exists $x^2 \in M^2$ such that $H^1(x^1) = H^2(x^2)$ for all corresponding $H^1 \in \mathcal{H}^1$, $H^2 \in \mathcal{H}^2$, and reciprocally, for all $x^2 \in M^2$, there exists $x^1 \in M^1$ such that $H^1(x^1) = H^2(x^2)$ for all corresponding $H^1 \in \mathcal{H}^1$, $H^2 \in \mathcal{H}^2$.*

DEFINITION 4.2. *The systems Σ^1 and Σ^2 are externally equivalent if and only if for all $x^1 \in M^1$, there exists $x^2 \in M^2$ such that the input-output maps corresponding to x^1 and x^2 coincide, i.e., $\mathcal{R}_{\Sigma^1}(x^1, u(\cdot)) = \mathcal{R}_{\Sigma^2}(x^2, u(\cdot))$ for all $u(\cdot) \in \mathcal{U}$, and reciprocally, for all $x^2 \in M^2$, there exists $x^1 \in M^1$ such that $\mathcal{R}_{\Sigma^1}(x^1, u(\cdot)) = \mathcal{R}_{\Sigma^2}(x^2, u(\cdot))$ for all $u(\cdot) \in \mathcal{U}$.*

Equivalently, Σ^1 and Σ^2 are externally equivalent if and only if their behaviors are equal. Clearly, if two systems are externally equivalent, then they are weakly externally equivalent.

PROPOSITION 4.3. *Assume that Σ^1 and Σ^2 are weakly externally equivalent and observable and that the codistributions $d\mathcal{H}^\alpha$, $\alpha = 1, 2$, have constant rank. Then there exists a unique diffeomorphism $\varphi : M^1 \to M^2$ with $\varphi^*(\mathcal{H}^2) = \mathcal{H}^1$.*

Proof. Let $x^1 \in M^1$. By definition, there exists $x^2 \in M^2$ such that $H^1(x^1) = H^2(x^2)$ for all corresponding $H^1 \in \mathcal{H}^1$, $H^2 \in \mathcal{H}^2$. Since $\mathcal{H}^2$ distinguishes points in M^2, it follows that x^2 is unique. Define $\varphi : M^1 \to M^2$, $\varphi(x^1) = x^2$. Using $\dim d\mathcal{H}^2 = \dim M^2$ and the inverse function theorem, it follows that φ is smooth. Indeed, for each $x^2 \in M^2$, there exists a neighborhood V of M^2 at x_2 and $\dim M^2$ independent functions $H_1^2, \dots, H_{\dim M^2}^2$ on V such that φ is given by

$$x^2 = (H_1^2, \dots, H_{\dim M^2}^2)^{-1}(H_1^1, \dots, H_{\dim M^2}^1)(x^1).$$

Analogously, we can construct the inverse mapping $\varphi^{-1} : M^2 \to M^1$, making use of the fact that Σ_1 is observable, which concludes the proof. □

COROLLARY 4.4. *Let the systems Σ^1 and Σ^2 be observable and the codistributions $d\mathcal{H}^\alpha$, $\alpha = 1, 2$, have constant rank. Then Σ^1 and Σ^2 are weakly externally equivalent if and only if they are externally equivalent.*

Proof. We already know that if the systems are externally equivalent, then they are weakly externally equivalent. Conversely, assume that Σ^1 and Σ^2 are weakly externally equivalent. From Proposition 4.3, we have that there exists a diffeomorphism $\varphi : M^1 \to M^2$ with $\varphi^*(\mathcal{H}^2) = \mathcal{H}^1$. Using this latter fact, and since the vector fields g_0^i, g_j^i are determined by their action as derivations on $\mathcal{H}^\alpha$, $\alpha = 1, 2$, we conclude that $\varphi_* g_0^1 = g_0^2$, $\varphi_* g_j^1 = g_j^2$, $j = 1, \dots, m$. ∎

Remark 4.5. The map φ in the previous proof is called a *state-space diffeomorphism.*

5. Gradient realization of a nonlinear control system. This section contains the main result of the paper. Under certain technical conditions, Theorem 5.4 characterizes when a nonlinear control systems admits a gradient realization. Before stating this result, we need to introduce the novel notion of *compatibility* between a nonlinear system and an affine connection.

DEFINITION 5.1 (compatibility). *Let ∇ be an affine connection on M. A nonlinear control system Σ of the form* (2.1) *is compatible with ∇ if and only if the following two conditions hold:*

(a) *For all vector fields $X_1, \dots, X_{s_1}$, $Y_1, \dots, Y_{s_2} \in \{g_0, g_1, \dots, g_m\}$, and all indexes $j, k = 1, \dots, m$,*

$$\mathcal{L}_{\langle X_1 : \langle X_2 : \langle \cdots : \langle X_{s_1} : g_j \rangle \rangle \cdots \rangle \rangle} \left[\mathcal{L}_{Y_1} \mathcal{L}_{Y_2} \cdots \mathcal{L}_{Y_{s_2}} V_k \right] = \mathcal{L}_{\langle Y_1 : \langle Y_2 : \langle \cdots : \langle Y_{s_2} : g_k \rangle \rangle \cdots \rangle \rangle} \left[\mathcal{L}_{X_1} \mathcal{L}_{X_2} \cdots \mathcal{L}_{X_{s_1}} V_j \right].$$

(b) *For all vector fields $X_1, \dots, X_{s_1}$, $Y_1, \dots, Y_{s_2}$, $Z_1, \dots, Z_{s_3} \in \{g_0, g_1, \dots, g_m\}$, and all indexes $j, k, l = 1, \dots, m$,*

$$\mathcal{L}_{\langle \langle X_1 : \langle X_2 : \langle \cdots : \langle X_{s_1} : g_j \rangle \rangle \cdots \rangle \rangle : \langle Y_1 : \langle Y_2 : \langle \cdots : \langle Y_{s_2} : g_k \rangle \rangle \cdots \rangle \rangle \rangle} [\mathcal{L}_{Z_1} \mathcal{L}_{Z_2} \cdots \mathcal{L}_{Z_{s_3}} V_l] = \mathcal{L}_{\langle Z_1 : \langle Z_2 : \langle \cdots : \langle Z_{s_3} : g_l \rangle \rangle \cdots \rangle \rangle} [\mathcal{L}_{\langle X_1 : \langle X_2 : \langle \cdots : \langle X_{s_1} : g_j \rangle \rangle \cdots \rangle \rangle} [\mathcal{L}_{Y_1} \mathcal{L}_{Y_2} \cdots \mathcal{L}_{Y_{s_2}} V_k]].$$

Remark 5.2. In case the distribution $\mathcal{S}_0$ (cf. (3.1)) is full-rank, note that property (b) in the above definition implies property (a) up to a constant on each connected component of M. To see this, one can use the symmetry of the symmetric product to deduce from (b) that

$$\mathcal{L}_{\langle Z_1 : \langle Z_2 : \langle \cdots : \langle Z_{s_3} : g_l \rangle \rangle \cdots \rangle \rangle} [\mathcal{L}_{\langle X_1 : \langle X_2 : \langle \cdots : \langle X_{s_1} : g_j \rangle \rangle \cdots \rangle \rangle} [\mathcal{L}_{Y_1} \mathcal{L}_{Y_2} \cdots \mathcal{L}_{Y_{s_2}} V_k]] = \mathcal{L}_{\langle Z_1 : \langle Z_2 : \langle \cdots : \langle Z_{s_3} : g_l \rangle \rangle \cdots \rangle \rangle} [\mathcal{L}_{\langle Y_1 : \langle Y_2 : \langle \cdots : \langle Y_{s_2} : g_k \rangle \rangle \cdots \rangle \rangle} [\mathcal{L}_{X_1} \mathcal{L}_{X_2} \cdots \mathcal{L}_{X_{s_1}} V_j]].$$

Now, one concludes the result from the full-rankness of $\mathcal{S}_0$. Another interesting observation in this case is that the checkability of the compatibility condition can be performed taking a basis of vector fields in S_0, as we discuss later in Lemma 8.1.

Remark 5.3. Note that a locally gradient control system of the form (2.2) is compatible with the Levi-Civita connection associated with the pseudo-Riemannian metric $\mathcal{G}$. Indeed, let $\langle \cdot : \cdot \rangle$, $\{\cdot : \cdot\}$ denote, respectively, the symmetric product and the Beltrami bracket corresponding to $\nabla^{\mathcal{G}}$ and $\mathcal{G}$. Take $X_{r_1} = \operatorname{grad} V_{\alpha_{r_1}}$, $Y_{r_2} = \operatorname{grad} V_{\beta_{r_2}}$, $Z_{r_3} = \operatorname{grad} V_{\gamma_{r_3}}$, $r_i \in \{1, \dots, s_i\}$ (which can always be written at least locally); then

$$\begin{aligned}
&\mathcal{L}_{\langle X_1 : \langle X_2 : \langle \cdots : \langle X_{s_1} : g_j \rangle \rangle \cdots \rangle \rangle} \left[\mathcal{L}_{Y_1} \mathcal{L}_{Y_2} \cdots \mathcal{L}_{Y_{s_2}} V_k \right] \\
&\quad = \mathcal{L}_{\operatorname{grad}\{V_{\alpha_1} : \{V_{\alpha_2} : \{\cdots : \{V_{\alpha_{s_1}} : V_j\}\} \cdots\}\}} \left[\{V_{\beta_1} : \{V_{\beta_2} : \{\cdots : \{V_{\beta_{s_2}} : V_k\}\} \cdots\}\} \right] \\
&\quad = \mathcal{L}_{\operatorname{grad}\{V_{\beta_1} : \{V_{\beta_2} : \{\cdots : \{V_{\beta_{s_2}} : V_k\}\} \cdots\}\}} \left[\{V_{\alpha_1} : \{V_{\alpha_2} : \{\cdots : \{V_{\alpha_{s_1}} : V_j\}\} \cdots\}\} \right] \\
&\quad = \mathcal{L}_{\langle Y_1 : \langle Y_2 : \langle \cdots : \langle Y_{s_2} : g_k \rangle \rangle \cdots \rangle \rangle} \left[\mathcal{L}_{X_1} \mathcal{L}_{X_2} \cdots \mathcal{L}_{X_{s_1}} V_j \right]
\end{aligned}$$

and

$$\begin{aligned}
&\mathcal{L}_{\langle\langle X_1:\langle X_2:\langle\cdots:\langle X_{s_1}:g_j\rangle\rangle\cdots\rangle\rangle:\langle Y_1:\langle Y_2:\langle\cdots:\langle Y_{s_1}:g_k\rangle\rangle\cdots\rangle\rangle\rangle} \left[\mathcal{L}_{Z_1}\mathcal{L}_{Z_2}\cdots\mathcal{L}_{Z_{s_3}}V_l\right] \\
&\quad = \mathcal{L}_{\mathrm{grad}\{\{V_{\alpha_1}:\{V_{\alpha_2}:\{\cdots:\{V_{\alpha_{s_1}}:V_j\}\}\cdots\}\}:\{V_{\beta_1}:\{V_{\beta_2}:\{\cdots:\{V_{\beta_{s_2}}:V_k\}\}\cdots\}\}\}} \\
&\left[\{V_{\gamma_1}:\{V_{\gamma_2}:\{\cdots:\{V_{\gamma_{s_3}}:V_l\}\}\cdots\}\}\right] \\
&\quad = \mathcal{L}_{\mathrm{grad}\{V_{\gamma_1}:\{V_{\gamma_2}:\{\cdots:\{V_{\gamma_{s_3}}:V_l\}\}\cdots\}\}} \\
&\left[\{\{V_{\alpha_1}:\{V_{\alpha_2}:\{\cdots:\{V_{\alpha_{s_1}}:V_j\}\}\cdots\}\}:\{V_{\beta_1}:\{V_{\beta_2}:\{\cdots:\{V_{\beta_{s_2}}:V_k\}\}\cdots\}\}\}\right] \\
&\quad = \mathcal{L}_{\langle Z_1:\langle Z_2:\langle\cdots:\langle Z_{s_3}:g_l\rangle\rangle\cdots\rangle\rangle}[\mathcal{L}_{\langle X_1:\langle X_2:\langle\cdots:\langle X_{s_1}:g_j\rangle\rangle\cdots\rangle\rangle}[\mathcal{L}_{Y_1}\mathcal{L}_{Y_2}\cdots\mathcal{L}_{Y_{s_2}}V_k]]
\end{aligned}$$

as claimed.

Now, we come to the main result of the paper.

THEOREM 5.4. *Let Σ be a nonlinear control system of the form (2.1). Let ∇ be a torsion-free affine connection defined on the state manifold M. Assume that Σ is observable with $\dim d\mathcal{H}$ constant, compatible with ∇, and that the distribution $\mathcal{S}_0$ is full-rank. Then, Σ is a locally gradient control system with respect to a pseudo-metric whose Levi-Civita connection is ∇ if and only if its prolonged system Σ^p and its gradient extension Σ^e are weakly externally equivalent.*

Proof. Consider a locally gradient control system Σ on $(M,\mathcal{G})$ (cf. (2.2)), together with its prolongation Σ^p on TM and its gradient extension Σ^e on T^*M. Recall that in the induced bundle coordinates (x^a,v^a) on TM, (x^a,p_a) on T^*M, the musical isomorphisms associated with $\mathcal{G}$ read $\flat_{\mathcal{G}}(x^a,v^a)=(x^a,\mathcal{G}_{ab}v^b)$ and $\sharp_{\mathcal{G}}(x^a,p_a)=(x^a,\mathcal{G}^{ab}p_b)$. We are going to show that $\flat_{\mathcal{G}}$ is actually an isomorphism between the prolongation and the gradient extension, i.e., we will prove that $\flat_{\mathcal{G}}(x_p(\cdot))=x_e(\cdot)$ along the solutions of (2.7) and (2.11), respectively. This will be a consequence of the following equalities:

$$\begin{aligned}
&(\flat_{\mathcal{G}})_* g_i^{\mathrm{C}} = \mathrm{grad}_{\mathcal{G}^\nabla} V^{g_i}\circ\flat_{\mathcal{G}}\,, && V^{g_j}\circ\flat_{\mathcal{G}} = V_j^{\mathrm{C}}\,, \\
&(\flat_{\mathcal{G}})_* g_j^{\mathrm{V}} = \mathrm{grad}_{\mathcal{G}^\nabla} V_j^{\mathrm{V}}\circ\flat_{\mathcal{G}}\,, && V_j^{\mathrm{V}}\circ\flat_{\mathcal{G}} = V_j^{\mathrm{V}}
\end{aligned} \tag{5.1}$$

for all $i=0,1,\ldots,m$, $j=1,\ldots,m$. In order to show (5.1), we will make use of the following identities:

$$(\flat_{\mathcal{G}})_*\left(\frac{\partial}{\partial x^a}\right) = \frac{\partial}{\partial x^a} + \frac{\partial\mathcal{G}_{cb}}{\partial x^a}v^b\frac{\partial}{\partial p_c}\,, \quad (\flat_{\mathcal{G}})_*\left(\frac{\partial}{\partial v^a}\right) = \mathcal{G}_{ab}\frac{\partial}{\partial p_b}\,.$$

Let $g\in\mathfrak{X}(M)$. In local coordinates, $g=g^a\partial/\partial x^a$. Using (2.5), we get

$$(\flat_{\mathcal{G}})_*(g^{\mathrm{C}}) = g^a\frac{\partial}{\partial x^a} + \left\{g^c\frac{\partial\mathcal{G}_{ab}}{\partial x^c} + \mathcal{G}_{ac}\frac{\partial g^c}{\partial x^b}\right\}v^b\frac{\partial}{\partial p_a}\,.$$

On the other hand, we have that

$$\mathrm{grad}_{\mathcal{G}^\nabla} V^g\circ\flat_{\mathcal{G}} = g^a\frac{\partial}{\partial x^a} + \left\{\mathcal{G}_{bc}\frac{\partial g^c}{\partial x^a} + 2\mathcal{G}_{bc}\Gamma^c_{ad}g^d\right\}v^b\frac{\partial}{\partial p_a}\,.$$

Now, suppose that g is a locally gradient vector field. In local coordinates, this means that $\mathcal{G}_{ac}g^c=\partial V/\partial x^a$, for a certain function V, which in turn implies that $\partial\{\mathcal{G}_{ac}g^c\}/\partial x^b=\partial\{\mathcal{G}_{bc}g^c\}/\partial x^a$, that is,

$$\mathcal{G}_{ac}\frac{\partial g^c}{\partial x^b} = \frac{\partial\mathcal{G}_{bc}}{\partial x^a}g^c + \mathcal{G}_{bc}\frac{\partial g^c}{\partial x^a} - \frac{\partial\mathcal{G}_{ac}}{\partial x^b}g^c\,.$$

Substituting into the above expression for $(\flat_{\mathcal{G}})_*(g^{\mathrm{C}})$,

$$\begin{aligned}(\flat_{\mathcal{G}})_*(g^{\mathrm{C}}) &= g^a\frac{\partial}{\partial x^a}+\left\{g^c\frac{\partial \mathcal{G}_{ab}}{\partial x^c}+\frac{\partial \mathcal{G}_{bc}}{\partial x^a}g^c+\mathcal{G}_{bc}\frac{\partial g^c}{\partial x^a}-\frac{\partial \mathcal{G}_{ac}}{\partial x^b}g^c\right\}v^b\frac{\partial}{\partial p_a}\\ &= g^a\frac{\partial}{\partial x^a}+\left\{g^c\left(\frac{\partial \mathcal{G}_{ab}}{\partial x^c}+\frac{\partial \mathcal{G}_{bc}}{\partial x^a}-\frac{\partial \mathcal{G}_{ac}}{\partial x^b}\right)+\mathcal{G}_{bc}\frac{\partial g^c}{\partial x^a}\right\}v^b\frac{\partial}{\partial p_a}\\ &= g^a\frac{\partial}{\partial x^a}+\left\{2g^c\mathcal{G}_{bd}\Gamma^d_{ac}+\mathcal{G}_{bc}\frac{\partial g^c}{\partial x^a}\right\}v^b\frac{\partial}{\partial p_a}=\mathrm{grad}_{\mathcal{G}^\nabla}V^g\circ\flat_{\mathcal{G}}\,.\end{aligned}$$

Therefore, the first equality in (5.1) holds for every $i=0,1,\dots,m$. The equality $(\flat_{\mathcal{G}})_* g_j^{\mathrm{V}}=\mathrm{grad}_{\mathcal{G}^\nabla}V_j^{\mathrm{V}}\circ\flat_{\mathcal{G}}$, $j=1,\dots,m$, follows by considering (2.6) and the fact that the vector fields g_j are gradient by hypothesis,

$$(\flat_{\mathcal{G}})_*(g^{\mathrm{V}})=\mathcal{G}_{ab}g^b\frac{\partial}{\partial p_a}=\frac{\partial V}{\partial x^a}\frac{\partial}{\partial p_a}=\mathrm{grad}_{\mathcal{G}^\nabla}V^{\mathrm{V}}\circ\flat_{\mathcal{G}}\,.$$

As for $V^{g_j}\circ\flat_{\mathcal{G}}=V_j^{\mathrm{C}}$, for each $v\in T_xM$, we compute $V^{g_j}\circ\flat_{\mathcal{G}}(v)=\mathcal{G}_{ab}v^bg_j^a=\partial V_j/\partial x^b\cdot v^b=\langle dV_j,v\rangle=V_j^{\mathrm{C}}(v)$, where, with a slight abuse of notation, we have used the bracket $\langle\cdot,\cdot\rangle$ to denote the contraction between a covector and a vector. In the remainder of the paper, the intended use of $\langle\,.\,,\,.\,\rangle$ should be clear from the context. The last equality follows trivially. Consequently, the prolongation and the gradient extension of a nonlinear system Σ which is itself gradient are externally equivalent, in particular weakly externally equivalent systems.

To prove the converse implication, we need some intermediate steps that we describe in what follows. □

LEMMA 5.5. *Let Σ be a nonlinear system of the form* (2.1)*. Under the hypothesis of Theorem* 5.4*, assume that the prolongation Σ^p and the gradient extension Σ^e are weakly externally equivalent. Then there exists a unique diffeomorphism $\varphi:TM\to T^*M$ such that*

$$\begin{aligned}&(\varphi)_*g_i^{\mathrm{C}}=\mathrm{grad}_{\mathcal{G}^\nabla}V^{g_i}\circ\varphi\,, && V^{g_j}\circ\varphi=V_j^{\mathrm{C}}\,,\\ &(\varphi)_*g_j^{\mathrm{V}}=\mathrm{grad}_{\mathcal{G}^\nabla}V_j^{\mathrm{V}}\circ\varphi\,, && V_j^{\mathrm{V}}\circ\varphi=V_j^{\mathrm{V}}\end{aligned}\tag{5.2}$$

for all $i=0,1,\dots,m$, $j=1,\dots,m$. Moreover, φ is a bundle morphism over the identity $\mathrm{Id}_M:M\to M$, i.e., in natural coordinates $\varphi(x,v)=(x,\phi(x,v))$, for certain map $\phi:T_xM\to T_x^*M$, $x\in M$.

Proof. By Proposition 3.2 and Corollary 3.6, we have that both the prolongation and the gradient extension are observable systems. Since they are also weakly externally equivalent by assumption, Corollary 4.4 ensures that there exists a unique diffeomorphism $\varphi:TM\to T^*M$ verifying (5.2). Applying now Corollary 4.4 to $\Sigma^1=\Sigma=\Sigma^2$, we deduce that there exists a unique diffeomorphism from M to M mapping the original nonlinear system to itself, namely, the identity mapping. Using uniqueness and the fact that φ satisfies (5.2), it then follows that φ is of the form $\varphi(x,v)=(x,\phi(x,v))$, for certain map $\phi:T_xM\to T_x^*M$, $x\in M$. □

LEMMA 5.6. *Under the same assumptions as in Lemma* 5.5*, there exists a unique pseudo-Riemannian metric $\mathcal{G}$ on M such that $\flat_{\mathcal{G}}=\varphi$, i.e., $\flat_{\mathcal{G}}(v)=\phi(x,v)$ for all $v\in T_xM$.*

Proof. It follows from $V^{g_j}\circ\varphi=V_j^{\mathrm{C}}$ (cf. (5.2)) and the structure of the diffeomorphism φ that

$$\langle\phi(x,v),g_j(x)\rangle=\langle dV_j(x),v\rangle\quad\forall v\in T_xM\,,\ j=1,\dots,m\,.$$

Furthermore, from $(\varphi)_* g_i^{\mathrm{C}} = \operatorname{grad} V^{g_i} \circ \varphi$ (see (5.2)), it follows that

$$\mathcal{L}_{\operatorname{grad} V^{g_i}} V^{g_j} \circ \varphi = \mathcal{L}_{g_i^{\mathrm{c}}} V_j^{\mathrm{C}}, \quad i = 0, 1, \ldots, m, \; j = 1, \ldots, m.$$

Using now Lemma 3.4(i), we get $\langle \phi(x, v), \langle g_i : g_j \rangle(x) \rangle = \langle d\left(\mathcal{L}_{g_i} V_j\right)(x), v \rangle$. In general for all $v \in T_x M$,

$$\begin{aligned} &\langle \phi(x, v), \langle X_1 : \langle X_2 : \langle X_3, \cdots : \langle X_s : g_j \rangle \rangle \cdots \rangle \rangle(x) \rangle \\ &\quad = \langle d\left(\mathcal{L}_{X_1} \mathcal{L}_{X_2} \cdots \mathcal{L}_{X_s} V_j\right)(x), v \rangle, \end{aligned} \tag{5.3}$$

with the X_r, $r = 1, \ldots, s$, equal to some g_i, $i = 0, 1, \ldots, m$. Since the right-hand side of this equation is linear in v and the distribution generated by the space S_0 is full-rank by hypothesis, it follows that for each $x \in M$ there exists a unique matrix $\mathcal{G}(x)$ such that $\phi(x, v) = \mathcal{G}(x) v$. Since φ is a diffeomorphism, $\mathcal{G}(x)$ is nonsingular for every x and depends smoothly on the base point. Consider the adjoint mapping of φ, $\varphi^T : TM \to T^*M$, defined by $\langle \varphi(v), w \rangle = \langle v, \varphi^T(w) \rangle$, $v, w \in T_x M$, $x \in M$. Then, $\varphi^T(x, v) = (x, \mathcal{G}^T(x) v)$. It follows from (5.3) that $\mathcal{G}(x)$ satisfies

$$\varphi^T(\langle X_1 : \langle X_2 : \langle X_3, \cdots : \langle X_s : g_j \rangle \rangle \cdots \rangle \rangle(x)) = d\left(\mathcal{L}_{X_1} \mathcal{L}_{X_2} \cdots \mathcal{L}_{X_s} V_j\right)(x), \tag{5.4}$$

with the X_r as above. Let us see now that $\mathcal{G}(x) = \mathcal{G}^T(x)$. Note that in local coordinates $(\varphi)_* g_j^{\mathrm{V}} = \operatorname{grad}_{\mathcal{G}^\nabla} V_j^{\mathrm{V}} \circ \varphi$ yields

$$\begin{pmatrix} I & 0 \\ \frac{\partial}{\partial x}\left(\mathcal{G}(x) v\right) & \mathcal{G}(x) \end{pmatrix} \begin{pmatrix} 0 \\ g_j(x) \end{pmatrix} = \begin{pmatrix} 0 \\ \left(\frac{\partial V_j}{\partial x}\right)^T (x) \end{pmatrix}$$

or, equivalently, $\mathcal{G}(x) g_j(x) = \left(\partial V_j / \partial x\right)^T (x)$, $j = 1, \ldots, m$, which in intrinsic terms, can be written as $\varphi(g_j) = dV_j$. Now,

$$\begin{aligned} &\langle \varphi\left(\langle X_1 : \langle X_2 : \langle X_3, \cdots : \langle X_{s_1} : g_j \rangle \rangle \cdots \rangle \rangle\right), \langle Y_1 : \langle Y_2 : \langle Y_3, \cdots : \langle Y_{s_2} : g_k \rangle \rangle \cdots \rangle \rangle \rangle \\ &= \langle \langle X_1 : \langle X_2 : \langle X_3, \cdots : \langle X_{s_1} : g_j \rangle \rangle \cdots \rangle \rangle, \varphi^T\left(\langle Y_1 : \langle Y_2 : \langle Y_3, \cdots : \langle Y_{s_2} : g_k \rangle \rangle \cdots \rangle \rangle\right) \rangle. \end{aligned}$$

Using (5.4), the latter is equal to

$$\begin{aligned} &\langle \langle X_1 : \langle X_2 : \langle X_3, \cdots : \langle X_{s_1} : g_j \rangle \rangle \cdots \rangle \rangle, d\mathcal{L}_{Y_1} \mathcal{L}_{Y_2} \cdots \mathcal{L}_{Y_{s_2}} V_k \rangle \\ &\quad = \langle d\mathcal{L}_{X_1} \mathcal{L}_{X_2} \cdots \mathcal{L}_{X_{s_1}} V_j, \langle Y_1 : \langle Y_2 : \langle \cdots : \langle Y_{s_2} : g_k \rangle \rangle \cdots \rangle \rangle \rangle, \end{aligned}$$

where in the last equality we have used the property (a) of the compatibility definition between the nonlinear system Σ and the affine connection ∇. Finally,

$$\begin{aligned} &\langle \varphi\left(\langle X_1 : \langle X_2 : \langle X_3, \cdots : \langle X_{s_1} : g_j \rangle \rangle \cdots \rangle \rangle\right), \langle Y_1 : \langle Y_2 : \langle Y_3, \cdots : \langle Y_{s_2} : g_k \rangle \rangle \cdots \rangle \rangle \rangle \\ &\quad = \langle \varphi^T\left(\langle X_1 : \langle X_2 : \langle X_3, \cdots : \langle X_{s_1} : g_j \rangle \rangle \cdots \rangle \rangle\right), \langle Y_1 : \langle Y_2 : \langle \cdots : \langle Y_{s_2} : g_k \rangle \rangle \cdots \rangle \rangle \rangle. \end{aligned}$$

By the assumption on the full-rankness of the distribution $\mathcal{S}_0$, we conclude that

$$\begin{aligned} &\varphi\left(\langle X_1 : \langle X_2 : \langle X_3, \cdots : \langle X_{s_1} : g_j \rangle \rangle \cdots \rangle \rangle\right) \\ &\quad = \varphi^T\left(\langle X_1 : \langle X_2 : \langle X_3, \cdots : \langle X_{s_1} : g_j \rangle \rangle \cdots \rangle \rangle\right), \end{aligned}$$

which in turn implies that $\varphi(x) = \varphi^T(x)$, i.e., the matrix $\mathcal{G}(x)$ is symmetric. □

LEMMA 5.7. *Under the same assumptions as in Lemma* 5.5*, the torsion-free affine connection* ∇ *is the Levi-Civita connection corresponding to the pseudo-Riemannian metric* $\mathcal{G}$*.*

Proof. First of all, note that

$$
\begin{aligned}
(5.5)\quad & \langle V^{\langle\langle X_1:\langle X_2:\langle\cdots:\langle X_s:g_j\rangle\rangle\cdots\rangle\rangle:\langle Y_1:\langle Y_2:\langle\cdots:\langle Y_{s_2}:g_k\rangle\rangle\cdots\rangle\rangle\rangle}, d(\mathcal{L}_{Z_1}\mathcal{L}_{Z_2}\cdots\mathcal{L}_{Z_{s_3}}V_l)\rangle \\
&= \mathcal{L}_{\langle\langle X_1:\langle X_2:\langle\cdots:\langle X_s:g_j\rangle\rangle\cdots\rangle\rangle:\langle Y_1:\langle Y_2:\langle\cdots:\langle Y_{s_2}:g_k\rangle\rangle\cdots\rangle\rangle\rangle}\left[\mathcal{L}_{Z_1}\mathcal{L}_{Z_2}\cdots\mathcal{L}_{Z_{s_3}}V_l\right] \\
&= \mathcal{L}_{\langle Z_1:\langle Z_2:\langle\cdots:\langle Z_{s_3}:g_l\rangle\rangle\cdots\rangle\rangle}\left[\mathcal{L}_{\langle X_1:\langle X_2:\langle\cdots:\langle X_s:g_j\rangle\rangle\cdots\rangle\rangle}\left[\mathcal{L}_{Y_1}\mathcal{L}_{Y_2}\cdots\mathcal{L}_{Y_{s_2}}V_k\right]\right] \\
&= \langle\left(\mathcal{L}_{\langle X_1:\langle X_2:\langle\cdots:\langle X_s:g_j\rangle\rangle\cdots\rangle\rangle}\left[\mathcal{L}_{Y_1}\mathcal{L}_{Y_2}\cdots\mathcal{L}_{Y_{s_2}}V_k\right]\right)^{\mathrm{C}}\circ\varphi^{-1}, \\
&\quad d(\mathcal{L}_{Z_1}\mathcal{L}_{Z_2}\cdots\mathcal{L}_{Z_{s_3}}V_l)\rangle,
\end{aligned}
$$

where in the second equality we have used the property (b) of the compatibility definition between the nonlinear system Σ and the affine connection ∇. Since the observation space of the nonlinear system Σ is generated by the functions of the form $\mathcal{L}_{Z_1}\mathcal{L}_{Z_2}\cdots\mathcal{L}_{Z_{s_3}}V_l$, and Σ is observable by hypothesis, we conclude that

$$
\begin{aligned}
&V^{\langle\langle X_1:\langle X_2:\langle\cdots:\langle X_s:g_j\rangle\rangle\cdots\rangle\rangle:\langle Y_1:\langle Y_2:\langle\cdots:\langle Y_{s_2}:g_k\rangle\rangle\cdots\rangle\rangle\rangle}\circ\varphi \\
&\quad = \left(\mathcal{L}_{\langle X_1:\langle X_2:\langle\cdots:\langle X_s:g_j\rangle\rangle\cdots\rangle\rangle}\left[\mathcal{L}_{Y_1}\mathcal{L}_{Y_2}\cdots\mathcal{L}_{Y_{s_2}}V_k\right]\right)^{\mathrm{C}}.
\end{aligned}
$$

Given the structure of the mapping φ (cf. Lemmas 5.5 and 5.6) and (5.4), this equality can be rewritten as

$$
\begin{aligned}
&\mathcal{G}(\langle\langle X_1:\langle X_2:\langle\cdots:\langle X_s:g_j\rangle\rangle\cdots\rangle\rangle:\langle Y_1:\langle Y_2:\langle\cdots:\langle Y_{s_2}:g_k\rangle\rangle\cdots\rangle\rangle\rangle,\cdot) \\
&\quad = d\langle\varphi(\langle Y_1:\langle Y_2:\langle\cdots:\langle Y_{s_2}:g_k\rangle\rangle\cdots\rangle\rangle\rangle), \langle X_1:\langle X_2:\langle\cdots:\langle X_s:g_j\rangle\rangle\cdots\rangle\rangle\rangle \\
&\quad = d\left(\mathcal{G}(\mathrm{grad}_{\mathcal{G}}\left(\mathcal{L}_{Y_1}\mathcal{L}_{Y_2}\cdots\mathcal{L}_{Y_{s_2}}V_k\right), \mathrm{grad}_{\mathcal{G}}\left(\mathcal{L}_{X_1}\mathcal{L}_{X_2}\cdots\mathcal{L}_{X_s}V_j\right))\right) \\
&\quad = d\{\mathcal{L}_{Y_1}\mathcal{L}_{Y_2}\cdots\mathcal{L}_{Y_{s_2}}V_k : \mathcal{L}_{X_1}\mathcal{L}_{X_2}\cdots\mathcal{L}_{X_s}V_j\}_{\mathcal{G}}\,.
\end{aligned}
$$

Since $\mathrm{grad}_{\mathcal{G}}\{f:g\}_{\mathcal{G}} = \langle\mathrm{grad}_{\mathcal{G}}\, f : \mathrm{grad}_{\mathcal{G}}\, g\rangle_{\nabla^{\mathcal{G}}}$, we conclude

$$
\begin{aligned}
&\langle\langle X_1:\langle X_2:\langle\cdots:\langle X_s:g_j\rangle\rangle\cdots\rangle\rangle:\langle Y_1:\langle Y_2:\langle\cdots:\langle Y_{s_2}:g_k\rangle\rangle\cdots\rangle\rangle\rangle \\
&\quad = \langle\langle X_1:\langle X_2:\langle\cdots:\langle X_s:g_j\rangle\rangle\cdots\rangle\rangle:\langle Y_1:\langle Y_2:\langle\cdots:\langle Y_{s_2}:g_k\rangle\rangle\cdots\rangle\rangle\rangle_{\mathcal{G}}\,.
\end{aligned}
$$

Using the fact that $\mathcal{S}_0$ is full-rank, we deduce that $\langle X:Y\rangle = \langle X:Y\rangle_{\mathcal{G}}$ for all X, $Y\in\mathfrak{X}(M)$. Finally, using the fact that ∇ is torsion-free, we compute

$$
\nabla_X Y = \frac{1}{2}\left(\langle X:Y\rangle + [X,Y]\right) = \frac{1}{2}\left(\langle X:Y\rangle_{\mathcal{G}} + [X,Y]\right) = \nabla^{\mathcal{G}}_X Y \quad \forall X,Y\in\mathfrak{X}(M)\,,
$$

which concludes the result. □

We are now ready to conclude the proof of Theorem 5.4.

Proof of Theorem 5.4. Assume the prolongation Σ^p and the gradient extension Σ^e are weakly externally equivalent. From Lemmas 5.5, 5.6, and 5.7, we deduce the existence of a pseudo-Riemannian metric $\mathcal{G}$ on M such that $\nabla = \nabla^{\mathcal{G}}$ and the unique diffeomorphism between TM and T^*M relating Σ^p and Σ^e and verifying (5.2) is $\flat_{\mathcal{G}}$. From $(\flat_{\mathcal{G}})_* g_j^{\mathrm{V}} = \mathrm{grad}_{\mathcal{G}^\nabla} V_j^{\mathrm{V}}\circ\flat_{\mathcal{G}}$, we deduce $\flat_{\mathcal{G}}(g_j) = dV_j$, and hence $\mathrm{grad}_{\mathcal{G}}\, V_j = g_j$, $j=1,\ldots,m$. Finally, we show that g_0 is a locally gradient vector field. From $(\flat_{\mathcal{G}})_* g_0^{\mathrm{C}} = \mathrm{grad}_{\mathcal{G}^\nabla} V^{g_0}\circ\flat_{\mathcal{G}}$ and the local expression (2.8) of the Christoffel symbols of the Levi-Civita connection $\nabla^{\mathcal{G}}$, we deduce that

$$
\frac{\partial}{\partial x^b}\left(\mathcal{G}_{ac}g_0^c\right) = \frac{\partial}{\partial x^a}\left(\mathcal{G}_{bc}g_0^c\right) \quad \forall a,b=1,\ldots,n\,,
$$

which implies that the one-form $\flat_{\mathcal{G}}(g_0)$ is closed. □

Example 5.8. Consider a linear input-state-output system Σ on $M = \mathbb{R}^n$, i.e., $\dot{x} = Ax + Bu$, $y = Cx$, $x \in \mathbb{R}^n$, with A an $(n \times n)$-matrix, B an $(n \times m)$-matrix, and C an $(m \times n)$-matrix. Assume Σ is observable and controllable. Consider the trivial connection ∇ on $\mathbb{R}^n$ whose Christoffel symbols are given by $\Gamma^a_{bc} = 0$, $1 \leq a, b, c \leq n$. One can easily verify that Σ is compatible with ∇, and, using the hypothesis of controllability, that the distribution $\mathcal{S}_0$ has full-rank. The prolonged system consists of the system itself together with the variational equations $\dot{v} = Av + Bu^p$, $y^p = Cv$, and the gradient extension consists of the system itself together with the equations $\dot{p} = A^T p + C^T u^e$, $y^e = B^T p$. Hence the prolonged system and the gradient extension are weakly externally equivalent if and only if the impulse responses of $\dot{v} = Av + Bu^p$, $y^p = Cv$ and $\dot{p} = A^T p + C^T u^e$, $y^e = B^T p$ are equal, that is, $W(t) = W^T(t)$, with $W(t) := Ce^{At}B$. Thus from Theorem 5.4 we recover the classical result (see, e.g., [27]) that an observable and controllable linear system is a gradient system (with respect to the trivial connection) if and only if $W(t) = W^T(t)$.

Remark 5.9. Note that, given the torsion-free affine connection ∇, the pseudo-Riemannian metric $\mathcal{G}$ obtained in the proof of Theorem 5.4 is unique such that Σ is locally gradient with respect to it. In section 6 below, we investigate the uniqueness (up to isometry) of gradient realizations with the same input-output behavior.

Remark 5.10. In general, we cannot ensure that the drift vector field g_0 is globally gradient, unless we impose some additional conditions on the topology of the state space M (for instance, that the first Betti number of M is zero). This is analogous to the situation in the Hamiltonian setting [13].

Remark 5.11. As noted in section 2.2, one can verify that the pseudo-Riemannian metric on T^*M defined by $\mathcal{G}^\nabla$ corresponds to the pullback by $\sharp_{\mathcal{G}}$ of the complete lift $\mathcal{G}^{\mathrm{C}}$ to TM of the original metric $\mathcal{G}$ on M.

Remark 5.12. A different way to prove the same result which indeed keeps a closer parallelism with the proof for the Hamiltonian case [13] would be the following. Once one has proved Lemmas 5.5 and 5.6, instead of proving Lemma 5.7, one can show that

$$(\varphi)_* \langle X_1 : \langle X_2 : \langle \cdots : \langle X_s : g_j \rangle \rangle \cdots \rangle \rangle^{\mathrm{C}} = \operatorname{grad} V^{\langle X_1 : \langle X_2 : \langle \cdots : \langle X_s : g_j \rangle \rangle \cdots \rangle \rangle} \circ \varphi \tag{5.6}$$

for any $j \in \{1, \ldots, m\}$ and $X_r \in \{g_0, g_1, \ldots, g_m\}$, $r = 1, \ldots, s$. This can be done by considering the following vector fields on T^*M,

$$\begin{aligned} \mathcal{Z}_1 &= (\varphi)_* \langle X_1 : \langle X_2 : \langle \cdots : \langle X_s : g_j \rangle \rangle \cdots \rangle \rangle^{\mathrm{C}} \circ \varphi^{-1}, \\ \mathcal{Z}_2 &= \operatorname{grad} V^{\langle X_1 : \langle X_2 : \langle \cdots : \langle X_s : g_j \rangle \rangle \cdots \rangle \rangle} \end{aligned}$$

and showing that their action on the observation space $\mathcal{H}^e$ of Σ^e is the same. To see this, recall from Proposition 3.5 that $\mathcal{H}^e = V^{S_0} + (\mathcal{H} + \mathfrak{h})^{\mathrm{V}}$. Consider a function of the form $\mathcal{L}_{X_1} \mathcal{L}_{X_2} \cdots \mathcal{L}_{X_s} V_j$, with X_r, $r = 1, \ldots, s$, equal to g_i, $i = 0, 1, \ldots, m$, and $j = 1, \ldots, m$. Then,

$$\begin{aligned} &\mathcal{L}_{\mathcal{Z}_1} \left[(\mathcal{L}_{X_1} \mathcal{L}_{X_2} \cdots \mathcal{L}_{X_s} V_j)^{\mathrm{V}} \right] \\ &\quad = \left(\mathcal{L}_{\langle X_1 : \langle X_2 : \langle \cdots : \langle X_s : g_j \rangle \rangle \cdots \rangle \rangle^{\mathrm{C}}} \left[(\mathcal{L}_{X_1} \mathcal{L}_{X_2} \cdots \mathcal{L}_{X_s} V_j)^{\mathrm{V}} \circ \varphi \right] \right) \circ \varphi^{-1} \\ &\quad = \left(\mathcal{L}_{\langle X_1 : \langle X_2 : \langle \cdots : \langle X_s : g_j \rangle \rangle \cdots \rangle \rangle} \left[\mathcal{L}_{X_1} \mathcal{L}_{X_2} \cdots \mathcal{L}_{X_s} V_j \right] \right)^{\mathrm{V}}, \end{aligned}$$

where we have used twice the fact that φ is the identity mapping on the base manifold M. On the other hand,

$$\mathcal{L}_{\mathcal{Z}_2} \left[(\mathcal{L}_{X_1} \mathcal{L}_{X_2} \cdots \mathcal{L}_{X_s} V_j)^{\mathrm{V}} \right] = \left(\mathcal{L}_{\langle X_1 : \langle X_2 : \langle \cdots : \langle X_s : g_j \rangle \rangle \cdots \rangle \rangle} \left[\mathcal{L}_{X_1} \mathcal{L}_{X_2} \cdots \mathcal{L}_{X_s} V_j \right] \right)^{\mathrm{V}},$$

using property (ii) in Lemma 3.4. The same argument also guarantees that the action of $\mathcal{Z}_1$ and $\mathcal{Z}_2$ is the same over the vertical lifts of the functions spanning $\mathfrak{h}$. Finally, let $\langle Y_1 : \langle Y_2 : \langle \cdots : \langle Y_{s_2} : g_k \rangle \rangle \cdots \rangle \rangle \in S_0$ and consider the corresponding function on T^*M, $V^{\langle Y_1:\langle Y_2:\langle\cdots:\langle Y_{s_2}:g_k\rangle\rangle\cdots\rangle\rangle}$. Then,

$$
\begin{aligned}
(5.7)\qquad & \mathcal{L}_{\mathcal{Z}_1}\left[V^{\langle Y_1:\langle Y_2:\langle\cdots:\langle Y_{s_2}:g_k\rangle\rangle\cdots\rangle\rangle}\right] \\
&= \left(\mathcal{L}_{\langle X_1:\langle X_2:\langle\cdots:\langle X_s:g_j\rangle\rangle\cdots\rangle\rangle^{\mathrm{C}}}\left[V^{\langle Y_1:\langle Y_2:\langle\cdots:\langle Y_{s_2}:g_k\rangle\rangle\cdots\rangle\rangle}\circ\varphi\right]\right)\circ\varphi^{-1} \\
&= \left(\mathcal{L}_{\langle X_1:\langle X_2:\langle\cdots:\langle X_s:g_j\rangle\rangle\cdots\rangle\rangle^{\mathrm{C}}}\left[(\mathcal{L}_{Y_1}\mathcal{L}_{Y_2}\cdots\mathcal{L}_{Y_{s_2}}V_k)^{\mathrm{C}}\right]\right)\circ\varphi^{-1} \\
&= \left(\mathcal{L}_{\langle X_1:\langle X_2:\langle\cdots:\langle X_s:g_j\rangle\rangle\cdots\rangle\rangle}\left[\mathcal{L}_{Y_1}\mathcal{L}_{Y_2}\cdots\mathcal{L}_{Y_{s_2}}V_k\right]\right)^{\mathrm{C}}\circ\varphi^{-1},
\end{aligned}
$$

where we have used (5.4). In addition,

$$
(5.8)\quad \mathcal{L}_{\mathcal{Z}_2}\left[V^{\langle Y_1:\langle Y_2:\langle\cdots:\langle Y_{s_2}:g_k\rangle\rangle\cdots\rangle\rangle}\right] = V^{\langle\langle X_1:\langle X_2:\langle\cdots:\langle X_s:g_j\rangle\rangle\cdots\rangle\rangle:\langle Y_1:\langle Y_2:\langle\cdots:\langle Y_{s_2}:g_k\rangle\rangle\cdots\rangle\rangle\rangle},
$$

where we have used property (i) in Lemma 3.4. Now, (5.5) implies that (5.7) and (5.8) coincide. Therefore, $\mathcal{Z}_1$ and $\mathcal{Z}_2$ coincide over $\mathcal{H}^e$, and this concludes the proof of (5.6).

Now, one can proceed by taking local coordinates $(x^1, \ldots, x^n)$ in M such that every coordinate function x^i is of the form $\mathcal{L}_{X_1}\cdots\mathcal{L}_{X_s}V_j$ for a certain $j \in \{1, \ldots, m\}$ and certain vector fields $X_r \in \{g_0, g_1, \ldots, g_m\}$, $r = 1, \ldots, s$. It follows from (5.4) that there exists n independent vector fields $k^1, \ldots, k^n$ of the form $\langle X_1 : \langle X_2 : \langle \cdots : \langle X_s : g_j \rangle\rangle \cdots \rangle\rangle$ such that $\flat_{\mathcal{G}}(k^i) = dx^i$. Finally, spelling out (5.6) for the vector fields k^i and making use of the symmetry of $\mathcal{G}$, one obtains that the Christoffel symbols of the affine connection ∇ are precisely given by (2.8), which concludes the result.

6. Uniqueness of the gradient realization. In this section, we investigate the gradient analogue of the following well-known result for Hamiltonian systems: if two minimal Hamiltonian systems have the same input-output map, then they are symplectomorphic [3, 22]. We will see how the setting of Theorem 5.4 also provides sufficient conditions under which a similar result holds for gradient realizations.

In [25], Varaiya conjectured that if there exists a state-space diffeomorphism between two locally controllable gradient systems, then the diffeomorphism is actually an isometry between the underlying pseudo-Riemannian manifolds (see also [26]). Subsequently, in [1, 2], Basto Gonçalves produced an example of two locally controllable and observable gradient systems living on the same state space with state-space diffeomorphism given by the identity mapping, where, however, the Riemannian metrics are different; thus providing a counterexample to the conjecture by Varaiya. For the sake of completeness, we review it in the following.

Example 6.1 (see [1, 2]). Consider two gradient systems Σ^1 and Σ^2 on $M^1 = M^2 = \mathbb{R}^4$ with Riemannian metrics $\mathcal{G}^1$ and $\mathcal{G}^2$ given, respectively, by

$$
\begin{aligned}
\mathcal{G}^1(x_1, x_2, x_3, x_4) &= dx_1 \otimes dx_1 + e^{-x_4}dx_2 \otimes dx_2 + e^{-x_1}dx_3 \otimes dx_3 + e^{-x_3}dx_4 \otimes dx_4\,, \\
\mathcal{G}^2(x_1, x_2, x_3, x_4) &= dx_1 \otimes dx_1 + e^{-x_4}dx_2 \otimes dx_2 + \left(e^{-x_1} + e^{x_3}\right)dx_3 \otimes dx_3 \\
&\quad + e^{-x_3}\left(1 + e^{2x_1}\right)dx_4 \otimes dx_4 - e^{x_1}\left(dx_3 \otimes dx_4 + dx_4 \otimes dx_3\right).
\end{aligned}
$$

Furthermore, let Σ^1 and Σ^2 have both zero drift vector fields and the same output functions given by

$$
y_1 = V_1(x) := x_1\,, \quad y_2 = V_2(x) := x_2 + x_3 + x_4\,.
$$

From the definition of $\mathcal{G}^1$ and $\mathcal{G}^2$, it easily follows that the input vector fields of both systems are the same, i.e.,

$$\operatorname{grad}_{\mathcal{G}^1} V_1 = \operatorname{grad}_{\mathcal{G}^2} V_1 = \frac{\partial}{\partial x_1}\,,$$
$$\operatorname{grad}_{\mathcal{G}^1} V_2 = \operatorname{grad}_{\mathcal{G}^2} V_2 = e^{x_4}\frac{\partial}{\partial x_2} + e^{x_1}\frac{\partial}{\partial x_3} + e^{x_3}\frac{\partial}{\partial x_4}\,.$$

Therefore, Σ^1 and Σ^2 are externally equivalent with state-space diffeomorphism given by the identity mapping $\mathrm{Id} : \mathbb{R}^4 \to \mathbb{R}^4$. However, the metrics $\mathcal{G}^1$ and $\mathcal{G}^2$ are different, and hence the identity mapping is *not* an isometry. It should also be noted that Σ^1 and Σ^2 are both controllable and observable.

The following result shows that, under the hypotheses of Theorem 5.4, a state-space diffeomorphism linking two gradient systems is an isometry, *provided* the state-space diffeomorphism is already known to respect the affine connections determined by their respective pseudo-Riemannian metrics. A similar statement is already contained in [1, 2]. Here we make use of an argument given in [13, p. 58] for the case of Hamiltonian systems.

PROPOSITION 6.2. *Let Σ^1 and Σ^2 be two gradient systems with state spaces $\big(M^1, \mathcal{G}^1\big)$ and $\big(M^2, \mathcal{G}^2\big)$, respectively. For $i = 1, 2$, assume that Σ^i is observable with $\dim d\mathcal{H}^i$ constant, and that the distribution $\mathcal{S}_0^i$ is full-rank. Furthermore, let Σ^1 and Σ^2 be externally equivalent with the corresponding state-space diffeomorphism $\psi : M^1 \to M^2$ satisfying*

$$\psi_*(\nabla^{\mathcal{G}^1}_X Y) \circ \psi^{-1} = \nabla^{\mathcal{G}^2}_{\psi_* X \circ \psi^{-1}}(\psi_* Y \circ \psi^{-1}) \quad \forall X, Y \in \mathfrak{X}(M^1)\,. \tag{6.1}$$

Then $\psi^* \mathcal{G}^2 = \mathcal{G}^1$, that is, ψ is an isometry.

Proof. By Lemmas 5.5 and 5.6, the map $\varphi^i = \flat_{\mathcal{G}^i}$ is the unique diffeomorphism satisfying (5.2) for system Σ^i, $i = 1, 2$. It is easily checked that since Σ^1 and Σ^2 are externally equivalent with state-space diffeomorphism ψ, then their prolongations Σ^{1p} and Σ^{2p} are externally equivalent with uniquely determined state-space diffeomorphism given by $\psi_* : TM^1 \to TM^2$. Furthermore, it can be readily checked that the gradient extensions Σ^{1e} and Σ^{2e} are externally equivalent with state-space diffeomorphism $\psi^* : T^*M^2 \to T^*M^1$, *provided* ψ satisfies (6.1). This is because (6.1) implies that ψ^* respects the Riemannian extensions $\mathcal{G}^{\nabla^{\mathcal{G}^1}}$ and $\mathcal{G}^{\nabla^{\mathcal{G}^2}}$ determined, respectively, by the affine connections $\nabla^{\mathcal{G}^1}$ and $\nabla^{\mathcal{G}^2}$. Therefore, by the uniqueness of all these state-space diffeomorphisms, we obtain the following commutative diagram:

$$\begin{array}{ccc} TM^1 & \xrightarrow{\psi_*} & TM^2 \\ {\scriptstyle\varphi^1}\downarrow & & \downarrow{\scriptstyle\varphi^2} \\ T^*M^1 & \xleftarrow[\psi^*]{} & T^*M^2 \end{array}$$

that is,

$$\psi^* \circ \varphi^2 \circ \psi_* = \varphi^1\,. \tag{6.2}$$

Recalling that $\varphi^i = \flat_{\mathcal{G}^i}$, $i = 1, 2$, it is readily seen that (6.2) is equivalent to

$$\psi^* \mathcal{G}^2 = \mathcal{G}^1, \tag{6.3}$$

that is, $\psi : \big(M^1, \mathcal{G}^1\big) \to \big(M^2, \mathcal{G}^2\big)$ is an isometry. ∎

Remark 6.3. Note that in Example 6.1 the torsion-free connections determined by $\mathcal{G}^1$ and $\mathcal{G}^2$ are *different*, and hence the identity map does not respect them.

Remark 6.4. Since (6.2) is equivalent to (6.3), one may also conclude that under the conditions of Theorem 5.4, the state-space diffeomorphism $\psi : M^1 \to M^2$ is an isometry if and only if $\psi^* : T^*M^2 \to T^*M^1$ is a state-space diffeomorphism between Σ^{1e} and Σ^{2e}.

7. Conclusions. We have discussed necessary and sufficient conditions for a nonlinear control system to be realizable as a gradient control system with respect to a pseudo-Riemannian metric whose Levi-Civita connection coincides with a given affine connection. The results rely on a suitable notion of compatibility of the system with respect to the given affine connection, and on the input-output behavior of the prolonged system and the gradient extension. The symmetric product associated with an affine connection plays a key role in the discussion. We believe that the developments in this paper not only give insight in the system-theoretic properties of the physically motivated class of gradient control systems, but also shed light on the differential-geometric properties of gradient and Lagrangian control systems. Future work will include the investigation of necessary and sufficient conditions that guarantee the existence of an affine connection such that the hypothesis of Theorem 5.4 are satisfied, the development of equivalent characterizations in terms of the input-output behavior of the original nonlinear system, and the study of the application of the results to specific classes of nonlinear systems, such as bilinear, homogeneous, and polynomial systems.

8. Appendix. In this appendix we present a simplifying result concerning the compatibility hypothesis in the statement of Theorem 5.4. In general, checking conditions (a) and (b) in the definition of compatibility between the affine connection ∇ and the nonlinear system Σ cannot be performed for every possible choice of vector fields in $\{g_0, g_1, \dots, g_m\}$ and $\{V_1, \dots, V_m\}$. The following result shows that it is enough to check the compatibility condition on a basis of vector fields and the corresponding associated functions once we know that the prolongation and the gradient extension of Σ are weakly externally equivalent.

LEMMA 8.1. *Let ∇ be a torsion-free affine connection. Assume Σ is observable with $\dim d\mathcal{H}$ constant, and that the distribution $\mathcal{S}_0$ is full-rank. Assume the prolongation Σ^p and the gradient extension Σ^e of Σ are weakly externally equivalent. Then Σ is compatible with ∇ if and only if properties* (a) *and* (b) *are verified by a basis of vector fields in S_0.*

Proof. Let $R_1, \dots, R_n$ be linearly independent vector fields of the form $R_i = \langle X_1^i : \langle X_2^i : \langle \cdots : \langle X_{s_i}^i : g_{j_i} \rangle \rangle \cdots \rangle \rangle$, $i = 1, \dots, n$. Let V_{R_i} denote the function on M given by $\mathcal{L}_{X_1^i} \cdots \mathcal{L}_{X_{s_i}^i} V_{j_i}$. From (5.4), we know that $\varphi^T(R_i) = dV_{R_i}$. Assume properties (a) and (b) in the definition of the compatibility condition (cf. Definition 5.1) are verified by any combination of the vector fields $R_1, \dots, R_n$ and the functions $V_{R_1}, \dots, V_{R_n}$. Let $X = \langle X_1 : \langle X_2 : \langle \cdots : \langle X_s : g_k \rangle \rangle \cdots \rangle \rangle$ be any element of S_0, and $V_X = \mathcal{L}_{X_1} \mathcal{L}_{X_2} \cdots \mathcal{L}_{X_s} V_k$ the associated function on M. Since $\mathcal{S}_0$ is full-rank, we have that $X = \sum_{i=1}^n f_X^i R_i$. Then,

$$dV_X = d\mathcal{L}_{X_1} \mathcal{L}_{X_2} \cdots \mathcal{L}_{X_s} V_k = \varphi^T(X) = \sum_{i=1}^n f_X^i \varphi^T(R_i) = \sum_{i=1}^n f_X^i dV_{R_i}\,.$$

Now, let us see that properties (a) and (b) are naturally verified by all possible choices of vector fields in S_0 and generating functions in $\mathcal{H}$. First,

$$\begin{aligned}
&\mathcal{L}_{\langle X_1:\langle X_2:\langle\cdots:\langle X_{s_1}:g_j\rangle\rangle\cdots\rangle\rangle}\left[\mathcal{L}_{Y_1}\mathcal{L}_{Y_2}\cdots\mathcal{L}_{Y_{s_2}}V_k\right]\\
&\quad=\sum_{i=1}^n f_Y^i dV_{R_i}\left(\sum_{j=1}^n f_X^j R_j\right)=\sum_{i,j=1}^n f_Y^i f_X^j dV_{R_j}(R_i)=\sum_{j=1}^n f_X^j dV_{R_j}\left(\sum_{i=1}^n f_X^i R_i\right)\\
&\qquad\qquad=\mathcal{L}_{\langle Y_1:\langle Y_2:\langle\cdots:\langle Y_{s_2}:g_k\rangle\rangle\cdots\rangle\rangle}\left[\mathcal{L}_{X_1}\mathcal{L}_{X_2}\cdots\mathcal{L}_{X_{s_1}}V_j\right],
\end{aligned}$$

where we have used the fact that condition (a) is verified by the vector fields $R_1,\ldots,R_n$ and the functions $V_{R_1},\ldots,V_{R_n}$. Second,

$$\begin{aligned}
(8.1)\qquad &\mathcal{L}_{\langle\langle X_1:\langle X_2:\langle\cdots:\langle X_{s_1}:g_j\rangle\rangle\cdots\rangle\rangle:\langle Y_1:\langle Y_2:\langle\cdots:\langle Y_{s_2}:g_k\rangle\rangle\cdots\rangle\rangle\rangle}\left[\mathcal{L}_{Z_1}\mathcal{L}_{Z_2}\cdots\mathcal{L}_{Z_{s_3}}V_l\right]\\
&\quad=\sum_{i=1}^n f_Z^i dV_{R_i}\left(\sum_{j=1}^n f_{\langle X:Y\rangle}^j R_j\right)=\sum_{i,j=1}^n f_Z^i f_{\langle X:Y\rangle}^j dV_{R_j}(R_i)\\
&\quad=\sum_{j=1}^n f_{\langle X:Y\rangle}^j dV_{R_j}\left(\sum_{i=1}^n f_Z^i R_i\right)=\left\langle\sum_{j=1}^n f_{\langle X:Y\rangle}^j dV_{R_j},Z\right\rangle.
\end{aligned}$$

Let us compute the coefficients $f_{\langle X:Y\rangle}^j$. We have

$$\begin{aligned}
&\langle\langle X_1:\langle X_2:\langle\cdots:\langle X_{s_1}:g_j\rangle\rangle\cdots\rangle\rangle:\langle Y_1:\langle Y_2:\langle\cdots:\langle Y_{s_2}:g_k\rangle\rangle\cdots\rangle\rangle\rangle\\
&\quad=\sum_{i,j=1}^n\langle f_X^i R_i:f_Y^j R_j\rangle=\sum_{i,j=1}^n\left(f_X^i f_Y^j\langle R_i:R_j\rangle+f_X^i R_i[f_Y^j]R_j+f_Y^j R_j[f_X^i]R_i\right)\\
&\quad=\sum_{k=1}^n\left(\sum_{i,j=1}^n f_X^i f_Y^j f_{\langle R_i:R_j\rangle}^k+\sum_{i=1}^n f_X^i R_i[f_Y^k]+\sum_{j=1}^n f_Y^j R_j[f_X^k]\right)R_k\,.
\end{aligned}$$

Now, note that $\sum_{k=1}^n\langle f_{\langle R_i:R_j\rangle}^k dV_{R_k},R_l\rangle=\sum_{k=1}^n\langle f_{\langle R_i:R_j\rangle}^k dV_{R_l},R_k\rangle$ using condition (a) for the vector fields $R_1,\ldots,R_n$ and the functions $V_{R_1},\ldots,V_{R_n}$. Moreover, using condition (b), $\sum_{k=1}^n\langle f_{\langle R_i:R_j\rangle}^k dV_{R_l},R_k\rangle=\langle dV_{R_l},\langle R_i:R_j\rangle\rangle=\langle d(dV_{R_i}[R_j]),R_l\rangle$. Hence, $\sum_{k=1}^n f_{\langle R_i:R_j\rangle}^k dV_{R_k}=d(dV_{R_i}[R_j])$. On the other hand,

$$\begin{aligned}
f_X^i R_i[f_Y^k]dV_{R_k}&=f_X^i\langle df_Y^k,R_i\rangle dV_{R_k}\\
&=f_X^i\langle dV_{R_k},R_i\rangle df_Y^k+f_X^i\left(df_Y^k\wedge dV_{R_k}\right)(R_i,\cdot).
\end{aligned}$$

Since $f_X^i\left(df_Y^k\wedge dV_{R_k}\right)(R_i,\cdot)=f_X^i\left(d\left(f_Y^k dV_{R_k}\right)\right)(R_i,\cdot)=f_X^i\left(d\left(dV_Y\right)\right)(R_i,\cdot)=0$, we have

$$f_X^i R_i[f_Y^k]dV_{R_k}=f_X^i\langle dV_{R_k},R_i\rangle df_Y^k\,.$$

Analogously, one can see that $f_Y^j R_j[f_X^k]dV_{R_k} = f_Y^j\langle dV_{R_k}, R_j\rangle df_X^k$. Finally,

$$\begin{aligned}\sum_{k=1}^{n} f^k_{\langle X:Y\rangle} dV_{R_k} &= \sum_{k=1}^{n}\left(\sum_{i,j=1}^{n} f_X^i f_Y^j f^k_{\langle R_i:R_j\rangle} + \sum_{i=1}^{n} f_X^i R_i[f_Y^k] + \sum_{j=1}^{n} f_Y^j R_j[f_X^k]\right) dV_{R_k}\\ &= \sum_{i,j=1}^{n} f_X^i f_Y^j d(dV_{R_i}[R_j]) + \sum_{i,j=1}^{n} f_X^i\langle dV_{R_j}, R_i\rangle df_Y^j + \sum_{i,j=1}^{n} f_Y^j\langle dV_{R_i}, R_j\rangle df_X^i\\ &= d\left(\sum_{i,j=1}^{n} f_X^i f_Y^j dV_{R_i}[R_j]\right) = d(\mathcal{L}_Y[V_X])\,.\end{aligned}$$

Plugging this equality into (8.1), we get the desired result. □

Acknowledgment. The authors would like to thank the reviewers for their helpful remarks on how to improve the presentation of the paper.

OPTIMAL CONTROL PROBLEMS WITH FINAL OBSERVATION GOVERNED BY EXPLOSIVE PARABOLIC EQUATIONS*

H. AMANN† AND P. QUITTNER‡

Abstract. We study optimal control problems with final observation. The governing parabolic equations or systems involve superlinear nonlinearities, and their solutions may blow up in finite time. Our proof of the existence, regularity, and optimality conditions for an optimal pair is based on uniform a priori estimates for the approximating solutions. Our conditions on the growth of the nonlinearity are essentially optimal. In particular, we also solve a long-standing open problem of Lions concerning singular systems.

Key words. optimal control problem, nonlinear parabolic equation, blow-up, final observation, optimality conditions, strong nonlinearities

1. Introduction.

In his book [21], Lions studied several optimal control problems governed by nonlinear parabolic equations of the form

$$\partial_t y - \Delta y = y^\lambda + u, \qquad x \in \Omega,\ t \in [0,T], \tag{1.1}$$

where Ω is a bounded domain in $\mathbb{R}^n$, $\lambda \in \{2,3\}$, $u = u(x,t)$ is the control, and $y = y(x,t)$ is the state variable. Equation (1.1) is complemented by suitable boundary and initial conditions, for example,

$$y = 0 \ \text{ on } \partial\Omega \times (0,T), \qquad y(\cdot,0) = y_0, \tag{1.2}$$

where $y_0 \in L_\infty(\Omega)$. If u is regular enough, then the state problem (1.1)–(1.2) possesses a unique strong solution $y = y(u)$ defined on the maximal existence interval J_u (see section 2 for the definition of a strong solution). However, even for smooth controls u, the solution $y(u)$ need not be global—the interval J_u need not coincide with $[0,T]$. In this case, $y(u)$ *blows up* at the time $t(u) := \sup J_u$; i.e., it develops a singularity and leaves its natural regularity class. After blow-up, the solution either can be continued in a weak sense (the blow-up is *incomplete* [16]) or such continuation is not possible (the solution blows up *completely* [9]).

Let $\mathbb{U}_{\rm ad}$ denote the set of admissible controls,

$$\mathbb{U}_{\rm ad}^G := \{u \in \mathbb{U}_{\rm ad} : \text{the solution } y(u) \text{ is global}\},$$

and let $\mathbb{J} = \mathbb{J}(y,u)$ be the cost functional. A standard way to solve the optimal control problem

$$\text{minimize } \mathbb{J}(y(u),u) \text{ over } u \in \mathbb{U}_{\rm ad}^G \tag{1.3}$$

is to consider controls u_k, $k = 1, 2, \dots$, such that $(\mathbb{J}(y(u_k), u_k))$ is a minimizing sequence for (1.3) and to show that a suitable subsequence of $((y(u_k), u_k))$ converges to an optimal pair $(y(u), u)$. Assume, for example, that $\mathbb{U}_{\rm ad}$ is a (weakly closed) subset of a reflexive Banach space. If $\mathbb{J}$ is coercive with respect to u (or $\mathbb{U}_{\rm ad}$ is bounded), then the sequence (u_k) is bounded and we may assume that $u_k \to u$ in the weak topology. Similarly, if $\mathbb{J}$ is coercive with respect to y (in a suitable space of functions defined in $Q := \Omega \times [0, T]$), then the sequence $(y(u_k))$ is bounded and standard compactness results for the state problem enable us to pass to the limit in order to find a minimizer for (1.3).

If we consider problems with final observation (where $\mathbb{J}$ depends just on u and the final value $y(\cdot, T)$), then the coerciveness of $\mathbb{J}$ provides a priori estimates for u_k and final values of $y(u_k)$. However, such estimates are, in general, not sufficient for the uniform boundedness of solutions $y(u_k)$ on the whole interval $[0, T]$. Consequently, we have to find sufficient conditions on λ and/or other parameters of the problem which guarantee a priori bounds for global solutions y of (1.1)–(1.2) depending only on suitable norms of u and $y(\cdot, T)$.

Let us discuss the question of a priori bounds for problems with final observation in the particular setting of [21, section I.10]. Fix $N > 0$, $q \ge 1$, $y_d \in L_q(\Omega)$, and set

$$\mathbb{J}(y, u) := \int_\Omega |y(x, T) - y_d(x)|^q \, dx + N \int_Q u^2(x, t) \, dx \, dt.$$

Assume also that $\mathbb{U}_{\rm ad} \subset L_2(Q)$ is closed and convex and that $\mathbb{U}_{\rm ad}^G \ne \emptyset$. If $\lambda = 2$, $q = 3$, and $n \le 3$, then [21, Theorem I.10.1] and its proof guarantee the required bounds for the solutions $y(u_k)$, hence the existence of an optimal pair (y, u). If, in addition, $n \le 2$, then optimality conditions for the optimal pair (y, u) were derived in [21, Theorem I.10.3]. On the other hand, the existence of an optimal pair in the case $\lambda = 3$, $q = 4$ (or $\lambda = 2$, $q < 3$) and the optimality conditions for $n = 3$ were left as open problems; see [21, Remarks I.10.1, I.10.2, and I.10.4]. Our results give, in particular, positive answers to all those open problems. In fact, we consider an arbitrary dimension n, exponents $q \ge 2$, $\lambda > 1$ (where either $y^\lambda := |y|^{\lambda-1} y$ or $y^\lambda := |y|^\lambda$), and controls $u \in L_r([0, T], L_2(\Omega))$, $r \ge 2$, and find sufficient conditions on q, λ, and r that guarantee the existence of optimal controls and the optimality conditions (see section 2 for precise statements of our results).

We also show that many of our conditions are essentially optimal. In particular, if $\mathbb{U}_{\rm ad} \subset L_\infty([0, T], L_2(\Omega))$, then our sufficient conditions on q and λ guaranteeing the existence of optimal controls have the form

$$\lambda < \frac{n+2}{(n-2)_+} \qquad \text{and} \qquad q \in \left((\lambda - 1)\frac{n}{2}, \frac{2n}{(n-4)_+} \right),$$

where $a_+ := \max(a, 0)$ and $a/b_+ := \infty$ if $a > 0$ and $b \le 0$. The upper bound for q is required by the (low) regularity of controls u: it guarantees $y(u) \in C([0, T], L_q(\Omega))$ so that $\mathbb{J}(y(u), u)$ is defined. If $q < (\lambda - 1)n/2$ or $\lambda > (n+2)/(n-2)_+$ and $n \le 10$, then we show that problem (1.3) need not be solvable even if the set $\mathbb{U}_{\rm ad}$ is a compact subset of $C^\infty(\bar\Omega \times [0, T])$ and $\mathbb{U}_{\rm ad}^G \ne \emptyset$; see Remark 3.4. This nonexistence result is due to the fact that the set $\mathbb{U}_{\rm ad}^G$ need not be closed in $\mathbb{U}_{\rm ad}$: if $u_k \in \mathbb{U}_{\rm ad}^G$, $u_k \to u \in \mathbb{U}_{\rm ad}$, then the limiting solution $y(u)$ may blow up at $t(u) < T$. The conditions on q show the importance of a good choice of the cost functional in order to control the equation. On the other hand, if $\lambda > (n+2)/(n-2)_+$, then (a strong) solvability of our control problem cannot be guaranteed for any q.

The solvability of (1.3) with $\mathbb{U}_{\rm ad}$, $\mathbb{J}$ as above was proved by Imanuvilov [18, Theorem 2.1] and Fursikov [15, Theorem 4.3] for $r = q = 2$ and any $\lambda > 1$, but their function $y(u)$ corresponding to the optimal control u need not be a strong solution in our sense. In fact, the results of [18], [15] also apply to the example of Remark 3.4(i), where $y(u)$ blows up at $t(u) < T$ (but can be continued in a weak sense). This lack of regularity causes serious problems in establishing the optimality conditions. In order to obtain these conditions, Imanuvilov and Fursikov have to assume $q = 2 \geq (\lambda - 1)n/2$; see [15, Theorem 5.1]. Note also that the proofs in [18], [15] substantially use the choice $q = 2$ and hence require $\lambda \leq 1 + 4/n$. In particular, if $n = 3$, then their method cannot be used in the case $\lambda = 3$, $q = 4$ mentioned above.

Our proof of a priori estimates is based on energy and perturbation arguments in [25], [27]. The same approach can be used for more general problems. For example, the case of general second-order elliptic operators and/or general nonlinearities with polynomial growth can be solved by adopting the proofs in [26]. Similarly, if one considers linear or nonlinear parabolic equations complemented by nonlinear Neumann boundary conditions of the form $\partial_\nu y = y^\lambda$ or $\partial_\nu y = y^\lambda + u$, then one can use estimates in [28] and [11].

In this paper we consider two modifications of the model problem (1.1)–(1.2): a problem with multiplicative control and a problem governed by a parabolic system.

In the case of multiplicative control we replace the state equation (1.1) by

$$\partial_t y - \Delta y = y^\lambda + uy, \qquad x \in \Omega,\ t \in [0,T], \tag{1.4}$$

and we prove the required a priori bounds by using the energy and perturbation arguments mentioned above. This study is motivated by the fact that multiplicative controls often appear in the literature.

In section 6 we investigate the existence of optimal controls for problems governed by the system

$$\left.\begin{aligned} \partial_t y_1 - \Delta y_1 &= \kappa y_1 y_2 - b y_1 + u, && x \in \Omega,\ t \in [0,T], \\ \partial_t y_2 - d\Delta y_2 &= a y_1, && x \in \Omega,\ t \in [0,T], \end{aligned}\right\} \tag{1.5}$$

which is complemented by suitable boundary and (nonnegative) initial conditions. Here $d \geq 0$, $\kappa, a > 0$, $b \in \mathbb{R}$, and u is a nonnegative control. System (1.5) (with $d = 0$ and $u = 0$) was derived in [19] as a model for the dynamics of a nuclear reactor close to a stationary state. The state variables y_1 and y_2 correspond to the neutron flux and the temperature, respectively, and the constant κ represents the temperature feedback (cf. also [29]). Since this system (with $d \geq 0$, $\kappa > 0$, and $u = 0$) possesses an interesting dynamics with possible blow-up in finite time, it became the object of study of many mathematical papers (see [10], [17], [23], [24], [31], [32], and the references therein). We consider the case $d = \kappa = 1$ and study the corresponding optimal control problem with final observation. Since the energy arguments used in the case of (1.1) or (1.4) cannot be applied, we use a different approach to the proof of a priori bounds.

This paper is organized as follows. In section 2 we formulate our main results (Theorems 2.3, 2.6, 2.8, and 2.10). Sections 3 and 4 are devoted to the proof of existence of optimal controls and optimality conditions, respectively, for the problem governed by the model equation (1.1). Problems governed by (1.4) and (1.5) are studied in sections 5 and 6, respectively. In the appendix we recall, for the reader's convenience, from [6] the basic existence, uniqueness, and stability results for semilinear parabolic equations which are the fundament for our investigations.

2. Main results. First we introduce some notation which will be used throughout this paper. If $a, b \in \mathbb{R}$, then we denote $a \vee b := \max(a, b)$ and $a \wedge b := \min(a, b)$. If $p \in (1, \infty)$, then p' is the dual exponent defined by $1/p + 1/p' = 1$. For $X \subset \mathbb{R}^n$ we write $\mathcal{D}(X)$ for the space of smooth functions with compact support in X. The symbols w and w^* are used to denote the weak and weak-star topology, respectively. By Ω we mean an open bounded subset of $\mathbb{R}^n$ having a smooth boundary Γ. We also set $Q := \Omega \times J$ and $\Sigma := \Gamma \times J$, where $J := [0, T]$ with a fixed $T > 0$. By $\mathcal{B}$ we denote one of the boundary operators γ, ∂_ν, where γ is the trace operator and ∂_ν is the derivative with respect to ν, the outer unit normal on Γ.

Let $s \in [-2, 2]$ and $1 < q < \infty$. We write $W_q^s := W_q^s(\Omega)$ for the usual Sobolev–Slobodeckiĭ spaces; hence $W_q^0 = L_q(\Omega)$. If $\mathcal{B} = \gamma$, then we set

$$W_{q,\mathcal{B}}^s := \begin{cases} \{\, u \in W_q^s;\ \mathcal{B}u = 0 \,\}, & 1/q < s \le 2, \\ W_q^s, & 0 \le s < 1/q, \\ (W_{q',\mathcal{B}}^{-s})', & -2 \le s < 0, \quad s \ne -1 + 1/q, \end{cases}$$

where X' denotes the dual space to X. If $\mathcal{B} = \partial_\nu$, then

$$W_{q,\mathcal{B}}^s := \begin{cases} \{\, u \in W_q^s;\ \mathcal{B}u = 0 \,\}, & 1 + 1/q < s \le 2, \\ W_q^s, & 0 \le s < 1 + 1/q, \\ (W_{q',\mathcal{B}}^{-s})', & -2 \le s < 0, \quad s \ne -2 + 1/q. \end{cases}$$

In either case the dual spaces are determined by means of the standard L_q-duality pairing. We also set $S_q := \{-2 + 1/q, -1 + 1/q, 1/q, 1 + 1/q\}$.

Weak and strong solutions. Consider the problem

$$\left.\begin{aligned} \partial_t y - \Delta y &= f && \text{in } Q, \\ \mathcal{B}y &= 0 && \text{on } \Sigma, \\ y(\cdot, 0) &= y^0 && \text{in } \Omega, \end{aligned}\right\} \tag{2.1}$$

where $y^0 \in L_1(\Omega)$ and $f \in L_1(Q)$.

DEFINITION 2.1. *Assume that $s \in [0, 2] \setminus S_q$ and $1 < p, q < \infty$. A* weak $L_p(W_q^s)$-solution *of* (2.1) on $[0, t]$, $0 < t \le T$, *is a function $y \in L_{p,\mathrm{loc}}([0, t), W_{q,\mathcal{B}}^s)$ such that*

$$\int_0^t \int_\Omega (-\partial_t \varphi - \Delta \varphi) y \, dx \, d\tau = \int_0^t \int_\Omega \varphi f \, dx \, d\tau + \int_\Omega \varphi(0) y^0 \, dx$$

for any $\varphi \in \mathcal{D}(\overline{\Omega} \times [0, t))$ satisfying $\mathcal{B}\varphi = 0$ on $\Gamma \times [0, t]$. It is global *if $t = T$ and $y \in L_p((0, T), W_{q,\mathcal{B}}^s)$.*

The differential operator $\mathcal{C} := 1 - \Delta$ defines an isomorphism between $W_{q,\mathcal{B}}^2$ and $L_q(\Omega)$, and this isomorphism admits a unique extension to an isomorphism $C = C_s$ between $W_{q,\mathcal{B}}^s$ and $W_{q,\mathcal{B}}^{s-2}$ for any $s \in [0, 2] \setminus S_q$ (see [1]). Moreover, $-A := 1 - C$ generates a strongly continuous analytic semigroup $\{e^{-tA};\ t \ge 0\}$ on $W_{q,\mathcal{B}}^r$ for $r \in [-2, s] \setminus S_q$, and

$$(t \mapsto e^{-tA} x) \in C\big([0, T], W_{q,\mathcal{B}}^r\big) \cap C\big((0, T], W_{q,\mathcal{B}}^s\big) \tag{2.2}$$

with

$$\|e^{-tA} x\|_{W_{q,\mathcal{B}}^s} \le c t^{(r-s)/2} \, \|x\|_{W_{q,\mathcal{B}}^r}, \qquad 0 < t \le T, \tag{2.3}$$

for $x \in W^r_{q,\mathcal{B}}$ (cf. [1, Theorem 5.2] and [2, Theorem V.2.1.3]). Then, provided $1 < q < n/(n-2)$ and $0 \le s < 2 - n/q'$, (the weak form of) problem (2.1) is equivalent to the abstract evolution equation

$$\dot{y} + Ay = f \text{ in } [0,T], \qquad y(0) = y^0, \tag{2.4}$$

(see [6] for details).

DEFINITION 2.2. *A weak $L_p(W^s_q)$-solution y of (2.1) on $[0,t]$ is a* strong $L_p(W^s_q)$-solution *if*

$$y \in W^1_{r,\mathrm{loc}}([0,t), W^{s-2}_{q,\mathcal{B}}) \cap L_{r,\mathrm{loc}}([0,t), W^s_{q,\mathcal{B}})$$

for some $r > 1$ and (2.4) is satisfied a.e. in $[0,t]$. If, in addition, $y \in C^\rho([0,t), W^s_{q,\mathcal{B}})$ for some $\rho \in [0,1)$ then y is called a strong $C^\rho(W^s_q)$-solution.

A model problem. Now we are ready to formulate the main results of this paper. First consider the optimal control problem (1.3) for the model state equation

$$\left.\begin{aligned} \partial_t y - \Delta y &= |y|^{\lambda-1}y + u && \text{in } Q,\\ \mathcal{B}y &= 0 && \text{on } \Sigma,\\ y(\cdot,0) &= y^0 && \text{in } \Omega, \end{aligned}\right\} \tag{2.5}$$

where $\mathcal{B} \in \{\gamma, \partial_\nu\}$. As already announced in the introduction, instead of the operator $-\Delta$ and the model nonlinearity $|y|^{\lambda-1}y$, we could handle a general second-order elliptic operator $\mathcal{A}$ and a general superlinear function $f(x,y)$ satisfying suitable growth conditions (see [26] for details).

In the following theorem we consider cost functionals $\mathbb{J}$ which depend on the final value of y and which satisfy the coercivity condition

$$\mathbb{J}(y,u) \ge c_1 \|y(\cdot,T)\|_{L_q(\Omega)} - c_2, \tag{2.6}$$

with positive constants c_1 and c_2.

THEOREM 2.3. *Let*

$$1 < \lambda < \frac{n+2}{(n-2)_+}, \tag{2.7}$$

$$q \in \left((\lambda-1)\frac{n}{2}, \frac{2n}{(n-4)_+}\right) \qquad \text{and} \qquad q \ge 2. \tag{2.8}$$

Suppose that $r \ge 2$ satisfies

$$\frac{1}{r} < 1 - \frac{n}{4} + \frac{n}{2q} \tag{2.9}$$

and

$$r > \frac{\lambda+1}{\lambda}\,\frac{\lambda n - (n+4)}{n+2-\lambda(n-2)} - \frac{2}{\lambda}. \tag{2.10}$$

Assume that $y^0 \in W^2_{q,\mathcal{B}}$ and $\mathbb{U}_{\mathrm{ad}}$ is a weakly compact subset of $L_r(J, L_2(\Omega))$. If $u \in \mathbb{U}_{\mathrm{ad}}$, then (2.5) has a unique strong $L_{r\lambda}(L_{2\lambda})$-solution defined on the maximal existence interval J_u.

Assume $\mathbb{U}^G_{\mathrm{ad}} \ne \emptyset$. Let (2.6) be true and assume that $\mathbb{J}$ can be written in the form $\mathbb{J}(y,u) = \mathbb{J}_T(y(\cdot,T),u)$, where $\mathbb{J}_T : L_q(\Omega) \times (L_r(J, L_2(\Omega)), w) \to \mathbb{R}$ is lower semicontinuous. Then the optimal control problem (1.3) governed by (2.5) has a solution.

Remark 2.4. (i) Theorem 2.3 remains true if we replace the nonlinearity $|y|^{\lambda-1}y$ with $|y|^{\lambda}$; see Remark 3.3.

(ii) Let λ, q, r satisfy (2.7)–(2.10), $y^0 \in W^2_{q,\mathcal{B}}$,

$$\mathbb{J}(y,u) := \int_\Omega |y(x,T) - y_d(x)|^q \, dx + N \int_0^T \left(\int_\Omega u^2(x,t)\, dx \right)^{r/2} dt, \tag{2.11}$$

where $y_d \in L_q(\Omega)$, $N \geq 0$, and let $\mathbb{U}_{\rm ad} \subset L_r(J, L_2(\Omega))$ be closed, convex, and bounded. Then all assumptions of Theorem 2.3 are satisfied provided $\mathbb{U}^G_{\rm ad} \neq \emptyset$. In addition, if $N > 0$, then $\mathbb{U}_{\rm ad}$ need not be bounded (we can replace the set $\mathbb{U}_{\rm ad}$ in problem (1.3) with $\tilde{\mathbb{U}}_{\rm ad} := \mathbb{U}_{\rm ad} \cap \mathbb{B}_R$, where $\mathbb{B}_R$ is a large closed ball in $L_r(J, L_2(\Omega))$).

(iii) If $r = 2$, then conditions (2.7)–(2.10) in Theorem 2.3 read

$$1 < \lambda < \frac{3n+8}{(3n-4)_+}, \qquad q \in \left((\lambda-1)\frac{n}{2}, \frac{2n}{(n-2)_+} \right), \qquad \text{and} \qquad q \geq 2.$$

In particular, if $n \leq 3$, then we may choose $\lambda = 3$ and $q = 4$ (cf. the open problems of Lions mentioned above). □

Example 2.5. Let $\lambda, q, r, y^0, \mathbb{J}, \mathbb{U}_{\rm ad}$ be as in Remark 2.4(ii). Assume $|y^0| \leq C_0$ for some $C_0 \geq 0$ and $\{u \in L_\infty(Q)\,;\, |u| \leq C_0^\lambda\} \subset \mathbb{U}_{\rm ad}$. Then $\mathbb{U}^G_{\rm ad} \neq \emptyset$; hence the optimal control problem (1.3) has a solution. In fact, the solution $\tilde{y}$ of the linear problem

$$\left.\begin{aligned} \partial_t \tilde{y} - \Delta \tilde{y} &= 0 && \text{in } Q, \\ \mathcal{B}\tilde{y} &= 0 && \text{on } \Sigma, \\ \tilde{y}(\cdot,0) &= y^0 && \text{in } \Omega, \end{aligned}\right\}$$

satisfies $|\tilde{y}| \leq C_0$ by the maximum principle; thus $u := -|\tilde{y}|^{\lambda-1}\tilde{y} \in \mathbb{U}^G_{\rm ad}$ (the function $y := \tilde{y}$ is a global solution of (2.5)).

Optimality conditions. In order to obtain the optimality conditions, we restrict ourselves to the case $r = 2$ and we also fix

$$\mathbb{J}(y,u) := \int_\Omega |y(x,T) - y_d(x)|^q \, dx + N \int_Q u^2(x,t)\, dx\, dt, \tag{2.12}$$

where $q > 1$, $y_d \in L_q(\Omega)$, and $N \geq 0$ are given. This particular choice of r and $\mathbb{J}$ corresponds to the setting of Lions in [21].

THEOREM 2.6. *Let the assumptions of Theorem* 2.3 *be fulfilled and let, moreover,* $r = 2$, $\mathbb{U}_{\rm ad}$ *be convex, and* $\mathbb{J}$ *be as in* (2.12). *If* (y,u) *is an optimal pair for problem* (1.3) *governed by* (2.5) *and* p *is the solution of*

$$\left.\begin{aligned} -\partial_t p - \Delta p &= \lambda |y|^{\lambda-1} p && \text{in } Q, \\ \mathcal{B}p &= 0 && \text{on } \Sigma, \\ p(\cdot,T) &= q|y(\cdot,T) - y_d|^{q-2}(y(\cdot,T) - y_d) && \text{in } \Omega, \end{aligned}\right\} \tag{2.13}$$

then

$$\int_Q (p + 2Nu)(v-u)\, dx\, dt \geq 0 \qquad \text{for all } v \in \mathbb{U}_{\rm ad}.$$

Remark 2.7. (a) The existence of an optimal pair (y,u) in Theorem 2.6 is guaranteed by Theorem 2.3. The solvability of (2.13) follows from Lemma 4.1 and Remark 4.2 below.

(b) As in Remark 2.4(ii), in Theorem 2.6 we can allow $\mathbb{U}_{\rm ad}$ to be any closed convex subset of $L_2(Q)$ if $N > 0$.

Multiplicative controls. Next we consider the optimal control problem (1.3) governed by the equation

$$\left.\begin{aligned} \partial_t y - \Delta y &= |y|^{\lambda-1}y + uy && \text{in } Q,\\ \mathcal{B}y &= 0 && \text{on } \Sigma,\\ y(\cdot,0) &= y^0 && \text{in } \Omega, \end{aligned}\right\} \tag{2.14}$$

where $\mathcal{B} \in \{\gamma, \partial_\nu\}$.

THEOREM 2.8. *Let* (2.6), (2.7), *and* (2.8) *be satisfied, let* $y^0 \in W^2_{q,\mathcal{B}}$, *let* $\mathbb{U}_{\rm ad} \subset L_\infty(Q)$ *be* w^**-sequentially compact, and let* $\mathbb{U}^G_{\rm ad} \neq \emptyset$. *Assume that* $\mathbb{J}$ *can be written in the form* $\mathbb{J}(y,u) = \mathbb{J}_T(y(\cdot,T),u)$, *where* $\mathbb{J}_T : L_q(\Omega) \times (L_\infty(Q), w^*) \to \mathbb{R}$ *is sequentially lower semicontinuous. Then problem* (1.3) *governed by* (2.14) *has a solution.*

Remark 2.9. Similarly as in Remark 2.4(ii) and Example 2.5, all assumptions of Theorem 2.8 concerning $\mathbb{U}_{\rm ad}$ and $\mathbb{J}$ are satisfied if, for example, $|y^0| \le C_0$, $D_1 \ge C_0^{\lambda-1}$, $D_2 \ge 0$, $N \ge 0$,

$$\mathbb{U}_{\rm ad} = \{u \in L_\infty(Q) : -D_1 \le u \le D_2\},$$

and

$$\mathbb{J}(y,u) = \int_\Omega |y(x,T) - y_d(x)|^q \, dx + N\|u\|_{L_\infty(Q)}.$$

Again, we may take $D_1 = \infty$ and/or $D_2 = \infty$ if $N > 0$.

Control of systems. Finally, let us formulate our result concerning the parabolic system

$$\left.\begin{aligned} \partial_t y_1 - \Delta y_1 &= y_1 y_2 - b y_1 + u && \text{in } Q,\\ \partial_t y_2 - \Delta y_2 &= a y_1 && \text{in } Q,\\ \mathcal{B}y_1 = \mathcal{B}y_2 &= 0 && \text{on } \Sigma,\\ y_1(\cdot,0) &= y_1^0 && \text{in } \Omega,\\ y_2(\cdot,0) &= y_2^0 && \text{in } \Omega, \end{aligned}\right\} \tag{2.15}$$

where $a > 0$, $b \in \mathbb{R}$, $\mathcal{B} \in \{\gamma, \partial_\nu\}$,

$$y_1^0, y_2^0 \ge 0, \qquad y_1^0, y_2^0 \in C^2(\bar\Omega), \qquad \mathcal{B}y_1^0 = \mathcal{B}y_2^0 = 0, \tag{2.16}$$

$$u \in L_r(J, L_z^+(\Omega)), \qquad r, z > 1, \quad \frac{1}{r} + \frac{n}{2z} < 1. \tag{2.17}$$

As usual, $L_r(J, L_z^+(\Omega))$ is the set of positive functions in $L_r(J, L_z(\Omega))$. The regularity assumption (2.17) guarantees that (2.15) possesses a unique strong solution (defined on the maximal existence interval J_u) and that this solution is Hölder continuous in both x and t.

THEOREM 2.10. *Consider problem* (2.15) *with* $a > 0$, $b \in \mathbb{R}$. *Let* (2.16) *and* (2.17) *be satisfied, where either* $\mathcal{B} = \partial_\nu$ *and* $n \le 3$ *or* $\mathcal{B} = \gamma$ *and* $n \le 2$. *Assume that* $\mathbb{U}_{\rm ad}$ *is a compact set in* $L_r(J, L_z^+(\Omega))$, $\mathbb{U}^G_{\rm ad} \neq \emptyset$, *and* $\mathbb{J}$ *can be written in the form* $\mathbb{J}(y,u) = \mathbb{J}_T(y_1(T),u)$, *where*

$$\mathbb{J}_T : L_q(\Omega) \times L_r(J, L_z^+(\Omega)) \to \mathbb{R} \quad \textit{is lower semicontinuous,}$$

$q \in [1,\infty]$, *and* $\mathbb{J}(y,u) \ge c_1\|y_1(T)\|_{L_q(\Omega)} - c_2$. *Then the optimal control problem* (1.3) *governed by* (2.15) *has a solution.*

Remark 2.11. As above, we can easily find examples of $\mathbb{U}_{\rm ad}$ and $\mathbb{J}$ satisfying the compactness and lower semicontinuity assumptions in Theorem 2.10. The assumption $\mathbb{U}^G_{\rm ad} \ne \emptyset$ is satisfied if, for example, $\mathcal{B} = \gamma$, $b \ge 0$, $0 \in \mathbb{U}_{\rm ad}$, and y_1^0, y_2^0 are small enough (e.g., in $L_\infty(\Omega)$). This is due to the fact that in this case, zero is an asymptotically stable equilibrium of (2.15) with $u = 0$. If $\mathcal{B} = \partial_\nu$, $y_1^0 = y_2^0 = 0$, and $0 \in \mathbb{U}_{\rm ad}$, then obviously $0 \in \mathbb{U}^G_{\rm ad}$.

3. Solvability of the model problem.

Proof of Theorem 2.3. Set $s := 0$, $q := 2\lambda$, and $p := r\lambda$. Since $r \ge 2$ and $1 < \lambda < \frac{n+2}{(n-2)_+}$, there exists $\sigma \notin S_q$ satisfying

$$\frac{2}{r\lambda'} < \sigma < \frac{2}{r} \wedge \Big(2 - \frac{n}{2\lambda'}\Big).$$

Now Theorem A.1 guarantees the existence of a unique $L_{r\lambda}(L_{2\lambda})$-solution y of (2.5) defined on the maximal existence interval J_u. Fixing $u \in \mathbb{U}^G_{\rm ad}$, this solution is global and $|y|^\lambda \in L_r(J, L_2(\Omega))$. The Sobolev maximal regularity for (2.5), [2, Theorem III.4.10.2] and interpolation theorems in [4] (also see [3, Theorem 3]) imply

$$y \in W^1_r(J, L_2(\Omega)) \cap L_r(J, W^2_{2,\mathcal{B}}) \hookrightarrow C(J, W^1_{2,\mathcal{B}}) \cap C(J, W^z_{q,\mathcal{B}}) \cap L_{r\lambda}(J, L_{2\lambda}(\Omega)) \tag{3.1}$$

for any

$$z < 2 - \frac{n}{2} + \frac{n}{q} - \frac{2}{r},$$

where the embedding into $C(J, W^z_{q,\mathcal{B}}) \cap L_{r\lambda}(J, L_{2\lambda}(\Omega))$ is compact.

Let (y_k, u_k) be a minimizing sequence for problem (1.3). We may assume $u_k \to u$ weakly in $L_r(J, L_2(\Omega))$ and $\|u_k\|_{L_r(J,L_2(\Omega))} \le C_r$. Part (a) of the proof of [6, Theorem 1.1] shows that there exists $t_0 > 0$ independent of k such that

$$y_k \text{ are uniformly bounded in } L_{r\lambda}([0,t_0], L_{2\lambda}(\Omega)). \tag{3.2}$$

Set $u_k(x,t) := 0$ for $t \in (T, 2T]$ and consider problem (2.5) with J replaced by $[0,2T]$. This problem possesses a unique $L_{r\lambda}(L_{2\lambda})$-solution $\tilde{y}_k$ defined on the maximal existence interval $J_{\tilde{y}_k} \subset [0,2T]$. The function $w_k(t) := \tilde{y}_k(T+t)$ is the $L_{r\lambda}(L_{2\lambda})$-solution of (2.5) with $u \equiv 0$, initial condition $w_k(0) = y_k(T)$, and the maximal existence interval $J_{w_k} \subset [0,T]$. The boundedness of $\mathbb{J}(y_k, u_k)$ implies a bound for $y_k(T)$ in $L_q(\Omega)$, and the well posedness of (2.5) in $L_q(\Omega)$, guaranteed by Lemma 3.1 below, shows the existence of $t_1 > 0$ such that $[0,t_1] \subset J_{w_k}$ for any k. Consequently, all solutions y_k can be continued on the interval $[T, T+t_1]$. Now Lemma 3.2 below implies $\|y_k(\tau)\|_{L_q(\Omega)} \le C_q$ for any $\tau \in [0,T]$.

Let $\tau^* = \tau^*(C_r, C_q)$ be from Lemma 3.1. Fixing $\delta \in (0, t_0 \wedge \tau^*)$ and using the last statement of Lemma 3.1 for $w_k(t) := y_k(\tau + t)$, $t \in [0, \tau^*]$, $\tau \in [t_0 - \delta, T - \tau^*]$, we get a uniform bound for y_k in $L_{r\lambda}([t_0, T], L_{2\lambda}(\Omega))$. This bound and (3.2) show the boundedness of $|y_k|^{\lambda-1}y_k$ in $L_r(J, L_2(\Omega))$. As in (3.1), we get that the sequence $(|y_k|^{\lambda-1}y_k)$ is compact in $L_r(J, L_2(\Omega))$ and $(y_k(T))$ is compact in $L_q(\Omega)$. Now it is easy to pass to the limit to get a solution of (1.3). ∎

Let λ, q be as in Theorem 2.3 and let $r \ge 2$ satisfy (2.9). These assumptions guarantee that there exists $s \notin S_q$ such that

$$0 \vee \Big(\frac{n}{q} - \frac{n}{\lambda}\Big) \vee \Big[\frac{n}{q} - \frac{1}{\lambda}\Big(2 + \frac{n}{q}\Big)\Big] < s < \frac{2}{\lambda} \wedge \Big(2 + \frac{n}{q} - \frac{n}{2} - \frac{2}{r}\Big) \wedge \Big[\frac{1}{\lambda}\Big(2 + \frac{n}{q}\Big) - \frac{2}{r} - \frac{n}{2} + 2\Big]. \tag{3.3}$$

LEMMA 3.1. *Let λ, q be as in Theorem 2.3 and let $r \geq 2$ satisfy (2.9). Assume $u \in L_r(J, L_2(\Omega))$. Then problem (2.5) is well posed in $L_q(\Omega)$. More precisely, if the norm of u in $L_r(J, L_2(\Omega))$ is bounded by a constant C_r, $y^0 \in L_q(\Omega)$, $\|y^0\|_{L_q(\Omega)} \leq C_q$, and s satisfies (3.3), then there exist $\tau^* = \tau^*(C_r, C_q) > 0$ and a unique solution*

$$y \in C([0, \tau^*], L_q(\Omega)) \cap C((0, \tau^*], W^s_{q,\mathcal{B}}). \tag{3.4}$$

In addition, this solution satisfies

$$\|y(t)\|_{L_q(\Omega)} + t^{s/2}\|y(t)\|_{W^s_{q,\mathcal{B}}} \leq C, \qquad t \in (0, \tau^*], \tag{3.5}$$

where C depends only on s, C_r, C_q (and q, r, λ, Ω). If $\hat{q} \geq q$ satisfies

$$\hat{q} < \frac{2n}{(n-4)_+} \qquad \text{and} \qquad \frac{1}{r} < 1 - \frac{n}{4} + \frac{n}{2\hat{q}}, \tag{3.6}$$

then

$$y \in C((0, \tau^*], L_{\hat{q}}(\Omega)) \tag{3.7}$$

and

$$\|y(t)\|_{L_{\hat{q}}(\Omega)} \leq C(\delta, \hat{q}, C_r, C_q), \qquad t \in [\delta, \tau^*], \quad \delta \in (0, \tau^*). \tag{3.8}$$

Finally,

$$y \in C([\delta, \tau^*], W^1_{2,\mathcal{B}}(\Omega)) \cap L_{r\lambda}([\delta, \tau^*], L_{2\lambda}(\Omega)) \tag{3.9}$$

for any $\delta > 0$, and the norm of y in this space can be bounded by $C(\delta, C_r, C_q)$.

Proof. The proof of the first part is an easy modification of [8, Theorem 4.1]. In fact, let X be the Banach space of all functions

$$y \in C([0, \tau^*], L_q(\Omega)) \cap C((0, \tau^*], W^s_{q,\mathcal{B}})$$

for which

$$\|y\|_X := \sup_{t \in (0, \tau^*]} (\|y(t)\|_{L_q(\Omega)} + t^{s/2}\|y(t)\|_{W^s_{q,\mathcal{B}}}) < \infty.$$

Then it is sufficient to use the Banach fixed point theorem for the mapping

$$Ky(t) = e^{-At}y^0 + \int_0^t e^{-A(t-\tau)}(|y(\tau)|^{\lambda-1}y(\tau) + u(\tau))\, d\tau$$

in a large closed ball $\mathbb{B}$ of X with radius R, where A is as in (2.4). For example, assume that $y \in \mathbb{B}$ and denote by $\|\cdot\|_s$ the norm in $W^s_{q,\mathcal{B}}$. Fixing s satisfying (3.3), there exists

$$z \in (1, q] \quad \text{such that} \qquad \lambda\left(\frac{n}{q} - s\right) \vee \lambda\left(\frac{2}{r} + \frac{n}{2} - 2\right) < \frac{n}{z} < 2 + \frac{n}{q} - s\lambda. \tag{3.10}$$

Choose $\sigma_1 \in (s\lambda, 2+n/q-n/z)$ and $\sigma_2 \in (s+2/r, 2+n/q-n/2)$, $\sigma_1, \sigma_2 \notin S_q$. Then we have $L_z(\Omega) \hookrightarrow W^{\sigma_1-2}_{q,\mathcal{B}}$ and $L_2(\Omega) \hookrightarrow W^{\sigma_2-2}_{q,\mathcal{B}}$; hence it follows from (2.3) that

$$\begin{aligned}
t^{s/2}\|Ky(t)\|_s &\le C(C_q) + Ct^{s/2}\int_0^t (t-\tau)^{(\sigma_1-s)/2-1}\||y(\tau)|^{\lambda-1}y(\tau)\|_{\sigma_1-2}\,d\tau \\
&\quad + Ct^{s/2}\int_0^t (t-\tau)^{(\sigma_2-s)/2-1}\|u(\tau)\|_{\sigma_2-2}\,d\tau \\
&\le C(C_q) + Ct^{s/2}\int_0^t (t-\tau)^{(\sigma_1-s)/2-1}\|y(\tau)\|_s^{\lambda}\,d\tau \\
&\quad + Ct^{s/2}\int_0^t (t-\tau)^{(\sigma_2-s)/2-1}\|u(\tau)\|_{L_2(\Omega)}\,d\tau \\
&\le C(C_q) + CR^{\lambda}t^{s/2}\int_0^t (t-\tau)^{(\sigma_1-s)/2-1}\tau^{-s\lambda/2}\,d\tau \\
&\quad + CC_rt^{s/2}\left(\int_0^t (t-\tau)^{r'[(\sigma_2-s)/2-1]}\,d\tau\right)^{1/r'},
\end{aligned}$$

which shows $t^{s/2}\|Ky(t)\|_s < R/2$ if $R = R(C_q)$ is large enough and $t = t(R, C_r)$ is small enough. Similar arguments show the same bound for $\|Ky(t)\|_{L_q(\Omega)}$ and the fact that K is a contraction. Obviously, the fixed point of K is a solution of our problem. Uniqueness of this solution in the class (3.4) can be proved in the same way as in [7, pp. 295–296].

We have $W^s_{q,\mathcal{B}} \hookrightarrow L_{q_1}(\Omega)$ whenever $n/q_1 > n/q - s$. Due to the upper bound for s in (3.3), q_1 is restricted by the conditions

$$\frac{n}{q_1} > -2 + \frac{2}{r} + \frac{n}{2} \quad \text{and} \quad \frac{n}{q_1} > \frac{n}{q} - \varepsilon(q), \tag{3.11}$$

where

$$\varepsilon(q) := \frac{2}{\lambda} + \frac{n}{\lambda q} + 2 - \frac{2}{r} - \frac{n}{2} > 0.$$

Let $\hat q \ge q$ satisfy (3.6). If $n/\hat q > n/q - \varepsilon(q)$, then $W^s_{q,\mathcal{B}} \hookrightarrow L_{\hat q}(\Omega)$ since the second inequality in (3.6) guarantees that the first condition in (3.11) is satisfied with $q_1 = \hat q$. Consequently, (3.7) and (3.8) follow from (3.4) and (3.5). If $n/\hat q \le n/q - \varepsilon(q)$, then we fix $q_1 > q$ satisfying (3.11) (this is possible due to (2.9)). Now the first part of the lemma with q replaced by q_1 (and $t = 0$ replaced by $t = \delta_1$, where $\delta_1 > 0$ is small) implies $y \in C((\delta_1, \tau^*], W^{s_1}_{q_1,\mathcal{B}})$. Similarly as above, $W^{s_1}_{q_1,\mathcal{B}} \hookrightarrow L_{q_2}(\Omega)$, where

$$\frac{n}{q_2} > -2 + \frac{2}{r} + \frac{n}{2} \quad \text{and} \quad \frac{n}{q_2} > \frac{n}{q_1} - \varepsilon(q_1).$$

Repeating this bootstrapping argument finitely many times, we obtain (3.7) and (3.8).

It remains to prove (3.9) and the corresponding bound. Fix $\delta \in (0, \tau^*)$ and set $t_0 := \delta/2$, $J_0 := [t_0, \tau^*]$, and $J^* := [\delta, \tau^*]$. Taking $R > 1$ large and $\hat q$ close to its upper bound, we have $\hat q > \lambda$ and $|y|^{\lambda} \in L_R(J_0, L_{\hat q/\lambda}(\Omega))$. Set $f_1 := |y|^{\lambda-1}y$ and $f_2 := u$. Writing $y = y_1 + y_2 + y_3$, where $\mathcal{B}y_i = 0$, $i = 1, 2, 3$, and

$$\left.\begin{aligned}
&\partial_t y_1 - \Delta y_1 = f_1 \quad \text{in } \Omega \times J_0, \qquad y_1(t_0) = 0, \\
&\partial_t y_2 - \Delta y_2 = f_2 \quad \text{in } \Omega \times J_0, \qquad y_1(t_0) = 0, \\
&\partial_t y_3 - \Delta y_3 = 0 \quad \text{in } \Omega \times J_0, \qquad y_1(t_0) = y(t_0),
\end{aligned}\right\} \tag{3.12}$$

the maximal Sobolev regularity implies

$$y_1 \in W^1_R(J_0, L_{\hat{q}/\lambda}(\Omega)) \cap L_R(J_0, W^2_{\hat{q}/\lambda,\mathcal{B}}) \hookrightarrow C(J_0, W^1_{2,\mathcal{B}})$$

since we can take $\hat{q} > 2\lambda n/(n+2)$ and R arbitrarily large. Similar arguments guarantee $y_2 \in C(J_0, W^1_{2,\mathcal{B}})$ and $y_3 \in C(J^*, W^1_{2,\mathcal{B}})$; hence $y \in C(J^*, W^1_{2,\mathcal{B}})$ (and the corresponding estimate in this space is valid).

Choose $k > 1$ such that $\hat{q} > (\lambda - 1/k)n/2$ and fix $m \in \mathbb{N}$ such that $k^m\hat{q} > 2\lambda$. Choose also $R > r\lambda^{m+1}$. Set $t_i := \delta/2 + i\delta/(2m+2)$, $J_i := [t_i, \tau^*]$, and $\hat{q}_i := k^i\hat{q}$, $i = 1, 2, \dots, m$. Notice that $y_2, y_3 \in L_{r\lambda}(J_1, L_{2\lambda}(\Omega))$ and $W^2_{\hat{q}/\lambda,\mathcal{B}} \hookrightarrow L_{\hat{q}_1}(\Omega)$; hence $y_1 \in L_R(J_1, L_{\hat{q}_1}(\Omega))$. Consequently, $|y|^\lambda$ can be written in the form

$$|y|^\lambda = \tilde{f}_1 + \tilde{f}_2, \qquad \tilde{f}_1 \in L_{R/\lambda}(J_1, L_{\hat{q}_1/\lambda}(\Omega)), \quad \tilde{f}_2 \in L_r(J_1, L_2(\Omega)).$$

Writing $y = \tilde{y}_1 + \tilde{y}_2 + \tilde{y}_3$, where $\mathcal{B}\tilde{y}_i = 0$, $i = 1, 2, 3$, and $\tilde{y}_1, \tilde{y}_2, \tilde{y}_3$ satisfy (3.12) with f_1, f_2, J_0, t_0 replaced by $\tilde{f}_1, \tilde{f}_2, J_1, t_1$, respectively, we obtain as above $\tilde{y}_2, \tilde{y}_3 \in L_{r\lambda}(J_2, L_{2\lambda}(\Omega))$ and $\tilde{y}_1 \in L_{R/\lambda}(J_2, L_{\hat{q}_2}(\Omega))$. Repeating this argument m times we get

$$y \in L_{r\lambda}(J^*, L_{2\lambda}(\Omega)) + L_{R/\lambda^m}(J^*, L_{\hat{q}_m}(\Omega)) = L_{r\lambda}(J^*, L_{2\lambda}(\Omega))$$

(and the corresponding estimates), which concludes the proof. □

LEMMA 3.2. *Let λ, q, r be as in Theorem 2.3. Let $t_1 > 0$, $u \in L_r([0, T + t_1], L_2(\Omega))$, and let its norm in this space be bounded by a positive constant C_r. Assume that y is a global solution of (2.5) (with J replaced by $[0, T + t_1]$) and $y^0 \in W^2_q(\Omega)$, $\|y^0\|_{W^2_q(\Omega)} \le C_q$. Then there exists a constant $C = C(C_r, C_q, t_1)$ such that $\|y(t)\|_{L_q(\Omega)} \le C$ for any $t \in [0, T]$.*

Proof. The proof is a modification of the proof of the main result in [25] (cf. also [26] and [27, proof of Theorem 5.1]).

All our constants (and bounds) in this proof may change from line to line and may depend on C_r, C_q, t_1. First we deduce from Lemma 3.1 and the beginning of the proof of Theorem 2.3 that $y \in C([0, T + t_1], W^1_{2,\mathcal{B}})$ and there exists $\tau > 0$ such that

$$y \text{ is bounded in } C([0, \tau], L_q(\Omega)) \text{ by a constant } C = C(C_q, C_r). \tag{3.13}$$

Denote

$$V(t) = \frac{1}{2}\int_\Omega |\nabla y(x,t)|^2\,dx - \frac{1}{\lambda+1}\int_\Omega |y(x,t)|^{\lambda+1}\,dx.$$

If u is smooth, then

$$V'(t) = -\int_\Omega (\partial_t y)^2\,dx + \int_\Omega u\partial_t y\,dx \le \frac{1}{2}\int_\Omega u^2\,dx - \frac{1}{2}\int_\Omega (\partial_t y)^2\,dx;$$

hence

$$V(\tau_2) - V(\tau_1) \le C - \frac{1}{2}\int_{\tau_1}^{\tau_2}\int_\Omega (\partial_t y)^2\,dx\,dt. \tag{3.14}$$

Now let u be general. Approximating u by smooth functions u_k we see that (3.14) remains true for any $u \in L_r([0, T + t_1], L_2(\Omega))$.

We will show that $V(t)$ is bounded for $t \in [0, T]$. The upper estimate for $V(t)$ follows immediately from (3.14). To prove the lower estimate we assume on the

contrary that $V(t_0) \le -(C+K)$ for some $t_0 \in [0,T]$, where C is from (3.14) and $K \gg 1$. Then (3.14) guarantees $V(t) \le -K$ for all $t \ge t_0$. Multiplying the equation in (2.5) by y and integrating over Ω we obtain

$$\begin{aligned} \frac{1}{2}\frac{d}{dt}\int_\Omega y^2\,dx &= -2V(t) + c_1\int_\Omega |y|^{\lambda+1}\,dx + \int_\Omega uy\,dx \\ &\ge K + c_2\left(\int_\Omega y^2\,dx\right)^{(\lambda+1)/2} - C_2\int_\Omega u^2\,dx, \end{aligned} \tag{3.15}$$

where the inequality is true for all $t \ge t_0$. Denote $Y(t) = \int_{t_0}^t \int_\Omega y^2\,dx\,dt$. Then integrating estimate (3.15) we get

$$Y' \ge c_3 Y^{(\lambda+1)/2} + 2K(t-t_0) - C_3.$$

Let $K \ge 10C_3/t_1$. Integrating the inequality $Y' \ge 2K(t-t_0) - C_3$ on $[t_0, t_0+t_1/2]$ we obtain

$$Y(t_0+t_1/2) \ge K\frac{t_1^2}{4} - C_3\frac{t_1}{2} \ge K\frac{t_1^2}{5}.$$

We also have

$$Y' \ge c_3 Y^{(\lambda+1)/2} \quad \text{for} \quad t \ge t_0 + \frac{t_1}{2}.$$

Since the solution of the equation $Z'(t) = c_3 Z^{(\lambda+1)/2}(t)$ for $t \ge 0$, $Z(0) = Kt_1^2/5$, blows up at $t < t_1/2$ if K is large enough, the function $Y(t) \ge Z(t-t_0-t_1/2)$ blows up at some $t < T + t_1$, which yields a contradiction. Hence K has to be bounded by a constant depending only on c_3, C_3, t_1, and λ. Consequently, V is bounded on $[0,T]$ and (3.14) provides a bound for y in the space $W_2^1([0,T], L_2(\Omega))$.

If $\lambda < 1 + 4/n$, then Lemma 3.1 with q replaced by $\tilde{q} := 2$ and $\hat{q}$ replaced by q guarantees a bound for y in $L_\infty([\tau,T], L_q(\Omega))$ which (together with (3.13)) implies the assertion.

Let $\lambda \ge 1 + 4/n$. Since y is bounded in $W_2^1([0,T], L_2(\Omega)) \hookrightarrow L_\infty([0,T], L_2(\Omega))$, we have

$$\int_0^T \|uy\|_{L_1(\Omega)}^z\,dt \le C\int_0^T \|u\|_{L_2(\Omega)}^z\,dt \le C, \qquad z \le r.$$

Using this bound and the boundedness of V on $[0,T]$, we obtain from the equality in (3.15)

$$\int_0^T \|y(t)\|_{L_{\lambda+1}(\Omega)}^{z(\lambda+1)}\,dt \le C\left(1 + \int_0^T \|\partial_t y(t) y(t)\|_{L_1(\Omega)}^z\,dt\right).$$

In particular, if $z = 2$, then this estimate, the bound for y in $W_2^1([0,T], L_2(\Omega))$ and

$$\|\partial_t y(t) y(t)\|_{L_1(\Omega)} \le \|\partial_t y(t)\|_{L_2(\Omega)} \|y(t)\|_{L_2(\Omega)} \le C\|\partial_t y\|_{L_2(\Omega)}$$

guarantee a uniform bound for y in

$$X_z := L_{z(\lambda+1)}([0,T], L_{\lambda+1}(\Omega)).$$

Interpolating between the bound of y in X_z and in $W_2^1([0,T],L_2(\Omega))$ yields a bound in $L_\infty([0,T],L_m(\Omega))$ provided

$$m < \lambda + 1 - \frac{\lambda - 1}{z+1} \tag{3.16}$$

(cf. [25, (12)]). If $r > 2$, then we will use the bootstrapping procedure in [25] in order to get these estimates for some $z > 2$. Replacing u by y, p by λ, q by z, $\tilde{q}$ by $\tilde{z}$, and λ by m in [25], denoting

$$\lambda_1 := (\lambda+1)/\lambda, \qquad \theta := \frac{\lambda+1}{\lambda-1}\,\frac{m-2}{m}, \qquad \beta := \frac{2}{(1-\theta)\tilde{z}},$$

and assuming the estimate in X_z for some $z \ge 2$, we get for $\tilde{z} > z$

$$\begin{aligned}
\int_0^T \|y(t)\|_{L_{\lambda+1}(\Omega)}^{\tilde{z}(\lambda+1)}\,dt &\le C\left(1 + \int_0^T \|\partial_t y(t) y(t)\|_{L_1(\Omega)}^{\tilde{z}}\,dt\right)\\
&\le C\left(1 + \int_0^T \|\partial_t y(t)\|_{L_{m'}(\Omega)}^{\tilde{z}}\,dt\right)\\
&\le C\left(1 + \int_0^T \|\partial_t y(t)\|_{L_{\lambda_1}(\Omega)}^{\theta\tilde{z}} \|\partial_t y(t)\|_{L_2(\Omega)}^{(1-\theta)\tilde{z}}\,dt\right)\\
&\le C\left(1 + \left(\int_0^T \|\partial_t y(t)\|_{L_{\lambda_1}(\Omega)}^{\theta\beta'\tilde{z}}\,dt\right)^{1/\beta'}\right)\\
&\le C\left(1 + \left(\int_0^T \|y(t)\|_{L_{\lambda+1}(\Omega)}^{\theta\beta'\tilde{z}\lambda}\,dt\right)^{1/\beta'}\right),
\end{aligned}$$

provided $\tilde{z} \le r$ and

$$u \in L_{\theta\beta'\tilde{z}}(J, L_{\lambda_1}(\Omega)). \tag{3.17}$$

Recall from [25] that the bootstrap condition $\theta\beta' \le \lambda_1$ is satisfied if m is chosen close to its upper bound and $\tilde{z}$ is close to z. For such m and $\tilde{z}$, one can even check that $\theta\beta' < (\lambda+1)r/(\lambda r+2)$ provided $\tilde{z} < r$. Consequently, $\theta\beta'\tilde{z} \vee \tilde{z} < r$ (and (3.17) is true) whenever $\tilde{z} < (\lambda r+2)/(\lambda+1)$. Hence, we obtain a bound for y in X_z for any

$$z < (\lambda r+2)/(\lambda+1). \tag{3.18}$$

Recall that this guarantees a bound in $L_\infty([0,T],L_m(\Omega))$ for any m satisfying (3.16). Using (2.10) we can find z satisfying (3.18) and $m \in ((\lambda-1)n/2, q]$ such that (3.16) is true. Now we can use Lemma 3.1 with q replaced by m and $\hat{q}$ replaced by q to get a bound for y in $L_\infty([\tau,T],L_q(\Omega))$ which (together with (3.13)) concludes the proof. □

Remark 3.3. We announced in Remark 2.4(i) that Theorem 2.3 remains true if we replace the nonlinearity $|y|^{\lambda-1}y$ with $|y|^\lambda$. Let us sketch the proof of this statement.

Since y satisfies

$$\partial_t y - \Delta y = |y|^\lambda + u \ge u \qquad \text{in } Q,$$

the parabolic maximum principle implies $y \geq y_L$, where y_L is the solution of the linear problem

$$\left.\begin{aligned} \partial_t y_L - \Delta y_L &= u && \text{in } Q,\\ \mathcal{B} y_L &= 0 && \text{on } \Sigma,\\ y_L(\cdot,0) &= y^0 && \text{in } \Omega. \end{aligned}\right\}$$

Using the same arguments as in (3.1) we see that $y_L \in L_{r\lambda}(J, L_{2\lambda}(\Omega))$ and that the norm of y_L in this space can be bounded by the norm of u in $L_r(J, L_2(\Omega))$ and a suitable norm of y^0. Notice that

$$|y|^\lambda = |y|^{\lambda-1} y + 2|y^-|^{\lambda-1} y^-,$$

where $y^- := -\min(0, y)$ is bounded above by $|y_L|$; hence $2|y^-|^{\lambda-1}y^-$ is bounded in $L_r(J, L_2(\Omega))$. Consequently, replacing u with $\tilde{u} := u + 2|y^-|^{\lambda-1}y^-$, we can repeat word by word the proof of Theorem 2.3.

Optimality of the growth bounds.

Remark 3.4. (i) Consider problem (2.5) with Ω being the unit ball in R^n, $n \geq 3$, $\mathcal{B} = \gamma$, and $\lambda > (n+2)/(n-2)_+$. If $n > 10$, then assume also

$$\lambda < 1 + 4\frac{n - 4 + 2\sqrt{n-1}}{(n-2)(n-10)}. \tag{3.19}$$

Choose a smooth radial, radially decreasing function $\psi : \bar{\Omega} \to \mathbb{R}^+$ satisfying $\psi(0) > 0$ and $\psi(x) = 0$ for $x \in \Gamma$ and denote by w_α the (classical) solution of (2.5) with $u = 0$ and $y^0 = \alpha\psi$, $\alpha \geq 0$. We deduce from [22] and an obvious modification of [20] that there exists $\alpha^* > 0$ with the following property: if $\alpha < \alpha^*$, then $w_\alpha(t)$ exists for all $t \in \mathbb{R}^+$ and $w_\alpha(t) \to 0$ as $t \to \infty$; if $\alpha > \alpha^*$, then this solution blows up in finite time completely.

From now on fix $y^0 = \alpha^*\psi$. Let y_k be the solution of (2.5) with $u = 0$ and the nonlinearity y^λ replaced by $\min(y^\lambda, k)$, $k = 1, 2, \ldots$. Then y_k are globally defined classical solutions, $y_{k+1} \geq y_k$. Set $y^*(t) = \lim_{k\to\infty} y_k(t)$. The results in [22] and [16] guarantee that $y^* \in L_{p,\mathrm{loc}}([0,\infty), L_p(\Omega))$ is a weak solution of (2.5) with $u = 0$ and that there exists $T^* \in (0,\infty)$ such that y^* is a classical solution on $(0, T^*)$ but it blows up at $t = T^*$ in the $L_\infty(\Omega)$-norm. In particular, $w_{\alpha^*} = y^*|_{[0,T^*)}$. Next [12] shows that y^* is a classical solution for all t except for finitely many points $T_0 = T^* < T_1 < \cdots < T_k$. Choose $T > T^*$ such that $T \neq T_j$ for any j and let $y_d(x) := y^*(x, T)$. Choose also $0 < t_1 < t_2 < T^*$ and a smooth function $U : \bar{\Omega} \times [0, T] \to [0,\infty)$ with support $K_U \subset \Omega \times [t_1, t_2]$, $K_U \neq \emptyset$, and denote by y^*_β the solution of (2.5) with $u = \beta U$ and $y^0 = \alpha^*\psi$.

Since $y^* > 0$ in K_U and $y^*_{-\beta} \to y^*$ uniformly in K_U as $\beta \to 0+$, fixing $b > 0$ small we have $|y^*_{-b}|^{\lambda-1} y^*_{-b} - bU \geq 0$ in K_U. Consequently, the maximum principle implies $y^*_{-b} \geq 0$. Choose $\beta \in (0, b]$. Since $y^*(t_2) - y^*_{-\beta}(t_2)$ belongs to the interior of the positive cone in $C^1(\bar{\Omega})$ and $w_\alpha(t_2) \to w_{\alpha^*}(t_2) = y^*(t_2)$ in $C^1(\bar{\Omega})$ as $\alpha \to \alpha^*-$, there exists $\alpha < \alpha^*$ such that $y^*_{-\beta}(t_2) \leq w_\alpha(t_2)$. Now the maximum principle implies $y^*_{-\beta}(t) \leq w_\alpha(t)$ for any $t \geq t_2$ and $y^*_\beta \geq y^*_{-b} \geq 0$ for any $t \geq 0$; hence $y^*_{-\beta}$ is a global nonnegative classical solution. On the other hand, if $\beta \geq 0$, then $y^*_\beta \geq y^*$; hence y^*_β blows up at finite time $T_\beta \leq T^*$ in the $L_\infty(\Omega)$-norm and, consequently, in the $L_q(\Omega)$-norm for any $q > n(\lambda-1)/2$ (cf. [14], [30]).

Let $\mathbb{U}_{\rm ad} = \{\beta U\,;\,\beta \in [-b,b]\}$. Fix $q > n(\lambda-1)/2$ and set $\mathbb{J}(y,u) = \int_\Omega |y(T) - y_d|^q\,dx$. The above arguments show that y^*_β is a global $L_\infty(L_q)$-solution of (2.5) if and only if $\beta < 0$. Moreover, $\beta \mapsto \mathbb{J}(y^*_\beta, \beta U)$ is decreasing on $[-b,0)$. Hence the optimal control problem (1.3) does not have a solution with $y \in L_\infty(J, L_q(\Omega))$.

(ii) Consider problem (2.5) with Ω being the unit ball in R^n and $\mathcal{B} = \gamma$ and let $1 \le q < (\lambda-1)n/2$. Then there exists a smooth radial positive function y^0 such that the solution y of (2.5) with $u = 0$ blows up at $t = T$ in the L_∞-norm and satisfies $\partial_t y \ge 0$, $y_d := y(\cdot,T) \in L_q(\Omega)$ (see [14]). Let U be a smooth nonnegative function with support $K \subset \{(x,t)\,;\,|x| < 1/2\}$, $K \ne \emptyset$, and $u_c := cU$. Then there exists $\varepsilon > 0$ such that the solution y of (2.5) with u replaced by $u_{-\varepsilon}$ remains positive. Let $\mathbb{U}_{\rm ad} = \{u_c\,;\,c \in [-\varepsilon, 0]\}$ and

$$\mathbb{J}(y,u) = \left| \int_\Omega |y(x,T)|^q\,dx - \int_\Omega y_d^q\,dx \right|.$$

Then $(y(u_{-1/k}), u_{-1/k})$, $k \ge k_0$, is obviously a minimizing sequence for the control problem (1.3), but $y(u_0)$ is not a (classical) global solution of (2.5).

4. Proof of the optimality conditions. We start with the following technical lemma concerning linear problems.

LEMMA 4.1. *Suppose that $\beta > 2 \vee (n+2)/2$ and $2 \le q < 2n/(n-2)_+$. Given $a \in L_\beta(Q)$, $u \in L_2(Q)$, and $y^0 \in L_{q'}(\Omega)$, the problem*

$$\left.\begin{aligned} \partial_t y - \Delta y &= ay + u && \text{in } Q,\\ \mathcal{B}y &= 0 && \text{on } \Sigma,\\ y(\cdot,0) &= y^0 && \text{in } \Omega \end{aligned}\right\} \tag{4.1}$$

has a unique solution

$$y \in C([0,T], L_{q'}(\Omega)) \cap C((0,T], L_q(\Omega)) \cap L_2(Q).$$

The map

$$L_\beta(Q) \times L_2(Q) \times L_{q'}(\Omega) \to L_2(Q) \times L_q(\Omega), \qquad (a,u,y^0) \mapsto (y, y(T)),$$

is analytic and bounded on bounded sets.

Proof. (i) Writing (4.1) in the abstract form

$$\dot y + Ay = ay + u \quad \text{in } (0,T], \qquad y(0) = y^0,$$

and denoting $U(t) := e^{-tA}$, we see that we have to prove the unique solvability of

$$y = U * (ay) + U * u + Uy^0 \tag{4.2}$$

in appropriate spaces.

(ii) Fix $s \in [0,1) \setminus \{1/q'\}$ such that $q \le 2n/(n-2s)_+$. Then $W^s_{q',\mathcal{B}} \hookrightarrow L_2(\Omega)$. Hence we infer from (2.3) (with q replaced by q' and $r := 0$) that

$$\|U(t)y^0\|_{L_2(\Omega)} \le c\|U(t)y^0\|_{W^s_{q',\mathcal{B}}} \le ct^{-s/2}\|y^0\|_{L_{q'}(\Omega)}, \qquad 0 < t \le T.$$

Since $s < 1$ it follows that

$$(y^0 \mapsto Uy^0) \in \mathcal{L}\big(L_{q'}(\Omega), L_2((0,T), L_2(\Omega))\big) = \mathcal{L}\big(L_{q'}(\Omega), L_2(Q)\big),$$

where $\mathcal{L}(X,Y)$ denotes the space of continuous linear operators from X to Y.

(iii) It is easy to see that

$$(u \mapsto U * u) \in \mathcal{L}(L_2(Q)).$$

(iv) Put $1/r := 1/\beta + 1/2 < 1$ and note that

$$L_r(\Omega) \hookrightarrow W^{-2+\gamma}_{2,\mathcal{B}} \quad \text{if} \quad 1/2 \geq 1/r + (\gamma - 2)/n,$$

that is, if $0 \leq \gamma \leq 2 - n/\beta$.

(v) For $m \in \mathbb{R}$ we write $L_{2,m}(Q)$ for $L_2(Q)$ endowed with the equivalent norm

$$y \mapsto \left(\int_0^T e^{-2mt} \|y(t)\|^2_{L_2(\Omega)}\, dt \right)^{1/2}.$$

From (iv), Hölder's inequality, and (2.3) (with $q = 2$ and $r := \gamma - 2$) we infer that

$$\begin{aligned} \|U * (ay)(t)\|_{L_2(\Omega)} &\leq c \int_0^t (t-\tau)^{\gamma/2-1} \|a(\tau)\|_{L_\beta(\Omega)} \|y(\tau)\|_{L_2(\Omega)}\, d\tau \\ &= ce^{mt} \int_0^t (t-\tau)^{\gamma/2-1} e^{-m(t-\tau)} \|a(\tau)\|_{L_\beta(\Omega)} e^{-m\tau} \|y(\tau)\|_{L_2(\Omega)}\, d\tau. \end{aligned}$$

Thus, by Young's inequality for convolutions (cf. the proof of [5, Lemma 3]), followed by Hölder's inequality,

$$\begin{aligned} \|U * (ay)\|_{L_{2,m}(Q)} &\leq cI(m) \left(\int_0^T \big(\|a(\tau)\|_{L_\beta(\Omega)} e^{-m\tau} \|y(\tau)\|_{L_2(\Omega)} \big)^r\, d\tau \right)^{1/r} \\ &\leq cI(m) \|a\|_{L_\beta(Q)} \|y\|_{L_{2,m}(Q)}, \end{aligned}$$

where

$$I(m) := \left(\int_0^T t^{(\gamma/2-1)\beta'} e^{-\beta' mt}\, dt \right)^{1/\beta'},$$

provided $\gamma > 2/\beta$. Such a choice is possible by (iv), thanks to $2/\beta < 2 - n/\beta$.

(vi) For $a \in L_\beta(Q)$ set $T_a(y) := U * (ay)$. Then (v) implies

$$(a \mapsto T_a) \in \mathcal{L}\big(L_\beta(Q), \mathcal{L}(L_{2,m}(Q))\big)$$

and

$$\|T_a\|_{\mathcal{L}(L_{2,m}(Q))} \leq cI(m) \|a\|_{L_\beta(Q)}.$$

Note that, by Lebesgue's theorem, $I(m) \to 0$ as $m \to \infty$. Thus, given $R > 0$, there exists $m := m_R > 0$ such that $\|T_a\|_{\mathcal{L}(L_{2,m}(Q))} \leq 1/2$ for all $a \in L_\beta(Q)$ satisfying $\|a\|_{L_\beta(Q)} \leq R$. Consequently, $1 - T_a$ has a bounded inverse on $L_{2,m}(Q)$, and the map $a \mapsto (1 - T_a)^{-1}$ is analytic for $\|a\|_{L_\beta(Q)} \leq R$. Hence, by (4.2),

$$y = (1 - T_a)^{-1}(U * u + Uy^0) \in L_2(Q)$$

for $\|a\|_{L_\beta(Q)} \le R$, thanks to (ii) and (iii), and the map

$$L_\beta(Q) \times L_2(Q) \times L_{q'}(\Omega) \to L_2(Q), \quad (a, u, y^0) \mapsto y$$

is analytic and bounded on bounded sets.

(vii) Let

$$q' \le q_1 \le 2 \le q_2 \le q \quad \text{with} \quad \frac{1}{n} > \frac{1}{q_1} - \frac{1}{q_2}.$$

Choose s such that

$$1 + n\left(\frac{1}{2} - \frac{1}{q_1}\right) > s > n\left(\frac{1}{2} - \frac{1}{q_2}\right). \tag{4.3}$$

Then there exists $\xi \in (1/2, 1)$ such that $2 - 2\xi + n(1/2 - 1/q_1) > s$. This choice of s, ξ guarantees

$$W^s_{2,\mathcal{B}} \hookrightarrow L_{q_2}(\Omega) \tag{4.4}$$

and

$$L_{q_1}(\Omega) \hookrightarrow W^{s-2+2\xi}_{2,\mathcal{B}}. \tag{4.5}$$

(viii) Let q_1, q_2, s, ξ be as in (vii). For $m \in \mathbb{R}$ we denote by $C_{1-\xi,m}((0,T], L_{q_2}(\Omega))$ the Banach space of all $v \in C((0,T], L_{q_2}(\Omega))$ such that $\sup_{0<t\le T} t^{1-\xi}\|v(t)\|_{L_{q_2}(\Omega)} < \infty$, endowed with the norm

$$\|v\|_{C_{1-\xi,m}} := \sup_{0<t\le T} t^{1-\xi} e^{-mt} \|v(t)\|_{L_{q_2}(\Omega)}.$$

It is an easy consequence of (2.3), (4.4), and (4.5) that

$$(y^0 \mapsto Uy^0) \in \mathcal{L}(L_{q_1}(\Omega), C_{1-\xi,m}((0,T], L_{q_2}(\Omega))).$$

(ix) Let q_1, q_2, s, ξ be as in (vii). Using (2.3) we get

$$\begin{aligned} \|U * u(t)\|_{L_{q_2}(\Omega)} &\le c\|U * u(t)\|_{W^s_{2,\mathcal{B}}} \le c \int_0^t (t-\tau)^{-s/2} \|u(\tau)\|_{L_2(\Omega)}\, d\tau \\ &\le ct^{(1-s)/2}\|u\|_{L_2(Q)} \le c\|u\|_{L_2(Q)} \end{aligned}$$

for $0 < t \le T$. In particular,

$$(u \mapsto U * u) \in \mathcal{L}(L_2(Q), C_{1-\xi,m}((0,T], L_{q_2}(\Omega))).$$

(x) Let q_1, q_2, s, ξ be as in (vii) such that s also satisfies

$$2 - \frac{n+2}{\beta} > s - n\left(\frac{1}{2} - \frac{1}{q_2}\right).$$

Then there exists $\eta > 1/\beta$ such that

$$2 - \frac{n}{\beta} - 2\eta > s - n\left(\frac{1}{2} - \frac{1}{q_2}\right).$$

Hence

$$L_r(\Omega) \hookrightarrow W^{s-2+2\eta}_{2,\mathcal{B}}, \tag{4.6}$$

where $1/r := 1/\beta + 1/q_2$. With this choice it follows that

$$\begin{aligned} e^{-mt}\|U*(ay)(t)\|_{L_{q_2}(\Omega)} &\le ce^{-mt}\|U*(ay)(t)\|_{W^s_{2,\mathcal{B}}} \\ &\le ce^{-mt}\int_0^t (t-\tau)^{\eta-1}\|a(\tau)\|_{L_\beta(\Omega)}\|y(\tau)\|_{L_{q_2}(\Omega)}\,d\tau \\ &\le c\int_0^t (t-\tau)^{\eta-1}\tau^{\xi-1}e^{-m(t-\tau)}\|a(\tau)\|_{L_\beta(\Omega)}\,d\tau\ \|y\|_{C_{1-\xi,m}} \end{aligned}$$

for $0 < t \le T$. Thus, by Hölder's inequality,

$$t^{1-\xi}e^{-mt}\|U*(ay)(t)\|_{L_{q_2}(\Omega)} \le cK(t,m)\|a\|_{L_\beta(Q)}\|y\|_{C_{1-\xi,m}},$$

where

$$\begin{aligned} K(m,t) &:= t^{1-\xi}\left(\int_0^t (t-\tau)^{(\eta-1)\beta'}\tau^{(\xi-1)\beta'}e^{-\beta' m(t-\tau)}\,d\tau\right)^{1/\beta'} \\ &= t^{\eta-1/\beta}\left(\int_0^1 (1-\sigma)^{(\eta-1)\beta'}\sigma^{(\xi-1)\beta'}e^{-\beta' mt(1-\sigma)}\,d\sigma\right)^{1/\beta'}. \end{aligned}$$

Fix any $\delta \in (0,T)$. Then $K(t,m) \to 0$ as $m \to \infty$ by Lebesgue's theorem, uniformly with respect to $t \in [\delta, T]$. If $0 < t \le \delta$, then

$$K(t,m) \le c\delta^{\eta-1/\beta}.$$

Thus, given $R > 0$, it follows that we can fix $m > 0$ such that

$$\|T_a\|_{\mathcal{L}(C_{1-\xi,m}((0,T],L_{q_2}(\Omega)))} \le 1/2$$

for all $a \in L_\beta(Q)$ satisfying $\|a\|_{L_\beta(Q)} < R$. Now we infer from (viii) and (ix) that

$$y = (1-T_a)^{-1}(U*u + Uy^0) \in C_{1-\xi,m}((0,T],L_{q_2}(\Omega))$$

for $y^0 \in L_{q_1}(\Omega)$ and $\|a\|_{L_\beta(Q)} < R$ and that the map

$$L_\beta(Q)\times L_2(Q)\times L_{q_1}(\Omega) \to C_{1-\xi,m}((0,T],L_{q_2}(\Omega)), \qquad (a,u,y^0)\mapsto y$$

is analytic and bounded on bounded sets. Using this property for the couple $(q_1,q_2) := (q',2)$ and, subsequently, for $(q_1,q_2) := (2,q)$, we see that the map

$$L_\beta(Q)\times L_2(Q)\times L_{q'}(\Omega) \to L_q(\Omega), \qquad (a,u,y^0)\mapsto y(T)$$

is analytic and bounded on bounded sets. This concludes the proof. □

Remark 4.2. Lemma 4.1 guarantees the solvability of (2.13): notice that $r = 2$ and (2.9) imply $q < 2n/(n-2)_+$, that $a := \lambda|y|^{\lambda-1} \in L_\beta(Q)$ for some $\beta > 2\vee(n+2)/2$ due to $y \in L_{2\lambda}(Q)$ and $\lambda < (n+2)/(n-2)_+$, and that $p(\cdot,T) \in L_{q'(\Omega)}$ due to $y(\cdot,T) \in L_q(\Omega)$.

Proof of Theorem 2.6. Choose $v \in \mathbb{U}_{\rm ad}$, $\mu \in [0,1]$ and let y_μ be the solution of (2.5) with u replaced by $u + \mu(v-u)$. If μ is small enough, say $\mu \le \mu_0$, then due to

the stability estimates in Theorem A.1 and the regularity results in Theorem 2.3, the solution y_μ is global and satisfies

$$\|y_\mu - y\|_{L_{2\lambda}(Q)} + \|y_\mu(\cdot,T) - y(\cdot,T)\|_{L_q(\Omega)} \le C\mu\|v-u\|_{L_2(Q)}. \tag{4.7}$$

Assume $\mu \le \mu_0$ and set $z_\mu := (y_\mu - y)/\mu$. Then z_μ solves the problem

$$\left.\begin{aligned} \partial_t z_\mu - \Delta z_\mu &= a_\mu z_\mu + (v-u), && x\in\Omega,\ t\in J,\\ \mathcal{B}z_\mu &= 0, && x\in\Gamma,\ t\in J,\\ z_\mu(\cdot,0) &= 0, \end{aligned}\right\} \tag{4.8}$$

where $a_\mu := \lambda\int_0^1 |y+\theta(y_\mu - y)|^{\lambda-1}\,d\theta$. Let z be the solution of

$$\left.\begin{aligned} \partial_t z - \Delta z &= az + (v-u), && x\in\Omega,\ t\in J,\\ \mathcal{B}z &= 0, && x\in\Gamma,\ t\in J,\\ z(\cdot,0) &= 0, \end{aligned}\right\}$$

where $a := \lambda|y|^{\lambda-1}$. Set $\beta := 2\lambda/(\lambda-1)$. Since $a_\mu \to a$ in $L_\beta(Q)$ as $\mu\to 0$, Lemma 4.1 implies

$$z_\mu(\cdot,T) \to z(\cdot,T) \quad \text{in } L_q(\Omega). \tag{4.9}$$

Set

$$\mathcal{I}_1(\mu) := \int_\Omega |y_\mu(\cdot,T) - y^*|^q\,dx, \qquad \mathcal{I}_2(\mu) := N\int_Q (u+\mu(v-u))^2\,dx\,dt.$$

The mapping $L_q(\Omega)\to\mathbb{R} : \varphi \mapsto \int_\Omega |\varphi - y^*|^q\,dx$ is convex. Hence

$$\begin{aligned} q\int_\Omega |y(\cdot,T)-y^*|^{q-2}(y(\cdot,T)-y^*)z_\mu(\cdot,T)\,dx &\le \frac{\mathcal{I}_1(\mu)-\mathcal{I}_1(0)}{\mu}\\ &\le q\int_\Omega |y_\mu(\cdot,T)-y^*|^{q-2}(y_\mu(\cdot,T)-y^*)z_\mu(\cdot,T)\,dx. \end{aligned}$$

Since (4.7) implies

$$|y_\mu(\cdot,T)-y^*|^{q-2}(y_\mu(\cdot,T)-y^*) \to |y(\cdot,T)-y^*|^{q-2}(y(\cdot,T)-y^*)$$

in $L_{q'}(\Omega)$ and (4.9) is true, we see that $\mathcal{I}_1$ is right differentiable at 0 and $\mathcal{I}_1'(0+) = \int_\Omega p(\cdot,T)z(\cdot,T)\,dx$. We also have $\mathcal{I}_2'(0) = 2N\int_Q u(v-u)\,dx\,dt$ and

$$(\mathcal{I}_1+\mathcal{I}_2)(\mu) = \mathbb{J}(y_\mu, u+\mu(v-u)) \ge J(y,u) = (\mathcal{I}_1+\mathcal{I}_2)(0);$$

hence

$$\int_\Omega p(\cdot,T)z(\cdot,T)\,dx + 2N\int_Q u(v-u)\,dx\,dt \ge 0.$$

Consequently, it is sufficient to show that

$$\int_\Omega p(\cdot,T)z(\cdot,T)\,dx = \int_Q p(v-u)\,dx\,dt.$$

Let $\varphi_k \in \mathcal{D}(\Omega)$ be such that $\varphi_k \to p(\cdot,T)$ in $L_{q'}(\Omega)$ and $a_k \in \mathcal{D}(Q)$ be such that $a_k \to a$ in $L_\beta(Q)$. Let p_k be the solution of (2.13) with $a = \lambda|y|^{\lambda-1}$ replaced by a_k and the final condition replaced by $p_k(\cdot,T) = \varphi_k$. Then p_k is smooth and $p_k \to p$ in $L_2(Q)$ due to Lemma 4.1. Notice that $z \in L_{2\lambda}(Q)$ due to Theorem A.1 (cf. the beginning of the proof of Theorem 2.3); hence $az \in L_2(Q)$, and the maximal Sobolev regularity implies $\partial_t z, \Delta z \in L_2(Q)$. We have

$$\begin{aligned}\int_Q p_k(v-u)\,dx\,dt &= \int_Q p_k(\partial_t z - \Delta z - az)\,dx\,dt\\ &= \int_Q (-\partial_t p_k - \Delta p_k - a p_k) z\,dx\,dt + \int_\Omega \varphi_k z(\cdot,T)\,dx\\ &= \int_Q (a_k - a) p_k z\,dx\,dt + \int_\Omega \varphi_k z(\cdot,T)\,dx \to \int_\Omega p(\cdot,T) z(\cdot,T)\,dx,\end{aligned}$$

since the p_k stay bounded in $L_2(Q)$ due to Lemma 4.1. Now

$$\int_Q p_k(v-u)\,dx\,dt \to \int_Q p(v-u)\,dx\,dt$$

concludes the proof. □

5. The case of a multiplicative control.

Proof of Theorem 2.8. The proof is almost the same as in Theorem 2.3 (but the solutions y are more regular now). The only nontrivial modification is required in the estimate of the function V and the $L_2(Q)$-norm of $\partial_t y$ in the proof of Lemma 3.2.

Hence, assume $y \in C([0,T+t_1], W^1_{2,\mathcal{B}})$ is a solution of (2.14), where $t_1 > 0$ is fixed. Since $\mathbb{U}_{\rm ad}$ is bounded in $L_\infty(Q)$, there exists a constant M such that $\|u\|_{L_\infty(Q)} \le M$ for all $u \in \mathbb{U}_{\rm ad}$. Let V be defined as in the proof of Lemma 3.2. Then

$$\begin{aligned}V'(t) &= -\int_\Omega (\partial_t y)^2(t)\,dx + \int_\Omega u y \partial_t y(t)\,dx\\ &\le \frac{M^2}{2}\int_\Omega y^2(t)\,dx - \frac{1}{2}\int_\Omega (\partial_t y)^2(t)\,dx.\end{aligned} \tag{5.1}$$

Let $\tau < 1$, $\tau \le T + t_1$, and $t \in [0,\tau]$. Denoting $C_0 := \int_\Omega y^2(x,0)\,dx$, we have

$$\int_\Omega y^2(t)\,dx = C_0 + 2\int_0^t\int_\Omega y\partial_t y\,dx\,dt \le C_0 + \int_0^\tau\int_\Omega y^2\,dx\,dt + \int_0^\tau\int_\Omega (\partial_t y)^2\,dx\,dt.$$

Integrating this estimate over $t \in [0,\tau]$, we get

$$\int_0^\tau\int_\Omega y^2\,dx\,dt \le C_0\tau + \tau\int_0^\tau\int_\Omega y^2\,dx\,dt + \tau\int_0^\tau\int_\Omega (\partial_t y)^2\,dx\,dt;$$

hence

$$\int_0^\tau\int_\Omega y^2\,dx\,dt \le \frac{C_0\tau}{1-\tau} + \frac{\tau}{1-\tau}\int_0^\tau\int_\Omega (\partial_t y)^2\,dx\,dt. \tag{5.2}$$

Let $\tau_1 \in (0,1)$ be defined by $\frac{\tau_1}{1-\tau_1}M^2 = \frac{1}{2}$ and $\tau \in [0,\tau_1]$ (enlarging M we may assume $\tau_1 \le T + t_1$). Then integrating (5.1) and using (5.2) we arrive at

$$V(\tau) - V(0) \le \frac{C_0}{4} - \frac{1}{4}\int_0^\tau\int_\Omega (\partial_t y)^2\,dx\,dt, \qquad \tau \in [0,\tau_1]. \tag{5.3}$$

This estimate guarantees $V(t) \le V(0) + C_0/4$ on $[0,\tau_1]$.

Fix $\delta \in (0, t_1 \wedge \tau_1)$ and assume $V(t_0) \ll -1$ for some $t_0 \in [0, \tau_1 - \delta]$. Then (5.3) implies $V(t) \le -K \ll -1$ for all $t \in [\tau_1 - \delta, \tau_1]$. As in (3.15) we have

$$\frac{1}{2}\frac{d}{dt}\int_\Omega y^2\,dx = -2V(t) + c_1\int_\Omega |y|^{\lambda+1}\,dx + \int_\Omega uy^2\,dx$$
$$\ge K + c_2\left(\int_\Omega y^2\,dx\right)^{(\lambda+1)/2}$$

for any $t \in [\tau_1 - \delta, \tau_1]$. In the same way as in the proof of Lemma 3.2, this inequality yields a contradiction if $K = K(\lambda, c_2, \delta)$ is large enough. Consequently,

$$V(t) \ge -C \qquad \text{for all } t \in [0, \tau_1 - \delta]. \tag{5.4}$$

Now (5.3) implies $\int_0^{\tau_1-\delta}\int_\Omega (\partial_t y)^2\,dx\,dt \le C$; hence $\int_\Omega y^2(t)\,dx \le C$ for t belonging to $[0, \tau_1 - \delta]$. In particular, $\int_\Omega y^2(\tau_1 - \delta)\,dx \le C_1$, where C_1 does not depend on u.

Repeating the estimates above on the interval $[\tau_1 - \delta, 2\tau_1 - \delta]$ instead of $[0, \tau_1]$ and then on $[2\tau_1 - 2\delta, 3\tau_1 - 2\delta]$, etc., we obtain the desired bounds for $V(t)$, $\|y(t)\|_{L_2(\Omega)}$, $t \in J$, and $\|\partial_t y\|_{L_2(Q)}$. □

6. Parabolic systems.

Proof of Theorem 2.10. Let $\varphi_1 > 0$ be an eigenfunction corresponding to the first eigenvalue μ_1 of the problem $-\Delta\varphi = \mu\varphi$ in Ω, $\mathcal{B}_1\varphi = 0$ on Γ. Notice that φ_1 is a positive constant if $\mathcal{B}_1 = \partial_\nu$; hence the weighted Lebesgue space $L_1(\Omega, \varphi_1(x)\,dx)$ equals $L_1(\Omega)$ in this case.

We shall prove that

(i) any bound of $y_1(t)$ in $L_p(\Omega, \varphi_1(x)\,dx)$ or $L_p(\Omega)$, $p \ge 1$, implies a bound of $y_2(t)$ in the same space;

(ii) the space $X := L_1(\Omega, \varphi_1(x)\,dx) \times L_1(\Omega, \varphi_1(x)\,dx)$ is a *continuation space* for problem (2.15); that is, if the solution y is defined on $[0, T^*]$, $T^* > 0$, and $\|y(T^*)\|_X \le M$, then this solution can be continued for $t \in [T^*, T^* + \tau]$, where $\tau = \tau(M) > 0$. In addition, $\|u(t)\|_{L_\infty(\Omega)\times L_\infty(\Omega)} \le C(\delta, M)$ for any $t \in [T^* + \delta, T^* + \tau]$ and $\delta > 0$;

(iii) all global solutions of problem (2.15) with u bounded in $L_r(J, L_z^+(\Omega))$ and $y_1(T)$ bounded in $L_q(\Omega)$ are uniformly bounded in $L_\infty(Q)$.

Then the conclusion follows similarly as in the proof of Theorem 2.3.

(i) Let $u \in \mathbb{U}_{\rm ad}$. Set $w := y_2^2/2 - by_2 - ay_1$. One can easily verify

$$\partial_t w - \Delta w \le -au \le 0;$$

hence the comparison principle guarantees $w \le C$ in Q, where C does not depend on u. This estimate implies

$$y_2^2 \le C(1 + y_1), \tag{6.1}$$

and the conclusion follows.

(ii) Set $z := ay_1 + by_2$. Then

$$\partial_t z - \Delta z = ay_1y_2 + au \le C(1 + z^{3/2}) + au. \tag{6.2}$$

Since $n < 4$ if $\mathcal{B} = \partial_\nu$ and $n < 3$ if $\mathcal{B} = \gamma$, the problem $\partial_t\tilde z - \Delta\tilde z = C(1 + |\tilde z|^{3/2}) + au$, $\mathcal{B}\tilde z = 0$, is well posed in $X_1 := L_1(\Omega, \varphi_1(x)\,dx)$ due to [30] and [13], respectively. More precisely, if $\|\tilde z(0)\|_{X_1} \le M$, then there exists $\tau = \tau(M) > 0$ such that the solution $\tilde z$ exists on $[0, \tau]$ and satisfies $\|\tilde z(t)\|_{L_\infty(\Omega)} \le C(\delta, M)$ for any $t \in [\delta, \tau]$ and $\delta > 0$.

A comparison argument shows that the same estimate is true for the function z. In particular, the space X is a continuation space for (2.15) in the sense described above.

(iii) Now assume that u belongs to a bounded set in $\mathbb{U}_{\rm ad}^G \subset L_r(J, L_z^+(\Omega))$ and $y_1(T)$ is bounded in $L_1(\Omega)$. The above arguments show that the solution y can be continued for $t \in [0, T+\tau]$, where $\tau > 0$ does not depend on u and $u(x,t) := 0$ if $t > T$. Multiplying the second equation in (2.15) with φ_1 and using (6.1) we obtain

$$\partial_t \int_\Omega y_2\varphi_1\,dx + \mu_1 \int_\Omega y_2\varphi_1\,dx = a\int_\Omega y_1\varphi_1\,dx \ge c\int_\Omega y_2^2\varphi_1\,dx - C$$
$$\ge c\left(\int_\Omega y_2\varphi_1\,dx\right)^2 - C$$

for any $t \in [0, T+\tau]$. Using standard blow-up arguments (cf. the arguments following (3.15) in the proof of Lemma 3.2), this estimate guarantees a uniform bound for $y_2(t)$, $t \in [0, T+\tau/2]$, in the weighted space $L_1(\Omega, \varphi_1(x)\,dx)$. Integrating the second equation in (2.15) we now obtain

$$\int_0^{T+\tau/2}\int_\Omega y_1\varphi_1\,dx\,dt \le C. \tag{6.3}$$

The first equation in (2.15) implies

$$\int_\Omega y_1\varphi_1\,dx\Big|_{t_1}^{t_2} + (\mu_1 + b)\int_{t_1}^{t_2}\int_\Omega y_1\varphi_1\,dx\,dt \ge 0;$$

hence using (6.3) we deduce

$$\int_\Omega y_1(t_2)\varphi_1\,dx \ge \int_\Omega y_1(t_1)\varphi_1\,dx - C \tag{6.4}$$

for any $t_1, t_2 \in [0, T+\tau/2]$, $t_2 > t_1$.

Obviously, (6.3) and (6.4) imply a uniform estimate for $y_1(t)$, $t \in J$, in the space $L_1(\Omega, \varphi_1(x)\,dx)$. Now (i) and (ii) imply uniform bounds for y_1, y_2 in $L_\infty([\delta, T]\times\Omega)$ for any $\delta > 0$. Since the bounds for y_1, y_2 in $L_\infty([0,\delta]\times\Omega)$ for $\delta > 0$ small enough are guaranteed by the well posedness of (2.15) in $L_\infty(\Omega)\times L_\infty(\Omega)$ and the boundedness of u in $L_r(J, L_z(\Omega))$, the conclusion follows. □

Appendix: The basic existence, uniqueness, and stability theorem for semilinear problems. For the reader's convenience we collect here the main existence, uniqueness, and stability results for strong solutions of the semilinear problem

$$\dot y + Ay = F(y) \text{ in } [0,T], \qquad y(0) = y^0, \tag{A.1}$$

where $A = A_s$ is the isomorphism between $W^s_{q,\mathcal{B}}$ and $W^{s-2}_{q,\mathcal{B}}$ mentioned in section 2. They follow from [6, Theorems 3.3 and 3.4] and [5, Theorems 5 and 7(ii)]. Analogous results are true in the case of systems.

We write $C_b^{1-}(Y, X)$ for the space of all maps from Y into X which are uniformly Lipschitz continuous on bounded sets. If X and Y are paces of functions defined on $[0,T]$, then $F : X \to Y$ is said to possess the Volterra property if, given any $u \in X$ and $t \in (0,T)$, the restriction of $F(u)$ to $[0,t]$ depends on the values of $u\,|\,[0,t]$ only.

THEOREM A.1. *Assume*

$$s, \sigma \notin S_q, \quad 0 \le s < \sigma < 2, \tag{A.2}$$

and suppose that $r > 1$, $r \neq 2/(\sigma - s)$, $\sigma - 2/r \notin S_q$, $y^0 \in Y^0 := W_{q,\mathcal{B}}^{\sigma-2/r}$. *Denote* $X_t := L_r([0,t], W_{q,\mathcal{B}}^{\sigma-2})$.

If $r < 2/(\sigma - s)$, *fix* $p \in [1, 2/(s - \sigma + 2/r))$ *and set* $Y_t := L_p([0,t], W_{q,\mathcal{B}}^s)$,
if $r > 2/(\sigma - s)$, *fix* $\rho \in [0, (\sigma - s - 2/r)/2)$ *and set* $Y_t := C^\rho([0,t], W_{q,\mathcal{B}}^s)$.

Let $F \in C_b^{1-}(Y_T, X_T)$ *have the Volterra property. If* $r < 2/(\sigma - s)$ *or* $r > 2/(\sigma - s)$, *then* (A.1) *has a unique strong* $L_p(W_q^s)$- *or* $C^\rho(W_q^s)$-*solution* $y(y^0, F)$, *respectively, defined on the maximal existence interval* $[0, t(y^0, F))$. *If* $y(y^0, F) \in Y_{t(y^0,F)}$ *or* $F(y(y^0, F)) \in X_{t(y^0,F)}$, *then* $y(y^0, F)$ *is global.*

The map $(y^0, F) \mapsto y(y^0, F)$ *is Lipschitz continuous in the following sense: Fix* $t < t(y^0, F)$ *(we can take* $t = t(y^0, F) = T$ *if* $y(y^0, F)$ *is global). Let* $\omega_1 > 0$, *and let* $\omega_2 : \mathbb{R}^+ \to \mathbb{R}^+$ *be an increasing function*

$$\left.\begin{aligned} &\|y^0\|_{Y^0} + \|F(0)\|_{X_T} \le \omega_1, \\ &\|F(y_1) - F(y_2)\|_{X_T} \le \omega_2(R)\|y_1 - y_2\|_{Y_T} \end{aligned}\right\} \tag{A.3}$$

for any $R > 0$ *and* $y_1, y_2 \in Y_T$ *whose norms are bounded by* R. *Fix* $R > \|y(y^0, F)\|_{Y_t}$. *Then there exist positive constants* ε, c *(depending only on* R, t, ω_1, ω_2*) with the following property: If* $\tilde{y}^0 \in Y^0$, $\tilde{F} \in C_b^{1-}(Y_T, X_T)$ *has the Volterra property,* $\tilde{y}^0$ *and* $\tilde{F}$ *satisfy* (A.3), *and*

$$\|y^0 - \tilde{y}^0\|_{Y^0} + \sup_{\|y\|_{Y_T} \le R} \|(F - \tilde{F})(y)\|_{X_T} \le \varepsilon,$$

then $t \le t(\tilde{y}^0, \tilde{F})$, $y(\tilde{y}^0, \tilde{F}) \in Y_t$, *and*

$$\|y(y^0, F) - y(\tilde{y}^0, \tilde{F})\|_{Y_t} \le c\left(\|y^0 - \tilde{y}^0\|_{Y^0} + \sup_{\|y\|_{Y_T} \le R} \|(F - \tilde{F})(y)\|_{X_T}\right).$$

If $y = y(y^0, F)$ *is global, then*

$$y \in L_r(J, W_{q,\mathcal{B}}^{\tilde{\sigma}}) \cap W_r^1(J, W_{q,\mathcal{B}}^{\tilde{\sigma}-2}) \tag{A.4}$$

for any $\tilde{\sigma} < \sigma$, *and the norm of* y *in this space can be estimated by a constant* $C = C(\|F(y)\|_{X_T}, \|y^0\|_{Y^0})$.

OPTIMAL SOLUTION OF INVESTMENT PROBLEMS VIA LINEAR PARABOLIC EQUATIONS GENERATED BY KALMAN FILTER*

NIKOLAI DOKUCHAEV†

Abstract. We consider optimal investment problems for a diffusion market model with nonobservable random drifts that evolve as an Itô's process. Admissible strategies do not use direct observations of the market parameters, but rather use historical stock prices. For a nonlinear problem with a general performance criterion, the optimal portfolio strategy is expressed via the solution of a scalar minimization problem and a linear parabolic equation with coefficients generated by the Kalman filter.

Key words. optimal portfolio, nonobservable parameters, Kalman filter

1. Introduction. The paper investigates an optimal investment problem for a market which consists of a locally risk free asset, bond or bank account with interest rate $r(t)$, and a finite number n of risky stocks. We assume that the vector of stock prices $S(t)$ evolves according to an Itô stochastic differential equation $dS_i(t) = S_i(t)[a_i(t)\ dt + \sum_j \sigma_{ij}(t)\ dw_j(t)]$, $i = 1, \dots, n$, with a vector of appreciation rates $a(t)$ and a volatility matrix $\sigma(t)$. The problem goes back to Merton [26], who found strategies which solve the optimization problem in which $\mathbf{E}U(X(T))$ is to be maximized, where $X(T)$ represents the wealth at the final time T, and where $U(\cdot)$ is a utility function. If the market parameters are observed, then the optimal strategies (i.e., current vector of stock holdings) are functions of the current vector $(r(t), a(t), \sigma(t), S(t), X(t))$ (see, e.g., the survey in Hakansson [15] and Karatzas and Shreve [18]). But in practice, $a(t)$ and $\sigma(t)$ have to be estimated from historical stock prices or some other observation process. There are many papers devoted to estimation of $(a(\cdot), \sigma(\cdot))$, mainly based on modifications of Kalman–Bucy filtering or the maximum likelihood principle (see, e.g., Lo [25], Chen and Scott [3], Pearson and Sun [27]). Unfortunately, the process $a(\cdot)$ is usually hard to estimate in real-time markets, because the drift term, $a(\cdot)$, is usually overshadowed by the diffusion term, $\sigma(\cdot)$. On the other hand, $\sigma(t)$ can, in principle, be found from stock prices. Thus, there remains the problem of optimal investment with unobservable $a(\cdot)$.

In fact, the problem is one of linear filtering. If $R_i(t)$ is the return on the ith stock, then $dR(t) = a(t)dt + \sigma(t)dw(t)$, so the estimation of $a(t)$ given $\{R(\tau), \tau < t\}$ (or $\{S(\tau), \tau < t\}$) is a linear filtering problem. If $a(\cdot)$ is conditionally Gaussian, then the Kalman filter provides the estimate which minimizes the error in the mean square sense.

A popular tool in optimal control and filtering theory is the separation theorem. This theorem has an analog in portfolio theory: it is the so-called "certainty equivalence principle": agents who know the solution of the optimal investment problem

for the case of directly observable $a(t)$ can solve the problem with unobservable $a(t)$ by substituting $\mathbf{E}\{a(t)|S(\tau), \tau < t\}$ (see, e.g., Gennotte [14]). Unfortunately, this principle does not hold in the general case of nonlog utilities (see Kuwana [21]). Note that this principle is unrelated to the much more recent notion of "certainty equivalent value" to be found in the work of Frittelli [13].

Williams [30], Detemple [4], Dothan and Feldman [11], Gennotte [14], and Brennan [2] solved the investment problem using the Kalman–Bucy filter and dynamic programming. By this method, the optimal strategy can be calculated via solution of the Bellman parabolic equation; this equation is nonlinear.

Karatzas [16], Karatzas and Zhao [20], Dokuchaev and Zhou [10], and Dokuchaev and Teo [9] have obtained optimal portfolio strategies in general non-Gaussian setting, but only for case of time independent coefficients.

An approach based on Malliavin calculus gives a possibility of considering a more general setting. Lakner [22], [23] assumes that $S(\cdot)$ and $w(\cdot)$ have equal dimension (as we do), and that $r(\cdot)$ and $\sigma(\cdot)$ are deterministic. This again guarantees that the filtration of $S(\cdot)$ is Brownian. Results from filtering theory give a representation of the optimal portfolio, which is explicit in terms of a conditional expectation of a Malliavin derivative when the $a_i(\cdot)$ are Ornstein–Uhlenbeck processes independent of $w(\cdot)$. Karatzas and Xue [19] assume that there are more Brownian motions than stocks. They assume that $r(\cdot)$ and $\sigma(\cdot)$ are adapted to the observable $S(\cdot)$. After projecting onto an n-dimensional Brownian motion which generates the same filtration as $S(\cdot)$, they obtain a reduced, completely observable model; existence of an optimal portfolio follows, but the optimal strategy is, as usual, defined only implicitly.
