4. Contraction semigroups, boundary control systems, and their parameterization. In the previous section we have associated with the skew-symmetric operator $\mathcal{J}$ a Dirac structure $\mathcal{D}_{\mathcal{J}}$. In this section, we shall define dynamic systems with inputs, states, and outputs with respect to this Dirac structure. These systems will be boundary control systems in the sense of the semigroup theory [3], which implies that the controls and observations act on the boundary of the spatial domain. With respect to the Dirac structure $\mathcal{D}_{\mathcal{J}}$ it is possible to define many systems. However, we consider only those systems for which the energy does not grow when the input is zero. This implies that the associated semigroup is contractive. We parameterize all these systems by nN-dimensional linear subspaces of the port variables. As a consequence of this parameterization, we identify those systems for which the associated semigroup is unitary.

We begin by showing that $\mathcal{J}$ is the infinitesimal generator of a contraction semigroup for appropriate choices of the boundary conditions.

4.1. Contraction semigroups associated with $\mathcal{D}_{\mathcal{J}}$. We begin by studying the differential operator $\mathcal{J}$ for different boundary conditions. As stated above, we want to characterize those boundary conditions for which the associated differential operator is the infinitesimal generator of a strongly continuous semigroup. Furthermore, this semigroup must be contractive, i.e., $\|T(t)e\| \leq \|e\|$ for all $t \geq 0$ and $e \in L^2((a,b);\mathbb{R}^n)$. We obtain this characterization of the boundary conditions by using Theorem 3.1.6 of [9]. For the history of this result, we refer to the bibliographical comments at the end of [9].

Before stating this result, we recall the following parameterization. Let $\Sigma = \left(\begin{smallmatrix} 0 & I \\ I & 0 \end{smallmatrix}\right)$. A full rank matrix W of size $nN \times 2nN$ satisfies

$$W\Sigma W^T \geq 0 \tag{4.1}$$

if and only if

$$W = S\begin{pmatrix} I+V & I-V \end{pmatrix} \tag{4.2}$$

with S an invertible matrix, and V satisfying $VV^T \leq I$; see the appendix for a proof.

In the following theorem it is shown that if the port variables are restricted to the kernel of W, then this defines the domain of a contraction semigroup associated with the operator $\mathcal{J}$.

THEOREM 4.1. *Let W be a full rank matrix of size $k \times 2nN$. Define the operator J_W and its domain, $D(J_W)$, as*

$$J_W e = \mathcal{J} e \tag{4.3}$$

and

$$\begin{aligned} D(J_W) = \Bigg\{ & e \in L^2((a,b),\mathbb{R}^n) \mid \textit{the port variable associated with } e, \\ & \begin{pmatrix} f_\partial \\ e_\partial \end{pmatrix}, \textit{ is in } \ker W \textit{ and there exists} \\ & \textit{an } f \in L^2((a,b);\mathbb{R}^n) \textit{ such that } (f, f_\partial, e, e_\partial) \in \mathcal{D}_{\mathcal{J}} \Bigg\}. \end{aligned} \tag{4.4}$$

Then J_W generates a contraction semigroup $(T(t))_{t\geq 0}$ on $L^2((a,b);\mathbb{R}^n)$ if and only if $k = nN$ and (4.1) holds.

Furthermore, J_W is the infinitesimal generator of a unitary semigroup on $L^2((a,b);\mathbb{R}^n)$ if and only if $k = nN$ and $W\Sigma W^T = 0$.

Proof. It is well known that operator A is the infinitesimal generator of a contraction semigroup if and only if it is maximally dissipative, i.e., it is dissipative:

$$\mathrm{Re}\langle Az, z\rangle \leq 0$$

for all $z \in D(A)$, and it is not a proper restriction of any other dissipative operator [24].

In [9] a characterization of maximal dissipative differential operators in terms of their boundary conditions is given. However, their formulation is not precisely the one we are using. Hence in the next step we relate their notation with ours. Once that is done, the proof of the theorem is straightforward.

Step 1. Define on $D(\mathcal{J}) = H^N((a,b),\mathbb{C}^n)$ the operator

$$\mathcal{A}_0^* = i\mathcal{J}.$$

Then it is easy to see that $\mathcal{A}_0 = i\mathcal{J}$ with $D(\mathcal{A}_0) = \{e \in H^N((a,b),\mathbb{C}^n) \mid \frac{d^{N-1}e}{dz^{N-1}}(b) = \cdots e(b) = 0$ and $\frac{d^{N-1}e}{dz^{N-1}}(a) = \cdots e(a) = 0\}$.

Using Theorem 3.1 and Definition 3.6 we have for all $e_1, e_2 \in D(\mathcal{J})$

$$\begin{aligned}
\langle \mathcal{A}_0^* e_1, e_2\rangle - \langle e_1, \mathcal{A}_0^* e_2\rangle &= i\langle \mathcal{J}e_1, e_2\rangle + i\langle e_1, \mathcal{J}e_2\rangle \\
&= i\left\langle \begin{pmatrix} e_1(b) \\ \vdots \\ \frac{d^{N-1}e_1}{dz^{N-1}}(a) \end{pmatrix}, Q_{\mathrm{ext}} \begin{pmatrix} e_2(b) \\ \vdots \\ \frac{d^{N-1}e_2}{dz^{N-1}}(a) \end{pmatrix} \right\rangle_{\mathbb{C}^{2nN}} \\
&= i\left\langle \begin{pmatrix} f_{1,\partial} \\ e_{1,\partial} \end{pmatrix}, \Sigma \begin{pmatrix} f_{2,\partial} \\ e_{2,\partial} \end{pmatrix} \right\rangle_{\mathbb{C}^{2nN}} \\
&= i\left[\langle f_{1,\partial}, e_{2,\partial}\rangle_{\mathbb{C}^{nN}} + \langle e_{1,\partial}, f_{2,\partial}\rangle_{\mathbb{C}^{nN}}\right],
\end{aligned}$$

where we have used (3.10). Define operators Γ_1 and Γ_2 from $H^N((a,b),\mathbb{C}^n)$ to $\mathbb{C}^{nN}$ as

$$\Gamma_1 e = if_\partial, \quad \Gamma_2 e = e_\partial. \tag{4.5}$$

It is clear that these mappings are onto. Furthermore, we have that

$$\langle \mathcal{A}_0^* e_1, e_2\rangle - \langle e_1, \mathcal{A}_0^* e_2\rangle = \langle \Gamma_1 e_1, \Gamma_2 e_2\rangle_{\mathbb{C}^{nN}} - \langle \Gamma_2 e_1, \Gamma_1 e_2\rangle_{\mathbb{C}^{nN}}. \tag{4.6}$$

Step 2. Using (4.6), Theorem 3.1.6 of [9] characterizes all maximally accumulative extensions of $\mathcal{A}_0$. An operator A is defined to be accumulative if $\mathrm{Im}\langle Az, z\rangle \leq 0$ for all $z \in D(A)$. It is maximally accumulative, when it has no nontrivial accumulative extension. It is easy to see that A is a maximal accumulative extension of $\mathcal{A}_0$ if and only if $-iA$ is a maximal dissipative extension of $\mathcal{J}$ with the domain $D(\mathcal{A}_0)$.

Step 3. Theorem 3.1.6 of [9] states that any maximally accumulative extension of $\mathcal{A}_0$ is given by

$$A_K = \mathcal{A}_0^*$$

with

$$D(A_K) = \{e \in D(\mathcal{A}_0^*) \mid (K-I)\Gamma_1 e - i(K+I)\Gamma_2 e = 0\},$$

where $K : \mathbb{C}^{nN} \mapsto \mathbb{C}^{nN}$ with $\|K\| \leq 1$. Using the result obtained in the previous step and (4.5), we see that any maximal dissipative extension of $\mathcal{J}, D(\mathcal{A}_0)$, is given by

$$-iA_K = -i\mathcal{A}_0^* = \mathcal{J}$$

with the domain

$$\begin{aligned} D(A_K) &= \{e \in D(\mathcal{A}_0^*) \mid (K-I)\Gamma_1 e - i(K+I)\Gamma_2 e = 0\} \\ &= \{e \in H^N((a,b),\mathbb{C}^n) \mid (K-I)f_\partial - (K+I)e_\partial = 0\}, \end{aligned}$$

where $K : \mathbb{C}^{nN} \mapsto \mathbb{C}^{nN}$ with $\|K\| \leq 1$. Using Lemma A.1 we see that $-iA_K = J_W$ with $W = S(I-K, I+K)$, where S is an arbitrary, invertible matrix. Since we are interested only in real conditions, we have to take K real valued. Hence we have obtained a complete characterization of all boundary conditions for which the differential operator is the infinitesimal generator of a contraction semigroup.

Step 4. The proof of the unitary case is done very similarly. ∎

One may wonder why we have parameterized the boundary port variables using the W instead of the V, since if two W's have the same V, then the associated semigroups are the same. In the following subsection, the boundary variables are decomposed into inputs and outputs. For this splitting the W is important. More specifically, different W's lead to different systems, although the semigroup may be the same.

4.2. Boundary control system and port conjugated output. In the previous subsection we have derived the family of contraction semigroups from the Dirac structure $\mathcal{D}_\mathcal{J}$ associated with a skew-symmetric differential operator $\mathcal{J}$. More precisely, we have parameterized these semigroups by a family of subspaces of the port boundary variables defined as the kernel of a class of matrices W (matrices of size $nN \times 2nN$ satisfying (4.1)). In the following theorem, we use this W to define boundary inputs/controls. Since the rank of W is nN and since we have $2nN$ boundary variables, we see that we use half of the set of boundary variables to define inputs. We show that the other half may be regarded as outputs. Note that the terms input and output are used here to make the relation with infinite-dimensional systems theory. It does not necessarily mean that the input is completely free, i.e., it can be chosen arbitrarily in $L^2_{\text{loc}}((0,\infty);\mathbb{R}^{nN})$, nor does it imply that for every initial condition in $L^2((a,b);\mathbb{R}^n)$ the output is well defined. The system class which is considered is the class of boundary control systems. For more information on this class, we refer the reader to section 3.3 of [3].

Using the splitting of the boundary ports into inputs and outputs, we consider in Theorems 4.4 and 4.6 some special choices which lead to classical power balance equations in the so-called impedance and scattering variables form.

THEOREM 4.2. *For the differential operator $\mathcal{J}$ and the associated Dirac structure $\mathcal{D}_\mathcal{J}$ (see Theorem* 3.6*), we consider the dynamical system*

$$(\dot{x}(t), f_\partial(t), x(t), e_\partial(t)) \in \mathcal{D}_\mathcal{J}, \quad t \geq 0, \tag{4.7}$$

where $(f_\partial(t), e_\partial(t))$ are the boundary port variables associated with $x(t)$; see Definition 3.5*.*

Let W be a full rank matrix of size $nN \times 2nN$ satisfying (4.1)*, and define $\mathcal{B} : H^N((a,b),\mathbb{R}^n) \to \mathbb{R}^{nN}$ as*

$$\mathcal{B}x(t) := W \begin{pmatrix} f_\partial(t) \\ e_\partial(t) \end{pmatrix}. \tag{4.8}$$

Then system (4.7) *with the input defined as*

$$u(t) = \mathcal{B}x(t) \tag{4.9}$$

is a boundary control system.

Furthermore, let $\tilde{W}$ *be a full rank matrix of size* $nN \times 2nN$ *with* $\binom{W}{\tilde{W}}$ *invertible. If we define the linear mapping* $\mathcal{C} : H^N((a,b),\mathbb{R}^n) \to \mathbb{R}^{nN}$ *as*

$$\mathcal{C}x(t) := \tilde{W}\begin{pmatrix} f_\partial(t) \\ e_\partial(t) \end{pmatrix} \tag{4.10}$$

and the output as

$$y(t) = \mathcal{C}x(t), \tag{4.11}$$

then for $u \in C^2((0,\infty);\mathbb{R}^{nN})$, $x(0) \in H^N((a,b),\mathbb{R}^n)$, *and* $\mathcal{B}x(0) = u(0)$, *the following balance equation is satisfied:*

$$\frac{1}{2}\frac{d}{dt}\|x(t)\|^2 = \frac{1}{2}\begin{pmatrix} u^T(t) y^T(t) \end{pmatrix} P_{W,\tilde{W}} \begin{pmatrix} u(t) \\ y(t) \end{pmatrix}, \tag{4.12}$$

where

$$P^{-1}_{W,\tilde{W}} = \begin{pmatrix} W\Sigma W^T & W\Sigma \tilde{W}^T \\ \tilde{W}\Sigma W^T & \tilde{W}\Sigma \tilde{W}^T \end{pmatrix}. \tag{4.13}$$

Furthermore, we have that the matrix $\left(\begin{smallmatrix} W\Sigma W^T & W\Sigma \tilde{W}^T \\ \tilde{W}\Sigma W^T & \tilde{W}\Sigma \tilde{W}^T \end{smallmatrix}\right)$ *is invertible if and only if* $\binom{W}{\tilde{W}}$ *is invertible.*

REMARK 4.3. *The system defined by* (4.7)–(4.9) *may be equivalently written in the more usual form of a boundary control system:*

$$\begin{aligned} \dot{x}(t) &= \mathcal{J}x(t), \\ \mathcal{B}x(t) &= u(t). \end{aligned} \tag{4.14}$$

Proof of Theorem 4.2. In Steps 1 and 2 we show that we have a boundary control system. In Steps 3 and 4, we prove (4.12) and (4.13), respectively. For a boundary control system we have to show that for zero inputs, the system is a C_0-semigroup, and furthermore that there exists a bounded operator B mapping onto the domain of $\mathcal{B}$ and such that $\mathcal{B}Bu = u$ for all $u \in \mathbb{R}^{nN}$.

Step 1. As mentioned above, we have to show that J_W defined as

$$J_W x = \mathcal{J}x$$

on

$$D(J_W) = D(\mathcal{J}) \cap \ker \mathcal{B}$$

is an infinitesimal generator. This follows directly from Theorem 4.1.

Step 2. We have to find a bounded linear operator B such that $Bu \in D(\mathcal{B}) = H^N((a,b);\mathbb{R}^{nN})$ and $\mathcal{B}Bu = u$ for all $u \in \mathbb{R}^{nN}$.

Let $\{u^1,\dots,u^{nN}\}$ be the standard basis of the input space $\mathbb{R}^{nN}$, i.e., $u^i = (\delta_{ij})^T_{j=1,\dots,nN}$. Since R_{ext} is invertible, and since W has rank nN there exists for every u^i a $v^i \in \mathbb{R}^{2nN}$ such that

$$WR_{\text{ext}}v^i = u^i. \tag{4.15}$$

Let v_k^i denote the kth block of v^i, $k = 1, \ldots, 2N$. Using functions $f_{r,j}$ and $f_{l,j}$ introduced in Lemma A.3, we define the ith column of B as

$$B_i = \sum_{k=1}^{N} v_k^i f_{r,k-1}(z) + \sum_{k=1}^{N} v_{k+N}^i f_{l,k-1}(z).$$

It is straightforward that B is a bounded operator mapping onto the domain of $\mathcal{J}$. Furthermore, by Definition 3.5 we have that

$$\mathcal{B}B_i = WR_{\text{ext}} \begin{pmatrix} B_i(b) \\ \vdots \\ \frac{d^{N-1}B_i(b)}{dz^{N-1}} \\ B_i(a) \\ \vdots \\ \frac{d^{N-1}B_i(a)}{dz^{N-1}} \end{pmatrix}.$$

Now by definition

$$\frac{d^p B_i}{dz^p}(z) = \sum_{k=1}^{N} v_k^i f_{r,k-1}^{(p)}(z) + \sum_{k=1}^{N} v_{k+N}^i f_{l,k-1}^{(p)}(z).$$

From (A.3) and (A.4) of Lemma A.3, we have that

$$\frac{d^p B_i}{dz^p}(b) = v_{p+1}^i \quad \text{and} \quad \frac{d^p B_i}{dz^p}(a) = v_{p+N+1}^i,$$

and so B satisfies

$$\mathcal{B}Bu = WR_{\text{ext}} \begin{pmatrix} v_1^i \\ \vdots \\ v_{2N}^i \end{pmatrix} = u^i.$$

Step 3. By the definition of B and $D(J_W)$, we see that the conditions stated in the theorem are the same as $x(0) - Bu(0) \in D(J_W)$. Hence by Theorem 3.3.3 of [3] we have that there exists a classical solution of (4.7)–(4.9). Hence, in particular, $x(t) \in H^N((a,b), \mathbb{R}^n)$ holds pointwise in t, $x(t)$ is differentiable as a function of t, and $\dot{x}(t) = \mathcal{J}x(t)$. Using this, we obtain

$$\begin{aligned} \frac{d}{dt}\|x(t)\|^2 &= \frac{d}{dt}\langle x(t), x(t)\rangle \\ &= \langle \dot{x}(t), x(t)\rangle + \langle x(t), \dot{x}(t)\rangle \\ &= \langle \mathcal{J}x(t), x(t)\rangle + \langle x(t), \mathcal{J}x(t)\rangle \\ &= \begin{pmatrix} f_\partial^T(t) & e_\partial^T(t) \end{pmatrix} \Sigma \begin{pmatrix} f_\partial(t) \\ e_\partial(t) \end{pmatrix}. \end{aligned} \tag{4.16}$$

On the other hand, we have that

$$\begin{pmatrix} u \\ y \end{pmatrix} = \begin{pmatrix} W \\ \tilde{W} \end{pmatrix} \begin{pmatrix} f_\partial \\ e_\partial \end{pmatrix}. \tag{4.17}$$

Combining this with (4.16) gives that

$$\begin{aligned}\frac{d}{dt}\|x(t)\|^2 &= \begin{pmatrix} u^T(t) & y^T(t)\end{pmatrix}\begin{pmatrix} W \\ \tilde{W}\end{pmatrix}^{-T}\Sigma\begin{pmatrix} W \\ \tilde{W}\end{pmatrix}^{-1}\begin{pmatrix} u(t) \\ y(t)\end{pmatrix} \\ &= \begin{pmatrix} u^T(t) & y^T(t)\end{pmatrix} P_{W,\tilde{W}}\begin{pmatrix} u(t) \\ y(t)\end{pmatrix}. \qquad (4.18)\end{aligned}$$

Hence we have proved (4.12).

Step 4. By the definition of $P_{W,\tilde{W}}$, we see that

$$P_{W,\tilde{W}}^{-1} = \begin{pmatrix} W \\ \tilde{W}\end{pmatrix}\Sigma\begin{pmatrix} W \\ \tilde{W}\end{pmatrix}^T = \begin{pmatrix} W\Sigma W^T & W\Sigma\tilde{W}^T \\ \tilde{W}\Sigma W^T & \tilde{W}\Sigma\tilde{W}^T\end{pmatrix},$$

which shows (4.13). From this equality the last assertion of the theorem follows directly. □

Now we consider two particular cases which are canonical. For the first choice of inputs and outputs, the system becomes a lossless system. For the second choice of inputs and outputs, the balance (4.12) becomes canonical for scattering variables. We begin by characterizing the case when the boundary control system becomes a lossless system.

THEOREM 4.4. *Let W and $\tilde{W}$ be $nN \times 2nN$ matrices with W having full rank and satisfying* (4.1). *Associate with these matrices the following system:*

$$\dot{x}(t) = \mathcal{J}x(t), \qquad (4.19)$$

$$u(t) = W\begin{pmatrix} f_\partial(t) \\ e_\partial(t)\end{pmatrix}, \qquad (4.20)$$

$$y(t) = \tilde{W}\begin{pmatrix} f_\partial(t) \\ e_\partial(t)\end{pmatrix}, \qquad (4.21)$$

where $(f_\partial(t), e_\partial(t))$ are the boundary port variables associated with $x(t)$; see Definition 3.5.

The above system is a boundary control system. Furthermore, it satisfies for all $u \in C^2((0,\infty);\mathbb{R}^{nN})$, $x(0) \in H^N((a,b);\mathbb{R}^n)$ with $u(0) = W\left(\begin{smallmatrix} f_\partial(0) \\ e_\partial(0)\end{smallmatrix}\right)$ the balance equation

$$\frac{1}{2}\frac{d}{dt}\|x(t)\|^2 = u(t)^T y(t) \qquad (4.22)$$

if and only if the following conditions are satisfied:

$$W = S\begin{pmatrix} I+V & I-V\end{pmatrix} \quad \text{with } S \text{ invertible and } V \text{ unitary}, \qquad (4.23)$$

$$\tilde{W} = \tilde{S}\begin{pmatrix} I+\tilde{V} & I-\tilde{V}\end{pmatrix} \quad \text{with } \tilde{S} \text{ invertible and } \tilde{V} \text{ unitary}, \qquad (4.24)$$

$$I = 2\tilde{S}(I-\tilde{V}V^T)S^T. \qquad (4.25)$$

Furthermore, under condition (4.23) *the associated semigroup is unitary.*

Proof. Looking at Theorem 4.2 we see that we only have to check that $P_{W,\tilde{W}}$ equals $\left(\begin{smallmatrix} 0 & I \\ I & 0\end{smallmatrix}\right)$. By (4.13) this is equivalent to $W\Sigma W^T = \tilde{W}\Sigma\tilde{W}^T = 0$ and $\tilde{W}\Sigma W^T = I$. By Lemma A.1 we see that the first conditions are equivalent to (4.23) and (4.24), respectively. Direct calculation gives that $\tilde{W}\Sigma W^T = I$ is the same as (4.25). □

Taking in the above theorem, $V = I$, $\tilde{V} = -I$, and $S = \tilde{S} = \frac{1}{2}I$, we obtain the following special case.

COROLLARY 4.5. *Under the general conditions as stated in Theorem* 4.4 *consider the system defined by*

$$\dot{x}(t) = \mathcal{J}x(t), \tag{4.26}$$

$$u(t) = f_\partial(t), \tag{4.27}$$

$$y(t) = -e_\partial(t), \tag{4.28}$$

where $(f_\partial(t), e_\partial(t))$ *are the boundary port variables associated with* $x(t)$*; see Definition* 3.5.

The above system is a boundary control system with the associated semigroup unitary. Furthermore, it satisfies for all $u \in C^2((0,\infty);\mathbb{R}^{nN})$, $x(0) \in H^N((a,b);\mathbb{R}^n)$, *and* $u(0) = f_\partial(0)$ *the following balance equation:*

$$\frac{1}{2}\frac{d}{dt}\|x(t)\|^2 = u(t)^T y(t). \tag{4.29}$$

In the following theorem we characterize the scattering case.

THEOREM 4.6. *Let* W *and* $\tilde{W}$ *be* $nN \times 2nN$ *matrices with* W *having full rank and satisfying* (4.1). *Associate with these matrices the following system:*

$$\dot{x}(t) = \mathcal{J}x(t), \tag{4.30}$$

$$u(t) = W\begin{pmatrix} f_\partial(t) \\ e_\partial(t) \end{pmatrix}, \tag{4.31}$$

$$y(t) = \tilde{W}\begin{pmatrix} f_\partial(t) \\ e_\partial(t) \end{pmatrix}, \tag{4.32}$$

where $(f_\partial(t), e_\partial(t))$ *are the boundary port variable associated with* $x(t)$*; see Definition* 3.5.

The above system is a boundary control system. Furthermore, it satisfies for all $u \in C^2((0,\infty);\mathbb{R}^{nN})$, $x(0) \in H^N((a,b);\mathbb{R}^n)$ *with* $u(0) = W\left(\begin{smallmatrix} f_\partial(0) \\ e_\partial(0) \end{smallmatrix}\right)$ *the balance equation*

$$\frac{1}{2}\frac{d}{dt}\|x(t)\|^2 = \|u(t)\|^2 - \|y(t)\|^2 \tag{4.33}$$

if and only if the following conditions are satisfied:

$$W = S\begin{pmatrix} I+V & I-V \end{pmatrix} \quad \text{with } 4S(I+VV^T)S^T = I, \tag{4.34}$$

$$\tilde{W} = \tilde{S}\begin{pmatrix} -I-V^T & I-V^T \end{pmatrix} \quad \text{with } 4\tilde{S}(I-V^TV)\tilde{S}^T = I. \tag{4.35}$$

Proof. Looking at Theorem 4.2 we see that we only have to check that $P_{W,\tilde{W}}$ equals $\left(\begin{smallmatrix} 2I & 0 \\ 0 & -2I \end{smallmatrix}\right)$. By (4.13) this is equivalent to $W\Sigma W^T = \frac{1}{2}I$, $\tilde{W}\Sigma\tilde{W}^T = -\frac{1}{2}I$, and $W\Sigma\tilde{W}^T = 0$.

It is easy to show that if both (4.34) and (4.35) hold, then (4.33) holds. So it remains to show the converse. Using the standard representation of W (see (4.2)), we get that $W\Sigma W^T = \frac{1}{2}I$ is equivalently written as (4.34).

Since $\tilde{W}\Sigma\tilde{W}^T = -\frac{1}{2}I$, we see that $\tilde{W}$ is of full rank. Furthermore, from the relation $W\Sigma\tilde{W}^T = 0$, we obtain that the range of $\Sigma\tilde{W}^T$ is contained in the kernel of

W. By Lemma A.2 we have that the kernel of W equals the range of $\left(\begin{smallmatrix} I-V \\ -I-V \end{smallmatrix}\right)$. Since both the range of this matrix and that of $\Sigma\tilde{W}^T$ is of dimension nN, we find that

$$\Sigma\tilde{W}^T = \begin{pmatrix} I-V \\ -I-V \end{pmatrix} \tilde{S}^T$$

for some invertible $\tilde{S}$. Hence we have shown that the representation of (4.35) holds. The last part of this equation follows directly from the fact that $\tilde{W}\Sigma\tilde{W}^T = -\frac{1}{2}I$. □

Choosing in the above theorem $V = 0$ and $S = \tilde{S} = \frac{1}{2}I$ gives the following corollary.

COROLLARY 4.7. *Consider the system defined as*

$$\dot{x}(t) = \mathcal{J}x(t), \tag{4.36}$$

$$u(t) = \frac{1}{2}\left(f_\partial(t) + e_\partial(t)\right), \tag{4.37}$$

$$y(t) = \frac{1}{2}\left(f_\partial(t) - e_\partial(t)\right), \tag{4.38}$$

where $(f_\partial(t), e_\partial(t))$ are the boundary port variable associated with $x(t)$; see Definition 3.5.

The above system is a boundary control system with the associated semigroup a contraction. Furthermore, for $u \in C^2((0,\infty);\mathbb{R}^{nN})$, $x(0) \in H^N((a,b);\mathbb{R}^n)$, and $u(0) = \frac{1}{2}\left(f_\partial(0) + e_\partial(0)\right)$ we have that

$$\frac{1}{2}\frac{d}{dt}\|x(t)\|^2 = \|u(t)\|^2 - \|y(t)\|^2. \tag{4.39}$$

In the previous theorems we have seen that for the same Dirac structure the properties of the PDE, obtained by a choice of the inputs and outputs, can be completely different. Hence for the same underlying Dirac structure, many different system theoretic properties are possible. It is even possible that the PDE has no solution for the trivial input signal. Let us illustrate this situation in more detail in the following simple example.

Example 4.8. Consider the PDE on $[a,b]$

$$\frac{\partial x}{\partial t}(t,z) = \frac{\partial x}{\partial z}(t,z). \tag{4.40}$$

Following section 3, we see that $N = n = 1$, and $P(1) = 1$. The boundary port variables (see Definition 3.5) are

$$\begin{pmatrix} f_\partial(t) \\ e_\partial(t) \end{pmatrix} = \frac{1}{\sqrt{2}}\begin{pmatrix} x(t,b) - x(t,a) \\ x(t,b) + x(t,a) \end{pmatrix}.$$

A short calculation gives that the PDE as discussed in Theorem 4.2 is (4.40) with the boundary input

$$u(t) = s\sqrt{2}\left[x(t,b) - vx(t,a)\right] \tag{4.41}$$

and output

$$y(t) = \frac{1}{\sqrt{2}}\left(\tilde{w}_2 + \tilde{w}_1\right)x(t,b) + \frac{1}{\sqrt{2}}\left(\tilde{w}_2 - \tilde{w}_1\right)x(t,a), \tag{4.42}$$

where s is a nonzero scalar, v is an element of $[-1,1]$, and $\tilde{w}_1, \tilde{w}_2$ are such that $\tilde{w}_2(1+v) - \tilde{w}_1(1-v) \neq 0$. As shown in Theorem 4.2 for any choice of $v \in [-1,1]$, we have that the PDE (4.40) with input (4.41) and output (4.42) has a unique classical solution provided the initial condition and the input are sufficiently smooth. Although the underlying Dirac structure stays the same, the system theoretic properties may be different for different choices of v. For instance, if $v = 1$, then the associated semigroup is unitary, whereas for $v = 0$, the associated semigroup is zero for $t \geq (b-a)$; see also [31].

Now one may wonder which (linear combination) of the boundary port variables may serve as an input, by which we only mean that it may be chosen in some sufficiently large (linear) space. Note that the choice, $u(t) = f_\partial(t) - e_\partial(t)$, gives that the input is located at $z = a$. Since (4.40) represents the left shift, it may be clear that the value of x at a cannot be an input. Even more, for $u \equiv 0$, the PDE does not have a solution.

5. Port Hamiltonian system. In this section, we define port Hamiltonian systems associated with (constant) skew-symmetric matrix operators. These systems are defined in terms of network-based modeling [1, 18, 28] which is based on the definition of two objects: the interconnection structure defined by a Dirac structure and the Hamiltonian function representing the total energy of the system. First, using the definition of the Dirac structure associated with a skew-symmetric operator given in section 3, we define a port Hamiltonian system with boundary port variables. Second, using the results of section 4, we formulate these port Hamiltonian systems as boundary control systems. In subsection 5.2 we treat extensively the example of the Timoshenko beam.

5.1. Linear port Hamiltonian systems with boundary port variables. We now extend the definition of linear port Hamiltonian systems as defined for finite-dimensional state spaces [28] to infinite-dimensional state spaces. The interconnection structure is defined by a Dirac structure associated with the skew-symmetric differential operator according to Theorem 3.6. The Hamiltonian function, generating this port Hamiltonian system, is defined by a coercive operator relating the state variable to the effort variable.

In the introductory example of the section 2, the skew-symmetric operator was the 2×2 matrix differential operator of differential order 1 corresponding to the canonical interdomain coupling, and the Dirac structure was the Stokes–Dirac structure. The symmetric operator was defined by the elasticity modulus and the mass distribution defining the elastodynamic energy of the string.

DEFINITION 5.1. *Consider the domain $Z = (a,b) \subset \mathbb{R}$. Let the space of flow variables $\mathcal{F}_Z$ be equal to $L^2((a,b);\mathbb{R}^n)$ and let the space of effort variables $\mathcal{E}_Z$ be equal to $\mathcal{F}_Z$. Consider an $n \times n$ matrix skew-symmetric differential operator of differential order N denoted as $\mathcal{J}$ defined by* (3.1) *and* (3.2). *Define the bond space $\mathcal{B} = \mathcal{F}_Z \times \mathbb{R}^{nN} \times \mathcal{E}_Z \times \mathbb{R}^{nN}$ and the Dirac structure $\mathcal{D}_\mathcal{J}$ associated with the skew-symmetric differential operator $\mathcal{J}$ as defined in Theorem* 3.6. *Let $\mathcal{L}$ be a coercive-symmetric operator on $\mathcal{E}_Z$. The port Hamiltonian system with the boundary port variables associated with $\mathcal{J}$ and generated by $\mathcal{L}$ is defined by*

$$(\dot{x}(t), f_\partial(t), \mathcal{L}x(t), e_\partial(t)) \in \mathcal{D}_\mathcal{J}, \quad t \geq 0, \tag{5.1}$$

where $\left(\begin{smallmatrix} f_\partial \\ e_\partial \end{smallmatrix}\right)$ is the boundary port associated with $e := \mathcal{L}x$ according to Definition 3.5.

REMARK 5.2. *It may be noted that the system in Definition* 5.1 *corresponds to*

the abstract system $\dot{x}(t) = A\,x(t)$ *defined by the differential operator*

$$A = \mathcal{J}\mathcal{L} \tag{5.2}$$

which need not be skew-symmetric nor have constant coefficients.

It is also worth making explicit the Hamiltonian function representing the energy of the system

$$H(x) = \frac{1}{2}\langle x,\, \mathcal{L}x\rangle, \tag{5.3}$$

where $\langle\cdot,\cdot\rangle$ denotes the natural inner product on the space $\mathcal{E}_Z$. The port Hamiltonian system of section 4 may hence be seen as a particular case with $\mathcal{L} = I$.

Noting that $\frac{dH(x(t))}{dt} = \langle\dot{x}(t),\, \mathcal{L}x(t)\rangle$, by the definition of Dirac structure, one obtains the following energy balance equation:

$$\frac{dH(x(t))}{dt} = \frac{1}{2}\left(f_\partial^T(t), e_\partial^T(t)\right)\Sigma\begin{pmatrix} f_\partial(t) \\ e_\partial(t)\end{pmatrix}.$$

This expresses that the variation of the energy of the boundary port Hamiltonian system is equal to the flow of energy at the boundary of the system's domain.

This also motivates us to take the state space equal to those x for which the Hamiltonian is finite. Since $\mathcal{L}$ is coercive on $\mathcal{E}_Z = L^2((a,b);\mathbb{R}^n)$, we see that the state space $\mathcal{X}$ is $L^2((a,b);\mathbb{R}^n)$ with the new inner product

$$\langle x_1, x_2\rangle_{\mathcal{X}} = \langle x_1, \mathcal{L}x_2\rangle_{L^2((a,b);\mathbb{R}^n)}. \tag{5.4}$$

In the previous definition we have defined linear port Hamiltonian systems with boundary port variables using the definition of Dirac structure for which the port variables are not split into input and output variables. However, we have seen in section 4 that using a specific subspace of the port variables, one may define input and output variables as belonging to complementary subspaces of the boundary port variables. Moreover, by choosing in an appropriate way these subspaces, one may define a boundary control system with its associated semigroup being a contraction. In the following, we reformulate the boundary port Hamiltonian system of Definition 5.1 as a boundary control system. We use the parameterization of the input and output variables and the contractive semigroups associated with the Dirac structure $\mathcal{D}_\mathcal{J}$ given in section 4. The state variables have become the image of the effort variables through the coercive operator $\mathcal{L}^{-1}$.

THEOREM 5.3. *The port Hamiltonian system of Definition* 5.1 *may be formulated as a boundary control system on the state space* $\mathcal{X}$*:*

$$(\dot{x}(t), f_\partial(t), \mathcal{L}x(t), e_\partial(t)) \in \mathcal{D}_\mathcal{J}, \quad t \geq 0, \tag{5.5}$$

with the input variables defined by choosing some full rank matrix W *of size* $nN \times 2nN$ *satisfying* (4.1) *and the map*

$$\mathcal{B}x(t) = W\begin{pmatrix} f_\partial(t) \\ e_\partial(t)\end{pmatrix} = u(t) \tag{5.6}$$

on the domain

$$D(\mathcal{B}) = D(\mathcal{J}). \tag{5.7}$$

Furthermore, define the port conjugated output

$$y(t) = \tilde{W} \begin{pmatrix} f_\partial(t) \\ e_\partial(t) \end{pmatrix}$$

with $\tilde{W}$ *a full rank matrix of size* $nN \times 2nN$ *with* $\begin{pmatrix} W \\ \tilde{W} \end{pmatrix}$ *invertible. Then for* $u \in C^2((0,\infty);\mathbb{R}^{nN})$, $x(0) \in H^N((a,b),\mathbb{R}^n)$, *and* $u(0) = \mathcal{B}x(0)$, *the following balance equation is satisfied:*

$$\frac{d}{dt}H(x(t)) = \frac{1}{2}(u^T(t) \quad y^T(t))P_{W,\tilde{W}} \begin{pmatrix} u(t) \\ y(t) \end{pmatrix}, \tag{5.8}$$

where $P_{W,\tilde{W}}$ *is defined in* (4.13).

The proof is a straightforward extension of the proof of Theorem 4.1 using the following lemma.

LEMMA 5.4. *Assume that* W *satisfies* (4.1). *The differential operator* $A_W = \mathcal{J}\mathcal{L}$ *with the domain* $D(A_W) = \{x \in \mathcal{X} \mid \mathcal{L}x \in D(J_W)\}$ (*see* (4.4)) *generates a contraction semigroup on* $\mathcal{X}$.

Proof. We first show that A_W is dissipative. For $x \in D(A_W)$, we have that

$$\langle x, A_W x\rangle_{\mathcal{X}} = \langle x, \mathcal{J}\mathcal{L}x\rangle_{\mathcal{X}} = \langle x, \mathcal{L}\mathcal{J}\mathcal{L}x\rangle_{L_2} = \langle e, \mathcal{J}e\rangle_{L_2},$$

where $e = \mathcal{L}x$. Since $e \in D(J_W)$ and since J_W is a restriction of $\mathcal{J}$, we find that

$$\langle x, A_W x\rangle_{\mathcal{X}} = \langle e, J_W e\rangle_{L_2},$$

which is nonpositive, since J_W generates a contraction semigroup on $L^2((a,b);\mathbb{R}^n)$.

It is not hard to show that $A_W^* = J_W^*\mathcal{L}$ with $D(A_W^*) = \{x \in \mathcal{X} \mid \mathcal{L}x \in D(J_W^*)\}$. Using an argument similar to that above, we find that on $D(A_W^*)$

$$\langle x, A_W^* x\rangle_{\mathcal{X}} \leq 0.$$

Hence we conclude that A_W generates a contraction semigroup on $\mathcal{X}$. ∎

5.2. Example: The Timoshenko's beam model. Timoshenko's beam model describes the infinitesimal planar deformations of a flexible beam reduced to its neutral fiber with some particular geometrical assumptions. We briefly recall the Hamiltonian formulation as proposed by Golo, Talasila, and van der Schaft [6]. Note that this corresponds to taking the Legendre transform of the usual Lagrangian formulation. Consider the spatial domain $Z = [a,b]$. Denote the angular displacement by q_θ, the transversal displacement of the beam by q_y, and the conjugated momenta by p_θ and p_y. The elastic potential energy density is given by $\mathcal{U}(q) = \frac{1}{2}\int_Z F^T q\, dz$, where the strain wrench (torque and force) is $F = K\,q$. Let $K = \operatorname{diag}(c_\theta, c_y)$ denote the positive definite compliance matrix which depends on the elasticity properties of the material and its geometry. The kinetic energy is given by $\mathcal{K}(p) = \frac{1}{2}\int_Z v^T p\, dz$, where the coenergy variable is the velocity $v = M^{-1}\,p$. M denotes the positive definite inertia matrix which is given as $M = \operatorname{diag}(\iota, \mu)$ with ι the momentum of inertia of the beam per unit length and μ the mass per unit length. It is immediate that $F = \delta_q\mathcal{U}(q)$ and $v = \delta_p\mathcal{K}(q)$, where δ denotes the variational derivative [20].

Choose the state vector x as

$$x = \begin{pmatrix} q_\theta \\ q_y \\ p_\theta \\ p_y \end{pmatrix} = \begin{pmatrix} q \\ p \end{pmatrix}.$$

The Timoshenko beam model may be expressed as the following Hamiltonian evolution equations [6, 7]:

$$\frac{\partial x}{\partial t} = \mathcal{J} \begin{pmatrix} \frac{\partial \mathcal{H}}{\partial q} \\ \frac{\partial \mathcal{H}}{\partial p} \end{pmatrix}, \tag{5.9}$$

where $\mathcal{H}(q,p) = \mathcal{U}(q) + \mathcal{K}(p)$ is the total elastodynamic energy of the beam, and the skew-symmetric differential operator $\mathcal{J}$ is

$$\mathcal{J} = \begin{pmatrix} 0_2 & \begin{pmatrix} \frac{\partial}{\partial z} & 0 \\ -1 & \frac{\partial}{\partial z} \end{pmatrix} \\ \begin{pmatrix} \frac{\partial}{\partial z} & 1 \\ 0 & \frac{\partial}{\partial z} \end{pmatrix} & 0_2 \end{pmatrix}. \tag{5.10}$$

We now derive the port Hamiltonian formulation of this system. The time variation of the energy variables is defined as flow variables:

$$\frac{\partial}{\partial t} \begin{pmatrix} q \\ p \end{pmatrix} := \begin{pmatrix} f_q \\ f_p \end{pmatrix}.$$

The variational derivative of the total energy $\delta_x \mathcal{H}$ defines the effort variables:

$$\begin{pmatrix} e_q \\ e_p \end{pmatrix} := \mathcal{L} \begin{pmatrix} q \\ p \end{pmatrix} = \begin{pmatrix} K & 0 \\ 0 & M^{-1} \end{pmatrix} \begin{pmatrix} q \\ p \end{pmatrix}. \tag{5.11}$$

Note that

$$\mathcal{L} \begin{pmatrix} q \\ p \end{pmatrix} = \begin{pmatrix} \frac{\partial \mathcal{H}}{\partial q} \\ \frac{\partial \mathcal{H}}{\partial p} \end{pmatrix}.$$

More precisely,

$$e_q = \begin{pmatrix} c_\theta & 0 \\ 0 & c_y \end{pmatrix} \begin{pmatrix} q_\theta \\ q_y \end{pmatrix} = \begin{pmatrix} T \\ F_y \end{pmatrix} \tag{5.12}$$

is the vector composed of the torque and the force, and

$$e_p = \begin{pmatrix} \iota^{-1} & 0 \\ 0 & \mu^{-1} \end{pmatrix} \begin{pmatrix} p_\theta \\ p_y \end{pmatrix} = \begin{pmatrix} \omega \\ v_y \end{pmatrix} \tag{5.13}$$

is the vector composed of the angular and longitudinal velocities.

Hence, according to the evolution equation (5.9), the flow variables are related to the coenergy variables by the skew-symmetric differential operator $\mathcal{J}$ defined in (3.1)

$$\begin{pmatrix} f_q \\ f_p \end{pmatrix} = \mathcal{J} \begin{pmatrix} e_q \\ e_p \end{pmatrix}.$$

This differential operator may be written as

$$\mathcal{J} = P(0) + P(1)\frac{\partial}{\partial z},$$

where

$$P(0) = \begin{pmatrix} 0_2 & \begin{pmatrix} 0 & 0 \\ -1 & 0 \end{pmatrix} \\ \begin{pmatrix} 0 & 1 \\ 0 & 0 \end{pmatrix} & 0_2 \end{pmatrix}, \quad P(1) = \begin{pmatrix} 0_2 & \begin{pmatrix} 1 & 0 \\ 0 & 1 \end{pmatrix} \\ \begin{pmatrix} 1 & 0 \\ 0 & 1 \end{pmatrix} & 0_2 \end{pmatrix}.$$

The symmetric matrix Q corresponding to the bilinear term on the boundary variables in Theorem 3.1 and given in (3.5) reduces to $Q = P(1)$. The matrix R_{ext} defining the boundary port variables equals (see (3.7))

$$R_{\text{ext}} = \frac{\sqrt{2}}{2} \begin{pmatrix} 0 & 0 & 1 & 0 & 0 & 0 & -1 & 0 \\ 0 & 0 & 0 & 1 & 0 & 0 & 0 & -1 \\ 1 & 0 & 0 & 0 & -1 & 0 & 0 & 0 \\ 0 & 1 & 0 & 0 & 0 & -1 & 0 & 0 \\ 1 & 0 & 0 & 0 & 1 & 0 & 0 & 0 \\ 0 & 1 & 0 & 0 & 0 & 1 & 0 & 0 \\ 0 & 0 & 1 & 0 & 0 & 0 & 1 & 0 \\ 0 & 0 & 0 & 1 & 0 & 0 & 0 & 1 \end{pmatrix}. \tag{5.14}$$

According to Definition 3.5 the port variables are

$$\begin{pmatrix} f_\partial \\ e_\partial \end{pmatrix} = R_{\text{ext}} \begin{pmatrix} \mathcal{L} & 0 \\ 0 & \mathcal{L} \end{pmatrix} \begin{pmatrix} q(b) \\ p(b) \\ q(a) \\ p(a) \end{pmatrix}.$$

Considering relations (5.11), (5.12), and (5.13),

$$\begin{pmatrix} f_\partial \\ e_\partial \end{pmatrix} = \frac{\sqrt{2}}{2} \begin{pmatrix} \omega(b) - \omega(a) \\ v_y(b) - v_y(a) \\ T(b) - T(a) \\ F_y(b) - F_y(a) \\ T(b) + T(a) \\ F_y(b) + F_y(a) \\ \omega(b) + \omega(a) \\ v_y(b) + v_y(a) \end{pmatrix}.$$

The associated Dirac structure is given by

$$\mathcal{D}_{\mathcal{J}} = \left\{ \begin{pmatrix} f_q \\ f_p \\ f_\partial \\ e_q \\ e_p \\ e_\partial \end{pmatrix} \;\middle|\; \begin{pmatrix} e_q \\ e_p \end{pmatrix} \in H^1((a,b);\mathbb{R}^4), \mathcal{J} \begin{pmatrix} e_q \\ e_p \end{pmatrix} = \begin{pmatrix} f_q \\ f_p \end{pmatrix}, \quad \begin{pmatrix} f_\partial \\ e_\partial \end{pmatrix} = R_{\text{ext}} \begin{pmatrix} T(b) \\ F_y(b) \\ \omega(b) \\ v_y(b) \\ T(a) \\ F_y(a) \\ \omega(a) \\ v_y(a) \end{pmatrix} \right\}.$$

We now illustrate the derivation of boundary control systems from the port Hamiltonian system using two different choices of the matrix W defining them according to Theorem 5.3. The first choice corresponding to the boundary control system is

associated with a unitary semigroup and in the other choice corresponds to a system in the scattering representation.

For the unitary case let us choose the matrix W given in (4.2) with the invertible matrix S and matrix V satisfying $VV^T = I$ chosen as follows:

$$S = \frac{1}{2\sqrt{2}} \begin{pmatrix} -I_2 & I_2 \\ I_2 & I_2 \end{pmatrix} \text{ and } V = \begin{pmatrix} 0 & I_2 \\ -I_2 & 0 \end{pmatrix}.$$

This choice corresponds to define the inputs

$$\begin{aligned} u &= S \begin{pmatrix} I_4 + V & I_4 - V \end{pmatrix} \begin{pmatrix} f_\partial \\ e_\partial \end{pmatrix} \\ &= \frac{1}{\sqrt{2}} \begin{pmatrix} -I_2 & 0 & 0 & I_2 \\ 0 & I_2 & I_2 & 0 \end{pmatrix} \begin{pmatrix} f_\partial \\ e_\partial \end{pmatrix} = \begin{pmatrix} \omega(a) \\ v_y(a) \\ T(b) \\ F_y(b) \end{pmatrix}. \end{aligned}$$

The unitary semigroup associated with the boundary control $u = 0$ corresponds to the following boundary conditions:

$$\omega(a,t) = v_y(a,t) = M(b,t) = F_y(b,t) = 0,$$

which are the so-called *clamped-free* boundary conditions. According to Theorem 4.4 the output conjugated to this input is

$$y = \tilde{S}(I_4 + \tilde{V} \quad I_4 - \tilde{V}) \begin{pmatrix} f_\partial \\ e_\partial \end{pmatrix}$$

with $\tilde{V}$ unitary, $\tilde{S}$ invertible, and

$$2\tilde{S}\big(I_4 - \tilde{V}V^T\big)S = I_4.$$

For example, choosing $\tilde{V} = -V = \left(\begin{smallmatrix} 0 & -I_2 \\ I_2 & 0 \end{smallmatrix}\right)$ and $\tilde{S} = S = \frac{1}{2\sqrt{2}} \left(\begin{smallmatrix} -I_2 & I_2 \\ I_2 & I_2 \end{smallmatrix}\right)$ we obtain

$$y = \begin{pmatrix} -T(a) \\ -F_y(a) \\ \omega(b) \\ v_y(b) \end{pmatrix}.$$

For the contractive case, let us choose the matrix W given in (4.2) with the invertible matrix S and matrix V, satisfying $VV^T \leq I$, chosen as follows:

$$S = \frac{\sqrt{2}}{4} \begin{pmatrix} I_2 & I_2 \\ -I_2 & I_2 \end{pmatrix} \text{ and } V = \begin{pmatrix} 0 & 0 \\ 0 & 0 \end{pmatrix}.$$

According to Theorem 5.3 the inputs are

$$u = \frac{\sqrt{2}}{4} \begin{pmatrix} I_2 & I_2 & I_2 & I_2 \\ -I_2 & I_2 & -I_2 & I_2 \end{pmatrix} \begin{pmatrix} f_\partial \\ e_\partial \end{pmatrix} = \frac{1}{2} \begin{pmatrix} \omega(b) + T(b) \\ v_y(b) + F_y(b) \\ \omega(a) - T(a) \\ v_y(a) - F_y(a) \end{pmatrix}.$$

For $\tilde{S}$ (see Theorem 4.6) we choose S and so the outputs are

$$y = \frac{\sqrt{2}}{4}\begin{pmatrix} I_2 & I_2 & -I_2 & -I_2 \\ -I_2 & I_2 & I_2 & -I_2 \end{pmatrix}\begin{pmatrix} f_\partial \\ e_\partial \end{pmatrix} = -\frac{1}{2}\begin{pmatrix} \omega(a) + T(a) \\ v_y(a) + F_y(a) \\ \omega(b) - T(b) \\ v_y(b) - F_y(b) \end{pmatrix}.$$

In this case, the boundary inputs and outputs correspond to the *scattering variables* and $\frac{1}{2}\|x(t)\|^2_{\mathcal{X}} = \|u(t)\|^2 - \|y(t)\|^2$.

6. Conclusion and further work. The work presented in this paper relates the structure of a class of linear infinite-dimensional dynamical models induced by the physical modeling (existence of energy function, power continuous interconnection structure) with system theoretical properties (passivity, etc.). More precisely, we have defined a class of infinite-dimensional linear systems associated with skew-symmetric differential operators and we have related them to boundary control systems. Knowing the underlying physical structure and the system theoretical notions will be very useful in the further analysis and design for our class of infinite-dimensional systems, for instance, in the construction of stabilizing feedbacks.

Therefore, we have, in the first instance, defined a Dirac structure on a Hilbert space associated with skew-symmetric differential operators with constant coefficients. Using the Stokes theorem, we have defined port boundary variables as the image of the boundary values under a linear map, which is derived from the differential operator. Then we have shown that the differential operator together with the boundary port variables defines a Dirac structure on a vector space (the space of bond variables) endowed with a canonical symmetric pairing. This defines the geometrical structure associated with the initial PDE.

In the second instance, we have shown that one may derive from the Dirac structure infinitesimal generators of contraction semigroups. These infinitesimal generators are obtained by restricting the domain of the skew-symmetric operator to parameterized subspaces. More precisely, we have shown that we have obtained a parameterization of all the contraction semigroups which are associated with the skew-symmetric operator.

In the third instance, we have derived a formulation of our class of infinite-dimensional systems as boundary control systems associated with the class of contraction semigroups obtained from the Dirac structure. We have defined outputs conjugated to the inputs of the boundary control systems in such a way that the system satisfies a power balance equation in a way similar to dissipative systems [25].

In the fourth instance, these results are used to define infinite-dimensional port Hamiltonian systems. These systems are defined with respect to the Dirac structure associated with a skew-symmetric differential operator and a coercive operator defining the Hamiltonian functional, i.e., the total energy of the system. Again from such a port Hamiltonian system one may derive a class of boundary control system associated with contraction semigroups. This is illustrated by the example of Timoshenko's beam.

A natural question is the relation of our class of systems, especially the Hamiltonian systems with the systems nodes (see [26]), and with the class of well-posed linear systems. This has been partially done in [31] for the system nodes and in [32] for well-posed systems (using the idea of feedback). Another issue is the generalization of this work to PDEs on an n-dimensional spatial domain.

Finally, this works also opens the way for the generalization to infinite-dimensional systems of the synthesis of stabilizing controllers using the immersion and Hamiltonian reduction proposed in [13, 22].

Appendix. Technical lemmas.

LEMMA A.1. *Let W be an $nN \times 2nN$ matrix and let $\Sigma = \left(\begin{smallmatrix} 0 & I \\ I & 0 \end{smallmatrix}\right)$. Then W has rank nN and $W\Sigma W^T \geq 0$ if and only if there exist a matrix $V \in \mathbb{R}^{nN \times nN}$ and an invertible matrix $S \in \mathbb{R}^{nN \times nN}$ such that*

$$W = S(I + V \quad I - V) \tag{A.1}$$

with $VV^T \leq I$.

Furthermore, $W\Sigma W^T = 0$ if and only if V is unitary.

Proof. If W is of the form (A.1), then we find

$$W\Sigma W^T = S\begin{pmatrix} I + V & I - V \end{pmatrix} \Sigma \begin{pmatrix} I + V^T \\ I - V^T \end{pmatrix} S^T = S[2I - 2VV^T]S^T,$$

which is nonnegative, since $VV^T \leq I$.

Now we prove that if W is of full rank and is such that $W\Sigma W^T \geq 0$, then (A.1) holds. Writing W as $W = (W_1 \quad W_2)$, we have that $W\Sigma W^T \geq 0$ is equivalent to $W_1 W_2^T + W_2 W_1^T \geq 0$. Hence

$$(W_1 + W_2)(W_1 + W_2)^T \geq (W_1 - W_2)(W_1 - W_2)^T \geq 0. \tag{A.2}$$

If $x \in \ker((W_1 + W_2)^T)$, then the above inequality implies that $x \in \ker((W_1 - W_2)^T)$. Thus $x \in \ker(W_1^T) \cap \ker(W_2^T)$. Since W has full rank, this implies that $x = 0$. Hence $W_1 + W_2$ is invertible.

Using (A.2) once again, we see that

$$(W_1 + W_2)^{-1}(W_1 - W_2)(W_1 - W_2)^T(W_1 + W_2)^{-T} \leq I$$

and thus $V := (W_1 + W_2)^{-1}(W_1 - W_2)$ satisfies $VV^T \leq I$. Summarizing, we have

$$\begin{aligned}(W_1 \quad W_2) &= \frac{1}{2}(W_1 + W_2 + W_1 - W_2 \quad W_1 + W_2 - W_1 + W_2) \\ &= \frac{1}{2}(W_1 + W_2)(I + V \quad I - V).\end{aligned}$$

Defining $S := \frac{1}{2}(W_1 + W_2)$, we have shown the representation (A.1).

If instead of inequality we have equality for W, then it is easy to show that we have equality in the equation for V as well. Thus V is unitary. ∎

LEMMA A.2. *Suppose that the $nN \times 2nN$ matrix W can be written in the format of (A.1), i.e., $W = S(I+V \quad I-V)$ with S and V square matrices, and S is invertible. Then the kernel of W equals the range of $\left(\begin{smallmatrix} I-V \\ -I-V \end{smallmatrix}\right)$.*

If V is unitary, then the kernel of W equals the range of ΣW^T.

Proof. Let $\left(\begin{smallmatrix} x_1 \\ x_2 \end{smallmatrix}\right)$ be in the range of $\left(\begin{smallmatrix} I-V \\ -I-V \end{smallmatrix}\right)$. By equality (A.1), we have that

$$\begin{aligned}W\begin{pmatrix} x_1 \\ x_2 \end{pmatrix} &= S\begin{pmatrix} I + V & I - V \end{pmatrix}\begin{pmatrix} x_1 \\ x_2 \end{pmatrix} \\ &= S\begin{pmatrix} I + V & I - V \end{pmatrix}\begin{pmatrix} I - V \\ -I - V \end{pmatrix} l = 0.\end{aligned}$$

Hence we see that the range of $\left(\begin{smallmatrix} I-V \\ -I-V \end{smallmatrix}\right)$ lies in the kernel of W. It is easy to show that W has rank nN, and so the kernel of W has dimension nN. Thus, if we can show that the $2nN \times nN$ matrix $\left(\begin{smallmatrix} I-V \\ -I-V \end{smallmatrix}\right)$ has full rank, then we have proved the first assertion. If this matrix would not have full rank, then there should be a nontrivial element in its kernel. It is easy to see that the kernel consists of zero only, and so we have proved the first part of the lemma.

Suppose now that V is unitary, then

$$\begin{pmatrix} I-V \\ -I-V \end{pmatrix} = \begin{pmatrix} -I+V^T \\ -I-V^T \end{pmatrix} V = -\Sigma W^T S^{-T} V.$$

Since the range of ΣW^T equals the range of $-\Sigma W^T S^{-T} V$, we have proved the second assertion. ∎

LEMMA A.3. *Given the interval $[a,b]$ and a positive number $N \in \mathbb{N}$. There exist polynomials $f_{lj}(z), f_{rj}(z), j = 0, \ldots, N-1$, such that*

$$\begin{aligned} \frac{d^k f_{l,j}}{dz^k}(a) &= \delta_{kj}, \quad k = 0, \ldots, N-1, \\ \frac{d^k f_{l,j}}{dz^k}(b) &= 0, \quad k = 0, \ldots, N-1, \end{aligned} \tag{A.3}$$

and

$$\begin{aligned} \frac{d^k f_{r,j}}{dz^k}(a) &= 0, \quad k = 0, \ldots, N-1, \\ \frac{d^k f_{r,j}}{dz^k}(b) &= \delta_{kj}, \quad k = 0, \ldots, N-1. \end{aligned} \tag{A.4}$$

Proof. Since the construction of $f_{r,j}$ is very similar to that of $f_{l,j}$, we show only how $f_{l,j}$ is constructed. These functions are constructed using backward induction. It is easily seen that

$$f_{l,N-1}(z) := \frac{1}{(N-1)!}(z-a)^{N-1}(z-b)^N \frac{1}{(a-b)^N}$$

satisfies condition (A.3). Suppose next that we have constructed the functions $f_{l,j}(z)$ for $j = j_0+1, \ldots, N-1$. We next construct $f_{l,j_0}(z)$. Define $\tilde{f}_{l,j_0}(z)$ as

$$\tilde{f}_{l,j_0}(z) = \frac{1}{j_0!}(z-a)^{j_0}(z-b)^N \frac{1}{(a-b)^N}.$$

It is easy to see that

$$\frac{d^k \tilde{f}_{l,j_0}}{dz^k}(a) = \delta_{kj_0}, \quad k = 0, \ldots, j_0,$$

and

$$\frac{d^k \tilde{f}_{l,j_0}}{dz^k}(b) = 0, \quad k = 0, \ldots, N-1.$$

If we define the function $f_{l,j_0}(z)$ as

$$f_{l,j_0}(z) = \tilde{f}_{l,j_0}(z) - \sum_{i=j_0+1}^{N-1} \frac{d^i f_{l,j_0}}{dz^i}(a) f_{l,i}(z),$$

then it is straightforward to see that it satisfies (A.3). ∎

MEAN-VARIANCE HEDGING WHEN THERE ARE JUMPS*

ANDREW E. B. LIM†

Abstract. In this paper, we consider the problem of mean-variance hedging in an *incomplete market* where the underlying assets are jump diffusion processes which are driven by Brownian motion and doubly stochastic Poisson processes. This problem is formulated as a stochastic control problem, and closed form expressions for the optimal hedging policy are obtained using methods from stochastic control and the theory of backward stochastic differential equations. The results we have obtained show how backward stochastic differential equations can be used to obtain solutions to optimal investment and hedging problems when discontinuities in the underlying price processes are modeled by the arrivals of Poisson processes with stochastic intensities. Applications to the problem of hedging default risk are also discussed.

Key words. jump diffusion, stochastic intensity, doubly stochastic Poisson process, mean-variance hedging, incomplete markets, backward stochastic differential equations, default risk

1. Introduction.

Much of the literature on asset price modeling is motivated by the observation that simple models, like Black–Scholes, fail to account for important features of price processes that are observed in data. For example, the log-returns process of real-world asset prices are not normally distributed but exhibit higher peaks and heavier tails, implying a greater probability of extreme price movements than predicted by Black–Scholes. In addition, the price processes of real-world assets are typically not continuous, but may jump (in a nonpredictable way) in response to news or other surprise events. For a number of years, researchers have focused on developing a richer class of asset price models that include jumps as well as stochastic parameters; see, for example, [3, 12, 20]. While the adoption of these models in asset pricing (where simulation can be used) is fairly widespread, their use in dynamic optimization problems like hedging and optimal investment, when the market is incomplete, has been quite limited. This paper is concerned with the problem of *dynamic mean-variance hedging* in an *incomplete market* when there are *random parameters* and *discontinuities* in the price processes. We assume that uncertainty is modeled by Brownian motion and a doubly stochastic Poisson process with intensity that is predictable with respect to the Brownian filtration. We derive expressions for the optimal hedging strategy using methods from stochastic control and the theory of *backward stochastic differential equations* (BSDEs).

While the theory of BSDEs has played an important role in the analysis and solution of mean-variance hedging problems with random parameters (see [25, 27]), it is typically assumed that price processes are continuous and driven by Brownian motion. (We note, however, that generalizations to the continuous semimartingale setting have recently appeared; see Bobrovnytska and Schweizer [6].) One contribution of this paper is to show how BSDEs can be used when there are jumps. In this regard,

we determine conditions under which the relevant BSDEs have unique solutions, and derive an expression for the optimal hedging strategy in terms of these. In particular, we show how the hedging strategy should respond to news that indicates a higher or lower probability of a sudden price change (i.e., an increase or decrease in the intensity of the jump process).

An alternative approach to mean-variance hedging uses the projection theorem and convex duality and typically assumes that price processes are *continuous* semimartingales; see, for example, [9, 14, 23, 30, 32]. Exceptions include [22], which considers the problem of local risk minimization for a model with jumps under the assumption that the stochastic intensity is independent of the processes driving the stock price processes, and the recent paper by Arai [1], which generalizes the methods in [30] to the discontinuous case. Some key differences between [1] and this paper include the generality of the price processes (discontinuous semimartingales v's processes driven by Brownian motion and a doubly stochastic Poisson process) and the methods that are used to solve the problem (duality v's stochastic control). A key issue in both [1] and this paper concerns the so-called *variance optimal (signed) martingale measure*. In the continuous semimartingale case, the variance optimal signed martingale measure is actually a probability measure, but this is not necessarily the case when there are jumps. (We show this in our example.) For this reason, additional assumptions are needed when dealing with discontinuous problems. In the context of this paper, some of these assumptions are required to prove solvability of one of the BSDEs. On the other hand, the additional structure in our model allows us to dispense with some of the assumptions imposed in [1]. Furthermore, under additional assumptions on the liability, we also prove solvability of the hedging problem, even when the variance optimal martingale measure is *not* a probability measure.

The bulk of the literature on optimal portfolio choice and dynamic hedging has focused, primarily, on market models with *continuous* price processes, and relatively little has been done using models with price discontinuities (some recent exceptions include [2, 15, 18, 26, 28, 29]). This paper may be regarded as a contribution to this literature. In the papers [2, 18], the problem of utility maximization when there are discontinuous price processes is solved using convex duality. Unlike the model in [29] as well as in the present paper, however, the market models in [2, 18] are *complete*. Similar methods are used in [28] to solve a continuous time mean-variance problem with a bankruptcy prohibition when there are price discontinuities, but once again, market completeness is assumed. Finally, the paper [15] discusses the issues of model calibration and optimal portfolio computation in a discontinuous price setting while the recent paper [26] solves a portfolio choice problem with regime switching and price discontinuities.

Finally, the results in this paper may also be regarded as a contribution to the literature on hedging default risk in an *incomplete* market. In particular, doubly stochastic Poisson processes have recently been used to model events default [4, 11, 21] and for this reason, the problem of optimal investment or hedging with default sensitive assets and/or liabilities may be formulated as an optimal investment/hedging problem with asset prices modeled as jump-diffusions. (For further discussion on this issue, the reader can consult [24].) The problem of hedging in a complete market with default risk is studied in Blanchet-Scalliet and Jeanblanc [5]. It should be noted, however, that the market model in [5] is different from ours in a number of ways, and for this reason our result cannot really be regarded as a *faithful* generalization of theirs. For example, we assume that parameters (and in particular

the default intensity) are predictable with respect to Brownian motion, whereas the results in [5] allow for a more general class of parameters. Also, we are assuming that assets remain tradable after a jump occurs, whereas the results in [5] apply to the case when the underlying asset (a zero-coupon bond) ceases to be tradable the instant a jump (i.e., default) occurs.

The outline of this paper is as follows. In section 2, we present the model for the financial market, and formulate the hedging problem as a stochastic control problem. In section 3, the optimal hedging portfolio is derived. In particular, the results in this section depend on the solvability of a certain BSDE that is driven by Brownian motion and the Poisson process. In section 4, solvability of this backwards equation is discussed in greater detail. In particular, we prove solvability under the assumption that a certain local martingale is a positive martingale (the *"martingale condition"*), and derive necessary and sufficient conditions for this to hold. This condition is difficult to check, however, due to its complicated dependence on the problem parameters, which motivates our analysis in section 5 where simple conditions under which the "martingale condition" can be checked are derived. In particular, we show that the "martingale condition" holds when the market is complete, and it is easy to check when the parameters are deterministic. In addition, we also derive conditions on the *liability* under which the hedging problem will still have a solution, *even if the "martingale condition" is not satisfied*. In particular, we show in section 5.4 that solvability can be guaranteed, irrespective of the *"martingale condition," whenever the liability is measurable with respect to the Brownian motion*, which is the case for the continuous time version of Markowitz's mean-variance portfolio selection problem. In section 6, we compare the assumptions made in Arai [1] with those in this paper. In section 7, we present an example where an explicit expression of the optimal hedging strategy can be calculated. We conclude in section 8.

This paper is a substantially expanded version of the conference paper [24]. In particular, the detailed proof of optimality, existence of solutions of the associated BSDEs, necessary and sufficient conditions for the "martingale condition" to be satisfied, comparisons with the paper [1], and the example are not found in the earlier version.

2. Formulation. Let $(\Omega, \mathcal{F}, \mathbb{P})$ be a complete probability space. We assume throughout that all stochastic processes are defined on a finite time horizon $[0, T]$. Suppose that $W(t) \triangleq (W_1(t), \ldots, W_d(t))'$ is a d-dimensional standard Brownian motion on this space defined on $[0, T]$ and $\mathbb{F} \triangleq \{\mathcal{F}_t\}_{t\geq 0}$ is the filtration generated by $W(t)$ augmented by the null sets of $\mathbb{P}$. Let $N(t) \triangleq (N_1(t), \ldots, N_n(t))'$, where $N_i(t)$ is a *doubly stochastic Poisson process* (or a *Cox process*) with an $\mathbb{F}$-predictable nonnegative intensity $\lambda_i(t)$. In relation to $N(t)$, we denote by $\mathbb{D} \triangleq \{\mathcal{D}_t\}_{t\geq 0}$ the filtration generated by $N(t)$ augmented by the $\mathbb{P}$-null sets. We assume throughout that conditional on $\mathcal{F}_T$, $N_i(\cdot)$ is a nonhomogeneous Poisson process with intensity $\lambda_i(t)$, and (conditional on $\mathcal{F}_T$) $N_i(\cdot)$ and $N_j(\cdot)$ are independent when $i \neq j$. It should be noted that the construction of such processes $N_i(t)$ is fairly standard; see, for example, [4]. Finally, let $\mathbb{G}$ denote the filtration $\{\mathcal{G}_t\}_{t\geq 0}$, where $\mathcal{G}_t \triangleq \mathcal{F}_t \vee \mathcal{D}_t$, the smallest filtration containing $\mathbb{F}$ and $\mathbb{D}$. Here, $\mathcal{G}_t$ may be regarded as the information available to the investor at time t. The filtrations $\mathbb{F}$ and $\mathbb{G}$ satisfy the following property (see [7] for a detailed study).

PROPOSITION 2.1 (martingale invariance property). *Every $\mathbb{F}$-martingale under $\mathbb{P}$ is also a $\mathbb{G}$-martingale under $\mathbb{P}$.*

Proof. By the construction of doubly stochastic Poisson processes with $\mathbb{F}$-predictable intensity, $\mathcal{G}_t$ and $\mathcal{F}_T$ are independent, given $\mathcal{F}_t$. The result now follows from the observation that this property is equivalent to $\mathbb{E}[X|\mathcal{F}_t] = \mathbb{E}[X|\mathcal{G}_t]$ for every $\mathcal{F}_T$-measurable random variable X. □

The *martingale invariance property* is studied in detail in [7] and is a common *assumption* in the literature on default risk modeling [4, 13] as well as hedging and portfolio choice with jumps [5]. It holds in the setting of this paper due to the structure of our stochastic model.

We introduce the following notation.

- $\mathcal{P}^2(\mathbb{G}, \mathbb{R}^m)$: the set of $\mathbb{G}$-predictable, $\mathbb{R}^m$-valued processes on $[0, T]$ under $\mathbb{P}$ with norm
$$\|f\|_2 := \left(\mathbb{E}^{\mathbb{P}} \int_0^T |f(t)|^2 \, dt\right)^{\frac{1}{2}} < \infty.$$
- $\mathcal{L}^\infty(\mathbb{G}, \mathbb{R}^m)$: the set of $\mathbb{G}$-adapted $\mathbb{P}$-essentially bounded $\mathbb{R}^m$-valued processes on $[0, T]$.

We refer to processes belonging to $\mathcal{P}^2(\mathbb{G}, \mathbb{R}^m)$ as being *square integrable*, while those that belong to $\mathcal{L}^\infty(\mathbb{G}, \mathbb{R}^m)$ are *uniformly bounded*.

Suppose that there are $m + 1$ tradable assets with prices $B(t)$, $P_1(t), \ldots, P_m(t)$, where $B(t)$ is the price of the money market account with interest rate $r(t)$, and $P_i(t)$ is the price of the ith risky asset. We assume throughout that $B(t)$ and $P_i(t)$ are solutions of the following stochastic differential equations:

$$\begin{cases} dB(t) = r(t)B(t)\, dt, \quad B(0) = 1, \\ dP_i(t) = P_i(t)\mu_i(t)\, dt + P_i(t)\sigma_i(t)dW(t) + P_i(t)\theta_i(t)dN(t), \quad P_i(0) = P_i^0. \end{cases} \tag{2.1}$$

The process $\theta_{ij}(t)$ determines the relative change in the price $P_i(t)$ given an arrival of the jth doubly stochastic Poisson process $N_j(t)$. On the other hand, since the sum of doubly stochastic Poisson processes is itself a doubly stochastic Poisson process, an equivalent interpretation of (2.1) replaces $N(t) = [N_1(t), \ldots, N_n(t)]'$ with a single doubly stochastic Poisson process $\bar{N}(t)$ with intensity $\bar{\lambda}(t) \triangleq \lambda_1(t) + \cdots + \lambda_n(t)$. Conditional on an arrival of $\bar{N}(t)$, the relative change in the price of asset j is $\theta_{ij}(t)$ with probability $\lambda_j(t)/\bar{\lambda}(t)$. In this regard, the components of $\theta_i(t)$ represent possible "jump sizes" with the distribution of the jumps determined by the intensities $\lambda_1(t), \ldots, \lambda_n(t)$. The $\mathbb{F}$-predictability of the $\theta_i(t)$ and $\lambda_i(t)$ implies that the possible jump sizes as well as their distributions depend on "available information," as captured by $\mathbb{F}$.

We assume that the investor in this financial market faces some liability, which we model by a random variable ξ. (For example, ξ may be a contingent claim written on a default event, which itself affects the price of the underlying asset.) Broadly speaking, the investor would like to reduce the uncertainty by investing in the financial market to minimize his/her risk. We shall assume throughout that the following assumptions are satisfied.

Assumption (A).

- $r(t)$, $\mu_i(t)$, $\sigma_{ik}(t)$, $\theta_{ij}(t)$, and $\lambda_j(t)$ are *uniformly bounded* and $\mathbb{F}$-predictable on $[0, T]$ for $i = 1, \ldots, m$, $j = 1, \ldots, n$, and $k = 1, \ldots, d$. That is, there is a constant K such that $|\mu_i(t)| \leq K$ for all $t \in [0, T]$, $\mathbb{P}$-a.s. (and likewise for the other parameters).
- There exists a constant $\delta > 0$ such that $\lambda_i(t) \geq \delta$ for all $t \in [0, T]$, $\mathbb{P}$-a.s.

- $\xi \in L^\infty(\mathcal{G}_T)$, where

$$L^\infty(\mathcal{G}_T) = \{Y : \Omega \to \mathbb{R} \,|\, Y \text{ is } \mathcal{G}_T\text{-measurable and } |Y| < K \ \mathbb{P}\text{-a.s. for some constant } K < \infty\}.$$

  Throughout this paper, random variables satisfying this property are said to be *uniformly bounded*.
- There exists a constant $\delta > 0$ such that

$$\Sigma(t) \triangleq \sigma(t)\sigma(t)' + \theta(t)D(t)\theta(t)' \geq \delta I \quad \text{for all } t \in [0, T], \tag{2.2}$$

  where $D(t) \triangleq \operatorname{diag}(\lambda_1(t), \ldots, \lambda_n(t))$.

The uniform bound on $\lambda_i(t)$ implies that $\mathbb{E}(\int_0^t \lambda_i(s)ds) < \infty$ for all $t \in [0,T]$ from which it follows that the *compensated Poisson process* $M_i(t) \triangleq N_i(t) - \int_0^t \lambda_i(s)\,ds$ is a $\mathbb{G}$-martingale (see Lemma 6.6.3 in [4]). We define the vector process $M(t) \triangleq [M_1(t), \ldots, M_n(t)]'$.

We emphasize again the parameters in our market model (2.1), and in particular the arrival rate intensities $\lambda_i(t)$ of the Poisson processes, are $\mathbb{F}$-predictable processes. Such an assumption is common in the literature on default risk modeling (and particularly in pricing applications) and the reader may consult [4, 11, 21] for more details. Finally, since the market (2.1) is incomplete, *perfect replication* is generally not possible. For this reason, as in [6, 9, 14, 25, 28, 32], we adopt the mean-square error as a measure of *closeness* between the terminal wealth and the liability; see (2.6) below.

Observing that the price of the risky assets can also be written in the form

$$dP_i(t) = P_i(t)[\mu_i(t) + \theta_i(t)\lambda(t)]\,dt + P_i(t)\sigma_i(t)\,dW(t) + P_i(t)\theta_i(t)\,dM(t), \tag{2.3}$$

where $\lambda(t) \triangleq [\lambda_1(t), \ldots, \lambda_n(t)]'$, and denoting by $\pi(t) \triangleq [\pi_1(t), \ldots, \pi_m(t)]'$ the vector of *dollar amounts* invested in the *risky* assets at time t, it is easy to show that the wealth process associated with self-financing investment in (2.3) is

$$\begin{cases} dx(t) = [r(t)x(t) + \pi(t)'b(t)]\,dt + \pi(t)'\sigma(t)\,dW(t) + \pi(t)'\theta(t)\,dM(t), \\ x(0) = x_0, \end{cases} \tag{2.4}$$

where

$$\begin{aligned} b(t) &\triangleq [b_1(t), \ldots, b_m(t)]', \quad b_i(t) \triangleq \mu_i(t) + \theta_i(t)\lambda(t) - r(t), \\ \sigma(t) &\triangleq [\sigma_1(t)', \ldots, \sigma_m(t)']', \\ \theta(t) &\triangleq [\theta_1(t)', \ldots, \theta_m(t)']'. \end{aligned}$$

Note that $\pi_0(t)$, the amount invested in the bond $B(t)$, does not need to be specified since it is determined by the amounts $\pi_1(t), \ldots, \pi_m(t)$ invested in the risky asset and the wealth $x(t)$ at time t through the equation $\pi_0(t) = x(t) - \sum_{i=1}^m \pi_i(t)$. The class of admissible policies is

$$\mathcal{U} = \left\{ \pi : [0, T] \times \Omega \to \mathbb{R}^m \,\middle|\, \pi(t) \text{ is } \mathbb{G}\text{-predictable and } \mathbb{E}\int_0^t |\pi(t)|^2\,dt < \infty \right\}. \tag{2.5}$$

Consider an agent who faces a time T liability ξ. Throughout this paper, we assume that the value of ξ is contingent on the history of the Poisson processes $N(t)$ as well as the Brownian motion $W(t)$. By virtue of this dependence, the investor

faces uncertainty in the value of the liability ξ. One method of reducing this risk is to invest in assets (or *hedging instruments*) that depend, as much as possible, on the same sources of uncertainty $N(t)$ and $W(t)$ that affect the liability. In doing this, a natural objective is to find a *hedging/investment portfolio* $\pi(t)$ such that the terminal value of this investment $x(T)$ is as "close as possible" to the value of ξ. This motivates our model of asset prices (2.1) which are driven by $N(t)$ and $W(t)$, and the following stochastic control problem:

$$\begin{cases} \min\limits_{\pi(\cdot)\in\mathcal{U}} \mathbb{E}[\xi - x(T)]^2 \\ \text{subject to} \\ \quad dx(t) = [r(t)x(t) + \pi(t)'b(t)]\,dt + \pi(t)'\sigma(t)\,dW(t) + \pi(t)'\theta(t)\,dM(t), \\ \quad x(0) = x_0, \\ \quad \pi(\cdot) \in \mathcal{U}. \end{cases} \tag{2.6}$$

In a *complete market* (see section 5.1), an investor *with the appropriate initial wealth* x_0 can eliminate all the risk by replicating ξ; that is, there is a unique value of x_0 and an associated trading strategy $\pi(\cdot)$ such that an investor, starting with x_0 and investing according to $\pi(\cdot)$, will have a terminal wealth satisfying $x(T) = \xi$, $\mathbb{P}$-a.s.; see, for example, [5], which deals with this issue in the context of hedging default risk in a complete market. In the case of an incomplete market, however, perfect replication is usually not possible, no matter what the value of the investor's initial wealth. On the other hand, superreplication (i.e., finding a portfolio such that $x(T) \geq \xi$, $\mathbb{P}$-a.s.) may be possible, but is typically infeasible since the initial wealth required to superreplicate a claim is often too large to be of practical use. As a compromise, an investor in an incomplete market (or, for that matter, in a complete market but with insufficient initial capital to replicate the claim) may seek to solve (2.6).

3. Optimal hedging portfolio. Our solution of the optimal hedging problem (2.6) will involve, in an essential way, the following *backward stochastic differential equations*[1] (BSDEs):

$$\begin{cases} dp(t) = -p(t)\left[2r(t) - \left(b(t) + \dfrac{\sigma(t)\Lambda(t)}{p(t)}\right)'\Sigma(t)^{-1}\left(b(t) + \dfrac{\sigma(t)\Lambda(t)}{p(t)}\right)\right]dt \\ \qquad\qquad + \Lambda(t)'\,dW(t), \\ p(T) = 1, \end{cases} \tag{3.1}$$

$$\begin{cases} dh(t) = \left\{r(t)h(t) + \left(b(t) + \dfrac{\sigma(t)\Lambda(t)}{p(t)}\right)'\Sigma(t)^{-1}\Big(\sigma(t)\eta(t) + \theta(t)D(t)\kappa(t)\Big)\right. \\ \qquad\qquad \left. - \dfrac{\eta(t)'\Lambda(t)}{p(t)}\right\}dt + \eta(t)'\,dW(t) + \kappa(t)'\,dM(t), \\ h(T) = \xi. \end{cases} \tag{3.2}$$

Throughout this paper, a *solution of* (3.1) denotes a pair of processes $(p(t), \Lambda(t))$ such that $p(t)$ is $\mathbb{G}$-*adapted*, *strictly positive*, and *uniformly bounded*, and $\Lambda(t) =$

[1] Although in common use, the term *backward stochastic differential equation* is somewhat misleading in that these equations do not involve time reversal in any way. Furthermore, parameters of these equations as well as the solutions are constrained to be adapted to the "forward" filtration.

$(\Lambda_1(t), \ldots, \Lambda_d(t))'$ is $\mathbb{G}$-*predictable* and *square integrable* under $\mathbb{P}$; that is,

$$(p(t), \Lambda(t)) \in \mathcal{L}^\infty(\mathbb{G}, \mathbb{R}) \times \mathcal{P}^2(\mathbb{G}, \mathbb{R}^d).$$

In this paper, we define a *solution of* (3.2) as a triple $(h(t), \eta(t), \kappa(t))$ such that $h(t)$ is $\mathbb{G}$-*adapted* and *uniformly bounded* and $\eta(t) = (\eta_1(t), \ldots, \eta_d(t))'$ and $\kappa(t) = (\kappa_1(t), \ldots, \kappa_n(t))'$ are $\mathbb{G}$-*predictable* and *square integrable* under $\mathbb{P}$; that is,

$$(h(t), \eta(t), \kappa(t)) \in \mathcal{L}^\infty(\mathbb{G}, \mathbb{R}) \times \mathcal{P}^2(\mathbb{G}, \mathbb{R}^d) \times \mathcal{P}^2(\mathbb{G}, \mathbb{R}^n). \tag{3.3}$$

Note that standard existence and uniqueness results for linear BSDEs driven by Brownian motion and jump processes (such as [31]) do not apply in (3.2) since the coefficient of the component $\eta(t)$ in the drift may be unbounded due to dependence on the square integrable term $\Lambda(t)$. In the case of (3.1), however, there are no terms involving the increment $dM(t)$ since the parameters are assumed to be $\mathbb{F}$-predictable. For this reason, the results obtained in Lim [25] can be applied to establish existence of this equation. This can be summarized as follows.

PROPOSITION 3.1. *Suppose that Assumption* (A) *holds. Then there exists a unique solution* $(p(t), \Lambda(t))$ *of* (3.1) *Moreover, there are finite constants* $0 < \delta_1 < \delta_2 < \infty$ *such that* $\delta_1 \le p(t) \le \delta_2$ *for all* $t \in [0, T]$, $\mathbb{P}$*-a.s. Finally, the stochastic differential equation*

$$\begin{cases} d\rho(t) = -\rho(t)\gamma(t)'\, dW(t), \\ \rho(0) = 1, \end{cases} \tag{3.4}$$

where

$$\gamma(t) \triangleq \sigma(t)'\Sigma(t)^{-1}\left(b(t) + \frac{\sigma(t)\Lambda(t)}{p(t)}\right) - \frac{\Lambda(t)}{p(t)},$$

has a unique solution $\rho(t) = e^{-\frac{1}{2}\int_0^t |\gamma(s)|^2 ds - \int_0^t \gamma(s)' dW(s)}$ *and* $\rho(t)$ *is a strictly positive square integrable martingale.*

Proof. Existence and uniqueness of a solution $(p(t), \Lambda(t)) \in \mathcal{L}^\infty(\mathbb{G}, \mathbb{R}) \times \mathcal{P}^2(\mathbb{G}, \mathbb{R}^d)$ of (3.1) follows from Theorem 5.1 of [25]. The existence of positive constants δ_1 and δ_2 such that $\delta_1 \le p(t) \le \delta_2$ is shown in the proof of this same theorem. That $\rho(t)$ is a strictly positive square integrable martingale follows from Theorem 4.1 in [25]. □

The (martingale) density process $\rho(t)$ in Proposition 3.1 is related to the Radon–Nikodým derivative that defines the $\mathbb{P}$-equivalent probability measure known as the *variance optimal martingale measure* (VMM), which is a fundamental object associated with the mean-variance hedging problem; see, for example, [9, 14, 23, 32] for more on the VMM, and see [25] for the connection between the nonlinear BSDE (3.1) and the VMM in the case of Brownian information. In this regard, the density process associated with the hedging problem (2.6) (introduced below in (4.2)) may be regarded as a generalization of (3.4) in the case when there are jumps. Further discussion on this point follows Theorem 4.3.

The remainder of this section will be devoted to proving optimality of the portfolio

$$\pi(t) = \Sigma(t)^{-1}\left[\sigma(t)\eta(t) + \theta(t)D(t)\kappa(t) + \left(b(t) + \frac{\sigma(t)\Lambda(t)}{p(t)}\right)(h(t^-) - x(t^-))\right] \tag{3.5}$$

under the assumption that (3.2) *has a solution.* (Solvability of (3.2) will be addressed in section 4.) In order to prove optimality, a number of issues need to be resolved.

First, we need to show that the stochastic differential equation (2.6) for the wealth process $x(t)$ has a solution under (3.5). This is not immediately obvious since the coefficients of $x(t)$ in (2.6) under (3.5) are generally unbounded due to dependence on the square integrable process $\Lambda(t)$. As a consequence, standard existence and uniqueness results from the theory of linear stochastic differential equations do not immediately apply since boundedness of coefficients is usually required for these results to hold. (See, for example, [19].)

A second important issue concerns the admissibility (and in particular square integrability) of (3.5) (see the definition (2.5)), which is an important part of the proof of optimality in Theorem 3.5. Once again, however, square integrability of (3.5) is not immediately apparent since the product of the square integrable process $\Lambda(t)$ and the wealth process $x(t)$ is not necessarily square integrable.

The following results resolve the technical issues discussed above. Proposition 3.2 shows that the wealth process (2.6) under (3.5) has a solution $x(t)$. Proposition 3.3 is a technical result concerning the integrability of solutions of linear BSDEs which is used in the proof of Proposition 3.4 where square integrability (and hence admissibility) of (3.5) is established. Optimality of (3.5) is proven in Theorem 3.5. (A similar optimality proof is given in Hu and Zhou [16], though for a problem that involves neither jumps nor a random terminal condition.) We mention again that the results below are based on the assumption that (3.2) has a solution. Solvability of (3.2) is discussed in a later section.

PROPOSITION 3.2. *Suppose that* (3.2) *has a solution* $(h(t), \eta(t), \kappa(t))$ *satisfying the conditions* (3.3). *Then the stochastic differential equation* (2.6) *under the portfolio* $\pi(t)$ *given by* (3.5) *has a solution* $\bar{x}(t)$.

Proof. A solution of (2.6) under (3.5) can be constructed as follows. Define

$$\begin{cases} dY(t) = -r(t)Y(t)\,dt - \{A(t) + \gamma(t)Y(t)\}'\,dW(t) \\ \qquad\qquad -\{B(t) + \psi(t)Y(t)\}'\,dM(t), \\ Y(0) = p(0)[h(0) - x(0)], \end{cases} \tag{3.6}$$

where $\gamma(t)$ and $\psi(t)$ are defined by

$$\gamma(t) \triangleq \sigma(t)'\Sigma(t)^{-1}\left(b(t) + \frac{\sigma(t)\Lambda(t)}{p(t)}\right) - \frac{\Lambda(t)}{p(t)}, \tag{3.7}$$

$$\psi(t) \triangleq \theta(t)'\Sigma(t)^{-1}\left(b(t) + \frac{\sigma(t)\Lambda(t)}{p(t)}\right), \tag{3.8}$$

and

$$A(t) \triangleq p(t)\Big[\sigma(t)\Sigma(t)^{-1}\big(\sigma(t)\eta(t) + \theta(t)D(t)\kappa(t)\big) - \eta(t)\Big],$$
$$B(t) = p(t)\Big[\theta(t)'\Sigma(t)^{-1}\big(\sigma(t)\eta(t) + \theta(t)D(t)\kappa(t)\big) - \kappa(t)\Big].$$

Observe that $\gamma(t)$ and $\psi(t)$ are *square integrable*. We denote the components of $\gamma(t)$ and $\psi(t)$ by $\gamma_i(t)$ and $\psi_i(t)$; that is, $\gamma(t) \triangleq [\gamma_1(t), \ldots, \gamma_n(t)]'$ and $\psi(t) \triangleq [\psi_1(t), \ldots, \psi_n(t)]'$. Denoting $\Delta N_j(t) \triangleq N_j(t) - N_j(t^-)$, it can be shown (using Ito's formula) that $Y(t) = \Phi(t)\{Y(0) + Z(t)\}$, where

$$\Phi(t) = e^{\int_0^t [-r(s) - \frac{1}{2}|\gamma(s)|^2 + \psi(s)'\lambda(s)]\,ds - \int_0^t \gamma(s)'\,dW(s)} \times \prod_{i=1}^{n} \prod_{0<s_i\le t} (1 - \psi_i(s_i)\Delta N_i(s_i)) \tag{3.9}$$

and

$$Z(t) \triangleq -\int_0^t \Phi(s)^{-1}\left[\gamma(s)'B(t) + \sum_{i=1}^n \frac{\psi_i(s)}{1-\psi_i(s)}\lambda_i(s)A_i(s)\right]ds$$
$$-\int_0^t \Phi(s)^{-1}B(s)'\,dW(s) - \sum_{i=1}^n \int_0^t \Phi(s)^{-1}\frac{A_i(s)}{1-\psi_i(s)}\,dM_i(s). \tag{3.10}$$

Note that (3.9) and (3.10) are well-defined processes. Finally, it can be shown using Ito's formula that $\bar{x}(t) \triangleq h(t) - Y(t)/p(t)$ is a solution of (2.6) when the portfolio is (3.5), which implies in turn that the wealth process under (3.5) is well defined. □

The following technical result is required in the proof of Proposition 3.4.

PROPOSITION 3.3. *Suppose that $r(t)$, $\alpha(t)$, $\beta(t)$, and $\lambda_1(t), \ldots, \lambda_n(t)$ are uniformly bounded $\mathbb{G}$-predictable processes on $[0, T]$, τ is a $\mathbb{G}$-stopping time, and $Y \in \mathcal{G}_\tau$ satisfies $\mathbb{E}|Y|^2 < \infty$. Then the BSDE*

$$\begin{cases} dy(t) = \Big[r(t)y(t) + \alpha(t)'q(t) + \beta(t)'z(t)\Big]\,dt + q(t)'\,dW(t) + z(t)'\,dM(t), \\ y(\tau) = Y \end{cases} \tag{3.11}$$

has a unique solution

$$(y(t),\, z(t),\, q(t)) \in \mathcal{L}^2(\mathbb{G},\, \mathbb{R}) \times \mathcal{P}^2(\mathbb{G},\, \mathbb{R}^d) \times \mathcal{P}^2(\mathbb{G},\, \mathbb{R}^n).$$

Moreover, there is a constant $c < \infty$ that depends only on $r(t)$, $\alpha(t)$, $\beta(t)$, and $\lambda_1(t), \ldots, \lambda_n(t)$ (but not the stopping time τ) such that

$$\mathbb{E}\int_0^\tau \left[|q(t)|^2 + \sum_{i=1}^n \lambda_i(t)|z_i(t)|^2\right]ds \le 2\mathbb{E}|Y|^2 e^{2c[1+c(n+1)]T}. \tag{3.12}$$

Proof. Existence and uniqueness for (3.11) can be shown as in Theorem 1 of [31] and the bound (3.12) can be derived along the lines of Lemma 1 in [31]. Because of constraints on the length of this paper, details have not been provided but can be obtained from the author upon request. □

The following result establishes admissibility of (3.5).

PROPOSITION 3.4. *Suppose that* (3.2) *has a solution* $(h(t), \eta(t), \kappa(t))$ *such that* (3.3) *is satisfied. Then the portfolio* $\pi(t)$ *given by* (3.5) *is square integrable and hence admissible.*

Proof. Throughout this proof, $\pi(t)$ denotes the portfolio (3.5) and $\bar{x}(t)$ denotes the solution of the wealth process (2.6) under (3.5). (Recall, by Proposition 3.2, that (2.6) has a solution under (3.5).) Since (3.1) and (3.2) have solutions, the process $p(t)[h(t) - \bar{x}(t)]^2$ is well defined and Ito's formula gives

$$p(t)(h(t) - \bar{x}(t))^2 = p(0)(h(0) - \bar{x}(0))^2$$
$$+ \int_0^t p(t)\Big\{\kappa(t)'D(t)\kappa(t) + \eta(t)'\eta(t)$$
$$-[\sigma(t)\eta(t) + \theta(t)D(t)\kappa(t)]'\Sigma(t)^{-1}[\sigma(t)\eta(t) + \theta(t)D(t)\kappa(t)]\Big\}\,dt$$
$$+ \int_0^t \Big[(h(t) - \bar{x}(t))^2\Lambda(t) + 2p(t)(h(t) - \bar{x}(t))(\eta(t) - \sigma(t)'\pi(t))\Big]'\,dW(t)$$

$$+\int_0^t \sum_{i=1}^n p(t)(\kappa(t)-\theta(t)'\pi(t))_i^2\,dM_i(t)$$
$$+\int_0^t 2p(t)(h(t^-)-\bar{x}(t^-))(\kappa(t)-\theta(t)'\pi(t))'\,dM(t).$$

(A similar calculation for the case of general $\pi(t)$ is given in (3.21) below.) Noting that the stochastic integrals are local martingales, there exists an increasing sequence of stopping times $\{\tau_i\}$ such that $\tau_i \uparrow T$ as $i \to \infty$ and

$$\begin{aligned}(3.13)\qquad &\mathbb{E}\{p(T\wedge\tau_i)(h(T\wedge\tau_i)-\bar{x}(T\wedge\tau_i))^2\} = p(0)(h(0)-\bar{x}(0))^2\\ &\quad+\mathbb{E}\int_0^{T\wedge\tau_i} p(t)\Big\{\kappa(t)'D(t)\kappa(t)+\eta(t)'\eta(t)\\ &\quad-[\sigma(t)\eta(t)+\theta(t)D(t)\kappa(t)]'\Sigma(t)^{-1}[\sigma(t)\eta(t)+\theta(t)D(t)\kappa(t)]\Big\}\,dt.\end{aligned}$$

Since there is a constant $\delta>0$ such that $p(t)\geq\delta$ for all $t\in[0,T]$, $\mathbb{P}$-a.s. (Proposition 3.1), it follows that

$$\begin{aligned}(3.14)\qquad &\delta\mathbb{E}[h(T\wedge\tau_i)-\bar{x}(T\wedge\tau_i)]^2\\ &\quad\leq \mathbb{E}[p(T\wedge\tau_i)(h(T\wedge\tau_i)-\bar{x}(T\wedge\tau_i))^2]\\ &\quad\leq p(0)(h(0)-x(0))^2+\mathbb{E}\int_0^T p(t)\Big\{\kappa(t)'D(t)\kappa(t)+\eta(t)'\eta(t)\\ &\quad-[\sigma(t)\eta(t)+\theta(t)D(t)\kappa(t)]'\Sigma(t)^{-1}[\sigma(t)\eta(t)+\theta(t)D(t)\kappa(t)]\Big\}\,dt\end{aligned}$$

(where the second inequality follows from (3.13), the nonnegativity of the integrand, and the fact that $T\wedge\tau_i\leq T$). In other words, $h(T\wedge\tau_i)-\bar{x}(T\wedge\tau_i)\in\mathcal{L}^2(\mathbb{G},\mathbb{R})$. Finally, noting (by assumption) that $h(t)$ is uniformly bounded (since, by assumption, (3.3) is satisfied), it follows that

$$\bar{x}(T\wedge\tau_i)=h(T\wedge\tau_i)-[h(T\wedge\tau_i)-\bar{x}(T\wedge\tau_i)]\in\mathcal{L}^2(\mathbb{G},\mathbb{R}).$$

We have shown that the wealth-portfolio pair $(\bar{x}(t),\pi(t))$ given by (2.6) and (3.5) satisfy the system of equations

$$(3.15)\qquad \begin{cases} dy(t)=\{r(t)y(t)+b(t)'\pi(t)\}\,dt+\pi(t)'\sigma(t)\,dW(t)+\pi(t)'\theta(t)\,dM(t),\\ y(T\wedge\tau_i)=\bar{x}(\tau_i\wedge T),\end{cases}$$

where $\bar{x}(T\wedge\tau_i)$ is a square integrable $\mathcal{G}_{T\wedge\tau_i}$-measurable random variable. Setting

$$q(t)=\sigma(t)'\pi(t),\quad z(t)=\theta(t)'\pi(t)$$

or, equivalently,

$$(3.16)\qquad \pi(t)=\Sigma(t)^{-1}[\sigma(t)q(t)+\theta(t)D(t)z(t)]$$

and substituting into (3.15), it follows that $(y(t),\,q(t),\,z(t))=(\bar{x}(t),\,\sigma(t)'\bar{\pi}(t),\theta(t)'\bar{\pi}(t))$ is the solution of the following BSDE on the random time horizon $[0,\,T\wedge\tau_i]$:

$$(3.17)\qquad \begin{cases} dy(t)=\Big[r(t)y(t)+b(t)'\Sigma(t)^{-1}\sigma(t)q(t)+b(t)'\Sigma(t)^{-1}\theta(t)D(t)z(t)\Big]\,dt\\ \qquad\qquad+q(t)'\,dW(t)+z(t)'\,dM(t),\quad t\in[0,\,T\wedge\tau_i),\\ y(T\wedge\tau_i)=\bar{x}(T\wedge\tau_i).\end{cases}$$

In particular, (3.17) is a linear BSDE with a square integrable terminal condition $y(T\wedge\tau_i)=\bar{x}(T\wedge\tau_i)$ at the stopping time $T\wedge\tau_i$ with (by Assumption (A)) uniformly bounded parameters $r(t)$, $b(t)'\Sigma(t)^{-1}\sigma(t)$, $b(t)'\Sigma(t)^{-1}\theta(t)D(t)$, and $\lambda_1(t),\dots,\lambda_n(t)$. It follows immediately from Proposition 3.3, and particularly the bound (3.12), that there is a constant $c<\infty$ (which depends only on the parameters $r(t)$, $b(t)$, $\sigma(t)$, $\theta(t)$, and $\lambda_i(t)$ but not the stopping time τ_i) such that

$$\begin{aligned}(3.18)\qquad &\mathbb{E}\biggl\{\int_0^{T\wedge\tau_i}|q(s)|^2\,ds+\sum_{i=1}^n\int_0^{T\wedge\tau_i}\lambda_i(s)|z_i(s)|^2\,ds\biggr\}\\&\quad\le 2\mathbb{E}|\bar{x}(T\wedge\tau_i)|^2e^{2c[1+c(1+n)]T}.\end{aligned}$$

Furthermore, since

$$(3.19)\qquad \mathbb{E}|\bar{x}(T\wedge\tau_i)|^2\le 2\mathbb{E}|h(T\wedge\tau_i)|^2+2\mathbb{E}|\bar{x}(T\wedge\tau_i)-h(T\wedge\tau_i)|^2\le K,$$

where $K<\infty$ is a constant independent of i (by virtue of the uniform bound on $h(t)$ and the bound (3.14)), it follows from (3.18) and (3.19) that

$$\mathbb{E}\biggl\{\int_0^{T\wedge\tau_i}|q(t)|^2\,dt+\sum_{i=1}^n\int_0^{T\wedge\tau_i}\lambda_i(t)|z_i(t)|^2\,dt\biggr\}\le 2Ke^{2c[1+c(1+n)]T}<\infty,$$

and the monotone convergence theorem gives

$$\mathbb{E}\biggl\{\int_0^{T}|q(t)|^2\,dt+\sum_{i=1}^n\int_0^{T}\lambda_i(t)|z_i(t)|^2\,dt\biggr\}<\infty.$$

The square integrability of (3.5) follows from the relationship (3.16) between $\pi(t)$ and $(q(t),z(t))$. □

The following result establishes optimality of (3.5).

THEOREM 3.5. *Assume that* (3.2) *has a solution*

$$(h(t),\eta(t),\kappa(t))\in\mathcal{L}^\infty(\mathbb{G},\mathbb{R})\times\mathcal{P}^2(\mathbb{G},\mathbb{R}^d)\times\mathcal{P}^2(\mathbb{G},\mathbb{R}^n).$$

Then (3.5) *is the optimal hedging portfolio for* (2.6). *The optimal cost is*

$$\begin{aligned}J^*=p(0)(h(0)-x(0))^2+\mathbb{E}\int_0^T p(t)\Bigl\{&\eta(t)'\eta(t)+\kappa(t)'D(t)\kappa(t)\\&-[\sigma(t)\eta(t)+\theta(t)D(t)\kappa(t)]'\Sigma(t)^{-1}[\sigma(t)\eta(t)+\theta(t)D(t)\kappa(t)]\Bigr\}\,dt.\end{aligned}\tag{3.20}$$

Proof. Let $\pi(t)$ be an *arbitrary* admissible policy and $x(t)$ the associated wealth process. From Ito's formula,

$$\begin{aligned}&d\{p(t)(h(t)-x(t))^2\}\\&\quad=\biggl\{(h(t)-x(t))^2\\&\qquad\times\Bigl[-2r(t)p(t)+p(t)\Bigl(b(t)+\frac{\sigma(t)\Lambda(t)}{p(t)}\Bigr)'\Sigma(t)^{-1}\Bigl(b(t)+\frac{\sigma(t)\Lambda(t)}{p(t)}\Bigr)\Bigr]\\&\qquad+2r(t)p(t)(h(t)-x(t))^2+2p(t)(h(t)-x(t))\end{aligned}$$

$$
\begin{aligned}
&\times\Big[\Big(b(t)+\frac{\sigma(t)\Lambda(t)}{p(t)}\Big)'\Sigma(t)^{-1}[\sigma(t)\eta(t)+\theta(t)D(t)\kappa(t)]-\frac{\eta(t)'\Lambda(t)}{p(t)}\Big]\\
&+p(t)[\kappa(t)'D(t)\kappa(t)]+p(t)\pi(t)\Sigma(t)\pi(t)\\
&-2p(t)\pi(t)'[\sigma(t)\eta(t)+\theta(t)D(t)\kappa(t)+b(t)(h(t)-x(t))]\\
&+2(h(t)-x(t))(\eta(t)-\sigma(t)'\pi(t))'\Lambda(t)\Big\}\,dt\\
&+\Big[(h(t)-x(t))^2\Lambda(t)+2p(t)(h(t)-x(t))(\eta(t)-\sigma(t)'\pi(t))\Big]'dW(t)\\
&+\sum_{i=1}^{n}p(t)(\kappa(t)-\theta(t)'\pi(t))_i^2\,dM_i(t)\\
&+2p(t)(h(t^-)-x(t^-))(\kappa(t)-\theta(t)'\pi(t))'dM(t).
\end{aligned}
\tag{3.21}
$$

Since the stochastic integrals are local martingales, there is a sequence of stopping times $\{\tau_i\}$ such that $\tau_i\uparrow T$ as $i\uparrow\infty$ and

$$
\begin{aligned}
&\mathbb{E}\,[p(T\wedge\tau_i)(h(T\wedge\tau_i)-x(T\wedge\tau_i))^2]\\
&=p(0)(h(0)-x(0))^2+\mathbb{E}\int_0^{T\wedge\tau_i}p(t)\Big\{\kappa(t)'D(t)\kappa(t)+\eta(t)'\eta(t)\\
&-[\sigma(t)\eta(t)+\theta(t)D(t)\kappa(t)]'\Sigma(t)^{-1}[\sigma(t)\eta(t)+\theta(t)D(t)\kappa(t)]\Big\}\,dt\\
&+\mathbb{E}\int_0^{T\wedge\tau_i}p(t)\Big[\pi(t)-\Sigma(t)^{-1}\Big(\sigma(t)\eta(t)+\theta(t)D(t)\kappa(t)\\
&+\Big(b(t)+\frac{\sigma(t)\Lambda(t)}{p(t)}\Big)(h(t^-)-x(t^-))\Big)\Big]\\
&\times\Sigma(t)\Big[\pi(t)-\Sigma(t)^{-1}\Big(\sigma(t)\eta(t)+\theta(t)D(t)\kappa(t)\\
&+\Big(b(t)+\frac{\sigma(t)\Lambda(t)}{p(t)}\Big)(h(t^-)-x(t^-))\Big)\Big]\,dt,
\end{aligned}
$$

where the integrand in the expression above is obtained, after several (long!) lines of algebra, from the integrand for the finite variation term in (3.21). Finally, noting that $p(t)$ is uniformly bounded (Proposition 3.1), $h(t)$ is uniformly bounded (by assumption), and $\mathbb{E}[\sup_{t\in[0,\,T]}|x(t)|^2]<\infty$, it follows from the dominated convergence theorem (on the left-hand side) and the monotone convergence theorem (on the right) that

$$
\begin{aligned}
&\mathbb{E}p(T)(h(T)-x(T))^2\\
&=p(0)(h(0)-x(0))^2+\mathbb{E}\int_0^{T}p(t)\Big\{\kappa(t)'D(t)\kappa(t)+\eta(t)'\eta(t)\\
&-[\sigma(t)\eta(t)+\theta(t)D(t)\kappa(t)]'\Sigma(t)^{-1}[\sigma(t)\eta(t)+\theta(t)D(t)\kappa(t)]\Big\}\,dt\\
&+\mathbb{E}\int_0^{T}p(t)\Big[\pi(t)-\Sigma(t)^{-1}\Big(\sigma(t)\eta(t)+\theta(t)D(t)\kappa(t)\\
&+\Big(b(t)+\frac{\sigma(t)\Lambda(t)}{p(t)}\Big)(h(t^-)-x(t^-))\Big)\Big]\Sigma(t)\Big[\pi(t)-\Sigma(t)^{-1}\Big(\sigma(t)\eta(t)+\theta(t)D(t)\kappa(t)\\
&+\Big(b(t)+\frac{\sigma(t)\Lambda(t)}{p(t)}\Big)(h(t^-)-x(t^-))\Big)\Big]\,dt.
\end{aligned}
$$

The claim in Theorem 3.5 follows immediately from this equation and the fact that $p(T) = 1$ and $h(T) = \xi$. □

4. Existence of solutions for (3.2): General results. The solution of (2.6), as stated in Theorem 3.5, depends on the solvability of (3.1)–(3.2). While solvability of (3.1) can be established using the results from [25], which can be applied since the parameters are $\mathbb{F}$-predictable and bounded (see Proposition 3.1), solvability of (3.2) is not so clear. In particular, (3.2) may have unbounded parameters (due to dependence on the component $\Lambda(t)$ of the solution of (3.1)), and for this reason standard existence results for BSDEs driven by jump processes (such as [31]) do not apply.

In the following two sections, we address the question of existence of solutions of (3.2). We begin by presenting a general *"martingale condition"* under which solvability of (3.2) can be guaranteed (Theorem 4.3). This condition (which can be stated in terms of a certain local martingale being a strictly positive martingale) is required in order to construct a solution of (3.2), and is analogous to the assumption in [1] that the variance optimal (signed) martingale measure is a $\mathbb{P}$-equivalent *probability* measure. Following this, we show in Theorem 4.4 that strict positivity of the local martingale in the "martingale condition" is not only necessary, but also sufficient for the "martingale condition" to hold.

Recall the processes $\gamma(t)$ and $\psi(t)$ defined in (3.7)–(3.8). Observe that $\gamma(t)$ and $\psi(t)$ are square integrable $\mathbb{G}$-predictable processes under $\mathbb{P}$. We can rewrite (3.2) as

$$\begin{cases} dh(t) = r(t)h(t)\,dt + \eta(t)'[\gamma(t)\,dt + dW(t)] + \kappa(t)'[D(t)\psi(t) + dM(t)], \\ h(T) = \xi. \end{cases} \tag{4.1}$$

We can construct a solution of (4.1) using the Girsanov transformation and the martingale representation theorem for jump-diffusion processes driven by Brownian motion and doubly stochastic Poisson processes (see Propositions 4.1 and 4.2). In this regard, consider the following stochastic differential equation:

$$\begin{cases} dY(t) = -Y(t^-)\Big\{\gamma(t)'\,dW(t) + \psi(t)'\,dM(t)\Big\}, \\ Y(0) = 1. \end{cases} \tag{4.2}$$

It is easy to show that $Y(t) = \rho(t)\zeta(t)$, where

$$\begin{aligned} d\rho(t) &= -\rho(t^-)\gamma(t)'\,dW(t), \quad \rho(0) = 1, \\ d\zeta(t) &= -\zeta(t^-)\psi(t)'\,dM(t), \quad \zeta(0) = 1. \end{aligned}$$

We can write the solution of these equations as

$$\begin{aligned} \rho(t) &= e^{-\frac{1}{2}\int_0^t |\gamma(s)|^2 ds - \int_0^t \gamma(s)' dW(s)}, \\ \zeta(t) &= e^{\int_0^t \psi(s)'\lambda(s) ds} \prod_{i=1}^{n} \prod_{0<s_i\le t} \Big(1 - \psi_i(s_i)\Delta N(s_i)\Big), \end{aligned}$$

where $\ln(\mathbf{1} - \psi(s))$ is an n-dimensional column vector with entries $\ln(1 - \psi_i(s))$. Assuming that $Y(t)$ is a positive $\mathbb{G}$-martingale under $\mathbb{P}$, we can define a probability measure $\mathbb{Q}$ equivalent to $\mathbb{P}$ on $(\Omega, \mathcal{G}_T)$ by

$$\frac{d\mathbb{Q}}{d\mathbb{P}}\Big|_{\mathcal{G}_T} = Y(T), \quad \mathbb{P}\text{-a.s.} \tag{4.3}$$

The following is taken from [4, Proposition 6.6.8] (see also [10, Proposition 6, p. 361]).

PROPOSITION 4.1 (Girsanov). *Assume that $Y(t)$ is a positive $\mathbb{G}$-martingale under $\mathbb{P}$ and that the Radon–Nikodým density of $\mathbb{Q}$ with respect to $\mathbb{P}$ is given by* (4.2)–(4.3). *Then the process $\bar{W}(t) = W(t) + \int_0^t \gamma(s)\,ds$ is a $\mathbb{G}$-Brownian motion under $\mathbb{Q}$, and $\bar{M}(t) = M(t) + \int_0^t D(s)\psi(s)\,ds = N(t) - \int_0^t D(s)[\mathbf{1} - \psi(s)]\,ds$ is a $\mathbb{G}$-martingale under $\mathbb{Q}$. In addition, if $\psi(t)$ is $\mathbb{F}$-predictable, then $N(t)$ is an $\mathbb{F}$-conditional Poisson process with respect to $\mathbb{G}$ under $\mathbb{Q}$ with intensity $D(t)[\mathbf{1} - \psi(t)]$.*

The following result can be obtained by a fairly straightforward extension of the proof of martingale representation theorem for continuous martingales with respect to a Brownian filtration (see, for example, [33]). For more results on martingale representation for processes other than Brownian motion, see [34].

PROPOSITION 4.2 (martingale representation). *Let $\{Z(t)\}_{t\in[0,\,T]}$ be a square integrable $\mathbb{G}$-martingale under $\mathbb{P}$. Then, there are unique square integrable $\mathbb{G}$-predictable processes $f(t)$ and $g_1(t), \ldots, g_n(t)$ such that*

$$Z(t) = Z(0) + \int_0^t f(s)'\,dW(s) + \sum_{i=1}^{n} \int_0^t g_i(s)'\,dM_i(s). \tag{4.4}$$

The following result gives general conditions under which (3.2) can be solved.

THEOREM 4.3. *Suppose that Assumption* (A) *is satisfied. If the solution $Y(t)$ of* (4.2) *is a strictly positive $\mathbb{G}$-martingale under $\mathbb{P}$, then the BSDE* (3.2) *has a unique solution $(h(t), \eta(t), \kappa(t))$ such that $h(t)$ is uniformly bounded and*

$$\mathbb{E}\int_0^T \left\{ |\eta(t)|^2 + \sum_{i=1}^{n} \lambda_i(t)|\kappa_i(t)|^2 \right\} dt < \infty. \tag{4.5}$$

Before presenting the proof of Theorem 4.3, the following remarks are in order. Recall that the set of all $\mathbb{P}$-equivalent probability measures $\mathbb{Q}$ can be represented by (4.3) and a pair of $\mathbb{G}$-predictable processes $(\gamma(t), \psi(t))$ such that $Y(t)$ is a positive martingale. The equivalent *martingale* measures (EMMs) is the set of $\mathbb{P}$-equivalent measures under which discounted price processes $P_i(t)/B(t)$ obtained from (2.1) are martingales. Using this characterization and the model (2.1) for the price processes, it can be shown that any pair $(\gamma(t), \psi(t))$ associated with an EMM can be written in the form

$$\begin{bmatrix} \gamma \\ \psi \end{bmatrix} = \begin{bmatrix} \sigma'\Sigma^{-1}b + (I - \sigma'\Sigma^{-1}\sigma)Z_1 - \sigma'\Sigma^{-1}\theta D^{\frac{1}{2}} Z_2 \\ \theta'\Sigma^{-1}b - \theta'\Sigma^{-1}\sigma Z_1 - D^{\frac{1}{2}}(I - D^{\frac{1}{2}}\theta'\Sigma^{-1}\theta D^{\frac{1}{2}})Z_2 \end{bmatrix} \tag{4.6}$$

for some choice of $\mathbb{G}$-predictable processes $(Z_1(t), Z_2(t))$, where $D(t)^{\frac{1}{2}} \triangleq \operatorname{diag}(\lambda_1(t)^{\frac{1}{2}}, \ldots, \lambda_n(t)^{\frac{1}{2}})$. In particular, the (nonempty) set of EMMs is not a singleton when there are no arbitrage opportunities and the market is incomplete. Comparing (4.6) with (3.7)–(3.8) we see that the SRE chooses the EMM corresponding to

$$Z_1(t) = -\frac{\Lambda(t)}{p(t)}, \quad Z_2(t) = 0.$$

When $\theta \equiv 0$, which corresponds to the case when the price processes (2.1) are driven by Brownian motion and are independent of the jump processes, the EMM induced by $(p(t), \Lambda(t))$ coincides with the so-called *variance optimal martingale measure* associated with the mean-variance hedging when the price processes are driven

by Brownian motion; see [9, 14, 23, 25, 32] as well as the remarks following Proposition 3.1.

The proof of Theorem 4.3 is as follows.

Proof. We prove this result by constructing the solution of (4.1).

By assumption, we have $Y(T) > 0$ a.s. and $\mathbb{E}^{\mathbb{P}}[Y(T)] = 1$ so we can define a probability measure $\mathbb{Q}$ that is equivalent to $\mathbb{P}$ with Radon–Nikodým derivative (4.3). Moreover, it follows from the Girsanov theorem (Proposition 4.1) that $\bar{W}(t) = W(t) + \int_0^t \gamma(s)\,ds$ is a $\mathbb{G}$-Brownian motion under $\mathbb{Q}$ and, from the $\mathbb{F}$-predictability of $\psi_i(t)$, that $N_i(t)$ is a doubly stochastic Poisson process under $\mathbb{Q}$ with $\mathbb{F}$-predictable intensity $\lambda_i(t)(1-\psi_i(t))$.

Define

$$h(t) = B(t)\,\mathbb{E}^{\mathbb{Q}}\left[\frac{\xi}{B(T)} \;\middle|\; \mathcal{G}_t\right].$$

It follows that $h(t)/B(t)$ is a $\mathbb{G}$-martingale with respect to the probability measure $\mathbb{Q}$. Furthermore, since ξ is uniformly bounded, it follows that $h(t)/B(t)$ is uniformly bounded. The uniform boundedness of $h(t)$ now follows from the fact that $B(t)$ is uniformly bounded. From the martingale representation theorem (Proposition 4.2) there are $\mathbb{G}$-predictable $\mathbb{Q}$-square integrable processes $\bar{\eta}(t)$ and $\bar{\kappa}(t)$ such that

$$\frac{h(t)}{B(t)} = \mathbb{E}^{\mathbb{Q}}\Big[\frac{\xi}{B(T)}\Big] + \int_0^t \bar{\eta}(s)'\,d\bar{W}(s) + \int_0^t \bar{\kappa}(s)'\,d\bar{M}(s), \tag{4.7}$$

where $\bar{M}_i(t) \triangleq N_i(t) - \int_0^t \lambda_i(s)(1-\psi_i(s))\,ds$ is a $\mathbb{G}$-martingale with respect to $\mathbb{Q}$. Applying Ito's formula to (4.7), we obtain

$$\begin{cases} dh(t) = r(t)h(t)\,dt + \eta(t)'\,d\bar{W}(t) + \kappa(t)'\,d\bar{M}(t), \\ h(T) = \xi, \end{cases}$$

where $\eta(t) \triangleq B(t)\bar{\eta}(t)$ and $\kappa(t) \triangleq B(t)\bar{\kappa}(t)$. Changing measure from $\mathbb{Q}$ back to $\mathbb{P}$ shows that $(h(t), \eta(t), \kappa(t))$ is the solution of (4.1), as required. Uniqueness can be seen by carrying out the reverse of this procedure and using the uniqueness of the representation (4.7).

Next we show the integrability properties (4.5) are satisfied. (Note that (4.5) involves an expectation under $\mathbb{P}$, whereas $\bar{\eta}(t)$ and $\bar{\kappa}(t)$ are only $\mathbb{Q}$-square integrable.) Since $B(t)$ is uniformly bounded, (4.5) can be shown by establishing the inequality

$$\mathbb{E}^{\mathbb{P}} \int_0^T \left\{ |\bar{\eta}(t)|^2 + \sum_{i=1}^n \lambda_i(t)|\bar{\kappa}_i(t)|^2 \right\} dt < \infty.$$

Let $Z(t) \triangleq h(t)/B(t)$. Since ξ is uniformly bounded under $\mathbb{Q}$ and $\mathbb{P}$ is equivalent to $\mathbb{Q}$, there is a constant $C < \infty$ such that $|Z(t)| < C$ for all $t \in [0, T]$, $\mathbb{P}$-a.s. It follows from (4.7) that

$$\begin{aligned} Z(t) = Z(0) &+ \int_0^t [\bar{\eta}(s)'\gamma(s) + \bar{\kappa}(s)'D(s)\psi(s) - \bar{\kappa}(s)'\lambda(s)]\,ds \\ &+ \int_0^t \bar{\eta}(s)'\,dW(t) + \int_0^t \bar{\kappa}(s)'\,dN(s). \end{aligned}$$

From Ito's formula,

$$Z(t)^2 = Z(0)^2 + \int_0^t \left\{ 2Z(s^-) \left[\bar{\eta}(s)'\gamma(s) + \sum_{i=1}^n \lambda_i(s)\bar{\kappa}_i(s)\psi_i(s) \right] + |\bar{\eta}(s)|^2 + \sum_{i=1}^n \lambda_i(s)\bar{\kappa}_i(s)^2 \right\} ds + \int_0^t 2Z(s^-)\bar{\eta}(s)'\, dW(s) + \sum_{i=1}^n \int_0^t [2\bar{\kappa}_i(s)Z(s^-) + \bar{\kappa}_i(s)^2]\, dM_i(s).$$

The stochastic integrals above are local martingales, and hence there is a sequence of stopping times $\{\tau_i\}$ such that

$$\mathbb{E}[Z(T\wedge\tau_n)^2] = Z(0)^2 + \mathbb{E}\left[\int_0^{T\wedge\tau_n} \left\{ 2Z(s^-) \left[\bar{\eta}(s)'\gamma(s) + \sum_{i=1}^n \lambda_i(s)\bar{\kappa}_i(s)\psi_i(s) \right] + |\bar{\eta}(s)|^2 + \sum_{i=1}^n \lambda_i(s)\bar{\kappa}_i(s)^2 \right\} ds \right].$$

That is,

$$\begin{aligned} (4.8)\qquad & \mathbb{E}\int_0^{T\wedge\tau_n} \left[|\bar{\eta}(s)|^2 + \sum_{i=1}^n \lambda_i(s)\bar{\kappa}_i(s)^2 \right] ds + Z(0)^2 \\ &= \mathbb{E}[Z(T\wedge\tau_n)^2] - \mathbb{E}\int_0^{T\wedge\tau_n} 2Z(s^-) \left[\bar{\eta}(s)'\gamma(s) + \sum_{i=1}^n \lambda_i(s)\bar{\kappa}_i(s)\psi_i(s) \right] ds \\ &\le \mathbb{E}[Z(T\wedge\tau_n)^2] + \mathbb{E}\int_0^{T\wedge\tau_n} 2C|\bar{\eta}(s)|\,|\gamma(s)|\, ds \\ &\quad + \sum_{i=1}^n \int_0^{T\wedge\tau_n} 2C\lambda_i(s)\,|\bar{\kappa}_i(s)|\,|\psi_i(s)|\, ds, \end{aligned}$$

where we have used the fact that $|Z(t)| \le C$ to obtain the inequality in (4.8). Next, using the inequality $2ab \le a^2 + b^2$, it follows that

$$\begin{aligned} (4.9)\qquad & \mathbb{E}\int_0^{T\wedge\tau_n} 2C|\bar{\eta}(s)|\,|\gamma(s)|\, ds \\ &= \mathbb{E}\int_0^{T\wedge\tau_n} 2C\left(\frac{|\bar{\eta}(s)|}{\delta} \right) \delta|\gamma(s)|\, ds \\ &\le \mathbb{E}\int_0^{T\wedge\tau_n} C\left\{ \frac{|\bar{\eta}(s)|^2}{\delta^2} + \delta^2|\gamma(s)|^2 \right\} ds \\ &= \mathbb{E}\int_0^{T\wedge\tau_n} \left\{ \frac{1}{2}|\bar{\eta}(s)|^2 + 2C^2|\gamma(s)|^2 \right\} ds, \end{aligned}$$

where the last equality follows from choosing the constant $\delta = \sqrt{2C}$. A similar calculation again with $\delta = \sqrt{2C}$ gives

$$\mathbb{E}\int_0^{T\wedge\tau_n} 2C\lambda_i(s)\,|\bar{\kappa}_i(s)|\,|\psi_i(s)|\,ds \tag{4.10}$$
$$\leq \mathbb{E}\int_0^{T\wedge\tau_n}\left\{\frac{\lambda_i(s)}{2}|\bar{\kappa}_i(s)|^2+2C^2\lambda_i(s)|\psi_i(s)|^2\right\}ds.$$

Substituting (4.9) and (4.10) into (4.8) it follows that

$$\mathbb{E}\int_0^{T\wedge\tau_n}\left[|\bar{\eta}(s)|^2+\sum_{i=1}^n\lambda_i(s)\bar{\kappa}_i(s)^2\right]ds+Z(0)^2$$
$$\leq \mathbb{E}[Z(T\wedge\tau_n)^2]+2C^2\mathbb{E}\int_0^{T\wedge\tau_n}\left\{|\gamma(s)|^2+\sum_{i=1}^n\lambda_i(s)|\psi_i(s)|^2\right\}ds$$
$$+\frac{1}{2}\mathbb{E}\int_0^{T\wedge\tau_n}\left[|\bar{\eta}(s)|^2+\lambda_i(s)|\bar{\kappa}_i(s)|^2\right]ds.$$

Rearranging and letting $n\to\infty$ it follows from Fatou's lemma that

$$\frac{1}{2}\mathbb{E}\int_0^{T}\left[|\bar{\eta}(s)|^2+\sum_{i=1}^n\lambda_i(s)\bar{\kappa}_i(s)^2\right]ds+Z(0)^2$$
$$\leq \mathbb{E}|\xi|^2+2C^2\mathbb{E}\int_0^{T}\left\{|\gamma(s)|^2+\sum_{i=1}^n\lambda_i(s)|\psi_i(s)|^2\right\}ds<\infty,$$

which implies (4.5). □

By Theorem 4.3, (3.2) has a unique solution if the local martingale $Y(t)$ is a strictly positive martingale. For this to hold, it is clearly *necessary* that $-\infty<\psi_i(t)<1$ for a.e. $t\in[0,T]$, $\mathbb{P}$-a.s. The following result shows that this condition is also sufficient.

THEOREM 4.4. *Suppose that Assumption* (A) *is satisfied. Then the solution* $Y(t)$ *of* (4.2) *is a strictly positive* $\mathbb{G}$*-martingale with respect to* $\mathbb{P}$ *if and only if*

$$\psi_i(t)<1 \text{ for a.e. } t\in[0,T],\ \mathbb{P}\text{-a.s.} \tag{4.11}$$

In particular, there is a unique solution $(h(t),\eta(t),\kappa(t))$ *of* (3.2) *such that* $h(t)$ *is uniformly bounded and* $(\eta(t),\kappa(t))$ *satisfy the integrability conditions* (4.5) *if* (4.11) *is satisfied.*

Proof. For notational convenience we assume that $W(t)$ and $N(t)$ are one-dimensional processes. The extension to the multidimensional case can be done using the same approach (at the cost of more cumbersome notation).

By Ito's formula it can be shown that $Y(t)=\rho(t)\zeta(t)$, where $\rho(t)$ and $\zeta(t)$ denote the solutions of

$$d\rho(t)=-\rho(t^-)\gamma(t)\,dW(t),\quad \rho(0)=1,$$
$$d\zeta(t)=-\zeta(t^-)\psi(t)\,dM(t),\quad \zeta(0)=1.$$

By Proposition 3.1, $\rho(t)=e^{-\frac{1}{2}\int_0^t|\gamma(s)|^2ds-\int_0^t\gamma(s)'dW(s)}$ is a strictly positive $\mathbb{F}$-martingale under $\mathbb{P}$ and hence, by the *martingale invariance property* (Proposition 2.1), is also a strictly positive $\mathbb{G}$-martingale under $\mathbb{P}$. In addition, it is easy to show that

$$\zeta(t)=e^{\int_0^t\psi(s)\lambda(s)ds}\prod_{0<s\leq t}\Big(1-\psi(s)\triangle N(s)\Big).$$

It follows that strict positivity of $Y(t) = \rho(t)\zeta(t)$ implies that (4.11) is satisfied.

Conversely, suppose that (4.11) is satisfied. This implies that $Y(t) = \rho(t)\zeta(t)$ is strictly positive, so we need only show that $Y(t)$ is a martingale. Observe first that $1-\psi(t) > 0$ for a.e. $t \in [0, T]$, $\mathbb{P}$-a.s. Furthermore, we have $0 < \int_0^T (1-\psi(t))\lambda(t)\,dt < \infty$, $\mathbb{P}$-a.s. Indeed, this follows from the square integrability of $\psi(t)$ (which implies in turn that $\int_0^T (1-\psi(t))\,dt < \infty$) and the uniform bound on $\lambda(t)$ (see Assumption (A)). We now show that $\mathbb{E}^{\mathbb{P}}[\zeta(t)|\mathcal{G}_s \vee \mathcal{F}_T] = \zeta(s)$ for $s < t$. First,

$$
\begin{aligned}
(4.12)\quad & \mathbb{E}^{\mathbb{P}}[\zeta(t)|\mathcal{G}_s \vee \mathcal{F}_T] \\
&= e^{\int_0^t \psi(u)\lambda(u)du} \prod_{0<u\le s} (1-\psi(s)\triangle N(s))\mathbb{E}^{\mathbb{P}}\left[\prod_{s<u\le t}(1-\psi(u)\triangle N(u))\Big|\mathcal{G}_s \vee \mathcal{F}_T\right] \\
&= \zeta(s)e^{\int_s^t \psi(u)\lambda(u)du}\mathbb{E}^{\mathbb{P}}\left[\prod_{s<u\le t}(1-\psi(u)\triangle N(u))\Big|\mathcal{F}_T\right],
\end{aligned}
$$

where the second equality follows from the definition of $\zeta(t)$ and the observation that conditional on $\mathcal{F}_T$, $\sigma\{N(u) - N(s),\ s < u \le t\}$ is independent of $\mathcal{G}_s$ by virtue of the independent increment property of Poisson processes. On the other hand, conditioning on $N(t) - N(s)$ we obtain

$$
\begin{aligned}
(4.13)\quad & \mathbb{E}^{\mathbb{P}}\left[\prod_{s<u\le t}(1-\psi(u)\triangle N(u))\,\Big|\,\mathcal{F}_T\right] \\
&= \mathbb{E}^{\mathbb{P}}\left[\mathbb{E}^{\mathbb{P}}\left\{\prod_{s<u\le t}(1-\psi(u)\triangle N(u))\,\Big|\,\sigma\{N(t)-N(s)\}\vee\mathcal{F}_T\right\}\Big|\,\mathcal{F}_T\right].
\end{aligned}
$$

By Lemma 3.1 in [8], the arrival times of $N(u)$ on $(s, t]$, conditional on $\mathcal{F}_T$ and $N(t) - N(s) = k$, are distributed like k independent random variables on $(s, t]$ with density $\lambda(u)/\int_s^t \lambda(v)\,dv$. It follows that

$$
\mathbb{E}^{\mathbb{P}}\left\{\prod_{s<u\le t}(1-\psi(u)\triangle N(u))\,\Big|\,\sigma\{N(t)-N(s)\}\vee\mathcal{F}_T\right\} = \left[\frac{\int_s^t (1-\psi(u))\lambda(u)\,du}{\int_s^t \lambda(u)\,du}\right]^{N(t)-N(s)},
$$

where the right-hand side is finite since $0 < \int_0^T (1-\psi(t))\lambda(t)\,dt < \infty$ $\mathbb{P}$-a.s. Substituting this into (4.13) we obtain

$$
\mathbb{E}^{\mathbb{P}}\left[\prod_{s<u\le t}(1-\psi(u)\triangle N(u))\,\Big|\,\mathcal{F}_T\right] = e^{-\int_s^t \psi(u)\lambda(u)du}
$$

and (4.12) gives $\mathbb{E}^{\mathbb{P}}[\zeta(t)\,|\,\mathcal{G}_s \vee \mathcal{F}_T] = \zeta(s)$. Finally, since

$$
\begin{aligned}
\mathbb{E}^{\mathbb{P}}[Y(t)|\mathcal{G}_s] &= \mathbb{E}^{\mathbb{P}}[\rho(t)\mathbb{E}^{\mathbb{P}}\{\zeta(t)\,|\,\mathcal{G}_s \vee \mathcal{F}_T\}\,|\,\mathcal{G}_s] = \mathbb{E}^{\mathbb{P}}[\rho(t)\zeta(s)|\mathcal{G}_s] \\
&= \mathbb{E}^{\mathbb{P}}[\rho(t)|\mathcal{G}_s]\zeta(s) = \rho(s)\zeta(s) = Y(s),
\end{aligned}
$$

it follows that $Y(t)$ is a martingale, as claimed.

The existence and uniqueness of solutions of (3.2) satisfying the boundedness and integrability conditions follows from Theorem 4.3. □

From the proof of Theorem 4.4, it is easy to show that $\zeta(t)$ is a strictly positive $\mathbb{G}$-martingale under $\mathbb{P}$ if and only if the condition (4.11) is satisfied.

5. Solvability of (3.2): Special cases. The conditions in Theorems 4.3 and 4.4 for solvability of (3.2) are cumbersome because they involve the solution $(p(t), \Lambda(t))$ of (3.1) in the definition of $\psi(t)$; see (3.8). We now consider some simple special cases where the condition in Theorem 4.4 can be expressed explicitly in terms of the parameters of the problem or otherwise easily checked. Whether there are easily verifiable general conditions remains an open question. In the case of *continuous* price processes, the simplifications resulting from the assumption of a complete market (section 5.1) or deterministic parameters (section 5.2) are well known, being situations where the VMM coincides with the so-called *minimal martingale measure*; see [14, 23, 30]. In sections 5.3 and 5.4, we show that (3.2) and the hedging problem (2.6) may still be solvable even when the martingale condition is not satisfied, so long as the liability ξ is suitably restricted.

5.1. Complete market. In this section, we assume conditions which guarantee completeness of the financial market (2.1) and show, under these assumptions, that (3.2) is solvable. More specifically, we shall assume that $m+d = n$ (that is, the number of risky assets m is equal to the number of independent sources of uncertainty $n+d$) and that the matrix

$$\Gamma(t) \triangleq \begin{bmatrix} \sigma(t) & \theta(t)D(t)^{\frac{1}{2}} \end{bmatrix} \tag{5.1}$$

is invertible. These assumptions imply that the linear equation

$$b(t) = \sigma(t)\gamma^*(t) + \theta(t)D(t)\psi^*(t) = \Gamma(t) \begin{bmatrix} \gamma^*(t) \\ D(t)^{\frac{1}{2}}\psi^*(t) \end{bmatrix} \tag{5.2}$$

has a unique solution $(\gamma^*(t), \psi^*(t))$. In addition, we shall assume that the unique solution $Y^*(t)$ of the stochastic differential equation

$$\begin{cases} dY^*(t) = -Y^*(t^-)\{\gamma^*(t)'\, dW(t) + \psi^*(t)'\, dM(t)\}, \\ Y^*(0) = 1, \end{cases} \tag{5.3}$$

where $(\gamma^*(t), \psi^*(t))$ is the solution of (5.2), is a positive martingale. Under these assumptions, one can show that the market is complete. More specifically, since $\rho^*(t)$ is a positive martingale, we can define a $\mathbb{P}$-equivalent probability measure $\mathbb{Q}$ via the Radon–Nikodým derivative

$$\frac{d\mathbb{Q}}{d\mathbb{P}} = Y^*(T) \tag{5.4}$$

such that $W^*(t) \triangleq W(t) + \int_0^t \gamma^*(s)\, ds$ is a $\mathbb{G}$-Brownian motion and $M^*(t) \triangleq M(t) + \int_0^t D(s)\psi^*(s)\, ds$ is a $\mathbb{G}$-martingale under $\mathbb{Q}$ (Proposition 4.1). Moreover, it is easy to show that the discounted price processes $P_i(t)/B(t)$ are $\mathbb{G}$-martingales under $\mathbb{Q}$, and hence $\mathbb{Q}$ is a $\mathbb{P}$-*equivalent martingale measure* (EMM). To see that this $\mathbb{Q}$ is unique, observe that any positive martingale $Y^*(t)$ satisfying $\mathbb{E}^{\mathbb{P}}Y^*(T) = 1$ is also the solution of an equation of the form (5.3) for appropriately chosen $\mathbb{G}$-predictable processes $(\gamma^*(t), \psi^*(t))$. (See [17, Proposition 6.20] and also p. 162 of [4].) In addition, $(\gamma^*(t), \psi^*(t))$ is necessarily a solution of (5.2) in order for the discounted price processes $P_i(t)/B(t)$ to be martingales. The invertibility of $\Gamma(t)$ implies that there is exactly one solution of (5.2) and hence at most one EMM. That is, invertibility of $\Gamma(t)$ together with the property that the solution $Y^*(t)$ of (5.3) is a positive martingale

imply that the market is *complete*. The following result shows that these conditions imply that (3.2) with parameters (3.7)–(3.8) has a unique solution.

PROPOSITION 5.1. *If Assumption* (A) *holds,* $\Gamma(t)$ *is invertible, and the solution* $Y^*(t)$ *of* (5.3) *is a positive martingale, then* (3.2) *has a unique solution.*

Proof. Denoting

$$X(t) = \begin{bmatrix} \gamma^*(t) \\ D(t)^{\frac{1}{2}}\psi^*(t) \end{bmatrix} \tag{5.5}$$

and noting the invertibility of $D(t)^{\frac{1}{2}} = \operatorname{diag}(\lambda_1(t)^{\frac{1}{2}}, \ldots, \lambda_n(t)^{\frac{1}{2}})$ (see Assumption (A)) it follows that the unique solution $(\gamma^*(t), \psi^*(t))$ of (5.2) can be constructed from (5.5) and the solution $X(t)$ of the linear equation

$$b(t) = \Gamma(t)X(t), \quad \text{a.e. } t \in [0, T], \ \mathbb{P}\text{-a.s.} \tag{5.6}$$

Hence, we shall focus on (5.6) and construct the solution of (5.2) once the solution of (5.6) has been found.

The solution $X(t)$ of (5.6) can be written in the form

$$X(t) = \Gamma(t)'K(t) + \big[I - \Gamma(t)(\Gamma(t)\Gamma(t)')^{-1}\Gamma(t)\big]Z(t) \tag{5.7}$$

for appropriate choices of $K(t)$ and $Z(t)$. In particular, $\Gamma(t)'K(t)$ is the projection of $X(t)$ into the space spanned by the columns of $\Gamma(t)'$, while the vector $[I - \Gamma(t)(\Gamma(t)\Gamma(t)')^{-1}\Gamma(t)]Z(t)$ is the projection of $X(t)$ onto its orthogonal complement. Invertibility of $\Gamma(t)$ implies that

$$I - \Gamma(t)(\Gamma(t)\Gamma(t)')^{-1}\Gamma(t) = 0. \tag{5.8}$$

Substituting (5.7) into (5.6) (and noting (5.8)) gives

$$b(t) = \Gamma(t)\Gamma(t)'K(t) = \Sigma(t)K(t),$$

implying in turn that

$$K(t) = \Sigma(t)^{-1}b(t),$$

where $\Sigma(t)$ is defined by (2.2). It follows from (5.7) that

$$X(t) = \Gamma(t)'\Sigma(t)^{-1}b(t) = \begin{bmatrix} \sigma(t)'\Sigma(t)^{-1}b(t) \\ D(t)^{\frac{1}{2}}\theta(t)'\Sigma(t)^{-1}b(t) \end{bmatrix},$$

and hence, by (5.5), we have

$$\gamma^*(t) = \sigma(t)'\Sigma(t)^{-1}b(t), \quad \psi^*(t) = \theta(t)'\Sigma(t)^{-1}b(t). \tag{5.9}$$

On the other hand, substituting (5.1) into (5.8) and using the definition (5.1) of $\Gamma(t)$ implies

$$\begin{bmatrix} \sigma'\Sigma^{-1}\sigma & \sigma'\Sigma^{-1}\theta D^{\frac{1}{2}} \\ D^{\frac{1}{2}}\theta'\Sigma^{-1}\sigma & D^{\frac{1}{2}}\theta'\Sigma^{-1}\theta D^{\frac{1}{2}} \end{bmatrix} = \begin{bmatrix} I & 0 \\ 0 & I \end{bmatrix}$$

and hence

$$\sigma(t)'\Sigma(t)^{-1}\sigma(t) = I, \quad \theta(t)'\Sigma(t)^{-1}\sigma(t) = 0.$$

It follows from (3.7)–(3.8) that

$$\gamma(t) = \sigma(t)'\Sigma(t)^{-1}b(t), \quad \psi(t) = \theta(t)'\Sigma(t)^{-1}b(t). \tag{5.10}$$

Comparing (5.10) with (5.9) it is clear that $(\gamma(t), \psi(t)) = (\gamma^*(t), \psi^*(t))$. In other words, the density process $Y(t)$ defined by (4.2) and (3.7)–(3.8) coincides with the density process $Y^*(t)$ corresponding to the unique EMM. Therefore, $Y(t)$ is a positive martingale (since $Y^*(t)$ is a positive martingale) and hence, by Theorem 4.3, (3.2) has a solution. □

The following result gives a condition for solvability of (3.2) in terms of the parameters of the problem.

PROPOSITION 5.2. *If Assumption* (A) *holds and* $\Gamma(t)$ *is invertible, then* $\gamma(t)$ *and* $\psi(t)$*, given by* (3.7) *and* (3.8)*, respectively, simplify to*

$$\gamma(t) = \sigma(t)'\Sigma(t)^{-1}b(t), \quad \psi(t) = \theta(t)'\Sigma(t)^{-1}b(t). \tag{5.11}$$

Furthermore, if $\psi_i(t) < 1$ *for a.e.* $t \in [0, T]$, $\mathbb{P}$*-a.s.,* $i = 1, 2, \ldots, n$*, then* (3.2) *has a unique solution.*

Proof. We have already shown in the proof of Proposition 5.1 that invertibility of $\Gamma(t)$ implies (5.11); see (5.10). By Corollary 4.4 and Theorem 4.3, the boundedness assumption of $\ln(1 - \psi_i(t))$ implies solvability of (3.2). □

5.2. Deterministic parameters. If the coefficients $r(t)$, $\mu_i(t)$, $\sigma_i(t)$, $\theta_i(t)$, and $\lambda_i(t)$ are all deterministic, then $\Lambda(t) \equiv 0$, and (3.1)–(3.2) become

$$\begin{cases} \dot{p}(t) = -p(t)[2r(t) - b(t)'\Sigma(t)^{-1}b(t)], \\ p(T) = 1, \end{cases} \tag{5.12}$$

$$\begin{cases} dh(t) = \Big\{ r(t)h(t) + b(t)'\Sigma(t)^{-1}[\sigma(t)\eta(t) + \theta(t)D(t)\kappa(t)] \Big\}\, dt \\ \qquad\qquad + \eta(t)'\, dW(t) + \kappa(t)'\, dM(t), \\ h(T) = \xi. \end{cases}$$

In addition, it follows from (3.7)–(3.8) that

$$\gamma(t) = \sigma(t)'\Sigma(t)^{-1}b(t), \quad \psi(t) = \theta(t)'\Sigma(t)^{-1}b(t).$$

The following result is an immediate consequence of Theorems 4.3 and 4.4.

PROPOSITION 5.3. *Suppose that the coefficients* $r(t)$*,* $\mu_i(t)$*,* $\sigma_i(t)$*,* $\theta_i(t)$*, and* $\lambda_i(t)$ *are all deterministic. If* $\psi_i(t) < 1$ *for a.e.* $t \in [0, T]$*,* $\mathbb{P}$*-a.s. for* $i = 1, \ldots, n$*, then* (3.2) *has a unique solution.*

Although the solvability condition in Proposition 5.3 resembles that in Proposition 5.2, Proposition 5.3 applies to complete and incomplete markets (with deterministic parameters), while Proposition 5.2 applies to complete markets (with possibly random parameters).

5.3. Case $Y(t)$ is not a positive martingale. If the process $Y(t)$ defined by (4.2) is not a strictly positive martingale, which occurs for instance if $\psi_i(t) \not< 1$, as required in Theorem 4.4, then the construction in the proof of Theorem 4.3 cannot be used in general to obtain a solution of (3.2). In this section, we show that while (3.2) may not be solvable for arbitrary ξ, it may nevertheless have a solution if ξ is restricted to an appropriate class of random variables.

Suppose that the vector $\psi(t)$ given by (3.8) is partitioned such that $\psi(t) = \big[\psi^1(t)',\ \psi^2(t)'\big]'$, where $\psi^1(t) = [\psi_1(t), \ldots,\ \psi_L(t)]'$ denotes the first L entries of $\psi(t)$, and $\psi^2(t) = [\psi_{L+1}(t), \ldots,\ \psi_n(t)]'$ denotes the remaining $n - L$ entries. Let $N(t) = \big[N^1(t),\ N^2(t)\big]$ and $M(t) = \big[M^1(t),\ M^2(t)\big]$ be partitioned similarly. Throughout this section (as well as in the next), $\mathbb{D}^i = \mathcal{D}_t^i$ denotes the filtration generated by $N^i(t)$ augmented by the $\mathbb{P}$-null sets of $\mathcal{F}$, and $\mathbb{G}^i = \{\mathcal{G}_t^i\}_{t\geq 0}$, where $\mathcal{G}_t^i \triangleq \mathcal{D}_t^i \vee \mathcal{F}_t$ is the smallest σ-algebra containing $\mathcal{D}_t^i$ and $\mathcal{F}_t$ for $i = 1, 2$.

Suppose that $Y(t)$ is *not* a positive $\mathbb{G}$-martingale, but that $Y^1(t)$ defined by

$$\begin{cases} dY^1(t) = -Y^1(t^-)\{\gamma(t)'\,dW(t) + \psi^1(t)'\,dM^1(t)\}, \\ Y^1(0) = 1 \end{cases} \tag{5.13}$$

is a positive $\mathbb{G}$-martingale under $\mathbb{P}$. Such a situation may arise, for instance, if $\psi_i(t) < 1$ and is uniformly bounded away from 1 for $i = 1, \ldots, L$, while $\psi_i \not< 1$ for $i = L+1, \ldots, n$. While (3.2) will not generally be solvable in this situation, there is a solution if ξ is restricted as follows.

PROPOSITION 5.4. *If $Y^1(t)$ is a positive $\mathbb{G}$-martingale under $\mathbb{P}$ and $\xi \in \mathcal{G}_T^1$, then there exists a solution $(h(t), \eta(t), \kappa(t))$ of (3.2) such that $h(t)$ is $\mathbb{G}^1$-adapted (and hence $\mathbb{G}$-adapted), $\eta(t)$ and $\kappa(t)$ are $\mathbb{G}^1$-predictable (and hence $\mathbb{G}$-predictable), and $\kappa(t) = [\kappa^1(t),\ \kappa^2(t)]$, where $\kappa^2(t) \equiv 0$.*

Proof. Since by assumption $Y^1(t)$ is a positive $\mathbb{G}$-martingale under $\mathbb{P}$, we can define a $\mathbb{P}$-equivalent measure $\mathbb{Q}^1$ via

$$\frac{d\mathbb{Q}^1}{d\mathbb{P}} = Y^1(T).$$

By the Girsanov theorem, $\bar{W}(t) \triangleq W(t) + \int_0^t \gamma(s)\,ds$ is a $\mathbb{G}$-Brownian motion under $\mathbb{Q}^1$ and the components $N_i(t)$ of $N(t)$ are doubly stochastic Poisson process with $\mathbb{F}$-predictable intensities $\lambda_i(t)(1 - \psi_i(t))$ when $i = 1, \ldots, L$, and $\lambda_i(t)$ when $i = L+1, \ldots, n$ (see Proposition 4.1); in particular, this implies that $M^1(t) = N^1(t) - \int_0^t D^1(s)(\mathbf{1} - \psi^1(s))\,ds = M^1(t) + \int_0^t D^1(s)\psi^1(s)\,ds$ is a $\mathbb{G}$-martingale under $\mathbb{Q}$.

Let $h(t)$ be the $\mathbb{G}^1$-adapted process defined via

$$\frac{h(t)}{B(t)} = \mathbb{E}^{\mathbb{Q}^1}\left[\frac{\xi}{B(T)}\Big|\mathcal{G}_t^1\right]. \tag{5.14}$$

Since $h(t)/B(t)$ is a $\mathbb{G}^1$-martingale under $\mathbb{Q}^1$ and $\mathbb{G}^1$ is generated by $\{W(t),\ 0 \leq t \leq T\}$ and $\{N^1(t),\ 0 \leq t \leq T\}$, it follows from the martingale representation theorem that there are $\mathbb{G}^1$-predictable processes $\bar{\eta}(t)$ and $\bar{\kappa}^1(t)$ such that

$$\frac{h(t)}{B(t)} = \mathbb{E}^{\mathbb{Q}^1}\left[\frac{\xi}{B(T)}\right] + \int_0^t \bar{\eta}(s)'\,d\bar{W}(s) + \int_0^t \bar{\kappa}^1(s)'\,d\bar{M}^1(s).$$

Substituting $\eta(t) \triangleq B(t)\bar{\eta}(t)$ and $\kappa^1(t) \triangleq B(t)\bar{\kappa}^1(t)$ and changing measure from $\mathbb{Q}^1$ back to $\mathbb{P}$ gives

$$\begin{cases} dh(t) = r(t)h(t)\,dt + \eta(t)'[\gamma(t)\,dt + dW(t)] \\ \quad\ +\kappa^1(t)'[D^1(t)\psi^1(t)\,dt + dM^1(t)], \\ h(T) = \xi, \end{cases} \tag{5.15}$$

where $D^1(t) \triangleq \operatorname{diag}\{\lambda_1(t), \ldots, \lambda_L(t)\}$. Setting $\kappa(t) = [\kappa^1(t)', \kappa^2(t)']'$, where the components $\kappa^2(t) = [\kappa_{L+1}(t), \ldots, \kappa_n(t)]' \equiv 0$, it follows from (5.15) that the triple $(h(t), \eta(t), \kappa(t))$ is also a solution of (3.2). Square integrability of $(\eta(t), \kappa(t))$ can be proven along the same lines as in the proof of Theorem 4.3. □

The following necessary and sufficient condition for $Y^i(t)$ to be a strictly positive martingale can be shown along the lines of Theorem 4.4.

PROPOSITION 5.5. *Suppose that Assumption* (A) *is satisfied. Then* $Y^1(t)$ *is a strictly positive* $\mathbb{G}$*-martingale under* $\mathbb{P}$ *if and only if for* $i = 1, \ldots, L$, $\psi_i^1(t) < 1$ *for a.e.* $t \in [0, T]$, $\mathbb{P}$*-a.s.*

5.4. "No common jumps." We say that the liability ξ and the asset prices $P_1(t), \ldots, P_m(t)$ have *no common jumps* if there is no jump component $N_j(t)$ that affects both the value of the liability ξ *and* the asset prices $P_i(t)$ $(i = 1, \ldots, m)$. The extreme case of this corresponds to the liability ξ being constant, which arises in the problem of *mean-variance portfolio selection*, but is also satisfied if ξ is measurable with respect to the history of the Brownian motion.

More generally, if $\mathcal{G}_T^1$ denotes the σ-algebra generated by $\{W(t),\ 0 \le t \le T\}$ and $\{N^1(t),\ 0 \le t \le T\}$, where without loss of generality we take $N^1(t)$ to be the first L components $(N_1(t), \ldots, N_L(t))$ of $N(t)$, then there are no common jumps if $\xi \in \mathcal{G}_T^1$ and the price processes $P_i(t)$ given by (2.1) are such that the matrix $\theta(t) = [\theta^1(t),\ \theta^2(t)]$ satisfies

$$\theta^1(t) \equiv 0, \tag{5.16}$$

where $\theta^1(t) = [\theta_1^1(t),\ \ldots, \theta_L^1(t)]$ and $\theta^2(t) = [\theta_{L+1}^2(t), \ldots,\ \theta_n^2(t)]$ are the first L columns and the remaining $n - L$ columns of $\theta(t)$, respectively. Proposition 5.6 states that the BSDE (3.2) *always has a solution when there are no common jumps*. (This result is stronger than existence results established in Theorems 4.3 and 4.4, where strict positivity of $Y(t)$ (or equivalently that $\psi_i(t) < 1$) must be satisfied in order to guarantee existence.)

PROPOSITION 5.6. *Suppose that Assumption* (A) *holds. If* $\xi \in \mathcal{G}_T^1$ *and* $\theta^1(t) \equiv 0$, *then* (3.2) *has a solution* $(h(t), \eta(t), \kappa(t)) \in \mathcal{L}^\infty(\mathbb{G}, \mathbb{R}) \times \mathcal{P}^2(\mathbb{G}, \mathbb{R}^d) \times \mathcal{P}^2(\mathbb{G}, \mathbb{R}^n)$.

Proof. We prove this result by constructing a solution of (3.2). Consider first the following BSDE:

$$\begin{cases} dh(t) = r(t)h(t)\,dt + \eta(t)'[\gamma(t)\,dt + dW(t)] + \kappa(t)'\,dM(t), \\ h(T) = \xi. \end{cases} \tag{5.17}$$

Let $\rho(t)$ denote the solution of

$$\begin{cases} d\rho(t) = -\rho(t^-)\gamma(t)'\,dW(t), \\ \rho(0) = 1, \end{cases}$$

where $\gamma(t)$ is given by (3.7) (see also (3.4)). By Proposition 3.1, we know that $\rho(t)$ is a positive $\mathbb{F}$-martingale. It follows from the *martingale invariance property* (see Proposition 2.1) that $\rho(t)$ is a positive $\mathbb{G}$-martingale under $\mathbb{P}$ and hence defines a $\mathbb{P}$-equivalent probability measure $\mathbb{Q}$ via

$$\frac{d\mathbb{Q}}{d\mathbb{P}} = \rho(T).$$

By the Girsanov theorem, $\bar{W}(t) = W(t) + \int_0^t \gamma(s)\,ds$ is a $\mathbb{G}$-Brownian motion under $\mathbb{Q}$ and $N_i(t)$ $(i = 1, \dots, n)$ are doubly stochastic Poisson processes under $\mathbb{Q}$ with (unchanged) $\mathbb{F}$-predictable intensities $\lambda_i(t)$; see Proposition 4.1. Therefore, we can use the same approach as in the proof of Theorem 4.3 to construct a solution of (5.17). In particular, by the martingale representation theorem (Proposition 4.2), we can (uniquely) define $(h(t), \bar{\eta}(t), \bar{\kappa}^1(t))$ via

$$\frac{h(t)}{B(t)} = \mathbb{E}^{\mathbb{Q}}\Big[\frac{\xi}{B(T)}\Big|\mathcal{G}_t^1\Big] = \mathbb{E}^{\mathbb{Q}}\Big[\frac{\xi}{B(T)}\Big] + \int_0^t \bar{\eta}(t)'\,d\bar{W}(t) + \int_0^t \bar{\kappa}^1(t)'\,dM^1(t), \tag{5.18}$$

where $\bar{\eta}(t)$ and $\bar{\kappa}^1(t)$ are $\mathbb{G}^1$-predictable (and hence $\mathbb{G}$-predictable) processes (of dimension d and L, respectively) and $M^1(t)$ is the compensated Poisson process associated with $N^1(t)$. Moreover, setting $\bar{\kappa}(t) = [\bar{\kappa}^1(t)',\, \bar{\kappa}^2(t)']' = [\bar{\kappa}^1(t),\, 0]$, where $\bar{\kappa}^2(t)$ is an $(n-L)$-dimensional vector of zeros, it is clear that (5.18) implies

$$\frac{h(t)}{B(t)} = \mathbb{E}^{\mathbb{Q}}\Big[\frac{\xi}{B(T)}\Big] + \int_0^t \bar{\eta}(t)'d\bar{W}(t) + \int_0^t \bar{\kappa}(t)'dM(t).$$

By Ito's formula, it can be shown that

$$(h(t),\, \eta(t),\, \kappa(t)) = (h(t),\, B(t)\bar{\eta}(t),\, B(t)\bar{\kappa}(t))$$

is a solution of (5.17). Furthermore, this solution is unique due to the uniqueness of martingale representation. Finally, since $\kappa^2(t) = B(t)\bar{\kappa}^2(t) \equiv 0$ it follows from (5.16) that

$$\theta(t)'D(t)\kappa(t) = \theta^1(t)D^1(t)\kappa^1(t) + \theta^2(t)D^2(t)\kappa^2(t) \equiv 0, \tag{5.19}$$

and hence, by (3.8), that

$$\kappa(t)'D(t)\psi(t) \equiv 0.$$

Therefore, the solution of (5.17) is also a solution of (3.2), which establishes our result. □

An important special case is the one where the liability ξ is deterministic, which arises in the problem of mean-variance portfolio selection. Propositions 3.5 and 5.6 imply that (3.2) *always has a solution* and the mean-variance hedging problem (2.6) can be solved, with optimal policy (3.5), without having to assume that the solution of (4.2) is a strictly positive martingale.

COROLLARY 5.7. *Suppose that Assumption* (A) *holds and ξ is $\mathcal{F}_T$-measurable. (In particular, ξ may be deterministic.) Then* (3.2) *has a unique solution* $(h(t), \eta(t), \kappa(t))$, *where* $\kappa(t) \equiv 0$.

6. Some remarks about assumptions. In Arai [1], the problem of mean-variance hedging when underlying prices are discontinuous semimartingales is addressed. We now comment briefly on the assumptions made in [1] and how these compare with those in this paper.

Several differences between the problem formulations in [1] and the present paper should be clarified before comparing the assumptions. First, the price processes in [1] are discontinuous semimartingales, while those in this paper (2.1) have additional structure in that they are driven by Brownian motion and a doubly stochastic Poisson process with $\mathbb{F}$-predictable parameters. Second, it is assumed in [1] that all price

processes have been discounted using the money market account, so stochastic interest rates are not addressed explicitly (they are combined with the other prices through the discounting). This contrasts with (2.1) and (2.6), where price and wealth processes are not discounted. Third, the contingent claim in [1] (what we call ξ) is square integrable, whereas we are assuming that it is bounded. (This was used in the proof of Theorem 4.3. It should be possible to relax this assumption, but this is left for future work.) Finally, the methods adopted in [1] are different from those in the present paper. More specifically, [1] extends the analysis in [30], based on convex duality, to the discontinuous setting, whereas we use stochastic control methods together with the theory of BSDEs.

These differences being understood, we now examine the relationship between the assumptions in [1] and those in this paper. Not surprisingly, the additional structure in our model means that some of the assumptions invoked in [1] are not required here.

Assumptions in Arai [1].

(A1) The variance optimal (signed) martingale measure $\mathbb{Q}$ is a $\mathbb{P}$-equivalent measure; equivalently, $\mathbb{Q}$ has a density process $Z(t)$ that is a strictly positive $\mathbb{P}$-martingale.

(A2) $Z(t)$ satisfies the *reverse Hölder inequality*; that is, there is a constant $C > 0$ such that

$$\mathbb{E}\left[\left(\frac{Z(T)}{Z(\tau)}\right)^2 \Big| \mathcal{H}_\tau\right] \le C$$

for every $\mathbb{H}$-stopping time τ, where $\mathbb{H} = \{\mathcal{H}_t\}_{t\ge 0}$ denotes the underlying filtration.

(A3) There exists a constant $C > 0$ such that $Z(t^-) \le CZ(t)$ for all $t \in [0, T]$, $\mathbb{P}$-a.s.

The density process $Y(t)$ in (4.2) plays an analogous role to the density process $Z(t)$ in [1]. A priori, neither $Z(t)$ nor $Y(t)$ is positive, and hence, only define signed measures. This is the reason why (A1) is needed in [1]. The assumption that $Y(t)$ is a positive martingale in Theorem 4.3 is analogous to this.

Because of the structure of our model, neither (A2) nor (A3) is required in this paper. In particular, it can be shown that the solution $(p(t), \Lambda(t))$ of (3.1) satisfies

$$\frac{1}{p(t)} = \mathbb{E}\left[\left(\frac{Y(T)}{Y(t)}\right)^2 \Big| \mathcal{G}_t\right].$$

It follows that the bound $\delta_1 \le p(t) \le \delta_2$ (Proposition 3.1) guarantees that the reverse Hölder inequality is *automatically* satisfied in this paper and does not need to be assumed. Again, this comes from the structure that we impose on our model.

7. Example. We now present an example with constant parameters (but random liability) for which explicit solutions of (3.1)–(3.2) can be obtained. In particular, we show how formulas for the solution $(h(t), \eta(t), \kappa(t))$ of (3.2) can be derived, and the insights that this gives into the structure of the optimal hedging portfolio.

For this example, we assume that the interest rate r for the money market account $B(t)$ is constant, and a single underlying risky asset

$$dP(t) = P(t)\{\mu\, dt + \sigma\, dW(t) + \theta\, dN(t)\} \tag{7.1}$$

with deterministic parameters μ, σ, and θ. We assume that the arrival rate λ is constant.

Observe first that the market is arbitrage free: the measure $\bar{\mathbb{Q}}$ that makes

$$\bar{W}(t) \triangleq -\frac{t}{\sigma}[r-\mu-\theta\lambda]+W(t)$$

a Brownian motion but leaves the rate λ of $N(t)$ unchanged is an equivalent martingale measure. On the other hand, it follows from Proposition 5.3 that (3.2) has a solution if $\psi<1$, where

$$\gamma=\sigma'\Sigma^{-1}b=\frac{\sigma b}{\sigma^2+\theta^2\lambda},\quad \psi=\theta\Sigma^{-1}b=\frac{\theta b}{\sigma^2+\theta^2\lambda}.$$

In particular, it is possible for the market to be arbitrage free but for $\psi<1$ not to be satisfied. We assume for the remainder that $\psi<1$.

Consider a liability of the form $\xi=\mathbf{1}_{\tau\le T}[A-y(\tau)]^+e^{r(T-\tau)}$, where τ denotes the first arrival time of $N(t)$ and $y(t)$ is the solution of the stochastic differential equation

$$dy(t)=y(t)\{r\,dt+q\,d\bar{W}(t)\}=y(t)\{(r+q\gamma)\,dt+q\,dW(t)\},$$

where $\bar{W}(t)=W(t)+\gamma t$ is a Brownian motion under the equivalent probability measure $\mathbb{Q}$ associated with (γ,ψ) via (4.2)–(4.3). In this model, we assume that "default" occurs at a random time τ that corresponds to the arrival time of the first Poisson event, and that the value of the liability is determined by the value of $[A-y(t)]^+$ at the time of this arrival (i.e., the default event). In particular, if $y(t)$ is significantly smaller than A, then the event of default is more costly for the investor.

By Theorem 3.5 the optimal policy is given by (3.5). Since the parameters μ, σ, θ, and λ of the price process (7.1) in this example are deterministic, it follows that $\Lambda\equiv 0$, so computing the optimal policy (3.5) boils down to finding $(h(t),\,\eta(t),\,\kappa(t))$ by solving (3.2). As in the proof of Theorem 4.3, the solution of (3.2) can be represented in the form

$$h(t)=e^{-r(T-t)}\mathbb{E}^{\mathbb{Q}}[\xi\,|\,\mathcal{G}_t]=e^{-r(T-t)}\mathbb{E}^{\mathbb{Q}}\Big[\mathbf{1}_{\tau\le T}(A-y(\tau))^+e^{r(T-\tau)}\,\Big|\,\mathcal{G}_t\Big]. \tag{7.2}$$

To get something more explicit for $h(t)$, it is convenient to introduce the process

$$z(t)=\int_{s=0}^{t}e^{r(t-s)}[A-y(s)]^+\mathbf{1}_{N(s^-)=0}\,dN(s).$$

Note that

$$z(t)=\mathbf{1}_{\tau\le t}[A-y(\tau)]^+e^{r(t-\tau)}=\mathbf{1}_{N(t)\ge 1}[A-y(\tau)]^+e^{r(t-\tau)},$$

which coincides with the value of the liability given that default occurred before time t. Observing that

$$\mathbf{1}_{\tau\le T}[A-y(\tau)]^+e^{r(T-\tau)}=\mathbf{1}_{\tau\le t}(A-y(\tau))^+e^{r(T-\tau)}+\mathbf{1}_{t<\tau\le T}(A-y(\tau))^+e^{r(T-\tau)},$$

we see from (7.2) that

$$h(t)=\mathbf{1}_{\tau\le t}e^{-r(\tau-t)}(A-y(\tau))^+ +\mathbf{1}_{\tau>t}e^{-r(T-t)}\mathbb{E}^{\mathbb{Q}}\Big[\mathbf{1}_{t<\tau\le T}(A-y(\tau))^+e^{r(T-\tau)}\,\Big|\,\mathcal{G}_t\Big].$$

Observing that

$$\begin{aligned}
&e^{-r(T-t)}\mathbb{E}^{\mathbb{Q}}\Big[\mathbf{1}_{t<\tau\le T}(A-y(\tau))^+e^{r(T-\tau)}\,\Big|\,\mathcal{G}_t\Big]\\
&=e^{-r(T-t)}\mathbb{E}^{\mathbb{Q}}\Big[\mathbb{E}^{\mathbb{Q}}\Big\{\mathbf{1}_{t<\tau\le T}(A-y(\tau))^+e^{r(T-\tau)}\,\Big|\,\mathcal{G}_t\vee\mathcal{F}_T\Big\}\,\Big|\mathcal{G}_t\Big]\\
&=e^{-r(T-t)}\mathbb{E}^{\mathbb{Q}}\left[\int_{s=t}^{T}\lambda(1-\psi)e^{-\lambda(1-\psi)(s-t)}(A-y(s))^+e^{r(T-s)}\,ds\,\Big|\,\mathcal{G}_t\right]\\
&=\int_{s=t}^{T}\lambda(1-\psi)e^{-\lambda(1-\psi)(s-t)}P(t,\,s,\,y(t))\,ds,
\end{aligned}$$

where

$$\begin{aligned}
P(t,\,s,\,y)=Ae^{-r(s-t)}\Phi\Big(\frac{\log(A/y)-(r-\frac{1}{2}q^2)(s-t)}{q\sqrt{s-t}}\Big)\\
-y\Phi\Big(\frac{\log(A/y)-(r+\frac{1}{2}q^2)(s-t)}{q\sqrt{s-t}}\Big),
\end{aligned}$$

denotes the price of a European put option on $y(\cdot)$ with strike A maturing at $s>t$, when $y(t)=y$. It follows that

$$h(t)=\mathbf{1}_{\tau\le t}\,e^{r(t-\tau)}(A-y(\tau))^+ +\mathbf{1}_{\tau>t}\int_{s=t}^{T}\lambda(1-\psi)e^{-\lambda(1-\psi)(s-t)}P(t,\,s,\,y(t))\,ds$$

or, equivalently,

$$\begin{aligned}
h(t)&=\mathbf{1}_{N(t)\ge 1}\,e^{r(t-\tau)}(A-y(\tau))^+\\
&\quad+\mathbf{1}_{N(t)=0}\int_{s=t}^{T}\lambda(1-\psi)e^{-\lambda(1-\psi)(s-t)}P(t,\,s,\,y(t))\,ds\\
&=z(t)+\mathbf{1}_{N(t)=0}\int_{s=t}^{T}\lambda(1-\psi)e^{-\lambda(1-\psi)(s-t)}P(t,\,s,\,y(t))\,ds\qquad(7.3)\\
&=f(t,\,y(t),\,z(t),\,N(t)),
\end{aligned}$$

where

$$f(t,\,y,\,z,\,i)=z+\mathbf{1}_{i=0}\int_{s=t}^{T}\lambda(1-\psi)e^{-\lambda(1-\psi)(s-t)}P(t,\,s,\,y)\,ds.$$

In order to compute the optimal portfolio, we need to find the components $(\eta(t),\,\kappa(t))$ of the solution of (3.2) or (4.1), which in this example is

$$\begin{cases}dh(t)=rh(t)\,dt+\eta(t)\,d\bar{W}(t)+\kappa(t)\,d\bar{M}(t),\\ h(T)=\mathbf{1}_{\tau\le T}[A-y(\tau)]^+e^{r(T-\tau)}.\end{cases}\qquad(7.4)$$

Applying Ito's formula to $h(t)=f(t,\,y(t),\,z(t),\,N(t))$ gives

$$\begin{aligned}
dh(t)=\Big\{&f_t(t,\,y(t),\,z(t^-),\,N(t^-))+ry(t)f_y(t,\,y(t),\,z(t^-),\,N(t^-))\\
&+\frac{1}{2}\sigma^2y^2f_{yy}(t,\,y(t),\,z(t^-),\,N(t^-))
\end{aligned}$$

$$
\begin{aligned}
&+\lambda(1-\psi)\Big[\mathbf{1}_{N(t^-)=0}\Big(f(t,\,y(t),\,(A-y(t))^+,\,1)-f(t,\,y(t),\,0,\,0)\Big)\\
&\quad+\mathbf{1}_{N(t^-)\geq 1}\Big(f(t,\,y(t),\,z(t),\,N(t^-)+1)-f(t,\,y(t),\,z(t^-),\,N(t^-))\Big)\Big]\Big\}\,dt\\
&+\sigma y f_y(t,\,y(t),\,z(t^-),\,N(t^-))\,d\bar{W}(t)\\
&+\Big\{\mathbf{1}_{N(t^-)=0}\Big[f(t,\,y(t),\,(A-y(t))^+,\,1)-f(t,\,y(t),\,0,\,0)\Big]\\
&\quad+\mathbf{1}_{N(t^-)\geq 1}\Big[f(t,\,y(t),\,z(t),\,N(t^-)+1)-f(t,\,y(t),\,z(t^-),\,N(t^-))\Big]\Big\}\,d\bar{M}(t).
\end{aligned}
$$

Comparing coefficients with (7.4) we obtain

$$
\begin{aligned}
\eta(t) &= \eta(t,\,y(t),\,z(t^-),\,N(t^-)) = \sigma y f_y(t,\,y(t),\,z(t^-),\,N(t^-))\\
\kappa(t) &= \kappa(t,\,y(t),\,z(t^-),\,N(t^-))\\
&= \mathbf{1}_{N(t^-)=0}\Big[f(t,\,y(t),\,(A-y(t))^+,\,1)-f(t,\,y(t),\,0,\,0)\Big]\\
&\quad+\mathbf{1}_{N(t^-)\geq 1}\Big[f(t,\,y(t),\,z(t),\,N(t^-)+1)-f(t,\,y(t),\,z(t^-),\,N(t^-))\Big].
\end{aligned}
$$

In particular, by (7.3) we have

$$
\eta(t) = \begin{cases} \sigma y(t)\displaystyle\int_{s=t}^{T}\lambda(1-\psi)e^{-\lambda(1-\psi)(s-t)}P_y(t,\,s,\,y(t))\,ds, & N(t^-)=0,\\ 0, & N(t^-)\geq 1,\end{cases}
$$

$$
\kappa(t) = \begin{cases} (A-y(t))^+ - \displaystyle\int_{s=t}^{T}\lambda(1-\psi)e^{-\lambda(1-\psi)(s-t)}P(t,\,s,\,y(t))\,ds, & N(t^-)=0,\\ 0, & N(t^-)\geq 1.\end{cases}
$$

Finally, it follows from Theorem 3.5 that the optimal portfolio is

$$
\pi(t) = \Sigma^{-1}\Big[\sigma\eta(t)+\theta\lambda\kappa(t)+b(h(t^-)-x(t^-))\Big].
$$

The term $\sigma\,\eta(t)$ hedges the uncertainty due to the Brownian motion fluctuations, while $\theta\lambda\kappa(t)$ hedges the loss at the instant of a jump. The last term which involves $f(t^-,\,y(t^-),\,N(t^-))-x(t^-)$ is concerned with minimizing the difference between the value of the portfolio at $x(t^-)$ and the value of the liability $h(t^-)$. Note that $\kappa(t)\equiv 0$ immediately after the first jump occurs. This is natural since the value of the liability ξ does not depend on jumps that may occur after the first. On the other hand, prior to the first jump, the "size" of $\kappa(t)$ depends both on the *time to maturity* $T-t$ as well as $P(t,\,y(t))$, the (stochastic) *cost of default*. In particular, if $y(t)$ is "close to" (or bigger than) A, then the impact of default is small and $(A-y(t))^+=0$ and $P(t,\,y(t))\approx 0$. In such a case, $\theta\lambda\kappa(t)$ will also be small.

8. Conclusion. In recent years, much effort has gone into the task of developing more sophisticated asset price models which are capable of reproducing some of the empirical features of price processes that are observed in data. One product of this endeavor has been the introduction of processes with jumps and stochastic parameters as an alternative to the Black–Scholes model. In this paper, we consider the problem of

mean-variance hedging in an incomplete market where the price processes have jumps (modeled by a doubly stochastic Poisson process) and parameters may be stochastic. This differs from almost all papers in the literature on mean-variance hedging where continuity of the tradable asset prices is usually assumed. We formulate this problem as a stochastic control problem and derive closed form expressions for the optimal hedging portfolio using the theory of backward stochastic differential equations. In particular, we show how the BSDE theory can be extended from the Brownian motion setting to handle problems with jumps.

Another application of this work relates to the problem of hedging default risk when the default is modeled in the reduced form setting. Considered in this way, the results of this paper extend, in some sense, those of Blanchet-Scalliet and Jeanblanc [5], where the problem of hedging default risk in a *complete* market is discussed.

Acknowledgments. The author would like to thank Kiseop Lee, the associate editor, and two anonymous reviewers for their feedback, as well as the corresponding editor Tyrone Duncan for his efficient handling of this paper. All errors are the responsibility of the author.

CONTROLLER DESIGN VIA NONSMOOTH MULTIDIRECTIONAL SEARCH*

PIERRE APKARIAN† AND DOMINIKUS NOLL‡

Abstract. We propose an algorithm which combines multidirectional search (MDS) with nonsmooth optimization techniques to solve difficult problems in automatic control. Applications include static and fixed-order output feedback controller design, simultaneous stabilization, H_2/H_∞-synthesis, and much else. We show how to combine direct search techniques with nonsmooth descent steps in order to obtain convergence certificates in the presence of nonsmoothness. Our technique is efficient when small and medium size controllers for plants with large state dimension are sought. Our numerical testing includes several benchmark examples. For instance, our algorithm needs 0.41 s to compute a static output feedback stabilizing controller for the Boeing 767 flutter benchmark problem [E. E. J. Davison, *IFAC Technical Committee Reports*, Pergamon Press, Oxford, 1990], a system with 55 states. The first static controller without performance specifications for this system was obtained in [J. Burke, A. Lewis, and M. Overton, *SIAM J. Optim.*, 15 (2003), pp. 751–779].

Key words. *NP*-hard design problems, static output feedback, fixed-order synthesis, simultaneous stabilization, mixed H_2/H_∞-synthesis, pattern search algorithm, moving polytope, nonsmooth analysis, spectral bundle method, ε-subgradients, bilinear matrix inequality (BMI)

1. Introduction.

Pattern search or moving polytope methods belong to a large class of derivative-free optimization methods referred to as direct search (DS) techniques. In this paper, we present a nonsmooth modification of Virginia Torczon's multidirectional search (MDS) [66, 67] algorithm and apply it to a broad class of problems in automatic control. We aim at several nonconvex and even *NP*-hard problems, for which LMI techniques or algebraic Riccati equations are impractical. In particular, we propose algorithmic solutions for static and fixed-order output feedback control, simultaneous stabilization problems, and mixed H_2/H_∞-control.

1.1. Direct search methods.

The idea of DS methods can be traced back to the pioneering work of Box [11] and Hook and Jeeves [37], who first coined the term "direct search." The MDS algorithm is due to Torczon [66, 67] and is directly inspired by the work of Spendley, Hext, and Himsworth [63], and the popular method of Nelder and Mead [55]. MDS significantly revived the interest in DS methods, because it came with a sound convergence theory [66]. This is in contrast with the Nelder–Mead algorithm, which may fail to converge even for smooth convex objective functions; see [52]. Later, Torczon generalized her work to the entire class of DS techniques [67].

DS methods compute local minima of unconstrained optimization programs:

$$\text{minimize} \quad f(x),\ x \in \mathbb{R}^n, \tag{1}$$

where $f : \mathbb{R}^n \to \mathbb{R}$ is a $\mathcal{C}^1$ function. DS techniques are *derivative-free* in the sense that they do not require gradient information in order to *compute* descent steps. This is a convenient feature if derivatives or their finite difference approximations are not available and/or too expensive to compute or when automatic differentiation is hindered by the presence of for loops in the function evaluation.

However, contrary to what the name suggests, the term derivative-free does not mean that derivatives do not altogether exist. On the contrary, DS methods are designed for $\mathcal{C}^1$ functions, and their convergence theory is heavily based on differentiability [67]. Problems encountered when search methods are used with genuinely nonsmooth criteria are discussed in [46].

DS techniques can also be used for constrained optimization programs. The ideas to attack those range from quadratic or exact penalty techniques over barrier functions to the augmented Lagrangian method.

1.2. Nonsmoothness. In the present paper, we apply the ideas of MDS to several constrained and unconstrained optimization problems in automatic control, where nonsmooth functions like the maximum eigenvalue function, the spectral abscissa, the distance to instability, and the H_∞-norm arise naturally. Due to the failure of convergence under nonsmoothness, DS methods may not be applied in their original form and additional tools from nonsmooth optimization are required. An algorithm combining both ideas is what will eventually emerge. Using nonsmooth techniques in control design is not altogether a new idea; see, e.g., [62, 61, 44, 53, 40]. What has not been tried before is combining nonsmooth techniques with DS strategies.

The lack of a convergence certificate under nonsmoothness has not prevented practitioners from applying DS methods in such cases. It is often argued that the contingency of a failure due to nonsmoothness is a remote one. The argument on which such reasoning is usually based is that even nonsmooth functions are, as a rule, almost everywhere differentiable, so that nonsmooth points are never encountered in practice. Our present work reveals this as an illusory argument. Nonsmoothness may and will cause failure of DS techniques, as we demonstrate by several striking examples.

In response, we show how MDS can be combined with nonsmooth descent steps in order to avoid the typical failure, where simplices shrink and iterates converge to a nonstationary point, which we also call a *dead point*. It is crucial to be able to distinguish dead points from local minima, and this is done by adding a nonsmooth stopping test to the usual hand tools of MDS. Such a test either indicates success or allows one to escape from a dead point, keeping the search algorithm moving.

However, this is not the end of the story. Calling for a nonsmooth stopping test whenever the simplex shrinks below a certain threshold may keep MDS moving, but it is not strong enough to ensure convergence. In order to get a convergence certificate in the presence of nonsmoothness, we need to supply MDS with *quantified descent steps* similar to those employed by nonsmooth optimization techniques to ensure convergence. We will refer to these two types of nonsmooth substrata to MDS as *crisis intervention* and *crisis prevention*. While crisis intervention is done only occasionally, being therefore less costly, crisis prevention is more complex, as it requires that the nonsmooth technique assists the search during the whole process.

We will indicate in which way crisis intervention and crisis prevention should be organized for application in automatic control, but our approach is in principle open to more general nonsmooth objectives.

We mention that a different approach to integrate nonsmoothness into MDS was recently proposed by Audet and Dennis [7, 1] for general locally Lipschitz functions. Their approach and ours are somewhat complementary. While we are more specific as far as the applications are concerned, our combined method can accommodate composite functions with the spectral abscissa, which are not even locally Lipschitz smooth. Also, our intervention technique is applicable to other derivative-free method, like for instance the wedge algorithm of Marrazzi and Nocedal [51].

The paper is organized as follows. We start with an introductory section 2, where three nonsmooth criteria are discussed. We proceed with the central sections 3 and 4, where we indicate why and in which form nonsmoothness arises in automatic control. In section 5 we briefly recall the mode of operation of MDS, including the possibility of the two types of intervention steps, by which the failure at dead points can be avoided. In section 6 we proceed to the implementation of *crisis intervention* and *crisis prevention* for nonsmooth objectives like the maximum eigenvalue function, the spectral abscissa, and the H_∞-norm. Crisis intervention is discussed in section 6, while the more sophisticated crisis prevention is discussed in section 7. Numerical experiments to validate the proposed tools and techniques are discussed in section 8 for a rich set of control applications.

1.3. Notation. Notation from convex and nonsmooth analysis are covered by [35] and [22]. We let $\mathbb{S}^m$ denote the set of $m \times m$ symmetric matrices, equipped with the scalar product $\langle X, Y\rangle = X \cdot Y = \operatorname{Tr}(XY)$. Let $\mathbb{M}_n$ be the space of real $n \times n$ matrices, $\mathbb{M}_{n,m}$ the space of $n \times m$ matrices, equipped with the corresponding scalar product $\langle X, Y\rangle = \operatorname{Tr}(X^{\mathrm{T}}Y)$, where X^{T} is the transpose of the matrix X, $\operatorname{Tr} X$ its trace. For complex matrices X^{H} stands for its transconjugate. For Hermitian or symmetric matrices, $X \succ Y$ means that $X - Y$ is positive definite, $X \succeq Y$ that $X - Y$ is positive semidefinite. We shall use superscripts for the iteration index, lower scripts to indicate vector components. Our notation from feedback control is standard and follows, e.g., [14].

2. Examples of nonsmooth functions in control. In this section we briefly discuss several nonsmooth functions arising in automatic control applications.

Our first example is the maximum eigenvalue function $\lambda_1 : \mathbb{S}^m \to \mathbb{R}$, defined on the space $\mathbb{S}^m$ of symmetric $m \times m$ matrices. We will use composite functions of the form $f(x) = \lambda_1(\mathcal{B}(x))$, where $\mathcal{B} : \mathbb{R}^n \to \mathbb{S}^n$ is usually a bilinear, quadratic, or class $\mathcal{C}^2$-operator. The interest in $f = \lambda_1 \circ \mathcal{B}$ stems from the fact that the matrix inequality $\mathcal{B}(x) \preceq 0$ is equivalent to the scalar constraint $f(x) \leq 0$. Notice that λ_1 is convex, which gives f a lot of structure. For instance, the Clarke subdifferential of f (cf. [22]) is the set

$$\partial f(x) = \mathcal{B}'(x)^\star[\partial\lambda_1(\mathcal{B}(x))] = \{\mathcal{B}'(x)^\star Z : Z = QYQ^{\mathrm{T}},\, Y \succeq 0, \operatorname{Tr}(Y) = 1\}, \tag{2}$$

where the columns of the matrix Q form an orthonormal basis of the eigenspace of $\lambda_1(\mathcal{B}(x))$. Here and in what follows, $\mathcal{B}'(x)$ denotes the derivative of $\mathcal{B}$ at x, understood as a linear operator $\mathbb{R}^n \to \mathbb{S}^m$, while $\mathcal{B}'(x)^\star$ denotes its adjoint, mapping $\mathbb{S}^m \to \mathbb{R}^n$. A case of special interest is when $\mathcal{B}$ is quadratic:

$$\mathcal{B}(x) = A_0 + \sum_{i=1}^n x_i A_i + \sum_{i,j=1}^n x_i x_j B_{ij}.$$

Then $\mathcal{B}'(x)d = \sum_{i=1}^n d_i A_i + \sum_{i,j=1}^n (x_i d_j + x_j d_i) B_{ij}$, and the adjoint is obtained as

$$(\mathcal{B}'(x)^\star Z)_i \;=\; \left(A_i + \sum_{j=1}^n x_j B_{ij} + x_j B_{ji} \right) \cdot Z.$$

Our second example of a nonsmooth function is the pseudospectral abscissa. Following Trefethen [68], the pseudospectral abscissa of a matrix $A \in \mathbb{M}_m$ is defined as

$$\alpha_\varepsilon(A) \;=\; \max \{ \operatorname{Re} \lambda : \lambda \in \Lambda_\varepsilon(A) \},$$

where Λ_ε is the ε-pseudospectrum of A, that is, the set of all eigenvalues of matrices $A + E$ with euclidean norm $\|E\| \le \varepsilon$. For $\varepsilon = 0$ we recover $\alpha = \alpha_0$, the spectral abscissa, $\Lambda = \Lambda_0$ the spectrum of A. Our second class of nonsmooth functions is now of the form $g(x) = \alpha(\mathcal{A}(x))$ or $g(x) = \alpha_\varepsilon(\mathcal{A}(x))$, where $\mathcal{A}$ is a smooth operator defined for $x \in \mathbb{R}^n$ with values in the matrix space $\mathbb{M}_m$. Use of this function for static feedback synthesis was first proposed by Burke, Lewis, and Overton in [17, 18]. We will discuss this particular application in sections 6 and 8.1. The interest in $g = \alpha \circ \mathcal{A}$ is obviously due to the fact that $\mathcal{A}(x) \in \mathbb{M}_m$ is Hurwitz if and only if $g(x) < 0$. Notice that $g = \alpha \circ \mathcal{A}$ is smooth at x when $\alpha(\mathcal{A}(x)) = \operatorname{Re} \lambda_i(\mathcal{A}(x))$ for a single eigenvalue, where complex conjugate pairs are counted once. On the other hand, g is nonsmooth in general for multiple eigenvalues. What is worse is that neither $g = \alpha \circ \mathcal{A}$ nor $g = \alpha_\varepsilon \circ \mathcal{A}$ is locally Lipschitz function in general [17], which makes the functions somewhat delicate to handle.

Notice that function evaluation for α_ε may be based on the criss-cross method in [19], a generically globally quadratically convergent algorithm, which bears some resemblance with the Hamiltonian algorithm [12] to compute the H_∞-norm. For smooth points x, the criss-cross algorithm computes the gradient, while it still gives a subgradient of $\alpha_\varepsilon \circ \mathcal{A}$ at x if x is a nonsmooth point.

Our third example is the H_∞-norm. Notice that the stability requirement $\alpha_\varepsilon(A) < 0$ is equivalent to the estimate $\|(sI - A)^{-1}\|_\infty < \varepsilon^{-1}$. This means that α_ε could be avoided and replaced by composite functions of the H_∞-norm.

Consider the H_∞-norm of a nonzero transfer matrix function $G(s)$:

$$\|G\|_\infty \;=\; \sup_{\omega \in \mathbb{R}} \overline{\sigma}\left(G(j\omega)\right),$$

where G is stable and $\overline{\sigma}(X)$ is the maximum singular value of X. Suppose $\|G\|_\infty = \overline{\sigma}\left(G(j\omega)\right)$ is attained at some frequency ω, where the case $\omega = \infty$ is allowed. Let $G(j\omega) = U \Sigma V^{\mathrm{H}}$ be a singular value decomposition. Pick u the first column of U, v the first column of V, that is, $u = G(j\omega)v/\|G\|_\infty$. Then the linear functional

$$\begin{aligned} \phi(H) = \operatorname{Re}\left(u^{\mathrm{H}} H(j\omega) v\right) \;&=\; \|G\|_\infty^{-1} \operatorname{Re} \operatorname{Tr} v v^{\mathrm{H}} G(j\omega)^{\mathrm{H}} H(j\omega) \\ &= \|G\|_\infty^{-1} \operatorname{Re} \operatorname{Tr} G(j\omega)^{\mathrm{H}} u u^{\mathrm{H}} H(j\omega) \end{aligned}$$

is continuous on the space $\mathbf{H}_\infty$ of stable transfer functions and is a subgradient of $\|\cdot\|_\infty$ at G [13]. More generally, assume the columns of Q_u form an orthonormal basis of the eigenspace of $G(j\omega)G(j\omega)^{\mathrm{H}}$ associated with the largest eigenvalue $\lambda_1\left(G(j\omega)G(j\omega)^{\mathrm{H}}\right) = \overline{\sigma}(G(j\omega))^2$, and assume the columns of Q_v form an orthonormal

basis of the eigenspace of $G(j\omega)^H G(j\omega)$, associated with the same eigenvalue; then for every $Y_v \succeq 0$, $Y_u \succeq 0$ with $\mathrm{Tr}\,(Y_v) = 1$ and $\mathrm{Tr}\,(Y_u) = 1$,

(3)
$$\phi(H) = \|G\|_\infty^{-1}\,\mathrm{Re}\;\mathrm{Tr}\,Q_v Y_v Q_v^{\mathrm{H}} G(j\omega)^{\mathrm{H}} H(j\omega) = \|G\|_\infty^{-1}\mathrm{Re}\,\mathrm{Tr}\,G(j\omega)^{\mathrm{H}} Q_u Y_u Q_u^{\mathrm{H}} H(j\omega)$$

are subgradients of $\|\cdot\|_\infty$ at G, where Y_v and Y_u are (complex) Hermitian matrices. Finally, assume that $G(s)$ is rational, and that there exist finitely many frequencies $\omega_1, \ldots, \omega_p$ where the supremum $\|G\|_\infty = \overline{\sigma}(G(j\omega_\nu))$ is attained. Then the subgradients of $\|\cdot\|_\infty$ at G are precisely of the form

$$\phi(H) = \|G\|_\infty^{-1}\,\mathrm{Re}\;\sum_{\nu=1}^{p} \mathrm{Tr}\,G(j\omega_\nu)^{\mathrm{H}} Q_\nu Y_\nu Q_\nu^{\mathrm{H}} H(j\omega_\nu),$$

where the columns of Q_ν form an orthonormal basis of the eigenspace of $G(j\omega_\nu)$ $G(j\omega_\nu)^{\mathrm{H}}$ associated with the leading eigenvalue $\|G\|_\infty^2$, and where $Y_\nu \succeq 0$, $\sum_{\nu=1}^{p}$ $\mathrm{Tr}(Y_\nu) = 1$. See [22, Prop. 2.3.12 and Thm. 2.8.2] for this.

Suppose now we have a smooth operator $\mathcal{G}$, mapping $\mathbb{R}^n$ onto the space $\mathbf{H}_\infty$ of stable transfer functions G. Then the composite function $n(x) = \|\mathcal{G}(x)\|_\infty$ is Clarke subdifferentiable at x with

$$\partial n(x) \;=\; \mathcal{G}'(x)^\star[\partial\|\cdot\|_\infty\,(\mathcal{G}(x))],$$

where $\partial\|\cdot\|_\infty$ is the subdifferential of the H_∞-norm above. In section 6 we will compute this adjoint $\mathcal{G}'(x)^\star$ in a more specific situation. Suitable chain rules for this case are covered by [22, sect. 2.3].

3. Nonsmoothness in control. In automatic control, difficulties with computing derivatives arise frequently. This happens, for instance, when design specifications include time-domain constraints (settling-time, overshoot) and function evaluations depend on simulations or experiments. But even genuine nonsmoothness arises when criteria like the maximum eigenvalue function, the spectral abscissa, or the H_∞-norm are optimized. For a large class of problems in robust control theory, these nonsmooth criteria can be avoided since a smooth reformulation is available. The price to pay is a significant increase of the number of variables. There are situations where this becomes the major impediment to currently available optimization codes.

The situation we have in mind occurs for problems where bilinear matrix inequalities (BMIs) arise:

(4)
$$\begin{array}{ll} \text{minimize} & a^{\mathrm{T}}x + b^{\mathrm{T}}y, \quad x \in \mathbb{R}^r, \quad y \in \mathbb{R}^s \\ \text{subject to} & A_0 + \displaystyle\sum_{i=1}^{r} x_i A_i + \sum_{j=1}^{s} y_j B_j + \sum_{\ell=1}^{r}\sum_{k=1}^{s} x_\ell y_k C_{\ell k} \preceq 0, \end{array}$$

with $a \in \mathbb{R}^r$, $b \in \mathbb{R}^s$ and $A_i, B_j, C_{\ell k} \in \mathbb{S}^m$ given. Typically in (4) the decision vector splits into $x \in \mathbb{R}^r$, which gathers all free components or gains in the controller to be designed, while $y \in \mathbb{R}^s$ regroups the Lyapunov variables. All our examples discussed in section 8 may be brought to this form. In order to understand the problem better, let us discuss an application of particular importance.

3.1. Static output-feedback synthesis. It is well known that static output H_2- or H_∞-synthesis are NP-hard problems (cf. [56]), which may be cast as BMI-optimization programs. Given the plant

$$\begin{bmatrix} \dot{x} \\ z \\ y \end{bmatrix} = \begin{bmatrix} A & B_1 & B_2 \\ C_1 & D_{11} & D_{12} \\ C_2 & D_{21} & 0 \end{bmatrix} \begin{bmatrix} x \\ w \\ u \end{bmatrix}$$

with $x \in \mathbb{R}^{n_1}$, $u \in \mathbb{R}^{m_2}$, $w \in \mathbb{R}^{m_1}$, $y \in \mathbb{R}^{p_2}$, $z \in \mathbb{R}^{p_1}$, we ask for a static feedback control law $u = Ky$ such that the closed-loop system is internally stable and, moreover, a suitable operator norm of the performance channel $w \to z$ is minimized. For the H_∞-norm, the existence of such a K with the norm estimate $\|T_{w\to z}(K)\|_\infty < \gamma$ is equivalent to the existence of a Lyapunov matrix $Y \in \mathbb{S}^{n_1}$ satisfying $Y \succ 0$ and

$$\begin{bmatrix} (A+B_2KC_2)^{\mathrm{T}}Y + Y(A+B_2KC_2) & Y(B_1+B_2KD_{21}) & (C_1+D_{12}KC_2)^{\mathrm{T}} \\ * & -\gamma I & (D_{11}+D_{12}KD_{21})^{\mathrm{T}} \\ * & * & -\gamma I \end{bmatrix} \prec 0. \tag{5}$$

If we optimize the gain γ, we obtain a BMI program (4) with unknown variables $\gamma \in \mathbb{R}$, $K \in \mathbb{R}^{m_2\times p_2}$, and $Y \in \mathbb{S}^{n_1}$. We may identify $x \in \mathbb{R}^r$ with the true decision variables γ and K, so $r = 1 + m_2p_2$, while $y \in \mathbb{R}^s$ gathers the Lyapunov variables Y, so $s = n_1(n_1+1)/2$. If the system size n_1 is large, the number of Lyapunov variables is dominant. A somewhat extreme example is the Boeing 767 under flutter condition (AC10), treated in section 8, where $n_1 = 55$, while $m_2 = p_2 = 2$. Here the BMI problem has 1490 variables, while there are only 4 true decision parameters (see [47, 24] for details).

The BMI problem (4) can be handled via smooth techniques by exploiting stationarity conditions [41] or via interior-point methods [36] and [49, 48]. An alternative is to use augmented Lagrangian techniques like Mosheyev and Zibulevsky [54]; see also [45] and [65]. Their approach extends naturally to nonlinear SDPs like (4). Unfortunately, all these approaches lead to large-size optimization problems even for control problems of moderate sizes due to the presence of Lyapunov variables y. One way to partly alleviate the difficulty in the nonlinear case is to use the projection lemma [27], whenever possible, to reduce at least the number of variables in x. The new cast is then a program with LMI constraints in tandem with nonlinear equality constraints:

$$\min\left\{ c^{\mathrm{T}}y : A_0 + \sum_{i=1}^{r} y_iA_i \preceq 0,\ h(y) = 0 \right\} \tag{6}$$

where $h : \mathbb{R}^n \to \mathbb{R}^p$ represents a finite number of nonlinear equality constraints. As suggested by our notation, the projection lemma reduces the x part in (4) to size $r = 1$ (to size $r = 0$ for pure stabilization), but gives only a slight reduction of the number s of Lyapunov variables y. The additional benefit of the projection lemma is that it avoids the redundancies of the controller state-space representations. For static output-feedback stabilization (northwest $(1,1)$ block in inequality (5)), a controller-free version is as follows: A stabilizing static controller K exists if there

exist Lyapunov matrices Y_1, $Y_2 \in \mathbb{S}^{n_1}$ such that

$$\begin{aligned} \mathcal{N}_Q^{\mathrm{T}} \left(A^{\mathrm{T}} Y_1 + Y_1 A\right) \mathcal{N}_Q &\prec 0, \\ \mathcal{N}_P^{\mathrm{T}} \left(A Y_2 + Y_2 A^{\mathrm{T}}\right) \mathcal{N}_P &\prec 0, \\ \begin{bmatrix} Y_1 & I \\ I & Y_2 \end{bmatrix} \succ 0, \qquad & Y_1 Y_2 - I = 0, \end{aligned}$$

where $\mathcal{N}_P$ and $\mathcal{N}_Q$ are bases of the nullspaces of C and B^{T}, respectively. A version including H_∞-norm performance has the same form and may be found, e.g., in [59].

Different techniques have been developed to solve problems (5), (6) or problems with more general matrix inequality and equality constraints. Leibfritz and Mustafa [49, 48] use interior-point techniques in tandem with ideas from sequential quadratic programming to separate Lyapunov and true decision variables in the tangent programs. A successive SDP approach is given in [25] and an augmented Lagrangian approach in [6]. These techniques are supported by local and global convergence theory [59], but have shown some limitations:

- Our experiments have revealed size limitations to about 1500 variables [5]. This allows solving problems with up to $n_1 = 40$ states.
- The transformation of (4) into (6) is not always possible. Only a restricted and well-identified class of problems is amenable to the projection lemma. A prominent case where this is *not* possible is simultaneous stabilization, considered in section 8.

In our testing, we have compared the nonsmooth MDS method to the BMI-based methods in [5, 65] (see the corresponding column in Table 2).

4. Nonsmoothness by avoiding Lyapunov variables. For large systems, the number $s = n_1(n_1+1)/2$ of Lyapunov variables y is a serious obstacle to the BMI-optimization approach (4) or (6). It seems natural to consider alternatives where Lyapunov variables y can be avoided, so that the optimization concentrates on the true decision variables $x = (\gamma, K)$. This is possible if one accepts nonsmooth optimization programs. Here we propose to replace (5) by the following constrained program:

$$\begin{array}{ll} \text{minimize} & \|T_{w\to z}(K,s)\|_\infty \\ \text{subject to} & \alpha_\varepsilon\left(A + B_2 K C_2\right) \le 0, \\ & K \in \mathbb{R}^{m_2 \times p_2}, \end{array} \tag{7}$$

for fixed $\varepsilon \ge 0$, where the performance channel $w \to z$ is specified by the transfer function

$$\begin{gathered} T_{w\to z}(K,s) \;=\; \mathcal{C}(K)\left(sI - \mathcal{A}(K)\right)^{-1}\mathcal{B}(K) + \mathcal{D}(K), \\ \mathcal{A}(K) := A + B_2 K C_2,\; \mathcal{B}(K) := B_1 + B_2 K D_{21},\; \mathcal{C}(K) := C_1 + D_{12} K C_2, \\ \mathcal{D}(K) := D_{11} + D_{12} K D_{21}. \end{gathered} \tag{8}$$

An alternative is the constrained program

$$\begin{array}{ll} \text{minimize} & \|T_{w\to z}(K,s)\|_\infty \\ \text{subject to} & \left\|\left(sI - \mathcal{A}(K)\right)^{-1}\right\|_\infty \le \varepsilon^{-1}, \\ & K \in \mathbb{R}^{m_2 \times p_2}. \end{array} \tag{9}$$

Notice that in both programs, the controller K has to be stabilizing, or what is the same, iterates have to be feasible. This requires a feasible initial point K^0, which we compute by the unconstrained optimization program (with $\varepsilon \ge 0$ fixed):

$$\text{minimize} \quad \alpha_\varepsilon\left(A + B_2 K C_2\right), K \in \mathbb{R}^{m_2 \times p_2}. \tag{10}$$

Using (10) for static feedback control has first been proposed in [17, 19].

Remark. Notice an important difference between programs like (7), (9) and program (10), used to initialize the others. While all programs encountered are nonconvex and often exhibit multiple local minima, it is usually satisfactory to accept a local minimum of the H_∞-norm in (7), (9), because the controller K is always stabilizing. This is different in program (10), where a local minimum K is useless as long as it satisfies $\alpha(A + B_2KC_2) \geq 0$, because it does not provide a stabilizing controller. In such a case, we have to restart the algorithm. Notice, however, that this does not mean that we require the full machinery of a global optimization technique, because we are not interested in *the* global minimum of (10). A value $\alpha < 0$ is all what is wanted. □

Similar nonsmooth formulations can be obtained for various other robust control problems, such as static and fixed-order stabilization, H_2- and H_∞-synthesis problems, simultaneous (multimodel) synthesis problems, control design with fixed structure controllers, robust synthesis and synthesis problems involving scaling and multipliers, and linear parameter-varying syntheses, to cite just a few.

Some of these problems are investigated in section 8. Our experiments seem to indicate that as soon as Lyapunov variables y in (4) dominate, nonsmooth programs like (7), (9) in conjunction with nonsmooth techniques are very attractive. The MDS algorithm and more general DS or pattern search techniques, supplemented by nonsmooth techniques, are serious alternatives to BMI- or LMI-based methods. This is most promising when the number of controller variables $x = (\gamma, K)$ is small. In our experiments, small means not more than 30–35 controller variables x. This situation occurs when simple controllers for large systems are sought. For problems with high-order controllers, a pure nonsmooth approach is inevitable. This is investigated in [3].

Remark. We end this paragraph by pointing the reader to a very important feature of optimization programs (7), (9), (10), which seem to invite techniques like MDS. Namely, in MDS and other search algorithms exact function evaluations can often be avoided. All that is needed is that we be able to compare the value of the objective at the different nodes to the current best value. This is in perfect agreement with function evaluations for α_ε, λ_1 and the H_∞-norm, which are all based on iterative procedures. For instance, the bisection algorithm for the H_∞-norm [12] need not be run to completion, a premature stopping criterion can be exploited to enhance efficiency. This renders our present approach open to larger problem sizes. □

5. The MDS algorithm with nonsmooth steps. In this section we give a description of the MDS algorithm and indicate in which way a nonsmooth step may be added to cope with nonsmoothness. For an in-depth discussion of MDS in the smooth case the interested reader is referred to [66].

The MDS algorithm requires a "seed" or base point v_0 and an initial simplex S in $\mathbb{R}^n$ with vertices $v_0, v_1, \ldots, v_n$. The vertices are then relabeled so that v_0 becomes the best vertex, that is, $f(v_0) \leq f(v_i)$ for $i = 1, \ldots, n$. The initial S is chosen from one of three different shapes; see Figure 1. The scaled simplex is used when prior knowledge on the problem scaling is available, but right-angled and regular simplices are generally preferred in the absence of information. The algorithm updates the current simplex S into a new simplex S^+ by performing three types of operations, which drive the search for a better point: reflection, expansion, and contraction; see Figure 2. First vertices $v_1, \ldots, v_n$ are reflected through the current best vertex v_0 to give $r_1, \ldots, r_n$. If a reflected vertex r_i gives a better function value than v_0, the algorithm tries an expansion step. This is done by increasing the distance between v_0 and r_i for

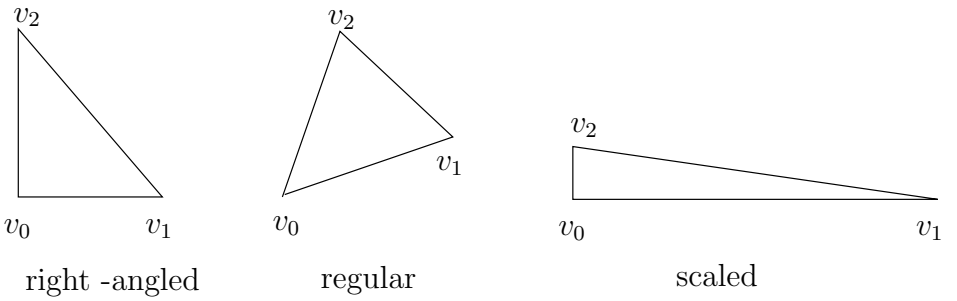

FIG. 1. *Selection of initial simplex.*

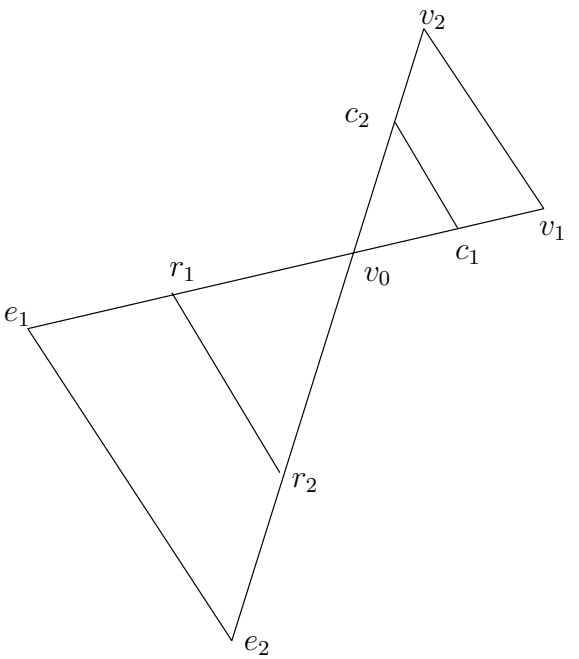

FIG. 2. *Reflection, expansion, and contraction of current simplex.*

$i = 1, \ldots, n$ and yields new expansion vertices e_i for $i = 1, \ldots, n$. The current simplex S is then replaced by either $S^+ = \{v_0, r_1, \ldots, r_n\}$ or $S^+ = \{v_0, e_1, \ldots, e_n\}$, depending on whether the best point was among the reflection or expansion vertices. If neither reflection nor expansion provide a point better than v_0, a contraction step is performed. This is done by decreasing the distances from v_0 to $v_1, \ldots, v_n$. If a point better than v_0 is found among the contraction vertices $c_1, \ldots, c_n$, the simplex S is replaced by $S^+ = \{v_0, c_1, \ldots, c_n\}$. To complete one iteration (or sweep) of the algorithm, v_0^+ is taken to be the best vertex of S^+.

In the presence of nonsmoothness, we endow the MDS algorithm with a fourth element. MDS may take a nonsmooth step w away from the current best node v_0 under consideration. In our applications, w will typically be the result of a nonsmooth descent step away from v_0, computed at the beginning of each sweep of MDS. If the sweep produces a new vertex v_0^+ better than w, MDS ignores w and keeps moving as

1. Select initial simplex $S = \{v_0, \ldots, v_n\}$, where v_0 is the best vertex. Fix an expansion factor $\mu \in (1, \infty)$ and a contraction factor $\theta \in (0, 1)$, and an intervention tolerance $\omega > 0$.
2. Given the current simplex S with best vertex v_0, call for a nonsmooth step w if the size of S is below threshold ω. If $w = v_0$ stop at critical point v_0.
3. Perform a reflection step $r_i = v_0 - (v_i - v_0)$. Compute $f(r_i)$.
4. If improvement $f(r_i) < f(v_0)$
   perform expansion step $e_i = (1 - \mu)v_0 + r_i$. Compute $f(e_i)$.
   If improvement $f(e_i) < f(v_0)$
   put $S^+ = \{v_0, e_1 \ldots, e_n\}$. Goto step 5.
   else
   put $S^+ = \{v_0, r_1 \ldots, r_n\}$. Goto step 5.
   else
   perform contraction step $c_i = (1 + \theta)v_0 - \theta r_i$. Compute $f(c_i)$. Put $S^+ = \{c_0, \ldots, c_n\}$.
5. Compare best vertex in S^+ to $f(w)$. If w is better, replace S^+ by new simplex containing w as a vertex. Otherwise accept S^+. Go back to step 2 to loop on.

FIG. 3. *MDS with nonsmooth steps.*

planned. On the other hand, if w is better than all the nodes tested by MDS during reflection, expansion, and contraction, we include w among the vertices of the new simplex S^+. In that event, we have to decide in which way the old vertices produced by MDS are recycled, or whether new nodes need to be created. This will obviously depend on geometrical properties. One possibility is to abandon the worst among the nodes of S^+ found by MDS and add the new node w as best point. If this produces angles below a certain threshold, one has to (partly) abandon S^+ and add new vertices to avoid bad geometry. In such a case, one can also build a completely new simplex with right-angled or regular geometry, using w as seed point. In our tests, we have observed that it is beneficial in such a situation to switch between the geometries (regular, right angled) in order to give MDS some additional help to move on. But all these considerations are clearly heuristic, depend on the context, and will need further testing.

In order to avoid serious slowdown of MDS, the nonsmooth step w is only solicited when the size of the simplex is below a certain threshold ω. Large S indicate that MDS is making good progress, so a costly nonsmooth step should be avoided. The situation we expect is that most of the time the point w is not better than the new best point v_0^+ of S^+ found by MDS. In that case, w plays a role similar to the Cauchy point in trust region methods. That is, it is hardly ever taken as the new iterate, but gives a convergence certificate. In our case, this will be made precise in Theorem 1. The different ways in which w may be computed will be explained subsequently. We sum up the above discussion in the pseudocode shown in Figure 3.

The following sections will show how the nonsmooth steps $v_0 \to w$ may be computed. From step 2 of the algorithm it is clear that the minimal requirement any w should satisfy is that $0 \notin \partial f(v_0)$ should give $f(w) < f(v_0)$, so when $w = v_0$, the algorithm stops with $0 \in \partial f(v_0)$.

The choice of the intervention tolerance ω should be compared to the usual stopping tests for smooth versions of MDS. Modern implementations use the relative size of the current simplex as a stopping test:

$$\frac{1}{\max(1,\ \|v_0\|)}\ \max_{1\le i\le n}\|v_i - v_0\| < \varepsilon, \tag{11}$$

where v_0 is the current best vertex of $S = \{v_0, \dots, v_n\}$ and $\varepsilon > 0$ is a prescribed tolerance. If a crisis intervention strategy is used, ω should be chosen slightly larger than the size (11). In the case of crisis prevention, an even larger ω is chosen.

The choice of the initial simplex S is a relatively unexplored topic. The convergence proof in [66] requires only that S be nondegenerate, which means that the $n+1$ points $\{v_0, v_1, \dots, v_n\}$ defining the simplex must span $\mathbb{R}^n$. Otherwise, MDS would only search over the subspace spanned by the degenerate simplex.

6. Nonsmooth stopping tests. Our first strategy is crisis intervention and uses a very small threshold ω. This means that the nonsmooth descent step $v_0 \to w$ is called for only when MDS gets stalled. What this essentially amounts to is a nonsmooth optimality test, which will either show that we are at a local minimum (or critical point) or give us a descent step $v_0 \to w$ to escape from the current point v_0, allowing MDS to move on. This strategy is preferable if nonsmooth descent steps are expensive. During the following we compute these steps for the criteria presented in section 2 and for the programs in section 4.

6.1. Maximum eigenvalue function. This case is well known. From the formula (2) of the Clarke subdifferential of $f = \lambda_1 \circ \mathcal{B}$ we see that $0 \in \partial f(x^*)$ if and only if the value t of the following semidefinite program is zero:

$$\min\{t : Q^{\mathrm{T}}[\mathcal{B}'(x^*)d]Q \preceq tI, \|d\| \le 1\}.$$

On the other hand, when the value is negative, the optimal solution (t, d) of this SDP gives the steepest descent direction d for $f = \lambda_1 \circ \mathcal{B}$ at x^*. If x^* is the current best vertex v_0 in MDS, then the nonsmooth stopping test either shows $0 \in \partial f(x^*)$ or produces w with $f(w) < f(x^*)$ of the form $w = x^* + \tau d$, where $\tau > 0$ is found by a suitable line search.

6.2. Spectral abscissa. This is a more difficult case. Consider the minimization program

$$\min_{x\in\mathbb{R}^n} g(x) = \alpha\left(\mathcal{F}(x)\right),$$

where $\mathcal{F} : \mathbb{R}^n \to \mathbb{M}_m$ is smooth. Since α is not even locally Lipschitz in general, we need a more elaborate way to obtain a stopping test.

Suppose MDS gets stalled at x^* and we want to know whether x^* is a local minimum of g or a dead point. We use the following lemma.

LEMMA 1. *Let $F \in \mathbb{M}_m$. Then $\alpha(F) \le t$ if and only if there exists $Y \in \mathbb{S}^m$, $0 \prec Y \prec I$, such that $F^{\mathrm{T}}Y + YF - 2tY \preceq 0$.* □

For a bounded set of matrices F, the condition number of Y is bounded. The inequality $Y \succ 0$ can therefore be replaced by $Y \succeq \theta I$ for a fixed small enough $\theta > 0$, uniformly over all F in that bounded set. Assume now that we have chosen an initial iterate x_0 such that $L = \{x \in \mathbb{R}^n : g(x) \le g(x_0)\}$ is bounded. Since we use a method of descent type, all our iterates x lie in L, so that the condition number of the

Lyapunov matrices Y arising at the corresponding $F = \mathcal{F}(x)$ are uniformly bounded: $\theta I \preceq Y \preceq I$ for some $0 < \theta \ll 1$. This allows us to consider the optimization program

$$\text{(P)} \qquad \begin{array}{ll} \text{minimize} & t \\ \text{subject to} & Y \succeq \theta I,\ Y \preceq I, \\ & \mathcal{F}(x)^{\mathrm{T}} Y + Y\mathcal{F}(x) - 2tY \preceq 0, \end{array}$$

with decision vector $(x, t, Y) \in \mathbb{R}^n \times \mathbb{R} \times \mathbb{S}^m$. Let $x^* \in L$. Define $F^* = \mathcal{F}(x^*)$ and $t^* = \alpha(F^*)$. Correspondingly, compute Y^* with $\theta I \preceq Y^* \preceq I$ such that $F^{*T}Y^* + Y^*F^* - 2t^*Y^* \preceq 0$. As a consequence of Lemma 1 we have the following proposition.

PROPOSITION 1. *$x^* \in L$ is a local minimum of $g = \alpha \circ \mathcal{F}$ if and only if (x^*, t^*, Y^*) is a local minimum of program* (P). □

In order to decide whether the latter is the case, we use a general result from [9]. Define $f(x, t, Y) = t$ and

$$\mathcal{G}(x,t,Y) = \begin{bmatrix} Y - I & 0 & 0 \\ 0 & \theta I - Y & 0 \\ 0 & 0 & \mathcal{F}(x)^{\mathrm{T}} Y + Y\mathcal{F}(x) - 2tY \end{bmatrix}. \tag{12}$$

Then (P) is equivalent to the abstract program

$$\min f(x,t,Y) \ \text{ subject to } \ \mathcal{G}(x,t,Y) \in \mathbb{S}^{3m}_{-}.$$

Assume that Robinson's constraint qualification [9] is satisfied for this program. Then if (x^*, t^*, Y^*) is a local minimum, the tangent program

$$\begin{array}{ll} \text{minimize} & f'(x^*,t^*,Y^*)^{\mathrm{T}}(\delta x, \delta t, \delta Y) \\ \text{subject to} & \mathcal{G}'(x^*,t^*,Y^*)(\delta x, \delta t, \delta Y) \in T(\mathbb{S}^{3m}_{-}, \mathcal{G}(x^*,t^*,Y^*)) \end{array} \tag{13}$$

has the unique solution $(\delta x, \delta t, \delta Y) = (0, 0, 0)$. Here $T(\mathbb{S}^{3m}_{-}, G)$ is the Clarke tangent cone, which according to [9] is $T(\mathbb{S}^{3m}_{-}, G) = \{Z \in \mathbb{S}^{3m} : Q^{\mathrm{T}} Z Q \preceq 0\}$ if $\lambda_1(G) = 0$, where the columns of the matrix Q are an orthonormal basis of the eigenspace of G associated with the maximum eigenvalue $\lambda_1(G) = 0$, while $T(\mathbb{S}^{3m}_{-}, G) = \mathbb{S}^{3m}$ if $\lambda_1(G) < 0$, $T(\mathbb{S}^{3m}_{-}, G) = \emptyset$ if $\lambda_1(G) > 0$.

It turns out that optimality of $(0, 0, 0)$ in (13) is a condition which may be checked by solving an SDP. Indeed, observe that

$$f'(x^*,t^*,Y^*)^{\mathrm{T}}(\delta x, \delta t, \delta Y) = \delta t$$

and

$$\mathcal{G}'(x^*,t^*,Y^*)(\delta x, \delta t, \delta Y) \ = \ \begin{bmatrix} \delta Y & 0 & 0 \\ 0 & -\delta Y & 0 \\ 0 & 0 & \delta Z \end{bmatrix},$$

where as before $\mathcal{G}'$ denotes the differential of the operator $\mathcal{G}$, and where we use the shorthand notation

$$\begin{aligned} Z^* &:= \mathcal{F}(x^*)^{\mathrm{T}} Y^* + Y^* \mathcal{F}(x^*) - 2t^* Y^*, \\ \delta Z &:= [\mathcal{F}'(x^*)\delta x]^{\mathrm{T}} Y^* + \mathcal{F}(x^*)^{\mathrm{T}} \delta Y + Y^* [\mathcal{F}'(x^*)\delta x] + \delta Y \mathcal{F}(x^*) - 2t^* \delta Y - 2\delta t Y^*. \end{aligned}$$

Clearly, the tangent cone in question is

$$T(\mathbb{S}^{3m}_{-}, \mathcal{G}(x^*,t^*,Y^*)) \ = \ T(\mathbb{S}^{m}_{-}, Y^* - I) \times T(\mathbb{S}^{m}_{-}, \theta I - Y^*) \times T(\mathbb{S}^{m}_{-}, Z^*),$$

so we have to compute these three tangent cones.

Let Q_1 be an orthonormal basis of the eigenspace of $Y^* - I$ associated with the eigenvalue 0, and let Q_θ be a basis of the eigenspace of $\theta I - Y^*$ associated with the eigenvalue 0. Finally, let P be a basis of the eigenspace of Z^* associated with the eigenvalue 0. Then the tangent program becomes

$$\begin{array}{ll} \text{minimize} & \delta t \\ \text{subject to} & Q_1^{\mathrm{T}} \delta Y Q_1 \preceq 0, \\ & Q_\theta^{\mathrm{T}} \delta Y Q_\theta \succeq 0, \\ & P^{\mathrm{T}} \delta Z P \preceq 0, \\ & \|\delta x\| \le 1,\ |\delta t| \le 1,\ \|\delta Y\| \le 1. \end{array} \tag{14}$$

This is an SDP in the unknown variable $(\delta x, \delta t, \delta Y)$. The decision is now as follows. If our tangent program reveals (x^*, t^*, Y^*) as a critical point, we stop and thereby accept the solution proposed by MDS. Otherwise, δx will show us the way to escape from the current point x^*. In terms of the MDS algorithm, when $x^* = v_0$, the nonsmooth descent step will be $w = x^* + \tau \delta x$ for some $\tau > 0$ found by a line search.

6.3. Stopping test for the H_∞-norm. For constrained programs like those in section 4, the situation is principally the same as in the unconstrained case. When we get stalled at some iterate K^*, we would like to know whether we have a local minimum (a KKT point), or whether we could keep making progress by avoiding a dead point.

In this section, we consider a stopping test for the nonsmooth program (9), which is based on the frequency domain representation of the H_∞-norm.

Suppose we have reached an iterate K^* such that $\|T_{w\to z}(K^*)\|_\infty = \gamma^*$ and $\|(sI - \mathcal{A}(K^*))^{-1}\|_\infty = \varepsilon^{-1}$. We want to decide whether K^* is a critical point of the program

$$\min\{\|T_{w\to z}(K)\|_\infty : \|(sI - \mathcal{A}(K))^{-1}\|_\infty \le \varepsilon^{-1}\}.$$

This may be based on a nonsmooth stationarity test, which checks whether or not $0 \in \partial n(K^*) + \mathbb{R}_+ \partial m(K^*)$, where $n(K) = \|T_{w\to z}(K)\|_\infty$, $m(K) = \max(0, \|\,(sI - \mathcal{A}(K))^{-1}\|_\infty - \varepsilon^{-1})$ (see [22, Thm. 6.1.1, Prop. 3.3.1]). We therefore need to compute the subdifferentials $\partial n(K^*)$ and $\partial m(K^*)$.

Let us start with $\partial n(K^*)$, which is more general. The subdifferential $\partial m(K^*)$ will then follow as a special case. Recall that $T_{w\to z}(K, s)$ is of the form

$$T_{w\to z}(K, s) = \mathcal{C}(K)(sI - \mathcal{A}(K))^{-1}\mathcal{B}(K) + \mathcal{D}(K),$$

where $\mathcal{A}(K)$, $\mathcal{B}(K)$, $\mathcal{C}(K)$, and $\mathcal{D}(K)$ are given in (8). Defining $\mathcal{F}(K, s) = (sI - \mathcal{A}(K))^{-1}$, we obtain the derivative $T'_{w\to z}$ of $T_{w\to z}$ at K^* as

$$\begin{aligned} T'_{w\to z}(K^*)\,\delta K(s) = {} & D_{12}\,\delta K\, C_2 \mathcal{F}(K^*, s)\mathcal{B}(K^*) \\ & + \mathcal{C}(K^*)\mathcal{F}(K^*, s)B_2\,\delta K\, C_2 \mathcal{F}(K^*, s)\mathcal{B}(K^*) \\ & + \mathcal{C}(K^*)\mathcal{F}(K^*, s)B_2\,\delta K\, D_{21} + D_{12}\,\delta K\, D_{21}. \end{aligned} \tag{15}$$

Now let $\phi = \phi_Y$ be a subgradient of $\|\cdot\|_\infty$ at $T_{w\to z}(K^*)$ of the form (3), specified by $Y \succeq 0$, $\mathrm{Tr}(Y) = 1$ and with $\|T_{w\to z}(K^*)\|_\infty$ attained at frequency ω. We wish

to compute $\Phi_Y := T'_{w\to z}(K^*)^\star \phi_Y \in \mathbb{M}_{m_2,p_2}$. The adjoint $T'_{w\to z}(K^*)^\star$ acts on ϕ_Y through

$$\begin{aligned}
&\langle T'_{w\to z}(K^*)^\star \phi_Y, \delta K\rangle \\
&\quad = \langle T'_{w\to z}(K^*)\delta K, \phi_Y\rangle \\
&\quad = \|T_{w\to z}(K^*)\|_\infty^{-1}\mathrm{Re}\,\mathrm{Tr}\,\left(T_{w\to z}(K^*,j\omega)^{\mathrm{H}} QYQ^{\mathrm{H}} T'_{w\to z}(K^*)\delta K\,(j\omega)\right) \\
&\quad = \|T_{w\to z}(K^*)\|_\infty^{-1}\mathrm{Re}\,\mathrm{Tr}\,\big[C_2\mathcal{F}(K^*,j\omega)\mathcal{B}(K^*)T_{w\to z}(K^*,j\omega)^{\mathrm{H}} QYQ^{\mathrm{H}} D_{12} \\
&\qquad + C_2\mathcal{F}(K^*,j\omega)\mathcal{B}(K^*)T_{w\to z}(K^*,j\omega)^{\mathrm{H}} QYQ^{\mathrm{H}}\mathcal{C}(K^*)\mathcal{F}(K^*,j\omega)B_2 \\
&\qquad + D_{21}T_{w\to z}(K^*,j\omega)^{\mathrm{H}} QYQ^{\mathrm{H}}\mathcal{C}(K^*)\mathcal{F}(K^*,j\omega)B_2 \\
&\qquad + \ D_{21}T_{w\to z}(K^*,j\omega)^{\mathrm{H}} QYQ^{\mathrm{H}} D_{12}\,\big]\,\delta K.
\end{aligned}$$

In consequence, the Clarke subgradients of $n = \|\cdot\|_\infty \circ T_{w\to z}$ at K^* are of the form

$$\begin{aligned}
\Phi_Y = \|T_{w\to z}(K^*)\|_\infty^{-1}\mathrm{Re}\,&\big[C_2\mathcal{F}(K^*,j\omega)\mathcal{B}(K^*)T_{w\to z}(K^*,j\omega)^{\mathrm{H}} QYQ^{\mathrm{H}} D_{12} \\
&+ C_2\mathcal{F}(K^*,j\omega)\mathcal{B}(K^*)T_{w\to z}(K^*,j\omega)^{\mathrm{H}} QYQ^{\mathrm{H}}\mathcal{C}(K^*)\mathcal{F}(K^*,j\omega)B_2 \\
&+ D_{21}T_{w\to z}(K^*,j\omega)^{\mathrm{H}} QYQ^{\mathrm{H}}\mathcal{C}(K^*)\mathcal{F}(K^*,j\omega)B_2 \\
&+ D_{21}T_{w\to z}(K^*,j\omega)^{\mathrm{H}} QYQ^{\mathrm{H}} D_{12}\big]^{\mathrm{T}},
\end{aligned}$$

or more simply,

$$\Phi_Y = \|T_{w\to z}(K^*)\|_\infty^{-1}\mathrm{Re}\,\left\{G_{21}(K^*,j\omega)\,T_{w\to z}(K^*,j\omega)^{\mathrm{H}} QYQ^{\mathrm{H}} G_{12}(K^*,j\omega)\right\}^{\mathrm{T}},$$

where

$$\begin{aligned}
G_{21}(K^*,j\omega) &:= C_2\mathcal{F}(K^*,j\omega)\mathcal{B}(K^*) + D_{21}, \\
G_{12}(K^*,j\omega) &:= \mathcal{C}(K^*)\mathcal{F}(K^*,j\omega)B_2 + D_{12}.
\end{aligned}$$

The subdifferential of the function $m(.)$ is obtained through similar calculations. We first note that up to a constant term, the second component of $m(.)$ is $\|\mathcal{F}(K)\|_\infty$, a simplification of $T_{w\to z}(K)$ with $\mathcal{C}(K) = I$, $\mathcal{B}(K) = I$, and $\mathcal{D}(K) = 0$. Assuming this time that the supremum is attained at frequency ω', the Clarke subgradients of $\|\mathcal{F}(K)\|_\infty$ at K^* are of the form

$$\Psi_{\widehat{Y}} := \|\mathcal{F}(K^*)\|_\infty^{-1}\mathrm{Re}\,\left\{C_2\mathcal{F}(K^*,j\omega')\mathcal{F}(K^*,j\omega')^{\mathrm{H}}\widehat{Q}\widehat{Y}\widehat{Q}^{\mathrm{H}}\mathcal{F}(K^*,j\omega')B_2\right\}^{\mathrm{T}},$$

with $\widehat{Y} \succeq 0$, $\mathrm{Tr}\,(\widehat{Y}) = 1$. Since both components of the max function $m(\cdot)$ are active at K^*, the subdifferential of m at K^* is the convex hull of the origin with the subdifferential of $\|\mathcal{F}(K)\|_\infty$ at K^* [22]. Those subgradients are therefore of the form $\Psi_{\widehat{Y}}$, $\widehat{Y} \succeq 0$, and $\mathrm{Tr}\,(\widehat{Y}) \le 1$. These formulae are easily adapted if the first H_∞-norm is attained at frequencies $\omega_1, \ldots, \omega_p$, and the second at $\omega'_1, \ldots, \omega'_q$.

Suppose $\|T_{w\to z}(K^*)\|_\infty$ is attained at a single ω, and $\|\mathcal{F}(K^*)\|_\infty$ at a single ω'. Then the optimality test leads to solving the optimization program

$$\min\{\|\Phi_Y + \Psi_{\widehat{Y}}\|_2 : Y \succeq 0, \mathrm{Tr}\,(Y) = 1, \widehat{Y} \succeq 0\,\}$$

which is a low-dimensional SDP. If the value of this program is 0, then K^* is a critical point.

7. Crisis prevention. The nonsmooth stopping tests developed in the previous section could be adapted to many other programs. We should be aware, however, that the steps $v_0 \to w$ they generate are steepest descent steps, which cannot guarantee convergence under nonsmoothness (see [50] for a discussion). Put differently, even though the stopping test may allow us to move on, we have no guarantee that an accumulation point of the sequence so generated would not be another dead point. In order to exclude this categorically, a more sophisticated strategy, crisis prevention, is required. Here we get a convergence certificate, which is built on the possibility to *quantify* descent.

A well-known tool of convex nonsmooth analysis which allows us to quantify descent is ε-subgradients (see [35, Thm. 1.1.5]). Since our present criteria are nonconvex, those may not be used directly and some modifications are required (see [57, 58]). But the idea is essentially the same.

7.1. Quantitative descent for $f = \lambda_1 \circ \mathcal{B}$. To begin with, let us examine a strategy suited for eigenvalue optimization, used in the simultaneous stabilization problem section 8.3. We consider a nonconvex maximum eigenvalue function of the form

$$f(x) = \lambda_1 \left(\mathcal{B}(x)\right) \tag{16}$$

with a bilinear (or more generally $\mathcal{C}^2$) operator $\mathcal{B}$. We solve the unconstrained optimization problem:

$$\text{minimize} \quad f(x) = \lambda_1 \left(\mathcal{B}(x)\right), \ x \in \mathbb{R}^n.$$

We follow [57, 58], which extends previous work by Cullum, Donath, and Wolfe [23] and Oustry [60], where affine operators were used, to more general functions $f = \lambda_1 \circ \mathcal{B}$. We use an approximation $\delta_\varepsilon f(x)$ of the ε-subdifferential $\partial_\varepsilon f(x)$ of f at the current x, called the *ε-enlarged subdifferential.* We compute the approximate subgradient $g \in \delta_\varepsilon f(x)$, which gives rise to the so-called *steepest ε-enlarged descent direction.* Let us define

$$\delta_\varepsilon f(x) \ = \ \left\{ \mathcal{B}'(x)^\star Z : Z = Q_\varepsilon Y Q_\varepsilon^{\mathrm{T}}, \ Y \succeq 0, \ \mathrm{tr}(Y) = 1, \ Y \in \mathbb{S}^{r(\varepsilon)} \right\},$$

where the first $r(\varepsilon)$ eigenvalues of $\mathcal{B}(x) \in \mathbb{S}^m$ are those which satisfy $\lambda_i > \lambda_1 - \varepsilon$, and where the columns of the $r(\varepsilon) \times m$-matrix Q_ε form an orthonormal basis of the invariant subspace associated with these eigenvalues. Then

$$\partial f(x) \subset \delta_\varepsilon f(x) \subset \partial_\varepsilon f(x),$$

and $\delta_\varepsilon f(x)$ is an inner approximation of $\partial_\varepsilon f(x)$, which has the advantage of being computable. Namely, the direction of steepest ε-enlarged descent d is obtained as

$$d = -\frac{g}{\|g\|}, \quad g = \mathrm{argmin} \left\{ \|g\| : g \in \delta_\varepsilon f(x) \right\}. \tag{17}$$

The solution g of (17) is the projection of the origin onto the compact convex set $\delta_\varepsilon f(x)$. This is in complete analogy with the direction of steepest descent, which is obtained by projecting the origin onto the subdifferential $\partial f(x) = \delta_0 f(x)$. What would be the most useful is the direction of steepest ε-descent, obtained by projecting 0 onto $\partial_\varepsilon f(x)$, but this quantity is difficult to compute (see, however, [35] for some ideas how this may be tried).

1. Given iterate x, stop if $0 \in \partial f(x) = \delta_0 f(x)$, because x is a critical point. Otherwise choose $\varepsilon > 0$.
2. Given $\varepsilon > 0$, compute the direction d of steepest ε-enlarged descent by solving (19). Let (t, d) be the solution.
3. If $d = 0$ (and hence $t = 0$), then $0 \in \delta_\varepsilon f(x)$. Decrease ε and go back to step 2.
4. If $d \neq 0$, then $0 \notin \delta_\varepsilon f(x)$ and we obtain $x^+ = x + \tau d$ with $f(x^+) < f(x)$ using a line search like in [57]. Let $w = x^+$ be the intervention step for MDS and quit.

FIG. 4. *Quantified descent $v_0 \to w$ for $f = \lambda_1 \circ \mathcal{B}$.*

Contrary to $\partial_\varepsilon f(x)$, the support function of the compact convex set $\delta_\varepsilon f(x)$ is known explicitly. We have (cf. [23, 60, 57])

$$\tilde{f}'_\varepsilon(x; d) \;:=\; \max\{g^{\mathrm{T}} d : g \in \delta_\varepsilon f(x)\} \;=\; \lambda_1\left(Q_\varepsilon^{\mathrm{T}}\,[\mathcal{B}'(x)d]\,Q_\varepsilon\right),$$

where $\tilde{f}'_\varepsilon(x; d)$ is the directional derivative considered in [23, 60]. Therefore, the direction of steepest ε-enlarged descent is found by solving the program

$$\min_{\|d\| \le 1} \lambda_1\left(Q_\varepsilon^{\mathrm{T}}\,[\mathcal{B}'(x)d]\,Q_\varepsilon\right), \tag{18}$$

and the solution $\mathbf{d} = -g/\|g\|$ satisfies

$$-\|g\| = -\mathrm{dist}\,(0, \delta_\varepsilon f(x)) = \tilde{f}'_\varepsilon(x; d) < 0.$$

Notice that (18) is equivalent to the SDP

$$\begin{array}{ll} \text{minimize} & t \\ \text{subject to} & Q_\varepsilon^{\mathrm{T}}\,[\mathcal{B}'(x)d]\,Q_\varepsilon \preceq tI, \\ & \|d\| \le 1. \end{array} \tag{19}$$

A descent direction d for $f = \lambda_1 \circ \mathcal{B}$ at x is therefore found as soon as the value of (19) is negative, and the corresponding d gives even a quantifiable descent in the sense of Theorem 1 below. The appealing feature of this method is that the size of the LMI in (18) and (19) is $r(\varepsilon)$, which is usually small. An important consequence is that it can be solved very cheaply if a dual SDP formulation is used. Altogether we have the crisis prevention method shown in Figure 4.

The possible decrease $f(x^+) < f(x)$ is quantified by the following result, whose proof is given in [57] for a spectral bundle algorithm which generates descent steps as above. Since the convergence properties of the nonsmooth MDS method hinge on the properties of the sequence of Cauchy points w, the result carries over to our present situation.

THEOREM 1. *Consider the minimization of $f = \lambda_1 \circ \mathcal{B}$. Suppose x^0 is such that $\{x \in \mathbb{R}^n : f(x) \le f(x^0)\}$ is compact. Let the sequence x^k with starting point x^0 be generated by the MDS method with nonsmooth descent step. Suppose at stage k the parameter ε_k is chosen according to the ε-management of* [57, 58]. *Then there exists a constant $C > 0$ such that the nonsmooth MDS method achieves a decrease of at least $f(x^{k+1}) - f(x^k) \le -C\,\Delta_{\varepsilon_k}\,|\tilde{f}'_{\varepsilon_k}(x^k; d^k)|^2$, where d^k is the direction of steepest ε_k-enlarged descent at x^k and $\Delta_{\varepsilon_k} = \lambda_{r(\varepsilon_k)} - \lambda_{r(\varepsilon_k)+1}$. Moreover, some subsequence of x^k converges to a critical point of f.* ∎

7.2. Quantifiable descent for $g = \alpha \circ \mathcal{F}$. In this section we discuss the difficult case of the spectral abscissa. Due to its highly nonsmooth character, quantified decrease for $g = \alpha \circ \mathcal{F}$ is more difficult to guarantee than for $f = \lambda_1 \circ \mathcal{B}$.

Let us again take recourse to the SDP formulation of α. Suppose $g(x^*) = \alpha(\mathcal{F}(x^*)) = t^*$. We wish to decrease the value of g in a neighborhood U of x^*. Following Lemma 1, for fixed $0 < \theta \ll 1$, there exists $Y^* \in [\theta I, I]$ such that $\lambda_1(\mathcal{B}(x^*, Y^*, t^*)) = 0$, where we define $\mathcal{B}(x, Y, t) := \mathcal{F}(x)^{\mathrm{T}} Y + Y\mathcal{F}(x) - 2tY \preceq 0$. Finding Y^* amounts to solving an SDP. Now let us introduce

$$\widetilde{\mathcal{B}}(x, Y, t) = \begin{bmatrix} Y - I & 0 & 0 \\ 0 & \theta I - Y & 0 \\ 0 & 0 & \mathcal{B}(x, Y, t) \end{bmatrix}.$$

Then decreasing the value $g(x) = t$ below t^* is equivalent to decreasing the value t of the program

$$\begin{array}{ll} \text{minimize} & t \\ \text{subject to} & \widetilde{\mathcal{B}}(x, Y, t) \preceq 0 \end{array}$$

below t^*. We obtain such a decrease $t < t^*$ using Kiwiel's progress function [43], which in our situation may be written as

$$\kappa(x, Y, t; t^*) = \lambda_1 \begin{bmatrix} t - t^* & 0 \\ 0 & \widetilde{\mathcal{B}}(x, Y, t) \end{bmatrix} =: \lambda_1 \left(\widehat{\mathcal{B}}(x, Y, t; t^*) \right).$$

We have the following.

LEMMA 2. *Suppose $g(x^*) = \alpha(\mathcal{F}(x^*)) = t^*$. Then decrease $t = g(x) < g(x^*) = t^*$ is achieved for some x in a neighborhood U of x^* if and only if $\kappa(x, Y, t; t^*) < 0$ for suitable Y.* ∎

What we are interested in is quantified decrease in the same sense as used before, so we use the ε-enlarged subdifferential $\delta_\varepsilon \kappa$ of the maximum eigenvalue function $\kappa = \lambda_1 \circ \widehat{\mathcal{B}}$. The procedure, whose convergence theory is covered by [57], is shown in Figure 5.

Notice that the costly part here is computing Y^*. The second SDP in step 3 is of small size, since the corresponding LMI is in the space of $r(\varepsilon) \times r(\varepsilon)$ matrices. Repeating this step to identify a suitable ε is therefore not expensive. This has the interesting feature that as long as ε-steepest descent steps are taken, the large SDP need not be solved at all. This makes a pure nonsmooth descent method seem attractive. Such an approach is developed in [32] for large SDPs arising as relaxations of integer programs. Similar to that reference, solving the SDP dual of (7.2) is more efficient. Finally, we stress that extending the quantified descent step for the spectral abscissa to a broader class of problems like those in (4) is straightforward and left to the reader.

Remark. As soon as search directions based on the ε-enlarged subdifferential are used, a good choice of ε is required. Based on extensive numerical testing, we have used a very small $\varepsilon = 1e{-}9$ for stopping tests, while good progress in a descent step seems to ask for moderate values $\varepsilon \in [0.01\,; 0.1]$. This is what has been used in section 8.

8. Numerical experiments. In this section, we test the MDS algorithm with nonsmooth descent steps on a wide range of synthesis problems from the literature.

1. Given $g(x^*) = \alpha\left(\mathcal{F}(x^*)\right) = t^*$, quit if the stopping test (14) indicates a critical point. Otherwise:
2. Solve an SDP to compute Y^* such that $\lambda_1\left(\mathcal{B}(x^*, Y^*, t^*)\right) = 0$. Choose $\varepsilon > 0$.
3. Given $\varepsilon > 0$, compute $d = (\delta x, \delta Y, \delta t)$, the direction of steepest ε-enlarged descent of $\kappa(\cdot,\cdot,\cdot; t^*)$ at the point (x^*, Y^*, t^*) by solving the SDP:

$$\begin{aligned} &\text{minimize} && \rho \\ &\text{subject to} && \widehat{Q}_\varepsilon^{\mathrm{T}}\left[\widehat{\mathcal{B}}'(x^*, Y^*, t^*; t^*)\, d\right]\widehat{Q}_\varepsilon \preceq \rho I, \\ &&& \|\delta x\| \le 1,\ \|\delta Y\| \le 1,\ |\delta t| \le 1. \end{aligned}$$

   Here the $r(\varepsilon)$ columns of $\widehat{Q}_\varepsilon$ are an orthonormal basis of the invariant subspace of $\widehat{\mathcal{B}}(x^*, Y^*, t^*; t^*)$ associated with its ε-largest eigenvalues. Let $d = (\delta x, \delta Y, \delta t)$ be the solution.
4. If $d = 0$, then $0 \in \delta_\varepsilon \kappa(x^*, Y^*, t^*; t^*)$. Decrease ε and go back to step 3.
6. Having found $d \neq 0$, decrease the value of κ using a line search as in [57]. The corresponding step $x^+ = x^* + \tau\delta x$ decreases g accordingly. Let $w = x^+$ be the intervention step for MDS, and quit.

FIG. 5. *Quantified descent step $v_0 \to w$ for $g = \alpha \circ \mathcal{F}$.*

Computations were performed on a (low-level) SUN-Blade Sparc with 256 RAM and a 650 MHz sparcv9 processor. LMI-related computations needed for nonsmooth descent steps were performed using either the LMI Control Toolbox [28] or our homemade SDP code [5]. The contraction and expansion parameters were set to $\theta = 0.5$ and $\mu = 2.0$ throughout.

8.1. Static output-feedback stabilization. We start with static output-feedback stabilization without any performance specification. Solving (10) is a pure feasibility problem and somewhat simpler than the problems examined in what follows. It is used to initialize the constrained problem (9).

In our implementation, the MDS code was stopped as soon as a strictly negative spectral abscissa was obtained. Restarts were used as soon as the nonsmooth optimality test indicated a local minimum $\bar{x}$ of $g = \alpha \circ \mathcal{F}$ with positive value $g(\bar{x}) > 0$. We also encountered dead points, where the nonsmooth stopping test indicated a way to move on. What helps in this case is to restart MDS with the new seed proposed by the spectral bundling step, and change the geometry of the simplex. In all tests, the initial seed point was chosen to be the origin of the variable space. The vertices of the initial S are then relabeled so that v_0 is the best vertex. Contrary to what might seem plausible, MDS frequently encounters dead points and fails when run in default mode without nonsmooth steps. We discuss some of these at the end of this section.

As emphasized in the introductory section, the nonsmooth MDS is fairly insensitive to the number of states, since Lyapunov variables are not involved. A striking example is the Boeing 767 flutter problem (AC10), which our algorithm solved in 0.41-s cpu, starting from the initial point $K = 0$. This indicates that this problem is not as difficult as the size would suggest. (In fact, some of our smaller problems turned out more difficult.) The nonsmooth MDS technique appears surprisingly efficient compared to the gradient sampling algorithm proposed in [18], which for this problem required hours of cpu time and several hundreds of restarts. This example is

TABLE 1
Static output-feedback stabilization right-angled simplex.

Problem	(n, m, p)	Iteration	cpu (s)	Reference

AC10	$(55, 2, 2)$	3	0.41	[47]
HF1	$(130, 1, 2)$	Stable	–	[47]

also included in the library [47] and has been solved by the technique of [49, 48].

Example. Let us illustrate a typical difficulty related to nonsmoothness of the spectral abscissa, when MDS stops at an iterate K^* where several eigenvalues of the closed-loop spectrum are active. This happens, e.g., in Horisberger's example with seed point at the origin and with the regular simplex geometry. When nonsmooth descent is switched off, MDS eventually hits such a nonsmooth iterate and starts contracting the simplex. This yields the static (nonstabilizing) gain

$$K = [\,-5.9176e{-}01 \quad 7.1864e{+}00 \quad -3.1396e{+}01 \quad 3.5870e{+}01\,],$$

with closed-loop spectrum

$$\Lambda(A + B_2KC_2) = \begin{cases} -6.6646e{-}01 \pm 6.2303e{+}01j \\ -3.9851e{+}00 \pm 1.8336e{+}01j \\ -7.8086e{+}00 \pm 4.0906e{+}00j \\ 5.4005e{-}01 \pm 8.3040e{-}01j \\ 5.4005e{-}01 \end{cases}.$$

The question is now whether we are at a dead point or at a local minimum. If the technique discussed in section 6 is switched on, a nonsmooth descent step $v_0 \to w$ is performed, which reduces the spectral abscissa from $5.4005e{-}01$ to $5.183e{-}01$. This is followed by a number of reflection/expansion/contraction steps of MDS, yielding the iterate

$$K = [\,-2.0595e-01 \quad 6.4949e+00 \quad -3.1503e+01 \quad 3.6173e{+}01\,]$$

with closed-loop spectrum

$$\Lambda(A + B_2KC_2) = \begin{cases} -6.7523e{-}01 \pm 6.2320e{+}01j \\ -4.1595e{+}00 \pm 1.8393e{+}01j \\ -7.5240e{+}00 \pm 4.9624e{+}00j \\ 4.7250e{-}01 \pm 3.8239e{-}01j \\ 4.7250e{-}01 \end{cases}.$$

The nonsmooth stopping test now clearly identifies this as a local minimum (a critical point), since no descent direction exists. At this stage a restart of MDS is inevitable, because $\alpha(A + B_2KC_2) = 4.7250e{-}01 > 0$.

Our testing has shown that the following simple trick is successful when a restart is due. We keep the current best point but switch geometries, for instance from regular to right-angled or vice versa. In the example, we switched from regular to right-angled

simplices, which generated different search directions. MDS was now successful and reached a stabilizing gain:

$$K = [\,3.1794e{+}01 \quad 6.4949e{+}00 \quad 4.3250e{+}02 \quad 5.1173e{+}01\,],$$

with corresponding spectral abscissa $\alpha(A + B_2KC_2) = -4.1442e{-}01 < 0$. ∎

8.2. Static and fixed-order output-feedback H_∞-synthesis. This section reports experiments with static and fixed-order output-feedback H_∞-synthesis. The out-set is from section 3, the extension to fixed-order problems is standard [6]. We solve program (9), using the corresponding controllers K^0 computed via (10) as initial value.

Results achieved with nonsmooth MDS are based on the infinite barrier

$$B(K) = \begin{cases} \|T_{w\to z}(s,K)\|_\infty & \text{if } \alpha(A + B_2KC_2) \le -\tau, \\ +\infty & \text{otherwise,} \end{cases} \tag{20}$$

where $\tau > 0$ is some small fixed threshold. The infinite barrier function works surprisingly well with the MDS technique, as also witnessed by [10] in different contexts. Function evaluation for the H_∞-norm is based on the efficient bisection algorithm in [12]. See also the MATLAB implementation described in [26]. A catalog of results is displayed in Table 2. The H_∞ performance achieved with the MDS method "H_∞ MDS" as well as with the spectral quadratic SDP method "H_∞ AL" in [5] are described. For completeness, in column "H_∞ full" the performance of the full-order H_∞ controller (computed by LMIs or algebraic Riccati equations) is shown and gives a lower bound for the H_∞-gain.

TABLE 2
Static and fixed-order H_∞-synthesis with MDS algorithm best results with right-angled and regular simplices stopping tolerance $\varepsilon = 1e{-}9$.

Problem	Order	Iteration	cpu (s)	H_∞ MDS	H_∞ AL	H_∞ full
Transport airplane	Static	37	20	2.34	2.22	1.60
VTOL helicopter	Static	10	2.69	0.190	0.157	0.096
Chemical reactor	Static	38	16.96	1.183	1.202	1.141
Piezoelectric actuator	Static	112	8.62	$1.76e{-}4$	$3.05e{-}3$	$9.63e{-}5$
AC10	Static	72	612	14.22	Intractable	0.052
HF1	Static	11	1100	0.447	Intractable	0.449

The choice of the simplex geometry, right-angled or regular, may influence the computed solution. Contrary to what might be guessed, the regular geometry is not always better than the right-angled geometry. We have therefore decided to test both and report the best result. This is reasonably affordable with regard to cpu time, as seen in Table 2 even for high-order systems. The initial seed point was the origin in all examples. As already discussed in [5], the augmented Lagrangian (AL) technique is no longer operational for systems with roughly more than 40 states. Again, we would like to stress the good results obtained with the MDS method for the Boeing 767 problem (AC10). Actually, the projective SDP code of MATLAB ran into difficulties to solve the LMI problem corresponding to the (convex) full-order problem and diagnosed the problem as infeasible after more than 4 hours of execution time in default mode.

The computed static controller obtained by the MDS method for the Boeing 767 flutter problems (AC10) is

$$K_{\text{static}} = \begin{bmatrix} -0.0966 & 0.0000 \\ 3.1681 & 0.0000 \end{bmatrix}.$$

The large-size HF1 problem is taken from the library [47]. It does not require prior stabilization as the plant is open-loop stable. Hence, $K = 0$ may serve as a starting point for the H_∞-optimization in Table 2. Here the static gain $K = [\,1.9943 \quad -3.4943\,]$ is found.

8.3. Simultaneous stabilization problems. Simultaneous stabilization is a longstanding problem in the automatic control literature. It consists in the search of a single controller which stabilizes a finite set of plants. This is of great practical interest in different situations. A system may have several modes of operation, but the controller is required to stabilize all modes. A more challenging situation is when the system may be subject to different failures such as actuator/detector breakdown, which often result in drastic deviations of the plant from its nominal description. The controller is then required to stabilize normal and abnormal operating modes. Unfortunately, the simultaneous stabilization problem has no analytical solution for more than two plants and is classified as NP-hard [8]. Existing techniques usually try to verify sufficient conditions. If successful, this leads to high-order controllers. Our experiments indicate that local optimization techniques and in particular DS methods may be of interest for designing simpler controllers, which is crucial for applications.

For single-input single-output systems $\{G_i(s),\, i = 1, \ldots, q\}$, the simultaneous stabilization problem can be formulated as follows:

- find a controller with transfer function

$$K(s,x) = \frac{N_K(s,x)}{D_K(s,x)} = \frac{x_1 s^m + \cdots + x_m s + x_{m+1}}{s^n + x_{m+2}s^{n-1} + \cdots + x_{m+n}s + x_{m+n+1}}, \tag{21}$$

  where as before $x := [x_1 \cdots x_{m+n+1}]^{\mathrm{T}}$ gathers the decision variables,
- such that the closed-loop characteristic polynomials

$$p_i(s,x) := N_{G_i}(s)N_K(s,x) + D_{G_i}(s)D_K(s,x)$$

  have only stable roots for $i = 1, \ldots, q$.

This may be addressed by the optimization program

$$\underset{x \in \mathbb{R}^{m+n+1}}{\text{minimize}} \; \max_{i=1,\ldots,q} \; \mathrm{Re}\,(\text{roots of } p_i(s,x)) \tag{22}$$

and a simultaneous stabilizing controller is found as soon as the value of this program is < 0. Program (22) resembles the static stabilization formulation discussed in section 8.1 and we follow a similar line of attack.

A challenging variant of this problem is the strong stabilization problem, where the controller itself is required to be stable. This is incorporated into the cast (22) by just adding $D_K(s,x)$ to the family of plant polynomials.

TABLE 3
*Simultaneous stabilization with MDS right-angled simplex * strong stabilization problem.*

Problem	Order	Iteration	cpu (s)	Restart	Reference
F4e aircraft	Static	2	0.71	None	[2]
cao	Static	13	0.28	None	[20]
cao	1	1	0.25	3	[20]
henrion	1	2	0.51	None	[34]
bredemann1*	1	6	2.05	3	[16, p. 68]
bredemann2*	1	3	0.82	3	[15]

In this testing, the nonsmooth MDS was again successful on a list of applications from the literature. Restarts have been used with a different initial seed point when an unsatisfactory local minimum was encountered. Often we obtained simpler controllers than those previously published and derived from constructive sufficient conditions. For example, the method in [16] yields a fifth-order controller for example bredemann1, whereas the MDS technique was able to show that first-order strong simultaneous stabilization is possible. A similar comment applies to example bredemann2.

An alternative cast for simultaneous stabilization is via Hermite–Fujiwara matrices. In this setting, the nonsmooth program (22) reduces to a finite set of quadratic matrix inequality constraints [33]:

$$\mathcal{H}(x) := \sum_{i=1}^{m+n+1} \sum_{j=i}^{m+n+1} x_i x_j H_{ij} \prec 0,$$

where the decision vector x comprises controller parameters in (21). Here MDS is applied to the eigenvalue optimization program

$$\min_x \lambda_1 \left(\mathcal{H}(x)\right). \tag{23}$$

We apply MDS to a problem from [33], which consists in the simultaneous stabilization of four plants. Hence, x is required to be strictly feasible for four quadratic matrix inequalities of the form (23). This problem is of special interest because numerous dead points and unsatisfactory local minima were found if different seed points were used.

TABLE 4

Simultaneous stabilization using Hermite–Fujiwara BMI characterization final spectrum of quadratic SDP results with two starting points and regular simplices.

Seed	$1, 1, -1, -1$	$-1, -1, 1, 1$
Final iterate	$3.5068, 4.2139, 0.0925, 0.0925$	$-4.4420, 0.4275, 0.5059, 0.1618$
Final spectrum of quadratic SDP (23)	$-1.3846e{+}03$	$-2.2926e{+}03$
	$-1.0473e{+}03$	$-3.7468e{+}02$

	$-6.3137e{-}01$	$1.8528e{-}01$
Controller	$\dfrac{3.5068s + 4.2139}{9.2540e{-}02s + 9.2540e{-}02}$	none

Example. For the purpose of testing, MDS was first run without nonsmooth steps. Table 4 shows two scenarios with default MDS. In column 2 the nonsmooth stopping test from section 7.1 was switched on as soon as MDS got stalled. It reveals that we are at a dead point and not at a local minimum. While nonsmooth steps $v_0 \to w$ allowed MDS to move on, crisis intervention ultimately did not lead to a stabilizing controller

in this case. The procedure gets again stalled and this time achieves convergence to an infeasible local minimum. □

Example (continued). In a second testing, we examined this case more closely. As it is too late to shut the stable door after the horse has gone, we opted to used the ε-descent nonsmooth technique of section 7.1 in order to avoid failure. We call for a nonsmooth step as soon as the MDS simplex shrinks below $\omega = 0.1$ in relative size. Starting with the same initial point, the simultaneous stabilization problem is now satisfactorily solved in a few iterations: four MDS iterations and a single call for the nonsmooth intervention technique of section 7.1. The evolution of the maximum eigenvalue of the quadratic SDP in (23) as a function of the iteration index is the five-element sequence

$$\{6.5072e{+}01,\ 1.5172e{+}01,\ 5.1720e{+}00,\ 2.868e{+}00,\ -1.4778e{+}00\},$$

where the nonsmooth descent step $v_0 \to w$ corresponds to the decrease from $5.1720e{+}00$ to $2.868e{+}00$. Note that since sole stabilization is of interest, the algorithm has been stopped as soon as the maximum eigenvalue was found negative. The associated first-order controller solution is described by the transfer function

$$K(s) = \frac{4.9843s - 4.2577}{4.2783e{-}01s + 6.2861e{-}01}. \qquad \square$$

Example (continued). In our third experiment, we assess the performance of the nonsmooth descent technique alone. We no longer sample the space using MDS. Instead we follow descent steps $v_0 \to w$ proposed by the nonsmooth technique in section 7.1. This option corresponds to a pure spectral bundle method [57]. With the same starting point causing failure of the default MDS, the problem is now solved in seven calls according to the sequence

$$\{65.0718,\ 43.0862,\ 39.8725,\ 20.1852,\ 19.9853,\ 3.5719,\ 2.8877,\ -0.0228\}.$$

The resulting stabilizing controller is

$$K(s) = \frac{0.6029s + 1.115}{0.03361s + 0.1064}.$$

All controllers computed in this application have significantly different pole/zero patterns, but all stabilize the four-plant family. □

8.4. Mixed H_2/H_∞ state-feedback synthesis. Mixed H_2/H_∞-synthesis with state- or output-feedback is one of those archetype problems which cannot be simplified using the projection lemma and resist to linearizing changes of variable like [30]. What remains are special BMI techniques or algorithmic approaches like the one we propose here. The mixed H_2/H_∞ state-feedback synthesis problem is as follows. Given a synthesis state-space representation

$$\begin{cases} \dot{x} = Ax + B_{1,2}w_2 + B_{1,\infty}w_\infty + B_2u, \\ z_2 = C_{1,2}x + D_{12,2}u, \\ z_\infty = C_{1,\infty}x + D_{11,\infty}w_\infty + D_{12,\infty}u, \end{cases}$$

the goal is to compute a state-feedback control law $u = Kx$ such that

- the closed-loop system is asymptotically stable, i.e., $\alpha(A + B_2K) < 0$,
- the H_2-norm of the channel $\|T_{w_2 \to z_2}(K, s)\|_2$ is minimized subject to an H_∞-norm constraint on the channel $\|T_{w_\infty \to z_\infty}(K, s)\|_\infty \le \gamma$.

An example of this type is given in [31], and we reexamine it here using our nonsmooth MDS. We proceed as follows. First a state-feedback gain satisfying both stability and the H_∞ constraint is computed as in section 8.2. In a second phase, the H_2-norm is added and minimized, using an infinite barrier

(24)
$$B(K) = \begin{cases} \|T_{w_2\to z_2}(K,s)\|_2 & \text{if } \alpha(A+B_2K) \le -\tau \text{ and } \|T_{w_\infty\to z_\infty}(K,s)\|_\infty \le \gamma, \\ +\infty & \text{otherwise,} \end{cases}$$

now maintaining the constraints of phase 1.

With data imported from [31] and $\gamma = 2$, MDS computed a gain K in 25 MDS iterations within 11.1 s of cpu time. The solution found is

$$K = [\,1.8236,\ 2.5648e{-}01,\ -2.0453e{-}01\,]$$

with $\|T_{w_2\to z_2}(K,s)\|_2 = 7.502e{-}01$. The H_∞-norm constraint was of course active at this point. Note *en passant* that this result outperforms those achieved via the spectral augmented Lagrangian method in [65], which gave $\|T_{w_2\to z_2}(K,s)\|_2 = 0.8384$, and the successive linearization approach in [31], which found $\|T_{w_2\to z_2}(K,s)\|_2 = 0.8930$. Since this problem has multiple local minima, this fact does not imply that any one of those methods is better than any other, except perhaps for cases where a solution without optimality certificate is presented. The solution in [65] is a local minimum, and we checked optimality of our present K by adapting the nonsmooth frequency domain test for program (9) from section 6. This requires not much extra work, as the H_2-norm is smooth (see [13]). We observed that the H_∞-norm is attained at a single frequency, which seems to be rather the rule than the exception.

9. Conclusion. We have proposed a new algorithmic strategy for difficult and even NP-hard synthesis problems in automatic control, which are inaccessible via convexity methods. Our algorithm combines DS methods like Torczon's MDS with spectral bundle techniques, imported from nonsmooth optimization, in order to cope with typical nonsmooth criteria in control like the spectral abscissa, the maximum eigenvalue function, or the H_∞-norm. Our approach is a serious alternative to nonlinear programming algorithms based on bilinear matrix inequalities, as long as the number of *controller* decision variables is not too large. Since our approach avoids Lyapunov variables, it may be used to design small- or medium-size controllers even for very large systems, as witnessed by the Boeing 767 and Heat Flow (HF1) benchmark examples, systems with 55 and 130 states, respectively. As soon as the number of controller gain parameters gets sizable, the search method is often too slow, and pure nonsmooth approaches like spectral bundling perform better. How those should be organized for control applications is discussed in [3]. In a similar vein, a pure nonsmooth and frequency-domain approach for solving multidisk problems is proposed in [4]. A nonsmooth spectral bundle method for solving state-space BMI programs is developed in [64].

Our approach combines MDS with suitable nonsmooth descent steps. This gives a convergence certificate toward critical points, an important feature lacking in all the heuristic approaches proposed to date. We have observed that MDS is fairly insensitive to noise corrupting the function evaluation. This makes it particularly useful in control applications, where objective functions typically result from iterative procedures to compute the H_∞- or H_2-norm. We have noticed that in the neighborhood of nonsmooth surfaces, gradient directions behave irregularly and are often distorted and unreliable, while progress is still achievable with MDS.

In conclusion, we believe the proposed framework is very versatile and can accommodate a vast array of design problems, expanding on those discussed in this paper. Structured feedback design is near at hand, while robust control is currently under investigation.

Acknowledgment. Fruitful discussions with Adrian Lewis and Michael Overton are gratefully acknowledged.

ON THE CONTROLLABILITY OF A FRACTIONAL ORDER PARABOLIC EQUATION*

SORIN MICU† AND ENRIQUE ZUAZUA‡

Abstract. The null-controllability property of a $1-d$ parabolic equation involving a fractional power of the Laplace operator, $(-\Delta)^\alpha$, is studied. The control is a scalar time-dependent function $g=g(t)$ acting on the system through a given space-profile $f=f(x)$ on the interior of the domain. Thus, the control g determines the intensity of the space control f applied to the system, the latter being given a priori. We show that, if $\alpha \leq 1/2$ and the shape function f is, say, in L^2, no initial datum belonging to any Sobolev space of negative order may be driven to zero in any time. This is in contrast with the existing positive results for the case $\alpha > 1/2$ and, in particular, for the heat equation that corresponds to $\alpha = 1$. This negative result exhibits a new phenomenon that does not arise either for finite-dimensional systems or in the context of the heat equation.

On the contrary, if more regularity of the shape function f is assumed, then we show that there are initial data in any Sobolev space H^m that may be controlled. Once again this is precisely the opposite behavior with respect to the control properties of the heat equation in which, when increasing the regularity of the control profile, the space of controllable data decreases.

These results show that, in order for the control properties of the heat equation to be true, the dynamical system under consideration has to have a sufficiently strong smoothing effect that is critical when $\alpha = 1/2$ for the fractional powers of the Dirichlet Laplacian in $1-d$. The results we present here are, in nature and with respect to techniques of proof, similar to those on the control of the heat equation in unbounded domains in [S. Micu and E. Zuazua, *Trans. Amer. Math. Soc.*, 353 (2000), pp. 1635–1659] and [S. Micu and E. Zuazua, *Portugal. Math.*, 58 (2001), pp. 1–24].

We also discuss the hyperbolic counterpart of this problem considering a fractional order wave equation and some other models.

Key words. null controllability, parabolic equation, fractional power of the Laplace operator

1. Introduction.

It is generally considered that, due to the strong dissipative effect on the high modes, parabolic equations behave like ordinary differential equations (i.e., finite-dimensional dynamical systems) from a control theoretical point of view. This is true for instance for the heat equation concerning the problem of null controllability, i.e., that of driving solutions from a given initial configuration to equilibrium, in several respects: (a) both finite-dimensional systems and the heat equation are controllable in an arbitrarily short time; (b) the controls may be taken to be arbitrarily smooth. In this way, for instance, the heat equation in bounded domains is controllable with L^2-controls for initial data in a Sobolev space of arbitrary negative order, in an arbitrarily short time and with controls supported in an arbitrarily small

subdomain. Recently it was proved, however, that this is not true in unbounded domains (see [17] and [18]).

The object of this article is to further investigate to what extent this analogy is systematically true or whether it is related to the intrinsic properties of the heat equation.

To do this we consider the following *null-controllability problem: Given* $T > 0$ *and* $f \in L^2(0,\pi)$*, for any* $u^0 \in L^2(0,\pi)$ *find a control* $g \in L^2(0,T)$ *such that the solution* u *of the problem*

$$\begin{cases} u_t + (-\Delta)^\alpha u = g(t)f(x), & x \in (0,\pi),\ t \in (0,T), \\ u = 0, & x \in \{0,\pi\},\ t \in (0,T), \\ u(0,x) = u^0(x), & x \in (0,\pi), \end{cases} \tag{1.1}$$

satisfies

$$u(T,\,\cdot\,) = 0. \tag{1.2}$$

Here and in what follows $(-\Delta)^\alpha$ denotes the fractional power of order $\alpha > 0$ of the Dirichlet Laplacian that we shall denote by A_α. More precisely,

$$\begin{gathered} A_\alpha : D(A_\alpha) \subset L^2(\Omega) \to L^2(\Omega), \\ D(A_\alpha) = \left\{ u \in L^2(0,\pi) \,:\, u = \sum_{n\geq 1} a_n \sin(nx) \text{ and } \sum_{n\geq 1} |a_n|^2 n^{4\alpha} < \infty \right\}, \\ u(x) = \sum_{n\geq 1} a_n \sin(nx) \;\longrightarrow\; A_\alpha u(x) = \sum_{n\geq 1} a_n n^{2\alpha} \sin(nx). \end{gathered} \tag{1.3}$$

Equation (1.1) is of parabolic type for any $\alpha > 0$. In the absence of control, solutions of (1.1) decay exponentially as $t \to \infty$ in, say, L^2. When $\alpha = 1$ we recover the classical heat equation.

When $0 < \alpha < 1$, (1.1) is a model example of parabolic dynamical system with weaker diffusivity (subdiffusion). Fractional equations of diffusion type are useful models for the description of transport processes in complex systems, slower than the Brownian diffusion. The list of systems displaying such anomalous dynamic behavior is quite extensive: charge carrier transport in amorphous semiconductors, nuclear magnetic resonance diffusometry in percolative and porous media, transport on fractal geometries, diffusion of a scalar tracer in an array of convection rolls, dynamics of a bead in a polymeric network, transport in viscoelastic materials, etc. (see [16] and [12]).

The state of system (1.1) is u and the control, which acts on its right-hand side term as an external source, is given by $g(t)f(x)$, where the shape function $f = f(x)$ is given and the intensity $g = g(t)$ is at our disposal. Such types of controls are sometimes called "lumped" or "bilinear" (see, for instance, [1] and [11]).

The null-controllability problem (1.1)–(1.2) has been considered and solved in [7] for the case $\alpha > 1/2$. The proof in [7] is based on the fact that the null-control problem may be rewritten as a *problem of moments* of the following form: *Find* $g \in L^2(0,T)$ *such that*

$$\int_0^T g(t) e^{\lambda_n t} dt = \beta_n \quad \forall n \geq 1, \tag{1.4}$$

where $\beta_n = -\pi a_n/2f_n$ *depend on the Fourier coefficients* $(a_n)_{n\geq 1}$ *of the initial data to be controlled and those of the control profile* $(f_n)_{n\geq 1}$.

Here λ_n is the sequence of the (real) eigenvalues of the equation under consideration: $\lambda_n = n^{2\alpha}$.

It is by now well known—and this is the second ingredient in the proof of [7]—that if

$$\lambda_n \sim cn^{\gamma} \quad \text{as} \quad n \to \infty \tag{1.5}$$

for some $\gamma > 1$ and a positive constant $c > 0$, then (1.4) has L^2-solutions if the values β_n do not increase too much.

This result may be proved by means of a careful evaluation of the norm of a biorthogonal sequence to the family of exponentials $\{e^{\lambda_n t}\}_{n\geq 1}$ and it is related to the Müntz theorem (see [20]), guaranteeing that the family of exponentials $\{e^{\lambda_n t}\}_{n\geq 1}$ is linearly independent in $L^2(0,T)$ if and only if

$$\sum_{n=1}^{\infty} \frac{1}{|\lambda_n|} < \infty. \tag{1.6}$$

In the context of system (1.3), condition (1.5) and, implicitly, (1.6) are verified if and only if $\alpha > 1/2$.

According to this analysis, it was proved in [7] that, when $\alpha > 1/2$, and when the control profile f satisfies the condition

$$\lim_{n\to\infty} \left(\left| \int_0^{\pi} f(x) \sin(nx) dx \right| e^{\eta\lambda_n} \right) > 0 \quad \forall \eta > 0, \tag{1.7}$$

system (1.1) is null controllable in the sense above for an arbitrarily short time and with smooth time-dependent controls g.

It is important to note that, according to condition (1.7), the shape function f is not "too regular." In particular, its Fourier coefficients may not decay faster than a suitable exponential function. Obviously, one can find control profiles f with such a property in any Sobolev space $H^s(0,\pi)$ and, in particular, in $L^2(0,\pi)$.

The present paper deals with the case $\alpha \leq 1/2$. As we shall see, the behavior of the system from the control theoretical point of view is, surprisingly, the opposite one.

Concerning the growth condition (1.5) on the spectrum, the case $\alpha = 1/2$ is critical and the condition, clearly, does not hold when $0 < \alpha < 1/2$. The same can be said about the summability condition (1.6). In this sense, the situation we are dealing with is similar to that in [17] and [18], where the heat equation in the half-line and half-space was considered. Indeed, in [17] it was proved that when $\lambda_n = n$, the corresponding moment problem (1.4) has a solution only if the β_n grows very fast as n tends to infinity.[1] Since β_n is, essentially, the ratio between the Fourier coefficients of the initial data to be controlled and those of the control profile f, we concluded that no regular nontrivial initial data allow a L^2-solution of the moment problem, when the profile is not too smooth. Accordingly L^2-controls may not exist either. The same can be said about the control problem (1.1) in the whole range $0 < \alpha \leq 1/2$.

[1] Recently, the results of [17] and [18], and more precisely its consequences in the context of unique continuation, were generalized in [5] to the case of parabolic equations with a potential, by means of Carleman inequalities.

This negative result shows that the parabolic nature of the equation and the infinite velocity of propagation do not suffice to guarantee the controllability of the system. On the contrary, we see that, in order for the control properties of the heat equation to be true, very much like in the finite-dimensional theory, the underlying semigroup is required to have a very strong dissipative effect that fails when $\alpha \leq 1/2$.

To be more precise, we shall show that

- if the shape function f satisfies (1.7), no initial data in any negative Sobolev space may be controlled to zero;
- if this function is more regular, for instance, if it satisfies

$$\left| \int_0^\pi f(x) \sin(nx) dx \right| \leq e^{-\eta \lambda_n} \tag{1.8}$$

for some $\eta > T$, then there are initial data in any Sobolev space $H^m(0,\pi)$ that are null controllable in time T with L^2-controls.

As we said above, and contrary to intuition, this behavior is in opposition to the control properties of the heat equation corresponding to $\alpha = 1$.

Let us mention that the property

$$\sum_{n=1}^{\infty} \frac{1}{|\lambda_n|} > \infty \tag{1.9}$$

of the eigenvalues of the differential operator leads to a result of no spectral controllability in the case of the heat equation in multidimensional problems (see [1, Theorem IV.1.3, p. 178]). On the other hand, under hypothesis (1.9), Fattorini [6] shows that for any $T > 0$ there exist a shape function $f \in L^2(0,\pi)$ and an initial datum $u^0 \in L^2(0,\pi)$ which cannot be driven to zero in time T by means of a control of type $f(x)g(t)$. The proofs of these results are based on the fact that an entire function which vanishes at every λ_n is identically zero and are related to the methods we use in our article. However, note that, given a shape function f, we describe the space of the initial data which cannot be controlled to zero in finite time.

It is also interesting to compare the results we obtain in this paper with those that one could expect from the application of the methodology in the articles by Lebeau and Robbiano [13] and Lebeau and Zuazua [14]. In [13] and [14] an iterative method was developed to prove the null controllability of the heat equation when the control acts in an open subset of the domain where the equation holds. The same method can be used to deal with control mechanisms as in (1.1). Their main idea was to split the time interval into a sequence of decreasing consecutive subintervals. In each of these intervals an increasing finite number of Fourier components (determined by a diadic decomposition) is controlled to zero, the control being applied in two steps. In a first step (in half of the subinterval) where a nontrivial control is applied, an estimate based on Carleman inequalities guarantees that the size of the control does not grow faster than an exponential factor, in which the maximal eigenfrequency of the eigenfunctions under consideration enters. It was then shown that the dissipative property of the heat equation in the remaining half of the subinterval was able to compensate this exponential growth. A careful analysis of the method of proof in [13] and [14] shows that it works if $\alpha > 1/2$. The results of the present paper show that the results this method yields are sharp in the sense that completely opposite results hold when $\alpha \leq 1/2$. This fact confirms once more that the control theoretical results of the heat equation do hold because of its very strong dissipative properties.

The paper is organized as follows. In section 2 we present the controllability problem and some equivalent formulations. Some known results are also mentioned. In section 3 our main controllability results for the case $\alpha \leq 1/2$ are stated. They are based on two propositions concerning entire functions that are proven in section 4. In section 5 we give a negative result concerning the dual observability inequality (with respect to the control problem). In section 6 we analyze the controllability properties of a hyperbolic equation involving the same operator $(-\Delta)^\alpha$:

$$u_{tt} + (-\Delta)^\alpha u = g(t)f(x).$$

In this case the situation is even worse since the classical control properties of the $1-d$ wave equation (that correspond to the exponent $\alpha = 1$) fail for all $\alpha < 1$. Some comments and open problems are included in section 7.

2. Problem formulation and existing results. We first observe that the operator A_α in (1.3) is well defined since $(\sqrt{2}\sin(nx)/\sqrt{\pi})_{n\geq 1}$ forms an orthonormal basis in $L^2(0,\pi)$. Moreover, the operator A_α is densely defined and is self-adjoint in $L^2(0,\pi)$.

The eigenvalues of the operator A_α are given by

$$\lambda_n = n^{2\alpha} \quad \forall n \geq 1 \tag{2.1}$$

with eigenfunctions

$$\varphi_n = \sin(nx) \quad \forall n \geq 1. \tag{2.2}$$

With this notation the control problem for system (1.1) can be formulated as follows: Given $T > 0$, $f \in L^2(0,\pi)$ and $u^0 \in L^2(0,\pi)$ find $g \in L^2(0,T)$ such that the solution u of problem

$$\begin{cases} u_t + A_\alpha u = g(t)f(x), & x \in (0,\pi),\ t \in (0,T), \\ u = 0, & x \in \{0,\pi\},\ t \in (0,T), \\ u(0,x) = u^0(x), & x \in (0,\pi), \end{cases} \tag{2.3}$$

satisfies

$$u(T,\,\cdot\,) = 0. \tag{2.4}$$

An initial datum u^0 with such property is said to be *null controllable* in time T. If all initial data in $L^2(0,\pi)$ are null controllable we say that (2.3) is null controllable in $L^2(0,\pi)$.

The goal is to drive the initial datum u^0 to rest by using a control with a given shape $f(x)$ in space at each time. Then the control $g(t)$ determines the intensity of the control profile applied to the system.

Let us first give the following variational characterization of controllable initial data.

LEMMA 2.1. *The initial datum $u^0 \in L^2(0,\pi)$ is null controllable in time T with control $g \in L^2(0,T)$ if and only if the identity*

$$-\int_0^\pi u^0(x)\varphi(0,x)dx = \int_0^T g(t)\left(\int_0^\pi f(x)\varphi(t,x)dx\right)dt \tag{2.5}$$

holds for any $\varphi^T \in L^2(0,\pi)$ *with* $\varphi(t,x)$ *solution of the adjoint equation*

$$\begin{cases} -\varphi_t + A_\alpha \varphi = 0, & x \in (0,\pi),\ t \in (0,T), \\ \varphi = 0, & x \in \{0,\pi\},\ t \in (0,T), \\ \varphi(T,x) = \varphi^T(x), & x \in (0,\pi). \end{cases} \tag{2.6}$$

Proof. The proof follows immediately by multiplying (2.3) by φ, the solution of (2.6), integrating in $(0,T)\times\Omega$, and taking into account that A_α is self-adjoint. ∎

Since $(\sin(nx))_{n\geq 1}$ is complete in $L^2(0,\pi)$, considering $\varphi^T(x) = \sin(nx)$ for each $n \geq 1$ in Lemma 2.1, the following equivalent condition for the null-controllability results.

LEMMA 2.2. *An initial datum* $u^0 \in L^2(0,\pi)$ *of the form*

$$u^0(x) = \sum_{n\geq 1} a_n \sin(nx) \tag{2.7}$$

is null controllable in time T *if and only if there exists* $g \in L^2(0,T)$ *such that, for any* $n \geq 1$,

$$f_n \int_0^T g(t) e^{\lambda_n t} dt = -\frac{\pi}{2} a_n, \tag{2.8}$$

where

$$f_n = \int_0^\pi f(x) \sin(nx) dx. \tag{2.9}$$

Note that (2.8) is a *moment problem.*

Note also that, given an arbitrary initial datum u^0, a necessary condition for this moment problem to have a solution is that

$$f_n = \int_0^\pi f(x) \sin(nx) dx \neq 0 \quad \forall n \geq 1. \tag{2.10}$$

Indeed, if there exists $k \geq 1$ such that $f_k = 0$, the kth equation in (2.8) does not hold except for the case $a_k = 0$. In fact, if $f_k = 0$, it is easy to see that the kth Fourier component of the solution of the controlled problem (1.1) is invariant in time. This makes the controllability property impossible unless $a_k = 0$.

From now on we shall suppose that f verifies (2.10).

Let us now recall the following result from [7].

THEOREM 2.1. *Let* $\alpha > 1/2$ *and suppose that the Fourier coefficients of* f *satisfy* (2.10) *and the following additional condition:*

$$\liminf_{n\to\infty} |f_n| e^{\eta n^{2\alpha}} > 0 \tag{2.11}$$

for any $\eta > 0$.

Then, the initial state $u^0 = \sum_{n\geq 1} a_n \sin(nx)$ *is null controllable in time* $T > 0$ *by means of a control* $g \in L^2(0,T)$ *if, for some* $M, \eta > 0$,

$$|a_n| \leq M e^{n^{2\alpha} T} e^{-(\pi+\eta)n}, \quad n = 1, 2, \ldots. \tag{2.12}$$

Moreover, when this holds, the control g may be chosen to be in $C^m([0,T])$ for all $m \geq 1$.

REMARK 2.1. *The right-hand side term in* (2.12) *tends to infinity as $n \to \infty$. Thus, Theorem* 2.1 *implies, for instance, that any initial data in $L^2(0,\pi)$ are null controllable in any time $T > 0$. This result is in contrast with which we shall prove for the case $\alpha \leq 1/2$ that no initial data in a negative Sobolev space may be driven to zero in finite time with an L^2-control g.*

REMARK 2.2. *Condition* (2.11) *requires the shape function $f = f(x)$ to be not "too regular." Obviously, one can find control profiles f with such a property in any Sobolev space $H^s(0,\pi)$, but a too fast exponential decay rate of the Fourier coefficients of f is incompatible with* (2.11). *In particular, when f is a Gaussian function,* (2.11) *fails for $\alpha = 1$, i.e., for the classical heat equation.*

3. Controllability results in the case $\alpha \leq 1/2$. Let us now address the case $0 < \alpha \leq 1/2$. Throughout this section we will assume that $0 < \alpha \leq 1/2$. However, some of the results we present here are valid for all $\alpha > 0$. This will be indicated explicitly when it is the case.

3.1. The main negative result. The following result is completely different from that obtained in Theorem 2.1.

THEOREM 3.1. *Let $0 < \alpha \leq 1/2$ and suppose that the Fourier coefficients of f satisfy* (2.11). *Then any nontrivial initial state $u^0 = \sum_{n\geq 1} a_n \sin(nx)$ with the property that for any $\mu > 0$ there exists a constant $C_\mu > 0$ such that*

$$|a_n| \leq C_\mu e^{\mu n^{2\alpha}} \quad \forall n \geq 1 \tag{3.1}$$

cannot be driven to zero in time $T > 0$ by means of a control $g \in L^2(0,T)$, whatever $T > 0$ is.

REMARK 3.1. *The right-hand side term in* (3.1) *grows exponentially as $n \to \infty$. Thus, Theorem* 3.1 *implies that there is no initial datum in any Sobolev space of negative order that might be null controllable in any time $T > 0$ with controls g in $L^2(0,T)$.*

Consequently, this result is in opposition to the positive one in Theorem 2.1 *for the case $\alpha > 1/2$.*

In particular, Theorem 3.1 *means that choosing quite irregular control profiles f, as one is required to do when $\alpha > 1/2$ according to* (2.11), *is a very bad choice when $\alpha \leq 1/2$.*

REMARK 3.2. *From* (3.1) *it seems that, as α increases, the class of data for which the null-controllability property fails increases as well. However, a careful analysis of the proof of the theorem and Proposition* 3.2 *shows the contrary. Indeed, for the null-controllability property to fail, not all, but only part, of the Fourier coefficients of the initial datum must satisfy* (3.1). *Indeed, instead of* (3.1) *it is sufficient to have*

$$|a_{n_k}| \leq C_\mu e^{\mu n_k^{2\alpha}} \quad \forall k \geq 1 \tag{3.2}$$

for a suitable subsequence $(n_k)_{k\geq 1}$ (see Lemma 4.2 *and Remark* 4.2) *satisfying*

$$|n_{k+1} - n_k| \geq \frac{1}{2\alpha} k^{\frac{1}{2\alpha}-1} - 2 \quad \forall k \geq 1. \tag{3.3}$$

Note that (3.3) *shows that the distance between two consecutive terms of the sequence $(n_k)_{k\geq 1}$ decreases when α increases. Hence, the same happens to the class of*

data for which the null-controllability property fails. This agrees with the first intuition that suggests that, as the dissipativity of the system increases, its controllability properties improve.

A dramatic change in the controllability properties arises when $\alpha = 1/2$. *For* $\alpha > 1/2$ *the control problem is very well behaved (see Theorem* 2.1). *On the contrary, the controllability properties are very poor when* $\alpha \leq 1/2$. *Note that the same occurs with the spectral property* (1.6). *Something similar happens in* (3.3) *where, when* $\alpha > 1/2$, *the gap condition is fulfilled for all indices* k *without extracting subsequences.*

3.2. Proof of the negative result. According to Lemma 2.2, the property of null controllability of $u^0 = \sum_{n\geq 1} a_n \sin(nx)$ is equivalent to the existence of a function $g \in L^2(0,T)$ such that, for any $n \geq 1$, (2.8) is verified.

Before getting into the proof of Theorem 3.1 let us first give an equivalent condition for the existence of such a control function g.

PROPOSITION 3.1. *The following assertions are equivalent:*

(a) *There exists* $g \in L^2(0,T)$ *such that the following holds:*

$$\int_0^T g(s) e^{n^{2\alpha} s} ds = \alpha_n \quad \forall n \geq 1. \tag{3.4}$$

(b) *There exists an entire function* F *of exponential type* $\leq T/2$, *with*

$$\int_{-\infty}^{\infty} |F(iy)|^2 \, dy < \infty \tag{3.5}$$

and such that

$$F(n^{2\alpha}) = \alpha_n e^{-n^{2\alpha} T/2} \quad \forall n \geq 1. \tag{3.6}$$

Recall that an entire function is said to be of exponential type $\leq B$ if there exists a positive constant $A > 0$ such that (see [21])

$$|F(z)| \leq A e^{B|z|} \quad \forall z \in \mathbb{C}. \tag{3.7}$$

REMARK 3.3. *Several remarks are in order:*

- *Proposition* 3.1 *is a very general result in which the explicit values of the coefficients* α_n *and the eigenvalues* $\lambda_n = n^{2\alpha}$ *do not matter.*
- *The proof of Proposition* 3.1 *uses the Fourier transform and the Paley–Wiener theorem and will be given in the next section.*
- *As the proof of this proposition shows, the function* F *in* (b) *is uniformly bounded along the imaginary axis.*
- *From Proposition* 3.1, *in order to characterize the null-controllable initial data it is necessary and sufficient to characterize the sequences* $\{F(n^{2\alpha})\}_{n\geq 1}$ *that may be obtained by means of entire functions* F *of exponential type* $\leq T/2$ *satisfying* (3.5).

The following proposition provides significant information on the rate of growth of $F(n^{2\alpha})$ for functions F as above.

PROPOSITION 3.2. *Let* $F : \mathbb{C} \to \mathbb{C}$ *be a function satisfying the following properties:*

(i) F *is an entire function of exponential type* $\leq T/2$;
(ii) $\int_{-\infty}^{\infty} |F(iy)|^2 \, dy < \infty$;

(iii) *for any* $\delta > 0$ *there exists* $C_\delta > 0$ *such that*

$$|F(n^{2\alpha})| \leq C_\delta e^{\delta n^{2\alpha}} e^{-n^{2\alpha}T/2} \quad \forall n \geq 1.$$

Then, necessarily, $F \equiv 0$.

The proof of Proposition 3.2 is based on a result of Duffin and Schaeffer (see [4] and also [3, p. 191]) which gives conditions for the boundedness of an analytic function in a sector of the complex plane if its boundedness on a sequence of complex numbers is assumed. In our case, the information we have on the behavior of $F(n^{2\alpha})$ allows us to construct an analytic function in the right half-plane which is bounded on a sequence of complex numbers close to n and to apply the mentioned result. The complete proof of Proposition 3.2 will be given in the next section.

Let us now show how Theorem 3.1 follows from Propositions 3.1 and 3.2.

If u^0 is null controllable, then the existence of a function F as in Proposition 3.1 is ensured with $\lambda_n = n^{2\alpha}$ and $\alpha_n = -a_n/(2f_n)$. Hence, F satisfies conditions (i)–(ii) in Proposition 3.2. Then, condition (3.1) on the Fourier coefficients of u^0 and condition (2.11) on the shape function f imply that

$$|F(n^{2\alpha})| \leq Ce^{(\mu+\eta)n^{2\alpha}} e^{-n^{2\alpha}T/2}. \tag{3.8}$$

Since μ and η are arbitrary, the function F also satisfies property (iii) from Proposition 3.2.

It follows that $F \equiv 0$ and, consequently, under the growth condition (3.1) and with control profiles satisfying (2.11), the only controllable initial datum is the trivial one. □

3.3. Other controllability properties. As we have said before, condition (2.11) indicates that the shape function f is not "too regular." Let us now show that assuming more regularity on f may increase the space of controllable data. This fact is also in opposition to the behavior of the system in the case $\alpha > 1/2$, in which increasing the regularity of the profile f reduces the space of controllable data.

PROPOSITION 3.3. *Let* $\alpha \leq 1/2$ *and suppose that there exists* $\eta > T$ *such that*

$$|f_n| \leq e^{-\eta n^{2\alpha}} \quad \forall n \geq 1. \tag{3.9}$$

Then there are initial data in any Sobolev space $H^m(0,\pi)$ *which are null controllable by means of a control function* $g \in L^2(0,T)$.

REMARK 3.4. *It is important to note that the result in Proposition* 3.3 *holds for* $\alpha > 1/2$ *as well. However, in this case, as mentioned above, one can prove much better results guaranteeing that all initial data in* $L^2(0,\pi)$ *are controllable even if condition* (3.9) *is not satisfied.*

Proof. From Lemma 2.2 and Proposition 3.1, it follows that an initial datum whose Fourier coefficients are given by

$$a_n = -2f_n F(n^{2\alpha}) e^{\frac{T}{2}n^{2\alpha}},$$

where

$$F(z) = \frac{\sin\left(\frac{T}{2}zi\right)}{\frac{T}{2}zi},$$

is null controllable in time T.

The initial datum with these Fourier coefficients belongs to any Sobolev space $H^m(0,\pi)$ with $m \geq 0$. Indeed,

$$\sum_{n\geq 1} |a_n|^2 n^{2m} \leq 4 \sum_{n\geq 1} |f_n|^2 |F(n^{2\alpha})|^2 n^{2m} e^{Tn^{2\alpha}}.$$

We now use in an essential way that F is of exponential type $\leq T/2$. This is obvious in this case in view of the explicit form of F. It follows that

$$\sum_{n\geq 1} |a_n|^2 n^{2m} \leq 4 \sum_{n\geq 1} e^{-2\eta n^{2\alpha}} \frac{e^{Tn^{2\alpha}}}{\left(\frac{Tn^{2\alpha}}{2}\right)^2} e^{Tn^{2\alpha}} n^{2m} < \infty. \qquad \square$$

As we mentioned above, when $\alpha > 1/2$, if the regularity of the shape function increases, the space of controllable initial data diminishes. As we have just proved, this is no longer true if $\alpha \leq 1/2$. In this case, some regular initial data may be controlled only if more regularity is assumed for the shape function f.

REMARK 3.5. *There exists an alternative proof for the above proposition which allows us to construct an explicit null-controllable initial datum under hypothesis* (3.9). *Indeed, let $g \in L^2(0,T)$ such that the solution u_1 of the ordinary differential equation*

$$\begin{cases} u_1' + u_1 = g(t) f_1, & t \in (0,T), \\ u_1(0) = 1 \end{cases} \tag{3.10}$$

satisfies $u_1(T) = 0$.

Now, for each $n \geq 2$, solve the following backward ordinary differential equation:

$$\begin{cases} u_n' + n^{2\alpha} u_n = g(t) f_n, & t \in (0,T), \\ u_n(T) = 0. \end{cases} \tag{3.11}$$

It is easy to see that

$$|u_n(0)| \leq \sqrt{T} |f_n| e^{Tn^{2\alpha}} ||g||_{L^2}.$$

Under hypothesis (3.9) *the initial datum*

$$u^0 = \sin(x) + \sum_{n\geq 2} u_n(0) \sin(nx)$$

belongs to $H^m(0,\pi)$ for any $m \geq 0$ and it is null controllable.

This example can easily be generalized by choosing first the control corresponding to a finite number of Fourier components, and then determining the other Fourier components of the controllable initial datum from the final equilibrium condition in terms of this control.

More precisely, fix a finite $N \geq 1$ and an arbitrary choice of the first N Fourier components of the initial datum to be controlled: $a_1, \ldots, a_N$. Let $g = g(t)$ be such that each of the solutions of

$$\begin{cases} u_n' + n^{2\alpha} u_n = g(t) f_n, & t \in (0,T), \\ u_n(0) = a_n \end{cases} \tag{3.12}$$

satisfies $u_n(T) = 0$ for all $n = 1, \ldots, N$. The existence of this control g is guaranteed. Indeed, system (3.12) *is controllable since the classical Kalman rank condition is satisfied.*

Once this is done for each $n \geq N+1$ we solve the backward problem

$$\begin{cases} u_n' + n^{2\alpha} u_n = g(t) f_n, & t \in (0,T), \\ u_n(T) = 0. \end{cases} \tag{3.13}$$

Under assumption (3.9) *the controlled initial datum*

$$u^0 = \sum_{n=1}^{N} a_n \sin(nx) + \sum_{n \geq N+1} u_n(0) \sin(nx)$$

belongs to $H^m(0,\pi)$ for any $m \geq 0$.

3.4. Partial controllability. In order to better explain the previous result it is convenient to introduce the following definition.

DEFINITION 3.1. *The initial datum $u^0 \in L^2(0,\pi)$ is N-partially controllable in time $T > 0$ if there exists $g = g_N \in L^2(0,T)$ such that the solution u of* (2.3) *verifies*

$$\Pi_N(u(T,\cdot)) = 0, \tag{3.14}$$

where Π_N is the orthogonal projection over the space generated by the first N eigenfunctions $(\sqrt{2}\sin(nx)/\sqrt{\pi})_{1 \leq n \leq N}$.

Arguing as in Lemma 2.2 we can show that the N-partial controllability problem is equivalent to a finite moment problem and more precisely to the existence of $g_N \in L^2(0,T)$ such that

$$f_n \int_0^T g_N(t) e^{\lambda_n t} dt = -\frac{\pi}{2} a_n \quad \text{for any } 1 \leq n \leq N. \tag{3.15}$$

A function g_N with property (3.15) will be called N-partial control. Its existence is easy to prove since, as mentioned above, the Kalman rank condition is satisfied. The lack of controllability properties proved above on the case $\alpha \leq 1/2$ suggests that the controls g_N should diverge as $N \to \infty$. Let us check this fact in a simple but illustrative example.

The system is N-partially controllable if and only if, for all $k \geq 1$, there exists $g_{k,N} \in L^2(0,T)$ such that

$$\int_0^T g_{k,N}(t) e^{\lambda_n t} dt = \delta_{kn} \text{ for any } 1 \leq n \leq N. \tag{3.16}$$

If $(g_{k,N})_{N \geq 1}$ is bounded in $L^2(0,T)$, there exists a subsequence which weakly converges as $N \to \infty$ to $g_k \in L^2(0,T)$ and

$$\int_0^T g_k(t) e^{\lambda_n t} dt = \delta_{kn} \quad \forall n \geq 1. \tag{3.17}$$

But relation (3.17) cannot hold since $(e^{\lambda_n t})_{n \geq 1, n \neq k}$ is complete in $L^2(0,T)$ (the divergence property (1.6) still holds if one exponent is eliminated). Hence, $(g_{k,N})_{N \geq 1}$ may not be bounded in $L^2(0,T)$.

A sequence $(g_k)_{k \geq 1}$ with property (3.17) is called biorthogonal to $(e^{\lambda_n t})_{n \geq 1}$. When $\alpha \leq 1/2$ such a biorthogonal sequence does not exist. From the controllability point of view the fact that, for k fixed, $g_{k,N}$ diverges as $N \to \infty$ means that it is impossible to control to zero one Fourier mode of the initial datum. This is in

agreement with the positive result in Proposition 3.3 indicating that taking a more smooth control profile may increase the space of controllable data. Note that, as the Fourier components of the control profile f decay faster, the impact of the controls on the high frequencies decreases. This does help in building smooth data that are controllable, as the construction of Remark 3.5 shows.

In fact, according to Theorem 3.1, if the Fourier coefficients of the initial datum are not large enough, the sequence of N-partial controls $(g_N)_{N\geq 1}$ diverges and no control exists. □

The previous notion of N-partial controllability can be extended as follows: Given a subset $I \subset \mathbb{N}$ of indices we introduce the subspace H_I of $L^2(0,\pi)$ spanned by the eigenfunctions of the Laplacian with indices in I. More precisely,

$$H_I = \left\{ \varphi \in L^2(0,\pi) \,:\, \varphi(x) = \sum_{j\in I} a_j \sin(jx),\ \sum_{j\in I} |a_j|^2 < \infty \right\}. \tag{3.18}$$

We then introduce the orthogonal projection Π_I from $L^2(0,\pi)$ into H_I.

Definition 3.2. *System* (2.3) *is H_I-partially controllable in time $T > 0$ if for every initial datum $u^0 \in L^2(0,\pi)$ there exists a control $g \in L^2(0,T)$ such that the solution u of* (2.3) *verifies*

$$\Pi_I(u(T,\cdot)) = 0. \tag{3.19}$$

This control property is also equivalent to finding $g_I \in L^2(0,T)$ such that

$$f_j \int_0^T g_I(t) e^{\lambda_j t} dt = -\frac{\pi}{2} a_j \quad \forall j \in I. \tag{3.20}$$

Obviously, this generalizes the N-partial controllability problem that corresponds to the case where $I = \{1, 2, \dots, N\}$.

As mentioned in the introduction, the solvability of (3.19) and/or (3.20) depends on the summability condition

$$\sum_{j\in I} \frac{1}{|\lambda_j|} < \infty. \tag{3.21}$$

In the case under consideration, $\lambda_j = j^{2\alpha}$. Therefore, we see that (3.21) is satisfied under the following conditions:

1. When $\alpha > 1/2$ for $I = \mathbb{N}$. In this case partial controllability turns out to be complete null controllability.
2. When $0 < \alpha \leq 1/2$ for a suitable subsequence I_α of $\mathbb{N}$. It is obvious that one needs to consider a strict subsequence I_α of $\mathbb{N}$. Moreover, as α decreases, the subsequence I_α becomes more and more sparse in $\mathbb{N}$ and, therefore, the property of partial controllability weaker and weaker. This result agrees with a first intuition suggesting that an increase of diffusivity enhances the null-controllability properties of the system.

4. Proofs of some technical results.

4.1. Proof of Proposition 3.1. First of all we observe that

$$\int_0^T g(s)e^{n^{2\alpha}s}ds = \int_{-T/2}^{T/2} g(s+T/2)e^{n^{2\alpha}(s+T/2)}ds$$
$$= e^{n^{2\alpha}T/2}\int_{-T/2}^{T/2} g(s+T/2)e^{n^{2\alpha}s}ds = e^{n^{2\alpha}T/2}\int_{-T/2}^{T/2} h(s)e^{n^{2\alpha}s}ds$$

with $h(s) = g(s+T/2)$.

Hence, statement (a) of Proposition 3.1 is equivalent to the following one:

(4.1)

(a′) $\exists h \in L^2(-T/2, T/2)$ such that $\int_{-T/2}^{T/2} h(s)e^{n^{2\alpha}s}ds = e^{-n^{2\alpha}T/2}\alpha_n \quad \forall n \geq 1.$

We now prove that (a′) and (b) are equivalent.

- (a′) ⇒ (b).
  Let H be the Fourier transform of $h(s)1_{(-T/2,T/2)}$, i.e.,

  $$H(z) = \int_{-T/2}^{T/2} h(s)e^{-izs}ds,$$

  and let $F(z) = H(iz)$. According to the Paley–Wiener theorem (see, for instance, [3] or [21]), we know that $H : \mathbb{C} \to \mathbb{C}$ is an entire function of exponential type $\leq T/2$ and such that $\int_{-\infty}^{\infty} \mid H(x) \mid^2 dx < \infty$. Consequently, F is also an entire function of exponential type $\leq T/2$ such that $\int_{-\infty}^{\infty} \mid F(ix) \mid^2 dx < \infty$.
  Moreover, in view of (4.1),

  $$F(n^{2\alpha}) = H(in^{2\alpha}) = \int_{-T/2}^{T/2} h(s)e^{n^{2\alpha}s}ds = e^{-n^{2\alpha}T/2}\alpha_n.$$

  This shows that (b) holds.
- (b) ⇒ (a′).
  Let F be an entire function of exponential type $\leq T/2$, with $\int_{-\infty}^{\infty} \mid F(ix) \mid^2 dx < \infty$ and such that (3.6) holds.
  We then set $H(z) = F(-iz)$, which is also an entire function of exponential type $\leq T/2$ with $\int_{-\infty}^{\infty} \mid H(x) \mid^2 dx < \infty$.
  From the Paley–Wiener theorem we deduce that there exists $h \in L^2(-\frac{T}{2}, \frac{T}{2})$ such that

  $$H(z) = \int_{-T/2}^{T/2} h(s)e^{-izs}ds.$$

  We have that

  $$\int_{-T/2}^{T/2} h(s)e^{n^{2\alpha}s}ds = H(in^{2\alpha}) = F(n^{2\alpha}) = \alpha_n e^{-n^{2\alpha}T/2}$$

  and (a′) is verified.

This completes the proof of Proposition 3.1. □

4.2. Properties of the eigenvalues. Let us recall that the operator A_α we are dealing with has a sequence of eigenvalues $\lambda_n = n^{2\alpha}$, $n \geq 1$. Recall also that we are dealing with the case $0 < \alpha \leq 1/2$. In this section we deduce some properties of these eigenvalues.

LEMMA 4.1. *The sequence $(\lambda_n)_{n\geq 1}$ has the following properties:*

1. *It is strictly increasing and* $\lim_{n\to\infty} \lambda_n = \infty$.
2. *For any $n \geq 1$,*

$$\lambda_{n+1} - \lambda_n \leq \frac{2\alpha}{n^{1-2\alpha}}. \tag{4.2}$$

Proof. The first part is obvious. For the second one let us note that

$$\lambda_{n+1} - \lambda_n = (n+1)^{2\alpha} - n^{2\alpha} = n^{2\alpha}\left[\left(\frac{1}{n}+1\right)^{2\alpha} - 1\right]$$

and use the fact that for any $x > 0$ there exists ξ in $[0, x]$ such that

$$(x+1)^{2\alpha} = 1 + 2\alpha x + 2\alpha(2\alpha-1)\frac{x^2}{2}(\xi+1)^{2\alpha-2} \leq 1 + 2\alpha x.$$

It follows that

$$\lambda_{n+1} - \lambda_n = n^{2\alpha}\left[\left(\frac{1}{n}+1\right)^{2\alpha} - 1\right] \leq n^{2\alpha}\left[\left(1 + 2\alpha\frac{1}{n}\right) - 1\right] = \frac{2\alpha}{n^{1-2\alpha}}. \qquad \square$$

Concerning the distribution of the sequence $(\lambda_n)_{n\geq 1}$ the following can be said.

LEMMA 4.2. *There exists an increasing sequence $(n_k)_{k\in\mathbb{N}^*}$ in $\mathbb{N}^*$ such that*

1. *there exists $\beta > 0$ such that $0 < \beta < n_{k+1}^{2\alpha} - n_k^{2\alpha}$, for any $k \geq 1$;*
2. *for any $k \geq 1$, $|k - n_k^{2\alpha}| \leq \alpha$.*

Proof. If $\alpha = 1/2$, we may take $n_k = k$ and both properties are verified.

Consider now the case $\alpha < 1/2$. If $k = 1$, we take $n_k = 1$. Suppose that $k \geq 2$. Let $n'_k = \inf\{n \in \mathbb{N}^* : k \leq n^{2\alpha}\}$. We have

$$(n'_k - 1)^{2\alpha} < k \leq (n'_k)^{2\alpha}$$

and $n'_k > 1$.

Define

$$n_k = \begin{cases} n'_k - 1 & \text{if } k - (n'_k-1)^{2\alpha} \leq (n'_k)^{2\alpha} - k, \\ n'_k & \text{if } (n'_k)^{2\alpha} - k < k - (n'_k-1)^{2\alpha}. \end{cases}$$

Taking Lemma 4.1 into account we obtain that

$$\begin{aligned} |k - (n_k)^{2\alpha}| &= \min\{k - (n'_k-1)^{2\alpha},\, (n'_k)^{2\alpha} - k\} \leq \frac{1}{2}\left(k - (n'_k-1)^{2\alpha} + (n'_k)^{2\alpha} - k\right) \\ &= \frac{1}{2}\left((n'_k)^{2\alpha} - (n'_k-1)^{2\alpha}\right) = \frac{1}{2}(\lambda_{n'_k} - \lambda_{n'_k-1}) \leq \frac{\alpha}{(n'_k-1)^{1-2\alpha}} \leq \alpha \end{aligned}$$

and the second property of the statement of the Lemma is verified. On the other hand

$$\begin{aligned} |n_k^{2\alpha} - n_{k-1}^{2\alpha}| &\geq 1 - \left(|n_k^{2\alpha} - k| + |n_{k-1}^{2\alpha} - (k-1)|\right) \\ &\geq 1 - \alpha\left[\frac{1}{(n'_k-1)^{1-2\alpha}} + \frac{1}{(n'_{k-1}-1)^{1-2\alpha}}\right] \geq 1 - 2\alpha > 0 \end{aligned}$$

and the first property is verified as well. □

REMARK 4.1. *Lemma* 4.2 *says that there exists a subsequence* $(\lambda_{n_k})_{k\geq 1}$ *of the sequence of eigenvalues* $(\lambda_n)_{n\geq 1}$ *such that*

- $|\lambda_{n_k} - k| \leq \alpha$ *for all* $k \geq 1$*;*
- $|\lambda_{n_k} - \lambda_{n_{k-1}}| > \beta > 0$ *for all* $k \geq 2$.

This subsequence (λ_{n_k}) *will be used to prove Proposition* 3.2.

REMARK 4.2. *The subsequence* $(n_k)_{k\geq 1}$ *constructed in the proof of Lemma* 4.2 *satisfies*

$$|n_{k+1} - n_k| \geq \frac{1}{2\alpha} k^{\frac{1}{2\alpha}-1} - 2 \quad \forall k \geq 1. \tag{4.3}$$

Indeed,

$$n_{k+1} - n_k \geq n'_{k+1} - n'_k - 1 \geq (k+1)^{\frac{1}{2\alpha}} - k^{\frac{1}{2\alpha}} - 2 \geq \frac{1}{2\alpha} k^{\frac{1}{2\alpha}-1} - 2.$$

4.3. Proof of Proposition 3.2. We introduce the function $G : \mathbb{C} \to \mathbb{C}$:

$$G(z) = e^{Tz/2} F(z). \tag{4.4}$$

In view of properties (i)–(ii) of F it is immediate that

$$G \text{ is an entire function of exponential type } \leq T; \tag{4.5}$$

$$\int_{-\infty}^{\infty} |\, G(iy)\,|^2 \, dy < \infty; \tag{4.6}$$

$$\forall \delta > 0 : |\, G(n^{2\alpha})\,| \leq C_\delta e^{\delta n^{2\alpha}} \quad \forall n \geq 1. \tag{4.7}$$

Moreover, G is bounded on the negative semiaxis, i.e.,

$$\exists L > 0 : |\, G(-x)\,| \leq L \quad \forall x \geq 0. \tag{4.8}$$

Property (4.8) is an immediate consequence of the fact that F is of exponential type $\leq T/2$.

We now introduce

$$G_1(z) = G\left(-ze^{i\pi/4}\right) \tag{4.9}$$

and apply the Phragmén–Lindelöf theorem to G_1 in the sector $|\arg z| < \pi/4$ to deduce that there exists $M_1 > 0$ such that

$$|\, G_1(z)\,| \leq M_1 \quad \forall z \in \mathbb{C} : |\arg z| \leq \pi/4. \tag{4.10}$$

This is possible since

$$G_1 \text{ is analytic on } \mathbb{C}; \tag{4.11}$$

$$G_1 \text{ is bounded when } \arg z = \pm\pi/4; \tag{4.12}$$

$$|\, G_1(z)\,| = O\left(e^{|z|^\beta}\right) \text{ for some } \beta < 2, \text{ as } |\, z\,| \to \infty. \tag{4.13}$$

Note that (4.12) holds because G is bounded along the imaginary axis by (4.6) and on the negative semiaxis by (4.8). On the other hand, (4.13) holds for any $\beta > 1$ since $|\, G_1(z)\,| = O\left(e^{T|z|}\right)$, due to (4.5).

As a consequence of (4.10) we deduce that

$$| G(z) | \leq M_1 \tag{4.14}$$

for all $z \in \mathbb{C}$ with $\arg(z) \in [\pi/2, \pi]$.

In a similar way we may prove the existence of $M_2 > 0$ such that

$$| G(z) | \leq M_2 \tag{4.15}$$

for all $z \in \mathbb{C}$ with $\arg(z) \in [\pi, 3\pi/2]$. Hence, G is bounded in the half complex plane $\operatorname{Re} z \leq 0$.

Let us now consider the function

$$H_\delta(z) = G(z)e^{-\delta z} = e^{Tz/2}e^{-\delta z}F(z) \tag{4.16}$$

defined on the half-plane $\operatorname{Re} z \geq 0$. It is easy to see that H_δ satisfies the following properties:

$$H_\delta \text{ is analytic on the closed half-plane } \operatorname{Re} z \geq 0; \tag{4.17}$$

$$H_\delta \text{ is of exponential type;} \tag{4.18}$$

$$\exists C_\delta > 0 :| H_\delta(n^{2\alpha}) | \leq C_\delta \quad \forall n \geq 1; \tag{4.19}$$

$$H_\delta \text{ is bounded on the imaginary axis.} \tag{4.20}$$

We now introduce the indicator function

$$h_{H_\delta}(\theta) = \limsup_{r\to\infty} \left[\frac{1}{r}\log\left|H_\delta\left(re^{i\theta}\right)\right|\right] \quad \forall\theta \in \left[-\frac{\pi}{2}, \frac{\pi}{2}\right]. \tag{4.21}$$

Lemma 4.3. *For any $\delta < T$, there exists a positive constant $A > 0$ such that*

$$h_{H_\delta}(\theta) \leq A\cos\theta \quad \forall\theta \in [-\pi/2, \pi/2]. \tag{4.22}$$

Proof of Lemma 4.3. We have

$$\begin{aligned}\log\left|H_\delta\left(re^{i\theta}\right)\right| &= \log\left|e^{(T-2\delta)re^{i\theta}/2}F\left(re^{i\theta}\right)\right| \\ &= \log\left|e^{(T-2\delta)re^{i\theta}/2}\right| + \log\left|F\left(re^{i\theta}\right)\right| = \frac{(T-2\delta)r\cos\theta}{2} + \log\left|F\left(re^{i\theta}\right)\right|.\end{aligned} \tag{4.23}$$

On the other hand, arguing as in the proof of Proposition 3.1, we deduce from the Paley–Wiener theorem the existence of a function $\psi \in L^2(-T/2, T/2)$ such that

$$F(z) = \int_{-T/2}^{T/2} \psi(s)e^{zs}ds.$$

Therefore

$$\left|F\left(re^{i\theta}\right)\right| \leq \int_{-T/2}^{T/2} | \psi(s) | e^{sr\cos\theta}ds \leq e^{Tr|\cos\theta|/2}\int_{-T/2}^{T/2} | \psi(s) | ds. \tag{4.24}$$

Combining (4.22) and (4.24) we deduce that

$$\log\left|H_\delta\left(re^{i\theta}\right)\right| \leq (T-\delta)r | \cos\theta | + \log \| \psi \|_{L^1(-T/2, T/2)}. \tag{4.25}$$

From (4.25) we easily deduce that (4.21) holds with

$$A = T - \delta. \qquad \square \tag{4.26}$$

Let us now return to the proof of Proposition 3.2. By a result of Duffin and Schaeffer [4] (see also [3, p. 191]) we have the following theorem.

THEOREM 4.1. *Let f be analytic in $\mid \arg(z) \mid \leq \gamma \leq \pi/2$ and suppose that its indicator function h_f satisfies*

$$\mid h_f(\theta) \mid \leq a \mid \cos\theta \mid + b \mid \sin\theta \mid \quad \forall \mid \theta \mid \leq \gamma \tag{4.27}$$

with $a, b > 0$ and $b < \pi$.

If $(\nu_k)_{k\geq 1}$ is an increasing sequence of real numbers such that

$$\nu_{k+1} - \nu_k \geq \beta > 0 \quad \forall k \geq 1, \tag{4.28}$$

$$\mid \nu_k - k \mid \leq L \quad \forall k \geq 1, \tag{4.29}$$

and $f(\nu_k)$ is bounded, then $f(x)$ is bounded for all $x > 0$.

We apply Theorem 4.1 to the function H_δ with $\nu_k = \lambda_{n_k} = n_k^{2\alpha}$, where n_k are given by Lemma 4.2. The sequence $(\nu_k)_{k\geq 1}$ satisfies the hypotheses of Theorem 4.1. Moreover,

$$|H_\delta(\nu_k)| = |G(\nu_k)|e^{-\delta\nu_k} = |G(\lambda_{n_k})|e^{-\delta n_k^{2\alpha}} \leq C_\delta.$$

We deduce from Theorem 4.1 that H_δ is bounded on the positive real axis. Since, by (4.20), H_δ is also bounded on the imaginary axis, we deduce, by the Phragmén–Lindelöf theorem, that H_δ is bounded in the half-plane $\operatorname{Re} z \geq 0$ for all $0 < \delta < S$.

Consequently,

- G is bounded on the half-plane $\operatorname{Re} z \leq 0$;
- $\mid G(z) \mid \leq C(\delta)e^{\delta|z|}$ on the half-plane $\operatorname{Re} z \geq 0$ for all $0 < \delta < S$;
- G is entire;
- $\int_{-\infty}^{\infty} \mid G(iy) \mid^2 dy < \infty$.

According to the Paley–Wiener theorem, these properties are sufficient to guarantee that $G \equiv 0$. $\square$

5. On the lack of observability estimates. A natural approach to the problem of null controllability of heat equations consists in dealing with the dual observability problem for the adjoint system (see, for instance, [8], [22], and [23]).

More precisely, the null controllability of system (2.3) in $L^2(0,\pi)$ with controls in $L^2(0,T)$ is equivalent to the existence of a positive constant $C > 0$ such that

$$\| \varphi(0) \|^2_{L^2(0,\pi)} \leq C \int_0^T \left| \int_0^\pi \varphi(t,x) f(x) dx \right|^2 dt \quad \forall \varphi^T \in L^2(0,\pi), \tag{5.1}$$

where φ is the solution of (2.6).

As we have shown in Theorem 3.1, when $0 < \alpha \leq 1/2$, the null-controllability result is false and therefore (5.1) does not hold. In fact, according to the statement of Theorem 3.1, it turns out that all the possible weaker versions of (5.1) in which the L^2-norm of the left-hand side is replaced by an $H^{-\sigma}$-norm for any $\sigma > 0$ are false as well.

In this section we describe how the lack of observability inequalities of form (5.1) may be proved directly.

In view of the Fourier series expansion of the solution φ of (2.6) we have

$$\varphi(t,x)=\sum_{n\geq 1} a_n e^{-n^{2\alpha}(T-t)}\sin(nx).$$

Thus (5.1) is equivalent to

$$\sum_{n\geq 1}|a_n|^2 e^{-2n^{2\alpha}T}\leq C\int_0^T\left|\sum_{n\geq 1}a_n f_n e^{-n^{2\alpha}t}\right|^2 dt. \tag{5.2}$$

Inequalities of form (5.2) are well known to be true when $\alpha>1/2$ (see, for instance, [7] and [19]). But they fail when $\alpha\leq 1/2$ since the series $\sum_{n\geq 1}1/n^{2\alpha}$ diverges in that case (see [17]). More precisely, the following negative result holds.

PROPOSITION 5.1. *When $0<\alpha\leq 1/2$ there is no sequence $(\rho_n)_{n\geq 1}$ of positive weights, i.e., $\rho_n>0$ for all $n\geq 1$, such that*

$$\sum_{n\geq 1}\rho_n|b_n|^2\leq\int_0^T\left|\sum_{n\geq 1}b_n e^{-n^{2\alpha}t}\right|^2 dt \tag{5.3}$$

for all finite sequence $(b_n)_{n\geq 1}$.

This result excludes inequality (5.2) and any other weaker version of it. Observe that an inequality like (5.2) is equivalent to the null controllability in time T of all initial data in the class

$$H=\left\{u^0=\sum_{n\geq 1}a_n\sin(n\pi):\sum_{n\geq 1}|a_n|^2/\rho_n<\infty\right\},$$

and, according to the result of Theorem 3.1, we know that this is false for all sequences of weights $(\rho_n)_{n\geq 1}$.

Proposition 5.1 is an immediate consequence of the following one.

PROPOSITION 5.2. *Let $(\nu_n\}_{n\geq 1}$ be an increasing sequence of positive real numbers. Assume that there exists a sequence of positive weights $(\rho_n)_{n\geq 1}$ such that*

$$\sum_{n\geq 1}\rho_n\,|a_n|^2\leq\int_0^T\left|\sum_{n\geq 1}a_n e^{-\nu_n t}\right|^2 dt \tag{5.4}$$

for all finite sequence $(a_n)_{n\geq 1}$. Then, necessarily,

$$\sum_{n\geq 1}\frac{1}{\nu_n}<\infty. \tag{5.5}$$

We refer to Proposition 3.5 in [17] for a proof.

The proof of Proposition 5.2 provides in fact a stronger result. Namely, it shows that if the sequence $(\nu_n)_{n\geq 1}$ is such that for some n_0 and $\rho>0$ we have

$$\rho\,|a_{n_0}|^2\leq\int_0^1\left|\sum_{n\geq 0}a_n e^{-\nu_n t}\right|^2 dt \tag{5.6}$$

for all finite sequence $(a_n)_{n\geq 1}$, then, necessarily,

$$\sum_{n\geq 1} \frac{1}{\nu_n} < \infty. \tag{5.7}$$

Inequalities of form (5.6) are related to the so-called spectral controllability problem, which consists in analyzing whether all the eigenfunctions may be driven to zero in finite time. Theorem 3.1 provides a negative answer.[2] Proposition 5.1 provides a second proof of this negative result in which the effect of the divergence of the series $\sum_{n\geq 1} 1/\nu_n$ is clearly seen.

Note that spectral controllability also implies that all finite combinations of eigenfunctions are controllable and also show the controllability property in the infinite-dimensional space generated by the eigenfunctions, with suitable weights as the frequency increases.

The results on partial controllability of section 3.4 can also be understood in terms of observability inequalities. Indeed, the H_I-partial controllability property is equivalent to the observability property (5.1) in the subspace of solutions of the adjoint system (2.6) with initial data φ^T in H_I, i.e., of solutions φ of (2.6) involving only the Fourier coefficients with indices $j \in I$. This turns out to be equivalent to an inequality of the form

$$\sum_{j\in I} |a_j|^2 e^{-2\lambda_j T} \leq C \int_0^T \left| \sum_{j\in I} a_j e^{-\lambda_j t} \right|^2 dt \tag{5.8}$$

for all finite sequence $(a_n)_{n\geq 1}$.

Inequality (5.8) holds provided the subsequence $(\lambda_j)_{j\in I}$ fulfills a gap condition and the summability condition

$$\sum_{j\in I} \frac{1}{|\lambda_j|} < \infty. \tag{5.9}$$

As indicated in section 3.4 these conditions are satisfied provided the sequence I is sparse enough.

6. A hyperbolic problem. In this section we consider a hyperbolic system involving the operator A_α and address the corresponding control problem: Given $T > 0$, $f \in L^2(0,\pi)$, and initial data (u^0, u^1), find $g \in L^2(0,T)$ such that the solution u of the problem

$$\begin{cases} u_{tt} + A_\alpha u = g(t)f(x), & x \in (0,\pi),\ t \in (0,T), \\ u = 0, & x \in \{0,\pi\},\ t \in (0,T), \\ u(0,x) = u^0(x), \quad u_t(0,x) = u^1(x), & x \in (0,\pi), \end{cases} \tag{6.1}$$

satisfies

$$u(T,\cdot) = u_t(T,\cdot) = 0. \tag{6.2}$$

[2] In fact the lack of (5.6) for any index n_0 shows that there is no single eigenfunction that may be driven to zero in final time with $L^2(0,T)$ controls.

Note that system (6.1) is a generalization of the wave equation

$$u_{tt} - u_{xx} = g(t)f(x)$$

that corresponds to the case $\alpha = 1$. In the absence of control (i.e., when $g = 0$) system (6.1) is conservative and generates a group of isometries in the corresponding energy space.

The eigenvalues corresponding to (6.1) are given by $i\nu_n$, $n \in \mathbb{Z}^*$, where

$$\nu_n = \operatorname{sgn}(n)|n|^\alpha \quad \forall n \neq 0.$$

When $\alpha \geq 1$ system (6.1) is controllable provided the control profile is such that all the Fourier components do not vanish. In particular that is the case for the wave equation in time $T = 2\pi$. As we shall see, the situation is even better when $\alpha > 1$, in which case the control property holds for an arbitrarily short time $T > 0$.

More precisely, the following holds.

THEOREM 6.1. *Let $\alpha \geq 1$ and f_k given by* (2.9) *satisfying* (2.10). *Any initial state in the space*

$$H = \left\{ (u^0, u^1) = \sum_{k\in\mathbb{Z}^*} a_k(\frac{1}{k^\alpha\, i}, -1)\sin(kx) : \sum_{k\in\mathbb{Z}^*} \frac{|a_k|^2}{|f_k|^2} < \infty \right\}$$

is controllable in time $T \geq 2\pi$ if $\alpha = 1$ and any time $T > 0$ if $\alpha > 1$, by means of a control $g \in L^2(0,T)$.

Proof. We first claim that the controllability of all initial data from H is equivalent to the inequality

$$C \sum_{n\in\mathbb{Z}^*} |c_n|^2 \leq \int_0^T \left| \sum_{n\in\mathbb{Z}^*} c_n e^{i\nu_n t} \right|^2 \tag{6.3}$$

for every sequence $(c_n)_{n\in\mathbb{Z}^*} \in \ell^2$.

Indeed, as in Lemma 2.2, it is easy to show that the controllability of

$$(u^0, u^1) = \sum_{k\in\mathbb{Z}^*} a_k\Big(\frac{1}{k^\alpha\, i}, -1\Big)\sin(kx)$$

is equivalent to the following moment problem: Find $g \in L^2(0,T)$ such that

$$f_k \int_0^T g(t)e^{i\nu_k t}dt = a_k \quad \forall k \in \mathbb{Z}^*. \tag{6.4}$$

The moment problem (6.4) has a solution for any $(a_n/f_n)_{n\in\mathbb{Z}^*} \in \ell^2$ if and only if[3] the sequence $(e^{i\nu_n t})_{n\in\mathbb{Z}^*}$ is a Riesz–Fischer sequence in $L^2(0,T)$.

On the other hand, from the characterization of the Riesz–Fischer sequences (see [21, Theorem 3, p. 155]), it follows that the sequence $(e^{i\nu_n t})_{n\in\mathbb{Z}^*}$ is a Riesz–Fischer sequence in $L^2(0,T)$ if and only if (6.3) holds. This proves the claim.

We deduce that the moment problem (6.4) has a solution for any $(a_n/f_n)_{n\in\mathbb{Z}^*} \in \ell^2$ if and only if (6.3) holds.

[3]This is an immediate consequence of the definition of *Riesz–Fischer sequence*. Recall that a sequence of vectors $(x_n)_{n\in\mathbb{Z}^*}$ belonging to a Hilbert space H is said to be a Riesz–Fischer sequence if the moment problem $(x, x_n) = c_n$ for all $n \in \mathbb{Z}^*$ has a solution $x \in H$ for any $(c_n)_{n\in\mathbb{Z}^*} \in \ell^2$.

This can also be seen by the so-called HUM method by Lions [15] (see Remark 6.1).

Let us now show that, in the case $\alpha \geq 1$, (6.3) holds under the restrictions on T in the statement of the theorem. Indeed, from [2] (see also [9] and [10]), it follows that (6.3) holds for any $T > 2\pi/\gamma_\infty$ if

$$\liminf_{|n|\to\infty} |\nu_{n+1} - \nu_n| \geq \gamma_\infty > 0. \tag{6.5}$$

Since $|\nu_{n+1} - \nu_n| = (n+1)^\alpha - n^\alpha$, it follows that property (6.5) holds for any $T > 2\pi$ if $\alpha = 1$ (since $\gamma_\infty = 1$) and for any $T > 0$ if $\alpha > 1$ (since $\gamma_\infty = \infty$). Moreover, when $\alpha = 1$, in view of the time-orthogonality of the complex exponentials involved in the Fourier series development of solutions, property (6.5) holds for $T = 2\pi$ as well.

This completes the proof of the theorem. □

REMARK 6.1. *The controllability of* (6.1) *with initial data in* H *and controls in* $L^2(0,T)$ *is equivalent to the existence of a positive constant* $C > 0$ *such that*

$$||(\varphi^0, \varphi^1)||^2_{H'} \leq C \int_0^T \left| \int_0^\pi \varphi(t,x) f(x) dx \right|^2 dt,$$

$$\forall (\varphi^0, \varphi^1) \in H' = \left\{ (\varphi^0, \varphi^1) = \sum_{k\in\mathbb{Z}^*} a_k \left(\frac{1}{k^\alpha\, i}, -1 \right) \sin(kx) : \sum_{k\in\mathbb{Z}^*} |a_k|^2 |f_k|^2 < \infty \right\}, \tag{6.6}$$

where (φ, φ_t) *is the solution of*

$$\begin{cases} \varphi_{tt} + A_\alpha \varphi = 0, & x \in (0,\pi),\ t \in (0,T), \\ \varphi = 0, & x \in \{0,\pi\},\ t \in (0,T), \\ \varphi(0,x) = \varphi^0(x), \quad \varphi_t(0,x) = \varphi^1(x), & x \in (0,\pi). \end{cases} \tag{6.7}$$

Inequality (6.6) *is usually called the* observation inequality.

Using the Fourier expansion of the solutions of (6.7) *it is easy to see that* (6.6) *may be written as* (6.3). *Inequality* (6.3) *may be proved by means of the classical Ingham inequality* (*see* [21]).

Once inequality (6.6) *is known to hold, the control* $g = g(t)$ *can be built by minimizing the quadratic functional*

$$J(\varphi^0, \varphi^1) = \frac{1}{2} \int_0^T \left| \int_0^\pi \varphi(t,x) f(x) dx \right|^2 dt + \langle (u^1, -u^0), (\varphi^0, \varphi^1) \rangle \tag{6.8}$$

in the space H'. *Indeed, under the assumption that* $(u^1, -u^0) \in H$ (*the dual of* H') *the functional* J *is continuous, convex, and coercive in the Hilbert space* H'. *Thus its minimum exists. It is then easy to see that the control* g *we are looking for is* $g(t) = \int_0^\pi \hat{\varphi}(t,x) f(x) dx$, *where* $\hat{\varphi}$ *is the solution of* (6.7) *with the minimizer of* J *as initial datum.*

The proof of Theorem 6.1 is based on inequality (6.3), which holds in the case $\alpha \geq 1$. Nevertheless, if $\alpha < 1$, there exists no uniform gap between two consecutive eigenvalues and (6.3) does not hold. The controllability properties are very different in this case.

In fact, when $0 < \alpha < 1$ system (6.1) is very badly controllable. Even the *spectral control property* fails to hold. We recall that system is said to be spectrally controllable if all initial data consisting in a single eigenfunction of the system may be controlled.

THEOREM 6.2. *If $\alpha < 1$, equation (6.1) is not spectrally controllable in any time $T > 0$.*

Proof. Suppose that (6.1) is spectrally controllable. Hence, every eigenfunction of system (6.1) may be driven to zero by using a control in $L^2(0,T)$.

But an initial datum of the form $(u^0, u^1) = (1/k^\alpha\, i, -1)\sin(kx)$ is controllable if and only if there exists $g \in L^2(0,T)$ such that

$$\int_0^T g(t)e^{i\nu_n t}dt = \delta_{nk}/f_k \quad \forall n \neq 0. \tag{6.9}$$

From the Paley–Wiener theorem we obtain that (6.9) implies the existence of an entire function G of exponential type $T/2$, such that $\int_{-\infty}^{\infty} |G(x)|^2 dx < \infty$ and $G(\nu_n) = 0$ for all $n \neq 0, k$.

Let $n_G(r)$ denote the number of zeros of the function G which belong to the ball of center zero and radius r,

$$n_G(r) = \#\{z \in \mathbb{C} \,:\, G(z) = 0 \text{ and } |z| \leq r\}.$$

We have

$$n_G(r) = 2\#\{n \in \mathbb{N}^* \,:\, n^\alpha \leq r\} = 2\left[r^{\frac{1}{\alpha}}\right].$$

Since $\alpha < 1$ it follows that

$$\lim_{r\to\infty} n_G(r)/r = \infty. \tag{6.10}$$

We need now the following result, which is a consequence of the well-known Jensen formula (see [21, Theorems 2 and 3, pp. 59–61]): *if f is an entire nontrivial function of exponential type, then $n_f(r)/r$ remains bounded as r tends to infinity.*

From (6.10) and the previous theorem it follows that $G \equiv 0$, which contradicts (6.9). □

Our results show that for the hyperbolic equation (6.1) the critical exponent becomes $\alpha = 1$, instead of the exponent $\alpha = 1/2$ we have obtained for the parabolic equations (2.3).

7. Comments.

7.1. More general $1 - d$ problems. In this article we have considered the problem of controllability of a parabolic equation involving the fractional power of the Laplace operator. The control has a fixed shape, given by the function f. The problems of distributed control of the form $v(t,x)1_\omega$, with ω a subinterval of $(0,\pi)$, or of boundary control $v(t)$ may also be considered and will be treated elsewhere by similar techniques. The $1-d$ analysis on the wave equation in section 6 may also be carried out for the Schrödinger and the beam equations.

7.2. Multidimensional problems. In several space dimensions, $N \geq 2$, similar problems can be analyzed. Consider the Dirichlet problem,

$$\begin{cases} u_t + (-\Delta)^\alpha u = g(t)f(x) & \text{in } \Omega \times (0,T), \\ u = 0 & \text{on } \partial\Omega \times (0,T), \\ u(0,x) = u^0(x) & \text{in } \Omega. \end{cases} \tag{7.1}$$

Here Ω is a bounded domain of $\mathbb{R}^N$.

By Weyl's theorem, the spectrum of the Laplacian grows as the frequency increases in the following way: $\lambda_n \sim c(\Omega)n^{2/N}$.

According to this, the spectrum of the α-power of the Laplacian, $(-\Delta)^\alpha$, grows at a rate $n^{2\alpha/N}$ as $n \to \infty$. The critical case is then $\alpha = N/2$. One can then expect to obtain positive results for $\alpha > N/2$ and negative ones, as those presented here, for $\alpha \leq N/2$. An analysis of this multidimensional problem is also to be done.

STATE FEEDBACK H_∞ CONTROL FOR A CLASS OF NONLINEAR STOCHASTIC SYSTEMS*

WEIHAI ZHANG† AND BOR-SEN CHEN‡

Abstract. This paper discusses the H_∞ control problem for a class of nonlinear stochastic systems with both state- and disturbance-dependent noise. By means of Hamilton–Jacobi equations, both infinite and finite horizon nonlinear stochastic H_∞ control designs are developed.

Some results on nonlinear H_∞ control of deterministic systems are generalized to a stochastic setting. We introduce some useful concepts such as "zero-state observability" and "zero-state detectability" which, together with the stochastic LaSalle invariance principle, yield some valuable consequences in infinite horizon nonlinear stochastic H_∞ control.

Key words. H_∞ control, nonlinear stochastic systems, Hamilton–Jacobi equation, zero-state observability, zero-state detectability

1. Introduction.

In practice, when the exogenous disturbance enters the system, an H_∞ control design is often first considered, when a control law is sought to efficiently eliminate the effect of the disturbance; see [12], [13] and the references therein. Theoretically, study of H_∞ control first starts from the deterministic linear systems, and the derivation of the state-space formulation of the standard H_∞ control leads to a breakthrough; details can be found in the prize-winning paper [17]. From the viewpoint of the state space, the linear H_∞ control problem can be converted into the study of a game-theoretic Riccati equation, and the "completion of square methodology," similar to the linear quadratic (LQ) and linear quadratic Gaussian (LQG) theories, can be applied; see [15], [16], [20], [21], [25], and [30].

Soon after the appearance of [17], the nonlinear H_∞ control problem (on deterministic systems) was investigated by many authors; see [5], [14], [18], and [19]. From the time-domain perspective, an H_∞ norm of the transfer function is nothing else but the $\mathcal{L}_2$-induced norm of the input-output operator with initial state zero. This important feature makes it possible to develop nonlinear or stochastic H_∞ theory. Van der Schaft [5] made a contribution to the state feedback H_∞ control for nonlinear deterministic systems with infinite time horizon, where a relatively deep tool, i.e., the strict relation between Hamilton–Jacobi equations (HJEs) and invariant manifolds of Hamiltonian vector fields, was applied. Using this tool, he showed that a local solution to the primal nonlinear H_∞ control exists if its linearized H_∞ control problem is solvable. The authors of [18] and [19] dealt with the output feedback H_∞ control of nonlinear deterministic systems with incomplete state information, and a separation principle was obtained. In [5], [18], and [19], the differential geometric approaches

were employed, which cannot be directly extended to stochastic H_∞ control for technical reasons. Chen, Tseng, and Vang [14] present a fuzzy treatment for nonlinear H_2/H_∞ control, and [11] treats the singular H_∞ control of nonlinear systems.

In recent years, stochastic H_∞ control systems, such as Markovian jump systems [22], [23], [24], H_∞ Gaussian control design [3], and Itô differential systems (systems governed by the Itô equation) have received a great deal of attention (see [2], [28], [30], [33], [34], [35], [36], and the references therein). H_∞ control has significant application in other problems, such as filtering theory [4]. Up to now, most of the work on stochastic H_∞ control for the Itô differential systems concentrated on the linear case, while for the general nonlinear systems, few results have been reported.

This paper will follow along the lines of [5] to study stochastic H_∞ control (including infinite and finite time horizons) for a class of affine nonlinear Itô differential systems, mainly using the completion of square methodology. To achieve our goal, some essential difficulties must be overcome. For instance, in order to discuss the relation between external stability and the existence of global solutions of the corresponding HJE, the so-called stochastic dissipative theory is developed, which can be viewed as a generalized version of [10]. Likewise, to present sufficient conditions for a closed-loop system to be internally stable, zero-state observability and detectability are introduced for nonlinear stochastic systems which, combined with the stochastic LaSalle invariance principle [8], yield some valuable consequences.

Section 2 develops the dissipative theory for stochastic systems paralleling that of [10]. Theorem 2.1 is an important result of this section, which extends Theorem 1 of [7], and will be used in section 3. Similar to applications of Theorem 1 of [7] in [6], [7], and [9], we also believe that Theorem 2.1 can be applied to nonlinear stochastic stability and stabilization, which merits further study. Section 3 is concerned with the infinite horizon H_∞ control of nonlinear affine stochastic systems, where the H_∞-norm is expressed by the norm of the nonlinear perturbation operator $\tilde{\mathcal{L}}_{zd}$. Theorem 3.1 and Corollary 3.1 extend Theorem 16 and Corollary 17 of [5], respectively. Lemma 3.2 may be viewed as the "nonlinear stochastic bounded real lemma (SBRL)." Section 4 is devoted to the finite horizon H_∞ control of affine nonlinear time-varying stochastic systems, and necessary and sufficient conditions for nonlinear H_∞ control are derived (Theorems 4.1 and 4.2). It is shown that a finite horizon H_∞ control can be converted into solving a stochastic game problem, while (u_T^*, d_T^*) is in fact the saddle point of this game. The relation between finite and infinite time HJEs has also been clarified, specifically, under some precise conditions; the solution of the finite time HJE converges to that of the infinite time HJE. Section 5 ends this paper with some remarks.

For convenience, we adopt the following notation:

$\mathcal{S}_n$: the set of all real $n \times n$ symmetric matrices;

A': the transpose of the corresponding matrix A;

$A \geq 0 (A > 0)$: the positive semidefinite (positive definite) matrix A;

I: the identity matrix;

$C_0^2(\{t > 0\} \times U)$: the class of functions $V(t, x)$ twice continuously differential with respect to $x \in U$ and once continuously differential with respect to $t > 0$ except possibly at the point $x = 0$;

$C^2(U)$: the class of functions $V(x)$ twice continuously differential with respect to $x \in U$.

2. Dissipative stochastic systems. Consider the following nonlinear stochastic controlled system governed by the Itô differential equation (the time variable t is

suppressed):

$$\begin{cases} dx(t) = (f(x) + g(x)u)dt + (h(x) + l(x)u)dW, \\ \qquad f(0) = 0, h(0) = 0, \\ z = m(x),\ m(0) = 0. \end{cases} \tag{1}$$

In the above, f, g, h, l, and m are uniformly continuous and Lipschitz satisfying a linear growth condition, which guarantees that (1) has a unique strong solution [32]. $x(t) \in \mathcal{R}^n$ is called the system state, and $z(t) \in \mathcal{R}^{n_z}$ is the regulated output. $W(t)$ is the one-dimensional standard Wiener process defined on the complete probability space $(\Omega, \mathcal{F}, \mathcal{P})$, with the natural filter $\mathcal{F}_t$ generated by $W(\cdot)$ up to time t. $u(t) \in \mathcal{R}^{n_u}$ is the control input, which is an adapted process with respect to $\{\mathcal{F}_t\}_{t\geq 0}$, and causes system (1) to have a unique strong solution under the above conditions. The dissipative dynamic system theory was founded in [10] and has become an important tool in studying the stability and stabilization of nonlinear systems; see [6], [7], and [9]. In recent years, the theory of [10] has been extended to stochastic systems in various different ways by many researchers [27], [29], [37]. In the following, we develop a parallel dissipative theory for stochastic systems which is slightly different from the previous references and is self-contained.

An admissible control set $\mathcal{L}^2_{\mathcal{F}}([s,T], \mathcal{R}^{n_u})$ consists of all adapted and measurable processes $u(t)$ with respect to $\mathcal{F}_t$, such that

$$\|u\|^2_{\mathcal{L}^2([s,T])} := E\int_s^T \|u(t)\|^2\, dt < \infty, \qquad s \geq 0.$$

In the terminology of [10], a function $w(\cdot,\cdot) : \mathcal{R}^{n_u} \times \mathcal{R}^{n_z} \mapsto \mathcal{R}$ associated with system (1) is called the supply rate on $[s, \infty)$ if it has the following property: for any $u \in \mathcal{L}^2_{\mathcal{F}}([s,T], \mathcal{R}^{n_u})$, $x(s) \in \mathcal{R}^n$, the controlled output $z(t) = m(x(t))$ of (1) is such that

$$E\int_s^T |w(u(t), z(t))|\, dt < \infty \ \forall\ \ T \geq s \geq 0.$$

Definition 2.1. *System* (1) *with supply rate* w *is said to be dissipative on* $[s, \infty)$, $s \geq 0$, *if there exists a nonnegative continuous function* $V : \mathcal{R}^n \mapsto \mathcal{R}^+$, *called the storage function, such that for all* $t \geq s \geq 0$, $x(s) \in \mathcal{R}^n$,

$$EV(x(t)) - V(x(s)) \leq E\int_s^t w(u(\tau), z(\tau))\, d\tau. \tag{2}$$

As in deterministic systems [10], (2) can be called the dissipative inequality.

Proposition 2.1. *If there exists a Lyapunov function* V *defined on* $\mathcal{R}^n$ *(i.e.,* $V \in \mathcal{C}^2(\mathcal{R}^n)$ *and is positive definite) satisfying*

$$\mathcal{L}_u V(x) \leq w(u, z)\ \ \forall (u, z) \in \mathcal{R}^{n_u} \times \mathcal{R}^{n_z},$$

then system (1) *is dissipative with supply rate* w *on* $[s, \infty)$ *for any* $s \geq 0$, *where* $\mathcal{L}_u$ *is the infinitesimal generator of the equation*

$$dx = (f(x) + g(x)u)dt + (h(x) + l(x)u)dW. \tag{3}$$

Proof. By Itô's formula, for any $t \geq s \geq 0$, $x(s) \in \mathcal{R}^n$,

$$V(x(t)) - V(x(s)) = \int_s^t \mathcal{L}_u V(x)\, dt + \int_s^t \frac{\partial V'(x)}{\partial x}(h(x) + l(x)u)\, dW.$$

Calculating the above expectation, we get

$$EV(x(t)) - V(x(s)) = E\int_s^t \mathcal{L}_u V(x)\,dt \le E\int_s^t w(u(t), z(t))\,dt.$$

This ends the proof. □

DEFINITION 2.2. *An available storage with supply rate w on $[s,\infty)$, $s \ge 0$, is defined by*

$$\begin{aligned} V_{a,s}(x) &= -\inf_{u\in\mathcal{L}^2_{\mathcal{F}}([s,t];\mathcal{R}^{n_u}),t\ge s,x(s)=x\in\mathcal{R}^n} E\int_s^t w(u(s),z(s))\,ds \\ &= \sup_{u\in\mathcal{L}^2_{\mathcal{F}}([s,t];\mathcal{R}^{n_u}),t\ge s,x(s)=x\in\mathcal{R}^n} -E\int_s^t w(u(s),z(s))\,ds. \end{aligned} \tag{4}$$

A stochastic version of Proposition 2.3 of [9] is as follows.

PROPOSITION 2.2. *If system* (1) *with supply rate w is dissipative on $[s,\infty)$, $s \ge 0$, then the available storage $V_{a,s}(x)$ is finite for each $x \in \mathcal{R}^n$. Moreover, for any possible storage function V_s,*

$$0 \le V_{a,s}(x) \le V_s(x) \quad \forall x \in \mathcal{R}^n. \tag{5}$$

$V_{a,s}$ is itself a possible storage function. Conversely, if $V_{a,s}$ is finite for each $x \in \mathcal{R}^n$, then system (1) *is dissipative on $[s,\infty)$.*

Proof. $V_{a,s} \ge 0$ is obvious. Next, by Definition 2.1, if system (1) with supply rate w is dissipative on $[s,\infty)$, then (2) holds for some storage function V_s. So for any $x(s) = x \in \mathcal{R}^n$, $t \ge s \ge 0$,

$$V_s(x) \ge -E\int_s^t w(u(\tau),z(\tau))\,d\tau + EV_s(x(t)) \ge -E\int_s^t w(u(\tau),z(\tau))\,d\tau,$$

which yields

$$\begin{aligned} V_s(x) &\ge \sup_{t\ge s,u\in\mathcal{L}^2_{\mathcal{F}}([s,t],\mathcal{R}^{n_u}),x(s)=x} -E\int_s^t w(u(\tau),z(\tau))\,d\tau \\ &= -\inf_{t\ge s,u\in\mathcal{L}^2_{\mathcal{F}}([s,t],\mathcal{R}^{n_u}),x(s)=x} E\int_s^t w(u(\tau),z(\tau))\,d\tau = V_{a,s}(x). \end{aligned}$$

Therefore, $V_{a,s}$ is finite and (5) holds. The rest can be done along the lines of [10] mainly using the relation

$$V_{a,s}(x) + E\int_s^t w(u(\tau),z(\tau))\,d\tau \ge EV_{a,s}(x(t)). \tag{6}$$ □

The following general theorem with $w(u,z) = z'Qz + 2z'Su + u'Ru$ will be used in section 3, where $Q \in \mathcal{S}_{n_z}$, $S \in \mathcal{R}^{n_z\times n_u}$, and $R \in \mathcal{S}_{n_u}$ are constant matrices. The following assumption is necessary.

Assumption 2.1. The storage function of (4), if it exists, belongs to $C^2(\mathcal{R}^n)$.

THEOREM 2.1. *A necessary and sufficient condition for system* (1) *to be dissipative on $[s,\infty)$ with respect to a supply rate $w(\cdot,\cdot)$ is that there exists $V_s \in C^2(\mathcal{R}^n)$:*

$\mathcal{R}^n \mapsto \mathcal{R}^+, V_s(0) = 0, \tilde{l} : \mathcal{R}^n \mapsto \mathcal{R}^q$, *and* $\tilde{w} : \mathcal{R}^n \mapsto \mathcal{R}^{q\times n_u}$ *for some integer* $q > 0$, *such that*

$$m'Qm - \frac{\partial V_s'}{\partial x} f - \frac{1}{2} h' \frac{\partial^2 V_s}{\partial x^2} h = \tilde{l}'\tilde{l}, \tag{7}$$

$$R - \frac{1}{2} l' \frac{\partial^2 V_s}{\partial x^2} l = \tilde{w}'\tilde{w}, \tag{8}$$

$$2S'm - g' \frac{\partial V_s}{\partial x} - l' \frac{\partial^2 V_s}{\partial x^2} h = 2\tilde{w}'\tilde{l}. \tag{9}$$

Proof. If system (1) is dissipative on $[s, \infty)$ with respect to a supply rate $w(\cdot, \cdot)$, by Proposition 2.2, $V_{a,s}$ is a possible storage function, which satisfies (6). By (6) with any $x(s) = x \in \mathcal{R}^n$ and Assumption 2.1, we have

$$-\frac{EV_{a,s}(x(t)) - V_{a,s}(x)}{t-s} + \frac{E\int_s^t w(u(\tau), z(\tau))\, d\tau}{t-s} \geq 0, \qquad t > s.$$

Let $t \downarrow s$ in the above and note that (applying Itô's formula)

$$EV_{a,s}(x(t)) = V_{a,s}(x) + E\int_s^t \left(\frac{\partial V_{a,s}'}{\partial x}(f + gu) + \frac{1}{2}(h + lu)' \frac{\partial^2 V_{a,s}}{\partial x^2}(h + lu) \right) d\tau,$$

it follows that

$$\begin{aligned} J(x,u) := {} & m'Qm + 2m'Su + u'Ru - \frac{\partial V_{a,s}'}{\partial x}(f + gu) \\ & -\frac{1}{2}(h + lu)' \frac{\partial^2 V_{a,s}}{\partial x^2}(h + lu) \geq 0 \end{aligned} \tag{10}$$

for all x and u. Obviously, by the fact that the right-hand side of (10) is quadratic in u, there exist $\tilde{l} : \mathcal{R}^n \mapsto \mathcal{R}^q$, and $\tilde{w} : \mathcal{R}^n \mapsto \mathcal{R}^{q\times n_u}$ (not necessarily unique), such that

$$J(x,u) = (\tilde{l}(x) + \tilde{w}(x)u)'(\tilde{l}(x) + \tilde{w}(x)u).$$

By comparing the coefficients of the same powers of u, we deduce (7), (8), and (9). The inverse can be very easily shown by noting that for any $x(s) = x \in \mathcal{R}^n$, we have

$$\begin{aligned} E\int_s^t w(u(\tau), z(\tau))\, d\tau = {} & E\int_s^t (\tilde{l}(x) + \tilde{w}(x)u)'(\tilde{l}(x) + \tilde{w}(x)u)\, d\tau \\ & + EV_s(x(t)) - V_s(x) \geq EV_s(x(t)) - V_s(x). \end{aligned}$$

Theorem 2.1 is complete. □

Theorem 2.1 will have important applications in stochastic stabilization, which will be further studied in our future work. In this paper, we mainly study the dissipative systems with $w(u,z) = \gamma^2 u'u - z'z$ called finite gain systems. When $w(u,z) = u'z$, it is called a passive system [9], which is very useful in the study of nonlinear stochastic stability. If (2) is replaced by

$$EV(x(t)) - V(x(s)) = E\int_s^t w(u(s), z(s))\, ds \quad \forall (u,z) \in \mathcal{R}^{n_u} \times \mathcal{R}^{n_z}, \tag{11}$$

system (1) is said to be lossless.

Remark 2.1. For stochastic system $dx = m(x,u)dt+\sigma(x)dW$, a more general definition for stochastic dissipativeness can be found in [29, Defs. 4.1 and 4.2]. However, Definition 2.1 above is sufficient for our purposes. In particular, when $w(u,z) = u'z$, by using the well-known Dynkin's formula, it can be seen that Definition 2.1 extends Definition 4.1 of [27] for stochastic passive systems.

Remark 2.2. If in (2) and (4), $s = 0$ and t is any bounded stopping time, then [37] gave Definitions 2.1 and 2.2 for the following general nonlinear stochastic system:

$$dx = f(x,u)dt + g(x,u)dW, \qquad x(0) = x \in \mathcal{R}^n.$$

Here, we take the terminal time t to be any fixed scalar only for technical reasons.

3. Infinite horizon H_∞ control. To treat the infinite horizon H_∞ control problem, we need the following definitions of stochastic stability and observability.

3.1. Stochastic stability and observability.

DEFINITION 3.1 (see [1]). *Consider the stochastic unforced system*

$$dx = f(x)\,dt + h(x)\,dW, \quad x(0) = x_0 \in \mathcal{R}^n, \quad f(0) = h(0) = 0. \tag{12}$$

(a) $x \equiv 0$ *of* (12) *is said to be stable in probability if for any* $\epsilon > 0$,

$$\lim_{x_0 \to 0} P\left(\sup_{t\geq 0} \|x(t)\| > \epsilon\right) = 0. \tag{13}$$

(b) $x \equiv 0$ *of* (12) *is said to be locally asymptotically stable in probability if* (13) *holds and*

$$\lim_{x_0 \to 0} P\left(\lim_{t\to\infty} x(t) = 0\right) = 1.$$

(c) $x \equiv 0$ *of* (12) *is said to be globally asymptotically stable in probability if* (13) *holds and*

$$P\left(\lim_{t\to\infty} x(t) = 0\right) = 1.$$

(d) $x \equiv 0$ *of* (12) *is said to be asymptotically mean square stable if* $\lim_{t\to\infty} E\|x(t)\|^2 = 0$.

(e) $x \equiv 0$ *of* (12) *is said to be exponentially mean square stable if there exist* ϱ *and* $\rho > 0$, *such that* $E\|x(t)\|^2 \leq \rho\|x_0\|^2 \exp(-\varrho t)$.

It is very well known that for the linear time-invariant stochastic systems (LTISS), (d) *is equivalent to* (e) [1]. *The following definition can be thought of an extension of the observability in nonlinear deterministic systems.*

DEFINITION 3.2. *We say that the following system* (*or* $[f(x), l(x)|h(x)]$)

$$dx = f(x)\,dt + l(x)\,dW, \qquad z = h(x), \tag{14}$$

is locally zero-state detectable if there is a neighborhood N *of* 0 *such that for all* $x(0) = x_0 \in N$,

$$z(t) = h(x(t)) = 0 \text{ a.s. } \forall t \geq 0 \Rightarrow P\left(\lim_{t\to\infty} x(t) = 0, x(0) = x_0\right) = 1.$$

If $N = \mathcal{R}^n$, (14) *is called zero-state detectable. Equation* (14) *is locally (resp., globally) zero-state observable if there is a neighborhood* N *of* 0 *such that for all* $x_0 \in N$ *(resp.,* $\mathcal{R}^n$*),* $z(t) \equiv 0$ *implies* $x_0 \equiv 0$.

Obviously, for the LTISS

$$dx = Fx\,dt + Lx\,dW, \qquad z = Hx, \tag{15}$$

the local zero-state observability (detectability) is equivalent to the global zero-state observability (detectability). In particular, when (15) is observable (detectable), we also call $[F, L|H]$ observable (detectable).

The following lemma, used in the next subsection, can be called the stochastic version of LaSalle's invariance principle [8].

LEMMA 3.1. *Assume there exists a Lyapunov function V such that*

$$\mathcal{L}_{u\equiv 0}V(x) \le 0$$

for any $x \in \mathcal{R}^n$; then the solution $x(t)$ of (12) tends in probability to the largest invariant set whose support is contained in the locus $\Upsilon := \{x : \mathcal{L}_{u\equiv 0}V(x) = 0\}$ for any $t \ge 0$.

3.2. Main results. Consider the nonlinear stochastic system

$$\begin{cases} dx = (f(x) + g(x)u + k(x)d)dt + (h(x) + l(x)d)dW,\ f(0) = 0,\ h(0) = 0, \\ z = \begin{bmatrix} m(x) \\ u \end{bmatrix}, m(0) = 0, \end{cases} \tag{16}$$

where $d(t)$ stands for the exogenous disturbance, which is an adapted process with respect to $\mathcal{F}_t$. Under very mild conditions, (16) has a unique strong solution $x(t)$ or, for clarity, $x(t, u, d, x(t_0), t_0)$ [32] on any finite interval $[t_0, T]$ with initial state $x(t_0) \in \mathcal{R}^n$. Let $\mathcal{L}^2_{\mathcal{F}}(\mathcal{R}_+, \mathcal{R}^{n_y})$ denote a space composed of all nonanticipative stochastic processes $y(t)_{t\ge 0}$ with respect to $\mathcal{F}_t$, such that

$$\|y\|_{\mathcal{L}^2(\mathcal{R}_+)} := \left(E\int_0^\infty \|y(t)\|^2\,dt\right)^{1/2} < \infty.$$

Obviously, $\mathcal{L}^2_{\mathcal{F}}(\mathcal{R}_+, \mathcal{R}^{n_y})$ is a Hilbert space equipped with the inner product

$$\langle y_1, y_2\rangle = E\int_0^\infty y_1'(t)y_2(t)\,dt\ \forall y_1, y_2 \in \mathcal{L}^2_{\mathcal{F}}(\mathcal{R}_+, \mathcal{R}^{n_y}).$$

DEFINITION 3.3 (infinite horizon nonlinear state feedback H_∞ control). *Given $\gamma > 0$, we want to find an admissible control u^*_∞, such that for any $d \ne 0 \in \mathcal{L}^2_{\mathcal{F}}(\mathcal{R}^+, \mathcal{R}^{n_d})$, when $x(0) = 0$, the following inequality holds:*

$$\|z\|_{\mathcal{L}^2(\mathcal{R}_+)} \le \gamma\|d\|_{\mathcal{L}^2(\mathcal{R}_+)}. \tag{17}$$

Equation (17) is equivalent to $\|\tilde{\mathcal{L}}_{zd}\|_\infty \le \gamma$, where the perturbation operator $\tilde{\mathcal{L}}_{zd}$ is defined by $\tilde{\mathcal{L}}_{zd} : \mathcal{L}^2_{\mathcal{F}}(\mathcal{R}_+, \mathcal{R}^{n_d}) \mapsto \mathcal{L}^2_{\mathcal{F}}(\mathcal{R}_+, \mathcal{R}^{n_z})$ as

$$\tilde{\mathcal{L}}_{zd}(d) = z(x(t, u^*_\infty, d, 0, 0)), \quad t \ge 0, \quad d \in \mathcal{L}^2_{\mathcal{F}}(\mathcal{R}_+, \mathcal{R}^{n_d}),$$

$$\begin{aligned} \|\tilde{\mathcal{L}}_{zd}\|_\infty &= \sup_{d\in\mathcal{L}^2_{\mathcal{F}}(\mathcal{R}_+,\mathcal{R}^{n_d}), d\ne 0, x(0)=0} \frac{\|z\|_{\mathcal{L}^2(\mathcal{R}_+)}}{\|d\|_{\mathcal{L}^2(\mathcal{R}_+)}} \\ &= \sup_{d\in\mathcal{L}^2_{\mathcal{F}}(\mathcal{R}_+,\mathcal{R}^{n_d}), d\ne 0} \frac{\{E\int_0^\infty (\|m(x(t, u^*_\infty, 0, 0))\|^2 + \|u^*_\infty\|^2)\,dt\}^{1/2}}{\{E\int_0^\infty \|d\|^2\,dt\}^{1/2}}. \end{aligned} \tag{18}$$

Compared with the definition of linear (uncertain) time-invariant stochastic H_∞ [2], we find that the internal mean square stability is required therein. Naturally, in the

nonlinear case, we expect the closed-loop system to be of some internal stability, which will be guaranteed by (17) *together with zero-state observability or zero-state detectability. As pointed out by* [5], *it is easier to consider first an infinite horizon nonlinear state feedback* H_∞ *control as in Definition* 3.3. *More specifically, if we let* $u \equiv 0$, $z = m(x)$, $\hat{\mathcal{L}}_{zd} := m(x(t,0,d,0,0))$, *and take* d *as a control variable, then when* $\|\hat{\mathcal{L}}_{zd}\|_\infty \le \gamma$ *for some* $\gamma > 0$, *the nonlinear system*

$$\begin{cases} dx = (f(x) + k(x)d)dt + (h(x) + l(x)d)dW,\ f(0) = 0,\ h(0) = 0, \\ z = m(x),\ m(0) = 0 \end{cases} \tag{19}$$

is said to be externally stable or $\mathcal{L}^2$ *input-output stable. We refer the reader to* [2] *for the definition of external stability of linear stochastic systems.*

THEOREM 3.1. *Suppose there exists a nonnegative solution* $V \in C^2(\mathcal{R}^n)$ *to the HJE*

$$\begin{cases} \mathcal{H}^1_\infty(V(x)) := \frac{\partial V'}{\partial x} f + \frac{1}{2}(\frac{\partial V'}{\partial x} k + h' \frac{\partial^2 V}{\partial x^2} l)(\gamma^2 I - l' \frac{\partial^2 V}{\partial x^2} l)^{-1}(k' \frac{\partial V}{\partial x} + l' \frac{\partial^2 V}{\partial x^2} h) \\ \quad - \frac{1}{2} \frac{\partial V'}{\partial x} g g' \frac{\partial V}{\partial x} + \frac{1}{2} m' m + \frac{1}{2} h' \frac{\partial^2 V}{\partial x^2} h = 0, \\ \gamma^2 I - l' \frac{\partial^2 V}{\partial x^2} l > 0, V(0) = 0; \end{cases} \tag{20}$$

then

$$u^*_\infty = -g' \frac{\partial V}{\partial x} \tag{21}$$

is an H_∞ *control for system* (16).

Proof. By Itô's formula,

$$\begin{aligned} dV(x) = &\left[\frac{\partial V'}{\partial x}(f + gu + kd) + \frac{1}{2}(h + ld)' \frac{\partial^2 V}{\partial x^2}(h + ld) \right] dt \\ &+ \frac{\partial V'}{\partial x}(h + ld)\, dW(t). \end{aligned} \tag{22}$$

By completing the square together with (20), we have for any $T > 0$,

$$\begin{aligned} EV(x(T)) - V(0) = EV(x(T)) &= E \int_0^T \left[\frac{\partial V'}{\partial x}(f + gu + kd) \right. \\ &\qquad \left. + \frac{1}{2}(h + ld)' \frac{\partial^2 V}{\partial x^2}(h + ld) \right] dt \\ &= \frac{1}{2} E \int_0^T \left(\left\| u + g' \frac{\partial V}{\partial x} \right\|^2 + 2\mathcal{H}^1_\infty(V(x)) \right. \\ &\qquad - \| d - \left(\gamma^2 I - l' \frac{\partial^2 V}{\partial x^2} l \right)^{-1} \left(k' \frac{\partial V}{\partial x} + l' \frac{\partial^2 V}{\partial x^2} h \right) \|^2_{\gamma,l,V} \\ &\qquad \left. - \|z\|^2 + \gamma^2 \|d\|^2 \right) dt \\ &= \frac{1}{2} E \int_0^T \left(\left\| u + g' \frac{\partial V}{\partial x} \right\|^2 - \|z\|^2 + \gamma^2 \|d\|^2 \right. \\ &\qquad \left. - \| d - \left(\gamma^2 I - l' \frac{\partial^2 V}{\partial x^2} l \right)^{-1} \left(k' \frac{\partial V}{\partial x} + l' \frac{\partial^2 V}{\partial x^2} h \right) \|^2_{\gamma,l,V} \right) dt, \end{aligned} \tag{23}$$

where $\|Z(x)\|^2_{\gamma,l,V} := Z'(x)(\gamma^2 I - l'\frac{\partial^2 V}{\partial x^2} l)Z(x)$. Obviously, when $u = u^*_\infty$, (23) leads to

$$E\int_0^T \|z\|^2\,dt = -E\int_0^T \left\| d - \left(\gamma^2 I - l'\frac{\partial^2 V}{\partial x^2} l\right)^{-1}\left(k'\frac{\partial V}{\partial x} + l'\frac{\partial^2 V}{\partial x^2} h\right)\right\|^2_{\gamma,l,V} dt$$
$$-2EV(x(T)) + 2V(0) + \gamma^2 E\int_0^T \|d\|^2\,dt$$
$$\le \gamma^2 E\int_0^T \|d\|^2\,dt. \tag{24}$$

Let $T \to \infty$ in (24); then $\|\tilde{\mathcal{L}}_{zd}\|_\infty \le \gamma$ follows because of $V \ge 0$ and $V(0) = 0$. This ends the proof of Theorem 3.1. □

Remark 3.1. From the proof of Theorem 3.1, it can be seen that we have in fact obtained the identity

$$\mathcal{L}_{u,d}V(x) = \frac{\partial V'}{\partial x}(f + gu + kd) + \frac{1}{2}(h + ld)'\frac{\partial^2 V}{\partial x^2}(h + ld)$$
$$= \frac{1}{2}(\|u - u^*_\infty\|^2 - \|d - d^*_\infty\|^2_{\gamma,l,V} + 2\mathcal{H}^1_\infty(V(x)) - \|z\|^2 + \gamma^2\|d\|^2), \tag{25}$$

which will be used throughout this paper, where $\mathcal{L}_{u,d}$ is the infinitesimal generator of

$$dx = (f(x) + g(x)u + k(x)d)dt + (h(x) + l(x)d)dW$$

and

$$d^*_\infty = \left(\gamma^2 I - l'\frac{\partial^2 V}{\partial x^2} l\right)^{-1}\left(k'\frac{\partial V}{\partial x} + l'\frac{\partial^2 V}{\partial x^2} h\right).$$

We can also see that Theorem 3.1 still holds if HJE (20) is replaced by the Hamilton–Jacobi inequality

$$\mathcal{H}^1_\infty(V(x)) \le 0,\ \gamma^2 I - l'\frac{\partial^2 V}{\partial x^2} l > 0, \qquad V(0) = 0.$$

Remark 3.2. From inequality (24), it immediately follows that for any $d \in \mathcal{L}^2_{\mathcal{F}}(\mathcal{R}^+, \mathcal{R}^{n_d})$, we have $z \in \mathcal{L}^2_{\mathcal{F}}(\mathcal{R}^+, \mathcal{R}^{n_z})$, $u^*_\infty \in \mathcal{L}^2_{\mathcal{F}}(\mathcal{R}^+, \mathcal{R}^{n_u})$. However, we cannot assert $d^*_\infty \in \mathcal{L}^2_{\mathcal{F}}(\mathcal{R}^+, \mathcal{R}^{n_d})$.

The following result generalizes Corollary 17 of [5] to the stochastic case.

COROLLARY 3.1. *Under the condition of Theorem* 3.1, *if* $[f, h|m]$ *is zero-state observable, then any solution to HJE* (20) *satisfying* $V(x) > 0$ *for* $x \ne 0$, *and the closed-loop system* (*with* $d \equiv 0$)

$$dx = (f(x) + g(x)u^*_\infty)dt + h(x)dW \tag{26}$$

is locally asymptotically stable in probability. If V *is also proper (i.e., for each* $a > 0$, $V^{-1}([0, a])$ *is compact), then it is globally asymptotically stable in probability. Moreover,* $\lim_{t\to\infty} EV(x(t)) = 0$.

Proof. By (25), we have

$$\mathcal{L}_{u=u^*_\infty,d=0}V(x) = -\frac{1}{2}(\|d^*_\infty\|^2_{\gamma,l,V} + \|m(x)\|^2 + \|u^*_\infty\|^2)$$
$$\le -\frac{1}{2}\begin{bmatrix} m'(x) & u^{*\prime}_\infty \end{bmatrix}\begin{bmatrix} m(x) \\ u^*_\infty \end{bmatrix}. \tag{27}$$

If $V(x)$ is not strictly positive definite in Lyapunov's sense, then there exists $x_0 \neq 0$, such that $V(x_0) = 0$. Integrating from zero to T, and then taking expectation on both sides of (27), it follows that

$$0 \leq EV(x(T)) = -\frac{1}{2}E\int_0^T (\|m\|^2 + \|u_\infty^*\|^2)\, dt \leq 0. \tag{28}$$

Equation (28) concludes that $z(t)|_{u=u_\infty^*} \equiv 0, t \in [0,T]$, for any $T > 0$. From the zero-state observability of $[f, h|m]$, it is easy to prove the zero-state observability of $[f + gu_\infty^*, h|[m'\ u^{*\prime}{}_\infty]']$. According to the definition of zero-state observability, we must have $x(t) \equiv 0$ from $z(t)|_{u=u_\infty^*, d=0} \equiv 0$ a.s., which contradicts $x_0 \neq 0$. $V > 0$ is proved.

In addition, by the above analysis, we have

$$\Upsilon = \{x : \mathcal{L}_{u=u_\infty^*, d=0} V(x) = 0\} \subset \{x : m(x) = 0\} = \{0\}.$$

Hence, the asymptotic stability is proved by use of Lemma 3.1.

Finally, to show $\lim_{t\to\infty} EV(x(t)) = 0$, we apply Itô's formula to system (26); then for any $t > s > 0$,

$$\begin{aligned} V(x(t)) &= V(x(s)) + \int_s^t \mathcal{L}_{u=u_\infty^*, d=0} V(x(\tau))\, d\tau + \int_s^t h' \frac{\partial V}{\partial x}\, dW(\tau) \\ &= V(x(s)) - \frac{1}{2}\int_s^t (\|d_\infty^*\|_{\gamma,l,V}^2 + \|m(x)\|^2 + \|u_\infty^*\|^2)\, dt + \int_s^t h' \frac{\partial V}{\partial x}\, dW(\tau). \end{aligned}$$

So

$$\begin{aligned} E[V(x(t))|\mathcal{F}_s] &= E\left[V(x(s))|\mathcal{F}_s\right] - \frac{1}{2}E[\int_s^t (\|d_\infty^*\|_{\gamma,l,V}^2 + \|m(x)\|^2 + \|u_\infty^*\|^2)\, dt|\mathcal{F}_s\right] \\ &\quad + E\left[\int_s^t h' \frac{\partial V}{\partial x}\, dW(\tau)|\mathcal{F}_s\right] \\ &= V(x(s)) - \frac{1}{2}E\left[\int_s^t (\|d_\infty^*\|_{\gamma,l,V}^2 + \|m(x)\|^2 + \|u_\infty^*\|^2)\, dt|\mathcal{F}_s\right] \\ &\leq V(x(s)), \end{aligned}$$

which shows that $\{V(x(t)), \mathcal{F}_t\}$ is a nonnegative supermartingale. By Doob's convergence theorem and asymptotic stability, $V(x(\infty)) = \lim_{t\to\infty} V(x(t)) = 0$ a.s. Moreover, $\lim_{t\to\infty} EV(x(t)) = EV(x(\infty)) = 0$. The proof of this corollary is complete. □

Remark 3.3. By analogous discussions as in Corollary 3.1, if we replace zero-state observability with zero-state detectability, then Corollary 3.1 still holds except for $V > 0$.

We attempt to give an inverse result of Theorem 3.1; however, there remain some technical problems that cannot be overcome at present. Despite all that, we believe the following lemma, which can be called "nonlinear SBRL," will contribute to the inverse result of Theorem 3.1.

LEMMA 3.2. *For system* (19), $\gamma > 0$, *if there exists a nonnegative solution* $V \in C^2(\mathcal{R}^n) : \mathcal{R}^n \mapsto \mathcal{R}^+$ *to the HJE*

$$\begin{cases} \frac{\partial V'}{\partial x} f + \frac{1}{2}(\frac{\partial V'}{\partial x} k + h' \frac{\partial^2 V}{\partial x^2} l)(\gamma^2 I - l' \frac{\partial^2 V}{\partial x^2} l)^{-1} \\ \qquad \cdot (k' \frac{\partial V}{\partial x} + l' \frac{\partial^2 V}{\partial x^2} h) + \frac{1}{2} m'm + \frac{1}{2} h' \frac{\partial^2 V}{\partial x^2} h = 0, \\ \gamma^2 I - l' \frac{\partial^2 V}{\partial x^2} l > 0 \ \forall x \in \mathcal{R}^n, V(0) = 0, \end{cases} \tag{29}$$

then $\|\hat{\mathcal{L}}_{zd}\|_\infty \leq \gamma$ *for* $x(0) = 0$. *Conversely,* (i) *if there exists a positive definite function* $q : x \in \mathcal{R}^n \mapsto \mathcal{R}^+$, $q(0) = 0$, *such that for all* $x(0) = x \in \mathcal{R}^n, d \in \mathcal{L}^2_{\mathcal{F}}(\mathcal{R}_+, \mathcal{R}^{n_d})$,

$$\|z\|^2_{\mathcal{L}^2(\mathcal{R}_+)} \leq \gamma^2 \|d\|^2_{\mathcal{L}^2(\mathcal{R}_+)} + q(x), \qquad d \neq 0. \tag{30}$$

(ii) *The storage function* $V_{a,0} \in C^2(\mathcal{R}^n)$ *exists with* $\gamma^2 I - l' \frac{\partial^2 V_{a,0}}{\partial x^2} l > 0$ *for all* $x \in \mathcal{R}^n$, *where*

$$V_{a,0}(x) = - \inf_{d \in \mathcal{L}^2_{\mathcal{F}}([0,T];\mathcal{R}^{n_d}), T \geq 0, x(0) = x \in \mathcal{R}^n} E \int_0^T w(d, z)\, dt$$

with $w(d, z) = \frac{1}{2}\gamma^2 \|d\|^2 - \frac{1}{2}\|z\|^2$. *Then* $V_{a,0}$ *solves HJE* (29). *Moreover, for any solution* V *of* (29),

$$V \geq V_{a,0} \geq 0, V_{a,0}(0) = 0. \tag{31}$$

Proof. The first part is an immediate corollary of Theorem 3.1 ($g \equiv 0, u \equiv 0$). As to the inverse result, we first note that (30) concludes, for any $T \geq 0$, that

$$\|z\|^2_{\mathcal{L}^2([0,T])} \leq \gamma^2 \|d\|^2_{\mathcal{L}^2([0,T])} + q(x) \forall d \in \mathcal{L}^2_{\mathcal{F}}([0, T], \mathcal{R}^{n_d}).$$

Actually, for any $d \in \mathcal{L}^2_{\mathcal{F}}([0, T], \mathcal{R}^{n_d})$, if we let

$$\hat{d}(t) = \begin{cases} d(t), \ t \in [0, T], \\ 0, \ t \in (T, \infty), \end{cases}$$

then $\hat{d} \in \mathcal{L}^2_{\mathcal{F}}(\mathcal{R}_+, \mathcal{R}^{n_d})$. By (30),

$$\begin{aligned} \|z\|^2_{\mathcal{L}^2([0,T])} &\leq \|z\|^2_{\mathcal{L}^2(\mathcal{R}_+)} = \|z\|^2_{\mathcal{L}^2([0,T])} + \|z\|^2_{\mathcal{L}^2((T,\infty))} \\ &\leq \gamma^2 \|\hat{d}\|^2_{\mathcal{L}^2(\mathcal{R}_+)} + q(x) \\ &= \gamma^2 \|d\|^2_{\mathcal{L}^2([0,T])} + q(x). \end{aligned} \tag{32}$$

So

$$0 \leq V_{a,0}(x) \leq \frac{1}{2} q(x), \qquad V_{a,0}(0) = 0.$$

Take $R = \frac{1}{2}\gamma^2 I, S = 0, Q = -\frac{1}{2} I, V_s = V_{a,0}$, and

$$\tilde{w} = \frac{\sqrt{2}}{2} \left(\gamma^2 I - l' \frac{\partial^2 V_{a,0}}{\partial x^2} l \right)^{1/2}.$$

HJE (29) is derived from Theorem 2.1. It is easy to show that any solution V of (29) is a possible storage function with supply rate w. Therefore, (31) is followed from Proposition 2.2. ∎

For the LTISS

$$\begin{cases} dx = (Ax + Bu + Kd)dt + (Cx + Dd)dW, \\ z = \begin{bmatrix} Mx \\ u \end{bmatrix}. \end{cases} \tag{33}$$

Take $V(x) = \frac{1}{2}x'Px$; then Theorem 3.1 and Corollary 3.1 lead to the following corollary.

COROLLARY 3.2. *Suppose there exists a solution $P \geq 0$ to the generalized algebraic Riccati equation (GARE)*

$$\begin{cases} PA + A'P + C'PC + (PK + C'PD)(\gamma^2 I - D'PD)^{-1} \\ \qquad \cdot (K'P + D'PC) - PBB'P + M'M = 0, \\ \gamma^2 I - D'PD > 0 \end{cases} \tag{34}$$

for some $\gamma > 0$, then $u_\infty^*(x) = \tilde{k}x = -B'Px$ is an H_∞ control, which makes the closed-loop system satisfy $\|\tilde{\mathcal{L}}_{zd}\|_\infty \leq \gamma$. Additionally, if $[A, C|M]$ is observable, then (i) *$P > 0$;* (ii) *system*

$$dx = (A - BB'P)x\,dt + CxdW$$

is asymptotically mean square stable.

Proof. The first part is an immediate corollary of Theorem 3.1. As to the second part, (i) and (ii) are concluded from Corollary 3.1. □

Example 3.1. Consider the following nonlinear stochastic system with state-dependent noise:

$$dx = \left(\begin{bmatrix} x_1^3 - 2x_1 - 4x_2 \\ x_2^3 - 2x_2 \end{bmatrix} + \begin{bmatrix} 2x_1 \\ 2x_2 \end{bmatrix} u + \begin{bmatrix} 1 \\ 1 \end{bmatrix} d \right) dt + \begin{bmatrix} x_2^2 \\ x_1 x_2 \end{bmatrix} dW$$
$$z = \begin{bmatrix} 2(x_1 + x_2) \\ u(t) \end{bmatrix}.$$

Assume the disturbance attenuation $\gamma = 1$ for the H_∞ control designed for the above nonlinear stochastic system. Then, by Theorem 3.1 and Remark 3.1, we need to solve the following Hamilton–Jacobi inequality for H_∞ control:

$$\begin{aligned} \mathcal{H}_\infty^1(V(x)) = {} & \frac{\partial V'}{\partial x} \begin{bmatrix} x_1^3 - 2x_1 - 4x_2 \\ x_2^3 - 2x_2 \end{bmatrix} + \frac{1}{2}\frac{\partial V'}{\partial x} \begin{bmatrix} 1 \\ 1 \end{bmatrix} \begin{bmatrix} 1 & 1 \end{bmatrix} \frac{\partial V}{\partial x} \\ & - \frac{1}{2}\frac{\partial V'}{\partial x} \begin{bmatrix} 2x_1 \\ 2x_2 \end{bmatrix} \begin{bmatrix} 2x_1 & 2x_2 \end{bmatrix} \frac{\partial V}{\partial x} + 2(x_1 + x_2)^2 \\ & + \frac{1}{2} \begin{bmatrix} x_2^2 & x_1 x_2 \end{bmatrix} \frac{\partial^2 V}{\partial x^2} \begin{bmatrix} x_2^2 \\ x_1 x_2 \end{bmatrix} \leq 0. \end{aligned}$$

Let us choose the solution as $V(x) = x_1^2 p_1 + x_2^2 p_2$, for $p_1 > 0$, $p_2 > 0$. Then the

Hamilton–Jacobi inequality is given by

$$\begin{aligned}
\mathcal{H}^1_\infty(V(x)) &= \begin{bmatrix} \frac{\partial V}{\partial x_1} & \frac{\partial V}{\partial x_2} \end{bmatrix} \begin{bmatrix} x_1^3 - 2x_1 - 4x_2 \\ x_2^3 - 2x_2 \end{bmatrix} \\
&\quad + \frac{1}{2} \begin{bmatrix} \frac{\partial V}{\partial x_1} & \frac{\partial V}{\partial x_2} \end{bmatrix} \begin{bmatrix} 1 \\ 1 \end{bmatrix} \begin{bmatrix} 1 & 1 \end{bmatrix} \begin{bmatrix} \frac{\partial V}{\partial x_1} \\ \frac{\partial V}{\partial x_2} \end{bmatrix} \\
&\quad - \frac{1}{2} \begin{bmatrix} \frac{\partial V}{\partial x_1} & \frac{\partial V}{\partial x_2} \end{bmatrix} \begin{bmatrix} 2x_1 \\ 2x_2 \end{bmatrix} \begin{bmatrix} 2x_1 & 2x_2 \end{bmatrix} \begin{bmatrix} \frac{\partial V}{\partial x_1} \\ \frac{\partial V}{\partial x_2} \end{bmatrix} + 2(x_1 + x_2)^2 \\
&\quad + \frac{1}{2} \begin{bmatrix} x_2^2 & x_1 x_2 \end{bmatrix} \begin{bmatrix} \frac{\partial^2 V}{\partial x_1^2} & \frac{\partial^2 V}{\partial x_1 x_2} \\ \frac{\partial^2 V}{\partial x_2 x_1} & \frac{\partial^2 V}{\partial x_2^2} \end{bmatrix} \begin{bmatrix} x_2^2 \\ x_1 x_2 \end{bmatrix}, \\
\mathcal{H}^1_\infty(V(x)) &= \begin{bmatrix} 2x_1 p_1 & 2x_2 p_2 \end{bmatrix} \begin{bmatrix} x_1^3 - 2x_1 - 4x_2 \\ x_2^3 - 2x_2 \end{bmatrix} \\
&\quad + \frac{1}{2} \begin{bmatrix} 2x_1 p_1 & 2x_2 p_2 \end{bmatrix} \begin{bmatrix} 1 \\ 1 \end{bmatrix} \begin{bmatrix} 1 & 1 \end{bmatrix} \begin{bmatrix} 2x_1 p_1 \\ 2x_2 p_2 \end{bmatrix} \\
&\quad - \frac{1}{2} \begin{bmatrix} 2x_1 p_1 & 2x_2 p_2 \end{bmatrix} \begin{bmatrix} 2x_1 \\ 2x_2 \end{bmatrix} \begin{bmatrix} 2x_1 & 2x_2 \end{bmatrix} \begin{bmatrix} 2x_1 p_1 \\ 2x_2 p_2 \end{bmatrix} + 2(x_1 + x_2)^2 \\
&\quad + \frac{1}{2} \begin{bmatrix} x_2^2 & x_1 x_2 \end{bmatrix} \begin{bmatrix} 2p_1 & 0 \\ 0 & 2p_2 \end{bmatrix} \begin{bmatrix} x_2^2 \\ x_1 x_2 \end{bmatrix} \\
&= 2x_1^4 p_1 - 4x_1^2 p_1 - 8x_1 x_2 p_1 + 2x_2^4 p_2 - 4x_2^2 p_2 \\
&\quad + 2[x_1^2 p_1^2 + 2x_1 x_2 p_1 p_2 + x_2^2 p_2^2] \\
&\quad - 8[x_1^4 p_1^2 + 2x_1^2 x_2^2 p_1 p_2 + x_2^4 p_2^2] + 2[x_1^2 + x_2^2 + 2x_1 x_2] + [x_2^4 p_1 + x_1^2 x_2^2 p_2].
\end{aligned}$$

If we let $p_1 = 1$, $p_2 = 1$, i.e. $V(x) = x_1^2 + x_2^2$, then

$$\begin{aligned}
\mathcal{H}^1_\infty(V(x)) &= 2x_1^4 - 4x_1^2 - 8x_1 x_2 + 2x_2^4 - 4x_2^2 + 2[x_1^2 + 2x_1 x_2 + x_2^2] \\
&\quad - 8[x_1^4 + 2x_1^2 x_2^2 + x_2^4] \\
&\quad + 2[x_1^2 + x_2^2 + 2x_1 x_2] + [x_2^4 + x_1^2 x_2^2] \\
&= 2x_1^4 - 4x_1^2 - 8x_1 x_2 + 2x_2^4 - 4x_2^2 + 4[x_1^2 + 2x_1 x_2 + x_2^2] \\
&\quad - 8[x_1^4 + 2x_1^2 x_2^2 + x_2^4] + [x_2^4 + x_1^2 x_2^2] \\
&= -6x_1^4 - 5x_2^4 - 15x_1^2 x_2^2 \le 0;
\end{aligned}$$

i.e., if we choose $u^*_\infty(x) = -g' \frac{\partial V}{\partial x} = -[2x_1 \quad 2x_2] \begin{bmatrix} 2x_1 \\ 2x_2 \end{bmatrix} = -4x_1^2 - 4x_2^2$, then the H_∞ control is achieved.

To end this section, we add a few remarks on our above results.

Remark 3.4. Although in this paper W is assumed to be one-dimensional, all our results can be extended to the system with multiplicative noise as follows:

$$\begin{cases} dx = (f(x) + g(x)u + k(x)d)dt + \sum_{i=1}^N (h_i(x) + l_i(x)d)dW_i, \\ z = \begin{bmatrix} m(x) \\ u \end{bmatrix}. \end{cases}$$

In this case, HJE (20) becomes

$$\begin{cases} \frac{\partial V'}{\partial x} f + \frac{1}{2}(\frac{\partial V'}{\partial x} k + \sum_{i=1}^N h_i' \frac{\partial^2 V}{\partial x^2} l_i)(\gamma^2 I - \sum_{i=1}^N l_i' \frac{\partial^2 V}{\partial x^2} l_i)^{-1}(k' \frac{\partial V}{\partial x} + \sum_{i=1}^N l_i' \frac{\partial^2 V}{\partial x^2} h_i) \\ \quad -\frac{1}{2} \frac{\partial V'}{\partial x} g g' \frac{\partial V}{\partial x} + \frac{1}{2} m'm + \frac{1}{2} \sum_{i=1}^N h_i' \frac{\partial^2 V}{\partial x^2} h_i = 0, \\ \gamma^2 I - \sum_{i=1}^N l_i' \frac{\partial^2 V}{\partial x^2} l_i > 0, V(0) = 0. \end{cases}$$

Following [33], for the linear part, all our results can also be extended to the system with W being a multi-dimensional Wiener process.

Remark 3.5. In (16), if $l(x)d$ is replaced by $l(x)u$, then by the same discussion as in Theorem 3.1, we can show that Theorem 3.1 still holds if we substitute

$$\begin{cases} \frac{\partial V'}{\partial x} f + \frac{1}{2\gamma^2} \frac{\partial V'}{\partial x} k k' \frac{\partial V}{\partial x} - \frac{1}{2}(\frac{\partial V'}{\partial x} g + h' \frac{\partial^2 V}{\partial x^2} l)(I + l' \frac{\partial^2 V}{\partial x^2} l)^{-1} \\ \qquad \cdot (g' \frac{\partial V}{\partial x} + l' \frac{\partial^2 V}{\partial x^2} h) + \frac{1}{2} m' m + \frac{1}{2} h' \frac{\partial^2 V}{\partial x^2} h = 0, \\ I + l' \frac{\partial^2 V}{\partial x^2} l > 0, V(0) = 0 \end{cases}$$

and

$$u_\infty^*(x) = \tilde{k}(x) = -\left(I + l' \frac{\partial^2 V}{\partial x^2} l\right)^{-1} \left(g' \frac{\partial V}{\partial x} + l' \frac{\partial^2 V}{\partial x^2} h\right)$$

for (20) and (21), respectively.

4. Finite horizon nonlinear H_∞ control. In this section, we study the finite horizon H_∞ control problem. Suppose the system is governed by the following stochastic time-varying equation:

$$\begin{cases} dx = (f(t,x) + g(t,x)u + k(t,x)d)dt + (h(t,x) + l(t,x)d)dW, \\ \qquad f(t,0) = 0, h(t,0) = 0, \\ z(t) = \begin{bmatrix} m(t,x) \\ u \end{bmatrix}, \ m(t,0) = 0, \end{cases} \tag{35}$$

where $d \in \mathcal{L}_{\mathcal{F}}^2([0,T], \mathcal{R}^{n_d})$ represents the exogenous disturbance, and f, g, k, h, and l are vector-valued functions, jointly continuous in all arguments. The so-called finite horizon H_∞ control is to find, if existing, an $u_T^* \in \mathcal{L}_{\mathcal{F}}^2([0,T], \mathcal{R}^{n_u})$, such that for any given $\gamma > 0$, and all $d \neq 0 \in \mathcal{L}_{\mathcal{F}}^2([0,T], \mathcal{R}^{n_d})$, $x(0) = 0$, the closed-loop system satisfies

$$\|z\|_{\mathcal{L}^2([0,T])} \leq \gamma \|d\|_{\mathcal{L}^2([0,T])}. \tag{36}$$

Similar to the definition of $\tilde{\mathcal{L}}_{zd}$, a perturbation operator $\mathcal{L}_{zd}^T : \mathcal{L}_{\mathcal{F}}^2([0,T], \mathcal{R}^{n_d}) \mapsto \mathcal{L}_{\mathcal{F}}^2([0,T], \mathcal{R}^{n_z})$ can be defined, and (36) is equivalent to

$$\|\tilde{\mathcal{L}}_{zd}^T\|_{[0,T]} = \sup_{d \in \mathcal{L}_{\mathcal{F}}^2([0,T], \mathcal{R}^{n_d}), d \neq 0, x(0)=0} \frac{||z||_{\mathcal{L}^2([0,T])}}{\|d\|_{\mathcal{L}^2([0,T])}} \leq \gamma.$$

In particular, if we let $u \equiv 0$ and take d as a control variable in (35), then when $\|\mathcal{L}^T\|_{[0,T]} := \|\mathcal{L}_{zd}^T\|_{[0,T]} \leq \gamma$ for any given $\gamma > 0$, the system is said to have $\mathcal{L}_2$-gain less than or equal to γ.

In analogy with the proof of Theorem 3.1, the following result is easily obtained.

THEOREM 4.1. *Assume $V_T(t,x) \in C_0^2([0,T] \times \mathcal{R}^n)$ satisfies the HJE*

$$\begin{cases} \mathcal{H}_T^1(t,x) := \frac{\partial V_T}{\partial t} + \frac{\partial V_T'}{\partial x} f + \frac{1}{2}(\frac{\partial V_T'}{\partial x} k + h' \frac{\partial^2 V_T}{\partial x^2} l)(\gamma^2 I - l' \frac{\partial^2 V_T}{\partial x^2} l)^{-1}(k' \frac{\partial V_T}{\partial x} + l' \frac{\partial^2 V_T}{\partial x^2} h) \\ \qquad - \frac{1}{2} \frac{\partial V_T'}{\partial x} g g' \frac{\partial V_T}{\partial x} + \frac{1}{2} m' m + \frac{1}{2} h' \frac{\partial^2 V_T}{\partial x^2} h = 0, \\ \gamma^2 I - l' \frac{\partial^2 V_T}{\partial x^2} l > 0, V_T(T,x) = 0, V_T(t,0) = 0 \ \forall (t,x) \in [0,T] \times \mathcal{R}^n. \end{cases} \tag{37}$$

Then (u_T^*, d_T^*) *is a saddle point for the following stochastic game problem:*

$$\min_{u\in\mathcal{L}_{\mathcal{F}}^2([0,T],\mathcal{R}^{n_u})}\max_{d\in\mathcal{L}_{\mathcal{F}}^2([0,T],\mathcal{R}^{n_d})} E\int_0^T (\|z\|^2-\gamma^2\|d\|^2)\,dt,$$

where u_T^* *and* d_T^* *are defined, respectively, as*

$$u_T^* = -g'\frac{\partial V_T}{\partial x}$$

and

$$d_T^* = \left(\gamma^2 I - l'\frac{\partial^2 V_T}{\partial x^2}l\right)^{-1}\left(k'\frac{\partial V_T}{\partial x}+l'\frac{\partial^2 V_T}{\partial x^2}h\right).$$

Moreover, u_T^* *is an* H_∞ *control for system* (35)*, and* d_T^* *is the corresponding worst case disturbance.*

Below, we point out the relationship on the solutions between finite and infinite horizon HJEs. Let $V(x)$ and $V_T(t,x,Q(x))$ stand for the solutions of (20) and (37) with terminal condition $V_T(T,x)=Q(x)\ge 0$ for all $x\in\mathcal{R}^n$, respectively. A generalized version of Lemma 2.6 of [16] is as follows.

PROPOSITION 4.1. *If* $V(x)\ge Q(x)$ *for all* $x\in\mathcal{R}^n$*, then* $V(x)\ge V_T(t,x,Q(x))\ge V_T(t,x,0)=V_T(t,x)\ge 0$ *for all* $(t,x)\in[0,T]\times\mathcal{R}^n$.

Proof. For any initial time $t\ge 0$ and state $x(t):=x\in\mathcal{R}^n$, one only needs to note the following identities:

$$\begin{aligned}\frac{1}{2}E\int_t^T(\|z\|^2-\gamma^2\|d\|^2)\,dt &= V(x)-EV(x(T))\\ &\quad+\frac{1}{2}E\int_t^T(\|u-u_\infty^*\|^2-\|d-d_\infty^*\|_{\gamma,l,V}^2+2\mathcal{H}_\infty^1(V(x)))\,dt \qquad (38)\end{aligned}$$

and

$$\begin{aligned}\frac{1}{2}E\int_t^T(\|z\|^2-\gamma^2\|d\|^2)\,dt &= V_T(t,x,Q(x))-EV_T(T,x(T),Q(x))\\ &\quad+\frac{1}{2}E\int_t^T(\|u-u_T^*\|^2-\|d-d_T^*\|_{\gamma,l,V_T(t,x,Q(x))}^2+2\mathcal{H}_T^1(t,x))\,dt. \qquad (39)\end{aligned}$$

The rest is similar to the proof of Lemma 2.6 of [16] and is omitted. □

PROPOSITION 4.2. *There is at most one solution to* (37).

Proof. Otherwise, let $V_T^{(1)}(\cdot,\cdot)$ and $V_T^{(2)}(\cdot,\cdot)$ be two solutions of (37). Set

$$J_T(x,u,d,x(t_0),t_0)=\frac{1}{2}E\int_{t_0}^T(\|z\|^2-\gamma^2\|d\|^2)\,dt,$$

$$u_{i,T}^*=-g'\frac{\partial V_T^{(i)}}{\partial x},$$

and

$$d_{i,T}^*=\left(\gamma^2 I-l'\frac{\partial^2 V_T^{(i)}}{\partial x^2}l\right)^{-1}\left(k'\frac{\partial V_T^{(i)}}{\partial x}+l'\frac{\partial^2 V_T^{(i)}}{\partial x^2}h\right),\qquad i=1,2.$$

For any $x(s) = y$, $(s, y) \in [0, T) \times \mathcal{R}^n$, from (39), we have

$$\begin{aligned} J_T(x, u^*_{1,T}, d^*_{1,T}, y, s) = V_T^{(1)}(s, y) &\le J_T(x, u^*_{2,T}, d^*_{1,T}, y, s) \\ &\le J_T(x, u^*_{2,T}, d^*_{2,T}, y, s) = V_T^{(2)}(s, y). \end{aligned}$$

Also, we have $V_T^{(2)}(s, y) \le V_T^{(1)}(s, y)$, so $V_T^{(2)}(s, y) = V_T^{(1)}(s, y)$. □

PROPOSITION 4.3. *$V_T(\cdot, \cdot)$ is monotonically increasing with respect to $T > 0$.*

Proof. For any $0 \le s \le T_0 \le T_1 < \infty$, $x(s) = y \in \mathcal{R}^n$, still by (39), we have

$$\begin{aligned} J_{T_0}(x, u^*_{T_0}, d^*_{T_0}, y, s) = V_{T_0}(s, y) &\le J_{T_0}(x, u^*_{T_1}, d^*_{T_0}, y, s) \\ &\le J_{T_1}(x, u^*_{T_1}, d^*_{T_0}, y, s) \le J_{T_1}(x, u^*_{T_1}, d^*_{T_1}, y, s), \\ &= V_{T_1}(s, y). \end{aligned}$$

This proposition is complete. □

If system (35) is time invariant, and

$$\bar{V}(t, x) := \lim_{T \to \infty} V_T(t, x, Q(x))$$

exists, then $\bar{V}$ depends only on x and is a solution of (20). We refer the reader to the proof of Corollary 2.7 of [16]. In particular, if there exists $(u^*_\infty, d^*_\infty) \in \mathcal{L}^2_{\mathcal{F}}(\mathcal{R}_+, \mathcal{R}^{n_u}) \times \mathcal{L}^2_{\mathcal{F}}(\mathcal{R}_+, \mathcal{R}^{n_d})$, such that $J_\infty(x, u^*_\infty, d^*_\infty, y, s) < \infty$, then by making use of Propositions 4.1, 4.2, and 4.3, $\bar{V}(x)$ exists due to the monotonicity and uniform boundedness of $V_T(t, x)$.

In general, the inverse of Theorem 4.1 is not true; i.e., $\|\mathcal{L}^T_{zd}\|_{[0,T]} \le \gamma$ does not necessarily imply that HJE (37) has a solution. An inverse result will be presented in the following together with some other conditions. To this end, assume $u = \tilde{k}(t, x)$ is an H_∞ control law of (35). We define $\tilde{V}_{T,\tilde{k}}(s, x) : [0, T] \times \mathcal{R}^n \mapsto \mathcal{R}^+$ as

$$\begin{aligned} \tilde{V}_{T,\tilde{k}}(s, x) &= -\frac{1}{2} \inf_{d \in \mathcal{L}^2_{\mathcal{F}}([s,T], \mathcal{R}^{n_d}), u = \tilde{k}, x(s) = x} E \int_s^T (\gamma^2 \|d\|^2 - \|z\|^2)\, dt \\ &= \sup_{d \in \mathcal{L}^2_{\mathcal{F}}([s,T], \mathcal{R}^{n_d}), u = \tilde{k}, x(s) = x} -\frac{1}{2} E \int_s^T (\gamma^2 \|d\|^2 - \|z\|^2)\, dt. \end{aligned}$$

It is easy to test the following properties of $\tilde{V}_{T,\tilde{k}}$: (i) $\tilde{V}_{T,\tilde{k}} \ge 0$; (ii) $\tilde{V}_{T,\tilde{k}}(T, x) = 0$ for all $x \in \mathcal{R}^n$. The following proposition can also be shown in the same way as [9] and [26].

PROPOSITION 4.4. (i) *$\|\mathcal{L}^T_{zd}\|_{[0,T]} \le \gamma$ implies $\tilde{V}_{T,\tilde{k}}(s, 0) = 0$ for all $s \in [0, T]$.*

(ii) *$\tilde{V}_{T,\tilde{k}}$ is finite on $[0, T] \times \mathcal{R}^n$ if and only if there exists a nonnegative function $V(s, x) : [0, T] \times \mathcal{R}^n \mapsto \mathcal{R}^+$ satisfying the following integral dissipation inequality (IDI):*

$$EV(T, x(T)) - V(s, x) \le \frac{1}{2} E \int_s^T (\gamma^2 \|d\|^2 - \|z\|^2)\, dt. \tag{40}$$

Moreover, when $\tilde{V}_{T,\tilde{k}}(s, x)$ is finite, $\tilde{V}_{T,\tilde{k}}$ is itself a solution of (40).

In the literature, such as [5] and [26], to guarantee the finiteness of $\tilde{V}_{T,\tilde{k}}(s, x)$, an essential concept on the system theory called "reachability" is introduced. Checking

the proof of Lemma 2.3 of [26], it can be found that even under the assumption of reachability, it is not necessary to have $\tilde{V}_{T,\tilde{k}}(0,x) < \infty$ for all $x \in \mathcal{R}^n$.

LEMMA 4.1. *If $\tilde{V}_{T,\tilde{k}}(s,x) \in C_0^2([0,T]\times\mathcal{R}^n)$ is finite with $\gamma^2 I - l'\frac{\partial^2 \tilde{V}_{T,\tilde{k}}}{\partial x^2} l > 0$ for some $\gamma > 0$, and $\|\mathcal{L}_{zd}^T\|_{[0,T]} \le \gamma$, then $\tilde{V}_{T,\tilde{k}}$ solves the HJE*

$$\begin{cases} \mathcal{H}(V_{T,\tilde{k}}) := \frac{\partial V_{T,\tilde{k}}}{\partial t} + \frac{\partial V'_{T,\tilde{k}}}{\partial x}(f+g\tilde{k}) + \frac{1}{2}\left(\frac{\partial V'_{T,\tilde{k}}}{\partial x}k + h'\frac{\partial^2 V_{T,\tilde{k}}}{\partial x^2}l\right)\left(\gamma^2 I - l'\frac{\partial^2 V_{T,\tilde{k}}}{\partial x^2}l\right)^{-1} \\ \qquad\qquad \times\left(k'\frac{\partial V_{T,\tilde{k}}}{\partial x} + l'\frac{\partial^2 V_{T,\tilde{k}}}{\partial x^2}h\right) + \frac{1}{2}(m'm + \tilde{k}'\tilde{k}) + \frac{1}{2}h'\frac{\partial^2 V_{T,\tilde{k}}}{\partial x^2}h = 0, \\ \gamma^2 I - l'\frac{\partial^2 V_{T,\tilde{k}}}{\partial x^2}l > 0, V_{T,\tilde{k}}(T,x) = 0, V_{T,\tilde{k}}(t,0) = 0 \ \forall (t,x) \in [0,T]\times\mathcal{R}^n. \end{cases} \tag{41}$$

Proof. We have shown that $\tilde{V}_{T,\tilde{k}}$ satisfies the boundary conditions of (41) above. Now, let $\hat{V} = -\tilde{V}_{T,\tilde{k}}$; then by the dynamic programming principle, $\hat{V}$ solves the following HJE [32]:

$$-\frac{\partial \hat{V}}{\partial t} + \max_{d\in U} H\left(t,x,d,-\frac{\partial \hat{V}}{\partial x},-\frac{\partial^2 \hat{V}}{\partial x^2}\right) = 0, \tag{42}$$

where (U,ρ) is a Polish space, $U \subset \mathcal{R}^{n_d}$, and the generalized Hamiltonian function H is defined as

$$\begin{aligned} H\left(t,x,d,-\frac{\partial \hat{V}}{\partial x},-\frac{\partial^2 \hat{V}}{\partial x^2}\right) &:= -\frac{1}{2}\gamma^2\|d\|^2 + \frac{1}{2}\|z\|^2 \\ &\quad -\frac{\partial \hat{V}'}{\partial x}(f+g\tilde{k}+kd) - \frac{1}{2}(h+ld)'\frac{\partial^2 \hat{V}}{\partial x^2}(h+ld) \\ &= \mathcal{H}(\tilde{V}_{T,\tilde{k}}) - \frac{\partial \tilde{V}_{T,\tilde{k}}}{\partial t} - \frac{1}{2}\|d-\hat{d}_T\|^2_{\gamma,l,\tilde{V}_{T,\tilde{k}}} \end{aligned}$$

with $\hat{d}_T = (\gamma^2 I - l'\frac{\partial^2 \tilde{V}_{T,\tilde{k}}}{\partial x^2}l)^{-1}(k'\frac{\partial \tilde{V}_{T,\tilde{k}}}{\partial x} + l'\frac{\partial^2 \tilde{V}_{T,\tilde{k}}}{\partial x^2}h)$. Obviously,

$$\begin{aligned} \max_{d\in U} H\left(t,x,d,-\frac{\partial \hat{V}}{\partial x},-\frac{\partial^2 \hat{V}}{\partial x^2}\right) &= H\left(t,x,\hat{d}_T,\frac{\partial \tilde{V}_{T,\tilde{k}}}{\partial x},\frac{\partial^2 \tilde{V}_{T,\tilde{k}}}{\partial x^2}\right) \\ &= \mathcal{H}(\tilde{V}_{T,\tilde{k}}) - \frac{\partial \tilde{V}_{T,\tilde{k}}}{\partial t}. \end{aligned}$$

Therefore, (42) is equivalent to $\mathcal{H}(\tilde{V}_{T,\tilde{k}}) = 0$. The proof of this lemma is complete. □

THEOREM 4.2. *If there exists an H_∞ control $u = \tilde{k}(t,x)$ for system (35), such that the conditions of Lemma 4.1 hold, then HJE (37) admits a unique solution.*

Proof. Apply Lemma 4.1 and note identity (39). We have

$$\begin{aligned} E\int_t^T (\|z\|^2 - \gamma^2\|d\|^2)\,dt &= E\int_t^T \left(\left\|\tilde{k} + g'\frac{\partial \tilde{V}_{T,\tilde{k}}}{\partial x}\right\|^2 - \|d-\hat{d}_T\|^2_{\gamma,l,\tilde{V}_{T,\tilde{k}}} + 2\mathcal{H}(\tilde{V}_{T,\tilde{k}})\right)dt \\ &= E\int_t^T \left(\left\|\tilde{k} + g'\frac{\partial \tilde{V}_{T,\tilde{k}}}{\partial x}\right\|^2 - \|d-\hat{d}_T\|^2_{\gamma,l,\tilde{V}_{T,\tilde{k}}}\right)dt. \end{aligned}$$

Obviously, in order to have $\|\mathcal{L}_{zd}^T\|_{[0,T]} \leq \gamma$, we must take $\tilde{k} = -g' \frac{\partial \tilde{V}_{T,\tilde{k}}}{\partial x}$ as an H_∞. Substituting $\tilde{k}$ into (41), (37) is derived. Uniqueness is followed from Proposition 4.2. □

5. Concluding remarks. This paper has discussed the stochastic H_∞ control for nonlinear systems with both state- and disturbance-dependent noise, including finite and infinite horizon cases. It has been shown that both finite and infinite horizon stochastic H_∞ designs are associated with two kinds of HJEs. Some results of nonlinear H_∞ control [5] for deterministic systems are generalized to the stochastic case. There are several interesting problems which merit further study, for instance, the relation between HJEs and invariant manifolds of Hamiltonian vector fields, and the relation between the primal nonlinear stochastic system and its linearization. In addition, when the state is not completely available, we must consider the output feedback H_∞ control, as done in [18] and [19]. However, since the nonlinear stochastic H_∞ filtering has been investigated in [31], it is easier to treat the aforementioned issue using our nonlinear SBRL (Lemma 3.2). Finally, when the control u enters the diffusion term in (16) and (35), which form would the HJE take? This is a very interesting topic, but the results in this paper would not shed much light on this extension. One reason for this is that u and d are no longer separable in the HJE. If the diffusion term depends only on u (and not also on d), then the problem can be tractable.

Acknowledgments. The authors would like to thank the Associate Editor and the two reviewers for their constructive comments that lead to a significant improvement of the paper.

A PARAMETRIZATION OF SOLUTIONS OF THE DISCRETE-TIME ALGEBRAIC RICCATI EQUATION BASED ON PAIRS OF OPPOSITE UNMIXED SOLUTIONS*

HARALD K. WIMMER†

Abstract. The paper describes the set of solutions of the discrete-time algebraic Riccati equation. It is shown that each solution is a combination of a pair of opposite unmixed solutions. There is a one-to-one correspondence between solutions and invariant subspaces of the closed loop matrix of an unmixed solution. The results of the paper provide an extended counterpart of the parametrization theory of continuous-time algebraic Riccati equations by Willems, Coppel, and Shayman.

Key words. discrete-time algebraic Riccati equation, unmixed solutions, opposite solutions, parametrization by invariant subspaces, shorted operators, Schur complements

AMS subject classifications. 15A24, 93C55, 47A64

DOI. 10.1137/S0363012904441362

1. Introduction.

To a large extent the groundwork for the investigation of algebraic Riccati equations by geometric methods was laid by J. C. Willems. In his study of least squares stationary optimal control [24], he gave a complete description of the set of symmetric solutions of the real continuous-time algebraic Riccati equation (CARE)

$$-F^TX - XF + XGG^TX - Q = 0. \tag{1.1}$$

Assuming that (F, G) is controllable and that the associated Hamiltonian matrix

$$H = \begin{bmatrix} F & -GG^T \\ -Q & -F^T \end{bmatrix}$$

has no eigenvalues on the imaginary axis, Willems showed that (1.1) has a greatest solution X^+ and a least solution X^-. The eigenvalues of the corresponding closed loop matrix $F_{X^+} = F - GG^TX^+$ lie in the left half-plane and those of F_{X^-} are in the right half-plane. Moreover, according to [24] there is a one-to-one correspondence of solutions of (1.1) and invariant subspaces of F_{X^+} such that every solution of (1.1) can be expressed as a combination of X^+ and X^-. That result was refined by Coppel [5] and extended further by Shayman [23].

In this paper we consider the complex discrete-time algebraic Riccati equation (DARE)

$$X - F^*XF + (G^*XF + S)^*(R + G^*XG)^{-1}(G^*XF + S) - Q = 0. \tag{1.2}$$

We shall obtain a classification of solutions of (1.2) that corresponds to the Willems–Coppel–Shayman parametrization for (1.1).

Let us first recapitulate the parametrization result for the CARE (1.1). It will be assumed that elementary divisors of H have even degree when they belong to pure

†Mathematisches Institut, Universität Würzburg, Am Hubland, D-97074 Würzburg, Germany (wimmer@mathematik.uni-wuerzburg.de).

imaginary eigenvalues. A solution X of (1.1) is called *unmixed* [23] if the spectrum of $F_X = F - GG^TX$ satisfies

$$\sigma(F_X) \cap \sigma(-F_X^T) \subseteq i\mathbb{R}. \tag{1.3}$$

It is known (see, e.g., [12]) that there exists an unmixed solution of (1.1) if and only if the pair $(F,G) \in \mathbb{R}^{n\times n} \times \mathbb{R}^{n\times p}$ is *sign-controllable*, i.e., if $\lambda \in \sigma(F)$ and $\operatorname{rank}[\lambda I - F, G] < n$ imply $\operatorname{rank}\left[-\overline{\lambda} I - F, G\right] = n$. Let X_1 be an unmixed solution of (1.1). Then there exists a unique (unmixed) solution X_2 such that F_{X_1} and F_{X_2} have, at most, pure imaginary eigenvalues in common if and only if (F,G) is controllable. In that case (X_1, X_2) is called a *pair of opposite unmixed solutions* [23]. The extremal solutions (X^-, X^+) are an example of such a pair.

Let $\operatorname{Inv}(F)$ denote the set of F-invariant subspaces of $\mathbb{R}^n$. If $i\alpha$ is an eigenvalue of F on the imaginary axis, we set $E_{\pm i\alpha} = \operatorname{Ker}(F^2 + \alpha^2 I)^n$ and we define

$$E_{i\mathbb{R}}(F) = \bigoplus_{\alpha\in\mathbb{R}} E_{\pm i\alpha}.$$

The following theorem can be regarded as an updated version of the Willems–Coppel–Shayman theory. It combines results of [24], [5], and [23] with an approach by Scherer [22] and observations on shorted operators in section 3.

THEOREM 1.1. *Let Γ be the set of real symmetric solutions of* (1.1). *Assume that (F,G) is controllable. Let (X_1, X_2) be a pair of opposite unmixed solutions of*

$$-F^TX - XF + XGG^TX - Q = 0, \tag{1.1}$$

and let $F_{X_2} = F - GG^TX_2$ be the closed loop matrix corresponding to X_2. Set $\Delta = X_1 - X_2$. Define

$$\mathcal{N} = \{N \in \operatorname{Inv}(F_{X_2}) \mid E_{i\mathbb{R}}(F_{X_2}) \subseteq N\}.$$

If $N \in \mathcal{N}$, then

$$(\Delta\, N)^\perp \oplus (N \cap \operatorname{Im}\Delta) = \mathbb{R}^n.$$

Let P_N be the projection on $(\Delta\, N)^\perp$ along $(N \cap \operatorname{Im}\Delta)$. Define

$$\kappa(N) = X_1P_N + X_2(I - P_N).$$

Then $\kappa : \mathcal{N} \to \Gamma$ is a bijection. If $X \in \Gamma$, then

$$\kappa^{-1}(X) = \operatorname{Ker}(X - X_2).$$

It is not difficult to explain (see also [18]) why direct sum decompositions of the form

$$(\Delta\, N)^\perp \oplus N = \mathbb{R}^n \tag{1.4}$$

and associated projections P_N should play a role in the theory of the CARE. Consider (1.1) with $Q = 0$, i.e.,

$$\mathcal{C}(X) = -F^TX - XF + XGG^TX = 0. \tag{1.5}$$

If (F, G) is controllable and $\sigma(F) \cap \sigma(-F^T) = \emptyset$, then (1.5) has a unique nonsingular solution Δ (see, e.g., [22, p. 102]). Let $N = \operatorname{Im}(I, O)^T$ be invariant under F and let Δ be partitioned according to F such that

$$F = \begin{bmatrix} F_1 & F_{12} \\ 0 & F_2 \end{bmatrix} \text{ and } \Delta = \begin{bmatrix} \Delta_1 & \Delta_{12} \\ \Delta_{12}^T & \Delta_2 \end{bmatrix}.$$

Then Δ_1 is nonsingular [22]. Let $\widetilde{\Delta}_2 = \Delta_2 - \Delta_{12}^T \Delta_1^{-1} \Delta_{12}$ be the Schur complement of Δ with respect to N. Set

$$S = \begin{bmatrix} I & -\Delta_1^{-1}\Delta_{12} \\ 0 & I \end{bmatrix}.$$

Then $S^T \Delta S = \operatorname{diag}(\Delta_1, \widetilde{\Delta}_2)$ and

$$S^{-1} F S = \begin{bmatrix} F_1 & * \\ 0 & F_2 \end{bmatrix}.$$

It is obvious that

$$\widetilde{\Delta} = \begin{bmatrix} 0 & 0 \\ 0 & \widetilde{\Delta}_2 \end{bmatrix}$$

is a solution of (1.5). In the terminology of [2], [16], or [6], the matrix $\widetilde{\Delta}$ is a *shorted matrix* of Δ. In section 3 we shall give a basis-free description of $\widetilde{\Delta}$ and we shall see that $\widetilde{\Delta} = \Delta P_N$, where P_N is the projection corresponding to (1.4).

Notation: Let $\mathbb{D}$ be the open unit disk and $\partial\mathbb{D} = \{z \in \mathbb{C};\, |z| = 1\}$ be the unit circle. Let Λ be a set of complex numbers and define

$$\Lambda^{\triangledown} = \{\bar{\lambda}^{-1} \mid \lambda \in \Lambda,\, \lambda \neq 0\}.$$

To a matrix of complex rational functions of the form $W(s) = D + C(sI - A)^{-1}B$, we associate $W^{\triangledown}(s) = D^* + B^*(s^{-1}I - A^*)C^*$. For $\lambda \in \mathbb{C}$ put

$$E_\lambda(F) = \operatorname{Ker}(\lambda I - F)^n.$$

Then $E_\lambda(F)$ is a generalized eigenspace of F if $\lambda \in \sigma(F)$. In particular, $E_0(F) = \operatorname{Ker} F^n$. We set

$$E_{\partial\mathbb{D}} = \oplus\{E_\eta(F),\, \eta \in \partial\mathbb{D}\}.$$

A subspace V of $\mathbb{C}^n$ is a *spectral subspace* of F if $V = \oplus\{E_\lambda(F);\, \lambda \in T\}$ for some $T \subseteq \sigma(F)$. If K is a hermitian matrix, we write $K > 0$ ($K \geq 0$) when K is positive (semi)definite. If F is nonsingular, we set $F^{-*} = (F^*)^{-1}$.

The main result of this paper is Theorem 5.3. It describes a parametrization of the set of hermitian solutions of the DARE (1.2). The proof of that theorem will proceed in several stages. In section 2 we review basic facts on the DARE. We recall that the difference of two solutions of (1.2) satisfies an associated DARE of the form

$$X - F^*XF + F^*XG(R + G^*XG)^{-1}G^*XF = 0.$$

Such equations, where $X = 0$ is a solution, will be considered in section 4. We have indicated before that (1.4) is related to Schur complements and shorted operators. That subject will be touched upon in section 3.

The geometric theory of Willems [24] and Coppel [5] was carried over to the DARE (1.2) first by G. Ruckebusch [20], [21, p. 129] and then by Ran and Trentelman [19]. Those papers give a geometric characterization of the set of hermitian solutions in terms of the pair of extremal solutions.

2. Basic facts of the DARE: Definitions. There is a wide class of problems in systems and control theory that require solutions of the DARE

$$\mathcal{D}(X) = X - F^*XF + (G^*XF + S)^*(R + G^*XG)^{-1}(G^*XF + S) - Q = 0. \tag{2.1}$$

An important example is the discrete-time linear quadratic problem of optimal control. Let the system

$$x(t+1) = Fx(t) + Gu(t),\ x(0) = x_0$$

be stabilizable, and let

$$J(x_0, u) = \sum_{t=0}^{\infty} [x^*(t)\ \ u^*(t)] \begin{bmatrix} Q & S^* \\ S & R \end{bmatrix} \begin{bmatrix} x(t) \\ u(t) \end{bmatrix}$$

be a positive semidefinite performance index. Then (see, e.g., [9]) there exists an optimal control $u(t)$ which minimizes $J(x_0, u)$. The optimal cost is given by $J_{\text{opt}} = x_0^* X_{\text{opt}} x_0$, where X_{opt} is the smallest positive semidefinite solution of (2.1), and the optimal control is

$$u_{\text{opt}}(t) = -(R + G^*X_{\text{opt}}G)^{-1}(S + G^*X_{\text{opt}}F)x(t). \tag{2.2}$$

Thus (2.2) gives rise to the closed loop system

$$x(t+1) = [F - G(R + G^*X_{\text{opt}}G)^{-1}(S + G^*X_{\text{opt}}F)]x(t). \tag{2.3}$$

The matrices in (2.1) are assumed to be complex, $F \in \mathbb{C}^{n\times n}$, $G \in \mathbb{C}^{n\times m}$, $S \in \mathbb{C}^{m\times n}$, $R = R^* \in \mathbb{C}^{m\times m}$, and $Q = Q^* \in \mathbb{C}^{n\times n}$. We are concerned with hermitian solutions X of (2.1). In this section we assemble basic facts and concepts related to (2.1). With regard to (2.3) we define

$$F_X = F - G(R + G^*XG)^{-1}(G^*XF + S)$$

as the closed loop matrix corresponding to a solution X. We say that a solution X of the DARE (2.1) is *unmixed* if F_X has the property

$$\sigma(F_X) \cap \sigma(F_X)^{\nabla} \subseteq \partial\mathbb{D}, \tag{2.4}$$

i.e., if $\lambda \in \sigma(F_X)$ and $\lambda \neq 0$ and $|\lambda| \neq 1$, then $\overline{\lambda}^{-1} \notin \sigma(F_X)$. We say that (X_1, X_2) is a *pair of opposite unmixed solutions* if the corresponding closed loop matrices satisfy

$$\sigma(F_{X_1}) \cap \sigma(F_{X_2}) \subseteq \partial\mathbb{D} \cup \{0\}. \tag{2.5}$$

Let

$$M - sL = \begin{bmatrix} F & 0 & G \\ Q & I & S^* \\ S & 0 & R \end{bmatrix} - s \begin{bmatrix} I & 0 & 0 \\ 0 & F^* & 0 \\ 0 & G^* & 0 \end{bmatrix} \tag{2.6}$$

be the extended symplectic pencil associated with (2.1), and let

$$\Psi(s) = \begin{bmatrix} G^*(s^{-1}I - F^*)^{-1} & I \end{bmatrix} \begin{bmatrix} Q & S^* \\ S & R \end{bmatrix} \begin{bmatrix} (sI - F)^{-1}G \\ I \end{bmatrix} \tag{2.7}$$

be the associated Popov matrix. The following identities and facts can be found in [11], [13], and [17]. If X is a solution of (2.1), then

$$\det(M - sL) = \det(R + G^*XG)\det(sI - F_X)\det(I - sF_X^*). \tag{2.8}$$

It follows from (2.8) that there exists a solution of (2.1) only if $M - sL$ is nonsingular, i.e., if $\det(M - sL)$ is not the zero polynomial. In that case we call

$$\sigma(M - sL) = \{\lambda \in \mathbb{C} \mid \det(M - \lambda L) = 0\}$$

the set of *characteristic roots* of the pencil (2.6). It is obvious from (2.8) that $\sigma(F_X) \subseteq \sigma(M - sL)$. Hence, if 0 is a characteristic root of $M - sL$, then we have $0 \in \sigma(F_X)$ for all solutions X, which accounts for the singleton $\{0\}$ in (2.5). Let X_1 and X_2 be solutions of (2.1) such that (2.5) holds. Then it follows from (2.8) that both X_1 and X_2 are unmixed. Each solution X of (2.1) gives rise to a factorization of the Popov matrix $\Psi(s)$, namely

$$\Psi(s) = \Phi_X^\nabla(s)(R + G^*XG)\Phi_X(s) \tag{2.9}$$

with

$$\Phi_X(s) = I + (R + G^*XG)^{-1}(G^*XF + S)(sI - F)^{-1}G.$$

If $\Psi(s)$ satisfies

$$\Psi(\eta) > 0 \text{ for some } \eta \in \partial\mathbb{D}, \tag{Ψ}$$

then (2.9) implies

$$R + G^*XG > 0 \tag{2.10}$$

for all solutions X.

Arguments in section 4 show that the conditions (Ψ) and (2.10) are essential for the derivation of Theorem 5.3. Hence it is not within the scope of this paper to deal with DAREs of the form (1.2) where $(R + G^*XG)^{-1}$ is replaced by a generalized inverse $(R + G^*XG)^\#$.

Existence of unmixed solutions was studied in [4], [25], [3]. We note the following result of [3]. Suppose that (Ψ) holds, $\Psi(\eta) \geq 0$ for almost all $\eta \in \partial\mathbb{D}$, and $\operatorname{rank}(F - \lambda I) = n$ for all $\lambda \neq 0$. Then each unmixed set Λ gives rise to a unique solution X such that $\sigma(F_X) \subseteq \Lambda$. In particular there exists a unique pair (X_-, X_+) such that

$$\sigma(F_{X_-}) \subseteq \{0\} \cup \{\lambda \in \mathbb{C}\,;\, |\lambda| \geq 1\} \text{ and } \sigma(F_{X_+}) \subseteq \overline{\mathbb{D}}. \tag{2.11}$$

It is known that Cayley transformations allow a passage from continuous-time to discrete-time algebraic Riccati equations [15], [1]. The use of such transformations requires invertibility assumptions (see, e.g., [1, p. 81]) which are not met by the general hypotheses in the present paper. We note that in the case of $0 \in \sigma(M - sL)$ a computational procedure is available [7] to obtain an equivalent DARE of smaller order such that the associated closed loop matrices are nonsingular.

3. Shorted operators and oblique projections. Let N be a subspace of $\mathbb{C}^n$ and Δ be a hermitian $n \times n$ matrix.

LEMMA 3.1. (i) *If*

$$N = \operatorname{Im} \begin{bmatrix} I_t \\ 0 \end{bmatrix}, \quad \text{and if} \quad \Delta = \begin{bmatrix} \Delta_1 & \Delta_{21}^* \\ \Delta_{21} & \Delta_2 \end{bmatrix} \tag{3.1}$$

is partitioned conformably, then we have

$$\mathbb{C}^n = (\Delta N)^\perp \oplus N \tag{3.2}$$

if and only if Δ_1 is nonsingular.

(ii) *Assume* (3.2) *and let P_N be the projection on $(\Delta N)^\perp$ along N. Then the matrix ΔP_N is hermitian. If N and Δ are given as in* (3.1)*, then*

$$\Delta P_N = \operatorname{diag}(0, \tilde{\Delta}_2), \qquad \tilde{\Delta}_2 = \Delta_2 - \Delta_{21}^* \Delta_1^{-1} \Delta_{21}. \tag{3.3}$$

Proof. (i) Suppose $\det \Delta_1 = 0$. If $u_1 \in \operatorname{Ker}\ \Delta_1$, $u_1 \neq 0$, then

$$u = \begin{bmatrix} u_1 \\ 0 \end{bmatrix} \in N$$

and

$$u^* \Delta N = [u_1^* \ \ 0] \begin{bmatrix} \Delta_1 \\ \Delta_{21} \end{bmatrix} = 0.$$

Hence $(\Delta N)^\perp \cap N \neq 0$. Conversely, if Δ_1 is nonsingular, then

$$\Delta N = \operatorname{Im} \begin{bmatrix} \Delta_1 \\ \Delta_{21} \end{bmatrix} = \operatorname{Im} \begin{bmatrix} I_t \\ \Delta_{21} \Delta_1^{-1} \end{bmatrix}$$

and

$$(\Delta N)^\perp = \operatorname{Im} \begin{bmatrix} -\Delta_1^{-1} \Delta_{21}^* \\ I_{n-t} \end{bmatrix} \tag{3.4}$$

imply (3.2). (ii) From $\operatorname{Im} P_N = (\Delta N)^\perp$ and $\Delta \operatorname{Im} (I - P_N) = \Delta N$ follows $(I - P_N)^* \Delta P_N = 0$. Hence, $\Delta P_N = P_N^* \Delta P_N$ is hermitian. Because of (3.4) the projection matrix P_N is given by

$$P_N = \begin{bmatrix} 0 & -\Delta_1^{-1} \Delta_{21}^* \\ 0 & I_{n-t} \end{bmatrix},$$

which yields ΔP_N as a shorted operator in block diagonal form (3.3). ∎

The following observation is a special case of a formula for the inverse of a block matrix [10, p. 18]. It will be needed in the proof of Theorem 4.5, which deals with a nonsingular solution Δ of a special DARE and its inverse.

LEMMA 3.2. *Assume that Δ is nonsingular, set $W = \Delta^{-1}$, and let*

$$\Delta = \begin{bmatrix} \Delta_1 & \Delta_{21}^* \\ \Delta_{21} & \Delta_2 \end{bmatrix} \ \text{and} \ W = \begin{bmatrix} * & * \\ * & W_2 \end{bmatrix}$$

be partitioned accordingly. (i) *Then Δ_1 is nonsingular if and only if W_2 is nonsingular.* (ii) *If Δ_1 is nonsingular, then $\widetilde{\Delta}_2 = \Delta_2 - \Delta_{21}^* \Delta_1^{-1} \Delta_{21}$ is nonsingular and $\widetilde{\Delta}_2^{-1} = W_2$.*

Proof. We include a proof which is an application of the preceding lemma. Set $N = \operatorname{Im}[I_t \ O]^T$ and $M = N^\perp$. (i) Assume that Δ_1 is nonsingular, or equivalently (3.2). Because of $(\Delta N)^\perp = \Delta^{-1}N^\perp$ we can write (3.2) as $WM \oplus M^\perp = \mathbb{C}^n$, which in turn is equivalent to $(WM)^\perp \oplus M = \mathbb{C}^n$. Because of $M = \operatorname{Im}[O \ I_{n-t}]^T$ such a decomposition exists if and only if W_2 is nonsingular. (ii) From $\Delta P_N = \operatorname{diag}(0, \widetilde{\Delta}_2)$ follows

$$\Delta P_N \Delta^{-1} = \begin{bmatrix} 0 & 0 \\ * & \widetilde{\Delta}_2 W_2 \end{bmatrix}.$$

Obviously $\Delta P_N \Delta^{-1}$ is the projection on $N^\perp$ along ΔN. Thus we obtain $\widetilde{\Delta}_2 W_2 = I$. ∎

Let $K = \operatorname{Ker}\Delta$ and $V = \operatorname{Im}\Delta$. We assume $0 < n_c = \dim V < n$ such that the decomposition $\mathbb{C}^n = K \oplus V$ is nontrivial. Let $U \subseteq V$. Then $U^{\perp_c}$ shall denote the orthogonal complement of U with respect to V. Set $\Delta_c = \Delta_{|V}$. Then $\Delta_c : V \to V$ is hermitian and nonsingular.

LEMMA 3.3. *Let N be a subspace of $\mathbb{C}^n$ with $K \subseteq N$. Set $N_c = N \cap V$. Then*

$$(\Delta_c N_c)^{\perp_c} \oplus N_c = V \tag{3.5}$$

if and only if

$$(\Delta N)^\perp \oplus (N \cap \operatorname{Im}\Delta) = \mathbb{C}^n. \tag{3.6}$$

Proof. Note that $(\Delta N)^\perp = K \oplus (\Delta_c N_c)^{\perp_c}$ and $N \cap \operatorname{Im}\Delta = N_c$. ∎

4. A DARE with solution $X = 0$. In this section we deal with the equation

$$\mathcal{H}(Y) = Y - F^*YF + F^*YG(R + G^*YG)^{-1}G^*YF = 0, \tag{4.1}$$

where R is nonsingular. Set $\Gamma = GR^{-1}G^*$. Then

$$F_Y = F - G(R + G^*YG)^{-1}G^*YF = (I + \Gamma Y)^{-1}F,$$

and we have $\mathcal{H}(Y) = Y - F^*YF_Y = 0$. We first note two results on nonsingular solutions of (4.1).

LEMMA 4.1 (see [26, p. 931]). *Let Y be a hermitian nonsingular $n \times n$ matrix. Assume that F is nonsingular. Then Y is a solution of* (4.1) *if and only if $W = Y^{-1}$ satisfies the discrete-time Lyapunov equation*

$$W - FWF^* = -\Gamma. \tag{4.2}$$

LEMMA 4.2 (see [26, p. 932]). *Assume that F is nonsingular, (F, G) is controllable, $R > 0$, and $\sigma(F) \cap \sigma(F^{-*}) = \emptyset$. Then* (4.1) *has a unique nonsingular solution.*

The subsequent result deals with eigenvalues of F in $\{0\} \cup \partial\mathbb{D}$ and corresponding generalized eigenspaces.

LEMMA 4.3 (see [26, p. 933]). *Assume $R > 0$ and $\operatorname{rank}(F - \eta I, G) = n$ for all $\eta \in \partial\mathbb{D}$. If Y is a solution of* (4.1)*, then $E_0(F) + E_{\partial\mathbb{D}}(F) \subseteq \operatorname{Ker} Y$.*

COROLLARY 4.4 (see [26, pp. 923–924]). *Assume $R > 0$, $\operatorname{rank}[F - \lambda I, \ G] = n$ if $\lambda \neq 0$, and $\sigma(F) \cap \sigma(F)^\nabla \subseteq \partial\mathbb{D}$. Then* (4.1) *has a unique solution Δ with $\operatorname{Ker}\Delta = E_0(F) + E_{\partial\mathbb{D}}(F)$.*

It is easy to show (see also Proposition 5.2) that $(0, \Delta)$ is a pair of opposite unmixed solutions of $\mathcal{H}(Y) = 0$. Therefore, the following result can already be viewed as a special case of the main theorem.

THEOREM 4.5. *The assumptions on the DARE*

$$\mathcal{H}(Y) = Y - F^*YF + F^*YG(R + G^*YG)^{-1}G^*YF = 0 \tag{4.1}$$

are the following: $R > 0$, $\sigma(F) \cap \sigma(F)^{\nabla} \subseteq \partial\mathbb{D}$, *and* $\operatorname{rank}[F - \lambda I,\ G] = n$ *if* $\lambda \neq 0$. *Define*

$$K = E_0(F) + E_{\partial\mathbb{D}}(F),$$

and

$$\mathcal{T} = \{Y \mid \mathcal{H}(Y) = 0\},\quad \mathcal{N} = \{N \in \operatorname{Inv} F \mid K \subseteq N\}. \tag{4.3}$$

Let Δ *be the solution of* (4.1) *with* $\operatorname{Ker} \Delta = K$. *Then the following holds.*

(i) *If* Y *is a solution of* (4.1), *then* $\operatorname{Ker} Y \in \mathcal{N}$.

(ii) *If* $N \in \mathcal{N}$, *then*

$$\mathbb{C}^n = (\Delta N)^{\perp} \oplus (N \cap \operatorname{Im} \Delta), \tag{4.4}$$

and if P_N *is the projection of* $\mathbb{C}^n$ *on* $(\Delta N)^{\perp}$ *along* $N \cap \operatorname{Im} \Delta$, *then* $\tilde{Y} = \Delta P_N$ *is the unique solution of* (4.1) *with* $\operatorname{Ker} \tilde{Y} = N$.

(iii) *For* $N \in \mathcal{N}$ *set* $\tilde{\kappa}(N) = \Delta P_N$. *Then the map* $\tilde{\kappa} : \mathcal{N} \to \mathcal{T}$ *is a bijection, and for* $Y \in \mathcal{T}$ *we have* $\tilde{\kappa}^{-1}(Y) = \operatorname{Ker} Y$.

Proof. Let us first prove the theorem under the stronger assumption that F is nonsingular and $\sigma(F) \cap \sigma(F^{-*}) = \emptyset$. In that case we have $K = 0$ and the solution Δ is nonsingular such that $N \cap \operatorname{Im} \Delta = N$ and $\mathcal{N} = \operatorname{Inv} F$.

(i) This is obvious since $\mathcal{H}(Y) = Y - F^*YF_Y = 0$ is equivalent to $F_Y^{-*}Y = YF$.

(ii) Assume $N = \operatorname{Im}[I\ O]^T$ such that

$$F = \begin{bmatrix} F_1 & * \\ 0 & F_2 \end{bmatrix}. \tag{4.5}$$

It is known from Lemma 4.1 that $W = \Delta^{-1}$ satisfies

$$W - FWF^* = -GR^{-1}G^*. \tag{4.6}$$

Let

$$\Delta = \begin{bmatrix} \Delta_1 & \Delta_{21}^* \\ \Delta_{21} & \Delta_2 \end{bmatrix},\ G = \begin{bmatrix} * \\ G_2 \end{bmatrix},\ \text{and}\ \Delta^{-1} = W = \begin{bmatrix} * & * \\ * & W_2 \end{bmatrix}$$

be partitioned according to (4.5). To establish a decomposition

$$\mathbb{C}^n = (\Delta N)^{\perp} \oplus N, \tag{4.7}$$

we recall Lemma 3.1 and the fact that (4.7) holds if and only if Δ_1 is nonsingular. Thus, according to Lemma 3.2 we have to show that W_2 is nonsingular. From (4.6) we obtain

$$W_2 - F_2W_2F_2^* = -G_2R^{-1}G_2^*. \tag{4.8}$$

In the preceding Stein equation the pair (F_2, G_2) is controllable, $\sigma(F_2) \cap \sigma(F_2^{-*}) = \emptyset$, and $R > 0$. Therefore (see, e.g., [14, p. 453]) the matrix W_2 is nonsingular.

Now let us show that $\tilde{Y} = \Delta P_N$ is a solution of (4.1). Since Δ is assumed to be nonsingular we have $\operatorname{Ker} \tilde{Y} = \operatorname{Ker} P_N = N$. Hence it follows from Lemmas 3.1 and 3.2 that $\tilde{Y} = P_N^* \Delta P_N = \operatorname{diag}(0, \widetilde{\Delta}_2)$, and $\tilde{\Delta}_2 = \Delta_2 - \Delta_{21}\Delta_1^{-1}\Delta_{21}^*$ is nonsingular and $\widetilde{\Delta}_2^{-1} = W_2$. Consider the equation

$$\mathcal{H}_2(Y_2) = Y_2 - F_2^* Y_2 F_2 + F_2^* Y_2 G_2 (R + G_2^* Y_2 G_2)^{-1} G_2^* Y_2 F_2. \tag{4.9}$$

It is easy to check that $\mathcal{H}(\tilde{Y}) = \operatorname{diag}\bigl(0, \mathcal{H}_2(\tilde{\Delta}_2)\bigr)$. Hence $\tilde{Y}$ is a solution of (4.1) if and only if $\mathcal{H}_2(\widetilde{\Delta}_2) = 0$. To show that $\widetilde{\Delta}_2$ is a solution of (4.9) we use Lemma 4.1 again, which says that $\mathcal{H}_2(\widetilde{\Delta}_2) = 0$ is equivalent to

$$\widetilde{\Delta}_2^{-1} - F_2 \widetilde{\Delta}_2^{-1} F_2^* = -G_2 R^{-1} G_2^*. \tag{4.10}$$

We have seen that the solution Δ gives rise to (4.8). Therefore, because $W_2 = \widetilde{\Delta}_2^{-1}$, (4.10) is satisfied.

To prove uniqueness, take a solution Y of (4.1) with $\operatorname{Ker} Y = N$. Then $Y = \operatorname{diag}(0, Y_2)$, and Y_2 is nonsingular satisfying (4.9). According to Lemma 4.2 there exists a unique nonsingular solution of (4.9), namely, $\widetilde{\Delta}_2$. Hence $Y = \operatorname{diag}(0, \widetilde{\Delta}_2) = \tilde{Y}$. Part (iii) is an obvious consequence of (i) and (ii).

We now discard the assumptions about F made at the beginning and consider the case $K = E_0(F) + E_{\partial\mathbb{D}}(F) \neq 0$. Let $V = \oplus\{E_\lambda(F) \mid \lambda \neq 0, \lambda \notin \partial\mathbb{D}\}$ be the F-invariant complement of K such that $\mathbb{C}^n = K \oplus V$. Suppose

$$K = \operatorname{Im} \begin{bmatrix} I_{n_a} \\ 0 \end{bmatrix} \text{ and } V = \operatorname{Im} \begin{bmatrix} 0 \\ I_{n_c} \end{bmatrix} \tag{4.11}$$

such that

$$F = \begin{bmatrix} F_a & 0 \\ 0 & F_c \end{bmatrix}, \; G = \begin{bmatrix} * \\ G_c \end{bmatrix}.$$

Then $\sigma(F_a) \subseteq \{0\} \cup \partial\mathbb{D}$, F_c is nonsingular, and $\sigma(F_c) \cap \sigma(F_c^{-*}) = \emptyset$. It follows from Lemma 4.3 that Y is a solution of (4.1) if and only if $Y = \operatorname{diag}(0, Y_c)$ and Y_c is a solution of

$$\mathcal{H}_c(Y_c) = Y_c - F_c^* Y_c F_c + F_c^* Y_c G_c (R + G_c^* Y_c G_c)^{-1} G_c^* Y_c F_c = 0. \tag{4.12}$$

Set $\mathcal{T}_c = \{Y_c \mid \mathcal{H}_c(Y_c) = 0\}$ and let $\iota : \mathcal{T}_c \to \mathcal{T}$ be the bijection given by $\iota(Y_c) = \operatorname{diag}(0, Y_c)$. Let Δ_c be the unique nonsingular solution of (4.12). Then $\Delta = \operatorname{diag}(0, \Delta_c)$ is the unique solution of (4.1) with $\operatorname{Ker} \Delta = K$.

Let $\hat{N}_c \in \operatorname{Inv} F_c$. We embed $\hat{N}_c$ into the space

$$N_c = \left\{ \begin{bmatrix} 0 \\ x_c \end{bmatrix} \in \mathbb{C}^n, \, x_c \in \hat{N}_c \right\}$$

and define $\tau(\hat{N}_c) = K \oplus N_c$. Then $\tau : \operatorname{Inv} F_c \to \mathcal{N}$ is a bijection. In accordance with (4.7) we have

$$\mathbb{C}^{n_c} = (\Delta_c \hat{N}_c)^\perp \oplus \hat{N}_c, \tag{4.13}$$

which is equivalent to $V = (\Delta_c N_c)^{\perp_c} \oplus N_c$. Hence, it follows from Lemma 3.3 that $N = \tau(\hat{N}_c) \in \mathcal{N}$ satisfies (4.4). Let $P_{\hat{N}_c}$ be the projection corresponding to (4.13) and set $\tilde{\kappa}_c(\hat{N}_c) = \Delta_c P_{\hat{N}_c}$. We know that $\tilde{\kappa}_c : \text{Inv } F_c \to \mathcal{T}_c$ is a bijection. Define $\mu_c = \tilde{\kappa}_c^{-1}$, i.e., $\mu_c(Y_c) = \text{Ker } Y_c$, $Y_c \in \mathcal{T}_c$. The maps $\tilde{\kappa}_c$ and μ_c can now be extended to bijections between $\mathcal{T}$ and $\mathcal{N}$. For $Y \in \mathcal{T}$ define $\mu(Y) = \text{Ker } Y$. Then $\mu = \tau\mu_c\iota^{-1} : \mathcal{T} \to \mathcal{N}$, and μ is bijective. Let P_N be the projection arising from (4.4). For $N \in \mathcal{N}$ define $\tilde{\kappa}(N) = \Delta P_N$. In the setting of (4.11) we have $P_N = \text{diag}(I, P_{\hat{N}_c})$. Therefore

$$\tilde{\kappa}(N) = \text{diag}(0, \Delta_c P_{\hat{N}_c}) = \iota(\Delta_c P_{\hat{N}_c}) = \iota\tilde{\kappa}_c(\hat{N}_c) = \iota\tilde{\kappa}_c\tau^{-1}(N).$$

Hence $\tilde{\kappa} : \mathcal{N} \to \mathcal{T}$ and $\tilde{\kappa} = \mu^{-1}$. □

In order to characterize unmixed solutions of $\mathcal{D}(X) = 0$, we need a discrete-time counterpart of a result of Scherer [22, p. 106]. Let $A \in \mathbb{C}^{n\times n}$ and $M \in \text{Inv } A$; let $\bar{A}$ denote the endomorphism of $\mathbb{C}^n/M$ induced by A; and let $A_{|M}$ be the restriction of A to M. We define $\sigma_i(A, M) = \sigma(A_{|M})$ and $\sigma_o(A, M) = \sigma(\bar{A})$. Assumptions and definitions in the lemma below are those of Theorem 4.5 and its proof.

LEMMA 4.6. *For $N \in \mathcal{N}$ let $Y = \Delta P_N$ be the corresponding solution of* (4.1). (i) *Then $F = F_Y$ on N and $N \in \text{Inv } F_Y$, and we have*

$$\sigma_i(F_Y, N) = \sigma_i(F, N) \text{ and } \sigma_o(F_Y, N) = \sigma_o(F, N)^\nabla. \tag{4.14}$$

(ii) *The solution Y is unmixed if and only if $N \in \mathcal{N}$ is a spectral subspace of F.*

Proof. Let us assume for simplicity that F is nonsingular and $\sigma(F) \cap \sigma(F^{-*}) = \emptyset$.

(i) As before, suppose $N = \text{Im}\,[I\ O]^T$ and let F be given by (4.5). Then $\sigma_i(F, N) = \sigma(F_1)$ and $\sigma_o(F, N) = \sigma(F_2)$. From $Y = \Delta P_N = \text{diag}(0, \widetilde{\Delta}_2)$ follows

$$F_Y = (I + \Gamma Y)^{-1}F = \begin{bmatrix} F_1 & * \\ 0 & A_2 \end{bmatrix}$$

with $A_2 = (I + \Gamma_2\widetilde{\Delta}_2)^{-1}F_2$. Thus $\sigma_i(F_Y, N) = \sigma(F_1)$. On the other hand, $Y - F^*YF_Y = 0$ implies $A_2 = \widetilde{\Delta}_2^{-1}F_2^{-*}\widetilde{\Delta}_2$, and we obtain $\sigma(A_2) = \sigma(F_2)^\nabla$.

(ii) N is a spectral subspace of F if and only if

$$\sigma(F_1) \cap \sigma(F_2) = \emptyset. \tag{4.15}$$

The assumption $\sigma(F) \cap \sigma(F^{-*}) = \emptyset$ together with (4.14) imply

$$\sigma(F_Y) \cap \sigma(F_Y^{-*}) = [\sigma(F_1) \cup \sigma(F_2^{-*})] \cap [\sigma(F_1^{-*}) \cup \sigma(F_2)] =$$
$$[\sigma(F_2^{-*}) \cap \sigma(F_1^{-*})] \cup [\sigma(F_1) \cap \sigma(F_2)] = [\sigma(F_1) \cap \sigma(F_2)]^\nabla \cup [\sigma(F_1) \cap \sigma(F_2)].$$

Hence, the property that Y is unmixed, i.e., $\sigma(F_Y) \cap \sigma(F_Y^{-*}) = \emptyset$, is equivalent to (4.15). □

5. The main result. The passage from the general DARE

$$\mathcal{D}(X) = X - F^*XF + (G^*XF + S)^*(R + G^*XG)^{-1}(G^*XF + S) - Q = 0 \tag{5.1}$$

to an equation of the form $\mathcal{H}(Y) = 0$ in (4.1) is a crucial step in the derivation of our main theorem. It is based on the following lemma for which we refer to [19] and [8, Lemma 5.2] or [1, Lemma 6.8.9].

LEMMA 5.1. (i) *Let X_2 be a solution of $\mathcal{D}(X) = 0$. Then X is a solution of $\mathcal{D}(X) = 0$ if and only if $Y = X - X_2$ is a solution of*

$$\mathcal{H}_2(Y) = Y - F_{X_2}^* Y F_{X_2} + F_{X_2}^* YG[(R + G^* X_2 G) + G^* YG]^{-1} G^* Y F_{X_2} = 0. \tag{5.2}$$

(ii) *Let X_2 and X be solutions of $\mathcal{D}(X) = 0$. Set $Y = X - X_2$. Then*

$$F_X = F_{X_2} - G(R + G^* XG)^{-1} G^* Y F_{X_2}. \tag{5.3}$$

Thus, when a solution X_2 of (5.1) is at our disposal we can pass from (5.1) to (5.2) and apply the results of section 4.

PROPOSITION 5.2. *Assume* (Ψ) *and*

$$\operatorname{rank}[F - \lambda I,\ G] = n \ \text{ if } \lambda \neq 0. \tag{5.4}$$

Let X_2 be an unmixed solution of $\mathcal{D}(X) = 0$. Set $K = E_0(F_{X_2}) + E_{\partial\mathbb{D}}(F_{X_2})$. Then there exists a unique solution Δ of (5.2) with $\operatorname{Ker} \Delta = K$. *Moreover (X, X_2) is a pair of opposite unmixed solutions of $\mathcal{D}(X) = 0$ if and only if $X = X_2 + \Delta$.*

Proof. The assumption (Ψ) implies $R + G^* X_2 G > 0$ in (5.2). Clearly (5.4) implies the corresponding condition for $F = F_{X_2}$. The assumption that X_2 should be an unmixed solution of (5.1) is equivalent to

$$\sigma(F_{X_2}) \cap \sigma(F_{X_2})^{\triangledown} \subseteq \partial\mathbb{D}. \tag{5.5}$$

Hence it follows from Corollary 4.4 that (5.2) has a unique solution Δ with $\operatorname{Ker} \Delta = K$. Again it is no loss of generality to assume

$$K = \operatorname{Im} \begin{bmatrix} I_{n-n_c} \\ 0 \end{bmatrix}$$

and $F_{X_2} = \operatorname{diag}(F_a, F_c)$. Then $\Delta = \operatorname{diag}(0,\ \Delta_c)$, $\det \Delta_c \neq 0$. Obviously (5.5) implies that F_c is nonsingular and

$$\sigma(F_c) \cap \sigma(F_c^{-*}) = \emptyset. \tag{5.6}$$

Let X be a solution of (5.1). Set $Y = X - X_2$. Then $\mathcal{H}_2(Y) = 0$, or equivalently

$$Y - F_{X_2}^* Y F_X = 0. \tag{5.7}$$

Because of Lemma 4.3 we have $K \subseteq \operatorname{Ker} Y$. Hence $Y = \operatorname{diag}(0, Y_c)$. The identity (5.3) yields

$$F_X = \begin{bmatrix} F_a & * \\ 0 & B \end{bmatrix}. \tag{5.8}$$

From (5.7) we obtain

$$Y_c - F_c^* Y_c B = 0. \tag{5.9}$$

Let us consider the solution $X = X_2 + \Delta$ and let F_X be as in (5.8). In this case we have $Y = \Delta = \operatorname{diag}(0,\ \Delta_c)$. Thus (5.9) becomes $\Delta_c - F_c^* \Delta_c B = 0$, where F_c and Δ_c are nonsingular. Hence $B = \Delta_c^{-1} F_c^{-*} \Delta_c$, $\sigma(B) = \sigma(F_c^{-*})$, and

$$\sigma(F_X) = \sigma(F_a) \cup \sigma(B) = \sigma(F_a) \cup \sigma(F_c^{-*}).$$

Thus (5.6) implies $\sigma(F_X) \cap \sigma(F_{X_2}) = \sigma(F_a) \subseteq \{0\} \cup \partial\mathbb{D}$, and therefore (X, X_2) is a pair of opposite unmixed solutions.

Now consider a solution X such that $Y = X - X_2 \neq \Delta$. Then $Y = \operatorname{diag}(0, Y_c)$ and Y_c is singular. Take $w \in \operatorname{Ker} Y_c$, $w \neq 0$. Recall that F_c in (5.9) is nonsingular. Hence $F_c B w = 0$, and $\operatorname{Ker} Y_c$ is invariant under B. Therefore we can assume that w is an eigenvector of B, say $Bw = \lambda w$. Interchanging the role of X and X_2 in (5.3), we obtain

$$F_{X_2} = \operatorname{diag}(F_a, F_c) = F_X - G(R + G^* X_2 G)^{-1} G^*(-Y) F_X.$$

Hence $F_c = B - W Y_c B$ with some $n_c \times n_c$ matrix W. Thus $F_c w = Bw$. Therefore $\lambda \in \sigma(F_c)$, and $\lambda \notin (\{0\} \cup \partial\mathbb{D})$. On the other hand $\lambda \in \sigma(F_X) \cap \sigma(F_{X_2})$. Hence (X, X_2) is not a pair of opposite unmixed solutions. ∎

At this point the pieces can be put together.

THEOREM 5.3. *Let (X_1, X_2) be a pair of opposite unmixed solutions of the DARE $\mathcal{D}(X) = 0$ in (5.1). Set $\Delta = X_1 - X_2$ and*

$$F_{X_2} = F - G(R + G^* X_2 G)^{-1}(G^* X_2 F + S).$$

Let $\mathcal{S}$ be the set of hermitian solutions of $\mathcal{D}(X) = 0$, and define

$$\mathcal{N} = \{N \in \operatorname{Inv} F_{X_2} \mid E_0(F_{X_2}) + E_{\partial\mathbb{D}}(F_{X_2}) \subseteq N\}. \tag{5.10}$$

Assume (Ψ) and $\operatorname{rank}[F - \lambda I, G] = n$ if $\lambda \neq 0$. If $N \in \mathcal{N}$, then

$$(\Delta\, N)^\perp \oplus (N \cap \operatorname{Im} \Delta) = \mathbb{C}^n. \tag{5.11}$$

Let P_N be the projection on $(\Delta\, N)^\perp$ along $N \cap \operatorname{Im} \Delta$. Define

$$\kappa(N) = X_1 P_N + X_2(I - P_N). \tag{5.12}$$

Then $\kappa : \mathcal{N} \to \mathcal{S}$ is a bijection. If $X \in \mathcal{S}$, then

$$\kappa^{-1}(X) = \operatorname{Ker}(X - X_2).$$

Proof. Let $\mathcal{T}_2$ denote the set of hermitian solutions of $\mathcal{H}_2(Y) = 0$ in (5.2). By Lemma 5.1 we have $X \in \mathcal{S}$, if and only if $Y = X - X_2 \in \mathcal{T}_2$. Hence $\mathcal{S} = X_2 + \mathcal{T}_2$. If (X_1, X_2) is a pair of opposite unmixed solutions, then it follows from Proposition 5.2 that $\Delta = X_1 - X_2$ is the solution of (5.2) with $\operatorname{Ker} \Delta = E_0(F_{X_2}) + E_{\partial\mathbb{D}}(F_{X_2})$. Hence we can parametrize the set $\mathcal{T}_2$ according to Theorem 4.5. If we set $\tilde{\kappa}(N) = \Delta P_N$, then $\tilde{\kappa} : \mathcal{N} \to \mathcal{T}_2$ is a bijection with $\tilde{\kappa}^{-1}(Y) = \operatorname{Ker} Y$. Thus $\mathcal{S} = X_2 + \mathcal{T}_2$ gives rise to a bijection $\kappa : \mathcal{N} \to \mathcal{S}$ defined by $\kappa(N) = X_2 + \tilde{\kappa}(N)$. Then $\kappa(N) = X_2 + (X_1 - X_2)P_N$ yields (5.12). Finally, for $X \in \mathcal{S}$ we have $\kappa^{-1}(X) = \tilde{\kappa}^{-1}(X - X_2) = \operatorname{Ker}(X - X_2)$. ∎

COROLLARY 5.4. *A solution X of (5.1) is unmixed if and only if $\operatorname{Ker}(X - X_2)$ is a spectral subspace of F_{X_2}.*

Proof. Let X be a solution of (5.1) and set $Y = X - X_2$ such that Y is a solution of $\mathcal{H}_2(Y) = 0$ in (5.2). We claim that X is an unmixed solution of (5.1) if and only if the corresponding matrix Y is an unmixed solution of (5.2). Let A be the closed loop matrix associated with Y (with respect to $\mathcal{H}_2 = 0$), i.e.,

$$A = F_{X_2} - G[(R + G^* X_2 G) + G^* Y G]^{-1} G^* Y F_{X_2}.$$

Now the identity (5.3) shows that $A = F_X$. We can apply Lemma 4.6, which tells us that Y is an unmixed solution of (5.2) if and only if $N = \tilde{\kappa}^{-1}(Y) = \operatorname{Ker} Y$ is a spectral subspace of F_{X_2}. □

The pair of opposite solutions (X_-, X_+) satisfying (2.11) consists of the smallest and the greatest solution of (5.1), i.e., for each $X \in \mathcal{S}$ we have $X_- \leq X \leq X_+$. In that particular case, Theorem 5.3 can be obtained from a result on intervals of solutions in [27].

LINEAR PROGRAMMING APPROACH TO DETERMINISTIC LONG RUN AVERAGE PROBLEMS OF OPTIMAL CONTROL*

VLADIMIR GAITSGORY† AND SERGEY ROSSOMAKHINE†

Abstract. We establish that deterministic long run average problems of optimal control are "asymptotically equivalent" to infinite-dimensional linear programming problems (LPPs) and we establish that these LPPs can be approximated by finite-dimensional LPPs, the solutions of which can be used for construction of the optimal controls. General results are illustrated with numerical examples.

Key words. long run average optimal control, singularly perturbed control systems, occupational measures, averaging method, linear programming

1. Introduction and description of the problems. In this paper we show that, under some conditions, deterministic long run average problems of optimal control are "asymptotically equivalent" to infinite-dimensional linear programming problems (LPPs) and we establish that these LPPs can be approximated by finite-dimensional LPPs, the solutions of which can be used for numerical construction of the optimal controls.

Infinite horizon problems of optimal control have been studied intensively in both deterministic and stochastic settings (see Anderson and Kokotovic [3], Arisawa, Ishii, and Lions [5], Bardi and Capuzzo-Dolcetta [10], Bensoussan [12], Carlson, Haurie, and Leizarowitz [14], Colonius and Kliemann [17], Fleming and Soner [21], Grüne [29], Kushner [34], Kushner and Dupuis [35], Vigodner [46], and references therein). In the stochastic setting, the linear programming formulation is a common tool for treating the problems (see, e.g., Basak, Borkar, and Ghosh [11], Borkar [13], Hernandez-Lerma and Lasserre [31], Stockbridge [44], Yin and Zhang [48]). Finite-dimensional approximations of LPPs arising in stochastic optimal control problems were considered by Helmes and Stockbridge [30] and by Mendiondo and Stockbridge [38]. A linear programming approach to long run average optimal control problems in the deterministic setting appears to be new and, to the best of our knowledge, there are no publications devoted to this topic (under different assumptions and for a different problem, a linear programming formulation was discussed in Evans and Gomes [20]). A linear programming approach to deterministic optimal control problems on a finite time interval has been studied in Rubio [42].

Let us introduce the problems that we will be dealing with. Consider the control system

$$\dot{y}(\tau) \;=\; f(u(\tau), y(\tau)), \quad \tau \in [0, S], \tag{1}$$

where the function $f(u,y) : U \times \mathbb{R}^m \to \mathbb{R}^m$ is continuous in (u,y) and satisfies Lipschitz conditions in y; the controls are Lebesgue measurable functions $u(\tau) : [0,S] \to U$ and U is a compact metric space.

A pair $(u(\tau), y(\tau))$ is called *admissible* on the interval $[0,S]$ if (1) is satisfied for almost all $\tau \in [0,S]$ and $y(\tau) \in Y \ \ \forall \tau \in [0,S]$, where Y is a given compact subset of $\mathbb{R}^m$. The pair is called admissible on $[0,\infty)$ if it is admissible on any interval $[0,S]$, $S > 0$.

Let $g(u,y) : U \times \mathbb{R}^m \to \mathbb{R}^1$ be a continuous function. We will be considering the asymptotics of the optimal control problem

$$\frac{1}{S} \inf_{(u(\cdot),y(\cdot))} \int_0^S g(u(\tau), y(\tau)) d\tau \stackrel{\text{def}}{=} G(S), \tag{2}$$

where inf is over all admissible pairs on the interval $[0,S]$. Along with (2), we will be referring to the infinite time horizon optimal control problem

$$\inf_{(u(\cdot),y(\cdot))} \lim_{S\to\infty} \frac{1}{S} \int_0^S g(u(\tau), y(\tau)) d\tau \stackrel{\text{def}}{=} G_\infty, \tag{3}$$

where inf is over all admissible pairs on the interval $[0,\infty)$ such that the limit in the above expression exists. If this inf is sought over the periodic admissible pairs only, that is, over the pairs such that

$$(u(\tau), y(\tau)) = (u(\tau + T), y(\tau + T)) \ \forall \tau \geq 0 \tag{4}$$

for some $T > 0$, then (3) becomes equivalent to a so-called periodic optimization problem (see, e.g., Colonius [15])

$$\inf_{(u(\cdot),y(\cdot))} \frac{1}{T} \int_0^T g(u(\tau), y(\tau)) d\tau \stackrel{\text{def}}{=} G_{per}, \tag{5}$$

where inf is over the length of the time interval T and over the admissible pairs defined on $[0,T]$ which satisfy the periodicity condition $y(0) = y(T)$.

A very special family of admissible pairs on $[0,\infty)$ is that consisting of constant valued controls and corresponding steady state solutions of (1):

$$(u(\tau), y(\tau)) \ = \ (u,y) \ \in \ M \stackrel{\text{def}}{=} \{(u,y) \mid (u,y) \in U \times Y, \ f(u,y) = 0\}. \tag{6}$$

If inf is sought over the admissible pairs from this family, the problem (3) is reduced to

$$\inf_{(u,y)\in M} g(u,y) \stackrel{\text{def}}{=} G_{ss}, \tag{7}$$

which is called a steady state optimization problem. It is easy to see that the optimal values of the above introduced problems satisfy the inequalities

$$\overline{\lim}_{S\to\infty} G(S) \ \leq \ G_\infty \ \leq G_{per} \ \leq \ G_{ss}. \tag{8}$$

The approach that we are developing in the paper is based on a reformulation of problem (2) as the problem of minimization over the set of occupational measures generated on the interval $[0,S]$ by the admissible pairs of (1) and on the fact that this set is proven to converge (as $S \to \infty$) to a set of probability measures characterized by

linear constraints (as has been recently established in [26]). Note that it is the presence of this convergence that constitutes the main difference between our approach and a linear programming approach to deterministic optimal control problems on a finite time interval developed by Rubio [42].

Note also in conclusion that results obtained in the paper have a potential for applications in asymptotic and numerical analysis of singularly perturbed control systems (**SPCS**), which have been the focus of many researchers (see Alvarez and Bardi [1, 2], Artstein [6, 7], Colonius and Fabbri [16], Donchev and Dontchev [19], Gaitsgory [26], Grammel [28], Kabanov and Pergamenshchikov [32], Leizarowitz [36], Naidu [39], and Quincampoix and Watbled [41] for the most recent developments and also for references to earlier results in the area). One such application follows directly from the fact that tending S to infinity in problem (2) is equivalent to tending ϵ to zero in the problem

$$\inf_{(u^\epsilon(\cdot),y^\epsilon(\cdot))} \int_0^1 g(u^\epsilon(t),y^\epsilon(t))dt \stackrel{\text{def}}{=} G(\epsilon) \tag{9}$$

considered on the admissible pairs $(u^\epsilon(\cdot),y^\epsilon(\cdot)) \in U \times Y$ of the SPCS

$$\epsilon\frac{dy^\epsilon(t)}{dt} \;=\; f(u^\epsilon(t),y^\epsilon(t)), \tag{10}$$

where (9) and (10) are obtained from (2) and (1) with $\epsilon \stackrel{\text{def}}{=} \frac{1}{S}$ and with $t = \tau\epsilon, u^\epsilon(t) = u(\frac{t}{\epsilon}), y^\epsilon(t) = y(\frac{t}{\epsilon})$. By formally taking $\epsilon = 0$ in (9)–(10), one obtains the so-called reduced problem, which proves to be equivalent to the steady state optimization problem (7). This implies that the statement about the validity of the equality $\lim_{\epsilon\to 0} G(\epsilon) = G(0)$, which can be interpreted as a weak version of Tichonov's theorem for the SPCS under consideration, is true only if the "less than or equal to" inequalities in (8) are satisfied as exact equalities. More elaborate connections between SPCS and long run average problems of optimal control implying the applicability of results of this paper in dealing with SPCS have been established in Alvarez and Bardi [1, 2], Artstein and Gaitsgory [8], and Gaitsgory [24, 25]; different, Tichonov-theorem-type results can be found in Kokotovic, Khalil, and O'Reilly [33], O'Malley [40], and Veliov [45].

The paper is organized as follows. In section 2, we give the occupational measures formulation of problem (2). In section 3, we show that, as S tends to infinity, the set of occupational measures converges to the set of probability measures with linear constraints, and we introduce the infinite-dimensional LPP defined on this set, which determines the asymptotics of problem (2) (Propositions 2 and 5, Corollaries 3 and 6). In section 4, we establish that the infinite-dimensional LPP can be approximated by a finite-dimensional LPP (Propositions 7 and 9). In section 5, we discuss the possibility of using the solution of the latter to construct an approximation to the solution of the periodic optimization problem (5) and we also illustrate the idea of the construction with two numerical examples. The proofs for sections 3, 4, and 5 are given in section 6.

2. Occupational measures formulation. Let $\mathcal{P}(U \times Y)$ stand for the space of probability measures defined on the Borel subsets of $U \times Y$. Given an arbitrary admissible (on the interval $[0, S]$) pair $(u(\tau), y(\tau))$, one can define a probability measure $\gamma^{(u(\cdot),y(\cdot))} \in \mathcal{P}(U \times Y)$ by taking

$$\gamma^{(u(\cdot),y(\cdot))}(Q) \stackrel{\text{def}}{=} \frac{1}{S}\text{meas}\left\{\tau \;\middle|\; (u(\tau),y(\tau)) \in Q\right\} \tag{11}$$

for any Borel $Q \subset U \times Y$, where meas $\{\cdot\}$ stands for the Lebesgue measure on $[0, S]$. Such a probability measure is called the *occupational measure* generated by the pair $(u(\tau), y(\tau))$. Note that the occupational measure generated by a steady state admissible pair $(u(\tau), y(\tau)) = (u, y) \in M$ (as in (6)) is just the Dirac measure at (u, y).

It is easy to see that (11) is equivalent to the equality

$$\int_{U\times Y} \chi_Q(u,y)\gamma^{(u(\cdot),y(\cdot))}(du,dy) \;=\; \frac{1}{S}\int_0^S \chi_Q(u(\tau),y(\tau))d\tau, \tag{12}$$

where $\chi_Q(\cdot)$ is the indicator function of the set Q: $\chi_Q(u, y) = 1 \;\; \forall (u, y) \in Q$ and $\chi_Q(u, y) = 0 \;\; \forall (u, y) \notin Q$. The validity of (12) for any indicator function leads to the validity of a similar equality for the simple functions (that is, linear combinations of the indicator functions) and, thus, with the help of a standard approximation argument, leads to the validity of the equality

$$\int_{U\times Y} q(u,y)\gamma^{(u(\cdot),y(\cdot))}(du,dy) \;=\; \frac{1}{S}\int_0^S q(u(\tau),y(\tau))d\tau \tag{13}$$

for any continuous function $q(u, y) : U \times \mathbb{R}^m \to \mathbb{R}^1$.

Denote by $\Gamma(S) \subset \mathcal{P}(U \times Y)$ the set of all occupational measures generated by the admissible pairs on the interval $[0, S]$. Using this notation and (13), one can rewrite problem (2) in the equivalent form

$$\inf_{\gamma\in\Gamma(S)} \int_{U\times Y} g(u,y)\gamma(du,dy) \;=\; G(S). \tag{14}$$

In what follows, the convergence properties of $G(S)$ (as S tends to infinity) are established on the basis of the corresponding convergence properties of $\Gamma(S)$. To describe these convergence properties, let us introduce a metric ρ on $\mathcal{P}(U \times Y)$ as follows:

$$\rho(\gamma',\gamma'') \stackrel{\text{def}}{=} \sum_{j=1}^{\infty} \frac{1}{2^j} \left| \int_{U\times Y} q_j(u,y)\gamma'(du,dy) - \int_{U\times Y} q_j(u,y)\gamma''(du,dy) \right| \tag{15}$$

$\forall \gamma', \gamma'' \in \mathcal{P}(U \times Y)$, where $q_j(\cdot), j = 1, 2, \dots$, is a sequence of Lipschitz continuous functions which is dense in the unit ball of $C(U\times Y)$ (the space of continuous functions on $U \times Y$). Note that this metric is consistent with the weak convergence topology of $\mathcal{P}(U \times Y)$. Namely, a sequence $\gamma^k \in \mathcal{P}(U \times Y)$ converges to $\gamma \in \mathcal{P}(U \times Y)$ in this metric if and only if

$$\lim_{k\to\infty} \int_{U\times Y} q(u,y)\gamma^k(du,dy) \;=\; \int_{U\times Y} q(u,y)\gamma(du,dy) \tag{16}$$

for any continuous $q(u, y) : U \times Y \to \mathbb{R}^1$. Note also that, the space $\mathcal{P}(U\times Y)$ is known to be compact in its weak convergence topology and, hence, being equipped with the metric (15), it becomes a compact metric space.

Using the metric ρ, one can define the "distance" $\rho(\gamma, \Gamma)$ between $\gamma \in \mathcal{P}(U \times Y)$ and $\Gamma \subset \mathcal{P}(U\times Y)$ and define the Hausdorff metric $\rho_H(\Gamma_1, \Gamma_2)$ between $\Gamma_1 \subset \mathcal{P}(U\times Y)$ and $\Gamma_2 \subset \mathcal{P}(U \times Y)$ as follows:

$$\rho(\gamma,\Gamma) \stackrel{\text{def}}{=} \inf_{\gamma'\in\Gamma} \rho(\gamma,\gamma'), \qquad \rho_H(\Gamma_1,\Gamma_2) \stackrel{def}{=} \max\left\{ \sup_{\gamma\in\Gamma_1} \rho(\gamma,\Gamma_2), \sup_{\gamma\in\Gamma_2} \rho(\gamma,\Gamma_1) \right\}. \tag{17}$$

The following simple lemma is implied by the definitions above.

LEMMA 1. *Let Γ be a subset of $\mathcal{P}(U \times Y)$.*

(i) *If $\lim_{S\to\infty} \sup_{\gamma\in\Gamma(S)} \rho(\gamma, \Gamma) = 0$, then, for any continuous $q(u, y) : U \times Y \to \mathbb{R}^1$,*

$$\underline{\lim}_{S\to\infty} \inf_{\gamma\in\Gamma(S)} \int_{U\times Y} q(u, y)\gamma(du, dy) \;\geq\; \inf_{\gamma\in\Gamma} \int_{U\times Y} q(u, y)\gamma(du, dy).$$

(ii) *If $\lim_{S\to\infty} \rho_H(\Gamma(S), \Gamma) = 0$, then*

$$\lim_{S\to\infty} \inf_{\gamma\in\Gamma(S)} \int_{U\times Y} q(u, y)\gamma(du, dy) \;=\; \inf_{\gamma\in\Gamma} \int_{U\times Y} q(u, y)\gamma(du, dy).$$

Proof. The proof is obvious. □

3. Infinite-dimensional LPPs. Define the set $W \subset \mathcal{P}(U \times Y)$ by the equation

$$W \stackrel{\text{def}}{=} \{\gamma :\; \gamma \in \mathcal{P}(U \times Y);\; \int_{U\times Y} (\phi'(y))^T f(u, y)\gamma(du, dy) = 0 \;\; \forall \phi(\cdot) \in C^1\}, \tag{18}$$

where C^1 is the space of continuously differentiable functions $\phi(y) : \mathbb{R}^m \to \mathbb{R}^1$ and $\phi'(y)$ is a vector column of partial derivatives (the gradient) of $\phi(y)$.

Note that the set W can be empty. It is easy to see, for example, that W is empty if there exists a continuously differentiable function $\phi(\cdot) \in C^1$ such that

$$\max_{(u,y)\in U\times Y} (\phi'(y))^T f(u, y) \;< 0. \tag{19}$$

The set W is not empty if the set of steady state or periodic admissible pairs is not empty since the occupational measure generated by each such pair is contained in W. In fact, let $(u(\cdot), y(\cdot))$ be a periodic admissible pair (that is, (4) is satisfied with some positive T) and let $\gamma^{(u(\cdot),y(\cdot))}$ be the occupational measure generated by this pair on the interval $[0, T]$. Then, by (13),

$$\int_{U\times Y} (\phi'(y))^T f(u, y)\gamma^{(u(\cdot),y(\cdot))}(du, dy) \;=\; \frac{1}{T}\int_0^T (\phi'(y(\tau)))^T f(u(\tau), y(\tau))d\tau$$

$$= \;\; \frac{\phi(y(T)) - \phi(y(0))}{T} \;=\; 0 \quad \forall \phi(\cdot) \in C^1 \qquad \Rightarrow \qquad \gamma^{(u(\cdot),y(\cdot))} \in W.$$

PROPOSITION 2. *If the set W is empty, then there exists $S_0 > 0$ such that $\Gamma(S)$ is empty for $S \geq S_0$. If $\Gamma(S)$ is not empty for $S > 0$, then W is not empty and*

$$\lim_{S\to\infty} \sup_{\gamma\in\Gamma(S)} \rho(\gamma, W) = 0. \tag{20}$$

Proof. The proof is similar to the corresponding part of the proof of Theorem 2.1(i) in [26]. For the sake of completeness, we have displayed it in section 6. □

Assume that W is not empty and consider the problem

$$\min_{\gamma\in W} \int_{U\times Y} g(u, y)\gamma(du, dy) \stackrel{\text{def}}{=} G^*, \tag{21}$$

where $g(\cdot)$ is the same as in (14) (and the same as in (2)–(7)). It can be easily seen that the set W is convex and compact. Moreover, since both the objective function and the constraints defining W are linear in γ, problem (21) is that of infinite-dimensional linear programming (see, e.g., [4]).

COROLLARY 3. *The lower limit of the optimal values of* (2) *satisfies the inequality*

$$\underline{\lim}_{S\to\infty} G(S) \;=\; \underline{\lim}_{S\to\infty} \inf_{\gamma\in\Gamma(S)} \int_{U\times Y} g(u,y)\gamma(du,dy) \;\geq\; G^*.$$

Proof. The proof follows from Lemma 1(i), Proposition 2, and the validity of the representation (14). □

COROLLARY 4 (criteria of optimality). (i) *If an admissible pair* $(u(\cdot),y(\cdot)) : [0,\infty) \to U\times Y$ *is such that*

$$\lim_{S\to\infty} \frac{1}{S}\int_0^S g(u(\tau),y(\tau))d\tau \;=\; G^*,$$

then this pair is a solution of problem (3) *and* $G_\infty = G^*$.

(ii) *If a periodic (with a period* T*) admissible pair* $(u(\cdot),y(\cdot))$ *is such that*

$$\frac{1}{T}\int_0^T g(u(\tau),y(\tau))d\tau \;=\; G^*,$$

then this pair is a solution of problems (3) *and* (5)*, and also* $G_\infty = G_{per} = G^*$.

(iii) *If a steady state admissible pair* $(u(\tau),y(\tau)=(u,y)\in M$ *(as defined in* (6)*) is such that*

$$g(u,y) \;=\; G^*,$$

then this pair is a solution of problems (3), (5), *and* (7)*, and also* $G_\infty = G_{per} = G_{ss} = G^*$.

Proof. The proof follows from inequalities (8) and Corollary 3. □

Denote by $\mathcal{P}(U)$ the space of probability measures defined on the Borel subsets of U and consider the system

$$\dot y(\tau) \;=\; \bar f(\nu(\tau),y(\tau)), \quad \tau\in[0,S], \tag{22}$$

where $\nu(\tau)\in\mathcal{P}(U)$ are relaxed controls (see [47]) and $\bar f(\nu,u) \stackrel{\text{def}}{=} \int_U f(u,y)\nu(du)$.

A pair $(\nu(\tau),y(\tau))$ will be called *relaxed admissible* on the interval $[0,S]$ if (22) is satisfied for almost all $\tau\in[0,S]$ and $y(\tau)\in Y \;\; \forall\tau\in[0,S]$.

Assumption 1. For any Lipschitz continuous function $q(u,y) : U\times\mathbb{R}^m \to \mathbb{R}^1$,

$$\left|\frac{1}{S}\sup_{(u(\cdot),y(\cdot))}\int_0^S q(u(\tau),y(\tau))d\tau - \frac{1}{S}\sup_{(\nu(\cdot),y(\cdot))}\int_0^S \bar q(\nu(\tau),y(\tau))d\tau\right| \;\stackrel{\text{def}}{=}\; \alpha_q(S) \;\to\; 0 \tag{23}$$

as $S\to\infty$, where $\bar q(\nu,u) \stackrel{\text{def}}{=} \int_U q(u,y)\nu(du)$, with the first sup being over all admissible pairs and the second being over all relaxed admissible pairs.

Remark 1. The fulfillment of Assumption 1 is related to the applicability of Filippov–Wazewski type theorems on Y (see Frankowska and Rampazo [22]). In particular, it is satisfied with $\alpha_q(S)\equiv 0$ if Y is forward invariant with respect to the

solutions of system (1), that is, if for an arbitrary control $u(\tau)$, any solution $y(\tau)$ of (1) with the initial conditions in Y does not leave Y (see, e.g., Theorem 10.4.4 in Aubin and Frankowska [9]). Assumption 1 is also satisfied with $\alpha_q(S) \equiv 0$ if $f(u,y) \equiv f(y)$ (the case of uncontrolled dynamics, with inf's in (2)–(5) being over the admissible trajectories having different initial conditions). In this case U can be formally defined to consist of only one point and systems (1) and (22) are identical.

Assumption 1 is not satisfied if, for example, the set of admissible pairs is empty, while the set of relaxed admissible pairs is not, as in the case when $m = 1$, $f(u,y) = -y + u$, with U consisting of two points $U = \{-1, 1\}$, and Y consisting of one point $Y = \{0\}$.

PROPOSITION 5. *Let $\Gamma(S)$ be nonempty and Assumption 1 be satisfied. Then*

$$\lim_{S\to\infty} \rho_H(co\Gamma(S), W) \;=\; 0, \tag{24}$$

where $co\Gamma(S)$ stands for the convex hull of $\Gamma(S)$.

Proof. The proof of (24) is similar to the proof of Theorem 1(i) in [26], which was established under a stronger assumption implying the validity of Assumption 1. The necessary adjustments for the case under consideration are made in section 6. □

COROLLARY 6. *If Assumption 1 is satisfied, then the limit of the optimal value of (2) exists and is equal to G^*,*

$$\lim_{S\to\infty} G(S) \;=\; G^*. \tag{25}$$

Also, if the solution γ^* of problem (21) is unique, then, for any $\gamma^S \in \Gamma(S)$ such that $\lim_{S\to\infty} \int_{U\times Y} g(u,y)\gamma^S(du,dy) = G^*$,

$$\lim_{S\to\infty} \rho(\gamma^S, \gamma^*) \;=\; 0. \tag{26}$$

Proof. Since

$$\inf_{\gamma\in co\Gamma(S)} \int_{U\times Y} g(u,y)\gamma(du,dy) \;=\; \inf_{\gamma\in\Gamma(S)} \int_{U\times Y} g(u,y)\gamma(du,dy),$$

then, by (14),

$$\inf_{\gamma\in co\Gamma(S)} \int_{U\times Y} g(u,y)\gamma(du,dy) \;=\; G(S).$$

The validity of (25) follows now from Lemma 1(ii) and Proposition 5. The validity of (26) is, in turn, implied by (25) and Proposition 2. □

Note that the solution γ^* of problem (21) can be unique only if it is an extreme point of W (since (21) is an LPP) and that, using (24), one can show (although not shown here) that, for any extreme point γ of W, there exists $\gamma^S \in \Gamma(S)$ such that $\lim_{S\to\infty} \rho(\gamma^S, \gamma) \;=\; 0$.

Let γ^* be a solution of problem (21) which is an extreme point of W and let $\gamma^S \in \Gamma(S)$ satisfy (26). Assume that there exists an admissible pair $(u^{\gamma^*}(\cdot), y^{\gamma^*}(\cdot))$: $[0,\infty) \to U\times Y$ that generates γ^S on any interval $[0,S]$ (we will say that γ^* is generated by the pair on $[0,\infty)$ in this case). Then, for any continuous $q(u,y) : U \times Y \to \mathbb{R}^1$,

$$\lim_{S\to\infty} \frac{1}{S} \int_0^S q(u^{\gamma^*}(\tau), y^{\gamma^*}(\tau))d\tau = \int_{U\times Y} q(u,y)\gamma^*(du,dy) \tag{27}$$

and, in particular, for $q(u,y) = g(u,y)$,

$$\lim_{S\to\infty} \frac{1}{S}\int_0^S g(u^{\gamma^*}(\tau), y^{\gamma^*}(\tau))d\tau = \int_{U\times Y} g(u,y)\gamma^*(du,dy) = G^*.$$

Thus, by Corollary 4(i), this pair will be a solution of problem (3). Also, by Corollary 4(ii), (iii), this pair will be a solution of the periodic optimization problem (5) (and the steady state problem (7)) if it proves to be periodic (and, respectively, steady state).

4. Finite-dimensional approximations. Let $\{\phi_i(\cdot)\ , i = 1,2,\dots\}$ be a sequence of continuously differentiable functions such that any function $\phi(\cdot) \in C^1$ and its gradient $\phi'(\cdot)$ can be simultaneously approximated on Y by linear combinations of functions from $\{\phi_i(\cdot), i = 1,2,\dots\}$ and their corresponding gradients. That is, for any $\phi(\cdot) \in C^1$ and any $\delta > 0$, there exist $\beta_1,\dots,\beta_k$ (real numbers) such that

$$\max_{y\in Y}\left\{\left|\phi(y) - \sum_1^k \beta_i\phi_i(y)\right| + \left\|\phi'(y) - \sum_1^k \beta_i\phi_i'(y)\right\|\right\} \le\ \delta,$$

with $||\cdot||$ being a norm in $\mathbb{R}^m$. An example of such an approximating sequence is the sequence of monomials $y_1^{i_1}\dots y_m^{i_m}$, $i_1,\dots,i_m = 0,1,\dots$, where $y_j (j = 1,\dots,m)$ stands for the jth component of y (see, e.g., [37]).

Using the system $\{\phi_i(\cdot), i = 1,2,\dots\}$, one can represent the set W in the form of a countable system of equations:

$$W = \left\{\gamma \mid \gamma \in \mathcal{P}(U\times Y); \int_{U\times Y} (\phi_i'(y))^T f(u,y)\gamma(du,dy) = 0,\ i = 1,2,\dots\right\}. \tag{28}$$

Let us assume that the gradients $\phi_i'(\cdot), i = 1,\dots,N$, are linearly independent on any open ball B in $\mathbb{R}^m$ (that is, the equality $\sum_{i=1}^N v_i\phi_i'(y) = 0\ \forall y \in B$ can be valid only with $v_i = 0,\ i = 1,\dots,N$) and let us define the set W_N by truncation of the system of equations in (28):

$$W_N \stackrel{\text{def}}{=} \left\{\gamma \mid \gamma \in \mathcal{P}(U\times Y); \int_{U\times Y} (\phi_i'(y))^T f(u,y)\gamma(du,dy) = 0,\ i = 1,2,\dots,N\right\}. \tag{29}$$

Consider the LPP

$$\min_{\gamma\in W_N} \int_{U\times Y} q(u,y)\gamma(du,dy) \stackrel{\text{def}}{=} G_N. \tag{30}$$

Note that W_N is a convex and compact subset of $\mathcal{P}(U\times Y)$ and that $W \subset W_N$, which implies

$$G^* \ge G_N. \tag{31}$$

Note also that the set W_N is empty if (19) is true with $\phi(y) \stackrel{\text{def}}{=} \sum_{i=1}^N v_i\phi_i(y)$, where v_i are real numbers.

PROPOSITION 7. *The set W is not empty if and only if there exists $N_0 \ge 1$ such that W_N is not empty for $N \ge N_0$. If W is not empty, then*

$$\lim_{N\to\infty} \rho_H(W_N, W) = 0 \tag{32}$$

and

$$\lim_{N\to\infty} G_N = G^*. \tag{33}$$

Also, if γ_N is a solution of problem (30) *and $\lim_{N'\to\infty}\rho(\gamma_{N'},\gamma)=0$ for some subsequence of integers N' tending to infinity, then γ is a solution of* (21). *If the solution γ^* of problem* (21) *is unique, then, for any solution γ_N of* (30), $\lim_{N\to\infty}\rho(\gamma_N,\gamma^*)=0$.

Proof. By Lemma 1(ii), the validity of (33) follows from the validity of (32). The other statements included in the proposition readily follow from (32) and (33). The validity of (32) is established in section 6. □

Let us introduce another assumption which we need to consider.

Assumption 2. The inequality

$$\sum_{i=1}^{N} v_i(\phi_i'(y))^T f(u,y) \le 0 \quad \forall (u,y)\in U\times Y \tag{34}$$

is valid only with $v_i = 0 \ \ \forall\ i = 1,\dots,N$.

This assumption is satisfied if there exists a closed subset Y^* of Y with a nonempty interior such that from the validity of (34) it follows that $\sum_{i=1}^{N} v_i\phi_i'(y) = 0\ \forall y\in Y^*$ (the equality of v_i to zero is implied in this case by linear independence of $\phi_i'(\cdot)$). The existence of such Y^* can be guaranteed, for instance, in two cases specified in the statement below.

Proposition 8. *A closed set $Y^*\subset Y$ with a nonempty interior such that from the fact that*

$$(\phi'(y))^T f(u,y)\le 0 \quad \forall (u,y)\in U\times Y \tag{35}$$

it follows that $\phi'(y)=0\ \forall y\in Y^*$ exists if one of the following conditions is satisfied:

(i) *The set $f(y,U)\stackrel{\text{def}}{=}\{x\in\mathbb{R}^m : x = f(y,u),\ u\in U\}$ is convex for $y\in Y$, and there exists $\bar y\in \operatorname{int} Y$ such that*

$$0\in \operatorname{int} f(\bar y, U), \tag{36}$$

where "int" stands for the interior of the corresponding set.

(ii) *There exists $Y^0\subset Y$ such that the closure of Y^0 has a nonempty interior and such that any two points in Y^0 are connected by an admissible trajectory. That is, for any $y',y''\in Y^0$, there exists an admissible pair $(u(\tau),y(\tau))$ defined on some interval $[0,S]$ such that $y(0)=y'$ and $y(S)=y''$.*

Proof. The proof is in section 6. □

Remark 2. Note that Y^0 in Proposition 8(ii) can be equal to Y in which case Y is a subset of complete controllability of system (1) (see [29]). Note also that both Assumptions 1 and 2 can be easily verified if there exist positive definite matrices A_1 and A_2 such that

$$\begin{aligned}&(f(u,y')-f(u,y''))^T A_1(y'-y'')\\ &\quad\le -(y'-y'')^T A_2(y'-y'')\quad \forall y',y''\in\mathbb{R}^m,\ \forall u\in U.\end{aligned} \tag{37}$$

The latter is a Liapunov-type stability condition that implies the validity of Assumption 3.1 in [24] and, thus, guarantees the existence of a compact set $Y^*\subset\mathbb{R}^m$, which is forward invariant with respect to the solutions of system (1) and which is the global attractor for the solutions of this system starting outside Y^* (Theorem 3.1(ii)

in [24]). The existence of such Y^* leads to the fulfillment of Assumption 1 in case $Y^* \subset Y$. Also, the set Y^* contains all periodic and steady state solutions of the system (Lemma 3.1 in [24]) and, moreover, it can be shown that Y^* is equal to the closure of the set of all points belonging to the periodic orbits. The latter implies the validity of Proposition 8(ii) (and, hence, the validity of Assumption 2) if the interior of Y^* is not empty. Condition (37) is satisfied, for example, if system (1) is linear (that is, $f(u,y) = Ay + Du$, with $u \in U \subset \mathbb{R}^n$ and A, D being matrices of the corresponding dimensions) and if the eigenvalues of A have negative real parts. The nonemptiness of the interior of Y^* can be guaranteed in this case if U has a nonempty interior and if the Kalman controllability matrix $\{D, AD, \dots, A^{m-1}D\}$ has the rank m.

Assume that, for any $\Delta > 0$, Borel sets $Q^{\Delta}_{l,k} \subset U \times Y (l = 1, \dots, L^{\Delta}, k = 1, \dots, K^{\Delta})$ (called cells in what follows) are defined in such a way that two different cells do not intersect, the union of all cells is equal to $U \times Y$ and

$$\sup_{(u,y) \in Q^{\Delta}_{l,k}} ||(u,y) - (u_l, y_k)|| \le c\Delta, \quad c = \text{const}, \tag{38}$$

for some point $(u_l, y_k) \in Q^{\Delta}_{l,k}$, where, for simplicity of notation, it is assumed (from now on) that U is a compact subset of $\mathbb{R}^n$ and $||\cdot||$ stands for a norm in $\mathbb{R}^{n+m}$. Fix these points (u_l, y_k) $(l = 1, \dots, L^{\Delta},\ k = 1, \dots, K^{\Delta})$ and define a polyhedral set $W^{\Delta}_N \subset \mathbb{R}^{L^{\Delta} + K^{\Delta}}$ by the equation

$$W^{\Delta}_N \stackrel{\text{def}}{=} \left\{ \gamma = \{\gamma_{l,k}\} \ge 0 \ : \ \sum_{l,k} \gamma_{l,k} = 1, \right. \\ \left. \sum_{l,k} (\phi_i'(y_k))^T f(u_l, y_k) \gamma_{l,k} = 0,\ i = 1, 2, \dots, N \right\}, \tag{39}$$

where $\sum_{l,k} \stackrel{\text{def}}{=} \sum_{l=1}^{L^{\Delta}} \sum_{k=1}^{K^{\Delta}}$. Consider a finite-dimensional LPP

$$\min_{\gamma \in W^{\Delta}_N} \sum_{l,k} \gamma_{l,k} g(u_l, y_k) \stackrel{\text{def}}{=} G^{\Delta}_N. \tag{40}$$

Note that the set W^{Δ}_N is the set of probability measures on $U \times Y$ which assign nonzero probabilities only to the points (u_l, y_k), and, as such,

$$W^{\Delta}_N \subset W_N \quad \Rightarrow \quad G^{\Delta}_N \ge G_N. \tag{41}$$

PROPOSITION 9. *Let Assumption* 2 *be satisfied. Then the set W_N is not empty if and only if there exists $\Delta_0 > 0$ such that W^{Δ}_N is not empty for $\Delta \le \Delta_0$. If W_N is not empty, then*

$$\lim_{\Delta \to 0} \rho_H(W^{\Delta}_N, W_N) = 0 \tag{42}$$

and

$$\lim_{\Delta \to 0} G^{\Delta}_N = G_N. \tag{43}$$

Also, if γ^{Δ}_N is a solution of problem (40) *and $\lim_{\Delta' \to 0} \rho(\gamma^{\Delta'}_N, \gamma_N) = 0$ for some sequence of Δ' tending to zero, then γ_N is a solution of* (30). *If the solution γ_N of problem* (30) *is unique, then, for any solution γ^{Δ}_N of* (40), $\lim_{\Delta \to 0} \rho(\gamma^{\Delta}_N, \gamma_N) = 0$.

Proof. The proof is in section 6. □

5. Numerical solution of periodic optimization problems. Let us assume that a solution γ^* of problem (21) is unique and that it is generated by a T-periodic admissible pair $(u^{\gamma^*}(\cdot), y^{\gamma^*}(\cdot))$ (see Remark 3 about these assumptions below). Note that, due to Corollary 4(ii), this pair will be a solution of the periodic optimization problem (5). Let

$$\Theta \stackrel{\text{def}}{=} \{(u,y) \ : \ (u,y) = (u^{\gamma^*}(\tau), y^{\gamma^*}(\tau)) \text{ for some } \tau \in [0,T]\}. \tag{44}$$

This set can be considered as the graph of the optimal feedback control function, which is defined on the optimal state trajectory $\mathcal{Y} \stackrel{\text{def}}{=} \{y \ : \ (u,y) \in \Theta\}$ by the equation $\psi(y) \stackrel{\text{def}}{=} u \ \ \forall (u,y) \in \Theta$. For the definition of $\psi(\cdot)$ to make sense, it is assumed that the set Θ is such that from the fact that $(u',y) \in \Theta$ and $(u'',y) \in \Theta$ it follows that $u' = u''$ (this assumption is satisfied if the closed curve defined by $y^{\gamma^*}(\tau),\ \tau \in [0,T]$, does not intersect itself).

Let $\gamma_N^\Delta \stackrel{\text{def}}{=} \{\gamma_{l,k}^\Delta\}$ be a basic solution of the finite-dimensional LPP (40), that is, a solution of (40) which is an extreme point of W_N^Δ. Let

$$\Theta_N^\Delta \stackrel{\text{def}}{=} \{(u_l, y_k) \ : \ \gamma_{l,k}^\Delta > 0\}, \quad \mathcal{Y}_N^\Delta \stackrel{\text{def}}{=} \{y \ : \ (u,y) \in \Theta_N^\Delta\}, \quad \psi_N^\Delta(y) \stackrel{\text{def}}{=} u \ \forall (u,y) \in \Theta_N^\Delta, \tag{45}$$

where again it is assumed that from the fact that $(u',y) \in \Theta_N^\Delta$ and $(u'',y) \in \Theta_N^\Delta$ it follows that $u' = u''$. Note that the set Θ_N^Δ (and the set $\mathcal{Y}_N^\Delta$) can contain no more than $N+1$ elements since γ_N^Δ, being a basic solution of the LPP (40), has no more than $N+1$ positive elements (see, e.g., [18, p. 81]).

The two propositions below establish that the set Θ_N^Δ converges (in the specified sense) to the set Θ, thus leading to the corresponding convergences of $\mathcal{Y}_N^\Delta$ to $\mathcal{Y}$ and of $\psi_N^\Delta(y)$ to $\psi(y)$.

We will be using the following notation. B will stand for the open unit ball in $\mathbb{R}^{n+m}$: $B \stackrel{\text{def}}{=} \{(u,y) \ : \ ||(u,y)|| < 1\}$ and, for any $Q \subset U \times Y$, $\gamma_N^\Delta(Q)$ will denote the γ_N^Δ measure of Q: $\gamma_N^\Delta(Q) \stackrel{\text{def}}{=} \sum_{(u_l,y_k) \in Q \cap \Theta_N^\Delta} \gamma_{l,k}^\Delta$.

PROPOSITION 10. *Let Assumptions* 1 *and* 2 *be satisfied and let* γ^* *be the unique solution of* (21). *Then, corresponding to an arbitrary small* $r > 0$ *and arbitrary small* $\delta > 0$, *there exists* N_0 *such that, for* $N \geq N_0$ *and* $\Delta \leq \Delta_N$ *(*Δ_N *is positive and may depend on* N*),*

$$\gamma_N^\Delta(\Theta_N^\Delta / (\Theta + rB)) \ < \ \delta, \tag{46}$$

$$\Theta_N^{\Delta,\delta} \ \subset \ \Theta + rB, \tag{47}$$

where $\Theta_N^{\Delta,\delta} \stackrel{\text{def}}{=} \{(u_l, y_k) \ : \ \gamma_{l,k}^\Delta \geq \delta\}$.

Proof. The proof is in section 6. □

Assumption 3. For any $(u,y) \in cl\Theta$ (the closure of Θ) and any $r > 0$, the set $B_r(u,y) \stackrel{\text{def}}{=} ((u,y) + rB) \cap (U \times Y)$ has a nonzero γ^*-measure: $\gamma^*(B_r(u,y)) > 0$.

Note that this assumption is satisfied if the optimal control function $u^{\gamma^*}(\cdot) : [0,T] \to U$ is piecewise continuous and at every discontinuity point τ the value of $u^{\gamma^*}(\tau)$ is equal to either the limit from the left ($u^{\gamma^*}(\tau) = \lim_{\tau' \to \tau -} u^{\gamma^*}(\tau')$) or the limit from the right ($u^{\gamma^*}(\tau) = \lim_{\tau' \to \tau +} u^{\gamma^*}(\tau')$).

PROPOSITION 11. *Let the conditions of Proposition* 10 *and Assumption* 3 *be satisfied. Then, corresponding to an arbitrary small* $r > 0$*, there exists* N_0 *such that, for* $N \geq N_0$ *and* $\Delta \leq \Delta_N$ *(*Δ_N *is positive and may depend on* N*),*

$$\Theta \subset \Theta_N^\Delta + rB. \tag{48}$$

Proof. The proof is in section 6. □

Based on the consideration above, one can propose the following steps to construct an approximate solution to the periodic optimization problem (5):

(1) Find a basic solution γ_N^Δ and the optimal value G_N^Δ of the LPP (40) for N large and Δ small enough; the values of N and Δ can be identified as being, respectively, *large enough* and *small enough* if a further increase of N and a reduction of Δ lead only to insignificant changes of the optimal value G_N^Δ and, thus, the latter can be considered to be approximately equal to G^* (see Propositions 7 and 9).

(2) Define $\Theta_N^\Delta, \mathcal{Y}_N^\Delta, \psi_N^\Delta(y)$ as in (45). Note that, as follows from Propositions 10 and 11, if γ^* is the unique solution of (21) and it is generated by a periodic admissible pair, then one can expect that the points of $\mathcal{Y}_N^\Delta$ will be concentrated around a closed curve being the optimal state trajectory, while $\psi_N^\Delta(y)$ will give a pointwise approximation to the optimal feedback control.

(3) Extrapolate the function $\psi_N^\Delta(y)$ to some neighborhood of $\mathcal{Y}_N^\Delta$ and integrate system (1) starting from an initial point $y(0) \in \mathcal{Y}_N^\Delta$ and using the extrapolation of $\psi_N^\Delta(y)$ as the feedback control. One can expect that, thus, the obtained solution of the system will return to a small vicinity of the starting point $y(0)$ and it will be possible to identify the end point of the integration period, T^Δ, as the moment the solution enters this vicinity.

(4) Adjust the initial condition and/or control to obtain a periodic admissible pair $(u^\Delta(\tau), y^\Delta(\tau))$ defined on the interval $[0, T^\Delta]$. Find the integral

$$\frac{1}{T^\Delta} \int_0^{T^\Delta} g(u^\Delta(\tau), y^\Delta(\tau)) d\tau$$

and compare its value with G_N^Δ. If this value proves to be close to G_N^Δ, then, by Corollary 4(ii), the constructed admissible pair is a "good" approximation to the solution of the periodic optimization problem (5).

Remark 3. Under certain conditions (e.g., under the conditions mentioned in Remark 2), the set of occupational measures generated by periodic regimes is dense in W and $G^* = G_\infty = G_{per}$ (compare with Corollary 4). If this is the case, then the assumption that there exists a solution γ^* of problem (21), which is generated by a periodic admissible pair, is equivalent to the assumption that there exists a solution of the periodic optimization problem (5), and the assumption that γ^* is a unique solution of problem (21) implies that all solutions of (5) generate the same occupational measure (namely, γ^*). Note that these assumptions are difficult to verify and one may attempt to use the above steps to find an approximate solution of (5) without such a verification. If, as the result of executing these steps, a periodic admissible pair that gives the value of the objective function close to G_N^Δ is constructed, then one can consider this pair as an approximate solution to problem (5) and use it, if necessary, for further analysis of the existence and structure of the "exact" solution.

Let us illustrate the construction with the following two examples.

Example 1. Let k and ω be positive parameters such that

$$\omega > 1, \qquad k\omega < 1. \tag{49}$$

Consider a differential equation

$$\ddot{x}(\tau) + k\dot{x}(\tau) + \omega^2 x(\tau) = u(\tau), \tag{50}$$

where $x(\tau)$ and $u(\tau)$ are scalars and $u(\tau) \in [-1, 1]$. Via a standard replacement of variables (i.e., $x(\tau) = y_1(\tau)$ and $\dot{x}(\tau) = y_2(\tau)$), equation (50) is reduced to the system of the form (1) with

$$y \stackrel{\text{def}}{=} (y_1, y_2), \qquad f(u, y) \stackrel{\text{def}}{=} (\ y_2,\ -\omega^2 y_1 - k y_2 + u\ ), \qquad U = [-1, 1].$$

Since this system is linear and stable, condition (37) is satisfied and, hence, the system has a forward invariant set $Y^* \subset \mathbb{R}^2$ that is a global attractor for its solutions. The Kalman controllability matrix of the system has rank 2 and, consequently, the interior of Y^* is not empty. Thus, as follows from Remark 2, both Assumptions 1 and 2 are satisfied if Y is such that it contains Y^* (in what follows this is achieved by choosing Y large enough). Also, all periodic and steady state solutions of the system are contained in Y^*, which means that all such solutions are admissible, with the set of steady state admissible pairs (see (6)) being, in this case, equal to

$$M = \left\{(u, y)\ :\ u \in [-1, 1];\ y = (y_1, y_2),\ y_1 = \frac{u}{\omega^2},\ y_2 = 0\right\}.$$

Take

$$g(u, y) \stackrel{\text{def}}{=} u^2 - y_1^2 \tag{51}$$

and consider the steady state optimization problem (7). By the first inequality in (49), its solution and the optimal value are $u = 0, y_1 = y_2 = 0, G_{ss} = 0$. It is easy to verify that this steady state solution is not optimal in the corresponding periodic optimization problem (5). To see this, it is enough to consider the $\frac{2\pi}{\omega}$-periodic admissible pair $(u(\tau), y(\tau))$, with $u(\tau) = \cos(\omega\tau)$ and $y(\tau) = (\frac{1}{\omega k}\sin(\omega\tau), \frac{1}{k}\cos(\omega\tau))$. The value of the objective function obtained on this pair is

$$\tilde{G} \stackrel{\text{def}}{=} \frac{\omega}{2\pi}\int_0^{\frac{2\pi}{\omega}} \left(\cos^2(\omega\tau) - \frac{1}{\omega^2 k^2}\sin^2(\omega\tau)\right) d\tau \ = \ \frac{1}{2}\left(1 - \frac{1}{\omega^2 k^2}\right) \ < 0. \tag{52}$$

The last inequality follows from the second inequality in (49), which postulates smallness of the "friction coefficient" k compared to the "proper frequency" ω and, thus, makes it possible to diminish the value of the objective function via the resonance oscillations of the state variables (such an interpretation of the example was given by Pervozvanskii; see Examples 3.2 and 4.2 in [24]).

Let us demonstrate numerical results obtained with the use of the proposed linear programming approach for the case when $k = 0.3$ and $\omega = 2$. Note that, for these values of the parameters, $\tilde{G} = \frac{1}{2}(1 - \frac{1}{0.36}) \approx -0.889$.

Let us take $Y \stackrel{\text{def}}{=} \{(y_1, y_2) \mid y_i \in [-5, 5], i = 1, 2\}$ (it is straightforward to verify that $Y^* \subset Y$ in this case) and define

$$u_i \stackrel{\text{def}}{=} -1 + i\Delta, \quad y_{1,j} \stackrel{\text{def}}{=} -5 + j\Delta, \quad y_{2,k} \stackrel{\text{def}}{=} -5 + k\Delta, \tag{53}$$

where $i = 0, 1, \ldots, \frac{2}{\Delta}$ and $j, k = 0, 1, \ldots, \frac{10}{\Delta}$ (Δ being chosen in such a way that $\frac{2}{\Delta}$ is integer). Using a slightly different system of notation (adjusted to the case under

consideration and to the grid defined by (53)) and using monomials as the functions defining the constraints in (39), one can rewrite the LPP (40) in the form

$$\min_{\gamma\in W_N^\Delta}\sum_{i,j,k}((u_i)^2-(y_{1,j})^2)\gamma_{i,j,k}\stackrel{\text{def}}{=}G_N^\Delta, \tag{54}$$

with

(55)

$$W_N^\Delta\stackrel{\text{def}}{=}\left\{\gamma=\{\gamma_{i,j,k}\}\ge 0\colon \sum_{i,j,k}\gamma_{i,j,k}=1,\sum_{i,j,k}(\phi'_{l_1,l_2}(y_{1,j},y_{2,k}))^T f(u_i,y_{1,j},y_{2,k})\gamma_{i,j,k}=0,\right.$$
$$\left. l_1,l_2=0,1,\dots,N\right\},$$

where $\phi_{l_1,l_2}(y_1,y_2)\stackrel{\text{def}}{=}y_1^{l_1}y_2^{l_2}$. Problem (54) was solved for $N=7$ and $N=10$ and for $\Delta=0.2,0.1,0.05,0.025,0.0125$ (note that in both Examples 1 and 2 that follow we used ILOG CPLEX 8.0. (http://www.ilog.com) as a linear programming solver). The optimal values of the LPPs obtained with these values of the parameters are (respectively) $G_7^{0.2}\approx -1.312$, $G_7^{0.1}\approx -1.329$, $G_7^{0.05}\approx -1.331$, $G_7^{0.025}\approx -1.331$, $G_7^{0.0125}\approx -1.331$, and $G_{10}^{0.2}\approx -1.280$; $G_{10}^{0.1}\approx -1.325$, $G_{10}^{0.05}\approx -1.326$, $G_{10}^{0.025}\approx -1.327$, $G_{10}^{0.0125}\approx -1.327$. On the basis of these results and Proposition 9 (see (42)) one may conclude that $G_{10}=\lim_{\Delta\to 0}G_{10}^\Delta\approx -1.327$. Hence, by (31), $G^*\ge -1.327$ (within the given proximity). From Corollary 4(ii) (see also (8) and Corollary 3) it now follows that, if for some admissible T-periodical pair $(u(\tau),y(\tau))$,

$$\frac{1}{T}\int_0^T(u^2(\tau)-y_1^2(\tau))d\tau\ \approx -1.327, \tag{56}$$

then this pair is an approximate solution of problems (3) and (5).

Let $\{\gamma_{i,j,k}^{N,\Delta}\}$ stand for the solution of problem (54). The sets Θ_N^Δ and $\mathcal{Y}_N^\Delta$ can then be represented in the form

$$\Theta_N^\Delta=\{(u_i,y_{1,j},y_{2,k})\ :\ \gamma_{i,j,k}^{N,\Delta}\ne 0\},\qquad \mathcal{Y}_N^\Delta=\left\{(y_{1,j},y_{2,k})\ :\ \sum_i\gamma_{i,j,k}^{N,\Delta}\ \ne 0\right\}.$$

Let us mark with dots the points on the plane (y_1,y_2) which belong to $\mathcal{Y}_N^\Delta$ for $N=10$ and $\Delta=0.0125$. The result of such marking is depicted in Figure 1.

Figure 1 clearly identifies a closed curve, which one can expect to be an approximation to the optimal state trajectory. As can be seen from this figure, the value of y_1 is uniquely determined by the value of y_2 for $(y_1,y_2)\in\mathcal{Y}_N^\Delta$ with $y_1\ge 0$ and for $(y_1,y_2)\in\mathcal{Y}_N^\Delta$ with $y_1<0$. Having this in mind, let us mark with dots the points $(u_i,y_{2,k})$ on the plane (u,y_2) for which $\gamma_{i,j,k}^{N,\Delta}\ne 0$ and $y_{1,j}\ge 0$ (Figure 2) and, also, the points for which $\gamma_{i,j,k}^{N,\Delta}\ne 0$ and $y_{1,j}<0$ (Figure 3).

The points marked with the dots in Figure 2 define $\psi_N^\Delta(y)\stackrel{\text{def}}{=}\psi_N^\Delta(y_1,y_2)$ as a function of y_2 (denoted as $\bar\psi_N^\Delta(y_2)$) for $y_1\ge 0$, and the points marked with the dots in Figure 3 define $\psi_N^\Delta(y)\stackrel{\text{def}}{=}\psi_N^\Delta(y_1,y_2)$ as another function of y_2 (denoted as $\bar{\bar\psi}_N^\Delta(y_2)$) for $y_1<0$. Note that in both cases $(y_1,y_2)\in\mathcal{Y}_N^\Delta$. Let us extend the definition of

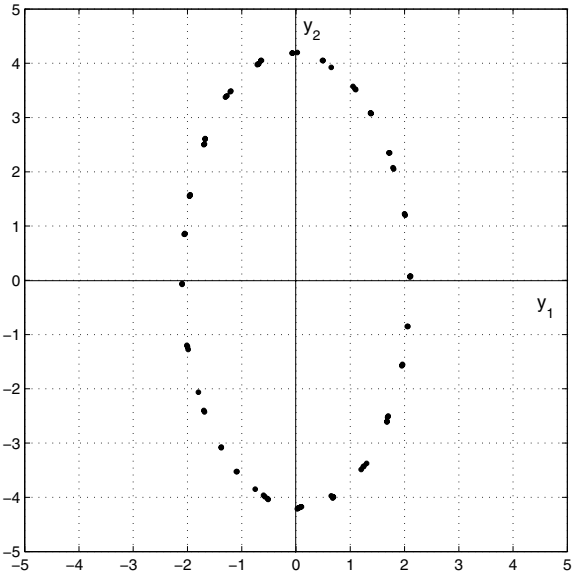

FIG. 1. $\mathcal{Y}_N^\Delta$.

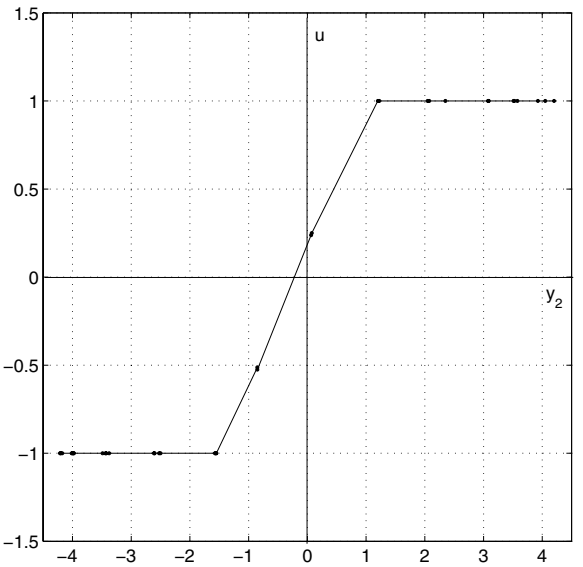

FIG. 2. $\psi_N^\Delta(y_1, y_2) = \bar{\psi}_N^\Delta(y_2)$ *for* $y_1 \geq 0$ *and* $(y_1, y_2) \in \mathcal{Y}_N^\Delta$.

$\psi_N^\Delta(y_1, y_2)$ by connecting the points in Figures 2 and 3 with piecewise linear functions (we will denote this extension also as $\psi_N^\Delta(y_1, y_2)$) and integrate the system with the feedback control thus obtained and with the initial condition being at one of the points marked in Figure 1. Denote by $\tilde{y}^\Delta(\tau) = (\tilde{y}_1^\Delta(\tau), \tilde{y}_2^\Delta(\tau))$ the resulting solution of the system and by $u^\Delta(\tau) = \psi_N^\Delta(\tilde{y}_1^\Delta(\tau), \tilde{y}_2^\Delta(\tau))$ the corresponding open loop control. The function $\tilde{y}^\Delta(\tau)$ proves to be nonperiodic but it returns to a small vicinity of $\tilde{y}^\Delta(0)$

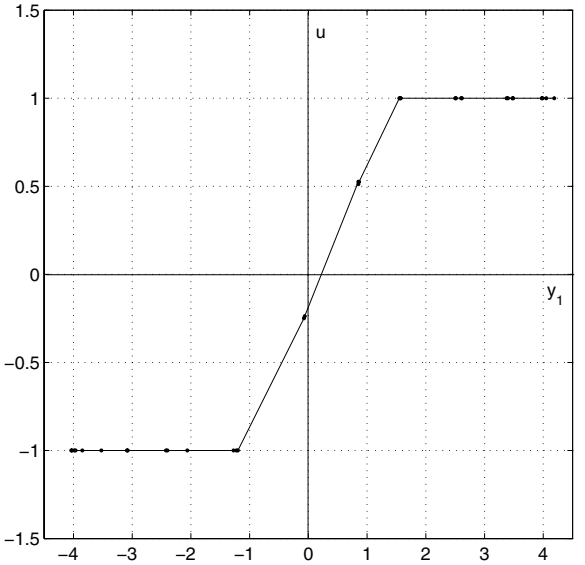

FIG. 3. $\psi_N^\Delta(y_1, y_2) = \bar{\psi}_N^\Delta(y_2)$ *for* $y_1 < 0$ *and* $(y_1, y_2) \in \mathcal{Y}_N^\Delta$.

with $\tau \approx 3.16$. Take $T^\Delta \stackrel{\text{def}}{=} 3.16$ and denote by $y^\Delta(\tau)$ the solution of the system which is obtained when applying the control $u^\Delta(\tau)$ on the interval $[0, T^\Delta]$ and which satisfies the periodicity condition $y^\Delta(0) = y^\Delta(T^\Delta)$. Note that such a solution exists, it is unique and, for the system under consideration, it can be easily found numerically (see, e.g., [23, p. 39]). The periodic admissible pair $(u^\Delta(\tau), y^\Delta(\tau))$ that has been constructed by following the indicated steps is shown in Figures 4 and 5.

The value of the objective function calculated on this pair is approximately equal to -1.324. Comparing it with (56), one can see that it is close to the optimal one and, hence, the pair $(u^\Delta(\tau), y^\Delta(\tau))$ can be considered to be an approximate solution to problem (5). Let us emphasize that we have not verified the assumptions that the solution of the periodic optimization problem (5) exists and that it is unique. Based on the form of the obtained approximate solution, one may conjecture that these assumptions are satisfied in the given example.

Example 2. Consider system (1) with

$$y \stackrel{\text{def}}{=} (y_1, y_2), \qquad u \stackrel{\text{def}}{=} (u_1, u_2), \qquad f(u, y) \stackrel{\text{def}}{=} (\, -y_1 + u_1,\ -y_2 + u_2)$$

(that is, $n = 2$ and $m = 2$) and with

$$U \stackrel{\text{def}}{=} [-1, 1] \times [-1, 1], \qquad Y \stackrel{\text{def}}{=} [-1, 1] \times [-1, 1].$$

As in Example 1, the system under consideration is linear and stable, and, hence, it has a forward invariant set Y^* which is also a global attractor of its solutions. Moreover, it can be easily verified that Y^* coincides with Y introduced above. This implies that both Assumptions 1 and 2 are satisfied (see Remarks 1 and 2).

Let the function $g(u, y)$ be defined by the equation

$$g(u, y) \stackrel{\text{def}}{=} -y_1 u_2 + y_2 u_1 \tag{57}$$

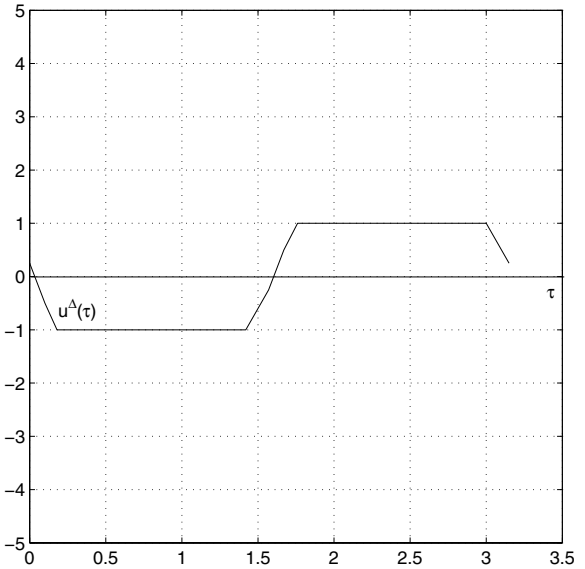

FIG. 4. $u^{\Delta}(\tau)$.

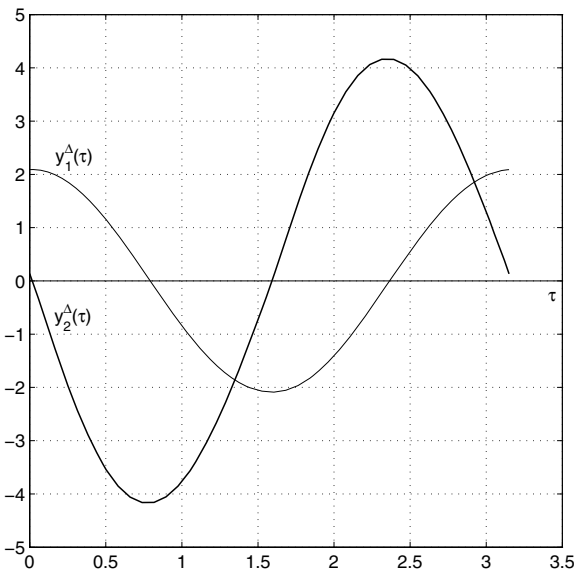

FIG. 5. $y_1^{\Delta}(\tau)$ *and* $y_2^{\Delta}(\tau)$.

and let

$$u_{1,i}^{\Delta} \stackrel{\text{def}}{=} -1+i\Delta, \quad u_{2,l}^{\Delta} \stackrel{\text{def}}{=} -1+l\Delta, \quad y_{1,j}^{\Delta} \stackrel{\text{def}}{=} -1+j\Delta, \quad y_{2,k}^{\Delta} \stackrel{\text{def}}{=} -1+k\Delta, \tag{58}$$

where $i,l,j,k = 0,1,\dots,\frac{2}{\Delta}$ (Δ is such that $\frac{2}{\Delta}$ is integer). The LPP (40) takes the

form

$$\min_{\gamma\in W_N^\Delta}\sum_{i,l,j,k}(-y_{1,j}^\Delta u_{2,l}^\Delta + y_{2,k}^\Delta u_{1,i}^\Delta)\gamma_{i,l,j,k} \stackrel{\text{def}}{=} G_N^\Delta, \tag{59}$$

where

(60)

$$W_N^\Delta \stackrel{\text{def}}{=} \left\{ \gamma = \{\gamma_{i,l,j,k}\} \geq 0 \ : \ \sum_{i,l,j,k}\gamma_{i,l,j,k} = 1, \right.$$
$$\left. \sum_{i,l,j,k}(\phi'_{l_1,l_2}(y_{1,j},y_{2,k}))^T f(u_{1,i},u_{2,l},y_{1,j},y_{2,k})\gamma_{i,l,j,k} = 0, l_1,l_2 = 0,1,\dots,N \right\},$$

with $\phi_{l_1,l_2}(y_1,y_2) \stackrel{\text{def}}{=} y_1^{l_1}y_2^{l_2}$.

Problem (59) was solved for $N = 10$ and for $\Delta = 0.2, 0.1, 0.05, 0.025$, 0.0125, 0.00625, and 0.003125. The optimal values of the LPPs obtained with these parameters are $G_{10}^{0.2} \approx -0.7035$, $G_{10}^{0.1} \approx -0.7579$, $G_{10}^{0.05} \approx -0.7671$, $G_{10}^{0.025} \approx -0.7678$, $G_{10}^{0.0125} \approx -0.7679$, $G_{10}^{0.00625} \approx -0.7679$, $G_{10}^{0.003125} \approx -0.7679$.

Similarly to Example 1, one may conclude that $G^* \geq G_{10} = \lim_{\Delta\to 0} G_{10}^\Delta \approx -0.7679$. Consequently, by Corollary 4(ii), if for some admissible T-periodic pair $(u(\tau), y(\tau))$,

$$\frac{1}{T}\int_0^T (-y_1(\tau)u_2(\tau) + y_2(\tau)u_1(\tau))d\tau \ \approx -0.7679, \tag{61}$$

then this pair is an approximate solution of the periodic optimization problem under consideration.

Let $\{\gamma_{i,l,j,k}^{N,\Delta}\}$ be the solution of problem (59). Then

$$\Theta_N^\Delta = \{(u_{1,i}^\Delta, u_{2,l}^\Delta, y_{1,j}^\Delta, y_{2,k}^\Delta) \ : \ \gamma_{i,l,j,k}^{N,\Delta} \neq 0\}, \qquad \mathcal{Y}_N^\Delta = \left\{ (y_{1,j}^\Delta, y_{2,k}^\Delta) \ : \ \sum_{i,l}\gamma_{i,l,j,k}^{N,\Delta} \ \neq 0 \right\}.$$

Figure 6 represents the result of marking with dots the points on the plane (y_1, y_2) which belong to $\mathcal{Y}_N^\Delta$ for $N = 10$ and $\Delta = 0.003125$.

The image created by the points marked in Figure 6 reminds a square. The analysis of the results of the linear programming solution showed that the function $\psi_N^\Delta(y) \stackrel{\text{def}}{=} \psi_N^\Delta(y_1, y_2)$ is equal to $(-1, 1)$ at every point belonging to the upper side of the "square," and it is equal to $(-1, -1)$, $(1, -1)$, and $(1, 1)$ at the points belonging to, respectively, left, bottom, and right sides of the square. Let us extend the definition of $\psi_N^\Delta(y)$ as follows:

$u_1 = -1,\ u_2 = 1$ for $-0.5 < y_1 \leq 0.9,\ 0.5 \leq y_2 \leq 0.9$;
$u_1 = -1,\ u_2 = -1$ for $-0.9 \leq y_1 \leq -0.5,\ -0.5 < y_2 \leq 0.9$;
$u_1 = 1,\ u_2 = -1$ for $-0.9 \leq y_1 < 0.5,\ -0.9 \leq y_2 \leq 0.5$;
$u_1 = 1,\ u_2 = 1$ for $0.5 \leq y_1 \leq 0.9,\ -0.9 \leq y_2 < 0.5$.

Proceeding as in Example 1, we integrate the system with thus defined feedback control and with the initial condition being at one of the points marked in Figure 6. The resulting solution of the system $\tilde{y}^\Delta(\tau) = (\tilde{y}_1^\Delta(\tau), \tilde{y}_2^\Delta(\tau))$ remains in the area of definition of the feedback control and it returns to a small vicinity of $\tilde{y}^\Delta(0)$ with $\tau \approx 6.1$.

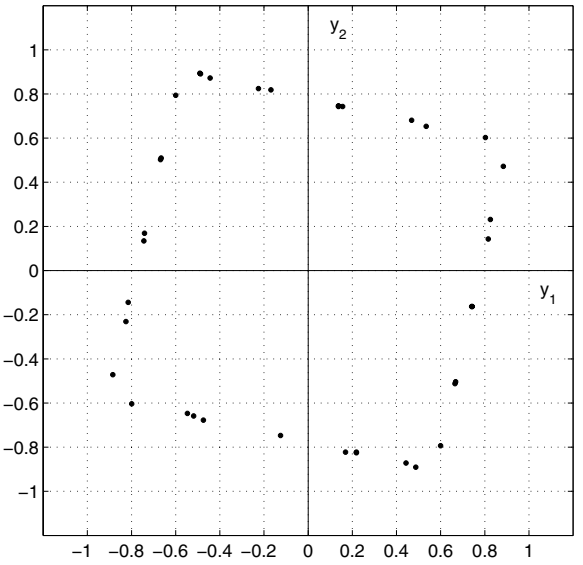

FIG. 6. $\mathcal{Y}_N^\Delta$.

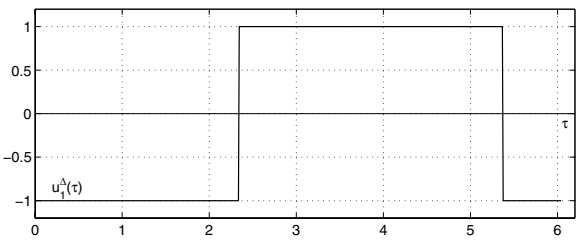

FIG. 7. $u_1^\Delta(\tau)$.

Take $T^\Delta \stackrel{\text{def}}{=} 6.1$. Let $u^\Delta(\tau) = (u_1^\Delta(\tau), u_2^\Delta(\tau))$ be the open loop control defined by the feedback control on the trajectory specified above and let $y^\Delta(\tau) = (y_1^\Delta(\tau), y_2^\Delta(\tau))$ be the solution of the system obtained with this open loop control which satisfies the periodicity condition: $y^\Delta(0) = y^\Delta(T^\Delta)$. The components of the constructed periodic admissible pair $(u^\Delta(\tau), y^\Delta(\tau))$ are shown in Figures 7, 8, and 9.

The value of the objective function calculated on the pair $(u^\Delta(\tau), y^\Delta(\tau))$ is approximately equal to -0.7679 and, hence, this pair is an approximate solution to problem (5). Note that in this example too the assumptions that the solution of the periodic optimization problem (5) exists and that it is unique have not been verified. However, again, based on the form of the obtained approximate solution, one may conjecture that the solution exists and that it has a form similar to that of the obtained approximate solution.

Example 2 (continued). The set of steady state admissible pairs in Example 2 is equal to

$$M = \{(u, y) \ : \ u = (u_1, u_2), \ \ y = (y_1, y_2), \quad y_i = u_i \in [0, 1], \ \ i = 1, 2\}.$$

One can see that, for every $(u, y) \in M$, $g(u, y) = 0$. Hence, $G_{ss} = 0 \ < G_{per} = G^* \approx -0.7679$. Consider the periodic optimization problem (5) in which $g(u, y)$ is replaced

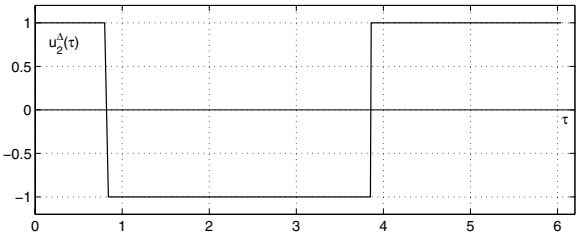

FIG. 8. $u_2^\Delta(\tau)$.

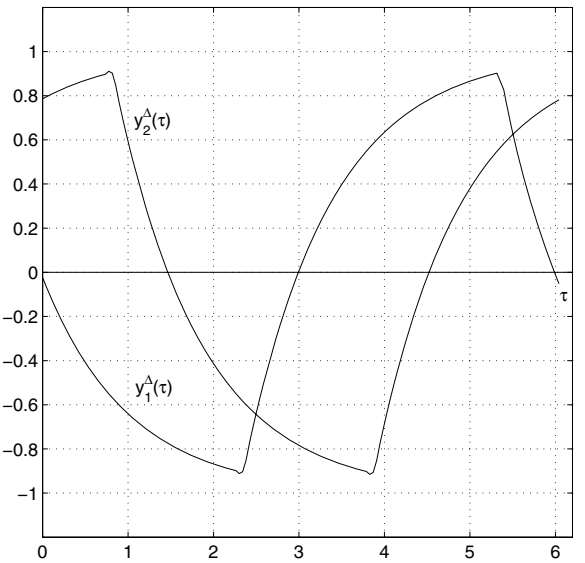

FIG. 9. $y_1^\Delta(\tau)$ *and* $y_2^\Delta(\tau)$.

by $g^\lambda(u,y)$,

$$g^\lambda(u,y) \stackrel{\text{def}}{=} -y_1u_2 + y_2u_1 + \lambda(u_1^2+u_2^2+y_1^2+y_2^2), \tag{62}$$

where $\lambda \geq 0$. For every $(u,y) \in M$, $g^\lambda(u,y) = \lambda(u_1^2+u_2^2+y_1^2+y_2^2)$. Consequently, the optimal value of the corresponding steady state optimization problem (denoted G_{ss}^λ) is equal to zero too: $G_{ss}^\lambda = 0 \ \forall\lambda \geq 0$. It is well known (see, e.g., [23]) that, if U and Y are convex, the system is linear, and the integrand in the objective function is convex, then the optimal values of the periodic and steady state optimization problems coincide. One can verify (by direct calculation) that the Hessian of the function $g^\lambda(u,y)$ has nonnegative eigenvalues for $\lambda \geq 0.5$. That is, this function is convex and, hence, $G_p^\lambda = G_{ss}^\lambda = 0 \ \forall\lambda \geq 0.5$, where G_p^λ stands for the optimal value of the periodic optimization problem (5) considered with $g^\lambda(u,y)$ instead of $g(u,y)$. Consider the LPP

$$\min_{\gamma\in W_N^\Delta} \sum_{i,l,j,k} (-y_{1,j}^\Delta u_{2,l}^\Delta + y_{2,k}^\Delta u_{1,i}^\Delta + \lambda((u_{1,i}^\Delta)^2 + (u_{2,l}^\Delta)^2 + (y_{1,j}^\Delta)^2 + (y_{2,k}^\Delta)^2))\gamma_{i,l,j,k} \stackrel{\text{def}}{=} G_N^{\Delta,\lambda}, \tag{63}$$

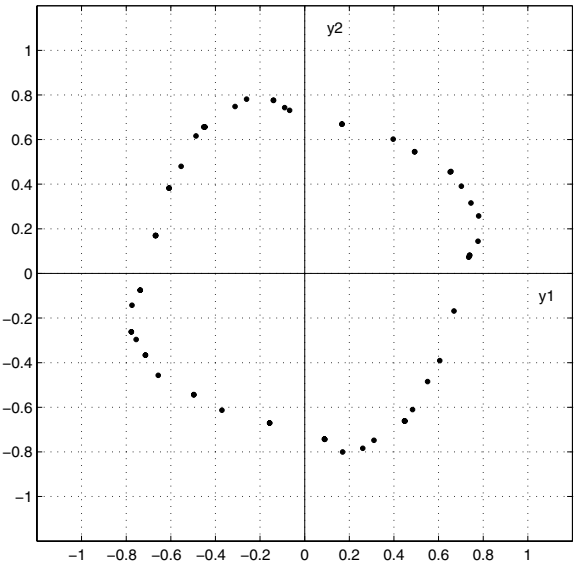

FIG. 10. $\mathcal{Y}_N^\Delta$ *for* $\lambda = 0.2$.

where W_N^Δ is as in (60). As above, the solution of this problem with $N = 10$ and $\Delta = 0.003125$ allows one to find an approximation to the solution of the corresponding periodic optimization problem for different λ. In particular, for $\lambda = 0.2, 0.33, 0.35$, the approximations to the optimal values of the latter are, respectively, $G_{per}^{0.2} \approx -0.2767$, $G_{per}^{0.33} \approx -0.0358$, $G_{per}^{0.35} \approx -0.0050$. For $\lambda \geq 0.36$, $G_{per}^{\lambda} \approx G_{ss}^{\lambda} = 0$ (for $\lambda \geq 0.5$, this being due to the convexity of the function $g^\lambda(u, y)$). Figures 10–13, represent the results of marking with dots the points on the plane (y_1, y_2) which belong to $\mathcal{Y}_N^\Delta$ for $\lambda = 0.2, 0.33, 0.35, 0.36$ ($N = 10$, $\Delta = 0.003125$).

6. Proofs for sections 3, 4, and 5.

Proof of Proposition 2. To prove the validity of (20), let us define $\kappa(S)$ by the equation

$$\kappa(S) \stackrel{\text{def}}{=} \sup_{\gamma \in \Gamma(S)} \rho(\gamma, W) \tag{64}$$

and show that $\kappa(S)$ tends to zero as S tends to infinity. Assume it is not the case. Then there exist a positive number δ and sequences $S^k \to \infty$, $\gamma^k \in \Gamma(S^k)$, such that $\rho(\gamma^k, W) \geq \delta$ for $k = 1, 2, \ldots$. Without loss of generality one may assume that there exists $\lim_{k\to\infty} \gamma^k \stackrel{\text{def}}{=} \gamma \in \mathcal{P}(U \times Y)$ (since $\mathcal{P}(U \times Y)$ is compact). From the continuity of the metric it follows that

$$\rho(\gamma, W) \geq \delta. \tag{65}$$

By the definition of the convergence in $\mathcal{P}(U \times Y)$ (see (16)),

$$\lim_{k\to\infty} \int_{U\times Y} (\phi'(y))^T f(u, y)\gamma^k(du, dy) \;=\; \int_{U\times Y} (\phi'(y))^T f(u, y)\gamma(du, dy) \tag{66}$$

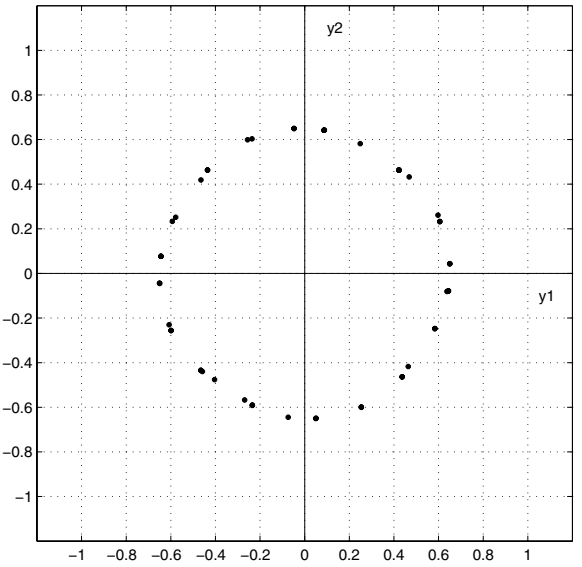

FIG. 11. $\mathcal{Y}_N^{\Delta}$ *for* $\lambda = 0.33$.

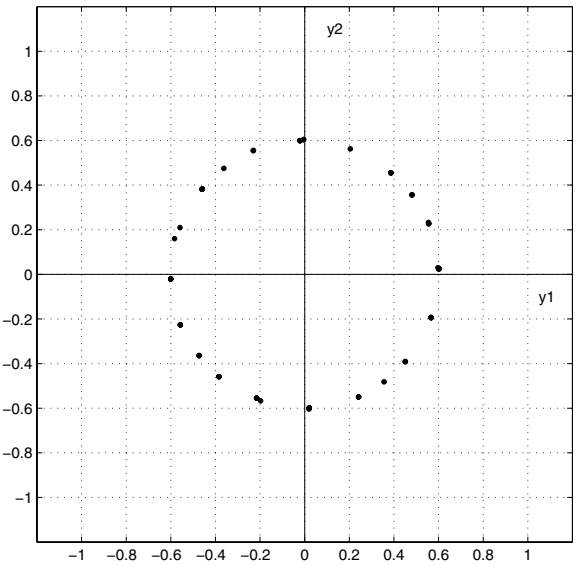

FIG. 12. $\mathcal{Y}_N^{\Delta}$ *for* $\lambda = 0.35$.

for any $\phi \in C^1$. Also, from the fact that $\gamma^k \in \Gamma(S^k)$ it follows that there exists an admissible pair $(u^k(\tau), y^k(\tau))$ defined on the interval $[0, S^k]$ such that

$$\int_{U\times Y} (\phi'(y))^T f(u,y)\gamma^k(du,dy) \;=\; \frac{1}{S^k}\int_0^{S^k} (\phi'(y^k(\tau)))^T f(u^k(\tau), y^k(\tau))d\tau.$$

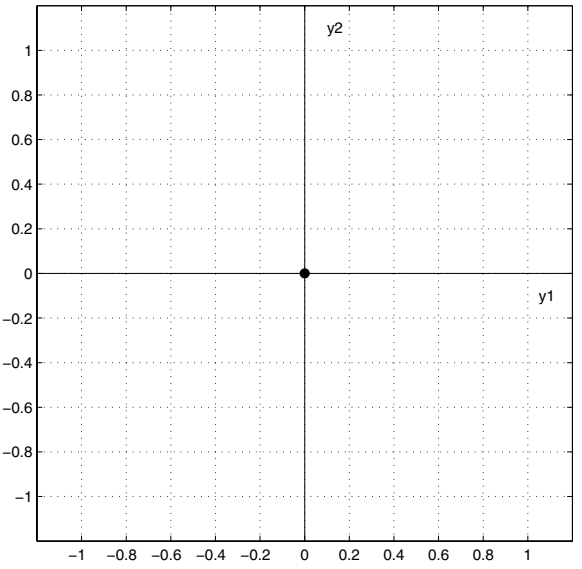

FIG. 13. $\mathcal{Y}_N^{\Delta}$ *for* $\lambda = 0.36$.

The second integral is apparently equal to

$$\frac{\phi(y^k(S^k)) - \phi(y^k(0))}{S^k}$$

and tends to zero as S^k tends to infinity (since $y^k(\tau) \in Y \ \forall \ \tau \in [0, S^k]$ and Y is a compact set). This and (66) imply that

$$\int_{U\times Y} (\phi'(y))^T f(u,y)\gamma(du,dy) \ = \ 0 \ \forall \phi \in C^1 \quad \Rightarrow \quad \gamma \ \in \ W.$$

The latter contradicts (65) and, hence, $\kappa(S)$ defined in (64) tends to zero as S tends to infinity. This proves (20).

From the consideration above it follows that, if there exists a sequence of S^k tending to infinity such that $\Gamma(S^k) \neq \emptyset$, then the set W is not empty. Hence, if the latter is empty, then $\Gamma(S) = \emptyset$ for all S large enough. □

Proof of Proposition 5. Let $\hat{Y}$ be a compact set which contains Y in its interior and let $q_l(u,y) : U \times \hat{Y} \to \mathbb{R}^1$, $l = 1, 2, \dots$, be a sequence of Lipschitz continuous functions which is dense in $C(U \times \hat{Y})$ (the space of continuous functions on $U \times \hat{Y}$). Let

(67)
$$h(u,y) = (q_1(u,y), \dots, q_j(u,y)), \qquad \bar{h}(\nu,y) = (\bar{q}_1(\nu,y), \dots, \bar{q}_j(\nu,y)), \quad j = 1, 2, \dots,$$

where $\bar{q}_j(\nu,u) \stackrel{\text{def}}{=} \int_U q_j(u,y)\nu(du)$. Define the sets $V_h(S,y)$ and $\bar{V}_h(S,y)$ by the equations

$$V_h(S) \stackrel{\text{def}}{=} \bigcup_{\big(u(\cdot),\ y(\cdot)\big)} \left\{ \frac{1}{S} \int_0^S h\big(u(\tau), y(\tau)\big) d\tau \right\},$$

$$\bar{V}_h(S) \stackrel{\text{def}}{=} \bigcup_{\big(\nu(\cdot),\ y(\cdot)\big)} \left\{ \frac{1}{S} \int_0^S \bar{h}\big(\nu(\tau), y(\tau)\big) d\tau \right\},$$

where the unions are over all admissible and relaxed admissible pairs, respectively.

Let d_H stand for the Hausdorff metric defined on compact subsets of $\mathbb{R}^j$ by the Euclidean norm. Using a standard argument based on the separability of convex sets (see, e.g., Lemma 4.2 in [26]), one can verify that Assumption 1 is equivalent to the statement that, for any $h(\cdot)$ and $\bar{h}(\cdot)$ as in (67),

$$d_H(\bar{co}V_h(S), \bar{co}\bar{V}_h(S)) \stackrel{\text{def}}{=} \kappa_h(S) \ \to \ 0 \tag{68}$$

as $S \to \infty$, where $\bar{co}$ stands for the closed convex hull of the corresponding set.

From the definition of the metric ρ in the form (15) and the convexity of W it follows that $\sup_{\gamma \in \Gamma(S)} \rho(\gamma, W) = \sup_{\gamma \in co\Gamma(S)} \rho(\gamma, W)$. Hence, by (20),

$$\lim_{S \to \infty} \sup_{\gamma \in co\Gamma(S)} \rho(\gamma, W) = 0$$

and, to prove (24), it is enough to show that

$$\sup_{\gamma \in W} \rho(\gamma, co\Gamma(S)) \le \kappa(S), \qquad \lim_{S \to \infty} \kappa(S) = 0. \tag{69}$$

Let us take an arbitrary $\gamma \in W$. From Lemma 5.1 in [26] and Theorem 4.1 in [43] it follows (see [26]) that there exist a probability space $(\Omega, \mathcal{F}, P)$ and a $(\mathcal{P}(U) \times \mathbb{R}^m)$-valued random process $(\nu(\tau), y(\tau)) = (\nu(\tau, \omega), y(\tau, \omega))$ such that (i) for any $h(\cdot)$ and $\bar{h}(\cdot)$ defined in (67),

$$E[\bar{h}(\nu(\tau, \omega), y(\tau, \omega))] \ = \ \int_{U \times Y} h(u, y) \gamma(du, dy) \ \ \forall \tau \ge 0; \tag{70}$$

and (ii) for some $\Omega' \subset \Omega$ with $P(\Omega') = 1$ and for any $\omega \in \Omega'$, the pair $(\nu(\cdot, \omega), y(\cdot, \omega))$ is relaxed admissible on any interval $[0, S]$.

From (ii) it follows that

$$\frac{1}{S} \int_0^S \bar{h}\big(\nu(\tau, \omega), y(\tau, \omega)\big) d\tau \ \in \ \bar{V}_h(S) \ \ \forall \omega \in \Omega',$$

while (i) implies that

$$\int_{U \times Y} h(u, y) \gamma(du, dy) \ = \ E \frac{1}{S} \int_0^S [\bar{h}\big(\nu(\tau, \omega), y(\tau, \omega)\big)] d\tau \ \in \ \bar{co}\bar{V}_h(S).$$

Using the above inclusion and taking into account (68) (as well as the fact that γ is an arbitrary element of W), one can conclude that

$$\bigcup_{\gamma \in W} \left\{ \int_{U \times Y} h(u, y) \gamma(du, dy) \right\} \ \subset \ \bar{co}V_h(S) \ + \ \kappa_h(S) B_j, \tag{71}$$

where B_j is the closed unit ball in $\mathbb{R}^j$ (j is the number of components of $h(\cdot)$; see (67)). Applying now Lemma 3.5 from [27] in exactly the same way as it is done

on page 335 in [26], one can prove the validity of (69). This completes the proof of (24). □

Proof of Proposition 7 *(continued).* Since $W \subset W_N$, to prove that (32) is valid, it is enough to show that

$$\lim_{N\to\infty} \sup_{\gamma\in W_N} \rho(\gamma, W) = 0. \tag{72}$$

Assume it is not true. Then there exist a positive number δ, a subsequence of positive integers $N' \to \infty$, and a sequence of probability measures $\gamma_{N'} \in W_{N'}$ such that $\rho(\gamma_{N'}, W) \geq \delta$. Due to the compactness of $\mathcal{P}(U \times Y)$, one may assume (without loss of generality) that there exists $\bar{\gamma} \in \mathcal{P}(U \times Y)$ such that

$$\lim_{N'\to\infty} \rho(\gamma_{N'}, \bar{\gamma}) = 0 \qquad \Rightarrow \qquad \rho(\bar{\gamma}, W) \geq \delta. \tag{73}$$

From the fact that $\gamma_{N'} \in W_{N'}$ it follows that, for any integer i and $N' \geq i$,

$$\int_{U\times Y} (\phi_i'(y))^T f(u,y)\gamma_{N'}(du,dy) = 0 \quad \Rightarrow \quad \int_{U\times Y} (\phi_i'(y))^T f(u,y)\bar{\gamma}(du,dy) = 0.$$

Since the latter is valid for any $i = 1, 2, \dots$, one can conclude that $\bar{\gamma} \in W$, which contradicts (73). This proves (32). □

Proof of Proposition 8. In case (i), from (36) it follows that there exist an open ball $B \subset Y$ centered at $\bar{y}$ and a number $r > 0$ such that the closed ball $\bar{B}_r$ centered at 0 and having the radius $r > 0$ will satisfy the inclusion

$$\bar{B}_r \subset f(y, U) \quad \forall y \in B. \tag{74}$$

Let us show that, if $\phi(\cdot)$ satisfies (35), then $\phi'(y) = 0\ \forall y \in B$ and, thus, Y^* can be taken to be equal to the closure of B. Assume that $\phi'(y) \neq 0$ for some $y \in B$. By (74), there exist $u \in U$ such that $\frac{r}{||\phi'(y)||}\phi'(y) = f(y,u)$. Hence, by (35),

$$(\phi'(y))^T\phi'(y) = \frac{||\phi'(y)||}{r}(\phi'(y))^T f(y,u) \leq 0 \quad \Rightarrow \quad \phi'(y) = 0.$$

The obtained contradiction proves the statement.

In case (ii), let us show that Y^* can be taken to be equal to the closure of Y^0. To show this, it is enough to establish that from (35) it follows that $\phi(y) = \text{ const } \forall y \in Y^0$ (which leads to that $\phi(y) = \text{ const } \forall y \in Y^*$ and, hence, to that $\phi'(y) = 0\ \forall y \in \text{int } Y^*$).

Let $y', y'' \in Y^0$ and $(u(\tau), y(\tau))$ be an admissible pair such that $y(0) = y'$ and $y(S) = y''$. Then, by (35),

$$\phi(y'') - \phi(y') = \int_0^S (\phi'(y(\tau)))^T f(u(\tau), y(\tau))d\tau \leq 0 \quad \Rightarrow \quad \phi(y'') \leq \phi(y').$$

Since y', y'' are arbitrary points in Y^0, the latter implies that

$$\phi(y) = \text{ const } \forall y \in Y^0. \qquad \square$$

Proof of Proposition 9. First, note that, by (41), the set W_N is not empty if W_N^Δ is not empty.

Let us assume that the set W_N is not empty and show that W_N^Δ is not empty and that (42) is valid (the validity of (43) follows from (42) on the basis of Lemma 1(ii);

the other statements included in the proposition are immediate consequences of (42) and (43)).

From (38) and the fact that the functions $(\phi_i'(y))^T f(u,y)$ are continuous it follows that

$$\sup_{(u,y)\in Q_{l,k}^{\Delta}} |(\phi_i'(y))^T f(u,y) - (\phi_i'(y_k))^T f(u_l,y_k)| \le \kappa(\Delta), \quad i=1,\dots,N, \tag{75}$$

for some $\kappa(\Delta)$ such that $\lim_{\Delta\to 0}\kappa(\Delta)=0$. Define the set $Z_N^{\Delta}\subset \mathbb{R}^{L^{\Delta}+K^{\Delta}}$ by the equation

$$Z_N^{\Delta} \stackrel{\text{def}}{=} \left\{ \gamma=\{\gamma_{l,k}\}\ge 0 \ : \ \sum_{l,k}\gamma_{l,k}=1, \ \left|\sum_{l,k}(\phi_i'(y_k))^T f(u_l,y_k)\gamma_{l,k}\right| \le \kappa(\Delta), \right. \\ \left. i=1,2,\dots,N \right\}. \tag{76}$$

For any Δ, let $\gamma^{\Delta}\in W_N$ be such that $\rho(\gamma^{\Delta},Z_N^{\Delta}) = \max_{\gamma\in W_N}\rho(\gamma,Z_N^{\Delta})$ (γ^{Δ} exists since W_N is compact) and show that

$$\lim_{\Delta\to 0}\max_{\gamma\in W_N}\rho(\gamma,Z_N^{\Delta}) = \lim_{\Delta\to 0}\rho(\gamma^{\Delta},Z_N^{\Delta}) = 0. \tag{77}$$

Let $\gamma_{l,k}^{\Delta}\stackrel{\text{def}}{=}\int_{Q_{l,k}^{\Delta}}\gamma^{\Delta}(du,dy)$. By (75),

$$\left|\sum_{l,k}(\phi_i'(y_k))^T f(u_l,y_k)\gamma_{l,k}^{\Delta}\right| \\ = \left|\sum_{l,k}(\phi_i'(y_k))^T f(u_l,y_k)\gamma_{l,k}^{\Delta} - \int_{U\times Y}(\phi_i'(y))^T f(u,y)\gamma^{\Delta}(du,dy)\right| \\ \le \sum_{l,k}\int_{Q_{l,k}^{\Delta}}|(\phi_i'(y_k))^T f(u_l,y_k)-(\phi_i'(y))^T f(u,y)|\gamma^{\Delta}(du,dy) \le \kappa(\Delta), \quad i=1,2,\dots,N.$$

Hence, denoting $\tilde{\gamma}^{\Delta}\stackrel{\text{def}}{=}(\gamma_{l,k}^{\Delta})$, one obtains that $\tilde{\gamma}^{\Delta}\in Z_N^{\Delta}$ and, consequently,

$$\rho(\tilde{\gamma}^{\Delta},Z_N^{\Delta})=0. \tag{78}$$

Let $q(u,y):U\times Y\to\mathbb{R}^1$ be an arbitrary continuous function and let $\kappa_q(\Delta)$ be such that

$$\sup_{(u,y)\in Q_{l,k}^{\Delta}}|q(u,y)-q(u_l,y_k)| \le \kappa_q(\Delta), \qquad \lim_{\Delta\to 0}\kappa_q(\Delta)=0.$$

Then

$$\left|\int_{U\times Y}q(u,y)\gamma^{\Delta}(du,dy) - \sum_{l,k}q(u_l,y_k)\gamma_{l,k}^{\Delta}\right| \\ = \left|\sum_{l,k}\int_{Q_{l,k}}q(u,y)\gamma^{\Delta}(du,dy) - \sum_{l,k}\int_{Q_{l,k}}q(u_l,y_k)\gamma^{\Delta}(du,dy)\right| \le \kappa_q(\Delta).$$

The fact that the latter inequality is valid for an arbitrary continuous $q(u,y)$ implies that $\lim_{\Delta\to 0}\rho(\gamma^\Delta,\tilde\gamma^\Delta)=0$, which, along with (78), implies the validity of (77).

By (41), $\max_{\gamma\in W_N^\Delta}\rho(\gamma,W_N)=0$. Hence, to prove (42), it is enough to establish that

$$\lim_{\Delta\to 0}\max_{\gamma\in W_N}\rho(\gamma,W_N^\Delta)=0. \tag{79}$$

Since (as can be easily verified using the triangle inequality),

$$\max_{\gamma\in W_N}\rho(\gamma,W_N^\Delta)\le\max_{\gamma\in W_N}\rho(\gamma,Z_N^\Delta)+\max_{\gamma\in Z_N^\Delta}\rho(\gamma,W_N^\Delta)$$

and since (77) has been already verified, equality (79) will be established if one shows that

$$\lim_{\Delta\to 0}\max_{\gamma\in Z_N^\Delta}\rho(\gamma,W_N^\Delta)\ =\ \lim_{\Delta\to 0}\rho(\bar\gamma^\Delta,W_N^\Delta)\ =0, \tag{80}$$

where $\bar\gamma^\Delta=\{\bar\gamma^\Delta_{l,k}\}\in Z_N^\Delta$ is such that $\rho(\bar\gamma^\Delta,W_N^\Delta)=\max_{\gamma\in Z_N^\Delta}\rho(\gamma,W_N^\Delta)$ for any $\Delta>0$.

Let $q_j(\cdot)$ be the same as in definition (15) of the metric ρ. Consider the following finite-dimensional linear program:

$$F_J(\Delta)\stackrel{\text{def}}{=}\min_{\gamma=\{\gamma_{l,k}\}\in W_N^\Delta}\sum_{j=1}^{J}\frac{1}{2^j}\left|\sum_{l,k}q_j(u_l,y_k)\gamma_{l,k}-\sum_{l,k}q_j(u_l,y_k)\bar\gamma^\Delta_{l,k}\right|. \tag{81}$$

To prove that (80) is valid, it is enough to show that

$$\lim_{\Delta\to 0}F_J(\Delta)\ =\ 0,\qquad J=1,2,\dots. \tag{82}$$

Below it is shown that the optimal value of the problem dual to (81) tends to zero as Δ tends to zero. Since the latter coincides with $F_J(\Delta)$, this will prove (82). Also, from (82) it follows that $F_J(\Delta)$ is bounded and, hence, W_N^Δ is not empty for Δ small enough (see, e.g., Theorem 2 on page 129 in [18]).

Let us rewrite problem (81) in the equivalent form:

$$F_J(\Delta)\ =\ \min_{\gamma=\{\gamma_{l,k}\}\in W_N^\Delta}\sum_{j=1}^{J}\frac{1}{2^j}\theta_j, \tag{83}$$

where

$$-\sum_{l,k}q_j(u_l,y_k)\gamma_{l,k}+\theta_j\ge-\sum_{l,k}q_j(u_l,y_k)\bar\gamma^\Delta_{l,k}, \tag{84}$$

$$\sum_{l,k}q_j(u_l,y_k)\gamma_{l,k}+\theta_j\ge\sum_{l,k}q_j(u_l,y_k)\bar\gamma^\Delta_{l,k}. \tag{85}$$

The problem dual to (83)–(85) is

$$F_J(\Delta)\ =\ \max_{\lambda_i,\mu_j,\eta_j,\zeta}\sum_{j=1}^{J}(-\mu_j+\eta_j)\left(\sum_{l,k}q_j(u_l,y_k)\bar\gamma^\Delta_{l,k}\right)+\zeta, \tag{86}$$

where $\lambda_i, i = 1, \dots, N$; μ_j, η_j, $j = 1, \dots J$, and ζ satisfy the following relationships:

$$\sum_{i=1}^{N} \lambda_i (\phi_i'(y^k))^T f(u_l, y_k) + \sum_{j=1}^{J} (-\mu_j + \eta_j) q_j(u_l, y_k) + \zeta \le 0, \tag{87}$$

$l = 1, 2, \dots, L^\Delta$, $k = 1, 2, \dots, K^\Delta$, and

$$\mu_j + \eta_j = \frac{1}{2^j}, \qquad \mu_j \ge 0, \ \eta_j \ge 0, j = 1, , 2, \dots, J. \tag{88}$$

Before proving (82), let us verify that $F_J(\Delta)$ is bounded for Δ small enough (which, by (81), is equivalent to that W_N^Δ is not empty). Assume it is not. Then there exist a sequence $\Delta^r, r = 1, 2, \dots, \lim_{r\to\infty} \Delta^r = 0$, and sequences λ_i^r, μ_j^r, η_j^r, ζ^r, satisfying (87)–(88) with $\Delta = \Delta^r$, $r = 1, 2, \dots$, such that $\lim_{r\to\infty}(\zeta^r + \sum_{i=1}^N |\lambda_i^r|) = \infty$ and

$$\lim_{r\to\infty} \frac{\zeta^r}{\zeta^r + \sum_{i=1}^N |\lambda_i^r|} \stackrel{\text{def}}{=} a \ge 0, \qquad \lim_{r\to\infty} \frac{\lambda_i^r}{\zeta^r + \sum_{i=1}^N |\lambda_i^r|} \stackrel{\text{def}}{=} v_i,$$

where

$$a + \sum_{i=1}^{N} |v_i| = 1. \tag{89}$$

Dividing (87) by $\zeta^r + \sum_{i=1}^N |\lambda_i^r|$ and passing to the limit as $r \to \infty$, one can obtain

$$\sum_{i=1}^{N} v_i (\phi_i'(y))^T f(u, y) + a \le 0 \quad \forall (u, y) \in U \times Y, \tag{90}$$

where it is taken into account that every point $(u, y) \in U \times Y$ can be presented as the limit of (u_l, y_k) belonging to the sequence of cells $Q_{l,k}^{\Delta^r}$ such that $(u, y) \in Q_{l,k}^{\Delta^r}$.

Two cases are possible: $a > 0$ and $a = 0$. If $a > 0$, then the validity of (90) implies that the function $\phi(y) \stackrel{\text{def}}{=} \sum_{i=1}^N v_i \phi_i(y)$ satisfies (19) which would lead to W_N being empty. The set W_N, however, is not empty (by our assumption) and, hence, the only case to consider is $a = 0$. In this case, (90) becomes

$$\sum_{i=1}^{N} v_i (\phi_i'(y))^T f(u, y) \le 0 \quad \forall (u, y) \in U \times Y. \tag{91}$$

By Assumption 2, (91) can be valid only with all v_i being equal to zero. This contradicts (89) and, thus, proves that $F_J(\Delta)$ is bounded for Δ small enough (and that W_N^Δ is not empty).

From the fact that $F_J(\Delta)$ is bounded it follows that a solution $\lambda_i^\Delta, i = 1, \dots, N$; μ_j^Δ, η_j^Δ, $j = 1, \dots, J$, and ζ^Δ of the problem (86)–(88) exists. Using this solution,

one can obtain the following estimates:

$$\begin{aligned}
0 \le F_J(\Delta) &= \sum_{j=1}^{J}(-\mu_j^\Delta + \eta_j^\Delta)\left(\sum_{l,k} q_j(u_l, y_k)\bar\gamma_{l,k}^\Delta\right) + \zeta^\Delta \\
&= \sum_{l,k}\bar\gamma_{l,k}^\Delta\left(\sum_{j=1}^{J}(-\mu_j^\Delta + \eta_j^\Delta)q_j(u_l, y_k)\right) + \zeta^\Delta \\
&\le \sum_{l,k}\bar\gamma_{l,k}^\Delta\left(-\sum_{i=1}^{N}\lambda_i^\Delta(\phi_i'(y^k))^T f(u_l, y_k) - \zeta^\Delta\right) + \zeta^\Delta \\
&= -\sum_{i=1}^{N}\lambda_i^\Delta\left(\sum_{l,k}(\phi_i'(y^k))^T f(u_l, y_k)\bar\gamma_{l,k}^\Delta\right) \le \sum_{i=1}^{N}|\lambda_i^\Delta|\kappa(\Delta),
\end{aligned}$$

where the last two relationships are implied by the fact that $\bar\gamma^\Delta = \{\bar\gamma_{l,k}^\Delta\} \in Z_N^\Delta$ (see (76)).

To prove (82), it is now sufficient to show that $\sum_{i=1}^N |\lambda_i^\Delta|$ remains bounded as $\Delta \to 0$. Assume it is not. Then there exists a sequence $\Delta^r, r = 1, 2, \dots, \lim_{r\to\infty}\Delta^r = 0$, and sequences $\lambda_i^r, \mu_j^r, \eta_j^r, \zeta^r$, satisfying (87)–(88) with $\Delta = \Delta^r$, $r = 1, 2, \dots$, such that

(92)
$$\lim_{r\to\infty}\sum_{i=1}^{N}|\lambda_i^r| = \infty, \qquad \lim_{r\to\infty}\frac{\zeta^r}{\sum_{i=1}^N|\lambda_i^r|} = 0, \qquad \lim_{r\to\infty}\frac{\lambda_i^r}{\sum_{i=1}^N|\lambda_i^r|} \stackrel{\text{def}}{=} v_i, \qquad \sum_{i=1}^{N}|v_i| = 1.$$

Dividing (87) by $\sum_{i=1}^N|\lambda_i^r|$ and passing to the limit as $r \to \infty$, one obtains that the inequality (91) is valid, which, by Assumption 2, implies that $v_i = 0$, $i = 1, \dots, N$. This contradicts the last equality in (92) and, thus, proves (82). □

Proof of Proposition 10. Assume that (46) is not true. Then there exist a number $r > 0$ and a sequence N_i tending to infinity as i tends to infinity and there exist sequences $\Delta_{i,j}$, with each $\Delta_{i,j}$ tending to zero as j tends to infinity (with i being fixed) such that

$$\begin{aligned}
\gamma_{N_i}^{\Delta_{i,j}}((U\times Y)/(\Theta + rB)) = \gamma_{N_i}^{\Delta_{i,j}}(\Theta_{N_i}^{\Delta_{i,j}}/(\Theta + rB)) \ &\ge \ \delta \\
\Rightarrow \gamma_{N_i}^{\Delta_{i,j}}(\Theta + rB) \ &< \ 1 - \delta.
\end{aligned} \tag{93}$$

Due to compactness of $\mathcal{P}(U \times Y)$, one may assume (without loss of generality) that there exists $\gamma_{N_i} \in \mathcal{P}(U \times Y)$ such that $\lim_{j\to\infty}\rho(\gamma_{N_i}^{\Delta_{i,j}}, \gamma_{N_i}) = 0$. Hence, since $\Theta + rB$ is an open set,

$$\underline{\lim}_{j\to\infty}\gamma_{N_i}^{\Delta_{i,j}}(\Theta + rB) \ \ge \ \gamma_{N_i}(\Theta + rB). \tag{94}$$

By Proposition 9, γ_{N_i} is a solution of problem (30). Consequently, by Proposition 7 and the fact that γ^* is the unique solution of (21),

$$\lim_{i\to\infty}\rho(\gamma_{N_i}, \gamma^*) = 0 \qquad \Rightarrow \qquad \underline{\lim}_{i\to\infty}\gamma_{N_i}(\Theta + rB) \ \ge \ \gamma^*(\Theta + rB) \ = \ 1. \tag{95}$$

The relationships (94) and (95) imply that, for i and j large enough, $\gamma_{N_i}^{\Delta_{i,j}}(\Theta + rB) \ge 1 - \delta$. This contradicts (93) and, thus, proves (46). The inclusion (47) follows from (46). □

Proof of Proposition 11. Assume that the proposition is not true. Then there exist a number $r > 0$ and sequence: $(u_i, y_i) \in \Theta,\ N_i,\ \Delta_{i,j},\ i = 1, 2, \dots,\ j = 1, 2, \dots,$ with

$$\lim_{i\to\infty}(u_i, y_i) = (\bar{u}, \bar{y}) \in cl\Theta, \qquad \lim_{i\to\infty} N_i = \infty, \qquad \lim_{j\to\infty} \Delta_{i,j} = 0$$

such that

$$d((u_i, y_i), \Theta_{N_i}^{\Delta_{i,j}}) \geq r \qquad \Rightarrow \qquad d((\bar{u}, \bar{y}), \Theta_{N_i}^{\Delta_{i,j}}) \geq \frac{r}{2}, \tag{96}$$

where $d((u, y), Q)$ stands for the distance between a point $(u, y) \in U \times Y$ and a set $Q \subset U \times Y$: $d((u, y), Q) \stackrel{\text{def}}{=} \inf_{(u',y')\in Q}\{||(u, y) - (u', y')||\}$. The second inequality in (96) implies that

$$\left((\bar{u}, \bar{y}) + \frac{r}{2}B\right) \cap \Theta_{N_i}^{\Delta_{i,j}} = \emptyset \qquad \Rightarrow \qquad \gamma_{N_i}^{\Delta_{i,j}}\left((\bar{u}, \bar{y}) + \frac{r}{2}B\right) = 0.$$

Similarly to the proof of Proposition 10, one may assume, without loss of generality, that there exists $\gamma_{N_i} \in \mathcal{P}(U \times Y)$ such that $\lim_{j\to\infty} \rho(\gamma_{N_i}^{\Delta_{i,j}}, \gamma_{N_i}) = 0$. Hence, since the set $(\bar{u}, \bar{y}) + \frac{r}{2}B$ is open,

$$0 \ = \ \lim_{j\to\infty} \gamma_{N_i}^{\Delta_{i,j}}\left((\bar{u}, \bar{y}) + \frac{r}{2}B\right) \ \geq \ \gamma_{N_i}\left((\bar{u}, \bar{y}) + \frac{r}{2}B\right).$$

As in the proof of Proposition 10, γ_{N_i} is a solution of problem (30) (see Proposition 9). Consequently, from Proposition 7 and from the fact that γ^* is the unique solution of (21) it follows that

$$\lim_{i\to\infty} \rho(\gamma_{N_i}, \gamma^*) = 0 \qquad \Rightarrow \qquad 0 \ = \ \lim_{i\to\infty} \gamma_{N_i}\left((\bar{u}, \bar{y}) + \frac{r}{2}B\right) \ \geq \ \gamma^*\left((\bar{u}, \bar{y}) + \frac{r}{2}B\right).$$

The latter contradicts Assumption 3 and, thus, proves the proposition. □

Acknowledgments. We thank J.-P. Aubin for inspiring discussions (during V. Gaitsgory's visits to Universities of Dauphine and Paris 1 in 2002–2004). We also express our gratitude to O. Alvarez, M. Bardi, and V. Veliov for supplying us with important references on the subject matter.

BIFURCATIONS OF 1-PARAMETER FAMILIES OF CONTROL-AFFINE SYSTEMS IN THE PLANE*

BRONISLAW JAKUBCZYK† AND WITOLD RESPONDEK‡

Abstract. We define bifurcations of control-affine systems in the plane and classify all generic 1-parameter bifurcations at control-regular points. More precisely, we classify topological bifurcations of invariants of usual feedback equivalence. Such bifurcations form six different classes: two bifurcations of equilibrium sets, two bifurcations of critical sets, and two bifurcations of pairs of invariants. We also classify all generic 1-parameter families of control-affine systems with respect to orbital feedback equivalence.

Key words. control system, bifurcation, invariants, classification, orbital feedback equivalence, 1-parameter families

1. Introduction.

In this paper we define and study bifurcations of 1-parameter families of smooth, control-affine systems

$$\Sigma \ : \ \dot{\xi} = f(\xi, \epsilon) + g(\xi, \epsilon)u,$$

where ξ lies in an open subset $X \subset \mathbb{R}^2$ or in a differential manifold $X = M^2$ and $u \in \mathbb{R}$. We classify the generic bifurcations at control-regular points (i.e., with $g(\xi, \epsilon) \neq 0$).

A local bifurcation of a parameter dependent dynamical system $\dot{\xi} = f(\xi, \epsilon)$ occurs at an equilibrium if there is a change, when the parameter ϵ varies, of topological character of the solution curves nearby the equilibrium (see, e.g., [IJ], [Ku]). Understanding bifurcations of such equations is important from several points of view, and the already known classification is rather rich (see, e.g., [AAIS]).

Analogous definition of bifurcation applied to a control system is not suitable since the set of trajectories of Σ is rich. (Local invariants of the feedback group include functional invariants, already for generic systems on $\mathbb{R}^2$; see [JR1], [JR2], [Zh].)

Therefore we consider only the most characteristic trajectories: constant trajectories, time-critical trajectories, and so-called, fast (quasi) trajectories. Thus, we attach to our system three basic invariants (equivariants) of feedback transformations. Namely, the *equilibria set* and the *critical set* are defined, respectively, by

$$E_\epsilon = \{p \in X \mid f(p, \epsilon) \text{ and } g(p, \epsilon) \text{ are linearly dependent}\},$$

$$C_\epsilon = \{p \in X \mid [g, f](p, \epsilon) \text{ and } g(p, \epsilon) \text{ are linearly dependent}\},$$

where $[g, f] = Df\, g - Dg\, f$ is the Lie bracket of g and f. The *canonical foliation* $\mathcal{G}_\epsilon$ (foliation of *fast trajectories*) consists of orbits (nonparameterized integral curves) of the control vector field $g(\cdot, \epsilon)$. Note that the fast trajectories are not true trajectories of Σ but only "asymptotic trajectories," corresponding to "arbitrarily large" control.

The choice of these invariants is additionally justified by the following remarks. Consider a generic system $\Sigma : \dot{\xi} = f(\xi) + ug(\xi)$, $\xi \in X$, $u \in \mathbb{R}$, and piecewise continuous control. (a) The pair of invariants $(E, \mathcal{G})$ determines the set of unparameterized trajectories of Σ in the region X, where $g(\xi) \neq 0$. Namely, the trajectories of Σ are exactly the piecewise C^1 curves in X intersecting the leaves of $\mathcal{G}$ transversally at points $p \in X \setminus E$ and tangent to the leaves at points in E. If we add to the invariants the "drift direction transversal to the leaves of $\mathcal{G}$," then the same remark is valid for oriented, unparameterized trajectories. (b) It follows from (a) that all controllability properties of Σ, expressed in terms of oriented unparameterized trajectories, are determined by the pair $(E, \mathcal{G})$ and the "drift direction." (c) Locally time-minimal and time-maximal trajectories are contained in C.

We will study bifurcations of these invariants. Roughly speaking (see Definition 2.1 for a rigorous statement), a bifurcation occurs if the triplet of basic invariants $(E_\epsilon, C_\epsilon, \mathcal{G}_\epsilon)$ at ϵ_0 is not topologically conjugated to the triplets at nearby values of ϵ. The same definition can be used for any subset of the triplet $(E_\epsilon, C_\epsilon, \mathcal{G}_\epsilon)$. In particular, we define bifurcations of the equilibrium set E_ϵ (E-bifurcations), of the critical set C_ϵ (C-bifurcations), as well as bifurcations of the pairs (E_ϵ, C_ϵ), $(E_\epsilon, \mathcal{G}_\epsilon)$, and $(C_\epsilon, \mathcal{G}_\epsilon)$.

In our considerations we will use the following local prenormal form of Σ:

$$\Sigma_{pre} \ : \quad \dot{x} = f_1(x, y, \epsilon), \quad \dot{y} = u,$$

where (x, y) are in a neighborhood of $0 \in \mathbb{R}^2$. Namely, every system Σ can be transformed to Σ_{pre} by a family of local diffeomorphisms $(x, y) = \phi_\epsilon(\xi)$, which rectify the vector fields $g(\xi, \epsilon)$ to $\partial/\partial y$, and by a static feedback transformation. For Σ_{pre},

$$E_\epsilon = \{(x, y) : f_1(x, y, \epsilon) = 0\}, \qquad C_\epsilon = \left\{(x, y) : \frac{\partial f_1}{\partial y}(x, y, \epsilon) = 0\right\},$$

and

$$\mathcal{G}_\epsilon = \{x = \text{const}\}.$$

From the last expression for C_ϵ, it is clear that C_ϵ consists of locally time-critical curves (time-minimal, if $f_1 \partial^2 f_1/\partial y^2 < 0$, and time-maximal, if $f_1 \partial^2 f_1/\partial y^2 > 0$).

Our first main result says that, generically, there are only six nonequivalent bifurcations of planar systems Σ at control-regular points. Throughout the paper, by a generic system Σ we mean a 1-parameter family of pairs (f, g) of vector fields that belongs to a dense set $\mathcal{GS}$, which is a countable intersection of open and dense subsets in the C^∞ Whitney topology of the space of all pairs (f, g) defined on $X \times I$ (see [Hi] for properties of the Whitney topology). The set of generic systems $\mathcal{GS}$ is given by the transversality conditions (G1)–(G6) in Theorem 3.3 and Lemma 4.4.

THEOREM 1.1. *Let Σ be a smooth, generic, 1-parameter family of control-affine systems. If $g(p, \epsilon_0) \neq 0$ and Σ bifurcates locally at (p, ϵ_0), then the bifurcation is equivalent to one of the following:*

(i) *an E-bifurcation, which can be of two types described in section 2.1;*
(ii) *a C-bifurcation, which can be of two types described in section 2.2;*
(iii) *an $E\mathcal{G}$-bifurcation (or an EC-bifurcation), described in section 2.3;*
(iv) *a $C\mathcal{G}$-bifurcation described in section 2.4.*

Here equivalence of bifurcations is understood as equivalence of the triples of invariants $(E_\epsilon, C_\epsilon, \mathcal{G}_\epsilon)$ under smooth, invertible local transformations of the form

$$\tilde{\xi} = \phi(\xi, \epsilon), \qquad \tilde{\epsilon} = \eta(\epsilon). \tag{Eq}$$

The above theorem is a consequence of our second main result, Theorem 3.3, which locally classifies generic families Σ under smooth orbital feedback equivalence. This C^∞ classification holds at control-regular points.

Using weaker, topological equivalence (Eq), a classification of generic bifurcations of $(E_\epsilon, C_\epsilon, \mathcal{G}_\epsilon)$ at points where g vanishes is also possible but requires different techniques. As the results in [Ru] show, there are four additional bifurcations in that case. A generic local topological classification of 1-parameter families, around points where g vanishes, gives seven nonequivalent families (four that bifurcate and three that do not).

Clearly, the set of equilibria, the set of (time) critical trajectories, and the set of fast trajectories have already proved their importance in several problems concerning control-affine planar systems. In constructing the time-optimal synthesis on $\mathbb{R}^2$ for a system $\dot{x} = f(x) + ug(x)$ with constraints $|u| \leq 1$, both the equilibria set and the critical set play an important role, while the set of fast trajectories is not significant; see [Ba1], [Ba2], [BsP], [BP], [Su1], [Su2]. In studying generic controllability problems and singularities of the boundary of the reachable set for such systems [Da1], [Da2], the equilibrium set is important, while the other two invariants do not appear. The main role is played by two vector fields, X_+ and X_-, $X_\pm = f \pm g$, and by two foliations of oriented orbits of these vector fields, called limiting directions [Da2]. In that case the problem is reduced to local classification of two generic, oriented foliations. See [Da2] and [BsP], which summarize deep studies of planar systems with constraints from controllability and optimal control points of view.

The study of bifurcations of control systems was initiated by Abed and Fu [AF1], [AF2], in a different setting, for systems of the form $\dot{\xi} = f(\xi, u, \epsilon)$. They assumed that the uncontrolled system, defined by taking $u = 0$, undergoes a bifurcation at $\epsilon = \epsilon_0$, and they studied stabilizability of the system by quadratic and cubic feedbacks.

Our approach is close in spirit to that of Kang [Ka1], who studied bifurcations of the set of equilibria and of the linear approximation of the system at an equilibrium.

A control system does not need a parameter to bifurcate—the control can play the same role. This point of view is presented by Krener, Kang, and Chang [KKC]. They consider systems $\dot{\xi} = f(\xi, u)$, for which the set of equilibria is conveniently parameterized by the control u. According to their definition, a control bifurcation takes place at an equilibrium if the linear approximation of the system looses stabilizability.

2. Bifurcations. We will use the following definition of bifurcation. For a subset $\Omega \subset X \times I$ and a fixed parameter $\epsilon \in I = (a, b)$ we denote $\Omega_\epsilon = \{\xi \in X : (\xi, \epsilon) \in \Omega\}$. Assume $0 \in I$. We denote the system Σ with a fixed value ϵ of parameter by Σ_ϵ.

DEFINITION 2.1. *We say that the family Σ does not bifurcate, locally at $(\xi_0, \epsilon_0) = (p, 0)$, if there exits a neighborhood $\Omega \subset X \times I$ of $(p, 0)$ and a family of homeomorphisms $\chi_\epsilon : \Omega_\epsilon \to \Omega_0$, continuous with respect to (ξ, ϵ), such that for Σ_ϵ restricted to Ω_ϵ we have*

$$\chi_\epsilon(E_\epsilon) = E_0, \quad \chi_\epsilon(C_\epsilon) = C_0, \quad \text{and} \quad \chi_\epsilon(\mathcal{G}_\epsilon) = \mathcal{G}_0$$

for all $\epsilon \in I$ close enough to 0. Otherwise we say that Σ bifurcates locally *or has a* local bifurcation *at $(\xi, \epsilon) = (p, 0)$.*

Analogous definition applies to bifurcations at arbitrary (ξ_0, ϵ_0). Strictly speaking, in our definition we should say that the triple $(E_\epsilon, C_\epsilon, \mathcal{G}_\epsilon)$ bifurcates or that Σ bifurcates with respect to $(E_\epsilon, C_\epsilon, \mathcal{G}_\epsilon)$. The same definition will be used for any subset of the triplet $(E_\epsilon, C_\epsilon, \mathcal{G}_\epsilon)$. In particular, we define bifurcations of the equilibrium set E_ϵ, of the critical set C_ϵ, and of the pairs (E_ϵ, C_ϵ), $(E_\epsilon, \mathcal{G}_\epsilon)$, and $(C_\epsilon, \mathcal{G}_\epsilon)$.

In the above definition we use a family of homeomorphisms χ_ϵ. Another possibility is to use, instead, a family of smooth diffeomorphisms ϕ_ϵ. We will call the corresponding bifurcations *topological* and *differential* bifurcations. In turns out, however, that in both topological and smooth categories the bifurcations of generic 1-parameter families of control-affine planar systems are the same at control-regular points.

DEFINITION 2.2. *We say that two (local) bifurcations of Σ_ϵ and $\tilde{\Sigma}_\epsilon$ are locally equivalent if there is a local, smooth, invertible transformation $(\tilde{\xi}, \tilde{\epsilon}) = (\phi(\xi, \epsilon), \eta(\epsilon))$ which transforms the triple $(E_\epsilon, C_\epsilon, \mathcal{G}_\epsilon)$ into the triple $(\tilde{E}_{\tilde{\epsilon}}, \tilde{C}_{\tilde{\epsilon}}, \tilde{\mathcal{G}}_{\tilde{\epsilon}})$.*

Assuming that the families of vector fields $f(\xi, \epsilon)$ and $g(\xi, \epsilon)$ are expressed in coordinates on $X \subset \mathbb{R}^2$ as column vectors, we define the functions of (ξ, ϵ):

$$e = \det(f, g), \qquad c = \det([g, f], g).$$

For Σ in the prenormal form we have $e(x, y, \epsilon) = f_1(x, y, \epsilon)$ and $c(x, y, \epsilon) = \frac{\partial f_1}{\partial y}(x, y, \epsilon)$.

Below we will describe in detail all generic planar bifurcations. To simplify the notation, we will denote the state of the transformed system $\tilde{\Sigma}_{\tilde{\epsilon}}$ by $\tilde{\xi} = (x, y)$, its control by $\tilde{u} = v$, and its parameter by $\tilde{\epsilon} = \epsilon$. This system will be in the prenormal form Σ_{pre}. Then its canonical foliation will be in the form

$$\mathcal{G}_\epsilon = \{x = \text{const}\}.$$

Let $\varphi_\epsilon(x, y) = \varphi(x, y, \epsilon)$ be a smooth function. We will denote by $d\varphi$ the differential of φ in the (x, y)-space and by $D\varphi$ the differential in the (x, y, ϵ)-space, that is,

$$d\varphi = \left(\frac{\partial \varphi}{\partial x}, \frac{\partial \varphi}{\partial y}\right), \qquad D\varphi = \left(\frac{\partial \varphi}{\partial x}, \frac{\partial \varphi}{\partial y}, \frac{\partial \varphi}{\partial \epsilon}\right).$$

By $\operatorname{hess}(\varphi)$ we denote the matrix of second order partial derivatives of φ with respect to x, y, and $L_g\varphi$ denotes the derivative of φ along g.

2.1. *E*-bifurcations. Consider Σ around a point $(p, \epsilon_0) \in X \times I$ such that $g(p, \epsilon_0) \neq 0$ and assume that the equilibrium set E_ϵ locally bifurcates while the invariants C_ϵ and $\mathcal{G}_\epsilon$ do not bifurcate at ϵ_0. We will call such a phenomenon an *equilibria bifurcation* or an *E-bifurcation.*

PROPOSITION 2.3. *For a generic Σ, an E-bifurcation appears at a point $(\xi, \epsilon) = (p, \epsilon_0)$ if and only if the following conditions are fulfilled at this point:*

$$e = 0, \quad c = 0, \quad L_g c \neq 0, \quad de = 0, \quad \det \operatorname{hess}(e) \neq 0, \quad \text{and} \quad De \neq 0.$$

Such a bifurcation is equivalent to one of the two which are described by the following families of invariants: $C_\epsilon = \{y = 0\}$, $\mathcal{G}_\epsilon = \{x = \text{const}\}$ and

$$E_\epsilon = \{x^2 + y^2 = \epsilon\} \quad \text{or} \quad E_\epsilon = \{x^2 - y^2 = \epsilon\}.$$

Moreover, $E_\epsilon = \{x^2 + y^2 = \epsilon\}$ corresponds to $\det \operatorname{hess}(e) > 0$, while $E_\epsilon = \{x^2 - y^2 = \epsilon\}$ corresponds to $\det \operatorname{hess}(e) < 0$.

Description of the *E*-bifurcations. In the first E-bifurcation, called *birth of equilibria*, the equilibrium set E_ϵ is empty, for $\epsilon < 0$, it consists of a single point

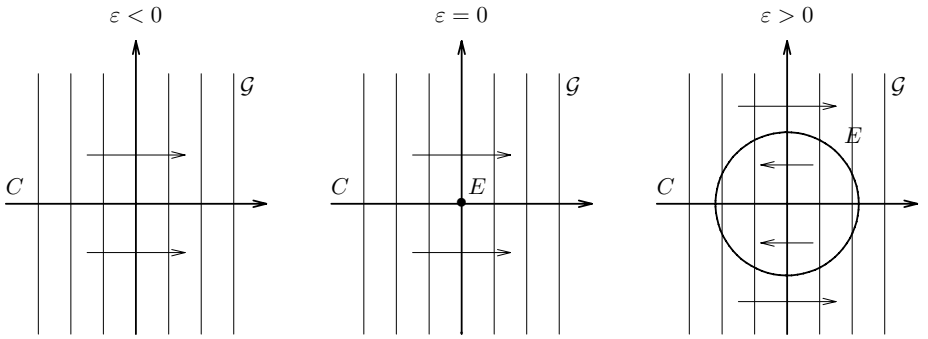

FIG. 2.1. *E-bifurcation (birth of equilibria).*

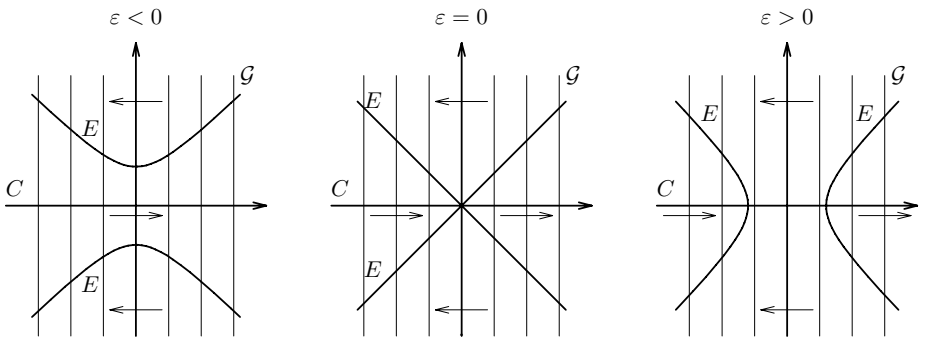

FIG. 2.2. *E-bifurcation (cross of equilibria).*

$(0,0) \in \mathbb{R}^2$, for $\epsilon = 0$, and of a circle of equilibria, for $\epsilon > 0$ (see Figure 2.1). The arrows in the figures will symbolically denote the direction of the drift f, transverse to $\mathcal{G}_\epsilon$.

In the second E-bifurcation, called *cross of equilibria* (Figure 2.2), the equilibrium set E_ϵ consists of two curves that do not intersect, for $\epsilon \neq 0$. The two curves approach each other when ϵ tends to zero and, for $\epsilon = 0$, the set E_0 is formed by two curves which intersect (transversally, if we consider differential bifurcations).

Notice that the fact that E_ϵ bifurcates implies that the pairs (E_ϵ, C_ϵ) and $(E_\epsilon, \mathcal{G}_\epsilon)$ bifurcate as well (although neither C_ϵ nor $\mathcal{G}_\epsilon$, considered separately, bifurcates). For instance, in the case of the birth of equilibria bifurcation, the curves E_ϵ and C_ϵ do not intersect for $\epsilon < 0$ (since E_ϵ is empty), their intersection is one point, for $\epsilon = 0$, and consists of two points for $\epsilon > 0$.

2.2. *C*-bifurcations. Consider a system Σ around a point (p, ϵ_0) such that $g(p, \epsilon_0) \neq 0$ and assume that the critical set C_ϵ locally bifurcates while the equilibrium set E_ϵ and the canonical foliation $\mathcal{G}_\epsilon$ do not bifurcate at $\epsilon = \epsilon_0$. We will call such a bifurcation *critical set bifurcation* or *C-bifurcation*. Generically, only two such bifurcations are possible.

PROPOSITION 2.4. *A generic family Σ has a C-bifurcation at a point $(\xi, \epsilon) = (p, \epsilon_0)$ if and only if the following conditions are fulfilled at this point:*

$$e \neq 0, \quad c = 0, \quad dc = 0, \quad L_g^2 c \neq 0, \quad \det \operatorname{hess}(c) \neq 0, \quad Dc \neq 0.$$

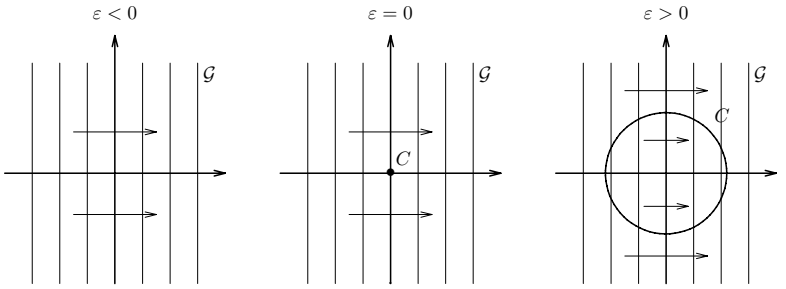

FIG. 2.3. *C-bifurcation (birth of critical curve).*

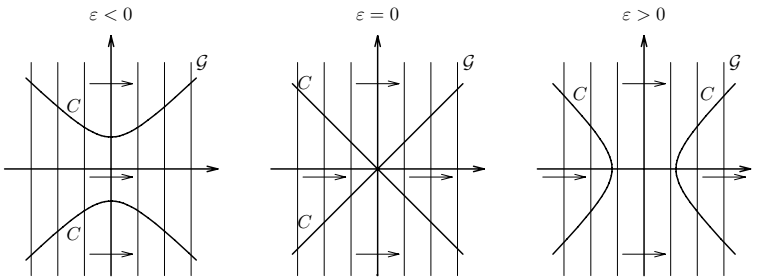

FIG. 2.4. *C-bifurcation (cross of critical curves).*

Such a bifurcation is equivalent to one of the two which are described by the following invariants: $E_\epsilon = \emptyset$ *(empty set),* $\mathcal{G}_\epsilon = \{x = \text{const}\}$ *and*

$$C_\epsilon = \{x^2 + y^2 = \epsilon\} \quad \text{or} \quad C_\epsilon = \{x^2 - y^2 = \epsilon\}.$$

In these bifurcations, the critical curve bifurcates in exactly the same way as the equilibria curve does in the E-bifurcations, which is illustrated in Figures 2.3 and 2.4 (the first corresponds to $\det \operatorname{hess}(c) > 0$, while the second corresponds to $\det \operatorname{hess}(c) < 0$).

2.3. *EG*-bifurcations or *EC*-bifurcations. Consider a generic family Σ such that neither of the invariants E_ϵ, C_ϵ, $\mathcal{G}_\epsilon$ bifurcates, while the pair $(E_\epsilon, \mathcal{G}_\epsilon)$ bifurcates. We call this *EG-bifurcation*. Only one such bifurcation is possible.

PROPOSITION 2.5. *A generic family* Σ *has a local EG-bifurcation at a point* (p, ϵ_0) *if and only if the conditions*

$$e = 0, \quad c = 0, \quad L_g c = 0, \quad L_g^2 c \neq 0, \quad de \neq 0, \quad dc \neq 0$$

are fulfilled at this point and the differentials De and Dc are linearly independent. Such a bifurcation is locally equivalent to one with the invariants $\mathcal{G}_\epsilon = \{x = \text{const}\}$ *and*

$$E_\epsilon = \{y^3 + (x - \epsilon)y + x = 0\},$$

$$C_\epsilon = \{3y^2 + x - \epsilon = 0\}.$$

Description of the *EG*-bifurcation. Both the equilibria set $E_\epsilon = \{e_\epsilon = 0\}$ and the critical set $C_\epsilon = \{c_\epsilon = 0\}$ are smooth curves and, considered separately, they do not bifurcate. The equilibria curve E_ϵ passes, for any value of ϵ, through the

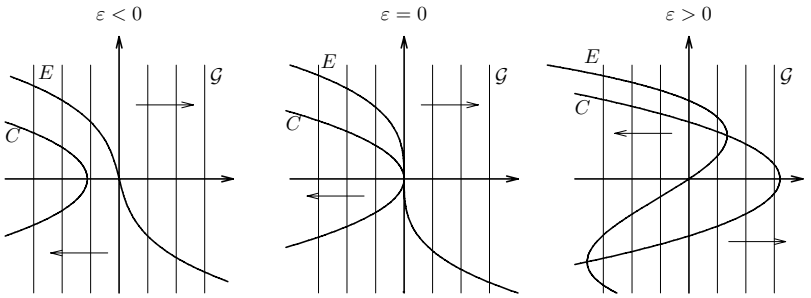

FIG. 2.5. *EG-bifurcation,* $\gamma = 1$.

origin $(0,0)$ (Figure 2.5, with the drift direction chosen so that $\gamma = 1$ in Theorem 3.3). We can equivalently write $E_\epsilon = \{x = y(\epsilon - y^2)(y+1)^{-1}\}$. Thus, the curve E_ϵ intersects each curve $\{x = c = \text{const}\}$ of $\mathcal{G}_\epsilon$ at zeros of the function $f(y) = y(\epsilon - y^2)(y+1)^{-1} - c$, i.e., it intersects it once if $\epsilon \leq 0$ and three times if $\epsilon > 0$ (for $x = c$ small enough).

Observe that the pair (E_ϵ, C_ϵ) also has a bifurcation. Eliminating x from the equations for E_ϵ and C_ϵ we get $2y^3 + 3y^2 = \epsilon$. For small y, the function on the left behaves like $3y^2$, which gives no solutions, if $\epsilon < 0$, and two solutions, if $\epsilon > 0$. Thus, for $\epsilon < 0$, the curves E_ϵ and C_ϵ do not intersect, for $\epsilon = 0$ they just intersect at $(0,0) \in \mathbb{R}^2$ (and are tangent), for $\epsilon > 0$ they intersect at two different points close to $(0,0)$. At the points of intersection, the curve E_ϵ is tangent to the curves of $\mathcal{G}_\epsilon$. Thus the above bifurcation can be called either an $E\mathcal{G}$-bifurcation or an EC-bifurcation.

2.4. $C\mathcal{G}$-bifurcations. We will analyze families Σ for which neither of the invariants E_ϵ, C_ϵ, $\mathcal{G}_\epsilon$, considered separately, bifurcates while the pair $(C_\epsilon, \mathcal{G}_\epsilon)$ bifurcates. We will call this a *$C\mathcal{G}$-bifurcation*. For generic Σ only one such bifurcation appears.

PROPOSITION 2.6. *For a generic family Σ a local $C\mathcal{G}$-bifurcation appears at a point (p, ϵ_0) if and only if the conditions*

$$e \neq 0, \quad c = 0, \quad L_g c = 0, \quad L_g^2 c = 0, \quad L_g^3 c \neq 0, \quad dc \neq 0, \quad d(L_g c) - (L_g^4 c / 7 L_g^3 c)\, dc \neq 0$$

are fulfilled at this point and the differentials Dc and $D(L_g c)$ are linearly independent. Such a $C\mathcal{G}$-bifurcation is locally equivalent to one having $E_\epsilon = \emptyset$, $\mathcal{G}_\epsilon = \{x = \text{const}\}$, and

$$C_\epsilon = \{y^3 + (x - \epsilon)y + x = 0\}.$$

Description of the $C\mathcal{G}$-bifurcation. Here, for any ϵ the critical curve C_ϵ passes through the origin in $\mathbb{R}^2$. We can equivalently write $C_\epsilon = \{x = y(\epsilon - y^2)(y+1)^{-1}\}$. Thus, the critical curve C_ϵ intersects each curve $\{x = c = \text{const}\}$ of $\mathcal{G}_\epsilon$ at zeros of the function $f(y) = y(\epsilon - y^2)(y+1)^{-1} - c$, i.e., it intersects it once if $\epsilon \leq 0$ and three times if $\epsilon > 0$ for $x = c$ small enough (Figure 2.6, with $\theta = 1$ and with the drift direction corresponding to $a(0,0) > 0$ in Theorem 3.3).

Observe that neither of the invariants E_ϵ, C_ϵ, $\mathcal{G}_\epsilon$, considered separately, bifurcates. Since $E = \emptyset$, there is neither $E\mathcal{G}$-bifurcation nor EC-bifurcation in this case.

When considering differential bifurcations, we can give an alternative description of the above $C\mathcal{G}$-bifurcation. The critical curve $C_\epsilon = \{c_\epsilon = 0\}$ is a regular curve passing through the origin for any value of ϵ. If $\epsilon < 0$, the critical curve intersects transversally all integral curves $\{x = \text{const}\}$ of $\mathcal{G}_\epsilon$. For $\epsilon = 0$ the critical curve C_0 is tangent at $(0,0) \in \mathbb{R}^2$ to the integral curve $\{x = 0\}$ of $\mathcal{G}_0$. Finally, for $\epsilon > 0$ it becomes tangent to exactly two integral curves of $\mathcal{G}_\epsilon$ at two points close to $(0,0)$.

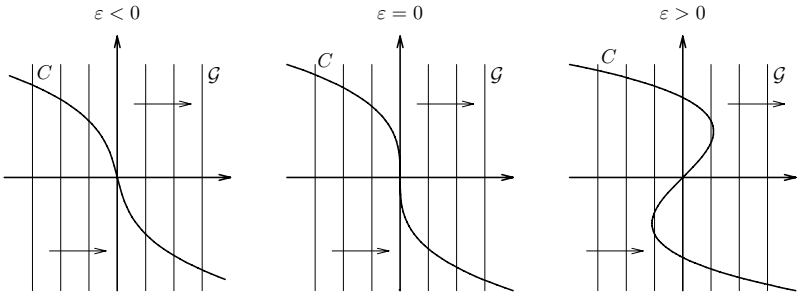

FIG. 2.6. *$C\mathcal{G}$-bifurcation, $a(0,0) > 0$.*

3. Orbital classification of 1-parameter families.

3.1. Equivalence of families. Consider a family of control systems on $X \subset \mathbb{R}^2$

$$\Sigma \ : \quad \dot{\xi} = f(\xi, \epsilon) + g(\xi, \epsilon)u, \tag{3.1}$$

where $u \in \mathbb{R}$ and $\epsilon \in I$ (open interval). Here $f(\xi, \epsilon) = f_\epsilon(\xi)$ and $g(\xi, \epsilon) = g_\epsilon(\xi)$ are families of vector fields on X, C^∞-smooth with respect to (ξ, ϵ).

Consider C^∞ local invertible transformations $X \times \mathbb{R} \times I \to X \times \mathbb{R} \times I$ of the form

$$\Gamma \ : \ \begin{array}{rcl} \tilde{\xi} & = & \phi(\xi, \epsilon) = \phi_\epsilon(\xi), \\ \tilde{u} & = & \psi(\xi, u, \epsilon) = \psi_\epsilon(\xi, u), \\ \tilde{\epsilon} & = & \eta(\epsilon), \end{array}$$

where ψ is affine with respect to u so that $u = \psi^{-1}(\xi, \tilde{u}, \epsilon) = \alpha(\xi, \epsilon) + \beta(\xi, \epsilon)\tilde{u}$. Invertibility at (ξ_0, ϵ_0) means that $d\phi_{\epsilon_0}(\xi_0)$ is of rank 2 and $\beta(\xi_0, \epsilon_0) \neq 0$, $\eta'(\epsilon_0) \neq 0$.

A *feedback transformation* $\Gamma = (\phi, \psi, \eta)$ brings Σ into $\tilde{\Sigma}$: $\dot{\tilde{\xi}} = \tilde{f}(\tilde{\xi}, \tilde{\epsilon}) + \tilde{g}(\tilde{\xi}, \tilde{\epsilon})\tilde{u}$, with $\tilde{f}_{\tilde{\epsilon}} = \tilde{f}(\cdot, \tilde{\epsilon})$ and $\tilde{g}_{\tilde{\epsilon}} = \tilde{g}(\cdot, \tilde{\epsilon})$ given by

$$\tilde{f}_{\tilde{\epsilon}} = (\phi_\epsilon)_*(f_\epsilon + \alpha_\epsilon g_\epsilon), \qquad \tilde{g}_{\tilde{\epsilon}} = (\phi_\epsilon)_*(\beta_\epsilon g_\epsilon),$$

where $\tilde{\epsilon} = \eta(\epsilon)$, $\alpha_\epsilon = \alpha(\cdot, \epsilon)$, and $\beta_\epsilon = \beta(\cdot, \epsilon)$. Throughout, for any vector field f and any diffeomorphism $\tilde{\xi} = \phi(\xi)$ we denote $(\phi_* f)(\tilde{\xi}) = d\phi(\xi) \cdot f(\xi)$, where $\xi = \phi^{-1}(\tilde{\xi})$.

An *orbital feedback transformation* $\Gamma_{orb} = (\phi, \psi, h, \eta)$ contains additionally a family of positive valued smooth functions $h_\epsilon(\xi) = h(\xi, \epsilon)$ which change the time scale of the system according to $dt/d\tau = h(\xi, \epsilon)$. Thus, by definition, Γ_{orb} transforms Σ into $\tilde{\Sigma}$ with $\tilde{f}_{\tilde{\epsilon}} = (\phi_\epsilon)_*(h_\epsilon f_\epsilon + h_\epsilon \alpha_\epsilon g_\epsilon)$ and $\tilde{g}_{\tilde{\epsilon}} = (\phi_\epsilon)_*(h_\epsilon \beta_\epsilon g_\epsilon)$. We can incorporate the action of h_ϵ on g_ϵ by choosing $\hat{\alpha}_\epsilon = h_\epsilon \alpha_\epsilon$ and $\hat{\beta}_\epsilon = h_\epsilon \beta_\epsilon$. The transformation becomes

$$\tilde{f}_{\tilde{\epsilon}} = (\phi_\epsilon)_*(h_\epsilon f_\epsilon + \hat{\alpha}_\epsilon g_\epsilon), \qquad \tilde{g}_{\tilde{\epsilon}} = (\phi_\epsilon)_*(\hat{\beta}_\epsilon g_\epsilon), \tag{3.2}$$

where $\tilde{\epsilon} = \eta(\epsilon)$. Throughout the paper we assume that the functions h_ϵ are positive valued and constant on the trajectories of g_ϵ, i.e., the derivative of h_ϵ along g_ϵ vanishes:

$$L_{g_\epsilon} h_\epsilon = 0. \tag{3.3}$$

We shall suppress the dependence on ϵ in our notation, writing the relations (3.2), (3.3) in the form $\tilde{f} = \phi_*(hf + \hat{\alpha}g)$, $\tilde{g} = \phi_*(\hat{\beta}g)$, and $L_g h = 0$.

DEFINITION 3.1. *Two families Σ and $\tilde{\Sigma}$ are called* locally orbitally feedback equivalent *(or* orbitally equivalent*) at (ξ_0, ϵ_0) and $(\tilde{\xi}_0, \tilde{e}_0)$, respectively, if there exists a local, invertible at (ξ_0, ϵ_0), C^∞-transformation $\Gamma_{orb} = (\phi, \psi, h, \eta)$, satisfying*

$(\phi,\eta)(\xi_0,\epsilon_0)=(\tilde\xi_0,\tilde\epsilon_0)$, *with* $h(\xi,\epsilon)$ *positive valued and* $L_gh=0$, *transforming* Σ *into* $\tilde\Sigma$. *If* $h\equiv 1$, *then we say that* Σ *and* $\tilde\Sigma$ *are locally feedback equivalent.*

Orbital feedback equivalence, defined by relations (3.2) and (3.3) (introduced in [J1] as "mild feedback equivalence"), allows one to get a simple classification of generic families. The equivalence does not change basic features of Σ. Namely, consider again the functions

$$e=\det(f,g),\qquad c=\det([g,f],g).$$

Replacing f and g by the orbitally equivalent pair

$$\tilde f=h\,f+\alpha\,g,\qquad \tilde g=\beta\,g\qquad\text{with}\quad L_gh=0$$

gives $[\tilde g,\tilde f]=h\beta[g,f]+\varphi g$, where $\varphi=\beta L_g(\alpha)-\alpha L_g(\beta)-hL_f(\beta)$, and so

$$\tilde e=h\beta\,e,\qquad \tilde c=h\beta^2c. \tag{3.4}$$

The following fact follows then immediately from (3.4) and from the equalities $E_\epsilon=\{p\in X\ :\ e(p,\epsilon)=0\}$ and $C_\epsilon=\{p\in X\ :\ c(p,\epsilon)=0\}$.

PROPOSITION 3.2. *If* Σ *and* $\tilde\Sigma$ *are orbitally feedback equivalent, via the transformation* $\Gamma_{orb}=(\phi,\psi,h,\eta)$, *then the ideals* (e) *and* (c) *generated by the functions* $e(\xi,\epsilon)$ *and* $c(\xi,\epsilon)$, *respectively, are transformed by the map* (ϕ,η) *(remain unchanged, if* $(\phi,\eta)=id$*). In particular, with* $\tilde\epsilon=\eta(\epsilon)$, *we have*

$$\phi_\epsilon(E_\epsilon)=\tilde E_{\tilde\epsilon},\quad \phi_\epsilon(C_\epsilon)=\tilde C_{\tilde\epsilon},\quad\text{and}\quad \phi_\epsilon(\mathcal{G}_\epsilon)=\tilde{\mathcal{G}}_{\tilde\epsilon}.$$

The above property of E, C, $\mathcal{G}$ and of the ideals (e), (c) is called *equivariance*. Thus E, C, $\mathcal{G}$ are said to be *equivariant* or, by abuse of language, *invariant* with respect to orbital feedback equivalence.

3.2. Classification theorem. Let Σ be a smooth family of systems (3.1). Consider the functions $e=\det(f,g)$ and $c=\det([g,f],g)$ depending on (ξ,ϵ). We introduce the sequence of functions of (ξ,ϵ):

$$c^0=e,\quad c^1=c,\qquad c^k=L_g^{k-1}c,\quad k\ge 2.$$

Denote by $j(c^i,c^{i+1})$ and $J(c^i,c^{i+1},c^{i+2})$ the Jacobians with respect to ξ and (ξ,ϵ),

$$j(c^i,c^{i+1})=\det\left(dc^i,dc^{i+1}\right),$$

$$J(c^i,c^{i+1},c^{i+2})=\det\left(Dc^i,Dc^{i+1},Dc^{i+2}\right),$$

where $dh=(\partial h/\partial\xi_1,\partial h/\partial\xi_2)$ and $Dh=(\partial h/\partial\xi_1,\partial h/\partial\xi_2,\partial h/\partial\epsilon)$.

The following theorem classifies generic Σ under the orbital feedback equivalence. To simplify the exposition, we denote the state of the transformed system by $\tilde\xi=(x,y)\in\mathbb{R}^2$ and its control by $\tilde u=v$. In the last column below we list codes of invariants (they are defined after the theorem) describing the equivalence class. The diagrams in Figures 3.1 and 3.2 explain the structure of the classification as well as relations between the codes and the corresponding invariant conditions expressed in terms of e, $c^1,c^2,\dots$, and their differentials.

THEOREM 3.3. *A generic family Σ, given by* (3.1)*, is locally orbitally feedback equivalent, around any point at which g does not vanish, to one of the following canonical forms at $0 \in \mathbb{R}^2$ and $\epsilon = 0$, where the code appearing in the last column characterizes the systems equivalent to the normal form:*

$$
\begin{array}{lllll}
(O) & \dot{x} = y + 1, & \dot{y} = v, & (11), \\
(E) & \dot{x} = y, & \dot{y} = v, & (01), \\
(C) & \dot{x} = \tau y^2 + 1, & \dot{y} = v, & (101), \\
(EC) & \dot{x} = y^2 + \gamma x, & \dot{y} = v, & (0_1 01), \\
(C\mathcal{G}) & \dot{x} = \delta y^3 + xy + 1, & \dot{y} = v, & (10_1 01), \\
(E_{bif}) & \dot{x} = \sigma_e y^2 + x^2 - \epsilon, & \dot{y} = v, & (\overline{0_{01}0}1), \\
(C_{bif}) & \dot{x} = \sigma_c y^3 + (x^2 - \epsilon)y + 1, & \dot{y} = v, & (1\overline{0_{01}0}1), \\
(E\mathcal{G}_{bif}) & \dot{x} = y^3 + (x - \epsilon)y + \gamma x, & \dot{y} = v, & (\overline{0_1 0_1 0}1). \\
(C\mathcal{G}_{bif}) & \dot{x} = y^4 + (\theta x - \epsilon)y^2 + xy + a(x, \epsilon), & \dot{y} = v, & (1\overline{0_1 0_1 0}1)_{mod}.
\end{array}
$$

Above a is a smooth function of (x, ϵ) satisfying $a(0,0) \neq 0$ and $\operatorname{sgn} a(0,0) = \kappa$. The integers τ, γ, δ, σ_e, σ_c, θ, and κ take values ± 1 and are orbitally feedback invariant.

The class of families (3.1)*, which are locally orbitally equivalent at (p, ϵ_0) to one of the above canonical forms, is characterized by the following conditions at (p, ϵ_0):*

$$
\text{(G1)} \qquad (c^i, c^{i+1}, c^{i+2}, c^{i+3}) \neq (0,0,0,0) \qquad \text{for} \quad i = 0, 1,
$$

$$
\text{(G2)} \qquad (c^i, c^{i+1}, c^{i+2}, dc^i) \neq (0,0,0,0) \qquad \text{for} \quad i = 0, 1,
$$

$$
\text{(G3)} \qquad (c^i, Dc^i) \neq (0,0) \qquad \text{for} \quad i = 0, 1,
$$

$$
\text{(G4)} \qquad (c^i, dc^i, \det \operatorname{hess}(c^i)) \neq (0,0,0) \qquad \text{for} \quad i = 0, 1,
$$

$$
\text{(G5)} \qquad (c^i, c^{i+1}, c^{i+2}, J(c^i, c^{i+1}, c^{i+2})) \neq (0,0,0,0) \qquad \text{for} \quad i = 0, 1,
$$

$$
\text{(G6)} \qquad (c^i, c^{i+1}, c^{i+2}, dc^{i+1}_{mod}) \neq (0,0,0,0) \qquad \text{for} \quad i = 0, 1.
$$

Above, in condition (G6)*, we use the functions $c^1_{mod} = c^1$ and $c^2_{mod} = c^2 - (c^5/7c^4)c^1$.*

The conditions (G1)–(G5) *are equivalent to the following condition:*

$$
\text{(G)} \qquad (c^i, c^{i+1}, j(c^i, c^{i+1}), J(c^i, c^{i+1}, j(c^i, c^{i+1}))) \neq (0,0,0,0) \qquad \text{for} \quad i = 0, 1.
$$

Remark 3.1. Notice that any orbital feedback transformation preserving the prenormal form $\Sigma_{pre} : \dot{x} = f_1(x, y, \epsilon)$, $\dot{y} = u$ satisfies $\tilde{x} = \phi(x, \epsilon)$. Therefore the orbital feedback classification of families Σ of control-affine systems in the plane reduces to the classification of families of systems $\dot{x} = f_1(x, v, \epsilon)$ on the line under the invertible transformations $\tilde{x} = \phi(x, \epsilon)$, $\tilde{v} = \psi(x, v, \epsilon)$, $\tilde{e} = \eta(\epsilon)$ and time rescaling $dt = h(x, \epsilon)d\tau$. The above theorem can be reformulated as local classification of such systems.

Remark 3.2. For generic families Σ, the sets $E = \{(p, \epsilon) : e(p, \epsilon) = 0\}$ and $C = \{(p, \epsilon) : c(p, \epsilon) = 0\}$ are submanifolds in $X \times I$. Their singularities of contact with the foliations $\{\epsilon = \text{const}\}$ and $\{\epsilon = \text{const}, x = \text{const}\}$ (in the notation of the above theorem) are very simple. For more degenerated families this aspect of our

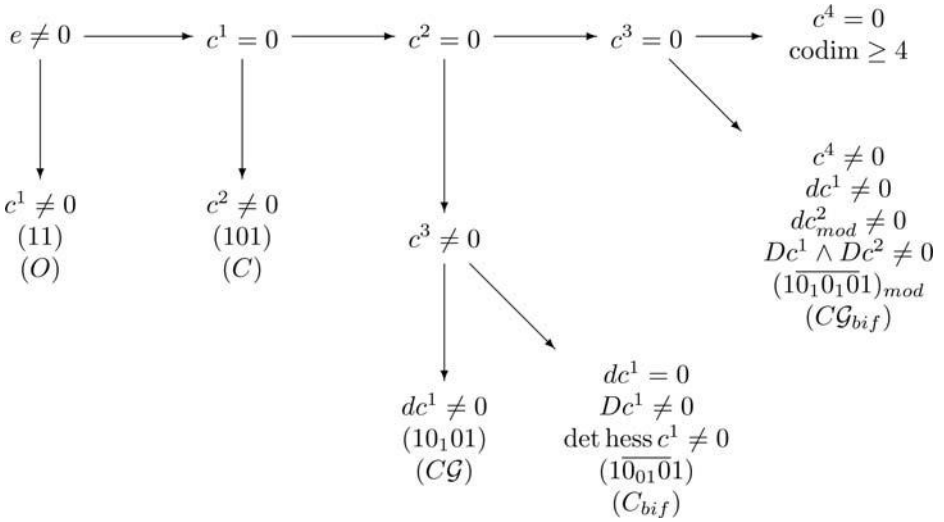

FIG. 3.1. *Bifurcation diagram out of equilibria.*

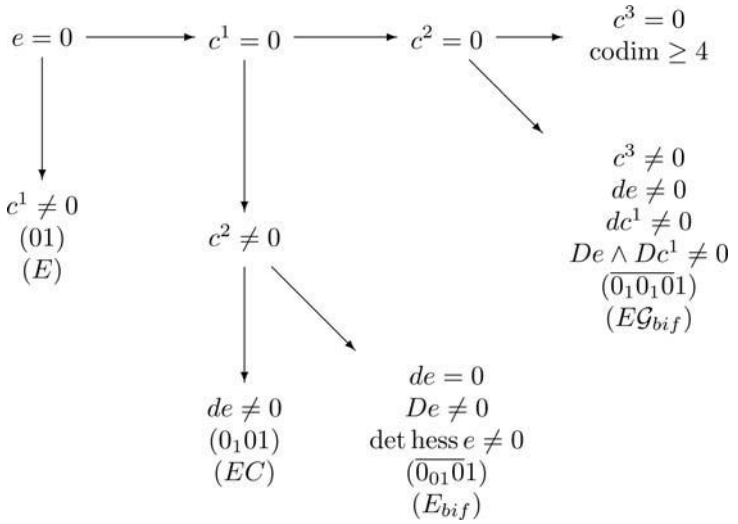

FIG. 3.2. *Bifurcation diagram at equilibria.*

problem is nontrivial. In understanding general singularities of contact of the sets E and C the results in [Go] and [Za] should be helpful.

To characterize the equivalence classes we encode our invariants (equivariants) in a compact way by introducing the following notation. We define the *code of the first level* of Σ at the point (p, ϵ_0) to be equal to $(\chi^0\ \chi^1\ \cdots)$, where $\chi^i = 0$ if $c^i(p, \epsilon_0) = 0$ and $\chi^i = 1$ if $c^i(p, \epsilon_0) \neq 0$. We will need only sequences of finite length, namely, we cut the sequence χ^i after 1 appears for the first time, for $i \geq 1$ (further χ^i are not invariant). Thus codes of the first level are of minimal length 2, of the form

$$(0 \cdots 01) \quad \text{or} \quad (10 \cdots 01).$$

Note that if a function $\varphi : X \to \mathbb{R}$ vanishes at p, then the next invariant fact about the ideal generated by φ is vanishing or not of $d\varphi$ at p. This will be encoded by 0_0 (meaning $\varphi(p) = 0$, $d\varphi(p) = 0$) and 0_1 (meaning $\varphi(p) = 0$, $d\varphi(p) \neq 0$). If φ depends also on ϵ, we still mean the differential $d\varphi$ taken with respect to $\xi \in X$, only.

We define the *code of the second level* of the family Σ, at a given point, as its code of the first level with each zero in it having the subscript 0 or 1, depending on whether the differential dc^i of the corresponding c^i vanishes. Since for each 0 which is followed by 1 in the code of the first level we have $dc^i \neq 0$ (because $L_g c^i = c^{i+1}$ does not vanish), we should always place the subscript 1. This subscript will be omitted. Thus, for example, instead of the code $(10_1 0_1 1)$ we write $(10_1 01)$ and this means that, at the given point, $e \neq 0$, $L_g c = L_g^2 c = 0$, $L_g^3 c \neq 0$, and $dc \neq 0$.

If $\varphi : X \to \mathbb{R}$ and $\varphi(p) = 0$, $d\varphi(p) = 0$, then the next invariant fact about the ideal generated by φ is whether the Hessian $\operatorname{hess}(\varphi)$ has full rank at p. We write

$$0_{01} \quad \text{if} \quad \varphi(p) = 0,\ d\varphi(p) = 0,\ \text{and}\ \det \operatorname{hess}(\varphi)(p) \neq 0,$$

$$0_{00} \quad \text{if} \quad \varphi(p) = 0,\ d\varphi(p) = 0,\ \text{and}\ \det \operatorname{hess}(\varphi)(p) = 0.$$

(The point p is replaced by (p, ϵ_0), if φ depends on ϵ.)

The *code of the third level* of the system at a given point is defined as its code of the second level, completed with the information about vanishing or not of the determinant of the Hessian. We put the subscript 01 to any of the first two or three functions in the sequence $c^0, c^1, \ldots$, if it vanishes at the given point, its differential also vanishes, and the determinant of the Hessian is nonzero. For example, the system has the code $(10_{01}01)$ if and only if, at the given point, $e \neq 0$, $c^1 = c^2 = 0$, $c^3 \neq 0$, $dc^1 = 0$, and $\det \operatorname{hess}(c) \neq 0$. The subscript 00 will not appear in our classification since it describes singularities of higher codimension.

Finally, the *complete code*, or simply the *code*, is the code of appropriate level completed with the information about linear independence of the differentials Dc^i of the functions c^i, which is marked by overlying the corresponding zeros. We add this information only in the cases where it does not follow from the basic code. For example, the code $(10_1 01)$ is complete because it follows from the code that $dc^1 \neq 0$, $L_g c^1 = 0$, and $L_g c^2 \neq 0$, which means that dc^1 and dc^2 are linearly independent and thus so are Dc^1 and Dc^2. The complete code $(\overline{0_1 0_1 0}1)$ is equivalent to the conditions $c^0 = e = 0$, $c^1 = c = 0$, $c^2 = 0$, $c^3 \neq 0$, $dc^0 \neq 0$, $dc^1 \neq 0$ and to linear independence of Dc^0, Dc^1, and Dc^2. They are equivalent to the conditions stated in Proposition 2.5 (linear independence of Dc^0, Dc^1 is equivalent to linear independence of Dc^0, Dc^1, and Dc^2, since $L_g c^0 = 0$, $L_g c^1 = 0$, and $L_g c^2 \neq 0$).

The complete code $(1\overline{0_1 0_1 0}1)$ means that, at the given point, $e \neq 0$, $c^1 = c^2 = c^3 = 0$, $c^4 \neq 0$, $dc^1 \neq 0$, $dc^2 \neq 0$, and Dc^1, Dc^2, Dc^3 are linearly independent. The condition $dc^2 \neq 0$ here is not feedback invariant; therefore in the theorem we use a modified version of this code $(1\overline{0_1 0_1 0}1)_{mod}$, which means that we replace the condition $dc^2 \neq 0$ with the condition $dc^2_{mod} = dc^2 - (c^5/7c^4)dc^1 \neq 0$ (which is orbitally feedback invariant; cf. Lemma 3.9). The set of conditions defined by $(1\overline{0_1 0_1 0}1)_{mod}$ is equivalent to the condition stated in Proposition 2.6.

We will show in section 3.3 that the following holds.

PROPOSITION 3.4. (i) *The conditions* (G1)–(G6)*, as well as* (G) *and the conditions defined by the codes listed in Theorem* 3.3*, are invariant under orbital feedback equivalence.* (ii) *The conditions* (G1)–(G5) *are equivalent to the condition* (G).

3.3. More about invariants. We will systematize the already introduced invariants and describe some new ones which appeared in the classification theorem. We define them for the system Σ given by $\dot{\xi} = f(\xi) + ug(\xi)$ and assume that $g(p) \neq 0$. (Analogous definitions are valid for the family $\dot{\xi} = f(\xi, \epsilon) + ug(\xi, \epsilon)$, with p replaced

by (p, ϵ_0) and $g(p, \epsilon_0) \neq 0$.) At nonequilibrium points it is convenient to replace the system with the 1-form ω uniquely defined by the equations (cf., e.g., [Su1])

$$\omega(g) \equiv 0, \qquad \omega(f) \equiv 1.$$

Replacing f, g by an equivalent pair $\tilde{f} = hf + \alpha g,\ \tilde{g} = \beta g$ gives new $\tilde{\omega} = h^{-1}\omega$.

The *multiplicity* of Σ at p is defined by

$$\mu(p) = \min\{k \geq 0 : (L_g^k c)(p) \neq 0\}.$$

Here and below we use the functions $e = \det(f, g)$ and $c = \det([g, f], g)$. By definition $\mu(p) = \infty$, if such k does not exist, and $\mu(p) = 0$ if $p \notin C$. At nonequilibrium points, the multiplicity μ can be equivalently defined using the 1-form ω:

$$\mu(p) = \min\{k \geq 0 : \omega(ad_g^{k+1} f)(p) \neq 0\}, \quad p \notin E.$$

If $p \in C = \{c = 0\}$ and $dc(p) \neq 0$, then, geometrically, multiplicity $\mu(p)$ is the order of tangency (plus one) of the critical curve to the trajectory of g at p.

Recall the functions $c^0 = e,\ c^1 = c$, and generally $c^k = L_g^{k-1} c$, for $k \geq 2$. At any $p \in X$ we define two sequences of ideals of function germs at p generated by $c^1, \ldots, c^k$ and, respectively, by $c^0, \ldots, c^k$:

$$I_p^k = I_p(c^1, \ldots, c^k), \quad J_p^k = I_p(c^0, c^1, \ldots, c^k).$$

At nonequilibrium points $p \notin E$, we similarly define

$$c_1 = \omega([g, f]), \quad c_2 = \omega([g, [g, f]]), \quad c_k = \omega(ad_g^k f)$$

and

$$I_{k,p} = I_p(c_1, \ldots, c_k).$$

PROPOSITION 3.5. *The ideals I_p^k, J_p^k, $I_{k,p}$ and the multiplicity $\mu(p)$ are invariant (more exactly, equivariant) under orbital feedback equivalence and $I_p^k = I_{k,p}$, if $p \notin E$.*

PROPOSITION 3.6. *If $p \notin E$ and the multiplicity $\mu(p) = \mu$ is odd, then the index*

$$\sigma_{\mu+1}(p) := \operatorname{sgn} c_{\mu+1}(p) = \operatorname{sgn} (e\, c^{\mu+1})(p)$$

is well defined and invariant under orbital feedback equivalence.

We first prove the following useful lemma (we define $I_p^0 = I_{0,p} = \{0\}$ and $c_0 = 1$).

LEMMA 3.7. *If $\tilde{f} = h\, f + \alpha\, g$ and $\tilde{g} = \beta\, g$, where $L_g h = 0$, then we have for $k \geq 1$*

$$\tilde{c}^k = h\beta^{k+1} c^k \mod I_p^{k-1}, \qquad \tilde{c}_k = \beta^k c_k \mod I_{k-1,p},$$

$$\tilde{c}^k = h\beta^{k+1} c^k + m_k h \beta^k L_g \beta\, c^{k-1}, \qquad \mod c^1, c^2, \ldots, c^{k-2},$$

$$\tilde{c}_k = \beta^k c_k + n_k \beta^{k-1} L_g \beta\, c_{k-1}, \qquad \mod c_1, c_2, \ldots, c_{k-2},$$

where $m_1 = 0$, $m_k = m_{k-1} + k$, and $n_1 = 0$, $n_k = n_{k-1} + k - 1$, $k \geq 2$.

Proof. Recall that (formula (3.4)) replacing f and g by the orbitally equivalent pair $\tilde{f} = h\, f + \alpha\, g$, $\tilde{g} = \beta\, g$, gives $\tilde{c} = h\beta^2 c$, $\tilde{e} = h\beta\, e$, and $\tilde{\omega} = h^{-1}\omega$.

We will use induction with respect to k. For $k=1$ we have $\tilde{c}^1 = \tilde{c} = h\beta^2 c = h\beta^2 c^1$. Let the first relation hold for $k-1$. Since $\tilde{c}^k = L_{\tilde{g}}\tilde{c}^{k-1}$ and $\tilde{c}^{k-1} = h\beta^k c^{k-1} + \sum_{i\le k-2}\varphi_i c^i$ (the induction assumption), we get from the Leibniz formula $L_g(\varphi\psi) = \psi L_g(\varphi) + \varphi L_g\psi$ that $L_{\tilde{g}}\tilde{c}^{k-1} = h\beta^k L_{\tilde{g}} c^{k-1} = h\beta^{k+1}c^k \mod I_p^{k-1}$. This implies the first formula. The third formula can be proved analogously.

The second and the fourth formulas follow from $ad_{\tilde{g}}\tilde{f} = h\beta\, ad_g f \mod g$ and the relation

$$ad_{\tilde{g}}^k \tilde{f} = h\beta^k ad_g^k f + n_k h\beta^{k-1} L_g\beta\, ad_g^{k-1} f \mod g,\ ad_g f, \dots,\ ad_g^{k-2} f,$$

which can be easily proved by induction, for $k \ge 2$, using the general property of Lie bracket $[\varphi f, \psi g] = \varphi\psi[f,g] + \varphi(L_f\psi)\, g - \psi(L_g\varphi)\, f$ and the property $L_g h = 0$. □

Proof of Proposition 3.5. It is enough to show invariance when the state transformation is $\phi = id$. Then the equality of ideals $I_p^k = \tilde{I}_p^k$, $J_p^k = \tilde{J}_p^k$, and $I_{k,p} = \tilde{I}_{k,p}$ follows, by induction with respect to k, from the lemma and nonvanishing of h and β.

Finally, the equality $I_p^k = I_{k,p}$ follows from equivariance of both ideals and the fact that for the system in the prenormal form Σ_{pre} we have

$$c^k = \frac{\partial^k f_1}{\partial y^k}, \qquad c_k = \frac{1}{f_1}\frac{\partial^k f_1}{\partial y^k}.$$

(f_1 does not vanish at $p \notin E$.) Invariance of $\mu(p)$ is a consequence of $I_p^k = \tilde{I}_p^k$ and the fact that $\mu(p)$ is the minimal k such that I_p^k contains functions nonvanishing at p. □

Proof of Proposition 3.6. Invariance of $\operatorname{sgn} c_k(p)$ and of $\operatorname{sgn}(e\, c^k)(p)$ in Proposition 3.6 follows from the lemma, the fact that the functions in I_p^{k-1} and $I_{k-1,p}$ vanish at p, if $\mu(p) = k$, and from $\beta(p) \ne 0$, $h(p) > 0$ (note that $\tilde{e} = h\beta e$). The equality $\operatorname{sgn} c_k(p) = \operatorname{sgn}(e\, c^k)(p)$ follows from the formulas for c_k and c^k in the proof of Proposition 3.5, for the system Σ_{pre}, and from $e = f_1$. □

We introduce new invariants. The *signature indices* of e and c is defined by

$$\sigma_e(p) = \operatorname{sgn}(\det \operatorname{hess}(e)(p)) \quad \text{if} \quad p \in E, \quad de(p) = 0,$$

$$\sigma_c(p) = \operatorname{sgn}(\det \operatorname{hess}(c)(p)) \quad \text{if} \quad p \in C, \quad dc(p) = 0.$$

The *stability index* is defined as

$$\gamma(p) = \operatorname{sgn}\lambda(p) \qquad \text{if} \quad p \in C \cap E, \quad de(p) \ne 0,$$

where λ is the eigenvalue of the uncontrollable mode of the linear part of Σ, at p.

Moreover, the following discrete invariants can be defined at nonequilibrium points of a given multiplicity (assuming, additionally, $dc(p) \ne 0$ for $\delta(p)$):

$$\tau(p) = \operatorname{sgn}(\omega(ad_g^2 f))(p) = \operatorname{sgn}(e\, L_g c)(p) = \sigma_2(p), \qquad \mu(p) = 1,$$

$$\delta(p) = -\operatorname{sgn}(\omega(ad_f^2 g)\, \omega(ad_g^3 f))(p) = \operatorname{sgn}(L_f c\, L_g^2 c)(p), \qquad \mu(p) = 2,$$

$$\kappa(p) = \operatorname{sgn}(\omega(ad_g^4 f))(p) = \operatorname{sgn}(e\, L_g^3 c)(p) = \sigma_4(p), \qquad \mu(p) = 3.$$

PROPOSITION 3.8. *All the indices τ, δ, κ, σ_e, σ_c, γ are well defined and are invariants of orbital feedback equivalence.*

Proof. Invariance of τ and κ follows from Proposition 3.6.

To show invariance of δ we take $\tilde f = h\,f+\alpha\,g$ and $\tilde g = \beta\,g$. Then $[\tilde f,\tilde g] = h\beta[f,g]+\varphi g$ and from our assumption $L_g h = 0$ we see that $[\tilde f,[\tilde f,\tilde g]] = [hf+\alpha g, h\beta[f,g]+\varphi g] = h^2\beta[f,[f,g]]+\alpha\beta h[g,[f,g]]-h\beta(L_{[f,g]}h)f \mod g, ad_f g$. Since $\mu(p)=2$ and so $p\in C$, the vectors g, $[f,g]$, and $[g,[f,g]]$ are linearly dependent at p and so $L_{[f,g]}h(p)=0$, by $L_g h = 0$ and $\omega([f,g])(p)=0$. This means that the second term in the expression for $[\tilde f,[\tilde f,\tilde g]](p)$ vanishes at p. Thus $\tilde\omega(ad^2_{\tilde f}\tilde g)(p) = (h\beta\omega(ad^2_f g))(p)$. From Lemma 3.7 we have $\tilde\omega(ad^3_{\tilde g}\tilde f)(p) = (\beta^3\omega(ad^3_g f))(p)$, which means that the factor $(h\beta^4)(p)$ appears in the expression for δ, after the transformation. This factor is positive, and thus the first formula for δ gives orbital feedback invariant. The invariance of the second formula for δ follows analogously. Equality of both formulas is easy to see for the system Σ_{pre}.

Invariance of σ_e and σ_c follows from $\det \operatorname{hess}(\varphi\psi))(p) = \varphi^2(p)\det\operatorname{hess}(\psi)(p)$, which holds if $\psi(p)=0$ and $d\psi(p)=0$.

Finally, invariance of γ is a consequence of independence of the eigenvalue λ of the feedback transformations and of the positivity of h. The proof is complete. □

For characterizing the last normal form in Theorem 3.3 and defining the invariant θ appearing there we need the condition $dc^2 \neq 0$ which, however, is not feedback invariant (by Lemma 3.7 we have $\tilde c^1 = h\beta^2 c^1$, $\tilde c^2 = h\beta^3 c^2 + 2h\beta^2 L_g\beta\, c^1$, and $d\tilde c^2|_p = h\beta^3 dc^2|_p + 2h\beta^2 L_g\beta\, dc^1|_p$, if $c^1(p)=c^2(p)=0$). Thus, we introduce modified versions of the functions c^2 and c_2:

$$c^2_{mod} = c^2 - \frac{c^5}{7c^4}c^1, \qquad c_{2\,mod} = c_2 - \frac{c_5}{10c_4}c_1.$$

They are defined at p if $c^4(p)\neq 0$ (equivalently, $c_4(p)\neq 0$) and $e(p)\neq 0$, for $c_{2\,mod}$.

LEMMA 3.9. *If $\mu(p)=3$ for Σ given by (f,g), and $\tilde f = hf+\alpha g$, $\tilde g = \beta g$, $L_g h = 0$, then*

$$d\tilde c^2_{mod}|_p = h\beta^3 dc^2_{mod}|_p, \qquad d\tilde c_{2\,mod}|_p = \beta^2 dc_{2\,mod}|_p.$$

Thus, with $\beta(p)\neq 0$, the conditions $dc^2_{mod}(p)\neq 0$ and $dc_{2\,mod}(p)\neq 0$ are invariant.

Proof. We prove only the first equality, using the third formula in Lemma 3.7. (The proof of the second equality uses the fourth formula in Lemma 3.7 and is analogous.) Denote $a = L_g\beta/\beta$. From $\mu(p)=3$ we have $c^1(p)=c^2(p)=c^3(p)=0$. Thus, by Lemma 3.7,

$$\begin{aligned}
\tilde c^2 &= h\beta^3(c^2+2ac^1),\\
\tilde c^4|_p &= h\beta^5 c^4|_p,\\
\tilde c^5|_p &= h\beta^6(c^5+14ac^4)|_p,\\
d\tilde c^1|_p &= h\beta^2 dc^1|_p,\\
d\tilde c^2|_p &= h\beta^3(dc^2+2adc^1)|_p.
\end{aligned}$$

Using also $\tilde c^1(p)=0$, we get

$$d\tilde c^2_{mod}|_p = d\tilde c^2|_p - \frac{\tilde c^5}{7\tilde c^4}d\tilde c^1|_p = h\beta^3(dc^2+2a\,dc^1)|_p - h\beta^3\frac{c^5+14ac^4}{7c^4}dc^1|_p,$$

thus $d\tilde c^2_{mod}|_p = h\beta^3(dc^2-(c^5/7c^4)dc^1)|_p = h\beta^3 dc^2_{mod}|_p$, by $c^1(p)=0$. □

If $e(p)\neq 0$, then the condition $dc^2_{mod}(p)\neq 0$ is equivalent to $(L_f c^2_{mod}, L_g c^2_{mod})|_p \neq (0,0)$. If, additionally, $\mu(p)=3$, then $c^3(p) = L_g c^2(p) = 0$ and $dc^2_{mod}(p)\neq 0$ is

equivalent to $L_f c^2_{mod}(p) \neq 0$. Similarly, $dc_{2\,mod}(p) \neq 0$ is equivalent to $L_f c_{2\,mod}(p) \neq 0$. The following definition is then correct if $\mu(p) = 3$, $e(p) \neq 0$, and $dc^2_{mod}(p) \neq 0$:

$$\theta(p) = \operatorname{sgn}(L_f c_{2\,mod})(p) = \operatorname{sgn}(e\, L_f c^2_{mod})(p).$$

PROPOSITION 3.10. *θ is invariant under orbital feedback equivalence.*

Proof. With $\tilde f = h\, f + \alpha\, g$, $\tilde g = \beta g$, we have $\tilde e = h\beta e$ and, by Lemma 3.9 and $dc^2_{mod}(g)|_p = 0$ (since $c^2(p) = c^3(p) = 0$), the expression $\tilde e\, L_{\tilde f} \tilde c^2_{mod}|_p = \tilde e\, d\tilde c^2_{mod}(\tilde f)|_p$ is equal to $h^3\beta^4 e\, dc^2_{mod}(f)|_p = h^3\beta^4 e\, L_f c^2_{mod}|_p$. Since h is positive, $\operatorname{sgn}(e\, L_f c^2_{mod})(p)$ does not change. Similarly we check that $\operatorname{sgn}(L_f c_{2\,mod})(p)$ does not change. Equality of both expressions for $\theta(p)$ can be checked directly for the prenormal form Σ_{pre}. □

To prove Proposition 3.4, note that the ideals I^k, J^k introduced earlier are well defined for the family $\Sigma:\ \dot\xi = f(\xi,\epsilon) + u g(\xi,\epsilon)$ and consist of functions of (ξ,ϵ). We denote by I^k_{p,ϵ_0} and J^k_{p,ϵ_0} the corresponding ideals of function germs at (p,ϵ_0). They have the same invariant properties as I^k_p and J^k_p.

Proof of Proposition 3.4. (i) To show invariance of conditions (G1), (G2), (G6) we reformulate them in invariant terms, using the ideals I^k_{p,ϵ_0} and J^k_{p,ϵ_0}, and use Proposition 3.5. Denote by C^∞_{p,ϵ_0} the ideal of all smooth function germs at (p,ϵ_0). From the definition of the ideals I^k_{p,ϵ_0} and J^k_{p,ϵ_0} we easily see that these conditions are equivalent to

$$\text{(G1)} \qquad J^3_{p,\epsilon_0} = C^\infty_{p,\epsilon_0}, \qquad I^4_{p,\epsilon_0} = C^\infty_{p,\epsilon_0},$$

$$\text{(G2)} \qquad J^2_{p,\epsilon_0} \neq C^\infty_{p,\epsilon_0} \Longrightarrow dc^0(p,\epsilon_0) \neq 0, \qquad I^3_{p,\epsilon_0} \neq C^\infty_{p,\epsilon_0} \Longrightarrow dc^1(p,\epsilon_0) \neq 0,$$

$$\text{(G3)} \qquad J^2_{p,\epsilon_0} \neq C^\infty_{p,\epsilon_0} \Longrightarrow dc^1(p,\epsilon_0) \neq 0, \qquad I^3_{p,\epsilon_0} \neq C^\infty_{p,\epsilon_0} \Longrightarrow dc^2_{mod}(p,\epsilon_0) \neq 0,$$

and, thus, they are invariant. (In the last implication we use the invariance of the condition $dc^2_{mod}(p,\epsilon_0) \neq 0$, implied by Lemma 3.9.) Invariance of each of the conditions (G3) and (G4) is a consequence of the fact that the ideals generated by c^i, $i = 0$, 1, are invariant. Invariance of (G5) follows from the invariance of the ideals J^2_{p,ϵ_0} and I^3_{p,ϵ_0}. Invariance of the ideal generated by c^i and c^{i+1} implies invariance of (G).

Finally, invariance of the conditions defined by each of the codes listed in Theorem 3.3 is easy to show using Proposition 3.5 and Lemma 3.7. In the case of the code $(1\overline{0_1 0_1 0}1)_{mod}$, the condition $dc^2_{mod}(p,\epsilon_0) \neq 0$ is invariant by Lemma 3.9.

(ii) Throughout the proof all functions are assumed to be evaluated at (p,ϵ_0). The symbol $*$ stands for nonzero numbers. For a function $h = h(x,y,\epsilon)$ we will denote its partial derivatives by h_x, h_y, h_ϵ. We assume Σ in the prenormal form Σ_{pre}, then $c^{i+1} = c^i_y$, $i \geq 0$.

(G1)–(G5) $\Longrightarrow$ (G). Assume that (G1)–(G5) hold but (G) does not hold, that is, for $i = 0$ or 1,

$$(c^i, c^{i+1}, j, J(c^i, c^{i+1}, j)) = (0,0,0,0), \quad \text{where} \quad j = j(c^i, c^{i+1}) = c^i_x c^{i+1}_y - c^i_y c^{i+1}_x.$$

We have $c^i = 0$, $c^i_y = c^{i+1} = 0$ and $j = c^i_x \cdot c^{i+1}_y = 0$. In the subcase $c^i_x = 0$, we have $dc^i = 0$, $j_y = 0$, $j_x = \operatorname{hess}(c^i)$, and then $J(c^i, c^{i+1}, j) = c^i_\epsilon \cdot c^{i+2} \cdot \operatorname{hess}(c^i) = 0$. Thus either (G2) or (G3) or (G4) is violated. In the subcase $c^{i+1}_y = c^{i+2} = 0$ we have $j_y = c^i_x c^{i+2}_y = c^i_x c^{i+3}$ and $J(c^i, c^{i+1}, j) = -(c^i_x \cdot c^{i+1}_\epsilon - c^{i+1}_x \cdot c^i_\epsilon) \cdot c^i_x \cdot c^{i+3} = 0$. Thus either (G1) or (G2) or (G5) is violated.

(G) $\Longrightarrow$ (G1)–(G5). Note that if $j(c^i, c^{i+1}) \neq 0$, then we have $dc^i \neq 0 \neq dc^{i+1}$ and $(c^{i+1}, c^{i+2}) = (c^i_y, c^{i+1}_y) \neq (0,0)$. Thus, if (G) holds for $i = 0$ or 1, with $(c^i, c^{i+1}, j(c^i, c^{i+1})) \neq (0,0,0)$, then it is easy to see that (G1)–(G5) hold for i. So we can assume that, for $i = 0$ or 1,

$$(c^i, c^{i+1}, j(c^i, c^{i+1}), J(c^i, c^{i+1}, j(c^i, c^{i+1}))) = (0,0,0,*).$$

We have $c^i_y = c^{i+1} = 0$ and thus $j(c^i, c^{i+1}) = c^i_x \cdot c^{i+1}_y = 0$. In the subcase $c^i_x = 0$, we have $J(c^i, c^{i+1}, j(c^i, c^{i+1})) = c^i_\epsilon \cdot c^{i+1}_y \cdot \operatorname{hess}(c^i) \neq 0$, in particular, $c^{i+1}_y = c^{i+2} \neq 0$. It follows that (G1)–(G5) hold for i. In the subcase $c^{i+1}_y = c^i_{yy} = 0$ we have $J(c^i, c^{i+1}, j(c^i, c^{i+1})) = -(c^i_x \cdot c^{i+1}_\epsilon - c^{i+1}_x \cdot c^i_\epsilon) \cdot c^i_x \cdot c^{i+2}_y \neq 0$, in particular, $c^{i+2}_y = c^{i+3} \neq 0$. It follows that (G1)–(G5) hold for i. □

4. Main proofs. In this section we will prove our main results, Theorems 1.1 and 3.3. We will also prove Propositions 2.3, 2.4, 2.5, and 2.6. When proving these results we will use the following corollary of the Mather theorem on universal unfoldings (cf., e.g., Theorem 14.8 in [BL] or Chapters IV and XI in [Ma]).

THEOREM 4.1 (Mather theorem). *Let $\varphi = \varphi(z, w)$ be a C^∞-function from a neighborhood of $(0,0) \in \mathbb{R} \times \mathbb{R}^p$ into $\mathbb{R}$. Assume that $k \geq 2$ and*

$$\frac{\partial^i \varphi}{\partial z^i}(0,0) = 0$$

for $1 \leq i \leq k-1$ and

$$\frac{\partial^k \varphi}{\partial z^k}(0,0) \neq 0.$$

Then there exists a local transformation $z = \psi(\bar{z}, w)$ invertible with respect to $\bar{z}$, such that

$$\varphi(\psi(\bar{z}, w), w) = \sigma \bar{z}^k + \sum_{i=0}^{k-2} a_i(w) \bar{z}^i,$$

where $\sigma = 1$ if k is odd, $\sigma = \pm 1$ if k is even, and $a_i(0) = 0$ for $1 \leq i \leq k-2$.

We consider points where $g(p, \epsilon) \neq 0$; thus we assume Σ in the prenormal form

$$\Sigma_{pre}: \quad \dot{x} = f_1(x, y, \epsilon), \quad \dot{y} = u.$$

The proof of the first part of Theorem 3.3 will be based on the following lemma.

LEMMA 4.2. *If Σ has finite multiplicity $\mu = k - 1 \geq 1$ at $(0,0) \in \mathbb{R}^2 \times \mathbb{R}$, then it is locally feedback equivalent to*

$$\Sigma_{\epsilon\, spe}: \quad \dot{x} = y^k + \sum_{i=0}^{k-2} a_i(x, \epsilon) y^i, \quad \dot{y} = u,$$

where $a_i(x, \epsilon)$ are smooth functions and $a_1(0,0) = \cdots = a_{k-2}(0,0) = 0$. Moreover, the orbital feedback transformation $\Gamma_\epsilon = (\phi, \psi, \eta, h)$ of the form

$$\tilde{x} = \phi(x, \epsilon), \quad \tilde{y} = \bar{\psi}(x, \epsilon) y, \quad \tilde{\epsilon} = \eta(\epsilon), \quad h = h(x, \epsilon)$$

satisfying $h\,(\partial\phi/\partial x)^{-1} \bar{\psi}^k = 1$, $h(x, \epsilon) > 0$, transforms $\tilde{\Sigma}_{\tilde{\epsilon}\, spe}$ into $\Sigma_{\epsilon\, spe}$ with

$$\text{(TF)} \qquad a_i = \bar{h}\, \bar{\psi}^i\, \tilde{a}_i(\phi, \eta), \qquad i = 0, \ldots, k-2,$$

where $\bar{h} = h\,(\partial\phi/\partial x)^{-1}$.

Further normalization of the special normal form $\Sigma_{\epsilon\, spe}$ in Lemma 4.2 to the normal forms in Theorem 3.3 will be done case by case, using the transformation formula (TF) in the lemma.

The proof of the second part of Theorem 3.3 follows from two lemmas.

LEMMA 4.3. *Any 1-parameter family Σ of systems which satisfies the conditions* (G1)–(G6) *of Theorem* 3.3 *at a point (ξ, ϵ) has, at this point, one of the nine codes of invariants listed in this theorem.*

LEMMA 4.4. *Conditions* (G1), (G2), ..., (G6) *are generic. More precisely, the set of 1-parameter families of pairs (f, g) of vector fields satisfying the conditions* (G1)–(G6) *in Theorem* 3.3, *at every point (ξ, ϵ) where $g(\xi, \epsilon) \neq 0$, is a countable intersection of open and dense subsets in the C^∞ Whitney topology of the space of pairs (f, g) defined on $X \times I$ (in particular, it is dense).*

Proof of Lemma 4.2. Finite multiplicity at $(0, 0)$ implies that $g(0, 0) \neq 0$. Thus, we can bring Σ to the prenormal form $\dot{x} = f_1(x, y, \epsilon)$, $\dot{y} = u$. The fact that multiplicity is equal to $\mu = k - 1$ is equivalent to

$$\frac{\partial^k f_1}{\partial y^k}(0, 0, 0) \neq 0, \qquad \frac{\partial^i f_1}{\partial y^i}(0, 0, 0) = 0, \qquad i = 1, \ldots, k-1$$

(cf. section 3.3). Using Theorem 4.1 for the function $\varphi = f_1$, with $z = y$, $w = (x, \epsilon)$, we find an invertible with respect to $\tilde{y}$ transformation $y = \psi(x, \tilde{y}, e)$ which brings the function $f_1 = f_1(x, y, \epsilon)$ into the polynomial form, with respect to $\tilde{y}$. This transformation applied to $\Sigma_{\epsilon\, pre}$ gives $\tilde{\Sigma}_\epsilon$ of the form $\dot{x} = \sigma\tilde{y}^k + \sum_{0 \leq i \leq k-2} a_i \tilde{y}^i$, $\dot{\tilde{y}} = (\partial\psi/\partial y)^{-1} u$. Since $\partial\psi/\partial y$ does not vanish (by invertibility of ψ), we can define new $\tilde{u} = (\partial\psi/\partial y)^{-1} u$. If $\sigma = -1$, then we additionally change $x \mapsto -x$ and obtain the system equations in the form $\Sigma_{\epsilon\, spe}$. □

Proof of Lemma 4.3. We fix a point of consideration $(\xi, \epsilon) = (p, \epsilon_0)$ (all equalities will be meant at this point, only). Condition (G1) says that there cannot be more then three consecutive zeros in a code (of the first level) at (p, ϵ_0) of a family Σ which satisfies condition (G1). Thus the codes of the first level are (11), (01), (101), (001), (1001), (0001), and (10001). We will call the number of zeros in the code of the first level "deficiency of the code." Thus, (G1) admits codes of deficiency 0, 1, 2 and 3. Below we determine the corresponding complete codes admitted by (G1)–(G6).

The possible codes of the second level are (11), (01), (101) (deficiency 0 or 1), $(0_1 01)$, $(0_0 01)$, $(1_0 1_1 01)$, $(1_0 0_0 01)$ (deficiency 2), and the codes of deficiency 3: $(0_1 0_1 01)$, $(0_1 0_0 01)$, $(0_0 0_1 01)$, $(0_0 0_0 01)$, $(1_0 1_1 01)$, $(1_0 1_0 0_0 01)$, $(1_0 0_0 1_1 01)$, and $(1_0 0_0 0_0 01)$. Note that the codes of deficiency 0 and 1 are complete.

For the codes $(0_0 01)$ and $(1_0 0_0 01)$ of deficiency 2 we apply condition (G4), which says that if c^i and dc^i vanish, then we have $\det \operatorname{hess}(c^i) \neq 0$ This gives the codes $(0_{01} 01)$, $(1_0 1_{01} 01)$ of level 3. Thus the codes of level 3, with deficiency 2, which are admissible are $(0_1 01)$, $(1_0 1_1 01)$, $(0_{01} 01)$, and $(1_0 1_{01} 01)$. Condition (G3) implies that if c^i and dc^i vanish, we have $\frac{\partial c^i}{\partial \epsilon} \neq 0$. Thus, among codes of deficiency 2, the complete admissible codes are $(0_1 01)$, $(1_0 1_1 01)$, $(\overline{0_{01}} 01)$ and $(1_0 \overline{1_{01}} 01)$ (by $dc^i = 0$ and $c^{i+2} \neq 0$, the conditions $\frac{\partial c^i}{\partial \epsilon} \neq 0$, and "$Dc^i$, Dc^{i+1} linearly independent", are equivalent).

Condition (G2) implies that if there are three zeros in the code of first level, i.e., $(c^i, c^{i+1}, c^{i+2}) = (0, 0, 0)$, then $dc^i \neq 0$. Thus all the codes of deficiency 3 satisfying condition (G2) have the subscript 1 at the first zero. Similarly, condition (G6) implies that if $(c^i, c^{i+1}, c^{i+2}) = (0, 0, 0)$, then $dc^{i+1} \neq 0$ ($dc^2_{mod} \neq 0$, if $i = 1$). Thus, among all possible codes of the second level, of deficiency 3, only the codes $(0_1 0_1 01)$ and $(1_0 1_0 1_1 01)_{mod}$ are admitted by conditions (G1), (G2), and (G6).

Finally, condition (G5) says that for codes of deficiency 3, the Jacobian is nonzero. Thus, the admissible complete codes of deficiency 3 are $(\overline{0_1 0_1 0}1)$ and $(1\overline{0_1 0_1 0}1)_{mod}$. In this way we conclude that the codes characterized by conditions (G1)–(G6) are (11), (01), (101), $(0_1 01)$, $(10_1 01)$, $(\overline{0_{01}0}1)$, $(1\overline{0_{01}0}1)$, $(\overline{0_1 0_1 0}1)$, and $(1\overline{0_1 0_1 0}1)_{mod}$. □

Proof of Lemma 4.4. We shall use the Thom transversality theorem (cf. [Hi, Chapter 3, Theorem 2.8]). Consider the space $J^k\Sigma$ of k-jets of pairs of families of vector fields (f, g) defined on $X \times I$. Let $S_1, \ldots, S_N$ be a family of submanifolds in $J^k\Sigma$ and $\operatorname{codim} S_i > \dim(X \times I) = 3$. Thom's theorem says, in particular, that the set of pairs (f, g) of families of vector fields, whose k-jet extensions do not intersect the submanifolds $S_1, \ldots, S_N$, is a countable intersection of open and dense subsets in the space of C^∞ pairs (f, g), with the C^∞ Whitney topology. Thus, it is enough to show that the set of k-jets of (f, g) which do not satisfy one of the conditions (G1)–(G6) consists of a finite number of submanifolds of codimension not less then 4.

Proposition 3.4 says that each of the conditions (G1)–(G6) is orbitally feedback invariant. Thus, it is enough to consider the 5-jets of (f, g) for the system in prenormal form Σ_{pre} for which $g = \partial/\partial y$, $f = f_1\partial/\partial x$, and

$$c^i = \frac{\partial^i f_1}{\partial y^i}.$$

Condition (G1) is not satisfied at some point if either $f_1 = 0$, $\partial f_1/\partial y = 0$, $\partial^2 f_1/\partial y^2 = 0$, and $\partial^3 f_1/\partial y^3 = 0$, or $\partial f_1/\partial y = 0$, $\partial^2 f_1/\partial y^2 = 0$, $\partial^3 f_1/\partial y^3 = 0$, and $\partial^4 f_1/\partial^4 y = 0$. Clearly, both conditions define submanifolds in $J^4\Sigma$ of codimension 4.

Condition (G2) is violated at some point if $f_1 = 0$, $\partial f_1/\partial y = 0$, $\partial^2 f_1/\partial y^2 = 0$, and $\partial f_1/\partial x = 0$, or $\partial f_1/\partial y = 0$, $\partial^2 f_1/\partial y^2 = 0$, $\partial^3 f_1/\partial y^3 = 0$, and $\partial^2 f_1/\partial x \partial y = 0$. Again, both conditions define submanifolds in $J^4\Sigma$ of codimension 4. Similarly negation of condition (G3) defines two submanifolds in $J^4\Sigma$ of codimension 4.

Negation of condition (G6) gives two submanifolds of codimension 4 in $J^5\Sigma$: $f_1 = 0$, $\partial f_1/\partial y = 0$, $\partial^2 f_1/\partial y^2 = 0$, $\partial^2 f_1/\partial y \partial x = 0$, and $\partial f_1/\partial y = 0$, $\partial^2 f_1/\partial y^2 = 0$, $\partial^3 f_1/\partial y^3 = 0$, $\partial^3 f_1/\partial y^2 \partial x - (f_1^{(5)}/7f_1^{(4)})\partial^2 f_1/\partial y \partial x = 0$, $f_1^{(4)} \neq 0$, where $f_1^{(i)}$ is the ith partial derivative of f_1 with respect to y. ($f_1^{(4)} \neq 0$ is implied by (G1).)

Negation of condition (G4) means $c^i = 0$, $dc^i = 0$, $\det \operatorname{hess}(c^i) = 0$ (for each $i = 0, 1$), where $c^0 = f_1$ and $c^1 = \partial f_1/\partial y$. The corresponding set in $J^4\Sigma$ is, for each $i = 0, 1$, the union of two submanifolds $c^i = 0$, $dc^i = 0$, $\operatorname{hess}(c^i) = 0$ and $c^i = 0$, $dc^i = 0$, $\operatorname{rank} \operatorname{hess}(c^i) = 1$, in the space of 2-jets of functions c^i (and so in $J^4\Sigma$). The first submanifold is given by 6 independent equations, so it is of codimension 6, and the second is given by 4 independent equations (it has codimension 4). Here we use the fact that the set of symmetric 2×2 matrices of rank 1 is a codimension 1 submanifold in the space of all symmetric 2×2 matrices.

Similarly, the negation of condition (G5) defines the set $c^i = 0$, $c^{i+1} = 0$, $c^{i+2} = 0$, $J(c^i, c^{i+1}, c^{i+2}) = 0$, for each $i = 0, 1$. Since, for the prenormal form, $c^{i+1} = \partial c^i/\partial y$ and $c^{i+2} = \partial^2 c^i/\partial y^2$, it follows that the Jacobian matrix has two zero elements and vanishing of the Jacobian is equivalent to one of the conditions $\partial^3 c^i/\partial y^3 = 0$ (which defines a submanifold S_1 of codimension 4) or $\det A = 0$, where A is the 2×2 matrix with entries $(\partial c^i/\partial x, \partial c^i/\partial \epsilon)$ in the first row and $(\partial^2 c^i/\partial y \partial x, \partial^2 c^i/\partial y \partial \epsilon)$ in the second row. Again, the set of 2×2 matrices with determinant zero consists of matrices of rank 1, which form a submanifold of codimension 1 in the set of all 2×2 matrices, and of the zero matrix (submanifold of codimension 4). Altogether, this means that negative of condition (G5) gives three submanifolds (for each $i = (0, 1)$) in $J^4\Sigma$: S_2 of codimensions $3 + 1 = 4$ and S_3 of codimension $3 + 4 = 7$, and the third one S_1, of codimension 4, which was defined earlier. This completes the proof. □

Proof of Theorem 3.3. From Lemma 4.4 it follows that the class of systems Σ characterized by the conditions (G1)–(G6), satisfied at every (p, ϵ), where $g(p, \epsilon) \neq 0$, is generic. Lemma 4.3 implies that, at every such (p, ϵ), the system satisfying (G1)–(G6) fulfils exactly one of the conditions defined by the codes listed in the first part of the theorem. It is easy to check that for any of the nine normal forms listed in the theorem the corresponding conditions defined by the codes are satisfied. Moreover, they are invariant under orbital feedback equivalence (Proposition 3.4). Thus the conditions defined by the codes are necessary for equivalence of Σ to a given canonical form.

In the remaining part of the proof we will show their sufficiency. We will call Σ generic if it satisfies (G1)–(G6). Consider a generic Σ around (p, ϵ_0). Without loosing generality we can choose $(p, \epsilon_0) = (0, 0)$. Since in each code (of the first level) in Theorem 3.3 we have at most three 0, followed by 1, in each case the multiplicity μ is finite and equal to 0, 1, 2, or 3. We shall proceed in order of increasing multiplicity.

$\boldsymbol{\mu = 0}$. This appears in the codes (11) and (01). We first bring the system to the prenormal form $\dot{x} = f_1(x, y, \epsilon)$, $\dot{y} = u$. For both codes (11) and (01), the 1 at the second place means that $c(0, 0) = \partial f_1/\partial y(0, 0, 0) \neq 0$. Thus we can choose the new coordinate $\tilde{y} = f_1(x, y, \epsilon) - f_1(0, 0, 0)$ and applying a feedback transformation $u \to \tilde{u} = \psi(x, y, u)$ we bring the system to the form $\dot{x} = y + a$, $\dot{y} = u$, where $a = f_1(0, 0, 0) = e(0, 0, 0)$. In the case of the code (01) we have $a = e(0, 0, 0) = 0$, that is, we get the canonical form (E). In the case (11) we have $a \neq 0$. Changing x, y for x/a and y/a gives the system equation $\dot{x} = y + 1$, i.e., the canonical form (O).

When the multiplicity is $\mu = 1$, 2, or 3 we can apply Lemma 4.2 and bring Σ to the special normal form $\Sigma_{\epsilon\, spe}$. Its further simplification will be done case by case using the transformation formula (TF) in Lemma 4.2. We will write only the first equation of the system, the second being always $\dot{y} = u$, after a suitable feedback modification.

$\boldsymbol{\mu = 1}$. We have $\mu = 1$ in the codes (101), $(0_1 01)$, $(\overline{0_{01}0}1)$. The special normal form in Lemma 4.2 is

$$\dot{x} = y^2 + a_0(x, \epsilon).$$

In the case of the code (101) we have e nonvanishing and so $a_0(0, 0) \neq 0$. We can choose the new coordinate $\tilde{x} = \phi(x, \epsilon) = \int_0^x 1/a_0(s, \epsilon) ds$, then a_0 becomes 1, i.e., the first system equation becomes $\dot{\tilde{x}} = y^2/a_0(x, \epsilon) + 1$. Choosing $\tau = \operatorname{sgn} a_0(0, 0)$ and $\tilde{y} = y\sqrt{\tau/a_0(x, \epsilon)}$ we bring the system to the canonical form (C): $\dot{x} = \tau y^2 + 1$.

In the case $(0_1 01)$ we have $a_0(0, 0) = 0$ and $\partial a_0/\partial x(0, 0) \neq 0$. Thus, we can choose as the new coordinate $\tilde{x} = \phi(x, \epsilon) = a_0(x, \epsilon)$ and change the time scale by $h = \pm(\partial\phi/\partial x)^{-1}$, with h positive. Then the first system equation becomes $\dot{x} = \pm y^2 \pm x$. Changing possibly x for $-x$ we get the canonical form (EC): $\dot{x} = y^2 \pm x$.

The code $(\overline{0_{01}0}1)$ implies $a_0(0, 0) = 0$, $da_0(0, 0) = 0$, and $\partial^2 a_0/\partial x^2(0, 0) \neq 0$. Applying, e.g., Theorem 4.1, we see that we can change the coordinate x for $\tilde{x} = \phi(x, \epsilon)$ so that, taking also $h = \pm(\partial\phi/\partial x)^{-1}$, we get the new coefficient a_0 in the form $a_0 = \pm x^2 + k(\epsilon)$, where k is a smooth function. Changing, if necessary, x for $-x$ and $k(\epsilon)$ for $-k(\epsilon)$ we bring the system to the form $\dot{x} = \pm y^2 + x^2 + k(\epsilon)$. Linear independence of De and Dc, implied by the code $(\overline{0_{01}0}1)$, gives $(\partial k/\partial\epsilon)(0) \neq 0$ and thus replacing $k(\epsilon)$ with ϵ brings the system to the canonical form (E_{bif}): $\dot{x} = \pm y^2 + x^2 + \epsilon$.

$\boldsymbol{\mu = 2}$. This concerns the codes $(10_1 01)$, $(1\overline{0_{01}0}1)$, and $(\overline{0_1 0_1 0}1)$. We will treat the first two cases together. They have the code of the first level (1001) so, in the

special normal form $\Sigma_{\epsilon\, spe}$ in Lemma 4.2, we have the first system equation

$$\dot{x} = y^3 + a_1(x,\epsilon)y + a_0(x,\epsilon)$$

and $a := e(0,0,0) = a_0(0,0) \neq 0$. We change the time scale by $h = a_0^{-1}\operatorname{sgn} a$ to get the new $a_0 = \pm 1$ and then change y for $\tilde{y} = y\,h^{1/3}$. We obtain the first system equation $\dot{x} = y^3 + a_1(x,\epsilon)y \pm 1$ (with a_1 changed). It remains to normalize a_1.

In the case (10_101) we have $dc(0,0,0) \neq 0$, so $\partial a_1/\partial x(0,0) \neq 0$. This allows us to introduce the new coordinate $\tilde{x} = a_1(x,\epsilon)$. Changing simultaneously the time scale with the positive valued function $h = \pm(\partial a_1/\partial x)^{-1}$ we get the system $\dot{x} = \pm y^3 \pm xy \pm 1$. Changing possibly x for $-x$ we get the last term $a_0 = 1$. Finally, replacing if necessary y by $-y$, we obtain $a_1 = x$ and the desired canonical form (C$\mathcal{G}$): $\dot{x} = \pm y^3 + xy + 1$.

In the case of the code $(1\overline{0_{01}0}1)$ we have $dc(0,0,0) = 0$ and $\det \operatorname{hess}(c) \neq 0$. Since in this case $c = 3y^2 + a_1(x,\epsilon)$, we have $\partial a_1/\partial x(0,0) = 0$ and $\partial^2 a_1/\partial x^2(0,0) \neq 0$. Applying, e.g., Theorem 4.1 we see that we can change the coordinate x for $\tilde{x} = \phi(x,\epsilon)$ so that the function a_1 becomes $a_1 = x^2 + k(\epsilon)$. Changing simultaneously the time scale with the function $h = \pm(\partial\phi/\partial x)^{-1}$ we bring the system to the form $\dot{x} = \pm y^3 \pm (x^2 \pm k(\epsilon))y \pm 1$. Linear independence of Dc^1 and Dc^2, implied by the code $(1\overline{0_{01}0}1)$, gives $\partial k/\partial\epsilon(0) \neq 0$. Thus, we can replace $\pm k(\epsilon)$ with new ϵ, which gives $\dot{x} = \pm y^3 \pm (x^2 - \epsilon)y \pm 1$. Finally, changing possibly x for $-x$, and y for $-y$ brings the system to the canonical form (C_{bif}): $\dot{x} = \pm y^3 + (x^2 - \epsilon)y + 1$.

The last two cases, with the codes $(\overline{0_10_10}1)$ (where $\mu = 2$) and $(1\overline{0_10_10}1)_{mod}$ (where $\mu = 3$), are more complicated and will be treated together.

The difficulty in reaching the canonical form is reduced to the following lemma (whose proof is given below after completing the proof of Theorem 3.3) on equivalence of ratios of smooth 1-parameter families of functions. For $\varphi = \varphi(x,y)$ denote $\varphi'_x = \partial\varphi/\partial x$ and $\nabla\varphi = (\partial\varphi/\partial x, \partial\varphi/\partial y)$.

LEMMA 4.5. *Let $A(x,y)$ and $B(x,y)$ be families of smooth functions defined for (x,y) in a neighborhood of $(0,0) \in \mathbb{R}^2$ and assume that* (i) *$A'_x(0,0) \neq 0$ and $B'_x(0,0) \neq 0$;* (ii) *$\nabla A(0,0)$ and $\nabla B(0,0)$ are linearly independent. Then there is a smooth, local, invertible transformation $(\tilde{x},\tilde{y}) = \chi(x,y)$ of the form $\tilde{x} = \phi(x,y)$, $\tilde{y} = \eta(y)$, with $\chi(0,0) = (0,0)$, such that*

$$\frac{A^3}{B^2} \circ \chi(x,y) = \frac{(x-y)^3}{x^2}.$$

We continue the proof of Theorem 3.3. Consider a family Σ with one of the codes $(\overline{0_10_10}1)$ and $(1\overline{0_10_10}1)_{mod}$. We transform the system to the special normal form $\Sigma_{\epsilon\, spe}$ in Lemma 4.2, where $k = 3$ and $k = 4$, respectively. Then, bringing the system to the corresponding canonical form will be done in two steps.

Step 1. We transform x and ϵ so that the new coefficients of the systems

$$\dot{x} = y^3 + Ay + B, \qquad \dot{y} = u, \qquad \text{and}$$
$$\dot{x} = y^4 + Ay^2 + By + a_0, \quad \dot{y} = u,$$

satisfy the condition

$$A^3B^{-2} = (x-\epsilon)^3x^{-2},$$

where A, B, and a_0 are functions of (x,ϵ). This is possible by Lemma 4.5 (where ϵ is changed for y). Indeed, it follows from the conditions defined by the codes $(\overline{0_10_10}1)$

and $(1\overline{0_1 0_1 0}1)_{mod}$ that the functions $A(x,\epsilon)$ and $B(x,\epsilon)$ satisfy the assumptions of the lemma, with y replaced by ϵ. Applying the transformation χ of the lemma and an appropriate change of the time scale we obtain again the systems in the special normal forms above, with the new coefficients $A = (x-\epsilon)\bar{A}$ and $B = x\bar{B}$ satisfying the condition $A^3B^{-2} = (x-\epsilon)^3x^{-2}$, i.e., $\bar{A}^3\bar{B}^{-2} = 1$. ($\bar{A}$ and $\bar{B}$ are nonvanishing functions of (x,ϵ).)

Step 2. In the first case we define the orbital transformation

$$x = \tilde{x}, \quad y = \bar{B}^{1/3}\tilde{y}, \quad \epsilon = \tilde{\epsilon}, \quad h = \pm\bar{B}^{-1}$$

and check easily that under the condition $\bar{A}^3\bar{B}^{-2} = 1$, implying $\bar{A} = \bar{B}^{2/3}$, the system in the special form is transformed to $\dot{x} = \pm(y^3 + (x-\epsilon)y + x)$. Changing, possibly, y for $-y$ we finally come to the desired canonical form (E$\mathcal{G}_{bif}$): $\dot{x} = y^3 + (x-\epsilon)y \pm x$.

In the second case the condition $\bar{A}^3\bar{B}^{-2} = 1$, which gives $\bar{A} = \bar{B}^{2/3}$, implies that the orbital transformation $x = \tilde{x},\ y = \bar{B}^{1/3}\tilde{y},\ \epsilon = \tilde{\epsilon},\ h = \bar{B}^{-4/3}$ brings the system in the special form to the last canonical form (C$\mathcal{G}_{bif}$): $\dot{x} = y^4 + (x-\epsilon)y^2 + xy + a(x,\epsilon)$. The proof of Theorem 3.3 is complete. □

Proof of Lemma 4.5. We will reduce the problem to a special case and apply the homotopy method. By (i) we can choose new coordinate $\tilde{x} = B(x,y)$ and then assume that $B = x$. The equation $A(x,y) = 0$ has a locally unique solution $x = k(y)$, by the implicit function theorem (use condition (i)). Moreover, we can write $A(x,y) = (x-k(y))\bar{A}(x,y)$, where $\bar{A}(0,0) \neq 0$. From condition (ii) and $B = x$ it follows that $k'(0) \neq 0$, so we can take $\tilde{y} = k(y)$ as new coordinate. Then

$$\frac{A^3}{B^2} = gb, \qquad \text{where} \qquad g = \frac{(x-y)^3}{x^2} = (x-y)\left(1-\frac{y}{x}\right)^2$$

and $b(x,y) = \bar{A}^3(x,y)$, $b(0,0) > 0$. (We can assume that $\bar{A}(0,0) > 0$ since, in the contrary, we can change $x = B \mapsto -x = -B$, and $y \mapsto -y$.)

We include the functions g and $g\,b$ into the family

$$F(x,y,t) = g(x,y)\,a(x,y,t),$$

where $t \in [0,1]$ and

$$a(x,y,t) = 1 + t(b(x,y) - 1).$$

Since $b(0,0) > 0$, we have $a(0,0,t) > 0$ for $t \in [0,1]$. We will find a vector field of the form

$$Y = \frac{\partial}{\partial t} + u(y,t)\frac{\partial}{\partial y} + v(x,y,t)\frac{\partial}{\partial x}$$

such that $u(0,t) = 0$, $v(0,0,t) = 0$, and $L_Y F = 0$. ($L_Y F$ denotes the directional derivative of F along Y.) This will mean that F is constant on the trajectories of Y. In particular, if $\psi_t(x,y,0)$ is the trajectory of Y after time t, starting from $(x,y,0)$, then

$$F(\psi_t(x,y,0)) = F(\psi_0(x,y,0)) = F(x,y,0).$$

(The trajectory from $(0,0,0)$ is well defined for $t \in [0,1]$, since $u(0,t) = v(0,0,t) = 0$; thus it is also defined for such t from $(x,y,0)$, for (x,y) small.) It follows from the definition of the function F that $F(x,y,0) = g(x,y)$ and $F(x,y,1) = g(x,y)\,b(x,y)$.

Thus, taking in the above equality $t = 1$ we get the assertion of the proposition with χ defined by

$$\psi_1(x, y, 0) = (\chi(x, y), 1).$$

It remains to solve the equation $L_Y F = 0$. It takes the form

$$gb + u(g'_y a + g a'_y) + v(g'_x a + g a'_x) = 0 \tag{LF}$$

with $u = u(y, t)$ and $v = v(x, y, t)$ unknown. Given that $g = (x - y)(1 - y/x)^2$ we compute

$$g'_y = -3\left(1 - \frac{y}{x}\right)^2, \quad g'_x = \left(1 - \frac{y}{x}\right)^2 \left(1 + 2\frac{y}{x}\right),$$

which allows us to divide (LF) over $(1 - y/x)^2$. We get the equivalent equation

$$(x - y)b + u(3a + (x - y)a'_y) + v(a + 2ay/x + (x - y)a'_x) = 0.$$

Since $a(0, 0, t) > 0$, the coefficient $C = -3a + (x - y)a'_y$ at u is invertible in a neighborhood of $(0, 0, t)$, $t \in [0, 1]$. Dividing the equation over C and replacing b by $\tilde{b} = b/C$ and v by $\tilde{v} = v/(xC)$ we get the simpler equation

$$(x - y)\tilde{b} + u + \tilde{v}(xa + 2ya + x(x - y)a'_x) = 0.$$

We note that the coefficient $E = xa + 2ya + x(x - y)a'_x$ at $\tilde{v}$ has the property $\partial E/\partial x(0, 0, t) = a(0, 0, t) > 0$. We can thus use it as a local coordinate and introduce the local coordinates $(\tilde{x}, y, t)$ in a neighborhood of the segment $(0, 0, t)$, $t \in [0, 1]$, where $\tilde{x} = E(x, y, t)$. Note that if $y = 0$, then $\tilde{x} = E = 0$ if and only if $x = 0$. The function $(x - y)\tilde{b}(x, y, t) =: c(\tilde{x}, y, t)$ can be decomposed into

$$c(\tilde{x}, y, t) = c_0(y, t) + \tilde{x}c_1(\tilde{x}, y, t) \quad \text{with} \quad c_0(0, t) = 0.$$

(The latter equality follows from the former by putting $\tilde{x} = y = 0$.) Then our equation becomes

$$c_0(y, t) + \tilde{x}c_1(\tilde{x}, y, t) + u(y, t) + \tilde{v}(\tilde{x}, y, t)\tilde{x} = 0$$

and it has a solution $u(y, t) = -c_0(y, t)$, $\tilde{v}(\tilde{x}, y, t) = -c_1(\tilde{x}, y, t)$. This solution satisfies

$$u(0, t) = -c_0(0, t) = 0, \quad v(0, 0, t) = 0.$$

(We recall that $v = \tilde{v}xC$ and, if $y = 0$, then $\tilde{x} = 0$ if and only if $x = 0$.) In this way we have constructed the vector field Y satisfying $L_Y F = 0$, and the above conditions guarantee that the trajectory starting from $(x, y, t) = (0, 0, 0)$ satisfies $\psi_t(0, 0, 0) = (0, 0, t)$, in particular $\psi_1(0, 0, 0) = (\chi(0, 0), 1) = (0, 0, 1)$, as required. □

Proof of Theorem 1.1 *and Propositions* 2.3, 2.4, 2.5, and 2.6. Theorem 1.1 follows from Propositions 2.3, 2.4, 2.5, and 2.6, thus we only prove the propositions. They are rather straightforward consequences of Theorem 3.3.

Consider a generic family Σ. By Lemma 4.4 we can assume that genericity means that Σ satisfies the conditions (G1)–(G6) of Theorem 3.3. Lemma 4.3 implies that Σ has one of the codes in Theorem 3.3, at a given point (p, ϵ_0). By Theorem 3.3, the

family Σ is locally orbitally feedback equivalent to one of the normal forms: (O), (E), (C), (EC), (C$\mathcal{G}$), (E_{bif}), (C_{bif}), ($E\mathcal{G}_{bif}$), or ($C\mathcal{G}_{bif}$).

Observe that the normal forms (O), (E), (C), (EC), and (C$\mathcal{G}$) do not depend on the parameter ϵ so neither do the equivariants $\mathcal{I}_\epsilon = (E_\epsilon, C_\epsilon, \mathcal{G}_\epsilon)$. Thus, if the family Σ is equivalent at (p, ϵ_0) to one of those forms, it does not bifurcate at (p, ϵ_0).

It is straightforward to check that for the remaining four normal forms (E_{bif}), (C_{bif}), ($E\mathcal{G}_{bif}$), and ($C\mathcal{G}_{bif}$) the invariant condition expressed in the corresponding code in Theorem 3.3 is equivalent to the condition given in the respective Proposition 2.3, 2.4, 2.5, or 2.6. Thus, it is enough to analyze the invariants $\mathcal{I}_\epsilon = (E_\epsilon, C_\epsilon, \mathcal{G}_\epsilon)$, for each of the four normal forms, and show two facts: (i) the invariants are of the form stated in the propositions; (ii) they undergo the corresponding bifurcation described in the proposition. Statement (ii) was proved in the description of bifurcations given after the statements of the propositions. Thus we only check statement (i).

Clearly, for all of the normal forms (E_{bif}), (C_{bif}), ($E\mathcal{G}_{bif}$), and ($C\mathcal{G}_{bif}$) we have $\mathcal{G}_\epsilon = \{x = \text{const}\}$. Moreover, for the first one

$$(E_{bif}) \qquad \dot{x} = \sigma_e y^2 + x^2 - \epsilon, \qquad \dot{y} = v,$$

with $\sigma_e = \pm 1$, the equilibrium and critical sets are given by

$$E_\epsilon = \{x^2 + \sigma_e y^2 = \epsilon\}, \qquad C_\epsilon = \{y = 0\},$$

respectively. This together with the description of the corresponding bifurcations of E_ϵ in section 2.1 proves Proposition 2.3.

In the normal form

$$(C_{bif}) \qquad \dot{x} = \sigma_c y^3 + (x^2 - \epsilon)y + 1, \qquad \dot{y} = v$$

(where $\sigma_c = \pm 1$), the equilibrium set of E_ϵ is empty in a neighborhood of $(0, 0)$ and the critical set is given (after replacing y by $3^{-1/2}y$) by $C_\epsilon = \{x^2 + \sigma_c y^2 = \epsilon\}$. Thus this family has one of C-bifurcations (section 2.2). This proves Proposition 2.4.

In the case of normal form

$$(E\mathcal{G}_{bif}) \qquad \dot{x} = y^3 + (x - \epsilon)y + \gamma x, \qquad \dot{y} = v,$$

at $(0, 0)$ (where $\gamma = \pm 1$) the equilibrium set E_ϵ and the critical set C_ϵ are given by

$$E_\epsilon = \{y^3 + (x - \epsilon)y + \gamma x = 0\} \qquad \text{and} \qquad C_\epsilon = \{3y^2 + x - \epsilon = 0\}.$$

Replacing y for γy we get the same equation for C_ϵ and $E_\epsilon = \{y^3 + (x - \epsilon)y + x = 0\}$. Thus, the family ($E\mathcal{G}_{bif}$) has an $E\mathcal{G}$-bifurcation at $(0, 0)$, as shown in section 2.3.

In the normal form

$$(C\mathcal{G}_{bif}) \qquad \dot{x} = y^4 + (\theta x - \epsilon)y^2 + xy + a(x, \epsilon), \qquad \dot{y} = v,$$

the equilibrium set E_ϵ is empty and the critical set is $C_\epsilon = \{4y^3 + 2(\theta x - \epsilon)y + x = 0\}$. Replacing x, y, and ϵ by $\theta x/2$, $\theta y/2$, and $\epsilon/2$ we get $C_\epsilon = \{y^3 + (x - \epsilon)y + x = 0\}$. This shows Proposition 2.6. The proof is complete. □

OPTION PRICING WITH MARKOV-MODULATED DYNAMICS*

A. JOBERT† AND L. C. G. ROGERS†

Abstract. Markov-modulated models for equity prices have recently been extensively studied in the literature. In this paper, we apply some old results on the Wiener–Hopf factorization of Markov processes to a range of option-pricing problems for such models. The first example is the perpetual American put, where the exact (numerical) solution is obtained without discretizing any PDE. We then show how the methodology of Rogers and Stapleton [*Finance Stoch.*, 2 (1997), pp. 3–17] can be used to tackle finite-horizon problems and illustrate the methodology by pricing European, American, single barrier, and double barrier options under Markov-modulated dynamics.

Key words. Markov-modulated, Markov-chain, option, Black–Scholes model, Wiener–Hopf factorization, risk-sensitive control, regime switching

1. Introduction.

Though outstandingly successful as a leading-order model for an asset price, the familiar log-Brownian paradigm fails in various ways, such as the fact that implied volatility is not constant. Among the many attempted variations and extensions, one of the most natural is to allow the dynamics of the underlying process to be a log-Brownian motion whose volatility and rate of return are stochastic in some way. Allowing the volatility to be stochastic is the central theme of the extensive literature on *stochastic volatility modeling*, of which [24, 15, 13, 2, 14] make up a small sample. Allowing the rate of return to be stochastic is of relevance to portfolio optimization, but not to asset pricing,[1] and the literature on *risk-sensitive optimal control* develops this theme in various ways; see, for example [5, 6, 3, 20].

Perhaps the simplest way to introduce additional randomness into the standard log-Brownian model is to let the volatility and rate of return be functions of a finite-state Markov chain; we can imagine that such a model might describe regime-switching behavior of some kind, perhaps related to the business cycle, or other economic indicators. The terms *regime-switching* and *Markov-modulated dynamics* are used to describe such models, and there are already interesting contributions here, such as applications to option pricing [12, 11, 10, 9, 8, 4, 26], portfolio optimization [27, 25], and optimal trading strategies [28]. In applications, it is likely that the number of states of the Markov chain will be small (otherwise estimation becomes a problem), and it is then natural to think of such a model as "nearly" a log-Brownian motion, with occasional parameter shifts. Some explicit solutions can be found for a two-state Markov chain, but as the problems get harder we are soon led into PDE-related numerical methods (smoothed approximation of boundary conditions [26], two-point boundary value problems [28], discretization of associated dynamic programming equations [12]). The coupled PDEs which arise in these models will rarely be soluble in closed form, though finite-difference methods are still quite competitive.

[1]Of course, for asset pricing we change measure so that the rate of return becomes the riskless rate.

This paper approaches such models from a different direction: by viewing the Markov-modulated asset as nearly a Markov chain. This approach relies on some old work on Wiener–Hopf factorization of Markov processes (and in particular, Markov chains) dating back to the paper of Barlow, Rogers, and Williams [1] from 1980; the focus is on level-crossings of the asset price process. We find a quite different toolkit applies in this approach, namely, linear algebra; this leads to numerical schemes that are very efficient and quite able to handle moderate-sized problems, which we will illustrate by pricing a perpetual American put[2] on such an asset. Let us emphasize immediately a key difference between the present approach and the traditional PDE approach: here we shall be obtaining (numerically) *exact* solutions to the problem, *not* just approximations. There is no need to solve any dynamic programming equation or discretize any PDE.

Next, we move to a pricing framework with finite time horizon and Markov regimes. The approach here extends the methodology developed by Rogers and Stapleton [22] for the standard log-Brownian model and is illustrated by pricing the European call, the American put, and finally double barrier options.

2. General setup and noisy Wiener–Hopf factorization. The stock price is modeled as

$$dS_t = S_t[\sigma(\xi_t)dW_t + r(\xi_t)dt], \tag{1}$$

where W_t is a standard Brownian motion, r denotes as usual the risk-free interest rate, σ denotes the Markov-modulated volatility of the stock, and ξ is an irreducible Markov chain with values in the finite set I, $|I| = d$. Notice that the riskless rate may vary with the underlying Markov chain. The log price $X_t = \log(S_t)$ then satisfies

$$dX_t = \sigma(\xi_t)dW_t + \left[r(\xi_t) - \frac{1}{2}\sigma(\xi_t)^2\right]dt, \tag{2}$$

which can be rewritten as, say,

$$dX_t = \sigma(\xi_t)dW_t + v(\xi_t)dt. \tag{3}$$

The idea of the Wiener–Hopf factorization approach is to study the crossings back and forth over levels of X. To help in this, define for $t \geq 0$[3]

$$\tau_t^{\pm} \equiv \inf\{u : \pm X_u > t\}. \tag{4}$$

We aim to characterize the distribution of the times $\tau_t^{\pm}$ and the law of the chain at these times, and to do this we will seek martingales M_t^f of the following form:

$$M_t^f = \exp\left(-\int_0^t r(\xi_u)du\right) f(\xi_t, X_t) \tag{5}$$

for some function f. Itô's formula gives, up to a local martingale part,

$$dM_t^f \doteq \exp\left(-\int_0^t r(\xi_u)du\right)\left[(Q-R)f + \frac{1}{2}\Sigma f_{XX} + Vf_X\right]dt, \tag{6}$$

[2]This problem was solved for a two-state chain by Guo and Zhang [12].

[3]With the usual convention that $\inf(\emptyset) = \infty$.

where R is the diagonal matrix whose ith diagonal element is equal to $r(i)$, Σ is the diagonal matrix whose ith diagonal element is equal to $\sigma(i)^2$, and $V = R - \frac{1}{2}\Sigma$. We therefore require

$$(Q - R)f + \frac{1}{2}\Sigma f_{XX} + V f_X = 0. \tag{7}$$

Seeking separable f of the form $f(\xi_t, X_t) = g(\xi_t)\exp(-\lambda X_t)$ gives rise to the following equation to be solved in λ and g:

$$(Q - R)g + \frac{1}{2}\lambda^2\Sigma g - \lambda V g = 0, \tag{8}$$

Now this is just the "quadratic eigenvalue" problem considered by Kennedy and Williams [17], which can be reduced to a standard eigenvalue problem as follows. Premultiplying the above equation by $2\Sigma^{-1}$ gives

$$2\Sigma^{-1}(Q - R)g + \lambda^2 g - 2\lambda\Sigma^{-1}Vg = 0. \tag{9}$$

This can be reformulated as a system of equations

$$\left\{ \begin{array}{ll} \lambda g & = h, \\ \lambda h & = 2\Sigma^{-1}Vh - 2\Sigma^{-1}(Q - R)g, \end{array} \right. \tag{10}$$

which can be rewritten as the following (standard) eigenvalue problem:

$$A \left(\begin{array}{c} g \\ h \end{array} \right) \equiv \left(\begin{array}{cc} 0 & I \\ -2\Sigma^{-1}(Q - R) & 2\Sigma^{-1}R - I \end{array} \right) \left(\begin{array}{c} g \\ h \end{array} \right) = \lambda \left(\begin{array}{c} g \\ h \end{array} \right). \tag{11}$$

If (g, λ) solve (11), then

$$M_t^f = \exp\left(-\int_0^t r(\xi_u)du - \lambda X_t \right) g(\xi_t) \tag{12}$$

is a martingale. The argument given in [1] serves to show that there are exactly d eigenvalues of A in the left open half plane, and d in the right open half plane, a fact that will be needed later.

3. Markov-modulated perpetual American put. Our goal in this section is to compute the value

$$v(j, x) \equiv \sup_{\tau} E\left[\exp\left(-\int_0^{\tau} r(\xi_s)ds \right) (K - e^{X_\tau})^+ \mid \xi_0 = j, X_0 = x \right] \tag{13}$$

of the perpetual American put with Markov-modulated dynamics. The special case of the problem where there is no Markov modulation (that is, $|I| = 1$) is well known:[4] the optimal rule is to wait until the price of the asset falls below some critical boundary value L^*, and then immediately exercise. Standard first passage time calculations for Brownian motion lead to the following closed-form expression for the perpetual American put:

$$v(x) = \left\{ \begin{array}{ll} K - \exp(x) & \text{if } x \leq \log(L^*), \\ (K - L^*)(L^*)^\gamma \exp(-\gamma x) & \text{if } x > \log(L^*), \end{array} \right. \tag{14}$$

where $\gamma = 2r/\sigma^2$, $L^* = \gamma K/(\gamma + 1)$.

[4]See the original solution of McKean [19] and Karatzas [16] for a discussion in a more general setting.

When $|I| > 1$, the optimal rule is to exercise when the price of the asset falls below some critical level, which depends on the current state of the modulating Markov chain ξ. This intuitively obvious form of the solution follows immediately from the next simple result.

PROPOSITION 1. *If $\varphi(x) \equiv (K - e^x)^+$, then for each $j \in I$ the function*

$$x \mapsto v(j,x) - \varphi(x)$$

is nondecreasing in $(0, \log(K))$.

Proof. Pick $0 < x < x + \delta < \log(K)$ and let τ^* denote the optimal stopping time to be used if $X_0 = x$. We consider instead what would happen if we were to use the stopping rule τ^* but with initial log-price $x + \delta$. Using the elementary inequality $(a-b)^+ \geq a^+ - b^+$, we get[5]

$$\begin{aligned}
v(j, x+\delta) &\equiv \sup_\tau E[e^{-R(\tau)}\varphi(X_\tau)|\, \xi_0 = j, X_0 = x+\delta] \\
&\geq E[e^{-R(\tau^*)}\varphi(X_{\tau^*})|\, \xi_0 = j, X_0 = x+\delta] \\
&= E[e^{-R(\tau^*)}\varphi(X_{\tau^*} + \delta)|\, \xi_0 = j, X_0 = x] \\
&= E[e^{-R(\tau^*)}(K - e^{X(\tau^*)+\delta})^+|\, \xi_0 = j, X_0 = x] \\
&= E[e^{-R(\tau^*)}(K - e^{X(\tau^*)} - (e^\delta - 1)e^{X(\tau^*)})^+|\, \xi_0 = j, X_0 = x] \\
&\geq E[e^{-R(\tau^*)}\{\, (K - e^{X(\tau^*)})^+ - (e^\delta - 1)e^{X(\tau^*)}\,\}|\, \xi_0 = j, X_0 = x] \\
&= v(j,x) - (e^\delta - 1)E[e^{-R(\tau^*)}e^{X(\tau^*)}|\, \xi_0 = j, X_0 = x] \\
&\geq v(j,x) - (e^\delta - 1)e^x \\
&= v(j,x) - \varphi(x) + \varphi(x+\delta),
\end{aligned}$$

using the fact that $e^{-R(t)+X(t)}$ is a martingale, and therefore a supermartingale. ∎

Immediately from Proposition 1, the optimal stopping time is of the form

$$\tau = \inf\{t : X_t < b(\xi_t)\}, \tag{15}$$

where the constants $(b_i)_{i\in I}$ must be found.

This problem was solved by Guo and Zhang [12] in the simple case of two states, where a closed-form expression can be derived for the price. Note that -1 is always an eigenvalue of A, which is a key observation that makes the two-state problem tractable. However, the current methodology will work for any number of states. The time-0 value of the stopping rule (15) defined by the levels $(b_i)_{i\in I}$ is

$$v(j,x) = \mathbf{E}\left[\exp\left(-\int_0^\tau r(\xi_t)dt\right)(K - \exp(b(\xi_\tau)))^+ | S_0 = \exp(x); \xi_0 = j\right] \tag{16}$$

There are thus two problems:

(1) Given some thresholds b_i, derive the value function;

(2) find the optimal b_i.

PROBLEM 1. *Let us suppose given $(b_i)_{i\in I}$, where without loss of generality*[6] *$b_1 > b_2 > \cdots > b_d$; our goal is to compute the value function associated with this set of threshold levels.*

[5] We use the abbreviation $R(t) \equiv \int_0^t r(\xi_s)ds$.

[6] This assumption amounts to an inessential relabeling of the states and is merely for convenient discussion. When it comes in practice to identifying the thresholds, no assumption is made on the ordering, and all possible orderings are considered. We show in Proposition 2 that there is a unique solution for the thresholds, whose ordering is determined by the parameters of the problem.

Let us start with x in the interval $[b_1, \infty)$. Here, the value function is larger than the payoff function whatever the initial state. Recall that we are looking for a martingale M_t^f of the form of (5) for some function f which satisfies (7) and which will be represented as a weighted sum

$$f(\xi, x) = \Sigma_{i=1}^d w_i g_i(\xi) \exp(-\lambda_i x), \tag{17}$$

where for each i, (λ_i, g_i) satisfies (8), with $\lambda_i > 0$. We restrict our attention to the d eigenvalues with positive real part because this means that the martingale

$$M_t \equiv \exp\left(-\int_0^t r(\xi_u)du\right) \sum_i w_i g_i(\xi_t) \exp(-\lambda_i X_t)$$

is bounded on $[0, \tau_1]$, where $\tau_1 \equiv \inf\{t : X_t < b_1\}$. Therefore we may apply the optional sampling theorem to obtain

$$\begin{aligned} &\mathbf{E}\left[\exp\left(-\int_0^{\tau_1} r(\xi_u)du\right) \sum_i w_i g_i(\xi_{\tau_1}) \exp(-\lambda_i X_{\tau_1}) \;\middle|\; X_0 = x, \xi_0 = j\right] \\ &= \sum_i w_i g_i(j) \exp(-\lambda_i x). \end{aligned} \tag{18}$$

This is the expression for the value function over the interval $[b_1, \infty)$. In particular, for $j = 1$, this completes the determination of the time-0 price when the underlying chain is initially in state 1, provided we impose

$$(K - \exp(b_1))^+ = \sum_i w_i g_i(1) \exp(-\lambda_i b_1). \tag{19}$$

This gives us a first equation satisfied by the d unknown weights w, and

$$v(1, x) = \begin{cases} K - \exp(x) & \text{if } x \le b_1, \\ \sum_i w_i g_i(1) \exp(-\lambda_i x) & \text{if } x \ge b_1, \end{cases} \tag{20}$$

where w still needs to be determined. Continuity at b_1 in (19) restricts w to a $(d-1)$-dimensional subspace; to go further, we must look at the next interval $I_2 = [b_2, b_1]$ and match values and slopes of V across b_1.

When $x \in I_2$, ξ can jump to state 1, causing exercise to happen. So we now need to modify slightly the Wiener–Hopf argument and the equation for f. Let $\tilde{\Sigma}$, $\tilde{R}$, $\tilde{V}$ be the diagonal matrices defined in the following way: for every $i = 2, \ldots, d$, $\tilde{\Sigma}(i,i) = \sigma(i)^2$, $\tilde{R}(i,i) = r(i)$ and $\tilde{V} = \tilde{R} - \frac{1}{2}\tilde{\Sigma}$. Let $\tilde{Q}$ be the submatrix derived from Q by removing its first row and first column.

We still seek a martingale M_t^f of the form of (5) for some function f, which now satisfies the following modified equation:

$$(\tilde{Q} - \tilde{R})f + \frac{1}{2}\tilde{\Sigma} f_{XX} + \tilde{V} f_X + \tilde{K} = 0, \tag{21}$$

where $\tilde{K}$ is defined so that it accounts for jumps to the payoff function in state 1: $\tilde{K} = \tilde{q}(K - \exp(x))$, where $\tilde{q}$ denotes a $(d-1)$-dimensional vector, such that $\tilde{q}(i) = q_{i1}$ for every $i = 2, \ldots, d$. The value function over the interval $[b_2, b_1]$ is characterized by (21).

A particular solution to (21) is easily obtained and is of the form $B + C\exp(x)$. The homogeneous equation

$$(\tilde{Q} - \tilde{R})f + \frac{1}{2}\tilde{\Sigma}f_{XX} + \tilde{V}f_X = 0 \tag{22}$$

is structurally similar to (7) and is solved similarly. Let $\tilde{\lambda_i}$ and $\tilde{g_i}$ denote the $2(d-1)$ corresponding eigenvalues and eigenvectors for this new problem. For any scalars $\tilde{w_i}$,

$$\exp\left(-\int_0^t r(\xi_u)du\right)\left(\Sigma_{i=1}^{2(d-1)}\tilde{w_i}\exp(-\tilde{\lambda_i}X_t)\tilde{g_i}(\xi_t) + B + C\exp(X_t)\right) \tag{23}$$

is a martingale, at least if we stop at first exit from I_2, and is bounded up to that time. Provided that we ensure that $v(j,\cdot)$ joins in a C^1 fashion across b_1, for $j = 2,\dots,d$, we therefore have for any $x \in I_2$, and any $j = 2\dots d$,

(24)

$$\mathbf{E}^{x,j}\left[\exp\left(-\int_0^{\tau_2} r(\xi_u)du\right)\left(\sum_i \tilde{w_i}\tilde{g_i}(\xi_{\tau_2})\exp(-\tilde{\lambda_i}X_{\tau_2}) + B_j + C_j\exp(X_{\tau_2})\right)\right]$$
$$= \sum_i \tilde{w_i}\tilde{g_i}(j)\exp(-\tilde{\lambda_i}x) + B_j + C_j\exp(x),$$

where $\tau_2 = \min\{t : X_t \le b_2\}$, and $\mathbf{E}^{x,j}$ denotes the usual expectation conditional upon $X_0 = x$, $\xi_0 = j$. This is the expression for the value function in the interval I_2; in particular, for $j = 2$, this completes the determination of the time-0 price when the underlying chain is initially in state 2, provided we impose continuity at b_2.

Notice that at the end of the first step, we were left with $d-1$ degrees of freedom. Once we have solved the problem over the interval $[b_2, b_1]$, matching the values and the slopes of $v(j,\cdot)$, $j = 2,\dots,d$ across b_1, we have $2\times(d-1)$ new linear equations, for the $2(d-1)$ new unknowns $\tilde{w_i}$. Continuity across b_2 of $v(2,\cdot)$ provides us with another equation so that at the end of our second step, we are left with $d-2$ degrees of freedom.

From the above, it is now clear that we can proceed recursively, from b_1 to b_d, by solving d successive problems of this type and considering the standard eigenvalue problem associated with our modified setup and our updated generator for the underlying Markov chain. At the end of the dth problem over the interval $[b_d, b_{d-1}]$, we no longer have any degrees of freedom, once we have imposed the continuity of $v(d,x)$ across b_d. Finally, over $[0, b_d]$, we have: $v(1,x) = \cdots = v(d,x) = K - \exp(x)$. This deals with the first problem, namely, given thresholds to compute the value function.[7]

PROBLEM 2. *The method just presented shows how for any given sequence of threshold values we may compute the value. For optimality, we need to make $v(j,\cdot)$ be C^1 at b_j for $j = 1,\dots,d$. This gives us d nonlinear equations to be solved in d unknowns, which can be solved by standard numerical techniques; we used sequential quadratic programming. The latter optimization routine is converging efficiently toward a set of b values which make v to be C^1. It remains to check that*

$$(Q - R)v + \frac{1}{2}\Sigma v_{XX} + V v_X \le 0$$

[7]The above procedure leaves us in fact with a linear system to solve in order to determine the unknown weights on every subinterval: d weights on $[b_1,\infty)$, $2\times(d-1)$ weights on $[b_2,b_1]$, $2\times(d-2)$ weights on $[b_3,b_2]$, ... and finally 2 weights on $[b_d,b_{d-1}]$. This gives rise to a linear system with d^2 unknowns and d^2 equations.

everywhere; from this, it follows that the solution v found is in fact optimal. The following results deals with this point.

PROPOSITION 2. *Suppose that thresholds $(b_j) < \log K$ have been found such that the (unique) bounded solution f to the coupled system of ODEs*

$$\frac{1}{2}\sigma_i^2 f_{XX}(i,X) + V_i f_X(i,X) - r_i f(i,X) + \sum_j q_{ij} f(j,X) = 0 \qquad (X > b_i), \tag{25}$$

$$f(i,X) = \varphi(X) \qquad (X \le b_i) \tag{26}$$

is C^1 in X at each point (j, b_j). Then the (b_j) are uniquely determined, and f is the value of the problem.

Proof. The proof proceeds in a number of steps. Given the thresholds (b_j), we set $\tau^* = \inf\{t : X_t \le b(\xi_t)\}$, and we observe that

$$f(\xi_{t\wedge\tau^*}, X_{t\wedge\tau^*}) \exp\{-R(t\wedge\tau^*)\} \text{ is a bounded martingale,}$$

and so in particular

$$f(j,x) = E\big[\, \varphi(X_{\tau^*}) e^{-R(\tau^*)} \,\big|\, \xi_0 = j, X_0 = x \,\big].$$

Since $\varphi \ge 0$, it follows that $f > 0$.

(i) We claim that $f(j,x) > \varphi(x)$ whenever $x > b_j$. To see why, let $\tau_0 \equiv \inf\{t : f(\xi_t, X_t) \le \varphi(X_t)\} \le \tau^*$, and observe that

$$\begin{aligned} f(j,x) &= E\big[\, \varphi(X_{\tau^*}) e^{-R(\tau^*)} \,\big|\, \xi_0 = j, X_0 = x \,\big] \\ &= E\big[\, (K - e^{X(\tau^*)}) e^{-R(\tau^*)} \,\big|\, \xi_0 = j, X_0 = x \,\big] \\ &= E\big[\, \varphi(X_{\tau_0}) e^{-R(\tau_0)} \,\big|\, \xi_0 = j, X_0 = x \,\big] \\ &= E\big[\, (K - e^{X(\tau_0)}) e^{-R(\tau_0)} \,\big|\, \xi_0 = j, X_0 = x \,\big]. \end{aligned}$$

The fact that $\exp(X_t - R_t)$ is a martingale[8] tells us that

$$E\big[\, K e^{-R(\tau^*)} \,\big|\, \xi_0 = j, X_0 = x \,\big] = E\big[\, K e^{-R(\tau_0)} \,\big|\, \xi_0 = j, X_0 = x \,\big],$$

whence immediately $\tau^* = \tau_0$, and the claim is proved.

(ii) We claim next that $f(j,\cdot) - \varphi(\cdot)$ is nondecreasing in $(0, \log(K))$. The proof of this is in effect a reprise of the proof of Proposition 1. As there, we take two starting points $x, x+\delta \in (0, \log(K))$, and let τ denote the stopping time that would be used if we started from x. Using the fact that $f \ge \varphi$, we have

$$\begin{aligned} f(j,x+\delta) &= E[e^{-R(\tau)} f(\xi_\tau, X_\tau) |\, \xi_0 = j, X_0 = x+\delta] \\ &\ge E[e^{-R(\tau)} \varphi(X_\tau) |\, \xi_0 = j, X_0 = x+\delta] \\ &= E[e^{-R(\tau)} \varphi(X_\tau + \delta) |\, \xi_0 = j, X_0 = x] \\ &= E[e^{-R(\tau)} (K - e^{X(\tau)+\delta})^+ |\, \xi_0 = j, X_0 = x] \\ &= E[e^{-R(\tau)} (K - e^{X(\tau)} - (e^\delta - 1) e^{X(\tau)})^+ |\, \xi_0 = j, X_0 = x] \\ &\ge E[e^{-R(\tau)} \big\{\, (K - e^{X(\tau)})^+ - (e^\delta - 1) e^{X(\tau)} \,\big\} |\, \xi_0 = j, X_0 = x] \\ &= f(j,x) - (e^\delta - 1) E[e^{-R(\tau)} e^{X(\tau)} |\, \xi_0 = j, X_0 = x] \\ &\ge f(j,x) - (e^\delta - 1) e^x \\ &= f(j,x) - \varphi(x) + \varphi(x+\delta). \end{aligned}$$

[8] It is in fact the discounted stock price.

(iii) The final step is to prove that

$$\Phi(i,x) \equiv \frac{1}{2}\sigma_i^2 f_{XX}(i,X) + V_i f_X(i,X) - r_i f(i,X) + \sum_j q_{ij} f(j,X) \le 0 \tag{27}$$

in $X \le b_i$. From (26), we have that in fact

$$\Phi(i,x) = -r_i K + \sum_{j \ne i} (f(j,X) - \varphi(X)),$$

which is seen to be nondecreasing in $[0, b_i]$, in view of point (ii) proved above. It is therefore sufficient to prove that $\Phi(i, b_i-) \le 0$ to establish (27). By the C^1 property of the solution f, we note that all of the terms in $\Phi(i,\cdot)$ are continuous across b_i except perhaps the second derivative term; thus any discontinuity in Φ is entirely accounted for by the jump in this. But now consider the function $f(i,\cdot) - \varphi(\cdot)$. Its second derivative at b_i- is zero, and yet its second derivative at b_i+ must be nonnegative, since the function is nonnegative to the right of b_i, and the function and its first derivative both vanish there. We deduce that the change in the second derivative of $f(i,\cdot)$ at b_i is nonnegative, and the conclusion (27) follows.

(iv) The standard verification argument for optimal control now shows that stopping at τ^* is optimal and that f is the value function of the problem. □

As a check, take the case $d = 1$, which is the standard perpetual American put problem mentioned earlier; we have $R = r$, $\Sigma = \sigma^2$, $V = r - \frac{1}{2}\sigma^2$, $Q = 0$ and set $\gamma = 2r/\sigma^2$. Now the matrix A defined at (11) is simply

$$A = \begin{pmatrix} 0 & 1 \\ \gamma & \gamma - 1 \end{pmatrix}$$

with eigenvalues γ and -1, so the solution is of the form

$$v(x) = \begin{cases} K - \exp(x) & \text{if } x \le b, \\ w \exp(-\gamma x) & \text{if } x > b, \end{cases} \tag{28}$$

where the critical level b and the weight w are to be determined. The C^1 condition for v at b becomes

$$\begin{cases} K - \exp(b) &= w \exp(-\gamma b), \\ \exp(b) &= \gamma w \exp(-\gamma b), \end{cases}$$

from which we easily deduce the form given in (14).

3.1. Numerical results.

3.1.1. Two states. First, we check that we recover the results of Guo and Zhang [12] for the simple case of two states. The strike K is taken to be equal to 5,

$$R = \begin{pmatrix} 0.03 & 0 \\ 0 & 0.03 \end{pmatrix},$$

$$Q = \begin{pmatrix} -1 & 1 \\ 1 & -1 \end{pmatrix},$$

$$\Sigma = \begin{pmatrix} 0.25 & 0 \\ 0 & 0.81 \end{pmatrix}.$$

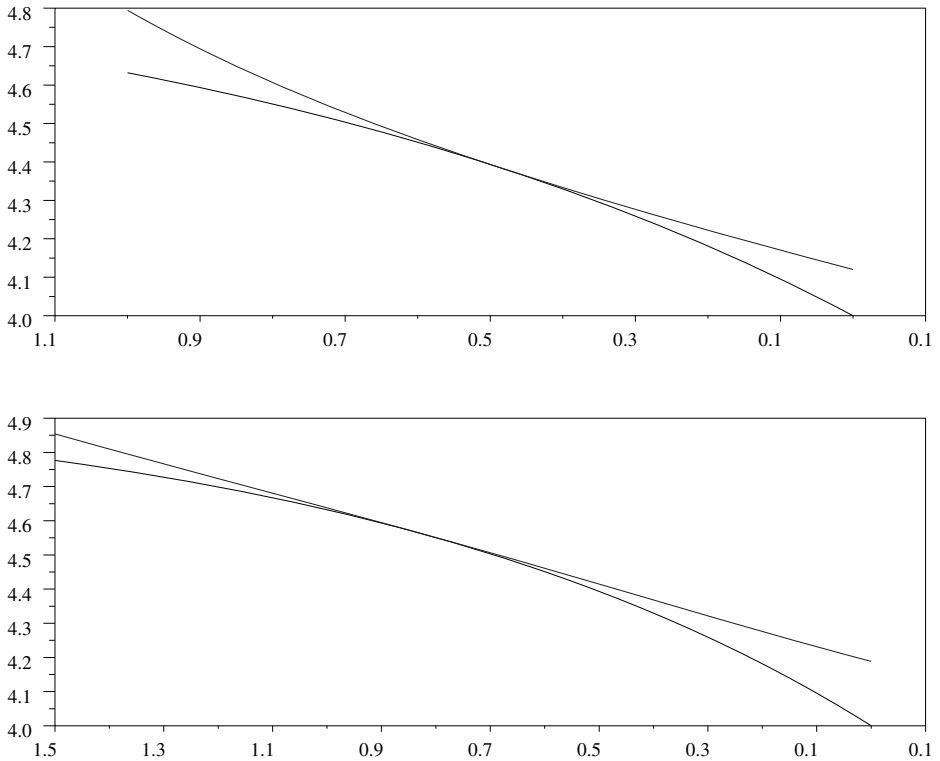

FIG. 1. *Perpetual American put with two states (value function against log price).*

This gives optimal thresholds: $\exp(b) = (0.612, 0.441)$, which is close to Guo and Zhang's solution $(0.614, 0.441)$. Figure 1 plots the price of the Markov-modulated perpetual American put in every state of the chain and enables us to visualize the corresponding smooth pasting conditions. Above the optimal thresholds, where smooth pasting occurs, the upper curve is the value function for the perpetual American put and the lower curve is the reward function. Below the optimal thresholds, the value function is equal to the reward function represented by the lower curve. We keep drawing the upper curve below the optimal thresholds for the sole purpose of assessing the quality of smooth pasting. All the plots below are drawn using a logarithmic scale for the stock price.

Decreasing the volatility in the second state,

$$\Sigma = \begin{pmatrix} 0.25 & 0 \\ 0 & 0.49 \end{pmatrix},$$

leads to higher optimal thresholds $\exp(b) = (0.801, 0.646)$. On the other hand, increasing the jump intensity from state 2 to state 1, where $\sigma_2^2 = 0.81$ and $\sigma_1^2 = 0.25$, decreases the average volatility and we expect therefore our optimal thresholds to be bigger, which turns out to be the case: $\exp(b) = (0.633, 0.455)$.

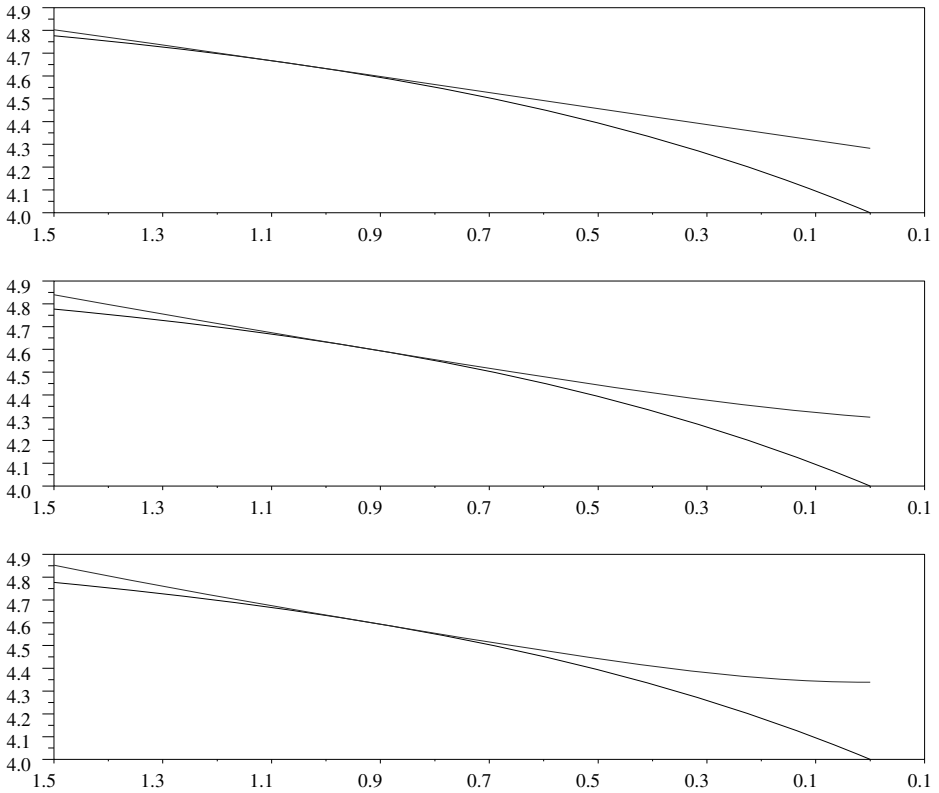

FIG. 2. *Perpetual American put with three states (value function against log price).*

3.1.2. Three states. Consider now the case of an underlying Markov chain with three states (high, low, and intermediate levels for the volatility):

$$R = \begin{pmatrix} 0.03 & 0 & 0 \\ 0 & 0.03 & 0 \\ 0 & 0 & 0.03 \end{pmatrix},$$

$$Q = \begin{pmatrix} -2 & 1 & 1 \\ 1 & -2 & 1 \\ 1 & 1 & -2 \end{pmatrix},$$

$$\Sigma = \begin{pmatrix} 0.25 & 0 & 0 \\ 0 & 0.50 & 0 \\ 0 & 0 & 0.81 \end{pmatrix}.$$

This gives the following thresholds: $\exp(b) = (0.600, 0.544, 0.455)$. Figure 2 plots the results.

3.1.3. More states. The methodology specified above enables us to deal with a moderately large number of states; in this example, there are eight. In each of the states, r is taken to be equal to 0.03. The jump intensities from one state to another are taken to be equal to 1, the volatility matrix is given by a diagonal matrix with diagonal entries $(0.35, 0.4, 0.6, 0.7, 0.75, 0.8, 0.85, 0.9)$, and in Figure 3, we plot

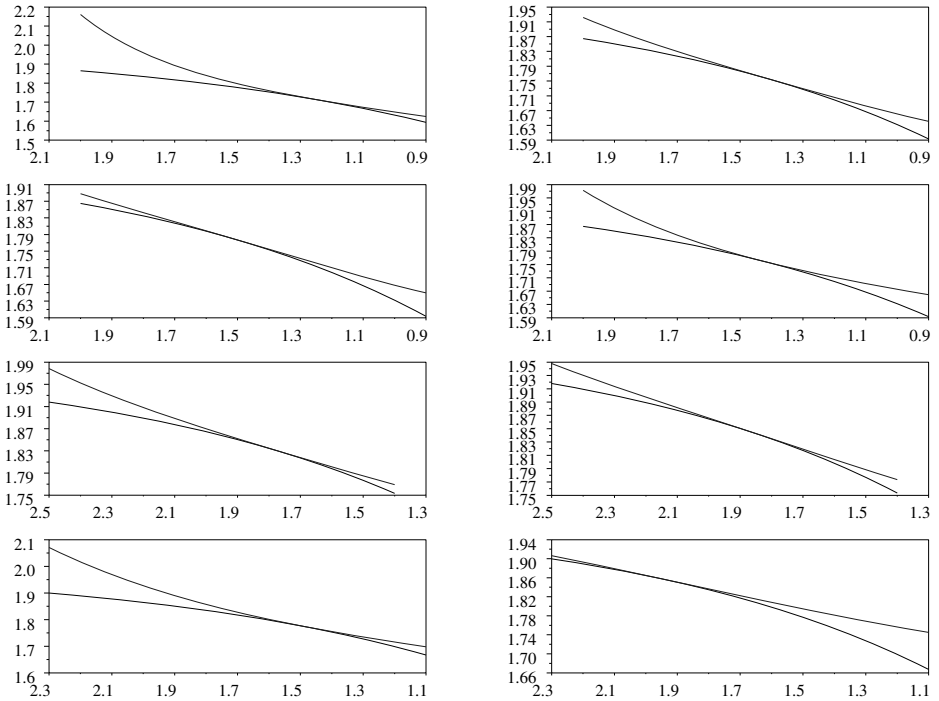

FIG. 3. *Perpetual American put with eight states (value function against log price).*

the value functions for the eight states of the chain, with the corresponding optimal thresholds,

$$\exp(b) = (0.290, 0.239, 0.238, 0.227, 0.220, 0.169, 0.155, 0.140).$$

As one would expect, the less volatile a state is, the bigger is the corresponding threshold.

4. Binomial pricing with Markov regimes. The standard binomial pricing method approximates the log-price process by a random walk, which jumps at the times $\Delta t, 2\Delta t, \ldots$ and, at each jump, moves either up or down. The probability of an up step and the size of the jump are chosen to match the drift and variance to the Black–Scholes asset. In this section, we will extend the alternative random walk approximation introduced by Rogers and Stapleton [22] to the case of Markov regimes.

With X still denoting the Markov-modulated log-price (2), the idea of [22] was to fix some $\Delta x > 0$ and view X only at the discrete set of times at which it has moved by Δx from where we last observed it. Formally, if

$$\begin{cases} \tau_0 = 0, \\ \tau_{n+1} \equiv \inf\{t > \tau_n : |X(t) - X(\tau_n)| > \Delta x\} \quad \text{if } n \geq 0, \end{cases} \tag{29}$$

then we take $(X(\tau_n))$ as the discrete approximation to X, observed for ν steps, where $\nu \equiv \sup\{n : \tau_n < T\}$ (T is the expiry of the option). We need to compute the distribution of $(X(\tau_1), \xi(\tau_1))$. Take $X_0 = 0$, $\tau \equiv \tau_1$ for notational simplicity.

Let λ_i and g_i denote the eigenvalues and the eigenvectors of the eigenvalue problem (11):

$$\begin{pmatrix} 0 & I \\ -2\Sigma^{-1}(Q-R) & 2\Sigma^{-1}R - I \end{pmatrix} \begin{pmatrix} g \\ h \end{pmatrix} = \lambda \begin{pmatrix} g \\ h \end{pmatrix}.$$

There are d negative and d positive eigenvalues. For any scalars w_i,

$$\exp\left(-\int_0^t r(\xi_u)du\right) \Sigma_{i=1}^{2d} w_i g_i(\xi_t) \exp(-\lambda_i X_t)$$

is a martingale, so by the optional sampling theorem,

(30)
$$\mathbf{E}\left[\exp\left(-\int_0^\tau r(\xi_u)du\right) \sum_i w_i g_i(\xi_\tau) \exp(-\lambda_i X_\tau) | X_0 = 0, \xi_0 = j\right] = \sum_i w_i g_i(j).$$

The discounted probability of an upwards step from state j to state k is given by

$$P^+_{j,k} = \mathbf{E}\left[\exp\left(-\int_0^\tau r(\xi_u)du\right) \mathbf{I}\{X_\tau = \Delta x, \xi_\tau = k\} | \xi_0 = j\right] \tag{31}$$

where $\mathbf{I}$ denotes the indicator function. Therefore, in order to find $P^+_{j,k}$ we need to solve the following system:

$$\begin{cases} \sum_i w_i g_i(\xi) \exp(-\lambda_i \Delta x) = \mathbf{I}\{\xi = k\} & \forall \xi = 1, \ldots, d, \\ \sum_i w_i g_i(\xi) \exp(+\lambda_i \Delta x) = 0 & \forall \xi = 1, \ldots, d. \end{cases} \tag{32}$$

This leaves us with $2d$ equations for the $2d$ unknown weights, from which we calculate the discounted probability of an upwards step. Similarly, we can compute the probability of a downwards step from state j to state k by replacing in the above system Δx with $-\Delta x$. When the initial logarithmic price is equal to x, the price of a standard European call option in this Markov-modulated framework is now computed using the following dynamic programming equation, written using vector notation:

$$\begin{cases} V_0(x) = (\exp(x) - K)^+, \\ V_{n+1}(x) = P^+ V_n(x + \Delta x) + P^- V_n(x - \Delta x), \end{cases} \tag{33}$$

where n is the number of time steps to go before expiry T. The matrices P^+ and P^- are defined above and denote, respectively, the up and down transition matrices for the underlying Markov chain.

Observe that (as in Rogers and Stapleton [22]) this approximation is well suited to pricing barrier options; we merely change appropriately the matrices $P^\pm$ at the vertices adjacent to the barrier(s).

Once we have computed the discounted probabilities of an upwards and a downwards step, it remains for us to deal with the fact that the number ν of time steps is random. One solution to this problem is to match bond prices so that

$$\mathbf{E}\left[\exp\left(-\int_0^T r(\xi_u)du\right) 1\right] \simeq \mathbf{E}\left[\exp\left(-\int_0^{\tau_\nu} r(\xi_u)du\right) 1\right]. \tag{34}$$

Let $\overline{P} = P^+ + P^-$. From the above, it is enough to find ν so that

$$\pi \overline{P}^{\nu} 1 = \pi \exp\left[T(Q-R)1\right], \tag{35}$$

where π denotes the invariant distribution of the underlying Markov chain. This simple approximation turns out to give very satisfactory results for the Markov-modulated setup.

Notice finally that for the case of the American put, the dynamic programming equation for the value function now becomes

$$\begin{cases} V_0(x) = (\exp(x) - K)^+, \\ V_{n+1}(x) = \max\{(K - \exp(x))^+, P^+ V_n(x + \Delta x) + P^- V_n(x - \Delta x)\}. \end{cases} \tag{36}$$

The case of the finite expiry Markov-modulated American put was tackled by Buffington and Elliott [4] but only in the case of a two-state Markov chain and by extending the Barone-Adesi–Whaley analytic approximation.

4.1. Numerical results.

4.1.1. Markov-modulated European call. One way of checking our results is to consider the case when the chain switches between two identical states for the volatility. The price in each state should then be equal approximately to the Black–Scholes price for this given volatility. The expiry time is taken to be equal to one year; the initial stock price is $S_0 = 95$. The strike is $K = 100$. Finally, the size of the space grid is taken to be $\Delta x = 0.022$. We take

$$R = \begin{pmatrix} 0.03 & 0 \\ 0 & 0.03 \end{pmatrix},$$

$$Q = \begin{pmatrix} -0.01 & 0.01 \\ 0.01 & -0.01 \end{pmatrix},$$

$$\Sigma = \begin{pmatrix} 0.25 & 0 \\ 0 & 0.25 \end{pmatrix}.$$

The price in each state of the chain is found to be equal to 17.9667, compared to the Black–Scholes value of 17.9506 (relative error: 0.0009).

4.1.2. Markov-modulated American put. Here we compare with the prices tabulated in [21].

(i) Let us first consider the case of two identical states, with $T = 0.5$, $\Delta x = 0.022$, $X_0 = \log(85)$, $K = 100$:

$$R = \begin{pmatrix} 0.06 & 0 \\ 0 & 0.06 \end{pmatrix},$$

$$Q = \begin{pmatrix} -0.01 & 0.01 \\ 0.01 & -0.01 \end{pmatrix},$$

$$\Sigma = \begin{pmatrix} 0.16 & 0 \\ 0 & 0.16 \end{pmatrix}.$$

The price in each of the two states is found to be equal to 18.0285, which needs to be compared with the value 18.0374 found by Rogers [21] (relative error: 0.0005).

(ii) Let us now decrease the volatility in the second state:

$$\Sigma = \begin{pmatrix} 0.16 & 0 \\ 0 & 0.10 \end{pmatrix}.$$

The prices in each of the two states are now found to be $(17.3070, 16.7677)$. Decreasing the volatility decreases the price in the two states, as expected. Correspondingly, increasing the volatility in one of the states increases the price in the two states, as shown by

$$\Sigma = \begin{pmatrix} 0.40 & 0 \\ 0 & 0.16 \end{pmatrix},$$

where the price is now given by $(20.3454, 19.1986)$.

(iii) Taking example (i) and changing just the start value X_0 to $\log(100)$ allows us to compare our values with other values in [22]. We find the price is $(9.9279, 9.9279)$, to be compared with 9.9458 (relative error: 0.00192). Taking $X_0 = \log(115)$, the price is $(5.1109, 5.1109)$, to be compared with 5.1265 (relative error: 0.00304).

It therefore turns out that the random walk approximation provides an accurate and very quick method for Markov-modulated asset dynamics.

The solution for the finite expiry American put should provide a way of checking the results of the preceding section for the perpetual American put, by letting T tend to ∞. For the example of Guo and Zhang [12], where $\exp(b) = (0.616, 0.441)$, the time-0 price of the Markov-modulated perpetual American putm, $(4.2239, 4.2758)$, compares well with our results for the finite expiry American put when $T = 40$: $(4.2180, 4.2692)$ (relative errors: 0.00139, 0.00155).

A similar check can be made for the perpetual American put example with three states, where the prices are $(4.2278, 4.2486, 4.2706)$, to be compared with $(4.2244, 4.2439, 4.2631)$ for the finite expiry case, where $T = 40$ (relative errors: 0.0008, 0.0011, 0.0017).

4.1.3. Markov-modulated barrier options. In this section, we price a number of double knockout barrier options in a Markov-modulated setup.

(i) Let us first consider the case of constant barriers, where we compare our results with those of Geman and Yor [7]. With two identical states, taking $T = 1$, $X_0 = \log(100)$, $K = 100$, $\Delta x = 0.022$, $b^* = \log(150)$, and $b_* = \log(75)$, and

$$R = \begin{pmatrix} 0.05 & 0 \\ 0 & 0.05 \end{pmatrix},$$

$$Q = \begin{pmatrix} -0.01 & 0.01 \\ 0.01 & -0.01 \end{pmatrix},$$

$$\Sigma = \begin{pmatrix} 0.25 & 0 \\ 0 & 0.25 \end{pmatrix}.$$

the price of the double knockout is then found to be $(0.8994, 0.8994)$, to be compared with the value 0.89 computed by Geman and Yor [7] (relative error: 0.01061).

(ii) Changing K to 87.5 and b_* to $\log(50)$, the price becomes $(3.8274, 3.8274)$, to be compared with 3.8075 from Geman and Yor (relative error: 0.00519).

(iii) The next example is the same as the previous one, but now we have two different volatility levels:

$$\Sigma = \begin{pmatrix} 0.50 & 0 \\ 0 & 0.25 \end{pmatrix}.$$

The price of the double knockout is now equal to $(2.6055, 2.5882)$.

(iv) We finally consider the case of a double knockout with moving barriers, which are linear for the log-price $b^* = \log(U)+\Delta x_1 t$ and $b_* = \log(L)+\Delta x_2 t$. We compare our results with those of Kunitomo and Ikeda [18] Let us take: $T = 0.5$, $X_0 = \log(1000)$, $K = 1000$, $\Delta x_1 = 0.1$, $\Delta x_2 = -0.1$, $L = 500$, and $U = 1500$:

$$R = \begin{pmatrix} 0.05 & 0 \\ 0 & 0.05 \end{pmatrix},$$

$$Q = \begin{pmatrix} -0.01 & 0.01 \\ 0.01 & -0.01 \end{pmatrix},$$

$$\Sigma = \begin{pmatrix} 0.04 & 0 \\ 0 & 0.04 \end{pmatrix}.$$

The price of the double knockout in this Markov-modulated setup is found to be $(67.2596, 67.2596)$, to be compared with 67.78 from Kunitomo and Ikeda [18] and 67.7834 from Rogers and Zane [23] (relative error: 0.00773).

5. Conclusions. We have shown how to use classical results from the Wiener–Hopf factorization of Markov processes to price options on a Markov-modulated asset. Such a model can accommodate "bull" and "bear" markets, as well as changes in interest rate and volatility. This method has been applied to the optimal stopping problem of the Markov-modulated perpetual American put. It yields a very efficient and accurate numerical method, which amounts to computing the eigenvalues and eigenvectors of some particular matrices. There is no dynamic programming nor discretization of any PDE. Finally, with a finite time horizon, the approach can be used to construct a modified binomial lattice methodology, which has been applied to the European call, the American put, and double barrier options in a Markov-modulated setup. This modified binomial method turns out to provide an efficient numerical scheme for Markov-modulated option pricing.

SUPERVISORY CONTROL OF DISCRETE EVENT SYSTEMS WITH CTL* TEMPORAL LOGIC SPECIFICATIONS*

SHENGBING JIANG† AND RATNESH KUMAR‡

Abstract. The supervisory control problem of discrete event systems with temporal logic specifications is studied. The full branching time logic of CTL* is used for expressing specifications of discrete event systems. The control problem of CTL* is reduced to the decision problem of CTL*. A small model theorem for the control of CTL* is obtained. It is shown that the control problem of CTL* (resp., CTL) is complete for deterministic double (resp., single) exponential time. A sound and complete supervisor synthesis algorithm for the control of CTL* is provided. Special cases of the control of computation tree logic (CTL) and linear-time temporal logic are also studied.

Key words. discrete event system, supervisory control, temporal logic, computation tree logic, linear-time temporal logic

1. Introduction.

Discrete event systems (DESs) involve discrete-valued quantities that evolve in response to certain discrete qualitative changes, called *events*. Examples of events include arrival of a customer in a queue, termination of an algorithm in a computer program, loss of a message packet in a communication network, and breakdown of a machine in a manufacturing system. The theory of supervisory control of DESs was introduced by Ramadge and Wonham [28] for designing controllers so that the controlled system satisfies certain desired qualitative constraints, such as a buffer in a manufacturing system should never overflow, or a message sequence in a communication network must be received in the same order as it was transmitted. Many extensions of the basic supervisory control problem such as control with partial observations, decentralized control, modular control, control of nondeterministic systems, and control of infinite behaviors represented by ω-languages, have been studied [16].

In the supervisory control framework for discrete-event systems, an uncontrolled discrete event system, called plant, is modeled as a state machine, the event set of which is finite and is partitioned into the set of controllable and uncontrollable events. The language generated by such a state machine is used to describe the behavior of the plant at the logical level. The control task is formulated as that of the synthesis of a controller, called a supervisor, which exercises control over the plant by dynamically disabling some of the controllable events so that the plant achieves a certain desired behavior, called a specification, which is typically expressed as a formal language.

In this paper, we consider temporal logic [6, 12] as a means to express the control specification.

Temporal logic was studied initially to investigate the manner in which temporal operators are used in natural language arguments [11]. It provided a formal way of qualitatively describing and reasoning about how the truth values of assertions change over time. In [27], Pnueli first argued that temporal logic is appropriate for reasoning about nonterminating concurrent programs such as operating systems and network communication protocols. Now temporal logic is a widely active area of research and has been used in all aspects of concurrent program design, including specification, verification, and mechanical program synthesis.

Temporal logic is an effective means of control specification, and researchers have used it for this purpose. For example, [32, 21, 23, 22, 4] used linear-time temporal logic (LTL); [25, 24] used real-time temporal logic (RTTL) and [2] used metric temporal logic (MTL) (both RTTL and MTL are LTL with real time constraints); [1] used computation tree logic (CTL). Temporal logic was also used in [14, 26, 34, 30, 31] for the study of discrete event systems.

These works on a temporal logic approach for control of discrete event systems are limited in one way or other. For example, the main focus in [32, 21, 22, 25] was verification and analysis (no synthesis was performed). In [23, 24], methods were given for the supervisor synthesis for systems with safety specifications only. In [4] supervisory synthesis for propositional-LTL formulas is considered; no test for the existence of a supervisor is provided, a supervisor is synthesized based only on a "one-step look-ahead," and all controllable events are unobservable. In [2], a sound but not complete (see Remark 7) algorithm was given for the synthesis of supervisors for systems with MTL specifications. In [1], the control problem for systems with CTL specifications was studied. But there are some errors and limitations with the result of [1]. First, the semantics of CTL is defined by using $*$-languages (languages of finite strings [16]) in [1]. This is incorrect, since CTL has a branching-time structure and it is known ([6], and also Example 1) that CTL and $*$-languages are incomparable. Besides, CTL can express liveness properties which cannot be expressed by $*$-languages. Second, only *state-based* supervisors were considered in [1]. (Such a supervisor determines its control based only on the present state, ignoring the information about the state sequence the plant has visited in the past.) Third, the algorithm presented in [1], which works for a restricted class of CTL formulas and has a linear complexity in the number of states in the plant and the length of the CTL formulas, is erroneous (see Remark 6).

The work on "module checking" [20] can be viewed as dual to a supervisory control problem. The goal there is to have an "open system" (a plant in the setting of supervisory control) so that the "closed system" (the controlled system in the setting of supervisory control) satisfies the given CTL* specification for all possible environments (supervisors in the setting of supervisory control). Dually, in the setting of supervisory control, the goal is to have an open system so that the closed system satisfies the given CTL* specification for at least one possible environment. Duality lies in the following equivalence: an open system has the property that all the closed systems (that are induced by the various environments) satisfy a CTL* specification f if and only if it is not the case that there exists an environment so that the closed system satisfies the specification $\neg f$. Note that the former is a module-checking problem whereas the latter is a supervisory control problem.

With the above analogy, our work on supervisory control can be viewed as an *extension* of the work presented in the setting of module checking. In the setting of

module checking, the state set is partitioned into the system states and the environment states, and any subset of the feasible events can occur when the system is in one of its environment states. This, in our setting of supervisory control, translates to having

1. states where either all events are controllable (the environment states of module checking) or all events are uncontrollable (the system states of module checking), and
2. the supervisor (the environment in the setting of module checking) is a *deterministic* system.

Our setting is more general: *all states* can have some events that are controllable and others that are uncontrollable, and the supervisor we design can be a *nondeterministic* system. (See Example 1.)

The setting of "control of reactive systems" [18] has a more ambitious goal: synthesize a controller (which disables events in system states) so that the controlled system satisfies the given CTL* specification for all possible environments (which disables events in environment states). Since it is again possible to disable a set of feasible events in a system state (through a controller), this, in the supervisory control setting, translates to having the following:

1. all events are controllable in all states, and
2. the supervisor is a deterministic system.

As explained above, such restrictions are not present in the setting of supervisory control. It should be noted that in the setting of "control of reactive systems," there are two types of "players," a controller/supervisor and the environment. The supervisory control setting allows only one type of player, namely, a controller/supervisor, whereas the environment is always the "maximal" one (that never disables any event). Thus there are also some differences between the settings.

The work on "robust satisfaction" [19] does consider nondeterministic environments (i.e., supervisors). But the composition mechanism, through which the system and the environment interact, brings about additional restrictions, namely,

1. all events in all states are controllable,
2. exactly one controllable event is enabled in each state, and
3. the environment only "observes" the current state of the system (and not the particular event executed by the system),

The existence of the first two restrictions can be argued as follows: in the setting of "robust satisfaction," the environment, based on its present state, generates a unique output (which is an input for the system) that enables that particular event (and nothing else) in the system. Note that by outputting a certain event, the environment can enable that particular event in the system (equivalently, disable others), thereby making all events controllable in all states of the system. A justification for the third restriction is that the environment updates its state based on only the output generated by the system, which is a function of only the system's state. It should be noted that the setting of "robust satisfaction" allows a type of partial observation since the interacting systems only observe each others' outputs, whereas the supervisory control setting we consider assumes a complete observation of events. Thus there are also some differences between the two settings.

In this paper we study the supervisory control problem for plants possessing *uncontrollable* events with specifications expressed in the full branching time logic of CTL* and allowing supervisors to be *nondeterministic*. The reason for allowing nondeterminism is that the class of nondeterministic supervisors is more powerful than

that of deterministic ones, as is illustrated by Example 1, which makes it possible for a supervisor to exist for a larger class of CTL* specifications. Our approach to supervisor synthesis is based on reduction to satisfiability: We show that a supervisor exists if and only if a certain CTL* specification is satisfiable, and whenever this holds a corresponding satisfying model serves as a supervisor. A corollary of this result is that a deterministic supervisor exists if and only if a deterministic satisfying model exists. Thus the approach developed here can be used to determine the existence of a general nondeterministic as well as a deterministic supervisor, and furthermore following our approach a supervisor (nondeterministic or deterministic) can be obtained when one exists.

Note that randomized nondeterministic control is commonly used in the setting of stochastic systems (see, for example, [15]), whereas the use of nondeterministic supervisors in context of discrete-event systems was first explored in [13]. A formal definition of a nondeterministic control policy, its representation as a nondeterministic state machine, and a means to implement it (also see Remark 2) were first introduced in [17]. The nondeterminism in a supervisor state machine is represented by nondeterministic choices and epsilon-transitions. A nondeterministic choice corresponds to randomly choosing one of the control decisions (from among a set of choices determined off-line) on an observation, whereas an epslion-transition corresponds to randomly changing the control decision (again in accordance with choices determined off-line) without any observation. As explained in [17], a nondeterministic choice can be implemented by a "coin-toss," whereas an epsilon-transition can be implemented using a "random-timer." The results in [17] indicate that when the desired specification is language based, there is no gain to having nondeterministic control (over deterministic control) under complete observation of events. However, the situation is different when there is partial observation—a weaker notion of observability is needed for the existence of the supervisor. Further, this weaker property is algebraically better behaved than observability (such as it is closed under union). The present paper demonstrates that even under complete observation of events there is a gain to having nondeterministic supervisors if the desired specifications are expressed in CTL* (which is more expressive than the language-based specifications).

The paper is organized as follows. First a brief introduction to CTL* is given. Next, the control problem of CTL* is reduced to the decision problem of CTL* and a small model theorem for the control of CTL* is derived. It is further shown that the control problem of CTL* (resp., CTL) is complete for deterministic double (resp., single) exponential time, where a decision problem is said to be complete for a certain computation complexity if both the lower and upper complexity bounds of the problem are the same. A sound and complete supervisor synthesis algorithm for the control of CTL* is provided. Special cases of the control of computation tree logic (CTL) and linear-time temporal logic (LTL) are also studied. For these special cases we are able to provide more efficient algorithms. Finally, an illustrative example is given.

2. Introduction to CTL* and tree automaton. CTL* is also called full branching time logic because of its branching time structure, i.e., at each moment, there may exist alternate courses representing different possible futures. It was proposed in [7] as an unifying framework, subsuming both CTL and LTL, as well as a number of other logic systems. Here we give a brief introduction to CTL*. For a complete introduction to temporal logic, see [6].

Let $M = (Q, AP, R, L)$ be a state transition graph (also called the *Kripke structure* [6]), where Q is the set of states (finite or infinite), AP is a finite set of atomic

proposition symbols, $R \subseteq Q \times Q$ is a total transition relation, i.e., for every $s \in Q$ there is a $s' \in Q$ such that $R(s, s')$, and $L : Q \to 2^{AP}$ is a function that labels each state with a set of atomic propositions that are true at that state. A path in M is defined as an infinite sequence of states, $\pi = (s_0(\pi), s_1(\pi), \ldots)$ such that for every $i \in \{0, 1, \ldots\}$, $(s_i(\pi), s_{i+1}(\pi)) \in R$.

Using the atomic propositions and boolean connectives such as conjunction, disjunction, and negation, we can construct more complex expressions describing properties of states. However, we are also interested in describing the properties of sequences (and more generally of tree structures) of states that the system can visit. Temporal logic is a formalism for describing properties of sequences of states as well as of tree structures of states. Such properties are expressed using *temporal operators* and *path quantifiers* of the temporal logic. These operators and quantifiers can be nested with boolean connectives to generate more complex temporal logic specifications.

The following temporal operators are used for describing the properties along a specific path:

- X ("next time"): requires that a property hold in the next state of the path.
- U ("until"): used to combine two properties. The combined property holds if there is a state on the path where the second property holds, and at every preceding state on the path, the first property holds.
- F ("eventually" or "in the future"): used to assert that a property will hold at some future state on the path.
- G ("always" or "globally"): specifies that a property holds at every state on the path.
- B ("before"): also combines two properties. It requires that if there is a state on the path where the second property holds, then there exists a preceding state on the path where the first property holds.

We have following relations among the above operators, where f denotes a temporal logic specification:

- $Ff \equiv trueUf$,
- $Gf \equiv \neg F \neg f$,
- $fBg \equiv \neg(\neg fUg)$.

Thus one can use X and U to express the other temporal operators.

To describe the branching time structure starting at a particular state, two path quantifiers are used:

- A : for all paths and
- E : for some paths.

These two quantifiers are used in a particular state to specify that all the paths or some of the paths starting at that state have some property. The two quantifiers are related by

- $A \equiv \neg E \neg$.

There are two types of formulas in CTL*: *state formulas* (which are true in a specific state) and *path formulas* (which are true along a specific path). Now we give the definition of CTL* formulas. In the following we assume that p is an atomic proposition, f_1 and f_2 are state formulas, and g_1 and g_2 are path formulas.

Syntax. We inductively define a class of state formulas using rules S1–S3 below and a class of path formulas using rules P1–P3 below:

S1 If $p \in AP$, then p is a state formula.

S2 If f_1 and f_2 are state formulas, then so are $\neg f_1$ and $f_1 \wedge f_2$.

S3 If g_1 is a path formula, then Eg_1 and Ag_1 are state formulas.

P1 Each state formula is also a path formula.

P2 If g_1 and g_2 are path formulas, then so are $\neg g_1$ and $g_1 \wedge g_2$.

P3 If g_1 and g_2 are path formulas, then so are Xg_1 and $g_1 U g_2$.

CTL* formulas are the state formulas generated by the above rules. The length of a formula is the number of boolean, temporal, and path quantifier operators in the formula.

The restricted logic CTL is obtained by restricting the syntax to disallow boolean combinations and nestings of temporal operators. Formally, rules P1–P3 are replaced by

P0 If f_1 and f_2 are state formulas, then Xf_1 and $f_1 U f_2$ are path formulas.

Then CTL formulas are the state formulas generated by rules S1–S3 and P0.

The logic LTL is obtained by removing rules S2–S3, i.e., LTL formulas are state formulas in the form of Ag where g is any path generated by rules S1 and P1–P3. Note instead of defining LTL as path formulas (g) as in [6], we define LTL as state formulas (Ag) as in [3]. This is because for the LTL control problem studied in this paper, we want *all* paths starting from the initial state of the plant to satisfy some required property which can be expressed by a LTL formula of the form Ag.

Note that the only restriction in CTL is that every temporal operator in the formula is immediately preceded by a path quantifier, whereas the only restriction in LTL is that except for the path quantifier A appearing at the beginning of the formula no other path quantifiers exist in the formula. CTL and LTL have different expressive power. For example, the CTL formula $AGEFp$ cannot be expressed by any LTL formula, and the LTL formula $AFGp$ cannot be expressed by any CTL formula, but AGp can be viewed as either a CTL formula or an LTL formula.

Semantics. We define the semantics of CTL* with respect to a state transition graph $M = (Q, AP, R, L)$. For a state formula f, the notation $< M, s >\models f$ (resp., $< M, s >\not\models f$) means that f holds (resp., does not hold) at state s in M. For a path formula g, the notation $< M, \pi >\models g$ (resp., $< M, \pi >\not\models g$) means that g holds (resp., does not hold) along the path π in M. The relation $\models$ is defined inductively as follows:

1. $< M, s >\models p$ if and only if $p \in L(s)$ $\forall p \in AP$.
2. $< M, s >\models \neg f_1$ if and only if $< M, s >\not\models f_1$.
3. $< M, s >\models f_1 \wedge f_2$ if and only if $< M, s >\models f_1$ and $< M, s >\models f_2$.
4. $< M, s >\models Eg_1$ if and only if there exists a path π starting at s such that $< M, \pi >\models g_1$.
5. $< M, s >\models Ag_1$ if and only if for every path π starting at s, we have $< M, \pi >\models g_1$.
6. $< M, \pi >\models f$ if and only if $< M, s_0(\pi) >\models f$, for any state formula f.
7. $< M, \pi >\models \neg g_1$ if and only if $< M, \pi >\not\models g_1$.
8. $< M, \pi >\models g_1 \wedge g_2$ if and only if $< M, \pi >\models g_1$ and $< M, \pi >\models g_2$.
9. $< M, \pi >\models Xg_1$ if and only if $< M, \pi^1 >\models g_1$, where $\pi^1 = (s_1(\pi), s_2(\pi), \ldots)$.
10. $< M, \pi >\models g_1 U g_2$ if and only if there exists a k such that $< M, \pi^k >\models g_2$ and for all $j \in \{0, 1, \ldots, k-1\}$, $< M, \pi^j >\models g_1$, where $\pi^k = (s_k(\pi), s_{k+1}(\pi), \ldots)$.

Remark 1. In the above, the CTL* is interpreted over nonterminating paths. In some cases, we may need to study the systems with terminating behaviors. So the definition of CTL* semantics needs to be extended to finite paths. In this paper, we only consider the systems with nonterminating behaviors and hence use only the above definition.

The following examples show that temporal logic formulas can be used to express

properties such as safety, nonblocking, liveness, and stability.

AGp means that "*for all paths* (A) starting at the present state, *globally* (G) at every state along these paths p is true." It is a safety property.

$AGEFp$ means that "*for all paths* (A) starting from the present state, *globally* (G) for every state along these paths *there exists* (E) a path starting from that state such that *in future* (F) p holds at a state on that path." It is a nonblocking property.

$AG(p_1 \Rightarrow AFp_2)$ means that "*for all paths* (A) starting from the present state, *globally* (G) for every state s along these paths, if p_1 is true at the state s, then p_2 will be true at some *subsequent state along every path* (AF) starting from the state s." It is a liveness property.

$AFGp$ means that "*for all paths* (A) starting from the present state, *eventually* (F) p holds *globally* G". It is a property of stability which requires that the system should eventually reach a set of states where p holds and stay there forever.

DEFINITION 1. *We say that a state formula f is* satisfiable *provided that for some state transition graph M and some state s in M we have $< M, s > \models f$, in which case M is called a* model *for f.*

The decision problem of a temporal logic formula is to test whether the given formula is satisfiable. We have following results for the decision problems of CTL* and CTL.

THEOREM 1 (see [9, 5]). *Given a CTL* formula f, f is satisfiable if and only if it is satisfiable in a finite state transition graph with number of nodes at most double exponential in the length of the formula f.*

THEOREM 2 (see [6]). *The decision problem of CTL* (resp., CTL) is complete for deterministic double (resp., single) exponential time.*

Theorem 1 is called the *small model theorem* for the decision of CTL*. It states that a CTL* formula is satisfiable if and only if it is satisfiable in a *small* finite model, where *small* means that the size of the model is bounded by some function of the length of the given formula. Theorem 2 states that the lower as well as the upper bound of the complexity of the decision problem for CTL* (resp., CTL) is deterministic double (resp., single) exponential in the length of the given formula. (By double (resp., single) exponential we mean $exp(exp(n))$ (resp., $exp(n)$), where $exp(n)$ is a function c^n for some $c > 1$.)

To test the satisfiability of a CTL* formula f, we have the following sound and complete decision procedure [6, 9, 8], the complexity of which is double exponential in the length of the specification CTL* formula.

1. Derive a Rabin tree automaton for the CTL* formula f [9]. The number of states (resp., acceptance condition pairs) of the Rabin tree automaton is double (resp., single) exponential in the length of the formula f.
2. Test the emptiness of the Rabin tree automaton [8]. If the Rabin tree automaton is empty, then the CTL* formula f is not satisfiable; otherwise the formula f is satisfiable, and a model for f can be extracted from the Rabin tree automaton. The complexity of this step is polynomial in the number of states of the Rabin tree automaton and exponential in the number of acceptance condition pairs of the Rabin tree automaton.

The notion of Rabin tree automaton is described below. For simplicity, we consider only the finite automaton on infinite binary trees. The infinite binary tree is the set $T = pr(\{0, 1\}^\omega)$. The elements of T are called nodes, and the empty word ϵ is the root of T. For all $x \in T$, $x \cdot 0$ and $x \cdot 1$ are the left and right successors of x,

respectively. A path π of the tree T is a subset of T such that the root ϵ is in π, and $\forall x \in \pi$, one and only one of $x \cdot 0$ and $x \cdot 1$ is in π. Note that a path of T corresponds a unique word in $\{0,1\}^\omega$. Given an alphabet Σ, a Σ-labeled tree (called Σ-tree) is a function $V : T \to \Sigma$ that maps each node of T to a letter in Σ.

A Rabin tree automaton (on infinite binary Σ-tree) is $\mathcal{A} = (Q, \Sigma, \delta_{\mathcal{A}}, q_0, F)$, where Q is a finite state set, Σ is a finite alphabet set, $\delta_{\mathcal{A}} : Q \times \Sigma \to 2^{Q \times Q}$ is the transition function, $q_0 \in Q$ is the initial state, and $F = \{(G_i, R_i) \mid G_i \cup R_i \subseteq Q, i = 1, \ldots, k\}$ is the Rabin acceptance condition. A run r of $\mathcal{A}$ on an input Σ-tree V is a Q-labeled tree $r : T \to Q$ such that $r(\epsilon) = q_0$ and $\forall\ x \in T$, $(r(x \cdot 0), r(x \cdot 1)) \in \delta_{\mathcal{A}}(r(x), V(x))$. We say that $\mathcal{A}$ accepts an input Σ-tree V if and only if there exists a run r of $\mathcal{A}$ on V such that for each path π of r, there exists a pair (G_i, R_i) in F such that π visits G_i infinitely often and R_i finitely often.

To test the satisfiability of a CTL (a special case of CTL*) formula f, the following more efficient sound and complete decision procedure exists [6], the complexity of which is single exponential in the length of the specification CTL formula:

1. Construct a tableau for the CTL formula f, where a tableau is a state transition structure derived for the given temporal logic formula from which a model of the given formula can be extracted as a subtransition structure whenever that formula is satisfiable. The number of states of the tableau for the CTL formula f is exponential in the length of f.
2. Test the tableau for the existence of a model for f. If there does not exist a model for f in the tableau, then the CTL formula f is not satisfiable; otherwise the formula f is satisfiable, and a model for f can be extracted from the tableau. The complexity of this step is polynomial in the number of states of the tableau.

3. Supervisory control for CTL* specification. In this section, we study the supervisory control problem for systems with CTL* temporal logic specifications. From now on, we assume that the uncontrolled discrete event plant P is modeled by a six tuple: $P = (X, \Sigma, \delta_P, x_0, AP, L_P)$, where X is a finite set of states; Σ is a finite set of event labels that is the disjoint union of Σ_c, the set of controllable events, and Σ_u, the set of uncontrollable events; $\delta_P : X \times \Sigma \to X$ is a partial function defined at each state in X for a subset of Σ; $x_0 \in X$ is the initial state of P; AP is the finite set of atomic proposition symbols with $AP \cap X = \emptyset$; and $L_P : X \to 2^{AP \cup \{\neg p | p \in AP\}}$ is a labeling function such that $\forall x \in X$, $\forall p \in AP$, $p \in L_P(x) \Rightarrow \neg p \notin L_P(x)$. Here for a state x, $p \in L_P(x)$ means that p holds at x, $\neg p \in L_P(x)$ means that p does not hold at x, and if for some atomic proposition p such that neither p nor $\neg p$ is in $L_P(x)$, then it means that p may or may not hold at x. Note from the definition of the transition function δ_P that we are assuming P to be deterministic.

A supervisor S is modeled by a six tuple: $S = (Y, \Sigma, \delta_S, y_0, AP, L_S)$, where Y is a set of states (finite or infinite); Σ and AP are the same sets as given in P; $\delta_S : Y \times \Sigma \to 2^Y$ is a total function defined at each state in Y for each event in Σ; $y_0 \in Y$ is the initial state of S; and $L_S : Y \to 2^{AP \cup \{\neg p | p \in AP\}}$ is a labeling function similar to that in P such that $\forall y \in Y$, $\forall p \in AP$, $p \in L_P(y) \Rightarrow \neg p \notin L_P(y)$. Note from the definition of the transition function δ_S that S is allowed to be nondeterministic. The class of nondeterministic supervisors is more powerful than that of deterministic supervisors, as illustrated by Example 1.

The controlled plant is obtained by the strict synchronous composition of P and S, denoted by $P||S$, which is defined as $P||S = (Z, \Sigma, \delta_{P||S}, z_0, AP, L_{P||S})$, where $Z = X \times Y$ is the state set; Σ and AP are the same sets as given in P; and $\delta_{P||S} : Z \times \Sigma \to 2^Z$

is the state transition function for $P||S$. Let $\sigma \in \Sigma$ and $(x, y) \in X \times Y = Z$; then we define $\delta_{P||S}$ as

$$\delta_{P||S}((x,y),\sigma) = \begin{cases} \{(\delta_P(x,\sigma), z) \mid z \in \delta_S(y,\sigma)\} & \text{if } \delta_P(x,\sigma) \text{ is defined and } \delta_S(y,\sigma) \neq \emptyset; \\ \emptyset & \text{otherwise.} \end{cases}$$

$z_0 = (x_0, y_0) \in Z$ denotes the initial state of $P||S$, and $L_{P||S} : Z \to 2^{AP \cup \{\neg p | p \in AP\}}$ is the labeling function for $P||S$, which is defined as $L_{P||S}(x, y) = L_P(x) \cup L_S(y)$.

We use $M_{P||S} = (Z, R, AP, L)$ to denote the state transition graph of $P||S$, where Z and AP are the same sets as given in $P||S$; $R \subseteq Z \times Z$ is the transition relation with $R = \{(z, z') \mid \exists \sigma \in \Sigma \ s.t. \ z' \in \delta_{P||S}(z, \sigma)\}$; and $L : Z \to 2^{AP}$ is the labeling function which is defined as $\forall z \in Z$, $L(z) = L_{P||S}(z) \cap AP$.

We require that all the supervisors derived should be control-compatible and propositionally consistent with respect to the plant. The control-compatibility of a supervisor requires that when controlling the plant P, the supervisor should never disable an uncontrollable transition in P, where a transition is called an uncontrollable transition if it is labeled by an uncontrollable event. Next, since the propositional labeling of a state $z = (x, y) \in Z$ of $P||S$ is obtained as $L_P(x) \cup L_S(y)$, it is possible that the label of z contains $p \in AP$ as well as its negation (for example, when $p \in L_P(x)$ and $\neg p \in L_S(y)$). We exclude such state machines from being a supervisor by requiring the propositional consistency property defined below.

DEFINITION 2. *A supervisor S is said to be* control-compatible *with respect to a given plant P if for any $s \in \Sigma^*$, $\sigma \in \Sigma_u$, and $z = (x, y) \in \delta_{P||S}(z_0, s)$ such that σ is defined at state x of P, it holds that σ is also defined at state y of S. A supervisor S is said to be* propositionally consistent *with respect to a given plant P if it holds in $P||S$ that for every state $z \in Z$ reachable from z_0, we have $\forall p \in AP$, $p \in L_{P||S}(z) \Rightarrow \neg p \notin L_{P||S}(z)$.*

The supervisory control problem for systems with temporal logic specifications is formulated as follows:

> Let P be a deterministic nonterminating plant with $\Sigma = \Sigma_c \cup \Sigma_u$. For a given CTL* formula f, find a control-compatible and propositionally consistent supervisor S for P such that $P||S$ is nonterminating and $< M_{P||S}, \ z_0 > \models f$, where $M_{P||S}$ is the state transition graph of $P||S$ and z_0 is the initial state of $P||S$.

Before solving the above control problem, we give the definition of the controllability of CTL* formulas.

DEFINITION 3. *Given a nonterminating plant P, a CTL* formula f is said to be controllable with respect to P, also called* P-controllable*, if there exists a control-compatible and propositionally consistent supervisor S such that $P||S$ is nonterminating and $< M_{P||S}, z_0 > \models f$.*

In Definition 3, the supervisor S need not be finite. Through the *small model theorem* derived below, we demonstrate that if a CTL* formula f is controllable, then f can be enforced by a *finite* supervisor. In other words, we don't impose the finiteness of a supervisor a priori in the definition of controllability. Also, the supervisor is allowed to be nondeterministic since in some situations only a nondeterministic supervisor can achieve a given CTL* specification. This is illustrated by the following example.

EXAMPLE 1. *The plant P is shown in Figure* 1(a)*, where $X = \{x_0, x_1, x_2, x_3\}$, $\Sigma = \Sigma_c = \{a, b, c, d, e\}$, $AP = \{p_1, p_2\}$, $L_P(x_0) = L_P(x_1) = AP$, $L_P(x_2) = \{p_1, \neg p_2\}$, and $L_P(x_3) = \{\neg p_1, p_2\}$. (We adopt the following convention for the figures we draw:*

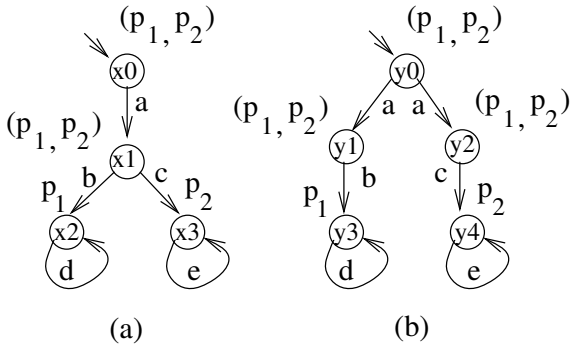

FIG. 1. *Nondeterministic supervisor.*

if an atomic proposition p is not labeled at a state x, then it means that p does not hold at x, i.e., $\neg p \in L_P(x)$.) The specification is described by the CTL *formula $EXAGp_1 \wedge EXAGp_2$, where $EXAGp_i$ has the following meaning: "Exists* (E) *a path (starting from the initial state) such that from the next* (X) *state all paths* (A) *always* (G) *satisfy p_i." Note that the given plant does not satisfy the specification since starting from the only next state x_1, all paths do not always satisfy p_1 and p_2.*

Further, there does not exist a deterministic supervisor that can achieve the specification since AGp_1 and AGp_2 can not be satisfied simultaneously at state x_1. But we can have a nondeterministic supervisor S to achieve the specification, which is shown in Figure 1(b).

Also note that the $*$-language as well as ω-language of the controlled plant is the same as that of the uncontrolled plant, i.e., $L(P||S) = L(P) = a(bd^* + ce^*)$ and $L_\omega(P||S) = L_\omega(P) = a(bd^\omega + ce^\omega)$. This implies that the above CTL *specification can not be expressed by a regular $*$-language or a regular ω-language.*

Remark 2. A formal treatment of nondeterministic control policy, its representation as a state machine, and its implementation are given in [17]. The essential idea is that the control action selection of a nondeterministic supervisor is done on-line nondeterministically from among a set of choices determined off-line. Also, the control action can be changed on-line nondeterministically (before any new observation) in accordance with choices determined off-line. (This feature of nondeterministic control is not being used in the present paper.) The on-line choices, once made, can be used to affect the set of control action choices in future. A nondeterministic control map with above features may be implemented as a control and observation compatible nondeterministic state machine introduced in [17]. (In the context of the present paper, we are assuming a complete observation of events and so only control compatibility is required; observation compatibility is automatically guaranteed.) It is further argued in [17] that to implement a nondeterministic supervisor a mechanism is needed for the on-line nondeterministic selection of the control action (from the set of choices computed off-line), and another mechanism is needed to determine when to nondeterministically change the control action. For the first purpose, a "coin toss" (with as many possible outcomes as the number of control action choices) can be used. For the second purpose, a "random timer" can be used. In the lack of any new observation, the control action is changed if and when the timer goes off.

In the following, we reduce the problem of the control of CTL* to that of the

decision of CTL*, then use the results for the decision of CTL* to solve the control problem of CTL*. We first encode all the controllable sub-trees embedded in the "plant-tree" P by a CTL formula f_P defined as follows.

Add new fresh atomic propositions. Extend AP to $AP' := AP \cup X$. Each state of the plant is viewed as a new atomic proposition. For each $x \in X$, the proposition x holds at state x and at no other state of P.

Encode the initial state of P using formula f_0 defined as

$$f_0 := x_0.$$

This says that in a model for f_0, the atomic proposition x_0 holds at the initial state of the model.

Encode the state set of P using formula $f_1 := f_{11} \wedge f_{12}$ defined as

$$f_{11} := AG\Big(\bigvee_{x\in X} x\Big) \bigwedge_{x\in X} AG\Big(x \Rightarrow \bigwedge_{x'\neq x} \neg x'\Big),$$

$$f_{12} := \bigwedge_{x\in X} AG\Big[x \Rightarrow \bigwedge_{p\in(L_P(x)\cap AP)} p \bigwedge_{\neg p\in(L_P(x)\cap \overline{AP})} \neg p\Big],$$

and $\overline{AP} = \{\neg p \mid p \in AP\}$. In the above, f_{11} states that if M is a model for f_{11}, then every state in M should be labeled with one and only one atomic proposition $x \in X$; f_{12} states that if M is a model for f_{12}, then any atomic proposition which holds (resp., does not hold) at the state x of P should also hold (resp., should not hold) at states in M which are labeled by the proposition x.

Encode the transitions of P using formula f_2 defined as

$$f_2 := \bigwedge_{x\in X} AG\Big(x \Rightarrow AX\Big(\bigvee_{x'\in I_x} x'\Big)\Big),$$

where $I_x = \{x' \mid \exists \sigma \in \Sigma$ such that $x' = \delta_P(x,\sigma)\}$. The formula f_2 states that if M is a model for f_2, s is a state in M labeled with the atomic proposition x, and s' is a successor of s in M labeled with the atomic proposition x', then there must exist a transition from x to x' in P.

Encode the uncontrollable transitions of P using formula f_3 defined as

$$f_3 := \bigwedge_{x\in X} AG\Big(x \Rightarrow \bigwedge_{x'\in I_x^u} EXx'\Big),$$

where $I_x^u = \{x' \mid \exists \sigma \in \Sigma_u$ such that $x' = \delta_P(x,\sigma)\}$. The formula f_3 states that if M is a model for f_3, s is a state in M labeled with the atomic proposition x, and there exists an uncontrollable transition from state x to another state x' in P, then there must exist a successor s' of s in M such that x' is labeled at s'.

Encode all uncontrollable sub-trees of P using the formula f_P defined as

$$f_P := f_0 \wedge f_1 \wedge f_2 \wedge f_3.$$

Remark 3. From the above definition it follows that f_P encodes some information of the plant P. It should be noted that f_P does not contain all the information of P

since from a model M of f_P we cannot reconstruct the plant state machine P. This is because when we encode the transitions (resp., uncontrollable transitions) of P by f_2 (resp., f_3), we require only that the state x' is one step reachable from x, and we ignore all other information such as how many transitions exist between x and x' in P and what are the event labels of these transitions. But the information encoded by f_P is enough for the control of P which is shown in Theorem 3 below.

The following lemma shows that f_P is satisfied by the plant P.

PROPOSITION 1. *Let P be a nonterminating plant and $M_P = (X, R_P, AP', L'_P)$ be the state transition graph of P with $AP' = AP \cup X$, $R_P = \{(x, x') \in X \times X \mid \exists \sigma \in \Sigma,\ x' = \delta_P(x, \sigma)\}$, $L'_P(x) = (L_P(x) \cap AP) \cup \{x\}\ \forall x \in X$. Then it holds that $< M_P, x_0 > \models f_P$, where f_P is as defined above.*

Proof. Since $x_0 \in L'_P(x_0)$, obviously $< M_P, x_0 > \models f_0$. Next, for each state x in M_P, we have

- $[x \in L_P(x)] \bigwedge_{x' \neq x} [x' \notin L_P(x)] \Rightarrow < M_P, x_0 > \models f_{11}$;
- $[\forall p \in (L_P(x) \cap AP), p \in L'_P(x)] \wedge [\forall \neg p \in (L_P(x) \cap \overline{AP}), p \notin L'_P(x)]$ $\Rightarrow < M_P, x_0 > \models f_{12}$;
- $[\forall x' \in \{x' \mid (x, x') \in R_P\}, \exists \sigma \in \Sigma, x' = \delta_P(x, \sigma)] \Rightarrow < M_P, x_0 > \models f_2$;
- $[\forall x' \in \{x' \mid \exists \sigma \in \Sigma_u, x' = \delta_P(x, \sigma)\}, (x, x') \in R_P] \Rightarrow < M_P, x_0 > \models f_3$.

Combining the above implications, we obtain $< M_P, x_0 > \models f_P$. ∎

The following theorem reduces the control problem of CTL* to the decision problem of CTL*.

THEOREM 3. *Given a CTL* formula f and a deterministic nonterminating plant P encoded by the CTL formula f_P, f is P-controllable if and only if the CTL* formula $f \wedge f_P$ is satisfiable.*

Proof. For the necessity, suppose there exists a control-compatible and propositionally consistent supervisor $S = (Y, \Sigma, \delta_S, y_0, AP, L_S)$ such that $< M_{P||S}, z_0 > \models f$. Then we can get a model $M' = (Z, R, AP', L')$ for $f \wedge f_P$ from $M_{P||S} = (Z, R, AP, L)$ as follows: $\forall z = (x, y) \in Z$, $L'(z) = L(z) \cup \{x\}$. Since $< M_{P||S}, z_0 > \models f$, it is obvious that M' is also a model for f, i.e., $< M', z_0 > \models f$. For the formula $f_P = f_0 \wedge f_{11} \wedge f_{12} \wedge f_2 \wedge f_3$, we have the following. Since $z_0 = (x_0, y_0)$, $x_0 \in L'(z_0)$, this implies $< M', z_0 > \models f_0$. Since $M_{P||S}$ can be viewed a subgraph embedded in P, M' is also a subgraph embedded in P. This implies that $< M', z_0 > \models f_{11} \wedge f_2$. From the definition of $L_{P||S}$ and the propositional consistency of S, we know that $< M', z_0 > \models f_{12}$. Further, from the control-compatibility of S, we have $< M', z_0 > \models f_3$. Combining these, we get $< M', z_0 > \models f \wedge f_P$, i.e., $f \wedge f_P$ is satisfiable.

For the sufficiency, let $M = (Q, R, AP', L)$ be a model of $f \wedge f_P$, i.e., $\exists q_0 \in Q$, $< M, q_0 > \models f \wedge f_P$. We can get a supervisor $S = (Y, \Sigma, \delta_S, y_0, AP, L_S)$ from M as follows: $Y \subseteq Q$ is the set of states which are reachable from q_0 in M; $\forall y \in Y,\ \forall \sigma \in \Sigma,$

$$\delta_S(y, \sigma) = \{y' \mid [(y, y') \in R] \wedge [x' = \delta_P(x, \sigma)],\ \text{where } \{x'\} = L(y') \cap X \text{ and } \{x\} = L(y) \cap X\};$$

$y_0 = q_0$; and $\forall y \in Y, L_S(y) = L(y) \cap (AP \cup \{\neg p | p \in AP\})$. Since M is a model of f_P, it ensures that S is control-compatible with respect to P, and further because P is deterministic, S is propositionally consistent with respect to P. Also because P is deterministic, $P||S$ has the same graph as S, and hence it is nonterminating and $< M_{P||S}, z_0 > \models f$. So f is P-controllable. ∎

Now from the small model theorem for the decision of CTL* (Theorem 1), we have the following small model theorem for the control of CTL*.

THEOREM 4. *Given a CTL* formula f and a deterministic nonterminating plant P, f is P-controllable if and only if there exists a* finite *state control-compatible*

and propositionally consistent supervisor S such that $P||S$ is nonterminating and $< M_{P||S}, z_0 > \models f$.

Proof. The sufficiency is obvious. For necessity, from Theorem 3 we know that if f is P-controllable, then $f \wedge f_P$ is satisfiable. Further, from Theorem 1, we have that if $f \wedge f_P$ is satisfiable, then there exists a finite state transition graph $M = (Q, R, AP', L)$ such that $\exists q_0 \in Q,\ < M, q_0 > \models f \wedge f_P$. Using the same method as that in the proof of Theorem 3, we can obtain a finite state control-compatible and propositionally consistent supervisor S from M such that $P||S$ is nonterminating and $< M_{P||S}, z_0 > \models f$. So the theorem holds. □

From Theorem 2, we have the following result for the complexity of control problem for CTL* (resp., CTL).

THEOREM 5. *The control problem for CTL* (resp., CTL) is complete for deterministic double (resp., single) exponential time in the length of the specification formula.*

Proof. From Theorem 3 and the definition of f_P, whose length is polynomial in the number of states of P, we know that the control problem for CTL* (resp., CTL) is polynomial-time reducible to the decision problem for CTL* (resp., CTL). From Theorem 2 we have that the complexity of testing the satisfiability for CTL* (resp., CTL) has an upper bound of deterministic double (resp., single) exponential time in the length of the specification formula. So the control problem for CTL* (resp., CTL) is upper bounded by deterministic double (resp., single) exponential time in the length of the specification formula. This establishes the desired upper bound of the complexity of the control problem.

To establish the desired lower bound of the complexity of the control problem, in view of Theorem 2 it suffices to show that the decision problem can be polynomially reduced to a control problem. For the decision problem of CTL* (resp., CTL), we can view it as a control problem for the plant $P = (X, \Sigma, \delta_P, x_0, AP, L_P)$ with $X = \{x_0\}$; $\Sigma = \Sigma_c = \{\sigma\}$; $x_0 = \delta_P(x_0, \sigma)$; $L_P(x_0) = \emptyset$, where the goal of the control is to find a supervisor that the controlled plant satisfies the given CTL* (resp., CTL) formula. If a supervisor S exists for the above control problem, we can directly use $M_{P||S}$ as the model of the given CTL* (resp., CTL) formula. Since the decision problem for CTL* (resp., CTL) has a lower bound complexity of deterministic double (resp., single) exponential time in the length of the specification formula, we must have that the complexity of the control problem for CTL* (resp., CTL) is lower bounded by deterministic double (resp., single) exponential time in the length of the specification formula. □

From Theorem 3, we know that an algorithm for the supervisor synthesis for CTL* control can be obtained from the decision procedure of CTL*. Let f be a CTL* specification formula and P be a deterministic nonterminating plant; then a supervisor synthesis algorithm is as follows.

ALGORITHM 1. SUPERVISOR SYNTHESIS ALGORITHM FOR CTL* CONTROL.

1. Test the satisfiability of the CTL* formula $f \wedge f_P$. This step is done by using the decision procedure for CTL* as follows:
   (a) Construct a Rabin tree automaton for the CTL* formula f using the method given in [9].
   (b) Construct a tree-automaton for f_P directly from the plant P; this tree automaton has the same state set as P and has no acceptance conditions.
   (c) Construct the Rabin tree automaton for $f \wedge f_P$ from the synchronous composition of the above two tree automata.

(d) Test the emptiness of the set of trees accepted by the Rabin tree automaton for $f \wedge f_P$ [8]. The set of trees accepted by the tree automaton is empty if and only if $f \wedge f_P$ is not satisfiable. If $f \wedge f_P$ is satisfiable, then go to next step; otherwise stop the algorithm and output that "no supervisor exist."

2. If $f \wedge f_P$ is satisfiable, extract a model for the formula $f \wedge f_P$ from its nonempty Rabin tree automaton using the result given in [8].
3. Derive a supervisor from the model for the formula $f \wedge f_P$ by using the method in the proof of Theorem 3.

Remark 4. From Theorem 3, and using an argument similar to the soundness and completeness of the decision procedure for CTL* [9, 8], we can conclude that Algorithm 1 for control synthesis for CTL* is sound and complete. Algorithm 1 has a worst case complexity of double exponential in the length of the CTL* formula f and polynomial in the size of the plant P. This is because the Rabin tree automaton for the specification formula f has a number of states that *is* double exponential in the length of f and has a number of acceptance condition pairs which *is* single exponential in the length of f, and the tree automaton for f_P has the same state set as P and has no acceptance condition, so the final Rabin tree automaton for $f \wedge f_P$ has a number of states which *is* double exponential in the length of f and linear in the number of states of the plant, and it has a number of acceptance condition pairs which *is* single exponential in the length of the specification formula f only.

For an easy synchronous composition of tree automata for f and f_P, it is required that the two tree automata have the same branching degree. To compute the branching degree of a CTL* formula f, we first express it in its *positive normal form* by pushing negations as far inward as possible using De Morgan's law ($\neg(f_1 \vee f_2) \equiv \neg f_1 \wedge \neg f_2$, $\neg(f_1 \wedge f_2) \equiv \neg f_1 \vee \neg f_2$) and the dualities ($\neg AGf_1 \equiv EF\neg f_1$, $\neg A[f_1 U f_2] \equiv E[\neg f_1 B f_2]$, etc.). Then the branching degree of f, denoted by d_f, can be chosen to be the total number of the existential path quantifier "E" in its positive normal form. Similarly, we can get the branching degree of f_P, denoted by d_{f_P}. Then we can choose $d = d_f + d_{f_P}$ as the branching degree of the tree automata models for f and f_P. Next we give an example to illustrate how to compute the branching degree of a CTL* formula and how to derive a tree automaton with a required branching degree for the encoding f_P of P that has the same state set as P.

EXAMPLE 2. *Consider the encoding f_P for the plant P of Example* 1 *and suppose now that $\Sigma_u = \{b\}$. Suppose the specification is given by $f = EXAGp_1$. Then there is one E in the formula f_P because of the uncontrollable transition from x_1 to x_2 in P, and there is one E in f. So the required branching degree of the tree automata for f and f_P can be chosen to be* $1 + 1 = 2$.

A tree automaton for f_P with the required branching degree of 2 *(i.e., the automaton on binary trees) can be obtained as follows: $\mathcal{A} = (X, 2^{AP \cup X}, \delta_{\mathcal{A}}, x_0, \{(X, X)\})$, where X, AP, and x_0 are the same as in P, $\delta_{\mathcal{A}} : X \times 2^{AP \cup X} \to 2^{X^2}$ is given as $\delta_{\mathcal{A}}(x_0, (p_1, p_2, x_0)) = \{(x_1, x_1)\}$, $\delta_{\mathcal{A}}(x_1, (p_1, p_2, x_1)) = \{(x_2, x_2), (x_2, x_3), (x_3, x_2)\}$, $\delta_{\mathcal{A}}(x_2, (p_1, x_2)) = \{(x_2, x_2)\}$, $\delta_{\mathcal{A}}(x_3, (p_2, x_3)) = \{(x_3, x_3)\}$. Note that the uncontrollable transition from x_1 to x_2 in P is captured in $\mathcal{A}$ by requiring that x_2 be included in every state pair in $\delta_{\mathcal{A}}(x_1, (p_1, p_2, x_1))$. It can be verified that any infinite binary tree that is accepted by $\mathcal{A}$ satisfies the formula f_P.*

Remark 5. The supervisory control problem for language-based specifications is typically of two types: (i) the target control problem (where a supervisor is designed so that the controlled language equals the specification language) and (ii) the range

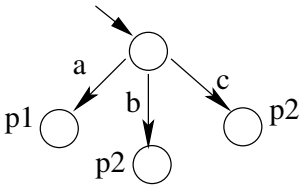

FIG. 2. *A counter example to* [1].

control problem (where a supervisor is designed so that the controlled language is bounded by a lower bound and an upper bound specification languages). Obviously the range control problem is more general since the two bounds can be the same, in which case it is the same as the target control problem. For the range control problem, *any* supervisor is acceptable as long as the controlled language lies in the specified range. If none exists, then one can consider minimal relaxations of the two bounds so that a supervisor will exist.

The situation is even more general for a CTL* specification: a pair of LTL formulae f and g may be chosen to serve as lower and upper bounds for the ω-language of the controlled plant. Then the single LTL formula $\neg f \wedge g$ specifies a range for the controlled ω-language. Of course, more general specifications can be specified in CTL* than just the simple range for ω-language. Similar to the approach taken for the language range control, here we are seeking *any* supervisor that enforces the given CTL* specification. (Algorithm 1 finds one such supervisor.) Now if none exists, then one would like to consider a minimal relaxation of the given CTL* specification for which a supervisor will exist. This topic is not within the scope of the present paper but may be addressed by introducing an order relation over the class of all CTL* formulas defined over a fixed set of atomic propositions using the simulation preorder. We say $f_1 \leq f_2$ if and only if a model M_1 of f_1 is simulated by a model M_2 of f_2. (A simulation relation is a preorder over the set of all models since it is reflexive and transitive but not antisymmetric.) Minimal relaxations of a specification formula can be defined with respect to this order relation.

3.1. Supervisory control for CTL specification. If the specification is given as a CTL formula, we may view it as a CTL* formula and use Algorithm 1 for a supervisor synthesis for CTL control. But this method has a double exponential complexity in the length of the specification formula. From Theorem 3, we know that the control problem for a CTL formula f can be reduced to the decision problem for the formula $f \wedge f_P$. Since f_P by its definition is also a CTL formula, $f \wedge f_P$ is a CTL formula, and so we can get a supervisor synthesis algorithm for the control of the CTL formula f from the decision procedure for the CTL formula $f \wedge f_P$ with a worst-case complexity of single exponential in the length of the CTL specification formula (as opposed to double exponential for the more general case of a CTL* specification). In the appendix, we present a detailed supervisor synthesis algorithm for CTL control.

Remark 6. In [1], the CTL control problem was also studied. But the author restricted the problem by only considering the state-based supervisors and a special class of CTL formulas. Also note that the method in [1] gives wrong results even for some CTL formulas which do belong to the special class of formulas considered in [1]. To see this, consider the example shown in Figure 2, where a, b, c all are controllable

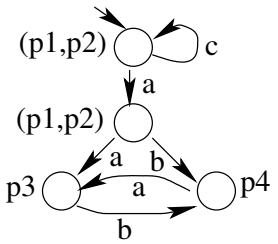

FIG. 3. *An example for the completeness of LTL control.*

events. Then the control action of enabling all a, b, c will let EXp_1 hold at the initial state, and the control action of enabling only b and c will let AXp_2 hold at the initial state. In [1], it was claimed that in order to let $EXp_1 \wedge AXp_2$ hold at the initial state, we may take the conjunction of the control actions for EXp_1 and AXp_2, i.e., enabling b and c would ensure that $EXp_1 \wedge AXp_2$ will hold at the initial state. It is obvious that under this control action, EXp_1 does not hold at the initial state. So the method in [1] gives a wrong result for the above example.

3.2. Supervisory control for LTL specification. Let us next consider the special case of LTL. Recall that LTL is obtained by restricting CTL* in that except for the path quantifier A appearing at the beginning of the formula no other path quantifiers exist in the formula. If the specification f is given as a LTL formula, then we have two different ways to solve the control problem:

1. View the LTL formula as a CTL* formula and directly use Algorithm 1 for the supervisor synthesis of LTL control.
2. First use a tableau construction method such as the one given in [10] to convert the LTL formula into a nondeterministic Buchi automaton; next use the method in [29] to change the nondeterministic Buchi automaton into a deterministic Rabin automaton; next derive a new Rabin automaton from the synchronous composition of the plant automaton and the specification Rabin automaton; and finally use the approach in [33] to solve the control problem on this final Rabin automaton.

These two methods have a same worst-case complexity which is polynomial in the size of the plant and double exponential in the length of the specification LTL formula.

We next propose a supervisor synthesis algorithm for the control of LTL which has a smaller complexity (single exponential in the length of the LTL formula as opposed to double exponential) but it is only sound (and not complete). We first change the LTL formula into a CTL formula by inserting the path quantifier A before every temporal operator in the formula and removing any repeated A; then we apply Algorithm 2 (given in the appendix) for the supervisor synthesis for this CTL formula. From the semantics of CTL and LTL, we know that the supervisor derived does work for the original LTL formula. The worst-case complexity of this method is the same as that for Algorithm 2 which is polynomial in the size of the plant and single exponential in the length of the specification LTL formula.

This method, however, is not complete, i.e., when it answers "no" for the existence of a supervisor, there may still exist a supervisor that can enforce the given LTL specification. Consider, for example, the system shown in Figure 3, for which the specification is given as $A[(p_1 U p_3) \vee (p_2 U p_4)]$. Assuming that the event c is the only controllable event, it is obvious that the specification can be enforced if the supervisor

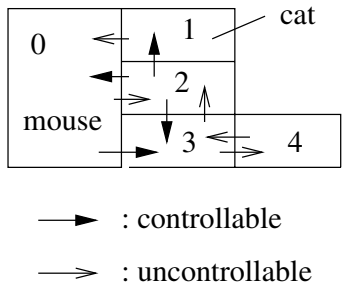

FIG. 4. *Mouse in a maze.*

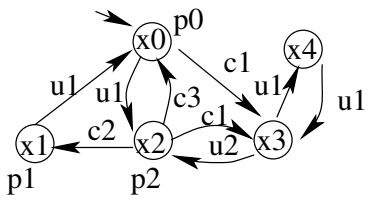

FIG. 5. *Plant model.*

disables c at the initial state. But if we transfer the specification into a CTL formula $A(p_1 U p_3) \vee A(p_2 U p_4)$ using the method described above, then it is easy to verify that no supervisor exists.

Remark 7. The algorithm given in [2] for the control of MTL (LTL together with real-time constraints) is sound but not complete, which was not clarified there. Since an LTL formula is also an MTL formula, we can apply the algorithm given in [2] to the example of Figure 3. The algorithm in [2] will answer "no" for the existence of a supervisor for the above example. But we know that a supervisor does exist, thereby demonstrating the incompleteness of the algorithm given in [2].

4. Illustrative example. In this section, we give a simple example to illustrate our result. This is a traffic control problem of a mouse in a maze. The maze, shown in Figure 4, consists of five rooms connected by various one-way passages, where some of them can be closed through control. There is also a cat which alway stays in room 1. The mouse is initially in room 0, but it can visit other rooms by using one-way passages. Our task is to design a supervisor to control the passages in order to guarantee that

Spec 1 The mouse never visits room 1 where the cat stays (this is a safety property).

Spec 2 The mouse can go to room 0 for play at any time it wants to (this is a nonblocking property).

Spec 3 The mouse shall visit room 2 for food infinitely often (this is a liveness property).

Spec 4 The mouse shall never be locked in a room (this is a nonterminating property).

The above problem can be formulated as a supervisory control problem of a discrete event system with a CTL specification as follows. The system is modeled as a plant $P = (X, \Sigma, \delta_P, x_0, AP, L_P)$, which is shown in Figure 5, where $X = \{x_i, i = 0, 1, 2, 3, 4\}$; $\Sigma = \{c_1, c_2, c_3, u_1, u_2\}$, $\Sigma_c = \{c_1, c_2, c_3\}$; $AP = \{p_0, p_1, p_2\}$; $L_P(x_0) =$

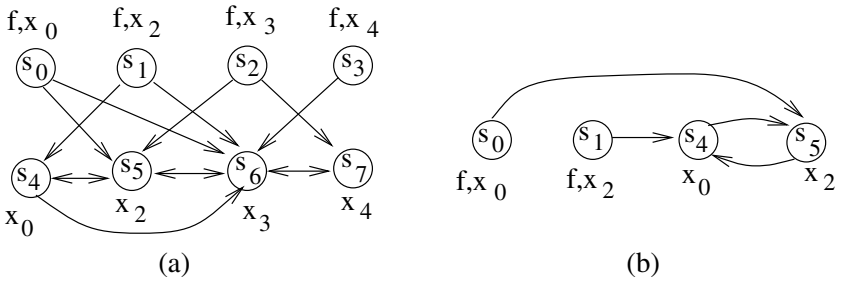

FIG. 6. *Tableau and model for $f \wedge f_P$.*

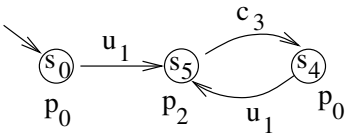

FIG. 7. *Supervisor for the cat-mouse example.*

$\{p_0, \neg p_1, \neg p_2\}$, $L_P(x_1) = \{\neg p_0, p_1, \neg p_2\}$, $L_P(x_2) = \{\neg p_0, \neg p_1, p_2\}$, $L_P(x_3) = L_P(x_4) = \{\neg p_0, \neg p_1, \neg p_2\}$. The specification is given by the CTL formula $f = AG\neg p_1 \wedge AGEFp_0 \wedge AGAFp_2 \wedge AGEXtrue$, where the ith conjunct corresponds to the Spec i.

Now we can use Algorithm 2 for the supervisor synthesis of the above control problem. We first obtain the tableau T for the formula $f \wedge f_P$, where f_P is the CTL formula encoding the plant P (for brevity f_P is omitted here). The tableau $T = (S_T, AP', R_T, L_T)$ is shown in Figure 6(a), where for $0 \leq i \leq 3$, $L_T(s_i) = \{f\} \cup L_T(s_{i+4})$, and for $i > 3$,

$$
\begin{aligned}
L_T(s_4) = \{&p_0, \neg p_1, \neg p_2, AG\neg p_1, AGEFp_0, AGAFp_2, AGEXtrue, AXAG\neg p_1, EFp_0,\\
&AXAGEFp_0, AFp_2, AXAGAFp_2, EXtrue, AXAGEXtrue, AXAFp_2,\\
&x_0, EXx_2\};\\
L_T(s_5) = \{&\neg p_0, \neg p_1, p_2, AG\neg p_1, AGEFp_0, AGAFp_2, AGEXtrue, AXAG\neg p_1, EFp_0,\\
&AXAGEFp_0, AFp_2, AXAGAFp_2, EXtrue, AXAGEXtrue, EXEFp_0, x_2\};\\
L_T(s_6) = \{&\neg p_0, \neg p_1, \neg p_2, AG\neg p_1, AGEFp_0, AGAFp_2, AGEXtrue, AXAG\neg p_1, EFp_0,\\
&AXAGEFp_0, AFp_2, AXAGAFp_2, EXtrue, AXAGEXtrue, EXEFp_0,\\
&AXAFp_2, x_3, EXx_2, EXx_4\};\\
L_T(s_7) = \{&\neg p_0, \neg p_1, \neg p_2, AG\neg p_1, AGEFp_0, AGAFp_2, AGEXtrue, AXAG\neg p_1, EFp_0,\\
&AXAGEFp_0, AFp_2, AXAGAFp_2, EXtrue, AXAGEXtrue, EXEFp_0,\\
&AXAFp_2, x_4, EXx_3\}.
\end{aligned}
$$

Next a model $M = (Q, R, AP', L)$ for $f \wedge f_P$ is derived and this is shown in Figure 6(b), where $Q = \{s_0, s_1, s_4, s_5\} \subset S_T$, $R = R_T|_Q$ and $L = L_T|_Q$, the restriction of R_T and L_T, respectively, to Q.

Finally a supervisor S is obtained from M and is shown in Figure 7. It follows

that the mouse moves between rooms 0 and 2 only, and hence obviously the controlled system $P||S$ satisfies the given specification.

5. Conclusion. We studied the supervisory control problem for systems with temporal logic specifications. The full branching time logic of CTL* is used for expressing the control specifications. The main contributions of the paper are summarized as follows:

1. CTL* temporal logic allows the control constraints on the sequences of states which can be also captured by a regular $*$-language or ω-language, as well as on the more general branching structures of states which cannot be captured by a regular $*$-language or ω-language as shown in Example 1.
2. For the first time a sound and complete supervisory synthesis algorithm for CTL* specifications has been obtained. (Supervisors are allowed to be nondeterministic as this allows for the existence of a supervisor for a larger class of CTL* specifications.)
3. By reducing the control problem to the decision problem, a small model theorem for the CTL* control is derived.
4. The computational complexity of the control algorithms have been derived: the control problem for CTL* (resp., CTL) is complete for deterministic double (resp., single) exponential time in the length of the specification formula. Further, it is polynomial in the number of plant states.
5. Usage of temporal logic specifications does not increase the computational complexity of supervisor synthesis (compared to that of formal language/ automata-based specifications).

The last point above requires further clarification. In some cases, a property may be expressed by either a CTL* formula or by a $*$-language or a ω-language. So for these cases we can compare our method with that based on finite state automaton. If we use a finite state automaton accepting a $*$-language to give the specification, then the supervisor synthesis is polynomial in the product of the number of plant states and the number of the states of the specification automaton. From the known tableau construction methods, we know that the number of states in an automaton model of a temporal logic formula is exponential in the length of the formula (whenever the formula can be represented by an automaton). So if we start with a temporal logic specification (that can be also expressed as an automaton) and convert it to an automaton, and apply the existing supervisory control theory results, then the resulting computational complexity will be polynomial in the number of plant states and single exponential in the length of the temporal logic specification formula. This matches the complexity of our algorithm, and so there is no loss of computational complexity from the approach developed above, yet there is a gain in expressibility since a temporal logic formula is more compact. The use of temporal logic shifts the burden from the user (who gives the specification) to the supervisor designer (who computes the supervisor)—computation of supervisor for a temporal logic specification although more involved, has the same complexity.

A. Supervisor synthesis for CTL specification. We assume that the given CTL formula f is in *positive normal form*. We use $\sim f_1$ to denote the formula in positive normal form equivalent to $\neg f_1$. We begin with a few definitions taken from [6]. The *closure* of f, $\mathrm{cl}(f)$, is the smallest set of formulas containing f and satisfying

- each subformula of f that is a state formula is in $\mathrm{cl}(f)$;
- if EXf_1, EGf_1, $E[f_1Uf_2]$, or $E[f_1Bf_2]$ is in $\mathrm{cl}(f)$, then, respectively, $EXEXf_1$, $EXEGf_1$, $EXE[f_1Uf_2]$, or $EXE[f_1Bf_2]$ is in $\mathrm{cl}(f)$;

- if AFf_1, AGf_1, $A[f_1Uf_2]$, or $A[f_1Bf_2]$ is in $\mathrm{cl}(f)$, then, respectively, $AXAFf_1$, $AXAGf_1$, $AXA[f_1Uf_2]$, or $AXA[f_1Bf_2]$ is in $\mathrm{cl}(f)$.

The *extended closure* of f is defined as $\mathrm{ecl}(f) = \mathrm{cl}(f) \cup \{\sim f_1 | f_1 \in \mathrm{cl}(f)\}$. Note that $|\mathrm{ecl}(f)| = O(|f|)$, where $|f|$ denotes the length of f.

We say that a formula is *elementary* provided that it is a proposition, is the negation of a proposition, or is in the form of AXf_1 or EXf_1. Any other formula is *nonelementary*. Each nonelementary formula may be viewed as either a conjunctive α-formula, $\alpha = \alpha_1 \wedge \alpha_2$, or a disjunctive β-formula, $\beta = \beta_1 \vee \beta_2$. Clearly, $f_1 \wedge f_2$ is an α formula and $f_1 \vee f_2$ is a β formula. A formula such as AGf_1, $A[f_1Uf_2]$, $A[f_1Bf_2]$, etc., may be classified as an α or β formula based on its fix-point characterization; e.g., $AGf_1 = f_1 \wedge AXAGf_1$ is an α formula and $EFf_1 = f_1 \vee EXEFf_1$ is a β formula. The classification for all nonelementary formulas is given as

$\alpha - formula$ $\alpha = \alpha_1 \wedge \alpha_2$,

$$\begin{array}{lll}
\alpha = f_1 \wedge f_2, & \alpha_1 = f_1, & \alpha_2 = f_2, \\
\alpha = A[f_1Bf_2], & \alpha_1 = \sim f_2, & \alpha_2 = f_1 \vee AXA[f_1Bf_2], \\
\alpha = E[f_1Bf_2], & \alpha_1 = \sim f_2, & \alpha_2 = f_1 \vee EXE[f_1Bf_2], \\
\alpha = AGf_1, & \alpha_1 = f_1, & \alpha_2 = AXAGf_1, \\
\alpha = EGf_1, & \alpha_1 = f_1, & \alpha_2 = EXEGf_1;
\end{array}$$

$\beta - formula$ $\beta = \beta_1 \vee \beta_2$,

$$\begin{array}{llll}
\beta = f_1 \vee f_2, & \beta_1 = f_1 & \beta_2 = f_2, \\
\beta = A[f_1Uf_2], & \beta_1 = f_2, & \beta_2 = f_1 \wedge AXA[f_1Uf_2], \\
\beta = E[f_1Uf_2], & \beta_1 = f_2, & \beta_2 = f_1 \wedge EXE[f_1Uf_2], \\
\beta = AFf_1, & \beta_1 = f_1, & \beta_2 = AXAFf_1, \\
\beta = EFf_1, & \beta_1 = f_1, & \beta_2 = EXEFf_1.
\end{array}$$

A state transition graph $M = (Q, R, AP, L)$ is called a *structure* if the relation R is required to be total; otherwise M is called a *prestructure*. An *interior* node of a prestructure is one with at least one successor. A *frontier* node is one with no successors. A prestructure $M_1 = (Q_1, R_1, AP, L_1)$ is said to be *contained* in a structure $M_2 = (Q_2, R_2, AP, L_2)$ whenever $Q_1 \subseteq Q_2$, $R_1 \subseteq R_2$, and $L_1 = L_2|Q_1$, the restriction of L_2 to Q_1; M_1 is said to be *cleanly embedded* in M_2 provided M_1 is contained in M_2, and also every interior node of M_1 has the same set of successors as its corresponding node in M_2.

The following consistency requirements are associated with the labeling function L of a (pre)structure. Since we consider the control of CTL, the definition of L is extended as $L : Q \to 2^{ecl(f)}$, where f is the specification formula. $\forall q \in Q$, we have zero-step consistency rules,

ZS0 $p \in L(q) \Rightarrow \sim p \notin L(q)$;
ZS1 $\alpha \in L(q) \Rightarrow [(\alpha_1 \in L(q)) \wedge (\alpha_2 \in L(q))]$;
ZS2 $\beta \in L(q) \Rightarrow [(\beta_1 \in L(q)) \vee (\beta_2 \in L(q))]$;

one-step consistency rules,

OS0 $AXp \in L(q) \Rightarrow [\forall q' \in Q,\ ((q, q') \notin R) \vee (p \in L(q'))]$;
OS1 $EXp \in L(q) \Rightarrow [\exists q' \in Q,\ ((q, q') \in R) \wedge (p \in L(q))]$.

A *fragment* is a prestructure whose graph is a directed acyclic graph (DAG) such that all its nodes satisfy rules ZS0–ZS2 and OS0 and all its interior nodes satisfy rule OS1.

A formula of the form $A[pUp']$ or $E[pUp']$ is called an *eventuality* formula. Since AFp' and EFp' are special cases of $A[pUp']$ and $E[pUp']$, respectively, they are also eventuality formulas.

An eventuality formula (AFp', $A[pUp']$, EFp', or $E[pUp']$) is said to be *fulfilled* in a structure $M = (Q, AP, R, L)$ if $\forall q \in Q$:

- $AFp' \in L(q)$ (resp., $A[pUp'] \in L(q)$) implies that there is a finite fragment, called DAG$[q, AFp']$ (resp., DAG$[q, A[pUp']]$), rooted at q and *cleanly embedded* in M such that *for all frontier nodes* t of the fragment, $p' \in L(t)$, and for all interior nodes u of the fragment, *true* (resp., p) $\in L(u)$;
- $EFp' \in L(q)$ (resp., $E[pUp'] \in L(q)$) implies that there is a finite fragment, called DAG$[q, EFp']$ (resp., DAG$[q, E[pUp']]$), rooted at q and *cleanly embedded* in M such that for *some frontier node* t of the fragment, $p' \in L(t)$, and there exists one path from q to t in the fragment such that for all interior nodes u along the path, *true* (resp., p) $\in L(u)$.

An eventuality formula (AFp', $A[pUp']$, EFp', or $E[pUp']$) is said to be *pseudo-fulfilled* in a structure $M = (Q, AP, R, L)$ if $\forall q \in Q$,

- $AFp' \in L(q)$ (resp., $A[pUp'] \in L(q)$) implies that there is a finite fragment, called DAG$[q, AFp']$ (resp., DAG$[q, A[pUp']]$), rooted at q and *contained* in M such that *for all frontier nodes* t of the fragment, $p' \in L(t)$, and for all interior nodes u of the fragment, *true* (resp., p) $\in L(u)$;
- $EFp' \in L(q)$ (resp., $E[pUp'] \in L(q)$) implies that there is a finite fragment, called DAG$[q, EFp']$ (resp., DAG$[q, E[pUp']]$), rooted at q and *contained* in M such that for *some frontier node* t of the fragment, $p' \in L(t)$, and there exists one path from q to t in the fragment such that for all interior nodes u along the path, *true* (resp., p) $\in L(u)$.

Now we present a supervisor synthesis algorithm for the control of CTL, which is based on the decision procedure for CTL [6]. The algorithm differs from the decision procedure as follows:

- A modular method is used for the tableau construction. It ensures that the worst-case complexity of the algorithm is polynomial in the size of the plant.
- A supervisor, not a model, is finally synthesized.

Let f be the given CTL specification formula, f_P be the CTL formula encoding the given deterministic nonterminating plant P, and $AP' = AP \cup X$ be the extended atomic proposition set. Since we require the controlled plant to be nonterminating, we can assume that f is in the form of $f = f' \wedge AGEXtrue$. Then the algorithm is given as follows.

ALGORITHM 2. SUPERVISOR SYNTHESIS ALGORITHM FOR CTL SPECIFICATION.

1. Test the satisfiability of the CTL formula $f \wedge f_P$. This step is done by using the decision procedure for CTL as follows:
   (a) Construct a tableau T for the CTL formula $f \wedge f_P$. We use a modular method to obtain the tableau T as follows:
      i. Construct a tableau T_f for the CTL specification formula f. T_f is constructed from a bipartite graph $T_0 = (C \cup D, R_{CD} \cup R_{DC}, AP, L_0)$, where nodes in C are called states, nodes in D are called prestates, and each node is uniquely identified by its label defined by L_0; $R_{CD} \subseteq C \times D$ and $R_{DC} \subseteq D \times C$ are transition relations; $L_0 : C \cup D \rightarrow ecl(f)$ is the labeling function. Initially, C, R_{CD}, and R_{DC} are all empty, and D contains a single prestate d labeled with f. Repeat the following until no more nodes and transitions can be added into T_0: let e be a frontier node of T_0,
         - if $e \in D$, then let $\{L_i \subseteq ecl(f) \mid 1 \leq i \leq k\}$ be the set of all possible labels such that $\forall i \in \{1, 2, \ldots, k\}$, "$[L_i$ is a minimal

superset of $L_0(e)$] $\wedge$ [L_i satisfies rules ZS0-ZS2] $\wedge$ [$\forall p \in AP$, $(p \in L_i) \vee (\neg p \in L_i)$]," and for each L_i create a state c_i with $L_0(c_i) = L_i$, and add c_i into C if $c_i \notin C$, and (e, c_i) into R_{DC};

- if $e \in C$ labeled with the next time formulas

$$\{AXp_1, \ldots, AXp_j, EXp'_1, \ldots, EXp'_k\},$$

then $\forall i \in \{1, \ldots, k\}$, create prestates d_i labeled with $\{p_1, \ldots, p_j, p'_i\}$, and add d_i into D if $d_i \notin D$, and (e, d_i) into R_{CD}.

The tableau T_f is obtained as $T_f = (C_f, R_f, AP, L_f)$, where $C_f = C$, $R_f = R_{CD} \circ R_{DC}$, and $L_f = L_0|_C$, the restriction of L_0 to C.

ii. Derive the tableau T for $f \wedge f_P$ from the synchronous composition of the plant $P = (X, \Sigma, \delta_P, x_0, AP, L_P)$ and the tableau $T_f = (C_f, R_f, AP, L_f)$ as follows: $T = (S_T, R_T, AP', L_T)$, where

- $S_T \subseteq C_f \times X$ is the state set, $S_T = \{(t, x) \in C_f \times X |\ L_f(t)$ and $L_P(x)$ are propositionally consistent$\}$, where "$L_f(t)$ and $L_P(x)$ are propositionally consistent" means that $\forall p \in AP$, $[p \in (L_f(t) \cup L_P(x)) \Rightarrow \neg p \notin (L_f(t) \cup L_P(x))]$;
- $AP' = AP \cup X$;
- $R_T \subseteq S_T \times S_T$ is the transition relation, $R_T = \{((t, x), (t', x')) \in S_T \times S_T |\ (t, t') \in R_f,$ and $\exists \sigma \in \Sigma\ s.t.\ \delta_P(x, \sigma) = x'\}$;
- L_T is the labeling function defined as $\forall (t, x) \in S_T \times S_T$, $L_T((t, x)) = L_f(t) \cup L_P(x) \cup \{x\} \cup \{EXy |\ y \in X, \exists \sigma_u \in \Sigma_u, y = \delta_P(x, \sigma_u)\}$.

(b) Test the tableau T for the existence of a model for $f \wedge f_P$. This is done by first pruning (see below) the tableau T to ensure that the consistency and pseudofulfillment of eventualities are satisfied in T, then checking in the pruned tableau T whether there exists a state s_0 such that $\{f, x_0\} \subseteq L_T(s_0)$. If there exists such a state, then and only then $f \wedge f_P$ is satisfiable. If $f \wedge f_P$ is satisfiable, then go to next step; otherwise stop the algorithm and output that "no supervisor exists."

The pruning of T is achieved by repeatedly applying the following deletion rules until no more nodes can be deleted from T:

- Delete any state which has no successors.
- Delete any state which violates rule OS1.
- Delete any state s such that $\exists r \in L_T(s)$, r is an eventuality formula, and r is not pseudofulfilled at s.

To test the pseudofulfillment of an eventuality formula at each state in T, the following ranking procedure can be used. For an $A[pUq]$ eventuality, initially assign rank 1 to all nodes labeled with q and rank ∞ to all other nodes. Then for each node s and each formula r such that $EXr \in L_T(s)$, define $SUCC_r(s) = \{s' \mid (s, s') \in R, r \in L_T(s')\}$ and compute $\text{rank}(SUCC_r(s)) = \min_{s'}\{\text{rank}(s') \mid s' \in SUCC_r(s)\}$. Now for each node s of rank ∞ such that $p \in L_T(s)$, let $\text{rank}(s) = 1 + \max_r\{\text{rank}(SUCC_r(s)) |\ EXr \in L_T(s)\}$. Since $AGEXtrue$ is contained in f, the formula $EXtrue$ is labeled at every node in T. So the above procedure is well defined. Repeatedly apply the above ranking procedure until stabilization. A node s has a finite rank if and only if $A[pUq]$ is pseudofulfilled at s in T. Testing for the pseudofulfillment of AFq follows from above since it is a special case of

$A[pUq]$. For testing the pseudofulfillment of $E[pUq]$, a similar procedure as above can be applied, with the only modification that $\text{rank}(s) = 1 + min_r\{\text{rank}(SUCC_r(s)) \mid EXr \in L_T(s)\}$. Testing for the pseudofulfillment of EFq is again a special case of $E[pUq]$.

2. Extract a model M for the formula $f \wedge f_P$ from the tableau T. $M = (Q, R, AP', L)$ is extracted from $T = (S_T, R_T, AP', L_T)$ as follows [6]. For each state s in S_T and each eventuality q in $ecl(f)$, we construct a directed acyclic graph rooted at s, DAGG$[s,\ q]$. If the eventuality $q \in L_T(s)$, then DAGG$[s,\ q]$ = DAG$[s,\ q]$; otherwise DAGG$[s, q]$ is taken to be the subgraph consisting of s and a sufficient set of successors to ensure that one-step consistency rules OS0-1 are satisfied. Next we take each DAGG$[s, q]$ and arrange them in a matrix by putting DAGG$[s_j, q_i]$ in the ith row and the jth column of the matrix. The matrix has a dimension of $m \times n$, where m (resp., n) is the number of eventualities (resp., states) in the tableau T. Then we connect all the DAGGs in the matrix together in the following way: for any frontier node s in the ith row, merge it with the corresponding root node s of DAGG$[s, q_{i+1}]$ in the $(i+1)$th row; for any frontier node s in the last row, merge it with the corresponding root node s of DAGG$[s, q_1]$ in the first row. We use $M = (Q, R, AP', L)$ to represent the above finite state transition graph, where Q is the set of states in the graph, R is the transition relation of the graph, and L is the labeling function for each state in the graph which is a natural extension of L_T. M defines a model for $f \wedge f_P$, i.e., $\exists q_0 \in Q$ such that $< M, q_0 > \models f \wedge f_P$.
3. Derive a supervisor S from the model M of $f \wedge f_P$. Since $M = (Q, R, AP', L)$ is a model of $f \wedge f_P$, we know that $\exists q_0 \in Q,\ < M, q_0 > \models f \wedge f_P$. We can get a control-compatible and propositionally consistent supervisor $S = (Y, \Sigma, \delta_S, y_0, L_S)$ from M using the same method as given in the proof of Theorem 3 as follows: $Y \subseteq Q$ is the set of states which are reachable from q_0 in M; $\forall y \in Y,\ \forall \sigma \in \Sigma$,

$$\delta_S(y, \sigma) = \{y' \mid [(y, y') \in R] \wedge [x' = \delta_P(x, \sigma)], \\ \text{where } \{x'\} = L(y') \cap X \text{ and } \{x\} = L(y) \cap X\};$$

$y_0 = q_0$; and $\forall y \in Y, L_S(y) = L(y) \cap (AP \cup \{\neg p | p \in AP\})$.

Remark 8. *From Theorem* 3*, and using an argument similar to the soundness and completeness of the decision procedure for CTL* [6]*, we can conclude that Algorithm* 2 *for control synthesis for CTL is sound and complete. It is easy to check that Algorithm* 2 *has a worst-case complexity of single exponential in the length of the specification CTL formula* f *and polynomial in the number of states of the plant* P*. It matches the lower bound complexity of the CTL control problem given in Theorem* 5.

EXISTENCE OF OPTIMAL POLICIES FOR SEMI-MARKOV DECISION PROCESSES USING DUALITY FOR INFINITE LINEAR PROGRAMMING*

DIEGO KLABJAN† AND DANIEL ADELMAN‡

Abstract. Semi-Markov decision processes on Borel spaces with deterministic kernels have many practical applications, particularly in inventory theory. Most of the results from general semi-Markov decision processes do not carry over to a deterministic kernel since such a kernel does not provide "smoothness." We develop infinite dimensional linear programming theory for a general stochastic semi-Markov decision process. We give conditions, general enough to allow deterministic kernels, for solvability and strong duality of the resulting linear programs. By using the developed linear programming theory we give conditions for the existence of a stationary deterministic policy for deterministic kernels, which is optimal among all possible policies.

Key words. semi-Markov decision processes, linear programming, optimal policies

1. Introduction. A semi-Markov decision process (SMDP) on Borel state and action spaces is said to have a Dirac's transition law if the state at the next decision epoch is uniquely determined by a given function evaluated at the current state-action pair. Such models are simple to state but turn out to be even more difficult to study and analyze than their true stochastic counterparts. They have many practical applications, for example, in inventory routing (Adelman (2003)). In a companion paper, Adelman and Klabjan (2005) provide a new SMDP formulation for a widely studied, classical inventory control problem. This problem generalizes the classical economic order quantity problem to a multi-item setting. Most existing SMDP theory does not apply to Dirac's transition laws.

Nearly all approaches to the question of whether there exists an optimal policy require the transition law to be strongly continuous, but a Dirac's transition law is at best only weakly continuous. Strong continuity ensures that "smoothness" is maintained in the optimality equations. For example, existing approaches are based on either the vanishing discount rate methodology (Hernández-Lerma and Lasserre (1990), Vega-Amaya (1993)), or policy iteration (Luque-Vásquez and Hernández-Lerma (1999), Hernández-Lerma and Lasserre (1997)); see also the series of monographs by Hernández-Lerma (1989) and Hernández-Lerma and Lasserre (1996b, 1999). An alternative approach presented by Bhattacharya and Majumdar (1989) is to allow weak continuity of the kernel but to impose equicontinuity of the discounted value functions. Unfortunately, Dirac's transition laws do not provide equicontinuity.

A recent approach in the literature that assumes weak continuity of the transition law is infinite linear programming, developed for the discrete-time case, i.e., Markov

decision processes, by Hernández-Lerma and González-Hernández (1998), Hernández-Lerma and Lasserre (1996a), and Hernández-Lerma and Lasserre (1994). However, existing theory also requires that the expected transition times between decision epochs be lower bounded away from zero. The only exception that we are aware of is the work by Vega-Amaya (2003) in the context of zero-sum semi-Markov games, where the author assumes the transition time to be positive and not necessarily bounded away from zero. This condition is trivially satisfied in the case of discrete time periods. When satisfied in the semi-Markov case it is well known that there exists a transformation of the problem into discrete-time, employed, for instance, by Bhattacharya and Majumdar (1989), Vega-Amaya (1993), and Luque-Vásquez and Hernández-Lerma (1999) although not using linear programming. Unfortunately, for the inventory control applications we have in mind, this condition is violated. It is possible to have multiple decision epochs at the same instant of time.

In this paper, we relax both of the above assumptions. We assume instead that the transition law is weakly continuous, and that the expected transition time *plus* current cost, rather than just the former, is lower bounded away from zero. Therefore, all our results apply to the more restrictive settings in the references above. Instead of seeking transformations to a discrete-time Markov control setting, we work directly with a new infinite linear programming formulation of the SMDP, presented in section 3.1, which extends the formulation of Fox (1966) in finite spaces to Borel spaces and the infinite linear programming formulation of discrete time MDP by Hernández-Lerma and Lasserre (1994). For a general stochastic SMDP, we establish a set of conditions under which this infinite linear program possesses strong duality, i.e., there is no duality gap and primal-dual optimal solutions are attained. Although the infinite linear programming approach to the Borel setting leads to the existence of an optimal policy that is stationary randomized, to date this approach has not been fruitful in showing the existence of an optimal policy that is stationary deterministic. We provide this result when the transition law is Dirac's under a strong recurrence condition. In a companion paper (Adelman and Klabjan (2005)), we show that all the conditions in this paper are verifiable in an inventory application.

We owe a debt of gratitude to Hernández-Lerma and González-Hernández (1998), Hernández-Lerma and Lasserre (1996a), and Hernández-Lerma and Lasserre (1994) for their key insight that infinite linear programming can handle weakly continuous transition laws. This was indeed fortuitous, as what originally prompted our interest in it was one of the authors' use of it in an approximate dynamic programming framework to generate near optimal control policies in inventory routing; see Adelman (2003). In future work, our duality results will prove useful in devising stronger, and possibly even convergent, approximate dynamic programming methodologies.

In section 2 we formulate a general semi-Markov decision process. In section 3 we formulate our primal-dual pair of infinite linear programs and give conditions for strong duality. In section 4, we provide results specialized to the case of a Dirac's transition law.

2. Semi-Markov control model. The semi-Markov control model is defined by $(X, A, \{A(x) : x \in X\}, Q', c')$, where X is the state space and A is the control set. We assume that both X and A are Borel spaces. For each $x \in X$ we are given a nonempty Borel subset $A(x) \subseteq A$, which specifies the set of *admissible controls*, if the state of the system is x. We assume that $K = \{(x, a) : x \in X, a \in A(x)\}$ is a Borel subset of $X \times A$. Let Q' represent the *time-dependant transition law*. If the system is in state $x \in X$ and control action $a \in A(x)$ is taken, then the system's next

state is in B after transition time $t \in T = [0, \infty)$ with probability $Q'(t, B|x, a)$, where $B \subseteq X$ is a Borel set. If the system is in state $x \in X$ and control action $a \in A(x)$ is selected leading to a state x' after a transition time t, then the system incurs a cost $c'(t, x', x, a)$. This cost includes the immediate cost of action a as well as any additional cost occurring during the transition to the next state.

For any Borel set $B \subseteq X$, and for any $(x, a) \in K$ the function $Q'(\cdot, B|x, a)$ is a distribution function, i.e.,

- $Q'(t, B|x, a) = 0$ for every $t \leq 0$,
- $Q'(t, B|x, a)$ is a monotone lower semicontinuous function in t, and
- $\lim_{t\to\infty} Q'(t, X|x, a) = 1$.

We denote by x_n the state of the system at the nth decision time t_n and by $a_n \in A(x_n)$ the corresponding control action. The *transition time* $\delta_{n+1} = t_{n+1} - t_n$ has distribution $F(\cdot|x_n, a_n) = Q'(\cdot, X|x_n, a_n)$. For every Borel set $B \subseteq X$ and for every $(x, a) \in K$ let $Q(B|x, a) = \lim_{t\to\infty} Q'(t, B|x, a)$ denote the probability that the system is in a state from B in the next decision epoch when action a is chosen in state x. We call Q the *transition law*. Observe that Q is a stochastic kernel on X.

We denote by H_n the state of all *admissible histories* until the nth transition. Formally, $H_0 = X$ and $H_n = (K \times T)^n \times X$, where $h_n = (x_0, a_0, \delta_1, \dots, x_{n-1}, a_{n-1}, \delta_n, x_n) \in H_n$ encodes the history of the process.

DEFINITION 1. *A* policy π *is a sequence* $\pi = \{\pi_n\}_{n=0}^{\infty}$ *of stochastic kernels* π_n *on* A *satisfying* $\pi_n(A(x_n)|h_n) = 1$ *for every admissible history* $h_n \in H_n$ *and for every* $n \in \mathbb{N}$. *A policy* π *is a* stationary randomized policy *if there exists a stochastic kernel* ϕ *such that* $\pi_n(\cdot|h_n) = \phi(\cdot|x_n)$ *for each* $h_n \in H_n$ *and for each* $n \in \mathbb{N}$. *A policy* $\pi = \{\pi_n\}_{n=0}^{\infty}$ *is a* stationary deterministic policy *if there exists a measurable function* $f : X \to A$ *such that* $\pi_n(\cdot|h_n)$ *is concentrated at* $f(x_n) \in A(x_n)$ *for each* $n \in \mathbb{N}$. *We denote by* Π *the set of all policies and by* Π_{SD} *the subset of all stationary deterministic policies.*

Every initial distribution ν (which is a probability measure on X) and every policy π determine a unique probability measure P_ν^π and a stochastic process $\{(x_n, a_n, \delta_n), n = 0, 1, \dots\}$ on $\Omega = (X \times A \times T)^\infty$ (theorem of Ionescu Tulcea; see, e.g., Ash (1972, pp. 109) for a proof). We denote by E_ν^π the expectation operator with respect to P_ν^π and for $x \in X$ let E_x^π be equal to E_ν^π, where ν is the Dirac measure concentrated on x. The *mean holding time* in state x under a control $a \in A(x)$ is

$$\tau(x, a) = \int_T t\, F(\mathrm{d}t|x, a) = \int_T t\, Q'(\mathrm{d}t, X|x, a).$$

DEFINITION 2. *Given an initial distribution* ν *and a policy* π, *the* long-run expected average cost *is defined as*

$$J(\pi, \nu) = \limsup_{n\to\infty} \frac{E_\nu^\pi(\sum_{k=0}^{n-1} c'(t_k, x_{k+1}, x_k, a_k)}{E_\nu^\pi(t_n)}.$$

Let $J^* = \inf_\nu \inf_\pi J(\pi, \nu)$. A pair (ν^*, π^*) is a *minimum pair* if $J(\nu^*, \pi^*) = J^*$. The average cost problem is the problem of finding a minimum pair. For $x \in X$ let $J(x) = \inf_{\pi\in\Pi} J(\pi, x)$ be the *optimal average cost function*. A policy π^* is *average cost optimal* if $J(\pi^*, x) = J(x)$ for every $x \in X$. It is easy to see that

$$J(\pi, \nu) = \limsup_{n\to\infty} \frac{E_\nu^\pi(\sum_{k=0}^{n-1} c(x_k, a_k))}{E_\nu^\pi(\sum_{k=0}^{n-1} \tau(x_k, a_k))},$$

where

$$c(x,a) = \int_X \int_T c'(t,x',x,a) Q'(\mathrm{d}t, \mathrm{d}x' | x, a).$$

Note that a Markov control model is a semi-Markov control model with transition times equal to 1 with probability 1.

A special class of semi-Markov processes includes those with the transition law concentrated at a single state.

DEFINITION 3. *The transition law is a* Dirac's transition law *if there exists a measurable function* $s : X \times A \to X$ *such that*

$$Q(B|x,a) = \begin{cases} 1 & s(x,a) \in B, \\ 0 & \text{otherwise} \end{cases} \tag{1}$$

for every Borel measurable set $B \subseteq X$.

DEFINITION 4. *A transition law* Q *is* weakly continuous *if* $h : X \times A \to \mathbb{R}$ *defined by*

$$h(x,a) = \int_X u(y) Q(\mathrm{d}y | x, a)$$

is a continuous bounded function on K *for every continuous bounded function* u *on* X. *Kernel* Q *is* strongly continuous *if* h *is a continuous bounded function on* K *for every measurable bounded function* u *on* X.

If Q is a Dirac's transition law, then $h(x,a) = u(s(x,a))$. In this case Q is weakly continuous if and only if s is a continuous function (consider $u(x) = x$ for all $x \in X$). However, Q is typically not strongly continuous.

For this semi-Markov decision process, the *average cost optimality equation* is

$$u(x) = \inf_{a \in A(x)} \left\{ c(x,a) - g\tau(x,a) + \int_X u(y) Q(\mathrm{d}y | x, a) \right\}.$$

In the case of a Dirac's transition law, this simplifies to

$$u(x) = \inf_{a \in A(x)} \{ c(x,a) - g\tau(x,a) + u(s(x,a)) \}. \tag{2}$$

3. Linear programming and semi-Markov control models with the average cost criterion. In this section we develop a linear programming formulation for the semi-Markov control model. The formulation is based on the prior work on infinite-dimensional linear programming for Markov control models of Hernández-Lerma and Lasserre (1999, pp. 203–249). A thorough coverage of infinite-dimensional linear programs is given by Anderson and Nash (1987).

3.1. Linear programs. Given a Borel space Z and a measurable weight function $f \geq 1$, let $\mathbb{B}_f(Z)$ be the Banach space of measurable functions u with finite *f-norm*

$$\|u\|_f = \sup_Z \frac{|u(s)|}{|f(s)|}.$$

In addition, let $\mathbb{M}_f(Z)$ be the Banach space of signed measures μ on the Borel space on Z with finite f *total variation norm*

$$\|\mu\|_f^{\mathrm{TV}} = \sup_{\|u\|_f \le 1} \left| \int_Z u \, \mathrm{d}\mu \right|.$$

The *total variation norm* of μ is $\|\mu\|_{\mathrm{TV}} = \|\mu\|_1$. It it easy to see that

$$\|\mu\|_{\mathrm{TV}} \le \|\mu\|_f^{\mathrm{TV}}. \tag{3}$$

See, e.g., Hernández-Lerma and Lasserre (1999, pp. 2–3) for a proof that $\mathbb{B}_f(Z)$ and $\mathbb{M}_f(Z)$ are Banach spaces. Let $\mathcal{B}(Z)$ be the Borel σ-algebra on Z and let $\mathbb{C}_b(Z)$ be the set of all continuous, bounded functions on Z.

Let $w : K \longrightarrow \mathbb{R}, w_0(x) : X \longrightarrow \mathbb{R}$ be defined as

$$w(x,a) = \tau(x,a) + c(x,a), \tag{4}$$

$$w_0(x) = \inf_{a \in A(x)} w(x,a). \tag{5}$$

To define linear programs corresponding to the semi-Markov control process, we need the following assumptions.

Assumption A1. *$w(x,a)$ is lower semicontinuous and $\{a \in A(x) : w(x,a) \le r\}$ is compact for every $x \in X$ and $r \in \mathbb{R}$.*

Assumption A2. *τ and c are nonnegative measurable functions.*

Assumption A3. *$w(x,a) \ge 1$ for every $(x,a) \in K$.*

Assumption A4. *There exists a finite constant $k \in \mathbb{R}$ such that*

$$\int_X w_0(y) Q(\mathrm{d}y|x,a) \le k \cdot w(x,a)$$

for every $(x,a) \in K$.

Due to Assumption A1, w_0 is well defined, the infimum can be replaced by the minimum, and, in addition, w_0 is measurable (Rieder (1978)). Assumption A3 can be relaxed to $\tau(x,a) + c(x,a) \ge \epsilon$ for every $(x,a) \in K$ and a given $\epsilon > 0$. By Assumption A3, $\mathbb{B}_{w_0}(X)$ is a well-defined Banach space, and, by Assumption A1, $\mathbb{M}_{w_0}(X)$ is a well defined Banach space. Since every lower semicontinuous function is measurable, it follows from the same two assumptions that $\mathbb{M}_w(K)$ is a well-defined Banach space. Observe also that Assumption A2 implies that $\tau \in \mathbb{B}_w(K)$ and $c \in \mathbb{B}_w(K)$.

Consider the following primal/dual linear programs on the dual pairs defined as $(\mathbb{M}_w(K), \mathbb{B}_w(K)), (\mathbb{R} \times \mathbb{M}_{w_0}(X), \mathbb{R} \times \mathbb{B}_{w_0}(X))$. The primal problem is

$$\inf \int_K c(x,a) \mu(\mathrm{d}(x,a)) \tag{6a}$$

$$\int_K \tau(x,a) \mu(\mathrm{d}(x,a)) = 1 \tag{6b}$$

$$\mu((B \times A) \cap K) - \int_K Q(B|x,a) \mu(\mathrm{d}(x,a)) = 0 \qquad \text{for every } B \in \mathcal{B}(X) \tag{6c}$$

$$\mu \ge 0, \mu \in \mathbb{M}_w(K), \tag{6d}$$

and the dual problem reads

$$\sup \rho \tag{7a}$$

$$\tau(x,a)\rho + u(x) - \int_X u(y) Q(\mathrm{d}y|x,a) \le c(x,a) \qquad \text{for every } (x,a) \in K \tag{7b}$$

$$\rho \in \mathbb{R}, u \in \mathbb{B}_{w_0}(X). \tag{7c}$$

We denote by $\inf(P)$, $\sup(D)$ the optimal value of the primal, dual linear program, respectively.

To see that (6) and (7) are indeed a primal-dual pair consider the following operators. Let $L_0 : \mathbb{M}_w(K) \longrightarrow \mathbb{M}_{w_0}(X)$ be defined as

$$(L_0\mu)(B) = \mu(B \times A) - \int_K Q(B|x,a)\mu(\mathrm{d}(x,a)) \qquad \text{for every } B \in \mathcal{B}(X)$$

and let $L : \mathbb{M}_w(K) \longrightarrow \mathbb{R} \times \mathbb{M}_{w_0}(X)$ be

$$L\mu = \left(\int_K \tau(x,a)\mu(\mathrm{d}(x,a)), L_0\mu \right).$$

The adjoint operator $L^* : \mathbb{R} \times \mathbb{B}_{w_0}(X) \longrightarrow \mathbb{B}_w(K)$ is given by

$$L^*(\rho,u)(x,a) = \tau(x,a)\rho + u(x) - \int_X u(y)Q(\mathrm{d}y|x,a)$$

for every $(\rho,u) \in \mathbb{R} \times \mathbb{B}_{w_0}(X)$ and $(x,a) \in K$. To see that $L^*(\rho,u) \in \mathbb{B}_w(K)$, let $(\rho,u) \in \mathbb{R} \times \mathbb{B}_{w_0}(X)$. Then

$$\left| \frac{\tau(x,a)\rho}{w_(x,a)} \right| \leq |\rho|, \tag{8}$$

$$\left| \frac{u(x)}{w(x,a)} \right| = \left| \frac{u(x)}{w_0(x)} \right| \cdot \frac{w_0(x)}{w(x,a)} \leq \left| \frac{u(x)}{w_0(x)} \right| \leq \|u\|_{w_0}, \tag{9}$$

$$\left| \frac{\int_X u(y)Q(\mathrm{d}y|x,a)}{w(x,a)} \right| \leq \|u\|_{w_0} \frac{\int_X w_0(y)Q(\mathrm{d}y|x,a)}{w(x,a)} \leq \|u\|_{w_0} k, \tag{10}$$

where (8) follows by Assumption A2 and (4), (9) by definition (5), and (10) by Assumption A4. It follows that the linear operator L is continuous with respect to the weak topology—see, e.g., Anderson and Nash (1987, pp. 35–40)—and therefore (7) is a dual linear program to (6). It implies that under A1–A4 we can apply results from Anderson and Nash (1987).

3.2. Results. A linear program is *consistent* if it has a feasible solution and it is *solvable* if there is a feasible solution that attains the optimal objective value. If (6), (7), is solvable, then we can replace inf, sup, in (6a), (7a), by min, max, and we write the corresponding value as $\min(P), \max(D)$, respectively. In this section we discuss the relation between the linear programs and the underlying semi-Markov control model and we give no duality gap and solvability results.

DEFINITION 5. *A function g on Z is a* strictly unbounded function *if there is a nondecreasing sequence of compact sets $Z_n \uparrow Z$ such that* $\lim_{n\to\infty} \inf\{g(x)|x \notin Z_n\} = \infty$.

If Z is compact, then any function is strictly unbounded by considering $Z_n = Z$ for every n. If Z is open but bounded, then a strictly unbounded function must be discontinuous at the boundary of Z.

We need the following additional assumptions.

ASSUMPTION A5. *There is a policy π and an initial distribution ν such that $J(\pi,\nu) < \infty$.*

ASSUMPTION A6. *The transition law is weakly continuous.*

ASSUMPTION A7. *τ is a nonnegative, continuous, bounded function.*

ASSUMPTION A8. *w is strictly unbounded on K.*

Note that Assumptions A1 and A7 imply that c is lower semicontinuous and Assumption A7 yields $\tau \in \mathbb{C}_b(K)$.

Next we give some known results that will be used in subsequent sections. The following theorem is proved in Dynkin and Yushkevich (1979, pp. 88–89).

THEOREM 1. *Let μ be a probability measure on $X \times A$ concentrated on K. Then there exists a stochastic kernel π on A such that*

$$\mu(B \times C) = \int_B \pi(C|x)\hat{\mu}(\mathrm{d}x) \qquad \text{for every } B \in \mathcal{B}(X), C \in \mathcal{B}(A),$$

where $\hat{\mu}(\cdot) = \mu(\cdot \times A)$ is the marginal of μ on X.

DEFINITION 6. *A measure μ on Z is* tight *if for each $\epsilon > 0$ there is a compact set $C \subseteq Z$ such that $\mu(Z \setminus C) < \epsilon$.*

The proofs of the following two theorems are given in Billingsley (1968).

THEOREM 2. *Let Γ be a bounded family of nonnegative measures on Z. Then Γ is tight if and only if there is a strictly unbounded function $g \geq 1$ such that $\sup_{\mu\in\Gamma} \int_Z g \,\mathrm{d}\mu < \infty$. If Γ is a set of probability measures, then the condition $g \geq 1$ can be relaxed to $g \geq 0$.*

THEOREM 3 (due to Prohorov). *Let Γ be a family of probability measures on a Borel space Z. If Γ is tight, then for each sequence $\{\mu_n\}$ in Γ there is a subsequence $\{\mu_m\}$ and a probability measure μ such that*

$$\int_Z u \,\mathrm{d}\mu_m \longrightarrow \int_Z u \,\mathrm{d}\mu \tag{11}$$

for every $u \in \mathbb{C}_b(Z)$.

We say that measures $\{\mu_m\}_m$ converge *weakly* to a measure μ if (11) holds. We will repeatedly use the following corollary.

COROLLARY 1. *Let Γ be a family of nonnegative measures on a Borel space Z. Assume that there exists a constant $K < \infty$ such that $0 < \|\mu\|_{TV} < K$. In addition, let there exist a strictly unbounded function $g \geq 1$ such that $\sup_{\mu\in\Gamma} \int_Z g \,\mathrm{d}\mu < \infty$. Then for each sequence $\{\mu_n\}$ in Γ there is a subsequence $\{\mu_m\}$ and a measure μ such that $\{\mu_m\}$ converges weakly to μ.*

Proof. Let $\{\mu_n\}$ be a sequence in Γ.

If $\liminf_n \|\mu_n\|_{\mathrm{TV}} = 0$, there there exists a subsequence $\{\mu_m\}$ of $\{\mu_n\}$ such that $\lim_m \|\mu_m\|_{\mathrm{TV}} = 0$. But then for any $u \in \mathbb{C}_b(Z)$ and any m we have $|\int_Z u \,\mathrm{d}\mu_m| \leq M\|\mu_m\|_{\mathrm{TV}}$, where $|u(s)| \leq M < \infty$ for any $s \in Z$. Hence $\{\mu_m\}$ converges weakly to the 0 measure.

Let now $\liminf_n \|\mu_n\|_{\mathrm{TV}} > 0$. Without loss of generality we assume that $\|\mu_n\|_{\mathrm{TV}} > m > 0$ for every n. Consider the set $\tilde{\Gamma}$ of probability measures defined as $\{\mu/\|\mu\|_{\mathrm{TV}} : \mu \in \Gamma\}$. We have

$$\sup_{\tilde{\mu}\in\tilde{\Gamma}} \int_Z g \,\mathrm{d}\tilde{\mu} \leq \frac{\sup_{\mu\in\Gamma} \int_Z g \,\mathrm{d}\mu}{m} < \infty$$

by assumption. Therefore by Theorem 2, $\tilde{\Gamma}$ is tight. By Prohorov's theorem we have that there is a weakly convergent subsequence $\{\tilde{\mu}_p\}$ that converges to a measure $\tilde{\mu}$. There is a subsequence $\{\mu_m\}$ of $\{\mu_p\}$ such that $\lim_m \|\mu_m\|_{\mathrm{TV}} = Q$. Clearly

$0 < Q < K$. Now for every $u \in \mathbb{C}_b(Z)$ we have

$$\lim_m \int_Z u \, \mathrm{d}\mu_m = \lim_m \left(\int_Z u \, \mathrm{d}\tilde{\mu}_m \cdot \|\mu_m\|_{\mathrm{TV}} \right) = Q \lim_m \int_Z u \, \mathrm{d}\tilde{\mu}_m = Q \int_Z u \, \mathrm{d}\tilde{\mu}.$$

Therefore $\{\mu_m\}$ converges weakly to $\mu = Q\tilde{\mu}$. □

3.2.1. Consistency and solvability. In this section we give results regarding consistency and solvability of (6) and (7). We first address consistency.

THEOREM 4. *Assume Assumptions* A1–A8 *hold.* (6) *and* (7) *are consistent, and* $\inf(P) = J^*$.

The following lemma is proved by Hernández-Lerma and Lasserre (1999, pp. 225).

LEMMA 1. *Let* $\{\mu_n\}$ *be a sequence of measures on* S *and* μ *a measure on* S *such that* $\{\mu_n\}$ *converges weakly to* μ. *If* $c \geq 0$ *is a lower semicontinuous function on* S, *then*

$$\liminf_n \int_S c \, \mathrm{d}\mu_n \geq \int_S c \, \mathrm{d}\mu.$$

In addition we need the following lemma.

LEMMA 2. *If* $\{\mu_n\}_n$ *converges weakly to* μ, *then for every* $v \in \mathbb{C}_b(X)$ *we have*

$$\lim_{n\to\infty} \int_X v \, \mathrm{d}L_0(\mu_n) = \int_X v \, \mathrm{d}L_0(\mu).$$

Proof. We have

$$\begin{aligned} \int_X v \, \mathrm{d}L_0(\mu) &= \int_K v \cdot \left(1 - \int_X Q(\mathrm{d}y|x,a)\right) \mu(\mathrm{d}(x,a)) \\ &= \lim_{n\to\infty} \int_K v \cdot \left(1 - \int_X Q(\mathrm{d}y|x,a)\right) \mu_n(\mathrm{d}(x,a)) \\ &= \lim_{n\to\infty} \int_X v \, \mathrm{d}L_0(\mu_n) = 0, \end{aligned}$$

where the first equality follows from the definition of the adjoint operator (see section 3.1), and the second equality follows from Assumption A6 and the definition of weak convergence. □

Proof of Theorem 4. (7) is consistent by taking $\rho = 0$, $u = 0$.

Next we address consistency of (6). Consider a policy π and an initial distribution ν such that $J(\pi,\nu) < \infty$. For every integer $n \geq 1$ let us define the probability measure on K as

$$\mu_n(\Omega) = \frac{1}{n} \sum_{i=0}^{n-1} P_\nu^\pi((x_i,a_i) \in \Omega).$$

From Assumption A7 it follows that there exists a constant $M < \infty$ such that $\tau(x,a) \leq M$ for every $(x,a) \in K$. Then

$$\begin{aligned} \int_K w \, \mathrm{d}\mu_n &= \frac{\sum_{k=0}^{n-1} E_\nu^\pi(w(x_k,a_k))}{n} = \frac{\sum_{k=0}^{n-1} E_\nu^\pi(w(x_k,a_k))}{\sum_{k=0}^{n-1} E_\nu^\pi(\tau(x_k,a_k))} \cdot \frac{\sum_{k=0}^{n-1} E_\nu^\pi(\tau(x_k,a_k))}{n} \\ &\leq (J(\pi,\nu)+1) \cdot M < \infty. \end{aligned}$$

This implies that we can use Corollary 1 since by Assumption A8 w is strictly unbounded and $\|\mu_n\|_{\mathrm{TV}} = 1$. Let $\{\mu_m\}_m$ be a subsequence that convergence weakly to μ.

Since every μ_m is a probability measure, so is μ. For a subsequence l of m we have

$$J(\pi,\nu) = \limsup_n \frac{\int_K c\,\mathrm{d}\mu_n}{\int_K \tau\,\mathrm{d}\mu_n} \geq \limsup_m \frac{\int_K c\,\mathrm{d}\mu_m}{\int_K \tau\,\mathrm{d}\mu_m} = \lim_l \frac{\int_K c\,\mathrm{d}\mu_l}{\int_K \tau\,\mathrm{d}\mu_l}. \tag{12}$$

In addition, there exists a subsequence k of l such that

$$\liminf_l \int_K c\,\mathrm{d}\mu_l = \lim_k \int_K c\,\mathrm{d}\mu_k. \tag{13}$$

It follows from (12) that

$$J(\pi,\nu) \geq \lim_k \frac{\int_K c\,\mathrm{d}\mu_k}{\int_K \tau\,\mathrm{d}\mu_k}. \tag{14}$$

By Lemma 1 and (13) we obtain $\lim_k \int_K c\,\mathrm{d}\mu_k \geq \int_K c\,\mathrm{d}\mu$. Since by Assumption A7 $\tau \in \mathbb{C}_b(K)$, we have that $\lim_k \int_K \tau\,\mathrm{d}\mu_k = \int_K \tau\,\mathrm{d}\mu$.

We first show that $\int_K \tau\,\mathrm{d}\mu > 0$. To the contrary, assume that $\int_K \tau\,\mathrm{d}\mu = 0$. Note that $\int_K c\,\mathrm{d}\mu_k = \int_K w\,\mathrm{d}\mu_k \geq \int_K \mathrm{d}\mu_k = 1$. Let us fix an $\epsilon > 0$. There exists an integer k_1 such that for every $k \geq k_1$ we have $\int_K \tau\,\mathrm{d}\mu_k \leq \epsilon$. Then for any $k \geq k_1$ it follows

$$\frac{\int_K c\,\mathrm{d}\mu_k}{\int_K \tau\,\mathrm{d}\mu_k} \geq \frac{1}{\epsilon}.$$

Since ϵ is an arbitrarily small number, it follows that $\lim_k \frac{\int_K c\,\mathrm{d}\mu_k}{\int_K \tau\,\mathrm{d}\mu_k} = \infty$, which contradicts (14) and the assumption that $J(\pi,\nu) < \infty$.

We conclude that $0 < \int_K \tau\,\mathrm{d}\mu < M$. This in turn implies that

$$J(\pi,\nu) \geq \lim_k \frac{\int_K c\,\mathrm{d}\mu_k}{\int_K \tau\,\mathrm{d}\mu_k} = \frac{\lim_k \int_K c\,\mathrm{d}\mu_k}{\lim_k \int_K \tau\,\mathrm{d}\mu_k} \geq \frac{\int_K c\,\mathrm{d}\mu}{\int_K \tau\,\mathrm{d}\mu}.$$

Next we show that μ satisfies (6c). Let $\mathcal{X}$ denote the characteristic or the indicator function of a set. Since for every $B \in \mathcal{B}(X)$ we have

$$P_\nu^\pi(x_i \in B) = E_\nu^\pi(\mathcal{X}_B(x_i)) = E_\nu^\pi(Q(B|x_{i-1}, a_{i-1}))$$

and for every k

$$\int_K Q(B|x,a)\mathrm{d}\mu_k = \frac{1}{k}\sum_{i=0}^{k-1} E_\nu^\pi(Q(B|x_i,a_i)),$$

an easy calculation shows that for every k

$$\mu_k(B \times A) = \int_K Q(B|x,a)\mathrm{d}\mu_k + \frac{P_\nu^\pi(x_{k-1} \in B) - \nu(B)}{k}.$$

Note that the last equality can be rewritten as $L_0(\mu_k) = (P_\nu^\pi(x_{k-1} \in B) - \nu(B))/k$. By considering $v = 1$ in Lemma 2 and the above equality, we obtain that $L_0(\mu) = 0$. Hence μ satisfies (6c).

Consider now the measure

$$\tilde{\mu} = \frac{\mu}{\int_K \tau \, \mathrm{d}\mu}.$$

Clearly $\tilde{\mu}$ satisfies (6b) and by the above argument it satisfies (6c) as well. We also have

$$\int_K w \, \mathrm{d}\tilde{\mu} = \frac{\int_K w \, \mathrm{d}\mu}{\int_K \tau \, \mathrm{d}\mu} = 1 + \frac{\int_K c \, \mathrm{d}\mu}{\int_K \tau \, \mathrm{d}\mu} \leq 1 + J(\pi, \nu) < \infty,$$

showing that $\tilde{\mu} \in \mathbb{M}_w(K)$. Therefore $\tilde{\mu}$ is a feasible solution to (6). Note also that $\int_K c \, \mathrm{d}\tilde{\mu} \leq J(\pi, \nu)$. Since π is an arbitrary policy and ν an arbitrary initial probability distribution, it follows that $\inf(P) \leq J^*$.

It remains to be seen that $J^* \leq \inf(P)$. Since (6) is feasible, there exists a feasible solution μ. If $\int_K c \, \mathrm{d}\mu = \infty$, then there is nothing to prove and therefore we assume that $\int_k c \, \mathrm{d}\mu < \infty$. Then by Assumption A3 and feasibility of μ, $0 < \mu(K) \leq \int_K w \, \mathrm{d}\mu = 1 + \int_K c \, \mathrm{d}\mu < \infty$ and therefore $\mu(K) < \infty$. By Theorem 1, there exists a policy π such that

$$\frac{\mu(B \times C)}{\mu(X \times A)} = \int_B \pi(C|x)\tilde{\mu}(\mathrm{d}x) \qquad \text{for every } B \in \mathcal{B}(X), C \in \mathcal{B}(A). \tag{15}$$

For any randomized stationary policy π, $n \geq 2$, $x \in X$, $B \in \mathcal{B}(X)$, and a measurable function f on K we denote

$$\begin{aligned} f(x, \pi) &= \int_A f(x, a)\pi(\mathrm{d}a|x), \\ Q(B|x, \pi) &= \int_A Q(B|x, a)\pi(\mathrm{d}a|x), \\ Q^n(B|x, \pi) &= P_x^\pi(x_n \in B) = \int_X Q^{n-1}(B|y, \pi)Q(\mathrm{d}y|x, \pi), \\ Q^1(B|x, \pi) &= Q(B|x, \pi). \end{aligned}$$

Then we have

$$\int_K f \, \mathrm{d}\mu/\mu(X \times A) = \int_X f(x, \pi)\tilde{\mu}(\mathrm{d}x), \tag{16}$$

$$E_{\tilde{\mu}}^\pi(f(x_n, a_n)) = \int_X \int_X f(y, \pi)Q^n(\mathrm{d}y|x, \pi)\tilde{\mu}(\mathrm{d}x), \tag{17}$$

$$\tilde{\mu}(B) = \int_X Q^n(B|x, \pi)\tilde{\mu}(\mathrm{d}x), \tag{18}$$

where the first two equalities follow from (15) and aforementioned notation, and the last equality follows by iteratively applying (6c). It follows that

$$J^* \leq J(\pi, \tilde{\mu}) = \frac{\int_K c \, \mathrm{d}\mu/\mu(X \times A)}{\int_K \tau \, \mathrm{d}\mu/\mu(X \times A)} = \int_K c \, \mathrm{d}\mu.$$

Since μ is an arbitrary feasible measure to (6), we conclude that $J^* \leq \inf(P)$. □

Next we discuss solvability.

THEOREM 5. *If Assumptions* A1–A8 *hold, then* (6) *is solvable.*

Proof. Since (6) is consistent by Theorem 4, for every nonnegative integer n there is a feasible measure μ_n to (6) such that

$$\inf(P) \leq \int_K c(x,a)\mu_n(\mathrm{d}(x,a)) \leq \inf(P) + \frac{1}{n} < \infty. \tag{19}$$

Since μ_n is feasible to (6) and from (19) it follows that

$$\|\mu_n\|_w^{\mathrm{TV}} \leq \int_K w \,\mathrm{d}\mu_n = \int_K (\tau + c)\mathrm{d}\mu_n = 1 + \int_K c \,\mathrm{d}\mu_n \leq 2 + \inf(P).$$

If in addition we use (3), we get that $0 < \|\mu_n\|_{\mathrm{TV}} \leq 2 + \inf(P) < \infty$. By Assumption A8 and since $\sup \int_K w \,\mathrm{d}\mu_n$ is bounded, we can use Corollary 1. Let μ_m be a subsequence that converges weakly to a measure μ. We claim that μ is an optimal solution to (6).

From Lemma 1 and (19) it follows that $\int_K c \,\mathrm{d}\mu \leq \inf(P)$. If μ is feasible to (6), then this implies that μ is optimal.

Now we show that μ is feasible to (6). Since by Assumption A7 $\tau \in \mathbb{C}_b(K)$, it follows

$$1 = \int_K \tau \,\mathrm{d}\mu_m \longrightarrow \int_K \tau \,\mathrm{d}\mu$$

and therefore τ satisfies (6b). In turns it implies that

$$\|\mu\|_w^{\mathrm{TV}} \leq \int_K \tau \,\mathrm{d}\mu + \int_K c \,\mathrm{d}\mu \leq 1 + \inf(P)$$

and therefore $\mu \in \mathbb{M}_w(K)$. Since μ_m are feasible, it follows that $L_0(\mu_m) = 0$ for every m and in turn we can apply Lemma 2 with $v = 1$. Therefore μ satisfies (6c). ∎

Next we address solvability of (7). A sequence $\{(\rho_n, u_n)\}_n$ of feasible solutions to (7) is a *maximizing sequence* if $\lim_{n\to\infty} \rho_n = \sup(D)$.

THEOREM 6. *Assume that Assumptions* A1–A4 *hold. If there exists a maximizing sequence* $\{(\rho_n, u_n)\}_n$ *to* (7) *such that* $\|u_n\|_{w_0} \leq r < \infty$ *for a constant* r*, then* (7) *is solvable.*

Proof. Let $\rho = \sup(D)$ and let us define

$$u(x) = \limsup_{n\to\infty} u_n(x).$$

By assumption $\|u\|_{w_0} \leq r$ and therefore $u \in \mathbb{B}_{w_0}(X)$. For every $y \in X$ we have $|u_n(y)| \leq r w_0(y)$ and by Assumption A4 $\int_X w_0(y) Q(\mathrm{d}y|x,a) \leq k w(x,a) < \infty$, which justifies using Fatou's lemma with respect to $Q(\cdot|x,a)$. Since (ρ_n, u_n) satisfies (7b), we have that for every $(x,a) \in K$ and every n

$$\tau(x,a)\rho_n + u_n(x) \leq \int_X u_n(y) Q(\mathrm{d}y|x,a) + c(x,a).$$

After taking lim sup, using $\lim_n \rho_n = \rho$, and applying Fatou's lemma, we obtain

$$\tau(x,a)\rho + u(x) - \int_X u(y) Q(\mathrm{d}y|x,a) \leq c(x,a).$$

Therefore (ρ, u) is a feasible solution to (7) with value $\sup(D)$ and therefore it is an optimal solution. ∎

3.2.2. No duality gap. In this section we prove that under our assumptions there is no duality gap.

THEOREM 7. *If Assumptions* A1–A8 *hold, then* $\sup(D) = \inf(P)$.

Proof. Let

$$H = \left\{ (L\mu, \int_K c \, \mathrm{d}\mu + r) : \mu \in \mathbb{M}_w^+(K), r \geq 0 \right\},$$

where $\mathbb{M}_w^+(K)$ is the set of all nonnegative measures in $\mathbb{M}_w(K)$. By a theorem from Anderson and Nash (1987, pp. 52), if H is closed in the weak topology of $(\mathbb{R} \times \mathbb{M}_{w_0}(X) \times \mathbb{R}, \mathbb{R} \times \mathbb{B}_{w_0}(X) \times \mathbb{R})$, then there is no duality gap.

To this end, let $(D, \geq)$ be a directed set and let $\{\mu_\alpha, r_\alpha\}_{\alpha \in D}$ be a net (see, e.g., Ash (1972) for a definition of directed sets and nets) in $\mathbb{M}_w(K) \times \mathbb{R}_+$ such that

$$\int_K \tau \, \mathrm{d}\mu_\alpha \to r_*, \tag{20}$$

$$\int_X u \, \mathrm{d}L_0(\mu_\alpha) \to \int_X u \, \mathrm{d}\upsilon_* \qquad \text{for every } u \in \mathbb{C}_b(X),$$

$$\int_K c \, \mathrm{d}\mu_\alpha + r_\alpha \to \rho_*. \tag{21}$$

By using Corollary 1 we show that there exists a nonnegative measure $\mu \in \mathbb{M}_w(X)$ and $r \in \mathbb{R}_+$ such that

$$r_* = \int_K \tau \, \mathrm{d}\mu, \tag{22}$$

$$\upsilon_* = L_0(\mu), \tag{23}$$

$$\rho_* = \int_K c \, \mathrm{d}\mu + r_*. \tag{24}$$

Since $r_\alpha \geq 0, \int_K c \, \mathrm{d}\mu_\alpha \geq 0$ and by (21), it follows that $\int_K c \, \mathrm{d}\mu_\alpha$ are bounded for $\alpha \geq \alpha_0$ for an $\alpha_0 \in D$. Therefore by (20) it follows that there exists $\alpha_1 \in D, \alpha_1 > \alpha_0$ such that $\int_K w \, \mathrm{d}\mu_\alpha$ is bounded and positive for $\alpha \geq \alpha_1$. There exists a constant K such that $\|\mu_\alpha\|_w^{\mathrm{TV}} \leq K$ for every $\alpha \geq \alpha_1$. This in turn implies that $\|\mu_\alpha\|_{\mathrm{TV}} \leq \|\mu_\alpha\|_w^{\mathrm{TV}} \leq K$ for every $\alpha \geq \alpha_1$. We conclude that $\{\mu_\alpha\}_{\alpha \geq \alpha_1}$ is bounded. By Assumption A8 and by using Corollary 1 we obtain that there is a subsequence $\{\mu_m\}_m$ that converges weakly to a measure μ.

Since $\tau \in \mathbb{C}_b(K)$ by Assumption A7, it immediately follows that $r_* = \int_K \tau \, \mathrm{d}\mu$. Hence we have (22). By Lemma 1, we have

$$\int_K w \, \mathrm{d}\mu \leq 1 + \liminf_m \int_K c \, \mathrm{d}\mu_m < \infty$$

and therefore $\mu \in \mathbb{M}_w(K)$. Using again Lemma 1 and taking lim inf in (21) we get

$$\rho_* \geq \liminf_m \int_K c \, \mathrm{d}\mu_n + \liminf_m r_m \geq \int_K c \, \mathrm{d}\mu.$$

Thus we can define $r_* = \rho_* - \int_K c \, \mathrm{d}\mu \geq 0$ and we obtain (24). By using Lemma 2 we establish (23) and thus we have shown the theorem. □

3.2.3. Randomized optimal policies and optimality equation on a subset of states. In this section we show, under generous assumptions, that there exists a minimum pair and that that the optimality equation has a solution on a subset of states.

THEOREM 8. *Assume that Assumptions* A1–A8 *hold and that* (7) *is solvable. Let* μ, (ρ, u) *be an optimal solution to* (6), (7), *respectively, and let* $\hat{\mu}$ *be the marginal of* μ *on* X. *Then*

(a) $J^* = \rho$, *and there exists a stationary randomized policy* π^* *and an initial distribution* $\hat{\mu}^*$ *such that* $(\hat{\mu}^*, \pi^*)$ *is a minimum pair, and*

$$J(x, \pi^*) = \rho \tag{25}$$

holds for $\hat{\mu}^*$*-almost all* $x \in X$;

(b) [*complementary slackness*] *and for* μ*-almost all* $(x, a) \in K$ *we have*

$$\tau(x, a)J^* + u(x) = c(x, a) + \int_X u(y)Q(\mathrm{d}y|x, a); \tag{26}$$

(c) *if we denote*

$$S = \{x \in X : \text{there exists } a \in A(x) \text{ such that } (26) \text{ holds for } (x, a)\}, \tag{27}$$

and

$$S^* = S \cap \{x \in S : u(x) < \infty\},$$

and we assume $S^* \neq \emptyset$, *then there exists a stationary policy* $f^* \in \Pi_{SD}$ *such that*

$$\begin{aligned} u(x) &= \min_{a \in A(x)} \left\{ c(x, a) - \tau(x, a)J^* + \int_X u(y)Q(\mathrm{d}y|x, a) \right\} \\ &= c(x, f^*(x)) - \tau(x, f^*(x))J^* + \int_X u(y)Q(\mathrm{d}y|x, f^*(x)) \end{aligned} \tag{28}$$

for every $x \in S^*$.

Proof. We first prove (a). Note that by Theorem 7 we have $\rho = J^*$. Since $0 < \mu(X \times A) \leq \int_{X \times A} w \, \mathrm{d}\mu = 1 + J^* < \infty$, we use Theorem 1 for $\mu/\mu(X \times A)$ to decompose this measure into a policy π^* and initial distribution $\hat{\mu}^*$. It follows from the proof of Theorem 4 that $(\hat{\mu}^*, \pi^*)$ is a minimum pair. The individual ergodic theorem (see, e.g., Yosida (1978)) yields (25).

Next we prove (b). Let q be a measurable function defined by

$$\tau(x, a)J^* + u(x) + q(x, a) = c(x, a) + \int_X u(y)Q(\mathrm{d}y|x, a). \tag{29}$$

Since (ρ, u) is feasible to (7), $q \geq 0$ for every $(x, a) \in K$. After integrating (29) with respect to μ we obtain

$$J^* + \int_K u \, \mathrm{d}\mu + \int_K q \, \mathrm{d}\mu = \int_K c \, \mathrm{d}\mu + \int_K u \, \mathrm{d}\mu, \tag{30}$$

where we have used that μ satisfies (6b) and from (6c) it follows

$$\int_K \left(\int_X u(y)Q(\mathrm{d}y|x, a) \right) \mu(\mathrm{d}(x, a)) = \int_K u \, \mathrm{d}\mu.$$

Since $\mu, (\rho, u)$ are optimal for the primal, dual linear programs, respectively, it follows $J^* = \int_K c \, \mathrm{d}\mu$. This together with

$$\left| \int_K u \, \mathrm{d}\mu \right| \leq k\|u\|_{w_0} \int_K w \, \mathrm{d}\mu = k\|u\|_{w_0}(1 + J^*) < \infty$$

and (30) yields $\int_K q \, \mathrm{d}\mu = 0$. Since q is nonnegative, we get that $q(x, a) = 0$ for μ-almost all (x, a), which completes the proof of the first statement.

It remains to show the last statement. For every $x \in S$ let $\bar{A}(x)$ be the set of all $a \in A(x)$ such that (x, a) satisfies (26). Note that by definition $\bar{A}(x) \neq \emptyset$. After integrating (26) with respect to $\pi^*(\mathrm{d}a|x)$ we obtain

$$u(x) = \int_{\bar{A}(x)} \left[c(x, a) + \int_X u(y) Q(\mathrm{d}y|x, a) - \tau(x, a) J^* \right] \pi^*(\mathrm{d}a|x).$$

Since $u(x) < \infty$ for $x \in S^*$ it follows from the measurable selection theorem of Blackwell and Ryll-Nardzewski (see, e.g., Dynkin and Yushkevich (1979, pp. 255)) that there exists a stationary deterministic policy f^* such that

$$\begin{aligned} &\int_{\bar{A}(x)} \left[c(x, a) + \int_X u(y) Q(\mathrm{d}y|x, a) - \tau(x, a) J^* \right] \pi^*(\mathrm{d}a|x) \\ &\geq c(x, f^*(x)) + \int_X u(y) Q(\mathrm{d}y|x, f^*(x)) - \tau(x, f^*(x)) J^*. \end{aligned}$$

The other inequality follows from feasibility of u to (7). This establishes the second part. □

4. Dirac's transition laws. Next we study Dirac's kernels. Note that in this case Assumption A4 is equivalent to

$$w_0(s(x, a)) \leq k w(x, a)$$

for every $(x, a) \in K$ and Assumption A6 requires s to be continuous. Under a Dirac's transition kernel the corresponding primal linear program is

$$\inf \int_K c(x, a) \mu(\mathrm{d}(x, a)) \tag{31a}$$

$$\int_K \tau(x, a) \mu(\mathrm{d}(x, a)) = 1 \tag{31b}$$

$$\mu((B \times A) \cap K) - \mu(\{(x, a) \in K : s(x, a) \in B\}) = 0 \qquad \text{for every } B \in \mathcal{B}(X) \tag{31c}$$

$$\mu \geq 0, \mu \in \mathbb{M}_w(K), \tag{31d}$$

and the corresponding dual problem reads

$$\sup \rho \tag{32a}$$

$$\tau(x, a)\rho + u(x) - u(s(x, a)) \leq c(x, a) \qquad \text{for every } (x, a) \in K \tag{32b}$$

$$\rho \in \mathbb{R}, u \in \mathbb{B}_{w_0}(X). \tag{32c}$$

By using a stronger version of Theorem 8 and a more stringent assumption we show the existence of a deterministic stationary optimal policies for all the states.

ASSUMPTION A9. *There exist constants $C < \infty$, $\Gamma < \infty$ such that for every measurable subset $S \subseteq X$ there is a measurable function $f : X \setminus S \to A$ with the property that for every $x' \in X \setminus S$ there exists a finite integer N and a set of states $x_0, x_1, \ldots, x_N$ with*

- $x_0 = x'$,
- $a_n = f(x_n) \in A(x_n)$ *for every* $n = 0, \ldots, N-1$,
- $x_{n+1} = s(x_n, a_n)$ *for every* $n = 0, \ldots, N-1$,
- $x_N \in S$,
- $\sum_{n=0}^{N-1} c(x_n, a_n) \leq C$, *and*
- $\sum_{n=0}^{N-1} \tau(x_n, a_n) \leq \Gamma$.

This assumption requires that any two states communicate (select S to be a single state) and the cost and the time of the path between any two states must be uniformly upper bounded.

For Dirac's kernels, we can strengthen Theorem 8 by showing that there exists an optimal policy whose sample path satisfies the average cost optimality equation.

THEOREM 9. *Assume that Assumptions* A1–A8 *hold and that* (32) *is solvable with* (ρ, u) *being an optimal solution. Furthermore, assume that there exists a constant* N *such that* $N > u(x) > -N$ *for every* $x \in X$. *Then there exists a stationary deterministic policy* $f^* \in \Pi_{SD}$ *and a nonempty set* $L \subseteq X$ *such that the average cost optimality equation* (2) *holds for every* $x \in L$ *and*

$$J(x) = J(f^*, x) = J^*$$

for every $x \in L$, *i.e.,* f^* *is an optimal stationary deterministic policy for all* $x \in L$.

The following lemma holds for general kernels.

LEMMA 3. *If Assumption* A3 *holds and* $J(\pi, \nu) < \infty$ *for a policy* π *and initial distribution* ν, *then* $\lim_{n\to\infty} \sum_{i=0}^{n-1} E_\nu^\pi(\tau(x_i, a_i)) = \infty$.

Proof. Suppose that $0 \leq \lim_{n\to\infty} \sum_{i=0}^{n-1} E_\nu^\pi(\tau(x_i, a_i)) < \infty$. Then there is a constant $K \geq 0$ such that

$$\sum_{i=0}^{n-1} E_\nu^\pi(\tau(x_i, a_i)) \leq K$$

for every n. By assumption we have

$$J(\pi, \nu) = \limsup_{n\to\infty} \frac{E_\nu^\pi(\sum_{k=0}^{n-1} c(x_k, a_k))}{E_\nu^\pi(\sum_{k=0}^{n-1} \tau(x_k, a_k))} = \limsup_{n\to\infty} \frac{E_\nu^\pi(\sum_{k=0}^{n-1} w(x_k, a_k))}{E_\nu^\pi(\sum_{k=0}^{n-1} \tau(x_k, a_k))} - 1 < \infty.$$

From Assumption A3 we obtain

$$\infty > 1 + J(\pi, \nu) \geq \limsup_n \frac{n}{K} = \infty,$$

which is a contradiction. □

Proof of Theorem 9. We use the same notation as in the proof of Theorem 8. We first show that there exists a trajectory, whose state-action pairs satisfy the optimality equation. For any $\omega \in \Omega$ let us define $r(\omega) = \sum_{i=1}^{\infty} q(x_i, a_i)$. Since u is dual feasible, we clearly have $r \geq 0$. In addition, let $r_n(\omega) = \sum_{i=1}^{n} q(x_i, a_i)$. We note that $r_1 \leq r_2 \leq r_3 \leq \cdots$ and for any $\omega \in \Omega$ we have $\lim_{n\to\infty} r_n(\omega) = r(\omega)$.

Next we show that for every n we have

$$\int_{\omega\in\Omega} r_n(\omega) P_{\hat{\mu}}^\pi(\mathrm{d}\omega) = 0. \tag{33}$$

We show this by induction. We first note that from (16), (18), and complementary slackness for every n it follows

$$0 = \frac{\int_K q \, \mathrm{d}\mu}{\mu(K)} = \int_X q(x,\pi)\hat{\mu}(\mathrm{d}x) = \int_X \int_X q(y,\pi) Q^n(dy|x,\pi)\hat{\mu}(\mathrm{d}x). \tag{34}$$

For $n = 1$ we have

$$\int_{\omega\in\Omega} r_1(\omega) P^\pi_{\hat{\mu}}(\mathrm{d}\omega) = E^\pi_{\hat{\mu}}(q(x_1,a_1)) = \int_X \int_X q(y,\pi) Q(dy|x,\pi)\hat{\mu}(\mathrm{d}x) = 0,$$

where the second equality follows from (17) and the last one from (34). Assume now that (33) holds for $n-1$. Then

$$\begin{aligned}
\int_{\omega\in\Omega} r_n(\omega) P^\pi_{\hat{\mu}}(\mathrm{d}\omega) &= \int_{\omega\in\Omega} (r_{n-1}(\omega) + q(x_n,a_n)) P^\pi_{\hat{\mu}}(\mathrm{d}\omega) \\
&= \int_{\omega\in\Omega} q(x_n,a_n) P^\pi_{\hat{\mu}}(\mathrm{d}\omega) \qquad (35) \\
&= E^\pi_{\hat{\mu}}(q(x_n,a_n)) = \int_X \int_X q(y,\pi) Q^n(dy|x,\pi)\hat{\mu}(\mathrm{d}x) = 0, \qquad (36)
\end{aligned}$$

where (35) holds by the induction assumption and (36) follows from (17) and (34). Thus we have shown (33) for every n.

By the monotone convergence theorem it follows that

$$\int_{\omega\in\Omega} r(\omega) P^\pi_{\hat{\mu}}(\mathrm{d}\omega) = \lim_{n\to\infty} \int_{\omega\in\Omega} r_n(\omega) P^\pi_{\hat{\mu}}(\mathrm{d}\omega) = 0.$$

Hence there exists ω such that $r(\omega) = 0$, i.e., there is a trajectory that satisfies the optimality equation.

Let L be the set of all $x \in X$ with the property that there exists a trajectory ω with $x_0 = x$ and $r(\omega) = 0$. For every $x \in L$ let $\bar{A}(x) = \{a \in A(x) : q(x,a) = 0, s(x,a) \in L\}$. By definition of L, it follows that $\bar{A}(x) \neq \emptyset$. Now we use the measurable selection theorem of Blackwell and Ryll-Nardzewski as in the proof of Theorem 8. We obtain a stationary deterministic policy f^* satisfying

$$u(x) = c(x, f^*(x)) - \tau(x, f^*(x))J^* + u(s(x, f^*(x))) \tag{37}$$

and such that $q(x, f^*(x)) = 0$ for every $x \in L$. In other words, for every $x \in L$ we have $s(x, f^*(x)) \in L$ and (37) holds.

Let now $x \in L$. Then by iteratively applying (37) for every n it follows that

$$J^* = \frac{\sum_{i=0}^{n-1} c(x_i, f^*(x_i))}{\sum_{i=0}^{n-1} \tau(x_i, f^*(x_i))} + \frac{u(x_n) - u(x)}{\sum_{i=0}^{n-1} \tau(x_i, f^*(x_i))}. \tag{38}$$

If $\tau(x_i, f^*(x_i)) = 0$ for every i, then

$$0 = \sum_{i=0}^{n-1} c(x_i, f^*(x_i)) + u(x_n) - u(x)$$

and in turn by Assumption A3

$$0 = \sum_{i=0}^{n-1} w(x_i, f^*(x_i)) + u(x_n) - u(x) \geq n + u(x_n) - u(x).$$

This can be rewritten as $u(x_n) \leq -n + u(x)$. As n tends to infinity, this yields a contradiction since by assumption u is lower bounded.

We conclude that there exists $\bar{i}$ such that $\tau(x_{\bar{i}}, f^*(x_{\bar{i}})) > 0$. For $n \geq \bar{i}$ we have that $\{\sum_{i=0}^{n-1} \tau(x, f^*(x))\}_n$ is a nondecreasing sequence of positive values and it is therefore bounded away from 0. This in turn implies by taking lim sup in (38) and considering u is bounded that $J(f^*, x) < \infty$. As n goes to infinity, the second term goes to 0 since u is bounded in X and Lemma 3. Therefore $J^* = J(f^*, x) = J(x)$. □

Under the conditions stated in Theorem 9, clearly the conclusions of Theorem 8 hold. Before proving the main result, we need two additional statements.

PROPOSITION 1. *Let $\bar{x} \in X$ be a fixed state. If Assumption* A9 *holds and if u is feasible to* (32)*, then there exists a constant M such that $-M \leq u(x) - u(\bar{x}) \leq M$ for every $x \in X$.*

Proof. Consider $x \in X$ and let (u, ρ) be a feasible solution to (32). Then by Assumption A9 with $x' = x$ and $S = \{\bar{x}\}$ there is a sequence of state-action pairs $(x_i, a_i), a_i \in A(x_i)$ for $i = 0, 1, \ldots, N-1$ such that $x_0 = x, x_N = \bar{x}$. By iteratively using (32b) for $x_i, i = 0, 1, \ldots, N-1$ and then summing up the inequalities we obtain that

$$u(x) \leq \sum_{i=0}^{N-1} c(x_i, a_i) - \rho \sum_{i=0}^{N-1} \tau(x_i, a_i) + u(\bar{x}) \leq C + |\rho| \cdot \Gamma + u(\bar{x}) \leq C + J^* \cdot \Gamma + u(\bar{x}).$$

On the other hand, again by Assumption A9 there exists a sequence of state-action pairs $(x_i, a_i), a_i \in A(x_i)$ for $i = 0, 1, \ldots, N$ with $x_0 = \bar{x}$ and $x_N = x$. Similarly as above we obtain

$$u(\bar{x}) \leq \sum_{i=0}^{N-1} c(x_i, a_i) - \rho \sum_{i=0}^{N-1} \tau(x_i, a_i) + u(x) \leq C + |\rho| \cdot \Gamma + u(x) \leq C + J^* \cdot \Gamma + u(x).$$

This completes the proof by taking $M = C + J^* \cdot \Gamma$. □

We are now ready to prove solvability of (32).

COROLLARY 2. *Under Assumptions* A1–A4 *and Assumption* A9*,* (32) *is solvable.*

Proof. Let $\{\rho_n, u_n\}_n$ be a maximizing sequence. Note that if (ρ, u) is feasible to (32), then for every $r \in \mathbb{R}$ the pair $(\rho, u - r)$ is feasible as well. Therefore $\{\rho_n, \hat{u}_n\}_n$ is a maximizing sequence as well, where $\hat{u}_n = u_n - u_n(\bar{x})$ and $\bar{x} \in X$ is a fixed state. By Proposition 1 $\hat{u}_n$ are bounded since $\hat{u}_n(\bar{x}) = 0$. By Theorem 6, we get that (32) is solvable. □

We summarize the linear programming results in the following proposition.

THEOREM 10. *Assume that Assumptions* A1–A9 *hold. The problems* (31) *and* (32) *are consistent, solvable, and there is no duality gap. There exists a nonempty set $L \subseteq X$, a deterministic stationary policy f^*, and a function $u \in \mathbb{B}_{w_0}(X)$ such that the average cost optimality equation*

$$\begin{aligned} u(x) &= \min_{a \in A(x)} \{c(x, a) - J^* \tau(x, a) + u(s(x, a))\} \\ &= c(x, f^*(x)) - J^* \tau(x, f^*(x)) + u(s(x, f^*(x))) \end{aligned} \tag{39}$$

holds for every $x \in L$ and $s(x, f^*(x)) \in L$ for every $x \in L$. In addition, for every $x \in L$, f^* is the optimal policy and

$$J^* = J(f^*, x) = J(x)$$

for every $x \in L$.

Proof. The first statement has already been proved. The last statement follows from Theorem 9 and Corollary 2. ∎

We are now ready to state the main result in the Dirac's case.

THEOREM 11. *Under Assumptions* A1–A9*, for every* $x_0 = x \in X$ *there exists an optimal deterministic stationary policy* f^**. For every* $x \in X$ *we have* $J(x) = J(f^*, x) = J^*$.

Proof. Let L and f^* be as in Theorem 10 and let f be as in Assumption A9 with respect to this particular L. Consider the deterministic stationary policy $\hat{f}$ defined for any $x \in X$ as

$$\hat{f}(x) = \begin{cases} f(x) & x \in X \setminus L, \\ f^*(x) & x \in L. \end{cases}$$

We claim that the value of this policy is J^* for any $x_0 = x \in X$, which shows the statement.

Let $x_0 = x \in X$ be an initial state. By Assumption A9 policy $\hat{f}$ leads in at most N steps to a state in L and then the policy follows f^*. It is clear that $\sum_{k=0}^{\infty} \tau(x_k, \hat{f}(x_k)) > 0$ and therefore $J(\hat{f}, x) < \infty$. By Lemma 3 it follows that

$$\sum_{k=0}^{\infty} \tau(x_k, \hat{f}(x_k)) = \infty. \tag{40}$$

For any $n \geq N$ we have

$$\begin{aligned} \frac{\sum_{k=0}^{n-1} c(x_k, \hat{f}(x_k))}{\sum_{k=0}^{n-1} \tau(x_k, \hat{f}(x_k))} &= J^* + \frac{\sum_{k=0}^{n-1} \Big(c(x_k, \hat{f}(x_k)) - J^* \tau(x_k, \hat{f}(x_k)) \Big)}{\sum_{k=0}^{n-1} \tau(x_k, \hat{f}(x_k))} \\ &= J^* + \frac{\sum_{k=0}^{N-1} \Big(c(x_k, \hat{f}(x_k)) - J^* \tau(x_k, \hat{f}(x_k)) \Big) + u(\hat{x}) - u(x_n)}{\sum_{k=0}^{n-1} \tau(x_k, \hat{f}(x_k))} \qquad (41) \\ &\leq J^* + \frac{2M}{\sum_{k=0}^{n-1} \tau(x_k, \hat{f}(x_k))}, \end{aligned}$$

where M is as in Proposition 1. (41) follows since for $x_k, k \geq N$ we have $c(x_k, \hat{f}(x_k)) - J^* \tau(x_k, \hat{f}(x_k)) = c(x_k, f^*(x_k)) - J^* \tau(x_k, f^*(x_k)) = u(x_k) - u(x_{k+1})$ by using (39).

Taking the lim sup over n on both sides and considering (40) we obtain $J(\hat{f}, x) \leq J^*$, which completes the proof. ∎

Acknowledgments. The authors thank two anonymous referees for many helpful comments. In particular, the authors acknowledge an anonymous referee for pointing out a subtle error in an early version of the manuscript.

A REPRESENTATION THEOREM FOR THE ERROR OF RECURSIVE ESTIMATORS*

LÁSZLÓ GERENCSÉR†

Dedicated to Peter Caines in honor of his 60th birthday

Abstract. The ultimate objective of this paper is to develop new techniques that can be used for the analysis of performance degradation due to statistical uncertainty for a wide class of linear stochastic systems. For this we need new technical tools similar to those used in [L. Gerencsér, *Statist. Plann. Inference*, 41 (1994), pp. 303–325]. The immediate technical objective is to extend the previous technical results to the Djereveckii–Fradkov–Ljung scheme with enforced boundedness. Our starting point is a standard approximation of the estimation error used in the asymptotic theory of recursive estimation. Tight control of the difference between the estimation error and its standard approximation, referred to as *residuals*, is a crucial point in our applications. The main technical advance of the present paper is a set of strong approximation theorems for three closely related recursive estimation algorithms in which, for any $q \geq 1$, the L_q-norms of the residual terms are shown to tend to zero with rate $N^{-1/2-\varepsilon}$ with some $\varepsilon > 0$. This is a significant extension of previous results for the recursive prediction error or RPE estimator of ARMA processes given in [L. Gerencsér, *Systems Control Lett.*, 21 (1993), pp. 347–351]. Two useful corollaries will be derived. In the first a standard transform of the estimation-error process for the basic recursive estimation method, Algorithm CR, will be shown to be L-mixing, while in the second the asymptotic covariance matrix of the estimator for the same method will be given. Applications to multivariable adaptive prediction and the minimum-variance self-tuning regulator for ARMAX systems will be described.

Key words. adaptive prediction, stochastic complexity, recursive estimation, L-mixing processes, asymptotic covariance, stochastic adaptive control

1. Introduction.

The ultimate objective of this paper is to develop new techniques for the analysis of performance degradation due to statistical uncertainty for a wide class of linear stochastic systems. Performance degradation due to statistical uncertainty, called *regret*, following [46], can be computed at a single time moment, yielding instantaneous regret, or it can be summed over time, yielding cumulative regret. The objective of the paper is to develop new techniques that can be used for analyzing the pathwise (almost sure) asymptotics of the cumulative regret for a class of adaptive prediction and stochastic adaptive control problems.

A number of examples on the interaction of identification and control are available in the *identification for control* literature, see [29, 40, 41]. While those papers contain fundamentally new ideas, the analysis they present contains heuristic elements. In particular, they assume the independence of actually weakly dependent quantities in order to simplify the computation of the instantaneous regret. The present paper lays the foundations for a rigorous discussion of these heuristic arguments. Special examples of these new technical tools have been developed in the context of adaptive prediction of ARMA processes in [24].

The immediate *technical objective* is a detailed analysis of the Djereveckii–Fradkov–Ljung (DFL) scheme with enforced boundedness, given as *Algorithm DFL*, (3.53)–(3.54). This is a practically useful recursive estimation method introduced in [11, 12, 51] with a wide range of applications; see [3, 53]. The algorithm in its original form is given under (3.50) and (3.51) which is a potentially divergent procedure. To ensure convergence the original method is modified by enforced boundedness, a device that has been widely used in practice and rigorously analyzed in [19]. The study of the DFL scheme is reduced to the study of two related stochastic approximation methods, Algorithm DR (discrete-time recursion) and Algorithm CR (continuous-time recursion), described in section 3. The conditions under which these methods are analyzed are very close to what we had in [19]. However, a critical condition imposed on the initialization of the process has been significantly simplified. Our conditions will be compared with other conditions used in the literature, in particular with those in [3], with emphasis on the so-called "boundedness condition."

Asymptotic properties of recursive estimation processes are established in classical theory by using a series of approximations (see, e.g., [54]). Thus we get a standard approximation of the error term, see, e.g., [65] for a lucid exposition, for which limit results are easily established. Tight control of the difference between the estimation error and its standard approximation, that will be referred to as *residuals*, is crucial in the analysis of performance degradation due to statistical uncertainty; see [24].

The *main technical advance* of the present paper is a set of strong approximation theorems for three closely related recursive estimation algorithms, given as Theorems 4.1–4.3, in which, for any $q \geq 1$, the L_q-norms of the residual terms are shown to tend to zero with rate $N^{-1/2-\varepsilon}$ with some $\varepsilon > 0$. This is a significant extension of a previous result given in [19], where only the rate of convergence for the L_q-norms of the estimation error has been established and the explicit approximation of the estimation error and the residual term is not discussed at all. It extends also the result of [22] on the residual of the recursive prediction error estimator for ARMA processes. The proof is quite demanding: in addition to some basic inequalities developed in [17] the proof relies on [19] and uses a nontrivial moment inequality for weighted multiple integrals of L-mixing processes given in [21]. Preliminary versions of the results of section 4 have been formulated in [20].

In comparison the material of sections 5 and 6 are relatively straightforward corollaries demanding numerous small steps, though. In Theorem 5.1 a standard transform of the estimation-error process for the basic recursive estimation method, Algorithm CR, will be shown to be L-mixing, while in Theorem 6.2 the asymptotic covariance matrix of the estimator for the same method will be given.

The *significance* of the results of the present paper is demonstrated by describing two applications in section 7. In the first example the pathwise cumulative regret is quantified for an online adaptive predictor of multivariable linear stochastic systems. In the second example a similar measure of performance degradation for the minimum-variance self-tuning regulator is computed. Both applications follow the arguments of [24], but heavily rely on the results of the present paper. A further application for indirect adaptive control of multivariable linear stochastic systems is given in [27]. We think that the results are tailored to the needs of the users and they will pave the way to many further applications.

To motivate the studies carried out in this paper we will first give an illuminative application of less known technical results on off-line prediction error identification methods for ARMA processes. The application, given as Theorem 2.1, provides the answer to a basic problem of the theory of *stochastic complexity*, developed by Rissa-

nen; see [58]: the performance degradation of adaptive predictors. The extension of this results to adaptive predictors using online estimation requires the extension of the relevant technical tools. First, a strong approximation result for recursive prediction error identification methods for ARMA processes will be given as Theorem 2.4, this is also the starting point for the investigations of the present paper. Two important corollaries are Theorems 2.5 and 2.6. The relevance of these results in analyzing performance degradation in the context of online adaptive prediction of ARMA processes will be described, culminating in Theorem 2.7. This theorem will be considered as a benchmark in future applications.

2. Adaptive prediction. Basic notions and conditions. An adaptive predictor for ARMA processes is obtained if we use estimated system-parameters in the prediction equation at time n as if it was the true value. Then we may ask, how much do we lose in prediction accuracy due to the inexact knowledge of the parameters. First, we consider adaptive predictors using off-line estimation and indicate the nature of technical results that are needed for the analysis. Then, using the strong approximation result (2.23) we arrive at analogous technical results for recursive estimation, which in turn can be applied to derive interesting properties of real-time adaptive predictors.

The set of real numbers will be denoted by $\mathbb{R}$, the p-dimensional Euclidean space will be denoted by $\mathbb{R}^p$. The Euclidean norm of $x \in \mathbb{R}^p$ will be denoted by $|x|$. We shall often use subscripts to indicate partial derivatives.

Let (y_n), $0 \le n < \infty$, be a wide-sense stationary ARMA (p, q) process satisfying the difference equation

$$\sum_{i=0}^{p} b_i^* y_{n-i} = \sum_{j=0}^{q} c_j^* e_{n-j},$$

or in shorthand notation $B^*y = C^*e$, where B^* and C^* are polynomials of the backward-shift operator of degree p and q, respectively. Define the polynomial $B^*(z^{-1}) = \sum_{i=0}^{p} b_i^*(z^{-i})$ and similarly $C^*(z^{-1})$. To estimate the system-parameters b_i^*, c_j^* from observed data (y_n) using the prediction error method the following technical assumption is assumed.

CONDITION 2.1. *The polynomials B^*, C^* are stable and relative prime, $b_0^* = c_0^* = 1$ and $b_p^* \neq 0$, $c_q^* \neq 0$.*

The condition $b_p^* \neq 0$, $c_q^* \neq 0$ has been assumed to allow the extension of our results to cases when the degree of one of the polynomials B^* or C^*, but not both, is overestimated. The relevant work that we use is [1]. To characterize the noise process we shall need the following definition that has been introduced in [17].

DEFINITION 2.1. *We say that a discrete-time $\mathbb{R}^p$-valued stochastic process (u_n) is* M-bounded *if, for all $1 \le q < \infty$,*

$$M_q(u) := \sup_{n \ge 0} \mathrm{E}^{1/q} |u_n|^q < \infty. \tag{2.1}$$

In this case we also write $u_n = O_M(1)$. For a stochastic process $(z_n), n \ge 0$, and a positive sequence (c_n) we write $z_n = O_M(c_n)$ if $u_n = z_n/c_n = O_M(1)$.

A basic tool that we will use is the theory of L-mixing processes, elaborated in [17] and used to solve some hard problems in system identification; see [18, 19, 22, 38, 43]. This concept is a generalization of what is called "exponentially stable processes" in the system identification literature, see Definition 3.1 in Section 8.3 of [6] or [53]. We

give the definition here for discrete-time processes. Let a probability space $(\Omega, \mathcal{F}, P)$ be given together with a pair of families of σ-algebras $(\mathcal{F}_n, \mathcal{F}_n^+), n = 0, 1, \dots$, such that (i) $\mathcal{F}_n \subset \mathcal{F}$ is monotone increasing, (ii) $\mathcal{F}_n^+ \subset \mathcal{F}$ is monotone decreasing, and (iii) $\mathcal{F}_n$ and $\mathcal{F}_n^+$ are independent for all n. For $n < 0$ we set $\mathcal{F}_n^+ = \mathcal{F}_0^+$.

DEFINITION 2.2. *A stochastic process $u = (u_n)$, $n = 0, 1, \dots$, is L-mixing with respect to $(\mathcal{F}_n, \mathcal{F}_n^+)$ if it is $\mathcal{F}_n$-adapted, M-bounded, and for all $q \geq 1$, with $\tau = 0, 1, \dots$ and*

$$\gamma_q(\tau, u) = \gamma_q(\tau) = \sup_{n \geq \tau} \mathrm{E}^{1/q} |u_n - \mathrm{E}\ (u_n | \mathcal{F}_{n-\tau}^+)|^q,$$

we have

$$\Gamma_q = \Gamma_q(u) = \sum_{\tau=0}^{\infty} \gamma_q(\tau) < \infty. \tag{2.2}$$

The process u is L^+-mixing if, in addition, for all $q \geq 1$ there exist $C_q, c_q > 0$ such that for all nonnegative integers τ,

$$\gamma_q(\tau, u) \leq C_q (1 + \tau)^{-1-c_q}.$$

Discussion of L-mixing. The prime example for L-mixing processes is a sequence of i.i.d. random variables with finite moments of all orders. The response of an exponentially stable linear filter, with an L-mixing process as its input, is L-mixing. Products of L-mixing processes are also L-mixing. These properties make sure that the *verification* of L-mixing is typically easy in problems of system identification. The same invariance properties hold for the class of L^+-mixing processes. For "exponentially stable processes" we would require that $\gamma_q(\tau)$ converges to 0 geometrically fast, at least for some values of q, typically for $q = 4$. We shall need conditions for higher order moments to derive sharp bounds for the error terms in certain uniform laws of large numbers.

CONDITION 2.2. *The system-noise process (e_n), $0 \leq n < \infty$, defined over an underlying probability space $(\Omega, \mathcal{F}, P)$, is an M-bounded process. Moreover there is an increasing sequence of σ-fields $(\mathcal{F}_n)$, $0 \leq n < \infty$, $(\mathcal{F}_n) \subset \mathcal{F}$, such that (e_n) is a martingale difference process with constant conditional variance:*

$$\mathrm{E}(e_n | \mathcal{F}_{n-1}) = 0, \qquad \mathrm{E}(e_n^2 | \mathcal{F}_{n-1}) = \sigma^2 = \mathrm{const.}$$

almost surely. Finally, we assume that (e_n) is L-mixing with respect to a pair of families of σ-algebras $(\mathcal{F}_n, \mathcal{F}_n^+)$.

It follows that (e_n) is a wide-sense stationary orthogonal process. Conditions 2.1 and 2.2 together will be called the *standard conditions* for ARMA processes.

Discussion of the moment condition. The difference between our conditions and the conditions given in standard works such as [6] or [35] is that, there only the condition

$$M_4(e) := \sup_{n \geq 0} \mathrm{E}^{1/4} |e_n|^4 < \infty$$

is required. See the comment to Definition 3.1 in Section 8.3 of [6], or condition (4.1.20) of [35]. Thus our condition is much stronger, but our conclusions given in Theorem 2.2 will be also significantly stronger than the results of [6, 35] given in

terms of classical concepts such as strong consistency, central limit theorem, or the law of iterated logarithm, which all follow from our result and the corresponding result for martingales. M-boundedness could be relaxed by requiring the uniform boundedness of moments of *sufficiently high order*, however the order of the moments would depend on the order of the ARMA process, i.e., on p and q. This is due to the fact that in our proof we rely on Kolmogorov's continuity theorem for random fields to get sharp bounds for the error terms in uniform laws of large numbers, which requires the existence of finite moments up to an order strictly greater than $(p+q)$ in the present application; see Theorem 8.3.

Set $\theta^* = (b_1^*, \dots, b_p^*, c_1^*, \dots, c_q^*)^T$. Let $D_C \subset \mathbb{R}^q$ denote the set of vectors $(c_1, \dots, c_q)$ such that the corresponding polynomial C^* is stable, let $D_B = \mathbb{R}^p$ and let

$$D_\theta = D_B \times D_C \subset \mathbb{R}^{p+q}.$$

Let $D_{\theta 0} \subset D_\theta$ be a compact domain such that $\theta^* \in \operatorname{int} D_{\theta 0}$. Then the *prediction error method* for estimating the parameter θ^* is defined as follows (cf., e.g., [6, 35]): first take an arbitrary $\theta \in D_{\theta 0}$ and define an estimated prediction error process $\bar{\varepsilon} = (\bar{\varepsilon}_n(\theta))$ by the inverse equation

$$C\bar{\varepsilon} = By \tag{2.3}$$

using zero initial conditions. Define the cost function

$$V_N(\theta) = \frac{1}{2} \sum_{n=1}^{N} \bar{\varepsilon}_n^2(\theta).$$

Minimizing $V_N(\theta)$ over $D_{\theta 0}$ yields an estimate $\widehat{\theta}_N$.

A precise definition of $\widehat{\theta}_N$ taking into account the possibility of the existence of several local minima can be given as follows: let $\Omega' \subset \Omega$ be a measurable set such that the equation

$$\frac{\partial}{\partial \theta} V_N(\theta) = 0$$

has a unique solution in the interior of $D_{\theta 0}$ denoted by $\operatorname{int} D_{\theta 0}$ on the event $\Omega' \subset \Omega$. Then this solution will be accepted as $\widehat{\theta}_N$ on Ω', while $\widehat{\theta}_N$ is defined as an arbitrary $D_{\theta 0}$-valued random variable on $\Omega \setminus \Omega'$. It can be shown that we can take Ω' so that $P(\Omega') > 1 - C_q N^{-q}$ for any $q > 0$, see [18, Lemma 2.1], the proof of which is partially based on [1].

Remark. The uniqueness result of [1] remains valid if we redefine D_θ so that the degree of one of the polynomials B^* or C^*, but not both, is overestimated. This is why $b_p^* \neq 0$, $c_q^* \neq 0$ has been assumed in Condition 2.1.

The quantity to be studied in the context of adaptive prediction is the prediction error $\bar{\varepsilon}_n(\widehat{\theta}_{n-1})$. We ask how much do we lose in prediction accuracy due to the statistical uncertainty present in $\widehat{\theta}_{n-1}$. A basic result says that, assuming that the standard conditions, Conditions 2.1 and 2.2, are satisfied then the excess in mean prediction error, also called the *regret*, see [46], satisfies

$$\mathrm{E}(\bar{\varepsilon}_n^2(\widehat{\theta}_{n-1}) - e_n^2) = \frac{\sigma^2(e)}{n}(p+q)(1+o(1)). \tag{2.4}$$

This result is given in [24] and, under different conditions in [64]. It extends the result of [8] for AR processes. A similar result for the cumulative regret for Gaussian linear regression was proved in [56] (see also Theorem 5.3 in [58]).

Summation over n in (2.4) gives that the left-hand side is asymptotically equivalent to $\sigma^2(e)(p+q)\log N$. It has been shown in Theorem 1.1. of [24] that we can remove the expectation operator and we get the following *pathwise* result for the cumulative regret.

THEOREM 2.1. *Assume that the standard conditions, Conditions* 2.1 *and* 2.2*, are satisfied. Then*

$$\lim_{N\to\infty}\frac{1}{\log N}\lim_{N\to\infty}\sum_{n=1}^{N}(\bar{\varepsilon}_n^2(\widehat{\theta}_{n-1})-e_n^2)=\sigma^2(e)(p+q)\quad\text{a.s.} \tag{2.5}$$

This result, under different conditions, was given for AR processes in [36, 37]. The much more difficult ARMA case was solved in [24, 64], using different conditions and different methods. Note that classical limit theorems are not suitable to derive (2.5). Both results, (2.4) and (2.5), play prominent role in the theory of stochastic complexity. The quantity

$$C_{1,N}=\sum_{n=1}^{N}\bar{\varepsilon}_n^2(\widehat{\theta}_{n-1}) \tag{2.6}$$

is called a predictive stochastic complexity in [58].

Technical tools: Strong approximations. Now we come to some technical details that are essential in the proof of the above results. A key point is a characterization of the estimation error process which is more accurate than previously known results. Define the asymptotic cost function by

$$W(\theta)=\lim_{n\to\infty}\frac{1}{2}\mathrm{E}\,\bar{\varepsilon}_n^2(\theta).$$

In the Gaussian case this is the asymptotic log-likelihood function modulo constants. It is easy to see that $W_\theta(\theta^*)=0$, where $_\theta$ denotes differentiation with respect to θ. Also it is well known that

$$R^*=W_{\theta\theta}(\theta^*)=\lim_{n\to\infty}\mathrm{E}\,\bar{\varepsilon}_{\theta n}(\theta^*)\bar{\varepsilon}_{\theta n}(\theta^*)^T$$

is nonsingular and in fact positive definite. Then we have the following representation of the estimation error (cf. [18]).

THEOREM 2.2. *Assume that the standard conditions for ARMA processes, Conditions* 2.1 *and* 2.2*, are satisfied, then we have*

$$\widehat{\theta}_N-\theta^*=-(R^*)^{-1}\frac{1}{N}\sum_{n=1}^{N}\bar{\varepsilon}_{\theta n}(\theta^*)e_n+O_M(N^{-1}). \tag{2.7}$$

The *main contribution* of Theorem 2.2 is that the residual term has been shown to be of the order of magnitude $O_M(N^{-1})$. This is an improvement over the classical results of [50, 59] in the ARMA case. The significance of this improvement is easily demonstrated: the residual term is sufficiently small so that limit theorems such as the law of iterated logarithms (LIL) and invariance principles for the estimator process

can be immediately derived using martingale limit theory (cf. [33]). But the real motivation behind Theorem 2.2 had been the need to verify Rissanen's tail condition for Gaussian ARMA processes, introduced in the seminal paper [57], which in turn can be used to derive a lower bound for the cumulative loss in performance of any adaptive predictor for Gaussian ARMA processes (cf. [26]).

Discussion of mixing conditions. There are a number of other notions of mixing. The best known notion is ϕ-mixing, an excellent and concise introduction to which is given in Chapter 7.2 of [15]. The measure of mixing for two σ-algebras $\mathcal{G}$ and $\mathcal{H}$ is defined for any $1 \leq p \leq \infty$ as follows:

$$\phi_p(\mathcal{G}|\mathcal{H}) = \sup_{A \in \mathcal{G}} ||P(A|\mathcal{H}) - P(A)||_p, \tag{2.8}$$

where $||\xi||_p$ denotes the L_p-norm of the random variable ξ. It can be shown that for $p = 1$ we have $\frac{1}{2}\phi_1(\mathcal{G}|\mathcal{H}) = \alpha(\mathcal{G}, \mathcal{H})$, where

$$\alpha(\mathcal{G}, \mathcal{H}) = \sup_{A \in \mathcal{G}, B \in \mathcal{H}} |P(AB) - P(A)P(B)| \tag{2.9}$$

is the familiar measure of strong mixing. Similarly, we have for $p = \infty$

$$\phi_\infty(\mathcal{G}|\mathcal{H}) = \sup_{A \in \mathcal{G}, B \in \mathcal{H}, P(B) > 0} |P(A|B) - P(A)| \tag{2.10}$$

which is the familiar measure of uniform mixing. A stochastic process (x_n) is then ϕ_p-mixing if with

$$\phi_p(n) = \phi_p(\mathcal{F}_n|\mathcal{F}_n^+),$$

where now $\mathcal{F}_n = \sigma\{x_i, i \leq n\}$, $\mathcal{F}_n^+ = \sigma\{x_i, i \geq n\}$, we have $\lim_{n\to\infty} \phi_p(n)$.

In contrast to L-mixing, the *verification* of even the weakest form of ϕ-mixing, which is called for historical reasons strong mixing or α-mixing, is nontrivial even for Gaussian processes (see Chapter 17 of [42]). On the other hand, measurable static functions of ϕ-mixing processes are ϕ-mixing, while this may not be the case, e.g., for discontinuous functions of L-mixing processes. (For a positive statement see [23, Theorem II.7].)

From the point of view of *usefulness* both notions are equally useful for *off-line estimation*. Namely, the key technical device in analyzing off-line estimators is a kind of improved Hölder inequality, see Lemma 8.1 of section 8, or Chapter 7.2 of [15], or Appendix III of [33]. In fact, it can be shown that the theorem remains valid even if the assumption that (e_n) is L-mixing is completely removed, since the remaining conditions imply the validity of certain improved Hölder inequalities. The situation is quite different for recursive estimation methods, where L-mixing is heavily exploited. Further discussion on this will be given in section 3.

The first step in the proof of Theorem 2.1 is to consider a second-order Taylor series expansion of the terms on the left-hand side. The estimation error process is handled using a standard transformation in the stochastic approximation literature. Define a piecewise constant continuous-time extension of $\widehat{\theta}_n$, and, denoting the time variable by t, introduce a new process by first normalizing $(\widehat{\theta}_t - \theta^*)$ to $t^{1/2}(\widehat{\theta}_t - \theta^*)$ and then using an exponential change of time-scale $t = e^s$. Thus we get a new process

$$\psi_s = e^{s/2}(\widehat{\theta}_{e^s} - \theta^*). \tag{2.11}$$

A key observation is that the *transformed process* (ψ_s) is L-mixing with respect to $(\mathcal{F}_{e^s}, \mathcal{F}^+_{e^s})$. For the definition of L-mixing in continuous time see the next section. The proof of this fact is based on Theorem 2.2 and the following simple result given as Theorem 3.3 in [24].

LEMMA 2.1. *Let $(u_t), t \geq 0$, be a zero-mean L-mixing process with respect to some pair of families of σ-algebras $(\mathcal{F}_t, \mathcal{F}^+_t)$. Let*

$$x_T = T^{-1/2} \int_1^T u_t dt. \tag{2.12}$$

Then the process $(y_s) = (x_{e^s})$ is L-mixing with respect to the pair of families of σ-algebras $(\mathcal{F}_{e^s}, \mathcal{F}^+_{e^s})$.

With this observation it can be shown that the process $\bar{\varepsilon}_n(\theta^*)$ and its gradient are asymptotically independent of $(\widehat{\theta}_N - \theta^*)$, which is exploited in proving (2.4). On the other hand, it can be shown that the result given in (2.5) is essentially a law of large numbers in the new time-scale.

Now we come to the extensions of the above results for the case of online or *recursive estimation* of θ^*. The most widely used recursive estimation methods for ARMA processes is the recursive prediction error (RPE) method, which in the case of Gaussian processes reduces to the recursive maximum-likelihood (RML) method; see [6, 53]. This procedure serves as a *benchmark* for the general theory to be developed in section 3, in particular it is a prime example for the Djereveckii–Fradkov–Ljung scheme or DFL scheme. For both theoretical and practical reasons we consider RPE estimator processes $\widehat{\widehat{\theta}}_n$ using a resetting mechanism to enforce the boundedness of the estimator. The convergence analysis for such a procedure has been given in Theorem 4.2 of [19].

We will now give the details of the RPE method for ARMA processes and a set of technical conditions that we use to guarantee convergence. The conditions are simpler than those given in section 4 of [19]. We will shortly indicate how the present conditions imply the conditions given for the DFL scheme in the next section. Most of the discussion of these conditions will be deferred to the next section.

The definition of the RPE method *without resetting* is

$$\widehat{\widehat{\theta}}_{n+1} = \widehat{\widehat{\theta}}_n - \frac{1}{n+1} (\widehat{\widehat{R}}_n)^{-1} \frac{\partial}{\partial \theta} \varepsilon_{n+1} \cdot \varepsilon_{n+1}, \tag{2.13}$$

$$\widehat{\widehat{R}}_{n+1} = \widehat{\widehat{R}}_n + \frac{1}{n+1} \left(\left(\frac{\partial}{\partial \theta} \varepsilon_{n+1} \right) \left(\frac{\partial}{\partial \theta} \varepsilon_{n+1} \right)^T - \widehat{\widehat{R}}_n \right) \tag{2.14}$$

with some initial conditions $(\widehat{\widehat{\theta}}_0, \widehat{\widehat{R}}_0)$, where ε_n and $\frac{\partial}{\partial \theta} \varepsilon_n$ denote online estimates of $\bar{\varepsilon}_n(\theta^*)$ and $\frac{\partial}{\partial \theta} \bar{\varepsilon}_n(\theta)|_{\theta=\theta^*}$. These are obtained by using the most recent estimations of B^* and C^* in the linear filters defining the current values of $\bar{\varepsilon}_n(\theta^*)$ and $\frac{\partial}{\partial \theta} \bar{\varepsilon}_n(\theta)|_{\theta=\theta^*}$.

Thus, e.g., ε_{n+1} is defined by the time-varying filter

$$(\widehat{\widehat{C}}_n \varepsilon)_{n+1} = (\widehat{\widehat{B}}_n y)_{n+1}. \tag{2.15}$$

For further details see [53].

The RPE method without resetting is a special case of a general recursive estimation scheme, called the DFL scheme, to be described in details in the next section; see (3.50)–(3.51). Note that together with θ^* we also estimate the matrix R^*.

It is well known from simulation examples that the RPE method may diverge, unless some precaution is taken. This difficulty is often dealt with a controversial "boundedness condition" first formulated in [51]. This will be discussed in detail in the context of the DFL method. A convergent *truncated* RPE method has been given in section 4 of [19], which we now describe. Let

$$D_R = \mathbb{R}^+(p \times p) \quad \text{and} \quad D = D_\theta \times D_R,$$

where $\mathbb{R}^+(p \times p)$ denotes the set of symmetric, positive definite $p \times p$ matrices. Let $D_{\theta 0} \subset D_\theta$ be a compact set containing θ^* in its interior, and similarly let $D_{R0} \subset D_R$ be a compact set containing R^* in its interior and let $D_0 = D_{\theta 0} \times D_{R0}$.

Resetting. If at any time n the next estimator $(\hat{\hat{\theta}}_{n+1}, \hat{\hat{R}}_{n+1})$ would leave D_0, then we redefine its value by resetting it to the initial value, i.e.,

$$\text{for} \quad (\hat{\hat{\theta}}_{n+1}, \hat{\hat{R}}_{n+1}) \notin \operatorname{int} D_0 \quad \text{reset as} \quad (\hat{\hat{\theta}}_{n+1}, \hat{\hat{R}}_{n+1}) := (\hat{\hat{\theta}}_0, \hat{\hat{R}}_0). \tag{2.16}$$

To avoid being trapped to the boundary of the truncation domain the initial value $(\hat{\hat{\theta}}_0, \hat{\hat{R}}_0)$ must be aligned to $D_{\theta 0} \times D_{R0}$, as described in Condition 3.4. This condition is given in terms of the so-called associated ordinary differential equation (ODE). Define for $\theta \in D_\theta$

$$R^*(\theta) = \lim_{n \to \infty} \mathrm{E} \bar{\varepsilon}_{\theta n}(\theta) \bar{\varepsilon}_{\theta n}(\theta)^T. \tag{2.17}$$

Then obviously $R^* = R^*(\theta^*)$. With this notation the associated ODE, with the time variable v, is defined as

$$\begin{aligned} \dot{\theta}_v &= -R_v^{-1} \frac{\partial}{\partial \theta} W(\theta_v), \\ \dot{R}_v &= R^*(\theta_v) - R_v. \end{aligned} \tag{2.18}$$

The right-hand side is defined in $D_\theta \times D_R$. This is the usual way of defining the associated ODE; see [3, 53]. However in [19] as well as later in this paper we will define the associated ODE by using a change of time-scale $t = e^v$.

The condition ensuring that resetting works for the general recursive estimation methods given in section 3, including the DFL scheme is Condition 3.4. Following the arguments of section 4 of [19] it is easy to see that the first part of Condition 3.4, requiring a certain kind of asymptotic stability of the associated ODE, follows for the RPE method. Namely, it follows directly from [1] that (2.18) has a unique stationary point in $D_\theta \times D_R$, which is (θ^*, R^*). It is also easy to see that this equilibrium point is asymptotically stable, since the eigenvalues of the Jacobian matrix of the right-hand side of the ODE at (θ^*, R^*) are all -1. Now it is easy to show that the associated ODE is globally asymptotically stable in $D_\theta \times D_R$. For the proof we need the observation that $W(\theta_v)$ is nonincreasing as long as R_v is positive definite, and R_v is bounded and positive definite as long as θ_v belongs to a fixed compact set.

Let $x_n = (\hat{\hat{\theta}}_n, \hat{\hat{R}}_n)$ denote the estimator at time n, let $z = (\theta, R)$ denote a running parameter, and let $z(v, u, \xi)$ denote the solution of (2.18) with initial value ξ at time u. Then it follows that for every $\xi \in D_0$, $v \geq u \geq 0$ the solution $z(v, u, \xi) \in D$ is defined for $1 \leq s \leq t < \infty$, it converges to $x^*(\theta^*, R^*)$ for $t \to \infty$ and we have, with some C_0 and $\alpha = 1 - c$ with arbitrary small $c > 0$,

$$\left\| \frac{\partial}{\partial \xi} z(v, u, \xi) \right\| \leq C_0 e^{-\alpha(v-u)}. \tag{2.19}$$

It follows, using a change of time-scale $t = e^v$, that the first part of Condition 3.4 is satisfied. Here $\|\cdot\|$ denotes the operator norm of a matrix.

To ensure the validity of the second part of Condition 3.4 we have to assume that some a priori knowledge of the system-parameters θ^* and the Hessian R^*, say $\xi_0 = (\widehat{\widehat{\theta}}_0, \widehat{\widehat{R}}_0)$ are available. They can be obtained, e.g., from an off-line estimation.

CONDITION 2.3. *Let $D_0 = D_{\theta 0} \times D_{R0} \subset D_\theta \times D_R$ be a compact truncation domain such that $x^* = (\theta^*, R^*) \in \text{int } D_0$.* (i) *It is assumed that there exists a compact convex domain $D_0' \subset D$ such that for all $v \geq u \geq 0$,*

$$z(v,u,\xi) \in D_0' \quad \text{for } \xi \in D_0 \quad \text{and } z(v,u,\xi) \in D \quad \text{for } \xi \in D_0'. \tag{2.20}$$

(ii) *It is assumed that we have an initial estimate $\xi_0 = (\widehat{\widehat{\theta}}_0, \widehat{\widehat{R}}_0)$ such that for any $v \geq u \geq 0$ we have $z(v,u,\xi_0) \in \text{ int } D_0$.*

Remark. Since our objective is to restate Theorem 4.2 of [19], part (iii) of Condition 3.4 of the present paper need not be required at this time, since it was not required in [19] either; it is special addition for the present paper.

To ensure the stability of the time-varying filter (2.15) given as $(\widehat{\widehat{C}}_n\varepsilon)_{n+1} = (\widehat{\widehat{B}}_n y)_{n+1}$ we need a second condition imposed on the truncation domain (cf. Condition 3.7 given for the DFL method). Let us consider a fixed state-space realization of the inverse system (2.3) and let the state-transition matrix be denoted by $\widetilde{C}$. In [19] this is given as the so-called companion matrix corresponding to the polynomial C (see Condition 4.5 of [19]). Let $D_{B0} \subset D_B$ and $D_{C0} \subset D_C$ be compact domains and let

$$D_{\theta 0} = D_{B0} \times D_{C0}.$$

Now Condition 3.7 would read as follows.

CONDITION 2.4. *Let $D_{\tilde{C}0}$ denote the set of matrices $\tilde{C}$, when C is taken from D_{C0}. Then $D_{\tilde{C}0}$ is jointly stable in the sense that there exists a single $q \times q$ symmetric positive definite matrix U and $0 < \lambda < 1$ such that for all $\tilde{C} \in D_{\tilde{C}0}$,*

$$\widetilde{C}^T U \widetilde{C} \;\leq\; \lambda U.$$

It follows that there exists some $c > 0$ such that for any sequence $(\tilde{C}_n)$ with $\tilde{C}_n \in D_{\tilde{C}0}$ we have

$$||\tilde{C}_n \cdots \tilde{C}_0|| \leq c\lambda^{n/2}. \tag{2.21}$$

A discussion of the joint stability condition. Condition 2.4 above is required only to ensure that (2.21) holds. In the system identification literature it had been occasionally implicitly assumed that the individual stability of each $\tilde{C} \in D_{\tilde{C}0}$ implies (2.21); see, e.g., [34]. This is easily seen to be wrong. One way to ensure Condition 2.4 is to choose the truncation domain D_0 small, but this is obviously not practical. A better way is to use a suitable realization of the inverse system (2.3). To indicate the potential of alternative realizations let us consider a Gilbert–Kalman realization of the inverse system (see [44]). Assume that the roots of the polynomial $C = C(z^{-1})$ are all real and simple and let them be denoted by λ_i. Then we will have

$$\tilde{C} = \text{diag}(\lambda_i),$$

and obviously any compact set of matrices $D_{\tilde{C}0}$ is jointly stable. Potentially useful alternative realizations are given in [55]. A second way of ensuring the validity of

(2.21) is given in [3]. This will be discussed in connection with the DFL scheme in the next section.

Finally we will need two additional conditions for the noise process. First, the M-boundedness of (e_n) is further strengthened by assuming the existence and boundedness of certain exponential moments.

CONDITION 2.5. *We assume that $|e_n|^2$ is in class M^*; i.e., for some $\varepsilon > 0$ we have*

$$\sup_n \mathrm{E}\ \exp \varepsilon |e_n|^2 < \infty.$$

This condition is certainly satisfied if (e_n) is a stationary Gaussian process. The role of this condition will be discussed in section 3 in the context of the DFL scheme.

Secondly, we need to be more specific on the mixing rate of (e_n). The condition to follow is motivated by Lemma 3.1 in [24], which states for continuous-time L-mixing processes (cf. Definition 3.2) that, if (u_t) is an L-mixing process, then $\gamma_q(\tau, u) \leq 4\Gamma_q(u)/\tau$ for all $q \geq 1$ and $\tau \geq 0$. The validity of a slightly stronger inequality is required by the following condition in discrete time (cf. Condition 3.9 given for the DFL scheme).

CONDITION 2.6. *We assume that (e_n) is L^+-mixing with respect to a pair of families of σ-algebras $(\mathcal{F}_n, \mathcal{F}_n^+)$.*

The role of this condition is in the analysis of the difference between the "frozen parameter" process $\bar{\varepsilon}_n(\theta)$ evaluated at $\theta = \widehat{\theta}_n$ and its online estimate ε_n, see [19, Lemma 5.6] restated as Lemma 3.2 of the present paper. From the purely technical point of view, L^+-mixing is used in [19, Theorem 6.1]. In view of the general theorem for the DFL scheme, given as Theorem 3.3, we get the following result (see also Theorem 4.2 of [19]):

THEOREM 2.3. *Let (y_n) be an ARMA process satisfying the standard conditions, Conditions* 2.1 *and* 2.2. *Consider the RPE estimator $(\widehat{\widehat{\theta}}_N, \widehat{\widehat{R}}_N)$ defined by* (2.13), (2.14), *modified by a resetting mechanism given under* (2.16). *Let the truncation domain be of the form*

$$D_0 = D_{\theta 0} \times D_{R0} \quad \text{with} \quad D_{\theta 0} = D_{B0} \times D_{C0}.$$

Assume that D_0 satisfies Condition 2.3 *and D_{C0} satisfies Condition* 2.4. *Finally let the innovation process satisfy the additional conditions, Conditions* 2.5 *and* 2.6. *Then for the recursive estimators $(\widehat{\widehat{\theta}}_N, \widehat{\widehat{R}}_N)$ we have*

$$\widehat{\widehat{\theta}}_N - \theta^* = O_M(N^{-1/2}) \quad \textit{and} \quad \widehat{\widehat{R}}_N - R^* = O_M(N^{-1/2}). \tag{2.22}$$

One of the special features of this result is that the *moments* of the estimation error are bounded from above. While the above theorem is certainly of interest, it is obviously much weaker than the characterization of the off-line estimator given in Theorem 2.2. But Theorem 2.3 is a key technical tool in deriving a strong approximation theorem relating the RPE estimator to the off-line prediction error estimator. This result is given in [22], stating that under the conditions of Theorem 4.2 of [19] (and thus under the conditions of Theorem 2.3) we have

$$\widehat{\widehat{\theta}}_N - \widehat{\theta}_N = O_M\left(\frac{\log N}{N}\right). \tag{2.23}$$

Combining (2.23) with Theorem 2.2 we get the following result.

THEOREM 2.4. *Under the conditions of Theorem* 2.3 *we have*

$$\widehat{\widehat{\theta}}_N - \theta^* = -(R^*)^{-1}\frac{1}{N}\sum_{n=1}^{N}\overline{\varepsilon}_{\theta n}(\theta^*)e_n + O_M\left(\frac{\log N}{N}\right). \tag{2.24}$$

This strong approximation result provides a very precise characterization of $\widehat{\widehat{\theta}}_N$. The control of moments of the residual term is an essential feature of the result that is very much exploited in deriving Theorems 2.7 and 2.8. A direct corollary of the above theorem is the following.

THEOREM 2.5. *Under the conditions of Theorem* 2.3 *we have*

$$\mathrm{E}N(\widehat{\widehat{\theta}}_N - \theta^*)(\widehat{\widehat{\theta}}_N - \theta^*)^T = \sigma^2(R^*)^{-1} + O(N^{-1/2}\log N). \tag{2.25}$$

Finally, taking into account Theorem 2.2, (2.23), and Lemma 2.1 we get the following result.

THEOREM 2.6. *Under the conditions of Theorem* 2.3 *the transformed process*

$$\psi_s = e^{s/2}(\widehat{\widehat{\theta}}_{e^s} - \theta^*) \tag{2.26}$$

is L-mixing *with respect to* $(\mathcal{F}_{e^s}, \mathcal{F}^+_{e^s})$.

The above three results, Theorems 2.4, 2.5, and 2.6, are the key tools in extending Theorem 2.1 to adaptive predictors using recursive estimators rather than off-line estimators (cf. [24]). Thus we get the following *key result*.

THEOREM 2.7. *Under the conditions of Theorem* 2.3 *we have*

$$\lim_{N\to\infty}\frac{1}{\log N}\lim_{N\to\infty}\sum_{n=1}^{N}(\overline{\varepsilon}_n^2(\widehat{\widehat{\theta}}_{n-1}) - e_n^2) = \sigma^2(e)(p+q) \quad \text{a.s.} \tag{2.27}$$

In addition, the above proposition remains valid, if we replace $\overline{\varepsilon}_n(\widehat{\widehat{\theta}}_{n-1})$ by its online computed approximation ε_n; see (2.15).

THEOREM 2.8. *Under the conditions of Theorem* 2.3 *we have*

$$\lim_{N\to\infty}\frac{1}{\log N}\lim_{N\to\infty}\sum_{n=1}^{N}(\varepsilon_n^2 - e_n^2) = \sigma^2(e)(p+q) \quad \text{a.s.} \tag{2.28}$$

The main *contribution* of the present paper is the extension of the technical results given as Theorems 2.4, 2.5, and 2.6 to general recursive estimation schemes that include the DFL scheme with enforced boundedness, given as (3.53)–(3.54). The extension of Theorem 2.4 uses the results of [17, 19] but requires an additional technical tool given in [21]. This extension will be given in section 3. The extensions of Theorems 2.5 and 2.6 are obtained using straightforward, though numerous, approximations in sections 5 and 6. The present paper actively uses the results of [17, 19, 21]. To facilitate reading, these relevant results are summarized in section 8.

3. General recursive estimation schemes. The prime objective of this section is to formulate a general recursive estimation method, the DFL scheme with enforced boundedness, together with conditions that ensure its convergence. It is given as Algorithm DFL under (3.53)–(3.54), developed in [11, 12, 51], see also the books [3, 13, 53].

But first we present two closely related recursive algorithms: Algorithm CR (continuous-time recursion), (3.16), and Algorithm DR (discrete-time recursion), (3.34),

which can be interpreted as "frozen parameter" approximations to the DFL scheme. The main results of the paper will be formulated and proved for the continuous-time method, Algorithm CR. The connection between the continuous-time and the discrete-time algorithms is straightforward. In contrast, the connection between Algorithm DR and the DFL scheme is not straightforward at all, but it has been worked out in [19, sections 6 and 7]. Details will be given while discussing the DFL method.

Our first tentative general method is a continuous-time recursive estimation process without resetting, given by a random differential equation of the form

$$\dot{x}_t = \frac{1}{t}(H(t, x_t, \omega) + \delta H(t, \omega)), \qquad x_1 = \xi_1, \tag{3.1}$$

defined over the underlying probability space $(\Omega, \mathcal{F}, P)$. Here x_t indicates an estimator sequence and $H = (H(t, x, \omega))$ is a random field defined in $[1, \infty) \times D$, where D is a bounded open domain in $\mathbb{R}^p \times \Omega$ and $\delta H(t, \omega))$ is a perturbation term to be described later. The advantage of continuous time is that some calculations can be carried out more easily than in discrete time.

The technical conditions that we impose on $H(t, x, \omega)$ will be tuned to fit the DFL scheme, given by (3.53) and (3.51) below. A continuous-time example for a random field $H(t, x, \omega)$ that is motivated by the DFL scheme is the following:

$$H(t, x, \omega) = \varepsilon(t, x, \omega)\eta(t, x, \omega), \tag{3.2}$$

where $\varepsilon(t, x, \omega)$ and $\eta(t, x, \omega)$ are stationary, jointly Gaussian processes, defined by finite-dimensional stable linear filters applied to a standard Wiener-process (w_s):

$$\varepsilon(t, x, \omega) = \int_{-\infty}^{t} h_\varepsilon(t - s, x) dw_s, \qquad \eta(t, x, \omega) = \int_{-\infty}^{t} h_\eta(t - s, x) dw_s, \tag{3.3}$$

such that in an appropriate state-space representation the state-space matrices corresponding to the impulse responses $h_\varepsilon(\tau, x)$ and $h_\eta(\tau, x)$ are sufficiently smooth functions of the parameter x. In the recursive maximum likelihood identification method for discrete-time Gaussian ARMA processes $\varepsilon(n, x, \omega)$ would be the estimated input noise, with x being the system-parameter and $\eta(n, x, \omega)$ would be its negative gradient with respect to x, assuming stationary initialization for both processes. To specify the conditions to be imposed we need some preliminary technical details. The notion of M-bounded processes will now be extended to parameter-dependent, continuous-time processes.

DEFINITION 3.1. *Let $D_0 \subset \mathbb{R}^p$ be a compact set and let $(u_t(x))$ be an $\mathbb{R}^k$-valued measurable stochastic process defined on $\Omega \times \mathbb{R}^+ \times D_0$, where $\mathbb{R}^+ = \{t : t \geq 0\}$. We say that $(u_t(x))$ is M-bounded (in D_0) if for all q with $1 \leq q < \infty$ we have*

$$M_q(u) = \sup_{\substack{t \geq 0 \\ x \in D_0}} \mathrm{E}^{1/q} |u_t(x)|^q < \infty. \tag{3.4}$$

If $(u_t(x))$ is M-bounded, then we write $= O_M(1)$. We shall use the same terminology if x or t degenerates into a single point. If c_t is a sequence of positive numbers, then we write $u_t(x) = O_M(c_t)$ if $u_t(x)/c_t = O_M(1)$.

The notion of L-mixing will now be extended to parameter-dependent, continuous-time processes. Let a probability space $(\Omega, \mathcal{F}, P)$ be given together with a pair of families of σ-algebras $(\mathcal{F}_t, \mathcal{F}_t^+)$ such that (i) $\mathcal{F}_t \subset \mathcal{F}$ is monotone increasing, (ii) $\mathcal{F}_t^+ \subset \mathcal{F}$

is monotone decreasing and $\mathcal{F}_t^+$ is right continuous in t, i.e., $\mathcal{F}_s^+ = \sigma\{\bigcup_{0<\varepsilon} \mathcal{F}_{s+\varepsilon}^+\}$, and (iii) $\mathcal{F}_t$ and $\mathcal{F}_t^+$ are independent for all t. For $s<0$ we set $\mathcal{F}_s^+ = \mathcal{F}_0^+$.

DEFINITION 3.2. *Let $D_0 \subset \mathbb{R}^p$ be a compact set and let $(u_t(x))$ be an $\mathbb{R}^k$-valued measurable stochastic process defined on $\Omega \times \mathbb{R}^+ \times D_0$. We say that $u = (u_t(x))$ is L-mixing with respect to $(\mathcal{F}_t, \mathcal{F}_t^+)$, uniformly in x for $x \in D_0$, if it is $\mathcal{F}_t$-progressively measurable, M-bounded (in D_0) and if for all $q \geq 1$ with*

$$\gamma_q(\tau, u) = \gamma_q(\tau) = \sup_{\substack{t \geq \tau \\ x \in D_0}} \mathrm{E}^{1/q} |u_t(x) - \mathrm{E}\,(u_t(x) | \mathcal{F}_{t-\tau}^+)|^q, \qquad \tau \geq 0,$$

we have

$$\Gamma_q = \Gamma_q(u) = \int_0^\infty \gamma_q(\tau) d\tau < \infty. \tag{3.5}$$

We say that $(u_t(x))$, $t \geq 0$, $x \in D_0$, is L^+-mixing with respect to $(\mathcal{F}_t, \mathcal{F}_t^+)$, uniformly in x for $x \in D_0$, if in addition for all $q \geq 1$ there exist $C_q, c_q > 0$ such that for all $\tau \geq 0$

$$\gamma_q(\tau, u) \leq C_q (1+\tau)^{-1-c_q}. \tag{3.6}$$

The definition extends to parameter-free processes (u_t) and to discrete-time processes $(u_n(x))$. In the latter case we set

$$\Gamma_q = \Gamma_q(u) = \sum_{\tau=0}^\infty \gamma_q(\tau) < \infty. \tag{3.7}$$

CONDITION 3.1. *The process $H = (H(t,x,\omega))$ is assumed to be defined in $\Omega \times \mathbb{R}^+ \times D$, where $D \subset \mathbb{R}^p$ is an open domain, it is three times continuously differentiable with respect to x for $x \in D$ almost surely and for any compact set $D_0 \subset D$ H and its derivatives up to order 3 are M-bounded in D_0. Furthermore $(H(t,x,\omega))$ and its first derivative $H_x = (H_x(t,x,\omega))$ are L^+-mixing with respect to $(\mathcal{F}_t, \mathcal{F}_t^+)$, uniformly in $x \in D_0$.*

In [19] we used the finite difference field of $H = (H(t,x,\omega))$ to capture the smoothness of $H(t,x,\omega)$. In general, we considered the process

$$\Delta u/\Delta x\ (t, x, x+h, \omega) = |u_t(x+h) - u_t(x)|/|h|$$

defined for $t \geq 0$, $x \neq x+h \in D$. We say that $u = (u_t(x))$ is *M-Lipschitz continuous* with respect to x in D_0, if the process $\Delta u/\Delta x$ defined above is M-bounded; i.e., if for all $1 \leq q < \infty$ we have

$$M_q(\Delta u/\Delta x) = \sup_{\substack{t \geq 0 \\ x \neq x+h \in D_0}} \mathrm{E}^{1/q} |u_t(x+h) - u_t(x)|^q/|h| < \infty.$$

Condition 1.1. of [19] is then as follows.

CONDITION H. *The processes $(H(t,x,\omega))$ and $(\Delta H/\Delta x(t,x,x+h,\omega))$ are assumed to be separable and L^+-mixing with respect to $(\mathcal{F}_t, \mathcal{F}_t^+)$, uniformly in $x, x+h \in D$.*

It is easy to see that Condition H is implied by Condition 3.1.

A discussion of L-mixing. We give further details for comparing L-mixing and ϕ-mixing as described in Chapter 7.2 of [15]. In L-mixing we consider projections on the relative future defined by $\mathcal{F}_{t-\tau}^+$ and the resulting approximation error is

$$\mathrm{E}^{1/q} |u_t - \mathrm{E}\,(u_t | \mathcal{F}_{t-\tau}^+)|^q \leq \gamma_q(\tau, u) \tag{3.8}$$

for $\tau \geq 0$. In ϕ-mixing we consider projections on the past and the corresponding error from the mean, defined as

$$||P(A|\mathcal{H}) - P(A)||_p \tag{3.9}$$

for $A \in \mathcal{G}$. Assuming that there is a random variable Φ such that

$$||P(A|\mathcal{H}) - P(A)|| \leq \Phi \tag{3.10}$$

for all $A \in \mathcal{G}$, we have the following proposition (see Proposition 2.6, (2.23), of Chapter 7.2 of [15]). Let Z be a $\mathcal{G}$-measurable random variable such that $||Z||_s$ is finite and let $r, s > 1$ be such that $r^{-1} + s^{-1} = 1$. Then

$$||\mathrm{E}(Z|\mathcal{H}) - \mathrm{E}(Z)||_p \leq 2||\Phi||_p^{1/r}||\mathrm{E}(|Z|^s|\mathcal{H})||_p^{1/s}. \tag{3.11}$$

Now if (u_t), $t \geq 0$, is L-mixing with respect to $(\mathcal{F}_t, \mathcal{F}_t^+)$, then taking the conditional expectation of $u_t - \mathrm{E}\ (u_t|\mathcal{F}_{t-\tau}^+)$ with respect to $\mathcal{F}_{t-\tau}$ (cf. (3.8)), we get by Jensen's inequality and the assumed independence of $\mathcal{F}_{t-\tau}$ and $\mathcal{F}_{t-\tau}^+$

$$\mathrm{E}^{1/q}|\mathrm{E}\ (u_t|\mathcal{F}_{t-\tau}) - \mathrm{E}\ (u_t)|^q \leq \gamma_q(\tau, u). \tag{3.12}$$

In this respect the two notions of mixing lead to similar conclusions.

We will need to strengthen the condition on the M-boundedness of H_x as follows for reasons that will be discussed later, following Condition 3.8.

CONDITION 3.2. *$H(t, x, \omega)$ is piecewise continuous in t almost surely, and for any compact set $D_0 \subset D$ there exists a random variable $L_t = L_t(\omega) \geq 0$ such that for all $x \in D_0$*

$$|H_x(t, x, \omega)| \leq L_t(\omega)$$

and here L_t is in class M^*, i.e., for some $\varepsilon > 0$ we have

$$\sup_t \mathrm{E} \exp(\varepsilon L_t) < \infty. \tag{3.13}$$

In [19] we had a weaker condition (see Condition 1.2 of [19]).

CONDITION L. *$H(t, x, \omega)$ is piecewise continuous in t, and for any compact set $D_0 \subset D$ is Lipschitz-continuous in x for $x \in D_0$ almost surely with a (t, ω)-dependent Lipschitz constant $L_t = L_t(\omega) \geq 0$; i.e., for $x, x' \in D_0$ we have*

$$|H(t, x, \omega) - H(t, x', \omega)| \leq L_t(\omega)|x - x'|,$$

where L_t is in class M^*.

Assuming that $(\delta H(t, \omega))$ is piecewise continuous in t almost surely, a solution (x_t) of (3.1) exists almost surely in some finite or infinite interval. A central role in the analysis of (x_t) is played by the mean-field of $H(t, x, \omega)$. To simplify the presentation it is assumed that the mean-field is essentially independent of t, but a small perturbation is allowed: we have $\mathrm{E}H(t, x, \omega) = G(x) + \delta G(t, x)$, where $\delta G(t, x)$ is small in a sense to be specified below.

CONDITION 3.3. *We have for any compact set $D_0 \subset D$ and $t \geq 0$, $x \in D_0$*

$$\mathrm{E}H(t, x, \omega) = G(x) + \delta G(t, x),$$

where $\delta G(t,x) = O(t^{-1/2-\varepsilon})$ *uniformly in* $x \in D_0$, *with some* $\varepsilon > 0$. $G(y)$ *has continuous and bounded partial derivatives up to third order. Finally, we assume that*

$$G(x) = 0 \tag{3.14}$$

has a unique solution x^* *in* D.

Remark. In [19] the slightly weaker condition $\delta G(t,x) = O(t^{-1/2})$ has been used (see Condition 1.3 of [19]). Also only differentiability up to order 2 was required.

Let us now consider the associated ODE

$$\dot{y}_t = \frac{1}{t} G(y_t), \qquad y_s = \xi,\ s \geq 1. \tag{3.15}$$

Under the condition above, (3.15) has a unique solution in some finite or infinite interval, which we denote by $y(t,s,\xi)$. It is well known that $y(t,s,\xi)$ is a twice continuously differentiable function of ξ. The celebrated ODE principle states that the solution trajectories of the random differential equation (3.1), under additional conditions, follow the solution trajectories of the associated ODE (3.15).

Interpreting (3.1) as a continuous-time stochastic approximation method for solving the nonlinear algebraic equation $G(x) = 0$, an obvious difference compared to classical theory (see [54]) is that G is not defined on the whole space. Thus we are led to the study of recursive estimation methods *constrained* to a fixed domain D. In fact for theoretical reasons it is better to assume that the estimator process is constrained to a *compact* domain $D_0 \subset D$. One way to enforce boundedness of the estimation process is to restart it whenever it would leave D_0. Such a *truncated* version of (3.1) is described by Algorithm CR below, following [19]. A short discussion on the resetting mechanism to follow will be given in the context of the DFL scheme.

Algorithm CR. Consider a continuous-time recursion given by a random differential equation

$$\dot{x}_t = \frac{1}{t}(H(t,x_t,\omega) + \delta H(t,\omega)), \qquad x_1 = \xi_1 \tag{3.16}$$

combined with the following *resetting* mechanism. Let $D_0 \subset D$ denote a compact truncation domain such that $x^* \in \text{ int } D_0$. Let us initialize (3.16) at some time $\sigma \geq 1$ and let $x_\sigma = \xi_1 \in \text{int} D_0$. Let

$$\tau(\sigma) = \min\{t : t > \sigma, x_t \in \partial D_0\}, \tag{3.17}$$

where ∂D_0 denotes the boundary of D_0. Then we reset x to $x_1 = \xi_1$, which is formally stated by requiring that the right-hand side limit of x_t at $t = \tau = \tau(\sigma)$ will be ξ_1:

$$x_{\tau+} = \xi_1. \tag{3.18}$$

Thus we get a piecewise continuous trajectory (x_t) defined in some finite or infinite interval.

Remark. An alternative resetting mechanism, used in the analysis of discrete-time processes, is obtained by putting

$$x_t = \xi_1 \quad \text{for} \quad n < t \leq n+1 \ \text{ if } \ x_\tau \in \partial D_0 \ \text{ for } \ n < \tau \leq n+1. \tag{3.19}$$

To ensure that the estimator sequence is not bounced back and forth by resetting we need to impose some condition on the shape and relative position of the truncation

domain, x^* and ξ_1, which is captured via the flow induced by the ODE. For this, first we need to define the star-like closure of the set D_0, relative to x^*, as follows:

$$D_0^* = \{y : y = x^* + \lambda(x - x^*),\ 0 \le \lambda \le 1, x \in D_0\}.$$

The condition below is a simplified and corrected version of Condition 1.5. of [19]. The simplification is that the condition on the position of the initial value $x_1 = \xi_1$ has been relaxed, while the correction is that an additional compact convex set D_0' containing the truncation domain has been introduced that has been implicitly used in the final step of the proof of Theorem 1.1. of [19]; see (2.10) of [19].

CONDITION 3.4. *Let $D_0 \subset D$ be a compact truncation domain such that $x^* \in \text{int}D_0$. We assume the following.* (i) *There exists a compact convex set $D_0' \subset D$ such that*

$$y(t,s,\xi) \in D_0' \quad \text{for } \xi \in D_0 \quad \text{and } y(t,s,\xi) \in D \quad \text{for } \xi \in D_0' \tag{3.20}$$

for all $t \ge s \ge 1$. In addition $\lim_{t\to\infty} y(t,s,\xi) = x^*$ for $\xi \in D$ and

$$\left\| \frac{\partial}{\partial \xi} y(t,s,\xi) \right\| \le C_0 (s/t)^\alpha \tag{3.21}$$

with some $C_0 \ge 1, \alpha > 0$ for all $\xi \in D_0'$ and $t \ge s \ge 1$. (ii) *We have an initial estimate $x_1 = \xi_1$ such that for all $t \ge s \ge 1$ we have $y(t,s,\xi_1) \in$ int D_0.* (iii) *Finally, for the star-like closure of the set D_0 we have $D_0^* \subset D$.*

In [19] we had a the following stability condition (Condition 1.5 of [19] with minor corrections added).

CONDITION D. (i) *For every $\xi \in D_0$, $t \ge s \ge 1$, $y(t,s,\xi) \in D$ is defined for $1 \le s \le t < \infty$ and converges to x^* for $t \to \infty$ and we have with some $C_0, \alpha > 0$*

$$\left\| \frac{\partial}{\partial \xi} y(t,s,\xi) \right\| \le C_0 (s/t)^\alpha. \tag{3.22}$$

(ii) *We assume that the initial condition ξ_1 is in* int D_{00}, *where $D_{00} \subset$* int D_0 *is a compact domain which is invariant for* (3.15) *such that for any $t > s \ge 1$,*

$$y(t,s,D_{00}) = \{y(t,s,\xi) : \xi \in D_{00}\} \subset \text{ int } D_{00}.$$

Remark. Since our objective is to restate Theorem 4.2 of [19], part (iii) of Condition 3.4 of the present paper need not be verified for this purpose, since it was not required in [19]; it is special addition for the present paper.

Remark. The condition on the existence of D_0' can be removed if D itself is convex. Indeed, the ODE given by (3.15) becomes autonomous after a change of time-scale $t = e^v$ (see below), thus the remaining condition in part (i) of Condition 3.4 implies that the set

$$D_0'' = \{y : y = y(t,s,\xi), \xi \in D_0,\ t \ge s \ge 1\}$$

is invariant for the ODE. It is easy to see that it is also compact, so we can take for D_0' the convex envelope of D_0''. We will show below that part (ii) of Condition D follows from part (ii) of Condition 3.4. Finally, part (iii) of Condition 3.4 is a minor additional technical condition needed for the present paper.

We shall use subscripts to indicate partial derivatives below. Using a change of time-scale $t = e^v$, $s = e^u$, the inequality (3.21) is equivalent to the condition that, for the solutions of the differential equation

$$\frac{d}{dv} z_v = G(z_v), \qquad z_u = \xi,\ u \geq 0, \tag{3.23}$$

denoted by $z(v, u, \xi)$ we have the stability condition

$$\|z_\xi(v, u, \xi)\| \leq C_0 e^{-\alpha(u-v)}.$$

It can be shown that if for $\xi = x^*$ we can verify $\|z_\xi(v, u, x^*)\| \leq C_0' e^{-\alpha(u-v)}$ with some C_0', then the above stability condition follows from the remaining components of Condition 3.4. Equivalently, it can be shown that if $\|y_\xi(t, s, x^*)\| \leq C_0'(s/t)^\alpha$ with some C_0', then (3.21) follows from the remaining components of Condition 3.4.

Setting

$$A^* = \frac{\partial G(x)}{\partial x}\Big|_{x=x^*}, \tag{3.24}$$

we have $y_\xi(t, s, x^*) = e^{A^*(\log t - \log s)}$. The exponent α can be related to the eigenvalues of the Jacobian matrix A^* as follows. Let

$$\alpha^* = \min_i\{-\Re\lambda_i(A^*)\}, \quad i = 1, \ldots, p, \tag{3.25}$$

where $\lambda_i(A^*)$ denote the eigenvalues of A^* and $\Re$ denotes real part. Then, denoting the spectral norm by $||.||_{sp}$ we have $||e^{A^*(\log t - \log s)}||_{sp} = e^{-\alpha^*(\log t - \log s)} = (s/t)^{\alpha^*}$. Since for any square matrix B we have $\lim_n ||B^n||^{1/n} = ||B||_{sp}$, we conclude that by taking

$$\alpha = \alpha^*_-, \tag{3.26}$$

where α^*_- denotes any number that is smaller than α^*, we have

$$||e^{A^*(\log t - \log s)}|| \leq C_0 e^{-\alpha(\log t - \log s)} = C_0(s/t)^\alpha \tag{3.27}$$

with some $C_0 > 0$. If the Jordan form of A^* is diagonal, then we can take $\alpha = \alpha^*$.

LEMMA 3.1. *Condition* 3.4(ii) *implies Condition* D(ii).

Proof. Both Condition 3.4(ii) and Condition D(ii) can be trivially rewritten in terms of the solutions of the ODE (3.23), denoted by $z(v, u, \xi)$. Let $D_0^+ \subset D$ be a small open neighborhood of D_0 such that

$$I(D_0^+) = \bigcup_{\xi \in D_0^+, t \geq 0} z(t, 0, \xi) \subset D.$$

Then it is easily seen that $I(D_0^+)$ is an open invariant set containing D_0. It is a well-known result of Krasovskii (see Theorem 5.3 of his 1963 book) that Conditions 3.3 and 3.4 imply the existence of a C^2 Lyapunov function V with domain of definition $I(D_0^+)$ such that $V(z) > 0$ for $z \neq x^*$, $V(x^*) = 0$, and

$$\frac{d}{dv} V(z(v, u, \eta)) < 0 \quad \text{for} \quad \eta \in D_0,\ z(v, u, \eta) = z \neq x^*,$$

and $V(z)$ tends to $+\infty$ when z tends to the boundary of $I(D_0^+)$. Since the Jacobian $A^* = (\partial/\partial z)\ G(z)|_{z=x^*}$ is strictly stable, V can be chosen so that its Hessian $(\partial^2/\partial z^2)\ V(z)|_{z=x^*}$ is positive definite.

Let us consider the level sets

$$U_V(c) = \{z : V(z) \le c\} \quad \text{and} \quad S_V(c) = \{z : V(z) = c\}.$$

For sufficiently small c the set $S_V(c)$ is C^1 isomorphic to a sphere. Let us now reverse time and consider the differential equation

$$\frac{d}{du}\overline{z}_u = -G(\overline{z}_u), \qquad \overline{z}_0 = \zeta \in S_V(c),$$

the solution of which is denoted by $\overline{z}(u, 0, \zeta)$. Let the solution $\overline{z}(u, 0, \zeta) \in D_0$ exist for $u \le u^*(\zeta) \le \infty$. Obviously we have, with $\eta \in D_0,\ \zeta = z(v, 0, \eta) \in S_V(c)$,

$$\overline{z}(v, 0, \zeta) = \eta.$$

For any $\zeta \in S_V(c)$ we choose a finite backward travel time denoted by $w = w(\zeta)$ such that $0 < w(\zeta) \le u^*(\zeta)$, and such that w is a C^1 function. Consider the set

$$D_{00} = \{z : z = \overline{z}(u, 0, \zeta) \ \text{ with some } \ \zeta \in S_V(c),\ 0 \le u \le w(\zeta)\} \ \cup \ U_V(c).$$

It is easy to see that D_{00} is compact and invariant for the ODE (3.23). Furthermore it is easy to see that for any $\zeta \in S_V(c)$ and $0 \le u < w(\zeta)$ (with strict inequality) the point $\overline{z}(u, 0, \zeta)$ is in the interior of D_{00}.

Now let $c \le V(\xi_1)$ and let ζ_1 be the point where the trajectory $z(v, 0, \xi_1)$ hits $S_V(c)$, say for $v = v(\xi_1)$. Choosing the backward travel time w so that $w(\zeta_1) > v(\xi_1)$, the above defined set D_{00} will satisfy the second part of Condition D, and the lemma follows. □

Finally, consider the perturbation term $\delta H(t, \omega)$. Following [19] and motivated by the application for the DFL scheme, we will use the following condition.

CONDITION 3.5. *$(\delta H(t, \omega))$ is a measurable M-bounded process, which is piecewise continuous in t almost surely, moreover there exists an $\varepsilon > 0$ such that for any fixed $q > 1$ and for any $s \ge 1$,*

$$\sup_{s \le \sigma \le qs} \int_{\sigma}^{\tau(\sigma) \wedge q\sigma} \frac{1}{r} |\delta H(r, \omega)| dr = O_M(s^{-1/2-\varepsilon}). \tag{3.28}$$

It is no loss of generality to assume that $\varepsilon < 1/2$. We assume that the ε's showing up here and in Condition 3.3 *are identical.*

Remark. In [19] the slightly weaker condition

$$\sup_{s \le \sigma \le qs} \int_{\sigma}^{\tau(\sigma) \wedge q\sigma} \frac{1}{r} |\delta H(r, \omega)| dr = O_M(s^{-1/2}) \tag{3.29}$$

was required (see Condition 1.6 of [19]). This is sufficient to establish a rate of convergence result for the moments.

The above condition seems to be hard to verify, since it involves $\tau(\sigma)$, which itself is defined in terms of the process (x_t). In fact, the condition seems to be artificially tuned so that the proof can be carried out. An alternative, seemingly more useful, condition implying Condition 3.5 would be

$$\sup_{s \le \sigma \le qs} \int_{\sigma}^{q\sigma} \frac{1}{r} |\delta H(r, \omega)| dr = O_M(s^{-1/2-\varepsilon}), \tag{3.30}$$

which is independent of the stopping time $\tau(\sigma)$. The latter is certainly satisfied if $\delta H(r,\omega) = O_M(r^{-1/2-\varepsilon})$. The prominent role of Condition 3.5 will become clear in the context of the DFL scheme, see (3.56) and Lemma 3.2. The following is given in Theorem 1.1 of [19].

THEOREM 3.1. *Consider the continuous-time recursive estimation process defined by* (3.16) *with the resetting mechanism* (3.17) *and* (3.18). *Assume that Conditions* 3.1–3.5 *are satisfied, moreover Condition* 3.4 *is satisfied with* $\alpha > 1/2$. *Then the solution* (x_t) *is defined for all* $t \in [1,\infty)$ *with probability* 1 *and* $x_t = O_M(t^{-1/2})$. *Moreover, the following stronger result also holds: for any fixed* $1 < q < \infty$ *we have*

$$x_t^* = \sup_{t \le s \le qt} |x_s| = O_M(t^{-1/2}).$$

As has been noted at the end of section 2 in [19], using the alternative resetting method (3.19) does not affect the validity of Theorem 1.1 of [19].

Definition of $\overline{\alpha}$. In subsequent analysis a crucial role will be played by the *gap* between α, introduced in Condition 3.4, and $1/2$, therefore we introduce a separate notation: we write

$$\overline{\alpha} = \alpha - 1/2. \tag{3.31}$$

An example: a recursive estimation method is called a stochastic Newton method if the Jacobian matrix of the right-hand side of the associated ODE at $x = x^*$ is $-I$, where I is an identity matrix. Then we can take $\alpha^* = \alpha = 1$ and $\overline{\alpha} = 1/2$.

Let us now consider *discrete-time* processes of the form

$$x_{n+1} = x_n + \frac{1}{n+1}(H(n+1,x_n,\omega) + \delta H(n+1,\omega)), \quad x_0 = \xi_0 \in \text{ int } D_0. \tag{3.32}$$

Boundedness of the estimator sequence will be enforced by a *resetting* mechanism. Let $D_0 \subset D$ be a compact domain. If x_{n+1} leaves D_0, then we redefine x_{n+1} to be x_0. To formalize this: at any time n let x_{n+1-} denote the value of x computed at time $n+1$ by (3.32) and let

$$B_{n+1} = \{\omega : x_{n+1-} \notin \text{int} D_0\}. \tag{3.33}$$

Algorithm DR. A discrete-time recursive estimation process with resetting is defined as follows: we define x_{n+1} by

$$x_n + (1 - \chi_{B_{n+1}})\frac{1}{n+1}(H(n+1,x_n,\omega) + \delta H(n+1,\omega)) + \chi_{B_{n+1}}(x_0 - x_n). \tag{3.34}$$

Remark. Note that the correction term on the right-hand side was $H(n,x_n,\omega)$ in [19]. The present notation fits the applications better: the estimator based on observations up to time n is updated by a new observation received at time $n+1$.

A standard way of analyzing this algorithm is to use continuous-time imbedding and this route has been followed in [19]. A more recent approach, in which the error that arises via this imbedding procedure is eliminated, is a discrete-time ODE method, developed in [25]. Here we follow the approach of [19], with a minor modifications. Let $(H^c(t,x,\omega))$ be the piecewise constant continuous-time extensions of $(H(n,x,\omega))$:

$$H^c(t,x,\omega) = H(n,x,\omega) \quad \text{for} \quad 1 \le n \le t < n+1. \tag{3.35}$$

Define $\delta H^c(t,x,\omega)$ in a similar manner. Let the exit time $\tau(\sigma)$ for any nonnegative integer σ be defined as

$$\tau(\sigma) = \min\{n : n \text{ integer},\ n > \sigma, x_{n-} \notin \operatorname{int} D_0\}. \tag{3.36}$$

CONDITION 3.6. *$(\delta H(n,\omega))$ is a measurable M-bounded process, moreover there exists an $\varepsilon > 0$ such that for any fixed $q > 1$ and for any integers $s \geq \sigma \geq 1$, with $[x]$ denoting integer part, we have*

$$\sup_{s \leq \sigma \leq [qs]} \sum_{r=\sigma}^{\tau(\sigma)\wedge[q\sigma]} \frac{1}{r} |\delta H(r,\omega)| dr = O_M(s^{-1/2-\varepsilon}). \tag{3.37}$$

It is easy to see that Condition 3.5 follows with the modified resetting mechanism (3.19). The following result is an easy corollary of Theorem 3.1 and has been established in [19] as Theorem 1.2.

THEOREM 3.2. *Consider the discrete-time recursive estimation process with resetting defined by* (3.34). *Let $(H^c(t,x,\omega))$ be the piecewise constant continuous-time extensions of $(H(n,x,\omega))$ defined under* (3.35). *Assume that $H^c(t,x,\omega)$ satisfies Conditions* 3.1–3.4 *and the latter condition is satisfied with $\alpha > 1/2$. Let $\delta H^c(n,\omega)$ satisfy Condition* 3.6, *with $\tau(\sigma)$ defined as in* (3.36). *Then we have $x_n = O_M(n^{-1/2})$.*

Let us now consider a general recursive estimation scheme developed in [11, 12, 51], see also [3, 13, 53], which will be called the DFL scheme. Its basic building block is a parameter-dependent vector-valued process $(\overline{\phi}_n(x))$, with $x \in D \subset \mathbb{R}^p$, where D is an open domain, defined by the state-space equation

$$\overline{\phi}_{n+1}(x) = A(x)\overline{\phi}_n(x) + B(x)e_n, \tag{3.38}$$

with some nonrandom initial condition $\overline{\phi}_1(x)$, the value of which is often assumed to be zero. The dimensionality of $\overline{\phi}_n(x)$ will be denoted by r. In the analysis of [19], as in all other works on the analysis of the DFL scheme we have to ensure that for any choice of $x = x_n \in D$ the time-varying system

$$\phi_{n+1} = A(x_n)\phi_n + B(x_n)e_n, \quad \phi_0 = 0, \tag{3.39}$$

is bounded input-bounded output (BIBO) stable. This is ensured by the following condition.

CONDITION 3.7. *The functions $A(x), B(x)$ are three times continuously differentiable in D. Moreover, the family of matrices $A(x)$, $x \in D_0$, with D_0 being the preselected truncation domain, is jointly stable in the sense that there exist a single symmetric positive definite $r \times r$ matrix V and $0 < \lambda < 1$ such that for all $x \in D_0$,*

$$A^T(x)VA(x) \leq \lambda V.$$

Discussion of the joint stability condition. In the case of recursive estimation of linear stochastic systems the joint stability condition can be satisfied by an appropriate realization of system (3.38). Namely, in these cases (3.38) has the structure

$$\overline{\phi}_{1,n+1} = A_1\overline{\phi}_{1,n} + B_1 e_n, \tag{3.40}$$

$$\overline{\phi}_{2,n+1}(x) = A_2(x)\overline{\phi}_{2,n}(x) + B_2(x)\overline{\phi}_{1,n+1}, \tag{3.41}$$

where $\overline{\phi}_{1,n}$ is independent of x and is observable. Thus it is sufficient to ensure the joint stability of (3.41), which has an observable input. For any fixed x and

nonsingular $T = T(x)$ we have the system equivalence

$$(A_2(x), B_2(x), I) = (T(x)A_2(x)T^{-1}(x), T(x)B_2(x), T(x)^{-1}), \tag{3.42}$$

and the latter realization can also be used to compute $\overline{\phi}_{2,n+1}(x)$. Assume that $A(x)$ is stable for all $x \in D$. Choosing $T(x)$ so that $T(x)A_2(x)T^{-1}(x)$ is a contraction for all $x \in D$ and assuming that $T(x)$ is continuous in x, it is easy to see that Condition 3.7 is satisfied for the transformed system with any compact $D_0 \subset D$. In addition, assuming that $(A_2(x), B_2(x), I)$ uniquely determines x, the same holds for the equivalent system $(T(x)A_2(x)T^{-1}(x), T(x)B_2(x), T(x)^{-1})$.

Assuming joint stability of $(A(x))$, it follows that there exists some $c > 0$ such that for any sequence $(A(x_n))$ with $x_n \in D_0$ we have

$$||A(x_n) \cdots A(x_0)|| \le c\lambda^{n/2}. \tag{3.43}$$

In fact, this is the key property that we need in the analysis. An alternative method for ensuring the validity of (3.43) used in [3] is to require that the sequence $(A(x_n))$, or equivalently the sequence (x_n), is *slowly varying*. This method will be discussed later.

The input noise (e_n) is assumed to satisfy two conditions (see Conditions 2.5 and 2.6 of [19].)

CONDITION 3.8. *We assume that (e_n) is a wide-sense stationary process and that $|e_n|^2$ is in class M^*; i.e., for some $\varepsilon > 0$ we have*

$$\sup_n \mathrm{E}\ \exp \varepsilon |e_n|^2 < \infty.$$

Condition 3.8 is standard in the Chinese school for recursive estimation (see, e.g., [7]) and is certainly satisfied for wide-sense stationary Gaussian sequences. The weaker condition that (e_n) is M-bounded is assumed also in the special case of (3.53), given as Example 1, p. 215 of [3], (see Condition (A'5) on p. 290 of [3]). The existence of finite moments of all orders for certain state variables is required also in the general model of recursive estimation of [3], see Condition (A'5) on p. 290 of [3].

Discussion of Condition 3.8. Assume $\delta H(r, \omega) = 0$ identically and that no resetting takes place in the interval $[1, t]$. Then we have

$$x_t - y_t = \int_1^t \frac{1}{r}(H(r, x_r, \omega) - G(y_r))\ dr. \tag{3.44}$$

Now we can bound the right-hand side from above in two ways as

$$\begin{aligned} &\left| \int_1^t \frac{1}{r}(H(r, x_r, \omega) - G(x_r))\ dr \right| + \int_1^t \frac{1}{r} L|x_r - y_r|\ dr, \\ &\left| \int_1^t \frac{1}{r}(H(r, y_r, \omega) - G(y_r))\ dr \right| + \int_1^t \frac{1}{r} L_r|x_r - y_r|\ dr. \end{aligned} \tag{3.45}$$

In both cases we can apply the Bellman–Gronwall lemma. In the first case we need only the Lipschitz continuity of G, while H may be even discontinuous (which is the case, e.g., for the signed least mean squares (LMS) methods), but the first term is hard to analyze, unless H is a Markov process for any fixed x (see Chapter 1 of Part II of [3]). In the second case we need the Lipschitz continuity of H and Condition 3.8 has to be imposed on L_r to ensure that the application of the Bellman–Gronwall lemma gives

meaningful result. On the other hand, the analysis of the first term is significantly simpler, since it is essentially the integral of a zero-mean L-mixing process.

CONDITION 3.9. *We assume that* (e_n) *is* L^+*-mixing with respect to a pair of families of* σ*-algebras* $(\mathcal{F}_n, \mathcal{F}_n^+)$.

The role of this condition will be discussed in connection with Lemma 3.2, see also [19, Lemma 5.6 and Theorem 6.1]. Now we are ready to define a random field $H(n, x, \omega)$ in terms of $\overline{\phi}_n(x)$ as follows:

$$H(n, x, \omega) = Q(\overline{\phi}_n(x)), \tag{3.46}$$

where for the sake of simplicity Q is a quadratic function from $\mathbb{R}^r$ to $\mathbb{R}^p$. An alternative, more general definition would be

$$H(n, x, \omega) = F(Q(\overline{\phi}_n(x)), x), \tag{3.47}$$

where Q is quadratic and F is linear in Q and three times continuously differentiable in its second variable x. Also define the mean-field

$$G(x) = \lim_{n\to\infty} \mathrm{E}\, Q(\overline{\phi}_n(x)). \tag{3.48}$$

It is easy to see that $G(x)$ is well defined, since $\overline{\phi}_n(x)$ is asymptotically wide-sense stationary: in fact $\overline{\phi}_n(x) = \overline{\phi}_{*n}(x) + O_M(\beta^n)$, where $\overline{\phi}_{*n}(x)$ is wide-sense stationary and $0 < \beta < 1$, and thus

$$G(x) = \mathrm{E}\, Q(\overline{\phi}_n(x)) + O(\beta^n). \tag{3.49}$$

The estimation problem in the context of the DFL scheme is then to solve the nonlinear algebraic equation

$$G(x) = 0$$

based on observations of $Q(\overline{\phi}_n(x))$. It is assumed that a unique solution x^* exists in D and in fact $x^* \in D_0$. In identification problems the estimation of x^* can be carried out in an off-line fashion, but this is not the case in stochastic adaptive control. Thus we focus on recursive estimation of x^*.

It is not difficult to see (cf. [19]) that under Conditions 3.7, 3.8, and 3.9 the piecewise constant continuous-time extension of the random field $H(n, x, \omega)$ defined by (3.46) satisfies Conditions 3.1, 3.2, and 3.3 with G defined under (3.48). In fact, in the latter condition $\delta G(t, x)$ decays exponentially fast to zero.

We use an iterative procedure, in which the estimate of x^* at time n will be denoted by x_n. To update this estimate we should use the correction term $Q(\overline{\phi}_n(x_n))$, but this frozen parameter value cannot be easily computed. In fact in stochastic adaptive control problems it cannot be computed at all. Hence we generate an online approximation of $Q(\overline{\phi}_n(x_n))$ and thus we arrive at the following first version of the DFL method: define recursively

$$\phi_{n+1} = A(x_n)\phi_n + B(x_n)e_n, \tag{3.50}$$

$$x_{n+1} = x_n + \frac{1}{n} Q(\phi_{n+1}) \tag{3.51}$$

with initial conditions $x_0 = \xi_0 \in \mathrm{int} D_0$ and ϕ_0 a constant, nonrandom initial state. It is assumed that $Q(\phi_{n+1})$ is *computable* by coupling a physical system with our computer.

Discussion on the DFL scheme. The applicability of this general estimation scheme in the theory of recursive identification of linear stochastic systems has been discussed in more details [53], albeit its analysis has not been complete. Further examples of application are given in [3]. Here also a rigorous and detailed analysis of a nonlinear modification of the DFL scheme is given, using a Markovian dynamics in generating the state sequence (ϕ_n). This setup extends the range of applicability of the method, but the verification of the existence of the solution of a Poisson equation, (see Condition (A.4) of Chapter 1.1, Part II in [3]) seems to be hard. A special case of the DFL scheme is stochastic linear regression, in which $\overline{\phi}_n$ does not depend on x at all and $H(n, x, \omega)$ is of the form

$$H(n, x, \omega) = Q(l(\overline{\phi}_n, x)) \tag{3.52}$$

with l being linear in both $\overline{\phi}$ and x, has been analyzed in [7, 14, 47].

It is well known from simulations that the DFL scheme may diverge, unless some precaution is taken. The above procedure will therefore be modified so that the estimates x_n will be enforced to stay in a compact domain $D_0 \subset D$, such that $x^* \in \mathrm{int}D_0$. This will be achieved by a *resetting* mechanism: if x_{n+1} leaves D_0 we redefine it to be $x_0 = \xi_0$. To formalize this procedure let x_{n+1-} denote the value of x computed at time $n+1$ by (3.51). Then if $x_{n+1-} \notin \mathrm{int}D_0$, then we reset it to its initial value ξ_0. To formalize the procedure let

$$B_{n+1} = \{\omega : x_{n+1-} \notin \mathrm{int}D_0\}.$$

Then we define the following algorithm.

Algorithm DFL. The DFL scheme with resetting:

$$\phi_{n+1} = A(x_n)\phi_n + B(x_n)e_n, \tag{3.53}$$

$$x_{n+1} = x_n + (1 - \chi_{B_{n+1}})\frac{1}{n+1}Q(\phi_{n+1}) + \chi_{B_{n+1}}(x_0 - x_n). \tag{3.54}$$

An additional stopping time is used in [3] to ensure the validity of (3.43) by ensuring that the sequence $(A(x_n))$, or equivalently the sequence (x_n), is *slowly varying.* Following [3, (3.1.2) on p. 291] for any positive integer σ define the stopping time

$$\nu(\sigma) = \min\{n : n \text{ integer}, \ n > \sigma, |x_{n+1} - x_n| > \delta\}, \tag{3.55}$$

where σ is some fixed positive number. It is well known that if δ is sufficiently small, then (3.43) holds. However, the a priori determination of a right value of δ seems to be hard.

Discussion of the "boundedness condition." The eventual divergence of the DFL scheme is often dealt with the controversial "boundedness condition" first formulated in [51] requiring that the estimator process visits a compact domain of attraction of the ODE infinitely often. A lucid exposition of the underlying principle is given in [52, Lemma 1.12], which is considered there as the key tool for the ODE method. Almost sure convergence using the above "boundedness condition" has also been established for a nonlinear, Markovian extension of the DFL method in [3, Part II, Chapter 1.9, Theorem 15]. Unfortunately, the "boundedness condition" is much too restrictive: it is a condition on the process itself that we analyze and it is not clear at all if it is satisfied even for basic methods such as RPE for ARMA processes.

One way to enforce the boundedness of the estimation process is to consider a compact truncation domain containing the true parameter in its interior and to

"project" the estimator back to this domain if it would leave it; see [51, 45]. It is easy to see that this procedure may fail even for deterministic algorithms, namely the ODE, which approximates the evolution of the discrete-time algorithm, may force us to move out of the truncation domain.

A rigorous treatment of the boundedness problem has been given in [3], where the estimator process is stopped if it leaves a prescribed compact domain containing the true parameter in its interior. Denoting by $\Omega' \subset \Omega$ the event that the estimator process is never stopped, the almost sure convergence of the estimator process has been established on Ω'; see [3, Part II, Chapter 1.6, Proposition 11]. But convergence with probability strictly smaller than 1 is not satisfactory from the practical point of view. The above *truncated* version of the DFL methods has been given and analyzed in [19].

The definition of the truncation domain requires some a priori knowledge of the system-parameters no matter what truncation procedure we use. This may seem to be a restrictive assumption, but even deterministic iterative methods for optimization may fail without good initialization.

In practice we start with an initial value and a truncation domain which may or may not satisfy our conditions. If it does not and the solution trajectory of the associated ODE starting at $x_0 = \xi_0$ does hit the boundary of D_0, then a heuristic argument, following [19], shows that the estimator process will be likely to hit the neighborhood of the same point of the boundary of the truncation domain. This phenomenon can be detected during the computations and a larger truncation domain can be chosen. Such an adaptive choice of the truncation domain has not yet been studied. A special case when the boundedness problem does not arise is the use of a stochastic regression approach, such as extended least squares (ELS); see [53].

To connect the DFL scheme with Algorithm DR define

$$\delta H(n,\omega) = Q(\phi_n) - Q(\overline{\phi}_n(x_n)). \tag{3.56}$$

Then (3.54) can be written in the form of (3.34). A critical point in the analysis of the DFL scheme is that the perturbation term $\delta H(n,\omega)$ is *not given a priori*, rather it is defined via the recursive procedure itself. In fact, the analysis of $\delta H(n,\omega)$ is a substantial component of the convergence analysis of the DFL-method, which has been worked out in [19, sections 5 and 6], leading to the following result (cf. Lemma 5.6 of [19]).

LEMMA 3.2. *Consider the DFL scheme defined by* (3.53)–(3.54). *Assume that Conditions* 3.7, 3.8, *and* 3.9 *are satisfied. In addition assume that Condition* 3.4 *is satisfied with* $\alpha > 1/2$. *Then* $(\delta H(n,\omega))$ *defined by* (3.56) *is an* M*-bounded process, moreover there exists an* ε *with* $0 < \varepsilon < 1/2$ *such that for any fixed* $q > 1$ *and for any integer* $s \geq 1$ *and integers* σ,

$$\sup_{s \leq \sigma \leq [qs]} \sum_{\sigma}^{\tau(\sigma) \wedge [q\sigma]} \frac{1}{r} |\delta H(r,\omega)| dr = O_M(s^{-1/2-\varepsilon}). \tag{3.57}$$

In short, $(\delta H(n,\omega))$ satisfies Condition 3.6. Postulating the validity of Condition 3.4 we conclude that all conditions of Theorem 3.2 are satisfied and thus we get the following result.

THEOREM 3.3. *Consider the DFL scheme defined by* (3.53)–(3.54). *Assume that Conditions* 3.7, 3.8, *and* 3.9 *are satisfied. In addition assume that Condition* 3.4 *is satisfied with* $\alpha > 1/2$. *Then we have* $x_n = O_M(n^{-1/2})$.

Discussion of the result. A special feature of the above result is that the *moments* of the estimation error are bounded from above. The only alternative result

on the moments of the estimation error in the context of the DFL scheme seems to be Proposition 24 of [3, Part II, Chapter 1.10] where the L_2 moments of the error of the stopped process is shown to be of the order $1/n$.

Almost sure convergence of the DFL scheme has been stated in [51] using the controversial "boundedness condition," requiring that the estimator process visits a compact domain of attraction of the ODE infinitely often. See also [52, Lemma 1.12] for a related result. Almost sure convergence using the above "boundedness condition" has also been established for a nonlinear, Markovian extension of the DFL method in [3, Part II, Chapter 1.8, Theorem 15]. The almost sure convergence of the estimator process has been established on a set $\Omega' \subset \Omega$ of probability strictly less than 1; see [3, Part II, Chapter 1.6, Proposition 11 and Chapter 3.4, Theorem 17].

An alternative set of results are obtained for stochastic regression models developed in [47]. Results on the rate of almost sure convergence are given in [7, 14]. See also Theorem 2 of [4] or Theorem 1 of [10]. The main shortcoming of stochastic regression, such as ELS, see [53], compared to the DFL scheme is that its range of applicability is limited. For example, in estimating an ARMA process by ELS we must impose the condition that the polynomial $C - 1/2$ is positive real.

Further discussion on mixing conditions. L-mixing and ϕ-mixing can both be used to derive two main results of [19], (Theorems 1.1 and 1.2), restated here as Theorems 3.1 and 3.2. In both results the key technical device is an improved Hölder inequality, see Lemma 8.1 of section 8, or Chapter 7.2 of [15], or Appendix III of [33]. An improved Hölder inequality of [15] is restated as Lemma 8.2. The situation is quite different for the DFL scheme, where L^+-mixing has been heavily exploited for deriving Theorem 3.3, in particular in proving Lemma 3.2 (see sections 5 and 6 of [19], in particular Theorem 6.1 in [19]).

4. Strong approximation of the estimation error. The main result of the present paper is a significant extension of Theorem 2.4 for the three, closely related recursive estimation schemes presented in the previous section. These extensions will be stated and proved in this section. The analysis will be carried out in detail for Algorithm CR, given by (3.16) and the resetting mechanism (3.17) and (3.18); see Theorem 4.1. The proof is nontrivial and relies on the results of [17, 19, 21]. The corresponding results for Algorithms DR and DFL will then follow by relatively simple arguments. The extension of the two other main results for the RPE method, given in section 2 as Theorems 2.5 and 2.6, will be given in the next two sections. Note that the conditions for the next theorem are identical with the conditions of Theorem 3.1.

THEOREM 4.1. *Consider the continuous-time recursive estimation scheme, Algorithm CR, given by* (3.16) *with the resetting mechanism* (3.17) *and* (3.18). *Assume that Conditions* 3.1–3.5 *are satisfied and Condition* 3.4 *is satisfied with* $\alpha > 1/2$. *Then the solution of* (3.16), (x_t), *is defined for all* $t \in [1, \infty)$ *with probability* 1 *and we have with*

$$\varepsilon_x = \min(\overline{\alpha}, \varepsilon)_-,$$

where c_- *is any number smaller than* c, $\overline{\alpha}$ *is given by* (3.31), *and* ε *is given in Condition* 3.5,

$$x_t - x^* = \int_1^t \frac{\partial}{\partial \xi} y(t, s, x^*) \frac{1}{s} H(s, x^*, \omega) ds + O_M(t^{-1/2-\varepsilon_x}). \tag{4.1}$$

Discussion of the result. The bound $O_M(t^{-1/2-\varepsilon_x})$ cannot be improved in general. Indeed, let $\delta H(t, \omega) = 0$, then $\varepsilon_x = \overline{\alpha}_- = \alpha_- - 1/2$, where $\alpha = \alpha^*_-$ (see (3.31), (3.26),

and (3.25)). Thus

$$-1/2 - \varepsilon_x = -\alpha^*_-.$$

Consider now a linear process with additive, state-independent, bounded noise, i.e., let $H(t,x,\omega) = A^*x + u_t$, where (u_t) is a zero-mean L-mixing bounded process. Then Algorithm CR reads

$$\dot{x}_t = \frac{1}{t}(A^*x_t + u_t), \qquad x_1 = \xi_1. \tag{4.2}$$

Assuming that A^* is stable, the boundedness of (u_t) implies the boundedness of (x_t), hence taking a sufficiently large truncation domain no resetting will take place ever. Obviously we have $x^* = 0$ and we can write the exact equality

$$x_t = \left(\frac{\partial}{\partial\xi}y(t,1,x^*)\right)\cdot\xi_1 + \int_1^t \frac{\partial}{\partial\xi}y(t,s,x^*)\frac{1}{s}H(s,x^*,\omega)ds \tag{4.3}$$

with

$$\frac{\partial}{\partial\xi}y(t,s,x^*) = e^{A^*(\log t - \log s)}.$$

Thus the residual term, the first term on the right-hand side of (4.3), is $e^{A^*\log t}\xi_1$, since now $s = 1$. Thus we have

$$||e^{A^*\log t}||_{sp} = t^{-\alpha^*}, \tag{4.4}$$

and since for any square matrix B we have $||B|| \geq ||B||_{sp}$, we conclude that

$$||e^{A^*\log t}|| \geq t^{-\alpha^*}. \tag{4.5}$$

Thus there exists a ξ_1 such that

$$|e^{A^*\log t}\xi_1| \geq t^{-\alpha^*}|\xi_1|, \tag{4.6}$$

implying that the result of the theorem is sharp.

To interpret this result note that the matrix $(\frac{\partial}{\partial\xi})y(t,s,x^*)$ is the sensitivity matrix, which indicates the relative effect of a perturbation of the initial condition at time s on the solution of (3.15) at time t. Thus the dominant term on the right-hand side represents the cumulative effect of the ideal correction terms $\frac{1}{s}H(s,x^*,\omega)$ at time t. A similar representation of the error $x_t - x^*$ for classical Robbins–Monroe processes, had been implicitly used already in [54]. The above dominant term has been explicitly presented for a class of stopped stochastic approximation processes in Lemma 3.1 of [65].

The novelty of the present result is that it is stated for a general recursive estimation scheme, that can handle the widely used DFL scheme, a crucial boundedness assumption enforced by a resetting mechanism and a tight upper bound for the residual term has been obtained. A relatively straightforward corollary of Theorem 4.1 is the following discrete-time result, in which the conditions are identical with the conditions of Theorem 3.2.

THEOREM 4.2. *Consider the discrete-time recursive estimation process, Algorithm DR, with resetting defined by* (3.34). *Let* $(H^c(t,x,\omega))$ *be the piecewise constant continuous-time extension of* $(H(n,x,\omega))$ *defined under* (3.35). *Assume that*

$(H^c(t,x,\omega))$ satisfies Conditions 3.1–3.4 *and Condition* 3.4 *is satisfied with* $\alpha > 1/2$. *Let* $\delta H(n,\omega)$ *satisfy Condition* 3.6, *with* $\tau(\sigma)$ *defined in* (3.36). *Then we have, with* $\varepsilon_x = \min(\overline{\alpha},\varepsilon)_-$, *where* $\overline{\alpha}$ *is given by* (3.31) *and* ε *is given by Condition* 3.6,

$$x_N - x^* = \sum_{n=1}^{N} \frac{\partial y}{\partial \xi}(N,n,x^*)\frac{1}{n}H(n,x^*,\omega) + O_M(N^{-1/2-\varepsilon_x}).$$

Specializing the last result to the DFL scheme we get a result that is very useful for applications (see section 7).

THEOREM 4.3. *Consider the DFL scheme defined by* (3.53)–(3.54). *Assume that the state-space equation* (3.38) *satisfies Condition* 3.7, *the noise process* (e_n) *satisfies Conditions* 3.8 *and* 3.9, *and the associated ODE satisfies Condition* 3.4 *with* $\alpha > 1/2$. *Let* $\varepsilon_x = \min(\overline{\alpha},\varepsilon)_-$, *where* $\overline{\alpha}$ *is defined under* (3.31) *and* ε *is given by Lemma* 3.2. *Then we have*

$$x_N - x^* = \sum_{n=1}^{N} \frac{\partial y}{\partial \xi}(N,n,x^*)\frac{1}{n}Q(\overline{\phi}_n(x^*)) + O_M(N^{-1/2-\varepsilon_x}).$$

Remark. The proof of Lemma 5.6 in [19], based on Theorem 6.1 of the same paper, implies that in Condition 3.5 we have $\varepsilon < 1/2$. Thus in the present case it is not our choice to have $\varepsilon < 1/2$. It follows that the upper bound for the residual term cannot be as small as $O_M(N^{-1})$, in contrast to what we had for the off-line prediction error method for ARMA processes; see Theorem 2.2.

The above results take a particularly attractive form for partially *stochastic Newton methods*. A recursive estimation method is called a partially stochastic Newton method if the Jacobian matrix of the right-hand side of the associated ODE at $x = x^*$ is of the form

$$\begin{pmatrix} -I & 0 \\ X & Y \end{pmatrix},$$

where I is an identity matrix. An example, the standard recursive prediction error estimation of ARMA processes, in which both the system-parameter θ^* and the Hessian of asymptotic cost function R^* are estimated and the estimates of the system-parameters are updated using Newton-like steps, is a partially stochastic Newton method with respect to the system-parameters.

The above decomposition of the Jacobian is in one-to-one correspondence with the splitting of the parameter vector x as $x = (x^1, x^2)$. With this notation it is easy to see that

$$\frac{\partial}{\partial \xi^1} y(t,s,\xi)_{|\xi=x^*} = \left(\frac{s}{t} I, 0\right)$$

for $s \le t$ and the statement of Theorem 4.3 simplifies to the following.

THEOREM 4.4. *Assume that the conditions of Theorem* 4.3 *are satisfied and that we can split the parameter vector* x *as* $x = (x^1, x^2)$ *so that the estimation method is a partially stochastic Newton method with respect to* x^1. *Let* (Q^1, Q^2) *be the corresponding splitting of* Q. *Then we have with the same* ε_x *as in Theorem* 4.3

$$x_N^1 - x^{1*} = \frac{1}{N}\sum_{n=1}^{N} Q^1(\overline{\phi}_n(x^*)) + O_M(N^{-1/2-\varepsilon_x}).$$

Theorem 4.4 is an extension of Theorem 2.4 to general partially stochastic Newton methods, but with a weaker error term, since $\varepsilon_x < 1/2$.

The result given as (2.23) can also be extended. Let the off-line estimator $\hat{x}_N$ of x^* be defined as the solution of

$$U_N(x) = \sum_{n=1}^{N} Q^1(\overline{\phi}_n(x)) = 0$$

with respect to x. The handling of multiple solutions is precisely described in [18]. Then it is easy to see that Theorem 2.2 can be extended and noting that the Jacobian matrix of the right-hand side of the associated ODE at $x = x^*$ is of the form given above, we get for the first component of $\hat{x}$

$$\hat{x}_N^1 - x^{1*} = \frac{1}{N} \sum_{n=1}^{N} Q^1(\overline{\phi}_n(x^*)) + O_M(N^{-1}).$$

Combining this with Theorem 4.4 and writing $\widehat{\widehat{x}}_N = x_N$ we get

$$\widehat{\widehat{x}}_N^1 - \hat{x}_N^1 = O_M(N^{-1/2-\varepsilon_x}) \tag{4.7}$$

which is an extension of (2.23), albeit with a weaker error term.

Discussion of the result. To *compare* these results with the results of [3, 45] we note that the limit results of [3] are of classical nature: weak convergence and CLT (central limit theorem), which are not strong enough for calculating performance degradation that we called pathwise cumulative regret. The same remark applies to the weak-convergence results of [45].

In the case of stochastic regression methods, developed in [47] and extended in [7, 14], tight bounds for the almost sure rate of convergence of the estimator process are given. But even these results are not applicable in general to get exact asymptotic results for the pathwise cumulative regret, except in very special cases, such as the minimum-variance self-tuning regulator for ARX systems; see [49]. For ARMAX systems these techniques yield only qualitative results; see [48].

Further discussion on mixing conditions. The proof of Theorem 4.1 relies on a moment inequality for weighted multiple integrals of L-mixing processes given in [21]. It is likely that this result can be extended to ϕ-mixing processes, since it is based on the repeated use of an improved Hölder inequality, which does have its variant for ϕ-mixing processes; see Lemmas 8.1 and 8.2 of section 8 and Chapter 7.2 of [15] for further results. Thus it is likely that L-mixing and ϕ-mixing can both be used to derive the results of the present section for Algorithms CR and DR, given as Theorems 4.1 and 4.2.

The situation is quite different for the DFL scheme, where L^+-mixing has already been heavily exploited for getting the rate of convergence of higher order moments; see Theorem 3.3. Furthermore, L^+-mixing is very much used in the context of all three algorithms (Algorithm CR, Algorithm DR, and the DFL scheme) in deriving the results of sections 4 and 5. Moreover, the formulation of the main result of section 5 is given in terms of the concept of L-mixing. It is not clear if a similar result holds in the context of ϕ-mixing. Even the following simple related problem seems to be open: under what conditions is the response of an exponentially stable linear filter, with a ϕ_p-mixing process as its input, ϕ_p-mixing?

Proof of Theorem 4.1. Assume $x^* = 0$. Also we can assume that $\delta G = 0$, namely the term $\delta G(t, x_t)$ can be merged with $\delta H(t, \omega)$. Indeed, the condition that $\delta G(t, x) = O(t^{-1/2-\varepsilon})$ uniformly in x for $x \in D_0$, see Condition 3.3, implies that Condition 3.5 remains valid when $\delta H(t, \omega)$ is replaced by $\delta H(t, \omega) + \delta G(t, x_t)$.

Let us consider the process (x_t) on the interval $[s, qs)$ with $s \geq 1$, $q > 1$, and let $\overline{y}_t$ denote the solution of the ODE (3.15) starting from x_s at time s. Let C_s denote the event that x_t hits ∂D_0 in $[s, qs)$. Then we can write $x_t - \overline{y}_t$ as

$$(1 - \chi_{C_s}) \int_s^t \frac{\partial}{\partial \xi} y(t, r, x_r) \cdot \frac{1}{r} \left(\overline{H}(r, x_r, \omega) + \delta H(r, \omega) \right) \, dr + \chi_{C_s}(x_t - \overline{y}_t) \tag{4.8}$$

with $\overline{H}(r, x, \omega) = H(x, r, \omega) - G(r, x)$ by using Lemma 8.6. Let us now take into account the fact that $y_\xi(t, r, x)$ and $\overline{H}(r, x, \omega)$ are continuously differentiable with respect to x. Hence we can write

$$\frac{\partial}{\partial \xi} y(t, r, x_r) = \frac{\partial}{\partial \xi} y(t, r, 0) + \int_0^1 \frac{\partial^2}{\partial \xi^2} y(t, r, \lambda x_r) d\lambda \cdot x_r$$

and

$$\overline{H}(r, x_r, \omega) = \overline{H}(r, 0, \omega) + \int_0^1 \frac{\partial}{\partial x} \overline{H}(r, \lambda x_r, \omega) d\lambda \cdot x_r.$$

Substituting into (4.8) we get that the first integral on the right-hand side of (4.8) can be written as the sum of the following five terms:

$$\begin{aligned}
I_1 &= \int_s^t \frac{\partial}{\partial \xi} y(t, r, 0) \cdot \frac{1}{r} \overline{H}(r, 0, \omega) dr, \\
I_2 &= \int_s^t \frac{\partial}{\partial \xi} y(t, r, 0) \cdot \frac{1}{r} \int_0^1 \frac{\partial}{\partial x} \overline{H}(r, \lambda x_r, \omega) d\lambda \cdot x_r dr, \\
I_3 &= \int_s^t \int_0^1 \frac{\partial^2}{\partial \xi^2} y(t, r, \lambda x_r) d\lambda \cdot x_r \cdot \frac{1}{r} \overline{H}(r, 0, \omega) dr, \\
I_4 &= \int_s^t \int_0^1 \frac{\partial^2}{\partial \xi^2} y(t, r, \lambda x_r) d\lambda \cdot x_r \cdot \frac{1}{r} \int_0^1 \frac{\partial}{\partial x} \overline{H}(r, \lambda' x_r, \omega) d\lambda' \cdot x_r dr, \\
I_5 &= \int_s^t \frac{\partial}{\partial \xi} y(t, r, x_r) \cdot \frac{1}{r} \delta H(r, \omega) dr.
\end{aligned}$$

We will later also write $I_1 = I_{1,t} = I_{1,t,s}$ when we want to emphasize the dependence of I_1 on t and s. Then we can write

$$x_t - \overline{y}_t = (1 - \chi_{C_s})(I_1 + I_2 + I_3 + I_4 + I_5) + \chi_{C_s}(x_t - \overline{y}_t). \tag{4.9}$$

We will approximate I_2 and I_3 so that we replace λx_r and $\lambda' x_r$ by 0 and define

$$\begin{aligned}
I_2^* &= \int_s^t \frac{\partial}{\partial \xi} y(t, r, 0) \cdot \frac{1}{r} \int_0^1 \frac{\partial}{\partial x} \overline{H}(r, 0, \omega) d\lambda \cdot x_r dr, \\
I_3^* &= \int_s^t \int_0^1 \frac{\partial^2}{\partial \xi^2} y(t, r, 0) d\lambda \cdot x_r \cdot \frac{1}{r} \overline{H}(t, 0, \omega) dr.
\end{aligned}$$

For the sake of notational homogenity we will also write $I_1 = I_1^*$.

LEMMA 4.1. *We have for fixed q and any $s \le t \le qs$,*

$$x_t - \overline{y}_t = I_1^* + I_2^* + I_3^* + O_M(s^{-1/2-\varepsilon}). \tag{4.10}$$

Remark. It will be clear from the proof of the lemma that in the case $\delta H(t,\omega) = 0$ the last term becomes $O_M(s^{-1})$. Indeed the error term $O_M(s^{-1/2-\varepsilon})$ shows up only in the last step of the proof, in the estimation of the effect of I_5. Thus a key factor in the accuracy of the ODE approximation is the perturbation term $\delta H(t,\omega)$.

Proof. Estimation of I_2. We claim that for $s \le t \le qs$ we have

$$I_2 = I_2^* + O_M(s^{-1}). \tag{4.11}$$

Indeed, fix λ and integrate first with respect to r. We expand $\frac{\partial}{\partial x}\overline{H}^i(r, \lambda x_r, \omega)$ (for $i = 1, \dots, p$) into a Taylor series about 0 once more to obtain

$$\frac{\partial}{\partial x}\overline{H}^i(r, \lambda x_r, \omega) = \frac{\partial}{\partial x}\overline{H}^i(r, 0, \omega) + \left(\int_0^1 \frac{\partial^2}{\partial x^2}\overline{H}^i(r, \lambda'\lambda x_r, \omega)d\lambda'\right) \cdot x_r.$$

The expression under the integral term here can be shown to be $O_M(1)$ by the same argument that we used above, since $\overline{H}$ is assumed to have continuous third derivatives almost surely which are also M-bounded. Thus we get $\frac{\partial}{\partial x}\overline{H}(r, \lambda x_r, \omega) = \frac{\partial}{\partial x}\overline{H}(r, 0, \omega) + O_M(r^{-1/2})$. Integration with respect to λ from 0 to 1 and multiplication by $r^{-1}x_r = O_M(r^{-3/2})$ yield an error term $O_M(r^{-2})$. Finally, since $\|\frac{\partial}{\partial \xi}y(t, r, 0)\| \le C_0(r/t)^\alpha$ we get

$$I_2 = \int_s^t \frac{\partial}{\partial \xi}y(t, r, 0) \cdot \frac{1}{r}\frac{\partial}{\partial x}\overline{H}(r, 0, \omega) \cdot x_r dr + O_M(s^{-1}) \tag{4.12}$$

as stated. Note that the dominant term can be estimated by using the moment inequality given as Theorem 8.1. Thus we also get $I_2 = O_M(s^{-1/2})$.

Estimation of I_3. We claim that for $s \le t \le qs$ we have

$$I_3 = I_3^* + O_M(s^{-1}). \tag{4.13}$$

Indeed, in the inner integrand of I_3 we can write

$$\frac{\partial^2}{\partial \xi^2}y(t, r, \lambda x_r) = \frac{\partial^2}{\partial \xi^2}y(t, r, 0) + \left(\int_0^1 \frac{\partial^3}{\partial \xi^3}y(t, r, \lambda'\lambda x_r)d\lambda'\right) \cdot x_r, \tag{4.14}$$

where the last term is to be interpreted as the product of a 4-tensor with a 1-tensor yielding a 3-tensor, thus interpreting $\cdot$ as a tensor product. Substituting (4.14) into the expression of I_3 we get for fixed λ, λ' the product of the following two terms:

$$\frac{\partial^2}{\partial \xi^2}y(t, r, 0) \cdot x_r \cdot \frac{1}{r}\overline{H}(r, 0, \omega) = O_M(r^{-3/2}),$$
$$\frac{\partial^3}{\partial \xi^3}y(t, r, \lambda'\lambda x_r) \cdot x_r \cdot x_r \cdot \frac{1}{r}\overline{H}(r, 0, \omega) = O_M(r^{-2}),$$

where we used the fact that the partial derivatives of $y(t, r, \xi)$ with respect to ξ are bounded by a deterministic constant; see Lemma 8.8. Integrating from s to t the contribution of the integral of the second term is $O_M(s^{-1})$, thus we get

$$I_3 = \int_s^t \left(\frac{\partial^2}{\partial \xi^2}y(t, r, 0) \cdot x_r\right) \cdot \frac{1}{r}\overline{H}(r, 0, \omega)dr + O_M(s^{-1}) \tag{4.15}$$

as stated. Note that the expected upper bound $I_3 = O_M(s^{-1/2})$ cannot be readily derived from the above approximation: we cannot use the moment inequality given as Theorem 8.1 since the weights x_r are random!

Estimation of I_4. We claim that for $s \le t \le qs$ we have

$$I_4 = O_M(t^{-1}). \tag{4.16}$$

Indeed, by Theorem 3.1 we have $x_r = O_M(r^{-1/2})$, hence for fixed λ, λ' the contribution of the term $r^{-1}x_r \cdot x_r$, interpreted as an appropriate tensor product, is $O_M(r^{-2})$. On the other hand, $\|y_{\xi\xi}(t,r,x)\| \le C_0, (r/t)^\alpha \le C_1'$ with some $C_0', C_1' > 0$, uniformly in x for $x \in D_0$ (cf. Lemma 8.8). Third,

$$\left\| \frac{\partial}{\partial x} H(r, \lambda' x_r, \omega) \right\| \le \sup_{x \in D_0^*} \left\| \frac{\partial}{\partial x} H(r, x, \omega) \right\| \triangleq H_x^*(x, r, \omega), \tag{4.17}$$

where D_0^* denotes the star-like closure of D_0. Since by assumption $D_0^* \subset \mathrm{int} D$ and the partial derivative $H_{xx}(r,x,\omega)$ exists and is continuous almost surely and is M-bounded, we get by the maximal inequality, given as Theorem 8.3, that the right-hand side of (4.17) is $O_M(1)$. Hence we finally get, using the triangle inequality, that

$$I_4 = O_M\left(\int_s^t C_0 (r/t)^\alpha r^{-2} dr \right) = O_M(s^{-1})$$

as stated.

Estimation of the effect of $I_{5,t}$. We claim that for $s \le t \le qs$

$$(1 - \chi_{C_s})\ I_{5,t} = O_M(s^{-1/2-\varepsilon}). \tag{4.18}$$

Indeed, we have

$$(1 - \chi_{C_s})\ |I_{5,t}| \le (1 - \chi_{C_s}) \int_s^{t \wedge \tau(s)} \left\| \frac{\partial}{\partial \xi} y(t, r, 0) \right\| \ \frac{1}{r} |\delta H(r, \omega)|\ dr,$$

since for $t > \tau(s)$ we have $1 - \chi_{C_s} = 0$. Noting that $\|y_\xi(t,r,0)\| \le C_0$ and taking into account Condition 3.5 we get the claim.

Write now $x_t - \overline{y}_t$ as

$$I_1 + I_2 + I_3 + I_4 + (1 - \chi_{C_s}) I_5 - \chi_{C_s}(I_1 + I_2 + I_3 + I_4) + \chi_{C_s}(x_t - \overline{y}_t), \tag{4.19}$$

and estimate the contribution of the last two terms. Note that

$$I_1 + I_2 + I_3 + I_4 = \int_s^t \frac{\partial}{\partial \xi} y(t, r, x_r) \cdot \frac{1}{r} \overline{H}(r, x_r, \omega)\ dr = O_M(1). \tag{4.20}$$

Indeed, $||y_\xi(t,r,x_r)|| \le C_0$ and $\overline{H}(r, x_r, \omega)$ is M-bounded; see the argument leading to (4.17). Similarly $|x_t - \overline{y}_t| = O_M(1)$, actually we have $|x_t - \overline{y}_t| = O(1)$. As for χ_{C_s} we have the following lemma that has been given as Lemma 2.3 in [19].

LEMMA 4.2. *Consider the continuous-time recursive estimation scheme given by* (3.16) *with the resetting mechanism* (3.17) *and* (3.18). *Assume that Conditions* 3.1–3.5 *are satisfied. Let* C_s *denote the event that* x_t *hits* ∂D_0 *in the interval* $[s, qs)$. *Then for any* $m \ge 1$ *we have* $P(C_s) = O(s^{-m})$.

Thus the contribution of the last two terms in (4.19) is $O_M(s^{-m})$ for any $m \geq 1$ and with this Lemma 4.1 has been proved. □

Our next step is to show that the dominant term is I_1^*; i.e., the terms I_2^* and I_3^* are negligible. This is stated in the next lemma, which is the *key lemma* for the proof of Theorem 4.1. Its proof requires a new tool, specially designed for the present application: moment inequalities for double integrals of L-mixing processes.

LEMMA 4.3. *We have for* $s \leq t \leq qs$

$$x_t - \overline{y}_t = I_1^* + O_M(s^{-1/2-\varepsilon}).$$

Proof. In order to obtain sharper estimates of I_2^* and I_3^* let us write

$$I_2^* + I_3^* = \int_s^t g_r x_r \, dr, \tag{4.21}$$

where the matrix-valued process (g_r) is defined by

$$g_r = \frac{\partial}{\partial \xi} y(t, r, 0) \cdot \frac{1}{r} \frac{\partial}{\partial x} \overline{H}(r, 0, \omega) + \frac{\partial^2}{\partial \xi^2} y(t, r, 0) \cdot \frac{1}{r} \overline{H}(r, 0, \omega). \tag{4.22}$$

Thus we can write Lemma 4.1 as

$$x_t = \overline{y}_t + I_1^* + \int_s^t g_r x_r dr + O_M(s^{-1/2-\varepsilon}). \tag{4.23}$$

If we had $x_r = x$ a small constant, then we could write the integral on the right-hand side of (4.23) as $\int_s^t g_r dr \cdot x$, which then could be estimated by the moment inequality given as Theorem 8.1, since both $\overline{H}_x(r, 0, \omega)$ and $\overline{H}(r, 0, \omega)$ are zero-mean L-mixing processes. If x is small, then the contribution of this term will be negligible. To show that the second term in (4.23) is indeed negligible we iterate (4.23), i.e., substitute x_r by the expression that is given by (4.23). Writing $I_1^* = I_{1,t}^*$ we get for x_t the expression

$$\overline{y}_t + I_{1,t}^* + \int_s^t g_r \left(\overline{y}_r + I_{1,r}^* + \int_s^r g_p x_p dp + O_M(s^{-1/2-\varepsilon}) \right) dr + O_M(s^{-1/2-\varepsilon}). \tag{4.24}$$

Let us set

$$J_1 = \int_s^t g_r \overline{y}_r dr, \qquad J_2 = \int_s^t g_r I_{1,r}^* dr, \qquad J_3 = \int_s^t g_r \int_s^r g_p x_p \, dp \, dr.$$

The last term of the double integral in (4.24) yields $\int_s^t g_r O_M(s^{-1/2-\varepsilon}) dr = O_M(s^{-1/2-\varepsilon})$ since $\int_s^t g_r dr = O_M(1)$, therefore the effect of this term can be merged into the final residual term of (4.24). Thus we get

$$x_t - \overline{y}_t = I_{1,t}^* + J_1 + J_2 + J_3 + O_M(s^{-1/2-\varepsilon}). \tag{4.25}$$

We show that $J_1 + J_2 + J_3 = O_M(s^{-1})$.

Estimation of J_1. To estimate J_1 write it as

$$J_1 = \int_s^t g_r y(r, s, x_s) dr = L_1(x_s) \quad \text{with} \quad L_1(x) = \int_s^t g_r y(r, s, x) dr.$$

Note that $L_1(0) = 0$. To estimate $L_1(x_s)$ consider a Taylor series expansion of $L_1(x)$ around 0:

$$L_1(x_s) = \int_0^1 L_{1x}(\lambda x_s)d\lambda \cdot x_s, \tag{4.26}$$

where $L_{1x} = (\partial/\partial x)L_1(x)$. It is easy to see that in computing L_{1x} differentiation and integration can be interchanged, thus we can write

$$L_{1x}(x) = \int_s^t \left(\frac{\partial}{\partial \xi} y(t,r,0) \cdot \frac{1}{r} \frac{\partial}{\partial x} \overline{H}(r,0,\omega) + \frac{\partial^2}{\partial \xi^2} y(t,r,0) \cdot \frac{1}{r} \overline{H}(r,0,\omega) \right) \cdot \frac{\partial}{\partial x} y(r,s,x)\ dr. \tag{4.27}$$

Since $y_\xi(t,r,0)$, $y_{\xi\xi}(t,r,0)$, and $y_x(r,s,x)$ are deterministic and bounded and $\overline{H}_x(r,0,\omega)$ and $\overline{H}(r,0,\omega)$ are zero-mean L-mixing processes we get by the moment inequality, given as Theorem 8.1, that for each fixed $x \in D_0$

$$L_{1x}(x) = O_M\left(\int_s^t \frac{1}{r^2} dr \right)^{1/2} = O_M(s^{-1/2}).$$

Using similar arguments and taking into account that G is three-times continuously differentiable, we obtain that $L_{1xx}(x) = (\partial^2/\partial x^2)L_1(x) = O_M(s^{-1/2})$. Using now the maximal inequality, given as Theorem 8.3, we get

$$\|L_{1x}(\lambda x_s)\| \le \sup_{x \in D_0^*} \|L_{1x}(x)\| = O_M(s^{-1/2}).$$

Taking into account that $x_s = O_M(s^{-1/2})$ we finally get

$$J_1 = L_1(x_s) = O_M(s^{-1}). \tag{4.28}$$

Estimation of J_2. To estimate J_2 let us use the definition of $I_{1,t}^*$ and write

$$J_2 = \int_s^t g_r \int_s^r f_{1,v} \overline{H}(v,0,\omega) dv,$$

where the modulating function $f_{1,v}$ is

$$f_{1,v} = \frac{\partial}{\partial \xi} y(r,v,0) \cdot \frac{1}{v}.$$

Write g_r as

$$g_r = f_{2,1,r} \frac{\partial}{\partial x} \overline{H}(r,0,\omega) + f_{2,2,r} \overline{H}(r,0,\omega),$$

where the modulating functions are

$$f_{2,1,r} = \frac{\partial}{\partial \xi} y(t,r,0) \cdot \frac{1}{r} \quad \text{and} \quad f_{2,2,r} = \frac{1}{r} \frac{\partial^2}{\partial \xi^2} y(t,r,0) \cdot \frac{1}{r}.$$

Noting that $y_\xi(t,r,0)$ and $y_{\xi\xi}(t,r,0)$ are bounded and applying the moment inequality for double integrals of L-mixing processes, given as Theorem 8.2 in section 8, we get

$$J_2 = O_M(s^{-1}). \tag{4.29}$$

Estimation of J_3. For J_3 we get, after interchanging the order of integration,

$$J_3 = \int_s^t g_p x_p \left(\int_p^t g_r dr \right) \, dp.$$

For the inner integral we have

$$\int_p^t g_r dr = O_M(p^{-1/2})$$

by the moment inequality given as Theorem 8.1. Since $g_p = O_M(p^{-1})$ we have $g_p x_p = O_M(p^{-3/2})$ and thus the integrand of the outer integral is of the order of magnitude $O_M(p^{-2})$. It follows that

$$J_3 = O_M(s^{-1}). \tag{4.30}$$

Thus we conclude that indeed $J_1 + J_2 + J_3 = O_M(s^{-1})$, and substituting this into (4.25) the proof of Lemma 4.3 is complete. □

Pasting together. Let us now take a subdivision of the half-line $[1, \infty)$ by the points q^i with $q > 1$ and let us consider an interval $q^n \le t < q^{n+1}$. Let us define for $i \ge 1$

$$\delta_i = I^*_{1,q^i,q^{i-1}} = \int_{q^{i-1}}^{q^i} \frac{\partial}{\partial \xi} y(q^i, r, 0) \frac{1}{r} \overline{H}(r, 0, \omega) dr.$$

Note that $\delta_i = O_M(q^{-i/2})$.

LEMMA 4.4. *We have for* $q^n \le t < q^{n+1}$

$$x_t - y_t = \sum_{i=1}^n \frac{\partial}{\partial \xi} y(t, q^i, 0) \delta_i + I^*_{1,t,q^n} + O_M(q^{-n(1/2+\varepsilon_x)}). \tag{4.31}$$

Proof. Using Lemma 8.7 of section 8 with $s_i = q^i$, $i = 0, 1, \ldots, n$, $s_{n+1} = t$, we get the following expression for $x_t - y_t$:

$$\sum_{i=1}^n \int_0^1 \frac{\partial}{\partial \xi} y(t, q^i, w(\lambda)) \, d\lambda \cdot \left(x_{q^i} - y(q^i, q^{i-1}, x_{q^{i-1}}) \right) + \left(x_t - y(t, q^n, x_{q^n}) \right), \tag{4.32}$$

where $w(i, \lambda) = (1 - \lambda) y(q^i, q^{i-1}, x_{q^{i-1}}) + \lambda x_{q^i}$. Taking into account Lemma 4.3 write the ith local tracking error $x_{q^i} - y(q^i, q^{i-1}, x_{q^{i-1}})$ in the form $I^*_{1,q^i,q^{i-1}} + O_M(q^{-(i-1)(1/2+\varepsilon)}) = \delta_i + O_M(q^{-(i-1)(1/2+\varepsilon)})$ to get

$$\begin{aligned} x_t - y_t = \sum_{i=1}^n \int_0^1 \frac{\partial}{\partial \xi} y(t, q^i, w(\lambda)) d\lambda \cdot \left(\delta_i + O_M(q^{-(i-1)(1/2+\varepsilon)}) \right) \\ + I^*_{1,t,q^n} + O_M(q^{-n(1/2+\varepsilon)}). \end{aligned} \tag{4.33}$$

To estimate the cumulative effect of the error terms $O_M(q^{-(i-1)(1/2+\varepsilon)})$ note that we have

$$\| y_\xi(t, q^i, w(i, \lambda)) \| \le C_0 (q^i/t)^\alpha \le C_0 (q^i/q^n)^\alpha = C_0 q^{-\alpha(n-i)},$$

thus we get an upper bound

$$\sum_{i=1}^{n}\int_0^1 C_0 q^{-\alpha(n-i)}\cdot O_M(q^{-(i-1)(1/2+\varepsilon)})+O_M(q^{-n(1/2+\varepsilon)}). \tag{4.34}$$

This expression can be estimated from above by using the remark after Lemma 8.5 of section 8, given as (8.6), applied for the sequences $(q^{-\alpha i})$ and $(q^{-(1/2+\varepsilon)i})$, the convolution of which is bounded from above by $C\ \max(q^{-\alpha n}, q^{-(1/2+\varepsilon)n})$ assuming that $\alpha\neq 1/2+\varepsilon$. Since $\max(-\alpha,-(1/2+\varepsilon))=-\min(\alpha,1/2+\varepsilon)=-(1/2+\min(\overline{\alpha},\varepsilon))$, we get

$$x_t-y_t=\sum_{i=1}^{n}\int_0^1\frac{\partial}{\partial\xi}y(t,q^i,w(i,\lambda))d\lambda\cdot\delta_i+I^*_{1,t,q^n}+O_M(q^{-n(1/2+\varepsilon_x)}). \tag{4.35}$$

To further simplify the right-hand side of (4.34) we replace $w(i,\lambda)$ by 0. Note that by Lemma 8.8 of section 8

$$\left\|\frac{\partial}{\partial\xi}y(t,q^i,w(i,\lambda))-\frac{\partial}{\partial\xi}y(t,q^i,0)\right\|\le C_0'(q^i/t)^\alpha|w(i,\lambda)|,$$

and hence cumulative error of this approximation is majorized by $C_0'\sum_{i=1}^n(q^i/t)^\alpha\cdot|w(i,\lambda)|\cdot\delta_i$. Note that $w(i,\lambda)=O_M(q^{-i/2})$, uniformly in λ since $x_{q^i}=O_M(q^{-i/2})$ by Theorem 3.1 and $|\overline{y}_{q^i}|=|y(q^i,q^{i-1},x_{q^{i-1}})|\le C_0|x_{q^{i-1}}|$, therefore $w(i,\lambda)\cdot\delta_i=O_M(q^{-i})$ uniformly in λ. Thus the the cumulative error of the last approximation is bounded from above by

$$C_0'\sum_{i=1}^{n}(q^i/t)^\alpha\cdot O_M(q^{-i})\le\sum_{i=1}^{n}q^{-\alpha(n-i)}\cdot O_M(q^{-i})=O_M(q^{-n\alpha'})$$

with $\alpha'=\min(\alpha,1)_-$, by the remark after Lemma 8.5, given as (8.6). Since $1/2+\varepsilon<1$, we have $\alpha'\ge\min(\alpha,1/2+\varepsilon)_-=\varepsilon_x$ and with this the proof of the lemma is complete. □

Now the ith term on right-hand side of (4.31) can be written as

$$\begin{aligned}\frac{\partial}{\partial\xi}y(t,q^i,0)\int_{q^{i-1}}^{q^i}\frac{\partial}{\partial\xi}y(q^i,r,0)\frac{1}{r}\overline{H}(r,0,\omega)dr\\ =\int_{q^{i-1}}^{q^i}\frac{\partial}{\partial\xi}y(t,r,0)\frac{1}{r}\overline{H}(r,0,\omega)dr,\end{aligned} \tag{4.36}$$

thus the cumulative contribution of the dominant terms in (4.31) is exactly what is the dominant term in Theorem 4.1. Since $y_t=O(t^{-\alpha})=O(t^{-(1/2+\overline{\alpha})})$ the term can be merged into the residual term $O_M(q^{-n(1/2+\varepsilon_x)})$ and thus the proof of Theorem 4.1 has been completed. □

Proof of Theorem 4.2. Let $(H^c(t,x,\omega))$ be the piecewise constant extension of $(H(n,x,\omega))$ defined under (3.35) and define a piecewise linear extension of (x_n) for $1\le n\le t\le n+1$ by

$$x^l_t=(t-n)x_n+(n+1-t)x_{n-1}\quad\text{if}\quad x_{n-}\in\mathrm{int}D_0,\quad x^l_1=x_0=\xi_0. \tag{4.37}$$

On the other hand, if $x_{n-} \notin \text{int}D_0$, then we reset x^l to its initial value ξ_0 at time $t = n$ and put a hold on the recursion until $t = n + 1$; i.e., we set

$$x_t^l = \xi_0 \quad \text{for} \quad 1 \le n < t \le n+1 \quad \text{if} \quad x_{n-} \notin \text{int}D_0. \tag{4.38}$$

Now it is easy to see that in intervals $n \le t \le n+1$ where no resetting takes place (x_t^l) satisfies a differential equation of the form

$$\dot{x}_t^l = \frac{1}{t}(H^c(t, x, \omega) + \delta H(t, \omega)), \tag{4.39}$$

where $\delta H(t, \omega) = \delta H^c(n, \omega) + O_M(t^{-1})$, cf. [19, (2.13)]. The conditions of Theorem 4.1 can be easily verified for the above procedure, except that we use the alternative resetting mechanism given by (3.17) and (3.19). Thus we get by Theorem 4.1

$$x_t^l - x^* = \int_1^t \frac{\partial}{\partial \xi} y(t, s, x^*) \frac{1}{s} H^c(s, x^*, \omega) ds + O_M(t^{-1/2-\varepsilon_x}). \tag{4.40}$$

Let $t = N$ be an integer and let $n \le s < n + 1$, with n being integer. We have

$$\left\| \frac{\partial}{\partial \xi} y(t, s, x^*) - \frac{\partial}{\partial \xi} y(t, n, x^*) \right\| \le C_0' \left(\frac{s}{t}\right)^{\alpha} \frac{1}{t}. \tag{4.41}$$

Indeed, by Lemma 8.8

$$||y_{r\xi}(t, r, x^*)|| \le C_0'(r/t)^{\alpha} \cdot \left\| \frac{1}{t} G_{\xi}(x^*) \right\|.$$

Integrating $y_{r\xi}(t, r, \xi)$ between n and s we get (4.41). Now replacing $y_{\xi}(t, s, x^*)$ by $y_{\xi}(t, n, x^*)$ in (4.40), noting that $\frac{1}{s} - \frac{1}{n} = O(\frac{1}{s^2})$ and taking into account that $\overline{H}^c(t, x^*, \omega)$ is M-bounded we get that the cumulative error is of the order of magnitude

$$O_M\left(\int_1^t \left(\frac{s}{t}\right)^{\alpha} \cdot \frac{1}{s^2}\, ds \right) = O_M(t^{-1}), \tag{4.42}$$

which can be merged into the residual term $O_M(t^{-1/2-\varepsilon_x})$ and thus the proof of Theorem 4.2 is complete. □

Proof of Theorem 4.3. Defining H and δH as in (3.46) and (3.56), the conditions of Theorem 4.1 have been verified in section 5 of [19]. In particular, the critical Condition 3.5 is verified in Lemma 5.6 in [19] (restated as Lemma 3.2 in the present paper), thus the claim follows. □

5. The transformed error process is *L*-mixing. In this section we derive a useful corollary of Theorem 4.1, stating that an appropriate transformation of the error process $x_t - x^*$ is L-mixing. Define the transformed process

$$\tilde{x}_r = e^{r/2}(x_{e^r} - x^*). \tag{5.1}$$

The weak limit of the shifted process $(\tilde{x}_{r+\rho})$, when $\rho \to \infty$, is established in [5] and Theorem 13, Chapter 4.5, Part II of [3], under conditions, which are different from the conditions of the present paper. It is proven that $(\tilde{x}_{r+\rho})$ converges weakly to the solution of the linear stochastic differential equation

$$d\tilde{z}_r = (A^* + I/2)\tilde{z}_r + d\tilde{w}_r, \tag{5.2}$$

with zero initial condition; in short,

$$(\tilde{x}_{r+\rho}) \to (\tilde{z}_r) \tag{5.3}$$

in a weak sense, where (cf. (3.24))

$$A^* = \frac{\partial G(x)}{\partial x}\Big|_{x=x^*},$$

assuming that $(A^* + I/2)$ is stable. Here $d\tilde{w}_r$ is the stochastic differential of a Wiener-process, with some covariance matrix $P^* dt$. The weak limit $(\tilde{z}_r)$ is an L-mixing process with respect to the pair of σ-algebras $(\tilde{\mathcal{F}}_r, \tilde{\mathcal{F}}_r^+)$ generated by the past and future increments of the Wiener-process $(\tilde{w}_r)$, respectively. Hence it is indicated, but not implied by (5.3), that the transformed process $(\tilde{x}_r)$ itself is also L-mixing with respect to some pair of σ-algebras $(\tilde{\mathcal{F}}_r, \tilde{\mathcal{F}}_r^+)$. We prove that this is indeed the case.

The emphasis is on the nonasymptotic nature of our result. An analogous result for off-line prediction error estimators of ARMA parameters has been proved in [24]. It extends to RPE estimators due to the strong approximation result given in [22]. It has also been shown in [24] that this result is instrumental in deriving a pathwise characterization of performance degradation of an online adaptive predictor. Like in section 4, we assume that $\delta G(t, y) = 0$, which implies $\mathrm{E} H(s, x^*, \omega) = 0$ exactly for all s.

THEOREM 5.1. *Consider the continuous-time recursive estimation scheme given by* (3.16) *with the resetting mechanism* (3.17) *and* (3.18). *Assume that the conditions of Theorem* 4.1 *are satisfied. Then the transformed process* $(\tilde{x}_r)$ *is* L*-mixing with respect to* $(\mathcal{F}_{e^r}, \mathcal{F}_{e^r}^+)$.

Proof. Approximation, dynamic representation, and discretization of the process $(\tilde{x}_r)$. By Theorem 4.1 the dominant term in the error process is

$$\int_1^t \frac{\partial}{\partial \xi} y(t, s, x^*) \frac{1}{s} H(s, x^*, \omega) ds,$$

and the error term is $O_M(t^{-1/2+\varepsilon_x})$. We transform the dominant term and the residual term $O_M(t^{-1/2+\varepsilon_x})$ in the same way as the error process itself (cf. (5.1)): we multiply by $t^{1/2}$ and introduce the new variables $t = e^r$ and $s = e^p$.

Now, since $\frac{\partial}{\partial \xi} y(t, s, x^*)$ is the solution of the variational equation

$$\frac{\partial}{\partial t} \frac{\partial}{\partial \xi} y(t, s, x^*) = \frac{1}{t} A^* \frac{\partial}{\partial \xi} y(t, s, x^*)$$

with initial condition $\frac{\partial}{\partial \xi} y(s, s, x^*) = I$, we get, using an exponential change of time-scale followed by an inverse change of time-scale, that

$$\frac{\partial}{\partial \xi} y(t, s, x^*) = e^{A^* \log(t/s)}.$$

Thus the dominant term in the error process gets transformed into

$$\tilde{x}_{1,r} = e^{r/2} \int_0^r e^{A^*(r-p)} H(e^p, x^*, \omega) dp. \tag{5.4}$$

Now Theorem 4.1 implies the following.

CLAIM. *We have*

$$\tilde{x}_r - \tilde{x}_{1,r} = O_M(e^{-\varepsilon_x r}). \tag{5.5}$$

A dynamic representation of $\tilde{x}_{1,r}$ is obtained by differentiating (5.4) with respect to r. Then we get that $\tilde{x}_{1,r}$ satisfies the differential equation

$$\frac{d}{dr}\tilde{x}_{1,r} = (A^* + I/2)\tilde{x}_{1,r} + e^{r/2}H(e^r, x^*, \omega), \qquad r \geq 0. \tag{5.6}$$

The dynamics satisfied by $(\tilde{x}_{1,r})$ is similar to the dynamics satisfied by (z_r), given by (5.2), but the process $e^{r/2}H(e^r, x^*, \omega)$ is not a good approximation to the increments of a Wiener-process; it is not even M-bounded. This difficulty can be avoided using discretization and averaging. Take a small, fixed positive number h and consider the discrete-time sampled process $\tilde{x}_{1,nh}$. It satisfies the discrete-time dynamics

$$\tilde{x}_{1,(n+1)h} = e^{(A^*+I/2)h}\tilde{x}_{1,nh} + \int_{nh}^{(n+1)h} e^{(A^*+I/2)((n+1)h-p)}e^{p/2}H(e^p, x^*, \omega)dp.$$

Note that the input process is obtained as a weighted average of the input process of (5.6) over the interval $[nh, (n+1)h]$. Denote the second term on the right-hand side, which is the input process for the discretized system, by $(\tilde{u}_{1,n})$; i.e., set

$$\tilde{u}_{1,n+1} = \int_{nh}^{(n+1)h} e^{(A^*+I/2)((n+1)h-p)}e^{p/2}H(e^p, x^*, \omega)dp. \tag{5.7}$$

The discrete-time dynamics.

$$\tilde{x}_{1,(n+1)h} = e^{(A^*+I/2)h}\tilde{x}_{1,nh} + \tilde{u}_{1,n+1}, \qquad n \geq 0, \tag{5.8}$$

with zero initial condition. In what follows we develop a series of approximations of the process $\tilde{u}_{1,n+1}$.

An averaging effect for the process $(\tilde{u}_{1,n})$. Going back to the original time-scale in (5.7) we can write $\tilde{u}_{1,n+1}$ as

$$\tilde{u}_{1,n+1} = \int_{e^{nh}}^{e^{(n+1)h}} \left(\frac{s}{e^{(n+1)h}}\right)^{(-A^*-I/2)} \frac{1}{s^{1/2}} H(s, x^*, \omega)ds. \tag{5.9}$$

CLAIM U1. *For the order of magnitude of* $(\tilde{u}_{1,n+1})$ *we have*

$$\tilde{u}_{1,n+1} = O_M(h^{1/2}). \tag{5.10}$$

Indeed, using the moment inequality given as Theorem 8.1 we get that for any $q \geq 1$

$$\mathrm{E}^{1/q}|\tilde{u}_{1,n+1}|^q \leq C_q\left(\int_{e^{(nh}}^{e^{(n+1)h}} \left\|\left(\frac{s}{e^{(n+1)h}}\right)^{(-A^*-I/2)} \frac{1}{s^{1/2}}\right\|^2 ds\right)^{1/2} \cdot M_q^{1/2}(H(x^*))\Gamma_q^{1/2}(H(x^*)).$$

Note that for $e^{nh} \leq s \leq e^{(n+1)h}$, $0 < h \leq h_0$, with some $0 < h_0$ fixed,

$$\left\|\left(\frac{s}{e^{(n+1)h}}\right)^{(-A^*-I/2)}\right\| = ||e^{(p-(n+1)h)(-A^*-I/2)}|| \leq C, \tag{5.11}$$

where C is independent of n and h, since the set of matrices $e^{(p-(n+1)h)(-A^*-I/2)}$ with p varying between nh and $(n+1)h$ is compact. Thus we get

$$\mathrm{E}^{1/q}|\tilde{u}_{1,n+1}|^q \le C_q\left(\int_{e^{nh}}^{e^{(n+1)h}} C^2\frac{1}{s}ds\right)^{1/2}\cdot M_q^{1/2}(H(x^*))\Gamma_q^{1/2}(H(x^*)),$$

and the right-hand side is $O(h^{1/2})$ indeed, as stated.

Truncated averaging: The process $(\tilde{u}_{2,n})$ and choosing δ_n and ε_δ. To eliminate the dependence in the process $(\tilde{u}_{1,n})$ we follow standard procedures, as described, e.g., in [42]. First we remove a small portion of the integral by decreasing the upper limit of the integration to $e^{(n+1)h}-\delta_{n+1}$ with some positive δ_{n+1}. Since the original range of the integration has length $e^{(n+1)h}-e^{nh}=O(he^{nh})$ a reasonable choice for δ_{n+1} is

$$\delta_{n+1} = he^{\varepsilon_\delta nh} \tag{5.12}$$

with $0<\varepsilon_\delta<1$. Thus we define

$$\tilde{u}_{2,n+1} = \int_{e^{nh}}^{e^{(n+1)h}-\delta_{n+1}}\left(\frac{s}{e^{(n+1)h}}\right)^{(-A^*-I/2)}\frac{1}{s^{1/2}}H(s,x^*,\omega)ds. \tag{5.13}$$

Claim U2. *We have for $h>0$*

$$\tilde{u}_{1,n+1}-\tilde{u}_{2,n+1} = O_M(h^{1/2}e^{-(1-\varepsilon_\delta)nh/2}) \quad\text{and}\quad \tilde{u}_{1,n+1}-\tilde{u}_{2,n+1}=O_M(h^{1/2}). \tag{5.14}$$

For the proof first note that

$$e^{(n+1)h}-\delta_{n+1}\ge e^{nh}. \tag{5.15}$$

Indeed, this is equivalent to $\delta_{n+1}\le e^{(n+1)h}-e^{nh}=e^{nh}(e^h-1)$ and since $\delta_{n+1}<he^{nh}$ and $h<(e^h-1)$, the validity of (5.15) follows.

The error of the approximation is

$$\tilde{u}_{1,n+1}-\tilde{u}_{2,n+1} = \int_{e^{(n+1)h}-\delta_{n+1}}^{e^{(n+1)h}}\left(\frac{s}{e^{(n+1)h}}\right)^{(-A^*-I/2)}\frac{1}{s^{1/2}}H(s,x^*,\omega)ds,$$

which can be estimated by the moment inequality given as Theorem 8.1. Thus we get that $\mathrm{E}^{1/q}|\tilde{u}_{1,n+1}-\tilde{u}_{2,n+1}|^q$ is bounded from above by

$$C_q\left(\int_{e^{(n+1)h}-\delta_{n+1}}^{e^{(n+1)h}}\left\|\left(\frac{s}{e^{(n+1)h}}\right)^{(-A^*-I/2)}\frac{1}{s^{1/2}}\right\|^2 ds\right)^{1/2}\cdot M_q^{1/2}(H(x^*))\Gamma_q^{1/2}(H(x^*)).$$

Taking into account the kernel estimate given above as (5.11) we get for $\mathrm{E}^{1/q}|\tilde{u}_{1,n+1}-\tilde{u}_{2,n+1}|^q$ the upper bound

$$C_q\left(\int_{e^{(n+1)h}-\delta_{n+1}}^{e^{(n+1)h}}\frac{C^2}{s}ds\right)^{1/2}\cdot M_q^{1/2}(H(x^*))\Gamma_q^{1/2}(H(x^*)). \tag{5.16}$$

For the integral term we have

$$\left(\int_{e^{(n+1)h}-\delta_{n+1}}^{e^{(n+1)h}}\frac{1}{s}ds\right)^{1/2} = (\log e^{(n+1)h}-\log(e^{(n+1)h}-\delta_{n+1}))^{1/2},$$

which is majorized by

$$\left(\delta_{n+1}/(e^{(n+1)h}-\delta_{n+1})\right)^{1/2}.$$

Since $e^{(n+1)h}-\delta_{n+1}\geq e^{nh}$, we can continue the above inequality to get

$$\left(\int_{e^{(n+1)h}-\delta_{n+1}}^{e^{(n+1)h}}\frac{1}{s}ds\right)^{1/2}\leq\left(\delta_{n+1}/e^{nh}\right)^{1/2}.$$

Taking into account the definition of δ_{n+1} we get

$$\left(\delta_{n+1}/e^{nh}\right)^{1/2}=\left(he^{\varepsilon_\delta nh}/e^{nh}\right)^{1/2}=h^{1/2}e^{(\varepsilon_\delta-1)nh/2}.$$

Combining the latter inequalities with (5.16) we get the first part of Claim U2, given as (5.14), while the second part is a trivial consequence.

The independent sequence $(\tilde{u}_{3,n})$. This is a key step in our arguments. We complete the construction of an approximating process of $(\tilde{u}_{1,n})$ by projecting $\tilde{u}_{2,n+1}$ on the relative future $\mathcal{F}^+_{e^{nh}-\delta_n}$. In fact, assuming that the conditional expectation operator and integration can be interchanged, we define

$$\tilde{u}_{3,n+1}=\int_{e^{nh}}^{e^{(n+1)h}-\delta_{n+1}}\left(\frac{s}{e^{(n+1)h}}\right)^{(-A^*-I/2)}\frac{1}{s^{1/2}}\mathrm{E}(H(s,x^*,\omega)|\mathcal{F}^+_{e^{nh}-\delta_n})ds. \tag{5.17}$$

It is obvious that $(\tilde{u}_{3,n})$ constitutes an independent sequence of random variables adapted to $\mathcal{F}_{e^{nh}}$.

Remark. We will now approximate the process $\tilde{u}_{2,n+1}$ and get two dual error bounds. The first error bound ensures that the error is exponentially decaying, but there is multiplicative factor h^{-c} with $c>0$, while the second bound ensures that the approximating process itself is of the order $O_M(h^{1/2})$.

Claim U3. *We have with* $c>0$ *that shows up in Condition* 3.1 *(see the definition of* L^+*-mixing), the following two estimates:*

$$\tilde{u}_{2,n+1}-\tilde{u}_{3,n+1}=O_M(h^{-c}e^{-(1/2+c\varepsilon_\delta)nh}) \text{ and } \tilde{u}_{2,n+1}-\tilde{u}_{3,n+1}=O_M(h^{1/2}). \tag{5.18}$$

First we show that $(\tilde{u}_{3,n+1})$ is an M-bounded sequence. Indeed, write $\tilde{u}_{3,n+1}$ as

$$\tilde{u}_{3,n+1}=\mathrm{E}\left(\int_{e^{nh}}^{e^{(n+1)h}-\delta_{n+1}}\left(\frac{s}{e^{(n+1)h}}\right)^{(-A^*-I/2)}\frac{1}{s^{1/2}}H(s,x^*,\omega)ds \;\middle|\; \mathcal{F}^+_{e^{nh}-\delta_n}\right)$$

and estimate the L_q-norm of the right-hand side using Jensen's inequality. Taking into account (5.10), modified so that upper limit of the integration is reduced to the nonrandom upper limit $e^{(n+1)h}-\delta_{n+1}$, we get the claimed M-boundedness of $(\tilde{u}_{3,n+1})$ and in fact we get

$$\tilde{u}_{3,n+1}=O_M(h^{1/2}), \tag{5.19}$$

and thus the second part of the Claim U3 is proved.

To bound the approximation error more accurately define for $e^{nh}\leq s\leq e^{(n+1)h}-\delta_{n+1}$

$$v_s=\left|\left(\frac{s}{e^{(n+1)h}}\right)^{(-A^*-I/2)}\frac{1}{s^{1/2}}\left(H(s,x^*,\omega)-\mathrm{E}(H(s,x^*,\omega)|\mathcal{F}^+_{e^{nh}-\delta_n})\right)\right|.$$

Then obviously

$$|\tilde{u}_{2,n+1} - \tilde{u}_{3,n+1}| \le \int_{e^{nh}}^{e^{(n+1)h}-\delta_{n+1}} v_s ds.$$

and by the triangle inequality for the L_q-norm for $q \ge 1$,

$$\mathrm{E}^{1/q}|\tilde{u}_{2,n+1} - \tilde{u}_{3,n+1}|^q \le \int_{e^{nh}}^{e^{(n+1)h}-\delta_{n+1}} \mathrm{E}^{1/q} v_s^q ds. \tag{5.20}$$

To estimate v_s, note that $||(s/e^{(n+1)h})^{(-A^*-I/2)}|| \le C$ with some C for all s, n, and h with $0 < h \le h_0$ and $s^{-1/2} \le e^{-nh/2}$. On the other hand, we have for any $q \ge 1$

$$\mathrm{E}^{1/q}|(H(s,x^*,\omega) - \mathrm{E}(H(s,x^*,\omega)|\mathcal{F}^+_{e^{nh}-\delta_n}))|^q \le \gamma_q(s-(e^{nh}-\delta_n), H(x^*)),$$

and thus

$$\mathrm{E}^{1/q} v_s^q \le Ce^{-nh/2}\gamma_q(s-(e^{nh}-\delta_n), H(x^*)).$$

It follows that $\mathrm{E}^{1/q}|\tilde{u}_{3,n+1} - \tilde{u}_{2,n+1}|^q$ can be bounded from above by

$$Ce^{-nh/2}\int_{e^{nh}}^{e^{(n+1)h}-\delta_{n+1}} \gamma_q(s-(e^{nh}-\delta_n), H(x^*))ds. \tag{5.21}$$

By Condition 3.1 $\gamma_q(s-(e^{nh}-\delta_n), H(x^*)) \le C(1+\delta_n)^{-1-c}$. Furthermore, note that the range of $\tau(s) = s-(e^{nh}-\delta_n)$ is included in the semi-infinite interval $[\delta_n, \infty)$; thus

$$\begin{aligned}\int_{e^{nh}}^{e^{(n+1)h}-\delta_{n+1}} \gamma_q(s-(e^{nh}-\delta_n), H(x^*))ds &\le \int_{\delta_n}^{\infty} \gamma_q(\tau, H(x^*))d\tau \\ &\le C'(1+\delta_n)^{-c} < C'\delta_n^{-c}.\end{aligned}$$

Combining this with (5.21) and taking into account the definitions of the lag δ_n given by (5.12), we get for any $1 \le q < \infty$

$$\mathrm{E}^{1/q}|\tilde{u}_{2,n+1} - \tilde{u}_{3,n+1}|^q \le C_q e^{-nh/2} h^{-c} e^{-c\varepsilon_\delta nh}$$

with some C_q, which is independent of n and h and this is equivalent to the first part of Claim U3, given as (5.18).

The final approximating process $(\tilde{x}_{3,nh})$. We are going to define a final approximation to $\tilde{x}_{nh}$ that plays a key role in subsequent analysis. This is obtained from the discrete-time dynamics (5.8) so that $\tilde{u}_{1,n+1}$ is replaced by $\tilde{u}_{3,n+1}$. Thus we define the process $(\tilde{x}_{3,(n+1)h})$ by

$$\tilde{x}_{3,(n+1)h} = e^{(A^*+I/2)h}\tilde{x}_{3,nh} + \tilde{u}_{3,n+1}, \qquad n \ge 0, \tag{5.22}$$

with zero initial condition. Let

$$\tilde{\mathcal{F}}_r = \mathcal{F}_{e^r} \quad \text{and} \quad \tilde{\mathcal{F}}^+_r = \mathcal{F}^+_{e^r}.$$

We claim that the approximating process $(\tilde{x}_{3,nh})$ is L-mixing with respect to $(\tilde{\mathcal{F}}_{nh}, \tilde{\mathcal{F}}^+_{nh})$.

Indeed, since the real parts of the eigenvalues of A^* are less than or equal to α^* and $\alpha < \alpha^*$, the spectral norm of $e^{(A^*+I/2)h}$ is less than $e^{-\overline{\alpha}h}$ and hence there exists a $C > 0$ such that for any positive integer m

$$||e^{(A^*+I/2)mh}|| \le Ce^{-\overline{\alpha}mh}. \tag{5.23}$$

The input process $(\tilde{u}_{3,n})$ is an M-bounded, independent, $\tilde{\mathcal{F}}_{nh}$-adapted sequence, hence it is L-mixing with respect to $(\tilde{\mathcal{F}}_{nh}, \tilde{\mathcal{F}}^+_{nh})$. Thus the output process $(\tilde{x}_{3,nh})$ is L-mixing with respect to $(\tilde{\mathcal{F}}_{nh}, \tilde{\mathcal{F}}^+_{nh})$, by Lemma 8.4, as stated.

To get an accurate bound for the estimation error $\tilde{x}_{nh} - \tilde{x}_{3,nh}$ let us introduce the notations

$$\varepsilon_{x2} = \min(\overline{\alpha}, (1 - \varepsilon_\delta)/2), \tag{5.24}$$

$$\varepsilon_{x3} = \min(\overline{\alpha}, 1/2 + c\varepsilon_\delta). \tag{5.25}$$

Obviously $\varepsilon_{x2}, \varepsilon_{x3} > 0$. To formulate the next result note that if (ξ_t) and (η_t) are stochastic processes such that $\xi_t = O_M(c_t)$ and $\eta_t = O_M(d_t)$, where $c_t, d_t > 0$, then, trivially,

$$\xi_t + \eta_t = O_M(c_t + d_t). \tag{5.26}$$

LEMMA 5.1. *The final approximation error $\tilde{x}_{(n+1)h} - \tilde{x}_{3,(n+1)h}$ is given by*

$$\tilde{x}_{(n+1)h} - \tilde{x}_{3,(n+1)h} = O_M(e^{-\varepsilon_x nh} + h^{1/2}e^{-\varepsilon_{x2}nh} + h^{-c}e^{-\varepsilon_{x3}nh}) = O_M(1). \tag{5.27}$$

Proof. The proof is almost trivial. It is easy to see, using the moment inequality given as Theorem 8.1, that both $(\tilde{x}_{nh})$ and $(\tilde{x}_{3,nh})$ are M-bounded, which implies the second part of the claim. To prove the first part, first note that the first term on the right-hand side comes from (5.5). Next note that the error process $(\tilde{x}_{1,(n+1)h} - \tilde{x}_{3,(n+1)h})$ satisfies

$$(\tilde{x}_{1,(n+1)h} - \tilde{x}_{3,(n+1)h}) = e^{(A^*+I/2)h}(\tilde{x}_{1,nh} - \tilde{x}_{3,nh}) + (\tilde{u}_{1,n+1} - \tilde{u}_{3,n+1}), \qquad n \ge 0,$$

with zero initial conditions. For the input process $(\tilde{u}_{1,n+1} - \tilde{u}_{3,n+1})$ the combination of the upper bounds given in Claims U2 and U3, or equivalently in (5.14) and (5.18), is used. Applying Lemma 8.5 we get the second and third terms on the right-hand side of (5.27), which is thus proved. □

To complete the proof of Theorem 5.1 we first note that defining

$$r_n = \tilde{x}_{3,nh} - \tilde{x}_{nh},$$

this residual process is L-mixing with respect to $(\tilde{\mathcal{F}}_{nh}, \tilde{\mathcal{F}}^+_{nh})$. Indeed, (r_n) is M-bounded and $\tilde{\mathcal{F}}_{nh}$-measurable. On the other hand, writing (5.27) in the form $r_n = O_M(e^{-\varepsilon'_x nh})$ we get for any integer $\tau \ge 0$

$$\gamma_q(\tau, r) = \sup_{n \ge \tau} \mathrm{E}^{1/q}|r_n - \mathrm{E}\,[r_n|\mathcal{F}^+_{n-\tau}]\,|^q \le 2 \sup_{n \ge \tau} \mathrm{E}^{1/q}|r_n|^q \le 2C_q e^{-\varepsilon'_x \tau h} \tag{5.28}$$

with some finite C_q. The right-hand side is obviously summable over τ and thus we get the claim.

Since the class of L-mixing processes is closed under addition, it follows that $\tilde{x}_{nh}$ is also L-mixing with respect to $(\tilde{\mathcal{F}}_{nh}, \tilde{\mathcal{F}}^+_{nh})$. The second remark we need is that the

processes $(\tilde{x}_{nh+d})$ and $(\tilde{x}_{3,nh+d})$, with $0 \le d < h$ fixed, can be analyzed similarly and it is easy to see that all the relevant estimates are valid uniformly in d. Thus we conclude that the processes $(\tilde{x}_{nh+d})$ are L-mixing with respect to $(\tilde{\mathcal{F}}_{nh+d}, \tilde{\mathcal{F}}^+_{nh+d})$, uniformly in d for $0 \le d < h$. Applying Corollary 3.5 of [24], restated as Lemma 8.3 in section 8, implies that the continuous-time process $(\tilde{x}_r)$ itself is L-mixing with respect to $(\tilde{\mathcal{F}}_r, \tilde{\mathcal{F}}^+_r) = (\mathcal{F}_{e^r}, \mathcal{F}^+_{e^r})$ and the proof is complete. □

6. The asymptotic covariance matrix. The asymptotic covariance matrix for Algorithm DFL, (3.53)–(3.54), has been rigorously derived in Theorem 13, Chapter 4.5, Part II of [3] in a *series* model, where the initial time tends to infinity, and thus the probability of exiting the truncation domain tends to 0. The asymptotic covariance matrix of Robbins–Monroe-type recursive estimators has been known for long time; cf., e.g., [54]. Here the correction term $H(n, x, \omega)$ is assumed to form an independent sequence; see Condition A.3 in Chapter 2.3 of [54]. The asymptotic covariance matrix for the RPE estimator of ARMA processes has been first given in [60] using the eventually false a priori assumption that the nontruncated estimator sequence converges almost surely. It is likely that the analysis of the cited paper carries over to truncated estimators.

The purpose of this section is to derive the asymptotic covariance matrix for the general continuous-time recursive estimator process, Algorithm CR, given in (3.16) equipped with a resetting mechanism defined under (3.17) and (3.18). The study of the discrete-time procedure, Algorithm DR, given in (3.34) and Algorithm DFL, given under (3.53)–(3.54), with resetting mechanisms defined in section 3, can be reduced to the study of Algorithm CR, as pointed out in sections 3 and 4. The main advance of this section relative to the cited result of [3] is that the asymptotic covariance matrix for the DFL scheme with enforced boundedness is obtained for a *single* process.

We also get a rate of convergence for the covariance-matrix sequence, which is useful in applications such as the analysis of performance degradation to statistical parametric uncertainty. For the present section we need the following additional condition.

CONDITION 6.1. *We assume that* $(H(s, x^*, \omega))$ *is asymptotically wide-sense stationary in the following sense: there exists a zero-mean, wide-sense stationary process* $(H_0(s, x^*, \omega))$ *such that*

$$\eta_s = H(s, x^*, \omega) - H_0(s, x^*, \omega) = O_M(s^{-1-\varepsilon_H}) \tag{6.1}$$

with some $\varepsilon_H > 0$.

This condition is easily verified in system identification. In fact, if we consider the general estimation scheme of section 3 defined by (3.53)–(3.54), then it is easy to see that we have $\eta_s = O_M(e^{-\beta s})$ with some $\beta > 0$. Now we have the following modification of Theorem 4.1.

THEOREM 6.1. *Consider the continuous-time recursive estimation scheme given by* (3.16) *with the resetting mechanism* (3.17) *and* (3.18). *Assume that the conditions of Theorem* 4.1 *are satisfied and in addition Condition* 6.1 *is also satisfied. Recall that* $\varepsilon_x = \min(\overline{\alpha}, \varepsilon)_-$, *where* $\overline{\alpha}$ *is defined under* (3.31) *and* ε *is given in Condition* 3.5. *Then we have*

$$x_t - x^* = \int_1^t \frac{\partial}{\partial \xi} y(t, s, x^*) \frac{1}{s} H_0(s, x^*, \omega) ds + O_M(t^{-1/2-\varepsilon_x}), \tag{6.2}$$

and the wide-sense stationary process $(H_0(s, x^*, \omega))$ *is* L^+*-mixing.*

Proof. Consider the expression for the error $x_t - x^*$ that has been given in Theorem 4.1, or in (4.1). The difference between (4.1) and (6.2) is in the dominant terms and this difference can be majorized by

$$\int_1^t \left| \frac{\partial}{\partial \xi} y(t, s, x^*) \frac{1}{s} \eta_s \right| ds \le \int_1^t C_0 (s/t)^\alpha \left| \frac{1}{s} \eta_s \right| ds,$$

due to Condition 3.4. Taking the L_q-norm of both sides with some $q \ge 1$ and applying the triangle inequality for L_q-norms we get an upper bound of the form

$$C_q \int_1^t C_0 (s/t)^\alpha \frac{1}{s} s^{-1-\varepsilon_H} ds,$$

which is majorized by $C_q' t^{-1-\varepsilon_H}$. Thus the difference between the dominant terms is certainly $O_M(t^{-1/2-\varepsilon_x})$ and thus (6.2) follows.

To prove that $(H_0(s, x^*, \omega))$ is L^+-mixing, note that repeating the argument leading to (5.28) gives that for any integer $\tau \ge 0$

$$\gamma_q(\tau, \eta) \le 2 C_q \tau^{-1-\varepsilon_H},$$

and hence (η_s) is L^+-mixing. Since the class of L^+-mixing processes is closed under addition, it follows that $(H_0(s, x^*, \omega))$ is also L^+-mixing and the proof is complete. □

Remark. There is no loss of generality to assume that

$$\gamma_q(\tau, H_0) \le C_q (1 + \tau)^{-1-c_q}$$

for all $\tau \ge 0$ with the same C_q, c_q as in Condition 3.1 requiring that H and $\Delta H / \Delta x$ be L^+-mixing.

To formulate the basic result of this section we need some notations. Denoting the autocovariance matrix of $H_0(s, x^*, \omega)$ by $\rho(\tau)$, i.e., setting

$$\rho(\tau) = \mathrm{E}\,[H_0(s + \tau, x^*, \omega) H_0^T(s, x^*, \omega)] = \mathrm{E}\,[H_0(\tau, x^*, \omega) H_0^T(0, x^*, \omega)],$$

we define a basic quantity:

$$P^* = \int_{-\infty}^{\infty} \rho(\tau) d\tau. \tag{6.3}$$

Since the process $(H_0(s, x^*, \omega))$ is L-mixing, the above integral converges. Indeed, since $H_0 = (H_0(s, x^*, \omega))$ is a wide-sense stationary zero-mean L-mixing process, using Lemma 8.1 with $p = q = 2$, we get

$$\rho(\tau) \le C \gamma_2(|\tau|, H_0) \tag{6.4}$$

with some $C > 0$, thus integrability follows.

It is easy to see, cf. Lemma 6.4 below, that the matrix P^* is the asymptotic covariance matrix of the arithmetic mean

$$\frac{1}{2T} \int_{-T}^{T} H_0(s, x^*, \omega) ds,$$

i.e., we have

$$P^* = \lim_{T \to \infty} 2T\ \mathrm{E}\ \left[\left(\frac{1}{2T} \int_{-T}^{T} H_0(s, x^*, \omega) ds \right) \left(\frac{1}{2T} \int_{-T}^{T} H_0(s, x^*, \omega) ds \right)^T \right]. \tag{6.5}$$

We will also need the notation introduced in (3.24):

$$A^* = \left.\frac{\partial G(x)}{\partial x}\right|_{x=x^*}.$$

The value of the asymptotic covariance matrix can be easily guessed. Namely, the assumed validity of (5.3) implies that, $t^{1/2}(x_t - x^*)$ is asymptotically normally distributed with zero mean and covariance matrix S^*, which satisfies the Lyapunov equation (6.6) below. This result on the asymptotic covariance matrix of the estimator has strong roots in the classical theory of stochastic approximation; see [54]. The closest to our result is Theorem 13, Chapter 4.5, Part II of [3].

THEOREM 6.2. *Consider the continuous-time recursive estimation scheme given by* (3.16) *with the resetting mechanism* (3.17) *and* (3.18). *Assume that the conditions of Theorem* 4.1 *are satisfied and in addition* $(H(s, x^*, \omega))$ *satisfies Condition* 6.1. *Then the asymptotic covariance matrix of the error process* $(x_t - x^*)$, *defined by*

$$S^* = \lim_{t\to\infty} t\mathrm{E}[(x_t - x^*)(x_t - x^*)^T],$$

exists and it satisfies the Lyapunov equation

$$(A^* + I/2)S^* + S^*(A^* + I/2)^T + P^* = 0, \tag{6.6}$$

where A^* *is defined, (see also* (3.24)*) and* P^* *is defined by* (6.3). *More exactly we have with some* $\varepsilon_{xx} > 0$

$$\mathrm{E}[(x_t - x^*)(x_t - x^*)^T] = \frac{1}{t}S^* + O(t^{-1-\varepsilon_{xx}}).$$

Remark. In the case of a stochastic Newton method, i.e. when $A^* = -I$, we get

$$S^* = P^*.$$

In the context of Algorithm DFL, (3.53)–(3.54), this can be directly seen from Theorem 4.4.

Take the example of the recursive least squares (LSQ) estimation of an AR(p) process given

$$y_n = (\theta^*)^T\phi_n + e_n,$$

where θ^* is the p-dimensional AR-parameter, $\phi_n = (-y_{n-1}, \dots, -y_{n-p})^T$, and e_n is the noise term with variance $\sigma^2(e)$. AR processes are special in the sense that the off-line LSQ estimator can be computed *exactly* in a recursive fashion, thus the off-line and online estimators, if properly initialized, coincide and their asymptotic covariance is the same. A nontrivial corollary of Theorem 6.2 is that this is still the case if both estimators are forced to stay inside a compact domain using truncation for the off-line estimator and resetting for the online estimator.

Let

$$R^* = \mathrm{E}\phi_n\phi_n^T$$

assuming stationarity of ϕ_n. Then, under well-known conditions the asymptotic covariance matrix of the LSQ estimator is known to be

$$S^* = \sigma^2(e)(R^*)^{-1}.$$

For the recursive least squares (RLSQ) estimator we have the updating term, with $x = \theta$,

$$H_n(s, \theta, \omega) = R^{-1}\phi_n(y_n - \phi_n^T\theta)$$

from which we get

$$G(\theta) = \theta^* - \theta,$$

thus the RLSQ method is a stochastic Newton method. Since

$$H_n(s, \theta^*, \omega) = R^{-1}\phi_n e_n,$$

we get

$$P^* = \sigma^2(e)(R^*)^{-1}$$

which indeed agrees with S^*.

Remark. For the discrete-time method, Algorithm DR, we have

$$x_t^l - x^* = \int_1^t \frac{\partial}{\partial \xi} y(t, s, x^*)\frac{1}{s}H^c(s, x^*, \omega)ds + O_M(t^{-1/2-\varepsilon_x});$$

see (4.40) and the analysis given below is applicable. Note however that now we get the familiar expression, see [54],

(6.7)
$$P^* = \int_{-\infty}^{\infty} \mathrm{E}\,[H_0^c(\tau, x^*, \omega)H_0^{cT}(0, x^*, \omega)]d\tau = \sum_{-\infty}^{\infty} \mathrm{E}\,[H_0(m, x^*, \omega)H_0^T(0, x^*, \omega)].$$

Proof of Theorem 6.2.

Reduction to the process $(\tilde{x}_{3,nh})$. The claim of the theorem can be reformulated in terms of the transformed process, with $t = e^r$, as follows: we have with some $\varepsilon_{xx} > 0$

$$\mathrm{E}[\tilde{x}_r\tilde{x}_r^T] = S^* + O(e^{-\varepsilon_{xx}r}). \tag{6.8}$$

Now by Lemma 5.1 we have with $r = nh$ the following expression for $x_t - x^* = e^{-r/2}\tilde{x}_r$:

$$\frac{1}{e^{nh/2}}\tilde{x}_{3,nh} + \frac{1}{e^{nh/2}}O_M(e^{-\varepsilon_x nh} + h^{1/2}e^{-\varepsilon_{x2}nh} + h^{-c}e^{-\varepsilon_{x3}nh}). \tag{6.9}$$

Multiplying both sides by $e^{nh/2}$, squaring them, and taking into account the second part of Lemma 5.1, we get the following key lemma.

Lemma 6.1. *We have with* $r = nh$,

$$\mathrm{E}[\tilde{x}_r\tilde{x}_r^T] = \mathrm{E}[\tilde{x}_{3,nh}\tilde{x}_{3,nh}^T] + O(e^{-\varepsilon_x nh} + h^{1/2}e^{-\varepsilon_{x2}nh} + h^{-c}e^{-\varepsilon_{x3}nh}). \tag{6.10}$$

This error estimate seems to be fragile, due to Terms 3 and 4 on the right-hand side, in view of the fact that the left-hand side is $O(h)$, but this weakness will be eliminated at the very end of the proof of Theorem 6.2 by appropriate choice of h.

Thus the study of the covariance matrix of x_t is reduced to the study of the covariance matrix of $\tilde{x}_{3,nh}$, which will be denoted by $R_{3,n}^{\tilde{x}}$:

$$R_{3,n}^{\tilde{x}} = \mathrm{E}\,[\tilde{x}_{3,nh}\tilde{x}_{3,nh}^T].$$

Now change n to $n+1$ and note that $\tilde{x}_{3,(n+1)h}$ is defined via the discrete-time dynamical system (5.22), in which the input process $(\tilde{u}_{3,n+1})$ consists of a sequence of independent random variables. The covariance matrix of $\tilde{u}_{3,m}$ will be denoted by

$$R^{\tilde{u}}_{3,m} = \mathrm{E}[\tilde{u}_{3,m}\tilde{u}^T_{3,m}].$$

In what follows we shall develop a sequence of approximations of $\tilde{u}_{3,m}$ to get a nice approximation for $R^{\tilde{u}}_{3,m}$.

The approximating process $(\tilde{u}_{4,m})$. Let us recall, see (5.9), that in the original time-scale we have

$$\tilde{u}_{1,m+1} = \int_{e^{mh}}^{e^{(m+1)h}} \left(\frac{s}{e^{(m+1)h}}\right)^{(-A^*-I/2)} \frac{1}{s^{1/2}} H(s, x^*, \omega) ds.$$

Approximate $\tilde{u}_{1,m+1}$ by replacing the kernel within the integrand by 1; i.e., set

$$\tilde{u}_{4,m+1} = \int_{e^{mh}}^{e^{(m+1)h}} \frac{1}{s^{1/2}} H(s, x^*, \omega) ds.$$

Claim U4. *We have*

$$\tilde{u}_{1,m+1} - \tilde{u}_{4,m+1} = O_M(h^{3/2}). \tag{6.11}$$

To prove the claim note that the approximation error can be written as

$$\tilde{u}_{1,m+1} - \tilde{u}_{4,m+1} = \int_{e^{mh}}^{e^{(m+1)h}} \left(\left(\frac{s}{e^{(m+1)h}}\right)^{(-A^*-I/2)} - I\right) \frac{1}{s^{1/2}} H(s, x^*, \omega) ds.$$

Using the moment inequality given as Theorem 8.1 we get for any $q \geq 2$ that $\mathrm{E}^{1/q}|\tilde{u}_{1,m+1} - \tilde{u}_{4,m+1}|^q$ is bounded from above by

$$C_q \left(\int_{e^{mh}}^{e^{(m+1)h}} \left\| \left(\left(\frac{s}{e^{(m+1)h}}\right)^{(-A^*-I/2)} - I\right) \frac{1}{s^{1/2}} \right\|^2 ds\right)^{1/2} M_q^{1/2}(H(x^*))\Gamma_q^{1/2}(H(x^*)).$$

Now, $\|(s/e^{(m+1)h})^{(-A^*-I/2)} - I\| = \|e^{(-A^*-I/2)(\log s - (m+1)h)} - I\| \leq ch$, with some c, which depends only on A^*, for $0 < h \leq h_0$, since $-h \leq (\log s - (m+1)h) \leq 0$. (Apply a Taylor series expansion of the matrix exponential to get the desired inequality.) Thus we get

$$\mathrm{E}^{1/q}|\tilde{u}_{1,m+1} - \tilde{u}_{4,m+1}|^q \leq C_q \left(\int_{e^{mh}}^{e^{(m+1)h}} (ch)^2 \frac{1}{s} ds\right)^{1/2} M_q^{1/2}(H(x^*))\Gamma_q^{1/2}(H(x^*)),$$

and from here

$$\mathrm{E}^{1/q}|\tilde{u}_{1,m+1} - \tilde{u}_{4,m+1}|^q \leq Ch^{3/2},$$

where C is independent of h and thus Claim U4 follows.

The approximating process $(\tilde{u}_{5,m+1})$. This approximation is obtained by replacing $\frac{1}{s^{1/2}}$ within the integral by a constant:

$$\tilde{u}_{5,m+1} = \frac{1}{e^{mh/2}} \int_{e^{mh}}^{e^{(m+1)h}} H(s, x^*, \omega) ds.$$

CLAIM U5. *We have*

$$\tilde{u}_{4,m+1} - \tilde{u}_{5,m+1} = O_M(h^{3/2}). \tag{6.12}$$

Indeed, we have

$$\tilde{u}_{5,m+1} - \tilde{u}_{4,m+1} = \int_{e^{mh}}^{e^{(m+1)h}} \left(\frac{1}{e^{mh/2}} - \frac{1}{s^{1/2}} \right) H(s, x^*, \omega) ds,$$

and we can apply the moment inequality given as Theorem 8.1. For this purpose we estimate the integrand

$$0 \le \left(\frac{1}{e^{mh/2}} - \frac{1}{s^{1/2}} \right) \le \left(\frac{1}{e^{mh/2}} - \frac{1}{e^{(m+1)h/2}} \right) \le \frac{1}{(e^{mh/2})^2} (e^{(m+1)h/2} - e^{mh/2})$$

$$\le \frac{1}{e^{mh/2}} (e^{h/2} - 1) \le \frac{1}{e^{mh/2}} h$$

for small h. Thus we get the following upper bound for $\mathrm{E}^{1/q} |\tilde{u}_{5,m+1} - \tilde{u}_{4,m+1}|^q$ with $q \ge 2$:

$$C_q \left(\int_{e^{mh}}^{e^{(m+1)h}} \left(\frac{1}{e^{mh/2}} - \frac{1}{s^{1/2}} \right)^2 ds \right)^{1/2} M_q^{1/2}(H(x^*)) \Gamma_q^{1/2}(H(x^*))$$

$$\le C_q \left(\int_{e^{mh}}^{e^{(m+1)h}} \frac{h^2}{e^{mh}} ds \right)^{1/2} M_q^{1/2}(H(x^*)) \Gamma_q^{1/2}(H(x^*)) = O(h^{3/2}),$$

and the claim follows.

The approximating process $(\tilde{u}_{6,m+1})$. This approximation is obtained by replacing $H(s, x^*, \omega)$ by $H_0(s, x^*, \omega)$ in the definition of $\tilde{u}_{6,m+1}$, i.e., we define

$$\tilde{u}_{6,m+1} = \frac{1}{e^{mh/2}} \int_{e^{mh}}^{e^{(m+1)h}} H_0(s, x^*, \omega) ds. \tag{6.13}$$

CLAIM U6. *We have*

$$\tilde{u}_{5,m+1} - \tilde{u}_{6,m+1} = O_M(h e^{-mh(1/2+\varepsilon_H)}) \quad \textit{and} \quad \tilde{u}_{5,m+1} - \tilde{u}_{6,m+1} = O_M(h^{1/2}). \tag{6.14}$$

Indeed, we have, using (6.1),

$$\tilde{u}_{5,m+1} - \tilde{u}_{6,m+1} = \frac{1}{e^{mh/2}} \int_{e^{mh}}^{e^{(m+1)h}} \eta_s ds$$

$$= \frac{1}{e^{mh/2}} (e^{(m+1)h} - e^{mh}) O_M(e^{-mh(1+\varepsilon_H)}) = O_M(h e^{-mh(1/2+\varepsilon_H)})$$

and the first part of the claim follows. The second part is a direct consequence of Theorem 8.1.

Summarizing the equations expressing the approximation errors between the successive values $\tilde{u}_3, \tilde{u}_2, \tilde{u}_1, \tilde{u}_4, \tilde{u}_5, \tilde{u}_6$ given by (5.14), (5.18), (6.11), (6.12), (6.14) we get the following lemma.

LEMMA 6.2. *Let c be as in Condition* 3.1*, requiring that H be L^+-mixing. Then we have*

$$\tilde{u}_{3,m} = \tilde{u}_{6,m} + \delta\tilde{u}, \tag{6.15}$$

where

$$\delta\tilde{u} = O_M(h^{-c}e^{-(1/2+c\varepsilon_\delta)mh} + h^{1/2}e^{-(1-\varepsilon_\delta)mh/2} + h^{3/2} + he^{-mh(1/2+\varepsilon_H)}),$$

and all error terms are also $O_M(h^{1/2})$.

Squaring this equation we get, for $R^{\tilde{u}}_{3,m+1} = \mathrm{E}\,[\tilde{u}_{3,m}\tilde{u}^T_{3,m}]$,

$$R^{\tilde{u}}_{3,m+1} = \mathrm{E}\,[\tilde{u}_{6,m}\tilde{u}^T_{6,m}] + \delta R, \tag{6.16}$$

where

$$\delta R = O(h^{1/2-c}e^{-(1/2+c\varepsilon_\delta)mh} + he^{-(1-\varepsilon_\delta)mh/2} + h^2 + h^{3/2}e^{-mh(1/2+\varepsilon_H)}).$$

The covariance matrix of $\tilde{u}_{6,m+1}$. Next we show that the covariance matrix of the approximation $\tilde{u}_{6,m+1}$ can be expressed in terms of the matrix P^*. This is no surprise in view of the assumed validity of (6.5), but to capture the rate of convergence extra work is needed.

LEMMA 6.3. *Let c be as in Condition* 3.1, *requiring that H be L^+-mixing. Then we have*

$$\mathrm{E}[\tilde{u}_{6,m+1}\tilde{u}^T_{6,m+1}] = hP^* + O(h^{1-c}e^{-cmh}). \tag{6.17}$$

Proof. Consider normalized arithmetic means of the form

$$s_{A,B} = \frac{1}{(B-A)^{1/2}}\int_A^B H_0(s, x^*, \omega)ds$$

with $A < B$. It is obvious that

$$\mathrm{E}\,[s_{A,B}\ s^T_{A,B}] = \frac{1}{B-A}\int_A^B\int_A^B \rho(s-s')\ ds\ ds',$$

where $\rho(\tau)$ is the autocovariance function of the process $H_0 = (H_0(s, x^*, \omega))$.

Note that if $H_0 = (H_0(s, x^*, \omega))$ is a wide-sense stationary zero-mean L^+-mixing process then we have, using (6.4) and the inequality $\gamma_2(|\tau|, H_0) \le C(1+|\tau|)^{-c}$,

$$\rho(\tau) \le C(1+|\tau|)^{-c} \tag{6.18}$$

with some $C, c > 0$. Applying Lemma 6.4 below with

$$A = e^{mh} \quad \text{and} \quad B = e^{(m+1)h},$$

we have $(B-A) = e^{mh}(h + O(h^2))$ for small h. Thus we get, using the inequality $(1+B-A)^{-c} < C'(B-A)^{-c}$,

$$\frac{1}{B-A}\int_A^B\int_A^B \rho(s-s')\ ds\ ds' = P^* + O(e^{-cmh}h^{-c}),$$

and from here we get for the covariance matrix of $\tilde{u}_{6,m+1}$,

$$\mathrm{E}[\tilde{u}_{6,m+1}\tilde{u}^T_{6,m+1}] = \frac{1}{e^{mh}}\int_{e^{mh}}^{e^{(m+1)h}}\int_{e^{mh}}^{e^{(m+1)h}} \rho(s-s')dsds' = \frac{B-A}{e^{mh}}(P^* + O(e^{-cmh}h^{-c})),$$

and Lemma 6.3 follows. ∎

LEMMA 6.4. *Let $(\rho(\tau))$, $-\infty < \tau < \infty$, be a matrix-valued measurable function process, satisfying $||\rho(\tau)|| \le C(1+|\tau|)^{-c}$ with some $C, c > 0$. Then we have for any $A < B$*

$$\frac{1}{B-A}\int_A^B \int_A^B \rho(s-s')ds\ ds' = P^* + O((1+B-A)^{-c}).$$

Proof. Introduce the new variables $\tau = s - s', \mu = s + s'$. This change of coordinates has a Jacobian with determinant 2, i.e., $d\tau\ d\mu = 2ds\ ds'$. The new variable τ takes its values between $-(B-A)$ and $B-A$ and for each fixed τ the possible values of μ are in the interval $(2A+|\tau|, 2B-|\tau|)$. Thus

$$\begin{aligned} P_{A,B} &= \frac{1}{B-A}\int_{-(B-A)}^{B-A}\int_{2A+|\tau|}^{2B-|\tau|} \rho(\tau)\frac{1}{2}d\tau\ d\mu \\ &= \frac{1}{B-A}\int_{-(B-A)}^{B-A}(2B-2A-2|\tau|)\rho(\tau)\frac{1}{2}d\tau\ d\mu = \int_{-(B-A)}^{B-A}\left(1-\frac{|\tau|}{B-A}\right)\rho(\tau)d\tau. \end{aligned}$$

From here it follows immediately that $||P_{A,B}||$ can be written as

$$\left\|\frac{1}{B-A}\int_A^B\int_A^B \rho(s-s')ds\ ds'\right\| \le \int_{-(B-A)}^{B-A}||\rho(\tau)||d\tau \le \int_{-\infty}^{\infty}||\rho(\tau)||d\tau. \tag{6.19}$$

This inequality will be used subsequently. Now, write

$$\int_{-(B-A)}^{B-A}\left(1-\frac{|\tau|}{B-A}\right)\rho(\tau)d\tau = \int_{-(B-A)}^{B-A}\rho(\tau)d\tau - \int_{-(B-A)}^{B-A}\frac{|\tau|}{B-A}\rho(\tau)d\tau.$$

Then

$$\begin{aligned} \int_{-(B-A)}^{B-A}\rho(\tau)d\tau - P^* &= \int_{-(B-A)}^{B-A}\rho(\tau)d\tau - \int_{-\infty}^{\infty}\rho(\tau)d\tau \\ &= -\int_{-\infty}^{-(B-A)}\rho(\tau)d\tau - \int_{B-A}^{\infty}\rho(\tau)d\tau. \end{aligned}$$

Taking into account that $||\rho(\tau)|| \le C(1+|\tau|)^{-1-c}$, we get that

$$\left\|-\int_{-\infty}^{-(B-A)}\rho(\tau)d\tau - \int_{B-A}^{\infty}\rho(\tau)d\tau\right\| \le \frac{2C}{c}(1+B-A)^{-c}. \tag{6.20}$$

On the other hand,

$$\int_{-(B-A)}^{B-A}\frac{|\tau|}{B-A}||\rho(\tau)||d\tau \le \int_{-(B-A)}^{B-A}\frac{|\tau|}{B-A}C(1+|\tau|)^{-1-c}d\tau.$$

Write $|\tau|C(1+|\tau|)^{-1-c} \le (1+|\tau|)C(1+|\tau|)^{-1-c} = C(1+|\tau|)^{-c}$ and use the symmetry of the last integrand above to get the upper bound

$$\begin{aligned} 2\int_0^{B-A}\frac{1}{B-A}C(1+\tau)^{-c}d\tau &\le \frac{2}{B-A}\frac{C}{(-c+1)}(1+\tau)^{-c+1}|_0^{B-A} \\ &= \frac{2}{B-A}\frac{C}{(-c+1)}((1+B-A)^{-c+1}-1)) \le C'(1+B-A)^{-c} \end{aligned}$$

and combining this with (6.20) the proposition of the lemma follows. □

The final approximation of $R^{\tilde{u}}_{3,m+1}$. Combining (6.16) and (6.17) we get

$$\begin{aligned} R^{\tilde{u}}_{3,m+1} &= \mathrm{E}[\tilde{u}_{3,m}\tilde{u}^T_{3,m}] \\ &= hP^* + O(h^{1-c}e^{-cmh} + h^{1/2-c}e^{-(1/2+c\varepsilon_\delta)mh} \\ &\quad + he^{-(1-\varepsilon_\delta)mh/2} + h^2 + h^{3/2}e^{-mh(1/2+\varepsilon_H)}). \end{aligned} \tag{6.21}$$

To simplify notations write the residual terms in the form $h^{\beta_i}e^{-\varepsilon_i mh}$, $i = 1, \dots, 5$, with

$$\begin{aligned} &\beta_1 = 1 - c, && \varepsilon_1 = c, \\ &\beta_2 = 1/2 - c, && \varepsilon_2 = 1/2 + c\varepsilon_\delta, \\ &\beta_3 = 1, && \varepsilon_3 = (1 - \varepsilon_\delta)/2, \\ &\beta_4 = 2, && \varepsilon_4 = 0, \\ &\beta_5 = 3/2, && \varepsilon_5 = 1/2 + \varepsilon_H. \end{aligned} \tag{6.22}$$

Obviously we have $\varepsilon_i > 0$ for $i \neq 4$. For $i = 4$ we have $\varepsilon_4 = 0$, but then $\beta_4 = 2$. With this notations we can formulate the following lemma.

LEMMA 6.5. *We have with* $h^{\beta_i}e^{-\varepsilon_i mh}$, $i = 1, \dots, 5$, *defined under* (6.22)

$$R^{\tilde{u}}_{3,m+1} = \mathrm{E}\,[\tilde{u}_{3,m}\tilde{u}^T_{3,m}] = hP^* + \sum_{i=1}^{5} O(h^{\beta_i}e^{-\varepsilon_i mh}). \tag{6.23}$$

The discrete-time Lyapunov equation. Consider the discrete-time dynamics followed by $(\tilde{x}_{3,nh})$, given by (5.22). Since the input process is a sequence of independent random variables it follows that the covariance matrix of $\tilde{x}_{3,nh}$, denoted by $R^{\tilde{x}}_{3,n}$ $R^{\tilde{x}}_{3,n+1}$, satisfies the Lyapunov equation

$$R^{\tilde{x}}_{3,n+1} = e^{(A^*+I/2)h}R^{\tilde{x}}_{3,n}e^{(A^*+I/2)^T h} + R^{\tilde{u}}_{3,n+1},$$

with zero initial condition. Substituting $R^{\tilde{u}}_{3,n+1}$ from (6.23) and setting $n = m$, we get

$$R^{\tilde{x}}_{3,m+1} = e^{(A^*+I/2)h}R^{\tilde{x}}_{3,m}e^{(A^*+I/2)^T h} + hP^* + \sum_{i=1}^{5} O(h^{\beta_i}e^{-\varepsilon_i mh}). \tag{6.24}$$

Solving this iteratively in the range $0 \le m \le n$ we get

$$\begin{aligned} R^{\tilde{x}}_{3,n+1} &= \sum_{m=0}^{n} e^{(A^*+I/2)(n-m)h}\ hP^*\ e^{(A^*+I/2)^T(n-m)h} \\ &\quad + \sum_{m=0}^{n} e^{(A^*+I/2)(n-m)h}\left(\sum_{i=1}^{5} h^{\beta_i}e^{-\varepsilon_i mh}\right)e^{(A^*+I/2)^T(n-m)h}. \end{aligned} \tag{6.25}$$

The contributions of the terms $h^{\beta_i}e^{-\varepsilon_i mh}$, $i = 1, \dots, 5$, are estimated as follows:

$$\begin{aligned} \Delta_i &= \left\| \sum_{m=0}^{n} e^{(A^*+I/2)(n-m)h}Ch^{\beta_i}e^{-\varepsilon_i mh}e^{(A^*+I/2)^T(n-m)h} \right\| \\ &\le C' \sum_{m=0}^{n} e^{-2\overline{\alpha}(n-m)h} \cdot h^{\beta_i}e^{-\varepsilon_i mh}. \end{aligned}$$

Applying Lemma 8.5 we get, assuming that $2\overline{\alpha} \neq \varepsilon_i$, with

$$\overline{\varepsilon}_i = \min(2\overline{\alpha}, \varepsilon_i) \tag{6.26}$$

the upper bound

$$\Delta_i \leq C' h^{\beta_i} e^{-\overline{\varepsilon}_i nh} / |e^{2\overline{\alpha}h} - e^{\varepsilon_i h}| = O(h^{\beta_i - 1} e^{-\overline{\varepsilon}_i nh}), \tag{6.27}$$

and thus

$$\begin{aligned} R^{\tilde{x}}_{3,n+1} &= \sum_{m=0}^{n} e^{(A^* + I/2)(n-m)h}\ hP^*\ e^{(A^* + I/2)^T (n-m)h} \\ &\quad + \sum_{m=0}^{n} O(h^{\beta_i - 1} e^{-\overline{\varepsilon}_i nh}). \end{aligned} \tag{6.28}$$

Obviously we have $\overline{\varepsilon}_i > 0$ for $i \neq 4$. For $i = 4$ we have $\overline{\varepsilon}_4 = 0$, but then $\beta_4 = 2$.

Next we consider the first dominant term on the right-hand side of (6.28) and define its approximation by setting $m' = n - m$ and extending the summation to ∞:

$$R^{\tilde{x}d}_{3,n+1} = \sum_{m=0}^{n} e^{(A^* + I/2)(n-m)h} hP^* e^{(A^* + I/2)^T (n-m)h}, \tag{6.29}$$

$$R^{\tilde{x}}_{3*} = \sum_{m'=0}^{\infty} e^{(A^* + I/2)m'h} hP^* e^{(A^* + I/2)^T m'h}. \tag{6.30}$$

Claim. *We have*

$$R^{\tilde{x}d}_{3,n+1} - R^{\tilde{x}}_{3*} = O(e^{-2\overline{\alpha}nh}). \tag{6.31}$$

Indeed, writing $m' = n - m$ and taking out the left factor $e^{(A^* + I/2)(n+1)h}$ and the right factor $e^{(A^* + I/2)^T (n+1)h}$ we have

$$\begin{aligned} R^{\tilde{x}d}_{3,n+1} - R^{\tilde{x}}_{3*} &= \sum_{m'=n+1}^{\infty} e^{(A^* + I/2)m'h} hP^* e^{(A^* + I/2)^T m'h} \\ &= e^{(A^* + I/2)(n+1)h} \left(\sum_{m=0}^{\infty} e^{(A^* + I/2)mh} hP^* e^{(A^* + I/2)^T mh} \right) e^{(A^* + I/2)^T (n+1)h}, \end{aligned}$$

the operator norm of which is obviously majorized by $C' e^{-2\overline{\alpha}nh}$, as claimed.

Lemma 6.6. *We have*

$$R^{\tilde{x}}_{3*} - S^* = O(h). \tag{6.32}$$

Proof. The covariance matrix $R^{\tilde{x}}_{3*}$ is the solution of the algebraic Lyapunov equation

$$R^{\tilde{x}}_{3*} = e^{(A^* + I/2)h} R^{\tilde{x}}_{3*} e^{(A^* + I/2)^T h} + hP^*.$$

Taking into account the equality $e^{(A^* + I/2)h} = I + (A^* + I/2)h + O(h^2)$, this can be written as

$$R^{\tilde{x}}_{3*} = (I + (A^* + I/2)h + O(h^2)) R^{\tilde{x}}_{3*} (I + (A^* + I/2)^T h + O(h^2)) + hP^*,$$

which is simplified to

$$0 = (A^* + I/2)R_{3*}^{\tilde{x}} + R_{3*}^{\tilde{x}}(A^* + I/2)^T + P^* + O(h),$$

and the stability of $(A^* + I/2)$ implies the claim. □

Combining (6.28), (6.31), and (6.32) we get, assuming that $2\overline{\alpha} \neq \varepsilon_i$,

$$R_{3,n+1}^{\tilde{x}} = S^* + O(e^{-2\overline{\alpha}nh} + h) + \sum_{i=1}^{5} O(h^{\beta_i - 1} e^{-\overline{\varepsilon}_i nh}). \tag{6.33}$$

The final approximation of $R_{3,n+1}^{\tilde{x}}$. For a given r we choose h and n in the following way: let $\varepsilon_h > 0$ and let h satisfy

$$e^{-\varepsilon_h r} \leq h \leq 2e^{-\varepsilon_h r}, \tag{6.34}$$

and in addition let r be an integer multiple of h, say, $r = nh$. Then from (6.33) we get

$$R_{3,n+1}^{\tilde{x}} = S^* + O(e^{-2\overline{\alpha}nh} + e^{-\varepsilon_h nh}) + \sum_{i=1}^{5} O(e^{-(\beta_i - 1)\varepsilon_h nh} e^{-\overline{\varepsilon}_i nh}). \tag{6.35}$$

Combining this with (6.10) and substituting $h = e^{-\varepsilon_h r} = e^{-\varepsilon_h nh}$ we get

$$\begin{aligned} \mathrm{E}[\tilde{x}_{nh}\tilde{x}_{nh}^T] &= S^* + O(e^{-2\overline{\alpha}nh} + e^{-\varepsilon_h nh}) + \sum_{i=1}^{5} O(e^{-(\beta_i - 1)\varepsilon_h nh} e^{-\overline{\varepsilon}_i nh}) \\ &\quad + O(e^{-\varepsilon_x nh} + e^{-\varepsilon_h nh/2} e^{-\varepsilon_{x2} nh} + e^{c\varepsilon_h nh} e^{-\varepsilon_{x3} nh}). \end{aligned} \tag{6.36}$$

The generic form of the error terms is $O(e^{-\gamma nh})$, where the values of γ are the following:

$$\begin{array}{lll} 2\overline{\alpha}, & \varepsilon_h, & (\beta_i - 1)\varepsilon_h + \overline{\varepsilon}_i,\ i = 1, \ldots, 5, \\ \varepsilon_x, & \varepsilon_h/2 + \varepsilon_{x2}, & c\varepsilon_h - \varepsilon_{x3}. \end{array}$$

Obviously for sufficiently small ε_h all these constants are positive and thus (6.8) and the claim of Theorem 6.2 follows. □

7. Two applications. The usefulness of the results of the present paper is demonstrated by describing two applications. In the first example the pathwise cumulative regret is quantified for an online adaptive predictor of multivariable linear stochastic systems; see (7.8). It is a previously unpublished result, presented at MTNS '96. In the second example a similar measure of performance degradation for the minimum-variance self-tuning regulator is considered. This problem, that had been formulated as far back as 1971 in [2] in a slightly different context from ours, has been solved only in 1994; see [28]. The result of [28] is restated in (7.19). A further application for indirect adaptive control of multivariable linear stochastic systems is given in [27]. All these applications rely on the results of the present paper, in particular Theorems 4.3, 5.1, and 6.2.

Multivariable adaptive prediction. Let (y_n), $0 \leq n < \infty$, be a vector-valued, wide-sense stationary stochastic process defined by a finite-dimensional linear stochastic system:

$$y = H(\theta^*)e. \tag{7.1}$$

Here $H(\theta) = I + C(\theta)(q^{-1}I - A(\theta))^{-1}B(\theta)$ is a square, causal, rational transfer function of the backward shift operator q^{-1}.

CONDITION 7.1. *$H(\theta)$ is defined for $\theta \in D$, where $D \subset \mathbb{R}^p$ is an open set and in its state-space realization the matrices $(A(\theta), B(\theta), C(\theta))$ are twice continuously differentiable functions of θ. Moreover, $H(\theta)$ is stable and inverse stable.*

CONDITION 7.2. *The system-noise process (e_n), $0 \leq n < \infty$, is an M-bounded, vector-valued wide-sense stationary orthogonal process. In addition there is an increasing sequence of σ-fields $(\mathcal{F}_n)$, $0 \leq n < \infty$, such that (e_n) is a martingale difference process with constant conditional covariance:*

$$\mathrm{E}\,[e_n|\mathcal{F}_{n-1}] = 0, \qquad \mathrm{E}(e_n e_n^T|\mathcal{F}_{n-1}) = \Lambda^*$$

almost surely, with $\Lambda^* > 0$.

These conditions will be called the standard conditions for multivariable linear stochastic systems. In the multivariable version of the prediction error method we have to estimate θ^* and Λ^* jointly to improve efficiency. Let $\theta \in D$ and let Λ be a symmetric positive definite matrix and then define the second order stationary process $\bar{\varepsilon}(\theta)$ by

$$\bar{\varepsilon}(\theta) = H^{-1}(\theta)y.$$

Then define the cost function

$$V_N(\theta, \Lambda) = \frac{1}{2}\sum_{n=1}^{N} \bar{\varepsilon}_n^T(\theta)\Lambda^{-1}\bar{\varepsilon}_n(\theta) + \frac{N}{2}\log\ \det\Lambda. \tag{7.2}$$

If (e_n) is an i.i.d. sequence of Gaussian random vectors with distribution $N(0, \Lambda^*)$, then $V_N(\theta, \Lambda)$ is the negative conditional log-likelihood function, except for an additive constant. This cost function will be minimized in (θ_N, Λ_N) and the minimizing value, the off-line estimator of (θ^*, Λ^*) will be denoted by $(\widehat{\theta}_N, \hat{\Lambda}_N)$. A more precise definition of $(\widehat{\theta}_N, \hat{\Lambda}_N)$, taking into account the possibility of the existence of several local minima, can be given following [18].

Define the asymptotic cost function by

$$W(\theta, \Lambda) = \lim_{n\to\infty} \frac{1}{2}\mathrm{E}\,[\bar{\varepsilon}_n^T(\theta)\Lambda^{-1}\bar{\varepsilon}_n(\theta)] + \frac{1}{2}\log\ \ \det\Lambda. \tag{7.3}$$

It is easy to see that for any symmetric, positive definite Λ,

$$W_\theta(\theta^*, \Lambda) = 0. \tag{7.4}$$

The Hessian of W with respect to θ at (θ^*, Λ^*) is

$$R^* = W_{\theta\theta}(\theta^*, \Lambda^*) = \lim_{n\to\infty} \mathrm{E}\,[\bar{\varepsilon}_{\theta n}^T(\theta^*)(\Lambda^*)^{-1}\bar{\varepsilon}_{\theta n}(\theta^*)]. \tag{7.5}$$

The above cost function can be treated with the extension of the DFL scheme indicated by an alternative definition of the random filed $H(n, x, \omega)$ in (3.47).

CONDITION 7.3. *Equation* (7.4) *has a unique solution $\theta = \theta^*$ for any symmetric, positive definite Λ and the Hessian matrix $W_{\theta\theta}(\theta^*, \Lambda^*)$ is positive definite.*

The *performance index* of interest is the squared absolute value of the prediction error. Let $\Sigma_{\theta\theta}$ be the asymptotic covariance matrix of the off-line prediction error estimator $\widehat{\theta}_n$. Then it is well known that $\Sigma_{\theta\theta} = (R^*)^{-1}$. Let

$$T^* = 2\frac{\partial^2}{\partial\theta^2} \lim_{n\to\infty} \mathrm{E}\,[\bar{\varepsilon}_n^T(\theta)\bar{\varepsilon}_n(\theta)]\ \big|_{\theta=\theta^*} \tag{7.6}$$

be the second order sensitivity matrix of the performance index. Then we have the following result.

THEOREM 7.1. *Let us consider a multivariable system satisfying Conditions* 7.1, 7.2, *and* 7.3. *In addition assume that* (e_n) *is L-mixing. Then we have almost surely*

$$\lim_{N\to\infty}\sum_{n=1}^{N}(|\overline{\varepsilon}_n(\widehat{\theta}_{n-1})|^2-|e_n|^2)/\log N=\frac{1}{2}\mathrm{Tr}T^*\Sigma_{\theta\theta}. \tag{7.7}$$

The expression $\frac{1}{2}\mathrm{Tr}T^*$ will be called the *normalized cost of adaptation*. An important difference between ARMA and multivariable systems is that, unless $\Lambda^*\neq cI$, with c being a scalar, the trace formula given on the right-hand side of (7.7) cannot be further simplified. However, it can be shown that $\frac{1}{2}\mathrm{Tr}T^*\Sigma_{\theta\theta}$ is invariant with respect to diffeomorphic transformation of the parameter space, while restriction of the parameter space, i.e., writing $\theta=g(\eta)$ with $\dim\eta<\dim\theta$, with g being a smooth function, reduces the normalized cost of adaptation. Note that, the normalized cost of adaptation is not determined solely by structural parameters, it may depend also on the actual multivariable system, unlike in the ARMA case.

To extend this result for adaptive predictors defined in terms of recursive estimators we rely on Theorem 4.3 and we get the following result.

CLAIM. *Let* $\widehat{\widehat{\theta}}_n$ *be a recursive estimator of* θ^* *with asymptotic covariance matrix* $\overline{\Sigma}_{\theta\theta}$. *Then under appropriate technical conditions, obtained by specializing the conditions of Theorem* 4.3, *we have*

$$\lim_{N\to\infty}\sum_{n=1}^{N}(|\overline{\varepsilon}_n(\widehat{\widehat{\theta}}_{n-1})|^2-|e_n|^2)/\log N=\frac{1}{2}\mathrm{Tr}T^*\overline{\Sigma}_{\theta\theta} \tag{7.8}$$

almost surely. In analogy with the ARMA case, if we use a stochastic Newton method, then we have

$$\overline{\Sigma}_{\theta\theta}=\Sigma_{\theta\theta}.$$

The minimum-variance self-tuning regulator. Consider now a stochastic control system in ARMAX(n,m,p) representation defined by the relation

$$A^*(q^{-1})y=q^{-1}B^*(q^{-1})u+C^*(q^{-1})e, \tag{7.9}$$

where $A^*(q^{-1})$, $B^*(q^{-1})$, and $C^*(q^{-1})$ are polynomials of the backward shift operator q^{-1} of degree n,m,p, respectively. Their coefficients are denoted by a_i^*,b_i^*,c_i^*, respectively, with $a_0^*=1$, $a_n^*\neq 0$, $b_0^*\neq 0$, $b_m^*\neq 0$, $c_0^*=1$, $c_p^*\neq 0$. Here u is the input process, e is the noise process, and y is the output process. The notation u is a shorthand for $(u(t))$, $0\le t\le\infty$. Assume that the polynomials B^* and C^* are stable and that $\deg C^*\le\deg A^*$. By extending the vector $(c_1^*,\dots,c_p^*)$ with zeros, if necessary, we can actually assume that $\deg A^*=\deg C^*$. The stochastic process e is a zero-mean wide-sense stationary orthogonal process; i.e., for all $t,s\ge 0$ we have $\mathrm{E}e(t)=0$ and $\mathrm{E}\,[e(s)e(t)]=\sigma^2(e)\delta_{st}$, where δ_{st} is the Kronecker symbol.

The minimum-variance control for the ARMAX system given under (7.9) is given by (cf. [2])

$$q^{-1}B^*u=(A^*-C^*)y. \tag{7.10}$$

Using this control law we get, under the assumption that the initial values are all zero, $y(t) = e(t)$. Equation (7.10) can be written in the form

$$u(t-1) = -(\eta^*)^T \phi(t), \tag{7.11}$$

where

$$\eta^* = \frac{1}{b_0^*}(a_1^* - c_1^*, \ldots, a_n^* - c_n^*, b_1^*, \ldots, b_m^*)^T \tag{7.12}$$

and

$$\phi(t) = (-y(t-1), \ldots, -y(t-n), u(t-2), \ldots, u(t-m-1)). \tag{7.13}$$

If the values of the parameters of the stochastic control system are unknown, then a stochastic adaptive control procedure will be needed. Within stochastic adaptive control a special procedure is the self-tuning regulation, that has been proposed in [2] for minimum-variance control. For a new perspective of this procedure see [63]. This is a stochastic approximation procedure defined as follows: let $\hat{\eta}(0)$ be an initial estimate of η^* and let $\hat{\eta}(t-1)$ be an estimate computed at time $t-1$. Then define the control action by

$$u(t-1) = -\hat{\eta}(t-1)\, \phi(t). \tag{7.14}$$

This is followed by observing $y(t)$ which is generated by (7.9). Finally we generate the next estimates $\hat{\eta}(t)$ by

$$\hat{\eta}(t) = \hat{\eta}(t-1) + R^{-1}\frac{1}{t}\, \phi(t) y(t), \tag{7.15}$$

where R is a symmetric positive definite matrix. A basic question in the context of stochastic adaptive control is the characterization of the performance degradation

$$y^2(t) - e^2(t) \tag{7.16}$$

and to establish its pathwise properties. This problem was first formulated in [2]. It has been open for a long time, until a solution was presented in [28], using the results of the present paper.

The performance of the minimum-variance self-tuning regulator had been studied in [48, 49]. In [48] the right order of magnitude for the so-called cumulative regret was found for general ARMAX systems. In [49] the right constant in a tight upper bound for cumulative regret had been obtained for ARX systems. For a survey see [46]. Note, however, that in these papers the so-called indirect adaptive control procedures had been considered, where identifiability is ensured by the injection of rare shocks with diminishing frequency into the system. Similar results were obtained in [31, 32].

Let $D \subset \mathbb{R}^{n+m}$ be a set of candidate controller parameters to be specified below. For any $\eta \in D$ and for $t \geq 0$ we consider the control law

$$u(t-1) = -\eta^T \phi(t),$$

where $\phi(t)$ is defined above in (7.13). Thus we get a closed-loop system in which both u and y depend on η. To stress this dependence we write $u(t) = \bar{u}(t, \eta)$ and

$y(t) = \bar{y}(t, \eta)$. Let D denote the open set of η's in $\mathbb{R}^{m+n}$ such that the closed-loop system is stable. Define the nonlinear vector-valued function

$$G(\eta) \triangleq \lim_{t\to\infty} \mathrm{E}\,[\,\bar{\phi}(t,\eta)\bar{y}(t,\eta)]. \tag{7.17}$$

It is easy to see that we have $G(\eta^*) = 0$.

Let S^* denote the asymptotic covariance matrix of $\hat{\eta}(t)$; i.e., let

$$S^* = \lim_{t\to\infty} t \cdot \mathrm{E}\,[(\hat{\eta}(t) - \eta^*)(\hat{\eta}(t) - \eta^*)^T],$$

assuming that the limit exists. Define the *second order sensitivity matrix*

$$T^* = \lim_{t\to\infty} \mathrm{E}\left[\frac{\partial^2}{\partial\eta^2}_{|\eta=\eta^*} \bar{y}^2(t,\eta)\right]. \tag{7.18}$$

Claim (see [28]). *Consider the minimum-variance self-tuning regulator for an ARMAX(n, m, p) system given by* (7.15). *Then, under appropriate technical conditions, obtained by specializing the conditions of Theorem* 4.3, *we have the following pathwise characterization of the cumulative performance degradation:*

$$\lim_{N\to\infty} \sum_{t=1}^{N} (y^2(t) - e^2(t))/\log N = \frac{1}{2}\mathrm{Tr}\; T^*S^* \tag{7.19}$$

almost surely. Moreover, for any symmetric positive definite R we have

$$\frac{1}{2}\mathrm{Tr}\; T^*S^* \geq \sigma^2(e)(m+n). \tag{7.20}$$

The inequality (7.20) *is an equality if and only if $R = -G_\eta(\eta^*)$ and $C^* = 1$.*

The proof of (7.19) follows [24]. We note in passing that it has been a common belief that $G_\eta(\eta^*)$ is not computable. However, using a technique of Hjalmarsson (cf. [39]) it can be shown that for certain interesting physical systems $G_\eta(\eta^*)$ is in fact computable. The proof of (7.19) follows [24].

Conclusion. Performance degradation due to statistical uncertainty, also called regret, is of great interest in adaptive prediction and control of stochastic systems. To quantify the pathwise cumulative regret we need technical tools similar to those developed in [24] in the context of adaptive prediction of ARMA processes. These new tools have been developed in this paper. The usefulness of the results in stochastic adaptive control has been demonstrated for the minimum-variance self-tuning regulator for ARMAX systems in section 7; see also [28]. A further application for indirect adaptive control of multivariable linear stochastic systems is given in [27].

The results can be also applied in the context of identification for control; see [29, 40, 41]. For any fixed feedback strategy the covariance matrix of the estimation error and consequently the cumulative regret over any finite horizon will depend on the feedback strategy. The cumulative regret over finite horizon distorts the performance of the controller and this distortion can be precisely characterized using the results of the present paper. Thus a controller with optimal overall performance over a fixed finite horizon can be developed, at least in theory, i.e., pretending that we know the systems dynamics.

A further potential area of application is adaptive experimental design, see [30], in which the objective function to be minimized is the trace of the covariance matrix

of the estimation error, which can be computed experimentally for any fixed input pattern.

Another more classical possible application is the derivation of limit results such as LIL and invariance principles along the lines of [38].

The scope of applications can be enlarged by extending the technical results themselves. The extension of the results of the present paper to Kiefer–Wolfwitz-type stochastic approximation procedures, such as the simultaneous perturbation stochastic approximation, or SPSA, method due to Spall [61, 62] seems to be possible.

8. Auxiliary results.

LEMMA 8.1. *Let (x_t), $t \geq 0$, be a zero-mean L-mixing process with respect to $(\mathcal{F}_t, \mathcal{F}_t^+)$ and let y be an $\mathcal{F}_s$-measurable random variable for some $0 \leq s \leq t$, such that its moments, which appear in the inequality below, are finite. Then for every $1 \leq p, q \leq \infty$ such that $1/p + 1/q = 1$ we have*

$$|\mathrm{E} x_t y| \leq 2\gamma_p(t-s, x)\mathrm{E}^{1/q}|y|^q.$$

Analogous inequalities for strong mixing stationary sequences are given in [9] and for uniformly mixing stationary sequences in [42]. A concise survey of these inequalities is given in Chapter 7.2 of [15] and Appendix III of [33]. Here we restate an improved Hölder inequality under the weakest condition on mixing, namely strong-mixing or α-mixing (cf. Corollary 2.5 of Chapter 7.2 of [15]).

LEMMA 8.2. *Let $p, q, r > 1$ be such that $p^{-1} + q^{-1} + r^{-1} = 1$. Let Y and Z be $\mathcal{H}$-measurable and $\mathcal{G}$-measurable random variables such that $||Y||_q$ and $||Z||_r$ are finite, respectively. Then*

$$|\mathrm{E}[YZ] - \mathrm{E}[Y]\mathrm{E}[Z]| \leq C\alpha(\mathcal{H}, \mathcal{G})^{1/p}||Y||_q||Z||_r. \tag{8.1}$$

The improved Hölder inequality of Lemma 8.1 plays a key role in deriving the following moment inequality (cf. Theorem 1.1 in [17]).

THEOREM 8.1. *Let (u_t), $t \geq 0$, be a zero-mean L-mixing process. Let (f_t) be a function in $L_2[0, T]$. Then we have for all $m \geq 2$ with $C_m = 2(m-1)^{1/2}$*

$$\mathrm{E}^{1/m}\left|\int_0^T f_s u_s ds\right|^m \leq C_m \left(\int_0^T f_t^2 dt\right)^{1/2} M_m^{1/2}(u) \cdot \Gamma_m^{1/2}(u).$$

Extension of the statement to vector-valued processes is an elementary exercise, but obviously the constant C_m will be different. Extension to random (f_t) is not possible in general, but an extension is possible for multiple integrals with deterministic kernel (cf. [21]). Here we need only the following special result.

THEOREM 8.2. *Let (u_t) and (v_t) be zero-mean L-mixing processes. Then we have*

$$I_{T_0} = \int_{T_0}^T \frac{1}{t} u_t \int_{T_0}^t \frac{1}{s} v_s ds dt = O_M(T_0^{-1}).$$

The following simple lemma is stated as Corollary 3.5 in [24].

LEMMA 8.3. *Let $(\mathcal{F}_t, \mathcal{F}_t^+)$ be a pair of families of σ-algebras as in section 3 and let (x_t), $t \geq 0$, be an $\mathcal{F}_t$-adapted, measurable stochastic process. Then (x_t) is L-mixing with respect to $(\mathcal{F}_t, \mathcal{F}_t^+)$ if and only if the processes (x_{n+d}) are L-mixing with respect to $(\mathcal{F}_{n+d}, \mathcal{F}_{n+d}^+)$, uniformly in d for $0 \leq d < 1$.*

Let us consider a stochastic process $(u_n(\theta))$ with $\theta \in D \subset \mathbb{R}^p$, where D is an open set, which is measurable, separable, M-bounded, and M-Lipschitz continuous in θ for $\theta \in D$. By Kolmogorov's theorem the realizations of $(x_n(\theta))$ are continuous in θ with probability 1, hence we can define for almost all ω

$$u_n^* = \max_{\theta \in D_0} |u_n(\theta)|,$$

where $D_0 \subset D$ is a compact domain. The following result is given as Theorem 3.4 in [17].

THEOREM 8.3. *Assume that $(u_n(\theta))$ is a stochastic process which is measurable, separable, M-bounded, and M-Lipschitz continuous in θ for $\theta \in D$. Let u_n^* be the random variable defined above. Then we have for all positive integers q and $s > p$*

$$M_q(u^*) \le C(M_{qs}(u) + M_{qs}(\Delta u/\Delta\theta)),$$

where C depends only on p, q, s, and D_0, D.

A continuous-time version of the following lemma was given in [17] as Lemma 2.4.

LEMMA 8.4. *Let (u_n), $n \ge 0$, be a zero-mean L-mixing $\mathbb{R}^p$-valued process and define another $\mathbb{R}^p$-valued process (x_n) by*

$$x_{n+1} = Ax_n + u_n, \qquad x_0 = 0,$$

where the spectral norm of A is smaller than 1, say, we have $||A^n|| \le C\alpha^n$ with some $C > 0$ and $0 < \alpha < 1$. Then the output process (x_n) is L-mixing.

The first part of the following result was stated in Lemma 7.4 of [19]. The second part of the quoted lemma was not correctly stated and is therefore restated and proved here.

LEMMA 8.5. *Let (u_n), $n \ge 0$, be an M-bounded process and define a process (x_n) by*

$$x_{n+1} = \lambda x_n + \rho^n u_n, \qquad x_0 = 0, \tag{8.2}$$

where $0 < \lambda < \rho$. Then for any $m \ge 1$ we have

$$\mathrm{E}^{1/m}|x_n|^m \le \frac{\rho^n}{\rho - \lambda} M_m(u).$$

On the other hand, if $0 < \rho < \lambda$, then we have

$$\mathrm{E}^{1/m}|x_n|^m \le \frac{\lambda^n}{\lambda - \rho} M_m(u).$$

Proof. Let $0 < \lambda < \rho$ and set $z_n = \rho^{-n} x_n$. Then we have, after multiplying (8.2) by $\rho^{-(n+1)}$,

$$z_{n+1} = \lambda\rho^{-1} z_n + \rho^{-1} u_n,$$

which can be solved explicitly for z_n to get

$$z_n = \sum_{i=0}^{n-1} (\lambda\rho^{-1})^i \rho^{-1} u_{n-1-i}.$$

Using the triangle inequality for the $L_m(\Omega, \mathcal{F}, P)$-norm and the condition $0 < \lambda < \rho$ we get

$$M_m(z) \le (1 - \lambda\rho^{-1})^{-1}\rho^{-1}M_m(u)$$

from which the first proposition follows.

A useful reformulation of the above argument is the following: writing

$$x_n = \rho^n z_n = \sum_{i=0}^{n-1} \lambda^i \rho^{n-1-i} u_{n-1-i} \tag{8.3}$$

we have

$$\mathrm{E}^{1/m}|x_n|^m \le \sum_{i=0}^{n-1} \lambda^i \rho^{n-1-i} \mathrm{E}^{1/m}|u_{n-1-i}|^m \le \sum_{i=0}^{n-1} \lambda^i \rho^{n-1-i} M_q(u). \tag{8.4}$$

Thus it is sufficient to establish that for $0 < \lambda < \rho$

$$\sum_{i=0}^{n-1} \lambda^i \rho^{n-1-i} \le \frac{\rho^n}{\rho - \lambda} \tag{8.5}$$

and this is obtained from the above argument with $u_n = 1$ for all n. The advantage of this reformulation is that the left-hand side is the convolution of the sequences (λ^n) and (ρ^n) and thus it is symmetric in λ and ρ.

In the case when $0 < \rho < \lambda$ we use (8.4) to estimate $\mathrm{E}^{1/m}|x_n|^m$, but the role of λ and ρ is interchanged; thus we get

$$\mathrm{E}^{1/m}|x_n|^m \le \frac{\lambda^n}{\lambda - \rho} M_m(u). \qquad \square$$

Remark. A simple corollary is that

$$\sum_{i=0}^{n-1} \lambda^i \rho^{n-1-i} \le \frac{\max\ (\lambda^n, \rho^n)}{|\rho - \lambda|}. \tag{8.6}$$

The lemma below has been used for ODE analysis of stochastic approximation processes in [16]. The conditions are similar to Condition 3.4(i). Consider the ODE

$$\dot{y}_t = F(t, y_t), \qquad y_s = \xi,\ s \ge 1. \tag{8.7}$$

The solution of the above ODE will be denoted by $y(t, s, \xi)$ in the time interval where it exists and is unique.

CONDITION 8.1. *$F = (F(t, y))$ is defined for $t \ge 1$, $y \in D$, where $D \subset \mathbb{R}^p$ is an open set and F is continuously differentiable in (t, y). It is assumed that there exists a compact domain $D_0' \subset D$ such that $y(t, s, \xi) \in D$ for all $\xi \in D_0'$ and $1 \le s \le t < \infty$.*

LEMMA 8.6. *Assume that Condition 8.1 is satisfied. Let (x_t), $1 \le t < \infty$, be a continuous, piecewise continuously differentiable curve such that $x_t \in D_0'$ for $t \ge 1$ and $x_1 = y_1 = \xi \in D_0'$. Then for $t \ge 1$*

$$x_t - y_t = \int_1^t \frac{\partial}{\partial \xi} y(t, r, x_r)\,(\dot{x}_r - F(r, x_r))\ dr. \tag{8.8}$$

Proof. Write $z_r = y(t, r, x_r)$. Obviously the left-hand side of (8.8) can be written as $z_t - z_1$ and we have

$$z_t - z_1 = \int_1^t \dot{z}_r dr = \int_1^t (y_r(t, r, x_r) + y_\xi(t, r, x_r)\dot{x}_r)\ dr. \tag{8.9}$$

Taking into account the equality $y_r(t, r, x_r) = -y_\xi(t, r, x_r) \cdot F(t, x_r)$ we get the lemma. □

A discretized version of the above lemma has been used implicitly in the final step of the proof of Theorem 1.1 of [19], see (2.10) of [19]. We now formulate this lemma with explicit conditions. It has been used in the proof of Lemma 4.4.

CONDITION 8.2. *Let $D_0' \subset D$ be a compact domain as in Condition* 8.1. *Assume that D_0' is convex and that there exists a compact set $D_0 \subset D_0'$ such that for all $x \in D_0$ and $t \geq s \geq 1$ we have $y(t, s, x) \in D_0'$.*

Let $1 = s_0 \leq s_2 \leq \cdots \leq s_n \leq s_{n+1} = t$ and let $(x_{s_i}) \in D_0$, $i = 0, 1, \ldots, n$, be a sequence such that $x_1 = y_1 = \xi \in D_0$. These points are considered as approximations to $y_{s_i} = y(s_i, 1, \xi)$. We will estimate the tracking error $x_t - y_t$ in terms of *local tracking* errors

$$(x_{s_i} - y(s_i, s_{i-1}, x_{s_{i-1}})).$$

LEMMA 8.7. *Let $F = (F(t, y))$ satisfy Conditions* 8.1 *and* 8.2 *and let $(x_{s_i}) \in D_0$, $i = 0, 1, \ldots, n$, be a sequence such that $x_1 = y_1 = \xi$. Then*

$$x_t - y_t = (x_t - y(t, s_n, x_{s_n})) + \sum_{i=1}^n \int_0^1 \frac{\partial}{\partial \xi} y(t, s_i, w(i, \lambda))\ d\lambda \cdot (x_{s_i} - y(s_i, s_{i-1}, x_{s_{i-1}})),$$

where $w(i, \lambda) = (1 - \lambda)y(s_i, s_{i-1}, x_{s_{i-1}}) + \lambda x_{s_i}$.

Proof. Consider the sequence $z_i = y(t, s_i, x_{s_i})$, $i = 0, 1, \ldots, n$. Then $z_0 = y_t$ and we can write

$$\begin{aligned} x_t - y_t &= (x_t - z_n) + \sum_{i=1}^n (z_i - z_{i-1}) \\ &= (x_t - y(t, s_n, x_{s_n})) + \sum_{i=1}^n (y(t, s_i, x_{s_i}) - y(t, s_{i-1}, x_{s_{i-1}})). \end{aligned} \tag{8.10}$$

Now for $1 \leq s \leq s' \leq t$ we have $y(t, s, x) = y(t, s', y(s', s, x))$. Setting $s = s_{i-1}$, $s' = s_i$, $x = x_{s_{i-1}}$, the ith term of the right-hand side of (8.10) thus becomes

$$\begin{aligned} &y(t, s_i, x_{s_i}) - y(t, s_i, y(s_i, s_{i-1}, x_{s_{i-1}})) \\ &\qquad = \int_0^1 \frac{\partial}{\partial \xi} y(t, s_i, w(i, \lambda))\ d\lambda \cdot (x_{s_i} - y(s_i, s_{i-1}, x_{s_{i-1}})) \end{aligned}$$

with $w(i, \lambda) = (1 - \lambda)y(s_i, s_{i-1}, x_{s_{i-1}}) + \lambda x_{s_i}$ for $0 \leq \lambda \leq 1$. Note that $w(i, \lambda) \in D_0'$ for $i = 1, \ldots, n$ since D_0' is convex and thus $y(t, s_i, w(i, \lambda))$ is well defined, and the lemma follows. □

Let $G = (G(y))$ be defined in an open set $D \subset \mathbb{R}^p$ and consider the ODE

$$\dot{y}_t = \frac{1}{t} G(y_t), \qquad y_s = \xi,\ s \geq 1. \tag{8.11}$$

We will have conditions that ensure that the above ODE has a unique solution in some finite or infinite interval, which we denote by $y(t,s,\xi)$. We assume the validity of the following condition, which is weaker than Conditions 3.3 and 3.4.

CONDITION 8.3. *G has continuous partial derivatives up to second order for $y \in D$. There exist compact sets $D_0 \subset D_0' \subset D$ such that for all $\xi \in D_0$, $t \geq s \geq 1$, we have $y(t,s,\xi) \in D_0'$ and*

$$\|y_\xi(t,s,\xi)\| \leq C_0(s/t)^\alpha \tag{8.12}$$

with some $C_0 \geq 1$, $\alpha > 0$. Let $||\partial^i G(y)/\partial y^i|| \leq L$ for $y \in D_0'$ and $i = 0,1,2$.

We prove that the stability expressed by the condition above is in a sense inherited by the second order derivatives of $y(t,s,\xi)$.

LEMMA 8.8. *Let G satisfy Condition 8.3. Then for all $\xi \in D_0$, $t \geq s \geq 1$,*

$$\|y_{\xi\xi}(t,s,\xi)\| \leq L\alpha^{-1}C_0^3 \cdot (s/t)^\alpha,$$
$$\|y_{s\xi}(t,s,\xi)\| \leq (L\alpha^{-1}+1)LC_0^3 \cdot \frac{1}{s}(s/t)^\alpha.$$

Remark. From the proof below it follows that if G is three times continuously differentiable, then with some constant C_0' we have $\|y_{\xi\xi\xi}(t,s,\xi)\| \leq C_0'(s/t)^\alpha$.

Proof. Use a change of time-scale $t = e^v$, $s = e^u$, and consider the differential equation

$$\frac{d}{dv}z_v = G(z_v), \qquad z_u = \xi,\ u \geq 0,$$

with its solution being denoted by $z(v,u,\xi)$, $v \geq u \geq 0$. Then (8.12) implies

$$\|z_\xi(v,u,\xi)\| \leq C_0 e^{-\alpha(u-v)}, \tag{8.13}$$

and the propositions of the lemma are equivalent to, after the substitution $u = \log t$ and $v = \log s$,

$$\|z_{\xi\xi}(v,u,\xi)\| \leq L\alpha^{-1}C_0^3 \cdot e^{-\alpha(v-u)},$$
$$\|z_{u\xi}(v,u,\xi)\| \leq (L\alpha^{-1}+1)LC_0^3 \cdot e^{-\alpha(v-u)}.$$

Now we have

$$\frac{\partial}{\partial v}z_\xi(v,u,\xi) = G_y(z(v,u,\xi)) \cdot z_\xi(v,u,\xi), \qquad z_\xi(u,u,\xi) = I. \tag{8.14}$$

It is easy to see that $z_{\xi\xi}(v,u,\xi)$ exists and is continuous in (v,u,ξ). From (8.14) we get

$$\frac{\partial}{\partial v}z_{\xi\xi}(v,u,\xi) = G_{yy}(z(v,u,\xi)) \cdot z_\xi(v,u,\xi)z_\xi(v,u,\xi) + +G_y(z(v,u,\xi)) \cdot z_{\xi\xi}(v,u,\xi)$$

with $z_{\xi\xi}(u,u,\xi) = 0$. Since the operator norm of the first term is majorized by $LC_0^2e^{-2\alpha(u-v)}$ and since the time-varying linear differential equation with transition matrix $G_y(z(v,u,\xi))$ is exponentially stable due to (8.13), we get the first claim of the lemma from the identity

$$\int_0^t e^{-\alpha(v-r)}e^{-2\alpha r}dr = e^{-\alpha v}\int_0^v e^{-\alpha r}dr < \alpha^{-1}e^{-\alpha v}.$$

To estimate the mixed derivatives, take into account $z_u(v,u,\xi) = -z_\xi(v,u,\xi)\cdot G(\xi)$ to get

$$z_{u\xi}(v,u,\xi) = -z_{\xi\xi}(v,u,\xi)\cdot G(\xi) - z_\xi(v,u,\xi)\cdot G_\xi(\xi),$$

from which the second claim follows using (8.13) and the proven first part of the lemma. □

Acknowledgments. The author expresses his thanks to Peter Caines for arranging a long-term visit to McGill University and for numerous fruitful discussions on stochastic systems. The help of Zsuzsanna Vágó, Zalán Mátyás, and Zsanett Orlovits in rereading the manuscript of the paper is also gratefully acknowledged.

STATE FEEDBACK IMPULSE ELIMINATION FOR SINGULAR SYSTEMS OVER A HERMITE DOMAIN*

DANIEL COBB†

Abstract. We reduce the problem of impulse elimination via state feedback in singular differential equations to algebra. Our results are developed for systems over an arbitrary Hermite domain. We show that the established theories for the time-invariant and the real analytic time-varying settings can be unified in this way. Besides the constant and real analytic functions, several other function rings are considered. Our algebraic theory is applied to these cases, providing solutions to the impulse elimination problem for classes of systems not previously studied. In particular, our work allows the restriction of the feedback matrix to certain function rings.

Key words. singular systems, impulse elimination, algebraic systems, state feedback

1. Introduction.

We are interested in the problem of designing a state feedback law $u = K(t)\,x$ for a time-varying singular differential equation

$$E(t)\,\dot{x} = A(t)\,x + B(t)\,u \tag{1}$$

such that the closed-loop system

$$E(t)\,\dot{x} = (A(t) + B(t)\,K(t))\,x \tag{2}$$

exhibits no impulsive transients. The matrices E, A, and B are assumed to have entries in an appropriate set of functions on $\mathbb{R}$ (possibly constant) with $E(t), A(t) \in \mathbb{R}^{n\times n}$, $B(t) \in \mathbb{R}^{n\times m}$, and $K(t) \in \mathbb{R}^{m\times n}$. This problem has been treated in a variety of contexts over the past 25 years [10], [16], [12], [13], [4], [17], [18]. For example, we originally posed and solved the problem for the time-invariant (i.e., constant matrix) case in [10].

For time-invariant systems, the fact that solutions of (2) can exhibit impulsive behavior was originally established in [14] and [15, Ch. 22]. One method of analysis is based on the Weierstrass decomposition [8, Thm. 3, p. 28]: Given E, A with $\det(sE - A) \not\equiv 0$, there exist nonsingular $P, Q \in \mathbb{R}^{n\times n}$ such that

$$PEQ = \begin{bmatrix} I & 0 \\ 0 & N \end{bmatrix}, \quad PAQ = \begin{bmatrix} X & 0 \\ 0 & I \end{bmatrix},$$

where N is nilpotent. If $N \neq 0$, the solution of (1) contains an impulsive term of the form

$$z = -\sum \delta^{(k-1)} N^k z_o. \tag{3}$$

(See [19] for details.) More generally, when $E(t)$ and $A(t)$ are analytic functions, it is shown in [3] that an expression similar to (3) holds under mild assumptions.

Since impulses must be interpreted as unbounded, conventional notions of closed-loop stability dictate that K be chosen to make (2) impulse free. For the time-invariant case, we established a necessary and sufficient condition ([10, Thm. 6]) under which such a matrix K exists. This condition can be written

$$\operatorname{Im} E + A \operatorname{Ker} E + \operatorname{Im} B = \mathbb{R}^n.$$

Since then, two alternative proofs of this result have appeared. (See [12, Thm. 2.5.1] and [13, Thm. 3-2.1].)

The work of Campbell and Petzold [3] extended the theory of singular systems (1) to the time-varying setting, where E, A, and B are matrices over the real analytic functions on $\mathbb{R}$. More recently, the corresponding impulse elimination problem was solved by Wang in [4, Thm. 4.1]. In this case, necessary and sufficient conditions for impulse elimination are

$$\operatorname{Im} E(t) + A(t) \operatorname{Ker} E(t) + \operatorname{Im} B(t) = \mathbb{R}^n \quad \forall t,$$
$$\operatorname{rank} E(t) = \text{constant}.$$

Our contention is that the impulse elimination problem is primarily a problem in algebra. Indeed, after careful examination (and some modification), the arguments in [4] can be reduced to algebraic manipulations over a certain class of rings. Pursuing this idea not only leads to a unification of the time-invariant and analytic time-varying theories, but also yields a more general framework in which the impulse elimination problem for other classes of time-varying systems can be solved with little extra effort.

An important consequence of our approach is that it allows the entries of K to be restricted to certain function rings (although E, A, and B must share the same restriction). Hence, we are able to solve a wide variety of constrained feedback problems which have not been considered in the literature.

Our algebraic theory is the subject of sections 2 and 3. In section 4, we apply our results to various types of time-varying singular systems.

2. Algebraic preliminaries. Let R be a commutative ring (with identity). If $x_1, \ldots, x_k \in R$, a *Bezout identity* is an equation of the form $\sum a_i x_i = 1$ ($a_i \in R$). For a matrix $M \in R^{p \times q}$, let

$$\operatorname{rank} M = \max \left\{ k \;\middle|\; M \text{ has a nonzero } k\text{th-order minor} \right\} \tag{4}$$

and

$$\rho M = \max \left\{ k \;\middle|\; \text{the } k\text{th-order minors of } M \text{ satisfy a Bezout identity} \right\}. \tag{5}$$

Obviously, $\operatorname{rank} M \geq \rho M$ for any M. It can be shown that $\operatorname{rank} M$ and ρM are invariant under left and right unimodular transformations. (See [1, p. 25].) If $R = \mathbb{R}$, then $\operatorname{rank} M = \rho M$. We denote this common value by $\operatorname{rank}_{\mathbb{R}} M$.

Consider the set G of all triples (P, Q, D), where $P, Q, D \in R^{n \times n}$ and P, Q are unimodular. Define the binary operation

$$(P_1, Q_1, D_1) * (P_2, Q_2, D_2) = (P_2 P_1, Q_1 Q_2, D_1 Q_2 + Q_1 D_2).$$

It is routine to verify that G has the structure of a group. Now consider pairs (E, A), where $E, A \in R^{n \times n}$. We may define a right group action on the set of all (E, A) according to

$$(E, A) \cdot (P, Q, D) = (PEQ, P(AQ + ED)). \tag{6}$$

The *orbit* of particular (E, A) is the set of all pairs $(\widetilde{E}, \widetilde{A})$ such that $(\widetilde{E}, \widetilde{A}) = (E, A) \cdot (P, Q, D)$ for some P, Q, D. It is easy to verify that the set of all orbits forms a partition of $R^{n\times n} \times R^{n\times n}$.

Following the terminology of Campbell and Petzold [3], we say (E, A) is in *standard canonical form* if

$$E = \begin{bmatrix} I & 0 \\ 0 & N \end{bmatrix}, \quad A = \begin{bmatrix} X & 0 \\ 0 & I \end{bmatrix}, \tag{7}$$

where N is strictly upper triangular with E, A identically partitioned. Similar to their notion of "analytic solvability" for systems (1), we say $(E, A) \in R^{n\times n} \times R^{n\times n}$ is *algebraically solvable* if its orbit under (6) contains a member in standard canonical form. (The degenerate cases (I, X) and (N, I) are also allowed.) We say that (E, A) has *unit index* if the orbit of (E, A) contains a member in standard canonical form with $N = 0$. It is clear from the definitions that algebraic solvability is invariant under the group action (6).

The question arises whether a unit index orbit can contain a member in standard canonical form with $N \neq 0$. Fortunately, the next result answers this question in the negative.

THEOREM 2.1. *Suppose* (E, A) *has unit index and* $(E, A)\cdot(P, Q, D)$ *is in standard canonical form* (7). *Then* $N = 0$.

Proof. Suppose (E, A) belongs to an orbit with two members in standard canonical form, one with $N = 0$ and the other with $N \neq 0$. Then there exist D and unimodular P and Q such that

$$P \begin{bmatrix} I & 0 \\ 0 & 0 \end{bmatrix} = \begin{bmatrix} I & 0 \\ 0 & N \end{bmatrix} Q^{-1},$$

$$P \left(\begin{bmatrix} X & 0 \\ 0 & I \end{bmatrix} + \begin{bmatrix} I & 0 \\ 0 & 0 \end{bmatrix} DQ^{-1} \right) = \begin{bmatrix} Y & 0 \\ 0 & I \end{bmatrix} Q^{-1}$$

for some X and Y and some strictly upper triangular $N \neq 0$. Let

$$\begin{bmatrix} D_{11} & D_{12} \\ D_{21} & D_{22} \end{bmatrix} = DQ^{-1}, \quad P_1 = P \begin{bmatrix} I & D_{12} \\ 0 & I \end{bmatrix},$$

and $X_1 = X + D_{11}$. Then

$$P_1 \begin{bmatrix} I & 0 \\ 0 & 0 \end{bmatrix} = P \begin{bmatrix} I & D_{12} \\ 0 & I \end{bmatrix} \begin{bmatrix} I & 0 \\ 0 & 0 \end{bmatrix} = P \begin{bmatrix} I & 0 \\ 0 & 0 \end{bmatrix} = \begin{bmatrix} I & 0 \\ 0 & N \end{bmatrix} Q^{-1}, \tag{8}$$

$$\begin{aligned} P_1 \begin{bmatrix} X_1 & 0 \\ 0 & I \end{bmatrix} &= P \begin{bmatrix} I & D_{12} \\ 0 & I \end{bmatrix} \begin{bmatrix} X_1 & 0 \\ 0 & I \end{bmatrix} \\ &= P \begin{bmatrix} X + D_{11} & D_{12} \\ 0 & I \end{bmatrix} \\ &= P \left(\begin{bmatrix} X & 0 \\ 0 & I \end{bmatrix} + \begin{bmatrix} I & 0 \\ 0 & 0 \end{bmatrix} DQ^{-1} \right) \\ &= \begin{bmatrix} Y & 0 \\ 0 & I \end{bmatrix} Q^{-1}. \end{aligned} \tag{9}$$

Let

$$\begin{bmatrix} P_{11} & P_{12} \\ P_{21} & P_{22} \end{bmatrix} = P_1, \quad \begin{bmatrix} Q_{11} & Q_{12} \\ Q_{21} & Q_{22} \end{bmatrix} = Q^{-1}.$$

From (8), $P_{21} = NQ_{21}$ and $NQ_{22} = 0$. From (9), $P_{22} = Q_{22}$. Since N is strictly triangular and nonzero, there exist an integer $q > 1$ and x such that $N^q = 0$ and $N^{q-1}x \neq 0$. Since P_1 is unimodular, there exist y and z such that

$$\begin{bmatrix} 0 \\ x \end{bmatrix} = P_1 \begin{bmatrix} y \\ z \end{bmatrix},$$

$$x = P_{21}y + P_{22}z = NQ_{21}y + Q_{22}z.$$

Multiplying by N^{q-1} yields

$$N^{q-1}x = N^q Q_{21}y + N^{q-1}Q_{22}z = 0,$$

which is a contradiction. □

In practice, algebraic solvability may be difficult to establish, so we introduce a more direct condition that will suit our purposes just as well. We say that (E, A) is *presolvable* if *any one* of the following conditions holds:

(PS1) $\operatorname{Im} E + A \operatorname{Ker} E = R^n$,

(PS2) $\operatorname{Im} E \cap A \operatorname{Ker} E \neq 0$,

(PS3) $\operatorname{Ker} E \cap \operatorname{Ker} A \neq 0$.

Algebraic solvability and standard canonical form are related to existence and uniqueness of solutions of (1), as discussed in [3]. However, presolvability is a purely algebraic condition, having no simple connection to the dynamics of (1). Nevertheless, we can prove the following.

THEOREM 2.2.

(1) *Algebraic solvability implies presolvability.*

(2) *Presolvability is invariant under the group action* (6).

Proof. (1) There exist P, Q, and D that put (E, A) in standard canonical form. Suppose $N = 0$. Then

$$\begin{aligned} P(\operatorname{Im} E + A \operatorname{Ker} E) &= P\left(\operatorname{Im} E + A \operatorname{Ker} E + EDQ^{-1} \operatorname{Ker} E\right) \\ &= \operatorname{Im} PEQ + PAQ \operatorname{Ker} PEQ + PED \operatorname{Ker} PEQ \\ &\supset \operatorname{Im} PEQ + P(AQ + ED) \operatorname{Ker} PEQ \\ &= \operatorname{Im} \begin{bmatrix} I \\ 0 \end{bmatrix} + \operatorname{Im} \begin{bmatrix} 0 \\ I \end{bmatrix} \\ &= R^n, \end{aligned}$$

so (PS1) holds.

If $N \neq 0$, there exists an integer $q > 1$ such that $N^q = 0$ and $N^{q-1} \neq 0$. Choose any $x \in R^n$ such that $N^{q-1}x \neq 0$, set $y = N^{q-2}x$, and $z = Ny$. Then $z \neq 0$. Let

$$v = Q \begin{bmatrix} 0 \\ y \end{bmatrix} - D \begin{bmatrix} 0 \\ z \end{bmatrix}, \quad w = Q \begin{bmatrix} 0 \\ z \end{bmatrix}.$$

Then $w \neq 0$ and

$$P(Ev - Aw) = PEQ \begin{bmatrix} 0 \\ y \end{bmatrix} - P(AQ + ED) \begin{bmatrix} 0 \\ z \end{bmatrix} = \begin{bmatrix} 0 \\ Ny - z \end{bmatrix} = 0,$$

so $Ev = Aw$. Also,

$$P(Ew) = PEQ \begin{bmatrix} 0 \\ z \end{bmatrix} = \begin{bmatrix} 0 \\ Nz \end{bmatrix} = 0,$$

so $w \in \operatorname{Ker} E$ and $Aw \in \operatorname{Im} E \cap A \operatorname{Ker} E$. If $Aw \neq 0$, (PS2) holds; if $Aw = 0$, (PS3) holds.

(2) To prove invariance of presolvability, first suppose (PS1) holds for (E, A). Then

$$\begin{aligned}\operatorname{Im} PEQ + P(AQ + ED) \operatorname{Ker} PEQ &= P\left(\operatorname{Im} E + \left(A + EDQ^{-1}\right) \operatorname{Ker} E\right) \\ &= P\left(\operatorname{Im} E + \left(A + EDQ^{-1}\right) \operatorname{Ker} E + EDQ^{-1} \operatorname{Ker} E\right) \\ &\supset P\left(\operatorname{Im} E + \left(\left(A + EDQ^{-1}\right) - EDQ^{-1}\right) \operatorname{Ker} E\right) \\ &= R^n,\end{aligned}$$

so (PS1) also holds for $(E, A) \cdot (P, Q, D)$ and $(E, A) \cdot (P, Q, D)$ is presolvable.

Now assume that (PS2) holds for (E, A), but not for $(E, A) \cdot (P, Q, D)$. Then there exist x, y such that $Ex = 0$ and $Ey = Ax \neq 0$. Hence, $x \neq 0$,

$$P(AQ + ED) Q^{-1} x = PE\left(y + DQ^{-1}x\right) \in \operatorname{Im} PEQ \cap P(AQ + ED) \operatorname{Ker} PEQ = 0,$$

$$0 \neq Q^{-1}x \in \operatorname{Ker} PEQ \cap \operatorname{Ker} P(AQ + ED). \tag{10}$$

This establishes (PS3), and therefore, presolvability relative to $(E, A) \cdot (P, Q, D)$.

Finally, suppose that (PS3) holds for (E, A), but $(E, A) \cdot (P, Q, D)$ fails to satisfy (PS2). Then there exists $x \neq 0$ such that $Ex = Ax = 0$ and

$$P(AQ + ED) Q^{-1} x = PEDQ^{-1}x \in \operatorname{Im} PEQ \cap P(AQ + ED) \operatorname{Ker} PEQ = 0.$$

Hence, (10) again holds, verifying (PS3) and presolvability of $(E, A) \cdot (P, Q, D)$. □

If (E, A) has unit index, it turns out that the matrix D plays no essential role in establishing standard canonical form. This is made precise in the next theorem.

THEOREM 2.3. *If (E, A) has unit index, then there exists a unimodular $Q \in R^{n\times n}$ such that,* for every *$D \in R^{n\times n}$, there exists a unimodular $P \in R^{n\times n}$ which yields standard canonical form* (7) *with $N = 0$.*

Proof. Suppose (P_1, Q_1, D_1) achieves standard canonical form for some X_1 and with $N = 0$. Let $Q = Q_1$ and let D be given. Setting

$$\begin{bmatrix} D_{11} & D_{12} \\ D_{21} & D_{22} \end{bmatrix} = Q_1^{-1}(D - D_1), \quad P_2 = \begin{bmatrix} I & -D_{12} \\ 0 & I \end{bmatrix},$$

$X = X_1 + D_{11}$, and $P = P_2 P_1$ yields

$$PEQ = P_2(P_1 E Q_1) = \begin{bmatrix} I & 0 \\ 0 & 0 \end{bmatrix},$$

$$\begin{aligned} P(AQ + ED) &= P_2\left(P_1(AQ_1 + ED_1) + (P_1 E Q_1) Q_1^{-1}(D - D_1)\right) \\ &= \begin{bmatrix} I & -D_{12} \\ 0 & I \end{bmatrix} \left(\begin{bmatrix} X_1 & 0 \\ 0 & I \end{bmatrix} + \begin{bmatrix} D_{11} & D_{12} \\ 0 & 0 \end{bmatrix} \right) \\ &= \begin{bmatrix} X & 0 \\ 0 & I \end{bmatrix}. \end{aligned}$$ □

For an arbitrary commutative ring R, we can establish necessary conditions under which (E, A) has unit index. First we need a lemma.

LEMMA 2.4. *Let $M \in R^{n\times n}$. If there exist unimodular $P, Q \in R^{n\times n}$ such that*

$$PMQ = \begin{bmatrix} I & 0 \\ 0 & 0 \end{bmatrix}, \tag{11}$$

then $\operatorname{rank} M = \rho M$.

Proof. Suppose the identity matrix in (11) is $n_1 \times n_1$. Then it is clear by definitions (4) and (5) that

$$\operatorname{rank} PMQ = n_1 = \rho PMQ.$$

The result follows from invariance of rank and ρ under unimodular transformations. □

THEOREM 2.5. *If (E, A) has unit index, then*

(1) $\operatorname{rank} E = \rho E$,

(2) $\operatorname{Im} E + A \operatorname{Ker} E = R^n$,

(3) (E, A) *is presolvable.*

Proof. (1) This follows from standard canonical form and Lemma 2.4.

(2) Invoking standard canonical form,

$$\begin{aligned} P\left(\operatorname{Im} E + A \operatorname{Ker} E\right) &= P\left(\operatorname{Im} E + A \operatorname{Ker} E + EDQ^{-1} \operatorname{Ker} E\right) \\ &= \operatorname{Im} PEQ + PAQ \operatorname{Ker} PEQ + PED \operatorname{Ker} PEQ \\ &\supset \operatorname{Im} PEQ + P\left(AQ + ED\right) \operatorname{Ker} PEQ \\ &= \operatorname{Im} \begin{bmatrix} I \\ 0 \end{bmatrix} + \begin{bmatrix} X & 0 \\ 0 & I \end{bmatrix} \operatorname{Im} \begin{bmatrix} 0 \\ I \end{bmatrix} \\ &= \operatorname{Im} \begin{bmatrix} I \\ 0 \end{bmatrix} + \operatorname{Im} \begin{bmatrix} 0 \\ I \end{bmatrix} \\ &= R^n. \end{aligned}$$

(3) This is obvious from part (2). □

Let $B \in R^{n\times m}$. The group action (6) may be extended to triples (E, A, B) according to

$$(E, A, B) \cdot (P, Q, D) = \left(PEQ, P\left(AQ + ED\right), PB\right). \tag{12}$$

In [16] we introduced the concept of "impulse controllability," which is fundamental to the study of state feedback in singular systems. We can adapt this idea to the algebraic setting by taking its feedback characterization as the definition. We say that $K \in R^{m\times n}$ is *impulse eliminating* if $(E, A + BK)$ has unit index. The triple (E, A, B) is *impulse controllable* if there exists an impulse eliminating K.

THEOREM 2.6. *Impulse controllability is invariant under* (12).

Proof. Suppose (E, A, B) is impulse controllable, and let K be impulse eliminating. Choose any P, Q, D, and let $K_1 = KQ$. Then

$$\left(PEQ, P\left(AQ + ED\right) + \left(PB\right) K_1\right) = \left(PEQ, P\left(\left(A + BK\right) Q + ED\right)\right),$$

which lies in the same orbit as $(E, A + BK)$ and, hence, has unit index. Thus $\left(PEQ, P\left(AQ + ED\right), PB\right)$ is impulse controllable. □

THEOREM 2.7. *If (E, A, B) is impulse controllable, then*

(1) $\operatorname{rank} E = \rho E$,

(2) $\operatorname{Im} E + A \operatorname{Ker} E + \operatorname{Im} B = R^n$.

Proof. Suppose $(E, A+BK)$ has unit index. From Theorem 2.5, part (1), $\operatorname{rank} E = \rho E$. By Theorem 2.5, part (2),

$$\begin{aligned}\operatorname{Im} E + A \operatorname{Ker} E + \operatorname{Im} B &\supset \operatorname{Im} E + A \operatorname{Ker} E + BK \operatorname{Ker} E \\ &\supset \operatorname{Im} E + (A+BK) \operatorname{Ker} E = R^n. \qquad \square\end{aligned}$$

We conclude this section by proving a pair of lemmas which will be useful in what follows, and which hold for any commutative ring.

LEMMA 2.8. *Let $M \in R^{p\times q}$. The following statements are equivalent:*

(1) $\operatorname{Im} M = R^p$,

(2) *M has a right inverse,*

(3) $\rho M = p$.

Proof. (1)⇒(2) Let $e_1, \dots, e_p$ be the canonical unit vectors in R^p. Since $\operatorname{Im} M = R^p$, there exist $x_1, \dots, x_p \in R^q$ such that $Mx_i = e_i$. Let $L = \begin{bmatrix} x_1 & \cdots & x_p \end{bmatrix}$. Then $MLe_i = Mx_i = e_i$, so $ML = I$.

(2)⇒(3) Suppose $ML = I$. From the Binet–Cauchy formula,

$$\sum_{1\le j_1<\cdots<j_p\le q} M \begin{pmatrix} 1 & \cdots & p \\ j_1 & \cdots & j_p \end{pmatrix} L \begin{pmatrix} j_1 & \cdots & j_p \\ 1 & \cdots & p \end{pmatrix} = \det I = 1,$$

so $\rho M = p$.

(3)⇒(1) There exist $x_{j_1\cdots j_p} \in R$ such that

$$\sum_{1\le j_1<\cdots<j_p\le q} x_{j_1\cdots j_p} M \begin{pmatrix} 1 & \cdots & p \\ j_1 & \cdots & j_p \end{pmatrix} = 1. \tag{13}$$

Traversing the ith row and expanding by minors yields

$$M \begin{pmatrix} 1 & \cdots & p \\ j_1 & \cdots & j_p \end{pmatrix} = \sum_{l=1}^{p} (-1)^{i+j_l} m_{ij_l} M \begin{pmatrix} 1 & \cdots & i-1 & i+1 & \cdots & p \\ j_1 & \cdots & j_{l-1} & j_{l+1} & \cdots & j_p \end{pmatrix}, \tag{14}$$

where $M = [m_{ij}]$. Combining (13) and (14), we obtain $y_{ij} \in R$ such that $\sum_j y_{ij} m_{ij} = 1$. Let $k \ne i$ and replace the ith row of M with the kth row. This yields the calculation

$$\begin{aligned}\sum_{l=1}^{p} (-1)^{i+j_l} m_{kj_l} M \begin{pmatrix} 1 & \cdots & i-1 & i+1 & \cdots & p \\ j_1 & \cdots & j_{l-1} & j_{l+1} & \cdots & j_p \end{pmatrix} \\ = M \begin{pmatrix} 1 & \cdots & i-1 & k & i+1 & \cdots & p \\ & j_1 & & \cdots & & j_p & \end{pmatrix} = 0.\end{aligned}$$

Hence, $\sum_j y_{ij} m_{kj} = 0$. Let

$$y_i = \begin{bmatrix} y_{i1} \\ \vdots \\ y_{iq} \end{bmatrix}.$$

Then My_i is equal to the ith unit vector e_i. Let $x \in R^p$ and

$$z = \begin{bmatrix} y_1 & \cdots & y_p \end{bmatrix} x.$$

Then

$$Mz = \begin{bmatrix} My_1 & \cdots & My_p \end{bmatrix} x = \begin{bmatrix} e_1 & \cdots & e_p \end{bmatrix} x = x.$$

Since x is arbitrary, $\operatorname{Im} M = R^p$. □

LEMMA 2.9. *Let*

$$E = \begin{bmatrix} E_{11} & 0 \\ 0 & 0 \end{bmatrix}, \quad A = \begin{bmatrix} A_{11} & A_{12} \\ A_{21} & A_{22} \end{bmatrix}, \quad B = \begin{bmatrix} B_1 \\ B_2 \end{bmatrix},$$

where $E_{11} \in R^{n_1 \times n_1}$, $A_{ij} \in R^{n_i \times n_j}$, *and* $B_i \in R^{n_i \times m}$.

(1) (E, A) *has unit index iff* E_{11} *and* A_{22} *are unimodular.*

(2) $\rho E = n_1$ *and* $\operatorname{Im} E + A \operatorname{Ker} E + \operatorname{Im} B = R^n$ *iff* E_{11} *is unimodular and* $\rho \begin{bmatrix} A_{22} & B_2 \end{bmatrix} = n_2$.

Proof. (1) (Necessary) From Theorem 2.3, there exist unimodular P and Q so that (PEQ, PAQ) is in standard canonical form with $N = 0$. Let

$$\begin{bmatrix} P_{11} & P_{12} \\ P_{21} & P_{22} \end{bmatrix} = P, \quad \begin{bmatrix} Q_{11} & Q_{12} \\ Q_{21} & Q_{22} \end{bmatrix} = Q^{-1}.$$

Then

$$PE = \begin{bmatrix} I & 0 \\ 0 & 0 \end{bmatrix} Q^{-1}$$

implies $Q_{12} = 0$, so Q_{11} and Q_{22} are unimodular. Also, $P_{11}E_{11} = Q_{11}$ and $P_{21}E_{11} = 0$, so E_{11} is unimodular and $P_{21} = 0$. It follows from

$$PA = \begin{bmatrix} X & 0 \\ 0 & I \end{bmatrix} Q^{-1}$$

that $P_{22}A_{22} = Q_{22}$, so A_{22} is unimodular.

(Sufficient) Let

$$P = \begin{bmatrix} E_{11}^{-1} & -E_{11}^{-1}A_{12}A_{22}^{-1} \\ 0 & A_{22}^{-1} \end{bmatrix}, \quad Q = \begin{bmatrix} I & 0 \\ -A_{22}^{-1}A_{21} & I \end{bmatrix},$$

and $D = 0$. Then

$$PEQ = \begin{bmatrix} I & 0 \\ 0 & 0 \end{bmatrix}, \quad P(AQ + ED) = \begin{bmatrix} E_{11}^{-1}\left(A_{11} - A_{12}A_{22}^{-1}A_{21}\right) & 0 \\ 0 & I \end{bmatrix}.$$

(2) (Necessary) Unimodularity of E_{11} follows from the definition of ρ. Thus

$$\operatorname{Ker} E = \operatorname{Im} \begin{bmatrix} 0 \\ I \end{bmatrix}, \quad \operatorname{Im} \begin{bmatrix} E_{11} & A_{12} & B_1 \\ 0 & A_{22} & B_2 \end{bmatrix} = \operatorname{Im} E + A \operatorname{Ker} E + \operatorname{Im} B = R^n.$$

For any $w \in R^{n_2}$, there exist x, y, z such that

$$\begin{bmatrix} 0 \\ w \end{bmatrix} = \begin{bmatrix} E_{11} & A_{12} & B_1 \\ 0 & A_{22} & B_2 \end{bmatrix} \begin{bmatrix} x \\ y \\ z \end{bmatrix},$$

so

$$w = \begin{bmatrix} A_{22} & B_2 \end{bmatrix} \begin{bmatrix} y \\ z \end{bmatrix}$$

and $\operatorname{Im} \begin{bmatrix} A_{22} & B_2 \end{bmatrix} = R^{n_2}$. The result follows from Lemma 2.8.

(Sufficient) The definition of ρ gives $\rho E = n_1$. Let $v \in R^{n_1}$ and $w \in R^{n_2}$. Then there exist y and z such that $A_{22}y + B_2 z = w$. Set $x = E_{11}^{-1}(v - A_{12}y - B_1 z)$. Then

$$\begin{bmatrix} E_{11} & A_{12} & B_1 \\ 0 & A_{22} & B_2 \end{bmatrix} \begin{bmatrix} x \\ y \\ z \end{bmatrix} = \begin{bmatrix} v \\ w \end{bmatrix},$$

so

$$\operatorname{Im} E + A \operatorname{Ker} E + \operatorname{Im} B = \operatorname{Im} \begin{bmatrix} E_{11} & A_{12} & B_1 \\ 0 & A_{22} & B_2 \end{bmatrix} = R^n. \qquad \square$$

3. Pencils over a Hermite domain. We say R is a *Hermite domain* if it is an integral domain and, for every $a, b \in R$, there exist $u, v, x, y \in R$ such that $ux + vy = 1$ and $ax + by = 0$ [2, p. 469]. It should be noted that the definition of a Hermite domain varies in the literature. For example, [6, p. 345] gives a definition which is different from, but is implied by, the one given in [2]. In particular, every Bezout domain is Hermite [2, Thm. 3.2], and, therefore, every principal ideal domain, field, etc. is also a Hermite domain. For the remainder of this section, our standing assumption is that R is a Hermite domain (as in [2]).

One advantage of working in a Hermite domain is that matrices over R can be triangularized: For any $M \in R^{p\times q}$ $(p \neq q)$, there exists a lower triangular $L \in R^{\min\{p,q\}\times\min\{p,q\}}$ and a unimodular $Q \in R^{q\times q}$ such that

$$MQ = \begin{cases} \begin{bmatrix} L & 0 \end{bmatrix}, & p < q, \\ \begin{bmatrix} L \\ 0 \end{bmatrix}, & p > q. \end{cases}$$

A similar result, in which $\operatorname{Ker} M$ plays a special role, was established for real analytic functions in [5]. The arguments used in [5] are essentially algebraic and can be adapted to any Hermite domain. Since these ideas are central to our results, we develop the underlying algebraic arguments in detail, culminating in Theorem 3.3 and its corollary.

LEMMA 3.1. *Let $M \in R^{2\times 2}$ with at least one first-row entry nonzero. There exists a unimodular $Q \in R^{2\times 2}$ such that MQ is lower triangular with its $1,1$ entry nonzero.*

Proof. Let $\begin{bmatrix} a & b \end{bmatrix}$ be the first row of M and choose $u, v, x, y \in R$ such that $ux + vy = 1$ and $ax + by = 0$. Let

$$Q = \begin{bmatrix} v & x \\ -u & y \end{bmatrix}.$$

Then MQ is lower triangular and $\det Q = 1$, so Q is unimodular. The first row of MQ is $\begin{bmatrix} a & b \end{bmatrix} Q \neq 0$, but the $1,2$ entry of MQ is zero, so its $1,1$ entry must be nonzero. $\square$

LEMMA 3.2. *Let $M \in R^{p\times q}$ with at least one first-row entry nonzero. There exists a unimodular $Q \in R^{q\times q}$ such that MQ has the form*

$$MQ = \begin{bmatrix} a & 0 \\ b & C \end{bmatrix} \tag{15}$$

with $a \neq 0$.

Proof. Q will be constructed as a series of column permutations and transformations of the form

$$\begin{bmatrix} v & & x & \\ & I & & \\ -u & & y & \\ & & & I \end{bmatrix},$$

where u, v, x, and y are as in the proof of Lemma 3.1. The product of such transformations is unimodular.

Begin operating on M by permuting its columns so that either the $1,1$ or $1,2$ entry is nonzero. Applying Lemma 3.1 to the upper left 2×2 submatrix yields a matrix of the form

$$\begin{bmatrix} d & 0 & e \\ f & g & h \\ j & k & L \end{bmatrix},$$

where $d, f, g \in R$ and $d \neq 0$. The $1,3$ entry may be brought to zero by applying Lemma 3.1 to the 2×2 submatrix formed from the first two rows and the first and third columns. Proceeding inductively across the first row, we achieve the form (15) with $a \neq 0$. □

THEOREM 3.3. *Let $M \in R^{p\times q}$. If $\operatorname{rank} M = k > 0$, then there exist $L \in R^{p\times k}$ with $\operatorname{rank} L = k$ and a unimodular $Q \in R^{q\times q}$ such that*

$$MQ = \begin{bmatrix} L & 0 \end{bmatrix}. \tag{16}$$

Proof. Although we will make use of row permutations in achieving our result, these may be reversed at the end without disturbing the form (16). Since $M \neq 0$, there exists a row permutation that places a nonzero entry in the first row. Applying Lemma 3.2, we achieve the form (15) with $a \neq 0$. Suppose $\operatorname{rank} C \geq k$. Then C has a kth-order minor $\mu \neq 0$, and $a\mu$ is a $(k+1)$th-order minor of MQ. Since R is an integral domain, $a\mu \neq 0$, which contradicts $\operatorname{rank} M = k$. Thus $\operatorname{rank} C \leq k-1$.

If $k > 1$, the same arguments may then be applied to C, yielding a matrix of the form

$$\begin{bmatrix} a & 0 & 0 \\ d & e & 0 \\ f & g & H \end{bmatrix},$$

where $e \in R - \{0\}$ and $\operatorname{rank} H \leq k-2$. Proceeding inductively, we eventually achieve (16) with k nonzero columns. Since Q is unimodular, $\operatorname{rank} L = \operatorname{rank} M = k$. □

COROLLARY 3.4. *Let $M \in R^{p\times q}$.*

(1) *If $\rho M = p$, then there exists a unimodular Q such that*

$$MQ = \begin{bmatrix} I & 0 \end{bmatrix}.$$

(2) *If $\operatorname{rank} M = k$, then there exist $L \in R^{k\times k}$ with $\operatorname{rank} L = k$ and unimodular P and Q such that*

$$PMQ = \begin{bmatrix} L & 0 \\ 0 & 0 \end{bmatrix}.$$

(3) *If* $\operatorname{rank} M = \rho M$, *then there exist unimodular* P *and* Q *such that*

$$PMQ = \begin{bmatrix} I & 0 \\ 0 & 0 \end{bmatrix}.$$

(4) *If* $\operatorname{rank} M = \rho M = p$, *then there exists* $L \in R^{(q-p)\times q}$ *such that* $\begin{bmatrix} M \\ L \end{bmatrix}$ *is unimodular.*

Proof. (1) From Theorem 3.3, there exists Q_1 and L such that

$$MQ_1 = \begin{bmatrix} L & 0 \end{bmatrix}.$$

But $\rho L = \rho M = p$, so L is unimodular. Let

$$Q = Q_1 \begin{bmatrix} L^{-1} & 0 \\ 0 & I \end{bmatrix}.$$

(2) From Theorem 3.3, there exist $L_1 \in R^{k\times k}$and $L_2 \in R^{(p-k)\times k}$ with

$$\operatorname{rank} \begin{bmatrix} L_1 \\ L_2 \end{bmatrix} = k$$

and a unimodular Q such that

$$MQ = \begin{bmatrix} L_1 & 0 \\ L_2 & 0 \end{bmatrix}.$$

Also, there exist $L \in R^{k\times k}$ with $\operatorname{rank} L = k$ and a unimodular P such that

$$\begin{bmatrix} L_1^T & L_2^T \end{bmatrix} P^T = \begin{bmatrix} L^T & 0 \end{bmatrix}.$$

Hence,

$$PMQ = \left((MQ)^T P^T\right)^T = \left(\begin{bmatrix} L_1^T & L_2^T \\ 0 & 0 \end{bmatrix} P^T\right)^T = \begin{bmatrix} L^T & 0 \\ 0 & 0 \end{bmatrix}^T.$$

(3) Suppose $\operatorname{rank} M = k$. From part (2), there exist L, P_1, Q such that

$$P_1 MQ = \begin{bmatrix} L & 0 \\ 0 & 0 \end{bmatrix},$$

where $L \in R^{k\times k}$. Since $\rho M = k$, L is unimodular. Let

$$P = \begin{bmatrix} L^{-1} & 0 \\ 0 & I \end{bmatrix} P_1.$$

(4) From part (1), there exists a unimodular Q such that

$$MQ = \begin{bmatrix} I & 0 \end{bmatrix}.$$

Then

$$\begin{bmatrix} J \\ L \end{bmatrix} = Q^{-1}$$

is unimodular, and

$$J = \begin{bmatrix} I & 0 \end{bmatrix} Q^{-1} = M. \qquad \square$$

Corollary 3.4, part (4) is contained in Lemma 59, p. 345 of [6]. However, our proof is more directly applicable to our development.

Another advantage of working in an integral domain is that, if $M \in R^{p\times p}$, $x \in R^p$, and $Mx = 0$, then either $x = 0$ or $\det M = 0$, since

$$(\det M)\, x = (\operatorname{adj} M)\, Mx = 0.$$

We will make frequent use of this fact in developing our main results.

The next result is complementary to Theorem 2.5, part (2).

THEOREM 3.5. *If* $\operatorname{Im} E + A \operatorname{Ker} E = R^n$, *then* (E, A) *has unit index.*

Proof. If $E = 0$, then $\operatorname{Im} A = R^n$. From Lemma 2.8, A is unimodular. Then the standard canonical form with $N = 0$ is achieved by letting $P = A^{-1}$, $Q = I$, and $D = 0$. If $E \neq 0$, we apply Corollary 3.4, part (2) to obtain

$$PEQ = \begin{bmatrix} E_{11} & 0 \\ 0 & 0 \end{bmatrix}, \quad PAQ = \begin{bmatrix} A_{11} & A_{12} \\ A_{21} & A_{22} \end{bmatrix}$$

with $\det E_{11} \neq 0$. Let

$$\begin{bmatrix} x_1 \\ x_2 \end{bmatrix} = x \in R^n.$$

Since R is an integral domain, $PEQx = 0$ implies $x_1 = 0$, so

$$\operatorname{Ker} PEQ = \operatorname{Im} \begin{bmatrix} 0 \\ I \end{bmatrix},$$

$$\operatorname{Im} \begin{bmatrix} E_{11} & A_{12} \\ 0 & A_{22} \end{bmatrix} = \operatorname{Im} PEQ + PAQ \operatorname{Ker} PEQ = P(\operatorname{Im} E + A \operatorname{Ker} E) = R^n.$$

From Lemma 2.8, E_{11} and A_{22} are unimodular. From Lemma 2.9, part (1), (E, A) has a unit index. $\square$

The next theorem, complementary to Theorem 2.7, is our main result.

THEOREM 3.6. *If*

(1) $\operatorname{rank} E = \rho E$,

(2) $\operatorname{Im} E + A \operatorname{Ker} E + \operatorname{Im} B = R^n$,

(3) (E, A) *is presolvable,*

then (E, A, B) *is impulse controllable.*

Proof. Presolvability of (E, A) admits three cases. If (PS1) holds, (E, A) has unit index from Theorem 3.5. Setting $K = 0$, $(E, A + BK)$ has unit index and (E, A, B) is impulse controllable. To analyze the remaining cases, we invoke Corollary 3.4, part (3). Let

$$\begin{bmatrix} I & 0 \\ 0 & 0 \end{bmatrix} = PEQ, \quad \begin{bmatrix} A_{11} & A_{12} \\ A_{21} & A_{22} \end{bmatrix} = PAQ, \quad \begin{bmatrix} B_1 \\ B_2 \end{bmatrix} = PB,$$

where partitioning conforms to $n = n_1 + n_2$. If (PS2) holds,

$$\operatorname{Im} \begin{bmatrix} I \\ 0 \end{bmatrix} \cap \operatorname{Im} \begin{bmatrix} A_{12} \\ A_{22} \end{bmatrix} = \operatorname{Im} PEQ \cap PAQ \operatorname{Ker} PEQ = P(\operatorname{Im} E \cap A \operatorname{Ker} E) \neq 0,$$

so there exist x and y such that

$$\begin{bmatrix} y \\ 0 \end{bmatrix} = \begin{bmatrix} A_{12} \\ A_{22} \end{bmatrix} x \neq 0.$$

Hence, $x \neq 0$ and $A_{22}x = 0$. Since R is an integral domain, $\det A_{22} = 0$. Similarly, if (PS3) holds,

$$\operatorname{Ker} \begin{bmatrix} A_{12} \\ A_{22} \end{bmatrix} = \operatorname{Ker} PEQ \cap \operatorname{Ker} PAQ = Q^{-1} (\operatorname{Ker} E \cap \operatorname{Ker} A) \neq 0,$$

so there exists $x \neq 0$ such that

$$\begin{bmatrix} A_{12} \\ A_{22} \end{bmatrix} x = 0.$$

Hence, $A_{22}x = 0$ and $\det A_{22} = 0$. In either case, we need consider only singular A_{22}.

Note that

$$\begin{aligned} \operatorname{Im} \begin{bmatrix} I & A_{12} & B_1 \\ 0 & A_{22} & B_2 \end{bmatrix} &= \operatorname{Im} PEQ + PAQ \operatorname{Ker} PEQ + \operatorname{Im} PB \\ &= P (\operatorname{Im} E + A \operatorname{Ker} E + \operatorname{Im} B) \\ &= R^n, \end{aligned}$$

so $\operatorname{Im} \begin{bmatrix} A_{22} & B_2 \end{bmatrix} = R^{n_2}$. Let $r = \operatorname{rank} A_{22}$. From Corollary 3.4, part (2), there exist P_1 and Q_1 such that

$$P_1 A_{22} Q_1 = \begin{bmatrix} \widehat{A} & 0 \\ 0 & 0 \end{bmatrix},$$

where $\widehat{A} \in R^{r \times r}$. Let

$$\begin{bmatrix} \overline{B} \\ \overline{C} \end{bmatrix} = P_1 B_2.$$

Then

$$\operatorname{Im} \begin{bmatrix} \widehat{A} & \overline{B} \\ 0 & \overline{C} \end{bmatrix} = \operatorname{Im} \begin{bmatrix} P_1 A_{22} Q_1 & P_1 B_2 \end{bmatrix} = P_1 \operatorname{Im} \begin{bmatrix} A_{22} & B_2 \end{bmatrix} = R^{n_2}$$

and $\operatorname{Im} \overline{C} = R^{n_2 - r}$. From Corollary 3.4, part (1) and Lemma 2.8, there exists a unimodular Q_2 such that

$$\overline{C} Q_2 = \begin{bmatrix} I & 0 \end{bmatrix}.$$

Let

$$\begin{bmatrix} \widetilde{B} & \widehat{B} \end{bmatrix} = \overline{B} Q_2$$

and

$$P_2 = \begin{bmatrix} I & -\widetilde{B} \\ 0 & I \end{bmatrix}.$$

Then

$$\operatorname{Im}\begin{bmatrix} \widehat{A} & 0 & \widehat{B} \\ 0 & I & 0 \end{bmatrix} = \operatorname{Im}\left(P_2 \begin{bmatrix} \widehat{A} & \overline{B} \\ 0 & \overline{C} \end{bmatrix} \begin{bmatrix} I & 0 \\ 0 & Q_2 \end{bmatrix} \right) = P_2 \operatorname{Im}\begin{bmatrix} \widehat{A} & \overline{B} \\ 0 & \overline{C} \end{bmatrix} = R^{n_2},$$

and $\operatorname{Im}[\widehat{A} \quad \widehat{B}] = R^r$, so Lemma 2.8 guarantees the existence of a right inverse. From Corollary 3.4, part (4), there are W and Y such that

$$U = \begin{bmatrix} \widehat{A} & \widehat{B} \\ W & Y \end{bmatrix}$$

is unimodular. Let $K_1 \in R^{m \times n_1}$ be arbitrary,

$$K_2 = Q_2 \begin{bmatrix} W & Y \\ 0 & I \end{bmatrix} Q_1^{-1}, \quad K = \begin{bmatrix} K_1 & K_2 \end{bmatrix} Q^{-1}.$$

Then

$$\begin{aligned} P_2 P_1 \left(A_{22} + B_2 K_2 \right) Q_1 &= P_2 P_1 A_{22} Q_1 + \left(P_2 P_1 B_2 Q_2 \right) \left(Q_2^{-1} K_2 Q_1 \right) \\ &= \begin{bmatrix} \widehat{A} & 0 \\ 0 & 0 \end{bmatrix} + \begin{bmatrix} 0 & \widehat{B} \\ I & 0 \end{bmatrix} \begin{bmatrix} W & Y \\ 0 & I \end{bmatrix} \\ &= U, \end{aligned}$$

so $A_{22} + B_2 K_2$ is unimodular. From Lemma 2.9, part (1),

$$\left(PEQ, P\left(A + BK \right) Q \right) = \left(\begin{bmatrix} I & 0 \\ 0 & 0 \end{bmatrix}, \begin{bmatrix} A_{11} + B_1 K_1 & A_{12} + B_1 K_2 \\ A_{21} + B_2 K_1 & A_{22} + B_2 K_2 \end{bmatrix} \right)$$

has a unit index, so $(E, A + BK)$ has a unit index and (E, A, B) is impulse controllable. □

Let $\mathcal{I}$ be the set of all impulse eliminating K. The arguments used in the proof of Theorem 3.6 can be generalized to construct a large subset of $\mathcal{I}$. We begin by fixing $P_1, P_2, Q, Q_1, Q_2, A_{22}, B_2, \widehat{A}, \widehat{B}$ as above. Then, for any K_1, W, Y, T, V with V and

$$U = \begin{bmatrix} \widehat{A} & \widehat{B} \\ W & Y \end{bmatrix}$$

unimodular, we set

$$K_2 = Q_2 \begin{bmatrix} W & Y \\ 0 & I \end{bmatrix} \begin{bmatrix} I & 0 \\ T & V \end{bmatrix} Q_1^{-1}.$$

It follows that

$$P_2 P_1 \left(A_{22} + B_2 K_2 \right) Q_1 = \begin{bmatrix} \widehat{A} & 0 \\ 0 & 0 \end{bmatrix} + \begin{bmatrix} 0 & \widehat{B} \\ I & 0 \end{bmatrix} \begin{bmatrix} W & Y \\ 0 & I \end{bmatrix} = U \begin{bmatrix} I & 0 \\ T & V \end{bmatrix}$$

is unimodular. Setting $K = \begin{bmatrix} K_1 & K_2 \end{bmatrix} Q^{-1}$ guarantees that $(E, A + BK)$ has unit index.

We note that the map $\pi\left(K_1, W, Y, T, V \right) = K$ is one-to-one. Indeed, if we choose K in the range of π, then K_1 is uniquely determined, and setting $L = Q_2^{-1} K_2 Q_1$ yields

$$\begin{bmatrix} W & Y \\ 0 & I \end{bmatrix} \begin{bmatrix} I & 0 \\ T & V \end{bmatrix} = \begin{bmatrix} L_{11} & L_{12} \\ L_{21} & L_{22} \end{bmatrix},$$

so

$$T = L_{21}, \quad V = L_{22}, \quad Y = L_{12}L_{22}^{-1}, \quad W = L_{11} - L_{12}L_{22}^{-1}L_{21}.$$

Hence, π may be considered a parametrization of the set of all impulse eliminating K with unimodular V (i.e., the 2,2 block of $Q_2^{-1}K_2Q_1$). Unfortunately, this may not be a complete parametrization of $\mathcal{I}$, as the example

$$E = \begin{bmatrix} 0 & 0 \\ 0 & 0 \end{bmatrix}, \quad A = \begin{bmatrix} 1 & 0 \\ 0 & 0 \end{bmatrix}, \quad B = \begin{bmatrix} 0 & 0 \\ 1 & 0 \end{bmatrix}$$

illustrates. Here, direct calculation shows that $\mathcal{I}$ consists of all matrices of the form

$$K = \begin{bmatrix} k_{11} & k_{12} \\ k_{21} & k_{22} \end{bmatrix}$$

with k_{12} a unit. However, π only yields those matrices of the form

$$K = \begin{bmatrix} W + YT & YV \\ T & V \end{bmatrix}$$

with V and Y units. Although π does predict that $k_{12} = YV$ must be a unit, it does not allow $k_{22} = V$ to be a nonunit, in spite the admissibility of such values. Hence, the range of π is a proper subset of $\mathcal{I}$.

4. Applications to time-varying singular systems. In this section, we consider time-varying differential equations

$$E(t)\,\dot{x} = A(t)\,x + B(t)\,u, \tag{17}$$

where the entries of E, A, and B belong to a ring of real-valued functions on $\mathbb{R}$. We assume $E(t), A(t) \in \mathbb{R}^{n\times n}$ and $B(t) \in \mathbb{R}^{n\times m}$. The interesting case occurs when $E(t)$ is singular on a subset of $\mathbb{R}$. Such systems have been studied at length under the assumption that E, A, and B are either constant [7] or real analytic [3], [4]. We will show that these cases fit into our algebraic framework and examine certain additional classes of functions that can be treated in our setting. Our work does not apply to problems where E, A, B, and K are allowed to have arbitrary entries in C^n (as in [17] and [18]), since C^n is not Hermite.

In studying (17), it is useful to consider a change of variables of the form $x = Q(t)\,z$, where $Q(t)$ is everywhere nonsingular and where both Q and Q^{-1} belong to a given class of functions. Assuming differentiability of Q, direct substitution yields the equivalent system

$$P(t)\,E(t)\,Q(t)\,\dot{z} = P(t)\left(A(t)\,Q(t) - E(t)\,\dot{Q}(t)\right)z + P(t)\,B(t)\,u, \tag{18}$$

where $P(t)$ is also nonsingular for every t. (Note the relationship of (18) to the group action (12).)

Another important consideration in working with any kind of differential equation is that of solvability. Roughly, this means that (17) exhibits existence and uniqueness of solutions over a large class of forcing functions u. In the case of equations based on matrices over the real analytic functions $\mathcal{A}(\mathbb{R})$, Campbell and Petzold [3] define (E, A) to be *analytically solvable* if, for every C^n function u, the system

$$E(t)\,\dot{x} = A(t)\,x + u \tag{19}$$

has at least one C^1 solution x on $\mathbb{R}$ and no two distinct solutions coincide for any t. They then proceed to show that analytic solvability is equivalent to the existence of analytic nonsingular matrices P and Q that put (18) into standard canonical form. Hence, analytic solvability is equivalent to algebraic solvability.

In the time-invariant setting, analytic solvability of (17) reduces to the condition that the matrix pencil (E, A) be *regular*, i.e.,

$$\det(sE - A) \not\equiv 0. \tag{20}$$

(See [8, pp. 45–49].) From [8, Thm. 3, p. 28], (20) is equivalent to the existence of nonsingular $P, Q \in \mathbb{R}^{n\times n}$ that put the pencil into *Weierstrass canonical form*:

$$PEQ = \begin{bmatrix} I & 0 \\ 0 & N \end{bmatrix}, \quad PAQ = \begin{bmatrix} X & 0 \\ 0 & I \end{bmatrix}, \tag{21}$$

where N is nilpotent. Since $\dot{Q} = 0$, (21) and (7) are the same, so (20) is equivalent to algebraic solvability.

In addition to solvability, we note that the unit index property is a natural concept in both the constant and real analytic settings, occurring iff $N \equiv 0$.

In order to study the impulsive behavior of singular systems, we must adopt a more sophisticated viewpoint based on distribution theory. In (19) we may investigate the consequences of applying an input u, which is arbitrary C^1 up to time $t = t_0$ and drops abruptly to 0 at t_0. As discussed in [15, Ch. 22], the resulting solution exists as a distribution and is, in fact, the unique distribution x satisfying $x(t) = 0$ for $t < t_0$ and

$$E(t)\,\dot{x} = A(t)\,x + \delta_{t_0} E(t_0)\,x_0, \tag{22}$$

where δ_{t_0} is the unit impulse and $x_0 = \lim_{t\to t_0^-} x(t)$. Equation (22) gives a precise meaning to the natural response of (17) with arbitrary initial conditions.

Our principal objective is to find a matrix $K(t)$, whose entries reside in the *same ring of functions as the entries of* E, A, *and* B, and such that the state feedback law $u = K(t)\,x$ yields a unit index closed-loop system

$$E(t)\,\dot{x} = (A(t) + B(t)\,K(t))\,x + \delta_{t_0} E(t_0)\,x_0. \tag{23}$$

Thus we are simultaneously treating a wide variety of constrained feedback problems, which have not been considered in the literature.

In order to apply our results to (17), we first need to identify a function ring R that satisfies the conditions that (1) R is an Hermite domain, (2) R is closed under differentiation, (3) solvability in the classical sense implies presolvability, and (4) the analytic and algebraic notions of the unit index property coincide. Note that it follows from (4) that the analytic and algebraic notions of impulse controllability must also coincide. Once these conditions are established, we are guaranteed that the results of sections 2 and 3 apply to systems over R. In particular, Theorems 2.7 and 3.6 give necessary and sufficient algebraic conditions under which (17) is impulse controllable. It remains only to translate conditions (1) and (2) from Theorems 2.7 and 3.6 into analytic terms.

For the remainder of this paper, we restrict ourselves to subrings R (with identity) of $\mathcal{A}(\mathbb{R})$. Properties (1) and (2) will have to be established case by case. On the other hand, (3) and (4) hold automatically for $\mathcal{A}(\mathbb{R})$ as a consequence of previous results.

Indeed, condition (3) may be established by examining the proof of Theorem 2 in [3]. In light of our Theorem 3.3 and its corollary, the arguments used by Campbell and Petzold carry over verbatim to R, demonstrating that analytic solvability of (E, A) guarantees algebraic solvability and, therefore, presolvability. To establish (4), suppose (E, A) is analytically (and algebraically) solvable. If $N \equiv 0$, then (E, A) has unit index in the algebraic sense with $D = -\dot{Q}$. Conversely, suppose (E, A) has an algebraic unit index. Then, from Theorem 2.3, we may choose Q such that setting $D = -\dot{Q}$ yields P that achieves (21) with $N = 0$. Hence, the two notions of unit index coincide. This establishes that our algebraic theory applies to any Hermite subring of $\mathcal{A}(\mathbb{R})$ which is closed under differentiation.

Time-invariant systems. To treat time-invariant systems

$$E\dot{x} = Ax + Bu,$$

set $R = \mathbb{R}$. Since $\mathbb{R}$ is a field, it is Hermite. Viewing $\mathbb{R}$ as the set of constant functions, it is closed under differentiation. We therefore conclude that Theorems 2.7 and 3.6 specialize to the characterization of time-invariant impulse controllability first established in [16]. The proofs of Theorems 2.7 and 3.6 thus constitute an alternative to the known proofs of this result, as presented in [10, Thm. 6], [12, Thm. 2.5.1], and [13, Thm. 3-2.1].

General analytic systems. For $R = \mathcal{A}(\mathbb{R})$, [5, Lem. 1] shows that $\mathcal{A}(\mathbb{R})$ is Hermite. (In fact, it is shown in [11, Thm. 1.19], that $\mathcal{A}(\mathbb{R})$ is a Bezout domain.) R is closed under differentiation, so conditions (1) and (2) of Theorems 2.7 and 3.6 are necessary and sufficient for impulse controllability. It remains to link the algebraic conditions to analytic conditions on $E(t)$, $A(t)$, and $B(t)$.

THEOREM 4.1. *Conditions* (1) *and* (2) *of Theorems* 2.7 *and* 3.6 *hold for* $R = \mathcal{A}(\mathbb{R})$ *iff* $\operatorname{rank}_{\mathbb{R}} E(t)$ *is constant and* $\operatorname{Im} E(t) + A(t) \operatorname{Ker} E(t) + \operatorname{Im} B(t) = \mathbb{R}^n$ *for every* $t \in \mathbb{R}$.

Proof. (Sufficient) Suppose $\operatorname{rank}_{\mathbb{R}} E(t) = k$. Then $\operatorname{rank} E = k$ and, from Corollary 3.4, part (2), there exist unimodular P and Q such that

$$PEQ = \begin{bmatrix} E_{11} & 0 \\ 0 & 0 \end{bmatrix},$$

where $E_{11} \in R^{k \times k}$ and $\operatorname{rank} E_{11} = k$. But $\operatorname{rank}_{\mathbb{R}} E_{11}(t)$ must also be constant, so E_{11} is unimodular. Let

$$\begin{bmatrix} A_{11} & A_{12} \\ A_{21} & A_{22} \end{bmatrix} = PAQ, \quad \begin{bmatrix} B_1 \\ B_2 \end{bmatrix} = PB.$$

Then

$$\operatorname{Im} \begin{bmatrix} E_{11}(t) & A_{12}(t) & B_1(t) \\ 0 & A_{22}(t) & B_2(t) \end{bmatrix} = \operatorname{Im} E(t) + A(t) \operatorname{Ker} E(t) + \operatorname{Im} B(t) = \mathbb{R}^n$$

for every t, so $\operatorname{rank}_{\mathbb{R}} \begin{bmatrix} A_{22}(t) & B_2(t) \end{bmatrix} = n - k$. Let $\{\mu_i(t)\}$ be the $(n-k)$th-order minors of $\begin{bmatrix} A_{22}(t) & B_2(t) \end{bmatrix}$. Each μ_i is an analytic function and the μ_i have no common zero. Hence, $u = \sum \mu_1^2$ has no zero and is therefore a unit of R. Also,

$$\sum \left(\frac{\mu_i}{u} \right) \mu_i = 1,$$

so $\rho \left[\begin{array}{cc} A_{22} & B_2 \end{array} \right] = n-k$. From Corollary 3.4, part (1), there exists a unimodular Q_1 such that

$$\left[\begin{array}{cc} A_{22} & B_2 \end{array} \right] Q_1 = \left[\begin{array}{cc} I & 0 \end{array} \right].$$

If $x \in R^{n-k}$, then

$$\left[\begin{array}{cc} A_{22} & B_2 \end{array} \right] Q_1 \left[\begin{array}{c} x \\ 0 \end{array} \right] = x,$$

so $x \in \operatorname{Im} \left[\begin{array}{cc} A_{22} & B_2 \end{array} \right]$. But x is arbitrary, so $\operatorname{Im} \left[\begin{array}{cc} A_{22} & B_2 \end{array} \right] = R^{n-k}$. The theorem follows from Lemma 2.8 and Lemma 2.9, part (2).

(Necessary) From Corollary 3.4, part (3), there exist unimodular P and Q such that

$$P(t) E(t) Q(t) = \left[\begin{array}{cc} I & 0 \\ 0 & 0 \end{array} \right]$$

for every t. Hence, $\operatorname{rank}_{\mathbb{R}} E(t)$ is constant. Let $x \in \mathbb{R}^n$. Viewing x as a constant function, it follows from $\operatorname{Im} E + A \operatorname{Ker} E + \operatorname{Im} B = R^n$ that there exist $u \in R^m$ and $y, z \in R^n$ such that $Ez = 0$ and $Ey + Az + Bu = x$. But this means $E(t) z(t) = 0$ and $E(t) y(t) + A(t) z(t) + B(t) u(t) = x$ for every t, so $\operatorname{Im} E(t) + A(t) \operatorname{Ker} E(t) + \operatorname{Im} B(t) = \mathbb{R}^n$. □

Theorem 4.1 shows that Theorems 2.7 and 3.6 specialize to Theorem 4.1 of [4] for systems over the real analytic functions.

Now we apply our theory to classes of time-varying singular systems (17) which have not been previously studied.

Polynomial systems. Let $R = \mathbb{R}[t]$ be the polynomials on $\mathbb{R}$ with real coefficients. $\mathbb{R}[t]$ is a subring of $\mathcal{A}(\mathbb{R})$ containing 1 and a principal ideal domain, so it is Hermite. $\mathbb{R}[t]$ is closed under differentiation. Theorem 4.1 applies to $\mathbb{R}[t]$ without modification.

Periodic systems. Let $\mathcal{P}(\tau)$ be the analytic functions on $\mathbb{R}$ with period $\tau > 0$. (τ need not be the fundamental period.) $\mathcal{P}(\tau)$ is a subring of $\mathcal{A}(\mathbb{R})$ containing 1 and is closed under differentiation.

THEOREM 4.2. *$\mathcal{P}(\tau)$ is a Bezout domain.*

Proof. We need to show that every finitely generated ideal in $\mathcal{P}(\tau)$ is principal. It suffices to show that, for every $a, b \in \mathcal{P}(\tau)$, there exists $c \in \mathcal{P}(\tau)$ such that $cR = aR + bR$. In view of [9, Thm. 3.7, p. 78], a and b have finitely many zeros in any bounded interval. Let $\{z_1, \ldots, z_q\}$ be the common zeros of a and b in the interval $[0, \tau)$, counting multiplicities, and define

$$c(t) = \prod_k \left(e^{2\pi i \frac{t}{\tau}} - e^{2\pi i \frac{z_k}{\tau}} \right).$$

Then $c \in \mathcal{P}(\tau)$ with zeros $\{z_k\}$, and c is a common divisor of a and b. Let $\overline{a} = a/c$ and $\overline{b} = b/c$. If $x, y \in R$, then

$$ax + by = c\left(\overline{a}x + \overline{b}y\right) \in cR,$$

so $aR + bR \subset cR$. To prove the converse, note that $\overline{a}$ and $\overline{b}$ have no common zero, so $u = \overline{a}^2 + \overline{b}^2$ has no zero and is, therefore, a unit of R. For any $r \in R$, set $x = \overline{a}r/u$ and $y = \overline{b}r/u$. Then

$$cr = cr\frac{\overline{a}^2 + \overline{b}^2}{u} = ax + by \in aR + bR,$$

so $cR \subset aR + bR$. □

It follows from Theorem 4.2 that $\mathcal{P}(\tau)$ is a Hermite domain. It can be further shown that $\mathcal{P}(\tau)$ is a principal ideal domain. Theorem 4.1 applies to $\mathcal{P}(\tau)$ without modification.

Systems analytic at ∞. Let $\mathcal{A}_\infty(\mathbb{R})$ be the subring of $\mathcal{A}(\mathbb{R})$ consisting of all functions analytic at ∞. (x analytic at ∞ means that $x\left(\frac{1}{t}\right)$ is analytic at 0.) From the chain rule,

$$\dot{x}\left(\frac{1}{t}\right) = -t^2 \frac{d}{dt}\left(x\left(\frac{1}{t}\right)\right),$$

so $\mathcal{A}_\infty(\mathbb{R})$ is closed under differentiation.

THEOREM 4.3. *$\mathcal{A}_\infty(\mathbb{R})$ and $\mathcal{P}(\tau)$ are isomorphic.*

Proof. Let

$$\phi(t) = \begin{cases} \tan\left(\pi \frac{t}{\tau}\right), & t \neq \left(k+\frac{1}{2}\right)\tau, \\ \infty, & t = \left(k+\frac{1}{2}\right)\tau. \end{cases}$$

ϕ has period τ and is analytic, except for poles at $\left(k+\frac{1}{2}\right)\tau$. $1/\phi$ is analytic about $\left(k+\frac{1}{2}\right)\tau$, where it has a zero. For any $x \in \mathcal{A}_\infty(\mathbb{R})$, define $x_p(t) = x(\phi(t))$. Then x_p has period τ. Since $x\left(\frac{1}{t}\right)$ is analytic about 0, x_p is analytic about $\left(k+\frac{1}{2}\right)\tau$ and therefore on all of $\mathbb{R}$. Hence, the map $h : x \to x_p$ takes $\mathcal{A}_\infty(\mathbb{R})$ into $\mathcal{P}(\tau)$ and is obviously a ring homomorphism. Since the range of ϕ is $\mathbb{R}$, $x_p \equiv 0$ implies $x \equiv 0$, and h is $1-1$. Given any $x_p \in \mathcal{P}(\tau)$, $x(t) = x_p\left(\frac{\tau}{\pi}\arctan(t)\right)$ defines a function in $\mathcal{A}_\infty(\mathbb{R})$. But $\frac{\tau}{\pi}\arctan(\phi(t)) = t$, so $h(x) = x_p$ and h is onto. □

It follows from Theorems 4.2 and 4.3 that $\mathcal{A}_\infty(\mathbb{R})$ is a Hermite domain.

The conditions of Theorem 4.1 must be augmented to handle analyticity at ∞.

THEOREM 4.4. *Conditions* (1) *and* (2) *of Theorems* 2.7 *and* 3.6 *hold for $R = \mathcal{A}_\infty(\mathbb{R})$ iff*

$$\operatorname*{rank}_{\mathbb{R}} E(t) = \operatorname*{rank}_{\mathbb{R}} E(\infty),$$

$$\operatorname{Im} E(t) + A(t)\operatorname{Ker} E(t) + \operatorname{Im} B(t) = \operatorname{Im} E(\infty) + A(\infty)\operatorname{Ker} E(\infty) + \operatorname{Im} B(\infty) = \mathbb{R}^n$$

for every $t \in \mathbb{R}$.

Proof. (Sufficient) Suppose $\operatorname{rank}_{\mathbb{R}} E(t) = k$. As in the proof of Theorem 4.1, there exist unimodular P and Q such that

$$PEQ = \begin{bmatrix} E_{11} & 0 \\ 0 & 0 \end{bmatrix},$$

where $E_{11} \in R^{k\times k}$ and $\operatorname{rank} E_{11} = k$. But $\operatorname{rank}_{\mathbb{R}} E_{11}(t) = \operatorname{rank}_{\mathbb{R}} E_{11}(\infty) = k$, so E_{11} is unimodular. Then

$$\operatorname{Im}\begin{bmatrix} E_{11}(t) & A_{12}(t) & B_1(t) \\ 0 & A_{22}(t) & B_2(t) \end{bmatrix} = \operatorname{Im} E(t) + A(t)\operatorname{Ker} E(t) + \operatorname{Im} B(t) = \mathbb{R}^n$$

for every t (including $t = \infty$), so $\operatorname{rank}_{\mathbb{R}}\begin{bmatrix} A_{22}(t) & B_2(t) \end{bmatrix} = n - k$ and the minors $\{\mu_i\}$ have no common finite or infinite zero. The remainder of the sufficiency proof proceeds without modification.

(Necessary) From Corollary 3.4, part (3), there exist unimodular P and Q such that

$$P(t)E(t)Q(t) = P(\infty)E(\infty)Q(\infty) = \begin{bmatrix} I & 0 \\ 0 & 0 \end{bmatrix}.$$

Hence, $\operatorname{rank}_{\mathbb{R}} E(t) = \operatorname{rank}_{\mathbb{R}} E(\infty)$. Let $x \in \mathbb{R}^n$. Viewing x as a constant function, there exist $u \in R^m$ and $y, z \in R^n$ such that $Ez = 0$ and $Ey + Az + Bu = x$. But this means

$$E(t) z(t) = E(\infty) z(\infty) = 0,$$

$$E(t) y(t) + A(t) z(t) + B(t) u(t) = E(\infty) y(\infty) + A(\infty) z(\infty) + B(\infty) u(\infty) = x.$$

Since x is arbitrary, the theorem follows. □

Example. We close this section with a simple example illustrating how our results may be applied to periodic systems. Let

$$T(t) = \begin{bmatrix} \cos t & \sin t \\ -\sin t & \cos t \end{bmatrix},$$

and note that T is unimodular over $\mathcal{P}(2\pi)$. Consider the singular system with

$$E = \begin{bmatrix} 0 & T \\ 0 & 0 \end{bmatrix}, \quad A = \begin{bmatrix} I & 0 \\ 0 & I \end{bmatrix}, \quad B = \begin{bmatrix} 0 \\ I \end{bmatrix}.$$

(E, A, B) is already in standard canonical form, so it is analytically and algebraically solvable. A simple calculation shows that $u \equiv 0$ leads to

$$\begin{bmatrix} x_1 \\ x_2 \\ x_3 \\ x_4 \end{bmatrix} = \begin{bmatrix} -\delta_{t_0} x_{03} \\ -\delta_{t_0} x_{04} \\ 0 \\ 0 \end{bmatrix}.$$

We wish to find an *analytic periodic* state feedback matrix $K(t)$ to eliminate impulses in the closed-loop system.

Note that $\operatorname{rank}_{\mathbb{R}} E(t) = 2$,

$$\operatorname{Ker} E(t) = \operatorname{Im} \begin{bmatrix} I \\ 0 \end{bmatrix},$$

$$\operatorname{Im} E(t) + A(t) \operatorname{Ker} E(t) + \operatorname{Im} B(t) = \operatorname{Im} \begin{bmatrix} T(t) & I & 0 \\ 0 & 0 & I \end{bmatrix} = \mathbb{R}^4$$

for every t. Theorems 3.6 and 4.1 guarantee that (E, A, B) is impulse controllable.

As in the proof of Theorem 3.6, we obtain the unimodular matrices

$$P = \begin{bmatrix} I & 0 \\ 0 & I \end{bmatrix}, \quad Q = \begin{bmatrix} 0 & I \\ T^T & 0 \end{bmatrix}.$$

Then

$$\begin{bmatrix} A_{11} & A_{12} \\ A_{21} & A_{22} \end{bmatrix} = PAQ = Q,$$

so $A_{22} = 0$, $r = 0$, and $P_1 = Q_1 = P_2 = Q_2 = I$. Let $K_1, V, Y \in (\mathcal{P}(2\pi))^{2\times 2}$ with V, Y unimodular, and apply the parametrization π, as described at the end of section 3. This yields the state feedback matrix

$$K = \begin{bmatrix} K_1 & YV \end{bmatrix} Q^{-1} = \begin{bmatrix} K_1 & YV \end{bmatrix} \begin{bmatrix} 0 & T \\ I & 0 \end{bmatrix} = \begin{bmatrix} YV & K_1 T \end{bmatrix} \in (\mathcal{P}(2\pi))^{2\times 4}$$

and the periodic closed-loop system

$$\begin{bmatrix} 0 & T(t) \\ 0 & 0 \end{bmatrix} \dot{x} = \begin{bmatrix} I & 0 \\ Y(t)V(t) & I + K_1(t)T(t) \end{bmatrix} x. \tag{24}$$

Our theory guarantees that (24) has a unit index. This can be verified directly by interchanging the block columns of (24) and applying Lemma 2.9, part (1).

5. Conclusion. Our work demonstrates that the solutions of the state feedback impulse elimination problem, as originally developed for the time-invariant and time-varying cases in [10] and [4], share a common algebraic basis. Once exposed, this structure lends itself naturally to numerous generalizations, requiring only a small amount of analytic effort to turn the problem into algebra. The rings discussed in this paper are only a few of the many possibilities. For example, it is easy to show that similar conclusions hold for the real analytic functions with an isolated singularity at ∞, those with a pole or removable singularity at ∞, those with a zero of order at least k at a fixed point in $\mathbb{R} \cup \{\infty\}$, rational functions with no pole in $\mathbb{R}$, etc. Perhaps the greatest challenge is to fully exploit our theory by proposing a Hermite domain which is not principal ideal domain, Bezout, etc. We leave this challenge for further research.

Acknowledgement. The author wishes to thank Nigel Boston for his many helpful suggestions during the course of this research.

HIGH-GAIN STATE FEEDBACK ANALYSIS BASED ON SINGULAR SYSTEM THEORY*

DANIEL COBB† AND JACOB EAPEN†

Abstract. We consider linear, time-invariant state-space systems under high-gain state feedback. The analysis is couched in terms of singular system theory and Grassman manifolds. Our work is distinguished from that of other authors by the fact that we do not allow a gain-dependent state coordinate change. Simple necessary and sufficient conditions are proven under which a singular system is a high-gain limit of a given state-space system. It is shown that the feedback matrix achieves a limit on an appropriate Grassmanian, so infinite gains constitute well-defined mathematical objects. The special cases of minimum-order stable and zeroth-order limits are studied in depth, including an analysis of solution behavior. Finally, the classical "cheap control" problem is interpreted within the context of our results.

Key words. high-gain feedback, state feedback, singular systems

AMS subject classifications. 93B52, 93B55, 93B05

DOI. 10.1137/040620060

1. Introduction.

Consider the linear, time-invariant state-space system

$$\dot{x} = Ax + Bu, \tag{1}$$

where $A \in \mathbb{R}^{n\times n}$ and $B \in \mathbb{R}^{n\times m}$. For any $K \in \mathbb{R}^{m\times n}$, we may apply state feedback

$$u = -Kx + v, \tag{2}$$

yielding the closed-loop system

$$\dot{x} = (A - BK)x + Bv. \tag{3}$$

In this paper, we are interested in the "high-gain limits" of (3) as $\|K\| \to \infty$. We seek a characterization of all such limits for a given system (1). In addition, we will specialize our results to certain important classes of limits and develop conditions under which a limit of (2) constitutes a well-defined system in its own right. We will then apply our results to the classical "cheap control" problem.

Numerous references deal with the issue of high-gain limits under state feedback. For example, early papers such as [1] treat high gain in a classical singular perturbation context. Much of this work can be viewed largely as a special case of our results. The details will be provided in sections 4–6.

More recent efforts, such as [2], [3], and [4], study high-gain limits in great depth. However, this body of work is fundamentally different from ours in that a K-dependent coordinate change is allowed, while our approach admits no coordinate change. The consequences of the two approaches are strikingly different. Indeed, consider the 1st-order system

$$\dot{x} = u$$

with feedback

$$u = -kx + v.$$

Our analysis (and that of [1]) dictates that the closed-loop system be written

$$-\frac{1}{k}\dot{x} = x - \frac{1}{k}v,$$

yielding $x = 0$ in the limit. Note that controllability is progressively weakened as k increases, and lost entirely for $k = \infty$. This is precisely the effect one would observe in practice, with the variable x representing the fixed (i.e., *K-independent*) state of the plant.

On the other hand, the analyses in [2], [3], and [4] allow a *K-dependent* coordinate change. In this case, the kth closed-loop system becomes

$$p_k q_k \dot{z} = -p_k k q_k z + p_k v,$$

where $x = q_k z$, and p_k, q_k are arbitrary nonzero sequences. For any $g \neq 0$, setting

$$p_k = 1, \quad q_k = \frac{1}{kg}$$

yields the controllable limit $z = gv$. The problem here is that the loss of controllability is masked by the coordinate change $z = kgx$, which scales the physical state x progressively higher as $k \to \infty$.

Another phenomenon that can occur with a K-dependent coordinate change is illustrated by the example

$$\dot{x} = \begin{bmatrix} 0 & 1 \\ 0 & 0 \end{bmatrix} x + \begin{bmatrix} 0 \\ 1 \end{bmatrix} u, \tag{4}$$
$$u = -\begin{bmatrix} k^2 & 1 \end{bmatrix} x.$$

Let $x = Q_k z$ and premultiply (4) by P_k, where P_k, Q_k are nonsingular. Then

$$P_k Q_k \dot{z} = P_k \begin{bmatrix} 0 & 1 \\ -k^2 & -1 \end{bmatrix} Q_k z, \tag{5}$$

which is equivalent to a system of the form

$$X_k \dot{z} = z. \tag{6}$$

If $Q_k = I$,

$$X_k = \begin{bmatrix} -\frac{1}{k^2} & -\frac{1}{k^2} \\ 1 & 0 \end{bmatrix} \to \begin{bmatrix} 0 & 0 \\ 1 & 0 \end{bmatrix}, \tag{7}$$

irrespective of P_k. On the other hand, setting $P_k = I$ and

$$Q_k = \begin{bmatrix} \frac{1}{k} & 0 \\ 0 & 1 \end{bmatrix}$$

yields

$$X_k = \begin{bmatrix} -\frac{1}{k^2} & -\frac{1}{k} \\ \frac{1}{k} & 0 \end{bmatrix} \to 0. \tag{8}$$

Substituting (7) and (8) into (6) produces vastly different results. In particular, (7) produces impulses, while (8) does not. (See [9, Ch. 22].) Losing track of the impulsive behavior in (6) and (8) is again due to the progressive redefinition of the state.

Our approach disallows coordinate changes of the state x. A moment's reflection indicates that, in our setting, the high-gain limits of (3) form a subset of those in [2], [3], and [4]. Nevertheless, characterization of these "fixed coordinate" limits requires an independent analysis. Although the limits we obtain must satisfy the necessary conditions proven in [2] and [3], we will establish alternative conditions, which are arguably simpler and both necessary and sufficient. We will also conduct a careful analysis of stable and "zeroth-order" limits, which heretofore have not been explicitly studied in the literature, at least at this level of generality.

One of our objectives is to establish results which are dual to those we developed for observers in [6]. To this end, much of our work relies on the theory of differentiable manifolds. (See, e.g., [10].)

Throughout the paper, we assume for convenience that $\operatorname{rank} B = m$. For a system where this is not the case, an input coordinate change $\widehat{u} = Tu$ can be used to reduce the problem to our framework.

2. Preliminaries. Before we can talk about the limits of (1), we need some elementary results from singular system theory. Consider the matrix differential equation

$$E\dot{x} = Fx + Gu, \tag{9}$$

where $E, F \in \mathbb{R}^{n\times n}$ and $G \in \mathbb{R}^{n\times m}$. We assume the matrix pencil (E, F) is *regular*, i.e.,

$$\Delta(s) = |sE - F| \not\equiv 0.$$

The roots of Δ are the *eigenvalues* of the system. Consider the *Stiefel manifold* $\mathcal{V}_n\left(\mathbb{R}^{n\times(2n+m)}\right)$ of all $\begin{bmatrix} E & F & G \end{bmatrix} \in \mathbb{R}^{n\times(2n+m)}$ with full rank. Also, let

$$\Sigma(n,m) = \left\{ \begin{bmatrix} E & F & G \end{bmatrix} \;\middle|\; \Delta \not\equiv 0 \right\}.$$

Since $\Delta \not\equiv 0$ implies $\begin{bmatrix} E & F \end{bmatrix}$ has full rank, $\Sigma(n,m) \subset \mathcal{V}_n\left(\mathbb{R}^{n\times(2n+m)}\right)$. Both $\Sigma(n,m)$ and $\mathcal{V}_n\left(\mathbb{R}^{n\times(2n+m)}\right)$ are complementary to algebraic varieties in $\mathbb{R}^{n\times(2n+m)}$ and are, therefore, open and dense in $\mathbb{R}^{n\times(2n+m)}$.

Since premultiplication of (9) by a nonsingular matrix M does not affect the dynamics of (9), it is natural to identify systems of the form (9), which are related by such a transformation. On the other hand, right multiplication of E and A amounts to a coordinate change, so we avoid such transformations, retaining the coordinate-dependent nature of conventional state-space theory. We claim that this approach leads to a simpler theory overall.

With these ideas in mind, we couch our problem in terms of the *Grassman manifold* $\mathcal{G}_n\left(\mathbb{R}^{2n+m}\right)$. A Grassmanian is obtained by applying the equivalence relation

$$\begin{bmatrix} E_1 & F_1 & G_1 \end{bmatrix} \approx \begin{bmatrix} E_2 & F_2 & G_2 \end{bmatrix} \quad \text{iff} \quad \exists \text{ nonsingular } M \ni \begin{bmatrix} E_1 & F_1 & G_1 \end{bmatrix} = M \begin{bmatrix} E_2 & F_2 & G_2 \end{bmatrix} \tag{10}$$

to $\mathcal{V}_n\left(\mathbb{R}^{n\times(2n+m)}\right)$ and forming the quotient manifold $\mathcal{G}_n\left(\mathbb{R}^{2n+m}\right)$ with dimension $n(n+m)$. Charts on $\mathcal{G}_n\left(\mathbb{R}^{2n+m}\right)$ may be constructed by setting n columns of

$[E \quad F \quad G]$ to the $n \times n$ identity matrix and varying the remaining entries. Doing this in all $\binom{2n+m}{n}$ ways generates an atlas for $\mathcal{G}_n\left(\mathbb{R}^{2n+m}\right)$. We denote points in $\mathcal{G}_n\left(\mathbb{R}^{2n+m}\right)$ by $[E,F,G]$. Setting

$$\mathcal{L}(n,m) = \left\{ [E,F,G] \in \mathcal{G}_n\left(\mathbb{R}^{2n+m}\right) \;\middle|\; \Delta \not\equiv 0 \right\}$$

is consistent with the quotient structure of $\mathcal{G}_n\left(\mathbb{R}^{2n+m}\right)$, since premultiplication of $\begin{bmatrix} E & F & G \end{bmatrix}$ by a nonsingular M scales Δ by a nonzero constant. Let

$$\mu : \mathcal{V}_n\left(\mathbb{R}^{2n+m}\right) \to \mathcal{G}_n\left(\mathbb{R}^{2n+m}\right)$$

be the submersion defined by $\begin{bmatrix} E & F & G \end{bmatrix} \to [E,F,G]$. Then μ is continuous and open (see [10, Prop. 6.1.5]). Hence, $\mathcal{L}(n,m) = \mu\left(\Sigma(n,m)\right)$ is an open, dense submanifold of $\mathcal{G}_n\left(\mathbb{R}^{2n+m}\right)$. This makes $\mathcal{L}(n,m)$ an analytic manifold of dimension $n(n+m)$. We studied $\mathcal{L}(n,m)$ in [5].

We will make frequent use of the Weierstrass decomposition ([8, pp. 24–28]): For any regular pencil (E,F), there exists nonsingular M,N such that

$$MEN = \begin{bmatrix} I & 0 \\ 0 & E_f \end{bmatrix}, \qquad MFN = \begin{bmatrix} F_s & 0 \\ 0 & I \end{bmatrix}, \tag{11}$$

where E_f is nilpotent. E_f and F_s are unique up to similarity. Define the *order* of (E,F) to be $\operatorname{ord}(E,F) = \deg \Delta$ (i.e., the dimension of F_s) and the *index* $\operatorname{ind}(E,F)$ to be the smallest integer $q \geq 1$ such that $E_f^q = 0$. The functions ord and ind are uniquely defined on $\Sigma(n,m)$. In fact, both are invariant under the equivalence (11), so we may apply them to points in $\mathcal{L}(n,m)$:

$$\begin{aligned} \operatorname{ord}[E,F,G] &= \operatorname{ord}(E,F), \\ \operatorname{ind}[E,F,G] &= \operatorname{ind}(E,F). \end{aligned}$$

Eigenvalues are also invariant over orbits in $\mathcal{V}_n(\mathbb{R}^{n\times(2n+m)})$, so we may refer to a point $[E,F,G]$ as being *stable* if all its eigenvalues λ satisfy $\operatorname{Re}\lambda < 0$ and $\operatorname{ind}[E,F,G] = 1$.

We will need to consider solutions of (9). To this end, we review some basic facts from the theory of distributions. (See, e.g., [11].) Let $\mathcal{D}$ be the space of C^∞ functions $\phi : \mathbb{R} \to \mathbb{R}$ with bounded support, and let $\mathcal{D}'$ denote the dual space of $\mathcal{D}$. A *distribution* f is any member of $\mathcal{D}'$. Each locally L^1 function f (i.e., L^1 on bounded intervals) may be considered a distribution, since it determines a functional $\phi \to \int f\phi$. The unit impulse δ is defined to be the evaluation functional $\langle \delta, \phi \rangle = \phi(0)$. Every distribution has a derivative defined by $\langle \dot{f}, \phi \rangle = -\langle f, \dot{\phi} \rangle$; thus $\langle \delta^{(i)}, \phi \rangle = (-1)^i \phi^{(i)}(0)$. A sequence of distributions f_k is said to converge *weak** to f if $\langle f_k, \phi \rangle \to \langle f, \phi \rangle$ for every $\phi \in \mathcal{D}$. One advantage of working with distributions is that differentiation is a weak*-continuous operation. Besides weak* convergence, we will sometimes refer to uniform convergence $f_k \to f$ on an interval in $\mathcal{I} \subset \mathbb{R}$. This simply means that there exist locally L^1 functions g_k, g defined on $\mathcal{I}$ such that $\langle f_k, \phi \rangle = \langle g_k, \phi \rangle$, $\langle f, \phi \rangle = \langle g, \phi \rangle$ for all ϕ with support in $\mathcal{I}$ and $g_k \to g$ uniformly. Let $U \subset \mathbb{R}$ be the largest open set such that $\operatorname{supp}\phi \subset U$ implies $\langle f, \phi \rangle = 0$. The *support* of f is $\operatorname{supp} f = U^c$. Let $\mathcal{D}'_+$ be the distributions with support in $[0,\infty)$.

In order to apply arbitrary initial conditions x_0 to (9), it is convenient to consider the augmented system

$$E\dot{x} = Fx + Gu + \delta E x_0, \tag{12}$$

which yields a unique solution $x \in \mathcal{D}'_+$. (See [9, Ch. 22] for details.). Let

$$\begin{bmatrix} G_s \\ G_f \end{bmatrix} = MG, \quad \begin{bmatrix} x_s \\ x_f \end{bmatrix} = N^{-1}x, \quad \begin{bmatrix} x_{0s} \\ x_{0f} \end{bmatrix} = N^{-1}x_0 \tag{13}$$

and $\exp(F_s) : \mathbb{R} \to \mathbb{R}^{\deg \Delta \times \deg \Delta}$ be given by

$$\exp(F_s)t = \begin{cases} e^{tF_s}, & t \geq 0, \\ 0, & t < 0. \end{cases}$$

Define the *state-transition matrix*

$$\Phi = N \begin{bmatrix} \exp(F_s) & 0 \\ 0 & -\sum_{i=0}^{q-1} \delta^{(i)} E_f^i \end{bmatrix} M. \tag{14}$$

Direct calculation shows that Φ is the inverse Laplace transform of $(sE - A)^{-1}$, so Φ may be viewed as a map on $\Sigma(n, 0)$, obviously $1 - 1$. Since Φ is $1 - 1$, it varies over each orbit in $\Sigma(n, 0)$, so Φ cannot be defined consistently on $\mathcal{L}(n, 0)$. Φ may be extended trivially to $\Sigma(n, m)$, with similar consequences. The state transition matrix relates to the system (12) as follows.

THEOREM 1.

(1) $E\dot{\Phi} = A\Phi + \delta I$.

(2) *The solution of* (12) *is* $x = \Phi E x_0 + \Phi * Gu$.

(3) *The system* (12) *is asymptotically stable iff* ΦE *is bounded and decays asymptotically to* 0.

Proof. (1) and (2) follow by direct calculation.

(3) By asymptotic stability, we mean that, for $u \equiv 0$, we have conditions (a) $x(t) \to 0$ as $t \to \infty$ for every x_0, and (b) $\sup_t |x(t)| \to 0$ as $x_0 \to 0$. Boundedness and decay of ΦE are equivalent to the eigenvalues λ of F_s satisfying $\operatorname{Re} \lambda < 0$ and $E_f = 0$.

(Sufficient) From (11) and (14),

$$\Phi E = N \begin{bmatrix} \exp(F_s) & 0 \\ 0 & 0 \end{bmatrix} N^{-1},$$

so conditions (a) and (b) are met relative to $\Phi E x_0$.

(Necessary) We have $\Phi(t) E x_0 \to 0$ for every x_0, so

$$\Phi E = N \begin{bmatrix} \exp(F_s) & 0 \\ 0 & -\sum_{i=0}^{q-1} \delta^{(i)} E_f^{i+1} \end{bmatrix} N^{-1} \to 0,$$

which implies F_s is stable. Furthermore, $\Phi E x_0$ is bounded for every x_0, so ΦE is bounded, which implies it contains no impulses, i.e., $E_f = 0$. ∎

3. The manifold of closed-loop systems. The present paper closely follows the development of [6], where the dual problem of the limiting behavior of state observers under high-gain feedback was studied. One might speculate that the state feedback case should be obtained from [6] merely be taking the "transpose" of all theorems. While some theorems do transfer over in this way, much of the state feedback theory is different. One way to see that this must be true is to observe that, in both cases, systems are identified when they are related by left multiplication by a

nonsingular M. In contrast, pure transposition of the observer problem would require *right* multiplication by M, leading to a K-dependent coordinate change, which we explicitly avoid.

The closed-loop system (3) for a given plant (1) imbeds naturally into $\mathcal{L}(n,m)$ via the map $K \to [I, A - BK, B]$. We denote the image of $\mathbb{R}^{m\times n}$ under this map by $\mathcal{C}_r$. We further denote the closure of $\mathcal{C}_r$ in $\mathcal{L}(n,m)$ by $\mathcal{C}$ and consider the set $\mathcal{C}_s = \mathcal{C} - \mathcal{C}_r$. $\mathcal{C}$ may be regarded as the set of all limits of (3), $\mathcal{C}_r$ the full-order limits (i.e., ordinary state-space systems) and $\mathcal{C}_s$ the singular limits (i.e., generalized state-space systems). Another way to define $\mathcal{C}$, $\mathcal{C}_r$, and $\mathcal{C}_s$ is via the submersion μ. Let

$$\Omega_r = \left\{ \begin{bmatrix} M & M(A-BK) & MB \end{bmatrix} \;\middle|\; M \text{ nonsingular} \right\}.$$

Obviously, $\Omega_r \subset \Sigma(n,m)$. Let Ω be the closure of Ω_r in $\Sigma(n,m)$, and $\Omega_s = \Omega - \Omega_r$. It is easy to see that $\mathcal{C} = \mu(\Omega)$, $\mathcal{C}_r = \mu(\Omega_r)$, and $\mathcal{C}_s = \mu(\Omega_s)$.

We need the following lemma to prove Theorem **??**, which establishes the basic structure of $\mathcal{C}$.

LEMMA 2. *Let $X, Y \in \mathbb{R}^{n\times n}$ with $\operatorname{rank}[X \quad Y] = n$. There exist $K_k \in \mathbb{R}^{m\times n}$ and nonsingular $X_k \in \mathbb{R}^{n\times n}$ such that $X_k \to X$ and $X_k B K_k \to Y$ iff $\operatorname{rank}[XB \quad Y] = m$.*

Proof. (Necessary) For large k,

$$\operatorname{rank}\begin{bmatrix} XB & Y \end{bmatrix} \le \operatorname{rank}\begin{bmatrix} X_k B & X_k B K_k \end{bmatrix} = \operatorname{rank}\begin{bmatrix} B & BK_k \end{bmatrix} = m.$$

Suppose

$$\operatorname{rank}\begin{bmatrix} XB & Y \end{bmatrix} < m,$$

and let $R \subset \mathbb{R}^n$ be a subspace such that

$$\operatorname{Im} B \oplus R = \mathbb{R}^n.$$

Then $\dim R = n - m$, and

$$\begin{aligned} \operatorname{rank}\begin{bmatrix} X & Y \end{bmatrix} &= \dim(\operatorname{Im} X + \operatorname{Im} Y) \\ &= \dim(XR + \operatorname{Im} XB + \operatorname{Im} Y) \\ &\le \dim XR + \dim(\operatorname{Im} XB + \operatorname{Im} Y) \\ &\le \dim R + \operatorname{rank}\begin{bmatrix} XB & Y \end{bmatrix} \\ &< n. \end{aligned}$$

From this contradiction, we conclude

$$\operatorname{rank}\begin{bmatrix} XB & Y \end{bmatrix} = m.$$

(Sufficient) Let

$$\begin{aligned} R &= \operatorname{Im} XB \cap \operatorname{Im} Y, \\ S &= \operatorname{Ker} X \cap \operatorname{Im} B, \end{aligned}$$

$p = \dim R$, and $q = \dim S$. Then

$$m = q + \operatorname{rank} XB,$$

and there exists a nonsingular $T \in \mathbb{R}^{n\times n}$ such that

$$YT = \begin{bmatrix} Y_1 & Y_2 \end{bmatrix}$$

with $\operatorname{Im} Y_1 = R$ and

$$\operatorname{Im} XB \cap \operatorname{Im} Y_2 = 0.$$

Hence, we may select $H \in \mathbb{R}^{m\times p}$ such that $XBH = Y_1$. Also,

$$\operatorname{rank} XB + \operatorname{rank} Y_2 = \operatorname{rank} \begin{bmatrix} XB & Y_2 \end{bmatrix} \leq \operatorname{rank} \begin{bmatrix} XB & Y \end{bmatrix} = m,$$

so

$$\operatorname{rank} Y_2 \leq q.$$

We may choose $J \in \mathbb{R}^{m\times q}$ such that $\operatorname{Im} BJ = S$. Then $XBJ = 0$, and

$$\operatorname{rank} BJ = q \geq \operatorname{rank} Y_2.$$

Thus there exists $Z \in \mathbb{R}^{n\times n}$ such that $ZBJ = Y_2$.

Let $Z_k = X + \frac{1}{k}Z$ and, for each k, select nonsingular $Z_{kj} \to Z_k$ as $j \to \infty$. We may select a sequence $j_k \uparrow \infty$ such that

$$\|Z_{kj_k} - Z_k\| < \frac{1}{k^2}$$

for every k. Setting $X_k = Z_{kj_k}$, we have

$$\|X_k - X\| \leq \|X_k - Z_k\| + \|Z_k - X\| = \frac{1}{k^2} + \frac{1}{k}\|Z\|,$$

so $X_k \to X$. Let $K_k = \begin{bmatrix} H & kJ \end{bmatrix} T^{-1}$. Then

$$\begin{aligned} X_k B K_k &= \begin{bmatrix} X_k BH & k(X_k - Z_k)BJ + kZ_k BJ \end{bmatrix} T^{-1} \\ &= \begin{bmatrix} X_k BH & k(Z_{kj_k} - Z_k)BJ + kXBJ + ZBJ \end{bmatrix} T^{-1} \\ &\to \begin{bmatrix} Y_1 & Y_2 \end{bmatrix} T^{-1} \\ &= Y. \qquad \square \end{aligned}$$

THEOREM 3.
(1) $\mathcal{C} = \{[X, XA - Y, XB] \in \mathcal{L}(n,m) \mid \operatorname{rank} \begin{bmatrix} XB & Y \end{bmatrix} = m\}$.
(2) *$\mathcal{C}$ is a regular submanifold of $\mathcal{L}(n,m)$ with dimension nm.*
(3) *$\mathcal{C}_r$ is a (relatively) open, dense submanifold of $\mathcal{C}$*
(4) *$[X, XA - Y, XB] \in \mathcal{C}_s$ iff $\operatorname{rank} \begin{bmatrix} XB & Y \end{bmatrix} = m$ with X singular.*

Proof. (1) Let

$$\Omega_e = \left\{ \begin{bmatrix} X & XA - Y & XB \end{bmatrix} \in \mathcal{V}_n\left(\mathbb{R}^{2n+m}\right) \;\middle|\; \operatorname{rank} \begin{bmatrix} XB & Y \end{bmatrix} = m \right\}.$$

Setting $X = M$ and $Y = MBK$ yields

$$\begin{bmatrix} X & XA - Y & XB \end{bmatrix} = \begin{bmatrix} M & M(A - BK) & MB \end{bmatrix},$$
$$\operatorname{rank} \begin{bmatrix} XB & Y \end{bmatrix} = \operatorname{rank} \begin{bmatrix} MB & MBK \end{bmatrix} = \operatorname{rank} \begin{bmatrix} B & BK \end{bmatrix} = m,$$

so $\Omega_r \subset \Omega_e \cap \Sigma(n,m)$. It suffices to show that the closure of Ω_r in $\mathcal{V}_n\left(\mathbb{R}^{2n+m}\right)$ is Ω_e, because then the closure of Ω_r in $\Sigma(n,m)$ is $\Omega = \Omega_e \cap \Sigma(n,m)$, and part (1) follows from $\mu(\Omega_r) = \mathcal{C}_r$, $\mu(\Omega) = \mathcal{C}$.

For any nonsingular $T \in \mathbb{R}^{n\times n}$, let

$$L_T = \begin{bmatrix} T^{-1} & T^{-1}A & T^{-1}B \\ 0 & -I & 0 \end{bmatrix}.$$

Choose X, Y such that

$$\begin{bmatrix} X & Y \end{bmatrix} L_I = \begin{bmatrix} X & XA - Y & XB \end{bmatrix} \in \Omega_e.$$

L_T has independent rows, so $\operatorname{rank}\begin{bmatrix} X & Y \end{bmatrix} = n$. From Lemma 2, there exist sequences X_k and K_k, with X_k nonsingular, such that $X_k \to X$ and $X_k B K_k \to Y$. Hence,

$$\begin{bmatrix} X_k & X_k(A - BK_k) & X_k B \end{bmatrix} \to \begin{bmatrix} X & XA - Y & XB \end{bmatrix},$$

and the closure of Ω_r contains Ω_e. Conversely, if

$$\begin{bmatrix} X_k & X_k(A - BK_k) & X_k B \end{bmatrix} \to \begin{bmatrix} X & F & G \end{bmatrix} \in \mathcal{V}_n\left(\mathbb{R}^{2n+m}\right),$$

then $X_k \to X$ and $G = XB$. Let $Y = XA - F$. Then

$$\begin{aligned} \operatorname{rank}\begin{bmatrix} X & Y \end{bmatrix} &= \operatorname{rank}\begin{bmatrix} X & Y \end{bmatrix}\begin{bmatrix} I & A \\ 0 & -I \end{bmatrix} \\ &= \operatorname{rank}\begin{bmatrix} X & F \end{bmatrix} \\ &= \operatorname{rank}\begin{bmatrix} X & F & G \end{bmatrix} \\ &= n, \end{aligned}$$

$$X_k B K_k = X_k A - X_k(A - BK_k) \to Y,$$

so, from Lemma 2,

$$\operatorname{rank}\begin{bmatrix} XB & Y \end{bmatrix} = m.$$

Hence, $\begin{bmatrix} X & F & G \end{bmatrix} \in \Omega_e$, and Ω_e contains the closure of Ω_r.

(2) This part of the proof will be based on the following construction. Choose a nonsingular T such that

$$T^{-1}B = \begin{bmatrix} 0 \\ I \end{bmatrix},$$

and consider the diagram

$$\begin{array}{ccccc} & \widehat{h} & & \widehat{g} & \\ \mathcal{V}_m\left(\mathbb{R}^{m+n}\right) & \to & \mathcal{V}_n\left(\mathbb{R}^{2n}\right) & \to & \mathcal{V}_n\left(\mathbb{R}^{2n+m}\right) \\ \downarrow \pi & & \downarrow \nu & & \downarrow \mu \\ \mathcal{G}_m\left(\mathbb{R}^{m+n}\right) & \to & \mathcal{G}_n\left(\mathbb{R}^{2n}\right) & \to & \mathcal{G}_n\left(\mathbb{R}^{2n+m}\right), \\ & h & & g & \end{array}$$

where

$$\begin{aligned} \widehat{g}\left(\begin{bmatrix} \widetilde{X} & Y \end{bmatrix}\right) &= \begin{bmatrix} \widetilde{X} & Y \end{bmatrix} L_T, \\ \widehat{h}(Z) &= \begin{bmatrix} I & 0 \\ 0 & Z \end{bmatrix}, \end{aligned}$$

and μ, ν, and π are the standard submersions. We note that

$$\widehat{g}\left(M\begin{bmatrix}\widetilde{X} & Y\end{bmatrix}\right) = M\widehat{g}\left(\begin{bmatrix}\widetilde{X} & Y\end{bmatrix}\right),$$

and

$$\widehat{h}\,(NZ) = \begin{bmatrix}I & 0\\ 0 & N\end{bmatrix}\widehat{h}\,(Z)$$

for any nonsingular M, N, so g and h may be defined to make the diagram commute. We are mainly interested in the compositions $f = g \circ h$ and $\widehat{f} = \widehat{g} \circ \widehat{h}$. Note that $\widehat{g}$, $\widehat{h}$, and hence $\widehat{f}$ are $1-1$. Furthermore, if

$$\widehat{g}\left(\begin{bmatrix}\widetilde{X}_a & Y_a\end{bmatrix}\right) = M\widehat{g}\left(\begin{bmatrix}\widetilde{X} & Y\end{bmatrix}\right),$$

we obtain

$$\widehat{g}\left(\begin{bmatrix}\widetilde{X}_a & Y_a\end{bmatrix}\right) = \widehat{g}\left(M\begin{bmatrix}\widetilde{X} & Y\end{bmatrix}\right),$$

so

$$\begin{bmatrix}\widetilde{X}_a & Y_a\end{bmatrix} = M\begin{bmatrix}\widetilde{X} & Y\end{bmatrix}$$

and g is $1-1$. Now suppose

$$\widehat{h}\,(Z_a) = M\widehat{h}\,(Z)\,.$$

Then

$$\begin{bmatrix}I & 0\\ 0 & Z_a\end{bmatrix} = \begin{bmatrix}M_{11} & M_{12}\\ M_{21} & M_{22}\end{bmatrix}\begin{bmatrix}I & 0\\ 0 & Z\end{bmatrix}.$$

Inspection of the block matrix equations yields $Z_a = M_{22}Z$ with M_{22} nonsingular, so h and f are $1-1$.

Let $\mathcal{C}_e = \mu\,(\Omega_e)$. Since $\mathcal{L}(n,m)$ is open in $\mathcal{G}_n\left(\mathbb{R}^{2n+m}\right)$, it suffices to demonstrate that $\mathcal{C}_e$ satisfies (2), because then $\mathcal{C} = \mathcal{C}_e \cap \mathcal{L}(n,m)$ inherits the same properties. We begin by showing that $f\left(\mathcal{G}_m\left(\mathbb{R}^{m+n}\right)\right) = \mathcal{C}_e$. Consider any point $[X, XA - Y, XB] \in \mathcal{C}_e$. Setting $\widetilde{X} = XT$ and partitioning

$$\begin{bmatrix}\widetilde{X}_1 & \widetilde{X}_2\end{bmatrix} = \widetilde{X},$$

with $\widetilde{X}_1 \in \mathbb{R}^{n\times(n-m)}$, $\widetilde{X}_2 \in \mathbb{R}^{n\times m}$, we obtain

$$\operatorname{rank}\begin{bmatrix}\widetilde{X}_2 & Y\end{bmatrix} = \operatorname{rank}\begin{bmatrix}\widetilde{X}T^{-1}B & Y\end{bmatrix} = \operatorname{rank}\begin{bmatrix}XB & Y\end{bmatrix} = m,$$

$$\operatorname{rank}\begin{bmatrix}\widetilde{X}_1 & \widetilde{X}_2 & Y\end{bmatrix} = \operatorname{rank}\begin{bmatrix}XT & Y\end{bmatrix} = \operatorname{rank}\begin{bmatrix}X & Y\end{bmatrix} = n,$$

so $\operatorname{rank}\widetilde{X}_1 = n - m$. Hence, there exists $Z_1 \in \mathbb{R}^{m\times m}$, $Z_2 \in \mathbb{R}^{m\times n}$, and a nonsingular M such that

$$M\begin{bmatrix}\widetilde{X}_1 & \widetilde{X}_2 & Y\end{bmatrix} = \begin{bmatrix}I & 0 & 0\\ 0 & Z_1 & Z_2\end{bmatrix},$$

and

$$\operatorname{rank}\begin{bmatrix} Z_1 & Z_2 \end{bmatrix} = m.$$

It follows that

$$f\left([Z_1, Z_2]\right) = g\left(\left[\widetilde{X}, Y\right]\right) = [X, XA - Y, XB],$$

which yields the desired result. In fact, letting functions ϕ range over an atlas of $\mathcal{G}_m\left(\mathbb{R}^{n+m}\right)$, $\left\{\phi \circ f^{-1}\right\}$ becomes an atlas for $\mathcal{C}_e$, making f an analytic diffeomorphism between $\mathcal{G}_m\left(\mathbb{R}^{n+m}\right)$ and $\mathcal{C}_e$.

As a map into $\mathcal{G}_n\left(\mathbb{R}^{2n+m}\right)$, we can prove that f is analytic by showing that g and h are analytic. Let $\xi \in \mathcal{G}_n\left(\mathbb{R}^{2n}\right)$, and choose charts ϕ on $\mathcal{G}_n\left(\mathbb{R}^{2n}\right)$ and $\psi \in \mathcal{G}_n\left(\mathbb{R}^{2n+m}\right)$ such that ξ and $g(\xi)$ lie in the domains of ϕ and ψ, respectively. Then $\psi \circ g \circ \phi^{-1}$ is a rational function, where the denominator has no zero, and is thus analytic. Since ϕ, ψ are arbitrary, g is analytic. Analyticity of h is proved similarly.

To show that $\mathcal{C}_e$ is a submanifold of $\mathcal{G}_n\left(\mathbb{R}^{2n+m}\right)$, we must also prove that f has full rank. We need to show that the derived linear function f_* at each point of $\mathcal{G}_m\left(\mathbb{R}^{n+m}\right)$ is $1-1$. From [10, Prop. 4.3.1], $f_* = g_* \circ h_*$, so it suffices to prove that g_* and h_* are $1-1$. Since $g \circ \nu = \mu \circ \widehat{g}$, the same theorem guarantees

$$g_* \circ \nu_* = \mu_* \circ \widehat{g}_*.$$

Since $\widehat{g}$ is $1-1$ and μ_*, ν_* are onto,

$$\begin{aligned} \operatorname{rank} g_* &= \operatorname{rank}\left(\mu_* \circ \widehat{g}_*\right) \\ &\geq \operatorname{rank} \widehat{g}_* - \left(\dim \mathcal{V}_n\left(\mathbb{R}^{2n+m}\right) - \operatorname{rank} \mu_*\right) \\ &= 2n^2 - \left(n(2n+m) - n(n+m)\right) \\ &= n^2, \end{aligned}$$

so g_* is $1-1$. Unfortunately, this calculation does not work for h_*. To prove h_* is $1-1$, consider any point $\xi \in \mathcal{G}_m\left(\mathbb{R}^{n+m}\right)$ and a chart ϕ whose coordinate domain contains ξ. Applying ϕ amounts to choosing m columns $\{c_i\}$ of $\begin{bmatrix} Z_1 & Z_2 \end{bmatrix}$, setting them equal to the $m \times m$ identity matrix, and allowing the remaining entries to vary, forming an $m \times n$ matrix $\widetilde{Z}$. In a neighborhood of $h(\xi)$, each point of $\mathcal{G}_n(\mathbb{R}^{2n})$ may be represented as $\begin{bmatrix} I & S_1 \\ 0 & S_2 \end{bmatrix}$, where the columns $\{c_i\}$ of $\begin{bmatrix} S_1 \\ S_2 \end{bmatrix}$ are $\begin{bmatrix} 0 \\ I \end{bmatrix}$. This generates a chart ψ of $\mathcal{G}_n\left(\mathbb{R}^{2n}\right)$, whose coordinate domain contains $h(\xi)$. It is easy to see that

$$\psi\left(h\left(\phi^{-1}\left(\widetilde{Z}\right)\right)\right) = \begin{bmatrix} 0 \\ \widetilde{Z} \end{bmatrix}.$$

From [10, p. 58], h_* has matrix representation $\frac{\partial\left(\psi \circ h \circ \phi^{-1}\right)}{\partial \widetilde{Z}}$. But $\psi \circ h \circ \phi^{-1}$ is linear, so

$$h_*\left(\widetilde{Z}\right) = \begin{bmatrix} 0 \\ \widetilde{Z} \end{bmatrix},$$

which is $1-1$. Hence, we conclude that $\mathcal{C}_e$ is an nm-dimensional submanifold of $\mathcal{G}_n\left(\mathbb{R}^{2n+m}\right)$.

Finally we prove regularity of $\mathcal{C}_e$. We need to show that the topologies that $\mathcal{C}_e$ inherits from $\mathcal{G}_m\left(\mathbb{R}^{m+n}\right)$ (through f) and from $\mathcal{G}_n\left(\mathbb{R}^{2n+m}\right)$ (as a subset) coincide.

Since f is analytic, it is continuous, and $f^{-1}\left(W \cap f\left(\mathcal{G}_m\left(\mathbb{R}^{m+n}\right)\right)\right) = f^{-1}\left(W\right)$ is open in $\mathcal{G}_m\left(\mathbb{R}^{m+n}\right)$ for every open $W \subset \mathcal{G}_n\left(\mathbb{R}^{2n+m}\right)$. To prove the converse, let $U \subset \mathcal{G}_m\left(\mathbb{R}^{m+n}\right)$ be open. Then $\pi^{-1}\left(U\right)$ is open. For any $Z \in \pi^{-1}\left(U\right)$ there exists $\varepsilon > 0$ such that the ball $B\left(Z, \varepsilon\right) \subset \pi^{-1}\left(U\right)$. Then $NB\left(Z, \varepsilon\right) \subset \pi^{-1}\left(U\right)$ for every nonsingular N. Let

$$\widetilde{L} = \begin{bmatrix} T & A \\ 0 & -I \\ 0 & 0 \end{bmatrix},$$

and define

$$\begin{aligned} W_Z &= \left\{ M^{-1} B\left(\widehat{f}\left(Z\right), \frac{\varepsilon}{2\left\|\widetilde{L}\right\|}\right) \;\middle|\; M \text{ nonsingular} \right\} \\ &= \mu^{-1}\left(\mu\left(B\left(\widehat{f}\left(Z\right), \frac{\varepsilon}{2\left\|\widetilde{L}\right\|}\right)\right)\right), \end{aligned}$$

$$W = \bigcup_{Z \in \pi^{-1}(U)} W_Z.$$

Since μ is open, each W_Z and, therefore, W are open. It suffices to show that

$$\widehat{f}\left(\pi^{-1}\left(U\right)\right) = W \cap \widehat{f}\left(\mathcal{V}_m\left(\mathbb{R}^{m+n}\right)\right). \tag{15}$$

Indeed, since W is a union of orbits in $\mathcal{V}_n(\mathbb{R}^{2n+m}), \mu(W \cap A) = \mu(W) \cap \mu(A)$ for any A, from which it follows that

$$\begin{aligned} f\left(U\right) &= \mu\left(\widehat{f}\left(\pi^{-1}\left(U\right)\right)\right) \\ &= \mu\left(W \cap \widehat{f}\left(\mathcal{V}_m\left(\mathbb{R}^{m+n}\right)\right)\right) \\ &= \mu\left(W\right) \cap \mu\left(\widehat{f}\left(\mathcal{V}_m\left(\mathbb{R}^{m+n}\right)\right)\right) \\ &= \mu\left(W\right) \cap \mathcal{C}_e, \end{aligned}$$

so $f\left(U\right)$ is (relatively) open in $\mathcal{C}_e$.

To prove (15), first note that $Z \in \pi^{-1}\left(U\right)$ implies $\widehat{f}\left(Z\right) \in W_Z$, so

$$\widehat{f}\left(\pi^{-1}\left(U\right)\right) \subset W \cap \widehat{f}\left(\mathcal{V}_m\left(\mathbb{R}^{m+n}\right)\right).$$

Conversely, suppose $Z_a \in \mathcal{V}_m(\mathbb{R}^{m+n})$, $\Delta \in B\big(0, \frac{\varepsilon}{2\|\widetilde{L}\|}\big)$, and nonsingular M satisfy

$$M^{-1}\left(\widehat{f}\left(Z\right) + \Delta\right) = \widehat{f}\left(Z_a\right).$$

Then

$$\left\|M\widehat{f}\left(Z_a\right) - \widehat{f}\left(Z\right)\right\| < \frac{\varepsilon}{2\left\|\widetilde{L}\right\|}.$$

But

$$M\widehat{f}(Z_a) - \widehat{f}(Z) = \left(M \begin{bmatrix} I & 0 \\ 0 & Z_a \end{bmatrix} - \begin{bmatrix} I & 0 \\ 0 & Z \end{bmatrix} \right) L_T$$

and $L_T \widetilde{L} = I$, so

$$\left\| M \begin{bmatrix} I & 0 \\ 0 & Z_a \end{bmatrix} - \begin{bmatrix} I & 0 \\ 0 & Z \end{bmatrix} \right\| \leq \left\| M\widehat{f}(Z_a) - \widehat{f}(Z) \right\| \left\| \widetilde{L} \right\| < \frac{\varepsilon}{2}.$$

Partitioning M, we obtain

$$\|M_{22} Z_a - Z\| < \frac{\varepsilon}{2}$$

(assuming an appropriate norm). Let N be a nonsingular matrix such that

$$\left\| N^{-1} - M_{22} \right\| < \frac{\varepsilon}{2\|Z_a\|}.$$

Then

$$\left\| N^{-1} Z_a - Z \right\| \leq \left\| N^{-1} - M_{22} \right\| \|Z_a\| + \|M_{22} Z_a - Z\| < \varepsilon,$$

so $Z_a \in NB(Z, \varepsilon)$. Hence,

$$\widehat{f}\left(\pi^{-1}(U)\right) \supset M^{-1} B \left(\widehat{f}(Z), \frac{\varepsilon}{2\left\| \widetilde{L} \right\|} \right) \cap \widehat{f}\left(\mathcal{V}_m\left(\mathbb{R}^{m+n}\right)\right)$$

for every nonsingular M, and

$$\widehat{f}\left(\pi^{-1}(U)\right) \supset W \cap \widehat{f}\left(\mathcal{V}_m\left(\mathbb{R}^{m+n}\right)\right).$$

(3) Density of $\mathcal{C}_r$ follows from the definition of $\mathcal{C}$. To show $\mathcal{C}_r$ is open in $\mathcal{C}$, it suffices to show that Ω_r is open in Ω. Let $\sigma \in \Omega_r$ and $\sigma_k \in \Omega$ with $\sigma_k \to \sigma$. Then there exist $M, X_k, Y_k \in \mathbb{R}^{n \times n}$, and $K \in \mathbb{R}^{m \times n}$, with M nonsingular and

$$\operatorname{rank} \begin{bmatrix} X_k B & Y_k \end{bmatrix} = m,$$

such that

$$\begin{aligned} \sigma &= \begin{bmatrix} M & M(A - BK) & MB \end{bmatrix}, \\ \sigma_k &= \begin{bmatrix} X_k & X_k A - Y_k & X_k B \end{bmatrix}. \end{aligned}$$

Since $\sigma_k \to \sigma$, $X_k \to M$, thus X_k is nonsingular for large k and

$$\operatorname{rank} \begin{bmatrix} B & X_k^{-1} Y_k \end{bmatrix} = m.$$

Then $\operatorname{Im} X_k^{-1} Y_k \subset \operatorname{Im} B$, so there exists $K_k \in \mathbb{R}^{m \times n}$ such that $X_k^{-1} Y_k = B K_k$. Therefore,

$$\sigma_k = \begin{bmatrix} X_k & X_k(A - BK_k) & X_k B \end{bmatrix} \in \Omega_r,$$

and Ω_r is open in Ω.

(4) (Sufficient) This follows from the definition of Ω_s and $\mathcal{C}_s = \mu(\Omega_s)$.
(Necessary) Assume X is nonsingular. From part (1),

$$\operatorname{rank}\begin{bmatrix} B & X^{-1}Y \end{bmatrix} = \operatorname{rank}\begin{bmatrix} XB & Y \end{bmatrix} = m,$$

so $\operatorname{Im} X^{-1}Y \subset \operatorname{Im} B$, and there exists $K \in \mathbb{R}^{m\times n}$ such that $X^{-1}Y = BK$. It follows that

$$[X, XA - Y, XB] = [X, X(A - BK), XB] \in \mathcal{C}_r,$$

which is a contradiction. ∎

Theorem 3, part (4) characterizes all degenerate closed-loop systems $\mathcal{C}_s$. This corresponds to applying a sequence of feedback matrices K_k such that $\|K_k\| \to \infty$, driving some or all eigenvalues to ∞ in magnitude. Since $\mathcal{C}_s$ is obtained with no state coordinate change, $\mathcal{C}_s$ must be a subset of the high-gain limits considered in [2] and [3]. In particular, each point in $\mathcal{C}_s$ must satisfy the necessary conditions established in [2, Thm. 1] and [3, Cor. 4.3]. Compared with these results, our characterization of $\mathcal{C}_s$ has a very different form, is necessary *and* sufficient, and is arguably simpler.

4. Stable and zeroth-order limits. In this section, we study certain subsets of $\mathcal{C}$ which have special significance. In particular, we examine those systems in $\mathcal{C}$ which are stable (i.e., all eigenvalues satisfy $\operatorname{Re}\lambda < 0$) and those with order 0. We begin with a discussion of an important submanifold of $\mathcal{C}$, which will help simplify the development. Let

$$\mathcal{C}_I = \{[X, I, XB] \in \mathcal{C}\}.$$

$\mathcal{C}_I$ is simply the set of points in $\mathcal{C}$ with no eigenvalue at 0. Each point in $\mathcal{C}_I$ corresponds to a system

$$X\dot{x} = x + XBv + \delta X x_0 \tag{16}$$

with state transition matrix determined by

$$X\dot{\Phi} = \Phi + \delta I.$$

From Theorem 3, part (1), we obtain

$$\mathcal{C}_I = \left\{ [X, I, XB] \in \mathcal{G}_n\left(\mathbb{R}^{2n+m}\right) \;\middle|\; \operatorname{rank}\begin{bmatrix} XB & XA - I \end{bmatrix} = m \right\}.$$

The next result gives several alternative characterizations of $\mathcal{C}_I$.

THEOREM 4. *For any $X \in \mathbb{R}^{n\times n}$, the following are equivalent:*
(1) $\operatorname{rank}[XB \quad XA - I] = m$.
(2) $\operatorname{Ker}[X \quad I] \subset \operatorname{Im}\left[\begin{smallmatrix} B & A \\ 0 & -1 \end{smallmatrix}\right]$.
(3) $\operatorname{Im}(AX - I) \subset \operatorname{Im} B$.
(4) *There exists $U \in \mathbb{R}^{m\times n}$ such that $AX + BU = I$.*

Proof. (1 $\iff$ 2) From elementary linear algebra,

$$\begin{aligned} \operatorname{rank}\begin{bmatrix} XB & XA - I \end{bmatrix} &= \operatorname{rank}\begin{bmatrix} X & I \end{bmatrix}\begin{bmatrix} B & A \\ 0 & -I \end{bmatrix} \\ &\geq \operatorname{rank}\begin{bmatrix} B & A \\ 0 & -I \end{bmatrix} - \left(2n - \operatorname{rank}\begin{bmatrix} X & I \end{bmatrix}\right) \\ &= (n + m) - (2n - n) \\ &= m \end{aligned} \tag{17}$$

with equality iff

$$\operatorname{Ker}\begin{bmatrix} X & I \end{bmatrix} \subset \operatorname{Im}\begin{bmatrix} B & A \\ 0 & -I \end{bmatrix}.$$

(2 $\Longleftrightarrow$ 3) Condition (2) is equivalent to saying that, for each x, there exist y, z such that

$$\begin{bmatrix} B & A \\ 0 & -I \end{bmatrix} \begin{bmatrix} y \\ z \end{bmatrix} = \begin{bmatrix} -x \\ Xx \end{bmatrix}. \tag{18}$$

Writing out the equations, (18) is the same as $By = (AX - I)\,x$, which is a restatement of (3).

(3 $\Longleftrightarrow$ 4) Condition (3) says that there exists U such that $AX - I = -BU$, which is the same as (4). □

Theorem 4, part (4) indicates that $\mathcal{C}_I$ is nonempty iff $\begin{bmatrix} A & B \end{bmatrix}$ has full rank; i.e., iff 0 is a controllable mode of (1). In this case, the affine set

$$\mathcal{W} = \left\{ \begin{bmatrix} X \\ U \end{bmatrix} \in \mathbb{R}^{2n \times n} \;\middle|\; AX + BU = I \right\}$$

will prove central to our theory. The next result gives a precise relationship between $\mathcal{C}_I$ and $\mathcal{W}$.

Theorem 5.

(1) $[X, I, XB] \in \mathcal{C}_I$ *iff there exists* $U \in \mathbb{R}^{m \times n}$ *such that* $\begin{bmatrix} X \\ U \end{bmatrix} \in \mathcal{W}$. *In this case,* U *is unique.*

(2) *Let* $K_k \in \mathbb{R}^{m \times n}$. *Then* $[I, A - BK_k, B] \to [X, I, XB] \in \mathcal{C}_I$ *as* $k \to \infty$ *iff* $A - BK_k$ *is nonsingular for large* k *and* $(A - BK_k)^{-1} \to X$. *In this case,* $-K_k(A - BK_k)^{-1} \to U$.

(3) $\mathcal{C}_I$ *is a (relatively) open, dense submanifold of* $\mathcal{C}$, *diffeomorphic to* $\mathcal{W}$.

Proof.

(1) All but uniqueness is a restatement of Theorem 4, part (4). Uniqueness follows from $BU = I - AX$ and $\operatorname{rank} B = m$.

(2) If $(A - BK_k)^{-1} \to X$,

$$[I, A - BK_k, B] = \left[(A - BK_k)^{-1}, I, (A - BK_k)^{-1} B \right] \to [X, I, XB]. \tag{19}$$

To prove the converse, we note that μ is a submersion, so there exist nonsingular M_k such that

$$M_k \begin{bmatrix} I & A - BK_k & B \end{bmatrix} \to \begin{bmatrix} X & I & XB \end{bmatrix}.$$

Hence, $M_k \to X$ and $M_k (A - BK_k) \to I$, so $A - BK_k$ is nonsingular for large k, and

$$(A - BK_k)^{-1} = (M_k (A - BK_k))^{-1} M_k \to X.$$

If $[X, I, XB] \in \mathcal{C}_I$, part (1) indicates that there exists a unique U such that $AX + BU = I$. Then

$$BK_k (A - BK_k)^{-1} = A (A - BK_k)^{-1} - I \to AX - I = -BU,$$

$$K_k (A - BK_k)^{-1} \to -U.$$

(3) Consider the open, dense subset

$$\Omega_I = \left\{ \begin{bmatrix} X & Y \end{bmatrix} L_I \in \mathcal{V}_n\left(\mathbb{R}^{2n+m}\right) \;\middle|\; \operatorname{rank}\begin{bmatrix} XB & Y \end{bmatrix} = m, \quad \det\left(AX - Y\right) \neq 0 \right\}$$

of Ω. Since μ is a submersion, $\mathcal{C}_I = \mu\left(\Omega_I\right)$ is open and dense in $\mathcal{C}$. The map

$$f : \begin{bmatrix} X \\ U \end{bmatrix} \to [X, I, XB]$$

takes $\mathcal{W}$ onto $\mathcal{C}_I$ by (1). Since U is uniquely determined by X, f is $1-1$. Both $\mathcal{W}$ and $\mathcal{C}_I$ are covered by single coordinate domains. One may construct an affine chart ϕ for $\mathcal{W}$ and apply the chart

$$\psi : [X, I, XB] \to X$$

to $\mathcal{C}_I$. Then $\psi \circ f \circ \phi^{-1}$ is an affine diffeomorphism, so f is a diffeomorphism. ∎

Since closed-loop systems in $\mathcal{C}_I$ (or, alternatively, $\mathcal{W}$) have no eigenvalue at 0, $\mathcal{C}_I$ contains all stable limits and all zeroth-order limits. The structure of $\mathcal{W}$ is dual to the structure of the manifold $\mathcal{V}$ we studied in [5].

Restricting to $\mathcal{C}_I$ yields a surprising result related to controllability of the closed-loop system (16).

THEOREM 6. *Let* $[X, I, XB] \in \mathcal{C}_I$. *Then* $\operatorname{rank} X \geq n-m$ *with equality iff* $XB = 0$.

Proof. $\begin{bmatrix} A & B \end{bmatrix}$ has full rank, so we may choose nonsingular M, N such that

$$MB = \begin{bmatrix} 0 \\ I \end{bmatrix}, \quad MAN = \begin{bmatrix} I & 0 \\ \widetilde{A}_{21} & \widetilde{A}_{22} \end{bmatrix}. \tag{20}$$

Let

$$\begin{bmatrix} \widetilde{X}_{11} & \widetilde{X}_{12} \\ \widetilde{X}_{21} & \widetilde{X}_{22} \end{bmatrix} = N^{-1} X M^{-1}, \quad \begin{bmatrix} \widetilde{U}_1 & \widetilde{U}_2 \end{bmatrix} = U M^{-1}.$$

Then

$$\begin{bmatrix} \widetilde{X}_{11} & \widetilde{X}_{12} \\ A_{21}\widetilde{X}_{11} + A_{22}\widetilde{X}_{21} + \widetilde{U}_1 & A_{21}\widetilde{X}_{12} + A_{22}\widetilde{X}_{22} + \widetilde{U}_2 \end{bmatrix} = M\left(AX + BU\right)M^{-1} = I,$$

so X and XB have the form

$$X = N \begin{bmatrix} I & 0 \\ X_{21} & X_{22} \end{bmatrix} M, \quad XB = N \begin{bmatrix} 0 \\ X_{22} \end{bmatrix}.$$

Hence, $\operatorname{rank} X \geq n - m$ with equality iff $X_{22} = 0$. ∎

Theorem 6 states that high-gain limits of (3), where the rank of X degenerates maximally, have the unfortunate property that the input v exerts no control whatsoever on the system. This is undoubtedly a limitation for control problems where closed-loop tracking to a reference input is required.

Now we consider the special cases of minimum-order stable and zeroth-order limits. By applying essentially the same arguments as in [5], several results are obtained immediately. These are summarized in Theorems 7 and 8. The first is based on the following construction. Choose any nonsingular matrix T such that

$$T^{-1}B = \begin{bmatrix} 0 \\ I \end{bmatrix}, \tag{21}$$

and let

$$\begin{bmatrix} \widetilde{A}_{11} & \widetilde{A}_{12} \\ \widetilde{A}_{21} & \widetilde{A}_{22} \end{bmatrix} = T^{-1}AT, \tag{22}$$

where $\widetilde{A}_{22} \in \mathbb{R}^{m\times m}$. If (A, B) is stabilizable,

$$\operatorname{rank} \begin{bmatrix} \lambda I - \widetilde{A}_{11} & -\widetilde{A}_{12} & 0 \\ -\widetilde{A}_{21} & \lambda I - \widetilde{A}_{22} & I \end{bmatrix} = n$$

for every λ with $\operatorname{Re}\lambda \geq 0$. Hence, $\operatorname{rank} \begin{bmatrix} \lambda I - \widetilde{A}_{11} & \widetilde{A}_{12} \end{bmatrix} = n - m$ (i.e., $(\widetilde{A}_{11}, \widetilde{A}_{12})$ is stabilizable). We may thus choose Λ such that $\widetilde{A}_{11} - \widetilde{A}_{12}\Lambda$ is stable and set

$$X = T \begin{bmatrix} \left(\widetilde{A}_{11} - \widetilde{A}_{12}\Lambda\right)^{-1} & 0 \\ -\Lambda\left(\widetilde{A}_{11} - \widetilde{A}_{12}\Lambda\right)^{-1} & 0 \end{bmatrix} T^{-1}, \tag{23}$$

$$U = \begin{bmatrix} -\left(\widetilde{A}_{21} - \widetilde{A}_{22}\Lambda\right)\left(\widetilde{A}_{11} - \widetilde{A}_{12}\Lambda\right)^{-1} & I \end{bmatrix} T^{-1}. \tag{24}$$

By direct calculation, $AX + BU = I$, so $\begin{bmatrix} X \\ U \end{bmatrix} \in \mathcal{W}$ and $\xi = [X, I, 0] \in \mathcal{C}_I$. Note that $\operatorname{ind}\xi = 1$ and $(\widetilde{A}_{11} - \widetilde{A}_{12}\Lambda)^{-1}$ is stable, so ξ is stable. From Theorem 1, part (1), the state transition matrix is

$$\Phi = T \begin{bmatrix} \left(\widetilde{A}_{11} - \widetilde{A}_{12}\Lambda\right)\exp\left(\widetilde{A}_{11} - \widetilde{A}_{12}\Lambda\right) & 0 \\ -\Lambda\left(\left(\widetilde{A}_{11} - \widetilde{A}_{12}\Lambda\right)\exp\left(\widetilde{A}_{11} - \widetilde{A}_{12}\Lambda\right) + \delta I\right) & -\delta I \end{bmatrix} T^{-1}, \tag{25}$$

so

$$\Phi X = T \begin{bmatrix} \exp\left(\widetilde{A}_{11} - \widetilde{A}_{12}\Lambda\right) & 0 \\ -\Lambda\exp\left(\widetilde{A}_{11} - \widetilde{A}_{12}\Lambda\right) & 0 \end{bmatrix} T^{-1}. \tag{26}$$

Letting

$$\begin{bmatrix} \widetilde{x}_{01} \\ \widetilde{x}_{02} \end{bmatrix} = T^{-1}x_0,$$

we obtain the solution of (16):

$$x = T \begin{bmatrix} I \\ -\Lambda \end{bmatrix} \exp\left(\widetilde{A}_{11} - \widetilde{A}_{12}\Lambda\right)\widetilde{x}_{01}.$$

THEOREM 7.

(1) *$\mathcal{C}_s$ contains a stable point iff (A, B) is stabilizable.*

(2) *If $\xi \in \mathcal{C}_s$ is stable, then $\operatorname{ord}\xi \geq n - m$ with equality iff $\xi = [X, I, 0]$, where X has the structure* (23).

Proof. See [6, Thms. 4.2 and 4.3]. ∎

We are also interested in the zeroth-order closed-loop limits

$$\mathcal{C}_0 = \left\{ \xi \in \mathcal{C} \;\middle|\; \operatorname{ord} \xi = 0 \right\}.$$

$\mathcal{C}_0$ corresponds precisely to those $\xi = [X, I, XB] \in \mathcal{C}_I$ with X nilpotent. From Theorem 1, part (1), the state transition matrix is

$$\Phi = -\sum_{i=0}^{q-1} \delta^{(i)} X^i, \tag{27}$$

so the solution of (16) is

$$x = \Phi X x_0 + \Phi * v = -\sum_{i=0}^{n-1} X^{i+1} B v^{(i)} - \sum_{i=1}^{n-1} \delta^{(i-1)} X^i x_0.$$

The system corresponds to successive differentiation of the input v plus a "noise" term.

THEOREM 8.

(1) *$\mathcal{C}_0$ is nonempty iff (A, B) is controllable.*

(2) *If (A, B) is controllable and $m = 1$, $\mathcal{C}_0$ is a singleton.*

(3) *If (A, B) is controllable, $m = 1$, $\xi_k \in \mathcal{C}_r$, and all eigenvalues λ_{ik} of ξ_k satisfy $|\lambda_{ik}| \to \infty$, then ξ_k converges to the unique point in $\mathcal{C}_0$.*

(4) *If (A, B) is controllable and $m > 1$, $\mathcal{C}_0$ is uncountable and unbounded (as a subset of $\mathcal{W}$).*

(5) *Every $\xi \in \mathcal{C}_0$ satisfies* $\operatorname{ind} \xi \geq \frac{n}{m}$.

Proof. See [6, Thms. 5.1–5.3]. □

Next, we consider $\mathcal{C}_r$ approximations $[I, A - BK_k, B]$ to certain points in $\mathcal{C}_s$. This is important in applications, since points with singular X can be achieved as limits only as $\|K_k\| \to \infty$ in (3). In view of (12), the closed-loop system (3) can be written equivalently as

$$(A - BK_k)^{-1} \dot{x} = x + (A - BK_k)^{-1} B v + \delta (A - BK_k)^{-1} x_0, \tag{28}$$

yielding state transition matrix

$$\Phi_k = (A - BK_k) \exp (A - BK_k) \tag{29}$$

and solution

$$x_k = \Phi_k (A - BK_k)^{-1} x_0 + \Phi_k * Bv. \tag{30}$$

We are interested in finding a sequence $\{K_k\}$ that yields not only convergence of $[I, A - BK_k, B]$ in $\mathcal{C}$, but also the strongest possible convergence of the forced and natural response in (30).

We begin by considering stable systems.

THEOREM 9. *Let $\xi \in \mathcal{C}_s$ be stable with* $\operatorname{ord} \xi = n - m$, *and let*

$$K_k = \begin{bmatrix} \widetilde{A}_{21} + k\Lambda & \widetilde{A}_{22} + kI \end{bmatrix} T^{-1}, \tag{31}$$

$$\xi_k = [I, A - BK_k, B].$$

Then

(1) $\xi_k \to \xi$,

(2) $\Phi_k (A - BK_k)^{-1}$ *is uniformly bounded,*

(3) $\Phi_k \to \Phi$ *uniformly on* $[\varepsilon, \infty)$ *for every* $\varepsilon > 0$,

(4) $\Phi_k \to \Phi$ *weak*,*

where Φ *is given by* (25).

Proof.

(1)–(3) See [6, Thm. 6.2].

(4) From (2), (3), $(A - BK_k)^{-1} \Phi_k \to X\Phi$ weak*. Since differentiation is weak* continuous,

$$\Phi_k = (A - BK_k)^{-1} \dot{\Phi}_k - \delta I \to X\dot{\Phi} - \delta I = X. \qquad \square$$

The results of [1] can be interpreted in terms of Theorems 7 and 9. In [1], the special case

$$K_\mu = -\frac{1}{\mu} K \tag{32}$$

is considered, where K is a fixed matrix and $\mu > 0$ is small. Adopting (21) and (22) and setting

$$\begin{bmatrix} \widetilde{K}_1 & \widetilde{K}_2 \end{bmatrix} = KT,$$

it is assumed in [1, equations (32) and (33)] that $\widetilde{K}_2$ and $\widetilde{A}_{11} - \widetilde{A}_{12}\widetilde{K}_2^{-1}\widetilde{K}_1$ are stable. Under these conditions, (32) constitutes an alternative to (31). Indeed, define

$$\Gamma_\mu = \mu\widetilde{A}_{22} + \widetilde{K}_2, \quad \Delta_\mu = \widetilde{A}_{11} - \widetilde{A}_{12}\Gamma_\mu^{-1}\left(\mu\widetilde{A}_{21} + \widetilde{K}_1\right),$$

and note that Γ_μ and Δ_μ are stable for small $\mu > 0$. Block matrix inversion reveals

$$\begin{aligned} X &= T \begin{bmatrix} \Delta_\mu^{-1} & -\mu\Delta_\mu^{-1}\widetilde{A}_{12}\Gamma_\mu^{-1} \\ -\Gamma_\mu^{-1}\left(\mu\widetilde{A}_{21} + \widetilde{K}_1\right)\Delta_\mu^{-1} & \mu\left(\Gamma_\mu^{-1} + \Gamma_\mu^{-1}\left(\mu\widetilde{A}_{21} + \widetilde{K}_1\right)\Delta_\mu^{-1}\widetilde{A}_{12}\Gamma_\mu^{-1}\right) \end{bmatrix} T^{-1} \\ &\to T \begin{bmatrix} \left(\widetilde{A}_{11} - \widetilde{A}_{12}\widetilde{K}_2^{-1}\widetilde{K}_1\right)^{-1} & 0 \\ -\widetilde{K}_2^{-1}\widetilde{K}_1\left(\widetilde{A}_{11} - \widetilde{A}_{12}\widetilde{K}_2^{-1}\widetilde{K}_1\right)^{-1} & 0 \end{bmatrix} T^{-1}, \end{aligned}$$

which is the same as (23) with $\Lambda = \widetilde{K}_2^{-1}\widetilde{K}_1$. Although the structures (31) and (32) are slightly different, the methods of [6, Thm. 6.2] can easily be modified to prove Theorem 9 relative to (32). Note that, in [1], only asymptotic stability for each $\mu > 0$ is actually proven.

Now consider zeroth-order systems $\xi \in \mathcal{C}_0$. Theorem 8, part (1), guarantees that (A, B) is controllable. From [15, pp. 342–343], there exist $\widetilde{K} \in \mathbb{R}^{m\times n}, w \in \mathbb{R}^m$ such that $(A - B\widetilde{K}, Bw)$ is controllable with $A - B\widetilde{K}$ nilpotent. Thus there exists a nonsingular N such that

$$N^{-1}\left(A - B\widetilde{K}\right)N = \begin{bmatrix} 0 & 1 & & \\ & \ddots & \ddots & \\ & & \ddots & 1 \\ & & & 0 \end{bmatrix}, \quad N^{-1}Bw = \begin{bmatrix} 0 \\ \vdots \\ 0 \\ 1 \end{bmatrix}.$$

THEOREM 10. *Let*

$$\beta_{ik} = \binom{n}{i} k^{n-i}, \quad \widehat{K}_k = \begin{bmatrix} \beta_{0k} & \cdots & \beta_{n-1,k} \end{bmatrix},$$

$$K_k = \widetilde{K} + w\widehat{K}_k N^{-1},$$

$$\xi_k = [I, A - BK_k, B].$$

Then

(1) ξ_k *converges to a point in* $\mathcal{C}_0$,

(2) $\Phi_k \to \Phi$ *uniformly on* $[\varepsilon, \infty)$ *for every* $\varepsilon > 0$,

(3) $\Phi_k \to \Phi$ *weak*,*

where Φ *is given by* (27).

Proof.

(1) From Theorem 5, part (2), it suffices to prove that $(A - BK_k)^{-1} \to X$ for some nilpotent X. This follows by the same arguments as in [6, Thm. 6.3].

(2), (3) See [6, Thm. 6.3]. ∎

Note that, in Theorem 10, boundedness of the natural response matrix $\Phi_k(A - BK_k)^{-1}$ was dropped. This is a consequence of the appearance of impulses in Φ when $\xi \in \mathcal{C}_0$ and $X \neq 0$. We can, in fact, prove a stronger result, which demonstrates the disastrous effect of driving the system to a limit with $\operatorname{ord} \xi < n - m$.

THEOREM 11. *Let* $m < n$, $1 < p \leq \infty$, *and* $\xi_k \in \mathcal{C}$ *be stable for all* k. *If the eigenvalues* λ_{ik} *of* ξ_k *satisfy* $\max_i \{|\lambda_{ik}|\} \to \infty$ *as* $k \to \infty$, *then* $\|\Phi_k X_k\|_p \to \infty$.

Proof. See [6, Thm. 6.4]. ∎

5. The limiting compensator. The state feedback law (2) may be written

$$\begin{bmatrix} I & K \end{bmatrix} \begin{bmatrix} u \\ x \end{bmatrix} = v. \tag{33}$$

This suggests that compensators of the form (2) are naturally identified with points $[I, K]$ in the Grassmanian $\mathcal{G}_m(\mathbb{R}^{m+n})$. In the proof of Theorem **??**, we considered the maps $g : \mathcal{G}_n(\mathbb{R}^{2n}) \to \mathcal{G}_n(\mathbb{R}^{2n+m})$ and $h : \mathcal{G}_m(\mathbb{R}^{m+n}) \to \mathcal{G}_n(\mathbb{R}^{2n})$ defined by

$$g\left(\left[\widetilde{X}, Y\right]\right) = \left[\widetilde{X}T^{-1}, \widetilde{X}T^{-1}A - Y, \widetilde{X}T^{-1}B\right], \tag{34}$$

$$h([Z_1, Z_2]) = \left(\begin{bmatrix} I & 0 \\ 0 & Z_1 \end{bmatrix}, \begin{bmatrix} 0 \\ Z_2 \end{bmatrix}\right), \tag{35}$$

where T is given by (21). The composition $f = g \circ h$ was shown to be an analytic diffeomorphism between the manifolds $\mathcal{G}_m(\mathbb{R}^{m+n})$ and $\mathcal{C}_e = f(\mathcal{G}_m(\mathbb{R}^{m+n}))$, with $\mathcal{C}_e$ regular in $\mathcal{G}_n(\mathbb{R}^{2n+m})$. Consider the open, dense submanifolds $\mathcal{F} = f^{-1}(\mathcal{C})$ and $\mathcal{F}_r = f^{-1}(\mathcal{C}_r)$ of $\mathcal{G}_m(\mathbb{R}^{m+n})$, and let $\mathcal{F}_s = f^{-1}(\mathcal{C}_s)$. The next result establishes basic properties of state feedback (33).

THEOREM 12.

(1) $\mathcal{F}_r = \{[I, K] \in \mathcal{G}_m(\mathbb{R}^{m+n}) \mid K \in \mathbb{R}^{m \times n}\}$.

(2) $\mathcal{F}_s = \{[Z_1, Z_2] \in \mathcal{F} \mid \det Z_1 = 0\}$.

Proof. (1) The result follows by the calculation

$$\begin{aligned} f([I,K]) &= g(h([I,K])) \\ &= g\left(\begin{bmatrix} I & 0 \\ 0 & I \end{bmatrix}, \begin{bmatrix} 0 \\ K \end{bmatrix}\right) \\ &= \left[T^{-1}, T^{-1}A - T^{-1}BK, T^{-1}B\right] \\ &= [I, A - BK, B]. \end{aligned}$$

(2) This follows from $\mathcal{F}_r = \{[Z_1, Z_2] \in \mathcal{G}_m(\mathbb{R}^{m+n}) \mid \det Z_1 \neq 0\}$ and $\mathcal{F}_s = \mathcal{F} - \mathcal{F}_r$. ∎

The properties of f guarantee that, if K_k is any sequence of feedback matrices such that the closed-loop system (3) converges in $\mathcal{C}$, then the sequence $[I, K_k]$ also converges in $\mathcal{G}_m(\mathbb{R}^{m+n})$. By Theorem 12, degeneration of (3) to a point in $\mathcal{C}_s$ occurs iff $[I, K_k]$ converges to a point in $\mathcal{F}_s$. In other words, the limiting compensator always exists, and it is singular iff the limiting closed-loop system is singular. Compensators in $\mathcal{F}_s$ are not physically realizable, since they correspond to feedback laws of the form

$$Z_1 u = -Z_2 x + v$$

with Z_1 singular. Yet, as a mathematical object, each compensator in $\mathcal{F}$ determines a well-defined closed-loop system.

For the special case of minimum-order stable limits, as in Theorem 7, we can obtain the form of Z_1 and Z_2 explicitly.

THEOREM 13. *If* $\xi = [X, I, XB]$ *is given by* (23), *then* $f^{-1}(\xi) = \left[0, \begin{bmatrix} \Lambda & I \end{bmatrix}\right]$.

Proof. Choose a representative $\begin{bmatrix} Z_1 & Z_2 \end{bmatrix}$ for $f^{-1}(\xi)$. From (23), (34), and (35),

$$\begin{bmatrix} I & 0 \\ 0 & Z_1 \end{bmatrix} T^{-1} = MT \begin{bmatrix} \left(\widetilde{A}_{11} - \widetilde{A}_{12}\Lambda\right)^{-1} & 0 \\ -\Lambda\left(\widetilde{A}_{11} - \widetilde{A}_{12}\Lambda\right)^{-1} & 0 \end{bmatrix} T^{-1}$$

for some nonsingular M. Hence, $Z_1 = 0$ and

$$\begin{bmatrix} \widetilde{A}_{11} - \widetilde{A}_{12}\Lambda \\ 0 \end{bmatrix} = MT \begin{bmatrix} I \\ -\Lambda \end{bmatrix}.$$

Letting

$$\begin{bmatrix} \widetilde{M}_{11} & \widetilde{M}_{12} \\ \widetilde{M}_{21} & \widetilde{M}_{22} \end{bmatrix} = MT,$$

we obtain $\widetilde{M}_{21} = \widetilde{M}_{22}\Lambda$. Also, from (34) and (35),

$$\begin{bmatrix} 0 \\ Z_2 \end{bmatrix} = \begin{bmatrix} I & 0 \\ 0 & 0 \end{bmatrix} T^{-1}A - M,$$

so

$$Z_2 = -\widetilde{M}_{22}\begin{bmatrix} \Lambda & I \end{bmatrix}.$$

Since $\operatorname{rank}\begin{bmatrix} Z_1 & Z_2 \end{bmatrix} = m$, $\widetilde{M}_{22}$ is nonsingular. Premultiplication of $\begin{bmatrix} Z_1 & Z_2 \end{bmatrix}$ by $-\widetilde{M}_{22}^{-1}$ yields the desired result. ∎

We conclude this section by examining behavior of the input function u under high-gain feedback. For simplicity, we will consider only the case where $v = 0$. If we apply the feedback gains K_k to (3), then both u and x depend on k and are related by the feedback law

$$u_k = K_k x_k.$$

In Theorems 9 and 10, we established cases under which the state-transition matrix Φ_k converges in two different topologies. More generally, consider the linear subspace

$$\mathcal{D}_0' = C[0,\infty) + \operatorname{span}\left\{\delta, \dot{\delta}, \ddot{\delta}, \dots\right\} \subset \mathcal{D}_+',$$

where $C[0,\infty)$ is the set of continuous functions on $\mathbb{R}$ with support in $[0,\infty)$. Both weak* convergence and uniform convergence on every $[\varepsilon,\infty)$ correspond to specific topologies on $\mathcal{D}_0$. It is easy to show that both make $\mathcal{D}_0$ a topological vector space.

THEOREM 14. *Suppose $\mathcal{D}_0$ is given a topology that makes it a topological vector space. If $[I, A - BK_k, B] \to [X, I, XB] \in \mathcal{C}_I$ and $\Phi_k \to \Phi$ in $\mathcal{D}_0$, then $u_k \to U\Phi x_0$ in $\mathcal{D}_0$.*

Proof. From (29) and Theorem 5, part (2),

$$\begin{aligned} U\Phi + K_k (A - BK_k)^{-1} \Phi_k &= \left(U + K_k (A - BK_k)^{-1}\right)\Phi + K_k (A - BK_k)^{-1} (\Phi_k - \Phi) \\ &\to 0, \end{aligned}$$

so

$$u_k = -K_k (A - BK_k)^{-1} \Phi_k x_0 \to U\Phi x_0. \qquad \square$$

Theorem 14 can be extended to $v \neq 0$ through the choice of an appropriate space of inputs v and exploiting the properties of the convolution operator. We leave the details to the reader.

6. Application to cheap control. A classical problem in the theory of linear-quadratic optimal control is the "cheap control" problem, where an input function $u^*(t)$ is sought to minimize the cost

$$J(\varepsilon) = \int_0^\infty x^T x + \varepsilon u^T u dt$$

subject to (1), with fixed initial condition x_0 and small $\varepsilon \geq 0$. For $\varepsilon > 0$, this problem has been extensively studied (e.g., see [13], [7], [12], [14]). The solution is obtained by constructing the unique positive definite symmetric solution $P(\varepsilon)$ of the algebraic Riccati equation

$$P(\varepsilon)A + A^T P(\varepsilon) - \frac{1}{\varepsilon} P(\varepsilon) B B^T P(\varepsilon) + I = 0.$$

Then, for each x_0, the optimal u and x are related by the feedback law

$$u^* = -\frac{1}{\varepsilon} B^T P(\varepsilon) x^*,$$

yielding the closed-loop system

$$\left(A - \frac{1}{\varepsilon} B B^T P(\varepsilon)\right)^{-1} \dot{x}^* = x^* + \delta \left(A - \frac{1}{\varepsilon} B B^T P(\varepsilon)\right)^{-1} x_0$$

(cf. (28)).

For $\varepsilon = 0$, we adopt (21) and (22), let

$$\begin{bmatrix} \widetilde{Q}_{11} & \widetilde{Q}_{12} \\ \widetilde{Q}_{12}^T & \widetilde{Q}_{22} \end{bmatrix} = T^T T,$$

and let Γ be the unique positive definite symmetric solution of the reduced Riccati equation

$$\Gamma\left(\widetilde{A}_{11} - \widetilde{A}_{12}\widetilde{Q}_{22}^{-1}\widetilde{Q}_{12}^T\right) + \left(\widetilde{A}_{11} - \widetilde{A}_{12}\widetilde{Q}_{22}^{-1}\widetilde{Q}_{12}^T\right)^T \Gamma - \Gamma\widetilde{A}_{12}\widetilde{Q}_{22}^{-1}\widetilde{A}_{12}^T\Gamma + \widetilde{Q}_{11} - \widetilde{Q}_{12}\widetilde{Q}_{22}^{-1}\widetilde{Q}_{12}^T = 0.$$

Setting

$$\Lambda = \widetilde{Q}_{22}^{-1}\left(A_{12}^T\Gamma + \widetilde{Q}_{12}^T\right) \tag{36}$$

leads to values of X, U, and Φ according to (23), (24), and (25). It is shown in [14, Cor. 2.6.1] that $J(0)$ is minimized, subject to (1), by $x^* = \Phi x_0$ and $u^* = U\Phi x_0$. Furthermore, [14, Thm. 2.7.1] indicates that

$$\left(A - \frac{1}{\varepsilon}BB^T P(\varepsilon)\right)^{-1} \to X$$

as $\varepsilon \to 0^+$. These facts are now interpreted in the context of the present paper.

THEOREM 15. *For each $\varepsilon \geq 0$, let $\xi_\varepsilon^* \in \mathcal{C}_r$ be the optimal closed-loop system in the cheap control problem. Then $\xi_\varepsilon^* \to \xi_0^*$ in $\mathcal{C}$ as $\varepsilon \to 0^+$, where ξ_0^* is stable and $\operatorname{ord}\xi_0^* = n - m$. The limiting system ξ_0^* is determined uniquely by the singular compensator $\left[0, \begin{bmatrix}\Lambda & I\end{bmatrix}\right] \in \mathcal{G}_m(\mathbb{R}^{m+n})$ as in Theorem 13, where Λ is given by (36).*

7. Conclusions. In this paper, we have developed a general theory of high-gain state feedback, retaining a fixed state coordinate system. For many control problems, this approach lends itself to a more natural interpretation of results than if the coordinates were allowed to vary with the feedback gain. Relationships to other seminal work in the area have been drawn. As in our earlier similar work on high-gain observers, the present paper has focused primarily on system parameter convergence and behavior of solutions, particularly in the cases of stable and zeroth-order limits. A unique aspect of our results is that even infinite state feedback gains are identified with specific mathematical objects. As future work, we hope to be able to extend our results to observer-based output feedback and, ultimately, to general output feedback.

RENDEZVOUS IN HIGHER DIMENSIONS*

STEVE ALPERN† AND VIC BASTON‡

Abstract. Two players are placed on the integer lattice Z^n (consisting of points in n-dimensional space with all coordinates integers) so that their vector difference is of length 2 and parallel to one of the axes. Their aim is to move to an adjacent node in each period, so that they meet (occupy same node) in least expected time $R(n)$, called the rendezvous value. We assume they have no common notion of directions or orientations (i.e., no common notion of "clockwise"). We extend the known result $R(1) = 3.25$ of Alpern and Gal to obtain $R(2) = 197/32 = 6.16$, and the bounds $2n \leq R(n) \leq \left(32n^3 + 12n^2 - 2n - 3\right)/12n^2$. For $n = 2$ we characterize the set of all optimal strategies and show that none of them simultaneously maximizes the probability of meeting by time t for all t. This behavior differs from that found by Anderson and Fekete, and the authors, for the related problem where the players are initially placed at diagonals of one of the squares of the lattice Z^2.

1. Introduction. This paper generalizes the (player-asymmetric) rendezvous problem on the line [6] to higher dimensions. That problem, which we call here $\Gamma(1)$, asks how two unit-speed players initially placed a fixed distance D apart on the line, and faced in random directions (which they each call "forward"), can meet in minimum expected time. Neither knows the direction to the other, nor do they have a common notion of a "positive" or "forward" direction. By taking $D = 2$ we may model the line as the lattice $Z = Z^1$ of integers, with the players moving to adjacent nodes (integers) in each integer period, until the first (meeting) time that they occupy the same node. (Taking D even ensures they will not pass each other on the line without meeting.) A strategy for each player can be taken as a sequence of F's (for forward) and B's (for backward), which determines a player's motion relative to his starting node and his initial direction. Adopting Player I's coordinate system, with his initial node as 0 and his forward direction to the right, we equiprobably place Player II at the nodes -2 and +2. We may consider that there are four *agents* of Player II, two starting at -2 (facing in either direction) and two at +2. It was shown in [6] that the strategy pair

$$(1) \qquad (F, F, B, B, B, B) \text{ (for Player I) and } (F, B, B, B, F, F) \text{ (for II)}$$

is optimal, having minimum expected meeting time 13/4 (called the *rendezvous value* and, since the line has dimension $n = 1$, denoted here by $R(1) = 13/4 = 3.25$). It is easy to verify the expected meeting time 13/4 for this strategy pair (though establishing optimality is obviously harder). If the two players start facing each

other (that is, Player II starts at +2 facing left), then since they both start with a forward move they meet at time $t = 1$ at node +1. This corresponds to the upper right entry in the *meeting time matrix* (2) for the four agents of Player II, and the reader should verify the other three. The expected meeting time is therefore $(2 + 1 + 6 + 4)/4 = 13/4$.

(2)

location\direction	$\rightarrow$	$\leftarrow$
+2	2	1
−2	6	4

The optimal strategy (1) for $\Gamma(1)$ is almost a *wait for mommy* (WFM) strategy in which Player I (Mommy) optimally searches out the possible initial starting points of II (Child), while II stays still. In fact (F, F, B, B, B, B) is such a Mommy strategy, though II does not wait. However, note that II is indeed back at his starting node at the two times $t = 2, 6$ that I might search it. At the intermediate time $t = 4$, Player II searches out a possible starting point of I. So we may call this strategy an *alternating wait for mommy* (AWFM) strategy, in which the players alternate taking the role of Mommy and searching out starting points of the other. Such strategies will play a role in the higher dimensional games. (The analysis of more general linear rendezvous problems can be found in [11] and [5].)

To generalize this problem to n dimensions, we consider the game $\Gamma(n)$ in which the two players are initially placed in the lattice Z^n (n-vectors of integers, with nodes adjacent if they differ by 1 in one coordinate and are identical in the others) so that their vector difference is of length 2 and parallel to one of the coordinate axes. We assume that they do not know the initial location of the other, and that they have no common ordering of the axes (in particular, no common notion of clockwise for the planar problem, $n = 2$). Note that while restricting the players to move in the lattice Z^n rather than the Euclidean space R^n does not essentially change the problem when $n = 1$, it certainly does so for $n > 1$.

The organization and main results of the paper are as follows. In section 2, we give a rigorous definition of the rendezvous problem on the planar lattice Z^2, for a general distribution of the initial vector between the players. The presentation is similar but simpler than that given in [3] and contains some general optimality conditions.

In sections 3 and 4 we solve the planar rendezvous problem $\Gamma(2)$, establishing (Theorem 14) that the rendezvous value is $R(2) = 197/32$. Although the AWFM strategy is not optimal, a variation of it called the nearly alternating wait for mommy (NAWFM) strategy (drawn in Figure 4) is optimal. We also determine the full set of optimal strategies (Theorem 15). We show that, unlike the situation in $\Gamma(1)$, no strategy in $\Gamma(2)$ is *uniformly optimal*, in the sense that it simultaneously maximizes the probability of meeting by time t, for all t.

The results on planar rendezvous which we establish in section 4 may be contrasted with related results with different assumptions. It is shown in [4] that the players can do better (lower expected meeting time) if they have a common notion of clockwise. Our results may also be contrasted with those for the planar rendezvous model introduced by Anderson and Fekete [9] and extended by the authors [3], for the *diagonal start problem* (players start at opposite diagonals of a square in the Z^2 lattice). In that model all optimal strategies are uniformly optimal and having a common notion of clockwise does not help the players.

In section 5, we obtain (Theorem 16) bounds on the rendezvous value $R(n)$, showing that it is asymptotically bounded above by $8n/3$. These results are the first obtained for rendezvous in more than two dimensions, and are reported in the book [7],

which attributes them to an earlier version of this paper. Section 6 gives a discussion of some of our results.

The version of rendezvous search adopted in this paper is the so-called *player-asymmetric* (or just asymmetric) version, in which the players can have distinct strategies. For example, they may have mobile phones and agree which role each will take, e.g., one Mommy and one Child in the WFM strategy pair. The other, *player-symmetric* version (where they both must adopt the same mixed strategy) will not be discussed here, but can be found in [1], [8], and [10].

A general survey of the rendezvous search problem can be found in [2] and a unified presentation of results up to 2003 can be found in Book II of [7]. The main works on planar rendezvous are [9] and [13], together with our work cited above.

2. Rendezvous in the plane: Strategies and agents. In this section we give a formal presentation of rendezvous on the planar lattice Z^2 without a common notion of clockwise. A similar but more general presentation is given in [3]. The (lattice) distance d between two nodes is defined as the sum of the edges in a shortest connecting path, or equivalently $d\left((z_1, z_2), (w_1, w_2)\right) = |z_1 - w_1| + |z_2 - w_2|$. At time $t = 0$, nature places the two players on even nodes with the vector v from I to II drawn from a given distribution. (A node $z \in Z^2$ is called *even* if the sum of its coordinates is even; otherwise it is called *odd*.) In every time period each player must move to an adjacent node. This restriction, combined with the "even distance" initial placement (originating in the interval network of Howard [12]), ensures that the two players will always have the same parity and that they cannot pass each other on an edge without meeting at a node.

We analyze the progress of the game in terms of Player I's coordinate system (and sense of clockwise). In this perspective, the initial random placement is achieved by nature placing I at the origin facing north ($\mathcal{N}$) and placing II at the even node v_i, with probability p_i, $i = 1, \ldots, K$, facing equiprobably in any of the four possible directions, and with either the same or opposite notion of clockwise as Player I. Aside from this section, dealing with arbitrary initial locations v_i, we will be mainly concerned with the game $\Gamma(2)$ described in the Introduction. We denote this general planar game by $\Gamma = \Gamma(v_1, \ldots, v_k; p_1, \ldots, p_K)$. In terms of this more general framework, the game $\Gamma(2)$ can be defined in the following way.

DEFINITION 1. *The game* $\Gamma(2)$ *begins with Player I initially placed at the origin* $(0, 0)$ *and II initially placed equiprobably at one of the four nodes* $v_1 = (0, 2)$, $v_2 = (2, 0)$, $v_3 = (0, -2)$, $v_4 = (-2, 0)$.

When the game begins, the players have no common notion of locations or directions in the plane, and no common notion of clockwise. As observers, we adopt I's coordinate system. The orientations of Player II can be seen as transformations (or rigid motions, or symmetries) of the "standard orientation" of Player I. Figure 1 shows the eight equiprobable orientations.

The orientations in the top row ($k = 0$) all have the same notion of clockwise as Player I (the usual one), with the upper left orientation the standard one, and the one in column j obtained from it by applying the 90° clockwise rotation $\mathcal{R}$ to it j times. The orientations in the bottom row ($k = 1$) have the other (reversed) notion of clockwise, and can be obtained from the one above by a single application of the reflection ϕ about the vertical axis. Formally,

$$\mathcal{R}^j = \text{clockwise rotation by angle } j\ \pi/2,\ j = 0, 1, 2, 3, \tag{3}$$

$$\phi(w_1, w_2) = (-w_1, w_2), \text{ and the eight orientations of II are} \tag{4}$$

$$\phi^k \mathcal{R}^j,\ j = 0, 1, 2, 3;\ k = 0, 1. \tag{5}$$

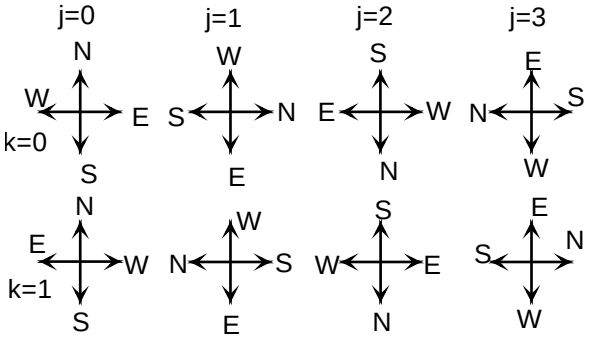

FIG. 1. *Eight orientations in the plane.*

The orientations determine how Player II will move when given an instruction (strategy). For example, if the instruction is for II to go E (east), then (in Player I's coordinate system, which we also adopt as observers) he will go S (south) if he has orientation $j = 1, k = 0$; he will go N if he has orientation $j = 3$, $k = 1$.

We can now define a strategy and show how a pair of strategies determines a set of meeting times for the two players, one for each initial configuration (initial location v_i and initial orientation j, k).

DEFINITION 2. *A* strategy *for a player (in* Γ *or* $\Gamma(2)$*) is a sequence of directions* $D_t \in \{N = (0,1), E = (1,0), S = (0,-1), W = (-1,0)\}$, $t = 1, 2, \ldots$. *A player pursuing this strategy moves successively one unit in his direction* $D_0, D_1, \ldots$, *according to his initial orientation. Equivalently, it can be seen as his net displacement* $f(t)$ *at time* t *from his initial location, given by* $f(0) = (0,0)$ *and for* $t \geq 1$,

$$f(t) = \sum_{m=1}^{t} D_m. \tag{6}$$

So for example the strategy beginning $N, E, E,$ (I's strategy, thick grey line in Figure 2) corresponds to a net displacement function f with

$$[f(0), f(1), f(2), f(3)] = [(0,0), (0,1), (1,1), (2,1)]. \tag{7}$$

We shall deal with strategy pairs (f, g) where Player I adopts f and II adopts g. Sometimes we will use the symmetric notation (f_1, f_2). In this setting, the location of Player I at time t is simply $f(t)$, while the location of II (in I's coordinate system) depends on his initial configuration, as described below. If the initial configuration (i, j, k) gives Player II initial location v_i and orientation $\phi^k \mathcal{R}^j$, then the location of Player II at time t under strategy g is given by

$$g_{i,j,k}(t) = v_i + \phi^k \mathcal{R}^j (g(t)). \tag{8}$$

It is useful to note that if $g(t) = (x, y)$, then the displacements of the eight agents starting at v_i at time t are of the form $(\pm x, \pm y)$ or $(\pm y, \pm x)$. If none of the conditions $xy = 0$ (at least one 0) or $|x| = |y|$ hold, there are eight distinct displacements; if exactly one of these conditions holds there are four distinct displacements; if both hold ($x = y = 0$), all agents are back at their starting node v_i.

DEFINITION 3. *The* $8K$ *(in our example,* 32*) paths* $g_{i,j,k}$ *are called the* agents *of Player II. We call* $g_{i,j,k}$ *the* agent starting at v_i in direction j, with the same (if $k = 0$)

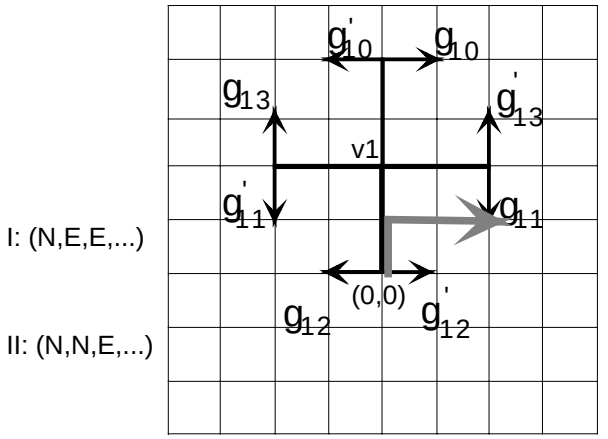

FIG. 2. *Meetings at $t \leq 3$ for (N,E,E,...), (N,N,E,...).*

or different (if $k = 1$) notion of clockwise as I. *Each agent from v_i is the actual path of Player II with probability $p_i/8$. We will sometimes use the simpler two subscript agent notation $g_{i,j} = g_{i,j,0}$ and $g'_{i,j} = g_{i,j,1}$.*

The time taken for agent $g_{i,j,k}$ to be met by Player I is called its *meeting time* and denoted

$$\omega_{i,j,k}(f,g) = \min\{t : f(t) = g_{i,j,k}(t)\}, \tag{9}$$

and the time required to meet *all* the agents is called *maximum time* $M(f,g)$, where

$$M(f,g) = \max_{i,j,k} \omega_{i,j,k}(f,g). \tag{10}$$

For each time t we calculate the number of agents x_t that Player I meets (for the first time) at time t as

$$x_t = x_t(f,g) = \#\{(i,j,k) : \omega_{i,j,k}(f,g) = t\}, \tag{11}$$

and we call the sequence $[x_1, x_2, \ldots, x_M]$ the *agent number profile*, or sometimes just *agent profile*, or just *profile*. Figure 2 illustrates several important concepts for the case where the strategy pair begins with (N,E,E,...) for I and (N,N,E,...) for II. Player I's path $(0,0),(0,1),(1,1),(2,1)$ for $t \leq 3$ is shown in a thick grey line. The possible paths taken by II if he starts at $v_1 = (0,2)$, that is, the 8 paths $g_{1,j,k}(t)$, $j = 0,\ldots 3$, $k = 0,1$, are drawn in medium black lines starting at $v_1 = (0,2)$. Note that all the paths $g_{1,j,0}(t) = g_{1,j}(t)$ in our notation make *right* turns at move 3, while the $g'_{1,j} = g_{1,j,1}$ make *left* turns. Note that Player I meets agents $g'_{1,2}$ and $g_{1,2}$ at node $(0,1)$ at time 1, and meets agent $g_{1,1}$ at node $(2,1)$ at time 3. Thus in our notation we have $\omega_{1,2,0} = \omega_{1,2,1} = 1$ and $\omega_{1,1,0} = 3$. Note that when there are no turns since the last return to a starting point (a single direction is repeated), agents with a common notion of that direction will be at the same location, so if one is met, the other will be also. Since Player I will not meet agents from any nodes other than v_1 by time 3, it can be seen that he meets two agents at time $t = 1$, no agents at time $t = 2$, and one agent at time $t = 3$, so that $x_1 = 2, x_2 = 0$, $x_3 = 1$, and the agent number profile begins $[2,0,1,\ldots]$. For comparison with a later table (18) we write this as a table of

$\omega_{i,j,k}$, with blank entries depending on the strategy for $t > 3$.

(12)

$\omega_{i,j,k}$	$k=0$				$k=1$			
j	0	1	2	3	0	1	2	3
$i=1$		3	1				1	

Given a strategy pair (f, g), the expected value of the meeting times $\omega_{i,j,k}$ is called the *expected meeting time* and denoted $T(f, g)$. Thus

$$T(f,g) = \frac{1}{8}\sum_{i,j,k} p_i \omega_{i,j,k}(f,g), \quad \text{or simply} \tag{13}$$

$$= \frac{1}{32}\sum_{i,j,k} \omega_{i,j,k}(f,g) \text{ for } \Gamma(2). \tag{14}$$

If $M = M(f, g)$ is finite, we may also calculate $T(f, g)$ for $\Gamma(2)$ by the meeting number sequence $x = [x_1, x_2, \ldots, x_M]$ as

$$T(f,g) = \frac{1}{32}\sum_{t=1}^{M} t\ x_t. \tag{15}$$

The rendezvous value R for the game Γ is the least expected time,

$$R(\Gamma) = \min_{f,g} T(f,g), \tag{16}$$

and any pair f, g achieving the minimum is called *optimal.*

We know that $R(\Gamma)$ is finite because M, and hence T, is finite for the WFM strategy.

A stronger notion of optimality is the following.

DEFINITION 4. *A strategy pair is called* uniformly optimal *if for all t it maximizes the probability that the players have met by time t. (Note that if there is a uniformly optimal strategy, then all optimal strategies must be uniformly optimal.)*

A uniformly optimal strategy maximizes the expected utility $U(\omega)$ of the meeting time ω as long as the utility function U is nonincreasing in ω (earlier meetings are preferred to later ones); an optimal strategy is only required to accomplish this for the particular utility function $U(\omega) = -\omega$.

The authors have shown that, given the order in which the agents are met, any optimal strategy pair is greedy in the sense that the next agent is met as quickly as possible, with both players taking geodesics to the next meeting point. The following result was proved without the assumption that the players must move in each period (that is, staying still was allowed), and hence shows that our assumption here that they must move does not take away any optimal strategies.

THEOREM 5 (see [3]). *Let (f_1, f_2) be an optimal strategy pair. Define $\omega^0 = 0$ and let $\omega^1 < \omega^2 < \cdots < \omega^N$ denote the associated set of meeting times with the $8K$ agents, listed in increasing order. Let d denote the graph distance on the lattice Z^2. Then*

$$d\left(f_i\left(\omega^{m-1}\right), f_i\left(\omega^m\right)\right) = \omega^m - \omega^{m-1}, \text{ for } i = 1, 2 \text{ and } m = 1, \ldots, N. \tag{17}$$

In other words, both players move in time-minimizing paths between consecutive meeting points. In particular, neither player ever stays still, and consequently both players are at even (odd) nodes at all even (odd) times. Furthermore, if the agent $g_{i,j,k}$ is met at time ω^m, then that meeting point $f_1(\omega^m) = g_{i,j,k}(\omega^m)$ is a lattice midpoint of the locations of I and agent $g_{i,j,k}$ of II at time ω^{m-1}, and hence occurs at the earliest possible time (given their locations at time ω^{m-1}).

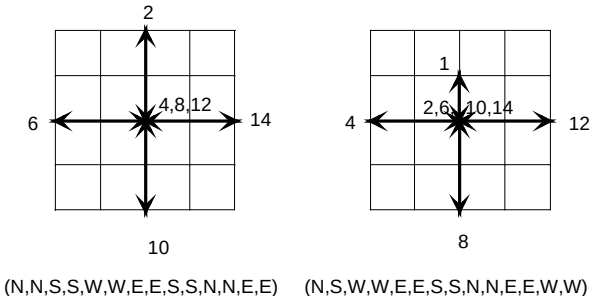

FIG. 3. *An AWFM strategy* $(\breve{f}, \breve{g})$ *for* $n = 2$.

3. Analysis of Γ(2). In this section we develop some fundamental lemmas for the problem $\Gamma(2)$. In the following section these lemmas will be applied to solve $\Gamma(2)$, in the sense of finding all optimal strategies and the rendezvous value. It will be convenient to introduce the notation $\mathcal{S} = \{(0,2),(2,0),(0,-2),(-2,0)\}$ for the set of Player II starting nodes, and $\mathcal{S}_0$ for the set $\mathcal{S}$ augmented by Player I's starting point $(0,0)$. Note that all nodes in $\mathcal{S}_0$ have even parity.

The main results of this section are Theorems 13, 14, and 15, which together determine the rendezvous value $R(\Gamma(2)) = 197/32$ and the complete set of optimal strategies for $\Gamma(2)$. Since we know players following optimal strategies will move in every period (never stay still), we will henceforth only consider strategies with this property. Since the players both start (in $\mathcal{S}_0$) at nodes of even parity, it follows that both are at even nodes at even times and at odd nodes at odd times.

3.1. Special strategies. We now define some particular strategies, AWFM (valid for all $\Gamma(n)$) and NAWFM (for $\Gamma(2)$). In [7], a family of strategies called AWFM was proposed for the general parallel start game $\Gamma(n)$. The players alternate taking the role of Mommy (searching out the starting points of the other) and Child (coming back to one's starting point to be found there when the other comes looking). We will use these strategies to analyze the $n-$dimensional case in the final section.

DEFINITION 6. *A strategy in* $\Gamma(n)$ *is called AWFM if* (a) *Player I successively visits the* $2n$ *possible starting locations of II (in any order) at times* $\mathcal{T}_1 = \{2, 6, \ldots, 2+4(2n-1)\}$, *while returning to his start* $(0,0)$ *at the intermediate times* $\mathcal{T}_2 = \{4, 8, \ldots, 4(2n-1)\}$, *and* (b) *Player II makes his first move a single unit in any direction, is back at his start at times* $\mathcal{T}_1$, *and visits all but one of the possible initial locations of I at times* $\mathcal{T}_2$. *The maximum time for this strategy is clearly* $M = 2 + 4(2n-1)$, *or* $M = 14$ *for* $n = 2$.

It was shown in [7] that, for $n = 2$, any AWFM strategy (as illustrated in Figure 3) gives the maximal probability of meeting by time t for any $t \leq 7$, and suggested that this strategy might in fact be optimal (like the $n = 1$ version, where optimality was established in [6]), or even uniformly optimal.

The meeting time sequence x for $(\breve{f}, \breve{g})$ (and indeed for any AWFM strategy) is given by

$$x = [2,6,0,6,0,6,0,4,0,4,0,2,0,2] \text{ with } T\left(\breve{f}, \breve{g}\right) = \frac{198}{32}.$$

The strategy $(\tilde{f}, \tilde{g})$ drawn in Figure 4 has a lower expected meeting time T than AWFM. Note that I's strategy $\tilde{f}$ is the same as that for AWFM $(\breve{f})$ up to time 10,

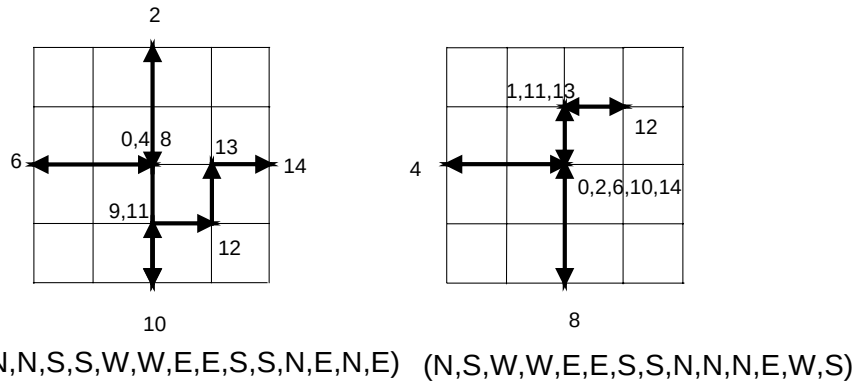

FIG. 4. *The NAWFM strategy* $(\tilde{f}, \tilde{g})$.

but then I goes from $(0,-2)$ to $(2,0)$ without going back through his starting point $(0,0)$. For this reason we call $(\tilde{f}, \tilde{g})$ the NAWFM strategy.

The expected meeting time for the NAWFM strategy pair $(\tilde{f}, \tilde{g})$ can be evaluated by considering the following table of $\omega_{i,j,k}(\tilde{f}, \tilde{g})$ and setting x_t to be the number of t's found in the table. The entries $\omega_{i,j,k}$ in the following table are calculated as in the earlier simpler table (12) which was based on the strategy of Figure 2.

(18)

$\omega_{i,j,k}\left(\tilde{f}, \tilde{g}\right)$	$k = 0$				$k = 1$			
j	0	1	2	3	0	1	2	3
$i = 1, (0,2)$	2	2	1	2	2	2	1	2
$i = 2, (2,0)$	4	8	12	13	14	12	4	8
$i = 3, (0,-2)$	10	4	8	10	9	10	8	10
$i = 4, (-2,0)$	6	6	4	6	4	6	6	6

This gives the agent number profile of

$$x = x\left(\tilde{f}, \tilde{g}\right) = [2,6,0,6,0,6,0,4,0,4,0,2,1,1] \tag{19}$$

(e.g., there are six 2's, so $x_2 = 6$), and hence by (14) or (15),

$$T\left(\tilde{f}, \tilde{g}\right) = \frac{197}{32}. \tag{20}$$

3.2. Nodes with multiple agents. It will turn out from our subsequent analysis that optimal strategies necessarily involve some simultaneous meetings of Player I with two or more agents of Player II. Since this necessitates several agents being simultaneously at a common node, we now analyze how this can occur (both for agents from the same starting node and from different starting nodes).

LEMMA 7 (same starting point). *Suppose that there are $m > 1$ distinct agents from a common starting node v who are all at the same node $z \neq v$ at the same time t. Then*

(i) *$m = 2$ and the agents have distinct notions of clockwise.*
(ii) *The line between v and z makes an angle $r\pi/4$ with the vertical, $r \in \{0,1,2,3\}$.*
(iii) *If r is odd, then the two agents have distinct notions of north (distinct j) and will move to distinct locations at the next move.*

Proof. (i) The four rotations $\mathcal{R}^j$ take any nonzero vector into four distinct vectors, so agents at the same location must have different notions of clockwise, and hence there can be at most two of them.

(ii) By part (i), the $m = 2$ agents at z have distinct notions of clockwise (k equal to 0 and 1) and so by (8) have respective locations

$$v + \mathcal{R}^j(g(t)) \text{ and } v + \phi\mathcal{R}^{j'}(g(t)), \text{ both equal to } z.$$

(Recall that ϕ is the reflection $(w_1, w_2) \to (-w_1, w_2)$ about the vertical axis, and $\mathcal{R}^j$ is the clockwise rotation by $j\pi/2$, $j = 0, 1, 2, 3$). Consequently both $\mathcal{R}^j$ and $\phi\mathcal{R}^{j'}$ take $g(t)$ into $w = z - v$, and hence w is a nonzero fixed point of $(\phi\mathcal{R}^{j'})(\mathcal{R}^j)^{-1} = \phi\mathcal{R}^{j'-j} = \phi\mathcal{R}^n$, $n = j' - j$. If $n = 0$, w lies on the vertical axis (invariant set for ϕ), so $r = 0$; if $n = 1$, $\phi\mathcal{R}^n(w_1, w_2) = (-w_2, -w_1)$, so the fixed points form the line $w_2 = -w_1$, an angle $3\pi/4$ with the vertical; if $n = 2$, then $\phi\mathcal{R}^n(w) = (w_1, -w_2)$ with the fixed point line $w_2 = -w_2$ (the horizontal axis), so $r = 2$; if $n = 3$, then the fixed set w of $\phi\mathcal{R}^n$ is the line $w_1 = w_2$, so $r = 1$. Note that in all cases, n and r have the same parity.

(iii) By the previous remark, if r is odd, then $n = j' - j$ is odd, so the rotations $\mathcal{R}^j$ and $\mathcal{R}^{j'}$ are not the same or opposite ($j \neq -j'$), and hence the moves of the two agents (namely $\mathcal{R}^j(g(t+1) - g(t))$ and $\phi\mathcal{R}^{j'}(g(t+1) - g(t))$) will be distinct, in fact at right angles to each other. (This can also be seen from Figure 1, which shows that two such agents will have no direction notion in common.) ∎

LEMMA 8 (different starting points). *Suppose that agents from $m > 1$ distinct starting points are simultaneously at a common node z. Then*

(i) *If $m = 2$, z lies on the (Euclidean) perpendicular bisector $B(a, b)$ of the two starting points a, b.*

(ii) *If $m > 2$, z is the origin $(0, 0)$.*

Proof. The vectors $z - v$, for the distinct starting points v, are equivalent under rotations, and in particular all have the same Euclidean length (moreover, the set of the absolute values of their two coordinates are the same). Since the Euclidean equidistant set of two points a, b at even lattice distance is their perpendicular bisector $B(a, b)$, this gives (i). The only point equidistant from three starting points is the origin (in either metric), giving (ii). ∎

LEMMA 9. *There can be at most two agents at a common location z at any odd time t. Hence $x_t \leq 2$ for odd t.*

Proof. Assume $x_t \geq 3$. Since t is odd, z has odd parity, and hence $z \neq (0, 0)$. Hence by Lemma 8(ii) , the agents come from at most two distinct starting nodes $a, b \in \mathcal{S}$. Since by Lemma 7(i) at most two agents can come from a single starting point, we conclude that $a \neq b$ and $x_t \leq 4$. By Lemma 8(i), z belongs to the perpendicular bisector $B(a, b)$ of a and b, which can only contain odd parity nodes z if $a = -b$, and either z_1 or z_2 is 0. Without loss of generality we may assume $a = (2, 0)$, $b = (-2, 0)$, and $z_1 = 0$. Since by Lemma 7(ii) the vectors $z - a$ and $z - b$ make angles $r\pi/4$ with the vertical, the coordinate z_2 must be 2, 0, or -2, but all these possibilities result in an even parity z, whereas z is odd, contradicting the assumption. ∎

3.3. Starting point meetings (SPMs). Lemma 7(i) says that the only place to simultaneously meet more than two agents from a common starting node v is at v itself. Consequently, meetings of this type are important and will be given a special name.

DEFINITION 10. *We say there is an* SPM *at time t and node z if either I meets an agent of II at $z = (0, 0)$ (called* Type I*) or Player I meets an agent starting at $z \in \mathcal{S}$ at that node z (called* Type II*). We denote this (either case) as* SPM(t).

Note that the *type* of the SPM is the name of the Player who is back at his starting point at the time of the meeting. Some elementary properties of SPMs are given below.

LEMMA 11 (starting point meetings).

(i) *SPM(t) implies t is even,* $x_{t+1} = 0$, *and* $x_t \leq 6$.

(ii) $x_t > 4$ *implies SPM(t), and hence for even* $t, x_t + x_{t+1} \leq 6$ *(so* $x_i \leq 6$ *for all* i*).*

(iii) $x_t + x_{t+1} \leq 4$ *if no SPM at even time* t.

(iv) *If SPM(t) and SPM(t+2), then the corresponding types are distinct.*

Proof. (i) Since an SPM must occur at a node z in $\mathcal{S}_0$, which contains only even nodes, the time t must be even. Note that at an SPM, one of the players is at his start, while the other is some vector $\mathcal{R}^j(0,2)$ away from his start. Since the difference between their starts has the form $\mathcal{R}^k(0,2)$, their difference at an SPM is of the form $\mathcal{R}^k(0,2) + \mathcal{R}^j(0,2)$, and their distance is 4. So the earliest time for the next meeting is $t+2$, and hence $x_{t+1} = 0$. Suppose the SPM is of Type II. At time $t-1$, Player I will be at some node z' adjacent to z, and there will also be exactly two agents (counting both met and unmet agents) at z' from the starting point z. Since there are only 8 agents who start at z, I can meet at most $8 - 2 = 6$ new agents at time t at z. If the SPM is of Type I, there will be 8 agents at the origin at time t (including ones already met) since $g(t)$ will be a rotation of $(2,0)$. As in the previous argument, I will have met two of them on the previous move. So in either case we have $x_t \leq 6$.

(ii) If the first part of (ii) is true, the second part (the "hence") follows from $x_t + x_{t+1} \leq 6 + 0 = 6$, by part (i) and Lemma 9. So we need only prove the first part.

Suppose I meets $x_t > 4$ agents at some location z at some (even) time t, and there is no SPM. So $z \neq (0,0)$ (otherwise we have a Type I SPM). Suppose $z \notin \mathcal{S}$. Since at most two agents can come from any starting point (Lemma 7(i)), the agents who met at time t must come from at least three distinct starting nodes, and hence (Lemma 8(ii)) $z = (0,0)$, again contradicting our assumption. So we may assume that $z \in \mathcal{S}$ and II is not back at his starting point (otherwise we have a Type II SPM). Since we know $z \neq (0,0)$, Lemma 8(ii) says I can meet agents from at most two starting points. Since II is not back at his start at time t, Lemma 7(i) says there are at most two from each, so in total at most four, contradicting the assumption $x_t > 4$, and we are done.

(iii) Assuming there is no SPM at time t, part (ii) implies that $x_t \leq 4$. If $x_t \leq 2$, the result follows from Lemma 9 (without any other assumptions), so we can assume that $x_t \geq 3$. Hence by Lemma 7(i), agents from at least two starting points a and b must be met at time t at a node z, and by Lemma 8(i), $z \in B(a,b)$.

Suppose $z \in \mathcal{S}$, in which case we can assume without loss of generality that $z = (0,2)$, with $a = (2,0)$ and $b = (-2,0)$. In this case $g(t)$ is a rotation of $(2,2)$, which means the unmet agents at time t are at lattice distance 4 from z and cannot be met before time $t+2$. So $x_t + x_{t+1} \leq x_t + 0 \leq 4$, as required.

Suppose $z \notin \mathcal{S}$. Since $z \neq (0,0)$ (this would be an SPM), we can assume that I meets two agents from a and at least one from b. By Lemma 7(ii), we know that $z - a$ makes an angle $r\pi/4$ with the vertical. If $a = -b$ ("opposite" starting points) then the only nodes z with this property on $B(a,b)$ are in $\mathcal{S}_0$, which we have ruled out. So assume without loss of generality that $a = (2,0)$ and $b = (0,2)$, in which case the only z's in $B(a,b)$ with the required angle property are $(1,1)$ and $(2,2)$. If $z = (2,2)$, then $g(t)$ is a rotation of $(2,0)$, and the same observation as in the previous paragraph gives $x_{t+1} = 0$, and we are done. If $z = (1,1)$, then $g(t) = (1,1)$ and there will be four met and unmet agents at z at time t. However, by Lemma 7(iii) these agents will occupy all four nodes adjacent to z at time $t-1$, and again at time $t+1$. By the $t-1$

observation, we have $x_t \leq 3$, and by the $t+1$ observation and Lemma 9 we know that of the maximum of two agents at I's location z' at $t+1$, one has already been met, so $x_{t+1} \leq 1$. Hence $x_t + x_{t+1} \leq 3+1 = 4$, as required.

(iv) If SPM(t) is of Type II and occurs at some $v \in \mathcal{S}$, then SPM(t+2) cannot occur at another $v' \in \mathcal{S}$ (also be of Type II), because $d(v, v') = 4$. If SPM(t) is of Type I, then at time t all unmet agents are at distance 4 from the origin, and hence cannot get there for another Type I meeting before time $t+4$. So consecutive SPMs cannot be of the same type. □

LEMMA 12. *If SPM(t) but not SPM(t + 2), then $x_{t+2} \leq 2$ and $x_{t+2} + x_{t+3} \leq 3$.*

Proof. Since SPM(t), one of the players is at his start at time t. By renaming them, if necessary, we may assume that Player I is at the origin at time t (Type I). The proof now divides into cases according to the location z of Player I at time $t+2$.

$z = (0,0)$ At time t, unmet agents are at distance 4 from z, so at time $t+2$ they are at distance at least 2 from z, and hence $x_{t+2} = 0$. Since $t+3$ is odd, $x_{t+3} \leq 2$ by Lemma 9 and the result follows.

$z \in S$ By symmetry, we may assume $z = (0,2)$. We may assume that at time $t+2$ Player II is not at his starting point ($g(t+2) \neq (0,0)$), since otherwise we have SPM$(t+2)$. If $x_{t+2} \leq 1$, the result follows from Lemma 9, so we may assume $x_{t+2} \geq 2$. The agents who met at time $t+2$ must have starting points $(-2,0)$ or $(2,0)$, since those from $(0,-2)$ were at distance at least 4 from z at time t. The agents who met at time $t+2$ must be at locations $(-2,2)$ and $(2,2)$ at time t. Although there may be two agents at each of these nodes at time t, at most one of these (from each) can get to z by time $t+2$, since they have different notions of clockwise. Thus $x_{t+2} \leq 2$. In this case we have $g(t+2) = (2,2)$, so all unmet agents at time $t+2$ are at distance from z of at least 4 and cannot be met at time $t+3$. Hence $x_{t+2} + x_{t+3} \leq 2$.

$z = (\pm 1, \pm 1)$ By symmetry we take $z = (1,1)$. It is easy to check that the only new agents met at time $t+2$ were at $(2,2)$ at time t. There are at most four of these, two each starting from $(0,2)$ and $(2,0)$. Those from the same starting point have different notions of clockwise (by Lemma 7(i)), and since $g(t+2)$ is a rotation of $(1,1)$, they will be at different locations at time $t+2$. Hence at most one from each of $(0,2)$ and $(2,0)$ will meet I at $(1,1)$ at time $t+2$, and so $x_{t+2} \leq 2$. If $x_{t+2} < 2$, then the result follows from Lemma 9. Assuming $x_{t+2} = 2$, the situation is as stated above, and the only nodes with unmet agents within distance 2 of $(1,1)$ at time $t+2$ are $(3,1), (-1,1), (1,3)$, and $(1,-1)$, that is, the four starting points added to $(1,1)$. Player I can meet agents from only one of these nodes at time $t+3$, at respective nodes $z' = (2,1), (0,1), (1,2)$, and $(1,0)$. If z' is $(2,1)$ (the analysis for $(1,2)$ is similar), the only agents there come from $w = (3,1)$ at $t+2$ and (by Lemma 7 (iii)) go to different locations (namely z' and $(3,0)$) at time $t+3$. So in this case $x_{t+3} = 1$ and we are done. If z' is $(0,1)$ (the case $(1,0)$ is similar), then any agents he meets there were at $w = (-1,1)$ at time $t+2$ and come from one of the starting points ($(-2,0)$ and $(0,2)$). By Lemma 7(i), there can be at most one of these. □

4. Optimal strategies. In this section we first obtain a partial characterization of optimal strategies, show that the NAWFM strategy $(\tilde{f}, \tilde{g})$ is optimal, and finally give a complete characterization of optimality. We can always rename the players so that the first SPM, if there are any, is of Type II. *We adopt this labeling throughout this section.* The following important result determines the existence and type of the

potential SPMs at all even times except for $t = 14$. We shall see later that optimal strategies may or may not have an SPM at time 14.

THEOREM 13. *Any optimal strategy pair in* $\Gamma(2)$ *has SPMs of alternating Types II, I, II, I, II, at times* $2, 4, 6, 8,$ *and* 10*, and no SPM at time* 12.

Proof. To any meeting profile $[x_1, x_2, \dots]$, where x_t denotes the number of new agents met at time t, we associate the integer $T^* = \sum_t t x_t$, which is 32 times the expected meeting time. To aid the reader, we will highlight the numbers x_t in the profile relevant to the argument by grouping them with a $\overbrace{\ \ }$. The NAWFM strategy has the agent number profile $[2, 6, 0, 6, 0, 6, 0, 4, 0, 4, 0, 2, 1, 1]$, for which $T^* = 197$ (expected meeting time 197/32), and hence any optimal strategy has $T^* \le 197$. We will establish the SPM claims successively for $t = 2, 4, 6, 8, 10,$ and 12 by rejecting as optimal any strategy which produces a partial agent number sequence $[x_1, \dots, x_k]$ for which the smallest possible value of T^* exceeds 197. Note that for any strategy we have $x_1 = 2$.

SPM(2) Suppose that $x_2 + x_3 \le 4$. Then by Lemma 11(ii) the meeting profile minimizing T^* is $[2, \overbrace{4, 0}, 6, 0, 6, 0, 6, 0, 6, 0, 2]$, with $T^* = 202 > 197$. Hence any optimal strategy has $x_2 + x_3 > 4$, which by Lemma 11(iii) implies the required result SPM(2).

SPM(4) If there is no SPM at time 4, then by Lemma 12 and the established result SPM(2), we have $x_4 + x_5 \le 3$. So by Lemma 11(ii), the minimizing profile is $[2, 6, 0, \overbrace{3, 0}, 6, 0, 6, 0, 6, 0, 3]$, with $T^* = 206 > 197$, contradicting optimality.

SPM(6) If there is no SPM at time 6, then by SPM(4) and Lemma 12 we have $x_6 + x_7 \le 3$. Hence by Lemma 11(ii), the minimizing profile is $[2, 6, 0, 6, 0, \overbrace{3, 0}, 6, 0, 6, 0, 3]$, with $T^* = 200 > 197$.

We now summarize our findings for $t \le 7$. Since the SPMs at $t = 2, 4, 6$ are of alternating type, it is easy to verify that the meeting profile for any optimal strategy starts with

$$[2, 6, 0, 6, 0, 6, 0], \text{ with contribution } T^{**} \text{ to } T^* \text{ of} \tag{21}$$

$$T^{**} = (2 \times 1) + (6 \times 2) + (6 \times 4) + (6 \times 6) = 74. \tag{22}$$

Furthermore, there are precisely two starting nodes a, $b \in \mathcal{S}$, which have not been Type II SPMs (not been visited by I) by time 6. From each of these nodes, two agents have been met at time 4 (the Type I SPM at the origin), and the remaining six agents have not been met by time 6.

Suppose $x_8 + x_9 \le 2$. Then by (21) and Lemma 11(ii), the best profile is $[2, 6, 0, 6, 0, 6, 0, 2, 0, 6, 0, 4]$, with $T^* = 198 > 197$. Hence

$$x_8 + x_9 \ge 3 \text{ and (since } x_9 \le 2 \text{ by Lemma 9)} \tag{23}$$

$$x_8 > 0. \tag{24}$$

We now continue to establish further SPMs.

SPM(8) Suppose there is no SPM at time 8. Then by the established SPM at time 6 and Lemma 12, we have $x_8 \le 2$ and $x_8 + x_9 \le 3$. Hence by (23)

$$x_8 + x_9 = 3 \text{ and } x_9 \ge 1. \tag{25}$$

If we *also* have $x_{10} + x_{11} \le 4$, then $[2, 6, 0, 6, 0, 6, 0, \overbrace{2, 1}, \overbrace{4, 0}, 5]$ is the best profile, with $T^* = 74 + 125 = 199 > 197$. Hence we have $x_{10} + x_{11} \ge 5$.

So by Lemma 11(iii) we have SPM(10), and by Lemma 11(i) we have that $x_{11} = 0$. Hence $x_{10} \geq 5$. The SPM at time 10 cannot be Type I, since in that case Player I could meet at most two agents each from the unvisited nodes a and b, contradicting the result $x_{10} \geq 5$. Thus it is of Type II, with Player I meeting at least five agents at the node (say) a. Since there were six agents from a unmet at time 7, he can have met at most $6 - 5 = 1$ of these at times 8 and 9. Since (25) $x_9 \geq 1$ and the only agents that Player I can meet at time 9 come from a (since they are back at a at the Type II SPM at time 10), we must have $x_9 = 1$, and hence by (25), $x_8 = 2$. Thus the other agent met by I at some node c at time 8 must come from b. Since the SPM at time 6 was of Type II, this agent was back at b then, so $d(b, c) \leq 8 - 6 = 2$. Now Player I goes from some node $e \in \mathcal{S}$ at time 6 (since there was a Type II SPM then), to c at time 8, and to $a \in \mathcal{S}$ at time 10. Since $d(e, a) = 4$, it follows that the distance from c to all three nodes $a, b, e \in \mathcal{S}$ is no more than 2. Hence c must be the origin, and since I met an agent at c at time 8, there was an SPM at time 8, contradicting our initial assumption.

By alternation of types for consecutive SPMs, the SPM at time 8 must be of Type I, so at most two agents from each of the unvisited starting points a and b can be met at time 8, and (by Lemma 11(i)) none at time 9, meaning $x_8 \leq 4$ and $x_9 = 0$.

SPM(10) Suppose there is no SPM at time 10. Then, since we have established SPM(8), it follows from Lemma 12 that $x_{10} \leq 2$ and $x_{10} + x_{11} \leq 3$. If $x_8 + x_9 \leq 3$, it follows from the previous remark and (21) that the best profile satisfying the known constraints is $[\overbrace{2, 6, 0, 6, 0, 6, 0}, \overbrace{3, 0}, \overbrace{2, 1}, 6]$. But this has $T^* = 201 > 197$, so $x_8 + x_9 \geq 4$, and by the remarks above this paragraph $x_8 = 4$. Thus, after time 8, I can meet at most four agents at any SPM of Type II, and hence (by Lemma 7(i)) at most four agents at any time after 8. Hence the best profile is $[\overbrace{2, 6, 0, 6, 0, 6, 0}, \overbrace{4, 0}, \overbrace{2, 1}, 4, 1]$, with $T^* = 198 > 197$. Hence there is an SPM at time 10, which must be of Type II, at node (say) a.

Not SPM(12) Suppose there is an SPM at time 12, which by alternation would have to be of Type I. By Lemma 7(i), I can meet at most two agents from the sole unvisited node b at time 12, so $x_{12} \leq 2$ and (by Lemma 11(i)) $x_{13} = 0$. Hence the best profile would be $[2, 6, 0, 6, 0, 6, 0, 4, 0, 4, 0, 2, 0, 2]$, with $T^* = 198 > 197$. So there is no SPM at time 12. □

We can now use the pattern of SPMs established for optimal strategies in Theorem 13 to determine the unique optimal agent number profile and thus the rendezvous value of $\Gamma(2)$.

THEOREM 14. *The rendezvous value for* $\Gamma(2)$ *is* $197/32$ *and the NAWFM strategy* $(\tilde{f}, \tilde{g})$ *is optimal. Furthermore, every optimal strategy has the agent number profile* $[2, 6, 0, 6, 0, 6, 0, 4, 0, 4, 0, 2, 1, 1]$.

Proof. Consider an agent number profile x corresponding to an optimal strategy. According to (21) the profile must begin with $[2, 6, 0, 6, 0, 6, 0]$. Theorem 13 says that at time $t = 8$ there is a Type I SPM (at the origin), so I will meet there two agents from each of the two starting nodes he has not visited. Hence $x_8 = 4$ and $x_9 = 0$ (by Lemma 11(i)). At time $t = 10$, Theorem 13 says that I will visit his third Player II starting point. Of the eight agents who started there, two were met at the origin at each of the Type I SPMs at $t = 4$ and 8, so $x_{10} = 8 - 2 - 2 = 4$, and again $x_{11} = 0$. So the agent number profile x must be of the form

$$[2, 6, 0, 6, 0, 6, 0, 4, 0, 4, 0, x_{12}, x_{13}, x_{14}].$$

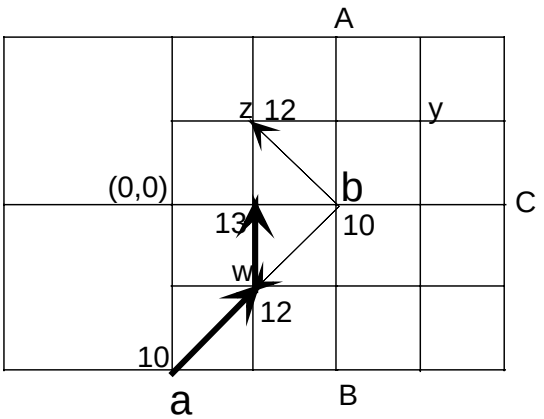

FIG. 5. *Analysis for* $t = 10$ *to* 14.

Since there is no SPM at time 12, it follows from Lemma 12 that $x_{12} \leq 2$ and $x_{12} + x_{13} \leq 3$. So the best profile satisfying all known constraints is

$$\left[2, 6, 0, 6, 0, 6, 0, 4, 0, 4, 0, \overbrace{2, 1}, 1\right],$$

which is (19) the profile of the NAWFM strategy $(\tilde{f}, \tilde{g})$ and has $T^* = 197$. Hence NAWFM is optimal, and the rendezvous value is 197/32. □

We now use the last two theorems to derive the full set of optimal strategy pairs for Γ. We describe the situation in I's coordinate system, but we will not use the agent analysis for II. We begin our analysis at the end of move 10 ($t = 10$). According to Theorem 13, I is at one of the previously unvisited nodes of $\mathcal{S}$, say a, and II (all four remaining agents of) is at the other one, b. Player I can deduce that II is at b, while II knows only that the vector to I is one of the four rotations of $(2, 2)$. We know from the optimal profile of Theorem 14 that they must meet with conditional probability 1/2 at times 12 (two agents of the remaining 4) and 13 (one agent of the remaining 2) and conditional probability 1 at time 14 (the remaining agent must be met). We will find it easier to use a conditional probability analysis, rather than an agent analysis.

If a and b are opposite starting points ($a = -b$) in $\mathcal{S}$, then the only possible location for a meeting at time 12 is the unique midpoint of a and b, namely the origin. But this would constitute an SPM at time 12, which we have ruled out in Theorem 13. The situation from times 10 to 14 is illustrated in Figure 5, with $a = (0, -2)$ and $b = (2, 0)$. Let w denote I's location at time 12. For a meeting, w has to be at one of the three midpoints of a and b : the origin, $(1, -1)$, or $(2, -2)$. The first would imply SPM(12), so can be excluded (Theorem 13). The last would require each player to move 2 units in the same direction on moves 11 and 12. This would leave the players 4 units apart if they fail to meet at time 12, in which case there could not be a meeting at time 13. So w must be the unique Euclidean midpoint of a and b. In our drawing, this gives $w = (1, -1)$. Since the optimal profile has no meeting at time 11, I may get to w in either of the two possible ways (indicated by a diagonal arrow). To achieve a possible meeting at w at time 12, II must move to a diagonally opposite node from his location b at time 10 (must make a turn at time 12). Since he does not know where w is, such a move sequence might lead him to any of the four nodes w, z, y, and

$(3,-1)$). How can II choose among these four directions so as to reach w at time 12 with conditional probability 1/2?

To answer this question, recall (from Theorem 13) that there were Type I SPMs at times 4 and 8. This means Player II has visited two of the possible Player I starting points, that is, two of the three nodes A, B, and C. (He has not visited the actual starting point at the origin or the game would be over.) Now there are two cases. Either (1) he did not visit C (visited two *opposite* starting nodes of I, A and B) or (2) he visited C (two *adjacent* possible starting nodes of I, C and either A or B). He will know which case he is in according to whether he searched adjacent or opposite nodes.

Suppose (1) that Player II did not visit C, and so visited A and B. In this case he can distinguish the vertical coordinate (directions of his searches) from the horizontal (unsearched directions), and for example could determine the origin (I's starting point) with probability 1/2 (he could equiprobably reach the origin or C in two moves). However, the node w (which he needs to reach at time 12 with conditional probability 1/2) is indistinguishable from three other nodes z, y, and $(3,-1)$, and so could not be reached with conditional probability greater than 1/4. Hence he cannot ensure a meeting at time 12 with the required conditional probability 1/2, and so a strategy that did not visit C cannot be optimal.

So an optimal strategy for II must have visited C, that is, previously searched two *adjacent* possible starting nodes of I. In this case II can determine w with the required conditional probability 1/2 as *the node e in the direction opposite the midpoint of the two Player I starting nodes he has visited.* (If he visited A and C, then $e = w$; if B and C, then $e = z$.) Optimal play must bring him to w with conditional probability 1/2, so he must move to e (in either of the two possible ways, since the optimal profile has no meeting at $t = 11$) at time 12. This is indicated by the thin lines going out from b. (This is not a mixed strategy; II goes for his uniquely defined node e.) Assuming II does not meet I at time 12, his location at that time must be $e = z$, and I can deduce this. So to achieve a possible meeting at time 13 (required by the optimal profile), I must move to the unique lattice midpoint of w and z (the node (1,0) in our figure). Player II can conclude at time 12 that Player I is either at w or y. So he must move back toward b equiprobably in either way (toward w or toward y). (Again, this is not a mixed strategy—in agent formulation, one of the two remaining agents will go towards b clockwise, and the other counterclockwise.) If the players have not met by time 13, they both can deduce the location of the other; I is at $(1,0)$ and II is at $(2,1)$. Now they can agree to meet for sure at time 14 at either of their two midpoints: (i) b or (ii) z. This leads to two types of strategy, according to whether they both choose (i) or they both choose (ii).

Hence we have established the following theorem.

THEOREM 15. *A strategy pair is optimal in* $\Gamma(2)$ *if and only if it is one of the following two types,* (i) *and* (ii).

Player I orders the starting points of II as V_1, V_2, V_3, V_4 in any way so long as the first two are adjacent ($V_1 \neq -V_2$). On the first 10 *moves, he goes to V_1 and back, V_2 and back, and to V_3. On moves* 11 *and* 12 *he goes (in either of the two ways) to the unique Euclidean midpoint w of V_3 and V_4. At time* 13 *he goes to the unique midpoint of the origin, w, and V_4. At time* 14, *he either* (i) *goes to V_4 or* (ii) *goes in the same direction as on move* 13.

Player II goes in any direction on move 1, *returning to his start on move* 2. *On moves* 3 *to* 6, *and on moves* 7 *to* 10, *he goes, respectively, to two adjacent possible starting nodes W_1 and W_2 and back to his start. On moves* 11 *and* 12, *he goes (in*

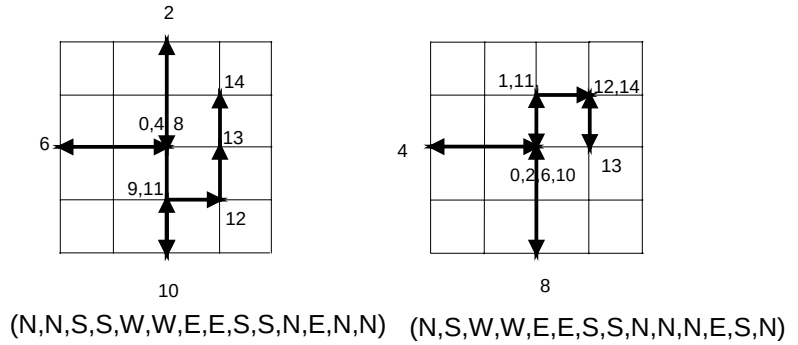

FIG. 6. *Optimal strategy for* Γ *of type* (ii).

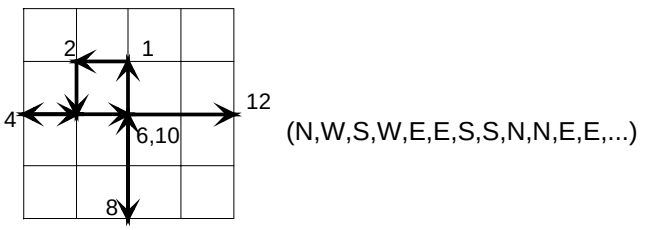

FIG. 7. *Strategy with meeting probability* 31/32 *by time* 12.

either of the two possible ways) to the node e diagonally opposite his start and in the direction opposite to the Euclidean midpoint of W_1 *and* W_2. *On move* 13, *he goes to either of the two midpoints of e and his start. On move* 14, *he goes either to* (i) *his starting point or* (ii) *back to e.*

The strategy $(\tilde{f}, \tilde{g})$ is of type (i). In Figure 6 we give an example of an optimal strategy of type (ii).

Although the NAWFM strategy is optimal, it is not *uniformly optimal*—it does not maximize the probability of meeting by time t for all t. In particular, it does not maximize the probability of meeting by time 12. After move 12, Player I has met 30 of the 32 agents, so the probability that the players have met by time 12 is 30/32. Consider the 12 move strategy for Player I given by $(N, W, S, W, E, E, S, S, N, N, E, E, \dots)$, and drawn in Figure 7. Assuming Player II is back at his start at times 4, 8, and 12, the only agents not met by time 12 have starting point $(0, 2)$. Of the eight agents who started there, two could be met at $(0, 1)$ at time 1, one (only one since this involves a turn) could be met at $(-1, 1)$ at time 2, and two could be met at the origin at both times 6 and 10. This would leave only one agent unmet by time 12, or a 31/32 probability of rendezvous by that time, better than NAWFM. In fact, the agents can be met at the times mentioned above if Player II adopts the move sequence $(N, E, W, S, S, S, N, N, W, W, E, E, \dots)$. Hence the NAWFM strategy is optimal but not uniformly optimal and, as mentioned in Definition 4, there cannot be any uniformly optimal strategy for the game $\Gamma = \Gamma_P$. As mentioned in [3], this is qualitatively distinct from the situation for the diagonal start game Γ_D, where there is a uniformly optimal strategy (and hence all optimal strategies are uniformly optimal). The (uniformly) optimal strategies for the diagonal start game (without common clockwise) are as follows (Corollary 23 of [3]): Player I cyclically orders adjacent (distance 2)

starting nodes as v_1, v_2, v_3, v_4 in any manner. He moves to the midpoint of v_1 and v_4 at time 1, and then cyclically searches the vertices v_i at time $2i$. Player II moves in any direction D_i (of the four possible) at times $i = 1, 3, 5, 7$, going in the opposite direction $-D_i$ at times $i+1$. The only restriction is that $D_7 = \pm D_1$, that is, II must move in the same or opposite direction on move 7 as he did on move 1 (not at right angles). The particular strategy pair of $(N, W, S, S, E, E, N, N), (N, S, N, S, N, S, N, S)$ was earlier shown to be optimal for the common clockwise version of the diagonal start problem by Anderson and Fekete [9], and an easy symmetric argument shows that it does equally well (same expected meeting time) in the no common clockwise version.

5. Rendezvous in higher dimensions. This section determines an upper bound for the rendezvous value $R(n)$ of the game $\Gamma(n)$ which generalizes the game $\Gamma(2)$ of the previous section (as well as the game $\Gamma(1)$ solved in [6]) to n dimensions. The strategy pair giving this bound is the AWFM (Definition 6), which assumes no common ordering of the coordinate axes. Some ideas on lower bounds are also given at the end of the section.

THEOREM 16. *Suppose that two players are initially placed on the n-dimensional integer lattice so that their difference vector is two units long and parallel to one of the coordinate axes. Assume that the players have no common notion of location and no common labeling of the coordinates axes. The rendezvous value $R(n)$ for this game $\Gamma(n)$ satisfies the inequality*

$$2n \leq R(n) \leq \frac{32n^3 + 12n^2 - 2n - 3}{12n^2}. \tag{26}$$

Consequently, we have the asymptotic result

$$2 \leq \lim_{n\to\infty} R(n)/n \leq \frac{8}{3}. \tag{27}$$

Proof. We will need to consider two subsidiary problems $\Gamma_1(m)$ and $\Gamma_2(m)$, for $m = 1, \ldots, 2n$. Both of these problems begin at time $t = 0$ with the placement of Players I and II, respectively, at a pair of nodes A and B which are two units apart along a line parallel to some coordinate axis. Then Player I is displaced to a node A' along a similar two unit line which is not the one leading to B. Player I is told the node A. In the problem $\Gamma_1(m)$, Player I is told $m-1$ directions which are certain to include the direction to B, and Player II is told m such directions. In problem $\Gamma_2(m)$, both players are told m such directions. Special cases of these problems, for $n = 2$, are drawn in Figures 8 and 9.

In order to estimate the rendezvous value $R(n)$ of the original problem $\Gamma(n)$, we must obtain estimates on the respective asymmetric rendezvous values $w_1(m)$ and $w_2(m)$ of $\Gamma_1(m)$ and $\Gamma_2(m)$ for various m (corresponding to the dimension n, which is implicit in our notation).

Suppose that in the problem $\Gamma_1(m)$, the first two moves of the players are as follows: Player I goes to the node A (which he knows) while Player II goes 2 steps randomly in one of the m indicated directions. With probability $1/m$, II will pick the direction to A, and the meeting time will be $t = 2$. Otherwise the two players will be in the initial position of the other problem $\Gamma_2(m-1)$, with the roles (of I and II) reversed. Hence we have

$$w_1(m) \leq \frac{1}{m}(2) + \frac{m-1}{m}(2 + w_2(m-1)). \tag{28}$$

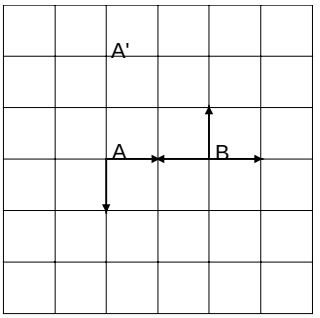

FIG. 8. *Start in* $\Gamma_1(3)$.

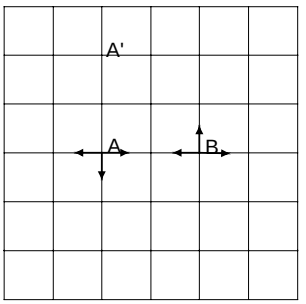

FIG. 9. *Start in* $\Gamma_2(3)$.

Similarly, in the initial position of $\Gamma_2(m)$, the same type of strategy for the first two moves gives

$$w_2(m) \leq \frac{1}{m}(2) + \frac{m-1}{m}(2 + w_1(m)). \tag{29}$$

From these two inequalities we obtain upper bounds $w_i(m) \leq \bar{w}_i(m)$ by solving the associated equalities. This gives us the solutions

$$\bar{w}_1(m) = \frac{4m+1}{3}, \tag{30}$$

$$\bar{w}_2(m) = \frac{-1+3m+4m^2}{3m}. \tag{31}$$

This is consistent with the trivial base case $\Gamma_2(1)$, where I and II start 4 units apart with knowledge of the other's direction, with rendezvous value $w_2(1) = 2$ corresponding to a meeting at A. This case is illustrated in Figure 10.

We now consider the original game $\Gamma(n)$. Suppose that in their first two moves one player (I) goes two units in his forward direction, while the other (II) goes in some direction and then back to his start. With probability $1/(2n)^2$ the two players will go towards each other and meet at time $t = 1$. If Player I goes in the direction of II (probability $1/2n$) and II does not go in the direction of I (probability $(2n-1)/(2n)$), then the two will meet at time $t = 2$ at II's initial location. In the remaining case, I will find himself displaced two units from his start and know of one direction from his start which does not lead to II's starting location. Meanwhile, II will be at his start and not know of any of the $2n$ directions which are not correct. Consequently

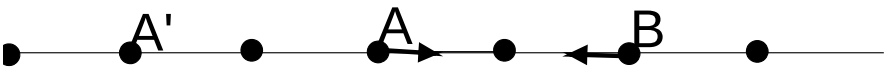

FIG. 10. *Start in* $\Gamma_2(1)$.

the situation at time $t = 2$ will be identical to that of the problem $\Gamma_1(2n)$. Therefore we have the estimate

$$R(n) \leq \left(\frac{1}{(2n)^2}\right) 1 + \left(\frac{1}{2n}\right)\left(\frac{2n-1}{2n}\right) 2 + \left(\frac{2n-1}{2n}\right)(2 + w_1(2n)).$$

Estimating w_1 by the formula (30) for $\bar{w}_1$, and simplifying, we get

$$R(n) \leq \frac{32n^3 + 12n^2 - 2n - 3}{12n^2}, \text{ and hence}$$

$$\lim_{n\to\infty} R(n)/n \leq \frac{8}{3}, \text{ the required right inequality.}$$

We note again that the value of the right-hand side of the top inequality is 13/4 for $n = 1$, which is the *exact* asymmetric rendezvous value for the line as derived in [6] for known initial distance $D = 2$. The strategy pair which gives this expected meeting time is the one which converts $\Gamma(n)$ into $\Gamma_1(2n)$ and thereafter converts each problem $\Gamma_1(m)$ into $\Gamma_2(m-1)$ and each problem $\Gamma_2(m)$ into $\Gamma_1(m)$, $m = 2n, 2n-1, \ldots, 1$ (assuming the players don't meet earlier). It is an AWFM strategy.

We can obtain a lower bound on $R(n)$ by giving the players some additional information and determining their optimal strategy pair in that situation. The simplest way to do this is to give the players common notions of directions. In this case it is well known (see [6] or [9] for one- or two-dimensional arguments) that the players should always move in opposite directions, and that the rendezvous problem is consequently equivalent to one where Player II is stationary and Player I moves with their combined speeds, here equal to 2. The least expected time for Player I to reach the $2n$ possible locations of the stationary Player II, moving with speed 2, is obtained by a path which reaches these locations at the $2n$ times $1, 3, 5, \ldots, 2i-1, \ldots, 2(2n)-1$, while returning to his start in between. The expected time is consequently given by

$$\frac{1}{2n}\sum_{i=1}^{2n}(2i-1) = 2n.$$

Thus the asymptotic value of $R^a(n)/n$ lies between 2 and 8/3, completing the proof of Theorem 16. □

A player-symmetric version of this n-dimensional problem, where both players must follow the same mixed strategy, is analyzed in [7, section 18.2.2]. An alternative treatment of the player-asymmetric problem is outlined in section 18.2.1, based on a direct evaluation of the expected meeting meeting time for the NAWFM strategy. An anonymous referee has observed that this can be simply evaluated by defining random variables X and Y to be, respectively, the first time that I reaches the starting point of II and the first time that II reaches the starting point of I. The meeting time $\min(X, Y)$ can then be calculated from standard results on random variables.

6. Discussion of results. A natural question that arises from our analysis is whether one might be able to obtain a relatively simple analytical expression for the rendezvous value $R(n)$ of $\Gamma(n)$ for $n \geq 3$. The indications from the results on $\Gamma(2)$ are somewhat equivocal. Theorem 14 states that every optimal strategy pair in $\Gamma(2)$ has the same agent number profile and the same holds for $\Gamma(1)$. Furthermore, Theorem 13 tells us that, in all optimal strategy pairs of $\Gamma(2)$, the players initially move to an SPM position and then go as quickly as possible from one SPM position to another until a player has met most of the other player's agents. The reason for this is that a player can meet comparatively few agents of the other player at points which are not either possible starting points of that player or his own starting point. It is intuitively clear that this property holds for $\Gamma(n)$ with $n \geq 3$ so we would expect there would be a similar emphasis on SPM positions for these problems. It also suggests that $R(n)$ is likely to be much nearer the upper bound than the lower bound in Theorem 16, particularly when account is taken of the fact that the lower bound is obtained by considering a corresponding problem in which the players are given important extra information. On the other hand, Theorem 15 detailing the optimal strategy pairs for $\Gamma(2)$ demonstrates that although the players have some freedom in the order in which the SPM positions are visited, it is not unrestricted. For $\Gamma(2)$, by looking at the moves which enabled the final agents to be met, it was comparatively easy to see what modifications to AWFM were needed if better expected meeting times were to be achieved and the restrictions on the SPM positions arose from these modifications. However, even if optimal strategy pairs in $\Gamma(n)$ are modifications of AWFM, the number of possible modifications is likely to increase substantially as n increases and, in addition, there is the difficulty of picturing the situation, particularly with regard to agents.

WHAT PERIODIC SIGNALS CAN AN EXPONENTIALLY STABILIZABLE LINEAR FEEDFORWARD CONTROL SYSTEM ASYMPTOTICALLY TRACK?*

EERO IMMONEN† AND SEPPO POHJOLAINEN†

Abstract. We study asymptotic tracking and rejection of continuous periodic signals in the context of exponentially stabilizable linear infinite-dimensional systems. Our reference signals are in Sobolev-type spaces $H(\omega_n, f_n)$ and they (as well as the disturbance signals) are generated by an infinite-dimensional exogenous system. We show that there exists a feedforward controller which achieves output regulation if and only if the so-called regulator equations are satisfied and a decomposability condition holds. For SISO systems this result allows us to completely answer the question posed in the title: We show that if the stabilized plant does not have transmission zeros at the frequencies $i\omega_n$ of the reference signals, then all reference signals in $H(\omega_n, f_n)$ can be asymptotically tracked in the presence of disturbances if and only if

$$\left(H_K(i\omega_n)^{-1}[1 - H_d(n)]f_n^{-1}\right)_{n\in I} \in \ell^2.$$

Here $H_K(i\omega_n)$, $n \in I$, is the transfer function of the stabilized plant evaluated at $i\omega_n$, and $(H_d(n))_{n\in I}$ is a sequence of disturbance coefficients for the stabilized plant. Moreover, the sequence $(f_n)_{n\in I}$ consists of weights for the Fourier coefficients of the reference signals. We give four examples to illustrate the theory.

Key words. output regulation, infinite-dimensional systems, regulator equations, Fourier series, Sobolev spaces, periodic signals

1. Introduction.

In this paper we study regulation of periodic signals in the context of exponentially stabilizable linear infinite-dimensional systems. By regulation we mean that the output of the system asymptotically tracks given suitably smooth periodic reference signals generated by an infinite-dimensional exogenous system and asymptotically rejects disturbance signals generated by the same exogenous system.

Periodic signals are often encountered, e.g., in acoustics, electric motors, and mechanical systems [12], and various forms of this regulation problem have been intensively studied for several decades. The regulation problem for finite-dimensional signals (generated by finite-dimensional exosystems) and finite-dimensional linear systems was solved quite completely in the 1970s by Francis, Wonham, Davison, and others [7, 9, 10]. Many authors have since generalized these results for infinite-dimensional systems and finite-dimensional reference/disturbance signals: Pohjolainen [17, 18], Hämäläinen and Pohjolainen [11], Logemann and Owens [16], Byrnes et al. [3], and others.

For finite-dimensional reference and disturbance signals it is well known that there are two basic control configurations that guarantee regulation: the feedforward and feedback controllers [7]. The feedforward controller does not lead to a robust design. Robustness means that the control configuration can achieve regulation in spite of variations in the system's and controller's parameters.

In the feedback control design the controller must incorporate a model of the exogenous system according to the internal model principle. This introduces additional dynamics in the feedback loop and thus makes stabilization of the closed loop system a more difficult task, especially in the infinite-dimensional case. The advantage of the feedback controller is that it provides robustness. This is often stated in the following form: Stability of the closed loop system implies regulation.

In this paper we consider the problem of constructing a feedforward controller for exponentially stabilizable infinite-dimensional systems and uniformly continuous periodic reference and disturbance signals. Since such periodic signals may contain an infinite number of distinct frequency components, they must be generated by an infinite-dimensional exogenous system. Hence our results extend the infinite-dimensional feedforward controllers of [3, 16] to allow for infinite-dimensional reference and disturbance signals.

Our approach has been inspired by [4, 5], where the regulation problem with an infinite-dimensional exogenous system was formulated but not rigorously solved. The solution presented in this paper relies on a construction of a scale of Sobolev-type spaces of periodic uniformly continuous functions. This construction makes it possible to completely resolve the existence of a regulating feedforward controller in the single input single output (SISO) case; a characterization in terms of solvability of the so-called regulator equations [3, 9] is given in Theorem 3.1.

In Theorem 4.5 and Corollary 4.7 we assume that the transfer function of the stabilized plant is invertible on the spectrum of the exosystem. We prove that in this case a necessary and sufficient condition for the solvability of the regulation problem is that the transfer function does not approach zero asymptotically too rapidly on that spectrum. In the engineering language this condition says that the amount of damping on the high frequency components determines precisely how nonsmooth the reference/disturbance signals are that the system can asymptotically track/reject. The condition given in terms of weighting coefficients in the aforementioned Sobolev-type spaces makes it possible to single out those spaces which contain signals that can be tracked/rejected by a given system.

To the authors' knowledge the results of this article are new even for finite-dimensional systems. Moreover, they complement and improve those in [14], where the exosystem was built so that it can generate (at least) one given scalar-valued reference signal with ℓ^1 Fourier coefficients. In [14] the authors found a sufficient condition for the asymptotic tracking of this reference signal to occur, under the assumption of exponential stabilizability of the plant. In this paper, the exosystem is constructed so that precisely all reference signals in a Sobolev-type space can be generated; we pose—and completely solve—the problem of asymptotic tracking of all such reference signals and construct the actual control law which achieves output regulation. The construction of this paper also shows that the exogenous signal generator can, in a certain sense, be made isomorphic to a function space (Theorem 2.8). This feature yields two important observations which cannot be made from the results of [14]: (i) the approach of this paper suggests a direct generalization via considering reference signals in more general function spaces (e.g., vector-valued continuous periodic functions in the MIMO case), and (ii) the exosystem becomes an artificial device—we do not need to know its dynamical behavior in order to achieve output regulation (see Theorem 4.5 and Corollary 4.6). More profoundly, as opposed to [14], the results of this paper yield (for SISO systems) a complete answer, via the new condition (4.17), to the question posed in the title.

We conclude this section with a brief outline of the contents of the article. In

section 2 we define the plant and the reference signals that we want to asymptotically track; for this we introduce the Sobolev-type spaces $H(f_n, \omega_n)$. Furthermore, we construct the exogenous system that we assume is generating the reference and disturbance signals. We also formulate the output regulation problem (ω_n, f_n)-RP in section 2. In section 3 we show that for exponentially stabilizable plants the solvability of the (ω_n, f_n)-RP is equivalent to the solvability of the regulator equations and a decomposability condition. This result is then applied in section 4, where the solution of the regulator equations is considered. We obtain an explicit expression for a candidate operator L in the solution of the (ω_n, f_n)-RP. The continuity of L determines whether or not this regulation problem is solvable, and it can be verified by checking condition (4.17). Furthermore, assuming solvability of the output regulation problem, we explicitly write out, in terms of the reference signals, the control law achieving output regulation in Corollary 4.6. We conclude section 4 with two results which show that the capability of output regulation is in some cases an intrinsic property of the plant—different stabilizing feedbacks result in the same capability of output regulation. Finally, in the four examples of section 5 we solve the (ω_n, f_n)-RP in several situations: We consider a finite-dimensional plant, a delay-differential equation, and a heat equation with Neumann boundary conditions. In the last example we show that there are infinite-dimensional systems which cannot track all reference signals in any standard Sobolev space $H^{\alpha}_{per}(0, p)$ of periodic functions [15], even if there are no transmission zeros at the frequencies of the reference signals. These examples demonstrate an important new result of the paper: Transmission zeros are not the only cause of output regulation problems, even for finite-dimensional systems. The intrinsic "smoothness" of the plant in part determines which signals can be regulated. For certain finite-dimensional systems this smoothness is characterized by the relative degree of the plant, as shown in section 5.

1.1. Notation and conventions. For complex separable Hilbert spaces E and F, $\mathcal{L}(E, F)$ denotes the space of bounded linear operators $E \to F$, and E' denotes the space of bounded linear functionals on E. Inner product on E is denoted by $\langle \cdot, \cdot \rangle_E$ (the subscript E is omitted if no confusion can arise). Norm on E is denoted by $\|\cdot\|_E$ (the subscript E is omitted if no confusion can arise). The product space $E \times F$ is endowed with the norm $\sqrt{\|\cdot\|_E^2 + \|\cdot\|_F^2}$ which makes it a Hilbert space. The resolvent set of a closed linear operator $S : E \to F$ is denoted by $\rho(S)$. $R(\lambda, S)$ denotes (whenever it exists) the resolvent operator $(\lambda I - S)^{-1}$. If $\widetilde{E}$ is a subspace of E, then $S|_{\widetilde{E}}$ denotes the restriction of S to $\widetilde{E}$. For $s > \frac{1}{2}$, $H^s_{per}(0, p)$ denotes the Sobolev space of those p-periodic functions f (see [15]) satisfying $\sum_{k=-\infty}^{\infty} (1 + |\frac{2\pi k}{p}|^2)^s |\hat{f}(k)|^2 < \infty$, where $\hat{f}(k)$, $k \in \mathbb{Z}$, denotes a Fourier coefficient. $\Re(z)$ denotes the real part of a complex number z. A sequence $(f_n) \subset \mathbb{C}$ is $\mathcal{O}(g_n)$ for some positive sequence $(g_n) \subset \mathbb{R}$ as $n \to \infty$ if $|f_n| \leq M g_n$ for some $M > 0$ and all sufficiently large $n \geq 0$.

2. Formulation of the problem. In this section, we define the plant and the reference signals that we want to asymptotically track. Furthermore, we construct the exogenous systems that we assume are generating the reference signals. We also formulate the output regulation problem (ω_n, f_n)-RP.

2.1. The plant. We consider a plant described by the following (possibly infinite-dimensional) control system for $t \geq 0$:

$$\dot{z}(t) = Az(t) + Bu(t) + \mathcal{U}_{dist}(t), \tag{2.1a}$$

$$y(t) = Cz(t) + Du(t), \tag{2.1b}$$

$$z(0) = z_0 \in Z, \tag{2.1c}$$

where $z(t) \in Z$ is the state of the system (Z is a separable complex Hilbert space), A generates a C_0-semigroup of linear operators $T_A(t)$ on Z, $u(t) \in U$ is an input, and $y(t) \in Y$ is the output. The input space U is a complex separable Hilbert space and the output space $Y = \mathbb{C}$. The control operator $B \in \mathcal{L}(U, Z)$, the observation operator $C \in \mathcal{L}(Z, Y) = Z'$, and the feedthrough operator $D \in \mathcal{L}(U, Y)$. The pair (A, B) is assumed to be exponentially stabilizable; i.e., we assume that there exists $K \in \mathcal{L}(Z, U)$ such that $A+BK$ generates an exponentially stable C_0-semigroup on Z. The term $\mathcal{U}_{dist}(t)$ represents a disturbance (to be defined shortly). Finally, since we allow z_0 to be outside of $\mathcal{D}(A)$, (2.1a) is to be considered in the mild sense [6].

2.2. Sobolev spaces $H(f_n, \omega_n)$ and the exogenous system. Throughout this article, we assume that the periodic reference signals are in Sobolev spaces $H(\omega_n, f_n)$.

DEFINITION 2.1. *Let $I \subset \mathbb{Z}$, let $p > 0$, and let $\omega_n = \frac{2\pi n}{p}$ for every $n \in I$. Let $(f_n)_{n\in I} \subset \mathbb{R}$ such that $f_n \geq 1$ for each $n \in I$ and $(f_n^{-1})_{n\in I} \in \ell^2$. The Sobolev space $H(f_n, \omega_n)$ is defined as $\{\, u : \mathbb{R} \to \mathbb{C} \mid u(t) = \sum_{n\in I} a_n e^{i\omega_n t}$ for each $t \in \mathbb{R}$, $\sum_{n\in I} |f_n|^2|a_n|^2 < \infty$, and $(a_n)_{n\in I} \subset \mathbb{C}\,\}$.*

PROPOSITION 2.2. *Each $u \in H(f_n, \omega_n)$ is uniformly continuous and p-periodic. Moreover, $H(f_n, \omega_n)$ is a Hilbert space with respect to the inner product $\langle u, v\rangle_f = \sum_{n\in I} a_n\overline{b_n}|f_n|^2$. Here $u(t) = \sum_{n\in I} a_n e^{i\omega_n t}$ and $v(t) = \sum_{n\in I} b_n e^{i\omega_n t}$ for every $t \in \mathbb{R}$. Moreover, $\overline{b_n}$ denotes the complex conjugate of b_n.*

Proof. The uniform continuity and p-periodicity of $u(t)$ are evident. It is also easy to see that $H(f_n, \omega_n)$ is an inner product space. The completeness arguments follow those in [2, pp. 124–125]. ∎

These Sobolev spaces generalize certain Sobolev spaces of periodic functions [15] in the following way.

PROPOSITION 2.3. *Let $I = \mathbb{Z}$, $\gamma > \frac{1}{2}$, and $f_n = \sqrt{1+\omega_n^2}^{\,\gamma}$ for each $n \in \mathbb{Z}$. Then $H(f_n, \omega_n) = H^\gamma_{per}(0, p)$.*

Proof. By definition, $H^\gamma_{per}(0, p)$ is the Sobolev space of p-periodic functions u satisfying $\sum_{k=-\infty}^{\infty}(1 + |\frac{2\pi k}{p}|^2)^\gamma|\hat{u}(k)|^2 < \infty$, where $\hat{u}(k)$, $k \in \mathbb{Z}$, denotes a Fourier coefficient (see [15]). Hence $H^\gamma_{per}(0, p) \subset H(f_n, \omega_n)$. To prove the converse inclusion, we need only observe that absolutely and uniformly convergent trigonometric series of periodic functions are Fourier series (see, e.g., [2, p. 202]). ∎

Let the sequences $(\omega_n)_{n\in I}$ and $(f_n)_{n\in I}$ be fixed in the remainder of this subsection. We next construct an exogenous system which generates the functions in $H(f_n, \omega_n)$. To this end, let W be a Hilbert space with inner product $\langle\cdot,\cdot\rangle$ and an orthonormal basis $(\phi_n)_{n\in I}$. Set $S = \sum_{n\in I} i\omega_n\langle\cdot, \phi_n\rangle\phi_n$ with $\mathcal{D}(S) = \{\, w \in W \mid \sum_{n\in I} |\omega_n|^2|\langle w, \phi_n\rangle|^2 < \infty\,\}$. It is clear that S generates the C_0-semigroup $T_S(t) = \sum_{n\in I} e^{i\omega_n t}\langle\cdot, \phi_n\rangle\phi_n$ in W.

LEMMA 2.4. *Consider the sequence $(f_n)_{n\in I}$. Let $\mathcal{F} : \mathcal{D}(\mathcal{F}) \subset W \to W$ be such that*

$$\mathcal{F}w = \sum_{n\in I} f_n\langle w, \phi_n\rangle\phi_n, \quad \mathcal{D}(\mathcal{F}) = \left\{ w \in W \;\middle|\; \sum_{n\in I} |f_n|^2|\langle w, \phi_n\rangle|^2 < \infty \right\}. \tag{2.2}$$

Then the operator $\mathcal{F}$ is linear, closed, and densely defined in W. Moreover, $\mathcal{F}^{-1} \in \mathcal{L}(W)$.

Proof. The linearity of $\mathcal{F}$ is evident. Clearly all elements $w \in W$ for which $\langle w, \phi_n \rangle = 0$ for $|n| \geq M$ lie in $\mathcal{D}(\mathcal{F})$ and form a dense set in W. Hence $\mathcal{F}$ is densely defined in W. Let $(w_k)_{k\geq 0} \subset \mathcal{D}(\mathcal{F})$ be a sequence such that $w_k \to w$ as $k \to \infty$ and $\mathcal{F}w_k \to y \in W$ as $k \to \infty$. Since the sequence $(\mathcal{F}w_k)_{k\geq 0}$ converges, it is bounded, and $\sup_{k\geq 0} \sum_{n\in I} |f_n|^2 |\langle w_k, \phi_n \rangle|^2 < \infty$. This implies that $\sum_{n\in I} |f_n|^2 |\langle w, \phi_n \rangle|^2 < \infty$, i.e., $w \in \mathcal{D}(\mathcal{F})$. Now for each $n \in I$, $\langle y, \phi_n \rangle = \lim_{k\to\infty} \langle \mathcal{F}w_k, \phi_n \rangle = \lim_{k\to\infty} f_n \langle w_k, \phi_n \rangle = f_n \langle w, \phi_n \rangle = \langle \mathcal{F}w, \phi_n \rangle$, and so $\mathcal{F}w = y$. This proves that $\mathcal{F}$ is a closed operator. It is plain to see that $\mathcal{F}^{-1} = \sum_{n\in I} f_n^{-1} \langle \cdot, \phi_n \rangle \phi_n$ and that $\mathcal{F}^{-1}$ is bounded in W since $(f_n^{-1})_{n\in I} \in \ell^2$. ∎

THEOREM 2.5. *With $\mathcal{F}$ as in (2.2), define $\langle x, y \rangle_{\mathcal{F}} = \langle \mathcal{F}x, \mathcal{F}y \rangle$ for every $x, y \in \mathcal{D}(\mathcal{F})$. Then $\langle \cdot, \cdot \rangle_{\mathcal{F}}$ is an inner product on $\mathcal{D}(\mathcal{F})$, and the space $W_{\mathcal{F}} = (\mathcal{D}(\mathcal{F}), \langle \cdot, \cdot \rangle_{\mathcal{F}})$ is a Hilbert space such that*

1. *$W_{\mathcal{F}} \hookrightarrow W$;*
2. *the restriction $T_S(t)|_{W_{\mathcal{F}}}$ of $T_S(t)$ to $W_{\mathcal{F}}$ is a C_0-semigroup on $W_{\mathcal{F}}$.*

Proof. Let $\|\cdot\|_{\mathcal{F}}$ denote the norm induced by $\langle \cdot, \cdot \rangle_{\mathcal{F}}$. It is readily verified that $\langle \cdot, \cdot \rangle_{\mathcal{F}}$ satisfies the axioms of inner product because $f_n \geq 1$ for every $n \in I$. By Lemma 2.4, $\mathcal{F}$ is a closed operator with a bounded inverse. Let $|\cdot|_{\mathcal{F}}$ denote the graph norm in $\mathcal{D}(\mathcal{F})$. That $W_{\mathcal{F}}$ is a Hilbert space now follows from the estimates (valid for every $w \in \mathcal{D}(\mathcal{F})$)

$$|w|_{\mathcal{F}} = \|w\|_W + \|\mathcal{F}w\|_W = \|\mathcal{F}^{-1}\mathcal{F}w\|_W + \|\mathcal{F}w\|_W \tag{2.3}$$

$$\leq \big[\|\mathcal{F}^{-1}\|_{\mathcal{L}(W)} + 1\big] \|\mathcal{F}w\|_W = \big[\|\mathcal{F}^{-1}\|_{\mathcal{L}(W)} + 1\big] \|w\|_{\mathcal{F}} \tag{2.4}$$

$$\leq \big[\|\mathcal{F}^{-1}\|_{\mathcal{L}(W)} + 1\big] (\|\mathcal{F}w\|_W + \|w\|_W) \tag{2.5}$$

$$= \big[\|\mathcal{F}^{-1}\|_{\mathcal{L}(W)} + 1\big] |w|_{\mathcal{F}} \tag{2.6}$$

and the fact that $\mathcal{D}(\mathcal{F})$ is a Banach space when endowed with the graph norm. Additionally, since $f_n \geq 1$ for every $n \in I$, we have that

$$\|w\|_W^2 = \sum_{n\in I} |\langle w, \phi_n \rangle|^2 \leq \sum_{n\in I} |f_n|^2 |\langle w, \phi_n \rangle|^2 = \|w\|_{\mathcal{F}}^2 \quad \forall w \in \mathcal{D}(\mathcal{F}), \tag{2.7}$$

which shows that $W_{\mathcal{F}} \hookrightarrow W$.

It remains to show that the restriction $T_S(t)|_{W_{\mathcal{F}}}$ of $T_S(t)$ to $W_{\mathcal{F}}$ is a C_0-semigroup. For arbitrary $w \in \mathcal{D}(\mathcal{F})$,

$$\|T_S(t)w\|_{\mathcal{F}}^2 = \sum_{n\in I} |f_n|^2 |e^{i\omega_n t}|^2 |\langle w, \phi_n \rangle|^2 = \sum_{n\in I} |f_n|^2 |\langle w, \phi_n \rangle|^2 = \|w\|_{\mathcal{F}}^2, \tag{2.8}$$

which shows that $W_{\mathcal{F}}$ is $T_S(t)$-invariant and that $T_S(t)|_{W_{\mathcal{F}}}$ is an isometry (and hence bounded) for each $t \geq 0$. The semigroup property of $T_S(t)|_{W_{\mathcal{F}}}$ is easy to verify using the semigroup property of $T_S(t)$ in W and the $T_S(t)$-invariance of $W_{\mathcal{F}}$. We show the strong continuity of $T_S(t)|_{W_{\mathcal{F}}}$. Let $w \in \mathcal{D}(\mathcal{F})$. Then

$$\|T_S(t)|_{W_{\mathcal{F}}} w - w\|_{\mathcal{F}}^2 = \sum_{n\in I} |f_n|^2 |e^{i\omega_n t} - 1|^2 |\langle w, \phi_n \rangle|^2 = \sum_{n\in I} |(e^{i\omega_n t} - 1) f_n \langle w, \phi_n \rangle|^2 \tag{2.9}$$

$$= \|T_S(t)\mathcal{F}w - \mathcal{F}w\|_W^2 \to 0 \quad \text{as } t \to 0^+ \tag{2.10}$$

because $T_S(t)$ is strongly continuous on W. This completes the proof. ∎

LEMMA 2.6. *Let $Q : \mathcal{D}(Q) \subset W \to \mathbb{C}$ be such that*

$$Qw = \sum_{n\in I} \langle w, \phi_n\rangle \quad \forall w \in \mathcal{D}(Q) = \left\{ w \in W \;\middle|\; \left|\sum_{n\in I} \langle w, \phi_n\rangle\right| < \infty \right\}. \tag{2.11}$$

Then $Q \in \mathcal{L}(W_{\mathcal{F}}, \mathbb{C})$, where $W_{\mathcal{F}}$ is defined as in Theorem 2.5.

Proof. Since $(f_n^{-1})_{n\in I} \in \ell^2$, we have for some $M > 0$ by the Schwarz inequality that

$$|Qw| \le \sum_{n\in I} |\langle w, \phi_n\rangle||f_n f_n^{-1}| \le M\|w\|_{\mathcal{F}} \quad \forall w \in W_{\mathcal{F}}, \tag{2.12}$$

and so $Q \in \mathcal{L}(W_{\mathcal{F}}, \mathbb{C})$. ∎

DEFINITION 2.7 (the exogenous system). *Let $S_{\mathcal{F}}$ denote the generator of $T_S(t)|_{W_{\mathcal{F}}}$ on $W_{\mathcal{F}}$ (cf. Theorem 2.5). With the above definitions and notation, the exogenous system is given as*

$$\dot{w}(t) = S_{\mathcal{F}} w(t), \quad w(0) = w_0 \in W_{\mathcal{F}}, \tag{2.13a}$$

$$y_{ref}(t) = Qw(t), \quad t \ge 0, \tag{2.13b}$$

$$\mathcal{U}_{dist}(t) = Pw(t) \tag{2.13c}$$

on the state space $W_{\mathcal{F}}$. Here $P \in \mathcal{L}(W_{\mathcal{F}}, Z)$ is some known disturbance operator and (2.13a) *is to be considered in the mild sense.*

The exosystem (2.13) is capable of generating precisely the reference signals in the Sobolev space $H(f_n, \omega_n)$. Moreover, for each $y_{ref} \in H(f_n, \omega_n)$, there is exactly one initial state $w_0 \in W_{\mathcal{F}}$ such that $QT_S(t)|_{W_{\mathcal{F}}} w_0 = y_{ref}(t)$ for $t \ge 0$. These facts follow from the next theorem.

THEOREM 2.8. *There exists a bounded linear bijection $\mathcal{T} : H(f_n, \omega_n) \to W_{\mathcal{F}}$ such that for $y_{ref} \in H(f_n, \omega_n)$ we have that $\mathcal{T} y_{ref} = w_0$ with $QT_S(t)|_{W_{\mathcal{F}}} w_0 = y_{ref}(t)$ for each $t \ge 0$.*

Proof. Let $y_{ref} \in H(f_n, \omega_n)$ be such that $y_{ref}(t) = \sum_{n\in I} a_n e^{i\omega_n t}$. By our assumption, the estimate $\sum_{n\in I} |f_n|^2 |a_n|^2 < \infty$ holds. Define a mapping $\mathcal{T} : H(f_n, \omega_n) \to W_{\mathcal{F}}$ as

$$\mathcal{T} y_{ref} = \sum_{n\in I} a_n \phi_n = w_0. \tag{2.14}$$

Then $\mathcal{T}$ is linear and bounded. By the definition of $W_{\mathcal{F}}$, it is clear that $\mathcal{T}$ is surjective. If $\mathcal{T} y_{ref} = 0$, then $a_n = 0$ for every $n \in I$ by the orthonormality of $(\phi_n)_{n\in I}$ in W. Consequently $y_{ref} = 0$, and hence $\mathcal{T}$ is injective. Moreover, $T_S(t)|_{W_{\mathcal{F}}} w_0 = \sum_{n\in I} e^{i\omega_n t} a_n \phi_n$ for each $t \ge 0$, and so

$$QT_S(t)|_{W_{\mathcal{F}}} w_0 = \sum_{n\in I} a_n e^{i\omega_n t} = y_{ref}(t) \quad \forall t \ge 0. \tag{2.15}$$

The proof is complete. ∎

2.3. The output regulation problem (ω_n, f_n)-RP. Let $(\omega_n)_{n\in I}$ and $(f_n)_{n\in I}$ be as in Definition 2.1. Let $W_{\mathcal{F}}$ be as in Theorem 2.5 and let $S_{\mathcal{F}}$ be as in (2.13a). The task is to find a feedback control law

$$u(t) = Kz(t) + Lw(t) \tag{2.16}$$

such that $K \in \mathcal{L}(Z, U)$, $L \in \mathcal{L}(W_{\mathcal{F}}, U)$, and

- $A+BK$ is the generator of an exponentially stable C_0-semigroup $T_{A+BK}(t)$ on Z;
- for the closed loop system on $Z \times W_{\mathcal{F}}$ given by

$$\dot{z}(t) = (A+BK)z(t) + (BL+P)w(t), \tag{2.17a}$$

$$\dot{w}(t) = S_{\mathcal{F}}w(t), \tag{2.17b}$$

the tracking error

$$e(t) = y(t) - y_{ref}(t) = (C+DK)z(t) + (DL-Q)w(t) \to 0 \text{ as } t \to \infty \tag{2.18}$$

for all initial conditions $z(0) = z_0 \in Z$ and $w(0) = w_0 \in W_{\mathcal{F}}$.

3. A characterization of the solvability of the (ω_n, f_n)-RP. In Theorem 3.1 below we present a characterization for the solvability of the output regulation problem (ω_n, f_n)-RP in terms of the solvability of the so-called regulator equations, a decomposition property, and two continuity conditions. The result is an extension of Theorem IV.1 in [3] and Theorem 3.1 in [14]. In [3] Byrnes et al. proved this result for finite-dimensional exogenous systems, while in [14] the authors generalized Theorem IV.1 in [3] to cover output regulation of at least one given periodic reference signal (generated by an infinite-dimensional exosystem) in the case in which the feedthrough operator $D = 0$. In the exogenous system of [14] both the observation operator Q and the initial state $w(0)$ depend on the signal to be regulated; Theorem 3.1 in [14] provides a necessary and sufficient condition that this reference signal can be regulated. In Theorem 3.1 below we obtain a complete characterization for output regulation of all reference signals in a Sobolev-type space.

THEOREM 3.1. *Let $I \subset \mathbb{Z}$, $(\omega_n)_{n\in I}$, and $(f_n)_{n\in I}$ be fixed. Let the pair (A,B) be exponentially stabilizable with $K \in \mathcal{L}(Z,U)$. Then there exists an $L \in \mathcal{L}(W_{\mathcal{F}},U)$ such that the (ω_n, f_n)-RP is solvable using the control law $u(t) = Kz(t)+Lw(t)$ if and only if there exists a decomposition $L = \Gamma - K\Pi$, where $\Gamma \in \mathcal{L}(W_{\mathcal{F}},U)$ and $\Pi \in \mathcal{L}(W_{\mathcal{F}},Z)$ satisfy the following regulator equations for every $n \in I$:*

$$A\Pi\phi_n + B\Gamma\phi_n + P\phi_n = \Pi S_{\mathcal{F}}\phi_n, \tag{3.1a}$$

$$C\Pi\phi_n + D\Gamma\phi_n = 1. \tag{3.1b}$$

Proof (necessity). By the assumptions, the control law $u(t) = Kz(t) + Lw(t)$ solves the (ω_n, f_n)-RP. Hence by definition $L \in \mathcal{L}(W_{\mathcal{F}},U)$. Since $A+BK$ generates the exponentially stable C_0-semigroup $T_{A+BK}(t)$ on Z, the growth bound $\omega(T_{A+BK}) = \inf_{t>0}(\frac{1}{t}\log\|T_{A+BK}(t)\|) < 0$. On the other hand, $T_S(t)|_{W_{\mathcal{F}}}$ is an isometric (semi)group on each of the spaces $W_{\mathcal{F}}$, so its growth bound is 0. Corollary 8 in [21] then guarantees that the linear operator $\Pi : W_{\mathcal{F}} \to Z$ defined as

$$\Pi w = \int_0^\infty T_{A+BK}(t)(BL+P)T_S(-t)|_{W_{\mathcal{F}}} w dt \quad \forall w \in W_{\mathcal{F}} \tag{3.2}$$

is the unique bounded (i.e., $\mathcal{L}(W_{\mathcal{F}},Z)$) solution of the Sylvester-type operator equation $\Pi S_{\mathcal{F}} = (A+BK)\Pi + BL + P$ in $\mathcal{D}(S_{\mathcal{F}})$. Consequently, if we choose $\Gamma = L + K\Pi \in \mathcal{L}(W_{\mathcal{F}},U)$, it is clear that $\Pi S_{\mathcal{F}}\phi_n = A\Pi\phi_n + B\Gamma\phi_n + P\phi_n$ for each $n \in \mathbb{Z}$. We also have the decomposition $L = \Gamma - K\Pi$.

We next show that also the second regulator equation (3.1b) is satisfied with these choices of Π and Γ. To this end, consider the composite operator $\mathcal{A}$ on the composite state space $Z \times W_{\mathcal{F}}$ (see (2.17)) defined as

$$\mathcal{A} = \begin{pmatrix} A+BK & BL+P \\ 0 & S_{\mathcal{F}} \end{pmatrix}. \tag{3.3}$$

Since $A+BK$ generates the C_0-semigroup $T_{A+BK}(t)$ on Z and $S_{\mathcal{F}}$ generates the C_0-semigroup $T_S(t)|_{W_{\mathcal{F}}}$ on $W_{\mathcal{F}}$, it is clear that $\mathcal{A}$ generates a C_0-semigroup $T_{\mathcal{A}}(t)$ on $Z \times W_{\mathcal{F}}$ because $BL+P \in \mathcal{L}(W_{\mathcal{F}}, Z)$ (see also [6, Lemma 3.2.2]). An easy calculation reveals that this semigroup is given by

$$T_{\mathcal{A}}(t) = \begin{pmatrix} T_{A+BK}(t) & \int_0^t T_{A+BK}(\tau)(BL+P)T_S(t-\tau)|_{W_{\mathcal{F}}} d\tau \\ 0 & T_S(t)|_{W_{\mathcal{F}}} \end{pmatrix}. \tag{3.4}$$

Now choose an arbitrary eigenvector ϕ_n, $n \in I$, of $S_{\mathcal{F}}$. Then

$$T_{\mathcal{A}}(t)\left(\begin{smallmatrix} \Pi\phi_n \\ \phi_n \end{smallmatrix}\right) = \begin{pmatrix} T_{A+BK}(t)\Pi\phi_n + \int_0^t T_{A+BK}(\tau)(BL+P)e^{i\omega_n(t-\tau)}\phi_n d\tau \\ e^{i\omega_n t}\phi_n \end{pmatrix}. \tag{3.5}$$

According to the first regulator equation (3.1a), for each $t \geq \tau \geq 0$ we have that

$$(BL+P)e^{i\omega_n(t-\tau)}\phi_n = \big[\Pi S_{\mathcal{F}} - (A+BK)\Pi\big]e^{i\omega_n(t-\tau)}\phi_n. \tag{3.6}$$

A direct calculation then shows that for $0 < \tau < t$ (recall that $\Pi(\mathcal{D}(S_{\mathcal{F}})) \subset \mathcal{D}(A) = \mathcal{D}(A+BK)$)

$$\frac{d}{d\tau}\Big(T_{A+BK}(\tau)\Pi e^{i\omega_n(t-\tau)}\phi_n\Big) = T_{A+BK}(\tau)(A+BK)\Pi e^{i\omega_n(t-\tau)}\phi_n \tag{3.7}$$

$$- T_{A+BK}(\tau)\Pi i\omega_n e^{i\omega_n(t-\tau)}\phi_n \tag{3.8}$$

$$= T_{A+BK}(\tau)\big[(A+BK)\Pi - \Pi S_{\mathcal{F}}\big]e^{i\omega_n(t-\tau)}\phi_n. \tag{3.9}$$

Hence for $t \geq 0$,

$$\int_0^t T_{A+BK}(\tau)(BL+P)e^{i\omega_n(t-\tau)}\phi_n d\tau \tag{3.10}$$

$$= \int_0^t T_{A+BK}(\tau)\big[\Pi S_{\mathcal{F}} - (A+BK)\Pi\big]e^{i\omega_n(t-\tau)}\phi_n d\tau \tag{3.11}$$

$$= -\int_0^t \frac{d}{d\tau}\Big(T_{A+BK}(\tau)\Pi e^{i\omega_n(t-\tau)}\phi_n\Big)d\tau \tag{3.12}$$

$$= -T_{A+BK}(t)\Pi\phi_n + \Pi e^{i\omega_n t}\phi_n, \tag{3.13}$$

and so

$$T_{\mathcal{A}}(t)\left(\begin{smallmatrix} \Pi\phi_n \\ \phi_n \end{smallmatrix}\right) = \begin{pmatrix} T_{A+BK}(t)\Pi\phi_n - T_{A+BK}(t)\Pi\phi_n + \Pi e^{i\omega_n t}\phi_n \\ e^{i\omega_n t}\phi_n \end{pmatrix} = \begin{pmatrix} \Pi e^{i\omega_n t}\phi_n \\ e^{i\omega_n t}\phi_n \end{pmatrix}. \tag{3.14}$$

Since the (ω_n, f_n)-RP is solvable, the tracking error corresponding to the particular initial states $z(0) = \Pi\phi_n \in Z$ and $w(0) = \phi_n \in W_{\mathcal{F}}$ (for arbitrary $n \in I$) satisfies

$$e(t) = (C+DK, DL-Q)T_{\mathcal{A}}(t)\left(\begin{smallmatrix} \Pi\phi_n \\ \phi_n \end{smallmatrix}\right) = (C\Pi + DK\Pi + DL - Q)e^{i\omega_n t}\phi_n \tag{3.15}$$

$$= (C\Pi + D\Gamma - Q)e^{i\omega_n t}\phi_n, \tag{3.16}$$

which tends to 0 as $t \to \infty$. But this is possible only if $C\Pi\phi_n + D\Gamma\phi_n = Q\phi_n = 1$ for every $n \in I$. Hence also the second regulator equation (3.1b) is satisfied.

(Sufficiency) Choose $L = \Gamma - K\Pi \in \mathcal{L}(W_{\mathcal{F}}, U)$, where $\Pi \in \mathcal{L}(W_{\mathcal{F}}, Z)$ and $\Gamma \in \mathcal{L}(W_{\mathcal{F}}, U)$ satisfy the regulator equations (3.1) for every $n \in I$. Consider the control law $u(t) = Kz(t) + Lw(t)$. Since by the assumptions the C_0-semigroup $T_{A+BK}(t)$ generated by $A + BK$ is exponentially stable, it remains to show that the error term $e(t) \to 0$ as $t \to \infty$ for any $z(0) = z_0 \in Z$ and $w(0) = w_0 \in W_{\mathcal{F}}$.

Let $z_0 \in Z$ and $w_0 \in W_{\mathcal{F}}$ be arbitrary. Consider the semigroup $T_{\mathcal{A}}(t)$ (see (3.4)) generated by $\mathcal{A}$ (see (3.3)) on $Z \times W_{\mathcal{F}}$. Then

$$T_{\mathcal{A}}(t)\left(\begin{smallmatrix} z_0 \\ w_0 \end{smallmatrix}\right) = \begin{pmatrix} T_{A+BK}(t)z_0 + \int_0^t T_{A+BK}(\tau)(BL+P)T_S(t-\tau)|_{W_{\mathcal{F}}} w_0 d\tau \\ T_S(t)|_{W_{\mathcal{F}}} w_0 \end{pmatrix}. \tag{3.17}$$

Now an application of the Lebesgue dominated convergence theorem and relations (3.11)–(3.13) yields

$$\int_0^t T_{A+BK}(\tau)(BL+P)T_S(t-\tau)|_{W_{\mathcal{F}}} w_0 d\tau \tag{3.18}$$

$$= \int_0^t T_{A+BK}(\tau)(BL+P) \sum_{n\in I} e^{i\omega_n(t-\tau)} \langle w_0, \phi_n \rangle \phi_n d\tau \tag{3.19}$$

$$= \sum_{n\in I} \langle w_0, \phi_n \rangle \int_0^t T_{A+BK}(\tau)(BL+P) e^{i\omega_n(t-\tau)} \phi_n d\tau \tag{3.20}$$

$$= \sum_{n\in I} \langle w_0, \phi_n \rangle \left[-T_{A+BK}(t)\Pi\phi_n + \Pi e^{i\omega_n t}\phi_n \right] \tag{3.21}$$

$$= \Pi T_S(t)|_{W_{\mathcal{F}}} w_0 - T_{A+BK}(t)\Pi w_0 \quad \forall t \geq 0, \tag{3.22}$$

since $\Pi \in \mathcal{L}(W_{\mathcal{F}}, Z)$ and $w_0 \in W_{\mathcal{F}}$.

Using this information we can work out the explicit expression for the tracking error $e(t)$ as follows.

(3.23)
$$e(t) = (C + DK, DL - Q) T_{\mathcal{A}}(t)\left(\begin{smallmatrix} z_0 \\ w_0 \end{smallmatrix}\right)$$

(3.24)
$$= (C+DK)T_{A+BK}(t)z_0 + (C+DK)\int_0^t T_{A+BK}(\tau)(BL+P)T_S(t-\tau)|_{W_{\mathcal{F}}} w_0 d\tau$$

(3.25)
$$+ (DL-Q)T_S(t)|_{W_{\mathcal{F}}} w_0$$

(3.26)
$$= (C+DK)T_{A+BK}(t)(z_0 - \Pi w_0) + (C\Pi + DK\Pi + DL - Q)T_S(t)|_{W_{\mathcal{F}}} w_0$$

(3.27)
$$= (C+DK)T_{A+BK}(t)(z_0 - \Pi w_0) + (C\Pi + D\Gamma - Q)T_S(t)|_{W_{\mathcal{F}}} w_0$$

(3.28)
$$= (C+DK)T_{A+BK}(t)(z_0 - \Pi w_0) \quad \forall t \geq 0$$

by the second regulator equation (3.1b) and the fact that the operator $C\Pi + D\Gamma - Q \in \mathcal{L}(W_{\mathcal{F}}, Y)$.

By our assumption, $T_{A+BK}(t)$ is exponentially stable. Consequently, $e(t) \to 0$ for every $z_0 \in Z$ and $w_0 \in W_{\mathcal{F}}$. This shows that the control law $u(t) = Kz(t) + Lw(t)$ solves the (ω_n, f_n)-RP. The proof is complete. ∎

Remark 3.2. In the sufficiency part of Theorem 3.1, mere weak stability of the semigroup $T_{A+BK}(t)$ (i.e., that $f(T_{A+BK}(t)z_0) \to 0$ for every $z_0 \in Z$ and every $f \in Z'$ as $t \to \infty$) would guarantee that $|e(t)| \to 0$ as $t \to \infty$. Whenever the semigroup $T_{A+BK}(t)$ is exponentially stable, we in fact obtain exponentially fast decay of $|e(t)|$.

Remark 3.3. Theorem 3.1 shows that if $u(t) = Kz(t) + Lw(t)$ solves the (ω_n, f_n)-RP, then *necessarily* $L = \Gamma - K\Pi$, i.e., the operators K and L cannot be independent of each other. This shows that although small additive bounded perturbations to K do not affect exponential stability of $T_{A+BK}(t)$ [8], such perturbations do in general destroy output regulation. To the authors' knowledge this fact has not been explicitly stated before in related earlier work, e.g., [3, 14].

4. Solution of the regulator equations—SISO systems. In this section we solve the regulator equations (3.1) for SISO systems under the assumption that the stabilized plant does not have transmission zeros at the Fourier frequencies $i\omega_n$ of the reference signals. These solutions are then used to construct a candidate operator L for the solution of the output regulation problem (ω_n, f_n)-RP; its continuity determines whether or not the problem is solvable. Using this explicit series representation for L, in condition (4.17) we completely characterize the solvability of the (ω_n, f_n)-RP by the growth of the transfer function of the stabilized plant on the imaginary axis. Furthermore, we obtain an explicit expression, in terms of the reference signals, for the control law which achieves output regulation. Our arguments are similar to those in [14]; however, our results are more complete here. In particular, for SISO systems we derive the verifiable condition (4.17) which completely answers the question posed in the title.

Throughout this section, we assume that the plant is a SISO system and that the sequences $(\omega_n)_{n\in I}$ and $(f_n)_{n\in I}$ (see Definition 2.1) are fixed. Moreover, we assume that the stabilizing feedback $K \in \mathcal{L}(Z, U)$ for the pair (A, B) is fixed.

DEFINITION 4.1. *The transfer function $H(s)$ of the plant is defined as $H(s) = CR(s, A)B + D$ for every $s \in \rho(A)$. The transfer function $H_K(s)$ of the stabilized plant is defined as $H_K(s) = (C + DK)R(s, A + BK)B + D$ for $s \in \rho(A + BK)$. The sequence of disturbance coefficients for the stabilized plant is defined as $(H_d(n))_{n\in I} = ((C + DK)R(i\omega_n, A + BK)P\phi_n)_{n\in I} \subset \mathbb{C}$.*

DEFINITION 4.2. *The plant (respectively, stabilized plant) has a transmission zero at $s = s_0$ if $H(s_0) = 0$ (respectively, $H_K(s_0) = 0$).*

The next lemma shows that in $\rho(A)$ the concept of transmission zero does not depend on K; for the case $D = 0$ the result was stated in Lemma V.2 of [3].

LEMMA 4.3. *Let $s_0 \in \rho(A) \cap \rho(A + BK)$. Then the plant has a transmission zero at $s = s_0$ if and only if the stabilized plant has a transmission zero at $s = s_0$.*

Proof. Let $s = s_0$ be a transmission zero of the plant. Clearly $CR(s_0, A)B + D = 0$ if and only if

$$\ker \begin{pmatrix} C & D \\ s_0 I - A & -B \end{pmatrix} \neq \{0\}, \tag{4.1}$$

where the domain of definition of the operator $\mathcal{R} = \left(\begin{smallmatrix} C & D \\ s_0 I - A & -B \end{smallmatrix}\right)$ is $\mathcal{D}(A) \times \mathbb{C}$. Let

$0 \neq \left(\begin{smallmatrix} x \\ u \end{smallmatrix}\right) \in \ker \mathcal{R}$. Then since $x = R(s_0, A)Bu$, we must have that $u \neq 0$. Moreover,

$$\begin{pmatrix} C & D \\ s_0 I - A & -B \end{pmatrix} \begin{pmatrix} I & 0 \\ K & I \end{pmatrix} \begin{pmatrix} I & 0 \\ -K & I \end{pmatrix} \begin{pmatrix} x \\ u \end{pmatrix} = 0, \tag{4.2}$$

which implies

$$\begin{pmatrix} C + DK & D \\ s_0 I - A - BK & -B \end{pmatrix} \begin{pmatrix} x \\ u - Kx \end{pmatrix} = 0. \tag{4.3}$$

Let $\mathcal{R}_K = \left(\begin{smallmatrix} C+DK & D \\ s_0 I - A - BK & -B \end{smallmatrix}\right)$ with $\mathcal{D}(\mathcal{R}_K) = \mathcal{D}(\mathcal{R})$. If $x = 0$, then $0 \neq \left(\begin{smallmatrix} 0 \\ u \end{smallmatrix}\right) \in \ker \mathcal{R}_K$. On the other hand, if $x \neq 0$, then $0 \neq \left(\begin{smallmatrix} x \\ u - Kx \end{smallmatrix}\right) \in \ker \mathcal{R}_K$. In any case $\ker \mathcal{R}_K \neq \{0\}$. The above means that $(C + DK)R(s_0, A + BK)B + D = 0$, i.e., that the stabilized plant has a transmission zero at $s = s_0$.

Similar arguments show that the converse also holds. We omit the details. ∎

PROPOSITION 4.4. *Let $n \in I$. If the stabilized plant does not have a transmission zero at $s = i\omega_n$, and if we define $L\phi_n = H_K(i\omega_n)^{-1}[1 - H_d(n)]$, then*

$$\Pi\phi_n = R(i\omega_n, A + BK)\big[BL\phi_n + P\phi_n\big], \tag{4.4}$$

$$\Gamma\phi_n = L\phi_n + K\Pi\phi_n \tag{4.5}$$

are solutions of the regulator equations (3.1).

Proof. Since $S\phi_n = i\omega_n\phi_n$, it is clear that if we solve the equations

$$(A + BK)\Pi\phi_n + BL\phi_n + P\phi_n = i\omega_n\Pi\phi_n, \tag{4.6a}$$

$$(C + DK)\Pi\phi_n + DL\phi_n = 1 \tag{4.6b}$$

for $\Pi\phi_n$ and $L\phi_n$, and then set $\Gamma\phi_n = L\phi_n + K\Pi\phi_n$, we simultaneously solve regulator equations (3.1) for $\Pi\phi_n$ and $\Gamma\phi_n$. From (4.6a) we obtain

$$(A + BK)\Pi\phi_n + BL\phi_n + P\phi_n = i\omega_n\Pi\phi_n \Leftrightarrow \Pi\phi_n = R(i\omega_n, A + BK)(BL\phi_n + P\phi_n) \tag{4.7}$$

because $A + BK$ generates an exponentially stable C_0-semigroup. Applying this expression for $\Pi\phi_n$ to (4.6b) yields

$$(C + DK)R(i\omega_n, A + BK)(BL\phi_n + P\phi_n) + DL\phi_n = 1 \tag{4.8}$$

$$\Leftrightarrow \big[(C + DK)R(i\omega_n, A + BK)B + D\big]L\phi_n + (C + DK)R(i\omega_n, A + BK)P\phi_n = 1 \tag{4.9}$$

$$\Leftrightarrow H_K(i\omega_n)L\phi_n + H_d(n) = 1 \tag{4.10}$$

$$\Leftrightarrow H_K(i\omega_n)^{-1}\big[1 - H_d(n)\big] = L\phi_n \tag{4.11}$$

by the assumption that $H_K(i\omega_n) \neq 0$. Hence equations (4.6) have a unique solution which is also a solution of the regulator equations (3.1). ∎

THEOREM 4.5. *Suppose that for every $n \in I$, $s = i\omega_n$ is not a transmission zero of the stabilized plant. Define*

$$L = \sum_{n \in I} H_K(i\omega_n)^{-1}[1 - H_d(n)]\langle \cdot, \phi_n \rangle. \tag{4.12}$$

Then the (ω_n, f_n)-RP is solvable using the control law $u(t) = Kz(t) + Lw(t)$ if and only if $L \in \mathcal{L}(W_{\mathcal{F}}, U)$.

Proof (necessity). If the control law $u(t) = Kz(t) + Lw(t)$ solves the (ω_n, f_n)-RP, then by definition L must be in $\mathcal{L}(W_{\mathcal{F}}, U)$.

(Sufficiency) Suppose that $L \in \mathcal{L}(W_{\mathcal{F}}, U)$. Then the linear operator $\Pi : W_{\mathcal{F}} \to Z$ defined by $\Pi w = \int_0^\infty T_{A+BK}(\tau)(BL+P)T_S(-\tau)|_{W_{\mathcal{F}}} w d\tau$ for each $w \in W_{\mathcal{F}}$ is in $\mathcal{L}(W_{\mathcal{F}}, Z)$. Since $T_S(-t)|_{W_{\mathcal{F}}}\phi_n = e^{-i\omega_n t}\phi_n$ and $R(i\omega_n, A+BK)z = \int_0^\infty e^{-i\omega_n t} T_{A+BK}(t) z dt$ for every $z \in Z$ (Proposition 5.1.5 in [1]), we have that $\Pi\phi_n = R(i\omega_n, A+BK)(BL+P)\phi_n$ for each n. Consequently, by Proposition 4.4 the operators Π and $\Gamma = K\Pi + L \in \mathcal{L}(W_{\mathcal{F}}, U)$ solve the regulator equations (3.1) for every $n \in I$. Theorem 3.1 then guarantees that the (ω_n, f_n)-RP is solvable with the control law $u(t) = Kz(t) + Lw(t)$. ∎

COROLLARY 4.6. *Suppose that the assumptions of Theorem* 4.5 *are satisfied and that* L *defined in* (4.12) *is in* $\mathcal{L}(W_{\mathcal{F}}, U)$*, so that* (ω_n, f_n)*-RP is solvable using* $u(t) = Kz(t) + Lw(t)$*. Then for every* $y_{ref} \in H(f_n, \omega_n)$ *the corresponding control law* $u_{y_{ref}}(t)$ *which achieves output regulation of* $y_{ref}(t)$ *is given by*

$$u_{y_{ref}}(t) = Kz(t) + \sum_{n\in I} H_K(i\omega_n)^{-1}[1 - H_d(n)] y_n e^{i\omega_n t} \quad \forall t \geq 0, \tag{4.13}$$

where $y_{ref}(t) = \sum_{n\in I} y_n e^{i\omega_n t}$ *for each* t.

Proof. Let $y_{ref} \in H(f_n, \omega_n)$ be fixed, and let $y_{ref}(t) = \sum_{n\in I} y_n e^{i\omega_n t}$ for each t. By Theorem 2.8 the corresponding initial state of the exosystem $w(0) = \sum_{n\in I} y_n \phi_n \in W_{\mathcal{F}}$. Using continuity we work out $Lw(t) = LT_S(t)|_{W_{\mathcal{F}}} w(0)$ as

$$LT_S(t)|_{W_{\mathcal{F}}} w(0) = \sum_{n\in I} y_n LT_S(t)|_{W_{\mathcal{F}}}\phi_n \tag{4.14}$$

$$= \sum_{n\in I} y_n L e^{i\omega_n t}\phi_n \tag{4.15}$$

$$= \sum_{n\in I} y_n e^{i\omega_n t} H_K(i\omega_n)^{-1}[1 - H_d(n)] \quad \forall t \geq 0 \tag{4.16}$$

because $\phi_n \in W_{\mathcal{F}}$ for every $n \in I$ and $T_S(t)|_{W_{\mathcal{F}}}\phi_n = T_S(t)\phi_n = e^{i\omega_n t}\phi_n$ for each $n \in I$. The proof is completed by the observation that in our construction the control law $u(t) = Kz(t) + LT_S(t)|_{W_{\mathcal{F}}} w(0)$ achieves asymptotic tracking of $QT_S(t)|_{W_{\mathcal{F}}} w(0) = y_{ref}(t)$. ∎

In particular, if there are no disturbances and the plant is already exponentially stable, then the control law (4.13) reduces to the remarkably simple $u_{y_{ref}}(t) = \sum_{n\in I} H(i\omega_n)^{-1} y_n e^{i\omega_n t}$. Corollary 4.6 shows, under certain assumptions, that once we know that (ω_n, f_n)-RP is solvable, knowledge of the dynamical behavior of the exogenous system is irrelevant for asymptotic tracking of the reference signals (we need to have knowledge of the sequence $(P\phi_n)_{n\in I} \subset Z$ though): It is irrelevant *how* the control signal (4.13) is generated.

The following corollary characterizes the solvability of the (ω_n, f_n)-RP by the asymptotic behavior of $H_K(i\omega_n)^{-1}[1 - H_d(n)]$ as $n \to \pm\infty$.

COROLLARY 4.7. *Suppose that the assumptions of Theorem* 4.5 *are satisfied. Let* L *be defined as in* (4.12)*. Then the control law* $u(t) = Kz(t) + Lw(t)$ *solves the* (ω_n, f_n)*-RP if and only if*

$$\left(H_K(i\omega_n)^{-1}[1 - H_d(n)] f_n^{-1}\right)_{n\in I} \in \ell^2. \tag{4.17}$$

In the disturbance-free case (i.e., whenever $P = 0$*), the above condition reduces to* $(H_K(i\omega_n)^{-1} f_n^{-1})_{n\in I} \in \ell^2$.

Proof. Since $W_{\mathcal{F}}$ is a Hilbert space, by the Riesz representation theorem $L \in \mathcal{L}(W_{\mathcal{F}}, U) = \mathcal{L}(W_{\mathcal{F}}, \mathbb{C})$ if and only if there exists a unique element $l \in W_{\mathcal{F}}$ such that $Lw = \langle w, l\rangle_{\mathcal{F}}$ for every $w \in W_{\mathcal{F}}$. Then we must have that $\langle \phi_n, l\rangle |f_n|^2 = H_K(i\omega_n)^{-1}[1 - H_d(n)]$, or $\langle l, \phi_n\rangle = \overline{H_K(i\omega_n)^{-1}[1 - H_d(n)]}|f_n|^{-2}$ for every $n \in I$. But the element l thus defined is in $W_{\mathcal{F}}$ if and only if

$$\sum_{n\in I} |\langle l, \phi_n\rangle|^2 |f_n|^2 = \sum_{n\in I} |H_K(i\omega_n)^{-1}[1 - H_d(n)]|^2 |f_n|^{-2} < \infty. \tag{4.18}$$

This and Theorem 4.5 give the desired result. ∎

The above results formalize the intuitive idea that in order to be able to track a periodic reference signal, the stabilized plant should not attenuate high frequency oscillations too drastically and at the same time the reference signal should be smooth enough. We conclude this section with some results which in some cases simplify the verification of condition (4.17).

THEOREM 4.8. *Let A generate an exponentially stable C_0-semigroup and let $A + BK$, for $K \in \mathcal{L}(Z, U)$, also generate an exponentially stable C_0-semigroup. Then there exist $m, M \geq 0$ (which do not depend on $n \in I$) such that $\|CR(i\omega_n, A)B\| \leq m\|CR(i\omega_n, A + BK)B\| \leq M\|CR(i\omega_n, A)B\|$ for each $n \in I$.*

Proof. By an elementary calculation, we have that $CR(i\omega_n, A)B[I + KR(i\omega_n, A + BK)B] = CR(i\omega_n, A + BK)B$ and that $CR(i\omega_n, A)B = CR(i\omega_n, A + BK)B[I - KR(i\omega_n, A)B]$ for every $n \in I$. Since A and $A + BK$ generate exponentially stable C_0-semigroups, $\|R(i\omega_n, A)\|$ and $\|R(i\omega_n, A + BK)\|$ are uniformly bounded in n, according to the Riemann–Lebesgue lemma [6]. The desired conclusion now follows by some obvious norm estimates. ∎

According to Theorem 4.8, if $D = 0$, if there are no disturbances, and if both A and $A + BK$ generate exponentially stable C_0-semigroups, then $(H(i\omega_n)f_n^{-1})_{n\in I} \in \ell^2$ if and only if $(H_K(i\omega_n)f_n^{-1})_{n\in I} \in \ell^2$. In particular, the capability of output regulation is an intrinsic property of the plant which is independent of the stabilizing feedback K.

COROLLARY 4.9. *Let A and $A + BK$, where $K \in \mathcal{L}(Z, U)$, generate exponentially stable analytic C_0-semigroups.*

1. *For $D = 0$, condition (4.17) holds if $(H(i\omega_n)^{-1}[1 - H_d(n)]f_n^{-1})_{n\in I} \in \ell^2$.*
2. *For $D \neq 0$, condition (4.17) holds if $H(i\omega_n) \neq 0$ for each $n \in I$ and $([1 - H_d(n)]f_n^{-1})_{n\in I} \in \ell^2$.*

Proof. The case $D = 0$ is settled by Theorem 4.8.

Let $D \neq 0$. By exponential stability and Lemma 4.3, for all $n \in I$ we have $H_K(i\omega_n) \neq 0$. Since A and $A + BK$ generate exponentially stable analytic semigroups, we have $\lim_{n\to\pm\infty} H_K(i\omega_n) = D \neq 0$. Consequently, for some $\delta > 0$ we have $\delta < \inf_{n\in I} |H_K(i\omega_n)| < \sup_{n\in I} |H_K(i\omega_n)| < \infty$, and so

$$\left|H_K(i\omega_n)^{-1}[1 - H_d(n)]f_n^{-1}\right| \leq \frac{1}{\delta}\left|[1 - H_d(n)]f_n^{-1}\right| \quad \forall n \in I. \tag{4.19}$$

This shows that condition (4.17) holds if $([1 - H_d(n)]f_n^{-1})_{n\in I} \in \ell^2$. ∎

5. Examples.

Example 5.1. Consider a finite-dimensional exponentially stable SISO plant that is not subject to any disturbances (i.e., $P = 0$). Consider reference signals in the Sobolev space $H^{\gamma}_{per}(0, p)$, $\gamma > \frac{1}{2}$; i.e., set $I = \mathbb{Z}$ and $f_n = \sqrt{1 + \omega_n^2}^{\,\gamma}$ for each $n \in \mathbb{Z}$. Let N denote the relative degree of the transfer function $H(s)$ of the plant, and assume that there are no transmission zeros in the set of Fourier frequencies $\{\, i\omega_n \mid n \in \mathbb{Z} \,\}$ of the reference signals.

By the relative degree condition, $H(i\omega_n)^{-1}$ is $\mathcal{O}(|\omega_n|^N)$ as $n \to \pm\infty$. If we define L as in (4.12) (with $K = 0$ since the plant is already stable), then it is easy to see that $L \in \mathcal{L}(W_{\mathcal{F}}, U)$ if $\gamma > N + \frac{1}{2}$. This implies that for such γ, all reference signals $y_{ref} \in H^\gamma_{per}(0,p)$ can be asymptotically tracked using the control law $u(t) = Lw(t)$ by Theorem 4.5. On the other hand, for $\gamma \leq N + \frac{1}{2}$, there are reference signals in $H^\gamma_{per}(0,p)$ which cannot be asymptotically tracked by Corollary 4.7.

Example 5.2. Consider the following scalar delay differential equation [19] with control and observation. Let $a > 0$, $r \neq 0$, $\tau_1 > \tau_2 > 0$, and

$$\dot{x}(t) = -ax(t) - b\big[x(t-\tau_1) + x(t-\tau_2)\big] + u(t), \tag{5.1a}$$

$$y(t) = rx(t), \quad t \geq 0. \tag{5.1b}$$

Taking initial conditions for $x(\cdot)$ into account, the pair (5.1) can be formulated as a plant of the form (2.1) in which $D = 0$ and $\mathcal{U}_{dist} = 0$ [6]. Moreover, it can be shown (see, e.g., [6, Lemma 4.3.9]) that the transfer function $H(s) = CR(s,A)B$ of the plant is given by

$$H(s) = \frac{r}{s + a + b(e^{-s\tau_1} + e^{-s\tau_2})} \tag{5.2}$$

for those $s \in \mathbb{C}$ at which the denominator is not equal to zero.

The semigroup generated by A is exponentially stable if and only if $s + a + b(e^{-s\tau_1} + e^{-s\tau_2}) \neq 0$ for all $s \in \{\, z \in \mathbb{C} \mid \Re(z) \geq 0 \,\}$ [6, Theorem 5.1.7]. Ruan and Wei [19] give a complete characterization (in terms of a, b, τ_1, and τ_2) of those instances in which all roots of equation $s + a + b(e^{-s\tau_1} + e^{-s\tau_2}) = 0$ have negative real parts. In their characterization, the parameter b lies on an interval (b_0^-, b_0^+). We assume that the semigroup generated by A is exponentially stable. By the above discussion, then $i\omega_n \in \rho(A)$ and $H(i\omega_n) \neq 0$ for every $n \in \mathbb{Z}$.

It is evident that for every $\gamma > \frac{3}{2}$, $\sum_{n=-\infty}^{\infty} |H(i\omega_n)^{-1}|^2 (1+\omega_n^2)^{-\gamma} < \infty$, and that for every $\gamma \leq \frac{3}{2}$, $\sum_{n=-\infty}^{\infty} |H(i\omega_n)^{-1}|^2 (1+\omega_n^2)^{-\gamma} = \infty$. Consequently, by Corollary 4.7 the system can track all reference signals in $H^\gamma_{per}(0,p)$ for $\gamma > \frac{3}{2}$. On the other hand, for $\gamma \leq \frac{3}{2}$ in every Sobolev space $H^\gamma_{per}(0,p)$ there are reference signals which cannot be asymptotically tracked.

Example 5.3. Consider a disturbance-free controlled one-dimensional heat equation on the interval $[0,1]$ with Neumann boundary conditions $\frac{\partial z(x,t)}{\partial t} = \frac{\partial^2 z(x,t)}{\partial^2 x} + Bu(t)$, $\frac{\partial z(0,t)}{\partial t} = \frac{\partial z(1,t)}{\partial t} = 0$, $z(x,0) = \psi(x)$. The output is given as $y(t) = Cz(t)$. The bounded control operator $B : \mathbb{C} \to L^2(0,1)$ is defined by $Bu = b(x)u$, with $b(x) = 2\chi_{[\frac{1}{2},1]}(x)$. Here $\chi_{[\epsilon,\delta]}(x)$ denotes the characteristic function of the interval $[\epsilon,\delta]$. The bounded observation operator $C : L^2(0,1) \to \mathbb{C}$ is defined by $C\psi = \int_0^1 c(x)\psi(x)dx$, with $c(x) = 2\chi_{[0,\frac{1}{2}]}(x)$.

It is well known how to put this system in the form (2.1) [3, 6, 14]. It can also be shown [3] that the transfer function of this heat plant is $H(s) = \frac{2\sinh(\sqrt{s}/2)}{s\sqrt{s}\cosh(\sqrt{s}/2)}$ for $s \in \rho(A)$. Now $i\omega_n = i\frac{2\pi n}{p} \in \rho(A)$ for $n \neq 0$ [3], and $i\omega_n$ is not a transmission zero of this plant for $n \neq 0$.

Let $I = \mathbb{Z} \setminus \{0\}$, and let $f_n = \sqrt{1+\omega_n^2}^{\,\gamma}$. Let K be any bounded exponentially stabilizing feedback for the pair (A,B) (such a K is of course known to exist [3]). Then by Lemma 4.3, $H_K(i\omega_n)^{-1}$ exists for $n \neq 0$. Let us define L as in (4.12) (with $P = 0$ and $D = 0$). By some elementary calculations [14], in this case $H_K(i\omega_n)^{-1} = H(i\omega_n)^{-1}[I - KR(i\omega_n, A)B]$ for every $n \in I$. It is easy to see that $\|I - KR(i\omega_n, A)B\|$

is uniformly bounded for $n \neq 0$. Moreover, $H(i\omega_n)^{-1} = \mathcal{O}(|\omega_n|^{\frac{3}{2}})$ as $n \to \pm\infty$. Consequently $(H_K(i\omega_n)^{-1}\sqrt{1+\omega_n^2}^{-\gamma})_{n\in I} \in \ell^2$ if $\gamma > 2$. By Corollary 4.7, this system is capable of asymptotically tracking those periodic reference signals in $H^\gamma_{per}(0,p)$, with $\gamma > 2$, that lack the constant term in the Fourier series description. More accurate information on the signals which can be asymptotically tracked could be obtained by working out the explicit expression for $H_K(s)$.

We remark that Byrnes et al. (see sections III and VI of [3]) have thoroughly studied and simulated output regulation problems for the above heat plant in the case of constant and sinusoidal reference/disturbance signals. On the other hand, while in [14] the above system was used to track one p-periodic reference signal, here we may use Corollary 4.6 to track all sufficiently smooth p-periodic signals which lack the constant term in the Fourier series description.

Example 5.4. In this example we show that there exist infinite-dimensional systems which cannot track all reference signals in $H^\gamma_{per}(0,p)$ for any $\gamma > \frac{1}{2}$, even if there are no transmission zeros in the set of Fourier frequencies of the reference signals. This is in strong contrast to the finite-dimensional case, as is seen from Example 5.1 above. We refer the reader to [6, 20] for relevant notation and definitions.

Let $f \in \mathcal{D}(\mathbb{R})$ be a test function such that $\operatorname{supp}(f) \subset [0,a]$, where $0 < a < \infty$. Let $Z = \{\, g \in H^1(0,a) \mid g(a) = 0 \,\}$, where $H^1(0,a)$ denotes the standard Sobolev space. Since Z is the null space of a continuous linear functional, it is a closed subspace of $H^1(0,a)$. Let A be the generator of the left shift semigroup $T_A(t)$ on Z defined as $(T_A(t)g)(x) = g(x+t)$ for $x + t \leq a$, and $(T_A(t)g)(x) = 0$ otherwise, for every $g \in Z$. Clearly $T_A(t)$ is exponentially stable [8]. Let C be the point evaluation at the origin, i.e., $Cg = g(0)$ for every $g \in Z$. It is easy to show (see, e.g., [13]) that $C \in \mathcal{L}(Z,\mathbb{C})$. Finally, let $Bu = fu$ for $u \in \mathbb{C}$. Then evidently $B \in \mathcal{L}(\mathbb{C},Z)$. Moreover, the system (2.1) (with $D = 0$ and $\mathcal{U}_{dist} = 0$) has $f(t)$ as its impulse response [6]. In fact, $CT_A(t)B = [f(x+t)]_{x=0} = f(t)$ for every $t \geq 0$.

By applying Fourier transforms, we see that $H(i\omega) = \mathcal{F}(f)(i\omega)$ is a rapidly decreasing function. Hence $\sup_{\omega\in\mathbb{R}}(1+\omega^2)^N|H(i\omega)| < \infty$ for every $N \in \mathbb{N}$. For the purpose of output regulation, we may assume that $H(i\omega_n) \neq 0$ for every $n \in \mathbb{Z}$. Otherwise there would exist $m \in \mathbb{Z}$ such that the regulator equations (3.1) are not solvable for this m, and hence there would exist an infinite-dimensional system which cannot track all reference signals in $H^\gamma_{per}(0,p)$ for any $\gamma > \frac{1}{2}$. But by the above, $H(i\omega_n)^{-1}$ grows faster than every polynomial in n as $n \to \pm\infty$. By Corollary 4.7 and the fact that L (if it exists in $\mathcal{L}(W_{\mathcal{F}},\mathbb{C})$) is unique in this case, for arbitrary $\gamma > \frac{1}{2}$ there always exists $y_{ref} \in H^\gamma_{per}(0,p)$ which this system cannot asymptotically track using the control law $u(t) = Lw(t)$. In other words, if the system can asymptotically track all signals in $H(\omega_n, f_n)$, then $H(\omega_n, f_n) \subset C^\infty(\mathbb{R})$ (the space of infinitely smooth functions on $\mathbb{R}$). Moreover, the situation cannot be remedied using an auxiliary stabilizing feedback $Kz(t)$ by Theorem 4.8.

6. Conclusions. In this article we have studied regulation of periodic signals with a feedforward controller. We have constructed a scale of Sobolev-type spaces $H(\omega_n, f_n)$ for the reference signals. This construction played a key role as we showed that solvability of the regulation problem is equivalent to solvability of the regulator equations and a decomposability condition. In the case of SISO systems, assuming that the transfer function of the stabilized plant is invertible on the spectrum of the exosystem, we have completely characterized the reference signals which can be asymptotically tracked in the presence of disturbances.

Possible directions for future research include the design of a feedback controller

with robustness properties and the study of the internal model principle for infinite-dimensional exogenous systems. Additionally, the idea introduced in this article that the exogenous system is in a sense equivalent to the reference function space should be useful in generalizing our results for MIMO systems and reference functions which are not periodic.

ON ITERATIVE SOLUTIONS OF GENERAL COUPLED MATRIX EQUATIONS*

FENG DING† AND TONGWEN CHEN‡

Abstract. In this paper we study coupled matrix equations, which are encountered in many systems and control applications. First, we extend the well-known Jacobi and Gauss–Seidel iterations and present a large family of iterative methods, which are then applied to develop iterative solutions to coupled Sylvester matrix equations. The basic idea is to regard the unknown matrices to be solved as parameters of a system to be identified and to obtain the iterative solutions by applying a hierarchical identification principle. Next, we generalize the Sylvester equations to general coupled matrix equations, and propose a gradient-based iterative algorithm for the solutions, using a block-matrix inner product—the star ($\star$) product; we prove that the iterative algorithm always converges to the (unique) solutions for any initial values. One advantage of the algorithms proposed is that they require less storage space in implementation than existing numerical methods. Finally, we test the algorithms and show their effectiveness using numerical examples.

Key words. matrix equations, gradient search principle, Jacobi iteration, Gauss–Seidel iteration, Hadamard product, star product, hierarchical identification principle

1. Introduction.

In stability analysis of control systems and robust control [6], we often need to solve (coupled) matrix equations of the following forms:

- Continuous-time (CT) Sylvester equation: $AX + XB = C$.
- Discrete-time (DT) Sylvester equation: $AXB^{\mathrm{T}} + X = C$.
- Generalized Sylvester matrix equation: $AXB^{\mathrm{T}} + CXD^{\mathrm{T}} = F$.
- Coupled Sylvester matrix equations: $AX + YB = C$ and $DX + YE = F$.

Here, X and Y are unknown matrices in $\mathbb{R}^{m\times n}$; A, B, C, etc. represent constant (coefficient) matrices of appropriate dimensions (to be specified later).

The conventional method of solution is to expand the matrix equations to form a set of equations of the form $\mathcal{A}x = b$ by means of the Kronecker product. However, the dimensions of the associated matrix $\mathcal{A}$ are very high when m and n are large. Computational difficulties arise because excessive computer memory is required for computation and inversion of large matrices of size $(mn) \times (mn)$ or even $(2mn) \times (2mn)$.

Other methods are based on matrix transformations into forms for which solutions may be readily computed; examples of such forms include the Jordan canonical form [17], the companion form [4, 3], and the Hessenberg–Schur form [2, 15]. In this area, Chu gave an algorithm for solving generalized/coupled Sylvester equations [7]; Syrmos, Misra, and Aripirala [29], Stykel [28], and Takaba, Morihhira, and Katayama [30] discussed numerical solutions to generalized coupled Lyapunov equations; many authors studied least squares solutions of matrix equations of the form $AXB^* +$

$CYD^* = E$ based on the singular value decomposition of coefficient matrices [14, 1, 32, 26]; Jonsson and Kågström proposed recursive block algorithms for solving CT Sylvester equations, CT Lyapunov equations, and coupled Sylvester matrix equations [19, 20]; and finally, Borno presented a parallel algorithm for solving the coupled Lyapunov equations [5].

However, the above-mentioned algorithms all require computing some additional matrix transformation/decomposition; moreover, they are not suitable for more general coupled matrix equations of the form

$$\begin{cases} A_{11}X_1B_{11} + A_{12}X_2B_{12} + \cdots + A_{1p}X_pB_{1p} = C_1, \\ A_{21}X_1B_{21} + A_{22}X_2B_{22} + \cdots + A_{2p}X_pB_{2p} = C_2, \\ \quad \vdots \\ A_{p1}X_1B_{p1} + A_{p2}X_2B_{p2} + \cdots + A_{pp}X_pB_{pp} = C_p. \end{cases} \tag{1}$$

Here, $X_j \in \mathbb{R}^{m\times n}$ are the unknown matrices to be solved. For such coupled matrix equations, the above-mentioned methods require dealing with matrices whose dimensions grow quickly as m, n, and p increase—a major disadvantage. We would like to comment that the coupled matrix equations in (1) are quite general and include many matrix equations, e.g., the ones mentioned above [29, 28] as special cases; in particular, they also encompass generalized (coupled) Lyapunov and Sylvester equations which occur in the study of linear jump parameter systems [5].

Iterative algorithms are popular in the areas of matrix algebra and system identification [16, 22, 24, 25]. For example, Starke and Niethammer reported an iterative method for solutions of CT Sylvester equations by using the SOR (successive overrelaxation) technique [27], and Mukaidani, Xu, and Mizukami discussed an iterative algorithm for generalized algebraic Lyapunov equations [24]. In our work, we focus on numerical solutions for coupled Sylvester matrix equations and general coupled matrix equations in (1), and we present the gradient-based iterative algorithms by using the gradient search principle and the hierarchical identification principle. We mention that least squares iterative algorithms were given in [9] for coupled matrix equations and gradient-based iterative algorithms in [10] for noncoupled matrix equations.

For matrix equations, exact solutions are important, but it is often not necessary to compute exact solutions for many applications such as stability analysis in control systems, and approximate solutions are sufficient. Also, if parameters in system matrices contain uncertainty, it is not possible to obtain exact solutions for robust stability analysis [9, 10, 13, 24, 23, 21].

The paper is organized as follows. In section 2, we extend the well-known Jacobi and Gauss–Seidel iterations and present a large family of iterative methods for linear equations. In sections 3 and 4, we derive gradient-based iterative algorithms for, respectively, coupled Sylvester matrix equations and general coupled matrix equations, and we study the convergence properties of the algorithms. In section 5 we present two examples to illustrate the effectiveness of the algorithms proposed in the paper. Finally, we offer some concluding remarks in section 6.

2. A large family of iterative methods. Consider the equation

$$Ax = b, \quad A \in \mathbb{R}^{n\times n}, \quad b \in \mathbb{R}^n. \tag{2}$$

Here, $A = [a_{ij}]$ is a full-rank matrix with nonzero diagonal elements and $x \in \mathbb{R}^n$ is an unknown vector to be computed. Letting D denote the diagonal part, L and U the

strictly lower and upper triangular parts of A, we have

$$D = \operatorname{diag}[a_{11},\ a_{22},\ \ldots,\ a_{nn}] \in \mathbb{R}^{n\times n},$$

$$L = \begin{bmatrix} 0 & 0 & \cdots & \cdots & 0 \\ a_{21} & 0 & \ddots & & \vdots \\ a_{31} & a_{32} & 0 & \ddots & \vdots \\ \vdots & & \ddots & \ddots & 0 \\ a_{n1} & a_{n2} & \cdots & a_{n,n-1} & 0 \end{bmatrix} \in \mathbb{R}^{n\times n},$$

$$U = \begin{bmatrix} 0 & a_{12} & a_{13} & \cdots & a_{1n} \\ 0 & 0 & a_{23} & & a_{2n} \\ \vdots & \ddots & \ddots & \ddots & \vdots \\ \vdots & & \ddots & \ddots & a_{n-1,n} \\ 0 & \cdots & \cdots & 0 & 0 \end{bmatrix} \in \mathbb{R}^{n\times n}.$$

The matrices just defined satisfy $L + D + U = A$. In this case both the Jacobi and Gauss–Seidel iterations [16] can be applied to give an iterative solution $x(k)$ of x in the form of

$$Mx(k) = Nx(k-1) + b, \quad k = 1, 2, 3, \ldots ;$$

for the Jacobi method, $M = D$ and $N = -(L + U)$; for the Gauss–Seidel method, $M = L + D$ and $N = -U$.

The main drawback of the Jacobi and Gauss–Seidel iterations is that they do not guarantee that $x(k)$ converges to the exact solution $x = A^{-1}b$. This inspires us to study new iterative methods.

Let $G_k \in \mathbb{R}^{n\times n}$ be a matrix to be determined and let $\mu > 0$ be the step size or the convergence factor. We present a large family of iterative methods as follows:

$$x(k) = x(k-1) + \mu G_k[b - Ax(k-1)], \quad k = 1, 2, 3, \ldots . \tag{3}$$

This family includes the Jacobi and Gauss–Seidel iterations as special cases. For example, when $G_k = D^{-1}$ and $\mu = 1$, we get the Jacobi method; when $G_k = (L+D)^{-1}$ and $\mu = 1$, we obtain the Gauss–Seidel method.

THEOREM 1. *For the iterative algorithm in* (3)*, assume system* (2) *has a unique solution. Then the iterative solution* $x(k)$ *in* (3) *converges to the exact solution* x *(i.e.,* $\lim_{k\to\infty} x(k) = x$*) for any initial values* $x(0)$ *if there exists* $\varepsilon > 0$ *independent of* k *such that*

$$\mu(G_kA)^{\mathrm{T}}(G_kA) + \varepsilon I \le (G_kA)^{\mathrm{T}} + (G_kA) \quad \textit{for all } k. \tag{4}$$

Here I *represents an identity matrix of appropriate dimensions. In fact, if* $(G_kA)^{\mathrm{T}} + (G_kA)$ *is positive definite, a conservative choice of the convergence factor can be given by*

$$0 < \mu < \frac{\lambda_{\min}[(G_kA)^{\mathrm{T}} + (G_kA)]}{\lambda_{\max}[(G_kA)^{\mathrm{T}}(G_kA)]} \quad \textit{for all } k,$$

where $\lambda_{\max}(\lambda_{\min})$ *denotes the maximum (resp., minimum) eigenvalue.*

Note that for time-invariant systems of the form $x(k) = Hx(k-1),\ H \in \mathbb{R}^{n\times n}$; the fact that all eigenvalues of H are inside the unit circle guarantees the convergence of $x(k)$ to zero as $k \to \infty$. But for time-varying systems of the form $x(k) = H_k x(k-1),\ H_k \in \mathbb{R}^{n\times n}$, such a conclusion is no longer true because the condition that all the eigenvalues of H_k are inside the unit circle is neither sufficient nor necessary for stability—see the appendix for some stability examples. In the following, we give a proof of Theorem 1 based on the Lyapunov stability theorem.

Proof. Define the error vector

$$\tilde{x}(k) = x(k) - x.$$

Substituting (3) into the above equation and using (2) yield

$$\begin{aligned}\tilde{x}(k) &= \tilde{x}(k-1) + \mu G_k\left[Ax - Ax(k-1)\right]\\ &= \tilde{x}(k-1) - \mu G_k A\tilde{x}(k-1)\\ &= [I - \mu G_k A]\tilde{x}(k-1).\end{aligned}$$

Define a nonnegative definite Lyapunov function

$$S(k) = \tilde{x}^{\mathrm{T}}(k)\tilde{x}(k).$$

Hence

$$\begin{aligned}S(k) &= \tilde{x}^{\mathrm{T}}(k-1)[I - \mu(G_k A)^{\mathrm{T}}][I - \mu G_k A]\tilde{x}(k-1)\\ &= \tilde{x}^{\mathrm{T}}(k-1)\tilde{x}(k-1) - \mu\tilde{x}^{\mathrm{T}}(k-1)[G_k A + (G_k A)^{\mathrm{T}} - \mu(G_k A)^{\mathrm{T}}(G_k A)]\tilde{x}(k-1)\\ &= S(k-1) - \mu\tilde{x}^{\mathrm{T}}(k-1)[G_k A + (G_k A)^{\mathrm{T}} - \mu(G_k A)^{\mathrm{T}}(G_k A)]\tilde{x}(k-1).\end{aligned}$$

Using (4), it is not difficult to get

$$\begin{aligned}\Delta S(k) &:= S(k) - S(k-1)\\ &= -\mu\tilde{x}^{\mathrm{T}}(k-1)[G_k A + (G_k A)^{\mathrm{T}} - \mu(G_k A)^{\mathrm{T}}(G_k A)]\tilde{x}(k-1)\\ &\le -\mu\varepsilon\tilde{x}^{\mathrm{T}}(k-1)\tilde{x}(k-1) \le 0.\end{aligned}$$

So we have $S(k) \to 0$ as $k \to \infty$. This proves Theorem 1. □

It is well known that if all eigenvalues of $(I - D^{-1}A)$ are inside the unit circle, the Jacobi iterative solution will converge to the exact solution, and if all eigenvalues of $[I - (L+D)^{-1}A]$ are inside the unit circle, the Gauss–Seidel solution will converge to the exact solution. Thus introducing a convergence factor μ in the Jacobi and the Gauss–Seidel iterations can relax their convergence conditions because for appropriate values of μ, $(I - \mu D^{-1}A)$ and $[I - \mu(L+D)^{-1}A]$ may have all eigenvalues inside the unit circle. We can also draw the following corollaries from Theorem 1.

COROLLARY 1. *If we take $G_k = D^{-1}$, then the Jacobi iteration with the convergence factor μ,*

$$x(k) = x(k-1) + \mu D^{-1}[b - Ax(k-1)],$$

yields $\lim_{k\to\infty} x(k) = x$ if $A^{\mathrm{T}}D^{-1} + D^{-1}A$ is a positive-definite matrix, and

$$0 < \mu < \frac{\lambda_{\min}[A^{\mathrm{T}}D^{-1} + D^{-1}A]}{\lambda_{\max}[A^{\mathrm{T}}D^{-2}A]}.$$

COROLLARY 2. *If we take* $G_k = (L+D)^{-1}$, *then the Gauss–Seidel iteration with the convergence factor* μ,

$$x(k) = x(k-1) + \mu(L+D)^{-1}[b - Ax(k-1)],$$

also yields $\lim_{k\to\infty} x(k) = x$ *if* $A^{\mathrm{T}}(L+D)^{-\mathrm{T}} + (L+D)^{-1}A > 0$, *and*

$$0 < \mu < \frac{\lambda_{\min}[A^{\mathrm{T}}(L+D)^{-\mathrm{T}} + (L+D)^{-1}A]}{\lambda_{\max}[A^{\mathrm{T}}(L+D)^{-\mathrm{T}}(L+D)^{-1}A]}.$$

COROLLARY 3. *If we take* $G_k = A^{\mathrm{T}}$, *then the gradient iterative algorithm* [9],

$$\begin{cases} x(k) = x(k-1) + \mu A^{\mathrm{T}}[b - Ax(k-1)], \quad k = 1,\ 2,\ 3,\ \ldots, \\ 0 < \mu < \frac{2}{\lambda_{\max}[A^{\mathrm{T}}A]} \quad or \quad 0 < \mu < \frac{2}{\|A\|^2}, \end{cases} \tag{5}$$

yields $\lim_{k\to\infty} x(k) = x$. *Here,* $\|X\|^2 = \mathrm{tr}[XX^{\mathrm{T}}]$.

COROLLARY 4. *If* A *is a nonsquare* $m \times n$ *full column-rank matrix and we take* $G_k = (A^{\mathrm{T}}A)^{-1}A^{\mathrm{T}}$, *then the following least squares iterative algorithm leads to* $\lim_{k\to\infty} x(k) = x$ [9]:

$$x(k) = x(k-1) + \mu(A^{\mathrm{T}}A)^{-1}A^{\mathrm{T}}[b - Ax(k-1)], \quad 0 < \mu < 2.$$

Later we will use the iterative algorithm in (5) to develop iteration techniques for general coupled matrix equations.

3. Coupled Sylvester equations. In this section, we apply a hierarchical identification principle to solve the coupled Sylvester matrix equation

$$\begin{cases} AX + YB = C, \\ DX + YE = F. \end{cases} \tag{6}$$

Here $A,\ D \in \mathbb{R}^{m\times m}$, $B,\ E \in \mathbb{R}^{n\times n}$, and $C,\ F \in \mathbb{R}^{m\times n}$ are given constant matrices; $X,\ Y \in \mathbb{R}^{m\times n}$ are the unknown matrices to be solved.

First, let us introduce some notation. I_n is the $n \times n$ identity matrix. For two matrices M and N, $M \otimes N$ is their Kronecker product. For two $m \times n$ matrices X and Y with

$$X = [\ x_1, \quad x_2, \quad \ldots, \quad x_n\ ] \in \mathbb{R}^{m\times n},$$

$\mathrm{col}[X]$ is an mn-dimensional vector formed by columns of X,

$$\mathrm{col}[X] = \begin{bmatrix} x_1 \\ x_2 \\ \vdots \\ x_n \end{bmatrix},$$

and

$$\mathrm{col}[X, Y] = \begin{bmatrix} \mathrm{col}[X] \\ \mathrm{col}[Y] \end{bmatrix} \in \mathbb{R}^{2mn}.$$

The following result is well known.

LEMMA 1. *System* (6) *has a unique solution*

$$\text{col}[X, Y] = S_2^{-1}\text{col}[C, F] \tag{7}$$

if and only if the matrix

$$S_2 := \begin{bmatrix} I_n \otimes A & B^{\mathrm{T}} \otimes I_m \\ I_n \otimes D & E^{\mathrm{T}} \otimes I_m \end{bmatrix} \in \mathbb{R}^{(2mn)\times(2mn)}$$

is nonsingular and the corresponding homogeneous matrix equation ($AX + YB = \mathbf{0},\ DX + YE = \mathbf{0}$) *has a unique solution:* $X = Y = \mathbf{0}$.

According to the hierarchical identification principle [11, 12], system (6) is decomposed into two subsystems and then, based on the gradient search principle, the parameters of each subsystem are identified. In this way we derive the iterative algorithm. The details are as follows.

Define two matrices

$$b_1 := \begin{bmatrix} C - YB \\ F - YE \end{bmatrix}, \tag{8}$$

$$b_2 := [C - AX,\ F - DX]. \tag{9}$$

Then from (6), we obtain two fictitious subsystems

$$S_1: \quad \begin{bmatrix} A \\ D \end{bmatrix} X = b_1,$$

$$S_2: \quad Y[B,\ E] = b_2.$$

Let $X(k)$ and $Y(k)$ be the estimates or iterative solutions of X and Y, associated with subsystems S_1 and S_2. Then using the gradient search principle or applying Corollary 3 to S_1 and S_2 leads to the following recursive equations:

$$X(k) = X(k-1) + \mu \begin{bmatrix} A \\ D \end{bmatrix}^{\mathrm{T}} \left\{ b_1 - \begin{bmatrix} A \\ D \end{bmatrix} X(k-1) \right\}, \tag{10}$$

$$Y(k) = Y(k-1) + \mu\{b_2 - Y(k-1)[B,\ E]\}[B,\ E]^{\mathrm{T}}. \tag{11}$$

Here, $\mu > 0$ is the iterative step size or convergence factor to be given later. Substituting (8) into (10) and (9) into (11) gives

$$\begin{aligned} X(k) &= X(k-1) + \mu \begin{bmatrix} A \\ D \end{bmatrix}^{\mathrm{T}} \left\{ \begin{bmatrix} C - YB \\ F - YE \end{bmatrix} - \begin{bmatrix} A \\ D \end{bmatrix} X(k-1) \right\} \\ &= X(k-1) + \mu \begin{bmatrix} A \\ D \end{bmatrix}^{\mathrm{T}} \begin{bmatrix} C - YB - AX(k-1) \\ F - YE - DX(k-1) \end{bmatrix}, \end{aligned} \tag{12}$$

$$\begin{aligned} Y(k) &= Y(k-1) + \mu\{[C - AX,\ F - DX] - Y(k-1)[B,\ E]\}[B,\ E]^{\mathrm{T}} \\ &= Y(k-1) + \mu[C - AX - Y(k-1)B,\ F - DX - Y(k-1)E][B,\ E]^{\mathrm{T}}. \end{aligned} \tag{13}$$

Because the expressions on the right-hand sides of (12) and (13) contain the unknown parameter matrices Y and X, it is impossible to realize the algorithm in (12) and (13). According to the hierarchical identification principle, the unknown variables Y in (12) and X in (13) are replaced by their estimates $Y(k-1)$ and $X(k-1)$ at

time $k-1$. Hence, we obtain the iterative solutions $X(k)$ and $Y(k)$ for the coupled Sylvester equation in (6):

$$\begin{aligned} X(k) &= X(k-1) \\ &+\mu \begin{bmatrix} A \\ D \end{bmatrix}^{\mathrm{T}} \begin{bmatrix} C - AX(k-1) - Y(k-1)B \\ F - DX(k-1) - Y(k-1)E \end{bmatrix}, \end{aligned} \tag{14}$$

$$\begin{aligned} Y(k) &= Y(k-1) \\ &+\mu[C - AX(k-1) - Y(k-1)B,\ F - DX(k-1) - Y(k-1)E][B,\ E]^{\mathrm{T}}. \end{aligned} \tag{15}$$

The convergence factor may be taken to satisfy

$$0 < \mu < \frac{2}{\lambda_{\max}[A^{\mathrm{T}}A] + \lambda_{\max}[D^{\mathrm{T}}D] + \lambda_{\max}[BB^{\mathrm{T}}] + \lambda_{\max}[EE^{\mathrm{T}}]} =: \mu_0 \tag{16}$$

or

$$0 < \mu < \frac{2}{\|A\|^2 + \|B\|^2 + \|D\|^2 + \|E\|^2}.$$

To initialize the algorithm, we take $X(0) = Y(0) = \mathbf{0}$ or some small real matrix, e.g., $X(0) = Y(0) = 10^{-6}\mathbf{1}_{m\times n}$ with $\mathbf{1}_{m\times n}$ being an $m \times n$ matrix whose elements are all 1.

THEOREM 2. *If the coupled Sylvester equation in* (6) *has unique solutions* X *and* Y*, then for any initial values, the iterative solutions* $X(k)$ *and* $Y(k)$ *given by the algorithm in* (14)–(15) *converge to the solutions* X *and* Y*:*

$$\lim_{k\to\infty} X(k) = X, \qquad \lim_{k\to\infty} Y(k) = Y.$$

The proof of Theorem 2 is omitted here but can be given later with the proof of Theorem 3.

In order to enhance the convergence properties, normally we should choose a large convergence factor μ which leads to a fast convergence rate of $X(k)$ to X and $Y(k)$ to Y; but too large μ may violate the condition of this theorem (also see (23)). Usually, there exists some best μ so that a fast convergence rate can be achieved—see the examples to be studied later.

4. General coupled matrix equations. In this section, we will generalize the Sylvester system of equations and introduce the block-matrix inner product to develop iterative solutions for a more general coupled matrix equations of the form

$$\begin{cases} A_{11}X_1B_{11} + A_{12}X_2B_{12} + \cdots + A_{1p}X_pB_{1p} = C_1, \\ A_{21}X_1B_{21} + A_{22}X_2B_{22} + \cdots + A_{2p}X_pB_{2p} = C_2, \\ \quad \vdots \\ A_{p1}X_1B_{p1} + A_{p2}X_2B_{p2} + \cdots + A_{pp}X_pB_{pp} = C_p. \end{cases} \tag{17}$$

Here, $A_{ij} \in \mathbb{R}^{m\times m}$, $B_{ij} \in \mathbb{R}^{n\times n}$, and $C_i \in \mathbb{R}^{m\times n}$ are given constant matrices; $X_i \in \mathbb{R}^{m\times n}$ are the unknown matrices to be determined.

Here, we succinctly express the iterative solutions by using the block-matrix inner product [9]—the star product, denoted by $\star$—which differs from the Hadamard (inner)

product [18, 8, 31] or the general matrix multiplication. Let

$$X=\begin{bmatrix} X_1 \\ X_2 \\ \vdots \\ X_p \end{bmatrix}\in\mathbb{R}^{(mp)\times n},\quad Y=\begin{bmatrix} Y_1 \\ Y_2 \\ \vdots \\ Y_p \end{bmatrix}\in\mathbb{R}^{(np)\times m},\quad X_i,\, Y_i^{\mathrm{T}}\in\mathbb{R}^{m\times n},$$

$$S_A=\begin{bmatrix} A_{11} & A_{12} & \cdots & A_{1p} \\ A_{21} & A_{22} & \cdots & A_{2p} \\ \vdots & \vdots & & \vdots \\ A_{p1} & A_{p2} & \cdots & A_{pp} \end{bmatrix},\quad S_B=\begin{bmatrix} B_{11} & B_{12} & \cdots & B_{1p} \\ B_{21} & B_{22} & \cdots & B_{2p} \\ \vdots & \vdots & & \vdots \\ B_{p1} & B_{p2} & \cdots & B_{pp} \end{bmatrix},$$

$$S_{B^{\mathrm{T}}}=\begin{bmatrix} B_{11}^{\mathrm{T}} & B_{12}^{\mathrm{T}} & \cdots & B_{1p}^{\mathrm{T}} \\ B_{21}^{\mathrm{T}} & B_{22}^{\mathrm{T}} & \cdots & B_{2p}^{\mathrm{T}} \\ \vdots & \vdots & & \vdots \\ B_{p1}^{\mathrm{T}} & B_{p2}^{\mathrm{T}} & \cdots & B_{pp}^{\mathrm{T}} \end{bmatrix},$$

$$S_p=\begin{bmatrix} B_{11}^{\mathrm{T}}\otimes A_{11} & B_{12}^{\mathrm{T}}\otimes A_{12} & \cdots & B_{1p}^{\mathrm{T}}\otimes A_{1p} \\ B_{21}^{\mathrm{T}}\otimes A_{21} & B_{22}^{\mathrm{T}}\otimes A_{22} & \cdots & B_{2p}^{\mathrm{T}}\otimes A_{2p} \\ \vdots & \vdots & & \vdots \\ B_{p1}^{\mathrm{T}}\otimes A_{p1} & B_{p2}^{\mathrm{T}}\otimes A_{p2} & \cdots & B_{pp}^{\mathrm{T}}\otimes A_{pp} \end{bmatrix}.$$

Then the block-matrix star product is defined as

$$X\star Y=\begin{bmatrix} X_1 \\ X_2 \\ \vdots \\ X_p \end{bmatrix}\star\begin{bmatrix} Y_1 \\ Y_2 \\ \vdots \\ Y_p \end{bmatrix}=\begin{bmatrix} X_1Y_1 \\ X_2Y_2 \\ \vdots \\ X_pY_p \end{bmatrix},$$

$$X\star S_B=\begin{bmatrix} X_1B_{11} & X_1B_{12} & \cdots & X_1B_{1p} \\ X_2B_{21} & X_2B_{22} & \cdots & X_2B_{2p} \\ \vdots & \vdots & & \vdots \\ X_pB_{p1} & X_pB_{p2} & \cdots & X_pB_{pp} \end{bmatrix}.$$

The definitions of $S_A\star X$ and $S_A\star S_B$ can be found in [9]. In the above definitions, we assume that the dimensions of matrices are compatible. The block matrix star Kronecker product, denoted by $\circledast$, is defined by

$$S_{B^{\mathrm{T}}}\circledast S_A=S_p\,.$$

For the Hadamard product (denoted by $\circ$), we have $X\circ Y=Y\circ X$, but $X\circ S_A$ is not defined. For the star product, taking into account the dimension compatibility, we have $AB\star C=A(B\star C)\neq(AB)\star C$ (the multiplier and multiplicand matrices are not necessarily of the same size); in general, $A\star B\neq B\star A$, $A\star B\star C=(A\star B)\star C\neq A\star(B\star C)$.

Let $I_{mp\times m}=[I_m,\ I_m,\ \ldots,\ I_m]^{\mathrm{T}}\in\mathbb{R}^{(mp)\times m}$. Then the star product has the following properties:

$$I_{mp\times m}^{\mathrm{T}}X\star Y=[X_1,\ X_2,\ \ldots,\ X_p]Y=\sum_{i=1}^{p}X_iY_i,$$

$$\operatorname{tr}\left\{ X_i^{\mathrm{T}} \begin{bmatrix} A_{1i} \\ A_{2i} \\ \vdots \\ A_{pi} \end{bmatrix}^{\mathrm{T}} \begin{bmatrix} \tilde{C}_1 \\ \tilde{C}_2 \\ \vdots \\ \tilde{C}_p \end{bmatrix} \star \begin{bmatrix} B_{1i}^{\mathrm{T}} \\ B_{2i}^{\mathrm{T}} \\ \vdots \\ B_{pi}^{\mathrm{T}} \end{bmatrix} \right\} = \operatorname{tr}\left\{ \begin{bmatrix} A_{1i}X_iB_{1i} \\ A_{2i}X_iB_{2i} \\ \vdots \\ A_{pi}X_iB_{pi} \end{bmatrix}^{\mathrm{T}} \begin{bmatrix} \tilde{C}_1 \\ \tilde{C}_2 \\ \vdots \\ \tilde{C}_p \end{bmatrix} \right\},$$

$$\left\| \begin{bmatrix} A_{1i} \\ A_{2i} \\ \vdots \\ A_{pi} \end{bmatrix}^{\mathrm{T}} \begin{bmatrix} \tilde{C}_1 \\ \tilde{C}_2 \\ \vdots \\ \tilde{C}_p \end{bmatrix} \star \begin{bmatrix} B_{1i}^{\mathrm{T}} \\ B_{2i}^{\mathrm{T}} \\ \vdots \\ B_{pi}^{\mathrm{T}} \end{bmatrix} \right\|^2 \le \sum_{j=1}^{p} \|A_{ji}B_{ji}\|^2 \left\| \begin{bmatrix} \tilde{C}_1 \\ \tilde{C}_2 \\ \vdots \\ \tilde{C}_p \end{bmatrix} \right\|^2.$$

LEMMA 2. *Equation* (17) *has unique solutions* X_i *if and only if the matrix* S_p *is nonsingular; in this case, the unique solutions are given by*

$$\operatorname{col}[X_1, X_2, \ldots, X_p] = S_p^{-1}\operatorname{col}[C_1, C_2, \ldots, C_p].$$

and if $C_i = \mathbf{0}$ $(i = 1,\ 2,\ \cdots,\ p)$*, the corresponding homogeneous equation in* (17) *has unique solutions* $X_i = \mathbf{0}$ $(i = 1,\ 2,\ \ldots,\ p)$.

The iterative solution for the general coupled matrix equation in (17) is obtained by generalizing that for the coupled Sylvester equation in (6); to do this, we first consider the coupled Sylvester equation in (6) in the more general form

$$\begin{cases} AXI_B + I_AYB = C, \\ DXI_E + I_DYE = F, \end{cases}$$

whose iterative solution in (14)–(15) can be expressed as

$$X(k) = X(k-1)$$

$$+\mu \begin{bmatrix} A \\ D \end{bmatrix}^{\mathrm{T}} \left\{ \begin{bmatrix} C - AX(k-1)I_B - I_AY(k-1)B \\ F - DX(k-1)I_E - I_DY(k-1)E \end{bmatrix} \star [I_B,\ I_E]^{\mathrm{T}} \right\}, \tag{18}$$

$$Y(k) = Y(k-1)$$

$$+\mu \begin{bmatrix} I_A \\ I_D \end{bmatrix}^{\mathrm{T}} \left\{ \begin{bmatrix} C - AX(k-1)I_E - I_DY(k-1)B \\ F - DX(k-1)I_E - I_DY(k-1)E \end{bmatrix} \star [B,\ E]^{\mathrm{T}} \right\}. \tag{19}$$

If I_A, I_B, I_D, and I_E are identity matrices of appropriate dimensions, then the algorithm in (18) and (19) is equivalent to the algorithm given in (14) and (15).

Let $X_i(k)$ be the estimates or iterative solutions of X_i. For (17), we propose the following iterative algorithm to compute the solutions X_i $(i = 1,\ 2,\ \ldots,\ p)$:

$$X_i(k) = X_i(k-1)$$

$$+\mu \begin{bmatrix} A_{1i} \\ A_{2i} \\ \vdots \\ A_{pi} \end{bmatrix}^{\mathrm{T}} \begin{bmatrix} C_1 - \sum_{j=1}^{p} A_{1j}X_j(k-1)B_{1j} \\ C_2 - \sum_{j=1}^{p} A_{2j}X_j(k-1)B_{2j} \\ \vdots \\ C_p - \sum_{j=1}^{p} A_{pj}X_j(k-1)B_{pj} \end{bmatrix} \star [B_{1i},\ B_{2i},\ \ldots,\ B_{pi}]^{\mathrm{T}}, \tag{20}$$

$$0 < \mu < 2\left(\sum_{i=1}^{p}\sum_{j=1}^{p} \|A_{ij}B_{ij}\|^2 \right)^{-1} =: \mu_0. \tag{21}$$

THEOREM 3. *If the matrix equation in* (17) *has unique solutions* X_i, $i = 1,\ 2,\ \ldots,\ p$, *then the iterative solutions* $X_i(k)$ *given by the algorithm in* (20) *and* (21) *converge to the solutions* X_i *for any initial value:*

$$\lim_{k\to\infty} X_i(k) = X_i, \quad i = 1,\ 2,\ \ldots,\ p.$$

Proof. Define the estimation error matrices

$$\tilde{X}_i(k) = X_i(k) - X_i.$$

Let

$$\begin{bmatrix} \tilde{C}_1(k) \\ \tilde{C}_2(k) \\ \vdots \\ \tilde{C}_p(k) \end{bmatrix} = \begin{bmatrix} \sum_{j=1}^{p} A_{1j}\tilde{X}_j(k-1)B_{1j} \\ \sum_{j=1}^{p} A_{2j}\tilde{X}_j(k-1)B_{2j} \\ \vdots \\ \sum_{j=1}^{p} A_{pj}\tilde{X}_j(k-1)B_{pj} \end{bmatrix}.$$

By using (17) and (20), it is not difficult to get

$$\tilde{X}_i(k) = \tilde{X}_i(k-1) - \mu \begin{bmatrix} A_{1i} \\ A_{2i} \\ \vdots \\ A_{pi} \end{bmatrix}^{\mathrm{T}} \begin{bmatrix} \tilde{C}_1(k) \\ \tilde{C}_2(k) \\ \vdots \\ \tilde{C}_p(k) \end{bmatrix} \star [B_{1i},\ B_{2i},\ \ldots,\ B_{pi}]^{\mathrm{T}}.$$

Taking the norm on the above equation and using the star product properties, we have

$$\begin{aligned} \|\tilde{X}_i(k)\|^2 \le \|\tilde{X}_i(k-1)\|^2 &- 2\mu \operatorname{tr}\left\{ \begin{bmatrix} A_{1i}\tilde{X}_i(k-1)B_{1i} \\ A_{2i}\tilde{X}_i(k-1)B_{2i} \\ \vdots \\ A_{pi}\tilde{X}_i(k-1)B_{pi} \end{bmatrix}^{\mathrm{T}} \begin{bmatrix} \tilde{C}_1(k) \\ \tilde{C}_2(k) \\ \vdots \\ \tilde{C}_p(k) \end{bmatrix} \right\} \\ &+ \mu^2 \sum_{j=1}^{p} \|A_{ji}B_{ji}\|^2 \left\| \begin{bmatrix} \tilde{C}_1(k) \\ \tilde{C}_2(k) \\ \vdots \\ \tilde{C}_p(k) \end{bmatrix} \right\|^2. \end{aligned} \tag{22}$$

Define a nonnegative definite function:

$$V(k) = \sum_{i=1}^{p} \|\tilde{X}_i(k)\|^2.$$

By using (22), it follows that

$$\begin{aligned} V(k) &\le V(k-1) - 2\mu \left\| \begin{bmatrix} \tilde{C}_1(k) \\ \tilde{C}_2(k) \\ \vdots \\ \tilde{C}_p(k) \end{bmatrix} \right\|^2 + \mu^2 \sum_{i=1}^{p}\sum_{j=1}^{p} \|A_{ji}B_{ji}\|^2 \left\| \begin{bmatrix} \tilde{C}_1(k) \\ \tilde{C}_2(k) \\ \vdots \\ \tilde{C}_p(k) \end{bmatrix} \right\|^2 \\ &= V(k-1) - \mu \left(2 - \mu \sum_{i=1}^{p}\sum_{j=1}^{p} \|A_{ij}B_{ij}\|^2 \right) \sum_{i=1}^{p} \|\tilde{C}_i(k)\|^2 \\ &\le V(0) - \mu \left(2 - \mu \sum_{i=1}^{p}\sum_{j=1}^{p} \|A_{ij}B_{ij}\|^2 \right) \sum_{l=1}^{\infty}\sum_{i=1}^{p} \|\tilde{C}_i(l)\|^2. \end{aligned} \tag{23}$$

If the convergence factor μ is chosen to satisfy

$$0 < \mu < 2 \left(\sum_{i=1}^{p}\sum_{j=1}^{p} \|A_{ij}B_{ij}\|^2 \right)^{-1},$$

then

$$\sum_{k=1}^{\infty}\sum_{i=1}^{p} \|\tilde{C}_i(k)\|^2 < \infty.$$

It follows that as $k \to \infty$,

$$\sum_{i=1}^{p} \|\tilde{C}_i(k)\|^2 = \sum_{j=1}^{p} \|A_{ij}\tilde{X}_j(k-1)B_{ij}\|^2 = 0$$

or

$$\sum_{j=1}^{p} A_{ij}\tilde{X}_j(k-1)B_{ij} \to \mathbf{0}, \quad i = 1,\ 2,\ \ldots,\ p.$$

According to Lemma 2, this complete the proof of Theorem 3. □

Let

$$X(k) = \begin{bmatrix} X_1(k) \\ X_2(k) \\ \vdots \\ X_p(k) \end{bmatrix} \in \mathbb{R}^{(mp)\times n}, \quad C = \begin{bmatrix} C_1 \\ C_2 \\ \vdots \\ C_p \end{bmatrix} \in \mathbb{R}^{(mp)\times n}.$$

Then (17) can be simply expressed as

$$S_A \star X \star S_B I_{np\times n} = C.$$

By using the star product properties, (20) can be written in the following more compact form:

$$X(k) = X(k-1) + \mu S_A^{\mathrm{T}} \begin{bmatrix} C_1 - \sum_{j=1}^{p} A_{1j} X_j(k-1) B_{1j} \\ C_2 - \sum_{j=1}^{p} A_{2j} X_j(k-1) B_{2j} \\ \vdots \\ C_p - \sum_{j=1}^{p} A_{pj} X_j(k-1) B_{pj} \end{bmatrix} \star S_{B^{\mathrm{T}}}$$

$$= X(k-1) + \mu S_A^{\mathrm{T}} [C - S_A \star X(k-1) \star S_B I_{np \times n}] \star S_{B^{\mathrm{T}}}. \tag{24}$$

The convergence factor in the algorithm in (20) or (24) may also be taken as

$$0 < \mu < 2 \left\{ \sum_{i=1}^{p} \sum_{j=1}^{p} \lambda_{\max}[A_{ij} A_{ij}^{\mathrm{T}}] \lambda_{\max}[B_{ij} B_{ij}^{\mathrm{T}}] \right\}^{-1}.$$

5. Examples. In this section, we present two examples to illustrate the performance of the proposed algorithms.

Example 1. Suppose that the coupled Sylvester matrix equations are $AX + YB = C$ and $DX + YE = F$ with

$$A = \begin{bmatrix} 2.00 & 1.00 \\ -1.00 & 2.00 \end{bmatrix}, \quad B = \begin{bmatrix} 1.00 & -0.20 \\ 0.20 & 1.00 \end{bmatrix}, \quad C = \begin{bmatrix} 13.20 & 10.60 \\ 0.60 & 8.40 \end{bmatrix},$$

$$D = \begin{bmatrix} -2.00 & -0.50 \\ 0.50 & 2.00 \end{bmatrix}, \quad E = \begin{bmatrix} -1.00 & -3.00 \\ 2.00 & -4.00 \end{bmatrix}, \quad F = \begin{bmatrix} -9.50 & -18.00 \\ 16.00 & 3.50 \end{bmatrix}.$$

Then the unique solutions of X and Y from (7) are

$$X = \begin{bmatrix} x_{11} & x_{12} \\ x_{21} & x_{22} \end{bmatrix} = \begin{bmatrix} 4.00 & 3.00 \\ 3.00 & 4.00 \end{bmatrix},$$

$$Y = \begin{bmatrix} y_{11} & y_{12} \\ y_{21} & y_{22} \end{bmatrix} = \begin{bmatrix} 2.00 & 1.00 \\ -2.00 & 3.00 \end{bmatrix}.$$

Taking $X(0) = Y(0) = 10^{-6}\mathbf{1}_{2\times 2}$, we apply the algorithm in (14) and (15) to compute $X(k)$ and $Y(k)$. The iterative solutions $X(k)$ and $Y(k)$ are shown in Table 1, where

$$\delta = \sqrt{\frac{\|X(k) - X\|^2 + \|Y(k) - Y\|^2}{\|X\|^2 + \|Y\|^2}}$$

is the relative iteration error. The errors δ with different convergence factors μ are shown in Figure 1. From Table 1 and Figure 1, it is clear that the errors are becoming smaller and smaller and go to zero as k increases. This indicates that the proposed algorithm is effective. The effect of changing the convergence factor μ is also illustrated in Figure 1. We see that for $\mu = 1/101.16, 1/38.47, 1/30, 1/20$, the

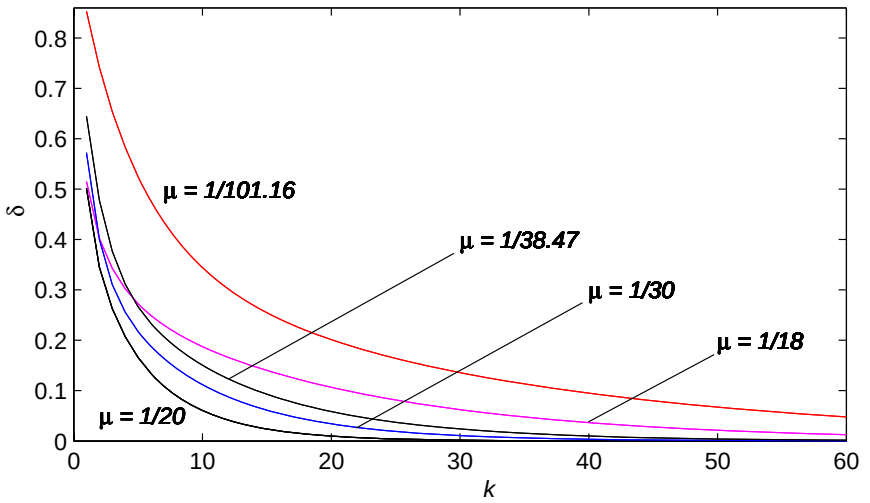

FIG. 1. *The relative error* δ *versus* k. $\mu = [\|A\|^2 + \|B\|^2 + \|D\|^2 + \|E\|^2]^{-1} = 1/101.16$, $\mu_0 = 2/38.47$, $\mu = \{\lambda_{\max}[A^{\mathrm{T}}A] + \lambda_{\max}[D^{\mathrm{T}}D] + \lambda_{\max}[BB^{\mathrm{T}}] + \lambda_{\max}[EE^{\mathrm{T}}]\}^{-1} = 1/38.47$.

larger the convergence factor μ is, the faster the convergence rate of the algorithm (or, the smaller the iteration error). However, if we keep enlarging μ, e.g., $\mu = 1/18$, the iteration error will become larger. Thus, there exists a best convergence factor such that the fastest convergence rate is obtained. This is still a topic left for the future.

Example 2. Suppose that the coupled matrix equations are

$$A_{11}X_1B_{11} + A_{12}X_2B_{12} = C_1,$$
$$A_{21}X_1B_{21} + A_{22}X_2B_{22} = C_2,$$

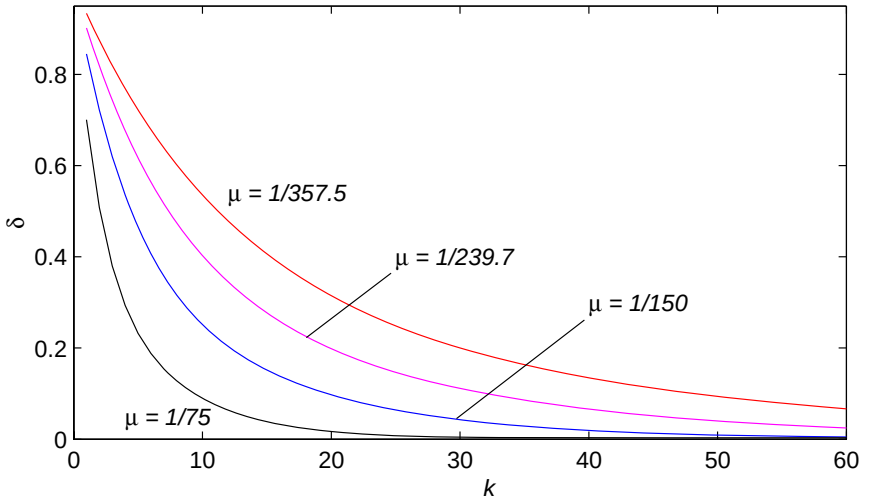

FIG. 2. *The relative error δ versus k.* $\mu = (\sum_{i=1}^{2}\sum_{j=1}^{2}\|A_{ij}B_{ij}\|^2)^{-1} = 1/357.5$, $\mu_0 = 2/239.7$, $\mu = \{\sum_{i=1}^{2}\sum_{j=1}^{2}\lambda_{\max}[A_{ij}^{\mathrm{T}}A_{ij}]\lambda_{\max}[B_{ij}^{\mathrm{T}}B_{ij}]\}^{-1} = 1/239.7$.

where

$$A_{11} = \begin{bmatrix} 3.00 & -2.00 \\ -1.00 & 1.00 \end{bmatrix}, \quad B_{11} = \begin{bmatrix} 1.00 & 1.00 \\ -1.00 & -2.00 \end{bmatrix}, \quad A_{12} = \begin{bmatrix} 2.00 & 1.00 \\ 1.00 & -2.00 \end{bmatrix},$$

$$B_{12} = \begin{bmatrix} 1.00 & -2.00 \\ -1.00 & 2.00 \end{bmatrix}, \quad C_1 = \begin{bmatrix} 1.30 & -3.60 \\ -2.10 & -1.30 \end{bmatrix},$$

$$A_{21} = \begin{bmatrix} 1.00 & 2.00 \\ 1.50 & -1.00 \end{bmatrix}, \quad B_{21} = \begin{bmatrix} 2.00 & -1.00 \\ 1.00 & 2.00 \end{bmatrix}, \quad A_{22} = \begin{bmatrix} 1.00 & -2.00 \\ 2.00 & -1.00 \end{bmatrix},$$

$$B_{22} = \begin{bmatrix} 1.00 & -1.00 \\ -2.00 & 1.00 \end{bmatrix}, \quad C_2 = \begin{bmatrix} 17.40 & 24.10 \\ 12.55 & 2.20 \end{bmatrix}.$$

Taking $X_1(0) = X_2(0) = 10^{-6}\mathbf{1}_{2\times 2}$, we apply the algorithm in (20)–(21) to compute $X_1(k)$ and $X_2(k)$. The iterative errors δ with different convergence factors μ are shown in Figure 2.

From Figure 2, we conclude that as μ increases from $\mu = 1/357.5, 1/239.7, 1/150$ to $1/75$, the iteration errors become smaller and smaller and eventually go to zero. This confirms the proposed theorems. In simulation, as we gradually enlarge μ, e.g., when $\mu > 1/70$, the errors become larger, and the algorithm diverges for $\mu > 1/65$.

6. Conclusions. Gradient iterative algorithms for solving Sylvester coupled matrix equations and general coupled matrix equations are studied by using the gradient search principle. The analysis indicates that, as in the least squares iterative algorithms in [9], the gradient iterative algorithms can achieve good convergence properties for any initial values. The family of iterative methods proposed for linear (coupled) matrix equations can be extended to study iterative solutions of other linear or nonlinear matrix equations, e.g., Riccati equations.

Appendix. Examples on stability. For a time-varying system,

$$x(k) = H_k x(k-1),\ H_k \in \mathbb{R}^{n\times n},\ x(0) = x_0 \neq 0, \tag{25}$$

even if H_k is stable for any k, i.e., all eigenvalues of H_k are inside the unit circle, there is no guarantee that system (25) is stable, implying $x(k) \to 0$. For example, take

$$H_k = \frac{1}{8}\begin{bmatrix} 0 & 9+(-1)^k 7 \\ 9-(-1)^k 7 & 0 \end{bmatrix}.$$

The two eigenvalues of H_k, $\pm\frac{1}{\sqrt{2}}$, are inside the unit circle, but the transition matrix of the system is given by

$$L_k = \begin{cases} \begin{bmatrix} 0 & 2^{-2k} \\ 2^k & 0 \end{bmatrix}, & k \text{ is odd}, \\ \begin{bmatrix} 2^k & 0 \\ 0 & 2^{-2k} \end{bmatrix}, & k \text{ is even}. \end{cases}$$

Clearly, the system $x(k) = H_k x(k-1)$ is unstable.

For another example, take

$$H_k = \begin{bmatrix} 1-(-1)^k & 0 \\ 0 & 1+(-1)^k \end{bmatrix}$$

or

$$H_k = \begin{cases} \begin{bmatrix} 2 & 0 \\ 0 & 0 \end{bmatrix}, & k \text{ is odd}, \\ \begin{bmatrix} 0 & 0 \\ 0 & 2 \end{bmatrix}, & k \text{ is even}. \end{cases}$$

One eigenvalue of H_k is 2, outside the unit circle, but the system $x(k) = H_k x(k-1)$ is exponentially stable.

SOME NEW REGULARITY PROPERTIES FOR THE MINIMAL TIME FUNCTION*

GIOVANNI COLOMBO†, ANTONIO MARIGONDA†, AND PETER R. WOLENSKI‡

Abstract. A minimal time problem with linear dynamics and convex target is considered. It is shown, essentially, that the epigraph of the minimal time function $T(\cdot)$ is φ-convex (i.e., it satisfies a kind of exterior sphere condition with locally uniform radius), provided $T(\cdot)$ is continuous. Several regularity properties are derived from results in [G. Colombo and A. Marigonda, Calc. Var. Partial Differential Equations, 25 (2005), pp. 1–31], including twice a.e. differentiability of $T(\cdot)$ and local estimates on the total variation of DT.

Key words. nonsmooth analysis, proximally smooth and φ-convex sets, small time controllability, functions with φ-convex epigraph

AMS subject classifications. 49N05, 49J52

DOI. 10.1137/050630076

1. Introduction.

The regularity of the minimal time function $T(\cdot)$ is a widely studied topic (see, e.g., [5, 24, 6, 7, 8, 25, 3] and references therein), under different viewpoints. In particular, it is proved in [7] that with linear dynamics and convex target, $T(\cdot)$ is semiconvex provided the Petrov condition holds. The latter is equivalent to the Lipschitz continuity of $T(\cdot)$ near the target and thus is a type of *strong* local controllability condition. Since $T(\cdot)$ is not necessarily convex (see p. 100 in [14]) even for a point-target, this is a natural regularity class for a linear minimum time problem.

Classical examples, however, exhibit minimal time functions that are not locally Lipschitz even though the system is small time locally controllable (see, e.g., [3, Example 2.7, p. 242]). Therefore, it is natural to seek conditions that identify regularity properties of $T(\cdot)$ in situations where $T(\cdot)$ is not locally Lipschitz. This motivated the results in [12], where a class of lower semicontinuous functions was studied whose epigraph satisfy an external sphere condition with locally uniform radius; this property, for general sets, is often referred to as *positive reach* [16], *φ-convexity* [15], or *proximal smoothness* [11]. Such functions are semiconvex if and only if they are locally Lipschitz and therefore are a good candidate to extend the result in [7] under more general controllability conditions. In [12], functions with φ-convex epigraph were shown to have several fine properties. In particular, a function in this class is of locally bounded variation; moreover, a.e. x admits a neighborhood where the function is indeed semiconvex, and as a consequence it is twice differentiable almost everywhere.

It will be shown below that the epigraph of $T(\cdot)$ is φ-convex, under suitable controllability assumptions. More precisely, we prove that for a linear control problem with a convex target S, the epigraph of $T(\cdot)$ is φ-convex (Theorem 3.7), provided T is continuous. Our assumptions are satisfied in several situations, including, e.g., the

case where the system fulfils the Kalman rank condition and the target is the origin. An example where small time controllability does not hold, yet is covered by Theorem 3.7, is presented in section 2.4.

Our analysis depends on a representation formula for the normal cone to sublevel sets of T, which is proved using simple tools of convex analysis together with Pontryagin's maximum principle. The techniques used here are essentially linear, due to the repeated use of explicit formulas. The main difficulty to handle is the possibility of having points where both the subdifferential and the superdifferential of T are empty, due to the lack of Lipschitz continuity. Finally, the regularity results in [12] are applied to $T(\cdot)$, and the corresponding properties of T are listed in Corollary 3.8.

We recall that for nonlinear dynamics, the semiconvexity of $T(\cdot)$ is generally not present (see, e.g., [6, Example 4.3]). However, in analogy with [6] and [8], one may expect regularity results of a similar nature under more restrictive assumptions on the target and dynamics. We mention that proving such a nonlinear result by methods analogous to ours must overcome two main difficulties: first, the existing nonlinear results rely either on the Lipschitz continuity of $T(\cdot)$ (see [7]) or are rather general, but provide substantially weaker estimates (see [8]); second, weaker controllability conditions lead to singularities of $T(\cdot)$ that are of both semiconvex and semiconcave type (see [4]) together with cusp points. Hence it is not clear how to obtain a nonlinear version of our Theorem 3.1, and this will be a topic of future research.

2. Preliminaries. This section briefly introduces concepts from nonsmooth analysis, geometric measure theory, and control theory.

2.1. Nonsmooth analysis. A standard reference for the nonsmooth concepts introduced here is [10]. Let $K \subseteq \mathbb{R}^n$ be closed. We denote, for $x \in \mathbb{R}^n$,

$$\begin{array}{rcll} d_K(x) & = & \min\{\|y-x\| : y \in K\} & \text{(the distance of } x \text{ from } K\text{)}, \\ \pi_K(x) & = & \{y \in K : \|y-x\| = d_K(x)\} & \text{(the projections of } x \text{ onto } K\text{)}, \\ B(K,\rho) & = & \{y \in \mathbb{R}^n : d_K(y) \le \rho\}. & \end{array}$$

A vector v is a *proximal normal* to K at $x \in K$ (notated by $v \in N_K^P(x)$) if there exists $\sigma = \sigma(v,x) \ge 0$ such that

$$\langle v, y-x\rangle \le \sigma\|y-x\|^2 \quad \text{for all } y \in K. \tag{2.1}$$

For $v \neq 0$, then $v \in N_K^P(x)$ if and only if this there exists $\lambda > 0$ such that $\pi_K(x+\lambda v) = \{x\}$. If K is convex, then $N_K^P(x)$ equals the normal cone $N_K(x)$ to K at x as defined in convex analysis, namely, the set of vectors $v \in \mathbb{R}^n$ for which

$$\langle v, y-x\rangle \le 0 \quad \text{for all } y \in K.$$

Suppose $f : \mathbb{R}^n \to \mathbb{R}\cup\{+\infty\}$ is lower semicontinuous and $\mathrm{epi}(f) := \{(x,\xi) : \xi \ge f(x)\}$ and $\mathrm{dom}(f) = \{x \in \mathbb{R}^n : f(x) < +\infty\}$ are its epigraph and (effective) domain, respectively. Let $x \in \mathrm{dom}(f)$. A vector $\zeta \in \mathbb{R}^n$ is a *proximal subgradient* of f at x (notated by $\zeta \in \partial_P f(x)$) if $(\xi,-1) \in N^P_{\mathrm{epi}(f)}(x, f(x))$; equivalently (see [10, Theorem 1.2.5]), $\xi \in \partial_P f(x)$ if and only if there exist $\sigma, \eta > 0$ such that

$$f(y) \ge f(x) + \langle \zeta, y-x\rangle - \sigma\|y-x\|^2 \quad \text{for all } y \in B(x,\eta). \tag{2.2}$$

The following class of sets (see [11, section 4]) will play a major role in our analysis.

Definition 2.1. *Suppose $K \subseteq \mathbb{R}^n$ is closed and $r > 0$. Then K is* r-proximally smooth *if the distance function d_K is continuously differentiable on $B(K,r)\setminus K$.*

Geometrically, in virtue of [11, Theorem 4.1], this means that every nonzero proximal normal to K is realized by an r-ball, i.e.,

$$\langle v, y - x\rangle \le \frac{1}{2r}\|y - x\|^2 \tag{2.3}$$

for all $x, y \in K$ and $v \in N_K^P(x)$, $\|v\| = 1$. Moreover, if K is proximally smooth, then the Clarke normal cone to K at x coincides with $N_K^P(x)$ for all $x \in K$, and in particular $N_K^P(x)$ is nontrivial (see [11]) at all points x on the boundary of K.

Proximal smoothness is rather restrictive for noncompact sets such as epigraphs. The following generalization allows for the constant in (2.3) to depend on x.

DEFINITION 2.2. *Suppose $K \subseteq \mathbb{R}^n$ is closed and $\varphi : K \to [0, +\infty)$ is continuous. We say that K is φ-convex if*

$$\langle v, y - x\rangle \le \varphi(x)\|y - x\|^2 \tag{2.4}$$

for all $x, y \in K$ and $v \in N_K^P(x)$ with $\|v\| = 1$.

Comparing (2.3) and (2.4) reveals that K is r-proximally smooth if and only if it is φ-convex with $\varphi(x) = \frac{1}{2r}$ for all $x \in K$. Such sets are also referred to as prox-regular in [22], and several characterizations are known (see [16, 11, 22]). However, they will not be used here. We recall that, in particular, convex sets, or sets with a $\mathcal{C}^{1,1}$-boundary, are φ-convex.

If K is the epigraph of a continuous function $T(\cdot)$, then the φ-convexity condition (2.4) takes the form

$$\langle (\zeta, \xi), (y, \beta) - (x, \alpha)\rangle \le \varphi(x, \alpha)(\|\zeta\| + |\xi|)\,(\|y - x\|^2 + |\beta - \alpha|^2) \tag{2.5}$$

for all $x, y \in \mathrm{dom}(T)$, $\alpha \ge T(x)$, $\beta \ge T(y)$, $(\zeta, \xi) \in N^P_{\mathrm{epi}(T)}(x, \alpha)$, with $\varphi : \mathrm{epi}(T) \to [0, +\infty)$ continuous.

2.2. Geometric measure theory. The study of some fine regularity properties of φ-convex sets and functions with φ-convex epigraph is taken up in [12] and will be quoted here. Stating these requires concepts from geometric measure theory [1, 20].

For $0 \le k \le n$, the k-dimensional Hausdorff measure in $\mathbb{R}^n$ is denoted by $\mathcal{H}^k$. The Hausdorff dimension of a set E is $\mathcal{H} - \dim(E) := \inf\{k \ge 0 : \mathcal{H}^k(E) = 0\}$. A set $E \subseteq \mathbb{R}^n$ is *countably k-rectifiable* if there exist countably many Lipschitz functions $f_i : \mathbb{R}^k \to \mathbb{R}^n$ such that

$$\mathcal{H}^k\left(E \setminus \bigcup_{i=0}^{+\infty} f_i(\mathbb{R}^k)\right) = 0.$$

Let $\Omega \subset \mathbb{R}^n$ be open, and $u \in L^1(\Omega)$; we say that u is a *function of bounded variation in Ω* ($u \in BV(\Omega)$) if the distributional derivative of u is representable by a finite Radon measure in Ω, i.e., if

$$\int_\Omega u \frac{\partial \varphi}{\partial x_i}\, dx = -\int_\Omega \varphi\, dD_i u \text{ for all } \varphi \in C_c^\infty(\Omega),\ i = 1, \dots, n,$$

for some finite Radon measure $Du = (D_1 u, \dots, D_n u)$.

2.3. Control theory: Generalities. We consider throughout the paper a linear control system of the form

$$\left\{\begin{array}{lcl} \dot{y}(t) & = & Ay(t)+u(t) \quad \text{a.e.},\\ u(t) & \in & \mathcal{U} \ \text{a.e.},\\ y(0) & = & x, \end{array}\right. \tag{2.6}$$

where $A \in \mathrm{Mat}_{n\times n}(\mathbb{R})$. The control set $\mathcal{U} \subset \mathbb{R}^n$ is compact and convex, and the control function $u(\cdot)$ is measurable. For all $t > 0$, we denote by $\mathcal{U}^t_{\mathrm{ad}}$ the set of admissible controls, i.e., the measurable functions $u : [0,t] \to \mathbb{R}^n$, such that $u(t) \in \mathcal{U}$ a.e. on $[0,t]$. For any $u(\cdot) \in \mathcal{U}^t_{\mathrm{ad}}$, the unique Carathéodory solution of (2.6) is denoted by $y^{x,u}(\cdot)$.

Suppose we are now given a closed nonempty set $S \subset \Omega$, which is called the *target set*. For fixed $x \notin S$, the *minimal time* $T(x)$ to reach S from x is defined by

$$T(x) := \inf\{T \geq 0 \,:\, \exists\, u(\cdot) \text{ such that } y^{x,u}(T) \in S\}.$$

When the set of controls $u(\cdot)$ steering x to S is empty, then $T(x) = +\infty$. Since the velocity sets $F(y) := \{Ay + u \,:\, u \in \mathcal{U}\}$ are convex, then standard arguments (see [9, Theorem 9.2.i, p. 311]) show the infimum is actually a minimum (provided it is finite); that is, there exists an optimal control steering x to S in the minimal time.

The reachable set from a point $x \in \Omega$ in time T is the set

$$R^T(x) = \{y(T) : y(\cdot) \text{ satisfies (2.6)}\}.$$

If $\bar{x} \in R^T(x)$, then $\bar{x}$ is *realized* by the control function $\bar{u}(\cdot)$ if $\bar{x} = y^{x,\bar{u}}(T)$. Note that $\bar{x} \in R^T(x)$ is realized by $\bar{u}(\cdot)$ if and only if the (equivalent) formulas

$$\bar{x} = e^{AT}x + \int_0^T e^{A(T-t)}\bar{u}(t)\,dt \quad \text{and} \quad x = e^{-AT}\bar{x} - \int_0^T e^{-At}\bar{u}(t)\,dt \tag{2.7}$$

hold. It is well known that $R^T(x)$ is convex and compact. It is convenient to also notate as $R^T_-(\bar{x})$ the reversed-time reachable set from a point $\bar{x}$, which is the reachable set associated to the dynamics $\dot{y} = -Ay - u$. Namely,

$$R^T_-(\bar{x}) = \{y(T) : \dot{y}(t) = -Ay(t) - u(t),\ u(\cdot) \in \mathcal{U}^T_{\mathrm{ad}} \text{ a.e.},\ y(0) = \bar{x}\}.$$

It is clear that $\bar{x} \in R^T(x)$ if and only if $x \in R^T_-(\bar{x})$. For $r > 0$, let

$$\begin{aligned} S(r) &= \{x \in \mathbb{R}^n : T(x) \leq r\},\\ \mathcal{R} &= \{x \in \mathbb{R}^n : T(x) < +\infty\}, \end{aligned}$$

and observe

$$S(r) = \bigcup_{\bar{x}\in S,\, 0\leq T\leq r} R^T_-(\bar{x}).$$

Recall that a closed set $S \subseteq \Omega$ is *strongly invariant* for the system (2.6) if for all $x \in S$ and $T > 0$, one has $R^T(x) \subseteq S$. Analogously, S is *weakly invariant* (or *viable*) if for all $x \in S$ and all small $T > 0$, there exists a trajectory of (2.6) which remains in S for all $t \in [0,T]$.

A major tool in our analysis is the minimized Hamiltonian $h : \mathbb{R}^n \times \mathbb{R}^n \to \mathbb{R}$, given by

$$h(x,\zeta) = \langle Ax,\zeta\rangle + \min_{u\in\mathcal{U}}\langle u,\zeta\rangle. \tag{2.8}$$

It is known that a set S is weakly invariant for the dynamics (2.6) if $h(x,\zeta)\le 0$ for all $x\in S$ and $\zeta\in N_S^P(x)$ (see [24], [10, Theorem 2.10]).

The *adjoint equation* associated with (2.6) is

$$\begin{cases} \dot p(t) = -A^\top p(t), \\ p(T) = \bar p, \end{cases} \tag{2.9}$$

and an adjoint arc is

$$p(t) = e^{A^\top(T-t)}\bar p, \tag{2.10}$$

which is the solution of (2.9). Pontryagin's maximum principle is stated next.

PROPOSITION 2.3 (maximum principle). *Suppose $\bar x\in R^T(x)$ is realized by $\bar u(\cdot)$. Then $\bar x\in$ bdry $R^T(x)$ (= the boundary of $R^T(x)$) if and only if there exists $\bar p\neq 0$ so that the solution $\bar p(\cdot)$ of* (2.9) *satisfies*

$$\langle \bar p(t),\bar u(t)\rangle = \max_{u\in U}\langle \bar p(t),u\rangle \tag{2.11}$$

for almost all $t\in[0,T]$. Moreover, in this case, $p(t)\in N_{R^t(x)}\big(y^{x,\bar u}(t)\big)$ for each $t\in[0,T]$.

A standard reference for the proof is [17, section 13].

2.4. Continuity of the minimal time function. Continuity properties of the minimal time function is a widely studied topic, mainly in connection with controllability. We refer to Chapter IV in [3] and references therein for an introduction to the subject.

DEFINITION 2.4. *The control system* (2.6) *is* small time controllable *(STC) near the target S if $S\subseteq$ int $S(r)$ for all small $r>0$.*

We collect some known results relating STC to continuity of $T(\cdot)$, with main emphasis on a target more general than a singleton, in the following theorem.

THEOREM 2.5. *Assume (for simplicity) that S is compact.*

(1) *Suppose $S=\{0\}$ and $0\in$ rel int $S(r)$ for all $r>0$. Then $T(\cdot)$ is continuous on $\mathcal{R}$.*

(2) (Generalized Petrov condition.) *Suppose there exist $\delta>0$ and a continuous nondecreasing function $\mu:[0,\delta]\to[0,+\infty)$ with the properties*

(a) *$\mu(0)=0$, $\mu(\rho)>0$ for $\rho>0$, and $\int_0^\delta \frac{d\rho}{\mu(\rho)}<+\infty$;*

(b) *for all $x\in B(S,\delta)\setminus S$ there exists $\bar s\in\pi_S(x)$ such that*

$$h(x,x-\bar s)\le -\mu(\|x-\bar s\|)\|x-\bar s\|. \tag{2.12}$$

Then the system (2.6) *is STC near S and the minimal time function is continuous in a neighborhood of S.*

(3) (Second order Petrov condition.) *Suppose that S is the closure of an open set with $\mathcal{C}^2$-boundary, and assume that there exist $\delta>0$ and $\eta>0$ such that for all $x\in B(S,\delta)\setminus S$,*

(a) *$h(x,Dd_S(x))\le 0$,*

(b) $\langle Dd_S(x), A^2x\rangle + 2\left\langle \langle D^2 d_S(x), Ax\rangle, Ax\right\rangle \leq -\eta$.

Then the system (2.6) *is STC near* S *and the minimal time function is Hölder continuous with exponent* $1/2$ *in a neighborhood of* S.

(4) *Suppose* $S = \{0\}$ *and* $\mathcal{U} = \{Bu : u \in \mathbb{R}^m,\ u \in [-1,1]^m\}$, $B \in Mat_{n\times m}(\mathbb{R})$. *The following are equivalent for a fixed integer* k, $k = 0, 1, \ldots, n-1$.

(a) $T(\cdot)$ *is Hölder continuous in* $\mathbb{R}^n$ *with exponent* $1/(k+1)$;

(b) (Kalman rank condition)

$$\operatorname{rank}[B, AB, \ldots, A^kB] = n.$$

Proof. The proof of (1) is in [14, Theorem II.4.3]. Various versions of (2), obtained with different methods, can be found, e.g., in [24], [6], [7, Chapter 8, section 8.2], [23], [18], [21], [19]. Condition (3) is a particular case of a controllability result contained in [19]. The proof of (4) can be found in [2, Chapter 2, section 6]. □

We will consider a slightly more general situation, where the continuity of the minimal time function is not directly linked to an STC condition. We illustrate this with a simple example.

Example 1. *Let* $\alpha > 1$ *and* $S = \{(x,y) \in \mathbb{R}^2 : y \geq |x|^\alpha\}$. Let $\mathcal{U} = [-1,1]$ and consider the linear control system

$$\left\{ \begin{array}{rcl} \dot{x} &=& u \in \mathcal{U}, \\ \dot{y} &=& 0. \end{array} \right. \tag{2.13}$$

None of the conditions listed in Theorem 2.5 is satisfied in a neighborhood of S, and actually $\mathcal{R} = \mathbb{R} \times [0, +\infty)$ is not a neighborhood of S. Let $x > 0$, $0 \leq y < x^\alpha$. Then $T(x,y) = x - y^{1/\alpha}$, which is continuous on $\mathcal{R} \setminus S$ but not locally Lipschitz. We observe that for all (x,y), there exists a control $u(x,y)$ (actually $u(x,y) = -\operatorname{sgn}(x)$) such that $A(x,y) + u(x,y) = (u(x,y), 0)$ points toward S. However, the angle between the vector pointing to S and the external normal to S is not uniformly bounded away from 0, and in fact this angle tends to 0 as $(x,y) \to (0,0)$. We estimate its rate of convergence to 0 along the x-axis. Let $\xi(x) = x + \alpha x^{2\alpha-1}$. Observe that the segment joining $(\xi(x), 0)$ and (x, x^α) is orthogonal to the graph of $y = x^\alpha$ at (x, x^α). Moreover, $\xi(x) \sim x$ for $x \to 0$ and

$$d_S((\xi(x), 0)) = x^\alpha \sqrt{1 + \alpha^2 x^{2(\alpha-1)}} \sim x^\alpha \text{ for } x \to 0.$$

Finally,

$$\begin{aligned} \min_{u\in[-1,1]} \left\langle (u,0), \frac{(\xi(x),0) - (x,x^\alpha)}{d_S(\xi(x),0)} \right\rangle &= \frac{x - \xi(x)}{d_S(\xi(x),0)} \\ &= -\frac{\alpha x^{\alpha-1}}{\sqrt{1 + \alpha^2 x^{2(\alpha-1)}}} \\ &\leq -\text{const}\,(d_S(\xi(x),0))^{\frac{\alpha-1}{\alpha}}. \end{aligned}$$

□

In this example, the angle satisfies an estimate of the type (2.12). However, this estimate does not hold in an entire neighborhood of S, and the continuity of T in $\mathcal{R}$ is not covered by any of the statements in Theorem 2.5. The forthcoming paper [19] contains a result covering the Hölder continuity of T in $\mathcal{R}$ also in the above example.

3. The epigraph of the minimal time function, and differentiability properties. We repeat the setting we are concerned with. We consider the linear system

$$\left\{\begin{array}{lcll} \dot{y}(t) & = & Ay(t)+u(t) & \text{a.e.,} \\ y(0) & = & x, & \\ u(t) & \in & \mathcal{U} & \text{a.e.} \end{array}\right. \tag{3.1}$$

with $\mathcal{U} \subseteq \mathbb{R}^n$ compact and convex. Let $S \neq \emptyset$ be the target set.

Let $\delta > 0$ be given, and set $\mathcal{R}_\delta = S(\delta) \setminus S$. We make the following further assumptions:

(H1) S is closed and convex, and $h(x,\zeta) \leq 0$ for all $x \in S$ and $\zeta \in N_S(x)$;

(H2) $T(\cdot)$ is continuous in $S(\delta)$.

Observe that (H1) and (H2) do not imply STC, because $S(\delta)$ is not required to be a neighborhood of S. Such a situation is illustrated by Example 1.

The following result is an easy consequence of (H1).

PROPOSITION 3.1. *Under the above assumption* (H1)*, the sets $S(r)$ are compact and convex, and if $r_1 \leq r_2$ we have $S(r_1) \subseteq S(r_2)$. Therefore $\mathcal{R}$ is convex.*

We need a few technical lemmas. A version of Lemmas 3.2 and 3.3 already appeared in [13, section 2]. We repeat the proofs here, in order to make this paper more self-contained. The first two concern a representation of the normal cone to the level sets of T and of the proximal subdifferential of T.

LEMMA 3.2. *Let* (H1) *hold, and let $r \geq 0$, $x \in \mathbb{R}^n$ with $T(x) = r$, and $\bar{x} \in S \cap R^r(x)$. Then*

$$N_{S(r)}(x) = \Big\{ -e^{A^\top r}\bar{p} : \bar{p} \in [-N_S(\bar{x})] \cap N_{R^r(x)}(\bar{x}) \Big\}, \tag{3.2}$$

and therefore the right-hand side is independent of $\bar{x} \in S \cap R^r(x)$.

Proof (see also [13, Theorems 4 and 8]).

"$\subseteq$." Let $\zeta \in N_{S(r)}(x)$. Then, by convexity,

$$\langle \zeta, y - x \rangle \leq 0 \quad \text{for all } y \in S(r). \tag{3.3}$$

Let $\bar{u}(\cdot) \in \mathcal{U}_{ad}^r$ be an admissible control that realizes $\bar{x}$, and thus (2.7) holds with $T = r$. The rest of the proof is broken into two claims. □

Claim 1. $e^{-A^\top r}\zeta \in N_S(\bar{x})$.

Proof of Claim 1. Let $\bar{y} \in S$, and define

$$y = e^{-Ar}\bar{y} - \int_0^r e^{-At}\bar{u}(t)\,dt, \tag{3.4}$$

which therefore belongs to $S(r)$. We have

$$\begin{aligned} \langle e^{-A^\top r}\zeta, \bar{y} - \bar{x} \rangle &= \langle \zeta, e^{-Ar}\bar{y} - e^{-Ar}\bar{x} \rangle \\ &= \langle \zeta, y - x \rangle \quad \text{(by (2.7) and (3.4))} \\ &\leq 0 \quad \text{(by (3.3) and since } y \in S(r)\text{)}. \end{aligned}$$

It follows that $e^{-A^\top r}\zeta \in N_S(\bar{x})$.

Claim 2. $-e^{-A^\top r}\zeta \in N_{R^r(x)}(\bar{x})$.

Proof. First note that $x \in R^r_-(\bar{x}) \subseteq S(r)$, and therefore $\zeta \in N_{R^r_-(\bar{x})}(x)$. By Proposition 2.3 applied to the reversed time data $-A$ and $-\mathcal{U}$, we have that for all $t \in [0, r]$,

$$\left\langle -e^{-A^\top t}\zeta, \bar{u}(t) \right\rangle = \max_{u \in U} \left\langle -e^{-A^\top t}\zeta, u \right\rangle. \tag{3.5}$$

Now suppose $\bar{y} \in R^r(x)$, so that

$$\bar{y} = e^{Ar}x + \int_0^r e^{A(r-t)}u(t)\,dt$$

for some $u(\cdot) \in \mathcal{U}^r_{ad}$. We have

$$\begin{aligned}\left\langle -e^{-A^\top r}\zeta, \bar{y} - \bar{x} \right\rangle &= \left\langle -e^{-A^\top r}\zeta, \int_0^r e^{A(r-t)}\big(u(t) - \bar{u}(t)\big)\,dt \right\rangle \\ &= \int_0^r \left\langle -e^{-A^\top t}\zeta, u(t) - \bar{u}(t) \right\rangle dt \\ &\le 0,\end{aligned}$$

where the last inequality follows from (3.5). The validity of Claim 2 is now established.

It is clear that the "$\subseteq$" inclusion in (3.2) follows from Claims 1 and 2.

"$\supseteq$." Let $\bar{x} \in S \cap R^r(x)$, and let $\bar{p} \in [-N_S(\bar{x})] \cap N_{R^r(x)}(\bar{x})$. Let $y \in S(r)$ and $\bar{y} \in S \cap R^r(y)$. Respectively, let $u(\cdot), \bar{u}(\cdot) \in \mathcal{U}^T_{ad}$ realize $\bar{y}$, $\bar{x}$, and thus

$$\begin{aligned} y &= e^{-Ar}\bar{y} - \int_0^r e^{-At}u(t)\,dt, \\ x &= e^{-Ar}\bar{x} - \int_0^r e^{-At}\bar{u}(t)\,dt. \end{aligned} \tag{3.6}$$

We have

$$\begin{aligned}\left\langle -e^{A^\top r}\bar{p}, y - x \right\rangle &= \left\langle -\bar{p}, e^{Ar}\big(y - x\big) \right\rangle \\ &= \left\langle -\bar{p}, \bar{y} - \bar{x} \right\rangle + \int_0^r \left\langle -p(t), \bar{u}(t) - u(t) \right\rangle dt\end{aligned}$$

by (3.6). Since $-\bar{p} \in N_S(\bar{x})$, the first term on the right-hand side of the previous expression is nonpositive. By the maximum principle, the second term is also nonpositive. Hence the assertion $-e^{A^\top r}\bar{p} \in N_{S(r)}(x)$ follows, and the proof is concluded. ∎

LEMMA 3.3. *Let the assumption* (H1) *hold. Let $x \in S(r)$, $T(x) = r > 0$ and let $\bar{x} \in S \cap R^r(x)$. Then a vector ζ belongs to $\partial_P T(x)$ if and only if*

$$h(x, \zeta) = -1$$

and

$$-e^{-A^\top r}\zeta \in \big[-N_S(\bar{x})\big] \cap N_{R^r(x)}(\bar{x}).$$

Proof. By Theorem 5.1 in [25],

$$\partial_P T(x) = N_{S(r)}(x) \bigcap \big\{\zeta : h(x, \zeta) = -1\big\}. \tag{3.7}$$

Then the statement follows from Lemma 3.2. ∎

The next three lemmas concern the Hamiltonian, mainly in connection with normal vectors to the epigraph of T.

LEMMA 3.4. *Let $r > 0$, $x_0 \in S(r)$. If $\zeta \in N_{S(r)}(x_0)$, then $h(x_0, \zeta) \leq 0$.*

Proof. By contradiction, let $\zeta \in N_{S(r)}(x_0)$ be such that $h(x_0, \zeta) > 0$. By definition of Hamiltonian, we have $\zeta \neq 0$. Let $x(\cdot)$ be an optimal trajectory starting from $x(0) = x_0$ and let $u(\cdot)$ be an optimal control realizing $x(\cdot)$. Let $z = x_0 + \zeta$. We are now going to contradict the dynamic programming principle. Indeed, by convexity of $S(r)$, it is enough to show that there exists $\eta > 0$ such that $x(t) \in B(z, \|\zeta\|)$ for all $t \in (0, \eta)$. In fact this implies that $x(t) \notin S(r)$ for all $t \in (0, \eta)$, i.e., there exists $0 < \bar{t} < T(x_0)$ such that $T(x(\bar{t})) > T(x_0)$, which is against the optimality of $x(\cdot)$. We have

$$\begin{aligned}\frac{d}{dt}\|x(t) - z\|^2 &= \frac{d}{dt}\langle x(t) - x_0 - \zeta, x(t) - x_0 - \zeta\rangle \\ &= 2\langle \dot{x}(t), x(t) - x_0 - \zeta\rangle \\ &= 2\langle \dot{x}(t), x(t) - x_0\rangle - 2\langle Ax(t) + u(t), \zeta\rangle \\ &\leq 2\left(K^2 t - h(x(t), \zeta)\right),\end{aligned}$$

where K is a bound on $\|\dot{x}\|$. According to our hypothesis $h(x(0), \zeta) > 0$, so for small t we have by continuity $\frac{d}{dt}\|x(t) - z\|^2 < 0$, which implies $x(t) \in B(z, \|\zeta\|)$. ∎

LEMMA 3.5. *Let (H1) hold. Let $r > 0$, and let $x_0 \in \mathbb{R}^n$ be such that $T(x_0) = r$. If $(\zeta, 0) \in N^P_{\mathrm{epi}(T)}(x_0, T(x_0))$, then $\zeta \in N_{S(r)}(x_0)$ and $h(x_0, \zeta) \leq 0$.*

Proof. In view of Lemma 3.4, it is enough to show that $\zeta \in N_{S(r)}(x_0)$. To this aim, observe that there exists $\sigma > 0$ such that

$$\langle(\zeta, 0), (y, \xi) - (x_0, T(x_0))\rangle \leq \sigma(\|x_0 - y\|^2 + |T(x_0) - \xi|^2) \tag{3.8}$$

for all $(y, \xi) \in \mathrm{epi}(T)$. In particular, for $y \in S(r)$ and $\xi = r$ the inequality (3.8) yields

$$\langle \zeta, y - x_0\rangle \leq \sigma\|x_0 - y\|^2,$$

and this says that $\zeta \in N^P_{S(r)}(x_0)$. Since $S(r)$ is convex, this fact is equivalent to $\zeta \in N_{S(r)}(x_0)$. The proof is concluded. ∎

LEMMA 3.6. *Let $r > 0$, $x_0 \in S(r)$, $T(x_0) = r$. If $(\zeta, -1) \in N^P_{\mathrm{epi}(T)}(x_0, T(x_0))$, then $h(x_0, \zeta) = -1$.*

Proof. By hypothesis, $\zeta \in \partial_P T(x_0)$; then apply Lemma 3.3. ∎

The following is the main result of the paper.

THEOREM 3.7. *Consider the system* (3.1) *with the assumptions* (H1), (H2). *Then there exists a continuous function φ such that the epigraph of $T_{|\mathcal{R}_\delta}$ is φ-convex.*

Proof. The proof consists of two steps. In the first step we establish an inequality of the type (2.5) for a particular choice of points in $\mathrm{epi}(T)$ by assuming that S is compact. In the second, we show that the inequality proved in the first step holds in general.

Step 1. Let S be compact. We claim that there exists $K = K(\delta) > 0$ with the following property: for all $x_1, x_2 \in \mathcal{R}_\delta$, for all $(\zeta, \xi) \in N^P_{\mathrm{epi}(T)}(x_1, T(x_1))$ with $\xi \in \{0, -1\}$ it holds

$$\langle(\zeta, \xi), (x_2, T(x_2)) - (x_1, T(x_1))\rangle \leq K(\|\zeta\| + |\xi|)(\|x_2 - x_1\|^2 + |T(x_2) - T(x_1)|^2). \tag{3.9}$$

Proof of Step 1. Let $r_1 = T(x_1)$, $r_2 = T(x_2)$. Let u_i be an optimal control steering x_i to $\bar{x}_i \in S$ in time r_i for $i = 1, 2$. Take $(\zeta, \xi) \in N^P_{\mathrm{epi}(T)}(x_1, T(x_1))$.

We have the following possibilities:

1. $\xi = -1$: in this case $\zeta \in \partial_P T(x_1)$ and, by Lemma 3.3, we have $h(x_1, \zeta) = -1$ and there exists $p \in N_{R^{r_1}(x_1)}(\bar{x}_1) \cap [-N_S(\bar{x}_1)]$ such that $\zeta = -e^{A^\top r_1} p$.
2. $\xi = 0$: in this case, by Lemma 3.5 we have $\zeta \in N_{S(r_1)}(x_1)$ and $h(x_1, \zeta) \le 0$, and by Lemma 3.2 there exists $p \in N_{R^{r_1}(x_1)}(\bar{x}_1) \cap [-N_S(\bar{x}_1)]$ such that $\zeta = -e^{A^\top r_1} p$.

In both cases, we have the existence of $p \in N_{R^{r_1}(x_1)}(\bar{x}_1) \cap [-N_S(\bar{x}_1)]$ such that $\zeta = -e^{A^\top r_1} p$. By the Pontryagin maximum principle,

$$\langle p(t), u_1(t) \rangle = \max_{u \in \mathcal{U}} \langle p(t), u \rangle$$

for a.e. t, where $p(t) = e^{A^\top (r_1 - t)} p$, and $\zeta = -p(0) (= -p)$.

Now suppose $r_2 \le r_1$ and define

$$\begin{aligned} y &:= e^{A(r_1 - r_2)} x_1 + \int_0^{r_1 - r_2} e^{A(r_1 - r_2 - t)} u_1(t)\, dt \\ &= e^{-Ar_2} \bar{x}_1 - \int_{r_1 - r_2}^{r_1} e^{A(r_1 - r_2 - t)} u_1(t)\, dt. \end{aligned}$$

We have

$$\begin{aligned} \langle \zeta, x_2 - x_1 \rangle &= \langle p(r_1 - r_2) - p(0), x_2 - x_1 \rangle + \langle -p(r_1 - r_2), x_2 - y \rangle \\ &\quad + \langle -p(r_1 - r_2), y - x_1 \rangle \\ &=: \text{(I)} + \text{(II)} + \text{(III)}. \end{aligned}$$

We estimate separately each term of the above sum:

$$\begin{aligned} |\text{(I)}| &= \left| \langle (e^{A^\top r_2} - e^{A^\top r_1}) p, x_2 - x_1 \rangle \right| = \left| \langle e^{A^\top r_2} (Id - e^{A^\top (r_1 - r_2)}) p, x_2 - x_1 \rangle \right| \\ &\le k_2'(r_1 - r_2) \|p\| \, \|x_2 - x_1\| \le k_2'' \|p\| (\|x_2 - x_1\|^2 + |r_2 - r_1|^2), \end{aligned}$$

where $k_2', k_2'' \in \mathbb{R}$ are positive constants, and Id denotes the identity matrix. Furthermore, observe that $\|p\| \le k \|\zeta\|$, with k independent of ζ, r_1, r_2 because δ is finite. So it holds

$$|\text{(I)}| \le k_2 \|\zeta\| (\|x_2 - x_1\|^2 + |r_2 - r_1|^2),$$

where k_2 is a positive constant independent of $x_2, x_1, r_2, r_1, \zeta$.

Let us now consider (II). First observe that

$$\begin{aligned} x_2 - y &= e^{-r_2 A} (\bar{x}_2 - \bar{x}_1) + \int_{r_1 - r_2}^{r_1} e^{A(r_1 - r_2 - t)} u_1(t)\, dt - \int_0^{r_2} e^{-At} u_2(t)\, dt \\ &= e^{-r_2 A} (\bar{x}_2 - \bar{x}_1) + \int_{r_1 - r_2}^{r_1} e^{A(r_1 - r_2 - t)} (u_1(t) - u_2(t - r_1 + r_2))\, dt. \end{aligned}$$

Then

$$\text{(II)} = \langle -e^{A^\top r_2} p, x_2 - y \rangle = \langle -p, \bar{x}_2 - \bar{x}_1 \rangle + \int_{r_1 - r_2}^{r_1} \langle p(t), u_2(t - r_1 + r_2) - u_1(t) \rangle\, dt.$$

By observing that $-p \in N_S(\bar{x}_1)$ and by the maximum principle, we have that (II) ≤ 0. Let us now consider (III). First, observe that

$$y - x_1 = \int_0^{r_1 - r_2} \dot{x}_1(t)\, dt = \int_0^{r_1 - r_2} (Ax_1(t) + u_1(t))\, dt,$$

where

$$x_1(t) := e^{At}x_1 + \int_0^t e^{A(r_1 - t)}u_1(t)\, dt$$

is the optimal trajectory associated with x_1 and $u_1(t)$.

Let us define

$$k_3'' = \max\{\|A\|\|x\| + \|u\| : x \in \mathcal{R}_\delta,\ u \in \mathcal{U}\}.$$

Then we have that

$$\text{(III)} = \int_0^{r_1 - r_2} \langle p(t) - p(r_1 - r_2), Ax_1(t) + u_1(t)\rangle\, dt + \int_0^{r_1 - r_2} \langle -p(t), Ax_1(t) + u_1(t)\rangle\, dt.$$

We have also the following estimate, valid for all $t \in [0, r_1 - r_2]$:

$$\begin{aligned} |\langle p(t) - p(r_1 - r_2), Ax_1(t) + u_1(t)\rangle| &\leq k_3''\|p(t) - p(r_1 - r_2)\| \\ &\leq k_3'\|p\|(r_1 - r_2) \\ &\leq k_3\|\zeta\|(r_1 - r_2). \end{aligned}$$

So the first integral in (III) can be majorized by

$$k_3\|\zeta\||r_1 - r_2|^2,$$

where k_3 is a positive constant independent of $x_1, x_2, r_1, r_2, \zeta$. By the maximum principle, the second integral in (III) is

$$\int_0^{r_1 - r_2} [\langle -p(t), Ax_1(t)\rangle - \max_{u \in \mathcal{U}} \langle p(t), u\rangle]\, dt.$$

The following estimates hold, for a suitable constant k_4, independent of $x_1, x_2, r_1, r_2, \zeta$:

$$\begin{aligned} \int_0^{r_1 - r_2} \langle -p(t), Ax_1(t)\rangle &= \int_0^{r_1 - r_2} \Big[\langle p(0) - p(t), Ax_1(t)\rangle \\ &\qquad + \langle -p(0), A(x_1(t) - x_1)\rangle\Big]\, dt \\ &\quad + \int_0^{r_1 - r_2} \langle -p(0), Ax_1\rangle\, dt \\ &\leq k_4\|\zeta\||r_1 - r_2|^2 + \int_0^{r_1 - r_2} \langle \zeta, Ax_1\rangle\, dt, \\ \int_0^{r_1 - r_2} -\max_{u \in \mathcal{U}} \langle p(t), u\rangle\, dt &= \int_0^{r_1 - r_2} \min_{u \in \mathcal{U}} \langle p(0) - p(t), u\rangle\, dt \\ &\quad + \int_0^{r_1 - r_2} \min_{u \in \mathcal{U}} \langle -p(0), u\rangle\, dt \\ &\leq k_4\|\zeta\||r_1 - r_2|^2 + \int_0^{r_1 - r_2} \min_{u \in \mathcal{U}} \langle \zeta, u\rangle\, dt. \end{aligned}$$

Therefore,

$$(\mathrm{III}) \le k_4' \|\zeta\| \, |r_1 - r_2|^2 + (r_1 - r_2) h(x_1, \zeta).$$

Now we have to distinguish two cases:

1. If $\xi = -1$, then $h(x_1, \zeta) = -1$ and so putting together the estimates on (I), (II), and (III) we obtain that

$$\langle \zeta, x_2 - x_1 \rangle \le r_2 - r_1 + k' \|\zeta\| |r_1 - r_2|^2 + k'' \|\zeta\| (\|x_2 - x_1\|^2 + |r_2 - r_1|^2),$$

which may be written, for a suitable constant k_5 independent of $x_1, x_2, r_1, r_2, \zeta$, as

$$\langle (\zeta, -1), (x_2, T(x_2)) - (x_1, T(x_1)) \rangle \le k_5 (\|\zeta\| + 1)(\|x_2 - x_1\|^2 + |T(x_2) - T(x_1)|^2)$$

for all $x_1, x_2 \in \mathcal{R}_\delta$ and for all $(\zeta, -1) \in N^P_{\mathrm{epi}(T)}(x_1)$.

2. If $\xi = 0$, then $h(x_1, \zeta) \le 0$ and so

$$(\mathrm{III}) \le k_4' \|\zeta\| \, |r_1 - r_2|^2.$$

Putting the estimates together, we obtain

$$\langle \zeta, x_2 - x_1 \rangle \le k' \|\zeta\| \, |r_1 - r_2|^2 + k'' \|\zeta\| (\|x_2 - x_1\|^2 + |r_2 - r_1|^2),$$

which may be written, for a suitable constant k_5 independent of $x_1, x_2, r_1, r_2, \zeta$, as

$$\langle (\zeta, 0), (x_2, T(x_2)) - (x_1, T(x_1)) \rangle \le k_5 \|\zeta\| (\|x_2 - x_1\|^2 + |T(x_2) - T(x_1)|^2)$$

for all $x_1, x_2 \in \mathcal{R}_\delta$ and for all $(\zeta, 0) \in N^P_{\mathrm{epi}(T)}(x_1)$.

In both cases, we obtain (3.9).

The case $r_2 > r_1$ is similar. Let $u_i(\cdot) \in \mathcal{U}^{r_i}_{\mathrm{ad}}$ be controls steering x_i to $\overline{x}_i \in S$ in the optimal times r_i, $i = 1, 2$, together with adjoint arcs $p_i : [0, r_i] \to \mathbb{R}^n$, $p_i(t) = e^{A^\top (r_i - t)} \overline{p}_i$. Now set $\tilde{p}(t) = e^{A^\top (r_2 - t)} \overline{p}_1$ for $t \in [0, r_2]$ and observe that, for $t \in [r_2 - r_1, r_2]$, $u_1(t - (r_2 - r_1)) \in \mathrm{Argmax}_{u \in \mathcal{U}} \langle \tilde{p}(t), u \rangle$. Choose now, for $t \in [0, r_2 - r_1]$, $\bar{u}(t) \in \mathcal{U}$ such that $\bar{u}(t) \in \mathrm{Argmax}_{u \in \mathcal{U}} \langle \tilde{p}(t), u \rangle$, and set

$$\tilde{u}(t) = \begin{cases} \bar{u}(t), & t \in [0, r_2 - r_1], \\ u_1(t - (r_2 - r_1)), & t \in (r_2 - r_1, r_2]. \end{cases}$$

Define

$$y = e^{-A(r_2 - r_1)} x_1 - \int_0^{r_2 - r_1} e^{-At} \bar{u}(t) \, dt = e^{-A r_2} \bar{x}_1 - \int_0^{r_2} e^{-At} \tilde{u}(t) \, dt.$$

Now the estimates proceed analogously to the previous case $r_2 \le r_1$, with $\tilde{p}, \tilde{u}$ in place of p_1, u_1. The proof of Step 1 is concluded.

Step 2. Let $T : \mathbb{R}^n \to \mathbb{R}^+ \cup \{+\infty\}$ be lower semicontinuous and proper, with a φ-convex domain $D = \{x \in \mathbb{R}^n : T(x) < +\infty\}$ and such that

1. T is continuous on D.
2. For all $R > 0$ there exists $\sigma = \sigma(R) > 0$ such that for all $x, y \in D \cap \bar{B}(0, R)$ and for all $(\zeta, \xi) \in N^P_{\mathrm{epi}(T)}(x, T(x))$ with $\xi \in \{0, 1\}$ it holds

$$\langle (\zeta, \xi), (y, T(y)) - (x, T(x)) \rangle \le \sigma(\|\zeta\| + |\xi|)(\|y - x\|^2 + |T(y) - T(x)|^2).$$

Then there exists a continuous $\overline{\varphi}$ such that $\mathrm{epi}(T)$ is $\overline{\varphi}$-convex.

Proof of Step 2. We have to prove that given $(x,\alpha),(y,\beta)\in \operatorname{epi}(T)$ with $\|x\|,\|y\|\le R$ and $(\zeta,\xi)\in N^P_{\operatorname{epi}(T)}(x,\alpha)$ with $\xi\in\{0,-1\}$, there exists $\sigma'=\sigma'(R)>0$ such that

$$\langle(\zeta,\xi),(y,\beta)-(x,\alpha)\rangle\le\sigma'(\|\zeta\|+|\xi|)(\|y-x\|^2+|\alpha-\beta|^2).$$

Let $\alpha>T(x)$. Two cases may occur:

1. If $(x,\alpha)\in\operatorname{int}\operatorname{epi}(T)$, then $N^P_{\operatorname{epi}(T)}(x,\alpha)=\{(0,0)\}$, and there is nothing to prove.
2. Suppose $(x,\alpha)\in\operatorname{bdry}\operatorname{epi}(T)$. Let $(\zeta,\xi)\neq(0,0)$ be such that $(\zeta,\xi)\in N^P_{\operatorname{epi}(T)}(x,\alpha)$. Without loss of generality, suppose that $\|(\zeta,\xi)\|=1$. Assume that (ζ,ξ) is realized by an r-ball, with $2r\sigma\le 1$. We claim that $\xi=0$. In fact, by contradiction, let $\xi\neq 0$; since (ζ,ξ) is normal to an epigraph, we necessarily have that $\xi<0$. Then there exists $0<\varepsilon<\alpha-T(x)$ such that

$$\|(x,\alpha-\varepsilon)-(x+r\zeta,\alpha+r\xi)\|^2<r^2.$$

This means that $(x,\alpha-\varepsilon)\in B((x+r\zeta,\alpha+r\xi),r)$, which is a contradiction since $(x,\alpha-\varepsilon)\in\operatorname{epi}(T)$. So, if $(x,\alpha)\in\operatorname{bdry}\operatorname{epi}(T)$ and $0\neq(\zeta,0)\in N^P_{\operatorname{epi}(T)}(x,\alpha)$, by the continuity of T on D and the same argument of Lemma 3.5 we have that $\zeta\in N_D$. Since D is φ-convex,

$$\langle\zeta,y-x\rangle\le\varphi(x)\|\zeta\|\,\|y-x\|^2\qquad\text{for all } x,y\in D,$$

and so

$$\langle(\zeta,0),(y,\beta)-(x,\alpha)\rangle\le(\sigma\vee\varphi(x))\|\zeta\|(\|y-x\|^2+|\alpha-\beta|^2).$$

It remains to consider the case $\alpha=T(x)$. Define

$$z=x+\frac{1}{2\sigma}\frac{\zeta}{\|(\zeta,\xi)\|},\qquad\qquad \chi=T(x)+\frac{1}{2\sigma}\frac{\xi}{\|(\zeta,\xi)\|}.$$

Let $(y,\beta)\in\operatorname{epi}(T)$ with $\beta>T(y)$ and $y\neq x$. The segment connecting (z,χ) and (y,β) contains a point (y',β') which lies on the boundary of $\operatorname{epi}(T)$, so $\beta'=T(y')$. Thus we have

$$d((x,T(x)),(z,\chi))<d((y',T(y)),(z,\chi))<d((y,\beta),(z,\chi)).$$

By direct computation the desired inequality follows. By the arbitrariness of R, the proof is concluded. □

Remark. (1) The problem in Example 1 satisfies the assumptions of Theorem 3.7, although STC does not hold.

(2) If (H1) and (H2) are valid in the whole of $\mathcal{R}$, then there exists a continuous function φ such that the epigraph of T is φ-convex. Indeed, it is enough to apply Theorem 3.7 in $\mathcal{R}_\delta$ for all $\delta>0$.

In [12], functions with φ-convex epigraph were studied. As a corollary of the above result, we list some regularity properties of the minimal time function, which are direct consequences of Theorem 3.7 and of [12].

COROLLARY 3.8. *Let the assumption of Theorem* 3.7 *hold. Then,*

1. *for a.e.* $x \in \mathcal{R}_\delta$, *there exists* $\varepsilon = \varepsilon(x)$ *such that* T *is semiconvex on* $B(x, \varepsilon(x))$;
2. *in particular,* T *is twice differentiable a.e. on* $\mathcal{R}_\delta$, *in the sense that for a.e.* $x \in \mathcal{R}_\delta$ *there exists a symmetric* $n \times n$ *matrix* X_x *such that*

$$DT(y) = DT(x) + X_x(y - x) + o(\|y - x\|)$$

for $y \to x$, $y \in \operatorname{dom}(DT)$ *and, as* $y \to x$, $y \in \operatorname{dom}(T)$,

(3.10)
$$\left| T(y) - T(x) - \langle DT(x), y - x\rangle - \frac{1}{2}\langle X_x(y - x), y - x\rangle \right| = o(\|y - x\|^2);$$

3. *for a.e.* $x \in \mathcal{R}_\delta$, *there exist* $\epsilon = \epsilon(x) > 0$ *and* $c = c(x) \geq 0$ *such that for all* $\nu \in \mathbb{R}^n$, *with* $\|\nu\| = 1$, *we have* $\frac{\partial^2 T}{\partial \nu^2} \geq -c$ *in the sense of distributions in* $B(x, \varepsilon)$;
4. *set, for* $1 \leq k \leq n$,

$$\Sigma_k = \{x \in \operatorname{int}\operatorname{dom}(T) : \mathcal{H} - dim(\partial_P T(x)) \geq k\};$$

then Σ_k *is countably* $\mathcal{H}^{n-k}$*-rectifiable;*
5. *let* $\operatorname{int}\operatorname{dom}(T)$ *be nonempty; then, for all open set* $\Omega \subseteq \operatorname{int}\operatorname{dom}(T)$, $T \in BV(\Omega)$; *moreover, for a.e.* $x \in \Omega$, *there exists* $\varepsilon = \varepsilon(x)$ *such that* $DT \in BV(B(x, \varepsilon))$.

Proof. Extend T to $\mathbb{R}^n$ by setting $T(x) = +\infty$ if $x \notin \mathcal{R}_\delta$. By standard arguments, T is lower semicontinuous on $\mathbb{R}^n$. By Theorem 3.7, epi(T) is φ-convex. Then the statements (1)–(5) are direct consequences of corresponding properties proved in [12], to which all the following citations refer. Statement 1 follows from Theorem 6.1; 2 and 3 are Corollaries 6.1 and 6.2, respectively; 4 is Proposition 5.1, while 5 is Propositions 7.1 and 7.2. □
