DISTRIBUTED CONTROL OF SPATIALLY REVERSIBLE INTERCONNECTED SYSTEMS WITH BOUNDARY CONDITIONS*

CÉDRIC LANGBORT† AND RAFFAELLO D'ANDREA‡

Abstract. We present a class of spatially interconnected systems with boundary conditions that have close links with their spatially invariant extensions. In particular, well-posedness, stability, and performance of the extension imply the same characteristics for the actual, finite extent system. In turn, existing synthesis methods for control of spatially invariant systems can be extended to this class. The relation between the two kinds of systems is proved using ideas based on the "method of images" of partial differential equations theory and uses symmetry properties of the interconnection as a key tool.

Key words. spatially distributed control, symmetric systems, boundary conditions

1. Introduction.

Many systems consist of the interconnection of a large number of identical subunits which interact with their nearest neighbors. Examples of such interconnected systems include formations of autonomous vehicles [11], [22], cross-directional control in the pulp and paper and chemical process industry [13], [14], "smart structures" (large arrays of distributed micro electromechanical actuators and sensors) [2], and semidiscretized partial differential equations [3].

Over the years, several frameworks for control of interconnected systems have been proposed that all assumed the existence of a particular mathematical structure induced by the interconnection. Early works [3], [17] showed that some systems, especially semidiscretized partial differential equations, can sometimes be treated as systems over modules. More recently, the papers [1], [5], [15] have considered so-called spatially invariant systems and used Fourier techniques or algebraic transformations to derive implementable and scalable optimal control algorithms, even in the limit of an infinite number of subunits. While some practical systems can be accurately modelled as being spatially invariant (e.g., circular plastic extrusion machines or very large arrays of sensors and actuators), most examples do not fall into this category because they are of finite extent and possess boundary conditions. This is why much of the current research is geared toward spatially varying systems, in an effort to adapt methods from the monodimensional time-varying case [8].

The approach taken in this paper is different, as we show that analysis and synthesis for the actual finite extent system with boundary conditions can sometimes be performed by studying a larger, spatially invariant system. The key assumption for this result is another structural property which we call spatial reversibility. In short,

we prove that a lack of spatial invariance can be made up for by spatial reversibility of the finite extent system with boundary conditions and that, in turn, any technique designed for spatially invariant systems can be used in that case too. A major difference between spatial invariance and spatial reversibility is that the former is a property of the interconnection while the latter is a property of the subsystems. In the language of [6], spatial reversibility is an *internal symmetry* while spatial invariance is a *global symmetry* of the system.

Our method borrows concepts from two different lines of thought. First, the idea of associating a larger spatially invariant system to the actual finite extent system is very similar in nature to the "lifting technique" introduced in [12] to relate linear time-periodic to linear time-invariant systems or to the method of [13] used to prove robustness of cross-directional controllers. Second, the motivation for considering symmetries of the system comes from the so-called "method of images" used in potential theory. The main issue that has to be addressed in order to establish a real link between finite extent and spatially invariant systems is that the boundary conditions are lost in this correspondence. One would like to consider finite extent systems, the solution of which can be recovered from the spatially invariant system in spite of this information loss. The method of images gives an example in which such a situation is at hand, although in a different context. It essentially states that boundary conditions for Laplace's equation

$$\Delta u = 0 \text{ in } U; \qquad u = g \text{ on } \partial U$$

on some simple domains $U \subset \mathbb{R}^n$ (e.g., half-spaces) can be dropped as such since its solution can be determined by solving a similar equation on the whole of $\mathbb{R}^n$, provided "mirror-image singularities" are introduced [20], [9]. The main reason why this technique works is that the Laplacian has some symmetry properties—namely, it commutes with any isometry of $\mathbb{R}^n$. It is thus natural to hope that spatial symmetry is also relevant for our problem.

It should be noted that an "embedding technique" similar to the method of images was already used in [3] to handle boundary conditions for the particular example of the semidiscretized heat equation on a finite interval. However, it was not emphasized that the possibility of using such a technique was due to symmetries of the problem.

The paper is organized as follows. After giving general preliminaries and notions on finite extent and spatially invariant systems in sections 2 and 3, we define spatial reversibility in section 4 and explain how it allows us to relate well-posedness, stability, and performance of these two kinds of systems. Section 5 presents practical examples of spatially reversible systems and section 6 is devoted to synthesis of distributed controllers for an $\mathcal{H}_\infty$ criterion. In particular, section 6.2 is largely independent from the rest, as it illustrates how the specific results of [5] can be adapted to this finite extent problem. Finally section 7 contains some generalizations of the core results, while concluding remarks can be found in section 8.

2. Modelling spatially interconnected systems. In this section, we introduce our notation and define the basic objects of interest. The goal is to provide a framework in which infinite, periodic, and finite extent systems can be handled simultaneously.

2.1. Signal spaces. Unless otherwise stated, $\mathbb{M}$ will stand for any one of the following three sets: $\{1, \dots, L\}$ for some integer $L > 0$, $\mathbb{Z}_{2L}$ (the group of integers

modulo $2L$), and $\mathbb{Z}$. We define $\ell_2^q(\mathbb{M})$ as the space of functions $x : \mathbb{M} \to \mathbb{R}^q$ such that

$$\|x\|^2_{\ell_2^q(\mathbb{M})} := \sum_{s\in\mathbb{M}} x(s)^* x(s) < \infty.$$

Then $\mathcal{L}_2^q(\mathbb{M})$ is defined as the Hilbert space of functions $x : \mathbb{R}^+ \to \ell_2^q(\mathbb{M})$ such that

$$\|x\|^2_{\mathcal{L}_2^q(\mathbb{M})} := \int_0^\infty \|x(t)\|^2_{\ell_2^q(\mathbb{M})} dt < \infty.$$

When the dimension of the target space is clear from the context or is irrelevant, we omit the superscript q and simply write $\ell_2(\mathbb{M})$ and $\mathcal{L}_2(\mathbb{M})$. Finally, if J is a matrix, we will abuse notation and identify it with the operator that associates $y \in \ell_2(\mathbb{M})$ to $x \in \ell_2(\mathbb{M})$ such that $y(s) = Jx(s)$ for all $s \in \mathbb{M}$.

2.2. Systems. Let a linear time-invariant, finite dimensional, dynamical system with input (d, v^+, v^-) and output (z, w^+, w^-) be given in state space by

$$\frac{d}{dt}x(t) = A_{\mathrm{TT}}x(t) + A_{\mathrm{TS}_+}v^+(t) + A_{\mathrm{TS}_-}v^-(t) + B_{\mathrm{T}}d(t)\ ;\ x(0) = x^0, \tag{1a}$$

$$w^+(t) = A_{\mathrm{ST}_+}x(t) + A_{\mathrm{SS}_{+,+}}v^+(t) + A_{\mathrm{SS}_{+,-}}v^-(t) + B_{\mathrm{S}_+}d(t), \tag{1b}$$

$$w^-(t) = A_{\mathrm{ST}_-}x(t) + A_{\mathrm{SS}_{-,+}}v^+(t) + A_{\mathrm{SS}_{-,-}}v^-(t) + B_{\mathrm{S}_-}d(t), \tag{1c}$$

$$z(t) = C_{\mathrm{T}}x(t) + C_{\mathrm{S}_+}v^+(t) + C_{\mathrm{S}_-}v^-(t) + Dd(t), \tag{1d}$$

where $x(t)$, $d(t)$, and $z(t)$ belong to $\mathbb{R}^{n_{\mathrm{T}}}$, $\mathbb{R}^m$, and $\mathbb{R}^p$, respectively, for all $t \geq 0$, and $v^+(t), v^-(t), w^+(t), w^-(t)$ all belong to $\mathbb{R}^n$. We also let $n_{\mathrm{S}} := 2n$. To such a system, which we call the *basic building block*, we can associate three different spatially interconnected systems as follows.

2.2.1. Infinite system. Let the *shift operator* $\mathbf{S}$ be defined on $\ell_2(\mathbb{Z})$ by

$$(\mathbf{S}v)(s) := v(s+1) \text{ for all } s. \tag{2}$$

$\mathbf{S}$ is clearly an isometry. We introduce the operator $\Delta_{\mathrm{S}} := \mathbf{diag}(\mathbf{S}I_n, \mathbf{S}^{-1}I_n)$ on $\ell_2^{n_{\mathrm{S}}}(\mathbb{Z})$. The infinite system associated to building block (1) is described by

$$\frac{d}{dt}x(t) = A_{\mathrm{TT}}x(t) + A_{\mathrm{TS}}v(t) + B_{\mathrm{T}}d(t) \quad \text{for all } t \geq 0\ ;\ x(0) = x^0, \tag{3a}$$

$$(\Delta_{\mathrm{S}} - A_{\mathrm{SS}})\,[v(t)] = A_{\mathrm{ST}}x(t) + B_{\mathrm{S}}d(t) \ \text{ for all } t \geq 0, \tag{3b}$$

$$z(t) = C_{\mathrm{T}}x(t) + C_{\mathrm{S}}v(t) + Dd(t) \quad \text{for all } t \geq 0, \tag{3c}$$

where we have used the shorthand

$$A_{\mathrm{ST}} := \begin{pmatrix} A_{\mathrm{ST}_+} \\ A_{\mathrm{ST}_-} \end{pmatrix},\ A_{\mathrm{SS}} := \begin{pmatrix} A_{\mathrm{SS}_{+,+}} & A_{\mathrm{SS}_{+,-}} \\ A_{\mathrm{SS}_{-,+}} & A_{\mathrm{SS}_{-,-}} \end{pmatrix},\ B_{\mathrm{S}} := \begin{pmatrix} B_{\mathrm{S}_+} \\ B_{\mathrm{S}_-} \end{pmatrix},$$

$$A_{\mathrm{TS}} := \begin{pmatrix} A_{\mathrm{TS}_+} & A_{\mathrm{TS}_-} \end{pmatrix},\ C_{\mathrm{S}} := \begin{pmatrix} C_{\mathrm{S}_+} & C_{\mathrm{S}_-} \end{pmatrix}.$$

In (3), the triple $(x(t), v(t), z(t))$ is sought in $\ell_2^{n_{\mathrm{T}}}(\mathbb{Z}) \times \ell_2^{n_{\mathrm{S}}}(\mathbb{Z}) \times \ell_2^p(\mathbb{Z})$ for all $t \geq 0$, when an initial condition $x^0 \in \ell_2^{n_{\mathrm{T}}}(\mathbb{Z})$ and a disturbance d such that $d(t) \in \ell_2^m(\mathbb{Z})$ for all $t \geq 0$ are given. The question of whether such a triple exists is addressed in section 3. We answer it by rewriting the infinite set of differential-algebraic equations

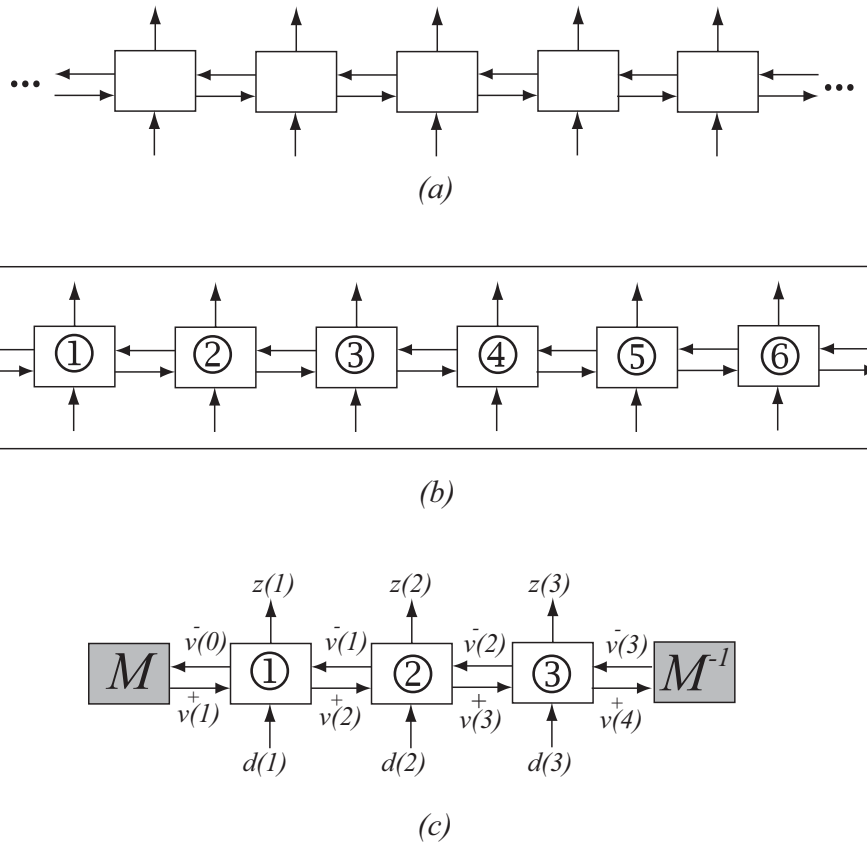

FIG. 1. *The three types of interconnected systems.* (a) *Infinite system.* (b) *Periodic system for* $L = 3$. (c) *Finite extent system for* $L = 3$ *(time dependence of signals is not indicated to simplify notation).*

(3) as an abstract differential equation on the Hilbert space $\ell_2^{n_{\mathrm{T}}}(\mathbb{Z})$. However, it should be noted that infinite interconnected systems appear more naturally in the form of (3) than as abstract differential equations. Indeed, consider the block diagram pictured in Figure 1(a). Each box stands for an instance of the basic building block (1) that exchanges signals v^+, v^-, w^+, and w^- with its neighbors according to the interconnection relation

$$[v^+(t)](s+1) = [w^+(t)](s), \ s \in \mathbb{Z}, \tag{4a}$$

$$[v^-(t)](s-1) = [w^-(t)](s), \ s \in \mathbb{Z}, \tag{4b}$$

where we have indexed the subsystems by $s \in \mathbb{Z}$ and considered all signals mentioned before as vector-valued functions on $\mathbb{Z}$ for all t. Introducing v such that

$$[v(t)](s) := \big([v^+(t)](s), [v^-(t)](s)\big) \ \text{ for all } t \geq 0 \tag{5}$$

and recalling the definition of the operator Δ_{S}, it is easy to see that conditions (4) and the state space description of each subsystem yield differential-algebraic equations (3).

2.2.2. Periodic system. A periodic interconnected system is also captured by (3) but with the operators $\mathbf{S}$ and Δ_{S} now defined, respectively, on $\ell_2(\mathbb{Z}_{2L})$ and

$\ell_2^{n_s}(\mathbb{Z}_{2L})$. In particular, the shift operator $\mathbf{S}$ is still defined by (2) but addition should now be understood modulo $2L$. Accordingly, the triple $(x(t), v(t), z(t))$ is sought in $\ell_2^{n_T}(\mathbb{Z}_{2L}) \times \ell_2^{n_s}(\mathbb{Z}_{2L}) \times \ell_2^{p}(\mathbb{Z}_{2L})$ for all $t \geq 0$, when an initial condition $x^0 \in \ell_2^{n_T}(\mathbb{Z}_{2L})$ and a disturbance d such that $d(t) \in \ell_2^{m}(\mathbb{Z}_{2L})$ for all $t \geq 0$ are given.

The physical interconnection corresponding to a periodic system is illustrated in Figure 1(b). The subsystems are again instances of the basic building block and are interconnected according to the relation

$$[v^+(t)](s+1) = [w^+(t)](s),\ s \in \mathbb{Z}_{2L}, \tag{6a}$$

$$[v^-(t)](s-1) = [w^-(t)](s),\ s \in \mathbb{Z}_{2L}. \tag{6b}$$

For reasons that should become clear in section 3, we will say that periodic and infinite systems are spatially invariant.

2.2.3. Finite extent system. Unlike infinite and periodic systems that can be readily defined in a formal setting, finite extent systems are easier to introduce through the physical interconnection they describe. Consider the block diagram of Figure 1(c). As in the infinite and periodic case, each box represents an instance of the basic building block, except the two end ones, which specify boundary conditions. More precisely, if we index subsystems by $1 \leq s \leq L$, the interconnection relation between neighboring subsystems now is

$$[v^+(t)](s+1) = [w^+(t)](s),\ 1 \leq s \leq L-1, \tag{7a}$$

$$[v^-(t)](s-1) = [w^-(t)](s),\ 2 \leq s \leq L, \tag{7b}$$

$$[v^+(t)](1) = M[w^-(t)](1), \tag{7c}$$

$$[v^-(t)](L) = M^{-1}[w^+(t)](L), \tag{7d}$$

where M is a nonsingular matrix called the *boundary conditions matrix*. We can represent such a finite extent system by a set of differential-algebraic equations formally similar to that describing infinite and periodic systems. To this end, we need to introduce the operator Δ_{BC} as follows. First, if $v = (v^+, v^-)$ belongs to $\ell_2^{n_s}(\{1, \ldots, L\})$, we define the vector $\overrightarrow{v} \in \mathbb{R}^{n_s L}$ by

$$\overrightarrow{v} = \left(v^+(1), \ldots, v^+(L), v^-(1), \ldots, v^-(L)\right).$$

The map $\overrightarrow{\cdot}$ is an isomorphism of $\mathbb{R}$-vector spaces and its inverse will be denoted $\overleftarrow{\cdot}$. As a consequence, we can define another isomorphism, also denoted $\overleftarrow{\cdot}$, between the space of $n_s L \times n_s L$ real matrices and the space of endomorphisms of $\ell_2^{n_s}(\{1, \ldots, L\})$ by

$$\overleftarrow{J}\, v := \overleftarrow{(J\, \overrightarrow{v})} \text{ for all } J \in \mathbb{R}^{n_s L \times n_s L},\ v \in \ell_2^{n_s}(\{1, \ldots, L\}).$$

With this notation, we can rewrite the interconnection relation (7) as

$$w = \overleftarrow{\mathcal{C}}\, v$$

for the invertible *interconnection matrix* $\mathcal{C}$. In the remainder of this paper, we will let $\overleftarrow{\mathcal{C}} =: \Delta_{\text{BC}}$. Then, introducing again signal v as per (5), a finite extent system can be represented by the following set of differential-algebraic equations:

$$\frac{d}{dt}x(t) = A_{\text{TT}}x(t) + A_{\text{TS}}v(t) + B_{\text{T}}d(t) \ \text{ for all } t \geq 0\ ;\ x(0) = x^0, \tag{8a}$$

$$(\Delta_{\text{BC}} - A_{\text{SS}})[v(t)] = A_{\text{ST}}x(t) + B_{\text{S}}d(t) \ \text{ for all } t \geq 0, \tag{8b}$$

$$z(t) = C_{\text{T}}x(t) + C_{\text{S}}v(t) + Dd(t) \ \text{ for all } t \geq 0, \tag{8c}$$

which is formally similar to (3). The triple $(x(t), v(t), z(t))$ is sought in $\ell_2^{n_{\mathrm{T}}}(\{1,\dots,L\}) \times \ell_2^{n_{\mathrm{S}}}(\{1,\dots,L\}) \times \ell_2^{p}(\{1,\dots,L\})$ for all $t \geq 0$, when an initial condition $x^0 \in \ell_2^{n_{\mathrm{T}}}(\{1,\dots,L\})$ and a disturbance d such that $d(t) \in \ell_2^{m}(\{1,\dots,L\})$ for all $t \geq 0$ are given.

As already mentioned in the introduction, analysis is much more tractable for spatially invariant systems than for finite extent systems, especially if L is large. Hence, it would be desirable to know what relationships exist between them. The main goal of the next sections is to show that stability and performance of the spatially invariant systems actually imply similar properties for the corresponding finite extent system, provided some reversibility properties are satisfied. A proof of this statement, which we call the method of images, as well as a precise definition of what we call "reversibility" are given in section 4. Before presenting these results, more should be said about well-posedness, stability, and performance.

3. Well-posedness, stability, and performance. We have just seen that all interconnected systems of interest can be captured by the following equations:

$$\frac{d}{dt}x(t) = A_{\mathrm{TT}}x(t) + A_{\mathrm{TS}}v(t) + B_{\mathrm{T}}d(t) \quad \text{for all } t \geq 0;\ x(0) = x^0, \tag{9a}$$

$$(\Delta - A_{\mathrm{SS}})\,[v(t)] = A_{\mathrm{ST}}x(t) + B_{\mathrm{S}}d(t) \ \text{ for all } t \geq 0, \tag{9b}$$

$$z(t) = C_{\mathrm{T}}x(t) + C_{\mathrm{S}}v(t) + Dd(t) \quad \text{for all } t \geq 0, \tag{9c}$$

where

$$\begin{array}{ll} \Delta = \Delta_{\mathrm{BC}} & \text{for a finite extent system,} \\ \Delta = \Delta_{\mathrm{S}} & \text{for an infinite or periodic system.} \end{array}$$

System (9) is said to be *well-posed* if the bounded linear operator $(\Delta - A_{\mathrm{SS}}) : \ell_2^{n_{\mathrm{S}}}(\mathbb{M}) \to \ell_2^{n_{\mathrm{S}}}(\mathbb{M})$ is invertible. Assume system (9) is well-posed and let an initial state $x^0 \in \ell_2(\mathbb{M})$ and a disturbance $d \in \mathcal{L}_2(\mathbb{M})$ be given. We can write

$$v(t) = (\Delta - A_{\mathrm{SS}})^{-1}\left(A_{\mathrm{ST}}x(t) + B_{\mathrm{S}}d(t)\right) \quad \text{for all } t \geq 0 \tag{10}$$

and, in turn, x will satisfy

$$\frac{d}{dt}x(t) = \mathbf{A}x(t) + \mathbf{B}d(t) \ \text{ for all } t \geq 0, \tag{11a}$$

$$x(0) = x^0, \tag{11b}$$

where

$$\mathbf{A} = \left(A_{\mathrm{TT}} + A_{\mathrm{TS}}(\Delta - A_{\mathrm{SS}})^{-1}A_{\mathrm{ST}}\right);\ \mathbf{B} = \left(B_{\mathrm{T}} + A_{\mathrm{TS}}(\Delta - A_{\mathrm{SS}})^{-1}B_{\mathrm{S}}\right). \tag{12}$$

Note that operators $\mathbf{A}$ and $\mathbf{B}$ are bounded and thus, in particular, $\mathbf{A}$ generates a strongly continuous semigroup of operators $\{\Phi(t)\}_{t\geq 0}$ on $\ell_2(\mathbb{M})$. We can even write

$$\Phi(t) = e^{t\mathbf{A}}, \tag{13}$$

where the exponential is defined by the usual power series. As a result [4], (11a) has a unique weak solution on $[0,T]$ for any $x^0 \in \ell_2(\mathbb{M})$ and $d \in \mathcal{L}_2(\mathbb{M})$, which is the mild solution given by

$$x(t) = e^{t\mathbf{A}}x^0 + \int_0^t e^{(t-\tau)\mathbf{A}}(\mathbf{B}d(\tau))d\tau\ .$$

The *solution* of well-posed system (9) on the interval $[0,T]$ is the unique triple (x,v,z) such that x is the mild solution of (11a) on $[0,T]$ and (9c) and (10) are satisfied for all $0 \le t \le T$. It is not hard to see that if (x,v,z) is the solution of a periodic or infinite system for initial condition x^0 and disturbance $d(t)$, then $(\tilde{x},\tilde{v},\tilde{z})$ is another solution for initial condition $\mathbf{S}x^0$ and disturbance $\mathbf{S}d(t)$, where

$$\tilde{x}(t) = \mathbf{S}[x(t)],\ \tilde{v}(t) = \mathbf{S}[v(t)],\ \tilde{z}(t) = \mathbf{S}[z(t)] \text{ for all t.}$$

This is the reason why we chose to call these systems spatially invariant. The physical explanation of this invariance is that all subsystems in block diagrams 1(a) and 1(b) are identical and interconnected to their neighbors in the same way.

We now show that well-posedness can be characterized algebraically.

PROPOSITION 3.1. (i) *A finite extent system is well-posed if and only if* $(I-N)$ *is invertible, where* N *is defined as*

(14)
$$\left(\begin{array}{c|c} MA_{\mathrm{SS}_{-,+}} \quad 0^{n\times n(L-1)} & MA_{\mathrm{SS}_{-,-}} \quad 0^{n\times n(L-1)} \\ \hline \mathcal{T}_{\mathrm{L}}(A_{\mathrm{SS}_{+,+}}) & \mathcal{T}_{\mathrm{L}}(A_{\mathrm{SS}_{+,-}}) \\ \hline \mathcal{T}_{\mathrm{U}}(A_{\mathrm{SS}_{-,+}}) & \mathcal{T}_{\mathrm{U}}(A_{\mathrm{SS}_{-,-}}) \\ \hline 0^{n\times n(L-1)} \quad M^{-1}A_{\mathrm{SS}_{+,+}} & 0^{n\times n(L-1)} \quad M^{-1}A_{\mathrm{SS}_{+,-}} \end{array}\right),$$

and the rectangular Toeplitz matrices $\mathcal{T}_{\mathrm{U}}(K)$ *and* $\mathcal{T}_{\mathrm{L}}(K)$ *in* $\mathbb{R}^{n(L-1)\times nL}$ *satisfy*

$$\mathcal{T}_{\mathrm{U}}(K) := \begin{pmatrix} 0 & K & \cdots & \cdots & 0 \\ 0 & \ddots & \ddots & & \vdots \\ \vdots & \ddots & \ddots & \ddots & \vdots \\ 0 & \cdots & 0 & 0 & K \end{pmatrix};\ \mathcal{T}_{\mathrm{L}}(K) := \begin{pmatrix} K & 0 & \cdots & \cdots & 0 \\ 0 & \ddots & \ddots & & \vdots \\ \vdots & \ddots & \ddots & \ddots & \vdots \\ 0 & \cdots & 0 & K & 0 \end{pmatrix}$$

for any given $K \in \mathbb{R}^{n\times n}$.

(ii) *A periodic (respectively, infinite) system is well-posed if and only if* $(\Delta(\lambda) - A_{\mathrm{SS}})$ *is invertible for all* $\lambda \in \mathbb{U}$ *(respectively, for all* $\lambda \in \partial\mathbb{D}$*), where*

$$\Delta(\lambda) := \mathbf{diag}(\lambda I_n, \lambda^{-1} I_n) \text{ and } \partial\mathbb{D} := \{z \in \mathbb{C}, |z| = 1\}, \mathbb{U} := \{z \in \mathbb{C}, z^{2L} = 1\}.$$

Proof. (i) Since the interconnection matrix $\mathcal{C}$ is invertible, so is Δ_{BC}. It is easy to see that N satisfies $\overleftarrow{N} = \Delta_{\mathrm{BC}}^{-1} A_{\mathrm{SS}}$. Hence matrix $(I-N)$ is nonsingular if and only if $(\Delta_{\mathrm{BC}} - A_{\mathrm{SS}})$ is. Since $\ell_2(\{1,\ldots,L\})$ is finite dimensional, $(\Delta_{\mathrm{BC}} - A_{\mathrm{SS}})^{-1}$ is bounded whenever it exists.

(ii) We first study the periodic case. Let $v \in \ell_2(\mathbb{Z}_{2L})$ be given. It has a discrete Fourier transform $\hat{v} \in \ell_2(\mathbb{U})$ defined by

$$\hat{v}(\lambda) = \sum_{s=1}^{2L} v(s)\lambda^s \text{ for all } \lambda \in \mathbb{U}.$$

Now assume $(\Delta(\lambda) - A_{\mathrm{SS}})$ is invertible for all $\lambda \in \mathbb{U}$. Then n defined by

$$n(s) = \frac{1}{2L} \sum_{\lambda\in\mathbb{U}} \lambda^{-s} \left(\Delta(\lambda) - A_{\mathrm{SS}}\right)^{-1} \hat{v}(\lambda)$$

is a well-defined function on $\mathbb{Z}_{2L}$. Also, noting that

$$\hat{n}(\lambda) = \left(\Delta(\lambda) - A_{\mathrm{SS}}\right)^{-1} \hat{v}(\lambda) \text{ for all } \lambda \tag{15}$$

and using Parseval's identity, we get that

$$\|n\|_{\ell_2(\mathbb{Z}_{2L})} \leq \max_{\lambda\in\mathbb{U}} \overline{\sigma}((\Delta(\lambda) - A_{\rm ss})^{-1})\|v\|_{\ell_2(\mathbb{Z}_{2L})} < \infty.$$

Finally, it is easy to check that it satisfies

$$(\Delta_{\rm s} - A_{\rm ss})\, n = v. \tag{16}$$

This is the unique solution in $\ell_2(\mathbb{Z}_{2L})$ since any such solution must satisfy (15) and elements of $\ell_2(\mathbb{Z}_{2L})$ are fully specified by their Fourier coefficients. Hence, $(\Delta_{\rm s} - A_{\rm ss})^{-1}$ is well defined on $\ell_2(\mathbb{Z}_{2L})$ and has norm less than $\max_{\lambda\in\mathbb{U}} \overline{\sigma}((\Delta(\lambda) - A_{\rm ss})^{-1})$.

Conversely, assume $(\Delta(\lambda) - A_{\rm ss})$ is not invertible for some $\lambda = \lambda_0$ in $\mathbb{U}$ and let $n_0 \neq 0$ be in the corresponding null-space. Then n defined by

$$n(s) = \lambda_0^s n_0 \ \text{ for all } s$$

belongs to $\ell_2(\mathbb{Z}_{2L})$ and satisfies (16) with $v \equiv 0$. Hence operator $(\Delta_{\rm s} - A_{\rm ss})$ is not invertible on $\ell_2(\mathbb{Z}_{2L})$.

For the infinite system case, the proof of sufficiency is identical, replacing the discrete Fourier transform with a two-sided $\mathcal{Z}$-transform. For necessity, assuming that there exists $\lambda_0 = e^{i\omega_0} \in \partial\mathbb{D}$ such that $(\Delta(\lambda_0) - A_{\rm ss})$ is singular, we will show that $(\Delta_{\rm s} - A_{\rm ss})$ is not bounded below on $\ell_2(\mathbb{Z})$ and hence not injective. Let ξ_0 be a unitary vector in the null-space of $(\Delta(\lambda_0) - A_{\rm ss})$. Define the sequence of functions $\{u_k\}$ from $[0, 2\pi)$ to $\mathbb{R}$ by

$$u_k(\omega) = \begin{cases} 2^{\frac{k-1}{2}} \text{ if } |\omega - \omega_0| < \left(\frac{1}{2}\right)^k, \\ 0 \text{ otherwise,} \end{cases}$$

and, for each k, let $\hat{n}_k \in \ell_2(\partial\mathbb{D})$ be defined by $\hat{n}_k(\lambda) = u_k(\omega)\xi_0$ for all $\lambda = e^{i\omega}$ and n_k be the inverse $\mathcal{Z}$-transform of $\hat{n}_k$, which thus belongs to $\ell_2(\mathbb{Z})$. We have $\|n_k\|_{\ell_2(\mathbb{Z})} = 1$ for all k. Now, if we let $v_k = (\Delta_{\rm s} - A_{\rm ss})\, n_k$ for each k, we get

$$\|v_k\|^2_{\ell_2(\mathbb{Z})} = \|\hat{v}_k\|^2_{\ell_2(\partial\mathbb{D})} = 2^{(k-1)} \int_{\omega-(\frac{1}{2})^k}^{\omega+(\frac{1}{2})^k} |\left(\Delta(e^{i\omega}) - A_{\rm ss}\right) n_0|^2 d\omega.$$

Let $\epsilon > 0$. Since $\omega \mapsto \|\left(\Delta(e^{i\omega}) - A_{\rm ss}\right) n_0\|^2$ is continuous and $\left(\Delta(e^{i\omega_0}) - A_{\rm ss}\right) n_0 = 0$, there exists K such that

$$\|\left(\Delta(e^{i\omega}) - A_{\rm ss}\right) n_0\|^2 < \epsilon^2 \ \text{ for all } |\omega - \omega_0| < \left(\frac{1}{2}\right)^k,$$

provided $k > K$. Hence, $\|v_k\|_{\ell_2(\mathbb{Z})} < \epsilon$ for $k > K$. Since this holds for any $\epsilon > 0$, the sequence $\left\{\|v_k\|_{\ell_2(\mathbb{Z})}\right\}_k$ converges to zero, showing that $(\Delta_{\rm s} - A_{\rm ss})$ is not bounded below. □

Since $\mathbb{U} \subset \partial\mathbb{D}$, well-posedness of the infinite system implies well-posedness of the corresponding periodic system. For a well-posed system, one can define stability as follows.

Definition 3.2. *A well-posed system is stable if, in the absence of input* ($d \equiv 0$), *the weak solution* $x(t) \in \ell_2(\mathbb{M})$ *of* (11a) *is defined on* $\mathbb{R}^+$ *and satisfies*

$$\|x(t)\|_{\ell_2(\mathbb{M})} \xrightarrow[t\to\infty]{} 0 \ \textit{exponentially, irrespective of the initial condition } x^0 \ .$$

Equivalently, this means that there exist $M,\ \alpha > 0$ *such that*

$$\|\Phi(t)\|_{\ell_2(\mathbb{M})} \le Me^{-\alpha t} \quad \textit{for all } t \ge 0,$$

where the norm in the latter equation is the $\ell_2(\mathbb{M})$*-induced norm of an operator.*

It follows from the results of [1] that stability of periodic and infinite systems can be checked by looking at the corresponding Fourier-transformed systems. More precisely, if we associate the operator $\widehat{\mathbf{A}} := \mathcal{F}\mathbf{A}\mathcal{F}^{-1}$ on $\ell_2(\widehat{\mathbb{M}})$ to the operator $\mathbf{A}$ on $\ell_2(\mathbb{M})$, where

$$\begin{array}{ll} \widehat{\mathbb{M}} = \partial\mathbb{D}, & \mathcal{F} \text{ is the two-sided } \mathcal{Z}\text{-transform for an infinite system,} \\ \widehat{\mathbb{M}} = \mathbb{U}, & \mathcal{F} \text{ is the discrete Fourier transform for a periodic system,} \end{array}$$

then we have the following.

PROPOSITION 3.3 (see [1]). *The following hold:*

(i) $\widehat{\mathbf{A}}$ *is a multiplication operator; i.e., there exists a matrix-valued function* A *such that* $(\widehat{\mathbf{A}}\hat{f})(\lambda) = A(\lambda)\hat{f}(\lambda)$ *for all* $\hat{f} \in \ell_2(\widehat{\mathbb{M}})$.

(ii) *The periodic and infinite system* (9) *is stable if and only if* $A(\lambda)$ *is Hurwitz for all* $\lambda \in \widehat{\mathbb{M}}$.

Note that (ii) is in fact simpler than the general condition of [1] for stability, owing to the compactness of $\widehat{\mathbb{M}}$. Once again, since $\mathbb{U} \subset \partial\mathbb{D}$, stability of the infinite system implies stability of the corresponding periodic system.

It is easy to see that if a system is well-posed and stable then, for any $d \in \mathcal{L}_2(\mathbb{M})$, x and in turn z also belong to $\mathcal{L}_2(\mathbb{M})$. Such a system thus has a well-defined input/output map, T_{dz}. It is a bounded linear map from $\mathcal{L}_2(\mathbb{M})$ to $\mathcal{L}_2(\mathbb{M})$ and its induced norm, $\|T_{dz}\|_{\mathcal{L}_2(\mathbb{M})}$, characterizes the performance of the system. If it is strictly less than 1, we will say that the system is contractive.

4. Spatial reversibility and the method of images. We now turn our attention to a particular class of finite extent systems, as defined below.

DEFINITION 4.1. *Given a basic building block as per* (1) *and a nonsingular matrix* M*, we say that the block is (spatially)* M*-reversible if there exist matrices* $R \in \mathbb{R}^{m\times m}$*,* $P \in \mathbb{R}^{n_{\mathrm{T}}\times n_{\mathrm{T}}}$*, and* $U \in \mathbb{R}^{p\times p}$ *such that*

(i) $R^2 = I_m$, $P^2 = I_{n_{\mathrm{T}}}$, $U^2 = I_p$*; i.e.,* R*,* U*, and* P *are involutions,*

(ii)
$$\begin{pmatrix} P & 0 & 0 \\ 0 & Q & 0 \\ 0 & 0 & U \end{pmatrix} \begin{pmatrix} A_{\mathrm{TT}} & A_{\mathrm{TS}} & B_{\mathrm{T}} \\ A_{\mathrm{ST}} & A_{\mathrm{SS}} & B_{\mathrm{S}} \\ C_{\mathrm{T}} & C_{\mathrm{S}} & D \end{pmatrix} = \begin{pmatrix} A_{\mathrm{TT}} & A_{\mathrm{TS}} & B_{\mathrm{T}} \\ A_{\mathrm{ST}} & A_{\mathrm{SS}} & B_{\mathrm{S}} \\ C_{\mathrm{T}} & C_{\mathrm{S}} & D \end{pmatrix} \begin{pmatrix} P & 0 & 0 \\ 0 & Q & 0 \\ 0 & 0 & R \end{pmatrix},$$

where $Q := \left(\begin{smallmatrix} 0 & M \\ M^{-1} & 0 \end{smallmatrix}\right)$.

We will say that a finite extent, periodic, or infinite system is M-reversible if the basic building block is. When the finite extent system at hand has boundary conditions matrix M and is M-reversible, we will simply say that it is reversible without referring to the matrix. Our goal in this section is to relate the properties of reversible finite extent and periodic systems. This will require several properties that we explain in turn. We start with a result that motivates our use of the notion of spatial reversibility.

First, we introduce the reflection $\Upsilon : \ell_2(\mathbb{Z}_{2L}) \to \ell_2(\mathbb{Z}_{2L})$ such that $(\Upsilon x)(s) =$

$x(2L+1-s)$ for all s. Then we consider the following spaces of *reversible* signals:

$$\begin{aligned}\Re_{\mathrm{T}} &:= \{x \in \ell_2^{n_{\mathrm{T}}}(\mathbb{Z}_{2L}) : x = P\Upsilon x\}\,,\\ \Re_{\mathrm{S}} &:= \{v \in \ell_2^{n_{\mathrm{S}}}(\mathbb{Z}_{2L}) : v = Q\Upsilon v\ \}\,,\\ \Re_d &:= \{d \in \ell_2^{m}(\mathbb{Z}_{2L}) : d = R\Upsilon d\}\,,\\ \Re_z &:= \{z \in \ell_2^{p}(\mathbb{Z}_{2L}) : z = U\Upsilon z\}\,.\end{aligned}$$

Then the fact that Q and Υ, as seen as operators on $\ell_2^{n_{\mathrm{S}}}(\mathbb{Z}_{2L})$, satisfy

$$\Delta_{\mathrm{S}} Q = Q\Delta_{\mathrm{S}}^{-1}\ ;\ \Delta_{\mathrm{S}}\Upsilon = \Upsilon\Delta_{\mathrm{S}}^{-1} \tag{17}$$

yields the following property.

PROPOSITION 4.2. *Assume periodic system* (3) *is M-reversible and well-posed. Let the initial state x^0 belong to $\Re_{\mathrm{T}}$ and disturbance $d \in \mathcal{L}_2(\mathbb{Z}_{2L})$ satisfy $d(t) \in \Re_d$ for all $t \geq 0$. Then the corresponding solution (x, v, z) of* (8) *on $\mathbb{R}^+$ is spatially reversible, i.e., $x(t) \in \Re_{\mathrm{T}}$, $v(t) \in \Re_{\mathrm{S}}$, and $z(t) \in \Re_z$ for all $t \geq 0$.*

The proof relies on manipulations very similar to those used later for Theorem 4.5 and we thus omit it. Physically, Proposition 4.2 means that, for the right type of inputs and initial conditions, the signals flowing to the right from the Lth subsystem are related to those flowing to the left from the $(L+1)$th subsystem. Hence switching left and right is equivalent to operating Q on v, P on x, and R on z. This property allows us to draw a parallel between spatially reversible and *time-reversible* dynamical systems. Recall that a nonlinear autonomous dynamical system

$$\dot{x} = f(x) \tag{18}$$

is time-reversible if there exists an involution R that anticommutes with f. Then for every solution x of the differential equation (18) we have another, i.e., $\tilde{x} : t \mapsto \tilde{x}(t) = Rx(-t)$. If there exists $t^\star$ such that $x(t^\star) \in Fix(R) = \{\xi : \xi = R\xi\}$, then the solution x is reversible.

In both spatial and temporal cases, the key property is some kind of anticommutation of an involution with an evolution operator ((17) in the spatial case) and the result is that solutions either "come in pairs" or are reversible. It is because of this analogy that the denomination "spatially reversible" was used in our definition, although "symmetric" has sometimes been used in the literature with a somewhat similar meaning [16], [21]. This latter denomination is acceptable because (17) and Definition 4.1 essentially mean that the set of equations describing the periodic system is equivariant under the action of $\mathbb{Z}_2$. However, we feel that it is desirable to keep the adjective "symmetric" for systems that are invariant under the action of more general groups, as is done in [10].

The second useful result is given by the following proposition.

PROPOSITION 4.3. *A spatially reversible finite extent system is well-posed if the corresponding periodic system is well-posed.*

Proof. We use a contrapositive. Assume the finite extent system is not well-posed and let M be its boundary conditions matrix. We want to show that $(\Delta(\theta) - A_{\mathrm{ss}})$ is singular for some $\theta \in \mathbb{U}$. Let $\omega = e^{i\pi/L}$ so that

$$\mathbb{U} = \{1, \omega, \omega^2, \ldots, \omega^{(2L-1)}\}.$$

According to Proposition 3.1, there exists $x \neq 0$ such that $Nx = x$, where N is defined as in (14). Also, because of spatial reversibility, we have that $QA_{\mathrm{ss}} = A_{\mathrm{ss}}Q$,

namely,

$$\begin{pmatrix} MA_{\mathrm{SS}_{-,-}}M^{-1} & MA_{\mathrm{SS}_{-,+}}M \\ M^{-1}A_{\mathrm{SS}_{+,-}}M^{-1} & M^{-1}A_{\mathrm{SS}_{+,+}}M \end{pmatrix} = \begin{pmatrix} A_{\mathrm{SS}_{+,+}} & A_{\mathrm{SS}_{+,-}} \\ A_{\mathrm{SS}_{-,+}} & A_{\mathrm{SS}_{-,-}} \end{pmatrix}. \tag{19}$$

As a result, $\mathcal{Q}$ defined by

$$\mathcal{Q} := \left(\begin{array}{ccc|ccc} & & & 0 & & M \\ & 0 & & & \diagup & \\ & & & M & & 0 \\ \hline 0 & & M^{-1} & & & \\ & \diagup & & & 0 & \\ M^{-1} & & 0 & & & \end{array}\right)$$

commutes with N and $\mathcal{Q}x$ is also an eigenvector of N with eigenvalue 1. There are two cases as follows.

Case 1. $x = -\mathcal{Q}x$.

Since the Vandermonde matrix $V(\omega, \omega^3, \ldots, \omega^{(2L-1)})$ defined by

$$V(\omega, \omega^3, \ldots, \omega^{(2L-1)}) := \begin{pmatrix} I_n & \frac{1}{\omega}I_n & \cdots & \left(\frac{1}{\omega}\right)^{(L-1)} I_n \\ I_n & \frac{1}{\omega^3}I_n & \cdots & \left(\frac{1}{\omega^3}\right)^{(L-1)} I_n \\ \vdots & \vdots & & \vdots \\ I_n & \frac{1}{\omega^{(2L-1)}}I_n & \cdots & \left(\frac{1}{\omega^{(2L-1)}}\right)^{(L-1)} I_n \end{pmatrix}$$

is invertible, there exists $1 \le k \le L$ such that $\sum_{l=1}^{L} \left(\frac{1}{\omega^{(2k-1)}}\right)^{(l-1)} x_l \neq 0$, for otherwise we would have $x_1 = \cdots = x_L = 0$ and, in turn, since $x = -\mathcal{Q}x$, $x = 0$, a contradiction.

For this k, let

$$x^+ = \sum_{l=1}^{L} \left(\frac{1}{\omega^{(2k-1)}}\right)^{(l-1)} x_l \; ; \; x^- = \sum_{l=1}^{L} \left(\frac{1}{\omega^{(2k-1)}}\right)^{(l-1)} x_{(L+l)} \; ; \; X = \begin{pmatrix} x^+ \\ x^- \end{pmatrix}.$$

Note that $X = -QX \neq 0$ and

$$\begin{aligned} \omega^{(2k-1)}x^+ &= A_{\mathrm{SS}_{+,+}} \left[\omega^{(2k-1)} M x_{(L+1)} + x_1 + \cdots + \left(\frac{1}{\omega^{(2k-1)}}\right)^{(L-2)} x_{(L-1)}\right] \\ &\quad + A_{\mathrm{SS}_{+,-}} \left[\omega^{(2k-1)} M^{-1} x_1 + x_{(L+1)} + \cdots + \left(\frac{1}{\omega^{(2k-1)}}\right)^{(L-2)} x_{(2L-1)}\right] \\ &= A_{\mathrm{SS}_{+,+}} x^+ + A_{\mathrm{SS}_{+,-}} x^- \end{aligned}$$

since $x_L = -Mx_{(L+1)}, x_1 = -Mx_{2L}$, and $-\omega^{(2k-1)} = \left(\frac{1}{\omega^{(2k-1)}}\right)^{(L-1)}$.

Likewise, we get

$$\left(\frac{1}{\omega^{(2k-1)}}\right) x^- = A_{\mathrm{SS}_{-,+}} x^+ + A_{\mathrm{SS}_{-,-}} x^- \quad .$$

Hence, $(\Delta(\omega^{(2k-1)}) - A_{\mathrm{SS}})X = 0$ with $X \neq 0$.

Case 2. $x \neq -\mathcal{Q}x$.
Define $z := x + \mathcal{Q}x$. Since it is nonzero, it is an eigenvector of N with eigenvalue 1. Also, $z = \mathcal{Q}z$. Considering $V(1, \omega^2, \ldots, \omega^{(2L-2)})$ as for Case 1, one deduces that there exists $0 \leq k \leq (L-1)$ such that $\sum_{l=1}^{L} \left(\frac{1}{\omega^{(2k)}}\right)^{(l-1)} z_l \neq 0$.
Then, if we let

$$z^+ = \sum_{l=1}^{L} \left(\frac{1}{\omega^{(2k)}}\right)^{(l-1)} z_l;\ z^- = \sum_{l=1}^{L} \left(\frac{1}{\omega^{(2k)}}\right)^{(l-1)} z_{(L+l)};\ Z = \begin{pmatrix} z^+ \\ z^- \end{pmatrix},$$

we get $(\Delta(\omega^{(2k)}) - A_{\mathrm{SS}})Z = 0$ with $Z \neq 0$, after calculations similar to those of Case 1.

Hence, in any case, the periodic system is not well-posed. □

Remark 1. Note that the condition in Proposition 4.3 is sufficient but not necessary, as can be seen by considering the following case where $n = 1$, $M = 1$, and $L = 2$:

$$A_{\mathrm{SS}} = \begin{pmatrix} 3 & 2 \\ 2 & 3 \end{pmatrix}.$$

A_{SS} has an eigenvalue at 1, which means that the periodic system is not well-posed. However, the corresponding matrix $I - N$ is

$$I_4 - \begin{pmatrix} 2 & 0 & 3 & 0 \\ 3 & 0 & 2 & 0 \\ 0 & 2 & 0 & 3 \\ 0 & 3 & 0 & 2 \end{pmatrix} = \begin{pmatrix} -1 & 0 & -3 & 0 \\ -3 & 1 & -2 & 0 \\ 0 & -2 & 1 & -3 \\ 0 & -3 & 0 & -1 \end{pmatrix},$$

which is invertible.

In particular, this means that all analysis results pertaining to periodic systems only yield sufficient conditions for finite extent systems.

Finally, let $\mathbf{H} : \ell_2(\mathbb{Z}_{2L}) \to \ell_2(\{1, \ldots, L\})$ be defined by

$$(\mathbf{H}v)(s) = v(L + s) \text{ for all } s = 1, \ldots, L.$$

Note that the restriction of $\mathbf{H}$ to the reversible subspaces $\mathfrak{R}_{\mathrm{T}}$, $\mathfrak{R}_{\mathrm{S}}$, $\mathfrak{R}_d$, and $\mathfrak{R}_z$ is invertible with, for example,

$$(\mathbf{H}^{-1}_{|\mathfrak{R}_{\mathrm{s}}} v)(s) = \begin{cases} Qv(L + 1 - s) \text{ if } s = 1, \ldots, L, \\ v(s - L) \text{ if } s = (L + 1), \ldots, 2L, \end{cases} \tag{20}$$

and similar relations in the other cases.

PROPOSITION 4.4. *Assume the basic building block* (1) *is reversible. Then*

$$\mathbf{H}\, K = K\, \mathbf{H} \text{ for all matrix } K, \tag{21a}$$

$$\Delta_{\mathrm{S}} \mathbf{H}^{-1}_{|\mathfrak{R}_{\mathrm{s}}} = \mathbf{H}^{-1}_{|\mathfrak{R}_{\mathrm{s}}} \Delta_{\mathrm{BC}}, \tag{21b}$$

$$A_{\mathrm{SS}} \mathbf{H}^{-1}_{|\mathfrak{R}_{\mathrm{s}}} = \mathbf{H}^{-1}_{|\mathfrak{R}_{\mathrm{s}}} A_{\mathrm{SS}}, \tag{21c}$$

Proof. Equation (21a) is clear. Equation (21c) simply follows from the fact that A_{SS} and Q commute. For (21b), we start by showing that $\Delta_{\mathrm{BC}} = \mathbf{H}\Delta_{\mathrm{S}}\mathbf{H}^{-1}_{|\mathfrak{R}_{\mathrm{s}}}$. Let

$w = \mathbf{H}_{|\Re_S}^{-1} v$, $y = \Delta_S w$ and $z = \mathbf{H} y$. Then, for all $1 \le s \le L$,

$$z^+(s) = y^+(L+s) = w^+(L+s+1), \tag{22a}$$

$$z^-(s) = y^-(L+s) = w^-(L+s-1). \tag{22b}$$

If $1 \le s \le L-1$, (22a) means that $z^+(s) = v^+(s+1)$. For $s = L$, $L+s+1 = 2L+1 = 1 \bmod 2L$, and hence $z^+(L) = w^+(1) = Mv^-(L)$, using (20). Likewise, for $2 \le s \le L$, $z^-(s) = v^-(s-1)$ while $z^-(1) = w^-(L) = M^{-1}v^+(1)$. All in all, recalling interconnection relation (7), we see that $z = \Delta_{BC} v$. This shows that

$$\Delta_{BC} = \mathbf{H} \Delta_S \mathbf{H}_{|\Re_S}^{-1}. \tag{23}$$

Finally, (17) implies that $\Re_S$ is a stable subspace for operator Δ_S (i.e., $\Delta_S v \in \Re_S$ if $v \in \Re_S$). We can thus left-multiply (23) by $\mathbf{H}_{|\Re_S}^{-1}$ to get (ii). ∎

We are now in a position to state and prove the main theorem of this section.

THEOREM 4.5 (method of images). *Let a spatially M-reversible finite extent system be such that the corresponding periodic system is well-posed. For an input $d \in \mathcal{L}_2(\{1,\dots,L\})$ and initial state $x^0 \in \ell_2(\{1,\dots,L\})$, let $d^P(t) := \mathbf{H}_{|\Re_d}^{-1} d(t)$ and $(x^0)^P := \mathbf{H}_{|\Re_T}^{-1} x^0$. Let (x^P, v^P, z^P) be the spatially reversible solution of the periodic system with input d^P, initial state $(x^0)^P$. Then (x, v, z) defined by $x(t) := \mathbf{H} x^P(t)$, $v(t) := \mathbf{H} v^P(t)$, and $z(t) := \mathbf{H} z(t)^P$ for all $t \ge 0$ is the unique solution of the finite extent system with input d and initial condition x^0.*

Proof. First, according to Proposition 4.3, the finite extent system is well-posed since the periodic one is. The finite system thus has a unique solution (x, v, z), where x is the mild solution of (11a) for $\Delta = \Delta_{BC}$. Now, note that $x^P(t)$ satisfies

$$x^P(t) = e^{t\mathbf{A}} (x^0)^P + \int_0^t e^{(t-\tau)\mathbf{A}} (\mathbf{B} d^P)(\tau)\, d\tau \tag{24}$$

for $\mathbf{A} = A_{TT} + A_{TS}(\Delta_S - A_{SS})^{-1} A_{ST}$ and $\mathbf{B} = B_T + A_{TS}(\Delta_S - A_{SS})^{-1} B_S$. Hence

$$\left(\mathbf{H} x^P\right)(t) = \mathbf{H} e^{t\mathbf{A}} (x^0)^P + \mathbf{H} \int_0^t e^{(t-\tau)\mathbf{A}} (\mathbf{B} d^P)(\tau)\, d\tau. \tag{25}$$

Using relation (17) and the fact that A_{SS} commutes with Q, it is easy to see that the subspace $\Re_S$ is invariant for the mapping $(\Delta_S - A_{SS})$. Hence, we can write

$$\begin{aligned} \mathbf{H}(\Delta_S - A_{SS})_{|\Re_S}^{-1} &= \left((\Delta_S - A_{SS})_{|\Re_S} \mathbf{H}_{|\Re_S}^{-1}\right)^{-1} \\ &= \left(\mathbf{H}_{|\Re_S}^{-1} (\Delta_{BC} - A_{SS})_{|\Re_S}\right)^{-1}, \end{aligned}$$

where we have used Proposition 4.4. This, coupled with the fact that the basic building block is reversible, yields $\mathbf{H}\mathbf{A}x = \mathbf{A}_{BC}\mathbf{H}x$ for all $x \in \Re_T$ and $\mathbf{H}\mathbf{B}d = \mathbf{B}_{BC}\mathbf{H}d$ for all $d \in \Re_d$, where $\mathbf{A}_{BC} = A_{TT} + A_{TS}(\Delta_{BC} - A_{SS})^{-1} A_{ST}$ and $\mathbf{B}_{BC} = B_T + A_{TS}(\Delta_{BC} - A_{SS})^{-1} B_S$. In particular, this also implies that $\mathbf{H} e^{t\mathbf{A}} (x^0)^P = e^{t\mathbf{A}_{BC}} \mathbf{H} (x^0)^P$, since $(x^0)^P \in \Re_T$. All in all, plugging this back into (24) gives that

$$\mathbf{H} x^P(t) = e^{t\mathbf{A}_{BC}}\, \mathbf{H} (x^0)^P + \int_0^t e^{(t-\tau)\mathbf{A}_{BC}} \mathbf{B}_{BC} (\mathbf{H} d^P)(\tau) d\tau,$$

i.e., that $x(t) = \mathbf{H}x^P(t)$ for all $t \geq 0$ since $(x^0)^P$ and d^P are reversible by construction. Once this is known, it is clear that $v = \mathbf{H}v^P$ and $z = \mathbf{H}z^P$. ∎

An easy but fundamental corollary is that stability and performance of a spatially reversible finite extent system are related to similar properties of the corresponding periodic and infinite system.

COROLLARY 4.6. *If a spatially M-reversible, well-posed, periodic system is stable, then the corresponding finite extent system, with boundary conditions matrix M, is stable. Moreover, the input/output gains of the two systems satisfy*

$$\|T_{dz}\|_{\mathcal{L}_2(\{1,\dots,L\})} \leq \sqrt{\frac{1+\bar{\sigma}(R)^2}{1+\underline{\sigma}(U)^2}}\|T^P_{dz}\|_{\mathcal{L}_2(\mathbb{Z}_{2L})},$$

where T_{dz} and T^P_{dz} are the input/output map of the finite extent and periodic system, respectively. In particular, if R and U are unitary,

$$\|T^P_{dz}\|_{\mathcal{L}_2(\mathbb{Z}_{2L})} < 1 \Rightarrow \|T_{dz}\|_{\mathcal{L}_2(\{1,\dots,L\})} < 1\ .$$

Proof. We first prove stability. First assume that the periodic system is stable and pick an initial condition $x^0 \in \ell_2(\{1,\dots,L\})$ for the finite extent system. Let (x,v,z) be the corresponding solution in the absence of an input, which is uniquely determined since we assumed well-posedness. Let $(x^0)^P$ and x^P be defined as in Theorem 4.5. Then, Theorem 4.5 implies that, for all $t \geq 0$,

$$\|x(t)\|_{\ell_2(\{1,\dots,L\})} \leq \|x^P(t)\|_{\ell_2(\mathbb{Z}_{2L})} \xrightarrow[t\to\infty]{} 0 \text{ exponentially}$$

since the periodic system is stable. Since this holds for any x^0, the finite extent is stable.

For performance, using the notation of Theorem 4.5, we note that

$$\|d^P\|^2_{\mathcal{L}_2(\mathbb{Z}_{2L})} \leq \left(1+\bar{\sigma}(R)^2\right)\|d\|^2_{\mathcal{L}_2(\{1,\dots,L\})}\ .$$

Also $\|z^P\|^2_{\mathcal{L}_2(\mathbb{Z}_{2L})} \geq \left(1+\underline{\sigma}(U)^2\right)\|z\|^2_{\mathcal{L}_2(\{1,\dots,L\})}$. ∎

5. Examples. We now give some practical examples of spatially reversible systems and their corresponding boundary conditions.

Example 1 (two-sided platoon). The following is adapted from [19]. Consider the problem of controlling a platoon of L vehicles such that each has a constant velocity V and is halfway between its predecessor and successor in the line, in spite of external noise. This design requirement captures the notion of "safety" since it ensures that each vehicle is as far away as possible from its two closest neighbors. This system can be described by

$$\dot{e}(t,s) = -\mathrm{v}(t,s) + \frac{1}{2}\left(\mathrm{v}(t,s+1) + \mathrm{v}(t,s-1)\right), \tag{26a}$$

$$\dot{\mathrm{v}}(t,s) = a(t,s), \tag{26b}$$

$$\dot{a}(t,s) = -a(t,s) + u(t,s) + m(t,s), \tag{26c}$$

$$z(t,s) = e(t,s) \ \text{ for all } s = 1,\dots,L, \qquad t \geq 0, \tag{26d}$$

where, in a frame moving with constant velocity V, $\mathrm{v}(.,s)$, $a(.,s)$, $u(.,s)$, $m(.,s)$ are the velocity, acceleration, control, and external noise of the sth vehicle, respectively.

$e(.,s)$ is the difference between the position of the sth vehicle and the middle of its closest neighbors. This system can be put into the standard form (8) by choosing

$$x = \begin{pmatrix} e \\ \mathrm{v} \\ a \end{pmatrix},\ d = \begin{pmatrix} u \\ m \end{pmatrix}, \qquad n_{\mathrm{T}} = 3,\ n = 1,$$

$$A_{\mathrm{TT}} = \begin{pmatrix} 0 & -1 & 0 \\ 0 & 0 & 1 \\ 0 & 0 & -1 \end{pmatrix},\ A_{\mathrm{TS}} = \begin{pmatrix} \frac{1}{2} & \frac{1}{2} \\ 0 & 0 \\ 0 & 0 \end{pmatrix},\ B_{\mathrm{T}} = \begin{pmatrix} 0 & 0 \\ 0 & 0 \\ 1 & 1 \end{pmatrix},$$

$$A_{\mathrm{ST}} = \begin{pmatrix} 0 & 1 & 0 \\ 0 & 1 & 0 \end{pmatrix},\ A_{\mathrm{SS}} = \begin{pmatrix} 0 & 0 \\ 0 & 0 \end{pmatrix},\ B_{\mathrm{S}} = \begin{pmatrix} 0 & 0 \\ 0 & 0 \end{pmatrix},$$

$$C_{\mathrm{T}} = \begin{pmatrix} 1 & 0 & 0 \end{pmatrix},\ C_{\mathrm{S}} = \begin{pmatrix} 0 & 0 \end{pmatrix},\ D = \begin{pmatrix} 0 & 0 \end{pmatrix}.$$

Two different sets of relevant boundary conditions can be thought of that will yield a spatially reversible system. Both involve a virtual leader, located in front of the first vehicle of the platoon, and a virtual follower located behind the Lth vehicle of the platoon as follows:

- The virtual leader and follower have the same velocity as the first and last vehicle of the platoon, respectively. This case can be captured by the boundary conditions matrix $M = 1$ and can be used to specify that the platoon should follow the virtual leader. The corresponding finite extent system is then reversible with $P = U = R = I$.
- The virtual leader's (respectively, follower's) velocity is the opposite of the first (respectively, last) vehicle's. This boundary condition can be captured by taking $M = -1$ and corresponds to a case where the leader is reversing in front of the platoon. The corresponding finite extent system is reversible with $P = U = R = -I$.

Example 2 (heat equation). The following is the partial differential equation describing the diffusion of heat in a bar of unit length:

$$\frac{\partial x}{\partial t} = \frac{\partial^2 x}{\partial l^2} + d \ \text{ for all } l \in (0,1), \qquad t \geq 0, \tag{27a}$$

$$x(0,l) = x^0(l) \ \text{ for all } l \in (0,1), \tag{27b}$$

$$x(t,0) = x(t,1) = 0 \ \text{ for all } t \geq 0. \tag{27c}$$

In (27), $x(t,l) \in \mathbb{R}$ is the temperature at time t and position $l \in [0,1]$, and $d(t,l)$ is a distributed heat source. The Dirichlet boundary conditions (27c) mean that the temperature is held constant at both ends, while initial conditions (27b) specify that the initial temperature profile is x^0.

We discretize this equation in the spatial direction using a centered finite-difference method with step δ_l such that $\frac{1}{\delta_l} = L \in \mathbb{N}$. If we write $\bar{x}(t,s)$ for the approximation of $x\left(t, \left(s - \frac{1}{2}\right)\delta_l\right)$ and approximate $\frac{\partial x}{\partial l}(t,l)$ to second order in δ_l by

$$\frac{x(t, l + \frac{\delta_l}{2}) - x(t, l - \frac{\delta_l}{2})}{\delta_l}$$

for all $l \in [0, L]$, we get the following semidiscretized system, [3], [5]:

$$\frac{d\bar{x}}{dt}(t,s) = \frac{\bar{x}(t,s+1) - 2\bar{x}(t,s) + \bar{x}(t,s-1)}{\delta_l^2} + d\left(t, \left(s - \frac{1}{2}\right)\delta_l\right) \text{ for all } s = 1, \ldots, L, \qquad t \geq 0, \tag{28a}$$

$$\bar{x}(0,s) = x^0\left(\left(s - \frac{1}{2}\right)\delta_l\right) \tag{28b}$$

with boundary conditions

$$\bar{x}(t,0) = -\bar{x}(t,1);\ \bar{x}(t,L) = -\bar{x}(t,L+1). \tag{29}$$

The latter approximate the original boundary conditions (27c) up to order δ_l^2, which is also the order of accuracy of (28a). This system can be written as a finite extent system in standard form (8) with

$$x = z = \bar{x},\ n_{\mathrm{T}} = 1,\ n = 1,$$

$$A_{\mathrm{TT}} = -\frac{2}{\delta_l^2},\ A_{\mathrm{TS}} = \frac{1}{\delta_l^2}\begin{pmatrix} 1 & 1 \end{pmatrix},\ B_{\mathrm{T}} = 1,$$

$$A_{\mathrm{ST}} = \begin{pmatrix} 1 \\ 1 \end{pmatrix},\ A_{\mathrm{SS}} = \begin{pmatrix} 0 & 0 \\ 0 & 0 \end{pmatrix},\ B_{\mathrm{S}} = \begin{pmatrix} 0 \\ 0 \end{pmatrix},$$

$$C_{\mathrm{T}} = 1,\ C_{\mathrm{S}} = \begin{pmatrix} 0 & 0 \end{pmatrix},\ D = 0.$$

Then if we let $v^+(t,1) := \bar{x}(t,0)$ and $v^-(L) := \bar{x}(t,L+1)$, boundary conditions (29) can be rewritten as

$$v^+(t,1) = -w^-(t,1);\ v^-(t,L) = -w^+(t,L),$$

which corresponds to the boundary conditions matrix $M = -1$. It is then easy to see that the system is spatially reversible with $P = U = R = -I$.

6. Control synthesis for finite extent systems. We are now interested in solving the following $\mathcal{H}_\infty$ synthesis problem.

PROBLEM 1. *Given a finite extent system with boundary conditions (the plant), find another such system (the controller) such that the closed-loop is well-posed, stable, and contractive.*

It is also desirable that the algorithm for determining a satisfactory controller be computationally tractable, irrespective of the number of subsystems in the plant. Also note that we explicitly require the controller to have the same spatial structure as the plant, as shown in Figure 2. Hence we are aiming for a *distributed control strategy*, as opposed to a centralized strategy (in which all the subsystems of the plant are connected to the *same* controller) or decentralized strategy (in which subsystems of the controller are not interconnected with each other).

As is the case for analysis, Problem 1 has counterparts for the periodic and infinite systems corresponding to the plant. Their statements are obvious and they will be referred to as the periodic synthesis problem and infinite synthesis problem,

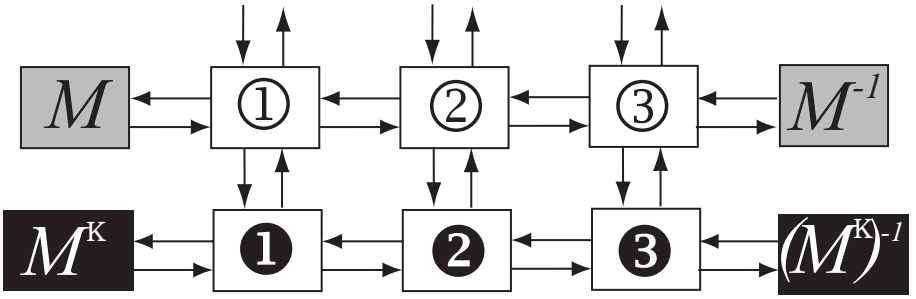

FIG. 2. *Interconnection of the finite extent plant and controller for $L = 3$. Note that feedback is distributed.*

respectively. Both the periodic synthesis problem and the infinite synthesis problem can be efficiently solved using the methods developed in [1] and [5]. The first involves solving a family of synthesis problems, parameterized by spatial frequency while, for the second, synthesis conditions take the form of a *single* linear matrix inequality (LMI). However, these are only sufficient conditions. In the recent past [18], [14], Problem 1 has been tackled in the following way:

1. Solve the periodic (respectively, infinite) synthesis problem for the periodic (respectively, infinite) system corresponding to the given, finite extent, plant. This results in a periodic (respectively, infinite) controller.
2. Supplement the periodic or infinite controller's realization with some "well-chosen" boundary conditions to obtain a finite extent one solving Problem 1.

This procedure implicitly assumes that the stability and performance of the finite extent closed-loop system can be derived from the properties of the spatially invariant one and that the influence of the controller's boundary conditions can be evaluated. As already noted in [18], the last point is delicate. Bluntly stated, it is not clear what "well-chosen" boundary conditions should be in the general case.

However, we have just established that such a link between finite extent and periodic systems exists in the case of spatial reversibility. In this framework, "well-chosen" also gains a clear meaning: given a realization of the closed-loop periodic system, a well-chosen boundary conditions matrix M^{K} for the controller should be such that the closed-loop system is spatially reversible with some boundary conditions matrix M^{C}. Indeed, if this is the case, Corollary 4.6 will guarantee stability and performance when the controller, which solves the periodic synthesis problem, is implemented on the finite plant, with boundary conditions M^{K}.

In the remaining sections, we develop tools to show that $M^{\mathrm{K}} = (M^*)^{-1}$ is a well-chosen boundary condition for the controller if the plant, with boundary conditions matrix M, is spatially reversible. More precisely, we show the following.

THEOREM 6.1. *Given a finite extent, spatially reversible plant, there exists a spatially reversible, finite extent controller, with $n_{\mathrm{T}}^{\mathrm{K}} = n_{\mathrm{T}}$, $n^{\mathrm{K}} = n$, and boundary conditions matrix $M^{\mathrm{K}} = (M^*)^{-1}$, that solves Problem* 1 *if the LMI conditions of* [5] (*equations* (34)) *are satisfied and if the plant's involutions R and U satisfy $R = \mathbf{diag}(R^u, R^d)$ and $U = \mathbf{diag}(U^y, U^z)$ with $R^d = \left(R^d\right)^* = \left(R^d\right)^{-1}$, $U^z = (U^z)^* = (U^z)^{-1}$.*

This means that $\mathcal{H}_\infty$ synthesis for a spatially reversible finite extent system (with boundary conditions) can be achieved by solving a convex problem, to determine

the controller's basic building block, and by "reading off" the controller's boundary conditions from the plant. The first step toward this synthesis result, which is also needed to make the statement of Problem 1 more rigorous, is the interconnection of reversible systems.

6.1. Interconnection of systems and spatial reversibility. The interconnection of two finite extent, periodic, or infinite systems is obtained by performing a linear fractional transformation of every pair of subsystems with the same index. This is depicted in Figure 2 in the case of finite extent systems.

More precisely, suppose we are given a plant with two sets of inputs (the exogenous disturbance $d \in \mathbb{R}^{m_d}$ and the control input $u \in \mathbb{R}^{m_u}$) and outputs (the performance output $z \in \mathbb{R}^{p_z}$ and the measured output $y \in \mathbb{R}^{p_y}$), as described by

$$\frac{d}{dt}x(t) = A_{\mathrm{TT}}x(t) + A_{\mathrm{TS}}v(t) + \begin{pmatrix} B_{\mathrm{T}}^u & B_{\mathrm{T}}^d \end{pmatrix}\begin{pmatrix} u(t) \\ d(t) \end{pmatrix},\ x(0) = x^0, \tag{30a}$$

$$(\Delta - A_{\mathrm{SS}})\,[v(t)] = A_{\mathrm{ST}}x(t) + \begin{pmatrix} B_{\mathrm{S}}^u & B_{\mathrm{S}}^d \end{pmatrix}\begin{pmatrix} u(t) \\ d(t) \end{pmatrix}, \tag{30b}$$

$$\begin{pmatrix} y(t) \\ z(t) \end{pmatrix} = \begin{pmatrix} C_{\mathrm{T}}^y \\ C_{\mathrm{T}}^z \end{pmatrix}x(t) + \begin{pmatrix} C_{\mathrm{S}}^y \\ C_{\mathrm{S}}^z \end{pmatrix}v(t) + \begin{pmatrix} D^{yu} & D^{yd} \\ D^{zu} & D^{zd} \end{pmatrix}\begin{pmatrix} u(t) \\ d(t) \end{pmatrix}. \tag{30c}$$

Then its interconnection with the controller given by

$$\frac{d}{dt}x^{\mathrm{K}}(t) = A_{\mathrm{TT}}^{\mathrm{K}}x^{\mathrm{K}}(t) + A_{\mathrm{TS}}^{\mathrm{K}}v^{\mathrm{K}}(t) + B_{\mathrm{T}}^{\mathrm{K}}y(t),\ x^{\mathrm{K}}(0) = (x^{\mathrm{K}})^0, \tag{31a}$$

$$(\Delta - A_{\mathrm{SS}})\,[v^{\mathrm{K}}(t)] = A_{\mathrm{ST}}^{\mathrm{K}}x^{\mathrm{K}}(t) + B_{\mathrm{S}}^{\mathrm{K}}y(t), \tag{31b}$$

$$u(t) = C_{\mathrm{T}}^{\mathrm{K}}x^{\mathrm{K}}(t) + C_{\mathrm{S}}^{\mathrm{K}}v^{\mathrm{K}}(t) + D^{\mathrm{K}}y(t) \ \text{ for all } t \geq 0 \tag{31c}$$

is the system obtained by eliminating u and y in (30) and (31). We emphasize that $[x^{\mathrm{K}}(t)](s) \in \mathbb{R}^{n_{\mathrm{T}}^{\mathrm{K}}}$ and $[(v^+)^K(t)](s),\ [(v^-)^K(t)](s) \in \mathbb{R}^{n^{\mathrm{K}}}$ for all $t \geq 0$, and s with $n_{\mathrm{T}}^{\mathrm{K}} \neq n_{\mathrm{T}}$ and $n^{\mathrm{K}} \neq n$ a priori. The dimensions of the matrices defining operator Δ in (31b) are thus chosen accordingly.

The corresponding closed-loop system equations can be put in standard form (8) using the permutation matrix

$$\Pi = \begin{pmatrix} I_n & 0 & 0 & 0 \\ 0 & 0 & I_{n^{\mathrm{K}}} & 0 \\ 0 & I_n & 0 & 0 \\ 0 & 0 & 0 & I_{n^{\mathrm{K}}} \end{pmatrix}$$

in order to group the spatial variables properly. This means that the closed-loop system is also a finite extent, periodic, or infinite system, depending on the case. A realization of the corresponding basic building block, when $D^{yu} = 0$, is given below. Note that this is not a restrictive assumption since one can always use loop-shifting

if this situation is not at hand (see [5] and references therein):

$$A^{\mathrm{C}}_{\mathrm{TT}} = \begin{pmatrix} A_{\mathrm{TT}} + B^u_{\mathrm{T}} D^{\mathrm{K}} C^y_{\mathrm{T}} & B^u_{\mathrm{T}} C^{\mathrm{K}}_{\mathrm{T}} \\ B^{\mathrm{K}}_{\mathrm{T}} C^y_{\mathrm{T}} & A^{\mathrm{K}}_{\mathrm{TT}} \end{pmatrix}, \quad A^{\mathrm{C}}_{\mathrm{TS}} = \begin{pmatrix} A_{\mathrm{TS}} + B^u_{\mathrm{T}} D^{\mathrm{K}} C^y_{\mathrm{S}} & B^u_{\mathrm{T}} C^{\mathrm{K}}_{\mathrm{S}} \\ B^{\mathrm{K}}_{\mathrm{T}} C^y_{\mathrm{S}} & A^{\mathrm{K}}_{\mathrm{TS}} \end{pmatrix} \Pi,$$

$$A^{\mathrm{C}}_{\mathrm{ST}} = \Pi \begin{pmatrix} A_{\mathrm{ST}} + B^u_{\mathrm{S}} D^{\mathrm{K}} C^y_{\mathrm{T}} & B^u_{\mathrm{S}} C^{\mathrm{K}}_{\mathrm{T}} \\ B^{\mathrm{K}}_{\mathrm{S}} C^y_{\mathrm{T}} & A^{\mathrm{K}}_{\mathrm{ST}} \end{pmatrix}, \quad A^{\mathrm{C}}_{\mathrm{SS}} = \Pi \begin{pmatrix} A_{\mathrm{SS}} + B^u_{\mathrm{S}} D^{\mathrm{K}} C^y_{\mathrm{S}} & B^u_{\mathrm{S}} C^{\mathrm{K}}_{\mathrm{S}} \\ B^{\mathrm{K}}_{\mathrm{S}} C^y_{\mathrm{S}} & A^{\mathrm{K}}_{\mathrm{SS}} \end{pmatrix} \Pi,$$

$$B^{\mathrm{C}}_{\mathrm{T}} = \begin{pmatrix} B^d_{\mathrm{T}} + B^u_{\mathrm{T}} D^{\mathrm{K}} D^{yd} \\ B^{\mathrm{K}}_{\mathrm{T}} D^{yd} \end{pmatrix}, \qquad B^{\mathrm{C}}_{\mathrm{S}} = \Pi \begin{pmatrix} B^d_{\mathrm{S}} + B^u_{\mathrm{S}} D^{\mathrm{K}} D^{yd} \\ B^{\mathrm{K}}_{\mathrm{S}} D^{yd} \end{pmatrix},$$

$$C^{\mathrm{C}}_{\mathrm{T}} = \begin{pmatrix} C^z_{\mathrm{T}} + D^{zu} D^{\mathrm{K}} C^y_{\mathrm{T}} & D^{zu} C^{\mathrm{K}}_{\mathrm{T}} \end{pmatrix}, \quad C^{\mathrm{C}}_{\mathrm{S}} = \begin{pmatrix} C^z_{\mathrm{S}} + D^{zu} D^{\mathrm{K}} C^y_{\mathrm{S}} & D^{zu} C^{\mathrm{K}}_{\mathrm{S}} \end{pmatrix} \Pi,$$

$$D^{\mathrm{C}} = D^{zd} + D^{zu} D^{\mathrm{K}} D^{yd}. \tag{32}$$

Using (32), it is easy to show the following.

PROPOSITION 6.2. *Let the plant, with boundary conditions matrix M, and the controller, with boundary conditions matrix M^{K}, be spatially reversible. Assume further that the involutions R and U for the plant and R^{K} and U^{K} for the controller satisfy $R^{\mathrm{K}} = U^y$ and $U^{\mathrm{K}} = R^u$, where U and R are partitioned conformably to the inputs and outputs as $R = \mathbf{diag}(R^u, R^d)$ and $U = \mathbf{diag}(U^y, U^z)$. Then their interconnection, which has $M^{\mathrm{C}} = \mathbf{diag}(M, M^{\mathrm{K}})$ as boundary conditions matrix, is spatially reversible with $R^{\mathrm{C}} = R^d$, $P^{\mathrm{C}} = \mathbf{diag}(P, P^{\mathrm{K}})$, and $U^{\mathrm{C}} = U^z$.*

Proposition 6.2, combined with Corollary 4.6, already gives a way to solve Problem 1: if the periodic synthesis problem can be (tractably) solved *by any means*, and if the resulting controller can be shown to be M^{K}-reversible for some matrix M^{K}, with $R^{\mathrm{K}} = U$ and $U^{\mathrm{K}} = R$, then this is the boundary conditions matrix that should be used for the finite extent controller.

6.2. Reversible infinite controllers for reversible infinite plants. In this section we give the second element needed to establish Theorem 6.1, namely, the following.

PROPOSITION 6.3. *Consider an M-reversible infinite plant. Assume the involutions R and U for the plant are of the type indicated in Theorem* 6.1. *Then it is always possible to solve the infinite synthesis problem with an $(M^*)^{-1}$-*reversible *controller, provided the LMI condition of* [5] (*equation* (34)) *is satisfied. Moreover, $R^{\mathrm{K}} = U^y$, $U^{\mathrm{K}} = R^u$, and $P^{\mathrm{K}} = P^*$ for this controller.*

It should be noted that this reversible controller is *not* necessarily the solution that one would obtain by directly solving (34)–(37) with a numerical solver such as those included in the LMI toolbox for MATLAB. However, if one has a solution, one can construct such an $(M^*)^{-1}$-reversible controller by following the steps of the proof.

Before proving Proposition 6.3, we should clarify why this implies Theorem 6.1. First, thanks to a theorem of [1] stating that the input/output gain of well-posed, stable systems over a group can be determined by a frequency-grid search, one can prove that contractiveness of the infinite system implies contractiveness of the corresponding periodic system, using arguments very similar to those of Proposition 3.3. As a result, the periodic system corresponding to the $(M^*)^{-1}$-reversible controller of Proposition 6.3 solves the periodic synthesis problem. The periodic closed-loop system is thus well-posed, stable, and contractive. It is also M^{C}-reversible with $M^{\mathrm{C}} = \mathbf{diag}(M, (M^*)^{-1})$ by virtue of Proposition 6.2. One can then apply the method of images to show that the corresponding finite extent closed-loop system is also well-posed and stable. Finally, since R^d and U^z are assumed to be unitary, Corollary 4.6 yields contractiveness of the finite extent closed-loop.

It might seem artificial to introduce the infinite system in order to solve Problem 1, while the method of images refers only to the periodic system. The main practical reason for using a finite controller corresponding to a reversible solution of the *infinite* synthesis problem is the following. Imagine the number L of subsystems in the finite extent system is changed to $L' \neq L$. Then the size of the corresponding periodic system also changes (from $2L$ to $2L'$) and so does the corresponding group $\mathbb{U}$, which now becomes $\mathbb{U}'$, the group of $(2L')$th root of unity. A solution of the periodic synthesis problem for $2L$ subsystems does not necessarily solve the same problem for $2L'$ subsystems since well-posedness, stability, and performance of the closed-loop all depend on the group $\mathbb{U}$, and $\mathbb{U}'$ may or may not be a subgroup of $\mathbb{U}$. Hence, if one uses a finite extent controller corresponding to a reversible solution of the periodic synthesis problem, one has to redo a synthesis if the number of subsystems in the finite extent plant changes. This is not desirable since this number is in fact irrelevant for a spatially reversible plant (only the boundary conditions matter). A reversible solution of the infinite synthesis problem, on the other hand, solves it irrespective of L.

Proof. The proof is by construction. For the reader's convenience and because they are used extensively in this proof, we first recall the notation and main results of [5].

Given a well-posed infinite plant with basic building block (1), let

$$H = \begin{pmatrix} I_n & 0 \\ 0 & -I_n \end{pmatrix}$$

and define the bilinear algebraic transformed system by

$$\overline{A_{\mathrm{SS}}} := H(A_{\mathrm{SS}} - I)(A_{\mathrm{SS}} + I)^{-1}, \tag{33a}$$

$$\begin{pmatrix} \overline{A_{\mathrm{ST}}} & \overline{B_{\mathrm{S}}} \end{pmatrix} := \sqrt{2}H(A_{\mathrm{SS}} + I)^{-1}\begin{pmatrix} A_{\mathrm{ST}} & B_{\mathrm{S}} \end{pmatrix}, \tag{33b}$$

$$\begin{pmatrix} \overline{A_{\mathrm{TS}}} \\ \overline{C_{\mathrm{S}}} \end{pmatrix} := \sqrt{2}\begin{pmatrix} A_{\mathrm{TS}} \\ C_{\mathrm{S}} \end{pmatrix}(A_{\mathrm{SS}} + I)^{-1}, \tag{33c}$$

$$\begin{pmatrix} \overline{A_{\mathrm{TT}}} & \overline{B_{\mathrm{T}}} \\ \overline{C_{\mathrm{T}}} & \overline{D} \end{pmatrix} := \begin{pmatrix} A_{\mathrm{TT}} & B_{\mathrm{T}} \\ C_{\mathrm{T}} & D \end{pmatrix} - \begin{pmatrix} A_{\mathrm{TS}} \\ C_{\mathrm{S}} \end{pmatrix}(A_{\mathrm{SS}} + I)^{-1}\begin{pmatrix} A_{\mathrm{ST}} & B_{\mathrm{S}} \end{pmatrix}, \tag{33d}$$

$$\overline{A}^{\mathrm{G}} = \begin{pmatrix} \overline{A_{\mathrm{TT}}} & \overline{A_{\mathrm{TS}}} \\ \overline{A_{\mathrm{ST}}} & \overline{A_{\mathrm{SS}}} \end{pmatrix},\ \overline{B}^{\mathrm{G}} = \begin{pmatrix} \overline{B_{\mathrm{T}}} \\ \overline{B_{\mathrm{S}}} \end{pmatrix},\ \overline{C}^{\mathrm{G}} = \begin{pmatrix} \overline{C_{\mathrm{T}}} & \overline{C_{\mathrm{S}}} \end{pmatrix},\ \overline{D}^{\mathrm{G}} = \overline{D}.$$

We also define several sets of scaling matrices:

$$\begin{aligned}
\mathcal{X}^{\mathrm{G}} &= \{X^{\mathrm{G}} = \mathbf{diag}(X_{\mathrm{T}}^{\mathrm{G}}, X_{\mathrm{S}}^{\mathrm{G}}),\ X_{\mathrm{T}}^{\mathrm{G}} \in \mathbb{R}^{n_{\mathrm{T}} \times n_{\mathrm{T}}},\ X_{\mathrm{T}}^{\mathrm{G}} > 0,\ X_{\mathrm{S}}^{\mathrm{G}} \in \mathbb{R}^{n_{\mathrm{S}} \times n_{\mathrm{S}}},\ X_{\mathrm{S}}^{\mathrm{G}} \text{ is symmetric}\}, \\
\mathcal{X}^{\mathrm{K}} &= \{X^{\mathrm{K}} = \mathbf{diag}(X_{\mathrm{T}}^{\mathrm{K}}, X_{\mathrm{S}}^{\mathrm{K}}),\ X_{\mathrm{T}}^{\mathrm{K}} \in \mathbb{R}^{n_{\mathrm{T}}^{\mathrm{K}} \times n_{\mathrm{T}}^{\mathrm{K}}},\ X_{\mathrm{T}}^{\mathrm{K}} > 0,\ X_{\mathrm{S}}^{\mathrm{K}} \in \mathbb{R}^{n_{\mathrm{S}}^{\mathrm{K}} \times n_{\mathrm{S}}^{\mathrm{K}}},\ X_{\mathrm{S}}^{\mathrm{K}} \text{ is symmetric}\}, \\
\mathcal{X}^{\mathrm{GK}} &= \{X = \mathbf{diag}(X_{\mathrm{T}}^{\mathrm{GK}}, X_{\mathrm{S}}^{\mathrm{GK}}),\ X_{\mathrm{T}}^{\mathrm{GK}} \in \mathbb{R}^{n_{\mathrm{T}} \times n_{\mathrm{T}}^{\mathrm{K}}},\ X_{\mathrm{S}}^{\mathrm{GK}} \in \mathbb{R}^{n_{\mathrm{S}} \times n_{\mathrm{S}}^{\mathrm{K}}}\}.
\end{aligned}$$

Then, the main synthesis result of [5] is the following.

THEOREM 6.4. *Let the columns of $\mathcal{N}_{\mathrm{Y}}$ span the null space of $((\overline{B^u}^{\mathrm{G}})^* \quad (\overline{D^{zu}}_g)^*)$ and let those of $\mathcal{N}_{\mathrm{X}}$ span the null space of $((\overline{C^y}^{\mathrm{G}})^* \quad (\overline{D^{yd}}^{\mathrm{G}})^*)$, respectively. Then there exists an infinite controller such that the closed-loop is well-posed, stable, and*

contractive if there exist X^{G} *and* Y^{G} *in* $\mathcal{X}^{\mathrm{G}}$ *satisfying the following LMI:*

$$\text{(34a)}\quad \begin{pmatrix} \mathcal{N}_{\mathrm{Y}} & 0 \\ 0 & I \end{pmatrix}^{*} \left(\begin{array}{cc} \begin{pmatrix} \overline{A}^{\mathrm{G}} Y^{\mathrm{G}} + Y^{\mathrm{G}} (\overline{A}^{\mathrm{G}})^{*} & Y^{\mathrm{G}} (\overline{C^{z}}^{\mathrm{G}})^{*} \\ \overline{C^{z}}^{\mathrm{G}} Y^{\mathrm{G}} & -I_{p_z} \end{pmatrix} & \begin{pmatrix} \overline{B^{d}}^{\mathrm{G}} \\ \overline{D^{zd}}^{\mathrm{G}} \end{pmatrix} \\ \begin{pmatrix} (\overline{B^{d}}^{\mathrm{G}})^{*} & (\overline{D^{zd}}^{\mathrm{G}})^{*} \end{pmatrix} & -I_{m_d} \end{array} \right) \begin{pmatrix} \mathcal{N}_{\mathrm{Y}} & 0 \\ 0 & I \end{pmatrix} < 0,$$

$$\text{(34b)}\quad \begin{pmatrix} \mathcal{N}_{\mathrm{X}} & 0 \\ 0 & I \end{pmatrix}^{*} \left(\begin{array}{cc} \begin{pmatrix} (\overline{A}^{\mathrm{G}})^{*} X^{\mathrm{G}} + X^{\mathrm{G}} \overline{A}^{\mathrm{G}} & X^{\mathrm{G}} \overline{B^{d}}^{\mathrm{G}} \\ (\overline{B^{d}}^{\mathrm{G}})^{*} X^{\mathrm{G}} & -I_{m_d} \end{pmatrix} & \begin{pmatrix} (\overline{C^{z}}^{\mathrm{G}})^{*} \\ (\overline{D^{zd}}^{\mathrm{G}})^{*} \end{pmatrix} \\ \begin{pmatrix} \overline{C^{z}}^{\mathrm{G}} & \overline{D^{zd}}^{\mathrm{G}} \end{pmatrix} & -I_{p_z} \end{array} \right) \begin{pmatrix} \mathcal{N}_{\mathrm{X}} & 0 \\ 0 & I \end{pmatrix} < 0,$$

$$\text{(34c)}\quad \begin{pmatrix} X_{\mathrm{T}}^{\mathrm{G}} & I \\ I & Y_{\mathrm{T}}^{\mathrm{G}} \end{pmatrix} \geq 0.$$

Because (34c) *is satisfied, there exist* X^{K} *and* Y^{K} *in* $\mathcal{X}^{\mathrm{K}}$ *and* X^{GK} *and* Y^{GK} *in* $\mathcal{X}^{\mathrm{GK}}$ *such that*

$$\text{(35)}\quad \begin{pmatrix} X^{\mathrm{G}} & X^{\mathrm{GK}} \\ (X^{\mathrm{GK}})^{*} & X^{\mathrm{K}} \end{pmatrix} = \begin{pmatrix} Y^{\mathrm{G}} & Y^{\mathrm{GK}} \\ (Y^{\mathrm{GK}})^{*} & Y^{\mathrm{K}} \end{pmatrix}^{-1}$$

and $n_{\mathrm{T}}^{\mathrm{K}} = n_{\mathrm{T}}$, $n_{\mathrm{S}}^{\mathrm{K}} = n_{\mathrm{S}}$.

Then defining

$$\text{(36)}\quad \overline{X} = \begin{pmatrix} X^{\mathrm{G}} & X^{\mathrm{GK}} \\ (X^{\mathrm{GK}})^{*} & X^{\mathrm{K}} \end{pmatrix},$$

we can construct a controller that solves the infinite synthesis problem in two steps as follows:

1. *Solve the LMI*

$$\text{(37)}\quad \begin{pmatrix} (\overline{A}^{\mathrm{C}})^{*} \overline{X} + \overline{X A}^{\mathrm{C}} & \overline{X B}^{\mathrm{C}} & (\overline{C}^{\mathrm{C}})^{*} \\ (\overline{B}^{\mathrm{C}})^{*} \overline{X} & -I & (\overline{D}^{\mathrm{C}})^{*} \\ \overline{C}^{\mathrm{C}} & \overline{D}^{\mathrm{C}} & -I \end{pmatrix} < 0,$$

which is affine in the unknown

$$\Theta := \begin{pmatrix} \overline{A}^{\mathrm{K}} & \overline{B}^{\mathrm{K}} \\ \overline{C}^{\mathrm{K}} & \overline{D}^{\mathrm{K}} \end{pmatrix},$$

where

$$\begin{pmatrix} \overline{A}^{\mathrm{C}} & \overline{B}^{\mathrm{C}} \\ \overline{C}^{\mathrm{C}} & \overline{D}^{\mathrm{C}} \end{pmatrix} = \begin{pmatrix} \overline{A}^{\mathrm{G}} & 0 & \overline{B^{d}}^{\mathrm{G}} \\ 0 & 0 & 0 \\ \overline{C^{z}}^{\mathrm{G}} & 0 & \overline{D^{zd}}^{\mathrm{G}} \end{pmatrix} + \begin{pmatrix} 0 & \overline{B^{u}}^{\mathrm{G}} \\ I & 0 \\ 0 & \overline{D^{zu}}^{\mathrm{G}} \end{pmatrix} \Theta \begin{pmatrix} 0 & I & 0 \\ \overline{C^{y}}^{\mathrm{G}} & 0 & \overline{D^{yd}}^{\mathrm{G}} \end{pmatrix}.$$

2. *Once* Θ *is known, make a change of coordinates that puts* $\overline{A_{\mathrm{SS}}}^{\mathrm{K}}$ *into the form*

$$\overline{A_{\mathrm{SS}}}^{\mathrm{K}} = \begin{pmatrix} A^{+} & 0 \\ 0 & A^{-} \end{pmatrix},$$

where both A^- and $-(A^+)$ are Hurwitz. This can always be achieved if $\overline{A_{\rm SS}}^{\rm K}$ has no eigenvalue on the imaginary axis. If this situation is not at hand, one can perturb $\overline{A_{\rm SS}}^{\rm K}$ so that it holds and LMI (34) will still be satisfied. Then let

$$H^{\rm K} = \begin{pmatrix} I_{n^+} & 0 \\ 0 & -I_{n^-} \end{pmatrix},$$

where $n^{\pm} = \dim(A^{\pm})$, and invert the bilinear algebraic transformation by

$$A^{\rm K}_{\rm SS} := (H^{\rm K} - \overline{A_{\rm SS}}^{\rm K})^{-1}(H^{\rm K} + \overline{A_{\rm SS}}^{\rm K}), \tag{38a}$$

$$(A^{\rm K}_{\rm ST} \quad B^{\rm K}_{\rm S}) := \sqrt{2}(H^{\rm K} - \overline{A_{\rm SS}}^{\rm K})^{-1}(\overline{A_{\rm ST}}^{\rm K} \quad \overline{B_{\rm S}}^{\rm K}), \tag{38b}$$

$$\begin{pmatrix} A^{\rm K}_{\rm TS} \\ C^{\rm K}_{\rm S} \end{pmatrix} := \sqrt{2} \begin{pmatrix} \overline{A_{\rm TS}}^{\rm K} \\ \overline{C_{\rm S}}^{\rm K} \end{pmatrix} (H^{\rm K} - \overline{A_{\rm SS}}^{\rm K})^{-1} H^{\rm K}, \tag{38c}$$

(38d)
$$\begin{pmatrix} A^{\rm K}_{\rm TT} & B^{\rm K}_{\rm T} \\ C^{\rm K}_{\rm T} & D^{\rm K} \end{pmatrix} := \begin{pmatrix} \overline{A_{\rm TT}}^{\rm K} & \overline{B_{\rm T}}^{\rm K} \\ \overline{C_{\rm T}}^{\rm K} & \overline{D}^{\rm K} \end{pmatrix} + \begin{pmatrix} \overline{A_{\rm TS}}^{\rm K} \\ \overline{C_{\rm S}}^{\rm K} \end{pmatrix} (H^{\rm K} - \overline{A_{\rm SS}}^{\rm K})^{-1} (\overline{A_{\rm ST}}^{\rm K} \quad \overline{B_{\rm S}}^{\rm K}),$$

to find the building block of an infinite controller solving the infinite synthesis problem.

Now assume that the plant at hand is M-reversible for some boundary conditions matrix M with $R^d = \left(R^d\right)^* = \left(R^d\right)^{-1}$ and $U^z = (U^z)^* = (U^z)^{-1}$. Because of spatial reversibility and since $QH = -HQ$, it is easy to see that

$$V\overline{A}^{\rm G}W = \overline{A}^{\rm G},\ \overline{C}^{\rm G}W = U\overline{C}^{\rm G},\ V\overline{B}^{\rm G} = \overline{B}^{\rm G}R,\ U\overline{D}^{\rm G} = \overline{D}^{\rm G}R, \tag{39}$$

where $V := \left(\begin{smallmatrix} P & 0 \\ 0 & -Q \end{smallmatrix}\right)$ and $W := \left(\begin{smallmatrix} P & 0 \\ 0 & Q \end{smallmatrix}\right)$.

Let $X^{\rm G}$, $Y^{\rm G}$ solve (34a)–(34b) for $\mathcal{N}_{\rm X}$ and $\mathcal{N}_{\rm Y}$. Then, pre- and postmultiplying (34a) by

$$\begin{pmatrix} I & 0 \\ 0 & \left(R^d\right)^* \end{pmatrix} \text{ and } \begin{pmatrix} I & 0 \\ 0 & R^d \end{pmatrix},$$

(34b) by

$$\begin{pmatrix} I & 0 \\ 0 & U^z \end{pmatrix} \text{ and } \begin{pmatrix} I & 0 \\ 0 & (U^z)^* \end{pmatrix},$$

and using (39), we get that $V^*X^{\rm G}W$, $WY^{\rm G}V^* \in \mathcal{X}^{\rm G}$ also satisfy (34a)–(34b) but with $\tilde{\mathcal{N}}_{\rm X} = \left(\begin{smallmatrix} W & 0 \\ 0 & R^d \end{smallmatrix}\right)\mathcal{N}_{\rm X}$ and $\tilde{\mathcal{N}}_{\rm Y} = \left(\begin{smallmatrix} V^* & 0 \\ 0 & (U^z)^* \end{smallmatrix}\right)\mathcal{N}_{\rm Y}$, the columns of which also satisfy the assumptions of Theorem 6.4.

Now an important point is that $X^{\rm G}$ and $Y^{\rm G}$ *also* satisfy (34a)–(34b) for $\tilde{\mathcal{N}}_{\rm X}$ and $\tilde{\mathcal{N}}_{\rm Y}$. In fact, the matrices do not matter as long as their columns span the appropriate null-spaces. (The reason why it is so can be easily understood if one follows the usual procedure for formulating $\mathcal{H}_\infty$ synthesis as a convex problem, as presented, e.g., in Chapter 7 of [7]. See Lemma 7.2 in particular.)

Hence averaging the two sets of LMIs, we see that

$$\tilde{X}^{\rm G} = \frac{1}{2}(X^{\rm G} + V^*X^{\rm G}W) \text{ and } \tilde{Y}^{\rm G} = \frac{1}{2}(Y^{\rm G} + WY^{\rm G}V^*)$$

solve (34) for $\tilde{\mathcal{N}}_{\mathrm{X}}$ and $\tilde{\mathcal{N}}_{\mathrm{Y}}$. Note that

$$Q^*\tilde{X}^{\mathrm{G}}Q = -\tilde{X}^{\mathrm{G}} \text{ and } Q\tilde{Y}^{\mathrm{G}}Q^* = -\tilde{Y}^{\mathrm{G}}.$$

In order to solve (35), one can choose a *full-rank* controller by picking

$$X_{\mathrm{S}}^{\mathrm{GK}} = \left(I - \tilde{X}_{\mathrm{S}}^{\ \mathrm{G}}\tilde{Y}_{\mathrm{S}}^{\ \mathrm{G}}\right),\ X_{\mathrm{S}}^{\mathrm{K}} = -(X_{\mathrm{S}}^{\mathrm{GK}})^*\tilde{Y}_{\mathrm{S}}^{\ \mathrm{G}},\ Y_{\mathrm{S}}^{\mathrm{GK}} = I.$$

Then easy algebra yields

$$Q^*X_{\mathrm{S}}^{\mathrm{GK}}Q^* = X_{\mathrm{S}}^{\mathrm{GK}},\ QX_{\mathrm{S}}^{\mathrm{K}}Q^* = -X_{\mathrm{S}}^{\mathrm{K}},$$

and, in turn, that $\overline{X}$ as per (36) satisfies

$$\begin{pmatrix} W^* & 0 \\ 0 & V \end{pmatrix}\overline{X}\begin{pmatrix} V & 0 \\ 0 & W^* \end{pmatrix} = \overline{X} = \overline{X}^* = \begin{pmatrix} V^* & 0 \\ 0 & W \end{pmatrix}\overline{X}\begin{pmatrix} W & 0 \\ 0 & V^* \end{pmatrix}.$$

Using this scaling and pre- and postmultiplying (37) by

$$\begin{pmatrix} W^* & 0 & 0 & 0 \\ 0 & V & 0 & 0 \\ 0 & 0 & \left(R^d\right)^* & 0 \\ 0 & 0 & 0 & U^z \end{pmatrix} \text{ and } \begin{pmatrix} W & 0 & 0 & 0 \\ 0 & V^* & 0 & 0 \\ 0 & 0 & R^d & 0 \\ 0 & 0 & 0 & (U^z)^* \end{pmatrix},$$

we see that if Θ is a solution, so is $\hat{\Theta} := \left(\begin{smallmatrix} W^* & 0 \\ 0 & R^u \end{smallmatrix}\right)\Theta\left(\begin{smallmatrix} V^* & 0 \\ 0 & U^y \end{smallmatrix}\right)$ because of (39). Hence, $\tilde{\Theta} := \frac{1}{2}(\Theta + \hat{\Theta})$ also satisfies LMI (37). Note that $\left(\begin{smallmatrix} W^* & 0 \\ 0 & R^u \end{smallmatrix}\right)\tilde{\Theta}\left(\begin{smallmatrix} V^* & 0 \\ 0 & U^y \end{smallmatrix}\right) = \tilde{\Theta}$, which means that the corresponding controller is such that

$$\begin{pmatrix} P^*\overline{A_{\mathrm{TS}}}^{\mathrm{K}} \\ R^u\overline{C_{\mathrm{S}}}^{\mathrm{K}} \end{pmatrix}Q^* = -\begin{pmatrix} \overline{A_{\mathrm{TS}}}^{\mathrm{K}} \\ \overline{C_{\mathrm{S}}}^{\mathrm{K}} \end{pmatrix}, \tag{40a}$$

$$Q^*\begin{pmatrix} \overline{A_{\mathrm{ST}}}^{\mathrm{K}}P^* & \overline{B_{\mathrm{S}}}^{\mathrm{K}}U^y \end{pmatrix} = \begin{pmatrix} \overline{A_{\mathrm{ST}}}^{\mathrm{K}} & \overline{B_{\mathrm{S}}}^{\mathrm{K}} \end{pmatrix},$$

$$Q^*\overline{A_{\mathrm{SS}}}^{\mathrm{K}}Q^* = -\overline{A_{\mathrm{SS}}}^{\mathrm{K}},$$

$$P^*\overline{A_{\mathrm{TT}}}^{\mathrm{K}}P^* = \overline{A_{\mathrm{TT}}}^{\mathrm{K}},\ P^*\overline{B_{\mathrm{T}}}^{\mathrm{K}} = \overline{B_{\mathrm{T}}}^{\mathrm{K}}U^y, \tag{40b}$$

$$\overline{C_{\mathrm{T}}}^{\mathrm{K}}P^* = R^u\overline{C_{\mathrm{T}}}^{\mathrm{K}},\ R^u\overline{D}^{\mathrm{K}}U^y = \overline{D}^{\mathrm{K}}.$$

This last relation implies that the spectrum of $\overline{A_{\mathrm{SS}}}^{\mathrm{K}}$ is symmetric with respect to the origin. Thus, if it does not contain any point on the imaginary axis, we will have $n^+ = \dim(A^+) = \dim(A^-) = n^-$. Also, because we picked a full-rank controller, we have $n_{\mathrm{S}}^{\mathrm{K}} = n_{\mathrm{S}}$ and thus $n^{\pm} = n$ and $H^{\mathrm{K}} = H$.

Now, plugging (40) into (38), we get

$$\begin{pmatrix} P^*A_{\mathrm{TS}}^{\mathrm{K}} \\ R^uC_{\mathrm{S}}^{\mathrm{K}} \end{pmatrix}Q^* = -\begin{pmatrix} A_{\mathrm{TS}}^{\mathrm{K}} \\ C_{\mathrm{S}}^{\mathrm{K}} \end{pmatrix},$$

$$Q^*\begin{pmatrix} A_{\mathrm{ST}}^{\mathrm{K}}P^* & B_{\mathrm{S}}^{\mathrm{K}}U^y \end{pmatrix} = -\begin{pmatrix} A_{\mathrm{ST}}^{\mathrm{K}} & B_{\mathrm{S}}^{\mathrm{K}} \end{pmatrix},$$

$$Q^*A_{\mathrm{SS}}^{\mathrm{K}}Q^* = A_{\mathrm{SS}}^{\mathrm{K}}, \tag{41a}$$

$$P^*A_{\mathrm{TT}}^{\mathrm{K}}P^* = A_{\mathrm{TT}}^{\mathrm{K}},\ P^*B_{\mathrm{T}}^{\mathrm{K}} = B_{\mathrm{T}}^{\mathrm{K}}U^y,$$

$$C_{\mathrm{T}}^{\mathrm{K}}P^* = C_{\mathrm{T}}^{\mathrm{K}},\ R^uD^{\mathrm{K}}U^y = D^{\mathrm{K}}. \tag{41b}$$

Finally, perform a state transformation on v^{K},

$$v^{\mathrm{K}} \to Hv^{\mathrm{K}},$$

to yield an $(M^*)^{-1}$-reversible controller with $R^{\mathrm{K}} = U^y$, $U^{\mathrm{K}} = R^u$, and $P^{\mathrm{K}} = P^*$ ∎

7. Some generalizations. In this section, we explain how some assumptions can be relaxed and our results extended to more general, spatially multidimensional, reversible systems.

7.1. The case where R^d and U^z are not unitary. Although Theorem 6.1 treats the case where both R^d and U^z are unitary, it is possible to handle cases where $\left(R^d\right)^* \neq (R^d)^{-1}$ or $(U^z)^* \neq (U^z)^{-1}$ as well. There are two cases as follows:

- $\overline{\sigma}(R^d) \leq \underline{\sigma}(U^z)$:
  If one replaces the $-I_{m_d}$ and $-I_{p_z}$ blocks in (34a)–(34b) by $-\left(R^d\right)^* R^d$ and $-U^z \left(U^z\right)^*$, respectively, i.e., if one starts with an infinite controller such that

$$\|T_{dz}\|_{\mathcal{L}_2(\mathbb{Z})} < \frac{\overline{\sigma}(R^d)}{\underline{\sigma}(U^z)},$$

  then following all the steps of the proof will yield an $(M^*)^{-1}$-*reversible* infinite controller such that the closed-loop system is well-posed, stable, and contractive. In turn, the corresponding periodic closed-loop system will also be contractive and, since

$$\sqrt{\frac{1+\underline{\sigma}(U^z)^2}{1+\overline{\sigma}(R^d)^2}} \geq 1,$$

  Corollary 4.6 implies that the finite extent closed-loop system is also contractive.
- $\overline{\sigma}(R^d) > \underline{\sigma}(U^z)$:
  In this case, it is possible to construct an $(M^*)^{-1}$-*reversible* infinite controller that guarantees contractiveness of the closed-loop system if the LMIs (34a)–(34b) have a solution. The corresponding periodic closed-loop will also be contractive but the finite extent one need not be. We have only the upper-bound

$$\|T_{dz}\|_{\mathcal{L}(\{1,\dots,L\})} < \sqrt{\frac{1+\underline{\sigma}(U^z)^2}{1+\overline{\sigma}(R^d)^2}}.$$

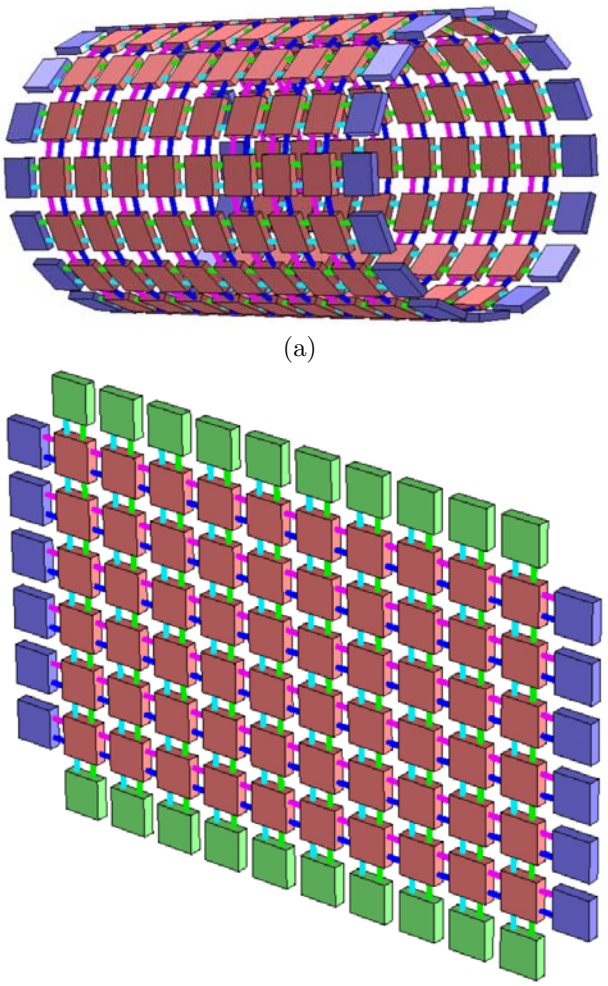
7.2. Multiple spatial dimensions. It is straightforward to extend our present results to cases where the subsystems are distributed on a multidimensional grid instead of a line. The basic building block then has two interconnection inputs (v_i^+, $v_i^- \in \mathbb{R}^{n_i}$) and outputs ($w_i^+$, $w_i^- \in \mathbb{R}^{n_i}$) per spatial dimension. The index s used to describe the finite extent interconnection now belongs to a cartesian product set of the form

$$\mathbb{M} = \mathbb{Z}_{l_1} \times \cdots \times \mathbb{Z}_{l_k} \times \{1,\dots,L_1\} \times \cdots \times \{1,\dots,L_d\}$$

where $k \geq 0,\ d > 0$ and there is a boundary conditions matrix $M_i,\ 1 \leq i \leq d$ associated with every nonperiodic spatial dimension. Likewise, the corresponding periodic and infinite systems are indexed over the set

$$\mathbb{M} = \mathbb{Z}_{l_1} \times \cdots \times \mathbb{Z}_{l_k} \times \mathbb{Z}_{2L_1} \times \cdots \times \mathbb{Z}_{2L_d} \text{ and } \mathbb{M} = \mathbb{Z}_{l_1} \times \cdots \times \mathbb{Z}_{l_k} \times \mathbb{Z}^d,$$

respectively. Examples of such spatially multidimensional finite extent systems are given in Figure 3 for $k = 1,\ d = 1$ and $k = 0,\ d = 2$.



(a)

(b)

FIG. 3. *Examples of spatially multidimensional interconnections. The inputs and outputs have been omitted for clarity.* (a) *All boundary conditions matrices are equal to* M_1. (b) *All boundary conditions matrices for lines (respectively, columns) are equal to* M_1 *(respectively,* M_2*).*

These spatially multidimensional systems can be represented by (9) if we let

$$v(t) := \left(v_1^+(t), v_1^-(t), \ldots, v_{k+d}^+(t), v_{k+d}^-(t)\right) \in \ell_2^{n_\mathrm{s}}(\mathbb{M})$$

for a suitable n_s and replace Δ_{BC} and Δ_s by multidimensional spatial operators that capture all $k+d$ dimensions.

For example, if $k = 1$, $d = 1$, and $\mathbf{S}_j$ is the shift operator in the jth spatial dimension ($1 \leq j \leq k+d$), Δ_s should then be taken to be the structured operator

$$\Delta_\mathrm{s} = \mathbf{diag}\left(\mathbf{S}_1 I_{n_1}, \mathbf{S}_1^{-1} I_{n_1}, \mathbf{S}_2 I_{n_2}, \mathbf{S}_2^{-1} I_{n_2}\right).$$

Spatial reversibility can then be defined as in the spatially monodimensional case, the only difference being that the basic building block's realization must now commute with several different matrices, one for each of the d spatial dimensions.

DEFINITION 7.1. *For $1 \leq i \leq d$, let $\mathcal{M}_i := \left(\begin{smallmatrix} 0 & M_i \\ M_i^{-1} & 0 \end{smallmatrix}\right)$ and*

$$Q_i := \mathbf{diag}(I_{n_1}, \ldots, I_{n_k}, I_{n_{k+1}}, \ldots, \mathcal{M}_i, \ldots, I_{n_{k+d}}).$$

We say that the basic building block and, in turn, the interconnections are spatially reversible if, for all i, there exist matrices $R_i \in \mathbb{R}^{m\times m}$, $P_i \in \mathbb{R}^{n_{\mathrm{T}}\times n_{\mathrm{T}}}$, and $U_i \in \mathbb{R}^{p\times p}$ such that

(i) *R_i, U_i, and P_i are involutions;*
(ii) *$R_iR_j = R_jR_i$, $P_iP_j = P_jP_i$, and $U_iU_j = U_jU_i$ for all $1 \leq i, j \leq d$;*
(iii)

$$\begin{pmatrix} P_i & 0 & 0 \\ 0 & Q_i & 0 \\ 0 & 0 & U_i \end{pmatrix} \begin{pmatrix} A_{\mathrm{TT}} & A_{\mathrm{TS}} & B_{\mathrm{T}} \\ A_{\mathrm{ST}} & A_{\mathrm{SS}} & B_{\mathrm{S}} \\ C_{\mathrm{T}} & C_{\mathrm{S}} & D \end{pmatrix} = \begin{pmatrix} A_{\mathrm{TT}} & A_{\mathrm{TS}} & B_{\mathrm{T}} \\ A_{\mathrm{ST}} & A_{\mathrm{SS}} & B_{\mathrm{S}} \\ C_{\mathrm{T}} & C_{\mathrm{S}} & D \end{pmatrix} \begin{pmatrix} P_i & 0 & 0 \\ 0 & Q_i & 0 \\ 0 & 0 & R_i \end{pmatrix}.$$

Condition (ii) is essential for the application of the method of images: it ensures that one can extend the finite extent system by reflection in the d spatial dimensions to yield a periodic one.

One can then proceed to analyze and perform distributed control synthesis for multidimensional spatially reversible systems. All proofs are similar to the spatially monodimensional case but require more intensive notational bookkeeping. The two most important results, corresponding to Corollary 4.6 and Theorem 6.1, are given below for the case where R_i and U_i are unitary for all $1 \leq i \leq d$.

THEOREM 7.2. *If a spatially multidimensional, reversible, well-posed, periodic system is stable, then the corresponding finite extent system is stable. Moreover, if R_i and U_i are unitary for all $1 \leq i \leq d$, the input/output gains of the two systems satisfy*

$$\|T^P_{dz}\|_{\mathcal{L}_2(\mathbb{Z}_{l_1}\times\cdots\times\mathbb{Z}_{l_k}\times\mathbb{Z}_{2L_1}\times\cdots\times\mathbb{Z}_{2L_d})} < 1 \Rightarrow \|T_{dz}\|_{\mathcal{L}_2(\mathbb{Z}_{l_1}\times\cdots\times\mathbb{Z}_{l_k}\times\{1,\ldots,L_1\}\times\cdots\times\{1,\ldots,L_d\})} < 1.$$

THEOREM 7.3. *Given a finite extent, spatially multidimensional reversible plant, there exists a spatially reversible, finite extent controller, with $n^{\mathrm{K}}_{\mathrm{T}} = n_{\mathrm{T}}$, $n^{\mathrm{K}} = n$, and boundary conditions matrix $M^{\mathrm{K}}_i = (M^*_i)^{-1}$, for each $1 \leq i \leq d$, that solves Problem 1 if*

(i) *the LMI conditions of* [5] *for the spatially multidimensional case are satisfied;*
(ii) *the plant's involutions R_i and U_i satisfy $R_i = \mathbf{diag}(R^u_i, R^d_i)$, $U_i = \mathbf{diag}(U^y_i, U^z_i)$ with R^d_i and U^z_i unitary for all $1 \leq i \leq d$.*

The conditions of item (i) are (34a), (34b), and (34c), supplemented by a fourth LMI (equation (92) in [5]) needed to guarantee that the matrix $\overline{A_{\mathrm{SS}}}^{\mathrm{K}}$ yields an *implementable* controller. This LMI is always trivially satisfied in the spatially monodimensional case or when $\overline{A_{\mathrm{SS}}}^{\mathrm{K}}$ is block diagonal. We refer to [5] for more details.

The spatially multidimensional reversible controller is constructed iteratively as follows: First, starting with any satisfactory controller and following steps that are identical to those of the proof of Proposition 6.3, we get controller number 1 such that

$$\begin{pmatrix} P_1 & 0 & 0 \\ 0 & Q^*_1 & 0 \\ 0 & 0 & U_1 \end{pmatrix} \begin{pmatrix} {A_{\mathrm{TT}}}^{\mathrm{K}}_1 & {A_{\mathrm{TS}}}^{\mathrm{K}}_1 & {B_{\mathrm{T}}}^{\mathrm{K}}_1 \\ {A_{\mathrm{ST}}}^{\mathrm{K}}_1 & {A_{\mathrm{SS}}}^{\mathrm{K}}_1 & {B_{\mathrm{S}}}^{\mathrm{K}}_1 \\ {C_{\mathrm{T}}}^{\mathrm{K}}_1 & {C_{\mathrm{S}}}^{\mathrm{K}}_1 & D^{\mathrm{K}}_1 \end{pmatrix} = \begin{pmatrix} {A_{\mathrm{TT}}}^{\mathrm{K}}_1 & {A_{\mathrm{TS}}}^{\mathrm{K}}_1 & {B_{\mathrm{T}}}^{\mathrm{K}}_1 \\ {A_{\mathrm{ST}}}^{\mathrm{K}}_1 & {A_{\mathrm{SS}}}^{\mathrm{K}}_1 & {B_{\mathrm{S}}}^{\mathrm{K}}_1 \\ {C_{\mathrm{T}}}^{\mathrm{K}}_1 & {C_{\mathrm{S}}}^{\mathrm{K}}_1 & D^{\mathrm{K}}_1 \end{pmatrix} \begin{pmatrix} P_1 & 0 & 0 \\ 0 & Q^*_1 & 0 \\ 0 & 0 & R_1 \end{pmatrix}.$$

Then *starting with controller number* 1 and proceeding similarly, we get controller number 2 such that

$$\begin{pmatrix} P_2 & 0 & 0 \\ 0 & Q_2^* & 0 \\ 0 & 0 & U_2 \end{pmatrix} \begin{pmatrix} A_{\mathrm{TT}2}^{\mathrm{K}} & A_{\mathrm{TS}2}^{\mathrm{K}} & B_{\mathrm{T}2}^{\mathrm{K}} \\ A_{\mathrm{ST}2}^{\mathrm{K}} & A_{\mathrm{SS}2}^{\mathrm{K}} & B_{\mathrm{S}2}^{\mathrm{K}} \\ C_{\mathrm{T}2}^{\mathrm{K}} & C_{\mathrm{S}2}^{\mathrm{K}} & D_2^{\mathrm{K}} \end{pmatrix} = \begin{pmatrix} A_{\mathrm{TT}2}^{\mathrm{K}} & A_{\mathrm{TS}2}^{\mathrm{K}} & B_{\mathrm{T}2}^{\mathrm{K}} \\ A_{\mathrm{ST}2}^{\mathrm{K}} & A_{\mathrm{SS}2}^{\mathrm{K}} & B_{\mathrm{S}2}^{\mathrm{K}} \\ C_{\mathrm{T}2}^{\mathrm{K}} & C_{\mathrm{S}2}^{\mathrm{K}} & D_2^{\mathrm{K}} \end{pmatrix} \begin{pmatrix} P_2 & 0 & 0 \\ 0 & Q_2^* & 0 \\ 0 & 0 & R_2 \end{pmatrix}.$$

The final controller, obtained after d such iterations, is spatially reversible because for $1 \le i, j \le d$, P_i and P_j, Q_i and Q_j, R_i and R_j, and U_i and U_j commute.

8. Conclusion. We have shown that a finite extent spatially reversible system is closely related to its periodic and infinite extensions and have demonstrated that synthesis for such systems can be performed with existing tools developed in the context of spatial invariance.

The synthesis LMI conditions that we use—which were already sufficient only for well-posedness, stability, and contractiveness of an infinite system [5]— are even more conservative for finite extent systems since well-posedness of the spatially invariant systems is not necessary for well-posedness of the finite extent system. However, when these LMI are feasible, the obtained controller guarantees stability and performance irrespective of the number of subsystems in the finite extent interconnection, with obvious consequences for system reconfiguration and fault tolerance. The boundary conditions matrix of the plant is the only relevant parameter.

OPTIMAL CONTROL OF ERGODIC CONTINUOUS-TIME MARKOV CHAINS WITH AVERAGE SAMPLE-PATH REWARDS*

XIANPING GUO† AND XI-REN CAO‡

Abstract. In this paper we study continuous-time Markov decision processes with the *average sample-path reward* (ASPR) criterion and possibly unbounded transition and reward rates. We propose conditions on the system's *primitive data* for the existence of ϵ-ASPR-optimal (deterministic) stationary policies in a class of randomized Markov policies satisfying some additional continuity assumptions. The proof of this fact is based on the *time discretization* technique, the martingale stability theory, and the concept of potential. We also provide both policy and value iteration algorithms for computing, or at least approximating, the ϵ-ASPR-optimal stationary policies. We illustrate with examples our main results as well as the difference between the ASPR and the average expected reward criteria.

Key words. average sample-path reward, continuous-time Markov chain, optimal stationary policy, policy and value iteration algorithms

1. Introduction.

Markov decision processes (MDPs) with the long-run *average expected reward* (AER) criterion have been widely studied in literature; see, for instance, the books [1, 6, 12, 22, 23, 25, 31, 32, 33, 35], the survey paper [3], and their extensive references. However, the *sample-path* reward corresponding to an optimal policy that maximizes the average expected rewards may have fluctuations from its expected reward value. To take these fluctuations into account, the *average sample-path reward* (ASPR) criterion has been proposed and studied; see, for instance, [3, 10, 15, 23, 24] and their extensive bibliographies. To the best of our knowledge, all the existing works with the ASPR criterion are on *discrete-time* MDPs. On the other hand, many real-world problems, for instance, in communication engineering, queueing systems, and other control problems, require continuous-time models. Therefore, there is a large amount of works in literature on continuous-time MDPs; see, for instance, [4, 5, 16, 18, 19, 20, 21, 26, 27, 29, 31, 35, 37, 39] and their references. All of these works, however, consider only the AER criterion. Our paper is a first attempt to fill the gap between the works on discrete-time MDPs with the ASPR criterion and those on continuous-time MDPs with the AER criterion.

Denumerable continuous-time MDPs are specified by the system's four *primitive data*: a countable state space S; action sets $A(i)$, which may depend on the current state $i \in S$; transition rates $q(j|i,a)$ with $a \in A(i)$ and $j \in S$; and reward rates $r(i,a)$ with $a \in A(i)$. In this paper, we consider these MDPs with the ASPR criterion in the class of randomized Markov policies satisfying some *additional* continuity assumptions.

The state processes here are possibly *nonhomogeneous* continuous-time Markov chains with possibly *unbounded* transition rates, and the reward rates may have *neither upper nor lower bounds*. Under suitable conditions on the primitive data, we first prove the existence of a solution to the optimality equation. The proof is constructive, using *policy iteration*, which is based on the concept of potentials [8, 7] and is rather different from both the "vanishing discount approach" in [16, 18, 19, 21, 26] and the "uniformization technique" in [29, 31, 36]. We then establish the existence of $\epsilon(\geq 0)$-ASPR-optimal stationary policies by introducing a *time-discretization approach* to continuous-time martingales and by using the *extended generator* technique. This approach is different from those used for the discrete-time case; see, for instance, [3, 6, 10, 15, 23, 24]. Also, we provide both policy and value iteration algorithms for computing, or at least approximating (when the algorithms take infinitely many steps to converge), $\epsilon(\geq 0)$-ASPR-optimal stationary policies. Furthermore, we use several examples to explain our conditions and to show the difference between the AER and ASPR criteria.

The policy iteration approach developed in this paper to establish a solution to the optimality equation does not require any result about discounted continuous-time MDPs. Thus, this approach is simple and direct. Also, our method to prove the existence of an ASPR-optimal stationary policy is straightforward and different from those in [29, 31, 36, 37], which require the *equivalence* between continuous- and discrete-time MDPs as well as results about discrete-time MDPs. Finally, it should be mentioned that the ergodicity results about continuous-time Markov chains and the convergence results for continuous martingales available in the literature *cannot* be applied to our problems because in this paper the Markov chains may be *nonhomogeneous* and the associated reward and transition rates may be *time-dependent* and *unbounded*. In addition, a key feature of our results is that the conditions are imposed on the *primitive data* (see (2.1)) and can be easily verified.

The rest of this paper is organized as follows. In section 2, we introduce the control model and the optimal control problem considered in this paper. After some technical preliminaries developed in section 3, we study the existence of the $\epsilon(\geq 0)$-ASPR optimal stationary policies in section 4. The policy and value iteration algorithms are described in section 5. Our hypotheses and the difference between the AER and ASPR criteria are illustrated with examples in section 6. We conclude in section 7 with some general remarks.

2. The optimal control problem. The control model that we are concerned with can be described by

$$\{S, A(i), q(j|i,a), r(i,a),\ i,j \in S\}, \tag{2.1}$$

where S is the *state space*; $A(i)$ is a set of *admissible actions* at state $i \in S$; $q(j|i,a)$ with $i,j \in S$ and $a \in A(i)$ are the system's *transition rates*; and $r(i,a)$ with $i \in S$ and $a \in A(i)$ are the *reward rates*. Let $K := \{(i,a) : i \in S,\ a \in A(i)\}$ be the set of all state-action pairs.

In this paper we assume that S is denumerable and in fact we write it as the set of nonnegative integers, i.e., $S = \{0, 1, 2, \ldots\}$. Furthermore, we assume that for each $i \in S$ the set $A(i)$ is a Borel space endowed with the Borel σ-algebra $\mathcal{B}(A(i))$. The transition rates $q(j|i,a)$ in (2.1) satisfy $q(j|i,a) \geq 0$ for all $(i,a) \in K$ and $j \neq i$. Moreover, we assume that the matrix $[q(j|i,a)]$ with (i,j)-element $q(j|i,a)$

is *conservative*, i.e.,

$$\sum_{j\in S} q(j|i,a) = 0 \quad \forall (i,a) \in K,$$

and *stable*, which means that

$$q(i) := \sup_{a\in A(i)} q_i(a) < \infty \quad \forall i \in S,$$

where $q_i(a) := -q(i|i,a) \geq 0$, for all $(i,a) \in K$. In addition, $q(j|i,a)$ is measurable in $a \in A(i)$ for each fixed $i, j \in S$.

Finally, the function $r(i,a)$ on K is a real-valued reward rate, and $r(i,a)$ is assumed to be measurable in $a \in A(i)$ for each fixed $i \in S$. (As $r(i,a)$ is allowed to take positive and negative values, it can be interpreted as a *cost rate* rather than a "reward" rate.)

We first introduce randomized Markov policies.

DEFINITION 2.1 (randomized Markov policies). *A randomized Markov policy is a function $\pi_t(B|i)$ that satisfies the following conditions:*

(1) *for each $i \in S$ and $B \in \mathcal{B}(A(i))$, the mapping $t \mapsto \pi_t(B|i)$ is Borel measurable on $[0,\infty)$, and*

(2) *for each $i \in S$ and $t \geq 0$, $B \mapsto \pi_t(B|i)$ is a probability measure on $\mathcal{B}(A(i))$.*

Let $A := \bigcup_{i\in S} A(i)$. A (deterministic) stationary policy is a function $f : S \to A$ such that $f(i)$ is in $A(i)$ for all $i \in S$.

Let Φ be the set of all randomized Markov policies and let F be the set of all stationary policies. Note that a function $f \in F$ can be viewed as a function $\pi_t(B|i) \in \Phi$ for which, for all $t \geq 0$ and $i \in S$, $\pi_t(\cdot|i)$ is the Dirac measure at $f(i)$. Thus, $F \subset \Phi$. We will write a randomized Markov policy $\pi_t(B|i)$ in Φ simply as (π_t). The subscript "t" in π_t indicates the possible dependence on time; it will be dropped for simplicity when there is no confusion.

For each $(\pi_t) \in \Phi$, the associated transition and reward rates are defined, respectively, as follows:

$$q(j|i,\pi_t) := \int_{A(i)} q(j|i,a)\pi_t(da|i) \quad \text{for } i,j \in S \text{ and } t \geq 0, \tag{2.2}$$

$$r(i,\pi_t) := \int_{A(i)} r(i,a)\pi_t(da|i) \quad \text{for } i \in S \text{ and } t \geq 0. \tag{2.3}$$

Obviously, the transition rate $q(j|i,\pi_t)$ and reward rate $r(i,\pi_t)$ can depend on time t if π is not stationary. When $\pi = f \in F$, we write $q(j|i,\pi_t)$ and $r(i,\pi_t)$ as $q(j|i,f(i))$ and $r(i,f(i))$, respectively.

For each $\pi := (\pi_t) \in \Phi$, let $Q(\pi_t) := [q(j|i,\pi_t)]$ with $t \geq 0$ be the transition rate matrices. Any (possibly substochastic and nonhomogeneous) transition function $\tilde{p}(s,i,t,j,\pi)$ such that

$$\lim_{\gamma\to 0^+} \frac{\tilde{p}(t,i,t+\gamma,j,\pi) - \delta_{ij}}{\gamma} = q(j|i,\pi_t) \quad \forall i,j \in S \text{ and } t \geq 0$$

is called a Q-*process* with the transition rate matrices $Q(\pi_t)$, where δ_{ij} is the Kronecker delta. To guarantee the existence of such a Q-process, we now define the class of admissible policies.

DEFINITION 2.2 (admissible policies). *A randomized Markov policy* (π_t) *in* Φ *is said to be admissible if* $q(j|i,\pi_t)$ *is continuous in* $t \geq 0$ *for each fixed* $i, j \in S$. *We denote by* Π *the class of all admissible policies.*

Π is *nonempty* because it contains F. Moreover, as shown in Example 6.3 below, Π contains a randomized Markov policy which is *not* in F.

On the other hand, $Q(\pi_t)$ is also conservative and stable, i.e.,

$$q_i(\pi_t) := -q(i|i,\pi_t) = \sum_{j\neq i} q(j|i,\pi_t) < \infty \quad \forall i \in S \text{ and } t \geq 0.$$

Hence, for each $\pi \in \Pi$, the existence of a Q-process such as the *minimum* Q-process denoted by $p^{\min}(s,i,t,j,\pi)$ (i.e., $p^{\min}(s,i,t,j,\pi) \leq \tilde{p}(s,i,t,j,\pi)$ for any Q-process $\tilde{p}(s,i,t,j,\pi)$) is guaranteed but is not necessarily regular; that is, we might have $\sum_{j\in S} p^{\min}(s,i,t,j,\pi) < 1$ for some $i \in S$ and $t \geq s \geq 0$ (see [13] or Theorem 4.2.6 in [2]).

To ensure the regularity of a Q-process, we use the following ergodicity conditions.

Assumption A. There exist a sequence $\{S_n,\ n \geq 1\}$ of subsets of S, a nondecreasing function $w \geq 1$ on S, and two constants $c > 0$ and $b \geq 0$, such that

(1) $\sup_{i\in S_n} q(i) < \infty$ for each $n \geq 1$, and $S_n \uparrow S$ in the sense of convergence of a set sequence;

(2) $\lim_{n\to\infty}[\inf_{j\notin S_n} w(j)] = +\infty$;

(3) $\sum_{j\in S} q(j|i,a)w(j) \leq -cw(i) + b\delta_{0i} \forall\ (i,a) \in K$; and

(4) for each $f \in F$, the minimum Q-process $p^{\min}(s,i,t,j,f)$ is *monotone*, i.e.,

$$\sum_{j\geq k} q(j|i,f(i)) \leq \sum_{j\geq k} q(j|i+1,f(i+1)) \quad \forall i,k \in S \text{ with } k \neq i+1,$$

and *irreducible*, i.e., for each pair of states i and j, either $q(j|i,f(i)) > 0$, or there are an integer l (which may depend on i, j, and f) and l states $i_1, i_2, \ldots, i_l$ with $i \neq i_1$, $j \neq i_l$, $i_{k-1} \neq i_k$, $k = 2, \ldots, l$, such that

$$q(i_1|i,f(i))q(i_2|i_1,f(i_1))\cdots q(i_l|i_{l-1},f(i_{l-1}))q(j|i_l,f(i_l)) > 0.$$

LEMMA 2.3. (a) *If Assumptions* A(1), A(2), *and* A(3) *hold, then for each* $\pi = (\pi_t) \in \Pi$ *the corresponding Q-process with transition rate matrices* $Q(\pi_t)$ *is regular; that is,*

$$\sum_{j\in S} p^{\min}(s,i,t,j,\pi) = 1 \quad \forall i \in S \text{ and } t \geq s \geq 0.$$

(b) *If Assumption* A *holds, then for each* $f \in F$ *the corresponding Q-process with transition rate matrices* $[Q(j|i,f(i))]$ *is ergodic, and its unique invariant probability measure* μ_f *(with* $\mu_f(i) > 0$ *for all* $i \in S$*) can be determined by the equation*

$$\sum_{i\in S} \mu_f(i)q(j|i,f(i)) = 0 \quad \forall j \in S. \tag{2.4}$$

Moreover, for each $i \in S$ *and* $t \geq 0$

$$\left|\sum_{j\in S} p^{\min}(0,i,t,j,f)h(j) - \mu_f(h)\right| \leq 2e^{-ct}\left[w(i) + \frac{b}{c}\right] \leq 2e^{-ct}\left(1 + \frac{b}{c}\right)w(i) \tag{2.5}$$

for any function h on S such that $|h| \le w$, where $\mu_f(h) := \sum_{j\in S} h(j)\mu_f(j)$.

Proof. (a) Under Assumptions A(1)–A(3), by Theorem 3.1 in [17] we see that (a) is true.

(b) By (a) and Proposition 5.4.1 in [2], we see that (2.4) is true. Moreover, from the proof of (3.9) in [30] we see that the condition (2.1) in [30] is not required for Theorem 2.2(ii) in [30]. Thus, by (3.9) in [30] and Assumption A we see that (2.5) is also true. □

Under Assumptions A(1)–A(3), Lemma 2.3 shows that for each $\pi = (\pi_t) \in \Pi$ a Q-process with transition rate matrices $Q(\pi_t)$ is regular. Thus, under Assumption A, we will denote by $\{x(t,\pi)\}$ the associated right-continuous Markov chain with values in S, and write the regular Q-process $p^{\min}(s,i,t,j,\pi)$ simply as $p(s,i,t,j,\pi)$. Furthermore, for each initial state $i \in S$ at time $s = 0$, we denote by $(\Omega, \mathcal{F}, P_i^\pi)$ the probability measure space determined by $p(s,i,t,j,\pi)$, by E_i^π the corresponding expectation operator, and by $x(t,\pi)(e)$ the value of $x(t,\pi)$ at $e \in \mathcal{F}$.

Remark 2.4. (a) For the case where $\sup_{i\in S} q(i) < \infty$ (see, for instance, [7, 26, 31, 35, 39]), Assumptions A(1) and A(2) are not required because they are used only to guarantee the regularity of a Q-process. For the case of *unbounded* transition rates (e.g., [18, 19]), the conditions for a Q-process to be regular are usually imposed on both the possibly *nonhomogeneous* minimum Q-processes and the transition rates. Hence, our Assumptions A(1)–A(3) are quite different from those in [18, 19].

(b) Assumptions A(1)–A(3) are an extension of both the "drift condition" in [30] and the hypotheses of Corollary 2.2.16 in [2] for a *homogeneous* Q-process to be regular. Assumption A(4) is a variant of the monotonicity conditions in Theorem 7.3.4 and the irreducibility conditions in Proposition 5.3.1 in [2].

(c) It should be mentioned that if there is a set $\bar{S}$ of transient states which is independent of stationary policies, then $\mu_f(i) = 0$ for each $i \in \bar{S}$ and $f \in F$. In this case, Lemma 3.4 below may *not* hold because its proof uses the result $\mu_f(i) > 0$ for all $i \in S$.

Now we define the ASPR criterion $V_{sp}(\cdot,\cdot)$ as follows: for each $\pi = (\pi_t) \in \Pi$ and $i \in S$

$$V_{sp}(\pi,i) := \limsup_{T\to\infty} \frac{1}{T}\left[\int_0^T r(x(t,\pi),\pi_t)dt\right], \tag{2.6}$$

where the subscript "sp" stands for "sample-path." Note that $V_{sp}(\pi,i)$ has been defined by the so-called *sample-path rewards* $r(x(t,\pi),\pi_t)$; therefore, it is a *random variable* rather than a number as in the AER-criterion defined as

$$\bar{V}(\pi,i) := \limsup_{T\to\infty} \frac{1}{T}\left[\int_0^T E_i^\pi r(x(t,\pi),\pi_t)dt\right] \tag{2.7}$$

(see [4, 7, 16, 19, 20, 21, 26, 27, 31, 35, 39], for instance). Thus, the following definition of optimal policies for the ASPR criterion is different from that for the AER criterion.

Definition 2.5. *For a given $\epsilon \ge 0$, a policy $\pi^* \in \Pi$ is said to be ϵ-ASPR-optimal if there exists a constant g^* such that*

$$P_i^{\pi^*}(V_{sp}(\pi^*,i) \ge g^* - \epsilon) = 1 \quad \textit{and} \quad P_i^\pi(V_{sp}(\pi,i) \le g^*) = 1 \quad \forall i \in S \textit{ and } \pi \in \Pi.$$

A 0-ASPR-optimal policy is simply called an ASPR-optimal policy.

The main goal of this paper is to give conditions on the primitive data in (2.1) that ensure the existence of an ASPR-optimal stationary policy.

3. Preliminaries. In this section we present some preliminary facts that are needed to prove our main results.

Let $w \geq 1$ be the function in Assumption A. Following the concept of a weighted supremum norm introduced by Lippman [28] and widely used by many authors (e.g., [23, p. 2]), we define the weighted supremum norm $\|v\|_w$ for a real-valued functions v on S by

$$\|v\|_w := \sup_{i \in S}[w(i)^{-1}|v(i)|]$$

and the Banach space by $B_w(S) := \{v : \|v\|_w < \infty\}$.

LEMMA 3.1. *Let $\bar{w}$ be any nonnegative function on S, and $\bar{c}$, $\bar{b}$ two constants such that $\bar{b} \geq 0$ and $\bar{c} \neq 0$. Then, for each $\pi = (\pi_t) \in \Pi$, the following statements are equivalent:*

(a) $\sum_{j \in S} p^{\min}(s, i, t, j, \pi)\bar{w}(j) \leq e^{-\bar{c}(t-s)}\bar{w}(i) + \frac{\bar{b}}{\bar{c}}[1 - e^{-\bar{c}(t-s)}]$ *for all $i \in S$ and $t \geq s \geq 0$;*

(b) $\sum_{j \in S} q(j|i, \pi_t)\bar{w}(j) \leq -\bar{c}\bar{w}(i) + \bar{b}$ *for all $i \in S$ and $t \geq 0$.*

Proof. See Lemma 3.2 in [16]. □

It should be noted that in Lemma 3.1, Assumption A is *not* required.

To establish the so-called optimality equation, we will use a *policy iteration algorithm* instead of the *vanishing discount approach* in [16, 19, 21, 26]. To state the policy iteration algorithm, in addition to Assumption A we also need the following standard continuity-compactness conditions (Assumption B); see, for instance, [3, 19, 23, 31, 35] and their references.

Assumption B. (1) For each $i \in S$, $A(i)$ is compact.

(2) $r(i, a)$ and $q(j|i, a)$ are continuous in $a \in A(i)$ for each fixed $i, j \in S$.

(3) The function $\sum_{j \in S} q(j|i, a)w(j)$ is continuous in $a \in A(i)$ for each fixed $i \in S$.

(4) There exists a positive constant M such that $|r(i, a)| \leq Mw(i)$ for all $i \in S$ and $a \in A(i)$.

In the spirit of the potential concept in [8, 7], for a given $f \in F$ and the corresponding unique invariant probability measure μ_f, we define the *potential*

$$u(f, i) := \int_0^\infty [E_i^f r(x(t, f), f(x(t, f))) - g(f)]dt \quad \forall\, i \in S, \tag{3.1}$$

where the constant $g(f)$ is defined as

$$g(f) := \sum_{j \in S} r(j, f(j))\mu_f(j). \tag{3.2}$$

LEMMA 3.2. *Let Assumptions* A *and* B(4) *hold. Then*

(a) *$g(f)$ and $\|u(f, \cdot)\|_w$ are both bounded in $f \in F$,*

(b) *the Poisson equation $g(f) = r(i, f(i)) + \sum_{j \in S} q(j|i, f(i))u(f, j)$ holds for all $i \in S$ and $f \in F$.*

Proof. By (3.1) and (2.5) we see that $\|u(f, \cdot)\|_w$ is bounded in $f \in F$. With the constants M, c, and b as in Assumptions A and B(4), by Lemma 3.1, (3.1), (2.5), and (2.7), we have $|\overline{V}(f, \cdot)| = |g(f)| \leq \frac{Mb}{c}$ for all $f \in F$, and so (a) follows. Obviously, (b) follows from Lemma 5.1 in [16]. □

Under Assumptions A and B, we now state the policy iteration algorithm.

POLICY ITERATION ALGORITHM 3.1.

Step I. Take $n = 0$ and $f_n \in F$.

Step II. Solve (2.4) for μ_{f_n} and then calculate $u(f_n, \cdot)$ and $g(f_n)$ as in (3.1) and (3.2).

Step III. Define a new stationary policy f_{n+1} in the following way:

Set $f_{n+1}(i) := f_n(i)$ for all $i \in S$ for which

$$r(i, f_n(i)) + \sum_{j \in S} q(j|i, f_n(i))u(f_n, j) = \max_{a \in A(i)} \left\{ r(i,a) + \sum_{j \in S} q(j|i,a)u(f_n, j) \right\}; \tag{3.3}$$

otherwise (i.e., when (3.3) does not hold), choose $f_{n+1}(i) \in A(i)$ such that

$$\begin{aligned} r(i, f_{n+1}(i)) &+ \sum_{j \in S} q(j|i, f_{n+1}(i))u(f_n, j) \\ &= \max_{a \in A(i)} \left\{ r(i,a) + \sum_{j \in S} q(j|i,a)u(f_n, j) \right\}. \end{aligned} \tag{3.4}$$

Step IV. If $f_{n+1}(i)$ satisfies (3.3) for all $i \in S$, then stop because (by Theorem 4.1 below) f_{n+1} is ASPR-optimal; otherwise, replace f_n with f_{n+1} and go back to *Step* II.

Finally, to prove the existence of an ASPR-optimal stationary policy, in addition to Assumptions A and B we propose the following conditions.

Assumption C. There exist nonnegative functions $w_k^* \geq 1$ on S as well as constants $c_k^* > 0$, $b_k^* \geq 0$, and $M_k^* > 0$ $(k = 1, 2)$ such that, for each $i \in S$ and $a \in A(i)$,

(1) $w^2(i) \leq M_1^* w_1^*(i)$ and $\sum_{j \in S} q(j|i,a)w_1^*(j) \leq -c_1^* w_1^*(i) + b_1^*$, and

(2) $[q(i)w(i)]^2 \leq M_2^* w_2^*(i)$ and $\sum_{j \in S} q(j|i,a)w_2^*(j) \leq -c_2^* w_k^*(i) + b_2^*$.

Remark 3.3. (a) Assumption C allows us to use the martingale stability theorem; see Lemma 3.11 in [22], for instance. However, it is not required when a solution u^* in (4.1) below and the transition rates are both uniformly bounded.

(b) Assumption C(2) is slightly different from Assumption B(4) in [16], but all conclusions in [16] still hold after Assumption B(4) in [16] is replaced by Assumption C(2) here.

For each $n \geq 1$, take f_n as the policy obtained in the policy iteration algorithm 3.1, and for each $i \in S$ let

$$\varepsilon(f_n, i) := r(i, f_n(i)) + \sum_{j \in S} q(j|i, f_n(i))u(f_{n-1}, j) - g(f_{n-1}). \tag{3.5}$$

LEMMA 3.4. *Let Assumptions* A, B, *and* C(2) *hold. Then* $g(f_{n+1}) > g(f_n)$ *when* $f_{n+1} \neq f_n$, *and for each* $i \in S$, $\varepsilon(f_n, i) \to 0$ *as* $n \to \infty$.

Proof. As in the proof of Theorem 5.2 and Lemma 5.3 in [16], by Lemma 3.2 above we obtain Lemma 3.4. □

Lemma 3.4 will be used to establish the optimality equation (4.1) below.

4. The existence of ASPR-optimal stationary policies. In this section, we state and prove our main result, Theorem 4.1.

THEOREM 4.1. *Under Assumptions* A, B, *and* C, *the following statements hold.*

(a) *There exist a unique constant* g^*, *a function* $u^* \in B_w(S)$, *and a stationary policy* $f^* \in F$ *satisfying the optimality equation*

$$g^* = r(i, f^*(i)) + \sum_{j \in S} q(j|i, f^*(i))u^*(j)$$

$$= \max_{a\in A(i)} \left\{ r(i,a) + \sum_{j\in S} q(j|i,a)u^*(j) \right\} \quad \forall i \in S. \tag{4.1}$$

(b) *The policy f^* in* (a) *is ASPR-optimal, and $P_i^{f^*}(V_{sp}(f^*,i) = g^*) = 1$ for all $i \in S$.*

(c) *A policy f in F is ASPR-optimal if and only if it realizes the maximum of* (4.1).

(d) *For given $\epsilon \geq 0$ and $f \in F$, if there is a function $\bar{u} \in B_w(S)$ such that*

$$g^* \leq r(i,f(i)) + \sum_{j\in S} q(j|i,f(i))\bar{u}(j) + \epsilon \quad \forall i \in S,$$

then f is ϵ-ASPR-optimal.

Proof. (a) Let $\{f_n\}$ be the sequence of the stationary policies obtained by the policy iteration algorithm 3.1. By Assumption B(1) and the Tichonoff theorem, the policy class F is compact. Thus, by Lemma 3.2(a), there exist a subsequence $\{f_{n_k}\}$ of $\{f_n\}$ and $u^* \in B_w(S)$ such that for each $i \in S$

$$\lim_{k\to\infty} u(f_{n_k},i) = u^*(i), \quad \lim_{k\to\infty} f_{n_k}(i) =: f^*(i), \quad \text{and} \quad \lim_{k\to\infty} g(f_{n_k}) =: g^*. \tag{4.2}$$

On the other hand, by Lemmas 3.2(b), (3.4), and (3.5), we have

$$\begin{aligned} g(f_{n_k}) &= r(i,f_{n_k}(i)) + \sum_{j\in S} q(j|i,f_{n_k}(i))u(f_{n_k},j) \\ &= \max_{a\in A(i)} \left\{ r(i,a) + \sum_{j\in S} q(j|i,a)u(f_{n_k},j) \right\} - \varepsilon(f_{n_k+1},i) \\ &\geq r(i,a) + \sum_{j\in S} q(j|i,a)u(f_{n_k},j) - \varepsilon(f_{n_k+1},i) \quad \forall i \in S \text{ and } a \in A(i). \end{aligned} \tag{4.3}$$

Letting $k \to \infty$ in (4.3), by the "extension of Fatou's Lemma" 8.3.7 in [23] and our Lemma 3.4 and (4.2), we have

$$\begin{aligned} g^* &= r(i,f^*(i)) + \sum_{j\in S} q(j|i,f^*(i))u^*(j) \\ &\geq r(i,a) + \sum_{j\in S} q(j|i,a)u^*(j) \quad \forall i \in S \text{ and } a \in A(i), \end{aligned}$$

and so

$$\begin{aligned} g^* &= r(i,f^*(i)) + \sum_{j\in S} q(j|i,f^*(i))u^*(j) \\ &= \max_{a\in A(i)} \left\{ r(i,a) + \sum_{j\in S} q(j|i,a)u^*(j) \right\} \quad \forall i \in S, \end{aligned}$$

which gives (4.1). Moreover, the proof of the uniqueness of the constant g^* satisfying (4.1) follows from Theorem 4.1(b) in [16] and Remark 3.3(b).

(b) To prove (b), for each $i \in S$, $\pi = (\pi_t) \in \Pi$, and $t \geq 0$, let

$$\Delta(i,\pi_t) := r(i,\pi_t) + \sum_{j\in S} q(j|i,\pi_t)u^*(j) - g^*, \tag{4.4}$$

$$\mathcal{F}_t(\pi) := \sigma\{x(s,\pi),\ 0 \le s \le t\},$$
$$g(i,\pi_t) := \sum_{j\in S} q(j|i,\pi_t)u^*(j). \tag{4.5}$$

In particular, let $\Delta(i,f(i)) =: r(i,f(i)) + \sum_{j\in S} q(j|i,f(i))u^*(j) - g^*$ for all $f \in F$.

We now define a (continuous-time) stochastic process,

$$M(t,\pi) := \int_0^t g(x(y,\pi),\pi_y)dy - u^*(x(t,\pi)) \quad \text{for } t \ge 0. \tag{4.6}$$

Then $\{M(t,\pi), \mathcal{F}_t(\pi),\ t \ge 0\}$ is a P_i^π-martingale in continuous-time; that is,

$$E_i^\pi[M(t,\pi)|\mathcal{F}_s(\pi)] = M(s,\pi) \quad \forall t \ge s \ge 0. \tag{4.7}$$

Indeed, for each $t \ge s \ge 0$, by (4.6) and the Markov property we have

$$\begin{aligned} E_i^\pi[M(t,\pi)|\mathcal{F}_s(\pi)] &= M(s,\pi) + E_i^\pi\left[\int_s^t g(x(y,\pi),\pi_y)dy|\mathcal{F}_s(\pi)\right] \\ &\quad + u^*(x(s,\pi)) - E^\pi_{x(s,\pi)}u^*(x(t,\pi)). \end{aligned} \tag{4.8}$$

Since $u^* \in B_w(S)$ (by (4.2) and Lemma 3.2(a)), it follows from Assumption A(3) that

$$\begin{aligned} \left|\sum_{j\in S} q(j|i,a)u^*(j)\right| &\le \|u^*\|_w\left[\sum_{j\in S} q(j|i,a)w(j) - 2q(i|i,a)w(i)\right] \\ &\le \|u^*\|_w[-cw(i) + b + 2q(i)w(i)] \\ &\le \|u^*\|_w[b + 2q(i)w(i)] \end{aligned} \tag{4.9}$$

for all $a \in A(i)$ and $i \in S$. Therefore, by (4.5) and (2.2) we obtain

$$|g(i,\pi_y)| \le \|u^*\|_w[b + 2q(i)w(i)] \quad \forall y \ge 0 \text{ and } i \in S. \tag{4.10}$$

On the other hand, by the Markov property we have

$$E_i^\pi\left[\int_s^t g(x(y,\pi),\pi_y)dy|\mathcal{F}_s(\pi)\right] = E^\pi_{x(s,\pi)}\left[\int_s^t g(x(y,\pi),\pi_y)dy\right],$$

which together with (4.10), Assumption C(2), Lemma 3.1, and Fubini's theorem gives

$$E_i^\pi\left[\int_s^t g(x(y,\pi),\pi_y)dy|\mathcal{F}_s(\pi)\right] = \int_s^t\left[E^\pi_{x(s,\pi)}g(x(y,\pi),\pi_y)\right]dy. \tag{4.11}$$

From Lemma 2.1(b) in [21] and (4.10) in [16] about the *extended generator* of a possibly nonhomogeneous continuous-time Markov process, by (4.11) and (4.5) we obtain

$$E_i^\pi\left[\int_s^t g(x(y,\pi),\pi_y)dy|\mathcal{F}_s(\pi)\right] = E^\pi_{x(s,\pi)}u^*(x(t,\pi)) - u^*(x(s,\pi)),$$

which together with (4.8) gives (4.7).

It follows from (4.7) that $\{M(n,\pi), \mathcal{F}_n(\pi),\ n \ge 1\}$ is also a P_i^π-martingale in discrete-time. Moreover, By Assumption C and Lemma 3.1 we have

$$E_i^\pi w_k^*(x(t,\pi)) \le w_k^*(i) + \frac{b_k^*}{c_k^*} \quad \forall t \ge 0 \text{ and } k = 1,2, \tag{4.12}$$

which together with (4.6), (4.10), the Hölder inequality, and Assumption C gives

$$
\begin{aligned}
&E_i^\pi[M(n+1,\pi)-M(n,\pi)]^2\\
&\quad= E_i^\pi\left[\int_n^{n+1} g(x(y,\pi),\pi_y)dy + u^*(x(n,\pi)) - u^*(x(n+1,\pi))\right]^2\\
&\quad\le 2E_i^\pi\left[\int_n^{n+1} g(x(y,\pi),\pi_y)dy\right]^2 + 2E_i^\pi[u^*(x(n+1,\pi)) - u^*(x(n,\pi))]^2\\
&\quad\le 2E_i^\pi\left[\int_n^{n+1} g^2(x(y,\pi),\pi_y)dy\right] \qquad \text{(by the Hölder inequality)}\\
&\qquad + 4\|u^*\|_w^2 E_i^\pi[w^2(x(n+1,\pi)) + w^2(x(n,\pi))]\\
&\quad\le 2E_i^\pi\left[\int_n^{n+1} \|u^*\|_w^2[b+2q(x(y,\pi))w(x(y,\pi))]^2dy\right] \quad \text{(by (4.10))}\\
&\qquad + 4M_1^*\|u^*\|_w^2 E_i^\pi[w_1^*(x(n+1,\pi)) + w_1^*(x(n,\pi))] \qquad \text{(by Assumption C(1))}\\
&\quad\le 4\|u^*\|_w^2 E_i^\pi\left[\int_n^{n+1} (b^2 + 4[q(x(y,\pi))w(x(y,\pi))]^2)dy\right]\\
&\qquad + 4M_1^*\|u^*\|_w^2 E_i^\pi[w_1^*(x(n+1,\pi)) + w_1^*(x(n,\pi))]\\
&\quad\le 4\|u^*\|_w^2 E_i^\pi\left[\int_n^{n+1} (b^2 + 4M_2^* w_2^*(x(y,\pi)))dy\right] \qquad \text{(by Assumption C(2))}\\
&\qquad + 4M_1^*\|u^*\|_w^2 E_i^\pi[w_1^*(x(n+1,\pi)) + w_1^*(x(n,\pi))],
\end{aligned}
$$

which gives

$$
\begin{aligned}
(4.13)\quad &E_i^\pi[M(n+1,\pi)-M(n,\pi)]^2\\
&\le 16\|u^*\|_w^2\left[b^2 + M_2^*\left(w_2^*(i) + \frac{b_2^*}{c_2^*}\right) + M_1^*\left(w_1^*(i) + \frac{b_1^*}{c_1^*}\right)\right] \quad \text{(by (4.12))}.
\end{aligned}
$$

This means that $E_i^\pi[M(n+1,\pi)-M(n,\pi)]^2$ is bounded in $n \ge 1$. Thus, by the martingale stability theorem (e.g., [22, p. 105], or Remark 11.2.6 in [23], for instance), we have

$$
\lim_{n\to\infty} \frac{M(n,\pi)}{n} = 0 \quad \text{a.s.} - P_i^\pi. \tag{4.14}
$$

On the other hand, for any $T \ge 1$, let $[T]$ be the unique integer such that $[T] \le T < [T]+1$. By (4.6) we have

$$
\frac{M(T,\pi)}{T} = \frac{[T]}{T}\left(\frac{M([T],\pi)}{[T]} + \frac{\int_{[T]}^T g(x(y,\pi),\pi_y)dy}{[T]} - \frac{u^*(x(T,\pi))}{[T]} + \frac{u^*(x([T],\pi))}{[T]}\right). \tag{4.15}
$$

Moreover, for any arbitrary $\epsilon > 0$, as in the proof of (4.13), by the Chebyshev's inequality we have

$$
\begin{aligned}
P_i^\pi\left(\frac{\left|\int_{[T]}^T g(x(y,\pi),\pi_y)dy\right|}{[T]} > \epsilon\right) &\le \frac{E_i^\pi\left[\int_{[T]}^T |g(x(y,\pi),\pi_y)|dy\right]^2}{\epsilon^2[T]^2}\\
&\le \frac{16\|u^*\|_w^2\left[b^2 + M_2^*\left(w_2^*(i) + \frac{b_2^*}{c_2^*}\right)\right]}{\epsilon^2[T]^2}. \qquad (4.16)
\end{aligned}
$$

Since $\sum_{[T]=1}^{\infty} \frac{1}{[T]^2} < \infty$, by (4.16) and the Borel–Cantelli lemma, we have

$$P_i^\pi \left(\limsup_{[T]} \left\{ \frac{\left| \int_{[T]}^{T} g(x(y,\pi),\pi_y)dy \right|}{[T]} > \epsilon \right\} \right) = 0.$$

Now let

$$E_{[T]} := \left\{ \frac{|\int_{[T]}^{T} g(x(y,\pi),\pi_y)dy|}{[T]} > \epsilon \right\} \in \mathcal{F},$$

$E := \limsup_{[T]} E_{[T]} \in \mathcal{F}$, and $E^c := \Omega - E$ being the complement of set E. Then $P_i^\pi(E^c) = 1$. Let $e \in E^c$, which means that e is in finitely many sets $E_{[T]}$. So there exists an integer $N_0(e)$ (depending on e) such that $e \notin E_{[T]}$ for all $[T] \geq N_0(e)$, i.e.,

$$\frac{\left| \int_{[T]}^{T} g(x(y,\pi)(e),\pi_y)dy \right|}{[T]} \leq \epsilon \quad \forall\ [T] \geq N_0(e) \text{ and } e \in E^c,$$

which together with $P_i^\pi(E^c) = 1$ yields

$$\lim_{[T]\to\infty} \frac{\int_{[T]}^{T} g(x(y,\pi),\pi_y)dy}{[T]} = 0 \quad \text{a.s.} - P_i^\pi. \tag{4.17}$$

Similarly, we have

$$\lim_{[T]\to\infty} \frac{u^*(x(T,\pi))}{[T]} = \lim_{[T]\to\infty} \frac{u^*(x([T],\pi))}{[T]} = 0 \quad \text{a.s.} - P_i^\pi. \tag{4.18}$$

Since $\lim_{T\to\infty} \frac{[T]}{T} = 1$, by (4.14), (4.15), (4.17), and (4.18), we have

$$\lim_{T\to\infty} \frac{M(T,\pi)}{T} = 0 \quad \text{a.s.} - P_i^\pi. \tag{4.19}$$

By (4.4)–(4.6) it follows that

$$M(t,\pi) = -\int_0^t r(x(y,\pi),\pi_y)dy + \int_0^t \Delta(x(y,\pi),\pi_y)dy - u^*(x(t,\pi)) + tg^*. \tag{4.20}$$

By (4.1), (4.4), (2.2), and (2.3), we have $\Delta(i,\pi_t) \leq 0$ and $\Delta(i, f^*(i)) = 0$ for all $t \geq 0$ and $i \in S$. Thus, by (4.18), (4.19), and (4.20) we obtain

$$P_i^\pi(V_{sp}(\pi,i) \leq g^*) = 1 \ \text{ and} \tag{4.21}$$

$$P_i^{f^*}(V_{sp}(f^*,i) = g^*) = 1, \tag{4.22}$$

which, together with the arbitrariness of π and i, give (b).

(c) By (b), it suffices to prove that $f(\in F)$ realizes the maximum of (4.1) if f is SPAR-optimal. Now suppose that f is SPAR-optimal but does not realize the maximum of (4.1). Then there exist some $i_0 \in S$ and a constant $\alpha(i_0, f) > 0$ (depending on i_0 and f) such that

$$g^* \geq [r(i,f(i)) + \alpha(i_0,f)\delta_{i_0 i}] + \sum_{j\in S} q(j|i,f(i))u^*(j) \quad \forall i \in S. \tag{4.23}$$

On the other hand, since f is SPAR-optimal, by (b) and (4.21) we have $V_{sp}(f,i) = g^*$ a.s. for all $i \in S$. Moreover, as in the proof of (4.22), from Lemma 3.2(b) we also have $V_{sp}(f,i) = g(f)$ a.s., and so

$$g^* = g(f) = \sum_{j\in S} \mu_f(j) r(j, f(j)). \tag{4.24}$$

Also, as in the proof of (4.12) in [16], by (4.23) and (4.24) as well as (2.7) we obtain

$$g^* \geq \sum_{j\in S} \mu_f(j)[r(j,f(j)) + \alpha(i_0,f)\delta_{i_0 j}] = g^* + \mu_f(i_0)\alpha(i_0,f),$$

which gives a contradiction because $\mu_f(i_0)$ and $\alpha(i_0,f)$ are both positive.

(d) Let $\Delta_{\bar{u}}(i,f(i)) := r(i,f(i)) + \sum_{j\in S} q(j|i,f(i))\bar{u}(j) - g^*$. Then, $\Delta_{\bar{u}}(i,f(i)) \geq -\epsilon$ for all $i \in S$. Thus, as in the proof of (4.21), we have

$$P_i^f(V_{sp}(f,i) \geq g^* - \epsilon) = 1,$$

which together with (b) gives (d). □

Theorem 4.1 is an important result: part (a) establishes the optimality equation (4.1) and the existence of a so-called *canonical* policy f^*, whereas part (b) further shows that the canonical policy f^* is ASPR-optimal.

Remark 4.2. (a) Under Assumptions A, B, and C(2) only, from the proof of Theorem 4.1 here and Theorem 4.1 in [16] we see that the canonical policy f^* in Theorem 4.1(a) is also optimal for the AER criterion. However, it is shown that an optimal stationary policy for the AER criterion may *not* be canonical [18]. Therefore, it is natural to *guess* that an ASPR-optimal stationary policy may *not* be canonical either. An attempt to answer this problem faces significant technical difficulties, and the problem remains unsolved to this date.

(b) From the proof of Theorem 4.1(b) and (c) we see that both Assumptions C(1) and C(2) are indeed required for the ASPR criterion. That is because (i) the proof of Theorem 4.1(b) and (c) uses the estimates in (4.13) and (4.16), and (ii) the proof of (4.13) and (4.16) is based on both Assumptions C(1) and C(2); see the proof of (4.12) and (4.24) (In the proof of the "if" part of Theorem 4.1(c), we cannot obtain (4.24) by the dominated convergence theorem because $V_{sp}(i,f)$ is defined via "limsup" instead of "lim.")

(c) To establish the optimality equation (4.1), we have used the *policy iteration algorithm* 3.1, instead of the "vanishing discount factor method" used in [16, 18, 19, 21, 26], for instance. It should be noted that our approach is *direct* because it does not require any result about discounted continuous-time MDPs. This is by way of the same logic introduced in [25] for *discrete-time* unichain MDPs. (A similar approach is adopted for discrete-time general MDPs with finite state and action sets in [9, 38] by using simple algebra and properties of the Cesaro-limit of a transition probability matrix and in [12, 31] by using vanishing discount factors.)

(d) We can also prove Theorem 4.1 by using the "vanishing discount factor method." More precisely, under Assumptions A and B, we can (i) establish the average optimality inequalities by using the α-discounted optimality equation in [17], (ii) obtain the optimality equation, and (iii) prove the existence of ASPR-optimal stationary policies under the additional Assumption C. However, this vanishing factor method needs *additional* results about discounted continuous-time MDPs in [17].

When the transition and reward rates are both *uniformly bounded*, we need to impose conditions only on the *embedded* Markov chains to guarantee the existence of SPAR-optimal stationary policies. This is stated in the following corollary.

COROLLARY 4.3. *Suppose the following conditions* (1)–(3) *are satisfied.*

(1) $\|q\| := \sup_{i\in S} q(i) < \infty$, $\|r\| := \sup_{i\in S, a\in A(i)} |r(i,a)| < \infty$.

(2) *For each* $i \in S$, $A(i)$ *is compact; and* $r(i,a)$ *and* $q(j|i,a)$ *are continuous in* $a \in A(i)$ *for each fixed* $i, j \in S$.

(3) *Either* $\inf_{i\neq j_0, a\in A(i)} q(j_0|i,a) > 0$ *for some* $j_0 \in S$; *or* $\sum_{j\in S} \sup_{i\in S, a\in A(i)} (\frac{q(j|i,a)}{\|q\|} + \delta_{ij}) < 2$.

Then, the following results hold.

(a) *There exists an ASPR-optimal stationary policy.*

(b) *For each* $\epsilon > 0$, *an* ϵ*-ASPR-optimal stationary policy can be obtained in a finite number of steps of the policy iteration algorithm* 3.1.

Proof. Define maps T_k on the set $M(S)$ of *bounded functions* on S as

$$T_k u(i) := \sup_{a\in A(i)} \left\{ \frac{r(i,a)}{\|q\|+1} + \sum_{j\in S} \left[\left(\frac{q(j|i,a)}{\|q\|+1} + \delta_{ij} \right) - \mu_k(j) \right] u(j) \right\} \tag{4.25}$$

for all $i \in S$, $u \in M(S)$, and $k = 1, 2$, where the measures μ_k on S are given by

$$\mu_1(j) := \inf_{i\in S, a\in A(i)} \left[\frac{q(j|i,a)}{\|q\|+1} + \delta_{ij} \right] \text{ and}$$

$$\mu_2(j) := \sup_{i\in S, a\in A(i)} \left[\frac{q(j|i,a)}{\|q\|+1} + \delta_{ij} \right] \text{ for } j \in S,$$

which correspond to the first and second hypotheses in the condition (3), respectively. Thus, the maps T_1 and T_2 are both contractive with contraction factors β_1 and β_2, respectively, where

$$\beta_1 := 1 - \mu_1(S) \in (0,1) \text{ and } \beta_2 := \mu_2(S) - 1 \in (0,1). \tag{4.26}$$

Hence, the Banach's fixed point theorem gives the existence of $u^* \in M(S)$, $f^* \in F$ and a unique constant g^* satisfying (4.1). Then, as in the proof of Theorem 4.1(a) and (d), we see that Corollary 4.3 is true. □

Remark 4.4. (a) The two sets in the condition (3) in Corollary 4.3 are variants of the ergodicity condition in [22] for discrete-time MDPs, and each set implies that the embedded chain with the transition probability $(\frac{q(j|i,f(i))}{1+\|q\|} + \delta_{ij})$ has a unique invariant probability measure; see p. 56 in [22], for instance. The difference between the "monotonicity" condition in Assumption A(4) and the condition (3) in Corollary 4.3 can be shown by examples.

(b) Corollary 4.3 can also be obtained by using the uniformization method in [29, 31, 36] and the equivalence between continuous- and discrete-time MDPs in [31, 36, 37], as well as the results for discrete-time MDPs in [3, 10, 14, 15, 22, 24, 32, 34], for instance.

5. Algorithms. Following the procedure in the proof of Theorem 4.1, we now provide a policy iteration algorithm to obtain ASPR-optimal stationary policies.

PROPOSITION 5.1. *Suppose that Assumptions* A, B, *and* C *hold. Then any limit point* f^* *of the sequence* $\{f_n\}$ *obtained by the policy iteration Algorithm* 3.1 *is ASPR-optimal.*

Proof. The proposition follows directly from the proof of Theorem 4.1. □

Under the conditions in Corollary 4.3, we provide a *value iteration algorithm* to compute $\epsilon(>0)$-ASPR-optimal stationary policies. It should be mentioned that, as in the proof of Corollary 4.3, the choice of $k = 1$ (or 2) corresponds to the first (or second) hypothesis in the condition (3) in Corollary 4.3. Thus, we will understand that k in this algorithm is *fixed*.

VALUE ITERATION ALGORITHM 5.1.

Step I. For a fixed $\epsilon > 0$, take arbitrarily $u_0 \in M(S)$.

Step II. If $T_k u_0 = u_0$, then obtain a policy f (in F) satisfying

$$r(i, f(i)) + \sum_{j\in S} q(j|i, f(i))u_0(j) = \sup_{a\in A(i)} \left\{ r(i,a) + \sum_{j\in S} q(j|i,a)u_0(j) \right\} \quad \forall i \in S,$$

and f is ASPR-optimal (by Theorem 4.1), stop; otherwise, calculate a positive integer $N \geq \frac{1}{\beta_k} \ln \frac{\epsilon(1-\beta_k)}{4(1+\|q\|)\|u_1-u_0\|} + 1$ with β_k as in (4.26), and $u_N := T_k^N u_0 = T_k(T_k^{N-1}u_0)$ (by (4.25)).

Step III. Choose $f_\epsilon(i) \in A(i)$ such that for each $i \in S$

$$r(i, f_\epsilon(i)) + \sum_{j\in S} q(j|i, f_\epsilon(i))u_N(j) \geq \sup_{a\in A(i)} \left\{ r(i,a) + \sum_{j\in S} q(j|i,a)u_N(j) \right\} - \frac{\epsilon}{2}.$$

Then we have the following facts.

PROPOSITION 5.2. *Under the conditions in Corollary* 4.3*, the policy f_ϵ obtained by the value iteration algorithm* 5.1 *is ϵ-ASPR-optimal.*

For the policy iteration algorithm 3.1, if we luckily choose an initial policy such that the algorithm 3.1 stops after a *finite* number of iterations, then Proposition 5.1 shows that an ASPR-optimal stationary policy can be computed. Otherwise, since the policy space F may be infinite, the algorithm 3.1 may not stop in any finite number of iterations. In this case, Proposition 5.1 shows that an ASPR-optimal stationary policy can be approximated. On the other hand, Proposition 5.2 implies that under the conditions in Corollary 4.3 an ϵ-ASPR-optimal stationary policy can indeed be computed in a finite number of iterations, where $\epsilon > 0$.

6. Examples. In this section, we illustrate our conditions and show the difference between the ASPR and AER criteria with examples.

Example 6.1 (a controlled birth-death system). Consider a controlled birth-death system in which the state variable denotes the population size at any time $t \geq 0$. There are "natural" birth and death rates denoted by *positive* constants λ and μ, respectively, as well as *nonnegative* emigration and immigration parameters. The two parameters are assumed to be controlled by a decision-maker and denoted by $h_1(i, a_1)$ and $h_2(i, a_2)$, respectively, which may depend on system's state i and decision variables a_1 and a_2 taken by the decision-maker. When the system is at state $i \in S := \{0, 1, \ldots\}$, the decision-maker takes an action $a := (a_1, a_2)$ from a *compact* set $A(i) =: A_1(i) \times A_2(i)$ of available actions, which increases/decreases the emigration parameter $h_1(i, a_1)$ and may incur a cost with rate $c(i, a_1)$, and also increases/decreases the immigration parameter $h_2(i, a_2)$ and gives a reward with rate $\bar{r}(i, a_2)$. Moreover, suppose that the benefit rate caused by a population is represented by $p > 0$. Then the *net* income rate in this system is $r(i, a) := pi + \bar{r}(i, a_2) - c(i, a_1)$ for each $i \in S$ and $a = (a_1, a_2) \in A(i)$. On the other hand, when there is no population in the system (i.e., $i = 0$), it is impossible to decrease/increase the emigration rate,

and so we have $h_1(0, a_1) \equiv 0$ for all $a_1 \in A_1(0)$. Also, in this case (i.e., $i = 0$) we may assume that the decision-maker hopes to increase the immigration rate, and then $h_2(0, a_2) > 0$ for all $a_2 \in A_2(0)$. (This assumption guarantees the irreducibility condition in Assumption A(4).)

We now formulate this system as a continuous-time Markov decision process. The corresponding transition rates $q(j|i, a)$ and reward rates $r(i, a)$ are given as follows.

For $i = 0$ and each $a = (a_1, a_2) \in A(0)$

$$q(1|0, a) = -q(0|0, a) := h_2(0, a_2) > 0,$$

and for $i \geq 1$ and all $a = (a_1, a_2) \in A(i)$

$$q(j|i, a) := \begin{cases} \mu i + h_1(i, a_1) & \text{if } j = i - 1, \\ -(\mu + \lambda)i - h_1(i, a_1) - h_2(i, a_2) & \text{if } j = i, \\ \lambda i + h_2(i, a_2) & \text{if } j = i + 1, \\ 0 & \text{otherwise;} \end{cases} \tag{6.1}$$

$$r(i, a) := pi + \bar{r}(i, a_2) - c(i, a_1) \quad \text{for } i \in S \text{ and } a = (a_1, a_2) \in A(i). \tag{6.2}$$

We aim to find conditions that ensure the existence of an ASPR-optimal stationary policy. To do this, in the spirit of Assumptions A, B, and C we consider the following conditions:

(E$_1$) (a) $\mu - \lambda > 0$. (b) Either $\kappa := \mu - \lambda + h_2^* - h_{1*} \leq 0$, or $\mu - \lambda > |h_2^* - h_{1*}|$ when $\kappa > 0$, where $h_2^* := \sup_{a_2 \in A_2(i), i \geq 1} h_2(i, a_2)$, $h_{1*} := \inf_{a_1 \in A_1(i), i \geq 1} h_1(i, a_1)$.

(E$_2$) For each fixed $i \in S$, the functions $h_1(i, \cdot)$, $h_2(i, \cdot)$, $c(i, \cdot)$, and $\bar{r}(i, \cdot)$ are all continuous.

(E$_3$) (a) There exist positive constants $L_k (k = 1, 2)$ such that $|c(i, a_1)| \leq L_1(i+1)$ and $|\bar{r}(i, a_2)| \leq L_2(i + 1)$ for all $i \in S$ and $(a_1, a_2) \in A_1(i) \times A_2(i)$. (b) $\|h_k\| := \sup_{i \in S, a_k \in A_k(i)} |h_k(i, a_k)| < \infty$, for $k = 1, 2$.

To further explain Example 6.1, we consider the *special* case of *birth-death processes with controlled immigration*. Consider a pest population in a region which may be isolated to prevent immigration. Let c denote the cost rate when immigration is always prevented, b denote the immigration rate without any control, and action $a \in [0, 1]$ denote the *level* of immigration prevented, where c and b are *fixed positive* constants. When the population size is $i \in S := \{0, 1, \ldots\}$, an action a from a set $A(i)$ consisting of available actions is taken. Then a cost rate ca is incurred, the immigration rate $(1 - a)b$ is permitted, and the evolution of the population depends on birth, death, and immigration with parameters λ, μ, and $(1 - a)b$, respectively, where λ and μ are given *positive constants*. Suppose that the damage rate caused by the pest is represented by $p > 0$. Then the reward rate is of the form $r(i, a) := -pi - ca$ for each $i \in S$ and $a \in A(i)$. Obviously, we have $A(i) := [0, 1]$ for each $i \geq 1$. However, when there is no pest in the region (i.e., $i = 0$), to guarantee the irreducibility condition in Assumption A(4) we need that $A(0) := [0, \beta]$ with a given $\beta \in (0, 1)$. (This, however, can be explained as follows: For the ecological balance of the region, the pest is not permitted to become extinct, and so the immigration rate $(1 - \beta)b > 0$ is left.) Using the notation in Example 6.1, for this model we have $h_1 \equiv 0$ and $h_2(i, a_2) = (1 - a)b$ with $a_2 := a$ here. Hence, when $\mu - \lambda > b$, the conditions E$_1$, E$_2$, and E$_3$ above are all satisfied.

Under E$_1$, E$_2$, and E$_3$, we obtain the following.

PROPOSITION 6.2. *Under conditions* E$_1$, E$_2$, *and* E$_3$, *the above controlled birth-death system satisfies the Assumptions* A, B, *and* C. *Therefore (by Theorem* 4.1*),*

there exists an ASPR-optimal stationary policy, which can be computed or at least approximated by the policy iteration algorithm 3.1.

Proof. We shall first verify Assumption A. Let $S_n := \{0, 1, \dots, n\}$ for each $n \geq 1$, $w(i) := i + 1$ for all $i \in S$, and

$$\rho := \frac{\mu - \lambda - h_2^* + h_{1*}}{2} = \mu - \lambda - \frac{\kappa}{2} > 0 \quad \text{when } \mu - \lambda > |h_2^* - h_{1*}|.$$

Then Assumptions A(1) and A(2) are obviously true. Moreover, for each $a = (a_1, a_2) \in A(i)$ with $i \geq 1$, by condition E_1 and (6.1), we have

$$\begin{aligned} \sum_{j \in S} q(j|i,a)w(j) &= (\lambda - \mu)(i+1) + \mu - \lambda - h_1(i,a_1) + h_2(i,a_2) \\ &\leq -(\mu - \lambda)w(i) + \kappa \\ &\leq \begin{cases} -(\mu - \lambda)w(i) & \text{when } \kappa \leq 0, \\ -\rho w(i) & \text{when } \kappa > 0 \quad (\text{and so } \rho > 0). \end{cases} \end{aligned} \tag{6.3}$$

In particular, for $i = 0$ and each $a = (a_1, a_2) \in A(0)$, we have

$$\sum_{j \in S} q(j|i,a)w(j) = h_2(0,a_2) \leq -(\mu - \lambda)w(0) + b' = -\rho w(0) + b' - \frac{\kappa}{2}, \tag{6.4}$$

where $b' := \mu - \lambda + \|h_2\| > 0$.

By the inequalities (6.3) and (6.4) we see that Assumption A(3) holds with $c := \mu - \lambda$ and $b := b'$ when $\kappa \leq 0$, or $c := \rho$ and $b := b'$ when $\kappa > 0$. Since $h_2(0, a_2) > 0$ for all $a_2 \in A_2(0)$, by (6.1) we see that Assumption A(4) is true. Hence Assumption A follows.

By E_3 and (6.2), we have $|r(i,a)| \leq pi + L_1(i+1) + L_2(i+1) \leq (p + L_1 + L_2)w(i)$ for all $i \in S$ and $a \in A(i)$, which verifies Assumption B(4). Hence, Assumption B is satisfied because Assumptions B(1), B(2), and B(3) follow from E_2 and the model's description.

Finally, to verify Assumption C we let

$$w_1^*(i) := i^2 + 1, \quad w_2^*(i) := i^4 + 1 \quad \forall i \in S. \tag{6.5}$$

Then

$$w^2(i) \leq M_1^* w_1^*(i), \quad [q(i)w(i)]^2 \leq M_2^* w_2^*(i) \quad \forall i \in S, \tag{6.6}$$

with $M_1^* := 3$ and $M_2^* := 8(\lambda + \mu + \|h_1\| + \|h_2\|)$.

Moreover, for each $i \geq 1$ and $a = (a_1, a_2) \in A(i)$, by (6.1), (6.5), and E_3, we have

$$\begin{aligned} \sum_{j \in S} q(j|i,a)w_1^*(j) &= -2i[\mu i + h_1(i,a_1)] + \mu i + h_1(i,a_1) \\ &\quad + 2i[\lambda i + h_2(i,a_2)] + \lambda i + h_2(i,a_2) \\ &\leq -2(\mu - \lambda)(i^2 + 1) + 3(\mu + \lambda + \|h_1\| + \|h_2\|)i. \end{aligned}$$

Hence, for each $i \geq \frac{3(\mu+\lambda+\|h_1\|+\|h_2\|)}{\mu-\lambda} + 1 =: i_*$, we have

$$\sum_{j \in S} q(j|i,a)w_1^*(j) \leq -(\mu - \lambda)w_1^*(i). \tag{6.7}$$

On the other hand, since $A(i)$ is assumed to be compact for each $i \in S$, by (6.1) and (6.5) we see that $\sum_{j\in S} q(j|i,a)w_1^*(j)$ and $(\mu-\lambda)w_1^*(i)$ are both bounded in $a \in A(i)$ and $i \le i_*$. Thus, from (6.7) there exists a positive constant b_1^* such that

$$\sum_{j\in S} q(j|i,a)w_1^*(j) \le -(\mu-\lambda)w_1^*(i) + b_1^* \quad \forall i \in S \text{ and } a \in A(i). \tag{6.8}$$

Also, for each $i \ge 1$ and $a \in A(i)$, by (6.1) and (6.5) we have

$$\sum_{j\in S} q(j|i,a)w_2^*(j) \le -2(\mu-\lambda)(i^4+1) - (\mu-\lambda)i^4 + c_3 i^3 + c_2 i^2 + c_1 i + c_0, \tag{6.9}$$

where the constants $c_k (k = 0, 1, 2, 3)$ are determined completely by λ, μ, $\|h_1\|$, and $\|h_2\|$. Similarly, by (6.9) and (6.1), there exists a positive constant b_2^* such that

$$\sum_{j\in S} q(j|i,a)w_2^*(j) \le -(\mu-\lambda)w_2^*(i) + b_2^* \quad \forall i \in S \text{ and } a \in A(i), \tag{6.10}$$

which, together with (6.8) and (6.6), verifies Assumption C. □

It should be noted that in Example 6.1 both the reward and transition rates are *unbounded*; see (6.1) and (6.2). Next, we will show that our admissible policy class Π can indeed be chosen to be larger than the usual stationary policy class F.

Example 6.3. In Example 6.1, for each $i \in S$ we take arbitrarily two actions $a^k(i)$ $(k = 1, 2)$ from $A(i)$ which may depend on i, and then define an admissible policy $\tilde\pi = (\tilde\pi_t)$ as

$$\tilde\pi_t(B|i) = \begin{cases} \dfrac{1}{2}e^{-\rho_0 it} & \text{if } B = \{a^1(i)\}, \\ 1 - \dfrac{1}{2}e^{-\rho_0 it} & \text{if } B = \{a^2(i)\}, \\ 0 & \text{otherwise} \end{cases} \tag{6.11}$$

for some fixed constant $\rho_0 > 0$.

Then, by (6.1), (6.11), and (2.2), we see that $\tilde\pi$ is in Π but *not* in F. Therefore, we have $\Pi \supset F$, but $\Pi \ne F$. It is also noted that the associated Q-process $p(s, i, t, j, \tilde\pi)$ is *nonhomogeneous*, and so is the associated continuous-time Markov chain $x(t, \tilde\pi)$. Moreover, the corresponding reward rates $r(i, \tilde\pi_t)$ are *time-dependent* and *unbounded*; see (6.2) and (2.3).

Finally, in the following example we show that *in general* the AER and ASPR criteria are different.

Example 6.4. Let $S := \{1, 2\}$. For some $\hat\pi = (\hat\pi_t)$, $f \in \Pi$, suppose that for $0 \le t \le 1$,

$$Q(\hat\pi_t) := \begin{pmatrix} -1+t & 1-t \\ 2-2t & -2+2t \end{pmatrix} \quad \text{and} \quad Q(f) := \begin{pmatrix} 0 & 0 \\ 0 & 0 \end{pmatrix}. \tag{6.12}$$

Let $t_0 := 1$, and define

$$Q(\tilde\pi_t) := \begin{cases} Q(\hat\pi_t) & \text{when } 0 \le t \le t_0, \\ Q(f) & \text{when } t \ge t_0. \end{cases} \tag{6.13}$$

By (6.12), (6.13), and Definition 2.2, we see that the associated policy $\tilde{\pi}$ belongs to Π. For reference, we recall that for any $\pi \in \Pi$ the associated regular Q-process $p(s,i,t,j,\pi)$ can be constructed as follows [13, 16, 17]: for $i,j \in S$ and $n \geq 0$, let

$$p_0(s,i,t,j,\pi) := \delta_{ij} e^{-\int_s^t q_i(\pi_y)dy}, \tag{6.14}$$

$$p_{n+1}(s,i,t,j,\pi) := \int_s^t e^{-\int_s^y q_i(\pi_v)dv} \sum_{k\neq i} q(k|i,\pi_y) p_n(y,k,t,j,\pi)dy. \tag{6.15}$$

Then

$$p(s,i,t,j,\pi) = \sum_{n=0}^{\infty} p_n(s,i,t,j,\pi). \tag{6.16}$$

For each $i,j \in S$, by (6.12)–(6.16), $p(0,i,t_0,j,\hat{\pi}) > 0$. Hence, $0 < p(0,i,t_0,2,\hat{\pi}) < 1$. Moreover,

$$p(s,i,t,j,\tilde{\pi}) = \begin{cases} p(s,i,t,j,\hat{\pi}) & \text{when } 0 \leq t \leq t_0, \\ p(s,i,t,j,f) & \text{when } t \geq s \geq t_0. \end{cases} \tag{6.17}$$

Let $r(1,a) = 0$, $r(2,a) = 1$ for all $a \in A(i)$ with $i = 1,2$. Then, by (6.12) and (6.13) we see that states 1 and 2 are absorbing after time t_0. By (6.12), (6.14)–(6.17), we get

$$p(t_0,i,t,i,\tilde{\pi}) = 1 \quad \forall i \in S \text{ and } t \geq t_0. \tag{6.18}$$

Noting that $r(1,\tilde{\pi}_t) = 0$ and $r(2,\tilde{\pi}_t) = 1$ for each $t \geq 0$, by (6.18) and (2.6) we have that for each $i \in S$

$$V_{sp}(\tilde{\pi},i) = 1 \quad \text{for any sample path in } \{x(t,\tilde{\pi}) = 2,\ t \geq t_0\}. \tag{6.19}$$

On the other hand, by the Chapman–Kolmogorov equation and (6.18), we have

$$\begin{aligned} p(0,i,t,2,\tilde{\pi}) &= p(0,i,t_0,1,\tilde{\pi})p(t_0,1,t,2,\tilde{\pi}) + p(0,i,t_0,2,\tilde{\pi})p(t_0,2,t,2,\tilde{\pi}) \\ &= p(0,i,t_0,2,\tilde{\pi}) < 1 \quad \forall t_0 \leq t. \end{aligned} \tag{6.20}$$

Using again $r(1,\tilde{\pi}_t) = 0$ and $r(2,\tilde{\pi}_t) = 1$ for each $t \geq 0$, by (6.20) and (2.7) we get

$$\begin{aligned} \bar{V}(\tilde{\pi},i) &= \limsup_{T\to\infty} \frac{\int_0^T p(0,i,t,2,\tilde{\pi})dt}{T} \\ &= \limsup_{T\to\infty} \frac{\int_{t_0}^T p(0,i,t,2,\tilde{\pi})dt}{T} \\ &= p(0,i,t_0,2,\hat{\pi}) < 1 \quad \forall i \in S, \end{aligned} \tag{6.21}$$

which together with (6.19) and $P_i^{\tilde{\pi}}(\{x(t,\tilde{\pi}) = 2,\ t \geq t_0\}) = p(0,i,t_0,2,\hat{\pi}) > 0$ shows the difference between the ASPR and AER criteria.

7. Concluding remarks. In the previous sections we have studied ASPR optimality for denumerable continuous-time Markov chains determined by possibly unbounded transition rates. Under suitable assumptions we have shown the existence of a solution to the optimality equation and the existence of an ASPR-optimal stationary policy. In addition, we have presented two algorithms to compute, or at least

approximate, the ASPR-optimal stationary policies. Our formulation and approach are sufficiently general and can be used to analyze other important problems, such as the relation among potentials, perturbation analysis, and Markov decision processes in general spaces, as well as minimax control problems. These problems, as far as we can tell, have not been previously studied for continuous-time Markov chains with unbounded transition or reward rates. It should be mentioned that Example 6.4 shows that *in general* the ASPR and AER criteria are different, and it is an interesting and challenging problem to further show the difference between the two criteria under some ergodicity condition. Also, it remains open to show that an ASPR-optimal stationary policy is *not* necessarily canonical. Research on these topics is in progress.

L^P-OPTIMAL BOUNDARY CONTROL FOR THE WAVE EQUATION*

M. GUGAT†, G. LEUGERING†, AND G. SKLYAR‡

Abstract. We study problems of boundary controllability with minimal L^p-norm ($p \in [2, \infty]$) for the one-dimensional wave equation, where the state is controlled at both boundaries through Dirichlet or Neumann conditions. The problem is to reach a given terminal state and velocity in a given finite time, while minimizing the L^p-norm of the controls. We give necessary and sufficient conditions for the solvability of this problem. We show as follows how this infinite-dimensional optimization problem can be transformed into a problem which is much simpler: The feasible set of the transformed problem is described by a finite number of simple pointwise equality constraints for the control function in the Dirichlet case while, in the Neumann case, an additional integral equality constraint appears. We provide explicit complete solutions of the problems for all $p \in [2, \infty]$ in the Dirichlet case and solutions for some typical examples in the Neumann case.

1. Introduction.

In this paper, we discuss two-sided Dirchlet or Neumann controls for the one-dimensional wave equation for p between 2 and ∞. We consider the problem of exact control; that is, starting from the zero position we want to reach a given terminal state in a given finite time. Our aim is to find control functions with minimal L^p-norm that steer the system to the target. For certain typical cases, we present explicit representations of such optimal control functions in terms of the given target state.

It is well known that, in the L^2-case, the optimal control functions can be characterized as the L^2-norm minimal solutions of a trigonometric moment problem, which has been analyzed in depth (see [4], [19], [15]). For the L^p-case ($p > 2$) there are only a few publications on the subject (see [2], [16], [12], [11], [14], [10]), and even the question of existence of solutions, which is equivalent to the question of L^p-controllability, has not been solved completely.

In the present paper, we give a complete analysis of this problem for the boundary control of the one-dimensional wave equation. The problem can be reduced to the case of the minimal time interval, where controllability is possible. This allows an answer to be given to the question of solvability of the problem of L^p-controllability in terms of the properties of the target states. We use the control function for the minimal time interval to transform the infinite-dimensional problem into a problem, which is much simpler because it has only a finite number of simple pointwise equality constraints with an additional integral equality constraint (see (3.29) below) in the Neumann case. The transformation is based upon the representation of the state as a trigonometric series and on the corresponding description of the feasible set by

a sequence of moment equations on the control time interval that is transformed into a sequence of moment equations on a shorter time interval, namely, the interval corresponding to the time that a characteristic curve needs to travel from one end of the string to the other.

In the Dirichlet case, solutions of our problem of optimal control exist for all time intervals which are at least as long as the time that waves need to travel from one boundary of the system to the other, provided that the functions that describe the target are sufficiently regular. The required regularity is that the initial state and the primitive of the initial velocity are both in the space $L^p(0, L)$. The optimal controls are given explicitly in terms of these functions for all $p \in [2, \infty)$. In general, the L^∞-norm minimal control is not determined uniquely. Hence, in general there is a set of L^∞-norm minimal controls that contains more than one element. This convex set contains a unique element with minimal L^2-norm. In Theorem 2.2, we give this element explicitly.

For Neumann boundary controls, the situation is more complicated. On the time interval that allows a characteristic curve to travel from one boundary of the system interval to the other, in general, controllability is possible up to a constant only, in the sense that instead of the desired target a state can be reached that differs from the desired target by an appropriate constant. If this time interval is enlarged by an arbitrarily small time, L^p-controllability is possible on the elongated time interval if and only if the target functions are sufficiently regular. In this case, the required regularity is that the initial velocity and the derivative of the initial state are both in the space $L^p(0, L)$. We transform the optimal control problem to a simpler problem, where the feasible set is defined by a finite number of constraints. For some cases, we give explicit expressions for the solution of the optimal control problem in terms of the given target state.

The relation between the L^p regularity of the controls and the data in the Neumann and Dirichlet cases is consistent with what is known in the classical L^2 theory. The form of the optimal solutions depends on the relation between the length of the time interval and the time that the waves need to travel from one boundary of the system to the other. The structure of the optimal control functions is, in general, quite complicated. The optimal controls usually do not show bang-bang behavior; this is also true in the L^∞-case. This may be surprising, since the optimal solutions of discretized problems often are of bang-bang type. The difference between the structure of the controls that solve the PDE-constrained optimization problem and controls that are solutions of discretized problems has been the subject of recent research; see [9], [21], and the references therein.

This paper is also a contribution to robust optimal control: We have found controls whose optimality is robust with respect to perturbations of the objective function. For symmetric targets in the case of Dirichlet boundary controls and for antisymmetric target states in the case of Neumann boundary controls, the controls that are optimal for L^p $(p > 2)$ are exactly the controls that are optimal with respect to the L^2-norm and sufficiently regular to be contained in the space L^p.

Our results are also interesting from the point of view of sensitivity analysis (see [3]), since they allow us to analyze how the solutions of the optimization problems depend on p, the target state, and the time interval.

The explicit solutions of problems of optimal control that we present provide valuable test examples for numerical methods.

In the linear case, L^p-boundary controls have been considered in Krabs and

Leugering [16], where $W^{1,p}$ and also L^p-Dirichlet controls for $p \in [2, \infty]$ are applied at one of the boundary points. Optimal control problems for first-order-in-time equations with distributed L^p-controls have been considered in Fabre, Puel, and Zuazua [5]. See also Glowinski and Lions [7], [8].

Our work is related to existing controllability results for nonlinear problems; see [6] for approximate controllability results for semilinear parabolic equations with L^p-interior or boundary controls and [20] for controllability results for a semilinear wave equation for a class of nonlinearities that grow superlinearly at infinity.

We hope that our results will prove helpful for future analysis of optimal control problems with nonlinear systems.

This paper is organized as follows. Section 2 considers the problem of Dirichlet boundary control. We define the exact optimal boundary control problem, give an exact controllability result (Theorem 2.1), and state Theorem 2.2, where boundary controls that solve the optimal control problem are given in terms of the target state. This result allows a sensitivity analysis for the optimal control problem that is the subject of the next section. Then examples for the solutions presented in Theorem 2.2 are given. For the proof of the results, a series representation of weak solutions of the initial value problem is given and the moment problem describing the successful controls is defined. Then the minimal time interval, where controllability holds, is studied (see Lemma 2.6). Longer time intervals are studied section 2.10. The corresponding moment equations are transformed to moment equations on the minimal time interval. This transformation allows us to prove Theorem 2.1. Also by transformation to a problem on the minimal time interval, Theorem 2.2 is proved. At the end of section 2, the cases of symmetric and antisymmetric targets are discussed.

In section 3, we consider the problem of Neumann boundary control. The optimal control problem is defined and an exact controllability result (Theorem 3.1) is given. A series representation of the weak solution of the initial value problem and the moment problem that describes the successful controls is stated. Exact controllability up to a constant is proved for the minimal time interval (see Lemma 3.2). For larger time intervals, exact controllability is proved. Theorem 3.4 on the solutions of the optimization problem for a certain range of control times is stated. Finally, the cases of symmetric and antisymmetric targets are considered.

2. Dirichlet boundary control. In this section we present a complete solution of the problem of L^p-norm minimal Dirichlet boundary control of our system.

2.1. The initial-value problem. Let an interval $[0, L]$, a time interval $[0, T]$, and a wave speed $c > 0$ be given. We consider the initial-value problem for the wave equation

$$y_{tt}(x,t) = c^2 y_{xx}(x,t), \quad (x,t) \in [0,L] \times [0,T], \tag{2.1}$$

subject to the initial conditions

$$y(x,0) = 0, \quad y_t(x,0) = 0, \quad x \in [0,L], \tag{2.2}$$

and the Dirichlet boundary conditions

$$y(0,t) = f_1(t), \quad y(L,t) = f_2(t), \quad t \in [0,T]. \tag{2.3}$$

For the description of the desired target state, we add the following end conditions:

$$y(x,T) = y_0(x), \quad y_t(x,T) = y_1(x), \quad x \in [0,L]. \tag{2.4}$$

The function y_0 is in the Hilbert space $L^2(0,L)$ of square integrable functions on the interval $(0,L)$, and the function y_1 is integrable such that $Y_1(x) = \int_0^x y_1(z)\,dz$ is in $L^2(0,L)$, so y_1 is contained in the corresponding Sobolev space $W^{-1,2}(0,L)$.

2.2. The optimization problem. For a fixed time $T > 0$ and a given value of $p \in [2,\infty)$, we consider the following optimization problem:

$$C(p):\ \inf\ \|f_1\|^p_{p,(0,T)} + \|f_2\|^p_{p,(0,T)} \text{ s.t. } f_1, f_2 \in L^p(0,T)$$

and the solution y of the initial boundary-value problem (2.1)–(2.3) satisfies the end conditions (2.4).

In the case $p = \infty$, our optimization problem is the following:

$$C(\infty):\ \inf\ \max\{\|f_1\|_{\infty,(0,T)},\ \|f_2\|_{\infty,(0,T)}\} \text{ s.t. } f_1, f_2 \in L^\infty(0,T)$$

and the solution y of (2.1)–(2.3) satisfies the end conditions (2.4).

Here, for $p \in [2,\infty)$, we use the norm

$$\|f\|_{p,(0,T)} = \left(\int_0^T |f(t)|^p\,dt\right)^{1/p},$$

and for $p = \infty$ we use the norm $\|f\|_{\infty,(0,T)} = \text{ess sup}\{|f(t)| :\ t \in (0,T)\}$.

2.3. Exact controllability.

THEOREM 2.1. *Let $p \in [2,\infty]$ and $T \geq L/c$ be given. The initial boundary-value problem* (2.1)–(2.3) *has a weak solution that satisfies the end conditions* (2.4) *with f_1, $f_2 \in L^p(0,T)$ if and only if the target states y_0, y_1 satisfy the following conditions: $y_0 \in L^p(0,L)$ and $Y_1 \in L^p(0,L)$, where $Y_1(x) = \int_0^x y_1(z)\,dz$, that is, $y_1 \in W^{-1,p}(0,L)$. This implies that problem $C(p)$ is solvable if and only if y_0 and Y_1 are in $L^p(0,L)$.*

A standard method for proving an exact controllability result of this type is to reduce the exact controllability problem to a moment problem and to prove the solvability of the moment problem using Ingham's classical inequalities (see [13]) or its generalizations (see [18], [16]). For the cases $p = 2$ and $p = \infty$, Ingham's results provide an alternative proof of Theorem 2.1. In this paper, we use a different approach: We give a solution of the moment problem explicitly (see section 2.9).

We expect that Theorem 2.1 holds for all $p \geq 1$, but for the case $1 \leq p < 2$ a different method of proof should be used.

In the next section we will state our main result, which gives the solution of problem $C(p)$ in terms of two functions that depend on the target states.

2.4. Solution of the optimal control problem. In this section we present optimal control functions that solve problem $C(p)$. For $p < \infty$, the solution is unique, and for $p = \infty$, we present one element on the set of L^∞-norm minimal controls, namely, the element of this convex set with minimal L^2-norm.

THEOREM 2.2. *Let $p \in [2,\infty]$ and a time $T \geq L/c$ be given. Choose a natural number k such that $kL/c \leq T < (k+1)L/c$. Define the function*

$$Y_1(x) = \int_0^x y_1(t)\,dt.$$

Assume that y_0, $Y_1 \in L^p(0,L)$ and define the functions g_1, g_2 in $L^p(0,L/c)$ by

$$\begin{aligned} g_1(t) &= \ \ y_0(ct)/2 \quad - (1/(2c))\ Y_1(ct), \\ g_2(t) &= y_0(L-ct)/2 + (1/(2c))\ Y_1(L-ct). \end{aligned}$$

If $p < \infty$, let $\hat{r}$ denote the real number that minimizes the function

$$h_p(r) = \left[\int_0^{T-kL/c} \frac{1}{(k+1)^{p-1}} \left[\left| g_1(t) + r \right|^p + \left| g_2(t) - r \right|^p \right] dt \right.$$

$$\left. + \int_{T-kL/c}^{L/c} \frac{1}{k^{p-1}} \left[\left| g_1(t) + r \right|^p + \left| g_2(t) - r \right|^p \right] dt \right],$$

while, if $p = \infty$, let $\hat{r}$ be the real number that minimizes

$$h_\infty(r) = \max \left[\|(g_1(t) + r)/(k+1)\|_{\infty,(0,T-kL/c)}, \|(g_2(t) - r)/(k+1)\|_{\infty,(0,T-kL/c)}, \right.$$

$$\left. \|(g_1(t) + r)/k\|_{\infty,(T-kL/c,L/c)}, \|(g_2(t) - r)/k\|_{\infty,(T-kL/c,L/c)} \right].$$

For $j \in \{0, \ldots, k\}$, define the intervals

$$I_j^1 = [jL/c,\, T - k(L/c) + jL/c],$$

and for $j \in \{0, \ldots, k-1\}$, define the intervals

$$I_j^2 = [T - k(L/c) + jL/c,\, (j+1)L/c].$$

For natural numbers j and n let $g_{b(n+j)} = g_1$ if $n + j$ is odd and $g_{b(n+j)} = g_2$ if $n + j$ is even. Then a solution of problem $C(p)$ is given by the pair of control functions $(f_1,\, f_2)$ defined as follows:

$$f_n(T-t) = \frac{(-1)^j\, g_{b(n+j)}(t - jL/c) - (-1)^n\, \hat{r}}{k+1} \tag{2.5}$$

for $n \in \{1, 2\}$, $j \in \{0, \ldots, k\}$, $t \in I_j^1$, and

$$f_n(T-t) = \frac{(-1)^j\, g_{b(n+j)}(t - jL/c) - (-1)^n \hat{r}}{k} \tag{2.6}$$

for $n \in \{1, 2\}$, $j \in \{0, \ldots, k-1\}$, $t \in I_j^2$.

If $p < \infty$, this is the unique solution of problem $C(p)$. If $p = \infty$, this is a solution of $C(\infty)$, namely, the element of the set of solutions that has the smallest L^2-norm.

For certain interesting target states, the value of $\hat{r}$ can be computed explicitly. If y_0 and y_1 are symmetric, $\hat{r} = Y_1(L)/(4c)$. In particular, in this case the value of $\hat{r}$ is independent of p. This implies that the solution is also independent of p. Hence for a symmetric target state with $y_0,\, Y_1 \in L^p(0, L)$, our optimal control that solves problem $C(p)$ also solves problem $C(q)$ for all $q \in [2, p]$.

Later we will characterize the feasible controls $(f_1,\, f_2)$ that steer the system to the desired target state as the solutions of a trigonometric moment problem. To do this, we need a series representation of the solution of the initial boundary-value problem that we obtain from the weak form of the problem.

Then we show that the set of successful controls can be described by a set of two equations for each $t \in [0, L/c]$. This leads to a family of optimization problems, with parameter $t \in [0, L/c]$, whose solutions are coupled by a constant r. The solutions of these optimization problems yield the values of the optimal controls up to the constant r, and thus we obtain a parametric family of successful controls with parameter r. Inserting the elements of this family into the objective function yields the values $h_p(r)$. The optimal control is the element of this family of controls for which the value $h_p(r)$ is minimal.

2.5. Sensitivity analysis for the optimal control problem. The explicit solutions that we have obtained allow a detailed study of their sensitivity with respect to data perturbations, which is useful for obtaining some idea about what might hold in the general case of optimal control problems with hyperbolic PDEs. Here we study only the continuity of the solutions of $C(p)$ as functions of the parameter p.

LEMMA 2.3. *The number $\hat{r}(p)$ that minimizes the function h_p depends continuously on p. In fact, if y_0 and Y_1 are in $L^q(0,L)$ for some $q \in [2,\infty]$, we have $\lim_{p\to q-} \hat{r}(p) = \hat{r}(q)$ and for $p_1 < q$ we have $\lim_{p_2\to p_1} \hat{r}(p_2) = \hat{r}(p_1)$.*

Proof. Case 1: If $h_q(\hat{r}(q)) = 0$, we have $\hat{r}(p) = \hat{r}(q)$ for all $p < q$. Case 2: Assume that $q < \infty$ and $h_q(\hat{r}(q)) > 0$. Then for all $p \in [2,q]$, $h_p(\hat{r}(p)) > 0$ and $h_p''(\hat{r}(p)) > 0$. Consider the function $F : [2,q] \times R \to R$, $F(p,r) = h_p'(r)$. Then for all $p \in [2,q]$, $F(p,\hat{r}(p)) = 0$ and $\partial_r F(p,\hat{r}(p)) = h_p''(\hat{r}(p)) > 0$. Hence the implicit function theorem implies that the function $\hat{r}$ is continuously differentiable on $[2,q]$. Case 3: $q = \infty$. Let $f_1(r)$, $f_2(r)$ denote the control functions defined in Theorem 2.2 that correspond to $r \in R$. Then for all $p \in [2,\infty)$ we have $h_p(r) = \|f_1(r)\|_{p,(0,T)}^p + \|f_2(r)\|_{p,(0,T)}^p$ and $h_\infty(r) = \max\{\|f_1(r)\|_{\infty,(0,T)} + \|f_2(r)\|_{\infty,(0,T)}\}$. Thus for all r, $\lim_{p\to\infty} h_p(r)^{1/p} = h_\infty(r)$. Moreover, the triangle inequality for the p-norm implies that for all $p \in [2,\infty)$, r_1, $r_2 \in R$, we have

(2.7)
$$|h_p(r_1)^{1/p} - h_p(r_2)^{1/p}| \le (\|f_1(r_1) - f_1(r_2)\|_{p,(0,T)}^p + \|f_2(r_1) - f_2(r_2)\|_{p,(0,T)}^p)^{1/p}.$$

For all $p \in [2,\infty]$ we have $h_p(\hat{r}(p))^{1/p} \le h_p(\hat{r}(\infty))^{1/p}$ and $\lim_{p\to\infty} h_p(\hat{r}(\infty))^{1/p} = h_\infty(\hat{r}(\infty))$, and hence the set $\{h_p(\hat{r}(p))^{1/p},\, p \in [2,\infty]\}$ is bounded. With the definition of h_p, this implies that the set $\{\hat{r}(p),\, p \in [2,\infty]\}$ is also bounded. Suppose that a sequence (p_k) converging to ∞ with $p_k \in [2,\infty)$ for all k is given and $\lim_k \hat{r}(p_k) = r_*$. Using (2.7) it can be shown that $h_\infty(r_*) = \lim_{p\to\infty} h_p(r_*)^{1/p} \le \limsup_{p\to\infty} h_p(\hat{r}(p))^{1/p} \le h_\infty(\hat{r}(\infty))$. Thus $h_\infty(r_*) \le h_\infty(\hat{r}(\infty))$. Since $\hat{r}(\infty)$ is the minimizer of h_∞ this implies that $h_\infty(r_*) = h_\infty(\hat{r}(\infty))$, and since the minimizer of h_∞ is determined uniquely, this implies that $r_* = \hat{r}(\infty)$, and the assertion follows. ∎

Lemma 2.3 and Theorem 2.2 imply the following proposition.

PROPOSITION 2.4. *Let $p \in [2,\infty]$ be given. Assume that y_0 and Y_1 are in $L^p(0,L)$. Consider a sequence $(q_k)_k$ ($q_k \le p$) that converges to $q_0 \le p$. Then for the solutions $(f_{1,k}, f_{2,k})^T$ of the optimization problems $C(q_k)$ presented in Theorem 2.2, we have*

$$\lim_{k\to\infty} \|f_{1,k} - f_{1,0}\|_{p,(0,T)} + \|f_{2,k} - f_{2,0}\|_{p,(0,T)} = 0,$$

where $(f_{1,0}, f_{2,0})$ is the solution of $C(q_0)$ presented in Theorem 2.2.

2.6. Examples. For our examples, let $L = 1$, $c = 1$, and $T = 3.25$, and hence $k = 3$.

2.6.1. Example 1. Let $y_0(x) = x - L/2$, $y_1(x) = 1$. For $p = \infty$, the optimal $\hat{r}$ is $5/28$ and we have $h_\infty(5/28) = 1/7$. Figure 2.1(a) shows the optimal controls. The thick lines show f_1 and the dotted line shows f_2. A plot of the corresponding optimal state y in the interior of the rectangle $[0,L] \times [0,T]$ is shown in Figure 2.1(b). Here the optimal state is piecewise linear and the optimal velocity is piecewise constant on areas that are bounded by characteristic curves in the interior of the rectangle $[0,L] \times [0,T]$.

2.6.2. Example 2. The desired state is $y_0(x) = x - L/2$, $y_1(x) = 0$. For $p = \infty$, the optimal $\hat{r}$ equals $-1/28$. For $p = 2$, the optimal $\hat{r}$ is $-1/80$. Figure 2.2(a) shows the optimal controls for $p = \infty$. The thick lines show f_1, and the dotted line shows f_2. Figure 2.2(b) is a plot of the corresponding state y in the interior of the rectangle $[0, L] \times [0, T]$. Due to the form of the target, the optimal state is piecewise linear and the optimal velocity is piecewise constant.

2.6.3. Example 3. In [21], [6] it is pointed out that the optimal boundary controls can also be determined as boundary traces of solutions of adjoint optimal control problems. This example illustrates that for $p \in [2, \infty)$, this approach yields the same controls as Theorem 2.1.

Consider the following optimal control problem:

$$\text{(A)} \qquad \inf \|v\|_{2,(0,2)} \text{ s.t. } y_{tt}(x,t) = y_{xx}(x,t),\ y(0,t) = 0,\ y(1,t) = v(t),$$

$y(x,0) = y^0(x),\ y_t(x,0) = 0,\ y(x,T) = y_t(x,T) = 0,\ (x,t) \in (0,1) \times (0,2)$.

Let $y^0 \in L^2(0,1)$ be continued to the interval $(-1,1)$ as the antisymmetric function y^0_a, that is, $y^0_a(x) = y^0(x)$ for $x \in (0,1)$, $y^0_a(x) = -y^0(-x)$ for $x \in (-1,0)$. Then problem (A) has the same solutions as problem $C(2)$ with $c = 1$, $L = T = 2$, $y_0(x) = y^0_a(x+1)$, $y_1(x) = 0$ in the sense that the optimal controls satisfy $f_2(t) = v(T-t) = -f_1(t)$. The adjoint optimization problem presented in [21] is

$$\inf \frac{1}{2} \int_0^2 |u_x(1,t)|^2\, dt + \int_0^1 y^0(x)u^1(x) - y^1(x)u^0(x)\, dx \text{ s.t. } u_{tt}(x,t) = u_{xx}(x,t),$$

$u(0,t) = u(1,t) = 0,\ u(x,0) = u^0(x),\ u_t(x,0) = u^1(x), (x,t) \in (0,1) \times (0,2)$.

The solution of this adjoint optimization problem is $u^0(x) = \text{const}$, $u^1(x) = -y^0(x)/2$, which yields the optimal control $v(t) = u_x(1,t) = y^0(1-t)/2$ for $t \in (0,1)$, $v(t) = u_x(1,t) = -y^0(t-1)/2$ for $t \in (1,2)$.

Theorem 2.2 yields exactly the same solutions. With $k = 1$, $g_1(t) = y^0_a(t-1)/2$, $g_2(t) = y^0_a(1-t)/2$, we have $\hat{r} = 0$, and hence for $t \in (0,1) = I^2_0$ we have $f_2(T-t) = g_2(t)$ and for $t \in (1,2) = I^2_1$ we have $f_2(T-t) = -g_1(t)$.

2.6.4. Example 4. For $p = \infty$, consider the following optimal control problem:

$$\text{(B)} \qquad \inf \|v\|_{\infty,(0,2)} \text{ s.t. } y_{tt}(x,t) = y_{xx}(x,t),\ y(0,t) = 0,\ y(1,t) = v(t),$$

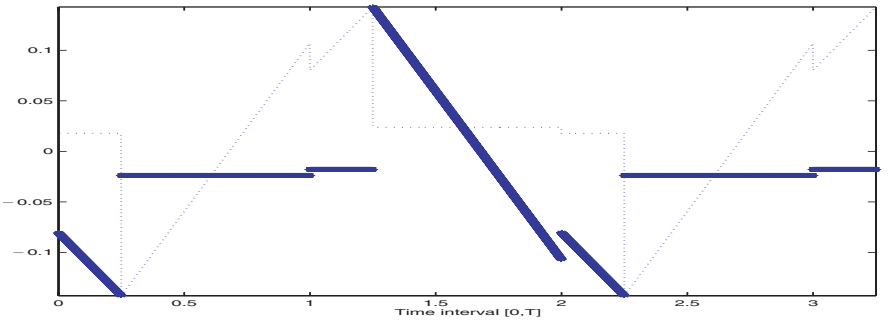
$y(x,0) = y^0(x),\ y_t(x,0) = 0,\ y(x,T) = y_t(x,T) = 0,\ (x,t) \in (0,1) \times (0,2)$.

Let $y^0 \in L^2(0,1)$ be continued to the interval $(-1,1)$ as the antisymmetric function y^0_a. Then problem (B) has the same solutions as problem $C(\infty)$ with $c = 1$, $L = T = 2$, $y_0(x) = y^0_a(x+1)$, $y_1(x) = 0$ in the sense that the optimal controls satisfy $f_2(t) = v(T-t) = -f_1(t)$.

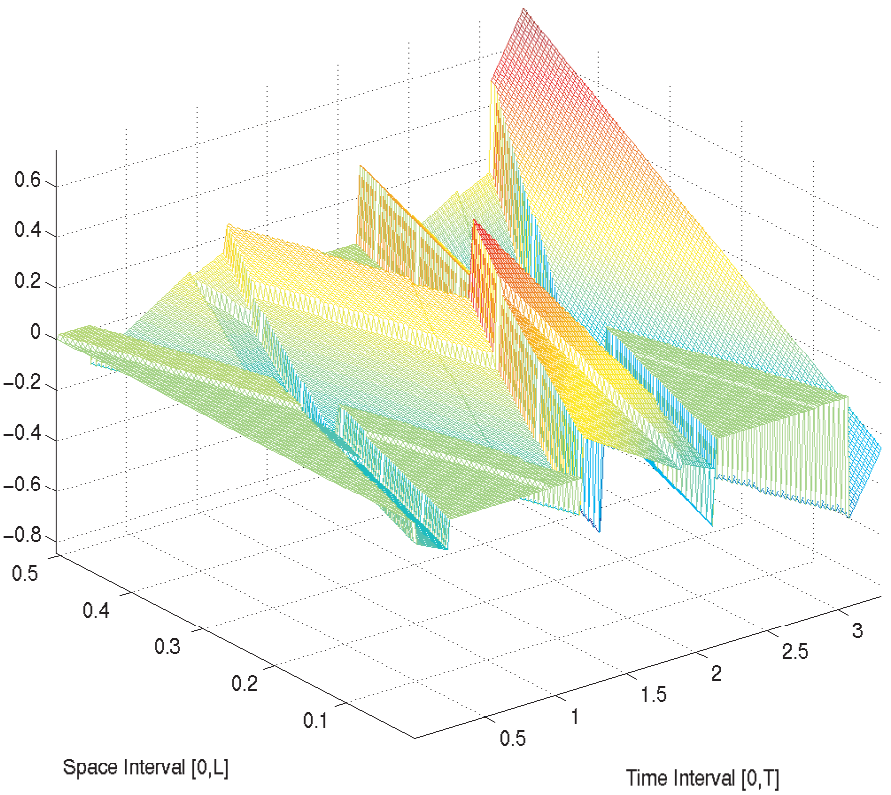
Following [6], for a given solution u of the adjoint optimization problem

$$\inf \frac{1}{2} \left(\int_0^2 |u_x(1,t)|\, dt \right)^2 + \int_0^1 y^0(x)u^1(x) - y^1(x)u^0(x)\, dx \text{ s.t. } u_{tt}(x,t) = u_{xx}(x,t),$$

$u(0,t) = u(1,t) = 0,\ u(x,0) = u^0(x),\ u_t(x,0) = u^1(x), (x,t) \in (0,1) \times (0,2)$ a solution v of problem (B) is quasi bang-bang in the sense that $v(t) \in \ \text{sign}(u_x(1,t))$.

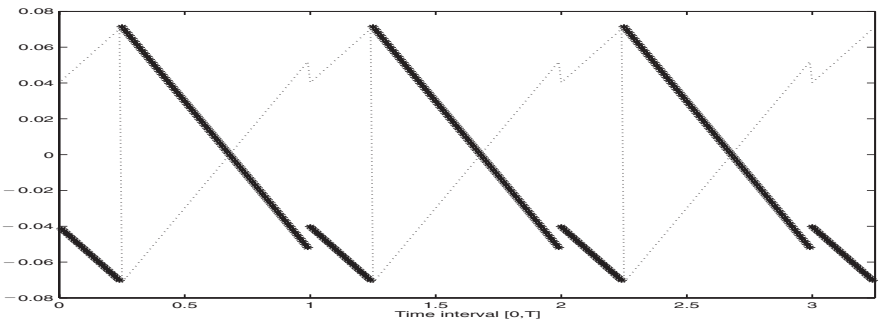


(a) The optimal controls

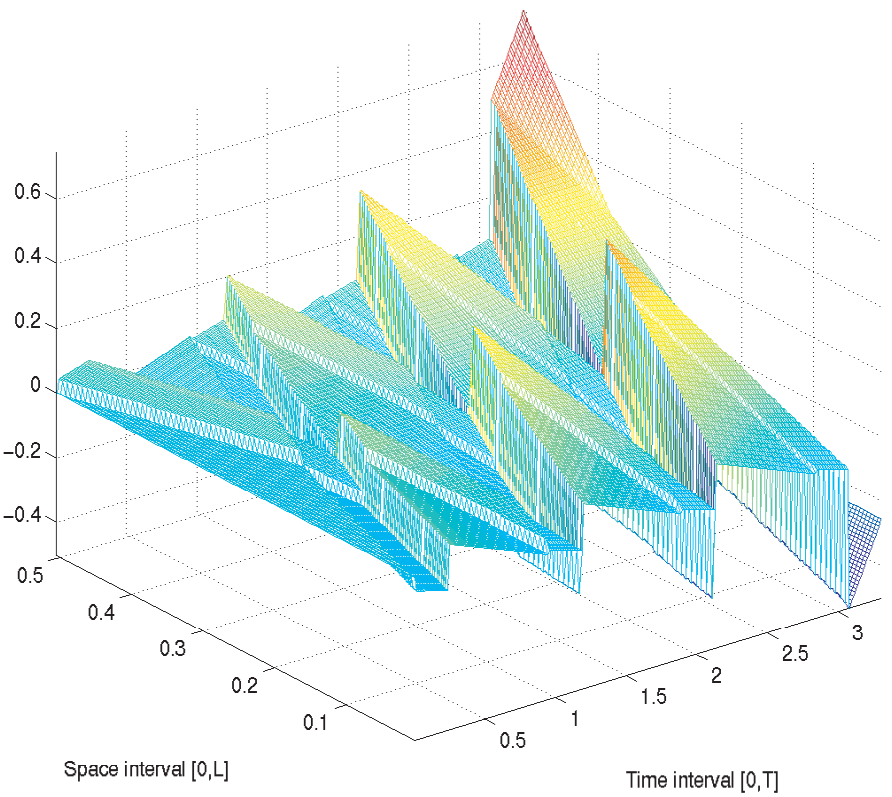


(b) The optimal state

FIG. 2.1.



(a) The optimal controls



(b) The optimal state

FIG. 2.2.

Assume that y^0 attains its infinity norm on a set of measure greater than zero. Then the necessary optimality conditions for the adjoint optimization problem imply that there is a constant $c_0 > 0$ such that for $t \in (0,1)$, $u_x(1,t) = y^0(1-t)c_0$ if $y^0(1-t) \in \{\|y^0\|_{\infty,(0,1)}, -\|y^0\|_{\infty,(0,1)}\}$, $u_x(1,t) = 0$ otherwise, and for $t \in (1,2)$, $u_x(1,t) = -y^0(t-1)c_0$ if $y^0(t-1) \in \{\|y^0\|_{\infty,(0,1)}, -\|y^0\|_{\infty,(0,1)}\}$, $u_x(1,t) = 0$ otherwise.

Theorem 2.2 yields exactly the same solutions (f_1, f_2) as in Example 3. The solution $v(t) = f_2(2-t)$ satisfies the quasi-bang-bang characterization given above, which is a restriction only on the set where y^0 attains its infinity norm. Note that $v(t)$ satisfies at the same time the quasi-bang-bang characterization and is given as the boundary trace of the optimal solution of the adjoint optimization problem for the L^2-case considered in Example 3.

2.7. Weak solutions of the initial-value problem. A general description of the weak form of the initial boundary-value problems with Dirichlet or Neumann boundary conditions can be found in [17]. The solution y of our initial boundary-value problem (2.1)–(2.3) has the series representation

$$y(x,t) = \sum_{j=1}^{\infty} (2c/L) \int_0^t [f_1(s) - (-1)^j f_2(s)] \sin\left((c\pi j/L)(t-s)\right)\, ds \sin\left((j\pi/L)x\right),$$

and for the time-derivative y_t we have

$$y_t(x,t) = \sum_{j=1}^{\infty} \frac{2c^2 j\pi}{L^2} \int_0^t [f_1(s) - (-1)^j f_2(s)] \cos\left((c\pi j/L)(t-s)\right)\, ds \sin\left((j\pi/L)x\right).$$

2.8. End conditions and a trigonometric moment problem. For $j \in \mathbb{N}$, define the function $\varphi_j(x) = (\sqrt{2}/\sqrt{L}) \sin(j\pi x/L)$ and the numbers

$$y_0^j = \int_0^L y_0(x)\varphi_j(x)\, dx,\ y_1^j = \int_0^L y_1(x)\varphi_j(x)\, dx.$$

Inserting the series representations of the solution y and its time derivative y_t into the end conditions (2.4) yields the trigonometric moment equations

$$\int_0^T (\sqrt{2}c/\sqrt{L})[f_1(s) - (-1)^j f_2(s)] \sin\left((c\pi j/L)(T-s)\right)\, ds = y_0^j, \tag{2.8}$$

$$\int_0^T (\sqrt{2}c^2\pi j/L^{3/2})[f_1(s) - (-1)^j f_2(s)] \cos\left((c\pi j/L)(T-s)\right)\, ds = y_1^j \tag{2.9}$$

for $j \in \mathbb{N}$. Hence, we have described the set of feasible controls as the solution set of a trigonometric moment problem. This approach to controllability via moment problems is well established (see, for example, [19], [1]).

2.9. The minimal time interval with controllability. In this section we study controllability on the time interval with $T = L/c$. Since this is the time that a characteristic curve starting at one end of the system needs to reach the other end, it is clear that this is the minimal time interval, where controllability for general target states $y_0 \in L^2(0,L)$, $y_1 \in W_2^{-1}$ can possibly hold.

DEFINITION 2.5. *A function $f \in L^2(0,L)$ is* symmetric with respect to the midpoint $L/2$ *if $f(L/2 - x) = f(L/2 + x)$ for all $x \in (0, L/2)$. The function f is*

antisymmetric *on the interval* $[0, L]$ *with respect to the midpoint* $L/2$ *if* $f(L/2 - x) = -f(L/2 + x)$ *for all* $x \in (0, L/2)$.

Remark 2.1. Each function $f \in L^2(0, L)$ can be written as a sum $f = f^{even} + f^{odd}$ with a symmetric function $f^{even} \in L^2(0, L)$ and an antisymmetric function $f^{odd} \in L^2(0, L)$. The functions f^{even} and f^{odd} are determined uniquely. Moreover, $f \in L^p(0, L)$ if and only if f^{even} and f^{odd} are in $L^p(0, L)$. In fact, we have

$$f^{even}(x) = (f(x) + f(L - x))/2, \qquad f^{odd}(x) = (f(x) - f(L - x))/2.$$

Note that $f^{even}(x) - f^{odd}(x) = f(L - x)$.

For given control functions f_1 and f_2 we introduce the sum

$$S(t) = (f_1(T - t) + f_2(T - t))/2 \tag{2.10}$$

and the difference

$$D(t) = (f_1(T - t) - f_2(T - t))/2. \tag{2.11}$$

The trigonometric moment equations (2.8), (2.9) are equivalent to two moment problems for the functions S and D. We start with the moment problem for D:

$$\int_0^{Tc} D(t/c)(\sqrt{2}/\sqrt{L}) \sin(2\pi j t/L)\, dt = y_0^{2j}/2, \tag{2.12}$$

$$\int_0^{Tc} D(t/c)(\sqrt{2}/\sqrt{L}) \cos(2\pi j t/L)\, dt = L y_1^{2j}/(4c\pi j). \tag{2.13}$$

This means that we know all the Fourier coefficients of the function $D(\cdot/c)$ except the coefficient that corresponds to the constant function. Hence there exists a real number r such that for all $x \in [0, L]$ we have

$$D\left(\frac{x}{c}\right) = r + \sum_{j=1}^{\infty} \frac{y_0^{2j}}{2} \sqrt{\frac{2}{L}} \sin\left(\frac{2\pi j x}{L}\right) - \frac{1}{2c} \sum_{j=1}^{\infty} \frac{-y_1^{2j} L}{2\pi j} \sqrt{\frac{2}{L}} \cos\left(\frac{2\pi j x}{L}\right).$$

We define the symmetric function

$$Y_1^{even}(x) = \sum_{j=1}^{\infty} -y_1^{2j} (L/(2\pi j)) \sqrt{(2/L)} \cos((2\pi j/L)x)$$

and the antisymmetric functions

$$y_1^{odd} = \sum_{j=1}^{\infty} (y_1^{2j}) \sqrt{(2/L)} \sin(2\pi j x/L), \; y_0^{odd} = \sum_{j=1}^{\infty} (y_0^{2j}) \sqrt{(2/L)} \sin(2\pi j x/L).$$

We have $(Y_1^{even})'(x) = y_1^{odd}$, and for the function D for all $x \in [0, L/c]$, we have

$$D(x) = r + y_0^{odd}(cx)/2 - (1/(2c))\, Y_1^{even}(cx). \tag{2.14}$$

Now we consider the moment problem for the function S:

$$\int_0^{Tc} S(t/c)(\sqrt{2}/\sqrt{L}) \sin((2j - 1)\pi t/L)\, dt = y_0^{2j-1}/2, \tag{2.15}$$

$$\int_0^{Tc} S(t/c)(\sqrt{2}/\sqrt{L}) \cos((2j - 1)\pi t/L)\, dt = L y_1^{2j-1}/(2(2j - 1)\pi c). \tag{2.16}$$

We define the symmetric functions

$$y_0^{even}(x) = \sum_{j=1}^{\infty} (y_0^{2j-1}) \sqrt{(2/L)} \sin((2j-1)\pi x/L),$$
$$y_1^{even}(x) = \sum_{j=1}^{\infty} (y_1^{2j-1}) \sqrt{(2/L)} \sin((2j-1)\pi x/L)$$

and the antisymmetric function

$$Y_1^{odd}(x) = \sum_{j=1}^{\infty} -y_1^{2j-1} (L/((2j-1)\pi)) \sqrt{(2/L)} \cos(((2j-1)\pi/L)x).$$

Then we have $(Y_1^{odd})'(x) = y_1^{even}(x)$. For the function S for all $x \in [0, L/c]$, we have

$$S(x) = y_0^{even}(cx)/2 - (1/(2c))\, Y_1^{odd}(cx). \tag{2.17}$$

Thus, for the control functions f_1, f_1 that steer the system to the target state in the time $T = L/c$, we have

$$f_1(T-t) = S(t) + D(t) = \quad r + y_0(ct)/2 - (1/(2c))\, Y_1(ct), \tag{2.18}$$
$$f_2(T-t) = S(t) - D(t) = -r + y_0(L-ct)/2 + (1/(2c))Y_1(L-ct), \tag{2.19}$$

where r is a real number.

This representation of the functions f_1 and f_2 implies that if y_0 and Y_1 are in the space $L^p(0, L)$, then the functions f_1 and f_2 are in the space $L^p(0, L/c)$. On the other hand, if f_1 and f_2 are in the space $L^p(0, L/c)$, then D and S also are in the space $L^p(0, L/c)$, which implies that y_0^{odd}, Y_1^{even}, y_0^{even}, Y_1^{odd} are in $L^p(0, L)$. This, in turn, is equivalent to the statement that y_0 and Y_1 are in $L^p(0, L)$. Thus, we have the following.

LEMMA 2.6. *Let $p \in [2, \infty]$ and $T = L/c$. If the control functions f_1 and f_2 are in $L^p(0, T)$, then the state $y(\cdot, T)$, $y_t(\cdot, T)$ that the system has reached at time T has the following regularity: $y(\cdot, T)$ is in $L^p(0, L)$ and $h(x) = \int_0^x y_t(z, T)\, dz$ is also in $L^p(0, L)$.*

For a given target state (y_0, y_1) with y_0, $Y_1 \in L^p(0, L)$, there exist control functions f_1 and f_2 in $L^p(0, T)$ that steer the system to this target; moreover, these controls are uniquely determined up to the constant r in (2.18), (2.19).

The uniqueness follows from the fact that the moment problem for S has a unique solution in $L^2(0, T)$ and the moment problem for D determines D up to a constant.

2.10. Controllability on larger time intervals. In this section we show how the question of controllability for a time interval $[0, T]$ with $T > L/c$ can be reduced to the question for the minimal time interval $[0, L/c]$ that was considered in the last section. This reduction depends upon the fact that all the trigonometric functions that appear in the moment equations have similar periodicity properties.

2.10.1. Transformation of the moment equations. Assume that $T \geq L/c$. Choose the natural number k such that $kL/c \leq T < (k+1)L/c$. Let the function $\varphi(s)$ be an element of the set $\{\sin((c\pi j/L)s), \cos((c\pi j/L)s)$ with $j \in \mathbb{N}$, j odd $\}$. Then we have $\varphi(s + L/c) = -\varphi(s)$, and for all functions $v \in L^2(0, T)$, the following equation

is valid:

$$\int_0^T v(s)\varphi(s)\,ds = \int_0^{T-kL/c} \left[\sum_{j=0}^{k}(-1)^j v(s+jL/c)\right]\varphi(s)\,ds + \int_{T-kL/c}^{L/c} \left[\sum_{j=0}^{k-1}(-1)^j v(s+jL/c)\right]\varphi(s)\,ds.$$

Define the function

$$\hat{v}(t) = \sum_{j=0}^{k}(-1)^j v(t+jL/c) \text{ for } t \in (0, T-kL/c), \tag{2.20}$$

$$\hat{v}(t) = \sum_{j=0}^{k-1}(-1)^j v(t+jL/c) \text{ for } t \in (T-kL/c, L/c). \tag{2.21}$$

Then

$$\int_0^{L/c} \hat{v}(s)\varphi(s)\,ds = \int_0^T v(s)\varphi(s)\,ds.$$

As in the last section, let the functions S and D be defined by (2.10) and (2.11). Then for a function S that satisfies the moment equations (2.15), (2.16) for all $j \in \mathbb{N}$, the corresponding function $\hat{v}$ must satisfy these moment equations with integrals on the interval $(0, L/c)$. In Lemma 2.6, we have stated that the moment equations (2.15), (2.16) with $T = L/c$ determine a unique solution $\hat{S}$, which is given by (2.17).

For a function D that satisfies the moment equations (2.12), (2.13), the corresponding function $\hat{v}$ is defined as in (2.20), (2.21) but the numbers $(-1)^j$ are replaced by 1 and must satisfy (2.12), (2.13) on the interval $(0, L/c)$. These moment equations determine $\hat{D}$, which is given by (2.14) up to a constant.

In what follows, let $\hat{D}$ be defined by the equation

$$\hat{D}(x) = y_0^{odd}(cx)/2 - (1/(2c))\, Y_1^{even}(cx) \tag{2.22}$$

and $\hat{S}$ by

$$\hat{S}(x) = y_0^{even}(cx)/2 - (1/(2c))\, Y_1^{odd}(cx). \tag{2.23}$$

So we see that we can describe the feasible controls, that is, the controls that steer the system to the target, by the following equations (with $\Delta = T - kL/c$):

$$\hat{S}(t) = \sum_{j=0}^{k}(-1)^j S(t+jL/c), \qquad \hat{D}(t) + \hat{r} = \sum_{j=0}^{k} D(t+jL/c), t \in (0, \Delta), \tag{2.24}$$

$$\hat{S}(t) = \sum_{j=0}^{k-1}(-1)^j S(t+jL/c), \qquad \hat{D}(t) + \hat{r} = \sum_{j=0}^{k-1} D(t+jL/c), t \in (\Delta, L/c), \tag{2.25}$$

where $\hat{r}$ can be any real number.

This means that we have reduced our problem of optimal control to an optimization problem with four affine linear pointwise equality constraints.

2.10.2. Proof of Theorem 2.1. Now we proceed to the proof of Theorem 2.1. It is clear that f_1 and f_2 are in $L^p(0,T)$ if and only if S and D are in $L^p(0,T)$.

If y_0 and Y_1 are in $L^p(0,L)$, Lemma 2.6 implies that we can find $\hat{S}$ and $\hat{D}$ in $L^p(0,L/c)$ that satisfy the moment equations (2.15), (2.16) and (2.12), (2.13), respectively. Then we can find functions S and D in $L^p(0,T)$ such that (2.24)–(2.25) hold, for example, with $\hat{r}=0$ and the definitions $D(t)=\hat{D}(t)$ and $S(t)=\hat{S}(t)$ for $t\in(0,L/c)$ and $0=D(t)=S(t)$ for $t\geq L/c$. In this way, we obtain feasible controls f_1 and f_2 in $L^p(0,T)$.

Now we prove the converse. Let f_1 and f_2 in the space $L^p(0,T)$ be given. Then the corresponding functions $\hat{D}$ and $\hat{S}$ defined by (2.24)–(2.25) with $\hat{r}=0$ are in the space $L^p(0,L/c)$. The corresponding controls on the time interval $(0,L/c)$ reach the same target as f_1 and f_2 on the time interval $(0,T)$ since they solve the corresponding moment problem on the shorter time interval $(0,L/c)$. Hence Lemma 2.6 implies that the corresponding target state has the desired regularity, namely, y_0 and Y_1 are in $L^p(0,L)$. So the proof of Theorem 2.1 is complete.

2.11. Transformation of the optimization problem. In section 2.10.1 we showed that the set of controls f_1, f_2 for which the corresponding state y satisfies the end conditions (2.4) can be described by (2.24)–(2.25), with S defined by (2.10), D defined by (2.11), $\hat{S}$ given by (2.23), and $\hat{D}$ as in (2.22).

Thus for $p<\infty$, problem $C(p)$ can be transformed into the following form:

$$\inf \|f_1\|^p_{p,(0,T)}+\|f_2\|^p_{p,(0,T)} \text{ s.t. } f_1,\ f_2\in L^p[0,T] \text{ and } S \text{ defined by (2.10)}$$

and D defined by (2.11) satisfy the constraints (2.24)–(2.25) for some $\hat{r}\in R$ with $\hat{S}$ given by (2.23) and $\hat{D}$ given by (2.22). For $p=\infty$, $C(p)$ is equivalent to the corresponding problem with objective function

$$\max\{\|f_1\|_{\infty,(0,T)},\ \|f_2\|_{\infty,(0,T)}\}.$$

2.11.1. Proof of Theorem 2.2. In this section, we use the transformed form of problem $C(p)$ that was given in the last section to prove Theorem 2.2.

First we consider the case $p<\infty$. Define the function

$$J(f_1,f_2)=\|f_1\|^p_{p,(0,T)}+\|f_2\|^p_{p,(0,T)},$$

which is the objective function of problem $C(p)$ for $p<\infty$. We have the representation

$$J(f_1,f_2)=\int_0^{T-kL/c}\sum_{j=0}^{k}\big|f_1(T-t-jL/c)\big|^p+\big|f_2(T-t-jL/c)\big|^p\,dt \tag{2.26}$$

$$+\int_{T-kL/c}^{L/c}\sum_{j=0}^{k-1}\big|f_1(T-t-jL/c)\big|^p+\big|f_2(T-t-jL/c)\big|^p\,dt.$$

Since $f_1(T-t)=S(t)+D(t)$ and $f_2(T-t)=S(t)-D(t)$, the constraints (2.24) imply (for a natural number n, let $b(n)=1$ if j is odd and $b(n)=2$ if j is even)

$$\sum_{j=0}^{k}(-1)^j f_{b(j+1)}(T-t-jL/c)=\hat{S}(t)+\hat{D}(t)+\hat{r}, \tag{2.27}$$

$$\sum_{j=0}^{k}(-1)^j f_{b(j)}(T-t-jL/c)=\hat{S}(t)-\hat{D}(t)-\hat{r} \tag{2.28}$$

for all $t \in (0, T - kL/c)$, and the constraints (2.25) imply

$$\sum_{j=0}^{k-1} (-1)^j f_{b(j+1)}(T - t - jL/c) = \hat{S}(t) + \hat{D}(t) + \hat{r}, \tag{2.29}$$

$$\sum_{j=0}^{k-1} (-1)^j f_{b(j)}(T - t - jL/c) = \hat{S}(t) - \hat{D}(t) - \hat{r} \tag{2.30}$$

for all $t \in (T - kL/c, L/c)$.

In our optimization problem, each point of the time interval $[0, T]$ corresponds to two equality constraints. The objective function J is given by an integral over the time interval $[0, T]$, where for each $t \in [0, T]$ the integrand is the sum of two terms, each of which depends only on function values that appear in exactly one of the constraints. The idea of our proof is that we can minimize the objective function J subject to the two pointwise constraints by minimizing for each point in time both parts of the integrand separately subject to the corresponding equality constraint.

The solutions of the resulting parametric family of optimization problems are given in the following lemma.

LEMMA 2.7. *Let $p \geq 2$, a natural number d, and a real number g be given. Consider the optimization problem*

$$H(p, d, g): \quad \min_{(f_0, \ldots, f_d) \in R^{d+1}} \sum_{j=0}^{d} |f_j|^p \ s.t. \quad \sum_{j=0}^{d} (-1)^j f_j = g.$$

The unique solution of $H(p, d, g)$ has the components $f_j = (-1)^j g/(d+1)$ and the optimal value is $|g|^p/(d+1)^{p-1}$.

Proof. $H(p, d, g)$ is a convex optimization problem with a strictly convex objective function, and hence it has at most one solution. The point with the components $(-1)^j g/(d+1)$ is feasible and satisfies the necessary optimality conditions, and hence it is the unique solution of $H(p, d, g)$. ∎

Let the number $\hat{r}$ be given. Representation (2.26) of the objective function J shows that in order to minimize J subject to our pointwise constraints, it suffices to choose the values of our control functions f_1, f_2 as follows: For $t \in [0, T - kL/c]$, let $f_j = f_{b(j+1)}(T - t - jL/c)$ $(j \in \{0, \ldots, k\})$ be such that they solve problem $H(p, k, \hat{S}(t) + \hat{D}(t) + \hat{r})$, that is,

$$f_{b(j+1)}(T - t - jL/c) = (-1)^j (\hat{S}(t) + \hat{D}(t) + \hat{r})/(k+1),$$

and let $f_j = f_{b(j)}(T - t - jL/c)$ be the solution of problem $H(p, k, \hat{S}(t) - \hat{D}(t) - \hat{r})$, that is,

$$f_{b(j)}(T - t - jL/c) = (-1)^j (\hat{S}(t) - \hat{D}(t) - \hat{r})/(k+1).$$

Similarly, for $t \in [T - kL/c, L/c]$, let $f_j = f_{b(j+1)}(T - t - jL/c)$ $(j \in \{0, \ldots, k-1\})$ be such that they solve problem $H(p, k-1, \hat{S}(t) + \hat{D}(t) + \hat{r})$, that is,

$$f_{b(j+1)}(T - t - jL/c) = (-1)^j (\hat{S}(t) + \hat{D}(t) + \hat{r})/k,$$

and let $f_j = f_{b(j)}(T - t - jL/c)$ be such that they solve problem $H(p, k-1, \hat{S}(t) - \hat{D}(t) - \hat{r})$, that is,

$$f_{b(j)}(T - t - jL/c) = (-1)^j (\hat{S}(t) - \hat{D}(t) - \hat{r})/k.$$

By Lemma 2.7, this yields the following value of the objective function:

$$J(f_1,f_2)=\int_0^{T-kL/c}(1/(k+1)^{p-1})\left[|\hat{S}(t)+\hat{D}(t)+\hat{r}|^p+|\hat{S}(t)-\hat{D}(t)-\hat{r}|^p\right]\,dt$$
$$+\int_{T-kL/c}^{L/c}(1/k^{p-1})\left[|\hat{S}(t)+\hat{D}(t)+\hat{r}|^p+|\hat{S}(t)-\hat{D}(t)-\hat{r}|^p\right]\,dt.$$

Since this value still depends on our choice of the real number $\hat{r}$, we define this value as $h_p(\hat{r})$. Now the problem remains to find the value of $\hat{r}$ for which the corresponding value of the objective function is minimal. Since the function h_p is strictly convex and differentiable, the equation $h_p'(\hat{r})=0$ uniquely determines the optimal value of $\hat{r}$.

Remember that due to (2.18) and (2.19), we can compute $\hat{S}+\hat{D}$ and $\hat{S}-\hat{D}$ from the given functions y_0 and Y_1, so the optimal value of $\hat{r}$ can be determined.

Now we come to the case $p=\infty$. Also in this case, we can transform our problem $C(\infty)$ into a problem with the four simple pointwise equality constraints (2.27)–(2.30):

$$\inf\ \ \max\{\|f_1\|_{\infty,(0,T)},\,\|f_2\|_{\infty,(0,T)}\}\ \text{s.t.}\ \ f_1,\,f_2\in L^\infty(0,T)$$

and there is a real number $\hat{r}$ such that f_1, f_2 satisfy (2.27)–(2.30).

In order to solve this problem, we look for solutions at each $t\in(0,T-kL/c)$ of the problems to minimize

$$\max\{|f_{b(j+1)}(T-t-jL/c)|,\ j\in\{0,\dots,k\}\}\ \text{s.t. (2.27) is satisfied,}$$
$$\max\{|f_{b(j)}(T-t-jL/c)|,\ j\in\{0,\dots,k\}\}\ \text{s.t. (2.28) is satisfied,}$$

and for each $t\in(T-kL/c,L/c)$ for solutions of the analogous problems with (2.29), (2.30), respectively. We present the solutions of the resulting parametric family of optimization problems in the following.

Lemma 2.8. *Let a natural number d and a real number g be given. Consider the optimization problem*

$$H(d,g):\quad \min_{(f_0,\dots,f_d)\in R^{d+1}}\max\{|f_j|,\ j\in\{0,\dots,d\}\}\ \ s.t.\ \ \sum_{j=0}^{d}(-1)^j f_j=g.$$

The unique solution of $H(d,g)$ has the components $f_j=(-1)^j g/(d+1)$ and the optimal value is $|g|/(d+1)$.

Proof. The point with the components $(-1)^j g/(d+1)$ is feasible. Hence the optimal value of $H(d,g)$ is $\le|g|/(d+1)$. Suppose that there exists a point $(h_0,\dots,h_d)$ with $\sum_{j=0}^d(-1)^j h_j=g$ and $\max|h_j|<|g|/(d+1)$. Then $|\sum_{j=0}^d(-1)^j h_j|<\sum_{j=0}^d|g|/(d+1)=|g|$, a contradiction. So the optimal value of $H(d,g)$ is $|g|/(d+1)$. Using a similar contradiction argument we see that for every solution $(h_0,\dots,h_d)$ of $H(d,g)$ we have $|h_j|=|g|/(d+1)$ for all j. Inserting this condition into the equation $\sum_{j=0}^d(-1)^j h_j=g$ yields $\sum_{j=0}^d(-1)^j\mathrm{sign}h_j=(d+1)\mathrm{sign}g$, and hence for all j we have $\mathrm{sign}h_j=(-1)^j\mathrm{sign}g$, and the assertion follows. □

In analogy to the case $p<\infty$, Lemma 2.8 yields the desired solutions. In order to obtain an optimal control in this case, we choose $\hat{r}$ such that it minimizes the function h_∞ defined as

$$h_\infty(r)=\max\Big\{\|(\hat{S}(t)+\hat{D}(t)+r)/(k+1)\|_{\infty,(0,T-kL/c)},$$
$$\|(\hat{S}(t)-\hat{D}(t)-r)/(k+1)\|_{\infty,(0,T-kL/c)},$$
$$\|(\hat{S}(t)+\hat{D}(t)+r)/k\|_{\infty,(T-kL/c,L/c)},\|(\hat{S}(t)-\hat{D}(t)-r)/k\|_{\infty,(T-kL/c,L/c)}\Big\}.$$

This determines the value of $\hat{r}$ uniquely. However, in the L^∞-case, the optimal control is in general not uniquely determined. For the given value of $\hat{r}$, our construction above yields the solution of (2.27)–(2.30) with minimal L^2-norm, which is in fact the same as our solution for the case $p = \infty$, so we have constructed the solution of problem $C(\infty)$ with minimal L^2-norm.

2.11.2. Symmetric targets. In this subsection, we assume that for all even $j \in \mathbb{N}$ we have

$$\int_0^L y_0(x)\varphi_j(x)\,dx = 0 = \int_0^L y_1(x)\varphi_j(x)\,dx. \tag{2.31}$$

This means that the functions y_0 and y_1 are even on the interval $[0, L]$ with respect to the midpoint $L/2$. This implies that Y_1 is antisymmetric. Thus, (2.22) implies that $\hat{D} = 0$. We have $h'(0) = 0$, and hence, in this case, the number $\hat{r} = 0$ is the optimal choice. On the time interval $(0, L/c)$ this yields the control functions $f_1(T-t) = y_0(ct)/2 - (1/(2c))Y_1(ct) = f_2(T-t)$. Also on larger time intervals $(0, T)$, for the optimal controls we have $f_1 = f_2$, since $g_1 = g_2$.

2.11.3. Antisymmetric targets. In this subsection, we assume that for all odd $j \in \mathbb{N}$ (2.31) holds. This means that the functions y_0 and y_1 are antisymmetric on the interval $[0, L]$ with respect to the midpoint $L/2$. Then Y_1 is symmetric, and in the statement of Theorem 2.2 we have $g_1(t) = -g_2(t)$. Therefore, for the optimal controls we have $f_1 = -f_2$.

3. Neumann boundary control. In this section we study the problem in which the system is controlled by Neumann boundary conditions.

3.1. The initial-value problem. Let a wave speed $c > 0$ be given. We consider the initial-value problem with the wave equation

$$y_{tt}(x,t) = c^2 y_{xx}(x,t), \quad (x,t) \in [0,L] \times [0,T], \tag{3.1}$$

subject to the initial conditions

$$y(x,0) = 0, \ y_t(x,0) = 0, \quad x \in [0,L], \tag{3.2}$$

and the Neumann boundary conditions

$$y_x(0,t) = -f_1(t), \ y_x(L,t) = f_2(t), \quad t \in [0,T]. \tag{3.3}$$

The desired target state is given in the following end conditions:

$$y(x,T) = y_0(x), \ y_t(x,T) = y_1(x), \quad x \in [0,L]. \tag{3.4}$$

The functions y_0, y_1 are in the space $L^2(0, L)$.

3.2. The optimization problem. For a fixed time $T > 0$ and a given value of $p \in [2, \infty)$, we consider the following optimization problem:

$$C(p): \ \inf \ \|f_1\|^p_{p,(0,T)} + \|f_2\|^p_{p,(0,T)} \text{ s.t. } f_1, f_2 \in L^p[0,T]$$

and the solution y of the initial boundary-value problem (3.1)–(3.3) satisfies the end conditions (3.4).

In the case $p = \infty$, the objective function is $\max\{\|f_1\|_{\infty,(0,T)}, \ \|f_2\|_{\infty,(0,T)}\}$.

3.3. Exact controllability.

THEOREM 3.1. *Let $p \in [2,\infty]$ and $T > L/c$ be given. The initial boundary-value problem* (3.1)–(3.3) *has a weak solution satisfying the end conditions* (3.4) *with $f_1,\ f_2 \in L^p(0,T)$ if and only if the target states $y_0,\ y_1$ satisfy the following conditions: $y_1 \in L^p(0,L)$ and $y_0 \in L^2(0,L)$ is such that the derivative y_0' in the sense of distributions is in the space $L^p(0,L)$, that is, $y_0 \in W_p^1(0,L)$. This implies that the optimization problem $C(p)$ has a solution if and only if y_0' and y_1 are in $L^p(0,L)$.*

3.4. Weak solution of the initial-value problem. The solution y of the initial boundary-value problem (3.1)–(3.3) has the series representation

$$y(x,t) = (c^2/L)\int_0^t [f_1(s)+f_2(s)](t-s)\,ds$$

$$+\sum_{j=1}^{\infty}(2/(cj\pi))\int_0^t [f_1(s)+(-1)^j f_2(s)]\,\sin\left((c\pi j/L)(t-s)\right)\,ds\cos\left((j\pi/L)x\right)$$

and for the time derivative y_t we obtain the series

$$y_t(x,t) = (c^2/L)\int_0^t [f_1(s)+f_2(s)]\,ds$$

$$+\sum_{j=1}^{\infty}(2/L)\int_0^t [f_1(s)+(-1)^j f_2(s)]\,\cos\left((c\pi j/L)(t-s)\right)\,ds\cos\left((j\pi/L)x\right).$$

3.5. End conditions and a trigonometric moment problem. For $j \in \mathbb{N}$, define the functions

$$\varphi_0(x) = 1/\sqrt{L},\ \varphi_j(x) = (\sqrt{2}/\sqrt{L})\,\cos(j\pi x/L),$$

and for $j \in \mathbb{N}\cup\{0\}$, define the numbers

$$y_0^j = \int_0^L y_0(x)\varphi_j(x)\,dx,\ y_1^j = \int_0^L y_1(x)\varphi_j(x)\,dx.$$

Inserting the series representation of the solution y and its time derivative y_t into the end conditions (3.4) yields the moment equations

$$\int_0^T (c^2/\sqrt{L})(f_1(T-s)+f_2(T-s))\,s\,ds = y_0^0, \tag{3.5}$$

$$\int_0^T (\sqrt{2}\sqrt{L}/(c\pi j))(f_1(T-s)+(-1)^j f_2(T-s))\sin\left((c\pi j/L)s\right)\,ds = y_0^j, \qquad j\in\mathbb{N}. \tag{3.6}$$

$$(c^2/\sqrt{L})\int_0^T f_1(T-s)+f_2(T-s)\,ds = y_1^0, \tag{3.7}$$

$$\int_0^T (\sqrt{2}/\sqrt{L})(f_1(T-s)+(-1)^j f_2(T-s))\cos\left((c\pi j/L)s\right)\,ds = y_1^j, \qquad j\in\mathbb{N}. \tag{3.8}$$

3.6. The minimal time interval with controllability up to a constant. In this section we study controllability on the time interval with $T = L/c$, which is the minimal time interval, where controllability for all target states y_0, y_1 in $L^2(0, L)$ can be possible.

For given control functions f_1 and f_2 we introduce the sum S as in (2.10) and the difference D as in (2.11). The trigonometric moment equations (3.5)–(3.8) are equivalent to two moment problems for the functions S and D.

The moment problem for the difference function D is

$$\int_0^{Tc} (L/(c^2(2j-1)\pi))D(x/c)\sqrt{(2/L)}\sin((2j-1)\pi x/L)\,dx = y_0^{2j-1}/2, \tag{3.9}$$

$$\int_0^{Tc} (1/c)D(x/c)\sqrt{(2/L)}\cos((2j-1)\pi x/L)\,dx = y_1^{2j-1}/2. \tag{3.10}$$

We define the antisymmetric functions

$$y_0^{odd}(x) = \sum_{j=1}^{\infty} (y_0^{2j-1})\sqrt{(2/L)}\cos((2j-1)\pi x/L),$$

$$y_1^{odd}(x) = \sum_{j=1}^{\infty} (y_1^{2j-1})\sqrt{(2/L)}\cos((2j-1)\pi x/L)$$

and the symmetric function

$$Y_0^{even}(x) = -\sum_{j=1}^{\infty} y_1^{2j-1}((2j-1)\pi/L)\sqrt{(2/L)}\sin(((2j-1)\pi/L)x).$$

Then $Y_0^{even}(x) = (y_0^{odd})'(x)$ and for all $t \in [0, L/c]$ we have

$$D(t) = (c/2)y_1^{odd}(ct) - (c^2/2)(y_0^{odd})'(ct). \tag{3.11}$$

Consider the moment problem for the function S:

$$\int_0^{Tc} (1/\sqrt{L})S(x/c)\,x\,dx = y_0^0/2, \tag{3.12}$$

$$\int_0^{Tc} S(x/c)(\sqrt{2/L})\sin\left((2\pi j/L)x\right)\,dx = c^2(2\pi j/L)y_0^{2j}/2, \tag{3.13}$$

$$\int_0^{Tc} (1/\sqrt{L})S(x/c)\,dx = y_1^0/(2c), \tag{3.14}$$

$$\int_0^{Tc} S(x/c)(\sqrt{2/L})\cos\left((2\pi j/L)x\right)\,dx = cy_1^{2j}/2, \qquad j \in \mathbb{N}. \tag{3.15}$$

This system of moment equations is in fact overdetermined. If we omit (3.12), the remaining system determines a unique solution.

We define the symmetric functions

$$y_0^{even}(x) = \sum_{j=1}^{\infty} (y_0^{2j})\sqrt{(2/L)}\cos(2j\pi x/L) + y_0^0/\sqrt{L},$$

$$y_1^{even}(x) = \sum_{j=1}^{\infty} (y_1^{2j})\sqrt{(2/L)}\cos(2j\pi x/L) + y_1^0/(c^2\sqrt{L})$$

and the antisymmetric function

$$Y_0^{odd}(x) = \sum_{j=1}^{\infty} -y_0^{2j}(2j\pi/L)\sqrt{(2/L)}\sin((2j\pi/L)x).$$

Note that in the definition of y_1^{even} in the constant term the wave speed c^2 appears. We have $(y_0^{even})'(x) = Y_0^{odd}(x)$. For the function S, we have for all $t \in [0, L/c]$

$$S(t) = (c/2)y_1^{even}(ct) - (c^2/2)\,(y_0^{even})'(ct) \tag{3.16}$$

since all the Fourier coefficients of S are determined by (3.13)–(3.15).

Thus the unique solution of the moment problem (3.6)–(3.8) with $T = L/c$ is

$$f_1(T-t) = S(t) + D(t) = (c/2)\big[y_1(ct) + ((1/c^2) - 1)(y_1^0/\sqrt{L})\big] - (c^2/2)y_0'(ct), \tag{3.17}$$

$$f_2(T-t) = S(t) - D(t) = (c/2)y_1(L-ct) - (c^2/2)y_0'(L-ct). \tag{3.18}$$

With these control functions at time $T = L/c$ the system reaches a target state of the form $y_0 + c_0$, y_1 since in the representation of the state $y(\cdot, T)$ as a series of the functions φ_j ($j \in \mathbb{N} \cup \{0\}$), all the coefficients for $j \neq 0$ are determined by (3.6). To find control functions that satisfy the first moment equation (3.5) with $c_0 = 0$, in general we need a longer time interval. (However, for antisymmetric targets it is possible; see section 3.8.2.) Thus we see that controllability to all target states in (y_0, y_1) with y_0' and y_1 in $L^2(0, L)$ is *not* possible; we have only the following result.

LEMMA 3.2. *Let $p \in [2, \infty]$ and $T = L/c$. If the control functions f_1 and f_2 are in $L^p(0, T)$, then the state $y(\cdot, T)$, $y_t(\cdot, T)$ that the system has reached at time T has the following regularity: $\partial_x y(\cdot, T)$ and $y_t(\cdot, T)$ are in $L^p(0, L)$.*

For a given target state (y_0, y_1) with y_0', $y_1 \in L^p(0, L)$, there exist control functions f_1 and f_2 in $L^p(0, T)$ that steer the system to a state of the form $(y_0 + c_0, y_1)$ with a real constant c_0; moreover, these controls are uniquely determined.

The states that can be reached at the time $T = L/c$ are exactly the states y_0, y_1 with y_0', $y_1 \in L^p(0, L)$ for which the controls f_1, f_2 given in (3.17), (3.18) satisfy (3.5). In this case, f_1, f_2 given in (3.17), (3.18) are the unique solution of $C(p)$.

3.7. Controllability on larger time intervals. In this section we show how the question of controllability for a time interval $(0, T)$ with $T > L/c$ can be solved by transformation of the moment equations to moment equations on the interval $(0, L/c)$. This reduction depends on the fact that all the trigonometric functions that appear in the moment equations have the same periodicity properties.

3.7.1. Transformation of the moment equations. Assume that $T > L/c$. Choose the natural number k such that $kL/c \leq T < (k+1)L/c$.

Let the function $\varphi(s)$ be an element of the set $\{1, \sin((c\pi 2j/L)s), \cos((c\pi 2j/L)s)$ with $j \in \mathbb{N}\}$. Then we have $\varphi(s + L/c) = \varphi(s)$, and for all functions $v \in L^2(0, T)$, the following equation is valid:

$$\int_0^T v(s)\varphi(s)\,ds \tag{3.19}$$

$$= \int_0^{T-kL/c} \left[\sum_{j=0}^{k} v(s + jL/c)\right] \varphi(s)\,ds + \int_{T-kL/c}^{L/c} \left[\sum_{j=0}^{k-1} v(s + jL/c)\right] \varphi(s)\,ds.$$

Define the function

$$\hat{v}(t) = \sum_{j=0}^{k} v(t + jL/c) \text{ for } t \in (0, T - kL/c), \tag{3.20}$$

$$\hat{v}(t) = \sum_{j=0}^{k-1} v(t + jL/c) \text{ for } t \in (T - kL/c, L/c). \tag{3.21}$$

Then

$$\int_0^{L/c} \hat{v}(s)\varphi(s)\,ds = \int_0^T v(s)\varphi(s)\,ds.$$

Again, let the functions S and D be defined by (2.10) and (2.11). Then for a function S that satisfies the moment equations (3.13)–(3.15) for all $j \in \mathbb{N}$, the corresponding function $\hat{v}$ must satisfy these moment equations with integrals on the interval $(0, L/c)$. In section 3.6 we have stated that these moment equations with $T = L/c$ determine a unique solution $\hat{S}$, which is given by (3.16).

For a function D that satisfies (3.9), (3.10) for all $j \in \mathbb{N}$, the corresponding function $\hat{v}$ is defined as in (2.20)–(2.21). Since $\hat{v}$ satisfies (2.20)–(2.21) on the interval $(0, L/c)$, as stated in section 3.6, it is determined uniquely and is given by (3.11). In what follows we call it $\hat{D}$. Thus we have

$$\hat{S}(t) = (c/2)y_1^{even}(ct) - (c^2/2)\,(y_0^{even})'(ct),$$
$$\hat{D}(t) = (c/2)y_1^{odd}(ct) - (c^2/2)\,(y_0^{odd})'(ct).$$

Let $\Delta = T - kL/c$. The set of feasible controls, that is, the controls that steer the system to the target, can be described by the equations

$$\hat{S}(t) = \sum_{j=0}^{k} S(t + jL/c),\ \hat{D}(t) = \sum_{j=0}^{k} (-1)^j D(t + jL/c), \qquad t \in (0, \Delta), \tag{3.22}$$

$$\hat{S}(t) = \sum_{j=0}^{k-1} S(t + jL/c),\ \hat{D}(t) = \sum_{j=0}^{k-1} (-1)^j D(t + jL/c), \qquad t \in (\Delta, L/c), \tag{3.23}$$

and the moment equation (3.12).

This means that we have reduced our problem of optimal control to an optimization problem with a finite number of simple pointwise equality constraints and one integral constraint.

In terms of f_1 and f_2, the constraints (3.22)–(3.23) can be written as

$$\hat{S}(t) + \hat{D}(t) = \sum_{j=0}^{k} f_{b(j+1)}(t + jL/c), \qquad t \in (0, \Delta), \tag{3.24}$$

$$\hat{S}(t) - \hat{D}(t) = \sum_{j=0}^{k} f_{b(j)}(t + jL/c), \qquad t \in (0, \Delta), \tag{3.25}$$

$$\hat{S}(t) + \hat{D}(t) = \sum_{j=0}^{k-1} f_{b(j+1)}(t + jL/c), \qquad t \in (\Delta, L/c), \tag{3.26}$$

$$\hat{S}(t) - \hat{D}(t) = \sum_{j=0}^{k-1} f_{b(j)}(t + jL/c), \qquad t \in (\Delta, L/c), \tag{3.27}$$

and $f_1 + f_2$ must satisfy (3.5). To transform (3.5), we use the equation

$$\int_0^T tS(t)\,dt$$

$$= \int_0^{T-kL/c} \sum_{j=0}^{k} (t + jL/c)S(t + jL/c)\,dt + \int_{T-kL/c}^{L/c} \sum_{j=0}^{k-1} (t + jL/c)S(t + jL/c)\,dt$$

$$= \int_0^{L/c} t\hat{S}(t)\,dt + \int_0^{L/c} \overline{S}(s)\,ds,$$

with

$$\overline{S}(t) = \sum_{j=0}^{k} j(L/c)S(t + jL/c) \text{ for } t \in [0, T - kL/c], \tag{3.28}$$

$$\overline{S}(t) = \sum_{j=0}^{k-1} j(L/c)v(t + jL/c) \text{ for } t \in [T - kL/c, L/c].$$

Since the function $\hat{S}$ is known, we can replace the moment equation (3.5) by

$$\int_0^{L/c} \overline{S}(t)\,dt = \sqrt{L}y_0^0/(2c^2) - \int_0^{L/c} t\hat{S}(t)\,dt =: R_0. \tag{3.29}$$

The description of the feasible controls by the equality constraints (3.24)–(3.29) allows us to prove Theorem 3.1.

3.7.2. Proof of Theorem 3.1. Now we come to the proof of Theorem 3.1. We use the fact that f_1 and f_2 are in $L^p(0,T)$ if and only if S and D are in $L^p(0,T)$.

Let f_1 and f_2 in the space $L^p(0,T)$ be given such that at time T, the system has reached the state $y(\cdot,T) = y_0$, $y_t(\cdot,T) = y_1$. The corresponding functions $\hat{D}$ and $\hat{S}$ defined by (3.22)–(3.23) are in the space $L^p(0,L/c)$. The corresponding controls on the time interval $(0,L/c)$ reach at time L/c a state of the form $y_0 + c_0$, y_1 since they solve the moment problem (3.13)–(3.15). Lemma 3.2 implies that y_1 and y_0' are in $L^p(0,L)$.

Now we show the converse. If y_0' and y_1 are in $L^p(0,L)$, Lemma 3.2 implies that we can find $\hat{S} \in L^p(0,L/c)$ that satisfies the moment equations (3.13)–(3.15) and $\hat{D} \in L^p(0,L/c)$ that satisfies (3.9), (3.10). Then we can find functions f_1 and f_2 in $L^p(0,T)$ such that (3.24)–(3.29) hold, for example, if $T - kL/c > 0$ with the definition

$$f_1(t + L/c) = f_2(t + L/c) = R_0\ c/(L(T - kL/c)),$$

$$f_1(t) = \hat{S}(t) + \hat{D}(t) - f_2(t + L/c),\ f_2(t) = \hat{S}(t) - \hat{D}(t) - f_1(t + L/c)$$

for $t \in (0, T-kL/c)$ and $f_1(t) = \hat{S}(t)+\hat{D}(t)$, $f_2(t) = \hat{S}(t)-\hat{D}(t)$ for $t \in (T-kL/c, L/c)$ and $f_1(t) = f_2(t) = 0$ otherwise. Then the constraints (3.24)–(3.29) hold, and thus we have found a successful control in the space $L^p(0,L)$. So we have proved Theorem 3.1.

3.8. Solution of the optimization problem $C(p)$. In this section we consider the case $L/c < T < 2L/c$, that is, $k = 1$. For $p = \infty$, this case has also been considered in [10], but here we provide a solution for $p < \infty$. We work with the transformed

form of problem $C(p)$, where the feasible set $F(p)$ is described by pointwise equality constraints and one integral constraint:

$$F(p) = \{f_1, f_2 \in L^p(0,T) : (3.24)\text{–}(3.27) \text{ hold}, \overline{S} \text{ defined by } (3.28) \text{ satisfies } (3.29)\}.$$

In our case $k = 1$, (3.26), (3.27) reduce to the equations

$$f_1(t) = \hat{S}(t) + \hat{D}(t),\ f_2(t) = \hat{S}(t) - \hat{D}(t),\ t \in (T - L/c,\ L/c). \tag{3.30}$$

This means that the values of all feasible controls, and thus also of the optimal control, are prescribed on the interval $(T - L/c,\ L/c)$. This fact has important consequences for the structure of the optimal controls: We see that the functions f_1 and f_2 can have any form, so in general there is no reason why they should have a bang-bang, bang-off, or a similar structure. The optimization only takes place on the two intervals $(0, T - L/c)$ and $(L/c, T)$. The constraints (3.24), (3.25) can be written as

$$f_2(t + L/c) = \hat{S}(t) + \hat{D}(t) - f_1(t),\ f_1(t + L/c) = \hat{S}(t) - \hat{D}(t) - f_2(t) \tag{3.31}$$

for all $t \in (0, T - L/c)$. On the middle interval $(T - L/c, L/c)$ we have $\overline{S}(t) = 0$ and on $(0, T - L/c)$ we have $\overline{S}(t) = (L/c)S(t + L/c)$, so (3.29) becomes

$$\int_0^{T-L/c} (L/c)(f_1(t + L/c) + f_2(t + L/c))/2\, dt = R_0.$$

We insert (3.31) and obtain the constraint

$$\int_0^{T-L/c} (L/c) \left[\hat{S}(t) - (f_1(t) + f_2(t))/2\right]\, dt = R_0,$$

and hence for $p < \infty$, problem $C(p)$ reduces to the problem of minimizing

$$\|f_1\|^p_{p,(0,\Delta)} + \|f_2\|^p_{p,(0,\Delta)} + \|\hat{S} + \hat{D} - f_1\|^p_{p,(0,\Delta)} + \|\hat{S} - \hat{D} - f_2\|^p_{p,(0,\Delta)}$$

$$\text{s.t. } f_1, f_2 \in L^p(0,\Delta), \int_0^{\Delta} (f_1(t) + f_2(t))/2\, dt$$

$$= \int_0^{\Delta} \hat{S}(t)\, dt - (c/L)R_0 (\text{with } \Delta = T - L/c).$$

We set $G = \hat{S} + \hat{D}$, $H = \hat{S} - \hat{D}$, and $C_0 = \int_0^{\Delta} \hat{S}(t)\, dt - (c/L)R_0$. Then we can write the above optimization problem in the form

$$\min_{f_1, f_2} \|f_1\|^p_{p,(0,\Delta)} + \|f_2\|^p_{p,(0,\Delta)} + \|G - f_1\|^p_{p,(0,\Delta)} + \|H - f_2\|^p_{p,(0,\Delta)}$$

s.t. $f_1,\ f_2 \in L^p(0,\Delta),\ \int_0^{\Delta} (f_1(t) + f_2(t))/2\, dt = C_0$. The corresponding necessary optimality condition states that there exists a Lagrange multiplier $\lambda \in R$ such that for all $t \in (0,\Delta)$ the following equations hold:

$$|f_1(t)|^{p-1}\text{sign}(f_1(t)) + |f_1(t) - G(t)|^{p-1}\text{sign}(f_1(t) - G(t)) = \lambda,$$
$$|f_2(t)|^{p-1}\text{sign}(f_2(t)) + |f_2(t) - H(t)|^{p-1}\text{sign}(f_2(t) - H(t)) = \lambda.$$

For the solution of the optimality system, we use the following lemma.

LEMMA 3.3. *Let $p \in [2, \infty)$. For a real number a, define the function*

$$h_a(x) = |x|^{p-1}\text{sign}(x) + |x-a|^{p-1}\text{sign}(x-a).$$

Then h_a is strictly increasing and $\lim_{x\to\infty} h_a(x) = \infty$, $\lim_{x\to-\infty} h_a(x) = -\infty$. So the inverse function $\psi_a = h_a^{-1}$ exists and is strictly increasing with $\lim_{\lambda\to\infty} \psi_a(\lambda) = \infty$, $\lim_{\lambda\to-\infty} \psi_a(\lambda) = -\infty$, and for all $\lambda \in R$ the equation $h_a(x) = \lambda$ has the unique solution $x = \psi_a(\lambda)$. For fixed λ, the function $a \mapsto \psi_a(\lambda)$ is continuous. If $p = 2$, we have $\psi_a(\lambda) = (\lambda + a)/2$.

Proof. Consider the function $g(x) = |x|^{p-1}\text{sign}(x)$. Then g is strictly increasing and $\lim_{x\to\infty} g(x) = \infty$, $\lim_{x\to-\infty} g(x) = -\infty$. Since $h_a(x) = g(x) + g(x-a)$, the assertions for h_a follow, except the continuity of the map $a \mapsto \psi_a(\lambda)$.

Define $F : R^2 \to R$, $F(a, x) = h_a(x)$. Then F is continuously differentiable and $F_x(a, x) = g'(x) + g'(x-a) > 0$ for $(a, x) \neq (0, 0)$. We have $F(a, \psi_a(\lambda)) = \lambda$, and hence the implicit function theorem implies the continuity of the map $a \mapsto \psi_a(\lambda)$ for $(a, \lambda) \neq (0, 0)$. Since $h_a(a) = g(a)$ and $h_a(0) = -g(a)$ we have $\psi_a(0) \in (-|a|, |a|)$, so the continuity for $a = \lambda = 0$ also follows. ∎

Hence for $p < \infty$, the solution of problem $C(p)$ can be characterized in the following form.

THEOREM 3.4. *Assume that $L/c < T < 2L/c$, $p \in [2, \infty)$, and that y_1 and y_0' are in $L^p(0, L)$. Let $G = \hat{S} + \hat{D}$, $H = \hat{S} - \hat{D}$, and $C_0 = \int_0^{T-L/c} \hat{S}(t)\,dt - (c/L)R_0$. Let $\lambda \in R$ be the uniquely determined solution of the equation*

$$\int_0^{T-L/c} \psi_{G(t)}(\lambda) + \psi_{H(t)}(\lambda)\,dt = 2C_0. \tag{3.32}$$

Then the unique solution of problem $C(p)$ is given by

$$f_1(t) = \psi_{G(t)}(\lambda),\ f_2(t) = \psi_{H(t)}(\lambda)$$

for $t \in (0, T - L/c)$ and, on the interval $(L/c, T)$, the control functions f_1, f_2 are defined by (3.31) *and on $(T - L/c, L/c)$ by* (3.30).

For $p = \infty$, $C(p)$ can be reduced to the following problem: Minimize

$$\max\{\|f_1\|_{\infty,(0,T-L/c)},\ \|f_2\|_{\infty,(0,T-L/c)},\ \|G - f_1\|_{\infty,(0,T-L/c)},\ \|H - f_2\|_{\infty,(0,T-L/c)}\}$$

s.t. $f_1,\ f_2 \in L^\infty(0, T - L/c)$, $\int_0^{T-L/c} (f_1(t) + f_2(t))/2\,dt = C_0$.

Again let $\Delta = T - L/c$. It is easy to see that the functions $f_1 = f_2 = C_0/\Delta$ on $(0, \Delta)$ satisfy the integral constraint. In fact, the number C_0/Δ is a lower bound for the optimal value of $C(\infty)$. It can happen that the L^∞-norm of the control functions is attainted in the middle interval $(\Delta, L/c)$, where their values are prescribed by (3.30). These observations yield the following lemma.

LEMMA 3.5. *Assume that $L/c < T < 2L/c$ and y_1 and y_0' are in $L^\infty(0, L)$. Set $C_1 = C_0/\Delta$. Assume that $\max\{\|G - C_1\|_{\infty,(0,\Delta)}, \|H - C_1\|_{\infty,(0,\Delta)}\} \le C_1$ or that $\max\{\|G\|_{\infty,(\Delta,L/c)}, \|H\|_{\infty,(\Delta,L/c)}\} \ge \max\{\|G - C_1\|_{\infty,(0,\Delta)}, \|H - C_1\|_{\infty,(0,\Delta)}\}$.*

Then a solution of $C(\infty)$ is $f_1 = f_2 = C_1$ on $(0, \Delta)$. On the interval $(L/c, T)$, the control functions f_1, f_2 are defined by (3.31) *and on $(\Delta, L/c)$ by* (3.30).

3.8.1. Symmetric targets. In this section we assume that y_0 and y_1 are symmetric with respect to $L/2$. Then we have $\hat{D} = 0$, which implies that $G = H = \hat{S}$. Theorem 3.4 yields the equation $f_1 = f_2$, which is also true for $p = \infty$ (see [10]).

If y_0 and y_1 are constant functions, we have $\hat{S}(t) = (c/2)y_1^{even}(ct) = K$, which is also a constant function. Equation (3.32) in Theorem 3.4 yields $\psi_K(\lambda) = C_0/(T - L/c)$; hence for $t \in (0, T - L/c)$ we have $f_1(t) = C_0/(T - L/c)$, $f_1(t + L/c) = K - C_0/(T - L/c)$ and $f_1(t) = K$ for $t \in (T - L/c, L/c)$. Note that this solution is independent of $p < \infty$. Since f_1 and f_2 are in $L^\infty(0, L)$, this implies that it is also the solution of $C(\infty)$ with minimal L^2-norm. If $K = 0$ (that is, $y_1 = 0$), this yields the bang-off-bang control presented in [2] for the case $p = \infty$.

3.8.2. Antisymmetric targets. In this section we assume that y_0 and y_1 are antisymmetric with respect to $L/2$. Then we have $\hat{S} = 0$, which implies that $\hat{D} = G = -H$ and $y_0^0 = 0$, and hence $R_0 = C_0 = 0$. Since $\psi_{-a}(0) = -\psi_a(0)$, Theorem 3.4 yields with $\lambda = 0$ the equation $f_1 = -f_2$, and for $p < \infty$ the optimal control satisfies $f_1(t) = \psi_{\hat{D}(t)}(0)$ on the interval $(0, T - L/c)$. Since $h_a(a/2) = 0$, this yields $f_1 = \hat{D}/2$ on $(0, T - L/c) \cup (L/c, T)$ and $f_1 = \hat{D}$ on $(T - L/c, L/c)$. Note that this solution is again independent of $p < \infty$. If y_1 and y_0' are in $L^\infty(0, L)$, this is also the solution with minimal L^2-norm of $C(\infty)$; this follows from the next lemma.

LEMMA 3.6. *If f_1, f_2 in $L^\infty(0, T)$ solve $C(p)$ for all $p \in [2, \infty)$, then f_1, f_2 also solve $C(\infty)$ and are the solution of $C(\infty)$ with minimal L^2-norm.*

For antisymmetric targets, we have $y_0^0 = 0$. Thus in this case, for the control functions with $f_1 = -f_2$, (3.5) is valid. This implies that for this class of target states, controllability is also possible on the time interval $[0, L/c]$.

Acknowledgments. The authors thank the referees for their comments.

ALMOST SURE STABILIZABILITY OF CONTROLLED DEGENERATE DIFFUSIONS*

MARTINO BARDI† AND ANNALISA CESARONI†

Abstract. We develop a direct Lyapunov method for the almost sure open-loop stabilizability and asymptotic stabilizability of controlled degenerate diffusion processes. The infinitesimal decrease condition for a Lyapunov function is a new form of Hamilton–Jacobi–Bellman partial differential inequality of second order. We give local and global versions of the first and second Lyapunov theorems, assuming the existence of a lower semicontinuous Lyapunov function satisfying such an inequality in the viscosity sense. An explicit formula for a stabilizing feedback is provided for affine systems with smooth Lyapunov function. Several examples illustrate the theory.

Key words. degenerate diffusion, almost sure stability, asymptotic stability, asymptotic controllability, stabilizability, stochastic control, viability, viscosity solutions, Hamilton–Jacobi–Bellman inequalities, nonsmooth analysis

1. Introduction.

For controlled diffusion processes in $\mathbb{R}^N$,

$$(CSDE)\begin{cases} dX_t = f(X_t,\alpha_t)dt + \sigma(X_t,\alpha_t)dB_t, \quad \alpha_t \in A, \quad t>0, \\ X_0 = x, \end{cases}$$

there are various possible notions of Lyapunov stability of an equilibrium, say, the origin. The stability in probability has been studied for a long time; we recall here the contributions of Kushner [31, 32], Has'minskii [26], and the recent book of Mao [36] for uncontrolled systems, and the work of Florchinger [21, 22, 23] and Deng, Krstić, and Williams [18] on feedback stabilization for $(CSDE)$; see also the references therein. The almost sure exponential stability was introduced and studied by Kozin [29] (see also [26]), and it implies that, for each fixed sample in a set of probability 1, the (uncontrolled) system is exponentially stable in the usual sense. In this paper we consider a property that we call almost sure stability, or uniform stability with probability 1. For an uncontrolled system it says that for any $\eta>0$ there exists $\delta>0$ such that, for any x with $|x|\le\delta$, the process satisfies $|X_t|\le\eta$ for all $t\ge 0$ almost surely (a.s.). Equivalently, for some increasing, continuous function γ null at 0, and for small $|x|$,

$$|X_t| \le \gamma(|x|) \quad \forall t \ge 0 \text{ a.s.} \tag{1.1}$$

This property describes a behavior very similar to a stable deterministic system. It is stronger than stability in probability and pathwise stability and, in fact, it is never verified by a nondegenerate process. More precisely, we study the *almost sure*

(stochastic open-loop) stabilizability of (*CSDE*), namely, that for each x as above there exists an admissible control function whose trajectory $\overline{X}_\cdot$ verifies a.s. $|\overline{X}_t| \le \eta$ (and $|\overline{X}_t| \le \gamma(|x|)$) for all t. If, in addition, $\lim_{t\to+\infty} \overline{X}_t = 0$ a.s., we say the system is *a.s. (stochastic open-loop) asymptotically stabilizable*. For deterministic systems ($\sigma \equiv 0$) the last property reduces to the well-known *asymptotic controllability*.

We follow the Lyapunov direct method and find that the *infinitesimal decrease condition* to be satisfied by a Lyapunov function V for our problem is

$$\max_{\alpha\in A,\, \sigma(x,\alpha)^T DV(x)=0} \left\{-DV(x)\cdot f(x,\alpha) - trace\left[a(x,\alpha)D^2V(x)\right]\right\} \ge l(x), \tag{1.2}$$

with $l \ge 0$ for mere Lyapunov stability and $l > 0$ for $x \ne 0$ for asymptotic stability, where $a := \sigma\sigma^T/2$. This is not a standard Hamilton–Jacobi–Bellman inequality, because the constraint on the control α depends on V. In fact it should be viewed rather as a system of PDEs and inequalities which, in the special case of uncontrolled diffusion, i.e., $\sigma = \sigma(x)$, reads

$$\begin{cases} \max_{\alpha\in A}\{-DV(x)\cdot f(x,\alpha)\} - trace\left[a(x)D^2V(x)\right] \ge l(x), \\ \sigma_i(x)\cdot DV(x) = 0 \quad \forall\, i, \end{cases} \tag{1.3}$$

where σ_i denotes the ith column of the matrix σ. To motivate the infinitesimal decrease condition (1.3), let us give a formal argument in the case V is of class $\mathcal{C}^2$. By applying Ito's formula to the inequality $dV(X_t)/dt \le l(X_t)$, we get

$$\left[DV(X_t)\cdot f(X_t,\alpha_t) + trace\left(a(X_t)D^2V(X_t)\right)\right]dt + \sigma^T(X_t)DV(X_t)dB_t \le l(X_t).$$

Now the properties of the Brownian motion lead to the conditions

$$\begin{aligned} DV(X_t)\cdot f(X_t,\alpha_t) + trace\left(a(X_t)D^2V(X_t)\right) &\le l(X_t), \\ \sigma^T(X_t)DV(X_t) &= 0, \end{aligned}$$

and the existence of a control α_t verifying this is clearly related to (1.3). A more detailed, yet still formal, derivation of (1.3) is the following. The Dynkin formula gives, for any control,

$$\mathbf{E}V(X_t) - V(x) = \mathbf{E}\int_0^t \left[DV(X_s)\cdot f(X_s,\alpha_s) + trace(a(X_s)D^2V(X_s))\right]ds,$$

and from the inequality in (1.3) one argues the existence of a control function such that

$$\mathbf{E}V(X_t) - V(x) \le -\mathbf{E}\int_0^t l(X_s)ds \le 0. \tag{1.4}$$

Therefore, the process $V(X_t)$ is a positive supermartingale. Following this argument, it can be proved that a function satisfying merely the Hamilton–Jacobi–Bellman inequality in (1.3) is a Lyapunov function for the stability in probability. The additional equalities $\sigma_i(x)\cdot DV(x) = 0$ in (1.3) say that there is diffusion only in the directions tangential to the level sets of V, and they are necessary conditions for the invariance of the sublevel sets of V for the process (*CSDE*). It turns out that the whole set (1.3) of equalities and inequalities implies the weak invariance, or viability, of the sublevel sets of V, i.e., the existence of a control that maintains forever a.s. the system in such

a set if the initial position is in the set. From this property it is possible to infer that, for some control,

$$V(X_t) - V(x) \leq -\int_0^t l(X_s)ds \leq 0 \quad \text{almost sure},$$

a stronger monotonicity-type property than (1.4), which allows us to prove the almost sure stability.

We define a Lyapunov function for the almost sure stability as a *lower semicontinuous* proper function V, continuous at 0 and satisfying (1.2) in the *viscosity sense*, and we call it a strict Lyapunov function if $l > 0$ off 0; see Definitions 2.3 and 2.4 below. Our main results are the natural extensions of the first and second Lyapunov theorems to the controlled diffusions:

> *The existence of a local Lyapunov function implies the almost sure (open-loop) stabilizability of (CSDE); a strict Lyapunov function implies the almost sure (open-loop) asymptotic stabilizability.*

The same proof provides their global versions as well: if V satisfies (1.2) in $\mathbb{R}^N \setminus \{0\}$, then $(CSDE)$ is also a.s. (open-loop) *Lagrange stabilizable*, i.e., for all initial points x there is a control such that (1.1) holds; moreover, if V is strict, then the system is *globally* a.s. (open-loop) asymptotically stabilizable. We also give sufficient conditions for the stability of viable (controlled invariant) sets more general than an equilibrium point, and for the a.s. exponential stability.

These facts are much easier to prove when the Lyapunov function is smooth, but this assumption is not necessary and would limit considerably their applicability. The nonexistence of smooth Lyapunov functions is well known in the deterministic case; see [30, 6] for stable uncontrolled systems, and see the surveys [43, 6] for asymptotically stable controlled systems. Here we give an example of an uncontrolled degenerate diffusion process that is a.s. stable but cannot have a continuous Lyapunov function (Example 1 in section 6). Moreover, in a companion paper [12] the second author proves a *converse Lyapunov theorem*, stating that any a.s. stabilizable system $(CSDE)$ has a lower semicontinuous (l.s.c.) local viscosity Lyapunov function.

All the results listed above refer to open-loop almost sure stabilizability. They raise the question of the existence of a stabilizing feedback. Here we give an answer only for affine systems with a smooth strict Lyapunov function. We adapt Sontag's method [41] to the stochastic setting and find an explicit formula for a feedback that renders the system a.s. asymptotically stable. The feedback stabilizability of controlled diffusions in the case of nonsmooth Lyapunov functions seems considerably harder and we are not aware of any paper on the subject.

In the last section we study some simple applications and examples. For instance, we consider a deterministic, asymptotically controllable system $\dot{X}_t = f(X_t, \alpha_t)$ with Lyapunov pair (V, L) and look for conditions on a stochastic perturbation that keep the system a.s. stabilizable with the same Lyapunov function V for some $l \leq L$.

Our proof of the first Lyapunov-type theorem is based on the observation that the infinitesimal decrease condition (1.2) has the rescaling property of the geometric PDEs arising in the level set approach to front propagation (see, e.g., [9, 40] and the references therein), and on a recent result of the first author and Jensen [11] on the viability, or controlled invariance, of general closed sets for controlled diffusions (see [3, 4] and the references therein for earlier work on viability for stochastic processes). For the second Lyapunov-type theorem we use also martingale inequalities and other properties of diffusions.

The first Lyapunov-type theorem on local almost sure stabilizability was announced in [8], where we presented the simpler proof for uncontrolled processes. In the forthcoming paper [13], the second author shows that the existence of an l.s.c. viscosity solution of the Hamilton–Jacobi–Bellman inequality,

$$\max_{\alpha\in A}\left\{-DV(x)\cdot f(x,\alpha)-trace\left[a(x,\alpha)D^2V(x)\right]\right\}\geq l(x),$$

implies the open-loop stabilizability in probability of $(CSDE)$. Converse theorems in this setting appears in the Ph.D. thesis [14] of the second author.

We conclude with some additional references. Nonsmooth Lyapunov functions for uncontrolled diffusion processes were studied by Ladde and Lakshmikantham [33] with Dini-type derivatives along sample paths, and by Aubin and Da Prato [5] by means of a stochastic contingent epiderivative. Recently, Arnold and Schmalfuss [1] gave an extension of Lyapunov's second method to random dynamical systems. Turning to deterministic controlled systems, we recall that Soravia [45] gave direct and inverse Lyapunov theorems for the open-loop stabilizability by means of viscosity solutions (in the more general context of differential games); Sontag and Sussmann [41, 44] did it for the asymptotic controllability (i.e., asymptotic open-loop stabilizability) by using Dini directional derivatives. Viscosity methods for stability problems were also used in [28, 46, 24]. There is a large literature on feedback stabilization: see [2, 42, 16], the surveys [43, 15, 6], and the references therein. We refer to [17, 7] for the basic theory of viscosity solutions, and to [34, 35, 9, 20, 48] for its applications to deterministic and stochastic optimal control.

The paper is organized as follows. In section 2 we give the main definitions and state the first and second Lyapunov-type theorems. Section 3 recalls some viability theory and then gives the proofs of the two main theorems. Section 4 covers feedback stabilization of affine systems with smooth Lyapunov functions. Section 5 contains some extensions to exponential stability, general equilibrium sets, and target problems. Section 6 is devoted to the examples.

2. Lyapunov functions for almost sure stabilizability and asymptotic stabilizability. We consider a controlled Ito stochastic differential equation,

$$(CSDE)\begin{cases} dX_t=f(X_t,\alpha_t)dt+\sigma(X_t,\alpha_t)dB_t, & t>0,\\ X_0=x, \end{cases}$$

where B_t is an M-dimensional Brownian motion. Throughout the paper we assume that f,σ are continuous functions defined in $\mathbb{R}^N\times A$, where A is a compact metric space, which take values, respectively, in $\mathbb{R}^N$ and in the space of $N\times M$ matrices, and satisfy

$$|f(x,\alpha)-f(y,\alpha)|+\|\sigma(x,\alpha)-\sigma(y,\alpha)\|\leq C|x-y| \quad \forall x,y\in\mathbb{R}^N, \quad \forall\alpha\in A. \tag{2.1}$$

We adopt the definition of admissible control function, or admissible system, of Haussmann and Lepeltier [27, Def. 2.2, p. 853]. For a given $x\in\mathbb{R}^N$ we denote by $\mathcal{A}_x$ the set of admissible control functions, by $\alpha_\cdot$ its generic element (although it is not a standard function $\mathbb{R}\to A$), and by $X_\cdot$ the corresponding solution of $(CSDE)$.

We define

$$a(x,\alpha):=\frac{1}{2}\sigma(x,\alpha)\sigma(x,\alpha)^T$$

and assume

$$\{(a(x,\alpha), f(x,\alpha)) \,:\, \alpha \in A\} \quad \text{is convex } \forall x \in \mathbb{R}^N. \tag{2.2}$$

DEFINITION 2.1 (almost sure stabilizability). *The system* $(CSDE)$ *is* a.s. (stochastic open-loop Lyapunov) stabilizable *at the origin if for every* $\eta > 0$ *there exists* $\delta > 0$ *such that, for any initial point* x *with* $|x| \le \delta$, *there exists an admissible control function* $\overline{\alpha}_\cdot \in \mathcal{A}_x$ *whose corresponding trajectory* $\overline{X}_\cdot$ *verifies* $|\overline{X}_t| \le \eta$ *for all* $t \ge 0$ *a.s.*

The system is a.s. (stochastic open-loop) Lagrange stabilizable, *or it has the property of* uniform boundedness of trajectories, *if for each* $R > 0$ *there is* $S > 0$ *such that for any initial point* x *with* $|x| \le R$ *there exists an admissible control function* $\overline{\alpha}_\cdot \in \mathcal{A}_x$ *whose corresponding trajectory* $\overline{X}_\cdot$ *verifies* $|\overline{X}_t| \le S$ *for all* $t \ge 0$ *a.s.*

Remark 1. The almost sure stabilizability implies that the origin is a *controlled equilibrium* of $(CSDE)$, i.e.,

$$\exists\, \overline{\alpha} \in A \,:\, f(0,\overline{\alpha}) = 0,\ \sigma(0,\overline{\alpha}) = 0.$$

In fact, the definition gives for any $\varepsilon > 0$ an admissible control such that the corresponding trajectory starting at the origin satisfies a.s. $|X_t| \le \varepsilon$ for all t, so $\mathbf{E}_x \int_0^{+\infty} |X_t| e^{-\lambda t} dt \le \frac{\varepsilon}{\lambda}$ for any $\lambda > 0$. Then $\inf_{\alpha_\cdot \in \mathcal{A}_x} \mathbf{E}_x \int_0^{+\infty} |X_t| e^{-\lambda t} dt = 0$. The convexity assumption (2.2) and an existence theorem for optimal controls [27] imply that the inf is attained, and the minimizing control produces a trajectory satisfying a.s. $|X_t| = 0$ for all $t \ge 0$. The conclusion follows from standard properties of stochastic differential equations.

Remark 2. As is common in the modern deterministic stability theory, the previous definitions can be reformulated in terms of the *comparison functions* introduced by Hahn [25]. We will use the class $\mathcal{K}$ of continuous functions $\gamma : [0,+\infty) \to [0,+\infty)$ strictly increasing and such that $\gamma(0) = 0$ and the class $\mathcal{K}_\infty$ of functions $\gamma \in \mathcal{K}$ such that $\lim_{r\to+\infty} \gamma(r) = +\infty$.

The system $(CSDE)$ is a.s. (open-loop) stabilizable at 0 if there exists $\gamma \in \mathcal{K}$ and $\delta_o > 0$ such that for any starting point x with $|x| \le \delta_o$

$$\exists\, \overline{\alpha}_\cdot \in \mathcal{A}_x \,:\quad |\overline{X}_t| \le \gamma(|x|) \quad \forall t \ge 0 \ \text{ a.s.}, \tag{2.3}$$

where $\overline{X}_t$ is the trajectory corresponding to $\overline{\alpha}_\cdot$. If (2.3) holds for some $\gamma \in \mathcal{K}_\infty$ and for all $x \in \mathbb{R}^N$, then the system is also a.s. (open-loop) Lagrange stabilizable.

DEFINITION 2.2 (almost sure asymptotic stabilizability). *The system* $(CSDE)$ *is* a.s. (stochastic open-loop) locally asymptotically stabilizable *(or* a.s. locally asymptotically controllable*) at the origin if for every* $\eta > 0$ *there exists* $\delta > 0$ *such that, for all* $|x| \le \delta$, *there exists an admissible control function* $\overline{\alpha}_\cdot \in \mathcal{A}_x$ *whose corresponding trajectory* $\overline{X}_\cdot$ *verifies a.s.*

$$|\overline{X}_t| \le \eta \quad \forall t \ge 0, \qquad \lim_{t\to+\infty} |\overline{X}_t| = 0.$$

The system is a.s. (stochastic open-loop) globally asymptotically stabilizable *(or* a.s. asymptotically controllable*) at the origin if there is* $\gamma \in \mathcal{K}_\infty$ *and for all* $x \in \mathbb{R}^N$ *there exists* $\overline{\alpha}_\cdot \in \mathcal{A}_x$ *whose trajectory* $\overline{X}_\cdot$ *satisfies a.s.*

$$|\overline{X}_t| \le \gamma(|x|) \quad \forall t \ge 0, \qquad \lim_{t\to+\infty} |\overline{X}_t| = 0.$$

Next we give the appropriate definition of a Lyapunov function for the study of almost sure stabilizability. We recall the definition of the second order semijet of an l.s.c. function V at a point x:

$$\mathcal{J}^{2,-}V(x) := \Big\{ (p,Y) \in \mathbb{R}^N \times S(N) : \text{ for } y \to x$$
$$V(y) \geq V(x) + p \cdot (y-x) + \frac{1}{2}(y-x) \cdot Y(y-x) + o(|y-x|^2) \Big\}.$$

DEFINITION 2.3 (control Lyapunov function). *Let $\mathcal{O} \subseteq \mathbb{R}^N$ be an open set containing the origin. A function $V : \mathcal{O} \to [0, +\infty)$ is a* control Lyapunov function *for the almost sure stability of $(CSDE)$ if*

(i) *V is lower semicontinuous;*

(ii) *V is continuous at 0 and* positive definite*, i.e., $V(0) = 0$ and $V(x) > 0$ for all $x \neq 0$;*

(iii) *V is* proper*, i.e., $\lim_{|x| \to +\infty} V(x) = +\infty$ or, equivalently, the level sets $\{x | V(x) \leq \mu\}$ are bounded for every $\mu \in [0, \infty)$;*

(iv) *for all $x \in \mathcal{O} \setminus \{0\}$ and $(p,Y) \in \mathcal{J}^{2,-}V(x)$ there exists $\overline{\alpha} \in A$ such that*

$$\sigma(x,\overline{\alpha})^T p = 0 \qquad \text{and} \qquad -p \cdot f(x,\overline{\alpha}) - \mathit{trace}\,[a(x,\overline{\alpha})Y] \geq 0. \tag{2.4}$$

Remark 3. The conditions (ii) and (iii) in the previous definition can be stated as

$$\exists\, \gamma_1, \gamma_2 \in \mathcal{K}_\infty \ : \ \gamma_1(|x|) \leq V(x) \leq \gamma_2(|x|) \ \forall\, x \in \mathbb{R}^N. \tag{2.5}$$

Therefore the level sets $\{V(x) \leq \mu\}$ of the Lyapunov function form a basis of neighborhoods of 0.

Remark 4. If the dispersion matrix σ does not depend on the control, then condition (iv) can be reformulated as follows:

V is a solution in viscosity sense in $\mathcal{O} \setminus \{0\}$ of the system

$$\begin{cases} \sigma(x)^T DV(x) = 0, \\ \max_{\alpha \in A} \left\{ -DV(x) \cdot f(x,\alpha) - \mathit{trace}\left[a(x,\alpha) D^2 V(x)\right] \right\} \geq 0. \end{cases}$$

In the general case, we can observe that if condition (iv) holds, then V in particular is a viscosity supersolution of

$$\max_{\alpha \in A} \left\{ -DV(x) \cdot f(x,\alpha) - \mathit{trace}\left[a(x,\alpha) D^2 V(x)\right] \right\} = 0. \tag{2.6}$$

Moreover, if the function V is at least differentiable, then condition (iv) can be stated more concisely as follows:

V is a supersolution in viscosity sense in $\mathcal{O} \setminus \{0\}$ of the equation

$$\max_{\{\alpha \in A \ | \ \sigma(x,\alpha)^T DV(x) = 0\}} \left\{ -DV(x) \cdot f(x,\alpha) - \mathit{trace}\left[a(x,\alpha) D^2 V(x)\right] \right\} = 0.$$

DEFINITION 2.4 (strict control Lyapunov function). *A function $V : \mathcal{O} \to [0, +\infty)$ is a* strict control Lyapunov function *for the almost sure stability of $(CSDE)$ if it satisfies conditions* (i), (ii), (iii) *in Definition* 2.3 *and* (iv)$'$ *for all $x \in \mathcal{O} \setminus \{0\}$ and $(p,Y) \in \mathcal{J}^{2,-}V(x)$ there exists $\overline{\alpha} \in A$ such that*

$$\sigma^T(x,\overline{\alpha}) p = 0 \quad \text{and} \quad -p \cdot f(x,\overline{\alpha}) - \mathit{trace}\,[a(x,\overline{\alpha})Y] - l(x) \geq 0 \tag{2.7}$$

for some positive definite and Lipschitz continuous $l : \mathcal{O} \to \mathbb{R}$.

Remark 5. In the inequality in (iv)$'$ we could take

$$p \cdot f(x, \overline{\alpha}) - trace\,[a(x, \overline{\alpha})Y] - l(x, \overline{\alpha}) \geq 0$$

for some continuous $l : \mathcal{O} \times A \to \mathbb{R}$, Lipschitz continuous in x uniformly in α, with $l(x, A)$ convex for all $x \in \mathcal{O}$, and such that $\tilde{l}(x) := \min_{\alpha \in A} l(x, \alpha)$ is positive definite. However, this would not increase the generality of the definition because V would also satisfy condition (2.7) with l replaced by $\tilde{l}$.

Our main results are the following versions for stochastic controlled systems of the first and the second Lyapunov theorems.

THEOREM 2.5 (almost sure stabilizability). *Assume* (2.1), (2.2), *and the existence of a control Lyapunov function* V. *Then*

(i) *the system* $(CSDE)$ *is a.s. stabilizable at the origin;*

(ii) *if, in addition, the domain* $\mathcal{O}$ *of* V *is all* $\mathbb{R}^N$, *the system is also a.s. Lagrange stabilizable, and for all* $x \in \mathbb{R}^N$ *there exists* $\overline{\alpha}_\cdot \in \mathcal{A}_x$ *such that the corresponding trajectory* $\overline{X}_\cdot$ *satisfies*

$$|\overline{X}_t| \leq \gamma_1^{-1}(\gamma_2(|x|)) \quad \forall\, t \geq 0 \quad a.s. \tag{2.8}$$

with $\gamma_1, \gamma_2 \in \mathcal{K}_\infty$ *verifying* (2.5).

THEOREM 2.6 (almost sure asymptotic stabilizability). *Assume* (2.1), (2.2), *and the existence of a strict control Lyapunov function* V. *Then*

(i) *the system* $(CSDE)$ *is a.s. locally asymptotically stabilizable at the origin;*

(ii) *if, in addition, the domain* $\mathcal{O}$ *of* V *is all* $\mathbb{R}^N$, *the system is a.s. globally asymptotically stabilizable.*

3. A viability theorem and the proofs of stabilizability. In this section we prove Theorems 2.5 and 2.6. Our main tool is a recent result in [11] about the almost sure viability (called also *controlled invariance* and *weak invariance*) of an arbitrary closed set for a controlled diffusion process. (See [3, 4] and the references therein for earlier related results.)

DEFINITION 3.1 (viable set). *A closed set* $K \subset \mathbb{R}^N$ *is* viable *or* controlled invariant *or* weakly invariant *for the stochastic system* $(CSDE)$ *if for all initial points* $x \in K$ *there exists an admissible control* $\alpha_\cdot \in \mathcal{A}_x$ *such that the corresponding trajectory* $X_\cdot$ *satisfies* $X_t \in K$ *for all* $t > 0$ *a.s.*

It is easy to see from its definition that the almost sure stabilizability follows from the viability of all the sublevel sets of any function satisfying conditions (i)–(iii) of Definition 2.3. The next result gives a geometric characterization of viable sets. It will allow us to check that the sublevel sets of a control Lyapunov function are viable by means of condition (iv) in Definition 2.3. The Nagumo-type geometric condition in the viability theorem is given in terms of the following *second order normal cone* to a closed set $K \subset \mathbb{R}^N$, first introduced in [10]:

$$\mathcal{N}_K^2(x) := \Big\{ (p, Y) \in \mathbb{R}^N \times S(N) : \text{ for } y \to x,\ y \in K,$$
$$p \cdot (y - x) + \frac{1}{2}(y - x) \cdot Y(y - x) \geq o(|y - x|^2) \Big\},$$

where $S(N)$ is the set of symmetric $N \times N$ matrices. Note that, if $(p, Y) \in \mathcal{N}_K^2(x)$ and $x \in \partial K$, the vector p is a generalized (proximal or Bony) interior normal to the set K at x. In particular, if ∂K is a smooth surface in a neighborhood of x, $p/|p|$ is

the interior normal and Y is related to the second fundamental form of ∂K at x; see [10].

THEOREM 3.2 (viability theorem [11]). *Assume* (2.1) *and* (2.2). *Then a closed set $K \subseteq \mathbb{R}^N$ is viable for* $(CSDE)$ *if and only if*

$$\forall x \in \partial K,\ \forall (p,Y) \in \mathcal{N}_K^2(x),\ \exists \alpha \in A\ :\ \ f(x,\alpha)\cdot p + trace\,[a(x,\alpha)Y] \geq 0. \tag{3.1}$$

The second tool for the proof of the Lyapunov-type theorem, Theorem 2.5, is the following lemma on the change of unknown for second order PDEs. It says that the Hamilton–Jacobi–Bellman inequality in condition (2.4) in the definition of a control Lyapunov function behaves as a *geometric equation* if the unknown satisfies also the condition in (2.4) of orthogonality between its gradient and the columns of the dispersion matrix σ. We refer the interested reader to the chapters by Evans and Souganidis in the book [9] for an introduction to the geometric PDEs of the theory of front propagation.

LEMMA 3.3. *Let v satisfy condition* (2.4) *for all $(p,Y) \in \mathcal{J}^{2,-}V(x)$, $x \in \mathbb{R}^N \setminus \{0\}$. Let ϕ be a twice continuously differentiable strictly increasing real map. Then $w = \phi \circ v$ is a viscosity supersolution of*

$$\max_{\alpha \in A} \left\{ -DV(x)\cdot f(x,\alpha) - trace\left[a(x,\alpha)D^2V(x)\right] \right\} = 0. \tag{3.2}$$

Proof. It is easy to check that, if $(p,Y) \in \mathcal{J}^{2,-}w(x)$, then

$$(\psi'(w(x))p, \psi'(w(x))Y + \psi''(w(x))p\otimes p) \in \mathcal{J}^{2,-}v(x),$$

where ψ is the inverse of ϕ and $p \otimes p$ is the $N \times N$ matrix whose (i,j) entry is $p_i p_j$. Then, for $(p,Y) \in \mathcal{J}^{2,-}w(x)$ and $x \neq 0$ there exists $\overline{\alpha}$ such that

$$\{-\psi'(w(x))p\cdot f(x,\overline{\alpha}) - trace\,[a(x,\overline{\alpha})\cdot(\psi'(w(x))Y + \psi''(w(x))p\otimes p)]\} \geq 0$$

and

$$trace\,[a(x,\overline{\alpha})\cdot\psi''(w(x))p\otimes p] = \frac{\psi''(w(x))}{(\psi'(w(x)))^2}|\sigma(x,\overline{\alpha})^T\psi'(w(x))p|^2 = 0.$$

Therefore

$$-\psi'(w(x))p\cdot f(x,\overline{\alpha}) - trace\,[a(x,\overline{\alpha})\cdot\psi'(w(x))Y] \geq 0$$

and we can conclude that

$$\sup_{\alpha\in A}\{-p\cdot f(x,\alpha) - trace\,[a(x,\alpha)\cdot Y]\} \geq 0. \qquad \square$$

Proof of Theorem 2.5. We begin with the proof of (ii). We fix an arbitrary $\mu > 0$ and consider the sublevel set of the function V,

$$K := \{x \,|\, V(x) \leq \mu\}.$$

We claim that K is viable. Then for all initial points $x \in \mathbb{R}^N$ there exists $\overline{\alpha}_\cdot \in \mathcal{A}_x$ such that the associated trajectory $\overline{X}_\cdot$ satisfies

$$\gamma_1(|\overline{X}_t|) \leq V(\overline{X}_t) \leq V(x) \leq \gamma_1(|x|) \quad \forall t \geq 0 \quad \text{a.s.},$$

which gives estimate (2.8). Then the system is a.s. stabilizable and Lagrange stabilizable because $\gamma_1^{-1} \circ \gamma_2 \in \mathcal{K}_\infty$.

To prove that K is viable we will check condition (3.1) of the viability theorem, Theorem 3.2. For a given $\lambda > 0$ we define the nondecreasing continuous real function

$$\psi_\lambda(t) = \begin{cases} 0, & t \le \mu, \\ \lambda(t-\mu), & \mu \le t, \le \mu + \frac{1}{\lambda}, \\ 1, & t \ge \mu + \frac{1}{\lambda}. \end{cases}$$

We claim that the function $\psi_\lambda \circ V$ is a viscosity supersolution of (3.2) for every λ. To prove the claim we choose a sequence ψ_n of strictly increasing, smooth real maps that converge uniformly on compact sets to ψ_λ. Then, for every n, the map $\psi_n \circ V$ is a viscosity supersolution of (3.2) by Lemma 3.3. By the stability of viscosity supersolutions with respect to uniform convergence, we get the claim.

Next we observe that the net $\psi_\lambda \circ V$ is increasing and converges as $\lambda \to +\infty$ to the indicator function

$$C(x) = \begin{cases} 0, & x \in K, \\ 1, & x \notin K. \end{cases}$$

Viscosity supersolutions are stable with respect to the pointwise increasing convergence (see, e.g., Prop. V.2.16, p. 306 of [7]). Therefore the indicator function C of K is a viscosity supersolution of (3.2). From the definitions it is easy to check that

$$\mathcal{J}^{2,-}C(x) = -\mathcal{N}_K^2(x) \quad \forall\, x \in \partial K.$$

By plugging this formula into (3.2) we obtain exactly condition (3.1) of the viability theorem and complete the proof of (ii).

To prove (i) we choose $\overline{\mu} > 0$ small enough so that $K := \{x \in \mathcal{O} : V(x) \le \mu\}$, for $\mu \le \overline{\mu}$, is closed in $\mathbb{R}^N$ (for instance, $\overline{\mu} < \inf_{y \in \partial\mathcal{O}} \liminf_{x \to y} V(x)$). Then the preceding part of this proof gives the viability of K and the estimate (2.8) for all x such that $V(x) \le \overline{\mu}$. Therefore, for some $\delta_o > 0$, (2.8) holds for all x with $|x| \le \delta_o$, and this gives the almost sure stabilizability of the origin. □

Next we give the proof of Theorem 2.6 about asymptotic stability. It is obtained by first applying Theorem 2.5 to a new system with an extra variable and then using martingale inequalities as, e.g., in [18].

Proof of Theorem 2.6. We consider the differential system

$$\begin{cases} dX_t &= f(X_t, \alpha_t)dt &+ \sigma(X_t, \alpha_t)dB_t, \\ dZ_t &= l(X_t)dt \end{cases}$$

with initial data $X_0 = x$ and $Z_0 = 0$. We rewrite this system in $\mathbb{R}^{N+1}$ as

$$(CSDE2) \begin{cases} d(X_t, Z_t) = \overline{f}(X_t, Z_t, \alpha_t)dt + \overline{\sigma}(X_t, Z_t, \alpha_t)d(B_t, 0), \quad t > 0, \\ (X_0, Z_0) = (x, 0), \end{cases}$$

where $\overline{f}(x, z, \alpha) = (f(x, \alpha), l(x))$ and $\overline{\sigma}(x, z, \alpha) = (\sigma(x, \alpha), 0)$. Clearly it satisfies conditions (2.1) and (2.2). Let us consider the function

$$\begin{aligned} W(x, z) :& \mathcal{O} \times \mathbb{R} \to \mathbb{R}, \\ & (x, z) \longmapsto V(x) + |z|. \end{aligned}$$

We claim that it is a Lyapunov function for $(CSDE2)$. In fact, W is positive definite (because $W \geq 0$ and $W = 0$ only for $(x, z) = (0, 0)$); W is l.s.c., continuous at $(0, 0)$, and proper since V is so. We have only to prove that W satisfies condition (2.4). Fix $x \neq 0$ and (x, z) with $z > 0$ and a smooth function ϕ such that $W - \phi$ has a local minimum at (x, z), i.e.,

$$V(x) + z - \phi(x, z) \leq V(y) + w - \phi(y, w),$$

for every (y, w), $w > 0$ in a neighborhood of (x, z). If we choose $w = z$ we get a minimum in x for the function $V(\cdot) - \phi(\cdot, z)$; therefore $(D_x\phi(x, z), D^2_{xx}\phi(x, z)) \in J^{2,-}V(x)$. If we choose $y = x$ we find a minimum in z for the smooth function $w \longmapsto w - \phi(x, w)$, so $D_z\phi(x, z) = 1$. Then there exists $\overline{\alpha} \in A$ such that $(\sigma(x, \overline{\alpha}), 0)^T (D_x\phi(x, z), 1) = 0$ and

$$\left\{-D\phi(x, z) \cdot \overline{f}(x, z, \overline{\alpha}) - trace\left[\overline{a}(x, z, \overline{\alpha})D^2\phi(x, z)\right]\right\}$$

$$= \left\{-(D_x\phi(x, z), 1) \begin{pmatrix} f(x, \overline{\alpha}) \\ l(x) \end{pmatrix} - trace\left[\begin{pmatrix} a(x, \overline{\alpha}) & 0 \\ 0 & 0 \end{pmatrix} D^2\phi(x, z)\right]\right\}$$

$$= \left\{-D_x\phi(x, z) \cdot f(x, \overline{\alpha}) - trace\left[a(x, \overline{\alpha})D^2_{xx}\phi(x, z)\right]\right\} - l(x) \geq 0,$$

since V is a strict Lyapunov function. Now fix (x, z) with $z < 0$ and let ϕ be a smooth function such that

$$V(x) - z - \phi(x, z) \leq V(y) - w - \phi(y, w)$$

for every (y, w), $w < 0$ in a neighborhood of (x, z). We argue as before and now get that there exists $\overline{\alpha} \in A$ such that $(\sigma(x, \overline{\alpha}), 0)^T \cdot (D_x\phi(x, z), -1) = 0$ and

$$-D_x\phi(x, z) \cdot f(x, \overline{\alpha}) - trace\left[a(x, \overline{\alpha})D^2_{xx}\phi(x, z)\right] + l(x)$$

$$> -D_x\phi(x, z) \cdot f(x, \overline{\alpha}) - trace\left[a(x, \overline{\alpha})D^2_{xx}\phi(x, z)\right] - l(x) \geq 0$$

because l is positive and V is a Lyapunov function. Finally, we consider $(x, 0)$ and a smooth function ϕ such that

$$V(x) - \phi(x, 0) \leq V(y) - w - \phi(y, w)$$

for every (y, w), $w < 0$ in a neighborhood of $(x, 0)$ and

$$V(x) - \phi(x, 0) \leq V(y) + w - \phi(y, w)$$

for all (y, w), $w > 0$ in a neighborhood of $(x, 0)$. Then $(D_x\phi(x, z), D^2_{xx}\phi(x, z)) \in J^{2,-}V(x)$, $D_z\phi(x, 0) \geq -1$, and $D_z\phi(x, 0) \leq 1$. Therefore there exists $\overline{\alpha} \in A$ such that $(\sigma(x, \overline{\alpha}), 0)^T \cdot (D_x\phi(x, z), D_z\phi(x, z)) = 0$ and

$$\left\{-D\phi(x, z) \cdot \overline{f}(x, z, \overline{\alpha}) - trace\left[\overline{a}(x, z, \overline{\alpha})D^2\phi(x, z)\right]\right\}$$

$$= \left\{-D_x\phi(x, z) \cdot f(x, \overline{\alpha}) - trace\left[a(x, \overline{\alpha})D^2_{xx}\phi(x, z)\right]\right\} - D_z\phi(x, z)l(x)$$

$$= \left\{-D_x\phi(x, z) \cdot f(x, \overline{\alpha}) - trace\left[a(x, \overline{\alpha})D^2_{xx}\phi(x, z)\right]\right\} - l(x) \geq 0.$$

This completes the proof of the claim, so we can apply Theorem 2.5 to get for every $x \in \mathcal{O}$ an admissible control $\overline{\alpha}_\cdot \in \mathcal{A}_x$ such that the corresponding trajectory $(\overline{X}_\cdot, \overline{Z}_\cdot)$ of (*CSDE*2) with initial data $(x,0)$ remains a.s. in the level set $K = \{(y,w) \in \mathcal{O} \times \mathbb{R} \,|\, W(y,w) \le W(x,0)\}$. Then, for all $t \ge 0$ and a.s., $\overline{X}_t \in \mathcal{O}$,

$$W(\overline{X}_t, \overline{Z}_t) = V(\overline{X}_t) + \overline{Z}_t = V(\overline{X}_t) + \int_0^t l(\overline{X}_s)ds \le W(x,0) = V(x)$$

and

$$0 \le V(\overline{X}_t) \le V(x) - \int_0^t l(\overline{X}_s)ds. \tag{3.3}$$

In particular, since $l \ge 0$, for some $r > 0$, $|\overline{X}_t| \le r$ for all t a.s.

Next we claim that $l(\overline{X}_t) \to 0$ a.s. as $t \to +\infty$. Let us assume by contradiction that the claim is not true: then there exist $\varepsilon > 0$, a subset $\Omega_\varepsilon \subseteq \Omega$ with $\mathbf{P}(\Omega_\varepsilon) > 0$, and for every $\omega \in \Omega_\varepsilon$ a sequence $t_n(\omega) \to +\infty$ such that $l(\overline{X}_{t_n}(\omega)) > \varepsilon$. We define

$$F(r) := \max_{|x| \le r, \alpha \in A} |f(x,\alpha)|, \qquad \Sigma(r) := \max_{|x| \le r, \alpha \in A} \|\sigma(x,\alpha)\|.$$

We compute

$$\mathbf{E}\left\{\sup_{t \le s \le t+h} |\overline{X}_s - \overline{X}_t|^2\right\}$$

$$= \mathbf{E}\left\{\sup_{t \le s \le t+h} \left|\int_t^s f(\overline{X}_u, \overline{\alpha}_u)du + \int_t^s \sigma(\overline{X}_u, \overline{\alpha}_u)dB_u\right|^2\right\}$$

$$\le 2\mathbf{E}\left\{\sup_{t \le s \le t+h} \left|\int_t^s f(\overline{X}_u, \overline{\alpha}_u)du\right|^2\right\} + 2\mathbf{E}\left\{\sup_{t \le s \le t+h} \left|\int_t^s \sigma(\overline{X}_u, \overline{\alpha}_u)dB_u\right|^2\right\}$$

$$\le 2F^2(r)h^2 + 2\mathbf{E}\left\{\sup_{t \le s \le t+h} \left|\int_t^s \sigma(\overline{X}_u, \overline{\alpha}_u)dB_u\right|^2\right\} =: K.$$

By Theorem 3.4 in [19] (the process $|\int_t^s \sigma(\overline{X}_u, \overline{\alpha}_u)dB_u|$ is a positive semimartingale) we get

$$K \le 2F^2(r)h^2 + 8 \sup_{t \le s \le t+h} \mathbf{E}\left\{\left|\int_t^s \sigma(\overline{X}_u, \overline{\alpha}_u)dB_u\right|^2\right\}$$

and by the Ito isometry,

$$K \le 2F^2(r)h^2 + 8\mathbf{E}\left\{\int_t^{t+h} |\sigma(\overline{X}_u, \overline{\alpha}_u)|^2 du\right\} \le 2F^2(r)h^2 + 8\Sigma^2(r)h.$$

Then, the Chebyshev inequality gives

$$\mathbf{P}\left\{\sup_{t \le s \le t+h} |\overline{X}_s - \overline{X}_t| > k\right\} \le \frac{\mathbf{E}\left\{\sup_{t \le s \le t+h} |\overline{X}_s - \overline{X}_t|^2\right\}}{k^2}$$

$$\le \frac{2F^2(r)h^2 + 8\Sigma^2(r)h}{k^2}.$$

Since l is continuous, we can fix δ such that $|l(x) - l(y)| \le \frac{\varepsilon}{2}$ if $|x - y| \le \delta$ and $|x|, |y| \le r$. We define

$$C := \left\{ \omega \in \Omega \ : \ \sup_{0 \le s \le h} |\overline{X}_s - x| \le \delta \right\}$$

and choose $0 < k < \mathbf{P}(\Omega_\varepsilon)$ and $h > 0$ depending on δ and ε such that

$$\mathbf{P}_x(C) \ge 1 - \frac{2F^2(r)h^2 + 8\Sigma^2(r)h}{\delta^2} \ge 1 + k - \mathbf{P}(\Omega_\varepsilon).$$

By the uniform continuity of l, the set

$$B := \left\{ \omega \in \Omega \ : \ \sup_{0 \le s \le h} |l(\overline{X}_s) - l(x)| \le \varepsilon/2 \right\}$$

contains C and then

$$\mathbf{P}_x(B) \ge 1 + k - \mathbf{P}(\Omega_\varepsilon). \tag{3.4}$$

From inequality (3.3), letting $t \to \infty$, we get

$$V(x) \ge \mathbf{E}_x \int_0^{+\infty} l(\overline{X}_s) ds \ge \int_{\Omega_\varepsilon} \int_0^{+\infty} l(\overline{X}_s)\, ds\, d\mathbf{P} \ge \int_{\Omega_\varepsilon} \sum_n \int_{t_n(\omega)}^{t_n(\omega)+h} l(\overline{X}_s) ds\, d\mathbf{P}$$

$$\ge \int_{\Omega_\varepsilon} \sum_n h \inf_{[t_n(\omega), t_n(\omega)+h]} l(\overline{X}_t) \ge h \sum_n \int_{\Omega_\varepsilon} \inf_{[t_n(\omega), t_n(\omega)+h]} l(\overline{X}_t) d\mathbf{P}$$

$$\ge h \sum_n \frac{\varepsilon}{2} \mathbf{P}\left[\left(\sup_{0 \le s \le h} |l(\overline{X}_s) - l(x)| \le \varepsilon/2 \mid x = \overline{X}_{t_n} \right) \cap \Omega_\varepsilon \right].$$

By the properties of the solutions of (*CSDE*) estimate (3.4) gives $\mathbf{P}\left(\sup_{0 \le s \le h} |l(\overline{X}_s) - l(x)| \le \varepsilon/2 \| \ x = \overline{X}_{t_n}\right) \ge 1 + k - \mathbf{P}_x(\Omega_\varepsilon)$ for every n. Therefore $\mathbf{P}\left[\left(\sup_{0 \le s \le h} |l(\overline{X}_s) - l(x)| \le \varepsilon/2 \| \ x = \overline{X}_{t_n}\right) \cap \Omega_\varepsilon\right] \ge k$ for every n. Then by the previous inequality, we get

$$V(x) \ge h \sum_n \frac{\varepsilon}{2} k = +\infty.$$

This gives a contradiction; thus $\mathbf{P}(\Omega_\varepsilon) = 0$ for every $\varepsilon > 0$. We have proved that $l(\overline{X}_t) \to 0$ a.s. as $t \to +\infty$, now the positive definiteness of l implies that $|\overline{X}_t| \to 0$ a.s. as $t \to +\infty$. □

Remark 6. If the function l is only nonnegative semidefinite, the proof of the last theorem gives, for any x, a control $\overline{\alpha}_\cdot$ whose trajectory $\overline{X}_t$ satisfies a.s. $V(\overline{X}_t) \le V(x)$ and $l(\overline{X}_t) \to 0$ as $t \to +\infty$. Then the set $\mathcal{L} := \{y \mid l(y) = 0\}$ is an attractor, for a suitable choice of the control, in the sense that $dist(\overline{X}_t, \mathcal{L}) \to 0$ a.s. as $t \to +\infty$. For uncontrolled diffusion processes, results of this kind can be found in [37] and [18] and are considered stochastic versions of a theorem by La Salle. The earlier paper of Kushner [32] also studies a stochastic version of the La Salle invariance principle, namely, that the omega limit set of the process is an invariant subset of $\mathcal{L}$ in a suitable sense.

4. Almost sure feedback stabilization of affine systems. In this section we give a result on the *feedback stabilizability* of systems affine in the control in the case where there exists a smooth strict control Lyapunov function. It is an analogue for the almost sure stability of a celebrated theorem of Artstein [2] and Sontag [42] for deterministic systems, extended by Florchinger [21] to the stability of controlled diffusions in probability.

We begin with the simple case of a single-input affine system with uncontrolled diffusion, that is,

$$dX_t = (f(X_t) + \alpha_t g(X_t))\, dt + \sigma(X_t) dB_t, \tag{4.1}$$

where f, g, σ are vector fields in $\mathbb{R}^N$ with $f(0) = 0$ and $\sigma(0) = 0$, B_t is a one-dimensional Brownian motion, and the control α_t takes values in $\mathbb{R}$. We seek a function $k : \mathbb{R}^N \to \mathbb{R}$, at least continuous in $\mathbb{R}^N \setminus \{0\}$, such that the origin is a.s. asymptotically stable for the stochastic differential equation

$$dX_t = (f(X_t) + k(X_t) g(X_t))\, dt + \sigma(X_t) dB_t. \tag{4.2}$$

Then k is called an *a.s. asymptotically stabilizing feedback* for the control system (4.1).

If there are no constraints on the control, a smooth strict control Lyapunov function V satisfies, in $\mathbb{R}^N \setminus \{0\}$,

$$f \cdot DV + trace\left[\frac{1}{2}\sigma\sigma^T D^2 V\right] + \inf_{\alpha \in \mathbb{R}} \{\alpha g \cdot DV\} \le -l, \qquad \sigma \cdot DV = 0.$$

Set $\gamma(x) := f \cdot DV + trace\left[\sigma\sigma^T D^2 V\right]/2 + l/2$ and observe that the inequality for V means

$$g(x) \cdot DV(x) = 0 \quad \Rightarrow \quad \gamma(x) \le -l(x)/2 < 0.$$

It is clear that $k(x) := -\gamma(x)/g(x) \cdot DV(x)$, $k(x) := 0$ if $g(x) \cdot DV(x) = 0$ could be a stabilizing feedback, but it is discontinuous where $g(x) \cdot DV(x)$ vanishes. If this case occurs, we build a continuous feedback by means of Sontag's universal formula [42], i.e.,

$$k(x) := -\frac{\gamma(x) + \sqrt{\gamma^2(x) + (g(x) \cdot DV(x))^4}}{g(x) \cdot DV(x)} \quad \text{if } g(x) \cdot DV(x) \neq 0, \tag{4.3}$$

and $k(x) = 0$ if $g(x) \cdot DV(x) = 0$. By the argument in [42], $k \in C(\mathbb{R}^N \setminus \{0\})$ if $V \in C^2(\mathbb{R}^N \setminus \{0\})$ and $k \in C^1(\mathbb{R}^N \setminus \{0\})$ if f, g, l are of class C^1 and $V \in C^3(\mathbb{R}^N \setminus \{0\})$. Moreover

$$(f + kg) \cdot DV + trace\left[\frac{1}{2}\sigma\sigma^T D^2 V\right] \le -\frac{l}{2}, \qquad \sigma \cdot DV = 0,$$

in $\mathbb{R}^N \setminus \{0\}$, so V is a strict Lyapunov function for (4.2) and the origin is a.s. asymptotically stable. In conclusion, k is a stabilizing feedback for the affine control system (4.1).

If the control must satisfy a hard constraint, say $\alpha \in [-1, 1]$, it is not hard to check that $k(x)$ can be used in a neighborhood of the origin provided that DV and $D^2 V$ are bounded near 0 and either $g(x) \to 0$ or $DV(x) \to 0$ as $x \to 0$.

Next we use the same idea for the more general system with both the drift and the diffusion terms affine in the control

$$dX_t = \left(f(X_t) + \sum_{i=1}^{P-1} \alpha_t^i g_i(X_t) \right) dt + \left(\sigma(X_t) + \alpha_t^P \tau(X_t) \right) dB_t, \tag{4.4}$$

where f, g_i, σ, τ are vector fields in $\mathbb{R}^N$, B_t is a standard one-dimensional Brownian motion, and the controls α_t^i, $i = 1, \dots, P$, are $\mathbb{R}$-valued. The existence of a strict control Lyapunov function V implies that for some real number r the vector $\sigma + r\tau$ is orthogonal to DV, so $\tau \cdot DV \neq 0$ at all points where $\sigma \cdot DV \neq 0$, and we can define for all $x \in \mathbb{R}^N \setminus \{0\}$,

$$h(x) := \begin{cases} 0 & \text{if } \sigma(x) \cdot DV(x) = 0, \\ -\frac{\sigma(x) \cdot DV(x)}{\tau(x) \cdot DV(x)} & \text{if } \sigma(x) \cdot DV(x) \neq 0. \end{cases}$$

PROPOSITION 4.1. *Assume system* (4.4) *has a strict control Lyapunov function* $V \in C^2(\mathbb{R}^N \setminus \{0\})$ *and the function* h *is continuous in* $\mathbb{R}^N \setminus \{0\}$. *Then there exists continuous functions* $k_i : \mathbb{R}^N \setminus \{0\} \to \mathbb{R}$, $i = 1, \dots, P-1$, *such that* $(k_1(x), \dots, k_{P-1}(x), h(x))$ *is an a.s. asymptotically stabilizing feedback for system* (4.4).

Moreover, $k_i(x) \in [-1, 1]$ *for* x *in a neighborhood of 0 if* DV *and* D^2V *are bounded near* 0, *and either* $DV(x) \to 0$ *or* $g_i(x) \to 0$ *for all* i *as* $x \to 0$.

Proof. We recall from [42] that the function $\phi(a, 0) := 0$ for $a < 0$, $\phi(a, b) := (a + \sqrt{a^2 + b^2})/b$ is real-analytic in the set $S := \{(a, b) \in \mathbb{R}^2 : b > 0 \text{ or } a < 0\}$. We set

$$\gamma(x) := f(x) \cdot DV(x) + trace \left[(\sigma(x) + h(x)\tau(x))(\sigma(x) + h(x)\tau(x))^T \frac{D^2V(x)}{2} \right] + \frac{l(x)}{2},$$

$$\beta(x) := \sum_{i=1}^{P-1} (g_i(x) \cdot DV(x))^2.$$

Since V is a strict control Lyapunov function,

$$\gamma(x) + \inf_{\alpha_i \in \mathbb{R}} \sum_{i=1}^{P-1} \alpha_i g_i(x) \cdot DV(x) \leq -\frac{l(x)}{2},$$

so, for $x \neq 0$,

$$\beta(x) = 0 \quad \Rightarrow \quad \gamma(x) \leq -l(x)/2 < 0.$$

Therefore $(\gamma(x), \beta(x)) \in S$. Now we define, for $i = 1, \dots, P-1$,

$$k_i(x) := -\phi(\gamma(x), \beta(x)) g_i(x) \cdot DV(x), \quad x \neq 0,$$

and $k(0) = 0$. Then $(k_1(x), \dots, k_{P-1}(x), h(x))$ is continuous in $\mathbb{R}^N \setminus \{0\}$ and satisfies

$$\left(f + \sum_{i=1}^{P-1} k_i g_i \right) \cdot DV + trace \left[(\sigma + h\tau)(\sigma + h\tau)^T \frac{D^2V}{2} \right] + \frac{l}{2}$$
$$= \gamma - \beta\phi(\gamma, \beta) = -\sqrt{\gamma^2 + \beta^2} < 0.$$

Since $(\sigma + h\tau) \cdot DV = 0$ by definition of h, V is a strict Lyapunov function for the equation

$$dX_t = \left(f(X_t) + \sum_{i=1}^{P-1} k_i(X_t) g_i(X_t) \right) dt + (\sigma(X_t) + h(X_t)\tau(X_t))\, dB_t.$$

Therefore the origin is a.s. asymptotically stable for this equation.

Finally, we check the boundedness of k in a neighborhood of 0. This is trivial for $\beta(x) = 0$. If $\beta(x) \neq 0$, then

$$|k| \leq \frac{|\gamma + |\gamma| + \beta|}{\sqrt{\beta}}.$$

Since either $DV \to 0$ or $g_i \to 0$ for all i, $\beta(x) \to 0$ as $x \to 0$. We fix $\delta > 0$ such that $\beta(x) \leq \delta$ implies $\gamma(x) < 0$ and then choose a neighborhood of the origin where $\beta(x) \leq \delta$. In this set $|k(x)| \leq \sqrt{\beta(x)} \to 0$. □

Remark 7. The proof above gives an explicit formula for the stabilizing feedback in terms of the data and the Lyapunov function V only, which reduces to (4.3) if $\tau \equiv 0$ and $P = 2$. From the formula, one sees that the feedback is C^1 in $\mathbb{R}^N \setminus \{0\}$ if h, f, g, σ, τ, and l are C^1 in $\mathbb{R}^N \setminus \{0\}$ and $V \in C^3(\mathbb{R}^N \setminus \{0\})$.

Note also that the continuity assumption on h is automatically satisfied if $\tau \cdot DV$ is either always nonnull or identically 0.

Finally, it is straightforward to extend the proposition to the case of M-dimensional noise with independent Brownian components $B_t^1, \ldots, B_t^M$ and a diffusion term of the form $\sum_{i=P}^{P+M-1} (\sigma_i + \alpha_t^i \tau_i)\, dB_t^i$, with σ_i, τ_i vector fields and α_t^i scalar controls.

5. Some variants and extensions. In this section we collect several remarks on other applications of our methods. We begin with the *almost sure exponential stabilizability*. It means that there exists a positive rate λ and $\gamma \in \mathcal{K}$ such that for every initial data x there exists an admissible control $\overline{\alpha}_\cdot \in \mathcal{A}_x$ whose corresponding trajectory $\overline{X}_\cdot$ satisfies

$$|\overline{X}_t| \leq e^{-\lambda t} \gamma(|x|) \quad \text{a.s.}$$

Proposition 5.1 (almost sure exponential stabilizability). *Under assumptions* (2.1) *and* (2.2)*, the null state is a.s. exponentially stabilizable for (CSDE) if there exists a control Lyapunov function V satisfying conditions* (i), (ii), (iii) *of Definition* 2.3 *and, for some $\lambda > 0$,*

(iv)′ *for every $(p, Y) \in \mathcal{J}^{2,-}V(x)$ there exists $\overline{\alpha} \in A$ such that*

$$\sigma(x, \overline{\alpha})^T p = 0 \quad \textit{and} \quad -p \cdot f(x, \overline{\alpha}) - \textit{trace}\,[a(x, \overline{\alpha})Y] - \lambda V(x) \geq 0.$$

Proof. We consider the system

$$\begin{cases} dX_t = f(X_t, \alpha_t)dt + \sigma(X_t, \alpha_t)dB_t, \\ dY_t = dt \end{cases}$$

with initial data $X_0 = x$ and $Y_0 = 0$, and the Lyapunov function $W(x, y) = e^{\lambda y} V(x)$. By applying Theorem 2.5 we obtain the existence of a control $\overline{\alpha}_\cdot$ such that the corresponding trajectory a.s. satisfies $V(\overline{X}_t) \leq V(x)e^{-\lambda t}$, which is the desired inequality. □

Next we extend the results of section 2 to the stabilizability of a general closed set $M \subseteq \mathbb{R}^N$. We denote by $d(x, M)$ the distance between a point $x \in \mathbb{R}^N$ and M.

DEFINITION 5.2 (almost sure stabilizability at M). *The system* $(CSDE)$ *is* a.s. (stochastic open-loop) stabilizable *at* M *if there exists* $\gamma \in \mathcal{K}$ *such that, for every* x *in a neighborhood of* M*, there is an admissible control function* $\overline{\alpha}_\cdot \in \mathcal{A}_x$ *whose trajectory* $\overline{X}_\cdot$ *verifies*

$$d(\overline{X}_t, M) \le \gamma(d(x, M)) \quad \forall\, t \ge 0 \quad a.s.$$

If, in addition,

$$\lim_{t \to +\infty} d(\overline{X}_t, M) = 0 \quad a.s.,$$

the system is a.s. (stochastic open-loop) locally asymptotically stabilizable *at* M.

If these properties hold for all $x \in \mathbb{R}^N$*, the system is* a.s. (stochastic open-loop) globally asymptotically stabilizable *at* M.

Remark 8. If M is a.s. stabilizable, then it is viable for $(CSDE)$. In fact, the definition gives for $x \in M$ and $\varepsilon > 0$ an admissible control such that a.s. $d(X_t, M) \le \varepsilon$ for all $t \ge 0$.

Then for such control and any $\lambda > 0$ $\mathbf{E}_x \int_0^{+\infty} d(X_t, M) e^{-\lambda t} dt \le \frac{\varepsilon}{\lambda}$, and so

$$\inf_{\alpha_\cdot \in \mathcal{A}_x} \mathbf{E}_x \int_0^{+\infty} d(X_t, M) e^{-\lambda t} dt = 0.$$

The convexity assumption (2.2) and an existence theorem for optimal controls [27] imply that the inf is attained, and the minimizing control produces a trajectory remaining in M for all $t \ge 0$.

DEFINITION 5.3 (control Lyapunov functions at M). *Let* $\mathcal{O}$ *be an open neighborhood of the closed set* M*. A function* $V : \mathcal{O} \to [0, +\infty)$ *is a control Lyapunov function at* M *for* $(CSDE)$ *if*

(i) V *is lower semicontinuous;*

(ii) *there exists* $\gamma_1 \in \mathcal{K}_\infty$ *such that* $V(x) \le \gamma_1(d(x, M))$ *for all* $x \in \mathcal{O}$*;*

(iii) *there exists* $\gamma_2 \in \mathcal{K}_\infty$ *such that* $\gamma_2(d(x, M)) \le V(x)$ *for all* $x \in \mathcal{O}$*;*

(iv) *for all* $x \in \mathcal{O} \setminus M$ *and* $(p, Y) \in \mathcal{J}^{2,-}V(x)$ *there exists* $\overline{\alpha} \in A$ *such that condition* (2.4) *holds.*

The function V *is a* strict control Lyapunov function *at* M *if it satisfies conditions* (i)–(iii) *and*

(iv)$'$ *for some Lipschitz continuous* $l : \mathcal{O} \to \mathbb{R}$*,* $l > 0$ *for all* $x \in \mathcal{O} \setminus M$ *and* $(p, Y) \in \mathcal{J}^{2,-}V(x)$*, there exists* $\overline{\alpha} \in A$ *such that condition* (2.7) *holds.*

Now we can state the analogues of the first and second Lyapunov theorems for the almost sure stabilizability at M. Their proofs are easily obtained from the arguments of Theorems 2.5 and 2.6 by using $d(x, M)$ instead of $|x|$ and noting that conditions (ii) and (iii) in the Definition 5.3 say that the sublevel sets of the Lyapunov function form a basis of neighborhoods of M.

THEOREM 5.4. *Assume* (2.1), (2.2)*, and the existence of a control Lyapunov function* V *at* M*. Then*

(i) *the system* $(CSDE)$ *is a.s. stabilizable at* M*;*

(ii) *if, in addition, the domain* $\mathcal{O}$ *of* V *is all* $\mathbb{R}^N$*, for all* $x \notin M$ *there exists* $\overline{\alpha}_\cdot \in \mathcal{A}_x$ *such that the corresponding trajectory* $\overline{X}_\cdot$ *satisfies*

$$d(\overline{X}_t, M) \le \gamma_1^{-1}(\gamma_2(d(x, M))) \quad \forall\, t \ge 0 \quad a.s.$$

with $\gamma_1, \gamma_2 \in \mathcal{K}_\infty$ from Definition 5.3*; in particular, if M is bounded, the system is also a.s. Lagrange stabilizable.*

THEOREM 5.5. *Assume* (2.1), (2.2)*, and the existence of a strict control Lyapunov function V at M. Then*

(i) *the system $(CSDE)$ is a.s. locally asymptotically stabilizable at M;*

(ii) *if, in addition, the domain $\mathcal{O}$ of V is all $\mathbb{R}^N$, the system is a.s. globally asymptotically stabilizable at M.*

Remark 9 (stochastic target problems and absorbing sets). A stochastic target problem consists of steering the state of the system $(CSDE)$ in finite time into a given closed set $\mathcal{T}$ (the target) by an appropriate choice of the control. One of the objects of interest is the set of initial positions from which this goal can be achieved a.s. in a given time t. We define these reachability sets for $t > 0$ as

$$\mathcal{R}(t) = \{x \in \mathbb{R}^N \mid \exists \alpha_\cdot \in \mathcal{A}_x \,:\, X_t \in \mathcal{T} \text{ a.s.}\}.$$

We consider a target $\mathcal{T}$ containing 0 and being invariant for the stochastic system and we assume there exists a global strict control Lyapunov function V as defined in (2.4) such that

$$\inf_{\mathbb{R}^N \setminus \mathcal{T}} l(x) = L > 0.$$

We are going to show that each reachability set $\mathcal{R}(t)$ lies between two sublevel sets of the Lyapunov function V. The arguments in the proof of Theorem 2.6 show that for every initial point $x \notin \mathcal{T}$ there exists a control $\overline{\alpha}_\cdot \in \mathcal{A}_x$ such that the first entry time $\overline{\tau}_x$ of the corresponding trajectory in the target is a.s. bounded by

$$\overline{\tau}_x \le \left(V(x) - \inf_{\partial \mathcal{T}} V(y)\right) \Big/ L. \tag{5.1}$$

In particular, since the target $\mathcal{T}$ is invariant, it is reached a.s. in a finite time, and as such time is also uniformly bounded, $\mathcal{T}$ is an *absorbing set* for the system according to the terminology in [5]. Next, from the assumptions and inequality (5.1) we get

$$\left\{x \in \mathbb{R}^N \mid V(x) \le Lt + \inf_{\partial \mathcal{T}} V(y)\right\} \subseteq \mathcal{R}(t).$$

Using Chebyshev inequality and estimates of the same kind as in the proof of Theorem 2.6 we can find also for every $t > 0$ a positive number $k(t)$ depending continuously on t such that

$$\mathcal{R}(t) \subseteq \{x \in \mathbb{R}^N \mid V(x) \le k(t)\}.$$

Let us mention that Soner and Touzi [39] developed recently a PDE approach to stochastic target problems; see also [40] and the references therein for some interesting applications to geometric PDEs and front propagation problems.

6. Examples. We begin with an example of an uncontrolled system that does not have a continuous Lyapunov function but has an l.s.c. Lyapunov function and therefore is a.s. stable. It shows that allowing V to be merely l.s.c. in Theorem 2.5 really increases the range of the applications. Our example is a variant of a deterministic one by Krasowski [30], namely,

$$\begin{cases} \dot{X}_t = Y_t, \\ \dot{Y}_t = -X_t + Y_t (X_t^2 + Y_t^2)^3 \sin^2\left(\frac{\pi}{X_t^2 + Y_t^2}\right); \end{cases}$$

see [6] for a discussion of this and other deterministic examples.

Example 1. We transform the previous system into polar coordinates and perturb it with a white noise tangential to the circles $C_n := \{(x,y) : |(x,y)| = \frac{1}{\sqrt{n}}\}$ and nondegenerate between two consecutive circles:

$$\begin{cases} d\rho_t &= \left[\rho_t^7 \sin^2(\theta_t) \sin^2(\frac{\pi}{\rho_t^2})\right] dt + \left[\sigma(\rho_t,\theta_t) \sin^2(\frac{\pi}{\rho_t^2})\right] dB_t, \\ d\theta_t &= \left[-1 + \rho_t^6 \sin(\theta_t)\cos(\theta_t) \sin^2(\frac{\pi}{\rho_t^2})\right] dt, \end{cases}$$

where B_t is a one-dimensional Brownian motion and σ satisfies the hypotheses for the existence and uniqueness of the solution of the stochastic differential equation. As in the undisturbed case, the circles C_n are a.s. invariant and any point in C_n is eventually reached a.s. by any trajectory starting in C_n. Then any Lyapunov function V is constant on C_n because $V(\rho_t,\theta_t) \le V(\rho_0,\theta_0)$ a.s., and $c_n := V_{|C_n} \ne c_{n-1} := V_{|C_{n-1}}$ at least on a subsequence. By property (iv) in Definition 2.3 of the Lyapunov function, for every (ρ,θ) in the interior of $C_{n-1} \setminus C_n$ and every $(p,X) \in \mathcal{J}^{2,-}V(\rho,\theta)$, we get $(\sigma(\rho,\theta)\sin^2(\frac{\pi}{\rho^2}),0)\cdot p = 0$. Since the diffusion is nondegenerate in the ρ direction in the interior of $C_{n-1} \setminus C_n$, from the previous equality we deduce that, for such (ρ,θ), every element in $\mathcal{J}^{2,-}V(\rho,\theta)$ is of the form $((0,p_2),X)$. This implies that the function V is constant in the ρ direction in the interior of $C_{n-1}\setminus C_n$ and cannot be continuous.

Now we check that the Lyapunov function of the undisturbed system in the unit ball does the job also for our perturbed stochastic system. We take

$$V(\rho,\theta) := \frac{1}{\sqrt{n}} \quad \text{for } \frac{1}{\sqrt{n}} < \rho \le \frac{1}{\sqrt{n-1}} \quad \forall\theta.$$

This is a positive definite function, l.s.c. and continuous at 0. We calculate its second order subjets and plug them into (2.4). If $\rho \ne \frac{1}{\sqrt{n}}$ for all n, $(p,\mathbf{X}) \in J^{2,-}V(\rho,\theta)$ if and only if $p = 0$ and $\mathbf{X} \le 0$, so condition (2.4) is trivially satisfied. On the other hand, $(p,\mathbf{X}) \in J^{2,-}V(\frac{1}{\sqrt{n}},\theta)$ if and only if

$$p = \begin{pmatrix} s \\ 0 \end{pmatrix},\ s \ge 0, \quad \text{and} \quad \mathbf{X} = \begin{pmatrix} a & b \\ b & c \end{pmatrix},\ c \le 0.$$

At the points with $\rho = \frac{1}{\sqrt{n}}$ the drift f of the system is $(0,-1)$ and the dispersion vector σ is $(0,0)$. Then

$$f\cdot p + \frac{1}{2} trace\left[\sigma\sigma^T\mathbf{X}\right] = 0, \qquad \sigma\cdot p = 0,$$

and condition (2.4) is satisfied. Therefore Theorem 2.5 applies and the system is a.s. Lyapunov stable at the origin.

The next two examples are about *stochastic perturbations of stabilizable systems*. We consider a deterministic controlled system in $\mathbb{R}^N$,

$$\dot{X}_t = f(X_t,\alpha_t), \tag{6.1}$$

globally asymptotically (open-loop) stabilizable at the origin, i.e., asymptotically controllable in the terminology of deterministic systems [43, 44]. By the converse Lyapunov theorem of Sontag [41, 44], there exists a strict continuous control Lyapunov

function for the system, i.e., for some positive definite continuous function L, a proper function V satisfying, in $\mathbb{R}^N \setminus \{0\}$,

$$\max_{\alpha \in A} \{-f(x,\alpha) \cdot DV\} - L(x) \geq 0 \tag{6.2}$$

in the viscosity sense. (This is perhaps not explicitly stated in the literature; the original result of Sontag [41] interprets this inequality in the sense of Dini derivatives of V along relaxed trajectories; the paper of Sontag and Sussmann [44] interprets it in the sense of directional Dini subderivatives; and both these senses are known to be equivalent to the viscosity one; see, e.g., [47, 7]).

In the following examples we perturb (6.1) in two different ways and give a condition under which V remains a control Lyapunov function for the almost sure stabilizability of the new stochastic system.

Example 2. Consider the controlled diffusion process

$$dX_t = f(X_t, \alpha)dt + \sigma(X_t)dB_t, \tag{6.3}$$

where B_t is an M-dimensional Brownian motion and σ a Lipschitzean $N \times M$ matrix. Then V *is a Lyapunov function for* (6.3) *if, for some open set* $\mathcal{O} \ni 0$ *and some continuous* $l : \mathcal{O} \to [0, +\infty)$, V *satisfies in viscosity sense in* $\mathcal{O} \setminus \{0\}$,

$$-trace\left[\frac{1}{2}\sigma\sigma^T D^2 V\right] + L - l \geq 0, \quad \sigma_i \cdot DV = 0 \quad \forall i, \tag{6.4}$$

and it is a strict Lyapunov function if l *is positive definite.*

In fact, this inequality and (6.2) give, for any $(p, \mathbf{X}) \in J^{2,-}V(x)$,

$$\max_{\alpha \in A} \{-f(x,\alpha) \cdot p\} - trace\left[\frac{1}{2}\sigma\sigma^T \mathbf{X}\right] - l \geq 0,$$

so V satisfies the inequality in condition (2.7), whereas the equality in condition (2.7) reduces to $\sigma_i \cdot p = 0$.

In the classical special case of $V(x) = |x|^2$ and $M = 1$, the sufficient condition (6.4) for V to be a Lyapunov function of (6.3) reads

$$l(x) := L(x) - |\sigma(x)|^2 \geq 0, \quad \sigma(x) \cdot x = 0.$$

For a noise of dimension $M = N$ an example of σ satisfying the orthogonality condition in (6.4) is

$$\sigma(x) = k\left(\mathbf{I} - \frac{DV(x) \otimes DV(x)}{|DV(x)|^2}\right)$$

for any constant k.

Example 3. Here we consider the perturbation of the deterministic system (6.1) by a function g of a K-dimensional diffusion process Y_t:

$$\begin{cases} \dot{X}_t = f(X_t, \alpha_t) + g(X_t, Y_t), \\ dY_t = b(Y_t, X_t, \alpha_t)dt + \tau(Y_t, X_t, \alpha_t)dB_t, \end{cases} \tag{6.5}$$

where the function $g : \mathbb{R}^n \times \mathbb{R}^K \to \mathbb{R}^n$ is Lipschitz continuous with $g(0, y) = 0$ for all y, B_t is a one-dimensional Brownian motion, and b, τ are vector fields in $\mathbb{R}^K$

with the usual assumptions. We are still assuming that (6.1) has a strict control Lyapunov function V, i.e., (6.2) holds with L positive definite. We are interested in the stabilizability of the perturbed system at the set $M := \{(x,y) \in \mathbb{R}^n \times \mathbb{R}^K \,:\, x = 0\}$, which corresponds to the origin of the unperturbed system (6.1); see Definition 5.2. Note that the assumption on g implies the viability of M for (6.5).

We claim that *the function V, defined by $V(x,y) := V(x)$ for all y, is a Lyapunov function at M for* (6.5) *(see Definition* 5.3*) if, for some open set $\mathcal{O} \ni 0$ and some continuous $l : \mathcal{O} \times \mathbb{R}^K \to [0,+\infty)$, V satisfies in viscosity sense in $\mathcal{O} \setminus \{0\}$,*

$$\inf_{y \in \mathbb{R}^K} \{-g(x,y) \cdot DV(x) - l(x,y)\} + L(x) \geq 0, \tag{6.6}$$

and V is a strict Lyapunov function if $l(x,y) > 0$ for all $x \neq 0$ and all y.

In fact, since $d((x,y),M) = |x|$, V satisfies conditions (i)–(iii) of Definition 5.3. By (6.2) and (6.6) V is also a viscosity supersolution in $\mathcal{O} \times \mathbb{R}^K \setminus M$ of

$$\sup_{a \in A} \{-f(x,a) \cdot DV(x)\} - g(x,y) \cdot DV(x) - l(x,y) \geq 0,$$

which is the inequality in (2.7) in this case, because V is constant in y. Finally, for the same reason, the condition in (2.7) of orthogonality of the diffusion vector to the level sets of V is trivially satisfied.

The inequality (6.6) is a smallness condition of the component of g in the direction of DV with respect to L in the set $\mathcal{O}$, uniformly in y. For $l \equiv 0$ and V smooth in $\mathcal{O} \setminus \{0\}$, it becomes

$$\sup_{y \in \mathbb{R}^K} g(x,y) \cdot DV(x) \leq L(x) \quad \text{in } \mathcal{O} \setminus \{0\}, \tag{6.7}$$

which is satisfied, in particular, if

$$\sup_{y \in \mathbb{R}^K} |g(x,y)| \leq L(x)/LipV,$$

where $LipV$ denotes the Lipschitz constant of V in $\mathcal{O}$. We recall that, under our assumption that the deterministic system (6.1) be asymptotically controllable, although V may not be smooth, it can be chosen semiconcave in $R^N \setminus \{0\}$ and therefore locally Lipschitz [38]. If we make this choice, it is enough that inequality (6.7) holds for all points $x \in \mathcal{O}$ where V is differentiable, and the last inequality is guaranteed for all perturbations g with small sup-norm with respect to y.

In the next two examples we give conditions on a radial function to be a Lyapunov function for almost sure stability.

Example 4. We consider as a candidate Lyapunov function for the general controlled system ($CSDE$) the function $V(x) = v(|x|)$, for some smooth $v : [0,+\infty) \to [0,+\infty)$ with $v'(r) > 0$ for $r > 0$. Since $DV(x) = xv'(|x|)/|x|$, in view of the orthogonality condition in (2.4), we restrict ourselves to controls $\alpha \in A$ such that

$$\sigma_i(x,\alpha) \cdot x = 0 \quad \forall\, i = 1, \dots, M. \tag{6.8}$$

We compute

$$trace\left[a(x,\alpha)D^2V(x)\right] = \frac{v'(|x|)}{|x|} trace\ a(x,\alpha) + \left(v''(|x|) - \frac{v'(|x|)}{|x|}\right) \frac{|\sigma(x,\alpha)^T x|^2}{|x|^2}$$

and use (6.8) to obtain that V is a Lyapunov function if and only if, in a neighborhood $\mathcal{O}$ of 0,

$$l(x) := \max_{\alpha\in A,\, \sigma(x,\alpha)^T x=0} [-f(x,\alpha)\cdot x - trace\, a(x,\alpha)]\, \frac{v'(|x|)}{|x|} \geq 0,$$

i.e.,

$$\min_{\alpha\in A,\, \sigma(x,\alpha)^T x=0} [f(x,\alpha)\cdot x + trace\, a(x,\alpha)] \leq 0. \tag{6.9}$$

This condition is independent of the choice of v. Moreover, if $l > 0$ and Lipschitz in $\mathcal{O}\setminus\{0\}$ and $l \to 0$ as $x \to 0$, then V is a strict Lyapunov function. Note that, although the radial component of the diffusion must be null by (6.8), its rotational component still plays a destabilizing role. In fact, $trace\, a(x,\alpha) \geq 0$ and whenever it is nonnull it must be compensated by a negative radial component of f.

In particular, a single-input affine system with uncontrolled diffusion and one-dimensional noise B_t,

$$dX_t = (f(X_t) + \alpha_t g(X_t))\, dt + \sigma(X_t) dB_t, \quad \alpha_t \in [-1,1],$$

has a radial Lyapunov function in $\mathcal{O}$ if and only if

$$\sigma(x)\cdot x = 0 \quad \text{and} \quad |g(x)\cdot x| \geq f(x)\cdot x + \frac{|\sigma(x)|^2}{2} \quad \text{in } \mathcal{O},$$

and $V(x) = |x|^2/2$ is a strict Lyapunov function in $\mathcal{O}$ if and only if

$$l(x) := |g(x)\cdot x| - f(x)\cdot x - \frac{|\sigma(x)|^2}{2} > 0 \quad \text{in } \mathcal{O}\setminus\{0\}.$$

Moreover, $k(x) := -sign(g(x)\cdot x)$ is a stabilizing feedback if $g(x)\cdot x$ does not change sign; if it does, k is discontinuous, and then a continuous stabilizing feedback in a neighborhood of 0 is given by the formula (4.3) in section 4.

Example 5. Here we study a system in $\mathbb{R}^2$ written in polar coordinates (ρ,θ) and look for radial Lyapunov functions, i.e., of the form $V(\rho,\theta) = v(\rho)$. Consider the stochastic controlled system:

$$(CSDE)\begin{cases} d\rho_t = f(\rho_t,\theta_t,\alpha_t)dt + \sigma(\rho_t,\theta_t,\alpha_t)dB_t, \\ d\theta_t = g(\rho_t,\theta_t,\alpha)dt + \tau(\rho_t,\theta_t,\alpha_t)dB_t, \end{cases}$$

where all functions f,σ,g,τ are 2π-periodic and B_t is (for simplicity) a one-dimensional Brownian motion. The conditions for a function $V = v(\rho)$ to be a Lyapunov function of this system at the set $M := \{(0,\theta) : \theta\in\mathbb{R}\}$ are the following. The orthogonality condition in (2.7) requires that for every (ρ,θ) there exists a subset $A(\rho,\theta) \neq \emptyset$ of the control set A such that

$$\sigma(\rho,\theta,\alpha) = 0 \qquad \forall \alpha \in A(\rho,\theta).$$

Then the condition (2.7) is satisfied if v is a viscosity supersolution of the ordinary differential inequality

$$\sup_{\alpha\in A(\rho,\theta)} \{-f(\rho,\theta,\alpha)\cdot v'(\rho)\} \geq 0$$

for $\rho > 0$ and for each fixed $\theta \in [0, 2\pi]$. Of course the same result can be obtained from the previous example with some calculations based on the Ito chain rule.

The last two examples are about the stabilization of systems to sets M different from the origin, namely, the complement of a ball and a periodic orbit.

Example 6. We consider the general system $(CSDE)$ and the set

$$M := \{x \mid |x| \geq R\} = \mathbb{R}^N \setminus B_R.$$

We assume M is viable for the system. We take the radial function V

$$V(x) := \begin{cases} R^2 - |x|^2 & |x| < R, \\ 0 & |x| \geq R \end{cases}$$

and use the calculations of Example 4 to see that V is a Lyapunov function at M if and only if for every x with $|x| < R$ there exists $\overline{\alpha} \in A$ such that

$$\sigma_i(x, \overline{\alpha}) \cdot x = 0 \quad \forall i \quad \text{and} \quad f(x, \overline{\alpha}) \cdot x + trace\ a(x, \overline{\alpha}) \geq 0.$$

Contrary to Example 4, here the rotational component of the diffusion has a stabilizing effect. In fact, the drift $f(x, a)$ is allowed also to point away from M if its negative radial component is compensated by the positive term $trace\ a(x, \overline{\alpha})$.

If $K \subset B_R$ is a compact set and

$$l(x) := \max_{\alpha \in A,\, \sigma(x,\alpha)^T x = 0} [f(x, \alpha) \cdot x + trace\, a(x, \alpha)] > 0 \quad \text{in } B_R \setminus K,$$

then M is locally asymptotically stable by Theorem 5.5, and for all initial points $x \notin K$ there is a control whose trajectories tend a.s. to M as $t \to +\infty$. In this case we can say that K can be made a.s. repulsive by a suitable choice of the controls. In particular, we have a criterion of instability of an equilibrium point.

Note also that if $l > 0$ on $\partial M = \partial B_R$, then for some control the trajectories starting in a suitable neighborhood of ∂M reach M in finite time a.s., as we observed in the last remark of section 5. In particular, if $l > 0$ in $\overline{B_R}$, then for every $x \in B_R$ there exists a control $\overline{\alpha}_\cdot$ such that the exit time of the corresponding trajectory $\overline{X}_\cdot$ from B_R is a.s. bounded by $(R^2 - |x|^2)/\min_{B_R} l$.

Example 7. Consider $(CSDE)$ in $\mathbb{R}^2$ and assume the circle $\gamma := \{x : |x| = R\}$ is a viable set. By the results of [11] this occurs if for all $x \in \gamma$ there exists $\overline{\alpha} \in A$ such that

$$\sigma(x, \overline{\alpha}) \cdot x = 0 \quad \text{and} \quad f(x, \overline{\alpha}) \cdot x + trace\, a(x, \overline{\alpha}) = 0.$$

Then γ is locally asymptotically stabilizable if, in a neighborhood $\{x : R - \varepsilon \leq |x| \leq R + \varepsilon\}$,

$$\max_{\alpha \in A,\, \sigma(x,\alpha)^T x = 0} [f(x, \alpha) \cdot x + trace\ a(x, \alpha)] > 0 \quad \text{if } |x| < R,$$

$$\min_{\alpha \in A,\, \sigma(x,\alpha)^T x = 0} [f(x, \alpha) \cdot x + trace\ a(x, \alpha)] < 0 \quad \text{if } |x| > R.$$

This follows immediately from the arguments of Examples 4 and 6.

THE APPROXIMATION OF HIGHER-ORDER INTEGRALS OF THE CALCULUS OF VARIATIONS AND THE LAVRENTIEV PHENOMENON*

ALESSANDRO FERRIERO†

Abstract. We prove the following approximation theorem: given a function $x : [a, b] \to \mathbb{R}^N$ in the Sobolev space $\mathbf{W}^{\nu+1,1}$, $\nu \geq 1$, and $\epsilon > 0$, there exists a function x_ϵ in $\mathbf{W}^{\nu+1,\infty}$ such that

$$\int_a^b \sum_{i=1}^m L_i(x_\epsilon^{(\nu)}, x_\epsilon^{(\nu+1)})\psi_i(t, x_\epsilon, x_\epsilon', \dots, x_\epsilon^{(\nu)}) < \int_a^b \sum_{i=1}^m L_i(x^{(\nu)}, x^{(\nu+1)})\psi_i(t, x, x', \dots, x^{(\nu)}) + \epsilon,$$

$$\begin{aligned} &x_\epsilon(a) = x(a), && x_\epsilon(b) = x(b),\\ &x_\epsilon'(a) = x'(a), && x_\epsilon'(b) = x'(b),\\ &\vdots\\ &x_\epsilon^{(\nu)}(a) = x^{(\nu)}(a), && x_\epsilon^{(\nu)}(b) = x^{(\nu)}(b), \end{aligned}$$

provided that, for every i in $\{1, \dots, m\}$, $L_i\psi_i$ is continuous in a neighborhood of x, L_i is convex in its second variable, and ψ_i evaluated along x has positive sign. We discuss the optimality of our assumptions comparing them with an example of Sarychev [*J. Dynam. Control Systems*, 3 (1997), pp. 565–588].

As a consequence, we obtain the nonoccurrence of the Lavrentiev phenomenon. In particular, the integral functional $\int_a^b L(x^{(\nu)}, x^{(\nu+1)})$ does not exhibit the Lavrentiev phenomenon for any given boundary values $x(a) = A$, $x(b) = B$, $x'(a) = A'$, $x'(b) = B'$, $\dots$, $x^{(\nu)}(a) = A^{(\nu)}$, $x^{(\nu)}(b) = B^{(\nu)}$.

Furthermore, we prove the following necessary condition: an action functional with Lagrangian of the form $\sum_{i=1}^m L_i(x^{(\nu)}, x^{(\nu+1)})\psi_i(t, x, x', \dots, x^{(\nu)})$, with $\nu \geq 0$, exhibiting the Lavrentiev phenomenon takes the value $+\infty$ in any neighborhood of a minimizer.

Key words. calculus of variations, Lavrentiev phenomenon, reparameterization

1. Introduction.

In 1926, Lavrentiev [11] proposed an example of a first-order integral functional of the calculus of variations, $\mathcal{I}(x) = \int_a^b L(t, x, x')$, whose infimum taken over the space of the absolutely continuous functions $\mathbf{W}^{1,1}(a, b)$ is strictly less than the infimum taken over the space of Lipschitz continuous functions $\mathbf{W}^{1,\infty}(a, b)$, with $x(a) = A$ and $x(b) = B$. Later, Manià [13] published a simpler example of the same phenomenon where the Lagrangian is

$$L_1(x')\psi_1(t, x) = |x'|^6(x^3 - t)^2.$$

Several papers have been devoted to the problem of finding conditions under which the Lavrentiev phenomenon does not occur: Angell [2], Clarke, Vinter [8], Ball, Mizel [3], Lowen [12], Alberti, Serra Cassano [1]. In a recent paper by Cellina, Ferriero, and Marchini [5] a large class of Lagrangians of the form $L_1(x, x')\psi_1(t, x)$ has been treated, including the autonomous and some nonautonomous cases, under no additional conditions besides the convexity of L_1 in x' and the positivity of ψ_1.

*Received by the editors November 14, 2003; accepted for publication (in revised form) October 9, 2004; published electronically June 27, 2005.

Besides the first-order case, the Lavrentiev phenomenon occurs as well in the case with $(\nu+1)$-order derivatives, $\mathcal{I}(x) = \int_a^b L(t, x, x', \dots, x^{(\nu+1)})$. For $\nu = 1$, in 1994 Cheng and Mizel [7] described a restricted Lavrentiev phenomenon in which the gap occurs for a dense subset of the absolutely continuous nonnegative functions, and they proved that even autonomous Lagrangian $L(x, x', x'')$ can exhibit it. Some years later Sarychev [15] proved that a class of Lagrangians of the form

$$L_1(x'')\psi_1(x, x') + L_2(x'')$$

exhibits the Lavrentiev phenomenon provided that $\psi_1(x, x') = \phi(kx - k|x' - 1|^{k-1} - (k-1)|x' - 1|^k)$ for appropriate constants k, that L_1, L_2, ϕ satisfy certain growth conditions, and that $\phi(0) = 0$. For example, $L_1(x'') = |x''|^7$, $L_2(x'') = \alpha|x''|^{3/2}$, $\phi_1(\cdot) = (\cdot)^2$, $k = 3$, and $\alpha > 0$ sufficiently small yield a Lagrangian whose integral exhibits the Lavrentiev phenomenon when the boundary values are $x(0) = 0$, $x(1) = 5/3$, $x'(0) = 1$, $x'(1) = 2$.

The Lagrangians proposed by Manià and Sarychev have the property that L_1 evaluated along the minimizer x is not integrable (this is possible because there exists at least one point t in $[a, b]$ such that ψ_1 evaluated along x in t is 0). A condition avoiding the occurrence of this fact will turn out, in this paper, to be essential for the nonoccurrence of the Lavrentiev phenomenon.

We prove the following general approximation theorem: let $x : [a, b] \to \mathbb{R}^N$ be a function in $\mathbf{W}^{\nu+1,1}$ (independently on whether is a minimizer or not), then the integrability of L_i evaluated along x (or the assumption that $\psi_i > 0$), for every i, implies that, given $\epsilon > 0$, there exists a function x_ϵ in $\mathbf{W}^{\nu+1,\infty}$ with the same boundary values of x in a and in b, i.e., $x_\epsilon(a) = x(a)$, $x_\epsilon(b) = x(b)$, $x'_\epsilon(a) = x'(a)$, $x'_\epsilon(b) = x'(b)$, $\dots$, $x^{(\nu)}_\epsilon(a) = x^{(\nu)}(a)$, $x^{(\nu)}_\epsilon(b) = x^{(\nu)}(b)$, such that

$$\begin{aligned}&\int_a^b \sum_{i=1}^m L_i(x^{(\nu)}_\epsilon, x^{(\nu+1)}_\epsilon)\psi_i(t, x_\epsilon, x'_\epsilon, \dots, x^{(\nu)}_\epsilon)\\ &< \int_a^b \sum_{i=1}^m L_i(x^{(\nu)}, x^{(\nu+1)})\psi_i(t, x, x', \dots, x^{(\nu)}) + \epsilon.\end{aligned}$$

We underline that an application of this result is the nonoccurrence of the Lavrentiev phenomenon for a class of functionals of the calculus of variations with $(\nu+1)$-order derivatives, $\nu \geq 1$. (The case $\nu = 0$, $m = 1$ has already been treated in [5]. The case $\nu = 0$, $m > 1$ can be obtained modifying slightly the proof of the main result of [5]; see [10].) Moreover, we infer a necessary condition for the Lavrentiev phenomenon.

In section 2 we state our results, we discuss the optimality of the assumptions, and we infer the nonoccurrence of the Lavrentiev phenomenon. In section 3 we prove the main result. In section 4 we deal with a necessary condition for the Lavrentiev phenomenon: a functional

$$\mathcal{I}(x) = \int_a^b \sum_{i=1}^m L_i(x^{(\nu)}, x^{(\nu+1)})\psi_i(t, x, x', \dots, x^{(\nu)}),$$

with $\nu \geq 0$, exhibiting the Lavrentiev phenomenon takes the value $+\infty$ in any neighborhood of a minimizer $\bar{x}$.

2. The main result and the Lavrentiev phenomenon. For $\delta > 0$, $B[c, \delta]$ denotes the closed ball in $\mathbb{R}^N$ centered in c with radius δ. For a function x in $\mathbf{C}^\nu[a, b]$,

with values in $\mathbb{R}^N$, the closed δ-tube along $(x, \dots, x^{(\nu)})$

$$\mathsf{T}^{\nu}_{\delta}[x] = \{(t, z_0, \dots, z_\nu) \in [a,b] \times \mathbb{R}^{(\nu+1)N} : \\ (z_0, \dots, z_\nu) \in B[x(t), \delta] \times \cdots \times B[x^{(\nu)}(t), \delta],\ t \in [a,b]\}$$

and the closed δ-neighborhood of the image $\mathrm{Im}(x^{(\nu)})$ of $x^{(\nu)}$

$$\mathsf{I}_{\delta}[x^{(\nu)}] = \{z \in \mathbb{R}^N : \mathrm{dist}(z, \mathrm{Im}(x^{(\nu)})) \le \delta\}$$

are compact sets.

We recall that the space $\mathbf{W}^{\nu+1,p}(a,b)$ can be seen as the space of functions x in $\mathbf{C}^{\nu}[a,b]$ such that $x^{(\nu)}$ is absolutely continuous with derivative in $\mathbf{L}^p(a,b)$, $p \ge 1$.

The following approximation theorem is our main result.

THEOREM 2.1. *Let x be a function in $\mathbf{W}^{\nu+1,1}(a,b)$, $\nu \ge 1$, and let the real-valued functions $L_1, \dots, L_m$ and $\psi_1, \dots, \psi_m$ be continuous on $\mathsf{I}_{\delta}[x^{(\nu)}] \times \mathbb{R}^N$ and on $\mathsf{T}^{\nu}_{\delta}[x]$, respectively, for some $\delta > 0$.*

Assume that, for every i in $\{1, \dots, m\}$,

- *$L_i(\xi, \cdot)$ is convex, for every ξ in $\mathsf{I}_{\delta}[x^{(\nu)}]$,*
- *ψ_i is nonnegative, and $\psi_i(t, x(t), x'(t), \dots, x^{(\nu)}(t)) > 0$, for every t in $[a,b]$.*

Then

(i) $\mathcal{I}(x) = \displaystyle\int_a^b \sum_{i=1}^{m} L_i(x^{(\nu)}(t), x^{(\nu+1)}(t)) \psi_i(t, x(t), x'(t), \dots, x^{(\nu)}(t))\, dt > -\infty$;

(ii) *given any $\epsilon > 0$, there exists a function x_ϵ in $\mathbf{W}^{\nu+1,\infty}(a,b)$ such that*

$$\mathcal{I}(x_\epsilon) < \mathcal{I}(x) + \epsilon,$$

and

$$\begin{aligned} &x_\epsilon(a) = x(a), && x_\epsilon(b) = x(b), \\ &x'_\epsilon(a) = x'(a), && x'_\epsilon(b) = x'(b), \\ &\vdots \\ &x^{(\nu)}_\epsilon(a) = x^{(\nu)}(a), && x^{(\nu)}_\epsilon(b) = x^{(\nu)}(b). \end{aligned}$$

As a corollary we obtain the nonoccurrence of the Lavrentiev phenomenon.

THEOREM 2.2. *Let $\Omega_0, \dots, \Omega_\nu$ be open sets in $\mathbb{R}^N$, $\nu \ge 1$, such that the set $E = \{x \in \mathbf{W}^{\nu+1,1}(a,b) : x(t) \in \Omega_0, \dots, x^{(\nu)}(t) \in \Omega_\nu\ \forall t \in [a,b]\}$ is nonempty.*

Let $L_1, \dots, L_m : \Omega_\nu \times \mathbb{R}^N \to \mathbb{R}$ and $\psi_1, \dots, \psi_m : [a,b] \times \Omega_0 \times \cdots \times \Omega_\nu \to (0, +\infty)$ be continuous and such that $L_i(\xi, \cdot)$ is convex, for any ξ in Ω_ν, and any i in $\{1, \dots, m\}$.

Then, for all boundary values $A, B \in \Omega_0$, $A^{(1)}, B^{(1)} \in \Omega_1$, $\dots$, $A^{(\nu)}, B^{(\nu)} \in \Omega_\nu$, the infimum of

$$\mathcal{I}(x) = \int_a^b \sum_{i=1}^{m} L_i(x^{(\nu)}(t), x^{(\nu+1)}(t)) \psi_i(t, x(t), x'(t), \dots, x^{(\nu)}(t))\, dt$$

over the space $E_{a,b} = \{x \in E : x(a) = A,\ x(b) = B,\ x'(a) = A^{(1)},\ x'(b) = B^{(1)},\ \dots,\ x^{(\nu)}(a) = A^{(\nu)},\ x^{(\nu)}(b) = B^{(\nu)}\}$ is equal to the infimum of the same functional $\mathcal{I}$ over the space $E_{a,b} \cap \mathbf{W}^{\nu+1,\infty}(a,b)$.

Proof. Let $\{x_n\}_n \subset E_{a,b}$ be a minimizing sequence for $\mathcal{I}$: by the fact that $\psi_i > 0$, for every i, the theorem follows from Theorem 2.1 applied to any x_n, with $\epsilon = 1/n$. ∎

Setting $m = 1$, $\psi_1 = 1$, and $L_1 = L$, we obtain that a Lagrangian depending only on $x^{(\nu)}$ and $x^{(\nu+1)}$ satisfies the assumptions of Theorem 2.2. Hence, the integral functional

$$\int_a^b L(x^{(\nu)}(t), x^{(\nu+1)}(t))dt$$

does not exhibit the Lavrentiev phenomenon, for any boundary values

$$\begin{aligned} &x(a) = A, && x(b) = B,\\ &x'(a) = A^{(1)}, && x'(b) = B^{(1)},\\ &\vdots\\ &x^{(\nu)}(a) = A^{(\nu)}, && x^{(\nu)}(b) = B^{(\nu)}. \end{aligned}$$

This extends some previous results ([1], [4]), where functionals without boundary conditions, or with boundary conditions only in a, have been considered.

We point out that the assumption $\psi_i(t, x(t), x'(t), \dots, x^{(\nu)}(t)) \neq 0\ \forall t \in [a, b]$ in Theorem 2.1 will be used only to infer that $\int_a^b L_i(x^{(\nu)}, x^{(\nu+1)})$ is finite, provided that $\mathcal{I}(x)$ is finite (point (a) in the proof). The theorem holds under the weaker assumption $\int_a^b |L_i(x^{(\nu)}, x^{(\nu+1)})| < +\infty$, for every i.

To verify how sharp our assumptions are, consider the following example of A. V. Sarychev [15]: for $\nu = 1$, $m = 1$, minimize the functional

$$\int_0^1 |x''(t)|^7[3x(t) - 3|x'(t) - 1|^2 - 2|x'(t) - 1|^3]^2 dt,$$

with boundary conditions $x(0) = 0$, $x(1) = 5/3$, $x'(0) = 1$, $x'(1) = 2$. He proved that the infimum taken over the space $\mathbf{W}^{2,1}(0, 1)$, assumed in $\bar{x}(t) = (2/3)\sqrt[2]{t^3} + t$, is strictly lower than the infimum taken over the space $\mathbf{W}^{2,\infty}(0, 1)$.

The assumption $\int_a^b |L_1(x', x'')| < +\infty$ along $\bar{x}$ is not verified. Indeed, setting $\psi_1(t, x, \xi) = [3x - 3|\xi - 1|^2 - 2|\xi - 1|^3]^2$ and $L_1(\xi, w) = |w|^7$, we see that $\psi_1 \geq 0$ (but, for example, $\psi_1(0, x(0), x'(0)) = 0$) and that

$$\int_0^1 |\bar{x}''(t)|^7 dt = \int_0^1 \frac{1}{(2\sqrt{t})^7} dt = +\infty.$$

3. Proof of the main theorem. In what follows, $\mathbf{x}$ denotes the matrix $(x, \dots, x^{(\nu-1)})$ and $\mathsf{x} = x^{(\nu-1)}$, so that $\mathsf{x}' = x^{(\nu)}$, $\mathsf{x}'' = x^{(\nu+1)}$ (similarly, $\mathbf{z} = (z, \dots, z^{(\nu-1)})$, and $\mathsf{z} = z^{(\nu-1)}$). The Lagrangian we consider takes the form

$$\sum_{i=1}^m L_i(\mathsf{x}'(t), \mathsf{x}''(t))\psi_i(t, \mathbf{x}(t), \mathsf{x}'(t)).$$

(In case $\nu = 1$, $\mathbf{x}$, x', x'' coincide with x, x', x'', respectively.)

(i) For every $t \in [a, b]$, $L_i(\mathsf{x}'(t), \mathsf{x}''(t)) \geq L_i(\mathsf{x}'(t), 0) + \langle p_0(t), \mathsf{x}''(t)\rangle$, where $p_0(t)$ is any selection from the subdifferential $\partial_w L_i(\mathsf{x}'(t), 0)$ of L_i with respect to its second variable. Set $E_i = \{t \in [a, b] : [L_i(\mathsf{x}'(t), \mathsf{x}''(t))]^- \neq 0\}$, so that

$$\begin{aligned} &\int_a^b [L_i(\mathsf{x}'(t), \mathsf{x}''(t))\psi_i(t, \mathbf{x}(t), \mathsf{x}'(t))]^- dt\\ &\leq -\int_{E_i} [L_i(\mathsf{x}'(t), 0) + \langle p_0(t), \mathsf{x}''(t)\rangle]\psi_i(t, \mathbf{x}(t), \mathsf{x}'(t))dt, \end{aligned}$$

for any i. Since ψ_i is bounded and, by Proposition 2 in [5], $p_0(t)$ is bounded, the claim follows by Hölder's inequality.

(ii) Fix $\epsilon > 0$; set $\bar\epsilon = \epsilon/m$. Without loss of generality, we shall assume $\epsilon < 1$, and also $\delta < 1$.

In case $\int_a^b L_i(\mathsf{x}'(t), \mathsf{x}''(t))\psi_i(t, \mathbf{x}(t), \mathsf{x}'(t))dt = +\infty$, for some i, any Lipschitz function x_ϵ satisfying the boundary conditions is acceptable. Hence we can assume, for every i,

$$\int_a^b L_i(\mathsf{x}'(t), \mathsf{x}''(t))\psi_i(t, \mathbf{x}(t), \mathsf{x}'(t))dt < +\infty.$$

The proof is in three steps. In Step (1) of the proof we introduce the new functions $\tilde L_i$ such that $\tilde L_i = L_i + \text{const}$ and such that their polar functions $\tilde L_i^*$ (with respect to the second variable) are nonnegative. In Step (3) we define a variation z_n in $\mathbf{W}^{\infty,1}(a,b)$, with the same boundary values of x in a and in b, such that $\mathcal{I}(z_n) < \mathcal{I}(x) + \epsilon$. In order to define z_n, in Step (2) we define a sequence of reparameterizations s_n of $[a,b]$.

Step (1). We claim that there exists functions $\tilde L_i$ and a constant η such that $\tilde L_i = L_i + \eta$ and $\tilde L_i^* \geq 0$, for any i.

In fact, consider the set

$$V_i = \{(\xi, p) : \xi \in \mathsf{I}_\delta[x^{(\nu)}],\, p \in \partial_w L_i(\xi, w),\, |w| \leq 1\}.$$

By Proposition 2 in [5], arguing by contradiction, we obtain that V_i is compact. Let $L_i^*(\xi, p) = \sup_{w\in\mathbb{R}^N} \langle p, w\rangle - L_i(\xi, w)$ be the polar function of L_i with respect to its second variable. Then, $\min_{V_i} L_i^*$ is attained and is finite. Applying Proposition 3 in [5], we obtain that $L_i^*(\xi, p) \geq \min_{V_i} L_i^*$, for every $\xi \in \mathsf{I}_\delta[x^{(\nu)}]$, for every $p \in \partial_w L_i(\xi, w)$ and for every $w \in \mathbb{R}^N$. Set $\eta = \min\{\min_{V_1} L_1^*, \dots, \min_{V_m} L_m^*\}$.

Consider $\tilde L_i(\xi, w) = L_i(\xi, w) + \eta$. Since $\partial_w L_i(\xi, w) = \partial_w \tilde L_i(\xi, w)$, we have that $\tilde L_i^*(\xi, p) \geq 0$, for any i. (We denote $\tilde{\mathcal{I}}_i$ the functional $\int_a^b \tilde L_i \psi_i$.)

(a) We set some preliminary constants, depending on $\bar\epsilon$ fixed, that we shall use in the following steps.

By the condition on ψ_i, there exists $c > 0$ such that $\psi_i(t, \mathbf{x}(t), \mathsf{x}'(t)) \geq c$, for every t in $[a,b]$, and we obtain

$$\begin{aligned} +\infty &> \int_a^b |L_i(\mathsf{x}'(t), \mathsf{x}''(t))\psi_i(t, \mathbf{x}(t), \mathsf{x}'(t))|dt + \eta \int_a^b \psi_i(t, \mathbf{x}(t), \mathsf{x}'(t))dt \\ &\geq \int_a^b |\tilde L_i(\mathsf{x}'(t), \mathsf{x}''(t))\psi_i(t, \mathbf{x}(t), \mathsf{x}'(t))|dt \geq c \int_a^b |\tilde L_i(\mathsf{x}'(t), \mathsf{x}''(t))|dt. \end{aligned}$$

Set $\ell_i = \int_a^b |\tilde L_i(\mathsf{x}'(s), \mathsf{x}''(s))|ds$, $\ell = \max\{\ell_1, \dots, \ell_m\}$, and Ψ and $\tilde{\mathbf{L}}$ the maximum value of $|\psi_1|, \dots, |\psi_m|$ over $\mathsf{T}_\delta^\nu[x]$ and of $|\tilde L_1|, \dots, |\tilde L_m|$ over $\mathsf{I}_\delta[x^{(\nu)}] \times B[0, |\mathsf{x}''(\tau)| + \delta]$, respectively. Denote $\alpha = \max\{1, (b-a)^\nu\}$.

From the uniform continuity of $\psi_1, \dots, \psi_m$ on $\mathsf{T}_\delta^\nu[x]$, we infer that we can fix $h \in \mathbb{N}$, $1/2^h < \delta$, such that whenever $(t_1, \mathbf{x}_1, \xi_1)$, $(t_2, \mathbf{x}_2, \xi_2) \in \mathsf{T}_\delta^\nu[x]$ and

$$|t_1 - t_2| \leq \frac{b-a}{2^h}, \quad |\mathbf{x}_{1,j} - \mathbf{x}_{2,j}| \leq \frac{1}{2^h}\ \forall j \in \{0, \dots, \nu-1\}, \quad |\xi_1 - \xi_2| \leq \frac{1}{2^h},$$

we have

$$|\psi_i(t_1, \mathbf{x}_1, \xi_1) - \psi_i(t_2, \mathbf{x}_2, \xi_2)| < \min\left\{\frac{\bar\epsilon}{8(\ell + \tilde{\mathbf{L}} + 1)},\, \frac{\bar\epsilon}{2(|\eta| + 1)(b-a)}\right\},$$

for any i.

Let $\theta : \mathbb{R} \to [0,1]$ be a $\mathbf{C}^\infty$ increasing function with value 0 on $(-\infty, 0]$ and 1 on $[1, +\infty)$. Observe that $1 \leq ||\theta^{(j)}||_\infty \leq ||\theta^{(j+1)}||_\infty$, for any $j \geq 0$. Set $\Theta = ||\theta^{(\nu+1)}||_\infty$.

There exists a point τ in (a,b) that is a Lebesgue point for the functions $\tilde{L}_1(\mathsf{x}'(\cdot), \mathsf{x}''(\cdot))\psi_1(\cdot, \mathbf{x}(\cdot), \mathsf{x}'(\cdot))$, $\ldots$, $\tilde{L}_m(\mathsf{x}'(\cdot), \mathsf{x}''(\cdot))\psi_m(\cdot, \mathbf{x}(\cdot), \mathsf{x}'(\cdot))$ and x'', $\mathsf{x}''(\tau)$ in $\mathbb{R}^N$. By definition of Lebesgue point, there exists a positive number ρ less than

$$\min\left\{\frac{1}{2^{h+4}(\nu+2)(\nu+1)\nu\Theta\alpha^2}, \frac{\bar{\epsilon}}{32\tilde{\mathbf{L}}\Psi}\right\}$$

such that, for any λ^-, λ^+ in $(0, \rho)$,

$$\int_{\tau-\lambda^-}^{\tau+\lambda^+} |\tilde{L}_i(\mathsf{x}'(t), \mathsf{x}''(t))\psi_i(t, \mathbf{x}(t), \mathsf{x}'(t)) - \tilde{L}_i(\mathsf{x}'(\tau), \mathsf{x}''(\tau))\psi_i(\tau, \mathbf{x}(\tau), \mathsf{x}'(\tau))|dt \leq (\lambda^+ + \lambda^-)\bar{\epsilon}$$

for any i, and

$$\int_{\tau-\lambda^-}^{\tau+\lambda^+} |\mathsf{x}''(t) - \mathsf{x}''(\tau)|dt \leq (\lambda^+ + \lambda^-)\frac{1}{2^{h+4}(\nu+1)\nu\Theta\alpha}.$$

Fix $t_0^- = (b-a)v^-/2^\gamma$, $t_0^+ = (b-a)v^+/2^\gamma$, where $\gamma \in \mathbb{N}$, $v^-, v^+ \in \{0, 1, \ldots, 2^\gamma\}$, $v^- < v^+$, are such that $\tau \in (\tau^-, \tau^+) \subset (\tau - \rho, \tau + \rho)$.

We define the absolutely continuous function $\mathsf{z}' : [a,b] \to \mathbb{R}^N$ by $\mathsf{z}'(t) = x^{(\nu)}(a) + \int_a^t \mathsf{z}''$, where

$$\mathsf{z}''(t) = \begin{cases} x^{(\nu+1)}(\tau) + \dfrac{1}{\tau^+ - \tau^-}\displaystyle\int_{\tau^-}^{\tau^+} [\mathsf{x}'' - \mathsf{x}''(\tau)], & t \in [\tau^-, \tau^+], \\ x^{(\nu+1)}(t), & \text{otherwise.} \end{cases}$$

By definition, $\mathsf{z}''(t) = \mathsf{x}''(t)$, $\mathsf{z}'(t) = \mathsf{x}'(t)$, for any t in $[a, \tau^-] \cup [\tau^+, b]$. For any t in $[\tau^-, \tau^+]$, we have that $\mathsf{z}''(t) \in B[0, |\mathsf{x}''(\tau)| + \delta/2]$ and

$$|\mathsf{z}'(t) - \mathsf{x}'(t)| \leq 2\int_{\tau^-}^{\tau^+} |\mathsf{x}''(\tau) - \mathsf{x}''| < (\tau^+ - \tau^-)\frac{1}{2^{h+3}(\nu+1)\nu\Theta\alpha}.$$

Step (2). Our purpose is to show that there exists a sequence of reparameterizations s_n of $[a,b]$ into itself such that $\mathsf{z}' \circ s_n$ is Lipschitz continuous on $[a,b]$.

From the uniform continuity of $x, \ldots, x^{(\nu)}$ on $[a, \tau^-] \cup [\tau^+, b]$, we infer that we can fix $k \in \mathbb{N}$, such that whenever $|s_1 - s_2| \leq (b-a)/2^k$, we have $|x^{(j)}(s_1) - x^{(j)}(s_2)| < (\tau^+ - \tau^-)^{\nu+2}$, for any j in $\{1, \ldots, \nu\}$.

For $v = 0, \ldots, 2^k - 1$, set $I_v = [(b-a)v/2^k, (b-a)(v+1)/2^k]$, $H_v = \int_{I_v} |\mathsf{z}''(s)|ds$, $\mu = \max\{2^{k+1}H_v/(b-a) : v = 0, \ldots, 2^k - 1\}$, and

$$T_{H_v} = \left\{s \in I_v : |\mathsf{z}''(s)| \leq \frac{2^{k+1}H_v}{b-a}\right\};$$

we have that $|T_{H_v}| \geq (b-a)/2^{k+1}$.

Since $\{(\mathsf{z}'(s), \mathsf{z}''(s)) : s \in \bigcup_{v=0}^{2^k-1} T_{H_v}\}$ belongs to a compact set and $L_1, \dots, L_m$ are continuous, there exists a constant M, such that

$$\left| \tilde{L}_i(\mathsf{z}'(s) + \xi, 2\mathsf{z}''(s) + w)\frac{1}{2} - \tilde{L}_i\Big(\mathsf{z}'(s) + \xi, \mathsf{z}''(s) + \frac{w}{2}\Big)\right| \leq M,$$

for any $s \in \bigcup_{v=0}^{2^k-1} T_{H_v}$, any $|\xi| \leq \delta$, any $|w| \leq \delta$, and any i.

For every $n \in \mathbb{N}$, set $S_n^v = \{s \in I_v : |\mathsf{z}''(s)| > n\}$. From the integrability of z'' it follows that $\int_{S_n^v} (|\mathsf{z}''(s)|/n - 1)ds$ converges to 0, as n goes to ∞. Hence, we can fix a subset Σ_n^v of T_{H_v} such that $|\Sigma_n^v| = 2\int_{S_n^v} (|\mathsf{z}''(s)|/n - 1)ds$.

We define the absolutely continuous functions t_n by $t_n(s) = a + \int_a^s t_n'$, where

$$t_n'(s) = \begin{cases} 1 + (|\mathsf{z}''(s)|/n - 1), & s \in S_n = \bigcup_{v=0}^{2^k-1} S_n^v, \\ 1 - 1/2, & s \in \Sigma_n = \bigcup_{v=0}^{2^k-1} \Sigma_n^v, \\ 1, & \text{otherwise.} \end{cases}$$

One verifies that t_n admits inverse function s_n on the interval $[a, b]$. Furthermore, for any v in $\{0, \dots, 2^k - 1\}$, the restriction of t_n to I_v maps I_v onto itself. Hence, $|t_n(s) - s| \leq (b - a)/2^k$, for any s in $[a, b]$. If n is greater than $|\mathsf{x}''(\tau)| + \delta/2$, the restriction of t_n to $[\tau^-, \tau^+]$ is the identity.

The function $\mathsf{z}' \circ s_n$ is Lipschitz continuous on $[a, b]$. In fact, fix t where $s_n'(t)$ exists: we obtain

$$\left|\frac{d(\mathsf{z}' \circ s_n)}{dt}(t)\right| = |\mathsf{z}''(s_n(t))s_n'(t)| \begin{cases} = n, & t \in S_n, \\ \leq \mu, & t \in \Sigma_n, \\ \leq n, & \text{otherwise.} \end{cases}$$

Step (3). We construct a function $z_n : [a, b] \to \mathbb{R}^N$, with the same boundary values of x in a and b, such that z_n belongs to $\mathbf{W}^{\nu+1,\infty}(a, b)$ and $\tilde{\mathcal{I}}_i(z_n) < \tilde{\mathcal{I}}_i(x) + \bar{\epsilon}/2$.

Set $f'(t) = \theta((t - \tau^-)/(\tau^+ - \tau^-))$, for any t in $[a, b]$ (the function θ as defined in point (a)): then f' is identically 0 on $[a, \tau^-]$, it is identically 1 on $[\tau^+, b]$, and $||f^{(j+1)}||_\infty = ||\theta^{(j)}||_\infty/(\tau^+ - \tau^-)^j$, for any $j \geq 0$.

We define ν absolutely continuous functions $z_{n,\nu-1}, \dots, z_{n,0} : [a, b] \to \mathbb{R}^N$ by

$$\begin{aligned} z_{n,\nu-1}(t) &= x^{(\nu-1)}(a) + \int_a^t \mathsf{z}' \circ s_n + f'(t)D_{\nu-1}, \\ z_{n,\nu-2}(t) &= x^{(\nu-2)}(a) + \int_a^t z_{n,\nu-1} + f'(t)D_{\nu-2}, \\ &\vdots \\ z_{n,0}(t) &= x(a) + \int_a^t z_{n,1} + f'(t)D_0, \end{aligned}$$

where, for any j in $\{0, \cdots, \nu - 2\}$,

$$D_j = x^{(j)}(b) - x^{(j)}(a) - \int_a^b z_{n,j+1}, \qquad D_{\nu-1} = x^{(\nu-1)}(b) - x^{(\nu-1)}(a) - \int_a^b \mathsf{z}' \circ s_n.$$

Set $z_n = z_{n,0}$. The derivatives of z_n up to the order $\nu+1$ are

$$\begin{aligned}
&z_n'(t) = z_{n,1}(t) + f''(t)D_0,\\
&z_n''(t) = z_{n,2}(t) + f'''(t)D_0 + f''(t)D_1,\\
&\vdots\\
&z_n^{(\nu-1)}(t) = z_{n,\nu-1}(t) + \textstyle\sum_{j=0}^{\nu-2} f^{(\nu-j)}(t)D_j,\\
&z_n^{(\nu)}(t) = \mathsf{z}'(s_n(t)) + \textstyle\sum_{j=0}^{\nu-1} f^{(\nu-j+1)}(t)D_j,\\
&z_n^{(\nu+1)}(t) = \mathsf{z}''(s_n(t))s_n'(t) + \textstyle\sum_{j=0}^{\nu-1} f^{(\nu-j+2)}(t)D_j.
\end{aligned}$$

We denote by H' the function $\sum_{j=0}^{\nu-1} f^{(\nu-j+1)}D_j$. By the properties of $f^{(j)}$ and s_n, we have that z_n belongs to $\mathbf{W}^{\nu+1,\infty}(a,b)$, with $||z_n^{(\nu+1)}||_\infty \le n + ||\mathsf{H}''||_\infty$ (where $||\cdot||_\infty$ is the essential supremum on (a,b)), and it has the same boundary values of x in a and b.

(b) We claim that $||z_n^{(j)} - x^{(j)}||_\infty \le 1/2^h$ and $||z_n^{(j)} \circ t_n - x^{(j)}||_\infty \le 1/2^h$, for any j in $\{0,\dots,\nu\}$, eventually in n.

In fact, for any n greater than $|\mathsf{x}''(\tau)| + \delta/2$, we have

$$\begin{aligned}
|D_{\nu-1}| &\le \int_a^{\tau^-} |\mathsf{x}' - \mathsf{x}'\circ s_n| + \int_{\tau^-}^{\tau^+} |\mathsf{x}' - \mathsf{z}'| + \int_{\tau^+}^b |\mathsf{x}' - \mathsf{x}'\circ s_n|\\
&\le (\tau^+ - \tau^-)^2\left[3\alpha(\tau^+-\tau^-)^\nu + \frac{1}{2^{h+3}(\nu+1)\nu\Theta\alpha}\right]\\
&\le (\tau^+ - \tau^-)^2 \frac{1}{2^{h+2}(\nu+1)\nu\Theta\alpha},\\
|D_{\nu-2}| &\le \int_a^{\tau^+}\left|\mathsf{x}'(t) - \mathsf{x}'(a) - \int_a^t \mathsf{z}'\circ s_n - f'(t)D_{n,\nu-1}\right| dt\\
&\quad + \int_{\tau^+}^b \left|\mathsf{x}'(t) - \mathsf{x}'(b) + \int_t^b \mathsf{z}'\circ s_n - [1-f'(t)]D_{n,\nu-1}\right| dt\\
&\le \int_a^{\tau^+}\int_a^t |\mathsf{x}' - \mathsf{z}'\circ s_n| dt + (\tau^+-\tau^-)|D_{n,\nu-1}| + \int_{\tau^+}^b\int_t^b |\mathsf{x}' - \mathsf{z}'\circ s_n| dt\\
&\le (\tau^+-\tau^-)^3\left[4\alpha(\tau^+-\tau^-)^{\nu-1} + \frac{1}{2^{h+3}(\nu+1)\nu\Theta\alpha}\right] + (\tau^+-\tau^-)|D_{\nu-1}|\\
&\le (\tau^+-\tau^-)^3 \frac{2}{2^{h+2}(\nu+1)\nu\Theta\alpha},\\
&\vdots\\
|D_j| &\le (\tau^+-\tau^-)^{\nu-j+1}\frac{\nu-j}{2^{h+2}(\nu+1)\nu\Theta\alpha} \le (\tau^+-\tau^-)^{\nu-j+1}\frac{1}{2^{h+2}(\nu+1)\Theta}\\
&\qquad\qquad \forall j\in\{0,\dots,\nu-1\},
\end{aligned}$$

so that $||\mathsf{H}'||_\infty \le \sum_{j=0}^{\nu-1} ||f^{(\nu-j+1)}||_\infty(\tau^+-\tau^-)^{\nu-j+1}/[2^{h+2}(\nu+1)\Theta] \le (\tau^+-\tau^-)/2^{h+2}$,

$||\mathsf{H}''||_\infty \le 1/2^{h+2}$, and

$$\begin{aligned}
|\mathsf{z}'(s_n(t)) - \mathsf{x}'(t)| &\le (\tau^+ - \tau^-)\left[3\alpha(\tau^+ - \tau^-)^{\nu+1} + \frac{1}{2^{h+3}(\nu+1)\nu\Theta\alpha}\right] \\
&\le \frac{1}{2^{h+2}(\nu+1)\nu\Theta\alpha}, \\
|z_{n,\nu-1}(t) - x^{(\nu-1)}(t)| &\le \int_a^b |\mathsf{z}' \circ s_n - \mathsf{x}'| + (b-a)|D_{\nu-1}| \le (1+b-a)|D_{\nu-1}| \\
&\le \frac{2\alpha}{2^{h+2}(\nu+1)\nu\Theta\alpha}, \\
&\vdots \\
|z_{n,j}(t) - x^{(j)}(t)| &\le \frac{(\nu-j+1)\alpha}{2^{h+2}(\nu+1)\nu\Theta\alpha} \le \frac{1}{2^{h+2}} \qquad \forall j \in \{0,\dots,\nu-1\}.
\end{aligned}$$

Hence, we can fix n such that $M\Psi|\Sigma_n| < \bar{\epsilon}/8$, $||z_n^{(j)} - x^{(j)}||_\infty \le 1/2^{h+1}$, and

$$||z_n^{(j)} \circ t_n - x^{(j)}||_\infty \le ||z_n^{(j)} \circ t_n - x^{(j)} \circ t_n||_\infty + ||x^{(j)} \circ t_n - x^{(j)}||_\infty \le 1/2^h,$$

for any j in $\{0,\dots,\nu\}$. The graph of the function $(\mathbf{z}_n, \mathsf{z}_n')$ is included in $\mathsf{T}_\delta^\nu[x]$, and $\mathsf{z}_n''(t) \in B[0, |\mathsf{x}''(\tau)| + \delta]$, for any t in $[\tau^-, \tau^+]$. (From what follows, it turns out that z_n is the sought variation x_ϵ.)

(c) We show that $\tilde{\mathcal{I}}_i(z_n) < \tilde{\mathcal{I}}_i(x) + \bar{\epsilon}/2$, for any i.

Using the change of variable formula [16], we compute $\tilde{\mathcal{I}}_i(z_n) - \tilde{\mathcal{I}}_i(x)$ as the sum of the following three appropriate terms:

$$\begin{aligned}
&\int_a^b \tilde{L}_i(\mathsf{z}_n'(t_n(s)), \mathsf{z}_n''(t_n(s)))\psi_i(t_n(s), \mathbf{z}_n(t_n(s)), \mathsf{z}_n'(t_n(s)))t_n'(s)ds \\
&- \int_a^b \tilde{L}_i(\mathsf{x}'(s), \mathsf{x}''(s))\psi_i(s, \mathbf{x}(s), \mathsf{x}'(s))ds \\
&= \int_a^b \left[\tilde{L}_i\left(\mathsf{z}_n'(t_n(s)), \mathsf{z}_n''(t_n(s))\right)t_n'(s) - \tilde{L}_i(\mathsf{z}_n'(t_n(s)), \mathsf{z}''(s) + t_n'(s)\mathsf{H}''(t_n(s)))\right] \\
&\qquad \times \psi_i(t_n(s), \mathbf{z}_n(t_n(s)), \mathsf{z}_n'(t_n(s)))ds \\
&\quad + \int_a^b \tilde{L}_i(\mathsf{z}_n'(t_n(s)), \mathsf{z}''(s) + t_n'(s)\mathsf{H}''(t_n(s))) \\
&\qquad \times [\psi_i(t_n(s), \mathbf{z}_n(t_n(s)), \mathsf{z}_n'(t_n(s))) - \psi_i(s, \mathbf{x}(s), \mathsf{x}'(s))]ds \\
&\quad + \int_a^b \left[\tilde{L}_i\left(\mathsf{z}_n'(t_n(s)), \mathsf{z}''(s) + t_n'(s)\mathsf{H}''(t_n(s))\right) - \tilde{L}_i(\mathsf{x}'(s), \mathsf{x}''(s))\right]\psi_i(s, \mathbf{x}(s), \mathsf{x}'(s))ds \\
&= I_i^1 + I_i^2 + I_i^3.
\end{aligned}$$

To estimate I_i^1, it is enough to estimate its integrand over the sets S_n and Σ_n (because it is identically 0 elsewhere). Since $\Sigma_n \subset T$ and $||\mathsf{H}''||_\infty \le \delta$, we obtain that

$$\begin{aligned}
&\tilde{L}_i\left(\mathsf{z}'(s) + \mathsf{H}'(t_n(s)), 2\mathsf{z}''(s) + \mathsf{H}''(t_n(s))\right)\frac{1}{2} \\
&- \tilde{L}_i\left(\mathsf{z}'(s) + \mathsf{H}'(t_n(s)), \mathsf{z}''(s) + \frac{\mathsf{H}''(t_n(s))}{2}\right) \le M,
\end{aligned}$$

for every s in Σ_n. By Propositions 3 and 4 in [5], for every s in S_n,

$$\tilde{L}_i\left(\mathsf{z}_n'(t_n(s)), n\frac{\mathsf{z}''(s)+t_n'(s)\mathsf{H}''(t_n(s))}{|\mathsf{z}''(s)|}\right)\frac{|\mathsf{z}''(s)|}{n}$$
$$-\tilde{L}_i(\mathsf{z}_n'(t_n(s)), \mathsf{z}''(s)+t_n'(s)\mathsf{H}''(t_n(s)))\le -\left(\frac{|\mathsf{z}''(s)|}{n}-1\right)\tilde{L}_i^*(\mathsf{z}_n'(t_n(s)),p)\le 0,$$

where $p\in\partial_w L_i(\mathsf{z}_n'(t_n(s)), n(\mathsf{z}''(s)+t_n'(s)\mathsf{H}''(t_n(s)))/|\mathsf{z}''(s)|)$. Using the fact that ψ_i is positive and bounded by Ψ, we have $I_i^1\le M\Psi|\Sigma_n|<\bar\epsilon/8$.

To estimate I_i^2, we observe that

$$\tilde{L}_i(\mathsf{z}_n'(t_n(s)), \mathsf{z}''(s)+t_n'(s)\mathsf{H}''(t_n(s)))=\begin{cases}\tilde{L}_i(\mathsf{z}_n'(s), \mathsf{z}''(s)+\mathsf{H}''(s)), & s\in[\tau^-,\tau^+],\\ \tilde{L}_i(\mathsf{x}'(s),\mathsf{x}''(s)), & \text{otherwise.}\end{cases}$$

By the fact that $|\psi_i(t_n(s),\mathbf{z}_n(t_n(s)),\mathsf{z}_n'(t_n(s)))-\psi_i(s,\mathbf{x}(s),\mathsf{x}'(s))|\le\bar\epsilon/[8(\ell+\tilde{\mathbf{L}}+1)]$, for any s in $[a,b]$, and that $\mathsf{z}''+\mathsf{H}''\in B[0,|\mathsf{x}''(\tau)|+\delta]$ on $[\tau^-,\tau^+]$, we have $I_i^2\le\bar\epsilon/8$.

To estimate I_i^3, it is enough to estimate the integrals over $[\tau^-,\tau^+]$ (because it is identically 0 elsewhere). Recalling that τ is a Lebesgue point for $\tilde{L}_i(\mathsf{x}'(\cdot),\mathsf{x}''(\cdot))\psi_i(\cdot,\mathbf{x}(\cdot),\mathsf{x}'(\cdot))$, we have

$$\begin{aligned}I_i^3&\le\int_{\tau^-}^{\tau^+}[\tilde{L}_i(\mathsf{z}_n'(s),\mathsf{z}''(s)+\mathsf{H}''(s))\psi_i(s,\mathbf{x}(s),\mathsf{x}'(s))\\&\qquad-\tilde{L}_i(\mathsf{x}'(\tau),\mathsf{x}''(\tau))\psi_i(\tau,\mathbf{x}(\tau),\mathsf{x}'(\tau))]ds+\frac{\bar\epsilon}{8}\\&\le 4\rho\tilde{\mathbf{L}}\Psi+\frac{\bar\epsilon}{8}<\frac{\bar\epsilon}{4}.\end{aligned}$$

Hence, $I_i^1+I_i^2+I_i^3<\bar\epsilon/2$, for any i.

Conclusion. We have obtained

$$\begin{aligned}&\int_a^b L_i(\mathsf{z}_n'(t),\mathsf{y}_n''(t))\psi_i(t,\mathbf{z}_n(t),\mathsf{z}_n'(t))dt-\int_a^b L_i(\mathsf{x}'(t),\mathsf{x}''(t))\psi_i(t,\mathbf{x}(t),\mathsf{x}'(t))dt\\&<\int_a^b[L_i(\mathsf{z}_n'(t),\mathsf{z}_n''(t))+\eta]\psi_i(t,\mathbf{z}_n(t),\mathsf{z}_n'(t))dt\\&\quad-\int_a^b[L_i(\mathsf{x}'(t),\mathsf{x}''(t))+\eta]\psi_i(t,\mathbf{x}(t),\mathsf{x}'(t))dt+\frac{\bar\epsilon}{2}\\&=\int_a^b\tilde{L}_i(\mathsf{z}_n'(t),\mathsf{z}_n''(t))\psi_i(t,\mathbf{z}_n(t),\mathsf{z}_n'(t))dt-\int_a^b\tilde{L}_i(\mathsf{x}'(s),\mathsf{x}''(s))\psi_i(s,\mathbf{x}(s),\mathsf{x}'(s))ds+\frac{\bar\epsilon}{2}\\&<\bar\epsilon.\end{aligned}$$

Hence, $\mathcal{I}(z_n)-\mathcal{I}(x)<\sum_{i=1}^m\bar\epsilon=\epsilon$.

So, setting $x_\epsilon=z_n$, we have proved the theorem.

4. A necessary condition for the Lavrentiev phenomenon. The content of this section is provided to show the following necessary condition: a functional

$$\mathcal{I}(x)=\int_a^b\sum_{i=1}^m L_i(x^{(\nu)},x^{(\nu+1)})\psi_i(t,x,x',\dots,x^{(\nu)}),$$

with $\nu \geq 0$, exhibiting the Lavrentiev phenomenon takes the value $+\infty$ in any neighborhood of a minimizer $\bar{x}$; or equivalently if $\mathcal{I}$ assumes only finite values on a neighborhood of $\bar{x}$, then $\mathcal{I}$ does not exhibit the Lavrentiev phenomenon.

This is proved in the following corollary to Theorem 2.1 and Theorem 1 in [5].

COROLLARY 4.1. *Let $\Omega_0, \ldots, \Omega_\nu$ be open sets in $\mathbb{R}^N$, $\nu \geq 0$, such that the set $E = \{x \in \mathbf{W}^{\nu+1,1}(a,b) : x(t) \in \Omega_0, \ \ldots, \ x^{(\nu)}(t) \in \Omega_\nu \ \forall t \in [a,b]\}$ is nonempty. Let $A, B \in \Omega_0$, $A^{(1)}, B^{(1)} \in \Omega_1, \ \ldots, \ A^{(\nu)}, B^{(\nu)} \in \Omega_\nu$ be given boundary values.*

Let $L_1, \ldots, L_m : \Omega_\nu \times \mathbb{R}^N \to \mathbb{R}$ and $\psi_1, \ldots, \psi_m : [a,b] \times \Omega_0 \times \cdots \times \Omega_\nu \to [0, +\infty)$ be continuous and such that $L_i(\xi, \cdot)$ is convex, for any ξ in Ω_ν, any i in $\{1, \ldots, m\}$.

Let

$$\mathcal{I}(x) = \int_a^b \sum_{i=1}^m L_i(x^{(\nu)}(t), x^{(\nu+1)}(t))\psi_i(t, x(t), x'(t), \ldots, x^{(\nu)}(t))dt$$

be a functional exhibiting the Lavrentiev phenomenon, and let $\bar{x}$ be a minimum of $\mathcal{I}$ over $E_{a,b} = \{x \in E : x(a) = A, \ x(b) = B, \ x'(a) = A^{(1)}, \ x'(b) = B^{(1)}, \ \ldots, \ x^{(\nu)}(a) = A^{(\nu)}, \ x^{(\nu)}(b) = B^{(\nu)}\}$.

Assume that for any $\delta > 0$ there exists $\sigma_\delta > 0$ such that $\sigma_\delta \to 0$, for $\delta \to 0$, and that ψ_i restricted to $\mathsf{T}^\nu_\delta[\bar{x}]$ may vanish only on the graph of $(\bar{x}, \bar{x}', \ldots, \bar{x}^{(\nu)})$ or on a σ_δ-neighborhood of $(a, A, \ldots, A^{(\nu)})$ or on a σ_δ-neighborhood of $(b, B, \ldots, B^{(\nu)})$, for any i in $\{1, \ldots, m\}$.

Then, for any $\epsilon > 0$, there exists x_ϵ in $E_{a,b}$ such that the graph of $(x_\epsilon, x'_\epsilon, \ldots, x^{(\nu)}_\epsilon)$ is included in $\mathsf{T}^\nu_\epsilon[\bar{x}]$ and $\mathcal{I}(x_\epsilon) = +\infty$.

Proof. Fix $\epsilon > 0$. From Theorem 2.1 and Theorem 1 in [5], it follows that $\int_a^b |L_i(\bar{x}^{(\nu)}, \bar{x}^{(\nu+1)})| = +\infty$, for at least one i in $\{1, \ldots, m\}$.

Without loss of generality, we suppose that $\int_a^{(a+b)/2} |L_i(\bar{x}^{(\nu)}, \bar{x}^{(\nu+1)})| = +\infty$.

Let $g : (-\infty, +\infty) \to [0,1]$ be a $\mathbf{C}^\infty$ increasing function with value 1 on $[b, +\infty)$ and 0 on $(-\infty, (a+b)3/4]$. We define the integrable function $x_{\delta,\nu+1} : [a,b] \to \mathbb{R}^N$ by

$$x_{\delta,\nu+1}(t) = \begin{cases} 0, & t \in [a, a+\sigma_\delta), \\ \bar{x}^{(\nu+1)}(t - \sigma_\delta), & \text{otherwise}, \end{cases}$$

and ν absolutely continuous functions $x_{\delta,j}(t) = A^{(j)} + \int_a^t x_{\delta,j+1} + g(t)D_{\delta,j}$, for any t in $[a,b]$, where $D_{\delta,j} = B^{(j)} - A^{(j)} - \int_a^b x_{\delta,j+1}$, for any j in $\{0, \ldots, \nu\}$.

Set $x_\delta = x_{\delta,0}$. The derivatives of x_δ up to the order $\nu + 1$ are

$$\begin{aligned} x'_\delta(t) &= x_{\delta,1}(t) + g'(t)D_{\delta,0}, \\ x''_\delta(t) &= x_{\delta,2}(t) + g''(t)D_{\delta,0} + g'(t)D_{\delta,1}, \\ &\vdots \\ x^{(\nu+1)}_\delta(t) &= x_{\delta,\nu+1}(t) + \textstyle\sum_{j=0}^\nu g^{(\nu-j+1)}(t)D_{\delta,j}. \end{aligned}$$

By definition, x_δ belongs to $\mathbf{W}^{\nu+1,1}(a,b)$, it has the same boundary values of $\bar{x}$ in a and in b, and, for j in $\{\nu, \nu+1\}$, for any t in $[a+\sigma_\delta, (a+b)3/4]$, we have $x^{(j)}_\delta(t) = \bar{x}^{(j)}(t - \sigma_\delta)$. Furthermore, there exist constants c_j, d_j, independent on δ, such that $|D_{\delta,j}| \leq c_j \int_{b-\sigma_\delta}^b |\bar{x}^{(\nu+1)}|$ and $||x_{\delta,j} - x^{(j)}_\delta||_\infty \leq d_j \int_{b-\sigma_\delta}^b |\bar{x}^{(\nu+1)}|$. Hence, for any j in $\{0, \ldots, \nu\}$,

$$||\bar{x}^{(j)} - x^{(j)}_\delta||_\infty \leq \left(c_j + ||g^{(\nu+1)}||_\infty \sum_{j=0}^\nu d_j \right) \int_{b-\sigma_\delta}^b |\bar{x}^{(\nu+1)}|.$$

By hypothesis, we can choose $\bar\delta > 0$ such that $(c_j + ||g^{(\nu+1)}||_\infty \sum_{j=0}^{\nu} d_j) \int_{b-\sigma_{\bar\delta}}^{b} |\bar x^{(\nu+1)}| < \epsilon$ and $\sigma_{\bar\delta} < (b-a)/4$.

Set $\Psi_i = \min\{\psi_i(t, x_{\bar\delta}(t), \dots, x_{\bar\delta}^{(\nu)}(t)) : t \in [a+\sigma_{\bar\delta}, (a+b)3/4]\}$: by hypothesis, Ψ_i is positive. We have obtained that the graph of $(x_{\bar\delta}, x'_{\bar\delta}, \dots, x_{\bar\delta}^{(\nu)})$ belongs to $\mathsf{T}_\epsilon^\nu[\bar x]$ and

$$\begin{aligned}
&\int_a^b |L_i(x_{\bar\delta}^{(\nu)}(t), x_{\bar\delta}^{(\nu+1)}(t))\psi_i(t, x_{\bar\delta}(t), \dots, x_{\bar\delta}^{(\nu)}(t))|dt \\
&\geq \int_{a+\sigma_{\bar\delta}}^{(a+b)3/4} |L_i(\bar x^{(\nu)}(t-\sigma_{\bar\delta}), \bar x^{(\nu+1)}(t-\sigma_{\bar\delta}))|\psi_i(t, x_{\bar\delta}(t), \dots, x_{\bar\delta}^{(\nu)}(t))dt \\
&\geq \Psi_i \int_a^{(a+b)/2} |L_i(\bar x^{(\nu)}(t), \bar x^{(\nu+1)}(t))|dt = +\infty.
\end{aligned}$$

From (i) in the proof of Theorem 2.1 and Theorem 1 in [5], we infer that $\mathcal{I}(x_{\bar\delta}) = +\infty$.

So, setting $x_\epsilon = x_{\bar\delta}$, we have proved the corollary. □

The corollary above applies to the functionals of Manià and Sarychev, for instance, and to the examples of functionals exhibiting the Lavrentiev phenomenon proposed in [3], [4], [11], [12], [13], [14], and [15].

Acknowledgment. We thank the anonymous referees for many interesting comments.

TIME-OPTIMAL SYNTHESIS FOR LEFT-INVARIANT CONTROL SYSTEMS ON $SO(3)$*

UGO BOSCAIN† AND YACINE CHITOUR‡

Abstract. Consider the control system (Σ) given by $\dot{x} = x(f + ug)$, where $x \in SO(3)$, $|u| \leq 1$, and $f, g \in so(3)$ define two perpendicular left-invariant vector fields normalized so that $\|f\| = \cos(\alpha)$ and $\|g\| = \sin(\alpha)$, $\alpha \in]0, \pi/4[$. In this paper, we provide an upper bound and a lower bound for $N(\alpha)$, the maximum number of switchings for time-optimal trajectories of (Σ). More precisely, we show that $N_S(\alpha) \leq N(\alpha) \leq N_S(\alpha) + 4$, where $N_S(\alpha)$ is a suitable integer function of α such that $N_S(\alpha) \underset{\alpha \to 0}{\sim} \pi/(4\alpha)$. The result is obtained by studying the time-optimal synthesis of a projected control problem on $\mathbb{R}P^2$, where the projection is defined by an appropriate Hopf fibration. Finally, we study the projected control problem on the unit sphere S^2. It exhibits interesting features which will be partly rigorously derived and partially described by numerical simulations.

Key words. optimal control, optimal synthesis, minimum time, $SO(3)$

1. Introduction.

Let (Σ) be the control system given by

$$\dot{x} = x(f + ug), \tag{1.1}$$

where $x \in SO(3)$, $|u| \leq 1$, and $f, g \in so(3)$ give rise to two nonzero perpendicular left-invariant vector fields on $SO(3)$. In this paper, we consider the following problem: given any pair of points x_1, x_2 of $SO(3)$, find a trajectory of (1.1) steering x_1 to x_2 in minimum time. That issue is known as the problem of determining the time-optimal synthesis (TOS) for (Σ). The strategy to determine a TOS usually consists of two steps:

1. Reduction procedure: it is based on the Pontryagin maximum principle (PMP) which is a first-order necessary condition for optimality. Roughly speaking, the PMP reduces the candidates for time optimality to the so-called extremals, which are solutions of a pseudo-Hamiltonian system. This reduction procedure may be refined using higher-order conditions, such as Clebsch–Legendre conditions, higher-order maximum principle, envelopes, conjugate points, and index theory (cf. for instance [2, 3, 5, 12, 18, 19, 21, 26, 27, 28, 30, 32, 33, 34, 35]).
2. Selection procedure: it consists of selecting the time-optimal trajectories among the extremals that passed the test of Step 1 (see for instance [8, 12, 16, 25]).

Step 1 is already nontrivial and, in general, the second one is extremely difficult: if the state space is two dimensional, the problem of determining the TOS for single-input control systems is now well understood [9, 11, 12, 14, 15, 23, 24, 32, 33]. However, for higher dimensions, very few examples of complete TOS for a nonlinear control system are available (see for instance [29]). Intermediate issues were thus deeply investigated:

determining estimates for the number of switchings of optimal trajectories, describing the local structure of optimal trajectories, finding families of trajectories sufficient for optimality (cf. [6, 13, 19, 22, 26, 28, 36]), etc.

For the control system (Σ), we normalize the two perpendicular vector fields induced by f and g in such a way that $\|f\| = \cos(\alpha)$, $\|g\| = \sin(\alpha)$, with $\alpha \in]0, \pi/2[$ (for the precise meaning of "perpendicular" and of the symbol $\|.\|$, we refer to section 2.1). Defining $X_+ := f + g$ and $X_- := f - g$, we have $\|X_+\| = \|X_-\| = 1$ and α is the angle between f and X_+.

By a standard argument (see section 2 below), one can show that every time optimal trajectory is a finite concatenation of bang arcs (i.e., $u \equiv \pm 1$) or singular arcs ($u = 0$) the Fuller phenomenon (i.e., existence of a trajectory of a control system joining two points in (finite) minimum time, with an infinite number of switchings, cf. [20,37]) never occurs. (A switching time—or simply a switching—along an extremal is a time t_0 so that the control u is not constant in any open neighborhood of t_0.) Moreover, one can easily show that the supremum $N(\alpha)$ of the number of switchings over all time optimal trajectories of (Σ) is finite.

By using the index theory developed by Agrachev, it is proved in [3] that

$$N(\alpha) \leq N_A := \left[\frac{\pi}{\alpha}\right], \tag{1.2}$$

where $[\cdot]$ stands for the integer part. That result was not only an indirect indication that $N(\alpha)$ would tend to ∞ as α tends to zero, but it also provided a hint on the asymptotic of $N(\alpha)$ as α tends to zero.

A related line of work regards the study of the distributional version of (Σ), which is the driftless control system given by $\dot{x} = x(u_1 f_1 + u_2 f_2)$, $|u_1|, |u_2| \leq 1$, and $f_1, f_2 \in so(3)$ linearly independent. Indeed, assuming that $\|f_1\| = \|f_2\|$, Sussmann and Tang [36] showed that time-optimal trajectories have at most four switchings and they provided a finitely parametrized family of trajectories sufficient for optimality. That result was extended to the general case (f_1 and f_2 just linearly independent; cf. [13]): time-optimal trajectories have at most five switchings. For both works, the elimination from optimality of extremals with, respectively, five or six bangs relies on the envelope theory developed in the context of control theory by Sussmann (cf. [35]).

In light of the previous results, there was strong evidence for two radically situations as α tends to zero: for (Σ), $N(\alpha)$ is expected to go to infinity, and as for the distributional control system, there exists a universal bound on the number of switchings. The main result of the present paper confirms that difference, i.e., $N(\alpha)$ tends to ∞ as α tends to zero. More precisely, we complete the inequality (1.2) as follows.

THEOREM 1. *Let (Σ) be the control system defined in (1.1) with f, g perpendicular so that $\|f\| = \cos(\alpha)$ and $\|g\| = \sin(\alpha)$, $\alpha \in]0, \pi/4[$. Then, if $N(\alpha)$ is the maximum number of switchings along a time-optimal trajectory of (Σ), we have*

$$N_S(\alpha) \leq N(\alpha) \leq N_S(\alpha) + 4, \text{ where } N_S(\alpha) := 2\left[\frac{\pi}{8\alpha}\right] - \left[2\left[\frac{\pi}{8\alpha}\right] - \frac{\pi}{4\alpha}\right]. \tag{1.3}$$

The above theorem improves (1.2) in two ways: (i) for α small, it (essentially) divides the upper bound of $N(\alpha)$ by four with respect to (1.2); and (ii) it provides a lower bound of $N(\alpha)$ differing from the upper bound by a constant.

The lower bound is in fact our main contribution and, to get it, one must prove the existence of time-optimal trajectories of (Σ) admitting at least a number of switchings equal to that lower bound. Our strategy consists of projecting the control problem

onto another $(\Sigma)_S$ defined next. First, let $\mathbb{R}P^2$ be the two-dimensional real projective space (i.e., the two-dimensional manifold made of the directions of $\mathbb{R}^3$) and fix a point $x_0 \in SO(3)$. Consider the Hopf fibration $\Pi : SO(3) \to \mathbb{R}P^2$ defined by $\mathrm{Ker} d\Pi(x_0) = Span\{x_0 f\}$, which means, roughly speaking, that Π annihilates the drift term f at x_0. Then, we project (Σ) by Π and obtain a single-input $SO(3)$-equivariant control system $(\Sigma)_S$ on $\mathbb{R}P^2$ given by $\dot{y} = y(f_S + u g_S)$, with $f_S = d\Pi(f)$ and $g_S = d\Pi(g)$, that is locally controllable. We then consider the minimum time problem for connecting $\Pi(x_0)$ to any other point of $\mathbb{R}P^2$.

In fact, we study a slightly different time optimal problem by lifting $(\Sigma)_S$ to the unit sphere S^2. By an abuse of notation, we still denote by $(\Sigma)_S$ the control system obtained in that way. Hence $\Pi(x_0)$ is identified with the north pole and $\mathbb{R}P^2$ is identified with $\underline{\mathcal{NH}}$, the subset of the sphere made of the union of $\mathcal{NH}$, the (open) top hemisphere of S^2, together with half of the equator.

The time optimal problem now consists of connecting, in minimum time, the north pole to any point of $\underline{\mathcal{NH}}$. Thanks to the suitable choice of the Hopf projection and since α belongs to the interval $]0, \pi/4[$, all extremals of the projected problem are bang-bang (i.e., they are a finite concatenation of trajectories corresponding to controls $+1$ or -1). Let $N_S(\alpha)$ be the supremum of the number of switchings for time-optimal trajectories of $(\Sigma)_S$ starting at the north pole and ending in $\underline{\mathcal{NH}}$ (such trajectories of $(\Sigma)_S$ are actually entirely contained in $\underline{\mathcal{NH}}$, see Lemma 7).

The use of the Hopf fibration Π is motivated by two facts: first, every time-optimal trajectory for the time optimal problem on $(\Sigma)_S$ staying in $\underline{\mathcal{NH}}$ is the projection by Π of a time-optimal trajectory for the time optimal problem on (Σ) and thus $N_S(\alpha) \leq N(\alpha)$. Taking full advantage of the theory developed in [12], we will actually compute *exactly* $N_S(\alpha)$ as given in (1.3). Second, using the fact that the fiber above $\Pi(x_0)$ is the support of a singular arc (for this problem singular arcs are integral curves of the drift xf), we show that every regular bang-bang trajectory with at least $N_S(\alpha) + 5$ cannot be optimal and thus, the upper bound.

It is then clear, by now, that the most delicate part of the argument relies on the exact determination of $N_S(\alpha)$. This is done by studying the TOS for the time optimal problem on $(\Sigma)_S$. Such a TOS is usually constructed, following the theory developed in [9, 11, 12, 14, 15, 23, 24, 32, 33], recursively on the number of extremals arcs, and by checking at each step whether they are optimal or not. For the problem on $\mathbb{R}P^2$, we are not able to complete all the steps of the above construction, which would imply as a by-product the existence of the TOS. In particular, we cannot show the optimality of all the extremals (i.e., the trajectories candidate for time optimality), but, from their study, we can demonstrate enough partial results in order to compute $N_S(\alpha)$ precisely and thus to conclude the proof of Theorem 1.

The complete time-optimal synthesis is then studied numerically (actually on the whole S^2) and is shown on the top of Figure 5.2. In particular, due to the compactness of S^2, one of the main issues is to understand the singularities developed by the minimum time wave front as it approaches the south pole. We provide numerical simulations that describe the evolution of the extremal front. As $\alpha \to 0$, these numerical simulations suggest the emergence of three cyclically alternating patterns of optimal synthesis, each of them depending on an arithmetic property of α.

The rest of the paper is organized as follows. Section 2 collects basic facts relative to the time-optimal trajectories of (Σ), and in section 3, the Hopf fibration is described and the proof of Theorem 1 is provided, assuming some facts about the time-optimal synthesis of $(\Sigma)_S$, whose arguments are deferred to the next section. In particular

we use the expression for $N_S(\alpha)$ and the relation between the length of interior bang arcs for the problem on $\mathbb{R}P^2$. The construction of the time-optimal synthesis of $(\Sigma)_S$ is investigated in section 4, where an exact computation of $N_S(\alpha)$ is established. We conclude the section with two remarks, the first one explaining the relation between the TOS on the sphere and the TOS of a controlled linear pendulum, and the second one establishing a link with an optimal control problem on $SU(2)$. Finally, in section 5, we provide the results of the numerical simulations, completing the study of the time-optimal synthesis (in particular of the possible behavior in a neighborhood of the south pole), and we propose some open problems stated as conjectures.

2. Statement of the problem and properties of optimal trajectories.

2.1. Basic facts. In this paper, we consider the control (Σ) given by (1.1), where $x \in SO(3)$, $|u| \leq 1$, and $f, g \in so(3)$. An admissible control u is a measurable function $u : [a, b] \to [-1, 1]$, where a, b depend (in general) on u; cf. [18]. A trajectory γ of (Σ) is an absolutely continuous curve $\gamma : J \to SO(3)$, where $J = [a, b]$ is a compact segment of $\mathbb{R}$ such that there exists an admissible control u for which $\dot\gamma(t) = \gamma(t)(f + u(t)g)$ holds a.e. in J. We then say that (γ, u), defined as before, is an admissible pair for (Σ).

Definition 1. *A trajectory γ of (Σ), defined on $[a, b]$, is time optimal if for every trajectory γ' of (Σ) defined on $[a', b']$ with $\gamma(a) = \gamma'(a')$ and $\gamma(b) = \gamma'(b')$, we have $b - a \leq b' - a'$.*

The Lie algebra $(so(3), [.,.])$ is isomorphic to the Lie algebra $(\mathbb{R}^3, \times)$, where $\times$ denotes the vector product. This isomorphism is realized by the map

$$\phi_L : so(3) \to \mathbb{R}^3 \tag{2.1}$$
$$\phi_L\left(\begin{pmatrix} 0 & -c & b \\ c & 0 & -a \\ -b & a & 0 \end{pmatrix}\right) := \begin{pmatrix} a \\ b \\ c \end{pmatrix},$$

and provides an inner product on $so(3)$ given by $\langle z_1, z_2\rangle := \langle \phi_L(z_1), \phi_L(z_2)\rangle$, where $z_1, z_2 \in so(3)$. The symbol $\langle .,.\rangle$ on the right-hand side of the above equation stands for the Euclidean inner product of $\mathbb{R}^3$. With this definition, it follows that $\langle z_1, z_2\rangle := -\frac{1}{2}Tr(z_1 z_2)$. In other words, this scalar product is the opposite of the Killing form on $so(3)$. In the following, $\|z\| := \sqrt{\langle z, z\rangle}$ and Id is the 3×3 identity matrix. We will sometimes consider the 2×2 matrix corresponding to the planar rotation of angle β and we use R_β to denote it.

In this paper, we will assume that f and g are perpendicular and normalized so that $\|f\| = \cos(\alpha)$ and $\|g\| = \sin(\alpha)$, $\alpha \in]0, \pi/2[$. Here, we adopt the following notation used throughout the paper, $c_\alpha := \cos(\alpha)$, $c_\alpha^2 := \cos^2(\alpha)$, $s_\alpha := \sin(\alpha)$, and $s_\alpha^2 := \sin^2(\alpha)$. We define $h := [f, g] = fg - gf$ and

$$X_+ := f + g, \quad X_- := f - g.$$

Note that $\|X_\varepsilon\| = 1$, with $\varepsilon = +, -$. For a vector field $z \in so(3)$, we use e^{tz} to denote the flow of z, acting on the right, so that $t \mapsto pe^{tz} \in SO(3)$ is the integral curve of z starting at p at time 0. Since z is linear, we have $e^{tz} = \sum_{n=0}^{\infty} \frac{(tz)^n}{n!}$. We use ad_z to denote the operator $w \mapsto [z, w]$, acting on vector fields. If z, w are vector fields, then $e^{t \operatorname{ad}_z}(w) := e^{tz} w e^{-tz}$. The Lie bracket relations between f, g, h are

$$[f, g] = h, \quad [g, h] = s_\alpha^2 f, \quad [h, f] = c_\alpha^2 g.$$

From them, one deduces the following classical relations that will be useful later:

$$e^{t\ \mathrm{ad}X_\varepsilon}(f) = (c_\alpha^2 + s_\alpha^2\cos(t))f + \varepsilon c_\alpha^2(1-\cos(t))g - \varepsilon\sin(t)h, \tag{2.2}$$

$$e^{t\ \mathrm{ad}X_\varepsilon}(g) = \varepsilon s_\alpha^2(1-\cos(t))f + (s_\alpha^2 + c_\alpha^2\cos(t))g + \sin(t)h, \tag{2.3}$$

$$e^{t\ \mathrm{ad}X_\varepsilon}(h) = \varepsilon s_\alpha^2\sin(t)f - c_\alpha^2\sin(t)g + \cos(t)h, \tag{2.4}$$

$$e^{t\ \mathrm{ad}X_\varepsilon}(X_{-\varepsilon}) = (\cos(2\alpha) + 2s_\alpha^2\cos(t))f + \varepsilon(\cos(2\alpha) - 2c_\alpha^2\cos(t))g - 2\varepsilon\sin(t)h, \tag{2.5}$$

$$e^{tX_\varepsilon} = Id + \sin(t)X_\varepsilon + (1-\cos(t))X_\varepsilon^2, \tag{2.6}$$

$$e^{tadf}(g) = \cos(tc_\alpha)g + \frac{\sin(tc_\alpha)}{c_\alpha}h. \tag{2.7}$$

2.2. Existence of optimal trajectories. A control system is *complete* if, for every measurable control function $u : [a,b] \to [-1,1]$ and every initial state p, there exists a trajectory γ corresponding to u, which is defined on the whole interval $[a,b]$ and satisfies $\gamma(a) = p$. Since $SO(3)$ is compact and the function $\mathcal{F}(x,u) := x(f+ug)$ is regular enough, the system (1.1) is complete. Note that (f,g) satisfies the strong bracket generating condition (cf. [31]) and the set of velocities $V(x) := \{x(f+ug),\ u \in [-1,1]\}$ is compact and convex. Then (cf. for instance [36]) we have the following proposition.

PROPOSITION 1. *For each pair of points p and q belonging to $SO(3)$, there exists a time-optimal trajectory joining p to q.*

2.3. Pontryagin maximum principle and switching functions. We next state the PMP (cf. [26]) for our minimum time problem on $SO(3)$. Define the following maps called, respectively, *Hamiltonian* and *minimized Hamiltonian*:

$$\mathcal{H} : T^*SO(3) \times [-1,1] \to \mathbb{R}, \quad \mathcal{H}(p,x,u) := \langle p, x(f+ug)\rangle, \tag{2.8}$$

$$H : T^*SO(3) \to \mathbb{R}, \quad H(p,x) := \min_{v\in[-1,1]} \mathcal{H}(p,x,v). \tag{2.9}$$

The PMP asserts that if $\gamma : [a,b] \to SO(3)$ is a time-optimal trajectory corresponding to a control $u : [a,b] \to [-1,1]$, then there exists a *nontrivial field of covectors along* γ, that is an absolutely continuous function $\lambda : t \in [a,b] \mapsto \lambda(t) \in T^*_{\gamma(t)}SO(3)$ (identified with $so(3)$) never vanishing and a constant $\lambda_0 \geq 0$ such that, for a.e. $t \in Dom(\gamma)$, we have

(i) $\dot\lambda(t) = -\frac{\partial\mathcal{H}}{\partial x}(\lambda(t),\gamma(t),u(t)) = -\lambda(t)(f+u(t)g)$,
(ii) $\mathcal{H}(\gamma(t),\lambda(t),u(t)) + \lambda_0 = 0$,
(iii) $\mathcal{H}(\gamma(t),\lambda(t),u(t)) = H(\gamma(t),\lambda(t))$.

Remark 1. The PMP is just a necessary condition for optimality. A trajectory γ (resp., a couple (γ,λ)) satisfying the conditions given by the PMP is said to be an *extremal* (resp., an *extremal pair*). An extremal corresponding to $\lambda_0 = 0$ is said to be an *abnormal extremal*, otherwise we call it a *normal extremal*. For a normal extremal, we can always normalize $\lambda_0 = 1$, and we do this all through the paper. Note that in general an extremal corresponds to more than one covector. For this reason, usually, one distinguishes between abnormal extremals that are *strict* (i.e., they correspond only to covectors satisfying $\lambda_0 = 0$) and abnormal extremals that are *nonstrict* (i.e., they correspond to covectors with $\lambda_0 = 0$ and to covectors with $\lambda_0 \neq 0$).

A control $u : [a,b] \to [-1,1]$ is said to be *bang-bang* if $u(t) \in \{-1,1\}$ a.e. in $[a,b]$. Moreover, if $u(t) \in \{-1,1\}$ and $u(t)$ is constant for almost every $t \in [a,b]$, then u is called a bang control. A *switching* time of u is a time $t \in [a,b]$ such that, for

every $\varepsilon > 0$, u is not bang on $(t-\varepsilon, t+\varepsilon) \cap [a,b]$. A control with a finite number of switchings is called *regular bang-bang*. A trajectory of Σ is a bang trajectory, bang-bang trajectory, or regular bang-bang trajectory, respectively, if it corresponds to a bang control, bang-bang control, or regular bang-bang control. The *switching functions*, associated with an extremal pair (γ, λ), are the three "components" of the covector $\lambda(t)$ on the basis $\{f, g, h\}$ transported to the point $\gamma(t)$. More precisely we have the following definition.

DEFINITION 2 (switching functions). *Let $\Phi_i(x,p)$ $(i = 1,2,3)$ be the Hamiltonian functions corresponding, respectively, to the vector fields f, g, h (cf.* [18]*), i.e., $\Phi_1(x,p) := \langle p, xf\rangle$, $\Phi_2(x,p) := \langle p, xg\rangle$, $\Phi_3(x,p) := \langle p, xh\rangle$ and (γ, λ) be an extremal pair. The switching functions associated with (γ, λ) are the evaluations of $\Phi_i(x,p)$ along the extremal, i.e.,*

$$\varphi_1(t) := \Phi_1(\gamma(t), \lambda(t)) = \langle \lambda(t), \gamma(t) f\rangle, \tag{2.10}$$

$$\varphi_2(t) := \Phi_2(\gamma(t), \lambda(t)) = \langle \lambda(t), \gamma(t) g\rangle, \tag{2.11}$$

$$\varphi_3(t) := \Phi_3(\gamma(t), \lambda(t)) = \langle \lambda(t), \gamma(t) h\rangle. \tag{2.12}$$

Remark 2. Note that the φ_i's are at least continuous and since λ never vanishes, the three switching functions cannot be all zero at the same time t. Moreover, using the switching functions, (ii) of PMP reads

$$\mathcal{H}(\lambda(t), \gamma(t), u(t)) = \varphi_1(t) + u(t)\varphi_2(t) + \lambda_0 = 0 \text{ a.e.} \tag{2.13}$$

The switching functions are important because they determine where the controls may switch. In fact, using the PMP, one easily gets the following proposition.

PROPOSITION 2. *A necessary condition for a time t to be a switching is that $\varphi_2(t) = 0$. Therefore, on any interval where φ_2 has no zeros (resp., finitely many zeros), the corresponding control is bang (resp., bang-bang). In particular, $\varphi_2 > 0$ (resp., $\varphi_2 < 0$) on $[a,b]$ implies $u = -1$ (resp., $u = +1$) a.e. on $[a,b]$. On the other hand, if φ_2 has a zero at t and $\dot\varphi_2(t)$ exists and is different from zero, then t is an isolated switching.*

As a corollary, it holds a.e. along an extremal trajectory that

$$u(t)\varphi_2(t) = -|\varphi_2(t)|. \tag{2.14}$$

An extremal trajectory γ of Σ defined on $[c,d]$ is said to be *singular* if the switching function φ_2 vanishes on $[c,d]$. To compute the control corresponding to a singular trajectory, one should compute the derivatives of the φ_i's. Using the Lie bracket relations between f, g, h, one gets the system of differential equations (called the *adjoint system*) satisfied a.e.:

$$\dot\varphi_1 = -u\varphi_3, \tag{2.15}$$

$$\dot\varphi_2 = \varphi_3, \tag{2.16}$$

$$\dot\varphi_3 = s_\alpha^2 u\varphi_1 - c_\alpha^2\varphi_2. \tag{2.17}$$

From (2.12) and (2.16), one immediately gets that φ_2 is at least a $\mathcal{C}^1$ function. Moreover, if γ is singular in $[a,b]$, then $\varphi_2 = 0$ and, from (2.16), we get $\varphi_3 = 0$ a.e. From (2.13) (cf. PMP (ii)), we get $\varphi_1 \equiv -1$ a.e. on $[a,b]$. From (2.17) we get $u = 0$ a.e., i.e., we have the following proposition.

PROPOSITION 3. *For the minimum time problem for (Σ), singular trajectories are integral curves of the drift, i.e., they correspond to a control a.e. vanishing.*

In what follows, we will use the following convention. The letter B refers to a bang trajectory and the letter S refers to a singular extremal trajectory. A concatenation of bang and singular trajectories will be labeled by the corresponding letter sequence, written in order from left to right. Sometimes, we will use a subscript to indicate the time duration of a trajectory so that we use B_t to refer to a bang trajectory defined on an interval of length t and, similarly, S_t for a singular trajectory defined on an interval of length t.

If we fix $u \in [-1, 1]$, then the integral curves of $x(f + ug)$ are periodic. In particular, the integral curves of xX_ε are periodic with period 2π while the integral curves of the drift xf are periodic with period $2\pi/c_\alpha$, which means the following proposition.

PROPOSITION 4. *If γ is an extremal trajectory of type B_t (resp., S_t), then $t < 2\pi$ (resp., $t < 2\pi/c_\alpha$).*

There are two quantities that remain constant along an extremal trajectory. The first one comes from the fact that the minimized Hamiltonian H is constant along the extremal pairs (γ, λ) (cf. (2.13) and (2.14)):

$$I_1 := -\varphi_1(t) + |\varphi_2(t)| = \lambda_0, \tag{2.18}$$

with λ_0 equal to 0 or 1 (cf. Remark 1). The second conserved quantity is

$$I_2 := c_\alpha^2\varphi_2^2 + s_\alpha^2\varphi_1^2 + \varphi_3^2 = K^2, \quad \text{for some } K \in \mathbb{R}. \tag{2.19}$$

Remark 3. Equations (2.15)–(2.17) are Hamiltonian equations on the dual of $so(3)$, with respect to the canonical Poisson structure induced by the brackets of $f, g, h \in so(3)$, and corresponding to the left-invariant Hamiltonian (2.8). The conserved quantity I_2 is the Casimir function (see for instance [1]).

There is a geometric interpretation of the above equations. Let (γ, λ) be a normal extremal lift of the time-optimal control problem. Then, the adjoint vector λ with coordinates $(\varphi_i)_{i=1,2,3}$ lies in the intersection of the region defined by (2.18) and the ellipsoid defined by (2.19).

2.4. Classification of optimal trajectories. In this section, we investigate the structure of time-optimal trajectories by analyzing the extremal flow defined in (2.15)–(2.17), subject to (2.18) and (2.19). First we study abnormal extremals (we prove that they are regular bang-bang and we establish a relation between the interior bang times). Then we study normal extremals that are bang-bang (again we find a relation between the interior bang times). Finally we study optimal trajectories containing a singular arc. The results presented in this section are well known, and some of them already contained in [3, 4], although in many cases without proof. To have a self-contained paper, we provide an argument for all of them.

2.4.1. Abnormal extremals. The following proposition describes the switching behavior of abnormal extremals.

PROPOSITION 5. *Let γ be an abnormal extremal. Then, it is regular bang-bang and the time duration between two consecutive switchings is always equal to π. In other words, γ is of kind $B_\pi B_\pi \cdots B_\pi B_t$ with $t \leq \pi$.*

Proof of Proposition 5. By definition, $\lambda_0 = 0$. Then (2.13) becomes

$$\varphi_1(t) = -u(t)\varphi_2(t) \quad \text{for a.e. } t \in Dom(\gamma). \tag{2.20}$$

If γ is singular on some interval $[c, d]$, then $\varphi_2 \equiv 0$ and from (2.16) $\varphi_3 \equiv 0$ on $[c, d]$. Equation (2.20) gives $\varphi_1 \equiv 0$, contradicting the nontriviality of λ (cf. Remark 2). Then γ cannot contain a singular arc. Therefore, $u^2 = 1$ a.e. $t \in Dom(\gamma)$.

From (2.17) and (2.20), we get a.e. $\dot{\varphi}_3(t) = (-s_\alpha^2 u(t)^2 - c_\alpha^2)\varphi_2(t) = -\varphi_2(t)$. This means that, in the (φ_3, φ_2) plane, the vector $z(t) := (\varphi_3(t), \varphi_2(t))$ rotates with angular velocity equal to 1 (cf. (2.16)). This implies γ is a regular bang-bang trajectory and the time duration between two consecutive switchings along γ is always equal to π. □

2.4.2. Normal bang-bang extremals. Let γ be a bang-bang trajectory starting at p_0 and ending at $p_0 e^{(t_0 X_+)} e^{(t_1 X_-)} e^{(t_2 X_+)} e^{(t_3 X_-)}$. The case in which the first bang is of kind X_- is similar. We have $\varphi_2(t_0) = \varphi_2(t_0 + t_1) = \varphi_2(t_0 + t_1 + t_2) = 0$ which implies

$$\begin{aligned} \langle \lambda(t_0 + t_1), p_2 e^{-t_1 adX_-}(g) \rangle &= \langle \lambda(t_0 + t_1), p_2 g \rangle \\ &= \langle \lambda(t_0 + t_1), p_2 e^{t_2 adX_+}(g) \rangle = 0, \end{aligned} \tag{2.21}$$

where $p_2 = p_0 e^{(t_0 X_+)} e^{(t_1 X_-)}$. We need the following definition. If z_1, z_2, z_3 are (possibly time-varying) vector fields of $SO(3)$, the application $q \mapsto q(z_1 \wedge z_2 \wedge z_3)$ is the *field of* 3*-vectors* associated with the z_i's, where $q(z_1 \wedge z_2 \wedge z_3)$ is an element of $\bigwedge^3 T_q SO(3)$, the 3-fold exterior power of $T_q SO(3)$. We now rewrite (2.21) by using fields of 3-vectors. We obtain

$$g \wedge e^{-t_1 adX_-}(g) \wedge e^{t_2 adX_+}(g) = 0. \tag{2.22}$$

Thanks to (2.3), (2.22) is equivalent to $r(t_1, t_2) f \wedge g \wedge h = 0$ for an appropriate real-valued function r. After computations, we get $r(t_1, t_2) = \sin(\frac{t_1 - t_2}{2})$. This implies that $t_1 = t_2 = t_3$.

Similar to what we did in the proof of Proposition 5, consider now a time-optimal trajectory of the form BB_TB, where B_T is a nontrivial interior bang arc associated with a normal extremal and $T \in]0, 2\pi[$. From (2.17) and (2.13) (with $\lambda_0 = 1$), we get $\dot{\varphi}_3 = -(\varphi_2 + s_\alpha^2 u)$. Using (2.16), this means that the vector $z = (\varphi_3, \varphi_2 + u s_\alpha^2)^T$ satisfies the differential equation

$$\dot{z} = \begin{pmatrix} 0 & -1 \\ 1 & 0 \end{pmatrix} z, \quad t \in]0, T[,$$

with boundary conditions (the switching conditions imply $\varphi_2(0) = \varphi_2(T) = 0$) $z(0) = (\varphi_3(0), u s_\alpha^2)$ and $z(T) = (\varphi_3(T), u s_\alpha^2)$. Using $\varphi_2(0) = 0$ and the fact that $u > 0$ (resp. $u < 0$) implies $0 > \dot{\varphi}_2(0) = \varphi_3(0)$ (resp. $0 < \dot{\varphi}_2(0) = \varphi_3(0)$), one easily gets $\tan(T/2) = \varphi_3(0)/(u s_\alpha^2) < 0$. It follows that $T \in (\pi, 2\pi)$. In summary, we have proved the following proposition.

PROPOSITION 6. *Let γ be a bang-bang normal extremal. Then the time duration T along an interior bang arc is the same for all interior bang arcs and verifies $\pi < T < 2\pi$.*

Remark 4. From Propositions 5 and 6, we get that, for an extremal bang-bang trajectory (normal or abnormal), the time duration T along an interior bang arc is the same for all interior bang arcs and verifies $\pi \leq T < 2\pi$.

2.4.3. Optimal trajectories containing a singular arc. The purpose of this section is to describe the structure of time-optimal trajectories containing singular arcs.

PROPOSITION 7. *Let γ be a time-optimal trajectory containing a singular arc. Then γ is of the type $B_t S_s B_{t'}$, with $s \leq \frac{\pi}{c_\alpha}$ if $t > 0$ or $t' > 0$ and $s < 2\frac{\pi}{c_\alpha}$ otherwise.*

Proof of Proposition 7. Let γ be a time-optimal trajectory containing a singular arc S_t, $t > 0$. From Proposition 3, we know that $t < 2\pi/c_\alpha$.

Assume now that γ contains a singular arc and a nontrivial interior bang arc. Then, we may assume that γ contains a piece of the type S_sB_t or B_tS_s (say the first), with B_t a complete bang arc. Then we have $\varphi_2(s) = \varphi_3(s) = \varphi_2(s+t) = 0$. This translates to $g \wedge h \wedge e^{tadX_\varepsilon}(g) = 0$. Using (2.3), it implies that $\cos(t) = 1$, i.e., $t = 2\pi$. This contradicts the time optimality of γ. Finally, from (2.7), we get $e^{\frac{\pi}{c_\alpha}adf}(g) = -g$. From this, we deduce for $t \geq 0$, $e^{\frac{\pi}{c_\alpha}f}e^{tX_\varepsilon} = e^{tX_{-\varepsilon}}e^{\frac{\pi}{c_\alpha}f}$. Therefore, for $t, s \geq 0$, we have $e^{sf}e^{tX_\varepsilon} = e^{(s-\frac{\pi}{c_\alpha})f}e^{tX_{-\varepsilon}}e^{\frac{\pi}{c_\alpha}f}$. Then, if $s > \frac{\pi}{c_\alpha}$ and $t > 0$ and taking into account what precedes, $e^{sf}e^{tX_\varepsilon}$ cannot be optimal. □

2.5. Uniform bound on the number of switchings for time-optimal trajectories. For $\alpha \in]0, \pi/2[$, let $N(\alpha)$ be the supremum of the number of switchings of any time-optimal trajectory on $SO(3)$. Thanks to the left invariance of the control system (1.1), we may assume that the supremum is taken over any time optimal trajectory starting at Id. In this section, we prove the following proposition.

PROPOSITION 8. *For $\alpha \in]0, \pi/2[$, $N(\alpha)$ is finite (and thus achieved).*

Proof of Proposition 8. Let us first prove the following claim.

CLAIM. Every optimal trajectory of (Σ) is a finite concatenation of bang and singular arcs.

Let $\gamma : [a, b] \to SO(3)$ be a time-optimal trajectory of (Σ). Let S be the set of zeros of φ_2 such that if $t \in S$, then φ_2 does not vanish identically in some neighborhood of t. Clearly, S is the set of times t such that $\gamma(t)$ is the junction of two bang arcs or the junction of a singular arc and a bang arc. The conclusion follows if S is finite. Reasoning by contradiction, S must have a limit point $\bar{t}$. Moreover $\bar{t} \in S$, otherwise φ_2 would vanish identically in a neighborhood of $\bar{t}$, contradicting the fact that $\bar{t}$ is a limit point of S. Note also that $\dot{\varphi}_2$ is continuous in an open (in $[a, b]$) neighborhood N of $\bar{t}$ (see Remark 2). By definitions of S and $\bar{t}$, there exists a sequence (t_n) in N converging to $\bar{t}$ such that $\varphi_2(t_n) \neq 0$. Choose n large enough so that if $[t'_n, t''_n]$ is the maximal subinterval containing t_n with $\varphi_2 \neq 0$ on (t'_n, t''_n), then $[t'_n, t''_n] \subset N$. Clearly, $\varphi_2(t'_n) = \varphi_2(t''_n) = 0$, γ is a bang arc on $[t'_n, t''_n]$, and $t''_n - t'_n$ tends to zero as n goes to infinity since t_n tends to $\bar{t}$. But, by Proposition 6, $t''_n - t'_n \geq \pi$ for n large enough. So we have reached a contradiction and S is finite. The claim is proved. □

To finish the proof of Proposition 8, it remains to show that the (finite) number of switchings for any time-optimal trajectory is uniformly bounded over $SO(3)$. The argument goes by contradiction: there would then exist a sequence of regular bang-bang time-optimal trajectories $B_{s_n}B_{T_n}\cdots B_{T_n}B_{t_n}$, where $s_n, t_n < 2\pi$, $\pi < T_n < 2\pi$, and the number of switchings m_n goes to infinity as n goes to infinity. Therefore, there exists a sequence of points (x_n) of $SO(3)$ such that the minimum time τ_n needed to connect Id to x_n by a trajectory of (Σ) goes to infinity as n goes to infinity.

To reach a contradiction, it is enough to show that there exists a time $\mathcal{T}$ so that, for every point $x \in SO(3)$, there exists a trajectory γ of (Σ) connecting Id to x with $T(\gamma) \leq \mathcal{T}$. By a compactness argument and thanks to the $SO(3)$-invariance of (Σ), that would result from the following fact: there exists $\bar{t} > 0$ and an open neighborhood $U \subset SO(3)$ of Id such that every point $x \in U$ can be reached from Id in time less than or equal to $\bar{t}$. The latter simply results from the facts that (Σ) has the accessibility property and e^{tf} is periodic. □

Remark 5. Since the degree of nonholonomy of the distribution generated by (f, g) is equal to 2, by standard controllability arguments, one can quantitatively relate the size of U and $\bar{t}$ as follows: U contains a ball of radius $\frac{C\bar{t}}{\alpha^2}$ for some positive

constant C. Therefore, $N(\alpha)$ can be bounded above by $\frac{C'}{\alpha^2}$, for some positive constant C'.

3. The Hopf fibration and proof of Theorem 1.

3.1. The Hopf projection. In this section, we describe explicitly the Hopf projection from $SO(3)$ to $\mathbb{R}P^2$. This projection provides $SO(3)$ with a structure of fiber bundle with base $\mathbb{R}P^2$ and fiber S^1. In what follows, we use the identification of $\mathbb{R}P^2$ with $S^2\backslash\sim$, where $\sim$ is the antipodal map, that is $\mathbb{R}P^2$ is the set of rows (y_1, y_2, y_3), $\sum y_i^2 = 1$, where $(y_1, y_2, y_3) \sim (-y_1, -y_2, -y_3)$. In what follows, $\mathbb{R}P^2$ is identified with the subset $\underline{\mathcal{NH}}$, made of the (open) top hemisphere together with half of the equator. Fix a point $y_0 \in \mathbb{R}P^2$. The Hopf projection is defined as

$$\begin{aligned}\Pi : SO(3) &\to \mathbb{R}P^2,\\ x &\mapsto y = y_0 x,\end{aligned}$$

where $y_0 x$ is the standard matrix product. Then, any left-invariant vector field $V : x \mapsto xv$ on $SO(3)$, $v \in so(3)$, is transformed by $d\Pi$ into the (left-equivariant) vector field $V_S = d\Pi(V) : y \mapsto yv$. In the following, we call, respectively, the control systems $\dot{x} = x(f + ug)$, $x \in SO(3)$, and $\dot{y} = y(f + ug)$, $y \in \mathbb{R}P^2$, the control systems *upstairs* and *downstairs*. As explained next, it is crucial to choose y_0 so that the drift term at the initial point, Idf, vanishes downstairs, so we require $\Pi(Id) = y_0$. Indeed, if this is the case, then (i) from the point y_0, we have local controllability (see next section) and this greatly helps in the construction of the optimal synthesis; and (ii) if a trajectory upstairs starts with a singular arc (that is, with $u \equiv 0$, i.e., it is an integral curve of the drift f), then its projection is a point. That suitable choice of y_0 is made possible by the following normalizations:

$$f = c_\alpha \begin{pmatrix} 0 & 1 & 0 \\ -1 & 0 & 0 \\ 0 & 0 & 0 \end{pmatrix} \text{ and } g = s_\alpha \begin{pmatrix} 0 & 0 & 0 \\ 0 & 0 & 1 \\ 0 & -1 & 0 \end{pmatrix}, \quad y_0 = (0, 0, 1).$$

In that way, the control system downstairs reads $\dot{y} = F_S(y) + uG_S(y)$, where $F_S(y) = yf$, $G_S(y) = yg$. In order to respect the convention in control theory where states are represented by column vectors and costates by row vectors, we will consider the transposed control system and, with the change of notations $y^T \to y$, $f^T = -f \to f$, $g^T = -g \to g$, we obtain downstairs

$$\left\{\begin{array}{rcl} \dot{y} &=& F_S(y) + uG_S(y), \quad |u| \le 1, \qquad \text{where} \\ F_S(y) &=& fy = f \times y = c_\alpha \begin{pmatrix} 0 & -1 & 0 \\ 1 & 0 & 0 \\ 0 & 0 & 0 \end{pmatrix} \begin{pmatrix} y_1 \\ y_2 \\ y_3 \end{pmatrix} = \begin{pmatrix} -y_2 \\ y_1 \\ 0 \end{pmatrix}, \\ G_S(y) &=& gy = g \times y = s_\alpha \begin{pmatrix} 0 & 0 & 0 \\ 0 & 0 & -1 \\ 0 & 1 & 0 \end{pmatrix} \begin{pmatrix} y_1 \\ y_2 \\ y_3 \end{pmatrix} = \begin{pmatrix} 0 \\ -y_3 \\ y_2 \end{pmatrix}. \end{array}\right. \tag{3.1}$$

3.2. Proof of Theorem 1. For the rest of the paper, we assume $\alpha \in]0, \pi/4[$. In this section we prove Theorem 1, using a lemma describing the structure of time-optimal trajectories of $(\Sigma)_S$ connecting the north pole to any point of $\underline{\mathcal{NH}}$, which will be studied in the next section.

LEMMA 1. *Consider the control system $(\Sigma)_S$ and the time-optimal trajectories connecting the north pole to any point of $\underline{\mathcal{NH}}$. Then*

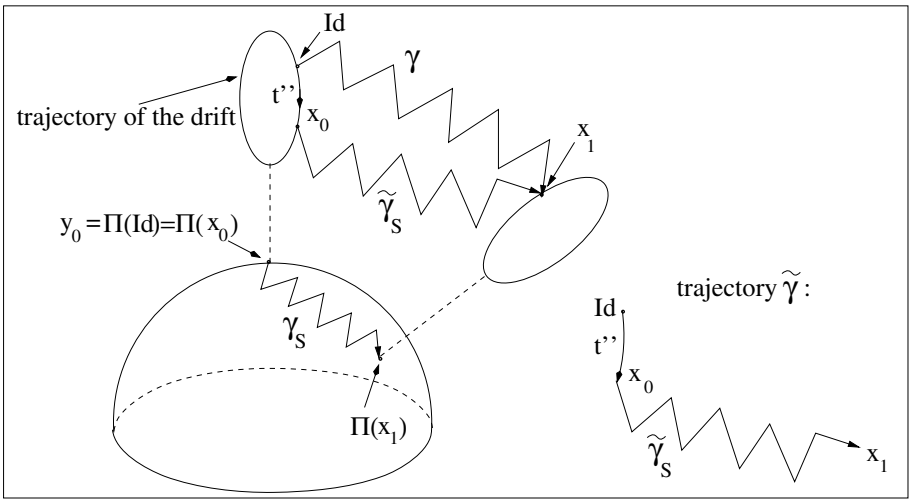

FIG. 3.1. *Proof of Theorem 1.*

(i) *They are regular bang-bang with same time durations for the interior bang arcs, i.e., they are of the type* $B_s B_{v(s)} \cdots B_{v(s)} B_t$, *where* $s \in [0, \pi]$, $t \in [0, v(s)]$ *and*

$$v(s) = \pi + 2 \arctan\left(\frac{s_s}{c_s + \cot^2(\alpha)}\right). \tag{3.2}$$

(ii) *Set* $N_0(\alpha) := 2\left[\frac{\pi}{8\alpha}\right]$. *Then the maximum number of switching of these trajectories is*

$$N_S(\alpha) = N_0(\alpha) - \left[N_0(\alpha) - \frac{\pi}{4\alpha}\right]. \tag{3.3}$$

The above formula means that $N_S(\alpha)$ *can take the values* $N_0(\alpha)$, $N_0(\alpha) + 1$, *or* $N_0(\alpha) + 2$.

(iii) *They are projections, through the Hopf map* Π, *of time-optimal trajectories of* (Σ) *starting at* Id.

Proof of Lemma 1. For the proof of (i), see Proposition 10 and Proposition 11. For the proof of (iii), see Lemma 7 and Lemma 8. For the proof of (ii) see Proposition 13. □

We now prove separately the two inequalities of Theorem 1.

Proof of the inequality $N_S(\alpha) \leq N(\alpha)$. From (iii) of Lemma 1, every time-optimal trajectory of $(\Sigma)_S$ connecting the north pole to any point of $\underline{\mathcal{NH}}$ is the projection by Π of a time-optimal trajectory of (Σ) with the same time duration (in particular, of the time-optimal trajectory connecting the two fibers). Therefore, $N_S(\alpha) \leq N(\alpha)$. □

Proof of the inequality $N(\alpha) \leq N_S(\alpha) + 4$. We refer to Figure 3.1. Consider a time-optimal trajectory γ of (Σ) containing $N(\alpha)$ switchings. With no loss of generality, we may assume that $N(\alpha) > 2$. By Propositions 6 and 7, we deduce that γ is regular bang-bang and is of the type $B_s B_T \cdots B_T B_t$, with $s, t \geq 0$, $\pi \leq T \leq 2\pi$. Since every subarc of a time-optimal trajectory is also time optimal, we may assume that $s = t = 0$. Let Id and x_1 be the initial and terminal points of γ and consider γ_S, a time-optimal trajectory for $(\Sigma)_S$ connecting $\Pi(Id)$ and $\Pi(x_1)$. From (i) of Lemma 1,

γ_S is of the type $B_{s'}B_{v(s')}\cdots B_{v(s')}B_{t'}$ with $s' \leq \pi$, $t' < v(s')$ and m interior bangs. We thus have $m \leq N_S(\alpha) - 1$. We now build, from γ_S, a suboptimal trajectory connecting Id and x_1 as follows: we can lift γ_S to $SO(3)$ to an admissible trajectory $\tilde{\gamma}_S$ of (Σ) connecting x_0 and x_1, with x_0 in the fiber of $\Pi(Id)$. It is also clear that γ_S and $\tilde{\gamma}_S$ have same time durations. By construction of the fiber of $\Pi(Id)$, we get $x_0 = e^{t''f}$ with $t'' \leq 2\pi$. Finally, the curve $\tilde{\gamma}$ obtained as the concatenation of $e^{t''f}$ and $\tilde{\gamma}_S$ is an admissible trajectory of (Σ) connecting Id and x_1. Its time duration is equal to

$$T(\tilde{\gamma}) = t'' + T(\tilde{\gamma}_S) = t'' + T(\gamma_S) = t'' + mv(s') + s' + t',$$

with $m \leq N_S(\alpha) - 1$. Since γ is time optimal, we have $T(\gamma) \leq T(\tilde{\gamma})$, which implies that

$$\Big(N(\alpha) - 1\Big)T \leq t'' + mv(s') + s' + t'.$$

Using all the estimates on T, s', t', t'' (i.e., $T \in [\pi, 2\pi)$ (cf. Remark 4), $s' \leq \pi,\ t' \leq \max_{s'\in[0,\pi]} v(s'),\ t'' < 2\pi$), we deduce that

$$\Big(N(\alpha) - 1\Big)\pi < N_S(\alpha)V(\alpha) + 3\pi, \text{ where } V(\alpha) := \max_{s\in[0,\pi]} v(s),$$

from which we have

$$N(\alpha) - N_S(\alpha) < N_S(\alpha)\frac{V(\alpha) - \pi}{\pi} + 4. \tag{3.4}$$

Set $r(\alpha) := N_S(\alpha)\frac{V(\alpha)-\pi}{\pi}$. A simple computation shows that

$$r(\alpha) = N_S(\alpha)\frac{2}{\pi}\arcsin(\tan^2(\alpha)).$$

Using (3.3), it is easy to see that $r(\alpha) \in]0, 1[$ on $]0, \pi/4[$. Since $N(\alpha)$ and $N_S(\alpha)$ are integers, we get $N(\alpha) - N_S(\alpha) \leq 4$. □

4. The time-optimal synthesis downstairs. In this section, to compute $N_S(\alpha)$, we study the time-optimal synthesis for the problem downstairs (3.1), starting from the point y_0.

DEFINITION 3. *A time-optimal synthesis for the problem downstairs* (3.1)*, starting from the point y_0, is a family of time-optimal trajectories* $\Gamma = \{\gamma_y : [0, b_y] \mapsto \mathbb{R}P^2,\ y \in \mathbb{R}P^2 :\ \gamma_y(0) = y_0,\ \gamma_y(b_y) = y\}$.

For that purpose, we use the theory of optimal syntheses on two-dimensional manifolds developed by Sussmann, Bressan, Piccoli and the first author in [9, 10, 11, 14, 15, 23, 24, 32, 33] and recently rewritten in [12]. The core of the theory consists of an explicit algorithmic construction (by induction on the number of switchings) of the optimal synthesis.

Note that the previous theory uses a more elaborated concept of synthesis, namely, that of *regular synthesis* (see for instance [8, 12, 16, 25] and cf. section 4.1.1).

In the following, in order to compute $N_S(\alpha)$ we just need to follow the steps of the algorithmic construction mentioned above, without requiring the existence of a regular synthesis. In what follows, by *time-optimal synthesis*, we refer to one in the sense of Definition 3, whose existence is simply guaranteed by Proposition 1.

Consider a two-dimensional smooth manifold M and the problem of computing the time-optimal synthesis from a fixed point $y_0 \in M$ for the control system:

$$\dot{y} = F(y) + uG(y),\quad y \in M,\quad |u| \leq 1, \tag{4.1}$$

where F and G are $\mathcal{C}^\infty$ vector fields. We introduce three functions:

$$\Delta_A(y) := \mathrm{Det}(F(y), G(y)) = F_1(y)G_2(y) - F_2(y)G_1(y), \tag{4.2}$$

$$\Delta_B(y) := \mathrm{Det}(G(y), [F,G](y)) = G_1(y)[F,G]_2(y) - G_2(y)[F,G]_1(y), \tag{4.3}$$

$$f_S(y) := -\Delta_B(y)/\Delta_A(y). \tag{4.4}$$

The sets $\Delta_A^{-1}(0), \Delta_B^{-1}(0)$ of zeros of Δ_A, Δ_B are, respectively, the set of points where F and G are parallel and the set of points where G is parallel to $[F,G]$. These loci are fundamental in the construction of the optimal synthesis. In fact, assuming that they are smooth embedded one-dimensional submanifold of M, we have the following:

- In each connected region of $M\backslash(\Delta_A^{-1}(0) \cup \Delta_B^{-1}(0))$, every extremal trajectory is bang-bang with at most one switching. Moreover, if the trajectory is switching, then the value of the control switches from -1 to $+1$ if $f_S > 0$ and from $+1$ to -1 if $f_S < 0$.
- The support of singular trajectories (that are trajectories for which the switching function identically vanishes, see Definition 4 below) is always contained in the set $\Delta_B^{-1}(0)$.
- A trajectory not switching on the set of zeros of G is an abnormal extremal (i.e., a trajectory with vanishing Hamiltonian) if and only if it switches on the locus $\Delta_A^{-1}(0)$.

Then the synthesis is built recursively on the number of switchings of extremal trajectories, canceling at each step the nonoptimal trajectories (see [12, Chapter 1]).

Remark 6. As we will see later (see Proposition 10), the condition $\alpha < \pi/4$ guarantees that *there are no singular trajectories* for the problem downstairs.

4.1. Basic definitions and facts on optimal synthesis on two-dimensional manifolds. Consider the minimum time problem for the control system (4.1). In this section, we recall some key facts for the construction of time-optimal synthesis following [12].

The first ingredient is, as usual, the PMP that, on a two-dimensional manifold, has exactly the same form as described in section 2.3 but with the following change of notation: $x \in SO(3) \to y \in M$, $\lambda(t) \in T_{\gamma(t)}SO(3) \to \lambda(t) \in T_{\gamma(t)}M$. As for the problem upstairs, switchings are described by the switching function given by Definition 4.

Definition 4 (switching function). *Let (γ, λ) be an extremal pair. The corresponding switching function is defined as $\phi(t) := \langle \lambda(t), G(\gamma(t))\rangle$.*

Again, ϕ is at least continuously differentiable ($\dot\phi(t) = \langle \lambda(t), [F,G](\gamma(t))\rangle$, cf. discussion in (2.16), and it determines the switching rule, according to Proposition 2 with the change of notation $\varphi_2 \to \phi$. Also, an extremal trajectory γ, defined on $[a,b]$, is called singular if $\phi \equiv 0$ in $[a,b]$. The following three lemmas illustrate the role of the two functions defined in (4.2) and (4.3). The proofs can be found in [9, 12, 24].

Lemma 2. *Let γ be an extremal trajectory that is singular in $[a,b] \subset Dom(\gamma)$. Then $\gamma|_{[a,b]}$ is associated with the so-called singular control $\varphi(\gamma(t))$, where*

$$\varphi(y) = -\frac{\nabla\Delta_B(y)\cdot F(y)}{\nabla\Delta_B(y)\cdot G(y)}, \tag{4.5}$$

with Δ_A and Δ_B defined in (4.2) *and* (4.3). *Moreover, on* $\mathrm{Supp}(\gamma)$, *$\varphi(y)$ is always well defined and its absolute value is less than or equal to* 1. *Finally* $\mathrm{Supp}(\gamma|_{[a,b]}) \subset \Delta_B^{-1}(0)$.

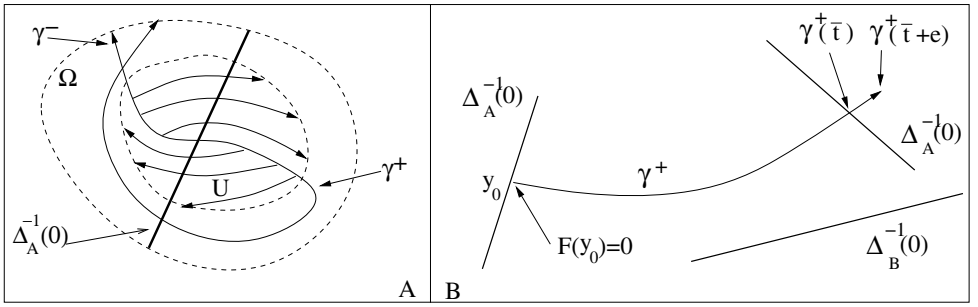

FIG. 4.1. *Lemma* 5 *and Lemma* 6.

LEMMA 3. *Let γ be an extremal bang-bang trajectory for the control problem* (4.1)*, $t_0 \in Dom(\gamma)$ be a time such that $\phi(t_0) = 0$ and $G(\gamma(t_0)) \neq 0$. Then, the following conditions are equivalent:* (i) *γ is an abnormal extremal;* (ii) *$\gamma(t_0) \in \Delta_A^{-1}(0)$; and* (iii) *$\gamma(t) \in \Delta_A^{-1}(0)$ for every time $t \in Dom(\gamma)$ such that $\phi(t) = 0$.*

The following lemma describes what happens when Δ_A and Δ_B are different from zero.

LEMMA 4. *Let $\Omega \subset M$ be an open set such that $\Omega \cap (\Delta_A^{-1}(0) \cup \Delta_B^{-1}(0)) = \emptyset$. Then all connected components of* $\mathrm{Supp}(\gamma) \cap \Omega$*, where γ is an extremal trajectory of* (4.1)*, are bang-bang with at most one switching. Moreover, if $f_S > 0$ throughout Ω, then $\gamma|_\Omega$ is associated with a constant control equal to $+1$ or -1 or has a switching from -1 to $+1$. If $f_S < 0$ throughout Ω, then $\gamma|_\Omega$ is associated with a constant control equal to $+1$ or -1 or has a switching from $+1$ to -1.*

DEFINITION 5. *Let $\gamma^+ : [0, \tau] \to M$ (resp. $\gamma^- : [0, \tau] \to M$) be the trajectory of* (4.1) *starting at y_0 and corresponding to the constant control $u \equiv 1$ (resp., $u \equiv -1$). For $t \in]0, \tau]$, let $\Gamma^+(t)$ (resp., $\Gamma^-(t)$) be the support of the curve $\gamma^+|_{[0,t]}$ (resp., $\gamma^-_{[0,t]}$).*

Under the assumption $F(y_0) = 0$ and $\Delta_B(y_0) \neq 0$, the next lemma (for a proof, see for instance [12, 26]) describes the shape of the optimal synthesis in a neighborhood of y_0. That local behavior of the optimal synthesis remains actually the same as long as $\Gamma^+(t)$ and $\Gamma^-(t)$ do not intersect $\Delta_B^{-1}(0)$ and $\Delta_A^{-1}(0)$ (except of course at y_0).

LEMMA 5. *Consider the control system* (4.1)*. Assume that $F(y_0) = 0$ and $\Delta_B(y_0) \neq 0$. Let Ω be an open neighborhood of y_0 such that $\Omega \cap \Delta_B^{-1}(0) = \emptyset$ and $\Omega \cap \Delta_A^{-1}(0)$ is an embedded one-dimensional submanifold of Ω. Let $\gamma^+ : [0, \tau] \to M$ (resp., $\gamma^- : [0, \tau] \to M$) be the trajectory of* (4.1) *starting at y_0 and corresponding to the constant control $u \equiv 1$ (resp., $u \equiv -1$). Then, for every $t_+, t_- \in]0, \tau[$ such that* (a) $\Gamma^+(t_+), \Gamma^-(t_-) \subset \Omega$, (b) $\Gamma^+(t_+) \cap \Delta_A^{-1}(0) = \Gamma^-(t_-) \cap \Delta_A^{-1}(0) = \{y_0\}$, *and* (c) $\Gamma^+(t_+) \cap \Gamma^-(t_-) = \{y_0\}$*, we have the following. There exists an open neighborhood U of $\Gamma^+(t_+) \cup \Gamma^-(t_-)$ contained in Ω such that, for every $y \in U$, there exists a unique extremal trajectory of* (4.1) *of the type $B_s B_t$ contained in U, which is time optimal and steers y_0 to y. In particular, the system* (4.1) *is controllable in U and γ^+ (resp., γ^-) is time optimal up to t_+ (resp., t_-); see Figure* 4.1(a).

Finally, we need one more lemma, related to Lemma 3 and whose hypotheses are illustrated in Figure 4.1(b).

LEMMA 6. *Consider the control system* (4.1)*. Assume that* (i) *$F(y_0) = 0$, $\Delta_B(y_0) \neq 0$,* (ii) *there exists $\bar{t}_+ > 0$ such that $\Gamma^+(\bar{t}_+) \cap \Delta_A^{-1}(0) = \{y_0, \gamma^+(\bar{t}_+)\}$, and* (iii) *there exists $\varepsilon > 0$ such that $\Gamma^+(\bar{t}_+ + \varepsilon) \cap \Delta_B^{-1}(0) = \emptyset$. Then γ^+ is extremal exactly up to time $\bar{t}_+$. Moreover, any extremal trajectory γ defined on $[0, T]$ with $T > \bar{t}_+$ and*

coinciding with γ^+ *on* $[0, \bar{t}_+]$ *switches at* $\bar{t}_+$ *to the constant control* $u \equiv -1$ *and thus* γ *is an abnormal extremal (cf. Lemma* 3*). A similar statement holds for* γ^-*.*

Remark 7. Under the hypotheses of Lemma 6, one can prove that the abnormal extremal γ restricted to an interval $[0, \bar{T}]$ is a *nonstrict abnormal extremal* if $\bar{T} < \bar{t}^+$, while it becomes a *strict abnormal extremal* if $\bar{T} \geq \bar{t}^+$ (cf. section 2.3). In other words, γ becomes a strict abnormal extremal after the first switching. These facts are analyzed in details in [11] and [12] (see Chapter 4, and in particular section 4.3, where strict abnormal extremals are called nontrivial abnormal extremals).

4.1.1. Frame curves and frame points. In this section, we briefly recall, for the sake of completeness, the main results of the theory developed in [23, 24] (see also [12]). That material is only used here and in section 5, where some numerical simulations and conjectures are presented. In [23, 24] (see also [12]), it was proved that the control system (4.1), under generic conditions on F and G (with the additional assumption $F(y_0) = 0$), admits a time-optimal *regular synthesis* in finite time T, starting from y_0. By generic conditions, we mean conditions verified on an open and dense subset of the set of $\mathcal{C}^\infty$ vector fields endowed with the $\mathcal{C}^3$ topology (see [12, formula 2.6, p. 39]). More precisely, let $\mathcal{R}(T)$ be the reachable set in time $T > 0$ given by

$$\begin{aligned}\mathcal{R}(T) := \{y \in M :\ &\exists\ b_y \in [0, T] \text{ and a trajectory} \\ &\gamma_y : [0, b_y] \to M \text{ of (4.1) such that } \gamma_y(0) = y_0,\ \gamma_y(b_y) = y\}.\end{aligned}$$

Then a *time-optimal regular synthesis* is defined by (i) a family of time-optimal trajectories $\Gamma = \{\gamma_y : [0, b_y] \to M,\ y \in \mathcal{R}(T) :\ \ \gamma_y(0) = y_0,\ \gamma_y(b_y) = y\}$ such that if $\gamma_y \in \Gamma$ and $\bar{y} = \gamma_{y(t)}$ for some $t \in [0, b_y]$, then $\gamma_{\bar{y}} = \gamma_y|_{[0,t]}$; and (ii) a stratification of $\mathcal{R}(T)$ (roughly speaking a partition of $\mathcal{R}(T)$ in manifolds of different dimensions; see [12, Definition 27, p. 56]) such that the optimal trajectories of Γ can be obtained from a feedback $u(y)$ satisfying

- on strata of dimension 2, $u(y) = \pm 1$;
- on strata of dimension 1, called *frame curves* (FC), $u(y) = \pm 1$ or $u(y) = \varphi(y)$, where $\varphi(y)$ is defined by (4.5).

The strata of dimension 0 are called *frame points* (FP). Every FP is an intersection of two FCs. In [24] (see also [12]), a complete classification of all types of FPs and FCs, under generic conditions, is provided. All the possible FCs are

- FCs of kind Y (resp., X), corresponding to subsets of the trajectories γ^+ (resp., γ^-) defined as the trajectory exiting y_0 with constant control $+1$ (resp., constant control -1);
- FCs of kind C, called *switching curves*, i.e., curves made of switching points;
- FCs of kind S, i.e., singular trajectories;
- FCs of kind K, called overlaps and reached optimally by two trajectories coming from different directions;
- FCs which are arcs of optimal trajectories starting at FPs. These trajectories "transport" special information.

The FCs of kind Y, C, S, K are depicted in Figure 4.2. There are 18 topological equivalence classes of FPs. A detailed description can be found in [10, 12, 24].

Remark 8. The proof of the existence of a regular synthesis is shown by means of a constructive algorithm (working recursively on the number of switchings) that builds explicitly the optimal trajectories (see [12, section 2.5, p. 56]). We stress the fact that the existence of a regular synthesis cannot be guaranteed before the complete

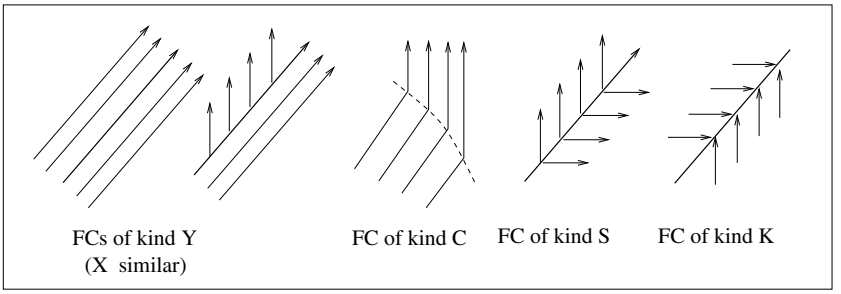

FIG. 4.2.

execution of the algorithm. Since for our system (3.1), we do not reach the end of that construction, we cannot conclude that such a regular synthesis exists. However, we conjecture that last fact (see also section 5).

4.2. The problem downstairs. In this section, we apply the theory recalled in section 4.1 to the control system (3.1) on S^2 in order to compute $N_S(\alpha)$, the maximum number of switchings for time-optimal trajectories connecting the north pole to any point of $\underline{NH}$. First we need some notations.

DEFINITION 6. *Set*

$$\begin{aligned} X_S^+(y) &= F_S(y) + G_S(y) = X^+ y = X^+ \times y \\ &= \begin{pmatrix} 0 & -c_\alpha & 0 \\ c_\alpha & 0 & -s_\alpha \\ 0 & s_\alpha & 0 \end{pmatrix} \begin{pmatrix} y_1 \\ y_2 \\ y_3 \end{pmatrix} = \begin{pmatrix} -c_\alpha y_2 \\ c_\alpha y_1 - s_\alpha y_3 \\ s_\alpha y_2 \end{pmatrix}, \\ X_S^-(y) &= F_S(y) - G_S(y) = X^- y = X^- \times y \\ &= \begin{pmatrix} 0 & -c_\alpha & 0 \\ c_\alpha & 0 & s_\alpha \\ 0 & -s_\alpha & 0 \end{pmatrix} \begin{pmatrix} y_1 \\ y_2 \\ y_3 \end{pmatrix} = \begin{pmatrix} -c_\alpha y_2 \\ c_\alpha y_1 + s_\alpha y_3 \\ -s_\alpha y_2 \end{pmatrix}. \end{aligned}$$

Let $\gamma : [t_1, t_2] \to S^2$ be a trajectory of (4.1). If γ corresponds to the constant control $+1$ (resp., -1) in $[t_1, t_2]$, we say that $\gamma|_{[t_1,t_2]}$ is a X^+–trajectory (resp., X^-–trajectory). Moreover, we call $\gamma^\pm$ the trajectories exiting the point x_0 with, respectively, constant control $+1$ and -1. Let $t_{op}^\pm$ be the last times for which $\gamma^\pm$ are optimal. We define $\gamma_{op}^\pm := \gamma^\pm|_{[0,t_{op}^\pm]}$. If $\gamma_1 : [a, b] \to S^2$ and $\gamma_2 : [b, c] \to S^2$ are trajectories of (3.1) such that $\gamma_1(b) = \gamma_2(b)$, then the concatenation $\gamma_2 * \gamma_1$ is the trajectory

$$(\gamma_2 * \gamma_1)(t) := \begin{cases} \gamma_1(t) \text{ for } t \in [a, b], \\ \gamma_2(t) \text{ for } t \in [b, c]. \end{cases}$$

Note that in the notation $\gamma_2 * \gamma_1$, γ_1 comes first.

The first quantities to be computed are $\Delta_A^{-1}(0), \Delta_B^{-1}(0)$ and the sign of f_S. Referring to Figure 4.4, we have for the system (3.1)

$$\begin{aligned} &\Delta_A^{-1}(0) = \{(y_1, y_2, y_3)^T \in S^2 : y_2 = 0\}, \\ &\Delta_B^{-1}(0) = \{(y_1, y_2, y_3)^T \in S^2 : y_3 = 0\}, \\ &f_S(y) > 0, \ \forall\, y \in \{(y_1, y_2, y_3)^T \in S^2 : y_2 y_3 > 0\}, \\ &f_S(y) < 0, \ \forall\, y \in \{(y_1, y_2, y_3)^T \in S^2 : y_2 y_3 < 0\}. \end{aligned}$$

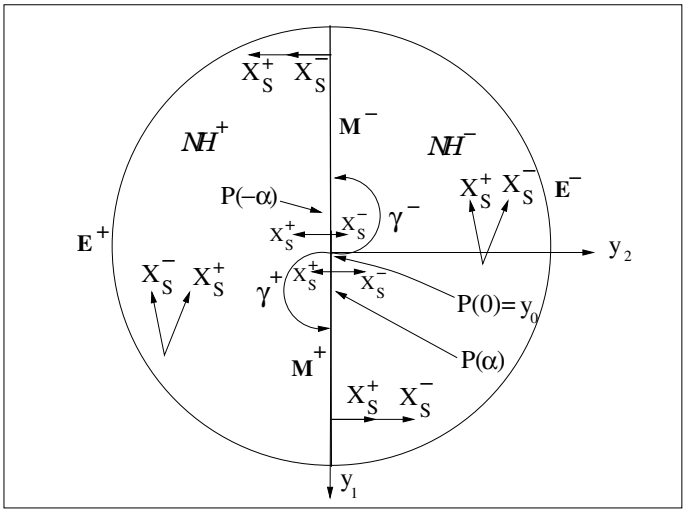

FIG. 4.3.

The set $\Delta_B^{-1}(0)$ is called the *equator* and $\Delta_A^{-1}(0)$ the *meridian*. Moreover, let $\mathcal{NH}$ be the (open) top hemisphere, i.e., the set of points $(y_1, y_2, y_3)^T$ so that $y_3 > 0$ and (see Figure 4.3)

$$\begin{aligned} \mathcal{NH}^+ &:= \{y \in \mathcal{NH} : y_2 < 0\}, \\ M^+ &= \{y \in \mathcal{NH} : y_1 > 0, y_2 = 0\}, \\ E^+ &= \{y \in S^2 : y_2 < 0, y_3 = 0\}. \end{aligned}$$

Similarly

$$\begin{aligned} \mathcal{NH}^- &= \{y \in \mathcal{NH} : y_2 > 0\}, \\ M^- &= \{y \in \mathcal{NH} : y_1 < 0, y_2 = 0\}, \\ E^- &= \{y \in S^2 : y_2 > 0, y_3 = 0\}. \end{aligned}$$

We also parametrize points y of the meridian by the oriented angle between $\overrightarrow{0y_0}$ and $\overrightarrow{0y}$. We use $P(\xi)$, $\xi \in [-\pi, \pi]$, to denote the point of the meridian defined by the angle ξ. Then $P(0) = y_0$ and $P(\alpha)$ (resp., $P(-\alpha)$) is the center of rotation in the north hemisphere of X_S^+ (resp. X_S^-). We also have that γ^+ (resp., γ^-), up to time π, is a half-circle with diameter $[y_0, P(2\alpha)]$ (resp., $[y_0, P(-2\alpha)]$); see Figure 4.3. From Lemma 4, Proposition 9 follows.

PROPOSITION 9. *Let $\gamma : [0, T] \to S^2$, $\gamma(0) = y_0$ be an optimal trajectory for the control system* (3.1). *Then*

- *γ has at most a $X^+ * X^-$ switching in $\mathcal{NH}^-$, that is, if* $\mathrm{Supp}(\gamma|_{[a,b]}) \subset \mathcal{NH}^-$, *then $\gamma|_{[a,b]}$ corresponds to one of the three following controls:*
  - (-) *$u = +1$ in $[a, b]$,*
  - (-) *$u = -1$ in $[a, b]$,*
  - (-) *there exists $c \in]a, b[$ such that $u = -1$ in $[a, c[$ and $u = +1$ in $]c, b]$;*
- *γ has at most an $X_S^- * X_S^+$ switching in $\mathcal{NH}^+$;*
- *γ has at most an $X_S^- * X_S^+$ switching in the region $\{x \in S^2 : y_2 > 0, y_3 < 0\}$;*
- *γ has at most an $X_S^+ * X_S^-$ switching in the region $\{x \in S^2 : y_2 < 0, y_3 < 0\}$.*

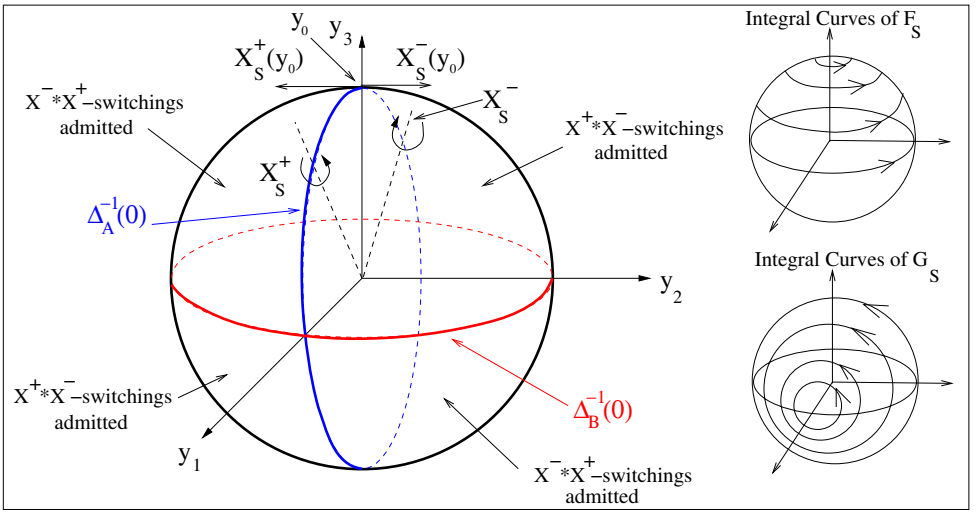

FIG. 4.4.

In Figure 4.4, the integral curves of F_S, G_S, X_S^+, X_S^- and the loci $\Delta_A^{-1}(0), \Delta_B^{-1}(0)$ are depicted. Moreover, the allowed switchings are indicated.

Remark 9. Note that, in $\mathcal{NH}^+$ (resp., $\mathcal{NH}^-$), X_S^+ points on the right (resp., on the left) of X_S^-, while, on the meridian, X_S^+ and X_S^- are parallel (see Figure 4.3). More precisely, X_S^+ and X_S^- point in the same direction on $\{P(\xi), \xi \in]\alpha, \pi-\alpha[\bigcup]-\pi+\alpha, -\alpha[\}$ and in opposite directions on $\{P(\xi), \xi \in]-\alpha, \alpha[\bigcup]\pi-\alpha, \pi]\ \bigcup\ [-\pi, -\pi+\alpha[\}$.

4.2.1. Two properties of extremal trajectories. The following two propositions are essential in the construction of the optimal synthesis.

PROPOSITION 10. *Every time-optimal trajectory of* (3.1)*, starting at the north pole, is regular bang-bang.*

Proof of Proposition 10. Since $\alpha < \frac{\pi}{4}$, by taking into account Lemmas 5 and 6, the curves γ^+ and γ^- defined in Definition 6 do not intersect the equator and are time optimal until the first time they meet the meridian, i.e., exactly up to time π. Moreover, since singular arcs are contained in the equator and thanks to Lemma 6, any time optimal trajectory γ of (3.1), with at least one switching, is of the form $B_s B_t \cdots$, with $s \in]0, \pi]$ and $t > 0$. Finally, since γ is the projection of a time-optimal trajectory $\tilde{\gamma}$ of (1.1), the latter is also of the type $B_s B_t \cdots$. Therefore, by Proposition 7, $\tilde{\gamma}$ and so γ, cannot contain any singular arc. □

PROPOSITION 11. *Let $\gamma : [0, T] \to S^2$ be a time-optimal trajectory for the control system* (3.1) *of the type $B_s B_{t_1} B_{t_2} \cdots$. Then, all time durations of interior bang arcs are equal to $v(s)$, where*

$$v(s) := \pi + 2 \arctan\left(\frac{s_s}{c_s + \cot^2(\alpha)}\right). \tag{4.6}$$

Proof of Proposition 11. Consider $\tilde{\gamma} : [0, T] \to SO(3)$, an optimal trajectory that projects on γ through the Hopf fibration Π. Thanks to Proposition 6 (see also Remark 4), we have $\tilde{\gamma} = B_s B_{t_1} B_{t_1} \cdots$, where $t_1 \in [\pi, 2\pi[$. Moreover, since that curve projects on a time-optimal trajectory for (3.1), we will establish a relation between s and t_1.

We start from the relations $\varphi_2(s) = \varphi_2(s + t_1) = 0$, which can be written as

$$\langle \lambda(s), G_S(\gamma(s)) \rangle = \langle \lambda(s + t_1), G_S(\gamma(s + t_1)) \rangle = 0. \tag{4.7}$$

Recall that $\lambda(s) = \lambda(0)e^{-sX_\varepsilon}$, $\lambda(s + t_1) = \lambda(0)e^{-sX_\varepsilon}e^{-t_1X_{-\varepsilon}}$ and $\gamma(s) = e^{sX_\varepsilon}\gamma(0)$, $\gamma(s + t_1) = e^{t_1X_{-\varepsilon}}e^{sX_\varepsilon}\gamma(0)$. Since γ is nontrivial, $\lambda(0)$ is a nonzero line vector of $\mathbb{R}^3$. Moreover, $\gamma(0) = y_0 = (0, 0, 1)^T$. Equation (4.7) can be written as

$$\lambda(0)e^{-sX_\varepsilon}(g \times e^{sX_\varepsilon}\gamma(0)) = 0, \quad \lambda(0)e^{-sX_\varepsilon}e^{-t_1X_{-\varepsilon}}(g \times e^{t_1X_{-\varepsilon}}e^{sX_\varepsilon}\gamma(0)) = 0.$$

The previous equations can be transformed to

$$\det(e^{sX_\varepsilon}\lambda(0)^T, g, e^{sX_\varepsilon}\gamma(0)) = 0, \quad \det(e^{t_1X_{-\varepsilon}}e^{sX_\varepsilon}\lambda(0)^T, g, e^{t_1X_{-\varepsilon}}e^{sX_\varepsilon}\gamma(0)) = 0$$

and then to

$$\det(e^{sX_\varepsilon}\lambda(0)^T, g, e^{sX_\varepsilon}\gamma(0)) = 0, \quad \det(e^{sX_\varepsilon}\lambda(0)^T, e^{-t_1X_{-\varepsilon}}g, e^{sX_\varepsilon}\gamma(0)) = 0.$$

Since $e^{sX_\varepsilon}\lambda(0)^T$ is not zero, we deduce that

$$\det(g, e^{sX_\varepsilon}\gamma(0), e^{-t_1X_{-\varepsilon}}g) = 0. \tag{4.8}$$

We end up with the relation

$$-s_\alpha^2 \cos(s - t_1/2) = c_\alpha^2 \cos(t_1/2). \tag{4.9}$$

Taking into account that $\pi \le t_1 < 2\pi$, we can simplify the previous equation to get (4.6). □

4.3. Construction of the time-optimal synthesis. In this section, we present, step by step, the construction of the TOS for (3.1). We will not complete that construction, but only provide here the steps for which the outcome is justified by a rigorous argument. For the other steps of the construction, we refer to the last section where we propose conjectures on their outcomes, which are supported by numerical simulation.

Step 1. By Lemmas 5 and 6, for every $\varepsilon > 0$, there exists an open neighborhood U of $\Gamma^+(\pi - \varepsilon) \cup \Gamma^-(\pi - \varepsilon)$ (recall Definition 5) where the time-optimal synthesis is described in Figure 4.5(a). Moreover, $t_{op}^+ = t_{op}^- = \pi$ (recall Definition 6).

Step 2. Taking into account the analysis of Sections 4.1 and 4.2, the time-optimal trajectories for the problem downstairs are described by the following proposition.

PROPOSITION 12. *Every time-optimal trajectory for the system* (3.1)*, starting from the north pole, is contained in the following two sets of extremals, which are parametrized by the length of the first bang arc, the one of the last bang arc, and the number of arcs:*

$$\Xi^+(s, t) = \overbrace{e^{X_S^\varepsilon t}e^{X_S^{-\varepsilon}v(s)} \cdots e^{X_S^- v(s)}e^{X_S^+ s}}^{m \quad terms} y_0, \tag{4.10}$$

$$\Xi^-(s, t) = \underbrace{e^{X_S^{\varepsilon'} t}e^{X_S^{-\varepsilon'}v(s)} \cdots e^{X_S^+ v(s)}e^{X_S^- s}}_{m' \quad terms} y_0, \tag{4.11}$$

where $s \in [0, \pi]$, $t \in [0, v(s)]$, the number of bang arcs (m and m', respectively) is an integer, and

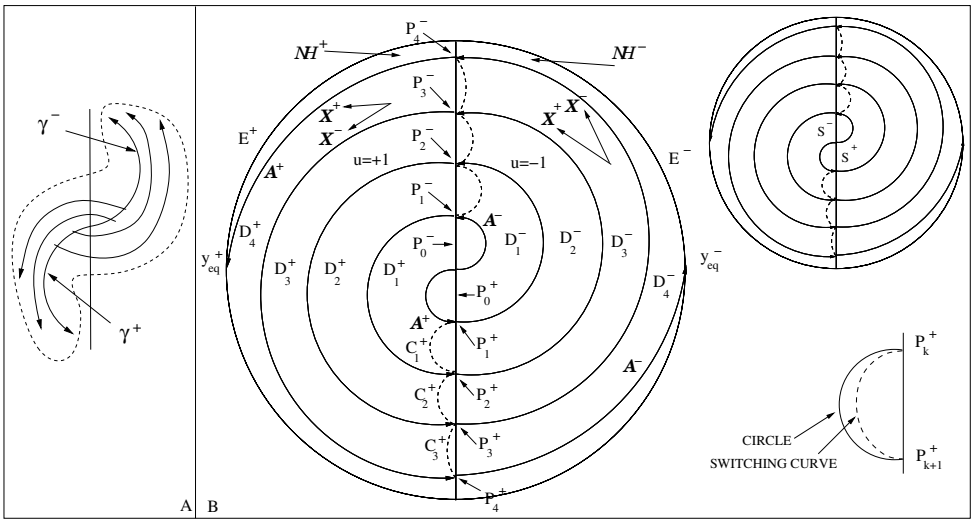

FIG. 4.5.

(-) $\varepsilon = +1$ *(resp.,* $\varepsilon = -1$*) if* m *is odd (resp., even);*
(-) $\varepsilon' = +1$ *(resp.,* $\varepsilon' = -1$*) if* m' *is even (resp., odd).*

Step 3. Let $\mathcal{A}^+$ and $\mathcal{A}^-$ be the two extremal trajectories starting, respectively, with controls $u \equiv 1$ and $u \equiv -1$, and switching after time π, i.e., corresponding, respectively, to $\Xi^+(\pi, \cdot)$ and $\Xi^-(\pi, \cdot)$. These two curves are abnormal extremals and their respective first bang arcs coincide with γ^+_{op} and γ^-_{op}. As explained in Remark 7, these two curves become strict abnormal extremals after time π.

To describe them, consider, for $\varepsilon = \pm$ and $0 \le k \le \tilde{k}$ ($\tilde{k}$ defined below), the half-circles $L^\varepsilon_k \subset Clos(\mathcal{NH}^\varepsilon)$, whose centers lie on $\overrightarrow{0P(\varepsilon\alpha)}$ and pass through the points $P^{-\varepsilon}_k$ and P^ε_{k+1}, where

$$P^+_n := P(2n\alpha), \quad P^-_n := P(-2n\alpha)$$

for the integers n so that $2n\alpha \le \frac{\pi}{2} + 2\alpha$. Note that $\frac{\pi}{2} + 2\alpha < \pi$ for $\alpha < \frac{\pi}{4}$ and, in fact, the last P^ε_n belongs to the bottom-half hemisphere, i.e., $n \le \tilde{k}$, where $\tilde{k} := 2 + \left[\frac{\pi}{4\alpha}\right]$. It is easy to see that $\mathcal{A}^+$ intersects the top half-meridian according to the following ordered sequence of points: y_0, P^+_1, P^-_2, $P^+_3, \ldots$. Similarly, $\mathcal{A}^-$ intersects the top half-meridian at y_0, P^-_1, P^+_2, $P^-_3, \ldots$. Moreover, let y^+_{eq} and y^-_{eq} be the antipodal points of the equator which are the respective first intersections of $\mathcal{A}^+$ and $\mathcal{A}^-$ with the equator. Note that they are reached at the same time T_{eq}. Finally, consider the open subset of the top hemisphere bounded below by the equator and obtained by removing the supports of $\mathcal{A}^+$ and $\mathcal{A}^-$ up to time T_{eq}, i.e., all the L^ε_k. That set is the disconnected union of the two "snake-shaped" simply connected regions S^+ and S^- (defined so that each S^ε contains the center of rotation of X^ε_S). Clearly S^+ and S^- are made of open segments of the meridian and open simply connected regions $D^\varepsilon_k \subset \mathcal{NH}^\varepsilon$ defined as follows. For $k = 0$, D^ε_0 is delimited by $\mathrm{Supp}(\gamma^\varepsilon_{op})$ and the segment $[P_0, P^\varepsilon_1]$ and, for $k \ge 1$, D^ε_k is delimited by L^ε_{k-1} on the top, L^ε_k on the bottoms, and by the segments $[P^{-\varepsilon}_{k-1}, P^{-\varepsilon}_k]$ and $[P^\varepsilon_k, P^\varepsilon_{k+1}]$ on the sides; see Figure 4.5(b).

In what follows, if A, B are two subsets of points of S^ε, we say that A is *above* B (or equivalently B is *below* A) if $A \subset D^{\varepsilon'}_k$ and $B \subset D^{\varepsilon''}_{k'}$ with $k < k'$, for some $\varepsilon', \varepsilon''$.

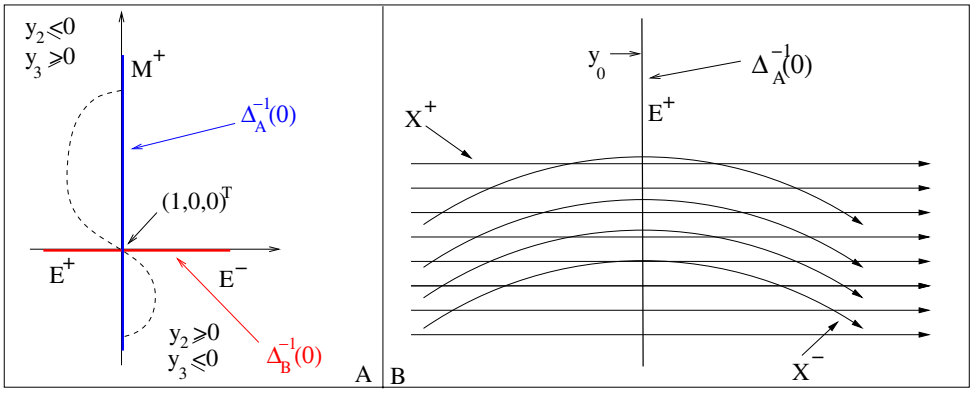

FIG. 4.6.

Step 4. The switching curves (SC), associated with the set of extremals given in (4.10) and (4.11), are defined as follows: they can be divided into two families, (C_k^+) and (C_k^-). If $\varepsilon = \pm$, $1 \le k \le N_0 - 1$, and $s \in [0, \pi]$, then

$$C_1^\varepsilon(s) = e^{X_S^\varepsilon v(s)} e^{X_S^{-\varepsilon} s} y_0, \quad C_{k+1}^\varepsilon(s) = e^{X_S^\varepsilon v(s)} C_k^{-\varepsilon}(s).$$

The boundary points of C_k^ε are $C_k^\varepsilon(0) = P_k^\varepsilon$ and $C_k^\varepsilon(\pi) = P_{k+1}^\varepsilon$. By using Proposition 9 and since $v(s) \ge \pi$, $s \in [0, \pi]$, the support of C_k^ε is contained in the subset of $Clos(\mathcal{NH}^\varepsilon)$, delimited by the half-circle centered on $\overrightarrow{0P(\alpha(2k+1))}$ and passing through the points $P_k^\varepsilon, P_{k+1}^\varepsilon$, and the segment of the meridian $[P_k^\varepsilon, P_{k+1}^\varepsilon]$; see Figure 4.5(b). In particular, a SC with boundary points in the top hemisphere is entirely contained in the top hemisphere and the intersection of its support with the top meridian reduces to its boundary points (see Lemma 3).

We next describe the shape of the first SC intersecting the equator. By symmetry, we may assume $\varepsilon = +$. We claim that its intersection with the equator reduces to the point $P(\frac{\pi}{2}) = (1, 0, 0)^T$. Indeed, by the switching rules established in Proposition 9, the SC intersecting the equator is contained in $\{y \in S^2 : y_2 \le 0, y_3 \ge 0\} \cup \{y \in S^2 : y_2 \ge 0, y_3 \le 0\}$. Taking into account the regularity of the SC and the values of its boundary points, the claim is proved; see Figure 4.6(a).

4.4. Computation of $N_S(\alpha)$. In the previous section, we provided detailed information about extremal trajectories and switching curves but we did not show that every extremal of (4.10) and (4.11) is in fact time optimal. Anyway, a rigorous derivation of $N_S(\alpha)$ is possible with the available knowledge of time-optimal trajectories combined with the subsequent lemmas.

LEMMA 7. *Every time-optimal trajectory γ starting at y_0 intersects the equator at most once.*

Proof of Lemma 7. We argue by contradiction. There would exist two distinct points of the equator q_i, q_f so that $\gamma(t_i) = q_i$, $\gamma(t_f) = q_f$ and $\gamma|_{(t_i,t_f)}$ is entirely contained in the (closed) bottom hemisphere. Let γ_{sing} be the integral curve of F_S (contained in the equator) connecting q_i to q_f. Consider now the region of the bottom hemisphere bounded by γ_{sing} and $\gamma|_{(t_i,t_f)}$. Taking into account, first, the relative positions of X_S^+, X_S^-, F_S, and G_S along the equator and, second, the sign of f_S in the bottom hemisphere, one can check that $T(\gamma_{sing}) \le T(\gamma|_{(t_i,t_f)})$. The argument is similar to that of [32] (see also [12]) and is based on the use of Stokes theorem. Since

time-optimal trajectories starting at y_0 do not contain a singular arc, it follows that γ cannot be time optimal. We have reached a contradiction. □

LEMMA 8. *Every time-optimal trajectory γ, starting at y_0 and remaining in $\underline{\mathcal{NH}}$, is the projection of a time-optimal trajectory of (Σ) starting at Id.*

Proof of Lemma 8. From the definition of the Hopf fibration, every trajectory γ of $(\Sigma)_S$, starting at y_0, associated with an admissible control u and staying in $\underline{\mathcal{NH}}$, is the projection of the trajectory $\bar{\gamma}$ of (Σ) starting at Id with the same control u. In particular, γ and $\bar{\gamma}$ have same time duration. It is clear that if γ is time optimal, then $\bar{\gamma}$ is also time optimal. □

LEMMA 9. *Recall that $S^\varepsilon \subset \mathcal{NH}$. With the notations above, choose any point y in the region S^ε and let γ_y be a time-optimal trajectory connecting the north pole y_0 to y. If $s \in]0, \pi[$ is the time duration of the first bang arc and $T(y)$ the total time duration of γ_y, then $\gamma_y|_{(s,T(y)]}$ is entirely contained in S^ε.*

Proof of Lemma 9. By the switching rules of Proposition 9, along every time-optimal trajectory contained in $\mathcal{NH}^\varepsilon$, the control must switch from ε to $-\varepsilon$, when arriving at a switching curve C_k^ε. In addition, the time-optimal trajectory switches from being an arc of a circle (integral curve of X_S^ε) to another arc of a circle of bigger radius (integral curve of $X_S^{-\varepsilon}$). After rectification of the flow of X_S^ε (i.e., the one entering the SC C_k^ε), and then by taking into account Remark 9, one gets the situation depicted in Figure 4.6(b).

By contradiction, we assume that there exists a time-optimal trajectory γ with time duration T and first bang arc time duration $s < T$ such that γ connects y_0 to $y \in S^\varepsilon$ and $\gamma|_{(s,T]}$ exits from S^ε. Let t' be the smallest time (in $[0, T]$) so that $\gamma|_{(t',T]}$ is entirely contained in S^ε. Then $\gamma(t')$ belongs to $\mathrm{Supp}(\mathcal{A}^+_{[0,T_{eq}]}) \cup \mathrm{Supp}(\mathcal{A}^-_{[0,T_{eq}]})$ (see step 3 of section 4.3 for the definition of T_{eq}). If $\gamma(t')$ is on the (top) meridian, then it has to switch so that the interior bang time duration is constant, equal to π. Therefore, $\gamma|_{(t',T]}$ will never re-enter S^+. We thus deduce that $\gamma(t')$ is not on the meridian and, with no loss of generality, we will assume that $\gamma(t')$ belongs to the (one-dimensional) interior of some L_k^+, $k \geq 1$. Now we make the following two claims.

CLAIM 1. *With the notations above, there exist $t'' < t' < t'''$ such that*

$$\gamma|_{(t',t''')} \subset D_k^{\varepsilon'} \subset S^\varepsilon \text{ and } \gamma|_{(t'',t')} \subset D_{k+1}^{\varepsilon'} \subset S^{-\varepsilon}, \text{ for some } \varepsilon' \in \{+,-\},$$

i.e., γ passes (backward in time) from S^ε to $S^{-\varepsilon}$ at time t' by going "down."

Proof of Claim 1. It is clear that there exists a neighborhood U of t' so that $\gamma|_U$ is an integral curve of $X_S^{-\varepsilon}$. Thanks to Remark 9 and to the argument above, $\gamma|_U$ intersects $Int(L_k^+)$ transversally (see Figure 4.7) in such a way that γ, run backward in time, goes from D_k^+ to D_{k+1}^+. Claim 1 is proved. □

Now, by definition of t', $\gamma(t') \in \mathcal{A}^\varepsilon|_{[0,T_{eq}]}$. Let γ_{ab} be the restriction of $\mathcal{A}^\varepsilon$ between y_0 and $\gamma(t')$. Consider $\tilde{\gamma}$, the concatenation of γ_{ab} and $\gamma|_{(t',T]}$. The conclusion of Lemma 9 will follow if one can show that the time duration T' of $\tilde{\gamma}$ is less than T, the time duration of γ. This, in turn, amounts to showing that T' (the time duration of γ_{ab}) is less than t' (the time duration of $\gamma|_{[0,t']}$). This is the object of the next claim.

CLAIM 2. *With the notations above, we have $T' < t'$.*

Proof of Claim 2. The trajectory γ, run backward in time from t', is an $X_S^{-\varepsilon'}$-integral curve until it hits a SC in some $D_L^\varepsilon \in \mathcal{NH}^{\varepsilon'}$, for some integer $L \geq k+1$, at a point $C_L^{\varepsilon'}(\bar{s})$, $\bar{s} \in]0, \pi[$. One can easily conclude that the only possibility is $L = k+1$. By Claim 1, a time-optimal trajectory can pass (backward in time) from S^ε to $S^{-\varepsilon}$ only by going down, i.e., by passing from some $D_k^{\varepsilon'}$ to $D_{k+1}^{\varepsilon'}$. Therefore, by

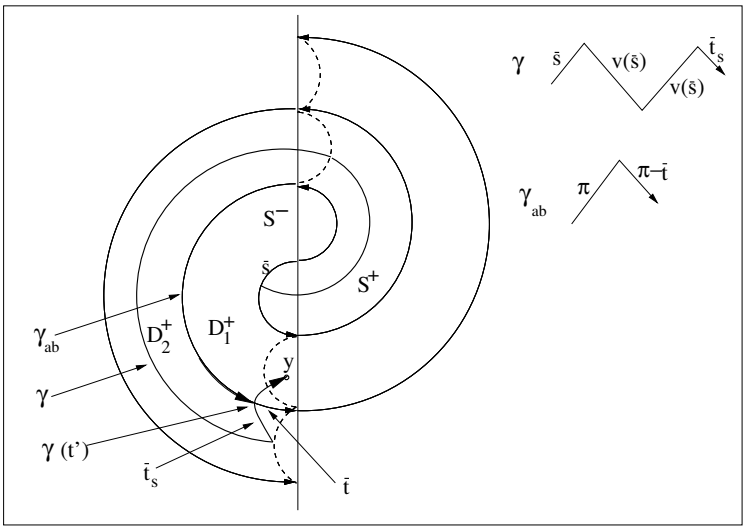

FIG. 4.7. *Proof of Lemma* 9. *Here to fix the ideas we set* $\varepsilon = -,\ \varepsilon' = +,\ k = 1$.

an elementary counting argument, one gets

$$t' = \bar{s} + t_{\bar{s}} + (k+1)v(\bar{s}),$$

where $t_{\bar{s}}$ is the time needed to go from $\gamma(t')$ to $C^+_{k+1}(\bar{s})$. On the other hand,

$$T' = (K+1)\pi - \tilde{t},$$

where $\tilde{t} \in]0, \pi[$ is the time needed for $\mathcal{A}^\varepsilon$ to go from $\gamma(t')$ to P^+_{k+1}. Since $v(\bar{s}) > \pi$, $T' < t'$. The proof of Lemma 9 is finished. □

Remark 10. Coupled with the proof of Claim 2, a simple continuity argument implies that $\mathcal{A}^+$ and $\mathcal{A}^-$ are time-optimal trajectories in the top hemisphere.

Gathering all the information on time-optimal trajectories, we are now able to compute $N_S(\alpha)$.

PROPOSITION 13. *For* $\alpha \in]0, \pi/4[$, *we have*

$$N_S(\alpha) := 2\left[\frac{\pi}{8\alpha}\right] - \left[2\left[\frac{\pi}{8\alpha}\right] - \frac{\pi}{4\alpha}\right]. \tag{4.12}$$

Proof of Proposition 13. Let $y \in S^+$ and γ be a time-optimal trajectory connecting y_0 to y. The point y belongs to some D^+_k, $k \le N_0$ and, by Lemma 9, γ remains in S^+. Since the function v takes values in $[\pi, \pi + \pi/2]$, it is easy to see from (4.10) and (4.11) and Remark 10 that γ, run backward in time, will go through the ordered sequence of regions D^+_k, D^-_{k-1}, D^+_{k-2}, etc. until hitting one of the two curves γ^+_{op} or γ^-_{op}. Moreover, in each of the regions D^ε_l, γ will switch *exactly* once, thanks to Proposition 9. Therefore, the number of times an optimal trajectory γ starting at y_0 switches is exactly equal to the number of times γ crosses the subset of the meridian

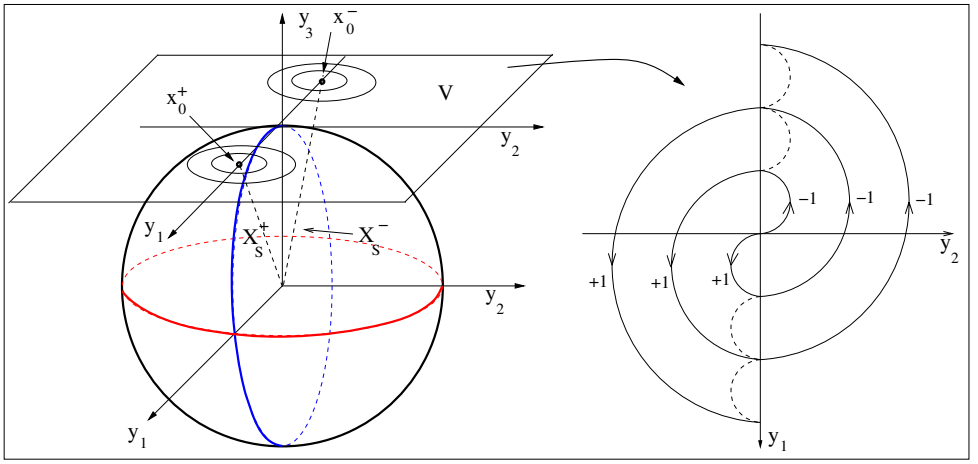

FIG. 4.8. *Stereographic projection and synthesis of the linear pendulum.*

contained in $\mathcal{NH}$. The same conclusion holds for points belonging to S^-, $\mathcal{A}^+$, and $\mathcal{A}^-$. By a systematic examination of all the possible cases, we end up with (4.12). Note that $N_S(\alpha)$ is the number of switchings for a time-optimal trajectory ending on the equator. □

4.5. Geometric remarks.

4.5.1. Relations with the linear pendulum. In a fixed neighborhood of the north pole, the control system on the sphere (3.1) behaves, when $\alpha > 0$ is small enough, as a controlled linear pendulum. More precisely, let us consider the stereographic projection of the sphere from the south pole $(0, 0, -1)$ on V, the tangent plane to the sphere at the north pole. If y_1, y_2, y_3 are the coordinates of the three-dimensional Euclidean space where the sphere is embedded, a system of coordinates on V is (y_1, y_2); see Figure 4.8. Let x_0^+ and x_0^- be the projections of the equilibrium points of X_S^+ and X_S^- in $\mathcal{NH}$.

An alternative way of parametrizing this problem (instead of fixing the radius of the sphere and varying the axes of rotations) consists of fixing the points $x_0^+ = (1, 0)^T$, $x_0^- = (-1, 0)^T$ and varying the radius r of the sphere. The relation between α and r is $\tan(\alpha) = 1/r$. The range $\alpha \in]0, \pi/4[$ becomes $r \in]1, \infty[$ and $\alpha \to 0$ corresponds to $r \to \infty$. In V, fix a ball $B(0, r_0)$ of radius $r_0 > 0$ centered in the origin, and consider the stereographic projection of the integral curves of X_0^+ and X_0^-. For $r \to \infty$, they become circles centered at the points $x_0^\pm$. Then, one easily sees that, in $B(0, r_0)$, the limit system (and the associated synthesis) corresponds to a controlled linear pendulum (with the associated synthesis) given by the equation $\dot{y}_1 = -y_2$, $\dot{y}_2 = y_1 - u$, $|u| \le 1$. Note that $\lim_{\alpha \to \infty} v(s) = \pi$, that is exactly the time duration of interior bang arcs for the linear pendulum.

4.5.2. The time-optimal problem on $SU(2)$. The optimal control problem on $\underline{NH}$ is the projection (by a Hopf fibration) of an optimal control problem on $SO(3)$. Similarly, the corresponding problem on the whole sphere S^2 is the projection (by an appropriate Hopf fibration) of an optimal control problem on $SU(2)$. Indeed, $SU(2)$ is the universal (double) covering of $SO(3)$ and they have the same Lie algebra $so(3)$. The existence of that double covering justifies, by a factor 2, the difference

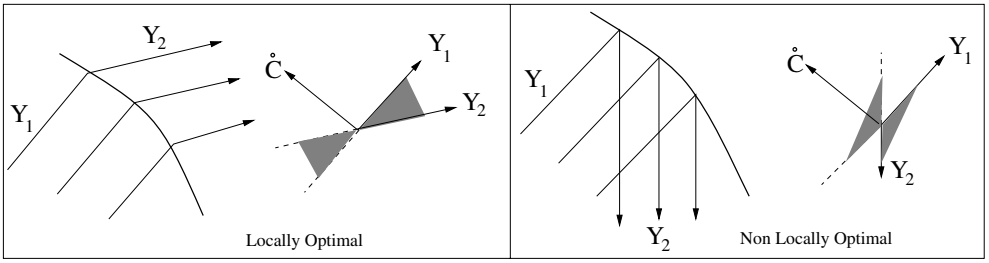

FIG. 5.1. *Definition 7.*

between our bound and the bound (1.2), on the maximal number of switchings for the control problem on $SO(3)$. Indeed, the index theory developed by Agrachev and Gamkrelidze in [3, 5] provides a bound on the number of switchings by proving that a certain extremal is not optimal because it loses *local optimality* working at the Lie algebraic level. This is why the upper bound in (1.2) corresponds (essentially) to a control problem on $SU(2)$, and thus, after projection, on a control problem on the whole sphere S^2, and not just on $\underline{NH}$. The other factor 2, of the difference between our bound and the bound given in (1.2), comes from the fact that in [3] the index of the second variation was estimated up to an additive factor 1 (see [3, p. 275]).

5. Conclusion and open problems. In the previous section, we derived a set of properties of the optimal synthesis that were sufficient to compute the maximum number of switchings of a time-optimal trajectory joining y_0 to any point of the north hemisphere. This enabled us to provide a precise estimate for $N(\alpha)$, $\alpha \in]0, \pi/4[$. However, the following questions remain unsolved.

Question 1. Are all the extremal trajectories (4.10) and (4.11) optimal in the north hemisphere?

The answer to this question depends on the answer to the next question.

Question 1′. In the north hemisphere, are the switching curves $C_k^\varepsilon(s)$, $s \in]0, \pi[$, locally optimal? (The points $s = 0, s = \pi$ are not included since we already know that the two abnormal extremal $\mathcal{A}^\pm$ are optimal in $\mathcal{NH}$.)

Roughly speaking we say that a switching curve is locally optimal if it never "reflects" the trajectories. More precisely, we have the following definition (clarified by Figure 5.1).

DEFINITION 7. *Consider a smooth switching curve C between two smooth vector fields Y_1 and Y_2 on a smooth two-dimensional manifold. Let $C(s)$ be a smooth parametrization of C. We say that C is locally optimal if, for every $s \in Dom(C)$, we have*

$$\dot{C}(s) \neq \alpha_1 Y_1(C(s)) + \alpha_2 Y_2(C(s)), \text{ for every } \alpha_1, \alpha_2 \text{ such that } \alpha_1 \alpha_2 \geq 0. \tag{5.1}$$

The points of a switching curve on which relation (5.1) is not satisfied are usually called "conjugate points."

Remark 11. Note that, if all the switching curves are locally optimal in the north hemisphere, it follows that the set of extremals (4.10) and (4.11) (restricted to $\underline{\mathcal{NH}}$) is an optimal synthesis for problem (3.1) on $\mathbb{R}P^2$. In this case, on $\mathbb{R}P^2$, the extremals (4.10) and (4.11) lose global optimality before losing local optimality.

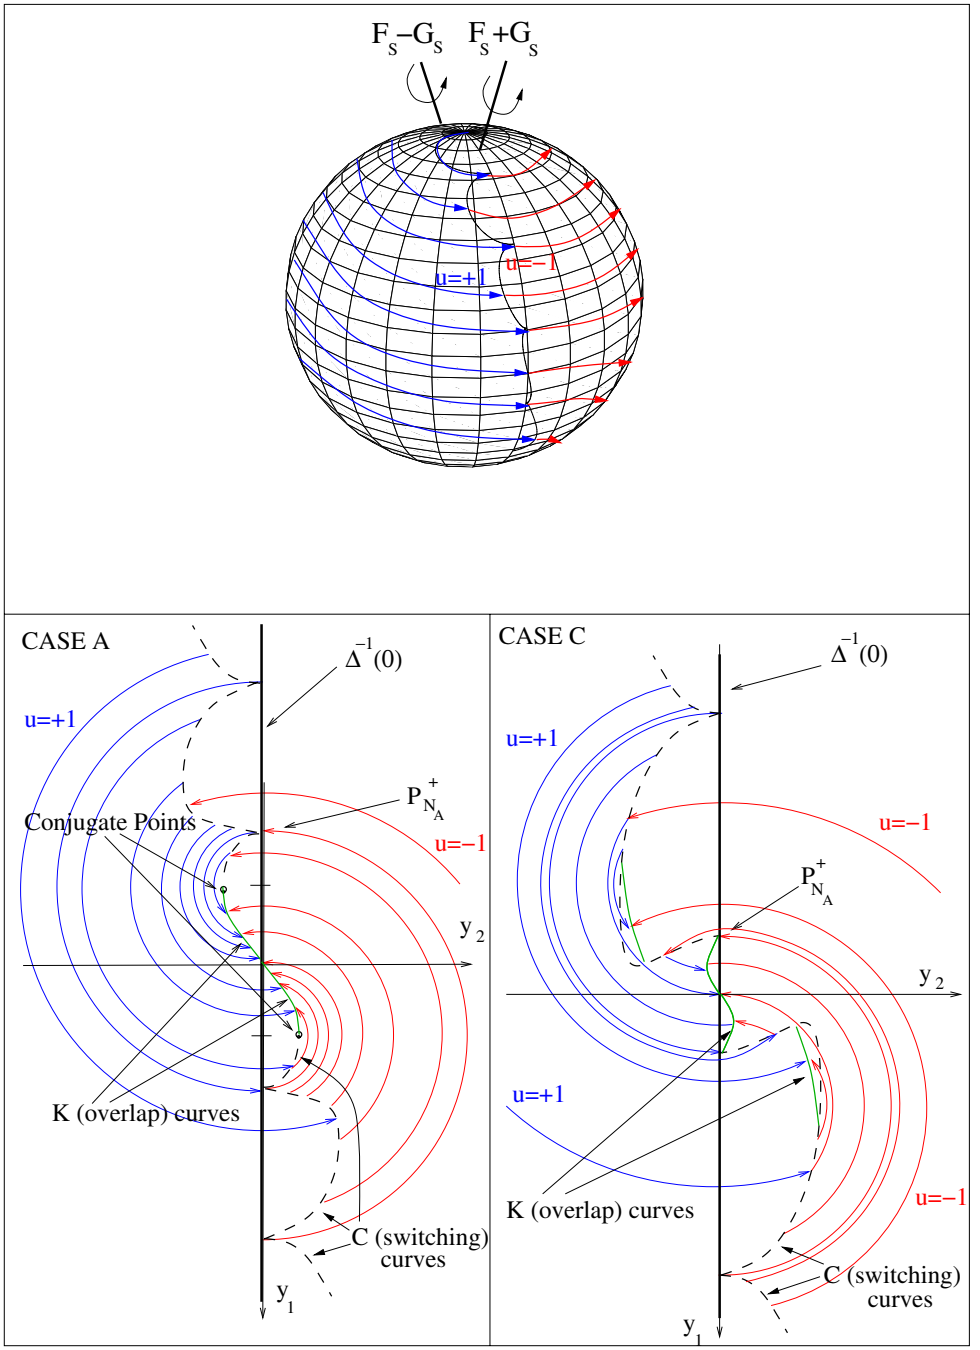

FIG. 5.2. *The time-optimal synthesis on the sphere (top) and optimal synthesis in a neighborhood of the south pole, Case A and Case C (bottom).*

Question 2. If the answer to Question 1′ is yes, what about the same question for the optimal control problem on S^2? More precisely, one would like to understand how the extremal trajectories (4.10) and (4.11) are going to lose optimality in a neighborhood of the south pole (i.e., if the loss of optimality is local or just global).

Question 3. What is the shape of the optimal synthesis in a neighborhood of the south pole?

In this section, we present the results of some numerical simulations which provide some hints regarding the above questions. More precisely we make the following observations.

- There is strong numerical evidence for a positive answer to Question 1′. This means that the switching curves in the north hemisphere never reflect trajectories. In other words, situations like those considered in the proof of Lemma 9 (cf. Figure 4.7) are not possible.
- As regards Question 2, we conjecture the following:

  C1. The curves $C_k^\varepsilon(s)$, $s \in]0, \pi[$ are locally optimal if and only if $X_S^+(C_k^\varepsilon(0)) = \alpha_1 X_S^- C_k^\varepsilon(0)$ and $X_S^+(C_k^\varepsilon(\pi)) = \alpha_2 X_S^- C_k^\varepsilon(\pi)$ with $\alpha_1, \alpha_2 \geq 0$ but not both vanishing.

  This condition is verified if and only if $k \leq \left[\frac{\pi-\alpha}{2\alpha}\right] - 1$, which simply follows from Remark 9.

  Set $N_A := \left[\frac{\pi}{2\alpha}\right]$. Analyzing the evolution of the minimum time wave front in a neighborhood of the south pole, it is reasonable to conjecture the following.

  C2. For $T \leq (N_A - 1)\pi$, the synthesis built above is optimal. Every $x \in S^2$ is reached in time $T \leq (N_A + 1)\pi$. sxsEvery optimal trajectory has at most N_A switchings and there exists an optimal trajectory having $N_A - 1$ switchings.

  On the top of Figure 5.2, the optimal synthesis is plotted.
- Regarding Question 3, numerical simulations suggest that the shape of the optimal synthesis for time $T > (N_A - 1)\pi$ depends on the remainder

$$r := \pi - 2\alpha N_A = \pi - 2\alpha \left[\frac{\pi}{2\alpha}\right].$$

  Note that r belongs to the interval $[0, 2\alpha[$. More precisely, we conjecture the following

  C3. For $\alpha \in]0, \pi/4[$, there exist two positive numbers α_1 and α_2 such that $0 < \alpha_1 < \alpha < \alpha_2 < 2\alpha$ and

    Case A: $r \in]\alpha_2, 2\alpha[$. The switching curve starting at $P_{N_A}^+$ glues to an overlap curve that passes through the origin (see the bottom of Figure 5.2, Case A).

    Case B: $r \in [\alpha_1, \alpha_2]$. An overlap curve starts exactly at $P_{N_A}^+$ and passes through the origin.

    Case C: $r \in]0, \alpha_1[$. The situation is more complicated and it is depicted in the bottom of Figure 5.2, Case C.

  For $r = 0$, the situation is the same as in Case A, but for the switching curve starting at $P_{N_A-1}^+$.

Acknowledgments. The authors are grateful to Andrei Agrachev for suggesting the problem and for many geometric hints. The authors would also like to thank Benedetto Piccoli, Gregorio Falqui, Mario Sigalotti, and Paolo Mason for helpful discussions.

GLOBAL EXACT BOUNDARY CONTROLLABILITY OF A CLASS OF QUASILINEAR HYPERBOLIC SYSTEMS OF CONSERVATION LAWS II*

DE-XING KONG† AND HUI YAO‡

Abstract. In this paper, by a new constructive method, the authors reprove the global exact boundary controllability of a class of quasilinear hyperbolic systems of conservation laws with linearly degenerate characteristics. It is shown that the system with nonlinear boundary conditions is globally exactly boundary controllable in the class of piecewise C^1 functions. In particular, the authors give the optimal control time of the system. Finally, a new example belonging to this kind of system is also provided.

Key words. quasilinear hyperbolic system, conservation laws, global exact boundary controllability, Cauchy problem, Goursat problem, classical discontinuous solution, contact discontinuity, optimal control time

1. Introduction.

Consider the following quasilinear system in a form of conservation laws:

$$\begin{cases} u_t + f(u,v)_x = 0, \\ v_t + g(u,v)_x = 0, \end{cases} \tag{1.1}$$

where $u = u(t,x)$ and $v = v(t,x)$ are unknown functions and f, $g \in C^2(\mathcal{N})$ for some closed bounded domain $\mathcal{N}$ in $\mathbb{R}^2$. Let $F = (f,g)^T$ and

$$\nabla F(U) = \begin{pmatrix} f_u & f_v \\ g_u & g_v \end{pmatrix},$$

where $U = (u,v)$. We assume that

(H_1) On the domain $\mathcal{N}$ under consideration, system (1.1) is *strongly strictly hyperbolic*, i.e., for any given $U \in \mathcal{N}$, $\nabla F(U)$ has two distinct real eigenvalues $\lambda_1(U)$, $\lambda_2(U)$:

$$\lambda_1(U) < 0 < \lambda_2(U) \quad \forall\, U \in \mathcal{N}. \tag{1.2}$$

Let $\vec{l}_i(U) = (l_{i1}(U), l_{i2}(U))$ (resp., $\vec{r}_i(U) = (r_{i1}(U), r_{i2}(U))^T$) be a left (resp., right) eigenvector corresponding to $\lambda_i(U)$ $(i = 1,2)$:

$$\vec{l}_i(U)\nabla F(U) = \lambda_i(U)\vec{l}_i(U) \qquad (\text{resp., } \nabla F(U)\vec{r}_i(U) = \lambda_i(U)\vec{r}_i(U)).$$

(H_2) System (1.1) is *linearly degenerate*:

$$\nabla\lambda_i(U)\cdot\vec{r}_i(U) \equiv 0 \quad (i = 1,2) \quad \forall\, U \in \mathcal{N}. \tag{1.3}$$

(H_3) For any given real number a, let $H_i^a \triangleq \{U \,|\, \lambda_i(U) = a\}$ $(i = 1, 2)$. For any given $U_1, U_2 \in H_i^a$, there exists a C^1 curve segment $U = U(\tau)$ $(\tau \in [\tau_1, \tau_2])$ in $\mathcal{N}$ such that

$$U(\tau_j) = U_j \quad (j = 1, 2) \quad \text{and} \quad U(\tau) \in H_i^a \quad \forall\, \tau \in [\tau_1, \tau_2] \tag{1.4}$$

and

$$\nabla \lambda_i (U(\tau)) \neq 0 \qquad \forall\, \tau \in [\tau_1, \tau_2] \quad (i = 1, 2). \tag{1.5}$$

(H_4) There are *global* Riemann invariants for the system (1.1)

$$R_1 = R_1(U), \quad R_2 = R_2(U). \tag{1.6}$$

Remark 1.1. *Any quasilinear hyperbolic system with two unknown functions*

$$\frac{\partial u_i}{\partial t} + \sum_{j=1}^{2} a_{ij}(u_1, u_2) \frac{\partial u_j}{\partial x} = 0 \qquad (i = 1, 2)$$

can always be reduced to a system with the diagonal form at least in a local domain. This means that for any quasilinear hyperbolic system with two unknown functions, the local Riemann invariants always exist. On the other hand, many physical systems (for example, the system of isentropic gas) always possess global Riemann invariants.

By the assumptions (H_2) and (H_4), in the Riemann invariants, (1.1) can be rewritten as

$$\begin{cases} \dfrac{\partial R_1}{\partial t} + \mu_1(R_2) \dfrac{\partial R_1}{\partial x} = 0, \\ \dfrac{\partial R_2}{\partial t} + \mu_2(R_1) \dfrac{\partial R_2}{\partial x} = 0, \end{cases} \tag{1.7}$$

where

$$\mu_1(R_2(U)) = \lambda_1(U) \quad \text{and} \quad \mu_2(R_1(U)) = \lambda_2(U). \tag{1.8}$$

Recently, Kong [5] investigates the following *exact boundary control problem* for the system (1.1). Consider system (1.1) posed on the domain

$$\mathcal{D} = \{(t, x) |\, t \geq 0, \ -1 \leq x \leq 1\}$$

with the nonlinear boundary conditions

$$\begin{array}{ll} B_1(u, v, t) + h_1(t) = 0 & \text{at } x = -1, \\ B_2(u, v, t) + h_2(t) = 0 & \text{at } x = 1 \end{array} \tag{1.9}$$

and the initial data

$$t = 0 : (u, v) = \begin{cases} \left(u_0^-(x), v_0^-(x)\right) & \forall\, x \in [-1, 0], \\ \left(u_0^+(x), v_0^+(x)\right) & \forall\, x \in [0, 1], \end{cases} \tag{1.10}$$

where $B_i(u, v, t)$ are given smooth functions, $(u_0^-(x), v_0^-(x)) \in \mathcal{N}$ and $(u_0^+(x), v_0^+(x)) \in \mathcal{N}$ are C^1 vector functions, defined for $x \in [-1, 0]$ and $x \in [0, 1]$, respectively, satisfying

$$\left(u_0^-(0), v_0^-(0)\right) \neq \left(u_0^+(0), v_0^+(0)\right). \tag{1.11}$$

EXACT BOUNDARY CONTROL PROBLEM. *Given*

$$U_z(x) = \begin{cases} (u_z^-(x), v_z^-(x)) \in C^1([-1,0]) \times C^1([-1,0]), \\ (u_z^+(x), v_z^+(x)) \in C^1([0,1]) \times C^1([0,1]), \end{cases} \qquad z = 0,\ T, \tag{1.12}$$

can we find a time $T > 0$ and control inputs $h_1(t)$, $h_2(t)$ in the class of piecewise C^1 functions defined on $[0,\ T]$, such that the boundary control system (1.1), (1.9) *has a piecewise C^1 solution $U = U(t,x)$ containing contact discontinuities and satisfying the initial condition* (1.10) *and the terminal condition*

$$U(T,x) = U_T(x)? \tag{1.13}$$

Kong [5] proves the following theorem.

THEOREM A. *Under the hypotheses (H_1)–(H_4), for given $U_z(x)$ $(z = 0, T)$ (see* (1.12)*) and for any $T > \bar{T}_0$, there exist piecewise C^1 control inputs $h_1(t)$ and $h_2(t)$ defined for $t \in [0,T]$ such that system* (1.1), (1.9) *possesses a piecewise C^1 solution $U = U(t,x)$ on the domain*

$$\mathcal{D}(T) = \{(t,x) |\ 0 \le t \le T,\ \ -1 \le x \le 1\} \tag{1.14}$$

containing four contact discontinuities and satisfying

$$U(0,x) = U_0(x), \quad U(T,x) = U_T(x) \quad \forall\ x \in [-1,1], \tag{1.15}$$

where $\bar{T}_0$ is defined by

$$\bar{T}_0 = \max\left\{-\frac{2}{\bar{\lambda}_1},\ \frac{2}{\underline{\lambda}_2}\right\} + \max\left\{-\frac{2}{\bar{\lambda}_1},\ \frac{2}{\underline{\lambda}_2},\ \frac{4}{\underline{\lambda}_2 - \bar{\lambda}_1}\right\}, \tag{1.16}$$

in which

$$\bar{\lambda}_1 = \max_{|R_2| \le M} \mu_1(R_2), \qquad \underline{\lambda}_2 = \min_{|R_1| \le M} \mu_2(R_1). \tag{1.17}$$

Here M is given by

$$M = \max_{\substack{z=0,T \\ i=1,2}} \left\{ \|R_i(u_z^-(x), v_z^-(x)\|_{C^0([-1,0])},\ \|R_i(u_z^+(x), v_z^+(x)\|_{C^0([0,1])} \right\}. \tag{1.18}$$

REMARK 1.2. *Theorem* A *shows that the system* (1.1) *with nonlinear boundary conditions* (1.9) *is globally exactly boundary controllable in the class of piecewise C^1 functions. However, the control time $\bar{T}_0$, defined by* (1.16), *is not optimal.*

In this paper, by a new constructive method, we reprove the global exact boundary controllability of the system (1.1) with the optimal control time. The main result is the following theorem.

THEOREM 1.1. *Under the hypotheses (H_1)–(H_4), for given $U_z(x)$ $(z = 0, T)$ (see* (1.12)*) and for any $T > T_0$, there exist piecewise C^1 control inputs $h_1(t)$ and $h_2(t)$ defined for $t \in [0,T]$ such that system* (1.1), (1.9) *possesses a piecewise C^1 solution $U = U(t,x)$, containing four contact discontinuities and satisfying* (1.15), *on the domain $\mathcal{D}(T)$, where T_0 is defined by*

$$T_0 = \max\left\{-\frac{2}{\bar{\lambda}_1},\ \frac{2}{\underline{\lambda}_2},\ \frac{4}{\underline{\lambda}_2 - \bar{\lambda}_1}\right\}. \tag{1.19}$$

REMARK 1.3. *Comparing* (1.16) *with* (1.19)*, we observe that* $\bar{T}_0 > T_0$*. The condition* $T > T_0$ *in Theorem* 1.1 *is sharp and* T_0 *is optimal in the sense that, if* $T \le T_0$*, we may find a pair of initial and terminal states such that no matter what control inputs we choose, the system will not go from the given initial state to the desired terminal state during the time interval* $[0, T]$*. In this sense,* T_0 *defined by* (1.19) *is called the optimal control time of the system* (1.1)*.*

In order to illustrate the assertion claimed in Remark 1.3, i.e., the affirmation that the condition $T > T_0$ in Theorem 1.1 is sharp and T_0 is optimal, for simplicity we only consider the case that the characteristics λ_1, λ_2 are constants. In the present situation, there are two cases

Case I: $0 < -\lambda_1 \le \lambda_2$;

Case II: $0 < \lambda_2 < -\lambda_1$.

For Case I, we find that $T_0 = -2/\lambda_1$. If $T \le T_0$, by the characteristic method, it is easy to show that, there exists a pair of initial and terminal states such that no matter what control inputs we choose, the system will not go from the given initial state to the desired terminal state during the time interval $[0, T]$. In fact, it suffices to take the pair of initial and terminal states satisfying

$$R_1\left(u_0^+(1), v_0^+(1)\right) \neq \begin{cases} R_1\left(u_T^-(\lambda_1 T + 1), v_T^-(\lambda_1 T + 1)\right) & \text{if } \lambda_1 T + 1 \le 0, \\ R_1\left(u_T^+(\lambda_1 T + 1), v_T^+(\lambda_1 T + 1)\right) & \text{if } \lambda_1 T + 1 \ge 0. \end{cases} \tag{1.20}$$

Noting that the Riemann invariant R_1 keeps continuous across the contact discontinuities corresponding to the characteristic filed λ_2, we observe that, for such a pair of initial and terminal states satisfying (1.20), no matter what control inputs we choose, the system will not go from the given initial state to the desired terminal state during the time interval $[0, T]$.

For Case II, we have a similar discussion.

REMARK 1.4. *The hypothesis* (H_3) *is a technical assumption only for constructing contact discontinuities, Kong* [5] *gives two examples to show that some physical systems always satisfy it. Moreover, if the initial and terminal data are* C^1 *smooth, then the hypothesis* (H_3) *is not needed. In this case, Theorem* 1.1 *is the result given in Li and Zhang* [9]*.*

REMARK 1.5. *As in other works (e.g.,* [9]*), the solution of our exact boundary control problem does not possess uniqueness. In fact, even if the initial and terminal data are smooth, the solution of the system does not have uniqueness either (see* [8]*,* [9]*). In particular, the control inputs are not unique. This is due to the fact that we have some freedom to choose the control inputs, because the waiting time* $T > T_0$*. This fact can be observed from the proof of* Theorem 1.1*.*

This paper is organized as follows. Theorem 1.1 is proved in section 2 by a new constructive method. Section 3 gives some important supplementary remarks, while section 4 provides a new example of system such as described in section 3, namely, the system for time-like extremal surfaces in the $(1+n)$-dimensional Minkowski space $\mathbb{R}^{1+n}$.

2. Proof of Theorem 1.1. For readers' convenience, before starting the proof of Theorem 1.1, we first recall the definition of contact discontinuity.

DEFINITION 2.1. *$U = U(t, x)$ is called a piecewise C^1 solution containing a kth $(k = 1, 2)$ contact discontinuity $x = x_k(t)$ if $U = U(t, x)$ satisfies the system* (1.1) *out of $x = x_k(t)$ in the classical sense and satisfies the Rankine–Hugoniot condition on*

$x = x_k(t)$, *i.e.*,

$$\sigma \cdot [U] = [F], \tag{2.1}$$

$$\sigma = \lambda_k\left(U^+\right) = \lambda_k\left(U^-\right), \tag{2.2}$$

where $U^{\pm} = U(t, x_k(t) \pm 0)$ *and* $\sigma = x_k'(t)$.

Let

$$\begin{array}{llll} A = (0,-1), & B = (0,1), & C = (T,1), & D = (T,-1), \\ O = (0,0), & N = (T,0), & E = (t_e, x_e), & F = (t_f, x_f), \end{array} \tag{2.3}$$

where E is the intersection point of the lines

$$L_1: \ x = \bar{\lambda}_1 t + 1 \quad \text{and} \quad L_2: \ x = \underline{\lambda}_2 t - 1 \tag{2.4}$$

and F is the intersection point of the lines

$$\bar{L}_1: \ x = \bar{\lambda}_1 (t - T) - 1 \quad \text{and} \quad \bar{L}_2: \ x = \underline{\lambda}_2 (t - T) + 1. \tag{2.5}$$

Noting (1.19) and $T > T_0$, we observe that

$$t_e < t_f. \tag{2.6}$$

Step 1: Generalized Riemann problem for the system (1.1). First, we solve the generalized Riemann problem for the system (1.1) with discontinuous initial data (1.10). The following lemma comes from [7].

LEMMA 2.1. *Under the hypotheses* (H_1)*–*(H_4)*, the generalized Riemann problem* (1.1), (1.10) *has a unique piecewise* C^1 *solution* $(u, v) = (u(t,x), v(t,x))$*, containing two* C^1 *contact discontinuities starting from* O*, on the maximum determined domain* Ω_1 *enclosed by the characteristics* $x = x_1(t)$, $x = x_2(t)$ *and the* x*-axis:*

$$\Omega_1 = \{(t,x) |\, 0 \le t \le t_p,\ x_2(t) \le x \le x_1(t)\}, \tag{2.7}$$

where $x = x_1(t)$ *satisfies*

$$\frac{dx_1(t)}{dt} = \lambda_1(u, v), \qquad x_1(0) = 1, \tag{2.8}$$

where $x = x_2(t)$ *satisfies*

$$\frac{dx_2(t)}{dt} = \lambda_2(u, v), \qquad x_2(0) = -1, \tag{2.9}$$

and while t_p *is the time coordinate of the intersection point, denoted by* $P = (t_p, x_p)$*, of the characteristic* $x = x_1(t)$ *with the characteristic* $x = x_2(t)$*. See Figure* 1.

The solution (u, v) of the generalized Riemann problem (1.1), (1.10) is denoted by $U = U_1(t,x)$ on the domain Ω_1, its two contact discontinuities are denoted by $x = \xi_1(t)$ and $x = \xi_2(t)$, respectively. By the definition of contact discontinuity, $x = \xi_i(t)$ $(i = 1, 2)$ satisfy

$$\frac{\xi_i(t)}{dt} = \lambda_i\left(U_1^{\pm}\right), \quad \xi_i(0) = 0 \quad (i = 1, 2). \tag{2.10}$$

Moreover, let $P_1 = (t_{p_1}, x_{p_1})$ (resp. $P_2 = (t_{p_2}, x_{p_2})$) be the the intersection point of the characteristic $x = x_2(t)$ (resp. $x = x_1(t)$) with the contact discontinuity $x = \xi_1(t)$ (resp. $x = \xi_2(t)$). See Figure 1.

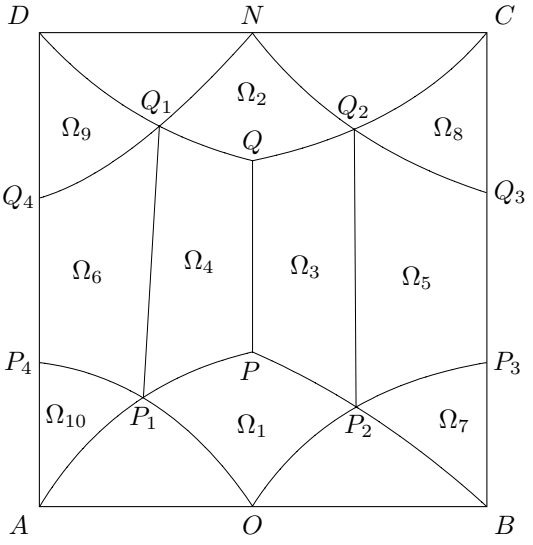

FIG. 1. *Domains* Ω_i $(i = 1, \ldots, 10)$*; characteristics:* $AP:\ x = x_2(t)$, $BP:\ x = x_1(t)$, $CQ:\ x = \tilde{x}_2(t)$, $DQ:\ x = \tilde{x}_1(t)$*; contact discontinuities:* $OP_1:\ x = \xi_1(t)$, $P_1P_4:\ x = \zeta_1(t)$, $OP_2:\ x = \xi_2(t)$, $P_2P_3:\ x = \zeta_2(t)$, $NQ_1:\ x = \tilde{\xi}_2(t)$, $Q_1Q_4:\ x = \tilde{\zeta}_2(t)$, $NQ_2:\ x = \tilde{\xi}_1(t)$, $Q_2Q_3:\ x = \tilde{\zeta}_1(t)$.

Similarly, we can solve the backward generalized Riemann problem for the system (1.1) with discontinuous initial data (1.13). We have the following lemma.

LEMMA 2.2. *Under the hypotheses* (H_1)*–*(H_4)*, the backward generalized Riemann problem* (1.1), (1.13) *has a unique piecewise* C^1 *solution* $(u, v) = (u(t, x), v(t, x))$*, containing two* C^1 *contact discontinuities starting from* N*, on the maximum determined domain* Ω_2 *enclosed by the characteristics* $x = \tilde{x}_1(t)$, $x = \tilde{x}_2(t)$ *and the line* $t = T$*:*

$$\Omega_2 = \{(t, x) |\, t_q \le t \le T,\ \tilde{x}_1(t) \le x \le \tilde{x}_2(t)\}, \tag{2.11}$$

where $x = \tilde{x}_1(t)$ *satisfies*

$$\frac{d\tilde{x}_1(t)}{dt} = \lambda_1\left(u, v\right), \qquad \tilde{x}_1(T) = -1, \tag{2.12}$$

where $x = x_2(t)$ *satisfies*

$$\frac{d\tilde{x}_2(t)}{dt} = \lambda_2\left(u, v\right), \qquad \tilde{x}_2(T) = 1 \tag{2.13}$$

and while t_q *is the time coordinate of the intersection point, denoted by* $Q = (t_q, x_q)$*, of the characteristic* $x = \tilde{x}_1(t)$ *with the characteristic* $x = \tilde{x}_2(t)$*. See Figure* 1.

The solution (u, v) of the backward generalized Riemann problem (1.1), (1.13) is denoted by $U = U_2(t, x)$ on the domain Ω_2, its two contact discontinuities are denoted by $x = \tilde{\xi}_1(t)$ and $x = \tilde{\xi}_2(t)$, respectively. By the definition of contact discontinuity, $x = \tilde{\xi}_i(t)$ $(i = 1, 2)$ satisfy

$$\frac{\tilde{\xi}_i(t)}{dt} = \lambda_i\left(U_2^{\pm}\right), \quad \tilde{\xi}_i(0) = 0 \quad (i = 1, 2). \tag{2.14}$$

Moreover, let $Q_1 = (t_{q_1}, x_{q_1})$ (resp. $Q_2 = (t_{q_2}, x_{q_2})$) be the the intersection point of the characteristic $x = \tilde{x}_1(t)$ (resp. $x = \tilde{x}_2(t)$) with the contact discontinuity $x = \tilde{\xi}_2(t)$ (resp. $x = \tilde{\xi}_1(t)$). See Figure 1.

REMARK 2.1. *From the argument mentioned above, we observe that*

$$0 \le t_p \le t_e, \qquad t_f \le t_q \le T. \tag{2.15}$$

Step 2: Mixed initial-boundary value problem for the system (1.1). Let Ω_3 be the domain enclosed by the characteristics PP_2 and QQ_2, and the straight line segments PQ and P_2Q_2. It is easy to see that the straight line PQ can be expressed by

$$x = x_p + \alpha(t - t_p) \triangleq c(t), \qquad t \in [t_p, t_q], \tag{2.16}$$

where α is the slope of the line PQ

$$\alpha = \frac{x_q - x_p}{t_q - t_p}. \tag{2.17}$$

Similarly, the straight line P_2Q_2 can be expressed by

$$x = x_{p_2} + \alpha_2(t - t_{p_2}) \triangleq c_2(t), \qquad t \in [t_{p_2}, t_{q_2}], \tag{2.18}$$

where α_2 is the slope of the line P_2Q_2

$$\alpha_2 = (x_{q_2} - x_{p_2})/(t_{q_2} - t_{p_2}). \tag{2.19}$$

Noting (1.7), the system (1.1) can be equivalently rewritten as

$$\begin{cases} \dfrac{\partial R_1}{\partial x} + \dfrac{1}{\mu_1(R_2)} \dfrac{\partial R_1}{\partial t} = 0, \\ \dfrac{\partial R_2}{\partial x} + \dfrac{1}{\mu_2(R_1)} \dfrac{\partial R_2}{\partial x} = 0 \end{cases} \tag{2.20}$$

for smooth solutions. We next consider the mixed initial-boundary value problem for the system (2.20) (equivalently, (1.1)) on the domain Ω_3 with the following boundary conditions:

on the characteristic PP_2: $x = x_1(t)$ $(t \in [t_{p_2}, t_p])$

$$R_2 = R_2(U_1(t, x_1(t))) \triangleq r_2(t), \qquad t \in [t_{p_2}, t_p], \tag{2.21}$$

on the characteristic QQ_2: $x = \tilde{x}_2$ $(t \in [t_q, t_{q_2}])$

$$R_1 = R_1(U_2(t, \tilde{x}_2(t))) \triangleq \tilde{r}_1(t), \qquad t \in [t_q, t_{q_2}] \tag{2.22}$$

and the initial condition on the line segment PQ

$$R_1 = s_1(t), \qquad R_2 = s_2(t), \quad t \in [t_p, t_q], \tag{2.23}$$

where $s_1(t)$, $s_2(t)$ are C^1 functions of $t \in [t_p, t_q]$. Here we have interchanged the role of x and t variables. In order to ensure that the mixed initial-boundary value problem (2.20)–(2.23) has a C^1 solution on Ω_3, the initial data $(s_1(t), s_2(t))$ must satisfy certain compatibility conditions. First of all, it is required that

$$s_1(t_p) = R_1(U_1(t_p, x_p)), \qquad s_2(t_q) = R_2(U_2(t_q, x_q)). \tag{2.24}$$

Moreover, it is also required that

$$s_1(t_q) = R_1(U_2(t_q, x_q)) = \tilde{r}_1(t_q), \qquad s_2(t_p) = R_2(U_1(t_p, x_p)) = r_2(t_p). \tag{2.25}$$

Notice that along the characteristic QQ_2: $x = \tilde{x}_2(t)$

$$\tilde{r}_1'(t) = \frac{\partial R_1}{\partial t} + \mu_2(R_1)\frac{\partial R_1}{\partial x} = (\mu_2(R_1) - \mu_1(R_2))\frac{\partial R_1}{\partial x}.$$

Then,

$$\tilde{r}_1'(t_q) = (\mu_2(R_1(U_2(t_q, x_q))) - \mu_1(R_2(U_2(t_q, x_q))))\,\frac{\partial R_1}{\partial x}(t_q, x_q). \tag{2.26}$$

On the other hand, along the line PQ: $x = c(t)$

$$s_1'(t) = \frac{\partial R_1}{\partial t} + \alpha\frac{\partial R_1}{\partial x} = (\alpha - \mu_1(s_2))\frac{\partial R_1}{\partial x}.$$

Then,

$$s_1'(t_q) = (\alpha - \mu_1(s_2(t_q)))\,\frac{\partial R_1}{\partial x}(t_q, x_q). \tag{2.27}$$

Therefore, we need that

$$s_1'(t_q) = \frac{\alpha - \mu_1(R_2(U_2(t_q, x_q)))}{\mu_2(R_1(U_2(t_q, x_q))) - \mu_1(R_2(U_2(t_q, x_q)))}\tilde{r}_1'(t_q). \tag{2.28}$$

Similarly, at (t_p, x_p) we require that

$$s_2'(t_p) = \frac{\alpha - \mu_2(R_1(U_1(t_p, x_p)))}{\mu_1(R_2(U_1(t_p, x_p))) - \mu_2(R_1(U_1(t_p, x_p)))}r_2'(t_p). \tag{2.29}$$

We have the following proposition.

PROPOSITION 2.1. *The angles formed by the line segment PQ and the characteristic QC, by the line segment PQ and the characteristic PB are less than π.*

Proof. Consider the angle between PQ and QC. The worst case is given by

$$P = \left(\frac{2}{\underline{\lambda}_2 - \underline{\lambda}_1}, \frac{\underline{\lambda}_1 + \underline{\lambda}_2}{\underline{\lambda}_2 - \underline{\lambda}_1}\right), \qquad Q = \left(T - \frac{2}{\underline{\lambda}_2 - \underline{\lambda}_1}, -\frac{\underline{\lambda}_1 + \underline{\lambda}_2}{\underline{\lambda}_2 - \underline{\lambda}_1}\right).$$

In the worst case, the slope of PQ is

$$\frac{dx}{dt} = \frac{2\,(\underline{\lambda}_1 + \underline{\lambda}_2)}{4 - T\,(\underline{\lambda}_2 - \underline{\lambda}_1)}.$$

In order to ensure the angle formed by the line segment PQ and the characteristic QC is less than π, it is sufficient to require that the slope of the line segment PQ is less than the slope of the characteristic QC, i.e.,

$$\frac{2\,(\underline{\lambda}_1 + \underline{\lambda}_2)}{4 - T\,(\underline{\lambda}_2 - \underline{\lambda}_1)} < \underline{\lambda}_2. \tag{2.30}$$

Noting (1.19) and $T > T_0$, we have

$$T > \frac{4}{\underline{\lambda}_2 - \bar{\lambda}_1}.$$

Hence, in order to guarantee the validity of inequality (2.30), it suffices to require that

$$T > \frac{2}{\underline{\lambda}_2}.$$

This is true because of (1.19) and the fact $T > T_0$.

Similarly, consider the angle between PQ and PB. The worst case is given by

$$P = \left(\frac{2}{\bar{\lambda}_2 - \bar{\lambda}_1}, \frac{\bar{\lambda}_1 + \bar{\lambda}_2}{\bar{\lambda}_2 - \bar{\lambda}_1}\right), \qquad Q = \left(T - \frac{2}{\bar{\lambda}_2 - \bar{\lambda}_1}, -\frac{\bar{\lambda}_1 + \bar{\lambda}_2}{\bar{\lambda}_2 - \bar{\lambda}_1}\right).$$

A similar argument yields

$$T > -\frac{2}{\bar{\lambda}_1}.$$

This is also true because of (1.19) and the fact $T > T_0$. Thus, the proof of Proposition 2.1 is completed. □

Therefore, using Lemma 2.3 and Remark 2.1 in [9], we obtain the following lemma.

LEMMA 2.3. *Under the hypotheses* (H_1)–(H_4), *the mixed initial-boundary value problem* (2.20)–(2.23) *admits a unique* C^1 *solution* $(R_1, R_2) = (R_1(t,x), R_2(t,x))$ *on* Ω_3, *provided that the compatibility conditions* (2.24)–(2.25) *and* (2.28)–(2.29) *hold.*

By Lemma 2.3, let $U = U_3(t,x)$ be the solution of the system (1.1) corresponding to $(R_1(t,x), R_2(t,x))$ given by Lemma 2.3 on the domain Ω_3.

On the other hand, let Ω_4 be the domain enclosed by the characteristics PP_1 and QQ_1, and the straight line segment PQ: $x = c(t) = x_p + \alpha(t - t_p)$, $t_p \le t \le t_q$ and the straight line segment P_1Q_1:

$$x = x_{p_1} + \alpha_1(t - t_{p_1}) \triangleq c_1(t), \qquad t \in [t_{p_1}, t_{q_1}], \tag{2.31}$$

where α_1 is the slope of the line P_1Q_1

$$\alpha_1 = \frac{x_{q_1} - x_{p_1}}{t_{q_1} - t_{p_1}}.$$

On the domain Ω_4, we consider the mixed initial-boundary value problem for the system (2.20) (equivalently, (1.1)) with the following boundary conditions:

on the characteristic PP_1: $x = x_2(t)$ $(t \in [t_{p_1}, t_p])$

$$R_1 = R_1(U_1(t, x_2(t))) \triangleq r_1(t), \qquad t \in [t_{p_1}, t_p], \tag{2.32}$$

on the characteristic QQ_1: $x = \tilde{x}_1(t)$ $t \in [t_q, t_{q_1}]$

$$R_2 = R_2(U_2(t, \tilde{x}_1(t))) \triangleq \tilde{r}_2(t), \qquad t \in [t_q, t_{q_1}] \tag{2.33}$$

and the initial condition on the line segment PQ

$$R_1 = s_1(t), \qquad R_2 = s_2(t), \quad t \in [t_p, t_q]. \tag{2.34}$$

As before, we choose $s_1(t)$, $s_2(t)$ to satisfy the compatibility conditions (2.28)–(2.29) and

$$\begin{aligned} s_1'(t_p) &= \frac{\alpha - \mu_1(R_2(U_1(t_p, x_p)))}{\mu_2(R_1(U_1(t_p, x_p))) - \mu_1(R_2(U_1(t_p, x_p)))} r_1'(t_p), \\ s_2'(t_q) &= \frac{\alpha - \mu_2(R_1(U_2(t_q, x_q)))}{\mu_1(R_2(U_2(t_q, x_q))) - \mu_2(R_1(U_2(t_q, x_q)))} \tilde{r}_2'(t_q). \end{aligned} \tag{2.35}$$

Similar to Proposition 2.1, we have the following.

PROPOSITION 2.2. *The angles formed by the line segment PQ and the characteristic QD and by the line segment PQ and the characteristic PA are less than π.*

Using Lemma 2.3 and Remark 2.1 in [9] again, we obtain the following lemma.

LEMMA 2.4. *Under the hypotheses (H_1)–(H_4), the mixed initial-boundary value problem* (2.20), (2.32)–(2.34) *admits a unique C^1 solution $(R_1, R_2) = (R_1(t,x), R_2(t,x))$ on Ω_4, provided that the compatibility conditions* (2.24)–(2.25), (2.28)–(2.29) *and* (2.35) *hold.*

We denote the solution of the system (1.1) corresponding to $(R_1(t,x), R_2(t,x))$, given by Lemma 2.4, on the domain Ω_4 by $U = U_4(t,x)$.

Step 3: Cauchy problem for the system (2.20). Consider the Cauchy problem in the x-direction for the system (2.20) with the following initial condition on the line segment P_2Q_2:

$$\begin{aligned} R_1(t, c_2(t)) &= R_1(U_3(t, c_2(t))) \triangleq \sigma_1(t), \\ R_2(t, c_2(t)) &= R_2(U_3(t, c_2(t))) \triangleq \sigma_2(t), \end{aligned} \qquad t \in [t_{p_2}, t_{q_2}]. \tag{2.36}$$

Similar to Proposition 2.1, we have the following.

PROPOSITION 2.3. *The angles formed by the line segment P_2Q_2 and the characteristic Q_2C, by the line segment P_2Q_2 and the characteristic P_2B are less than π.*

Proof. Consider the angle between P_2Q_2 and Q_2C. The worst case is given by

$$P_2 = \left(\frac{1}{\underline{\lambda}_2 - \underline{\lambda}_1}, \frac{\underline{\lambda}_2}{\underline{\lambda}_2 - \underline{\lambda}_1}\right), \qquad Q_2 = \left(T - \frac{1}{\underline{\lambda}_2 - \underline{\lambda}_1}, -\frac{\underline{\lambda}_1}{\underline{\lambda}_2 - \underline{\lambda}_1}\right).$$

In the worst case, the slope of P_2Q_2 is

$$\frac{dx}{dt} = \frac{\underline{\lambda}_1 + \underline{\lambda}_2}{2 - T(\underline{\lambda}_2 - \underline{\lambda}_1)}.$$

In order to ensure the angle formed by the line P_2Q_2 and the characteristic Q_2C is less than π, it is sufficient to require that the slope of the line P_2Q_2 is less than the slope of the characteristic Q_2C, i.e.,

$$\frac{\underline{\lambda}_1 + \underline{\lambda}_2}{2 - T(\underline{\lambda}_2 - \underline{\lambda}_1)} < \underline{\lambda}_2. \tag{2.37}$$

Noting (1.19) and $T > T_0$, we have

$$T > \frac{4}{\underline{\lambda}_2 - \bar{\lambda}_1}.$$

Hence, in order to guarantee the validity of inequality (2.37), it suffices to require that

$$T > \frac{1}{\underline{\lambda}_2}.$$

Of course, this is true because of (1.19) and the fact $T > T_0$.

Similarly, consider the angle between P_2Q_2 and P_2B. The worst case is given by

$$P_2 = \left(\frac{1}{\bar{\lambda}_2 - \bar{\lambda}_1}, \frac{\bar{\lambda}_2}{\bar{\lambda}_2 - \bar{\lambda}_1}\right), \qquad Q_2 = \left(T - \frac{1}{\bar{\lambda}_2 - \bar{\lambda}_1}, -\frac{\bar{\lambda}_1}{\bar{\lambda}_2 - \bar{\lambda}_1}\right).$$

A similar argument gives

$$T > -\frac{1}{\overline{\lambda}_1}.$$

Obviously, this is true because of (1.19) and the fact $T > T_0$. Thus, the proof of Proposition 2.3 is finished. □

Using the Corollary 2.1 in [9], we have the following lemma.

LEMMA 2.5. *Under the hypotheses* (H_1)–(H_4), *the Cauchy problem* (2.20), (2.36) *admits a unique* C^1 *solution* $(R_1, R_2) = (R_1(t,x), R_2(t,x))$ *on the maximum determined domain* Ω_5 *enclosed by the straight line segment* P_2Q_2, *the straight line segment* P_3Q_3, *the characteristic* P_2P_3: $x = \zeta_2(t)$ $(t \in [t_{p_2}, t_{p_3}])$ *and the characteristic* Q_2Q_3: $x = \tilde{\zeta}_1(t)$ $(t \in [t_{q_3}, t_{q_2}])$, *where* $P_3 = (t_{p_3}, 1)$ *is the intersection point of the characteristic* $x = \zeta_2(t)$ *with the line* BC, *and* $Q_3 = (t_{q_3}, 1)$ *is the intersection point of the characteristic* $x = \tilde{\zeta}_1(t)$ *with the line* BC, *while the characteristic* $\zeta = \tilde{\zeta}_1(t)$ *satisfies*

$$\frac{d\tilde{\zeta}_1(t)}{dt} = \mu_1(R_2), \qquad \tilde{\zeta}_1(t_{q_2}) = x_{q_2} \tag{2.38}$$

and the characteristic $\zeta = \zeta_2(t)$ *satisfies*

$$\frac{d\zeta_2(t)}{dt} = \mu_2(R_1), \qquad \zeta_2(t_{p_2}) = x_{p_2}. \tag{2.39}$$

See Figure 1.

We denote the solution of the system (1.1) corresponding to $(R_1(t,x), R_2(t,x))$, given by Lemma 2.5, on the domain Ω_5 by $U = U_5(t,x)$.

Similarly, we consider the Cauchy problem in the anti-x-direction for the system (2.20) with the following initial condition on the line segment P_1Q_1:

$$\begin{aligned} R_1(t, c_1(t)) &= R_1(U_4(t, c_1(t))) \triangleq \theta_1(t), \\ R_2(t, c_1(t)) &= R_2(U_4(t, c_1(t))) \triangleq \theta_2(t), \end{aligned} \qquad t \in [t_{p_1}, t_{q_1}]. \tag{2.40}$$

Similar to Proposition 2.3, we have the following.

PROPOSITION 2.4. *The angles formed by the line segment* P_1Q_1 *and the characteristic* Q_1D, *by the line segment* P_1Q_1 *and the characteristic* P_1A *are less than* π.

By the Corollary 2.1 in [9], we have the following lemma.

LEMMA 2.6. *Under the hypotheses* (H_1)–(H_4), *the Cauchy problem* (2.20), (2.40) *admits a unique* C^1 *solution* $(R_1, R_2) = (R_1(t,x), R_2(t,x))$ *on the maximum determined domain* Ω_6 *enclosed by the straight line segment* P_1Q_1, *the straight line segment* P_4Q_4, *the characteristic* P_1P_4: $x = \zeta_1(t)$ $(t \in [t_{p_1}, t_{p_4}])$ *and the characteristic* Q_1Q_4: $x = \tilde{\zeta}_2(t)$ $(t \in [t_{q_4}, t_{q_1}])$ (*see Figure* 1), *where* $P_4 = (t_{p_4}, 1)$ *is the intersection point of the characteristic* $\zeta = \zeta_1(t)$ *with the line* AD, *and* $Q_4 = (t_{q_4}, 1)$ *is the intersection point of the characteristic* $\zeta = \tilde{\zeta}_2(t)$ *with the line* AD, *while the characteristic* $\zeta = \zeta_1(t)$ *satisfies*

$$\frac{d\zeta_1(t)}{dt} = \mu_1(R_2), \qquad \zeta_1(t_{p_1}) = x_{p_1} \tag{2.41}$$

and the characteristic $\zeta = \tilde{\zeta}_2(t)$ *satisfies*

$$\frac{d\tilde{\zeta}_2(t)}{dt} = \mu_2(R_1), \qquad \tilde{\zeta}_2(t_{q_1}) = x_{q_1}. \tag{2.42}$$

See Figure 1.

Let $U = U_6(t,x)$ be the solution of the system (1.1) corresponding to $(R_1(t,x), R_2(t,x))$, given by Lemma 2.6, on the domain Ω_6.

Step 4: Goursat problem for the system (2.20). We next consider the Goursat problem in the x-direction for the system (2.20) with the following characteristic boundary conditions:

on the characteristic P_2B: $x = x_1(t)$ $(t \in [0, t_{p_2}])$

$$R_2 = R_2(U_1(t, x_1(t))) \triangleq \eta_2(t), \qquad t \in [0, t_{p_2}], \tag{2.43}$$

on the characteristic P_2P_3: $x = \zeta_2(t)$ $(t \in [t_{p_2}, t_{p_3}])$

$$R_1 = R_1(U_5(t, \zeta_2(t))) \triangleq \eta_1(t), \qquad t \in [t_{p_2}, t_{p_3}]. \tag{2.44}$$

By the Lemma 2.2 in [9], we have the following.

LEMMA 2.7. *Under the hypotheses* (H_1)*–*(H_4)*, the Goursat problem* (2.20), (2.43)*–*(2.44) *has a unique* C^1 *solution* $(R_1, R_2) = (R_1(t,x), R_2(t,x))$ *on the domain* Ω_7 *enclosed by the straight line segment* BP_3*, the characteristic* BP_2*:* $x = x_1(t)$ $(t \in [0, t_{p_2}])$ *and the characteristic* P_2P_3*:* $x = \zeta_2(t)$ $(t \in [t_{p_2}, t_{p_3}])$*. See Figure* 1*. Moreover, it holds that*

$$\begin{aligned} &R_1(t, \zeta_2(t)) = \eta_1(t) \qquad \forall\, t \in [t_{p_2}, t_{p_3}], \\ &R_2(t, x_1(t)) = \eta_2(t) \qquad \forall\, t \in [0, t_{p_2}]. \end{aligned} \tag{2.45}$$

Let $U = U_7(t,x)$ be the solution of the system (1.1) corresponding to $(R_1(t,x), R_2(t,x))$, given by Lemma 2.7, on the domain Ω_7.

Similarly, consider the Goursat problem in the x-direction for the system (2.20) with the following characteristic boundary conditions:

on the characteristic Q_2C: $x = \tilde{x}_2(t)$ $(t \in [t_{q_2}, T])$

$$R_1 = R_1(U_2(t, \tilde{x}_2(t))) \triangleq \tilde{\eta}_1(t), \quad t \in [t_{q_2}, T], \tag{2.46}$$

on the characteristic Q_2Q_3: $x = \tilde{\zeta}_1(t)$ $(t \in [t_{q_3}, t_{q_2}])$

$$R_2 = R_2(U_5(t, \tilde{\zeta}_1(t))) \triangleq \tilde{\eta}_2(t), \quad t \in [t_{q_3}, t_{q_2}]. \tag{2.47}$$

Similar to Lemma 2.7, we have the following.

LEMMA 2.8. *Under the hypotheses* (H_1)*–*(H_4)*, the Goursat problem* (2.20), (2.46)*–*(2.47) *has a unique* C^1 *solution* $(R_1, R_2) = (R_1(t,x), R_2(t,x))$ *on the domain* Ω_8 *enclosed by the straight line segment* Q_3C*, the characteristic* Q_2C*:* $x = \tilde{x}_2(t)$ $(t \in [t_{q_2}, T])$ *and the characteristic* Q_2Q_3*:* $x = \tilde{\zeta}_1(t)$ $(t \in [t_{q_3}, t_{q_2}])$*. See Figure* 1*. Moreover, it holds that*

$$\begin{aligned} &R_1(t, \tilde{x}_2(t)) = \tilde{\eta}_1(t) \quad \forall\, t \in [t_{q_2}, T], \\ &R_2(t, \tilde{\zeta}_1(t)) = \tilde{\eta}_2(t) \quad \forall\, t \in [t_{q_3}, t_{q_2}]. \end{aligned} \tag{2.48}$$

Let $U = U_8(t,x)$ be the solution of the system (1.1) corresponding to $(R_1(t,x), R_2(t,x))$, given by Lemma 2.8, on the domain Ω_8.

On the other hand, we consider the Goursat problem in the anti-x-direction for the system (2.20) with the following characteristic boundary conditions:

on the characteristic Q_1D: $x = \tilde{x}_1(t)$ $(t \in [t_{q_1}, T])$

$$R_2 = R_2(U_2(t, \tilde{x}_1(t))) \triangleq \tilde{\gamma}_2(t), \qquad t \in [t_{q_1}, T], \tag{2.49}$$

on the characteristic Q_1Q_4: $x = \tilde{\zeta}_2(t)$ $(t \in [t_{q_4}, t_{q_1}])$

$$R_1 = R_1(U_6(t, \tilde{\zeta}_2(t))) \triangleq \tilde{\gamma}_1(t), \qquad t \in [t_{q_4}, t_{q_1}]. \tag{2.50}$$

Similar to Lemma 2.8, we have the following.

LEMMA 2.9. *Under the hypotheses* (H_1)*–*(H_4)*, the Goursat problem* (2.20), (2.49)*–*(2.50) *has a unique* C^1 *solution* $(R_1, R_2) = (R_1(t,x), R_2(t,x))$ *on the domain* Ω_9 *enclosed by the straight line segment* Q_4D*, the characteristic* Q_1D*:* $x = \tilde{x}_1(t)$ $(t \in [t_{q_1}, T])$ *and the characteristic* Q_4Q_1*:* $x = \tilde{\zeta}_2(t)$ $(t \in [t_{q_4}, t_{q_1}])$*. See Figure* 1*. Moreover, it holds that*

$$\begin{aligned} &R_1(t, \tilde{\zeta}_2(t)) = \tilde{\gamma}_1(t) \quad \forall\, t \in [t_{q_4}, t_{q_1}], \\ &R_2(t, \tilde{x}_1(t)) = \tilde{\gamma}_2(t) \quad \forall\, t \in [t_{q_1}, T]. \end{aligned} \tag{2.51}$$

Let $U = U_9(t,x)$ be the solution of the system (1.1) corresponding to $(R_1(t,x), R_2(t,x))$, given by Lemma 2.9, on the domain Ω_9.

Finally, we consider the Goursat problem in the anti-x-direction for the system (2.20) with the following characteristic boundary conditions:

on the characteristic AP_1: $x = x_2(t)$ $(t \in [0, t_{p_1}])$

$$R_1 = R_1(U_1(t, x_2(t))) \triangleq \gamma_1(t), \qquad t \in [0, t_{p_1}], \tag{2.52}$$

on the characteristic P_1P_4: $x = \zeta_1(t)$ $(t \in [t_{p_1}, t_{p_4}])$

$$R_2 = R_2(U_6(t, \zeta_1(t))) \triangleq \gamma_1(t), \qquad t \in [t_{p_1}, t_{p_4}]. \tag{2.53}$$

Similar to Lemma 2.9, we have the following.

LEMMA 2.10. *Under the hypotheses* (H_1)*–*(H_4)*, the Goursat problem* (2.20), (2.52)*–*(2.53) *has a unique* C^1 *solution* $(R_1, R_2) = (R_1(t,x), R_2(t,x))$ *on the domain* Ω_{10} *enclosed by the straight line segment* AP_4*, the characteristic* AP_1*:* $x = x_2(t)$ $(t \in [0, t_{p_1}])$ *and the characteristic* P_1P_4*:* $x = \zeta_1(t)$ $(t \in [t_{p_1}, t_{p_4}])$*. See Figure* 1*. Moreover, it holds that*

$$\begin{aligned} &R_1(t, x_2(t)) = \gamma_1(t) \quad \forall\, t \in [0, t_{p_1}], \\ &R_2(t, \zeta_1(t)) = \gamma_2(t) \quad \forall\, t \in [t_{p_1}, t_{p_4}]. \end{aligned} \tag{2.54}$$

Let $U = U_{10}(t,x)$ be the solution of the system (1.1) corresponding to $(R_1(t,x), R_2(t,x))$, given by Lemma 2.10, on the domain Ω_{10}.

Step 5: Piecewise $\mathbf{C^1}$ solution with four $\mathbf{C^1}$ contact discontinuities. Now we choose $s_1(t)$, $s_2(t)$ in (2.23) from the space $C^1[t_p, t_q]$ so that the compatibility conditions (2.24)–(2.25), (2.28)–(2.29) and (2.35) are all satisfied and the C^0 norms of $s_1(t)$, $s_2(t)$ are bounded by M.

Define the piecewise C^1 function

$$U = U(t,x) = \begin{cases} U_1(t,x) & \text{for } (t,x) \in \Omega_1, \\ \cdots & \cdots \\ U_{10}(t,x) & \text{for } (t,x) \in \Omega_{10} \end{cases} \tag{2.55}$$

and the piecewise C^1 curves

$$
\begin{aligned}
&\ell_1 = \{\,(t,x)\,|\,x=\xi_1(t) \quad \text{for } t\in[0,t_{p_1}]; \qquad x=\zeta_1(t) \quad \text{for } t\in[t_{p_1},t_{p_4}]\},\\
&\ell_2 = \{\,(t,x)\,|\,x=\xi_2(t) \quad \text{for } t\in[0,t_{p_2}]; \qquad x=\zeta_2(t) \quad \text{for } t\in[t_{p_2},t_{p_3}]\},\\
&\tilde{\ell}_1 = \{\,(t,x)\,|\,x=\tilde{\xi}_1(t) \quad \text{for } t\in[t_{q_2},T]; \qquad x=\tilde{\zeta}_1(t) \quad \text{for } t\in[t_{q_3},t_{q_2}]\},\\
&\tilde{\ell}_2 = \{\,(t,x)\,|\,x=\tilde{\xi}_2(t) \quad \text{for } t\in[t_{q_1},T]; \qquad x=\tilde{\zeta}_2(t) \quad \text{for } t\in[t_{q_4},t_{q_1}]\}.
\end{aligned}
\tag{2.56}
$$

By the construction of U_i $(i=1,\dots,10)$, we observe that $U=U(t,x)$ defined by (2.55) is a C^1 function out of curves ℓ_1, ℓ_2, $\tilde{\ell}_1$ and $\tilde{\ell}_2$; meanwhile ℓ_1 (i.e., OP_4), ℓ_2 (i.e., OP_3), $\tilde{\ell}_1$ (i.e., NQ_3) and $\tilde{\ell}_2$ (i.e., NQ_4) are C^1 smooth curves. See Figure 1.

Obviously, $U=U(t,x)$, defined by (2.55), satisfies the system (1.1) on the domain $\mathcal{D}(T)$, but out of the curves ℓ_1, ℓ_2, $\tilde{\ell}_1$ and $\tilde{\ell}_2$, in the class sense. On the other hand, it is clear that $U=U(t,x)$ satisfies the condition (1.15).

In what follows, we show that the curves ℓ_1 and $\tilde{\ell}_1$ (resp., ℓ_2 and $\tilde{\ell}_2$) are contact discontinuities corresponding to $\lambda_1(U)$ (resp., $\lambda_1(U)$).

In fact, we only need to prove that the Rankine–Hugoniot conditions (2.1)–(2.2) hold on the curves $x=\zeta_1(t)$ $(t\in[t_{p_1},t_{p_4}])$, $x=\zeta_2(t)$ $(t\in[t_{p_2},t_{p_3}])$, $x=\tilde{\zeta}_1(t)$ $(t\in[t_{q_3},t_{q_2}])$ and $x=\tilde{\zeta}_2(t)$ $(t\in[t_{q_4},t_{q_1}])$.

It follows from (1.8) and (2.53) that

$$
\lambda_1\left(U_6\left(t,\zeta_1(t)\right)\right)=\lambda_1\left(U_{10}\left(t,\zeta_1(t)\right)\right)\triangleq\sigma(t)\quad\forall\ t\in[t_{p_1},t_{p_4}].
\tag{2.57}
$$

This is just the desired (2.2) for the case $k=1$ and $x=\zeta_1(t)$.

We next show that the Rankine–Hugoniot condition (2.1) holds on $x=\zeta_1(t)$.

By (H_3), we know that, for any fixed $t\in[t_{p_1},t_{p_4}]$, there exists a C^1 curve segment $U=U(\tau)$ $(\tau\in[\tau_1,\tau_2])$ in $\mathcal{N}$ such that

$$
U(\tau_1)=U_6(t,\zeta_1(t)),\qquad U(\tau_2)=U_{10}\left(t,\zeta_1(t)\right),
$$

and

$$
\lambda_1\left(U(\tau)\right)=\sigma(t)\quad\forall\ \tau\in[\tau_1,\tau_2]\,.
\tag{2.58}
$$

Differentiating (2.58) with respect to τ gives

$$
\nabla\lambda_1\left(U(\tau)\right)\cdot\frac{dU}{d\tau}(\tau)=0\quad\forall\ \tau\in[\tau_1,\tau_2]\,.
\tag{2.59}
$$

By (1.3), (1.5), and (2.59), we observe that $\frac{dU}{d\tau}(\tau)$ is proportional to $\vec{r}_2(U(\tau))$. Then we have

$$
\sigma(t)\frac{dU}{d\tau}(\tau)=\nabla F\left(U(\tau)\right)\frac{dU}{d\tau}(\tau)\quad\forall\ \tau\in[\tau_1,\tau_2]\,.
$$

Integrating this yields the Rankine–Hugoniot condition (2.1) on $x=\zeta_1(t)$.

Others are similar.

Step 6: Control inputs $h_1(t)$ and $h_2(t)$. Finally, we define $h_1(t)$ and $h_2(t)$ as follows:

$$
h_1(t)=\begin{cases}
-B_1(U_{10}(t,-1),t) & \text{as } t\in[0,t_{p_4}],\\
-B_1(U_6(t,-1),t) & \text{as } t\in[t_{p_4},t_{q_4}],\\
-B_1(U_9(t,-1),t) & \text{as } t\in[t_{q_4},T]
\end{cases}
\tag{2.60}
$$

and

$$h_2(t) = \begin{cases} -B_2(U_7(t,1),t) & \text{as } t \in [0, t_{p_3}], \\ -B_2(U_5(t,1),t) & \text{as } t \in [t_{p_3}, t_{q_3}], \\ -B_2(U_8(t,1),t) & \text{as } t \in [t_{q_3}, T]. \end{cases} \tag{2.61}$$

$h_1(t)$ and $h_2(t)$ are just the desired control inputs such that the system (1.1), (1.9) possesses a piecewise C^1 solution $U = U(t,x)$ containing four contact discontinuities and satisfying (1.15) on the domain $\mathcal{D}(T)$, provided that $T > T_0$. Thus, the proof of Theorem 1.1 is completed. □

3. Some remarks. In this section, we give some important supplementary remarks.

REMARK 3.1. *Some physical systems always satisfy the hypotheses* (H_1)*–*(H_4)*, for example, the system of isentropic gas with the Von Kármán–Tsien pressure law, the system of relativistic gas dynamics with the relativistic counterpart of the Chaplygin pressure law, etc. (see* [5]*).*

REMARK 3.2. *Consider the general quasilinear system of conservation laws*

$$\frac{\partial u}{\partial t} + \frac{\partial f(u)}{\partial x} = 0, \tag{3.1}$$

where $u = (u_1, \dots, u_n)^T$ *is the unknown vector function of* (t,x)*,* $f\colon \mathbb{R}^n \to \mathbb{R}^n$ *is a given* C^2 *vector function of* u*. Suppose that on the domain under consideration,* (3.1) *is a nonstrictly hyperbolic system with two characteristics, and each characteristic has a constant multiplicity, say, on the domain under consideration,*

$$\lambda_1(u) \equiv \cdots \equiv \lambda_m(u) \triangleq \lambda(u) < \mu(u) \triangleq \lambda_{m+1}(u) \equiv \cdots \equiv \lambda_n(u),$$

where $1 \le m \le n-1$*. When* $m > 1$ *or* $m < n-1$*, the system* (3.1) *is nonstrictly hyperbolic. In particular, when* $n \ge 4$ *and* $1 < m < n-1$*, the system* (3.1) *is rich, and* $\lambda(u)$*,* $\mu(u)$ *must be linearly degenerate (see* [1]*,* [4]*, or* [10]*). In this case, the system* (3.1) *can be rewritten as*

$$\begin{aligned} &\frac{\partial R_i}{\partial t} + \lambda(u)\frac{\partial R_i}{\partial x} = 0 \qquad (i = 1, \dots, m), \\ &\frac{\partial R_j}{\partial t} + \mu(u)\frac{\partial R_j}{\partial x} = 0 \qquad (j = m+1, \dots, n), \end{aligned} \tag{3.2}$$

where R_i $(i = 1, \dots, n)$ *are the Riemann invariants. For the present situation, we have a similar result.*

In fact, the rich systems generalize the class of 2×2 systems while preserving their essential properties:

(1) diagonalization with the help of the strict Riemann invariants;

(2) the infinite dimension of the entropy space.

See [10]. Therefore, noting the above properties and the linear degeneracy of the characteristic fields $\lambda(u)$, $\mu(u)$, in a manner completely similar to the proof of Theorem 1.1 we can obtain the conclusion stated in Remark 3.2. In this sense, we may call the system (3.1) (equivalently, (3.2)) a *generalized* 2×2 *system with linearly degenerate characteristics.*

REMARK 3.3. *Hypothesis* (H_3) *is a geometric assumption for constructing contact discontinuities with nonsmall jumps. It is needed since we do not require that the*

oscillations of $u_0^{\pm}(x)$, $v_0^{\pm}(x)$, $u_T^{\pm}(x)$, $v_T^{\pm}(x)$ *and the jumps* $|u_0^+(0) - u_0^+(0)|$, $|v_0^+(0) - v_0^+(0)|$, $|u_T^+(0) - u_T^+(0)|$, $|v_T^+(0) - v_T^+(0)|$ *are small. If the above jumps are small, then the hypothesis* (H_3) *is not needed. Moreover, in Theorem* 1.1*, a part of contact discontinuities in the solution* $U = U(t,x)$ *may disappear. If the initial and terminal functions are continuous at* $x = 0$*, then the contact discontinuities in* $U = U(t,x)$ *degenerate weak discontinuities. If the initial and terminal functions are* C^1 *smooth on* $[-1,1]$*, then the solution* $U = U(t,x)$ *is also* C^1 *smooth, in this case Theorem* 1.1 *is only the result given in* [9].

REMARK 3.4. *The hypothesis* (H_4) *is also needful since we do not require that the oscillations and jumps of the initial and terminal functions are small. If the oscillations and jumps of the initial and terminal functions are small, then the hypothesis* (H_4) *is not needed. Moreover, it is also required in the proof of Theorem* 1.1 *that the mapping defined by* (1.6) *is inverse, i.e., we can solve* U *from* (1.6).

4. A new example — the system for time-like extremal surfaces in the $(1+n)$-dimensional Minkowski space $\mathbb{R}^{1+n}$. In this section, we provide a new example of system such as described in Remark 3.2, namely, the system for time-like extremal surfaces in the $(1+n)$-dimensional Minkowski space $\mathbb{R}^{1+n}$.

We first give some notations and definitions.

Let $X = (t, x_1, \dots, x_n)^T$ be the position vector of a point in the $(1+n)$-dimensional Minkowski space $\mathbb{R}^{1+n}$. The scalar product of two vectors X and $\bar{X}$ is

$$X \cdot \bar{X} = \sum_{i=1}^{n} x_i \bar{x}_i - t\bar{t}; \tag{4.1}$$

in particular,

$$X \cdot X = \sum_{i=1}^{n} x_i^2 - t^2. \tag{4.2}$$

The Lorentz metric of the space $\mathbb{R}^{1+n}$ reads as

$$ds^2 = \sum_{i=1}^{n} dx_i^2 - dt^2. \tag{4.3}$$

A nonzero vector $X \in \mathbb{R}^{1+n}$ is called *space-like* (resp., *time-like or light-like*) if

$$X \cdot X > 0 \quad (\text{resp.}, \ < 0 \ \text{ or } \ = 0). \tag{4.4}$$

We now consider a smooth surface Σ in the space $\mathbb{R}^{1+n}$. Let a point $\mathbf{p}$ be in Σ, i.e., $\mathbf{p} \in \Sigma$. The surface Σ is said to be *time-like* (resp., *space-like or light-like*) at $\mathbf{p}$ if the unit normal vector of Σ at $\mathbf{p}$, denoted by $\vec{n}_p$, is space-like (resp., time-like or light-like). If Σ is time-like (resp., space-like or light-like) at every point $\mathbf{p} \in \Sigma$, then the surface Σ is called to be *time-like* (resp., *space-like or light-like*).

Let $z = (x_2, \dots, x_n)^T$. The local equation of a surface Σ in $\mathbb{R}^{1+n}$ in a suitable coordinate system can be written as

$$z = f(t, x_1) \quad \text{or} \quad z_j = f_j(t, x_1) \quad (j = 2, \dots, n). \tag{4.5}$$

In what follows, we use the notation

$$x = x_1$$

and we only consider the time-like[1] surfaces. By the definition, it is easy to prove the following.

PROPOSITION 4.1. *The surface Σ is time-like if and only if*

$$1+|f_x|^2-|f_t|^2-|f_t|^2|f_x|^2+\langle f_t,f_x\rangle^2>0.$$

DEFINITION 4.1. *The surface Σ is called an extremal surface if f is the critical point of the area functional*

$$I=\iint\sqrt{1+|f_x|^2-|f_t|^2-|f_t|^2|f_x|^2+\langle f_t,f_x\rangle^2}dxdt, \tag{4.6}$$

where $\langle\cdot,\cdot\rangle$ stands for the inner product.

More generally, we consider a vector function $\phi=(\phi_1,\dots,\phi_n)^T$, which is the critical point of the area functional

$$I=\iint\sqrt{1+|\phi_x|^2-|\phi_t|^2-|\phi_t|^2|\phi_x|^2+\langle\phi_t,\phi_x\rangle^2}dxdt, \tag{4.7}$$

where $\langle\cdot,\cdot\rangle$ stands for the inner product. The corresponding Euler–Lagrange equation is as follows:

$$\begin{aligned}&\left(\frac{\phi_t}{\sqrt{1+|\phi_x|^2-|\phi_t|^2-|\phi_t|^2|\phi_x|^2+\langle\phi_t,\phi_x\rangle^2}}\right)_t\\&+\left(\frac{\phi_x}{\sqrt{1+|\phi_x|^2-|\phi_t|^2-|\phi_t|^2|\phi_x|^2+\langle\phi_t,\phi_x\rangle^2}}\right)_x\\&+\left(\frac{|\phi_x|^2\phi_t-\langle\phi_t,\phi_x\rangle\phi_x}{\sqrt{1+|\phi_x|^2-|\phi_t|^2-|\phi_t|^2|\phi_x|^2+\langle\phi_t,\phi_x\rangle^2}}\right)_t\\&-\left(\frac{\langle\phi_t,\phi_x\rangle\phi_t-|\phi_t|^2\phi_x}{\sqrt{1+|\phi_x|^2-|\phi_t|^2-|\phi_t|^2|\phi_x|^2+\langle\phi_t,\phi_x\rangle^2}}\right)_x=0.\end{aligned} \tag{4.8}$$

REMARK 4.1. *In fact, $\phi=\phi(t,x)$ stands for a time-like extremal surface in the $(1+(1+n))$-dimensional Minkowski space $\mathbb{R}^{1+(1+n)}$.*

REMARK 4.2. *In particular, let (t,x,y) be points in the $(1+2)$-dimensional Minkowski space $\mathbb{R}^{1+2}$. We now consider a time-like extremal surface Σ_{1+2} taking the form*

$$y=\phi(t,x). \tag{4.9}$$

Corresponding to (4.8)*, the Euler–Lagrange equation reads as*

$$\left(\frac{\phi_t}{\sqrt{1+\phi_x^2-\phi_t^2}}\right)_t-\left(\frac{\phi_x}{\sqrt{1+\phi_x^2-\phi_t^2}}\right)_x=0, \tag{4.10}$$

which is the Born–Infeld equation (see [2]*).*

[1]The *time-like* corresponds to the relation of *cause and effect* in physics.

REMARK 4.3. *Recently, Brenier* [3] *suggests an equation for extremal surfaces in the* $(1+4)$*-dimensional Minkowski space, which is related to classical electrodynamics. By prescribing* $(t,s)\to(t,s,Y(t,s))$ *to be an extremal surface in the* $(1+4)$*-dimensional Minkowski space* (t,s,x_1,x_2,x_3) *with the signature* $(-,+,+,+,+)$*, we know that the area functional is*

$$I=\iint\sqrt{1+|\partial_s Y|^2-|\partial_t Y|^2-|\partial_s Y\times\partial_t Y|^2}dsdt. \tag{4.11}$$

The corresponding Euler–Lagrange equation is

(4.12)
$$\left(\frac{\phi_t}{\sqrt{1+|\phi_x|^2-|\phi_t|^2-|\phi_t\times\phi_x|^2}}\right)_t-\left(\frac{\phi_x}{\sqrt{1+|\phi_x|^2-|\phi_t|^2-|\phi_t\times\phi_x|^2}}\right)_x$$
$$+\left(\frac{\phi_x\times(\phi_t\times\phi_x)}{\sqrt{1+|\phi_x|^2-|\phi_t|^2-|\phi_t\times\phi_x|^2}}\right)_t-\left(\frac{\phi_t\times(\phi_t\times\phi_x)}{\sqrt{1+|\phi_x|^2-|\phi_t|^2-|\phi_t\times\phi_x|^2}}\right)_x=0,$$

where x *stands for* s *in* (4.11)*, and* $\phi=(\phi_1,\phi_2,\phi_3)^T$ *represents* Y *in* (4.11).

Let

$$u=\phi_x,\qquad v=\phi_t. \tag{4.13}$$

Then (4.8) can be equivalently rewritten as

$$\begin{cases} u_t-v_x=0,\\ \left(\dfrac{v}{\sqrt{1+|u|^2-|v|^2-|v|^2|u|^2+\langle u,v\rangle^2}}\right)_t\\ -\left(\dfrac{u}{\sqrt{1+|u|^2-|v|^2-|v|^2|u|^2+\langle u,v\rangle^2}}\right)_x\\ +\left(\dfrac{|u|^2v-\langle u,v\rangle u}{\sqrt{1+|u|^2-|v|^2-|v|^2|u|^2+\langle u,v\rangle^2}}\right)_t\\ -\left(\dfrac{\langle u,v\rangle v-|v|^2u}{\sqrt{1+|u|^2-|v|^2-|v|^2|u|^2+\langle u,v\rangle^2}}\right)_x=0 \end{cases} \tag{4.14}$$

for smooth solutions. The following lemma comes from [6].

LEMMA 4.1. *If the surface is time-like, that is,*

$$\triangle(u,v)\overset{\triangle}{=}1+|u|^2-|v|^2-|v|^2|u|^2+\langle u,v\rangle^2>0, \tag{4.15}$$

then (4.14) *is a nonstrictly hyperbolic system with two* n*-constant multiple eigenvalues:*

$$\lambda_1\equiv\cdots\equiv\lambda_n\overset{\triangle}{=}\lambda_-<\lambda_+\overset{\triangle}{=}\lambda_{n+1}\equiv\cdots\equiv\lambda_{2n}, \tag{4.16}$$

where

$$\lambda_\pm=\frac{1}{1+|u|^2}\left(-\langle u,v\rangle\pm\sqrt{1+|u|^2-|v|^2-|v|^2|u|^2+\langle u,v\rangle^2}\right);$$

moreover, the system (4.14) *is linear degenerate.*

Noting Remark 3.2, under suitable assumptions we can obtain the global exact boundary controllability for the system (4.14) (equivalently, (4.8)) in the class of piecewise C^1 functions. Here we omit the details.

Acknowledgments. The authors would like to thank the referee for pertinent comments and valuable suggestions. The first author (Kong) thanks Prof. Ta-Tsien Li for his constant encouragement and valuable suggestions. This work was completed while Kong was visiting University of Potsdam during the summer of 2003. Kong thanks Prof. B.-W. Schulze for his invitation and hospitality.

ON THE BACKWARD STOCHASTIC RICCATI EQUATION IN INFINITE DIMENSIONS*

GIUSEPPINA GUATTERI† AND GIANMARIO TESSITORE‡

Abstract. We study backward stochastic Riccati equations (BSREs) arising in quadratic optimal control problems with infinite dimensional stochastic differential state equations. We allow the coefficients, both in the state equation and in the cost, to be random. In such a context BSREs are backward stochastic differential equations existing in a non-Hilbert space and involving quadratic nonlinearities. We propose two different notions of solutions to BSREs and prove, for both of them, existence and uniqueness results. We also show that such solutions allow us to perform the synthesis of the optimal control. Finally we apply our results to the optimal control of a delay equation and of a wave equation with random damping.

Key words. backward stochastic differential equations, Riccati equation, linear quadratic optimal control, Hilbert spaces, stochastic coefficients

1. Introduction.

Backward stochastic Riccati differential equations (BSREs) naturally arise in the study of stochastic optimal linear quadratic control problems with stochastic coefficients.

The interest of proving existence and uniqueness results for such a class of equations was first addressed by Bismut in [2]. It was clear from the beginning that to study those highly nonlinear backward stochastic differential equations was already a challenging task in the finite dimensional case (see [3], [20], or the historical review in [12]). The difficulty comes essentially from the fact that, in its general formulation, the BSRE involves quadratic terms in both the unknowns (in particular in the so-called martingale term). Moreover the nonlinearity can be well defined only in a subset of the space of nonnegative matrices (where the equation naturally exists).

Several works followed the pioneering paper [2] (see [19], [12], [13], [14], [15]). In particular only very recently, in [21], the proof of the existence and uniqueness of a solution of the BSRE was given in the general case corresponding to a finite dimensional, linear quadratic problem with random coefficients and state- and control-dependent noise. This last result, somehow, completes the theory of finite dimensional BSREs. We remark that in all the above literature it is clear that the treatment of the equation cannot be solely based on general backward stochastic differential equation techniques but needs to exploit the interplay between the Riccati equation and its control theoretic interpretation (for results on general backward stochastic differential equations with quadratic nonlinearities see [11] and [17]).

On the other hand several works, motivated by control of stochastic partial differential equations, have been devoted to linear quadratic optimal control problems for infinite dimensional stochastic differential equations with deterministic coefficients

(see, for instance, [22] and references within). The corresponding Riccati equation is a deterministic nonlinear ODE in a suitable space of symmetric, nonnegative, Hilbert valued operators.

The present paper is, as far as we know, the first attempt to consider infinite dimensional BSREs. Such equations naturally arise in several models; namely they appear in all the situations in which one has to perform the synthesis of the optimal control for a linear quadratic problem having, as state equation, an infinite dimensional stochastic evolution equation with random coefficients (see examples in sections 9 and 10). We also emphasize that the study of infinite dimensional BSREs introduces specific new difficulties in the theory of backward stochastic differential equations. Specifically these are nonlinear backward stochastic differential equations that involve unbounded linear terms and quadratic nonlinearities. Moreover, and this is the main difficulty, they naturally exist in a non-Hilbertian infinite dimensional space.

In order to separate difficulties we consider here only the case in which the nonlinearity does not depend on the "martingale term" of the backward equation. In other words we consider the infinite dimensional analogue of the equation considered, in the finite dimensional case in [19]. We believe that, as we explain in the following, this case already presents serious new difficulties.

To be more precise: in this paper we consider a quadratic optimal control problem for a system governed by the following *state equation*:

$$\begin{cases} dy(t) = (Ay(t) + A_\sharp(t)y(t) + B(t)u(t))\,dt + C(t)y(t)\,dW(t), \quad t \in [0,T], \\ y(0) = x. \end{cases} \tag{1.1}$$

In the above equation y is the *state* of the system and u is the *control*; y has values in a Hilbert space H and u has values in another Hilbert space U; W is a cylindrical Ξ-valued Wiener process defined on a probability space $\{\Omega, \mathcal{F}, \mathbb{P}\}$, where Ξ is a third Hilbert space. Expanding notation with respect to an orthonormal basis $\{f_i : i \in \mathbb{N}\}$ in Ξ we have $C(t)y(t)\,dW(t) = \sum_{i=1}^{\infty} C_i(t)y(t)d\beta_i(t)$, where $\{\beta_i : i \in \mathbb{N}\} := \{(f_i, W)_\Xi : i \in \mathbb{N}\}$ is a family of standard independent Brownian motions.

We assume that the unbounded operator $A : \mathcal{D}(A) \subset H \to H$ is independent of $\omega \in \Omega$ and $t \in [0,T]$ and is the infinitesimal generator of a C_0-semigroup. On the contrary $A_\sharp$, B, and C are allowed to be random; namely they are bounded, operator valued, stochastic processes that we assume to be predictable relatively to the filtration $\mathcal{F} = \{\mathcal{F}_t : t \geq 0\}$ generated by W (this last condition is not restrictive; see Remark 2.4).

Our purpose is to minimize, over all predictable controls u, the quadratic cost functional

$$\mathbb{E}\int_0^T \left(|\sqrt{S}(s)y(s)|_H^2 + |u(s)|_U^2\right) ds + \mathbb{E}(P_T y(T), y(T))_H, \tag{1.2}$$

where S is a predictable stochastic process and P_T is a random variable, both taking values in the set of linear, symmetric, nonnegative, and bounded operators from H into H.

If we define the *stochastic value function* by

$$(P(t)x,x)_H \doteq \inf_u \mathbb{E}^{\mathcal{F}_t,\, y(t)=x}\left[\int_t^T \left(|\sqrt{S}(s)y(s)|_H^2 + |u(s)|_U^2\right) ds + (P_T y(T), y(T))_H\right], \tag{1.3}$$

then P solves, at least in a formal way, the following backward stochastic differential equation:

(1.4)
$$\begin{cases} -dP(t) = \Big(A^*P(t)+P(t)A+A_\sharp^*(t)P(t)+P(t)A_\sharp(t)-P(t)B(t)B^*(t)P(t)+S(t)\Big)\,dt \\ \qquad\qquad + \operatorname{Tr}[C^*(t)P(t)C(t)+C^*(t)Q(t)+Q(t)C(t)]\,dt+Q(t)\,dW(t), \quad t\in[0,T], \\ P(T) = P_T. \end{cases}$$

We notice that the unknowns in (1.4) are the two processes P and Q (the second one is sometimes referred to as a *martingale* term). Process P has values in the cone $\Sigma^+(H)$ of bounded, nonnegative, linear symmetric operators in H and process Q in the space $L_2(\Xi,\Sigma(H))$ of Hilbert–Schmidt operators from Ξ to the space $\Sigma(H)$ of bounded, linear symmetric operators in H. Moreover, again making the notation explicit, we have

$$\operatorname{Tr}[C^*(t)PC(t)+C^*(t)Q+QC(t)] = \sum_{i=1}^{\infty}[C_i^*(t)PC_i(t)+C_i^*(t)(Qf_i)+(Qf_i)C_i(t)].$$

The specificity of our situation resides in the fact that the above equation involves both the unbounded term A^*P+PA and the quadratic term PBB^*P. Moreover $\Sigma(H)$ is not a Hilbert space; thus some essential tools in stochastic calculus commonly used in the theory of backward stochastic differential equations, such as the Kunita–Watanabe martingale representation theorem, fail to hold. To overcome this difficulty one could try to compute the operator valued random variables on the vectors of a basis and then apply classical representation results to each component, but this procedure does not seem to allow the reconstruction of a suitable operator valued process Q. The point is that, due to the presence of an unbounded term, we cannot consider (1.4) in its classical sense. Normally this leads to a mild formulation of the equations. Here, due to the difficulty of handling the martingale representation term Q, this approach causes problems. As a matter of fact mild formulation requires defining the process like $s\to e^{(s-t)A^*}Q(s)e^{(s-t)A}h$, $h\in H$, while only the processes $Q(\cdot)h$ with h independent on t are well defined.

For the same reason, in the generality considered here, it seems difficult to show uniqueness of weak solutions of BSREs.

To cope with such a roadblock we propose the following strategy inspired by the notion of "strong solution" for partial differential equations; see [1] or [16] and references therein. Roughly speaking the method consists of first considering equations with more regular data and then defining the solution in the general case by a limiting procedure.

To continue with this program we devote the first part of the paper (up to section 5) to the case in which the process S and the random variable P_T (corresponding, respectively, to the running and final cost) take values in the Hilbert space $L_2(H)$ of Hilbert–Schmidt operators $H\to H$ (see assumption (A5)). To begin we prove existence, uniqueness, and stability with respect to approximations of the solution to a class of infinite dimensional backward stochastic differential equations with unbounded linear term and lipschitz nonlinearity; see Theorem 4.4. This result is essentially included in [10] in sofar as existence and uniqueness are concerned (except that we find a slightly more regular solution) while the part dealing with stability seems to be new and of independent interest.

The above general result is then applied to the affine Lyapunov equation

$$\begin{cases} -dP(t) = (A^*P(t) + P(t)A + \mathrm{Tr}[C^*(t)P(t)C(t) + C^*(t)Q(t) + Q(t)C(t)])\,dt \\ \qquad\qquad +(A^*_\sharp(t)P(t) + P(t)A_\sharp(t) + L(t))\,dt + Q(t)\,dW(t), \quad t \in [0,T], \\ P(T) = P_T \end{cases} \tag{1.5}$$

when L is a given Hilbert–Schmidt valued predictable process.

Then by fixed point technique and a priori estimates (see also [19]) we are able to show that if S and P_T take values in the Hilbert space $L_2(H)$, then (1.4) has, in $L_2(H)$, a unique *mild* solution (P,Q). By that we mean a pair of processes verifying $\mathbb{P}$-a.s. for all $t \in [0,T]$:

$$\begin{aligned} P(t) = &\int_t^T e^{(s-t)A^*}\mathrm{Tr}[C^*(s)P(s)C(s) + C^*(s)Q(s) + Q(s)C(s)]e^{(s-t)A}\,ds \\ &+e^{(T-t)A^*}P_Te^{(T-t)A} + \int_t^T e^{(s-t)A^*}Q(s)e^{(s-t)A}\,dW(s) \\ &+ \int_t^T e^{(s-t)A^*}S(s)e^{(s-t)A}\,ds + \int_t^T e^{(s-t)A^*}(A^*_\sharp(s)P(s) \\ &+P(s)A_\sharp(s) - P(s)B(s)B^*(s)P(s))e^{(s-t)A}\,ds. \end{aligned} \tag{1.6}$$

Moreover, we prove that such a solution can be approximated by the classical solutions of the equations obtained replacing A by its Yosida approximations. Once we have a solution to the Riccati equation it is easy to perform in this Hilbertian framework, the standard synthesis of the optimal control: that is, to verify that $(P(0)x,x)_H$ is the optimal cost and that the unique optimal control $\overline{u}$ verifies the *feedback law* $\overline{u}(t) = -B^*(t)P(t)\overline{y}(t)$ (see Theorem 5.14).

Hilbert–Schmidt Assumption (A5) is too restrictive in many of the concrete applications (see the example in section 10 and Remark 10.1) so it is necessary to complete the above mentioned programm in order to include in the theory general running costs S and final conditions P_T. In section 6 we introduce the concept of *generalized solutions* of (1.4). By this we mean limits (in a suitable sense) of solutions corresponding to Hilbert–Schmidt data S and P_T. We are able to prove, under fairly general assumptions, that a generalized solution, in the above sense, exists and is unique (see Theorem 6.6). Notice that if existence of a generalized solution is somehow expected, uniqueness seems a more interesting result; its proof is largely based on the control-theoretic interpretation of (1.4). Moreover, we show that such a solution still allows to perform the synthesis of the optimal control as in the Hilbert–Schmidt case (see again Theorem 6.6). We also notice that their control theoretic interpretation imply that generalized solutions enjoy "strong continuity" property (see Lemma 6.5).

In section 7 we prove that generalized solutions verify the following *variation of constants* formula:

$$\begin{aligned} (P(t)x,x)_H = &(L_{t,T}P_Tx,x)_H + \int_t^T (L_{t,s}S(s)x,x)_H\,ds \\ &- \int_t^T (L_{t,s}P(s)B(s)B^*(s)P(s)x,x)_H\,ds \quad \mathbb{P}\text{-a.s.}, \end{aligned} \tag{1.7}$$

where $L_{t,s}$ is the evolution operator corresponding to the Lyapunov equation (1.5) with $L = 0$. We are also able to show that there exists a unique process P verifying (1.7). Thus (1.7) can be regarded as an alternative definition of solution to the BSRE (1.4). We notice that in both the definitions of solution we propose that only the P term in the BSRE is characterized. This is natural from the point of view of control theory and, in any case, is enough to complete the synthesis of the optimal control, see also Remark 6.3.

In sections 9 and 10 we show that our general results can be applied to a variety of concrete examples. The first example is a minimization of variance problem for a delay equation with a stochastic coefficient. The interest of such an example is that on one side it is extremely simple (and consequently applicable to a wide range of concrete situations) on the other it is connected with financial applications. Namely it is a firs step towards a mean variance hedging problem for a market with stochastic variance and memory effects. The second example is an optimal control problem for a wave equation in random media. In this case a stochastic coefficient is introduced, in a realistic way, assuming that the equation is subject to a stochastic damping due to the media. We notice that for the example in section 9 the Hilbert–Schmidt assumption (A5) is verified and we obtain mild solutions of the corresponding Riccati equation. On the contrary, for the example in section 9 the Hilbert–Schmidt assumption (A5) is never verified and we have to use the concept of generalized solution of the Riccati equation.

2. Main notation and assumptions. By H, U, and Ξ we will always indicate real separable Hilbert spaces.

If K is a Hilbert space, its inner scalar product and norm will be denoted by $(\cdot,\cdot)_K$ and $|\cdot|_K$, omitting the K when no confusion is possible.

For any Banach space E by $\mathcal{B}(E)$ we denote its Borel σ-field.

For any pair K_1 and K_2 of separable real Hilbert spaces we denote by $L(K_1, K_2)$ the Banach space of linear and bounded operators from K_1 to K_2 endowed by the norm $|T|_{L(K_1,K_2)} = \sup_{\{x\in K_1, |x|_{K_1}=1\}} |Tx|_{K_2}$ (as usual $L(H) = L(H, H)$).

By $\Sigma(H)$ we denote the subspace of all symmetric and bounded operators, and by $\Sigma^+(H)$ the cone of $\Sigma(H)$ that contains all positive semidefinite operators.

$L_2(K, H)$ denotes the Hilbert space of Hilbert–Schmidt operators from K to H, endowed with the Hilbert–Schmidt norm $|T|^2_{L_2(K,H)} = \sum_{i=1}^{\infty} |Te_i|^2_H$ ($\{e_i : i \in \mathbb{N}\}$ being an orthonormal basis in K), and we set $L_2(H, H) = L_2(H)$. $\Sigma_2(H)$ is the subset of $L_2(H)$ that consists of all linear and symmetric operators, and $\Sigma_2^+(H)$ is the cone of $\Sigma_2(H)$ that consists of all nonnegative operators.

The cylindrical Wiener process. We fix a probability basis $(\Omega, \mathcal{F}, \mathbb{P})$. A cylindrical Wiener process with value in Ξ is a family $W(t)$, $t \geq 0$, of linear mappings $\Xi \to L^2(\Omega)$ such that

(i) for every $h \in \Xi$, $\{W(t)h,\, t \geq 0\}$ is a real (continuous) Wiener process;

(ii) for every $h, k \in \Xi$ and $t, s \geq 0$, $\mathbb{E}(W(t)h \cdot W(s)k) = (t \wedge s)(h, k)_\Xi$.

We denote by $\mathcal{F}_t$ its natural filtration augmented with the set $\mathcal{N}$ of $\mathbb{P}$-null sets of $\mathcal{F}$. As is well known, the filtration $\mathcal{F}_t$ satisfies the usual conditions. By $\mathbb{E}^{\mathcal{F}_t}$ we denote the conditional expectation with respect to $\mathcal{F}_t$.

Finally by $\mathcal{P}$ we denote the predictable σ-field on $\Omega \times [0, T]$.

Some classes of stochastic process. Let K be any separable Hilbert space and let $\mathcal{B}(K)$ be its Borel σ-field on K. The following classes of processes will be used in this work.

- $L^p_{\mathcal{P}}(\Omega\times[0,T];K)$, $p\in[1,+\infty]$ denotes the subset of $L^p(\Omega\times[0,T];K)$, given by all equivalence classes admitting a predictable version. This space is endowed with the natural norm

$$|Y|^p_{L^p_{\mathcal{P}}(\Omega\times[0,T];K)}=\mathbb{E}\int_0^T|Y_s|^p_K\,ds$$

  Elements of this space are defined up to modification.
- $L^p_{\mathcal{P}}(\Omega;L^2([0,T];K))$ denotes the space of equivalence classes of processes Y, admitting a predictable version such that the norm

$$|Y|^p_{L^p_{\mathcal{P}}(\Omega;L^2([0,T];K))}=\mathbb{E}\bigg(\int_0^T|Y_s|^2_K\,ds\bigg)^{p/2}$$

  is finite. Elements of this space are defined up to modification.
- $C_{\mathcal{P}}([0,T];L^p(\Omega;K))$ denotes the space of K-valued processes Y such that $Y:[0,T]\to L^p(\Omega,K)$ is continuous and Y has a predictable modification, endowed with the norm

$$|Y|^p_{C_{\mathcal{P}}([0,T];L^p(\Omega;K))}=\sup_{t\in[0,T]}\mathbb{E}|Y_t|^p_K$$

  Elements of $C_{\mathcal{P}}([0,T];L^p(\Omega;K))$ are identified up to modification.
- $L^p_{\mathcal{P}}(\Omega;C([0,T];K))$ denotes the space of predictable processes Y with continuous paths in K such that the norm

$$|Y|^p_{L^p_{\mathcal{P}}(\Omega;C([0,T];K))}=\mathbb{E}\sup_{t\in[0,T]}|Y_t|^p_K$$

  is finite. Elements of this space are defined up to indistinguishability.

Now let us consider the space $L(H)$ of linear and bounded operators from a separable Hilbert space H to H. Moreover, it turns out that the σ-field generated by the operator norm in $L(H)$ is too large. For instance if A generates a C_0 semigroup, the map $t\to e^{tA}$ is not even measurable with respect to such σ-field, see [5, pp. 23–24]. We are, therefore, led to introduce the σ-field

$$\mathcal{L}_S=\sigma\{\{T\in L(H):Tu\in A\},\ \text{where } u\in H \text{ and } A\in\mathcal{B}(H)\}.$$

Again following [5] the elements of $\mathcal{L}_S$ are called *strongly measurable*.

We notice that the maps $P\to|P|_{L(H)}$ and $(P,u)\to Pu$ are measurable from $(L(H),\mathcal{L}_S)$ to $(\mathbb{R},\mathcal{B}(\mathbb{R}))$ and from $(L(H)\times H,\mathcal{L}_S\otimes\mathcal{B}(H))$ to $(H,\mathcal{B}(H))$, respectively.

Moreover, $\mathcal{L}_S$ is identical to the weak σ-field

$$\mathcal{L}_S=\sigma\{\{T\in L(H):(Tu,x)_H\in A\},\ \text{where } u,x\in H \text{ and } A\in\mathcal{B}(\mathbb{R})\}.$$

We define the following spaces.

- $L^\infty_{\mathcal{P},S}(\Omega\times[0,T];L(H))$ the space of essentially bounded, strongly measurable predictable processes $Y:\Omega\times[0,T]\to L(H)$. That is, Y is measurable from $(\Omega\times[0,T],\mathcal{P})$ to $(L(H),\mathcal{L}_S)$ and the real valued random valued $|Y|_{L(H)}$ is in $L^\infty(\Omega\times[0,T];\mathbb{R})$. By $|Y|_{L^\infty_{\mathcal{P},S}(\Omega\times[0,T];L(H))}$ we indicate the norm of $|Y|_{L(H)}$ in $L^\infty(\Omega\times[0,T];\mathbb{R})$. Elements of this space are identified up to modification.
- $L^\infty_S(\Omega,\mathcal{F}_t;L(H))$ is the space of measurable maps $Y:(\Omega,\mathcal{F}_t)\to(L(H),\mathcal{L}_S)$ such that $|Y|_{L(H)}$ is in $L^\infty(\Omega;\mathbb{R})$. By $|Y|_{L^\infty_S(\Omega;L(H))}$ we indicate the norm of $|Y|_{L(H)}$ in $L^\infty(\Omega;\mathbb{R})$.

- $L^1_{\mathcal{P},S}([0,T];L^\infty(\Omega,L(H)))$ is the space of predictable, strongly measurable processes such that $|Y|_{L(H)}$ is in $L^1([0,T];L^\infty(\Omega;\mathbb{R}))$. By $|Y|_{L^1_{\mathcal{P},S}([0,T];L^\infty(\Omega,L(H)))}$ we indicate the norm of $|Y|_{L(H)}$ in $L^1([0,T];L^\infty(\Omega;\mathbb{R}))$. Elements of this space are identified up to modification.

We identically define, with trivial changes the spaces: $L^\infty_{\mathcal{P},S}(\Omega\times[0,T];\Sigma^+(H))$, $L^\infty_{\mathcal{P},S}(\Omega\times[0,T];L(U,H))$, $L^1_{\mathcal{P},S}([0,T];L^\infty(\Omega,\Sigma^+(H)))$, and $L^\infty_S(\Omega,\mathcal{F}_t;\Sigma^+(H))$. Elements of these spaces are identified up to modification.

Statement of the problem and general assumptions on the coefficients. We consider the following infinite dimensional stochastic differential equation:

$$\begin{cases} dy(s) = (Ay(s) + A_\sharp(s)y(s) + B(s)u(s))\,ds + C(s)y(s)\,dW(s), & s\in[t,T],\\ y(t) = x, \end{cases} \tag{2.1}$$

where y is an H valued process that represents the *state* of the system and is our unknown, u is the *control* and the initial data x is in H. To stress its dependence on u, t, and x we will denote the (mild; see Definition 3.1) solution of (2.1) by $y^{t,x,u}$ when needed.

Our purpose is to minimize with respect to u the cost functional

$$\begin{aligned} J(0,x,u) = \mathbb{E}\Bigg[\int_0^T \left((S(s)y^{0,x,u}(s), y^{0,x,u}(s))_H + |u(s)|^2_U\right)\,ds \\ +(P_T y^{0,x,u}(T), y^{0,x,u}(T))_H\Bigg]. \end{aligned} \tag{2.2}$$

We also introduce the following random variables for $t\in[0,T]$:

$$\begin{aligned} J(t,x,u) = \mathbb{E}^{\mathcal{F}_t}\Bigg[\int_t^T \left((S(s)y^{t,x,u}(s), y^{t,x,u}(s))_H + |u(s)|^2_U\right)\,ds \\ +(P_T y^{t,x,u}(T), y^{t,x,u}(T))_H\Bigg]. \end{aligned}$$

We will work under the following general assumptions on A, B, and C that will hold throughout the paper.

Hypothesis 2.1.

(A1) $A : D(A)\subset H\to H$ is the infinitesimal generator of a C_0 semigroup $e^{tA} : H\to H$.

(A2) We assume that $A_\sharp\in L^\infty_{\mathcal{P},S}(\Omega\times[0,T];L(H))$. We denote by $M_{A_\sharp}$ a positive constant such that

$$|A_\sharp(t,\omega)|_{L(U,H)}\le M_{A_\sharp},\quad \mathbb{P}\text{-a.s. and for a.e. } t\in(0,T).$$

Moreover, $B\in L^\infty_{\mathcal{P},S}(\Omega\times[0,T];L(U,H))$. We denote by M_B a positive constant such that

$$|B(t,\omega)|_{L(U,H)}\le M_B,\quad \mathbb{P}\text{-a.s. and for a.e. } t\in(0,T).$$

(A3) We assume that C is of the form: $C=\sum_{i=1}^\infty C_i(\cdot,f_i)_\Xi$, where $\{f_i : i\in\mathbb{N}\}$ is an orthonormal basis in Ξ. Moreover, we suppose that

$$C_i\in L^\infty_{\mathcal{P},S}(\Omega\times[0,T];L(H)) \quad\text{and}\quad \left(\sum_{i=1}^\infty |C_i(t,\omega)|^2_{L(H)}\right)^{1/2}\le M_C,$$
$$\mathbb{P}\text{-a.s. for a.e. } t\in(0,T)$$

for a suitable positive constant M_C.

On S and P_T we will need to play with two different sets of assumptions. We introduce both of them here

(A4) $S \in L^1_{\mathcal{P},S}([0,T];L^\infty(\Omega;\Sigma^+(H)))$ and $P_T \in L^\infty_S(\Omega,\mathcal{F}_T;\Sigma^+(H))$;

(A5) $S \in L^2_{\mathcal{P}}(\Omega\times[0,T];\Sigma^+_2(H))$ and $P_T \in L^2(\Omega,\mathcal{F}_T;\Sigma^+_2(H))$.

We introduce, for later use, the Yosida approximants of the unbounded operator A, letting

$$A_h = AJ(h,A), \quad \text{where} \quad J(h,A) = h(hI-A)^{-1}, \quad h:1,2,\dots.$$

We denote by M_A a positive constant such that

$$\sup_{t\in[0,T]} |e^{tA_h}|_{L(H)} \le M_A \quad \forall h\in\mathbb{N} \quad \text{and} \quad \sup_{t\in[0,T]} |e^{tA}|_{L(H)} \le M_A \tag{2.3}$$

Remark 2.2. If we set $\beta_i(t) := (f_i, W(t))_\Xi$, then $\{\beta_i : i\in\mathbb{N}\}$ is a family of independent standard (real valued) Brownian motions. Moreover, the term $C(t)y(t)dW(t)$ can be rewritten as $\sum_{i=1}^\infty C_i(t)y(t)\,d\beta_i(t)$.

Remark 2.3. In section 9 we show that assumptions (A1)–(A5) are satisfied by a general class of controlled stochastic delay equations. In section 10 we point out that for stochastic controlled partial differential equations, assumptions (A1)–(A4) are satisfied while (A5) typically fails. We also notice that when H is finite dimensional, (A5) and (A4) reduce to the requirements $S \in L^2_{\mathcal{P},S}([0,T];L^\infty(\Omega;\Sigma^+(H)))$ *and* $P_T \in L^\infty_S(\Omega,\mathcal{F}_T;\Sigma^+(H))$ which slightly generalize the assumptions in [19] and [12], [13], [14], where S is uniformly bounded.

Remark 2.4. The fact that in the previous assumptions measurability and predictability has always been required with respect to the filtration $\{\mathcal{F}_t : t\ge 0\}$ generated by the noise $\{W_t : t\ge 0\}$ is not restrictive. Such a condition can in fact be easily weakened by the following standard procedure.

Let $\widehat{\Xi}\supset\Xi$ be a larger separable Hilbert space and let $\{\widehat{W}_t : t\ge 0\}$ be a cylindrical Wiener process with values in $\widehat{\Xi}$. Moreover, let $\{\widehat{f}_i : i\in\mathbb{N}\}$ an orthonormal basis in $\widehat{\Xi}$ with $\{\widehat{f}_i : i\in\mathbb{N}\}\supset\{f_i : i\in\mathbb{N}\}$. Finally let $\widehat{C}_i = C_i$ if $f_i\in\Xi$, $\widehat{C}_i = 0$ if $f_i\notin\Xi$ and $\widehat{C} = \sum_{i=1}^\infty \widehat{C}_i(\cdot,\widehat{f}_i)_{\widehat{\Xi}}$. If now we replace Ξ by $\widehat{\Xi}$, W by $\widehat{W}$, and C by $\widehat{C}$, (2.1) is unchanged while in all the assumptions filtration $\{\mathcal{F}_t : t\ge 0\}$ can be replaced by filtration $\{\widehat{\mathcal{F}}_t : t\ge 0\}$ generated by $\widehat{W}$. In addition, in order to allow $\mathcal{F}_0$ to be nontrivial there are no difficulties in letting the noise W to be defined in $[-\rho,+\infty[$, for some $\rho>0$, instead that in $[0,+\infty[$.

3. The state equation. This section is devoted to the state equation (2.1). We recall the well known notion of *mild solution*.

DEFINITION 3.1. *Given $x\in H$ and $u\in L^2_{\mathcal{P}}(\Omega\times[t,T];U)$, a mild solution of* (2.1) *is a process $y\in L^2_{\mathcal{P}}(\Omega\times[t,T];H)$ such that, almost surely in $\Omega\times[t,T]$,*

$$y(s) = e^{(s-t)A}x + \int_t^s e^{(s-\sigma)A}\left[A_\sharp(\sigma)y(\sigma)+B(\sigma)u(\sigma)\right]d\sigma + \int_t^s e^{(s-\sigma)A}C(\sigma)y(\sigma)\,dW(\sigma).$$

The following existence and uniqueness result is now well known.

THEOREM 3.2. *Assume* (A1)–(A3). *Given any $x\in H$ and $u\in L^2_{\mathcal{P}}(\Omega\times[t,T];U)$ problem* (2.1) *has a unique mild solution $y\in C_{\mathcal{P}}([t,T];L^2(\Omega;H))$. Moreover,*

$$\sup_{s\in[t,T]}\mathbb{E}|y(s)|^2 \le C_2\Big[|x|^2 + \mathbb{E}\int_t^T |u(s)|^2\,ds\Big] \tag{3.1}$$

for a suitable constant C_2 depending on T, M_B, M_C $M_{A_\sharp}$, and M_A.

Finally if $p > 2$ and

$$\mathbb{E}\Big(\int_t^T |u(s)|^2\,ds\Big)^{\frac{p}{2}} < \infty,$$

then we have that $y \in L^p_{\mathcal{P}}(\Omega; C([t,T];H))$ and

$$\mathbb{E}\sup_{s\in[t,T]}|y(s)|^p \le C_p\left[|x|^p + \mathbb{E}\Big(\int_t^T |u(s)|^2\,ds\Big)^{\frac{p}{2}}\right] \tag{3.2}$$

for some positive constant C_p depending on p, T, M_B, M_C, M_A, and $M_{A_\sharp}$.

Proof. The argument is identical to the one included in [5, Theorem 7.4] and [7, Proposition 3.2]. The only difference is that here the operators B and C are stochastic processes. Anyway, thanks to their boundedness stated in Hypotheses 2.1, one can proceed exactly as in the above mentioned papers. □

To stress dependence on the initial data and on the control we will, when necessary, denote the above solution by $y^{t,x,u}$.

For all $x \in H$ and $u \in L^p_{\mathcal{P}}(\Omega; L^2([t,T];U))$, $p \ge 2$ we also introduce the following family of approximating problems, $h \in \mathbb{N}$:

$$\begin{cases} dy_h(s) = (A_h y_h(s) + A_\sharp(s)y_h(s) + B(s)u(s))\,dt + C(s)y_h(s)\,dW(s), \quad s \in [t,T], \\ y(t) = x. \end{cases} \tag{3.3}$$

It is well known (see [5]) that, under the same hypotheses of Theorem 3.2, problem (3.3) has, for every $h \in \mathbb{N}$, a unique *classical* solution $y_h \in L^p_{\mathcal{P}}(\Omega; C([t,T];H))$ that, when necessary, we will denote by $y_h^{t,x,u}$.

The following stability result for the approximated problems holds.

THEOREM 3.3. *Assume that $x_h \to x$ in H and $u_h \to u$ in $L^p_{\mathcal{P}}(\Omega; L^2([t,T];U))$, as $h \to \infty$. If $p = 2$, $y_h^{t,x_h,u_h} \to y^{t,x,u}$ in $C_{\mathcal{P}}([t,T]; L^2(\Omega;H))$. If $p > 2$, $y_h^{t,x_h,u_h} \to y^{t,x,u}$ in $L^p_{\mathcal{P}}(\Omega; C([t,T];H))$.*

Proof. The proof consists in a straightforward application of the parameter depending contraction argument (see, for instance, [24, Theorem 10.1]). The case with $p = 2$ is treated also in [22, Theorem 1.1]. For the case $p > 2$ it is enough to proceed as in [7, Proposition 3.2]. □

4. Backward stochastic equations: Stability with respect to approximations. In this section we prove, for later use, a result on the stability of a generic backward stochastic equation with value in an real and separable Hilbert space K and Lipschitz nonlinearity. Beside the same hypotheses on the noise introduced in the previous section, we are given

(i) a positive number $T > 0$;
(ii) an unbounded operator $G : D(G) \subset K \to K$ and a sequence of bounded operators $G_h : K \to K$;
(iii) a map $\psi : [0,T] \times \Omega \times K \times L_2(\Xi, K) \to K$;
(iv) a final data $\eta \in L^2(\Omega, \mathcal{F}_T, \mathbb{P}; K)$.

We assume the following.

Hypothesis 4.1.

1. G generates a C_0-semigroup $\{e^{tG} : t \ge 0\}$ in K.

2. There exists a constant M_G such that

$$\sup_{t\in[0,T]} |e^{tG_h}|_{L(H)} \le M_G \quad \forall h\in\mathbb{N} \quad \text{and} \quad \sup_{t\in[0,T]} |e^{tG}|_{L(H)} \le M_G. \tag{4.1}$$

3. $\sup_{t\in[0,T]} \left|e^{tG_h}x - e^{tG}x\right| \to 0$ for all $x\in K$.
4. ψ is measurable from $\mathcal{P}\otimes\mathcal{B}(K)\otimes\mathcal{B}(L_2(\Xi,K))$ to $\mathcal{B}(K)$ and $\mathbb{E}\int_0^T |\psi(s,0,0)|_K^2 ds < +\infty$
5. There exists a constant M_ψ such that, $\mathbb{P}$ almost surely for almost every $t\in[0,T]$, the following holds for all $Y_1,Y_2\in K$, $Z_1,Z_2\in L_2(\Xi,K)$:

$$|\psi(t,Y_1,Z_1)-\psi(t,Y_2,Z_2)|_K \le M_\psi\left(|Y_1-Y_2|_K + |Z_1-Z_2|_{L_2(\Xi,K)}\right). \tag{4.2}$$

We consider the following backward stochastic equation:

$$\begin{cases} dY(s) = -GY(s)\,ds - \psi(s,Y(s),Z(s))\,ds - Z(s)\,dW(s), \quad s\in[0,T], \\ Y(T)=\eta \end{cases} \tag{4.3}$$

and the following sequence of approximating problems:

$$\begin{cases} dY_h(s) = -G_hY_h(s)\,ds - \psi(s,Y_h(s),Z_h(s))\,ds - Z_h(s)\,dW(s), \quad s\in[0y,T], \\ Y_h(T)=\eta. \end{cases} \tag{4.4}$$

Definition 4.2. *A mild solution of* (4.3) *is a couple of predictable processes* (Y,Z) *such that* Y *belongs to* $L^2_{\mathcal{P}}(\Omega,C([0,T];K))$, Z *belongs to* $L^2_{\mathcal{P}}(\Omega\times[0,T];L_2(\Xi;K))$, *and they verify for all* $t\in[0,T]$

$$Y(t) = e^{(T-t)G}\eta + \int_t^T e^{(s-t)G}\psi(s,Y(s),Z(s))\,ds + \int_t^T e^{(s-t)G}Z(s)\,dW(s) \quad \mathbb{P}\text{-a.s.} \tag{4.5}$$

An identical definition is given for a mild solution of (4.4).

Remark 4.3. G_h being bounded, it is immediate to check that the couple (Y_h,Z_h) is a mild solution of (4.4) if and only if it is a classical solution of (4.4); that is, it verifies, for all $t\in[0,T]$,

$$Y_h(t) = \eta_h + \int_t^T (G_hY_h(s) + \psi(s,Y_h(s),Z_h(s)))\,ds + \int_t^T Z_h(s)\,dW(s) \qquad \mathbb{P}\text{-a.s.} \tag{4.6}$$

The following result will be used in several occasions in what follows. As far as the existence and uniqueness part is concerned, is very similar to the one included in [10] (except from the fact that we obtain a more regular solution). On the contrary the part dealing with stability with respect to approximations is new.

Theorem 4.4. *Under Hypothesis* 4.1 *problem* (4.3) *has a unique mild solution* (Y,Z). *Moreover,* for all $h\in\mathbb{N}$, *problem* (4.4) *has a unique classical (equivalently mild) solution* (Y_h,Z_h).

Finally

$$\lim_{h\to\infty}\mathbb{E}\Big(\sup_{t\in[0,T]}|Y_h(t)-Y(t)|_K^2\Big)=0, \quad \lim_{h\to\infty}\mathbb{E}\int_0^T |Z_h(s)-Z(s)|^2_{L_2(\Xi;K)}ds = 0. \tag{4.7}$$

Proof. Part I. *Existence and uniqueness for a simplified equation.* We consider the simplified equation

(4.8)
$$Y(t) = e^{(T-t)G}\eta + \int_t^T e^{(s-t)G}F(s)\,ds + \int_t^T e^{(s-t)G}Z(s)\,dW(s), \quad t \in [0,T],$$

with $F \in L^2_{\mathcal{P}}(\Omega\times[0,T];K)$. In [10, Proposition 2.1] it is shown that the above equation admits a unique solution $(Y,Z) \in L^2_{\mathcal{P}}(\Omega\times[0,T];K) \times L^2_{\mathcal{P}}(\Omega\times[0,T];L_2(\Xi;K))$ given explicitly by

$$Y(t) = e^{(T-t)G}(\mathbb{E}^{\mathcal{F}_t}\eta) + \int_t^T e^{(s-t)G}(\mathbb{E}^{\mathcal{F}_t}F(s))\,ds, \tag{4.9}$$

$$Z(t) = -e^{(T-t)G}V(t) - \int_t^T e^{(s-t)G}L(t,s)\,ds, \tag{4.10}$$

where V and L verify

$$\mathbb{E}^{\mathcal{F}_t}\eta = \eta - \int_t^T V(\sigma)\,dW(\sigma), \quad 0 \le t \le T, \tag{4.11}$$

$$\mathbb{E}^{\mathcal{F}_t}F(s) = F(s) - \int_t^s L(\sigma,s)\,dW(\sigma), \quad 0 \le t \le s \le T \tag{4.12}$$

(existence and uniqueness of V and L are given by the Kunita–Watanabe martingale representation result applied in the Hilbert space K; again see [10]).

We now estimate such a solution in a suitable norm. For every $\beta > 0$,

$$\mathbb{E}\sup_{t\in[0,T]} e^{2\beta t}|Y(t)|_K^2 \le 2M_G^2\left[\mathbb{E}\sup_{t\in[0,T]} e^{2\beta t}\left(\int_t^T \mathbb{E}^{\mathcal{F}_t}|F(\sigma)|_K\,d\sigma\right)^2 + \mathbb{E}\sup_{t\in[0,T]} e^{2\beta t}|\mathbb{E}^{\mathcal{F}_t}\eta|_K^2\right].$$

Since

$$\left(\int_t^T |F(\sigma)|_K\,d\sigma\right)^2 \le \int_t^T e^{-2\beta s}\,ds \int_t^T e^{2\beta s}|F(s)|_K^2\,ds \le \frac{e^{-2\beta t}}{2\beta}\int_t^T e^{2\beta s}|F(s)|_K^2\,ds,$$

one gets that, thanks to Jensen and Doob inequalities,

$$\begin{aligned}\mathbb{E}\sup_{t\in[0,T]} e^{2\beta t}\left(\int_t^T \mathbb{E}^{\mathcal{F}_t}|F(s)|_K\,ds\right)^2 &\le \mathbb{E}\sup_{t\in[0,T]}\left(\mathbb{E}^{\mathcal{F}_t}\sup_{t\in[0,T]} e^{\beta t}\int_t^T |F(s)|_K\,ds\right)^2\\ &\le 4\mathbb{E}\sup_{t\in[0,T]} e^{2\beta t}\left(\int_t^T |F(s)|_K\,ds\right)^2 \le \frac{4}{2\beta}\mathbb{E}\int_0^T e^{2\beta s}|F(\sigma)|_K^2\,ds.\end{aligned}$$

Thus we have, using again Doob inequality,

$$\mathbb{E}\sup_{t\in[0,T]} e^{2\beta t}|Y(t)|_K^2 \le \frac{4M_G^2}{\beta}\mathbb{E}\int_0^T e^{2\beta s}|F(\sigma)|_K^2\,ds + 8M_G^2 e^{2\beta T}\mathbb{E}|\eta|_K^2. \tag{4.13}$$

As far as Z is concerned we have

$$|Z(t)|^2_{L_2(\Xi;K)} \le 2M_G^2\bigg[|V(t)|^2_{L_2(\Xi;K)} + \frac{e^{-2\beta t}}{2\beta}\int_t^T e^{2\beta s}|L(t,s)|^2_{L_2(\Xi;K)}\,ds\bigg].$$

Therefore,

$$\begin{aligned}\mathbb{E}\int_0^T e^{2\beta t}|Z(t)|^2_{L_2(\Xi;K)}\,dt &\le 2M_G^2\bigg[\mathbb{E}\int_0^T e^{2\beta t}|V(t)|^2_{L_2(\Xi;K)}\,dt\\ &+\frac{1}{2\beta}\mathbb{E}\int_0^T\int_t^T e^{2\beta s}|L(t,s)|^2_{L_2(\Xi;K)}\,ds\,dt\bigg] \le 2M_G^2\bigg[4e^{2\beta T}\mathbb{E}|\eta|^2_K\\ &+\frac{1}{2\beta}\mathbb{E}\int_0^T e^{2\beta s}\int_0^s |L(t,s)|^2_{L_2(\Xi;K)}\,dt\,ds\bigg]\end{aligned}$$

and we can conclude

$$\mathbb{E}\int_0^T e^{2\beta t}|Z(t)|^2_{L_2(\Xi;K)}\,dt \le 2M_G^2\bigg[4e^{2\beta T}\mathbb{E}|\eta|^2_K + \frac{2}{\beta}\int_0^T e^{2\beta s}\mathbb{E}|F(s)|^2_K\,ds\bigg]. \tag{4.14}$$

In an identical way we can prove that for all $h \in \mathbb{N}$ there exists a unique couple of processes (Y_h, Z_h) that belongs to $L^2_{\mathcal{P}}(\Omega; C([0,T];K)) \times L^2_{\mathcal{P}}(\Omega\times[0,T];L_2(\Xi;K))$ verifying, for all $t \in [0,T]$,

$$Y_h(t) = e^{(T-t)G_h}\eta + \int_t^T e^{(s-t)G_h}F(s)\,ds + \int_t^T e^{(s-t)G_h}Z_h(s)\,dW(s) \qquad \mathbb{P}\text{-a.s.} \tag{4.15}$$

with $F \in L^2_{\mathcal{P}}(\Omega\times[0,T];K)$.

Moreover, Y_h and Z_h verify (4.13) and (4.14).

Part II. *Stability with respect to approximations of the simplified equation.* By (4.10), we have, for a.e. $t \in [0,T]$,

$$\begin{aligned}Z_h(t) - Z(t) &= -e^{(T-t)G_h}V(t) + e^{(T-t)G}V(t) - \int_t^T e^{(s-t)G_h}L(t,s)\,ds\\ &+\int_t^T e^{(s-t)G}L(t,s)\,ds \quad \mathbb{P}\text{-a.s.}\end{aligned} \tag{4.16}$$

with $V \in L^2_{\mathcal{P}}(\Omega\times[0,T];L_2(\Xi;K))$ and $L \in L^2_{\mathcal{P}}(\Omega\times[0,T]\times[0,T];L_2(\Xi;K))$.

By the dominated convergence theorem, we immediately have that

$$\lim_{h\to+\infty}\mathbb{E}\int_0^T |Z_h(t) - Z(t)|^2_{L_2(\Xi;K)}\,dt = 0. \tag{4.17}$$

Now we consider the term $Y_h - Y$. We have

$$Y_h(t) - Y(t) \quad \big[e^{(T-t)G_h}\eta - e^{(T-t)G}\eta\big] + \mathbb{E}^{\mathcal{F}_t}\int_t^T \big[e^{(s-t)G_h}F(s) - e^{(s-t)G}F(s)\big]\,ds.$$

To estimate the first term of the right-hand side we can proceed as follows:

$$\begin{aligned}&\mathbb{E}\sup_{t\in[0,T]}\big|\mathbb{E}^{\mathcal{F}_t}[e^{(T-t)G_h}\eta - e^{(T-t)G}\eta]\big|^2_K \le \mathbb{E}\sup_{t\in[0,T]}\big(\mathbb{E}^{\mathcal{F}_t}\big|e^{(T-t)G_h}\eta - e^{(T-t)G}\eta\big|_K\big)^2\\ &\le \mathbb{E}\sup_{t\in[0,T]}\Big(\mathbb{E}^{\mathcal{F}_t}\sup_{t\in[0,T]}\big|e^{(T-t)G_h}\eta - e^{(T-t)G}\eta\big|_K\Big)^2\\ &\le 4\mathbb{E}\Big(\sup_{t\in[0,T]}\big|\big[e^{(T-t)G_h}\eta - e^{(T-t)G}\eta\big]\big|_K\Big)^2 \le 4\mathbb{E}\Big(\sup_{t\in[0,T]}\big|\big[e^{(T-t)G_h}\eta - e^{(T-t)G}\eta\big]\big|^2_K\Big).\end{aligned}$$

Similarly, for the second,

$$\begin{aligned}
&\mathbb{E}\sup_{t\in[0,T]}\left|\mathbb{E}^{\mathcal{F}_t}\left[\int_t^T e^{(s-t)G_h}F(s)-e^{(s-t)G}F(s)\,ds\right]\right|_K^2\\
&\quad\le \mathbb{E}\sup_{t\in[0,T]}\left(\mathbb{E}^{\mathcal{F}_t}\int_t^T |e^{(s-t)G_h}F(s)-e^{(s-t)G}F(s)|_K\,ds\right)^2\\
&\quad\le \mathbb{E}\sup_{t\in[0,T]}\left(\mathbb{E}^{\mathcal{F}_t}\int_0^T \sup_{\sigma\in[0,T]}|e^{\sigma G_h}F(s)-e^{\sigma G}F(s)|_K\,ds\right)^2\\
&\quad\le 4\mathbb{E}\left(\int_0^T \sup_{\sigma\in[0,T]}|e^{\sigma G_h}F(s)-e^{\sigma G}F(s)|_K\,ds\right)^2\\
&\quad\le 4\,T\mathbb{E}\int_0^T \sup_{\sigma\in[0,T]}|e^{\sigma G_h}F(s)-e^{\sigma G}F(s)|_K^2\,ds.
\end{aligned}$$

Therefore, we get that

$$\begin{aligned}
\mathbb{E}\sup_{t\in[0,T]}|Y_h(t)-Y(t)|_K^2 &\le 8\mathbb{E}\left(\sup_{t\in[0,T]}|e^{(T-t)G_h}\eta-e^{(T-t)G}\eta|_K^2\right)\\
&\quad+8T\,\mathbb{E}\int_0^T \sup_{\sigma\in[0,T]}|e^{\sigma G_h}F(s)-e^{\sigma G}F(s)|_K^2\,ds.
\end{aligned}$$

By point (iii) in Hypothesis 4.1 and the dominated convergence theorem we can conclude

$$\mathbb{E}\sup_{t\in[0,T]}|Y_h(t)-Y(t)|_K^2\to 0. \tag{4.18}$$

Part III. *Conclusion.* We let, for $\beta>0$, $\mathbb{K}(\beta)=L^2_{\mathcal{P}}(\Omega,C([0,T];K))\times L^2_{\mathcal{P}}(\Omega\times[0,T];L_2(\Xi;K))$ endowed with the norm (equivalent to the natural one)

$$|(Y,Z)|^2_{\mathbb{K}(\beta)}=\mathbb{E}\sup_{t\in[0,T]}e^{2\beta t}|Y(t)|^2+\mathbb{E}\int_0^T e^{2\beta s}|Z(s)|^2ds.$$

Moreover, we define a map $\Gamma:\mathbb{K}(\beta)\to\mathbb{K}(\beta)$ and a sequence of maps $\Gamma_h:\mathbb{K}(\beta)\to\mathbb{K}(\beta)$, $h\in\mathbb{N}$, letting $\Gamma(\widehat{Y},\widehat{Z})=(Y,Z)$ (respectively, $\Gamma_h(\widehat{Y},\widehat{Z})=(Y_h,Z_h)$), where (Y,Z) (respectively, (Y_h,Z_h)) is the solution of (4.8) (respectively, (4.15)) with $F(s)=\psi(s,\widehat{Y}(s),\widehat{Z}(s))$.

We notice that F belongs to $L^2_{\mathcal{P}}(\Omega\times[0,T];K)$ thus the above definition is justified by part I of the present proof.

Moreover, (4.13) and (4.14) immediately yield the following inequality, holding for all $(\widehat{Y},\widehat{Z})$, $(\widetilde{Y},\widetilde{Z})$ in $\mathbb{K}(\beta)$,

$$|\Gamma(\widehat{Y},\widehat{Z})-\Gamma(\widetilde{Y},\widetilde{Z})|^2_{\mathbb{K}(\beta)}\le\frac{4M_G^2M_\psi^2}{\beta}|(\widehat{Y},\widehat{Z})-(\widetilde{Y},\widetilde{Z})|^2_{\mathbb{K}(\beta)},$$

and an identical formula holds (with the same constant) for Γ_h.

So we can conclude that, for β large enough, Γ and Γ_h are contractions in $\mathbb{K}(\beta)$. Clearly the unique fixed point of Γ (respectively, Γ_h) is the unique mild solution of (4.3) (respectively, (4.4)).

Finally by the parameter depending contraction principle (see [24, Theorem 10.1]), relation (4.7) follows immediately if we prove that for all fixed $(\widehat{Y},\widehat{Z}) \in L^2_{\mathcal{P}}(\Omega, C([0,T];K)) \times L^2_{\mathcal{P}}(\Omega\times[0,T];L_2(\Xi;K))$, letting $(Y,Z)=\Gamma(\widehat{Y},\widehat{Z})$ and $(Y_h,Z_h)=\Gamma_h(\widehat{Y},\widehat{Z})$, then

$$\mathbb{E}\sup_{t\in[0,T]}|Y(s)-Y_h(s)|^2+\mathbb{E}\int_0^T|Z(s)-Z_h(s)|^2ds\to 0 \quad \text{as } h\to\infty.$$

The above relation is an immediate consequence of (4.18) and (4.17), letting $F(s)=\psi(s,\widehat{Y}(s),\widehat{Z}(s))$ in part II of the present proof. □

Remark 4.5. As a byproduct of the previous argument we have the following estimate for the solution (Y,Z) of (4.3):

$$|(Y,Z)|^2_{\mathcal{K}(\beta)}\le\hat{C}\left[e^{2\beta T}\mathbb{E}|P_T|^2_{\Sigma_2(H)}+\frac{1}{\beta}\int_0^T e^{2\beta s}\mathbb{E}|\psi(s,0,0)|^2_{\Sigma_2(H)}ds\right], \tag{4.19}$$

holding for β large enough, depending on T, M_G, M_ψ, and for a suitable constant $\hat{C}$, depending on T, M_G.

To prove it *just* notice that, for β large enough, Γ is a $1/2$ contraction in $\mathcal{K}(\beta)$. Since $(Y,Z)=\lim_{n\to\infty}\Gamma^n(0,0)$ we have $|(Y,Z)|_{\mathcal{K}(\beta)}\le 2|\Gamma(0,0)|_{\mathcal{K}(\beta)}$ and the claim follows by (4.14) and (4.13).

An identical estimate holds (with the same constant) for the solution (Y_h,Z_h) of the approximating equation (4.4).

Remark 4.6. Notice that although the semigroup generated by G is not, in general, a contraction semigroup and $\psi(\cdot,0,0)$ is only in $L^2_{\mathcal{P}}(\Omega\times[0,T];K)$, Y nevertheless has continuous trajectories. This is not true for standard (forward) stochastic differential equations (that is when the initial datum is specified rather the final one). For instance, in Theorem 3.2, if u is in $L^2_{\mathcal{P}}(\Omega\times[0,T];K)$, then y is only mean-square continuous.

The reason for such extra regularity of Y can be found in relation (4.9), at least for the simplified equation. Indeed in (4.9) it is clear that Y can be represented only by conditional expectations and deterministic convolutions. In particular, no stochastic convolution is involved in (4.9).

5. The Riccati equation in the Hilbert–Schmidt case. The natural space in which the deterministic Riccati equation is studied is the space $\Sigma(H)$ that is not an Hilbert space. Thus (see the introduction) we initially consider the Riccati equation in the Hilbert space $\Sigma_2(H)$ of symmetric and Hilbert–Schmidt linear operators in H.

5.1. The Lyapunov equation. We start from the linear part of the Riccati equation. Namely we consider the Lyapunov equation

$$\begin{cases} -dP(t)=(A^*P(t)+P(t)A+A^*_\sharp(t)P(t)+P(t)A_\sharp(t)+L(t))\,dt+Q(t)\,dW(t)\\ \qquad\qquad +\mathrm{Tr}[C^*(t)P(t)C(t)+C^*(t)Q(t)+Q(t)C(t)]\,dt, \quad t\in[0,T],\\ P(T)=P_T, \end{cases} \tag{5.1}$$

where, defining the notation with respect to the basis $\{f_i : i \in \mathbb{N}\}$ of Ξ, for all $P \in \Sigma_2(H)$, and $Q \in L_2(\Xi, \Sigma_2(H))$,

$$\mathrm{Tr}[C^*(t)PC(t) + C^*(t)Q + QC(t)] = \sum_{i=1}^{\infty} [C_i^*(t)PC_i(t) + C_i^*(t)(Qf_i) + (Qf_i)C_i(t)].$$

In order to give a precise definition of the *mild solution* of (5.1) we introduce the family $\{e^{t\mathcal{A}} : t \geq 0\}$ of linear operators $\Sigma(H) \to \Sigma(H)$, letting

$$e^{t\mathcal{A}}X := e^{tA^*}Xe^{tA}, \quad t \geq 0,\ X \in \Sigma(H),$$

We notice that the above family is a semigroup of bounded operators in the sense that

$$e^{t\mathcal{A}}e^{s\mathcal{A}}X = e^{(t+s)\mathcal{A}}X, \quad X \in \Sigma(H),\ t, s \geq 0,$$

but is not necessarily strongly continuous, in $\Sigma(H)$; see also [1, Chapter 1]. On the other hand, if we restrict it to $\Sigma_2(H)$, then it becomes a strongly continuous semigroup. Namely we have the following result (also concerning approximations) that will considerably simplify our work.

LEMMA 5.1. *Under hypothesis* (A1) *the family of linear operators* $\{e^{t\mathcal{A}} : t \geq 0\}$ *is a strongly continuous semigroup of bounded operators in* $\Sigma_2(H)$.

Moreover, for all $X \in L_2(H)$,

$$\lim_{h \to \infty} \sup_{t \in [0,T]} |e^{tA_h^*}Xe^{tA_h} - e^{tA^*}Xe^{tA}|_{L_2(H)} = 0. \tag{5.2}$$

Proof. We prove only continuity for $t = 0$. The proof of continuity in a generic t follows by semigroup law. Moreover, (5.2) is proved by an identical argument. We fix $X \in L_2(H)$ and a basis $\{e_i : i \in \mathbb{N}\}$ in H. Clearly

$$\sum_{i=1}^{\infty} |e^{tA^*}Xe^{tA}e_i - Xe_i|_H^2 \leq 2\sum_{i=1}^{\infty} |e^{tA^*}Xe^{tA}e_i - e^{tA^*}Xe_i|_H^2 + 2\sum_{i=1}^{\infty} |e^{tA^*}Xe_i - Xe_i|_H^2.$$

We have to prove that both the above terms converge to 0 as $t \downarrow 0$. As far as the second is concerned, since

$$|e^{tA^*}Xe_i - Xe_i|_H^2 \leq 2(M_A^2 + 1)|Xe_i|_H^2 \quad \text{and} \quad \sum_{i=1}^{\infty} |Xe_i|_H^2 = |X|_{L_2(H)}^2 < +\infty,$$

the claim follows by the dominated convergence theorem. As far as the first is concerned, we have

$$\sum_{i=1}^{\infty} |e^{tA^*}Xe^{tA}e_i - e^{tA^*}Xe_i|_H^2 \leq M_A^2 \sum_{i=1}^{\infty} |Xe^{tA}e_i - Xe_i|_H^2 = M_A^2 \sum_{i=1}^{\infty} |X^*e^{tA^*}e_i - X^*e_i|_H^2,$$

and the claim follows again by the dominated convergence theorem. ∎

Let us denote by $\mathcal{A} : \mathcal{D}(\mathcal{A}) \subset \Sigma_2(H) \to \Sigma_2(H)$ the infinitesimal generator of the semigroup $\{e^{t\mathcal{A}} : t \geq 0\}$ in $\Sigma_2(H)$. Notice that

$$(\mathcal{A}Xx, y)_H = (Xx, Ay)_H + (XAx, y)_H, \quad X \in \mathcal{D}(\mathcal{A}),\ x, y \in \mathcal{D}(A).$$

We now assume that $P_T \in L^2(\Omega, \mathcal{F}_T; \Sigma_2(H))$ and $L \in L^2_{\mathcal{P}}(\Omega \times [0,T]; \Sigma_2(H))$ and give the following definition of a mild solution (P,Q) of (5.1) with values in Hilbert–Schmidt case. We need also the following approximations to $\mathcal{A}$.

DEFINITION 5.2. *We define a sequence of bounded operators* $\mathcal{A}_n : \Sigma_2(H) \to \Sigma_2(H)$ *as follows:*

$$\mathcal{A}_h X \doteq A_h^* X + X A_h, \quad X \in \Sigma_2(H), \quad h = 1, 2, \dots$$

DEFINITION 5.3. *A* mild solution *of problem* (5.1) *is a pair of processes*

$$(P,Q) \in L^2_{\mathcal{P}}(\Omega, C([0,T]; \Sigma_2(H))) \times L^2_{\mathcal{P}}(\Omega \times [0,T]; L_2(\Xi; \Sigma_2(H)))$$

that verifies, for all $t \in [0,T]$,

$$\begin{aligned} P(t) =& e^{(T-t)A^*} P_T e^{(T-t)A} + \int_t^T e^{(s-t)A^*} \left[L(s) + A_\sharp^*(s) P(s) + P(s) A_\sharp(s) \right] e^{(s-t)A} \, ds \\ &+ \int_t^T e^{(s-t)A^*} \mathrm{Tr}[C^*(s) P(s) C(s) + C^*(s) Q(s) + Q(s) C(s)] e^{(s-t)A} \, ds + \\ &+ \int_t^T e^{(s-t)A^*} Q(s) e^{(s-t)A} \, dW(s) \qquad \mathbb{P}\text{-a.s.} \end{aligned} \tag{5.3}$$

We also introduce the regularized versions of (5.1) corresponding to the ones we have introduced for the state equation. Namely we consider

$$\begin{cases} -dP_h(t) = \left(A_h^* P_h(t) + P_h(t) A_h + A_\sharp^*(t) P_h(t) + P_h(t) A_\sharp(t) + L(t) \right) dt \\ \qquad\quad + Q_h(t) \, dW(t) + \mathrm{Tr}[C^*(t) P_h(t) C(t) + C^*(t) Q_h(t) + Q_h(t) C(t)] \, dt, \quad t \in [0,T], \\ P(T) = P_T, \end{cases} \tag{5.4}$$

where A_h are the Yosida approximants of A. The definition of mild solution for the above equation is obtained from the one corresponding to (5.1) just by replacing A by A_h. Since A_h is bounded, mild solutions are classical solutions, i.e., they satisfy $\mathbb{P}$-a.s. for all $t \in [0,T]$:

$$\begin{aligned} P_h(t) = P_T &+ \int_t^T \left(A_h^* P_h(s) + P_h(s) A_h + A_\sharp^*(s) P_h(s) + P_h(s) A_\sharp(s) + L(s) \right) ds \\ &+ \int_t^T \mathrm{Tr}[C^*(s) P_h(s) C(s) + C^*(s) Q_h(s) + Q_h(s) C(s)] \, ds + \int_t^T Q_h(s) \, dW(s). \end{aligned}$$

THEOREM 5.4. *Assume hypotheses* (A1)–(A3). *Moreover, assume that* $P_T \in L^2_{\mathcal{P}}(\Omega, \mathcal{F}_T; \Sigma_2(H))$ *and* $L \in L^2_{\mathcal{P}}(\Omega \times [0,T]; \Sigma_2(H))$.

Then problem (5.1) *has a unique mild solution* $(P,Q) \in L^2_{\mathcal{P}}(\Omega, C([0,T]; \Sigma_2(H))) \times L^2_{\mathcal{P}}(\Omega \times [0,T]; L_2(\Xi; \Sigma_2(H)))$. *Moreover, for all* $h \in \mathbb{N}$, *problem* (5.4) *has a unique classical solution* $(P_h, Q_h) \in L^2_{\mathcal{P}}(\Omega, C([0,T]; \Sigma_2(H))) \times L^2_{\mathcal{P}}(\Omega \times [0,T]; L_2(\Xi; \Sigma_2(H)))$.

Finally the following stability result holds:

(5.5)
$$\lim_{h\to\infty}\mathbb{E}\Big(\sup_{t\in[0,T]}|P_h(t)-P(t)|^2_{\Sigma_2(H)}\Big)=0,\quad \lim_{h\to\infty}\mathbb{E}\int_0^T|Q_h(s)-Q(s)|^2_{L_2(\Xi;\Sigma_2(H))}ds=0.$$

Proof. The claim is a special case of Theorem 4.4, letting $K=\Sigma_2(H)$, $G=\mathcal{A}$, $G_h=\mathcal{A}_h$, $\eta=P_T$, and defining, for all $P\in\Sigma_2(H)$, $Q\in L_2(\Xi,\Sigma_2(H))$,

$$\psi(s,P,Q)=\mathrm{Tr}[C^*(s)PC(s)+C^*(s)Q+QC(s)]+L(s)+A^*_\sharp(s)P+PA_\sharp(s).$$

We have just to check that in this specific situation Hypothesis 4.1 holds, but this is a direct consequence of hypotheses (A1)–(A3) and of the fact that $L\in L^2_{\mathcal{P}}(\Omega\times[0,T];\Sigma_2(H))$. □

Remark 5.5. Remark 4.5 gives, in the present case, the following estimate for the solution (P,Q) of (5.1):

$$|(P,Q)|^2_{\mathcal{K}}\le\hat{C}\left[e^{2\beta T}\mathbb{E}|P_T|^2_{\Sigma_2(H)}+\frac{1}{\beta}\int_0^T e^{2\beta s}\mathbb{E}|L(s)|^2_{\Sigma_2(H)}ds\right]\tag{5.6}$$

holding for β large enough, depending on T, M_A, $M_{A_\sharp}$, M_C, and for a suitable constant $\hat{C}$, depending on T, M_A, $M_{A_\sharp}$.

An identical estimate holds (with the same constant) for the solution (P_h,Q_h) of the approximating equation (5.4).

The following result is a key step towards the *fundamental relation* (see Proposition 5.11). Moreover, it gives useful estimates on the solution to (5.1).

THEOREM 5.6. *Besides the hypotheses of Theorem* 5.4*, assume that P_T belongs to $L^\infty_S(\Omega,\mathcal{F}_T;L(H))$ and L belongs to $L^1_{\mathcal{P},S}([0,T];L^\infty(\Omega;L(H)))$. Let (P,Q) be the unique mild solution to* (5.1) *and let $y^{t,x,u}$ be the mild solution to* (2.1)*. Then for all $t\in[0,T]$, $x\in H$, $u\in L^2_{\mathcal{P}}(\Omega\times[0,T];U)$ it holds, $\mathbb{P}$-a.s., that*

$$\begin{aligned}(P(t)x,x)=\mathbb{E}^{\mathcal{F}_t}(P_Ty^{t,x,u}(T),y^{t,x,u}(T))+\mathbb{E}^{\mathcal{F}_t}\int_t^T[(L(s)y^{t,x,u}(s),y^{t,x,u}(s))\\ -2(P(s)B(s)u(s),y^{t,x,u}(s))]ds.\end{aligned}\tag{5.7}$$

Moreover, for all $t\in[0,T]$,

$$|P(t)|_{L(H)}\le C_2\left[|P_T|_{L^\infty_S(\Omega;L(H))}+\int_t^T|L(s)|_{L^\infty_S(\Omega;L(H))}\,ds\right]\qquad\mathbb{P}\text{-a.s.},\tag{5.8}$$

where C_2 is the positive constant depending only on $T,M_B,M_C,M_A,M_{A_\sharp}$ defined in (3.1)*.*

Similarly if, for all $h\in\mathbb{N}$, (P_h,Q_h) is the unique solution of problem (5.4) *and for all $t\in[0,T]$,*

$$|P_h(t)|_{L(H)}\le C_2\left[|P_T|_{L^\infty_S(\Omega;L(H))}+\int_t^T|L(s)|_{L^\infty_S(\Omega;L(H))}\,ds\right]\qquad\mathbb{P}\text{-a.s.}$$

Proof. The proof will be concluded in three steps. In the first we will prove (5.7) for $u\in L^6_{\mathcal{P}}(\Omega\times[0,T];U)$, then we will prove estimate (5.8), and finally we will extend (5.7) to all the admissible controls.

First step. The following argument is simple but has some delicate points; thus we expose it here in all details. Let $y_h = y_h^{t,x,u}$ be the classical solution to (3.3). By Theorem 3.3 we know that $y_h \in L^6_{\mathcal{P}}(\Omega, C([t,T];H))$ and $y_h \to y^{t,x,u}$ in $L^6_{\mathcal{P}}(\Omega, C([t,T];H))$ as $h \to \infty$.

Let $\Psi \in C^2(H)$ with $\Psi(y) = 1$ for $|y| \le 1$, $\Psi(y) = 0$ for $|y| \ge 2$ and $\Psi(y) \in [0,1] \forall y \in H$. Differentiating by the Itô rule we obtain (we consider $\Psi' \in H$, $\Psi'' \in L(H)$)

(5.9)
$$\begin{aligned} d_s[\Psi\left(y_h(s)/N\right)(P_h(s)y_h(s), y_h(s))] &= N^{-1}F_N(s)ds + G_N(s)dW_s \\ &\quad -\Psi(y_h(s)/N)[(L(s)y_h(s), y_h(s))_H - 2(P_h(s)B(s)u(s), y_h(s))_H]ds, \end{aligned}$$

where

$$\begin{aligned} F_N(s) &= \big(\Psi'(N^{-1}y_h(s)), [A_h y_h(s) + A_\sharp(s)y_h(s) \\ &\quad + B(s)u(s)]\big)_H (P_h(s)y_h(s), y_h(s))_H \\ &\quad + 2\sum_{i=1}^{\infty} \big(\Psi'(N^{-1}y_h(s)), C_i(s)y_h(s)\big)_H (P_h(s)C_i(s)y_h(s), y_h(s))_H \\ &\quad + \frac{1}{2N}\sum_{i=1}^{\infty} \big(\Psi''(N^{-1}y_h(s))C_i(s)y_h(s), C_i(s)y_h(s)\big)_H (P_h y_h(s), y_h(s))_H \\ &\quad + \sum_{i=1}^{\infty} \big(\Psi'(N^{-1}y_h(s)), C_i(s)y_h(s)\big)_H (Q_h^i y_h(s), y_h(s))_H, \end{aligned}$$

$$\begin{aligned} G_N(s)f_i &= 2\Psi(N^{-1}y_h(s))(P_h(s)C_i(s)y_h(s), y_h(s))_H \\ &\quad - \Psi(N^{-1}y_h(s))(Q_h^i(s)y_h(s), y_h(s))_H \\ &\quad + \frac{1}{N}(P_h(s)y_h(s), y_h(s))_H (\Psi'(N^{-1}y_h(s)), C_i(s)y_h(s))_H, \end{aligned}$$

where $Q_h^i = Q_h f_i$, with $\{f_i\}_{i\in\mathbb{N}}$ an orthonormal basis of Ξ.

As it can be easily verified $\mathbb{E}\int_t^T |F_N(s)|ds \le$ const. for all $N \in \mathbb{N}$. Moreover, since $\Psi(N^{-1}y) = 0$ and $\Psi'(N^{-1}y) = 0$ if $|y| > 2N$ we have, for all $N \in \mathbb{N}$,

$$\begin{aligned} \sum_{i=1}^{\infty} \mathbb{E}\int_t^T |G_N(s)f_i|_H^2 ds \le c_2 N^4 \Big\{ M_C^2 \mathbb{E}\int_t^T \sup_{s\in[t,T]} \|P_h(s)\|^2_{L(H)}\, ds \\ + \mathbb{E}\int_t^T \|Q_h(s)\|^2_{\Sigma_2(H)}\, ds \Big\} < +\infty, \end{aligned}$$

where c_2 is a positive universal constant. Finally $(Ly_h, y_h)_H$ and $(P_h Bu, y_h)$ belong to $L^1_{\mathcal{P}}(\Omega \times [t,T], \mathbb{R})$ and $\Psi(y_h(s)/N)$ converges to 1 $\mathbb{P}$-a.s. for all s.

Thus, first integrating in $[t,T]$ and then computing conditional expectation with respect to $\mathcal{F}_t$ ($\mathbb{E}^{\mathcal{F}_t}$) and finally letting $N \to 0$, relation (5.9) becomes

$$\begin{aligned} (P_h(t)x, x)_H = \mathbb{E}^{\mathcal{F}_t}(P_T y_h(T), y_h(T))_H + \mathbb{E}^{\mathcal{F}_t}\int_t^T \big[(L(s)y_h(s), y_h(s))_H \\ -2(P_h(s)B(s)u(s), y_h(s))_H\big]ds \end{aligned}$$

and the claim follows, letting $h \to +\infty$ thanks to (3.3) and (5.4).

Second step. The following L^∞ bound for the $L(H)$ norm of the mild solution to (5.1) will be important in the approach to the (nonlinear) Riccati equation. In the finite dimensional case a similar result is proved by a slightly different argument in [19]. Here is our proof. From the *first step* we know that for all $x \in H$, $\mathbb{P}$-a.s.

$$(P(t)x,x) = \mathbb{E}^{\mathcal{F}_t}(P_T y^{t,x,0}(T), y^{t,x,0}(T)) - \mathbb{E}^{\mathcal{F}_t}\int_t^T (L(s)y^{t,x,0}(s), y^{t,x,0}(s))ds; \tag{5.10}$$

consequently

$$|(P(t)x,x)| \le |P_T|_{L^\infty_{\mathcal{S}}(\Omega;L(H))}\mathbb{E}^{\mathcal{F}_t}|y^{t,x,0}(T)|^2 + \int_t^T |L(s)|_{L^\infty_{\mathcal{S}}(\Omega;L(H))}\mathbb{E}^{\mathcal{F}_t}|y^{t,x,0}(s)|^2 ds,$$

and by estimate (3.1) for $u \equiv 0$, with $\mathbb{E}$ replaced by $\mathbb{E}^{\mathcal{F}_t}$,

$$|(P(t)x,x)| \le C_2|P_T|_{L^\infty_{\mathcal{S}}(\Omega;L(H))} + C_2\int_t^T |L(s)|_{L^\infty_{\mathcal{S}}(\Omega;L(H))}ds \quad \forall x \in H,\ |x| \le 1,\ \mathbb{P}\text{-a.s.},$$

and the claim holds, H being separable. The same estimate holds true also for every $|(P_h(t)x,x)|$, since the constant C_2 does not depend on h.

Third step. For a general $u \in L^2_{\mathcal{P}}(\Omega\times[0,T];U)$ we choose a sequence $u_m \to u$ such that u_m is bounded and $u_m \to u$ in $L^2_{\mathcal{P}}(\Omega\times[0,T];U)$. By Theorem 3.3, $y^{t,x,u_m} \to y^{t,x,u}$ in $C_{\mathcal{P}}([t,T];L^2(\Omega;H))$ and, by the *second step*, $P \in L^\infty_{\mathcal{P},\mathcal{S}}(\Omega\times[0,T];L(H))$. Moreover,

$$\begin{aligned}
&\left|\mathbb{E}^{\mathcal{F}_t}\int_t^T (L(s)y^{t,x,u_m}(s), y^{t,x,u_m}(s))_H - (L(s)y^{t,x,u}(s), y^{t,x,u}(s))_H\, ds\right| \\
&\quad \le \Big[\Big(\sup_{s\in[t,T]}\mathbb{E}^{\mathcal{F}_t}|y^{t,x,u_m}(s)|^2\Big)^{1/2} + \Big(\sup_{s\in[t,T]}\mathbb{E}^{\mathcal{F}_t}|y^{t,x,u}(s)|^2\Big)^{1/2}\Big] \\
&\quad \times \Big(\sup_{s\in[t,T]}\mathbb{E}^{\mathcal{F}_t}|y^{t,x,u_m}(s) - y^{t,x,u}(s)|^2\Big)^{1/2}\int_t^T |L(s)|_{L^\infty_{\mathcal{S}}(\Omega,H)}\, ds.
\end{aligned}$$

Thus we can pass relation (5.7) to the limit as $m \to \infty$ obtaining the claim. ∎

5.2. Existence of a unique solution for the Riccati equation and the synthesis of the optimal control. In this section we prove the existence of a unique mild solution for the Riccati equation

$$\begin{cases}
-dP(t) = (A^*P(t) + P(t)A + \mathrm{Tr}[C^*(t)P(t)C(t) + C^*(t)Q(t) + Q(t)C(t)])\, dt \\
\quad -(P(t)B(t)B^*(t)P(t) - A^*_\sharp(t)P(t) - P(t)A_\sharp(t) - S(t))\, dt + Q(t)\, dW(t), \qquad t \in [0,T], \\
P(T) = P_T
\end{cases} \tag{5.11}$$

under assumptions (A1)–(A5).

The presence of a quadratic nonlinear term imposes the following approach (classical when dealing with the Riccati equation; see [22]) in solving the problem: first we will find a local solution and then we will prove some a priori estimate for the solution to guarantee the existence of a global solution. The method we use to prove the a priori bound is based on the so called *fundamental relation* (see Proposition 5.11) and uses, in an essential way, the control-theoretic interpretation of the Riccati equation.

We start extending the notion of *mild* solution given in section 5.1.

DEFINITION 5.7. *Fix $T_0 \in [0,T]$. A mild solution for problem* (5.11)*, considered in $[T_0,T]$ is a pair (P,Q) with*

$$P \in L^2_{\mathcal{P}}(\Omega, C([T_0,T];\Sigma_2(H))) \cap L^\infty_{\mathcal{P},S}(\Omega; C([T_0,T];\Sigma^+(H))),$$
$$Q \in L^2_{\mathcal{P}}(\Omega \times (T_0,T); L_2(\Xi;\Sigma_2(H)))$$

such that for all $t \in [T_0,T]$

(5.12)

$$\begin{aligned} P(t) &= \int_t^T e^{(s-t)A^*}\mathrm{Tr}[C^*(s)P(s)C(s) + C^*(s)Q(s) + Q(s)C(s)]e^{(s-t)A}\,ds \\ &+e^{(T-t)A^*}P_T e^{(T-t)A} + \int_t^T e^{(s-t)A^*}[S(s) + A^*_\sharp(s)P(s) + P(s)A_\sharp(s)]e^{(s-t)A}\,ds \\ &+\int_t^T e^{(s-t)A^*}Q(s)e^{(s-t)A}dW(s) - \int_t^T e^{(s-t)A^*}P(s)B(s)B^*(s)P(s)e^{(s-t)A}\,ds \quad \mathbb{P}\text{-a.s.} \end{aligned}$$

PROPOSITION 5.8 (local existence). *Under Hypotheses* (A1)–(A5) *there exists a $\delta \in]0,T]$ such that problem* (5.11) *has a unique mild solution in the interval $[T-\delta,T]$.*

Proof. To simplify the notation we will set

$$|P_T|_{L^\infty_S(\Omega;L(H))} = M_P, \qquad |S|_{L^1_{\mathcal{P},S}([0,T];L^\infty(\Omega;L(H)))} = M_S.$$

We choose $r > C_2(M_P + M_S)$ and δ such that $C_2[M_P + r^2\delta M_B^2 + M_S] \le r$.

We define

$$B(r) = \Big\{P \in L^2(\Omega; C([T-\delta,T];\Sigma_2(H))) : \sup_{t\in[T-\delta,T]} |P(t,\omega)|_{L(H)} \le r \quad \mathbb{P}\text{-a.e.}\Big\}$$

endowed with the norm

$$|P|^2_\beta = \mathbb{E}\sup_{t\in[T-\delta,T]} e^{2\beta t}|P(t)|^2_{\Sigma_2(H)}.$$

On $B(r)$ we construct the map $\Lambda : B(r) \to B(r)$, letting $\Lambda(K) = P$, where (P,Q) is the unique solution to (5.1) (in $[T-\delta,T]$) with $L = -KBB^*K$; that is,

$$\begin{aligned} P(t) &= \int_t^T e^{(s-t)A^*}\mathrm{Tr}[C^*(s)P(s)C(s) + C^*(s)Q(s) + Q(s)C(s)]e^{(s-t)A}\,ds \\ &+ \int_t^T e^{(s-t)A^*}S(s)e^{(s-t)A}\,ds + e^{(T-t)A^*}P_T e^{(T-t)A} \\ &+ \int_t^T e^{(s-t)A^*}Q(s)e^{(s-t)A}\,dW(s) \\ &- \int_t^T e^{(s-t)A^*}\left[A^*_\sharp(s)P(s) + P(s)A_\sharp(s) - K(s)B(s)B^*(s)K(s)\right]e^{(s-t)A}\,ds. \end{aligned}$$

We claim that the map Λ is a contraction in $B(r)$.

First of all we check that it maps $B(r)$ into itself. By Theorem 5.4 (applied in $[T-\delta,T]$) we know that $\Lambda(K)\in L^2_{\mathcal{P}}(\Omega\times[T-\delta,T];\Sigma_2(H))$. So it is enough to show that for all $t\in[T-\delta,T]$ it holds $|\Lambda(K)(t)|_{L(H)}\le r$ $\mathbb{P}$-a.s. Thanks to (5.8) we have that $\mathbb{P}$-a.s.

$$|\Lambda(K)(t)|_{L(H)}\le C_2\bigg[|P_T|_{L^\infty_S(\Omega,L(H))}+\int_{T-\delta}^T(|K(s)B(s)B^*(s)K(s)|_{L^\infty_S(\Omega,L(H))}$$
$$+|S(s)|_{L^\infty_S(\Omega,L(H))})\,ds\bigg]\le C_2[M_P+r^2\delta M_B^2+M_S]\le r.$$

Moreover, by (4.19) for all K_1 and K_2 in $B(r)$ (since (4.19) is stated in the whole $[0,T]$ we should, to be precise, extend $K_1(s)=K_2(s)=0$ for $s<T-\delta$)

$$|\Lambda(K_2)-\Lambda(K_1)|^2_\beta\le\frac{\hat C}{\beta}\int_{T-\delta}^T e^{2\beta s}\mathbb{E}|K_2BB^*K_2-K_1BB^*K_1|^2_{\Sigma_2(H)}ds.$$

Since $|K_i|_{\Sigma_2(H)}\le r$, $i=1,2$, $\mathbb{P}$-a.s. for all $t\in[T-\delta,T]$ the above relation gives

$$|\Lambda(K_2)-\Lambda(K_1)|^2_\beta\le\frac{\hat C}{\beta}r^2M_B^4\int_{T-\delta}^T e^{2\beta s}\mathbb{E}|K_2-K_1|^2_{\Sigma_2(H)}ds.$$

Therefore, if β is large enough, Λ is a contraction in $B(r)$. If P is its unique fixed point, the mild solution (P,Q) of (5.1) with $L=-PBB^*P$ is the unique mild solution of (5.11). □

Clearly local uniqueness of the solution immediately implies global uniqueness.

COROLLARY 5.9 (global uniqueness). *Let (P_i,Q_i), $i=1,2$, be two mild solutions of the Riccati equation* (5.11) *in the interval $[T_0,T]$ for some $T_0\in[0,T)$. Then $P_1(t)=P_2(t)$, $\mathbb{P}$-a.s. for all $t\in[T_0,T]$ and $Q_1(t)=Q_2(t)$, $\mathbb{P}$-a.s. for almost all $t\in[T_0,T]$.*

Remark 5.10. The length δ of the interval on which the mild solution of the Riccati equation exists depends only on T, M_A, $M_{A_\sharp}$, M_B, M_C, $|S|_{L^1_{\mathcal{P},S}([0,T];L^\infty(\Omega;L(H))}$ and $|P_T|_{L^\infty_S(\Omega;L(H))}$. Thus to extend the solution to the whole $[0,T]$ it is sufficient to establish an a priori bound for the $L^\infty(\Omega;L(H))$ norm of the P part of any local solution, independently on the length of the interval in which it is defined.

This will be done using the following consequence of Theorem 5.6. The next relation also has an obvious control-theoretic interpretation and will be essential in performing the synthesis of the optimal control.

PROPOSITION 5.11 (fundamental relation). *Assume* (A1)–(A5) *and let (P,Q) be the mild solution of* (5.11) *in an interval $[T_0,T]$. Then, for all $t\ge T_0$, $x\in H$ $u\in L^2_{\mathcal{P}}(\Omega\times[t,T];U)$ it holds*

$$(P(t)x,x)_H=J(t,x,u)-\mathbb{E}^{\mathcal{F}_t}\int_t^T|u(s)+B^*P(s)y^{t,x,u}(s)|^2_H\,ds. \tag{5.13}$$

Proof. We start by noticing that, by definition, (P,Q) is a mild solution of the Lyapunov equation (5.1) with $L=-PBB^*P+S$. Thus by (5.7)

$$(P(t)x,x)=\mathbb{E}^{\mathcal{F}_t}(P_Ty^{t,x,u}(T),y^{t,x,u}(T))+\mathbb{E}^{\mathcal{F}_t}\int_t^T|\sqrt{S}(s)y^{t,x,u}(s)|^2_Hds$$
$$-\mathbb{E}^{\mathcal{F}_t}\int_t^T\big[(y^{t,x,u}(s),[P(s)B(s)B^*(s)P(s)+S(s)]y^{t,x,u}(s))_H$$
$$+2(P(s)B(s)u(s),y^{t,x,u}(s))_H\big]ds.$$

Then the claim follows just adding and subtracting $\mathbb{E}^{\mathcal{F}_t}\int_t^T |u(s)|_U^2 ds$. □

PROPOSITION 5.12 (positivity and a priori estimate). *Let (P,Q) be the mild solution to (5.11) in $[T_0,T]$; then*

1. *for every $t\in[T_0,T]$ and $x\in H$, $(P(t)x,x)_H\geq 0$ $\mathbb{P}$-a.s.;*
2. *for every $t\in[T_0,T]$, $|P(t)|_{L(H)}\leq C_2[M_P+M_S]$ $\mathbb{P}$-a.s,*

where C_2 is the constant defined in Theorem 3.2.

Proof. If we apply (5.13) to $u\equiv 0$, we obtain for all $x\in H$ with $|x|_H\leq 1$ and for all $t\in[T_0,T]$

$$\begin{aligned}(P(t)x,x)_H &= \mathbb{E}^{\mathcal{F}_t}(P_T y^{t,x,0}(T), y^{t,x,0}(T))_H + \mathbb{E}^{\mathcal{F}_t}\int_t^T |\sqrt{S}(s)y^{t,x,0}(s)|_H^2\,ds\\ &\leq |P_T|_{L_S^\infty(\Omega,L(H))}\mathbb{E}^{\mathcal{F}_t}|y^{t,x,0}(T)|_H^2 + \int_t^T |S(s)|_{L_S^\infty(\Omega,L(H))}\mathbb{E}^{\mathcal{F}_t}|y^{t,x,0}(s)|_H^2\,ds\end{aligned}$$

and by (3.1)

(5.14)
$$(P(t)x,x)_H \leq C_2[|P_T|_{L_S^\infty(\Omega;L(H))} + |S|_{L^1_{\mathcal{P},S}([0,T];L^\infty(\Omega;L(H)))}] \quad \mathbb{P}\text{-a.s.} \quad \forall x: |x|_H\leq 1.$$

Then consider the following *closed loop* equation, starting at a certain instant $t\geq T_0$ with an arbitrary initial data $x\in H$:

$$\begin{cases} d\overline{y}(r) = [A\overline{y}(r) + A_\sharp(r)\overline{y}(r) - B(r)B^*(r)P(r)\overline{y}(r)]\,dr + C(r)\overline{y}(r)\,dW(r),\\ \overline{y}(t) = x.\end{cases} \tag{5.15}$$

Notice that if we replace $A_\sharp$ by $A_\sharp - BB^*P$, then assumptions of Theorem 3.2 still hold. Thus there exists a unique solution $\overline{y}\in L^p_{\mathcal{P}}(\Omega, C([t,T];H))$ for every $p\geq 2$. Applying then the fundamental relation (5.13) to $\overline{u} = -B^*P\overline{y}$ and consequently to $y^{t,x,\overline{u}} = \overline{y}$ we get

(5.16)
$$(P(t)x,x)_H = \mathbb{E}^{\mathcal{F}_t}(P_T\overline{y}(T),\overline{y}(T))_H + \mathbb{E}^{\mathcal{F}_t}\int_t^T [|\sqrt{S}(r)\overline{y}(r)|_H^2 + |B^*(r)P(r)\overline{y}(r)|_H^2]\,dr;$$

thus $(P(t)x,x)_H\geq 0$, $\mathbb{P}$-a.s. for all $x\in H$, and this together with (5.14) gives the claim. □

We summarize the content of the section in the following result.

THEOREM 5.13. *Assume* (A1)–(A5). *Problem* (5.11) *has a unique mild solution (P,Q) with the following regularity: $P\in L^2_{\mathcal{P}}(\Omega;C([0,T];\Sigma_2^+(H)))\cap L^\infty_{\mathcal{P},S}(\Omega;C([0,T];\Sigma^+(H)))$ and $Q\in L^2_{\mathcal{P}}(\Omega\times[0,T];L_2(\Xi;\Sigma_2(H)))$.*

Proof. The a priori estimate in Proposition 5.12 allows us to apply the local existence result in Proposition 5.8 recursively in time intervals of fixed length (see also Remark 5.10) to obtain a global solution of (5.11). Indeed, let $\tilde{M}_P = C_2(M_P+M_S)$; then it is enough to choose $\tilde{r}$ such that $\tilde{r} > C_2(\tilde{M}_P + M_S)$ and $\tilde{\delta}$ such that

$$C_2[\tilde{M}_P + \tilde{r}^2\tilde{\delta}M_B^2 + M_S]\leq \tilde{r}.$$

Then we can iterate the procedure in $[T-n\tilde{\delta}, T-(n-1)\tilde{\delta}]$ for a finite number of $n\geq 1$ until we cover the whole interval $[0,T]$. □

Now we are ready to solve the finite horizon problem in a standard way.

THEOREM 5.14. *Fix $T>0$ and $x\in H$. Then we have the following:*

1. *There exists a unique* optimal control. *That is a unique control* $\bar{u} \in L^2_{\mathcal{P}}(\Omega \times [0,T]; U)$ *such that*

$$J(0,x,\bar{u}) = \inf_{u \in L^2_{\mathcal{P}}(\Omega\times[0,T];U)} J(0,x,u).$$

2. *If* $\bar{y}$ *is the mild solution of the state equation corresponding to* $\bar{u}$ *(that is the* optimal state*), then* $\bar{y}$ *satisfies the* closed loop *equation*

(5.17)
$$\begin{cases} d_s\bar{y}(s) = [A\bar{y}(s) + A_\sharp(s)\bar{y}(s) - B(s)B(s)^*P(s)\bar{y}(s)]\,ds + C(s)\bar{y}(s)\,dW(s), \\ \bar{y}(0) = x. \end{cases}$$

3. *The following feedback law holds* $\mathbb{P}$*-a.s. for almost every* s*:*

$$\bar{u}(s) = -B^*(s)P(s)\bar{y}(s). \tag{5.18}$$

4. *The optimal cost is given by* $\mathbb{E}J(0,x,\bar{u}) = \mathbb{E}(P(0)x,x)_H$ *for all* $x \in H$.

Proof. Let (P,Q) be the unique mild solution to Riccati equation (5.11). Relation (5.13) becomes

$$J(0,x,u) = (P(0)x,x)_H + \mathbb{E}\int_0^T |u(s) + B^*P(s)y^{t,x,u}(s)|^2\,ds.$$

Thus $J(0,x,u) \geq (P(0)x,x)_H$ for all $u \in L^2_{\mathcal{P}}(\Omega \times [0,T]; U)$ and the equality holds if and only if (5.18) holds, that is, if and only if y solves (5.17) and $u = \bar{u}$. □

6. The general case. In order to get rid of assumption (A5) we introduce the following new notion of solution.

DEFINITION 6.1. *A process* $P \in L^\infty_{\mathcal{P},S}(\Omega\times[0,T];\Sigma^+(H))$ *is a* generalized solution *if there exists a sequence* (S^N,P^N,Q^N) *where*

(i) $S^N \in L^1_{\mathcal{P},S}([0,T];L^\infty(\Omega;\Sigma^+(H))) \cap L^2_{\mathcal{P}}(\Omega\times[0,T];\Sigma_2(H))$ *and there exists a positive function* $c \in L^1([0,T])$ *such that* $|S^N(t)|_{L(H)} \leq c(t)$*, for all* $N \in \mathbb{N}$*,* $\mathbb{P}$*-a.s. for a.e.* $t \in [0,T]$;

(ii) *the pair* (P^N,Q^N) *is a mild solution to the Riccati equation* (5.11) *in the space of Hilbert–Schmidt operators, with forcing term* S^N *and final data* $P^N_T = P^N(T)$*. Namely* (P^N,Q^N) *is the unique mild solution of*

$$\begin{cases} -dP^N(t) = (A^*P^N(t) + P^N(t)A + \mathrm{Tr}[C^*(t)P^N(t)C(t) + C^*(t)Q^N(t) \\ \qquad\qquad +Q^N(t)C(t)])\,dt + (A^*_\sharp(t)P^N(t) + P^N(t)A_\sharp(t) \\ \qquad\qquad - P^N(t)B(t)B^*(t)P^N(t) + S^N(t))\,dt + Q^N(t)\,dW(t), \quad t \in [0,T], \\ P^N(T) = P^N_T \end{cases}$$

such that

(iii) *for all* $x \in H$*,*

$$S^N(t,\omega)x \to S(t,\omega)x \text{ in } H \quad \mathbb{P} \text{ a.s. for a.e. } t \in [0,T];$$

(iv) *for every* $t \in [0,T]$ *and for all* $x \in H$*,*

$$P^N(t,\omega)x \to P(t,\omega)x \quad \text{in } H \qquad \mathbb{P} \text{ a.s.}$$

Remark 6.2. Although in the definition the value of $P(t)$ seem determined for a.e. t, point (iv) in the definition implies that there exists a version such that for all $t \in [0,T]$ and for all $x \in H$ the value of $P(t)x$ is determined $\mathbb{P}$-a.s. Actually we will show extra regularity property for the generalized solution if evaluated at a vector $x \in H$.

Remark 6.3. In the previous definition only the process P in the Riccati equation is characterized. On one hand this is natural for control theory since Q is not involved in the expression for the optimal cost or in the expression for the optimal feedback law (see Theorem 6.6). On the other hand it is a general feature of backward stochastic differential equations that the martingale representation term is only an auxiliary variable that can be determined computing the joint quadratic variation between the other unknown process and the noise; see [18]. We start by showing some regularity properties of the generalized solutions.

LEMMA 6.4. *Every generalized solution fulfills the fundamental relation, i.e., for all* $t \in [0,T]$, *for all* $x \in H$, *and for all* $u \in L^2_{\mathcal{P}}(\Omega \times [0,T]; U)$,

$$(P(t)x,x)_H = J(t,x,u) - \mathbb{E}^{\mathcal{F}_t} \int_t^T |u(s) + B^*(s)P(s)y(s)|^2 \, ds \qquad \mathbb{P}\text{- a.s.} \tag{6.1}$$

Proof. At each fixed N the pair (P^N, Q^N) is the mild solution of the Riccati equation; therefore, by Proposition 5.11, we have that for all $t \in [0,T]$ and $x \in H$:

$$(P^N(t)x,x)_H = \mathbb{E}^{\mathcal{F}_t}(P^N_T y(T), y(T))_H + \mathbb{E}^{\mathcal{F}_t} \int_t^T [|\sqrt{S^N}(s)y(s)|^2 + |u(s)|^2] \, ds$$
$$- \mathbb{E}^{\mathcal{F}_t} \int_t^T |u(s) + B^*(s)P^N(s)y(s)|^2 \, ds \qquad \mathbb{P}\text{-a.s.}$$

Now, we have to pass to the limit as $N \to \infty$ in the identity. We notice that if we show that the right-hand side converges in mean to

$$\mathbb{E}^{\mathcal{F}_t}(P_T y(T), y(T))_H + \mathbb{E}^{\mathcal{F}_t} \int_t^T [|\sqrt{S}(s)y(s)|^2 + |u(s)|^2] \, ds - \mathbb{E}^{\mathcal{F}_t} \int_t^T |u(s) + B^*(s)P(s)y(s)|^2 \, ds,$$

then the proof is completed just by choosing a subsequence on which convergence occurs $\mathbb{P}$ a.s.

Coming now to the proof of convergence, considering for instance the second term, by Jensen inequality it is enough to show that

$$\lim_{N\to\infty} \mathbb{E}\left| \int_t^T ((S - S^N)(s)y(s), y(s))_H ds \right| = 0.$$

Applying a first time dominated convergence theorem, we get $\mathbb{E}|((S - S^N)(t)y(t), y(t))_H| \to 0$ for all fixed $s \in [t,T]$. Then we notice that

$$\mathbb{E}|((S - S^N)(s)y(s), y(s))_H| \le 2c(s)\mathbb{E}|y(s)|^2,$$

where the map c is in $L^1([0,T])$ and the map $s \to \mathbb{E}|y(s)|^2$ is in $C([0,T];\mathbb{R})$. Thus we can apply a second time dominated convergence theorem to obtain the claim. Since the other terms can be treated in an identical way, the proof is completed. □

LEMMA 6.5. *Let $P(t)$ be any generalized solution. Then $P(t)x \in C_{\mathcal{P}}([0,T];L^p(\Omega;H))$ for all $x \in H$ and for all $p \geq 2$.*

Proof. We have to prove that, for all $x \in H$, $\lim_{r\to t} \mathbb{E}|[P(r)-P(t)]x|_H^p = 0$ or, equivalently,

$$\lim_{r\to t} \mathbb{E}|(P(r)x,x)_H - (P(t)x,x)_H|^p = 0 \quad \forall x \in H.$$

Let us consider the state equation corresponding to $u = 0$. Then for all $x \in H$ the following holds $\mathbb{P}$-a.s.:

$$(P(t)x,x)_H = \mathbb{E}^{\mathcal{F}_t}(P_T y(T), y(T))_H + \mathbb{E}^{\mathcal{F}_t}\int_t^T |\sqrt{S}(s)y(s)|^2\,ds$$
$$-\mathbb{E}^{\mathcal{F}_t}\int_t^T |B^*(s)P(s)y(s)|^2\,ds.$$

We set $y^{t,x} = y^{t,x,0}$ and we recall that $y^{t,x} \in L^p_{\mathcal{P}}(\Omega;C([0,T];H))$ for all $p \geq 2$ (see [7, Proposition 3.2]). Moreover, the map $(t,x) \to y^{t,x}(\cdot)$ is continuous from $[0,T]\times H$ to $L^p_{\mathcal{P}}(\Omega;C([0,T];H))$; again see [7, Proposition 3.3].

Taking all these facts into account, we have that, for all $0 \leq t \leq r \leq T$,

(6.2)

$$\begin{aligned}\mathbb{E}|(P(r)x,x)_H - (P(t)x,x)_H|^p &\leq c(p)\mathbb{E}|\mathbb{E}^{\mathcal{F}_r}(P_T y(T),y(T))_H - \mathbb{E}^{\mathcal{F}_t}(P_T y(T),y(T))_H|^p\\
&+ \mathbb{E}|\mathbb{E}^{\mathcal{F}_r}\int_r^T |\sqrt{S(s)}y^{r,x}(s)|_H^2\,ds - \mathbb{E}^{\mathcal{F}_t}\int_t^T |\sqrt{S(s)}y^{t,x}(s)|_H^2\,ds|^p\\
&+ \mathbb{E}|\mathbb{E}^{\mathcal{F}_r}\int_r^T |B^*(s)P(s)y^{r,x}(s)|_H^2\,ds - \mathbb{E}^{\mathcal{F}_t}\int_t^T |B^*(s)P(s)^{t,x}y(s)|_H^2\,ds|^p.\end{aligned}$$

Since $P_T \in L^\infty_{\mathcal{S}}(\Omega,\mathcal{F}_T,\mathbb{P},L(H))$ and consequently $(P_T y(T),y(T))_H \in L^p(\Omega,\mathcal{F}_T,\mathbb{P},\mathbb{R})$, for all $p \in [2,\infty[$ by the Kunita–Watanabe martingale representation theorem there exists a process Z in $L^p_{\mathcal{P}}(\Omega;L^2([0,T];\Xi^*))$ such that

$$\left|\mathbb{E}^{\mathcal{F}_r}(P_T y(T),y(T))_H - \mathbb{E}^{\mathcal{F}_t}(P_T y(T),y(T))_H\right| = \left|\int_r^t Z(s)\,dW(s)\right|.$$

Now fix $\tau \in [0,T]$; by Burkholder–Davies–Gundy inequalities and the dominated convergence theorem we get that

$$\begin{aligned}(6.3)\qquad &\lim_{r\uparrow\tau,\,t\downarrow\tau} \mathbb{E}|\mathbb{E}^{\mathcal{F}_r}(P_T y(T),y(T))_H - \mathbb{E}^{\mathcal{F}_t}(P_T y(T),y(T))_H|^p\\
&\quad = \lim_{r\downarrow\tau,\,t\uparrow\tau} \mathbb{E}\left|\int_t^r Z(s)\,dW(s)\right|^p \leq \lim_{r\downarrow\tau,\,t\uparrow\tau} \mathbb{E}\Big(\int_t^r |Z(s)|_{\Xi^*}^2\,ds\Big)^{p/2} = 0.\end{aligned}$$

Let us consider the second term on the right-hand side in (6.2):

$$\begin{aligned}(6.4)\qquad &\lim_{r\downarrow\tau,\,t\uparrow\tau} \mathbb{E}|\mathbb{E}^{\mathcal{F}_r}\int_r^T |\sqrt{S(s)}y^{r,x}(s)|_H^2\,ds - \mathbb{E}^{\mathcal{F}_t}\int_t^T |\sqrt{S(s)}y^{t,x}(s)|_H^2\,ds|^p\\
&\leq \lim_{r\downarrow\tau,\,t\uparrow\tau} \mathbb{E}|\mathbb{E}^{\mathcal{F}_r}\int_r^T |\sqrt{S(s)}y^{r,x}(s)|_H^2\,ds - \mathbb{E}^{\mathcal{F}_r}\int_t^T |\sqrt{S(s)}y^{t,x}(s)|_H^2\,ds|^p\\
&+ \lim_{r\downarrow\tau,\,t\uparrow\tau} \mathbb{E}|[\mathbb{E}^{\mathcal{F}_r} - \mathbb{E}^{\mathcal{F}_t}]\int_t^T |\sqrt{S(s)}y^{t,x}(s)|_H^2\,ds|^p.\end{aligned}$$

Setting $y^{r,x}(s) = x$ for $s \in [t, r]$, first splitting the above expression, and then applying the Jensen inequality we get

$$\lim_{r\downarrow\tau,\, t\uparrow\tau} \mathbb{E}|\mathbb{E}^{\mathcal{F}_r} \int_r^T |\sqrt{S(s)}y^{r,x}(s)|_H^2\, ds - \mathbb{E}^{\mathcal{F}_r} \int_r^T |\sqrt{S(s)}y^{t,x}(s)|_H^2\, ds$$
$$+\mathbb{E}^{\mathcal{F}_r} \int_t^r |\sqrt{S(s)}y^{t,x}(s)|_H^2\, ds|^p \le c(p)[\lim_{r\downarrow\tau,\, t\uparrow\tau} \mathbb{E}| \int_r^T (|\sqrt{S(s)}[y^{r,x}(s) - y^{t,x}(s)]|_H^2)\, ds|^p$$
$$+ \lim_{r\downarrow\tau,\, t\uparrow\tau} \mathbb{E}|\mathbb{E}^{\mathcal{F}_r} \int_t^r |\sqrt{S(s)}y^{t,x}(s)|_H^2\, ds|^p] \le C(T, p, M_S)$$
$$\times \lim_{r\downarrow\tau,\, t\uparrow\tau} \int_t^T \mathbb{E} \sup_{s\in[t,T]} (|[y^{r,x}(s) - y^{t,x}(s)]|_H^{2p})\, ds + C(T, p)$$
$$\times \lim_{r\downarrow\tau,\, t\uparrow\tau} \mathbb{E} \int_t^r |\sqrt{S(s)}y^{t,x}(s)|_H^{2p}\, ds].$$

Therefore, by the dominated convergence theorem we get that

$$\lim_{r\downarrow\tau,\, t\uparrow\tau} \mathbb{E}|\mathbb{E}^{\mathcal{F}_r} \int_r^T |\sqrt{S(s)}y^{r,x}(s)|_H^2\, ds - \mathbb{E}^{\mathcal{F}_r} \int_t^T |\sqrt{S(s)}y^{t,x}(s)|_H^2\, ds|^p = 0.$$

The second term on the right-hand side of (6.4) can be treated like the term $\mathbb{E}^{\mathcal{F}_r}(P_T y(T), y(T))_H$ in (6.3). The third term in (6.2) follows identically as does the second term in (6.2).

This concludes the proof of the lemma. □

Now we can state the main result of the paper.

THEOREM 6.6. *Assume that hypotheses* (A1)–(A4) *hold true. Then there exists a unique generalized solution of problem* (5.11).

Moreover, we have the following characterization of the optimal control: fix $T > 0$ and $x \in H$. Then

1. *there exists a unique control $\overline{u} \in L^2_{\mathcal{P}}(\Omega \times [0, T]; U)$ such that*
$$J(0, x, \overline{u}) = \inf_{u\in L^2_{\mathcal{P}}(\Omega\times[0,T];U)} J(0, x, u);$$
2. *if $\overline{y}$ is the mild solution of the state equation corresponding to $\overline{u}$ (that is, the optimal state), then $\overline{y}$ is the unique mild solution to the* closed loop *equation*
(6.5)
$$\begin{cases} d\overline{y}(r) = [A\overline{y}(r) + A_\sharp(r)\overline{y}(r) - B(r)B^*(r)P(r)\overline{y}(r)]\, dr + C\overline{y}(r)\, dW(r), \\ \overline{y}(0) = x; \end{cases}$$
3. *the following feedback law holds $\mathbb{P}$-a.s. for almost every s:*
$$\overline{u}(s) = -B^*(s)P(s)\overline{y}(s); \tag{6.6}$$
4. *the optimal cost is given by $J(0, x, \overline{u}) = (P(0)x, x)_H$.*

Proof. We divide the proof into three steps.

First step: *Existence of a generalized solution.* We fix a complete orthonormal basis $\{e_i : i \in \mathbb{N}\}$ in H and introduce, for each $N \in \mathbb{N}$, the finite dimensional projections $\Pi_N : H \to H : v \to \sum_{i=1}^N (v, e_i)_H e_i$. For each $N \in \mathbb{N}$ we define for (t, ω) fixed:

(6.7)
$$\Pi_N P_T(\omega)\Pi_N = P_T^N(\omega) \quad \text{and} \quad S^N(t,\omega) = \begin{cases} \Pi_N S(t,\omega)\Pi_N, & |S(t,\omega)|_{L(H)} \le N, \\ 0, & |S(t,\omega)|_{\Sigma(H)} > N. \end{cases}$$

First of all we notice that, from this definition, $P_T^N \in \Sigma_2^+(H)$, $\mathbb{P}$-a.s., for all $N \in \mathbb{N}$ and that for all $x \in H$, $(P_T^N x, x)_H \nearrow (P_T x, x)_H$, $\mathbb{P}$-a.s. Again from this definition it follows that $S^N(t,\omega) \in \Sigma_2^+(H)$, for all $N \in \mathbb{N}$ and that for all $x \in H$, $(S^N(t)x, x)_H \nearrow (S(t)x, x)_H$, $\mathbb{P}$-a.s. for a.e. $t \in [0,T]$. Moreover, $|S^N(t)|_{\Sigma(H)} \leq |S(t)|_{\Sigma(H)} \mathbb{P}$-a.s. for a.e. $t \in [0,T]$, so in particular (i) and (iii) in Definition 6.1 are verified. The pair (P_T^N, S^N) will become the data of the following approximating problems:

(6.8)
$$\begin{cases} -dP^N(t) = (A^*P^N(t) + P^N(t)A + A_\sharp^*(t)P^N(t) + P^N(t)A_\sharp(t) \\ \qquad\qquad - P^N(t)B(t)B^*(t)P^N(t))\,dt + S^N(t)dt + \mathrm{Tr}[C^*(t)P^N(t)C(t) \\ \qquad\qquad + C^*(t)Q^N(t) + Q^N(t)C(t)]\,dt + Q^N(t)\,dW(t), \quad t \in [0,T], \\ \\ P^N(T) = P_T^N. \end{cases}$$

We notice that the above equation satisfies the assumptions of Theorem 5.13. Thus for each fixed $N \in \mathbb{N}$ there exists a mild solution (P^N, Q^N) with $P^N \in L^2_{\mathcal{P}}(\Omega; C([0,T]; \Sigma_2^+(H))) \cap L^\infty_{\mathcal{P},S}(\Omega; C([0,T]; \Sigma^+(H)))$ and $Q^N \in L^2_{\mathcal{P}}(\Omega \times [0,T]; L_2(\Xi; \Sigma_2(H)))$. Notice that P^N has strongly continuous trajectories, so the final condition $P^N(T) = P_T^N$, $\mathbb{P}$-a.s. is attained.

Points (i)–(iii) in Definition 6.1 are satisfied by construction. We only have to show that (iv) holds true.

We fix $t \in [0,T]$. By Theorem 5.14

$$(P^N(t)x, x)_H = \inf\{J^N(t,x,u) : u \in L^2_{\mathcal{P}}(\Omega \times [0,T]; U)\},$$

where

$$J^N(t,x,u) = \mathbb{E}^{\mathcal{F}_t} \int_t^T \left[\left| \sqrt{S^N(s)}\, y^{t,x,u}(s) \right|_H^2 + |u(s)|^2 \right] ds + \left| \sqrt{P_T^N}\, y^{t,x,u}(T) \right|^2.$$

Clearly at each $u \in L^2_{\mathcal{P}}(\Omega \times [0,T]; U)$ fixed, we have that, for every $t \in [0,T]$ and $x \in H$, the sequence $\{J^N(t,x,u) : N \in \mathbb{N}\}$ is $\mathbb{P}$-a.s. nondecreasing. Moreover, it is bounded by $J(t,x,u) < +\infty$ $\mathbb{P}$-a.s. Thus the sequence of random variables $(P^N(t)x, x)_H = \inf_{u \in L^2_{\mathcal{P}}(\Omega \times [0,T]; U)} J^N(t,x,u)$ is nondecreasing as well. Since it is $\mathbb{P}$-a.s. bounded, it has a limit. It remains for us to show that this limit is actually of the form $(P(t)x, x)_H$ with $P \in L^\infty_{\mathcal{P},S}(\Omega \times [0,T]; \Sigma^+(H))$.

Let $\mathcal{D} \doteq \{x_i\}_{i \in \mathbb{N}}$ be a dense subset of H; then we can find a subset $\Omega_0 \subset \Omega$, with $P(\Omega_0) = 1$, such that for every $x_i \in \mathcal{D}$, $\exists \lim_{N \to +\infty} (P^N(t)x_i, x_i)_H$, for every $\omega \in \Omega_0$. Thus we define the limit $\phi(t, x_i, x_i)$ as follows:

$$\phi(t, x_i, x_i) = \begin{cases} \lim_{N \to +\infty} (P^N(t)x_i, x_i)_H & \forall x_i \in \mathcal{D} \quad \text{if } \omega \in \Omega_0, \\ 0 & \forall x_i \in \mathcal{D} \quad \text{if } \omega \notin \Omega_0. \end{cases}$$

For every $\omega \in \Omega_0$ the quadratic functional $\phi(t, x_i, x_i)$ defines a continuous, positive semidefinite, quadratic form on a dense subset. Indeed thanks to (5.8) one has the following uniform bound, modifying Ω_0 if necessary:

$$|\phi(t, x_i, x_i)| \leq \sup_{N \in \mathbb{N}} |P^N(t)|_{\Sigma(H)} |x_i|_H^2 \leq C_2(M_p + M_s)|x_i|_H^2 \quad \forall \omega \in \Omega_0.$$

Therefore, $\phi(t, x_i, x_i)$ can be extended to the whole $H \times H$ by density. Moreover, by the Riesz theorem we can associate with this quadratic form a linear, bounded symmetric, and positive semidefinite operator $P(t)$ such that for every $t \in [0,T]$

$$\phi(t, x, y) = (P(t)x, y)_H \quad \forall \omega \in \Omega_0 \quad \forall x, y \in H.$$

The following uniform bound is valid for all $t \in [0,T]$:

$$|P(t)|_{L(H)} \le C_2[M_P + M_S] \quad \forall \omega \in \Omega_0. \tag{6.9}$$

The process P is by construction predictable and strongly measurable. Finally, because the operators are positive and symmetric, the weak convergence also implies the strong convergence for all $t \in [0,T]$ we have that

$$|P^N(t)x - P(t)x|_H \to 0 \quad \forall \omega \in \Omega_0, \quad \forall x \in H. \tag{6.10}$$

This concludes the proof of the *first step* since (6.10) implies (iv) in the Definition 6.1.

Second step: *Characterization of the optimal control.* By Lemma 6.4 we know that any generalized solution verifies (6.1). In particular for $t = 0$ we have that

$$J(0,x,u) = (P(0)x,x)_H + \mathbb{E}\int_0^T |u(s) + B^*(s)P(s)y^{t,x,u}(s)|^2\, ds.$$

Thus $J(0,x,u) \ge (P(0)x,x)_H$ for all $u \in L^2_{\mathcal{P}}(\Omega \times [0,T];U)$, and the equality holds if and only if (6.6) holds, that is, if and only if y solves (6.5) and $u = \overline{u}$. This completely characterizes the optimal control. We notice that existence and uniqueness of a solution to the closed loop equation (6.5) are guaranteed since the assumptions of Theorem 3.2 are satisfied if $A_\sharp$ is replaced by $A_\sharp - BB^*P$.

Third step: *Uniqueness of the generalized solution.* Let P_1 and P_2 be two generalized solutions. We choose $\bar{u} = -B^*P_1\bar{y}$, where $\bar{y}$ solves (6.5) with P replaced by P_1. By the fundamental relation (6.1) and the characterization of the optimal control proved above we immediately have

$$(P_1(t)x,x)_H = J(t,x,\bar{u}) = (P_2(t)x,x)_H + \mathbb{E}^{\mathcal{F}_t}\int_t^T |\bar{u}(s) + B^*(s)P_2(s)\bar{y}(s)|^2\, ds \quad \mathbb{P}\text{-a.s.}$$

Thus $(P_1(t)x,x)_H \ge (P_2(t)x,x)_H$ $\mathbb{P}$-a.s. The claim follows by repeating the argument, choosing P_2 instead of P_1 and repeating the argument. □

Remark 6.7. The idea of regularizing the data and then defining a generalized notion of solution is rather classical in the PDE context; see, for instance, the definition of "strong solution" in [16], [1], and the references therein, although it seems to be the first time that is used in the context of the Riccati equation.

Remark 6.8. If assumptions (A1)–(A5) in Hypothesis 2.1 hold, then comparing relation (6.1) and relation (5.13) we immediately deduce that generalized solutions of (5.11) are mild solutions of (5.11) (see section 5 for definition of mild solutions) and vice versa. On the contrary, when (A5) fails, generalized solutions still exist and are unique while mild solutions cannot be defined.

7. Generalized solutions and variation of constant formula. The aim of this section is to give a further characterization of the generalized solution just defined. To this purpose we notice that the state equation defines an evolution operator in a suitable sense, and we recover a variation of the constant formula for the value function. The main ingredient is the fundamental relation (6.1) that on one hand is verified by the generalized solution and on the other hand will turn out to be essential to define the evolution operator.

DEFINITION 7.1. *Assume* (A1)–(A3) *and consider the state equation starting from* x *at time* $t \in [0,T]$ *and with control* $u = 0$*, namely*

$$\begin{cases} dy(s) = (Ay(s) + A_\sharp(s)y(s))\,ds + C(s)y(s)\,dW(s), & s \in [t,T], \\ y(t) = x. \end{cases}$$

We denote by $y^{t,x}$ *its mild solution and define the family of maps* $L_{t,\sigma} : L^\infty_S(\Omega, \mathcal{F}_\sigma; \Sigma(H)) \to L^\infty_S(\Omega, \mathcal{F}_t; \Sigma(H))$ *for* $0 \le t \le \sigma \le T$ *in the following way. For every* $V \in L^\infty_S(\Omega, \mathcal{F}_\sigma; \Sigma(H))$ *we define*

$$(L_{t,\sigma}Vx, x)_H = \mathbb{E}^{\mathcal{F}_t}(Vy^{t,x}(\sigma), y^{t,x}(\sigma))_H. \tag{7.1}$$

We collect some properties for the evolution operator $L_{t,\sigma}$ that can be easily deduced from its definition.

LEMMA 7.2. *The family of operators* $\{L_{t,\sigma} : 0 \le t \le \sigma \le T\}$ *has the following properties:*

1. *for every* $0 \le t \le \sigma \le T$ $L_{t,\sigma}$ *is a linear and bounded operator*
$$L_{t,\sigma} : L^\infty_S(\Omega, \mathcal{F}_\sigma; \Sigma(H)) \to L^\infty_S(\Omega, \mathcal{F}_t; \Sigma(H));$$
2. *for every* $0 \le t \le r \le \sigma \le T$ *one has that*
$$L_{t,\sigma} = L_{t,r} \circ L_{r,\sigma} \quad \mathbb{P}\text{-}a.s.;$$
3. *with fixed* $V \in L^\infty_S(\Omega, \mathcal{F}_\sigma; \Sigma(H))$, $x \in H$, *and* σ *in* $[0,T]$ *the map* $t \to (L_{t,\sigma}Vx, x)_H$ *belongs to* $C_{\mathcal{P}}([0,T]; L^p(\Omega, \mathbb{R}))$ *for all* $p \ge 2$.

Proof.

1. We have that
$$\begin{aligned} \sup_{x\in H, |x|_H \le 1} |(L_{t,\sigma}Vx, x)_H &= \sup_{x\in H, |x|_H \le 1} |\mathbb{E}^{\mathcal{F}_t}(Vy^{t,x}(\sigma), y^{t,x}(\sigma))_H| \\ &\le |V|_{L^\infty_S(\Omega,\mathcal{F}_\sigma;L(H))} \sup_{x\in H, |x|_H \le 1} \mathbb{E}|y^{t,x}(\sigma)|^2_H \le C_2|V|_{L^\infty_S(\Omega,\mathcal{F}_\sigma;L(H))}. \end{aligned}$$
2. The proof follows from the semigroup property of the solution $y^{t,x}(\sigma)$ and the property of conditional expectations with respect to the filtration $\mathcal{F}_t$.
3. The proof is identical to that of Lemma 6.5. □

We notice that the fundamental relation (6.1), evaluated at $u = 0$, can be rewritten in terms of the evolution operator and reads as follows, for all $t \in [0,T]$ and all $x \in H$:

$$\begin{aligned} (P(t)x, x)_H &= \mathbb{E}^{\mathcal{F}_t}(P_T y(T), y(T))_H + \mathbb{E}^{\mathcal{F}_t} \int_t^T |\sqrt{S}(s)y(s)|^2\,ds \\ &\quad - \mathbb{E}^{\mathcal{F}_t} \int_t^T |B^*(s)P(s)y(s)|^2\,ds \\ &= (L_{t,T}P_T x, x)_H + \int_t^T (L_{t,s}S(s)x, x)_H\,ds \\ &\quad - \int_t^T (L_{t,s}P(s)B(s)B^*(s)P(s)x, x)_H\,ds \quad \mathbb{P}\text{-a.s.} \end{aligned} \tag{7.2}$$

This relation suggests a new characterization for a solution of (5.11).

DEFINITION 7.3. *A variation of constants solution to problem* (5.11) *is a map* $P \in L^{\infty}_{\mathcal{P},S}((0,T)\times\Omega;\Sigma^{+}(H))$ *such that for all* $x \in H$, $\forall p \geq 1$, $Px \in C_{\mathcal{P}}([0,T];L^{p}(\Omega;H))$ *and the following variation of constant formula is verified,* $\mathbb{P}$*-a.s.,*

$$(P(t)x,x)_H = (L_{t,T}P_Tx,x)_H + \int_t^T (L_{t,s}S(s)x,x)_H\,ds - \int_t^T (L_{t,s}P(s)B(s)B^*(s)P(s)x,x)_H\,ds. \tag{7.3}$$

We can prove existence and uniqueness of such solutions.

THEOREM 7.4. *Assume* (A1)–(A4)*; then there exists a unique solution of problem* (5.11) *in the sense of Definition* 7.3.

Proof. We already know that the generalized solution defined in the previous section verifies (7.3) and it is regular enough to be a solution in the sense of Definition 7.3. It remains to prove the uniqueness of the solution in this class. Let P_1 and P_2 be two solutions in the sense of Definition 7.3 and denote by $\bar{P}$ their difference $\bar{P}(t) = P_1(t) - P_2(t)$. Then the following holds, for all $t \in [0,T]$ and $x \in H$, $\mathbb{P}$-a.s.:

$$(\bar{P}(t)x,x)_H = \int_t^T (L_{t,s}P_2(s)B(s)B^*(s)\bar{P}(s)x,x)_H + \int_t^T (L_{t,s}\overline{P}(s)B(s)B^*(s)P_1(s)x,x)_H\,ds.$$

Therefore, for every $t \in [0,T]$ we have that

$$\begin{aligned}|\overline{P}(t)|_{L(H)} &= \sup_{x\in H,|x|_H\leq 1}(\overline{P}(t)x,x)_H\\ &\leq \sup_{x\in H,|x|_H\leq 1}\int_t^T (L_{t,s}P_2(s)B(s)B^*(s)\overline{P}(s)x,x)_H\\ &\quad + \int_t^T (L_{t,s}\overline{P}(s)B(s)B^*(s)P_1(s)x,x)_H\,ds\\ &\leq C\int_t^T |\overline{P}(s)|_{L(H)}\,ds \quad \mathbb{P}\text{-a.s.},\end{aligned}$$

where C depends on C_2, M_B, $|P_1|_{L^{\infty}_{\mathcal{P},S}(\Omega\times[0,T];L(H))}$, and $|P_2|_{L^{\infty}_{\mathcal{P},S}(\Omega\times[0,T];L(H))}$.

Applying the Gronwall lemma to $s \to |\overline{P}(s)|_{L^{\infty}(\Omega,\mathcal{F}_s,L(H))}$ we get that $P_1(t) = P_2(t)$, $\mathbb{P}$-a.s. for all $t \in [0,T]$. □

Remark 7.5. Since the solution of Definition 7.3 is also the unique generalized solution, it is obvious that it allows the synthesis of optimal controls as in Theorem 6.6. □

8. Nonhomogeneous problem. As in [13] we consider a simple generalization of our original control problem that enlarges the set of applicability of our abstract results.

We fix $\eta \in L^2(\Omega,\mathcal{F}_T,\mathbb{P},H)$ and $\nu \in L^2_{\mathcal{P}}(\Omega\times[0,T],H)$ and instead of $J(0,x,u)$ we minimize

$$\begin{aligned}\widehat{J}(0,x,u) = \mathbb{E}\int_0^T \big((S(s)(y^{0,x,u}(s)-\nu(s)),(y^{0,x,u}(s)-\nu(s)))_H + |u(s)|_U^2\big)\,ds\\ +\mathbb{E}(P_T(y^{0,x,u}(T)-\eta),(y^{0,x,u}(T)-\eta))_H.\end{aligned}$$

We assume that (A1)–(A4) in Hypothesis 2.1 hold and let P be the unique generalized solution of the Riccati equation (5.11). Moreover, (p,q) with p in $L^2_{\mathcal{P}}(\Omega, C([0,T];H))$ and q in $L^2_{\mathcal{P}}(\Omega, L^2([0,T];L_2(\Xi,H)))$ is the unique mild solution of the backward equation

$$\begin{cases} dp(s)=\big(-A^*p(s) - A^*_\sharp(s)p(s) + P(s)B(s)B^*(s)p(s) - \mathrm{Tr}[C^*(s)q(s)]\big)\,ds \\ \qquad\quad -S(s)\nu(s)ds + q(s)dW(s), \quad s\in[0,T], \\ p(T)=P_T\eta, \end{cases} \tag{8.1}$$

where, defining notation with respect to the usual basis $\{f_i : i\in\mathbb{N}\}$ in Ξ,

$$\mathrm{Tr}[C^*(s)q(s)] = \sum_{i=1}^{\infty} C_i^*(s)(q(s),f_i).$$

Moreover, existence and uniqueness of a mild solution to (8.1) are guaranteed by Theorem 4.4, whose assumptions are easily verified.

The following is the analogue of Theorem 6.6.

THEOREM 8.1. *Assume that hypotheses* (A1)–(A4) *hold true. Then*

1. *there exists a unique control* $\overline{u}\in L^2_{\mathcal{P}}(\Omega\times[0,T];U)$ *such that*

$$\widehat{J}(0,x,\overline{u}) = \inf_{u\in L^2_{\mathcal{P}}(\Omega\times[0,T];U)} \widehat{J}(0,x,u);$$

2. *if* $\overline{y}$ *is the mild solution of the state equation corresponding to* $\overline{u}$ *(that is the optimal state), then* $\overline{y}$ *is the unique mild solution to the* closed loop *equation*

$$\begin{cases} d\overline{y}(r) = [A\overline{y}(r) + A_\sharp(r)\overline{y}(r) - B(r)B^*(r)P(r)\overline{y}(r) + B(r)B^*(r)p(r)]\,dr \\ \qquad\quad +C\overline{y}(r)\,dW(r), \\ \overline{y}(0) = x; \end{cases} \tag{8.2}$$

3. *the following feedback law holds* $\mathbb{P}$*-a.s. for almost every* s*:*

$$\overline{u}(s) = -B^*(s)P(s)\overline{y}(s) + B^*(s)p(s); \tag{8.3}$$

4. *the optimal cost is given by*

$$\begin{aligned}\widehat{J}(0,x,\overline{u}) = (P(0)x,x)_H - 2(p(0),x)_H + \mathbb{E}(P_T\eta,\eta)_H \\ +\mathbb{E}\int_0^T \big((S(s)\nu(s),\nu(s))_H - |B^*(s)p(s)|^2_H\big)ds.\end{aligned}$$

Proof. Let $(p_h,q_h)\in L^2_{\mathcal{P}}(\Omega;C([0,T];H))\times L^2_{\mathcal{P}}(\Omega;L^2([0,T];L_2(\Xi,H)))$, $h=1,2,\dots$, be the unique classical solution of the backward equation

$$\begin{cases} dp(s)=\big(-A^*_hp_h(s) - A^*_\sharp(s)p_h(s) + P(s)B(s)B^*(s)p_h(s) - \mathrm{Tr}[C^*(s)q_h(s)]\big)\,ds \\ \qquad\quad -S(s)\nu(s)ds + q_h(s)dW(s), \quad s\in[0,T], \\ p(T)=P_T\eta. \end{cases} \tag{8.4}$$

We proceed as in the proof of Theorem 5.6. Namely we choose $\Psi\in C^2(H)$ with $\Psi(y)=1$ for $|y|\le 1$, $\Psi(y)=0$ for $|y|\ge 2$, and $\Psi(y)\in[0,1]\forall y\in H$. Then we

differentiate $d\Psi(N^{-1}y_h(s))(p_h(s),y_h(s))_H$ by the Itô rule. We integrate in $[0,T]$ and compute the mean value. Finally we let $N\to+\infty$ to obtain

$$\begin{aligned}\mathbb{E}(P_T\eta,y_h(T))_H &= (p(0),x)_H+\mathbb{E}\int_0^T(P(s)B^*(s)B(s)p_h(s),y_h(s))_H ds\\ &\quad+\mathbb{E}\int_0^T[(u(s),B^*(s)p_h(s))_H-(S(s)\nu(s),y_h(s))_H]ds.\end{aligned}$$

Letting $h\to\infty$ we get by Theorems 3.3 and 4.4

$$\begin{aligned}\mathbb{E}(P_T\eta,y(T))_H &= (p(0),x)_H+\mathbb{E}\int_0^T(P(s)B^*(s)B(s)p(s),y(s))_H ds\\ &\quad+\mathbb{E}\int_0^T[(u(s),B^*(s)p(s))_H-(S(s)\nu(s),y(s))_H]ds.\end{aligned}$$

Thus by easy computations

$$\begin{aligned}\widehat{J}(0,x,u) &= \mathbb{E}\int_0^T|u(s)+B^*(s)P(s)y(s)-B^*(s)p(s)|^2\,ds+(P(0)x,x)_H\\ &\quad-2(p(0),x)_H+\mathbb{E}(P_T\eta,\eta)_H\\ &\quad+\mathbb{E}\int_0^T\Big[(S(s)\nu(s),\nu(s))_H-|B^*(s)p(s)|_H\Big]ds.\end{aligned}$$

The above relation completes the proof (notice that existence and uniqueness of the mild solution of (8.2) can be proved exactly as are existence and uniqueness of the mild solution of (2.1)). □

9. Example: Minimal variance problem for a stochastic equation with delay and random volatility. We consider the controlled stochastic differential equation with memory effects:

$$\text{(9.1)}\quad\begin{cases}d\xi(t)=\left[\displaystyle\int_{-1}^0\xi(t+\theta)\,a(d\theta)+r(t)u(t)\right]dt+\sum_{i=1}^d\sigma_i(t)\xi(t)d\beta_t^i,\quad t\in[0,T],\\ \\ \xi(0)=\mu_0,\quad \xi(\theta)=\nu_0(\theta),\qquad\text{for a.e. }\theta\in(-1,0),\end{cases}$$

where $\mu_0\in\mathbb{R}^n$, $\nu_0\in L^2((-1,0);\mathbb{R}^n)$, $(\Omega,\mathcal{E},\mathcal{P})$ is a complete probability space, $\{\beta_t^i:t\geq0,\ i=1,\dots,d\}$ are independent standard Brownian motions defined in Ω. Moreover, $\mathcal{F}_t$ denotes the σ-algebra generated by $\{\beta_\sigma^i,\ \sigma\in[0,t],\ i=1,\dots,d\}$ and augmented with the sets of $\mathcal{F}$ with $\mathbb{P}$-measure zero (see Remark 2.4 to see how this requirement can be relaxed, and notice that for some $i=1,\dots,d$, σ_i can be null).

We assume that a is a $L(\mathbb{R}^n,\mathbb{R}^n)$-valued finite measure on $[-1,0]$, $r:[0,T]\times\Omega\to L(\mathbb{R}^d,\mathbb{R}^n)$ is bounded and predictable stochastic process, and $\sigma_i:[0,T]\times\Omega\to L(\mathbb{R}^n,\mathbb{R}^n)$ are bounded and predictable stochastic processes, $i=1,\dots,d$.

We also consider the following cost functional of *minimal variance* type:

$$J(0,\mu_0,\nu_0,u)=\mathbb{E}\int_0^T|u(\tau)|^2_{\mathbb{R}^d}d\tau+\mathbb{E}(k(\xi(T)-\zeta),(\xi(T)-\zeta))_{\mathbb{R}^n},$$

where $k\in L^\infty(\Omega,\mathcal{F}_T,\mathbb{P};\Sigma^+(\mathbb{R}^n))$ and $\zeta\in L^2(\Omega,\mathcal{F}_T,\mathbb{P};\mathbb{R}^n)$.

Our purpose is to minimize $J(0,\mu_0,\nu_0,u)$ over all predictable controls $u:[0,T]\times\Omega\to\mathbb{R}^d$.

Following [4] and [6] we set $H=\mathbb{R}^n\times L^2((-1,0);\mathbb{R}^n)$,

$$\mathcal{D}(A)=\left\{\begin{pmatrix}\mu\\ \nu\end{pmatrix}\in H:\nu\in W^{1,2}((-1,0);\mathbb{R}^n)\text{ and }\nu(0)=\mu\right\},$$
$$A\begin{pmatrix}\mu\\ \nu\end{pmatrix}=\begin{pmatrix}\int_{-1}^0\nu(\theta)a(d\theta)\\ \frac{d\nu}{d\theta}\end{pmatrix}.$$

It is proved in [9], among other places, that A generates a strongly continuous semigroup in H (see also [6]). Moreover, if we set $U=\mathbb{R}^d$ and for $t\in[0,T]$, $\mu\in\mathbb{R}^n$, $\nu\in L^2((-1,0);\mathbb{R}^n)$, $u\in\mathbb{R}^d$,

$$x=\begin{pmatrix}\mu_0\\ \nu_0\end{pmatrix},\quad B(t)u=\begin{pmatrix}r(t)u\\ 0\end{pmatrix},\quad C_i(t)\begin{pmatrix}\mu\\ \nu\end{pmatrix}=\begin{pmatrix}\sigma_i(t)\mu\\ 0\end{pmatrix},$$
$$P_T\begin{pmatrix}\mu\\ \nu\end{pmatrix}=\begin{pmatrix}k(t)\mu\\ 0\end{pmatrix},\quad \eta=\begin{pmatrix}\zeta\\ 0\end{pmatrix},\quad y(\tau)=\begin{pmatrix}\xi(\tau)\\ \xi_\tau(\cdot)\end{pmatrix},$$

where $x_\tau(\theta)=x(\theta+\tau)$, $\tau\ge0$, $\theta\in[-1,0]$, then (9.1) is equivalent (see [4] and [6, Chapter 10]) to

$$\begin{cases}dy(\tau)=(Ay(\tau)+Bu_\tau)\ d\tau+\sum_{i=1}^d C_i(\tau)y(\tau)d\beta_\tau^i,\quad \tau\in[0,T],\\ y(0)=y_0.\end{cases}$$

Moreover, the cost functional becomes

$$\widehat{J}(0,x,u)=\mathbb{E}\int_0^T|u(\tau)|^2_{\mathbb{R}^d}ds+\mathbb{E}\left|\sqrt{P_T}(y(T)-\eta)\right|^2_H$$

Moreover, it is easy to verify that (A1)–(A5) of Hypothesis 2.1 hold. Thus Theorem 8.1 can be applied to obtain the synthesis of the optimal control. We notice that in this case the Riccati equation has a unique mild solution in the sense clarified by Definition 5.3.

Remark 9.1. We believe that the present example is interesting on its own because of its simplicity. Notice that the model is finite dimensional, but the presence of a simple delay term and of the stochastic coefficient σ immediately requires us to use backward stochastic Riccati equations in infinite dimensional spaces.

In addition it can be regarded as a first step towards realistic financial applications of the theory. Namely in [14] (see also [25]) the authors showed that the *mean variance hedging* problem for a (incomplete) *Black and Scholes market with stochastic volatility* can be treated as a singular linear quadratic control problem with stochastic coefficients. The solution of such problem requires one to prove existence and uniqueness of the solution of a backward stochastic Riccati equation in finite dimensions. On the other hand, in [8] it was pointed out that *memory effects* can be introduced in the market model describing the evolution of the share prices by a delay equation. Thus the present example can be seen as a contribution towards the solution of the mean variance hedging problem for a market with stochastic volatility and memory effects. To deal with the realistic formulation of the problem it would be necessary to allow

control dependent noise and singular costs. This complicates the form of the Riccati equation and requires careful mixing of the techniques developed in this paper to deal with infinite dimensional stochastic Riccati equations and of the ones developed in [14] and [23] to deal with singular control problems and control dependent noise. This will be the topis of a future work.

10. Example: Optimal control for a wave equation in random media with stochastic damping. In order to show that our general results can be applied to concrete controlled stochastic PDEs arising in applications we consider a stochastic wave equation with diffused control. We assume that the system is evolving in a random media, and this influences its evolution in two ways: through a stochastic force of elastic type (the term $\sum_{i=1}^{\infty} c_i(t,\zeta)\xi(t,\zeta)d\beta_i(t)$ below) and through a stochastic damping (the term $\mu(t,\zeta)\partial_t\xi(t,\zeta)dt$ below). Notice that in this model it is natural to introduce the stochastic coefficient μ; moreover, although only one coefficient is stochastic, the use of backward stochastic Riccati equations is necessary to solve the optimal control problem.

We consider the state equation

(10.1)
$$\begin{cases} d_t\partial_t\xi(t,\zeta) = \Delta_\zeta\xi(t,\zeta)dt + b(t,\zeta)u(t,\zeta)dt + \mu(t,\zeta)\partial_t\xi(t,\zeta)dt \\ \qquad\qquad + \sum_{i=1}^{\infty} c_i(t,\zeta)\xi(t,\zeta)d\beta_i(t), \quad \zeta\in\mathcal{D}, \quad t\in[0,T], \\ \xi(t,\zeta) = 0, \quad \zeta\in\partial\mathcal{D},\ t\in[0,T], \\ \\ \xi(0,\zeta) = x_0(\zeta),\ \partial_t\xi(0,\zeta) = v_0(\zeta), \quad \zeta\in\mathcal{D}, \end{cases}$$

and the cost functional

(10.2)
$$J(0,x,u) = \mathbb{E}\int_0^T\int_{\mathcal{D}}\left[\kappa_1(t,\zeta)\xi^2(t,\zeta) + \kappa_2(t,\zeta)\left(\frac{\partial\xi}{\partial t}(t,\zeta)\right)^2\right]d\zeta\,dt$$
$$+\mathbb{E}\int_0^T\int_{\mathcal{D}} u^2(t,\zeta)d\zeta\,dt\mathbb{E}\int_{\mathcal{D}}\left[\pi_1(\zeta)\xi^2(T,\zeta) + \pi_2(\zeta)\left(\frac{\partial\xi}{\partial t}(T,\zeta)\right)^2\right]d\zeta.$$

In the above formulae $\mathcal{D}\subset\mathbb{R}^d$ is a bounded domain with regular boundary. By $\mathcal{B}(\mathcal{D})$ we denote the Borel σ-field in $\mathcal{D}$.

Moreover, $\{\beta_i : i = 1,2,\dots\}$ are independent standard (real valued) Brownian motions defined on $(\Omega,\mathcal{F},\mathbb{P})$. We set $\mathcal{F}_t = \sigma\{\beta_i(s) : s\in[0,t],\ i = 1,2,\dots\}$ and denote by $\mathcal{P}$ the predictable σ-field in $\Omega\times[0,T]$.

On the coefficients we assume the following.

1. μ is a bounded measurable process defined on $([0,T]\times\Omega)\times\mathcal{D}$ endowed with the σ-field $\mathcal{P}\otimes\mathcal{B}(\mathcal{D})$ with values in $\mathbb{R}^+$ (with Borel σ-field).
2. b, κ_1, κ_2, and c_i, $i = 1,2,\dots$, are bounded measurable maps $[0,T]\times\mathcal{D}\to\mathbb{R}$. We assume that κ_1 and κ_2 have values in $\mathbb{R}^+$.
3. There exists a constant $M > 0$ such that $\sum_{i=1}^{\infty}|c_i(t,\zeta)|^2 \le M$ for a.e. $t\in[0,T]$ and a.e. $\zeta\in\mathcal{D}$.
4. π_1 and π_2 are bounded measurable maps $\mathcal{D}\to\mathbb{R}^+$.

Following, for instance, [1] we set

1. $H = H_0^1(\mathcal{D})\times L^2(\mathcal{D})$, $U = L^2(\mathcal{D})$;
2. $W(t) = \sum_{i=1}^{\infty} f_i\beta_i(t)$, where $\{f_i : i = 1,2,\dots\}$ is an orthonormal basis in an arbitrary separable real Hilbert space Ξ;

3. $\mathcal{D}(A) = \left[H^2(\mathcal{D}) \cap H_0^1(\mathcal{D})\right] \times H_0^1(\mathcal{D})$ and

$$\left(A\begin{pmatrix}\xi\\ v\end{pmatrix}\right)(\zeta) = \begin{pmatrix}v(\zeta)\\ \Delta_\zeta \xi(\zeta)\end{pmatrix}, \quad \begin{pmatrix}\xi\\ v\end{pmatrix} \in \mathcal{D}(A),$$
$$\left(A_\sharp(t)\begin{pmatrix}\xi\\ v\end{pmatrix}\right)(\zeta) = \begin{pmatrix}0\\ \mu(t,\zeta)\xi(\zeta)\end{pmatrix}, \quad \begin{pmatrix}\xi\\ v\end{pmatrix} \in H;$$

4. $(B(t)u)(\zeta) = \begin{pmatrix}0\\ b(t,\zeta)u(\zeta)\end{pmatrix}, \quad \left(C_i(t)\begin{pmatrix}\xi\\ v\end{pmatrix}\right)(\zeta) = \begin{pmatrix}0\\ c_i(t,\zeta)\xi(\zeta)\end{pmatrix};$
5. $\left(S(t)\begin{pmatrix}\xi\\ v\end{pmatrix}\right)(\zeta) = \begin{pmatrix}\kappa_1(t,\zeta)\xi(\zeta)\\ \kappa_2(t,\zeta)v(\zeta)\end{pmatrix}, \left(P_T(t)\begin{pmatrix}\xi\\ v\end{pmatrix}\right)(\zeta) = \begin{pmatrix}\pi_1(\zeta)\xi(\zeta)\\ \pi_2(\zeta)v(\zeta)\end{pmatrix},$
$x = \begin{pmatrix}x_0\\ v_0\end{pmatrix}.$

With this setting the state equation (10.1) is equivalent to (2.1) and the cost (10.2) is equivalent to (2.2). Moreover, it is easy to verify that assumptions (A1)–(A4) in Hypothesis 2.1 are verified. So in this case we can apply the results in Theorem 6.6 to obtain existence of a unique solution of the Riccati equation both in the "generalized" sense of Definition 6.1 and the "variation of constants" sense of Definition 7.3. Moreover, such a solution allows to perform the synthesis of the optimal control as it is stated in Theorem 6.6.

Remark 10.1. Notice that assumption (A5) is in general not satisfied; take, for instance, $\kappa_2 \equiv 1$ or $\pi_2 \equiv 1$.

Acknowledgments. We wish to thank Marco Fuhrman; we are indebted to him for his help and encouragement. We also thank the referees for their useful remarks.

RELAXATION OF AN OPTIMAL DESIGN PROBLEM WITH AN INTEGRAL-TYPE CONSTRAINT*

ERNESTO ARANDA† AND JOSÉ C. BELLIDO‡

Abstract. We study a new relaxation for a two-dimensional optimal design problem in conductivity consisting of determining how to mix two given conducting materials in order to minimize the amount of one of them, subject to a constraint on the efficiency of the conducting properties of the mixture. Our approach here is different from that obtained in [R. V. Kohn and G. Strang, *Comm. Pure Appl. Math.*, 39 (1986), pp. 113–137, 139–182, 353–377], and is based on a local reformulation of the optimal design problem by means of the introduction of new potentials. The concept of constrained quasiconvexification is used in an important way.

Key words. optimal design, relaxation, constrained quasiconvexification

1. Introduction. We would like to analyze the following optimal design problem. We have at our disposal two given conducting materials; one of them is a bad and cheap conductor and the other is better but also more expensive, and we want to fill out the domain Ω (a regular, open and simply connected set of $\mathbb{R}^2$) mixing those materials in order to minimize the amount of the most expensive conductor. The respective conductivities are α and β with $0 < \alpha < \beta$. If $\chi(x)$ is the characteristic function of the set where we put the material with conductivity α, the conductivity function in Ω is

$$a(x) = \chi(x)\alpha + (1 - \chi(x))\beta.$$

The electric potential of the body is given by the solution of the diffusion equation

$$\begin{cases} -\operatorname{div}(a(x)\nabla u(x)) = 0 & \text{in } \Omega, \\ a(x)\nabla u \cdot n = f & \text{on } \partial\Omega, \end{cases} \tag{1}$$

where $f \in H^{-\frac{1}{2}}(\partial\Omega)$ stands for the current flux on $\partial\Omega$ and n is the outer normal vector to $\partial\Omega$. We assume the compatibility condition

$$\int_{\partial\Omega} f\, ds = 0,$$

in order to guarantee the existence of the solution of (1). Recall that under that condition, (1) has a unique solution up to an additive constant. The optimal design

problem we want to address consists of finding a layout of material, i.e., a characteristic function χ, minimizing the functional

$$I(\chi) = \int_\Omega (1 - \chi(x))\, dx$$

under the integral-type constraint

$$J(\chi) = \int_\Omega \frac{1}{a(x)} |\nabla u(x)|^2\, dx \leq \gamma, \tag{2}$$

where $\gamma > 0$ is given. The integral $J(\chi)$ represents the rate at which energy is dissipated to heat in the composite material given by the design χ (the bigger this integral is, the more dissipation of energy and the less efficient the design is) so that (2) constrains the efficiency with which the conductivity a conducts the current load f through Ω.

A typical feature in optimal design problems like the one considered here is the lack of optimal solutions (see, for instance, [14]), so that relaxation is needed in order to understand the behavior of minimizing sequences. For our optimal design problem, relaxation has been analyzed in [10, 11, 12] using a suitable reformulation of the problem as a min-max variational problem amenable to relaxation. In that paper the authors also consider the case of multiple constraints of type (2) for several boundary data of f_i. In our work, we only deal with the case of a single integral constraint. Recent papers about this subject are [1, 7, 13].

In this paper, we propose a different approach to analyze relaxation of this optimal design problem. We reformulate this one, in an equivalent way, as a genuine vector variational problem subject to an integral-type constraint, and then study relaxation for this new problem. As usual, relaxation for variational problems is carried out on two different levels: convexified problems in which we change the energy density by a suitable convex envelope of it, and generalized problems in which we enlarge the set of admissible functions to the set of Young measures generated by sequences of admissible functions for the original problem. Very recently this approach has been successfully used in other optimal design problems in conductivity (see [4, 19] for the two-dimensional case and [5, 6] for the three-dimensional situation).

Let us see how we reformulate the optimal design problem as a vector variational problem subject to an integral constraint. The state equation (1) is equivalent to the existence of a stream function $v \in H^1(\Omega)$ such that

$$a(x)\nabla u(x) + T\nabla v(x) = 0, \quad \text{a.e. } x \in \Omega, \tag{3}$$

where T is the counterclockwise rotation of angle $\frac{\pi}{2}$ (see [9]). Due to the fact that u verifies the boundary condition

$$a\nabla u \cdot n = f,$$

(3) implies that the tangential derivative of v is equal to the negative normal component of $a\nabla u$. Hence, up to an arbitrary constant, the boundary values of v are determined by indefinite integration along the boundary

$$v = v_0 = -\int f\, ds \quad \text{on } \partial\Omega,$$

where $v_0 \in H^{\frac{1}{2}}(\partial\Omega)$.

Now we put the functions u and v together in a single field $U = (u, v)$ and consider the functions

$$W, V : \mathbb{M}^{2\times 2} \to \mathbb{R}^* = \mathbb{R} \cup \{+\infty\}$$

defined by

$$W(A) = \begin{cases} 0 & \text{if } A \in \Lambda_\alpha, \\ 1 & \text{if } A \in \Lambda_\beta \backslash \Lambda_\alpha, \\ +\infty & \text{otherwise,} \end{cases}$$

and

$$V(A) = \begin{cases} \frac{1}{\alpha} \left|A^{(1)}\right|^2 & \text{if } A \in \Lambda_\alpha, \\ \frac{1}{\beta} \left|A^{(1)}\right|^2 & \text{if } A \in \Lambda_\beta, \\ +\infty & \text{otherwise,} \end{cases}$$

where for $\delta > 0$

$$\Lambda_\delta = \left\{ A \in \mathbb{M}^{2\times 2} \ : \ \delta A^{(1)} + T A^{(2)} = 0 \right\}.$$

Here, $A^{(i)}$ stands for the i-row of the matrix A, $i = 1, 2$. Note that

$$\Lambda_\alpha \cap \Lambda_\beta = \begin{pmatrix} 0 \\ 0 \end{pmatrix},$$

so there is no ambiguity in the definition of V. We must take into account that W and V are not Carathéodory functions since they take on the value $+\infty$ in a noncontinuous way; however, V is continuous where it is finite and W too, except at the origin.[1] This fact will be important in the study of relaxation in the next section.

It is easy to realize that the original optimal design problem is equivalent to the following variational problem:

$$\text{minimize} \int_\Omega W(\nabla U(x))\, dx \tag{4}$$

over the class of admissible functions

$$\mathcal{U} = \left\{ U \in H^1(\Omega; \mathbb{R}^2),\ U^{(2)} = v_0 \text{ on } \partial\Omega \right\}$$

subject to

$$\int_\Omega V(\nabla U(x))\, dx \le \gamma.$$

Due to this equivalence, the new problem does not have a solution, and therefore we are interested in characterization of minimizing sequences for it. To this end, we will analyze relaxation of this variational problem, proving, at first step, a

[1] This fact is not a difficulty due to 0-1 law proved in [3, Theorem 1.3]. See section 3 for more details.

subrelaxation result in terms of the appropriate convex envelope and Young measures generated by sequences of admissible gradients. Indeed, that convex envelope is defined in the following fashion. For a fixed $x \in \Omega$, $\rho > 0$, set

$$W^\sharp(A,\rho) = \inf\left\{ \int_{\mathbb{M}^{2\times 2}} W(F)\, d\nu(F) \ : \ \nu \in \mathcal{A}(A,\rho) \right\}, \tag{5}$$

where $\mathcal{A}(A,\rho)$ is the set of homogeneous H^1 Young measures ν such that

$$\int_{\mathbb{M}^{2\times 2}} F\, d\nu(F) = A$$

and

$$\int_{\mathbb{M}^{2\times 2}} V(F)\, d\nu(F) = \rho.$$

This will be carried out in section 2.

As a second step, being the most important part of this paper and where the greatest emphasis is placed, we focus on the explicit computation of the envelope $W^\sharp$ and the optimal microstructures, that is to say, the minimizers of (5). Section 3 is devoted to that computation, whose conclusion is stated in the following theorem.

THEOREM 1. *Let $\mathcal{B}$ be the set of pairs of matrices and real numbers (A,ρ) defined by the two inequalities*

$$\left(\frac{\beta+\alpha}{\beta-\alpha}\right)\frac{\left|\alpha A^{(1)} + TA^{(2)}\right|^2}{\beta(\det A - \alpha^2\rho)} \le 1 + \left(\frac{\beta+\alpha}{\beta-\alpha}\right)\frac{\left|\beta A^{(1)} + TA^{(2)}\right|^2}{\alpha(\det A - \beta^2\rho)} \tag{6}$$

and

$$\alpha^2 \le \frac{\det A}{\rho} \le \beta^2. \tag{7}$$

The constrained envelope $W^\sharp$ is given by

$$W^\sharp(A,\rho) = \begin{cases} \left(\dfrac{\beta+\alpha}{\beta-\alpha}\right)\dfrac{\left|\alpha A^{(1)} + TA^{(2)}\right|^2}{\beta(\det A - \alpha^2\rho)} & \text{if } (A,\rho)\in\mathcal{B}, \\ +\infty & \text{otherwise.} \end{cases}$$

Moreover, if (6) *happens with equality, there exists a unique first order laminate,*

$$\nu = (1-t_0)\delta_{A_\alpha} + t_0\delta_{A_\beta},$$

which is the optimal microstructure (that is, $W^\sharp(A,\rho) = \int_{\mathbb{M}^{2\times 2}} W(F)\, d\nu(F)$ and ν has barycenter A).

On the contrary, if (6) *holds with strict inequality, the optimal microstructures are second order laminates*

$$\nu_{i,j} = (1-\sigma_{i,j})\delta_{A_{\alpha,j}} + \sigma_{i,j}(\rho_{i,j}\delta_{A_\beta} + (1-\rho_{i,j})\delta_{\bar{A}_{\alpha,i}}), \quad i,j = 1,2,\ i \ne j,$$

where

$$\sigma_{i,j} = \frac{t_0(r_j - r_i)}{t_0(1-r_i) - r_i(1-r_j)}, \qquad \rho_{i,j} = \frac{t_0(1-r_i) - r_i(1-r_j)}{r_j - r_i}.$$

In both cases, $t_0 = \left(\frac{\beta+\alpha}{\beta-\alpha}\right)\frac{\left|\alpha A^{(1)} + TA^{(2)}\right|^2}{\beta(\det A - \alpha^2\rho)}$.

The values r_i and the rest of the matrices will be defined in section 3.

Note also that the function $W^\sharp$ is well-defined for (A,ρ) such that $\det A = \alpha^2\rho$, because in that case, $A \in \Lambda_\alpha$. In this situation, $W(A,\rho) = 0$ and the laminate is $\nu = \delta_A$. In the same way, if $A \in \Lambda_\beta$, $W(A,\rho) = 1$ and the optimal is attained at the same laminate.

Before going into relaxation a word should be said about the envelope $W^\sharp$. Due to the fact that functions W, V are not Carathéodory functions, the infimum in (5) defined over homogeneous gradient Young measures could be different from (less than or equal to) the corresponding infimum defined over gradients, so that being rigorous we should say that $W^\sharp$ is a constrained semiconvex envelope instead of a constrained quasiconvexification. Anyhow, working with $W^\sharp$ is enough to have a relaxation result in our setting, and we are even able to give a full and explicit computation of it. Therefore, with a little abuse of language, we will refer to that function as constrained quasiconvexification.

It is worth saying that the approach presented here is not exclusively two-dimensional as it could seem being based on the fact that, for any solution of (6), there exists a conjugate. In the three-dimensional case the recent paper [6] analyzes classical questions of the calculus of variations for functionals depending on gradients and curls in dimension three, and the conclusions of that paper were implemented in the analysis of the relaxation of a three-dimensional optimal design problem related to the one considered here (cf. [5]). We think that the analysis presented here could be extended to the three-dimensional case following the ideas presented in those papers.

2. Relaxation. A general analysis of relaxation of variational problems under integral constraints has been carried out in [17] where densities W and V are Carathéodory functions. That analysis has been applied in that paper to obtain a subrelaxation (in the sense that the infimum of the relaxed problem is less than or equal to the original one) for general structural design problems in which also the fact of having non-Carathédory densities happen. We could apply those results to directly obtain a subrelaxation; however, we will go into the analysis of relaxation of problem (4) in a slightly different way. We get to improve the subrelaxation result, although we do not get a complete relaxation result; we will deal with this question at the end of the section. We would like to emphasize that the more important and interesting result of this paper is Theorem 1 rather than the results shown in this section, which are mainly of a technical nature (although of considerable theoretical interest). Any reader not particularly interested in the questions analyzed here can pass over this section, keeping in mind the conclusion of Theorem 2, and read directly to section 3.

PROPOSITION 1. *The infimum*

$$m^\sharp = \inf\left\{\int_\Omega W^\sharp(\nabla U(x), t(x))\,dx :\ U \in \mathcal{U},\ \|t\|_{L^\infty(\Omega)} \le M,\ \int_\Omega t(x)\,dx \le \gamma\right\}$$

is attained.

Proof. Let us call

$$I^\sharp(U,t) = \int_\Omega W^\sharp(\nabla U(x), t(x))\,dx.$$

This functional is coercive because of any function taking values on the set where $W^\sharp$ is finite is bounded. This property was proved in [4] in the context of another optimal design problem in conductivity, and the proof uses the essential fact that Sobolev

functions with gradients taking values on the support of function $W^\sharp$ are solutions of linear elliptic PDEs with uniformly bounded coefficients.

To apply the direct method we need to prove that the functional $I^\sharp$ is also weak and lower semicontinuous. To this end, it is enough to show that $W^\sharp$ verifies the following jointly convex property:

$$W^\sharp(A,\theta) \le \frac{1}{|\Omega|}\int_\Omega W^\sharp(A+\nabla V(y),\theta+t(y))\,dy,$$

for all $(A,\theta)\in \mathbb{M}^{2\times 2}\times\mathbb{R}$, $V\in H^1_0(\Omega;\mathbb{R}^2)$ and $t\in L^\infty(\Omega)$ with vanishing mean-value (cf. [8]).

Let $V\in H^1_0(\Omega;\mathbb{R}^2)$ and $t\in L^\infty(\Omega)$ such that $\int_\Omega t(y)\,dy=0$. For a.e. $y\in\Omega$, we can find a minimizing probability measure $\nu^y\in\mathcal{A}(A+\nabla V(y),\theta+t(y))$ such that

$$W^\sharp(A+\nabla V(y),\theta+t(y)) = \int_{\mathbb{M}^{2\times 2}} W(F)\,d\nu^y(F).$$

Proving that such a minimizing measure exists, there is an elementary fact of functional analysis due to the functional to minimize linear over measures, and the set $\mathcal{A}(A+\nabla V(y),\theta+t(y))$ is closed convex and consequently compact in the weak-$\star$ topology on the Radon measures' space.

Let us prove that the family of probability measures $\nu=\{\nu^y\}_{y\in\Omega}$ is an H^1 Young measure. To this end, we use [15, Theorem 8.16], which gives the following sufficient conditions for being a gradient Young measure: in our case, $\nu=\{\nu^y\}_{y\in\Omega}$ is a H^1 Young measure if it verifies

(a) $\nabla U(y)=\int_{\mathbb{M}^{2\times 2}} F\,d\nu^y(F)$ for some $U\in H^1$;

(b) $\int_{\mathbb{M}^{2\times 2}}\varphi(F)\,d\nu^y(F)\ge\varphi(\nabla U(y))$ for any quasiconvex function φ;

(c) $\int_\Omega\int_{\mathbb{M}^{2\times 2}}|F|^2\,d\nu^y(F)\,dy<\infty$.

(a) holds by definition of the set $\mathcal{A}(A,\rho)$, actually $U=V+A\cdot y$ in this case; (b) is true because each ν^y is a Young measure, as any term of a Young measure is a homogeneous Young measure itself, and consequently it verifies Jensen's inequality for any quasiconvex function (see [15]), and (c) holds because of the facts that $\operatorname{supp}(\nu^y)\subset\Delta$, a.e. $y\in\Omega$, and that the quadratic growth conditions on the function V are finite at any time.

Finally, the average measure of ν, $\bar\nu$ is an homogeneous H^1 Young measure belonging to $\mathcal{A}(A,\theta)$ and such that

$$\begin{aligned}\frac{1}{|\Omega|}\int_\Omega W^\sharp(A+\nabla V(y),\theta+t(y))\,dy &= \int_\Omega\int_{\mathbb{M}^{2\times 2}} W(F)\,d\nu^y(F)\,dy\\ &= \int_{\mathbb{M}^{2\times 2}} W(F)\,d\bar\nu(F)\ge W^\sharp(A,\theta).\end{aligned}$$

The averaging measure procedure is a standard technique when dealing with Young measures and can be checked at [15]. □

PROPOSITION 2. *If $\mathcal{A}$ stands for the set of H^1 Young measures such that there exists $U\in H^1(\Omega;\mathbb{R}^2)$ with*

$$\begin{aligned}\nabla U(x) &= \int_{\mathbb{M}^{2\times 2}} F\,d\nu^x(F),\\ U^{(2)} &= v_0 \quad \text{on } \partial\Omega,\end{aligned}$$

then the infimum

$$\tilde{m} = \inf \left\{ \int_\Omega \int_{\mathbb{M}^{2\times 2}} W(F)\, d\nu^x(F)\, dx : \right.$$
$$\left. \nu = \{\nu^x\}_{x\in\Omega} \in \mathcal{A},\ \int_\Omega \int_{\mathbb{M}^{2\times 2}} V(F)\, d\nu^x(F)\, dx \le \gamma \right\}$$

is attained.

The proof is standard and is based on the minimization of a linear functional on a closed convex set; see [15]. The following is a subrelaxation result.

THEOREM 2. *Under above conditions, if we put*

$$m = \inf \left\{ \int_\Omega W(\nabla U(x))\, dx \ :\ U \in \mathcal{U},\ \int_\Omega V(\nabla U(x))\, dx \le \gamma \right\},$$

then

$$\tilde{m} \le m^\sharp \le m.$$

Proof. The inequality

$$m^\sharp \le m$$

is trivial as a consequence of the definition of the constrained semiconvex envelope $W^\sharp$. Let us prove the other inequality. Let $U \in H^1(\Omega;\mathbb{R}^2)$, $t \in L^\infty(\Omega)$ be such that

$$U^{(2)} = v_0 \quad \text{on } \partial\Omega,$$

$$\int_\Omega W^\sharp(\nabla U(x), t(x))\, dx < +\infty,$$

$$\int_\Omega t(x)\, dx \le \gamma,$$

and

$$\|t\|_{L^\infty(\Omega)} \le M.$$

As was shown in the proof of Proposition 1, for a.e. $x \in \Omega$ there exists a homogeneous H^1 Young measure $\nu^x \in \mathcal{A}(\nabla U(x), t(x))$ such that

$$W^\sharp(\nabla U(x), t(x)) = \int_{\mathbb{M}^{2\times 2}} W(F)\, d\nu^x(F)$$

and the family of probability measures $\nu = \{\nu^x\}_{x\in\Omega}$ is an H^1 Young measure. Moreover, ν verifies

$$\int_\Omega \int_{\mathbb{M}^{2\times 2}} W(F)\, d\nu^x(F)\, dx = \int_\Omega W^\sharp(\nabla U(x), t(x))\, dx$$

and

$$\int_\Omega \int_{\mathbb{M}^{2\times 2}} V(F)\, d\nu^x(F)\, dx = \int_\Omega t(x)\, dx \le \gamma.$$

This finishes the proof. □

In order to obtain a full relaxation result it would be enough to prove the equality

$$m = \tilde{m}. \tag{8}$$

This fact would be true if, given any Young measure with support contained in the set where W is finite, Λ, and verifying the integral constrained, there exists a generating sequence of gradients such that it verifies all the admissibility constraints for the problem, and, further, those gradients take values on Λ. Otherwise, it could happen that for an optimal Young measure there is no admissible generating sequence taking values on Λ and therefore the inequality $\tilde{m} \leq m$ would be strict. That is to say, there is a gap between the values of the two infima. From the point of view of applications that is not really important because it just means that small errors in the designs would improve the cost, as is extensively discussed in [16]. In our case the authors have not been able to prove equality (8). Concretely, the difficulty is the following: given a Young measure with support contained on Δ and satisfying the integral constraint, we are able to find a generating sequence for the Young measure taking values on Δ, but it is not clear how to modify a generating sequence in order to make sure that such a constraint is verified.

The following result is an improvement of the subrelaxation result in the sense pointed out above.

THEOREM 3. *For any family of measures $\nu = \{\nu^x\}_{x\in\Omega}$ belonging to $\mathcal{A}$ and such that*

$$\operatorname{supp}(\nu^x) \subset \Lambda, \quad \text{a.e. } x \in \Omega,$$

there exists a sequence of gradients $\{\nabla U_j\}$ generating ν and verifying that, for any j,

(i) $U_j \in H^1(\Omega;\mathbb{R}^2)$, $\quad U_j^{(2)} = v_0$,

(ii) $\{|\nabla U_j|^2\}$ *is equi-integrable,*

(iii) $\nabla U_j(x) \in \Lambda$, $\quad$ *a.e.* $x \in \Omega$.

Proof. Let $\nu = \{\nu^x\}_{x\in\Omega}$, satisfying the hypotheses of the theorem, and let $\{\nabla \bar{U}_j\}$ be a sequence of gradients of functions in $H^1(\Omega;\mathbb{R}^2)$ generating ν such that $\{|\nabla \bar{U}_j|^2\}$ is equi-integrable and

$$\bar{U}_j^{(2)} = v_0 \quad \text{on } \partial\Omega.$$

Let us consider the function

$$\varphi(A) = \min\{|\alpha A^{(1)} + TA^{(2)}|^2, |\beta A^{(1)} + TA^{(2)}|^2\}.$$

It is obvious that the zero set of $\varphi(\cdot)$ is Λ and consequently

$$\int_{\mathbb{M}^{2\times 2}} \varphi(F)\, d\nu^x(F) = 0, \quad \text{a.e. } x \in \Omega.$$

Due to the growth conditions verified by φ and the equi-integrability of the sequence, it is true that

$$\lim_{j\to+\infty} \int_\Omega \varphi\left(\nabla \bar{U}_j(x)\right)\, dx = 0.$$

Moreover,

$$\varphi\left(\nabla \bar{U}_j(x)\right) = |\sigma_j(x)\nabla \bar{U}_j^{(1)}(x) + T\nabla \bar{U}_j^{(2)}(x)|^2,$$

for some $\sigma_j(x)$ taking values on $\{\alpha, \beta\}$. Hence, the above limit reads as

$$\lim_{j\to\infty} \int_\Omega |\sigma_j(x)\nabla \bar{U}_j^{(1)}(x) + T\nabla \bar{U}_j^{(2)}(x)|^2 dx = 0. \tag{9}$$

Solving the Neumann boundary values problem

$$\begin{cases} -\operatorname{div}(\sigma_j(x)\nabla u(x)) = 0 & \text{in } \Omega, \\ \sigma_j \nabla u \cdot n = f & \text{on } \partial\Omega, \end{cases}$$

and denoting by $U_j^{(1)}$ its solution (unique up to an additive constant) and $U_j^{(2)}$ the corresponding stream function, it is clear that this new sequence verifies (i) and (iii). Finally, if we prove that

$$\nabla \bar{U}_j - \nabla U_j \to 0, \quad \text{strong in } L^2, \tag{10}$$

the sequence $\{\nabla U_j\}$ generates ν and will verify (ii).

Let us see (10). By ellipticity,

$$\begin{aligned} \alpha \int_\Omega |\nabla U_j^{(1)}(x) - \nabla \bar{U}_j^{(1)}(x)|^2 \, dx \\ \leq \int_\Omega \langle \sigma_j(x)(\nabla U_j^{(1)}(x) - \nabla \bar{U}_j^{(1)}(x)), \nabla U_j^{(1)}(x) - \nabla \bar{U}_j^{(1)}(x)\rangle \, dx \end{aligned}$$

adding and subtracting $T\nabla U_j^{(2)}(x)$ and $T\nabla \bar{U}_j^{(2)}(x)$ in the first factor of the scalar product,

$$\begin{aligned} = \int_\Omega \langle -(\sigma_j(x)\nabla \bar{U}_j^{(1)}(x) + T\nabla \bar{U}_j^{(2)}(x)), \nabla U_j^{(1)}(x) - \nabla \bar{U}_j^{(1)}(x)\rangle \, dx \\ + \int_\Omega \langle \sigma_j(x)\nabla U_j^{(1)}(x) + T\nabla U_j^{(2)}(x), \nabla U_j^{(1)}(x) - \nabla \bar{U}_j^{(1)}(x)\rangle \, dx \\ + \int_\Omega \langle T\nabla \bar{U}_j^{(2)}(x) - T\nabla U_j^{(2)}(x), \nabla U_j^{(1)}(x) - \nabla \bar{U}_j^{(1)}(x)\rangle \, dx. \end{aligned}$$

The second term vanishes because of $\sigma_j(x)\nabla U_j^{(1)}(x) + T\nabla U_j^{(2)}(x) = 0$ a.e. $x \in \Omega$. The third term is equal, taking into account that the transpose matrix of T is $-T$, so this integral results in

$$\int_\Omega \langle \nabla \bar{U}_j^{(2)}(x) - \nabla U_j^{(2)}(x), T\nabla \bar{U}_j^{(1)}(x) - T\nabla U_j^{(1)}(x)\rangle \, dx$$

and, integrating by parts, it is equal to

$$\begin{aligned} -\int_\Omega \operatorname{div}(T\nabla \bar{U}_j^{(1)}(x) - T\nabla U_j^{(1)}(x))(\bar{U}_j^{(2)}(x) - U_j^{(2)}(x)) \, dx \\ + \int_{\partial\Omega} (\bar{U}_j^{(2)}(x) - U_j^{(2)}(x))((T\nabla \bar{U}_j^{(1)}(x) - T\nabla U_j^{(1)}(x)) \cdot n) \, dS, \end{aligned}$$

but the function $T\nabla\bar{U}_j^{(1)}(x) - T\nabla U_j^{(1)}(x)$ is obviously divergence-free, and the functions $U^{(2)}$ and $\bar{U}^{(2)}$ satisfy the same Dirichlet boundary condition. Therefore the third term also vanishes. Then applying Hölder's inequality,

$$\alpha \int_\Omega |\nabla U_j^{(1)}(x) - \nabla \bar{U}_j^{(1)}(x)|^2\,dx \le \lim_{j\to\infty} \int_\Omega |\sigma_j(x)\nabla \bar{U}_j^{(1)}(x) + T\nabla \bar{U}_j^{(2)}(x)|^2\,dx$$

and

$$\int_\Omega |\nabla U_j^{(1)}(x) - \nabla \bar{U}_j^{(1)}(x)|^2\,dx \to 0$$

by (9). For the second components a similar argument works. □

3. Proof of Theorem 1. This section is devoted to the computation of the constrained envelope defined by

$$W^\sharp(A,\rho) = \inf\left\{ \int_{\mathbb{M}} W(F)\,d\nu(F) : \nu \in \mathcal{A}(A,\rho)\right\},$$

where

$$\mathcal{A}(A,\rho) = \left\{ \nu \text{ homog. } H^1 \text{ Young meas.}, \int_{\mathbb{M}} F\,d\nu(F) = A,\ \int_{\mathbb{M}} V(F)\,d\nu(F) = \rho\right\}.$$

The proof follows along the lines of the computations in [18]. For the sake of clarity, we divide the proof into various steps.

Step 1. Let us consider ν a homogeneous H^1 Young measure with barycenter A. To avoid singular cases we first assume $A \notin \Lambda$.

By definition of W and V, we can restrict our attention to all admissible measures ν with support in Λ. That is,

$$\nu = (1-t)\nu_\alpha + t\nu_\beta, \quad t\in(0,1), \quad \operatorname{supp}(\nu_\alpha)\subset\Lambda_\alpha, \quad \operatorname{supp}(\nu_\beta)\subset\Lambda_\beta.$$

This decomposition would not be well-defined when the null matrix belongs to $\operatorname{supp}(\nu)$. However this situation cannot happen, as was proved in [3, Theorem 1.3]. There, it was shown that if null matrix belongs to $\operatorname{supp}(\nu)$, then $\nu = \delta_0$, and consequently it does not have barycenter $A \neq 0$.[2]

Let us start studying some properties of first and second moments of such admissible measures. Considering the respective first moments of ν_α and ν_β,

$$A_\alpha = \int_{\Lambda_\alpha} F\,d\nu_\alpha(F), \quad A_\beta = \int_{\Lambda_\beta} F\,d\nu_\beta(F).$$

It is clear that $A = (1-t)A_\alpha + tA_\beta$, with $A_\alpha \in \Lambda_\alpha$ and $A_\beta \in \Lambda_\beta$. Then, using the definition of Λ_δ, we can write

$$A_\alpha = \begin{pmatrix} z \\ \alpha T z\end{pmatrix}, \quad A_\beta = \begin{pmatrix} w \\ \beta T w\end{pmatrix}, \tag{11}$$

and therefore, it is an easy computation to obtain

$$z = \frac{1}{(1-t)(\beta-\alpha)}(\beta A^{(1)} + TA^{(2)}), \quad w = \frac{-1}{t(\beta-\alpha)}(\alpha A^{(1)} + TA^{(2)}). \tag{12}$$

[2] In the same way, gradients of admissible functions cannot take zero value.

Now, let us define the second moments

$$x_\alpha = \int_{\Lambda_\alpha} |F^{(1)}|^2 \, d\nu_\alpha(F), \quad x_\beta = \int_{\Lambda_\beta} |F^{(1)}|^2 \, d\nu_\beta(F).$$

From Jensen's inequality follows

$$\left.\begin{aligned} x_\alpha = \int_{\Lambda_\alpha} |F^{(1)}|^2 \, d\nu_\alpha(F) \geq \left| \int_{\Lambda_\alpha} F^{(1)} \, d\nu_\alpha(F) \right|^2 = |A_\alpha^{(1)}|^2 = |z|^2, \\ \text{and similarly} \quad x_\beta \geq |w|^2. \end{aligned}\right\} \tag{13}$$

On the other hand, using the weak continuity of the determinant and the fact that ν can be generated by a sequence satisfying the hypotheses of Theorem 3, it holds that

$$\det A = \int_{\mathbb{M}} \det F \, d\nu(F) = (1-t) \int_{\Lambda_\alpha} \det F \, d\nu_\alpha(F) + t \int_{\Lambda_\beta} \det F \, d\nu_\beta(F). \tag{14}$$

And now, taking into account that if $F \in \Lambda_\alpha$, then $\det F = \alpha |F^{(1)}|^2$, and $F \in \Lambda_\beta$ implies $\det F = \beta |F^{(1)}|^2$, it is obtained that

$$\det A = (1-t)\alpha \int_{\Lambda_\alpha} |F^{(1)}|^2 \, d\nu_\alpha(F) + t\beta \int_{\Lambda_\beta} |F^{(1)}|^2 \, d\nu_\beta(F).$$

So (14) reads as

$$\det A = (1-t)\alpha x_\alpha + t\beta x_\beta. \tag{15}$$

We now consider the integral constraint. By definition of V we have

$$\begin{aligned} \rho &= \int_{\mathbb{M}} V(F) \, d\nu(F) \\ &= (1-t) \int_{\Lambda_\alpha} \frac{1}{\alpha} \left| F^{(1)} \right|^2 \, d\nu_\alpha(F) + t \int_{\Lambda_\beta} \frac{1}{\beta} \left| F^{(1)} \right|^2 \, d\nu_\beta(F) \\ &= \frac{(1-t)}{\alpha} x_\alpha + \frac{t}{\beta} x_\beta. \end{aligned} \tag{16}$$

Therefore, from (15) and (16), the second moments of all admissible measures $\nu \in \mathcal{A}(A, \rho)$ such that $\nu = (1-t)\nu_\alpha + t\nu_\beta$, $t \in (0,1)$, have to verify

$$x_\alpha = \frac{\alpha(\det A - \beta^2 \rho)}{(1-t)(\alpha^2 - \beta^2)}, \qquad x_\beta = \frac{\beta(\det A - \alpha^2 \rho)}{t(\beta^2 - \alpha^2)}. \tag{17}$$

Step 2. Once we have explicit expressions of x_α and x_β, (13) reads as

$$\begin{aligned} \frac{\alpha(\det A - \beta^2 \rho)}{(1-t)(\alpha^2 - \beta^2)} &\geq \frac{1}{(1-t)^2(\beta - \alpha)^2} |\beta A^{(1)} + T A^{(2)}|^2, \\ \frac{\beta(\det A - \alpha^2 \rho)}{t(\beta^2 - \alpha^2)} &\geq \frac{1}{t^2(\beta - \alpha)^2} |\alpha A^{(1)} + T A^{(2)}|^2. \end{aligned} \tag{18}$$

First, note that $\det A - \beta^2\rho \leq 0$ and $\det A - \alpha^2\rho \geq 0$ (otherwise, first and second inequalities have no sense, respectively) and consequently

$$\alpha^2 \leq \frac{\det A}{\rho} \leq \beta^2. \tag{19}$$

On the other hand, if $\det A = \beta^2\rho$ or $\det A = \alpha^2\rho$, then $x_\alpha = 0$ or $x_\beta = 0$, and therefore $A \in \Lambda_\beta$ or $A \in \Lambda_\alpha$, respectively, but we have previously assumed that $A \notin \Lambda$. Then, for $A \notin \Lambda$ we can assume strict inequality in (19).

Therefore, making some easy computations, the first inequality is written as

$$t \leq 1 + \left(\frac{\beta+\alpha}{\beta-\alpha}\right) \frac{\left|\beta A^{(1)} + TA^{(2)}\right|^2}{\alpha(\det A - \beta^2\rho)},$$

and the second one is

$$t \geq \left(\frac{\beta+\alpha}{\beta-\alpha}\right) \frac{\left|\alpha A^{(1)} + TA^{(2)}\right|^2}{\beta(\det A - \alpha^2\rho)},$$

so that

$$\left(\frac{\beta+\alpha}{\beta-\alpha}\right) \frac{\left|\alpha A^{(1)} + TA^{(2)}\right|^2}{\beta(\det A - \alpha^2\rho)} \leq t \leq 1 + \left(\frac{\beta+\alpha}{\beta-\alpha}\right) \frac{\left|\beta A^{(1)} + TA^{(2)}\right|^2}{\alpha(\det A - \beta^2\rho)}, \tag{20}$$

which, in this particular case, implies

$$\left(\frac{\beta+\alpha}{\beta-\alpha}\right) \frac{\left|\alpha A^{(1)} + TA^{(2)}\right|^2}{\beta(\det A - \alpha^2\rho)} \leq 1 + \left(\frac{\beta+\alpha}{\beta-\alpha}\right) \frac{\left|\beta A^{(1)} + TA^{(2)}\right|^2}{\alpha(\det A - \beta^2\rho)}. \tag{21}$$

As a consequence, for all admissible $\nu = (1-t)\nu_\alpha + t\nu_\beta \in \mathcal{A}(A,\rho)$, (A,ρ) has to verify (19) and (21), which are the inequalities given in the statement of Theorem 1.

Step 3. Obtaining the value of $W^\sharp$ is a direct consequence of the definition of W and (20). If (A,ρ) satisfies (19) and (21),

$$\begin{aligned} W^\sharp(A,\rho) &= \inf\left\{\int_{\mathbb{M}} W(F)\,d\nu(F) : \nu \in \mathcal{A}(A,\rho)\right\} \\ &= \inf\left\{(1-t)\int_{\Lambda_\alpha} W(F)\,d\nu_\alpha(F) + t\int_{\Lambda_\beta} W(F)\,d\nu_\beta(F) : \nu \in \mathcal{A}(A,\rho)\right\} \\ &= \inf\{t : \nu \in \mathcal{A}(A,\rho)\} = \left(\frac{\beta+\alpha}{\beta-\alpha}\right) \frac{\left|\alpha A^{(1)} + TA^{(2)}\right|^2}{\beta(\det A - \alpha^2\rho)} \end{aligned}$$

for $A \notin \Lambda$.

Step 4. For the construction of the laminates, we will follow the idea presented in [18, 19]. First, we observe that for

$$t_0 = \left(\frac{\beta+\alpha}{\beta-\alpha}\right) \frac{\left|\alpha A^{(1)} + TA^{(2)}\right|^2}{\beta(\det A - \alpha^2\rho)}, \tag{22}$$

substituting in (12) and (17), we see that

$$x_\beta = \frac{\beta^2(\det A - \alpha^2\rho)^2}{|\alpha A^{(1)} + TA^{(2)}|^2(\beta+\alpha)^2} = |w|^2,$$

so that

$$\int_{\Lambda_\beta} |F^{(1)}|^2 \, d\nu_\beta(F) = |w|^2 = |A_\beta^{(1)}|^2,$$

and due to the strict convexity of the integrand $\nu_\beta = \delta_{A_\beta}$.

On the other hand, if we determine the rank-one directions going through A with extreme points on Λ_α and Λ_β, we must look for $A^\alpha \in \Lambda_\alpha$, $A^\beta \in \Lambda_\beta$, and $r \in [0,1]$ such that

$$A = (1-r)A^\alpha + rA^\beta \quad \text{and} \quad \det(A^\alpha - A^\beta) = 0. \tag{23}$$

After some manipulations, this condition implies that A and r have to satisfy

$$\begin{aligned} \frac{\alpha}{(1-r)^2(\beta-\alpha)^2}\left|\beta A^{(1)} + TA^{(2)}\right|^2 + \frac{\beta}{r^2(\beta-\alpha)^2}\left|\alpha A^{(1)} + TA^{(2)}\right|^2 \\ + \frac{\alpha+\beta}{r(1-r)(\beta-\alpha)^2}(\alpha A^{(1)} + TA^{(2)}) \cdot (\beta A^{(1)} + TA^{(2)}) = 0. \end{aligned} \tag{24}$$

Therefore, there will be such rank-one directions if A is such that the above expression has solutions for $r \in [0,1]$. We assert that if $(A,\rho) \in \mathcal{B}$, then there exists $r \in [0,1]$ satisfying (24).

Let us prove our claim. It is clear that condition $(A,\rho) \in \mathcal{B}$ implies (18). That is to say, $x_\alpha \geq |z|^2$ and $x_\beta \geq |w|^2$. Then, from (15) we deduce that

$$\det A \geq (1-t)\alpha|z|^2 + t\beta|w|^2,$$

which can be written as

$$\begin{aligned} t^2(\beta-\alpha)^2 \det A + t(\alpha|\beta A^{(1)} - TA^{(2)}|^2 - \beta|\alpha A^{(1)} + TA^{(2)}|^2 - (\beta-\alpha)^2 \det A) \\ +\beta|\alpha A^{(1)} + TA^{(2)}|^2 \leq 0. \end{aligned}$$

Now, if $P_A(t)$ stands for the second degree polynomial on the left-hand side, then $(A,\rho) \in \mathcal{B}$ implies $P_A(t)$ has its roots in $[0,1]$ (note that P_A is an upward parabola where $P_A(0)$ and $P_A(1)$ are positive and $t \in (0,1)$). Making some easy computations, it turns out that (24) can be written as $P_A(r) = 0$. That is, $(A,\rho) \in \mathcal{B}$ implies that there exist as many rank-one directions going through A with extreme points in Λ_α and Λ_β as roots in equation $P_A(r) = 0$.

Namely, if (21) happens with equality, then it is easy to realize that $x_\alpha = |z|^2$ and $x_\beta = |w|^2$. Therefore the laminate has to be $\nu = (1-t_0)\delta_{A_\alpha} + t_0\delta_{A_\beta}$ for t_0 given in (22). Note that A_α and A_β are only dependent on t_0 and A, so the laminate is unique. That is, $P_A(r)$ has only one solution.

On the contrary, if (21) is a strict inequality, then there are two solutions of $P_A(r) = 0$, denoted by r_i, $i = 1,2$, and therefore two rank-one directions going through A with extreme points in Λ_α and Λ_β. If we denote by $A_{\alpha,i}$ and $A_{\beta,i}$, $i = 1,2$, the extreme points in Λ_α and Λ_β, respectively, we can construct second order laminates in the following way.

Let us consider $\bar{A}_{\alpha,i} = A_\beta + \zeta_i(A_{\alpha,i} - A_{\beta,i})$ such that $\bar{A}_{\alpha,i} \in \Lambda_\alpha$. We have to adjust the parameter ζ_i conveniently. Making some easy computations,

$$A_\beta + \zeta_i(A_{\alpha,i} - A_{\beta,i}) = \begin{pmatrix} w + \zeta(z_i - w_i) \\ \alpha T\left(\frac{\beta}{\alpha}w + \frac{\zeta_i}{\alpha}(\alpha z_i - \beta w_i)\right) \end{pmatrix},$$

where z_i and w_i are the corresponding vectors for $A_{\alpha,i}$ and $A_{\beta,i}$ in the same way as (12).

This matrix will be in Λ_α if and only if

$$w + \zeta_i(z_i - w_i) = \left(\frac{\beta}{\alpha} w + \frac{\zeta_i}{\alpha}(\alpha z_i - \beta w_i)\right).$$

This implies $w - \zeta_i w_i = 0$, and thus

$$\zeta_i = \frac{r_i}{t_0}.$$

Then,

$$\bar{A}_{\alpha,i} = \begin{pmatrix} \bar{z}_i \\ \alpha T \bar{z}_i \end{pmatrix} \text{ for } \bar{z}_i = \frac{r_i}{t_0(1-r_i)(\beta-\alpha)}(\beta A^{(1)} + T A^{(2)})$$

and t given in (22).

In this situation, the laminates

$$\nu_{i,j} = (1-\sigma_{i,j})\delta_{A_{\alpha,j}} + \sigma_{i,j}(\rho_{i,j}\delta_{A_\beta} + (1-\rho_{i,j})\delta_{\bar{A}_{\alpha,i}}), \quad i,j = 1,2,\ i \neq j,$$

where

$$\sigma_{i,j} = \frac{t_0(r_j - r_i)}{t_0(1-r_i) - r_i(1-r_j)}, \qquad \rho_{i,j} = \frac{t_0(1-r_i) - r_i(1-r_j)}{r_j - r_i},$$

where t_0 is given in (22), are optimal microstructures,[3] and obviously

$$\int_{\mathbb{M}} W(F)\, d\nu_{i,j}(F) = \left(\frac{\beta+\alpha}{\beta-\alpha}\right) \frac{\left|\alpha A^{(1)} + T A^{(2)}\right|^2}{\beta(\det A - \alpha^2\rho)}, \quad i,j = 1,2,\ \ i \neq j.$$

Step 5. Finally, let us see what happens if $A \in \Lambda$. For instance, we assume $A \in \Lambda_\alpha$. Then $A_\alpha = A$, $A_\beta = 0$ and (15), (16) imply $\det A = \alpha^2\rho$, and as a consequence $t_0 = 0$. That is, $W^\sharp(A,\rho) = 0$. In the same way, if $A \in \Lambda_\beta$, $\det A = \beta^2\rho$ and $W^\sharp(A,\rho) = 1$. This finishes the proof.

Acknowledgements. The authors are grateful to Daniel Faraco for suggesting a more elegant proof of Theorem 2. The review work and suggestions of two anonymous referees is also greatly appreciated.

A CONVERSE LYAPUNOV THEOREM FOR LINEAR PARAMETER-VARYING AND LINEAR SWITCHING SYSTEMS*

FABIAN WIRTH†

Abstract. We study families of linear time-varying systems, where time variations have to satisfy restrictions on the dwell time, that is, on the minimum distance between discontinuities, as well as on the derivative in between discontinuities. Such classes of systems may be formulated as linear flows on vector bundles. The main objective of this paper is to construct parameter-dependent Lyapunov functions, which characterize the exponential growth rate. This is possible in the generic irreducible case. As an application the Gelfand formula is generalized to the class of systems studied here. In other words, the maximal exponential growth rate may be approximated by only considering the periodic systems in the family of time-varying systems. A perspective on the question of continuous dependence of the exponential growth rate on the data is given.

Key words. converse Lyapunov theorem, linear parameter-varying systems, linear switching systems, linear flows on vector bundles, Gelfand formula, periodic systems

1. Introduction.

In this paper we consider linear time-varying systems of the form

$$\dot{x}(t) = A(t)x(t), \tag{1.1}$$

where $A : \mathbb{R} \to \mathcal{M}$ is a measurable map, and $\mathcal{M}$ is a compact set of real or complex matrices of a given dimension. We are interested in the exponential growth rate of not one individual system but a set of systems described by a subset $\mathcal{A} \subset L^\infty(\mathbb{R}, \mathcal{M})$. The stability and spectral properties of such systems have been actively investigated over the past two decades.

In this paper we present a framework covering many of the systems studied in the areas of linear parameter-varying (LPV) systems with constraints on the derivative and of linear switching systems with dwell times. We introduce a certain class of linear time-varying systems that allows for (i) bounds on the minimal time between discontinuities and (ii) bounds on the derivative of parameter variations between discontinuities.

The main contribution of the present paper lies in the construction of parameterized Lyapunov functions that characterize the exponential growth rate of the system under consideration. The construction is possible in the generic irreducible case, in which the system leaves no nontrivial subspace invariant. For each parameter the corresponding Lyapunov function is a norm. One of the features of the Lyapunov functions is that for any solution the corresponding infinitesimal decay is upper bounded by the maximal growth rate. Also the exponential growth rate can be realized instantaneously from every initial condition of the state and the parameter. Under mild

assumptions the Lyapunov functions are Lipschitz continuous in both the state and the parameter. As in [25], it would be possible to consider smooth approximations to obtain differentiable Lyapunov functions, which still yield a decay arbitrarily close to the growth rate. This problem is not pursued here, as the method is well described in the literature; see [9, 25, 32].

Using the existence of Lyapunov functions, we give a fairly simple proof of a version of the Gelfand formula. By this result the exponential growth rate can be approximated to arbitrary precision using periodic parameter variations. This result would appear to be new for LPV systems with bounds on the derivative as well as for linear switching systems with dwell time.

The results obtained in this paper are generalizations of [34] on the exponential growth rate of families of time-varying systems with measurable parameter variations. The proofs are often similar, but more preparation has to be undertaken to proceed to the actual results. In [34] it is also shown how the same ideas yield results on the (Lipschitz) continuity of the growth rate as a function of the data. We briefly comment on this problem here; see [36] for further details.

It is interesting to note that the subject of exponential growth of certain sets of linear time-varying systems has been taken up by different communities over time. We will not try to give an overview of the relevant literature, but an effort has been made to at least cite landmarks in each of the areas, and the reader is invited to look for further references in these papers. The literature related to this problem is not readily accessible because the terms *families of linear time-varying systems*, *linear differential inclusions*, *LPV systems*, *linear flows on vector bundles*, and *linear switching systems* are different names for very similar situations. All these names cover at least the case in (1.1), where we consider $\mathcal{A} = L^\infty(\mathbb{R}, \mathcal{M})$.

Probably the oldest exponent of this area is formed by the theory of linear flows on vector bundles, which has been developed in the dynamical systems community at least since the 1970s. For a recent account of the state of the art insofar as it is related to control theory, we refer to [13]. In fact, in this book it is shown that a good deal of work is necessary before system (1.1) with $\mathcal{A} = L^\infty(\mathbb{R}, \mathcal{M})$ can be justifiably interpreted as a linear flow on a vector bundle. Another good general reference in this area is [8]. The problem of exponential growth rates is treated in [18].

Papers concerned with linear differential inclusions and families of time-varying systems often treat the case when $\mathcal{A} = L^\infty(\mathbb{R}, \mathcal{M})$. In this area a detailed description of spectral concepts is available (see [11, 12, 13]) and a good Lyapunov theory has been developed [5, 26, 34]. Furthermore, it is known that the uniform exponential growth rate can be approximated arbitrarily well by periodic systems. This result is sometimes called the Gelfand formula in reminiscence of the characterization of the spectral radius of bounded linear operators as the infimum of norms of its powers; see [7, 11, 16].

The control and robustness analysis of LPV systems have been actively investigated during the last decade. In particular, parameter-dependent quadratic Lyapunov functions for such systems are frequently discussed in the literature, and many sufficient results for the existence of Lyapunov functions have been obtained in the framework of linear matrix inequalities (LMIs); see [2, 3, 4, 6, 17, 21, 30, 31]. In some papers, however, the interesting added feature is that time variations are restricted by requiring certain bounds on the derivative of the parameter variations as well; see, e.g., [2]. Also for this case sufficient conditions for the existence of Lyapunov functions are available in terms of LMIs. It is interesting to note that the parameter variations

in this case may be interpreted as a solution set to a differential inclusion so that the results in [32] can be interpreted in such a manner as to yield a converse Lyapunov theorem also in this case; see Remark 3.3(i). A preliminary version of the present paper treats exclusively the case of parameter variations without discontinuities [35].

To complete the enumeration of different concepts we have to mention the term *linear switching system*, which is to be found most often in engineering literature. For an overview and much of the related literature we refer to [15, 23, 24]. For instance, the paper [1] analyzes conditions for exponential stability and gives a complete solution to the question of which systems stability can be determined based on knowledge of the Lie algebra generated by the systems matrices. While is often assumed in this area that the set of matrices $\mathcal{M}$ is a finite set, this does not really change the overall problem; as for inclusions at least, the exponential growth rate defined by $\mathcal{M}$ and its convex hull is the same.[1]

However, also in the analysis of linear switching systems a certain twist has been added, which consists of a condition on the minimal time that has to elapse between two discontinuities of the switching signal. This minimal time is called the *dwell time*. This approach derives its motivation in part from adaptive control and has been discussed in [27, 28]. Sufficient conditions for the existence of Lyapunov functions in terms of LMIs are available; see, e.g., [20].

We proceed as follows. In section 2 we introduce the exponential growth rate under the (essential) assumption of shift-invariance. This is one of the primary interests in this paper. The precise definition of the class of systems studied in the paper is given in section 3 introducing parameter variations defined by a value set, a set of admissible derivatives, and a dwell time.

One of our initial results will be that each system in this class defines a linear flow on a vector bundle. This concept from dynamical systems theory treats the following situation: Given a compact metric space M and a vector space $\mathbb{K}^n$, we consider a continuous dynamical system

$$\Phi : \mathbb{R} \times M \times \mathbb{K}^n \to M \times \mathbb{K}^n,$$

where each time-t map $\Phi_t : M \times \mathbb{K}^n \to M \times \mathbb{K}^n$ can be represented in the form $\Phi_t = (\Phi_t^1, \Phi_t^2)$ such that $\Phi_t^1 : M \to M$ is continuous and $\Phi_t^2 : M \times \mathbb{K}^n \to \mathbb{K}^n$ is a linear map in the second component. (Here we have described only *trivial* vector bundles, which are all that is needed in this paper. More generally, the described situation is only valid in appropriate local coordinates.)

So in particular, any LPV system and linear switching system with dwell time can be interpreted as such a linear flow. While this result is mostly of interest for classification purposes, it has the advantage nonetheless that the general results on linear flows are available. In particular, the general theory on linear flows provides results on growth rates, fiberwise Lyapunov functions, bifurcation theory, and Hartman–Grobman-type results; see, e.g., [8, 13].

In section 4 a rather tedious analysis of the concatenation structure within the set of admissible parameter variations is undertaken, which turns out to be vital in the

[1] In the literature on switching systems it is often assumed that parameter variations have to be piecewise constant with an arbitrarily small, positive, lower bound on the distance between discontinuities. With respect to the problem treated in this paper, note that there is no difference in the exponential growth rate, whether one considers parameter variations or switching signals in $L^\infty(\mathbb{R}, \mathcal{M})$ or in the subset thereof consisting of piecewise continuous functions with an (arbitrarily small) lower bound on the distance between discontinuities.

subsequent construction of Lyapunov functions. In section 5 irreducibility of a system is introduced and some immediate consequences of this property are shown. The assumption of irreducibility is used in section 6 to construct parameter-dependent Lyapunov norms that characterize the exponential growth rate. We particularly discuss the case of linear switching systems with dwell time, for which an easy interpretation is available. Finally, in section 7 the Gelfand formula is proved, and we comment on the question of continuous dependence on the systems parameters in section 8. The paper concludes with some final comments in section 9.

Finally, we would like to warn the reader that our use of the term *Lyapunov function* is not quite standard. It will be used to denote functions that characterize the exponential growth rate of the system if evaluated along trajectories. Now if the system is stable, then this will give the usual decrease condition. However, if the system is not exponentially stable, then we still speak of a Lyapunov function because of the characterization of the growth rate.

2. Families of linear time-varying systems. Let $\mathbb{K} = \mathbb{R}, \mathbb{C}$ denote the real or the complex field. In this paper we study families of continuous time LPV systems in $\mathbb{K}^n$ that are given in the form of linear systems subject to (time-varying) variations of certain parameters entering the equation. The parameter space Θ is taken to be a compact subset of $\mathbb{K}^m$, and the map $A : \Theta \to \mathbb{K}^{n\times n}$ that associates a matrix to a given parameter is assumed to be continuous. Parameter variations are always taken to be elements of $L^\infty(\mathbb{R}, \Theta)$. Every such parameter variation $\theta(\cdot)$ induces a time-varying linear system of the form

$$\dot{x}(t) = A(\theta(t))x(t), \quad t \in \mathbb{R}. \tag{2.1}$$

The corresponding evolution operator is denoted by $\Phi_\theta(t, s),\ t, s \in \mathbb{R}$.

The main object of this paper is to discuss families of linear time-varying systems defined by a set of admissible parameter variations $\mathcal{U} \subset L^\infty(\mathbb{R}, \Theta)$. An important property of these sets is the following.

Definition 2.1. *A set $\mathcal{U} \subset L^\infty(\mathbb{R}, \Theta)$ is called* shift-invariant *if for all $u \in \mathcal{U}$ and all $t \in \mathbb{R}$ the function $w(\cdot) := u(t + \cdot)$, defined by $w(s) = u(t + s)$, is an element of $\mathcal{U}$.*

We now define the primary interest in this paper, which is the (uniform) exponential growth rate associated with system (2.1). Given the map $A : \Theta \to \mathbb{K}^{n\times n}$ and the set of admissible parameter variations $\mathcal{U} \subset L^\infty(\mathbb{R}, \Theta)$, define for $t \geq 0$ the sets of finite time evolution operators

$$\mathcal{S}_t(A,\mathcal{U}) := \{\, \Phi_u(t, 0) \,|\, u \in \mathcal{U}\}, \quad \mathcal{S}(A,\mathcal{U}) := \bigcup_{t\geq 0} \mathcal{S}_t(A,\mathcal{U}).$$

We now introduce for $t > 0$ finite time growth constants given by

$$\widehat{\rho}_t(A,\mathcal{U}) := \sup\left\{ \frac{1}{t} \log \|S\| \;|\; S \in \mathcal{S}_t(A,\mathcal{U}) \right\}.$$

It is easy to see that under the assumption of shift-invariance of $\mathcal{U}$, the function $t \longmapsto t\widehat{\rho}_t(A,\mathcal{U})$ is subadditive. Using a folklore result (see, e.g., [22, pp. 27–28]), this implies that the following limit exists:

$$\widehat{\rho}(A,\mathcal{U}) := \lim_{t\to\infty} \widehat{\rho}_t(A,\mathcal{U}) = \inf_{t\geq 0} \widehat{\rho}_t(A,\mathcal{U}). \tag{2.2}$$

It is well known that an alternative way to describe $\hat{\rho}$ is given by

(2.3)
$$\widehat{\rho}(A,\mathcal{U}) = \inf\{\beta \in \mathbb{R} \mid \exists\, M \geq 1 \text{ such that } \|\Phi_u(t,0)\| \leq Me^{\beta t} \text{ for all } u \in \mathcal{U}, t \geq 0\}.$$

For this reason the quantity $\hat{\rho}(A,\mathcal{U})$ is called the *uniform exponential growth rate* of the family of linear time-varying systems of the form (2.1) given by $\mathcal{U}$ and A. An alternative way to define exponential growth is to employ a trajectorywise definition. In this case we define the Lyapunov exponent corresponding to an initial condition $x_0 \in \mathbb{K}^n \setminus \{0\}$ and $u \in \mathcal{U}$ by

$$\lambda(x_0,u) := \limsup_{t\to\infty} \frac{1}{t} \log \|\Phi_u(t,0)x_0\| \tag{2.4}$$

and define the exponential growth rate as $\kappa(A,\mathcal{U}) := \sup\{\lambda(x,u) \mid 0 \neq x \in \mathbb{K}^n,\, u \in \mathcal{U}\}$.

If $\mathcal{U}$ is shift-invariant and closed in the weak-* topology induced by $L^\infty(\mathbb{R},\mathbb{K}^m)$, then $\mathcal{U}$ is metrizable (recall that Θ is compact), and by [13, Lem. 4.2.4] the shift is continuous on $\mathcal{U}$ endowed with that topology. If also the map $(t,x,u) \mapsto \Phi_u(t,0)x$ is continuous jointly in all variables (which is affirmative if $u \mapsto \Phi_u(t,0)$ is uniformly continuous on compact time intervals), then the following time-t maps define a continuous dynamical system or a flow on $\mathcal{U} \times \mathbb{K}^n$:

$$(u,x) \mapsto (u(t+\cdot), \Phi_u(t,0)x)\,,$$

and in fact define a linear flow on the vector bundle $\pi : \mathcal{U} \times \mathbb{K}^n \to \mathcal{U}$. Under this assumption it follows using Fenichel's uniformity lemma that $\kappa(A,\mathcal{U}) = \hat{\rho}(A,\mathcal{U})$; see [13, Prop. 5.4.15].

The outlined setup works if we assume that the set $\mathcal{U}$ is convex and that the function A is affine in θ; see [13, Chap. 4]. These assumptions, however, are somewhat restrictive. In the following section, it is shown that LPV systems and linear switching systems with dwell times may be formulated as linear flows on vector bundles.

As it is our aim to construct a certain class of parameter-dependent Lyapunov functions, it should be noted that a general theory of quadratic Lyapunov functions for linear flows on vector bundles exists; see [8, Chap. 3]. However, this theory works with Lyapunov functions defined individually in every fiber; in our case, individually for every $u \in \mathcal{U}$. This is too fine a point of view for the results that we want to obtain. In particular, despite some effort on the part of the author, the fine point of view has not yielded a way of proving the Gelfand formula.

One might now be tempted to take a very coarse point of view and to look for norms that are Lyapunov functions for the whole system and characterize the quantity $\hat{\rho}(A,\mathcal{U})$, as for the case of linear differential inclusions [34]. However, the following lemma shows that this is not a very fruitful enterprise.

LEMMA 2.2. *Let $\mathcal{U} \subset L^\infty(\mathbb{R},\Theta)$ be shift-invariant and assume system* (2.1) *defines a linear flow on the vector bundle $\pi : \mathcal{U} \times \mathbb{K}^n \to \mathcal{U}$. Assume that the constant functions $u \equiv \theta, \theta \in \Theta$ are contained in $\mathcal{U}$. If there is a norm v on $\mathbb{K}^n$, such that for all $x \in \mathbb{K}^n$, $u \in \mathcal{U}$ and the corresponding evolution operator $\Phi_u(t,s)$ it holds that*

$$v(\Phi_u(t,0)x) \leq e^{\hat{\rho}(A,\mathcal{U})t}\, v(x) \quad \forall t \geq 0, \tag{2.5}$$

then $\hat{\rho}(A,\mathcal{U}) = \rho := \max\{\lambda(x,B) \mid 0 \neq x \in \mathbb{K}^n,\, B : \mathbb{R} \to A(\Theta)$ measurable$\}$, where $\lambda(x,B)$ denotes the Lyapunov exponent corresponding to the initial condition x and B defined as in (2.4).

Proof. Clearly, we only have to show that $\hat{\rho}(A,\mathcal{U}) \geq \rho$. Let v^* be the dual norm to v; see [19]. The assumption (2.5) implies that for all $A \in A(\Theta)$, all $x \in \mathbb{K}^n$, and all $l \in \mathbb{K}^n$ with $\langle l, x\rangle = v(x) = v^*(l) = 1$ we have $\langle l, Ax\rangle \leq \hat{\rho}(A,\mathcal{U})$ by [10, Thm. 4.6.3]. This, however, implies that $\rho \leq \hat{\rho}(A,\mathcal{U})$ by [5, Thm. 5]. □

By the previous lemma, a norm satisfying (2.5) can only exist for (2.1) if the parameter-varying system realizes the exponential growth, which is obtained by allowing all measurable functions with values in $A(\Theta)$; in other words, by studying (2.1) with $\mathcal{U} = L^\infty(\mathbb{R}, \Theta)$. For general sets of parameter variations this situation is rarely encountered. For this reason we use a different approach that introduces a family of norms with an extremal property. The idea of using parameter-dependent Lyapunov functions, proposed by several authors (see, e.g., [2, 20, 21]), can be made exact in this way. That is, a family of parameter-dependent Lyapunov norms may be constructed such that the exponential growth rate of system (2.1) is the incremental growth rate with respect to this family. Note that we cannot restrict our attention to quadratic norms to perform such a construction.

Remark 2.3. The main technical problem in this paper is that $\mathcal{S}(A,\mathcal{U})$ does not naturally carry the structure of a semigroup. As an example consider the case when $\mathcal{U}$ consists of all globally Lipschitz continuous functions with values in Θ and fixed Lipschitz constant L. For $u_1, u_2 \in \mathcal{U}$ the concatenation of $u_{1|[0,t]}$ and $u_{2|(t,\infty)}$ is an admissible parameter variation if and only if $u_1(t) = u_2(t)$. This complicates matters compared to the case of linear inclusions of the form

$$\dot{x} \in \{Ax \mid A \in A(\Theta)\},$$

as studied in [5, 11, 15, 16, 34] and references therein.

3. Parameter variations. We denote the space of nonempty, compact subsets of $\mathbb{K}^m$ by $\mathcal{K}(\mathbb{K}^m)$ and the subset of nonempty, convex, compact subsets of $\mathbb{K}^m$ by $\mathrm{Co}(\mathbb{K}^m)$. Both these spaces are complete metric spaces if endowed with the Hausdorff metric defined by

$$d_H(X,Y) := \max\left\{\max_{x\in X} \operatorname{dist}(x,Y), \quad \max_{y\in Y} \operatorname{dist}(y,X)\right\}.$$

All ensuing topological statements on $\mathcal{K}(\mathbb{K}^m), \mathrm{Co}(\mathbb{K}^m)$ should be understood with respect to this metric. The convex hull of a set X is denoted by $\operatorname{conv} X$. We denote by $X - y$ the set $\{x - y \mid x \in X\}$, as usual.

In the remainder of the paper the admissible parameter variations are described by the following data: a space of parameters $\Theta \in \mathcal{K}(\mathbb{K}^m)$ given as a finite union of pairwise disjoint compact convex sets Ω_j, $j = 1, \ldots, l$; a space describing the rate of parameter variation $\Theta_1 \in \mathrm{Co}(\mathbb{K}^m)$; a *dwell time* $h \in (0, \infty]$ that describes the minimal time between discontinuities; and a continuous map $A \in C(\mathbb{K}^m, \mathbb{K}^{n\times n})$. A system is therefore now a quadruple $\Sigma = (h, \Theta, \Theta_1, A) \in (0,\infty] \times \mathcal{K}(\mathbb{K}^m) \times \mathrm{Co}(\mathbb{K}^m) \times C(\mathbb{K}^m, \mathbb{K}^{n\times n})$. We will always assume that the following assumptions are satisfied:

(A1) $h \in (0, \infty]$;
(A2) $\Theta \subset \mathbb{K}^m$ is a finite, disjoint union of sets $\Omega_j \in \mathrm{Co}(\mathbb{K}^m)$, $j \in \{1, \ldots, l\}$. If $h = \infty$, then $l = 1$, i.e., Θ is compact and convex;
(A3) $\Theta_1 \in \mathrm{Co}(\mathbb{K}^m)$;
(A4) $0 \in \Theta_1$;
(A5) $A : \Theta \to \mathbb{K}^{n\times n}$ is a continuous map.

In some cases we will need an additional assumption that allows for additional freedom in the construction of parameter variations. Recall that the relative interior of a

convex set $\mathcal{M}$, denoted by $\operatorname{ri}\mathcal{M}$, is the interior of $\mathcal{M}$ in the relative topology of the affine space generated by $\mathcal{M}$. Or in other words, the interior of $\mathcal{M}$ relative to the smallest affine space containing $\mathcal{M}$. With this we formulate the following condition.

(A6) $0 \in \operatorname{ri}\Theta_1$ and $\operatorname{span}\Theta_1 \supset \operatorname{span}(\Omega_j - \eta_j)$, $j = 1, \dots, l$, for some $\eta_j \in \Omega_j$.

In order to denote the discontinuities of parameter variations, which for the purposes of this paper are discrete sets, we consider (bounded or unbounded) index sets $\mathcal{I} \subset \mathbb{Z}$. In the following it will always be tacitly assumed that these index sets are given as the intersection of a real interval with $\mathbb{Z}$, i.e., of the form $\mathcal{I} := [a, b] \cap \mathbb{Z}$, where $a, b \in \mathbb{R} \cup \{\pm\infty\}$.

DEFINITION 3.1. *Consider a system $\Sigma = (h, \Theta, \Theta_1, A)$ satisfying* (A1)–(A5). *If $h \in (0, \infty)$, a parameter variation $\theta : \mathbb{R} \to \Theta$ is called* admissible (*with respect to Σ*) *if there is an index set $\mathcal{I}_\theta \subset \mathbb{Z}$ and times $t_k, k \in \mathcal{I}_\theta$, such that*

(i) *$h \le t_{k+1} - t_k$ for $k \in \mathcal{I}_\theta, k < \sup \mathcal{I}_\theta$,*

(ii) *for $k \in \mathcal{I}_\theta, k < \sup \mathcal{I}_\theta$ the function θ is absolutely continuous on the interval $[t_k, t_{k+1})$ and satisfies*

$$\dot\theta(t) \in \Theta_1 \quad \text{a.e.} \tag{3.1}$$

(*This condition also applies to $(-\infty, \inf \mathcal{I}_\theta)$, resp., $(\sup \mathcal{I}_\theta, \infty)$, if $\inf \mathcal{I}_\theta$, resp., $\sup \mathcal{I}_\theta$, is finite.*)

If $h = \infty$, the admissible parameter variations are given as the set of absolutely continuous functions $\theta : \mathbb{R} \to \Theta$ satisfying (3.1) *a.e. on $\mathbb{R}$.*

The set of admissible parameter variations is denoted by $\mathcal{U}$ or $\mathcal{U}(h, \Theta, \Theta_1, A)$ if dependence on the data needs to be emphasized. By convention we let $t_0 > 0$, and $t_0(u)$ denotes the smallest positive discontinuity of a parameter variation u. If there is no such discontinuity, then we set $t_0(u) := \infty$.

Remark 3.2. (i) Note that the set $\mathcal{U}$ defined above is clearly shift-invariant, but not convex in general, because convex combinations of the admissible parameter variations would in general have too many switches. Thus [13, Chap. 4] is not directly applicable to our situation. We will be able to show the necessary properties of $\mathcal{U}$ by a different strategy, which also allows us to dispense with the assumption that A is affine.

(ii) In the case $h = \infty$, it is reasonable to assume that Θ itself is convex, as parameter variations cannot leave the sets Ω_j. So with the notation of (A2) we have $\hat\rho(\infty, \Theta, \Theta_1, A) = \max_j \hat\rho(\infty, \Omega_j, \Theta_1, A)$. Hence it is sufficient to assume Θ is convex.

(iii) Assumption (A4) guarantees that the constant trajectories $u \equiv \theta$, $\theta \in \Theta$ are admissible parameter variations. This assumption is not absolutely essential but simplifies several of the ensuing statements. It would, of course, be interesting to consider systems in which only the interplay of the continuous and discontinuous behavior allows for trajectories defined on $\mathbb{R}$. An example of this kind is given by $\Theta = [0, 2], \Theta_1 = [1, 2],\ h = 1$.

(iv) If Assumption (A6) is satisfied, then for a fixed convex component Ω_j of Θ the set of derivatives Θ_1 contains a neighborhood of 0 in the linear subspace $\operatorname{span}(\Omega_j - \eta_j)$ for $\eta_j \in \Omega_j$. Thus there is a constant $c > 0$ such that for any pair $\theta, \eta \in \Omega_j$ we have $c(\theta - \eta) \in \Theta_1$. Hence for all $t > \|\theta - \eta\|/c$ there is a $u \in \mathcal{U}$ with $u(0) = \theta, u(t) = \eta$. In particular, as the Ω_j are compact, there is a constant $\bar c > 0$ such that any pair $\theta, \eta \in \Omega_j$ may be connected by an admissible parameter variation in a time equal to $\bar c$ for all $j = 1, \dots, l$.

(v) We explicitly exclude the case in which the parameter variations $\theta(\cdot)$ are arbitrary (measurable) functions taking values in Θ. This corresponds to taking

$h = 0$ in a way that can be made precise. For this case the results analogous to those obtained in this paper are already available in the literature; see [5, 13, 16, 34, 37].

Remark 3.3. (i) In the literature on LPV systems it is often assumed that the parameter variations $\theta(\cdot)$ are continuously differentiable and that the derivative satisfies certain constraints. However, it can be shown that the exponential growth rates defined by the sets

$$\{\theta : \mathbb{R} \to \Theta \mid \theta \text{ is Lipschitz continuous and } \dot\theta(t) \in \Theta_1 \quad \text{a.e.}\}$$

and

$$\{\theta : \mathbb{R} \to \Theta \mid \theta \text{ is continuously differentiable and } \dot\theta(t) \in \Theta_1 \text{ for all } t \in \mathbb{R}\}$$

are the same [37] so that our setup from the point of view of stability theory encompasses this standard case. We find the set of Lipschitz continuous parameter variations easier to handle.

In fact, LPV systems are a special case, which may be subsumed under the following more general framework; see [37]. Consider systems of the form

$$\begin{aligned} \dot x(t) &= A(\theta(t))x(t), \quad t \in \mathbb{R}, \\ \dot\theta(t) &\in \mathcal{F}(\theta(t)) \quad \text{a.e. } t \in \mathbb{R}, \end{aligned} \tag{3.2}$$

where $A : \Theta \to \mathbb{K}^{n\times n}$ is a given continuous map, $\Theta \subset \mathbb{K}^m$ is a compact, pathwise connected set, and $\mathcal{F} : \Theta \to \mathbb{K}^m$ is an upper semicontinuous set-valued map with compact values that defines a complete dynamical system on Θ. Under controllability assumptions for the parameter variations, a number of the basic results of this paper hold. Let us point out that for systems of the form (3.2) with $\hat\rho < 0$ the natural attractor to consider is $\{0\} \times \Theta$. For this case a Lyapunov function theory exists. Namely, $\hat\rho < 0$ if and only if there exists a smooth Lyapunov function on $\mathbb{K}^n \times \Theta$ for the overall system (3.2); see [9, 32]. This result is therefore also applicable to the LPV systems commonly studied in the literature. With respect to this case, the contribution of the present paper is merely a construction of a particular type of Lyapunov functions (and a proof of the Gelfand formula, of course).

(ii) A further class of families of linear time-varying systems that has attracted widespread interest recently is the so-called *linear switching systems* with dwell times, as discussed in the introduction. These systems are often given by a finite set of matrices $\Theta = \{A_1, \dots, A_k\}$ and a restriction on discontinuities by two numbers $h > 0$ and $N \in \mathbb{N}$. In our terminology a parameter variation (in this context often called a switching function) is a piecewise constant function $\theta : \mathbb{R} \to \Theta$ such that on any compact time interval $[a, b]$ the number of discontinuities is bounded from above by

$$\frac{b-a}{h} + N.$$

The class of systems we have set up encompasses the case in which $N = 1$. The Ω_j are then simply singleton sets, and Θ_1 is irrelevant. There does not seem to be a significant technical obstacle to generalizing the results of this paper to the case $N > 1$. However, the framework used here does become rather tedious for larger N so that we have chosen to restrict the system class for the time being.

4. Concatenation of admissible parameter variations. In this section the basic machinery for describing our problem is set up. We introduce sets of parameter

variations that can be concatenated to a given one, and we analyze the associated sets of evolution operators. To this end some topological properties of the space of parameter variations are needed. These imply, in particular, that we are indeed dealing with certain linear flows on vectors bundles. Then several useful properties of the sets of evolution operators are collected that arise from the concatenation restrictions. As a by-product, it is obtained that the exponential growth rate is at least an upper semicontinuous function of the data.

As we will be dealing with set-valued maps, let us briefly recall that a set-valued map F from $X \subset \mathbb{K}^m$ to $\mathbb{K}^n$ is a map that associates to every point in X a subset of $\mathbb{K}^n$. We will encounter only the easy case, in which the images are compact sets. Such a map is called upper semicontinuous at $x \in X$ if for every $\varepsilon > 0$ there exists a $\delta > 0$ such that $\|x - \tilde{x}\| < \delta$ implies $F(\tilde{x}) \subset F(x) + \varepsilon B$, where B is the open unit ball in $\mathbb{K}^n$. The map F is called upper semicontinuous, if it is so at every $x \in X$, and locally Lipschitz continuous, if for every compact subset $K \subset X$ there is a constant L such that $d_H(F(x), F(y)) < L\|x - y\|$ for all $x, y \in K$.

If F is a set-valued map from $X_1 \times X_2$ to $\mathbb{K}^n$, then we call the above properties in x_1 uniform with respect to x_2 if the δ corresponding to an ε, resp., the L, can be chosen for x_1 uniformly for all $x_2 \in X_2$.

In this section we assume the system $\Sigma = (h, \Theta, \Theta_1, A)$ to be given. For ease of notation we will therefore suppress the dependence of $\hat{\rho}(A,\mathcal{U})$, $\mathcal{S}_t(A,\mathcal{U})$, etc. on these data. As we have noted before, simple concatenation of admissible parameter variations does not in general result in an admissible parameter variation. In contrast, for every admissible parameter variation $u \in \mathcal{U}$ and $t \geq 0$ there is a certain subset of $\mathcal{U}$ of admissible parameter variations w for which the following concatenation is also admissible:

$$(u \diamond_t w)(s) := \begin{cases} u(s), & s < t, \\ w(s-t), & t \leq s. \end{cases} \tag{4.1}$$

It is easy to see that this subset depends on the continuous extension of u at t from the left and, in the case $h \in (0, \infty)$, on the difference between the time instance t and the largest discontinuity of u smaller than t. To denote these quantities we define

$$u(t^-) := \lim_{s \nearrow t} u(s) \tag{4.2}$$

and

$$\tau^-(u,t) := \min\{h, t - \max\{t_k \mid t_k < t, \quad \text{where } t_k \text{ is a discontinuity of } u\}\}. \tag{4.3}$$

We first treat the case $h \in (0, \infty)$ and define for $(\theta, \tau) =: \omega \in \Theta \times [0, h)$ the set of concatenable parameter variations by

$$\mathcal{U}(\omega) := \mathcal{U}(\theta, \tau) := \{u \in \mathcal{U} \mid u(0) = \theta \quad \text{and} \quad h \leq t_0(u) + \tau\};$$

here τ represents the time elapsed since the last discontinuity. For $\tau = h$ and $\omega = (\theta, h)$,

$$\mathcal{U}(\omega) := \mathcal{U}(\theta, h) := \{u \in \mathcal{U} \mid u(0) = \theta \quad \text{or} \quad h \leq t_0(u)\}.$$

Note that with this definition we clearly have $\mathcal{U} = \cup_{\omega \in \Theta \times [0,h]} \mathcal{U}(\omega)$, as every admissible parameter variation is continuous on some interval of the form $[0, \tau]$.

The interpretation of the set $\mathcal{U}(\theta,\tau)$ is the following. Consider a parameter variation u defined on the interval $(-\infty,t)$ and the concatenation (4.1). If a discontinuity of u occurs in the interval $(t-h,t)$, then admissible concatenations in t have to result in a continuous function in t. This requires $u(t)=w(0)$. Additionally, w has to wait for a time span of length at least $h-\tau^-(u,t)$ until it is allowed to have a discontinuity, so $t_0(w)\geq h-\tau^-(u,t)$ is also necessary. If there is no discontinuity of u in $(t-h,t)$, equivalently if $\tau^-(u,t)=h$, then we can either introduce a discontinuity at t, in which case $t_0(w)\geq h$ is necessary, or we can continue continuously with $u(t)=w(0)$, in which case there is no restriction on the first discontinuity of w. In all, for $w\in\mathcal{U}$ the concatenation $u\diamond_t w$ defines an admissible parameter variation if and only if

$$w\in\mathcal{U}(u(t^-),\tau^-(u,t)).$$

Note that for $0\leq\tau_1<\tau_2\leq h$ we have

$$\mathcal{U}(\theta,\tau_1)\subset\mathcal{U}(\theta,\tau_2).$$

This implies that for $0\leq\tau\leq\tau^-(u,t)$ we have at least the property that if $w\in\mathcal{U}(u(t^-),\tau)$, then $u\diamond_t w$ from (4.1) defines an admissible parameter variation. Furthermore, it should be noted that the sets $\mathcal{U}(\theta,0)$ are not really needed for concatenation purposes but are included for continuity reasons.

In the case $h=\infty$ there is no need to account for discontinuities. We thus define for $\theta\in\Theta$ the set

$$\mathcal{U}(\theta):=\{u\in\mathcal{U}\mid u(0)=\theta\}.$$

For the sake of a unified notation, we define

$$\Pi(\Theta,h):=\begin{cases}\Theta\times[0,h] & \text{if } h\in(0,\infty),\\ \Theta & \text{if } h=\infty.\end{cases}$$

In the following we denote the restriction of a parameter variation u to an interval (a,b) by $u_{|(a,b)}$. Given the sets $\mathcal{U}(\omega),\omega\in\Pi(\Theta,h)$, we now define parameter variations that may be an "initial piece" for all parameter variations $w\in\mathcal{U}(\omega)$ by

$$\begin{aligned}\mathcal{B}(\theta,\tau)&:=\left\{u_{|(-\infty,t)}\mid u\in\mathcal{U},\ u(t^-)=\theta,\ \tau\leq\tau^-(u,t)\right\}\quad\text{if } h\in(0,\infty),\\ \mathcal{B}(\theta)&:=\left\{u_{|(-\infty,t)}\mid u\in\mathcal{U},\ u(t^-)=\theta\right\}\quad\text{else.}\end{aligned}$$

Note that any parameter variation defined on a finite interval (s,t) can be extended to an admissible parameter variation on $\mathbb{R}$ if the conditions of Definition 3.1 are respected on (s,t). We will therefore also use the notation $u_{|(s,t)}\in\mathcal{B}_t(\omega)$. The interpretation of this is that a suitable extension of $u_{|(s,t)}$ to $(-\infty,t)$ lies in $\mathcal{B}_t(\omega)$ for $\omega\in\Pi(\Theta,h)$.

In all we have introduced notation just to be able to make the following statement, which is now obvious.

LEMMA 4.1. *Consider a system $\Sigma=(h,\Theta,\Theta_1,A)$ satisfying* (A1)–(A5) *and let $u,w\in\mathcal{U}$. The concatenation* (4.1) *yields an admissible parameter variation $u\diamond_t w$ if and only if there exists $\omega\in\Pi(\Theta,h)$ such that*

$$u_{|(-\infty,t)}\in\mathcal{B}(\omega)\quad\textit{and}\quad w\in\mathcal{U}(\omega).$$

For each $\omega\in\Pi(\Theta,h)$ and $t\geq 0$ we define the set of evolution operators "starting in ω" by

$$\mathcal{S}_t(\omega):=\{\,\Phi_u(t,0)\mid u\in\mathcal{U}(\omega)\}. \tag{4.4}$$

Similarly, we define for $\omega, \zeta \in \Pi(\Theta, h)$ and for $t \geq 0$ the sets of evolution operators "starting in ω and ending at ζ" by

$$\begin{aligned}\mathcal{R}_t(\omega,\zeta) := \{\Phi_u(t,0) \,|\, & u \in \mathcal{U}(\omega), u_{|(-\infty,t)} \in \mathcal{B}(\zeta), \\ & \text{and for all } w \in \mathcal{U}(\zeta) \text{ it holds that } u \diamond_t w \in \mathcal{U}(\omega)\}.\end{aligned} \tag{4.5}$$

Thus by definition if $R \in \mathcal{R}_s(\omega,\zeta)$ and $S \in \mathcal{S}_t(\zeta)$, then $SR \in \mathcal{S}_{t+s}(\omega)$.

Remark 4.2. The definition of $\mathcal{R}_t(\omega,\zeta)$ might seem peculiar at first glance. In fact, in the case $h = \infty$ the third condition in (4.5) is superfluous. It is sufficient that $u(0) = \theta, u(t) = \eta$ in order for $u \diamond_t w \in \mathcal{U}(\theta)$ for all $w \in \mathcal{U}(\eta)$. However, if $h \in (0,\infty)$, then although the condition $u_{|(-\infty,t)} \in \mathcal{B}(\zeta)$ implies that $u \diamond_t w$ defines an admissible parameter variation if $w \in \mathcal{U}(\zeta)$, it does not automatically imply that this concatenation lies in $\mathcal{U}(\omega)$. For this, further restrictions regarding the discontinuities have to be observed. Namely, if $\omega = (\theta,\tau)$ and $\zeta = (\eta,\sigma)$, a short calculation shows that it is necessary that $t \geq \sigma - \tau$ to guarantee $u \diamond_t w \in \mathcal{U}(\omega)$ for all $w \in \mathcal{U}(\zeta)$. In particular, if $t \geq h$, then again the third condition in (4.5) is superfluous.

We now define

$$\mathcal{S}_{\leq T}(\omega) := \bigcup_{0\leq t\leq T} \mathcal{S}_t(\omega) \quad \text{and} \quad \mathcal{S}(\omega) := \bigcup_{t\geq 0} \mathcal{S}_t(\omega), \quad \text{resp.},$$
$$\mathcal{R}_{\leq T}(\omega,\zeta) := \bigcup_{0\leq t\leq T} \mathcal{R}_t(\omega,\zeta) \quad \text{and} \quad \mathcal{R}(\omega,\zeta) := \bigcup_{t\geq 0} \mathcal{R}_t(\omega,\zeta).$$

Note that for every $\omega \in \Pi(\Theta,h)$ the set $\mathcal{R}(\omega,\omega)$ is a semigroup.

Remark 4.3. It is useful to keep in mind the following remark on parameter variations connecting two points $\omega, \zeta \in \Pi(\Theta,h)$. If $h \in (0,\infty)$, then for all $\omega, \zeta \in \Theta \times [0,h]$ the set $\mathcal{R}_{2h}(\omega,\zeta)$ is not empty. For if $\omega = (\theta,\tau), \zeta = (\eta,\sigma)$, then it suffices to define $u(s) = \theta, 0 \leq s < h$ and $u(s) = \eta, h \leq s \leq 2h$. Similarly, if $h = \infty$ and (A6) holds, then it follows from Remark 3.2(iv) and the constant $\bar{c}$ used in that remark that $\mathcal{R}_{\bar{c}}(\theta,\eta) \neq \emptyset$ for all $\theta, \eta \in \Theta$.

In a first step let us clarify the continuity properties of the sets just defined. To this end we note the following consequence of the Arzela–Ascoli theorem.

LEMMA 4.4. *Let $\Theta \in \mathcal{K}(\mathbb{K}^m)$, $\Theta_1 \in \mathrm{Co}(\mathbb{K}^m), h \in (0,\infty]$ satisfy* (A1)–(A4) *and consider the space $\mathcal{U}$ of admissible parameter variations in the sense of Definition* 3.1.

Given $T > 0$ and sequences $\omega_k, \zeta_k \in \Pi(\Theta,h)$, $u_k \in \mathcal{U}(\omega_k)$ with $\Phi_{u_k}(T,0) \in \mathcal{R}(\omega_k,\zeta_k)$, there exist subsequences such that

(i) *the limits $\lim_{\mu\to\infty} \omega_{k_\mu} =: \omega$ and $\lim_{\mu\to\infty} \zeta_{k_\mu} =: \zeta$ exist;*
(ii) *$\{u_{k_\mu}\}_{\mu\in\mathbb{N}}$ converges in the weak-* topology on $[0,T]$ to an admissible parameter variation $u \in \mathcal{U}(\omega)$ with $\Phi_u(T,0) \in \mathcal{R}(\omega,\zeta)$.*

Furthermore,

$$\Phi_{u_{k_\mu}}(t,0) \to \Phi_u(t,0) \text{ uniformly on } [0,T].$$

Proof. Fix $T > 0$. By compactness we may assume that $\omega_k \to \omega$ and $\zeta_k \to \zeta$. For the case $h = \infty$ the claims are immediate from the Arzela–Ascoli theorem.

We now treat the case $h \in (0,\infty)$ and let $\omega_k =: (\theta_k,\tau_k) \to (\theta,\tau)$ and $\zeta_k =: (\eta_k,\sigma_k) \to (\eta,\sigma)$. For each k the function u_k has finitely many discontinuities on $[0,T]$, the number of which is bounded by $T/h + 1$. By choosing an appropriate subsequence we may therefore assume that the number of discontinuities of u_k is equal to a certain number $0 \leq l \leq T/h + 1$ independent of k. Furthermore, without

loss of generality the discontinuities $0 < s_{1k} < \cdots < s_{lk} \leq T$ of u_k converge to points $s_1, \ldots, s_l$ as $k \to \infty$. Clearly, $s_{j+1} - s_j \geq h, j = 1, \ldots, l-1$, as the same is true for the points $s_{1k}, \ldots, s_{lk}$ for all k.

As Θ and Θ_1 are bounded, the conditions of the Arzela–Ascoli theorem are satisfied by the u_k on $[s_j + \varepsilon, s_{j+1} - \varepsilon]$ for all $\varepsilon > 0$ small enough. By applying a diagonal sequence argument, we may assume that u_k converges to a function u uniformly on any interval of the form $[s_j + \varepsilon, s_{j+1} - \varepsilon]$ for $\varepsilon > 0$ small enough. If $s_1 > 0$, the same argument applies to the interval $[0, s_1 - \varepsilon]$. Similarly, if $s_l < T$, we can treat the interval $[s_l + \varepsilon, T]$ in this way. It follows that u is well defined on $[0, T] \setminus \{s_1, \ldots, s_l\}$. By continuous extension from the right in the points $s_1, \ldots, s_l$ we obtain that u is Lipschitz continuous on each of the intervals $[s_j, s_{j+1})$. By construction, $u(t) \in \Theta$ for all $t \in [0, T]$. Furthermore, $\dot{u}(\cdot)$ is the weak-* limit of an appropriate subsequence of the $\dot{u}_k(\cdot)$ (as Θ_1 is compact). By the convexity of Θ_1 it follows that $\dot{u}(t) \in \Theta_1$ for almost all $t \in [0, T]$. Hence u is admissible.

We now show that $u \in \mathcal{U}(\theta, \tau)$. If $\tau \in [0, h)$, then $s_1 > 0$ because $s_{1k} + \tau_k \geq h$ by definition, and hence $s_1 \geq h - \tau > 0$. Thus $u_k(0) = \theta_k \to \theta = u(0)$ by uniform convergence on $[0, s_1 - \varepsilon]$ for some $\varepsilon > 0$ small enough. This shows that $u \in \mathcal{U}(\theta, \tau)$. If $\tau = h$ and $s_1 > 0$, the same argument is applicable so that it remains to treat the case when $\tau = h$ and $s_1 = 0$. In this case we have defined $u(0)$ as the continuous extension of $u_{|(0,s_2)}$, so that $u(0) \neq \theta$ is possible. However, we also have $s_2 \geq h$, and so the first discontinuity of u occurs after time h. Thus $u \in \mathcal{U}(\theta, h)$ according to Definition 3.1. The arguments showing that $u_{|[0,T)} \in \mathcal{B}(\eta, \sigma)$ are completely analogous. To show that $\Phi_u(T, 0) \in \mathcal{R}_T(\omega, \zeta)$ we finally have to check that $T \geq \sigma - \tau$ by Remark 4.2. This follows by the assumption $T \geq \sigma_k - \tau_k$ for all k.

The final statement is now immediate from the uniform convergence of the u_k on $[0, T] \setminus \cup_{j=1}^{l} (s_j - \varepsilon, s_j + \varepsilon)$ for all small $\varepsilon > 0$. □

We note an immediate consequence, which is of independent interest, and which will turn out to be useful in section 7.

COROLLARY 4.5. *Given a system $\Sigma = (h, \Theta, \Theta_1, A)$ satisfying* (A1)–(A5)*, the set $\mathcal{U}$ is a metrizable compact space, and the map*

$$(t, u, x) \mapsto (u(t + \cdot), \Phi_u(t, 0)x) \tag{4.6}$$

defines a linear flow on the vector bundle $\pi : \mathcal{U} \times \mathbb{K}^n \to \mathcal{U}$.

Proof. It is a standard result that $L^\infty(\mathbb{R}, \operatorname{conv}\Theta)$ endowed with the weak-* topology is compact and metrizable. The shift $u(\cdot) \mapsto u(t + \cdot)$ is continuous on that space by [13, Lem. 4.2.4]. Lemma 4.4 shows that $\mathcal{U}$ is a compact subset of that space, and so in particular is also metrizable. Furthermore, by the same lemma it follows that (4.6) is continuous as a function of t, u, x. Linearity in the x component is clear by construction. □

We are now ready to prove an essential though fairly basic lemma concerning the dependence of the parameterized sets of transition operators on time and the parameters. To this end we introduce the set

$$W := \{(t, \omega, \zeta) \in \mathbb{R}_+ \times \Pi(\Theta, h)^2 \mid \mathcal{R}_t(\omega, \zeta) \neq \emptyset\}.$$

LEMMA 4.6. *Consider system* (2.1) *given by Σ satisfying* (A1)–(A5)*. Then*

(i) *for all $(t, \omega, \zeta) \in [0, \infty) \times \Pi(\Theta, h)^2$ the sets $\mathcal{S}_t(\omega)$ and $\mathcal{R}_t(\omega, \zeta)$ are compact.*

(ii) *the maps $\mathcal{S} : \mathbb{R}_+ \times \Pi(\theta, h) \to \mathcal{K}(\mathbb{K}^n)$, $\mathcal{R} : W \to \mathcal{K}(\mathbb{K}^n)$ given by*

$$(t, \omega) \mapsto \mathcal{S}_t(\omega), \quad (t, \omega, \zeta) \mapsto \mathcal{R}_t(\omega, \zeta) \tag{4.7}$$

are upper semicontinuous.

(iii) *assume* $h \in (0,\infty)$ *and denote* $\omega = (\theta,\tau), \zeta = (\eta,\sigma)$. *Then for fixed* $\theta \in \Theta$ *the maps in* (4.7) *are locally Lipschitz continuous in* t,τ *(resp., in* t,τ,σ *for fixed* θ,η*). For* $h = \infty$ *and* $\theta \in \Theta$ *(resp.,* $\theta,\eta \in \Theta$*) fixed, the maps are locally Lipschitz continuous in* t.

(iv) *if additionally* (A6) *holds, the maps from* (4.7) *are locally Lipschitz continuous on* $\mathbb{R}_+ \times \Pi(\Theta,h)$ *(resp.,* W*).*

(v) *if* (A6) *holds and* $\mathcal{S}(A,\mathcal{U})$ *is bounded, the Lipschitz constants with respect to* $\omega \in \Pi(\Theta,h)$ *(resp.,* $(\omega,\zeta) \in W$*) may be chosen uniformly in* t.

(vi) *if* $h \in (0,\infty)$ *and* $\mathcal{S}(A,\mathcal{U})$ *is bounded, the maps from* (4.7) *are upper semicontinuous in* (θ,τ) *(resp.,* $(\theta,\tau,\eta,\sigma)$*) uniformly in* t.

Proof. It is clear that each of the sets $\mathcal{S}_t(\theta,\tau), \mathcal{R}_t(\theta,\tau,\eta,\sigma)$ is bounded by the boundedness of $A(\Theta)$. From Lemma 4.4 it is now immediate that they are also closed, so that the proof of (i) is complete. Assertion (ii) is another immediate consequence of Lemma 4.4.

For the remaining statements we restrict our attention to the case $h \in (0,\infty)$ and the sets $\mathcal{S}_t(\theta,\tau)$, as the arguments for $h = \infty$, resp., $\mathcal{R}_t(\theta,\tau,\eta,\sigma)$, are of a very similar nature.

In order to show (iii), let θ be fixed and consider a compact time interval $[0,T]$. Let $t_1,t_2 \in [0,T]$ and $\tau_1,\tau_2 \in [0,h]$. We may assume without loss of generality that $\tau_1 \le \tau_2$. Note that in this case we have $\mathcal{S}_t(\theta,\tau_1) \subset \mathcal{S}_t(\theta,\tau_2)$ for all $t \ge 0$. Let $S = \Phi_u(t_2,0) \in \mathcal{S}_{t_2}(\theta,\tau_2)$ for some $u \in \mathcal{U}$. As $0 \in \Theta_1$, this implies that

$$\tilde{S} := \begin{cases} e^{A(\theta)t_1} & \text{if } t_1 \le \tau_2 - \tau_1, \\ \Phi_u(t_1 - (\tau_2 - \tau_1),0)e^{A(\theta)(\tau_2-\tau_1)} & \text{else} \end{cases}$$

is an element of $\mathcal{S}_{t_1}(\theta,\tau_1)$. We obtain for the second case that

$$\begin{aligned} \|S - \tilde{S}\| &\le \|S\|\|I - e^{A(\theta)(\tau_2-\tau_1)}\| + \|\Phi_u(t_2,t_1-(\tau_2-\tau_1)) - I\|\|\tilde{S}\| \\ &\le L|\tau_2 - \tau_1| + L(|t_2 - t_1| + |\tau_2 - \tau_1|) \end{aligned} \tag{4.8}$$

for a suitable constant L independent of S and θ (which exists as, by the compactness of Θ, the set of evolution operators of length t generated by the system is uniformly bounded for $t \in [0,T]$). It is now easy to check that the same estimates apply to the first case if we use $t_1 \le \tau_2 - \tau_1$ along the way.

Conversely, let $S = \Phi_u(t_1,0) \in \mathcal{S}_{t_1}(\theta,\tau_1)$ for some $u \in \mathcal{U}$. Then $S \in \mathcal{S}_{t_1}(\theta,\tau_2)$ by definition. If $t_2 \le t_1$, then $\tilde{S} := \Phi_u(t_2,0) \in \mathcal{S}_{t_2}(\theta,\tau_2)$. Otherwise, letting $\eta := u(t_1^-)$ we have $\tilde{S} := e^{A(\eta)(t_2-t_1)}S \in \mathcal{S}_{t_2}(\theta,\tau_2)$. Using this, the required Lipschitz estimate in $|t_1 - t_2|$ can be obtained easily.

Thus we have obtained the desired local Lipschitz estimate in (t,τ).

In order to show (iv) note that we have shown local Lipschitz continuity in t,τ uniformly in θ. Thus, if we prove Lipschitz continuity with respect to θ locally uniformly in t,τ, then we have overall local Lipschitz continuity. To this end it is sufficient to restrict our attention to one of the convex components Ω_j of Θ, which we now assume to be fixed. Fix $\theta_1,\theta_2 \in \Omega_j$. As (A6) holds, we may use Remark 3.2(iv) to obtain that the map $s \mapsto \theta_1 + sc(\theta_2 - \theta_1)/\|\theta_2 - \theta_1\|$, $s \in [0,\|\theta_2 - \theta_1\|/c]$ is the initial part of an admissible parameter variation connecting θ_1 and θ_2. Here $c > 0$ is a suitable constant depending only on Θ,Θ_1. Denote by $R \in \mathcal{S}_{\|\theta_2-\theta_1\|/c}(\theta_1,\tau)$ the corresponding evolution operator. For any $S = \Phi_u(t,0) \in \mathcal{S}_t(\theta_2,\tau)$ with $t \ge \|\theta_2 - \theta_1\|/c$, it follows that $\tilde{S} := \Phi_u(t - \|\theta_2 - \theta_1\|/c,0)R \in \mathcal{S}_t(\theta_1,\tau)$. Then again

$$\|S - \tilde{S}\| \le \|S\|\|I - R\| + \|\Phi_u(t,t - \|\theta_2 - \theta_1\|/c) - I\|\|\tilde{S}\|, \tag{4.9}$$

which allows for a Lipschitz estimate in $\|\theta_1 - \theta_2\|$ independently of $t \in [\|\theta_2 - \theta_1\|/c, T], \tau \in [0, h]$ as in (4.8), and using symmetry, the proof is complete. The case that $t < \|\theta_2 - \theta_1\|/c$ is an easy exercise.

(v) If the set of evolution operators of the system is bounded, then the expressions in (4.8) and (4.9) can be bounded independently of $S, \tilde{S}$ so that L does not depend on t, as desired.

(vi) On the bounded interval $[0, 3h]$ the assertion is clear from Lemma 4.4 so that we restrict our attention to $t \geq 3h$.

Fix $(\theta_0, \tau_0) \in \Theta \times [0, h]$. According to (i) the map $(\theta, \tau) \mapsto \mathcal{S}_{3h}(\theta, \tau)$ is upper semicontinuous at (θ_0, τ_0) so that for every $\varepsilon > 0$ there exists a $\delta > 0$ such that $\|\theta - \theta_0\| + |\tau - \tau_0| < \delta$ implies $\mathcal{S}_{3h}(\theta, \tau) \subset \mathcal{S}_{3h}(\theta_0, \tau_0) + \varepsilon B$. Let $t \geq 3h$, $\Phi_u(t, 3h)\Phi_u(3h, 0) \in \mathcal{S}_t(\theta, \tau)$ be arbitrary, and let $w \in \mathcal{U}(\theta_0, \tau_0)$ be such that $\|\Phi_u(s, 0) - \Phi_w(s, 0)\| < \varepsilon$ for all $s \in [0, 3h]$. The proof of Lemma 4.4 shows that we may assume that the discontinuities of u and w are no more than ε apart.

Let $s_u, s_w \in [0, 3h]$ be two discontinuities of u, resp., w with $|s_u - s_w| < \varepsilon$ (assuming they exist; if not, set $s_u := s_w := 3h/2$) and define

$$\tilde{u}(t) := \begin{cases} w(t), & t < s_w, \\ u(t - s_w + s_u), & t \geq s_w. \end{cases}$$

Then $\Phi_{\tilde{u}}(t, 0) \in \mathcal{S}_t(\theta_0, \tau_0)$ and we obtain that

$$\begin{aligned} \|\Phi_u(t, 0) - \Phi_{\tilde{u}}(t, 0)\| &\leq \|\Phi_u(t, s_u)\| \|\Phi_u(s_u, 0) - \Phi_w(s_w, 0)\| \\ &\quad + \|\Phi_u(t, t - s_w + s_u) - I\| \|\Phi_{\tilde{u}}(t, 0)\| \\ &\leq M(\|\Phi_u(s_u, 0) - \Phi_w(s_w, 0)\| + \|\Phi_u(t, t - s_w + s_u) - I\|), \end{aligned}$$

where M is some bound on the norm of $\Phi_u(t, 0), u \in \mathcal{U}, t \geq 0$. Using that $\|\Phi_u(s, 0) - \Phi_w(s, 0)\| < \varepsilon$ for all $s \in [0, 3h]$ and that $|s_u - s_w| < \varepsilon$, we see that the last bound may be made arbitrarily small by choosing δ small enough. As the bound is independent of t, this shows the assertion. □

Remark 4.7. It should be noted that without assumption (A6) the maps studied in the previous lemma need not be continuous in θ. As an example consider the convex subset of $\mathbb{R}^3$ given by

$$\Theta := \operatorname{conv}\{[0 \quad 0 \quad 1]'\} \cup \{[x \quad x^2 \quad 0]' \mid x \in [0, 1]\},$$

and let $\Theta_1 = \{0\} \times \{0\} \times [-1, 1]$, $A(z_1, z_2, z_3) = z_3 \in \mathbb{R}$, $h \in (0, \infty]$. For fixed $0 < t \leq 1$ and the initial value $\theta(0) = [0, 0, 0]$, the function

$$u(s) = [0, 0, s]', s \in [0, t]$$

defines an admissible parameter variation which yields the evolution operator $\Phi_u(t, 0) = \exp(t^2/2) \in \mathcal{S}_t(\theta(0), \tau), \tau \in [0, h]$. On the other hand, for arbitrary $1 \geq \varepsilon > 0$ and the parameter value $\theta(\varepsilon) = [\varepsilon, \varepsilon^2, 0]$ the only admissible parameter variation is the function $u_\varepsilon \equiv \theta(\varepsilon)$, as no point of the form $[\varepsilon, \varepsilon^2, z_3], z_3 \neq 0$, is contained in Θ. Hence

$$\mathcal{S}_t(\theta(\varepsilon), \tau) = \{1\}$$

as long as $t + \tau < h$. In particular, for all $t > 0$ small enough the map $\varepsilon \mapsto \mathcal{S}_t(\theta(\varepsilon), \tau)$ is discontinuous in $\varepsilon = 0$.

With arguments very similar to those employed in the proof of Lemma 4.4, a semicontinuity property of $\hat{\rho}$ may be shown. We denote the space of systems

$$\mathcal{L} := \{\Sigma := (h, \Theta, \Theta_1, A) \mid \Sigma \text{ satisfies (A1)–(A5)}\}$$

and endow it with the product topology inherited from $(0,\infty]\times\mathcal{K}(\mathbb{R}^{n\times n})\times \mathrm{Co}(\mathbb{R}^{n\times n})\times \mathcal{C}(\mathbb{R}^m, \mathbb{R}^{n\times n})$, where we consider the topology of locally uniform convergence on $\mathcal{C}(\mathbb{R}^m, \mathbb{R}^{n\times n})$.

PROPOSITION 4.8. *The map*

$$\hat{\rho} : \mathcal{L} \to \mathbb{R}, \qquad (h, \Theta, \Theta_1, A) \mapsto \hat{\rho}(h, \Theta, \Theta_1, A)$$

is upper semicontinuous.

Proof. It is sufficient to show that the maps $(h, \Theta, \Theta_1, A) \mapsto \hat{\rho}_t(h, \Theta, \Theta_1, A)$ are upper semicontinuous, as by (2.2) we have $\hat{\rho} = \inf_{t>0} \hat{\rho}_t$ and the infimum of upper semicontinuous maps is upper semicontinuous. So fix $t \geq 0$ and a sequence $\Sigma_k = (h_k, \Theta_k, \Theta_{1,k}, A_k) \to \Sigma = (h, \Theta, \Theta_1, A) \in \mathcal{L}$. We first consider the case $h \in (0,\infty)$. Let $u_k \in \mathcal{U}(\Sigma_k)$ be such that $\|\Phi_{u_k}(t,0)\| = \hat{\rho}_t(\Sigma_k)$. We may assume that $\lim_{k\to\infty} \Phi_{u_k}(t,0) =: S$ exists, and we now have to show that $S \in \mathcal{S}_t(\Sigma)$ because in this case $\hat{\rho}_t(\Sigma) \geq \limsup_{k\to\infty} \hat{\rho}_t(\Sigma_k)$.

Now, as in the proof of Lemma 4.4 we may choose a subsequence of the u_k such that the discontinuities of u_k on $[0,t]$ converge to finitely many points $s_1, \dots, s_l$. These are at least distance h apart. On the intervals of the form $[s_j + \varepsilon, s_{j+1} - \varepsilon]$, $j = 1, \dots, l$, we may (after going to a further subsequence) assume that the u_k converge uniformly and that their derivatives converge in the weak-* sense. Then it follows again that $u \in \mathcal{U}(\Sigma)$ and that $S = \Phi_u(t,0)$, as desired.

If $h = \infty$ and $h_k = \infty$, the same argument is applicable. We finally have to treat the case $h_k \in (0,\infty), h_k \to \infty$. In this case the number of discontinuities of u_k on $[0,t]$ is bounded by $t/h_k + 1$. Thus it may happen that for a given choice of t and $u_k \in \mathcal{U}(\Sigma_k)$ the discontinuities of u_k in $[0,t]$ converge to one point $s_1 \in [0,t]$. In this case the limit function u is not an element of $\mathcal{U}(h, \Theta, \Theta_1, A)$. However, we have $\Phi_u(t, s_1) \in \mathcal{S}(h, \Theta, \Theta_1, A)$ as well as $\Phi_u(s_1, 0) \in \mathcal{S}(h, \Theta, \Theta_1, A)$. Thus using (2.3), for every $\varepsilon > 0$ there is a constant M_ε such that

$$\|\Phi_u(t,0)\| \leq \|\Phi_u(t,s_1)\|\|\Phi_u(s_1,0)\| \leq M_\varepsilon^2 e^{(\hat{\rho}(h,\Theta,\Theta_1,A)+\varepsilon)t}.$$

As t is arbitrary, the last inequality implies that also in this case $\hat{\rho}(h, \Theta, \Theta_1, A) \geq \limsup_{k\to\infty} \hat{\rho}(h_k, \Theta_k, \Theta_{1k}, A_k)$, as desired. ∎

If we describe the exponential growth rate within the subsets of evolution operators with given initial and end conditions, this leads to the definitions

$$\widehat{\rho}_t(\omega) := \max\left\{\frac{1}{t}\log\|S\| \mid S \in \mathcal{S}_t(\omega)\right\}, \quad \widehat{\rho}_t(\omega,\zeta) := \max\left\{\frac{1}{t}\log\|S\| \mid S \in \mathcal{R}_t(\omega,\zeta)\right\}.$$

With this, the problem arises in which the functions $t \mapsto t\widehat{\rho}_t(\omega)$ and $t \mapsto t\widehat{\rho}_t(\omega,\zeta)$ are no longer subadditive, so that it does not follow automatically to what value they are converging, if at all. It is therefore useful to point out the following.

LEMMA 4.9. *Consider the system* (2.1) *with* (A1)–(A5) *and let one of the following assumptions be satisfied:*

(a) $h \in (0,\infty)$.

(b) $h = \infty$ *and* (A6) *is satisfied.*

Then there is a constant $C \in \mathbb{R}$ such that for all $\omega, \zeta \in \Pi(\Theta, h)$ we have

$$t\widehat{\rho}_t(\omega,\zeta) \geq t\hat{\rho} - C \quad \textit{for all } t > 0. \tag{4.10}$$

In particular, it follows for all $\omega, \zeta \in \Pi(\Theta, h)$ that

$$\widehat{\rho} = \lim_{t\to\infty} \widehat{\rho}_t(\omega,\zeta) = \lim_{t\to\infty} \widehat{\rho}_t(\omega).$$

Proof. Fix $\omega, \eta \in \Pi(\Theta, h)$. Clearly, for all $t \geq 0$ we have $\widehat{\rho}_t(\omega,\zeta) \leq \widehat{\rho}_t(\omega) \leq \widehat{\rho}_t$ so that in order to show the second assertion it is sufficient to show that $\widehat{\rho} \leq \liminf_{t\to\infty} \widehat{\rho}_t(\omega,\zeta)$. This, however, is an immediate consequence of (4.10).

In order to show (4.10), note that by (2.2) we can for each $t > 0$ choose a matrix $S_t \in \mathcal{S}_t$ with $\log \|S_t\| = t\widehat{\rho}_t \geq t\widehat{\rho}$. Then $S_t \in \mathcal{R}(\omega_1, \zeta_1)$ for suitable ω_1, ζ_1 (depending on t). If (a) holds, then we may by Remark 4.3 for each such S_t choose an $R_1 \in \mathcal{R}_{2h}(\omega, \omega_1)$ and an $R_2 \in \mathcal{R}_{2h}(\zeta_1, \zeta)$. With this choice we obtain that

$$R_2 S_t R_1 \in \mathcal{R}_{t+4h}(\omega,\zeta),$$

and so

$$\begin{aligned}(t+4h)\hat{\rho}_{t+4h}(\omega,\zeta) &\geq \log\|R_2 S_t R_1\| \geq \log\|S_t\|\|R_2^{-1}\|^{-1}\|R_1^{-1}\|^{-1} \\ &\geq t\widehat{\rho}_t - 2\log\max\{\|S^{-1}\| \mid S \in \mathcal{S}_{2h}\} \\ &\geq t\hat{\rho} - 2\log\max\{\|S^{-1}\| \mid S \in \mathcal{S}_{2h}\},\end{aligned}$$

which shows the assertion under assumption (a). To prove the assertion when (b) holds, we can use Remarks 4.3 and 3.2(iv), by which all pairs $\theta, \eta \in \Theta$ can be connected in time $\bar{c}$ independently of θ, η. The remaining arguments are then exactly the same as before. ∎

5. Irreducibility. We aim to construct parameter-dependent Lyapunov functions that exactly reflect the exponential growth rate of the system $\Sigma = (h, \Theta, \Theta_1, A)$. To this end it is crucial to assume the irreducibility of $A(\Theta)$. Recall that a set of matrices $\mathcal{M} \subset \mathbb{K}^{n\times n}$ is called irreducible, if only the trivial subspaces $\{0\}$ and $\mathbb{K}^n$ are invariant under all $A \in \mathcal{M}$, and called reducible otherwise.

Remark 5.1. (i) Note that the set of systems Σ for which $A(\Theta)$ is irreducible is open and dense in the set $\mathcal{L}$ of all systems satisfying (A1)–(A5), with the topology introduced just before Proposition 4.8.

(ii) If $A(\Theta)$ is reducible, we can find a similarity transformation T such that for all $\theta \in \Theta$ the transformed matrix $TA(\theta)T^{-1}$ is of the form

$$\begin{bmatrix} A_{11}(\theta) & A_{12}(\theta) & \dots & A_{1d}(\theta) \\ 0 & A_{22}(\theta) & \dots & A_{2d}(\theta) \\ & \ddots & \ddots & \vdots \\ 0 & & 0 & A_{dd}(\theta) \end{bmatrix}, \tag{5.1}$$

where the sets $A_{ii}(\Theta) \subset \mathbb{K}^{n_i\times n_i}$ are irreducible or $\{0\}$, $i = 1, \dots, d$. It is an easy exercise to show that in this case $\hat{\rho}(A, \mathcal{U}) = \max_{i=1,\dots,d} \hat{\rho}(A_i, \mathcal{U})$, where $A_i : \Theta \to \mathbb{K}^{n_i\times n_i}$ is the map $\theta \mapsto A_{ii}(\theta)$. Having said this, it is clear that for the analysis of $\hat{\rho}$ with respect to one system we can assume irreducibility without loss of generality.

The next simple lemma is crucial in the following construction.

LEMMA 5.2. *Let $\mathbb{K} = \mathbb{R}, \mathbb{C}$ and let $\mathcal{S} \subset \mathbb{K}^{n\times n}$ be an irreducible semigroup. For any family of sets $\mathcal{S}_t$, $t \in \mathbb{R}_+$, with*

$$\mathcal{S} = \bigcup_{t\geq 0} \mathcal{S}_t,$$

there are $\varepsilon > 0$ and $T \in \mathbb{R}_+$ such that for all $z \in \mathbb{K}^n, A \in \mathbb{K}^{n\times n}$ there is an $S \in \bigcup_{1\leq t\leq T} \mathcal{S}_t$ with

$$\|ASz\| \geq \varepsilon \|A\| \|z\|.$$

Proof. This is a minute generalization of [34, Lem. 3.1]. □

We now begin to study the consequences of irreducibility. The following properties are essential in our construction of Lyapunov functions.

PROPOSITION 5.3. *Consider system* (2.1) *with Assumptions* (A1)–(A5). *Assume that $A(\Theta)$ is irreducible and let one of the following assumptions be satisfied:*

(a) *$h \in (0, \infty)$.*

(b) *$h = \infty$ and* (A6) *is satisfied.*

Then for all $\omega, \zeta \in \Pi(\Theta, h)$,

(i) *the set $\mathcal{R}(\omega, \zeta)$ is irreducible.*

(ii) *the set $\mathcal{S}(\omega)$ is irreducible.*

Proof. (i) We first show the claim assuming (a). Fix an arbitrary nontrivial subspace X and let $\Phi_u(t, 0) \in \mathcal{R}(\omega, \zeta)$ with $t \geq 2h$ be such that $\Phi_u(t, 0)X = X$. (If no such Φ exists, we are done.) Let $t^* \in (0, t)$ be a discontinuity of u, or if such a discontinuity does not exist, let $t^* = t/2$. Denote $Y := \Phi_u(t^*, 0)X$. As $A(\Theta)$ is irreducible, there exists a $\theta^* \in \Theta$ such that $\exp(A(\theta^*)s)Y \not\subset Y$ for some $s \geq h$. Hence $\Phi_u(t, t^*) \exp(A(\theta^*)s)\Phi_u(t^*, 0)X \not\subset X$. On the other hand, $\Phi_u(t, t^*) \exp(A(\theta^*)s)\Phi_u(t^*, 0) \in \mathcal{R}(\omega, \zeta)$ because we may at time t^* jump to θ^*, remain there for the time s, and jump back to $u(t^*)$. This defines an admissible parameter variation, and the assertion follows.

Now assume that (b) holds and let X be a nontrivial invariant subspace for all $\Phi_u(t, 0) \in \mathcal{R}(\theta, \eta)$. Fix one of the corresponding parameter variations u. As $0 \in \Theta_1$, we also have for arbitrary $0 \leq s \leq t$ and all $r \geq 0$ that $\Phi_u(t, s) \exp(A(u(s))r)\Phi_u(s, 0) \in \mathcal{R}(\theta, \eta)$. Denoting $Y_s := \Phi_u(s, 0)X$ we obtain that $\exp(A(u(s))r)Y_s = Y_s$ for all $r \geq 0$, $s \in [0, t]$, so that $A(u(s))Y_s \subset Y_s$ for all $s \in [0, t]$.

Assume that $\dim Y_s = m$ for some $1 \leq m < n$ and denote the Grassmannian of m-dimensional subspaces of $\mathbb{K}^n$ by $G(n, m)$. Consider the induced differential equation on $G(n, m)$ given by

$$\dot{X}(s) = A(u(s))X(s). \tag{5.2}$$

Then the function $s \mapsto Y_s, s \in [0, t]$ is a solution of (5.2), as we have by the previous construction for all $s \in [0, t]$ that $\Phi_u(s, 0)X = Y_s$. On the other hand, we have

$$\frac{d}{ds} Y_s = \frac{d}{ds} \Phi_u(s, 0)X = A(u(s))\Phi_u(s, 0)X = A(u(s))Y_s \subset Y_s,$$

or in other words $\frac{d}{ds} Y_s = 0$ for all $s \in [0, t]$ in the Grassmannian. This shows that $Y_s \equiv X$ so that X is a common invariant subspace for all $A(u(s)), s \in [0, t]$. Under condition (A6), however, we may for arbitrary $\theta_1 \in \Theta$ choose an admissible parameter variation u such that for suitable times $0 \leq s \leq t$ we have $u(0) = \theta, u(s) = \theta_1, u(t) = \eta$.

By the previous argument this implies that X is an invariant subspace of $A(\theta_1)$ so that X is a common invariant subspace for all $A \in A(\Theta)$, which contradicts irreducibility of $A(\Theta)$. This completes the proof.

(ii) This is immediate from (i) as $\mathcal{S}(\omega) = \cup_{\zeta\in\Pi(\Theta,h)}\mathcal{R}(\omega,\zeta)$. □

6. Parameterized Lyapunov functions. In this section the main result of the paper is derived. In Theorem 6.4 we obtain the existence of parameterized Lyapunov functions that characterize the exponential growth rate. Also some results of the Lipschitz continuous dependence of the Lyapunov function on the parameter are presented.

The main step of the proof relies on the following construction. By Lemma 4.9 the exponential growth in $\mathcal{S}$ and in the subsets $\mathcal{S}(\omega)$, $\mathcal{R}(\omega,\eta)$ is essentially the same. It therefore makes sense to define limit sets as follows:

$$\mathcal{S}_\infty(\omega) := \{S \in \mathbb{K}^{n\times n} \mid \exists\, t_k \to \infty, S_k \in \mathcal{S}_{t_k}(\omega) : e^{-\hat\rho t_k} S_k \to S\}, \tag{6.1}$$

$$\mathcal{R}_\infty(\omega,\zeta) := \{S \in \mathbb{K}^{n\times n} \mid \exists\, t_k \to \infty, S_k \in \mathcal{R}_{t_k}(\omega,\zeta) : e^{-\hat\rho t_k} S_k \to S\}. \tag{6.2}$$

We note the following properties of $\mathcal{S}_\infty(\omega)$ and $\mathcal{R}_\infty(\omega,\zeta)$.

LEMMA 6.1. *Consider the system* (2.1) *with* (A1)–(A5). *Assume that* $A(\Theta)$ *is irreducible and let one of the following assumptions be satisfied:*

(a) $h \in (0,\infty)$.

(b) $h = \infty$ *and* (A6) *is satisfied.*

Then

(i) *the set* $\cup_{\omega\in\Pi(\Theta,h)}\mathcal{S}_\infty(\omega)$ *is bounded,*

and for all $\omega,\zeta \in \Pi(\Theta,h)$ *it holds that*

(ii) $\mathcal{R}_\infty(\omega,\zeta)$ *is a compact, nonempty set not equal to* $\{0\}$.

(iii) $\mathcal{S}_\infty(\omega)$ *is a compact, nonempty set not equal to* $\{0\}$.

(iv) *for every* $t \geq 0$ *we have that if* $R \in \mathcal{R}_t(\omega,\zeta)$ *and* $S \in \mathcal{S}_\infty(\zeta)$, *or if* $R \in \mathcal{R}_\infty(\omega,\zeta)$ *and* $S \in \mathcal{S}_t(\zeta)$, *then* $e^{-\hat\rho t}SR \in \mathcal{S}_\infty(\omega)$.

(v) *for every* $S \in \mathcal{S}_\infty(\omega)$ *and every* $t \in \mathbb{R}_+$ *there exist* $\zeta \in \Pi(\Theta,h)$, $R \in \mathcal{R}_t(\omega,\zeta)$, *and* $T \in \mathcal{S}_\infty(\zeta)$ *such that* $S = e^{-\hat\rho t}TR$.

(vi) $\mathcal{R}_\infty(\omega,\omega)$, $\mathcal{S}_\infty(\omega)$ *are irreducible.*

Proof. Without loss of generality, we may assume in this proof that $\hat\rho = 0$ by considering the map $\tilde A(\theta) := A(\theta) - \hat\rho I$.

(i) For ease of notation define

$$\delta := \min\{\|R^{-1}\|^{-1} \mid R \in \mathcal{S}_{\leq\gamma}\} > 0,$$

where $\gamma = 2h$ in the case (a) or $\gamma = \bar c$ in the case (b) is the constant described in Remark 4.3.

If the assertion is false, then there are $t_k \to \infty$, $S_k \in \mathcal{S}_{t_k}(\omega_k)$ with $\|S_k\| \to \infty$. Without loss of generality, we may assume that $S_k \in \mathcal{R}_{t_k}(\omega_k,\omega_k)$. To see this, note that by Remark 4.3 we can always ensure that $R_kS_k \in \mathcal{R}_{t_k}(\omega_k,\omega_k)$ for some $R_k \in \mathcal{S}_\gamma$. It is easy to see that $\|R_kS_k\| \geq \|S_k\|\|R_k^{-1}\|^{-1} \geq \|S_k\|\delta \to \infty$ as $k \to \infty$.

Fix some $\omega \in \Pi(\Theta,h)$. The set $\mathcal{R}(\omega,\omega)$ is a semigroup and irreducible by Proposition 5.3. We may therefore use Lemma 5.2 to find constants $1 \geq \varepsilon_1 > 0$ and $T > 0$ such that for all $x \in \mathbb{K}^n$ and all $B \in \mathbb{K}^{n\times n}$ there is an $R \in \mathcal{R}_{\leq T}(\omega,\omega)$ with $\|BRx\| \geq \varepsilon_1\|B\|\|x\|$.

Now define $\varepsilon := \min\{1,\varepsilon_1\delta^2\}$ and choose k large enough such that

$$\|S_k\| > 4/\varepsilon.$$

Fix $U \in \mathcal{R}_{\leq\gamma}(\omega_k, \omega)$ and $V \in \mathcal{R}_{\leq\gamma}(\omega, \omega_k)$ and pick an arbitrary $x_0 \in \mathbb{K}^n, \|x_0\| = 1$, such that $\|S_k x_0\| \geq \|S_k\| \varepsilon/2$. Then we can choose $R_1 \in \mathcal{R}_{\leq T}(\omega, \omega)$ such that

$$\begin{aligned}\|S_k V R_1 U S_k x_0\| &\geq \varepsilon_1 \|S_k V\| \|U S_k x_0\| \geq \varepsilon_1 \|S_k\| \|V^{-1}\|^{-1} \|U^{-1}\|^{-1} \|S_k x_0\| \\ &\geq \left(\|S_k\| \frac{\varepsilon}{2} \right)^2.\end{aligned}$$

Note that by construction $S_k V R_1 U S_k \in \mathcal{R}_{\leq 2t_k+T+2\gamma}(\omega_k, \omega_k)$. Applying the same arguments again, we can choose $R_2 \in \mathcal{R}_{\leq T}(\omega, \omega)$ such that

$$\|S_k V R_2 U S_k V R_1 U S_k x_0\| \geq \left(\|S_k\| \frac{\varepsilon}{2} \right)^3.$$

Arguing inductively we construct times τ_l with $l t_k \leq \tau_l \leq l(t_k + T + 2\gamma)$ and matrices $T_l \in \mathcal{R}_{\tau_l}(\omega_k, \omega_k)$ with

$$\frac{1}{\tau_l} \log \|T_l\| \geq \frac{l}{\tau_l} \log \left(\|S_k\| \frac{\varepsilon}{2} \right) \geq \frac{l}{\tau_l} \log 2 \geq \frac{1}{t_k + T + 2\gamma} \log 2 > 0.$$

This contradicts the assumption that $\limsup_{l\to\infty} \frac{1}{\tau_l} \log \|T_l\| \leq 0$, which follows from $\hat{\rho} = 0$.

(ii) A standard argument shows that $\mathcal{R}_\infty(\omega, \zeta)$ is closed and by part (i) it is bounded. Thus we have to show that there are nonzero elements. Now Lemma 4.9 shows that there exists a constant $C > 0$ and sequences $t_k \to \infty, S_k \in \mathcal{R}_{t_k}(\omega, \zeta)$ with $\|S_k\| \geq C$ for all $k \in \mathbb{N}$. By (i) the sequence is bounded so that it has a convergent subsequence with nonzero limit. By definition this limit is contained in $\mathcal{R}_\infty(\omega, \zeta)$.

(iii) As $\mathcal{R}_\infty(\omega, \zeta) \subset \mathcal{S}_\infty(\omega)$, it is clear from (i) that $\mathcal{S}_\infty(\omega)$ is nonempty and not equal to $\{0\}$. Closedness is immediate from the definition and so compactness follows from (i).

(iv) This is an easy exercise.

(v) Let $t_k \to \infty$, $u_k \in \mathcal{U}(\omega)$ be sequences such that $\Phi_{u_k}(t_k, 0) \to S \in \mathcal{S}_\infty(\omega)$. Fix $t \geq 0$. Applying Lemma 4.4 we may assume that there exists a $u \in \mathcal{U}(\omega)$ such that $\Phi_{u_k}(s, 0) \to \Phi_u(s, 0)$ uniformly for $s \in [0, t + 3h]$. For some $\zeta \in \Pi(\Theta, h)$, we have that $\Phi_u(t, 0) \in \mathcal{R}(\omega, \zeta)$.

We now treat the case $h \in (0, \infty)$. If the limit function u has no discontinuity in $(t, t+3h)$, then for all k large enough the parameter variations u_k have no discontinuity in $(t + h/2, t + 5h/2)$. This implies that we may introduce a discontinuity at $s = t + 3h/2$, and the functions

$$v_k(\sigma) := \begin{cases} u(\sigma) & \text{if } \sigma < t + 3h/2, \\ u_k(\sigma) & \text{if } \sigma \geq t + 3h/2 \end{cases}$$

are admissible parameter variations. Furthermore,

$$\Phi_{v_k}(t_k, 0) = \Phi_{u_k}(t_k, t + 3h/2) \Phi_u(t + 3h/2, 0)$$

and so

$$\begin{aligned}\|\Phi_{v_k}(t_k, 0) - \Phi_{u_k}(t_k, 0)\| \leq \|\Phi_{u_k}(t_k, t + 3h/2)\| \\ \times \|\Phi_{u_k}(t + 3h/2, 0) - \Phi_u(t + 3h/2, 0)\|,\end{aligned} \tag{6.3}$$

which converges to 0 for $k \to \infty$. (Here we are using (i) to bound the first factor on the right independently of t_k.) Now the construction implies that

$$\Phi_{v_k}(t_k, t) \in \mathcal{S}(\zeta).$$

If we extract a convergent subsequence of $\Phi_{v_k}(t_k, t)$ with limit T, then we have $T \in \mathcal{S}_\infty(\zeta)$. Also by (6.3) we have $S = T\Phi_u(t, 0)$. This shows the assertion.

If u has a discontinuity $s \in (t, t + 3h)$, then there exists a sequence $s_k \to s$, where each s_k is a discontinuity of u_k. This implies that the following function is an admissible parameter variation:

$$v_k(\sigma) := \begin{cases} u(\sigma), & 0 \le \sigma < s, \\ u_k(\sigma - s + s_k), & s \le \sigma \le t_k + s - s_k. \end{cases}$$

Again we see

$$\|\Phi_{v_k}(t_k + s - s_k, 0) - \Phi_{u_k}(t_k, 0)\| \le \|\Phi_{u_k}(t_k, s_k)\| \|\Phi_{u_k}(s_k, 0) - \Phi_u(s, 0)\|,$$

which converges to 0 by the uniform convergence of the u_k and as $s - s_k \to 0$. As before we may extract a convergent subsequence of the sequence $\Phi_{v_k}(t_k + s - s_k, t) \in \mathcal{S}(\zeta)$, and for the limit we have that $S = T\Phi_u(t, 0)$.

If $h = \infty$ and (A6) holds, then by Remark 3.2(iv) there are nonnegative times $s_k \to 0$ and $S_k \in \mathcal{R}_{s_k}(\zeta, u_k(t))$. Then we have

$$\Phi_{u_k}(t_k, t) S_k \Phi_u(t, 0) \in \mathcal{S}_{t_k + s_k}(\omega).$$

Defining $T_k := \Phi_k(t_k, t) S_k \in \mathcal{S}(\zeta)$ we may assume, without loss of generality, that $T_k \to T \in \mathcal{S}_\infty(\zeta)$, and it follows that $T\Phi_u(t, 0) = S$. This shows the assertion.

(vi) Fix $\omega \in \Pi(\Theta, h)$. As we have noted, the set $\mathcal{R}(\omega, \omega)$ is a semigroup, which is irreducible by Proposition 5.3. By (iv) it is easy to see that if $S \in \mathcal{R}(\omega, \omega) \cup \mathcal{R}_\infty(\omega, \omega)$ and $T \in \mathcal{R}_\infty(\omega, \omega)$, then $ST, TS \in \mathcal{R}_\infty(\omega, \omega)$ (where we have used the assumption $\hat{\rho} = 0$; otherwise some further factors appear according to (iv)). Using (ii) this shows that $\mathcal{R}_\infty(\omega, \omega)$ is a nonzero semigroup ideal of the irreducible semigroup

$$\mathcal{R}_\infty(\omega, \omega) \cup \mathcal{R}(\omega, \omega).$$

By [29, Lem. 1] this shows irreducibility of $\mathcal{R}_\infty(\omega, \omega)$. The second assertion follows from $\mathcal{R}_\infty(\omega, \omega) \subset \mathcal{S}_\infty(\omega)$. □

The following interesting observation is obtained through the previous proof.

COROLLARY 6.2. *Under the assumption of Lemma* 6.1 *the set* $\mathcal{S}(A, \mathcal{U})$ *is bounded if* $\hat{\rho} = 0$.

Proof. If the assertion is false, then there exists a sequence $\|S_k\| \to \infty$. This is brought to a contradiction in the proof of Lemma 6.1(i) of the previous theorem. □

We note the following corollary with respect to the maps $\omega \mapsto \mathcal{S}_\infty(\omega)$, $(\omega, \zeta) \mapsto \mathcal{R}_\infty(\omega, \zeta)$.

COROLLARY 6.3. *Consider system* (2.1) *with* (A1)–(A5). *Assume that* $A(\Theta)$ *is irreducible and let* (A6) *hold. Then the set-valued maps*

$$\omega \mapsto \mathcal{S}_\infty(\omega), \tag{6.4}$$

$$(\omega, \zeta) \to \mathcal{R}_\infty(\omega, \zeta) \tag{6.5}$$

are Lipschitz continuous on $\Pi(\Theta,h)$*, resp.,* $(\Pi(\Theta,h))^2$*, with respect to the Hausdorff topology.*

Proof. Without loss of generality, we may assume that $\hat\rho = 0$ so that in particular the set of evolution operators $\mathcal{S}(A,\mathcal{U})$ is bounded by Corollary 6.2. This and the assertions imply that Lemma 4.6(v) is applicable and the map $(\omega,t) \mapsto S_t(\omega)$ is Lipschitz continuous in ω uniformly in t. Thus if $S_k \to S$ for $S_k \in \mathcal{S}_{t_k}(\omega_1), t_k \to \infty$, then for $\omega_2 \in \Pi(\Theta,h)$ there exist evolution operators $R_k \in \mathcal{S}_{t_k}(\omega_2)$ with $\|S_k - R_k\| \le L\|\omega_1 - \omega_2\|$. We extract a convergent subsequence from the sequence $\{R_k\}_{k\in\mathbb{N}}$ with limit R. Then $\|S - R\| \le L\|\omega_1 - \omega_2\|$. By symmetry this implies the assertion. The proof for (6.5) is, of course, exactly the same. ∎

We now define for $\omega \in \Pi(\Theta,h)$ the function $v_\omega : \mathbb{K}^n \to \mathbb{R}_+$ by setting

$$v_\omega(x) := \max\{\|Sx\| \mid S \in \mathcal{S}_\infty(\omega)\}. \tag{6.6}$$

Using Lemma 6.1(iii) and (vi) it is easy to see that for every $\omega \in \Pi(\Theta,h)$ the function defined in (6.6) is a norm on $\mathbb{K}^n$. The following result shows that in this manner we have defined a family of parameterized Lyapunov functions for our system.

THEOREM 6.4. *Consider system* (2.1) *with* (A1)–(A5)*. Assume that* $A(\Theta)$ *is irreducible and let* $\omega \in \Pi(\Theta,h)$ *be arbitrary. Then*

(i) *for all* $u \in \mathcal{U}(\omega), t \ge 0$ *and all* $x \in \mathbb{K}^n$ *it holds that*

$$v_\zeta(\Phi_u(t,0)x) \le e^{\hat\rho t}\, v_\omega(x) \tag{6.7}$$

whenever $\Phi_u(t,0) \in \mathcal{R}_t(\omega,\zeta)$ *for* $\zeta \in \Pi(\Theta,h)$*. In particular, for all* $t \ge s \ge 0$ *it holds that*

$$v_{u(t^-),\tau^-(u,t)}(\Phi_u(t,0)x) \le e^{\hat\rho(t-s)}\, v_{u(s^-),\tau^-(u,s)}(\Phi(s,0)x).$$

(ii) *for every* $x \in \mathbb{K}^n$*,* $\omega \in \Pi(\Theta,h)$*, and* $t \ge 0$ *there exist* $u \in \mathcal{U}(\omega)$ *and a piecewise continuous map* $\zeta : [0,t] \to \Pi(\Theta,h)$*, with* $\zeta(0) = \omega$*, and such that for all* $s \in [0,t]$ *we have*

$$v_{\zeta(s)}(\Phi_u(s,0)x) = e^{\hat\rho s}\, v_\omega(x).$$

If $h = \infty$*, then* ζ *may be chosen to be continuous. If* $h < \infty$ *and* $\omega = (\theta,\tau) \in \Theta \times [0,h)$*, the function* ζ *may be chosen so that its discontinuities on* $[0,t)$ *coincide with those of* u*. Otherwise,* ζ *may have one further discontinuity at* 0*.*

Proof. Without loss of generality, we may assume that $\hat\rho = 0$.

(i) Fix $u \in \mathcal{U}(\omega), t \ge 0$ and assume that $\Phi_u(t,0) \in \mathcal{R}_t(\omega,\zeta)$ for a suitable $\zeta \in \Pi(\Theta,h)$. Assume furthermore that $v_\zeta(\Phi_u(t,0)x) > v_\omega(x)$. Then by definition $\|T\Phi_u(t,0)x\| > v_\omega(x)$ for some $T \in \mathcal{S}_\infty(\zeta)$. Now Lemma 6.1(iv) shows that $T\Phi_u(t,0) \in \mathcal{S}_\infty(\omega)$. Therefore $v_\omega(x) \ge \|T\Phi_u(t,0)x\|$, which is a contradiction.

The second assertion is simply a special case of the first statement.

(ii) Fix $x \in \mathbb{K}^n$, $\omega \in \Pi(\Theta,h)$, and $t \ge 0$ and let $S \in \mathcal{S}_\infty(\omega)$ be such that $\|Sx\| = v_\omega(x)$. By Lemma 6.1(iv) there exist $\hat\zeta \in \Pi(\Theta,h)$ and $\Phi_u(t,0) \in \mathcal{R}_t(\omega,\hat\zeta)$, $T \in \mathcal{S}_\infty(\hat\zeta)$ such that $S = T\Phi_u(t,0)$.

If $h = \infty$, we set $\zeta(s) = u(s)$, $s \in [0,t]$. To treat the case $h \in (0,\infty)$ let $\omega = (\theta,\tau)$. If $0 \le \tau < h$ and $t_0 \le t$ is the smallest positive discontinuity of u, then define $\zeta(s) = (u(s), \min\{\tau + s, h\})$ for $s \in [0,t_0]$ and $\zeta(s) = (u(t^-),\tau^-(u,t))$ for $s \in (t_0,t)$ and $\zeta(t) = \hat\zeta$. This is clearly a piecewise continuous map, whose discontinuities coincide with those

of u on $[0,t)$ and which satisfies $\zeta(0) = (\theta,\tau)$ as by assumption $u(0) = \theta$. This construction also works if $\omega = (\theta,h)$ and $u(0) = \theta$. Otherwise, if $u(0) \neq \omega$, we define $\zeta(0) = \omega$ and $\zeta(s) = (u(t^-), \tau^-(u,t))$ for $s \in (0,t)$ and $\zeta(t) = \hat{\zeta}$.

In all, ζ is defined in such a manner that for all $s \in (0,t]$ we have $\Phi_u(s,0) \in \mathcal{R}(\omega,\zeta(s))$, and for $s \in [0,t)$ it holds that $u(s+\cdot) \in \mathcal{U}(\zeta(s))$. Then it follows from Lemma 6.1(iv) that $T\Phi_u(t,s) \in \mathcal{S}_\infty(\zeta(s))$ for $s \in [0,t]$ and we have by part (i) for $s \in [0,t]$ that

$$v_\omega(x) = \|Sx\| = \|T\Phi_u(t,s)\Phi_u(s,0)x\| \leq v_{\zeta(s)}(\Phi_u(s,0)x) \leq v_\omega(x).$$

This concludes the proof. □

The previous result has a particularly easy interpretation in the case of linear switching systems, which we briefly discuss. Let $A(\Theta) = \{A_1,\dots,A_m\}$ be a finite, irreducible set and assume we are given a dwell time $h \in (0,\infty)$. As the system has no other possibility than to stay in a certain A_i for a time period of at least length h after a discontinuity, we see that for $\tau \in [0,h)$ we have $\mathcal{S}_\infty(i,\tau) = \mathcal{S}_\infty(i,h)e^{-\hat{\rho}(h-\tau)}e^{A(i)(h-\tau)}$. Thus the norms $v_{i,\tau}$ are related through the equality

$$v_{i,\tau}(x) = e^{-\hat{\rho}(h-\tau)}v_{i,h}(e^{A(i)(h-\tau)}x), \quad \tau \in [0,h].$$

It is therefore sufficient to consider the norms $v_i := v_{i,h}$. If we investigate (6.7) with this in mind, we see that after discontinuities this equation contains no information. To be precise, if u has a discontinuity at 0 and $u(t) = i, t \in [0,h)$, then for $t \in [0,h)$ (6.7) is equivalent to the tautology $v_i(e^{A(i)h}x) = v_i(e^{A(i)h}x)$. So after switching, a transient phase is allowed. The interesting information is contained in the other times and the result yields a finite number of norms, which are of interest. We summarize this in the following statement.

COROLLARY 6.5. *Let $\{A_1,\dots,A_m\} \subset \mathbb{K}^{n\times n}$ be a finite irreducible set and let $h \in (0,\infty)$. Then the following two statements are equivalent:*

(i) $\hat{\rho}(A_1,\dots,A_m,h) \leq \rho$.

(ii) *There are norms $v_1,\dots,v_m$ on $\mathbb{K}^n$ with the following properties:*

$$v_i(e^{A_i t}x) \leq e^{\rho t}v_i(x) \quad \text{for all } t \geq 0, x \in \mathbb{K}^n, i = 1,\dots,m, \tag{6.8}$$

$$v_j(e^{A_j t}x) \leq e^{\rho t}v_i(x) \quad \text{for all } t \geq h, x \in \mathbb{K}^n, i,j = 1,\dots,m. \tag{6.9}$$

Proof. (i)⇒(ii): By assumption we may apply the results of Theorem 6.4 to the system $\Sigma = (\Theta,\Theta_1,h,A)$ given by $\Theta = \{1,\dots,m\}, \Theta_1 = \{0\}, A(i) = A_i$. Define the norms v_i by $v_i := v_{i,h}$, where $v_{i,h}$ is defined according to (6.6). Now consider the admissible parameter variation $u \equiv i$. For this we have $u \in \mathcal{U}(i,h)$ and $\Phi_u(t,0) = e^{A_i t} \in \mathcal{R}_t((i,h),(i,h))$ for all $t \geq 0$ so that (6.7) implies (6.8). If we consider

$$u(t) := \begin{cases} i & \text{for } t < 0, \\ j & \text{for } t \geq 0, \end{cases}$$

then $u \in \mathcal{U}(i,h)$ and $\Phi_u(t,0) = e^{A_j t} \in \mathcal{R}_t((i,h),(j,h))$ for all $t \geq h$. In this case, (6.7) implies (6.9).

(ii)⇒(i): By the discussion in section 2 and by Corollary 4.5, it is sufficient to show that all Lyapunov exponents $\lambda(x,u)$ are upper bounded by ρ. So fix $0 \neq x \in \mathbb{K}^n$ and an admissible parameter variation u. If u has no discontinuities on an interval of the form (a,∞), where $a \geq 0$, the assertion is obvious from (6.8). Otherwise let $t_0,t_1,\dots$ denote the switching times of u and let $i(k)$ be such that $u(t) = i(k)$

for $t \in [t_k, t_{k+1})$. Without loss of generality let $t_0 = 0$, which we may assume as $\lambda(x,u) = \lambda(x, u(\cdot - t_0))$. Then we have by (6.8) that

$$v_{i(0)}(\exp(A_{i(0)}t)x) \leq e^{\rho t} v_{i(0)}(x) \quad \text{for } t \in [t_0 + h, t_1],$$

and so for $t \in [t_1 + h, t_2]$ it follows, again using (6.9), that

$$\begin{aligned} v_{i(1)}(\Phi_u(t,0)x) &= v_{i(1)}(\exp(A_{i(1)}(t-t_1))\exp(A_{i(0)}t_1)x) \\ &\leq e^{\rho(t-t_1)} v_{i(0)}(\exp(A_{i(0)}t_1)x) \leq e^{\rho t} v_{i(0)}(x). \end{aligned}$$

By induction we obtain for $t \in [t_k + h, t_{k+1}]$ that

$$\frac{1}{t}\log\left(v_{i(k)}(\Phi_u(t,0)x)\right) \leq \rho + \frac{1}{t}\log(v_{i(0)}(x)).$$

As the growth in the intervals $[t_k, t_k + h]$ is bounded, and as $v_{i(0)} \leq C v_i, i = 1, \ldots, m$, for a suitable constant C, this implies that $\lambda(x,u) \leq \rho$, as desired. ∎

We are now aiming at a continuity result for the norms v_ω. To this end we need a notion of distance between norms. We therefore introduce the space of continuous, positively homogeneous functions on $\mathbb{K}^n$ defined by

$$\text{Hom}\,(\mathbb{K}^n, \mathbb{R}) := \{f : \mathbb{K}^n \to \mathbb{R} \,|\, \forall \alpha \geq 0 : f(\alpha x) = \alpha f(x) \text{ and } f \text{ is continuous on } \mathbb{K}^n\}.$$

Clearly, all norms on $\mathbb{K}^n$ are elements of Hom $(\mathbb{K}^n, \mathbb{R})$. This space becomes a Banach space if equipped with the norm

$$\|f\|_{\infty,\text{hom}} := \max\{|f(x)| \mid \|x\|_2 = 1\}.$$

PROPOSITION 6.6. *Consider system* (2.1) *with* (A1)–(A5). *Assume that* $A(\Theta)$ *is irreducible and let* (A6) *hold. Then the map*

$$\omega \mapsto v_\omega \tag{6.10}$$

is Lipschitz continuous from $\Pi(\Theta, h)$ *to* Hom $(\mathbb{K}^n, \mathbb{R})$.

Proof. Fix $\omega, \zeta \in \Pi(\Theta, h)$. By definition we have

$$\|v_\omega - v_\zeta\|_{\infty,\text{hom}} = \max_{\|x\|_2 = 1} |v_\omega(x) - v_\zeta(x)|.$$

Fix $x \in \mathbb{K}^n$ and let $v_\omega(x) = \|\tilde{S}x\|$ for a suitable $\tilde{S} \in \mathcal{S}_\infty(\omega)$. Then there is a $T \in \mathcal{S}_\infty(\zeta)$ such that $\|\tilde{S} - T\| \leq d_H(\mathcal{S}_\infty(\omega), \mathcal{S}_\infty(\zeta))$ and we obtain

$$v_\omega(x) - v_\zeta(x) \leq \|\tilde{S}x\| - \|Tx\| \leq \|\tilde{S} - T\|\|x\| \leq C d_H(\mathcal{S}_\infty(\omega), \mathcal{S}_\infty(\zeta))\|x\|_2,$$

where C is a constant such that $\|x\| \leq C\|x\|_2$. This shows that

$$\|v_\omega - v_\zeta\|_{\infty,\text{hom}} \leq C d_H(\mathcal{S}_\infty(\omega), \mathcal{S}_\infty(\zeta)).$$

Now the assertion follows from Corollary 6.3. ∎

COROLLARY 6.7. *Consider system* (2.1) *with* (A1)–(A5). *Assume that* $A(\Theta)$ *is irreducible and let one of the following assumptions be satisfied:*

(a) $h \in (0, \infty)$.

(b) $h = \infty$ *and* (A6) *is satisfied.*

Then there exists a constant $1 \leq C \in \mathbb{R}$ *such that for all* $\omega, \zeta \in \Pi(\Theta, h)$ *and all* $x \in \mathbb{K}^n$ *we have*

$$C^{-1} v_\omega(x) \leq v_\zeta(x) \leq C v_\omega(x). \tag{6.11}$$

Proof. We may assume that $\hat{\rho} = 0$.

It is clearly sufficient to prove the inequality on the left-hand side, as the other follows by symmetry. Let $\omega, \zeta \in \Pi(\Theta, h)$ be arbitrary. Fix $x \in \mathbb{K}^n$ and let $S \in \mathcal{S}_\infty(\omega)$ be such that $v_\omega(x) = \|Sx\|$. Fix an arbitrary $\omega_0 \in \Pi(\Theta, h)$. Using Remark 4.3 we have that $\mathcal{R}_{\leq \max\{2h, \bar{c}\}}(\omega, \omega_0), \mathcal{R}_{\leq \max\{2h, \bar{c}\}}(\omega_0, \zeta) \neq \emptyset$. By Lemma 5.2 there exists $\varepsilon > 0$ such that for all $x \in \mathbb{K}^n, B \in \mathbb{K}^{n \times n}$ there is an $R \in \mathcal{R}_\infty(\omega_0, \omega_0)$ with

$$\|BRx\| \geq \varepsilon \|B\| \|x\|.$$

Choose $T_1 \in \mathcal{R}_{s_1}(\zeta, \omega_0), T_2 \in \mathcal{R}_{s_2}(\omega_0, \omega)$ for $s_1, s_2 \leq \max\{2h, \bar{c}\}$. Then we may choose $R \in \mathcal{R}_\infty(\omega_0, \omega_0)$ such that $ST_2RT_1 \in \mathcal{S}_\infty(\zeta)$ (by Lemma 6.1(iv)) and so that

$$\begin{aligned} v_\zeta(x) &\geq \|ST_2RT_1x\| \geq \varepsilon \|ST_2\| \|T_1x\| \\ &\geq \varepsilon (\min\{\|\Phi_u(s,0)^{-1}\|^{-1} \mid u \in \mathcal{U}, s \in [0, \max\{2h, \bar{c}\}]\})^2 \|Sx\| \geq C^{-1} v_\omega(x) \end{aligned}$$

for a constant $C \geq 1$ and independent of ω, ζ, and x. This shows the assertion. ∎

Remark 6.8. Note that the construction of parameterized Lyapunov functions for reducible systems is now an easy exercise by using the upper block triangular structure (5.1). In general, however, only a decay of $\hat{\rho} + \varepsilon$, where $\varepsilon > 0$ is arbitrary, will be achievable. See [16, 34] for related results in the case of linear inclusions.

7. The Gelfand formula. In this section we give an application of the existence of the parameterized Lyapunov functions we have described so far. One of the classical results in the analysis of families of linear time-varying systems states that under certain conditions the exponential growth rate can be approximated by just considering the subset of periodic systems within the family. Results to this effect can be found in [7, 11, 13, 16]. We now show that the same statement is true for our class of systems. In our case periodicity of the underlying parameter variation is the natural assumption, which is analyzed in what follows.

For $t \in \mathbb{R}_+$ we define the set of evolution operators corresponding to periodic $u \in \mathcal{U}$ by

$$\mathcal{P}_t := \bigcup_{\omega \in \Pi(\Theta, h)} \mathcal{R}_t(\omega, \omega).$$

Then we may define the normalized supremum over the spectral radii by

$$\bar{\rho}_t := \sup \left\{ \frac{1}{t} \log r(S) \mid S \in \mathcal{P}_t \right\},$$

and the supremum of the exponential growth rates obtainable by periodic parameter variations is defined by

$$\bar{\rho} := \limsup_{t \to \infty} \bar{\rho}_t.$$

As it is clear that $\bar{\rho}_t \leq \hat{\rho}_t$ for all $t \geq 0$, we obtain immediately that $\bar{\rho} \leq \hat{\rho}$. We intend to show that these quantities are equal. To this end we need the following lemma.

LEMMA 7.1. *Consider system* (2.1) *with* (A1)–(A5). *Assume that* $A(\Theta)$ *is irreducible and let one of the following assumptions be satisfied:*

(a) $h \in (0, \infty)$.
(b) $h = \infty$ *and* (A6) *is satisfied.*
Then there exist $\omega \in \Pi(\Theta, h)$, $x \in \mathbb{K}^n, v_\omega(x) = 1$, *and a sequence* $S_k \in \mathcal{R}_{t_k}(\omega, \omega)$, $t_k \geq 1$, *with*

$$e^{-\hat{\rho} t_k} S_k x \to x.$$

Proof. We may assume that $\hat{\rho} = 0$. Pick an arbitrary $\omega_0 \in \Pi(\Theta, h)$ and $z \in \mathbb{K}^n$ such that $v_{\omega_0}(z) = 1$. By Theorem 6.4(ii) there exist an ω_1 and $S_1 \in \mathcal{R}_1(\omega_0, \omega_1)$ such that $v_{\omega_1}(S_1 z) = v_{\omega_0}(z) = 1$. Applying this argument again, we see that there exist ω_2 and $S_2 \in \mathcal{R}_1(\omega_1, \omega_2)$ such that $v_{\omega_2}(S_2 S_1 z) = 1$. Repeating this argument inductively we obtain sequences $\{\omega_k\}_{k\in\mathbb{N}}$ and $\{S_k\}_{k\in\mathbb{N}}$ with

$$v_{\omega_k}(S_k S_{k-1}, \ldots, S_1 z) = 1 \quad \text{for all } k \in \mathbb{N}.$$

As $\Pi(\Theta, h)$ is compact, there exists a convergent subsequence $\omega_{k_l} \to \omega \in \Pi(\Theta, h)$. Applying Corollary 6.7 we may assume, without loss of generality, that $z_{k_l} := S_{k_l} S_{k_l - 1}, \ldots, S_1 z \to x$. We denote $T_{k_l} := S_{k_l} S_{k_l - 1}, \ldots, S_{k_{l-1}} \in \mathcal{R}(\omega_{k_{l-1}}, \omega_{k_l})$. After relabeling we return to the index k.

Now by Lemma 4.6(vi) and using assumption (a) or (b), the map $(\omega, \zeta) \to \mathcal{R}_t(\omega, \zeta)$ is upper semicontinuous uniformly in t (which is crucial, as we have no control over the length of the intervals needed to define the sequence $\{T_k\}$). Thus by convergence of $\omega_k \to \omega$ and for every $\varepsilon > 0$ there exists a k_0 such that for every $k \geq k_0$ there exists an $R_k \in \mathcal{R}(\omega, \omega)$ with $\|T_k - R_k\| < \varepsilon$ and so that $v_\omega(z_k - x) \leq \varepsilon$. Then we obtain that

$$\begin{aligned} v_\omega(R_k x - x) &\leq v_\omega(R_k - T_k) v_\omega(x) + v_\omega(T_k x - T_k z_k) + v_\omega(z_{k+1} - x) \\ &\leq \varepsilon \left(v_\omega(x) + v_\omega(T_k) + 1 \right). \end{aligned}$$

This implies that there exists a sequence $\{R_k\} \subset \mathcal{R}(\omega, \omega)$ with $R_k x - x \to 0$, as desired. □

Before we can state the main result of this section, we need a further observation for the case $h = \infty$.

PROPOSITION 7.2. *Let* $\Theta, \Theta_1 \in \mathrm{Co}\,(\mathbb{K}^m)$, $A \in C(\mathbb{K}^m, \mathbb{K}^{n\times n})$, *and* $h = \infty$ *satisfying* (A1)–(A5) *be given. Let* Θ_2 *be the largest convex set contained in* Θ_1 *such that* $0 \in \mathrm{ri}\,\Theta_2$. *Then*

$$\hat{\rho}(\infty, \Theta, \Theta_1, A) = \hat{\rho}(\infty, \Theta, \Theta_2, A).$$

Proof. It is clear that $\hat{\rho}(\infty, \Theta, \Theta_1, A) \geq \hat{\rho}(\infty, \Theta, \Theta_2, A)$ so that we only have to show the converse direction.

If $0 \in \mathrm{ri}\,\Theta_1$, there is nothing to show. Otherwise denote by X_2 the linear subspace generated by Θ_2 and denote by $X_2^\perp$ its orthogonal complement. Recall the definition (2.4) and choose $\theta(\cdot) \in \mathcal{U}$ such that for some $x_0 \neq 0$ we have

$$\hat{\rho}(\infty, \Theta, \Theta_1, A) = \lambda(x_0, \theta(\cdot)).$$

As mentioned before, this choice is possible using Corollary 4.5 and [13, Prop. 5.4.15].

Now θ may be decomposed as $\theta = \theta_1 + \theta_2$ such that $\dot{\theta}_1 : \mathbb{R}_+ \to X_2^\perp$ and $\dot{\theta}_2 : \mathbb{R}_+ \to \Theta_2$. Furthermore, as 0 is contained in the boundary of Θ_1, there exists a supporting hyperplane X in 0, which has to contain X_2. Hence there is a vector $d \neq 0$ such that

$\langle d, \dot\theta_1(t)\rangle \geq 0$ and $\langle d, \dot\theta_2(t)\rangle \equiv 0$ for all $t \geq 0$. Now Θ is compact and so $\langle d, \theta\rangle$ is bounded over $\theta \in \Theta$. This implies that the expression

$$c := \langle d, \theta(0)\rangle + \int_0^\infty \langle d, \dot\theta_1(t)\rangle dt = \lim_{t\to\infty} \langle d, \theta(t)\rangle$$

is well defined. If we introduce the set $\Theta_c := \{\eta \in \Theta \mid \langle d, \eta\rangle = c\}$, we see that

$$\operatorname{dist}(\theta(t), \Theta_c) \to 0 \text{ for } t \to \infty.$$

Thus for the set $\Theta_{c,\varepsilon} := \{\eta \in \Theta \mid \operatorname{dist}(\eta, \Theta_c) \leq \varepsilon\}$ we obtain $\theta(t) \in \Theta_\varepsilon$ for all t large enough. This implies that for all $\varepsilon > 0$ and for t large enough we have

$$\hat\rho(\infty, \Theta, \Theta_1, A) \geq \hat\rho(\infty, \Theta_{c,\varepsilon}, \Theta_1, A) \geq \lambda(\Phi_\theta(t,0)x_0, \theta(t+\cdot)) = \lambda(x_0, \theta(\cdot))$$

so that equality holds throughout. Now by Proposition 4.8 it follows that

$$\hat\rho(\infty, \Theta_c, \Theta_1, A) \geq \lim_{\varepsilon\to 0} \hat\rho(\infty, \Theta_{c,\varepsilon}, \Theta_1, A) = \hat\rho(\infty, \Theta, \Theta_1, A),$$

and the converse inequality holds because $\Theta_c \subset \Theta$. Furthermore, any admissible parameter variation with derivative in Θ_1, that remains in Θ_c, has to satisfy $\langle d, \theta(t)\rangle \equiv 0$. This implies $\langle d, \dot\theta(t)\rangle = 0$ a.e., from which it follows that $\dot\theta(t) \in \Theta_2$ a.e. Hence we have

$$\hat\rho(\infty, \Theta_c, \Theta_1, A) = \hat\rho(\infty, \Theta_c, \Theta_2, A).$$

This completes the proof. □

We are now ready to prove the main result of this section: the exponential growth rate $\hat\rho$ coincides with the maximum of the growth rates corresponding to periodic parameter variations $\bar\rho$.

THEOREM 7.3. *Consider a system* $\Sigma = (h, \Theta, \Theta_1, A)$ *satisfying* (A1)–(A5); *then*

$$\bar\rho(h, \Theta, \Theta_1, A) = \hat\rho(h, \Theta, \Theta_1, A). \tag{7.1}$$

Proof. Without loss of generality we may assume that $\hat\rho = 0$.

If $h = \infty$ and (A6) does not hold, then we may first assume that $0 \in \operatorname{ri}\Theta_1$ using Proposition 7.2. Let $X = \operatorname{span}\Theta_1$. Then with the notation $\Theta_z := \Theta \cap (z + X)$ we may write

$$\Theta = \bigcup_{z\in X^\perp} \Theta_z.$$

As each (nonempty) Θ_z is invariant under parameter variations with derivative in Θ_1, we see that

$$\hat\rho(\infty, \Theta, \Theta_1, A) = \sup_{z, \Theta_z \neq \emptyset} \hat\rho(\infty, \Theta_z, \Theta_1, A).$$

Thus if we can show the assertion for each of the terms on the right-hand side, it follows also for $(\infty, \Theta, \Theta_1, A)$. Note that (A6) is satisfied for $(\infty, \Theta_z, \Theta_1, A)$ so that from now on we may assume that $h \in (0, \infty)$ or (A6) is satisfied.

Furthermore, if $A(\Theta)$ is reducible, then there exists a regular $T \in \mathbb{K}^{n\times n}$ such that all matrices $A_0 \in A(\Theta)$ can be transformed to upper block triangular form as in (5.1). For this form it is easy to see that

$$\hat\rho(A,\mathcal{U}) = \max_{i=1,\dots,d} \hat\rho(A_i,\mathcal{U}) \quad \text{and} \quad \bar\rho(A,\mathcal{U}) = \max_{i=1,\dots,d} \bar\rho(A_i,\mathcal{U}). \tag{7.2}$$

Hence, if we show (7.1) for each of the irreducible blocks, then it follows for the overall system.

So assume now that $A(\Theta)$ is irreducible and that $h \in (0,\infty)$ or (A6) holds. By Lemma 7.1 there exist $\omega \in \Pi(\Theta,h), x \in \mathbb{K}^n, v_\omega(x) = 1$, and a sequence $S_k \in \mathcal{R}(\omega,\omega)$ such that $S_k x - x \to 0$. Then we have by [16, Lem. 2] for the eigenvalues $\lambda_i(k)$ of S_k that

$$0 \le \min_{1\le i\le n} 1 - |\lambda_i(k)| \le \min_{1\le i\le n} |1-\lambda_i(k)| \le C\|S_k x - x\|^{1/n},$$

where C is a constant depending only on the upper bound of $\|S_k\|$. Denoting by $\tilde\lambda_k$ an eigenvalue of S_k for which the minimum on the left is attained, we see that $|\tilde\lambda_k| \to 1$ as $k \to \infty$. As we have $|\tilde\lambda_k| \le 1$ and $t_k \ge 1$, we obtain $\bar\rho \ge 1/t_k \log|\tilde\lambda_k| \ge \log|\tilde\lambda_k|$, and it follows that $\bar\rho \ge 0$. This completes the proof. □

Remark 7.4. Note that the proof of the previous result shows for the particular case $\hat\rho = 0$ that

$$\limsup_{t\to\infty} \max\{r(S) \mid S \in \mathcal{P}_t\} = 0$$

holds. This statement is slightly stronger than that of Theorem 7.3.

8. Continuity of the exponential growth rate. One of the basic questions in stability theory is whether stability is a robust property in the space of systems. A first step toward answering this question is obtained by showing that the exponential growth rate is an upper semicontinuous function, because then the set of exponentially stable systems given by $\{\hat\rho < 0\}$ is open. It is, however, even more desirable to have continuous dependence of the growth rate on the data. We will first show that the Gelfand formula, which we just proved in Theorem 7.3, allows for an easy criterion of continuity. Unfortunately, we then have to present an example showing that, in the setup we have studied so far, $\hat\rho$ is not a continuous function of the data.

COROLLARY 8.1. *Let $\mathcal{N}$ be a subset of $\mathcal{L}$ such that the maps*

$$(h,\Theta,\Theta_1,A) \mapsto \mathcal{S}_t(h,\Theta,\Theta_1,A)$$

are continuous on $\mathcal{N}$ for all t large enough. Then the map

$$(h,\Theta,\Theta_1,A) \mapsto \hat\rho(h,\Theta,\Theta_1,A)$$

is continuous on $\mathcal{N}$.

Proof. We already know that $\hat\rho$ is upper semicontinuous on $\mathcal{N}$ by Proposition 4.8. The assumption implies that the maps $\bar\rho_t : \mathcal{N} \to \mathbb{R}$ are continuous for all t large enough by continuity of the spectral radius. Now $\bar\rho = \sup_{t>0} \bar\rho_t$ is lower semicontinuous as the supremum of continuous functions. Using Theorem 7.3, the function $\hat\rho = \bar\rho$ is both upper semicontinuous and lower semicontinuous, and thus continuous on $\mathcal{N}$. □

Example 8.2. Let $h = \infty$, $\Theta_1 := [-1,1] \times \{0\} \subset \mathbb{R}^2$, define $\Theta(0) = [0,2\pi] \times \{0\}$, and define the sets $\Theta(\phi) = B_\phi \Theta(0)$, where B_ϕ is the rotation matrix

$$B_\phi := \begin{bmatrix} \cos\phi & \sin\phi \\ -\sin\phi & \cos\phi \end{bmatrix}, \quad \phi \in (-\pi,\pi).$$

Define furthermore

$$A(\theta_1,\theta_2) = \begin{bmatrix} -1+3/2\cos^2\theta_1 & 1-3/2\sin\theta_1\cos\theta_1 \\ -1-3/2\sin\theta_1\cos\theta_1 & -1+3/2\sin^2\theta_1 \end{bmatrix}.$$

(The reader will most likely recognize the famous example of a periodic system of Hurwitz stable matrices that is unstable; see, e.g., [14, 33]. We recall the well-known fact that the characteristic polynomial of $A(\theta_1, \theta_2)$ is equal to $p(z) = z^2 + 1/2z + 1/2$ with zeros $-1/4 \pm i\sqrt{7}/4$ independent of θ.)

We will show that the exponential growth rate as a function of $\Theta(\phi)$ with all the other data left fixed has a discontinuity at 0. Clearly, the map $\phi \mapsto \Theta(\phi)$ is Lipschitz continuous.

For $0 \neq \phi \in (-\pi, \pi)$ only the constant functions are admissible parameter variations because Θ_1 only allows for variations in the first component. Hence for $\phi \neq 0$ we have $\hat{\rho}(\phi) = \max\{\operatorname{Re}\lambda \mid \lambda \in \sigma(B); B \in A(\Theta(\phi))\} = -1/4$.

On the other hand, time-varying systems are possible for $\phi = 0$ because $\Theta(0)$ is collinear to the admissible derivatives in Θ_1. In particular, we cannot expect the assumption of Corollary 8.1 to be satisfied, as with time-varying parameter variations we expect to be able to construct a much richer set of transition operators. In particular, if we define the admissible parameter variation

$$\theta(t) = \begin{cases} t, & t \in [0, 2\pi], \\ 4\pi - t, & t \in [2\pi, 4\pi], \end{cases}$$

and continue this function periodically, then we have the classical example on the interval $[0, 2\pi]$, where it is well known that

$$\Phi_\theta(2\pi, 0) = \begin{bmatrix} e^{\pi} & 0 \\ 0 & e^{-2\pi} \end{bmatrix}.$$

For the calculation of $\Phi_\theta(4\pi, 2\pi)$, numerical evaluation yields

$$\Phi_\theta(4\pi, 2\pi) = \begin{bmatrix} 0.0597 & -0.178 \\ 0.178 & 0.1932 \end{bmatrix}.$$

By calculating the spectral radius $r(\Phi_\theta(4\pi, 0)) = r(\Phi_\theta(4\pi, 2\pi)\Phi_\theta(2\pi, 0)) \approx 1.3799$, we see that the exponential growth rate corresponding to $\Theta(0)$ is positive.

The previous example is a bit unfair because the constraint on the derivative that can be effectively used is simply $\Theta_1 = \{0\}$ for $\phi \neq 0$. Another way of saying this is that there is a discontinuity hidden in the data in the previous example: at $\phi = 0$ the derivative constraint set changes discontinuously from $\{0\}$ to Θ_1. This shows that, so far, we were too lenient in our description of the system data.

With reasonable extra assumptions, however, it is possible to obtain (Lipschitz) continuity results in the spirit of [34], which for reasons of space appears in [36]; see also [37].

9. Conclusions. In this paper we have studied certain classes of families of LPV systems that are basically described by constraints on the distance between discontinuities and on the derivative in the time between discontinuities. Both the LPV system class and linear switching system class are special cases of the presented setup. For these classes parameter-dependent Lyapunov functions, which are norms for each fixed parameter, have been constructed in such a way that the resulting Lyapunov function characterizes the exponential growth rate in an infinitesimal manner. This result complements constructions of Lyapunov functions for linear inclusions in [5, 26, 34]. It was shown how the existence of such norms can be used to obtain a fairly simple proof of the Gelfand formula in this case. Conditions for continuous dependence of the growth rate on the data can be derived using the tools developed here. This is discussed in [36].

COMPUTATION OF THE (J, J')-LOSSLESS FACTORIZATION FOR GENERAL RATIONAL MATRICES*

DELIN CHU† AND DANIEL W. C. HO‡

Abstract. (J, J')-lossless factorization plays a central role in H_∞-control because it gives a simple and unified framework of H_∞-control from the viewpoint of classical network theory, and it includes the well-known inner–outer factorization of rational matrices, Wiener–Hopf factorization, and spectral factorization of positive rational matrices as special cases. However, up to now, there is still a lack of numerically reliable methods for this important factorization problem in a general setting. In this paper, we present necessary and sufficient solvability conditions and develop a numerically reliable algorithm based on a generalized eigenvalue approach for the (J, J')-lossless factorization of general rational matrices.

Key words. (J, J')-lossless factorization, rational matrix, eigenfactorization orthogonal transformation

1. Introduction.

Throughout this paper the following notation will be used:

- $J \in \mathbf{R}^{p\times p}$ *and* $J' \in \mathbf{R}^{m\times m}$ *are two given symmetric matrices.*
- $M \geq 0$ *means that* M *is symmetric and positive semidefinite.*
- *For any* $M, N \in \mathbf{R}^{n\times n}$ *with* M *nonsingular,* $\rho(M, N)$ *denotes the spectral radius of the pencil* $-sM + N$*, and* $\rho(N) := \rho(I, N)$*.*
- $\mathbf{C}_0, \mathbf{C}_+$ *denote the imaginary axis and open right half complex plane, respectively.*
- $\mathcal{R}^{p\times m}(s), \mathcal{RL}_\infty^{p\times m}(s)$ *denote the set of* $p \times m$ *real rational matrices and set of* $p \times m$ *proper real rational matrices having no poles on* $\mathbf{C}_0$*, respectively.*
- $G(s) = \left[\begin{array}{c|c} -sE + A & B \\ \hline C & D \end{array}\right]$ *means that* $G(s)$ *has a realization* $G(s) = D + C(sE - A)^{-1}B$*.*

The H_∞-control problem has been studied extensively based on several different approaches; see, e.g., [10, 14, 15, 17, 21, 22, 33, 35, 40] and the references therein. Among these approaches, the linear matrix inequality (LMI) approach [21, 22] has become very popular because it converts the H_∞-control problem into LMIs [19], where one works with larger size matrices to keep matrix equations linear rather than having to solve nonlinear matrix equations of Riccati type. This approach employs methods of semidefinite programming to compute the desired optimal H_∞-controllers. This is very attractive, because easy-to-use methods for semidefinite programming are readily available; see, e.g., [16, 20]. However, the computational complexity of this approach for a control plant with dimension n is up to $O(n^6)$ [44], which is rather high. Another remarkable approach is that of (J, J')-lossless factorization, which provides a simple and unified framework of an H_∞-control problem from the point of view of

classical network theory [2, 6, 9, 10, 13, 27, 30, 32, 33, 36, 38, 39]. This approach reduces the H_∞-control problem to a (J, J')-lossless factorization of a chain-scattering representation of the system. Generally, the existence and solution of the (J, J')-lossless factorization can be characterized by Riccati equations. Consequently, by the (J, J')-lossless factorization approach, the optimal controllers for the H_∞-control problem are obtained by solving the associated Riccati equations. Numerical methods for solving such Riccati equations have been developed in [4, 28, 34, 44], but these Riccati equations may become very ill-conditioned when the computed optimal H_∞-norm approaches the exact optimal H_∞-norm, which leads to these Riccati equations being very difficult to solve. Therefore, although every existing approach, including the LMI and (J, J')-lossless factorization approaches, has a method of solving the H_∞-control problem, many numerical problems associated with it remain to be studied.

In this paper, motivated by the importance of the (J, J')-lossless factorization for H_∞-control, we study the (J, J')-lossless factorization problem for general rational matrices.

DEFINITION 1 (see [36, 41]). (i) *A matrix* $\Theta(s) \in \mathcal{RL}_\infty^{p\times m}(s)$ *is* (J, J')*-unitary if*

$$\Theta^T(-s)J\Theta(s) = J' \quad \forall s \in \mathbf{C}.$$

(ii) *A matrix* $\Theta(s) \in \mathcal{RL}_\infty^{p\times m}(s)$ *is* (J, J')*-lossless if it is* (J, J')*-unitary and*

$$\Theta^T(\bar{s})J\Theta(s) \le J' \quad \forall s \in \mathbf{C}_0 \cup \mathbf{C}_+,$$

where $\bar{s}$ *is the complex conjugate of* s.

DEFINITION 2 (see [36, 41]). $G(s) \in \mathcal{R}^{p\times m}(s)$ *has a* (J, J')*-lossless factorization if it can be represented as a product*

$$G(s) = \Theta(s)\Xi(s),$$

where $\Theta(s) \in \mathcal{RL}_\infty^{p\times m}(s)$ *is* (J, J')*-lossless, and* $\Xi(s) \in \mathcal{R}^{m\times m}(s)$ *has neither zeros nor poles in* $\mathbf{C}_+$.

The notion of (J, J')-lossless factorization was first introduced in [41] in a geometrical context. It is a generalization of the well-known inner–outer factorization of rational matrices. It also includes spectral factorization and Wiener–Hopf factorization for positive rational matrices as special cases. Some connections between the (J, J')-lossless factorization and the chain-scattering formulation of H_∞-control were discussed in [10, 31]. The (J, J')-lossless factorization of proper rational matrices without zeros on $\mathbf{C}_0$ was studied in [29] based on the theory of conjugation developed in [36]. Later, the (J, J')-lossless factorization of general proper rational matrices was considered in [23], and the solvability conditions and state-space realizations of the factors $\Pi(s)$ and $\Theta(s)$ were derived there, based on a generalized eigenvalue approach. The (J, J')-lossless factorization problems in the setting of discrete-time systems with/without zeros on the unit circle were investigated in [7, 8]. The main existing result for the (J, J')-lossless factorization of general proper rational matrices can be summarized in Theorem 3 below, which is a slight extension of Theorem 1 in [23] and a continuous-time version of Theorem 7 in [7].

Assume that $G(s) = \left[\begin{array}{c|c} -sI + A & B \\ \hline C & D \end{array}\right] \in \mathcal{RL}_\infty^{p\times m}(s)$ is left invertible, i.e.,

$$\max_{s\in\mathbf{C}} \operatorname{rank} \begin{bmatrix} -sI + A & B \\ C & D \end{bmatrix} = n + m, \tag{1}$$

where $A \in \mathbf{R}^{n\times n}$, $B \in \mathbf{R}^{n\times m}$, $C \in \mathbf{R}^{p\times n}$, and $D \in \mathbf{R}^{p\times m}$. Then there exist an orthogonal matrix S and a nonsingular matrix T [25, 42] such that

$$S\begin{bmatrix} -sI+A & B \\ C & D \end{bmatrix}T = \begin{array}{c} \begin{matrix} n-n_{0\infty} & n_{0\infty} & m \end{matrix} \\ \begin{bmatrix} -sE_{nf}+A_{nf} & 0 & 0 \\ \star & -sE_{11}+A_{11} & A_{12} \\ \star & A_{21} & A_{22} \end{bmatrix} \end{array} \begin{matrix} \\ \}n_{0\infty} \\ \}m \end{matrix},$$

where E_{nf} is of full column rank, E_{11} is nonsingular, and

$$\begin{aligned} &\text{rank}\,(-sE_{nf}+A_{nf}) = n-n_{0\infty} \quad \forall s \in \mathbf{C}_0, \\ &\text{rank}\begin{bmatrix} -sE_{11}+A_{11} & A_{12} \\ A_{21} & A_{22} \end{bmatrix} = n_{0\infty}+m \quad \forall s \in \mathbf{C}\backslash\mathbf{C}_0. \end{aligned}$$

Partition S and T into

$$S = \begin{array}{c} \begin{matrix} n & p \end{matrix} \\ \begin{bmatrix} S_{11} & S_{12} \\ S_{21} & S_{22} \\ S_{31} & S_{32} \end{bmatrix} \end{array} \begin{matrix} \\ \}n_{0\infty} \\ \}m \end{matrix}, \quad T = \begin{array}{c} \begin{matrix} n-n_{0\infty} & n_{0\infty} & m \end{matrix} \\ \begin{bmatrix} T_{11} & T_{12} & T_{13} \\ T_{21} & T_{22} & T_{23} \end{bmatrix} \end{array} \begin{matrix} \}n \\ \}m \end{matrix}.$$

Furthermore, let the columns of the full column rank matrix

$$\begin{array}{c} \begin{matrix} r \end{matrix} \\ \begin{bmatrix} L_1 \\ L_2 \\ L_3 \end{bmatrix} \end{array} \begin{matrix} \}n \\ \}n \\ \}m \end{matrix}$$

span the stable eigenspace of the matrix pencil

$$\begin{bmatrix} -sI+A & 0 & B \\ -C^TJC & -sI-A^T & -C^TJD \\ D^TJC & B^T & D^TJD \end{bmatrix},$$

and let there exist a stable matrix $\Lambda \in \mathbf{R}^{r\times r}$ such that

$$\begin{bmatrix} A & 0 & B \\ -C^TJC & -A^T & -C^TJD \\ D^TJC & B^T & D^TJD \end{bmatrix}\begin{bmatrix} L_1 \\ L_2 \\ L_3 \end{bmatrix} = \begin{bmatrix} I_n & 0 & 0 \\ 0 & I_n & 0 \\ 0 & 0 & 0 \end{bmatrix}\begin{bmatrix} L_1 \\ L_2 \\ L_3 \end{bmatrix}\Lambda.$$

THEOREM 3 (cf. [7, 23]). *Given a $G(s) \in \mathcal{RL}_\infty^{p\times m}(s)$, let be its stabilizable and detectable realization, i.e.,*

$$\text{rank}\,[-sI+A \;\; B] = \text{rank}\begin{bmatrix} -sI+A \\ C \end{bmatrix} = n \qquad \forall s \in \mathbf{C}_0 \cup \mathbf{C}_+,$$

where $A \in \mathbf{R}^{n\times n}$, $B \in \mathbf{R}^{n\times m}$, $C \in \mathbf{R}^{p\times n}$, and $D \in \mathbf{R}^{p\times m}$. Then $G(s)$ has a (J, J')-lossless factorization if and only if the following conditions hold:

(i) *$G(s)$ is left invertible, i.e., (1) holds true.*

(ii) *There exists a nonsingular matrix $D_0 \in \mathbf{R}^{m\times m}$ such that $D_0^T S_{32} J S_{32}^T D_0 = J'$.*

(iii) *$r + n_{0\infty} = n$, matrix $[L_1\ T_{12}]$ is nonsingular, $X := [L_2\ 0][L_1\ T_{12}]^{-1} \geq 0$, and the algebraic Riccati equation*

$$YA^T + AY + YC^TJCY = 0 \tag{2}$$

has a solution $Y \geq 0$ such that $A + YC^TJC$ is stable.

(iv) *$\rho(XY) < 1$.*

Moreover, if the above conditions hold, then a (J, J')-lossless factorization is given by the factors $\Theta(s)$ and $\Xi(s)$:

$$\Theta(s) = \left[\begin{array}{cc|c} -sI+\Lambda & 0 & Z_1 \\ 0 & -sI+A & Z_2 \\ \hline CL_1+DL_3 & C & -S_{32}^T \end{array}\right] D_0, \tag{3}$$

$$\Xi(s) = -(J')^{-1} D_0^T \left[\begin{array}{c|c} -sI+A+YC^TJC & B+YC^TJD \\ \hline (S_{31}X+S_{32}JC)(I-YX)^{-1} & S_{32}JD \end{array}\right], \tag{4}$$

where

$$Z_1 = -\begin{bmatrix} I_r & 0 \end{bmatrix} \begin{bmatrix} L_1 - YL_2 & T_{12} \end{bmatrix}^{-1} (S_{31}^T + YC^TJS_{32}^T),$$
$$Z_2 = (I-YX)^{-1}Y(XS_{31}^T + C^TJS_{32}^T).$$

It is clear that Theorem 3 excludes all improper rational matrices. It is known that the state-space representation can only be used to describe proper rational matrices, while the descriptor-form representation can be used to describe any rational matrices. In [24], the (J, J')-lossless factorization problem for general rational matrices has been considered using the descriptor-form representation approach based on the concept of J-lossless conjugation [36]. The elegant results in [24] are based on (i) a realization of $G(s) = \left[\begin{array}{c|c} -sE+A & B \\ \hline C & D \end{array}\right]$, which is in standard form (i.e., there do not exist nonsingular matrices M and N and an integer $r > 0$ such that $M(-sE+A)N = \left[\begin{array}{cc} -s\hat{E}+\hat{A} & 0 \\ 0 & I_r \end{array}\right]$) and satisfies $E^2 = E$; (ii) the generalized Lyapunov equation

$$\begin{cases} AYE^T + EYA^T + EYC^TJCYE^T = 0, \quad E \text{ is singular,} \\ A^T + C^TJCYE^T - sE^T \text{ is nonsingular } \forall s \in \mathbf{C}_+, \quad EYE^T \geq 0, \\ \text{the null space of } YE^T \text{ contains the eigenspace of} \\ \quad -sE^T + A^T \text{ corresponding to the eigenvalues on } \mathbf{C}_0 \cup \{\infty\}; \end{cases} \tag{5}$$

and (iii) the existence of matrices $D_\pi \in \mathbf{R}^{m\times m}$, $K \in \mathbf{R}^{m\times n}$ and a (J, J')-lossless matrix D_c satisfying

$$\begin{bmatrix} \tilde{C} & D \end{bmatrix} = D_c \begin{bmatrix} K & D_\pi \end{bmatrix}, \ \tilde{C} \text{ is known.} \tag{6}$$

Theoretically, for any realization of $G(s)$, we can always find a new realization, which is in the standard form and satisfies $E^2 = E$. However, the computation of a realization of $G(s) \in \mathcal{R}^{p\times m}(s)$, which is in standard form and satisfies $E^2 = E$, is very ill-conditioned [37, 42] and cannot be obtained in a numerically reliable manner. This issue is easy to understand; for instance, let us consider a very simple example. Let $G(s)$ be of the form

$$G(s) = \left[\begin{array}{ccc|c} -sE_{11}+A_{11} & A_{12} & A_{13} & B_1 \\ A_{21} & 0 & 0 & B_2 \\ 0 & 0 & A_{33} & B_3 \\ \hline C_1 & C_2 & C_3 & D \end{array}\right], \quad E_{11} \text{ and } A_{33} \text{ are nonsingular.}$$

Then, in order to get a realization of $G(s)$, which is in standard form, we have to compute A_{33}^{-1}. However, it is well known that the computation of A_{33}^{-1} is numerically unstable and will contain a large error if A_{33} is ill-conditioned. This implies that the

computation of a realization of a given rational matrix $G(s)$, which is in standard form, is a difficult task in general and should be avoided if possible. Furthermore, the generalized Lyapunov equation (5) is very difficult to solve, and it is not clear under what conditions there exist D_π, K, and a (J, J')-lossless matrix D_c satisfying (6) because of the requirement that D_c be (J, J')-lossless. Thus, the computation of matrices $D_\pi \in \mathbf{R}^{m\times m}$, $K \in \mathbf{R}^{m\times n}$, and a (J, J')-lossless matrix D_c has to be studied further.

Although the (J, J')-lossless factorization has been studied by many researchers, up to now there is still a lack of numerically reliable methods for solving it with general rational matrices. In this paper we will develop a numerically reliable method to verify the solvability and construct a solution for the (J, J')-lossless factorization problem of general rational matrices. Our idea can be outlined as follows:

- For any rational matrix $G(s) \in \mathcal{R}^{p\times m}(s)$, $G(s)$ has a minimal realization of the descriptor-form $G(s) = [\begin{smallmatrix} -sE+A & B \\ \hline C & 0 \end{smallmatrix}]$ with $E, A \in \mathbf{R}^{n\times n}$, $B \in \mathbf{R}^{n\times m}$, and $C \in \mathbf{R}^{p\times n}$, i.e.,
$$\operatorname{rank}[\alpha E + \beta A \quad B] = \begin{bmatrix} \alpha E + \beta A \\ C \end{bmatrix} = n \quad \forall (\alpha, \beta) \in \mathbf{C}^2 \backslash \{(0, 0)\}.$$
Such a minimal realization can always be obtained from any given realization of $G(s)$ by using the well-known controllability–observability staircase form algorithm [25, 26, 42], which is numerically backward stable.
- $G(s)$ can be factored as
$$G(s) = \left[\begin{array}{c|c} -sE + A + BF & B \\ \hline C & 0 \end{array}\right] \left[\begin{array}{c|c} -sE + A & B \\ \hline -F & I \end{array}\right] \quad \forall F \in \mathbf{R}^{m\times n}.$$
We can choose F so that $G_1(s) := [\begin{smallmatrix} -sE+A+BF & B \\ \hline C & 0 \end{smallmatrix}]$ is proper, $G_2(s) := [\begin{smallmatrix} -sE+A & B \\ \hline -F & I \end{smallmatrix}]$, and $G_2^{-1}(s)$ has neither zeros nor poles in $\mathbf{C}_+$;
- By applying Theorem 3 to $G_1(s)$ we can get necessary and sufficient solvability conditions and a desired solution for the (J, J')-lossless factorization of $G(s)$. We will show that *the solvability conditions and the constructed solution in this way are independent of the parameter matrix F.*

2. Main results. In this section we will present numerically verifiable necessary and sufficient solvability conditions and establish a numerically reliable algorithm for solving the (J, J')-lossless factorization problem of general rational matrices.

The main result in this section is based on the following factorization.

THEOREM 4. *Given a rational matrix $G(s) \in \mathcal{R}^{p\times m}(s)$, let*

$$G(s) = \left[\begin{array}{c|c} -sE + A & B \\ \hline C & 0 \end{array}\right], \; E, A \in \mathbf{R}^{n\times n}, \; B \in \mathbf{R}^{n\times m}, \; C \in \mathbf{R}^{p\times n}, \tag{7}$$

be its minimal realization. There exist nonnegative integers n_1, n_2, and n_3 with $n_1 + n_2 + n_3 = n$, and orthogonal matrices $P, Q, U \in \mathbf{R}^{n\times n}$, $W \in \mathbf{R}^{m\times m}$, and $V \in \mathbf{R}^{(n_1+n_3)\times(n_1+n_3)}$, with U and V being partitioned as

$$U = \begin{array}{c} \begin{matrix} n_1+n_2 & n_3 \end{matrix} \\ \begin{bmatrix} U_{11} & U_{12} \\ U_{21} & U_{22} \end{bmatrix} \begin{matrix} \}n_1+n_2 \\ \}n_3 \end{matrix} \end{array}, \quad V = \begin{array}{c} \begin{matrix} n_3 & n_1 \end{matrix} \\ \begin{bmatrix} V_{11} & V_{12} \\ V_{21} & V_{22} \end{bmatrix} \begin{matrix} \}n_3 \\ \}n_1 \end{matrix} \end{array},$$
$$\operatorname{rank}(U_{11}) = n_1 + n_2, \quad \operatorname{rank}(V_{11}) = n_3$$

such that

$$\begin{bmatrix} U_{11} & 0 & U_{12} \\ 0 & I & 0 \\ U_{21} & 0 & U_{22} \end{bmatrix} \begin{bmatrix} P & 0 & 0 \\ 0 & I & 0 \\ 0 & 0 & P \end{bmatrix} \begin{bmatrix} -sE+A & B & -sE+A \\ C & 0 & C \\ -sE+A & B & 0 \end{bmatrix}$$
$$\times \begin{bmatrix} Q & 0 & 0 \\ 0 & W & 0 \\ 0 & 0 & Q \end{bmatrix} \begin{bmatrix} I_{n_1+n_2} & 0 & 0 & 0 & 0 \\ 0 & V_{11} & 0 & V_{12} & 0 \\ 0 & 0 & I_m & 0 & 0 \\ 0 & V_{21} & 0 & V_{22} & 0 \\ 0 & 0 & 0 & 0 & I \end{bmatrix}$$

$$= \begin{array}{c} \begin{matrix} n_1 & n_2 & n_3 & n_3 & m-n_3 & n \end{matrix} \\ \begin{bmatrix} -sE_{11}+A_{11} & -sE_{12}+A_{12} & A_{13} & 0 & B_{12} & \star \\ 0 & -sE_{22}+A_{22} & A_{23} & 0 & B_{22} & \star \\ 0 & A_{32} & A_{33} & B_{31} & 0 & \star \\ C_1 & C_2 & C_3 & 0 & 0 & \star \\ \star & \star & \star & \star & \star & \star \end{bmatrix} \end{array} \begin{matrix} \}n_1 \\ \}n_2 \\ \}n_3\,, \\ \}p \\ \}n \end{matrix} \tag{8}$$

where $\star$ *denotes the subblock, which we are not interested in, and*

$$\operatorname{rank}(E_{11}) = n_1,\ \operatorname{rank}(E_{22}) = n_2,\ \operatorname{rank}(B_{31}) = n_3, \tag{9}$$

$$\operatorname{rank} \begin{bmatrix} -sE_{22}+A_{22} & A_{23} \\ A_{32} & A_{33} \end{bmatrix} = n_2 + n_3 \quad \forall s \in \mathbf{C}. \tag{10}$$

Proof. The factorization (8) with properties (9) and (10) is constructed in the appendix. □

The numerical procedure in the appendix for computing the factorization (8) needs only $O(n^3 + m^3)$ flops. Furthermore,

$$\begin{bmatrix} U_{11} & 0 & U_{12} \\ 0 & I & 0 \\ U_{21} & 0 & U_{22} \end{bmatrix} \begin{bmatrix} P & 0 & 0 \\ 0 & I & 0 \\ 0 & 0 & P \end{bmatrix} \text{ and } \begin{bmatrix} Q & 0 & 0 \\ 0 & W & 0 \\ 0 & 0 & Q \end{bmatrix} \begin{bmatrix} I_{n_1+n_2} & 0 & 0 & 0 & 0 \\ 0 & V_{11} & 0 & V_{12} & 0 \\ 0 & 0 & I_m & 0 & 0 \\ 0 & V_{21} & 0 & V_{22} & 0 \\ 0 & 0 & 0 & 0 & I \end{bmatrix}$$

are orthogonal, and thus the computation of the factorization (8) is numerically backward stable [12].

COROLLARY 5. *With respect to factorization* (8),

$$G(s) = \left[\begin{array}{ccc|cc} -sE_{11}+A_{11} & -sE_{12}+A_{12} & A_{13} & 0 & B_{12} \\ 0 & -sE_{22}+A_{22} & A_{23} & 0 & B_{22} \\ 0 & A_{32} & A_{33} & B_{31} & 0 \\ \hline C_1 & C_2 & C_3 & 0 & 0 \end{array}\right] W^T. \tag{11}$$

Proof. First, a direct calculation yields that

$$\begin{bmatrix} P & 0 & 0 \\ 0 & I & 0 \\ 0 & 0 & P \end{bmatrix} \begin{bmatrix} -sE+A & B & -sE+A \\ C & 0 & C \\ -sE+A & B & 0 \end{bmatrix} \begin{bmatrix} Q & 0 & 0 \\ 0 & W & 0 \\ 0 & 0 & Q \end{bmatrix}$$
$$= \begin{bmatrix} P(-sE+A)Q & PBW & P(-sE+A)Q \\ CQ & 0 & CQ \\ P(-sE+A)Q & PBW & 0 \end{bmatrix}. \tag{12}$$

Next, since U and V are orthogonal, we have from (8) and using (12) that

$$\begin{bmatrix} P(-sE+A)Q & PBW & P(-sE+A)Q \\ CQ & 0 & CQ \\ P(-sE+A)Q & PBW & 0 \end{bmatrix} \begin{bmatrix} I_{n_1} \\ 0 \end{bmatrix}$$

$$= \begin{bmatrix} U_{11}^T & 0 & U_{21}^T \\ 0 & I & 0 \\ U_{12}^T & 0 & U_{22}^T \end{bmatrix} \begin{bmatrix} -sE_{11}+A_{11} \\ 0 \\ 0 \\ C_1 \\ \star \end{bmatrix}.$$

Note that $n = n_1 + n_2 + n_3$, and thus,

$$\begin{aligned} &[0 \;\; I_{n_3}]\, P(-sE+A)Q \begin{bmatrix} I_{n_1} \\ 0 \end{bmatrix} \\ &\quad = [0_{n_3\times(n_1+n_2)} \;\; I_{n_3} \;\; 0] \begin{bmatrix} P(-sE+A)Q & PBW & P(-sE+A)Q \\ CQ & 0 & CQ \\ P(-sE+A)Q & PBW & 0 \end{bmatrix} \begin{bmatrix} I_{n_1} \\ 0 \end{bmatrix} \\ (13) \quad &\quad = [0_{n_3\times(n_1+n_2)} \;\; I_{n_3} \;\; 0] \begin{bmatrix} U_{11}^T & 0 & U_{21}^T \\ 0 & I & 0 \\ U_{12}^T & 0 & U_{22}^T \end{bmatrix} \begin{bmatrix} -sE_{11}+A_{11} \\ 0 \\ 0 \\ C_1 \\ \star \end{bmatrix} = 0. \end{aligned}$$

Then we have from factorization (8), using (12), and equality $n = n_1 + n_2 + n_3$ that

$$\begin{bmatrix} U_{11} & 0 & 0 & 0 & U_{12} \\ 0 & I_{n_3} & 0 & 0 & 0 \\ 0 & 0 & I_p & 0 & 0 \end{bmatrix} \begin{bmatrix} P(-sE+A)Q & PBW & P(-sE+A)Q \\ CQ & 0 & CQ \\ P(-sE+A)Q & PBW & 0 \end{bmatrix}$$

$$\times \begin{bmatrix} I_{n_1+n_2} & 0 & 0 \\ 0 & V_{11} & 0 \\ 0 & 0 & I_m \\ 0 & V_{21} & 0 \\ 0 & 0 & 0 \end{bmatrix} = \begin{bmatrix} -sE_{11}+A_{11} & -sE_{12}+A_{12} & A_{13} & 0 & B_{12} \\ 0 & -sE_{22}+A_{22} & A_{23} & 0 & B_{22} \\ 0 & A_{32} & A_{33} & B_{31} & 0 \\ C_1 & C_2 & C_3 & 0 & 0 \end{bmatrix},$$

which give, along with the facts

$$\begin{bmatrix} [U_{11} \;\; 0]P(-sE+A)Q + [0 \;\; U_{12}]P(-sE+A)Q \\ [0 \;\; I_{n_3}]P(-sE+A)Q \end{bmatrix} = \begin{bmatrix} U_{11} & U_{12} \\ 0 & I \end{bmatrix} P(-sE+A)Q,$$

$$\begin{bmatrix} [U_{11} \;\; 0]PBW + [0 \;\; U_{12}]PBW \\ [0 \;\; I_{n_3}]PBW \end{bmatrix} = \begin{bmatrix} U_{11} & U_{12} \\ 0 & I \end{bmatrix} PBW,$$

$$CQ \begin{bmatrix} I_{n_1+n_2} & 0 \\ 0 & V_{11} \end{bmatrix} + CQ \begin{bmatrix} 0 & V_{21} \\ 0 & 0 \end{bmatrix} = CQ \begin{bmatrix} I & 0 & V_{21} \\ 0 & I & 0 \\ 0 & 0 & V_{11} \end{bmatrix} \quad (\text{since } V_{21} \in \mathbf{R}^{n_1\times n_3}),$$

that

$$\begin{bmatrix} U_{11} & U_{12} \\ 0 & I \end{bmatrix} P(-sE+A)Q \begin{bmatrix} I_{n_1+n_2} & 0 \\ 0 & V_{11} \end{bmatrix} + \begin{bmatrix} U_{11} & 0 \\ 0 & I \end{bmatrix} P(-sE+A)Q \begin{bmatrix} 0 & V_{21} \\ 0 & 0 \end{bmatrix}$$

$$= \begin{bmatrix} -sE_{11}+A_{11} & -sE_{12}+A_{12} & A_{13} \\ 0 & -sE_{22}+A_{22} & A_{23} \\ 0 & A_{32} & A_{33} \end{bmatrix} \tag{14}$$

and

$$\begin{bmatrix} U_{11} & U_{12} \\ 0 & I \end{bmatrix} PBW = \begin{bmatrix} 0 & B_{12} \\ 0 & B_{22} \\ B_{31} & 0 \end{bmatrix}, \quad CQ \begin{bmatrix} I & 0 & V_{21} \\ 0 & I & 0 \\ 0 & 0 & V_{11} \end{bmatrix} = [C_1 \;\; C_2 \;\; C_3]. \tag{15}$$

Because (13) means that

$$[0 \;\; U_{12}]\, P(-sE+A)Q \begin{bmatrix} V_{21} \\ 0 \end{bmatrix} = U_{12}\, [0 \;\; I_{n_3}]\, P(-sE+A)Q \begin{bmatrix} I_{n_1} \\ 0 \end{bmatrix} V_{21} = 0,$$

thus,

$$\begin{bmatrix} U_{11} & 0 \\ 0 & I \end{bmatrix} P(-sE+A)Q \begin{bmatrix} 0 & V_{21} \\ 0 & 0 \end{bmatrix} = \begin{bmatrix} U_{11} & U_{12} \\ 0 & I \end{bmatrix} P(-sE+A)Q \begin{bmatrix} 0 & V_{21} \\ 0 & 0 \end{bmatrix},$$

and hence we obtain, using (14) and the equality

$$\begin{bmatrix} I_{n_1+n_2} & 0 \\ 0 & V_{11} \end{bmatrix} + \begin{bmatrix} 0 & V_{21} \\ 0 & 0 \end{bmatrix} = \begin{bmatrix} I & 0 & V_{21} \\ 0 & I & 0 \\ 0 & 0 & V_{11} \end{bmatrix} \text{ (since } V_{21} \in \mathbf{R}^{n_1 \times n_3}),$$

that

$$\begin{bmatrix} U_{11} & U_{12} \\ 0 & I \end{bmatrix} P(-sE+A)Q \begin{bmatrix} I & 0 & V_{21} \\ 0 & I & 0 \\ 0 & 0 & V_{11} \end{bmatrix} = \begin{bmatrix} -sE_{11}+A_{11} & -sE_{12}+A_{12} & A_{13} \\ 0 & -sE_{22}+A_{22} & A_{23} \\ 0 & A_{32} & A_{33} \end{bmatrix}. \tag{16}$$

Obviously, (15) and (16) can be combined into the following compact form:

$$\begin{cases} \begin{bmatrix} U_{11} & U_{12} \\ 0 & I \end{bmatrix} P(-sE+A)Q \begin{bmatrix} I & 0 & V_{21} \\ 0 & I & 0 \\ 0 & 0 & V_{11} \end{bmatrix} = \begin{bmatrix} -sE_{11}+A_{11} & -sE_{12}+A_{12} & A_{13} \\ 0 & -sE_{22}+A_{22} & A_{23} \\ 0 & A_{32} & A_{33} \end{bmatrix}, \\ \begin{bmatrix} U_{11} & U_{12} \\ 0 & I \end{bmatrix} PBW = \begin{bmatrix} 0 & B_{12} \\ 0 & B_{22} \\ B_{31} & 0 \end{bmatrix}, \quad CQ \begin{bmatrix} I & 0 & V_{21} \\ 0 & I & 0 \\ 0 & 0 & V_{11} \end{bmatrix} = [C_1 \;\; C_2 \;\; C_3]. \end{cases} \tag{17}$$

Hence, Corollary 5 follows. □

Realization (11) is computed by a numerically backward stable manner in the sense that the factorization (8) is numerically backward stable. In the following, we show that the computation of realization (11) is numerically forward stable.

Let us denote the computed X using finite precision arithmetic by $\bar{X}$, as opposed to exact arithmetic, and denote the machine precision by ϵ. Let

$$
\begin{aligned}
P(-sE+A)Q &= -s\mathcal{E}^{(1)}+\mathcal{A}^{(1)},\\
P(-sE+A)Q\begin{bmatrix} V_{22} & 0 & V_{21}\\ 0 & I & 0\\ V_{12} & 0 & V_{11}\end{bmatrix} &= -s\mathcal{E}^{(2)}+\mathcal{A}^{(2)},\\
\begin{bmatrix} U_{11} & U_{12}\\ U_{21} & U_{22}\end{bmatrix} P(-sE+A)Q &= -s\mathcal{E}^{(3)}+\mathcal{A}^{(3)},\\
\begin{bmatrix} U_{11} & U_{12}\\ U_{21} & U_{22}\end{bmatrix} P(-sE+A)Q\begin{bmatrix} V_{22} & 0 & V_{21}\\ 0 & I & 0\\ V_{12} & 0 & V_{11}\end{bmatrix} &= -s\mathcal{E}^{(4)}+\mathcal{A}^{(4)},\\
\begin{bmatrix} U_{11} & U_{12}\\ 0 & I\end{bmatrix} P(-sE+A)Q\begin{bmatrix} I & 0 & V_{21}\\ 0 & I & 0\\ 0 & 0 & V_{11}\end{bmatrix} &= -s\mathcal{E}+\mathcal{A}
\end{aligned}
$$

and

$$
\begin{aligned}
\bar{P}(-sE+A)\bar{Q} &= -s\bar{\mathcal{E}}^{(1)}+\bar{\mathcal{A}}^{(1)} =: -s(\mathcal{E}^{(1)}+\Delta\mathcal{E}^{(1)})+(\mathcal{A}^{(1)}+\Delta\mathcal{A}^{(1)}),\\
\bar{P}(-sE+A)\bar{Q}\begin{bmatrix} \bar{V}_{22} & 0 & \bar{V}_{21}\\ 0 & I & 0\\ \bar{V}_{12} & 0 & \bar{V}_{11}\end{bmatrix} &= -s\bar{\mathcal{E}}^{(2)}+\bar{\mathcal{A}}^{(2)} =: -s(\mathcal{E}^{(2)}+\Delta\mathcal{E}^{(2)})+(\mathcal{A}^{(2)}+\Delta\mathcal{A}^{(2)}),\\
\begin{bmatrix} \bar{U}_{11} & \bar{U}_{12}\\ \bar{U}_{21} & \bar{U}_{22}\end{bmatrix}\bar{P}(-sE+A)\bar{Q} &= -s\bar{\mathcal{E}}^{(3)}+\bar{\mathcal{A}}^{(3)} =: -s(\mathcal{E}^{(3)}+\Delta\mathcal{E}^{(3)})+(\mathcal{A}^{(3)}+\Delta\mathcal{A}^{(3)}),\\
\begin{bmatrix} \bar{U}_{11} & \bar{U}_{12}\\ \bar{U}_{21} & \bar{U}_{22}\end{bmatrix}\bar{P}(-sE+A)\bar{Q}\begin{bmatrix} \bar{V}_{22} & 0 & \bar{V}_{21}\\ 0 & I & 0\\ \bar{V}_{12} & 0 & \bar{V}_{11}\end{bmatrix} &= -s\bar{\mathcal{E}}^{(4)}+\bar{\mathcal{A}}^{(4)}\\
&=: -s(\mathcal{E}^{(4)}+\Delta\mathcal{E}^{(4)})+(\mathcal{A}^{(4)}+\Delta\mathcal{A}^{(4)}),\\
\begin{bmatrix} \bar{U}_{11} & \bar{U}_{12}\\ 0 & I\end{bmatrix}\bar{P}(-sE+A)\bar{Q}\begin{bmatrix} I & 0 & \bar{V}_{21}\\ 0 & I & 0\\ 0 & 0 & \bar{V}_{11}\end{bmatrix} &= -s\bar{\mathcal{E}}+\bar{\mathcal{A}}\\
&=: -s(\mathcal{E}+\Delta\mathcal{E})+(\mathcal{A}+\Delta\mathcal{A}).
\end{aligned}
$$

Then we have

$$
-s\mathcal{E}+\mathcal{A} = \begin{bmatrix} [I_{n_1+n_2}\ \ 0]\,(-s\mathcal{E}^{(3)}+\mathcal{A}^{(3)})\begin{bmatrix} I_{n_1+n_2}\\ 0\end{bmatrix} & [I_{n_1+n_2}\ \ 0]\,(-s\mathcal{E}^{(4)}+\mathcal{A}^{(4)})\begin{bmatrix} 0\\ I_{n_3}\end{bmatrix}\\ [0\ \ I_{n_3}]\,(-s\mathcal{E}^{(1)}+\mathcal{A}^{(1)})\begin{bmatrix} I_{n_1+n_2}\\ 0\end{bmatrix} & [0\ \ I_{n_3}]\,(-s\mathcal{E}^{(2)}+\mathcal{A}^{(2)})\begin{bmatrix} I_{n_3}\\ 0\end{bmatrix}\end{bmatrix}
$$

and

$$
-s\Delta\mathcal{E}+\Delta\mathcal{A} = \begin{bmatrix} [I_{n_1+n_2}\ \ 0]\,(-s\Delta\mathcal{E}^{(3)}+\Delta\mathcal{A}^{(3)})\begin{bmatrix} I_{n_1+n_2}\\ 0\end{bmatrix} & [I_{n_1+n_2}\ \ 0]\,(-s\Delta\mathcal{E}^{(4)}+\Delta\mathcal{A}^{(4)})\begin{bmatrix} 0\\ I_{n_3}\end{bmatrix}\\ [0\ \ I_{n_3}]\,(-s\Delta\mathcal{E}^{(1)}+\Delta\mathcal{A}^{(1)})\begin{bmatrix} I_{n_1+n_2}\\ 0\end{bmatrix} & [0\ \ I_{n_3}]\,(-s\Delta\mathcal{E}^{(2)}+\Delta\mathcal{A}^{(2)})\begin{bmatrix} I_{n_3}\\ 0\end{bmatrix}\end{bmatrix}.
$$

Since we have from [12] that

$$\|\Delta\mathcal{E}^{(i)}\|_2 \approx \epsilon\|E\|_2, \quad \|\Delta\mathcal{A}^{(i)}\|_2 \approx \epsilon\|A\|_2, \quad i = 1, 2, 3, 4,$$

we thus have

$$\|\Delta\mathcal{E}\|_2 \approx \epsilon\|E\|_2, \quad \|\Delta\mathcal{A}\|_2 \approx \epsilon\|A\|_2. \tag{18}$$

Similarly, if we denote

$$\begin{bmatrix} U_{11} & U_{12} \\ 0 & I \end{bmatrix} PBW = \mathcal{B}, \quad CQ \begin{bmatrix} I & 0 & V_{21} \\ 0 & I & 0 \\ 0 & 0 & V_{11} \end{bmatrix} = \mathcal{C}$$

and

$$\begin{bmatrix} \bar{U}_{11} & \bar{U}_{12} \\ 0 & I \end{bmatrix} \bar{P}B\bar{W} = \bar{\mathcal{B}} =: \mathcal{B} + \Delta\mathcal{B}, \quad C\bar{Q} \begin{bmatrix} I & 0 & \bar{V}_{21} \\ 0 & I & 0 \\ 0 & 0 & \bar{V}_{11} \end{bmatrix} = \bar{\mathcal{C}} =: \mathcal{C} + \Delta\mathcal{C},$$

then we also have

$$\|\Delta\mathcal{B}\|_2 \approx \epsilon\|B\|_2, \quad \|\Delta\mathcal{C}\|_2 \approx \epsilon\|C\|_2. \tag{19}$$

Therefore, we have from (17), (18), and (19) that the computation of realization (11) is numerically forward stable [12].

We can now conclude that the importance of the factorization (8) is that it provides a numerically reliable way, with complexity $O(n^3 + m^3)$, to compute realization (11) of $G(s)$.

The following considerations are necessary preliminaries for Theorem 6 below.

Assume that $G(s) \in \mathcal{R}^{p\times m}(s)$, with a minimal realization (7), is left invertible, or equivalently,

$$\max_{s\in\mathbf{C}} \operatorname{rank} \begin{bmatrix} -sE + A & B \\ C & 0 \end{bmatrix} = n + m. \tag{20}$$

Then we have, using (17) and the nonsingularity of B_{31}, that

$$\max_{s\in\mathbf{C}} \operatorname{rank} \begin{bmatrix} -sE_{11} + A_{11} & -sE_{12} + A_{12} & A_{13} & B_{12} \\ 0 & -sE_{22} + A_{22} & A_{23} & B_{22} \\ C_1 & C_2 & C_3 & 0 \end{bmatrix} = \max_{s\in\mathbf{C}} \operatorname{rank} \begin{bmatrix} -sE + A & B \\ C & 0 \end{bmatrix} - n_3$$

$$= (n + m) - n_3 = n_1 + n_2 + n_3 + (m - n_3). \tag{21}$$

Therefore, the generalized lower triangular form [25, 42] of the pencil

$$\begin{bmatrix} -sE_{11} + A_{11} & -sE_{12} + A_{12} & A_{13} & B_{12} \\ 0 & -sE_{22} + A_{22} & A_{23} & B_{22} \\ C_1 & C_2 & C_3 & 0 \end{bmatrix}$$

is of the form

$$\mathcal{S}\begin{bmatrix} -sE_{11}+A_{11} & -sE_{12}+A_{12} & A_{13} & B_{12} \\ 0 & -sE_{22}+A_{22} & A_{23} & B_{22} \\ C_1 & C_2 & C_3 & 0 \end{bmatrix}\mathcal{T}$$

$$= \begin{array}{c} \begin{matrix} n_1+n_2-n_{0\infty} & n_{0\infty} & n_3 & m-n_3 \end{matrix} \\ \begin{bmatrix} -s\mathcal{E}_{nf}+\mathcal{A}_{nf} & 0 & 0 & 0 \\ -s\mathcal{E}_{10}+\mathcal{A}_{10} & -s\mathcal{E}_{11}+\mathcal{A}_{11} & \mathcal{A}_{12} & \mathcal{A}_{13} \\ -s\mathcal{E}_{20}+\mathcal{A}_{20} & \mathcal{A}_{21} & \mathcal{A}_{22} & \mathcal{A}_{23} \\ -s\mathcal{E}_{30}+\mathcal{A}_{30} & \mathcal{A}_{31} & \mathcal{A}_{32} & \mathcal{A}_{33} \end{bmatrix} \begin{matrix} \}n_{0\infty} \\ \}n_3 \\ \}m-n_3 \end{matrix} \end{array}, \tag{22}$$

where $\mathcal{S}$ and $\mathcal{T}$ are orthogonal, $\mathcal{E}_{nf}$ is of full column rank, $\mathcal{E}_{11}$ is nonsingular, and

$$\operatorname{rank}(-s\mathcal{E}_{nf}+\mathcal{A}_{nf}) = n_1+n_2-n_{0\infty} \quad \forall s \in \mathbf{C}_0,$$

$$\operatorname{rank}\begin{bmatrix} -s\mathcal{E}_{11}+\mathcal{A}_{11} & \mathcal{A}_{12} & \mathcal{A}_{13} \\ \mathcal{A}_{21} & \mathcal{A}_{22} & \mathcal{A}_{23} \\ \mathcal{A}_{31} & \mathcal{A}_{32} & \mathcal{A}_{33} \end{bmatrix} = n_{0\infty}+m \quad \forall s \in \mathbf{C}\backslash\mathbf{C}_0.$$

We partition $\mathcal{S}$ and $\mathcal{T}$ into

$$\mathcal{S} = \begin{array}{c} \begin{matrix} n_1 & n_2 & p \end{matrix} \\ \begin{bmatrix} \mathcal{S}_{11} & \mathcal{S}_{12} & \mathcal{S}_{13} \\ \mathcal{S}_{21} & \mathcal{S}_{22} & \mathcal{S}_{23} \\ \mathcal{S}_{31} & \mathcal{S}_{32} & \mathcal{S}_{33} \\ \mathcal{S}_{41} & \mathcal{S}_{42} & \mathcal{S}_{43} \end{bmatrix} \begin{matrix} \}n_{0\infty} \\ \}n_3 \\ \}m-n_3 \end{matrix} \end{array},$$

$$\mathcal{T} = \begin{array}{c} \begin{matrix} n_1+n_2-n_{0\infty} & n_{0\infty} & n_3 & m-n_3 \end{matrix} \\ \begin{bmatrix} \mathcal{T}_{11} & \mathcal{T}_{12} & \mathcal{T}_{13} & \mathcal{T}_{14} \\ \mathcal{T}_{21} & \mathcal{T}_{22} & \mathcal{T}_{23} & \mathcal{T}_{24} \\ \mathcal{T}_{31} & \mathcal{T}_{32} & \mathcal{T}_{33} & \mathcal{T}_{34} \\ \mathcal{T}_{41} & \mathcal{T}_{42} & \mathcal{T}_{43} & \mathcal{T}_{44} \end{bmatrix} \begin{matrix} \}n_1 \\ \}n_2 \\ \}n_3 \\ \}m-n_3 \end{matrix} \end{array}. \tag{23}$$

Obviously, factorization (22) has isolated the zeros of $G(s)$ on $\mathbf{C}_0$ and at infinity to

$$\begin{bmatrix} -s\mathcal{E}_{11}+\mathcal{A}_{11} & \mathcal{A}_{12} & \mathcal{A}_{13} \\ \mathcal{A}_{21} & \mathcal{A}_{22} & \mathcal{A}_{23} \\ \mathcal{A}_{31} & \mathcal{A}_{32} & \mathcal{A}_{33} \end{bmatrix}.$$

Let the columns of full column rank matrix $[L_1^T \;\; L_2^T \;\; L_3^T \;\; L_4^T \;\; L_5^T \;\; L_6^T]^T$ with $L_1, L_3 \in \mathbf{R}^{n_1\times r}$, $L_2, L_4 \in \mathbf{R}^{n_2\times r}$, $L_5 \in \mathbf{R}^{n_3\times r}$, and $L_6 \in \mathbf{R}^{(m-n_3)\times r}$ span the stable eigenspace of the pencil

$$\begin{bmatrix} -sE_{11}+A_{11} & -sE_{12}+A_{12} & 0 & 0 & A_{13} & B_{12} \\ 0 & -sE_{22}+A_{22} & 0 & 0 & A_{23} & B_{22} \\ -C_1^TJC_1 & -C_1^TJC_2 & -(sE_{11}+A_{11})^T & 0 & -C_1^TJC_3 & 0 \\ -C_2^TJC_1 & -C_2^TJC_2 & -(sE_{12}+A_{12})^T & -(sE_{22}+A_{22})^T & -C_2^TJC_3 & 0 \\ C_3^TJC_1 & C_3^TJC_2 & A_{13}^T & A_{23}^T & C_3^TJC_3 & 0 \\ 0 & 0 & B_{12}^T & B_{22}^T & 0 & 0 \end{bmatrix},$$

which gives

$$\begin{bmatrix} A_{11} & A_{12} & 0 & 0 & A_{13} & B_{12} \\ 0 & A_{22} & 0 & 0 & A_{23} & B_{22} \\ -C_1^T JC_1 & -C_1^T JC_2 & -A_{11}^T & 0 & -C_1^T JC_3 & 0 \\ -C_2^T JC_1 & -C_2^T JC_2 & -A_{12}^T & -A_{22}^T & -C_2^T JC_3 & 0 \\ C_3^T JC_1 & C_3^T JC_2 & A_{13}^T & A_{23}^T & C_3^T JC_3 & 0 \\ 0 & 0 & B_{12}^T & B_{22}^T & 0 & 0 \end{bmatrix} \begin{bmatrix} L_1 \\ L_2 \\ L_3 \\ L_4 \\ L_5 \\ L_6 \end{bmatrix}$$

$$= \begin{bmatrix} E_{11} & E_{12} & 0 & 0 & 0 & 0 \\ 0 & E_{22} & 0 & 0 & 0 & 0 \\ 0 & 0 & E_{11}^T & 0 & 0 & 0 \\ 0 & 0 & E_{12}^T & E_{22}^T & 0 & 0 \\ 0 & 0 & 0 & 0 & 0 & 0 \\ 0 & 0 & 0 & 0 & 0 & 0 \end{bmatrix} \begin{bmatrix} L_1 \\ L_2 \\ L_3 \\ L_4 \\ L_5 \\ L_6 \end{bmatrix} \Delta, \tag{24}$$

where $\Delta \in \mathbf{R}^{r\times r}$ is stable.

Now we are ready to present our main result.

THEOREM 6. *Given $G(s) \in \mathcal{R}^{p\times m}(s)$ with a minimal realization* (7)*, assume that factorization* (8) *and eigenfactorizations* (22) *and* (24) *have been determined. Then $G(s)$ has a (J, J')-lossless factorization if and only if the following conditions hold:*

(a) *$G(s)$ is left invertible; i.e., property* (20) *holds.*

(b) *There exists a nonsingular matrix $\mathcal{D}_0 \in \mathbf{R}^{m\times m}$ such that*

$$\mathcal{D}_0^T \begin{bmatrix} \mathcal{S}_{33} \\ \mathcal{S}_{43} \end{bmatrix} J \begin{bmatrix} \mathcal{S}_{33}^T & \mathcal{S}_{43}^T \end{bmatrix} \mathcal{D}_0 = J'. \tag{25}$$

(c) *We have*

$$r + n_{0\infty} = n_1 + n_2, \quad \begin{bmatrix} L_1 & \mathcal{T}_{12} \\ L_2 & \mathcal{T}_{22} \end{bmatrix} \text{ is nonsingular}, \tag{26}$$

$$\begin{bmatrix} E_{11}L_1 + E_{12}L_2 & E_{11}\mathcal{T}_{12} + E_{12}\mathcal{T}_{22} \\ E_{22}L_2 & E_{22}\mathcal{T}_{22} \end{bmatrix}^T \begin{bmatrix} L_3 & 0 \\ L_4 & 0 \end{bmatrix} \geq 0, \tag{27}$$

and the algebraic Riccati equation

$$E_{11}\mathcal{Y}_{11}A_{11}^T + A_{11}\mathcal{Y}_{11}E_{11}^T + E_{11}\mathcal{Y}_{11}C_1^T JC_1\mathcal{Y}_{11}E_{11}^T = 0 \tag{28}$$

has a solution $\mathcal{Y}_{11} \geq 0$ such that the pencil $-sE_{11} + A_{11} + E_{11}\mathcal{Y}_{11}C_1^T JC_1$ is stable.

(d) *We have*

$$\rho\left(\begin{bmatrix} L_1 & \mathcal{T}_{12} \\ L_2 & \mathcal{T}_{22} \end{bmatrix}, \begin{bmatrix} \mathcal{Y}_{11}E_{11}^T L_3 & 0 \\ 0 & 0 \end{bmatrix} \right) < 1. \tag{29}$$

Furthermore, in the case when conditions (a), (b), (c), *and* (d) *hold, if we define the following two QR factorizations:*

$$\hat{\mathcal{W}} \begin{bmatrix} S_{21}^T \\ S_{22}^T \end{bmatrix} = \begin{bmatrix} 0 \\ \mathcal{R}_{\hat{\mathcal{W}}} \end{bmatrix}, \quad \hat{\mathcal{W}}\hat{\mathcal{W}}^T = I, \quad \operatorname{rank}(\mathcal{R}_{\hat{\mathcal{W}}}) = n_{0\infty}, \tag{30}$$

$$\tilde{\mathcal{W}}\left(\begin{bmatrix} I_{n_1} & 0 & 0 \\ 0 & I_r & 0 \end{bmatrix}\begin{bmatrix} E_{11}\mathcal{Y}_{11}E_{11}^T L_3 \\ E_{11}L_1 + E_{12}L_2 \\ E_{22}L_2 \end{bmatrix}\right) = \begin{bmatrix} 0 \\ \mathcal{R}_{\tilde{\mathcal{W}}} \end{bmatrix},$$

$$\tilde{\mathcal{W}}\tilde{\mathcal{W}}^T = I, \quad \operatorname{rank}(\mathcal{R}_{\tilde{\mathcal{W}}}) = r, \tag{31}$$

and partition

$$\begin{bmatrix} \tilde{\mathcal{W}} & 0 \\ 0 & I \end{bmatrix}\begin{bmatrix} I & 0 \\ 0 & \hat{\mathcal{W}} \end{bmatrix}\begin{bmatrix} I & 0 & 0 \\ I & I & 0 \\ 0 & 0 & I_{n_2} \end{bmatrix} =: \begin{matrix} \\ \\ \end{matrix}\begin{matrix} n_1 & n_1+n_2 \\ \end{matrix}\begin{bmatrix} \mathcal{W}_{11} & \mathcal{W}_{12} \\ \mathcal{W}_{21} & \mathcal{W}_{22} \end{bmatrix}\begin{matrix} \}n_1 \\ \}n_1+n_2 \end{matrix}, \tag{32}$$

then a (J, J')-lossless factorization of $G(s)$ is given by the factors $\Theta(s)$ and $\Xi(s)$,

$$\Theta(s) = \left[\begin{array}{cc|c} -sE_\Theta + A_\Theta & 0 & \mathcal{Z}_1 \\ 0 & \mathcal{W}_{11}(-sE_{11} + A_{11}) & \mathcal{Z}_2 \\ \hline C_1L_1 + C_2L_2 + C_3L_5 & C_1 & -\begin{bmatrix} \mathcal{S}_{33} \\ \mathcal{S}_{43} \end{bmatrix}^T \end{array}\right]\mathcal{D}_0, \tag{33}$$

$$\Xi(s) = -(J')^{-1}\mathcal{D}_0^T\left[\begin{array}{c|c} sE_\Xi + A_\Xi & B_\Xi \\ \hline C_\Xi & 0 \end{array}\right]W^T, \tag{34}$$

where

$$-sE_\Theta + A_\Theta = [I_r \;\; 0]\,\hat{\mathcal{W}}\begin{bmatrix} E_{11} & E_{12} \\ 0 & E_{22} \end{bmatrix}\begin{bmatrix} L_1 - \mathcal{Y}_{11}E_{11}^T L_3 \\ L_2 \end{bmatrix}(-sI + \Delta),$$

$$\mathcal{Z}_1 = -[I_r \;\; 0]\,\hat{\mathcal{W}}\left(\begin{bmatrix} \mathcal{S}_{31} & \mathcal{S}_{32} \\ \mathcal{S}_{41} & \mathcal{S}_{42} \end{bmatrix}^T + \begin{bmatrix} E_{11}\mathcal{Y}_{11}C_1^T \\ 0 \end{bmatrix} J \begin{bmatrix} \mathcal{S}_{33} \\ \mathcal{S}_{43} \end{bmatrix}^T\right),$$

$$\mathcal{Z}_2 = -\mathcal{W}_{12}\begin{bmatrix} \mathcal{S}_{31} & \mathcal{S}_{32} \\ \mathcal{S}_{41} & \mathcal{S}_{42} \end{bmatrix}^T + \left(\mathcal{W}_{11} - \mathcal{W}_{12}\begin{bmatrix} I_{n_1} \\ 0 \end{bmatrix}\right)E_{11}\mathcal{Y}_{11}C_1^T J\begin{bmatrix} \mathcal{S}_{33} \\ \mathcal{S}_{43} \end{bmatrix}^T,$$

$$-sE_\Xi + A_\Xi = \left(\begin{bmatrix} -sE_{11} + A_{11} & -sE_{12} + A_{12} & A_{13} \\ 0 & -sE_{22} + A_{22} & A_{23} \\ 0 & A_{32} & A_{33} \end{bmatrix} + \begin{bmatrix} E_{11}\mathcal{Y}_{11}C_1^T J \\ 0 \\ 0 \end{bmatrix}[C_1 \;\; C_2 \;\; C_3]\right)\begin{bmatrix} L_1 - \mathcal{Y}_{11}E_{11}^T L_3 & \mathcal{T}_{12} & 0 \\ L_2 & \mathcal{T}_{22} & 0 \\ 0 & 0 & I \end{bmatrix},$$

$$B_\Xi = \begin{bmatrix} 0 & B_{12} \\ 0 & B_{21} \\ B_{31} & 0 \end{bmatrix},$$

$$C_\Xi = \begin{bmatrix} \mathcal{S}_{31} & \mathcal{S}_{32} & \mathcal{S}_{33}J \\ \mathcal{S}_{41} & \mathcal{S}_{42} & \mathcal{S}_{43}J \end{bmatrix}\begin{bmatrix} L_3 & 0 & 0 \\ L_4 & 0 & 0 \\ C_1L_1 + C_2L_2 & C_1\mathcal{T}_{12} + C_2\mathcal{T}_{22} & C_3 \end{bmatrix}.$$

Proof. The proof is given in section 3. ∎

Theorem 6 leads to the following algorithm for solving the (J, J')-lossless factorization problem.

ALGORITHM 1.

Input: $G(s) \in \mathcal{R}^{p\times m}(s)$ *with a minimal realization* (7).

Output: *A (J, J')-lossless factorization $G(s) = \Theta(s)\Xi(s)$ of $G(s)$ if possible.*

Step 1. *Compute the* $\max_{s\in\mathbf{C}} \operatorname{rank} \begin{bmatrix} -sE+A & B \\ C & 0 \end{bmatrix}$ *using the generalized lower triangular form* [25, 42] *of the pencil* $\begin{bmatrix} -sE+A & B \\ C & 0 \end{bmatrix}$. *If it equals $n + m$, continue the process. Otherwise, stop.*

Step 2. *Compute factorization* (8) *and the eigenfactorizations* (22) *and* (24).

Step 3. *Solve the algebraic Riccati equation* (28).

Step 4. *Verify conditions* (25), (26), (27), *and* (29). *If these conditions hold, continue. Otherwise, stop.*

Step 5. *Compute QR factorizations* (30) *and* (31) *and then do the partitioning* (32).

Step 6. *Compute the factors $\Theta(s)$ and $\Xi(s)$ by* (33) *and* (34). *Output $\Theta(s)$ and $\Xi(s)$ and then stop.*

We comment on Algorithm 1 as follows:

- The basis of Algorithm 1 is factorization (8), whose computation is numerically backward stable.
- Steps 1, 2, 4, and 5 are all implemented by only orthogonal transformations, which are numerically backward stable [12].
- The algebraic Riccati equation (28) in Step 3 can be solved by MATLAB code *care.m*, which is known to be numerically reliable.
- J' is symmetric and its inverse in Step 6 can be computed by SVDs or QR factorizations [12], which are numerically reliable. Moreover, its computation has no effect on Steps 1–5. Here we emphasize that it is almost impossible to avoid the computation of $(J')^{-1}$ in the (J, J')-lossless factorization problem.

Therefore, Algorithm 1 can be implemented in a numerically reliable manner.

In the following we give an example, produced by MATLAB, to illustrate Algorithm 1.

Example 1. Consider $G(s) \in \mathcal{R}^{3\times 2}(s)$ of the form

$$G(s) =: \left[\begin{array}{c|c} -sE+A & B \\ \hline C & 0 \end{array}\right],$$

where

$$E = \begin{bmatrix} -0.79648662531102 & -0.34408628966218 & -0.92919020476514 & -0.86759340177264 \\ -1.59637666711651 & -0.94742772442409 & -1.88152958422816 & -1.64655996556517 \\ -1.15895570567892 & -0.61226050785142 & -1.39417360448597 & -1.19527660654597 \\ -0.73210108350959 & -0.49401721140691 & -0.89220026767141 & -0.71378640906087 \end{bmatrix},$$

$$A = \begin{bmatrix} -0.54614732946469 & -0.33335809799803 & -0.58359526918812 & -0.51254534118206 \\ -0.41339349292044 & -0.33309306657012 & -0.67775758611413 & -0.19305827569214 \\ -0.17411088650387 & -0.13421301361811 & -0.36658641418862 & 0.02806619555373 \\ 0.02762027911712 & -0.02883001314100 & -0.17294923202402 & 0.19154703875993 \end{bmatrix},$$

$$B = \begin{bmatrix} 0.09377433103503 & 0.57046350715079 \\ 0.21622307574552 & 0.25020142641665 \\ 0.21193192933125 & 0.26835035557552 \\ 0.09482924580770 & -0.22040923528986 \end{bmatrix},$$

$$C = \begin{bmatrix} -1.42431328897985 & -2.68997314918496 & -0.51966015469511 & -2.34686842451761 \\ 0.36818972326874 & -1.72243610987038 & 2.02945944128574 & -1.02577475830025 \\ -3.36933791418090 & -2.94407864412045 & -3.90940468898360 & -3.24308590192695 \end{bmatrix}.$$

$G(s)$ is not proper and not stable (it has poles at 0.99992821324864, 1.0000025, 0740078, and ∞), and $G(s)$ has zeros at 0 and ∞. Let

$$J = \begin{bmatrix} 1 & 0 & 0 \\ 0 & -1 & 0 \\ 0 & 0 & -1 \end{bmatrix}, \quad J' = \begin{bmatrix} -1 & 0 \\ 0 & -1 \end{bmatrix}.$$

We aim at solving the (J, J')-lossless factorization problem using Algorithm 1.

First, we have that

$$\max_{s \in \mathbf{C}} \begin{bmatrix} -sE + A & B \\ C & 0 \end{bmatrix} = 6 = n + m.$$

Then we compute factorization (8) and eigenfactorizations (22) and (24) to get

$$n_1 = 2, \quad n_2 = n_3 = 1, \quad n_{0\infty} = 2, \quad r = 1.$$

Next, we solve the algebraic Riccati equation (28) to get $\mathcal{Y}_{11}$. We have verified that conditions (25), (26), (27), and (29) hold. Hence, the (J, J')-lossless factorization problem is solvable. Finally, we obtain the factor $\Theta(s)$ and $\Xi(s)$ as follows:

$$\Theta(s) = \left[\begin{array}{c|c} -sE_1 + A_1 & B_1 \\ \hline C_1 & D_1 \end{array}\right], \quad \Xi(s) = \left[\begin{array}{c|c} -sE_2 + A_2 & B_2 \\ \hline C_2 & 0 \end{array}\right],$$

where

$$E_1 = \begin{bmatrix} 1 & 0 & 0 \\ 0 & 0.01774809157525 & -0.06358913345474 \\ 0 & -0.00797313544766 & -0.10278316529096 \end{bmatrix},$$

$$A_1 = \begin{bmatrix} -1.00024697137514 & 0 & 0 \\ 0 & 0.01774668569757 & -0.06358649788333 \\ 0 & -0.00797309297453 & -0.10278354338532 \end{bmatrix},$$

$$B_1 = \begin{bmatrix} 0.00057439346062 & 0.00329848142888 \\ 0.07316225222884 & 0.03930299095489 \\ 0.14590579936467 & 0.28566107869004 \end{bmatrix},$$

$$D_1 = \begin{bmatrix} -0.00043278110916 & 1.73218301798980 \\ -0.57776923753157 & 1.63292687247408 \\ 0.81620027901348 & 1.15499257009050 \end{bmatrix},$$

$$C_1 = \begin{bmatrix} 0.00001056932855 & -0.72504644099477 & 0.40237228536648 \\ 0.00000747363261 & -1.09338239540910 & 1.45479511894656 \\ 0.00000528467535 & 0.09618079240102 & -1.25264068782599 \end{bmatrix}$$

and

$$E_2 = \begin{bmatrix} 0.01774809157525 & -0.06358913345474 & 0.47848254444975 & 0 \\ -0.00797313544766 & -0.10278316529096 & 0.10775627253774 & 0 \\ 0 & 0 & -0.26584884230443 & 0 \\ 0 & 0 & 0 & 0 \end{bmatrix},$$

$$A_2 = \begin{bmatrix} -0.01774720011926 & 0.06358729062381 & -0.14556383589018 & 0.00308271113730 \\ 0.00797077340375 & 0.10278851884865 & -1.90110351010103 & 0.02210167323039 \\ 0 & 0 & -0.39065207241599 & 0.00592368556175 \\ 0 & 0 & 0.22044279058618 & 0 \end{bmatrix},$$

$$B_2 = \begin{bmatrix} 0 & 0.04378720103054 \\ 0 & -0.52343364403428 \\ 0 & -0.17552423949623 \\ -0.03645315939670 & 0 \end{bmatrix},$$

$$C_2 = \begin{bmatrix} 0.70991171521262 & -1.86276740788912 & 5.43175549553726 & -0.16061664495765 \\ -0.41841225671249 & 0.23180092585230 & 1.89204730143784 & 0.11350319804946 \end{bmatrix}.$$

3. Proof of Theorem 6. In this section we always assume that *factorization* (8) *and eigenfactorizations* (22) *and* (24) *have been determined.* Our purpose here is to prove Theorem 6. For this, we need two supporting lemmas.

LEMMA 7. (i) *Given factorization* (8)*, there exist matrices* $K \in \mathbf{R}^{n_3 \times n_2}$ *and*

$$\begin{matrix} n_2 & n_3 \\ \end{matrix}$$
$$\begin{bmatrix} F_{12} & F_{13} \\ F_{22} & 0 \end{bmatrix} \begin{matrix} \}n_3 \\ \}m - n_3 \end{matrix}$$

such that

$$\text{(35)} \qquad \begin{cases} A_{32} + B_{31}F_{12} = B_{31}K, \ A_{33} + B_{31}F_{13} = -B_{31}, \\ \textit{the pencil } -sE_{22} + A_{22} + A_{23}K + B_{22}F_{22} \textit{ is stable.} \end{cases}$$

(ii) *The following equality holds:*

$$G(s) = G_1(s)G_2(s),$$

where

$$\text{(36)} \begin{cases} G_1(s) = \left[\begin{array}{cc|cc} -sE_{11} + A_{11} & -sE_{12} + A_{12} + A_{13}K + B_{12}F_{22} & A_{13} & B_{12} \\ 0 & -sE_{22} + A_{22} + A_{23}K + B_{22}F_{22} & A_{23} & B_{22} \\ \hline C_1 & C_2 + C_3K & C_3 & 0 \end{array}\right] \\ \qquad\quad =: \left[\begin{array}{c|c} -s\Theta + \Phi & \Psi \\ \hline \Pi & \mathcal{D} \end{array}\right], \\ G_2(s) = \left[\begin{array}{cc|cc} -sE_{22} + A_{22} & A_{23} & 0 & B_{22} \\ A_{32} & A_{33} & B_{31} & 0 \\ \hline -F_{12} & -F_{13} & I & 0 \\ -F_{22} & 0 & 0 & I \end{array}\right] W^T, \end{cases}$$

and $G_2(s)$ *and* $G_2^{-1}(s)$ *have neither zeros nor poles in* $\mathbf{C}_+$.

(iii) $G(s)$ *has a* (J, J')*-lossless factorization if and only if* $G_1(s)$ *has a* (J, J')*-lossless factorization. Moreover,* $G(s) = \Theta(s)\Xi(s)$ *is a* (J, J')*-lossless factorization*

of $G(s)$ if and only if $G_1(s) = \Theta(s)\hat{\Xi}(s)$ with $\hat{\Xi}(s) = \Xi(s)G_2^{-1}(s)$ is a (J, J')-lossless factorization of $G_1(s)$.

Proof. The minimality of realization (7) implies that

$$\operatorname{rank}[-sE + A \quad B] = n \quad \forall s \in \mathbf{C},$$

which, along with (17) gives

$$\operatorname{rank}[-sE_{22} + A_{22} \quad A_{23} \quad B_{22}] = n_2 \quad \forall s \in \mathbf{C},$$

and thus there exist matrices K and F_{22} such that the pencil $-sE_{22} + A_{22} + A_{23}K + B_{22}F_{22}$ is stable [42]. Since B_{31} is nonsingular, the existence of matrices F_{12} and F_{13} is obvious. Parts (ii) and (iii) follow directly from a simple verification. □

LEMMA 8. *Let Θ, Φ, Ψ, and Π be the same as those defined in* (36). *Then $\mathcal{Y} \geq 0$ satisfies*

$$\mathcal{Y}(\Phi\Theta^{-1})^T + (\Phi\Theta^{-1})\mathcal{Y} + \mathcal{Y}(\Pi\Theta^{-1})^T J(\Pi\Theta^{-1})\mathcal{Y} = 0, \tag{37}$$

and the matrix $\Phi\Theta^{-1} + \mathcal{Y}(\Pi\Theta^{-1})^T J(\Pi\Theta^{-1})$ is stable if and only if

$$\mathcal{Y} = \begin{bmatrix} E_{11}\mathcal{Y}_{11}E_{11}^T & 0 \\ 0 & 0 \end{bmatrix},$$

where $\mathcal{Y}_{11} \geq 0$ satisfies (28) *and the pencil $-sE_{11} + A_{11} + E_{11}\mathcal{Y}_{11}C_1^T JC_1$ is stable.*

Proof. It is easy to see that $\Phi\Theta^{-1}$ and $(\Pi\Theta^{-1})^T J(\Pi\Theta^{-1})$ are of the forms

$$\Phi\Theta^{-1} = \begin{bmatrix} H_{11} & H_{12} \\ 0 & H_{22} \end{bmatrix}, \quad (\Pi\Theta^{-1})^T J(\Pi\Theta^{-1}) = \begin{bmatrix} \Pi_{11} & \Pi_{12} \\ \Pi_{12}^T & \Pi_{22} \end{bmatrix},$$

where

$$\begin{aligned}
H_{11} &= A_{11}E_{11}^{-1}, \quad H_{22} = (A_{22} + A_{23}K + B_{22}F_{22})E_{22}^{-1}, \\
H_{12} &= (A_{12} + A_{13}K + B_{12}F_{22})E_{22}^{-1} - A_{11}E_{11}^{-1}E_{12}E_{22}^{-1}, \\
\Pi_{11} &= (C_1E_{11}^{-1})^T J(C_1E_{11}^{-1}), \quad \Pi_{12} = (C_1E_{11}^{-1})^T\{(C_2 + C_3K)E_{22}^{-1} - C_1E_{11}^{-1}E_{12}E_{22}^{-1}\}, \\
\Pi_{22} &= \{(C_2 + C_3K)E_{22}^{-1} - C_1E_{11}^{-1}E_{12}E_{22}^{-1}\}^T J(C_1E_{11}^{-1})^T \\
&\quad \{(C_2 + C_3K)E_{22}^{-1} - C_1E_{11}^{-1}E_{12}E_{22}^{-1}\}.
\end{aligned}$$

Since

$$\begin{bmatrix} (\Phi\Theta^{-1})^T & (\Pi\Theta^{-1})^T J(\Pi\Theta^{-1}) \\ 0 & -(\Phi\Theta^{-1}) \end{bmatrix} = \begin{bmatrix} H_{11}^T & 0 & \Pi_{11} & \Pi_{12} \\ H_{12}^T & H_{22}^T & \Pi_{12}^T & \Pi_{22} \\ 0 & 0 & -H_{11} & -H_{12} \\ 0 & 0 & 0 & -H_{22} \end{bmatrix},$$

and the stability of the pencil $-sE_{22} + A_{22} + A_{23}K + B_{22}F_{22}$ implies that H_{22}^T is stable and $-H_{22}$ is antistable, thus the stable eigendecomposition of the matrix

$$\begin{bmatrix} (\Phi\Theta^{-1})^T & (\Pi\Theta^{-1})^T J(\Pi\Theta^{-1}) \\ 0 & -(\Phi\Theta^{-1}) \end{bmatrix}$$

is of the form

$$(38)\quad \begin{bmatrix} (\Phi\Theta^{-1})^T & (\Pi\Theta^{-1})^T J(\Pi\Theta^{-1}) \\ 0 & -(\Phi\Theta^{-1}) \end{bmatrix} \begin{bmatrix} \mathcal{X}_{11} & 0 \\ \mathcal{X}_{21} & I \\ \mathcal{X}_{31} & 0 \\ 0 & 0 \end{bmatrix} = \begin{bmatrix} \mathcal{X}_{11} & 0 \\ \mathcal{X}_{21} & I \\ \mathcal{X}_{31} & 0 \\ 0 & 0 \end{bmatrix} \begin{bmatrix} \Omega_{11} & 0 \\ \Omega_{21} & H_{22}^T \end{bmatrix},$$

where the numbers of rows of $\mathcal{X}_{11}, \mathcal{X}_{21}$, and $\mathcal{X}_{31}$ are n_1, n_2, and n_1, respectively, and Ω_{11} is stable. It is well known [18] that

$$\begin{aligned} &\mathcal{Y} \ge 0 \text{ is the solution of the Lyapunov equation (37) such that} \\ &\qquad \Phi\Theta^{-1} + \mathcal{Y}(\Pi\Theta^{-1})^T J(\Pi\Theta^{-1}) \text{ is stable} \\ \iff &\mathcal{Y} = \begin{bmatrix} \mathcal{X}_{31} & 0 \\ 0 & 0 \end{bmatrix} \begin{bmatrix} \mathcal{X}_{11} & 0 \\ \mathcal{X}_{21} & I \end{bmatrix}^{-1} = \begin{bmatrix} \hat{\mathcal{Y}}_{11} & 0 \\ 0 & 0 \end{bmatrix} \ge 0, \quad H_{11} + \hat{\mathcal{Y}}_{11}\Pi_{11} \text{ is stable,} \\ (39)\quad \iff &\hat{\mathcal{Y}}_{11} \ge 0, \quad H_{11} + \hat{\mathcal{Y}}_{11}\Pi_{11} \text{ is stable,} \end{aligned}$$

where

$$\hat{\mathcal{Y}}_{11} := \mathcal{X}_{31}\mathcal{X}_{11}^{-1}.$$

Note that

$$H_{11} + \hat{\mathcal{Y}}_{11}\Pi_{11} = A_{11}E_{11}^{-1} + \hat{\mathcal{Y}}_{11}(C_1E_{11}^{-1})^T J(C_1E_{11}^{-1})$$

and

$$\begin{bmatrix} (A_{11}E_{11}^{-1})^T & (C_1E_{11}^{-1})^T J(C_1E_{11}^{-1}) \\ 0 & -(A_{11}E_{11}^{-1}) \end{bmatrix} \begin{bmatrix} \mathcal{X}_{11} \\ \mathcal{X}_{31} \end{bmatrix} = \begin{bmatrix} H_{11}^T & \Pi_{11} \\ 0 & -H_{11} \end{bmatrix} \begin{bmatrix} \mathcal{X}_{11} \\ \mathcal{X}_{31} \end{bmatrix} = \begin{bmatrix} \mathcal{X}_{11} \\ \mathcal{X}_{31} \end{bmatrix} \Omega_{11},$$

and thus we have from [18] that $\hat{\mathcal{Y}}_{11} \ge 0$ and $H_{11} + \hat{\mathcal{Y}}_{11}\Pi_{11}$ is stable if and only if

$$(40)\quad \begin{cases} \hat{\mathcal{Y}}_{11}(A_{11}E_{11}^{-1})^T + (A_{11}E_{11}^{-1})\hat{\mathcal{Y}}_{11} + \hat{\mathcal{Y}}_{11}(C_1E_{11}^{-1})^T J(C_1E_{11}^{-1})\hat{\mathcal{Y}}_{11} = 0, \\ \hat{\mathcal{Y}}_{11} \ge 0, \quad A_{11}E_{11}^{-1} + \hat{\mathcal{Y}}_{11}(C_1E_{11}^{-1})^T J(C_1E_{11}^{-1}) \text{ is stable.} \end{cases}$$

A simple calculation yields that $\hat{\mathcal{Y}}_{11}$ satisfies (40) if and only if $\hat{\mathcal{Y}}_{11} = E_{11}\mathcal{Y}_{11}E_{11}^T$, $\mathcal{Y}_{11} \ge 0$, (28) is satisfied, and the pencil $-sE_{11} + A_{11} + E_{11}\mathcal{Y}_{11}C_1^T JC_1$ is stable. Hence, Lemma 8 follows directly from (39). ∎

We are now ready to prove Theorem 6.

Proof. We prove Theorem 6 by the following four arguments.

Argument 1. Since $\mathcal{S}$ and $\mathcal{T}$ are orthogonal, we have from (22) that

$$\begin{bmatrix} E_{11} & E_{12} & 0 & 0 \\ 0 & E_{22} & 0 & 0 \\ 0 & 0 & 0 & 0 \end{bmatrix} \begin{bmatrix} \mathcal{T}_{11} & \mathcal{T}_{12} & \mathcal{T}_{13} & \mathcal{T}_{14} \\ \mathcal{T}_{21} & \mathcal{T}_{22} & \mathcal{T}_{23} & \mathcal{T}_{24} \\ \mathcal{T}_{31} & \mathcal{T}_{32} & \mathcal{T}_{33} & \mathcal{T}_{34} \\ \mathcal{T}_{41} & \mathcal{T}_{42} & \mathcal{T}_{43} & \mathcal{T}_{44} \end{bmatrix}$$

$$= \begin{bmatrix} \mathcal{S}_{11}^T & \mathcal{S}_{21}^T & \mathcal{S}_{31}^T & \mathcal{S}_{41}^T \\ \mathcal{S}_{12}^T & \mathcal{S}_{22}^T & \mathcal{S}_{32}^T & \mathcal{S}_{42}^T \\ \mathcal{S}_{13}^T & \mathcal{S}_{23}^T & \mathcal{S}_{33}^T & \mathcal{S}_{43}^T \end{bmatrix} \begin{bmatrix} \mathcal{E}_{nf} & 0 & 0 & 0 \\ \mathcal{E}_{10} & \mathcal{E}_{11} & 0 & 0 \\ \mathcal{E}_{20} & 0 & 0 & 0 \\ \mathcal{E}_{30} & 0 & 0 & 0 \end{bmatrix},$$

and thus

$$\begin{bmatrix} E_{11} & E_{12} \\ 0 & E_{22} \end{bmatrix} \begin{bmatrix} \mathcal{T}_{13} & \mathcal{T}_{14} \\ \mathcal{T}_{23} & \mathcal{T}_{24} \end{bmatrix} = 0, \quad \mathcal{S}_{23}^T \mathcal{E}_{11} = 0.$$

Because $\left[\begin{smallmatrix} E_{11} & E_{12} \\ 0 & E_{22} \end{smallmatrix}\right]$ and $\mathcal{E}_{11}$ are nonsingular, thus

$$\begin{bmatrix} \mathcal{T}_{13} & \mathcal{T}_{14} \\ \mathcal{T}_{23} & \mathcal{T}_{24} \end{bmatrix} = 0, \quad \mathcal{S}_{23} = 0. \tag{41}$$

Note that $\left[\begin{smallmatrix} \mathcal{T}_{11} & \mathcal{T}_{12} \\ \mathcal{T}_{21} & \mathcal{T}_{22} \end{smallmatrix}\right]$ is square and

$$\begin{bmatrix} \mathcal{T}_{11} & \mathcal{T}_{12} & \mathcal{T}_{13} & \mathcal{T}_{14} \\ \mathcal{T}_{21} & \mathcal{T}_{22} & \mathcal{T}_{23} & \mathcal{T}_{24} \\ \mathcal{T}_{31} & \mathcal{T}_{32} & \mathcal{T}_{33} & \mathcal{T}_{34} \\ \mathcal{T}_{41} & \mathcal{T}_{42} & \mathcal{T}_{43} & \mathcal{T}_{44} \end{bmatrix}$$

is orthogonal. Thus (41) yields that

$$\begin{bmatrix} \mathcal{T}_{31} & \mathcal{T}_{32} \\ \mathcal{T}_{41} & \mathcal{T}_{42} \end{bmatrix} = 0. \tag{42}$$

Therefore, the orthogonal matrices $\mathcal{S}$ and $\mathcal{T}$ in (22) are of the forms

$$\mathcal{S} = \begin{array}{c} \begin{matrix} n_1 & n_2 & p \end{matrix} \\ \begin{bmatrix} \mathcal{S}_{11} & \mathcal{S}_{12} & \mathcal{S}_{13} \\ \mathcal{S}_{21} & \mathcal{S}_{22} & 0 \\ \mathcal{S}_{31} & \mathcal{S}_{32} & \mathcal{S}_{33} \\ \mathcal{S}_{41} & \mathcal{S}_{42} & \mathcal{S}_{43} \end{bmatrix} \begin{matrix} \}n_{0\infty} \\ \}n_3 \\ \}m-n_3 \end{matrix} \end{array},$$

$$\mathcal{T} = \begin{array}{c} \begin{matrix} n_1+n_2-n_{0\infty} & n_{0\infty} & n_3 & m-n_3 \end{matrix} \\ \begin{bmatrix} \mathcal{T}_{11} & \mathcal{T}_{12} & 0 & 0 \\ \mathcal{T}_{21} & \mathcal{T}_{22} & 0 & 0 \\ 0 & 0 & \mathcal{T}_{33} & \mathcal{T}_{34} \\ 0 & 0 & \mathcal{T}_{43} & \mathcal{T}_{44} \end{bmatrix} \begin{matrix} \}n_1 \\ \}n_2 \\ \}n_3 \\ \}m-n_3 \end{matrix} \end{array}. \tag{43}$$

Moreover, we have from (22), (23), and (24) that

$$\begin{bmatrix} -s\Theta+\Phi & \Psi \\ \Pi & \mathcal{D} \end{bmatrix} \begin{bmatrix} I_{n_1} & 0 & 0 & 0 \\ 0 & I_{n_2} & 0 & 0 \\ 0 & -K & I & 0 \\ 0 & -F_{22} & 0 & I \end{bmatrix} = \begin{bmatrix} -sE_{11}+A_{11} & -sE_{12}+A_{12} & A_{13} & B_{12} \\ 0 & -sE_{22}+A_{22} & A_{23} & B_{22} \\ C_1 & C_2 & C_3 & 0 \end{bmatrix},$$

$$M \begin{bmatrix} -s\Theta+\Phi & 0 & \Psi \\ -\Pi^T J\Pi & -s\Theta^T-\Phi^T & -\Pi^T J\mathcal{D} \\ \mathcal{D}^T J\Pi & \Psi^T & \mathcal{D}^T J\mathcal{D} \end{bmatrix} N$$

$$= \begin{bmatrix} -sE_{11}+A_{11} & -sE_{12}+A_{12} & 0 & 0 & A_{13} & B_{12} \\ 0 & -sE_{22}+A_{22} & 0 & 0 & A_{23} & B_{22} \\ -C_1^T JC_1 & -C_1^T JC_2 & -(sE_{11}+A_{11})^T & 0 & -C_1^T JC_3 & 0 \\ -C_2^T JC_1 & -C_2^T JC_2 & -(sE_{12}+A_{12})^T & -(sE_{22}+A_{22})^T & -C_2^T JC_3 & 0 \\ C_3^T JC_1 & C_3^T JC_2 & A_{13}^T & A_{23}^T & C_3^T JC_3 & 0 \\ 0 & 0 & B_{12}^T & B_{22}^T & 0 & 0 \end{bmatrix},$$

where

$$M = \begin{bmatrix} I_{n_1} & 0 & 0 & 0 & 0 & 0 \\ 0 & I_{n_2} & 0 & 0 & 0 & 0 \\ 0 & 0 & I_{n_1} & 0 & 0 & 0 \\ 0 & 0 & 0 & I_{n_2} & K^T & F_{22}^T \\ 0 & 0 & 0 & 0 & I & 0 \\ 0 & 0 & 0 & 0 & 0 & I \end{bmatrix}, \; N = \begin{bmatrix} I_{n_1} & 0 & 0 & 0 & 0 & 0 \\ 0 & I_{n_2} & 0 & 0 & 0 & 0 \\ 0 & 0 & I_{n_1} & 0 & 0 & 0 \\ 0 & 0 & 0 & I_{n_2} & 0 & 0 \\ 0 & -K & 0 & 0 & I & 0 \\ 0 & -F_{22} & 0 & 0 & 0 & I \end{bmatrix}.$$

Hence,

$$\begin{bmatrix} \mathcal{S}_{11} & \mathcal{S}_{12} & \mathcal{S}_{13} \\ \mathcal{S}_{21} & \mathcal{S}_{22} & 0 \\ \mathcal{S}_{31} & \mathcal{S}_{32} & \mathcal{S}_{33} \\ \mathcal{S}_{41} & \mathcal{S}_{42} & \mathcal{S}_{43} \end{bmatrix} \begin{bmatrix} -sI + \Phi\Theta^{-1} & \Psi \\ \Pi\Theta^{-1} & \mathcal{D} \end{bmatrix}$$

$$\times \begin{bmatrix} E_{11}\mathcal{T}_{11} + E_{12}\mathcal{T}_{21} & E_{11}\mathcal{T}_{12} + E_{12}\mathcal{T}_{22} & 0 & 0 \\ E_{22}\mathcal{T}_{21} & E_{22}\mathcal{T}_{22} & 0 & 0 \\ -K\mathcal{T}_{21} & -K\mathcal{T}_{22} & \mathcal{T}_{33} & \mathcal{T}_{34} \\ -F_{22}\mathcal{T}_{21} & -F_{22}\mathcal{T}_{22} & \mathcal{T}_{43} & \mathcal{T}_{44} \end{bmatrix}$$

$$= \begin{bmatrix} -s\mathcal{E}_{nf} + \mathcal{A}_{nf} & 0 & 0 & 0 \\ -s\mathcal{E}_{10} + \mathcal{A}_{10} & -s\mathcal{E}_{11} + \mathcal{A}_{11} & \mathcal{A}_{12} & \mathcal{A}_{13} \\ -s\mathcal{E}_{20} + \mathcal{A}_{20} & \mathcal{A}_{21} & \mathcal{A}_{22} & \mathcal{A}_{23} \\ -s\mathcal{E}_{30} + \mathcal{A}_{30} & \mathcal{A}_{31} & \mathcal{A}_{32} & \mathcal{A}_{33} \end{bmatrix},$$

the columns of

$$\begin{bmatrix} E_{11}L_1 + E_{12}L_2 \\ E_{22}L_2 \\ L_3 \\ L_4 \\ L_5 - KL_2 \\ L_6 - F_{22}L_2 \end{bmatrix}$$

span the stable eigenspace of the pencil

$$\begin{bmatrix} -sI + \Phi\Theta^{-1} & 0 & \Psi \\ -(\Pi\Theta^{-1})^T J(\Pi\Theta^{-1}) & -sI - (\Phi\Theta^{-1})^T & -(\Pi\Theta^{-1})^T J\mathcal{D} \\ \mathcal{D}^T J(\Pi\Theta^{-1}) & \Psi^T & \mathcal{D}^T J\mathcal{D} \end{bmatrix},$$

and

$$\begin{bmatrix} \Phi\Theta^{-1} & 0 & \Psi \\ -(\Pi\Theta^{-1})^T J(\Pi\Theta^{-1}) & -(\Phi\Theta^{-1})^T & -(\Pi\Theta^{-1})^T J\mathcal{D} \\ \mathcal{D}^T J(\Pi\Theta^{-1}) & \Psi^T & \mathcal{D}^T J\mathcal{D} \end{bmatrix} \begin{bmatrix} E_{11}L_1 + E_{12}L_2 \\ E_{22}L_2 \\ L_3 \\ L_4 \\ L_5 - KL_2 \\ L_6 - F_{22}L_2 \end{bmatrix}$$

$$= \begin{bmatrix} I & 0 & 0 \\ 0 & I & 0 \\ 0 & 0 & 0 \end{bmatrix} \begin{bmatrix} E_{11}L_1 + E_{12}L_2 \\ E_{22}L_2 \\ L_3 \\ L_4 \\ L_5 - KL_2 \\ L_6 - F_{22}L_2 \end{bmatrix} \Delta.$$

Argument 2. Note that $G_1(s) = \left[\begin{array}{c|c} -sI + \Phi\Theta^{-1} & \Psi \\ \hline \Pi\Theta^{-1} & \mathcal{D} \end{array}\right]$, so the minimality of realization (7) and the stability of the pencil $-sE_{22} + A_{22} + A_{23}K + B_{22}F_{22}$ give that

$$\operatorname{rank}\begin{bmatrix} -sI + \Phi\Theta^{-1} & \Psi \end{bmatrix} = \operatorname{rank}\begin{bmatrix} -sI + \Phi\Theta^{-1} \\ \Pi\Theta^{-1} \end{bmatrix} = n_1 + n_2 \quad \forall s \in \mathbf{C}_0 \cup \mathbf{C}_+.$$

Thus, we have from Lemma 7(iii) and Theorem 3 that $G(s)$ has a (J, J')-lossless factorization if and only if $G_1(s)$ has a (J, J')-lossless factorization, or equivalently,

- the conditions in (a), (b) hold, $r + n_{0\infty} = n_1 + n_2$;
- $\begin{bmatrix} E_{11}L_1 + E_{12}L_2 & E_{11}\mathcal{T}_{12} + E_{12}\mathcal{T}_{22} \\ E_{22}L_2 & E_{22}\mathcal{T}_{22} \end{bmatrix}$ is nonsingular;
- $\mathcal{X} := \begin{bmatrix} L_3 & 0 \\ L_4 & 0 \end{bmatrix}\begin{bmatrix} E_{11}L_1 + E_{12}L_2 & E_{11}\mathcal{T}_{12} + E_{12}\mathcal{T}_{22} \\ E_{22}L_2 & E_{22}\mathcal{T}_{22} \end{bmatrix}^{-1} \geq 0$;
- the Lyapunov equation (37) has a solution $\mathcal{Y} \geq 0$ such that the matrix $\Phi\Theta^{-1} + \mathcal{Y}(\Pi\Theta^{-1})^T J(\Pi\Theta^{-1})$ is stable, and furthermore, $\rho(\mathcal{X}\mathcal{Y}) < 1$.

Argument 3. Since

$$\begin{bmatrix} E_{11}L_1 + E_{12}L_2 & E_{11}\mathcal{T}_{12} + E_{12}\mathcal{T}_{22} \\ E_{22}L_2 & E_{22}\mathcal{T}_{22} \end{bmatrix} \text{ is nonsingular} \Leftrightarrow \begin{bmatrix} L_1 & \mathcal{T}_{12} \\ L_2 & \mathcal{T}_{22} \end{bmatrix} \text{ is nonsingular},$$

$$\mathcal{X} \geq 0 \Leftrightarrow \begin{bmatrix} E_{11}L_1 + E_{12}L_2 & E_{11}\mathcal{T}_{12} + E_{12}\mathcal{T}_{22} \\ E_{22}L_2 & E_{22}\mathcal{T}_{22} \end{bmatrix}^T \begin{bmatrix} L_3 & 0 \\ L_4 & 0 \end{bmatrix} \geq 0,$$

and Lemma 8 yields that

$$\rho(\mathcal{X}\mathcal{Y}) < 1 \;\Leftrightarrow\; \rho\left(\begin{bmatrix} L_1 & \mathcal{T}_{12} \\ L_2 & \mathcal{T}_{22} \end{bmatrix}, \begin{bmatrix} \mathcal{Y}_{11}E_{11}^T L_3 & 0 \\ 0 & 0 \end{bmatrix}\right) < 1,$$

thus $G(s)$ has a (J, J')-lossless factorization if and only if conditions (a), (b), (c), and (d) hold.

Argument 4. Under the conditions in (a)–(d), according to Lemma 7(iii), Lemma 8, and Theorem 3, factors $\Theta(s)$ and $\Xi(s)$ are given by

$$\Theta(s) = \left[\begin{array}{cc|c} -sI + \Delta & 0 & Z_1 \\ 0 & -sI + \Phi\Theta^{-1} & Z_2 \\ \hline \Pi\Theta^{-1}\begin{bmatrix} E_{11}L_1 + E_{12}L_2 \\ E_{22}L_2 \end{bmatrix} + \mathcal{D}\begin{bmatrix} L_5 - KL_2 \\ L_6 - F_{22}L_2 \end{bmatrix} & \Pi\Theta^{-1} & -\begin{bmatrix} \mathcal{S}_{33} \\ \mathcal{S}_{43} \end{bmatrix}^T \end{array}\right] \mathcal{D}_0$$

$$= \left[\begin{array}{cc|c} -sI + \Delta & 0 & Z_1 \\ 0 & -s\Theta + \Phi & Z_2 \\ \hline \Pi\Theta^{-1}\begin{bmatrix} E_{11}L_1 + E_{12}L_2 \\ E_{22}L_2 \end{bmatrix} + \mathcal{D}\begin{bmatrix} L_5 - KL_2 \\ L_6 - F_{22}L_2 \end{bmatrix} & \Pi & -\begin{bmatrix} \mathcal{S}_{33} \\ \mathcal{S}_{43} \end{bmatrix}^T \end{array}\right] \mathcal{D}_0,$$

$$
\begin{aligned}
&\Xi(s)\\
&= -(J')^{-1}\mathcal{D}_0^T \left[\begin{array}{c|c} -sI + \Phi\Theta^{-1} + \mathcal{Y}(\Pi\Theta^{-1})^T J(\Pi\Theta^{-1}) & \Psi + \mathcal{Y}(\Pi\Theta^{-1})^T J\mathcal{D} \\ \hline \left(\begin{bmatrix} \mathcal{S}_{31} & \mathcal{S}_{32} \\ \mathcal{S}_{41} & \mathcal{S}_{42} \end{bmatrix}\mathcal{X} + \begin{bmatrix} \mathcal{S}_{33} \\ \mathcal{S}_{43} \end{bmatrix} J\Pi\Theta^{-1}\right)(I - \mathcal{Y}\mathcal{X})^{-1} & \begin{bmatrix} \mathcal{S}_{33} \\ \mathcal{S}_{43} \end{bmatrix} J\mathcal{D} \end{array}\right] G_2(s)\\
&= -(J')^{-1}\mathcal{D}_0^T \left[\begin{array}{c|c} -s\Theta + \Phi + \mathcal{Y}(\Pi\Theta^{-1})^T J\Pi & \Psi + \mathcal{Y}(\Pi\Theta^{-1})^T J\mathcal{D} \\ \hline \left(\begin{bmatrix} \mathcal{S}_{31} & \mathcal{S}_{32} \\ \mathcal{S}_{41} & \mathcal{S}_{42} \end{bmatrix}\mathcal{X} + \begin{bmatrix} \mathcal{S}_{33} \\ \mathcal{S}_{43} \end{bmatrix} J\Pi\Theta^{-1}\right)(I - \mathcal{Y}\mathcal{X})^{-1}\Theta & \begin{bmatrix} \mathcal{S}_{33} \\ \mathcal{S}_{43} \end{bmatrix} J\mathcal{D} \end{array}\right] G_2(s),
\end{aligned}
$$

where

$$
\Pi\Theta^{-1}\begin{bmatrix} E_{11}L_1 + E_{12}L_2 \\ E_{22}L_2 \end{bmatrix} + \mathcal{D}\begin{bmatrix} L_5 - KL_2 \\ L_6 - F_{22}L_2 \end{bmatrix} = C_1L_1 + C_2L_2 + C_3L_5,
$$

$$
\begin{aligned}
Z_1 &= -\begin{bmatrix} I_r & 0 \end{bmatrix}\left(\begin{bmatrix} E_{11}L_1 + E_{12}L_2 & E_{11}\mathcal{T}_{12} + E_{12}\mathcal{T}_{22} \\ E_{22}L_2 & E_{22}\mathcal{T}_{22} \end{bmatrix} - \mathcal{Y}\begin{bmatrix} L_3 & 0 \\ L_4 & 0 \end{bmatrix}\right)^{-1}\\
&\quad\times\left(\begin{bmatrix} \mathcal{S}_{31} & \mathcal{S}_{32} \\ \mathcal{S}_{41} & \mathcal{S}_{42} \end{bmatrix}^T + \mathcal{Y}(\Pi\Theta^{-1})^T J\begin{bmatrix} \mathcal{S}_{33} \\ \mathcal{S}_{43} \end{bmatrix}^T\right)\\
&= -\begin{bmatrix} I_r & 0 \end{bmatrix}\left(\begin{bmatrix} E_{11} & E_{12} \\ 0 & E_{22} \end{bmatrix}\begin{bmatrix} L_1 - \mathcal{Y}_{11}E_{11}^T L_3 & \mathcal{T}_{12} \\ L_2 & \mathcal{T}_{22} \end{bmatrix}\right)^{-1}\\
&\quad\times\left(\begin{bmatrix} \mathcal{S}_{31} & \mathcal{S}_{32} \\ \mathcal{S}_{41} & \mathcal{S}_{42} \end{bmatrix}^T + \begin{bmatrix} E_{11}\mathcal{Y}_{11}C_1^T \\ 0 \end{bmatrix} J\begin{bmatrix} \mathcal{S}_{33} \\ \mathcal{S}_{43} \end{bmatrix}^T\right),
\end{aligned}
$$

$$
\begin{aligned}
Z_2 &= (I - \mathcal{Y}\mathcal{X})^{-1}\mathcal{Y}\left(\mathcal{X}\begin{bmatrix} \mathcal{S}_{31} & \mathcal{S}_{32} \\ \mathcal{S}_{41} & \mathcal{S}_{42} \end{bmatrix}^T + (\Pi\Theta^{-1})^T J\begin{bmatrix} \mathcal{S}_{33} \\ \mathcal{S}_{43} \end{bmatrix}^T\right)\\
&= \begin{bmatrix} I \\ 0 \end{bmatrix}\left\{[E_{11}\mathcal{Y}_{11}E_{11}^T L_3 \;\; 0]\begin{bmatrix} E_{11}L_1 + E_{12}L_2 - E_{11}\mathcal{Y}_{11}E_{11}^T L_3 & E_{11}\mathcal{T}_{12} + E_{12}\mathcal{T}_{22} \\ E_{22}L_2 & E_{22}\mathcal{T}_{22} \end{bmatrix}^{-1}\right.\\
&\quad\left.\times\left(\begin{bmatrix} \mathcal{S}_{31} & \mathcal{S}_{32} \\ \mathcal{S}_{41} & \mathcal{S}_{42} \end{bmatrix}^T + \begin{bmatrix} E_{11}\mathcal{Y}_{11}C_1^T \\ 0 \end{bmatrix} J\begin{bmatrix} \mathcal{S}_{33} \\ \mathcal{S}_{43} \end{bmatrix}^T\right) + E_{11}\mathcal{Y}_{11}C_1^T J\begin{bmatrix} \mathcal{S}_{33} \\ \mathcal{S}_{43} \end{bmatrix}^T\right\},
\end{aligned}
$$

$$
\begin{aligned}
&\left(\begin{bmatrix} \mathcal{S}_{31} & \mathcal{S}_{32} \\ \mathcal{S}_{41} & \mathcal{S}_{42} \end{bmatrix}\mathcal{X} + \begin{bmatrix} \mathcal{S}_{33} \\ \mathcal{S}_{43} \end{bmatrix} J\Pi\Theta^{-1}\right)(I - \mathcal{Y}\mathcal{X})^{-1}\Theta\\
&\quad= \begin{bmatrix} \mathcal{S}_{31} & \mathcal{S}_{32} & \mathcal{S}_{33}J \\ \mathcal{S}_{41} & \mathcal{S}_{42} & \mathcal{S}_{43}J \end{bmatrix}\left(\begin{bmatrix} L_3 & 0 \\ L_4 & 0 \\ C_1L_1 + C_2L_2 & C_1\mathcal{T}_{12} + C_2\mathcal{T}_{22} \end{bmatrix}\right.\\
&\qquad\qquad\left.\times\begin{bmatrix} L_1 - \mathcal{Y}_{11}E_{11}^T L_3 & \mathcal{T}_{12} \\ L_2 & \mathcal{T}_{22} \end{bmatrix}^{-1} + \begin{bmatrix} 0 & 0 \\ 0 & 0 \\ 0 & C_3K \end{bmatrix}\right)\\
&\quad= \begin{bmatrix} \Pi_1 & \Pi_2 + \Pi_3K \end{bmatrix}.
\end{aligned}
$$

In the above, $\begin{bmatrix} \Pi_1 & \Pi_2 & \Pi_3 \end{bmatrix}$ is defined by

$$\begin{bmatrix} \Pi_1 & \Pi_2 & \Pi_3 \end{bmatrix} = C_\Xi \begin{bmatrix} L_1 - \mathcal{Y}_{11} E_{11}^T L_3 & \mathcal{T}_{12} & 0 \\ L_2 & \mathcal{T}_{22} & 0 \\ 0 & 0 & I \end{bmatrix}^{-1}.$$

Note that (22) with (43) together gives that

$$\begin{bmatrix} E_{11} & E_{12} \\ 0 & E_{22} \end{bmatrix} \begin{bmatrix} \mathcal{T}_{12} \\ \mathcal{T}_{22} \end{bmatrix} = \begin{bmatrix} \mathcal{S}_{21}^T \\ \mathcal{S}_{22}^T \end{bmatrix} \mathcal{E}_{11}, \quad \hat{\mathcal{W}} \left(\begin{bmatrix} E_{11} & E_{12} \\ 0 & E_{22} \end{bmatrix} \begin{bmatrix} \mathcal{T}_{12} \\ \mathcal{T}_{22} \end{bmatrix} \right) = \begin{bmatrix} 0 \\ \mathcal{R}_{\hat{\mathcal{W}}} \mathcal{E}_{11} \end{bmatrix},$$

which implies that

$$\left[\begin{array}{c|c} -sI + \Delta & Z_1 \\ \hline C_1 L_1 + C_2 L_2 + C_3 L_3 & 0 \end{array} \right] = \left[\begin{array}{c|c} -sE_\Theta + A_\Theta & \mathcal{Z}_1 \\ \hline C_1 L_1 + C_2 L_2 + C_3 L_3 & 0 \end{array} \right].$$

Furthermore, we have from (30), (31), and (32) that

$$\begin{bmatrix} \mathcal{W}_{11} & \mathcal{W}_{12} \\ \mathcal{W}_{21} & \mathcal{W}_{22} \end{bmatrix} \begin{bmatrix} E_{11} \mathcal{Y}_{11} E_{11}^T L_3 & 0 \\ E_{11} L_1 + E_{12} L_2 - E_{11} \mathcal{Y}_{11} E_{11}^T L_3 & E_{11} \mathcal{T}_{12} + E_{12} \mathcal{T}_{22} \\ E_{22} L_2 & E_{22} \mathcal{T}_{22} \end{bmatrix} = \begin{bmatrix} 0 \\ \Sigma \end{bmatrix}$$

with

$$\Sigma \in \mathbf{R}^{(n_1+n_2)\times(n_1+n_2)}, \quad \operatorname{rank}(\Sigma) = n_1 + n_2,$$

which yields [3, 11, 43] that

$$\begin{bmatrix} E_{11} \mathcal{Y}_{11} E_{11}^T L_3 & 0 \end{bmatrix} \begin{bmatrix} E_{11} L_1 + E_{12} L_2 - E_{11} \mathcal{Y}_{11} E_{11}^T L_3 & E_{11} \mathcal{T}_{12} + E_{12} \mathcal{T}_{22} \\ E_{22} L_2 & E_{22} \mathcal{T}_{22} \end{bmatrix}^{-1} = -\mathcal{W}_{11}^{-1} \mathcal{W}_{12},$$

and consequently, $Z_2 = \begin{bmatrix} \mathcal{W}_{11}^{-1} \mathcal{Z}_2 \\ 0 \end{bmatrix}$. Hence, we have that

$$\begin{aligned}
\Theta(s) &= \left[\begin{array}{cc|c} -sE_\Theta + A_\Theta & 0 & \mathcal{Z}_1 \\ 0 & -s\Theta + \Phi & \begin{bmatrix} \mathcal{W}_{11}^{-1} \mathcal{Z}_2 \\ 0 \end{bmatrix} \\ \hline C_1 L_1 + C_2 L_2 + C_3 L_5 & \Pi & -\begin{bmatrix} \mathcal{S}_{33} \\ \mathcal{S}_{43} \end{bmatrix}^T \end{array} \right] \mathcal{D}_0 \\
&= \left[\begin{array}{ccc|c} -sE_\Theta + A_\Theta & 0 & 0 & \mathcal{Z}_1 \\ 0 & -sE_{11} + A_{11} & -sE_{12} + A_{12} + A_{13}K + B_{12}F_{22} & \mathcal{W}_{11}^{-1} \mathcal{Z}_2 \\ 0 & 0 & -sE_{22} + A_{22} + A_{23}K + B_{22}F_{22} & 0 \\ \hline C_1 L_1 + C_2 L_2 + C_3 L_5 & C_1 & C_2 + C_3 K & -\begin{bmatrix} \mathcal{S}_{33} \\ \mathcal{S}_{43} \end{bmatrix}^T \end{array} \right] \mathcal{D}_0 \\
&= \left[\begin{array}{cc|c} -sE_\Theta + A_\Theta & 0 & \mathcal{Z}_1 \\ 0 & \mathcal{W}_{11}(-sE_{11} + A_{11}) & \mathcal{Z}_2 \\ \hline C_1 L_1 + C_2 L_2 + C_3 L_5 & C_1 & -\begin{bmatrix} \mathcal{S}_{33} \\ \mathcal{S}_{43} \end{bmatrix}^T \end{array} \right] \mathcal{D}_0,
\end{aligned}$$

and

$$\Xi(s) = -(J')^{-1}\mathcal{D}_0^T$$

$$\times \left[\begin{array}{ccc|cc} -sE_{11}+A_{11}+E_{11}\mathcal{Y}_{11}C_1^TJC_1 & -sE_{12}+A_{12}+A_{13}K+B_{12}F_{22}+E_{11}\mathcal{Y}_{11}C_1^TJ(C_2+C_3K) & A_{13}+E_{11}\mathcal{Y}_{11}C_1^TJC_3 & B_{12} \\ 0 & -sE_{22}+A_{22}+A_{23}K+B_{22}F_{22} & A_{23} & B_{22} \\ \hline \Pi_1 & \Pi_2+\Pi_3\mathcal{K} & \Pi_3 & 0 \end{array}\right] G_2(s)$$

$$= -(J')^{-1}\mathcal{D}_0^T$$

$$\times \left[\begin{array}{ccc|cc} -sE_{11}+A_{11}+E_{11}\mathcal{Y}_{11}C_1^TJC_1 & -sE_{12}+A_{12}+B_{12}F_{22}+E_{11}\mathcal{Y}_{11}C_1^TJC_2 & A_{13}+E_{11}\mathcal{Y}_{11}C_1^TJC_3 & 0 & B_{12} \\ 0 & -sE_{22}+A_{22}+B_{22}F_{22} & A_{23} & 0 & B_{22} \\ 0 & A_{32}+B_{31}F_{12} & A_{33}+B_{31}F_{13} & B_{31} & 0 \\ \hline \Pi_1 & \Pi_2 & \Pi_3 & 0 & 0 \end{array}\right] G_2(s)$$

(since $A_{32}+B_{31}F_{12}=B_{31}K,\ A_{33}+B_{31}F_{13}=-B_{31}$)

$$= -(J')^{-1}\mathcal{D}_0^T \left[\begin{array}{ccc|cc} -sE_{11}+A_{11}+E_{11}\mathcal{Y}_{11}C_1^TJC_1 & -sE_{12}+A_{12}+E_{11}\mathcal{Y}_{11}C_1^TJC_2 & A_{13}+E_{11}\mathcal{Y}_{11}C_1^TJC_3 & 0 & B_{12} \\ 0 & -sE_{22}+A_{22} & A_{23} & 0 & B_{22} \\ 0 & A_{32} & A_{33} & B_{31} & 0 \\ \hline \Pi_1 & \Pi_2 & \Pi_3 & 0 & 0 \end{array}\right] W^T$$

$$= -(J')^{-1}\mathcal{D}_0^T \left[\begin{array}{c|c} -sE_\Xi+A_\Xi & B_\Xi \\ \hline C_\Xi & 0 \end{array}\right] W^T. \qquad \square$$

4. Conclusions. We have obtained necessary and sufficient solvability conditions and developed a numerical algorithm based on a generalized eigenvalue approach for the (J, J')-lossless factorization of any general rational matrix $G(s) \in \mathcal{R}^{p\times m}(s)$. Our algorithm consists of factorization (8), eigenfactorizations (22) and (24), and the algebraic Riccati equation (28). Thus, the (J, J')-lossless factorization can be computed in a numerically reliable manner. A numerical example has also been given to illustrate the proposed algorithm.

Appendix. We construct factorization (8) by the following numerical procedure.

Step 1. Compute the generalized upper triangular form [25, 42] of the pencil $-sE + A$ to get orthogonal matrices P and Q such that

$$P(-sE+A)Q =: \begin{matrix} \\ \}n_1 \\ \}n_2 \\ \}n_3 \end{matrix} \begin{matrix} \begin{matrix} n_1 & n_2 & n_3 \end{matrix} \\ \begin{bmatrix} -sE_{11}^{(1)} + A_{11}^{(1)} & -sE_{12}^{(1)} + A_{12}^{(1)} & -sE_{13}^{(1)} + A_{13}^{(1)} \\ 0 & -sE_{22}^{(1)} + A_{22}^{(1)} & A_{23}^{(1)} \\ 0 & A_{32} & A_{33}^{(1)} \end{bmatrix} \end{matrix}, \tag{44}$$

where $E_{11}^{(1)}$ and $E_{22}^{(1)}$ are nonsingular and

$$\operatorname{rank} \begin{bmatrix} -sE_{22}^{(1)} + A_{22}^{(1)} & A_{23}^{(1)} \\ A_{32} & A_{33}^{(1)} \end{bmatrix} = n_2 + n_3 \quad \forall s \in \mathbf{C}.$$

Define

$$PB =: \begin{matrix} \begin{bmatrix} B_1^{(1)} \\ B_2^{(1)} \\ B_3^{(1)} \end{bmatrix} \end{matrix} \begin{matrix} \}n_1 \\ \}n_2 \\ \}n_3 \end{matrix}, \quad CQ =: \begin{matrix} \begin{matrix} n_1 & n_2 & n_3 \end{matrix} \\ \begin{bmatrix} C_1 & C_2 & C_3^{(1)} \end{bmatrix} \end{matrix}.$$

The minimality of realization (7) gives that

$$\operatorname{rank}\,(B_3^{(1)}) = n_3.$$

Step 2. Compute the QR factorization of $(B_3^{(1)})^T$ to get orthogonal matrix W such that

$$B_3^{(1)} W =: \begin{matrix} \begin{matrix} n_3 & m-n_3 \end{matrix} \\ \begin{bmatrix} B_{31} & 0 \end{bmatrix} \end{matrix}, \quad \operatorname{rank}(B_{31}) = n_3. \tag{45}$$

Define

$$\begin{bmatrix} B_1^{(1)} \\ B_2^{(1)} \end{bmatrix} W =: \begin{matrix} \begin{matrix} n_3 & m-n_3 \end{matrix} \\ \begin{bmatrix} B_{11}^{(2)} & B_{12}^{(2)} \\ B_{21}^{(2)} & B_{22}^{(2)} \end{bmatrix} \end{matrix} \begin{matrix} \}n_1 \\ \}n_2 \end{matrix}.$$

Step 3. Compute QR factorizations to get orthogonal matrices $\tilde{U}$, $\hat{U}$, and V with partitioning

$$\tilde{U} = \begin{matrix} \begin{matrix} n_1 & n_3 \end{matrix} \\ \begin{bmatrix} \tilde{U}_{11} & \tilde{U}_{12} \\ \tilde{U}_{21} & \tilde{U}_{22} \end{bmatrix} \end{matrix} \begin{matrix} \}n_1 \\ \}n_3 \end{matrix}, \quad \hat{U} = \begin{matrix} \begin{matrix} n_2 & n_3 \end{matrix} \\ \begin{bmatrix} \hat{U}_{11} & \hat{U}_{12} \\ \hat{U}_{21} & \hat{U}_{22} \end{bmatrix} \end{matrix} \begin{matrix} \}n_2 \\ \}n_3 \end{matrix}, \quad V = \begin{matrix} \begin{matrix} n_3 & n_1 \end{matrix} \\ \begin{bmatrix} V_{11} & V_{12} \\ V_{21} & V_{22} \end{bmatrix} \end{matrix} \begin{matrix} \}n_3 \\ \}n_1 \end{matrix}$$

such that

$$(46)\quad \hat{U}\begin{bmatrix} B_{21}^{(2)} \\ B_{31} \end{bmatrix} =: \begin{bmatrix} 0 \\ \hat{R}_B \end{bmatrix}, \quad \tilde{U}\begin{bmatrix} B_{11}^{(2)} \\ \hat{R}_B \end{bmatrix} =: \begin{bmatrix} 0 \\ \tilde{R}_B \end{bmatrix}, \quad \begin{bmatrix} E_{13}^{(1)} & E_{11}^{(1)} \end{bmatrix} V =: \begin{bmatrix} 0 & R_E \end{bmatrix},$$

where $\tilde{R}_B$, $\hat{R}_B$, and R_E are nonsingular. Since $E_{11}^{(1)}$ and B_{31} are nonsingular, we have that $\tilde{U}_{11}$, $\hat{U}_{11}$, and V_{11} are nonsingular [1, 3, 11, 43].

Step 4. Define

$$\begin{matrix} n_1+n_2 & n_3 \end{matrix}$$
$$\begin{matrix} \\ \\ \end{matrix}\begin{bmatrix} U_{11} & U_{12} \\ U_{21} & U_{22} \end{bmatrix}\begin{matrix} \}n_1+n_2 \\ \}n_3 \end{matrix} := U = \begin{bmatrix} \tilde{U}_{11} & 0 & \tilde{U}_{12} \\ 0 & I & 0 \\ \tilde{U}_{21} & 0 & \tilde{U}_{22} \end{bmatrix}\begin{bmatrix} I & 0 \\ 0 & \hat{U} \end{bmatrix}$$
$$= \begin{bmatrix} \tilde{U}_{11} & \tilde{U}_{12}\hat{U}_{21} & \tilde{U}_{12}\hat{U}_{22} \\ 0 & \hat{U}_{11} & \hat{U}_{12} \\ \tilde{U}_{21} & \tilde{U}_{22}\hat{U}_{21} & \tilde{U}_{22}\hat{U}_{22} \end{bmatrix}.$$

Then orthogonal matrices P, Q, U, V, and W above give factorization (8) with

$$\begin{bmatrix} -sE_{11}+A_{11} & -sE_{12}+A_{12} & -sE_{13}^{(4)}+A_{13}^{(4)} & B_{12} \\ 0 & -sE_{22}+A_{22} & A_{23}^{(4)} & B_{22} \end{bmatrix}$$
$$= \begin{bmatrix} U_{11} & U_{12} \end{bmatrix}\begin{bmatrix} -sE_{11}^{(1)}+A_{11}^{(1)} & -sE_{12}^{(1)}+A_{12}^{(1)} & -sE_{13}+A_{13}^{(1)} & B_{12}^{(2)} \\ 0 & -sE_{22}^{(1)}+A_{22}^{(1)} & A_{23}^{(1)} & B_{22}^{(2)} \\ 0 & A_{32} & A_{33}^{(1)} & 0 \end{bmatrix}$$

and

$$\begin{bmatrix} A_{13} \\ A_{23} \\ A_{33} \\ C_3 \end{bmatrix} = \begin{bmatrix} A_{13}^{(4)} & A_{11} \\ A_{23}^{(4)} & 0 \\ A_{33}^{(1)} & 0 \\ C_3^{(1)} & C_1 \end{bmatrix}\begin{bmatrix} V_{11} \\ V_{21} \end{bmatrix}.$$

A direct calculation yields that properties (9), (10), and (11) hold. □

The above procedures involves only the generalized upper triangular form (44) and four QR factorizations in (45) and (46). Hence, it needs only $O(n^3+m^3)$ flops [5].

ANALYSIS OF OPTIMAL CONTROL PROBLEMS FOR THE TWO-DIMENSIONAL THERMISTOR SYSTEM*

HYUNG-CHUN LEE† AND TIMOFEY SHILKIN‡

Abstract. An optimal control problem for the thermistor system is considered. First, the precise mathematical problem is established and the proof of existence of the optimal solution is given with appropriate function spaces. Then, Gâteaux differentiability is shown for the thermistor system, with respect to control, and the optimality system is obtained.

Key words. optimal control, thermistor system, Gâteaux derivatives

1. Introduction. Let Ω be a bounded domain in $\mathbb{R}^2$ with a smooth boundary $\partial\Omega$, and let $Q_T = \Omega \times (0,T)$. In this paper, we consider an optimal control problem for the system

$$\partial_t u - \operatorname{div}(\mu(\theta)\nabla u) = f \quad \text{in } Q_T, \tag{1.1}$$

$$\partial_t \theta - \Delta\theta = \mu(\theta)|\nabla u|^2 \quad \text{in } Q_T. \tag{1.2}$$

Here $u : Q_T \to \mathbb{R}$, $\theta : Q_T \to \mathbb{R}$ are the unknowns and $f : Q_T \to \mathbb{R}$, $\mu : \mathbb{R} \to \mathbb{R}$ are given. The function f will be the control of our optimal control problem. We assume that μ is a function of class C^1 satisfying the following assumption: there are positive constants μ_0, μ_1, and μ_2 such that

$$0 < \mu_0 \le \mu(s) \le \mu_1, \quad |\mu'(s)| \le \mu_2 \quad \forall s \in \mathbb{R}. \tag{1.3}$$

In this paper we study the following initial-boundary value problem for the system (1.1)–(1.2):

$$u|_{\partial\Omega} = 0, \quad u|_{t=0} = u_0, \tag{1.4}$$

$$\theta|_{\partial\Omega} = 0, \quad \theta|_{t=0} = \theta_0. \tag{1.5}$$

The main difficulty of the problem under consideration arises from the right-hand side of (1.2), which has the quadratic growth with respect to the gradient of unknown function u. Formally speaking, this means that our system belongs to *the class of systems having the strong nonlinearity.* Indeed, assuming that μ is smooth, we can introduce a new unknown vector function $U = (u, \theta)$ and get for it the system of type

$$\partial_t U - a(U)\Delta U = b(U, \nabla U), \tag{1.6}$$

where function b has quadratic growth with respect to ∇U:

$$|b(z,F)| \le C(1+|F|^2). \tag{1.7}$$

For the case of the scalar elliptic and parabolic equations having strong nonlinearities, the existence and regularity theory (based on the Leray–Schauder theory and a priori estimates in the smooth classes of functions) was developed by Ladyzhenskaya and Uraltseva [17] and Ladyzhenskaya, Solonnikov, and Uraltseva [18]. In contrast with the scalar case, there is no general existence and regularity theory for systems of types (1.6) and (1.7) and, moreover, examples show that without additional assumptions (such as special structure, etc.) such theories cannot be established; see, for instance, [10].

Existence of the weak solutions to the system (1.1)–(1.2) was proved in [21], where the mathematical treatment of this system appears, apparently for the first time. Unfortunately, the class of weak solutions considered in [21] does not provide Gâteaux differentiability of the nonlinear operator corresponding to the system (1.1)–(1.2). To study the optimal control problem for this system, we have to work with the class of strong solutions. The regularity theorem requires additional assumptions on f, which can be provided only by the appropriate choice of the cost functional of our problem. On the other hand, a carelessly chosen cost functional leads to the more complex form of the optimality system, which is unpleasant from the point of view of applications. So, to study an optimal control problem for the system (1.1)–(1.2), it is necessary to find the balance between the assumptions of f, which provide the regularity of our optimal solution and the form of the cost functional which, at least in principle, allows us to produce some reasonable numeric calculations. In our work, we suggest a form of the cost functional that satisfies these two requirements.

Regularity of weak solutions to the system (1.1)–(1.2) for the stationary case was studied, for example, in [5]. The complete regularity theory in the "elliptic-parabolic" case, i.e., the case when, in (1.1), the term containing the time derivative of u is absent, was developed in [2]. For the parabolic case, regularity of weak solutions to the system (1.1)–(1.2) was studied by Rodrigues in [21]. He studied the only special case, where the function μ is close to a constant (in the sense that $\mu_1 - \mu_0 \ll 1$). In the present work, we get rid of this restriction and prove the regularity of weak solutions of (1.1)–(1.2), from which Gâteaux differentiability of the nonlinear operator (1.1)–(1.2) on the functional class of strong solutions follows. This allows us to study the optimal control problem and derive the optimality system for our optimal control problem. We believe that our regularity theorem for the parabolic system (1.1)–(1.2) is one of the results of our work which is of independent interest.

The system (1.1)–(1.2) arises in many applications. For example, nonlinearities in (1.1) and (1.2) are typical for the description of *thermistors*, i.e., in studying the heat transfer in the resistor device whose resistance $\mu(\theta)$ depends on the temperature θ, and the volume heating is given by the Joule–Lentz law; see, for instance, [2, 5, 6, 7, 8, 13, 21] and references therein.

In our work, we explore the motivation of the system (1.1)–(1.2), which is borrowed from the paper [21]. Namely, in [21] it was shown that the system (1.1)–(1.2) describes eddy currents induced by a unidirectional external magnetic field of the form

$$H(x_1,x_2,x_3,t) = u(x_1,x_2,t)\vec{e}_3, \tag{1.8}$$

where $\vec{e}_3$ is a unit vector in the x_3-direction; see [21] for more details. Our problem is to find a control f such that the magnetic field of the form (1.8) and the temperature

field θ close to the given fields exist. We remark that in [21] the right-hand side f of (1.1) arises after reduction of the nonhomogeneous boundary conditions for u to the homogeneous conditions. So, in the physical case, f is the only time-dependent function, and hence the optimality system (2.14)–(2.16) obtained in Theorem 2.4 consists of a system of PDEs for the Lagrange multipliers and a second order ODE for f; see Remark 2.4 below. But for the sake of generality we also consider f depending on both time and spatial variables.

Note also that (1.1)–(1.2) can be considered also as a system modelling a unidirectional Poiseuille-type flow of a homogeneous incompressible Newtonian fluid whose viscosity is the temperature-dependent function; see [21] for more information. As we see, in most applications the system (1.1)–(1.2) arises in the two-dimensional case ($\Omega \subset \mathbb{R}^2$).

2. Notation and main results. We use the following notation for functional spaces:

- $L^p(\Omega)$, $L^p(Q_T)$ are the usual Lebesgue spaces with the notation
$$\|f\|_{p,\Omega} \equiv \|f\|_{L^p(\Omega)}, \qquad \|f\|_{p,Q_T} \equiv \|f\|_{L^p(Q_T)};$$
- $W_p^k(\Omega)$ is the usual Sobolev space (or Slobodetskii–Sobolev space in the case of noninteger k); see, for instance, [18, Chap. II, sections 2–3] for the definitions;
- $\mathring{W}_p^k(\Omega)$, $k > 1 - \frac{1}{p}$, is the subspace of functions from $W_p^k(\Omega)$ having zero traces on the boundary;
- $W_p^{-k}(\Omega) = (\mathring{W}_{p'}^k(\Omega))^*$, $\frac{1}{p} + \frac{1}{p'} = 1$, $p \geq 1$;
- $L^{r,s}(Q_T) \equiv L^s(0,T;L^r(\Omega))$, $\quad \|f\|_{L^{r,s}(Q_T)} \equiv (\int_0^T \|f(\cdot,t)\|_{r,\Omega}^s \, dt)^{1/s}$;
- $W_p^{1,0}(Q_T) \equiv L^p(0,T;W_p^1(\Omega)) = \{u \in L^p(Q_T) : \ \nabla u \in L^p(Q_T)\}$, $\|u\|_{W_p^{1,0}(Q_T)} \equiv \|u\|_{p,Q_T} + \|\nabla u\|_{p,Q_T}$;
- $W_p^{2,1}(Q_T) = \{u \in W_p^{1,0}(Q_T) : \ \nabla^2 u, \partial_t u \in L^p(Q_T)\}$, $\|u\|_{W_p^{2,1}(Q_T)} \equiv \|u\|_{W_p^{1,0}(Q_T)} + \|\nabla^2 u\|_{p,Q_T} + \|\partial_t u\|_{p,Q_T}$.

Let the functions $U, \Theta : Q_T \to \mathbb{R}$ and initial data $u_0, \theta_0 : \Omega \to \mathbb{R}$ be given and assume that

$$U, \Theta \in L^2(Q_T). \tag{2.1}$$

Let us introduce the cost functional

$$J(u,\theta,f) := \frac{1}{2}\|u - U\|_{2,Q_T}^2 + \frac{1}{2}\|\theta - \Theta\|_{2,Q_T}^2 + \frac{\beta_1}{2}\|f\|_{2q_0,Q_T}^{2q_0} + \frac{\beta_2}{2}\|\partial_t f\|_{2,Q_T}^2 \tag{2.2}$$

and suppose

$$q_0 > 1, \quad \beta_1 > 0, \quad \beta_2 \geq 0 \tag{2.3}$$

(without loss of generality, we can consider $q_0 \leq \frac{3}{2}$). Dealing with the system (1.1)–(1.2) we shall focus on the strong solutions (i.e., those for which both (1.1) and (1.2) hold a.e. in Q_T). Hence, we must assume some regularity of the initial data as well as compatibility conditions between initial and boundary data. For the sake of simplicity we consider the initial data satisfying the following restrictions:

$$u_0, \theta_0 \in C^2(\bar{\Omega}), \quad u_0|_{\partial\Omega} = \theta_0|_{\partial\Omega} = 0. \tag{2.4}$$

Denote $V := \{u \in W_2^{1,0}(Q_T) : \partial_t u \in L^2(0,T;W_2^{-1}(\Omega))\}$. Our optimal control problem is then the following.

Problem P. Find $(\hat{u},\hat{\theta},\hat{f}) \in V \times W_1^{2,1}(Q_T) \times L^2(Q_T)$, which minimize $J(u,\theta,f)$ among all the functions (u,θ,f) satisfying (1.1) in the sense of distributions, (1.2) a.e. in Q_T, and satisfying also (1.4) and (1.5) in the sense of traces.

Remark 2.1. In the case of $\beta_2 > 0$ we require also $\partial_t f \in L^2(Q_T)$.

Our principal results are the following theorems.

THEOREM 2.1 (existence of the optimal solution). *Assume that the conditions* (1.3), (2.1), (2.3), *and* (2.4) *hold. Then there is a number* $q > 1$ *depending only on* μ_0, μ_1, q_0, *and* Q_T *such that there is at least one optimal solution* $(\hat{u},\hat{\theta},\hat{f})$ *of Problem* P *belonging to the spaces*

$$\hat{u} \in C([0,T];L^2(\Omega)) \cap W_{2q}^{1,0}(Q_T), \quad \partial_t \hat{u} \in L^2(0,T;W_2^{-1}(\Omega)),$$
$$\hat{\theta} \in W_q^{2,1}(Q_T), \quad \hat{f} \in L^{2q_0}(Q_T),$$

and satisfying (1.1) *in the sense of distributions,* (1.2) *a.e. in* Q_T, *and* (1.4)–(1.5) *in the sense of traces. Moreover, if*

$$\beta_2 > 0, \tag{2.5}$$

we also have

$$\partial_t \hat{f} \in L^2(Q_T). \tag{2.6}$$

Remark 2.2. Theorem 2.1 remains true in the multidimensional case $\Omega \subset \mathbb{R}^n$, $n \geq 2$.

THEOREM 2.2 (regularity of the optimal solution). *Assume that the conditions* (1.3) *and* (2.3) *hold and let* $(\hat{u},\hat{\theta},\hat{f})$ *be an optimal solution obtained in Theorem* 2.1. *Then there is* $\alpha > 0$ *such that*

$$\hat{u} \in C^{\alpha,\alpha/2}(\bar{Q}_T), \tag{2.7}$$

the following inclusion holds:

$$\hat{u},\hat{\theta} \in W_4^{1,0}(Q_T), \tag{2.8}$$

and, moreover,

$$\hat{u},\hat{\theta} \in W_2^{2,1}(Q_T). \tag{2.9}$$

Finally, if we assume the condition (2.5) *holds, then*

$$\partial_t \hat{u}, \partial_t \hat{\theta} \in L^\infty(0,T;L^2(\Omega)) \cap W_2^{1,0}(Q_T), \tag{2.10}$$

$$\hat{\theta} \in C^{1/4}(\bar{Q}_T), \tag{2.11}$$

and

$$\hat{\theta} \in W_{2q_0}^{2,1}(Q_T), \quad \hat{u} \in W_{2q_0}^{2,1}(Q_T). \tag{2.12}$$

Now, we consider the nonlinear operator

$$(u,\theta) \mapsto F(u,\theta) = \begin{pmatrix} \partial_t u - \operatorname{div}(\mu(\theta)\nabla u), & \gamma_0 u - u_0 \\ \partial_t \theta - \Delta\theta - \mu(\theta)|\nabla u|^2, & \gamma_0 \theta - \theta_0 \end{pmatrix},$$

where γ_0 is the usual trace operator $\gamma_0 u = u|_{t=0}$. We also introduce the Banach spaces

$$\mathcal{W} = \{u \in W_{2q}^{2,1}(Q_T) : \ u|_{S_T} = 0\},$$
$$\mathcal{V} = \{f \in L^{2q}(Q_T) : \ \partial_t f \in L^2(Q_T)\},$$
$$\mathcal{H} = L^{2q}(Q_T) \times \mathring{W}_{2q}^{2-1/q}(\Omega),$$

where $S_T := \partial\Omega \times (0,T)$.

THEOREM 2.3 (Gâteaux differentiability). *Assume conditions* (1.3) *and* (2.4) *hold and function* μ *is of class* C^2. *Suppose also* $q > 1$. *Then the transformation* F *is Gâteaux differentiable as a map*

$$F : \mathcal{W} \times \mathcal{W} \to \mathcal{H} \times \mathcal{H}$$

and its derivative is

$$\delta F(u,\theta)(w,e) = \begin{pmatrix} \partial_t w - \operatorname{div}(\mu(\theta)\nabla w) - \operatorname{div}(\mu'(\theta)e\nabla u), & \gamma_0 w \\ \partial_t e - \Delta e - \mu'(\theta)e|\nabla u|^2 - 2\mu(\theta)\nabla u \cdot \nabla w, & \gamma_0 e \end{pmatrix}.$$

Moreover, if $(\hat{u},\hat{\theta},\hat{f})$ *is an optimal solution of Problem* P *satisfying* (2.12) *and* $q \in (1, q_0)$, *then*

$$\text{image of } \ \delta F(\hat{u},\hat{\theta}) = \mathcal{H} \times \mathcal{H}. \tag{2.13}$$

THEOREM 2.4 (optimality system). *Assume that all conditions of Theorems* 2.2 *and* 2.3 *hold and let* $(\hat{u},\hat{\theta},\hat{f})$ *be a solution of Problem* P *satisfying* (2.12). *Then there are functions* $(\hat{p},\hat{e}) \in W_2^{2,1}(Q_T) \times W_2^{2,1}(Q_T)$ *satisfying the system*

$$\partial_t \hat{p} + \operatorname{div}(\mu(\hat{\theta})\nabla\hat{p}) - \operatorname{div}(2\mu(\hat{\theta})\hat{e}\nabla\hat{u}) = \hat{u} - U, \quad \hat{p}|_{t=T} = 0, \quad \hat{p}|_{\partial\Omega} = 0, \tag{2.14}$$

$$\partial_t \hat{e} + \Delta\hat{e} - \mu'(\hat{\theta})\nabla\hat{u}\cdot\nabla\hat{p} + \mu'(\hat{\theta})|\nabla\hat{u}|^2\hat{e} = \hat{\theta} - \Theta, \quad \hat{e}|_{t=T} = 0, \quad \hat{e}|_{\partial\Omega} = 0, \tag{2.15}$$

$$-\beta_2 \frac{\partial^2 \hat{f}}{\partial t^2} + 2q_0\beta_1|\hat{f}|^{2q_0-2}\hat{f} = \hat{p}, \qquad \left.\frac{\partial \hat{f}}{\partial t}\right|_{t=0} = \left.\frac{\partial \hat{f}}{\partial t}\right|_{t=T} = 0. \tag{2.16}$$

Remark 2.3. Instead of the Neumann conditions it is possible to get in (2.16) some other boundary conditions. For instance, to get in (2.16) the homogeneous Dirichlet boundary conditions, one should look in Problem P for the minimum of J among all $f \in \mathcal{V}$ such that $f|_{t=0} = f|_{t=T} = 0$.

Remark 2.4. All results of our paper remain true if we consider the problem of minimization of the cost functional (2.2) (with $\beta_2 > 0$) among all functions $f \in W_2^1(0,T)$, which depend only on t and do not depend on the spatial variables. This case corresponds to the physically reasonable boundary conditions for the magnetic field. In this case we must put $\mathcal{V} = W_2^1(0,T)$ and the relation (2.16) must be substituted with the ODE

$$-\beta_2 \frac{d^2 \hat{f}}{dt^2} + 2q_0\beta_1|\hat{f}|^{2q_0-2}\hat{f} = [\hat{p}]_\Omega, \qquad \left.\frac{\partial \hat{f}}{\partial t}\right|_{t=0} = \left.\frac{\partial \hat{f}}{\partial t}\right|_{t=T} = 0, \tag{2.17}$$

where

$$[\hat{p}]_\Omega(t) \equiv \int_\Omega \hat{p}(x,t)\, dx.$$

Moreover, in this case we can put $q_0 = 1$ in (2.2) (and hence obtain the linear equation in (2.17)). All improvements that one should put into the proof of Theorem 2.4 to cover this case are obvious.

3. Proof of Theorem 2.1. Before we prove Theorem 2.1 let us formulate here one lemma on solutions of the linear parabolic systems with measurable coefficients. We are going to use it later.

LEMMA 3.1 (higher integrability of solutions to parabolic equations). *Assume $Q_T = \Omega \times (0,T)$, $\Omega \subset \mathbb{R}^n$, is a bounded domain with a boundary of class C^1, and a matrix $A(x,t) = (A_{ij}(x,t))$ satisfies the conditions*

$$\begin{gathered} \exists\, \nu_0 > 0 \quad \text{such that} \quad A_{ij}(x,t)\xi_i\xi_j \geq \nu_0|\xi|^2 \quad \forall \xi \in \mathbb{R}^n, \\ A_{ij} \in L^\infty(Q_T), \quad A_{ij} = A_{ji}. \end{gathered} \tag{3.1}$$

Assume also $f \in L^{2q_0}(Q_T)$, $u_0 \in W^1_{2q_0}(\Omega)$ for some $q_0 > 1$ and let $u \in C([0,T]; L^2(\Omega)) \cap W_2^{1,0}(Q_T)$ be a weak solution to the equation

$$\begin{gathered} \partial_t u - \operatorname{div}(A(x,t)\nabla u) = f \quad \text{in } Q_T, \\ u|_{\partial\Omega} = 0, \quad u|_{t=0} = u_0. \end{gathered} \tag{3.2}$$

Then there is a constant $q > 1$ depending only on n, q_0, ν_0, $\|A\|_{\infty,Q_T}$, and Q_T such that $u \in W^{1,0}_{2q}(Q_T)$, and the estimate

$$\|\nabla u\|_{2q,Q_T} \leq C(\|f\|_{2q,Q_T} + \|u_0\|_{W^1_{2q}(\Omega)})$$

holds.

Lemma 3.1 is proved in [3, Thm. 2.2, p. 272]. For the case of the homogeneous initial data see also [4, Thm. 3.III].

Now we turn to the proof of Theorem 2.1. Let $(u^m, \theta^m, f^m) \in V \times W_2^{2,1}(Q_T) \times L^{2q_0}(Q_T)$ be a sequence minimizing $J(u,\theta,f)$. Obviously, $\{f^m\}$ is bounded in $L^{2q_0}(Q_T)$. We also have the energy estimate

$$\sup_t \|u^m\|^2_{2,\Omega} + \|\nabla u^m\|^2_{2,Q_T} \leq C\|f^m\|^2_{2,Q_T} \tag{3.3}$$

and the following higher integrability of the first spatial gradient of u (see Lemma 3.1 above): there is $q > 1$ such that

$$\|\nabla u^m\|_{2q,Q_T} \leq C(\|f^m\|_{2q,Q_T} + \|u_0\|_{W^1_{2q}(\Omega)}). \tag{3.4}$$

From the heat equation (1.2) we get

$$\|\theta^m\|_{W^{2,1}_q(Q_T)} \leq \text{const. does not depend on } m. \tag{3.5}$$

Moreover, from (1.1) we obtain that $\{\partial_t u^m\}$ is bounded in $L^2(0,T; W_2^{-1}(\Omega))$. Hence $\{u^m\}$ is compact in $L^2(Q_T)$ and we can extract subsequences $\{u^m\}$, $\{\theta^m\}$, and $\{f^m\}$ such that

$$\begin{aligned} u^m &\rightharpoonup \hat{u} && \text{in } W^{1,0}_{2q}(Q_T), \\ \partial_t u^m &\rightharpoonup \partial_t \hat{u} && \text{in } L^2(0,T; W_2^{-1}(\Omega)), \\ \theta^m &\rightharpoonup \hat{\theta} && \text{in } W^{2,1}_q(Q_T), \\ f^m &\rightharpoonup \hat{f} && \text{in } L^{2q_0}(Q_T), \\ u^m &\to \hat{u} && \text{in } L^2(Q_T), \\ u^m &\to \hat{u} && \text{a.e. in } Q_T, \\ \theta^m &\to \hat{\theta} && \text{a.e. in } Q_T, \end{aligned} \tag{3.6}$$

and $(\hat{u}, \hat{\theta})$ satisfy (1.4) and (1.5). Convergences (3.6) make it possible to pass to the limit in the first equation, (1.1). So we have

$$\int_{Q_T} (-\hat{u}\partial_t w + \mu(\hat{\theta})\nabla\hat{u}\cdot\nabla w)\, dxdt = \int_{Q_T} \hat{f} w\, dxdt \quad \forall w \in C_0^1(Q_T).$$

As we lack strong convergence for ∇u^m, we cannot pass directly to the limit in the second equation, (1.2). Instead, we use the representation

$$\mu(\theta^m)|\nabla u^m|^2 = \operatorname{div}(\mu(\theta^m)u^m\nabla u^m) + f^m u^m - \frac{1}{2}\partial_t|u^m|^2 \quad \text{in } \mathcal{D}'(Q_T), \tag{3.7}$$

which follows from (1.1). Hence

$$\begin{aligned} &c\int_{Q_T} (-\theta^m\partial_t\eta + \nabla\theta^m\cdot\nabla\eta)\, dxdt \\ &= \int_{Q_T} \mu(\theta^m)u^m\nabla u^m\cdot\nabla\eta\, dxdt + \int_{Q_T}\left(f^m u^m\eta + \frac{1}{2}|u^m|^2\partial_t\eta\right) dxdt \quad \forall\eta\in C_0^1(Q_T). \end{aligned}$$

Passing to the limit in this equation, we obtain the same identity for $\hat{u}$, $\hat{\theta}$, and $\hat{f}$. Then using for $\hat{u}$ the relation (3.7) again, we obtain the identity

$$\int_{Q_T} (-\hat{\theta}\partial_t\eta + \nabla\hat{\theta}\cdot\nabla\eta)\, dxdt = \int_{Q_T} \mu(\hat{\theta})|\nabla\hat{u}|^2\eta\, dxdt \quad \forall\eta\in C_0^1(Q_T).$$

Hence $(\hat{u}, \hat{\theta})$ also satisfy (1.2). As J is lower semicontinuous with respect to the weak convergence, we obtain that $(\hat{u}, \hat{\theta}, \hat{f})$ is a solution of Problem P. In the case of $\beta_2 > 0$ we also have the boundedness of $\{\partial_t f^m\}$ in $L^2(Q_T)$, and hence (2.6) holds. Theorem 2.1 is proved.

4. Proofs of Theorems 2.2 and 2.3. In this section we study regularity of weak solutions obtained in Theorem 2.1. Our approach is very close to the method used in [2] for investigation of the thermistor system in the "semistationary" case, i.e., the system (1.1)–(1.2) in the case when the term $\partial_t u$ in the left-hand side of (1.1) is absent. Roughly speaking, our method differs from the approach of [2] only in the use of an additional Step 4 shown below. This step involves so-called "weak coercive estimates" for the spatial gradient of a solution to the heat equation by the appropriate negative norm of the right-hand side. Both the method in [2] and our method follow the general methodology developed in [17, 18], so here we only briefly sketch the proof of Theorem 2.2, assuming the solution is sufficiently smooth and deriving only a priori estimates for it. These estimates can be easily justified (when it is necessary) with the help of appropriate approximations. But to make our presentation more intelligible we skip technical details in our proof and refer readers to [17, 18] for the formal justification.

Step 1. To get (2.7) we use the following lemma from [18, Chap. III, Thms. 7.1 and 10.1].

LEMMA 4.1 (De Giorgi–Nash–Ladyzhenskaya–Uraltseva theorem). *Assume $Q_T = \Omega\times(0,T)$, $\Omega\subset\mathbb{R}^n$, is a bounded domain with a boundary of class C^1, and let $f\in L^{s,r}(Q_T)$, $u_0\in C^{\alpha_0}(\bar{\Omega})$ for some $\alpha_0>0$, $u_0|_{\partial\Omega}=0$, and*

$$\frac{1}{r} + \frac{n}{2s} < 1. \tag{4.1}$$

Assume (3.1) *holds and let* $u \in W_2^{1,0}(Q_T)$ *be a weak solution of* (3.2). *Then there is* $\alpha > 0$ *such that* $u \in C^{\alpha,\alpha/2}(\bar{Q}_T)$ *and*

$$\|u\|_{C^{\alpha,\alpha/2}(\bar{Q}_T)} \le C(\|f\|_{L^{s,r}(Q_T)} + \|u_0\|_{C^{\alpha}(\bar{\Omega})}). \tag{4.2}$$

Boundedness and Hölder continuity of solutions of the scalar equations with measurable coefficients were proved first by De Giorgi for elliptic equations and by Nash for homogeneous parabolic equations; see [9, 20] and [12, 15]. The nonhomogeneous parabolic analogue of the De Giorgi–Nash theorem we use here was proved by Ladyzhenskaya and Uraltseva. We note that from the inclusion $\hat{f} \in L^{2q_0}(Q_T)$ we obtain that (4.1) holds for $u = \hat{u}$, $n = 2$, $r = \frac{1}{2q_0}$, $s = \frac{1}{2q_0}$.

Step 2. For any function $u \in C^{\alpha,\alpha/2}(\bar{Q}_T) \cap L^2(0,T; \mathring{W}_2^1 \cap W_2^2(\Omega))$ the following inequality holds; see [18, Chap. V, eqs. (3.15) and (4.6)]:

$$\|\nabla u\|^4_{4,\Omega_\rho(x_0)\times(0,T)} \le C\|u\|^2_{C^{\alpha,\frac{\alpha}{2}}(\bar{Q}_T)} \rho^{2\alpha} \left\{ \|\nabla^2 u\|^2_{2,\Omega_{2\rho}\times(0,T)} + \frac{1}{\rho^2}\|\nabla u\|^2_{2,\Omega_{2\rho}\times(0,T)} \right\},$$

where $\Omega_\rho(x_0) = \Omega \cap B_\rho(x_0)$ and $x_0 \in \bar{\Omega}$ is arbitrary. The proof of this relation is based on a simple integration-by-parts trick,

$$\int_\Omega \zeta^2 |\nabla u|^4 \, dx - \int_\Omega \operatorname{div}(\zeta^2 |\nabla u|^2 \nabla u)(u(x) - u(x_0)) \, dx,$$

where $x_0 \in \bar{\Omega}$ and $\zeta \in C_0^\infty(B_{2\rho}(x_0))$ is a cut-off function; see [18] for details.

From the assumption of the smoothness of $\partial\Omega$, the existence of numbers N_0, ρ_0 follows such that for any $\rho \le \rho_0$ there is a finite covering of Ω by the sets of type $\Omega_\rho(x_i)$, $x_i \in \bar{\Omega}$, such that the total number of intersections of different $\Omega_{2\rho}(x_i)$ does not increase N_0. Hence we have the estimate

$$\|\nabla u\|^4_{4,Q_T} \le C\|u\|^2_{C^{\alpha,\alpha/2}(\bar{Q}_T)} \rho^{2\alpha} \left\{ \|\nabla^2 u\|^2_{2,Q_T} + \frac{1}{\rho^2}\|\nabla u\|^2_{2,Q_T} \right\}. \tag{4.3}$$

This inequality is valid for any $\rho < \rho_0$, where ρ_0 depends only on curvature of $\partial\Omega$, and C does not depend on ρ.

Step 3. Let (u, θ, f) satisfy (1.1), (1.2), (1.4), and (1.5). From (1.1), taking into account (1.3), we can estimate the second derivatives of u:

$$\sup_{t\in(0,T)} \|\nabla u\|^2_{2,\Omega} + \|\nabla^2 u\|^2_{2,Q_T} \le C(\|\nabla u\|^4_{4,Q_T} + \|\nabla\theta\|^4_{4,Q_T}) + C_{f,u_0}. \tag{4.4}$$

Step 4. To estimate $\|\nabla\theta\|_{4,Q_T}$ by $\|\nabla u\|_{4,Q_T}$ we take advantage of the special structure (3.7) of the term $\mu(\theta)|\nabla u|^2$. From (1.2) we have

$$\begin{gathered} \partial_t\theta - \Delta\theta = \operatorname{div}(\mu(\theta)u\nabla u) + fu - u\partial_t u, \\ \theta|_{\partial\Omega} = 0, \quad \theta|_{t=0} = \theta_0. \end{gathered}$$

Denote $v := \theta + \frac{1}{2}u^2$, $G := (\mu(\theta) + 1)u\nabla u$, $g := fu$, $v_0 \equiv \theta_0 + \frac{1}{2}u_0^2$. Hence

$$\begin{aligned} &\partial_t v - \Delta v = \operatorname{div} G + g, \\ &v|_{\partial\Omega} = 0, \quad v|_{t=0} = v_0. \end{aligned}$$

We split $v = v^{(1)} + v^{(2)}$, where $v^{(1)}$ and $v^{(2)}$ are solutions of problems

$$\begin{aligned} \partial_t v^{(1)} - \Delta v^{(1)} &= g, \\ v^{(1)}|_{\partial\Omega} = 0, \quad v^{(1)}|_{t=0} &= v_0, \end{aligned} \tag{4.5}$$

$$\begin{aligned} \partial_t v^{(2)} - \Delta v^{(2)} &= \operatorname{div} G, \\ v^{(2)}|_{\partial\Omega} = 0, \quad v^{(2)}|_{t=0} &= 0, \end{aligned} \tag{4.6}$$

respectively. For $v^{(1)}$ the well-known estimate

$$\|v^{(1)}\|_{W_2^{2,1}(Q_T)} \le C(\|g\|_{2,Q_T} + \|v_0\|_{W_2^1(\Omega)}) \tag{4.7}$$

holds, provided the corresponding compatibility condition $v_0|_{\partial\Omega} = 0$ for initial and boundary data holds. Using two-dimensional parabolic imbedding $W_2^{2,1}(Q_T) \hookrightarrow W_4^{1,0}(Q_T)$ (see [18, Chap. II, Lem. 3.3]) we arrive at the estimate

$$\begin{aligned} \|\nabla v^{(1)}\|_{4,Q_T} &\le \|v^{(1)}\|_{W_2^{2,1}(Q_T)} \le C\big(\|g\|_{2,Q_T} + \|v_0\|_{W_2^1(\Omega)}\big) \\ &\le C\big(\|u\|_{\infty,Q_T}\|f\|_{2,Q_T} + \|u_0^2\|_{W_2^1(\Omega)} + \|\theta_0\|_{W_2^1(\Omega)}\big). \end{aligned}$$

It is well known (see [14]) that for any $G \in L^4(Q_T;\mathbb{R}^2)$ the problem (4.6) has the unique solution belonging to the class $v^{(2)} \in W_4^{1,1/2}(Q_T)$ and, moreover, the estimate

$$\|\nabla v^{(2)}\|_{4,Q_T} \le C\|G\|_{4,Q_T} \le C\|u\|_{\infty,Q_T}\|\nabla u\|_{4,Q_T} \tag{4.8}$$

holds. In [14] the analogous problem was studied for the much more difficult case of the Stokes operator. For solutions of the heat equation, the estimate (4.8) can be justified by the simple duplication of all considerations from [14] with the obvious change of hydrodynamical potentials for heat potentials. Note that in our case no convexity condition on Ω is necessary.

Remark 4.1. Note that (4.8) also can be obtained by interpolation of the corresponding $L^2 - L^2$ and $L^\infty - BMO$ estimates; see [12, Chap. IV, Thm. 4.6] or [19, Chap. VII, section 2, Thm. 7.2]. Precisely, the following two estimates hold:

$$\|\nabla v^{(2)}\|_{L^2(Q_T)} \le C\|G\|_{L^2(Q_T)}, \qquad \|\nabla v^{(2)}\|_{BMO(Q_T)} \le C\|G\|_{L^\infty(Q_T)}.$$

The first estimate is obvious, and the proof of the second one is actually contained in [19, Chap. VII]; also see arguments there in the proof of Theorem 7.17 in sections 3–5.

So, we get

$$\begin{aligned} \|\nabla\theta\|_{4,Q_T} &\le \|\nabla v\|_{4,Q_T} + \left\|\frac{1}{2}\nabla u^2\right\|_{4,Q_T} \\ &\le \|\nabla v^{(1)}\|_{4,Q_T} + \|\nabla v^{(2)}\|_{4,Q_T} + \left\|\frac{1}{2}\nabla u^2\right\|_{4,Q_T} \\ &\le C\|u\|_{\infty,Q_T}(\|\nabla u\|_{4,Q_T} + \|f\|_{2,Q_T}) + C\|u_0^2\|_{W_2^1(\Omega)} + C\|\theta_0\|_{W_2^1(\Omega)} \end{aligned}$$

or taking into account (4.2)

$$\|\nabla\theta\|_{4,Q_T} \le C_{f,u_0,\theta_0}\|\nabla u\|_{4,Q_T} + C'_{f,u_0,\theta_0}. \tag{4.9}$$

Step 5. Gathering (4.2), (4.3), (4.4), and (4.9) together we obtain the estimate

$$\|\nabla u\|^4_{4,Q_T} \le C_{f,u_0,\theta_0}\rho^{2\alpha}\left\{\|\nabla u\|^4_{4,Q_T} + \frac{1}{\rho^2}\|\nabla u\|^2_{2,Q_T}\right\} + C'_{f,u_0,\theta_0},$$

which is true for any $\rho < \rho_0$. Choosing $\rho^{2\alpha} < (1/2C_{f,u_0,\theta_0})$ we get the inclusion (2.8) for $u\hat{u}$. The inclusion (2.8) for $\hat{\theta}$ follows from (4.9).

Step 6. From (2.8) we obtain that the right-hand side of the heat equation (1.2) belongs to $L^2(Q_T)$, and hence $\theta \in W_2^{2,1}(Q_T)$. The inclusion $u \in W_2^{2,1}(Q_T)$ follows from (4.4). So, (2.9) is proved.

Step 7. Assume conditions (2.6) hold. Differentiating (1.1)–(1.2) with respect to t, multiplying them by $\partial_t u$, $\partial_t\theta$, respectively, and integrating over Ω using the two-dimensional multiplicative inequality (see [16]),

$$\|v\|^4_{4,\Omega} \le C\|v\|^2_{2,\Omega}\|\nabla v\|^2_{2,\Omega} \quad \forall v \in \mathring{W}_2^1(\Omega), \tag{4.10}$$

and after routine calculations we arrive at the inequality

$$\frac{d}{dt}\big(\|\partial_t u\|^2_{2,\Omega} + \|\partial_t\theta\|^2_{2,\Omega}\big) + \|\partial_t\nabla u\|^2_{2,\Omega} + \|\partial_t\nabla\theta\|^2_{2,\Omega} \le C\|\nabla u\|^4_{4,\Omega}\big(\|\partial_t u\|^2_{2,\Omega} + \|\partial_t\theta\|^2_{2,\Omega}\big) + C_{f,u_0,\theta_0}.$$

Applying the Gronwall lemma we obtain (2.10).

Step 8. From (2.10) and (4.10) we get $\partial_t\theta \in L^4(Q_T)$, which together with (2.8) and the Sobolev imbedding theorem $W_4^1(Q_T) \hookrightarrow C^{1/4}(\bar{Q}_T)$ (as $Q_T \subset \mathbb{R}^3$) provides the inclusion (2.11). Moreover, $\partial_t\nabla u, \nabla^2 u \in L^2(Q_T)$, and by the three-dimensional Sobolev imbedding theorem $W_2^1(Q_T) \hookrightarrow L^6(Q_T)$ we also have $\nabla u \in L^6(Q_T)$. This means that the right-hand side of the heat equation (1.2) belongs to $L^3(Q_T)$ and, due to the coercive estimates for the heat operator, we obtain $\theta \in W_3^{2,1}(Q_T)$. As $q_0 \le \frac{3}{2}$, the inclusion (2.12) for θ is proved. The same inclusion for u follows now from the assumption $f \in L^{2q_0}(Q_T)$ and the usual coercive estimates for parabolic equations with smooth coefficients; see [18, Chap. IV, Thm. 9.1] (see also Lemma 4.2 below; here in our case $s = 2q_0$ and $r = \frac{4q_0}{2-q_0} > s$). Therefore, Theorem 2.2 is proved.

Now we turn to the proof of Theorem 2.3. Assume $n = 2$ and $q \in (1, 2)$. The two-dimensional parabolic imbedding theorems (see [18, Chap. II, Lem. 3.3]) provide the estimates

$$\|v\|_{W^{1,0}_{\frac{4q}{2-q}}(Q_T)} \le C\|v\|_{W^{2,1}_{2q}(Q_T)}, \quad v \in W^{2,1}_{2q}(Q_T), \tag{4.11}$$

and

$$\|v\|_{C^{\lambda,\lambda/2}(\bar{Q}_T)} \le C\|v\|_{W^{2,1}_{2q}(Q_T)}, \quad v \in W^{2,1}_{2q}(Q_T). \tag{4.12}$$

From (4.11) and (1.3) inclusions $\mu'(\theta)\nabla\theta\cdot\nabla u, |\nabla u|^2 \in L^{\frac{2q}{2-q}}(Q_T) \subset L^{2q}(Q_T)$ for $q > 1$ follow, and hence F really maps $\mathcal{W}\times\mathcal{W}$ into $\mathcal{H}\times\mathcal{H}$. By the definition of the Gâteaux derivative of F,

$$\delta F(u,\theta)(w,e) \equiv \frac{d}{ds}F(u+sw, \theta+se)\Big|_{s=0},$$

and hence for all $u, \theta, w, e \in \mathcal{W}$,

$$\delta F(u,\theta)(w,e) = \begin{pmatrix} \partial_t w - \operatorname{div}(\mu(\theta)\nabla w) - \operatorname{div}(\mu'(\theta)e\nabla u), & \gamma_0 w \\ \partial_t e - \Delta e - \mu'(\theta)e|\nabla u|^2 - 2\mu(\theta)\nabla u\cdot\nabla w, & \gamma_0 e \end{pmatrix}.$$

Because of (1.3), (4.11), (4.12), and continuity of μ'', it is easy to see that for each given $(u,\theta) \in \mathcal{W}\times\mathcal{W}$ the operator $\delta F(u,\theta)$ is linear and bounded as a map from $\mathcal{W}\times\mathcal{W}$ into $\mathcal{H}\times\mathcal{H}$. Indeed, for example,

$$\begin{aligned} \delta_u F_1(u,\theta)(w,e) &\equiv \partial_t w - \operatorname{div}(\mu(\theta)\nabla w) - \operatorname{div}(\mu'(\theta)e\nabla u) \\ &= \partial_t w - \mu(\theta)\Delta w - \mu'(\theta)\nabla\theta\cdot\nabla w \\ &\quad - \mu'(\theta)e\Delta u - \mu'(\theta)\nabla e\nabla u - \mu''(\theta)e\nabla\theta\cdot\nabla u. \end{aligned}$$

Hence

$$\begin{aligned} \|\delta_u F_1(u,\theta)(w,e)\|_{2q,Q_T} &\le \|\partial_t w\|_{2q,Q_T} + \mu_1\|\Delta w\|_{2q,Q_T} + \mu_2\|\nabla\theta\cdot\nabla w\|_{2q,Q_T} \\ &\quad + \mu_2\|e\Delta u\|_{2q,Q_T} + \mu_2\|\nabla e\cdot\nabla u\|_{2q,Q_T} \\ &\quad + \|\mu''(\theta)\|_{\infty,Q_T}\|e\nabla\theta\cdot\nabla u\|_{2q,Q_T}. \end{aligned} \tag{4.13}$$

Using the Hölder inequality and (4.11)–(4.12) we get

$$\begin{aligned} \|e\nabla\theta\cdot\nabla u\|_{2q,Q_T} &\le \|e\|_{\infty,Q_T}\|\nabla\theta\cdot\nabla u\|_{2q,Q_T} \\ &\le \|e\|_{\infty,Q_T}\|\nabla\theta\|_{\frac{4q}{2-q},Q_T}\|\nabla u\|_{4,Q_T} \\ &\le C\|\theta\|_{\mathcal{W}}\|u\|_{\mathcal{W}}\|e\|_{\mathcal{W}} \end{aligned}$$

and similar relations for all other terms in the right-hand side of (4.13). From the continuity of μ'' and (4.12), existence of the nondecreasing majorants $\mathcal{F}_1, \mathcal{F}_2$ follows such that

$$\|\mu''(\theta)\|_{\infty,Q_T} \le \mathcal{F}_1(\|\theta\|_{C(\bar{Q}_T)}) \le \mathcal{F}_2(\|\theta\|_{\mathcal{W}}).$$

Hence we obtain the final majorant $\mathcal{F}$ such that

$$\|\delta F(u,\theta)(w,e)\|_{\mathcal{H}\times\mathcal{H}} \le \mathcal{F}(\|u\|_{\mathcal{W}}, \|\theta\|_{\mathcal{W}})(\|w\|_{\mathcal{W}} + \|e\|_{\mathcal{W}}).$$

So the first part of Theorem 2.3 is proved.

Let us prove (2.13), i.e., for any given (g,a) and $(h,b) \in \mathcal{H}$ the system

$$\left.\begin{aligned} \partial_t w - \operatorname{div}(\mu(\hat{\theta})\nabla w) - \operatorname{div}(\mu'(\hat{\theta})e\nabla\hat{u}) &= g, \\ \partial_t e - \Delta e - \mu'(\hat{\theta})e|\nabla\hat{u}|^2 - 2\mu(\hat{\theta})\nabla\hat{u}\cdot\nabla w &= h, \\ w|_{\partial\Omega} = 0, \quad w|_{t=0} &= a, \\ e|_{\partial\Omega} = 0, \quad e|_{t=0} &= b \end{aligned}\right\} \tag{4.14}$$

is uniquely solvable on $\mathcal{W}\times\mathcal{W}$. This statement follows directly from properties (2.12) of the optimal solution $(\hat{u},\hat{\theta})$ and the following lemma on solutions to the linear parabolic systems we have already used several times (see [18, Thm. 9.1 of Chap. IV and Thm. 10.4 of Chap. VII]; see also [22]).

LEMMA 4.2 (coercive estimate for linear parabolic systems). *Assume $Q_T = \Omega\times(0,T)$, $\Omega \subset \mathbb{R}^n$, is a bounded domain with a boundary of class C^2, and assume also*

$$A_{ijkl} \in C(\bar{Q}_T), \quad b_{ijk} \in L^r(Q_T), \quad c_{ij} \in L^{r/2}(Q_T)$$

with

$$r > n + 2, \tag{4.15}$$

and A satisfying the strong ellipticity condition

$$\exists \nu_0 > 0 : \quad A_{ijkl}(x) B_{ij} B_{kl} \geq \nu_0 |B|^2 \quad \forall B \in \mathbb{M}^{n\times n},$$

$$A_{ijkl} A_{klij} = A_{jikl} = A_{ijlk}.$$

Then for any $s \in (1, r)$, $s \neq \frac{3}{2}$, and for arbitrary functions $f \in L^s(Q_T; \mathbb{R}^N)$, $u_0 \in \mathring{W}_s^{2-2/s}(\Omega; \mathbb{R}^N)$ there is a unique solution $u \in W_s^{2,1}(Q_T; \mathbb{R}^N)$ of the problem

$$\partial_t u_i - A_{ijkl}(x) u_{k,jl} + b_{ijk}(x) u_{j,k} + c_{ij}(x) u_j = f_i(x),$$
$$u|_{t=0} = u_0, \quad u|_{\partial\Omega} = 0.$$

Moreover, the estimate

$$\|u\|_{W_s^{2,1}(Q_T)} \leq C \left(\|f\|_{s,Q_T} + \|u_0\|_{W_s^{2-\frac{2}{s}}(\Omega)} \right)$$

holds for some constant C depending only on n, Ω, T, ν_0, and norms of the coefficients.

Indeed, we can rewrite the system (4.14) in the form

$$\left.\begin{aligned} \partial_t w - \mu(\hat\theta)\Delta w - \mu'(\hat\theta)\nabla\hat\theta \cdot \nabla w - \mu'(\hat\theta) e \Delta \hat u \\ - \mu'(\hat\theta)\nabla e \cdot \nabla \hat u - \mu''(\hat\theta) e \nabla\hat\theta \cdot \nabla \hat u = g, \\ \partial_t e - \Delta e - \mu'(\hat\theta) e |\nabla \hat u|^2 - 2\mu(\hat\theta)\nabla\hat u \cdot \nabla w = h, \\ w|_{\partial\Omega} = 0, \quad w|_{t=0} = a, \\ e|_{\partial\Omega} = 0, \quad e|_{t=0} = b. \end{aligned}\right\}$$

Due to (2.11) and (2.12), it is easy to see that its coefficients

$$\mu'(\hat\theta)\nabla\hat\theta, \quad \mu'(\hat\theta)\nabla\hat u, \quad \mu(\hat\theta)\nabla\hat u \in L^{4q_0}(Q_T), \tag{4.16}$$

$$\mu'(\hat\theta)\Delta\hat u, \quad \mu''(\hat\theta)\nabla\hat\theta \cdot \nabla\hat u, \quad \mu'(\hat\theta)|\nabla\hat u|^2 \in L^{2q_0}(Q_T) \tag{4.17}$$

satisfy conditions (4.15) with $n = 2$, $r = 4q_0$. Moreover, due to (2.11) the coefficient $\mu(\hat\theta(\cdot))$ is Hölder continuous. Hence the system (4.14) is uniquely solvable on $\mathcal{W} \times \mathcal{W}$ for any data in $\mathcal{H} \times \mathcal{H}$ as $q \in (1, q_0)$. The statement (2.13) and Theorem 2.3 are proved.

5. Proof of Theorem 2.4. We consider our cost functional J as a map

$$J : \mathcal{W} \times \mathcal{W} \times \mathcal{V} \to \mathbb{R},$$

and (1.1)–(1.2) as a restriction

$$F_*(u, \theta, f) = 0, \qquad F_* : \mathcal{W} \times \mathcal{W} \times \mathcal{V} \to \mathcal{H} \times \mathcal{H},$$

where

$$F_*(u, \theta, f) = \begin{pmatrix} \partial_t u - \operatorname{div}(\mu(\theta)\nabla u) - f, & \gamma_0 u - u_0 \\ \partial_t \theta - \Delta\theta - \mu(\theta)|\nabla u|^2, & \gamma_0\theta - \theta_0 \end{pmatrix}$$

(note that F_* differs from the map F in section 2 only by the additional argument f). Hence

$$\delta F_*(u,\theta,f)(w,\eta,h) = \begin{pmatrix} \partial_t w - \operatorname{div}(\mu(\theta)\nabla w) - \operatorname{div}(\mu'(\theta)\eta\nabla u) - h, & \gamma_0 w \\ \partial_t \eta - \Delta\eta - \mu'(\theta)\eta|\nabla u|^2 - 2\mu(\theta)\nabla u\cdot\nabla w, & \gamma_0\eta \end{pmatrix}.$$

Let us show that

$$\text{image of } \ \delta F_* = \mathcal{H}\times\mathcal{H}. \tag{5.1}$$

Let $(g,a),(d,b)\in\mathcal{H}$ be arbitrary. To find $(w,e,h)\in\mathcal{W}\times\mathcal{W}\times\mathcal{V}$ such that

$$\delta F_*(u,\theta,f)(w,e,h) = \begin{pmatrix} g,a \\ d,b \end{pmatrix}$$

it is enough to take $h\equiv 0$ and use the property (2.13) of δF. For any $((p,a),(e,b))\in \mathcal{H}'\times\mathcal{H}'$ consider Lagrangian

$$\mathcal{L}(u,\theta,f,p,e,a,b) \equiv J(u,\theta,f) + \left\langle F_*(u,\theta,f), \begin{pmatrix} p,a \\ e,b \end{pmatrix}\right\rangle,$$

where $\langle\cdot,\cdot\rangle$ is a duality relation between $\mathcal{H}$ and $\mathcal{H}'$.

From Theorem 2.3 and (5.1) it follows that J and F_* satisfy all conditions of Theorem 2.1.5 of [11]; see also [1, Chap. III, section 3.2, Thm. 3.2.2]. Hence if $(\hat u,\hat\theta,\hat f)$ is an optimal solution of Problem P, then there are Lagrange multipliers $((\hat p,\hat a),(\hat e,\hat b))\in\mathcal{H}'\times\mathcal{H}'$ satisfying

$$\delta_{(u,\theta,f)}\mathcal{L}(\hat u,\hat\theta,\hat f,\hat p,\hat e,\hat a,\hat b)(w,\eta,h) = 0 \quad \forall (w,\eta,h)\in\mathcal{W}\times\mathcal{W}\times\mathcal{V},$$

where $\delta_{(u,\theta,f)}\mathcal{L}$ is the Gâteaux derivative of $\mathcal{L}$ with respect to (u,θ,f). The last relation is equivalent to the following system:

$$\begin{aligned} &\textstyle\int_{Q_T}((\hat u - U)w + (\hat\theta-\Theta)\eta + 2q_0\beta_1|\hat f|^{2q_0-2}\hat f h + \beta_2\partial_t\hat f\partial_t h)\,dz \\ &\quad + \textstyle\int_{Q_T}(\partial_t w - \operatorname{div}(\mu(\hat\theta)\nabla w) - \operatorname{div}(\mu'(\hat\theta)\eta\nabla u) - h)\hat p\,dz \\ &\quad + \textstyle\int_{Q_T}(\partial_t\eta - \Delta\eta - 2\mu(\hat\theta)\nabla\hat u\cdot\nabla w - \mu'(\hat\theta)\eta|\nabla\hat u|^2)\hat e\,dz \\ &\quad + \langle\gamma_0 w,\hat a\rangle + \langle\gamma_0\eta,\hat b\rangle = 0 \quad \forall(w,\eta,h)\in\mathcal{W}\times\mathcal{W}\times\mathcal{V}, \end{aligned}$$

or equivalently

$$\begin{aligned} &c\textstyle\int_{Q_T}((\hat u - U)w + \partial_t w\hat p - \operatorname{div}(\mu(\hat\theta)\nabla w)\hat p - 2\mu(\hat\theta)\nabla\hat u\cdot\nabla w\hat e)\,dxdt \\ &+ \textstyle\int_{Q_T}((\hat\theta-\Theta)\eta - \operatorname{div}(\mu'(\hat\theta)\eta\nabla\hat u)\hat p + \partial_t\eta\hat e - \Delta\eta\hat e - \mu'(\hat\theta)\eta|\nabla\hat u|^2\hat e)\,dxdt \\ &+ \textstyle\int_{Q_T}(2q_0\beta_1|\hat f|^{2q_0-2}\hat f h + \beta_2\partial_t\hat f\partial_t h - \hat p h)dxdt + \langle\gamma_0 w,\hat a\rangle + \langle\gamma_0\eta,\hat b\rangle \\ &= 0 \quad \forall(w,\eta,h)\in\mathcal{W}\times\mathcal{W}\times\mathcal{V}. \end{aligned} \tag{5.2}$$

Define functions $(p,e)\in W_2^{2,1}(Q_T)\times W_2^{2,1}(Q_T)$ as a solution to the following system:

$$\left.\begin{aligned} \partial_t p + \operatorname{div}(\mu(\hat\theta)\nabla p) - \operatorname{div}(2\mu(\hat\theta)e\nabla\hat u) &= \hat u - U, \\ \partial_t e + \Delta e - \mu'(\hat\theta)\nabla\hat u\cdot\nabla p + \mu'(\hat\theta)|\nabla\hat u|^2 e &= \hat\theta - \Theta, \\ p|_{\partial\Omega} = 0, \quad e|_{\partial\Omega} = 0, \quad p|_{t=T} = 0, \quad e|_{t=T} &= 0. \end{aligned}\right\} \tag{5.3}$$

Existence and uniqueness of solutions to this backward parabolic system follow from Lemma 4.2, and conditions (2.1) and inclusions (4.17) and (4.16) hold for the coefficients of the system (5.3). Taking $h \equiv 0$ in (5.2), multiplying (5.3) by $(w, \eta) \in \mathcal{W} \times \mathcal{W}$, integrating by parts, and taking a difference with (5.2), we arrive at the identity

$$\begin{aligned} &\int_{Q_T} (\partial_t w - \operatorname{div}(\mu(\hat\theta)\nabla w) - \operatorname{div}(\mu'(\hat\theta)\eta\nabla\hat u))(p - \hat p)\, dxdt \\ &+ \int_{Q_T} (\partial_t \eta - \Delta\eta - \mu'(\hat\theta)\eta|\nabla\hat u|^2 - 2\mu(\hat\theta)\nabla\hat u \cdot \nabla w)(e - \hat e)\, dxdt \\ &+ \langle \gamma_0 w, \gamma_0 \hat p - \hat a\rangle + \langle \gamma_0\eta, \gamma_0\hat e - \hat b\rangle = 0 \quad \forall (w,\eta) \in \mathcal{W}\times\mathcal{W}. \end{aligned} \tag{5.4}$$

Take in (5.4) the test functions $(w, \eta) \in \mathcal{W} \times \mathcal{W}$ satisfying the system

$$\begin{gathered} \partial_t w - \operatorname{div}(\mu(\hat\theta)\nabla w) - \operatorname{div}(\mu'(\hat\theta)\eta\nabla\hat u)\operatorname{sign}(p - \hat p), \\ \partial_t \eta - \Delta\eta - \mu'(\hat\theta)\eta|\nabla\hat u|^2 - 2\mu(\hat\theta)\nabla\hat u\cdot\nabla w = \operatorname{sign}(e - \hat e), \\ \gamma_0 w = 0, \quad \gamma_0\eta = 0. \end{gathered}$$

Note that the right-hand sides of this system belong to $L^\infty(Q_T)$, and hence existence of the solution to this system in the class $W_{2q}^{2,1}(Q_T) \times W_{2q}^{2,1}(Q_T)$ follows for $q < q_0$ from Lemma 4.2 and conditions (4.17) and (4.16). Then from (5.4) the identities $p = \hat p$, $e = \hat e$ follow, and hence inclusions $\hat p, \hat\theta \in W_2^{2,1}(Q_T)$ hold. From (5.4) we also get $\hat a = \gamma_0\hat p$, $\hat b = \gamma_0\hat e$. Finally, taking in (5.2) $w = \eta = 0$ we get a relation

$$\int_{Q_T} (2q_0\beta_1|\hat f|^{2q_0-2}\hat f h + \beta_2\partial_t\hat f\partial_t h - \hat p h)dxdt = 0 \quad \forall h \in \mathcal{V},$$

which is the weak form of (2.16). Theorem 2.4 is proved.

STABILITY OF STOCHASTIC APPROXIMATION UNDER VERIFIABLE CONDITIONS*

CHRISTOPHE ANDRIEU†, ÉRIC MOULINES‡, AND PIERRE PRIOURET§

Abstract. In this paper we address the problem of the stability and convergence of the stochastic approximation procedure

$$\theta_{n+1} = \theta_n + \gamma_{n+1}[h(\theta_n) + \xi_{n+1}].$$

The stability of such sequences $\{\theta_n\}$ is known to heavily rely on the behavior of the mean field h at the boundary of the parameter set and the magnitude of the stepsizes used. The conditions typically required to ensure convergence, and in particular the boundedness or stability of $\{\theta_n\}$, are either too difficult to check in practice or not satisfied at all. This is the case even for very simple models. The most popular technique for circumventing the stability problem consists of constraining $\{\theta_n\}$ to a compact subset $\mathcal{K}$ in the parameter space. This is obviously not a satisfactory solution, as the choice of $\mathcal{K}$ is a delicate one. In this paper we first prove a "deterministic" stability result, which relies on simple conditions on the sequences $\{\xi_n\}$ and $\{\gamma_n\}$. We then propose and analyze an algorithm based on projections on adaptive truncation sets, which ensures that the aforementioned conditions required for stability are satisfied. We focus in particular on the case where $\{\xi_n\}$ is a so-called Markov state-dependent noise. We establish both the stability and convergence with probability 1 (w.p. 1) of the algorithm under a set of simple and verifiable assumptions. We illustrate our results with an example related to adaptive Markov chain Monte Carlo algorithms.

Key words. stochastic approximation, state-dependent noise, randomly varying truncation, adaptive Markov chain Monte Carlo

1. Introduction.

In many contexts it is of interest to find the roots of possibly nonlinear equations of the form

$$h(\theta) = 0, \qquad \theta \in \Theta, \tag{1.1}$$

for some mapping $h : \Theta \to \mathbb{R}^{n_\theta}$, where $\Theta \subset \mathbb{R}^{n_\theta}$ for some integer n_θ. Most of the methods for solving the previous equation are iterative, i.e., produce a sequence of iterates $\{\theta_n, n \geq 0\}$, which eventually converges to the set of solutions of (1.1),

$$\mathcal{S} := \{\theta \in \Theta, h(\theta) = 0\}. \tag{1.2}$$

Stochastic approximation (SA) is a class of algorithms for solving (1.1) in the situation where only noisy measurements of h are available. In its simplest form, the Robbins–Monro algorithm produces a sequence $\{\theta_n, n \geq 0\}$ defined recursively as

$$\theta_0 \in \Theta, \qquad \theta_{n+1} = \theta_n + \gamma_{n+1}\zeta_{n+1}, \quad n \geq 1, \tag{1.3}$$

where $\{\gamma_n, n \geq 1\}$ is a sequence of stepsizes satisfying standard conditions (say, $\gamma_n \downarrow 0$ and $\sum_{n\geq 1} \gamma_n = \infty$) and, for any $n \geq 1$, ζ_n is a noisy measurement of $h(\theta_n)$. It is useful to introduce the sequence $\{\xi_n, n \geq 1\}$ defined as

$$\zeta_{n+1} = h(\theta_n) + \xi_{n+1}, \tag{1.4}$$

which will be referred to as the *noise sequence*. Convergence of SA has been studied under various sets of assumptions for the mean field h and the noise sequence $\{\xi_n, n \geq 1\}$ since the early work of [22]; see also [5], [17], [23], [16], and the references therein. Essentially, convergence of the SA sequence can be established toward an *attractive* subset provided the sequence $\{\theta_n, n \geq 0\}$ is with probability 1 (w.p. 1) in a compact subset of Θ and is w.p. 1 infinitely often in the *domain of attraction* of this attractive subset. Showing in practice that $\{\theta_n, n \geq 0\}$ satisfies these boundedness and recurrence conditions proves to be a difficult task. The available results hold under conditions which are still restrictive, despite recent advances (see [1], [7], [6], and references therein). This major drawback has motivated the design of modified Robbins–Monro recursions. Probably the most widely used method in practice consists of constraining the sequence $\{\theta_n, n \geq 0\}$ to some compact set $\mathcal{K} \subset \Theta$ by means of a reprojection onto $\mathcal{K}$. This method has been thoroughly investigated in [23] (see also [8] and the references therein). Although relatively easy to implement, and appropriate when constraints about the system considered are available a priori, this approach becomes impractical and questionable in many situations.

Our contributions toward solving the stability and convergence problems are twofold. First we establish and prove in section 2 a general result of stability, Theorem 2.2, for deterministic sequences of the form given by (1.3)–(1.4). This key deterministic result assumes the existence of a global Lyapunov function for the mean field h and mild general assumptions about the noise and stepsize sequences. In contrast with previous results, the conditions required on the growth of the Lyapunov functions and the mean field h when θ approaches the boundaries of the parameter set Θ are minimal. As a consequence the result is applicable to quite general settings. We then show that, under the conditions that guarantee stability, the convergence of the deterministic sequence (1.3)–(1.4) is ensured (see Theorem 2.3).

Our second contribution here consists of proposing an SA algorithm (section 3) for which the aforementioned noise and stepsize conditions are satisfied w.p. 1. There are many different applications of stochastic approximations which imply markedly different types of assumptions on the noise sequence $\{\xi_n\}$. Whereas our deterministic stability and convergence results mentioned above can be applied quite generally, we focus in this paper on the subtle Markov state-dependent noise (see [23, Chapter 6, section 6.6] and section 3 in this paper) for which the availability of algorithms, whose convergence can be established under general but nevertheless verifiable assumptions, is still missing. The proposed algorithm is a modification of the classical Robbins–Monro procedure described in (1.3)–(1.4), based on truncations on adaptive truncation sets, in the spirit of the seminal works [11] and [10].

The convergence of SA with adaptive truncation sets has been considered under various conditions on the noise sequence $\{\xi_n\}$. These include state-independent noise conditions (see, for example, [12, section 2.4, pp. 42–44]) but also state-dependent martingale differences [30], [14], [9], [12, section 2.5, pp. 49–57] or state-dependent ϕ-mixing processes [9], [12, section 2.5, p. 49]. However, the application of this strategy to the Markovian state-dependent case requires even more care, and it is therefore not surprising to find that the results on the topic are scarce and have been obtained

under conditions that are more stringent than those considered in the present paper; see [31], [13] and, for the special case of ARMAX models, see [12, Chapter 6]. As we shall see, our procedure differs in some respects from the original procedure proposed in [11] and [10] and offers additional degrees of freedom. Our technique of proof for the stability relies on a novel approach and offers as a byproduct an explicit bound for the tail probability of the number of reprojections, which is found to be super-exponential under mild technical conditions.

In order to illustrate our findings and their applicability, we propose (see section 7) to analyze the convergence of an adaptive Markov chain Monte Carlo (MCMC) algorithm recently proposed in [19] and analyzed under more stringent conditions than those considered here. Other examples can be found in [2].

2. Key deterministic results. In this section we establish both stability and convergence results for deterministic recursions of the type described in (1.3)–(1.4). Before stating our first assumptions, some definitions and notation are needed. Let d be a positive integer. An element v of $\mathbb{R}^d$ is denoted by its column vector v and its transpose is denoted by v^{T}. For elements v, w of $\mathbb{R}^d$, we denote by $\langle v, w\rangle$ their inner product, so that $|v| = \sqrt{\langle v, v\rangle}$ denotes the norm of v. Our first assumption is the existence of a global Lyapunov function w for the mean field h. Denoting $\mathcal{W}_M := \{\theta \in \Theta, w(\theta) \le M\} \subset \Theta$ we assume the following:

(A1) Θ is an open subset of $\mathbb{R}^{n_\theta}$, $h : \Theta \to \mathbb{R}^{n_\theta}$ is continuous, and there exists a continuously differentiable function $w : \Theta \to [0, \infty)$ such that

(i) there exists $M_0 > 0$ such that

$$\mathcal{L} := \left\{\theta \in \Theta, \left\langle \nabla w(\theta), h(\theta)\right\rangle = 0\right\} \subset \{\theta \in \Theta, w(\theta) < M_0\};$$

(ii) there exists $M_1 \in (M_0, \infty]$ such that $\mathcal{W}_{M_1}$ is a compact set;

(iii) for any $\theta \in \Theta \setminus \mathcal{L}$, $\langle \nabla w(\theta) h(\theta)\rangle < 0$;

(iv) the closure of $w(\mathcal{L})$ has an empty interior.

If h is a gradient field, i.e., $h = -\nabla J$ for some lower bounded real valued and differentiable function $\theta \mapsto J(\theta)$, then the choice $w = J$ is appropriate, provided that J is continuously differentiable. Note that, in situations where the set of stationary points cannot be characterized explicitly, one might use Sard's theorem from differential geometry in order to check (A1)(iv). Indeed, Sard's theorem states that if w is n_θ-times continuously differentiable, then $w(\{\nabla w = 0\})$ has an empty interior.

Our approach to proving our stability and convergence results can be decomposed into two distinct steps. In the first step (this section), we establish deterministic conditions on a noise sequence $\{\xi_n\}$ and a stepsize sequence $\{\rho_n\}$, upon which a deterministic sequence $\{\theta_n\}$ defined as

$$\theta_0 \in \Theta \quad \theta_{n+1} = \theta_n + \rho_{n+1}[h(\theta_n) + \xi_{n+1}] \quad \text{for} \quad n \ge 0, \tag{2.1}$$

has the following properties: (i) It remains in a compact subset of Θ (see Theorem 2.2) and (ii) it converges to $\mathcal{L}$ (Theorem 2.3) provided that $\{\theta_n\}$ remains in a compact subset of Θ. In a second step—which is probabilistic in nature and depends on how the noise is generated—we develop a general algorithm for the case where $\{\xi_n\}$ follows a Markovian state-dependent dynamic, which allows one to show that the required condition on $\{\xi_n\}$ is satisfied w.p. 1 (sections 3–6).

Before proving Theorems 2.2 and 2.3 we prove in the following lemma a fundamental contraction property of the Lyapunov function w. This result is the crux of both the proof of stability and the proof of convergence.

LEMMA 2.1. *Assume* (A1). *Then*

(i) *Let* $\mathcal{K} \subset \Theta$ *be a compact subset such that* $0 < \inf_{\theta\in\mathcal{K}} |\langle \nabla w, h\rangle|$. *For any* $0 < \delta < \inf_{\theta\in\mathcal{K}} |\langle \nabla w, h\rangle|$, *there exist* $\lambda > 0$ *and* $\beta > 0$ *such that, for any* ρ, $0 \le \rho \le \lambda$, ζ, $|\zeta| \le \beta$, *and* $\theta \in \mathcal{K}$, $w(\theta + \rho h(\theta) + \rho\zeta) \le w(\theta) - \rho\delta$.

(ii) *For any* $M \in (M_0, M_1]$ (*where* M_0 *is defined in* (A1)(i) *and* M_1 *is defined in* (A1)(ii)), *there exist* $\lambda > 0$ *and* $\beta > 0$ *such that, for any* ρ, $0 \le \rho \le \lambda$, ζ, $|\zeta| \le \beta$, *and* $\theta \in \mathcal{W}_M$, $\theta + \rho h(\theta) + \rho\zeta \in \mathcal{W}_M$.

Proof. We first prove (i).For any $0 < \delta < \inf_{\theta\in\mathcal{K}} |\langle \nabla w, h\rangle|$, there exist $\lambda > 0$ and $\beta > 0$ such that, for all ρ, $0 \le \rho \le \lambda$, ζ, $|\zeta| \le \beta$, and t, $0 \le t \le 1$, we have for all $\theta \in \mathcal{K}$, $\theta + \rho t h(\theta) + \rho t\zeta \in \Theta$ and

$$\left|\left\langle \nabla w(\theta), h(\theta)\right\rangle - \left\langle \nabla w(\theta + \rho t h(\theta) + \rho t\zeta), h(\theta) + \zeta\right\rangle\right| \le \inf_{\theta\in\mathcal{K}} |\left\langle \nabla w, h\right\rangle| - \delta.$$

Then for any ρ, $0 \le \rho \le \lambda$, and ζ, $|\zeta| \le \beta$,

$$\begin{aligned} w(\theta + \rho h(\theta) + \rho\zeta) - w(\theta) &= \rho\left\langle \nabla w(\theta), h(\theta)\right\rangle + \rho \int_0^1 \left(\left\langle \nabla w(\theta + t\rho h(\theta) + t\rho\zeta), h(\theta) + \zeta\right\rangle \right. \\ &\qquad \left. - \left\langle \nabla w(\theta), h(\theta)\right\rangle\right) dt \\ &\le -\rho \inf_{\theta\in\mathcal{K}} |\left\langle \nabla w, h\right\rangle| + \rho\left(\inf_{\theta\in\mathcal{K}} |\left\langle \nabla w, h\right\rangle| - \delta\right) = -\rho\delta. \end{aligned}$$

We now prove (ii). Consider $M' \in (M_0, M)$. Since $\mathcal{W}_{M'}$ is compact and w continuous, there exists $\lambda_0 > 0$ and $\beta_0 > 0$ such that, for all $0 \le \rho \le \lambda_0$, $|\zeta| \le \beta_0$, and $\theta \in \mathcal{W}_{M'}$, $\theta + \rho h(\theta) + \rho\zeta \in \mathcal{W}_M$. We can apply (i) to the set $\mathcal{K} = \{\theta \in \Theta, M' \le w(\theta) \le M\}$ to show that there exists λ_1, β_1 such that, for all ρ, $0 \le \rho \le \lambda_1$, ζ, $|\zeta| \le \beta_1$, and $\theta \in \mathcal{K}$, $w(\theta + \rho h(\theta) + \rho\zeta) \le w(\theta) \le M$, showing that $\theta + \rho h(\theta) + \rho\zeta \in \mathcal{W}_M$. □

2.1. Boundedness. In this section, we show that, under (A1) and mild additional conditions on $\{\xi_n\}$ and $\{\rho_n\}$, the sequence defined in (2.1) remains in a compact subset of Θ.

THEOREM 2.2. *Assume* (A1). *For any* $M \in (M_0, M_1]$ *there exist* $\delta_0 > 0$ *and* $\lambda_0 > 0$ *such that, for all* $n \ge 1$, *all* $\theta_0 \in \mathcal{W}_{M_0}$, *all sequences* $\{\rho_k\}$ *of nonnegative integers, and all sequences* $\{\xi_k\}$ *of* n_θ*-dimensional vectors satisfying*

$$\sup_{1\le k\le n} \rho_k \le \lambda_0 \quad \textit{and} \quad \sup_{1\le k\le n} \left|\sum_{j=1}^{k} \rho_j \xi_j\right| \le \delta_0,$$

we have for $k \in \{1, \dots, n\}$, $w(\theta_k) \le M$, *where* $\theta_k = \theta_{k-1} + \rho_k h(\theta_{k-1}) + \rho_k \xi_k$.

Proof. Let M' be such that $M' \in (M_0, M)$. Lemma 2.1 shows that there exists $\lambda_0 > 0$, $\beta_0 > 0$ such that, for all θ, ρ, and ζ satisfying $w(\theta) \le M'$, $0 \le \rho \le \lambda_0$, and $|\zeta| \le \beta_0$,

$$w(\theta + \rho h(\theta) + \rho\zeta) \le M'. \tag{2.2}$$

By continuity of h and w there exists $\delta_0 \in (0, \beta_0]$ such that for all $(\theta, \bar\theta) \in \Theta \times \Theta$ satisfying $w(\theta) \le M$ and $|\theta - \bar\theta| \le \delta_0$, we have

$$|h(\bar\theta) - h(\theta)| \le \beta_0 \quad \text{and} \quad |w(\bar\theta) - w(\theta)| \le M - M'. \tag{2.3}$$

We will now prove by induction that, for all $k \in \{1, \dots, n\}$, $w(\bar{\theta}_k) \leq M'$, and $w(\theta_k) \leq M$, where the sequence $\{\bar{\theta}_k\}$ is defined recursively as $\bar{\theta}_0 = \theta_0$ and for all $k \in \{1, \dots, n\}$,

$$\bar{\theta}_k = \bar{\theta}_{k-1} + \rho_k h(\theta_{k-1}).$$

Under the stated assumptions $w(\theta_0) = w(\bar{\theta}_0) \leq M_0$ and since $0 \leq \rho_1 \leq \lambda_0$ and $|\theta_1 - \bar{\theta}_1| = |\rho_1 \xi_1| \leq \delta_0$, on the one hand Lemma 2.1 shows that $w(\bar{\theta}_1) = w(\bar{\theta}_0 + \rho_1 h(\bar{\theta}_0)) \leq M'$ and on the other hand $w(\theta_1) = w(\theta_0 + \rho_1 h(\theta_0) + \rho_1 \xi_1) \leq M$, which proves the result for $n = 1$. Assume now that the result holds up to $1 \leq k \leq n-1$ for $n > 1$. By construction, for $j \in \{1, \dots, k\}$, $\theta_j - \bar{\theta}_j = \theta_{j-1} - \bar{\theta}_{j-1} + \rho_j \xi_j$, which implies that

$$\theta_j - \bar{\theta}_j = \sum_{i=1}^{j} \rho_i \xi_i. \tag{2.4}$$

Under the stated assumptions and (2.3), for $j \in \{1, \dots, k\}$, $|\theta_j - \bar{\theta}_j| \leq \delta_0$ and $|h(\theta_j) - h(\bar{\theta}_j)| \leq \beta_0$. On the other hand,

$$\bar{\theta}_{k+1} = \bar{\theta}_k + \rho_{k+1} h(\theta_k) = \bar{\theta}_k + \rho_{k+1} h(\bar{\theta}_k) + \rho_{k+1} \left(h(\theta_k) - h(\bar{\theta}_k) \right).$$

Since $0 \leq \rho_{k+1} \leq \lambda_0$ and $w(\bar{\theta}_k) \leq M'$, Lemma 2.1 shows that $w(\bar{\theta}_{k+1}) \leq M'$. Using again that $|\theta_{k+1} - \bar{\theta}_{k+1}| \leq \delta_0$, (2.3) implies that $w(\theta_{k+1}) \leq M$, which concludes the proof. □

2.2. Convergence. Theorem 2.2 provides us with conditions on $\{\xi_n\}$ and $\{\rho_n\}$ upon which a sequence as defined in (2.1) stays within a compact subset of Θ. In the next theorem we show that, whenever $\{\theta_k\}$ stays in a compact subset of Θ, under mild additional assumptions it converges to $\mathcal{L}$. The key result of this section is the following theorem, adapted here from [14, Theorem 2] (see [12] for a similar result). This theorem states that whenever $\{\theta_i\}$ stays in a compact subset of Θ, under mild additional assumptions it converges to $\mathcal{L}$. For an integer d and A a subset of $\mathbb{R}^d$, we define $d(x, A) = \inf\{y \in A, |x - y|\}$. For any set $A \subset \Theta$ and any $\delta > 0$, we define $A_\delta := \{\theta \in \Theta, d(\theta, A) \leq \delta\}$; for any function $\phi : \Theta \to \mathbb{R}$, we define $\|\phi\|_A := \sup_{\theta \in A} |\phi(\theta)|$.

THEOREM 2.3. *Assume* (A1). *Let $\mathcal{K}$ be a compact subset of Θ such that $\mathcal{L} \cap \mathcal{K} \neq \emptyset$. Let $\{\rho_k\}$ be a monotone nonincreasing sequence of positive numbers such that $\rho_0 \leq \lambda_0$ (where λ_0 is given in Theorem* 2.2),

$$\sum_{k=1}^{\infty} \rho_k = \infty, \quad \textit{and} \quad \lim_{k \to \infty} \rho_k = 0.$$

Let $\{\xi_n\}$ be a sequence in $\mathbb{R}^{n_\theta}$ satisfying $\limsup_{k \to \infty} \sup_{l \geq k} |\sum_{i=k}^{l} \rho_i \xi_i| = 0$. Assume that the sequence defined by $\theta_k = \theta_{k-1} + \rho_k h(\theta_{k-1}) + \rho_k \xi_k$ is such that $\{\theta_k\} \subset \mathcal{K}$. Then, $\limsup_{k \to \infty} d(\theta_k, \mathcal{L} \cap \mathcal{K}) = 0$.

We preface the proof of this theorem with two lemmas. Lemmas 2.4 and 2.5 are proved under the assumptions of Theorem 2.3.

LEMMA 2.4. *Let $\mathcal{N} \subset \Theta$ be an open neighborhood of $\mathcal{L} \cap \mathcal{K}$. There exist positive constants δ, ε, and λ (depending only on the sets $\mathcal{N}$ and $\mathcal{K}$) such that for any $\delta' \in (0, \delta]$, $\lambda' \in (0, \lambda]$, and $\eta > 0$, one can find an integer N and a sequence $\{\bar{\theta}_j\}_{j \geq N}$ satisfying*

$$\sup_{j \geq N} |\theta_j - \bar{\theta}_j| \leq \delta', \quad \sup_{j \geq N} \rho_j \leq \lambda', \quad \textit{and} \quad \sup_{j \geq N} |w(\theta_j) - w(\bar{\theta}_j)| \leq \eta, \tag{2.5}$$

$$w(\bar{\theta}_j) \leq w(\bar{\theta}_{j-1}) - \rho_j \varepsilon + (\eta + \rho_j \varepsilon) \, \mathbb{1}_{\mathcal{N}}(\bar{\theta}_{j-1}) \quad \textit{for} \quad j \geq N + 1. \tag{2.6}$$

Proof. Let us choose $\delta_0 > 0$ such that the compact set $\mathcal{K}_{\delta_0} \subset \Theta$. The set $\mathcal{K}_{\delta_0} \setminus \mathcal{N}$ is compact and $\sup_{\mathcal{K}_{\delta_0}\setminus\mathcal{N}} \langle \nabla w, h\rangle < 0$. By Lemma 2.1, for any $\varepsilon > 0$ such that $\sup_{\theta\in\mathcal{K}_{\delta_0}\setminus\mathcal{N}} \langle \nabla w(\theta), h(\theta)\rangle < -\varepsilon$, one may choose $\lambda > 0$ and $\beta > 0$ small enough so that for any $\rho \in [0, \lambda]$, $|\zeta| \le \beta$, and $\theta \in \mathcal{K}_{\delta_0} \setminus \mathcal{N}$,

$$w(\theta + \rho h(\theta) + \rho\zeta) \le w(\theta) - \rho\varepsilon. \tag{2.7}$$

Using the uniform continuity of continuous functions on compact sets, for any $\eta > 0$ one may choose $\delta \in (0, \lambda\|h\|_{\mathcal{K}}]$ small enough so that for all $(\theta, \bar\theta) \in \mathcal{K}_{\delta_0} \times \mathcal{K}_{\delta_0}$ satisfying $|\theta - \bar\theta| \le \delta \le \lambda\|h\|_{\mathcal{K}}$,

$$|h(\theta) - h(\bar\theta)| \le \beta \quad \text{and} \quad |w(\theta) - w(\bar\theta)| \le \eta. \tag{2.8}$$

Under the stated conditions for all $\delta' \in (0, \delta]$ and $\lambda' \in (0, \lambda]$ there exists an integer N such that for any $n \ge N + 1$, $\rho_n \le \lambda'$ and $\left|\sum_{k=N+1}^{n} \rho_k\xi_k\right| \le \delta'$. Define recursively for $j \ge N$ the sequence $\{\bar\theta_j\}_{j\ge N}$ as $\bar\theta_N := \theta_N$ and for $j \ge N + 1$,

$$\bar\theta_j = \bar\theta_{j-1} + \rho_j h(\theta_{j-1}). \tag{2.9}$$

By construction, for $j \ge N+1$, $\bar\theta_j - \theta_j = \sum_{i=N+1}^{j} \rho_i\xi_i$ which implies that $\sup_{j\ge N} |\bar\theta_j - \theta_j| \le \delta'$. On the other hand, for $j \ge N + 1$,

$$\bar\theta_j = \bar\theta_{j-1} + \rho_j h(\bar\theta_{j-1}) + \rho_j \left(h(\theta_{j-1}) - h(\bar\theta_{j-1})\right), \tag{2.10}$$

and since $|\bar\theta_{j-1} - \theta_{j-1}| \le \delta' \le \delta$, (2.8) shows that $|h(\theta_{j-1}) - h(\bar\theta_{j-1})| \le \beta$. Thus, (2.7) implies that, whenever $\bar\theta_{j-1} \in \mathcal{K}_\delta \setminus \mathcal{N}$, $w(\bar\theta_j) \le w(\bar\theta_{j-1}) - \rho_j\varepsilon$. Now (2.8) implies that $|w(\bar\theta_j) - w(\bar\theta_{j-1})| \le \eta$ for any $\bar\theta_{j-1} \in \mathcal{K}_\delta$ and $|w(\theta_j) - w(\bar\theta_j)| \le \eta$ for any $\theta_j \in \mathcal{K}$, which concludes the proof. □

LEMMA 2.5. *Let ε be real constants, n be an integer, and let $-\infty < a_1 < b_1 < \cdots < a_n < b_n < \infty$ be real numbers. Let $\{u_j\}$ be a bounded real sequence such that, for any $\eta > 0$, there exists an integer J such that for all $j \ge J$,*

$$u_j \le u_{j-1} - \rho_j\varepsilon + (\eta + \rho_j\varepsilon)\mathbb{1}_A(u_{j-1}) \quad A = \bigcup_{i=1}^{n} [a_i, b_i]. \tag{2.11}$$

Then, the limit points of the sequence $\{u_j\}$ are included in A.

Proof. As $\{u_j\}$ is bounded, it has at least one limit point from the Bolzano–Weierstrass theorem. Let us denote by $\check a$ one of these limit points; since $\{u_j\}$ is bounded and satisfies (2.11), $\check a \ge a_1$. Now let us proceed by contradiction and assume that there exists $l \in \{1, 2, \ldots, n\}$ such that $\check a \in (b_l, a_{l+1})$, with the convention that $a_{n+1} = \infty$. For any $\epsilon > 0$ sufficiently small $[\check a - \epsilon, \check a + \epsilon] \subset A^c$. Now, for any integer j and any set $B \subset \mathbb{R}$, we define

$$\tau_B(j) = \inf\{k \ge j : u_k \in B\},$$

with the convention $\inf\emptyset = \infty$. Since $\sum_{k=1}^{\infty} \rho_k = \infty$ and $\{u_k\}_{k\ge0}$ is bounded, (2.11) implies that for any $\eta > 0$ and $j \ge J$, $\sigma(j) := \tau_A(j) < \infty$. Note also that for $k = j, \ldots, \sigma(j)$, $u_k \le u_j$. Since $\check a \in (b_l, a_{l+1})$ is a limit point, for any integer j, $\kappa(j) := \tau_{(b_l,\infty)}(j) < \infty$. Let $\eta > 0$ be such that, for any $j \ge J$, $0 < \eta < (\check a - \epsilon - b_l)/2$. Then for $j \ge J$, $u_{\kappa[\sigma(j)]} < (\check a - \epsilon + b_l)/2$ and for $k = \kappa[\sigma(j)], \ldots, \kappa(\sigma(\kappa[\sigma(j)])) - 1$, $u_k \le u_{\kappa[\sigma(j)]}$, which implies that for any $i \ge \kappa(\sigma(J))$, $u_i \le (\check a - \epsilon + b_l)/2$, which

contradicts the fact that $\check{a}$ is a limit point. Now using the same type of argument, one can show that if an accumulation point $\check{a} \in [a_k, b_k]$ for some $k \in 1, \ldots, n-1$, then there cannot be any accumulation point in $[a_l, b_l]$ for $n \geq l > k$. As a consequence there cannot be an accumulation point in an interval other than $[a_k, b_k]$. □

Proof of Theorem 2.3. We first prove that $\lim_{j\to\infty} w(\theta_j)$ exists. For any $\alpha > 0$, define the set $[w(\mathcal{L} \cap \mathcal{K})]_\alpha := \{x \in \mathbb{R} : d(x, w(\mathcal{L} \cap \mathcal{K})) \leq \alpha\}$. Since $\|w\|_{\mathcal{K}} < \infty$, $[w(\mathcal{L} \cap \mathcal{K})]_\alpha$ is a finite union of disjoint intervals of length at least equal to 2α. By Lemma 2.4, there exist positive constants δ, ε, λ such that for any $\delta' \in (0, \delta]$, $\lambda' \in (0, \lambda]$, and $\eta > 0$, one may find an integer N and a sequence $\{\bar{\theta}_j\}_{j\geq N}$ such that

$$\sup_{j\geq N} |\theta_j - \bar{\theta}_j| \leq \delta' \quad \text{and} \quad \sup_{j\geq N} |w(\theta_j) - w(\bar{\theta}_j)| \leq \eta$$

and

$$w(\bar{\theta}_j) \leq w(\bar{\theta}_{j-1}) - \rho_j\varepsilon + (\eta + \rho_j\varepsilon)\mathbb{1}_{[w(\mathcal{L}\cap\mathcal{K})]_\alpha}(w(\bar{\theta}_{j-1})) \quad \text{for any} \quad j \geq N+1,$$

where we have chosen $\mathcal{N} = w^{-1}(\text{int}([w(\mathcal{L}\cap\mathcal{K})]_\alpha))$ and used $\mathbb{1}_{\mathcal{N}}(\theta) \leq \mathbb{1}_{[w(\mathcal{L}\cap\mathcal{K})]_\alpha}(w(\theta))$. By Lemma 2.5, the limit points of the sequence $\{w(\bar{\theta}_j)\}$ are in $[w(\mathcal{L}\cap\mathcal{K})]_\alpha$ and, since $\sup_{j\geq N} |\theta_j - \bar{\theta}_j| \leq \delta'$, the limit points of the sequence $\{w(\theta_j)\}_{j\geq 0}$ are in $[w(\mathcal{L}\cap\mathcal{K})]_{\alpha'}$ for $\alpha' = \alpha + \eta$. Since α and η can be chosen arbitrarily small, this implies that the limit points of the sequence $\{w(\theta_j)\}_{j\geq 0}$ are included in $\bigcap_{\alpha>0}[w(\mathcal{L}\cap\mathcal{K})]_\alpha$. Because $\mathcal{L}\cap\mathcal{K}$ is a compact subset of $\mathbb{R}^{n_\theta}$ and w is continuous, $w(\mathcal{L}\cap\mathcal{K})$ is a compact subset of $\mathbb{R}$, which implies that $w(\mathcal{L}\cap\mathcal{K}) = \bigcap_{\alpha>0}[w(\mathcal{L}\cap\mathcal{K})]_\alpha$. Thus, the limit points of $\{w(\theta_j)\}$ belong to the set $w(\mathcal{L}\cap\mathcal{K})$.

On the other hand, $\limsup_{j\to\infty} |w(\theta_j) - w(\theta_{j-1})| = 0$, which implies that the set of limit points of $\{w(\theta_j)\}$ is an interval. Because $w(\mathcal{L})$ has an empty interior, the only intervals included in $w(\mathcal{L}\cap\mathcal{K})$ are isolated points, which shows that the limit $\lim_{j\to\infty} w(\theta_j)$ exists.

We now prove that $\limsup_{j\to\infty} d(\theta_j, \mathcal{L}\cap\mathcal{K}) = 0$. Let $\mathcal{N} \subset \mathcal{K}$ be an arbitrary neighborhood of $\mathcal{L}\cap\mathcal{K}$. From Lemma 2.4 there exist constants $\delta > 0$, $\varepsilon > 0$, $\lambda > 0$ such that for any $\delta' \in (0, \delta]$, $\lambda' \in (0, \lambda]$, and $\eta > 0$ one may find an integer N and a sequence $\{\bar{\theta}_j\}_{j\geq N}$ such that

$$\sup_{j\geq N} |\theta_j - \bar{\theta}_j| \leq \delta', \quad \sup_{j\geq N} \rho_j \leq \lambda', \quad \text{and} \quad \sup_{j\geq N} |w(\theta_j) - w(\bar{\theta}_j)| \leq \eta$$

and

$$w(\bar{\theta}_j) \leq w(\bar{\theta}_{j-1}) - \rho_j\varepsilon + (\eta + \rho_j\varepsilon)\mathbb{1}_{\mathcal{N}}(\bar{\theta}_{j-1}) \quad \text{for any} \quad j \geq N+1.$$

For $j \geq N$, define $\tau(j) := \inf\{k \geq 0, \bar{\theta}_{k+j} \in \mathcal{N}\}$. For any integer p, define $\tau^p(j) := \tau(j) \wedge p$, where $a \wedge b = \min(a, b)$. We have

$$w(\bar{\theta}_{j+\tau^p(j)}) - w(\bar{\theta}_j) = \sum_{i=j+1}^{j+\tau^p(j)} \{w(\bar{\theta}_i) - w(\bar{\theta}_{i-1})\} \leq -\varepsilon \sum_{i=j+1}^{j+\tau^p(j)} \rho_i, \tag{2.12}$$

with the convention that, for any sequence $\{a_i\}$ and any integer l, $\sum_{i=l+1}^{l} a_i = 0$. Therefore,

$$\begin{aligned} w(\theta_{j+\tau^p(j)}) - w(\theta_j) &= w(\theta_{j+\tau^p(j)}) - w(\bar{\theta}_{j+\tau^p(j)}) + w(\bar{\theta}_{j+\tau^p(j)}) - w(\bar{\theta}_j) + w(\bar{\theta}_j) - w(\theta_j) \\ &\leq 2\eta - \varepsilon \sum_{i=j+1}^{j+\tau^p(j)} \rho_i. \end{aligned}$$

Since $\{w(\theta_j)\}$ converges, for any $\varepsilon' > 0$ there exists $N' > N$ such that, for all $j \geq N'$,

$$-\varepsilon' < w(\theta_{j+\tau^p(j)}) - w(\theta_j) \leq 2\eta - \varepsilon \sum_{i=j+1}^{j+\tau^p(j)} \rho_i. \tag{2.13}$$

This implies that, for all $j \geq N'$ and all integer $p \geq 0$,

$$\sum_{i=j+1}^{j+\tau^p(j)} \rho_i \leq C(\varepsilon', \eta) := \varepsilon^{-1} (\varepsilon' + 2\eta). \tag{2.14}$$

Since $\sum_{i=j+1}^{j+\tau(j)} \rho_i = \lim_{p\to\infty} \sum_{i=j+1}^{j+\tau^p(j)} \rho_i$ and $\sum_{i=1}^{\infty} \rho_i = \infty$, the previous relation implies that, for all $j \geq N'$, $\tau(j) < \infty$, and $\sum_{i=j+1}^{j+\tau(j)} \rho_i \leq C(\varepsilon', \eta)$. For any integer p, $\theta_{j+p} - \theta_j = \sum_{i=j+1}^{j+p} \rho_i h(\theta_{i-1}) + \sum_{i=j+1}^{j+p} \rho_i \xi_i$, which implies that

$$|\theta_{j+p} - \theta_j| \leq \|h\|_{\mathcal{K}} \sum_{i=j+1}^{j+p} \rho_i + \left| \sum_{i=j+1}^{j+p} \rho_i \xi_i \right|.$$

Applying this inequality for $j \geq N'$ and $p = \tau(j)$ and using that, by definition, $\bar{\theta}_{j+\tau(j)} \in \mathcal{N}$,

$$d(\theta_j, \mathcal{N}) \leq |\bar{\theta}_{j+\tau(j)} - \theta_{j+\tau(j)}| + |\theta_{j+\tau(j)} - \theta_j| \leq \delta' + \|h\|_{\mathcal{K}}\, C(\varepsilon', \eta) + \left| \sum_{i=j+1}^{j+\tau(j)} \rho_i \xi_i \right|.$$

Since η, δ', and ε' can be chosen arbitrarily small, and $\limsup_{k\to\infty} \sup_{l\geq k} |\sum_{i=k}^{l} \rho_i \xi_i| = 0$, the latter inequality shows that $\lim_{j\to\infty} d(\theta_j, \mathcal{N}) = 0$. Since $\mathcal{N}$ is arbitrary, we thus have $\lim_{j\to\infty} d(\theta_j, \mathcal{L} \cap \mathcal{K}) = 0$. □

Note that the boundedness is here one of the required assumptions. It is therefore natural to try to apply Theorem 2.2. This is what motivates the next section, where we describe a modification of the stochastic approximation algorithm, which ensures that the conditions of Theorem 2.2 are satisfied. We consider here the Markov state-dependent noise, as it covers many applications of interest, encompasses the exogenous scenario and, as we shall see, leads to general and verifiable conditions.

3. Markov state-dependent noise. In this section, we describe our stochastic approximation procedure with adaptive truncation sets and introduce the relevant notation required in the Markovian state-dependent noise scenario (see [23, section 6.6, p. 159] for a detailed description and numerous examples). We first introduce a version without truncations of the algorithm in this setting (subsection 3.2) and describe our adaptive procedure in terms of this plain algorithm in subsection 3.1. This will prove extremely useful when proving that our procedure is stable in section 4 and particularly in section 5.

It is assumed hereafter that the state-space X and the parameter space Θ are equipped with a countably generated σ-field, $\mathcal{B}(\mathsf{X})$, and $\mathcal{B}(\Theta)$ (and measurability will always be defined w.r.t. these σ-fields).

3.1. Nonhomogeneous chain. Let $\boldsymbol{\rho} = \{\rho_n\}$ be a monotone nonincreasing sequence with $\rho_0 \leq 1$, define the product space $\bar{\mathsf{X}} := \mathsf{X} \cup \{x_c\} \times \bar{\Theta} := \Theta \cup \{\theta_c\}$, where $\theta_c \notin \Theta$ and $x_c \notin \mathsf{X}$ are two arbitrary cemetery points, and define the *nonhomogeneous*

Markov chain $\{Y_n^{\boldsymbol{\rho}} := (X_n, \theta_n)\}$ on $\bar{\mathsf{X}} \times \bar{\Theta}$ as follows. Set $\theta_0 = \theta \in \Theta$, $X_0 = x \in \mathsf{X}$, and for $n \geq 0$,

$$\theta_{n+1} = \begin{cases} \theta_n + \rho_{n+1} H(\theta_n, X_{n+1}) & \text{and} \quad X_{n+1} \sim P_{\theta_n}(X_n, \cdot) \quad \text{if} \quad \theta_n \in \Theta, \\ \theta_c & \text{and} \quad X_{n+1} = x_c \quad \text{if} \quad \theta_n \notin \Theta, \end{cases} \tag{3.1}$$

where it is assumed that the family of Markov transition probabilities $\{P_\theta, \theta \in \Theta\}$ and the field H satisfy the following conditions:

(A2) For any $\theta \in \Theta$, the Markov kernel P_θ has a single stationary distribution π_θ, $\pi_\theta P_\theta = \pi_\theta$. In addition $H : \Theta \times \mathsf{X} \to \Theta$ is measurable for all $\theta \in \Theta$, $\int_{\mathsf{X}} |H(\theta, x)| \pi_\theta(dx) < \infty$.

The existence and uniqueness of the invariant distribution can be guaranteed under classical irreducibility and recurrence conditions (see, e.g., [25, Chapters 9, 10]). We denote by $h(\theta) := \int_{\mathsf{X}} H(\theta, x) \pi_\theta(dx)$ the mean-field associated to this stochastic approximation procedure and define the noise sequence $\{\xi_n = H(\theta_{n-1}, X_n) - h(\theta_{n-1})\}$. Following [5], we will often write $H_\theta(x)$ as an equivalent expression for $H(\theta, x)$, h_θ for $h(\theta)$, etc.

We denote by $\mathcal{F} = \{\mathcal{F}_n, n \geq 0\}$ the natural filtration of this Markov chain, with $\mathcal{F}_n := \sigma((X_l, \theta_l), l \in \{0, \ldots, n\})$ and $\mathbb{P}_{x,\theta}^{\boldsymbol{\rho}}$ the probability measure on the canonical space $\left((\mathsf{X} \times \Theta)^{\mathbb{N}}, (\mathcal{B}(\mathsf{X}) \otimes \mathcal{B}(\Theta))^{\otimes \mathbb{N}}\right)$ generated by the nonhomogeneous Markov chain $\{Y_n^{\boldsymbol{\rho}}\}$ started from the initial conditions $(X_0, \theta_0) = (x, \theta) \in \mathsf{X} \times \Theta$ and using the sequence $\boldsymbol{\rho}$. Finally, it will be useful in what follows to introduce $\{Q_{\rho_n}\}$, the sequence of transition probabilities that generates the inhomogeneous Markov chain $\{Y_n^{\boldsymbol{\rho}}\}$, where for $\rho \geq 0$, Q_ρ is defined for any $(x, \theta) \in \mathsf{X} \times \Theta$, $A \in \mathcal{B}(\bar{\mathsf{X}})$, and $B \in \mathcal{B}(\bar{\Theta})$,

$$\begin{aligned} Q_\rho(x, \theta; A \times B) = & \int_A P_\theta(x, dy) \mathbb{1}\{\theta + \rho H(\theta, y) \in B\} \\ & + \delta_{\theta_c}(B) \int_A P_\theta(x, dy) \mathbb{1}\{\theta + \rho H(\theta, y) \notin \Theta\} \, . \end{aligned}$$

3.2. Homogeneous chain. Let $\{\mathcal{K}_q, q \geq 0\}$ be a sequence of compact subsets of Θ such that

$$\bigcup_{q \geq 0} \mathcal{K}_q = \Theta, \quad \text{and} \quad \mathcal{K}_q \subset \text{int}(\mathcal{K}_{q+1}), \quad q \geq 0, \tag{3.2}$$

where $\text{int}(A)$ denotes the interior of set A. Let $\boldsymbol{\gamma} = \{\gamma_k\}$ and $\boldsymbol{\epsilon} = \{\epsilon_k\}$ be two monotone nonincreasing sequences of positive numbers and let K be a subset of X. Let $\Phi : \mathsf{X} \times \Theta \to \mathsf{K} \times \mathcal{K}_0$ be a measurable function and $\phi : \mathbb{Z}^+ \to \mathbb{Z}$ be a function such that $\phi(k) > -k$ for any k. Our stochastic approximation algorithm with adaptive truncation sets is defined as a *homogeneous* Markov chain on $\mathsf{Z} := \mathsf{X} \times \Theta \times \mathbb{N} \times \mathbb{N} \times \mathbb{N}$,

$$\{Z_n := (X_n, \theta_n, \kappa_n, \varsigma_n, \nu_n)\} \in \mathsf{Z}^{\mathbb{N}}, \tag{3.3}$$

with the following transition at iteration $n + 1$:

- If $\nu_n = 0$, then draw $(X_{n+1}, \theta_{n+1}) \sim Q_{\gamma_{\varsigma_n}}(\Phi(X_n, \theta_n); \cdot)$; otherwise draw $(X_{n+1}, \theta_{n+1}) \sim Q_{\gamma_{\varsigma_n}}(X_n, \theta_n; \cdot)$.
- If $|\theta_{n+1} - \theta_n| \leq \epsilon_{\varsigma_n}$ and $\theta_{n+1} \in \mathcal{K}_{\kappa_n}$, then set $\kappa_{n+1} = \kappa_n$, $\varsigma_{n+1} = \varsigma_n + 1$, and $\nu_{n+1} = \nu_n + 1$; otherwise, set $\nu_{n+1} = 0$, $\kappa_{n+1} = \kappa_n + 1$, $\varsigma_{n+1} = \varsigma_n + \phi(\nu_n)$.

In other words, κ, ς, and ν are counters: κ is the index of the current active truncation set; ν counts the number of iterations since the last reinitialization; ς is the current

index in the sequences $\{\gamma_n\}$ and $\{\epsilon_n\}$, and therefore defines the current proposal kernel Q_γ. The event $\{\nu_n = 0\}$ means that a reinitialization occurs and the condition on ϕ ensures that the algorithm is reinitialized with a value for γ_{ς_n} smaller than that used the last time such an event occurred. This algorithm is reminiscent of the algorithm with adaptive truncation sets proposed in [11], [10]. When the current iterate wanders outside the active truncation set or when the difference between two successive values of the parameter is larger than a time-dependent threshold, then the algorithm is reinitialized with a smaller initial value of the stepsize and a larger truncation set. Various choices for the function ϕ can be considered. For example, the choice $\phi(k) = 1$ for all $k \in \mathbb{N}$ coincides with the procedure proposed in [10]: in this case $\varsigma_n = n$. Another sensible choice consists of setting $\phi(k) = 1 - k$ for all $k \in \mathbb{N}$, in which case the number of iterations between two successive reinitializations is not taken into account.

The intuitive motivation for this modification of the original stochastic approximation recursion lies in Theorem 2.2. Indeed, in order to ensure the stability of the algorithm it is required that the stepsizes not be too large and that the average effect of the noise be small in order for the drift $h(\theta)$ to dominate, and confine the recursion to a compact set. The reprojections act as a drastic drift toward the center of Θ when $\{\theta_n\}$ grows too rapidly and allow one to reinitialize the algorithm with a smaller stepsize and weaker noise inside a "ring" of the type $\{\theta \in \Theta : w(\theta) \in (M_0, M_1]\}$ (M_0 and M_1 are defined in (A1)) where the drift is strictly positive. The fact that M_0 and M_1 are unknown a priori is the reason for the adaptive truncations, which ensure that one eventually selects $\mathcal{K}_q$ large enough in order to have $\mathcal{L} \cap \mathcal{K}_q \neq \varnothing$. As we shall see, the limitation imposed on the increments of the sequence $\{\theta_n\}$ is required in order to ensure some type of homogeneity of the chain $\{\xi_n\}$, and therefore ergodicity properties of the noise sequence $\{\xi_n\}$.

In light of this heuristic, one can naturally propose many variations on this theme. We suggest here two possible extensions. First, one can suggest other strategies in order to adapt the magnitude of the stepsizes. Let $\{\gamma_{n,l}, n \geq 0, l \geq 0\}$ be an array of stepsizes. Then, when a reprojection occurs, instead of jumping forward in a unique sequence of stepsizes, it is possible to simply change the sequence of stepsizes from, say, l to $l + 1$. Another interesting variant of the proposed scheme consists of reinitializing the algorithm when $|\theta_n - \theta_{n-1}| > \epsilon_{\varsigma_{n-1}}$ without changing the truncation set. In either case the proof of convergence follows using the same types of arguments as those presented in this paper.

We now introduce some further notation and briefly state our main result. For μ a probability on Z, we denote $\bar{\mathbb{P}}_\mu$ (resp., $\bar{\mathbb{E}}_\mu$) the probability (resp., the expectation) on the canonical space $(\mathsf{Z}^{\mathbb{N}}, \mathcal{B}(\mathsf{Z})^{\otimes\mathbb{N}})$ associated to the Markov chain $\{Z_n\}$ with initial distribution μ. For $z \in \mathsf{Z}$ we set $\bar{\mathbb{P}}_z := \bar{\mathbb{P}}_{\delta_z}$, $\bar{\mathbb{E}}_z := \bar{\mathbb{E}}_{\delta_z}$ and for $(x, \theta) \in \mathsf{X} \times \Theta$,

$$\bar{\mathbb{P}}_{x,\theta} := \bar{\mathbb{P}}_{x,\theta,0,0,0} \quad \text{and} \quad \bar{\mathbb{E}}_{x,\theta} := \bar{\mathbb{E}}_{x,\theta,0,0,0}. \tag{3.4}$$

This probability measure depends upon the deterministic sequences $\boldsymbol{\gamma} = \{\gamma_n\}$ and $\boldsymbol{\epsilon} = \{\epsilon_n\}$; this will be implicit hereafter in order to alleviate notation. We define recursively $\{T_n, n \geq 0\}$ the sequence of successive reinitialization times

$$T_{n+1} = \inf\{k \geq T_n + 1,\ \nu_k = 0\}, \quad \text{with} \quad T_0 = 0, \tag{3.5}$$

where, by convention, $\inf\{\emptyset\} = \infty$. The following results hold under (A1), some regularity conditions on the family of transition probabilities $\{P_\theta, \theta \in \Theta\}$, and conditions

on the sequences $\boldsymbol{\gamma}$ and $\boldsymbol{\epsilon}$:

$$\inf_{(x,\theta)\in \mathsf{K}\times\mathcal{K}_0} \bar{\mathbb{P}}_{x,\theta}\left(\sup_{n\geq 0}\kappa_n<\infty\right) = \inf_{(x,\theta)\in \mathsf{K}\times\mathcal{K}_0} \bar{\mathbb{P}}_{x,\theta}\left(\bigcup_{n=0}^{\infty}\{T_n=\infty\}\right)=1;$$

i.e., the number of reinitializations of the procedure described above is finite $\bar{\mathbb{P}}_{x,\theta}$-a.s. for every $(x,\theta)\in \mathsf{K}\times\mathcal{K}_0$. Convergence will then follow using Theorem 2.3, for example.

4. Bound on $\bar{\mathbb{P}}_{x,\theta}(T_n<\infty)$. In this section we establish in Proposition 4.2 a bound on $\bar{\mathbb{P}}_{x,\theta}(T_n<\infty)$ in terms of the fluctuations of the noise sequence of the algorithm between successive reinitializations. Let $\mathcal{K}$ be a compact subset of Θ and let $\boldsymbol{\epsilon}=\{\epsilon_n\}$ be a nonincreasing sequence of positive numbers. We introduce

$$\sigma(\mathcal{K},\epsilon)=\sigma(\mathcal{K})\wedge\nu(\boldsymbol{\epsilon}),\quad \sigma(\mathcal{K})=\inf\{k\geq 1,\theta_k\notin\mathcal{K}\},\quad \nu(\boldsymbol{\epsilon})=\inf\{k\geq 1,|\theta_k-\theta_{k-1}|\geq\epsilon_k\},$$

and for a sequence $\mathbf{a}=\{a_k\}$ and an integer l, we define $\mathbf{a}^{\leftarrow l}=\{a_k^{\leftarrow l}\}$ as $a_k^{\leftarrow l}=a_{k+l}$. We now prove the following lemma, which relates the expectation of the homogeneous Markov chain $\{Z_n\}$, defined in subsection 3.2, to the expectation of a nonhomogeneous Markov chain $\{Y_n^{\boldsymbol{\rho}}\}$, defined in subsection 3.1, for a particular $\boldsymbol{\rho}$.

LEMMA 4.1. *For any $m\geq 1$, for any nonnegative measurable function $\Psi_m:(\mathsf{X}\times\Theta)^m\to\mathbb{R}^+$, for any integers p and q, for any $x,\theta\in\mathsf{X}\times\Theta$,*

$$\begin{aligned}\bar{\mathbb{E}}_{x,\theta,p,q,0}\left[\Psi_m(X_1,\theta_1,\ldots,X_m,\theta_m)\mathbb{1}_{\{T_1\geq m\}}\right]\\ =\mathbb{E}^{\gamma^{\leftarrow q}}_{\Phi(x,\theta)}\left[\Psi_m(X_1,\theta_1,\ldots,X_m,\theta_m)\mathbb{1}_{\{\sigma(\mathcal{K}_p,\epsilon^{\leftarrow q})\geq m\}}\right].\end{aligned}\tag{4.1}$$

Proof. We proceed by induction. Let $\Psi_1:\mathsf{X}\times\Theta\to\mathbb{R}^+$. We notice that $\mathbb{1}_{\{T_1\geq 1\}}=1$. This, combined with the definition of $\bar{\mathbb{E}}_{x,\theta,p,q,0}$, leads to

$$\bar{\mathbb{E}}_{x,\theta,p,q,0}[\Psi_1(X_1,\theta_1)\mathbb{1}_{\{T_1\geq 1\}}]=Q_{\gamma_q}(\Phi(x,\theta);\Psi_1),\tag{4.2}$$

and by definition,

$$\mathbb{E}^{\gamma^{\leftarrow q}}_{\Phi(x,\theta)}[\Psi_1(X_1,\theta_1)\mathbb{1}_{\{\sigma(\mathcal{K}_p,\epsilon^{\leftarrow q})\geq 1\}}]=Q_{\gamma_q}(\Phi(x,\theta);\Psi_1).\tag{4.3}$$

Now assume that the property is true for some $m\geq 1$. It is sufficient to prove the induction for functions Ψ_{m+1} of the form

$$\Psi_{m+1}(x_1,\theta_1,\ldots,x_{m+1},\theta_{m+1})=\psi_{m+1}(x_{m+1},\theta_{m+1})\Psi_m(x_1,\theta_1,\ldots,x_m,\theta_m),\tag{4.4}$$

with $\psi_{m+1}:\mathsf{X}\times\Theta\to\mathbb{R}^+$. In order to alleviate notation we will often write Ψ_m (resp., ψ_m) for $\Psi_m(x_1,\theta_1,\ldots,x_m,\theta_m)$ (resp., $\psi_m(x_m,\theta_m)$) in what follows. Consider

$$\begin{aligned}\bar{\mathbb{E}}_{x,\theta,p,q,0}[\Psi_{m+1}(X_1,\theta_1,\ldots,X_{m+1},\theta_{m+1})\mathbb{1}_{\{T_1\geq m+1\}}]\\ =\bar{\mathbb{E}}_{x,\theta,p,q,0}[\psi_{m+1}\Psi_m\mathbb{1}_{\{T_1\geq m\}}\mathbb{1}_{\{\theta_m\in\mathcal{K}_{\kappa_m}\}}\mathbb{1}_{\{|\theta_m-\theta_{m-1}|<\epsilon_{\varsigma_m}\}}].\end{aligned}\tag{4.5}$$

Now, by definition of the stopping time T_1, we have

$$\begin{aligned}\mathbb{1}_{\{\theta_m\in\mathcal{K}_{\kappa_m}\}}\mathbb{1}_{\{|\theta_m-\theta_{m-1}|<\epsilon_{\varsigma_m}\}}\mathbb{1}_{\{T_1\geq m\}}&=\mathbb{1}_{\{\theta_m\in\mathcal{K}_{\kappa_0}\}}\mathbb{1}_{\{|\theta_m-\theta_{m-1}|<\epsilon_{\varsigma_0+m}\}}\mathbb{1}_{\{T_1\geq m\}}\\ &=\mathbb{1}_{\{\theta_m\in\mathcal{K}_{\kappa_0}\}}\mathbb{1}_{\{|\theta_m-\theta_{m-1}|<\epsilon_{\varsigma_0+m}\}}\mathbb{1}_{\{\sigma(\mathcal{K}_{\kappa_0},\epsilon^{\leftarrow\varsigma_0})\geq m\}},\end{aligned}$$

from which we may deduce, using the induction assumption, that

$$
\begin{aligned}
&\bar{\mathbb{E}}_{x,\theta,p,q,0}[\Psi_{m+1}\mathbb{1}_{\{T_1\geq m+1\}}] \\
&\quad= \bar{\mathbb{E}}_{x,\theta,p,q,0}\left[\bar{\mathbb{E}}_{x,\theta,p,q,0}[\psi_{m+1}|X_m,\theta_m,\kappa_m,\varsigma_m,\nu_m]\right. \\
&\qquad\qquad \left.\cdot\mathbb{1}_{\{\theta_m\in\mathcal{K}_{\kappa_m}\}}\mathbb{1}_{\{|\theta_m-\theta_{m-1}|<\epsilon_{\varsigma_m}\}}\Psi_m\mathbb{1}_{\{T_1\geq m\}}\right] \\
&\quad= \bar{\mathbb{E}}_{x,\theta,p,q,0}\left[Q_{\gamma_{q+m+1}}(X_m,\theta_m;\psi_{m+1})\mathbb{1}_{\{\theta_m\in\mathcal{K}_p\}}\mathbb{1}_{\{|\theta_m-\theta_{m-1}|<\epsilon_{q+m}\}}\Psi_m\mathbb{1}_{\{T_1\geq m\}}\right] \\
&\quad= \mathbb{E}^{\gamma^{\leftarrow q}}_{\Phi(x,\theta)}\left[Q_{\gamma_{q+m+1}}(X_m,\theta_m;\psi_{m+1})\mathbb{1}_{\{\theta_m\in\mathcal{K}_p\}}\mathbb{1}_{\{|\theta_m-\theta_{m-1}|<\epsilon_{q+m}\}}\Psi_m\mathbb{1}_{\{\sigma(\mathcal{K}_p,\epsilon^{\leftarrow q})\geq m\}}\right] \\
&\quad= \mathbb{E}^{\gamma^{\leftarrow q}}_{\Phi(x,\theta)}\left[Q_{\gamma_{q+m+1}}(X_m,\theta_m;\psi_{m+1})\Psi_m\mathbb{1}_{\{\sigma(\mathcal{K}_p,\epsilon^{\leftarrow q})\geq m+1\}}\right] \\
&\quad= \mathbb{E}^{\gamma^{\leftarrow q}}_{\Phi(x,\theta)}\left[\Psi_{m+1}\mathbb{1}_{\{\sigma(\mathcal{K}_p,\epsilon^{\leftarrow q})\geq m+1\}}\right],
\end{aligned}
$$

which concludes the proof. □

Define, for any compact set $\mathcal{K}\subset\Theta$, $\boldsymbol{\epsilon}=\{\epsilon_k\}$, $\boldsymbol{\rho}=\{\rho_k\}$, and $1\leq l\leq n$, the partial sum

$$
S_{l,n}(\boldsymbol{\epsilon},\boldsymbol{\rho},\mathcal{K}) := \mathbb{1}_{\{\sigma(\mathcal{K},\boldsymbol{\epsilon})\geq n\}}\sum_{k=l}^{n}\rho_k(H(\theta_{k-1},X_k)-h(\theta_{k-1})), \tag{4.6}
$$

and for any $\delta\geq 0$ and any $M\in(M_0,M_1]$,

$$
A(\delta,\boldsymbol{\epsilon},M,\boldsymbol{\rho}) := \sup_{\theta\in\mathcal{K}_0}\sup_{x\in\mathsf{K}}\left\{\mathbb{P}^{\boldsymbol{\rho}}_{\Phi(x,\theta)}\left[\sup_{k\geq 1}|S_{1,k}(\boldsymbol{\epsilon},\boldsymbol{\rho},\mathcal{W}_M)|>\delta\right]+\mathbb{P}^{\boldsymbol{\rho}}_{\Phi(x,\theta)}[\nu(\boldsymbol{\epsilon})<\sigma(\mathcal{W}_M)]\right\}, \tag{4.7}
$$

where $\mathcal{K}_0$ is defined in (3.2) and $\mathcal{W}_M$, M_0, and M_1 are defined in (A1).

PROPOSITION 4.2. *Assume* (A1) *and that* $\mathcal{K}_0\subset\mathcal{W}_{M_0}$ (*where* M_0 *is defined in* (A1)). *Then for any* $M\in(M_0,M_1]$ *there exist an integer* n_0 *and a constant* $\delta_0>0$ *such that, for any* $n>n_0$, *we have*

$$
\sup_{(x,\theta)\in\mathsf{K}\times\mathcal{K}_0}\bar{\mathbb{P}}_{x,\theta}[T_n<\infty]\leq\prod_{l=n_0}^{n-1}\sup_{q\geq l}A(\delta_0,\boldsymbol{\epsilon}^{\leftarrow q},M,\boldsymbol{\gamma}^{\leftarrow q}),
$$

where T_n *is defined in* (3.5).

Proof. By Theorem 2.2, for any $M\in(M_0,M_1]$ there exist constants $\delta_0>0$ and $\lambda_0>0$ such that, for all $\theta_0\in\mathcal{W}_{M_0}$ (where M_0 is defined in (A1)), all integer $m\geq 1$, all sequences $\{\rho_k\}$ of nonnegative real numbers, and all sequences $\{\xi_k\}$ of n_θ-dimensional vectors satisfying $\sup_{1\leq k\leq m}\rho_k\leq\lambda_0$ and $\sup_{1\leq k\leq m}\left|\sum_{j=1}^{k}\rho_j\xi_j\right|\leq\delta_0$, we have $\sup_{1\leq k\leq m}w(\theta_k)\leq M$, where $\theta_k=\theta_{k-1}+\rho_k h(\theta_k)+\rho_k\xi_k$.

Now, choose n_0 such that $\mathcal{W}_M\subset\mathcal{K}_{n_0}$ and $\gamma_{n_0}\leq\lambda_0$, where λ_0 is given in Theorem 2.2. The existence of such a n_0 follows from (i) for all $M\in(M_0,M_1]$, the level set $\mathcal{W}_M$ is compact and $\bigcup_{p=0}^{\infty}\mathcal{K}_p$ is an increasing covering of Θ, and (ii) $\gamma_p\downarrow 0$ as $p\to\infty$. We notice that for any $l\geq 0$,

$$
T_{l+1}=T_l+T_1\circ\tau^{T_l}, \tag{4.8}
$$

where τ denotes the shift operator on the canonical space associated to the chain $\{Z_n\}$. Consequently, by the strong Markov property,

$$
\bar{\mathbb{P}}_{x,\theta}[T_{l+1}<\infty]=\bar{\mathbb{E}}_{x,\theta}\left[\mathbb{1}_{\{T_l<\infty\}}\bar{\mathbb{P}}_{Z_{T_l}}(T_1<\infty)\right]. \tag{4.9}
$$

Using Lemma 4.1, we have

$$\bar{\mathbb{P}}_{Z_{T_l}}\{T_1 < \infty\}\mathbb{1}_{\{T_l<\infty\}} = C(X_{T_l}, \theta_{T_l}, l, \varsigma_{T_l})\mathbb{1}_{\{T_l<\infty\}},$$

where, for any $x, \theta \in \mathsf{X} \times \Theta$ and any integers p and q,

$$C(x, \theta, p, q) = \mathbb{P}^{\boldsymbol{\gamma}^{\leftarrow q}}_{\Phi(x,\theta)}\left(\sigma(\mathcal{K}_p, \boldsymbol{\epsilon}^{\leftarrow q}) < \infty\right).$$

Now, for $p \geq n_0$, we have $\mathcal{W}_M \subset \mathcal{K}_{n_0} \subset \mathcal{K}_p$, showing that for any $x, \theta \in \mathsf{X} \times \Theta$ and integers $p, q \geq n_0$,

$$\begin{aligned} C(x, \theta, p, q) &\leq \mathbb{P}^{\boldsymbol{\gamma}^{\leftarrow q}}_{\Phi(x,\theta)}\left[\sigma(\mathcal{W}_M) \wedge \nu(\boldsymbol{\epsilon}^{\leftarrow q}) < \infty\right] \\ &\leq \mathbb{P}^{\boldsymbol{\gamma}^{\leftarrow q}}_{\Phi(x,\theta)}\left[\sigma(\mathcal{W}_M) < \infty, \sigma(\mathcal{W}_M) \leq \nu(\boldsymbol{\epsilon}^{\leftarrow q})\right] + \mathbb{P}^{\boldsymbol{\gamma}^{\leftarrow q}}_{\Phi(x,\theta)}\left[\nu(\boldsymbol{\epsilon}^{\leftarrow q}) < \sigma(\mathcal{W}_M)\right]. \end{aligned}$$

By Theorem 2.2, for any integer $m \geq 0$ and any integer $q \geq n_0$, we have

$$\{\sigma(\mathcal{W}_M) = m, m \leq \nu(\boldsymbol{\epsilon}^{\leftarrow q})\} \subset \left\{\sup_{k\in\{1,\ldots,m\}} |S_{1,k}(\boldsymbol{\epsilon}^{\leftarrow q}, \boldsymbol{\gamma}^{\leftarrow q}, \mathcal{W}_M)| > \delta_0\right\},$$

which implies that for any $x, \theta \in \mathsf{X} \times \Theta$, any $l \geq n_0$, and any $q \geq n_0$

$$\begin{aligned} C(x, \theta, l, q) \leq \mathbb{P}^{\boldsymbol{\gamma}^{\leftarrow q}}_{\Phi(x,\theta)}\left(\sup_{k\geq 1} |S_{1,k}(\boldsymbol{\epsilon}^{\leftarrow q}, \boldsymbol{\gamma}^{\leftarrow q}, \mathcal{W}_M)| > \delta_0\right) + \mathbb{P}^{\boldsymbol{\gamma}^{\leftarrow q}}_{\Phi(x,\theta)}(\nu(\boldsymbol{\epsilon}^{\leftarrow q}) \\ < \sigma(\mathcal{W}_M)) \leq A(\delta_0, \boldsymbol{\epsilon}^{\leftarrow q}, M, \boldsymbol{\gamma}^{\leftarrow q}). \end{aligned}$$

Combining the results above, we have, noting that $\varsigma_{T_l} \geq l$,

$$\begin{aligned} \bar{\mathbb{P}}_{Z_{T_l}}\left[T_1 < \infty\right]\mathbb{1}_{\{T_l<\infty\}} &\leq A(\delta_0, \boldsymbol{\epsilon}^{\leftarrow \varsigma_{T_l}}, M, \boldsymbol{\gamma}^{\leftarrow \varsigma_{T_l}})\mathbb{1}_{\{T_l<\infty\}} \\ &\leq \sup_{q\geq l} A(\delta_0, \boldsymbol{\epsilon}^{\leftarrow q}, M, \boldsymbol{\gamma}^{\leftarrow q})\mathbb{1}_{\{T_l<\infty\}}; \end{aligned}$$

the proof now follows from a straightforward backward induction using (4.9) for $l = n_0, \ldots, n-1$ and $n > n_0$. □

COROLLARY 4.3. *Assume* (A1) *and that* $\mathcal{K}_0 \subset \mathcal{W}_{M_0}$ (*where* M_0 *is defined in* (A1)). *Then for any* $M \in (M_0, M_1]$ *and* $n \geq n_0$, *there exists a constant* $C < \infty$ *such that for any* $m \geq n$,

$$\bar{\mathbb{P}}_{x,\theta}\left[\sup_{k\geq 1} \kappa_k \geq m\right] \leq C\left(\sup_{q\geq n} A(\delta_0, \boldsymbol{\epsilon}^{\leftarrow q}, M, \boldsymbol{\gamma}^{\leftarrow q})\right)^m,$$

where $\{\kappa_k\}$ *is the counter corresponding to the number of reinitializations defined in* (3.3).

Proof. We have

$$\left\{\sup_{k\geq 1} \kappa_k \geq m\right\} \subset \{T_m < \infty\},$$

and consequently,

(4.10)
$$\begin{aligned}\bar{\mathbb{P}}_{x,\theta}\left(\sup_{k\geq 1}\kappa_k \geq m\right) &\leq \bar{\mathbb{P}}_{x,\theta}\left(T_m < \infty\right) \leq \prod_{l=n_0}^{m-1} \sup_{q\geq l} A(\delta_0, \boldsymbol{\epsilon}^{\leftarrow q}, M, \boldsymbol{\gamma}^{\leftarrow q}) \\ &\leq \prod_{l=n_0}^{n-1} \sup_{q\geq n_0} A(\delta_0, \boldsymbol{\epsilon}^{\leftarrow q}, M, \boldsymbol{\gamma}^{\leftarrow q}) \prod_{l=n}^{m-1} \sup_{q\geq n} A(\delta_0, \boldsymbol{\epsilon}^{\leftarrow q}, M, \boldsymbol{\gamma}^{\leftarrow q}) \\ &\leq C\left(\sup_{q\geq n} A(\delta_0, \boldsymbol{\epsilon}^{\leftarrow q}, M, \boldsymbol{\gamma}^{\leftarrow q})\right)^m. \qquad \square\end{aligned}$$

In the next section we derive conditions on the family of Markov kernels $\{P_\theta, \theta \in \Theta\}$ and on the sequences $\boldsymbol{\epsilon} = \{\epsilon_k\}$ and $\boldsymbol{\gamma} = \{\gamma_k\}$, which ensure that $\sup_{q\geq n} A(\delta_0, \boldsymbol{\epsilon}^{\leftarrow q}, M, \boldsymbol{\gamma}^{\leftarrow q}) < 1$ for n large enough. It should be emphasized here that this involves studying only the fluctuations of the canonical "interprojections" processes, i.e., $\{Y_n^{\boldsymbol{\rho}}\}$ for $\boldsymbol{\rho} = \boldsymbol{\gamma}^{\leftarrow \varsigma_{T_0}}, \boldsymbol{\gamma}^{\leftarrow \varsigma_{T_1}}, \boldsymbol{\gamma}^{\leftarrow \varsigma_{T_2}}, \ldots$.

5. Control of the fluctuations. Our aim now is to find a bound for $A(\delta, \boldsymbol{\epsilon}, M, \boldsymbol{\rho})$ defined in (4.7), which requires the following conditions to hold. Define, for $V : \mathsf{X} \to [1, \infty)$ and $g : \mathsf{X} \to \mathbb{R}^{n_\theta}$, the norm

$$\|g\|_V = \sup_{x\in\mathsf{X}} \frac{|g(x)|}{V(x)}. \tag{5.1}$$

Consider the following assumptions:

(A3) For any $\theta \in \Theta$, the Poisson equation $g - P_\theta g = H_\theta - \pi_\theta(H_\theta)$ has a solution g_θ. There exist a function $W : \mathsf{X} \to [1, \infty]$ such that $\{x \in \mathsf{X}, W(x) < \infty\} \neq \emptyset$, constants $\alpha \in (0, 1]$, $p \geq 2$ such that for any compact subset $\mathcal{K} \subset \Theta$,

(i) the following holds:

$$\sup_{\theta\in\mathcal{K}} \|H_\theta\|_W < \infty, \tag{5.2}$$

$$\sup_{\theta\in\mathcal{K}} \left(\|g_\theta\|_W + \|P_\theta g_\theta\|_W\right) < \infty, \tag{5.3}$$

$$\sup_{(\theta,\theta')\in\mathcal{K}} |\theta - \theta'|^{-\alpha} \left\{\|g_\theta - g_{\theta'}\|_W + \|P_\theta g_\theta - P_{\theta'} g_{\theta'}\|_W\right\} < \infty. \tag{5.4}$$

(ii) there exist constants $\{C_k, k \geq 0\}$ such that, for any $k \in \mathbb{N}$, for any sequence $\boldsymbol{\rho} = \{\rho_k\}$, and for any $x \in \mathsf{X}$,

$$\sup_{\theta\in\mathcal{K}} \mathbb{E}_{x,\theta}^{\boldsymbol{\rho}}[W^p(X_k)\mathbb{1}_{\{\sigma(\mathcal{K})\geq k\}}] \leq C_k W^p(x). \tag{5.5}$$

(iii) there exist $\epsilon > 0$ and a constant C such that for any sequence $\boldsymbol{\rho} = \{\rho_k\}$ and for any $x \in \mathsf{X}$,

$$\sup_{\theta\in\mathcal{K}} \mathbb{E}_{x,\theta}^{\boldsymbol{\rho}}[W^p(X_k)\mathbb{1}_{\{\sigma(\mathcal{K})\wedge\nu_\epsilon\geq k\}}] \leq C W^p(x), \tag{5.6}$$

where

$$\nu_\epsilon = \inf\{k \geq 1, |\theta_k - \theta_{k-1}| > \epsilon\}. \tag{5.7}$$

Assumption (A3) states the existence and the regularity of the solutions of Poisson's equation for the family of transition kernels $\{P_\theta, \theta \in \Theta\}$. The conditions stated above are nonprimitive; a set of more tractable conditions implying (A3) is given in

section 6. Poisson's equation has proven to be fundamental in the analysis of additive functionals of Markov chains, in particular for establishing limit theorems such as the (functional) central limit theorem (see, e.g., [5], [26], [25, Chapter 17], [18], [16]); the existence of solutions to Poisson's equation is well established for geometrically ergodic Markov chains (see [26], [25, Chapter 17]); it has been more recently proven under assumptions weaker than geometric ergodicity (see [18, Theorem 2.3]); the regularity of the solution of Poisson's equation has been studied, under various ergodicity and regularity conditions on the mapping $\theta \mapsto P_\theta$, in [5], [4]. We stress here that the function W is global but that the bounds in (5.2), (5.3), (5.4), (5.5), and (5.6) depend on the particular compact $\mathcal{K}$ under consideration. We have the following.

LEMMA 5.1. *Assume* (A3). *Let $\mathcal{K}$ be a compact subset of Θ and $s \in \mathbb{N}$. There exists a constant C such that for any sequence $\boldsymbol{\epsilon} = \{\epsilon_k\}$ satisfying $0 < \epsilon_k \leq \epsilon$ for all $k \geq s$ (where ϵ is defined in* (A3)(iii)*), for any sequence $\boldsymbol{\rho} = \{\rho_k\}$ and for any $x \in \mathsf{X}$,*

$$\sup_{\theta \in \mathcal{K}} \sup_{k \geq 0} \mathbb{E}^{\boldsymbol{\rho}}_{x,\theta} \left[W^p(X_k) \mathbb{1}_{\{\sigma(\mathcal{K},\boldsymbol{\epsilon}) \geq k\}} \right] \leq C W^p(x).$$

Proof. Under (A3), there exists a constant C such that, for any sequence $\boldsymbol{\rho} = \{\rho_k\}$ and any $x \in \mathsf{X}$, we have

$$\sup_{\theta \in \mathcal{K}} \mathbb{E}^{\boldsymbol{\rho}}_{x,\theta}[W^p(X_k) \mathbb{1}_{\{\sigma(\mathcal{K}) \wedge \nu_\epsilon \geq k\}}] \leq C W^p(x),$$

where ν_ϵ is defined in (5.7). For any sequence $\boldsymbol{\epsilon} = \{\epsilon_k\}$ such that $\epsilon_k \leq \epsilon$ for any $k \geq s$,

$$\begin{aligned}
&\mathbb{E}^{\boldsymbol{\rho}}_{x,\theta}[W^p(X_{k+s}) \mathbb{1}_{\{\sigma(\mathcal{K}) \wedge \nu(\boldsymbol{\epsilon}) \geq k+s\}}] \\
&\quad = \mathbb{E}^{\boldsymbol{\rho}}_{x,\theta} \left[\mathbb{E}^{\boldsymbol{\rho}^{\leftarrow s}}_{X_s,\theta_s}[W^p(X_k) \mathbb{1}_{\{\sigma(\mathcal{K}) \wedge \nu(\boldsymbol{\epsilon}^{\leftarrow s}) \geq k\}} \mathbb{1}_{\{\sigma(\mathcal{K}) \wedge \nu(\boldsymbol{\epsilon}) \geq s\}}] \right] \\
&\quad \leq \mathbb{E}^{\boldsymbol{\rho}}_{x,\theta} \left[\sup_{\theta \in \mathcal{K}} \mathbb{E}^{\boldsymbol{\rho}^{\leftarrow s}}_{X_s,\theta}[W^p(X_k) \mathbb{1}_{\{\sigma(\mathcal{K}) \wedge \nu_\epsilon \geq k\}} \mathbb{1}_{\{\sigma(\mathcal{K}) \geq s\}}] \right] \\
&\quad \leq C \mathbb{E}^{\boldsymbol{\rho}}_{x,\theta}[W^p(X_s) \mathbb{1}_{\{\sigma(\mathcal{K}) \geq s\}}],
\end{aligned}$$

and the proof is concluded by (A3). □

PROPOSITION 5.2. *Assume* (A3). *Let $\mathcal{K}$ be a compact subset of Θ and let $\boldsymbol{\rho} = \{\rho_k\}$ and $\boldsymbol{\epsilon} = \{\epsilon_k\}$ be two nonincreasing sequences of positive numbers such that $\lim_{k \to \infty} \epsilon_k = 0$. Then, for p as defined in* (A3),

1. *there exists a constant C such that, for any $(x, \theta) \in \mathsf{X} \times \mathcal{K}$, any integer l, and any $\delta > 0$*

(5.8)
$$\mathbb{P}^{\boldsymbol{\rho}}_{x,\theta} \left(\sup_{n \geq l} |S_{l,n}(\boldsymbol{\epsilon}, \boldsymbol{\rho}, \mathcal{K})| \geq \delta \right) \leq C \delta^{-p} \left\{ \left(\sum_{k=l}^{\infty} \rho_k^2 \right)^{p/2} + \left(\sum_{k=l}^{\infty} \rho_k \epsilon_k^\alpha \right)^p \right\} W^p(x).$$

2. *there exists a constant C such that, for any $(x, \theta) \in \mathsf{X} \times \mathcal{K}$,*

$$\mathbb{P}^{\boldsymbol{\rho}}_{x,\theta} \left(\nu(\boldsymbol{\epsilon}) < \sigma(\mathcal{K}) \right) \leq C \left\{ \sum_{k=1}^{\infty} (\epsilon_k^{-1} \rho_k)^p \right\} W^p(x). \tag{5.9}$$

The proof is in Appendix A. We finally need a condition on the stepsize sequences, which will ensure that $A(\delta, \boldsymbol{\epsilon}^{\leftarrow q}, M, \boldsymbol{\rho}^{\leftarrow q}) \to 0$ when $q \to \infty$.

(A4) The sequences $\boldsymbol{\gamma} = \{\gamma_k\}$ and $\boldsymbol{\epsilon} = \{\epsilon_k\}$ are nonincreasing, positive and satisfy $\sum_{k=0}^{\infty} \gamma_k = \infty$, $\lim_{k\to\infty} \epsilon_k = 0$, and

$$\sum_{k=1}^{\infty} \left\{\gamma_k^2 + \gamma_k \epsilon_k^{\alpha} + (\epsilon_k^{-1}\gamma_k)^p\right\} < \infty,$$

where p and α are defined in (A3).

For instance, we may assume that $\sum_{k\geq 0} \gamma_k = \infty$ and $\sum_{k=0}^{\infty} \gamma_k^{\delta} < \infty$ for some $1 < \delta \leq p(1+\alpha)/(p+\alpha)$. Then, (A4) is verified by setting $\epsilon_k = C\gamma_k^{\eta}$ for some constant C and some η such that

$$\frac{\delta - 1}{\alpha} \leq \eta \leq \frac{p - \delta}{p}.$$

It is now straightforward to establish the following results.

PROPOSITION 5.3. *Assume* (A3) *and* (A4). *Then, for any subset* $\mathsf{K} \subset \mathsf{X}$ *such that* $\sup_{x\in\mathsf{K}} W(x) < \infty$, *any* $M \in (M_0, M_1]$, *and any* $\delta > 0$, *we have* $\lim_{k\to\infty} A(\delta, \boldsymbol{\epsilon}^{\leftarrow k}, M, \boldsymbol{\gamma}^{\leftarrow k}) = 0$, *where* $A(\delta, \boldsymbol{\epsilon}, M, \boldsymbol{\rho})$ *is given by* (4.7).

We may now summarize the discussion above to obtain the following stability result.

THEOREM 5.4. *Assume* (A1)–(A4). *Then, for any subset* $\mathsf{K} \subset \mathsf{X}$ *such that* $\sup_{x\in\mathsf{K}} W(x) < \infty$, $\mathcal{K}_0 \subset \mathcal{W}_{M_0}$ *(where* M_0 *is defined in* (A1)) *and any* $\rho \in (0,1)$, *there exists a constant* $C < \infty$ *such that, for all* $(x,\theta) \in \mathsf{X} \times \Theta$,

$$\bar{\mathbb{P}}_{x,\theta}\left[\sup_{n\geq 1} \kappa_n \geq k\right] \leq C\rho^k.$$

Hence, under the stated conditions, the tail probability of the number of reinitializations decreases faster than any exponential and $\sup_{n\geq 1} \kappa_n$ is finite $\bar{\mathbb{P}}_{x,\theta}$-a.s. Combining this result with Theorem 2.3, it is possible to obtain the following global convergence result.

THEOREM 5.5. *Assume* (A1)–(A4). *Let* $\mathsf{K} \subset \mathsf{X}$ *be such that* $\sup_{x\in\mathsf{K}} W(x) < \infty$ *and that* $\mathcal{K}_0 \subset \mathcal{W}_{M_0}$ *(where* M_0 *is defined in* (A1)), *and let* $\{Z_n\}$ *be as defined by* (3.3). *Then, for all* $(x,\theta) \in \mathsf{X} \times \Theta$, *we have* $\lim_{k\to\infty} d(\theta_k, \mathcal{L}) = 0$, $\bar{\mathbb{P}}_{x,\theta}$*-a.s.*

Proof. Define, for $k \geq 1$,

$$B_k = \limsup_{l\to\infty} \sup_{T_{k-1}+l\leq n} \left| \mathbb{1}_{\{n<T_k\}} \sum_{j=T_{k-1}+l}^{n} \gamma_{\varsigma_j} (H(\theta_{j-1}, X_j) - h(\theta_{j-1})) \right| \mathbb{1}_{\{T_{k-1}<\infty\}},$$

where ς_j and T_k are defined in section 3. We first show that, for any k and any $\delta > 0$, $\bar{\mathbb{P}}_{x,\theta}(|B_k| \geq \delta) = 0$ for all $(x,\theta) \in \mathsf{X} \times \Theta$. We have, by the strong Markov property and (4.6) that for $l \geq 1$

$$\bar{\mathbb{P}}_{x,\theta}\left(\sup_{T_{k-1}+l\leq n} \left| \mathbb{1}_{\{n<T_k\}} \sum_{j=T_{k-1}+l}^{n} \gamma_{\varsigma_j} (H(\theta_{j-1}, X_j) - h(\theta_{j-1})) \right| \mathbb{1}_{\{T_{k-1}<\infty\}} \geq \delta \right)$$
$$\leq \bar{\mathbb{E}}_{x,\theta}\left\{ C_l(X_{T_{k-1}}, \theta_{T_{k-1}}, \delta, \mathcal{K}_{k-1}, \varsigma_{T_{k-1}}) \mathbb{1}_{\{T_{k-1}<\infty\}} \right\},$$

where for any $x, \theta \in \mathsf{X} \times \Theta$, any $\delta > 0$, any set $\mathcal{K} \subset \Theta$, and any integer q,

$$C_l(x,\theta,\delta,\mathcal{K},q) = \mathbb{P}^{\boldsymbol{\gamma}^{\leftarrow q}}_{\Phi(x,\theta)}\left(\sup_{n\geq l} |S_{l,n}(\boldsymbol{\epsilon}^{\leftarrow q}, \boldsymbol{\gamma}^{\leftarrow q}, \mathcal{K})| \geq \delta \right).$$

By Proposition 5.2, for any compact subset $\mathcal{K}$, there exists a constant C such that, for all $q \geq 0$,

$$\sup_{(x,\theta)\in \mathsf{X}\times\Theta} C_l(x,\theta,\delta,\mathcal{K},q) \leq C\delta^{-p}\left\{\left(\sum_{j=l}^{\infty}\gamma_j^2\right)^{p/2} + \left(\sum_{j=l}^{\infty}\gamma_j\epsilon_j^{\alpha}\right)^{p}\right\},$$

which implies that, for all $k \geq 0$, $\bar{\mathbb{P}}_{x,\theta}(|B_k| \geq \delta) = 0$. Corollary 4.3 and Proposition 5.3 show that, for all $(x,\theta) \in \mathsf{K} \times \mathcal{K}_0$, $\kappa = \sup_k \kappa_k < \infty$ $\bar{\mathbb{P}}_{x,\theta}$-a.s. Set, for $k \geq 0$, $\bar{\theta}_k = \theta_{k+T_{\kappa-1}}$, $\bar{\gamma}_k = \gamma_{k+\varsigma_{T_{\kappa-1}}}$ and

$$\xi_k = H(\bar{\theta}_{k-1}, X_{k+T_{\kappa-1}}) - h(\bar{\theta}_{k-1}), \quad k \geq 1.$$

Then, $\bar{\theta}_k = \bar{\theta}_{k-1} + \bar{\gamma}_k h(\bar{\theta}_{k-1}) + \bar{\gamma}_k\xi_k$ and, since $T_\kappa = \infty$, for all $(x,\theta) \in \mathsf{K} \times \mathcal{K}_0$,

$$\limsup_{l\to\infty}\sup_{n\geq l}\left|\sum_{k=l}^{n}\bar{\gamma}_k\xi_k\right| = B_\kappa = 0, \quad \bar{\mathbb{P}}_{x,\theta}\text{-a.s.}$$

The proof follows from Theorem 2.3. □

6. Drift conditions. In this section, we give conditions which imply (A3) in terms of a minorization of the Markov kernel on a small set and a drift condition toward this small set (see [25] for definitions and main results). Denote, for $V : \mathsf{X} \to [1,\infty)$, $\mathcal{L}_V := \{g : \mathsf{X} \to \mathbb{R}^{n_\theta}, \sup_{x\in\mathsf{X}} \|g\|_V < \infty\}$, where $\|\cdot\|_V$ is defined in (5.1).

(DRI) For any $\theta \in \Theta$, P_θ is ψ-irreducible and aperiodic[1]. In addition there exist a function $V : \mathsf{X} \to [1,\infty)$ and constants $p \geq 2$ and $\beta \in [0,1]$ such that for any compact subset $\mathcal{K} \subset \Theta$,

(DRI1) there exist an integer m, constants $0 < \lambda < 1$, b, κ, $\delta > 0$, and a probability measure ν such that

$$\sup_{\theta\in\mathcal{K}} P_\theta^m V^p(x) \leq \lambda V^p(x) + b\mathbb{1}_{\mathsf{C}}(x), \tag{6.1}$$

$$\sup_{\theta\in\mathcal{K}} P_\theta V^p(x) \leq \kappa V^p(x) \qquad \forall x \in \mathsf{X}, \tag{6.2}$$

$$\inf_{\theta\in\mathcal{K}} P_\theta^m(x,A) \geq \delta\nu(A) \qquad \forall x \in \mathsf{C}, \quad \forall A \in \mathcal{B}(\mathsf{X}). \tag{6.3}$$

(DRI2) there exists C such that, for all $x \in \mathsf{X}$,

$$\sup_{\theta\in\mathcal{K}} |H_\theta(x)| \leq CV(x),$$
$$\sup_{(\theta,\theta')\in\mathcal{K}} |\theta-\theta'|^{-\beta}|H_\theta(x) - H_{\theta'}(x)| \leq CV(x).$$

(DRI3) there exists C such that, for all $(\theta,\theta') \in \mathcal{K} \times \mathcal{K}$,

$$\|P_\theta g - P_{\theta'} g\|_V \leq C\,\|g\|_V\,|\theta-\theta'|^\beta \qquad \forall g \in \mathcal{L}_V, \tag{6.4}$$

$$\|P_\theta g - P_{\theta'} g\|_{V^p} \leq C\,\|g\|_{V^p}\,|\theta-\theta'|^\beta, \qquad \forall g \in \mathcal{L}_{V^p}. \tag{6.5}$$

[1]We use the standard terminology and notation introduced in [25, Chapters 4, 5].

Assumption (DRI1) is classical in the Markov chain literature; it implies the existence of a stationary distribution π_θ for all $\theta \in \Theta$ and V^p-uniform ergodicity; i.e., for each $\theta \in \Theta$ there exist constants $C_\theta < \infty$ and $\rho_\theta \in [0,1)$ such that for any function $f \in \mathcal{L}_{V^p}$ and any integer $k > 0$,

$$\|P_\theta^k f - \pi_\theta(f)\|_{V^p} \le C_\theta \rho_\theta^k \|f\|_{V^p}.$$

Note that the constants C_θ and ρ_θ may be bounded over the compact sets of Θ; i.e., for each $\mathcal{K} \subset \Theta$, there exists $\bar{C} < \infty$ and $\bar{\rho} \in [0,1)$ such that $\sup_{\theta\in\mathcal{K}} C_\theta \le \bar{C}$ and $\sup_{\theta\in\mathcal{K}} \rho_\theta \le \bar{\rho}$. The regularity of the kernels $\theta \to P_\theta$ expressed in V and V^p norms is naturally less classical. The main result of this section follows.

PROPOSITION 6.1. *Assume* (DRI). *Then* (A2) *and* (A3) *are satisfied and for any* $0 < \alpha < \beta$,

$$\sup_{(\theta,\theta')\in\mathcal{K}\times\mathcal{K}} |\theta - \theta'|^{-\alpha} \, |h(\theta) - h(\theta')| < \infty. \tag{6.6}$$

The proof is in Appendix B.

7. Controlled MCMC algorithm. Markov chain Monte Carlo (MCMC), introduced in [24], is a popular computational method for generating samples from virtually any distribution π defined on a space $\mathsf{X} \subset \mathbb{R}^{n_x}$ (for some integer n_x). The method consists of simulating an ergodic Markov chain $\{X_n, n \ge 0\}$ on X with transition probability P such that π is a *stationary* distribution for this chain, i.e., $\pi P = \pi$. Let ψ be some π-integrable function $\psi : \mathsf{X} \to \mathbb{R}^{n_\psi}$ for some integer n_ψ. One can use the samples produced by the Markov chain to estimate integrals

$$\pi(\psi) := \int_{\mathsf{X}} \psi(x) \, \pi(dx)$$

with estimators of the type

$$S_n(\psi) = \frac{1}{n} \sum_{k=1}^{n} \psi(X_k). \tag{7.1}$$

In general the transition probability P of the Markov chain depends on some tuning parameter, say θ, defined on some space $\Theta \subset \mathbb{R}^{n_\theta}$ for some integer n_θ, and the convergence properties of the Monte Carlo averages in (7.1) might highly depend on a proper choice of this parameter.

We illustrate this here with the classical Metropolis–Hastings (MH) update, but it should be stressed at this point that the results presented in this paper apply to much more general settings. The MH algorithm requires the choice of a *proposal distribution* q. In order to simplify the discussion, we will assume that π and q admit densities with respect to the Lebesgue measure λ^{Leb}, denoted, with an abuse of notation, by π and q hereafter. The role of the distribution q consists of proposing potential transitions y for the Markov chain $\{X_n\}$. Given that the chain is currently at x, a candidate y is accepted with probability $\alpha(x,y)$ defined as

$$\alpha(x,y) = \begin{cases} 1 \wedge \frac{\pi(y)}{\pi(x)} \frac{q(y,x)}{q(x,y)} & \text{if } \pi(x)q(x,y) > 0 \\ 1 & \text{otherwise,} \end{cases}$$

where $a \wedge b := \min(a,b)$. Otherwise it is rejected and the Markov chain stays at its current location x. The transition kernel P of this Markov chain takes the form for

$x, A \in \mathsf{X} \times \mathcal{B}(\mathsf{X})$ of

$$P(x,A) = \int_A \alpha(x,y) q(x,y) \lambda^{\mathrm{Leb}}(dy) + \mathbb{1}_A(x) \int_{\mathsf{X}} (1 - \alpha(x,y)) q(x,y) \lambda^{\mathrm{Leb}}(dy). \tag{7.2}$$

The Markov chain P is reversible with respect to π and therefore admits π as an invariant distribution. Conditions on the proposal distribution q that guarantee irreducibility and positive recurrence are mild and many satisfactory choices are possible.

7.1. Symmetric random walk MH. We focus here on the symmetric increments random-walk MH algorithm (SRWM), which corresponds to the case where $q(x,y) = q(x-y)$ for some symmetric probability density q. Other examples are considered in [2]. The transition kernel of the SRWM algorithm is then given for $x, A \in \mathsf{X} \times \mathcal{B}(\mathsf{X})$ by

$$\begin{aligned} P_q^{\mathrm{SRW}}(x,A) = {} & \int_{A-x} \left(1 \wedge \frac{\pi(x+z)}{\pi(x)}\right) q(z)\, \lambda^{\mathrm{Leb}}(dz) \\ & + \mathbb{1}_A(x) \int_{\mathsf{X}-x} \left(1 - \left(1 \wedge \frac{\pi(x+z)}{\pi(x)}\right)\right) q(z)\, \lambda^{\mathrm{Leb}}(dz), \quad x \in \mathsf{X}, A \in \mathcal{B}(\mathsf{X}), \end{aligned} \tag{7.3}$$

where $A - x := \{z \in \mathsf{X}, x + z \in A\}$. A classical choice for the proposal distribution is $q = \phi_{0,\Gamma}$, where $\phi_{\mu,\Gamma}$ is the density of a multivariate normal distribution with mean μ and covariance matrix Γ. We will later on refer to this algorithm as the N-SRWM. It is well known that either too small or too large a covariance matrix will result in highly positively correlated Markov chains and therefore estimators $S_n(\psi)$ with large variance. In practice this covariance matrix Γ is determined by trial and error using several realizations of the Markov chain. This hand-tuning requires some expertise and can be time consuming.

In order to circumvent this problem, in the context of the N-SRWM update described above, the authors of [19] have proposed to "learn Γ on the fly." Their algorithm can be summarized as (see [19])

$$\begin{aligned} \mu_{n+1} &= \mu_n + \gamma_{n+1}(X_{n+1} - \mu_n), && n \geq 0, \\ \Gamma_{n+1} &= \Gamma_n + \gamma_{n+1}((X_{n+1} - \mu_n)(X_{n+1} - \mu_n)^{\intercal} - \Gamma_n), \end{aligned} \tag{7.4}$$

where

- X_{n+1} is drawn from $P_{\theta_n}(X_n, \cdot)$, where for $\theta = (\mu, \Gamma)$, $P_\theta := P^{\mathrm{SRW}}_{\phi_{0,\lambda\Gamma}}$ with $\lambda > 0$, a constant scaling factor depending only on the dimension of the state-space n_x and kept constant across the iterations.
- $\boldsymbol{\gamma} = \{\gamma_n\}$ is a nonincreasing sequence of positive stepsizes such that $\sum_{n=1}^{\infty} \gamma_n = \infty$ and $\sum_{n=1}^{\infty} \gamma_n^{1+\delta} < \infty$ for some $\delta > 0$ ([19] suggests the choice $\gamma_n = 1/n$).

It was realized in [3] that such a scheme is a particular case of a more general framework akin to stochastic control, combined with the use of the Robbins–Monro procedure. More precisely, let $\theta = (\mu, \Gamma) \in \Theta$, where $\Theta := \mathbb{R}^{n_x} \times \mathcal{C}_+^{n_x}$ and $\mathcal{C}_+^{n_x}$ is the cone of positive $n_x \times n_x$ matrices; then

$$H(x;\theta) = (x - \mu, (x-\mu)(x-\mu)^{\intercal} - \Gamma)^{\intercal}. \tag{7.5}$$

With this notation, the recursion in (7.4) may be written in the standard Robbins–Monro form as

$$\theta_{n+1} = \theta_n + \gamma_{n+1} H(X_{n+1}, \theta_n), \quad n \geq 0, \tag{7.6}$$

with $X_{n+1} \sim P_{\theta_n}(X_n, \cdot)$. For the present example, assuming that $\int_{\mathsf{X}} |x|^2 \pi(dx) < \infty$, one can easily check that

$$h(\theta) = \int_{\mathsf{X}} H(x,\theta)\pi(dx) = (\mu_\pi - \mu, (\mu_\pi - \mu)(\mu_\pi - \mu)^{\mathrm{T}} + \Gamma_\pi - \Gamma)^{\mathrm{T}}, \tag{7.7}$$

with μ_π and Γ_π the mean and covariance of the target distribution. It is assumed in the sequel that Γ_π is positive definite. We now analyze the corresponding homogeneous Markov chain $\{Z_n, n \geq 0\}$ as defined in section 3, i.e., prove under mild conditions on π that (A1)–(A3) are satisfied.

7.2. Condition (A1). In the algorithm described above the parameter estimates μ_n and Γ_n take the form of maximum likelihood estimates under the i.i.d. multivariate normal model. It therefore comes as no surprise if the appropriate Lyapunov function is

$$w(\mu,\Gamma) = -\int_{\mathsf{X}} \log\left(\frac{\pi(x)}{\phi_{0,\Gamma}(x)}\right)\pi(dx), \tag{7.8}$$

the Kullback–Leibler divergence between the target density π and a normal density $\phi_{0,\Gamma}$.

PROPOSITION 7.1. *Let h be as defined in* (7.7) *where π satisfies (M). Then* (A1) *is satisfied with w as in* (7.8). *Furthermore $\mathcal{L}$ is reduced to a single point, $\theta_\pi := (\mu_\pi, \Gamma_\pi)$.*

Proof. h is naturally continuous (and, as we shall see later, is in fact Lipschitz continuous under (DRI) (or when (DRI) is assumed) since Proposition 6.1 holds under (DRI). Now w is equal, up to multiplicative and additive constants, to

$$\log\det\Gamma + (\mu - \mu_\pi)^{\mathrm{T}}\Gamma^{-1}(\mu - \mu_\pi) + \mathrm{Tr}(\Gamma^{-1}\Gamma_\pi). \tag{7.9}$$

Using straightforward algebra, one can show that there exists a constant $C > 0$ such that

$$\begin{aligned} C\Big\langle \nabla w(\mu,\Gamma), h(\mu,\Gamma)\Big\rangle &= -2(\mu - \mu_\pi)^{\mathrm{T}}\Gamma^{-1}(\mu - \mu_\pi) \\ &\quad - \mathrm{Tr}(\Gamma^{-1}(\Gamma - \Gamma_\pi)\Gamma^{-1}(\Gamma - \Gamma_\pi)) - \big((\mu - \mu_\pi)^{\mathrm{T}}\Gamma^{-1}(\mu - \mu_\pi)\big)^2, \end{aligned} \tag{7.10}$$

that is, $\langle \nabla w(\theta), h(\theta)\rangle \leq 0$ for any $\theta = (\mu,\Gamma) \in \Theta$, with equality if and only if $\Gamma = \Gamma_\pi$ and $\mu = \mu_\pi$. As $w(\Theta) = [w(\mu_\pi,\Gamma_\pi), \infty)$ and w is continuous, any $w(\mu_\pi,\Gamma_\pi) < M_0 < M_1 < \infty$ satisfy (A1)(i) and (A1)(ii), and (A1)(iii) is automatically satisfied. Now as the set of stationary points $\mathcal{L}$ is reduced to a single point, (A1)(iv) is also satisfied. ∎

7.3. Condition (A3). In order to check (A3) in this case, we check (DRI). The geometric ergodicity of the random walk Metropolis–Hastings (RWMH) kernel has been studied by [27] and refined in [21]; the regularity of the RWMH has, to the best of our knowledge, not been considered in the literature. The geometric ergodicity of the RWMH kernel mainly depends on the tail properties of the target distribution π. We will therefore restrict our discussion to target distributions that satisfy the following set of conditions. These are not minimal but are easy to check in practice (see [21] for details).

(M) The probability density π has the following properties:

(i) It is bounded, bounded away from zero on every compact set, and continuously differentiable.

(ii) It is superexponential, i.e.,

$$\lim_{|x|\to+\infty} \left\langle \frac{x}{|x|}, \nabla \log \pi(x) \right\rangle = -\infty.$$

(iii) The contours $\partial \mathsf{A}(x) = \{y : \pi(y) = \pi(x)\}$ are asymptotically regular, i.e.,

$$\lim_{|x|\to+\infty} \sup \left\langle \frac{x}{|x|}, \frac{\nabla \pi(x)}{|\nabla \pi(x)|} \right\rangle < 0.$$

Note that this condition implies the existence and finiteness of μ_π and Γ_π. We now establish uniform minorization and drift conditions for P_q^{SRW} defined in (7.3). Let $\mathcal{M}(\mathsf{X})$ denote the set of probability densities w.r.t. the Lebesgue measure λ^{Leb}. Let $\varepsilon > 0$ and $\delta > 0$ and define the subset $\mathcal{K}_{\delta,\varepsilon} \subset \mathcal{M}(\mathsf{X})$,

$$\mathcal{K}_{\delta,\varepsilon} = \{q \in \mathcal{M}(\mathsf{X}), q(z) = q(-z) \quad \text{and} \quad |z| \le \varepsilon \Rightarrow q(z) \ge \delta\}. \tag{7.11}$$

PROPOSITION 7.2. *Assume* (M). *For any* $\eta \in (0,1)$, *set* $W = \pi^{-\eta}/(\inf_{\mathsf{X}} \pi^{-\eta})$. *Then,*

1. *any nonempty compact set* $\mathsf{C} \subset \mathsf{X}$ *is a* $(1,\delta)$*-small set for some* $\delta > 0$ *and some measure* ν,

$$\forall (x, A) \in \mathsf{C} \times \mathcal{B}(\mathsf{X}) \qquad \inf_{q \in \mathcal{K}_{\delta,\varepsilon}} P_q^{\mathrm{SRW}}(x, A) \ge \delta \nu(A). \tag{7.12}$$

2. *furthermore, for any* $\delta > 0$ *and* $\varepsilon > 0$,

$$\sup_{q \in \mathcal{K}_{\delta,\varepsilon}} \limsup_{|x|\to+\infty} \frac{P_q^{\mathrm{SRW}} W(x)}{W(x)} < 1, \tag{7.13}$$

$$\sup_{(x,q) \in \mathsf{X} \times \mathcal{K}_{\delta,\varepsilon}} \frac{P_q^{\mathrm{SRW}} W(x)}{W(x)} < +\infty. \tag{7.14}$$

3. *let* $q, q' \in \mathcal{M}(\mathsf{X})$ *be two symmetric probability distributions. Then, for any* $r \in [0,1]$ *and any* $g \in \mathcal{L}_{W^r}$ *we have*

$$\left\| P_q^{\mathrm{SRW}} g - P_{q'}^{\mathrm{SRW}} g \right\|_{W^r} \le 2 \|g\|_{W^r} \int_{\mathsf{X}} |q(z) - q'(z)| \lambda^{\mathrm{Leb}}(dz). \tag{7.15}$$

Proof. For any $x \in \mathsf{X}$, define the acceptance region $\mathsf{A}(x) = \{z \in \mathsf{X} - x; \pi(x+z) \ge \pi(x)\}$ and the rejection region $\mathsf{R}(x) = \{z \in \mathsf{X} - x; \pi(x+z) < \pi(x)\}$. From the definition, (7.11) of $\mathcal{K}_{\delta,\varepsilon}$ [27, Theorem 2.2] applies for any $q \in \mathcal{K}_{\delta,\varepsilon}$ and we can conclude that (7.12) is satisfied. Noting that the two sets $\mathsf{A}(x)$ and $\mathsf{R}(x)$ do not depend on the proposal distribution q, and using the conclusion of the proof of Theorem 4.3 of [21], we have

$$\inf_{q \in \mathcal{K}_{\delta,\varepsilon}} \liminf_{|x|\to+\infty} \int_{\mathsf{A}(x)} q(z) \lambda^{\mathrm{Leb}}(dz) > 0,$$

so that from the conclusion of the proof of Theorem 4.1 of [21],

$$\sup_{q \in \mathcal{K}_{\delta,\varepsilon}} \limsup_{|x|\to+\infty} \frac{P_q^{\mathrm{SRW}} W(x)}{W(x)} = 1 - \inf_{q \in \mathcal{K}_{\delta,\varepsilon}} \liminf_{|x|\to+\infty} \int_{\mathsf{A}(x)} q(z) \lambda^{\mathrm{Leb}}(dz) < 1,$$

which proves (7.13). Finally, for any $q \in \mathcal{K}_{\delta,\varepsilon}$,

$$\begin{aligned}\frac{P_q^{\mathrm{SRW}} W(x)}{W(x)} &= \int_{\mathsf{A}(x)} \frac{\pi(x+z)^{-\eta}}{\pi(x)^{-\eta}} q(z) \lambda^{\mathrm{Leb}}(dz) \\ &\quad + \int_{\mathsf{R}(x)} \left(1 - \frac{\pi(x+z)}{\pi(x)} + \frac{\pi(x+z)^{1-\eta}}{\pi(x)^{1-\eta}}\right) q(z) \lambda^{\mathrm{Leb}}(dz) \\ &\leq \sup_{0 \leq u \leq 1} (1 - u + u^{1-\eta}),\end{aligned}$$

which proves (7.14). Now notice that

$$\begin{aligned}P_q^{\mathrm{SRW}} g(x) - P_{q'}^{\mathrm{SRW}} g(x) &= \int_{\mathsf{X}} \alpha(x, x+z)(q(z) - q'(z)) g(x+z) \lambda^{\mathrm{Leb}}(dz) \\ &\quad + g(x) \int_{\mathsf{X}} \alpha(x, x+z)(q'(z) - q(z)) \lambda^{\mathrm{Leb}}(dz).\end{aligned}$$

We therefore focus, for $r \in [0,1]$ and $g \in \mathcal{L}_{W^r}$, on the term

$$\begin{aligned}&\frac{\left|\int_{\mathsf{X}} \alpha(x, x+z)(q(z) - q'(z)) g(x+z) \lambda^{\mathrm{Leb}}(dz)\right|}{\|g\|_{W^r} W^r(x)} \\ &\leq \frac{\int_{\mathsf{X}} \alpha(x, x+z) |q(z) - q'(z)| W^r(x+z) \lambda^{\mathrm{Leb}}(dz)}{W^r(x)} \\ &= \int_{\mathsf{A}(x)} \frac{\pi(x+z)^{-r\eta}}{\pi(x)^{-r\eta}} |q(z) - q'(z)| \lambda^{\mathrm{Leb}}(dz) \\ &\qquad + \int_{\mathsf{R}(x)} \frac{\pi(x+z)^{1-r\eta}}{\pi(x)^{1-r\eta}} |q(z) - q'(z)| \lambda^{\mathrm{Leb}}(dz) \\ &\leq \int_{\mathsf{X}} |q(z) - q'(z)| \lambda^{\mathrm{Leb}}(dz).\end{aligned}$$

We now conclude that for any $x \in \mathsf{X}$ and any $g \in \mathcal{L}_{W^r}$,

$$\frac{|P_q^{\mathrm{SRW}} g(x) - P_{q'}^{\mathrm{SRW}} g(x)|}{W^r(x)} \leq 2 \|g\|_{W^r} \int_{\mathsf{X}} |q(z) - q'(z)| \lambda^{\mathrm{Leb}}(dz). \qquad \square$$

One can specialize the regularity property (7.15) to the N-SRWM, where the proposal distribution q_θ is a zero-mean normal distribution with covariance matrix Γ, and for simplicity we set $q_\Gamma := \phi_{0,\Gamma}$.

LEMMA 7.3. *Let $\mathcal{K}$ be a convex compact subset of $\mathcal{C}_+^{n_x}$ and set $W = \pi^{-\eta}/(\inf_{\mathsf{X}} \pi^{-\eta})$ for some $\eta \in (0,1)$. For any $r \in [0,1]$, any $\Gamma, \Gamma' \in \mathcal{K} \times \mathcal{K}$, $g \in \mathcal{L}_{W^r}$, we have*

$$\left\| P_{q_\Gamma}^{\mathrm{SRW}} g - P_{q_{\Gamma'}}^{\mathrm{SRW}} g \right\|_{W^r} \leq \frac{2 n_x}{\lambda_{\min}(\mathcal{K})} \|g\|_{W^r} |\Gamma - \Gamma'|, \tag{7.16}$$

where $\lambda_{\min}(\mathcal{K})$ is the minimum possible eigenvalue for matrices in $\mathcal{K}$.

Proof. We have

$$\int_{\mathsf{X}} |q_\Gamma(z) - q_{\Gamma'}(z)| dz = \int_{\mathsf{X}} \left| \int_0^1 \frac{d}{dv} q_{\Gamma + v(\Gamma' - \Gamma)}(z) dv \right| dz$$

and let $\Gamma_v = \Gamma + v(\Gamma' - \Gamma)$, so that

$$\frac{d}{dv} \log q_{\Gamma + v(\Gamma' - \Gamma)}(z) = -\frac{1}{2} \mathrm{Tr} \left[\Gamma_v^{-1} (\Gamma' - \Gamma) + \Gamma_v^{-1} z z^{\intercal} \Gamma_v^{-1} (\Gamma' - \Gamma) \right],$$

and consequently,

$$\int_{\mathsf{X}} \left| \int_0^1 \frac{d}{dv} q_{\Gamma + v(\Gamma' - \Gamma)}(z) dv \right| dz \le \frac{n_x}{\lambda_{\min}(\mathcal{K})} |\Gamma' - \Gamma|,$$

where we have used the inequality

$$|\mathrm{Tr}[\Gamma_v^{-1} z z^{\intercal} \Gamma_v^{-1} (\Gamma' - \Gamma)]| \le |\Gamma' - \Gamma| \mathrm{Tr}[\Gamma_v^{-1} \Gamma_v^{-1} z z^{\intercal}]. \qquad \square$$

COROLLARY 7.4. *For any compact subset $\mathcal{K}$ of $\mathcal{C}_+^{n_x}$, there exists $C < \infty$ such that*

$$\left\| P_{q_\Gamma}^{\mathrm{SRW}} g - P_{q_{\Gamma'}}^{\mathrm{SRW}} g \right\|_{W^r} \le C \, \|g\|_{W^r} \, |\Gamma - \Gamma'|. \tag{7.17}$$

7.4. Convergence of the adaptive MCMC algorithm. The main result of this section is the following.

THEOREM 7.5. *Let $\pi \in \mathcal{M}(\mathsf{X})$ satisfying* (M). *Let $\{Z_n\}$ be the homogeneous Markov chain defined as in section* 3, *with H as in* (7.5), *$P_\theta := P_{\phi_{0,\lambda\Gamma}}^{\mathrm{SRW}}$ for some $\lambda > 0$ with $\theta = (\mu, \Gamma) \in \Theta = \mathbb{R}^{n_x} \times \mathcal{C}_+^{n_x}$, K a compact set, and $\boldsymbol{\gamma} = \{\gamma_n\}$ and $\boldsymbol{\epsilon} = \{\epsilon_n\}$ satisfying* (A4). *Then,* (A1)–(A3) *are satisfied for any $\mathcal{K}_0$ and $\theta_n \to \theta_\pi$ w.p.* 1, *where $\theta_\pi := (\mu_\pi, \Gamma_\pi)$ is the unique stationary point of $\{\theta_n\}$.*

Proof. (A1) is implied by Proposition 7.1. (A2) is satisfied by construction of P_θ and from (M) and the definition of H in (7.5). Now we prove that (DRI) is satisfied. Choose $V^p = W = \pi^{-\eta} / \inf_{\mathsf{X}} \pi^{-\eta}$ for $p \ge 2$ in Proposition 7.2; then (DRI1) and (DRI3) are satisfied. Now (DRI2) is satisfied since, from (7.5),

$$|H_\theta(x) - H_{\theta'}(x)| \le |\mu - \mu'| \{1 + |\mu + \mu'| + 2|x|\} + |\Gamma - \Gamma'|, \tag{7.18}$$

and $\|x\|_W + \||x|^2\| < \infty$ from (M). Theorem 5.5 now applies. $\square$

This result is an important step for the study of the asymptotic properties of $\{S_n\}$ in [2], in particular the proof that $\{S_n\}$ satisfies a central limit theorem.

Appendix A. Proof of Proposition 5.2. Denote

$$D(\boldsymbol{\epsilon}, \boldsymbol{\rho}, \mathcal{K}, x) = \sup_{k \ge 1} \sup_{\theta \in \mathcal{K}} \mathbb{E}_{x,\theta}^{\boldsymbol{\rho}} [W^p(X_k) \mathbb{1}_{\{\sigma(\mathcal{K}) \wedge \nu(\boldsymbol{\epsilon}) \ge k\}}].$$

We first consider the case $l = 1$. Denote

$$T_n = \sum_{k=1}^{n} \rho_k \left(g_{\theta_{k-1}}(X_k) - P_{\theta_{k-1}} g_{\theta_{k-1}}(X_k) \right) \mathbb{1}_{\{\sigma(\mathcal{K}) \wedge \nu(\boldsymbol{\epsilon}) \ge k\}},$$

Using $\mathbb{1}_{\{\sigma(\mathcal{K}) \wedge \nu(\boldsymbol{\epsilon}) \ge k\}} = \mathbb{1}_{\{\sigma(\mathcal{K}) \wedge \nu(\boldsymbol{\epsilon}) \ge k+1\}} + \mathbb{1}_{\{\sigma(\mathcal{K}) \wedge \nu(\boldsymbol{\epsilon}) = k\}}$, we may write $T_n = \sum_{i=1}^{5} T_n^{(i)}$,

where

$$T_n^{(1)} = \sum_{k=1}^{n} \rho_k \left(g_{\theta_{k-1}}(X_k) - P_{\theta_{k-1}} g_{\theta_{k-1}}(X_{k-1}) \right) \mathbb{1}_{\{\sigma(\mathcal{K}) \wedge \nu(\boldsymbol{\epsilon}) \geq k\}}, \tag{A.1}$$

$$T_n^{(2)} = \sum_{k=1}^{n-1} \rho_{k+1} \left(P_{\theta_k} g_{\theta_k}(X_k) - P_{\theta_{k-1}} g_{\theta_{k-1}}(X_k) \right) \mathbb{1}_{\{\sigma(\mathcal{K}) \wedge \nu(\boldsymbol{\epsilon}) \geq k+1\}}, \tag{A.2}$$

$$T_n^{(3)} = \sum_{k=1}^{n-1} (\rho_{k+1} - \rho_k) P_{\theta_{k-1}} g_{\theta_{k-1}}(X_k) \mathbb{1}_{\{\sigma(\mathcal{K}) \wedge \nu(\boldsymbol{\epsilon}) \geq k+1\}}, \tag{A.3}$$

$$T_n^{(4)} = \rho_1 P_{\theta_0} g_{\theta_0}(X_0) \mathbb{1}_{\{\sigma(\mathcal{K}) \wedge \nu(\boldsymbol{\epsilon}) \geq 1\}} - \rho_n P_{\theta_{n-1}} g_{\theta_{n-1}}(X_n) \mathbb{1}_{\{\sigma(\mathcal{K}) \wedge \nu(\boldsymbol{\epsilon}) \geq n\}}, \tag{A.4}$$

$$T_n^{(5)} = -\sum_{k=1}^{n-1} \rho_k P_{\theta_{k-1}} g_{\theta_{k-1}}(X_k) \mathbb{1}_{\{\sigma(\mathcal{K}) \wedge \nu(\boldsymbol{\epsilon}) = k\}}. \tag{A.5}$$

We now evaluate bounds for $T_n^{(i)}$, $i = 1, \ldots, 4$. In what follows, sequel C denotes a constant which depends only upon the compact set $\mathcal{K}$ through the quantities defined in the assumptions and whose value may change upon each appearance. We have

$$\sup_{\theta \in \mathcal{K}} \mathbb{E}^{\boldsymbol{\rho}}_{\theta,x} \left[\sup_{n \geq 0} \left| T_n^{(1)} \right|^p \right] \leq C \left(\sum_{k=0}^{\infty} \rho_k^2 \right)^{p/2} \sup_{\theta \in \mathcal{K}} \sup_k \mathbb{E}^{\boldsymbol{\rho}}_{x,\theta} \left[W^p(X_k) \mathbb{1}_{\{\sigma(\mathcal{K}) \wedge \nu(\boldsymbol{\epsilon}) \geq k\}} \right], \tag{A.6}$$

$$\sup_{\theta \in \mathcal{K}} \mathbb{E}^{\boldsymbol{\rho}}_{\theta,x} \left[\sup_{n \geq 0} \left| T_n^{(2)} \right|^p \right] \leq C \left(\sum_{k=1}^{\infty} \rho_k \epsilon_k^{\alpha} \right)^{p} \sup_{\theta \in \mathcal{K}} \sup_k \mathbb{E}^{\boldsymbol{\rho}}_{x,\theta} \left[W^p(X_k) \mathbb{1}_{\{\sigma(\mathcal{K}) \wedge \nu(\boldsymbol{\epsilon}) \geq k\}} \right], \tag{A.7}$$

$$\sup_{\theta \in \mathcal{K}} \mathbb{E}^{\boldsymbol{\rho}}_{\theta,x} \left[\sup_{n \geq 0} \left| T_n^{(3)} \right|^p \right] \leq C \rho_1^p \sup_{\theta \in \mathcal{K}} \sup_k \mathbb{E}^{\boldsymbol{\rho}}_{x,\theta} \left[W^p(X_k) \mathbb{1}_{\{\sigma(\mathcal{K}) \wedge \nu(\boldsymbol{\epsilon}) \geq k\}} \right], \tag{A.8}$$

$$\sup_{\theta \in \mathcal{K}} \mathbb{E}^{\boldsymbol{\rho}}_{\theta,x} \left[\sup_{n \geq 0} \left| T_n^{(4)} \right|^p \right] \leq C \left(\sum_{k=1}^{\infty} \rho_k^2 \right)^{p/2} \sup_{\theta \in \mathcal{K}} \sup_k \mathbb{E}^{\boldsymbol{\rho}}_{x,\theta} \left[W^p(X_k) \mathbb{1}_{\{\sigma(\mathcal{K}) \wedge \nu(\boldsymbol{\epsilon}) \geq k\}} \right]. \tag{A.9}$$

The proof of these inequalities can be adapted from [5, Part II, section 3.2]; see also [4, Chapter 6, Lemmas 6.2–6.4].

Proof of (A.6). Under (A3),

$$\sup_{\theta \in \mathcal{K}} \mathbb{E}^{\boldsymbol{\rho}}_{x,\theta} \left[(|g_{\theta_k}(X_{k+1})|^p + |P_{\theta_k} g_{\theta_k}(X_{k+1})|^p) \mathbb{1}_{\{\sigma(\mathcal{K}) \wedge \nu(\boldsymbol{\epsilon}) \geq k+1\}} \right] \leq C D(\boldsymbol{\epsilon}, \boldsymbol{\rho}, \mathcal{K}, x).$$

Since

$$\begin{aligned} \mathbb{E}^{\boldsymbol{\rho}}_{x,\theta} \left[(g_{\theta_k}(X_{k+1}) - P_{\theta_k} g_{\theta_k}(X_k)) \mathbb{1}_{\{\sigma(\mathcal{K}) \wedge \nu(\boldsymbol{\epsilon}) \geq k+1\}} \middle| \mathcal{F}_k \right] \\ = \left(P_{\theta_k} g_{\theta_k}(X_k) - P_{\theta_k} g_{\theta_k}(X_k) \right) \mathbb{1}_{\{\sigma(\mathcal{K}) \wedge \nu(\boldsymbol{\epsilon}) \geq (k+1)\}} = 0, \end{aligned}$$

$T_n^{(1)}$ is an ($\mathbb{R}^d$-valued) martingale. Using the Burkholder inequality [20, Theorem 2.10], we have

(A.10)
$$\mathbb{E}_{x,\theta}^{\boldsymbol{\rho}}\left[\left|T_n^{(1)}\right|^p\right] \le C_p \mathbb{E}_{x,\theta}^{\boldsymbol{\rho}}\left(\sum_{k=0}^{n-1} \rho_{k+1}^2 |g_{\theta_k}(X_{k+1}) - P_{\theta_k} g_{\theta_k}(X_k)|^2 \mathbb{1}_{\{\sigma(\mathcal{K})\wedge\nu(\boldsymbol{\epsilon})\ge k+1\}}\right)^{p/2},$$

where C_p is a universal constant. Using Minkowski's inequality, $\sup_{\theta\in\mathcal{K}}(\|g_\theta\|_V + \|P_\theta g_\theta\|_V) < \infty$, and (A3), we have

$$\mathbb{E}_{x,\theta}^{\boldsymbol{\rho}}\left[\left|T_n^{(1)}\right|^p\right] \le C\left(\sum_{k=1}^{\infty}\rho_k^2\right)^{p/2} D(\boldsymbol{\epsilon},\boldsymbol{\rho},\mathcal{K},x).$$

Since $T_n^{(1)}$ is a martingale in $\mathcal{L}^p$, then $|T_n^{(1)}|$ is a nonnegative submartingale in $\mathcal{L}^p$ and Doob's $\mathcal{L}^p$ inequality implies that

$$\mathbb{E}_{x,\theta}^{\boldsymbol{\rho}}\left[\sup_{n\ge1}\left|T_n^{(1)}\right|^p\right] \le C\left(\sum_{k=1}^{\infty}\rho_k^2\right)^{p/2} D(\boldsymbol{\epsilon},\boldsymbol{\rho},\mathcal{K},x),$$

which concludes the proof of (A.6).

Proof of (A.7). Under (A3), we have

$$\begin{aligned}
&\sup_{n\ge1}\left|\sum_{k=1}^{n-1}\rho_{k+1}\left(P_{\theta_k}g_{\theta_k}(X_k) - P_{\theta_{k-1}}g_{\theta_{k-1}}(X_k)\right)\ \mathbb{1}_{\{\sigma(\mathcal{K})\wedge\nu(\boldsymbol{\epsilon})\ge k+1\}}\right| \\
&\le C\sum_{k=0}^{\infty}\rho_{k+1}W(X_k)\,|\theta_k-\theta_{k-1}|^\alpha\ \mathbb{1}_{\{\sigma(\mathcal{K})\wedge\nu(\boldsymbol{\epsilon})\ge k+1\}}, \\
&\le C\sum_{k=0}^{\infty}\rho_{k+1}\epsilon_k^\alpha\ W(X_k)\ \mathbb{1}_{\{\sigma(\mathcal{K})\wedge\nu(\boldsymbol{\epsilon})\ge k+1\}}.
\end{aligned}$$

We conclude the proof by applying Minkowski's inequality.

Proof of (A.8). Under (A3),

$$\begin{aligned}
&\sup_{n\ge1}\left|\sum_{k=1}^{n-1}(\rho_{k+1}-\rho_k)P_{\theta_{k-1}}g_{\theta_{k-1}}(X_k)\ \mathbb{1}_{\{\sigma(\mathcal{K})\wedge\nu(\boldsymbol{\epsilon})\ge k+1\}}\right| \\
&\qquad\le C\sum_{k=1}^{\infty}(\rho_k-\rho_{k+1})W(X_k)\mathbb{1}_{\{\sigma(\mathcal{K})\wedge\nu(\boldsymbol{\epsilon})\ge k+1\}},
\end{aligned}$$

and the proof follows from Minkowski's inequality.

Proof of (A.9). Under (A3),

$$\begin{aligned}
&\sup_{n\ge1}\left|\rho_1 P_{\theta_0}g_{\theta_0}(X_0)\mathbb{1}_{\{\sigma(\mathcal{K})\wedge\nu(\boldsymbol{\epsilon})\ge1\}} - \rho_n P_{\theta_{n-1}}g_{\theta_{n-1}}(X_n)\mathbb{1}_{\{\sigma(\mathcal{K})\wedge\nu(\boldsymbol{\epsilon})\ge n\}}\right|^p \\
&\qquad\le C\left(\rho_1^p W^p(X_0)\ \mathbb{1}_{\{\sigma(\mathcal{K})\wedge\nu(\boldsymbol{\epsilon})\ge1\}} + \sup_{n\ge1}\rho_n^p W^p(X_n)\mathbb{1}_{\{\sigma(\mathcal{K})\wedge\nu(\boldsymbol{\epsilon})\ge n\}}\right) \\
&\qquad\le C\sum_{k=1}^{\infty}\rho_k^p W^p(X_k)\mathbb{1}_{\{\sigma(\mathcal{K})\wedge\nu(\boldsymbol{\epsilon})\ge k\}}.
\end{aligned}$$

The proof follows from (A3) and the inequality $\sum_{k=1}^n \rho_k^p \le \left(\sum_{k=1}^n \rho_k^2\right)^{p/2}$ for $p \ge 2$.

Since $T_n^{(5)} \mathbb{1}_{\{\sigma(\mathcal{K})\wedge\nu(\boldsymbol{\epsilon})\ge n\}} = 0$, we have

$$S_{1,n}(\boldsymbol{\epsilon},\boldsymbol{\rho},\mathcal{K}) = T_n \mathbb{1}_{\{\sigma(\mathcal{K})\wedge\nu(\boldsymbol{\epsilon})\ge n\}} = \sum_{i=1}^4 T_n^{(i)} \mathbb{1}_{\{\sigma(\mathcal{K})\wedge\nu(\boldsymbol{\epsilon})\ge n\}}.$$

The Markov inequality and Lemma 5.1 imply that

(A.11)
$$\mathbb{P}_{x,\theta}^{\boldsymbol{\rho}}\left(\sup_{n\ge1}|S_{1,n}(\boldsymbol{\epsilon},\boldsymbol{\rho},\mathcal{K})|\ge\delta\right) \le C\delta^{-p}\left\{\left(\sum_{k=1}^\infty \rho_k^2\right)^{p/2} + \left(\sum_{k=1}^\infty \rho_k \epsilon_k^\alpha\right)^p\right\} W^p(x).$$

The proof for all l then follows from the Markov property: for all $(x,\theta)\in\mathsf{X}\times\mathcal{K}$,

$$\begin{aligned}
&\mathbb{P}_{x,\theta}^{\boldsymbol{\rho}}\left(\sup_{n\ge1}|S_{l+1,n}(\boldsymbol{\epsilon},\boldsymbol{\rho},\mathcal{K})|\ge\delta\right)\\
&\quad= \mathbb{E}_{x,\theta}^{\boldsymbol{\rho}}\left(\mathbb{P}_{X_l,\theta_l}^{\boldsymbol{\rho}^{\leftarrow l}}\left(\sup_{n\ge1}|S_{1,n}(\boldsymbol{\epsilon}^{\leftarrow l},\boldsymbol{\rho}^{\leftarrow l},\mathcal{K})|\ge\delta\right)\mathbb{1}_{\{\sigma(\mathcal{K})\wedge\nu(\boldsymbol{\epsilon})\ge l\}}\right)\\
&\quad\le \mathbb{E}_{x,\theta}^{\boldsymbol{\rho}}\left(\sup_{\theta\in\mathcal{K}}\mathbb{P}_{X_l,\theta}^{\boldsymbol{\rho}^{\leftarrow l}}\left(\sup_{n\ge1}|S_{1,n}(\boldsymbol{\epsilon}^{\leftarrow l},\boldsymbol{\rho}^{\leftarrow l},\mathcal{K})|\ge\delta\right)\mathbb{1}_{\{\sigma(\mathcal{K})\wedge\nu(\boldsymbol{\epsilon})\ge l\}}\right).
\end{aligned}$$

Since the sequence $\boldsymbol{\epsilon}$ is nonincreasing, there exists an integer s such that for all l and all $k\ge s$, $\epsilon_k^{\leftarrow l}\le\epsilon$, for all $k\ge s$ (where ϵ is defined in (A3)) and Lemma 5.1 shows that there exists a constant C such that for any l, for any $x\in\mathsf{X}$, and any monotone nonincreasing sequence $\boldsymbol{\rho}$,

$$\sup_{\theta\in\mathcal{K}}\sup_{k\ge0}\mathbb{E}_{x,\theta}^{\boldsymbol{\rho}^{\leftarrow l}}[W^p(X_k)\mathbb{1}_{\{\sigma(\mathcal{K})\wedge\nu(\boldsymbol{\epsilon}^{\leftarrow l})\ge k\}}] \le CW^p(x).$$

The proof follows from (A.11).

It remains to bound $\mathbb{P}_{x,\theta}^{\boldsymbol{\rho}}(\nu(\boldsymbol{\epsilon})<\sigma(\mathcal{K})) \le \mathbb{P}_{x,\theta}^{\boldsymbol{\rho}}(\nu(\boldsymbol{\epsilon})\le\sigma(\mathcal{K}))$.

$$\begin{aligned}
\mathbb{P}_{x,\theta}^{\boldsymbol{\rho}}(\nu(\boldsymbol{\epsilon})\le\sigma(\mathcal{K})) &= \sum_{k=1}^\infty \mathbb{P}_{x,\theta}^{\boldsymbol{\rho}}(\nu(\boldsymbol{\epsilon})=k,\sigma(\mathcal{K})\ge k)\\
&= \sum_{k=1}^\infty \mathbb{P}_{x,\theta}^{\boldsymbol{\rho}}\left(|H(\theta_{k-1},X_k)|\ge\epsilon_k\rho_k^{-1},\sigma(\mathcal{K})\ge k,\nu(\boldsymbol{\epsilon})=k\right)\\
&\le C\sum_{k=1}^\infty(\epsilon_k^{-1}\rho_k)^p \sup_{k\ge0}\sup_{\theta\in\mathcal{K}}\mathbb{E}_{x,\theta}^{\boldsymbol{\rho}}[W^p(X_k)\mathbb{1}_{\{\sigma(\mathcal{K})\wedge\nu(\boldsymbol{\epsilon})\ge k\}}].
\end{aligned}$$

The proof follows from Lemma 5.1. □

Appendix B. Proof of Proposition 6.1. The following proposition is a partial restatement of [25, Theorem 2.3].

PROPOSITION B.1. *Suppose that P is irreducible and aperiodic and that $P^m(x,\cdot)\ge\mathbb{1}_C(x)\delta\nu(\cdot)$ for a set $C\in\mathcal{B}(\mathsf{X})$, some integer m and $\delta>0$ and that there is a drift to C in the sense that, for some $\lambda<1$, b, and a function $V:\mathsf{X}\to[1,\infty)$,*

(B.1) $$PV(x)\le\lambda V(x)\quad\forall x\notin C\quad\text{and}\quad\sup_{x\in C}(V(x)+PV(x))\le b.$$

Then, there exist constants K and $\rho < 1$, depending only upon m, δ, λ, b, such that, for all $x \in \mathsf{X}$ and all $g \in \mathcal{L}_V$,

$$\|P^k g - \pi(g)\|_V \leq K\rho^n \, \|g\|_V. \tag{B.2}$$

In addition, $u = \sum_{n\geq 0}(P^k g - \pi(g))$ is a solution of the Poisson equation $u - Pu = g - \pi(g)$.

We state [25, Theorem 2.3] in the strongly aperiodic case, i.e., where C is a $(1, \delta)$ small set. Explicit but intricate expressions for K and ρ (in terms of the constants m, δ, λ, b) are given in this reference. Partial extensions to the general aperiodic case are considered in [25, Theorem 2.4], based on splitting and regeneration techniques. Sharper and simpler bounds have been recently obtained in [15] using coupling technique. This result extends to V-norm results obtained earlier for the total variation distance by [29] (see also [28]). These results have been derived in the strongly aperiodic case; extensions to the general aperiodic case can be considered in the same framework.

PROPOSITION B.2. *Assume* (DRI1)–(DRI3). *Then, there exist a constant C and $\rho < 1$ such that, for all $g \in \mathcal{L}_{V^q}$, with $q = 1$ or $q = p$ and any $k \geq 0$,*

$$\sup_{\theta\in\mathcal{K}} \|P_\theta^k g - \pi_\theta(g)\|_{V^q} \leq C\rho^k \|g\|_{V^q}, \tag{B.3}$$

$$\sup_{(\theta,\theta')\in\mathcal{K}\times\mathcal{K}} |\theta - \theta'|^{-\beta} \|P_\theta^k g - P_{\theta'}^k g\|_{V^q} \leq C\|g\|_{V^q}. \tag{B.4}$$

Proof. Equation (B.3) follows from Proposition B.1. To prove (B.4) write, for all $(\theta, \theta') \in \Theta \times \Theta$, all $n \in \mathbb{N}$, and all $g \in \mathcal{L}_{V^q}$,

$$\begin{aligned} P_\theta^n g(x) - P_{\theta'}^n g(x) &= \sum_{j=0}^{n-1} P_\theta^j (P_\theta - P_{\theta'}) P_{\theta'}^{n-j-1} g(x) \\ &= \sum_{j=0}^{n-1} P_\theta^j (P_\theta - P_{\theta'})(P_{\theta'}^{n-j-1} g(x) - \pi_{\theta'}(g)). \end{aligned}$$

Equation (B.3) shows that there exists a constant C such that, for any $l \geq 0$,

$$\sup_{\theta\in\mathcal{K}} \|P_\theta^l g - \pi_\theta(g)\|_{V^q} \leq C\|g\|_{V^q} \, \rho^l \quad \text{and} \quad \sup_{j\geq 0} \sup_{\theta\in\mathcal{K}} \|P_\theta^j V^q\|_{V^q} < \infty.$$

Under assumption (DRI3) we thus have, for any $l \geq 0$,

$$\|(P_\theta - P_\theta')(P_{\theta'}^l g(x) - \pi_{\theta'}(g))\|_{V^q} \leq C|\theta - \theta'|^\beta \|(P_{\theta'}^l g(x) - \pi_{\theta'}(g))\|_{V^q} \leq C|\theta - \theta'|^\beta \|g\|_{V^q} \rho^l,$$

which concludes the proof. □

Proof of Proposition 6.1. Under (DRI1), P_θ is positive recurrent and admits a single stationary measure π_θ, which verifies $\sup_{\theta\in\mathcal{K}} \pi_\theta(V^p) < \infty$, which implies that $\sup_{\theta\in\mathcal{K}} |h(\theta)| < \infty$.

Proof of (6.6). Let $x_0 \in \mathsf{X}$ and $k \in \mathbb{N}$. Write $h(\theta) - h(\theta') = A(\theta, \theta') + B(\theta, \theta') + C(\theta, \theta')$, where

$$A(\theta, \theta') = \left(h(\theta) - P_\theta^k H_\theta(x_0)\right) + \left(P_{\theta'}^k H_{\theta'}(x_0) - h(\theta')\right), \tag{B.5}$$

$$B(\theta, \theta') = P_\theta^k H_\theta(x_0) - P_{\theta'}^k H_\theta(x_0), \tag{B.6}$$

$$C(\theta, \theta') = P_{\theta'}^k H_\theta(x_0) - P_{\theta'}^k H_{\theta'}(x_0). \tag{B.7}$$

Propositions B.1 and B.2 show that there exist constants C and $\rho < 1$ such that, for all $(\theta, \theta') \in \mathcal{K} \times \mathcal{K}$,

$$
\begin{aligned}
&|A(\theta,\theta')| \le C\,\rho^k \sup_{\theta\in\mathcal{K}} \|H_\theta\|_V\, V(x_0),\\
&|B(\theta,\theta')| \le C \sup_{\theta\in\mathcal{K}} \|H_\theta\|_V\, |\theta-\theta'|^\beta\, V(x_0),\\
&|C(\theta,\theta')| \le \int_{\mathsf{X}} P^k_{\theta'}(x_0,dy)|H_\theta(y)-H_{\theta'}(y)| \le C|\theta-\theta'|^\beta \int_{\mathsf{X}} P^k_{\theta'}(x_0,dy)V(y)\\
&\qquad\qquad \le C|\theta-\theta'|^\beta\, V(x_0).
\end{aligned}
$$

Hence, there exists a constant C such that, for all $(\theta, \theta') \in \mathcal{K} \times \mathcal{K}$,

$$
|h(\theta) - h(\theta')| \le C\, V(x_0)\, (\rho^k + |\theta-\theta'|^\beta). \tag{B.8}
$$

The proof is concluded by setting $k = [\beta \log|\theta-\theta'|/\log(\rho)]$ (where $[x]$ is the integer part of x) if $|\theta-\theta'| \le \delta < 1$ and $k = 1$ otherwise. □

Proof of (5.4). Using (6.6) and Propositions B.1 and B.2, there exists a constant C such that, for all $(\theta, \theta') \in \mathcal{K}$, we have

$$
\begin{aligned}
&|(P^k_\theta H_\theta(x) - h(\theta)) - (P^k_{\theta'}(x)H_{\theta'}(x) - h(\theta'))|\\
&\quad \le |P^k_\theta H_\theta(x) - P^k_\theta H_{\theta'}(x)| + |P^k_\theta H_{\theta'}(x) - P^k_{\theta'} H_{\theta'}(x)| + |h(\theta)-h(\theta')|\\
&\quad \le C|\theta-\theta'|^\beta V(x).
\end{aligned}
$$

On the other hand, by Proposition B.1, there exist constants $\rho < 1$ and C such that, for all $(\theta, \theta') \in \mathcal{K} \times \mathcal{K}$,

$$
|(P^k_\theta H_\theta(x) - h(\theta)) - (P^k_{\theta'} H_{\theta'}(x) - h(\theta'))| \le C\rho^k V(x).
$$

Hence, for any s and $N \ge s$, we have

$$
\begin{aligned}
|P^s_\theta g_\theta(x) - P^s_{\theta'} g_{\theta'}(x)| &\le \sum_{k=s}^{\infty} |(P^k_\theta H_\theta(x) - h(\theta)) - (P^k_{\theta'}(x) - h(\theta'))|\\
&\le CV(x)\, \left\{ N|\theta-\theta'|^\beta + \frac{\rho^{N+s}}{1-\rho} \right\}.
\end{aligned}
$$

The proof follows by setting $N = [\beta \log|\theta-\theta'|/\log\rho]$ for $|\theta-\theta'| \le \delta < 1$, $\theta \ne \theta'$, $N = s$ otherwise, and using the fact that for any $0 < \alpha < \beta$, $|\theta-\theta'|^\beta \log|\theta-\theta'|$ $= o(|\theta-\theta'|^\alpha)$. □

Proof of (5.6). Let $\boldsymbol{\rho} = \{\rho_k, k \ge 0\}$ be a nonincreasing sequence of positive numbers and let $\mathcal{K}$ be a compact subset of Θ. (DRI1) and (6.2) shows that, for all $k \ge 0$, $l \ge 0$, and all $x \in \mathsf{X}$,

$$
\sup_{\theta\in\mathcal{K}} \mathbb{E}^{\boldsymbol{\rho}}_{x,\theta}\left[V^p(X_{k+l})\mathbb{1}_{\{\sigma(\mathcal{K})\ge k+l\}} \mid \mathcal{F}_k\right] \le \kappa^l V^p(X_k)\mathbb{1}_{\{\sigma(\mathcal{K})\ge k\}}. \tag{B.9}
$$

We will show that there exist constants $\epsilon > 0$, $0 < \rho < 1$, and C such that, for all k,

$$
\mathbb{E}^{\boldsymbol{\rho}}_{x,\theta}\left[V^p(X_{k+m})\mathbb{1}_{\{\sigma(\mathcal{K})\wedge\nu_\epsilon\ge k+m\}} \mid \mathcal{F}_k\right] \le \rho V^p(X_k)\mathbb{1}_{\{\sigma(\mathcal{K})\wedge\nu_\epsilon\ge k\}} + C. \tag{B.10}
$$

For $n \in \mathbb{N}$, write $n = um + v$, where $v \in \{0, \dots, m-1\}$. Equation (B.10) shows that

$$
\mathbb{E}^{\boldsymbol{\rho}}_{x,\theta}\left[V^p(X_{um+v})\mathbb{1}_{\{\sigma(\mathcal{K})\wedge\nu_\epsilon\ge um+v\}}\right] \le \rho^u \mathbb{E}^{\boldsymbol{\rho}}_{x,\theta}[V^p(X_v)\mathbb{1}_{\{\sigma(\mathcal{K})\wedge\nu_\epsilon\ge v\}}] + \frac{C}{1-\rho}
$$

and the proof follows from (B.9). It remains to prove (B.10). We repeatedly use the following lemma adapted from [5, Lemma 3, p. 292].

LEMMA B.3. *Assume* (DRI). *Let* $\psi : \Theta \times \mathsf{X} \to \mathbb{R}$ *be a function verifying* $\sup_{\theta\in\mathcal{K}} \|\psi_\theta\|_{V^p} < \infty$. *Then, for any* $\epsilon > 0$ *and for any* $l \geq 1$ *there exists a constant* C *such that, for all* $k \geq 0$,

$$\mathbb{E}^{\boldsymbol{\rho}}_{x,\theta}\left[\psi_{\theta_k}(X_{k+l})\mathbb{1}_{\{\sigma(\mathcal{K})\wedge\nu_\epsilon\geq k+l\}} \mid \mathcal{F}_k\right] \leq \mathbb{E}^{\boldsymbol{\rho}}_{x,\theta}\left[P_{\theta_k}\psi_{\theta_k}(X_{k+l-1})\mathbb{1}_{\{\sigma(\mathcal{K})\wedge\nu_\epsilon\geq k+l-1\}} \mid \mathcal{F}_k\right] + C\kappa^l\epsilon^\alpha \sup_{\theta\in\mathcal{K}} \|\psi_\theta\|_{V^p}\, V^p(X_k)\mathbb{1}_{\{\sigma(\mathcal{K})\wedge\nu_\epsilon\geq k\}}.$$

Proof.

$$\begin{aligned}\mathbb{E}^{\boldsymbol{\rho}}_{x,\theta}\left[\psi(\theta_k, X_{k+l})\mathbb{1}_{\{\sigma(\mathcal{K})\wedge\nu_\epsilon\geq k+l\}} \mid \mathcal{F}_k\right] &= \mathbb{E}^{\boldsymbol{\rho}}_{x,\theta}\left[P_{\theta_{k+l-1}}\psi_{\theta_k}(X_{k+l-1})\mathbb{1}_{\{\sigma(\mathcal{K})\wedge\nu_\epsilon\geq k+l\}} \mid \mathcal{F}_k\right] \\ &= \mathbb{E}^{\boldsymbol{\rho}}_{x,\theta}\left[P_{\theta_k}\psi_{\theta_k}(X_{k+l-1})\mathbb{1}_{\{\sigma(\mathcal{K})\wedge\nu_\epsilon\geq k+l\}} \mid \mathcal{F}_k\right] + R_l,\end{aligned}$$

where

$$R_l = \mathbb{E}^{\boldsymbol{\rho}}_{x,\theta}\left[(P_{\theta_{k+l-1}} - P_{\theta_k})\psi_{\theta_k}(X_{k+l-1})\mathbb{1}_{\{\sigma(\mathcal{K})\wedge\nu_\epsilon\geq k+l\}} \mid \mathcal{F}_k\right].$$

Under (DRI3), there exists a constant C such that for all $x \in \mathsf{X}$,

$$|(P_{\theta_{k+l-1}} - P_{\theta_k})\psi_{\theta_k}(x)\mathbb{1}_{\{\sigma(\mathcal{K})\wedge\nu_\epsilon\geq k+l\}}| \leq C \sup_{\theta\in\mathcal{K}} \|\psi_\theta\|_{V^p}\, V^p(x)(l\epsilon)^\alpha \mathbb{1}_{\{\sigma(\mathcal{K})\wedge\nu_\epsilon\geq k+l\}}.$$

Finally, (DRI1) implies that

$$\mathbb{E}^{\boldsymbol{\rho}}_{x,\theta}\left[V^p(X_{k+l-1})\mathbb{1}_{\{\sigma(\mathcal{K})\wedge\nu_\epsilon\geq k+l\}} \mid \mathcal{F}_k\right] \leq \kappa^l V^p(X_k)\mathbb{1}_{\{\sigma(\mathcal{K})\wedge\nu_\epsilon\geq k\}},$$

which implies

$$|R_l| \leq C\kappa^l\,(l\epsilon)^\alpha \sup_{\theta\in\mathcal{K}} \|\psi_\theta\|_{V^p}\, V^p(X_k)\mathbb{1}_{\{\sigma(\mathcal{K})\wedge\nu_\epsilon\geq k\}}. \qquad \square$$

Using repeatedly the lemma above, we may write

$$\begin{aligned}&\mathbb{E}^{\boldsymbol{\rho}}_{x,\theta}\left[V^p(X_{k+m})\mathbb{1}_{\{\sigma(\mathcal{K})\wedge\nu_\epsilon\geq k+m\}} \mid \mathcal{F}_k\right] \\ &\quad\leq \mathbb{E}^{\boldsymbol{\rho}}_{x,\theta}\left[P_{\theta_k}V^p(X_{k+m-1})\mathbb{1}_{\{\sigma(\mathcal{K})\wedge\nu_\epsilon\geq k+m-1\}} \mid \mathcal{F}_k\right] \\ &\qquad\quad + C_m\epsilon^\alpha V^p(X_k)\mathbb{1}_{\{\sigma(\mathcal{K})\wedge\nu_\epsilon\geq k\}} \\ &\quad\leq \mathbb{E}^{\boldsymbol{\rho}}_{x,\theta}\left[P^2_{\theta_k}V^p(X_{k+m-2})\mathbb{1}_{\{\sigma(\mathcal{K})\wedge\nu_\epsilon\geq k+m-2\}} \mid \mathcal{F}_k\right] \\ &\qquad\quad + (C_m + C_{m-1}\kappa)\epsilon^\alpha V^p(X_k)\mathbb{1}_{\{\sigma(\mathcal{K})\wedge\nu_\epsilon\geq k\}} \\ &\quad\vdots \\ &\quad\leq P^m_{\theta_k}V^p(X_k)\mathbb{1}_{\{\sigma(\mathcal{K})\wedge\nu_\epsilon\geq k\}} + \left(\sum_{i=0}^{m-1} C_{m-i}\kappa^i\right)\epsilon^\alpha V^p(X_k)\mathbb{1}_{\{\sigma(\mathcal{K})\wedge\nu_\epsilon\geq k\}}.\end{aligned}$$

The proof follows from (DRI) for ϵ sufficiently small. $\square$

A STUDY ON THE SPECTRUM OF THE SAMPLED-DATA TRANSFER OPERATOR WITH APPLICATION TO ROBUST EXPONENTIAL STABILITY PROBLEMS*

TOMOMICHI HAGIWARA†

Abstract. This paper begins by studying some spectral properties of the transfer operators of sampled-data systems described by applying the lifting technique. Through a "nonasymptotic" characterization of the transfer operator, its spectrum is determined in terms of finite-dimensional eigenvalue problems. Then, it is shown that a close connection with such eigenvalue problems and the exponential stability condition can be exploited to study the robust internal (exponential) stability problem of sampled-data systems. Since the transfer operator is relevant to input-output characteristics, the relationship between input-output stability and internal stability is also discussed in the context of sampled-data systems.

Key words. sampled-data system, spectral analysis, robust stability, L_2-stability, exponential stability

1. Introduction.

The widespread use of digital controllers has stimulated the study of sampled-data systems with their intersample behavior taken into account, and a lot of important results have been obtained since the late 1980s. Among them are the studies on the H_∞ control problem [1, 2, 3, 4] and robust stability problem [5, 6, 7, 8, 9] of sampled-data systems, as well as the continuous-time lifting technique [1, 2, 10] and the frequency response theory [11, 12]. In the studies of the H_∞ control and robust stability problems, L_2-stability [13], L_2-induced norm [14], and H_∞ norm [15] of sampled-data systems play important roles, and these notions can be dealt with also in the frequency domain with the transfer operator [1, 2, 10, 11, 15] of sampled-data systems. Also, another frequency-domain study has been conducted in [16, 17] by introducing the notion of positive-real sampled-data systems, and some phase properties of sampled-data systems were discussed. This study has been extended in [18, 19], which lead to the positive-realness approach (or the passivity approach) to the robust stability analysis of sampled-data systems. Transfer operators play an important role also in such an approach.

Thus, it is important to study the properties of the transfer operators so that the scope of the frequency-domain studies of sampled-data systems can be extended further. In this paper, we focus on the spectrum of transfer operators, and clarify some useful spectral properties. More specifically, we show that the spectrum of the transfer operator can be characterized by means of finite-dimensional eigenvalue problems. Then, it is demonstrated that such spectral analysis is indeed useful in the study of sampled-data systems by applying it to the robust internal (exponential) stability analysis of sampled-data systems. Furthermore, since the transfer operator is relevant

to the input-output characteristics, we apply the results of the spectral analysis to relate (robust) L_2-stability and (robust) internal stability in the context of sampled-data systems. The consequent result is not surprising, but to the best knowledge of the author, studies relating robust L_2-stability and robust internal stability in the context of sampled-data systems are rare, with the study by the author and a colleague in [9] being an exception. Nevertheless, that study in [9] is limited to the case of additive and multiplicative perturbations, unfortunately, and it is quite hard to extend it to the general case. The present paper shows that our spectral analysis provides a simple and rigorous proof to relate these two stability notions. Here, it would be worth mentioning that a similar problem of relating L_2-stability and exponential stability has been studied, e.g., in [20, 21] for a class of (ordinary type of) infinite-dimensional systems, but those studies do not cover the present setting nor do our developments here follow similar techniques to those employed therein.

The contents of this paper are as follows. In section 2, we review the notion of the transfer operator $\widehat{G}(z)$ of sampled-data systems with a slight but crucial extension (i.e., its nonasymptotic characterization). This characterization allows us to introduce some appropriate nonzero initial states to the study of the mapping defined by the transfer operator, and makes it fairly easy to carry out the following discussions (e.g., the derivations of Theorem 5 and Proposition 7). In section 3, we study the spectral properties of the transfer operators, and show that they are nearly as amenable as those of compact normal operators, even though the transfer operators are generally noncompact and nonnormal. Based on these properties, we further show that the spectrum of the transfer operator $\widehat{G}(z)$ can be characterized with finite-dimensional eigenvalue problems for each z such that $\widehat{G}(z)$ is well-defined. Section 4 applies the spectral study in section 3 to the study of robust internal (exponential) stability of sampled-data systems against perturbations. More specifically, subsection 4.1 studies the case where the perturbations are identities up to a real scalar constant, and the basic result for this case is applied in subsection 4.2 to the study of robust internal stability of sampled-data systems with general perturbations. In particular, we give a rigorous proof to the equivalence of robust L_2-stability and robust internal stability when the nominal sampled-data system and perturbations are internally stable; roughly speaking, we show that whatever robust internal stability/robust performance problems we may consider in the sampled-data setting, the conditions in the L_2-stability context are enough to guarantee the robust stability/performance in the internal stability context, provided that the perturbations belong to the class of internally stable finite-dimensional LTI (linear time-invariant) or h-periodic systems (where h is the sampling period). Section 5 concludes the paper with some remarks.

We use the following notation in this paper: $\lambda(\cdot)$ denotes the set of the eigenvalues of a finite-dimensional matrix, while $\sigma(\cdot)$ denotes the spectrum of an operator. $\sigma_{le}(\cdot)$, $\sigma_{re}(\cdot)$, and $\sigma_e(\cdot)$ denote the left essential, right essential, and essential spectrum, respectively, [22]. Furthermore, whenever we refer to internal stability in what follows, it means exponential stability.

2. Transfer operators of sampled-data systems. In this paper, we deal with the sampled-data system Σ_0 shown in Figure 1, where P denotes the continuous-time generalized plant, Ψ the discrete-time controller, $\mathcal{H}$ the zero-order hold, and $\mathcal{S}$ the ideal sampler. Solid lines represent continuous-time (vector) signals, while dashed lines discrete-time (vector) signals. The underlying sampling period will be denoted by h. We assume that the state-space representations of P and Ψ are given,

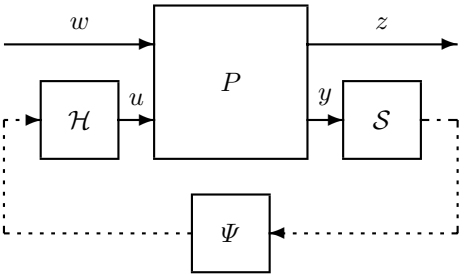

FIG. 1. *Open-loop sampled-data system* Σ_0.

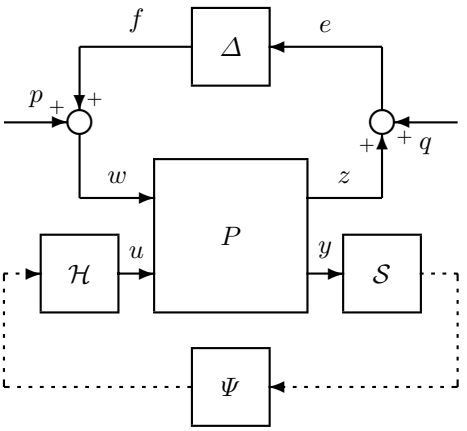

FIG. 2. *Closed-loop sampled-data system* Σ_Δ.

respectively, by

$$\begin{aligned} \frac{dx}{dt} &= Ax + B_1 w + B_2 u \\ z &= C_1 x + D_{11} w + D_{12} u \\ y &= C_2 x \end{aligned} \tag{1}$$

and

$$\begin{aligned} \xi_{k+1} &= A_\Psi \xi_k + B_\Psi y_k \\ u_k &= C_\Psi \xi_k + D_\Psi y_k, \end{aligned} \tag{2}$$

where $y_k = y(kh)$ and $u(t) = u_k$ $(kh \le t < (k+1)h)$. In the following arguments, we assume that Σ_0 is internally (exponentially) stable [13, 23]. For lack of better terminologies, we call Σ_0 an open-loop sampled-data system, while if w is given as $w = \Delta z$ with some causal mapping Δ, then we call the resulting system a closed-loop sampled-data system, which we denote by Σ_Δ. Also, the corresponding input-output mapping from $[p^T,\ q^T]^T$ to $[f^T,\ z^T]^T$ in Figure 2 will be denoted by $\mathcal{G}_\Delta$ in the following, when it is well-defined. If $\mathcal{G}_\Delta$ maps L_2 into L_2, and if its L_2-induced norm is bounded, then $\mathcal{G}_\Delta$ is said to be L_2-stable. In subsection 2.1, we review the lifted description and transfer operator [1, 2, 10, 11, 15] of the open-loop sampled-data system Σ_0. Then, in subsection 2.2, a slightly different interpretation of the transfer operators of sampled-data systems is given.

2.1. Lifted description and transfer operators of sampled-data systems. With a slight abuse of notation, the Hilbert space of square integrable vector functions over the time interval $[0, h)$ with the standard inner product will be denoted by $\mathcal{K}$, whatever the dimension of the vector may be. The Euclidean space with dimension $\dim(x)$ will be denoted by $\mathcal{F}_x$. We also define $\mathcal{F}_u$ and $\mathcal{F}_\xi$ in a similar way, and we further define $\mathcal{F} := \mathcal{F}_x \oplus \mathcal{F}_\xi$. Now, introduce the following matrices A_d, B_{d2}, and C_{d2}, and the operators $\mathbf{B}_1$, $\mathbf{C}_1$, $\mathbf{D}_{11}$, and $\mathbf{D}_{12}$:

$$A_d := \exp(Ah), \quad B_{d2} := \int_0^h \exp(A\sigma)B_2 d\sigma, \quad C_{d2} := C_2 \tag{3}$$

$$\mathbf{B}_1 : \ \mathcal{K} \ni w \mapsto \int_0^h \exp\left(A(h-\sigma)\right)B_1 w(\sigma)d\sigma \in \mathcal{F}_x \tag{4}$$

$$\mathbf{C}_1 : \ \mathcal{F}_x \ni x \mapsto z \in \mathcal{K}, \quad z(\theta) = C_1 \exp\left(A\theta\right)x \tag{5}$$

$$\mathbf{D}_{11} : \ \mathcal{K} \ni w \mapsto z \in \mathcal{K}, \quad z(\theta) = \int_0^\theta C_1 \exp\left(A(\theta-\sigma)\right)B_1 w(\sigma)d\sigma + D_{11}w(\theta) \tag{6}$$

$$\mathbf{D}_{12} : \ \mathcal{F}_u \ni u \mapsto z \in \mathcal{K}, \quad z(\theta) = \int_0^\theta C_1 \exp\left(A(\theta-\sigma)\right)B_2 d\sigma\, u + D_{12}u. \tag{7}$$

Then, the lifted description of the sampled-data system Σ_0 is given by

$$\chi_{k+1} = \mathcal{A}\chi_k + \mathcal{B}\widehat{w}_k, \quad \widehat{z}_k = \mathcal{C}\chi_k + \mathcal{D}\widehat{w}_k, \tag{8}$$

where $\chi_k := [x(kh)^T,\ \xi_k^T]^T$, and the associated transfer operator $\widehat{G}(z)$ is defined by

$$\widehat{G}(z) := \mathcal{C}(zI - \mathcal{A})^{-1}\mathcal{B} + \mathcal{D}, \tag{9}$$

where

$$\mathcal{A} := \begin{bmatrix} A_d + B_{d2}D_\Psi C_{d2} & B_{d2}C_\Psi \\ B_\Psi C_{d2} & A_\Psi \end{bmatrix} : \ \mathcal{F} \to \mathcal{F}, \quad \mathcal{B} := \begin{bmatrix} \mathbf{B}_1 \\ 0 \end{bmatrix} : \ \mathcal{K} \to \mathcal{F}$$

$$\mathcal{C} := \begin{bmatrix} \mathbf{C}_1 & \mathbf{D}_{12} \end{bmatrix} \begin{bmatrix} I & 0 \\ D_\Psi C_{d2} & C_\Psi \end{bmatrix} : \ \mathcal{F} \to \mathcal{K}, \quad \mathcal{D} := \mathbf{D}_{11} : \ \mathcal{K} \to \mathcal{K}. \tag{10}$$

In (8) above, $\widehat{w}$ and $\widehat{z}$ denote, respectively, the lifted representations of w and z (see the subsequent subsection for details). Note that $\mathcal{A}$ is a finite-dimensional matrix, and that $\widehat{G}(z)$ takes a value on the class of linear bounded operators on $\mathcal{K}$ for each z unless z is an eigenvalue of $\mathcal{A}$. The importance of $\widehat{G}(z)$ lies in that it captures all the intersample behavior (i.e., the aliasing phenomena) in Σ_0 [1, 2, 10, 15, 11].

In the following, we assume $\dim(w) = \dim(z)$ so that D_{11} is square, unless otherwise stated explicitly. Also, with a slight abuse of notation[1], the operator of multiplication by the matrix D_{11} that maps $w(\cdot) \in \mathcal{K}$ to $z(\cdot) = D_{11}w(\cdot) \in \mathcal{K}$ is also denoted by D_{11}. Then, the operator $\mathbf{D}_{11}$ given in (6), known as the compression operator, can be rewritten as $\mathbf{D}_{11} = \mathbf{D}_{110} + D_{11}$ with an obvious definition of $\mathbf{D}_{110}$, and accordingly, $\mathcal{D}$ can also be rewritten as $\mathcal{D} = \mathcal{D}_0 + D_{11}$. Then, $\mathcal{D}_0$ is compact, so that $\mathcal{D}$ (and thus $\widehat{G}(z)$) is compact if and only if $D_{11} = 0$ (see, e.g., [11]).

[1]It will be clear from the context whether D_{11} refers to the operator of multiplication or the underlying matrix. However, it would be worthwhile mentioning that whenever we refer to $\sigma_{le}(D_{11})$, $\sigma_{re}(D_{11})$, and $\sigma_e(D_{11})$, we are talking about D_{11} viewed as an operator, because otherwise these spectra are always empty.

2.2. Nonasymptotic input-output relations about EMP-signals. In this subsection, we aim at giving a "nonasymptotic" characterization of the transfer operator $\widehat{G}(z)$. That interpretation is not surprising and only a slight modification of the well known "asymptotic" interpretation of the transfer operator, and is largely a review of the preliminary part of the arguments in [24], but does play an important role in the subsequent arguments. As such, we review somewhat detailed descriptions for this interpretation. To this end, let us begin by reviewing the lifting technique used in the derivation of the lifted description of sampled-data systems. Given a (vector) signal w over the nonnegative time interval $[0, \infty)$, the lifting operation of w is defined as

$$w \mapsto \{\widehat{w}_k\}_{k=0}^{\infty}, \tag{11}$$

where $\widehat{w}_k$ is given by

$$\widehat{w}_k(\theta) = w(kh + \theta) \quad (0 \le \theta < h,\ k = 0, 1, 2, \cdots). \tag{12}$$

The signal w is called an EMP-signal of characteristic multiplier ζ [25] if its lifted representation satisfies

$$\widehat{w}_k(\theta) = \widehat{w}_0(\theta)\zeta^k \quad (0 \le \theta < h) \tag{13}$$

for some $\widehat{w}_0 \in \mathcal{K}$ and a complex number ζ, where EMP stands for "exponentially modulated periodic." In this case, let us denote the "initial function" $\widehat{w}_0$ of the EMP-signal w by $\widehat{w}_0 = \mathrm{INI}(w)$. Conversely, let us denote by $w = \mathrm{EMP}(\widehat{w}_0)$ the operation of constructing an EMP-signal w from the initial function $\widehat{w}_0$ according to (13) and then (12). Note in these notations that we suppress the underlying characteristic multiplier ζ for simplicity, and that $\mathrm{INI}(w)(\theta)$ is nothing but $w(\theta)$ for $0 \le \theta < h$.

It is a fact [11] that the output z of Σ_0 to the EMP-signal $w = \mathrm{EMP}(\widehat{w}_0)$ with characteristic multiplier $\zeta \notin \lambda(\mathcal{A})$ tends to some EMP-signal $z^\star$ of the same characteristic multiplier ζ and that the initial function $\widehat{z}_0 = \mathrm{INI}(z^\star)$ of the asymptotic response $z^\star$ is given by

$$\widehat{z}_0 = \widehat{G}(\zeta)\widehat{w}_0. \tag{14}$$

Note carefully that $\widehat{z}_0(\theta)$ $(0 \le \theta < h)$ in (14) is generally different from the actual response $z(t)$ $(0 \le t < h)$ of Σ_0 for the *zero initial state* (given by $z = \mathcal{D}\widehat{w}_0$), because the actual response z is not exactly an EMP-signal over the entire nonnegative time interval but it just tends to the EMP signal $z^\star$ as t goes to infinity.

However, given any $\widehat{w}_0 \in \mathcal{K}$, let us take $\widehat{z}_0$ given by (14) for $\zeta \notin \lambda(\mathcal{A})$, and let us construct the EMP-signals $w = \mathrm{EMP}(\widehat{w}_0)$ and $z = \mathrm{EMP}(\widehat{z}_0)$ with characteristic multiplier ζ. Then, it is easy to show that there exists an appropriate initial state χ_0 of Σ_0 (to be more precise, χ_0 is given by $(\zeta I - \mathcal{A})^{-1}\mathcal{B}\widehat{w}_0$) such that this EMP-signal input w *together with the initial state* χ_0 yields exactly the above-constructed EMP-signal output z over the entire nonnegative time interval $[0, \infty)$. Conversely, it is also easy to show that if under some initial state χ_0, the output z of Σ_0 to some EMP-signal input w with characteristic multiplier ζ is exactly an EMP-signal with the same characteristic multiplier over the whole nonnegative time interval $[0, \infty)$, then $\widehat{w}_0 = \mathrm{INI}(w)$ and $\widehat{z}_0 = \mathrm{INI}(z)$ are related by (14).

Now, let us introduce the following definition.

DEFINITION 1. *The EMP-signals w and z with the same characteristic multiplier are said to be consistent with the sampled-data system Σ_0 if there exists an initial state*

χ_0 of Σ_0 such that the input w yields exactly the output z over the entire nonnegative time interval $[0, \infty)$.

Then, the above arguments can be summarized as follows.

LEMMA 2. *Suppose that $\zeta \notin \lambda(\mathcal{A})$. The relation* (14) *holds if and only if the EMP-signals $w = EMP(\widehat{w}_0)$ and $z = EMP(\widehat{z}_0)$ with characteristic multiplier ζ are consistent with the sampled-data system Σ_0.*

3. Characterization of the spectrum of the transfer operator. The purpose of this section is to give a method for determining the spectrum of $\widehat{G}(\zeta)$ for $\zeta \notin \lambda(\mathcal{A})$. To give such a method, it is helpful to begin by studying some spectral properties of $\widehat{G}(\zeta)$. This is done in subsection 3.1, while in subsection 3.2 we give a method to determine $\sigma(\widehat{G}(\zeta))$.

3.1. Preliminary considerations on the spectrum. Let $\lambda(D_{11})$ denote the set of the eigenvalues of the matrix D_{11}. Then, it is easy to show that

$$\begin{aligned} \sigma_{le}(\widehat{G}(\zeta)) = \sigma_{re}(\widehat{G}(\zeta)) = \sigma_e(\widehat{G}(\zeta)) = \sigma_{le}(D_{11}) \\ = \sigma_{re}(D_{11}) = \sigma_e(D_{11}) = \sigma(D_{11}) = \lambda(D_{11}) \end{aligned} \tag{15}$$

(see, e.g., [22], in particular Proposition XI.4.2, and [26], in particular Corollary XXIII.2.5). Since the essential spectrum is a subset of the spectrum, it follows that $\lambda(D_{11})$ is a subset of $\sigma(\widehat{G}(\zeta))$ for any $\zeta \notin \lambda(\mathcal{A})$. Hence, to find all the points in the spectrum of $\widehat{G}(\zeta)$, it is enough for us to construct a method to check if $\gamma \notin \lambda(D_{11})$ is a point in the spectrum of $\widehat{G}(\zeta)$. Thus, we assume $\gamma \notin \lambda(D_{11})$ without loss of generality.

Since $\mathcal{D} = \mathcal{D}_0 + D_{11}$, we have

$$\gamma I - \widehat{G}(\zeta) = (\gamma I - D_{11})(I - \widehat{G}_\gamma(\zeta)), \tag{16}$$

where

$$\widehat{G}_\gamma(z) := (\gamma I - D_{11})^{-1} \left(\mathcal{C}(zI - \mathcal{A})^{-1}\mathcal{B} + \mathcal{D}_0 \right). \tag{17}$$

Hence, by (16), it is obvious that $\gamma I - \widehat{G}(\zeta)$ is invertible if and only if $I - \widehat{G}_\gamma(\zeta)$ is. Since $\widehat{G}_\gamma(\zeta)$ is a compact operator because $\mathcal{D}_0$ is, it follows that $\gamma \notin \lambda(D_{11})$ is a point in the spectrum of $\widehat{G}(\zeta)$ if and only if $\widehat{G}_\gamma(\zeta)$ has an *eigenvalue* at 1. This is an important step for the following discussion, while the following result will also be useful.

LEMMA 3. *If $\gamma_1 \in \partial\sigma(\widehat{G}(\zeta))$ and $\gamma_1 \notin \lambda(D_{11})$, then γ_1 is an isolated point of $\sigma(\widehat{G}(\zeta))$.*

Proof. By (15), the assertion follows immediately from Theorem XI.6.8 of [22]. □

Now, we are in a position to show the following result.

THEOREM 4. *$\sigma(\widehat{G}(\zeta)) \setminus \sigma_e(\widehat{G}(\zeta))$ coincides with $\sigma_p(\widehat{G}(\zeta)) \setminus \sigma_e(\widehat{G}(\zeta))$, where $\sigma_p(\cdot)$ denotes the point spectrum (i.e., the set of the eigenvalues of an operator). Furthermore, every $\gamma \in \sigma_p(\widehat{G}(\zeta)) \setminus \sigma_e(\widehat{G}(\zeta))$ is an isolated point of $\sigma(\widehat{G}(\zeta))$, and has finite multiplicity.*

Remark 3.1. The above assertion is well known for a compact operator and also for a normal operator ([22, Proposition XI.4.6]), but $\widehat{G}(\zeta)$ is generally noncompact and nonnormal. It is not hard to see that the assertion in particular implies that the accumulation points of $\sigma(\widehat{G}(\zeta))$ can exist only at $\sigma_e(\widehat{G}(\zeta)) = \lambda(D_{11})$, which consists

of finitely many points, and that $\sigma(\widehat{G}(\zeta)) \setminus \sigma_e(\widehat{G}(\zeta))$ (and thus $\sigma(\widehat{G}(\zeta))$, too) is a countable set. Hence, this proposition suggests that the properties of the spectrum of $\widehat{G}(\zeta)$ are almost as amenable as that of a compact normal operator.

Proof of Theorem 4. Since $\sigma_e(\widehat{G}(\zeta)) = \lambda(D_{11})$, for the first assertion it is enough to show that $\gamma \notin \lambda(D_{11})$ belongs to $\sigma(\widehat{G}(\zeta))$ only if it is an eigenvalue of $\widehat{G}(\zeta)$. To show this, suppose that $\gamma \notin \lambda(D_{11})$ is a point in $\sigma(\widehat{G}(\zeta))$. Then, by the arguments preceding Lemma 3, $\widehat{G}_\gamma(\zeta)$ has an eigenvalue at 1. This implies that there exists some nonzero $\widehat{w} \in \mathcal{K}$ such that $(I - \widehat{G}_\gamma(\zeta))\widehat{w} = 0$. Hence, it follows from (16) that $(\gamma I - \widehat{G}(\zeta))\widehat{w} = 0$, which implies that γ is an eigenvalue of $\widehat{G}(\zeta)$. This completes the proof for the first assertion.

As for the second assertion, it is a direct consequence from [22, Corollary XI.2.4] that $\gamma \in \sigma_p(\widehat{G}(\zeta)) \setminus \sigma_e(\widehat{G}(\zeta))$ (which we abbreviate as $\sigma_p \setminus \sigma_e$ in what follows) has finite multiplicity, since for $\gamma \notin \lambda(D_{11}) = \sigma_e(\widehat{G}(\zeta))$, $\gamma I - \widehat{G}(\zeta)$ is Fredholm [22]. Thus, it remains only to show that every $\gamma \in \sigma_p \setminus \sigma_e$ is an isolated point of $\sigma(\widehat{G}(\zeta))$. Let $\gamma \in \sigma_p \setminus \sigma_e$. If $\gamma \in \partial\sigma(\widehat{G}(\zeta))$, then the assertion follows immediately from Lemma 3. If $\gamma \notin \partial\sigma(\widehat{G}(\zeta))$, on the other hand, then $\gamma \in \sigma(\widehat{G}(\zeta))$ is an interior point of $\sigma(\widehat{G}(\zeta))$, and thus there exists some ε-neighborhood of γ contained in $\sigma(\widehat{G}(\zeta))$. This, together with the compactness of $\sigma(\widehat{G}(\zeta))$ means that we can take some number γ_1 such that $\gamma_1 \in \partial\sigma(\widehat{G}(\zeta))$ and at the same time γ_1 is not an isolated point of $\sigma(\widehat{G}(\zeta))$, where such γ_1 can always be taken so that $\gamma_1 \notin \lambda(D_{11})$ since $\lambda(D_{11})$ is only a finite set. This contradicts Lemma 3, and hence $\gamma \notin \partial\sigma(\widehat{G}(\zeta))$ cannot occur. This completes the proof. □

3.2. Reduction to a finite-dimensional eigenvalue problem. Theorem 4 tells us that in essence we have only to find the *eigenvalues* of the operator $\widehat{G}(\zeta)$ to determine its spectrum. The purpose of this subsection is to give a result with which we can characterize the eigenvalues of $\widehat{G}(\zeta)$ through a *finite-dimensional* eigenvalue problem, and this is facilitated by the "nonasymptotic" characterization of the transfer operator.

To this end, let us consider the closed-loop sampled-data system $\Sigma_{1/\gamma}$ (i.e., Σ_Δ with Δ set to $\frac{1}{\gamma}I$ in Figure 2), where γ is a nonzero complex number. Let $\zeta \notin \lambda(\mathcal{A})$, and suppose that the responses of w and z in this closed-loop sampled-data system under the input $p = 0$, $q = 0$ and some appropriate initial state $\chi_0 = [x(0)^T,\ \xi_0^T]^T$ are exactly EMP-signals of characteristic multiplier ζ over the entire nonnegative time interval. Then, it follows from Lemma 2 that (14) holds for $\widehat{w}_0 = \mathrm{INI}(w)$ and $\widehat{z}_0 = \mathrm{INI}(z)$. On the other hand, from Figure 2 (recall that $\Delta = \frac{1}{\gamma}I$), it is obvious that $\widehat{w}_0 = \frac{1}{\gamma}\widehat{z}_0$. Hence we are led to

$$(\gamma I - \widehat{G}(\zeta))\widehat{w}_0 = 0. \tag{18}$$

Thus, we can conclude that γ is an eigenvalue of $\widehat{G}(\zeta)$ if $\widehat{w}_0 \neq 0$. This suggests that we can determine the eigenvalues of the transfer operator of the open-loop sampled-data system Σ_0 by considering the responses of the closed-loop sampled-data system $\Sigma_{1/\gamma}$.

Now, when $q = 0$, the continuous-time part of $\Sigma_{1/\gamma}$ is described by

$$\frac{dx}{dt} = A_\gamma x + B_{1\gamma} p + B_{2\gamma} u, \quad z = C_{1\gamma} x + D_{11\gamma} p + D_{12\gamma} u, \quad y = C_2 x, \tag{19}$$

where

$$A_\gamma := A+B_1(\gamma I-D_{11})^{-1}C_1, \quad B_{1\gamma} := \gamma B_1(\gamma I-D_{11})^{-1}, \quad B_{2\gamma} := B_2+B_1(\gamma I-D_{11})^{-1}D_{12},$$

$$C_{1\gamma} := \gamma(\gamma I - D_{11})^{-1}C_1, \quad D_{11\gamma} := \gamma(\gamma I - D_{11})^{-1}D_{11}, \quad D_{12\gamma} := \gamma(\gamma I - D_{11})^{-1}D_{12}. \tag{20}$$

Hence, by also letting $p = 0$, the lifted description of this closed-loop "autonomous" sampled-data system $\Sigma_{1/\gamma}$ (i.e., without an external input) is given by

$$\chi_{k+1} = \mathcal{A}_\gamma \chi_k, \quad \widehat{z}_k = \mathcal{C}_\gamma \chi_k, \tag{21}$$

where $\mathcal{A}_\gamma$ and $\mathcal{C}_\gamma$ are, respectively, given by $\mathcal{A}$ and $\mathcal{C}$ in (10) with A, B_2, C_1, and D_{12} replaced by A_γ, $B_{2\gamma}$, $C_{1\gamma}$, and $D_{12\gamma}$ in (20), respectively. Note that $\mathcal{A}_\gamma$ is nothing but the state transition matrix of the "discrete-time equivalent" of $\Sigma_{1/\gamma}$.

We are in a position to state the following theorem.

THEOREM 5. *Given a complex number $\gamma \notin \lambda(D_{11})$ and a complex number $\zeta \notin \lambda(\mathcal{A})$, the operator $\widehat{G}(\zeta)$ has an eigenvalue at γ if and only if $\zeta I - \mathcal{A}_\gamma$ is not invertible.*

Proof. We first establish the assertion assuming $\gamma \neq 0$. Let us first prove the sufficiency. Suppose that $\zeta I - \mathcal{A}_\gamma$ is not invertible.

Then, by the first equation in (21), the system $\Sigma_{1/\gamma}$ has a nontrivial solution of the form

$$\chi_k = \chi_0 \zeta^k \tag{22}$$

for some nonzero initial state χ_0. Hence, by the second equation in (21), we can see that z is an EMP-signal with characteristic multiplier ζ. Since $w = \frac{1}{\gamma} z$, it follows that w is also an EMP-signal with the same characteristic multiplier (carefully note that w and z could be both zero at this stage of our discussion). Thus, by the arguments preceding this theorem, we are led to (18). Therefore, it remains only to show that $\widehat{w}_0 \neq 0$. To show this, suppose the contrary. Then, $w = 0$ so that $\Sigma_{1/\gamma}$ is essentially nothing but Σ_0 with $w = 0$. Then, the existence of the nontrivial solution (22) contradicts the assumption that $\zeta \notin \lambda(\mathcal{A})$.

To prove the necessity, suppose that $\widehat{G}(\zeta)\widehat{w}_0 = \gamma \widehat{w}_0$ for some $\widehat{w}_0 \neq 0$. Then, letting $\widehat{z}_0 := \gamma \widehat{w}_0$, Lemma 2 implies that the EMP-signals $w = \mathrm{EMP}(\widehat{w}_0)$ and $z = \mathrm{EMP}(\widehat{z}_0) = \gamma w$ with characteristic multiplier ζ are consistent with the open-loop sampled-data system Σ_0, so that these two EMP-signals can be represented as the responses of w and z in the closed-loop autonomous (i.e., $p = 0$, $q = 0$) system $\Sigma_{1/\gamma}$ for some appropriate initial state χ_0. Furthermore, since $w \neq 0$ is an EMP-signal, it follows readily that the discrete-time signal $\widehat{w}_k(\theta)$ is represented as $\widehat{w}_0(\theta)\zeta^k$, which is not identically zero as a sequence in k at least for some $\theta \in [0, h)$ (note that the "sampling" of $\widehat{w}_k(\cdot)$ at θ is well defined since the signal w is well behaved as a response of the *autonomous* sampled-data system $\Sigma_{1/\gamma}$). Thus, from a basic property of discrete-time systems, it must be true that ζ is an eigenvalue of the transition matrix of the discrete-time equivalent of $\Sigma_{1/\gamma}$ viewed at every sampling period h, which is given by $\mathcal{A}_\gamma$. This completes the proof for the case of $\gamma \neq 0$.

Finally, let us consider the case of $\gamma = 0$ (note that D_{11} is invertible in this case by the assumption $\gamma \notin \lambda(D_{11})$). In this case, it is enough to consider $\widehat{G}(\zeta) + \alpha I$ ($\alpha \neq 0$) and study the condition for it to have an eigenvalue at α. Noting that considering $\widehat{G}(\zeta) + \alpha I$ instead of $\widehat{G}(\zeta)$ is nothing but replacing D_{11} with $D_{11} + \alpha I$ (for which

$\alpha \notin \lambda(D_{11} + \alpha I)$), and observing the form of A_γ and $B_{2\gamma}$ given in (20), it is easy to see that the statement is valid even when $\gamma = 0$. □

Summarizing the arguments in this section, it follows that Theorems 4 and 5, together with (15), give a method to determine the spectrum of $\widehat{G}(\zeta)$ for each $\zeta \notin \lambda(\mathcal{A})$. That is, every point in $\lambda(D_{11})$ belongs to $\sigma(\widehat{G}(\zeta))$, and the remaining points in the spectrum can be found by searching for γ such that $\zeta I - \mathcal{A}_\gamma$ is not invertible[2]. Since the spectral radius of $\widehat{G}(\zeta)$ is no larger than $\|\widehat{G}(\zeta)\|$, it is enough to consider the disk $\{\gamma : |\gamma| \le \|\widehat{G}(\zeta)\|\}$ in such a search. An easily computable upper bound for $\|\widehat{G}(\zeta)\|$ can be obtained by an obvious extension of Theorem 1 of [27] (i.e., this theorem holds even if $|\zeta| \neq 1$) when $D_{11} = 0$; if $D_{11} \neq 0$, a simple upper bound is obtained from a triangle inequality in which the upper bound is increased by $\|D_{11}\|$. These considerations give a basis for the numerical computation of $\sigma(\widehat{G}(\zeta))$, but we do not pursue numerical studies in this paper. Instead, we advance our study to demonstrate the importance of our spectral analysis for theoretical studies such as the stability and robust stability problems of sampled-data systems.

Remark 3.2. We point out that most of the discussions in this section carries over, without essential difficulties, to the case where the generalized plant P is a finite-dimensional linear continuous-time h-periodic (FDLCP) system and Δ is an internally stable FDLCP system, where h is the sampling period; the only nontrivial point will be the treatment of the essential spectrum. However, it is not hard to see that (15) still holds with $\lambda(D_{11})$ replaced by

$$\lambda_{[0,h]}(D_{11}) := \{\lambda \,|\, \text{the set of } t \in [0,h] \text{ such that } |\det(\lambda I - D_{11}(t))| < \gamma \text{ has nonzero measure whenever } \gamma > 0\}, \tag{23}$$

which follows from section XXIII.2 of [26]. Thus, the arguments in this section still apply *mutatis mutandis*. The only point that requires some more careful arguments will be the isolatedness assertion in Theorem 4, since $\sigma_e(\widehat{G}(\zeta)) = \lambda_{[0,h]}(D_{11})$ can now form a closed curve; thus the arguments in the proof of Theorem 4 are not enough to establish the isolatedness of some eigenvalues within the essential spectrum radius. Fortunately, however, the isolatedness property is not relevant for Theorem 5, which will be used as a major tool in the following section which demonstrates the usefulness of the spectral analysis in this section.

4. Application to robust internal stability problems. In [16, 17], the positive-realness notion was introduced to sampled-data systems and some phase properties of sampled-data systems were also addressed. A more advanced study on the positive-realness of sampled-data systems was pursued, and the positive-realness gap index $\rho_{\min}$ was introduced in [18, 19]. It was also shown in [19] that this index plays an important role in the positive-realness approach (or the passivity approach) to the stability analysis of sampled-data systems. In this section, we first review the above-mentioned study in [19] briefly, and then show that our study in the preceding sections has an important application to such or more general stability and robust stability analysis.

In subsection 4.1, we deal with the gain margin analysis problem of sampled-data systems and derive some useful results by applying the spectral analysis in the

[2]It would be possible to determine the multiplicity of γ as an eigenvalue of $\widehat{G}(\zeta)$ by considering the geometric multiplicity of ζ as an eigenvalue of $\zeta I - \mathcal{A}_\gamma$, if we introduce some sort of controllability/observability conditions. However, we do not pursue this direction in this paper.

preceding section (in particular, Theorem 5). Then, such results will be applied in subsection 4.2 to give a result about robust stability of sampled-data systems.

4.1. Gain margin analysis for internal stability in the sampled-data context. The transfer operator $\widehat{G}(z)$ of the internally stable sampled-data system Σ_0 is said to be strongly positive-real [19] if there exists a positive number ε such that

$$\widehat{G}(z) + \widehat{G}(z)^* \geq \varepsilon I \quad (\forall |z| \geq 1). \tag{24}$$

The transfer operator $\widehat{G}(z)$ is not strongly positive-real, in general, but we can consider the following number:

$$\rho_{\min} := \inf_{\rho > 0} \left\{ \widehat{G}(z) + \rho I \text{ is strongly positive-real} \right\} \geq 0. \tag{25}$$

This number is called the positive-realness gap index for Σ_0, and plays an important role in the stability analysis as shown in [19]; one important result shown about this index is that for $k > 0$, the (negative feedback) closed-loop sampled-data system Σ_{-k} (i.e., Σ_Δ with Δ set to $-kI$), or to be more precise, the input-output mapping $\mathcal{G}_{-k}$ is L_2-stable if $0 < k < k_{\max}^{\mathrm{PR}}$, where

$$k_{\max}^{\mathrm{PR}} := 1/\rho_{\min}. \tag{26}$$

By a suitable construction of the generalized plant P, this "gain margin analysis problem" in the context of sampled-data control can represent a sort of stability-radius analysis problem with respect to the uncertainties in the physical parameters of the plant, and as such, to compute $k_{\max}^{\mathrm{PR}}$ is quite important. In [19], an efficient finite-dimensional state-space method for the computation of $\rho_{\min}$ and thus $k_{\max}^{\mathrm{PR}}$ was given. Furthermore, an iterative procedure was given to compute the number $k_{\max} (\geq k_{\max}^{\mathrm{PR}})$, which is defined as the largest $\bar{k}$ such that Σ_{-k} $(k > 0)$ is *internally* stable for all $k < \bar{k}$. However, in the derivation of that procedure, the following result was used *without proof*; we now give its proof by applying the spectral analysis results in the preceding section so that the procedure for computing $k_{\max}$ given in [19] is validated rigorously.

PROPOSITION 6. *If Σ_0 is internally stable, then Σ_{-k} is internally stable for all $k \in (0, k_{\max}^{\mathrm{PR}})$.*

Proof. Now, suppose the contrary. Then, by the definition of internal stability [13, 23], there exists some $k^\star \in (0, k_{\max}^{\mathrm{PR}})$ such that the state transition matrix of $\Sigma_{-k^\star}$ has an eigenvalue on or outside the unit circle, say at $\zeta^\star$. Therefore, it follows from the definition of $\mathcal{A}_\gamma$ that if we put $-\rho^\star := -1/k^\star$, then $\zeta^\star I - \mathcal{A}_{-\rho^\star}$ is not invertible where $|\zeta^\star| \geq 1$. Here, note that

$$\rho^\star > \rho_{\min} \geq 0 \tag{27}$$

since $0 < k^\star < k_{\max}^{\mathrm{PR}}$ by the assumption. Thus, by the properties of strongly positive-real transfer operators [19], we have $D_{11} + D_{11}^T + 2\rho^\star I > 0$. This in particular implies that $-\rho^\star \notin \lambda(D_{11})$. Summarizing the above arguments and applying Theorem 5, we are led to the conclusion that $\widehat{G}(\zeta^\star)$ has an eigenvalue at $-\rho^\star$. This in particular implies that $\widehat{G}(\zeta^\star) + \widehat{G}(\zeta^\star)^* + 2\rho^\star I \not> 0$. Since $|\zeta^\star| \geq 1$, it follows that $\widehat{G}(z) + \rho^\star I$ is not a strongly positive-real transfer operator, and hence $\rho^\star \leq \rho_{\min}$. This clearly contradicts (27). Hence, we have established that Σ_{-k} is internally stable for all $k \in (0, k_{\max}^{\mathrm{PR}})$. ∎

It would be worthwhile mentioning that the above proposition can be extended to Σ_k $(k > 0)$ by considering $-\widehat{G}(z)$ instead and redefining $\rho_{\min}$ and thus $k_{\max}^{\mathrm{PR}}$ accordingly.

Next, we claim Proposition 7 given below, which plays a crucial role in the robust stability analysis in the following subsection.

PROPOSITION 7. *Suppose that Σ_0 is internally stable. Then, for each fixed k, Σ_k is internally stable if and only if $\mathcal{G}_k$ is L_2-stable.*

Remark 4.1. This proposition does not say that an (open-loop) sampled-data system is internally stable if and only if it is L_2-stable, an assertion (the sufficiency part) that is obviously false; note that this proposition deals only with such (closed-loop) sampled-data systems that can arise from an internally stable sampled-data system. Note also that the condition $1/k \notin \lambda(D_{11})$, which is the well-posedness condition of Σ_k and at the same time the well-definedness condition for $\mathcal{G}_k$, is implicit in the proposition. To be more precise, if we say that Σ_k is internally stable or L_2-stable, it in particular means that $1/k \notin \lambda(D_{11})$. Further, note that this proposition shows in particular that $k_{\max,L_2} = k_{\max}$, where $k_{\max,L_2}$ denotes the largest number $\bar{k}$ such that $\mathcal{G}_k$ is L_2-stable whenever $0 < k < \bar{k}$, while $k_{\max}$ has been defined similarly but in terms of internal stability. It should be stressed, however, that the assertion of the above proposition holds even if $k > k_{\max}$, as long as Σ_k or $\mathcal{G}_k$ is stable for such k.

Proof of Proposition 7. Let us begin with the necessity part. It is not hard to see by the inspection of the procedure for computing $k_{\max}$ given in [19] that the set of k for which Σ_k is internally stable is a subset of those k for which Σ_k is L_2-stable[3]. Hence, the necessity assertion follows immediately. (Instead of this proof that is based on the transfer operator $\widehat{G}(z)$ and the spectral analysis results in the preceding section as a whole, an alternative proof is also possible in which we use the well-known fact that an internally stable sampled-data system is L_2-stable under mild conditions [13, 23].)

To show the sufficiency part, we assume that Σ_k is not internally stable for some k (i.e., $\zeta I - \mathcal{A}_\gamma$ with $\gamma := 1/k$ is not invertible for some $|\zeta| \geq 1$), and show that $\mathcal{G}_k$ is not L_2-stable. Here, it is enough to assume $1/k \notin \lambda(D_{11})$, because otherwise $\mathcal{G}_k$ is not L_2-stable as stated in Remark 4.1.

Since $\zeta \notin \lambda(\mathcal{A})$ by the internal stability assumption of Σ_0, it follows from Theorem 5 that $\widehat{G}(\zeta)\widehat{w}_0 = \gamma\widehat{w}_0$ for some $\widehat{w}_0 \neq 0$. Hence by Lemma 2, there exists an appropriate initial state $\chi_0 = \chi^\star$ of Σ_0 such that $w = \mathrm{EMP}(\widehat{w}_0)$ and $z = \gamma\mathrm{EMP}(\widehat{w}_0)$ are consistent with Σ_0 (the corresponding characteristic multiplier for the EMP signals is ζ throughout the proof). Now, let us denote by $z^\star$ the response of z in Σ_0 when its initial state is $\chi_0 = \chi^\star$ and its input is $w = 0$. Note that $z^\star \in L_2$ by the internal stability of Σ_0, which is well known, e.g., in the context of sampled-data H_2 problem [23]. Also, by linearity, it follows immediately that Σ_0 yields the response $z = \gamma\mathrm{EMP}(\widehat{w}_0) - z^\star$ when the initial state is $\chi_0 = 0$ and the input is $w = \mathrm{EMP}(\widehat{w}_0)$. Hence, it is easy to see that Σ_Δ with $\Delta = (1/\gamma)I$ yields $f = w = \mathrm{EMP}(\widehat{w}_0)$, $z = \gamma\mathrm{EMP}(\widehat{w}_0) - z^\star$, and $e = \gamma\mathrm{EMP}(\widehat{w}_0)$ when the initial state is $\chi_0 = 0$ and the inputs are $p = 0 \in L_2$ and

[3]In a sense, a direct application of the arguments in [19] is limited only to $k \in [0, k_{\max}]$. However, if Σ_k is internally stable for some $k = k^\star \notin [0, k_{\max}]$, then we can readily introduce a modified generalized plant $P_{k^\star}$ such that Σ_k can be viewed as $\Sigma_{k'}^\star$ (and thus $\Sigma_{k^\star}$ can be viewed as the open-loop sampled-data system $\Sigma_0^\star$), where $k' = k - k^\star$ and $\Sigma_k^\star$ denotes Σ_k with P replaced by $P_{k^\star}$ (this idea of introducing a modified generalized plant is quite similar to that employed in the procedure for computing $k_{\max}$; see [19] for details). Hence, we can repeat the same arguments on $\Sigma_k^\star$, which implies that the assertion can be established even for those k around $k^\star \notin [0, k_{\max}]$.

$q = z^\star \in L_2$. Noting that none of these f, w, z, and e belong to L_2 since $|\zeta| \geq 1$, we can conclude that $\mathcal{G}_k$ is not L_2-stable. □

Remark 4.2. Even though it can be seen that Proposition 6 is implied by Proposition 7, it should be noted that the independent proof of Proposition 6 is indispensable. This is because in the proof of Proposition 7, we have referred to the procedure for computing $k_{\max}$ stated in [19], which in turn has been validated rigorously by the very proof of Proposition 6.

4.2. Robust internal stability of sampled-data systems. Now, we are in a position to demonstrate the significance of Proposition 7, not merely in justifying the arguments of [19] about the computation of $k_{\max}$ through Proposition 6. More specifically, we give the following theorem about robust stability of the sampled-data system Σ_Δ, which clarifies the relationship between robust L_2-stability and robust internal (exponential) stability.

THEOREM 8. *Consider the closed-loop sampled-data system Σ_Δ shown in Figure* 2, *where we assume that D_{11} is possibly nonsquare and $\Delta \in \boldsymbol{\Delta}$ for some set $\boldsymbol{\Delta}$ of (possibly nonsquare) finite-dimensional linear time-invariant (FDLTI) internally stable systems, and suppose that Σ_0 is internally stable. Then, Σ_Δ is internally stable for all $\Delta \in \boldsymbol{\Delta}$ if and only if $\mathcal{G}_\Delta$ is L_2-stable for all $\Delta \in \boldsymbol{\Delta}$.*

Proof. The assertion is almost just a direct consequence from Proposition 7, but we need some careful arguments.

Let us begin with the sufficiency proof. Consider the (series-connected) open-loop sampled-data system $\Sigma_0\Delta$, and observe that it can be represented as the open-loop sampled-data system shown in Figure 1 with the generalized plant P replaced by $P_\Delta := P\,\mathrm{diag}[\Delta, I]$ (for which the "D_{11} matrix" is square and thus the preceding arguments apply). Also, by the internal stability assumptions, $\Sigma_0\Delta$ is internally stable. Thus, this reformation corresponds to replacing Σ_0 and Δ by $\Sigma_0\Delta$ and 1, respectively, if we interpret it in the closed-loop sampled-data system in Figure 2; let us denote by $\mathcal{G}'_\Delta$ the corresponding input-output mapping of thus reformed closed-loop sampled-data system. Since $\mathcal{G}_\Delta$ is L_2-stable for each $\Delta \in \boldsymbol{\Delta}$, it is straightforward to show that $\mathcal{G}'_\Delta$ is also L_2-stable for each $\Delta \in \boldsymbol{\Delta}$. Thus, applying Proposition 7 with $k = 1$ leads to the assertion.

To show the necessity, we also consider the closed-loop sampled-data system Σ_Δ with Σ_0 and Δ replaced by $\Delta\Sigma_0$ and 1, respectively, and denote by $\mathcal{G}''_\Delta$ the corresponding input-output mapping. Applying Proposition 7 with $k = 1$, it follows readily that both $\mathcal{G}'_\Delta$ and $\mathcal{G}''_\Delta$ are L_2-stable. In view of the linearity of Σ_0 and Δ (and thus the mapping $\mathcal{G}_\Delta$), it is not hard to show that L_2-stability of $\mathcal{G}'_\Delta$ and $\mathcal{G}''_\Delta$ implies that of $\mathcal{G}_\Delta$.

This completes the proof. □

Remark 4.3. If we recall Remark 3.2, it is not hard to see that Proposition 7 and Theorem 8 still hold even when P (and/or Δ) is a finite-dimensional linear continuous-time h-periodic system. Also, concerning Figure 2, a typical interpretation is that P_{22} (the subsystem from u to y) denotes the nominal plant, while the perturbed (actual) plant is represented by the upper LFT (linear fractional transformation) $\mathcal{F}_u(P, \Delta) =: P_{22\Delta}$. Since uncontrollable/unobservable modes do not affect internal (exponential) stability if and only if they are stable, this theorem in particular says that

(i) any robust stability condition such as the small-gain condition in particular guarantees that no unstable pole/zero cancellations can occur within $P_{22\Delta}$, irrespectively of Δ belonging to the perturbation set $\boldsymbol{\Delta}$ that the condition takes care of,

and it is obvious that

(ii) the discrete-time controller Ψ internally (exponentially) stabilizes any stabilizable detectable plants whose minimal realization coincides with that of $P_{22\Delta}$ for some Δ in the corresponding $\boldsymbol{\Delta}$.

In particular, (ii) implies that Ψ could internally stabilize also a lower-order plant than the generalized plant (because of stable pole/zero cancellations via Δ), even though this might not be necessarily clear in the above arguments where we treated Δ in such a way that it has an *independent state* from the nominal plant.

One important perturbation set $\boldsymbol{\Delta}$ is the set of norm-bounded LTI perturbations, for which the small-gain condition can be very conservative [6, 8]. To get around such conservatism, a necessary and sufficient condition has been derived [6, 8] *in the L_2-stability context*. The above theorem guarantees that such a necessary and sufficient condition is indeed necessary and sufficient for robust *internal* stability; this has already been shown for special perturbations (i.e., additive and multiplicative perturbations), including the case of unstable perturbations [9]. The above theorem in particular extends the previous results to the case of general perturbation structures but with stable perturbations.

To state the importance of this theorem more generally and precisely, we can rephrase it in the following way: whatever allowable perturbation sets/structures we may consider (for example, LTI/h-periodic perturbations, full-block/block-diagonal structures, real-parametric/dynamical perturbations, norm-bounded/unbounded perturbations, connected/nonconnected perturbation sets, convex/nonconvex perturbations with respect to the origin[4], and so on, as well as their arbitrary combinations), considering robust L_2-stability is enough to ensure robust *internal* stability; once a condition for robust L_2-stability under such FDLTI *stable* perturbations is established somehow, the condition automatically guarantees robust *internal* stability. It would also be worth stressing that the theorem applies even to such cases where some part of the perturbations are fictitious and introduced just for the robust performance analysis/synthesis (so that they do not affect internal stability) while the remaining part of the perturbations does represent the plant uncertainty, as in the main loop theorem. Robust internal stability is obviously guaranteed by robust L_2-stability even in such cases with robust performance taken into consideration.

5. Conclusion. In this paper, we first gave a nonasymptotic characterization of the transfer operator $\widehat{G}(z)$ of sampled-data systems, so that some appropriate nonzero initial states can be introduced into the study of the transfer operator $\widehat{G}(z)$. Based on such a characterization, we then studied the spectral properties of the transfer operator $\widehat{G}(z)$. More specifically, it was shown that the properties of the spectrum of $\widehat{G}(z)$ are nearly as amenable as those of compact normal operators, in spite of the generally noncompact and nonnormal nature of $\widehat{G}(z)$, and that the spectrum can be characterized with finite-dimensional eigenvalue problems. Exploiting a close relation with the eigenvalue problems and the condition for internal stability of sampled-data systems, we further extended our arguments on the spectral analysis of $\widehat{G}(z)$ to the robust internal stability analysis of sampled-data systems. To summarize the results very concisely, what we have shown is that robust L_2-stability and robust internal (exponential) stability are equivalent irrespective of the perturbation structures/sets to be considered, if the nominal sampled-data system is internally stable, if the

[4]We say here that $\boldsymbol{\Delta}$ is convex with respect to the origin if $\Delta \in \boldsymbol{\Delta}$ implies $k\Delta \in \boldsymbol{\Delta}$ for all $k \in [0, 1]$.

perturbations are either finite-dimensional LTI or h-periodic, and if the perturbations are internally stable. Although we confined our input-output stability notion to L_2-stability in this paper, it is not hard to see that Proposition 7 and thus Theorem 8 hold even if L_2-stability is replaced by L_p-stability, where $1 \leq p < \infty$. Hence, a solid theoretical basis is established for the robust stabilization/performance design for sampled-data systems even when it is carried out only under such input-output stability conditions as in [6]. Finally, it will be worthwhile mentioning that all the results in section 4 can be specialized to the continuous-time setting without any changes (since a continuous-time system can always be embedded into the class of sampled-data systems), and can readily be generalized to the discrete-time setting.

STOCHASTIC APPROXIMATIONS AND DIFFERENTIAL INCLUSIONS*

MICHEL BENAÏM†, JOSEF HOFBAUER‡, AND SYLVAIN SORIN§

Abstract. The dynamical systems approach to stochastic approximation is generalized to the case where the mean differential equation is replaced by a differential inclusion. The limit set theorem of Benaïm and Hirsch is extended to this situation. Internally chain transitive sets and attractors are studied in detail for set-valued dynamical systems. Applications to game theory are given, in particular to Blackwell's approachability theorem and the convergence of fictitious play.

Key words. stochastic approximation, differential inclusions, set-valued dynamical systems, chain recurrence, approachability, game theory, learning, fictitious play

1. Introduction.

1.1. Presentation. A powerful method for analyzing stochastic approximations or recursive stochastic algorithms is the so-called ODE (ordinary differential equation) method, which allows us to describe the limit behavior of the algorithm in terms of the asymptotics of a certain ODE,

$$\frac{dx}{dt} = F(x),$$

obtained by suitable averaging.

This method was introduced by Ljung [24] and extensively studied thereafter (see, e.g., the books by Kushner and Yin [23] or Duflo [14] for a comprehensive introduction and further references). However, until recently most works in this direction have assumed the simplest dynamics for F, for example, that F is linear or given by the gradient of a cost function. While this type of assumption makes perfect sense in engineering applications (where algorithms are often designed to minimize a cost function), there are several situations, including models of learning or adaptive behavior in games, for which F may have more complicated dynamics.

In a series of papers Benaïm [2, 3] and Benaïm and Hirsch [5] have demonstrated that the asymptotic behavior of stochastic approximation processes can be described with a great deal of generality beyond gradients and other simple dynamics. One of their key results is that the limit sets of the process are almost surely *compact connected attractor free* (or *internally chain transitive* in the sense of Conley [13]) for the deterministic flow induced by F.

The purpose of this paper is to show that such a dynamical system approach easily extends to the situation where the mean ODE is replaced by a differential inclusion. This is strongly motivated by certain problems arising in economics and game theory. In particular, the results here allow us to give a simple and unified presentation of Blackwell's approachability theorem, Smale's results on the prisoner's dilemma, and convergence of fictitious play in potential games. Many other applications[1] will be considered in a forthcoming paper, by Benaïm, Hofbauer, and Sorin [7], the present one being mainly devoted to theoretical issues.

The organization of the paper is as follows. Part 1 introduces the different notions of solutions, perturbed solutions, and stochastic approximations associated with a differential inclusion. Part 2 is devoted to the presentation of two classes of examples. Part 3 is a general study of the dynamical system defined by a differential inclusion. The main result (Theorem 3.6) on the limit set of a perturbed solution being internally chain transitive is stated. Then related notions—invariant and attracting sets, attractors, and Lyapunov functions—are analyzed. Part 4 contains the proof of the limit set theorem. Finally, Part 5 applies the previous results to two adaptive processes in game theory: approachability and fictitious play.

1.2. The differential inclusion. Let F denote a set-valued function mapping each point $x \in \mathbb{R}^m$ to a set $F(x) \subset \mathbb{R}^m$. We suppose throughout that the following holds.

Hypothesis 1.1 (standing assumptions on F).

(i) F is a closed set-valued map. That is,

$$\mathrm{Graph}(F) = \{(x, y) : y \in F(x)\}$$

is a closed subset of $\mathbb{R}^m \times \mathbb{R}^m$.

(ii) $F(x)$ is a nonempty compact convex subset of $\mathbb{R}^m$ for all $x \in \mathbb{R}^m$.

(iii) There exists $c > 0$ such that for all $x \in \mathbb{R}^m$

$$\sup_{z \in F(x)} \|z\| \leq c(1 + \|x\|),$$

where $\|\cdot\|$ denotes any norm on $\mathbb{R}^m$.

Definition I. *A* solution *for the differential inclusion*

$$\frac{d\mathbf{x}}{dt} \in F(\mathbf{x}) \tag{I}$$

with initial point $x \in \mathbb{R}^m$ is an absolutely continuous mapping $\mathbf{x} : \mathbb{R} \to \mathbb{R}^m$ such that $\mathbf{x}(0) = x$ and

$$\frac{d\mathbf{x}(t)}{dt} \in F(\mathbf{x}(t))$$

for almost every $t \in \mathbb{R}$.

Under the above assumptions, it is well known (see Aubin and Cellina [1, Chapter 2.1] or Clarke et al. [12, Chapter 4.1]) that (I) admits (typically nonunique) solutions through every initial point.

[1] As pointed out to us by an anonymous referee, applications to resource sharing may be considered as in Buche and Kushner [11], where the dynamics are given by a differential inclusion. Possible applications to engineering include dry friction; see, e.g., Kunze [22].

Remark 1.2. Suppose that a differential inclusion is given on a compact convex set $C \subset \mathbb{R}^m$, of the form $F(x) = \Phi(x) - x$, such that $\Phi(x) \subset C$ for all $x \in C$ and Φ satisfies Hypothesis 1.1(i) and (ii), with $\mathbb{R}^m$ replaced by C. Then we can extend it to a differential inclusion defined on the whole space $\mathbb{R}^m$: For $x \in \mathbb{R}^m$ let $P(x) \in C$ denote the unique point in C closest to x, and define $F(x) = \Phi(P(x)) - x$. Then F satisfies Hypothesis 1.1.

1.3. Perturbed solutions. The main object of this paper is paths which are obtained as certain (deterministic or random) perturbations of solutions of (I).

DEFINITION II. *A continuous function* $\mathbf{y} : \mathbb{R}_+ = [0, \infty) \to \mathbb{R}^m$ *will be called a* perturbed solution *to* (I) *(we also say a perturbed solution to* F*) if it satisfies the following set of conditions* (II):

(i) $\mathbf{y}$ *is absolutely continuous.*

(ii) *There exists a locally integrable function* $t \mapsto U(t)$ *such that*

(a)
$$\lim_{t\to\infty} \sup_{0\le v\le T} \left\| \int_t^{t+v} U(s)\, ds \right\| = 0$$
for all $T > 0$*; and*

(b) $\frac{d\mathbf{y}(t)}{dt} - U(t) \in F^{\delta(t)}(\mathbf{y}(t))$ *for almost every* $t > 0$*, for some function* $\delta : [0, \infty) \to \mathbb{R}$ *with* $\delta(t) \to 0$ *as* $t \to \infty$*. Here* $F^\delta(x) := \{y \in \mathbb{R}^m : \exists z : \|z - x\| < \delta,\ d(y, F(z)) < \delta\}$ *and* $d(y, C) = \inf_{c\in C} \|y - c\|$.

The purpose of this paper is to investigate the long-term behavior of $\mathbf{y}$ and to describe its limit set
$$L(\mathbf{y}) = \bigcap_{t\ge 0} \overline{\{\mathbf{y}(s) : s \ge t\}}$$
in terms of the dynamics induced by F.

1.4. Stochastic approximations. As will be shown here, a natural class of perturbed solutions to F arises from certain stochastic approximation processes.

DEFINITION III. *A discrete time process* $\{x_n\}_{n\in\mathbb{N}}$ *living in* $\mathbb{R}^m$ *is a* solution for (III) *if it verifies a recursion of the form*

$$x_{n+1} - x_n - \gamma_{n+1} U_{n+1} \in \gamma_{n+1} F(x_n), \tag{III}$$

where the characteristics γ *and* U *satisfy*

- $\{\gamma_n\}_{n\ge 1}$ *is a sequence of nonnegative numbers such that*
$$\sum_n \gamma_n = \infty, \qquad \lim_{n\to\infty} \gamma_n = 0;$$
- $U_n \in \mathbb{R}^m$ *are (deterministic or random) perturbations.*

To such a process is naturally associated a continuous time process as follows.

DEFINITION IV. *Set*
$$\tau_0 = 0 \quad \textit{and} \quad \tau_n = \sum_{i=1}^{n} \gamma_i \quad \textit{for } n \ge 1,$$
and define the continuous time affine interpolated process $\mathbf{w} : \mathbb{R}_+ \to \mathbb{R}^m$ *by*

$$\mathbf{w}(\tau_n + s) = x_n + s\frac{x_{n+1} - x_n}{\tau_{n+1} - \tau_n}, \quad s \in [0, \gamma_{n+1}). \tag{IV}$$

1.5. From interpolated process to perturbed solutions. The next result gives sufficient conditions on the characteristics of the discrete process (III) for its interpolation (IV) to be a perturbed solution (II). If (U_i) are random variables, assumptions (i) and (ii) below have to be understood with probability one.

PROPOSITION 1.3. *Assume that the following hold:*

(i) *For all* $T > 0$

$$\lim_{n\to\infty} \sup \left\{ \left\| \sum_{i=n}^{k-1} \gamma_{i+1} U_{i+1} \right\| : k = n+1, \dots, m(\tau_n + T) \right\} = 0,$$

where

$$m(t) = \sup\{k \geq 0 : t \geq \tau_k\}; \tag{1.1}$$

(ii) $\sup_n \|x_n\| = M < \infty$.

Then the interpolated process $\mathbf{w}$ *is a perturbed solution of* F.

Proof. Let $\mathbf{U}, \gamma : \mathbb{R}_+ \to \mathbb{R}^m$ denote the continuous time processes defined by

$$\mathbf{U}(\tau_n + s) = U_{n+1}, \qquad \gamma(\tau_n + s) = \gamma_{n+1}$$

for all $n \in \mathbb{N}$, $0 \leq s < \gamma_{n+1}$.

Then, for any t,

$$\mathbf{w}(t) \in x_{m(t)} + (t - \tau_{m(t)})[\mathbf{U}(t) + F(x_{m(t)})];$$

hence

$$\dot{\mathbf{w}}(t) \in \mathbf{U}(t) + F(x_{m(t)}).$$

Let us set $\delta(t) = \|\mathbf{w}(t) - x_{m(t)}\|$. Then obviously

$$F(x_{m(t)}) \subset F^{\delta(t)}(\mathbf{w}(t)).$$

In addition,

$$\delta(t) \leq \gamma_{m(t)+1}[\|U_{m(t)+1}\| + c(1 + M)]$$

hence goes to 0, using hypothesis (i) of the statement of the proposition. It remains to check condition (ii)(a) of (II), but one has

$$\left\| \int_t^{t+v} \mathbf{U}(s)ds \right\| \leq \gamma_{m(t)+1} \|U_{m(t)+1}\| + \left\| \sum_{\ell=m(t)+1}^{m(t+v)-1} \gamma_{\ell+1} U_{\ell+1} \right\|$$
$$+ \gamma_{m(t+v)+1} \|U_{m(t+v)+1}\|,$$

and the result follows from condition (i). □

Sufficient conditions. Let $(\Omega, \mathcal{F}, P)$ be a probability space and $\{\mathcal{F}_n\}_{n\geq 0}$ a filtration of $\mathcal{F}$ (i.e., a nondecreasing sequence of sub-σ-algebras of $\mathcal{F}$). We say that a stochastic process $\{x_n\}$ given by (III) satisfies the *Robbins–Monro condition with martingale difference noise* (Kushner and Yin [23]) if its characteristics satisfy the following:

(i) $\{\gamma_n\}$ is a deterministic sequence.

(ii) $\{U_n\}$ is *adapted* to $\{\mathcal{F}_n\}$. That is, U_n is measurable with respect to $\mathcal{F}_n$ for each $n \geq 0$.

(iii) $\mathsf{E}(U_{n+1} \mid \mathcal{F}_n) = 0$.

The next proposition is a classical estimate for stochastic approximation processes. Note that F does not appear. We refer the reader to (Benaïm [3, Propositions 4.2 and 4.4]) for a proof and further references.

PROPOSITION 1.4. *Let* $\{x_n\}$ *given by* (III) *be a Robbins–Monro equation with martingale difference noise process. Suppose that one of the following condition holds:*

(i) *For some* $q \geq 2$

$$\sup_n \mathsf{E}(\|U_n\|^q) < \infty$$

and

$$\sum_n \gamma_n^{1+q/2} < \infty.$$

(ii) *There exists a positive number* Γ *such that for all* $\theta \in \mathbb{R}^m$

$$\mathsf{E}(\exp(\langle \theta, U_{n+1} \rangle) \mid \mathcal{F}_n) \leq \exp\left(\frac{\Gamma}{2}\|\theta\|^2\right)$$

and

$$\sum_n e^{-c/\gamma_n} < \infty$$

for each $c > 0$.

Then assumption (i) *of Proposition* 1.3 *holds with probability* 1.

Remark 1.5. Typical applications are

(i) U_n uniformly bounded in L^2 and $\gamma_n = \frac{1}{n}$,

(ii) U_n uniformly bounded and $\gamma_n = o(\frac{1}{\log n})$.

2. Examples.

2.1. A multistage decision making model. Let A and B be measurable spaces, respectively called the *action space* and the *states of nature*; $E \subset \mathbb{R}^m$ a convex compact set called the *outcomes space*; and $H : A \times B \to E$ a measurable function, called the *outcome* function.

At discrete times $n = 1, 2 \ldots$ a decision maker (DM) chooses an action a_n from A and observes an outcome $H(a_n, b_n)$. We suppose the following.

(A) The sequence $\{a_n, b_n\}_{n \geq 0}$ is a random process defined on some probability space $(\Omega, \mathcal{F}, P)$ and adapted to some filtration $\{\mathcal{F}_n\}$. Here $\mathcal{F}_n$ has to be understood as the history of the process until time n.

(B) Given the history $\mathcal{F}_n$, DM and nature act independently:

$$\mathsf{P}((a_{n+1}, b_{n+1}) \in da \times db \mid \mathcal{F}_n) = \mathsf{P}(a_{n+1} \in da \mid \mathcal{F}_n)\mathsf{P}(b_{n+1} \in db \mid \mathcal{F}_n)$$

for any measurable sets $da \subset A$ and $db \subset B$.

(C) DM keeps track of only the cumulative average of the past outcomes,

$$x_n = \frac{1}{n}\sum_{i=1}^{n} H(a_i, b_i), \tag{2.1}$$

and his decisions are based on this average. That is,

$$\mathsf{P}(a_{n+1} \in da \mid \mathcal{F}_n) = Q_{x_n}(da),$$

where $Q_x(\cdot)$ is a probability measure over A for each $x \in E$, and $x \in E \mapsto Q_x(da) \in [0,1]$ is measurable for each measurable set $da \subset A$. The family $Q = \{Q_x\}_{x \in E}$ is called a *strategy* for DM.

Assumption (C) can be justified by considerations of limited memory and bounded rationality. It is partially motivated by Smale's approach to the prisoner's dilemma [27] (see also Benaïm and Hirsch [4, 5]), Blackwell's approachability theory ([8]; see also Sorin [28]), as well as fictitious play (Brown [10], Robinson [26]) and stochastic fictitious play (Benaïm and Hirsch [6], Fudenberg and Levine [15], Hofbauer and Sandholm [20]) in game theory (see the examples below).

For each $x \in E$ let

$$C(x) = \left\{ \int_{A \times B} H(a,b) Q_x(da) \nu(db) : \nu \in \mathcal{P}(B) \right\},$$

where $\mathcal{P}(B)$ denotes the set of probability measures over B. Then clearly

$$\mathsf{E}(H(a_{n+1}, b_{n+1}) \mid \mathcal{F}_n) \in C(x_n) \subset \overline{C}(x_n),$$

where $\overline{C}$ denote the smallest closed set-valued extension of C with convex values. More precisely, the graph of $\overline{C}$ is the intersection of all closed subsets $G \subset E \times E$ for which the fiber $G_x = \{y \in E : (x,y) \in G\}$ is convex and contains $C(x)$.

For $x \in \mathbb{R}^m$ let $P(x)$ denote the unique point in E closest to x. Extend $\overline{C}$ as in Remark 1.2 to a set-valued map on $\mathbb{R}^m$ by setting

$$\widehat{C}(x) = \overline{C}(P(x)).$$

Then the map

$$F(x) = -x + \overline{C}(P(x)) = -x + \widehat{C}(x) \tag{2.2}$$

clearly satisfies Hypothesis 1.1, and $\{x_n\}$ verifies the recursion

$$x_{n+1} - x_n = \frac{1}{n+1}(-x_n + H(a_{n+1}, b_{n+1})),$$

which can be rewritten as (see (III))

$$x_{n+1} - x_n \in \gamma_{n+1}[F(x_n) + U_{n+1}]$$

with $\gamma_n = \frac{1}{n}$ and $U_{n+1} = H(a_{n+1}, b_{n+1}) - \int_A H(a, b_{n+1}) Q_{x_n}(da)$. Hence, the conditions of Proposition 1.4 are satisfied and one deduces the following claim.

PROPOSITION 2.1. *The affine continuous time interpolated process* (IV) *of the process* $\{x_n\}$ *given by* (2.1) *is almost surely a perturbed solution of* F *defined by* (2.2).

Example 2.2 (Blackwell's approachability theory). A set $\Lambda \subset E$ is said to be *approachable* if there exists a strategy Q such that $x_n \to \Lambda$ almost surely. Blackwell [8] gives conditions ensuring approachability. We will show in section 5.1 how Blackwell's results can be partially derived from our main results and generalized (Corollary 5.2) in certain directions.

2.2. Learning in games. The preceding formalism is well suited to analyzing certain models of learning in games.

Consider the situation where m players are playing a game over and over. Let A^i (for $i \in I = \{1, \dots, m\}$) be a finite set representing the actions (pure strategies) available to player i, and let X^i be the finite dimensional simplex of probabilities over A^i (the set of mixed strategies for player i). For $i \in I$ we let A^{-i} and X^{-i} respectively denote the actions and mixed strategies available to the opponents of i. The payoff function to player i is given by a function $U^i : A^i \times A^{-i} \to \mathbb{R}$. As usual, we extend U^i to a function (still denoted U^i) on $X^i \times X^{-i}$, by multilinearity.

Example 2.3 (fictitious and stochastic fictitious play). Consider the game from the viewpoint of player i so that the DM is player i, and "nature" is given by the other players. In fictitious or stochastic fictitious play the outcome space is the space $X^i \times X^{-i}$ of mixed strategies, and the outcome function is the "identity" function $H : A^i \times A^{-i} \to X^i \times X^{-i}$ mapping every profile of actions a to the corresponding profile of mixed strategy δ_a.

Let

$$BR^i(x^{-i}) = \operatorname*{Argmax}_{a^i \in A^i} U^i(a^i, x^{-i}) \subset A^i$$

be the set of best actions that i can play in response to x^{-i}.

Both classical fictitious play (Brown [10], Robinson [26]) and stochastic fictitious play (Benaïm and Hirsch [6], Fudenberg and Levine [15], Hofbauer and Sandholm [20]) assume that the strategy of player i, $Q^i = \{Q^i_x\}$, can be written as

$$Q^i_x(a^i) = q^i(a^i, x^{-i}),$$

where $q^i : A^i \times X^{-i} \to [0, 1]$ is such that one of the following assumptions holds:

fictitious play assumption:

$$\sum_{a^i \in BR^i(x^{-i})} q^i(a^i, x^{-i}) = 1,$$

or *stochastic fictitious play assumption*, q^i is smooth in x^{-i} and

$$\sum_{a^i \in BR^i(x^{-i})} q^i(a^i, x^{-i}) \geq 1 - \delta$$

for some $0 < \delta \ll 1$.

In this framework, if a_ℓ denotes the profile of actions at stage ℓ, one has

$$x_n = \frac{1}{n} \sum_{\ell=1}^{n} a_\ell$$

and

$$x_{n+1} - x_n = \frac{1}{n+1}(a_{n+1} - x_n).$$

Thus for each i

$$\mathsf{E}(x^i_{n+1} - x^i_n \mid \mathcal{F}_n) \in \frac{1}{n+1}(\overline{BR}^i(x^{-i}_n) - x^i_n),$$

where $\overline{BR}^i(x^{-i}) \subset X^i$ is the convex hull of $BR^i(x^{-i})$ for the standard fictitious play, and $\overline{BR}^i(x^{-i}) = \sum_{a^i \in A^i} q^i(a^i, x^{-i})\delta_{a^i}$ for the stochastic fictitious play.

Thus the set-valued map F defined in (2.2) is given as

$$F^i(x) = -x + \overline{BR}^i(x^{-i}) \times X^{-i}.$$

Observe that if a subset $J \subset I$ of players plays a fictitious (or stochastic fictitious) play strategy, then F^i has to be replaced by

$$F^J(x) = \bigcap_{i \in J} F^i(x).$$

In particular, if all players play a fictitious play strategy, the differential inclusion induced by F is the best-response differential inclusion (Gilboa and Matsui [16], Hofbauer [19], Hofbauer and Sorin [21]), while if all play a stochastic fictitious play, F is a smooth best-response vector field (Benaïm and Hirsch [6], Fudenberg and Levine [15], Hofbauer and Sandholm [20]).

Example 2.4 (Smale approach to the prisoner's dilemma). We still consider the game from the viewpoint of player i, so that the DM is player i and nature the other players, but we take for H the payoff vector function

$$H : A^i \times A^{-i} \to E,$$
$$a \to U(a) = (U^1(a), \dots, U^m(a)),$$

where $E \subset \mathbb{R}^m$ is the convex hull of the payoff vectors $\{U(a)\}$.

This setting fits exactly with Smale's approach to the prisoner's dilemma [27] later revisited by Benaïm and Hirsch [4]. Details will be given in section 5.2, where Smale's approach will be reinterpreted in the framework of approachability.

3. Set-valued dynamical systems.

3.1. Properties of the trajectories of (I). Let $C^0(\mathbb{R}, \mathbb{R}^m)$ denote the space of continuous paths $\{\mathbf{z} : \mathbb{R} \to \mathbb{R}^m\}$ equipped with the topology of uniform convergence on compact intervals. This is a complete metric space for the distance $\mathbf{D}$ defined by

$$\mathbf{D}(\mathbf{x}, \mathbf{z}) = \sum_{k=1}^{\infty} \frac{1}{2^k} \min(\|\mathbf{x} - \mathbf{z}\|_{[-k,k]}, 1),$$

where $\|\cdot\|_{[-k,k]}$ stands for the supremum norm on $C^0([-k, k], \mathbb{R}^m)$.

Given a set $M \subset \mathbb{R}^m$, we let $S_M \subset C^0(\mathbb{R}, \mathbb{R}^m)$ denote the set of all solutions to (I) with initial conditions $x \in M$ ($S_M = \bigcup_{x \in M} S_x$), and $S_{M,M} \subset S_M$ the subset consisting of solutions $\mathbf{x}$ that remain in M (i.e., $\mathbf{x}(\mathbb{R}) \subset M$).

LEMMA 3.1. *Assume M compact. Then S_M is a nonempty compact set and $S_{M,M}$ is a compact (possibly empty) set.*

Proof. The first assertion follows from Aubin and Cellina [1, section 2.2, Theorem 1, p. 104]. The second easily follows from the first. □

3.2. Set-valued dynamical system induced by (I). The differential inclusion (I) induces a set-valued dynamical system $\{\Phi_t\}_{t \in \mathbb{R}}$ defined by

$$\Phi_t(x) = \{\mathbf{x}(t) : \mathbf{x} \text{ is a solution to (I) with } \mathbf{x}(0) = x\}.$$

The family $\Phi = \{\Phi_t\}_{t \in \mathbb{R}}$ enjoys the following properties:

(a) $\Phi_0(x) = \{x\}$;
(b) $\Phi_t(\Phi_s(x)) = \Phi_{t+s}(x)$ for all $t, s \geq 0$;
(c) $y \in \Phi_t(x) \Rightarrow x \in \Phi_{-t}(y)$ for all $x, y \in \mathbb{R}^m$, $t \in \mathbb{R}$;
(d) $(x,t) \mapsto \Phi_t(x)$ is a closed set-valued map with compact values (i.e., $\Phi_t(x)$ is a compact set for each t and x).

Properties (a), (b), (c) are immediate to verify, and property (d) easily follows from Lemma 3.1.

For subsets $T \subset \mathbb{R}$ and $A \subset \mathbb{R}^m$ we will define

$$\Phi_T(A) = \bigcup_{t \in T} \bigcup_{x \in A} \Phi_t(x).$$

Invariant sets.

DEFINITION V. *A set $A \subset \mathbb{R}^m$ is said to be*
(i) strongly invariant *(for Φ) if $A = \Phi_t(A)$ for all $t \in \mathbb{R}$;*
(ii) quasi-invariant *if $A \subset \Phi_t(A)$ for all $t \in \mathbb{R}$;*
(iii) semi-invariant *if $\Phi_t(A) \subset A$ for all $t \in \mathbb{R}$;*
(iv) invariant *(for F) if for all $x \in A$ there exists a solution $\mathbf{x}$ to* (I) *with $\mathbf{x}(0) = x$ and such that $\mathbf{x}(\mathbb{R}) \subset A$.*

We call a set A *strongly positive invariant* if $\Phi_t(A) \subset A$ for all $t > 0$.

At first glance (at least for those used to ordinary differential equations) the good notion might seem to be the one defined by strong invariance. However, this notion is too strong for differential inclusions, as shown by the simple example below (Example 3.2), and the main notions that will really be needed here are invariance and strong positive invariance. We have included the definition of quasi invariance mainly because some of our later results may be related to a paper by Bronstein and Kopanskii [9] making use of this notion.[2] Observe, however, that by Lemma 3.3 below, quasi invariance coincides with invariance for compact sets.

Example 3.2. (a) Let F be the set-valued map defined on $\mathbb{R}$ by $F(x) = -\operatorname{sgn}(x)$ if $x \neq 0$ and $F(0) = [-1, 1]$. Then $\Phi_t(0) = \{0\}$ for $t \geq 0$, and $\Phi_t(0) = [t, -t]$ for $t < 0$. Hence $\{0\}$ is invariant and strongly positively invariant but is not strongly invariant.

(b) Let now $F(x) = x$ for $x < 0$, $F(x) = 1$ for $x > 0$, and $F(0) = [0, 1]$. Then $\Phi_t(0) = \{0\}$ for $t \leq 0$, and $\Phi_t(0) = [0, t]$ for $t \geq 0$. Hence $\{0\}$ is invariant but not strongly positively invariant.

LEMMA 3.3. *Every invariant set is quasi-invariant. Every compact quasi-invariant set is invariant.*

Proof. Suppose that A is invariant. Let $x \in A$ and $\mathbf{x}$ be a solution to (I) with $\mathbf{x}(0) = x$ and $\mathbf{x}(\mathbb{R}) \subset A$. For all $t \in \mathbb{R}$ we have $x \in \Phi_t(\mathbf{x}(-t))$. Hence A is quasi-invariant.

Conversely suppose that A is quasi-invariant and compact. Choose $x \in A$ and fix $N \in \mathbb{N}$. Then for every $p \in \mathbb{N}$ there exists, by quasi invariance and by gluing pieces of solutions together, a solution $\mathbf{x}_{p,N}$ to (I) such that $\mathbf{x}_{p,N}(0) = x$ and for all $q \in \{-2^p, \ldots, 2^p\}$, $\mathbf{x}_{p,N}(\frac{qN}{2^p}) \in A$. By Lemma 3.1, the sequence $\{\mathbf{x}_{p,N}\}_{p \in \mathbb{N}}$ is relatively compact in $C^0([-N, N], \mathbb{R}^m)$. Let $\mathbf{x}_N$ be a limit point of this sequence. Then for each dyadic point $t = \frac{qN}{2^p}$, where $q \in \{-2^p, \ldots, 2^p\}$, $\mathbf{x}_N(t) \in \overline{A}$. Continuity of $\mathbf{x}_N$ implies $\mathbf{x}_N([-N, N]) \subset \overline{A}$. Now let $\mathbf{x}$ be a limit point of the sequence $\{\mathbf{x}_N\}_{N \in \mathbb{N}}$ in $C^0(\mathbb{R}, \mathbb{R}^m)$. Then $\mathbf{x}(\mathbb{R}) \subset \overline{A}$ and $\mathbf{x}$ is a solution to (I). □

[2] Invariant sets in Bronstein and Kopanskii [9] coincide with what we define here as strongly invariant sets.

Remark 3.4. A invariant together with strong positive invariance implies $\Phi_t(A) = A$ for $t > 0$.

3.3. Chain-recurrence and the limit set theorem. Given a set $A \subset \mathbb{R}^m$ and $x, y \in A$, we write $x \hookrightarrow_A y$ if for every $\varepsilon > 0$ and $T > 0$ there exists an integer $n \in \mathbb{N}$, solutions $\mathbf{x}_1, \dots, \mathbf{x}_n$ to (I), and real numbers $t_1, t_2, \dots, t_n$ greater than T such that

(a) $\mathbf{x}_i(s) \in A$ for all $0 \le s \le t_i$ and for all $i = 1, \dots, n$,
(b) $\|\mathbf{x}_i(t_i) - \mathbf{x}_{i+1}(0)\| \le \varepsilon$ for all $i = 1, \dots, n-1$,
(c) $\|\mathbf{x}_1(0) - x\| \le \varepsilon$ and $\|\mathbf{x}_n(t_n) - y\| \le \varepsilon$.

The sequence $(\mathbf{x}_1, \dots, \mathbf{x}_n)$ is called an (ε, T) chain (in A from x to y) for F.

DEFINITION VI. *A set $A \subset \mathbb{R}^m$ is said to be* internally chain transitive, *provided that A is compact and $x \hookrightarrow_A y$ for all $x, y \in A$.*

LEMMA 3.5. *An internally chain transitive set is invariant.*

Proof. Let A be such a set and $x \in A$. Let $(\mathbf{x}_1, \dots, \mathbf{x}_n)$ be an (ε, T) chain from x to x. Set $\mathbf{y}_{\varepsilon,T}(t) = \mathbf{x}_1(t)$ for $0 \le t \le T$ and $\mathbf{z}_{\varepsilon,T}(t) = \mathbf{x}_n(t_n + t)$ for $-T \le t \le 0$. By Lemma 3.1 we can extract from $(\mathbf{y}_{1/p,T})_{p\in\mathbb{N}}$ and $(\mathbf{z}_{1/p,T})_{p\in\mathbb{N}}$ some subsequences converging, respectively, to $\mathbf{y}_T$ and $\mathbf{z}_T$, where $\mathbf{y}_T$ and $\mathbf{z}_T$ are solutions to (I), $\mathbf{y}_T(0) = x = \mathbf{z}_T(0)$, $\mathbf{y}_T([0,T]) \subset A$, and $\mathbf{z}_T([-T,0]) \subset A$. The map $\mathbf{w}_T(t) = \mathbf{y}_T(t)$ for $t \ge 0$ and $\mathbf{w}_T(t) = \mathbf{z}_T(t)$ for $t \le 0$ is then a solution to (I) with initial condition x and such that $\mathbf{w}_T([-T,T]) \subset A$. By Lemma 3.1, again we extract from $(\mathbf{w}_T)_{T\ge 0}$ a subsequence converging to a solution $\mathbf{w}$ whose range lies in A and with initial condition x. □

This notion of recurrence due to Conley [13] for classical dynamical systems is well suited to the description of the asymptotic behavior of a perturbed solution to (I), as shown by the following theorem.

THEOREM 3.6. *Let $\mathbf{y}$ be a bounded perturbed solution to* (I). *Then, the limit set of $\mathbf{y}$,*

$$L(\mathbf{y}) = \bigcap_{t\ge 0} \overline{\{\mathbf{y}(s) : s \ge t\}},$$

is internally chain transitive.

This theorem is the set-valued version of the limit set theorem proved by Benaïm [2] for stochastic approximation and Benaïm and Hirsch [5] for asymptotic pseudotrajectories of a flow. We will deduce it from the more general results of section 4.

3.4. Limit sets. The set

$$\omega_\Phi(x) := \bigcap_{t\ge 0} \overline{\Phi_{[t,\infty)}(x)}$$

is the ω-limit set of a point $x \in \mathbb{R}^m$. Note that $\omega_\Phi(x)$ contains the limit sets $L(\mathbf{x})$ of all solutions $\mathbf{x}$ with $\mathbf{x}(0) = x$ but is in general larger than the union of these.

In contrast to the limit set of a solution, the ω-limit set of a point need not be internally chain transitive.

Example 3.7. Let F be the set-valued map defined on $\mathbb{R}$ by $F(x) = 1 - x$ for $x > 0$ and $F(0) = [0,1]$ and $F(x) = -x$ for $x < 0$. Then for every solution $\mathbf{x}$, one has $\lim_{t\to\infty} \mathbf{x}(t) = 0$ or 1. But $\omega_\Phi(0) = [0,1]$ is not internally chain transitive.

More generally one defines

$$\omega_\Phi(Y) := \bigcap_{t\ge 0} \overline{\Phi_{[t,\infty)}(Y)}.$$

DEFINITION VII. *A set Y is* forward precompact *if $\overline{\Phi_{[t,\infty)}(Y)}$ is compact for some $t > 0$.*

LEMMA 3.8. (i) *$\omega_\Phi(Y)$ is the set of points $p \in \mathbb{R}^m$ such that*

$$p = \lim_{n\to\infty} \mathbf{y}_n(t_n)$$

for some sequence $\{\mathbf{y}_n\}$ of solutions to (I) *with initial conditions $\mathbf{y}_n(0) \in Y$ and some sequence $\{t_n\} \in \mathbb{R}$ with $t_n \to \infty$.*

(ii) *$\omega_\Phi(Y)$ is a closed invariant (possibly empty) set. If Y is forward precompact, then $\omega_\Phi(Y)$ is nonempty and compact.*

Proof. Point (i) is easily seen from the definition.

(ii) Let $p = \lim_{n\to\infty} \mathbf{y}_n(t_n) \in \omega_\Phi(Y)$. Set $\mathbf{z}_n(s) = \mathbf{y}_n(t_n + s)$ for all $s \in \mathbb{R}$. By Lemma 3.1 we may extract from $(\mathbf{z}_n)_{n\geq 0}$ a subsequence converging to some solution $\mathbf{z}$ with $\mathbf{z}(0) = p$ and $\mathbf{z}(s) = \lim_{n_k\to\infty} \mathbf{y}_{n_k}(t_{n_k} + s) \in \omega_\Phi(Y)$. This proves invariance. The rest is clear. □

Note that the limit set $\omega_\Phi(Y)$ is in general not strongly positively invariant (e.g., in Example 3.7 for $x < 0$, $\omega_\Phi(x) = \{0\}$).

3.5. Attracting sets and attractors. For applications it is useful to characterize $L(\mathbf{y})$ in terms of certain compact invariant sets for Φ, namely, *the attractors,* as defined below.

Given a closed invariant set L, the induced set-valued dynamical system Φ^L is the family of (set-valued) mappings $\Phi^L = \{\Phi^L_t\}_{t\in\mathbb{R}}$ defined on L by

$$\Phi^L_t(x) = \{\mathbf{x}(t) : \mathbf{x} \text{ is a solution to (I) with } \mathbf{x}(0) = x \text{ and } \mathbf{x}(\mathbb{R}) \subset L\}.$$

Note that L is strongly invariant for Φ^L.

DEFINITION VIII. *A compact set $A \subset L$ is called an* attracting set *for Φ^L, provided that there is a neighborhood U of A in L (i.e., for the induced topology) with the property that for every $\varepsilon > 0$ there exists $t_\varepsilon > 0$ such that*

$$\Phi^L_t(U) \subset N^\varepsilon(A)$$

for all $t \geq t_\varepsilon$. Or, equivalently, $\Phi^L_{[t_\varepsilon,\infty)}(U) \subset N^\varepsilon(A)$. Here $N^\varepsilon(A)$ stands for the ε-neighborhood of A.

If, additionally, A is invariant, then A is called an attractor *for Φ^L.*

The set U is called a fundamental neighborhood *of A for Φ^L. If $A \neq L$ and $A \neq \emptyset$, then A is called a* proper attracting set *(or* proper attractor*) for Φ^L.*

Furthermore, an attracting set (respectively, attractor) for Φ is an attracting set (respectively, attractor) for Φ^L with $L = \mathbb{R}^m$.

Example 3.9. Let F be the set-valued map from Example 3.2(a), i.e., defined on $\mathbb{R}$ by $F(x) = -\operatorname{sgn}(x)$ if $x \neq 0$ and $F(0) = [-1, 1]$. Then $\{0\}$ is an attractor and every compact set $A \subset \mathbb{R}$ with $0 \in A$ is an attracting set.

PROPOSITION 3.10. *Let A be a nonempty compact subset of L, and U a neighborhood of A in L. Then the following hold:*

(i) *A is an attracting set for Φ^L with fundamental neighborhood U if and only if U is forward precompact and $\omega_{\Phi^L}(U) \subset A$. In this case $\omega_{\Phi^L}(U)$ is an attractor.*

(ii) *A is an attractor for Φ^L with fundamental neighborhood U if and only if U is forward precompact and $\omega_{\Phi^L}(U) = A$.*

Proof. (i) If A is an attracting set for Φ^L with fundamental neighborhood U, then $\omega_{\Phi^L}(U) \subset \bigcap_{\varepsilon>0} N^\varepsilon(A) \subset A$. Conversely, for t large enough $V_t = \overline{\Phi^L_{[t,\infty)}(U)}$ defines a

decreasing family of compact sets converging to $\omega_{\Phi^L}(U) \subset A$. Hence for any $\varepsilon > 0$ there exists t_ε with $V_{t_\varepsilon} \subset N^\varepsilon(A)$ and A is an attracting set. In particular, $\omega_{\Phi^L}(U)$ itself is an attracting set, invariant by Lemma 3.8(ii).

(ii) If $A = \omega_{\Phi^L}(U)$, then A is an attractor by (i). Conversely, if A is an attractor with fundamental neighborhood U, then $\omega_\Phi(U) \subset A$ by (i). Let $x \in A$. Since A is invariant, there exists a solution $\mathbf{y}$ to (I) with $\mathbf{y}(0) = x$ and $\mathbf{y}(\mathbb{R}) \subset A$. Set $\mathbf{y}_n(t) = \mathbf{y}(t-n)$. Then $\mathbf{y}_n(n) = x$, proving that $x \in \omega_{\Phi^L}(U)$ (by Lemma 3.8(i)). □

PROPOSITION 3.11. *Every attractor is strongly positively invariant. (Example* 3.2(a) *provides an attractor that is not strongly invariant.)*

Proof. By invariance, $A \subset \Phi_T^L(A)$ for all $T > 0$. Hence, given $t > 0$,

$$\Phi_t^L(A) \subset \Phi_{t+T}^L(A) \subset \Phi_{t+T}^L(U) \subset \Phi_{[t+T,\infty)}^L(U)$$

for all $T > 0$. Thus $\Phi_t^L(A) \subset N^\varepsilon(A)$ for all $\varepsilon > 0$, and hence $\Phi_t^L(A) \subset A$ for all $t > 0$. □

Remark 3.12. In the family of attracting sets A with a given fundamental neighborhood U, there exists a minimal one, which is in addition invariant, strongly positively invariant, and independent of the set U used to define the family. It is also the largest positively quasi-invariant set included in U.

Any attractor $A \subset L$ can be written as $A = \omega_{\Phi^L}(U)$ for some U. Hence any fundamental neighborhood uniquely determines the attractor A. This implies, as in Conley [13], that Φ^L can have at most countably many attractors.

3.6. Attractors and stability.

DEFINITION IX. *A set $A \subset L$ is* asymptotically stable *for Φ^L if it satisfies the following three conditions:*

(i) *A is invariant.*

(ii) *A is* Lyapunov stable; *i.e., for every neighborhood U of A there exists a neighborhood V of A such that $\Phi_{[0,\infty)}(V) \subset U$.*

(iii) *A is* attractive; *i.e., there is a neighborhood U of A such that for every $x \in U : \omega_\Phi(x) \subset A$.*

Alternatively, instead of (iii) *one could ask for the following weaker requirement:*

(iii′) *There is a neighborhood U of A such that for every solution $\mathbf{x}$ with $\mathbf{x}(0) \in U$ one has $L(\mathbf{x}) \subset A$.*

We show now that for compact sets the concepts of attractor and asymptotic stability are equivalent. The proof of Corollary 3.18 below shows that it makes no difference whether one uses (iii) or (iii′) in the definition of asymptotic stability.

We start with an upper bound for entry times.

LEMMA 3.13. *Let V be an open set and K compact such that for all solutions $\mathbf{x}$ with $\mathbf{x}(0) \in K$ there is $t > 0$ with $\mathbf{x}(t) \in V$. Then there exists $T > 0$ such that for every solution $\mathbf{x}$ with $\mathbf{x}(0) \in K$ there is $t \in [0, T]$ with $\mathbf{x}(t) \in V$.*

Proof. Suppose that there is no such upper bound T for the entry times into V. Then for each $n \in \mathbb{N}$ there is $\mathbf{x}_n(0) = x_n \in K$ and a solution $\mathbf{x}_n$ such that $\mathbf{x}_n(t) \notin V$ for $0 \le t \le n$. Since K is compact, we can assume that $x_n \to x \in K$. And by Lemma 3.1 a subsequence of $\mathbf{x}_n$ converges to a solution $\mathbf{x}$ with $\mathbf{x}(0) = x$ and $\mathbf{x}(t) \notin V$ for all $t > 0$. □

LEMMA 3.14. *If a closed set A is Lyapunov stable, then it is strongly positively invariant.*

Proof. A is the intersection of a family of strongly positively invariant neighborhoods. □

LEMMA 3.15. *If a compact set A satisfies* (ii) *and* (iii′), *it is attracting.*

Proof. Let B be a compact neighborhood of A, included in the fundamental neighborhood U, and let W be a neighborhood of A. A being Lyapunov stable, there exists an open neighborhood V of A with $\Phi^L_{[0,\infty)}(V) \subset W$. For any $x \in B$ and any solution $\mathbf{x}$ with $\mathbf{x}(0) = x$, there exists $t > 0$ with $\mathbf{x}(t) \in V$. Applying Lemma 3.13 implies $\Phi^L_T(B) \subset \Phi^L_{[0,T]}(V)$; hence $\Phi^L_{[T,\infty)}(B) \subset W$ and A is attracting. □

LEMMA 3.16. *If the set A is attracting and strongly positively invariant, then it is Lyapunov stable.*

Proof. Let A be attracting with fundamental neighborhood U, and V be any other (open) neighborhood of A. Then by definition there is $T > 0$ such that $\Phi^L_{[T,\infty)}(U) \subset V$. A being strongly positively invariant, $\Phi^L_{[0,T]}(A) \subset A$. Upper semicontinuity gives an $\varepsilon > 0$ such that $\Phi^L_{[0,T]}(N^\varepsilon(A)) \subset V$ and $N^\varepsilon(A) \subset U$. Hence $\Phi^L_{[0,\infty)}(N^\varepsilon(A)) \subset V$, which shows Lyapunov stability. □

COROLLARY 3.17. *For a compact set A, properties* (ii) *and* (iii′) *of Definition* IX, *together, are equivalent to attracting and strong positive invariance.*

COROLLARY 3.18. *A compact set A is an attractor if and only if it is asymptotically stable.*

We conclude with a simple useful condition ensuring that an open set contains an attractor.

PROPOSITION 3.19. *Let U be an open set with compact closure. Suppose that $\Phi_T(\overline{U}) \subset U$ for some $T > 0$. Then U is a fundamental neighborhood of some attractor A.*

Proof. Since Φ has a closed graph, $\Phi_T(\overline{U})$ is compact. Therefore $\Phi_T(\overline{U}) \subset V \subset \overline{V} \subset U$ for some open set V. By upper semicontinuity of Φ_T (which follows from property (d) of a set-valued dynamical system) there exists $\varepsilon > 0$ such that $\Phi_t(\overline{U}) \subset V$ for $T - \varepsilon \le t \le T + \varepsilon$. Let $t_0 = T(T+1)/\varepsilon$. For all $t \ge t_0$ write $t = kT + r$ with $k \in \mathbb{N}$ and $r < T$. Hence $t = k(T + r/k)$ with $0 \le r/k < \varepsilon$. Thus

$$\Phi_t(\overline{U}) = \Phi_{T+r/k} \circ \cdots \circ \Phi_{T+r/k}(\overline{U}) \subset V.$$

Hence $\omega_\Phi(U) = \bigcap_{t \ge t_0} \overline{\Phi_{[t,\infty)}(U)} \subset \overline{V} \subset U$ is an attractor with fundamental neighborhood U. □

3.7. Chain transitivity and attractors.

PROPOSITION 3.20. *Let L be internally chain transitive. Then L has no proper attracting set for Φ^L.*

Proof. Let $A \subset L$ be an attracting set. By definition, there exists a neighborhood U of A, and for all $\varepsilon > 0$ a number t_ε such that $\Phi^L_t(U) \subset N^\varepsilon(A)$ for all $t > t_\varepsilon$. Assume $A \ne L$ and choose ε small enough so that $N^{2\varepsilon}(A) \subset U$ and there exists $y \in L \setminus N^{2\varepsilon}(A)$. Then, for $T \ge t_\varepsilon$ and $x \in A$, there is no (ε, T) chain from x to y. In fact, $\mathbf{x}_1(0) \in N^{2\varepsilon}(A)$, and hence $\mathbf{x}_1(t_1) \in N^\varepsilon(A)$; by induction, $\mathbf{x}_i(t_i) \in N^\varepsilon(A)$ so that $\mathbf{x}_{i+1}(0) \in N^{2\varepsilon}(A)$ as well. Thus we arrive at a contradiction. □

Remark 3.21. This last proposition can also be deduced from Bronstein and Kopanskii [9, Theorem 1] combined with Lemma 3.1. Also the converse is true.

Recall that an attracting set (respectively, attractor) for Φ is an attracting set (respectively, attractor) for Φ^L with $L = \mathbb{R}^m$.

LEMMA 3.22. *Let A be an attracting set for Φ and L a closed invariant set. Assume $A \cap L \ne \emptyset$. Then $A \cap L$ is an attracting set for Φ^L.*

Proof. The proof follows from the definitions. □

If A is a set, then

$$B(A) = \{x \in \mathbb{R}^m : \omega_\Phi(x) \subset A\}$$

denotes its *basin of attraction*.

THEOREM 3.23. *Let A be an attracting set for Φ and L an internally chain transitive set. Assume $L \cap B(A) \neq \emptyset$. Then $L \subset A$.*

Proof. Suppose $L \cap B(A) \neq \emptyset$. Then there exists a solution $\mathbf{x}$ to (I) with $\mathbf{x}(0) = x \in B(A)$ and $\mathbf{x}(\mathbb{R}) \subset L$. Hence $d(\mathbf{x}(t), A) \to 0$ when $t \to \infty$, proving that L meets A. Proposition 3.20 and Lemma 3.22 imply that $L \subset A$. □

A *global attractor* for Φ is an attractor whose basin of attraction consists of all $\mathbb{R}^m$. If a global attractor exists, then it is unique and coincides with the maximal compact invariant set of Φ. The following corollary is an immediate consequence of Theorem 3.23 or even more easily of Lemma 3.5.

COROLLARY 3.24. *Suppose Φ has a global attractor A. Then every internally chain transitive set lies in A.*

3.8. Lyapunov functions.

PROPOSITION 3.25. *Let Λ be a compact set, $U \subset \mathbb{R}^m$ be a bounded open neighborhood of Λ, and $V : \overline{U} \to [0, \infty[$. Let the following hold:*

(i) *For all $t \geq 0$, $\Phi_t(U) \subset U$ (i.e., U is strongly positively invariant);*

(ii) *$V^{-1}(0) = \Lambda$;*

(iii) *V is continuous and for all $x \in U \setminus \Lambda$, $y \in \Phi_t(x)$ and $t > 0$, $V(y) < V(x)$;*

(iv) *V is upper semicontinuous, and for all $x \in \overline{U} \setminus \Lambda$, $y \in \Phi_t(x)$, and $t > 0$, $V(y) < V(x)$.*

(A) *Under* (i), (ii), *and* (iii), *Λ is a Lyapunov stable attracting set, and there exists an attractor contained in Λ whose basin contains U, and with $V^{-1}([0, r))$ as fundamental neighborhoods for small $r > 0$.*

(B) *Under* (i), (ii), *and* (iv), *there exists an attractor contained in Λ whose basin contains U.*

Proof. For the proof of (A), let $r > 0$ and $U_r = \{x \in U : V(x) < r\}$. Then $\{\overline{U}_r\}_{r>0}$ is a nested family of compact neighborhoods of Λ with $\bigcap_{r>0} \overline{U}_r = \Lambda$. Thus for $r > 0$ small enough, $\overline{U_r} \subset U$. Moreover, $\Phi_t(\overline{U}_r) \subset U_r$ for $t > 0$ by our hypotheses on U and V. Proposition 3.19 then implies the result.

For (B), let $A = \omega_\Phi(U)$, which is closed and invariant (by Lemma 3.8) and hence compact, since it is included in $\overline{U}$. Let $\alpha = \max_{y \in A} V(y)$ be reached at x, since V is upper semicontinuous. By invariance there exists a solution $\mathbf{x}$ and $t > 0$ with $z = \mathbf{x}(0) \in A$ and $\mathbf{x}(t) = x$. This contradicts (iv) unless $\alpha = 0$ and $A \subset \Lambda$. Thus U is a neighborhood of A, which is an attractor included in Λ. □

Remark 3.26. Given any attractor A, there exists a function V such that Proposition 3.25(iv) holds for $\Lambda = A$. Take $V(x) = \max\{d(y, A)g(t),\ y \in \Phi_t(x),\ t \geq 0\}$, where $d > g(t) > c > 0$ is any continuous strictly increasing function.

Let Λ be any subset of $\mathbb{R}^m$. A continuous function $V : \mathbb{R}^m \to \mathbb{R}$ is called a *Lyapunov function* for Λ if $V(y) < V(x)$ for all $x \in \mathbb{R}^m \setminus \Lambda$, $y \in \Phi_t(x)$, $t > 0$, and $V(y) \leq V(x)$ for all $x \in \Lambda$, $y \in \Phi_t(x)$, and $t \geq 0$. Note that for each solution $\mathbf{x}$, V is constant along its limit set $L(\mathbf{x})$.

The following result is similar to Benaïm [3, Proposition 6.4].

PROPOSITION 3.27. *Suppose that V is a Lyapunov function for Λ. Assume that $V(\Lambda)$ has empty interior. Then every internally chain transitive set L is contained in Λ and $V \mid L$ is constant.*

Proof. Let

$$v = \inf\{V(y) : y \in L\}.$$

Since L is compact and V is continuous, $v = V(x)$ for some point $x \in L$. Since L is invariant, there exists a solution $\mathbf{x}$ with $\mathbf{x}(t) \in L$ and $\mathbf{x}(0) = x$. Then $v = V(x) > V(\mathbf{x}(t))$, and thus is impossible for $t > 0$. Since $\mathbf{x}(t) \in \Phi_t(x)$, we conclude $x \in \Lambda$.

Thus v belongs to the range $V(\Lambda)$. Since $V(\Lambda)$ contains no interval, there is a sequence $v_n \notin V(\Lambda)$ decreasing to v. The sets $L_n = \{x \in L : V(x) < v_n\}$ satisfy $\Phi_t(\overline{L}_n) \subset L_n$ for $t > 0$. In fact, either $x \in \Lambda \cap \overline{L}_n$ and $V(y) \leq V(x) < v_n$ or $V(y) < V(x) \leq v_n$, for any $y \in \Phi_t(x)$, $t > 0$.

Thus, using Propositions 3.19 and 3.20, one obtains $L = \bigcap_n \overline{L}_n = \{x \in L : V(x) = v\}$. Hence V is constant on L. L being invariant, this implies, as above, $L \subset \Lambda$. □

COROLLARY 3.28. *Let V and Λ be as in Proposition* 3.27. *Suppose furthermore that V is C^m and Λ is contained in the critical points set of V. Then every internally chain transitive set lies in Λ and $V \mid L$ is constant.*

Proof. By Sard's theorem (Hirsch [18, p. 69]), $V(\Lambda)$ has empty interior and Proposition 3.27 applies. □

4. The limit set theorem.

4.1. Asymptotic pseudotrajectories for set-valued dynamics. The translation flow $\Theta : C^0(\mathbb{R}, \mathbb{R}^m) \times \mathbb{R} \to C^0(\mathbb{R}, \mathbb{R}^m)$ is the flow defined by

$$\Theta^t(\mathbf{x})(s) = \mathbf{x}(s + t).$$

A continuous function $\mathbf{z} : \mathbb{R}^+ \to \mathbb{R}^m$ is an asymptotic pseudotrajectory (APT) for Φ if

$$\lim_{t\to\infty} \mathbf{D}(\Theta^t(\mathbf{z}), S_{\mathbf{z}(t)}) = 0 \tag{4.1}$$

(or $\lim_{t\to\infty} \mathbf{D}(\Theta^t(\mathbf{z}), S) = 0$, where $S = \bigcup_{x\in\mathbb{R}^m} S_x$ denotes the set of all solutions of (I)).

Alternatively, for all T

$$\lim_{t\to\infty} \inf_{\mathbf{x}\in S_{\mathbf{z}}(t)} \sup_{0\leq s\leq T} \|\mathbf{z}(t + s) - \mathbf{x}(s)\| = 0.$$

In other words, for each fixed T, the curve

$$[0, T] \to \mathbb{R}^m : s \to \mathbf{z}(t + s)$$

shadows some Φ trajectory of the point $\mathbf{z}(t)$ over the interval $[0, T]$ with arbitrary accuracy for sufficiently large t. Hence $\mathbf{z}$ has a forward trajectory under Θ attracted by S. As usual, one extends $\mathbf{z}$ to $\mathbb{R}$ by letting $\mathbf{z}(t) = \mathbf{z}(0)$ for $t < 0$.

The next result is a natural extension of Benaïm and Hirsch [4], [5, Theorem 7.2].

THEOREM 4.1 (characterization of APT). *Assume $\mathbf{z}$ is bounded. Then there is equivalence between the following statements:*

(i) *$\mathbf{z}$ is an APT for Φ.*

(ii) *$\mathbf{z}$ is uniformly continuous, and any limit point of $\{\Theta^t(\mathbf{z})\}$ is in S.*

In both cases the set $\{\Theta^t(\mathbf{z});\ t \geq 0\}$ is relatively compact.

Proof. By hypothesis, $K = \overline{\{\mathbf{z}(t);\ t \geq 0\}}$ is compact.

For any $\varepsilon > 0$, there exists $\eta > 0$ such that $\|z - x\| < \varepsilon/2$, for any $x \in K$, any $z \in \Phi_s(x)$, and any $|s| < \eta$, using property (d) of the dynamical system.

$\mathbf{z}$ being an APT, there exists T such that $t > T$ implies

$$d(\mathbf{z}(t+s), \Phi_s(\mathbf{z}(t))) < \frac{\varepsilon}{2} \quad \forall |s| < \eta;$$

hence

$$\|\mathbf{z}(t+s) - \mathbf{z}(t)\| \leq \varepsilon$$

and $\mathbf{z}$ is uniformly continuous. Clearly any limit point belongs to S by the condition (4.1) above.

Conversely, if $\mathbf{z}$ is uniformly continuous, then the family of functions $\{\Theta^t(\mathbf{z});\ t \geq T\}$ is equicontinuous and hence (K being compact) relatively compact by Ascoli's theorem. Since any limit point belongs to S, property (4.1) follows. □

4.2. Perturbed solutions are APTs.

THEOREM 4.2. *Any bounded solution* $\mathbf{y}$ *of* (II) *is an APT of* (I).

Proof. Let us prove that $\mathbf{y}$ satisfies Theorem 4.1(ii). Set $v(t) = \dot{\mathbf{y}}(t) - U(t) \in F^{\delta(t)}(\mathbf{y}(t))$. Then,

$$\mathbf{y}(t+s) - \mathbf{y}(t) = \int_0^s v(t+\tau)d\tau + \int_t^{t+s} U(\tau)d\tau. \tag{4.2}$$

By assumption (iii) of (II), the second integral goes to 0 as $t \to \infty$. The boundedness of $\mathbf{y}$, $\mathbf{y}(\mathbb{R}) \subset M$, M compact (combined with the fact that F has linear growth) implies boundedness of v and shows that $\mathbf{y}$ is uniformly continuous. Thus the family $\Theta^t(\mathbf{y})$ is equicontinuous, and hence relatively compact. Let $\mathbf{z} = \lim_{t_n \to \infty} \Theta^{t_n}(\mathbf{y})$ be a limit point. Set $t = t_n$ in (4.2) and define $v_n(s) = v(t_n + s)$. Then, using the assumption (iii) on U, the second term in the right-hand side of this equality goes to zero uniformly on compact intervals when $n \to \infty$. Hence

$$\mathbf{z}(s) - \mathbf{z}(0) = \lim_{n \to \infty} \int_0^s v_n(\tau)d\tau.$$

Since (v_n) is uniformly bounded, it is bounded in $L^2[0,s]$, and by the Banach–Alaoglu theorem, a subsequence of v_n will converge weakly in $L^2[0,s]$ (or weak* in $L^\infty[0,s]$) to some function v with $v(t) \in F(\mathbf{z}(t))$, for almost every t, since $v_n(t) \in F^{\delta(t+t_n)}(\mathbf{y}(t+t_n))$ for every t. Here we use (ii) and that F is upper semicontinuous with convex values. In fact, by Mazur's theorem, a convex combination of $\{v_m, m \geq n\}$ converges almost surely to v and $\lim_{m\to\infty} \mathrm{Co}(\bigcup_{n \geq m} F^{\delta(t+t_n)}(\mathbf{y}(t+t_n))) \subset F(\mathbf{z}(t))$. Hence $\mathbf{z}(s) - \mathbf{z}(0) = \int_0^s v(\tau)d\tau$, proving that $\mathbf{z}$ is a solution of (I) and hence $\mathbf{z} \in S_{M,M}$. □

4.3. APTs are internally chain transitive.

THEOREM 4.3. *Let* $\mathbf{z}$ *be a bounded APT of* (I). *Then* $L(\mathbf{z})$ *is internally chain transitive.*

Proof. The set $\{\Theta^t(\mathbf{z}) : t \geq 0\}$ is relatively compact, and hence the ω-limit set of $\mathbf{z}$ for the flow Θ,

$$\omega_\Theta(\mathbf{z}) = \bigcap_{t \geq 0} \overline{\{\Theta^s(\mathbf{z}) : s \geq t\}},$$

is internally chain transitive. (By standard properties of ω-limit sets of bounded semiorbits, $\omega_\Theta(\mathbf{z})$ is a nonempty, compact, internally chain transitive set invariant under Θ; see Conley [13]; a short proof is also in Benaïm [3, Corollary 5.6].) By property (4.1), $\omega_\Theta(\mathbf{z}) \subset S$, the set of all solutions of (I).

Let $\Pi : (C^0(\mathbb{R}, \mathbb{R}^m), \mathbf{D}) \to (\mathbb{R}^m, \|\cdot\|)$ be the projection map defined by $\Pi(\mathbf{z}) = \mathbf{z}(0)$. One has $\Pi(\omega_\Theta(\mathbf{z})) = L(\mathbf{z})$. In fact if $p = \lim_{n\to\infty} \mathbf{z}(t_n)$, let $\mathbf{w}$ be a limit point of $\Theta^{t_n}(\mathbf{z})$. Then $\mathbf{w} \in \omega_\Theta(\mathbf{z})$ and $\Pi(\mathbf{w}) = p$.

It then easily follows that $L(\mathbf{z})$ is nonempty compact and invariant under Φ since $\omega_\Theta(\mathbf{z}) \subset S$. Since Π has Lipschitz constant 1, Π maps every (ε, T) chain for Θ to an (ε, T) chain for Φ. This proves that $L(\mathbf{z})$ is internally chain transitive for Φ. □

5. Applications.

5.1. Approachability. An application of Proposition 3.25 is the following result, which can be seen as a continuous asymptotic deterministic version of Blackwell's approachability theorem [8]. Note that one has no property on uniform speed of convergence.

Given a compact set $\Lambda \in \mathbb{R}^m$ and $x \in \mathbb{R}^m$, we let $\Pi_\Lambda(x) = \{y \in \Lambda : d^2(x, \Lambda) = \|x - y\|^2 = \langle x - y, x - y\rangle\}$.

COROLLARY 5.1. *Let $\Lambda \subset \mathbb{R}^m$ be a compact set, $r > 0$, and $U = \{x \in \mathbb{R}^m : d(x, \Lambda) < r\}$. Suppose that for all $x \in U \setminus \Lambda$ there exists $y \in \Pi_\Lambda(x)$ such that the affine hyperplane orthogonal to $[x, y]$ at y separates x from $x + F(x)$. That is,*

$$\langle x - y, x - y + v\rangle \le 0 \tag{5.1}$$

for all $v \in F(x)$. Then Λ contains an attractor for (I) *with fundamental neighborhood U.*

Proof. Set $V(x) = d(x, \Lambda)$. To apply Proposition 3.25 it suffices to verify condition (iii) of Proposition 3.25. Condition (i) will follow, and condition (ii) is clearly true.

Let $\mathbf{x}$ be a solution to (I) with initial condition $x \in U \setminus \Lambda$. Set $\tau = \inf\{t > 0 : \mathbf{x}(t) \in \Lambda\} \le \infty$, $g(t) = V(\mathbf{x}(t))$, and let $I \subset [0, \tau[$ be the set of $0 \le t < \tau$ such that $g'(t)$ and $\dot{\mathbf{x}}(t)$ exist and $\dot{\mathbf{x}}(t) \in F(\mathbf{x}(t))$. For all $t \in I$ and $y \in \Pi_\Lambda(\mathbf{x}(t))$

$$\begin{aligned} g(t + h) - g(t) &\le \|\mathbf{x}(t + h) - y\| - \|\mathbf{x}(t) - y\| \\ &= \|\mathbf{x}(t) + \dot{\mathbf{x}}(t)h - y\| - \|\mathbf{x}(t) - y\| + |h|\varepsilon(h), \end{aligned}$$

where $\lim_{h\to 0} \varepsilon(h) = 0$. Hence

$$\begin{aligned} g'(t) &\le \frac{1}{\|\mathbf{x}(t) - y\|}\langle \mathbf{x}(t) - y, \dot{\mathbf{x}}(t)\rangle \\ &= -g(t) + \frac{1}{\|\mathbf{x}(t) - y\|}\langle \mathbf{x}(t) - y, \mathbf{x}(t) - y + \dot{\mathbf{x}}(t)\rangle. \end{aligned}$$

Thus, $\dot{x} \in F(x)$ and (5.1) imply $g'(t) \le -g(t)$ for all $t \in I$. Since g and $\mathbf{x}$ are absolutely continuous, I has full measure in $[0, \tau[$. Hence $g(t) \le e^{-t}g(0)$ for all $t < \tau$. Therefore $V(\mathbf{x}(t)) < V(x)$ for all $0 < t < \tau$, which shows (iii). Finally, $V(\mathbf{x}(t)) \le e^{-t}V(x)$ shows that the sets $V^{-1}[0, r')$ (with $0 < r' \le r$) are fundamental neighborhoods of the attractor in Λ. □

In particular, if any point of E has a unique projection on Λ (for example, Λ convex), then $\overline{C} = C$, and one recovers exactly Blackwell's sufficient condition for approachability.

COROLLARY 5.2 (Blackwell's approachability theorem). *Consider the decision making process described in section* 2.1*, Example* 2.2*. Let $\Lambda \subset E$ be a compact set. Assume that there exists a strategy Q such that for all $x \in E \setminus \Lambda$ there exists $y \in \Pi_\Lambda(x)$ such that the hyperplane orthogonal to $[x, y]$ through y separates x from $\overline{C}(x)$. Then Λ is approachable.*

Proof. Let $L(x_n)$ denote the limit set of $\{x_n\}$. By Corollary 5.1, Λ is an attractor with fundamental neighborhood E, hence a global attractor. Thus Theorem 3.6 with Proposition 2.1 and Corollary 3.24 imply that $L(x_n)$ is almost surely contained in Λ. □

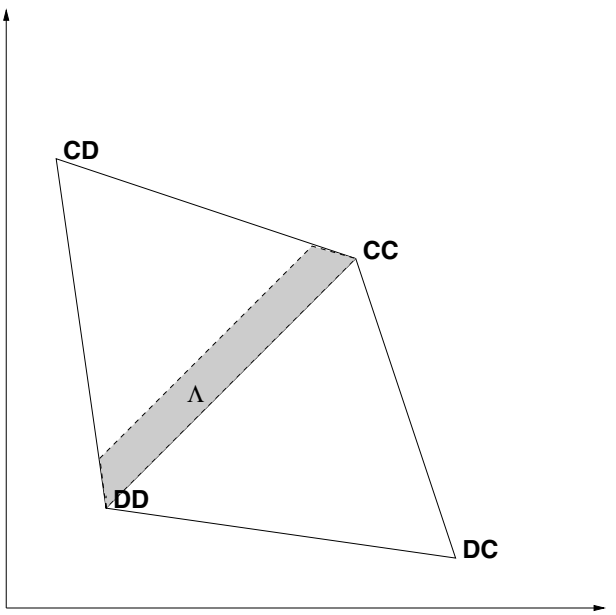
5.2. Smale's approach to the prisoner's dilemma. We develop here Example 2.4. Consider a 2×2 prisoner's dilemma game. Each player has two possible actions: cooperate (play C) or defect (play D). If both cooperate, each receives α; if both defect, each receives λ; if one cooperates and the other defects, the cooperator receives β and the defector γ. We suppose that $\gamma > \alpha > \lambda > \beta$, as is usual with a prisoner's dilemma game. We furthermore assume that

$$\gamma - \alpha < \alpha - \beta,$$

so that the outcome space E is the convex quadrilateral whose vertices are the payoff vectors

$$\mathbf{CD} = (\beta, \gamma), \qquad \mathbf{CC} = (\alpha, \alpha), \qquad \mathbf{DC} = (\gamma, \beta), \qquad \mathbf{DD} = (\lambda, \lambda);$$

see the figure below.



The outcome space E

Let δ be a nonnegative parameter. Adapting Smale [27] and Benaïm and Hirsch [4, 5], a *δ-good* strategy for player 1 is a strategy $Q^1 = \{Q^1_x\}$ (as defined in section 2.1) enjoying the following features:

$$Q^1_x(\text{play C}) = 1 \quad \text{if } x^1 > x^2$$

and

$$Q^1_x(\text{play C}) = 0 \quad \text{if } x^1 < x^2 - \delta.$$

The following result reinterprets the results of Smale [27] and Benaïm and Hirsch [4, 5] in the framework of approachability. It also provides some generalization (see Remark 5.4 below).

THEOREM 5.3. (i) *Suppose that player* 1 *plays a* δ*-good strategy. Then the set*

$$\Lambda = \{x \in E : x^2 - \delta \leq x^1 \leq x^2\}$$

is approachable.

(ii) *Suppose that both players play a* δ*-good strategy and that at least one of them is continuous (meaning that the corresponding function* $x \to Q^i_x$*(play* C*) is continuous). Then*

$$\lim_{n\to\infty} x_n = \mathbf{CC}$$

almost surely.

Proof. (i) Let $x \in E \setminus \Lambda$. If $x^1 > x^2$, then

$$C(x) = \overline{C}(x) = [\mathbf{CC}, \mathbf{CD}],$$

and the line $\{u \in \mathbb{R}^2 : u^1 = u^2\}$ separates x from $\overline{C}(x)$. Similarly if $x^1 < x^2 - \delta$, then

$$C(x) = \overline{C}(x) = [\mathbf{DD}, \mathbf{DC}],$$

which is separated from x by the line $\{u \in \mathbb{R}^2 : u^1 = u^2 - \delta\}$. Assertion (i) then follows from Corollary 5.2.

(ii) If both play a δ-good strategy, then (i) and its analogue for player 2 imply that the diagonal

$$\Delta = \{x \in E : x^1 = x^2\}$$

is approachable. Thus $L(x_n) \subset \Delta$. Also (by Proposition 2.1, Theorem 3.6, and Lemma 3.5) $L(x_n)$ is invariant under the differential inclusion induced by

$$F(x) = -x + \overline{C}(x),$$

where $C(x) = C^1(x) \cap C^2(x)$ and $C^i(x)$ is the convex set associated with Q^i (the strategy of player i). Suppose that one player, say 1, plays a continuous strategy. Then $\overline{C}(x) \subset \overline{C^1}(x) = C^1(x)$ and for all $x \in \Delta$, $C^1(x) = [\mathbf{CD}, \mathbf{CC}]$. Now, there is only one subset of Δ which is invariant under $\dot{x} \in -x + [\mathbf{CD}, \mathbf{CC}]$; this is the point $\mathbf{CC}$. This proves that $L(x_n) = \mathbf{CC}$. □

Remark 5.4. (i) In contrast to Smale [27] and Benaïm and Hirsch [4, 5], observe that assertion (i) makes no hypothesis on player 2's behavior. In particular, it is unnecessary to assume that player 2 has a strategy of the form defined by section 2.1.

(ii) The regularity assumptions (on strategies) are much weaker than in Benaïm and Hirsch [4, 5].

(iii) A 0-good strategy makes the diagonal Δ approachable. However, if both players play a 0-good strategy, then $\overline{C}(x) = E$ for all $x \in \Delta$, and we are unable to predict the long-term behavior of $\{x_n\}$ on Δ.

5.3. Fictitious play in potential games. Here we generalize the result of Monderer and Shapley [25]. They prove convergence of the classical discrete fictitious play process, as defined in Example 2.3, for n-linear payoff functions. Harris [17] studies the best-response dynamics in this case but does not derive convergence of fictitious play from it. Our limit set theorem provides the right tool for doing this, even in the following, more general setting.

Let X^i, $i = 1, \dots, n$, be compact convex subsets of Euclidean spaces and $U\colon X^1 \times \cdots \times X^n \to \mathbb{R}$ be a C^1 function which is concave in each variable. U is interpreted as the common payoff function for the n players. We write $x = (x^i, x^{-i})$ and define $BR^i(x^{-i}) := \operatorname{Argmax}_{x^i \in X^i} U(x)$ the set of maximizers. Then $x \mapsto BR(x) = (BR^1(x^{-1}), \dots, BR^n(x^{-n}))$ is upper semicontinuous (by Berge's maximum theorem, since U is continuous) with nonempty compact convex values. Consider the best response dynamics

$$\dot{\mathbf{x}} \in BR(\mathbf{x}) - \mathbf{x}. \tag{5.2}$$

Its constant solutions $\mathbf{x}(t) \equiv \hat{x}$ are precisely the Nash equilibria $\hat{x} \in BR(\hat{x})$; i.e., $U(\hat{x}) \geq U(x^i, \hat{x}^{-i})$ for all i and $x^i \in X^i$. Along a solution $\mathbf{x}(t)$ of (5.2), let $u(t) = U(\mathbf{x}(t))$. Then for almost all $t > 0$,

$$\dot{u}(t) = \sum_{i=1}^{n} \frac{\partial U}{\partial x^i}(\mathbf{x}(t))\dot{\mathbf{x}}^i(t) \tag{5.3}$$

$$\geq \sum_{i=1}^{n} [U(\mathbf{x}^i(t) + \dot{\mathbf{x}}^i(t), \mathbf{x}^{-i}(t)) - U(\mathbf{x}(t))] \tag{5.4}$$

$$= \sum_{i=1}^{n} \left[\max_{y^i \in X^i} U(y^i, \mathbf{x}^{-i}(t)) - U(\mathbf{x}(t)) \right] \geq 0, \tag{5.5}$$

where from (5.3) to (5.4) we use the concavity of U in x^i, and (5.5) follows from (5.2) and the definition of BR^i. Since the function $t \mapsto u(t)$ is locally Lipschitz, this shows that it is weakly increasing. It is constant in a time interval T, if and only if $\mathbf{x}^i(t) \in BR^i(\mathbf{x}^{-i}(t))$ for all $t \in T$ and $i = 1, \dots, n$, i.e., if and only if $\mathbf{x}(t)$ is a Nash equilibrium for $t \in T$ (but $\mathbf{x}(t)$ may move in a component of the set of Nash equilibria (NE) with constant U).

THEOREM 5.5. *The limit set of every solution of* (5.2) *is a connected subset of NE, along which U is constant. If, furthermore, the set $U(NE)$ contains no interval in $\mathbb{R}$, then the limit set of every fictitious play path is a connected subset of NE along which U is constant.*

Proof. The first statement follows from the above. The second statement follows from Theorem 3.6 together with Proposition 3.27 with $V = -U$ and $\Lambda = NE$. □

Remark 5.6. The assumption that the set $U(NE)$ contains no interval in $\mathbb{R}$ follows via Corollary 3.28 if U is smooth enough (e.g., in the n-linear case) and if each X^i has at most countably many faces, by applying Sard's lemma to the interior of each face.

Example 5.7 (2×2 coordination game). The global attractor of (5.2) consists of three equilibria and two line segments connecting them. The internally chain transitive sets are the three equilibria. Hence every fictitious play process converges to one of these equilibria.

The case of (continuous concave-convex) two-person zero-sum games was treated in Hofbauer and Sorin [21], where it is shown that the global attractor of (5.2) equals the set of equilibria. In this case the full strength of Theorem 3.6 and the notion of chain transitivity are not needed; the invariance of the limit set of a fictitious play path implies that it is contained in the global attractor; compare Corollary 3.24.

A SPILLOVER PHENOMENON IN THE OPTIMAL LOCATION OF ACTUATORS*

PASCAL HÉBRARD† AND ANTOINE HENROT‡

Abstract. In this paper, we are interested in finding the optimal location and shape of the actuators in a stabilization problem. Namely, we consider the one-dimensional wave equation damped by an internal feedback supported on a subdomain ω of given length. The criterion we want to optimize represents the rate of decay of the total energy of the system. It theoretically involves all the eigenmodes of the operator. From an engineering point of view, it seems more realistic to consider only a finite number of modes, say the N first ones. In that context, we are able to prove existence and uniqueness of an optimal domain ω_N^*: it is the better possible location for the actuators. We characterize this optimal domain and we point out the following strange phenomenon (at least for small lengths): the optimal domain ω_N^* which is the better one for the N first modes is actually the worse one for the $N+1$th mode. This looks like the well-known spillover phenomenon in control theory. At last, we will give some possible extension and open problems in higher dimension.

Key words. damped wave equation, optimal location, spillover, stabilization

DOI. 10.1137/S0363012903436247

1. Introduction.

In control and stabilization problems the choice of the best location (and shape) of the actuators is a very important and practical question. Among criterion which can be studied, the *rate of decay* of the energy of the system is an important one since it does not depend on the initial conditions. In the one-dimensional problem that we are going to consider here (wave equation with internal distributed control), it is known that this rate of decay is precisely the opposite of the spectral abscissa of the corresponding operator (see [9]). Therefore, optimizing this rate of decay consists in pushing *all* the eigenvalues as far as possible to the left in the complex plane. Among works in this direction, we refer, e.g., to [8] where it is proved that a constant damping is a local maximizer of the rate of decay [11], which shows that the constant damping is not a global maximizer and [5] where they show that we can achieve an arbitrarily large rate of decay by considering damping of the kind $a(x) = 1/(x+b)$ (see below for the mathematical model). In this work we will restrict ourselves to a damping of the kind $k\chi_\omega(x)$ where k is a (small) positive constant and χ_ω is the characteristic function of a subdomain ω of the string which is our main unknown.

In higher dimension, this spectral abscissa is also an important component of the rate of decay, but we must also consider a geometric quantity describing the time each high frequency (or waves with a little wave length) stays in the zone of control; see [3], [18].

From an engineering point of view, it seems to be difficult (and perhaps useless) to take into account an *infinite* number of modes. So, a more reasonable version of this

problem would be to consider only the N first modes. Indeed, the high frequencies are not too much penalizing for the vibrating structure. The aim of this paper is to show that if we choose the optimal domain, say ω_N^*, for the N first modes (we will prove that it exists and is unique), this domain behaves very poorly for the first mode that we have forgotten: the $(N+1)$th mode! More precisely, ω_N^* generally concentrates on the nodes of the $(N+1)$th mode, and therefore does not control it at all. Roughly speaking, *the best domain for the N first modes is the worse one for the $(N+1)$th mode!* In this paper, we are able to prove this result for dampers with *small* support, but actually we can observe numerically that, in general, the best damper for the N first modes behaves very poorly for the $N+1$th mode; see Figure 5.1 and section 5.2. Since the choice of N is generally arbitrary, it seems to be a very bad idea to look for the optimal zone of control for the N first modes. It is, somehow, as if we push the energy after the N first modes like in classical spillover phenomena, as described, for example, in [2]. In our paper, we choose to consider a wave packet constituted with all the low frequencies. In some sense, the phenomenon which occurs here seems similar to the one due to different group velocity as described in [25]; see also [26] for a survey, but in our case it is not only a question of low and high frequencies. Indeed, we could have chosen other wave packets, in particular with different group velocities. Actually, we can observe (at least numerically, we did not write proofs) the same phenomenon for any choice of wave packets. For example, if we want to damp at best the packet of eigenfrequencies $\lambda_1, \lambda_4, \lambda_5$, the optimal domain we get (which still exists and is unique) will mainly concentrate on the nodes of the second eigenfunction ϕ_2, which is the first frequency we have forgotten, and therefore will be unable to damp correctly this eigenmode. Nevertheless, E. Zuazua claims in [26] that *controlling a discrete version of a continuous wave model is often a bad way of controlling the continuous wave model itself.* We have another illustration of this phenomenon here.

The plan of this paper is the following. Section 2 deals with the mathematical model which is used and fix the notations. In section 3 we prove existence and uniqueness of the optimal domain and we characterize it. Section 4 is devoted to describe and prove the kind of spillover phenomenon that we have just described above. At last, in section 5, we will give some remarks and possible extensions to the two-dimensional case.

2. The mathematical model. Let us now give the model and the notations that we are going to use throughout this paper. We consider a string (a one-dimensional model), but it is essentially for technical reasons. We will say a few words, in section 5, about higher dimensional models, pointing out what has to be done to generalize our results.

So, let us denote by $\Omega = (0,1)$ the unit string that we suppose fixed at its extremities. We want to stabilize this string thanks to a damping acting only on a subdomain ω. More precisely, we consider the following modelling. The displacement u of the string in presence of viscous damping $2k\chi_\omega$ (where χ_ω denotes the characteristic function of the subdomain ω of positive length), satisfies the damped wave equation

$$\begin{cases} u_{tt}(x,t) - u_{xx}(x,t) + 2k\chi_\omega(x)u_t(x,t) = 0, \ x \in (0,1), t > 0 \\ u(0,t) = u(1,t) = 0, \ t > 0 \end{cases} \tag{2.1}$$

upon being set in motion by the initial disturbance

$$u(x,0) = u_0(x), \qquad u_t(x,0) = u_1(x) \qquad \forall x \in [0,1]. \tag{2.2}$$

The energy of the string at time t is defined by

$$E(t) = \int_0^1 \left[u_x^2(x,t) + u_t^2(x,t)\right] dx.$$

If ω has positive measure, this system is exponentially stable, i.e., its energy is known to obey (see, e.g., [6], [9])

$$E(t) \leq CE(0)e^{-2\tau t} \tag{2.3}$$

for some constants $C > 0$ and $\tau > 0$ independent of the initial data. We define the decay rate, as a function of k and ω, to be the largest such τ,

$$\tau(k,\omega) = \sup\{\tau' : \exists C(\tau') > 0 \; s.t. \; E(t) \leq CE(0)e^{-2\tau' t}, \\ \text{for every solution of (2.1) and (2.2)}\}.$$

Cox and Zuazua have shown in [9] that if χ_ω is of bounded variation, *i.e.,* ω is the union of a finite number of intervals, then $\tau(k,\omega)$ is equal to the opposite of the spectral abscissa of the operator A:

$$\tau(k,\omega) = -\mu = -\sup\{Re\,\lambda : \lambda \in sp(A)\},$$

where A denotes the linear operator associated to (2.1):

$$A = \begin{pmatrix} 0 & I \\ \frac{d^2}{dx^2} & -2k\chi_\omega(x) \end{pmatrix}, \qquad D(A) = (H^2(0,1) \cap H_0^1(0,1)) \times H_0^1(0,1) \tag{2.4}$$

and $sp(A)$ its spectrum. Therefore, a natural question would be to look for k and ω which minimize this spectral abscissa (or maximize $\tau(k,\omega)$).

In such a generality, looking for the maximizer of $(k,\omega) \mapsto \tau(k,\omega)$ is quite difficult. In [15], we explain (and we give justifications) how to simplify the problem by considering, instead of the decay rate, the quantity

$$J(\omega) = \inf_{n\in\mathbb{N}^*} \int_0^1 \chi_\omega(x)\phi_n^2(x)dx, \tag{2.5}$$

where $\mathbb{N}^*$ stands for the set of positive integers and $(\phi_n)_{n\in\mathbb{N}^*}$ denote the normalized eigenfunctions for the problem without damping, *i.e.,* $\phi_n = \sqrt{2}\sin n\pi x$. Actually, when k is not too large, we have $\tau(k,\omega) \simeq kJ(\omega)$, since $J(\omega)$ is nothing else but the derivative of τ with respect to k for $k = 0$. On the other hand, taking k large is not interesting at all, due to the classical *overdamping* phenomenon described, e.g., in [9], [12], [15]. Therefore, $J(\omega)$ gives a good approximation of the decay rate for small k. We also refer to [13] for a similar analysis.

As explained in the Introduction, it seems more realistic, at least from an engineering point of view, to take into consideration only a *finite* number of modes. It means that it seems reasonable to replace the functional J by the simpler J_N (where N is a given integer), defined by

$$J_N(\omega) = \min_{1\leq n\leq N} \int_0^1 \chi_\omega(x)\phi_n^2(x)dx. \tag{2.6}$$

Therefore, we are interested in solving the following problem:

$$\mathcal{P}_\omega \qquad \begin{cases} \text{Find } \omega^* \text{ subset of }]0,1[\text{ of measure, } l \text{ which maximizes} \\ J_N(\omega) = \min_{1\leq n\leq N} 2\int_0^1 \chi_\omega(x)\sin^2(n\pi x)\,dx. \end{cases}$$

In what follows, for each integer k and each function a, we will denote by $j_k(a)$ the quantity

$$j_k(a) = \int_0^1 a(x)\phi_k^2(x)dx\,.$$

We could also wonder whether J_N is a "good" approximation of J. Since it is proved in [15] that J has no maximizer in the class of characteristic functions (except for the particular case $l = 0.5$) while J_N has always a (unique) maximizer in this class (as proved below), it seems at first sight that it is not a good approximation. But, it becomes a good one if we accept working in the convex set $\mathcal{A}_l$ defined in (3.1). Actually, we can prove the following proposition.

PROPOSITION 2.1. *Let us consider the functionals J_N and J defined on the convex set $\mathcal{A}_l$ (defined in* (3.1)*), respectively, by $J_N(a) = \min_{1\le n\le N} j_n(a)$ and $J(a) = \inf_{n\in\mathbb{N}^*} j_n(a)$. Then J_N Γ-converge to J in the sense of De Giorgi. Moreover, let $\chi_{\omega_N^*}$ be the sequence of maximizers of J_N given by Theorem* 3.1*, then $\chi_{\omega_N^*}$ converges (up to a subsequence) weak-* to a maximizer of J and $\max_{\mathcal{A}_l} J = \lim_{N\to+\infty} J_N(\chi_{\omega_N^*})$.*

Proof. Since we are interested in a *maximization* problem, the definition of Γ-convergence reads here; see, e.g., [10]:

(i) For all sequence a_n in $\mathcal{A}_l$, which converge weak-* to a, $J(a) \ge \limsup J_N(a_N)$.
(ii) There exists one sequence a_n in $\mathcal{A}_l$, which converge weak-* to a, such that $J(a) \le \liminf J_N(a_N)$.

For (i), let us fix $\varepsilon > 0$ and choose an integer k_0 such that $J(a) \le j_{k_0}(a) \le J(a) + \varepsilon$. For every integer $N \ge k_0$, we have

$$J_N(a_N) \le j_{k_0}(a_N). \tag{2.7}$$

Now, $j_{k_0}(a_N) \to j_{k_0}(a)$ when $N \to +\infty$, therefore taking the lim-sup in both sides of (2.7) yields $\limsup J_N(a_N) \le \limsup j_{k_0}(a_N) = j_{k_0}(a) \le J(a) + \varepsilon$ which gives (i) since ε is arbitrary.

For (ii), it suffices to consider a constant sequence $a_n = a$ since $J(a) \le J_N(a)$.

Now, the last two claims come directly from the classical theorem of De Giorgi (see [10]) and the fact that the sequence $\chi_{\omega_N^*}$ is precompact in $\mathcal{A}_l$. □

The functional J may have several maxima but the characterization of ω_N^* which is given below (Theorem 4.1) shows that $\chi_{\omega_N^*}$ converges actually to the constant function $a(x) = l$ which is the more natural maximizer.

3. Existence, uniqueness, and characterization of the optimum. We begin by proving the following existence and uniqueness result for the optimal domain.

THEOREM 3.1. *The problem $\mathcal{P}_\omega$ has a unique solution ω_N^*. This solution is a union of at most N intervals. It is symmetric with respect to* $1/2$.

The proof of Theorem 3.1 will be done in several steps. First of all, we are going to use some kind of relaxation of the problem by introducing the convex hull $\mathcal{A}_l$ of the set of characteristic functions. Existence of an optimum in this set will be obtained easily. By characterization of this optimum thanks to the optimality conditions, we will be able to prove that it is indeed an extreme point of $\mathcal{A}_l$, i.e., the characteristic function of a subdomain. Uniqueness will then follow from the fact that the functional J is concave.

Step 1 (*relaxation*). The maximization problem is posed on the set of characteristic functions

$$\mathcal{L}_l = \left\{ a(x) \in L^\infty(0,1), a(x) = 0 \text{ or } 1 \, a.e., \int_0^1 a(x)\, dx = l \right\}.$$

This set is not very convenient for this maximization problem, since it is not closed for the natural topology associated to the functional J_N, namely the weak-star topology on $L^\infty(0,1)$. Indeed, J_N is clearly continuous for this topology. So, let us introduce the convex hull of $\mathcal{L}_l$,

$$\mathcal{A}_l = \left\{ a(x) \in L^\infty(0,1),\ 0 \le a(x) \le 1,\ \int_0^1 a(x)\, dx = l \right\} \tag{3.1}$$

which is also the closure of $\mathcal{L}_l$ for the weak-star topology on $L^\infty(0,1)$. The set $\mathcal{A}_l$ is compact for this topology, while $\mathcal{L}_l$ coincides with the set of extreme points of $\mathcal{A}_l$; see, e.g., [16]. Moreover, J_N has a natural extension (always denoted by J_N) to $\mathcal{A}_l$ defined by

$$\forall a \in \mathcal{A}_l, \qquad J_N(a) = \min_{1 \le n \le N} \int_0^1 a(x) \phi_n^2(x) dx. \tag{3.2}$$

It is clear that J_N is continuous on $\mathcal{A}_l$ for the weak-star topology. Therefore, J_N admits (at least) a maximum in $\mathcal{A}_l$.

Step 2 (*optimality conditions*). Let a^* such a maximum, and let us denote by $I(a^*)$ the active index-set

$$I(a^*) = \{k \in \{1, 2, \ldots, N\}, \text{ such that } j_k(a^*) = J_N(a^*)\}.$$

It is well known in nonsmooth analysis (see, e.g., [17]) that the subdifferential of J_N at a^* is given by

$$\partial J_N(a^*) := co\{\cup \partial j_k(a^*),\ k \in I(a^*)\}, \tag{3.3}$$

where *co* denotes the convex hull. Now, the j_k being linear, they are equal to their differential and the optimality condition reads

$$0 \in \partial J_N(a^*) + \lambda_0 L_0, \tag{3.4}$$

where λ_0 stands for a Lagrange multiplier taking into account the length constraint and L_0 is the linear form defined by $< L_0, h >= \int_0^1 h(x)\, dx$. What yields, thanks to (3.3) is

$$\left\{ \begin{array}{c} \exists (\lambda_k) \in [0,1],\ k \in I(a^*),\ \sum \lambda_k = 1,\ \exists \lambda_0 \in \mathbb{R} \text{ such that} \\ \forall h \in L^\infty([0,1]),\ h \text{ admissible}, \\ \displaystyle\sum_{k \in I(a^*)} \lambda_k \int_0^1 h(x) \phi_k^2(x)\, dx + \lambda_0 \int_0^1 h(x)\, dx = 0. \end{array} \right. \tag{3.5}$$

Step 3 (*maxima are characteristic functions*). Let us fix $\varepsilon \in (0, 1/2)$. We are going to prove that the set $A_\varepsilon = \{x \in \Omega \,|\, \varepsilon \le a^*(x) \le 1 - \varepsilon\}$ has zero measure for every $\varepsilon > 0$ which obviously implies that a^* is a characteristic function. Let us assume, for a contradiction, $|A_\varepsilon| > 0$ and let us use the optimality conditions (3.5). We choose h

with a support in A_ε: it is clearly admissible (we refer, e.g., to [7], [4] for the complete description of the cone of admissible functions for the set $\mathcal{A}_l$). This implies that

$$\sum_{k\in I(a^*)} \lambda_k \phi_k^2(x) + \lambda_0 = 0, \text{ for almost every } x \in A_\varepsilon \tag{3.6}$$

If A_ε has positive measure, this equality can be extended to the whole interval by analyticity of the eigenfunctions. But such an identity is impossible since the system of functions

$$\{1, \phi_1^2, \dots, \phi_k^2\} = \{1, 2\sin^2 n_1\pi x, \dots, 2\sin^2 n_k\pi x\} \text{ is linearly independent.} \tag{3.7}$$

Consequently, for all ε, A_ε has zero measure which proves the desired result.
Step 4 (*uniqueness and symmetry*). J_N is clearly a concave function as a minimum of linear functions. Therefore, if it would exist two distinct maxima a_1^* and a_2^*, all the points in the segment $[a_1^*, a_2^*]$ would also be maxima. But it is impossible since we have proved in step 3 that all the maxima were extreme points of the convex $\mathcal{A}_l$. Now, uniqueness implies symmetry of the minimizer with respect to 1/2 since $J_N(a(x)) = J_N(a(1-x))$.
Step 5 (*at most N connected components*). We recall that the maximum $a^* = \chi_{\omega^*}$ satisfies the optimality condition (3.5). Let us introduce

$$\Psi_\Lambda(x) = 2\sum_{k\in I(a^*)} \lambda_k \sin^2(k\pi x).$$

The Lagrangian of the maximization problem can be written as

$$L(a, \lambda_0, \Lambda) = \int_0^1 a(x)\Psi_\Lambda(x)dx + \lambda_0\left(\int_0^1 a(x)dx - l\right).$$

Now, for every admissible function h and every $\varepsilon > 0$ small enough, we have

$$L(\chi_{\omega^*} + \varepsilon h, \lambda_0, \Lambda) - L(\chi_{\omega^*}, \lambda_0, \Lambda) \le 0$$

which can be rewritten, thanks to the linearity of L with respect to its first variable,

$$L(h, \lambda_0, \Lambda) \le 0, \quad \text{for } h \text{ admissible.}$$

Now, we can choose as admissible h a function satisfying

$$\begin{array}{l} \forall x \in \omega^*,\ h(x) \le 0 \\ \forall x \in \omega^{*c},\ h(x) \ge 0 \\ \int_0^1 h(x)dx = 0. \end{array}$$

For such a choice we get,

$$\begin{array}{l} \forall x \in \omega^*,\ \Psi_\Lambda + \lambda_0 \ge 0 \\ \forall x \in \omega^{*c},\ \Psi_\Lambda + \lambda_0 \le 0. \end{array} \tag{3.8}$$

By continuity of ψ_Λ, equations (3.8) imply that for all $x \in \partial\omega^* \cap (0,1)$,

$$\psi_\Lambda(x) + \lambda_0 = 0. \tag{3.9}$$

Now

$$\psi_\Lambda(x) = \sum_{k\in I(a^*)} \lambda_k \left(1 - \cos(2k\pi x)\right) = 1 - \sum_{k\in I(a^*)} \lambda_k T_k(\cos 2\pi x),$$

where T_k is the kth Tchebyshev polynomial. Therefore, $\psi_\Lambda(x)$ is a polynomial in $\cos 2\pi x$ of degree less or equal to N and the equation $\psi_\Lambda(x) + \lambda_0 = 0$ has *at most* $2N$ solutions in $]0,1[$. Consequently, ω^* has at most N connected components unless if ω^* contains an interval of the kind $[0,\eta]$ (and also $[1-\eta,1]$ by symmetry). But this last case cannot happen since, for every small $\beta > 0$ and for every integer n, $\int_0^\eta \phi_n(x)dx < \int_\beta^{\beta+\eta} \phi_n(x)dx$. □

The equation (3.9) shows that the optimal domain ω^* is a level set of the function Ψ_Λ but, of course, it remains to find the Lagrange multipliers $\Lambda = (\lambda_k)_{k\in I(a^*)}$ and also to find $I(a^*)$. The following theorem gives the answer to the second question and also gives a practical way to determine ω^* *at least* for small l.

THEOREM 3.2. *For each integer N, there exists a real $l_N \le 1$ such that for $l \le l_N$, the optimal domain ω_N^* satisfies*

$$j_1(\omega_N^*) = j_2(\omega_N^*) = \cdots = j_N(\omega_N^*). \tag{3.10}$$

Remark 1. The relations (3.10) together with the description of ω_N^* as a symmetric union of at most N intervals yields a practical way to determine the optimum. Indeed, let us assume for example that $N = 2M$ is even. We write

$$\omega_N^* = \bigcup_{k=1}^{M} [a_k - l_k/2, a_k + l_k/2] \cup \bigcup_{k=1}^{M} [1 - a_k - l_k/2, 1 - a_k + l_k/2],$$

then the relations (3.10) with the supplementary equality $\sum_{k=1}^M l_k = l/2$ yields a $2M \times 2M$ nonlinear system whose (unique) solution gives the desired domain. We will use this remark later in section 4.

Remark 2. The relations (3.10) do not hold for any value of the constraint l as it is shown by the following (numerical) example. Take $N = 3$ and $l = 0.9$ then the optimal domain is

$$\omega_3^* = [0.0475707, 0.3417644] \cup [0.3441937, 0.6558063] \cup [0.6582356, 0.9524293]$$

which satisfies $j_1(\omega_3^*) > j_2(\omega_3^*) = j_3(\omega_3^*)$ and $J_3(\omega_3^*) = 0.987672$ while for the best domain satisfying $j_1 = j_2 = j_3$, we have only $J_3(\omega) = 0.987177$. Actually, we can see numerically that the constant l_N decreases when N increases.

Proof of Theorem 3.2. The first idea consists of transposing the problem in finite dimension thanks to the following trick. Let $\mathcal{K}_N^l$ be the subset of $\mathbb{R}^N$ defined by

$$\mathcal{K}_N^l = \{X = (x_1, x_2, \ldots, x_N), \text{ s.t. } \exists a \in \mathcal{A}_l \text{ with } x_i = j_i(a), i = 1, 2, \ldots, N\}. \tag{3.11}$$

We will also write $\mathcal{K}_N^l = \mathcal{K}$ when N and l are fixed, since no misunderstanding is possible. The set $\mathcal{K}$ is obviously convex and compact, since it is the image of $\mathcal{A}_l$ by the linear (continuous) functional $a \mapsto (j_1(a), j_2(a), \ldots, j_N(a))$. We will give in section 5 some supplementary properties of $\mathcal{K}$.

The first bissectrix $\Delta = \{X \in \mathbb{R}^N,\ x_1 = x_2 = \cdots = x_N\}$ meets $\mathcal{K}$ (take $a = l$ a constant: we have $j_i(a) = l$ for all i). Therefore, we can introduce the point X^*, the furthest point of $\Delta \cap \mathcal{K}$,

$$X^* = (x^*, x^*, \dots, x^*) \text{ with } x^* = \max\{x \text{ such that } X = (x, x, \dots, x) \in \Delta \cap \mathcal{K}\}.$$

Note that $x^* > l$ since $a = l$ cannot be the maximizer of J_N. The claim in Theorem 3.2 is equivalent to say that X^* solves the maximization problem

$$G(X^*) = \max_{X \in \mathcal{K}} G(X), \quad \text{where } G(X) = \min_{1 \le k \le N} \{x_k\}. \tag{3.12}$$

A geometrical interpretation of (3.12) consists in saying that there is no point of $\mathcal{K}$ in the quadrant

$$\mathcal{Q} = \{X = (x_1, x_2, \dots, x_N) \in \mathbb{R}^N;\ x_i > x^*, i = 1, 2, \dots, N\}.$$

To prove Theorem 3.2, we argue by contradiction. We will prove that if $\mathcal{Q} \cap \mathcal{K}$ is not empty, there exists a point of the bissectrix Δ in $\mathcal{Q} \cap \mathcal{K}$ (at least for l small enough) which contradicts the fact that X^* maximizes G on $\Delta \cap \mathcal{K}$. For that purpose, we introduce X_k to be the furthest point of $\mathcal{K}$ in the direction of x_k (the kth coordinate). Actually, we can determine X_k. Indeed, X_k is obtained by solving the maximization problem: find $a \in \mathcal{A}_l$ which maximizes $\int_0^1 a(x) \sin^2 k\pi x \, dx$. It follows from the proof of Theorem 3.1 (steps $2, 3, 5$, and, in particular relation (3.9)) that the maximizer is a characteristic function $\chi_{\omega_k^*}$, level set of the function $\sin^2 k\pi x$. Therefore,

$$\omega_k^* = \bigcup_{j=0}^{k-1} \left[\frac{2j+1}{2k} - \frac{l}{2k}, \frac{2j+1}{2k} + \frac{l}{2k} \right].$$

We can easily deduce the coordinates of X_k. For $k = 1$,

$$j_m(\omega_1^*) = l + (-1)^{m+1} \frac{\sin m\pi l}{m\pi} \tag{3.13}$$

while, for $k \ge 2$,

$$j_m(\omega_k^*) = l - \sum_{j=0}^{k-1} \frac{1}{m\pi} \sin \frac{m\pi l}{k} \cos \frac{2m\pi(2j+1)}{2k}.$$

Using $\sum_{j=0}^{k-1} \cos \frac{m\pi(2j+1)}{k} = 0$ for $m \neq k$, this yields

$$j_m(\omega_k^*) = l \text{ if } m \neq k \text{ and } j_k(\omega_k^*) = l + \frac{1}{\pi} \sin \pi l. \tag{3.14}$$

For simplicity, let us put the origin at X^*. In this case, to sum up the vertices of the set $\mathcal{K}$ in the direction of the coordinate axis are the points

$$X_1 = \begin{pmatrix} h \\ \beta_2 \\ \beta_3 \\ \vdots \\ \beta_N \end{pmatrix} \quad X_2 = \begin{pmatrix} -\alpha \\ h \\ -\alpha \\ \vdots \\ -\alpha \end{pmatrix} \quad X_3 = \begin{pmatrix} -\alpha \\ -\alpha \\ h \\ -\alpha \\ \vdots \end{pmatrix} \quad \dots \quad X_N = \begin{pmatrix} -\alpha \\ -\alpha \\ \vdots \\ -\alpha \\ h \end{pmatrix},$$

where

$$\begin{array}{l}\alpha = x^* - l > 0,\\ h = l + \frac{\sin \pi l}{\pi} - x^* > 0,\\ \text{and } \beta_i = l + (-1)^{i+1}\frac{\sin i\pi l}{i\pi} - x^*, i = 2, \ldots, N.\end{array} \tag{3.15}$$

As explained above, let us assume (for a contradiction) that there is a point $X_0 = (x_1^0, \ldots, x_N^0)^T$ in $\mathcal{Q} \cap \mathcal{K}$. We are looking for a point X, convex combination of $X^* = O$, X_0, X_1, $X_2, \ldots, X_N$ (which ensures that X will be in $\mathcal{K}$) that we want to be in the set $\mathcal{Q}$ and on the bissectrix Δ. Existence of such a point would lead to a contradiction since X^* maximizes G on $\Delta \cap \mathcal{K}$. We write X as

$$X = (1-s)O + tX_0 + \sum_{i=1}^{N} \lambda_i X_i,$$

where

$$0 < s \leq 1,\ 0 \leq t \leq 1,\ 0 \leq \lambda_i \leq 1,\ t + \sum_{i=1}^{N} \lambda_i = s. \tag{3.16}$$

Let us first express that X must belong to Δ. Writing $x_1 = x_2$, $x_1 = x_3$, etc. this yields the following system:

$$\left\{\begin{array}{c} tx_1^0 + \lambda_1 h - \lambda_2 \alpha = tx_2^0 + \lambda_1 \beta_2 + \lambda_2 h\\ tx_1^0 + \lambda_1 h - \lambda_3 \alpha = tx_3^0 + \lambda_1 \beta_3 + \lambda_3 h\\ \vdots\\ tx_1^0 + \lambda_1 h - \lambda_N \alpha = tx_N^0 + \lambda_1 \beta_N + \lambda_N h. \end{array}\right. \tag{3.17}$$

Summing these relations and using (3.16) gives

$$(N-1)tx_1^0 + (N-1)\lambda_1 h - \alpha(s - t - \lambda_1) = t\sum_{i=2}^{N} x_i^0 + \lambda_1 \sum_{i=2}^{N} \beta_i + h(s - t - \lambda_1)$$

what can be written, thanks to (3.15) is

$$t\left[\left(Nx_1^0 - \sum_{i=1}^{N} x_i^0\right) + \frac{\sin \pi l}{\pi}\right] + \lambda_1 \left[\sum_{i=2}^{N}(h - \beta_i) + \frac{\sin \pi l}{\pi}\right] = \frac{\sin \pi l}{\pi}\, s. \tag{3.18}$$

Let us introduce

$$\Sigma = \sum_{i=2}^{N}(h - \beta_i) + \frac{\sin \pi l}{\pi} = N\frac{\sin \pi l}{\pi} + \sum_{i=2}^{N}(-1)^i \frac{\sin i\pi l}{i\pi}.$$

From now on, we will assume $l \leq 1/(2N)$. Then, Σ is clearly positive. We get λ_1 from (3.18),

$$\lambda_1 = \left(\frac{\sin \pi l}{\pi}\, s - t\left[\left(Nx_1^0 - \sum_{i=1}^{N} x_i^0\right) + \frac{\sin \pi l}{\pi}\right]\right)/\Sigma. \tag{3.19}$$

Replacing in each equation (3.17) gives the value of λ_k,

$$\lambda_k = \frac{t(x_1^0 - x_k^0)}{\frac{\sin \pi l}{\pi}} + \frac{\lambda_1(h - \beta_k)}{\frac{\sin \pi l}{\pi}}. \tag{3.20}$$

We now use $h - \beta_k = \frac{\sin \pi l}{\pi} + (-1)^k \frac{\sin k\pi l}{k\pi}$ (see (3.15)) and we introduce normalized coordinates: $y_k^0 := \frac{x_k^0}{\frac{\sin \pi l}{\pi}}$. Therefore, (3.19) and (3.20) can be rewritten

$$\begin{aligned} \lambda_1 &= \frac{\frac{\sin \pi l}{\pi}}{\Sigma} \left(s - t - t \left(N y_1^0 - \sum_{i=1}^N y_i^0 \right) \right) \\ \lambda_k &= t(y_1^0 - y_k^0) + \frac{\frac{\sin \pi l}{\pi} + (-1)^k \frac{\sin k\pi l}{k\pi}}{\Sigma} \left(s - t - t \left(N y_1^0 - \sum_{i=1}^N y_i^0 \right) \right). \end{aligned} \tag{3.21}$$

We also compute x_1 $(= x_2 = \cdots = x_N)$, and easily obtain

$$x_1 = s \left(\frac{(\frac{\sin \pi l}{\pi})^2}{\Sigma} - \alpha \right) + t \left(x_1^0 + \alpha - \frac{(\frac{\sin \pi l}{\pi})^2}{\Sigma} - \frac{\frac{\sin \pi l}{\pi}}{\Sigma} \left(N x_1^0 - \sum_{i=1}^N x_i^0 \right) \right). \tag{3.22}$$

We recall that we want $\lambda_1 \geq 0$. So, we have the *first necessary condition*,

$$Q_1 := s - t \left(1 + N y_1^0 - \sum_{i=1}^N y_i^0 \right) \geq 0. \tag{3.23}$$

We will now express that every λ_k has also to be nonnegative. For that purpose, we introduce the (nonpositive) number

$$-\xi := \min_{1 \leq k \leq N} (y_1^0 - y_k^0), \tag{3.24}$$

and we assume the *second necessary condition*,

$$\xi t \leq \frac{\frac{\sin \pi l}{\pi} - \frac{\sin 3\pi l}{3\pi}}{\Sigma} Q_1. \tag{3.25}$$

Equation (3.24) together with (3.25) imply

$$\forall k,\ t(y_1^0 - y_k^0) \geq -\xi t \geq \frac{\frac{\sin 3\pi l}{3\pi} - \frac{\sin \pi l}{\pi}}{\Sigma} Q_1.$$

Therefore, from (3.20), it comes that

$$\lambda_k \geq \frac{\frac{\sin 3\pi l}{3\pi} + (-1)^k \frac{\sin k\pi l}{k\pi}}{\Sigma} Q_1. \tag{3.26}$$

For $k = 2, 3, 4$, it is clear that (3.26) with (3.23) imply $\lambda_k \geq 0$. For higher values of k, it is also true. Indeed, since $x \mapsto \sin x/x$ is decreasing for $x < \pi/2$, we have $\sin(3\pi l)/(3\pi) \geq \sin(k\pi l)/(k\pi)$ for $3 \leq k \leq N$.

In conclusion, if we assume (3.23), (3.25), and $l < 1/(2N)$, then $\lambda_k \geq 0$, for all $k \leq N$. Let us set,

$$\gamma = \frac{t}{s} \quad Y = 1 + N y_1^0 - \sum_{i=1}^N y_i^0.$$

Then (3.23) can be rewritten as $1-\gamma Y \geq 0$ and is obviously true for γ small enough. In the same way, (3.25) is

$$\xi\gamma \leq \frac{\frac{\sin \pi l}{\pi} - \frac{\sin 3\pi l}{3\pi}}{\Sigma}(1-\gamma Y),$$

which is also true for γ small since $\dfrac{\sin \pi l}{\pi} - \dfrac{\sin 3\pi l}{3\pi} > 0$.

It remains to be checked whether x_1, given by (3.22), is positive. With the previous notations,

$$x_1 = \gamma\left(x_1^0 - Y\frac{(\frac{\sin \pi l}{\pi})^2}{\Sigma} + \alpha\right) + \frac{(\frac{\sin \pi l}{\pi})^2}{\Sigma} - \alpha.$$

therefore if we are able to prove that $\dfrac{(\frac{\sin \pi l}{\pi})^2}{\Sigma} - \alpha > 0$, it will imply that $x_1 > 0$ for γ small enough.
Now, when $l \to 0$

$$\frac{(\frac{\sin \pi l}{\pi})^2}{\Sigma} \sim \begin{cases} \frac{l}{N} \text{ if } N \text{ is odd} \\ \frac{l}{N+1} \text{ if } N \text{ is even.} \end{cases} \tag{3.27}$$

On the other hand, the proof of Theorem 4.1 shows that, when $l \to 0$

$$x^* \sim j_1\left(\bigcup_{k=1}^{N}\left[\frac{k}{N+1} - \frac{l}{2N}\,,\, \frac{k}{N+1} + \frac{l}{2N}\right]\right) = l - \frac{1}{\pi}\sin\frac{\pi l}{2N}\sum_{k=1}^{N}\cos\frac{2k\pi}{N+1}.$$

Since $\sum_{k=1}^{N}\cos\frac{2k\pi}{N+1} = -1$, this yields

$$\alpha = x^* - l \sim \frac{1}{\pi}\sin\frac{\pi l}{2N} \sim \frac{l}{2N}$$

and the result follows from the comparison with (3.27). This finishes the proof of Theorem 3.2. □

4. The spillover phenomenon. We are going to describe more precisely the optimal domain ω_N^* when the length constraint l goes to zero. According to Theorem 3.1, ω_N^* is symmetric and has, at most, N connected components. Therefore,
in the case N even we write $N = 2K$ and there exists $0 < \alpha_1 < \alpha_2 < \cdots < \alpha_K < 1/2$ and $l_1, l_2, \ldots, l_K \geq 0$ such that

$$\omega_N^* = \left(\bigcup_{i=1}^{K}[\alpha_i - l_i/2,\, \alpha_i + l_i/2]\right)\bigcup\left(\bigcup_{i=1}^{K}[1-\alpha_i - l_i/2,\, 1-\alpha_i + l_i/2]\right)$$

in the case N odd we write $N = 2K+1$ and there exists $0 < \alpha_1 < \alpha_2 < \cdots < \alpha_K < 1/2$ and $l_1, l_2, \ldots, l_{K+1} \geq 0$ such that

$$\omega_N^* = \left(\bigcup_{i=1}^{K}[\alpha_i - l_i/2,\, \alpha_i + l_i/2]\right)\bigcup[1/2 - l_{K+1}/2,\, 1/2 + l_{K+1}/2]\ \ldots$$

$$\ldots\ \bigcup\left(\bigcup_{i=1}^{K}[1-\alpha_i - l_i/2,\, 1-\alpha_i + l_i/2]\right).$$

The main result of this section is the following theorem.

THEOREM 4.1. *When l goes to 0, the optimal domain for the N first modes ω_N^* concentrates around the nodes of the $N+1$th eigenfunction.*
More precisely,when $l \to 0^+$,

$$\forall i, \quad \alpha_i(l) \to \frac{i}{N+1}, \quad l_i(l) \sim \frac{l}{N}.$$

For the sake of simplicity, we are going to prove this result in the case $N = 2K$ even, the case N odd is exactly similar. We now express that ω_N^* satisfies

$$j_1(\omega_N^*) = j_2(\omega_N^*) = \cdots = j_N(\omega_N^*). \tag{4.1}$$

This yields

$$\begin{cases} \displaystyle\sum_{i=1}^{K} \left[\frac{1}{n\pi} \sin n\pi l_i \cos 2n\pi\alpha_i - \frac{1}{(n-1)\pi} \sin(n-1)\pi l_i \cos(2n-2)\pi\alpha_i \right] = 0 \\ \qquad \text{for } n = 2, 3, \ldots, N. \end{cases} \tag{4.2}$$

Asymptotically, when l goes to 0, the (α_i)s and the (l_i)s are therefore solutions of the linearized system (in a neighborhood of $l = 0$),

$$\sum_{i=1}^{K} l_i(\cos 2n\pi\alpha_i - \cos(2n-2)\pi\alpha_i) = 0, \qquad \text{for } n = 2, 3, \ldots, N. \tag{4.3}$$

Now if (l_p) is a sequence which tends to 0, after extracting a finite number of subsequence, we can write $l_i^p = t_i(l_p).l_p$ with $t_i(l_p) \in [0, 1]$ converging to t_i and $a_i(l_p)$ which converge to a_i. The system (4.3) leads to the following system:

$$\begin{cases} t_1 \sin \pi\alpha_1 \sin 3\pi\alpha_1 + t_2 \sin \pi\alpha_2 \sin 3\pi\alpha_2 + \cdots + t_K \sin \pi\alpha_K \sin 3\pi\alpha_K = 0 \\ t_1 \sin \pi\alpha_1 \sin 5\pi\alpha_1 + t_2 \sin \pi\alpha_2 \sin 5\pi\alpha_2 + \cdots + t_K \sin \pi\alpha_K \sin 5\pi\alpha_K = 0 \\ \vdots \\ t_1 \sin \pi\alpha_1 \sin(2k+1)\pi\alpha_1 + t_2 \sin \pi\alpha_2 \sin(2k+1)\pi\alpha_2 + \cdots \\ \qquad\qquad + t_K \sin \pi\alpha_K \sin(2k+1)\pi\alpha_K = 0 \\ \vdots \\ t_1 \sin \pi\alpha_1 \sin(4K-1)\pi\alpha_1 + t_2 \sin \pi\alpha_2 \sin(4K-1)\pi\alpha_2 + \cdots \\ \qquad\qquad + t_K \sin \pi\alpha_K \sin(4K-1)\pi\alpha_K = 0, \end{cases} \tag{4.4}$$

where we have to add the supplementary equation

$$t_1 + t_2 + \ldots t_K = 1/2. \tag{4.5}$$

This new system can be viewed as a $(2K-1) \times (2K-1)$ linear system with unknowns t_1, t_2, …, t_K. Of course these unknowns cannot all be equal to zero because of the supplementary equation (4.5). Therefore the matrix A of system (4.4) must be of rank less or equal to $K-1$. It means that

$$\text{all determinants } K \times K \text{ extracted from } A \text{ are equal to 0.} \tag{4.6}$$

Let us denote by $\mathcal{L}_1, \mathcal{L}_2, \ldots, \mathcal{L}_{2K-1}$, the lines of the matrix A,

(4.7)
$$A = \begin{pmatrix} \sin\pi\alpha_1 \sin 3\pi\alpha_1 & \ldots & \sin\pi\alpha_K \sin 3\pi\alpha_K \\ \sin\pi\alpha_1 \sin 5\pi\alpha_1 & \ldots & \sin\pi\alpha_K \sin 5\pi\alpha_K \\ \vdots & & \vdots \\ \sin\pi\alpha_1 \sin(4K-1)\pi\alpha_1 & \ldots & \sin\pi\alpha_K \sin(4K-1)\pi\alpha_K \end{pmatrix} \begin{matrix} \to \mathcal{L}_1 \\ \to \mathcal{L}_2 \\ \vdots \\ \to \mathcal{L}_{2K-1}. \end{matrix}$$

Now, let us compute the following $K \times K$ determinant:

$$D_0 = \det(\mathcal{L}_K + \mathcal{L}_K, \mathcal{L}_{K-1} + \mathcal{L}_{K+1}, \ldots, \mathcal{L}_1 + \mathcal{L}_{2K-1}).$$

According to (4.6), $D_0 = 0$.
On the other hand, for $k = 0, 1, \ldots, K-1$ and $i = 1, 2, \ldots, K$,

$$\sin(2(K-k)+1)\pi\alpha_i + \sin(2(K+k)+1)\pi\alpha_i = 2\sin(2K+1)\pi\alpha_i \cos 2k\pi\alpha_i.$$

Therefore

$$D_0 = 2^K \left(\prod_{i=1}^{K} \sin\pi\alpha_i\right) \left(\prod_{i=1}^{K} \sin(2K+1)\pi\alpha_i\right) D_0',$$

where D_0' is the determinant,

$$D_0' = \begin{vmatrix} 1 & 1 & \ldots & 1 \\ \cos 2\pi\alpha_1 & \cos 2\pi\alpha_2 & \ldots & \cos 2\pi\alpha_K \\ \vdots & \vdots & & \vdots \\ \cos 2(K-1)\pi\alpha_1 & \cos 2(K-1)\pi\alpha_2 & \ldots & \cos 2(K-1)\pi\alpha_K \end{vmatrix}.$$

This determinant D_0' can be computed thanks to Tchebyshev polynomials T_k, already introduced ($\cos kx = T_k(\cos x)$) with T_k of degree k and highest degree term is $2^{k-1}X^k$, $k \geq 1$. Since the family $(T_k)_{0 \leq k \leq K-1}$ is a basis of polynomial of degree less than $K-1$, we can write

$$D_0' = \left(\prod_{k=1}^{K-1} 2^{k-1}\right) \begin{vmatrix} 1 & 1 & \ldots & 1 \\ \cos 2\pi\alpha_1 & \cos 2\pi\alpha_2 & \ldots & \cos 2\pi\alpha_K \\ \vdots & \vdots & & \vdots \\ \cos^{K-1} 2\pi\alpha_1 & \cos^{K-1} 2\pi\alpha_2 & \ldots & \cos^{K-1} 2\pi\alpha_K \end{vmatrix}.$$

Now this last determinant is the so-called van der Mond determinant, so

$$\begin{aligned} D_0' &= 2^{\frac{(K-1)(K-2)}{2}} \prod_{1 \leq i < j \leq K} (\cos 2\pi\alpha_i - \cos 2\pi\alpha_j) \\ &= 2^{\frac{(K-1)(K-2)}{2}} \prod_{1 \leq i < j \leq K} 2(\cos^2 \pi\alpha_i - \cos^2 \pi\alpha_j) \\ &= 2^{(K-1)^2} \prod_{1 \leq i < j \leq K} (\cos^2 \pi\alpha_i - \cos^2 \pi\alpha_j). \end{aligned} \tag{4.8}$$

This last equality shows that D_0' cannot vanish (we recall that the (α_i) is an increasing sequence with $0 < \pi\alpha_i < \pi/2$). Moreover, the product $\prod_{i=1}^{K} \sin\pi\alpha_i$ is not zero

since, for all i, $\alpha_i \in]0,1/2[$. In conclusion, there exists $p \in \{1,2,\dots,K\}$ such that $\sin(2K+1)\pi\alpha_p = 0$, it means that there exists $q \in \{1,2,\dots,K\}$ such that $\alpha_p = \frac{q}{2K+1}$.

Let us now compute, in the same way, the following $K \times K$ determinant:

$$D_1 = \det(\mathcal{L}_K + \mathcal{L}_K, \mathcal{L}_{K-1} + \mathcal{L}_{K+1}, \dots, \mathcal{L}_2 + \mathcal{L}_{2K-2}, \mathcal{L}_1).$$

For the same reason as above, $D_1 = 0$. Grouping the sin terms yields

$$D_1 = 2^K \left(\prod_{i=1}^{K} \sin \pi\alpha_i \right) \left(\prod_{i=1,\,2\,,\dots,K\,;\,i\neq p} \sin(2K+1)\pi\alpha_i \right) D_1',$$

where D_1' is the determinant

$$D_1' = \begin{vmatrix} 1 & \dots & 0 & \dots & 1 \\ \cos 2\pi\alpha_1 & \dots & 0 & \dots & \cos 2\pi\alpha_K \\ \vdots & & \vdots & & \vdots \\ \cos 2(K-1)\pi\alpha_1 & \dots & \sin \frac{3\pi q}{2K+1} & \dots & \cos 2(K-1)\pi\alpha_K \end{vmatrix}.$$

Developing D_1' with respect to its pth column, it appears a $K-1 \times K-1$ determinant similar to D_0'. This shows that D_1' does not vanish. Therefore, there exists $r \neq p$ such that $\sin(2K+1)\pi\alpha_r = 0$, which means that there exists $s \in \{1,2,\dots,K\}$ such that $\alpha_r = \frac{s}{2K+1}$.

By computing successively, using the same method as for D_1, the determinants D_2, D_3, …, D_{K-1}, with

$$\begin{aligned} D_2 &= \det(\mathcal{L}_K + \mathcal{L}_K,\, \mathcal{L}_{K-1} + \mathcal{L}_{K+1}, \dots,\, \mathcal{L}_3 + \mathcal{L}_{2K-3},\, \mathcal{L}_2,\, \mathcal{L}_1 + \mathcal{L}_{2K-1}) \\ D_3 &= \det(\mathcal{L}_K + \mathcal{L}_K,\, \mathcal{L}_{K-1} + \mathcal{L}_{K+1}, \dots,\, \mathcal{L}_3,\, \mathcal{L}_2 + \mathcal{L}_{2K-2},\, \mathcal{L}_1 + \mathcal{L}_{2K-1}) \\ &\vdots \\ D_{K-1} &= \det(\mathcal{L}_K + \mathcal{L}_K,\, \mathcal{L}_{K-1},\, \mathcal{L}_{K-2} + \mathcal{L}_{K+2} \dots, \mathcal{L}_2 + \mathcal{L}_{2K-2},\, \mathcal{L}_1 + \mathcal{L}_{2K-1}), \end{aligned}$$

we can show that, for all $1 \le i \le K$, there exists p_i such that $\alpha_i = \frac{p_i\pi}{2K+1}$. Since the sequence (α_i) is increasing, we have

$$\forall i \in \{1,\, 2,\, \dots,\, K\} \quad \alpha_i = \frac{i\pi}{2K+1}.$$

Let us now show that the rank of the matrix A is exactly $K-1$. For that purpose, we compute the determinant D obtained from A by taking the $K-1$ first lines and removing the last column,

$$D = \left[\prod_{i=1}^{K-1} \sin \frac{i\pi}{2K+1} \right] \det \left(\left(\sin \frac{(2i+1)\pi j}{2K+1} \right)_{1 \le i,\, j \le K-1} \right).$$

Let us denote by U_n Tchebyshev's polynomial of second kind: $\sin n\theta = \sin\theta\, U_n(\cos\theta)$. We then obtain

$$D = \left[\prod_{i=1}^{K-1} \sin \frac{i\pi}{2K+1} \right] \det \left(\left(U_j \left(\sin \frac{(2i+1)\pi}{2K+1} \right) \right)_{1 \le i,\, j \le K-1} \right).$$

Since U_n has for first term $2^n X^n$, $n \geq 1$, we get

$$D = 2^{\frac{(K-2)(K-3)}{2}} \left(\prod_{i=1}^{K-1} \sin \frac{i\pi}{2K+1} \right) \left(\prod_{1 \leq i < j \leq K-1} \left(\cos \frac{(2i+1)\pi}{2K+1} - \cos \frac{(2j+1)\pi}{2K+1} \right) \right).$$

This proves that $D \neq 0$ and A has rank $K-1$. Therefore, its kernel is of dimension one.

Let us now show that $(1, 1, \ldots, 1)^t$ belongs to the kernel of A. For that purpose, we compute, for $1 \leq k \leq 2K-1$ the sum

$$S_k = 2 \sum_{l=1}^{K} \sin \frac{l\pi}{2K+1} \sin \frac{(2k+1)l\pi}{2K+1} = \sum_{l=1}^{K} \left[\cos \frac{2lk\pi}{2K+1} - \cos \frac{2l(k+1)\pi}{2K+1} \right].$$

Using $\sum_{l=1}^{K} \cos l\theta = \cos \frac{(K+1)\theta}{2} \cdot \frac{\sin \frac{K\theta}{2}}{\sin \frac{\theta}{2}}$, it comes that $S_k = 0$ if and only if

$$\cos \frac{(K+1)k\pi}{2K+1} \sin \frac{Kk\pi}{2K+1} \sin \frac{(k+1)\pi}{2K+1} = \cdots$$

$$\cdots = \cos \frac{(K+1)(k+1)\pi}{2K+1} \sin \frac{K(k+1)\pi}{2K+1} \sin \frac{k\pi}{2K+1}.$$

This last equality is easy to check.

In conclusion, since $(t_1, t_2, \ldots, t_K)^t$ belongs to the kernel of A and $t_1 + t_2 + \cdots + t_K = 1/2$, we get $t_1 = t_2 = \cdots = t_K = 1/(2K)$. Finally, for every subsequence (l_k) converging to 0, $(t_i(l_k))$ has a unique accumulation point; the whole sequence $t_i(l)$ converges to that point $1/K$. In the same way, the functions $\alpha_i(l)$ converge to $i/(K+1)$ when l goes to 0. □

5. Comments.

5.1. Possible remedies. To avoid the spillover phenomenon which is described here, we can imagine different possible strategies. The first one is obviously to take into account all eigenmodes, possibly with different weights for each (e.g., weights decreasing with the rank of the mode).

Another possibility could be inspired by the introduction of an artificial (numerical) viscosity like in papers [23], [24]. For the one-dimensional wave equation, these authors choose to introduce a semidiscrete term coming from $-h^2 u_{xxt}$. This has the great advantage to keep the decay properties of the discrete equation which are generally lost under the semidiscrete finite-differences scheme. It would be very interesting to see what is the impact of this viscosity term in the context of our paper.

5.2. Larger values of l. It is essentially for technical reasons that the "spillover" phenomenon is described in the case $l \to 0$. Actually, this phenomenon holds for most values of l. Figure 5.1 shows numerical results for $N = 3$. The left picture shows the optimal domain ω_3^* for each value of l. One obtains ω_3^* as the intersection of the vertical line $x = l$ with the interior of the three peeks. The right picture shows in boldface the graph of $l \mapsto J_3(\omega_3^*)$ and below, in medium, the graph of $l \mapsto j_4(\omega_3^*)$. We see that, in any case (unless for l close to 1), ω_3^* has a very poor behavior for the fourth eigenmode. One can find more examples in [14].

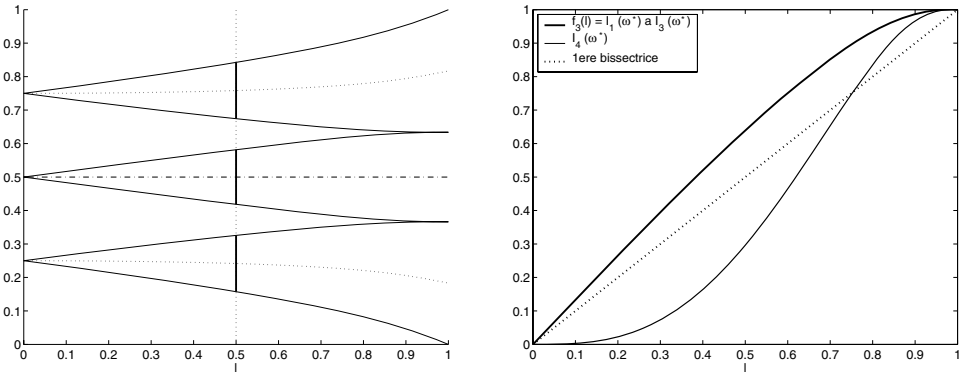

FIG. 5.1. Left: The optimal domain ω_3^* (read vertically). Right: Graphs of $J_3(\omega_3^*)$ (boldface) and $j_4(\omega_3^*)$

5.3. More about the set $\mathcal{K}$. For similar optimization problems, it is interesting to have a more precise description of the set $\mathcal{K}$ which is introduced in (3.11). In particular, a characterization of its boundary can be very useful. Let X be a point in $\mathcal{K}$. Then X belongs to $\partial\mathcal{K}$ if and only if there exists a unit vector $\mathbf{n}$ such that

$$\forall\, Y \in \mathcal{K} \quad (Y - X, \mathbf{n}) \leq 0.$$

Writing $\mathbf{n} = (n_1, n_2, \ldots, n_N)^T$, $X = (j_1(a), \ldots, j_N(a))^T$ and $Y = (j_1(b), \ldots, j_N(b))^T$, the latter reads

$$\forall b \in \mathcal{A}_l \quad \sum_{k=1}^{N} n_k j_k(b) \leq \sum_{k=1}^{N} n_k j_k(a).$$

In other terms, a is a maximizer of the functional $b \mapsto \sum_{k=1}^{N} n_k j_k(b)$. According to the proof of Theorem 3.1, it follows that a is necessarily the characteristic function of a set ω which is the union of at most $N+1$ intervals and is symmetric with respect to $1/2$. The fact that we can have $N+1$ intervals here is due to the fact that intervals of the kind $[0, \eta]$ or $[1-\eta, 1]$ are allowed here (see step 5 in the proof of Theorem 3.1). Figure 5.2 (left) shows the set $\mathcal{K}_2$ for $l = 0.3$. Its boundary is exactly the image of

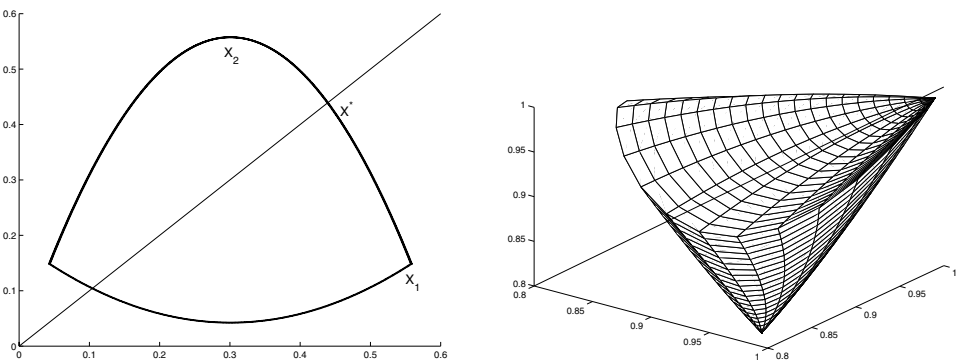

FIG. 5.2. Left: The set $\mathcal{K}_2$ for $l = 0.3$. Right: The set $\mathcal{K}_3$ for $l = 0.9$

characteristic functions χ_ω with ω as a symmetric (w.r.t. 1/2) set obtained as a union of one, two, or three intervals (in this last case two of the three intervals must touch 0 and 1). Figure 5.2 (right) shows the set $\mathcal{K}_3$ for $l = 0.9$. Its boundary is obtained with a symmetric union of one, two, three, or four intervals (in this last case two of the four intervals must touch 0 and 1). This picture shows a case where the first bissectrix does not cut the set $\mathcal{K}_3$ at the point which maximizes $\min(x_1, x_2, x_3)$; see Remark 2.

5.4. Generalization to the two-dimensional case. The existence and uniqueness part of Theorem 3.1 can be easily generalized to more general domains Ω in higher dimension if the following property holds:

$$\text{(5.1)} \quad \begin{cases} \text{Let } \varphi_1, \varphi_2, \dots, \varphi_N \text{ be the (normalized) eigenfunctions of the Laplace} \\ \text{operator on } \Omega \text{ with Dirichlet boundary conditions on } \partial\Omega, \text{ then} \\ \varphi_1^2, \varphi_2^2, \dots, \varphi_N^2 \text{ are linearly independent on } \omega. \end{cases}$$

Indeed, when we look at the proof of Theorem 3.1, we observe that it can easily be adapted to any dimension, the only technical point being (3.7).

The property (5.1) is obviously true for rectangles in two dimensions or, more generally, parallelepiped in N-dimension, but the authors do not know if it holds for every domain (even for a disc). For a related result in one dimension, see [19]. In this paper the authors prove that for a nonhomogeneous Sturm–Liouville eigenvalue problem, it happens very frequently that the N first eigenfunctions, with $N \geq 3$, have linearly dependent squares on some nontrivial interval. A transposition of this one-dimensional result to our case could lead to the following conjecture:

Open problem 1: Prove that for every domain Ω, there exists a domain $\tilde{\Omega}$ close to Ω such that the square of a given number of eigenfunctions of the Laplace–Dirichlet operator on $\tilde{\Omega}$ are linearly dependent. On the other hand, if the result (5.1) is wrong for some domain Ω, one can also imagine some genericity result in the spirit of [20], [21], [22] which could, for example, be stated like:

Open problem 2: Let Ω be an open set such that $\varphi_1^2, \varphi_2^2, \dots, \varphi_N^2$ are linearly dependent. Then, prove that there exists arbitrary small deformations of its boundary such that the square of the eigenfunctions of the perturbed domain become linearly independent.

Following step 5 of the proof of Theorem 3.1, if (5.1) is true (and therefore a unique optimal domain exists), this optimal domain can also be described as a level set of some linear combination of $\varphi_1^2, \varphi_2^2, \dots, \varphi_N^2$. Now, the other results of this paper, Theorems 3.2 and 4.1, seem more difficult to prove in the two-dimensional case, even if the authors believe that they are true.

DEGENERATE STOCHASTIC CONTROL PROBLEMS WITH EXPONENTIAL COSTS AND WEAKLY COUPLED DYNAMICS: VISCOSITY SOLUTIONS AND A MAXIMUM PRINCIPLE*

MINYI HUANG†, PETER E. CAINES‡, AND ROLAND P. MALHAMÉ§

Abstract. This paper considers a class of optimization problems arising in wireless communication systems. We analyze the optimal control and the associated Hamilton–Jacobi–Bellman (HJB) equations. It turns out that the value function is a unique viscosity solution of the HJB equation in a certain function class. To deal with the fast growth condition of the value function in establishing uniqueness, we construct particular semiconvex/semiconcave approximations for the viscosity sub/supersolutions, and obtain a maximum principle on unbounded domains. The localized envelope function technique introduced in this paper permits an analysis of the uniqueness of viscosity solutions defined on unbounded domains in cases with very general growth conditions when combined with appropriate system dynamics. The optimization problem with state constraints is also considered.

Key words. degenerate stochastic control, power control, HJB equations, dynamic programming, viscosity solutions

1. Introduction.

This paper is concerned with a class of optimization problems arising in power control for wireless communication systems, and forms a mathematical foundation for the results in [7, 8]. We will first formulate a class of degenerate stochastic control problems, which take the approach of regulating the state of a controlled process where an exogenous random parameter process is involved in the performance function, and then we use a communications application example to give a background illustration for the general formulation.

The random parameter process and the controlled process are denoted by $x_t \in \mathbb{R}^n$ and $p_t \in \mathbb{R}^n$, $t \in \mathbb{R}_+$, respectively. Suppose that x is modeled by the stochastic differential equation

$$dx = f(t,x)dt + \sigma(t,x)dw, \quad t \geq 0, \tag{1.1}$$

where f and σ are the drift and diffusion coefficients, respectively; w is an n dimensional standard Wiener process with covariance $Ew_t w_t^\tau = tI$; and the initial state x_0 is independent of $\{w_t,\ t \geq 0\}$ with finite exponential moment, i.e., $Ee^{2|x_0|} < \infty$.

The process p is governed by the model

$$dp = g(t, x, p, u)dt, \quad t \geq 0, \tag{1.2}$$

where the component $g_i(t, x, p, u)$, $1 \leq i \leq n$, controls the size of the increment dp_i at the time instant t, $u \in \mathbb{R}^n$, $|u_i| \leq u_{i\max}$, $1 \leq i \leq n$. Without loss of generality we set $u_{i\max} = 1$, and we shall write

$$x = [x_1, \ldots, x_n]^\tau, \qquad p = [p_1, \ldots, p_n]^\tau, \qquad u = [u_1, \ldots, u_n]^\tau.$$

In the regulation of p, we introduce the following cost function:

$$J = E \int_0^T [p^\tau C(x)p + 2D^\tau(x)p]dt, \tag{1.3}$$

where $T < \infty$; $C(x)$ and $D(x)$ are an $n \times n$ positive definite matrix and an $n \times 1$ vector, respectively; and the components of $C(x)$ and $D(x)$ are exponential functions of linear combinations of x_i, $1 \leq i \leq n$. For simplicity, in this paper we take $C_{ij}(x) = c_{ij}e^{x_i + x_j}$, $D_i(x) = d_i e^{x_i} + s_i$ for $1 \leq i, j \leq n$. This particular structure of the weight coefficients indicates that in the cost function each p_i is directly associated with the parameter component x_i for $1 \leq i \leq n$. Specifically, an expansion of the cost integrand will produce entries in the form of $c_{ij}(e^{x_i}p_i)(e^{x_j}p_j)$, $d_i e^{x_i}p_i$, $s_i p_i$, $1 \leq i, j \leq n$. Intuitively, such a cost structure indicates that the relative weight of each p_i is influenced only by the process x_i. The more general case of expressing the components of $C(x)$ and $D(x)$ as exponential functions of general linear combinations of x_i, $1 \leq i \leq n$, can be considered without further difficulty. We will give the complete optimal control formulation in section 2, where the technical assumptions of weak coupling for the dynamics (1.1)–(1.2) will be introduced.

1.1. The stochastic power control example. We now briefly describe the motivating stochastic power control problem for lognormal fading channels. In an urban environment, due to long distance transmission and reflections, the power attenuations of wireless networks are described by lognormal random processes. Let $x_i(t)$, $1 \leq i \leq n$, denote the power attenuation (expressed in dBs and scaled to the natural logarithm basis) at the instant t of the ith mobile user, and let $\alpha_i(t) = e^{x_i(t)}$ denote the actual attenuation. Based upon the work in [1], the power attenuation dynamics are given as a special form of (1.1):

$$dx_i = -a_i(x_i + b_i)dt + \sigma_i dw_i, \quad t \geq 0,\ 1 \leq i \leq n. \tag{1.4}$$

In (1.4) the constants $a_i, b_i, \sigma_i > 0$, $1 \leq i \leq n$. See [1] for a physical interpretation of the parameters, and furthermore, an experimental justification of the lognormal attenuation modeling may be found in the communications literature [5] using discrete time measurements. In a network, at time t the ith mobile user sends its power $p_i(t)$, and the received power at the base station is $e^{x_i(t)}p_i(t)$. The mobile user has to adjust its power p_i in real time so that a certain communication quality of service (QoS) is maintained. In [6, 7] the adjustment of the (sent) power vector p for the n users is modeled by simply taking $g(t, x, p, u) = u$ in (1.2), which is called the rate adjustment model. Based upon the system signal-to-interference ratio (SIR) requirements, the following averaged integrated performance function,

$$J = E \int_0^T \left\{ \sum_{i=1}^n \left[e^{x_i}p_i - \mu_i \left(\sum_{j=1}^n e^{x_j}p_j + \eta \right) \right]^2 + \lambda \sum_{i=1}^n p_i \right\} dt, \tag{1.5}$$

was employed in [7, 8], where $\eta > 0$ is the system background noise intensity, $\lambda \geq 0$, and μ_i, $1 \leq i \leq n$, is a set of positive numbers determined from the SIR requirements. The resulting power control problem is to adjust u as a function of the system state (x, p) so that the above performance function is minimized.

1.2. The main contents and organization. The analysis in this paper treats a general class of performance functions that have an exponential growth rate with respect to x_i, $1 \leq i \leq n$; hence this analysis covers the cost function in (1.5) and differs from that appearing in most stochastic control problems in the literature, where linear or polynomial growth conditions usually pertain [3, 12]. Two novel features of the class of models (1.1)–(1.2) are (i) neither the drift nor the diffusion of the state subprocess x is subject to control, and hence x may be regarded as an exogenous signal, and (ii) further, the controlled state subprocess p has no diffusion part. Hence (1.1)–(1.2) gives rise to degenerate stochastic control systems. Optimization of such systems leads to degenerate Hamilton–Jacobi–Bellman (HJB) equations, which in general do not admit classical solutions [4, 12].

This paper deals with the mathematical control theoretic questions arising from the class of stochastic optimal control problems considered in [7, 8], where some approximation and numerical methods are proposed for implementation of the control laws. For the resulting degenerate HJB equations, we adopt viscosity solutions and show that the value function of the optimal control is a viscosity solution. To prove uniqueness of the viscosity solution, we develop a localized semiconvex/semiconcave approximation technique. Specifically, we introduce particular localized envelope functions on the unbounded domain to generate semiconvex/semiconcave approximations on any compact set. Compared to previous works [4, 12], by use of the set of envelope functions we can treat very rapid growth conditions, and we note that no Lipschitz or Hölder-type continuity assumption is required for the function class involved. It is worthwhile to note that the localized envelope functions may be applied to generate local semiconvex/semiconcave approximations for viscosity solutions in risk-sensitive stochastic control problems with degenerate diffusions in which the cost involves an exponential function and usually has a very rapid growth.

We also consider the optimal control subject to state constraints, which leads to the formulation of constrained viscosity solutions to the associated second order HJB equations; this part is parallel to [11], where a first order HJB equation is investigated. The paper is organized as follows: in section 2 we state the existence and uniqueness of the optimal control and show that the value function is a viscosity solution to a degenerate HJB equation; we then give two theorems as the main results about the solution of the HJB equation. Section 3 is devoted to introducing a class of semiconvex/semiconcave approximations for continuous functions; this technique enables us to treat viscosity solutions with rapid growth. In section 4, we analyze the HJB equation and prove a maximum principle by which it follows that the HJB equation has a unique viscosity solution in a certain function class. Section 5 considers the control problem subject to state constraints.

Finally, we remark that in the case when an additional control term is introduced to the state subprocess x to give mathematically more general dynamics, one can also derive an HJB equation for the corresponding optimal control problem, which is interesting in its own right, and the semiconvex/semiconcave approximations and uniqueness analysis procedure developed in sections 3 and 4 may still be carried out under appropriate conditions. However, without further conditions for the dynamics of x in the controlled case, in general the control problem needs to be formulated

in a weak solution framework, and the resulting analysis is not in the scope of the present paper.

2. The optimal control and HJB equations. We define

$$z = \begin{pmatrix} x \\ p \end{pmatrix}, \qquad \psi = \begin{pmatrix} f \\ g \end{pmatrix}, \qquad G = \begin{pmatrix} \sigma \\ 0_{n\times n} \end{pmatrix}.$$

We now write (1.1) and (1.2) together in the vector form

$$dz = \psi dt + G dw, \quad t \geq 0. \tag{2.1}$$

In the following analysis we will denote the state variable by (x, p) or z, or in a mixing form; as we do in section 4, we may also write the arguments for the functions in (1.1)–(1.2) in a unified way in terms of (t, z). We write the integrand in (1.3) as $l(z) = l(x, p) = p^\tau C(x)p + 2D^\tau(x)p$. For notational clarity, hereafter we use x_t with a real-valued subscript t to denote the value of the vector process x at time t, and x_i with an integer subscript i to denote the ith component of x; the interpretation of the notation should be clear from the context. This convention also holds for other vector processes involved in the analysis.

The admissible control set is specified as

$$\mathcal{U} = \{u(\cdot) \mid u_t \text{ is adapted to } \sigma(z_s, s \leq t) \text{ and } u_t \in U \stackrel{\triangle}{=} [-1, 1]^n \ \forall 0 \leq t \leq T\}.$$

As is stated in the introduction, the initial state vector is independent of the $n \times 1$ Wiener process w_t, $t \geq 0$; we make the additional assumption that p has a deterministic initial value p_0 at $t = 0$. Then it is easily verified that $\sigma(z_s,\ s \leq t) = \sigma(x_s,\ s \leq t)$. Define $\mathcal{L} = \{u(\cdot) \mid u \text{ is adapted to } \sigma(z_s,\ s \leq t), u_t \in \mathbb{R}^n \text{ and } E\int_0^T |u_s|^2 ds < \infty\}$. If we endow $\mathcal{L}$ with an inner product $\langle u, u'\rangle \stackrel{\triangle}{=} E\int_0^T u^\tau u' ds$ for $u, u' \in \mathcal{L}$, then $\mathcal{L}$ constitutes a Hilbert space with the induced norm $\|u\| = \langle u, u\rangle^{\frac{1}{2}} \geq 0$, $u \in \mathcal{L}$. Under this norm, $\mathcal{U}$ is a bounded, closed, and convex subset of $\mathcal{L}$. Finally, the cost associated with the system (2.1) and a control $u \in \mathcal{U}$ is specified to be

$$J(s, z, u) = E\left[\int_s^T l(z_t)dt | z_s = z\right], \quad z \in \mathbb{R}^{2n}, \tag{2.2}$$

where $s \in [0, T]$ is taken as the initial time of the system; further, we set the value function

$$v(s, z) = \inf_{u\in\mathcal{U}} J(s, z, u), \quad z \in \mathbb{R}^{2n},$$

and simply write $J(0, z, u)$ as $J(z, u)$. The following assumptions on the time interval $[0, T]$ will be used in our further analysis.

(H1) In (1.1)–(1.2), $f \in C([0, T]\times\mathbb{R}^n, \mathbb{R}^n)$, $\sigma \in C([0, T]\times\mathbb{R}^n, \mathbb{R}^{n\times n})$, $g \in C([0, T]\times\mathbb{R}^{3n}, \mathbb{R}^n)$ and f, σ, g satisfy a uniform Lipschitz condition; i.e., there exists a constant $C_0 > 0$ such that $|f(t, x)-f(s, y)| \leq C_0(|t-s|+|x-y|)$, $|\sigma(t, x)-\sigma(s, y)| \leq C_0(|t-s|+|x-y|)$, $|g(t, x, p, u)-g(s, x, q, u)| \leq C_0(|t-s|+|p-q|)$, and $|g(t, x, p, u)-g(t, 0, p, u)| \leq C_0$ for all $t, s \in [0, T]$, $u \in U$, and $x, y, p, q \in \mathbb{R}^n$. In addition, there exists a constant C_σ such that $|\sigma_{ij}(t, x)| \leq C_\sigma$ for $(t, x) \in [0, T] \times \mathbb{R}^n$ and $1 \leq i, j \leq n$.

(H2) For $1 \leq i \leq n$, $f_i(x)$ can be written as $f_i(x) = -a_i(t)x_i + f_i^0(t, x)$, where $a_i(t) \geq 0$ for $t \in [0, T]$, and $\sup_{[0,T]\times\mathbb{R}^n} |f_i^0(t, x)| \leq C_{f^0}$ for a constant $C_{f^0} > 0$.

Throughout this paper we assume that (H1) holds. (H2) is used in Theorems 2.5 and 2.6 for proving uniqueness of the viscosity solution. Clearly (H2) holds for the lognormal fading channel model in the power control example.

Remark 1. Assumption (H1) ensures existence and uniqueness of the solution to (2.1) for any fixed $u \in \mathcal{U}$, where the Lipschitz condition with respect to t will be used to obtain certain estimates in the proof of uniqueness of the viscosity solution. Here σ is assumed to be bounded so as to lead to a finite cost for any initial state and admissible control u.

From (H1)–(H2) it is seen that the system model has the following important features: first, in the diffusion process x the evolution of x_i does not receive strong influence from the other state component x_k, $k \neq i$, in the sense that the cross term $f_i^0(t,x)$ is bounded by a constant; second, an arbitrary increase of x alone in the function $g(t,x,p,u)$ does not result in an unbounded increase in the magnitude of g, and hence x imposes only a relatively weak impact on the evolution of p. Due to the above features, we shall refer to the model (1.1)–(1.2) analyzed in this paper as having *weakly coupled dynamics,* and (H2) will be conveniently referred to as the weak coupling condition for x, which will be used to establish uniqueness of the viscosity solution.

PROPOSITION 2.1 (see [7, 8]). *Assuming in the control model* (1.2) *that* $g(t,x,p,u)$ *is linear in* p *and* u*, i.e., that there exist continuous matrix functions* A_t*,* B_t *on* $[0,T]$ *such that* $g(t,x,p,u) = A_t p + B_t u$*, then there exists an optimal control* $\widehat{u} \in \mathcal{U}$ *such that* $J(x_0,p_0,\widehat{u}) = \inf_{u\in\mathcal{U}} J(x_0,p_0,u)$*, where* (x_0,p_0) *is the initial state at time* $s=0$*; if, in addition,* B_t *is invertible for all* $t \in [0,T]$*, then the optimal control* $\widehat{u}$ *is unique and uniqueness holds in the following sense: if* $\widetilde{u} \in \mathcal{U}$ *is another control such that* $J(x_0,p_0,\widetilde{u}) = J(x_0,p_0,\widehat{u})$*, then* $P_\Omega(\widetilde{u}_s \neq \widehat{u}_s) > 0$ *only on a set of times* $s \in [0,T]$ *of Lebesgue measure zero, where* Ω *is the underlying probability sample space.*

PROPOSITION 2.2. *Assuming* (H1)–(H2)*, the value function* v *is continuous on* $[0,T]\times\mathbb{R}^{2n}$ *and*

$$|v(s,z)| \le C\left[1 + \sum_{i=1}^{n} e^{4z_i} + \sum_{i=n+1}^{2n} z_i^4\right], \tag{2.3}$$

where $C > 0$ *is a constant independent of* (s,z)*.*

Proof. The continuity of v can be established by use of (H1) and the continuous dependence of the cost (2.2) on the initial condition for the system (2.1) when $u \in \mathcal{U}$ is fixed. For an initial state $z_s = z$ and any fixed $u \in \mathcal{U}$, using (H2), we express $z_i(t)$, $1 \le i \le n$, in terms of $z_i|_{t=0}$ with a bounded term involving $z_k(s)$, $0 \le s \le t$, $k \neq i$, and get

$$\sup_{0\le t\le T} E e^{4z_i(t)} \le C_1\big(1 + e^{4z_i|_{t=0}}\big),$$

where $C_1 > 0$. By use of the structure of $C(x)$ and $D(x)$ in the cost integrand l, we obtain the estimates in a straightforward way,

$$\begin{aligned} |J(s,z,u)| &\le E\int_s^T |l(z_t)|dt \le E\int_s^T C_2\left[1 + \sum_{i=1}^{n} e^{4z_i(t)} + \sum_{i=n+1}^{2n} z_i^4(t)\right] dt \\ &\le C_3\left[1 + \sum_{i=1}^{n} e^{4z_i} + \sum_{i=n+1}^{2n} z_i^4\right], \end{aligned}$$

for constants C_2, C_3 independent of (s,z), and (2.3) follows. ∎

We see that in (2.1) the noise covariance matrix GG^τ is not of full rank. In general, under such a condition the corresponding stochastic optimal control problem does not admit classical solutions due to the degenerate nature of the arising HJB equations. Here we analyze viscosity solutions.

DEFINITION 2.3. *$\underline{v}(t,z) \in C([0,T]\times\mathbb{R}^{2n})$ is called a* viscosity subsolution *to the HJB equation*

$$
\begin{aligned}
0 &= -\frac{\partial v}{\partial t} + \sup_{u\in U}\left\{-\frac{\partial^\tau v}{\partial z}\psi\right\} - \frac{1}{2}\mathrm{tr}\left(\frac{\partial^2 v}{\partial z^2}GG^\tau\right) - l,\\
v|_{t=T} &= h(z), \quad z\in\mathbb{R}^{2n},
\end{aligned}
\tag{2.4}
$$

if $\underline{v}|_{t=T}\le h$, and for any $\varphi(t,z)\in C^{1,2}([0,T]\times\mathbb{R}^{2n})$, whenever $\underline{v}-\varphi$ takes a local maximum at $(t,z)\in[0,T)\times\mathbb{R}^{2n}$, we have

$$
-\frac{\partial \varphi}{\partial t} + \sup_{u\in U}\left\{-\frac{\partial^\tau \varphi}{\partial z}\psi\right\} - \frac{1}{2}\mathrm{tr}\left(\frac{\partial^2 \varphi}{\partial z^2}GG^\tau\right) - l \le 0, \quad z\in\mathbb{R}^{2n},
\tag{2.5}
$$

at (t,z). Here $\overline{v}(t,z)\in C([0,T]\times\mathbb{R}^{2n})$ is called a viscosity supersolution *to* (2.4) *if $\overline{v}|_{t=T}\ge h$, and in* (2.5) *we have an opposite inequality at (t,z), whenever $\overline{v}-\varphi$ takes a local minimum at $(t,z)\in[0,T)\times\mathbb{R}^{2n}$. Additionally, $v(t,z)$ is called a* viscosity solution *if it is both a viscosity subsolution and a viscosity supersolution.*

THEOREM 2.4. *The value function v is a viscosity solution to the HJB equation*

$$
\begin{aligned}
0 &= -\frac{\partial v}{\partial t} + \sup_{u\in U}\left\{-\frac{\partial^\tau v}{\partial z}\psi\right\} - \frac{1}{2}\mathrm{tr}\left(\frac{\partial^2 v}{\partial z^2}GG^\tau\right) - l,\\
v(T,z) &= 0.
\end{aligned}
\tag{2.6}
$$

Proof. The value function v is continuous (by Proposition 2.2) and satisfies the boundary condition in (2.6). Now, for any $\varphi(t,z)\in C^{1,2}([0,T]\times\mathbb{R}^{2n})$, suppose $v-\varphi$ has a local maximum at (s,z_0), $s<T$. We denote by $z^{(1)}$, $z^{(2)}$ the first n and last n, respectively, components of z. In the following proof, we assume that $\varphi(t,z)=0$ for all $z^{(1)}$ such that $|z^{(1)}-z_0^{(1)}|\ge C$ for a constant $C>0$; otherwise we can multiply $\varphi(t,z)$ by a C^∞ function $\zeta(z^{(1)})$ with compact support and $\zeta(z^{(1)})=1$ for $|z^{(1)}-z_0^{(1)}|\le\frac{C}{2}$. We take a constant control $u\in[-1,1]$ on $[s,T]$ to generate z_u with initial state $z_s=z_0$ and write $\Delta(t,z)=v(t,z)-\varphi(t,z)$. Since (s,z_0) is a local maximum point of $\Delta(t,z)$, we can find $\epsilon>0$ such that $\Delta(s_1,z)\le\Delta(s,z_0)$ for $|s_1-s|+|z-z_0|\le\epsilon$. For $s_1\in(s,T]$, $z_s=z_0$, write $1_{A^\epsilon}=1_{(|s_1-s|+|z_{s_1}-z_0|\ge\epsilon)}$. Then we get the lower bound estimate

$$
\begin{aligned}
&E[\Delta(s,z_0)-\Delta(s_1,z_{s_1})]\\
&\quad= E[\Delta(s,z_0)-\Delta(s_1,z_{s_1})](1-1_{A^\epsilon}) + E[\Delta(s,z_0)-\Delta(s_1,z_{s_1})]1_{A^\epsilon}\\
&\quad\ge E[\Delta(s,z_0)-\Delta(s_1,z_{s_1})]1_{A^\epsilon} \stackrel{\triangle}{=} S_0,
\end{aligned}
$$

and using basic estimates for the change of the value function with respect to different initial states (see, e.g., [12, 3] for standard techniques), it follows that

$$
\begin{aligned}
|S_0| &= O\left(Ee^{2|z_{s_1}^{(1)}|}1_{A^\epsilon}\right)\\
&= O\left(Ee^{2|z_{s_1}^{(1)}|}1_{(|z_{s_1}^{(1)}-z_0^{(1)}|\ge\epsilon/2)}\right) \qquad (2.7)\\
&= O(|s-s_1|^2) \qquad (2.8)
\end{aligned}
$$

when $s_1 \downarrow s$. Here we obtain (2.7) by the fact that $z_{s_1}^{(2)} \to z_0^{(2)}$ uniformly as $s_1 \downarrow s$, which follows from the Lipschitz and boundedness (w.r.t. increment in x) conditions for $g(t,x,p,u)$, and obtain the bound (2.8) using basic moment estimates for $|z_{s_1}^{(1)} - z_0^{(1)}|^2$. It follows from (2.8) that

$$\lim_{s_1 \downarrow s} \frac{1}{s_1 - s} E[\Delta(s, z_0) - \Delta(s_1, z_{s_1})] \geq 0. \tag{2.9}$$

However, for $s_1 \in (s, T]$ we also have

$$\begin{aligned} &\frac{1}{s_1 - s} E[\Delta(s, z_0) - \Delta(s_1, z_{s_1})] \\ &\quad \leq \frac{1}{s_1 - s} E\left[\int_s^{s_1} l(z_t)dt - \varphi(s, z_0) + \varphi(s_1, z_{s_1})\right] \\ &\quad \to \left[l + \frac{\partial \varphi}{\partial s} + \frac{\partial^\tau \varphi}{\partial z}\psi\Big|_u + \frac{1}{2}\mathrm{tr}\left(\frac{\partial^2 \varphi}{\partial z^2} GG^\tau\right)\right]\Bigg|_{(s,z_0)} \qquad \forall u \in U \end{aligned} \tag{2.10}$$

as $s_1 \downarrow s$, where we get the inequality by the principle of optimality, and obtain (2.10) by using Ito's formula to express $\varphi(s_1, z_{s_1})$ near (s, z_0) and then taking expectations. In the above, since v satisfies the growth condition in Proposition 2.2, $\varphi(t,z) = 0$ for $|z^{(1)} - z_0^{(1)}| \geq C$, all the expectations are finite. Therefore, for $z \in \mathbb{R}^{2n}$, by (2.9) and (2.10),

$$\frac{\partial \varphi}{\partial s} + \min_{u \in U}\left\{\frac{\partial^\tau \varphi}{\partial z}\psi\right\} + \frac{1}{2}\mathrm{tr}\left(\frac{\partial^2 \varphi}{\partial z^2} GG^\tau\right) + l \geq 0$$

at (s, z_0). On the other hand, if $v - \varphi$ has a local minimum at (s, z_0), $s < T$, then for any small $\varepsilon > 0$ we can choose sufficiently small $s_1 \in (s, T]$ and find a control $u \in \mathcal{U}$ generating z_u such that

$$\begin{aligned} &E\{v(s, z_0) - \varphi(s, z_0) - v(s_1, z_{s_1}) + \varphi(s_1, z_{s_1})\} \\ &\qquad \geq E\left\{\int_s^{s_1} l(z_t)dt + \varphi(s_1, z_{s_1}) - \varphi(s, z_0)\right\} - \varepsilon(s_1 - s). \end{aligned} \tag{2.11}$$

Similar to (2.8), we also have

$$E[\Delta(s, z_0) - \Delta(s_1, z_{s_1})] \leq O(|s - s_1|^2),$$

which, together with (2.11) and Ito's formula, gives

$$\frac{\partial \varphi}{\partial s} + \min_{u \in U}\left\{\frac{\partial^\tau \varphi}{\partial z}\psi\right\} + \frac{1}{2}\mathrm{tr}\left(\frac{\partial^2 \varphi}{\partial z^2} GG^\tau\right) + l \leq 0$$

at (s, z_0), so that the value function v is a viscosity solution. □

To analyze uniqueness of the viscosity solution, we introduce the function class $\mathcal{G}$ such that each $W \in \mathcal{G}$ satisfies the following:

(i) $W \in C([0,T] \times \mathbb{R}^{2n})$, and

(ii) for any $W \in \mathcal{G}$, there exist $C, k_1, k_2 > 0$ such that $|W(t,z)| \leq C[\sum_{i=1}^n e^{k_1|z_i|} + \sum_{i=1}^{2n} |z_i|^{k_2}]$.

Notice that in condition (ii), the constants C, k_1, k_2 may take a different set of values for different $W \in \mathcal{G}$. By Proposition 2.2 and Theorem 2.4 it follows that the

value function v is a viscosity solution to the HJB equation (2.6) in the class $\mathcal{G}$. We now state the uniqueness result for the viscosity solutions.

THEOREM 2.5. *Assuming that* (H1)–(H2) *hold, there exists a unique viscosity solution to* (2.6) *in the class* $\mathcal{G}$.

Here we state a general maximum principle on an unbounded domain for the HJB equation (2.6). By considering two possibly distinct viscosity solutions v_1 and v_2 and setting, respectively, $(v_1, v_2) = (\underline{v}, \overline{v})$ and $(v_2, v_1) = (\underline{v}, \overline{v})$ in Theorem 2.6, we obtain Theorem 2.5 as a corollary. The proof of the maximum principle is postponed to section 4.

THEOREM 2.6. *Assuming that* (H1)–(H2) *hold, if* $\underline{v}, \overline{v} \in \mathcal{G}$ *are the viscosity subsolution and supersolution to* (2.6)*, respectively, and* $\sup_{\partial^* Q_0}(\underline{v} - \overline{v}) < \infty$*, then*

$$\sup_{Q_0}(\underline{v} - \overline{v}) = \sup_{\partial^* Q_0}(\underline{v} - \overline{v}), \tag{2.12}$$

where $Q_0 = [0, T] \times \mathbb{R}^{2n}$, $\partial^* Q_0 = \{(T, z) : z \in \mathbb{R}^{2n}\}$.

3. Semiconvex and semiconcave approximations on compact sets. To facilitate our analysis, write the Hamiltonian

$$\widetilde{H}(t, z, u, \xi, V) = -\xi^\tau \psi(t, z, u) - \frac{1}{2}\mathrm{tr}\{VG(t, z)G^\tau(t, z)\} - l(z), \tag{3.1}$$

$$H(t, z, \xi, V) = \sup_{u \in U} \widetilde{H}(t, z, u, \xi, V),$$

where $\xi \in \mathbb{R}^{2n}$, V is a $2n \times 2n$ real symmetric matrix, and the other terms are defined in section 2. Then the HJB equation (2.6) may be written as

$$0 = -v_t + H(t, z, v_z, v_{zz}), \tag{3.2}$$

$$v(T, z) = 0. \tag{3.3}$$

DEFINITION 3.1 (see [12]). *A real value function* $\varphi(x)$ *defined on a convex set* $Q \subset \mathbb{R}^m$ *is said to be semiconvex on* Q *if there exists a constant* $C > 0$ *such that* $\varphi(x) + C|x|^2$ *is convex;* $\varphi(x)$ *is semiconcave on* Q *if* $-\varphi(x)$ *is semiconvex on* Q.

DEFINITION 3.2. *A real value function* $\varphi(x)$ *defined on a convex set* $Q \subset \mathbb{R}^m$ *is said to be locally semiconvex on* Q *if for any* $y \in Q$ *there exists a convex neighborhood* N_y *(relative to* Q*) of* y *such that* $\varphi(x)$ *is semiconvex on* N_y.

PROPOSITION 3.3. *If* $\varphi(x)$ *is locally semiconvex on a convex compact set* Q*, then* $\varphi(x)$ *is semiconvex on* Q.

Proof. For any $y \in Q$, there exists a convex set N_y open relative to Q such that $y \in N_y$ and $\varphi(x)$ is semiconvex on N_y. Thus there exists $C_y > 0$ such that $\varphi(x) + C_y|x|^2$ is convex on N_y. Since $\{N_y,\ y \in Q\}$ is an open cover of Q, there exists a finite subcover denoted by $\{N_{y_i},\ 1 \le i \le k\}$. Take $C = \max_{1 \le i \le k} C_{y_i}$, and then obviously $\varphi(x) + C|x|^2 \stackrel{\triangle}{=} \widehat{\varphi}(x)$ is convex on each N_{y_i}, $1 \le i \le k$. Now for any $x_1, x_2 \in Q$, $0 \le \lambda \le 1$, we prove that $\widehat{\varphi}(\lambda x_1 + (1 - \lambda)x_2) \le \lambda\widehat{\varphi}(x_1) + (1 - \lambda)\widehat{\varphi}(x_2)$. It suffices to consider the case $0 < \lambda < 1$. First, from the collection $\{N_{y_i},\ 1 \le i \le k\}$ we select open sets, without loss of generality, denoted as $\mathcal{N} \stackrel{\triangle}{=} \{N_{y_i},\ i = 1, \ldots, m \le k\}$

such that $L \triangleq \{x : x = \alpha x_1 + (1-\alpha)x_2,\ 0 \le \alpha \le 1\} \subset \cup_{N_{y_i} \in \mathcal{N}} N_{y_i}$. For simplicity we consider the case $m = 2$ and $x_1 \in N_{y_1}$, $x_2 \in N_{y_2}$. The general case may be treated inductively. To avoid triviality, we assume that neither N_{y_1} nor N_{y_2} covers L individually, and then we can find $x_a \in L$, $x_a \neq x_\lambda \triangleq \lambda x_1 + (1-\lambda)x_2$ such that $x_a \in N_{y_1} \cap N_{y_2}$ and $x_a = c_1 x_1 + (1-c_1)x_2$, $0 < c_1 < 1$. Without loss of generality we assume that x_λ is between x_1 and x_a. Then we further choose $x_b \in N_{y_1} \cap N_{y_2}$ such that $x_b = c_2 x_1 + (1-c_2)x_2$ and x_b is between x_a and x_2. Now it is obvious that $0 < c_2 < c_1 < \lambda < 1$. It is straightforward to verify that

$$x_\lambda = \frac{\lambda - c_1}{1-c_1} x_1 + \frac{1-\lambda}{1-c_1} x_a, \qquad x_a = \frac{c_1 - c_2}{\lambda - c_2} x_\lambda + \frac{\lambda - c_1}{\lambda - c_2} x_b, \qquad x_b = \frac{c_2}{c_1} x_a + \frac{c_1 - c_2}{c_1} x_2.$$

Hence we have

$$\widehat{\varphi}(x_\lambda) \le \frac{\lambda - c_1}{1-c_1}\widehat{\varphi}(x_1) + \frac{1-\lambda}{1-c_1}\widehat{\varphi}(x_a),$$

$$\widehat{\varphi}(x_a) \le \frac{c_1 - c_2}{\lambda - c_2}\widehat{\varphi}(x_\lambda) + \frac{\lambda - c_1}{\lambda - c_2}\widehat{\varphi}(x_b),$$

$$\widehat{\varphi}(x_b) \le \frac{c_2}{c_1}\widehat{\varphi}(x_a) + \frac{c_1 - c_2}{c_1}\widehat{\varphi}(x_2),$$

where we get the first two inequalities and the last one by the convexity of $\widehat{\varphi}(x)$ on N_{y_1} and N_{y_2}, respectively. By a simple transformation with the above inequalities to eliminate $\widehat{\varphi}(x_a)$ and $\widehat{\varphi}(x_b)$, we get

$$\widehat{\varphi}(x_\lambda) \le \lambda\widehat{\varphi}(x_1) + (1-\lambda)\widehat{\varphi}(x_2).$$

By arbitrariness of x_1, x_2 in Q it follows that $\widehat{\varphi}(x)$ is convex on Q. This completes the proof. □

We adopt the semiconvex/semiconcave approximation technique of [12, 2, 9, 10], but due to the highly nonlinear growth condition of the class $\mathcal{G}$, we apply a particular localized technique to construct envelope functions to generate semiconvex/semiconcave approximations on any bounded domain. For any $W \in \mathcal{G}$, define the upper/lower envelope functions with $\eta \in (0, 1]$,

$$W^\eta(t,z) = \sup_{(s,w)\in B^\eta(t,z)} \left\{ W(s,w) - \frac{1}{2\eta^2}(|t-s|^2 + |z-w|^2) \right\}, \tag{3.4}$$

$$W_\eta(t,z) = \inf_{(s,w)\in B^\eta(t,z)} \left\{ W(s,w) + \frac{1}{2\eta^2}(|t-s|^2 + |z-w|^2) \right\}, \tag{3.5}$$

where $B^\eta(t,z)$ denotes the closed ball (relative to $[0,T]\times\mathbb{R}^{2n}$) centering (t,z) with radius η. As will be shown in the following lemma, our construction above will generate semiconvex/semiconcave approximations to a given continuous function on a compact set for small η.

LEMMA 3.4. *For any fixed $W \in \mathcal{G}$ and compact convex set $Q \subset [0,T]\times\mathbb{R}^{2n}$, there exists a positive constant $\eta_Q \le 1$ depending only on Q such that for all $\eta \in (0, \eta_Q]$, $W^\eta(t,z)$ is semiconvex on Q, and $W_\eta(t,z)$ is semiconcave on Q.*

Proof. Since any fixed $W \in \mathcal{G}$ is uniformly continuous and bounded on any compact set Q, there exists $\overline{\eta}_Q > 0$ depending only on Q, so that for all positive $\eta \le \overline{\eta}_Q$ and $(t,z) \in Q$,

$$W^\eta(t,z) = \sup_{(s,w)\in B^{\eta/2}(t,z)} \left\{ W(s,w) - \frac{1}{2\eta^2}[|t-s|^2 + |z-w|^2] \right\}. \tag{3.6}$$

Indeed, we can find $\overline{\eta}_Q > 0$ such that for all $\eta \le \overline{\eta}_Q$, $|W(s,w) - W(t,z)| \le \frac{1}{16}$ for $(s,w) \in B^\eta(t,z)$, where $(t,z) \in Q$. Then for any (s,w) satisfying $\frac{\eta^2}{4} \le |s-t|^2 + |w-z|^2 \le \eta^2$, we have

$$W(s,w) - \frac{1}{2\eta^2}(|s-t|^2 + |w-z|^2) \le W(t,z) + \frac{1}{16} - \frac{1}{2\eta^2}\frac{\eta^2}{4} < W(t,z),$$

and (3.6) follows. In the following we assume $\eta \le \overline{\eta}_Q$. Next we show that for any $(t_0,z_0) \in Q$, $W^\eta(t,z)$ is semiconvex on $B^{\eta/4}(t_0,z_0) \cap Q$. It suffices to show that $W^\eta(t,z) + \frac{1}{2\eta^2}(t^2 + |z|^2)$ is convex on $B^{\eta/4}(t_0,z_0) \cap Q$. Denote

$$R(s,w,t,z) = W(s,w) - \frac{1}{2\eta^2}(|t-s|^2 + |z-w|^2) + \frac{1}{2\eta^2}(t^2 + |z|^2).$$

If $(t_1,z_1), (t_2,z_2) \in B^{\eta/4}(t_0,z_0) \cap Q$, we have $(t_2,z_2) \in B^{\eta/2}(t_1,z_1)$. For any $\lambda \in [0,1]$, we denote $(t_\lambda, z_\lambda) = (\lambda t_1 + (1-\lambda)t_2, \lambda z_1 + (1-\lambda)z_2) \in Q$. It is obvious that $B^{\eta/2}(t_\lambda,z_\lambda) \subset B^\eta(t_1,z_1) \cap B^\eta(t_2,z_2)$. Then it follows that

$$\begin{aligned}
&W^\eta(t_\lambda,z_\lambda) + \frac{1}{2\eta^2}[t_\lambda^2 + |z_\lambda|^2] \\
&\quad = \sup_{(s,w)\in B^\eta(t_\lambda,z_\lambda)} R(s,w,t_\lambda,z_\lambda) = \sup_{(s,w)\in B^{\eta/2}(t_\lambda,z_\lambda)} R(s,w,t_\lambda,z_\lambda) \\
&\quad = \sup_{(s,w)\in B^{\eta/2}(t_\lambda,z_\lambda)} [\lambda R(s,w,t_1,z_1) + (1-\lambda)R(s,w,t_2,z_2)] \\
&\quad \le \sup_{(s,w)\in B^{\eta/2}(t_\lambda,z_\lambda)} \lambda R(s,w,t_1,z_1) + \sup_{(s,w)\in B^{\eta/2}(t_\lambda,z_\lambda)} (1-\lambda)R(s,w,t_2,z_2) \\
&\quad \le \sup_{(s,w)\in B^\eta(t_1,z_1)} \lambda R(s,w,t_1,z_1) + \sup_{(s,w)\in B^\eta(t_2,z_2)} (1-\lambda)R(s,w,t_2,z_2) \\
&\quad = \lambda\left[W^\eta(t_1,z_1) + \frac{1}{2\eta^2}(t_1^2 + |z_1|^2)\right] + (1-\lambda)\left[W^\eta(t_2,z_2) + \frac{1}{2\eta^2}(t_2^2 + |z_2|^2)\right].
\end{aligned}$$

Thus $W^\eta(t,z)$ is semiconvex on $B^{\eta/4}(t_0,z_0) \cap Q$. Further, by Proposition 3.3, $W^\eta(t,z)$ is semiconvex on Q. Similarly we can prove that $W_\eta(t,z)$ is semiconcave on Q for $\eta \in (0, \widetilde{\eta}_Q]$, where $\widetilde{\eta}_Q \le 1$ depends only on Q. The lemma follows by taking $\eta_Q = \min\{\overline{\eta}_Q, \widetilde{\eta}_Q\}$. ∎

We use an example to illustrate the construction of the semiconvex approximation to a given function.

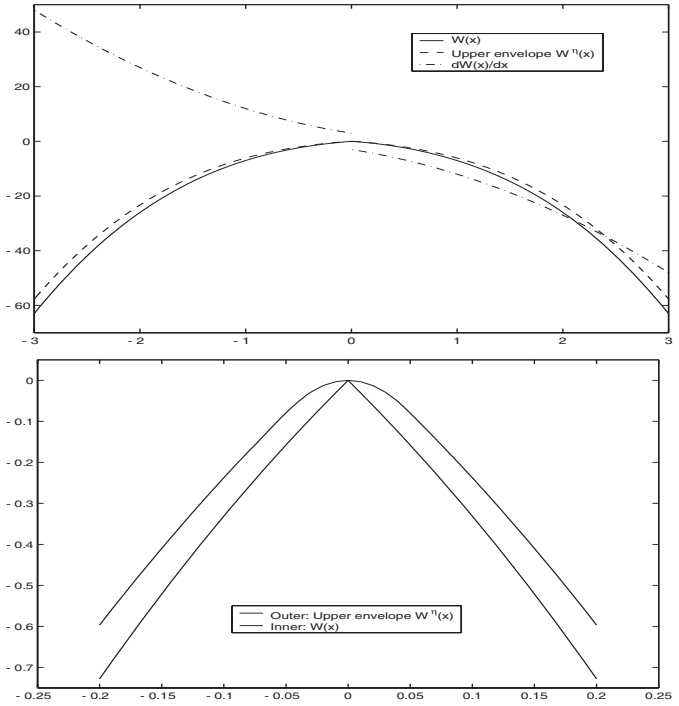

FIG. 3.1. *Semiconvex approximation with* $\eta = 0.125$. *Top: the curves in a large range. Bottom: the curves in the local region.*

Example 1. Consider a continuous function $W\colon \mathbb{R} \to \mathbb{R}$ defined as follows:

$$W(x) = \begin{cases} (x-1)^3 + 1 & \text{for } x \le 0, \\ -(x+1)^3 + 1 & \text{for } x > 0. \end{cases}$$

We take $0 < \eta \le 0.125$ and write

$$\theta(x) = 1 - x + \frac{1}{6\eta^2} - \sqrt{\left[1 - x + \frac{1}{6\eta^2}\right]^2 - (1-x)^2}, \quad x \le 0.$$

It is evident that the upper envelope function $W^\eta(x)$ is even on $\mathbb{R}$, and its value on $(-\infty, 0]$ is determined by

$$W^\eta(x) = \begin{cases} W(x+\eta) - \dfrac{1}{2} & \text{for } x \le 1 - \eta - \dfrac{1}{\sqrt{3\eta}}, \\ W(x+\theta(x)) - \dfrac{\theta^2(x)}{2\eta^2} & \text{for } 1 - \eta - \dfrac{1}{\sqrt{3\eta}} < x \le -3\eta^2, \\ W(0) - \dfrac{x^2}{2\eta^2} & \text{for } -3\eta^2 < x \le 0, \end{cases} \tag{3.7}$$

where $0 \le \theta(x) \le \eta \wedge |x|$ holds for $1 - \eta - \frac{1}{\sqrt{3\eta}} < x \le -3\eta^2$.

From Figure 3.1, it is seen that at $x = 0$ the first order derivative of $W(x)$ has a negative jump, which corresponds to a sharp turn at $x = 0$ on the function curve. After the semiconvexifying procedure, the sharp turn at $x = 0$ vanishes, as shown by the curve of $W^\eta(x)$.

We give a lemma which is parallel to the one in [12]. But here we do not make Lipschitz or Hölder-type continuity assumptions on W. For completeness we give the details.

LEMMA 3.5. *For $W \in \mathcal{G}$ and $\eta \in (0,1]$, W^η and W_η are equicontinuous (w.r.t. η) on any compact set $Q \subset [0,T] \times \mathbb{R}^{2n}$ and*

$$W^\eta(t,z) \le C\left[\sum_{i=1}^{n} e^{k_1|z_i|} + \sum_{i=1}^{2n} |z_i|^{k_2}\right], \tag{3.8}$$

$$W^\eta(t,z) = W(t_0,z_0) - \frac{1}{2\eta^2}(|t-t_0|^2 + |z-z_0|^2) \quad \text{for some } (t_0,z_0) \in B^\eta(t,z), \tag{3.9}$$

$$\frac{1}{2\eta^2}(|t-t_0|^2 + |z-z_0|^2) \to 0 \quad \text{uniformly on } Q \text{ as } \eta \to 0, \text{ and} \tag{3.10}$$

$$0 \le W^\eta(t,z) - W(t,z) \to 0 \quad \text{uniformly on } Q \text{ as } \eta \to 0, \tag{3.11}$$

where $C, k_1, k_2 > 0$ are constants independent of η. The estimates (3.8)–(3.10) *also hold when W^η is replaced by W_η, and*

$$0 \le W(t,z) - W_\eta(t,z) \to 0 \quad \text{uniformly on } Q \text{ as } \eta \to 0. \tag{3.12}$$

Proof. Inequality (3.8) follows from the definition of $\mathcal{G}$, and (3.9) is obvious. Moreover, by (3.9) we have

$$\frac{1}{2\eta^2}(|t-t_0|^2 + |z-z_0|^2) = W(t_0,z_0) - W^\eta(t,z) \le W(t_0,z_0) - W(t,z). \tag{3.13}$$

Since $|t-t_0| + |z-z_0| \to 0$ as $\eta \to 0$, by (3.13) and the uniform continuity of W on Q, (3.10) follows. The estimate (3.11) follows from (3.9) and (3.10). The equicontinuity of W^η (w.r.t. η) on Q can be established by (3.11) and the continuous dependence of W^η on $(\eta,t,z) \in [\varepsilon,1] \times Q$ for any $0 < \varepsilon \le 1$. The case of W_η can be treated similarly. □

We define

$$H^\eta(t,z,\xi,V) = \inf_{(s,w)\in B^\eta(t,z)} \sup_{u\in U} \widetilde{H}(s,w,u,\xi,V), \tag{3.14}$$

$$H_\eta(t,z,\xi,V) = \sup_{(s,w)\in B^\eta(t,z)} \sup_{u\in U} \widetilde{H}(s,w,u,\xi,V). \tag{3.15}$$

Then it can be shown that H^η and H_η converge to $H(t,z,\xi,V)$ uniformly on any compact subset of $[0,T] \times \mathbb{R}^{2n} \times \mathbb{R}^{2n} \times S^{2n}$ as $\eta \to 0$, where S^{2n} denotes the set of $2n \times 2n$ real symmetric matrices. The following lemma can be proved by a method similar to that in [4, 9, 10]; the proof is omitted here. Notice that the viscosity sub/supersolution properties hold on a domain smaller than $[0,T] \times \mathbb{R}^{2n}$.

LEMMA 3.6. *If $\underline{v}$ ($\overline{v}$, respectively) is a viscosity subsolution (supersolution, respectively) to* (3.2) *on $[0,T] \times \mathbb{R}^{2n}$, then $\underline{v}^\eta$ ($\overline{v}_\eta$, respectively) is a viscosity subsolution (supersolution, respectively) to HJB equation A (B, respectively) on $[0, T-\eta] \times \mathbb{R}^{2n}$, where the HJB equations A and B are given by*

$$A: \begin{cases} -v_t + H^\eta(t,z,v_z,v_{zz}) = 0, \\ v(T-\eta,z) = \underline{v}^\eta(T-\eta,z), \end{cases} \qquad B: \begin{cases} -v_t + H_\eta(t,z,v_z,v_{zz}) = 0, \\ v(T-\eta,z) = \overline{v}_\eta(T-\eta,z). \end{cases}$$

In the above, $\underline{v}^\eta$ and $\overline{v}_\eta$ are defined by (3.4)–(3.5).

4. Proof of Theorem 2.6. In this section we give a proof of Theorem 2.6. We note that certain technical but standard arguments are not included here for reasons of economy of exposition; complete references to the detailed versions of these parts of the proof are supplied at appropriate places in the text.

We follow the method in [12, 4], employing the particular structure of the system dynamics, and will make necessary modifications. For the viscosity subsolution and supersolution $\underline{v}, \overline{v} \in \mathcal{G}$ we prove that

$$\sup_{Q_1}(\underline{v}-\overline{v}) = \sup_{\partial^* Q_0}(\underline{v}-\overline{v}) \stackrel{\triangle}{=} c_0 \quad \text{for } Q_1 = [T_1, T]\times\mathbb{R}^{2n}, \tag{4.1}$$

where $T_1 = T - \frac{1}{4\Delta}$, $\Delta = 25n(C_g + C_\sigma) + 10C_{f^0}$, C_g is a finite constant such that for g given in (1.2), $|g_i(t,x,p,u)| \le C_g(1+\sum_{k=1}^n |p_k|)$ for $t\in[0,T]$, $x,p\in\mathbb{R}^n$, $u\in U$, $1\le i\le n$, and C_σ, C_{f^0} are given in assumptions (H1)–(H2) introduced in section 2. The maximum principle (2.12) follows by repeating the above procedure backward with time. Our proof by contradiction starts with the observation that if (4.1) is not true, there exists $(\hat{t},\hat{z})\in(T_1,T)\times\mathbb{R}^{2n}$ such that

$$\underline{v}(\hat{t},\hat{z}) - \overline{v}(\hat{t},\hat{z}) = c_0^+ > c_0. \tag{4.2}$$

We break the proof into several steps: (1) we construct a comparison function Λ depending on positive parameters α, β, ε, λ, and, based upon (4.2), Λ is used to induce a certain interior maximum; (2) using the viscosity sub/supersolution conditions, we get a set of inequalities at the interior maximum; and (3) we establish an inequality relation between α and β by taking appropriate vanishing subsequences of ε, λ, η, and this inequality relation is shown to lead to a contradiction. The weak coupling condition (H2) for x is used to obtain estimates used in Step 3 below.

Step 1 (constructing a comparison function and the interior maximum). To avoid introducing too many constants, we assume that $\underline{v}$ and $\overline{v}$ belong to the class $\mathcal{G}$ with associated constants $k_1 = k_2 = 4$. The more general case can be treated in exactly the same way. Now we define the comparison function

$$\begin{aligned}\Lambda(t,z,s,w) = {}& \frac{\alpha(2\mu T - t - s)}{2\mu T}\left\{\sum_{i=1}^n\left[e^{5\sqrt{z_i^2+1}} + e^{5\sqrt{w_i^2+1}}\right] + \sum_{i=1}^{2n}(z_i^6 + w_i^6)\right\}\\ & - \beta(t+s) + \frac{1}{2\varepsilon}|t-s|^2 + \frac{1}{2\varepsilon}|z-w|^2 + \frac{\lambda}{t-T_1} + \frac{\lambda}{s-T_1},\end{aligned}$$

where α, β, ε, λ are all taken from $(0,1]$; $\mu = 1 + \frac{1}{4T\Delta}$; $z,w\in\mathbb{R}^{2n}$; and $t,s\in(T_1,T]$. We write $\Phi(t,z,s,w) = \underline{v}^\eta(t,z) - \overline{v}_\eta(s,w) - \Lambda(t,z,s,w)$, where $\underline{v}^\eta$ and $\overline{v}_\eta$ are also in $\mathcal{G}$ by Lemma 3.5. Noticing that $\Phi\to-\infty$ as $t\wedge s\to T_1$ or $|z|+|w|\to\infty$, there exists (t_0,z_0,s_0,w_0) such that $\Phi(t_0,z_0,s_0,w_0) = \sup_{Q_1\times Q_1}\Phi(t,z,s,w)$. By $\Phi(t_0,z_0,s_0,w_0)\ge\Phi(T,0,T,0)$, one can find a constant C_α depending only on α such that (see Remark 2)

$$|z_0| + |w_0| + \frac{1}{2\varepsilon}|t_0-s_0|^2 + \frac{1}{2\varepsilon}|z_0-w_0|^2 \le C_\alpha \quad\text{and}\quad t_0, s_0 \in \left[T_1 + \frac{\lambda}{C_\alpha}, T\right]. \tag{4.3}$$

Combining $2\Phi(t_0,z_0,s_0,w_0)\ge\Phi(t_0,z_0,t_0,z_0)+\Phi(s_0,w_0,s_0,w_0)$, (4.3), and Lemma 3.5, we get for fixed $\alpha>0$ (see Remark 3)

$$\frac{1}{2\varepsilon}|t_0-s_0|^2 + \frac{1}{2\varepsilon}|z_0-w_0|^2 \to 0 \quad\text{uniformly as } \varepsilon\to 0. \tag{4.4}$$

In this section, we take $\beta \in (0, \frac{c_0^+ - c_0}{4T})$. We further show that there exists $\alpha_0 > 0$ such that for $\alpha < \alpha_0$ and for sufficiently small r_0 (which may depend upon α) and $\eta \le r_0$, $\varepsilon \le r_0$, $\lambda \le r_0$, the maximum of Φ on Q_1 is attained at an interior point (t_0, z_0, s_0, w_0) of the set

$$Q_\alpha = \left\{ (t,z,s,w) : T_1 + \frac{\lambda}{2C_\alpha} \le t,\ s \le T - \eta, \text{ and } |z|, |w| \le 2C_\alpha \right\}, \tag{4.5}$$

where C_α is determined in (4.3).

We begin by observing that $\Phi(t_0, z_0, s_0, w_0) \ge \Phi(\hat{t}, \hat{z}, \hat{t}, \hat{z})$ yields

$$\begin{aligned} \underline{v}^\eta(\hat{t},\hat{z}) - \overline{v}_\eta(\hat{t},\hat{z}) &\le \underline{v}^\eta(t_0,z_0) - \overline{v}_\eta(s_0,w_0) - \Lambda(t_0,z_0,s_0,w_0) + \Lambda(\hat{t},\hat{z},\hat{t},\hat{z}) \\ &\le \underline{v}^\eta(t_0,z_0) - \overline{v}_\eta(s_0,w_0) + 2\beta T + \frac{2\lambda}{\hat{t} - T_1} \\ &\quad + 2\alpha \left[\sum_{i=1}^n e^{5\sqrt{\hat{z}_i^2+1}} + \sum_{i=1}^{2n} \hat{z}_i^6 \right]. \end{aligned} \tag{4.6}$$

Let $\mathbb{H}^\beta$ stand for the assertion that there exists α_0 such that when $\alpha \le \alpha_0$ and $\max\{\eta, \varepsilon, \lambda\} \le r_0$ for sufficiently small r_0, (t_0, z_0, s_0, w_0) is an interior point of Q_α in (4.5).

If $\mathbb{H}^\beta$ is not true, then there exists an arbitrarily small $\alpha \in (0, 1]$ such that for this fixed α we can select $\eta^{(k)}, \varepsilon^{(k)}, \lambda^{(k)} \to 0$ for which the resulting $(t_0^{(k)}, z_0^{(k)}, s_0^{(k)}, w_0^{(k)}) \notin \mathrm{Int}(Q_\alpha)$. By (4.3) it necessarily follows that $t_0^{(k)} \vee s_0^{(k)} \ge T - \eta^{(k)} \to T$ and (4.4) gives $|t_0^{(k)} - s_0^{(k)}| + |s_0^{(k)} - w_0^{(k)}| \to 0$. It is also clear that $(t_0^{(k)}, z_0^{(k)}, s_0^{(k)}, w_0^{(k)})$ is contained in a compact set determined by α. Then by selecting an appropriate subsequence of $(t_0^{(k)}, z_0^{(k)}, s_0^{(k)}, w_0^{(k)})$ and taking the limit in (4.6) along this subsequence, we get

$$\begin{aligned} \underline{v}(\hat{t},\hat{z}) - \overline{v}(\hat{t},\hat{z}) &\le \underline{v}(T,z^\alpha) - \overline{v}(T,z^\alpha) + \frac{c_0^+ - c_0}{2} + 2\alpha \left[\sum_{i=1}^n e^{5\sqrt{\hat{z}_i^2+1}} + \sum_{i=1}^{2n} \hat{z}_i^6 \right] \\ &\le \frac{c_0^+ + c_0}{2} + 2\alpha \left[\sum_{i=1}^n e^{5\sqrt{\hat{z}_i^2+1}} + \sum_{i=1}^{2n} \hat{z}_i^6 \right], \end{aligned} \tag{4.7}$$

where z^α denotes the common limit of the selected subsequences of $z_0^{(k)}$ and $w_0^{(k)}$. Sending $\alpha \to 0$, we get $\underline{v}(\hat{t},\hat{z}) - \overline{v}(\hat{t},\hat{z}) < c_0^+$, which contradicts (4.2); hence $\mathbb{H}^\beta$ holds. From the argument leading to (4.7) it is seen that α_0 can be chosen independently of β.

Step 2 (applying Ishii's lemma). Hereafter, we assume that $\beta < \frac{c_0^+ - c_0}{4T}$, $\alpha < \alpha_0$, and $\max\{\eta, \varepsilon, \lambda\} \le r_0$ are always satisfied and thus $\mathbb{H}^\beta$ holds. We assume Φ attains a strict maximum at (t_0, z_0, s_0, w_0); otherwise we replace Λ by $\Lambda + |t - t_0|^2 + |s - s_0|^2 + |z - z_0|^4 + |w - w_0|^4$. Following the derivations in [12, 9, 4] and using the interior maximum obtained in Step 1, the semiconvexity of $\underline{v}^\eta$, and the semiconcavity of $\overline{v}_\eta$ for $\eta \le \eta_{Q_\alpha}$ by Lemma 3.4, and by Lemma 3.6, we obtain the so-called Ishii's lemma; i.e., there exist $2n \times 2n$ symmetric matrices M_k, $k = 1, 2$, such that

$$-\Lambda_t(t_0,z_0,s_0,w_0) + H^\eta(t_0,z_0,\Lambda_z(t_0,z_0,s_0,w_0),M_1) \le 0, \tag{4.8}$$

$$\Lambda_s(t_0,z_0,s_0,w_0) + H_\eta(s_0,w_0,-\Lambda_w(t_0,z_0,s_0,w_0),M_2) \ge 0, \tag{4.9}$$

$$\begin{pmatrix} M_1 & 0 \\ 0 & -M_2 \end{pmatrix} \le \begin{pmatrix} \Lambda_{zz} & \Lambda_{zw} \\ \Lambda_{zw}^\tau & \Lambda_{ww} \end{pmatrix} \Big|_{(t_0,z_0,s_0,w_0)}. \tag{4.10}$$

We note that it is important to have $t_0 \vee s_0 < T - \eta$ in order to establish (4.8)–(4.9) by Lemma 3.6 and an approximation procedure (see, e.g., [4] for the case of a bounded domain). Now (4.8) and (4.9) yield

$$\begin{aligned} &-\Lambda_t(t_0,z_0,s_0,w_0) - \Lambda_s(t_0,z_0,s_0,w_0) \\ &\quad \le H_\eta(s_0,w_0,-\Lambda_w(t_0,z_0,s_0,w_0),M_2) - H^\eta(t_0,z_0,\Lambda_z(t_0,z_0,s_0,w_0),M_1). \end{aligned} \tag{4.11}$$

Step 3 (estimates for LHS and RHS of (4.11)). The final stage in our deduction of a contradiction from (4.2) involves estimates of the LHS and RHS of (4.11). The estimates for both sides of (4.11) are taken at (t_0,z_0,s_0,w_0), but for brevity we omit the subscript 0 for each variable. We have

$$\begin{aligned} \text{LHS of (4.11)} &= \frac{\alpha}{\mu T}\left[\sum_{i=1}^n \left(e^{5\sqrt{z_i^2+1}} + e^{5\sqrt{w_i^2+1}}\right) + \sum_{i=1}^n (z_i^6 + w_i^6)\right] \\ &\quad + 2\beta + \frac{\lambda}{(t-T_1)^2} + \frac{\lambda}{(s-T_1)^2} \\ &\ge \frac{\alpha}{\mu T}\left[\sum_{i=1}^n \left(e^{5\sqrt{z_i^2+1}} + e^{5\sqrt{w_i^2+1}}\right) + \sum_{i=1}^n (z_i^6 + w_i^6)\right] + 2\beta \end{aligned} \tag{4.12}$$

and

$$\begin{aligned} \text{RHS of (4.11)} &= \sup_{u\in U}[\Lambda_w^\tau(t,z,s,w)\psi(\widehat{s},\widehat{w},u)] - \sup_{u\in U}[-\Lambda_z^\tau(t,z,s,w)\psi(\widehat{t},\widehat{z},u)] \\ &\quad + \frac{1}{2}\mathrm{tr}[G(\widehat{t},\widehat{z})G^\tau(\widehat{t},\widehat{z})M_1] - \frac{1}{2}\mathrm{tr}[G(\widehat{s},\widehat{w})G^\tau(\widehat{s},\widehat{w})M_2] + l(\widehat{z}) - l(\widehat{w}) \\ &\le \sup_{u\in U}[\Lambda_w^\tau(t,z,s,w)\psi(\widehat{s},\widehat{w},u) + \Lambda_z^\tau(t,z,s,w)\psi(\widehat{t},\widehat{z},u)] \\ &\quad + \frac{1}{2}\mathrm{tr}[G(\widehat{t},\widehat{z})G^\tau(\widehat{t},\widehat{z})M_1] - \frac{1}{2}\mathrm{tr}[G(\widehat{s},\widehat{w})G^\tau(\widehat{s},\widehat{w})M_2] - l(\widehat{z}) - l(\widehat{w}), \end{aligned}$$

which, together with (4.10) and (3.14)–(3.15), leads to

$$\begin{aligned} \text{RHS of (4.11)} &\le \sup_{u\in U}[\Lambda_w^\tau(t,z,s,w)\psi(\widehat{s},\widehat{w},u) + \Lambda_z^\tau(t,z,s,w)\psi(\widehat{t},\widehat{z},u)] \quad \left(\triangleq A_1\right) \\ &\quad + \frac{1}{2\varepsilon}\mathrm{tr}\{[G(\widehat{t},\widehat{z}) - G(\widehat{s},\widehat{w})]^\tau[G(\widehat{t},\widehat{z}) - G(\widehat{s},\widehat{w})]\} \quad \left(\triangleq A_2\right) \\ &\quad + \frac{\alpha(2\mu T - t - s)}{2\mu T} \\ &\quad \times \sum_{i,k=1}^n \frac{1}{2}\big[\sigma_{ik}^2(\widehat{t},\widehat{z})(\Gamma''(z_i) + 30z_i^4) \\ &\qquad\qquad + \sigma_{ik}^2(\widehat{s},\widehat{w})(\Gamma''(w_i) + 30w_i^4)\big] \quad \left(\triangleq A_3\right) \\ &\quad + [l(\widehat{z}) - l(\widehat{w})] \quad \left(\triangleq A_4\right) \\ &= A_1 + A_2 + A_3 + A_4, \end{aligned} \tag{4.13}$$

where $\Gamma(r) \triangleq e^{5\sqrt{r^2+1}}$, $\Gamma'' = \frac{d^2\Gamma}{dr^2}$ and $(\widehat{t}_0,\widehat{z}_0) \in B^\eta(t_0,z_0)$, $(\widehat{s}_0,\widehat{w}_0) \in B^\eta(s_0,w_0)$. Notice that the set $\mathcal{S}_{\eta,\varepsilon} = \{(t_0,z_0),(\widehat{t}_0,\widehat{z}_0),(s_0,w_0),(\widehat{s}_0,\widehat{w}_0)\}$ is contained in a compact

set Q_α^* determined by α. For $0 < \varepsilon \le 1$ appearing in $\Lambda(t,z,s,w)$, there exists $\eta_\varepsilon > 0$ such that, for all $0 < \eta \le \eta_\varepsilon$,

$$\text{RHS of (4.11)} \le A_1^0 + A_2^0 + A_3^0 + A_4^0 + \varepsilon, \tag{4.14}$$

where, again without writing the subscript 0 for (t_0, z_0, s_0, w_0), we define

$$\begin{aligned}
A_1^0 &= \sup_{u\in U}[\Lambda_w^\tau(t,z,s,w)\psi(s,w,u) + \Lambda_z^\tau(t,z,s,w)\psi(t,z,u)],\\
A_2^0 &= \frac{1}{2\varepsilon}\mathrm{tr}\{[G(t,z)-G(s,w)]^\tau[G(t,z)-G(s,w)]\},\\
A_3^0 &= \frac{\alpha(2\mu T - t - s)}{2\mu T}\sum_{i,k=1}^{n}\frac{1}{2}[\sigma_{ik}^2(t,z)(\Gamma''(z_i)+30z_i^4) + \sigma_{ik}^2(s,w)(\Gamma''(w_i)+30w_i^4)],\\
A_4^0 &= l(z) - l(w).
\end{aligned}$$

Since $\mathcal{S}_{\eta,\varepsilon}$ is contained in Q_α^* and the diameter of $\mathcal{S}_{\eta,\varepsilon}$ tends to 0 as $\eta, \varepsilon \to 0$, by taking an appropriate sequence $(\eta^{(k)}, \varepsilon^{(k)}, \lambda^{(k)}) \to 0$ satisfying $\eta^{(k)} \le \eta_{\varepsilon^{(k)}}$, we get convergent sequences $(t_0^{(k)}, z_0^{(k)})$, $(t_0^{(k)}, \widehat{z}_0^{(k)})$, $(s_0^{(k)}, w_0^{(k)})$, $(s_0^{(k)}, \widehat{w}_0^{(k)}) \to (\tilde{t}, \tilde{z})$ as $k \to \infty$. In the following we use the same C to denote different constants which are independent of α. Now we have the three relations

$$\limsup_{k\to\infty} \text{ LHS of (4.11)}(\eta^{(k)}, \varepsilon^{(k)}, \lambda^{(k)}) \ge \frac{2\alpha}{\mu T}\left[\sum_{i=1}^{n} e^{5\sqrt{\tilde{z}_i^2+1}} + \sum_{i=1}^{2n}|\tilde{z}_i|^6\right] + 2\beta, \tag{4.15}$$

$$\lim_{k\to\infty}(A_2^0 + A_4^0)\big(\eta^{(k)}, \varepsilon^{(k)}, \lambda^{(k)}\big) = 0, \tag{4.16}$$

$$\limsup_{k\to\infty} A_3^0\big(\eta^{(k)}, \varepsilon^{(k)}, \lambda^{(k)}\big) \le \frac{n\alpha C_\sigma(\mu T - \tilde{t})}{\mu T}\sum_{i=1}^{n}\left(25e^{5\sqrt{\tilde{z}_i^2+1}} + 30|\tilde{z}_i|^4\right), \tag{4.17}$$

where (4.15) follows from (4.12), and (4.16) follows from the continuity of $l(z)$, the Lipschitz continuity of $G(t,z)$ by assumption (H1), and (4.4). We proceed to analyze A_1^0:

$$\begin{aligned}
A_1^0 &\le \sup_{u\in U}\sum_{i=n+1}^{2n}[\Lambda_{z_i}(t,z,s,w)\psi_i(t,z,u) + \Lambda_{w_i}(t,z,s,w)\psi_i(s,w,u)]\\
&\quad + \sum_{i=1}^{n}[\Lambda_{z_i}(t,z,s,w)f_i(t,z) + \Lambda_{w_i}(t,z,s,w)f_i(s,w)] \stackrel{\triangle}{=} A_{11}^0 + A_{12}^0.
\end{aligned}$$

Then by (H1), (4.4), and recalling $|g_i(t,x,p,u)| \le C_g(1 + \sum_{k=1}^n |p_k|)$ for $t \in [0,T]$, $u \in U$, we have

$$\limsup_{k\to\infty} A_{11}^0\big(\eta^{(k)}, \varepsilon^{(k)}, \lambda^{(k)}\big) \le \frac{\alpha(\mu T - \tilde{t})}{\mu T}\sum_{i=n+1}^{2n} 12C_g\left[2n|\tilde{z}_i|^6 + |\tilde{z}_i|^5\right]. \tag{4.18}$$

Now we employ $a_i(t) \ge 0$ for $t \in [0,T]$ in the weak coupling condition (H2), and the Lipschitz property of $f_i(t,z) = a_i(t)z_i + f_i^0(t,z)$ by (H1) to obtain

$$
\begin{aligned}
A_{12}^0 &= \frac{\alpha(2\mu T - t - s)}{2\mu T} \\
&\quad \times \sum_{i=1}^n \left\{ \left[\frac{5z_i}{\sqrt{z_i^2+1}} e^{5\sqrt{z_i^2+1}} + 6z_i^5 + \frac{z_i - w_i}{\varepsilon} \right] [-a_i(t)z_i + f_i^0(t,z)] \right. \\
&\qquad \left. + \left[\frac{5w_i}{\sqrt{w_i^2+1}} e^{5\sqrt{w_i^2+1}} + 6w_i^5 + \frac{w_i - z_i}{\varepsilon} \right] [-a_i(s)w_i + f_i^0(s,w)] \right\} \\
&\le \frac{\alpha(2\mu T - t - s)}{2\mu T} \sum_{i=1}^n \left\{ \left[\frac{5z_i}{\sqrt{z_i^2+1}} e^{5\sqrt{z_i^2+1}} + 6z_i^5 \right] f_i^0(t,z) \right. \\
&\qquad \left. + \left[\frac{5w_i}{\sqrt{w_i^2+1}} e^{5\sqrt{w_i^2+1}} + 6w_i^5 \right] f_i^0(s,w) \right\} \\
&\quad + O\left(\frac{|t-s|^2}{\varepsilon} + \frac{|z-w|^2}{\varepsilon} \right).
\end{aligned} \tag{4.19}
$$

Hence, invoking (4.4), it follows that

$$
\limsup_{k\to\infty} A_{12}^0(\eta^{(k)}, \varepsilon^{(k)}, \lambda^{(k)}) \le \frac{\alpha C_{f^0}(\mu T - \tilde{t})}{\mu T} \sum_{i=1}^n \left[10 e^{5\sqrt{\tilde{z}_i^2+1}} + 12|\tilde{z}_i|^5 \right], \tag{4.20}
$$

which, together with (4.16)–(4.18), gives

$$
\begin{aligned}
&\limsup_{k\to\infty} \text{ RHS of (4.11) } (\eta^{(k)}, \varepsilon^{(k)}, \lambda^{(k)}) \\
&\quad \le \frac{[10C_{f^0} + 25n(C_\sigma + C_g)]\alpha(\mu T - \tilde{t})}{\mu T} \left[\sum_{i=1}^n e^{5\sqrt{\tilde{z}_i^2+1}} + \sum_{i=1}^{2n} |\tilde{z}_i|^6 + C \right] \\
&\quad \le \frac{\alpha}{2\mu T} \left[\sum_{i=1}^n e^{5\sqrt{\tilde{z}_i^2+1}} + \sum_{i=1}^{2n} |\tilde{z}_i|^6 + C \right],
\end{aligned} \tag{4.21}
$$

where C is independent of α. Hence it follows from (4.11), (4.15), and (4.21) that

$$
2\beta \le -\frac{3\alpha}{2\mu T} \left\{ \sum_{i=1}^n e^{5\sqrt{\tilde{z}_i^2+1}} + \sum_{i=1}^{2n} |\tilde{z}_i|^6 \right\} + \alpha C \le \alpha C. \tag{4.22}
$$

We recall from Step 1 that $\beta \le 1$ can take a strictly positive value from the interval $(0, \frac{c_0^+ - c_0}{4T})$ and $\alpha \in (0, \alpha_0)$. Letting $\alpha \to 0$ in (4.22) yields $\beta \le 0$, which is a contradiction to $\beta \in (0, \frac{c_0^+ - c_0}{4T})$, and this completes the proof.

Remark 2. By $\Phi(t_0, z_0, s_0, w_0) \ge \Phi(T, 0, T, 0)$ and $|\underline{v} - \overline{v}| = o([\sum_{i=1}^n (e^{5|z_i|} + e^{5|w_i|}) + \sum_{i=1}^{2n}(z_i^6 + w_i^6)])$, there exist $\delta_\alpha > 0$, $C > 0$ such that

$$
\begin{aligned}
&\frac{1}{2\varepsilon}|t_0 - s_0|^2 + \frac{1}{2\varepsilon}|z_0 - w_0|^2 + \frac{\lambda}{t_0 - T_1} + \frac{\lambda}{s_0 - T_1} \\
&\qquad + \delta_\alpha \left[\sum_{i=1}^n \left(e^{5\sqrt{1+z_{0,i}^2}} + e^{5\sqrt{1+w_{0,i}^2}} \right) + \sum_{i=1}^{2n} \left(z_{0,i}^6 + w_{0,i}^6 \right) \right] \le C.
\end{aligned}
$$

Then (4.3) follows readily.

Remark 3. By expanding $2\Phi(t_0, z_0, s_0, w_0) \geq \Phi(t_0, z_0, t_0, z_0) + \Phi(s_0, w_0, s_0, w_0)$ using all the individual terms, it can be shown that $\frac{1}{2\varepsilon}|t_0 - s_0|^2 + \frac{1}{2\varepsilon}|z_0 - w_0|^2$ is dominated by a continuous function $F(t_0, z_0, s_0, w_0)$, which goes to zero as $|t_0 - s_0| + |z_0 - w_0| \to 0$, which in turn follows from (4.3) when $\varepsilon \to 0$.

Remark 4. The proof of the theorem is based upon the methods in [12, 9, 10, 2]. Since here we deal with the function class $\mathcal{G}$ with a highly nonlinear growth condition on an unbounded domain, a localized semiconvex/semiconcave approximation technique is devised. The particular structure of the system dynamics also plays an important role in the proof of uniqueness, and in general it is more difficult to obtain uniqueness results under more general dynamics and the above fast growth condition. It is seen that the weak coupling feature of the dynamics of the state subprocess x is crucial for the above proof, and furthermore, when there exists an $a_i < 0$ (see assumption (H2)), the estimate (4.19) would not be valid.

5. Control with state constraints. In this section we consider the case when the state subprocess p is subject to constraints; i.e., the trajectory of each p_i must be maintained to be in a certain range. We term this situation as optimization under hard constraints. In [11] the author considered a deterministic model and obtained a constrained viscosity solution formulation for a first order HJB equation. Now due to the exogenous subprocess x, we come up with a second order HJB equation, and we will develop a similar formulation. Suppose that $u \in U$, where U is a compact convex set in $\mathbb{R}^n$, and that p satisfies $p_i \in [0, \overline{P}_i]$, where $\overline{P}_i$ is the upper bound. For simplicity we take $U = [-1, 1]^n$ and $\overline{P}_i = \infty$. For any fixed initial value $p_0 \geq 0$ (i.e., each $(p_0)_i \geq 0$), define the admissible control set

$$\begin{aligned}\mathcal{U}^{p_0} = \{u(\cdot) \mid u \text{ is adapted to } \sigma(z_s,\ s \leq t),\ u(t) \in U,\\ \text{and } P_\Omega(p_i(t) \geq 0 \ \text{ for all } 0 \leq t \leq T) = 1,\ 1 \leq i \leq n\}.\end{aligned}$$

In this section we consider the simple case of

$$g(t, x, p, u) = u.$$

Under the admissible control set $\mathcal{U}^{p_0}$, we will use the notation of section 2, for which the interpretation should be clear, and in the following we also use $\mathcal{U}^{p_0}$ with any initial time $s \leq T$. It is evident that $\mathcal{U}^{p_0}$ is a convex set. Under the norm $\|\cdot\|$ on $\mathcal{L}$ defined in section 2, $\mathcal{U}^{p_0}$ is also closed. Indeed, if $\|u^{(k)} - u\| \to 0$ as $k \to \infty$, where $u^{(k)} \in \mathcal{U}^{p_0}$, one can show that u will also generate positive p trajectories with probability 1 with initial value p_0. Thus $u \in \mathcal{U}^{p_0}$. As in the state unconstrained case, one can prove existence and uniqueness of the optimal control. Write

$$Q_T^0 = [0, T) \times \mathbb{R}^n \times (0, \infty)^n, \quad Q_T = [0, T) \times \mathbb{R}^n \times [0, \infty)^n,$$
$$\overline{Q}_T = [0, T] \times \mathbb{R}^n \times [0, \infty)^n.$$

We consider the HJB equation

$$\begin{aligned}0 &= -\frac{\partial v}{\partial t} + \sup_{u \in U}\left\{-\frac{\partial^\tau v}{\partial z}\psi\right\} - \frac{1}{2}\mathrm{tr}\left(\frac{\partial^2 v}{\partial z^2}GG^\tau\right) - l,\\ v|_{t=T} &= 0,\end{aligned} \tag{5.1}$$

where $(t, z) = (t, x, p) \in \overline{Q}_T$.

DEFINITION 5.1. *$v(t,z) \in C(\overline{Q}_T)$ is called a* constrained viscosity solution *to* (5.1) *if* (i) *$v|_{t=T} = 0$ and, for any $\varphi(t,z) \in C^{1,2}(\overline{Q}_T)$, whenever $v - \varphi$ takes a local maximum at $(t,z) \in Q_T^0$, we have*

$$-\frac{\partial \varphi}{\partial t} + \sup_{u \in U}\left\{-\frac{\partial^\tau \varphi}{\partial z}\psi\right\} - \frac{1}{2}\mathrm{tr}\left(\frac{\partial^2 \varphi}{\partial z^2} GG^\tau\right) - l \le 0, \quad z \in \mathbb{R}^{2n}, \tag{5.2}$$

at (t,z), and (ii) *for any $\varphi(t,z) \in C^{1,2}(\overline{Q}_T)$, whenever $v - \varphi$ takes a local minimum at $(t,z) \in Q_T$, in* (5.2) *we have an opposite inequality at (t,z). In short, we term the constrained viscosity solution $v(t,z) \in C(\overline{Q}_T)$ as a viscosity subsolution on Q_T^0 and a viscosity supersolution on Q_T.*

Remark 5. Conditions (i) and (ii) hold on Q_T^0 and Q_T, respectively. Here we give a heuristic interpretation on how the state constraints are captured by condition (ii). Suppose that $v - \varphi$ attains a minimum at $(\bar{t}, \overline{x}, \overline{p})$, where v is the value function and satisfies (5.1) at $(\bar{t}, \overline{x}, \overline{p})$ with classical derivatives, i.e.,

$$0 = -\frac{\partial v}{\partial t} + \left\{-\frac{\partial^\tau v}{\partial z}\psi\right\}\Big|_{u=\widehat{u}} - \frac{1}{2}\mathrm{tr}\left(\frac{\partial^2 v}{\partial z^2} GG^\tau\right) - l. \tag{5.3}$$

In addition, we assume that $\widehat{u}$ is admissible w.r.t. $(\overline{x}, \overline{p})$. Here $\bar{t} \in [0,T)$ and $\overline{p}$ lies on the boundary of $[0,\infty)^n$. By the necessary condition for a minimum, at $(\bar{t}, \overline{x}, \overline{p})$, we have

$$v_t - \varphi_t \ge 0, \quad v_{x_i} - \varphi_{x_i} = 0, \quad v_{x_i x_i} - \varphi_{x_i x_i} \ge 0, \quad 1 \le i \le n, \tag{5.4}$$

where the first inequality becomes equality when $\bar{t} \in (0,T)$. Since $\overline{p}$ is on the boundary of $[0,T)^n$, we can find an index set I such that $\overline{p}_i = 0$ when $i \in I$, and $\overline{p}_i > 0$ when $i \in \{1,\dots,n\}\backslash I$. Again, by the minimum property at $(\bar{t}, \overline{x}, \overline{p})$ we get

$$v_{p_i} - \varphi_{p_i} \ge 0 \quad \text{for } i \in I, \qquad v_{p_i} - \varphi_{p_i} = 0 \quad \text{for } i \in \{1,\dots,n\}\backslash I \tag{5.5}$$

at $(\bar{t}, \overline{x}, \overline{p})$. Since we assume that $\widehat{u}$ is admissible w.r.t. $(\overline{x}, \overline{p})$, then we have $\widehat{u}_i \ge 0$ for $i \in I$, and therefore by (5.5), at $(\bar{t}, \overline{x}, \overline{p})$

$$(v_p - \varphi_p)^\tau \widehat{u} \ge 0. \tag{5.6}$$

Now by (5.4) and (5.6) we see that

$$-\frac{\partial \varphi}{\partial t} + \left\{-\frac{\partial^\tau \varphi}{\partial z}\psi\right\}\Big|_{u=\widehat{u}} - \frac{1}{2}\mathrm{tr}\left(\frac{\partial^2 \varphi}{\partial z^2} GG^\tau\right) - l \ge 0,$$

and then condition (ii) holds at $(\bar{t}, \overline{x}, \overline{p})$.

As in section 2, we also define the set $\mathcal{U} = \{u(\cdot) | u \text{ is adapted to } \sigma(z_s,\ s \le t) \text{ and } u(t) \in U,\ t \le T\}$.

LEMMA 5.2. *For any initial pair (s_0, x_0, p_0) with each $(p_0)_i \ge 0$, and any $u \in \mathcal{U}$, there exists $\widetilde{u} \in \mathcal{U}^{p_0}$ such that*

$$P_\Omega\left\{\int_{s_0}^T |\widetilde{u} - u| ds \le 4\varepsilon\right\} = 1, \tag{5.7}$$

where with probability 1 *and for all* $1 \le i \le n$, *the constant* $\varepsilon > 0$ *satisfies*

$$\sup_{t\in[s_0,T]} \max\{-p_i(t, s_0, p_0, u), 0\} \le \varepsilon, \tag{5.8}$$

and $p(t, s_0, p_0, u)$ *denotes the value of* p *at* t *with initial condition* (s_0, p_0) *and control* u.

Proof. We need only to modify each component u_i of u in the following way. Define $\tau_i^0 = s_0$, and for $k \ge 1$,

$$\tau_i^k = \inf\{t > \tau_i^{k-1},\ p_i(t, s_0, p_0, \widetilde{u}) = 0\}, \tag{5.9}$$

$$\tau_i^k = T \quad \text{if } \ p_i(t, \tau_i^{k-1} + \varepsilon, p_i(\tau_i^{k-1} + \varepsilon), u) > 0 \quad \forall t \ge \tau_i^{k-1} + \varepsilon, \tag{5.10}$$

$$\widetilde{u}_i(t) = 1 \quad \text{on } [\tau_i^{k-1},\ \tau_i^{k-1} + \varepsilon), \tag{5.11}$$

$$\widetilde{u}_i(t) = u_i(t) \quad \text{on } [\tau_i^{k-1} + \varepsilon, \tau_i^k). \tag{5.12}$$

Then it is obvious that $\widetilde{u} \in \mathcal{U}^{p_0}$. Suppose that (5.7) is not true, and then there exist i and a set A^0 with $P_\Omega(A^0) > 0$ such that on A^0

$$\int_{s_0}^{T} |\widetilde{u}_i - u_i| ds > 4\varepsilon. \tag{5.13}$$

For any fixed $\omega \in A^0$, if $\tau_i^{k_0}$ is the last stopping time defined by (5.9) and (5.10), then by (5.13) we can easily show that $p_i(\tau_i^{k_0-1}, s_0, p_0, u) < -2\varepsilon$, which is a contradiction to (5.8). □

With Lemma 5.2, we can further show that the value function $v(t, z)$ is continuous on $\overline{Q}_T$ by a comparison method, as in the unconstrained case [3]. The details are omitted here. The growth condition of Proposition 2.2 also holds in the state constrained case.

PROPOSITION 5.3. *The value function* v *is a constrained viscosity solution to the HJB equation* (5.1).

Proof. We verify condition (i) first. For an initial condition pair (s, z) with $z \in Q_T^0$ and any $u \in U$ we construct control $\widetilde{u} = u$ on $[s, s+\varepsilon]$ and $\widetilde{u} = 0$ on $(s+\varepsilon, T]$. We see that when ε is sufficiently small, $\widetilde{u}$ is in the admissible control set w.r.t. (s, z) since each $p_i \in [0, \infty)$. All the remaining steps and the verification of condition (ii) can be done as in Theorem 2.4. □

A BOUNDED VARIATION CONTROL PROBLEM FOR DIFFUSION PROCESSES*

ANANDA WEERASINGHE†

Abstract. We consider an infinite horizon discounted cost minimization problem for a one-dimensional stochastic differential equation model. The available control is an added bounded variation process. The cost structure involves a running cost function and a proportional cost for the use of the control process. The running cost function is not necessarily convex. We obtain sufficient conditions to guarantee the optimality of the zero control. Also, for unbounded cost functions, we provide sufficient conditions which make our optimal state process a reflecting diffusion on a compact interval. In both cases, the value function is a C^2 function. For bounded cost functions, under additional assumptions, we obtain a complex optimal strategy which turned out to be a mixture of jumps and local-time-type processes. In this case, we show that the value function is only a C^1 function and that it fails to be a C^2 function. We also discuss a related variance control problem.

Key words. stochastic optimal control, optimal stopping, local-time processes, diffusions with reflections

1. Introduction.

Consider a weak solution to the one-dimensional stochastic differential equation

$$X_x(t) = x + \int_0^t \mu(X_x(s-))\,ds + \int_0^t \sigma(X_x(s-))\,dW(s) + A(t), \tag{1.1}$$

where $x \in \mathbb{R}$, $\{W(t) : t \geq 0\}$ is a standard one-dimensional Brownian motion adapted to a right-continuous filtration $\{\mathfrak{F}_t : t \geq 0\}$ on a probability space $(\Omega, \mathfrak{F}, P)$. The σ-algebra $\mathfrak{F}_0$ contains all the P-null sets in $\mathfrak{F}$, and the Brownian increments $W(t+s) - W(t)$ are independent of $\mathfrak{F}_t$ for all t and $s \geq 0$. The control process $A(\cdot)$ is $\{\mathfrak{F}_t\}$-adapted, right continuous with left limits, and of bounded variation on finite intervals. Also $A(0) = 0$. Let $|A|(\cdot)$ be the total variation process of $A(\cdot)$, where $|A|(t)$ is the total variation of $A(\cdot)$ on $[0,t]$. We further assume that for each $X_x(\cdot)$, there is an increasing sequence of stopping times (τ_n) with respect to $\{\mathfrak{F}_t\}$ such that $\lim_{n\to\infty} \tau_n = +\infty$ and

$$\text{(i)} \qquad E_x \int_0^{T\wedge\tau_n} [|\mu(X_x(s-))| + \sigma^2(X_x(s-))]\,ds < \infty \quad \text{for each } T > 0 \text{ and} \tag{1.2}$$

$$\text{(ii)} \qquad \lim_{n\to\infty} E_x \left[|X_x(\tau_n)| e^{-\alpha\tau_n} I_{[\tau_n<\infty]}\right] = 0,$$

where $\alpha > 0$ is a constant which represents the discount rate in (1.3).

The first condition above helps us make sense of (1.1) and the second condition will be used in the proof of the verification lemma in section 2. Similar conditions are

assumed in the verification theorems of [11, Theorem 4.1, p. 322], [21], and [35], all of which address similar singular control problems. If $E_x \int_0^T [|\mu(X_x(s-))| + \sigma^2(X_x(s-))]\, ds < \infty$ for each $T > 0$, then the choice $\tau_n \equiv +\infty$ a.s. for all n, satisfies (1.2).

The cost functional associated with (1.1) is given by

$$J(x, A) = E_x \int_0^\infty e^{-\alpha t}[C(X_x(t))\, dt + d|A|(t)], \tag{1.3}$$

where $C(\cdot)$ is a nonnegative running cost function with the additional properties described below, and $\alpha > 0$ is a constant which represents the discount factor.

We intend to minimize $J(x, A)$ over all available state processes satisfying (1.1), (1.2), and to find an optimal control $A(\cdot)$ to achieve the minimum value. We make the following assumptions on the functions $\mu(\cdot), \sigma(\cdot)$, and $C(\cdot)$ throughout this paper. Here μ', σ', and C' denote the first derivatives of μ, σ, and C, respectively.

(1.4) (i) The functions μ and σ are continuously differentiable on R,
$$\inf_R(\alpha - \mu'(y)) > 0, \inf_R \sigma(y) > 0, \text{ and } x\mu(x) < 0 \text{ for all } x \neq 0.$$

(1.5)

(ii)
$$\int_{-\infty}^0 \frac{\mu(x) - x}{\sigma^2(x)}\, dx = \int_0^\infty \frac{x - \mu(x)}{\sigma^2(x)}\, dx = +\infty.$$

(1.6) (iii) The cost function C is continuously differentiable on R, decreasing on $(-\infty, 0)$, increasing on $(0, +\infty)$, and it satisfies either $\liminf_{|x|\to\infty} \dfrac{C(x)}{|x|} > 0$ or $\limsup_{|x|\to\infty} \dfrac{C(x)}{|x|} < \infty$.

If $C(0) = r \neq 0$, we could introduce a new running cost function $\tilde{C}(x) = C(x) - r$ and define the functional $\tilde{J}(x, A)$ as similar to (1.3). Then $J(x, A) = \tilde{J}(x, A) + \frac{r}{\alpha}$ by (1.3), and hence the value functions V and $\tilde{V}$ defined as in (1.8) below are also related by $V(x) = \tilde{V}(x) + \frac{r}{\alpha}$. Therefore, without loss of generality, we assume $C(0) = 0$.

The assumption $x\mu(x) < 0$ for all $x \neq 0$ in (1.4) guarantees that the ordinary differential equation $\dot{x} = \mu(x)$ has a unique stable equilibrium point at the origin. This corresponds to (1.1) with the processes $A(\cdot)$ and $\sigma(\cdot)$ being identically zero. Hence, $X_x(\cdot)$ in (1.1) can be considered as a random perturbation of a stable dynamical system. We will provide two motivating examples from finance and operations research at the end of this section. In each example, the corresponding state process is a stochastic perturbation of a stable dynamical system.

Note that the diffusion coefficient $\sigma(\cdot)$ is allowed to be unbounded subject to the assumptions (1.4) and (1.5). Under assumptions (1.4)–(1.6), our main objectives here are to obtain sufficient conditions in terms of the functions μ, σ, and C for the following.

(i) Optimality of the zero control and the C^2 regularity of the corresponding value function.

(ii) Optimality of a reflected diffusion process in a compact interval and the C^2 regularity of the value function.

(iii) To illustrate the lack of C^2 regularity for the value function for a class of bounded cost functions regardless of the smoothness of μ, σ, and C, and to obtain an optimal policy.

(iv) To generalize the results in (i) and (ii) for a related variance control problem.

In cases (i), (ii), and (iv), the value function is a C^2 solution to the Hamilton–Jacobi–Bellman (HJB) equation (1.9), while in case (iii), it fails to be a C^2 function but it is a C^1 solution to the HJB equation (1.9). In (iv), we consider the problem of controlling the bounded variation process as well as the diffusion coefficient of (1.1). Our assumptions in (iv) guarantee the convexity of the value function, and hence it is optimal to choose the minimum diffusion coefficient. We generalize the results of [14], [21], and [35] to nonsymmetric diffusions and to a large class of nonsymmetric cost functions without the convexity assumption. In addition, we allow the cost functions to be of slow growth such as $C(x) \sim |x|^\alpha$ with $0 < \alpha < 1$, $C(x) \sim \log|x|$ for large $|x|$ as well as bounded cost functions. Here we employ the connection between stochastic control and optimal stopping, which is a known theme in optimal control theory. We refer to [3], [4], [5], [7], [15], [16], [27], and [35] for this approach. The articles [5], [15], and [16] consider the case of Brownian motion with an added bounded variation control process. The work of [5] considers the case of a diffusion process and their drift and diffusion coefficients are allowed to be time dependent, but the drift term is linear and the diffusion is independent of the space variable. The running cost function is a symmetric convex function in [5], [13], [15], and [16]. A control problem with a quite general cost function with a different cost structure was considered in [3].

For a given x in $\mathbb{R}$, we call $((\Omega, \mathfrak{F}, P), (\mathfrak{F}_t), W(\cdot), X_x(\cdot), A(\cdot))$ an admissible control system if (i) $X_x(\cdot)$ is a weak solution to (1.1), and (ii) $X_x(\cdot)$ satisfies (1.2) and $J(x, A) < +\infty$, where J is given in (1.3). To define the value function for the control problem, we first introduce

$$\mathcal{A}(x) = \{A(\cdot) : \ A(\cdot) \text{ is a bounded variation process in (1.1) with a corresponding admissible state process } X_x(\cdot)\}. \tag{1.7}$$

For each x in $\mathbb{R}$, using a reflecting diffusion on an interval containing the point x, one could obtain a control process $A(\cdot)$ so that the corresponding $J(x, A)$ is finite. Hence $\mathcal{A}(x)$ is nonempty and the value function is finite for all x. The value function is defined by

$$V(x) = \inf_{A \in \mathcal{A}(x)} J(x, A). \tag{1.8}$$

The formal HJB equation for the value function is given by

$$\min\left\{\frac{1}{2}\sigma^2(x)V''(x) + \mu(x)V'(x) - \alpha V(x) + C(x),\ 1 - |V'(x)|\right\} = 0 \text{ a.s. on } \mathbb{R}. \tag{1.9}$$

We show that under our assumptions, this value function is the minimal solution to (1.9).

The paper is organized as follows. In section 2, we establish several verification results. They will be used to sort out our optimal strategies. Some auxiliary results will be proved in section 3. In section 4, we show that when $\alpha - \mu'(x) \geq |C'(x)|$ for all x, then $A(\cdot)$ being identically zero is an optimal strategy and that the value function is a C^2 solution to (1.9). In section 5, when $(1+\varepsilon)(\alpha - \mu'(x)) < |C'(x)|$ for large $|x|$, for some $\varepsilon > 0$, we show that the value function is C^2 and the optimal state process

is a reflecting diffusion on a finite interval which contains the origin. Our approach in both sections 4 and 5 is to first observe that the value function can be completely determined by its first derivative and then to obtain this derivative function. In sections 4 and 5, we generalize the results of [35] to a large class of cost functions and to general diffusions, while section 6 is completely new. In section 5, we develop the idea of using a family of optimal stopping problems to obtain the derivative of the value function. In section 6, we consider the situation of bounded cost functions. If $\alpha - \mu'(x) \geq |C'(x)|$, then the results in section 4 remain valid and the zero control is optimal. Under additional symmetry assumptions, we obtain a complex optimal strategy which involves a possible jump at a stopping time followed by a local-time-type control when $|C'(x)|$ is larger than $\alpha - \mu'(x)$ in a large compact interval. In this case, the value function is a C^1 solution to (1.9) and it is C^2 everywhere except at two points. When μ is identically zero and σ is a constant, an example of a similar optimal process is given in Example 4.3, Chapter VIII of [11]. In section 7, we control the diffusion coefficient in addition to the bounded variation process. We observe that the monotonicity of the function $h(x) = \frac{C'(x)}{\alpha - \mu'(x)}$ implies the convexity of the value function related to the sections 4 and 5. Hence the choice of the minimal diffusion coefficient is optimal.

We intend to consider the ergodic control problem and Abelian limit relations between the value functions in a future work; see [34] for a related article. The articles [9] and [31] discuss issues related to the regularity of the value function in higher dimensions. The existence of an optimal Markovian control for related stochastic control problems was established in [20]. Next we describe two motivating examples from finance and operations research.

Example 1 (foreign exchange rates). We consider the currency exchange rate that governs the transactions between two countries. We assume that the economies of the two countries are stable and therefore the exchange rate fluctuates around a stable equilibrium point. In the presence of uncertainty, it is a common practice to model the currency exchange rate using stochastic differential equations (see Chapter 7 of [26] and also [8], [12], [18], and [25]). We consider the problem of a central bank in one of these countries which would like to keep the exchange rate as close as possible to a given target level through minimal intervention.

In several models (see [12], [18]), the exchange rate is assumed to take values in an exogenously given target interval which is called the "target band." To keep the exchange rates within the target band, the central bank may intervene while the exchange rate is still inside the band and there is empirical evidence to support this fact [6]. In [13], impulse control methods were used to find an optimal target zone. An exchange rate model with constant σ and discrete intervention times is considered in [25]. They derive an optimal target band in a specific example with a symmetric running cost function $C(\cdot)$. Also we refer the reader to [24] and [32] for related work. It is typically the responsibility of the central bank to have a monetary policy to guarantee the exchange rate to take values in the target band. The central bank may intervene in the foreign exchange market by adjusting the money supply, controlling the flow of foreign capitals via local interest rate adjustments, and by buying and selling large amounts of the foreign currency. These procedures imply a cost for the central bank and this cost increases with the level of intervention.

In our model, there is no exogenous target band for the exchange rate, but we consider a target value or a benchmark. There will be two types of costs involved: there is a running cost associated with the deviation of the exchange rate from the

target value and a cost for the intervention of the central bank which is proportional to the change in the interest rate. Our exchange rate model is described by (1.1). Here $X_x(t)$ represents the value of one unit of foreign currency in domestic currency units at time $t \geq 0$ and $X_x(0) = x$. The bounded variation control process $A(\cdot)$ in (1.1) represents the changes in the exchange rate due to the central bank interventions. We assume that the underlying cost of these interventions is proportional to the changes in the exchange rate and is represented by the total variation process. Without loss of generality, we consider the target level for the exchange rate to be at the origin, since if the target level were at $\rho > 0$ we could consider $X_x(t) - \rho$, which satisfies an equation similar to (1.1). The running cost function $C(\cdot)$ which satisfies (1.6) represents the cost due to the deviation of the exchange rate from the target. Notice that C has its absolute minimum at the target point. If there is no uncertainty, then the exchange rate should have a stable equilibrium point at the target level since we assume that μ and σ satisfy (1.4) and (1.5).

Our objective here is to find an optimal intervention policy $A(\cdot)$ of the central bank which minimizes the infinite horizon total cost $J(x, A)$ of (1.3), where $\alpha > 0$ is a constant discount factor. We would also like to derive conditions on μ, σ, and C which imply the existence of an optimal target band $[a^*, b^*]$ and also to obtain conditions which guarantee the nonexistence of an optimal target band. In [8], the authors address a similar problem for the geometric Brownian motion with $C(x) = x^2$ but allow the cost due to each intervention to have a fixed cost and a proportional cost. They also obtain an explicit expression for the value function. Our results are of more qualitative nature. In section 4, under assumptions (1.4)–(1.6) and (4.2), we guarantee the nonexistence of an optimal target band and show that it is optimal for the central bank not to intervene at all to minimize the cost functional $J(x, A)$. Our results in section 5 prove the existence of an optimal target band $[a^*, b^*]$ under assumptions (1.4)–(1.6) and (5.1)–(5.2). In Theorem 5.4, we derive an optimal intervention policy.

Example 2 (capacity change under uncertainty). Capacity change is the process of adding new facilities or deleting available facilities over time to satisfy a demand. Let $d(t)$ be the demand at time t and $e(t)$ be the available capacity at time t. We let $d(\cdot)$ and $e(\cdot)$ be random processes. At time t, if $e(t) < d(t)$, then a shortage cost will be paid. If $e(t) > d(t)$, then an overcapacity cost will be paid. Let $X_x(t) = d(t) - e(t)$ for $t \geq 0$ and $X_x(0) = x$. $X_x(\cdot)$ represents the "undercapacity" process and notice that $X_x(t)$ may take negative values. We introduce the penalty function C by letting $C(y)$ be the penalty paid per unit time if $X_x(t) = y$. If $|X_x(t)|$ is large, we expect that the corresponding penalty is also large and hence C satisfies the assumptions in (1.6) and $C(0) = 0$. Since the "overcapacity" and "undercapacity" penalty rates could be different, the function $C(\cdot)$ need not be symmetric. When a project is undertaken, the decision maker is provided with an initial fund and also an emergency fund. Initial funds are used by day-to-day control of the project to change the capacity $e(\cdot)$ continuously to match the demand process $d(\cdot)$, by using the future forecasts of the demand. Therefore, it is assumed that these changes are made so that the capacity process $e(\cdot)$ remain absolutely continuous with respect to t. However, uncertain future demands, significant forecasting errors or any other defects may result in critical shortages or unwanted gross surpluses of the capacity. Therefore, the $X_x(\cdot)$ process may deviate significantly from the origin. To correct these situations, the controller may use the emergency funds to provide or delete the additional capacity. These corrections are costly and the corresponding changes in capacity are represented by a bounded variation process $A(\cdot)$ which may allow jumps or nonabsolutely continuous changes with respect to t. It is assumed that the cost of

change of capacity is proportional to the amount changed. Thus, the total variation $|A|(t)$ represents the costs due to these emergency capacity changes during $[0,t]$. The decision maker would like to choose the $A(\cdot)$ process which minimizes the infinite horizon discounted cost $J(x,A) \equiv E_x \int_0^\infty e^{-\alpha t}[C(X_x(t))\,dt + d|A|(t)]$, where $\alpha > 0$ is a constant discount factor.

The condition $x\mu(x) < 0$ for $x \neq 0$ in (1.4) implies the stability of the system when there is no uncertainty or when perfect forecasting is available. With the above model, when μ, σ, and C are known to the decision maker, there are several issues of interest. The results in this paper will address the following issues.

1. Under what conditions should the controller rule out using emergency funds at all? We will provide an answer in section 4.
2. In general, what is the qualitative nature of the optimal strategies? Sections 4, 5, and 6 yield answers to this question.
3. When large losses are covered by an insurance, the cost function $C(\cdot)$ can be considered a bounded function satisfying (1.6) and thus $\lim_{|x|\to\infty} C(x)$ is finite. What are the available optimal strategies? We answer this question in section 6.

In a celebrated paper [22], Manne specified the demand as a Wiener process with a drift and used the regenerative behavior of $X_x(\cdot)$ to conclude that the optimal capacity can be found by considering an equivalent deterministic problem with a modified discount rate. In [10], Davis et al. considered the demand as a Poisson process with a similar infinite horizon cost functional related to a piecewise-deterministic Markov process. They developed algorithms to approximate the optimal strategy. In conclusion, they point out the importance as well as the difficulty of developing results of qualitative nature for optimal policies. Our results address this need when $X_x(\cdot)$ is modeled by (1.1). In [30], Ryan employs the geometric Brownian motion for the demand process and uses option pricing formulas to derive infinite horizon discounted cost. For a survey article on capacity expansion review, a list of references, and for new directions, we refer the reader to [33].

2. A verification lemma. The results in this section will enable us to obtain a lower bound for the value function. It is closely related to Theorem 2.1 of [21], Lemma 3.1 of [35], and also to the general verification theorems in Chapter 8 of [11]. We first establish the verification lemma under the assumption $\liminf_{|x|\to\infty} \frac{C(x)}{|x|} > 0$ and then we generalize it to the case $\limsup_{|x|\to\infty} \frac{C(x)}{|x|} < \infty$. We relabel these assumptions in (1.6). Let us assume

$$\text{either (i) } \liminf_{|x|\to\infty} \frac{C(x)}{|x|} > 0 \tag{2.1}$$

$$\text{or (ii) } \limsup_{|x|\to\infty} \frac{C(x)}{|x|} < \infty. \tag{2.2}$$

LEMMA 2.1. *Assume* (2.1). *Let $Q(x)$ be a twice continuously differentiable function satisfying the HJB equation* (1.9). *Then $V(x) \geq Q(x)$ for all x, where $V(x)$ is the value function given in* (1.8).

Proof. The proof is essentially the same as the proof of Lemma 3.1(a) of [35] with the following observations. First, by (2.1), there exist two constants C_0 and C_1 so that $C_1 > 0$ and $C(x) \geq C_0 + C_1|x|$ for all x. Second, we can use the sequence (τ_n) given in (1.2) in the proof of Lemma 3.1 in [35] and follow the proof there. ∎

Remark. The above lemma remains valid if Q is a C^2 function which satisfies

(2.3)
$$\operatorname{Min}\left\{\frac{1}{2}\sigma^2(x)Q''(x)+\mu(x)Q'(x)-\alpha Q(x)+C(x),1-|Q'(x)|\right\}\geq 0 \quad \text{for all } x.$$

COROLLARY 2.2. *Assume* (2.2). *Let $Q(x)$ be a twice continuously differentiable function which satisfies the HJB equation* (1.9). *Then $V(x)\geq Q(x)$ for all x, where V is the value function given in* (1.8).

Proof. Let $C(x)$ satisfy (2.2). Consider any process $X_x(\cdot)$ which satisfies (1.1) and (1.2) and has corresponding $J(x,A)<\infty$. Then $E_x\int_0^\infty e^{-\alpha t}\,d|A|(t)$ is finite. By (2.2) we have $C(x)<K_0+K_1|x|$ for all x, for some constants K_0 and $K_1>0$. We approximate $C(x)$ by a sequence of C^2 functions $\{C_N\}$ such that

(i) $C_N(0)=0$, C_N is increasing on $[0,\infty)$, and decreasing on $(-\infty,0)$;

(ii) $C_0(x)\geq C_N(x)\geq C(x)$ and $\lim_{N\to\infty}C_N(x)=C(x)$ for all x;

(iii) $C_N(x)\leq K_0+K_1|x|$ for all x and $C_N(x)=K_0+K_1|x|$ for $|x|\geq N+1$.

Next, we estimate $E_x[C_N(X_x(T))]$ by applying Itô's lemma to $C_N(X_x(T\wedge\tau_k))$, where (τ_k) is as in (1.2), and using the following facts:

(a) $\sup_R(|C_N'(x)|+|C_N''(x)|)<D_N$, where D_N is a positive constant;

(b) $\mu(x)C_N'(x)\leq 0$ for all x and $C_N''(x)=0$ when $|x|\geq N+1$; and

(c) $E_x\int_0^{T\wedge\tau_k}|C_N''(X_x(t))|\sigma^2(X_x(t))\,dt\leq D_N\,(\max_{|x|\leq N+1}\sigma^2(x))T$.

Thus, we obtain $E_x[C_N(X_x(T\wedge\tau_k)]\leq C_N(x)+B_N(T+E|A|(T))$, where B_N is a constant which depends only on N. Together with $E_x\int_0^\infty e^{-\alpha t}\,d|A|(t)<\infty$, we conclude

$$\begin{aligned}E_x\int_0^\infty e^{-\alpha t}C(X_x(t))\,dt &\leq E_x\left[\int_0^\infty e^{-\alpha t}C_N(X_x(t))\,dt\right]\\ &\leq E_x\left[\int_0^\infty e^{-\alpha t}C_0(X_x(t))\,dt\right]<+\infty.\end{aligned}$$

But $\lim_{N\to\infty}C_N(x)=C(x)$ for all x, and consequently $\lim_{N\to\infty}E_x\int_0^\infty e^{-\alpha t}C_N(X_x(t))\,dt=E_x\int_0^\infty e^{-\alpha t}C(X_x(t))\,dt$. We let $J_N(x,A)\equiv E_x\int_0^\infty e^{-\alpha t}(C_N(X_x(t))dt+d|A|(t))$. Then each $J_N(x,A)$ is finite and $\lim_{N\to\infty}J_N(x,A)=J(x,A)$. Since $C_N(x)\geq C(x)$, it follows that Q also satisfies $\operatorname{Min}\{\frac{1}{2}\sigma^2(x)Q''(x)+\mu(x)Q'(x)-\alpha Q(x)+C_N(x),1-|Q'(x)|\}\geq 0$ for all x. Thus, by Lemma 2.1 and the remark in (2.3), we obtain $J_N(x,A)\geq Q(x)$. Now letting N tend to infinity, we obtain $J(x,A)\geq Q(x)$ for all x. Hence the result. □

The following result will be used in section 6.

PROPOSITION 2.3. *Assume* (2.1) *or* (2.2). *Let Q be a bounded continuously differentiable function on R which is also twice continuously differentiable everywhere except on a finite set $\{b_1,b_2,\dots,b_N\}$. Also, assume that the limits, $\lim_{x\to b_j^-}Q''(x),\lim_{x\to b_j^+}Q''(x)$ exist and are finite for each $j=1,2,\dots,N$, and that Q satisfies the HJB equation* (1.9) *everywhere except on the set $\{b_1,b_2,\dots,b_N\}$. Then $V(x)\geq Q(x)$ for all x, where V is the value function in* (1.8).

Proof. Let $X_x(\cdot)$ be any admissible process which satisfies (1.1) and (1.2) and has corresponding $J(x,A)$ in (1.3) finite. Hence $E_x\int_0^\infty e^{-\alpha t}\,d|A|(t)$ and $E_x[|A|(T)]$ for any $T>0$ are finite. Next, consider the open set $G_n=\bigcup_{i=1}^N\left(b_i-\frac{1}{n},b_i+\frac{1}{n}\right)$. We can approximate Q by a sequence of C^2 functions $\{Q_n\}$ so that $Q(x)\equiv Q_n(x)$ for all x in $\mathbb{R}\setminus G_n$, $\lim_{n\to\infty}Q_n''(x)=Q''(x)$ for all $x\neq b_1,b_2,\dots,b_N$, and $|Q_n''(x)|\leq M_1$

for all x in G_1, where $M_1 > 0$ is a constant independent of n. By (1.9), we have $|Q'(x)| \le 1$ for all x. Thus $|Q_n'(x)| \le 1 + \rho_n$, where ρ_n is a positive constant and $\lim_{n\to\infty} \rho_n = 0$. Therefore, since Q is bounded, we can find a constant $M_2 > 0$ independent of n, so that $|Q_n(x)| < M_2$ for all n. Next, observe that $\frac{\sigma^2(x)}{2} Q_n''(x) + \mu(x)Q_n'(x) - \alpha Q_n(x) + C(x) \ge 0$ for all x in $\mathbb{R} \setminus G_n$, since $Q_n \equiv Q$ on $\mathbb{R} \setminus G_n$. On the other hand, $|\frac{\sigma^2(x)}{2} Q_n''(x) + \mu(x)Q_n'(x) - \alpha Q_n(x)| < M_3$ for all x in G_n, where $M_3 > 0$ is a constant independent of n. Using these estimates, Itô's lemma and following the computation in the proof of Lemma 3.1 in [35], we obtain

$$E_x\big[e^{-\alpha(T\wedge\tau_k)}|Q_n(X_x(T\wedge\tau_k))|\big] + J(x,A) \ge Q(x) + \epsilon_n(x,T,\tau_k), \tag{2.4}$$

where $\epsilon_n(x,T,\tau_k) = -\rho_n E_x \int_0^{T\wedge\tau_k} e^{-\alpha s}\, d|A|(s) - M_3 E_x \int_0^{T\wedge\tau_k} e^{-\alpha s} I_{G_n}(X_x(s-))\, ds$.

Therefore, by (2.4), we have

$$\begin{aligned} M_2 E_x\big(e^{-\alpha(T\wedge\tau_k)}\big) + J(x,A) &\ge Q(x) - \rho_n E_x \int_0^T e^{-\alpha s}\, d|A|(s) \\ &\quad - M_3 E_x \int_0^T e^{-\alpha s} I_{G_n}(X_x(s-))\, ds. \end{aligned} \tag{2.5}$$

Since $\int_0^t \sigma(X_x(s-)\, dW(s)$ is a continuous local Martingale and $\inf_{\mathbb{R}} \sigma(x) > 0$, it follows that $E_x \int_0^T I_{\{b_i i=1,\dots,N\}}(X_x(s-))\, ds = 0$ (see p. 225, Example 7.10 of [17]). Hence $\lim_{n\to\infty} E_x \int_0^T e^{-\alpha s} I_{G_n}(X_x(s-))\, ds = 0$. Now letting n tend to infinity in (2.5), we obtain $M_2 E_x(e^{-\alpha(T\wedge\tau_k)}) + J(x,A) \ge Q(x)$. Next, we let (τ_k) tend to infinity and then T tend to infinity to obtain $J(x,A) \ge Q(x)$ for all x. This completes the proof. □

3. An auxiliary result. Let $\sigma(\cdot)$ and $\mu(\cdot)$ satisfy assumptions (1.4) and (1.5), and $\sigma'(\cdot)$ be the derivative of $\sigma(\cdot)$. We consider a weak solution of

$$\begin{aligned} dY(t) &= [\sigma(Y(t))\sigma'(Y(t)) + \mu(Y(t))]\, dt + \sigma(Y(t))\, dW(t), \\ Y(0) &= x, \end{aligned} \tag{3.1}$$

where $\{W(t) : t \ge 0\}$ is a Brownian motion on some probability space $(\Omega, \mathfrak{F}, P)$ equipped with a Brownian filtration $\{\mathfrak{F}_t\}$. Let τ_∞ be the explosion time for $\{Y(t) : t \ge 0\}$. If $\sigma'(x)$ is a bounded function, then $\tau_\infty \equiv +\infty$ a.s. by Khasminski's criteria for nonexplosion [29, p. 297], and the following proposition is obvious. But we need it for the general case.

PROPOSITION 3.1. *Assume* (1.4) *and* (1.5). *Let* $\{Y(t) : t \ge 0\}$ *be a weak solution of* (3.1). *Then*

$$\int_0^{\tau_\infty} (\alpha - \mu'(Y(s)))\, ds = +\infty \text{ a.s. in } P. \tag{3.2}$$

To prove (3.2) we need the following technical lemma.

LEMMA 3.2. *Let* u *be the solution to the differential equation*

$$\frac{\sigma^2(x)}{2} u''(x) + (\sigma(x)\sigma'(x) + \mu(x))u'(x) - (\alpha - \mu'(x))u(x) = 0 \tag{3.3}$$

with the boundary conditions $u(0) = 1$ *and* $u'(0) = 0$. *Then* $u(x) \ge 1$ *for all* x, u *is increasing on* $(0, +\infty)$, *decreasing on* $(-\infty, 0)$, *and* $\lim_{x\to-\infty} u(x) = \lim_{x\to+\infty} u(x) = +\infty$.

Proof. This proof is elementary and we sketch the basic steps. First, observe that $u''(0) > 0$. Thus u has a strictly convex local minimum at the origin. Second, by (3.3), u cannot have any positive local maxima nor any negative local minima. By integrating (3.3), we obtain $u'(x) > 0$ for $x > 0$ and $u'(x) < 0$ for $x < 0$ and the estimate $u'(x) > \frac{2}{\sigma^2(x)}(\alpha x - \mu(x))$ for $x > 0$. Hence $u(x) > 1 + 2\int_0^x \frac{\alpha r - \mu(r)}{\sigma^2(r)}\, dr$. Using (1.5), it follows that $\lim_{x\to+\infty} u(x) = +\infty$. A similar proof yields $\lim_{x\to-\infty} u(x) = +\infty$. This completes the proof. □

Proof of Proposition 3.1. By Lemma 3.2, for $n > 1$, we can find $\alpha_n < 0 < \beta_n$ such that $u(\alpha_n) = u(\beta_n) = n$, α_n decreasing to $-\infty$ and β_n increasing to $+\infty$. For the process $\{Y(t)\}$ in (3.1) with $Y(0) = x$, let $n_0 > 1$ so that $\alpha_{n_0} < x < \beta_{n_0}$. For each $n \geq n_0$ we define the stopping time τ_n by

$$\begin{aligned} \tau_n &= \inf\{t \geq 0; Y(t) \notin (\alpha_n, \beta_n)\} \\ &= +\infty \text{ if the above set is empty.} \end{aligned} \tag{3.4}$$

Thus $\lim_{n\to\infty} \tau_n = \tau_\infty$ a.s., where τ_∞ is the explosion time of the process $\{Y(t)\}$ in (3.1).

For each x in $[\alpha_n, \beta_n]$, we introduce the function H_n by $H_n(x) = \frac{u(x)}{n}$. Then H_n satisfies (3.3) on $[\alpha_n, \beta_n]$ with $H_n(\alpha_n) = H_n(\beta_n) = 1$, $\frac{1}{n} \leq H_n(x) < 1$ for all x in (α_n, β_n) and H_n', H_n'' are bounded on $[\alpha_n, \beta_n]$. Next, we apply Itô's lemma to $H_n(Y(t))e^{-\int_0^t \gamma(Y(s))\, ds}$, where $\gamma(Y(t)) = (\alpha - \mu'(Y(t)))$, and we obtain

$$E_x\big[H_n(Y(T \wedge \tau_n))e^{-\int_0^{T\wedge\tau_n} \gamma(Y(t))\, dt}\big] = H_n(x).$$

Hence, by letting T tend to infinity,

$$E_x\big[e^{-\int_0^{\tau_n} \gamma(Y(t))\, dt} I_{[\tau_n<\infty]}\big] \leq H_n(x) = \frac{u(x)}{n}.$$

By letting τ_n increase to τ_∞ as n tends to infinity, we obtain

$$E_x\big[e^{-\int_0^{\tau_\infty} \gamma(Y(t))\, dt} I_{[\tau_\infty<\infty]}\big] = 0$$

and hence (3.2) follows. This completes the proof. □

4. Optimality of the zero control. Consider a weak solution of

$$Z_x(t) = x + \int_0^t \mu(Z_x(s))\, ds + \int_0^t \sigma(Z_x(s))\, dW(s) \tag{4.1}$$

corresponding to (1.1), where the process $A(\cdot)$ is identically zero. Our goal in this section is to furnish the conditions on $\mu(\cdot), \sigma(\cdot)$, and $C(\cdot)$ under which $\{Z_x(t) : t \geq 0\}$ is an optimal process for (1.8). Here we extend the results in section 4 of [35] for a larger class of cost functions and for general diffusions. Throughout this section, in addition to (1.4), (1.5), and (1.6), we also assume

$$\alpha - \mu'(x) \geq |C'(x)| \quad \text{for all } x. \tag{4.2}$$

Introduce a sequence of stopping times $\{\tau_n\}$ for each $n > |x|$ by

$$\begin{aligned} \tau_n &= \inf\{t \geq 0 : |Z_x(t)| \geq n\} \\ &= +\infty \text{ if the above set is empty.} \end{aligned} \tag{4.3}$$

PROPOSITION 4.1. *Assume* (1.4) *and* (1.5). *Then a weak solution* $\{Z_x(t) : t \geq 0\}$ *to* (4.1) *exists and satisfies*

$$\lim_{N\to\infty} E_x\left[|Z_x(\tau_N)|e^{-\alpha\tau_N} I_{[\tau_N<\infty]}\right] = 0. \tag{4.4}$$

Therefore, $Z_x(t)$ *is finite for each* $t > 0$ *and satisfies the admissibility condition* (1.2) *with respect to* $\{\tau_N\}$ *which is defined in* (4.3).

Proof. The existence of a weak solution to (4.1) follows from the assumptions (1.4) and (1.5). We need to establish (4.4). Let H_0 be the solution of

$$\frac{\sigma^2(x)}{2}H_0''(x)+\mu(x)H_0'(x) - \alpha H_0(x) = 0 \quad \text{for all } x, \text{ and} \tag{4.5}$$
$$H_0(0) = 1, \qquad H_0'(0) = 0.$$

Following the proof of the Proposition 4.1 of [35], we can establish $\lim_{x\to+\infty} H_0'(x) = +\infty$ and $\lim_{x\to-\infty} H_0'(x) = -\infty$. Using L'Hôpital rule, we conclude $\lim_{x\to-\infty} \frac{H_0(x)}{x} = -\infty$ and $\lim_{x\to+\infty} \frac{H_0(x)}{x} = +\infty$. Itô's lemma implies that $H_0(Z_x(t\wedge\tau_n))e^{-\alpha(t\wedge\tau_n)}$ is a positive martingale, and we obtain $E_x[|Z_x(\tau_n)|e^{-\alpha\tau_n}I_{[\tau_n<\infty]}] \leq \frac{nH_0(x)}{\text{Min}\{H_0(n),H_0(-n)\}}$ (see Proposition 4.1 of [35]). Consequently, $\lim_{N\to\infty} E_x[|Z_x(\tau_N)|e^{-\alpha\tau_N}I_{[\tau_N<\infty]}] = 0$. This also shows τ_∞, the explosion time for $\{Z_x(t) : t \geq 0\}$ is infinite a.s. To verify the admissibility condition (1.2), we observe $E_x[\int_0^{T\wedge\tau_N} (|\mu(Z_x(s))| + \sigma^2(Z_x(s)))\, ds] \leq T \cdot \max_{[-N,N]}(|\mu(x)| + \sigma^2(x)) < \infty$. Hence both conditions in (1.2) are satisfied and the proposition follows. □

Remarks.

1. Using (1.5), one can directly verify Khasminski's criteria for nonexplosion for $\{Z_x(t)\}$ (see [29, p. 297]).
2. Using Itô's lemma for $H_0(Z_x(T \wedge \tau_n))$, we can derive $E_x[H_0(Z_x(T))] \leq H_0(x)e^{\alpha T}$ and thus $E_x|Z_x(T)|$ is finite for each $T > 0$.

Our next step is to obtain a function W_∞ on $\mathbb{R}$ which satisfies the following conditions (4.6) and (4.7) everywhere on R:

$$\frac{\sigma^2(x)}{2}W_\infty''(x) + (\sigma(x)\sigma'(x) + \mu(x))W_\infty'(x) - (\alpha - \mu'(x))W_\infty(x) + C'(x) = 0 \tag{4.6}$$

and

$$|W_\infty(x)| \leq 1 \quad \text{for all } x. \tag{4.7}$$

Once we find a solution W_∞, we will be able to show that W_∞ is the derivative of the value function $V(x)$ and the process in (4.1) is optimal. To obtain a solution of (4.6) and (4.7), we employ the process $\{Y(t) : t \geq 0\}$ defined in (3.1). Let $\alpha_n < 0 < \beta_n$ be the constants introduced in the proof of Proposition 3.1. Introduce the function W_n which satisfies

$$\frac{\sigma^2(x)}{2}W_n''(x) + (\sigma(x)\sigma'(x) + \mu(x))W_n'(x) - (\alpha - \mu'(x))W_n(x) + C'(x) = 0 \tag{4.8}$$
$$\text{on } (\alpha_n, \beta_n),$$
$$W_n(\alpha_n) = -1 \quad \text{and} \quad W_n(\beta_n) = +1. \tag{4.9}$$

We extend W_n to $\mathbb{R}$ so that W_n satisfies (4.8) everywhere. The following lemma will lead to our main theorem.

LEMMA 4.2. *Assume* (1.4), (1.5), (1.6), *and* (4.2). *Let* W_n *be as defined above. Then the following conclusions hold.*

(i) $|W_n(x)| \le 1$ *on* (α_n, β_n) *and* $\lim_{n\to\infty} W_n(x)$ *exists for every* x.

(ii) *Let* $W_\infty(x) = \lim_{n\to\infty} W_n(x)$ *for each* x *in* $\mathbb{R}$. *Then* W_∞ *satisfies* (4.6) *and* (4.7). *Furthermore,* W_∞ *has the stochastic representation*

$$W_\infty(x) = E_x\left[\int_0^{\tau_\infty} e^{-\int_0^t \gamma(Y(s))\,ds} C'(Y(t))\,dt\right] \quad \text{for all } x, \tag{4.10}$$

where τ_∞ *is the explosion time of the process* $\{Y(t)) : t \ge 0\}$ *as in Proposition* 3.1, *and* $\gamma(y) = \alpha - \mu'(y)$ *for all* y.

Proof. If $W_n'(z) = 0$ for some z in (α_n, β_n), then

$$\frac{\sigma^2(z)}{2} W_n''(z) = (\alpha - \mu'(z))\left(W_n(z) - \frac{C'(z)}{\alpha - \mu'(z)}\right).$$

Hence, by (4.2), if $W_n(z) > 1$, then z is necessarily a local minimum and if $W_n(z) < -1$, then z is necessarily a local maximum. But $W_n(\alpha_n) = -1$ and $W_n(\beta_n) = 1$. Therefore, it follows that $|W_n(x)| \le 1$ on (α_n, β_n). Next we apply Itô's lemma to $W_n(Y(T \wedge \tau_n))e^{-\int_0^{T\wedge\tau_n} \gamma(Y(s))\,ds}$, where τ_n's are defined in (3.4) and obtain

$$\begin{aligned} &E_x\left[W_n(Y(T\wedge\tau_n))e^{-\int_0^{T\wedge\tau_n} \gamma(Y(s))\,ds}\right] \\ &\quad = W_n(x) - E_x\int_0^{T\wedge\tau_n} e^{-\int_0^t \gamma(Y(s))\,ds} C'(Y(t))\,dt. \end{aligned} \tag{4.11}$$

Using (4.2), we have

$$E_x\left[\int_0^{\tau_\infty} e^{-\int_0^t \gamma(Y(s))\,ds} |C'(Y(s))|\,ds\right] \le E_x\left[\int_0^{\tau_\infty} e^{-\int_0^t \gamma(Y(s))\,ds} \gamma(Y(t))\,dt\right] \le 1 \tag{4.12}$$

and $|W_n(x)| \le 1$ on $[\alpha_n, \beta_n]$. Thus by letting T tend to infinity in (4.11) we obtain

$$\left|W_n(x) - E_x\int_0^{\tau_n} e^{-\int_0^t \gamma(Y(s))\,ds} C'(Y(t))\,dt\right| \le E_x\left[e^{-\int_0^{\tau_n} \gamma(Y(s))\,ds}\right]. \tag{4.13}$$

By (4.12) we also have

$$\lim_{n\to\infty} E_x\int_0^{\tau_n} e^{-\int_0^t \gamma(Y(s))\,ds} C'(Y(t))\,dt = E_x\int_0^{\tau_\infty} e^{-\int_0^t \gamma(Y(s))\,ds} C'(Y(t))\,dt. \tag{4.14}$$

By letting n tend to infinity, the right-hand side of (4.13) becomes zero by Proposition 3.1. Hence by (4.13) and (4.14) we conclude that $W_\infty(x) \equiv \lim_{n\to\infty} W_n(x)$ exists, $W_\infty(x)$ has the representation (4.10) and $|W_\infty(x)| \le 1$ for all x by (4.12). It remains to verify that W_∞ also satisfies (4.6).

We fix a large interval $[-M, M]$ and consider $n > n_0$, where $[-M, M] \subseteq [\alpha_{n_0}, \beta_{n_0}]$. By integrating (4.8) twice, we obtain

$$\begin{aligned} W_n(x) = W_n(0) &- 2\int_0^x \frac{C(r) + \mu(r)W_n(r)}{\sigma^2(r)}\,dr + \sigma^2(0)W_n'(0)\int_0^x \frac{1}{\sigma^2(r)}\,dr \\ &+ 2\alpha\int_0^x \frac{1}{\sigma^2(y)}\int_0^y W_n(u)\,du\,dy \quad \text{for any } x \text{ in } [-M, M]. \end{aligned}$$

Since $|W_n(x)| \le 1, \lim_{n\to\infty} W_n(x) = W_\infty(x)$ and $|W_\infty(x)| \le 1$ for all x, it follows from the above equation that $\lim_{n\to\infty} W_n'(0) = \lambda_0$ exists and is finite. Also W_∞ satisfies

$$W_\infty(x) = W_\infty(0) - 2\int_0^x \frac{C(r)+\mu(r)W_\infty(r)}{\sigma^2(r)}\,dr + \lambda_0\sigma^2(0)\int_0^x \frac{1}{\sigma^2(r)}\,dr + 2\alpha\int_0^x \frac{1}{\sigma^2(y)}\int_0^y W_\infty(u)\,du\,dy \quad \text{for any } x \text{ in } [-M, M].$$

By differentiating this equation twice, we see that W_∞ satisfies (4.6) as desired and $W_\infty'(0) = \lambda_0$. This completes the lemma. □

Next we construct a function $F(x)$ so that $F'(x) \equiv W_\infty(x)$, $\alpha F(0) = \frac{\sigma^2(0)}{2} W_\infty'(0)$ and F will satisfy the HJB equation (1.9). Let

$$F(x) = \frac{\sigma^2(0)}{2\alpha} W_\infty'(0) + \int_0^x W_\infty(r)\,dr \quad \text{for all } x \text{ in } \mathbb{R}. \tag{4.15}$$

We claim that F satisfies

$$\frac{\sigma^2(x)}{2} F''(x) + \mu(x)F'(x) - \alpha F(x) + C(x) \equiv 0 \quad \text{for all } x \text{ in } \mathbb{R}. \tag{4.16}$$

Since $F'(x) \equiv W_\infty(x)$, clearly (4.16) holds at $x = 0$. Also W_∞ satisfies (4.6), thus the derivative of the left-hand side of (4.16) is equal to zero. Therefore, (4.16) holds for all x. Next we prove the main theorem in this section.

THEOREM 4.3. *Assume* (1.4), (1.5), (1.6), *and* (4.2). *Let F be defined by* (4.15). *Then $F(x) = V(x)$ for all x, where V is the value function given in* (1.8). *Moreover, the process $\{Z_x(t)\}$ defined by* (4.1) *is an optimal process for each x.*

Proof. By (4.16) and Lemma 4.2, F is a C^2 function which satisfies the HJB equation (1.9) and by the verification results in section 2, it follows that $F(x) \le V(x)$ for all x. But $\{Z_x(t) : t \ge 0\}$ in (4.1) is an admissible process as described in the Proposition 4.1. Applying Itô's lemma to $F(Z_x(T\wedge\tau_n))e^{-\alpha(T\wedge\tau_n)}$, where (τ_n) is given in (4.3), and using the Proposition 4.1, we obtain $F(x) = E_x\int_0^\infty e^{-\alpha t}C(Z_x(t))\,dt$. Thus $F(x) \ge V(x)$ and consequently, $F(x) \equiv V(x)$ for all x. Hence, the process $\{Z_x(t) : t \ge 0\}$ is optimal. □

5. A bounded optimal process.

5.1. Reflecting diffusion processes. In addition to (1.4), (1.5), and (1.6) we assume the following conditions in this section.

(5.1) (i) There exist two points $\theta_0 < \beta_0$ such that $|C'(x)| < (\alpha - \mu'(x))$ for all x in (θ_0, β_0) and $|C'(x)| > (\alpha - \mu'(x))$ outside the interval $[\theta_0, \beta_0]$.

(5.2) (ii) There is a $\varepsilon_0 > 0$ and a large $M > 0$ so that $|C'(x)| > (1+\varepsilon_0)(\alpha - \mu'(x))$ when $|x| > M$.

Remarks.

1. By (1.6), since $C'(0) = 0$, it follows that $\theta_0 < 0 < \beta_0$, $C'(x) + (\alpha - \mu'(x)) < 0$ for $x < \theta_0$ and $C'(x) - (\alpha - \mu'(x)) > 0$ for $x > \beta_0$.
2. Clearly $\lim_{|x|\to\infty} C(x) = +\infty$.

Under these assumptions, our candidate for an optimal process comes from a class of diffusion processes with reflection barriers at the points a and b, where $a < 0 < b$. Therefore, for each $a < 0 < b$, we consider a weak solution of

$$X_x(t) = x + \int_0^t \mu(X_x(s))\,ds + \int_0^t \sigma(X_x(s))\,dW(s) + K(t), \tag{5.3}$$

where $\{W(t) : t \geq 0\}$ is a Brownian motion and the bounded variation process $K(t)$ is given by

$$dK(t) = dL_a(t) - dL_b(t) \quad \text{for } t > 0 \text{ and} \tag{5.4}$$
$$d|K|(t) = dL_a(t) + dL_b(t) \quad \text{for } t > 0.$$

Here L_a and L_b are the local time processes of $\{X_x(t) : t \geq 0\}$ at the points a and b, respectively. If the initial point x is outside $[a, b]$, then there will be an initial jump from x to the nearest point of the set $\{a, b\}$. Hence, in this case we let $X_x(0-) = x$ and $|K|(0)$ is equal to the distance from x to $\{a, b\}$. Since $X_x(\cdot)$ satisfies assumption (1.2), it is an admissible process. The cost functional related to $X_x(\cdot)$ is given by

$$V_{ab}(x) = E_x \int_0^\infty e^{-\alpha t}(C(X_x(t))\, dt + d|K|(t)). \tag{5.5}$$

Using Itô's lemma, it is easy to verify that V_{ab} satisfies the differential equation

$$\frac{\sigma^2(x)}{2} V''_{ab}(x) + \mu(x)V'_{ab}(x) - \alpha V_{ab}(x) + C(x) = 0 \quad \text{for } a < x < b, \tag{5.6}$$

$$V'_{ab}(x) = -1 \text{ for } x \leq a \quad \text{and} \quad V'_{ab}(x) = 1 \quad \text{for } x \geq b. \tag{5.7}$$

Our aim here is to find a pair of points $a^* < b^*$ such that $V_{a^*b^*}$ is twice continuously differentiable and satisfies (5.6), (5.7), and, in addition to that, $V_{a^*b^*}$ satisfies $|V'_{a^*b^*}(x)| \leq 1$ for all x. Thus if we let $W(x) = V'_{a^*b^*}(x)$, it should satisfy

$$\frac{\sigma^2(x)}{2} W''(x) + (\sigma(x)\sigma'(x) + \mu(x))W'(x) - (\alpha - \mu'(x))W(x) + C'(x) = 0 \tag{5.8}$$

for $a^* < x < b^*$

and

$$W(a^*) = -1, \quad |W(x)| < 1 \text{ on } (a^*, b^*), \quad \text{and} \quad W(b^*) = 1. \tag{5.9}$$

For $V_{a^*b^*}$ to be twice continuously differentiable, W has to satisfy an additional requirement

$$W'(a^*) = W'(b^*) = 0. \tag{5.10}$$

Once we have the existence of a^* and b^*, it follows that $a^* < 0 < b^*$ by (5.8)–(5.10). Our approach here is first to derive such a function W together with an interval $[a^*, b^*]$ and then to construct $V_{a^*b^*}$ and to show that it is a C^2 solution to the HJB equation (1.9). As a first step, we need to obtain a C^1 solution to (5.8), (5.9), and (5.10). For this, we consider a class of optimal stopping problems.

5.2. A class of optimal stopping problems. Let $\{Y(t) : t \geq 0\}$ be a weak solution to (3.1) with $Y(0) = x$ as described in section 3, and let τ_∞ be the explosion time for $\{Y(t) : t \geq 0\}$. We introduce the function $\psi(x)$ by

$$\psi(x) = C'(x) - (\alpha - \mu'(x)) \quad \text{for all } x. \tag{5.11}$$

By assumption (5.1) (see also the remark after (5.1)), there is a point $\beta_0 > 0$ so that $\psi(\beta_0) = 0$ and

$$\psi(x) > 0 \quad \text{for all } x > \beta_0. \tag{5.12}$$

For each $p < \beta_0$ and $x \geq p$, introduce the stopping problem

$$R_p(x) = \inf_{0 \leq \tau \leq \tau_\infty} E_x \left[\int_0^{\tau \wedge \tau_p} e^{-\int_0^t \gamma(Y(s))\, ds} \psi(Y(t))\, dt \right], \tag{5.13}$$

where

$$\gamma(x) = \alpha - \mu'(x) \tag{5.14}$$

and

$$\begin{aligned} \tau_p &= \inf\{t \geq 0 : Y(t) \leq p\} \\ &= +\infty \text{ if the above set is empty.} \end{aligned} \tag{5.15}$$

For each $p < q$, introduce

$$R_{pq}(x) = E_x \int_0^{\tau_{pq}} e^{-\int_0^t \gamma(Y(s))\, ds} \psi(Y(t))\, dt \tag{5.16}$$

for each x in $[p, q]$, where $\tau_{pq} = \text{Min}\{\tau_p, \tau_q\}$. Using Itô's lemma, one can verify that R_{pq} satisfies

$$\begin{aligned} &\frac{1}{2}\sigma^2(x) R''_{pq}(x) + (\sigma(x)\sigma'(x) + \mu(x)) R'_{pq}(x) - (\alpha - \mu'(x)) R_{pq}(x) + \psi(x) = 0 \\ &\quad \text{for all } x \text{ in } (p, q) \end{aligned} \tag{5.17}$$

and

$$R_{pq}(p) = R_{pq}(q) = 0. \tag{5.18}$$

We extend R_{pq} to $\mathbb{R}$ so that it is a C^2 function which satisfies (5.17) everywhere. Using (5.12) and (5.17) we observe the following fact which will be used in the next few lemmas:

$$\text{for any } p < q, R_{pq} \text{ cannot have negative local minima on } (\beta_0, +\infty). \tag{5.19}$$

The next result contains the technical work necessary for finding a solution of (5.8)–(5.10).

LEMMA 5.1. *Assume* (5.1) *and* (5.2). *Then*

(i) *for each* $p < \beta_0$, *there exists a unique point* $\eta_p > \beta_0$ *such that* $R_{p\eta_p}$, *the solution of* (5.17) *and* (5.18) *with* $q = \eta_p$, *also satisfies* $R_{p\eta_p}(x) < 0$ *for all* x *in* (p, η_p), $R'_{p\eta_p}(\eta_p) = 0$, *and* $R''_{p\eta_p}(\eta_p) < 0$;

(ii) $R_{p\eta_p}$ *is increasing on* (β_0, η_p) *and decreasing on* (η_p, ∞), *and* $R_{p\eta_p}(x) < 0$ *on the set* $(p, \infty) \backslash \{\eta_p\}$;

(iii) *if* $p_1 < p_2 < \beta_0$, *then* $\beta_0 < \eta_{p_2} < \eta_{p_1}$ *and* $R_{p_1\eta_{p_1}}(x) < R_{p_2\eta_{p_2}}(x)$ *in* $[p_2, \eta_{p_2}]$;

(iv) *as a function of* p, η_p *is a continuous strictly decreasing function on the interval* $(-\infty, \beta_0)$;

(v) *if* $a < \beta_0$, *then* $\lim_{p \to a} R_{p\eta_p}(x) = R_{a\eta_a}(x)$ *for all* x *in* (a, η_a).

Proof. Let $p < \beta_0$ and $q = \beta_0$ in (5.17) and (5.18). Since $\psi < 0$ on (p, β_0), by Theorems 3 and 4 and the corollary in the pp. 6–7 of [28], we conclude

$$R_{p\beta_0}(x) < 0 \text{ for all } x \text{ in } (p, \beta_0), \quad R'_{p\beta_0}(p) < 0, \quad \text{and} \quad R'_{p\beta_0}(\beta_0) > 0. \tag{5.20}$$

Next, for each $p < \beta_0$, we pick a point $q_p > \beta_0$ so that $\int_p^{q_p} \psi(x)\,dx = 0$. We claim that for each $q > q_p$,

$$\sup_{[p,q]} R_{pq}(x) > 0. \tag{5.21}$$

Suppose (5.21) is false. Then there is a $q > q_p$ so that $\sup_{[p,q]} R_{pq} \le 0$. Hence $R'_{pq}(p) \le 0, R'_{pq}(q) \ge 0$ and by integrating (5.17), we have

$$\frac{\sigma^2(q)}{2} R'_{pq}(q) - \frac{\sigma^2(p)}{2} R'_{pq}(p) + \int_p^q \psi(x)\,dx = \alpha \int_p^q R_{pq}(x)\,dx. \tag{5.22}$$

Next, $\int_p^q \psi(x)\,dx > 0$ since $q > q_p > \beta_0$. Thus the left-hand side of (5.22) is strictly positive. But the right-hand side of (5.22) is negative, since $R_{pq}(x) \le 0$ on $[p, q]$. This is a contradiction and it proves (5.21).

For each $p < \beta_0$, we consider the set G defined by $G = \{q : q > p$ and $R_{pq}(x) < 0$ in $(p, q)\}$. By (5.20), β_0 is in G and thus G is nonempty. By (5.21), q_p is an upper bound for G. Thus $\sup G$ exists and is finite. We let $\eta_p = \sup G$. We intend to show that η_p is in G and $R'_{p\eta_p}(\eta_p) = 0$, similar to Lemma 4.3 in [27]. Clearly, $R_{p\eta_p}(x) \le 0$ for all x in (p, η_p). Suppose that $R_{p\eta_p}(x_0) = 0$ for some x_0 in (p, η_p). Then $R_{p\eta_p}(x_0)$ is a local maximum and by (5.17) we have $\psi(x_0) \ge 0$. Therefore, $x_0 \ge \beta_0$ and $R_{p\eta_p}$ will necessarily have a local minimum on (x_0, η_p). This contradicts (5.19). Hence $R_{p\eta_p}(x) < 0$ for all x in (p, η_p) and this implies that η_p is in G and $R'_{p\eta_p}(\eta_p) \ge 0$. Now suppose $R'_{p\eta_p}(\eta_p) > 0$. Then $R_{p\eta_p}$ is strictly increasing on an interval $[\eta_p - \epsilon, \eta_p + \epsilon]$. Let $y_0 = R_{p\eta_p}(\eta_p + \epsilon) > 0$ and $D(x)$ be the solution to the homogeneous equation $\frac{\sigma^2(x)}{2} D''(x) + (\sigma(x)\sigma'(x) + \mu(x))D'(x) - (\alpha - \mu'(x))D(x) = 0$ for all x in $(p, \eta_p + \epsilon)$ with the boundary conditions $D(p) = 0$ and $D(\eta_p + \epsilon) = y_0 > 0$. Using the corollary to Theorem 4 in page 7 of [28], we conclude that $D(x) > 0$ for all $x > p$. Now the uniqueness theorem for solutions to (5.17) (Theorem 7, page 13 of [28]) implies that $R_{p\eta_p+\epsilon}(x) = R_{p\eta_p}(x) - D(x)$, $R_{p\eta_p+\epsilon}(x) < 0$ for all x in $(p, \eta_p + \epsilon)$ and hence $\eta_p + \epsilon$ is in G. This is a contradiction and thus $R'_{p\eta_p}(\eta_p) = 0$. Using this together with $\psi(\eta_p) > 0$ yields $R''_{p\eta_p}(\eta_p) < 0$. Therefore, η_p satisfies all the conditions in part (i) of the lemma.

To obtain the uniqueness of η_p, suppose $\tilde{\eta}_p$ is another such point. Then $\tilde{\eta}_p$ is also in G and hence $\tilde{\eta}_p < \eta_p$. Consider the solution $R_{p\tilde{\eta}_p}$ of (5.17). Since $\tilde{\eta}_p$ is in G, we have $R''_{p\tilde{\eta}_p}(\tilde{\eta}_p) < 0$ and hence $\psi(\tilde{\eta}_p) \ge 0$. Consequently, $\tilde{\eta}_p \ge \beta_0$, but $\tilde{\eta}_p \ne \beta_0$ by (5.20). Hence $\tilde{\eta}_p > \beta_0$, $R_{p\tilde{\eta}_p}$ has a local maximum at $x = \tilde{\eta}_p$ and by (5.19), $R_{p\tilde{\eta}_p}$ is decreasing on $(\tilde{\eta}_p, \infty)$. Therefore, $R_{p\eta_p}$ and $R_{p\tilde{\eta}_p}$ meet at a point z in $(\tilde{\eta}_p, \eta_p)$. Now, by the uniqueness theorem for solutions to (5.17) on $[p, z]$, it follows that $R_{p\eta_p}(x) = R_{p\tilde{\eta}_p}(x)$ for all x in $[p, z]$. Hence $R_{p\eta_p}(\tilde{\eta}_p) = 0$ and this is a contradiction, since η_p is in G. Consequently, $\eta_p = \tilde{\eta}_p$ and part (i) follows.

Since $R_{p\eta_p}(\eta_p) = R'_{p\eta_p}(\eta_p) = 0$, $R_{p\eta_p}$ has a strict local maximum at $x = \eta_p$ by (5.17) and by applying (5.19), part (ii) follows.

To prove part (iii), let $p_1 < p_2 < \beta_0$ and suppose that $\eta_{p_1} \le \eta_{p_2}$. If $\eta_{p_1} = \eta_{p_2}$, since $R_{p_i\eta_{p_i}}(\eta_{p_i}) = R'_{p_i\eta_{p_i}}(\eta_{p_i}) = 0$ for $i = 1, 2$, by the uniqueness of solutions to (5.17) it follows that $p_1 = p_2$. Hence $\eta_{p_1} \ne \eta_{p_2}$ and we have $p_1 < p_2 < \beta_0 < \eta_{p_1} < \eta_{p_2}$. Since $R_{p_1\eta_{p_1}}(p_2) < 0$ and $R_{p_2\eta_{p_2}}(\eta_{p_1}) < 0$, there is a point c_1 such that $p_2 < c_1 < \eta_{p_1}$ and $R_{p_1\eta_{p_1}}(c_1) = R_{p_2\eta_{p_2}}(c_1)$. By part (ii), we can conclude $R_{p_1\eta_{p_1}}(\eta_{p_2}) < 0$ and $R_{p_2\eta_{p_2}}(\eta_{p_1}) < 0$ and this implies the existence of a point c_2 so that $\eta_{p_1} < c_2 < \eta_{p_2}$ and $R_{p_1\eta_{p_1}}(c_2) = R_{p_2\eta_{p_2}}(c_2)$. Hence, $R_{p_1\eta_{p_1}}$ and $R_{p_2\eta_{p_2}}$ are identical by the uniqueness of solutions to (5.17) (see Theorem 7, page 13 of [28]) and thus $p_1 = p_2$. This is

a contradiction. Hence $\eta_{p_2} < \eta_{p_1}$, thus by part (i) and again by the uniqueness of solutions to (5.17), we conclude $R_{p_1\eta_{p_1}}(x) < R_{p_2\eta_{p_2}}(x)$ for all x in $[p_2, \eta_{p_2}]$. This proves part (iii).

To prove part (iv), it remains to show η_p is continuous as a function of p for $p < \beta_0$. Let a be a point so that $a < \beta_0$, and (p_n) be any increasing sequence so that $\lim_n p_n = a$. Thus $p_n < a < \beta_0$. By part (iii), the sequence (η_{p_n}) is decreasing and $\eta_{p_n} > \eta_a$ for each n. Thus $\lim_n \eta_{p_n} \geq \eta_a$. Now suppose that $\lim_n \eta_{p_n} > \eta_a$. Then we can pick a point q so that $\lim_n \eta_{p_n} > q > \eta_a$ and consider a solution $R(x)$ to (5.17) with the initial condition $R(q) = R'(q) = 0$. Since $\psi(q) > 0$, by (5.17) we have $R''(q) < 0$, and R has a strict local maximum at $x = q$. Since R satisfies (5.17), we can also conclude that R has no local minima in (β_0, ∞) and it is increasing on $[\beta_0, q]$ and decreasing on $[q, +\infty)$. For each n, $R_{p_n\eta_{p_n}}(q) < 0$ and thus R meets $R_{p_n\eta_{p_n}}$ at some point in (q, η_{p_n}). But R cannot be identically equal to $R_{p_n\eta_{p_n}}$ and hence by applying the uniqueness theorem (Theorem 7, page 13 of [28]) we can conclude that $R(x) > R_{p_n\eta_{p_n}}(x)$ for each x in $[p_n, q]$ and thus $R(p_n) > 0$. Consequently, $R(a) \geq 0$. With a similar argument, R and $R_{a\eta_a}$ meet at a point in (η_a, q) and $R(\eta_a) < 0$. Consequently, $R(x) < R_{a\eta_a}(x)$ for all x in $[a, \eta_a]$. This yields $R(a) < 0$, which is a contradiction. Therefore, $\lim_n \eta_{p_n} = \eta_a$. A very similar proof can be given to show that if (p_n) is a decreasing sequence satisfying $p_n < \beta_0$ for all n and $\lim_n p_n = a$, then $\lim_n \eta_{p_n} = \eta_a$. Hence, part (iv) follows.

To prove part (v), we will show the following: if (p_n) is a monotone sequence with $\lim_{n\to\infty} p_n = a$, then $\lim_n R_{p_n\eta_{p_n}}(x) = R_{a\eta_a}(x)$ for each x in $[a, \eta_a]$. First, consider an increasing sequence (p_n) so that $\lim_{n\to\infty} p_n = a$. For each x in $[a, \eta_a]$, $R_{p_n\eta_{p_n}}(x)$ has the stochastic representation (5.16), since $[a, \eta_a] \subseteq [p_n, \eta_{p_n}]$. In (5.16), we relabel the stopping time $\tau_{p_n\eta_{p_n}}$ by τ_n for simplicity. Clearly, (τ_n) is decreasing and $\tau_n > \tau_{a\eta_a}$ for all n. $E_x[\tau_n]$ is given by formula (5.55) in page 343 of [17] with $a = p_n$ and $b = \eta_{p_n}$ (see also (5.59) in page 344 of [17]). By letting n tend to infinity there, we obtain $\lim_{n\to\infty} E_x[\tau_n] = E_x[\tau_{a\eta_a}]$. Thus $\lim_{n\to\infty} \tau_n = \tau_{a,\eta_a}$ a.s. Now again using (5.16) and the dominated convergence theorem, we obtain $\lim_{n\to\infty} R_{p_n\eta_{p_n}}(x) = R_{a\eta_a}(x)$ for each x in (a, η_a). Next, if (p_n) is a decreasing sequence so that $\lim_{n\to\infty} p_n = a$ and $p_n < \beta_0$ for all n, consider (5.16) to represent $R_{p_n\eta_{p_n}}(x)$ and $R_{a\eta_a}(x)$. Notice that $\tau_{p_n\eta_{p_n}}$ is increasing to $\tau_{a\eta_a}$ as n tends to infinity. Hence we apply the dominated convergence theorem to (5.16) and conclude that $\lim_{n\to\infty} R_{p_n\eta_{p_n}}(x) = R_{a\eta_a}(x)$ for all x in (a, η_a). This completes the proof. □

The next lemma derives an optimal stopping policy for the optimal stopping problem (5.13).

LEMMA 5.2. *Fix $p < \beta_0$. Consider $R_p(x)$ defined in* (5.13) *for each $x \geq p$. Let the function $R_{p\eta_p}$ and the point η_p be as in Lemma* 5.1. *Then*

(i) $R_p(x) = \begin{cases} R_{p\eta_p}(x) & \text{for } p \leq x \leq \eta_p, \\ 0 & \text{for } x > \eta_p. \end{cases}$

(ii) *The stopping rule τ^* given by* $\tau^* = \begin{cases} \min\{\tau_p, \tau_{\eta_p}\} & \text{when } p \leq x \leq \eta_p, \\ 0 & \text{when } x > \eta_p \end{cases}$

is optimal for the stopping problem (5.13).

Proof. Let

$$R(x) = \begin{cases} R_{p\eta_p}(x) & \text{for } x \leq \eta_p, \\ 0 & \text{for } x > \eta_p. \end{cases}$$

We observe that $R(x)$ is a C^1 function on $(p,+\infty)$, which is C^2 everywhere except at $x=\eta_p$. By Lemma 5.1, $R''(\eta_p^-)<0$. Clearly, $R''(\eta_p^+)=0$. Let $Y(0)=x>p$ and apply Itô's lemma (see [17, p. 219]) to $R(Y(t))e^{-\int_0^t \gamma(Y(s))\,ds}$ to obtain

$$E_x\left[R(Y(T\wedge\tau\wedge\tau_{pn}))e^{-\int_0^{T\wedge\tau\wedge\tau_{pn}}\gamma(Y(s))\,ds}\right]=R(x)$$

$$-E_x\left[\int_0^{T\wedge\tau\wedge\tau_{pn}} e^{-\int_0^t\gamma(Y(s))\,ds}\psi(Y(t))\,dt\right],$$

where $\tau_{pn}=\tau_p\wedge\tau_n$, $n>\eta_p$ is a large integer, and τ is any stopping time such that $\tau\le\tau_\infty$ a.s. Since $R(\cdot)$ is nonpositive and bounded below on $[p,+\infty)$, by letting T and n tend to infinity, we obtain $E_x[\int_0^{\tau\wedge\tau_p} e^{-\int_0^t\gamma(Y(s))\,ds}\psi(Y(t))\,dt]\ge R(x)$. Hence by (5.13), $R_p(x)\ge R(x)$ for all $x\ge p$. Let us define the stopping time τ^* as in the statement of Lemma 5.2(ii). Then, following the above calculations, we obtain $R(x)=E_x[\int_0^{\tau^*\wedge\tau_p} e^{-\int_0^t\gamma(Y(s))\,ds}\psi(Y(t))\,dt]$ for $x\ge p$. Consequently, $R_p(x)\equiv R(x)$ for all $x\ge p$. This completes the proof. □

LEMMA 5.3. *Consider the function $H(\cdot)$ defined by $H(p)=\min_{x\ge p}R_p(x)$ for each $p<\beta_0$. Then*

(i) *$H(\cdot)$ is continuous and increasing on $(-\infty,\beta_0)$, and*

(ii) $$\lim_{p\to\beta_0}H(p)=0 \quad \textit{and} \quad \lim_{p\to-\infty}H(p)<-2. \tag{5.23}$$

Proof. By the previous lemma, $H(p)=\min_{[p,\eta_p]}R_p(x)$ and $H(p)<0$ for each $p<\beta_0$. Moreover, by parts (ii) and (iii) of Lemma 5.1, it follows that $H(p)$ is increasing on $(-\infty,\beta_0)$. But $H(p)=\min_{[p,\beta_0]}R_p(x)$. Since $\psi>0$ on $(\beta_0,+\infty)$, $\inf_{[p,\eta_p]}\psi(x)=\inf_{[p,\beta_0]}\psi(x)$. Therefore, by (5.13) and (5.16), it easily follows that $\frac{1}{\alpha}\inf_{[p,\beta_0]}\psi(x)<H(p)<0$. Hence $\lim_{p\to\beta_0}H(p)=0$. Next, we show that $H(p)$ is continuous on $(-\infty,\beta_0)$. Let $a<\beta_0$, and we pick two points b and c so that $b<a<c<\beta_0$. For each p in $[b,c]$, consider the function $R_{p\eta_p}$ of Lemma 5.1 and we introduce the function $Q_p(x)$ defined on $[b,\eta_b]$ by

$$Q_p(x)=\begin{cases}R_{p\eta_p}(x) & \text{for } b\le x\le\eta_p,\\ 0 & \text{for } \eta_p\le x\le\eta_b.\end{cases}$$

Each Q_p is a C^1 function on $[b,\eta_b]$. If $b<p_1<p_2<c$, then $R_{p_1\eta_{p_1}}$ and $R_{p_2\eta_{p_2}}$ meet at some point on (η_{p_2},η_{p_1}) as observed in the proof of part (iii) of Lemma 5.1. Therefore, $R_{p_1\eta_{p_1}}(x)<R_{p_2\eta_{p_2}}(x)$ for all x in $[b,\eta_{p_2}]$. Consequently, we have $H(b)\le Q_p(x)\le\max_{[b,\eta_b]}Q_c(x)$ for all x in $[b,\eta_p]$ and for all p in $[b,c]$. Thus we can obtain a constant $M_1>0$ so that $\sup_{b\le p\le c}\sup_{b\le x\le\eta_b}|Q_p(x)|<M_1$. Next by integrating (5.17), we obtain

$$\frac{\sigma^2(x)}{2}Q_p'(x)=\int_x^{\eta_p}\psi(u)\,du-\mu(x)Q_p(x)-\alpha\int_x^{\eta_p}Q_p(u)\,du \quad \text{for } b\le x\le\eta_p,$$

and $Q_p'(x)=0$ for $x\ge\eta_p$. Thus using the estimate for $|Q_p(x)|$, we can find a constant $M_2>0$ so that $\sup_{b\le p\le c}\sup_{b\le x\le\eta_b}|Q_p'(x)|\le M_2$. Hence for each x,y in $[b,\eta_b]$, we have $|Q_p(x)-Q_p(y)|\le M_2|x-y|$ and in particular $|Q_p(x)|\le M_2|x-p|$. This in turn yields that $\lim_{p\to a}Q_p(a)=0$. Now let (p_n) be a sequence in (b,c)

so that $\lim_n p_n = a$. Then $H(p_n) = Q_{p_n}(x_n)$ for some x_n in $[p_n, \beta_0]$ by Lemma 5.1(ii). Thus $b \le p_n \le x_n \le \beta_0$. Let y be a limit point of (x_n). Then $a \le y \le \beta_0$ and $|Q_{p_n}(x_n) - Q_a(y)| \le |Q_{p_n}(x_n) - Q_{p_n}(y)| + |Q_{p_n}(y) - Q_a(y)|$. But $|Q_{p_n}(x_n) - Q_{p_n}(y)| \le M_2|x_n - y|$ and thus $\lim_{n\to\infty} |Q_{p_n}(x_n) - Q_{p_n}(y)| = 0$.

By part (v) of Lemma 5.1, and since $\lim_{p\to a} Q_p(a) = 0$ we have $\lim_{n\to\infty} |Q_{p_n}(y) - Q_a(y)| = 0$. Therefore, $\lim_{n\to\infty} Q_{p_n}(x_n) = Q_a(y)$ and, consequently, $\lim_{n\to\infty} H(p_n) = Q_a(y) \ge H(a)$. On the other hand, $H(a) = Q_a(x_0)$ for some x_0 in $[a, \beta_0]$ and thus $H(a) = \lim_{n\to\infty} Q_{p_n}(x_0) \ge \lim_{n\to\infty} H(p_n)$. Hence $H(\cdot)$ is continuous at $p = a$ for each $a < \beta_0$.

It remains to verify that $\lim_{p\to-\infty} H(p) < -2$. We pick $r_0 < -M$, where M is in (5.2). Then $\psi(x) < -(2+\varepsilon_0)\gamma(x)$ for all $x < r_0$. Let $p < r_0$ and $R_p(x)$ be given by (5.13). For any $p < r_0$, we obtain

$$R_p(x) \le E_x \int_0^{\tau_p \wedge \tau_{r_0}} e^{-\int_0^t \gamma(Y(s))\,ds} \psi(Y(t))\,dt \quad \text{for all } x \text{ in } (p, r_0).$$

Hence, we derive

$$R_p(x) < -(2+\varepsilon_0) + (2+\varepsilon_0) E_x\Big[e^{-\int_0^{\tau_p\wedge\tau_{r_0}} \gamma(Y(s))\,ds}\Big] \quad \text{for } p < x < r_0.$$

Since $H(p) \le R_p(x)$ and H is increasing on $(-\infty, \beta_0)$, we obtain

$$\lim_{p\to-\infty} H(p) \le -(2+\varepsilon_0) + (2+\varepsilon_0) \lim_{p\to-\infty} E_x\Big[e^{-\int_0^{\tau_p\wedge\tau_{r_0}} \gamma(Y(s))\,ds}\Big] \tag{5.24}$$

for any $x < r_0$, provided that the limit on right-hand side exists. Let τ_∞ be the explosion time for $\{Y(t) : t \ge 0\}$ as in Proposition 3.1, then it follows that

$$\begin{aligned} \lim_{p\to-\infty} E_x\Big[e^{-\int_0^{\tau_p\wedge\tau_{r_0}} \gamma(Y(s))\,ds}\Big] &= E_x\Big[e^{-\int_0^{\tau_\infty\wedge\tau_{r_0}} \gamma(Y(s))\,ds}\Big] \\ &= E_x\Big[e^{-\int_0^{\tau_{r_0}} \gamma(Y(s))\,ds} I_{[\tau_{r_0}<\tau_\infty]}\Big]. \end{aligned} \tag{5.25}$$

In the last equality we have used Proposition 3.1.

We let $P(x) = E_x[e^{-\int_0^{\tau_{r_0}} \gamma(Y(s))\,ds} I_{[\tau_{r_0}<\tau_\infty]}]$. We claim that $\lim_{x\to-\infty} P(x) = 0$. For each $N > |x|$, we define $P_N(x) = E_x[e^{-\int_0^{\tau_{r_0}} \gamma(Y(s))\,ds} I_{[\tau_{r_0}<\tau_{-N}]}]$, where τ_{-N} is defined by (5.15). By Itô's lemma, one can verify that

$$\begin{aligned} &\frac{\sigma^2(x)}{2} P_N''(x) + (\sigma(x)\sigma'(x) + \mu(x)) P_N'(x) - (\alpha - \mu'(x)) P_N(x) = 0 \\ &\text{on } (-N, r_0) \ \text{ and } \ P_N(-N) = 0,\ P_N(r_0) = 1. \end{aligned} \tag{5.26}$$

Observe that, $P_N(x) > 0$ on $(-N, r_0)$ and by (5.26), it cannot have positive local maxima. Hence P_N is increasing on $(-N, r_0)$. Since the solutions to (5.26) cannot intersect twice, it follows that $P_N(y) \ne P_{N'}(y)$ when $N \ne N'$ and $y < r_0$. Therefore, for a fixed $x < r_0$, as N tends to infinity, $\{P_N(x)\}$ is increasing and bounded above by 1. Let $P_\infty(x) = \lim_{N\to\infty} P_N(x)$. Then P_∞ also satisfies the same differential equation on $(-\infty, r_0)$ and $P_\infty(r_0) = 1$. It is clear that $P_\infty(x) \equiv P(x)$. Hence $P(x)$ satisfies (5.26) on $(-\infty, r_0)$ and we obtain

$$\frac{\sigma^2(r_0)}{2} P'(r_0) + \mu(r_0) = \frac{\sigma^2(x)}{2} P'(x) + \mu(x) P(x) + \alpha \int_x^{r_0} P(u)\,du. \tag{5.27}$$

Since P is increasing on $(-\infty, r_0)$, we let $\lim_{x\to-\infty} P(x) = \delta \geq 0$. If $\delta > 0$, then the right-hand side of (5.27) tends to infinity as x tend to $-\infty$. This leads to a contradiction.

Hence $\lim_{x\to-\infty} P(x) = 0$. Using this in (5.24), we obtain $\lim_{p\to-\infty} H(p) \leq -(2+\varepsilon_0)$. This completes the proof of Lemma 5.3. □

Our next proposition finds the two points a^*, b^* and a function W which satisfies (5.8)–(5.10).

PROPOSITION 5.4. *There exists two points a^*, b^* and a function W defined on $[a^*, b^*]$ satisfying* (5.8), (5.9), *and* (5.10). *Furthermore, $[\theta_0, \beta_0] \subseteq [a^*, b^*]$ and thus $[a^*, b^*]$ contains the origin. The function W can be extended to $\mathbb{R}$ so that $W(x) = -1$ for $x \leq a^*$ and $W(x) = 1$ for $x \geq b^*$. Then W is continuously differentiable on $\mathbb{R}$ and it is C^2 everywhere except at the points a^* and b^*.*

Proof. By Lemma 5.3, $H(p) = -2$ for some $p = p^*$ and we consider the corresponding function $R_{p^*}(x)$. Let a^* be a point where R_{p^*} achieves its absolute minimum. Then we have $p^* < a^* < \beta_0$ by Lemma 5.1 and $R_{p^*\eta_{p^*}}(a^*) = -2$. We let $b^* = \eta_{p^*}$. Then $p^* < a^* < \beta_0 < b^*$. Evaluating (5.17) at $x = a^*$ for $R_{p^*\eta_{p^*}}$, we obtain $C'(a^*) + (\alpha - \mu'(a^*)) \leq 0$ and thus $p^* < a^* \leq \theta_0 < \beta_0 < b^*$. Next we claim this absolute minimum point a^* is unique. For this, assume that $a_1 < a_2$ are two points of absolute minimum, and hence $R_{p^*\eta_{p^*}}(a_i) = -2$, and $p^* < a_1 < a_2 \leq \theta_0$. Then there will be a point of local maximum at $x = d$ in (a_1, a_2) and evaluating (5.17) at $x = d$ we obtain $C'(d) > -(\alpha - \mu'(d))$. Consequently, $C'(d) + (\alpha - \mu'(d)) > 0$ and hence $d > \theta_0$. This is a contradiction since $d < a_2 \leq \theta_0$. Therefore, the absolute minimum point $x = a^*$ is unique.

Next, we let $W(x) = R_{p^*\eta_{p^*}}(x) + 1$ on $[a^*, b^*]$. We extend W to $\mathbb{R}$ by $W(x) = -1$ for $x \leq a^*$ and $W(x) = +1$ for $x \geq b^*$. Also $W(a^*) = -1$, $W'(a^*) = 0$, and $W''(a^*+) \geq 0$. Using (5.17), it follows that W satisfies (5.8) and $W(b^*) = 1$. By the uniqueness of the absolute minimum point $x = a^*$ and by Lemma 5.1, it follows that $-1 < W(x) < 1$ on (a^*, b^*), $W(b^*) = 1$, $W'(b^*) = 0$, and $W''(b^*-) \leq 0$. Furthermore, W is continuously differentiable and C^2 everywhere except at the points a^* and b^*. This completes the proof. □

Next, we define the function $V^*(x)$ on $\mathbb{R}$ by

$$V^*(x) = \frac{C(a^*) - \mu(a^*)}{\alpha} + \int_{a^*}^{x} W(r)\, dr. \tag{5.28}$$

In the next theorem, we show that V^* is indeed the value function.

THEOREM 5.5. *Assume* (5.1) *and* (5.2). *Let a^* and b^* be the points described in Proposition* 5.4. *Consider the reflecting diffusion process $X_x^*(\cdot)$ on $[a^*, b^*]$ defined by* (5.3) *and* (5.4). *Then $\{X_x^*(t) : t \geq 0\}$ is an optimal process and the function V^* defined in* (5.28) *is the value function.*

Proof. Let $\{X_x^*(t) : t \geq 0\}$ be the reflecting diffusion on $[a^*, b^*]$ satisfying (5.3) and (5.4). Clearly, it is an admissible process which satisfies (1.2). The function V^* satisfies (5.6) and (5.7) and thus it is the pay-off function for $\{X_x^*(t) : t \geq 0\}$. Hence, we have $V^*(x) \geq V(x)$ for all x, where V is the value function given in (1.8).

To show that $V^*(x) \leq V(x)$ we will use the verification lemma. By Proposition 5.4, $|V^{*'}(x)| < 1$ on (a^*, b^*) and $|V^{*'}(x)| = 1$ outside (a^*, b^*). Also V^* satisfies (5.6) on (a^*, b^*). Let $I(x) = \frac{\sigma^2(x)}{2} V^{*''}(x) + \mu(x) V^{*'}(x) - \alpha V^*(x) + C(x)$ for each x. It remains to verify that $I(x) \geq 0$ outside (a^*, b^*). When $x < a^*$, by (5.28) we have $I(x) = \int_{a^*}^{x} [C'(u) + (\alpha - \mu'(u))]\, du$. But $C'(u) + (\alpha - \mu'(u)) < 0$ on $(-\infty, a^*)$ since $a^* \leq \theta_0$ as in Proposition 5.4. Thus, $I(x) > 0$ for $x < a^*$. Similarly, for $x > b^*$,

$I(x) = \int_{b^*}^{x} [C'(u) - (\alpha - \mu'(u))]\, du > 0$ since $b^* > \beta_0$ as described in the proof of Proposition 5.4. Consequently, V^* satisfies the HJB equation (1.9) and V^* is a C^2 function. Then by the verification lemma, $V^*(x) \leq V(x)$ for all x. Therefore, $V^*(x) = V(x)$ for all x and $\{X_x^*(t) : t \geq 0\}$ is an optimal process. This completes the proof. □

6. Bounded cost functions. The purpose of this section is to identify a new optimal strategy for a class of bounded cost functions and also to show that the value function is a C^1 function but it fails to be a C^2 function regardless of the smoothness of $\mu(\cdot)$, $\sigma(\cdot)$, and $C(\cdot)$.

Consider a bounded cost function $C(\cdot)$ which satisfies the basic assumption (1.6). Let $\|C\|_\infty = \sup_{\mathbb{R}} |C(x)|$ and using $A(t) \equiv 0$ for all t in (1.1) and in (1.3), we obtain

$$0 < V(x) \leq J(x,0) = E \int_0^\infty e^{-\alpha t} C(X_x(t))\, dt \leq \frac{\|C\|_\infty}{\alpha}, \tag{6.1}$$

where $V(\cdot)$ is the value function defined in (1.8). Therefore, if the value function is a C^1 solution of the HJB equation (1.9), then the set $\{x : |V'(x)| = 1\}$ should have finite Lebesgue measure and with the structure of our cost function, we expect the jump set $\{x : |V'(x)| = 1\}$ to be bounded. If the condition $|C'(x)| \leq \alpha - \mu'(x)$ holds for all x, then our results in section 4 remain valid, the set $\{x : |V'(x)| = 1\}$ is empty, and the zero control policy is an optimal strategy. But in the other cases, we cannot apply the results in section 5 since assumptions (5.1) and (5.2) imply that $C(\cdot)$ is unbounded.

In this section, we develop an interesting new optimal strategy when $|C'(x)| - (\alpha - \mu'(x))$ take large positive values on a large compact set. In addition to (1.4)–(1.6), we make the following assumptions.

(6.2) (i) Assume $\mu(\cdot)$ is an odd function and $\sigma(\cdot)$ and $C(\cdot)$ are even functions and $\lim_{x\to+\infty} C(x)$ is finite.

(6.3) (ii) Let $h(x) = \frac{C'(x)}{\alpha - \mu'(x)}$. There exists two points β_0 and δ_0 such that $0 < \beta_0 < \delta_0$, $0 < h(x) < 1$ on $(0, \beta_0) \cup (\delta_0, \infty)$ and $h(x) > 1$ on (β_0, δ_0). Also h is decreasing on the interval (δ_0, ∞).

(iii) There exist two points p_0 and q_0 which satisfy $\beta_0 < p_0 < q_0 < \delta_0$,

$$C(p_0) > \alpha p_0 - \mu(p_0) + \frac{\left(1 + 2\int_0^{\beta_0} \frac{C(r)}{\sigma^2(r)}\, dr\right)}{\int_0^{\beta_0} \frac{2}{\sigma^2(r)}\, dr} \tag{6.4}$$

and

$$\int_{p_0}^{q_0} \frac{2}{\sigma^2(x)} \int_{p_0}^{x} \psi(u)\, du\, dx > 1, \tag{6.5}$$

where $\psi(x) = C'(x) - (\alpha - \mu'(x))$ as in section 5.

With assumption (6.2), the value function will be an even function. By (6.3), we observe that $|C'(x)| > \alpha - \mu'(x)$ on $(-\delta_0, -\beta_0) \cup (\beta_0, \delta_0)$. The technical conditions (6.4) and (6.5) guarantee that the interval (β_0, δ_0) is quite large and also the function $\psi(x)$ takes large positive values on (β_0, δ_0). We intend to prove the existence of a feedback-type optimal strategy related to two points a^* and b^* so that $0 < \beta_0 < a^* < b^*$ as described below.

(a) If the initial point x is in $[-a^*, a^*]$, then our optimal state process is a reflecting diffusion on $[-a^*, a^*]$ with instantaneous reflections at $\pm a^*$ and satisfies (5.3) and (5.4) with $a = -a^*$ and $b = a^*$.

(b) If the initial point x is in $(a^*, b^*]$, our optimal process will be an initial jump to a^* and thereafter follows the reflecting diffusion described in (a). Similarly, if x is in $[-b^*, -a^*)$, then there will be an initial jump to $-a^*$.

(6.6) (c) If the initial position x is in $(b^*, +\infty)$, zero control will be used (i.e., $A(t) \equiv 0$) until the state process reaches b^* and then jumps to a^*. Thereafter, it follows the reflecting diffusion on $[-a^*, a^*]$. Similarly, if x is in $(-\infty, -b^*)$, use zero control until the state process reaches $-b^*$, then jump to $-a^*$ and follow the reflecting diffusion on $[-a^*, a^*]$.

Remarks.

1. If the initial point is in $(-\infty, -b^*) \cup (b^*, +\infty)$, then the state process satisfies (4.1) up to the entrance time to the interval $[-b^*, b^*]$ and has infinite explosion time as noticed in Proposition 4.1.
2. When μ is identically zero and σ is a constant, an example of an optimal control problem with a bounded cost function and an optimal policy similar to that above was given in Example 4.3, Chapter VIII of [11].

LEMMA 6.1. *For each $r > \beta_0$, there is a unique bounded solution $W_r(\cdot)$ to the boundary value problem*

$$\frac{\sigma^2(x)}{2} W_r''(x) + (\sigma(x)\sigma'(x) + \mu(x)) W_r'(x) - (\alpha - \mu'(x)) W_r(x) + C'(x) = 0 \tag{6.7}$$

for all $x \geq r$, and

$$W_r(r) = 1, \qquad \lim_{x \to \infty} W_r(x) = 0. \tag{6.8}$$

Furthermore, $W_r(\cdot)$ satisfies the following conditions.

(i) *$0 < W_r(x) \leq M_r$ for all $x \geq r$, where $M_r = \max\{1, \sup_{[r,\infty)} h(x)\}$ and h is as in* (6.3).

(ii) *There is a point $\eta_r > \delta_0$ such that $W_r(\cdot)$ is decreasing on $[\eta_r, \infty)$.*

(iii) *$W_r(x)$ and its derivative $W_r'(x)$ are jointly continuous with respect to (r, x) on the set $\{(r, x) : \beta_0 < r < x\}$.*

(iv) *Let p_0 and q_0 be as in* (6.5). *Then there exists a unique point b_0 such that $p_0 \leq b_0 < \delta_0$, and the corresponding function W_{b_0} satisfies $W_{b_0}'(b_0) = 0$ in addition to* (6.7) *and* (6.8) *above.*

Proof. We sketch the proof since it mostly depends on elementary calculus. We fix $r > \beta_0$. To obtain a solution W_r satisfying (6.7) and (6.8), we consider a sequence $\{W_N\}$ as follows. For each $N > r$, let W_N be the solution of the differential equation (6.7) on (r, N) with the boundary conditions $W_N(r) = 1$, $W_N(N) = 0$. Let $M_r = \max\{1, \sup_{[r,\infty)} h(x)\}$. Using (6.7) and by elementary calculus, $W_N(x) - M_r$ has no positive local maxima on (r, N). Similarly, W_N has no negative local minima on (r, N). Thus, $0 \leq W_N(x) \leq M_r$ on $[r, N]$. If $r < N_1 < N_2$, it follows that $0 \leq W_{N_1}(x) < W_{N_2}(x) \leq M_r$ for all x in $(r, N_1]$. Hence, for a fixed x, $\{W_N(x)\}$ is an increasing sequence in N and the limit $W_r(x) = \lim_{N \to \infty} W_N(x)$ exists. Thus, $0 < W_r(x) \leq M_r$ for all $x \geq r$, $W_r(r) = 1$. W_r also satisfies (6.7) and this can be verified as in the proof of Lemma 4.2(ii). This yields part (i).

Next we derive part (ii) and use it to obtain $\lim_{x \to \infty} W_r(x) = 0$. First, we show that W_r has no local minima on (δ_0, ∞). Suppose that W_r has a local minimum at z_0, where $z_0 > \delta_0$, then we can find a large enough N so that W_N has a local minimum

at y_1, a local maximum at y_2, $\delta_0 < y_1 < y_2 < N$ and $W_N(y_1) < W_N(y_2)$. Since W_N satisfies (6.7), we obtain that $h(y_1) \le W_N(y_1)$ and $W_N(y_2) \le h(y_2)$. This implies $h(y_1) < h(y_2)$ and it contradicts (6.3). Thus, W_r has no local minima on $(\delta_0, +\infty)$ and we deduce that there is a point $\eta_r \ge \delta_0$ so that W_r is monotone on $[\eta_r, +\infty)$. Hence, the limit $L \equiv \lim_{x\to+\infty} W_r(x)$ exists and $0 \le L \le M_r$. Our next step is to show that $L \le 1$. Suppose that $L > 1$. Then we can find a large N so that W_N has a local maximum at a point $z_1 > \eta_r$ and $W_N(z_1) > 1$. Using (6.7) for W_N at z_1 we obtain $C'(z_1) > (\alpha - \mu'(z_1))$ and this contradicts $z_1 > \eta_r > \delta_0$. Hence, $L \le 1$. Next, we show that W_r is decreasing on $[\eta_r, +\infty)$. We already know that it is monotone on $[\eta_r, +\infty)$. Suppose that W_r is increasing on $[\eta_r, +\infty)$. Since $L \le 1$ and $W_r(r) = 1$, there is a point $\xi > r$ such that $W_r(\xi) = \inf_{[r,+\infty)} W_r(x)$. Clearly $W_r(\xi) < 1$, and we let $r_1 = \inf\{a \ge r : W_r(x) < 1 \text{ on } (a, \xi)\}$. Thus $r_1 \ge r$, $W_{r_1}(x) \equiv W_r(x)$ for $x \ge r_1$ and $W_r'(r_1) \le 0$. Integrating (6.7), we obtain $\mu(\xi)W_r(\xi) + C(\xi) = \frac{\sigma^2(r_1)}{2} W_r'(r_1) + \mu(r_1) + C(r_1) + \alpha \int_{r_1}^{\xi} W_r(u)\,du$. This yields $\int_{r_1}^{\xi} \psi(u)\,du < 0$, where ψ is as in (6.5). Since $\beta_0 < r \le r_1$, this implies that $\xi > \delta_0$. This is a contradiction since W_r cannot have local minima on $(\delta_0, +\infty)$. Thus W_r is decreasing on $[\eta_r, +\infty)$ and part (ii) follows. To show that $\lim_{x\to+\infty} W_r(x) = 0$, we integrate (6.7) and use $W_r'(x) \le 0$ on $[\eta_r, +\infty)$ to obtain $\|C\|_\infty \ge C(x) \ge (\frac{\sigma^2(r)}{2} W_r'(r) + \mu(r) + C(r)) + \alpha \int_r^x W_r(u)\,du$. Thus $\int_r^{+\infty} W_r(u)\,du$ is convergent and $\lim_{x\to+\infty} W_r(x) = 0$. Hence, W_r satisfies (6.7) and (6.8).

To show the uniqueness of the solution to (6.7) and (6.8), let $r > \beta_0$ be fixed. Assume W_1 and W_2 are two solutions of (6.7) and (6.8). Introduce $U(x) = W_1(x) - W_2(x)$. Then $U(r) = 0$, $\lim_{x\to\infty} U(x) = 0$ and U is a bounded solution of the homogeneous, differential equation associated with (6.7). By elementary calculus, U is identically zero and $W_1(x) = W_2(x)$ for all $x \ge r$.

To prove (iii), take (r, x) so that $\beta_0 < r < x$. Pick r_1 and r_2 so that $\beta_0 < r_2 < r_1 < r$ and the solutions $W_{r_1}(x)$ and $W_{r_2}(x)$ are not identical to each other on $[r_1, \infty)$. Let $U(x) = W_{r_1}(x) - W_{r_2}(x)$. Then U is not identically zero on $[r_1, \infty)$ and is a solution of the homogeneous differential equation associated with (6.7). Furthermore, $\lim_{x\to\infty} U(x) = 0$. By an argument similar to the uniqueness proof above, $U(x) \ne 0$ for all $x \ge r_1$. Observe that for any $r > r_1$ fixed, the unique solution of (6.7) and (6.8) can be written as $W_r(x) = W_{r_1}(x) + (\frac{1 - W_{r_1}(r)}{U(r)})U(x)$ and thus $W_r'(x) = W_{r_1}'(x) + (\frac{1-W_{r_1}(r)}{U(r)})U'(x)$ for all $x \ge r$. Hence $W_r(x)$ and $W_r'(x)$ are jointly continuous in (r, x).

To obtain part (iv), let p_0 and q_0 be as in (6.5). If $W_{p_0}'(p_0) = 0$, then we can take $b_0^* = p_0$ and the proof is complete. Thus, let us consider $W_{p_0}'(p_0) \ne 0$. We claim $W_{p_0}'(p_0) > 0$. Suppose not; then $W_{p_0}'(p_0) < 0$. This yields $W_{p_0}(x) < 1$ for all $x > p_0$, otherwise there will be a local minima at $x = \xi$ so that $\xi > p_0$ and $W_{p_0}(\xi) < 1$. By evaluating (6.7) at $x = \xi$ we obtain $h(\xi) < 1$, where h is as in (6.3). Therefore, $\xi > \delta_0$, but by the proof of part (ii) above, W_{p_0} cannot have any local minima on (δ_0, ∞). Consequently, $W_{p_0}(x) < 1$ for all $x > p_0$. Next, we integrate (6.7) and use the above facts to obtain $\frac{\sigma^2(x)}{2} W_{p_0}'(x) + \mu(x) + C(x) < \frac{\sigma^2(p_0)}{2} W_{p_0}'(p_0) + \mu(p_0) + C(p_0) + \alpha \int_{p_0}^{x} W_{p_0}(u)\,du$ for all $x > p_0$ and consequently $\frac{\sigma^2(x)}{2} W_{p_0}'(x) + \int_{p_o}^{x} \psi(u)\,du < \frac{\sigma^2(p_0)}{2} W_{p_0}'(p_0) < 0$. Hence $W_{p_0}(q_0) + \int_{p_0}^{q_0} \frac{2}{\sigma^2(x)} \int_x^{p_0} \psi(u)\,du\,dx \le 1$ and by part (i), $W_{p_0}(q_0) > 0$. Thus, we obtain $\int_{p_0}^{q_0} \frac{2}{\sigma^2(x)} \int_x^{p_0} \psi(u)\,du\,dx < 1$ and this contradicts (6.5). Therefore, we conclude that $W_{p_0}'(p_0) > 0$. Since $\lim_{x\to\infty} W_{p_0}(x) = 0$, it follows that there is a point $r_0 > p_0$ such that $W_{p_0}(r_0) = 1$ and $W_{p_0}(x) < 1$ for all $x > r_0$. Hence, by the uniqueness of solutions to (6.7) and (6.8), $W_{p_0}(x) \equiv W_{r_0}(x)$ for all $x \ge r_0$. Now following an argument similar to the proof of Lemma 5.1 and using parts (i)–(iii), we

let $b_0 = \sup\{r : r \in [p_0, r_0] \text{ and } W_r'(r) > 0\}$, and obtain $W_{b_0}'(b_0) = 0$. Since $h(x) < 1$ for $x > \delta_0$, using the proofs of parts (i)–(iii), one can show that $W_r'(r) < 0$ for $r \geq \delta_0$ and thus $b_0 < \delta_0$ as claimed in part (iv).

To prove the uniqueness of b_0, assume that $\tilde{b}_0$ also satisfies part (iv). Without loss of generality, let $\tilde{b}_0 < b_0$. Then $\beta_0 < p_0 \leq \tilde{b}_0 < b_0 < \delta_0$. Next, we extend the corresponding functions W_{b_0} and $W_{\tilde{b}_0}$ to (β_0, ∞) as the solutions of (6.7) on (β_0, ∞). Then W_{b_0} has a local maxima at $x = b_0$. If $x = x_1$ is a local minimum for W_{b_0}, then by (6.7) we obtain $\psi(x_1) < 0$. Thus by (6.3), W_{b_0} cannot have local minima on $[\beta_0, \delta_0]$. Similarly, $W_{\tilde{b}_0}$ has a local maximum at $\tilde{b}_0$ and no local minima on $[\beta_0, \delta_0]$. Hence, W_{b_0} is increasing on $[\tilde{b}_0, b_0]$, $W_{\tilde{b}_0}$ is decreasing on $[\tilde{b}_0, b_0]$ and consequently W_{b_0} and $W_{\tilde{b}_0}$ meet at a point z in $(\tilde{b}_0, b_0)$. Now let $U(x) = W_{b_0}(x) - W_{\tilde{b}_0}(x)$ on (β_0, ∞). $U(x)$ is a solution of the homogeneous equation associated with (6.7), $U(z) = 0$ and $\lim_{x\to\infty} U(x) = 0$. Therefore, as in the proof of the uniqueness of solution of (6.7) and (6.8), $U(x)$ is identically zero on (β_0, ∞) and this leads to $\tilde{b}_0 = b_0$. This completes the proof. □

LEMMA 6.2. *There exist a point a^* such that $\beta_0 < a^* < \delta_0$ and a continuously differentiable function U_{a^*} defined on $[0, a^*]$ satisfying the following conditions.*

(i) *U_{a^*} satisfies the differential equation* (6.7) *on $(0, a^*)$.*

(ii) *$U_{a^*}(0) = 0$, $U_{a^*}(a^*) = 1$, $U_{a^*}'(a^*) = 0$, and $0 < U_{a^*}(x) < 1$ on $(0, a^*)$.*

Proof. For each $p > 0$, let U_p be the solution of (6.7) on $[0, p]$ with $U_p(0) = 0$ and $U_p(p) = 1$. Using (6.7), it follows that if U_p has a local minimum at a point z in $(0, p)$, then $U_p(z) > 0$. Hence, $U_p(x) > 0$ on $(0, p)$. Also, if U_p has a local maximum at a point z and $U_p(z) \geq 1$, then $C'(z) \geq (\alpha - \mu'(z))$ and thus $z \geq \beta_0$. Therefore, for each $p < \beta_0$, $0 < U_p(x) < 1$ on $(0, p)$ and $U_p'(p) \geq 0$. Suppose $U_p'(p) = 0$. Then, we extend U_p to $[0, \beta_0]$ as a solution of (6.7) and evaluate it at $x = p$. But $p < \beta_0$, therefore, $\psi(p) < 0$ and $U_p''(p) > 0$. Since $U_p(p) = 1$, this contradicts the fact $0 < U_p(x) < 1$ for $0 < x < p$. Hence, $U_p'(p) > 0$. Now consider $U_{\beta_0}(x)$. If $U_{\beta_0}'(\beta_0) = 0$, then we can take $a^* = \beta_0$, and we are done. Otherwise $U_{\beta_0}'(\beta_0) > 0$ and $0 < U_{\beta_0}(x) < 1$ on $(0, \beta_0)$. First, we estimate $U_{\beta_0}'(0)$. By integrating (6.7) and using $\mu(x)U_{\beta_0}(x) < 0$ on $(0, \beta_0)$, we obtain $U_{\beta_0}'(x) + \frac{2C(x)}{\sigma^2(x)} > \frac{\sigma^2(0)}{\sigma^2(x)} U_{\beta_0}'(0)$ for $0 < x < \beta_0$ and thus

$$1 + 2\int_0^{\beta_0} \frac{C(u)}{\sigma^2(u)}\, du > \sigma^2(0) U_{\beta_0}'(0) \int_0^{\beta_0} \frac{1}{\sigma^2(r)}\, dr. \tag{6.9}$$

We use (6.9) to show $U_{p_0}'(p_0) < 0$, where p_0 is given in (6.4) and $p_0 > \beta_0$. Consider $U_{p_0}(x)$ on $[0, p_0]$ and suppose that $\sup_{[0,p_0]} U_{p_0}(x) \leq 1$. Then $U_{p_0}(x) \leq 1 < U_{\beta_0}(x)$ for some x in (β_0, p_0), since $U_{\beta_0}'(\beta_0) > 0$ and $U_{\beta_0}(\beta_0) = 1$. Hence, U_{β_0} and U_{p_0} are two different solutions of (6.7). But $U_{\beta_0}(0) = U_{p_0}(0) = 0$, hence by the uniqueness of solutions to (6.7), $U_{\beta_0}(x) \neq U_{p_0}(x)$ for all $x > 0$ and $U_{\beta_0}'(0) \neq U_{p_0}'(0)$. Consequently, we have $0 < U_{p_0}(x) < U_{\beta_0}(x)$ for $0 < x < \beta_0$ and also $U_{p_0}'(0) < U_{\beta_0}'(0)$. By integrating (6.7) for U_{p_0}, we obtain $\frac{\sigma^2(p_0)}{2} U_{p_0}'(p_0) + \mu(p_0) + C(p_0) = \frac{\sigma^2(0)}{2} U_{p_0}'(0) + \alpha \int_0^{p_0} U_{p_0}(r)\, dr$ and hence $\frac{\sigma^2(p_0)}{2} U_{p_0}'(p_0) < \frac{\sigma^2(0)}{2} U_{\beta_0}'(0) + \alpha p_0 - \mu(p_0) - C(p_0)$. Using (6.4) and (6.9), we obtain

$$\frac{\sigma^2(p_0)}{2} U_{p_0}'(p_0) < \frac{\left[1 + 2\int_0^{\beta_0} \frac{C(u)}{\sigma^2(u)}\, du\right]}{\int_0^{\beta_0} \frac{2}{\sigma^2(r)}\, dr} + \alpha p_0 - \mu(p_0) - C(p_0) < 0.$$

This contradicts the fact $\sup_{[0,p_0]} U_{p_0}(x) \leq 1$. Thus $\sup_{[a,p_0]} U_{p_0}(x) > 1$. Now as similar to the proof of Lemma 5.1, we take $a^* = \sup\{p : 0 < p \leq p_0 \text{ and } U_p(x) < 1$

on $(0,p)\}$. Thus U_{a^*} satisfies (6.7) on $(0,a^*)$, $U_{a^*}(0)=0$, $U_{a^*}(a^*)=1$, $U'_{a^*}(a^*)=0$, and $\beta_0 \le a^* < p_0 < \delta_0$. This completes the proof. □

LEMMA 6.3. *Let W_r be the solution of* (6.7) *and* (6.8) *as described in Lemma* 6.1. *Introduce the function $G(\cdot)$ by $G(r)=\frac{\sigma^2(r)}{2}W'_r(r)+\int_{a^*}^{r}\psi(u)\,du$ for all $r\ge a^*$, where a^* is given in Lemma* 6.2.

Then there is a point b^* such that $G(b^*)=0$ and $b^*>b_0$, where b_0 is given in Lemma 6.1(iv). *Furthermore, W_{b^*} satisfies parts* (i)–(iii) *of Lemma* 6.1, *$0<W_{b^*}(x)<1$ on $(b^*,+\infty)$, and W_{b^*} is decreasing on $[b^*,+\infty)$.*

Proof. The function G is continuous on $[a^*,\infty)$ since $W'_r(x)$ is jointly continuous in (r,x) as shown in Lemma 6.1. By the same lemma, $G(b_0)>0$ since $\beta_0<a^*<b_0<\delta_0$. Furthermore, by (6.3), $\int_{\delta_0}^{\infty}\psi(u)\,du=-\infty$ and thus there is a point $b_1>\delta_0$ such that $\int_{a^*}^{b_1}\psi(u)\,du=0$ and $\int_{a^*}^{x}\psi(u)\,du>0$ for $a^*<x<b_1$. By the proof of part (iv) of Lemma 6.1, $W'_r(r)<0$ for all $r>\delta_0$ and therefore $G(b_1)<0$. Since G is continuous, there is a point b^* such that $b_1>b^*>b_0$ and $G(b^*)=0$.

We consider W_{b^*} on $[b^*,+\infty)$. Since $W'_{b^*}(b^*)+\int_{a^*}^{b^*}\psi(u)\,du=0$ and $\int_{a^*}^{b^*}\psi(u)\,du>0$, we obtain $W'_{b^*}(b^*)<0$. But $W_{b^*}(b^*)=1$ and $\lim_{x\to\infty}W_{b^*}(x)=0$. Let us show that W_{b^*} is decreasing on $[b^*,+\infty)$. Suppose not; then there exist a local minimum at a point $x=\xi_1$ and a local maximum at $x=\xi_2$ so that $\xi_2>\xi_1$ and $W_{b^*}(\xi_2)>W_{b^*}(\xi_1)$. Using (6.7), we obtain $\frac{C'(\xi_1)}{(\alpha-\mu'(\xi_1))}\le W_{b^*}(\xi_1)<W_{b^*}(\xi_2)\le\frac{C'(\xi_2)}{(\alpha-\mu'(\xi_2)}$. Hence, $h(\xi_1)<h(\xi_2)$. Also by integrating (6.7), we obtain $C(\xi_1)+\mu(\xi_1)<\mu(\xi_1)W_{b^*}(\xi_1)+C(\xi_1)=\frac{\sigma^2(b^*)}{2}W'_{b^*}(b^*)+\mu(b^*)+C(b^*)+\int_{b^*}^{\xi_1}\alpha W_{b^*}(u)\,du<C(b^*)+\mu(b^*)+\alpha(\xi_1-b^*)$. Therefore, $\int_{b^*}^{\xi_1}\psi(u)\,du<0$ and hence $\xi_1>\delta_0$, where δ_0 is given in (6.3). Thus $\delta_0<\xi_1<\xi_2$ and we have $h(\xi_1)<h(\xi_2)$. By (6.3), this is a contradiction. Hence W_{b^*} is decreasing on $(b^*,+\infty)$, $\lim_{x\to\infty}W_{b^*}(x)=0$ and $W'_{b^*}(b^*)<0$. This completes the proof. □

LEMMA 6.4. *There exists two points $0<a^*<b^*$ and a continuous function W on $[0,\infty)$ such that*

(i) *$\beta_0<a^*<p_0<b^*$, $W(0)=0$, $W(x)=1$ on $[a^*,b^*]$;*

(ii) *W is C^1 everywhere except at $x=b^*$, W satisfies* (6.7) *on $(0,a^*)\cup(b^*,+\infty)$, $W'(a^*)=0$, and $0<W(x)<1$ on $(0,a^*)\cup(b^*,+\infty)$; also the limits $W'(b^*-)$ and $W'(b^*+)$ exist and are finite;*

(iii) *let*

$$P(x)=\frac{1}{2}(\sigma^2(x)W'(x)-\sigma^2(0)W'(0))+\mu(x)W(x)+C(x) \qquad (6.10)$$
$$-\alpha\int_0^x W(u)\,du \quad \text{for } x\ne b^*;$$

then $P(x)\ge 0$ for all $x>0$, and $x\ne b^*$; furthermore, $P(b^*-)$ and $P(b^*+)$ are finite, $P(b^*-)>0$ and $P(b^*+)=0$.

Proof. Let the points a^* and b^* and the corresponding functions U_{a^*} and W_{b^*} be as described in Lemmas 6.2 and 6.3. Introduce the function W by

$$W(x)=U_{a^*}(x)I_{[0,a^*]}(x)+I_{(a^*,b^*)}(x)+W_{b^*}(x)I_{[b^*,\infty)}(x),$$

where I_A represents the indicator function of the set A. Then parts (i) and (ii) follows from Lemmas 6.2 and 6.3. Notice that $W'(b^*-)=0$ and $W'(b^*+)=W'_{b^*}(b^*+)<0$. It remains to verify part (iii).

Observe that $P'(x)=0$ on $(0,a^*)\cup(b^*,+\infty)$. Since $P(0)=0$, and using part (ii), we obtain $P(x)=0$ on $[0,a^*]$. Also $P(a^*)=0$ and this implies

that $C(a^*) + \mu(a^*) = \frac{\sigma^2(0)}{2} W'(0) + \alpha \int_0^{a^*} W(u)\,du$. Using this together with the fact $W(x) = 1$ on $[a^*, b^*]$ and (6.10), we obtain $P(x) = C(x) + \mu(x) - \alpha(x - a^*) - (C(a^*) + \mu(a^*)) = \int_{a^*}^{x} \psi(u)\,du$ for $a^* \le x < b^*$. But $\int_{a^*}^{x} \psi(u)\,du > 0$ for $a^* < x < b^*$ from the proof of Lemma 6.3. Hence $P(x) > 0$ on $[a^*, b^*)$ and $P(b^*-) > 0$. On the set $(b^*, +\infty)$, $P'(x) = 0$, since W_{b^*} satisfies (6.7). By a computation similar to above, we obtain

$$\begin{aligned} P(b^*+) &= \frac{\sigma^2(b^*)}{2} W'_{b^*}(b^*) + C(b^*) + \mu(b^*) \\ &\quad - \left(\frac{\sigma^2(0)}{2} W'(0) + \alpha \int_0^{a^*} W(u)\,du \right) - \alpha(b^* - a^*) \\ &= \frac{\sigma^2(b^*)}{2} W'_{b^*}(b^*) + C(b^*) + \mu(b^*) - (C(a^*) + \mu(a^*)) - \alpha(b^* - a^*) \\ &= \frac{\sigma^2(b^*)}{2} W'_{b^*}(b^*) + \int_{a^*}^{b^*} \psi(u)\,du. \end{aligned}$$

Thus $P(b^*+) = 0$ by using Lemma 6.3 and consequently $P(x) = 0$ for all $x > b^*$. This completes the proof. □

We construct an even function $F(\cdot)$ on $\mathbb{R}$ by

$$F(x) = \begin{cases} \dfrac{\sigma^2(0)}{2\alpha} W'(0) + \displaystyle\int_0^x W(u)\,du & \text{for } x \ge 0, \\ F(-x) & \text{for } x < 0, \end{cases} \tag{6.11}$$

where W is given in Lemma 6.4. Next, we describe the main theorem of this section.

THEOREM 6.5. *Assume* (1.4)–(1.6) *and* (6.2)–(6.5). *Let F be the function defined in* (6.11). *Then*

(i) *F is a bounded C^1-function which is C^2 everywhere except at $x = \pm b^*$ and F satisfies the HJB equation* (1.9) *everywhere except at the points $x = \pm b^*$;*

(ii) *$F(x) = V(x)$ for all x, where V is the value function given in* (1.8)*; let $0 < a^* < b^*$ be as in Lemma* 6.4*, then the strategy described in* (6.6) *is optimal.*

Proof. For part (i), we use Lemma 6.4. For $x \ge 0$, $F'(x) = W(x)$ by (6.11) and, therefore, $0 < F'(x) \le 1$, F is C^1 on $[0, \infty)$ and C^2 everywhere except at $x = b^*$. Furthermore, $\frac{1}{2}\sigma^2(x)F''(x) + \mu(x)F'(x) - \alpha F(x) + C(x) = P(x)$, where $P(\cdot)$ is given in Lemma 6.4 and $P(x) \ge 0$, $P(x) = 0$ on $[0, a^*] \cup (b^*, \infty)$, and $F'(x) = 1$ on $[a^*, b^*]$. Therefore, F satisfies (1.9) on $[0, \infty)$. By the proof of Lemma 6.1, $\int_0^\infty W(u)\,du$ is convergent, and hence F is bounded on $[0, \infty)$. Since F is an even function, part (i) follows.

For part (ii), we can apply Proposition 2.3 in section 2 to conclude that $F(x) \le V(x)$ for all x, where V is the value function in (1.8). To prove $F \ge V$, we begin with the strategy (6.6) with a^* and b^* as in Lemma 6.4. If the initial point x is in $[-a^*, a^*]$, then the strategy in (6.6) yields a reflecting diffusion on $[-a^*, a^*]$ which satisfies (5.3) and (5.4). Since F satisfies (5.6) and (5.7) on $[-a^*, a^*]$, F can be represented by (5.5) with respect to the reflecting diffusion on $[-a^*, a^*]$ and $F(x) \ge V(x)$ for all x in $[-a^*, a^*]$. If x is in $[a^*, b^*]$, then there is an initial jump to a^* and thereafter it follows a reflecting diffusion on $[-a^*, a^*]$. Since $W(x) = 1$ on $[a^*, b^*]$, we have $F(x) = F(a^*) + (x - a^*)$ and $F(x) \ge V(x)$ on $[a^*, b^*]$. Similarly, $F(x) \ge V(x)$ on $[-b^*, -a^*]$. If $x > b^*$, our candidate $\{X_x^*(t) : t \ge 0\}$ for an optimal process satisfies

(4.1) up to the first entrance time τ_{b^*} of $[-b^*, b^*]$ and at the time τ_{b^*} it will jump to a^* using the control process $A(\cdot)$ in (1.1). Thereafter, it remains in $[-a^*, a^*]$ as a reflecting diffusion satisfying (5.3) and (5.4). The process $X_x^*(\cdot)$ is admissible with respect to the stopping times $\{\tau_n\}$ defined is (4.3) and the explosion time of $X_x^*(\cdot)$ is infinity, as verified in Proposition 4.1. Also $P_x[\tau_{b^*} < \infty] = 1$, and this can be established by standard methods (see [17, p. 345]). To verify that the pay-off from $X_x^*(\cdot)$ is indeed $F(x)$, we apply Itô's lemma to $F(X_x^*(t))e^{-\alpha t}$ and obtain

$$F(x) = F(b^*)E_x(e^{-\alpha\tau_{b^*}}) + E_x\left[\int_0^{\tau_{b^*}} e^{-\alpha t}C(X_x^*(t))\,dt\right] \tag{6.12}$$
$$= F(a^*)E_x(e^{-\alpha\tau_{b^*}}) + E_x\left[\int_0^{\tau_{b^*}} e^{-\alpha t}(C(X_x^*(t))\,dt + d|A^*|(t))\right],$$

where $\{A^*(t)\}$ is the bounded variation control process associated with $X_x^*(\cdot)$ as in (1.1), and A^* satisfies $A^*(t) = 0, \quad 0 \le t < \tau_{b^*}, A^*(\tau_{b^*}) = -(b^* - a^*)$, and for $t > \tau_{b^*}$, $A^*(t) = A^*(\tau_{b^*}) + L_{-a^*}(t) - L_{a^*}(t)$, where L_{-a^*} and L_{a^*} are the local time processes at $-a^*$, and a^* is as described in (5.4). Since $F(a^*)$ can be represented by (5.5), (6.12) leads to $F(x) = E_x \int_0^\infty e^{-\alpha t}(C(X_x^*(t))\,dt + d|A^*|(t))$. Hence, $F(x) \ge V(x)$ for all $x \ge b^*$. Similar argument works when $x < -b^*$. Consequently, $F(x) = V(x)$ for all x and the strategy described in (6.6) is optimal. This completes the proof. □

Next, we give an explicit example which satisfies all our assumptions.

Example 6.6. Let $\mu(x) = -\theta x$ and $\sigma(x) = \sigma_0$, where θ and σ_0 are positive constants. Hence the zero-control in (1.1) yields on Ornstein–Uhlenbeck process. To construct a twice continuously differentiable even cost function $C(\cdot)$, we introduce two points $p_0 > 0$ and $q_0 > 0$ by $p_0 = \frac{3}{2}(\alpha+\theta) + \frac{\sigma_0}{\sqrt{\alpha+\theta}}$ and $q_0 = p_0 + \frac{\sigma_0}{\sqrt{\alpha+\theta}}$.

We take $C(x) = x^2$ on $[0, q_0]$. On $[q_0, +\infty]$, we construct $C(x)$ so that $C(\cdot)$ is C^2 on $[0,\infty), C'(x)$ is increasing on $[0, q_0 + 1]$, $C'(x)$ is nonnegative and decreasing on $[q_0 + 1, \infty)$, and $\int_{q_0}^\infty C'(u)\,du$ is finite. We extend $C(x)$ to $\mathbb{R}$ as an even function and consequently $C(\cdot)$ is a bounded cost function. Assumption (6.2) is obvious. In (6.3), $h(x) = \frac{C'(x)}{(\alpha+\theta)}$ for $x > 0$, $\beta_0 = \frac{(\alpha+\theta)}{2}$, and $\delta_0 > q_0 + 1$. Thus (6.3) is also satisfied. Let p_0 and q_0 be as introduced above. Condition (6.4) can be reduced to $(p_0 - \frac{(\alpha+\theta)}{2})^2 > \frac{\sigma_0^2}{(\alpha+\theta)} + \frac{(\alpha+\theta)^2}{3}$ and it is satisfied by our choice of p_0. Condition (6.5) can be reduced to $\frac{1}{3}(q_0^3 + 2p_0^3) > \frac{\sigma_0^2}{2} + p_0^2 q_0 + \frac{(\alpha+\theta)}{2}(q_0 - p_0)^2$ and this inequality is also satisfied by our choice of p_0 and q_0.

Hence, there exist two points $a^* > 0$ and $b^* > 0$ and an optimal strategy of the type described in (6.6). Moreover, the value function fails to be C^2 at the points $\pm b^*$.

7. Variance control. Here we allow the controller to control the diffusion coefficient in addition to the bounded variation control process. We assume that the controlled state process is a weak solution of the stochastic differential equation

$$X_x(t) = x + \int_0^t \mu(X_x(s-))\,ds + \int_0^t u(s)\,dW(s) + dA(x), \tag{7.1}$$

where x is in $\mathbb{R}, \{W(t) : t \ge 0\}$ is the Brownian motion adapted to a right continuous filtration $\{\mathfrak{F}_t : t \ge 0\}$ on a probability space $\{\mathfrak{F}_t\}$ and the bounded variation control process $A(\cdot)$ is $\{\mathfrak{F}_t\}$-adapted and satisfies all the conditions described below (1.1) in section 1. In addition, the process $\{u(t) : t \ge 0\}$ is $\{\mathfrak{F}_t\}$-adapted, and for each $t > 0, u(t)$ belongs to a control set $D(X_x(t-))$, where $D(y) \subseteq (0,\infty)$ for each y, and the collection of control sets $\mathcal{D} = \{D(y) : y \text{ is in } R\}$ is a priori known to the controller.

A process $X_x(\cdot)$ is *admissible* if it satisfies (7.1), $u(t)$ belongs to $D(X_x(t-))$ for each $t > 0$, and if there exists an increasing sequence of stopping times $\{\tau_n\}$ such that $\lim_{n\to\infty} \tau_n = +\infty$ and

$$\text{(7.2)} \quad \text{(i)} \qquad E_x \int_0^{T\wedge\tau_n} [|\mu(X_x(s-))| + (u(s))^2]\, ds < \infty \quad \text{for each } T > 0 \text{ and}$$

$$\text{(ii)} \qquad \lim_{n\to\infty} E_x\big[|X_x(\tau_n)| e^{-\alpha\tau_n} I_{[\tau_n<\infty]}\big] = 0.$$

The control problem addressed in this section is to minimize the function

$$J(x,u,A) = E_x \int_0^\infty e^{-\alpha t}[C(X_x(t))\, dt + d|A|(t)] \tag{7.3}$$

over all available state processes $X_x(\cdot)$ satisfying (7.1) and (7.2). The cost function $C(\cdot)$ satisfies assumption (1.6).

Analogous to section 1, we call $((\Omega, \mathfrak{F}, P), \{\mathfrak{F}_t\}, W(\cdot), X_x(\cdot), u(\cdot), A(\cdot))$ an admissible control system if (i) $X_x(\cdot)$ is a weak solution to (7.1) which also satisfies (7.2) with respect to control processes $u(\cdot)$, $A(\cdot)$, and (ii) $J(x,u,A)$ described in (7.3) is finite. We let

$$\Sigma(x) = \{(u(\cdot), A(\cdot)) : \text{ there exists an admissible state process } X_x(\cdot) \text{ which satisfies (7.1) corresponding to control processes } u(\cdot) \text{ and } A(\cdot)\}.$$

The value function $V(\cdot)$ is defined by

$$V(x) = \inf_{\Sigma(x)} J(x,u,A). \tag{7.4}$$

The key to the derivation of the optimal strategies in this section is the function $\sigma(\cdot)$ defined by

$$\sigma(y) = \inf\{u : u \in D(y)\}. \tag{7.5}$$

We make the following assumptions on the collection of control sets $\mathcal{D}$:

(7.6) (i) for each y, $\sigma(y)$ belongs to $D(y)$;

(7.7) (ii) the function $\sigma(\cdot)$ satisfies conditions (1.4) and (1.5).

In contrast to many articles in stochastic control, the control sets $D(y)$ need not be bounded. We assume condition (1.6) related to the cost function $C(\cdot)$. We need the following additional assumption in this section:

$$\text{the function } h(x) = \frac{C'(x)}{\alpha - \mu'(x)} \text{ is monotone increasing on } \mathbb{R}. \tag{7.8}$$

Condition (7.8) guarantees the convexity of the value function, and hence the use of minimal variance is optimal. The HJB equation related to this problem is given by

$$\min\left\{ \inf_{u\in\mathcal{D}(x)} \frac{u^2}{2} V''(x) + \mu(x)V'(x) - \alpha V(x) + C(x),\ 1 - |V'(x)| \right\} = 0. \tag{7.9}$$

Our next lemma will extend the verification results of section 2.

LEMMA 7.1. *Let $\sigma(\cdot)$ be defined by* (7.5) *and let the functions μ, σ, and C satisfy* (1.4)–(1.6) *and* (7.5)–(7.7). *Let Q be a twice continuously differentiable function which*

satisfies the HJB equation (7.9) *with* $Q''(x) \geq 0$ *for all* x. *Then* $Q(x) \leq V(x)$ *for all* x, *where* V *is the value function given by* (7.4).

Proof. Since $Q'' \geq 0$, observe that $\inf_{u \in \mathcal{D}(x)} \frac{u^2}{2} Q''(x) = \frac{\sigma^2(x)}{2} Q''(x)$, where $\sigma(\cdot)$ is given in (7.5). Since Q satisfies (7.9), it also satisfies (1.9) with the diffusion coefficient $\sigma(\cdot)$. For any admissible process $X_x(\cdot)$ with controls $u(\cdot)$ and $A(\cdot)$, we observe that

$$\frac{u(t)^2}{2} Q''(X_x(t-)) \geq \frac{\sigma^2(X_x(t-))}{2} Q''(X_x(t-)) \quad \text{for all } t \geq 0. \tag{7.10}$$

Using (7.10) in the proofs of Lemma 2.1 and Corollary 2.2, the conclusion follows. □

Remark. If $\sigma(\cdot)$ is as in (7.5) and Q is a C^2 function which satisfies (1.9) and $Q''(x) \geq 0$ for all x, then Q also satisfies (7.9).

Next, we describe the main theorem of this section.

THEOREM 7.2. *Assume the same conditions as in Lemma* 7.1. *Then the following holds.*

(i) *If* (4.2) *holds, then the process* $Z_x(\cdot)$ *of* (4.1) *is optimal for the variance control problem* (7.4).

(ii) *If* (5.1) *and* (5.2) *holds, then the reflecting diffusion process* $X_x^*(\cdot)$ *described in the Theorem* 5.5 *is optimal for* (7.4).

Proof. To prove part (i) we use the proof of Theorem 4.3. With the aid of Lemma 7.1, it suffices to show that $F''(x) \geq 0$ for all x, where F is given in (4.15). This will follow if we prove W_∞ in (4.15) is increasing. Suppose not, then there exist $z_1 < z_2$ so that $W_\infty(z_1) > W_\infty(z_2)$. Hence, we can find large n, so that W_n has a local maximum at ξ_1 and a local minimum at ξ_2, $\xi_1 < \xi_2$, $W_n(\xi_1) > W_n(\xi_2)$, and W_n satisfies (4.8). Using (4.8), it follows that $h(\xi_1) \geq W_n(\xi_1) > W_n(\xi_2) > h(\xi_2)$. This contradicts (7.8). Hence part (i) follows.

For part (ii), we follow the proof of Theorem 5.5. Again it suffices to show that the function W described in Proposition 5.4 is monotone increasing on $[a^*, b^*]$. This can be proved similarly to part (i). Thus V^* given in (5.28) satisfies the assumptions of Lemma 7.1, and the process $X_x^*(\cdot)$ described in Theorem 5.5 is optimal for the variance control problem. This completes the proof. □

GRAPH TOPOLOGIES, GAP METRICS, AND ROBUST STABILITY FOR NONLINEAR SYSTEMS*

W. BIAN† AND M. FRENCH†

Abstract. Graph topologies for nonlinear operators which admit coprime factorizations are defined w.r.t. a gain function notion of stability in a general normed signal space setting. Several metrics are also defined and their relationship to the graph topologies are examined. In particular, relationships between nonlinear generalizations of the gap and graph metrics, Georgiou-type formulae, and the graph topologies are established. Closed loop robustness results are given w.r.t. the graph topology, where the role of a coercivity condition on the nominal plant is emphasized.

Key words. gap metric, graph metric, graph topology, robust stability, nonlinear systems

1. Introduction.

The theory of coprime factorizations of linear signal operators is well known to be a significant tool in the study of robustness of stability for linear feedback systems and has been extensively studied (see [5, 16, 20]). Perturbations to normalized coprime factors form a good description of physically realistic deviations from nominal models, since they allow a unified treatment of both low and high frequency uncertainties [8]. In the linear theory, it is well known that the graph topology is the appropriate topological description for studying robustness of stability and that coprime factor perturbations can be used to induce the graph topology. Furthermore, the graph topology is metrizable, and both the gap metric [3, 21] and the graph metric [20] provide suitable metrizations, the former being more suitable for calculations by standard H^∞ optimizations, (although both metrics are topologically equivalent) [5, 16, 21]. There is thus a rich set of equivalences between the notions of coprime factorizations, gap/graph metrics and topologies and their attendant robust stability theorems. Moreover, this framework is a cornerstone of modern robust linear control theory.

Given the richness and importance of this framework in the linear setting, it is natural to seek extensions to the nonlinear case, and to alternative signal spaces. Indeed, by adopting a notion of stability corresponding to the existence of a linear gain (typically either in an L^2 or L^∞ setting), a number of authors have previously considered a nonlinear theory of coprime factorization. Here we highlight three contributions of particular relevance to the context of this paper. In [18], Verma defined a notion of coprime factorization for nonlinear mappings and presented a stability result for a nonlinear system. In [2], Anderson, James, and Limebeer generalized the linear theory of normalized coprime factor robustness optimization to the case of affine input nonlinear systems and presented an optimal robustness margin. In [10], a new definition of "normalized" was introduced for left representation for the graph of a nonlinear system and different gap metrics were studied. Many further pointers

to a growing literature on nonlinear coprime factorization can be found in the monograph [14] and the references therein.

On the other hand, the gap metric has also been generalized into a nonlinear setting in a fundamental contribution by Georgiou and Smith, [7]. In further recent papers [1, 22, 10], generalizations of Vinnicombe's ν-gap metric [21] to nonlinear operators have been considered (for linear systems the ν gap is always smaller than the gap and has sharper properties; however, the nonlinear theory does not as yet reflect these extra properties).

The purpose of this paper is three-fold.

1. To further extend the existing robust stability theory by replacing the restrictive requirement of the existence of an induced gain by the weaker requirement of the existence of a gain function; see also [7].

2. To provide the topological descriptions underpinning the convergence and robust stability notions in both the case of linear gain and gain function stability; in particular to provide a topological characterization of nonlinear gap topologies in terms of coprime factor perturbations.

3. To establish links between the nonlinear graph topologies, the recent results on the nonlinear gap metric [7], and other metrizations (e.g., graph metrics [20], and Georgiou-type formulae [4]).

In the context of the first and second items, directly related work of which the authors are aware can be found in [17], where a sufficient condition for the existence of coprime factorization of nonlinear mappings was given in the sense of IOS; we will show much more of the theory for linear gains can be extended to this more general setting. In [7], robustness of stability results was given in a gain function setting using a generalization of the gap metric. Interestingly, whilst the results in the gain function setting given in [7] implicitly define a notion of plant convergence, the underlying topology is not explicit. In particular, in contrast to the case of the linear gain, a metric was not defined, hence a topology cannot be automatically induced. One contribution of this paper is to provide the underlying topology, and to provide explicit metrizations. In the case of stability of nonlinear operators defined via a linear gain, we show that the graph metric naturally generalizes and induces the graph topology. In the more general case of gain function stability, we only show that the gap topology is stronger than the (weighted) graph topology. The converse relationship remains open. However, we do establish many other relationships and equivalences between a variety of gap and graph metrics and topologies.

An outline of this paper is as follows. Section 2 is devoted to the preliminaries, in particular known results on coprime factorization for nonlinear systems are briefly reviewed. The main results are arranged in three sections. In section 3, we define *pointwise* and *weighted* graph topologies and study the associated convergence over a general subset of signal operators admitting coprime factorizations. In section 4, we study the metrizability of the weighted graph topology. Seven gap metrics are considered. Equivalences and other relationships between the metrics and their associated topologies (including equivalence to the weighted graph topology) are presented. Finally in section 5, we apply the graph topologies to study the robust stability of nonlinear feedback systems. A summary and discussion of future work is given in section 6.

2. Background on coprime factorization. The material in this section is mostly directly based on (and straightforward generalizations of) work of previous authors [7, 17, 18, 19]. However, we need to present this material within the language of this paper and for completeness.

We let $\mathcal{U}$, $\mathcal{Y}$ be two signal spaces, respectively, representing the input and output signal spaces. These could be the spaces $L_n^\infty := L^\infty(\mathbb{R}_+, \mathbb{R}^n)$, $L_n^{\infty,e}$, L_n^p, $L_n^{p,e}$, l^p, or even a general set on which a truncation can be defined and for which any truncated domain is a normed linear space and $\sup_{\tau>0} \|T_\tau x\| < \infty$ implies $x \in \mathcal{U}_s$. In particular, for one-dimensional continuous domains, we define the truncation operator and the truncated norm for a signal u, say $u \in L_n^{\infty,e}$, by

$$(T_\tau u)(t) = \begin{cases} u(t), & t \le \tau \\ 0, & t > \tau \end{cases}, \qquad \|u\|_\tau = \|T_\tau u\|,$$

where norm of a normed space X is denoted by $\|\cdot\|_X$ or $\|\cdot\|$ if the usage is unambiguous. Note, however, that the notion of truncation and all the material in this paper equally apply to signal spaces with discrete domains, e.g., $L^\infty(\mathbb{Z}_+, \mathbb{R}^n)$, and to multidimensional domains, e.g., $L^\infty(\mathbb{R}_+^m, \mathbb{R}^n)$, under a suitably modified notion of truncation. Let $\mathcal{U}_s$, $\mathcal{Y}_s$ be the auxiliary normed subspaces which consist of all bounded signals in $\mathcal{U}$, $\mathcal{Y}$, respectively. In the case where $\mathcal{U}$ (resp., $\mathcal{Y}$) is a normed space, $\mathcal{U}_s = \mathcal{U}$ (resp., $\mathcal{Y}_s = \mathcal{Y}$). Typically, $\mathcal{U}$, $\mathcal{Y}$ are taken to be extended spaces (e.g., $L_n^{\infty,e}$), and $\mathcal{U}_s$, $\mathcal{Y}_s$ are their nonextended subspaces (e.g., L_n^∞).

The identity operator on any space Y is denoted by I_Y or I if the usage is clear. Given a matrix operator (A, B), let $(A, B)^\top$ be its transpose, that is $(A, B)^\top = \binom{A}{B}$. We also let $\mathcal{K}_\infty$ denote the set of functions $\omega : [0, \infty) \to [0, \infty)$ which are continuous, strictly increasing, and $\omega(0) = 0$, $\omega(\infty) = \infty$.

Any signal operator $P : \mathrm{Dom}(P) \to \mathcal{Y}$ is assumed to be causal and its domain is denoted by

$$\mathrm{Dom}(P) = \{u \in \mathcal{U}_s : Pu \in \mathcal{Y}_s\}.$$

It is worthwhile to observe that unstable plant operators $\hat{P}$ are often thought of as operators $\mathcal{U} \to \mathcal{Y}$ for suitably large signal spaces $\mathcal{U}$, $\mathcal{Y}$. We will only have to be interested in the relation between elements in $\mathrm{Dom}(P)$ and $\mathcal{Y}_s$ so do not consider the definition of P on the wider signal spaces. However, it should be noted that under extra assumptions such as causal extendibility [6] and for appropriate choices of signal space, the operator $P : \mathrm{Dom}(P) \to \mathcal{Y}_s$ uniquely extends to an operator $\hat{P} : \mathcal{U} \to \mathcal{Y}$, hence the topologies we will define on sets of operators $P : \mathrm{Dom}(P) \to \mathcal{Y}_s$ can be thought of as topologies on sets of operators $\hat{P} : \mathcal{U} \to \mathcal{Y}$.

Linear gains of operators $P : \mathrm{Dom}(P) \to \mathcal{Y}$ are defined by

$$\|P\| := \sup \left\{ \frac{\|Pu\|}{\|u\|} : u \in \mathrm{Dom}(P) \text{ with } \|u\| \neq 0 \right\}.$$

If P is causal, one can prove that

$$\|P\| = \sup \left\{ \frac{\|Pu\|_\tau}{\|u\|_\tau} : \tau > 0,\ u \in \mathrm{Dom}(P) \text{ with } \|u\|_\tau \neq 0 \right\}$$

which is used in [7] as the definition of linear gain. When P is a linear operator, $\|P\|$ is the induced operator norm of P. In the nonlinear setting, in contrast to linear systems, it is often the case that $\mathrm{Dom}(P) = \mathcal{U}_s$ and yet no linear gain exists. Therefore a weaker notion of stability is adopted, namely that of the existence of a gain function. The gain function of an operator P is defined by

$$\gamma(P)(r) := \sup\{\|Pu\|_\tau : \tau > 0,\ u \in \mathrm{Dom}(P) \text{ with } \|u\|_\tau \le r\} \quad \text{for } r \ge 0.$$

In the case where P is causal, we also have

$$\gamma(P)(r) = \sup\{\|Pu\| : u \in \mathrm{Dom}(P),\ \|u\| \le r\} \quad \text{for } r \ge 0.$$

We summarize elementary properties of the linear gain $\|P\|$ and the gain function $\gamma(P)$ in the following lemma.

LEMMA 2.1. *The linear gain and gain function have the following properties:*

1. $\gamma(P)(0) = 0$, *if* $P(0) = 0$,
2. $\gamma(P)(r_1) \le \gamma(P)(r_2)$, *if* $r_1 \le r_2$,
3. *For any two well-defined operators* P_1, P_2 *and any* $r > 0$, $\lambda \in \mathbb{R}$, *we have*

$$\begin{aligned} \|\lambda P_1\| = 0 &\iff P_1 = 0, & \gamma(P_1) = 0 &\iff P_1 = 0,\\ \|\lambda P_1\| &\le |\lambda|\|P_1\|, & \gamma(\lambda P_1)(r) &\le |\lambda|\gamma(P_1)(r),\\ \|P_1 + P_2\| &\le \|P_1\| + \|P_2\|, & \gamma(P_1 + P_2)(r) &\le \gamma(P_1)(r) + \gamma(P_2)(r),\\ \|P_1P_2\| &\le \|P_1\|\|P_2\|, & \gamma(P_1P_2)(r) &\le \gamma(P_1)(\gamma(P_2)(r)). \end{aligned}$$

4. $\gamma(P)(r) \le r\|P\|$ *for all* $r > 0$. *In particular, if* P *is linear and bounded, then* $\gamma(P)(r) = r\|P\|$.

DEFINITION 2.2. *A signal operator* P *is said to be*

(i) *gain stable if* $\|P\| < \infty$,

(ii) (gf)*-stable if* $\gamma(P)(r) < \infty$ *for each* $r \ge 0$.

We remark that gain stability implies (gf)-stability and both imply $P(\mathrm{Dom}(P)) \subset \mathcal{Y}_s$. In fact, a stable operator P maps bounded subsets of $\mathcal{U}_s$ into bounded subsets of $\mathcal{Y}_s$ (compare to [19]). As a shorthand, in the rest of this paper, a stable operator is taken to mean that the operator is stable in the sense of (gf)-stability unless specified otherwise.

DEFINITION 2.3. *A causal operator* $P : \mathrm{Dom}(P) \subset \mathcal{U}_s \to \mathcal{Y}$ *is said to admit a (right) coprime factorization if and only if there exist causal stable operators* $N : \mathcal{U}_s \to \mathcal{Y}_s$ *and* $D : \mathcal{U}_s \to \mathcal{U}_s$ *such that*

(i) D *is causally invertible with* $\mathrm{Dom}(D^{-1}) = \mathrm{Dom}(P)$,

(ii) $P = ND^{-1}$,

(iii) *there exists a causal stable mapping* $L : \mathcal{U}_s \times \mathcal{Y}_s \to \mathcal{U}_s$ *such that* $L(D, N)^\top = I$.

In that case, we also say that P *admits the coprime factorization* (N, D) *and we write* $P = ND^{-1}$. *For convenience, we call* L *the associated operator to this coprime factorization. The set of all coprime factorizations of* P *is denoted by* $\mathrm{rcf}(P)$.

In this definition, and henceforth, an operator $D : \mathcal{U}_s \to \mathcal{U}_s$ is said to be invertible with inverse D^{-1} if $D^{-1} : \mathrm{Dom}(D^{-1}) \subset \mathcal{U}_s \to \mathcal{U}_s$ is a well-defined operator and $DD^{-1}|_{\mathrm{Dom}(D^{-1})} = I$, $D^{-1}D|_{\mathcal{U}_s} = I$. Equivalently, D is required to be both left and right invertible.

DEFINITION 2.4. *Suppose* (N, D) *is a coprime factorization of* P. *If*

$$\|(D, N)^\top u\| = \|u\| \quad \text{for all } u \in \mathcal{U},$$

we say that (N, D) *is a normalized right coprime factorization of* P. *The set of all normalized right coprime factorizations is denoted by* $\mathrm{nrcf}(P)$.

Definitions 2.3 and 2.4 are generalizations of the coprime factorization and normalized coprime factorization for linear operators (see [20]) to the nonlinear case, as considered previously by various authors. Definition 2.3 is given by Verma and Hunt in [19] (see also [12, 18]) where the stability is in the sense of "bounded input implies bounded output" (resp., linear gain) between normed spaces. Sontag [17] also

defined the concept in which L is required to be of the form (B, A) with $A : \mathcal{Y} \to \mathcal{U}$, $B : \mathcal{U} \to \mathcal{U}$. Others using this Bezout identity to define coprime factorizations for nonlinear systems include Hammer [9], James, Smith, and Vinnicombe [10], Moore and Irlichet [11], etc. Whilst the Bezout identity $BN + AD = I$ always appears in the linear case, the more general form of L is less restrictive in the nonlinear setting. Generalizations of normalized coprime factorization, including those for specific signal operators, can be found in [2, 10, 13, 14, 15] and the references therein.

Existence and construction of (normalized) coprime factorizations for certain classes of nonlinear systems have been considered previously. For example, in [2, 10, 13, 15], normalized coprime factorizations for stabilizable nonlinear affine systems

$$x' = f(x) + g(x)u, \qquad y = C(x)$$

were constructed; Sontag [17] proved that, in the sense of IOS, if the above system with $C = I$ is smoothly input to stay stable by a controller of the form $u = k(x) + v$, then its input to state mapping $P : u \mapsto x$ admits a coprime factorization with $L = (I, A)$, where $-A$ is the memoryless operator induced by the smooth state feedback controller $u = k(x)$, N is the input to state mapping $v \mapsto x$ of the closed-loop system, and $D = I - AN$. Similar existence results were obtained by Verma and Hunt [19], in the sense of (gf)-stability, for the causal I/O mapping of the system

$$x'(t) = f(x(t), u(t), t), \qquad x(0) = x_0, \qquad y(t) = h(x(t), u(t), t)$$

in the case when $\mathcal{U}$, $\mathcal{Y}$ are L^p spaces. Other references to the state space construction of coprime factors can be found in [14] and the references therein.

The following two results can be found in [18] where the notion of stability is in the sense of a finite linear gain. However, the proofs remain valid in the context of (gf)-stability, hence we omit the proofs.

PROPOSITION 2.5. *Suppose P admits coprime right factorization (N, D). Then*

$$\mathrm{Graph}(P) := \{(u, Pu)^\top : u \in \mathrm{Dom}(P)\} = \{(Du, Nu)^\top : u \in \mathcal{U}_s\}.$$

Proof. See [18]. □

PROPOSITION 2.6. *$(N, D), (N_1, D_1) \in \mathrm{rcf}(P)$ if and only if there exists a causally stable operator U on $\mathcal{U}_s$, where U^{-1} exists, is stable, and is such that $N = N_1 U$, $D = D_1 U$.*

Proof. See [18]. □

If the coprime factorizations in Proposition 2.6 are also normalized, then we also have the following proposition.

PROPOSITION 2.7. *If $(N, D), (N_1, D_1) \in \mathrm{nrcf}$, then the operator U in Proposition 2.6 is such that $\|Uu\| = \|U^{-1}u\| = \|u\|$ for all $u \in \mathcal{U}_s$.*

Proof. Let $u \in \mathcal{U}_s$. By Proposition 2.6 and the definition of normalized coprime factorization, we see $\|U^{-1}u\| = \|(D, N)^\top U^{-1}u\| = \|(D_1, N_1)^\top U U^{-1}u\| = \|(D_1, N_1)^\top u\| = \|u\|$ and, similarly, $\|Uu\| = \|(D_1, N_1)^\top Uu\| = \|(D, N)^\top U^{-1}Uu\| = \|(D, N)^\top u\| = \|u\|$. This proves the proposition. □

3. Graph topologies. In this section, we will study graph topologies on the set of certain signal operators having coprime factorizations. As in the linear case, we will show that the graph topologies play a natural role in the theory of closed loop robust stability.

In practice, the signal spaces, operators, and associated coprime factorizations concerned are constrained to lie within certain classes for different control problems.

For example, one may only be interested in the case when $\mathcal{U} = L_n^{\infty,e}$, $\mathcal{Y} = L_m^{\infty,e}$, and where all operators considered lie in the subset of I/O operators of all affine (nonlinear) systems.

Here we list some particular categories that will be considered in this paper.

- Category nor : $\mathcal{U}, \mathcal{Y}$ are general signal spaces as assumed and all operators considered are those that admit normalized coprime factorizations in the sense defined in the last section.
- Category ω with $\omega \in \mathcal{K}_\infty$: $\mathcal{U}, \mathcal{Y}$ are general signal spaces and all operators F considered are such that $\mathrm{rcf}(F) \neq \emptyset$ and $\sup_{r>0} \frac{\gamma((N,D)^\top)(\omega(r))}{r} < \infty$ for all $(N, D) \in \mathrm{rcf}(F)$.
- Category $\mathbf{L}$: $\mathcal{U}$, $\mathcal{Y}$ are both the frequency domain Hardy spaces $\mathcal{H}_2$ (see [20]), operators are the real rational $p \times q$ transfer function matrices, and the associated coprime factorizations are those linear factorizations over $\mathcal{RH}_\infty$[1] as in [20] or [21].

Since $F \equiv 0$ has normalized coprime factorization $(0, I)$, we see that each category is nonempty.

The graph topologies will be defined on a general category although in the next section we mainly consider $\mathbf{N}_{\mathrm{nor}}(\mathcal{U}, \mathcal{Y})$ and $\mathbf{N}_\omega(\mathcal{U}, \mathcal{Y})$. So we use Γ to represent the category concerned and write

$$\mathbf{N}_\Gamma(\mathcal{U}, \mathcal{Y}) := \left\{ P : \mathrm{Dom}(P) \subset \mathcal{U} \to \mathcal{Y} : \begin{array}{l} P \text{ and the associated rcfs} \\ N, D \text{ are within category } \Gamma \end{array} \right\}.$$

Correspondingly, we have notations $\mathbf{N}_{\mathrm{nor}}(\mathcal{U}, \mathcal{Y})$, $\mathbf{N}_\omega(\mathcal{U}, \mathcal{Y})$, and $\mathbf{N}_{\mathbf{L}}(\mathcal{H}_2, \mathcal{H}_2) =: \mathbf{N}_{\mathbf{L}}$. For example

$$\mathbf{N}_{\mathrm{nor}}(\mathcal{U}, \mathcal{Y}) := \{P : \mathrm{Dom}(P) \subset \mathcal{U} \to \mathcal{Y} \text{ and } \mathrm{nrcf}(P) \neq \emptyset\}.$$

$$\mathbf{N}_\omega(\mathcal{U}, \mathcal{Y}) := \left\{ P : \mathrm{Dom}(P) \subset \mathcal{U} \to \mathcal{Y} : \begin{array}{l} \mathrm{rcf}(P) \neq \emptyset \text{ and for all } (N, D) \in \mathrm{rcf}(P), \\ \sup\limits_{r>0} \dfrac{\gamma((N,D)^\top)(\omega(r))}{r} < \infty \end{array} \right\}.$$

A graph topology for $\mathbf{N}_{\mathbf{L}}$, denoted by $\mathcal{T}_{\mathbf{L}}$, has been defined in [20] by the following local base for $P \in \mathcal{RH}_\infty$:

$$\mathcal{N}(N, D; \varepsilon) = \{N_1 D_1^{-1} : \|(N_1 - N, D_1 - D)^\top\|_\infty < \varepsilon,\ N, D, N_1, D_1 \in \mathcal{RH}_\infty\} \tag{3.1}$$

with $\varepsilon > 0, (N, D) \in \mathrm{rcf}(P)$, and $(N_1, D_1) \in \mathrm{rcf}(N_1 D_1^{-1})$, respectively. We will show that our L^2 topologies for $\mathbf{N}_{\mathbf{L}}$ are the same as $\mathcal{T}_{\mathbf{L}}$.

For notational ease in what follows, any pairs N, D or N_k, D_k are always assumed to be coprime factorizations of $P = ND^{-1}$ and $P_k = N_k D_k^{-1}$, respectively, and P and P_k are taken to be well-defined operators from $\mathrm{Dom}(P) \to \mathcal{Y}_s$, $\mathrm{Dom}(P_k) \to \mathcal{Y}_s$, respectively.

[1] $\mathcal{H}_2$ is the space of Fourier transforms of signals in $L^2(\mathbb{R}_+, \mathbb{R}^n)$ endowed with the norm $\|x\|_2^2 := \frac{1}{2\pi} \int_{-\infty}^{\infty} x^*(j\omega) x(j\omega) d\omega$. By Parseval's theorem, it is isometrically isomorphic to $L^2(\mathbb{R}_+, \mathbb{R}^n)$ and therefore the two notations are not distinguished. $\mathcal{RH}_\infty$ is the space of rational transfer functions of stable linear, time-invariant, continuous time systems endowed with the norm $\|P\|_\infty := \sup_{\omega \in \mathbb{R}} \bar{\sigma}[P(j\omega)]$, where $\bar{\sigma}$ denotes the maximum singular value. Equivalently, $\|P\|_\infty := \sup\{\|Pu\|_{\mathcal{H}_2} / \|u\|_{\mathcal{H}_2} : u \in \mathcal{H}_2, u \neq 0\}$. So by Paserval's theorem, the H_∞-norm in the frequency domain corresponds to the induced L^2 norm in the time domain.

3.1. Pointwise graph topology. Let $\Re$ be the vector space of all functions from $\mathbb{R}^+$ to $\mathbb{R}$. For any open subset $\Omega \subset \mathbb{R}$ and a finite subset $\{t_1, \dots, t_n\} \subset \mathbb{R}^+$, let

$$\mathcal{V}(t_1, \dots, t_n; \Omega) = \{f \in \Re : f(t_i) \in \Omega\}.$$

It can be proved that $\{\mathcal{V}(t_1, \dots, t_n; \Omega) : t_i \in \mathbb{R}^+,\ n > 0,\ \Omega \subset \mathbb{R},\ \Omega \text{ open}\}$ forms a subbase for a topology on $\Re$. Moreover, the family of subsets

$$\Re_0 = \{\mathcal{V}(t_1, \dots, t_n; \varepsilon) := \mathcal{V}(t_1, \dots, t_n; (-\varepsilon, \varepsilon)) : \varepsilon > 0,\ t_i \in \mathbb{R}^+,\ n > 0\}$$

is a base for the neighborhood of $f(t) \equiv 0$ in $\Re$ under such a topology.

For each $P \in \mathbf{N}_\Gamma(\mathcal{U}, \mathcal{Y})$ with coprime factorization (N, D) and each $V \in \Re_0$, we define

$$O(N, D; V) = \{P_1 = N_1 D_1^{-1} \in \mathbf{N}_\Gamma(\mathcal{U}, \mathcal{Y}) : \gamma((D - D_1, N - N_1)^\top) \in V\}.$$

Obviously, $P = ND^{-1} \in O(N, D; V)$ for each $V \in \Re_0$. Moreover, we have the following proposition.

PROPOSITION 3.1. *If $ND^{-1} \in O(N_1, D_1; V_1) \cap O(N_2, D_2; V_2)$, then there exist $V \in \Re_0$ such that $O(N, D; V) \subset O(N_1, V_1) \cap O(N_2, D_2; V_2)$.*

Proof. We may suppose $V_1 = \mathcal{V}(t_1, \dots, t_n; \varepsilon_1), V_2 = \mathcal{V}(s_1, \dots, s_m; \varepsilon_2)$ with $t_i > 0$, $s_j > 0$, $\varepsilon_k > 0$ $(i = 1, \dots, n,\ j = 1, \dots, m,\ k = 1, 2)$. Then $\varepsilon_1 - \gamma((D - D_1, N - N_1)^\top)(t_i)$ and $\varepsilon_2 - \gamma((D - D_2, N - N_2)^\top)(s_j)$ are all positive numbers. Let $\varepsilon > 0$ such that

$$\varepsilon < \min \begin{Bmatrix} \varepsilon_1 - \gamma((D - D_1, N - N_1)^\top)(t_i), & i = 1, \dots, n, \\ \varepsilon_2 - \gamma((D - D_2, N - N_2)^\top)(s_j), & j = 1, \dots, m \end{Bmatrix}.$$

If $\tilde{N}\tilde{D}^{-1} \in O(N, D; V)$ with $V = \mathcal{V}(t_1, \dots, t_n, s_1, \dots, s_m; \varepsilon)$, then

$$\begin{aligned} \gamma((\tilde{D} - D_1, \tilde{N} - N_1)^\top)(t_i) &\le \gamma((\tilde{D} - D, \tilde{N} - N)^\top)(t_i) + \gamma((D - D_1, N - N_1)^\top)(t_i) \\ &< \varepsilon_1 - \gamma((D - D_1, N - N_1)^\top)(t_i) \\ &+ \gamma((D - D_1, N - N_1)^\top)(t_i) = \varepsilon_1 \end{aligned}$$

for all $i = 1, \dots, n$. This gives $\tilde{N}\tilde{D}^{-1} \in O(N_1, D_1; V_1)$. Similarly, we can show $\tilde{N}\tilde{D}^{-1} \in O(N_2, D_2; V_2)$. Therefore, $\tilde{N}\tilde{D}^{-1} \in O(N_1, D_1; V_1) \cap O(N_2, D_2; V_2)$ which means $O(N, D; V) \subset O(N_1, D_1; V_1) \cap O(N_2, D_2; V_2)$. ∎

From the above result, it follows that a topology on $\mathbf{N}_\Gamma(\mathcal{U}, \mathcal{Y})$ can be uniquely determined by the base $\mathbb{B}$, where

$$\mathbb{B} = \{O(N, D; V) : ND^{-1} \in \mathbf{N}_\Gamma(\mathcal{U}, \mathcal{Y}),\ V \in \Re_0\},$$

and $\{O(N, D; V) : ND^{-1} = P,\ V \in \Re_0\}$ a local base of P. We denote this topology by $\mathcal{T}$ and call it the *pointwise* (*graph*) *topology* (see the preceding footnote). The following proposition provides an alternative base for this topology.

PROPOSITION 3.2. *Let Q_+ be the set of all positive rational numbers and*

$$O'(N, D; r, \varepsilon) = \{N_1 D_1^{-1} \in \mathbf{N}_\Gamma(\mathcal{U}, \mathcal{Y}) : \gamma((D - D_1, N - N_1)^\top)(r) < \varepsilon\}.$$

Then a base for the pointwise graph topology $\mathcal{T}$ is the family of subsets

$$\mathbb{B}' = \{O'(N, D; r, \varepsilon) : ND^{-1} \in \mathbf{N}_\Gamma(\mathcal{U}, \mathcal{Y}),\ r, \varepsilon \in Q_+\}.$$

Proof. Obviously $\mathbb{B}' \subset \mathbb{B}$. Suppose $O(N, D; V) \in \mathbb{B}$ with $V = \mathcal{V}(t_1, \dots, t_n; \varepsilon)$. Let $r, \varepsilon_1 \in Q$ such that $r > \max\{t_1, \dots, t_n\}$ and $\varepsilon_1 < \varepsilon$. Then for each $N_1 D_1^{-1} \in O'(N, D; r, \varepsilon_1)$, from Lemma 2.1 (2.), it follows that

$$\gamma((D_1 - D, N_1 - N)^\top)(t_i) \le \gamma((D_1 - D, N_1 - N)^\top)(t) < \varepsilon_1 < \varepsilon$$

for all $i = 1, \dots, n$. This means $N_1 D_1^{-1} \in O(N, D; V)$ and therefore $O'(N, D; r, \varepsilon) \subset O(N, D; V)$. Hence $\mathbb{B}$ and $\mathbb{B}'$ are equivalent. □

If we restrict our consideration to $\mathbf{N_L}$, from Lemma 2.1 (4.) and (3.1), we see

$$\begin{aligned} O'(N, D; r, \varepsilon) &= \{N_1 D_1^{-1} : \gamma((D - D_1, N - N_1)^\top)(r) < \varepsilon,\ N, D, N_1, D_1 \in \mathcal{RH}_\infty\} \\ &= \left\{N_1 D_1^{-1} : \|(D - D_1, N - N_1)^\top\| < \frac{\varepsilon}{r} =: \varepsilon_1,\ N, D, N_1, D_1 \in \mathcal{RH}_\infty\right\} \\ &= \mathcal{N}(N, D; \varepsilon_1), \end{aligned}$$

hence we have the following corollary.

COROLLARY 3.3. *The pointwise graph topology $\mathcal{T}$ in the category $\mathbf{L}$ is the same as the graph topology $\mathcal{T}_{\mathbf{L}}$.*

Now we begin to consider the convergence of sequences under the pointwise topology. The following result shows that any convergent sequence has only one limit.

PROPOSITION 3.4. *The pointwise graph topology $\mathcal{T}$ is Hausdorff. Therefore, the limit point of a convergent sequence is unique.*

Proof. Let $P_1 \neq P_2$ be two distinct plants. Then there exist $(N_1, D_1) \in \mathrm{rcf}(P_1)$, $(N_2, D_2) \in \mathrm{rcf}(P_2)$ with $(D_1, N_1)^\top \neq (D_2, N_2)^\top$. This shows

$$\varepsilon := \gamma((D_1 - D_2, N_1 - N_2)^\top)(r) > 0 \quad \text{for some } r > 0.$$

Consider the neighborhoods $O(N_1, D_1; r, \varepsilon/3)$ of P_1 and $O(N_2, D_2; r, \varepsilon/3)$ of P_2. If there exists $P = ND^{-1} \in O(N_1, D_1; r, \varepsilon/3) \cap O(N_2, D_2; r, \varepsilon/3)$, since

$$\begin{aligned} \gamma((N_1 - N_2, D_1 - D_2)^\top)(r) \le{}& \gamma((N_1 - N, D_1 - D)^\top)(r) \\ &+ \gamma((N_2 - N, D_2 - D)^\top)(r), \end{aligned}$$

we see $\gamma((N_1 - N_2, D_1 - D_2)^\top)(r) < \varepsilon$. This is a contradiction. Hence we have that $O(N_1, D_1; r, \varepsilon/3) \cap O(N_2, D_2; r, \varepsilon/3) = \emptyset$, which proves the proposition. □

Suppose $\{P_n\} \subset \mathbf{N}_\Gamma(\mathcal{U}, \mathcal{Y})$ is a sequence. We let $P_n \xrightarrow{\mathcal{T}} P$ denote the convergence of the sequence $\{P_n\}_{n \ge 1}$ to P under the graph topology $\mathcal{T}$. From Proposition 3.2, we see that $P_n \xrightarrow{\mathcal{T}} P$ means that, for any $r > 0$, $\varepsilon > 0$ and each coprime factorization ND^{-1} of P, there exist $n_0 > 0$ and coprime factorization $N_n D_n^{-1}$ of P_n such that $N_n D_n^{-1} \in O(N, D; r, \varepsilon)$ for all $n \ge n_0$. Necessary and sufficient conditions for this convergence are given below.

THEOREM 3.5. *The following statements are equivalent.*

(i) $P_n \xrightarrow{\mathcal{T}} P$.

(ii) *For each $(N, D) \in \mathrm{rcf}(P)$, there exists $(N_n, D_n) \in \mathrm{rcf}(P_n)$ such that*

$$\gamma((D_n - D, N_n - N)^\top)(r) \to 0 \quad \textit{for each } r > 0.$$

(iii) *There exists $(N, D) \in \mathrm{rcf}(P)$ and, for each n, there exists $(N_n, D_n) \in \mathrm{rcf}(P_n)$ such that*

$$\gamma((D_n - D, N_n - N)^\top)(r) \to 0 \quad \textit{for all } r > 0.$$

Proof. (ii)⇒(i) and (ii)⇒(iii) are immmediate; we need only to prove (i)⇒(ii) and (iii)⇒(ii).

(i)⇒(ii). Let $r > 0$ and $P = ND^{-1}$ be given. According to the assumptions, for each $\varepsilon > 0$ and $n > 0$, there exists coprime factorization $N_{n,\varepsilon}D_{n,\varepsilon}^{-1}$ of P_n and $n_\varepsilon > 0$ such that $N_{n,\varepsilon}D_{n,\varepsilon}^{-1} \in O(N, D; r, \varepsilon)$ for all $n \geq n_\varepsilon$. Let $\varepsilon = 1, 1/2, \ldots, 1/2^k, \cdot$, respectively, to obtain the corresponding integers $n_k := n_{1/2^k}$. Define

$$N_n = N_{n,1/2^k} \quad \text{and} \quad D_n = D_{n,1/2^k} \quad \text{for } n_k \leq n < n_{k+1}.$$

Then $N_nD_n^{-1}$ is a coprime factorization of P_n and $N_nD_n^{-1} \in O(N, D; r, 1/2^k)$ for $n \geq n_k$. Hence $\gamma((D_n - D, N_n - N)^\top)(r) \to 0$.

(iii)⇒(ii). Suppose $(\tilde{N}, \tilde{D})$ is an arbitrary coprime factorization of P. Then by Proposition 2.6, there exists stable operator U with $\tilde{N} = NU$, $\tilde{D} = DU$. Moreover, $(\tilde{N}_n, \tilde{D}_n) := (N_nU, D_nU)$ is a coprime factorization of P_n due to the same proposition. Using Lemma 2.1, we have

$$\gamma((\tilde{D}_n - \tilde{D}, \tilde{N}_n - \tilde{N})^\top)(r) \leq \gamma((D_n - D, N_n - N)^\top)(\gamma(U)(r)).$$

The stability of U and the assumption ensure $\gamma((\tilde{D}_n - \tilde{D}, \tilde{N}_n - \tilde{N})^\top)(r) \to 0$ as $n \to \infty$ and, therefore, (ii) has been established. This completes the proof. □

Because the continuity of a mapping from a first-countable topological space to another topological space can be described by the convergence of sequences, we have the following corollary.

COROLLARY 3.6. *Let Λ be a first-countable topological space, $P_\lambda : \Lambda \to \mathbf{N}_\Gamma(\mathcal{U}, \mathcal{Y})$. Then $\lambda \mapsto P_\lambda$ is continuous at $\lambda = \lambda_0$ under the pointwise graph topology $\mathcal{T}$ if and only if there exist coprime factorizations $P_{\lambda_0} = N_0D_0^{-1}$ and $P_\lambda = N_\lambda D_\lambda^{-1}$ for each $\lambda \in \Lambda$ such that*

$$\gamma((D_0 - D_\lambda, N_0 - N_\lambda)^\top)(r) \to 0 \quad \textit{for all } r \geq 0 \textit{ as } \lambda \to \lambda_0.$$

3.2. Weighted graph topology. In this section, we consider another topology on the set $\mathbf{N}_\Gamma(\mathcal{U}, \mathcal{Y})$, which will be related to a given function $\omega \in \mathcal{K}_\infty$ and a weighted gain $\|\cdot\|_\omega$ defined by

$$\|\mathbf{P}\|_\omega = \sup_{r>0} \frac{\gamma(\mathbf{P})(\omega(r))}{r} \quad \text{for any signal operator } \mathbf{P}.$$

It is straightforward to prove that $\|\cdot\|_\omega$ is a norm. Moreover, if $\omega(r) \geq c_1 r$ with $c_1 > 0$ for all $r > 0$, then $\|\mathbf{P}\|_\omega \geq c_1\|\mathbf{P}\|$. If $\mathbf{P}0 = 0$, $c_2 > 0$, and $\omega(r) \leq c_2 r$ for all $r > 0$, then $\|\mathbf{P}\|_\omega \leq c_2\|\mathbf{P}\|$.

Let

$$\Sigma = \{\mathbf{P} : \mathcal{U} \to \mathcal{U} \times \mathcal{Y} \text{ with } \|\mathbf{P}\|_\omega < \infty\},$$

It can be seen from the basic properties of γ that Σ is a linear space and therefore $(\Sigma, \|\cdot\|_\omega)$ is a normed space. The norm induces a corresponding topology on Σ, of which a local base of open ball neighborhoods of $\mathbf{P} \equiv 0$ is denoted by $\mathcal{B}$.

For each $P \in \mathbf{N}_\Gamma(\mathcal{U}, \mathcal{Y})$ with coprime factorization $P = ND^{-1}$ and each $V \in \mathcal{B}$, we denote by

$$O_\omega(N, D; V) = \{N_1D_1^{-1} \in \mathbf{N}_\Gamma(\mathcal{U}, \mathcal{Y}) : (D - D_1, N - N_1)^\top \in V\}.$$

Obviously, $P = ND^{-1} \in O_\omega(N, D; V)$ for each $V \in \mathcal{B}$. Moreover, we have the following proposition.

PROPOSITION 3.7. *If $ND^{-1} \in O_\omega(N_1, D_1; V_1) \cap O_\omega(N_2, D_2; V_2)$, then there exist $V \in \mathcal{B}$ such that $O_\omega(N, D; V) \subset O_\omega(N_1, V_1) \cap O_\omega(N_2, D_2; V_2)$.*

Proof. We may suppose that $V_i = \{\mathbf{P} \in \Sigma : \|\mathbf{P}\|_\omega < \varepsilon_i\}$ with $\varepsilon_i > 0$, $i = 1, 2$. Let

$$\alpha_i = \sup_{r>0} \frac{\gamma((D - D_i, N - N_i)^\top)(\omega(r))}{r}, \quad i = 1, 2$$

and let ε be a positive number such that $\varepsilon < \min\{\varepsilon_1 - \alpha_1, \varepsilon_2 - \alpha_2\}$. Then for each $\tilde{N}\tilde{D}^{-1} \in O_\omega(N, D; \varepsilon)$ and each $r > 0$, from the third property of γ, it follows that

$$\begin{aligned}\frac{\gamma((\tilde{D} - D_i, \tilde{N} - N_i)^\top)(\omega(r))}{r} &\le \frac{\gamma((\tilde{D} - D, \tilde{N} - N)^\top)(\omega(r))}{r} \\ &\quad + \frac{\gamma((D - D_i, N - N_i)^\top)(\omega(r))}{r} \\ &< \varepsilon + \alpha_i, \quad i = 1, 2.\end{aligned}$$

Hence

$$\sup_{r>0} \frac{\gamma((\tilde{D} - D_i, \tilde{N} - N_i)^\top)(\omega(r))}{r} \le \varepsilon + \alpha_i < \varepsilon_i - \alpha_i + \alpha_i = \varepsilon_i, \quad i = 1, 2.$$

This implies $\tilde{N}\tilde{D}^{-1} \in O_\omega(N_1, D_1; \varepsilon_1) \cap O_\omega(N_2, D_2; \varepsilon_2)$ and, therefore, $O_\omega(N, D; \varepsilon) \subset O_\omega(N_1, D_1; \varepsilon_1) \cap O_\omega(N_2, D_2; \varepsilon_2)$. □

Let

$$\mathbb{B}_\omega = \{O_\omega(N, D; V) : ND^{-1} \in \mathbf{N}_\Gamma(\mathcal{U}, \mathcal{Y}),\ V \in \mathcal{B}\}.$$

From the above result, it follows that a topology on $\mathbf{N}_\Gamma(\mathcal{U}, \mathcal{Y})$ can be uniquely determined with $\mathbb{B}_\omega$ as its base. We denote this topology by $\mathcal{T}_\omega$ and call it the *weighted (graph) topology* related to function ω. Obviously, $\mathcal{T}_\omega$ has a countable local base.

If $\mathbf{P} \in \Sigma$ is linear and $\omega(t) \equiv t$, then from Lemma 2.1 (4.), we see that $\|\mathbf{P}\|_\omega = \|\mathbf{P}\|$. Therefore, if we restrict attention to $\mathbf{N}_\mathbf{L}$, then for each $P = ND^{-1} \in \mathcal{RH}_\infty$ and $V = \{\mathbf{P} : \mathcal{H}_2 \to \mathcal{H}_2 \times \mathcal{H}_2,\ \|\mathbf{P}\|_\omega < \varepsilon\}$, we have

$$O_\omega(N, D; V) = \{N_1 D_1^{-1} : \|(N_1 - N, D_1 - D)^\top\| < \varepsilon,\ N, D, N_1, D_1 \in \mathcal{RH}_\infty\}$$

and $O_\omega(N, D; V) = \mathcal{N}(N, D; \varepsilon)$. This fact yields the following corollary.

COROLLARY 3.8. *For $\omega(t) \equiv t$ and $\mathbf{N}_\Gamma(\mathcal{U}, \mathcal{Y}) = \mathbf{N}_\mathbf{L}$, the weighted graph topology $\mathcal{T}_\omega$ is the same as the graph topology $\mathcal{T}_\mathbf{L}$ defined for $\mathbf{N}_\mathbf{L}(\mathcal{U}, \mathcal{Y})$.*

From Proposition 3.7, we see that a sequence of operators $\{P_n\}_{n\ge1}$ converging to P under this graph topology, denoted by $P_n \xrightarrow{\mathcal{T}_\omega} P$, means that, for any $\varepsilon > 0$ and each coprime factorization ND^{-1} of P, there exist $n_0 > 0$ and coprime factorization $N_n D_n^{-1}$ of P_n such that $\|(D_n - D, N_n - N)^\top\|_\omega < \varepsilon$ for all $n \ge n_0$.

Using a method similar to the one used in Proposition 3.4, we can also prove that the weighted topology is a Hausdorff topology. So a convergent sequence has a unique limit.

THEOREM 3.9. *$P_n \xrightarrow{\mathcal{T}_\omega} P$ if and only if for each coprime factorization ND^{-1} of P, there exists coprime factorization $N_n D_n^{-1}$ of P_n such that*

$$\sup_{r>0} \frac{\gamma((D_n - D, N_n - N)^\top)(\omega(r))}{r} \to 0.$$

Proof. The proof is omitted for brevity as it follows the same reasoning as used in the first part proof for Theorem 3.5. □

Two immediate corollaries are as follows.

COROLLARY 3.10. *If* $P_n \xrightarrow{\mathcal{T}_\omega} P$, *then* $P_n \to P$ *under the pointwise graph topology* $\mathcal{T}$.

COROLLARY 3.11. *Let* Λ *be a first-countable topological space,* $P_\lambda : \Lambda \to \mathbf{N}_\Gamma(\mathcal{U}, \mathcal{Y})$. *Then* $\lambda \mapsto P_\lambda$ *is continuous at* $\lambda = \lambda_0$ *under a weighted graph topology* $\mathcal{T}_\omega$ *if and only if for each coprime factorization* $P_{\lambda_0} = N_0 D_0^{-1}$, *there exist coprime factorization* $P_\lambda = N_\lambda D_\lambda^{-1}$ *for each* $\lambda \in \Lambda$ *such that*

$$\gamma((D_0 - D_\lambda, N_0 - N_\lambda)^\top)(r) \to 0 \quad \text{for all } r \geq 0 \text{ as } \lambda \to \lambda_0.$$

To conclude this section, we observe that given two functions $\omega_1, \omega_2 \in \mathcal{K}_\infty$, each generates a weighted graph topology $\mathcal{T}_{\omega_1}, \mathcal{T}_{\omega_2}$. If $\omega_1(r) \leq \omega_2(r)$ for all $r \in \mathbb{R}^+$, then $\|\mathbf{P}\|_{\omega_1} \leq \|\mathbf{P}\|_{\omega_2}$ for all $\mathbf{P} : \mathcal{U} \to \mathcal{U} \times \mathcal{Y}$. Therefore

$$O_{\omega_2}(N, D; V) \subset O_{\omega_1}(N, D; V) \quad \text{for all } ND^{-1} \in \mathbf{N}_\Gamma(\mathcal{U}, \mathcal{Y}),\ V \in \mathcal{B}.$$

This implies the following comparison theorem.

THEOREM 3.12. *Suppose* $\omega_1, \omega_2 \in \mathcal{K}_\infty$ *satisfying* $\omega_1(r) \leq \omega_2(r)$ *for all* $r > 0$. *Then* $\mathcal{T}_{\omega_2}$ *is stronger than* $\mathcal{T}_{\omega_1}$ *(i.e., any sequence converging under* $\mathcal{T}_{\omega_2}$ *will converge under* $\mathcal{T}_{\omega_1}$*). Additionally,* $\mathcal{T}_{c\omega_1}$ *and* $\mathcal{T}_{\omega_1}$ *are equivalent for any* $c > 0$ *(i.e., they induce the same convergence).*

In particular we have the following corollary.

COROLLARY 3.13. *The linear gain induces a graph topology (denoted by* $\mathcal{T}_{lg}$*) on* $\mathbf{N}_\Gamma(\mathcal{U}, \mathcal{Y})$. *If* $c_1 r \leq \omega(r) \leq c_2 r$ *for all* $r \geq 0$, *then* $\mathcal{T}_\omega$ *and* $\mathcal{T}_{lg}$ *are equivalent.*

Hence it can be seen that the weighted graph topologies inherit the partial order given by the natural partial order on the weights.

4. Metrizability. The question addressed in this section is simply whether the nonlinear graph topologies introduced earlier can be sensibly metrized. In the linear case it is well known that the answer is affirmative. We will show that useful metrics can also be given for the weighted nonlinear graph topology. We will introduce a number of metrics on specific subsets of $\mathbf{N}(\mathcal{U}, \mathcal{Y})$ and prove that some of them induce the weighted graph topology.

Throughout this section, we suppose $\omega \in \mathcal{K}_\infty$ is a given function, $\|\cdot\|_\omega$ is the weighted gain, and $\mathcal{U}$, $\mathcal{Y}$, $\mathcal{U}_s$, $\mathcal{Y}_s$ are defined as before. Every signal operator P (say) is assumed to be causal and $P(0) = 0$.

4.1. The metric formulas. We define

$$\begin{aligned}
\mathcal{Q} &= \{Q : \mathcal{U}_s \to \mathcal{U}_s \text{ is stable and } Q^{-1} \text{ exists and is also stable}\},\\
\mathcal{Q}^* &= \{Q : \mathcal{U}_s \to \mathcal{U}_s \text{ is stable and } Q^{-1} \text{ exists (bijective)}\},\\
\mathcal{Q}^s &= \{Q : \mathcal{U}_s \to \mathcal{U}_s \text{ is stable and surjective}\}.
\end{aligned}$$

The subsets of signal operators we will consider are $\mathbf{N}_\omega(\mathcal{U}, \mathcal{Y})$ and $\mathbf{N}_{\text{nor}}(\mathcal{U}, \mathcal{Y})$ as defined in the last section. Recall that

$$\begin{aligned}
\mathbf{N}_\omega(\mathcal{U}, \mathcal{Y}) &= \{P \in \mathbf{N}(\mathcal{U}, \mathcal{Y}) : \|(D, N)^\top\|_\omega < \infty \text{ for all } (N, D) \in \text{rcf}(P)\},\\
\mathbf{N}_{\text{nor}}(\mathcal{U}, \mathcal{Y}) &= \{P \in \mathbf{N}_\omega(\mathcal{U}, \mathcal{Y}) : \text{nrcf}(P) \neq \emptyset\}.
\end{aligned}$$

We now define seven functionals over the above sets:

$$d_1(P_1,P_2) = \max\{\vec{d}_1(P_1,P_2),\vec{d}_1(P_2,P_1)\}, \quad \text{for } P_1,P_2 \in \mathbf{N}_\omega(\mathcal{U},\mathcal{Y}),$$

$$\text{where } \vec{d}_1(P_1,P_2) := \sup_{(N_1,D_1)\in \mathrm{rcf}(P_1)} \inf_{(N_2,D_2)\in \mathrm{rcf}(P_2)} \|(D_1-D_2, N_1-N_2)^\top\|_\omega;$$

$$d_2(P_1,P_2) = \max\{\vec{d}_2(P_1,P_2),\vec{d}_2(P_2,P_1)\} \quad \text{for } P_1,P_2 \in \mathbf{N}_{\mathrm{nor}}(\mathcal{U},\mathcal{Y}),$$

$$\text{where } \vec{d}_2(P_1,P_2) = \inf_{\substack{Q\in\mathcal{Q}\\ \|Q\|\le 1}} \|(D_1-D_2Q, N_1-N_2Q)^\top\|_\omega,\ (N_i,D_i)\in \mathrm{nrcf}(P_i),\ i=1,2;$$

$$d_3(P_1,P_2) = \max\{\vec{d}_3(P_1,P_2),\vec{d}_3(P_2,P_1)\} \quad \text{for } P_1,P_2 \in \mathbf{N}_{\mathrm{nor}}(\mathcal{U},\mathcal{Y}),$$

$$\text{where } \vec{d}_3(P_1,P_2) = \inf_{\substack{Q\in\mathcal{Q}^*\\ \|Q\|\le 1}} \|(D_1-D_2Q, N_1-N_2Q)^\top\|_\omega,\ (N_i,D_i)\in \mathrm{nrcf}(P_i),\ i=1,2;$$

$$d_4(P_1,P_2) = \log(1+\max\{\vec{d}_4(P_1,P_2),\vec{d}_4(P_2,P_1)\}) \quad \text{for any } P_1,P_2 : \mathcal{U}\to\mathcal{Y},$$

$$\text{where } \vec{d}_4(P_1,P_2) = \begin{cases} \inf\left\{\|I-\Phi\|_\omega : \begin{array}{l}\Phi \text{ is a surjective mapping from}\\ \mathrm{Graph}(P_1) \text{ to } \mathrm{Graph}(P_2),\ \Phi(0)=0\end{array}\right\},\\ \infty \text{ if no such operator } \Phi \text{ exists;}\end{cases}$$

$$d_5(P_1,P_2) = \log(1+\max\{\vec{d}_5(P_1,P_2),\vec{d}_5(P_2,P_1)\}) \quad \text{for any } P_1,P_2 : \mathcal{U}\to\mathcal{Y},$$

$$\text{where } \vec{d}_5(P_1,P_2) = \begin{cases} \inf\left\{\|I-\Phi\|_\omega : \begin{array}{l}\Phi \text{ is a bijective mapping from}\\ \mathrm{Graph}(P_1) \text{ to } \mathrm{Graph}(P_2),\ \Phi(0)=0\end{array}\right\},\\ \infty \text{ if no such operator } \Phi \text{ exists;}\end{cases}$$

$$d_6(P_1,P_2) = \log(1+\max\{\vec{d}_6(P_1,P_2),\vec{d}_6(P_2,P_1)\}) \quad \text{for } P_1,P_2 \in \mathbf{N}_{\mathrm{nor}}(\mathcal{U},\mathcal{Y}),$$

$$\text{where } \vec{d}_6(P_1,P_2) = \inf_{Q\in\mathcal{Q}^*} \|(D_1-D_2Q, N_1-N_2Q)^\top\|_\omega,\ (N_i,D_i)\in \mathrm{nrcf}(P_i),\ i=1,2;$$

$$d_7(P_1,P_2) = \log(1+\max\{\vec{d}_7(P_1,P_2),\vec{d}_7(P_2,P_1)\}) \quad \text{for } P_1,P_2 \in \mathbf{N}_{\mathrm{nor}}(\mathcal{U},\mathcal{Y}),$$

$$\text{where } \vec{d}_7(P_1,P_2) = \inf_{Q\in\mathcal{Q}^s} \|(D_1-D_2Q, N_1-N_2Q)^\top\|_\omega,\ (N_i,D_i)\in \mathrm{nrcf}(P_i),\ i=1,2.$$

Notice, when ω is the identity d_3 is closely related to the graph metric studied in [20] for finite dimensional linear systems, while d_5 is the gap metric defined in [7] where $\vec{d}_5$ is extensively exploited for the robustness of stability of nonlinear systems. In most cases, $\vec{d}_5$ can be replaced by $\vec{d}_4$ as later shown in Lemma 5.1 . The functionals d_6 and d_7 are closely related to the Georgiou formula for the gap metric [4].

We will prove that $d_1,\dots,d_7$ are metrics on suitable sets of signal operators and show relations between all seven functionals $d_1,\dots,d_7$ and their induced topologies.

The results developed in this section are as follows:

1. The weighted topology $\mathcal{T}_\omega$ on $\mathbf{N}_{\mathrm{nor}}(\mathcal{U},\mathcal{Y})$ can be metrized by graph metrics d_2, d_3 provided $cr \le \omega(r)$;

2. The weighted graph topology can also be metrized by Georgiou and Smith's gap metrics d_4, d_5 provided $r \le \omega(r)$;

3. The graph metrics $\vec{d}_2$, $\vec{d}_3$ and gap metric $\vec{d}_5$ are equivalent to each other. Therefore, the graph metrics give rise to the same robust stability margin as the gap metric [7];

4. The gap metrics d_4 and d_5 can be equivalently expressed by the Georgiou-type formulae, d_7 and d_6, respectively.

The following diagrams show the relations among the discussed topologies and (gap) metrics that will be established.

$$d_1 \geq d_6, \qquad d_2 \geq d_3 \geq d_6 = d_5 \geq d_4 = d_7$$

Diagram 1: Metric relations.

$$\mathcal{T}_{d_1} \overset{\text{P}4.1}{\geq} \mathcal{T}_\omega \overset{\text{T}4.4}{=} \mathcal{T}_{d_2} \overset{\text{T}4.7}{=} \mathcal{T}_{d_3} \overset{\text{T}4.4}{=} \mathcal{T}_{d_5} \overset{\text{P}4.6}{=} \mathcal{T}_{d_6} \overset{\text{P}4.6}{\geq} \mathcal{T}_{d_4} \overset{\text{P}4.6}{=} \mathcal{T}_{d_7}$$
$$\mathcal{T}_\omega \overset{\text{C}3.10}{\geq} \mathcal{T}$$

Diagram 2: Topological relations.

Here, the letters "T," "P," and "C" represent "Theorem," "Proposition," and "Corollary," respectively, and $\mathcal{T}_{d_i}$ means the topology induced by d_i.

4.2. The gap metric d_1. The first result is the following proposition.

PROPOSITION 4.1. *$d_1(\cdot,\cdot)$ is a metric on $\mathbf{N}_\omega(\mathcal{U},\mathcal{Y})$, whose topology, $\mathcal{T}_{d_1}$, is stronger than the weighted graph topology $\mathcal{T}_\omega$.*

Proof. From Lemma 2.1 and the definition of d_1, it follows that to prove d_1 is a metric we need only to verify $d_1(P_1,P_2)=0$ implies $P_1=P_2$.

In fact $d_1(P_1,P_2)=0$ implies that for each $(N_1,D_1)\in \mathrm{rcf}(P_1)$,

$$\inf_{(N_2,D_2)\in \mathrm{rcf}(P_2)} \|(D_1-D_2,N_1-N_2)^\top\|_\omega = 0.$$

So there exists a sequence $\{(N_{2,n},D_{2,n})\}\subset \mathrm{rcf}(P_2)$ with $\|(D_1-D_{2,n},N_1-N_{2,n})^\top\|_\omega \to 0$ as $n\to\infty$, from which it follows that, for each $r>0$, $\gamma((D_1-D_{2,n},N_1-N_{2,n})^\top)(r)\to 0$ as $n\to\infty$. By Theorem 3.5, $P_n \xrightarrow{\mathcal{T}} P$ and therefore $P_2=P_1$.

Now we suppose $P_n\in\mathbf{N}_\omega(\mathcal{U},\mathcal{Y})$ with $d_1(P_n,P)\to 0$ as $n\to\infty$. Then

$$\sup_{(N,D)\in\mathrm{rcf}(P)} \inf_{(N_n,D_n)\in\mathrm{rcf}(P_n)} \|(D-D_n,N-N_n)^\top\|_\omega \to 0.$$

So, for each $ND^{-1}\in\mathrm{rcf}(P)$, $\inf_{(N_n,D_n)\in\mathrm{rcf}(P_n)}\|(D-D_n,N-N_n)^\top\|_\omega\to 0$ and therefore there exists $N_nD_n^{-1}\in\mathrm{rcf}(P_n)$ such that $\|(D_n-D,N_n-N)^\top\|_\omega\to 0$ as $n\to\infty$. This proves $P_n\xrightarrow{\mathcal{T}_\omega}P$ and hence $\mathcal{T}_{d_1}$ is stronger than $\mathcal{T}_\omega$. ∎

4.3. The graph metrics d_2 and d_3. In this subsection, we will show that both d_2 and d_3 are well-defined metrics on $\mathbf{N}_{\mathrm{nor}}(\mathcal{U},\mathcal{Y})$ and the topologies induced are equivalent to the weighted graph topology $\mathcal{T}_\omega$ provided $\omega(r)\geq cr$ with $c>0$.

PROPOSITION 4.2. *$d_2(\cdot,\cdot)$ is a metric defined on $\mathbf{N}_{\mathrm{nor}}(\mathcal{U},\mathcal{Y})$.*

Proof. First, we need to prove d_2 is well-defined, that is, $d_2(P_1,P_2)$ is independent of the choice of normalized coprime factorizations and is finite for all $P_1,P_2\in\mathbf{N}_{\mathrm{nor}}(\mathcal{U},\mathcal{Y})$. So let $P_i\in\mathbf{N}_{\mathrm{nor}}(\mathcal{U},\mathcal{Y})$, $(N_i,D_i),(\hat N_i,\hat D_i)\in\mathrm{nrcf}(P_i)$, $i=1,2$. By Propositions 2.6 and 2.7, there exist $Q_i\in\mathcal{Q}$ $(i=1,2)$ with $\|Q_iu\|=\|Q_i^{-1}u\|=\|u\|$ (for all $u\in\mathcal{U}_s$) such that $\hat D_i=D_iQ_i$, $\hat N_i=N_iQ_i$. Notice, for every stable operator A

$$\|AQ_1\|_\omega \leq \sup_{r>0}\frac{\gamma(A)(\gamma(Q_1)(\omega(r)))}{r} = \sup_{r>0}\frac{\gamma(A)(\omega(r))}{r} = \|A\|_\omega, \tag{4.1}$$

so we have

$$\begin{aligned}\inf_{\substack{Q\in\mathcal{Q}\\ \|Q\|\le 1}} \|(\hat{D}_1-\hat{D}_2Q,\hat{N}_1-\hat{N}_2Q)^\top\|_\omega &= \inf_{\substack{Q\in\mathcal{Q}\\ \|Q\|\le 1}} \|(D_1Q_1-D_2Q_2Q,N_1Q_1-N_2Q_2Q)^\top\|_\omega\\ &\le \inf_{\substack{\hat{Q}\in\hat{\mathcal{Q}}\\ \|\hat{Q}\|\le 1}} \|(D_1-D_2\hat{Q},N_1-N_2\hat{Q})^\top\|_\omega.\end{aligned}$$

Replacing Q_i by Q_i^{-1}, we see that the opposite inequality is also true and, therefore

$$\inf_{\substack{\hat{Q}\in\mathcal{Q}\\ \|\hat{Q}\|\le 1}} \|(D_1-D_2\hat{Q},N_1-N_2\hat{Q})^\top\|_\omega = \inf_{\substack{Q\in\mathcal{Q}\\ \|Q\|\le 1}} \|(\hat{D}_1-\hat{D}_2Q,\hat{N}_1-\hat{N}_2Q)^\top\|_\omega.$$

This shows the value of $\vec{d}_2(P_1,P_2)$ is independent of the choice of normalized coprime factorizations. Similarly, we can prove $\vec{d}_2(P_2,P_1)$ is independent of the choice of normalized coprime factorizations and hence so is d_2. Also, for any $Q\in\mathcal{Q}$ with $\|Q\|\le 1$, we have

$$\|(D_1-D_2Q,N_1-N_2Q)^\top\|_\omega \le \|(D_1,N_1)^\top\|_\omega + \|(D_2,N_2)^\top\|_\omega \le 2 < \infty.$$

Hence d_2 is well-defined.

Next we prove d_2 is a metric.

Obviously, d_2 is symmetric and $d_2(P,P)=0$ for any $P\in\mathbf{N}_{\mathrm{nor}}(\mathcal{U},\mathcal{Y})$. Conversely, suppose $d_2(P_1,P_2)=0$ with $P=N_1D_1^{-1}$, $P_2=N_2D_2^{-1}$. Then for all $n>0$, there exist $Q_n\in\mathcal{Q}$ such that $\|(D_1-D_2Q_n,N_1-N_2Q_n)^\top\|_\omega\to 0$ as $n\to\infty$, from which we have

$$\gamma((D_1-D_2Q_n,N_1-N_2Q_n)^\top)(r)\to 0 \quad \text{for all } r>0 \text{ as } n\to\infty.$$

By Proposition 2.6, (N_2Q_n,D_2Q_n) is also a coprime factorization of $P_n\equiv P_2$ for each n. From Theorem 3.5, it follows that $P_2=P_n\xrightarrow{\mathcal{T}}P_1$ in $\mathbf{N}(\mathcal{U},\mathcal{Y})$, which implies $P_1=P_2$ since the pointwise graph topology is Hausdorff.

To prove the triangle inequality, we suppose $N_iD_i^{-1}$ are normalized coprime factorizations for P_i with $i=1,2,3$. Then for each $\varepsilon>0$, there exists $Q_1,Q_2\in\mathcal{Q}$ with $\|Q_1\|\le 1$, $\|Q_2\|\le 1$ such that

$$\begin{aligned}\|(D_1-D_3Q_1,N_1-N_3Q_1)^\top\|_\omega &\le \vec{d}_2(P_1,P_3)+\varepsilon,\\ \|(D_3-D_2Q_2,N_3-N_2Q_2)^\top\|_\omega &\le \vec{d}_2(P_3,P_2)+\varepsilon.\end{aligned}$$

Since $Q_2Q_1\in\mathcal{Q}$, $\|Q_2Q_1\|\le 1$ and by using (4.1), we have

$$\begin{aligned}\vec{d}_2(P_1,P_2) &\le \|(D_1-D_2Q_2Q_1,N_1-N_2Q_2Q_1)^\top\|_\omega\\ &\le \|(D_1-D_3Q_1,N_1-N_3Q_1)^\top+(D_3Q_1-D_2Q_2Q_1,N_3Q_1-N_2Q_2Q_1)^\top\|_\omega\\ &\le \vec{d}_2(P_1,P_3)+\varepsilon+\|(D_3-D_2Q_2,N_3-N_2Q_2)^\top Q_1\|_\omega\\ &\le \vec{d}_2(P_1,P_3)+\vec{d}_2(P_3,P_2)+2\varepsilon \le d_2(P_1,P_3)+d_2(P_3,P_2)+2\varepsilon.\end{aligned}$$

Since ε is arbitrary, we see that $\vec{d}_2(P_1,P_2)\le d_2(P_1,P_3)+d_2(P_3,P_2)$. By changing the order of P_1, P_2 on the left-hand side (they are arbitrary) and noticing that the right-hand side is symmetric, we have $\vec{d}_2(P_2,P_1)\le d_2(P_1,P_3)+d_2(P_3,P_2)$. This proves the triangle inequality and completes the proof. ∎

PROPOSITION 4.3. *Suppose $c > 0$ and $cr \le w(r)$ for all $r \ge 0$. Then d_3 is a metric which is topologically equivalent to d_2 on $\mathbf{N}_{\rm nor}(\mathcal{U}, \mathcal{Y})$.*

Proof. The proof for the well-definedness and the triangle inequality for d_3 is exactly the same as in Proposition 4.2.

Suppose $d_3(P_1, P_2) = 0$. Hence there exists a sequence $\{Q_n\} \subset \mathcal{Q}^*$ satisfying

$$\|(D_1 - D_2Q_n, N_1 - N_2Q_n)^\top\|_\omega \to 0 \quad \text{as } n \to \infty, \tag{4.2}$$

and therefore there exists $n_0 > 0$ such that

$$\sup_{\|u\| \le \omega(r)} \|(D_1 - D_2Q_n, N_1 - N_2Q_n)^\top u\| < \frac{c}{2} r \quad \text{for all } r > 0,\ n \ge n_0.$$

For any $u \in \mathcal{U}_s$, let $r = \|u\|/c$. Then $\|u\| \le cr \le \omega(r)$ and therefore,

$$\|(D_1 - D_2Q_n, N_1 - N_2Q_n)^\top u\| < \frac{c}{2}\frac{\|u\|}{c} = \frac{1}{2}\|u\| \quad \text{for all } u \in \mathcal{U}_s,\ n \ge n_0.$$

Since (N_1, D_1), (N_2, D_2) are normalized coprime factorizations, we see that

$$\begin{aligned} \|Q_n u\| &= \|(D_2, N_2)^\top Q_n u\| \\ &\ge \|(D_1, N_1)^\top u\| - \|(D_1 - D_2Q_n, N_1 - N_2Q_n)^\top u\| \\ &\ge \|u\| - \frac{1}{2}\|u\| = \frac{1}{2}\|u\| \quad \text{for all } u \in \mathcal{U}_s,\ n \ge n_0. \end{aligned}$$

This means that $\|Q_n^{-1}\| \le 2$ and Q_n^{-1} is stable for all $n > n_0$. By Proposition 2.6, for all $n > n_0$, (N_2Q_n, D_2Q_n) is a coprime factorization of P_2. Also from (4.2), we see that

$$\gamma((D_1 - D_2Q_n, N_1 - N_2Q_n)^\top)(r) \to 0 \quad \text{for all } r > 0, \text{ as } n \to \infty.$$

From Theorem 3.5, it follows that $P_2 \equiv P_n \xrightarrow{\mathcal{T}} P_1$ in $\mathbf{N}(\mathcal{U}, \mathcal{Y})$, which implies $P_1 = P_2$. Hence d_3 is a well-defined metric on $\mathbf{N}_{\rm nor}(\mathcal{U}, \mathcal{Y})$.

To prove the equivalence between d_2 and d_3, we first notice that $d_3 \le d_2$. This yields that convergence under d_2 implies convergence under d_3. On the other hand, let $P_n, P \in \mathbf{N}_{\rm nor}(\mathcal{U}, \mathcal{Y})$ with $(N, D) \in \text{nrcf}(P)$, $(N_n, D_n) \in \text{nrcf}(P_n)$, and $d_3(P_n, P) \to 0$ as $n \to \infty$. Then $\vec{d}_3(P, P_n) \to 0$ which means

$$\inf_{Q \in \mathcal{Q}^*} \|(D - D_nQ_n, N - N_nQ_n)^\top\|_\omega \to 0 \quad \text{as } n \to \infty.$$

This shows that for each $\varepsilon \in (0, c/2]$, there exists $n_\varepsilon > 0$ such that

$$\|(D - D_nQ_n, N - N_nQ_n)^\top\|_\omega < \varepsilon \quad \text{for all } n \ge n_\varepsilon. \tag{4.3}$$

Without loss of generality, we may suppose that $n_{\varepsilon_1} \le n_{\varepsilon_2}$ if $\varepsilon_1 > \varepsilon_2$. By letting $\varepsilon = c/2$, we see that there exists $0 < n_0 \le n_\varepsilon$ such that for each $n \ge n_0$ there is $Q_n \in \mathcal{Q}^*$ satisfying

$$\sup_{\|u\| \le \omega(t)} \|(D - D_nQ_n, N - N_nQ_n)^\top u\| \le \frac{c}{2} r \quad \text{for all } r > 0,\ n \ge n_0.$$

Using the same method as used in the first part (just replace (N_1, D_1) by (N, D) and (N_2, D_2) by (N_n, D_n), respectively), we can prove that Q_n^{-1} is stable for $n \ge n_0$. So from (4.3), it follows that

$$\vec{d}_2(P, P_n) \le \|(D - D_nQ_n, N - N_nQ_n)^\top\|_\omega < \varepsilon \quad \text{for all } n \ge n_\varepsilon$$

and therefore $\vec{d}_2(P, P_n) \to 0$ as $n \to \infty$. Similarly, $\vec{d}_2(P_n, P) \to 0$ and therefore $d_2(P_n, P) \to 0$ as $n \to \infty$. This completes the proof. □

THEOREM 4.4. *Suppose $c > 0$ and $cr \le w(r)$ for all $r \ge 0$. Then the topology induced by either d_2 or d_3 is equivalent to the weighted graph topology $\mathcal{T}_\omega$ on $\mathbf{N}_{\rm nor}(\mathcal{U}, \mathcal{Y})$.*

Proof. By Proposition 4.3, we only need to show $d_3(P_n, P) \to 0$ if and only if $P_n \xrightarrow{\mathcal{T}_\omega} P$, for any $P_n, P \in \mathbf{N}_{\rm nor}(\mathcal{U}, \mathcal{Y})$.

First, suppose $d_3(P_n, P) \to 0$. Then for every normalized coprime factorization $P = ND^{-1}$, $P_n = N_n D_n^{-1}$, there exist $Q_n \in \mathcal{Q}^*$ such that

$$\|(D - D_nQ_n, N - N_nQ_n)^\top\|_\omega \to 0 \quad \text{as } n \to \infty. \tag{4.4}$$

Let $(\hat{N}, \hat{D})$ be an arbitrary coprime factorization of P. By Proposition 2.6, there exists stable operator Q on $\mathcal{U}_s$, with Q^{-1} also stable, such that $\hat{D} = DQ$, $\hat{N} = NQ$, from which we see that

$$\|Q\|_\omega = \|(D, N)^\top Q\|_\omega = \|(\hat{D}, \hat{N})^\top\|_\omega < \infty.$$

Write $\hat{D}_n = D_nQ_nQ$, $\hat{N}_n = N_nQ_nQ$. Then from (4.4), it follows that

$$\begin{aligned}\|(\hat{D} - \hat{D}_n, \hat{N} - \hat{N}_n)^\top\|_\omega &= \|(D - D_nQ_n, N - N_nQ_n)^\top Q\|_\omega \\ &\le \|(D - D_nQ_n, N - N_nQ_n)^\top\|\|Q\|_\omega \\ &= \frac{1}{c}\|(D - D_nQ_n, N - N_nQ_n)^\top\|_\omega\|Q\|_\omega \to 0 \quad \text{as } n \to \infty.\end{aligned}$$

Using the same method as used in Proposition 4.3, we can prove that $(\hat{N}_n, \hat{D}_n)$ is a coprime factorization of P_n for all large n. Hence from Theorem 3.9, we see that $P_n \xrightarrow{\mathcal{T}_\omega} P$.

Secondly, suppose $P_n, P \in \mathbf{N}_{\rm nor}(\mathcal{U}, \mathcal{Y})$ with $P_n \xrightarrow{\mathcal{T}_\omega} P$. Let (N, D) be a normalized coprime factorization of P. Then there exist coprime factorizations $N_nD_n^{-1}$ of P_n with $\|(D - D_n, N - N_n)^\top\|_\omega \to 0$ as $n \to \infty$. Therefore, $\{\|(D_n, N_n)^\top\|\}$ is bounded and $\|(D - D_n, N - N_n)^\top\| \to 0$. Hence

$$\|(D_n, N_n)^\top\| \to \|(D, N)^\top\| = 1 \quad \text{as } n \to \infty \tag{4.5}$$

and for each $\varepsilon > 0$, there exists $n_\varepsilon > 0$ such that

$$\|(D - D_n, N - N_n)^\top u\| \le \varepsilon\|u\| \quad \text{for all } u \in \mathcal{U}_s,\ n > n_\varepsilon. \tag{4.6}$$

Let $\hat{N}_n\hat{D}_n^{-1}$ be a normalized coprime factorization of P_n. Then there exists stable operator U_n on $\mathcal{U}_s$, where U_n^{-1} exists and is stable, such that $D_n = \hat{D}_nU_n$, $N_n = \hat{N}_nU_n$. Since $\|U_nu\| = \|(\hat{D}_n, \hat{N}_n)^\top U_nu\| = \|(D_n, N_n)^\top u\|$ for any $u \in \mathcal{U}_s$, we see $\{\|U_n\|_\omega\}$ is bounded and from (4.5) it follows that

$$\|U_n\| = \|(\hat{D}_n, \hat{N}_n)^\top U_n\| = \|(D_n, N_n)^\top\| \to 1 \quad \text{as } n \to \infty.$$

From (4.6), it follows that for each $u \in \mathcal{U}_s$ and each $n > n_\varepsilon$ that

$$\|U_nu\| = \|(D_n, N_n)^\top u\| \ge \|(D, N)^\top u\| - \|(D_n - D, N_n - N)^\top u\| \ge (1 - \varepsilon)\|u\|,$$

which implies that $\|U_n^{-1}u\| \le \frac{1}{1-\varepsilon}\|u\|$ and therefore $\|U_n^{-1}\| \le \frac{1}{1-\varepsilon}$. Since $\|U_n^{-1}\| \ge 1/\|U_n\|$, we see $\|U_n^{-1}\| \to 1$ as $n \to \infty$.

Let $Q_n u = U_n u/\|U_n\|$ for each $u \in \mathcal{U}_s$. Then $\|Q_n\| \le 1$ and since $Q_n^{-1} = U_n^{-1} \cdot \|U_n\|$ exists and is stable, we have $Q_n \in \mathcal{Q}^*$. Also

$$\begin{aligned}\|(\hat{D}_n U_n - \hat{D}_n Q_n, \hat{N}_n U_n - \hat{N}_n Q_n)^\top\|_\omega &= \|(\hat{D}_n, \hat{N}_n)^\top (U_n - Q_n)\|_\omega \\ &= \|(U_n - Q_n)\|_\omega = \frac{|\|U_n\| - 1|}{\|U_n\|}\|U_n\|_\omega \to 0,\end{aligned}$$

which implies

$$\begin{aligned}\vec{d}_3(P, P_n) &\le \|(D - \hat{D}_n Q_n, N - \hat{N}_n Q_n)^\top\|_\omega \\ &\le \|(D - \hat{D}_n U_n, N - \hat{N}_n U_n)^\top\|_\omega \\ &\quad + \|(\hat{D}_n U_n - \hat{D}_n Q_n, \hat{N}_n U_n - \hat{N}_n Q_n)^\top\|_\omega \to 0 \quad \text{as } n \to \infty.\end{aligned}$$

Similarly, for $\tilde{Q}_n u = U_n^{-1} u/\|U_n^{-1}\|$, we can prove

$$\vec{d}_3(P_n, P) \le \|(\hat{D}_n - D\tilde{Q}_n, \hat{N}_n - N\tilde{Q}_n)^\top\|_\omega \to 0 \quad \text{as } n \to \infty.$$

This shows $d_3(P_n, P) \to 0$ and completes the proof. □

We remark that the first part of the proof shows, in the case $cr \le \omega(r)$, that $P_n \xrightarrow{\mathcal{T}_\omega} P$ in $\mathbf{N}_{\text{nor}}(\mathcal{U}, \mathcal{Y})$ if and only if there exist normalized coprime factorization (N, D) of P and coprime factorizations (N_n, D_n) of P_n such that $\|(D - D_n, N - N_n)^\top\|_\omega \to 0$ as $n \to \infty$.

In the case of $\omega(r) = r$ and stability is taken to be in the sense of linear gain, the above theorem shows that the graph topology induced by the linear gain is metrizable.

4.4. The gap metrics d_4, d_5, d_6, and d_7. In this subsection, we present the metric properties of $d_4, \dots, d_7$ over the subset $\mathbf{N}_{\text{nor}}(\mathcal{U}, \mathcal{Y})$. In particular, the equivalence between the weighted graph topology and the topologies induced by either d_5 or d_6 will be established.

Using the same method as used in [7], we can prove that d_4, d_5 are pseudometrics on the set of signal operators from $\mathcal{U}$ to $\mathcal{Y}$ provided $\omega(r) \ge r$ for all $r > 0$. Here pseudometric means that $d_4(P_1, P_2) = 0$ (resp., $d_5(P_1, P_2) = 0$) does not necessarily imply $P_1 = P_2$ unless extra conditions are imposed. Moreover, as in [7], they are only "generalized" pseudometrics, which means that possibly (say) $d_5(P_1, P_2) = \infty$ for some P_1, P_2. The following comparison results show that they both become well-defined metrics if restricted to $\mathbf{N}_{\text{nor}}(\mathcal{U}, \mathcal{Y})$ (no extra condition required).

We first give a key lemma.

LEMMA 4.5. *Suppose $P_i \in \mathbf{N}_{\text{nor}}(\mathcal{U}, \mathcal{Y})$ with $(D_i, N_i) \in \text{nrcf}(P_i)$, $i = 1, 2$. Then there exists a mapping $\Phi : \text{Graph}(P_1) \to \text{Graph}(P_2)$ if and only if there exists a mapping $Q : \mathcal{U}_s \to \mathcal{U}_s$ such that*

$$\Phi \begin{pmatrix} D_1 \\ N_1 \end{pmatrix} u = \begin{pmatrix} D_2 \\ N_2 \end{pmatrix} Qu \quad \text{for all } u \in \mathcal{U}_s. \tag{4.7}$$

Moreover,

(i) *Φ is surjective if and only if Q is surjective;*

(ii) *$\|Q\| = \|\Phi\|$ and $\gamma(\Phi)(r) = \gamma(Q)(r)$ for any $r > 0$ (so Φ is stable if and only if Q is stable);*

(iii) *Φ is injective if and only if Q is injective;*

(iv) *$\|Q^{-1}\| = \|\Phi^{-1}\| =: \|\Phi^{-1}|_{\mathcal{M}_2}\|$ and $\gamma(\Phi^{-1})(r) = \gamma(Q^{-1})(r)$ for any $r > 0$;*

(v) *Φ is causal if and only if Q is causal, and $\Phi 0 = 0$ if and only if $Q0 = 0$.*

Proof. Write $\mathcal{M}_i = \mathrm{Graph}(P_i)$ for $i = 1, 2$.

Let $\Phi : \mathcal{M}_1 \to \mathcal{M}_2$ be a given mapping. Then, for any $u \in \mathcal{U}_s$, by Proposition 2.5, $\Phi(D_1, N_1)^\top u \in \mathcal{M}_2$ and therefore there exists $v_u \in \mathcal{U}_s$ such that $\Phi(D_1, N_1)^\top u = (D_2, N_2)^\top v_u$. Since $(D_2, N_2)^\top$ is left invertible, such a point v_u is unique. This yields that the mapping $Qu = v_u$ is well defined on $\mathcal{U}_s$ and satisfies (4.7).

Conversely, let Q be a given mapping on $\mathcal{U}_s$. For any $w \in \mathcal{M}_1$, let $\Phi w = (D_2, N_2)^\top Q L_1 w$, where L_1 is the left inverse of $(D_1, N_1)^\top$ which is stable by the definition of the coprime factorization. Then, obviously, Φ is a well-defined mapping from $\mathcal{M}_1$ to $\mathcal{M}_2$ satisfying (4.7).

Now we prove the other claims.

(i) First, we suppose $\Phi : \mathcal{M}_1 \to \mathcal{M}_2$ is given and surjective. Since $(D_1, N_1)^\top : \mathcal{U}_s \to \mathcal{M}_1$ is surjective, for any $v \in \mathcal{U}_s$ there exists $u \in \mathcal{U}_s$ with $\Phi(D_1, N_1)^\top u = (D_2, N_2)^\top v$. The left invertibility of $(D_2, N_2)^\top$ and (4.7) show $Qu = v$. Therefore, Q is surjective.

If Q is surjective on $\mathcal{U}_s$, then for any $w \in \mathcal{M}_2$, the surjectivity of $(D_2, N_2)^\top$ implies the existence of $u \in \mathcal{U}_s$ such that $(D_2, N_2)^\top Qu = w$. Hence $\Phi(D_1, N_1)^\top u = w$ which shows that Φ is surjective.

(ii) From (4.7), we see that

$$\|Qu\| = \left\| \begin{pmatrix} D_2 \\ N_2 \end{pmatrix} Qu \right\| = \left\| \Phi \begin{pmatrix} D_1 \\ N_1 \end{pmatrix} u \right\| \quad \text{for all } u \in \mathcal{U}_s. \tag{4.8}$$

Since $\|u\| = \|(D_1, N_1)^\top u\|$, $\mathcal{M}_1 = (D_1, N_1)^\top \mathcal{U}_s$, the conclusions follow.

(iii) From (4.7) and the left invertibility of $(D_i, N_i)^\top$ $(i = 1, 2)$, it follows that

$$\begin{aligned}
\Phi \text{ is injective } &\Leftrightarrow \Phi w_1 = \Phi w_2 \text{ implies } w_1 = w_2 \text{ for any } w_1, w_2 \in \mathcal{M}_1 \\
&\Leftrightarrow \Phi \begin{pmatrix} D_1 \\ N_1 \end{pmatrix} u_1 = \Phi \begin{pmatrix} D_1 \\ N_1 \end{pmatrix} u_2 \text{ implies } u_1 = u_2 \text{ for any } u_1, u_2 \in \mathcal{U}_s \\
&\Leftrightarrow \begin{pmatrix} D_2 \\ N_2 \end{pmatrix} Qu_1 = \begin{pmatrix} D_2 \\ N_2 \end{pmatrix} Qu_2 \text{ implies } u_1 = u_2 \text{ for any } u_1, u_2 \in \mathcal{U}_s \\
&\Leftrightarrow Qu_1 = Qu_2 \text{ implies } u_1 = u_2 \text{ for any } u_1, u_2 \in \mathcal{U}_s \\
&\Leftrightarrow Q \text{ is injective.}
\end{aligned}$$

(iv) Since $\|w\| \le \|\Phi^{-1}\| \|\Phi w\|$ for any $w \in \mathcal{M}_1$, we have

$$\|u\| = \left\| \begin{pmatrix} D_1 \\ N_1 \end{pmatrix} u \right\| \le \|\Phi^{-1}\| \left\| \Phi \begin{pmatrix} D_1 \\ N_1 \end{pmatrix} u \right\| = \|\Phi^{-1}\| \left\| \begin{pmatrix} D_2 \\ N_2 \end{pmatrix} Qu \right\| = \|\Phi^{-1}\| \|Qu\|$$

for any $u \in \mathcal{U}_s$. So $\|Q^{-1}\| \le \|\Phi^{-1}\|$. Similarly, for any $w = (D_1, N_1)^\top u \in \mathcal{M}_1$,

$$\left\| \begin{pmatrix} D_1 \\ N_1 \end{pmatrix} u \right\| = \|u\| \le \|Q^{-1}\| \|Qu\| = \|Q^{-1}\| \left\| \begin{pmatrix} D_2 \\ N_2 \end{pmatrix} Qu \right\| = \|Q^{-1}\| \left\| \Phi \begin{pmatrix} D_1 \\ N_1 \end{pmatrix} u \right\|$$

which gives the reverse inequality. Hence $\|Q^{-1}\| = \|\Phi^{-1}\|$.

For any $r > 0$, (4.8) and the surjectivity of $\Phi, (D_i, N_i)^\top$, and Q yield

$$\gamma(Q^{-1})(r) = \sup_{\|Qv\| \le r} \|v\| = \sup_{\|\Phi(D_1, N_1)^\top v\| \le r} \left\| \begin{pmatrix} D_1 \\ N_1 \end{pmatrix} v \right\| = \sup_{\|w\| \le r} \|\Phi^{-1} w\| = \gamma(\Phi^{-1})(r).$$

(v) Let L_1, L_2 be the associated operators to $(D_1, N_1)^\top$, $(D_2, N_2)^\top$, respectively. By applying L_2 to (4.7), we have $Qu = L_2\Phi(D_1, N_1)^\top$. By the definition of Φ, $\Phi w = (D_2, N_2)^\top Q L_1$. So, the conclusions follow from the preassumptions on signal operators. This completes the proof. □

PROPOSITION 4.6. *$\vec{d}_5(P_1, P_2) = \vec{d}_6(P_1, P_2)$, $\vec{d}_4(P_1, P_2) = \vec{d}_7(P_1, P_2)$ for $P_i \in \mathbf{N}_{\text{nor}}(\mathcal{U}, \mathcal{Y})$, $i = 1, 2$.*

Proof. Let Q be a given stable bijective mapping on $\mathcal{U}_s$. Then there exists a stable and bijective map $\Phi : \mathcal{M}_1 \to \mathcal{M}_2$ satisfying (4.7), for which

$$\|\Phi - I\|_\omega = \|(D_1, N_1)^\top - (D_2, N_2)^\top Q\|_\omega. \tag{4.9}$$

Therefore, $\vec{d}_5(P_1, P_2) \le \|(D_1, N_1)^\top - (D_2, N_2)^\top Q\|_\omega$ and $\vec{d}_5(P_1, P_2) \le \vec{d}_6(P_1, P_2)$ as Q is arbitrary.

Since $\Phi_1(D_1, N_1)^\top u = (D_2, N_2)^\top u$ is a bijective operator from $\mathcal{M}_1$ to $\mathcal{M}_2$ and $\|\Phi_1 - I\|_\omega < \infty$, we have

$$\vec{d}_5(P_1, P_2) = \inf\{\|\Phi - I\|_\omega : \Phi : \mathcal{M}_1 \to \mathcal{M}_2 \text{ bijective } \|\Phi - I\|_\omega < \infty\}.$$

Notice that $\|\Phi - I\|_\omega < \infty$ implies the stability of Φ. So, given any bijective map $\Phi : \mathcal{M}_1 \to \mathcal{M}_2$ with $\|\Phi - I\|_\omega < \infty$, by Lemma 4.5, there exists a stable, bijective mapping Q on $\mathcal{U}_s$ satisfying (4.7) and, therefore, (4.9). Hence $\vec{d}_6(P_1, P_2) \le \|\Phi - I\|_\omega$ which indicates that $\vec{d}_6(P_1, P_2) \le \vec{d}_5(P_1, P_2)$. This proves that $\vec{d}_6(P_1, P_2) = \vec{d}_5(P_1, P_2)$. The equality $\vec{d}_4(P_1, P_2) = \vec{d}_7(P_1, P_2)$ can be proved similarly. □

THEOREM 4.7. *d_5, d_6 are well-defined metrics on $\mathbf{N}_{\text{nor}}(\mathcal{U}, \mathcal{Y})$ and the graph topology $\mathcal{T}_\omega$ is equivalent to the topology induced by either d_5 or d_6, provided $r \le \omega(r)$ for all $r \ge 0$.*

Proof. Using the same methods as in Propositions 4.2 and 4.3, we see that d_6 is well-defined and $d_6(P_1, P_2) = 0$ if and only if $P_1 = P_2$ on $\mathbf{N}_{\text{nor}}(\mathcal{U}, \mathcal{Y})$. By Proposition 4.6, d_5 satisfies the same property.

To prove the triangle inequality for d_5, we suppose $P_1, P_2, P_3 \in \mathbf{N}_{\text{nor}}(\mathcal{U}, \mathcal{Y})$ and $\Phi_1 : \text{Graph}(P_1) \to \text{Graph}(P_2), \Phi_i : \text{Graph}(P_2) \to \text{Graph}(P_3)$ are bijective mappings. Then $\Phi := \Phi_2\Phi_1$ is a bijective mapping from $\text{Graph}(P_1)$ to $\text{Graph}(P_3)$ and $\Phi - I = (\Phi_2 - I)\Phi_1 - I$. So

$$\begin{aligned}\|\Phi - I\|_\omega &\le \|\Phi_2 - I\|\|\Phi_1\|_\omega + \|\Phi_1 - I\|_\omega \\ &\le \|\Phi_2 - I\|_\omega\|\Phi_1\|_\omega + \|\Phi_1 - I\|_\omega \\ &\le \|\Phi_2 - I\|_\omega(\|\Phi_1 - I\|_\omega) + 1 + \|\Phi_1 - I\|_\omega\end{aligned}$$

and therefore

$$\hat{d}_5(P_1, P_3) \le \hat{d}_5(P_1, P_2) + \hat{d}_5(P_2, P_3).$$

This means that d_5 satisfies the triangle inequality. Hence d_5 is a well-defined metric on $\mathbf{N}_{\text{nor}}(\mathcal{U}, \mathcal{Y})$ and so is d_6 because of Proposition 4.6.

Since $d_6 \le d_3$ and by Theorem 4.4, the convergence of the sequence under $\mathcal{T}_\omega$ implies the convergence under d_6. Conversely, if $d_6(P, P_n) \to 0$ as $n \to \infty$, then by using the same method as in Theorem 4.4 (see the Theorem's remark), we can prove that $P_n \xrightarrow{\mathcal{T}_\omega} P$. This shows the equivalence between $\mathcal{T}_\omega$ and the topology induced by either d_6 or d_5. □

Proposition 4.6 and Theorem 4.7 suggest that the two metrics d_3 and d_6 might be equivalent (we already know that $d_6 \le d_3$). In fact, Georgiou [4] has proved

$d_3(P_1,P_2) \le 2d_6(P_1,P_2)$ in the linear setting. In the nonlinear setting and in the case where $(D_2,N_2)^\top$ is incrementally stable, are where

$$\|(D_2,N_2)^\top\|_\triangle := \sup\left\{\frac{\|(D_2,N_2)^\top u_1 - (D_2,N_2)^\top u_2\|_\tau}{\|u_1-u_2\|_\tau} : \tau>0,\ u_1,u_2\in\mathcal{U}_s\right\} < \infty;$$

this claim can be proved by exactly the same technique as in [4].

Finally, we consider the relationship between d_1 and d_6. For $(N_i,D_i)\in \mathrm{rcf}(P_i)$, $i=1,2$, by Proposition 2.6, we have that

$$\inf_{Q\in\mathcal{Q}}\left\|\begin{pmatrix}D_1\\N_1\end{pmatrix}-\begin{pmatrix}D_2\\N_2\end{pmatrix}Q\right\|_\omega = \inf_{(\tilde N_2,\tilde D_2)\in\mathrm{rcf}(P_2)}\left\|\begin{pmatrix}D_1\\N_1\end{pmatrix}-\begin{pmatrix}\tilde D_2\\\tilde N_2\end{pmatrix}\right\|_\omega \le \vec d_1(P_1,P_2).$$

This gives a direct relation between d_1 and d_6 as below.

PROPOSITION 4.8. *For $P_i\in\mathbf{N}_{\mathrm{nor}}(\mathcal{U},\mathcal{Y})$ with $(D_i,N_i)\in\mathrm{nrcf}(P_i)$, $i=1,2$, $\vec d_1(P_1,P_2)\ge\vec d_6(P_1,P_2)$ and therefore $d_1(P_1,P_2)\ge d_6(P_1,P_2)$.*

5. Robustness of stability of nonlinear feedback systems. The importance of graph topology in the linear case is well known. In this section, we will show that it may also play a significant role in the nonlinear case by considering the system described by the configuration of Figure 5.1.

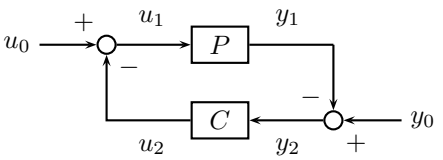

FIG. 5.1. *Standard feedback configuration.*

In this configuration, $u_i\in\mathcal{U}$, $y_i\in\mathcal{Y}$ for $i=0,1,2$, and both the plant P and compensator C are, in general, causal and nonlinear. We suppose all systems in this section are well-posed, that is, for each $(u_0,y_0)^\top\in\mathcal{U}_s\times\mathcal{Y}_s$, there exist unique signals $u_1,u_2\in\mathcal{U}$ and $y_1,y_2\in\mathcal{Y}$ such that

$$u_0=u_1+u_2,\qquad y_0=y_1+y_2,\qquad y_1=Pu_1,\qquad u_2=Cy_2,$$

and the feedback operator

$$H_{P,C}:\mathcal{W}_s\to\mathcal{W}\times\mathcal{W}:\begin{pmatrix}u_0\\y_0\end{pmatrix}\mapsto\left(\begin{pmatrix}u_1\\y_1\end{pmatrix},\begin{pmatrix}u_2\\y_2\end{pmatrix}\right)$$

is causal. Here, $\mathcal{W}_s=\mathcal{U}_s\times\mathcal{Y}_s,\mathcal{W}=\mathcal{U}\times\mathcal{Y}$. The feedback stability of this system is the requirement that $H_{P,C}$ is stable in a suitable sense. We are concerned with the following robustness problem: when is $H_{P_\lambda,C}$ stable given that $H_{P,C}$ is stable and P_λ is a perturbation to P?

In [7], this problem has been studied using a gap metric. Particularly, in the case where the linear gain is considered, it is proved that if $H_{P,C}$ is gain stable and P_λ is close enough to P in the sense of gap metric, then $H_{P_\lambda,C}$ is gain stable. Similar results are also given when $H_{P,C}$ is (gf)-stable with superlinear growth. However, in the (gf)-stability case, the notion of convergence was not made explicit as no topology was indicated. In this paper, we consider the robustness of (gf)-stability when the

convergence of P_λ to P is in the sense of any of the two graph topologies defined in the previous sections.

We suppose Λ is a topological space and for each $\lambda \in \Lambda$, P_λ is a perturbation to the nominal plant $P = P_{\lambda_0}$. Define $\mathcal{M} = \mathrm{Graph}(P)$, $\mathcal{M}_\lambda = \mathrm{Graph}(P_\lambda)$, $\mathcal{N} = \mathrm{Graph}(C)$, and let $\Pi_{\mathcal{M}//\mathcal{N}}$ be the parallel projection which maps $(u_0, y_0)^\top$ to $(u_1, y_1)^\top$ and $\Pi_{\mathcal{N}//\mathcal{M}} = I - \Pi_{\mathcal{M}//\mathcal{N}}$. It is known that $H_{P,C}$ is (gf)-stable (resp., gain stable) if and only if $\Pi_{\mathcal{M}//\mathcal{N}}$ is (gf)-stable (resp., gain stable); see [7].

A signal operator $F : \mathcal{U} \to \mathcal{Y}$ is said to be causally extendable if, for each $u \in \mathcal{U}$, $y = Fu$ and for each $\tau > 0$, there exists $u_\tau \in \mathrm{Dom}(F)$ such that $T_\tau(u, y)^\top = T_\tau(u_\tau, y_\tau)^\top$ with $y_\tau = Fu_\tau$. Henceforth, we suppose that P, C and each P_λ are causally extendable.

LEMMA 5.1. *Suppose Φ is a surjective mapping from $\mathcal{M}$ to $\mathcal{M}_\lambda$. Then, for any $z \in \mathcal{W}_s$ and any $\tau > 0$, there exists $x_\tau \in \mathcal{W}_s$ such that*

$$T_\tau z = T_\tau x_\tau + T_\tau(\Phi - I)\Pi_{\mathcal{M}//\mathcal{N}} T_\tau x_\tau \quad \textit{and} \quad T_\tau \Pi_{\mathcal{M}_\lambda//\mathcal{N}} z = T_\tau \Phi \Pi_{\mathcal{M}//\mathcal{N}} T_\tau x_\tau.$$

Proof. Let $H_{P_\lambda,C} z = (z_1, z_2)$ with $z_1 = (u_1, P_\lambda u_1)^\top$, $z_2 = (Cy_2, y_2)^\top$ for some $u_1 \in \mathcal{U}$, $y_2 \in \mathcal{Y}$. Then $z = z_1 + z_2$ and $\Pi_{\mathcal{M}_\lambda//\mathcal{N}} z = z_1$. By the causal extendability, for each $\tau > 0$, there exist $z_1^\tau \in \mathcal{M}_\lambda$, $z_2^\tau \in \mathcal{N}$ such that $T_\tau z_1 = T_\tau z_1^\tau$, $T_\tau z_2 = T_\tau z_2^\tau$. Since Φ is surjective from $\mathcal{M}$ to $\mathcal{M}_\lambda$, there exists $z_3^\tau \in \mathcal{M}$ with $\Phi z_3^\tau = z_1^\tau$. Write $x_\tau = z_3^\tau + z_2^\tau$. Then $x_\tau \in \mathcal{W}_s$ and $\Pi_{\mathcal{M}//\mathcal{N}} x_\tau = z_3^\tau$, $\Pi_{\mathcal{N}//\mathcal{M}} x_\tau = z_2^\tau$. Hence

$$\begin{aligned} T_\tau z &= T_\tau z_1 + T_\tau z_2 = T_\tau z_1^\tau + T_\tau z_2^\tau = T_\tau \Phi z_3^\tau + T_\tau z_2^\tau \\ &= T_\tau \Phi \Pi_{\mathcal{M}//\mathcal{N}} x_\tau + T_\tau \Pi_{\mathcal{N}//\mathcal{M}} x_\tau = T_\tau \Phi \Pi_{\mathcal{M}//\mathcal{N}} T_\tau x_\tau + T_\tau \Pi_{\mathcal{N}//\mathcal{M}} T_\tau x_\tau \\ &= T_\tau(\Phi - I)\Pi_{\mathcal{M}//\mathcal{N}} T_\tau x_\tau + T_\tau x_\tau \end{aligned}$$

and

$$T_\tau \Pi_{\mathcal{M}_\lambda//\mathcal{N}} z = T_\tau z_1 = T_\tau \Phi z_3^\tau = T_\tau \Phi \Pi_{\mathcal{M}//\mathcal{N}} x_\tau = T_\tau \Phi \Pi_{\mathcal{M}//\mathcal{N}} T_\tau x_\tau. \qquad \square$$

For our main results, we will always require that the nominal plant satisfies a k-coercive condition as stated below; note that this assumption will not be imposed on the perturbed plant P_λ.

DEFINITION 5.2. *A signal operator $P : \mathcal{U} \to \mathcal{Y}$ is said to be k-coercive, with $k \in \mathcal{K}_\infty$, if P has a coprime factorization (N, D) such that*

$$\|(D, N)^\top u\| \geq k(\|u\|) \quad \textit{for all } u \in \mathcal{U}_s. \tag{5.1}$$

Notice that P is k-coercive if and only if

$$\|Lw\| \leq k^{-1}(\|w\|) \quad \text{for all } w \in \mathrm{Graph}(P), \tag{5.2}$$

where L is the associated operator of (N, D). Hence any operator P with coprime factors is $\gamma(L)^{-1}$-coercive, where L is the associated operator of a coprime factorization, since (5.2) always holds with $k^{-1}(r) = \gamma(L)(r)$. It is of interest to observe that a linear operator with coprime factors is always k-coercive with $k(r) = cr$, $c > 0$. Also note that if P has a normalized coprime factorization, then P is 1-coercive and therefore c-coercive for any $c > 0$.

In the case when $k(r) = cr$ is linear, (5.2) is required by James, Smith, and Vinnicombe [10] in their definition of (right) coprime factorization, while (5.1) is

required by Verma [18] in one of his definitions and exploited for the stability of another system in the sense of linear gain.

PROPOSITION 5.3. *Suppose that the nominal plant P is k-coercive and $\lambda \mapsto P_\lambda$ is continuous at λ_0 under a weighted topology $\mathcal{T}_\omega$ with $w \in \mathcal{K}_\infty$. Then, for each λ, there exists a surjective mapping $\Phi_\lambda : \mathcal{M} \to \mathcal{M}_\lambda$ such that*

$$\sup_{r>0} \frac{\gamma(I-\Phi_\lambda)(k(\omega(r)))}{r} \to 0, \quad \text{as } \lambda \to \lambda_0. \tag{5.3}$$

Proof. Let ND^{-1} be the coprime factorization of $P = P_{\lambda_0}$ satisfying the coercive condition (5.1). From Corollary 3.11, it follows that P_λ has coprime factorization $N_\lambda D_\lambda^{-1}$ such that

$$\sup_{r>0} \frac{\gamma((D-D_\lambda, N-N_\lambda)^\top)(\omega(r))}{r} \to 0, \quad \text{as } \lambda \to \lambda_0. \tag{5.4}$$

For each $\lambda > 0$ and each $u \in \mathcal{U}_s$, let

$$\Phi_\lambda((Du, Nu)^\top) = ((D_\lambda u, N_\lambda u)^\top). \tag{5.5}$$

Φ_λ is a well-defined, causal, and surjective mapping from $\mathcal{M}$ to $\mathcal{M}_\lambda$ since $\Phi_\lambda w = ((D_\lambda, N_\lambda)^\top Lw)$ with L the left inverse of $(D,N)^\top$.

Now let $r > 0$, $(Du, Nu)^\top \in \mathcal{M}$ with $u \in \mathcal{U}_s$, and $\|(Du, Nu)^\top\| \le k(w(r))$. From (5.1), it follows that $\|u\| \le w(r)$, which implies

$$\|((D-D_\lambda)u, (N-N_\lambda)u)^\top\| \le \sup_{\|v\| \le w(r)} \|((D-D_\lambda)v, (N-N_\lambda)v)^\top\|.$$

Therefore

$$\begin{aligned} \gamma(I-\Phi_\lambda)(k(w(r))) &= \sup_{\substack{(Du,Nu)^\top \in \mathrm{Dom}(I-\Phi_\lambda) \\ \|(Du,Nu)^\top\| \le k(w(r))}} \|((D-D_\lambda)u, (N-N_\lambda)u)^\top\| \\ &\le \sup_{\|v\| \le w(r)} \|((D-D_\lambda)v, (N-N_\lambda)v)^\top\| \\ &= \gamma((D-D_\lambda, N-N_\lambda)^\top)(w(r)). \end{aligned} \tag{5.6}$$

By (5.4), we see that (5.3) holds. ∎

Remark. From (5.3), we see that $\|I-\Phi_\lambda\|_{k\circ\omega} \to 0$ which implies $\vec{\delta}(P, P_\lambda) \to 0$ under a new weighted function $\omega_1 = k \circ \omega$. However, we cannot show whether $\vec{\delta}(P_\lambda, P) \to 0$ unless each P_λ is also k-coercive. Also notice here the l.a.c. assumption was not imposed. So (5.3) does not imply $P_\lambda \to P$ under d_4.

Similarly, for the pointwise continuity, we have the following proposition.

PROPOSITION 5.4. *Suppose that P is k-coercive and $\lambda \mapsto P_\lambda$ is continuous at λ_0 under the pointwise topology $\mathcal{T}$. Then, the mapping $\Phi_\lambda : \mathcal{M} \to \mathcal{M}_\lambda$ defined in* (5.5) *is surjective and $\gamma(I-\Phi_\lambda)(r) \to 0$ for each $r > 0$, as $\lambda \to \lambda_0$.*

Henceforth, we define the map Φ_λ to be as in Proposition 5.3 or 5.4 and give robustness results under each graph topology. The following results follow as consequences of Proposition 5.3 or 5.4 and the results of [7]; however, we give the entire proofs for completeness. First, we consider the case when weighted topology is involved.

THEOREM 5.5. *Suppose P is k-coercive and $H_{P,C}$ is (gf)-stable. If $\lambda \mapsto P_\lambda$ is continuous at λ_0 under a weighted topology $\mathcal{T}_\omega$ with $\omega \in \mathcal{K}_\infty$ and for all $r > 0$*

$$\gamma(\Pi_{\mathcal{M}//\mathcal{N}})(r) \le k(w(r)), \tag{5.7}$$

then, for any $n > 0$, there exists a neighborhood V_n of λ_0 such that $H_{P_\lambda,C}$ is (gf)-stable for $\lambda \in V_n$ and

$$\gamma(\Pi_{\mathcal{M}_\lambda//\mathcal{N}})(r) \le \gamma(\Pi_{\mathcal{M}//\mathcal{N}})\left(\frac{n+1}{n}r\right) + \frac{1}{n}r.$$

Proof. Let $\tau > 0$, $r > 0$, and $z \in \mathcal{W}$ be given with $\|z\|_\tau \le r$. By Proposition 5.3, for each λ, there exists a surjective mapping $\Phi_\lambda : \mathcal{M} \to \mathcal{M}_\lambda$ satisfying (5.3). From Lemma 5.1, it follows that for each λ, there exists $x_\lambda^\tau \in \mathcal{W}_s$ such that

$$T_\tau x_\lambda^\tau = T_\tau z - T_\tau(\Phi_\lambda - I)\Pi_{\mathcal{M}//\mathcal{N}} T_\tau x_\lambda^\tau, \qquad T_\tau \Pi_{\mathcal{M}_\lambda//\mathcal{N}} z = T_\tau \Phi_\lambda \Pi_{\mathcal{M}//\mathcal{N}} T_\tau x_\lambda^\tau. \tag{5.8}$$

By (5.3) and the properties of γ, there exists a neighborhood V_n of λ_0 such that

$$\frac{\gamma(\Phi_\lambda - I)(\gamma(\Pi_{\mathcal{M}//\mathcal{N}})(\|x_\lambda^\tau\|_\tau))}{\|x_\lambda^\tau\|_\tau} \le \frac{\gamma(\Phi_\lambda - I)(k(w(\|x_\lambda^\tau\|_\tau)))}{\|x_\lambda^\tau\|_\tau} < \frac{1}{n+1}$$

for all $n > 0$ and $\lambda \in V_n$. So, from (5.8), it follows that

$$\begin{aligned}\|x_\lambda^\tau\|_\tau &\le \|z\|_\tau + \|(\Phi_\lambda - I)\Pi_{\mathcal{M}//\mathcal{N}} T_\tau x_\lambda^\tau\|_\tau \\ &\le \|z\|_\tau + \gamma(\Phi_\lambda - I)(\gamma(\Pi_{\mathcal{M}//\mathcal{N}})(\|x_\lambda^\tau\|_\tau)) \\ &\le \|z\|_\tau + \frac{1}{n+1}\|x_\lambda^\tau\|_\tau,\end{aligned}$$

which implies that $\|x_\lambda^\tau\|_\tau \le (n+1)\|z\|_\tau/n \le (n+1)r/n$ for all $\lambda \in V_n$. By (5.8), we have

$$T_\tau \Pi_{\mathcal{M}_\lambda//\mathcal{N}} z = T_\tau \Phi_\lambda \Pi_{\mathcal{M}//\mathcal{N}} T_\tau x_\lambda^\tau = T_\tau \Pi_{\mathcal{M}//\mathcal{N}} T_\tau x_\lambda^\tau + T_\tau(\Phi_\lambda - I)\Pi_{\mathcal{M}//\mathcal{N}} T_\tau x_\lambda^\tau$$

and therefore

$$\begin{aligned}\|\Pi_{\mathcal{M}_\lambda//\mathcal{N}} z\|_\tau &\le \|\Pi_{\mathcal{M}//\mathcal{N}} T_\tau x_\lambda^\tau\|_\tau + \|(\Phi_\lambda - I)\Pi_{\mathcal{M}//\mathcal{N}} T_\tau x_\lambda^\tau\|_\tau \\ &\le \gamma(\Pi_{\mathcal{M}//\mathcal{N}})\left(\frac{n+1}{n}r\right) + \frac{1}{n+1}\|x_\lambda\|_\tau \le \gamma(\Pi_{\mathcal{M}//\mathcal{N}})\left(\frac{n+1}{n}r\right) + \frac{1}{n}r.\end{aligned}$$

Since τ is arbitrary, $\gamma(\Pi_{\mathcal{M}_\lambda//\mathcal{N}})(r) \le \gamma(\Pi_{\mathcal{M}//\mathcal{N}})(\frac{n+1}{n}r)r + \frac{1}{n}r < \infty$ for $\lambda \in V_0$. ∎

We remark that condition (5.7) can be replaced by the weaker condition

$$\gamma(\Pi_{\mathcal{M}//\mathcal{N}})(r) \le k(cw(r)) \quad \text{with } c > 0$$

since P is also kc-coercive due to the remark made after Definition 5.2. This claim is also supported by Theorem 3.12 from which we see that $\lambda \mapsto P_\lambda$ is also continuous at λ_0 under a weighted topology $\mathcal{T}_{c\omega}$, so the ω in (5.7) can be replaced by $c\omega$. This replacement gives a weaker bound for $\gamma(\Pi_{\mathcal{M}//\mathcal{N}})(r)$.

In the case of the pointwise topology, we have the following theorem.

THEOREM 5.6. *Suppose that P is k-coercive, $H_{P,C}$ is (gf)-stable and $\lambda \mapsto P_\lambda$ is continuous at λ_0 under the pointwise topology $\mathcal{T}$. If, for each λ, $T_\tau(\Phi_\lambda - I)\Pi_{\mathcal{M}//\mathcal{N}}$ is continuous and compact as a mapping from any subset $S_r = \{w \in \mathcal{W} : \sup_{\tau>0} \|w\|_\tau \leq r\}$ to $\mathcal{W}$, then for each $r > 0$, there exists a neighborhood V_r of λ_0 in Λ such that $\gamma(H_{P_\lambda,C})(r) < \infty$ for all $\lambda \in V_r$. Here Φ_λ is defined as in* (5.5).

Proof. Let $r > 0$ and $w \in \mathcal{W}$ be given with $\|w\|_\tau \leq r$. Consider the operator

$$\mathbf{A}_\lambda : \mathbf{A}_\lambda x = w + (\Phi_\lambda - I)\Pi_{\mathcal{M}//\mathcal{N}} x, \quad x \in \mathcal{W}.$$

Since $H_{P,C}$ is stable, $\gamma(\Pi_{\mathcal{M}//\mathcal{N}})(k) < \infty$ for all $k > 0$. Using Proposition 5.3, we see there exists a neighborhood V_r of λ_0 such that

$$\|(\Phi_\lambda - I)\Pi_{\mathcal{M}//\mathcal{N}} x\|_\tau \leq \gamma(\Phi_\lambda - I)(\gamma(\Pi_{\mathcal{M}//\mathcal{N}})(2r)) < r \tag{5.9}$$

for all $x \in S_{2r}$ and $\lambda \in V_r$. This implies that $\|\mathbf{A}_\lambda x\|_\tau < \|w\|_\tau + r < 2r$ for all $x \in S_{2r}$. Due to our assumption, we may suppose that $\mathbf{A}_\lambda$ is continuous and compact on S_{2r}. From Schauder's fixed point theorem, it follows that there exists $x_\lambda \in S_{2r}$ such that

$$x_\lambda = w + (\Phi_\lambda - I)\Pi_{\mathcal{M}//\mathcal{N}} x_n \quad \text{for } \lambda \in V_r,$$

i.e.,

$$w = \Pi_{\mathcal{N}//\mathcal{M}} x_\lambda + \Phi_\lambda \Pi_{\mathcal{M}//\mathcal{N}} x_\lambda.$$

Since $\Pi_{\mathcal{N}//\mathcal{M}} x_\lambda \in \mathcal{N}$, $\Phi_\lambda \Pi_{\mathcal{M}//\mathcal{N}} x_\lambda \in \mathcal{M}_\lambda$, and the perturbed system is well-posed, we have

$$\Pi_{\mathcal{M}_\lambda//\mathcal{N}} w = \Phi_\lambda \Pi_{\mathcal{M}//\mathcal{N}} x_\lambda = \Pi_{\mathcal{M}//\mathcal{N}} x_\lambda + (\Phi_\lambda - I)\Pi_{\mathcal{M}//\mathcal{N}} x_\lambda$$

and therefore

$$\begin{aligned} \|\Pi_{\mathcal{M}_\lambda//\mathcal{N}} w\|_\tau &= \|\Pi_{\mathcal{M}//\mathcal{N}} x_\lambda\|_\tau + \|(\Phi_\lambda - I)\Pi_{\mathcal{M}//\mathcal{N}} x_\lambda\|_\tau \\ &\leq \gamma(\Pi_{\mathcal{M}//\mathcal{N}})(2r) + \gamma(\Phi_\lambda - I)(\gamma(\Pi_{\mathcal{M}//\mathcal{N}})(2r)) \\ &\leq \gamma(\Pi_{\mathcal{M}//\mathcal{N}})(2r) + r. \end{aligned}$$

Hence $\gamma(\Pi_{\mathcal{M}_\lambda//\mathcal{N}})(r) \leq \gamma(\Pi_{\mathcal{M}//\mathcal{N}})(2r) + r < \infty$ for $\lambda \in V_r$. ∎

With the technical assumption of compactness of $T_\tau(\Phi_\lambda - I)\Pi_{\mathcal{M}//\mathcal{N}}$, this result states the boundedness of $H_{P_\lambda,C}(u_0, y_0)^\top$ for $\|(u_0, y_0)^\top\| \leq r$ and λ sufficiently close to λ_0. Obviously, if the neighborhood V_r for (5.9) is independent of r, that is, if

$$\gamma(\Phi_\lambda - I)(\gamma(\Pi_{\mathcal{M}//\mathcal{N}})(2r)) < r \quad \text{for all } \lambda \text{ sufficiently close to } \lambda_0$$

hold for all (large) r, then $H_{P_\lambda,C}$ would be (gf)-stable.

6. Conclusions. The main contributions of this paper are as follows. Natural generalizations of the graph topology w.r.t. a gain function notion of stability for nonlinear systems in a general normed signal space setting were defined. Convergence in the graph topology was shown to have a natural application in robust stability results. Various metrizations of the graph topologies were given; in particular it was shown that the generalizations of the gap metric given by [7] and the natural generalization of the graph metric both induce the graph topology when the stability notion is that of an (unweighted) induced gain, subject to certain assumptions on local asymptotic completeness and the existence of normalized coprime factorizations.

Weaker results have been derived for the more general cases (including the weighted case). Georgiou-type formulae [4] have been derived and are shown to be equivalent to other alternative formulations of the gap metric.

There are many directions for future work. An important topic is the extension of the above results to the ν-gap setting; in particular, the investigation of a coprime factor characterization of the underlying induced topology of the nonlinear generalizations of the ν-gap. A more fundamental area for future research concerns the investigation of the continuity of the closed loop response w.r.t. gap perturbations to the loop, probably involving greater regularity assumptions [7]. A final area of worthy future study concerns the explicit study of the numerical computation of the gap, possibly based on the Georgiou-type formulae, but with additional regularity assumptions on the minimizer Q, perhaps allowed by greater regularity assumptions on P and C. In this regard, nonlinear generalizations of the commutant lifting theory may be the appropriate tool.

Acknowledgments. The second author would like to acknowledge the hospitality of M. C. Smith and the Cambridge University Engineering Department for a visit during which this paper was completed. Informative discussions with M. C. Smith are gratefully acknowledged. The authors also thank the referees for valuable suggestions concerning the definition of normalized coprime factorizations and the presentation of the paper.

CONSTRAINED STOCHASTIC LQ CONTROL WITH RANDOM COEFFICIENTS, AND APPLICATION TO PORTFOLIO SELECTION*

YING HU† AND XUN YU ZHOU‡

Abstract. This paper is devoted to the study of a stochastic linear-quadratic (LQ) optimal control problem where the control variable is constrained in a cone, and all the coefficients of the problem are random processes. Employing Tanaka's formula, optimal control and optimal cost are explicitly obtained via solutions to two extended stochastic Riccati equations (ESREs). The ESREs, introduced for the first time in this paper, are highly nonlinear backward stochastic differential equations (BSDEs), whose solvability is proved based on a truncation function technique and Kobylanski's results. The general results obtained are then applied to a mean-variance portfolio selection problem for a financial market with random appreciation and volatility rates, and with short-selling prohibited. Feasibility of the problem is characterized, and efficient portfolios and efficient frontier are presented in closed forms.

Key words. stochastic LQ control, extended stochastic Riccati equation, backward stochastic differential equation, mean-variance portfolio selection, efficient portfolio, efficient frontier

1. Introduction.

Linear-quadratic (LQ) optimal control is a problem where the system dynamics are linear in state and control variables and the cost functional is quadratic in the two variables. It is a classical yet fundamental problem in control theory, pioneered by Kalman [11] (for deterministic control). Extension to stochastic LQ control was first carried out by Wonham [25]. Bismut [3] performed a detailed analysis for stochastic LQ control with random coefficients. With the joint effort of many researchers in the last 40 years, there has been an enormously rich theory on LQ control, deterministic and stochastic alike. Recently, starting with Chen, Li, and Zhou [6], there has been emerging interest in the so-called *indefinite* stochastic LQ control, where, quite contrary to the conventional belief, the cost weighting matrices are allowed to be indefinite; see [7, 8, 1, 26]. This new theory turns out to be useful in solving the continuous-time version of Markowitz's Nobel-winning mean-variance portfolio selection model; see [28, 14, 16, 18, 13, 17]. For systematic accounts of the deterministic and stochastic LQ theory, refer to [2] and [27], respectively.

One of the elegant features of the LQ theory is that it is able to give in explicit forms the optimal state feedback control and the optimal cost value through the celebrated Riccati equation; hence the LQ control problem is completely solved. What essentially enables this closed-form solution, besides the special LQ structure, is that the control is *not* constrained. Specifically, since the control is unconstrained, the feedback control constructed via the Riccati equation is *automatically* admissible.

If, on the other hand, there are pointwise control constraints, then the whole LQ approach would collapse.

One should acknowledge that LQ control with control constraints is a well-posed problem which is important in both theory and applications. For example, in many real applications the control variable is required to take only nonnegative values. The mean-variance portfolio selection problem with no-shorting constraint, which is to be tackled in this paper, is exactly one of such problems. There were some attempts in attacking the deterministic LQ problems with positive controls; see for example [23, 5, 9]. In these works, however, only some implicit necessary and sufficient conditions for optimality were derived and some numerical schemes suggested, and the special LQ structure was not fully taken advantage of and no explicit result was obtained. On the other hand, to our best knowledge research on pointwise constrained stochastic LQ control has been completely absent in the literature.

The main purpose of this paper is to tackle a stochastic LQ control problem where the control variable is constrained in a cone (which, certainly, includes the nonnegative orthant in a Euclidean space as a special case), and all the coefficient matrices of the model are random. Moreover, the problem is allowed to be "singular" in the sense that the control weighting matrix in the cost functional is possibly singular. However, we are able to treat only the case when the state variable is scalar-valued, although it is sufficient to cover many meaningful practical applications, in particular in financial area where the one-dimensional wealth process is typically taken as the state. We aim to obtain *explicit* solutions comparable to the classical unconstrained-control counterpart. To this end, we introduce two equations termed extended stochastic Riccati equations (ESREs). These two equations are highly nonlinear backward stochastic differential equations (BSDEs), the solvability of which is interesting in its own right. Based on a truncation function technique and a delicate result of Kobylanski [12], we are able to prove the existence of solutions to the introduced ESREs. Then, applying Tanaka's formula and going through some detailed analysis, we obtain explicit optimal feedback control as well as the optimal cost value in terms of the solutions to the two ESREs.

The other purpose of the paper is to solve the continuous-time mean-variance portfolio selection model with short selling prohibition and random market parameters. Indeed, this is the very problem that motivated us to tackle the general constrained stochastic LQ problem. Notice that a mean-portfolio selection model with no-shorting was solved in [16] using Hamilton–Jacobi–Bellman equation and viscosity solution theory; however, among other additional assumptions all the market parameters are assumed to be deterministic in [16]. The partial differential equation approach there does not extend to the current case with random parameters. To overcome this difficulty, we reformulate the problem so that it falls exactly into the general constrained LQ problem that has been solved. Hence, by applying the general results obtained we are able to solve the portfolio selection problem, once again, explicitly and completely.

There are a large number of papers devoted to applying stochastic control theory for mean-variance efficient/hedging portfolio selection models; see, to name a few recent ones, [14, 21, 13, 18, 17, 22, 4]. While some of these works are on more general asset price models (such as semimartingale ones) and/or markets (including incomplete markets), none of them deal with directly constrained portfolios. As a result, the value functions there remain quadratic, which is no longer the case, as will be demonstrated in this paper, with the conic constrained portfolios.

The rest of the paper is organized as follows. In section 2 we formulate the constrained stochastic LQ model, and in section 3 we present some mathematical preliminaries including Tanaka's formula and the introduction of the two ESREs. Section 4 is devoted to the solvability of the ESREs in two common cases. Section 5 gives the solution to the LQ problem. Application of the general results to a mean-variance portfolio selection problem is presented in section 6. Finally, section 7 concludes the paper with some remarks.

2. Problem formulation. We assume throughout that $(\Omega, \mathcal{F}, \{\mathcal{F}_t\}_{t\geq 0}, P)$ is a given complete, filtered probability space and that $W(\cdot)$ is a k-dimensional standard Brownian motion on this space with $W(0) = 0$. In addition, we assume that $\mathcal{F}_t$ is the augmentation of $\sigma\{W(s) \,|\, 0 \leq s \leq t\}$ by all the P-null sets of $\mathcal{F}$. When no confusion would occur, we leave out P-a.s. for a statement that holds almost surely with respect to P.

Throughout this paper, we denote by $\mathbb{R}^m$ the set of m-dimensional *column* vectors, by $\mathbb{R}^m_+$ the set of m-dimensional column vectors whose components are nonnegative, by $\mathbb{R}^{m\times n}$ the set of $m \times n$ real matrices, and by $\mathbb{S}^n$ the set of symmetric $n \times n$ real matrices. Therefore, $\mathbb{R}^m \equiv \mathbb{R}^{m\times 1}$. If $M = (m_{ij}) \in \mathbb{R}^{m\times n}$, we denote its transpose by M', and its norm by $|M| = \sqrt{\sum_{i,j} m_{ij}^2}$. If $M \in \mathbb{S}^n$ is positive (positive semi-) definite, we write $M > (\geq)\ 0$. Suppose $\eta : \Omega \to \mathbb{R}^n$ is a $\mathcal{G}$-measurable random variable. We write $\eta \in L^2_{\mathcal{G}}(\Omega; \mathbb{R}^n)$ if η is square integrable (i.e., $E|\eta|^2 < \infty$), and $\eta \in L^\infty_{\mathcal{G}}(\Omega; \mathbb{R}^n)$ if η is uniformly bounded. Consider now the case when $f : [0, T] \times \Omega \to \mathbb{R}^n$ is an $\{\mathcal{F}_t\}_{t\geq 0}$-adapted process. If $f(\cdot)$ is square integrable (i.e., $E\int_0^T |f(t)|^2\, dt < \infty$) we shall write $f(\cdot) \in L^2_{\mathcal{F}}(0, T; \mathbb{R}^n)$; if $f(\cdot)$ is uniformly bounded (i.e., ess $\sup_{(t,\omega)\in[0,T]\times\Omega} |f(t)| < \infty$), then $f(\cdot) \in L^\infty_{\mathcal{F}}(0, T; \mathbb{R}^n)$. If $f(\cdot)$ has (P-a.s.) continuous sample paths and $E \sup_{t\in[0,\,T]} |f(t)|^2 < \infty$ we write $f(\cdot) \in L^2_{\mathcal{F}}(\Omega; C(0, T; \mathbb{R}^n))$. These definitions generalize in the obvious way to the case when $f(\cdot)$ is $\mathbb{R}^{n\times m}$- or $\mathbb{S}^n$-valued. In addition, we say that $N \in L^2_{\mathcal{F}}(0, T; \mathbb{S}^n)$ is positive (positive semi-) definite, which is sometimes denoted simply by $N > (\geq)\ 0$, if $N(t, \omega) > (\geq)\ 0$ for a.e. $t \in [0, T]$ and P-a.s., and say that N is uniformly positive definite if $N \geq cI_n$ for a.e. $t \in [0, T]$ and P-a.s. with some given deterministic constant $c > 0$, where I_n is the n-dimensional identity matrix.

Finally, for any real number we define $x^+ := \max\{x, 0\}$ and $x^- := \max\{-x, 0\}$.

Consider the following linear stochastic differential equation (SDE):

$$\text{(2.1)}\qquad \begin{cases} dx(t) &= [A(t)\,x(t) + B(t)\,u(t)]\,dt + [x(t)C(t)' + u(t)'D(t)']\,dW(t), \quad t \in [0, T], \\ x(0) &= x_0, \end{cases}$$

where A, B, C, and D are $\{\mathcal{F}_t\}_{t\geq 0}$-adapted processes (possibly matrix-valued), and $x_0 \in \mathbb{R}$ is a nonrandom scalar. Precise assumptions on these data will be specified below. Let $\Gamma \subset \mathbb{R}^m$ be a given closed cone; i.e., Γ is closed, and if $u \in \Gamma$, then $\alpha u \in \Gamma$ $\forall \alpha \geq 0$. Typical examples of such a cone are $\Gamma = \mathbb{R}^m_+$, $\Gamma = \{u \in \mathbb{R}^m \,|\, Mu \leq 0\}$, and $\Gamma = \{u \in \mathbb{R}^m \,|\, Mu = 0\}$, where $M \in \mathbb{R}^{n\times m}$. The class of *admissible controls* is the set

$$\mathcal{U} := \Big\{u(\cdot) \in L^2_{\mathcal{F}}(0, T; \mathbb{R}^m) \,\Big|\, \begin{array}{l} u(t) \in \Gamma,\ P-\text{a.s., a.e. } t \in [0, T], \text{ and (2.1) has a} \\ \text{unique solution under } u(\cdot) \end{array}\Big\}.$$

If $u(\cdot) \in \mathcal{U}$ and $x(\cdot)$ is the associated solution of (2.1), then we refer to $(x(\cdot), u(\cdot))$ as an *admissible pair*.

Suppose that the cost functional is given by

$$J(x_0, u(\cdot)) := E\Big\{\int_0^T \Big[Q(t)x(t)^2 + u(t)'R(t)u(t)\Big]\, dt + Gx(T)^2\Big\}. \tag{2.2}$$

Throughout this paper, we shall assume the following:

Assumption (A1):

$$\begin{cases} A,\, Q & \in & L^\infty_{\mathcal{F}}(0,\, T; \mathbb{R}), \\ B & \in & L^\infty_{\mathcal{F}}(0,\, T; \mathbb{R}^{1\times m}), \\ C & \in & L^\infty_{\mathcal{F}}(0,\, T; \mathbb{R}^{k}), \\ D & \in & L^\infty_{\mathcal{F}}(0,\, T; \mathbb{R}^{k\times m}), \\ R & \in & L^\infty_{\mathcal{F}}(0,\, T; \mathbb{S}^{m}), \\ G & \in & L^\infty_{\mathcal{F}_T}(\Omega;\, \mathbb{R}). \end{cases}$$

Note that all the parameters involved may be random. Also, by standard SDE theory, (2.1) admits a unique solution $x(\cdot) \in L^2_{\mathcal{F}}(\Omega;\, C(0,\, T;\, \mathbb{R}))$ for any $u(\cdot) \in L^2_{\mathcal{F}}(0,\, T;\, \mathbb{R}^m)$ under Assumption (A1). The *stochastic LQ problem* associated with (2.1)–(2.2) is as follows:

$$\begin{cases} \text{Minimize} & J(x_0, u(\cdot)), \\ \text{subject to} & (x(\cdot),\, u(\cdot)) \text{ admissible for (2.1).} \end{cases} \tag{2.3}$$

The problem (2.3) is said to be *finite* (w.r.t. x_0) if there exists some finite constant $K \in \mathbb{R}$ such that

$$J(x_0, u(\cdot)) \geq K \quad \forall\, u(\cdot) \in \mathcal{U},$$

and *solvable* (w.r.t. x_0) if there exists a control $u^*(\cdot) \in \mathcal{U}$ such that

$$J(x_0, u^*(\cdot)) \leq J(x_0, u(\cdot)) \quad \forall\, u(\cdot) \in \mathcal{U}.$$

In this case, the control $u^*(\cdot)$ is referred to as the *optimal control* (w.r.t. x_0). We say that (2.3) is *uniquely solvable* if it is solvable and the optimal control is unique. Note that a finite LQ problem is not necessarily solvable.

3. Preliminaries. In this section we present some mathematical preliminaries required in what follows, including in particular Tanaka's formula which plays a critical technical role in the subsequent analysis.

LEMMA 3.1 (Tanaka's formula). *Let $X(t)$ be a continuous semimartingale. Then*

$$\begin{aligned} dX^+(t) &= 1_{(X(t)>0)}dX(t) + \tfrac{1}{2}dL(t), \\ dX^-(t) &= -1_{(X(t)\leq 0)}dX(t) + \tfrac{1}{2}dL(t), \end{aligned} \tag{3.1}$$

where $L(\cdot)$ is an increasing continuous process, called the local time of $X(\cdot)$ at 0, satisfying

$$\int_0^t |X(s)|dL(s) = 0, \quad P - a.s.. \tag{3.2}$$

Proof. See, for example, [24, Chapter VI, Theorem 1.2, and Proposition 1.3]. □

Next, define the following mappings:

$$
\begin{aligned}
H_+(t,\omega,v,P,\Lambda) := \;& v'[R(t,\omega)+PD(t,\omega)'D(t,\omega)]v \\
& +2v'[B(t,\omega)'P+D(t,\omega)'PC(t,\omega)+D(t,\omega)'\Lambda], \\
H_-(t,\omega,v,P,\Lambda) := \;& v'[R(t,\omega)+PD(t,\omega)'D(t,\omega)]v \\
& -2v'[B(t,\omega)'P+D(t,\omega)'PC(t,\omega)+D(t,\omega)'\Lambda], \\
& (t,\omega,v,P,\Lambda)\in[0,T]\times\Omega\times\mathbb{R}^m\times\mathbb{R}\times\mathbb{R}^k,
\end{aligned}
\tag{3.3}
$$

and

$$
\begin{aligned}
&H_+^*(t,\omega,P,\Lambda) := \inf_{v\in\Gamma} H_+(t,\omega,v,P,\Lambda), \\
&H_-^*(t,\omega,P,\Lambda) := \inf_{v\in\Gamma} H_-(t,\omega,v,P,\Lambda), \quad (t,\omega,P,\Lambda)\in[0,T]\times\Omega\times\mathbb{R}\times\mathbb{R}^k.
\end{aligned}
\tag{3.4}
$$

Remark 3.1. $H_+^*(t,\omega,P,\Lambda)$ and $H_-^*(t,\omega,P,\Lambda)$ have finite values if $R(t,\omega)+PD(t,\omega)'D(t,\omega)>0$. Indeed, in this case, there exist $C_1(t,\omega,P,\Lambda)>0$, $C_2(t,\omega,P,\Lambda)>0$ such that

$$
H_+(t,\omega,v,P,\Lambda)\geq C_1|v|^2-C_2|v|=C_1|v|\left(|v|-\frac{C_2}{C_1}\right).
$$

If $|v|>\frac{C_2}{C_1}$, then $H_+>0$. Recall that $0\in\Gamma$, hence $\inf_{v\in\Gamma}H_+(t,\omega,v,P,\Lambda)\leq 0$. These facts imply that

$$
H_+^*(t,\omega,P,\Lambda)=\inf_{v\in\Gamma,|v|\leq\frac{C_2}{C_1}} H_+(t,\omega,v,P,\Lambda)\geq \min_{|v|\leq\frac{C_2}{C_1}} H_+(t,\omega,v,P,\Lambda)>-\infty.
$$

Hence, $\inf_{v\in\Gamma}H_+(t,\omega,v,P,\Lambda)$ is finite. The same is true for H_-.

Now we introduce the following two nonlinear backward stochastic differential equations—BSDEs (the arguments t and ω are suppressed):

$$
\begin{cases}
dP_+ = -\Big\{(2A+C'C)P_+ + 2C'\Lambda_+ + Q + H_+^*(P_+,\Lambda_+)\Big\}dt + \Lambda_+'dW, \quad t\in[0,\,T], \\
P_+(T)=G, \\
R+P_+D'D>0,
\end{cases}
\tag{3.5}
$$

$$
\begin{cases}
dP_- = -\Big\{(2A+C'C)P_- + 2C'\Lambda_- + Q + H_-^*(P_-,\Lambda_-)\Big\}dt + \Lambda_-'dW, \quad t\in[0,\,T], \\
P_-(T)=G, \\
R+P_-D'D>0.
\end{cases}
\tag{3.6}
$$

The equations (3.5) and (3.6) are referred to as the ESREs. The following gives a precise definition of their solutions.

Definition 3.1. *A stochastic process* $(P_+,\Lambda_+)\in L^2_{\mathcal{F}}(\Omega;C(0,\,T;\,\mathbb{R}))\times L^2_{\mathcal{F}}(0,\,T;\,\mathbb{R}^k)$ *is called a* solution *to the ESRE* (3.5) *if it satisfies the first equation of* (3.5) *in the Itô sense as well as the second (the terminal condition) and third (the positive definiteness) constraints of* (3.5). *A solution* (P_+,Λ_+) *of* (3.5) *is called* bounded *if* $P_+\in L^\infty_{\mathcal{F}}(0,\,T;\,\mathbb{R})$, *called* positive *(respectively,* nonnegative*) if* $P_+(t)>0$ *(respectively,* $P_+(t)\geq 0$*)* $\forall\ t\in[0,\,T]$ *and* P*-a.s., and called* uniformly positive *if* $P_+(t)\geq c$

$\forall\ t \in [0, T]$ *and* P*-a.s. with some deterministic constant* $c > 0$. *Similar terms can be defined for the other ESRE* (3.6).

4. Existence of solution to the ESREs. As the existence of a solution to the ESREs (3.5) and (3.6) is essential to solving the underlying stochastic LQ problem, we devote this section to this issue. Note that the existence problem is interesting in its own right from BSDE point of view, for both (3.5) and (3.6) are nonlinear BSDEs that do not satisfy the standard assumptions for existence.

We will deal with the following two cases.

Standard case. $Q \geq 0$, $R > 0$ with $R^{-1} \in L^{\infty}_{\mathcal{F}}(0, T; \mathbb{R}^{m\times m})$, and $G \geq 0$.

Singular case. $Q \geq 0$, $R \geq 0$, $G > 0$ with $G^{-1} \in L^{\infty}_{\mathcal{F}}(0, T; \mathbb{R})$, and $D'D > 0$ with $(D'D)^{-1} \in L^{\infty}_{\mathcal{F}}(0, T; \mathbb{R}^{m\times m})$.

4.1. Standard case. In this subsection we solve the standard case.

THEOREM 4.1. *For the standard case, there exists a bounded, nonnegative solution* (P_+, Λ_+) *(respectively,* (P_-, Λ_-)*) to the ESRE* (3.5) *(respectively,* (3.6)*).*

Proof. Let us first consider the following BSDE:

$$\begin{cases} dP_1 = -\Big\{(2A + C'C)P_1 + 2C'\Lambda_1 + Q\Big\}dt + \Lambda_1' dW, \quad t \in [0, T], \\ P_1(T) = G. \end{cases} \tag{4.1}$$

This is a linear BSDE with bounded coefficients (by virtue of Assumption (A1)), and with $Q \geq 0$ and $G \geq 0$. Hence there exists a unique, nonnegative bounded solution (P_1, Λ_1). Denote by $c_1 > 0$ an upper bound of P_1. Now, consider the following BSDE:

$$\begin{cases} dP = -F_1(t, P, \Lambda)dt + \Lambda' dW, \quad t \in [0, T], \\ P(T) = G, \end{cases} \tag{4.2}$$

where the function F_1 is defined by

$$\begin{aligned} F_1(t, \omega, P, \Lambda) := \quad & [2A(t, \omega) + C(t, \omega)'C(t, \omega)]P + 2C(t, \omega)'\Lambda + Q(t, \omega) \\ & + H^*_+(t, \omega, P^+, \Lambda)g_1(P^+), \ (t, \omega, P, \Lambda) \in [0, T] \times \Omega \times \mathbb{R} \times \mathbb{R}^k \end{aligned}$$

(recall that P^+ denotes the positive part of P), whereas $g_1 : \mathbb{R}^+ \to [0, 1]$ is a smooth truncation function satisfying $g_1(x) = 1$ for $x \in [0, c_1]$, and $g_1(x) = 0$ for $x \in [2c_1, +\infty)$.

The function F_1 is continuous in (P, Λ). To see this, for a given $n \in \mathbb{N}$ (the set of positive integers), if $|P| \leq n$, $|\Lambda| \leq n$, then by the assumption on R there exist two constants $C_1 > 0$ and $C_2(n) > 0$, such that

$$H_+(t, v, P^+, \Lambda) \geq C_1|v|^2 - C_2(n)|v|.$$

Thus, for $|P| \leq n, |\Lambda| \leq n$, the argument in Remark 3.1 results in

$$H^*_+(t, P^+, \Lambda) = \min_{v\in\Gamma, |v|\leq \frac{C_2(n)}{C_1}} H_+(t, v, P^+, \Lambda).$$

This implies that F_1 is continuous in (P, Λ).

On the other hand, there exists a $C_2 > 0$ such that

$$H_+(t, v, P^+, \Lambda) \geq C_1|v|^2 - C_2(P^+ + |\Lambda|)|v|,$$

which yields

$$0 \geq H_+^*(t, P^+, \Lambda) \geq -\frac{C_2^2(P^+ + |\Lambda|)^2}{4C_1}.$$

Hence, F_1 satisfies the hypothesis (H1) of Kobylanski [12] noting the role of the truncation function g_1. According to [12, Theorem 2.3], there is a bounded, maximal solution (see [12, p. 565] for its definition) (P_+, Λ_+) to the BSDE (4.2). Now, as $H_+^*(t, P, \Lambda) \leq 0$ and (P_1, Λ_1) is the only, hence maximal, bounded solution to (4.1), we get $P_+ \leq P_1 \leq c_1$. Furthermore, $G \geq 0$ and $Q \geq 0$ and $H_+^*(t, P^+, \Lambda) \geq -\frac{C_2^2(P^+ + |\Lambda|)^2}{4C_1}$ implies $P_+ \geq 0$, using the facts that (P_+, Λ_+) is the bounded, maximal solution to (4.2) and that (0,0) is an obvious solution to (4.2) with $G = 0$, $Q = 0$, and $H_+^*(t, P^+, \Lambda)g_1(P^+)$ replaced by $-\frac{C_2^2(P^+ + |\Lambda|)^2}{4C_1} g_1(P^+)$. This proves that (P_+, Λ_+) is a bounded nonnegative solution of the ESRE (3.5). The same argument concludes also the existence of a solution to the ESRE (3.6). □

4.2. Singular case. The singular case is the one that will be used in the financial application in the second half of the paper.

THEOREM 4.2. *For the singular case, there exists a bounded, uniformly positive solution* (P_+, Λ_+) *(respectively,* (P_-, Λ_-)*) to the ESRE* (3.5) *(respectively,* (3.6)*).*

Proof. Let us first consider the following BSDE (the argument t is suppressed):

$$\text{(4.3)} \quad \begin{cases} dP_2 = -[(2A + C'C)P_2 + 2C'\Lambda_2 + H^*(P_2, \Lambda_2)]dt + \Lambda_2' dW, \quad t \in [0, T], \\ P_2(T) = G, \\ P_2 > 0, \end{cases}$$

where

$$H^*(t, P, \Lambda) := -[PB + (C'P + \Lambda')D]P^{-1}(D'D)^{-1}[B'P + D'(PC + \Lambda)].$$

This is a BSDE studied independently in [13] and [10], using different approaches. The existence of its solution was proved in [13] with a rather involved proof, and was proved in [10] with a short proof, nonetheless, for the case $k = m$. For completeness, we will prove the existence of a solution to this BSDE using a simpler method in the lemma following the end of the proof of this theorem. By this lemma, there exists a unique bounded, uniformly positive solution (P_2, Λ_2). In particular, there exists a constant $c_2 > 0$ such that $P_2(t) \geq c_2$ $\forall t \in [0, T]$, P-a.s..

Now, let us consider the following BSDE:

$$\text{(4.4)} \quad \begin{cases} dP = -F_2(t, P, \Lambda)dt + \Lambda' dW, \quad t \in [0, T], \\ P(T) = G, \end{cases}$$

where

$$\begin{aligned} F_2(t, \omega, P, \Lambda) := \quad & [2A(t, \omega) + C(t, \omega)'C(t, \omega)]P + 2C(t, \omega)'\Lambda + Q(t, \omega) \\ & + H_+^*(t, \omega, P, \Lambda)g_2(P^+), \ (t, \omega, P, \Lambda) \in [0, T] \times \Omega \times \mathbb{R} \times \mathbb{R}^k \end{aligned}$$

with $g_2 : \mathbb{R}^+ \to [0, 1]$ being another smooth truncation function satisfying $g_2(x) = 0$ for $x \in [0, \frac{1}{2}c_2]$, and $g_2(x) = 1$ for $x \in [c_2, +\infty)$. As with the proof for the standard case we can show that the function F_2 is continuous in (P, Λ) and satisfies the assumption of [12]. Thus, there exists a bounded, maximal solution of the BSDE (4.4), denoted as (P_+, Λ_+).

Notice the following inequality:

$$\begin{aligned} H_+^*(t,P,\Lambda) &\geq \inf_{v\in\mathbb{R}^m} H_+(t,v,P,\Lambda) \\ &\geq \inf_{v\in\mathbb{R}^m} \{v'PD(t)'D(t)v + 2v'[B(t)'P + D(t)'PC(t) + D(t)'\Lambda]\} \\ &= H^*(t,P,\Lambda). \end{aligned}$$

Hence, noting $Q \geq 0$, the maximal solution argument gives

$$P_+(t) \geq P_2(t) \geq c_2, \quad \forall t \in [0,T].$$

This implies that (P_+, Λ_+) is actually a bounded, uniformly positive solution of the ESRE (3.5). The same argument also leads to the existence of a solution to the ESRE (3.6). □

LEMMA 4.1. *Equation* (4.3) *has a bounded, uniformly positive solution* (P_2, Λ_2).

Proof. Set

$$\alpha := 2A + C'C - (B + C'D)(D'D)^{-1}(B' + D'C), \ \beta := 2C - 2D(D'D)^{-1}(B' + D'C).$$

Then, (4.3) can be rewritten as

$$\text{(4.5)} \quad \begin{cases} dP_2 = -[\alpha P_2 + \beta'\Lambda_2 - \frac{1}{P_2}\Lambda_2'D(D'D)^{-1}D'\Lambda_2]dt + \Lambda_2'dW, \quad t \in [0,T], \\ P_2(T) = G, \\ P_2 > 0. \end{cases}$$

Let $c_3 > 0$ and $c_4 > 0$ be two constants satisfying $G \geq c_3$ and $|\alpha| \leq c_4$, and set

$$c_2 := c_3 e^{-c_4 T}.$$

Now, consider the following BSDE:

$$\text{(4.6)} \quad \begin{cases} dP = -[\alpha P^+ + \beta'\Lambda - \frac{1}{P}\Lambda'D(D'D)^{-1}D'\Lambda g_2(P)]dt + \Lambda'dW, \quad t \in [0,T], \\ P(T) = G, \end{cases}$$

where g_2 is the truncation function defined in the proof of Theorem 4.2 corresponding to the constant c_2. According again to [12, Theorem 2.3], there exists a bounded, maximal solution to this BSDE denoted as (P_2, Λ_2).

Finally, the following BSDE:

$$\text{(4.7)} \quad \begin{cases} dP = -[-c_4 P^+ + \beta'\Lambda - \frac{1}{P}\Lambda'D(D'D)^{-1}D'\Lambda g_2(P)]dt + \Lambda'dW, \quad t \in [0,T], \\ P(T) = c_3, \end{cases}$$

has an obvious solution $(c_3 e^{-c_4(T-t)}, 0)$. As (P_2, Λ_2) is a maximal solution to (4.6), we deduce that $P_2(t) \geq c_3 e^{-c_4(T-t)} \geq c_3 e^{-c_4 T} = c_2$. This implies that (P_2, Λ_2) is also a bounded, uniformly positive solution to (4.5), hence to (4.3). □

Remark 4.1. When there is no control constraint, i.e., when $\Gamma = \mathbb{R}^m$, then

$$H_+^*(t,P,\Lambda) = H_-^*(t,P,\Lambda) = -[PB + (C'P + \Lambda')D](R + PD'D)^{-1}[B'P + D'(PC + \Lambda)],$$

provided $R + PD'D > 0$. Hence both ESREs (3.5) and (3.6) reduce to the normal stochastic Riccati equation

$$
(4.8)\quad \begin{cases} dP = -\Big\{(2A + C'C)P + 2C'\Lambda + Q \\ \qquad\qquad - [PB + (C'P + \Lambda')D](R + PD'D)^{-1}[B'P + D'(PC + \Lambda)]\Big\}dt \\ \qquad\qquad + \Lambda' dW, \qquad t \in [0, T], \\ P(T) = G, \\ R + PD'D > 0. \end{cases}
$$

The above equation has been studied in great detail in [13, 10]. Moreover, in [10] the case when R is possibly indefinite was investigated.

Remark 4.2. The uniqueness of solutions to (3.5) and (3.6) will be proved in the next section, interestingly, as a direct consequence of the solution to the LQ problem. It should be noted that in [12], the uniqueness of solutions is proved under the additional assumption that the generator (i.e., the drift coefficient) is differentiable which is not satisfied here.

5. Solution to the LQ problem. In this section we give explicit solution to the LQ problem (2.1)–(2.2) in terms of the solutions to the two ESREs, for both the standard and singular cases defined in the previous section.

First, when $R + PD'D > 0$, define

$$
(5.1)\quad \begin{aligned} &\xi_+(t, \omega, P, \Lambda) := \operatorname{argmin}_{v\in\Gamma} H_+(t, \omega, v, P, \Lambda), \\ &\xi_-(t, \omega, P, \Lambda) := \operatorname{argmin}_{v\in\Gamma} H_-(t, \omega, v, P, \Lambda), \quad (t, \omega, P, \Lambda) \in [0, T] \times \Omega \times \mathbb{R} \times \mathbb{R}^k. \end{aligned}
$$

Note that the minimizers above are achievable due to a similar argument in Remark 3.1 and the assumption that Γ is closed.

THEOREM 5.1. *In both the standard and singular cases, let* $(P_+, \Lambda_+) \in L^2_{\mathcal{F}}(\Omega; C(0, T; \mathbb{R})) \times L^2_{\mathcal{F}}(0, T; \mathbb{R}^k)$ *and* $(P_-, \Lambda_-) \in L^2_{\mathcal{F}}(\Omega; C(0, T; \mathbb{R})) \times L^2_{\mathcal{F}}(0, T; \mathbb{R}^k)$ *be bounded, nonnegative (in the standard case) or bounded, uniformly positive (in the singular case) solutions to the ESREs* (3.5) *and* (3.6)*, respectively. Then the state feedback control,*

$$
(5.2)\qquad u^*(t) = \xi_+(t, P_+(t), \Lambda_+(t))x^+(t) + \xi_-(t, P_-(t), \Lambda_-(t))x^-(t),
$$

is optimal for the problem (2.1)–(2.2)*. Moreover, in this case the optimal cost is*

$$
(5.3)\qquad J^*(x_0) := \inf_{u(\cdot)\in\mathcal{U}} J(x_0, u(\cdot)) = P_+(0)(x_0^+)^2 + P_-(0)(x_0^-)^2.
$$

Proof. First note that Theorems 4.1 and 4.2 ensure that (3.5) and (3.6) admit bounded, nonnegative (in the standard case) or bounded, uniformly positive (in the singular case) solutions $(P_+, \Lambda_+) \in L^2_{\mathcal{F}}(\Omega; C(0, T; \mathbb{R})) \times L^2_{\mathcal{F}}(0, T; \mathbb{R}^k)$ and $(P_-, \Lambda_-) \in L^2_{\mathcal{F}}(\Omega; C(0, T; \mathbb{R})) \times L^2_{\mathcal{F}}(0, T; \mathbb{R}^k)$, respectively. Let $x(\cdot)$ be the solution of (2.1) under an arbitrary given admissible control $u(\cdot)$. By Tanaka's formula (Lemma 3.1), we obtain

$$
(5.4)\quad \begin{aligned} dx^+(t) = {} & 1_{(x(t)>0)}[A(t)x(t) + B(t)u(t)]dt + 1_{(x(t)>0)}[x(t)C(t)' + u(t)'D(t)']dW(t) \\ & + \frac{1}{2}dL(t), \end{aligned}
$$

where $L(\cdot)$ is the local time of $x(\cdot)$ at 0 as specified in Lemma 3.1. Applying Ito's formula to the above, we get

(5.5)
$$\begin{aligned}
& dx^+(t)^2 \\
= \;& 2x^+(t)\Big\{1_{(x(t)>0)}[A(t)x(t)+B(t)u(t)]dt + 1_{(x(t)>0)}[x(t)C(t)'+u(t)'D(t)']dW(t) \\
& \quad +\tfrac{1}{2}dL(t)\Big\} + 1_{(x(t)>0)}[x(t)C(t)'+u(t)'D(t)'][C(t)x(t)+D(t)u(t)]dt \\
= \;& \Big\{2A(t)x^+(t)^2 + 2u(t)'B(t)'x^+(t) + 1_{(x(t)>0)}[x(t)C(t)'+u(t)'D(t)'][C(t)x(t) \\
& \quad +D(t)u(t)]\Big\}dt + 2x^+(t)[x(t)C(t)'+u(t)'D(t)']dW(t),
\end{aligned}$$

where we have used the fact that $x^+(t)dL(t) = 0$ by virtue of (3.2). Using Ito's formula again to (3.5) and (5.5), and writing

(5.6)
$$\Theta_+(t) := -\left\{[2A(t)+C(t)'C(t)]P_+(t) + 2C(t)'\Lambda_+(t) + Q(t) + H_+^*(t, P_+(t), \Lambda_+(t))\right\},$$

we have (after some reorganization)

(5.7)
$$\begin{aligned}
& d[P_+(t)x^+(t)^2] \\
= \;& \Big\{u(t)'[1_{(x(t)>0)}P_+(t)D(t)'D(t)]u(t) + 2u(t)'[P_+(t)B(t)' + P_+(t)D(t)'C(t) \\
& \quad +D(t)'\Lambda_+(t)]x^+(t) \\
& \quad +[\Theta_+(t) + (2A(t)+C(t)'C(t))P_+(t) + 2C(t)'\Lambda_+(t)]x^+(t)^2\Big\}dt \\
& \quad +\Big\{2P_+(t)x^+(t)[x(t)C(t)'+u(t)'D(t)'] + x^+(t)^2\Lambda_+(t)'\Big\}dW(t).
\end{aligned}$$

Similarly, we can derive

(5.8)
$$\begin{aligned}
& d[P_-(t)x^-(t)^2] \\
= \;& \Big\{u(t)'[1_{(x(t)\le 0)}P_-(t)D(t)'D(t)]u(t) - 2u(t)'[P_-(t)B(t)' + P_-(t)D(t)'C(t) \\
& \quad +D(t)'\Lambda_-(t)]x^-(t) \\
& \quad +[\Theta_-(t) + (2A(t)+C(t)'C(t))P_-(t) + 2C(t)'\Lambda_-(t)]x^-(t)^2\Big\}dt \\
& \quad +\Big\{-2P_-(t)x^-(t)[x(t)C(t)'+u(t)'D(t)'] + x^-(t)^2\Lambda_-(t)'\Big\}dW(t),
\end{aligned}$$

where

(5.9)
$$\Theta_-(t) := -\left\{[2A(t)+C(t)'C(t)]P_-(t) + 2C(t)'\Lambda_-(t) + Q(t) + H_-^*(t, P_-(t), \Lambda_-(t))\right\}.$$

Next, we define, for $n \ge 1$, the following stopping time τ_n:

(5.10)
$$\begin{aligned}
\tau_n := \inf\Big\{t \ge 0 \;\Big|\; & \int_0^t \big\{|2P_+(s)x^+(s)[x(s)C(s)'+u(s)'D(s)'] + x^+(s)^2\Lambda_+(s)'|^2\big\}ds \\
& + \int_0^t \big\{|-2P_-(s)x^-(s)[x(s)C(s)'+u(s)'D(s)'] + x^-(s)^2\Lambda_-(s)'|^2\big\}ds \ge n\Big\} \wedge T,
\end{aligned}$$

where $\inf\emptyset := T$. Obviously, τ_n, $n \ge 1$, is an increasing sequence of stopping times converging to T almost surely.

Summing (5.7) and (5.8), taking integration from 0 to τ_n, and then taking expectation, we have (t is suppressed)

$$\begin{aligned}
&E\Big\{P_+(\tau_n)x^+(\tau_n)^2+P_-(\tau_n)x^-(\tau_n)^2\Big\}+E\Big\{\int_0^{\tau_n}[Q(t)x(t)^2+u(t)'R(t)u(t)]dt\Big\}\\
=\;& P_+(0)(x_0^+)^2+P_-(0)(x_0^-)^2\\
&+E\int_0^{\tau_n}\Big\{u'(R+1_{(x(t)>0)}P_+D'D+1_{(x(t)\le 0)}P_-D'D)u\\
&+2u'(P_+B'+P_+D'C+D'\Lambda_+)x^+-2u'(P_-B'+P_-D'C+D'\Lambda_-)x^-\\
&+[\Theta_++(2A+C'C)P_++2C'\Lambda_++Q](x^+)^2\\
&+[\Theta_-+(2A+C'C)P_-+2C'\Lambda_-+Q](x^-)^2\Big\}dt\\
=\;& P_+(0)(x_0^+)^2+P_-(0)(x_0^-)^2\\
&+E\int_0^{\tau_n}\Big\{u'(R+1_{(x(t)>0)}P_+D'D+1_{(x(t)\le 0)}P_-D'D)u\\
&+2u'(P_+B'+P_+D'C+D'\Lambda_+)x^+-2u'(P_-B'+P_-D'C+D'\Lambda_-)x^-\\
&-H_+^*(P_+,\Lambda_+)(x^+)^2-H_-^*(P_-,\Lambda_-)(x^-)^2\Big\}dt. \qquad (5.11)
\end{aligned}$$

Let us now send $n\to\infty$. Then by noting that $x(\cdot)\in L^2_{\mathcal{F}}(\Omega;C(0,T;\mathbb{R}))$ we get, from the dominated convergence theorem, that,

$$J(x_0,u(\cdot))=P_+(0)(x_0^+)^2+P_-(0)(x_0^-)^2+E\int_0^T\varphi(x(t),u(t))dt, \qquad (5.12)$$

where $\varphi(x(t),u(t))$ denotes the integrand on the right-hand side of (5.11).

Now, we are to show that $\varphi(x(t),u(t))\ge 0$ for any $t\in[0,T]$. Indeed, if $x(t)>0$ for some t, then set $u(t)=x(t)v(t)$. Notice $u(t)\in\Gamma$ if and only if $v(t)\in\Gamma$ since Γ is a cone. Then (again t is suppressed)

$$\begin{aligned}
\varphi(x,u)=\;& u'(R+P_+D'D)u+2u'(P_+B'+P_+D'C+D'\Lambda_+)x-H_+^*(P_+,\Lambda_+)x^2\\
=\;& [v'(R+P_+D'D)v+2v'(P_+B'+P_+D'C+D'\Lambda_+)]x^2-H_+^*(P_+,\Lambda_+)x^2\\
\ge\;& H_+^*(P_+,\Lambda_+)x^2-H_+^*(P_+,\Lambda_+)x^2=0. \qquad (5.13)
\end{aligned}$$

Moreover, the inequality becomes an equality when $u^*(t)=x(t)v^*(t)=x^+(t)\xi_+(t,P_+(t),\Lambda_+(t))\in\Gamma$. Next, if $x(t)<0$ for some t, then put $u(t)=-x(t)v(t)$. In this case,

$$\begin{aligned}
\varphi(x,u)=\;& u'(R+P_-D'D)u+2u'(P_-B'+P_-D'C+D'\Lambda_-)x-H_-^*(P_-,\Lambda_-)x^2\\
=\;& [v'(R+P_+D'D)v-2v'(P_-B'+P_-D'C+D'\Lambda_-)]x^2-H_-^*(P_-,\Lambda_-)x^2\\
\ge\;& H_-^*(P_-,\Lambda_-)x^2-H_-^*(P_-,\Lambda_-)x^2=0, \qquad (5.14)
\end{aligned}$$

where the equality holds at $u^*(t)=-x(t)v^*(t)=x^-(t)\xi_-(t,P_-(t),\Lambda_-(t))\in\Gamma$. Finally, when $x(t)=0$, then $\varphi(x,u)=u'(R+P_-D'D)u\ge 0$; here, the equality holds at $u^*(t)=0$.

The above analysis together with (5.12) shows that

$$J(x_0,u(\cdot))\ge P_+(0)(x_0^+)^2+P_-(0)(x_0^-)^2\ \ \forall u(\cdot)\in\mathcal{U}, \qquad (5.15)$$

whereas the equality is achieved when $u^*(\cdot)$ is defined by (5.2).

If we can prove that the control $u^*(\cdot)$ defined by (5.2) is in $L^2_{\mathcal{F}}(0,T;\mathbb{R}^m)$, then the proof of the theorem will be finished. To this end, first note that, as shown before, there exist two constants $C_1 > 0$ and $C_2 > 0$, such that

$$H_+(t,v,P,\Lambda) \geq C_1|v|^2 - C_2(|P|+|\Lambda|)v \geq C_1|v|[|v| - \frac{C_2}{C_1}(|P|+|\Lambda|)]. \tag{5.16}$$

Hence $H_+(t,v,P,\Lambda) > 0$ if $|v| > \frac{C_2}{C_1}(|P|+|\Lambda|)$. From the definition of $\xi_+(t,P,\Lambda)$, it follows that

$$|\xi_+(t,P,\Lambda)| \leq \frac{C_2}{C_1}(|P|+|\Lambda|). \tag{5.17}$$

The same is true for ξ_-.

Now, under the feedback control (5.2), the system dynamics (2.1) read

(5.18)
$$\begin{cases} dx(t) = & [A(t)x(t) + B(t)\xi_+(t,P_+(t),\Lambda_+(t))x^+(t) + B(t)\xi_-(t,P_-(t),\Lambda_-(t))x^-(t)]dt \\ & +[x(t)C(t)' + x^+(t)\xi_+(t,P_+(t),\Lambda_+(t))'D(t)' \\ & \quad +x^-(t)\xi_-(t,P_-(t),\Lambda_-(t))'D(t)']dW(t), \quad t\in[0,T], \\ x(0) = & x_0. \end{cases}$$

This equation has a unique continuous $\{\mathcal{F}_t\}_{t\geq 0}$-adapted solution; see the lemma following the end of the proof of this theorem. We denote this solution by $x^*(\cdot)$, and hence $u^*(t) = \xi_+(t,P_+(t),\Lambda_+(t))x^{*+}(t) + \xi_-(t,P_-(t),\Lambda_-(t))x^{*-}(t)$. The continuity of $x^*(\cdot)$ along with (5.17) leads to

$$\int_0^T (|x^*(t)|^2 + |u^*(t)|^2)dt < +\infty, \quad P-a.s.. \tag{5.19}$$

Denote by τ_n^*, $n \geq 1$, the sequence of stopping times defined by (5.10) where the state–control pair is taken as $(x^*(\cdot), u^*(\cdot))$. It follows from (5.19) that $\tau_n^* \to T$ as $n \to +\infty$, P-a.s.. On the other hand, (5.11) yields

(5.20)
$$\begin{aligned} &E\Big\{P_+(\tau_n^*)x^{*+}(\tau_n^*)^2 + P_-(\tau_n^*)x^{*-}(\tau_n^*)^2\Big\} + E\int_0^{\tau_n^*}[Q(t)x^*(t)^2 + u^*(t)'R(t)u^*(t)]dt \\ &\quad = P_+(0)(x_0^+)^2 + P_-(0)(x_0^-)^2. \end{aligned}$$

We are now in position to prove $u^*(\cdot) \in L^2_{\mathcal{F}}(0,T;\mathbb{R}^m)$. To do so, we will treat the standard case and the singular case separately.

For the standard case, denote by $c > 0$ such that $R \geq cI_m$; then it follows from (5.20) that

$$cE\int_0^{\tau_n^*} |u^*(t)|^2 dt \leq P_+(0)(x_0^+)^2 + P_-(0)(x_0^-)^2. \tag{5.21}$$

This implies that $u^*(\cdot) \in L^2_{\mathcal{F}}(0,T;\mathbb{R}^m)$.

For the singular case, construct a sequence of stopping times as follows:

$$\theta_n := \inf\left\{t \geq 0 \,\middle|\, \int_0^t (|x^*(s)|^2 + |C(s)x^*(s) + D(s)u^*(s)|^2)ds \geq n\right\} \wedge T.$$

Again θ_n increasingly converges to T a.s. due to (5.19). Rewrite (2.1) under $u^*(\cdot)$ as a kind of BSDE with a random terminal time,

(5.22)
$$\begin{cases} dx^*(t) = [(A - B(D'D)^{-1}D'C)x^*(t) + B(D'D)^{-1}D'z(t)]dt + z(t)'dW(t), \\ t \in [0, \tau_n^* \wedge \theta_n], \\ x^*(\tau_n^* \wedge \theta_n) = x^*(\tau_n^* \wedge \theta_n), \end{cases}$$

where $z(t) := C(t)x^*(t) + D(t)u^*(t)$. Theorem 4.2 provides that there is a constant $c > 0$ such that for any $t \in [0, T]$, $P_+(t) \geq c$ and $P_-(t) \geq c$. Thus, (5.20) with τ_n^* replaced by $\tau_n^* \wedge \theta_n$ leads to

$$cE[x^*(\tau_n^* \wedge \theta_n)^2] \leq P_+(0)(x_0^+)^2 + P_-(0)(x_0^-)^2.$$

On the other hand, the standard estimate for the BSDE (5.22) states that, for a constant $\tilde{c} > 0$,

$$\begin{aligned} E\int_0^{\tau_n^* \wedge \theta_n} (|x^*(s)|^2 + |z(s)|^2)ds &\leq \tilde{c}E[x^*(\tau_n^* \wedge \theta_n)^2] \\ &\leq \frac{\tilde{c}}{c}[P_+(0)(x_0^+)^2 + P_-(0)(x_0^-)^2]. \end{aligned}$$

Appealing to Fatou's lemma, we conclude that $x^*(\cdot) \in L^2_{\mathcal{F}}(0, T; \mathbb{R})$ and $z(\cdot) \times L^2_{\mathcal{F}}(0, T; \mathbb{R}^k)$. This in turn implies $u^*(\cdot) \in L^2_{\mathcal{F}}(0, T; \mathbb{R}^m)$ as $u^*(t) = [D(t)'D(t)]^{-1} D(t)'[z(t) - C(t)x^*(t)]$. □

LEMMA 5.1. *Equation* (5.18) *has a unique continuous* $\{\mathcal{F}_t\}_{t\geq 0}$*-adapted solution.*

Proof. Setting

$$\begin{aligned} &B_+(t) := B(t)\xi_+(t, P_+(t), \Lambda_+(t)), \ B_-(t) := B(t)\xi_-(t, P_-(t), \Lambda_-(t)), \\ &D_+(t) := D(t)\xi_+(t, P_+(t), \Lambda_+(t)), \ D_-(t) := D(t)\xi_-(t, P_-(t), \Lambda_-(t)), \end{aligned}$$

then (5.18) becomes

$$\begin{cases} dx(t) = & [A(t)x(t) + B_+(t)x^+(t) + B_-(t)x^-(t)]dt \\ & +[x(t)C(t)' + x^+(t)D_+(t)' + x^-(t)D_-(t)']dW(t), \quad t \in [0, T], \\ x(0) = & x_0. \end{cases} \tag{5.23}$$

Consider the following two linear SDEs:

(5.24)
$$\begin{cases} dx_+(t) = & [A(t) + B_+(t)]x_+(t)dt + x_+(t)[C(t) + D_+(t)]'dW(t), \quad t \in [0, T], \\ x_+(0) = & x_0^+, \end{cases}$$

and

(5.25)
$$\begin{cases} dx_-(t) = & [A(t) - B_-(t)]x_-(t)dt + x_-(t)[C(t) - D_-(t)]'dW(t), \quad t \in [0, T], \\ x_-(0) = & x_0^-. \end{cases}$$

It is well known that both (5.24) and (5.25) have unique continuous $\{\mathcal{F}_t\}_{t\geq 0}$-adapted solutions which can be represented explicitly as

$$\begin{aligned} x_+(t) = x_0^+ \exp\Big\{ &\int_0^t [A(s) + B_+(s)]ds + \int_0^t [C(s) + D_+(s)]'dW(s) \\ &- \frac{1}{2}\int_0^t |C(s) + D_+(s)|^2 ds\Big\} \end{aligned}$$

and

$$x_-(t) = x_0^- \exp\left\{\int_0^t [A(s) - B_-(s)]ds + \int_0^t [C(s) - D_-(s)]'dW(s) - \frac{1}{2}\int_0^t |C(s) - D_-(s)|^2 ds\right\}.$$

Define

$$x(t) := x_+(t) - x_-(t).$$

Since $x_+(t) \geq 0$, $x_-(t) \geq 0$, and $x_+(t)x_-(t) = 0$, we conclude that

$$x^+(t) = x_+(t), \quad x^-(t) = x_-(t) \ \ \forall t \in [0, T].$$

Subtracting (5.25) from (5.24) we get that $x(\cdot)$ is a continuous adapted solution of (5.23).

Let us turn to the uniqueness of the solution. Suppose that $x_1(\cdot)$ and $x_2(\cdot)$ are two continuous adapted solutions of (5.23). Put $\hat{x}(\cdot) := x_1(\cdot) - x_2(\cdot)$. We apply a linearization procedure as follows. Set

$$\alpha_+(t) := \frac{x_1^+(t) - x_2^+(t)}{x_1(t) - x_2(t)} 1_{\{x_1(t) \neq x_2(t)\}}, \ \alpha_-(t) := \frac{x_1^-(t) - x_2^-(t)}{x_1(t) - x_2(t)} 1_{\{x_1(t) \neq x_2(t)\}}.$$

Then $\hat{x}(\cdot)$ is a continuous adapted solution of the following linear SDE:

$$\text{(5.26)} \quad \begin{cases} d\hat{x}(t) = & [A(t) + B_+(t)\alpha_+(t) + B_-(t)\alpha_-(t)]\hat{x}(t)dt \\ & + \hat{x}(t)[C(t) + D_+(t)\alpha_+(t) + D_-(t)\alpha_-(t)]'dW(t), \quad t \in [0, T], \\ \hat{x}(0) = & 0. \end{cases}$$

Hence $\hat{x}(t) \equiv 0$ via a similar representation as (5.24) or (5.25), and the uniqueness of the solution is proved. □

Let us conclude this section by noting that a byproduct of Theorem 5.1 is the uniqueness of the solution to the ESREs (3.5) and (3.6). Indeed, consider an LQ control problem in an interval $[s, T]$, with $s \in [0, T)$, where the system dynamics is (2.1) with initial time s and initial state $x(s) = x_s \in L^2_{\mathcal{F}_s}(\Omega; \mathbb{R})$, and the cost functional is

$$J_s(x_s, u(\cdot)) := E\left\{\int_s^T \big[Q(t)x(t)^2 + u(t)'R(t)u(t)\big]dt + Gx(T)^2 \Big| \mathcal{F}_s\right\}.$$

Let $(P_+, \Lambda_+) \in L^2_{\mathcal{F}}(\Omega; C(0, T; \mathbb{R})) \times L^2_{\mathcal{F}}(0, T; \mathbb{R}^k)$ and $(P_-, \Lambda_-) \in L^2_{\mathcal{F}}(\Omega; C(0, T; \mathbb{R})) \times L^2_{\mathcal{F}}(0, T; \mathbb{R}^k)$ be *any* bounded, nonnegative (in the standard case) or bounded, uniformly positive (in the singular case) solutions to (3.5) and (3.6), respectively. Then, going through the same analysis as in the proof of Theorem 5.1 we deduce that the optimal cost is

$$\text{(5.27)} \qquad J_s^*(x_s) := \inf_{u(\cdot) \text{ admissible}} J_s(x_s, u(\cdot)) = P_+(s)(x_s^+)^2 + P_-(s)(x_s^-)^2.$$

This proves the following uniqueness result.

THEOREM 5.2. *Each of the ESREs* (3.5) *and* (3.6) *admits at most one bounded, nonnegative (in the standard case) or bounded, uniformly positive (in the singular case) solution.*

6. Application to a mean-variance portfolio selection problem. Consider a financial market with $m+1$ securities, consisting of a bank account and m stocks. The value of the bank account, $S_0(t)$, satisfies an ordinary differential equation,

$$\begin{cases} dS_0(t) = r(t)\, S_0(t)\, dt, \quad t \in [0,\, T], \\ S_0(0) = s_0 > 0, \end{cases} \tag{6.1}$$

where the interest rate $r(t) > 0$ is a deterministic, uniformly bounded, scalar-valued function. The price of each of the stocks, $S_1(t), \ldots, S_m(t)$, satisfies the SDE,

$$\begin{cases} dS_i(t) = S_i(t)\Big\{\mu_i(t)\, dt + \sum_{j=1}^m \sigma_{ij}(t)\, dW^j(t)\Big\}, \quad t \in [0,\, T], \\ S_i(0) = s_i > 0, \end{cases} \tag{6.2}$$

where $\mu_i(t) > 0$ and $\sigma_i(t) = [\sigma_{i1}, \ldots, \sigma_{im}(t)]$ are the appreciation rate and dispersion (or volatility) rate of the ith stock. Here, $\mu_i(t)$ and $\sigma_{ij}(t)$ are scalar-valued, $\{\mathcal{F}_t\}_{t\geq 0}$-adapted, uniformly bounded *stochastic processes*. Denoting

$$\sigma(t) := \begin{bmatrix} \sigma_1(t) \\ \vdots \\ \sigma_m(t) \end{bmatrix} \in \mathbb{R}^{m\times m}, \tag{6.3}$$

we assume throughout that $\sigma(t)$ is uniformly nondegenerate: that is, there exists a deterministic $\delta > 0$ such that

$$\sigma(t)\, \sigma(t)' \geq \delta\, I_m, \quad \forall\, t \in [0,\, T],\ P - a.s.. \tag{6.4}$$

In particular, $\sigma(t)$ must be nonsingular a.e. $t \in [0,\, T]$, P-a.s..

Suppose that the total wealth of an agent at time $t \geq 0$ is denoted by $x(t)$. If transaction costs and consumption are ignored and share trading takes place in continuous time, then we have

$$\begin{cases} dx(t) &= \Big\{r(t)\, x(t) + \sum_{i=1}^m [\mu_i(t) - r(t)]\, u_i(t)\Big\}\, dt \\ &\quad + \sum_{j=1}^m \sum_{i=1}^m \sigma_{ij}(t)\, u_i(t)\, dW^j(t), \quad t \in [0,\, T], \\ x(0) &= x_0 > 0, \end{cases} \tag{6.5}$$

where $u_i(t)$ is the total market value of the agent's wealth in the ith asset. We refer to $u(\cdot) := (u_1(\cdot), \ldots, u_m(\cdot))'$ as the *portfolio* of the agent. In our model, short-selling of the stocks is not allowed; hence we have the following constraints on a portfolio $u(\cdot) = (u_1(\cdot), \ldots, u_m(\cdot))'$:

$$u_i(t) \geq 0 \ \ \forall t \in [0,T], \ \ i = 1, \ldots, m. \tag{6.6}$$

Note that $u_0(\cdot)$ has been excluded from a portfolio since it is completely determined by the allocation of stocks and the total wealth $x(\cdot)$. Moreover, we do allow $u_0(t) < 0$, meaning that the agent is borrowing the amount $|u_0(t)|$ from the bank at rate $r(t)$.

DEFINITION 6.1. *A portfolio $u(\cdot)$ is said to be* admissible *if it is $\mathbb{R}^m$-valued, square-integrable (i.e., $E\int_0^T |u(t)|^2 dt < +\infty$), $\{\mathcal{F}_t\}_{t\geq 0}$-adapted, and satisfies* (6.6). *In this case, we refer to $(x(\cdot),\, u(\cdot))$ as an* admissible (wealth–portfolio) pair.

In a mean-variance portfolio selection problem, an agent's objective is to find an admissible portfolio $u(\cdot)$ such that the expected terminal wealth satisfies $Ex(T) = z$,

for some $z \geq x_0 e^{\int_0^T r(s)ds}$, while the risk measured by the variance of the terminal wealth

$$\text{Var } x(T) := E[x(T) - Ex(T)]^2 = E[x(T)]^2 - z^2 \tag{6.7}$$

is minimized. The restriction of the targeted payoff $z \geq x_0 e^{\int_0^T r(s)ds}$ is natural as the latter can always be achieved by putting all the money in the bank. Mathematically, it can be formulated as the following problem parameterized by $z \geq x_0 e^{\int_0^T r(s)ds}$:

$$\begin{cases} \text{Minimize} & J_{\text{MV}}(x_0, u(\cdot)) := E[x(T)]^2 - z^2, \\ \text{subject to:} & Ex(T) = z, \\ & (x(\cdot), u(\cdot)) \text{ is admissible for (6.5).} \end{cases} \tag{6.8}$$

The above problem is called *feasible* if there is at least one portfolio satisfying the constraints of (6.8). Finally, an optimal portfolio to (6.8) is called an *efficient portfolio* corresponding to z, the corresponding $(\text{Var } x(T), z)$ is called an *efficient point*, whereas the set of all the efficient points, with $z \geq x_0 e^{\int_0^T r(s)ds}$, is called an *efficient frontier*.

Equation (6.5) can be rewritten as

$$\begin{cases} dx(t) = [r(t)x(t) + B(t)u(t)]dt + u(t)'\sigma(t)dW(t), \\ x(0) = x_0, \end{cases} \tag{6.9}$$

where

$$B(t) := (\mu_1(t) - r(t), \ldots, \mu_m(t) - r(t)). \tag{6.10}$$

Since the problem (6.8) involves a terminal constraint $Ex(T) = z$, we first investigate conditions under which the problem is feasible for *any* $z \in [x_0 e^{\int_0^T r(s)ds}, +\infty)$.

THEOREM 6.1. *The mean-variance problem* (6.8) *is feasible for every* $z \in [x_0 e^{\int_0^T r(s)ds}, +\infty)$ *if and only if*

$$\sum_{i=1}^{m} E \int_0^T [\mu_i(t) - r(t)]^+ dt > 0. \tag{6.11}$$

Proof. We first prove the "if" part. Define

$$M_i := \{(t, \omega) : \mu_i(t, \omega) > r(t)\}, \quad i = 1, 2, \ldots, m.$$

Condition (6.11) implies that at least one of the sets M_i has a nonzero measure (in terms of the product of the Lebesgue measure and P). Suppose M_{i_0} has a nonzero measure. Construct a family of admissible portfolios $u^\beta(\cdot) := \beta u(\cdot)$, where $\beta \geq 0$ and the components of $u(\cdot)$ are all zero except its i_0th component which is defined to be

$$u_{i_0}(t, \omega) := \begin{cases} \mu_{i_0}(t, \omega) - r(t), & \text{if } (t, \omega) \in M_{i_0}, \\ 0, & \text{if } (t, \omega) \notin M_{i_0}. \end{cases} \tag{6.12}$$

Let $x^\beta(\cdot)$ be the wealth process corresponding to $u^\beta(\cdot)$. By linearity of the wealth equation, we have $x^\beta(t) = x^0(t) + \beta x^1(t)$, where $x^0(t) := x_0 e^{\int_0^t r(s)ds}$ and $x^1(\cdot)$ is the solution to the following equation:

$$\begin{cases} dx^1(t) = [r(t)x^1(t) + B(t)u(t)]dt + u(t)'\sigma(t)dW(t), \\ x^1(0) = 0. \end{cases} \tag{6.13}$$

Therefore, problem (6.8) is feasible for every $z \in [x_0 e^{\int_0^T r(s)ds}, +\infty)$ if there exists $\beta \geq 0$ such that $z = Ex^\beta(T) \equiv x^0(T) + \beta Ex^1(T)$. Equivalently, (6.8) is feasible for every $z \in [x_0 e^{\int_0^T r(s)ds}, +\infty)$ if $Ex^1(T) > 0$. However, applying Itô's formula we get

$$d[e^{\int_t^T r(s)ds} x^1(t)] = e^{\int_t^T r(s)ds} B(t)u(t)dt + \{\cdots\}dW(t).$$

Integrating from 0 to T and taking expectation we obtain

$$Ex^1(T) = E\int_0^T e^{\int_t^T r(s)ds} B(t)u(t)dt > 0, \tag{6.14}$$

due to the way $u(\cdot)$ was constructed. Consequently, (6.8) is feasible if (6.11) holds.

Conversely, suppose that problem (6.8) is feasible for every $z \in [x_0 e^{\int_0^T r(s)ds}, +\infty)$. Then for each z, there is an admissible portfolio $u(\cdot)$ so that $Ex(T) = z$. However, we can always decompose $x(t) = x^0(t) + x^1(t)$, where $x^1(\cdot)$ satisfies (6.13). This leads to $Ex^0(T) + Ex^1(T) = z$. Now, $Ex^0(T) \equiv z_0$ is independent of $u(\cdot)$; thus it is necessary that there is a $u(\cdot)$ with $Ex^1(T) > 0$. It follows then from (6.14) that (6.11) must be valid. □

Now we are going to solve the optimization problem (6.8) under the feasibility assumption (6.11). To handle the constraint $Ex(T) = z$ we apply the Lagrange multiplier technique. Define

$$\begin{aligned} J(x_0, u(\cdot), \lambda) :=\ & E\big\{x(T)^2 - z^2 - 2\lambda[x(T) - z]\big\} \\ =\ & E\big[|x(T) - \lambda|^2\big] - (\lambda - z)^2, \quad \lambda \in \mathbb{R}. \end{aligned} \tag{6.15}$$

Since $J_{\rm MV}(x_0, u(\cdot))$ is strictly convex in $u(\cdot)$ and the constraint function $Ex(T) - z$ is affine in $u(\cdot)$, we can apply the well-known duality theorem (see, e.g., [19]). Based on this theorem, we may first solve the following unconstrained problem parameterized by the Lagrange multiplier $\lambda \in \mathbb{R}$:

$$\begin{cases} \text{Minimize} & J(x_0, u(\cdot), \lambda) := E\big[|x(T) - \lambda|^2\big] - (\lambda - z)^2, \\ \text{subject to:} & (x(\cdot), u(\cdot)) \text{ is admissible for (6.9).} \end{cases} \tag{6.16}$$

This problem is exactly a singular case of the general LQ model solved in section 5, with $Q(t) = R(t) = 0$ and $\Gamma = \mathbb{R}^m_+$. Thus we will apply the general result to the problem. Let us first write down the specialization of the ESREs (3.5) and (3.6) as

$$\begin{cases} dP_+(t) = -[2r(t)P_+(t) + H^*_+(t, P_+(t), \Lambda_+(t))]dt + \Lambda_+(t)'dW(t), \quad t \in [0, T], \\ P_+(T) = 1, \\ P_+(t) > 0, \end{cases} \tag{6.17}$$

$$\begin{cases} dP_-(t) = -[2r(t)P_-(t) + H^*_-(t, P_-(t), \Lambda_-(t))]dt + \Lambda_-(t)'dW(t), \quad t \in [0, T], \\ P_-(T) = 1, \\ P_-(t) > 0, \end{cases} \tag{6.18}$$

where

$$\begin{aligned} H^*_+(t, P, \Lambda) &:= \min_{v \in \mathbb{R}^m_+} \{v'P\sigma(t)\sigma(t)'v + 2v'[B(t)'P + \sigma(t)\Lambda]\}, \\ H^*_-(t, P, \Lambda) &:= \min_{v \in \mathbb{R}^m_+} \{v'P\sigma(t)\sigma(t)'v - 2v'[B(t)'P + \sigma(t)\Lambda]\}. \end{aligned} \tag{6.19}$$

Also, define

$$\begin{aligned}&\xi_+(t,P,\Lambda) := \operatorname{argmin}_{v\in\mathbb{R}^m_+} H_+(t,v,P,\Lambda),\\ &\xi_-(t,P,\Lambda) := \operatorname{argmin}_{v\in\mathbb{R}^m_+} H_-(t,v,P,\Lambda),\quad (t,P,\Lambda)\in[0,T]\times\mathbb{R}\times\mathbb{R}^k.\end{aligned}\tag{6.20}$$

Clearly, Theorems 4.2 and 5.2 apply to (6.17) and (6.18) ensuring that they admit unique bounded, uniformly positive solutions.

LEMMA 6.1. *Assume that* (6.11) *holds, and let* $(P_+, \Lambda_+) \in L^2_{\mathcal{F}}(\Omega; C(0, T; \mathbb{R})) \times L^2_{\mathcal{F}}(0, T; \mathbb{R}^m)$ *and* $(P_-, \Lambda_-) \in L^2_{\mathcal{F}}(\Omega; C(0, T; \mathbb{R}))\times L^2_{\mathcal{F}}(0, T; \mathbb{R}^m)$ *be the unique bounded, uniformly positive solutions to the ESREs* (6.17) *and* (6.18)*, respectively. Then it must hold that*

$$P_+(0)e^{-2\int_0^T r(s)ds} - 1 \le 0, \quad \textit{and} \quad P_-(0)e^{-2\int_0^T r(s)ds} - 1 < 0.\tag{6.21}$$

Proof. Define $g(t) := P_-(t)e^{-2\int_t^T r(s)ds}$. Then it is straightforward that

$$dg(t) = -e^{-2\int_t^T r(s)ds}H^*_-(t, P_-(t), \Lambda_-(t))dt + e^{-2\int_t^T r(s)ds}\Lambda_-(t)'dW(t).$$

Integrating from 0 to T and taking expectation we have

$$1 - g(0) = -E\int_0^T e^{-2\int_t^T r(s)ds}H^*_-(t, P_-(t), \Lambda_-(t))dt \ge 0,\tag{6.22}$$

since $H^*_-(t, P_-(t), \Lambda_-(t)) \le 0$ by its very definition. Hence $P_-(0)e^{-2\int_0^T r(s)ds} \equiv g(0) \le 1$. Similarly, we can prove that $P_+(0)e^{-2\int_0^T r(s)ds} - 1 \le 0$.

It remains to prove the strict inequality $P_-(0)e^{-2\int_0^T r(s)ds} - 1 < 0$. In fact, if $P_-(0)e^{-2\int_0^T r(s)ds} - 1 = 0$, then it follows from (6.22) that $H^*_-(t, P_-(t), \Lambda_-(t)) = 0$, a.e. $t \in [0, T]$, P-a.s.. Thus we deduce, from the uniqueness of solution to the BSDE (6.18), that $P_-(t) = e^{2\int_t^T r(s)ds}$, and $\Lambda_-(t) = 0$. Consequently, $H^*_-(t, P_-(t), 0) = 0$.

On the other hand,

$$\begin{aligned}H^*_-(t, P_-(t), 0) &= \min_{v\in\mathbb{R}^m_+} P_-(t)[v'\sigma(t)\sigma(t)'v - 2v'B(t)']\\ &\le \min_{v\in\mathbb{R}^m_+} K_3[K_4|v|^2 - 2B(t)v],\end{aligned}$$

for some constants $K_3 > 0$ and $K_4 > 0$. Notice that the minimum value on the right-hand side of the above equation *strictly* negative whenever $B(t,\omega)^+ := (B_1(t,\omega)^+, \ldots, B_m(t,\omega)^+) \ne 0$. In view of the assumption (6.11), the set of (t,ω) on which $B(t,\omega)^+$ is nonzero has a nonzero measure. Thus we get a contradiction. ∎

Remark 6.1. One does not have the strict inequality $P_+(0)e^{-2\int_0^T r(s)ds} - 1 < 0$ since no information about $B(t,\omega)^- := (B_1(t,\omega)^-, \ldots, B_m(t,\omega)^-)$ is available. On the other hand, the inequality $P_-(0)e^{-2\int_0^T r(s)ds} - 1 < 0$ is exactly what is required in what follows.

THEOREM 6.2. *Let* $(P_+, \Lambda_+) \in L^2_{\mathcal{F}}(\Omega; C(0, T; \mathbb{R}))\times L^2_{\mathcal{F}}(0, T; \mathbb{R}^m)$ *and* $(P_-, \Lambda_-) \in L^2_{\mathcal{F}}(\Omega; C(0, T; \mathbb{R})) \times L^2_{\mathcal{F}}(0, T; \mathbb{R}^m)$ *be the unique bounded, uniformly positive solutions to the ESREs* (6.17) *and* (6.18)*, respectively. Then the state feedback control*

$$\begin{aligned}u^*(t) = {}&\xi_+(t, P_+(t), \Lambda_+(t))\left(x(t) - \lambda e^{-\int_t^T r(s)ds}\right)^+\\ &+ \xi_-(t, P_-(t), \Lambda_-(t))\left(x(t) - \lambda e^{-\int_t^T r(s)ds}\right)^-\end{aligned}\tag{6.23}$$

is optimal for the problem (6.16). *Moreover, in this case the optimal cost is*

(6.24)
$$J^*(x_0,\lambda) := \inf_{u(\cdot)\in L^2_{\mathcal{F}}(0,T;\mathbb{R}^m_+)} J(x_0,u(\cdot),\lambda)$$
$$= \begin{cases} [P_+(0)e^{-2\int_0^T r(s)ds}-1]\lambda^2 - 2[x_0P_+(0)e^{-\int_0^T r(s)ds}-z]\lambda + P_+(0)x_0^2 - z^2, \\ \qquad \text{if } x_0 > \lambda e^{-\int_0^T r(s)ds}, \\ [P_-(0)e^{-2\int_0^T r(s)ds}-1]\lambda^2 - 2[x_0P_-(0)e^{-\int_0^T r(s)ds}-z]\lambda + P_-(0)x_0^2 - z^2, \\ \qquad \text{if } x_0 \le \lambda e^{-\int_0^T r(s)ds}. \end{cases}$$

Proof. Set

$$y(t) := x(t) - \lambda e^{-\int_t^T r(s)ds}. \tag{6.25}$$

It turns out the wealth equation (6.9) in terms of $y(\cdot)$ has exactly the same form except for the initial condition,

$$\begin{cases} dy(t) = [r(t)y(t) + B(t)u(t)]dt + u(t)'\sigma(t)dW(t), \\ y(0) = x_0 - \lambda e^{-\int_0^T r(s)ds}, \end{cases} \tag{6.26}$$

whereas the cost function (6.15) can be written as

$$J(y_0,u(\cdot),\lambda) = Ey(T)^2 - (\lambda - z)^2. \tag{6.27}$$

The above problem (6.26)–(6.27) is exactly a special case of the general problem we have solved in section 5 (ignoring the constant term $-(\lambda-z)^2$ in (6.27)). Hence the optimal feedback control (6.23) follows from (5.2). Finally, the optimal cost is

$$J^*(x_0,\lambda) = P_+(0)[(x_0 - \lambda e^{-\int_0^T r(s)ds})^+]^2 + P_-(0)[(x_0 - \lambda e^{-\int_0^T r(s)ds})^-]^2 - (\lambda - z)^2$$

which equals the right-hand side of (6.24) after some simple manipulations. □

THEOREM 6.3 (efficient portfolios and efficient frontier). *Assume that* (6.11) *holds. Then the efficient portfolio corresponding to* $z \ge x_0 e^{\int_0^T r(s)ds}$, *as a feedback of the wealth process, is*

$$\begin{aligned} u^*(t) = {} & \xi_+(t,P_+(t),\Lambda_+(t))\left(x^*(t) - \lambda^* e^{-\int_t^T r(s)ds}\right)^+ \\ & + \xi_-(t,P_-(t),\Lambda_-(t))\left(x^*(t) - \lambda^* e^{-\int_t^T r(s)ds}\right)^-, \end{aligned} \tag{6.28}$$

where

$$\lambda^* := \frac{z - x_0P_-(0)e^{-\int_0^T r(s)ds}}{1 - P_-(0)e^{-2\int_0^T r(s)ds}}. \tag{6.29}$$

Moreover, the efficient frontier is

(6.30)
$$\operatorname{Var} x^*(T) = \frac{P_-(0)e^{-2\int_0^T r(s)ds}}{1 - P_-(0)e^{-2\int_0^T r(s)ds}}\left[Ex^*(T) - x_0e^{\int_0^T r(s)ds}\right]^2, \quad Ex^*(T) \ge x_0e^{\int_0^T r(s)ds}.$$

Proof. First note that λ^* in (6.29) is well defined thanks to Lemma 6.1. Now, if $z = x_0e^{\int_0^T r(s)ds}$, then it is straightforward that the corresponding efficient portfolio

is $u^*(t) \equiv 0$, meaning that all the wealth is to be put in the bank account. The resulting wealth process is $x^*(t) = x_0 e^{\int_0^t r(s)ds}$. On the other hand, in this case the associated $\lambda^* = x_0 e^{\int_0^T r(s)ds}$. Thus the portfolio given by (6.28) reduces to $u^*(t) \equiv 0$ with $x^*(t) = x_0 e^{\int_0^t r(s)ds}$. This implies that (6.28) is indeed the efficient portfolio when $z = x_0 e^{\int_0^T r(s)ds}$.

So now we need only to prove the theorem for any fixed $z > x_0 e^{\int_0^T r(s)ds}$. Applying the duality theorem (see, e.g., [19, p. 224, Theorem 1][1]) we have

(6.31)
$$J^*_{\mathrm{MV}}(x_0) := \inf_{u(\cdot)\in L^2_{\mathcal{F}}(0,T;\mathbb{R}^m_+)} J_{\mathrm{MV}}(x_0, u(\cdot)) = \sup_{\lambda\in\mathbb{R}} \inf_{u(\cdot)\in L^2_{\mathcal{F}}(0,T;\mathbb{R}^m_+)} J(x_0, u(\cdot), \lambda) > -\infty,$$

and the optimal feedback control for (6.8) is (6.28), due to Theorem 6.2, with λ replaced by λ^* which maximizes $J^*(x_0, \lambda)$ $(= \inf_{u(\cdot)\in L^2_{\mathcal{F}}(0,T;\mathbb{R}^m_+)} J(x_0, u(\cdot), \lambda))$ over $\lambda \in \mathbb{R}$.

If $\lambda \in (-\infty, x_0 e^{\int_0^T r(s)ds})$, then the expression (6.24) gives, taking into consideration (6.21) and the fact that $z \geq x_0 e^{\int_0^T r(s)ds}$,

$$\begin{aligned}
\frac{\partial}{\partial\lambda} J^*(x_0, \lambda) &= 2[P^+(0)e^{-2\int_0^T r(s)ds} - 1]\lambda - 2[x_0 P_+(0)e^{-\int_0^T r(s)ds} - z] \\
&\geq 2[P^+(0)e^{-2\int_0^T r(s)ds} - 1]x_0 e^{\int_0^T r(s)ds} \\
&\quad -2[x_0 P_+(0)e^{-\int_0^T r(s)ds} - x_0 e^{\int_0^T r(s)ds}] \\
&= 0.
\end{aligned}$$

Hence,

$$\sup_{\lambda\in\mathbb{R}} J^*(x_0, \lambda) = \sup_{\lambda\in[x_0 e^{\int_0^T r(s)ds}, +\infty)} J^*(x_0, \lambda).$$

But for $\lambda \in [x_0 e^{\int_0^T r(s)ds}, +\infty)$, it follows from (6.24) that $J^*(x_0, \lambda)$ is a quadratic function in λ whose maximizer is given by (6.29) (noticing Lemma 6.1), whereas

(6.32)
$$\begin{aligned}
J^*_{\mathrm{MV}}(x_0) &= \sup_{\lambda\in\mathbb{R}} \inf_{u(\cdot)\in L^2_{\mathcal{F}}(0,T;\mathbb{R}^m_+)} J^*(x_0, \lambda) \\
&= \sup_{\lambda\in\mathbb{R}} \Big\{ [P_-(0)e^{-2\int_0^T r(s)ds} - 1]\lambda^2 - 2[x_0 P_-(0)e^{-\int_0^T r(s)ds} - z]\,\lambda \\
&\qquad + P_-(0)x_0^2 - z^2 \Big\} \\
&= \frac{P_-(0)e^{-2\int_t^T r(s)ds}}{1 - P_-(0)e^{-2\int_0^T r(s)ds}} \left[z - x_0 e^{\int_0^T r(s)ds} \right]^2, \quad z \geq x_0 e^{\int_0^T r(s)ds}.
\end{aligned}$$

This proves (6.30), noting that $Ex^*(T) = z$. □

Corollary 6.1. *Assume that* (6.11) *holds. Then the efficient portfolio* (6.28) *can be rewritten as*

$$u^*(t) = \xi_-(t, P_-(t), \Lambda_-(t)) \left(\lambda^* e^{-\int_t^T r(s)ds} - x^*(t) \right). \tag{6.33}$$

[1] To be precise, one should apply [19, p. 236, Problem 7] together with the proof of [19, p. 224, Theorem 1] in our case, as there is an *equality* constraint in (6.8). To be able to use the result there, one needs to check a condition posed in [19, p. 236, Problem 7], namely, 0 is an interior point of the set $\mathcal{T} := \{Ex(T) - z \,\big|\, x(\cdot) \text{ is the wealth process of an admissible portfolio } u(\cdot) \text{ with } x(0) = x_0\}$. In view of Theorem 6.1 and the assumption (6.11), we have $[x_0 e^{\int_0^T r(s)ds} - z, +\infty) \subset \mathcal{T}$. Hence 0 is an interior point of $\mathcal{T}$ because $x_0 e^{\int_0^T r(s)ds} - z < 0$.

Proof. It suffices to prove that under the feedback policy (6.28) the corresponding wealth trajectory $x^*(\cdot)$ satisfies

$$x^*(t) - \lambda^* e^{-\int_t^T r(s)ds} \le 0. \tag{6.34}$$

To this end, write $y(t) := x^*(t) - \lambda^* e^{-\int_t^T r(s)ds}$. Then it is immediate from (6.9) that $y(\cdot)$ follows

$$\begin{cases} dy(t) = [r(t)y(t) + B_+(t)y^+(t) + B_-(t)y^-(t)]dt + [D_+(t)y^+(t) + D_-(t)y^-(t)]'dW(t), \\ y(0) = x_0 - \lambda^* e^{-\int_0^T r(s)ds}, \end{cases} \tag{6.35}$$

where

$$\begin{aligned} &B_+(t) := B(t)\xi_+(t, P_+(t), \Lambda_+(t)),\ B_-(t) := B(t)\xi_-(t, P_-(t), \Lambda_-(t)), \\ &D_+(t) := \sigma(t)'\xi_+(t, P_+(t), \Lambda_+(t)),\ D_-(t) := \sigma(t)'\xi_-(t, P_-(t), \Lambda_-(t)). \end{aligned}$$

Note that $y(0) = x_0 - \lambda^* e^{-\int_0^T r(s)ds} \le 0$ by virtue of (6.29) and the fact that $z \ge x_0 e^{\int_0^T r(s)ds}$. Hence the proof of Lemma 5.1 yields that $y^+(t) = y(0)^+ \exp\{\cdots\} = 0$, which proves that $y(t) \le 0$. □

It is interesting to note that, as indicated by the preceding theorem and corollary, after all only one of the two Riccati equations, (6.18) is necessary in the final solution to the portfolio selection problem. This is essentially due to the fact that one is only interested in the "nonsatiation portion" (i.e., that which corresponds to $z \ge x_0 e^{\int_0^T r(s)ds}$) of the entire variance-minimizing boundary. Because of this, the form of the efficient portfolio (6.33) turns out to be strikingly similar to its shorting-permitted counterpart [28]. In particular, if shorting is allowed, then the definition (6.20) should be modified so that $\xi_-(t, P, \Lambda)$ is the minimum point of $H_-(t, v, P, \Lambda)$ over $v \in \mathbb{R}^m$, or $\xi_-(t, P, \Lambda) = (\sigma(t)\sigma(t)')^{-1}\left[B(t)' + \sigma(t)\frac{\Lambda}{P}\right]$. Furthermore, if all the market coefficients are deterministic, then $\Lambda(t) \equiv 0$ and the result of [28] is recovered.

Also, it follows from (6.34) that the wealth trajectory under the efficient portfolio is capped almost surely at any time by the present value of a *deterministic* constant λ^*.

Finally, we remark that in the portfolio selection application the control (portfolio) constraint is taken to be $\Gamma = \mathbb{R}^m_+$, for it has significant financial interpretation (no-shorting). We can easily cope with other forms of constrained portfolio thanks to the general results established in sections 4–5. An example is, in the case of two stocks, $\Gamma = \{(u_1, u_2) \in \mathbb{R}^2 | u_1 \le 2u_2\}$. Such a constraint can be interpreted as maintaining certain weights on different stocks. Note that if we deal with a general portfolio constraint, then explicit characterization of the feasibility such as (6.11) may no longer be possible. However, it is still possible to obtain a certain implicit feasibility condition based on the dual of the constraint cone, Γ. Details are left to the interested reader.

7. Concluding remarks. In this paper, we have solved explicitly a stochastic LQ control problem where the control is constrained by a cone and all the coefficients are random. The solution is heavily dependent on the two nonlinear BSDEs which are introduced in this paper for the first time. The study on these two equations is interesting from the point view of BSDE theory. A continuous-time mean-variance portfolio selection problem has been then solved as a special case of the general constrained stochastic LQ model.

A major assumption of the paper is that the state variable be one-dimensional. Although this assumption is valid in many interesting applications including the financial one, it is a very challenging open problem to obtain an explicit solution to a multidimensional problem and study the possible associated BSDEs.

A PRIMAL-DUAL ACTIVE SET STRATEGY FOR OPTIMAL BOUNDARY CONTROL OF A NONLINEAR REACTION-DIFFUSION SYSTEM*

R. GRIESSE† AND S. VOLKWEIN†

Abstract. This paper is concerned with optimal boundary control of an instationary reaction-diffusion system in three spatial dimensions. This problem involves a coupled nonlinear system of parabolic differential equations with bilateral as well as integral control constraints. We include the integral constraint in the cost by a penalty term whereas the bilateral control constraints are handled explicitly. First- and second-order conditions for the optimization problem are analyzed. A primal-dual active set strategy is utilized to compute optimal solutions numerically. The algorithm is compared to a semismooth Newton method.

Key words. reaction-diffusion equations, optimal boundary control, bilateral and integral control constraints, primal-dual active set strategy, semismooth Newton methods

1. Introduction.

The subject matter of this paper is an optimal control problem for a coupled system of semilinear parabolic reaction-diffusion equations. The equations model a chemical or biological process where the species involved are subject to diffusion and reaction among each other. As an example, we consider the reaction $A+B \to C$ which obeys the law of mass action. To simplify the discussion, we assume that the backward reaction $C \to A+B$ is negligible and that the forward reaction proceeds with a constant (e.g., not temperature-dependent) rate. This leads to a coupled semilinear parabolic system for the respective concentrations; see (2.3). We consider the state equations in three spatial dimensions and prove existence and uniqueness of solutions in $W(0,T)$. This is a nontrivial result, and from the analysis in [9] it follows that higher order polynomial reaction terms do not admit solutions in $W(0,T)$, in three space dimensions. Simplifications to the two- or even one-dimensional situation are of course possible in a straightforward way.

The control function acts through the Neumann boundary values for one of the reaction components on some subset of the two-dimensional boundary manifold. It is natural to impose bilateral pointwise bounds on the control function: on one hand, the substance can never be extracted through the boundary, i.e., the lower control bound should be nonnegative. On the other hand, only a limited amount may be added *at any given time*. In addition, we impose a constraint on the *total amount* of control action. This scalar integral constraint (see (2.11)) is very much in contrast with the usual pointwise bounds.

Optimality conditions for optimal control problems governed by semilinear parabolic equations together with mixed inequality constraints were considered theoret-

ically in the literature. We refer, for instance, the reader to [5, 17, 30]. Note that the theory presented in [27] cannot be applied directly to system (2.3) since the assumptions for the semilinear part are not satisfied. Less attention is paid to the numerical realization of the infinite-dimensional optimality systems. Let us mention, for example, [22].

The integral constraint is included into the cost functional by a penalty term, whereas the bilateral control constraints are treated explicitly by a primal-dual active set strategy for nonlinear problems. The primal-dual active set method has proved to be an efficient numerical tool in the context of diverse applications; see, for instance, [1, 2, 12]. So far it was mainly investigated for linear-quadratic problems, which arise, for example, as a subproblem within SQP or Newton methods (compare, e.g., [13, 14, 21, 34]). Ito and Kunisch studied the primal-dual active set algorithm for nonlinear problems and bilateral control constraints in [19]. Utilizing the close relationship between the primal-dual active set strategy and semismooth Newton methods, local superlinear convergence was shown as well. Let us mention that the primal-dual active set strategy for nonlinear problems was already applied numerically, combined with SQP and nonlinear conjugate gradient methods in [8, 20] and [37], respectively. Semismooth Newton methods for general purpose nonlinear finite-dimensional optimal control problems are well studied; see, for instance, [24] and [7, section 7.5]. Much less is known about such methods in infinite dimensions, and specifically in the context of optimal control problems. Let us refer here, e.g., to [15, 16, 35]. We will compare the primal-dual active set strategy with a semismooth Newton method in the numerical test examples. Both utilize an inexact Newton method as an inner iteration. The penalty term leads to a nonquadratic objective, which gives rise to an interesting update step for the control constraint multiplier.

This paper is organized in the following manner. In section 2, the state equations are analyzed and the optimal control problem is investigated. The integral control constraint is treated using a penalization approach. Section 3 is devoted to the optimality conditions for the penalized optimization problem. The primal-dual active set algorithm and its relationship to a semismooth Newton method are discussed in section 4. Numerical examples are presented in section 5 and we draw some conclusions in the last section.

2. The problem formulation. The goal of this section is to introduce the infinite-dimensional optimal control problem. The cost functional is of tracking type, the equality constraints are given by a coupled nonlinear parabolic system, and the inequality constraints are bilateral control constraints as well as an integral constraint for the control. We study the state equations, propose the optimal control problem, and prove existence of optimal controls. Finally we introduce the optimization problem with the penalized objective.

2.1. The state equations. Let Ω denote an open and bounded subset of $\mathbb{R}^3$ with a Lipschitz-continuous boundary $\Gamma = \partial\Omega$ such that Γ is decomposed into two parts $\Gamma = \Gamma_n \cup \Gamma_c$ with $\Gamma_n \cap \Gamma_c = \emptyset$. For terminal time $T > 0$ let $Q = (0,T) \times \Omega$, let $\Sigma = (0,T) \times \Gamma$, and let $\Sigma_c = (0,T) \times \Gamma_c$.

By $L^2(0,T;H^1(\Omega))$ we denote the space of all measurable functions $\varphi : [0,T] \to H^1(\Omega)$, which are square integrable, i.e.,

$$\int_0^T \|\varphi(t)\|^2_{H^1(\Omega)} \,\mathrm{d}t < \infty,$$

where $\varphi(t)$ stands for the function $\varphi(t,\cdot)$ considered as a function in Ω only. The space $W(0,T)$ is defined by

$$W(0,T) = \{\varphi \in L^2(0,T;H^1(\Omega)) : \varphi_t \in L^2(0,T;H^1(\Omega)')\}. \tag{2.1}$$

Here $H^1(\Omega)'$ denotes the dual space of $H^1(\Omega)$. Recall that $W(0,T)$ is a Hilbert space endowed with the common inner product and the induced norm; see, e.g., [6, p. 286]. Since $W(0,T)$ is continuously embedded into $C([0,T];L^2(\Omega))$, the space of all continuous functions from $[0,T]$ into $L^2(\Omega)$, there exists a constant $C_W > 0$ satisfying

$$\|\varphi\|_{C([0,T];L^2(\Omega))} \le C_W \|\varphi\|_{W(0,T)} \quad \text{for all } \varphi \in W(0,T); \tag{2.2}$$

see [6, p. 287].

Suppose that d_1, d_2, d_3 and k_1, k_2, k_3 are positive constants. Moreover, let $\alpha \in L^\infty(0,T;L^2(\Gamma_c))$ denote a shape function with $\alpha \ge 0$ on Σ_c almost everywhere (a.e.). We consider the following system of semilinear parabolic equations, where c_i denotes the concentration of the ith substance:

$$(c_1)_t(t,x) = d_1\Delta c_1(t,x) - k_1 c_1(t,x)c_2(t,x) \qquad \text{for all } (t,x) \in Q, \tag{2.3a}$$

$$(c_2)_t(t,x) = d_2\Delta c_2(t,x) - k_2 c_1(t,x)c_2(t,x) \qquad \text{for all } (t,x) \in Q, \tag{2.3b}$$

$$(c_3)_t(t,x) = d_3\Delta c_3(t,x) + k_3 c_1(t,x)c_2(t,x) \qquad \text{for all } (t,x) \in Q \tag{2.3c}$$

together with the Neumann boundary conditions

$$d_1\frac{\partial c_1}{\partial n}(t,x) = 0 \qquad \text{for all } (t,x) \in \Sigma, \tag{2.3d}$$

$$d_2\frac{\partial c_2}{\partial n}(t,x) = u(t)\alpha(t,x) \qquad \text{for all } (t,x) \in \Sigma_c, \tag{2.3e}$$

$$d_2\frac{\partial c_2}{\partial n}(t,x) = 0 \qquad \text{for all } (t,x) \in \Sigma_n = \Sigma \setminus \Sigma_c, \tag{2.3f}$$

$$d_3\frac{\partial c_3}{\partial n}(t,x) = 0 \qquad \text{for all } (t,x) \in \Sigma \tag{2.3g}$$

and the initial conditions

$$c_1(0,x) = c_{10}(x) \quad \text{for all } x \in \Omega, \tag{2.3h}$$

$$c_2(0,x) = c_{20}(x) \quad \text{for all } x \in \Omega, \tag{2.3i}$$

$$c_3(0,x) = c_{30}(x) \quad \text{for all } x \in \Omega, \tag{2.3j}$$

where $c_{i0} \in L^2(\Omega)$ for $i = 1,2,3$.

The control $u \in L^2(0,T)$ enters the right-hand side of (2.3e) in the inhomogeneous Neumann condition. For instance, the function α models a spray nozzle moving over the control part Γ_c, and $u(t)$ denotes the intensity of the spray.

Remark 2.1. The parabolic problem for c_3, i.e., (2.3c) together with the Neumann boundary condition (2.3g) and initial condition (2.3j) can be solved independently of the problem for (c_1,c_2). Therefore, we will focus on the computation of c_1 and c_2 and, in particular, we are interested in weak solutions for c_1 and c_2. □

DEFINITION 2.2. *The two functions c_1 and c_2 in $W(0,T)$ are called* weak solutions *to systems* (2.3a), (2.3b), (2.3d)–(2.3f), (2.3h), *and* (2.3i) *provided the initial conditions*

$$c_1(0) = c_{10} \quad \textit{and} \quad c_2(0) = c_{20} \quad \textit{in } L^2(\Omega) \tag{2.4a}$$

hold and

$$\langle (c_1)_t(t), \varphi \rangle_{H^1(\Omega)', H^1(\Omega)} + \int_\Omega d_1 \nabla c_1(t) \cdot \nabla \varphi + k_1 c_1(t) c_2(t) \varphi \, \mathrm{d}x = 0, \tag{2.4b}$$

$$\begin{aligned} &\langle (c_2)_t(t), \varphi \rangle_{H^1(\Omega)', H^1(\Omega)} + \int_\Omega d_2 \nabla c_2(t) \cdot \nabla \varphi + k_2 c_1(t) c_2(t) \varphi \, \mathrm{d}x \\ &\quad = u(t) \int_{\Gamma_c} \alpha(t) \varphi \, \mathrm{d}x \end{aligned} \tag{2.4c}$$

for all $\varphi \in H^1(\Omega)$ *and almost all* $t \in [0,T]$. *In* (2.4b) *and* (2.4c), $\langle \cdot, \cdot \rangle_{H^1(\Omega)', H^1(\Omega)}$ *denotes the duality pairing between* $H^1(\Omega)$ *and its dual* $H^1(\Omega)'$.

The following theorem ensures that (2.4) possesses a unique solution. For a proof, which is based on Leray–Schauder's fixed point theorem and variational techniques, we refer the reader to [9, Theorem 2.3].

THEOREM 2.3. *For every control* $u \in L^2(0,T)$, *there exists a unique pair* $(c_1, c_2) \in W(0,T) \times W(0,T)$ *satisfying* (2.4). *Moreover, the estimate*

$$\|c_1\|_{W(0,T)} + \|c_2\|_{W(0,T)} \le C \left(1 + \|c_{10}\|_{L^2(\Omega)} + \|c_{20}\|_{L^2(\Omega)} + \|u\|_{L^2(0,T)}\right) \tag{2.5}$$

holds for a constant $C > 0$.

Theorem 2.3 also implies the unique solvability of the partial differential equation for the reaction product (2.3c), (2.3g), and (2.3j). This is formulated in the following corollary, which is proved in [9, Corollary 2.4].

COROLLARY 2.4. *Let* $c_{10}, c_{20} \in L^2(\Omega)$ *and* $u \in L^2(0,T)$ *be given and let* $(c_1, c_2) \in W(0,T) \times W(0,T)$ *denote the solution pair to* (2.4). *Then there exists a unique* $c_3 \in W(0,T)$ *satisfying*

$$c_3(0) = c_{30} \quad \text{in } L^2(\Omega) \tag{2.6a}$$

and

$$\langle (c_3)_t(t), \varphi \rangle_{H^1(\Omega)', H^1(\Omega)} + \int_\Omega d_3 \nabla c_3(t) \cdot \nabla \varphi \, \mathrm{d}x = \int_\Omega k_3 c_1(t) c_2(t) \varphi \, \mathrm{d}x \tag{2.6b}$$

for all $\varphi \in H^1(\Omega)$ *and almost all* $t \in [0,T]$.

To write the state equations as a nonlinear operator equation, we introduce the two Hilbert product spaces

$$\begin{aligned} X &= W(0,T) \times W(0,T) \times L^2(0,T), \\ Y &= L^2(0,T; H^1(\Omega)) \times L^2(0,T; H^1(\Omega)) \times L^2(\Omega) \times L^2(\Omega) \end{aligned}$$

endowed with their product topology and identify

$$Y' \equiv L^2(0,T; H^1(\Omega)') \times L^2(0,T; H^1(\Omega)') \times L^2(\Omega) \times L^2(\Omega).$$

Then we introduce the mapping $e : X \to Y'$ by

$$e(x) = \begin{pmatrix} e_1(x) \\ e_2(x) \\ c_1(0) - c_{10} \\ c_2(0) - c_{20} \end{pmatrix} \quad \text{for } x = (c_1, c_2, u) \in X,$$

where the operators $e_1, e_2 \colon X \times L^2(0,T;H^1(\Omega)) \to L^2(0,T;H^1(\Omega)')$ involve the variational formulation of the partial differential equations for c_1 and c_2, respectively, i.e.,

$$\begin{aligned}&\langle e_1(x), \varphi\rangle_{L^2(0,T;H^1(\Omega)'),L^2(0,T;H^1(\Omega))}\\ &\quad= \int_0^T \Big(\langle (c_1)_t(t), \varphi(t)\rangle_{H^1(\Omega)',H^1(\Omega)} + \int_\Omega d_1 \nabla c_1 \cdot \nabla \varphi + k_1 c_1 c_2 \varphi \,\mathrm{d}x \Big) \mathrm{d}t\end{aligned}$$

and

$$\begin{aligned}\langle e_2(x), \varphi\rangle_{L^2(0,T;H^1(\Omega)'),L^2(0,T;H^1(\Omega))} &= \int_0^T \Big(\langle (c_2)_t(t), \varphi(t)\rangle_{H^1(\Omega)',H^1(\Omega)} \,\mathrm{d}t\\ &\quad + \int_\Omega d_2 \nabla c_2 \cdot \nabla \varphi + k_2 c_1 c_2 \varphi \,\mathrm{d}x - u \int_{\Gamma_c} \alpha \varphi \,\mathrm{d}x \Big) \mathrm{d}t\end{aligned}$$

for $\varphi \in L^2(0,T;H^1(\Omega))$. Now, (2.4) is equivalent to the operator equation $e(x) = 0$ in Y' for $x = (c_1, c_2, u) \in X$.

2.2. The optimal control problem. Our goal is to drive the reaction-diffusion system from the given initial state near a desired terminal state. Hence, we introduce the cost functional

$$J(c_1, c_2, u) = \frac{1}{2} \int_\Omega \beta_1 \,|c_1(T) - c_{1T}|^2 + \beta_2 \,|c_2(T) - c_{2T}|^2 \,\mathrm{d}x + \frac{\gamma}{2} \int_0^T |u - u_d|^2 \,\mathrm{d}t,$$

where $\beta_1, \beta_2 \geq 0$, $\beta_1 + \beta_2, \gamma > 0$, $c_{1T}, c_{2T} \in L^2(\Omega)$ are given desired terminal states and $u_d \in L^2(0,T)$ denotes some nominal (or expected) control.

The closed and bounded convex set of admissible control parameters involves an integral constraint as well as bilateral control constraints:

$$\bar{U}_{\mathsf{ad}} = \left\{ u \in L^2(0,T) : \int_0^T u(t) \,\mathrm{d}t \leq u_c \text{ and } u_a \leq u \leq u_b \text{ in } [0,T] \right\} \subset L^\infty(0,T),$$

where u_a and u_b are given functions in $L^\infty(0,T)$ satisfying $u_a \leq u_b$ in $[0,T]$ a.e., and u_c is a positive constant.

Furthermore, let us define the closed convex set

$$\bar{K}_{\mathsf{ad}} = W(0,T) \times W(0,T) \times \bar{U}_{\mathsf{ad}}.$$

The infinite-dimensional optimal control problem can be expressed as

$$\text{(P)} \qquad \min J(x) \quad \text{such that (s.t.)} \quad x \in \bar{K}_{\mathsf{ad}} \text{ and } e(x) = 0.$$

The following theorem guarantees that (P) has a solution.

THEOREM 2.5. *Problem* (P) *possesses at least one optimal control.*

Proof. The claim follows by standard arguments: let $\{x^n\}_{n=1}^\infty$, $x^n = (c_1^n, c_2^n, u^n)$, be a minimizing sequence in $\bar{K}_{\mathsf{ad}}$ for the nonnegative cost J. Since J is radially unbounded, it follows from Theorem 2.3 that this sequence is bounded in X. Therefore,

there exists an element $x^* = (c_1^*, c_2^*, u^*) \in X$ such that

$$c_1^n \rightharpoonup c_1^* \quad \text{in } W(0,T) \text{ as } n \to \infty, \tag{2.7}$$

$$c_2^n \rightharpoonup c_2^* \quad \text{in } W(0,T) \text{ as } n \to \infty, \tag{2.8}$$

$$u^n \rightharpoonup u^* \quad \text{in } L^2(0,T) \text{ as } n \to \infty. \tag{2.9}$$

By assumption, $\alpha \in L^\infty(0,T;L^2(\Gamma_c))$ holds. Recall that there exists a constant $K_1 > 0$ such that

$$\|\psi\|_{L^2(\Gamma_c)} \le K_1 \|\psi\|_{H^1(\Omega)} \quad \text{for all } \psi \in H^1(\Omega);$$

see, e.g., [6, p. 258]. Thus, for $\varphi \in L^2(0,T;H^1(\Omega))$, the mapping $t \mapsto \int_{\Gamma_c} \alpha(t)\varphi(t)\,\mathrm{d}x$ belongs to $L^2(0,T)$ and

$$\lim_{n\to\infty} \int_0^T \big(u^n(t) - u^*(t)\big)\bigg(\int_{\Gamma_c} \alpha(t)\varphi(t)\,\mathrm{d}x\bigg)\mathrm{d}t = 0 \quad \text{for all } \varphi \in L^2(0,T;H^1(\Omega)).$$

From (2.7) and (2.8), we find for $i = 1, 2$,

$$\lim_{n\to\infty} \int_0^T \big\langle (c_i^n - c_i^*)_t(t), \varphi(t)\big\rangle_{H^1(\Omega)',H^1(\Omega)}\,\mathrm{d}t = 0 \quad \text{for all } \varphi \in L^2(0,T;H^1(\Omega))$$

and

$$\lim_{n\to\infty} \int_0^T \int_\Omega d_i \nabla\big(c_i^n - c_i^*\big)(t) \cdot \nabla\varphi(t)\,\mathrm{d}x\,\mathrm{d}t = 0 \quad \text{for all } \varphi \in L^2(0,T;H^1(\Omega)).$$

Next we consider the nonlinear terms. Using Hölder's inequality we infer that for $\varphi \in L^2(0,T;H^1(\Omega))$,

$$\begin{aligned}
\int_0^T \int_\Omega \big(c_1^n c_2^n - c_1^* c_2^*\big)\varphi\,\mathrm{d}x\,\mathrm{d}t &= \int_0^T \int_\Omega \big[\big(c_1^n - c_1^*\big)c_2^n + c_1^*\big(c_2^n - c_2^*\big)\big]\,\varphi\,\mathrm{d}x\,\mathrm{d}t \\
&\le \int_0^T \|c_1^n(t) - c_1^*(t)\|_{L^3(\Omega)} \|c_2^n(t)\|_{L^2(\Omega)} \|\varphi(t)\|_{L^6(\Omega)}\,\mathrm{d}t \\
&\quad + \int_0^T \|c_1^*(t)\|_{L^2(\Omega)} \|c_2^n(t) - c_2^*(t)\|_{L^3(\Omega)} \|\varphi(t)\|_{L^6(\Omega)}\,\mathrm{d}t \\
&\le \|c_1^n - c_1^*\|_{L^2(0,T;L^3(\Omega))} \|c_2^n\|_{C([0,T];L^2(\Omega))} \|\varphi\|_{L^2(0,T;L^6(\Omega))} \\
&\quad + \|c_1^*\|_{C([0,T];L^2(\Omega))} \|c_2^n - c_2^*\|_{L^2(0,T;L^3(\Omega))} \|\varphi\|_{L^2(0,T;L^6(\Omega))}.
\end{aligned} \tag{2.10}$$

Since $W(0,T)$ is continuously embedded into $C([0,T];L^2(\Omega))$ and compactly into $L^2(0,T;L^3(\Omega))$ (see, for instance, [33, p. 271]), the sequence $\|c_i^n\|_{C([0,T];L^2(\Omega))}$ is bounded and $\lim_{n\to\infty} \|c_i^n - c_i^*\|_{L^2(0,T;L^3(\Omega))} = 0$ for $i = 1, 2$. Thus, (2.10) yields

$$\lim_{n\to\infty} \int_0^T \int_\Omega \big(c_1^n c_2^n - c_1^* c_2^*\big)\varphi\,\mathrm{d}x\,\mathrm{d}t = 0 \quad \text{for all } \varphi \in L^2(0,T;H^1(\Omega)).$$

Using

$$\int_\Omega \big(c_i^n(0) - c_i^*(0)\big)\psi\,\mathrm{d}x = 0 \quad \text{for all } \psi \in L^2(\Omega) \text{ and } i = 1, 2,$$

we have $e(x^*) = 0$ in Y'. Since $\bar{U}_{\mathsf{ad}}$ is bounded, closed, and convex, $\bar{U}_{\mathsf{ad}}$ is weakly closed. This implies that $\bar{K}_{\mathsf{ad}}$ is also weakly closed. As J is weakly lower semicontinuous, the claim follows. ∎

2.3. The penalized optimization problem. In (P), we have two different types of inequality constraints for the control variable: a scalar integral constraint and an infinite-dimensional box-constraint. To handle the integral constraint

$$\int_0^T u \,\mathrm{d}t \le u_c \tag{2.11}$$

numerically, we introduce the penalized cost functional

$$J_\varepsilon(x) = J(x) + \frac{1}{\varepsilon} I(u) \quad \text{for all } x = (c_1, c_2, u) \in X \text{ and } \varepsilon > 0,$$

where the mapping $I : L^2(0,T) \to \mathbb{R}$ defined as

$$I(u) = g\bigg(\int_0^T u \,\mathrm{d}t - u_c \bigg),$$

where we choose $g = [\,\cdot\,]_+^3$ in $\mathbb{R}$ and $[s]_+ = \max\{0, s\}$, $s \in \mathbb{R}$, denotes the positive part function.

Remark 2.6. Of course, other choices for g are possible. To analyze second-order conditions later on, we make use of the fact that $g \in C^2$. Moreover, the property $g''(s) \ge 0$ for all $s \in \mathbb{R}$ ensures coercivity of the cost functional J_ε. □

The goal of this section is to analyze the optimal control problem with the penalized cost. The bilateral control constraints are treated explicitly and enforced numerically by primal-dual active set strategies; see sections 4 and 5. Lemma 2.7 is proved in [9, Lemmas 2.7 and 2.8].

LEMMA 2.7. *The function g is twice differentiable and its second derivative is Lipschitz-continuous. Moreover, the mapping $I : L^2(0,T) \to \mathbb{R}$ is weakly continuous. Moreover, I is twice continuously Fréchet-differentiable and its second Fréchet-derivative is Lipschitz-continuous in $L^2(0,T)$. In particular, the Fréchet-derivatives of I at $u \in L^2(0,T)$ are given by*

$$\nabla I(u)\delta u = g'\bigg(\int_0^T u \,\mathrm{d}t - u_c \bigg) \int_0^T \delta u \,\mathrm{d}t$$

and

$$\nabla^2 I(u)(\delta u, \widetilde{\delta u}) = g''\bigg(\int_0^T u \,\mathrm{d}t - u_c \bigg) \int_0^T \delta u \,\mathrm{d}t \int_0^T \widetilde{\delta u} \,\mathrm{d}t. \tag{2.12}$$

As the integral constraint is already included in the cost J_ε by a penalty term, we replace $\bar{U}_{\mathsf{ad}}$ by

$$U_{\mathsf{ad}} = \{u \in L^2(0,T) : u_a \le u \le u_b \text{ in } [0,T]\} \subset L^\infty(0,T)$$

and set $K_{\mathsf{ad}} = W(0,T) \times W(0,T) \times U_{\mathsf{ad}}$. Now the penalized optimal control problem has the form

$$\min J_\varepsilon(x) \quad \text{s.t.} \quad x \in K_{\mathsf{ad}} \text{ and } e(x) = 0. \tag{P_ε}$$

Utilizing Lemma 2.7, the next result can be proved analogously to Theorem 2.5.

THEOREM 2.8. *There exists at least one optimal solution to* (P_ε).

Proof. Because of Lemma 2.7 the mapping I is weakly continuous, so that the penalized cost functional J_ε is weakly lower semicontinuous on X. Thus, the proof is analogous to that of Theorem 2.5. ∎

In the next proposition we turn to the question whether solutions of (P_ε) converges to a solution to (P) if ε tends to zero.

PROPOSITION 2.9. *Assume that $\{\varepsilon_n\}_{n=0}^\infty \subset \mathbb{R}$ is a sequence converging to zero from above. Let $\{x_n\}_{n=0}^\infty$ denote a sequence of optimal solutions to $(\mathrm{P}_{\varepsilon_n})$. Then there exists at least one weak accumulation point $x^* \in X$ for $\{x_n\}_{n=0}^\infty$. That is, $x_{n'} \rightharpoonup x^*$ in X as $n' \to \infty$ for some subsequence $\{x_{n'}\}_{n'=0}^\infty$. In addition, every weak accumulation point x^* solves* (P).

Proof. Since $x_n = (c_{1n}, c_{2n}, u_n) \in X$ solves $(\mathrm{P}_{\varepsilon_n})$, the sequence $\{u_n\}_{n=0}^\infty$ belongs to U_{ad}. Thus, $\|u_n\|_{L^2(0,T)}$ is bounded by a constant which does not depend on n. Because of the a priori bound (2.5), the family of pairs $\{(c_{1n}, c_{2n})\}_{n=0}^\infty$ is also bounded in $W(0,T) \times W(0,T)$. Since X is reflexive, there exists a subsequence in K_{ad}, denoted by $\{x_{n'}\}_{n'=0}^\infty$, and an element $x^* = (c_1^*, c_2^*, u^*) \in X$ such that

$$x_{n'} \rightharpoonup x^* \quad \text{in } X \text{ as } n' \to \infty. \tag{2.13}$$

Reasoning as in the proof of Theorem 2.5, we find that $x^* \in K_{\mathsf{ad}}$ and $e(x^*) = 0$ in Y'. Since $x_{n'}$ solves $(\mathrm{P}_{\varepsilon_{n'}})$, we have

$$J_{\varepsilon_{n'}}(x_{n'}) = J(x_{n'}) + \frac{1}{\varepsilon_{n'}} I(u_{n'}) \le J(x) + \frac{1}{\varepsilon_{n'}} I(u) = J(x) \tag{2.14}$$

for all $x = (c_1, c_2, u) \in \bar{K}_{\mathsf{ad}}$. Hence,

$$0 \le I(u_{n'}) \le \varepsilon_{n'} \big(J(x) - J(x_{n'})\big) \quad \text{for all } x \in \bar{K}_{\mathsf{ad}}. \tag{2.15}$$

Choosing $x \in \bar{K}_{\mathsf{ad}}$ arbitrarily and using the boundedness of $x_{n'}$ and thus of $J(x_{n'})$, we obtain $I(u^*) = 0$ from passing to the limit in (2.15), applying Lemma 2.7. Thus, the integral constraint (2.11) is satisfied for u^*; hence $x^* \in K_{\mathsf{ad}}$ holds. Finally, it follows from weak lower semicontinuity of J and from (2.14) that

$$J(x^*) \le \liminf_{n' \to \infty} J(x_{n'}) \le \liminf_{n' \to \infty} J(x_{n'}) + \frac{1}{\varepsilon_{n'}} I(u_{n'}) \le J(x) \quad \text{for all } x \in \bar{K}_{\mathsf{ad}}$$

so that x^* solves (P). ∎

3. Optimality conditions. In section 2 we have introduced the optimal control problem (P_ε) and proved existence of optimal controls. This section is devoted to the analysis of necessary and sufficient optimality conditions for (P_ε).

3.1. Smoothness properties for *J* and *e*. We start by investigating differentiability properties of the cost functional as well as of the mapping describing the equality constraints. The proof of the following result is based on Lemma 2.7. For more details we refer the reader to [9, Proposition 3.1].

PROPOSITION 3.1. *The penalized cost functional J_ε and the mapping e are twice continuously Fréchet-differentiable and their second Fréchet-derivatives are Lipschitz-continuous on X.*

The linear operator $\nabla_{(c_1,c_2)} e(x) : W(0,T) \times W(0,T) \to Y'$ has the following property.

PROPOSITION 3.2. *For all $x \in X$, the linearization $\nabla_{(c_1,c_2)} e(x)$ is bijective. Moreover, for all $\delta x = (\delta c_1, \delta c_2, \delta u) \in N(\nabla e(x))$, we have*

$$\|\delta c_1\|^2_{W(0,T)} + \|\delta c_2\|^2_{W(0,T)} \le C_N \|\delta u\|^2_{L^2(0,T)} \tag{3.1}$$

for all $C_N > 0$, where $N(\nabla e(x))$ denotes the null space of the operator $\nabla e(x)$.

For a proof we refer the reader to [9, Proposition 3.2].

Remark 3.3. Proposition 3.2 implies the standard constraint qualification condition for x^* (see [28], for example), which in our case has the form

$$\begin{aligned}\begin{pmatrix} 0 \\ 0 \end{pmatrix} &\in \operatorname{int}\left\{ \begin{pmatrix} X \\ \nabla e(x^*)X \end{pmatrix} - \begin{pmatrix} K_{\mathsf{ad}} - x^* \\ Y' - e(x^*) \end{pmatrix} \right\} \\ &= \operatorname{int}\{X - (K_{\mathsf{ad}} - x^*)\} \times \operatorname{int}\{\nabla e(x^*)X\},\end{aligned} \tag{3.2}$$

where int S denotes the interior of a set S and $e'(x^*)$ is the Fréchet-derivative of the operator e at x^*. It follows from (3.2) that the set of Lagrange multipliers is nonempty and bounded; see [25], for instance. □

For every $\varepsilon > 0$, the Lagrange functional $L_\varepsilon : X \times Y \to \mathbb{R}$ associated with (P_ε) is given by

$$L_\varepsilon(x,p) = J_\varepsilon(x) + \langle e(x), p\rangle_{Y',Y}$$

for $x = (c_1, c_2, u) \in X$ and $p = (\lambda_1, \lambda_2, \mu_1, \mu_2) \in Y$. From Proposition 3.1 we conclude that L_ε is twice continuously Fréchet-differentiable and its second Fréchet-derivative is Lipschitz-continuous.

3.2. First-order necessary optimality conditions. This subsection is devoted to the presentation of the first-order necessary optimality conditions for (P_ε). Problem (P_ε) is a nonconvex programming problem so that different local minima might occur. Numerical methods will produce a local minimum close to their starting point. Therefore, we do not direct our investigation to global solutions of (P_ε). We will assume that a fixed reference solution $\hat{x}^\varepsilon = (\hat{c}_1^\varepsilon, \hat{c}_2^\varepsilon, \hat{u}^\varepsilon) \in K_{\mathsf{ad}}$ is given satisfying first- and second-order optimality conditions. Let us define the active sets at $\hat{x}^\varepsilon$ by $\hat{A}^\varepsilon = \hat{A}^\varepsilon_- \cup \hat{A}^\varepsilon_+$, where

$$\hat{A}^\varepsilon_- = \{t \in [0,T] : \hat{u}^\varepsilon(t) = u_a(t) \text{ a.e.}\} \quad \text{and} \quad \hat{A}^\varepsilon_+ = \{t \in [0,T] : \hat{u}^\varepsilon(t) = u_b(t) \text{ a.e.}\}.$$

The corresponding inactive set at x^ε is given by $\hat{I}^\varepsilon = [0,T] \setminus \hat{A}^\varepsilon$. First-order necessary optimality conditions are presented in the next theorem.

THEOREM 3.4. *Let $\hat{x}^\varepsilon = (\hat{c}_1^\varepsilon, \hat{c}_2^\varepsilon, \hat{u}^\varepsilon) \in K_{\mathsf{ad}}$ be a local solution to (P_ε). Then there exists a unique Lagrange multiplier $\hat{p}^\varepsilon = (\hat{\lambda}_1^\varepsilon, \hat{\lambda}_2^\varepsilon, \hat{\mu}_1^\varepsilon, \hat{\mu}_2^\varepsilon) \in W(0,T) \times W(0,T) \times L^2(\Omega) \times L^2(\Omega) \subsetneq Y$ such that the pair $(\hat{\lambda}_1^\varepsilon, \hat{\lambda}_2^\varepsilon)$ is weak solutions to the adjoint (or dual) equations*

$$-(\hat{\lambda}_1^\varepsilon)_t - d_1\Delta\hat{\lambda}_1^\varepsilon = -k_1\hat{c}_2^\varepsilon\hat{\lambda}_1^\varepsilon - k_2\hat{c}_2^\varepsilon\hat{\lambda}_2^\varepsilon \qquad \text{in } Q, \tag{3.3a}$$

$$-(\hat{\lambda}_2^\varepsilon)_t - d_2\Delta\hat{\lambda}_2^\varepsilon = -k_1\hat{c}_1^\varepsilon\hat{\lambda}_1^\varepsilon - k_2\hat{c}_1^\varepsilon\hat{\lambda}_2^\varepsilon \qquad \text{in } Q, \tag{3.3b}$$

$$d_1\frac{\partial\hat{\lambda}_1^\varepsilon}{\partial n} = 0 \qquad \text{on } \Sigma, \tag{3.3c}$$

$$d_2\frac{\partial\hat{\lambda}_2^\varepsilon}{\partial n} = 0 \qquad \text{on } \Sigma, \tag{3.3d}$$

$$\hat{\lambda}_1^\varepsilon(T) = -\beta_1(\hat{c}_1^\varepsilon(T) - c_{1T}) \qquad \text{in } \Omega, \tag{3.3e}$$

$$\hat{\lambda}_2^\varepsilon(T) = -\beta_2(\hat{c}_2^\varepsilon(T) - c_{2T}) \qquad \text{in } \Omega, \tag{3.3f}$$

and for $i = 1, 2$, we have

$$\hat{\mu}_i^\varepsilon = \hat{\lambda}_i^\varepsilon(0) \quad \text{in } \Omega. \tag{3.4}$$

Moreover, there is a Lagrange multiplier $\hat{\xi}^\varepsilon \in L^2(0,T)$ associated with the bilateral inequality constraint satisfying

$$\hat{\xi}^\varepsilon|_{\hat{A}_-^\varepsilon} \le 0, \quad \hat{\xi}^\varepsilon|_{\hat{A}_+^\varepsilon} \ge 0, \tag{3.5}$$

and the optimality condition

$$\gamma(\hat{u}^\varepsilon(t) - u_d(t)) + \frac{1}{\varepsilon}\, g'\bigg(\int_0^T \hat{u}^\varepsilon \,\mathrm{d}t - u_c\bigg) - \int_{\Gamma_c} \alpha(t)\hat{\lambda}_2^\varepsilon(t)\,\mathrm{d}x + \hat{\xi}^\varepsilon(t) = 0 \tag{3.6}$$

holds for almost all $t \in [0,T]$.

Proof. Because of Remark 3.3, there exists a Lagrange multiplier $\hat{p}^\varepsilon = (\hat{\lambda}_1^\varepsilon, \hat{\lambda}_2^\varepsilon, \hat{\mu}_1^\varepsilon, \hat{\mu}_2^\varepsilon) \in Y = [L^2(0,T;H^1(\Omega))]^2 \times [L^2(\Omega)]^2$ such that

$$\begin{aligned} \nabla_{(c_1,c_2)} L_\varepsilon(\hat{x}^\varepsilon, \hat{p}^\varepsilon) &= \nabla_{(c_1,c_2)} J(\hat{x}^\varepsilon) + \nabla_{(c_1,c_2)} e(\hat{x}^\varepsilon)^* \hat{p}^\varepsilon \\ &= 0 \quad \text{in } W(0,T) \times W(0,T). \end{aligned} \tag{3.7}$$

In (3.7) the operator $\nabla_{(c_1,c_2)} e(\hat{x}^\varepsilon)^*$ denotes the adjoint of $\nabla_{(c_1,c_2)} e(\hat{x}^\varepsilon)$. By Proposition 3.2, $\nabla_{(c_1,c_2)} e(\hat{x}^\varepsilon)^*$ is injective, so $\hat{p}^\varepsilon$ is unique. Next we prove that $\hat{\lambda}_1^\varepsilon$ and $\hat{\lambda}_2^\varepsilon$ are more regular than suggested by Y and belong to $W(0,T)$. Condition (3.7) is equivalent to

$$\begin{aligned} 0 &= \nabla_{(c_1,c_2)} L_\varepsilon(\hat{x}^\varepsilon, \hat{p}^\varepsilon)(\delta c_1, \delta c_2) \\ &= \int_\Omega \beta_1(\hat{c}_1^\varepsilon(T) - c_{1T})\delta c_1(T) + \beta_2(\hat{c}_2^\varepsilon(T) - c_{2T})\delta c_2(T)\,\mathrm{d}x \\ &\quad + \int_0^T \langle (\delta c_1)_t(t), \hat{\lambda}_1^\varepsilon(t)\rangle_{H^1(\Omega)',H^1(\Omega)} \mathrm{d}t \\ &\quad + \int_0^T \int_\Omega d_1 \nabla \delta c_1 \cdot \nabla \hat{\lambda}_1^\varepsilon + k_1(\delta c_1 \hat{c}_2^\varepsilon + \hat{c}_1^\varepsilon \delta c_2)\hat{\lambda}_1^\varepsilon \,\mathrm{d}x\,\mathrm{d}t \\ &\quad + \int_0^T \langle (\delta c_2)_t(t), \hat{\lambda}_2^\varepsilon(t)\rangle_{H^1(\Omega)',H^1(\Omega)} \mathrm{d}t \\ &\quad + \int_0^T \int_\Omega d_2 \nabla \delta c_2 \cdot \nabla \hat{\lambda}_2^\varepsilon + k_2(\delta c_1 \hat{c}_2^\varepsilon + \hat{c}_1^\varepsilon \delta c_2)\hat{\lambda}_2^\varepsilon \,\mathrm{d}x\,\mathrm{d}t \\ &\quad + \int_\Omega \delta c_1(0)\hat{\mu}_1^\varepsilon + \delta c_2(0)\hat{\mu}_2^\varepsilon \,\mathrm{d}x \end{aligned} \tag{3.8}$$

for all $(\delta c_1, \delta c_2) \in W(0,T) \times W(0,T)$, in particular for $\delta c_i(t) = \chi(t)\varphi$, where $\chi \in C_c^\infty(0,T)$ and $\varphi \in H_0^1(\Omega)$. Here, $C_c^\infty(0,T)$ denotes the space of infinitely differentiable functions on $(0,T)$ with compact support. We find

$$\begin{aligned} \int_0^T \langle (\delta c_i)_t(t), \hat{\lambda}_i^\varepsilon(t)\rangle_{H^1(\Omega)',H^1(\Omega)} \mathrm{d}t &= \bigg\langle \int_0^T \hat{\lambda}_i^\varepsilon(t)\dot{\chi}(t)\,\mathrm{d}t, \varphi \bigg\rangle_{L^2(\Omega)} \\ &= -\bigg\langle \int_0^T (\hat{\lambda}_i^\varepsilon)_t(t)\chi(t)\,\mathrm{d}t, \varphi \bigg\rangle_{H^1(\Omega)',H^1(\Omega)} \end{aligned}$$

for $i = 1, 2$, where $(\hat\lambda_i^\varepsilon)_t$ denotes the distributional derivative of $\hat\lambda_i^\varepsilon$ with respect to t. The remaining terms in (3.8) lead to

$$\begin{aligned}
&\int_0^T \int_\Omega d_1 \nabla \delta c_1 \cdot \nabla \hat\lambda_1^\varepsilon + k_1(\delta c_1 \hat c_2^\varepsilon + \hat c_1^\varepsilon \delta c_2)\hat\lambda_1^\varepsilon \,\mathrm{d}x\,\mathrm{d}t \\
&\quad + \int_0^T \int_\Omega d_2 \nabla \delta c_2 \cdot \nabla \hat\lambda_2^\varepsilon + k_2(\delta c_1 \hat c_2^\varepsilon + \hat c_1^\varepsilon \delta c_2)\hat\lambda_2^\varepsilon \,\mathrm{d}x\,\mathrm{d}t \\
&= \left\langle \int_0^T -d_1 \Delta \hat\lambda_1^\varepsilon - d_2 \Delta \hat\lambda_2^\varepsilon + (\hat c_1^\varepsilon + \hat c_2^\varepsilon)\big(k_1 \hat\lambda_1^\varepsilon + k_2 \hat\lambda_2^\varepsilon\big)\chi \,\mathrm{d}t, \varphi \right\rangle_{H^1(\Omega)', H^1(\Omega)}.
\end{aligned}$$

Inserting these expressions into (3.8) yields

$$\begin{aligned}
&\left\langle \int_0^T (\hat\lambda_1^\varepsilon + \hat\lambda_2^\varepsilon)_t \chi \,\mathrm{d}t, \varphi \right\rangle_{H^1(\Omega)', H^1(\Omega)} \\
&\quad = \left\langle \int_0^T d_1 \Delta \hat\lambda_1^\varepsilon + d_2 \Delta \hat\lambda_2^\varepsilon - (\hat c_1^\varepsilon + \hat c_2^\varepsilon)\big(k_1 \hat\lambda_1^\varepsilon + k_2 \hat\lambda_2^\varepsilon\big)\chi \,\mathrm{d}t, \varphi \right\rangle_{H^1(\Omega)', H^1(\Omega)}
\end{aligned}$$

for all $\chi \in C_c^\infty(0,T)$ and $\varphi \in H_0^1(\Omega)$. Since

$$d_1 \Delta \hat\lambda_1^\varepsilon + d_2 \Delta \hat\lambda_2^\varepsilon - (\hat c_1^\varepsilon + \hat c_2^\varepsilon)\big(k_1 \hat\lambda_1^\varepsilon + k_2 \hat\lambda_2^\varepsilon\big) \in L^2(0,T; H^1(\Omega))$$

holds and the set

$$\{\delta c : \delta c(t) = \chi(t)\varphi \text{ for } \chi \in C_c^\infty(0,T) \text{ and } \varphi \in H_0^1(\Omega)\}$$

is dense in $L^2(0,T; H^1(\Omega))$, we conclude that $(\hat\lambda_i^\varepsilon)_t \in L^2(0,T; H^1(\Omega)')$ and consequently $\hat\lambda_i^\varepsilon \in W(0,T)$ for $i = 1, 2$. Hence, (3.3a) and (3.3b) are proved. We notice that for all $\delta c_i \in W(0,T)$, $i = 1, 2$, we have

$$\begin{aligned}
&\int_0^T \langle (\hat\lambda_i^\varepsilon)_t(t), \delta c_i(t)\rangle_{H^1(\Omega)', H^1(\Omega)} \,\mathrm{d}t + \int_0^T \langle (\delta c_i)_t(t), \hat\lambda_i^\varepsilon(t)\rangle_{H^1(\Omega)', H^1(\Omega)} \,\mathrm{d}t \\
&\quad = \int_0^T \frac{\mathrm{d}}{\mathrm{d}t} \langle \hat\lambda_i^\varepsilon(t), \delta c_i(t)\rangle_{L^2(\Omega)} \,\mathrm{d}t \\
&\quad = \langle \hat\lambda_i^\varepsilon(T), \delta c_i(T)\rangle_{L^2(\Omega)} - \langle \hat\lambda_i^\varepsilon(0), \delta c_i(0)\rangle_{L^2(\Omega)}.
\end{aligned} \tag{3.9}$$

Choosing appropriate test functions in $W(0,T)$, we infer from (3.3a), (3.3b), (3.8), and (3.9) that (3.3c)–(3.3f) as well as (3.4) are satisfied. Because of optimality the following optimality inequality holds:

$$\nabla_u L_\varepsilon(\hat x^\varepsilon, \hat p^\varepsilon)(u - \hat u^\varepsilon) \geq 0 \quad \text{for all } u \in U_{\mathsf{ad}}.$$

Setting

$$\begin{aligned}
-\langle \hat\xi^\varepsilon, u - \hat u^\varepsilon\rangle_{L^2(0,T)} &= \nabla_u L_\varepsilon(\hat x^\varepsilon, \hat p^\varepsilon)(u - \hat u^\varepsilon) \\
&= \left\langle \gamma(\hat u^\varepsilon - u_d) - \int_{\Gamma_c} \alpha \hat\lambda_2^\varepsilon \,\mathrm{d}x, u - \hat u^\varepsilon \right\rangle_{L^2(0,T)} \\
&\quad + \frac{1}{\varepsilon} g'\bigg(\int_0^T \hat u^\varepsilon \,\mathrm{d}t - u_c \bigg) \int_0^T u - \hat u^\varepsilon \,\mathrm{d}t \\
&= \left\langle \gamma(\hat u^\varepsilon - u_d) + \frac{1}{\varepsilon} g'\bigg(\int_0^T \hat u^\varepsilon \,\mathrm{d}t - u_c \bigg) - \int_{\Gamma_c} \alpha \hat\lambda_2^\varepsilon \,\mathrm{d}x, u - \hat u^\varepsilon \right\rangle_{L^2(0,T)}
\end{aligned} \tag{3.10}$$

for all $u \in U$, we obtain (3.6). For the proof of (3.5) we refer the reader to [13]. ∎

Remark 3.5. From Remark 3.13, uniqueness of the Lagrange multiplier $\hat{\xi}^\varepsilon$ will follow later on. ∎

The following corollary provides an a priori estimate for the Lagrange multipliers $\hat{\lambda}_1^\varepsilon$ and $\hat{\lambda}_2^\varepsilon$ that will be used for the second-order optimality conditions; see section 3.3 and Theorem 3.15.

COROLLARY 3.6. *There exists a constant $C_\lambda > 0$ such that*

$$\begin{aligned} &\|\hat{\lambda}_1^\varepsilon\|_{L^2(0,T;L^4(\Omega))} + \|\hat{\lambda}_2^\varepsilon\|_{L^2(0,T;L^4(\Omega))} \\ &\quad \le C_\lambda\big(\|\hat{c}_1^\varepsilon(T) - c_{1T}\|_{L^2(\Omega)} + \|\hat{c}_2^\varepsilon(T) - c_{2T}\|_{L^2(\Omega)}\big). \end{aligned} \tag{3.11}$$

For the proof we refer the reader to [9, Corollary 3.6].

3.3. Second-order optimality conditions. In section 3.2 we have investigated the first-order necessary optimality conditions for (P_ε). To ensure that a solution $(\hat{x}^\varepsilon, \hat{p}^\varepsilon)$ satisfying (2.4), $\hat{x}^\varepsilon \in K_{\mathsf{ad}}$, (3.3), and (3.6) indeed solves (P_ε), we have to guarantee second-order sufficient optimality. This is the focus of this section. In order to introduce the critical cone in Definition 3.9, we recall the notions of tangent and normal cones.

DEFINITION 3.7. *Let K be a convex subset of a Hilbert space Z and $z \in K$. The set*

$$T_K(z) = \{\tilde{z} \in Z : \text{ there exists } z(\sigma) = z + \sigma\tilde{z} + o(\sigma) \in K \text{ as } \sigma \searrow 0\}$$

is called the tangent cone at the point z. *Moreover, the* normal cone N_K at the point z *is given by*

$$N_K(z) = \{\tilde{z} \in Z : \langle \tilde{z}, \hat{z} - z\rangle_Z \le 0 \text{ for all } \hat{z} \in K\}.$$

In the case of $z \notin K$ these two cones are set equal to the empty set.

For $K = K_{\mathsf{ad}}$ we have the following characterizations.

LEMMA 3.8. *Let $x = (c_1, c_2, u) \in K_{\mathsf{ad}}$.*

(a) $T_{K_{\mathsf{ad}}}(x) = W(0,T) \times W(0,T) \times T_{U_{\mathsf{ad}}}(u)$, *where*

$$T_{U_{\mathsf{ad}}}(u) = \{\tilde{u} \in L^2(0,T) : \tilde{u}(t) \in T_{[u_a(t),u_b(t)]}(u(t)) \text{ for } t \in [0,T] \text{ a.e.}\},$$

where for $a, b, s \in \mathbb{R}$ with $a \le b$

$$T_{[a,b]}(s) = \begin{cases} \mathbb{R}^+ = \{t \in \mathbb{R} : t \ge 0\} & \text{if } s = a, \\ \mathbb{R}^- = \{t \in \mathbb{R} : t \le 0\} & \text{if } s = b, \\ \mathbb{R} & \text{otherwise.} \end{cases}$$

(b) $N_{K_{\mathsf{ad}}}(x) = \{0\} \times \{0\} \times N_{U_{\mathsf{ad}}}(u)$, *where*

$$N_{U_{\mathsf{ad}}}(u) = \{\tilde{u} \in L^2(0,T) : \tilde{u}(t) \in N_{[u_a(t),u_b(t)]}(u(t)) \text{ for } t \in [0,T] \text{ a.e.}\}.$$

That is,

$$\tilde{u}(t) \in \begin{cases} \mathbb{R}^+ = \{t \in \mathbb{R} : t \ge 0\} & \text{if } u(t) = u_a(t), \\ \mathbb{R}^- = \{t \in \mathbb{R} : t \le 0\} & \text{if } u(t) = u_b(t), \\ \mathbb{R} & \text{otherwise.} \end{cases}$$

(c) *Moreover,*

(3.12)
$$T_{U_{\mathsf{ad}}}(\hat{u}^\varepsilon) \cap \{\hat{\xi}^\varepsilon\}^\perp = \{u \in L^2(0,T) : u \geq 0 \text{ on } \hat{A}^\varepsilon_-,\ u \leq 0 \text{ on } \hat{A}^\varepsilon_+, \text{ and } u = 0 \text{ on } \hat{A}^\varepsilon_\pm\},$$

where $\hat{\xi}^\varepsilon \in N_{U_{\mathsf{ad}}}$ *is the Lagrange multiplier introduced in Theorem* 3.4. $S^\perp$ *denotes the orthogonal complement of a set* S, *and* $\hat{A}^\varepsilon_\pm = \{t \in [0,T] : \hat{\xi}^\varepsilon > 0 \text{ or } \hat{\xi}^\varepsilon < 0 \text{ a.e.}\} \subset \hat{A}^\varepsilon$.

Proof. The characterization of the tangent and normal cones is a classical result. For a proof we refer the reader to [29]. What remains to show is (3.12). Because of (3.10) we have $\hat{\xi}^\varepsilon \in N_{U_{\mathsf{ad}}}(\hat{u}^\varepsilon)$ satisfying $\hat{\xi}^\varepsilon = 0$ on the set $[0,T] \setminus \hat{A}^\varepsilon_\pm$. Suppose that $t \in \hat{A}^\varepsilon_-$. We conclude $T_{[u_a(t),u_b(t)]}(\hat{u}^\varepsilon(t)) = \mathbb{R}^+$. Thus, $u \in T_{U_{\mathsf{ad}}}(\hat{u}^\varepsilon)$ implies $u \geq 0$ on $\hat{A}^\varepsilon_-$ by part (a). Analogously, $u \leq 0$ on $\hat{A}^\varepsilon_+$ holds. Hence,

$$T_{U_{\mathsf{ad}}}(\hat{u}^\varepsilon) \cap \{\hat{\xi}^\varepsilon\}^\perp = \{\tilde{u} \in L^2(0,T) : \tilde{u}(t) \in T_{[u_a(t),u_b(t)]}(\hat{u}^\varepsilon(t)) \text{ for } t \in [0,T] \text{ a.e.}\} \cap \left\{u \in L^2(0,T) : \int_{\hat{A}^\varepsilon_\pm} \hat{\xi}^\varepsilon u \,\mathrm{d}t = 0\right\}.$$

Since $\hat{\xi}^\varepsilon > 0$ and $u \geq 0$ on $\hat{A}^\varepsilon_- \cap \hat{A}^\varepsilon_\pm$, and $\hat{\xi}^\varepsilon < 0$ and $u \leq 0$ on $\hat{A}^\varepsilon_+ \cap \hat{A}^\varepsilon_\pm$, (3.12) holds, which completes the proof. ∎

Suppose that the point $\bar{x} = (\bar{c}_1, \bar{c}_2, \bar{u}) \in X$ satisfies the first-order necessary optimality conditions. By Proposition 3.2, there exist unique Lagrange multipliers $\bar{p} = (\bar{\lambda}_1, \bar{\lambda}_2, \bar{\mu}_1, \bar{\mu}_2) \in Y$ and $\bar{\xi} \in N_{U_{\mathsf{ad}}}$ satisfying the first-order necessary optimality conditions

$$\nabla_x L_\varepsilon(\bar{x}, \bar{p}) + (0,0,\bar{\xi})^{\mathsf{T}} = 0, \quad \bar{x} \in K_{\mathsf{ad}} \text{ and } e(\bar{x}) = 0. \tag{3.13}$$

Now we introduce the critical cone at $\bar{x}$.

Definition 3.9. *The* critical cone at $\bar{x}$ *is defined by*

$$C(\bar{x}) = \{\delta x \in T_{K_{\mathsf{ad}}}(\bar{x}) \cap \{(0,0,\bar{\xi})\}^\perp : \delta x \in N(\nabla e(\bar{x}))\}.$$

The critical cone at $\bar{x}$ is the set of directions of nonincrease of the cost that are tangent to the feasible set $\{x \in K_{\mathsf{ad}} : e(x) = 0\}$. This is formulated in the next lemma.

Lemma 3.10. *It follows that* $\nabla J_\varepsilon(\bar{x})\delta x = 0$ *for all* $\delta x \in C(\bar{x})$.

Proof. Let $\delta x = (\delta c_1, \delta c_2, \delta u) \in C(\bar{x})$. From (3.13), $\delta x \in N(\nabla e(\bar{x}))$ and $\delta x \in \{(0,0,\bar{\xi})\}^\perp$ we infer that

$$0 = \big(\nabla_x L_\varepsilon(\bar{x}, \bar{p}) + (0,0,\bar{\xi})^{\mathsf{T}}\big)\delta x = \nabla J_\varepsilon(\bar{x})\delta x,$$

which completes the proof. ∎

Now we turn to the *second-order necessary optimality conditions.* Let $\delta x = (\delta c_1, \delta c_2, \delta u) \in X$. We find

$$\begin{aligned} \nabla^2_x L_\varepsilon(\bar{x}, \bar{p})(\delta x, \delta x) &= \int_\Omega \beta_1 |\delta c_1(T)|^2 + \beta_2 |\delta c_2(T)|^2 \,\mathrm{d}x \\ &\quad + \frac{1}{\varepsilon}\nabla^2 I(\bar{u})(\delta u, \delta u) + \int_0^T \gamma |\delta u|^2 \,\mathrm{d}t \\ &\quad + \int_0^T \int_\Omega (2k_1\bar{\lambda}_1 + 2k_2\bar{\lambda}_2)\delta c_1 \delta c_2 \,\mathrm{d}x \,\mathrm{d}t. \end{aligned} \tag{3.14}$$

In Theorem 2.8 we have denoted by $\hat{x}^\varepsilon$ the local solution to (P_ε). The associated unique Lagrange multipliers are $\hat{p}^\varepsilon$ and $\hat{\xi}^\varepsilon$; see Theorem 3.4.

DEFINITION 3.11. *The* second-order necessary optimality conditions *are defined as*

$$\nabla_x^2 L_\varepsilon(\hat{x}^\varepsilon, \hat{p}^\varepsilon)(\delta x, \delta x) \geq 0 \quad \textit{for all } \delta x \in C(\hat{x}^\varepsilon). \tag{3.15}$$

Now let $\bar{x} = \hat{x}^\varepsilon$ be a local solution to (P_ε).

THEOREM 3.12. *The point $(\hat{x}^\varepsilon, \hat{p}^\varepsilon)$ satisfies the second-order necessary optimality condition* (3.15).

Proof. We apply analogous arguments as in the proof of Theorem 2.7 in [4]. The equality constraints can be written as

$$e(\hat{x}^\varepsilon) \in K_Y = \{0\} \subset Y,$$

where, of course, K_Y is a closed convex set. Thus, the result follows provided the following strict semilinearized qualification condition

$$0 \in \operatorname{int} \{\nabla e(\hat{x}^\varepsilon)((K_{\mathsf{ad}} - \hat{x}^\varepsilon) \cap \{(0,0,\hat{\xi}^\varepsilon)\}^\perp)\} \subset Y \tag{CQA}$$

holds. In our case, we have

$$(K_{\mathsf{ad}} - \hat{x}^\varepsilon) \cap \{(0,0,\hat{\xi}^\varepsilon)\}^\perp = W(0,T) \times W(0,T) \times \big((U_{\mathsf{ad}} - \hat{u}^\varepsilon) \cap \{\hat{\xi}^\varepsilon\}^\perp\big).$$

Let $z \in Y$ be arbitrary, close enough to zero. Then (CQA) follows if there exists an element $\delta x = (\delta c_1, \delta c_2, \delta u) \in W(0,T) \times W(0,T) \times (U_{\mathsf{ad}} - \hat{u}^\varepsilon) \cap \{\hat{\xi}^\varepsilon\}^\perp$ satisfying

$$\nabla e(\hat{x}^\varepsilon)\delta x = z. \tag{3.16}$$

Because of Proposition 3.2 the operator $\nabla_{(c_1,c_2)} e(\hat{x}^\varepsilon)$ is bijective. Thus, there exists even a unique pair $(\delta c_1, \delta c_2) \in W(0,T) \times W(0,T)$ such that

$$\nabla_{(c_1,c_2)} e(\hat{x}^\varepsilon)(\delta c_1, \delta c_2) = z - \nabla_u e(\hat{x}^\varepsilon)\delta u$$

for arbitrary $\delta u \in L^2(0,T)$. This gives (3.16) so that the claim follows. ∎

Remark 3.13. As is proved in [4], condition (CQA) implies uniqueness of the Lagrange multipliers $\hat{p}^\varepsilon$ and $\hat{\xi}^\varepsilon$. ∎

DEFINITION 3.14. *Suppose that $\bar{x}$ satisfies the first-order necessary optimality conditions with the associated unique Lagrange multipliers $\bar{p} \in Y$ and $\bar{\xi} \in N_{U_{\mathsf{ad}}}(\bar{u})$. At $(\bar{x}, \bar{p})$, the* second-order sufficient optimality condition *holds if there exists $\kappa > 0$ such that*

$$\nabla_x^2 L_\varepsilon(\bar{x}, \bar{p})(\delta x, \delta x) \geq \kappa \|\delta x\|_X^2 \quad \textit{for all } \delta x \in C(\bar{x}).$$

THEOREM 3.15. *If $\|\hat{c}_1^\varepsilon(T) - c_{1T}\|_{L^2(\Omega)} + \|\hat{c}_2^\varepsilon(T) - c_{2T}\|_{L^2(\Omega)}$ is sufficiently small, then the second-order sufficient optimality condition is satisfied.*

Proof. Let $\delta x = (\delta c_1, \delta c_2, \delta u) \in C(\hat{x}^\varepsilon) \setminus \{0\}$. Then, we have

$$\nabla^2 I(\hat{u}^\varepsilon)(\delta u, \delta u) = 6 \left[\int_0^T \hat{u}^\varepsilon \,\mathrm{d}t - u_c \right]_+ \left(\int_0^T \delta u \,\mathrm{d}t \right)^2 \geq 0.$$

Recall *Gagliardo–Nierenberg's inequality* (see, e.g., [32, p. 81]): for $\Omega \subset \mathbb{R}^3$ there exists a constant $C_{GN} > 0$ such that

$$\|\varphi\|_{L^4(\Omega)} \le C_{GN} \|\varphi\|_{H^1(\Omega)}^{3/4} \|\varphi\|_{L^2(\Omega)}^{1/4} \quad \text{for all } \varphi \in H^1(\Omega).$$

Hence, using Hölder's and Gagliardo–Nierenberg's inequality and (2.2) we find

$$\begin{aligned}
&\int_0^T \int_\Omega \big(k_1 \hat\lambda_1^\varepsilon + k_2 \hat\lambda_2^\varepsilon\big) \delta c_1 \delta c_2 \,\mathrm{d}x \,\mathrm{d}t \\
&\le \int_0^T \big(k_1 \|\hat\lambda_1^\varepsilon(t)\|_{L^4(\Omega)} + k_2 \|\hat\lambda_2^\varepsilon(t)\|_{L^4(\Omega)}\big) \|\delta c_1(t)\|_{L^4(\Omega)} \|\delta c_2(t)\|_{L^2(\Omega)} \,\mathrm{d}t \\
&\le \int_0^T C_{GN}\big(k_1 \|\hat\lambda_1^\varepsilon(t)\|_{L^4(\Omega)} + k_2 \|\hat\lambda_2^\varepsilon(t)\|_{L^4(\Omega)}\big) \\
&\quad \times \|\delta c_1(t)\|_{L^2(\Omega)}^{1/4} \|\delta c_1(t)\|_{H^1(\Omega)}^{3/4} \|\delta c_2(t)\|_{L^2(\Omega)} \,\mathrm{d}t \\
&\le C_{GN}\big(k_1 \|\hat\lambda_1^\varepsilon\|_{L^2(0,T;L^4(\Omega))} + k_2 \|\hat\lambda_2^\varepsilon\|_{L^2(0,T;L^4(\Omega))}\big) \\
&\quad \times \|\delta c_1\|_{C([0,T];L^2(\Omega))}^{1/4} \|\delta c_1\|_{L^2(0,T;H^1(\Omega))}^{3/4} \|\delta c_2\|_{C([0,T];L^2(\Omega))} \\
&\le C_{GN} C_W^{5/4} \big(k_1 \|\hat\lambda_1^\varepsilon\|_{L^2(0,T;L^4(\Omega))} + k_2 \|\hat\lambda_2^\varepsilon\|_{L^2(0,T;L^4(\Omega))}\big) \|\delta c_1\|_{W(0,T)} \|\delta c_2\|_{W(0,T)}.
\end{aligned}$$

Thus, (3.1) and (3.14) yield

$$\begin{aligned}
&\nabla_x^2 L_\varepsilon(\hat x^\varepsilon, \hat p^\varepsilon)(\delta x, \delta x) \\
&\ge \frac{\gamma}{2} \|\delta u\|_{L^2(0,T)}^2 + \frac{\gamma}{2C_N^2}\big(\|\delta c_1\|_{W(0,T)}^2 + \|\delta c_2\|_{W(0,T)}^2\big) \\
&\quad - 2C_{GN}^{5/4} C_W^2 \big(k_1 \|\hat\lambda_1^\varepsilon\|_{L^2(0,T;L^4(\Omega))} + k_2 \|\hat\lambda_2^\varepsilon\|_{L^2(0,T;L^4(\Omega))}\big) \|\delta c_1\|_{W(0,T)} \|\delta c_2\|_{W(0,T)} \\
&\ge \frac{\gamma}{2} \|\delta u\|_{L^2(0,T)}^2 + \big(\|\delta c_1\|_{W(0,T)}^2 + \|\delta c_2\|_{W(0,T)}^2\big) \\
&\quad \times \Big(\frac{\gamma}{2C_N^2} - K_1\big(\|\hat\lambda_1^\varepsilon\|_{L^2(0,T;L^4(\Omega))} + \|\hat\lambda_2^\varepsilon\|_{L^2(0,T;L^4(\Omega))}\big)\Big),
\end{aligned}$$

where we set $K_1 = \max(k_1, k_2) C_{GN}^{5/4} C_W^2 > 0$. Because of (3.11) we find

$$\begin{aligned}
&\nabla_x^2 L_\varepsilon(\hat x^\varepsilon, \hat p^\varepsilon)(\delta x, \delta x) \\
&\ge \frac{\gamma}{2} \|\delta u\|_{L^2(0,T)}^2 + \big(\|\delta c_1\|_{W(0,T)}^2 + \|\delta c_2\|_{W(0,T)}^2\big) \\
&\quad \times \Big(\frac{\gamma}{2C_N} - K_2\big(\|\hat c_1^\varepsilon(T) - c_{1T}\|_{L^2(\Omega)} + \|\hat c_2^\varepsilon(T) - c_{2T}\|_{L^2(\Omega)}\big)\Big)
\end{aligned}$$

with the constant $K_2 = K_1 C_\lambda > 0$. Now, for instance, if

$$\|\hat c_1^\varepsilon(T) - c_{1T}\|_{L^2(\Omega)} + \|\hat c_2^\varepsilon(T) - c_{2T}\|_{L^2(\Omega)} \le \frac{\gamma}{4K_2 C_N}$$

holds, the second-order sufficient optimality condition is satisfied for the coercivity constant $\kappa = \gamma \min(1, 1/C_N)/2$. ∎

Remark 3.16.

(1) Notice that smallness of the two terms $\|\hat c_i^\varepsilon(T) - c_{iT}\|_{L^2(\Omega)}$, $i = 1, 2$, ensures that

$$\nabla_x^2 L_\varepsilon(\hat x^\varepsilon, \hat p^\varepsilon)(\delta x, \delta x) \ge \kappa \|\delta x\|_X^2 \quad \text{for all } \delta x \in N(\nabla e(\hat x^\varepsilon)).$$

Since $C(\hat{x}^\varepsilon) \subset N(\nabla e(\hat{x}^\varepsilon))$ holds, the second-order sufficient optimality condition is satisfied; see Definition 3.14.

(2) Arguing as in the proof of Theorem 4.12 in [36] it follows that the second-order sufficient optimality condition is equivalent to the *strong quadratic growth condition*, i.e., equivalent to the existence of two constants $\varrho, \zeta > 0$ such that

$$J_\varepsilon(x) \geq J_\varepsilon(\hat{x}^\varepsilon) + \varrho \, \|x - \hat{x}^\varepsilon\|_X^2 + o(\|x - \hat{x}^\varepsilon\|_X^2) \quad \text{for all } x \in \mathcal{K}_\zeta(\hat{x}^\varepsilon)$$

with $\mathcal{K}_\zeta(\hat{x}^\varepsilon) = \{x \in K_{\mathsf{ad}} : e(x) = 0 \text{ and } \|x - \hat{x}^\varepsilon\|_X \leq \zeta\}$. ∎

4. The primal-dual active set method. In this section, we describe the primal-dual active set strategy for nonlinear problems and review convergence results. For more details and for the proofs we refer the reader to [19].

Because of Theorem 2.3 we can define the solution operator

$$\mathcal{S} : L^2(0,T) \to W(0,T) \times W(0,T)$$

by $(c_1, c_2) = \mathcal{S}(u)$ for $u \in L^2(0,T)$, where the pair $(c_1, c_2) \in W(0,T) \times W(0,T)$ is the solution of (2.4). Introducing the reduced cost functional

$$\hat{J}_\varepsilon(u) = J_\varepsilon(\mathcal{S}(u), u),$$

problem (P_ε) can be expressed as

$$(\hat{\mathrm{P}}_\varepsilon) \qquad \min \hat{J}_\varepsilon(u) \quad \text{s.t.} \quad u \in U_{\mathsf{ad}}.$$

Notice that $(\hat{\mathrm{P}}_\varepsilon)$ is a minimization problem with bilateral control constraints but with no equality constraints. The gradient of $\hat{J}_\varepsilon$ at a point $\hat{u}^\varepsilon \in L^2(0,T)$ is given

$$\nabla \hat{J}_\varepsilon(\hat{u}^\varepsilon) = \gamma(\hat{u}^\varepsilon - u_d) + \frac{1}{\varepsilon} \, g'\bigg(\int_0^T \hat{u}^\varepsilon \, \mathrm{d}t - u_c \bigg) - \int_{\Gamma_c} \alpha \hat{\lambda}_2^\varepsilon \, \mathrm{d}x \in L^2(0,T), \tag{4.1}$$

where $(\hat{\lambda}_1^\varepsilon, \hat{\lambda}_2^\varepsilon) \in W(0,T) \times W(0,T)$ solves (3.3) for the state pair $(\hat{c}_1^\varepsilon, \hat{c}_2^\varepsilon)$, which in turn is the solution of (2.4) for the control input $\hat{u}^\varepsilon$.

From Theorem 3.4 we derive that the first-order necessary optimality conditions

$$\langle \nabla \hat{J}_\varepsilon(\hat{u}^\varepsilon), u - \hat{u}^\varepsilon \rangle_{L^2(0,T)} \geq 0 \quad \text{for all } u \in U_{\mathsf{ad}}$$

are equivalent to

$$\gamma(\hat{u}^\varepsilon - u_d) + \frac{1}{\varepsilon} \, g'\bigg(\int_0^T \hat{u}^\varepsilon \, \mathrm{d}t - u_c \bigg) - \int_{\Gamma_c} \alpha \hat{\lambda}_2^\varepsilon \, \mathrm{d}x + \hat{\xi}^\varepsilon = 0 \quad \text{in } L^2(0,T), \tag{4.2a}$$

where the Lagrange multiplier $\hat{\xi}^\varepsilon \in N_{U_{\mathsf{ad}}}(\hat{u}^\varepsilon)$ associated with the bilateral control constraints satisfies

$$\hat{\xi}^\varepsilon = \max\big\{0, \hat{\xi}^\varepsilon + (\hat{u}^\varepsilon - u_b)\big\} + \min\big\{0, \hat{\xi}^\varepsilon + (\hat{u}^\varepsilon - u_a)\big\} \quad \text{in } L^2(0,T). \tag{4.2b}$$

In (4.2b) the functions max and min are interpreted as pointwise a.e. operations. We next specify the primal-dual active set method.

ALGORITHM 4.1 (primal-dual active set strategy).

(1) Choose $(u^0, \xi^0) \in L^2(0,T) \times L^2(0,T)$, $\sigma > 0$ and set $k = 0$.

(2) Determine the active sets

$$A_-^k = \Big\{ t \in [0,T] : u^k(t) + \frac{\xi^k(t)}{\sigma} < u_a(t) \Big\},$$
$$A_+^k = \Big\{ t \in [0,T] : u^k(t) + \frac{\xi^k(t)}{\sigma} > u_b(t) \Big\}$$

and set $I^k = [0,T] \setminus (A_-^k \cup A_+^k)$.

(3) If $k \geq 1$ and $A_+^k = A_+^{k-1}$, $A_-^k = A_-^{k-1}$, then STOP.

(4) Solve for $(c_1, c_2, u, \lambda_1, \lambda_2) \in W(0,T) \times W(0,T) \times L^2(I^k) \times W(0,T) \times W(0,T)$ the coupled nonlinear system

$$\text{(4.3)} \quad \begin{cases} (c_1)_t = d_1 \Delta c_1 - k_1 c_1 c_2 & \text{in } Q, \\ (c_2)_t = d_2 \Delta c_2 - k_2 c_1 c_2 & \text{in } Q, \\ d_1 \frac{\partial c_1}{\partial n} = 0 & \text{on } \Sigma, \\ d_2 \frac{\partial c_2}{\partial n} = u_a \alpha & \text{on } A_-^k \times \Gamma_c, \\ d_2 \frac{\partial c_2}{\partial n} = u_b \alpha & \text{on } A_+^k \times \Gamma_c, \\ d_2 \frac{\partial c_2}{\partial n} = u \alpha & \text{on } I^k \times \Gamma_c, \\ d_2 \frac{\partial c_2}{\partial n} = 0 & \text{on } \Sigma_n, \\ c_1(0) = c_{10} & \text{in } \Omega, \\ c_2(0) = c_{20} & \text{in } \Omega, \\ -(\lambda_1)_t = d_1 \Delta \lambda_1 - k_1 c_2 \lambda_1 - k_2 c_2 \lambda_2 & \text{in } Q, \\ -(\lambda_2)_t = d_2 \Delta \lambda_2 - k_1 c_1 \lambda_1 - k_2 c_1 \lambda_2 & \text{in } Q, \\ d_1 \frac{\partial \lambda_1}{\partial n} = 0 & \text{on } \Sigma, \\ d_2 \frac{\partial \lambda_2}{\partial n} = 0 & \text{on } \Sigma, \\ \lambda_1(T) = -\beta_1 (c_1(T) - c_{1T}) & \text{in } \Omega, \\ \lambda_2(T) = -\beta_2 (c_2(T) - c_{2T}) & \text{in } \Omega, \\ \gamma(u - u_d) = \int_{\Gamma_c} \alpha \lambda_2 \, \mathrm{d}x - \frac{1}{\varepsilon} g'\big(\int_0^T \bar{u}^k \, \mathrm{d}t - u_c \big) & \text{in } I^k \end{cases}$$

with $\bar{u}^k = u_a$ in A_-^k, $\bar{u}^k = u_b$ in A_+^k, and $\bar{u}^k = u$ in I^k.

(5) Set $(c_1^{k+1}, c_2^{k+1}, \lambda_1^{k+1}, \lambda_2^{k+1}) = (c_1, c_2, \lambda_1, \lambda_2)$, $u^{k+1} = u_a$ in A_-^k, $u^{k+1} = u_b$ in A_+^k, and $u^{k+1} = u$ in I^k and

$$\text{(4.4)} \quad \xi^{k+1} = \int_{\Gamma_c} \alpha \lambda_2^{k+1} \, \mathrm{d}x - \frac{1}{\varepsilon} g'\bigg(\int_0^T u^{k+1} \, \mathrm{d}t - u_c \bigg) - \gamma(u^{k+1} - u_d) \quad \text{in } [0,T].$$

Set $k = k+1$ and go back to step (2).

Remark 4.2.

(1) Notice that (4.3) are the first-order necessary optimality conditions for

$$(\hat{\mathrm{P}}_\varepsilon^k) \qquad \min \hat{J}_\varepsilon(u) \quad \text{s.t.} \quad u = u_a \text{ in } A_-^k \text{ and } u = u_b \text{ in } A_+^k,$$

which is a minimization problem without any inequality constraints.

(2) In section 5 we solve (4.3) using an inexact Newton method for $(\hat{\mathrm{P}}_\varepsilon^k)$. The inexact Newton step is computed by applying the conjugate gradient (CG) method with negative curvature test (see, e.g., [26, section 6.2]) to the Newton system (restricted to the inactive set I^k)

$$\nabla^2 \hat{J}_\varepsilon(u_i)_{|I^k}\, \delta u_{i|I^k} = -\nabla \hat{J}_\varepsilon(u_i)_{|I^k} \quad \text{for } i \geq 0 \tag{4.5}$$

with zero initial guess $\delta u_i \equiv 0$ in $A_-^k \cup A_+^k$ for all i. More precisely, if $R : L^2(I^k) \to L^2(0,T)$ is the linear extension-by-zero operator from the inactive set I^k to $(0,T)$, then (4.5) reads

$$\nabla^2 \hat{J}_\varepsilon(u_i)(R\,\delta u_{i|I^k}, R\,\cdot) = -\nabla \hat{J}_\varepsilon(u_i)(R\,\cdot) \quad \text{in } L^2(I^k) \text{ for } i \geq 0. \tag{4.6}$$

To compute the right-hand side in (4.5) for a given current iterate u_i we have to solve the state and adjoint equations. For each CG step, the solutions of one linearized state and one adjoint problem have to be computed.

(3) The strategy for choosing the current active sets A_-^k and A_+^k is based on convex analysis techniques (see [2, 18]). Because of the simple nature of the box constraints in $(\hat{\mathrm{P}}_\varepsilon)$ this strategy is related to strategies already used in [3, 11]. □

In the case of $g \equiv 0$, sufficient conditions for global convergence of Algorithm 4.1 were given in [19]. The proof is based theoretically on descent properties of the merit function $\Phi : L^2(0,T) \times L^2(0,T) \to \mathbb{R}$ defined as

$$\Phi(u,\xi) = \gamma^2 \int_0^T ([u-u_a]_+^2 + [u_b-u]_+^2)\,\mathrm{d}t + \int_{A_-(u)} [\xi]_-^2\,\mathrm{d}t + \int_{A_+(u)} [\xi]_+^2\,\mathrm{d}t,$$

where $[x]_+ = \max\{0,x\}$ and $[x]_- = -\min\{0,x\}$ denote the positive and negative part functions, respectively, and $A_-(u) = \{t \in [0,T] : u \leq u_a\}$, $A_+(u) = \{t \in [0,T] : u \geq u_b\}$.

By expressing the primal-dual active set method as a partial semismooth Newton algorithm for (4.2), sufficient conditions for superlinear convergence were also derived in [19]. Since only the nonlinearity due to the max and min operations is linearized, whereas $u \mapsto \mathcal{S}(u)$ is not, the method is called a partial semismooth Newton algorithm. Next we specify the nonlinear equation, which is the starting point for proving superlinear convergence of Algorithm 4.1. First notice that (4.2b) is equivalent to

$$\hat{\xi}^\varepsilon = \max\left\{0, \hat{\xi}^\varepsilon + \sigma(\hat{u}^\varepsilon - u_b)\right\} + \min\left\{0, \hat{\xi}^\varepsilon + \sigma(\hat{u}^\varepsilon - u_a)\right\} \quad \text{for every } \sigma > 0. \tag{4.7}$$

Choosing $\sigma = \gamma$ (an essential prerequisite in proving superlinear convergence) in (4.7) we find

$$-\hat{\xi}^\varepsilon + \max\left\{0, \hat{\xi}^\varepsilon + \gamma(\hat{u}^\varepsilon - u_b)\right\} + \min\left\{0, \hat{\xi}^\varepsilon + \gamma(\hat{u}^\varepsilon - u_a)\right\} = 0. \tag{4.8}$$

Inserting the optimality condition (4.2a) into (4.8) we derive

$$\begin{aligned} 0 \;&= \gamma(\hat{u}^\varepsilon - u_d) + \frac{1}{\varepsilon}\, g'\Big(\int_0^T \hat{u}^\varepsilon\,\mathrm{d}t - u_c\Big) - \int_{\Gamma_c} \alpha\hat{\lambda}_2^\varepsilon\,\mathrm{d}x \\ &\quad + \max\left\{0, \int_{\Gamma_c} \alpha\hat{\lambda}_2^\varepsilon\,\mathrm{d}x - \frac{1}{\varepsilon}\, g'\Big(\int_0^T \hat{u}^\varepsilon\,\mathrm{d}t - u_c\Big) + \gamma(u_d - u_b)\right\} \\ &\quad + \min\left\{0, \int_{\Gamma_c} \alpha\hat{\lambda}_2^\varepsilon\,\mathrm{d}x - \frac{1}{\varepsilon}\, g'\Big(\int_0^T \hat{u}^\varepsilon\,\mathrm{d}t - u_c\Big) - \gamma(u_a - u_d)\right\}. \end{aligned} \tag{4.9}$$

Notice that

$$a - b + \max\{0, b - c\} = a - c + \max\{0, c - b\} \quad \text{for all } a, b, c \in \mathbb{R}.$$

Taking

$$a = \gamma(\hat{u}^\varepsilon - u_d), \quad b = \int_{\Gamma_c} \alpha \hat{\lambda}_2^\varepsilon \, \mathrm{d}x - \frac{1}{\varepsilon} g'\Big(\int_0^T \hat{u}^\varepsilon \, \mathrm{d}t - u_c \Big), \quad c = \gamma(u_b - u_d)$$

we infer from (4.9) that (4.2) is equivalent to

$$\mathcal{F}(\hat{u}^\varepsilon) = 0 \quad \text{in } L^2(0,T) \tag{4.10}$$

with the nonlinear mapping $\mathcal{F} : L^2(0,T) \to L^2(0,T)$ given by

$$\begin{aligned} \mathcal{F}(u) \quad &= \gamma(u - u_b) \\ &\quad + \max\left\{0, \gamma(u_b - u_d) - \int_{\Gamma_c} \alpha\lambda_2 \, \mathrm{d}x + \frac{1}{\varepsilon} g'\Big(\int_0^T u \, \mathrm{d}t - u_c \Big) \right\} \\ &\quad + \min\left\{0, \int_{\Gamma_c} \alpha\lambda_2 \, \mathrm{d}x - \frac{1}{\varepsilon} g'\Big(\int_0^T u \, \mathrm{d}t - u_c \Big) - \gamma(u_a - u_d) \right\} \end{aligned}$$

for $u \in L^2(0,T)$, where $\lambda_2 = \lambda_2(u)$ depends on u via the nonlinear state and the linear adjoint equations.

Remark 4.3. Note that $\mathcal{F}$ is generalized differentiable in the sense of [15]; see also [35] for a related approach. This infinite-dimensional generalized differentiability concept of the max and min functions requires a norm gap, which is guaranteed by the smoothing properties of the mapping $u \mapsto \lambda_2(u)$: for each $u \in L^2(0,T)$, the argument under the max and min functions which depend on u is an element of $L^4(0,T)$, which can be seen as follows. First of all, $g'(\int_0^T u \, \mathrm{d}t - u_c)$ is a scalar. Secondly, with $\alpha \in L^\infty(0,T;L^2(\Gamma_c))$, we have

$$\int_0^T \left| \int_{\Gamma_c} \alpha\lambda_2 \, \mathrm{d}x \right|^p \, \mathrm{d}t \le \|\alpha\|^p_{L^\infty(0,T;L^2(\Gamma_c))} \int_0^T \|\lambda_2(t)\|^p_{L^2(\Gamma_c)} \, \mathrm{d}t.$$

As the trace operator is continuous from $H^{1/2}(\Omega)$ to $L^2(\Gamma_c)$, there exists a constant $C_T > 0$ such that

$$\|\varphi\|_{L^2(\Gamma_c)} \le C_T \, \|\varphi\|_{X^{1/2}(\Omega)} \quad \text{for all } \varphi \in H^{1/2}(\Omega).$$

Furthermore, by the interpolation inequality $\|\varphi\|_{H^{1/2}(\Omega)} \le C_I \|\varphi\|^{1/2}_{H^1(\Omega)} \|\varphi\|^{1/2}_{L^2(\Omega)}$ for all $\varphi \in H^1(\Omega)$ holds; see, e.g., [23]. Hence, we have

$$\int_0^T \left| \int_{\Gamma_c} \alpha\lambda_2 \, \mathrm{d}x \right|^p \, \mathrm{d}t \le (C_T C_I)^p \, \|\alpha\|^p_{C([0,T];L^2(\Gamma_c))} \int_0^T \|\lambda_2(t)\|^{p/2}_{H^1(\Omega)} \|\lambda_2(t)\|^{p/2}_{L^2(\Omega)} \, \mathrm{d}t.$$

Since λ_2 is an element of $W(0,T)$, we can estimate the second term in the integral on the right-hand side by $\|\lambda_2\|^{p/2}_{L^\infty(0,T;L^2(\Omega))}$ and find that the right-hand side remains finite for $1 \le p \le 4$. ∎

Next we turn to the semismooth Newton method, which—in contrast to Algorithm 4.1—also linearizes the mapping $u \mapsto \mathcal{S}(u)$. Moreover, in every iteration of the semismooth Newton method, only one Newton step toward the solution of step (4) is carried out. For details, we refer to [10]. Commonly, condition (4.2a) is linear in u and λ (and y), so δu^k does not appear in its linearization; see, for example, [19].

Finally, we mention that the choice of $\sigma = \gamma$ is only of theoretical interest. In the numerical implementation, usually σ is set to a larger value in order to prevent optimization variables to jump from the upper to the lower bound (or vice versa) in consecutive iterations; see [31].

5. Numerical examples. In this section, we describe the behavior of the primal-dual and the semismooth Newton methods by means of some examples of our penalized problem (P_ε). All coding is done in MATLAB using routines from the FEMLAB 2.2 package concerning the finite element implementation. The given CPU times were obtained on a standard 1700-MHz desktop PC. They include only the run time for the core algorithm, excluding the generation of the mesh, precomputing integrals, and incomplete Cholesky decompositions. The three-dimensional geometry of the problem is given by the annular cylinder between the planes $z = 0$ and $z = 0.5$ with inner radius 0.4 and outer radius 1.0 whose rotational axis is the z-axis (Figure 5.2). The control boundary Γ_c is the upper annulus, and we use the control shape function

$$\alpha(t,x) = \exp(-5[(x - 0.7\cos(2\pi t))^2 + (y - 0.7\sin(2\pi t))^2]); \tag{5.1}$$

see Figure 5.1. Note that α corresponds to a nozzle circling for $t \in [0,1]$ once around in counterclockwise direction at a radius of 0.7. For fixed t, α is a function which decays exponentially with the square of the distance from the current location of the nozzle.

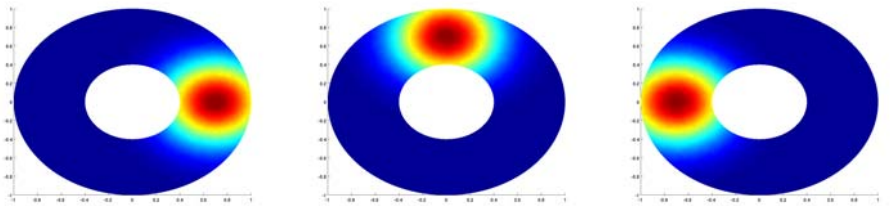

FIG. 5.1. *Control shape function* $\alpha(t,x)$ *at* $t = 0.0$, $t = 0.25$, *and* $t = 0.5$.

The "triangulation" of the domain Ω by tetrahedra is also shown in Figure 5.2. It was created using an initial mesh obtained from meshinit(fem, "Hmax," 0.4). As the geometry suggests that much of the reaction will take place near the top surface Γ_c of the annular cylinder, we refine this initial mesh near the top using the command meshinit(fem, "Hexpr," "0.4*(0.5 - z)+0.10,"...). The final mesh consists of 1797 points and 7519 tetrahedra. In the time direction, we use $T = 1$ and partition the interval into 100 subintervals of equal lengths. The values of the control u at the interval endpoints serve as optimization variables. We use the semi-implicit Euler time integration scheme for the state equations (2.3a)–(2.3b), where the nonlinearities are treated as explicit terms, i.e., they are always taken from the previous time step. In the adjoint equation, we use the same semi-implicit scheme, i.e., the right-hand side terms in (3.3a)–(3.3b) are taken from the previously computed time step. The elliptic problem which arises on each time level in the state and adjoint equations is solved

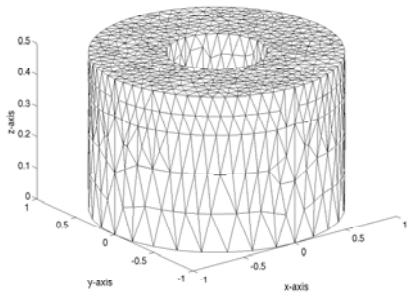

FIG. 5.2. *Domain $\Omega \subset \mathbb{R}^3$ and its triangulation with tetrahedra.*

using the conjugate gradient method with incomplete Cholesky preconditioning. Note that the preconditioner needs to be computed only once since the coefficient matrices are the same in each time step, provided the time step lengths are all identical.

The gradient of the reduced cost functional $\nabla \hat{J}_\varepsilon$ given in (4.1) is then assembled using the precomputed expressions $\int_{\Gamma_c} \alpha(t^i, x)\,\mathrm{d}x$. This strategy clearly follows the paradigm of optimize-then-discretize. Consequently, on the discrete level, the gradient and also the Hessian of the reduced cost functional are evaluated only to a certain accuracy, which depends on the level of discretization. Hence, even if the reduced Hessian system (4.5) was solved to full machine precision, the discrete solution of (3.6) would in general only be found up to a residual whose size depends on the level of discretization. For the discretization parameters given above, we used $\|\nabla \hat{J}_\varepsilon(u^n)_{|I^n}\|_{L^2(0,T)} \le 3 \times 10^{-3}$ as a termination criterion, which is evaluated by setting to zero the components of $\nabla \hat{J}_\varepsilon(u^n)$ which correspond to either of the active sets A_+^n or A_-^n. Of course, coincidence of the active sets on two consecutive iterations is also required for the algorithm to terminate.

5.1. Example 1. In the first example, we use the uniform control bounds

$$u_a \equiv 1, \qquad u_b \equiv 5. \tag{5.2}$$

Controlling the second substance, we wish to steer the concentration of the first substance to zero at the terminal time $T = 1$, i.e., we choose

$$\beta_1 = 1, \quad \beta_2 = 0, \quad c_{1T} \equiv 0. \tag{5.3}$$

The control cost parameter is $\gamma = 10^{-2}$, and the desired control is $u_d = 0$.

The chemical reaction is governed by (2.3a)–(2.3b) with parameters

$$d_1 = 0.15, \quad d_2 = 0.20, \quad k_1 = 1.0, \quad k_2 = 1.0. \tag{5.4}$$

As initial concentrations, we use

$$c_{10} \equiv 1.0, \qquad c_{20} \equiv 0.0. \tag{5.5}$$

The discrete optimal solution without integral constraint (2.11) yields

$$\int_0^T \hat{u}^\varepsilon(t)\,\mathrm{d}t = 4.2415, \qquad \hat{J}_\varepsilon(\hat{u}^\varepsilon) = 0.3186. \tag{5.6}$$

Run time: 527 s						Objective: 0.3256
						$\int_0^T u(t)\,\mathrm{d}t = 3.5803$

In order for this constraint to become relevant, we choose $u_c = 3.5$ and enforce it using the penalization parameter $\varepsilon = 1$. Below, we also study the dependence on ε of the solution and of the performance of the algorithms.

The numerical solution is obtained once using the primal-dual (Table 5.1) and once using the semismooth Newton method (Table 5.2), from a feasible initial guess $u^0 \equiv 3$. In both cases, the reduced Hessian system (4.5) was solved using the conjugate gradient method, although due to the use of an optimize-then-discretize strategy, the matrix we obtain as an approximation to the reduced Hessian $\nabla^2\hat{J}_\varepsilon(u^n)$ is only approximately symmetric. The discrete analogue of (4.6) is

$$R^\top\nabla^2\hat{J}_\varepsilon(u_i)R\,\delta u_{i|I^n} = -R^\top\nabla\hat{J}_\varepsilon(u_i) \quad \text{for } i \geq 0. \tag{5.7}$$

This linear system of equations is of size 100 minus the cardinality of the active sets, $|A_+^n|$ and $|A_-^n|$. Here, R is derived from the identity matrix by canceling the columns whose indices belong to either of the active sets. Our CG algorithm solves (5.7) by evaluating $\nabla^2\hat{J}_\varepsilon(u_i)\,\delta u_i$ and then disregarding the active components. It also respects the discrete $L^2(0,T)$-inner product. As the solution of (5.7) required only a few CG steps (Tables 5.1 and 5.2), no preconditioning was used here. Our CG method also features a coercivity check: should a direction of negative curvature be encountered, the CG iteration is terminated prematurely and we continue with the line search (see below). Additionally, we refer the reader to [12] for modification techniques of the Hessian matrix in the absence of sufficient coercivity.

The parameter σ which enters step (2) of Algorithm 4.1 (determining the active sets) was chosen as $\sigma = 10^2$. To determine the active and inactive sets A_-^k, A_+^k, and I^k, respectively, we check the corresponding inequalities pointwise at each time gridpoint. The solution is shown in Figures 5.3 and 5.4. Recall that without penalization, the optimal solution yielded an integral value of $\int_0^T \hat{u}^\varepsilon(t)\,\mathrm{d}t \approx 4.24$, while with the penalization parameter $\varepsilon = 1$, we are down to $\int_0^T \hat{u}^\varepsilon(t)\,\mathrm{d}t \approx 3.58$ which only marginally violates the bound of $u_c = 3.5$.

The primal-dual algorithm. In order to achieve local quadratic convergence, the conjugate gradient method inside the primal-dual algorithm for (4.5) was terminated when $\|r\| \leq \eta \cdot \|\nabla\hat{J}_\varepsilon(u^n)\|$, where r denotes the residual, $\|\cdot\|$ stands for the L^2-norm on $[0,T]$, and $\eta = \min\{0.5, \|\nabla\hat{J}_\varepsilon(u^n)\|\}$. Finally, an Armijo backtracking line search was employed in the direction δu^n obtained from (4.5) with trial step

lengths $\alpha_k = 2^{-k}$, $k = 0, 1, 2$, etc. A step of length α_k was accepted whenever $\hat{J}_\varepsilon(u^n + \alpha_k \delta u^n) \le \hat{J}_\varepsilon(u^n) + 10^{-4} \cdot \frac{\mathrm{d}}{\mathrm{d}\alpha} \hat{J}_\varepsilon(u^n + \alpha \delta u^n)|_{\alpha=0}$.

The semismooth Newton method. In the case of the semismooth Newton method (Table 5.2), the reduced Hessian system (4.5) was also solved inexactly. Here, the conjugate gradient iteration was terminated when $\lVert r \rVert \le 3 \times 10^{-4}$. That is, we use a constant threshold here which does not depend on the progress in the outer iteration.

Comparing the solutions. Both methods obtained the solution depicted in Figures 5.3 and 5.4 within 15 CG iterations in the case of the primal-dual active set method and 12 CG iterations in the case of the semismooth Newton method. Note, however, that the final residual $\lVert \nabla \hat{J}_\varepsilon(u^n)_{\lvert I^n} \rVert$ achieved in the primal-dual run is smaller since the residual only scarcely falls short of the desired tolerance of 3×10^{-3} in the next to last Newton step. The primal-dual and the semismooth Newton methods appear equally well-suited for this problem. They proved to be robust with respect to the choice of the initial guess.

Dependence on the penalty parameter ε. For our chosen $\gamma = 10^{-2}$ and $\varepsilon = 200$ the terms in the cost functional involving the control variable and the penalized integral constraint have the same weights. In the case of smaller values for $\varepsilon > 0$ (see our tests below) the penalization term becomes more significant. As mentioned

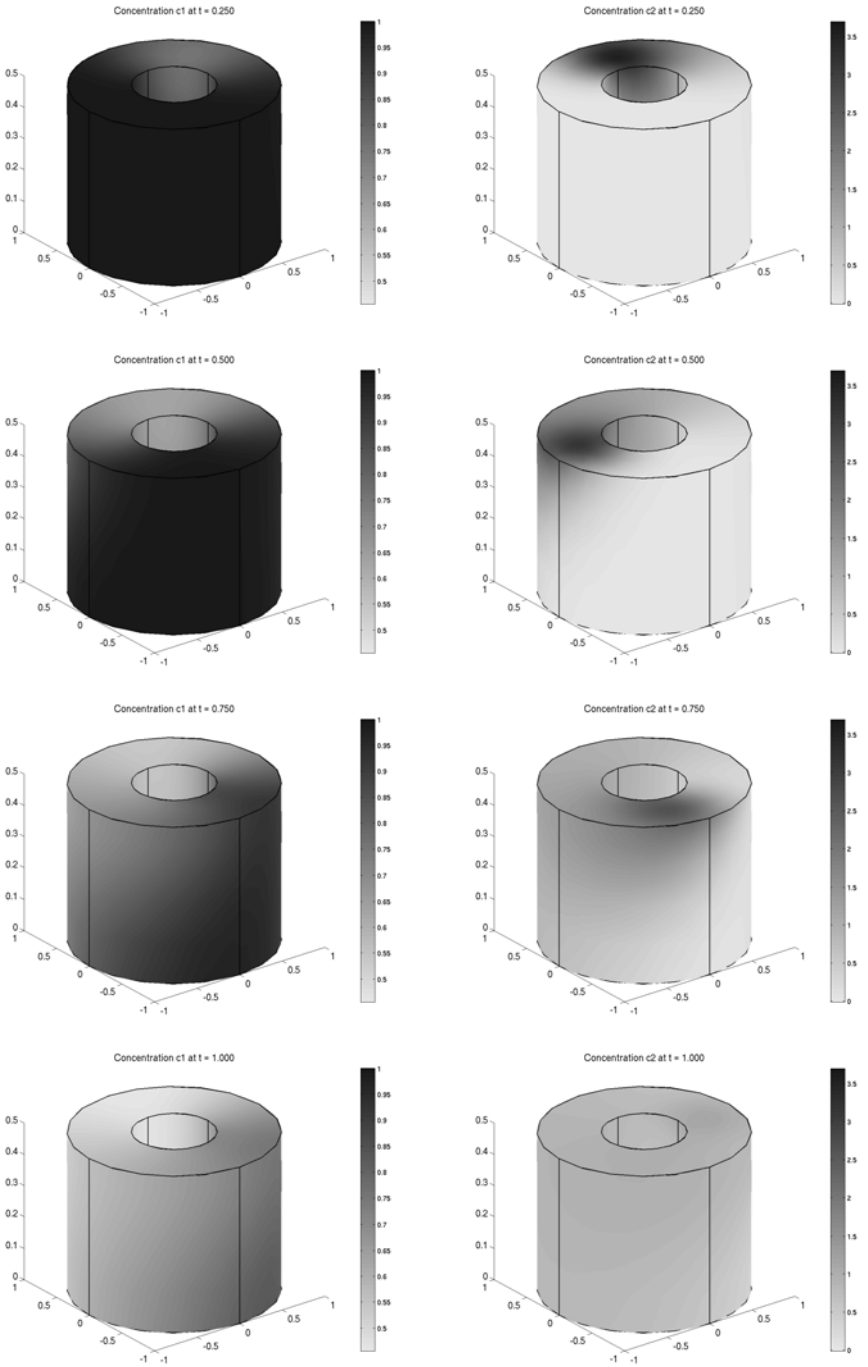

FIG. 5.4. *Example* 1 *for* $\varepsilon = 1$*: concentrations of substances* 1 *(left) and* 2 *(right) at times* $t = 0.25$*,* $t = 0.50$*,* $t = 0.75$*, and* $t = 1.00$*.*

in Proposition 2.9, the solutions of the penalized problem (P_ε) converge weakly to a feasible solution for the problem with strict integral constraint (P) as $\varepsilon \searrow 0$. This can be observed from Figure 5.5 and Table 5.3. One also notices that the problem becomes numerically more challenging as ε approaches zero.

5.2. Example 2. The second example was designed to be numerically more challenging. Recall that in the first example, the integral constraint was chosen such that it required a rather moderate modification of the optimal solution without integral constraint. To obtain a contrasting situation, we now use $\gamma = 10^{-3}$ as a weight for the control cost and $u_c = 1.8$ as a bound in the integral constraint. All other data are taken over from Example 1, including $\varepsilon = 1$. Note that the smaller γ leads to an increased control action, while the lowered integral constraint bound has the opposite effect. The optimal solution is depicted in Figure 5.6. It has been obtained with the primal-dual active set method as described for Example 1. One immediately observes that the active sets have an interesting structure in this example. In particular, when the control enters the lower bound for the first time, the constraint is only very weakly active. That is, the corresponding multiplier is close to zero, which makes proper identification of the active sets a challenge for both the primal-dual and semismooth Newton methods.

Table 5.4 shows the convergence history of the primal-dual active set algorithm again from an initial guess of $u_0 \equiv 3$. The angle between the search direction and the negative reduced objective's gradient is also given. The step length in the line search algorithm was always 1.

We observe that significantly more outer iterations are necessary in order to determine the active sets. Also, in every first Newton step, the primal-dual method starts over with a fairly large contribution of the penalty part $I(u)/\varepsilon$ to the objective. The first Newton steps taken all aim to reduce mainly this part of the objective. This can be seen from the zero angle between the search direction and the negative objective gradient. In other words, the reduced Hessian matrix is a multiple of the identity matrix, being dominated by $\nabla^2 I(u)/\varepsilon$ (see (2.12)).

INDIVIDUAL Q-LEARNING IN NORMAL FORM GAMES*

DAVID S. LESLIE† AND E. J. COLLINS‡

Abstract. The single-agent multi-armed bandit problem can be solved by an agent that learns the values of each action using reinforcement learning. However, the multi-agent version of the problem, the iterated normal form game, presents a more complex challenge, since the rewards available to each agent depend on the strategies of the others. We consider the behavior of value-based learning agents in this situation, and show that such agents cannot generally play at a Nash equilibrium, although if smooth best responses are used, a Nash distribution can be reached. We introduce a particular value-based learning algorithm, which we call individual Q-learning, and use stochastic approximation to study the asymptotic behavior, showing that strategies will converge to Nash distribution almost surely in 2-player zero-sum games and 2-player partnership games. Player-dependent learning rates are then considered, and it is shown that this extension converges in some games for which many algorithms, including the basic algorithm initially considered, fail to converge.

Key words. reinforcement learning, normal form games, stochastic approximation, multi-agent learning, player-dependent learning rates

DOI. 10.1137/S0363012903437976

1. Introduction.

We will study value-based learning agents in the multi-agent multi-armed bandit problem (more commonly known as an iterated normal form game). These simple agents adapt in a very similar manner to the reinforcement learning algorithm used by Sutton and Barto (1998) in the single-agent case. However, the multi-agent setting presents a significantly more complex problem, since the rewards available to each agent depend on the strategies of all the other learners and hence are not stationary.

In this paper we will show how to study the asymptotic behavior of these agents using the ODE method of stochastic approximation. The resulting dynamical systems can be analyzed to prove that convergence to equilibrium must occur for 2-player zero-sum games and 2-player partnership games (Proposition 4.2). However, it is shown that convergence does not occur for some specific games known to cause difficulties for all learning algorithms; player-dependent learning rates are then introduced, and convergence can then be proved to occur in a larger class of games (Proposition 5.4 and Corollary 5.6).

One of the best studied models of adaptation in iterated normal form games is fictitious play (Brown (1951), Fudenberg and Levine (1998)). However, this paradigm requires each player to know her own reward function, to observe the actions of all players, and to calculate expected rewards from this information. While this is realistic in some situations, it is clear that players of a game such as the stock

market, or animals involved in evolutionary games (Maynard Smith (1982)), do not know the relevant reward structures, while in potential applications of multi-agent learning (e.g., Boyan and Littman (1994), Singh and Bertsekas (1997), Crites and Barto (1998)) these requirements are also frequently not satisfied.

Therefore we study models of adaptation under which agents simply respond to observations of the rewards they receive for playing actions, as in the simple and successful approach used by Sutton and Barto (1998) to solve the single-agent multi-armed bandit problem. Agents estimate the value of each action, and play a strategy that is a simple function of these estimates; we will call such agents *value-based learners*. These learners take no account of the presence of other players of the game—the only information used is the reward received for each action played. Recent neurophysiological data from rhesus monkeys trying to perform a repetitive task (Glimcher, Dorris, and Bayer (2005)) suggests that value-based learning is actually employed in nature, adding extra interest to our investigations.

Other current approaches to learning in games include actor-critic learning, hypothesis-based learning, consistent learning, and alternative reinforcement learning models based on Roth and Erev (1995). Our value-based learning scheme compares favorably with these in terms of simplicity, form of convergence, and structure, respectively.

The Roth and Erev (1995) model of learning is the standard model of reinforcement learning in the game theory community. However, it has the disadvantages that it requires all rewards to be positive, and it uses rewards as "reinforcement signals" instead of information about the values of actions, despite the fact that strategies and values are "dimensionally different" quantities—strategies are probability distributions whereas rewards are arbitrary real numbers (the same criticism can be made of stimulus-response learning (Börgers and Sarin (1997))).

Actor-critic learning is a more sophisticated framework that explicitly links rewards and strategies. In this model, agents maintain separate value functions and strategies and map the value function to strategy space in order to update the strategy. It has been used in several recent approaches to learning in games (Borkar (2001), Bowling and Veloso (2002), Leslie and Collins (2003)), but, in contrast with the value-based approach considered in this paper, the extra complication involved in separating the values and the strategies is unnecessary and overly sophisticated when applied in a single-agent setting.

A different approach to the problem of learning in games has been to develop consistent (Hannan (1957)) reinforcement learning procedures (Baños (1968), Megido (1980), Auer et al. (1995), Hart and Mas-Colell (2001)). Hart and Mas-Colell (2000) show that the long-run average actions of players using a consistent algorithm will converge to a correlated equilibrium of the game (Aumann (1974)) (as opposed to a classical Nash equilibrium). However, it is often difficult to characterize the correlated equilibria (Fudenberg and Tirole (1991)), and the convergence is in the sense of the average action played, instead of convergence of actual play as developed in this paper.

An even more sophisticated framework is the hypothesis-testing formulation recently proposed by Foster and Young (2003). Here the players formulate hypotheses about opponent strategies and repeatedly test these hypotheses against observed play. It is shown that play is close to a Nash equilibrium of the repeated game formulation most of the time. However, the sophistication required from the players is greater than for virtually all other algorithms in the literature, and the scheme is clearly not applicable in the minimal information setting we consider here.

It is appropriate to comment here on a recent result of Hart and Mas-Colell (2003) showing that no "uncoupled" adaptive dynamics can converge to equilibrium in all games. The dynamics we consider in this paper are certainly uncoupled, and indeed the dynamics resulting from any system where players do not observe opponent payoffs must necessarily be uncoupled. However, as we shall see later, convergence to Nash distribution may be a more attainable goal than convergence to Nash equilibrium (see section 2 for details). Furthermore, the player-dependent learning rates introduced in section 5 are a further step away from the framework studied by Hart and Mas-Colell (2003), thus allowing convergence to be proved for a larger class of games than has been previously achieved.

This paper is therefore an analysis of a simple and intuitive learning procedure applied in the setting of normal form games with minimal information available to the players. In section 2 we discuss some difficulties faced by value-based learners in games, and propose the use of smooth best responses (also known as softmax action selection). This motivates our individual Q-learners, introduced in section 3, where we show how to characterize their behavior using stochastic approximation (Benaïm (1999)). The behavior of these learners in 2-player games is analyzed in section 4, where we show that strategy evolution is closely related to the smooth best response dynamics (Hofbauer and Hopkins (2005)); this is the same dynamical system that characterizes stochastic fictitious play (Benaïm and Hirsch (1999)), despite the fact that individual Q-learning uses significantly less information than stochastic fictitious play. However, previous work (Leslie and Collins (2003)) suggests that convergence to a fixed point can be proved to occur in a larger class of games if player-dependent learning rates are used to break symmetry between the players; this is studied in section 5. A problem with player-dependent learning rates is that the analytical methods so far developed do not apply for all games; section 6 uses graphical representations of games to investigate classes of games in which player-dependent learning rates can be analyzed.

2. Value-based players in games. In this section we will introduce our notation and discuss some problems faced by value-based players of games. In particular, we will show that value-based players cannot generally play at a Nash equilibrium, but if smooth best responses are used, equilibrium play becomes possible (although this will no longer be at the classical Nash equilibrium).

We start by introducing our notation and presenting a familiar example. A normal form game consists of N players, where each player $i \in \{1, \dots, N\}$ has a finite set A^i of actions and a reward function $r^i : A^1 \times \cdots \times A^N \to \mathbb{R}$. When the game is played, each player $i \in \{1, \dots, N\}$ selects an action $a^i \in A^i$ and then receives a reward which has expected value $r^i(a^1, \dots, a^N)$; each player tries to maximize her expected reward. A traditional 2-player example is rock-scissors-paper, where the action set for each player is {Rock, Scissors, Paper}, and the reward functions are given in the payoff matrix

$$\begin{array}{c} \\ \text{Rock} \\ \text{Scissors} \\ \text{Paper} \end{array} \begin{array}{c} \begin{array}{ccc} \text{Rock} & \text{Scissors} & \text{Paper} \end{array} \\ \begin{pmatrix} (0,0) & (1,-1) & (-1,1) \\ (-1,1) & (0,0) & (1,-1) \\ (1,-1) & (-1,1) & (0,0) \end{pmatrix} \end{array}, \tag{2.1}$$

where player 1's action determines the row, player 2's action determines the column, and an entry (x, y) means that player 1 receives reward x and player 2 receives reward y. Note that this is a 2-player zero-sum game, where for any joint action (a^1, a^2) the

rewards satisfy $r^1(a^1, a^2) + r^2(a^1, a^2) = 0$. We will also have occasion to consider partnership games, where for any joint action the reward given to each player is the same.

A mixed strategy for player i is an element $\pi^i \in \Delta^i$, where Δ^i is the set of probability distributions over the action space A^i; we will write $\pi^i(a^i)$ for the probability that player i selects action a^i when using strategy π^i. There are unique multilinear extensions of the reward functions, also denoted r^i, to the joint strategy space $\Delta = \Delta^1 \times \cdots \times \Delta^N$, and in further abuse of notation we will write $r^i(a^i, \pi^{-i})$ (resp., $r^i(\pi^i, \pi^{-i})$) for the expected reward that player i will receive if she plays action a^i (resp., strategy π^i) and the other players select actions according to the opponent mixed strategy $\pi^{-i} = (\pi^1, \ldots, \pi^{i-1}, \pi^{i+1}, \ldots, \pi^N)$.

Nash (1950) defined the classical solution concept for normal form games by observing that a rational player will not play a strategy π^i that does not maximize her expected reward given the opponent strategy π^{-i}. Thus a Nash equilibrium is a joint strategy $\tilde{\pi} \in \Delta$ satisfying, for each i,

$$r^i(\tilde{\pi}) \geq r^i(\pi^i, \tilde{\pi}^{-i}) \quad \text{for any } \pi^i \in \Delta^i.$$

Nash (1950) showed that at least one Nash equilibrium exists for any normal form game. In our rock-scissors-paper example, it is well known that there is a unique Nash equilibrium where each player plays the mixed strategy $(1/3, 1/3, 1/3)$, but in general there can be many Nash equilibria of a game. The problem of equilibrium selection (i.e., when faced with a game, how should players decide which Nash equilibrium strategy to play when many might exist) can be seen as a motivating factor for the study of learning in games (Fudenberg and Levine (1998)). An alternative perspective is to consider the Nash equilibria of a game as the only points to which a sensible learning procedure should converge—note that if only one player is present, then a Nash equilibrium is simply the action which returns the highest expected reward.

However, value-based approaches, as used by Sutton and Barto (1998) in the single-agent problem, encounter problems with Nash equilibria. At a Nash equilibrium, any action played by player i with positive probability will receive expected reward $\max_{a^i \in A^i} r^i(a^i, \tilde{\pi}^{-i})$, yet the equilibrium strategy might well require these maximizing actions to be played with specific and possibly unequal probabilities. For example, consider the game with payoff matrix

$$\begin{pmatrix} (2,0) & (0,1) \\ (0,2) & (1,0) \end{pmatrix},$$

which has a unique equilibrium where $\pi^1 = (2/3, 1/3)$ and $\pi^2 = (1/3, 2/3)$. At this equilibrium, both actions of both players get expected reward $2/3$, yet player 1 must favor action 1, and player 2 must favor action 2. Thus play at an equilibrium is not possible when the strategies played are restricted to be simple functions of the expected rewards (unless these functions are asymmetric under reordering of the actions).

A solution to this problem lies in using smooth best responses, which can also be considered as arising from a Bayesian uncertainty about the rewards (Harsanyi (1973)) and are closely related to the softmax exploration method of reinforcement learning (Sutton and Barto (1998)). If player i has estimates $Q^i(a^i)$ of the values of actions $a^i \in A^i$, then a smooth best response $\beta^i(Q^i) \in \Delta^i$ to these estimates is

given by

$$\beta^i(Q^i) = \underset{\pi^i \in \Delta^i}{\operatorname{argmax}} \left\{ \sum_{a^i \in A^i} \pi^i(a^i) Q^i(a^i) + \tau v^i(\pi^i) \right\}.$$

Here $\tau > 0$ is a temperature parameter, and $v^i : \Delta^i \to \mathbb{R}$ is a player-dependent smoothing function, which is a smooth, strictly differentiably concave function such that as π^i approaches the boundary of Δ^i, the slope of v^i becomes infinite (Fudenberg and Levine (1998)). As the temperature parameter $\tau \to 0$, $\beta^i(Q^i)$ approaches the set of best responses (i.e., strategies that select only actions a^i maximizing $Q^i(a^i)$). However, while there may be many best responses (e.g., suppose all the Q values are equal), the conditions on v^i imply that there is a unique smooth best response given τ and v^i (Fudenberg and Levine (1998)).

A familiar example of a smooth best response is Boltzmann action selection. Under this scheme, the smoothing functions are

$$v^i(\pi^i) = -\sum_{a^i \in A^i} \pi^i(a^i) \log \pi^i(a^i),$$

resulting in the smooth best response function

$$\beta^i(Q^i)(a^i) = \frac{\mathrm{e}^{Q^i(a^i)/\tau}}{\sum_{b^i \in A^i} \mathrm{e}^{Q^i(b^i)/\tau}}. \tag{2.2}$$

The use of smooth best responses means that, in general, Nash equilibria are no longer fixed points in strategy space, and an alternative equilibrium concept must be defined. (For example, consider a 1-player game with a unique optimal action; the conditions on v^1 mean that all actions are played with positive probability, which is clearly not a Nash equilibrium.) Given a set of smooth best response functions, β^i, we define a *Nash distribution* to be a joint mixed strategy $\pi \in \Delta$ such that, for each i,

$$\pi^i = \beta^i(r^i(\cdot, \pi^{-i})); \tag{2.3}$$

i.e., each player plays a smooth best response to the rewards arising from opponent play. Brouwer's fixed point theorem shows that such distributions must exist; Govindan, Reny, and Robson (2003) show that for small temperatures τ, the Nash equilibria of a game are approximated by Nash distributions (the proof of Harsanyi (1973) is insufficient in this case, because it relies on perturbations of the rewards having compact support). Note that the Nash distributions depend on the smooth best response functions β^i (through the particular choices of τ and v^i) as well as on the reward functions r^i—for the remainder of this paper we will assume that any particular player uses a fixed smooth best response function for all time.

Thus we have shown that a value-based approach cannot result in Nash equilibrium play in general games but can result in strategies that are close to a Nash equilibrium if players use smooth best responses. In the next section we will introduce a value-based learning algorithm incorporating this idea, which can therefore converge to a Nash distribution.

3. Individual *Q*-learning. Sutton and Barto (1998) show that a simple reinforcement learning scheme can be used to estimate action values in a single-agent task. The basic algorithm is given by

$$Q_{n+1}(a) = Q_n(a) + \lambda_{n+1} \mathbb{I}_{\{a_n = a\}} \{R_n - Q_n(a)\} \quad \text{for each } a \in A, \tag{3.1}$$

TABLE 1
Individual Q-learning.

Each player i selects an action a_n^i using the strategy $\beta^i(Q_n^i)$, receives reward R_n^i, and then updates Q_n^i according to

$$Q_{n+1}^i(a^i) = Q_n^i(a^i) + \lambda_{n+1}\mathbb{I}_{\{a_n^i = a^i\}}\frac{R_n^i - Q_n^i(a_n^i)}{\beta^i(Q_n^i)(a_n^i)} \quad \text{for each } a^i \in A^i, \tag{3.2}$$

where $\{\lambda_n\}_{n\geq 1}$ is a deterministic sequence of learning parameters satisfying

$$\sum_{n\geq 1}\lambda_n = \infty, \qquad \sum_{n\geq 1}(\lambda_n)^2 < \infty. \tag{3.3}$$

where a_n is the action selected at time n, and R_n is the subsequent reward. A similar scheme appears to fit recent neurophysiological data measured from the brains of rhesus monkeys learning to perform a repetitive task (Glimcher, Dorris, and Bayer (2005)). In applying (3.1), actions are selected in such a way that each action is played infinitely often, but as $n \to \infty$ the probability of playing any action which does not have a maximal Q value tends to 0. We will study an analogous system in the equivalent multi-agent task; N players are faced with a normal form game, which they play repeatedly, learning Q values by observing rewards. The algorithm we study is given in Table 1.

This scheme was originally suggested by Fudenberg and Levine (1998); it will be noticed that it is very similar to the standard reinforcement learning model (3.1). The first difference is that a player's strategy at any stage of the game is determined by the algorithm (as opposed to the single-agent case, where there is no need to be specific about action choices at any particular play). This is because the rewards observed by a particular player depend crucially on the strategies of the other players, so these strategies must be carefully specified. The second difference is that the reward prediction error $(R_n^i - Q_n^i(a_n^i))$ (Sutton and Barto (1998)) is divided by $\beta^i(Q_n^i)(a_n^i)$, the probability with which a_n^i was selected. This can be viewed as compensating for the fact that actions played with low probability do not receive frequent updates of their Q values, so when they are played any reward prediction error must have greater influence on the Q value than if frequent updates occur. Further, we will see in section 4 that this division by $\beta^i(Q_n^i)(a_n^i)$ results in a system that is closely related to the (well-studied) smooth best response dynamics (Hofbauer and Hopkins (2005)).

The conditions (3.3) on the learning parameters $\{\lambda_n\}_{n\geq 1}$ mean that standard theorems of stochastic approximation can be used (Benaïm (1999)). The interested reader may wish to consult Benaïm and Hirsch (1999) for an introduction to the ODE method of stochastic approximation in the context of game theory. Writing $Q_n = (Q_n^1, \ldots, Q_n^N)$, and writing $\beta^{-i}(Q_n)$ for the opponent mixed strategies resulting from the values Q_n, note that for each i and a^i

$$\begin{aligned}\mathbb{E}[Q_{n+1}^i(a^i) - Q_n^i(a^i) \mid Q_n] &= \lambda_{n+1} \times \beta^i(Q_n^i)(a^i) \times \frac{r^i(a^i, \beta^{-i}(Q_n)) - Q_n^i(a^i)}{\beta^i(Q_n^i)(a^i)} \\ &= \lambda_{n+1}\left\{r^i(a^i, \beta^{-i}(Q_n)) - Q_n^i(a^i)\right\}.\end{aligned}$$

The following lemma follows immediately from the results of Benaïm (1999).

LEMMA 3.1. *The values Q_n resulting from the individual Q-learning algorithm* (3.2) *converge almost surely to a connected internally chain-recurrent set*[1] *of the flow defined by the Q-learning ODE*

$$\frac{\mathrm{d}}{\mathrm{d}t}q_t^i(a^i) = r^i(a^i, \beta^{-i}(q_t)) - q_t^i(a^i) \quad \textit{for each } i \textit{ and } a^i, \tag{3.4}$$

provided that the Q_n remain bounded for all n.

This assumption of boundedness could be dropped if we used either fixed truncation to a bounded space (Kushner and Yin (1997)) or randomly varying truncations (Chen and Zhu (1986)); the former will change the differential equations to be studied a little, while the latter will have no consequence on the analysis of the asymptotic behavior. However, the purpose of this paper is not to investigate such issues, and in the numerical experiments carried out there were no problems with values growing large. Therefore in the interests of space we will be content to keep this as an assumption throughout the rest of the paper.

The first thing to notice about this algorithm is that convergence to a point can occur only at Nash distribution values. This follows from what is essentially a law of large numbers result, saying that convergence to a point can occur only if the expected change at that point is zero. Thus such a point must satisfy $Q^i(a^i) = r^i(a^i, \beta^{-i}(Q))$ for each i and a^i. However, if we write $\pi^i = \beta^i(Q^i)$, this translates to $\pi^i = \beta^i(r^i(\cdot, \pi^{-i}))$, which is precisely the definition of a Nash distribution (2.3). The learning algorithm can therefore be applied blindly in any game, and if convergence occurs, a Nash distribution must have been reached.

Our next step in analyzing this system is to consider whether the values of the players are ever consistent with the structure of the game; for example, if in a zero-sum game the values ever actually sum to zero. Writing

$$\mathcal{B} = \{(r^1(\cdot, \pi^{-1}), \ldots, r^N(\cdot, \pi^{-N})) : \pi \in \Delta\}$$

for the set of values that could arise from a joint mixed strategy, we call values Q_n *asymptotically belief-based* if the limit set of the values is contained in $\mathcal{B}$.

LEMMA 3.2. *The values Q_n resulting from the individual Q-learning algorithm* (3.2) *are almost surely asymptotically belief-based, provided that the Q_n remain bounded for all time.*

Proof. We will rewrite the Q-learning ODE (3.4) to show that $\mathcal{B}$ is a global attractor of the resulting flow, which suffices to show that the values Q_n resulting from (3.2) are asymptotically belief-based (Benaïm (1999)). Start by writing $q_t = (q_t^1(\cdot), \ldots, q_t^N(\cdot))$ and $r_t = (r^1(\cdot, \beta^{-1}(q_t)), \ldots, r^N(\cdot, \beta^{-N}(q_t)))$, so that

$$\frac{\mathrm{d}}{\mathrm{d}t}q_t = r_t - q_t.$$

This can be rewritten as

$$q_t = \mathrm{e}^{-t}q_0 + (1 - \mathrm{e}^{-t})\bar{r}_t,$$

[1] The concept of a chain-recurrent set is central to the ODE method of stochastic approximation and is developed fully in Benaïm (1999). In the interests of space, this theory is therefore not repeated here. Loosely, an internally chain-recurrent set of a flow is an invariant set of the flow such that a trajectory starting at any point of the set can return to its start point without ever leaving the set, when small "jumps" are allowed to be made. It will suffice to know that a connected internally chain-recurrent set of a flow is an invariant set of the flow containing no proper attractors.

where $\bar{r}_t = (\mathrm{e}^t - 1)^{-1} \int_0^t \mathrm{e}^s r_s \, \mathrm{d}s$ is a weighted average of r_s, $0 \le s \le t$. Since $r_s \in \mathcal{B}$ for all s, it follows immediately that $\bar{r}_t \in \mathcal{B}$ for all t. Therefore $q_t \to \mathcal{B}$ for any q_0, and $\mathcal{B}$ is a global attractor of the flow defined by (3.4). □

As well as being interesting in itself, this is crucial to the analysis of the next section, where we relate this value-based learning to the smooth best response dynamics, usually considered to arise from models of learning in which players use significantly more information on the structure of the game and observations of opponent play than is necessary for individual Q-learning.

4. 2-player games. In this section we will relate the Q-learning ODE (3.4) to the smooth best response dynamics in 2-player games, as suggested by Fudenberg and Levine (1998). This will allow us to characterize the limiting behavior of the individual Q-learning algorithm in certain classes of games.

The smooth best response (SBR) dynamics are defined by the ODE

$$\frac{\mathrm{d}}{\mathrm{d}t}\pi_t^i = \beta^i(r^i(\cdot, \pi_t^{-i})) - \pi_t^i \quad \text{for each } i \tag{4.1}$$

and have been shown to characterize stochastic fictitious play, in the same sense that (3.4) characterizes individual Q-learning (Benaïm and Hirsch (1999)). Fudenberg and Levine (1998) observe that for 2-player games, if strategies evolve according to these dynamics, the resultant rewards evolve according to the Q-learning ODE (3.4). This will be used in the proof of Lemma 4.1, where we show that a connected internally chain-recurrent set of the flow defined by the Q-learning ODE (3.4) corresponds to a connected internally chain-recurrent set of the SBR dynamics. By Lemma 3.1, this relates the limiting behavior of individual Q-learning with that of stochastic fictitious play, despite the fact that individual Q-learners have no information on the structure of the game and do not observe opponent play, both of which are necessary for stochastic fictitious play.

LEMMA 4.1. *For 2-player games, any connected internally chain-recurrent set of the Q-learning ODE* (3.4) *is of the form*

$$r(\mathcal{C}) := \{(r^1(\cdot, \pi^{-1}), \ldots, r^N(\cdot, \pi^{-N})) : \pi \in \mathcal{C}\},$$

where $\mathcal{C} \subset \Delta$ is a connected internally chain-recurrent set of the flow defined by the SBR dynamics (4.1).

Proof. Let $\mathcal{D}$ denote an arbitrary connected internally chain-recurrent set of the Q-learning ODE (3.4). Benaïm (1999, Proposition 5.3) shows that a set is connected internally chain-recurrent if and only if it is a compact invariant set admitting no proper attractor. Therefore, since the set $\mathcal{B}$ of belief-based values is a global attractor we must have $\mathcal{D} \subset \mathcal{B}$, and $q \in \mathcal{D}$ means that there exists $\pi \in \Delta$ such that $q^i(a^i) = r^i(a^i, \pi^{-i})$ for each i and a^i.

However, suppose π evolves according to the SBR dynamics (4.1), so that

$$\begin{aligned}
\frac{\mathrm{d}}{\mathrm{d}t} r^i(a^i, \pi_t^{-i}) &= \sum_{a^{-i} \in A^{-i}} \frac{\partial r^i(a^i, \pi^{-i})}{\partial \pi^{-i}(a^{-i})} \frac{\mathrm{d}}{\mathrm{d}t} \pi_t^{-i}(a^{-i}) \\
&= \sum_{a^{-i} \in A^{-i}} r^i(a^i, a^{-i}) \{\beta^{-i}(r^{-i}(\cdot, \pi_t^i))(a^{-i}) - \pi_t^{-i}(a^{-i})\} \\
&= r^i(a^i, \beta^{-i}(r^{-i}(\cdot, \pi_t^i))) - r^i(a^i, \pi_t^{-i}),
\end{aligned}$$

and the $r^i(a^i, \pi^{-i})$ evolve according to the same ODE as the $q^i(a^i)$. Note that this calculation is valid only for 2-player games.

Therefore trajectories of the Q-learning ODE (3.4) in $\mathcal{B}$ correspond to trajectories of the SBR dynamics (4.1) in Δ, and the invariant set $\mathcal{D}$ of (3.4) must be of the form $r(\mathcal{C})$, where $\mathcal{C} \subset \Delta$ is an invariant set of (4.1). Now since $\mathcal{D}$ admits no proper attractor, it follows that $\mathcal{C}$ admits no proper attractor. $\mathcal{C}$ may consist of several connected components, but any one of them will be a connected internally chain-recurrent set of the flow defined by the SBR dynamics (4.1) with $\mathcal{D} = r(\mathcal{C})$. □

This result allows us to characterize the limit set of the individual Q-learning algorithm in terms of the chain-recurrent sets of the SBR dynamics. These chain-recurrent sets are well studied, since they are the limit set of a stochastic fictitious play process (Benaïm and Hirsch (1999)), and in particular Hofbauer and Hopkins (2005) provide Lyapunov functions for 2-player zero-sum games and 2-player partnership games. This allows us to prove our first main proposition, which gives convergence results for individual Q-learning in these situations.

PROPOSITION 4.2. *In either 2-player zero-sum games, or 2-player partnership games with countably many Nash distributions (given the smooth best responses β^i), strategies of players using the individual Q-learning algorithm* (3.2) *will converge almost surely to a Nash distribution.*

Proof. Lemma 3.1 shows that the Q values converge to a connected internally chain-recurrent set of the Q-learning ODE (3.4). From Lemma 4.1 we know that this is of the form $r(\mathcal{C})$, where $\mathcal{C} \subset \Delta$ is a connected internally chain-recurrent set of flow defined by the SBR dynamics (4.1). In the games we consider, Hofbauer and Hopkins (2005) provide Lyapunov functions for the set of Nash distributions under the SBR dynamics, and this set is isolated (by assumption in the case of partnership games and by a result of Hofbauer and Hopkins (2005) for zero-sum games). Therefore Benaïm (1999, Corollary 6.6) shows that we can assume $\mathcal{C} = \{\tilde{\pi}\}$ where $\tilde{\pi}$ is a Nash distribution. Therefore $Q_n^i \to r^i(\cdot, \tilde{\pi}^{-i})$ for each i, and so $\beta^i(Q_n^i) \to \beta^i(r^i(\cdot, \tilde{\pi}^{-i}))$ by continuity. But $\tilde{\pi}$ is a Nash distribution, so $\beta^i(r^i(\cdot, \tilde{\pi}^{-i})) = \tilde{\pi}^i$, and we have shown that the strategies converge to a Nash distribution. □

We illustrate this convergence with the rock-scissors-paper game (2.1). This is a 2-player zero-sum game, and therefore strategies converge to the unique Nash distribution where all actions are played with probability 1/3 (this is the same as the Nash equilibrium, although for general games the Nash equilibria and Nash distributions do not coincide). In Figure 1 we see that despite erratic initial strategy shifts, the strategy of player 1 appears to be converging to the Nash distribution.

However, this convergent behavior does not occur for all games. Two classic examples of games that cause problems for learning algorithms are Shapley's variant of rock-scissors-paper (Shapley (1964)) and Jordan's 3-player matching pennies game (Jordan (1993)). In both of these games, the SBR dynamics (4.1) admit a unique linearly unstable fixed point, and an asymptotically stable limit cycle, for certain smooth best response functions β^i (Cowan (1992), Benaïm and Hirsch (1999)). We shall not reproduce all of these results for the Q-learning ODE but will show that in Shapley's game, using Boltzmann action selection (2.2), a Hopf bifurcation occurs at the unique Nash distribution as the temperature parameter tends to 0. This shows that for sufficiently small τ the Nash distribution is linearly unstable and a periodic orbit is an attractor. We use the symmetric formulation of Shapley's game, with payoff matrix

$$\begin{pmatrix} (0,0) & (1,0) & (0,1) \\ (0,1) & (0,0) & (1,0) \\ (1,0) & (0,1) & (0,0) \end{pmatrix}, \tag{4.2}$$

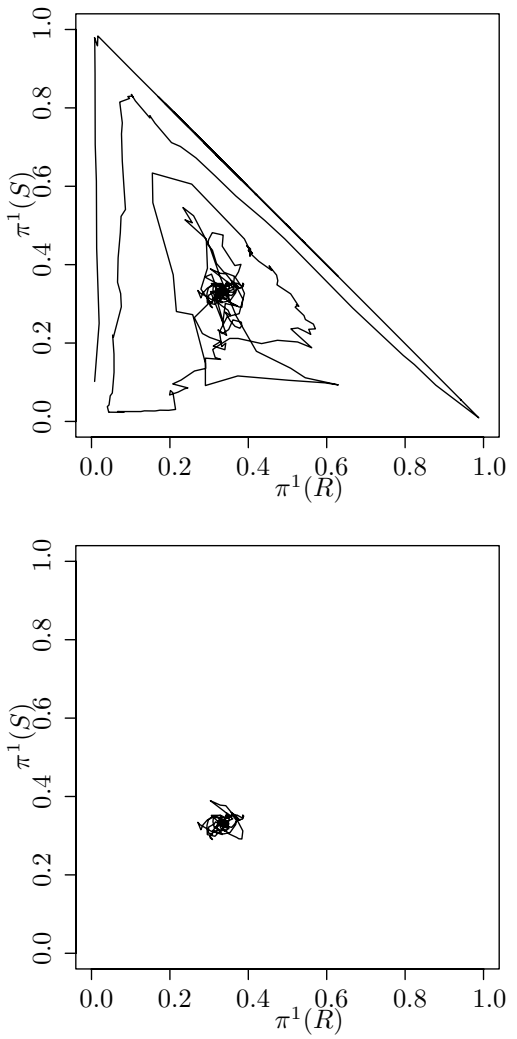

FIG. 1. *Strategies of player* 1 *in the rock-scissors-paper game* (2.1) *with Boltzmann action selection* ($\tau = 0.1$) *over* 5×10^5 *iterations of basic individual Q-learning* (3.2) *with* $\lambda_n = (n+100)^{-0.9}$. *The top diagram shows the entire learning run, whereas the bottom diagram omits the first* 10^4 *iterations, showing that strategies are converging to the unique Nash distribution.*

and therefore, for $i = 1, 2$,

$$\frac{\mathrm{d}}{\mathrm{d}t}Q^i(R) = \pi^{-i}(S) - Q^i(R),$$
$$\frac{\mathrm{d}}{\mathrm{d}t}Q^i(S) = \pi^{-i}(P) - Q^i(S),$$
$$\frac{\mathrm{d}}{\mathrm{d}t}Q^i(P) = \pi^{-i}(R) - Q^i(P).$$

The Jacobian for this system, evaluated at the unique Nash distribution where all Q

values have the value $1/3$, is given by

$$\begin{pmatrix} -1 & 0 & 0 & \frac{-1}{9\tau} & \frac{2}{9\tau} & \frac{-1}{9\tau} \\ 0 & -1 & 0 & \frac{-1}{9\tau} & \frac{-1}{9\tau} & \frac{2}{9\tau} \\ 0 & 0 & -1 & \frac{2}{9\tau} & \frac{-1}{9\tau} & \frac{-1}{9\tau} \\ \frac{-1}{9\tau} & \frac{2}{9\tau} & \frac{-1}{9\tau} & -1 & 0 & 0 \\ \frac{-1}{9\tau} & \frac{-1}{9\tau} & \frac{2}{9\tau} & 0 & -1 & 0 \\ \frac{2}{9\tau} & \frac{-1}{9\tau} & \frac{-1}{9\tau} & 0 & 0 & -1 \end{pmatrix},$$

which has eigenvalues

$$\frac{1}{6\tau}(1 - 6\tau \pm \sqrt{3}i), \quad \frac{1}{6\tau}(-1 - 6\tau \pm \sqrt{3}i), \quad -1, \quad -1.$$

As $\tau \to 0$, the real part of the first conjugate pair crosses the imaginary axis from the negative half-plane to the positive half-plane, resulting in a Hopf bifurcation, so for sufficiently small τ the fixed point is linearly unstable. Therefore by the results of Pemantle (1990), convergence to this fixed point is a probability zero event; in Figure 2 we see that in fact play cycles, as it would under the SBR dynamics, and as implied by the Hopf bifurcation. Previous work (Leslie and Collins (2003)) suggests that using player-dependent learning rates helps to break the symmetry that allows this cycling to occur. We will apply this idea to individual Q-learning in the next section.

5. Player-dependent learning rates. Returning to general N-player games, Leslie and Collins (2003) introduce player-dependent learning rates (PDLR) to break the symmetry that allows strategies to cycle under the SBR dynamics (4.1). Under this paradigm, each player's learning parameters decay to zero at different rates, resulting in a process which is a stochastic approximation of a singularly perturbed dynamical system. The algorithm we study is shown in Table 2; it is a simple extension of individual Q-learning (3.2) which incorporates PDLR. In fact the only difference between this and the individual Q-learning algorithm (3.2) is that each player uses her own sequence of learning parameters $\{\lambda_n^i\}_{n\geq 1}$.

Note that condition (5.2) is used for ease of exposition but is equivalent to the condition that either $\lambda_n^i/\lambda_n^j \to 0$ or $\lambda_n^j/\lambda_n^i \to 0$ whenever $i \neq j$, since if this latter condition is true we can assume that the players are indexed in such a way that (5.2) is true. A suitable choice of learning parameters would be to choose $\lambda_n^i = (n+C)^{-\rho^i}$, where the rate $\rho^i \in (0.5, 1]$ is chosen differently for each player; indeed if players are thought of as selecting their own learning rate ρ^i independently using any continuous distribution on $(0.5, 1]$, then the necessary conditions will be met with probability 1.

The more slowly a player's learning parameters decrease to 0, the more "responsive" that player will be, since greater emphasis is placed on recent observations when estimating an action's value. In contrast, players with more rapidly decreasing learning parameters are more "cautious," since their value estimates take greater account of the entire history of observed rewards. Condition (5.2) means that players with higher indices i are more responsive (and hence less cautious) than those with lower indices.

As observed in Leslie and Collins (2003), in order to analyze an algorithm incorporating PDLR theoretically, we need to make an assumption about what would happen to the more responsive players if the strategies of the $i-1$ most cautious players were fixed.

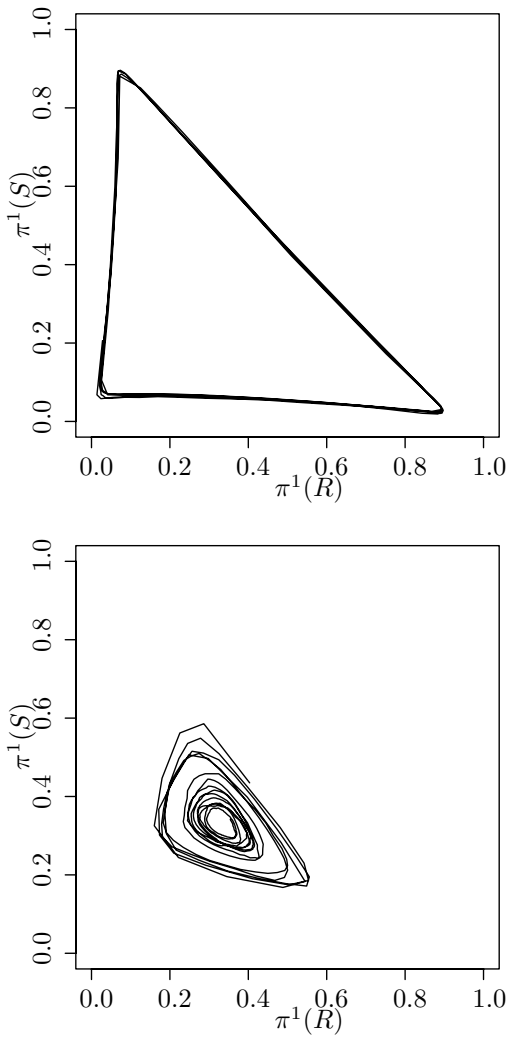

FIG. 2. *Strategies of player* 1 *in Shapley's game* (4.2) *with Boltzmann action selection* ($\tau = 0.1$) *over* 5×10^5 *iterations of basic individual Q-learning* (3.2) *with* $\lambda_n = (n + 100)^{-0.9}$ *(top) and of individual Q-learning with PDLR* (5.1)*, with* $\lambda_n^1 = (n + 100)^{-0.9}$ *and* $\lambda_n^2 = (n + 100)^{-0.7}$ *(bottom). The first* 1×10^4 *iterations are omitted in each case. For basic individual Q-learning* (3.2) *the strategies follow a limit cycle, while for individual Q-learning with PDLR* (5.1) *the strategies are spiraling anticlockwise toward the unique Nash distribution.*

ASSUMPTION 5.1. *For each* $i \in \{2, \ldots, N\}$ *there exists a function* $\tilde{q}^i : \Delta^1 \times \cdots \times \Delta^{i-1} \to \mathbb{R}^{|A^i|}$ *such that, for arbitrary fixed* $(Q^1, \ldots, Q^{i-1})$*, the ODE*

$$\frac{\mathrm{d}}{\mathrm{d}t} q_t^i(a^i) = r^i(a^i, [\pi^{(<i)}, B^{(>i)}[\pi^{(<i)}, \beta^i(q_t^i)]]) - q_t^i(a^i) \quad \textit{for each } a^i \in A^i$$

has the globally attracting fixed point $\tilde{q}^i(\pi^{(<i)})$*, where*

$$\pi^{(<i)} = (\beta^1(Q^1), \ldots, \beta^{i-1}(Q^{i-1}))$$

TABLE 2
Individual Q-learning with PDLR.

Each player i selects an action a_n^i using the strategy $\beta^i(Q_n^i)$, receives reward R_n^i, and then updates Q_n^i according to

$$Q_{n+1}^i(a^i) = Q_n^i(a^i) + \lambda_{n+1}^i \mathbb{I}_{\{a_n^i = a^i\}} \frac{R_n^i - Q_n^i(a_n^i)}{\beta^i(Q_n^i)(a_n^i)} \quad \text{for each } a^i \in A^i, \tag{5.1}$$

where for each i, $\{\lambda_n^i\}_{n\geq 1}$ is a deterministic sequence of learning parameters satisfying the conditions (3.3), and additionally

$$\lambda_n^i / \lambda_n^{i+1} \longrightarrow 0 \quad \text{as } n \longrightarrow \infty. \tag{5.2}$$

and $B^{(>i)} : \Delta^1 \times \cdots \times \Delta^i \to \Delta^{i+1} \times \cdots \times \Delta^N$ *is defined recursively by*

$$B^{(>(N-1))}(\pi^{(<N)}) = \beta^N(\tilde{q}^N(\pi^{(<N)})),$$
$$B^{(>(i-1))}(\pi^{(<i)}) = (\beta^i(\tilde{q}^i(\pi^{(<i)})), B^{(>i)}[\pi^{(<i)}, \beta^i(\tilde{q}^i(\pi^{(<i)}))]).$$

Although this looks technical, it can be expressed relatively simply: for any i, if the values (and hence strategies) of players $(1, \ldots, i-1)$ were fixed, the strategies of the more responsive players $(i, \ldots, N)$ would converge to a unique fixed point determined by the functions $\tilde{q}^i$ and $B^{(>i)}$. This assumption is satisfied for any 2-player game: for Q^1 fixed, player 2 simply faces a multi-armed bandit problem. However, it is clearly not always satisfied for general N-player games: in a 3-player partnership game, for Q^1 fixed the other two players still face a partnership game, which might well have more than one Nash distribution, and therefore more than one potential limit point for the more responsive players. We will investigate when Assumption 5.1 is satisfied using a graphical analysis in section 6, but in this section we will retain it as an assumption.

As with the basic individual Q-learning algorithm of section 3, it is immediate that convergence of algorithm (5.1) to a fixed point can occur only at Nash distribution values. Also analogously, we can prove the following lemma.

LEMMA 5.2. *Under Assumption* 5.1, *the values* Q_n^1 *resulting from individual Q-learning with PDLR* (5.1) *converge almost surely to a connected internally chain-recurrent set of the flow defined by the singularly perturbed Q-learning ODE*

$$\frac{\mathrm{d}}{\mathrm{d}t} q_t^1(a^1) = r^1(a^1, B^{(>1)}[\beta^1(q_t^1)]) - q_t^1(a^1) \quad \textit{for each } a^1 \in A^1, \tag{5.3}$$

provided that the Q_n *remain bounded for all time, where* $B^{(>1)}$ *is the function defined in Assumption* 5.1. *Additionally,*

$$\|Q_n^i - r^i(\cdot, [\beta^1(Q_n^1), B^{>1}[\beta^1(Q_n^1)]])\|_\infty \longrightarrow 0$$
$$\textit{almost surely for each } i > 1 \textit{ as } n \longrightarrow \infty.$$

Proof. This is immediate from the results of Leslie and Collins (2003) and Assumption 5.1. □

Note that Lemma 5.2 tells us we can analyze the asymptotic behavior of the algorithm as if the values of the remaining players have all converged to the fixed

point determined by the current strategy of the most cautious player, despite the fact that in reality all players adjust their values after every play of the game.

We will proceed to analyze the dynamical system (5.3) in two different ways: in section 5.1 we proceed as in section 4 and relate (5.3) to the singularly perturbed SBR dynamics (Leslie and Collins (2003)), while in section 5.2 we perform a direct analysis in a more restricted class of games.

5.1. Relating the singularly perturbed Q-learning ODE to the singularly perturbed SBR dynamics. Leslie and Collins (2003) study the singularly perturbed SBR dynamics, defined by

$$\frac{\mathrm{d}}{\mathrm{d}t}\pi_t^1 = \beta^1[r^1(\cdot, B^{(>1)}[\pi_t^1])] - \pi_t^1. \tag{5.4}$$

As in section 4, we will relate the singularly perturbed Q-learning ODE (5.3) to the singularly perturbed SBR dynamics (5.4).

LEMMA 5.3. *Any connected internally chain-recurrent set of the singularly perturbed Q-learning ODE* (5.3) *is of the form*

$$r^1(\mathcal{C}^1) := \{r^1(\cdot, B^{(>1)}(\pi^1)) : \pi^1 \in \mathcal{C}^1\},$$

where $\mathcal{C}^1 \subset \Delta^1$ is a connected internally chain-recurrent set of flow defined by the singularly perturbed SBR dynamics (5.4)*, and $B^{(>1)}$ is the function defined in Assumption* 5.1*.*

Proof. This lemma's proof is identical to that of Lemma 4.1, and will not be repeated here. □

As in section 4 this enables us to use previous results (Leslie and Collins (2003)) on more sophisticated forms of learning to prove convergence of the individual Q-learning algorithm with PDLR (5.1) to Nash distribution in certain classes of games.

PROPOSITION 5.4. *The strategies of players using the individual Q-learning algorithm with PDLR* (5.1) *will converge almost surely to a Nash distribution, provided that the Q_n remain bounded for all time, in the following games:*

(i) *2-player zero-sum games,*

(ii) *2-player partnership games,*

(iii) *Shapley's game* (4.2) *(if Boltzmann action selection is used), and*

(iv) *the N-player matching pennies game (Leslie and Collins* (2003)*) (if the smooth best responses are symmetric under a reordering of the actions).*

Proof. Leslie and Collins (2003) show that Assumption 5.1 holds for these games. The result therefore follows immediately from Lemmas 5.2 and 5.3 and the results of Leslie and Collins (2003) on the connected internally chain-recurrent sets of the singularly perturbed SBR dynamics. □

Thus the individual Q-learning algorithm with PDLR (5.1) is proved to converge in the same games as basic individual Q-learning (3.2). In addition, we have proved that individual Q-learning with PDLR will converge in two games (Shapley's game and the N-player matching pennies game) for which most learning algorithms fail to converge. Indeed the authors know of no adaptive algorithm that converges to either Nash equilibrium or Nash distribution in these games without using PDLR.

We illustrate these results with some numerical experiments using Shapley's game (4.2). As observed in section 4, the basic individual Q-learning algorithm (3.2) will cycle in this game. On the other hand, we have shown that the individual Q-learning algorithm with PDLR (5.1) will converge to the unique Nash distribution values. This is confirmed in Figure 2.

5.2. Direct analysis of the singularly perturbed Q-learning ODE. We now change our emphasis away from the SBR dynamics and instead analyze the singularly perturbed Q-learning ODE (5.3) directly in games where player 1 has 2 actions. We show here that convergence to Nash distribution occurs if Boltzmann action selection is used.

PROPOSITION 5.5. *Suppose player* 1 *has* 2 *actions and uses Boltzmann action selection* (2.2)*. Suppose further that the game and smooth best responses are such that there are countably many Nash distributions. Then, under Assumption* 5.1*, the strategies of players using the individual Q-learning algorithm with PDLR* (5.1) *converge almost surely to a Nash distribution, provided that the Q_n remain bounded for all time.*

Proof. By Lemma 5.2, the Q^1 values converge to a connected internally chain-recurrent set of the singularly perturbed Q-learning ODE (5.3). To ease notation, for this proof we will write

$$\pi_t(1) = \beta^1(q_t^1)(1) = \frac{\mathrm{e}^{q_t^1(1)/\tau}}{\mathrm{e}^{q_t^1(1)/\tau} + \mathrm{e}^{q_t^1(2)/\tau}} = (1 + \mathrm{e}^{\{q_t^1(2) - q_t^1(1)\}/\tau})^{-1} = 1 - \pi_t(2),$$
$$\hat{r}_t(a) = r^1(a, B^{>1}[\beta^1(q_t^1)]), \quad a = 1, 2.$$

Since $\beta^1(q_t^1) = (\pi_t(1), 1 - \pi_t(1))$, $\hat{r}_t(a)$ is a function of the scalar variable $\pi_t(1)$, which is in turn a function of $q_t^1(1)$ and $q_t^1(2)$. Hence

$$\begin{aligned}\frac{\mathrm{d}\hat{r}_t(a)}{\mathrm{d}t} &= \frac{\mathrm{d}\hat{r}_t(a)}{\mathrm{d}\pi_t(1)} \left\{ \frac{\partial \pi_t(1)}{\partial q_t^1(1)} \frac{\mathrm{d}q_t^1(1)}{\mathrm{d}t} + \frac{\partial \pi_t(1)}{\partial q_t^1(2)} \frac{\mathrm{d}q_t^1(2)}{\mathrm{d}t} \right\} \\ &= \frac{\mathrm{d}\hat{r}_t(a)}{\mathrm{d}\pi_t(1)} \pi_t(1)\pi_t(2) \frac{\mathrm{d}}{\mathrm{d}t} \{q_t^1(1) - q_t^1(2)\}.\end{aligned}$$

From this, it follows that

$$\begin{aligned}\frac{\mathrm{d}^2}{\mathrm{d}t^2} \{q_t^1(1) - q_t^1(2)\} &= \frac{\mathrm{d}}{\mathrm{d}t} \{\hat{r}_t(1) - \hat{r}_t(2) - q_t^1(1) + q_t^1(2)\} \\ &= \left[\pi_t(1)\pi_t(2) \left\{ \frac{\mathrm{d}\hat{r}_t(1)}{\mathrm{d}\pi_t(1)} - \frac{\mathrm{d}\hat{r}_t(2)}{\mathrm{d}\pi_t(1)} \right\} - 1 \right] \frac{\mathrm{d}}{\mathrm{d}t} \{q_t^1(1) - q_t^1(2)\}.\end{aligned}$$

Therefore $\frac{\mathrm{d}}{\mathrm{d}t}\{q_t^1(1) - q_t^1(2)\}$ does not change sign, and $\{q_t^1(1) - q_t^1(2)\}$ acts as a Lyapunov function. The result follows from Benaïm (1999, Corollary 6.6). □

Note that Proposition 5.5 provides an independent proof of the convergence of the individual Q-learning algorithm with PDLR (5.1) for the N-player matching pennies game that does not rely on the smooth best responses being symmetric under a reordering of the actions. Furthermore the following immediate corollary shows that the result can be applied directly in a wide class of games.

COROLLARY 5.6. *In a* 2*-player game where player* 1 *has* 2 *actions and uses Boltzmann action selection* (2.2)*, the strategies of players using the individual Q-learning algorithm with PDLR* (5.1) *converge almost surely to a Nash distribution, provided that the Q_n remain bounded for all time.*

Proof. As already noted, Assumption 5.1 holds automatically in 2-player games. Hence this is immediate from Proposition 5.5. □

This is comparable with a recent result (Berger (2005)) showing that fictitious play approaches equilibrium in nondegenerate $2 \times n$ games, although clearly more information is required for the players in a fictitious play process.

5.3. PDLR and Stackelberg equilibria. Here we discuss a point raised by an anonymous referee, concerning the relationship between PDLR and Stackelberg equilibria (equilibria in which one player selects her strategy first, in the knowledge that the other player will play an optimal action in response). If players used individual Q-learning with PDLR, it might be anticipated that a cautious player could gain an advantage by initially selecting a strategy and then relying on the fact that the responsive player will adapt quickly to this strategy. For example, in the battle of the sexes game with payoff matrix

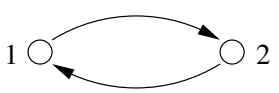
$$\begin{pmatrix} (10,1) & (0,0) \\ (0,0) & (1,10) \end{pmatrix},$$

player 1 could initially select row 1 with high probability, forcing a responsive player 2 to learn to play column 1; player 1 is acting as a Stackelberg leader.

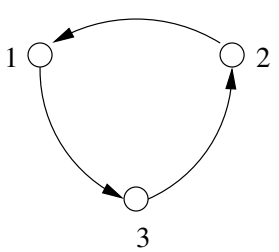
However, in the minimal information situation we consider here, player 1 cannot know in advance which strategy to select to achieve this effect, since the payoff matrix is not known. In the battle of the sexes game, ignoring stochastic effects, if player 1's initial strategy has $\pi^1(2) > 1/11$, then a responsive player 2 will play a strategy in which $\pi^2(2)$ is very nearly 1; the cautious player 1 will then slowly increase $\pi^1(2)$ until joint play reaches the Nash distribution where both players select action 2 with high probability. (Note that this is actually the equilibrium that would have been selected if player 2 was a Stackelberg leader.) Since $\pi^1(2) > 1/11$ with high probability, under reasonable assumptions about the initial Q values of the players, there is a high probability that play will converge to a Nash distribution different from that suggested by the Stackelberg theory. Thus the relationship between PDLR and Stackelberg equilibria is much less clear than might be expected.

6. Graphical analysis. The results of section 5 on individual Q-learning with PDLR rely on Assumption 5.1, which states that there is a unique limit point of the strategies of the more responsive players for any fixed values of the more cautious players $(1, \ldots, i-1)$. Although we have observed that this is always true for 2-player games, in this section we develop a graphical approach to analyzing when this is satisfied in general N-player games, building on previous graphical representations of games (Littman, Kearns, and Singh (2001), Koller and Milch (2003)).

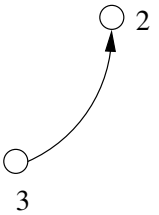
Given a game, we construct a graph by taking a node for each player and drawing a directed arc $\vec{ij}$ if the actions of player i directly affect the rewards of player j. Thus the graph of a (generic) 2-player game is given by



whereas the graph of the 3-player matching pennies game (Jordan (1993)), in which the rewards of player i are affected only by the actions of player $i+1$ (modulo 3), is given by



These graphs can be used to investigate Assumption 5.1 by removing node 1 (corresponding to the most cautious player) from the graph, then considering the behavior of the other players. The intuition behind this is that the fixed strategy of the most cautious player in Assumption 5.1 results in the other players facing a reduced game. For example, in the 3-player matching pennies game, removal of node 1 (and connected arcs) results in the graph



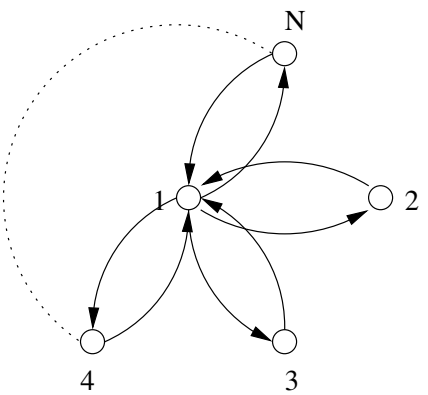
Thus for fixed Q^1, player 3's rewards are not affected by any other player, so Q_n^3 converges to unique values. But because of this, player 2's values must also converge to unique values, and so for fixed Q^1, the values (Q_n^2, Q_n^3) converge to a unique point, as required by Assumption 5.1.

In fact, this example generalizes very simply. If, after removal of a node, a graph has no directed cycle, then the players corresponding to nodes left in the graph will converge to a unique fixed point.

PROPOSITION 6.1. *Suppose that a game is such that removal of node* 1 *from the game graph results in a subgraph containing no directed cycles. Then Assumption* 5.1 *holds for this game.*

Proof. If the subgraph remaining after removal of node 1 has no directed cycle, then there exists at least one node with in-degree 0 (i.e., no arcs terminate at this node). The values of a player associated with such a node do not depend on the strategies of any other players (except perhaps the fixed strategy of player 1), and so the Q values of that player will converge almost surely to a unique point. Since the rewards, and hence strategies, of any player corresponding to a node with in-degree 0 are uniquely determined, given the fixed strategy of player 1, these nodes can be removed from the graph. This again results in a graph with no directed cycles, and we can proceed recursively to show that the rewards of all the players are uniquely determined by the values of player 1, as required in Assumption 5.1. □

From this proposition, it is immediate that Assumption 5.1 holds in games which have a graph with no directed cycle even before removal of a node, and games with a single directed cycle will clearly become acyclic if the node to be removed is part of that cycle. Consider also games with a star graph:



Here there is a distinguished player (the hub) connected to all others, but all non-distinguished players are disconnected from each other. This graph will become completely disconnected (and so obviously will have no directed cycle) if the node corresponding to the distinguished player is removed. A game such as this could have applications in computing, for example, where the distinguished player is a central resource, such as a server or router, and the other nodes correspond to users of the resource.

Although useful, this graphical approach is not sufficient in all situations. For example, consider a 3-player game in which the rewards of players 2 and 3 always sum to 0 for any fixed Q^1. Thus, the graph after removal of node 1 is the same as that of a 2-player game, and so (generically) contains a directed cycle. However, the resulting game is a 2-player zero-sum game, in which the players converge to a unique Nash distribution (Proposition 5.4 and Hofbauer and Hopkins (2005)). Therefore Assumption 5.1 is satisfied, even though the conditions of Proposition 6.1 are not.

7. Conclusion. We have shown that value-based learning agents cannot generally converge to a Nash equilibrium of a game, but if smooth best responses are used, a Nash distribution can be reached. Although Nash distributions are not generally the same as Nash equilibria, they are close if the temperature parameter of the smooth best responses is sufficiently small, and therefore we proposed that value-based learning agents should use smooth best responses to allow equilibrium play, even if this is not a classical Nash equilibrium.

Our value-based learning algorithm, individual Q-learning (3.2), is very similar to the simple and successful algorithm used by Sutton and Barto (1998) in the single-agent multi-armed bandit problem. We showed that convergence to a point that is not a Nash distribution is not possible and that the value estimates are asymptotically belief-based. Further, by relating the limiting behavior of the individual Q-learning algorithm to the SBR dynamics (a system previously used to characterize more sophisticated models of learning), it was shown that strategies of players converge almost surely to a Nash distribution for 2-player zero-sum games and 2-player partnership games.

The nonconvergence of strategies for certain games motivates the introduction of individual Q-learning with PDLR (5.1), resulting in cautious and responsive players. This modified algorithm converges to Nash distribution for the same games as basic individual Q-learning (3.2), and also for Shapley's game and the N-player matching pennies game. Moreover, convergence was shown to occur for any game in which player 1, the most cautious, has only 2 actions.

Finally, since the results on PDLR rely on an assumption about the behavior of the more responsive players if the values of player 1 were fixed, a simple graphical method was introduced to help determine when this assumption holds.

Acknowledgments. The authors thank three anonymous referees for helpful comments and Prof. Josef Hofbauer and Dr. Andy Wright for helpful discussions in the course of the research leading to this paper.

H_2 AND H_∞ FILTERING DESIGN SUBJECT TO IMPLEMENTATION UNCERTAINTY*

MAURÍCIO C. DE OLIVEIRA† AND JOSÉ C. GEROMEL‡

Abstract. This paper presents new filtering design procedures for discrete-time linear systems. It provides a solution to the problem of linear filtering design, assuming that the filter is subject to parametric uncertainty. The problem is relevant, since the proposed filter design incorporates real world implementation constraints that are always present in practice. The transfer function and the state space realization of the filter are simultaneously computed. The design procedure can also handle plant parametric uncertainty. In this case, the plant parameters are assumed not to be exactly known but belonging to a given convex and closed polyhedron. Robust performance is measured by the H_2 and H_∞ norms of the transfer function from the noisy input to the filtering error. The results are based on the determination of an upper bound on the performance objectives. All optimization problems are linear with constraint sets given in the form of LMI (linear matrix inequalities). Global optimal solutions to these problems can be readily computed. Numerical examples illustrate the theory.

Key words. robust filtering, implementation uncertainty, fragility, linear matrix inequalities

1. Introduction.

In the 1980s, a great deal of effort was dedicated to the study of implementation issues of filters and controllers [1, 2, 3, 4]. The motivation was to devise design techniques that would lead to filters and controllers that could perform well when implemented on a digital computer. The main objectives were (a) to minimize the degradation of performance caused by computation of signals in a finite precision computational architecture, and (b) to minimize the impact of truncation and rounding on the coefficients of the filter or controller. These objectives were addressed using many different techniques (see [1] for details). Among these techniques, a popular approach to dealing with degradation of the signals was to model rounding and truncation as noise [5], whereas rounding and truncation of the filter or controller coefficients was addressed by studying the *sensitivity* of these parameters to variations [1]. The great development of the computer industry in the 1990s brought to the signal processing and control practitioner processors with more and more bits of precision at very low cost, which somewhat dimmed the importance of the topic. The fact that every few years the computer industry provides processors with longer wordlength is used by some to justify the design of filters and controllers with little or no regard to finite precision perturbation effects. In fact, for many simple systems, this increase in wordlength means that the quantization effects can be practically ignored. However, faster and more precise computers also provide the opportunity to increase the complexity of the systems, in terms of both more sophisticated algorithms

and number of devices. As observed in [6], this increased complexity will eventually face limitations in bandwidth, that is, the speed at which the devices communicate, reducing the sampling rates (relative to the available processor wordlength). In this scenario, a careful analysis of perturbation effects on filters and controllers certainly will be required. Also, in many consumer electronics products, inexpensive processors (say, fixed point digital signal processors (DSPs)) are usually preferred. These processors often impose nontrivial wordlength limitations, and thus better design algorithms are needed to deal with them. Some recent efforts along this line are reported in [7].

In fact, the importance of robustness to filter and control parametric perturbations seems to have been *rediscovered* by the end of the 1990s with the paper [8]. This work, despite the controversy it raised [9], showed that many robust control design methods, which were targeted to deal with plant uncertainty, could be particularly sensitive to parameter uncertainty on the controller. The authors use a series of numerical examples to illustrate that a very small perturbation on the coefficients of controllers could lead to a loss of stability of the closed-loop system [8]. Since then, many authors have addressed the problem of robustness to parametric control or filter perturbation under the label of *fragility* [10, 11, 12, 13, 14].

While many works on filter *sensitivity* are more concerned with the problem of choosing an appropriate realization for a given filter transfer function [2, 3], many works on *fragility* seem to focus more on the robustness of the filter transfer function rather than its realization [12]. The approach developed in this paper blends these two issues by simultaneously designing the optimal filter transfer function *and* its realization. The strategy is to modify the filtering procedure introduced in [15] to take into account robustness with respect to filter parametric variations. Variations of the filter parameters are allowed inside a region specified by a quadratic matrix inequality. The maximum allowed norm of the filter uncertainty is specified as a percentage of the norm of the nominal filter parameters. The ability to specify the uncertainty in the filter parameters relative to the size of the nominal filter is especially important when the transfer function and the state space realization of the filter are to be designed simultaneously. This model is also very appropriate to model perturbations on the parameters coming from truncation on a floating-point computational architecture, where rounding and truncation introduce errors relative to the size of the original numbers.

In this paper, guaranteed cost functions are developed to provide upper bounds on the maximum value of the H_2 or H_∞ norm of the uncertain transfer function from an exogenous noise input to the filtering error on the filter uncertainty region. This paper introduces and completely solves these H_2 and H_∞ guaranteed cost filtering design problems. The design conditions are expressed as linear matrix inequalities (LMIs), and hence numerical solutions can be readily computed [16]. In contrast to [15, 17], the results specify not only the transfer function of the filter but also its realization. Illustrative examples show the effectiveness of the proposed approach. An interesting feature observed in the examples is that the filters designed by the proposed technique have less round-off gain than the standard Kalman filter [2, 5], although such a performance measure is not directly addressed in the optimization process. The design procedures introduced in this paper admit straightforward extensions to simultaneously handle plant parameter uncertainty specified in terms of convex bounded polyhedrons. These extensions can be derived to contemplate both the quadratic stability [17] and the extended stability [18] approaches. In the former, a single quadratic Lyapunov function is used to evaluate the performance on the

uncertainty region, while in the latter a parameter dependent Lyapunov function [19] is built.

The notation is standard. Lowercase letters denote vectors while capital letters represent matrices. The symbol $(^T)$ is used to indicate the transpose of vectors and matrices. If a symmetric matrix X is positive definite, this is indicated by $X > 0$.

2. Preliminary results on filtering. Consider the linear discrete-time time-invariant system

$$x(k+1) = Ax(k) + Bw(k), \tag{1}$$

$$z(k) = C_z x(k) + D_z w(k), \tag{2}$$

$$y(k) = C_y x(k) + D_y w(k), \tag{3}$$

where all matrices and vectors are assumed to have appropriate dimensions. The *optimal filtering* problem consists of designing a linear filter

$$x_f(k+1) = A_f x_f(k) + B_f y(k), \tag{4}$$

$$z_f(k) = C_f x_f(k) + D_f y(k), \tag{5}$$

which makes use of the plant output $y(k)$ to produce the filtered output $z_f(k)$, with the objective of minimizing a norm of the transfer function from the noise input $w(k)$ to the filtering error $e(k) := z(k) - z_f(k)$. Collecting the filter parameters in the matrix

$$\mathcal{F} := \begin{bmatrix} D_f & C_f \\ B_f & A_f \end{bmatrix}, \tag{6}$$

we can state the optimal filtering problem as the optimization problem

$$\min_{\mathcal{F}} \|H_{we}(z;\mathcal{F})\|_p. \tag{7}$$

The values of $p = \{2, \infty\}$ are the choices usually found in the literature. The next lemmas revisit the solutions of the optimal filtering problems given in [17]. The solution is given as LMI conditions formulated in terms of the transformed set of filter parameters

$$\mathcal{K} := \begin{bmatrix} R & L \\ F & Q \end{bmatrix}, \tag{8}$$

defined with respect to the above partitioning.

LEMMA 1 (H_2 filtering). *There exist a matrix $\mathcal{K}$, partitioned as in* (8)*, and symmetric matrices Y, Z, W such that the LMI*

$$\begin{bmatrix} Z & \bullet & \bullet & \bullet & \bullet \\ Z & Y & \bullet & \bullet & \bullet \\ A^TZ & A^TY + C_y^TF^T + Q^T & Z & \bullet & \bullet \\ A^TZ & A^TY + C_y^TF^T & Z & Y & \bullet \\ B^TZ & B^TY + D_y^TF^T & \mathbf{0} & \mathbf{0} & \mathbf{I} \end{bmatrix} > 0, \tag{9}$$

$$\begin{bmatrix} W & \bullet & \bullet & \bullet \\ C_z^T - C_y^TR^T - L^T & Z & \bullet & \bullet \\ C_z^T - C_y^TR^T & Z & Y & \bullet \\ D_z^T - D_y^TR^T & \mathbf{0} & \mathbf{0} & I \end{bmatrix} > 0, \tag{10}$$

$$\operatorname{trace}(W) < \mu \tag{11}$$

have a feasible solution if and only if the filter

$$\mathcal{F} = \begin{bmatrix} \mathbf{I} & \mathbf{0} \\ \mathbf{0} & V^{-1} \end{bmatrix} \mathcal{K} \begin{bmatrix} \mathbf{I} & \mathbf{0} \\ \mathbf{0} & Z^{-1}U^{-1} \end{bmatrix}, \tag{12}$$

where U and V are nonsingular otherwise arbitrary matrices chosen to satisfy $Y + VUZ = Z$, is such that

$$\|H_{we}(z;\mathcal{F})\|_2^2 < \mu. \tag{13}$$

LEMMA 2 (H_∞ filtering). *There exist a matrix $\mathcal{K}$, partitioned as in* (8)*, and symmetric matrices Y, Z such that the LMI*

(14)
$$\begin{bmatrix} Z & \bullet & \bullet & \bullet & \bullet & \bullet \\ Z & Y & \bullet & \bullet & \bullet & \bullet \\ A^TZ & A^TY + C_y^TF^T + Q^T & Z & \bullet & \bullet & \bullet \\ A^TZ & A^TY + C_y^TF^T & Z & Y & \bullet & \bullet \\ B^TZ & B^TY + D_y^TF^T & \mathbf{0} & \mathbf{0} & \mu\mathbf{I} & \bullet \\ \mathbf{0} & \mathbf{0} & C_z - RC_y - L & C_z - RC_y & D_z - RD_y & \mu\mathbf{I} \end{bmatrix} > 0$$

have a feasible solution if and and only if the filter $\mathcal{F}$ given in (12) *is such that*

$$\|H_{we}(z;\mathcal{F})\|_\infty < \mu. \tag{15}$$

The above lemmas are generalizations of the results obtained in [17]. Here, the assumptions that the filter(4)–(5) is strictly proper and that the matrix D_z is null have been removed. There is virtually no change from the proofs presented in [15, 17] to the ones required to prove Lemmas 1 and 2. These proofs are omitted for brevity and the interested reader is referred to [15, 17] for more details. The constraints stated in Lemmas 1 and 2 are all LMI, and hence solutions to the optimization problem (7) can be obtained by minimizing the scalar μ subject to the given inequalities. The resulting problems are convex and their global optimal solutions can be obtained via convex programming techniques [16].

Once a solution to the inequalities stated in Lemmas 1 or 2 has been found, the user is asked to pick an arbitrary nonsingular matrix U and then solve for V to satisfy $Y + VUZ = Z$ (or choose V and solve for U). This will produce the optimal filter parameters $\mathcal{F}$ through (12). Notice that this is done a posteriori, and that this arbitrary choice does not affect the optimality of the solution. In fact, it is possible to show that the transfer function of the filter associated with the parameters (12) is not affected by the choice of U and V (see [17] for details). The main role of these matrices is to parameterize a particular state space realization of the filter, a fact that will be explored in the next sections.

3. Problem statement. The main purpose of this paper is to derive conditions for the design of filters subject to parametric perturbations. More specifically, it is assumed that the parameters of the filter(4)–(5) are subject to an additive perturbation of the form

$$\mathcal{F} = \mathcal{F}_0 + \Delta_{\mathcal{F}}. \tag{16}$$

The symbol $\mathcal{F}_0$ denotes *nominal* filter parameters, and the unknown perturbation $\Delta_{\mathcal{F}}$ is assumed to be in the set

$$\mathbb{F}_{\mathcal{R}}(\mathcal{F}_0) := \left\{\Delta_{\mathcal{F}} \,:\, \Delta_{\mathcal{F}}^T\mathcal{R}^{-1}\Delta_{\mathcal{F}} \le \gamma^2\mathcal{F}_0^T\mathcal{R}^{-1}\mathcal{F}_0\right\}. \tag{17}$$

In contrast to the conventional norm bounded uncertainty model, where the right-hand side of the inequality given in (17) is usually constant, the uncertainty set $\mathbb{F}_{\mathcal{R}}(\mathcal{F}_0)$ relates the size of the parametric perturbation $\Delta_{\mathcal{F}}$ to the size of the nominal filter parameters $\mathcal{F}_0$. These factors are weighted by the inverse of an arbitrary positive definite matrix $\mathcal{R}$. In this way, by setting the scalar $0 \leq \gamma \leq 1$, the size of the perturbation $\Delta_{\mathcal{F}}$ can be specified *relative* to the size of the nominal filter parameters $\mathcal{F}_0$, which are yet to be determined. The inequality (17) can also be translated as a more standard norm bound relation of the kind

$$\Delta_{\mathcal{F}} \in \mathbb{F}_{\mathcal{R}}(\mathcal{F}_0) \quad \Rightarrow \quad \|\Delta_{\mathcal{F}}\|_{\mathcal{R}^{-1}} \leq \gamma \|\mathcal{F}_0\|_{\mathcal{R}^{-1}}, \tag{18}$$

where $\|\cdot\|_{\mathcal{R}}$ denotes a weighted Frobenius or two norm. This inequality is evidence that the norm of $\Delta_{\mathcal{F}} \in \mathbb{F}_{\mathcal{R}}(\mathcal{F}_0)$ is limited to being a fraction of the norm of the nominal filter $\mathcal{F}_0$. Another interpretation is obtained in terms of a norm bound on the amplitude of the noise signal

$$w_{\Delta_{\mathcal{F}}}(k) = \begin{pmatrix} w_y(k) \\ w_{x_f}(k) \end{pmatrix} := \Delta_{\mathcal{F}} \begin{pmatrix} y(k) \\ x_f(k) \end{pmatrix}, \tag{19}$$

for which

$$\Delta_{\mathcal{F}} \in \mathbb{F}_{\mathcal{R}}(\mathcal{F}_0) \quad \Rightarrow \quad \|w_{\Delta_{\mathcal{F}}}(k)\|_{\mathcal{R}^{-1}} \leq \gamma \left\| \mathcal{F}_0 \begin{pmatrix} y(k) \\ x_f(k) \end{pmatrix} \right\|_{\mathcal{R}^{-1}}. \tag{20}$$

The above interpretation relates the uncertainty set $\mathbb{F}_{\mathcal{R}}(\mathcal{F}_0)$ to the uncertainty models considered in the recent work [20].

The weighting factor $\mathcal{R}$ plays an interesting role in the definition of $\mathbb{F}_{\mathcal{R}}(\mathcal{F}_0)$ and can have a major impact on the reduction of the conservatism of the design conditions to be derived. Roughly speaking, the matrix $\mathcal{R}$ can play the same role as a *scaling matrix*[1] in robust H_∞ analysis [21]. Using the LMI conditions to be derived in the next section, one can simultaneously perform the design of both the filter parameters $\mathcal{F}$ and the scaling matrix $\mathcal{R}$. If desired, one can also set $\mathcal{R}$ to a constant value without destroying the linearity of the design conditions. However, notice that, if the objective of fixing $\mathcal{R}$ is to establish a certain fixed weight on (17–18) and (20), say, $\mathcal{R} = \bar{\mathcal{R}}$, then one can still use a scaling matrix $\mathcal{R} = \lambda\bar{\mathcal{R}}$, where λ is a positive scalar to be determined. Leaving the scalar λ as a variable can be of much help in reducing conservatism (see the numerical example in section 6).

Throughout the rest of this paper, the norm minimization problem defined in (7) is replaced with

$$\min_{\mathcal{F}_0} \rho_p\left(\mathcal{F}_0\right), \tag{21}$$

where the function ρ_p is a *guaranteed cost* function, that is, it satisfies the inequality

$$\|H_{we}(z; \mathcal{F}_0 + \Delta_{\mathcal{F}})\|_p \leq \rho_p(\mathcal{F}_0) \quad \forall \Delta_{\mathcal{F}} \in \mathbb{F}_{\mathcal{R}}(\mathcal{F}_0). \tag{22}$$

In other words, the function ρ_p is an upper bound to the H_p norm of the uncertain transfer function $H_{we}(z; \mathcal{F}_0 + \Delta_{\mathcal{F}})$ that holds for all $\Delta_{\mathcal{F}} \in \mathbb{F}_{\mathcal{R}}(\mathcal{F}_0)$.

[1] Notice that when $\mathcal{R}$ is a scalar it can be canceled on both sides of (17) and (18).

4. Main result. We are not aware of any available design technique that can effectively solve the filter design problems stated in the previous section, where the filter parameter is subject to uncertainties $\Delta_{\mathcal{F}} \in \mathbb{F}_{\mathcal{R}}(\mathcal{F}_0)$. In the following paragraphs we will show that a much simpler design problem, that is, one that can be stated as a set of LMI, can be obtained if uncertainties are introduced in the transformed set of parameters $\mathcal{K}$ defined in (8). That is, we will consider the filter design problem, where the transformed set of parameters $\mathcal{K}$ is perturbed as

$$\mathcal{K} = \mathcal{K}_0 + \Delta_{\mathcal{K}}, \qquad \Delta_{\mathcal{K}} \in \mathbb{F}_{\mathcal{W}}(\mathcal{K}_0), \tag{23}$$

where the scaling $\mathcal{W}$ will be chosen to maintain equivalence between $\mathbb{F}_{\mathcal{R}}(\mathcal{F}_0)$ and $\mathbb{F}_{\mathcal{W}}(\mathcal{K}_0)$. More specifically, $\mathcal{W}$ will be chosen to ensure that we can find the optimal solution to problem (21)–(22) by solving an equivalent but simpler problem, where the perturbations act on the transformed set of filter variables. This is made possible due to the result in the following lemma.

LEMMA 3. *Let $\mathcal{S}$ and $\mathcal{T}$ be any square and nonsingular matrices of appropriate dimensions. Then $\Delta_{\mathcal{F}} \in \mathbb{F}_{\mathcal{R}}(\mathcal{F}_0)$ if and only if $\mathcal{S}\Delta_{\mathcal{F}}\mathcal{T} \in \mathbb{F}_{\mathcal{S}\mathcal{R}\mathcal{S}^T}(\mathcal{S}\mathcal{F}_0\mathcal{T})$.*

Proof. The proof follows immediately from using the assumption that matrices $\mathcal{S}$ and $\mathcal{T}$ are nonsingular and properly factorizing the variables and matrices appearing in the definition of $\mathbb{F}_{\mathcal{R}}(\mathcal{F}_0)$. □

Lemma 3 deserves two remarks. The first is that it makes explicit how the scaling matrix $\mathcal{W}$ must be chosen to cope with the one to one change of variables in the form $\mathcal{K} = \mathcal{S}\mathcal{F}\mathcal{T}$ that will be used to parameterize the transformed set of filter parameters. Notice that the corresponding "transformed" scaling $\mathcal{W} = \mathcal{S}\mathcal{R}\mathcal{S}^T$ depends exclusively on $\mathcal{S}$. Second, equivalence between $\mathbb{F}_{\mathcal{R}}(\mathcal{F}_0)$ and $\mathbb{F}_{\mathcal{W}}(\mathcal{K}_0)$ is achieved when the change of variables is performed simultaneously on the nominal filter $\mathcal{F}_0$ and on the parametric uncertainty $\Delta_{\mathcal{F}}$. These properties enables us to determine a solution to problem (21) by equivalently rewriting the inequality that defines the guaranteed cost function (22) in the form

$$\|H_{we}(z; \mathcal{K}_0 + \Delta_{\mathcal{K}})\|_p \le \rho_p(\mathcal{K}_0) \quad \forall \Delta_{\mathcal{K}} \in \mathbb{F}_{\mathcal{S}\mathcal{R}\mathcal{S}^T}(\mathcal{K}_0), \tag{24}$$

which is expressed entirely in terms of the transformed variables $(\mathcal{K}_0, \Delta_{\mathcal{K}}) = (\mathcal{S}\mathcal{F}_0\mathcal{T}, \mathcal{S}\Delta_{\mathcal{F}}\mathcal{T})$. Notice that the assumption that $\mathcal{S}$ and $\mathcal{T}$ are nonsingular and square matrices is naturally satisfied whenever the order of the filter is the same as the order of the plant.

In the following lemma we develop an inequality associated with a perturbation on the transformed set of parameters $\mathcal{K}$. This inequality will be used to derive the main result of this paper.

LEMMA 4. *If there exists a symmetric and positive definite matrix $\mathcal{W}$ such that*

$$\begin{bmatrix} \mathcal{Q} + \mathcal{B}\mathcal{K}_0\mathcal{C} + \mathcal{C}^T\mathcal{K}_0^T\mathcal{B}^T - \mathcal{B}\mathcal{W}\mathcal{B}^T & \gamma\mathcal{C}^T\mathcal{K}_0^T \\ \gamma\mathcal{K}_0\mathcal{C} & \mathcal{W} \end{bmatrix} > 0, \tag{25}$$

then

$$\mathcal{Q} + \mathcal{B}\left(\mathcal{K}_0 + \Delta_{\mathcal{K}}\right)\mathcal{C} + \mathcal{C}^T\left(\mathcal{K}_0 + \Delta_{\mathcal{K}}\right)^T\mathcal{B}^T > 0 \quad \forall\, \Delta_{\mathcal{K}} \in \mathbb{F}_{\mathcal{W}}(\mathcal{K}_0). \tag{26}$$

Proof. Applying the Schur complement on (25), one obtains that for all $\Delta_{\mathcal{K}} \in \mathbb{F}_{\mathcal{W}}(\mathcal{K}_0)$,

$$\begin{aligned} \mathcal{Q} + \mathcal{B}\mathcal{K}_0\mathcal{C} + \mathcal{C}^T\mathcal{K}_0^T\mathcal{B}^T &> \mathcal{B}\mathcal{W}\mathcal{B}^T + \gamma^2\mathcal{C}^T\mathcal{K}_0^T\mathcal{W}^{-1}\mathcal{K}_0\mathcal{C} \\ &> \mathcal{B}\mathcal{W}\mathcal{B}^T + \mathcal{C}^T\Delta_{\mathcal{K}}^T\mathcal{W}^{-1}\Delta_{\mathcal{K}}\mathcal{C} \\ &> -\mathcal{B}\Delta_{\mathcal{K}}\mathcal{C} - \mathcal{C}^T\Delta_{\mathcal{K}}^T\mathcal{B}^T, \end{aligned}$$

which recovers (26). □

The condition stated in the above lemma is only sufficient. Yet it has been extensively used in the filtering and control to characterize computable robustness conditions as, for instance, in [12, 21]. However, notice that the scaling matrix $\mathcal{W}$ enters the above condition linearly so that is can be freely optimized. This will help reduce the conservatism of this condition.

The above two lemmas will be combined to show that the optimal solution to the problem (21) subject to the transformed guaranteed cost function (24), for $p = \{2, \infty\}$, can be formulated and solved in terms of LMI conditions. We first consider the case when the multiplier $\mathcal{R}$ is a free optimization variable.

THEOREM 1 (H_2 filtering). *If there exist matrices G and $\mathcal{K}_0$, partitioned as in* (8)*, and symmetric matrices Y, Z, W, E, H such that the LMI*

$$\begin{bmatrix} Z & \bullet & \bullet & \bullet & \bullet & \bullet & \bullet \\ Z & Y-H & \bullet & \bullet & \bullet & \bullet & \bullet \\ A^TZ & A^TY+C_y^TF^T+Q^T & Z & \bullet & \bullet & \bullet & \bullet \\ A^TZ & A^TY+C_y^TF^T & Z & Y & \bullet & \bullet & \bullet \\ B^TZ & B^TY+D_y^TF^T & \mathbf{0} & \mathbf{0} & \mathbf{I} & \bullet & \bullet \\ \mathbf{0} & \mathbf{0} & \gamma RC_y+\gamma L & \gamma RC_y & \gamma RD_y & E & \bullet \\ \mathbf{0} & \mathbf{0} & \gamma FC_y+\gamma Q & \gamma FC_y & \gamma FD_y & G^T & H \end{bmatrix} > 0, \tag{27}$$

$$\begin{bmatrix} W-E & \bullet & \bullet & \bullet & \bullet & \bullet \\ C_z^T-C_y^TR^T-L^T & Z & \bullet & \bullet & \bullet & \bullet \\ C_z^T-C_y^TR^T & Z & Y & \bullet & \bullet & \bullet \\ D_z^T-D_y^TR^T & \mathbf{0} & \mathbf{0} & \mathbf{I} & \bullet & \bullet \\ \mathbf{0} & \gamma RC_y+\gamma L & \gamma RC_y & \gamma RD_y & E & \bullet \\ \mathbf{0} & \gamma FC_y+\gamma Q & \gamma FC_y & \gamma FD_y & G^T & H \end{bmatrix} > 0, \tag{28}$$

$$\operatorname{trace}(W) < \mu \tag{29}$$

have a feasible solution, then the nominal filter

$$\mathcal{F}_0 = \begin{bmatrix} \mathbf{I} & \mathbf{0} \\ \mathbf{0} & V^{-1} \end{bmatrix} \mathcal{K}_0 \begin{bmatrix} \mathbf{I} & \mathbf{0} \\ \mathbf{0} & Z^{-1}U^{-1} \end{bmatrix}, \tag{30}$$

where U and V are nonsingular otherwise arbitrary matrices chosen to satisfy $Y + VUZ = Z$, is such that

$$\|H_{we}(z; \mathcal{F}_0 + \Delta_{\mathcal{F}})\|_2^2 \le \rho_2(\mathcal{F}_0) := \mu \quad \forall \Delta_{\mathcal{F}} \in \mathbb{F}_{\mathcal{R}}(\mathcal{F}_0), \tag{31}$$

where $\mathbb{F}_{\mathcal{R}}(\mathcal{F}_0)$ is as defined in (17) *with the scaling matrix*

$$\mathcal{R} := \begin{bmatrix} \mathbf{I} & \mathbf{0} \\ \mathbf{0} & V^{-1} \end{bmatrix} \begin{bmatrix} E & G \\ G^T & H \end{bmatrix} \begin{bmatrix} \mathbf{I} & \mathbf{0} \\ \mathbf{0} & V^{-T} \end{bmatrix}. \tag{32}$$

Proof. Defining

$$\Delta_{\mathcal{K}} := \begin{bmatrix} \Delta_R & \Delta_L \\ \Delta_F & \Delta_Q \end{bmatrix}, \qquad \mathcal{S} := \begin{bmatrix} \mathbf{I} & \mathbf{0} \\ \mathbf{0} & V \end{bmatrix}, \qquad \mathcal{T} := \begin{bmatrix} \mathbf{I} & \mathbf{0} \\ \mathbf{0} & UZ \end{bmatrix},$$

the nominal filter parameters (30) and their parametric perturbations can be recovered from $(\mathcal{K}_0, \Delta_{\mathcal{K}})$, for U, V, and Z nonsingular, by the formulas

$$\mathcal{F}_0 = \mathcal{S}^{-1}\mathcal{K}_0\mathcal{T}^{-1}, \quad \Delta_{\mathcal{F}} = \mathcal{S}^{-1}\Delta_{\mathcal{K}}\mathcal{T}^{-1}.$$

Hence, it is possible to conclude from the result of Lemma 3 that the constraint $\Delta_{\mathcal{F}} \in \mathbb{F}_{\mathcal{R}}(\mathcal{F}_0)$ can be replaced without loss of generality by $\Delta_{\mathcal{K}} \in \mathbb{F}_{\mathcal{S}\mathcal{R}\mathcal{S}^T}(\mathcal{K}_0)$, as indicated in (24).

With that in mind, it suffices to show that (27)–(29) guarantee robustness with respect to all $\Delta_{\mathcal{K}} \in \mathbb{F}_{\mathcal{S}\mathcal{R}\mathcal{S}^T}(\mathcal{K}_0)$. This can be done with the help of Lemma 4. Notice that a perturbed version of (9), where $\mathcal{K}$ is replaced with $\mathcal{K}_0 + \Delta_{\mathcal{K}}$, can be written as (26) with

$$\mathcal{Q} := \begin{bmatrix} Z & Z & ZA & ZA & ZB \\ Z & Y & YA & YA & YB \\ A^TZ^T & A^TY^T & Z & Z & \mathbf{0} \\ A^TZ^T & A^TY^T & Z & Y & \mathbf{0} \\ B^TZ & B^TY & \mathbf{0} & \mathbf{0} & \mathbf{I} \end{bmatrix}, \quad \mathcal{B} := \begin{bmatrix} \mathbf{0} & \mathbf{0} \\ \mathbf{0} & \mathbf{I} \\ \mathbf{0} & \mathbf{0} \\ \mathbf{0} & \mathbf{0} \\ \mathbf{0} & \mathbf{0} \end{bmatrix}, \quad \mathcal{C}^T := \begin{bmatrix} \mathbf{0} & \mathbf{0} \\ \mathbf{0} & \mathbf{0} \\ C_y^T & \mathbf{I} \\ C_y^T & \mathbf{0} \\ D_y^T & \mathbf{0} \end{bmatrix},$$

while a perturbed inequality (10) is in the form (26) with

$$\mathcal{Q} := \begin{bmatrix} W & C_z & C_z & D_z \\ C_z^T & Z & Z & \mathbf{0} \\ C_z^T & Z & Y & \mathbf{0} \\ D_z^T & \mathbf{0} & \mathbf{0} & \mathbf{I} \end{bmatrix}, \qquad \mathcal{B} := \begin{bmatrix} \mathbf{I} & \mathbf{0} \\ \mathbf{0} & \mathbf{0} \\ \mathbf{0} & \mathbf{0} \\ \mathbf{0} & \mathbf{0} \end{bmatrix}, \qquad \mathcal{C}^T := -\begin{bmatrix} \mathbf{0} & \mathbf{0} \\ C_y^T & \mathbf{I} \\ C_y^T & \mathbf{0} \\ D_y^T & \mathbf{0} \end{bmatrix}.$$

Therefore we can define the variables

$$\begin{bmatrix} E & G \\ G^T & H \end{bmatrix} := \mathcal{S}\mathcal{R}\mathcal{S}^T = \mathcal{W}$$

to obtain both inequalities (27) and (28) directly from Lemma 4. □

THEOREM 2 (H_∞ filtering). *If there exist matrices G and $\mathcal{K}_0$, partitioned as in* (8)*, and symmetric matrices Y, Z, E, H such that the LMI*

(33)
$$\begin{bmatrix} Z & \bullet & \bullet & \bullet & \bullet & \bullet & \bullet & \bullet \\ Z & Y-H & \bullet & \bullet & \bullet & \bullet & \bullet & \bullet \\ A^TZ & A^TY + C_y^TF^T + Q^T & Z & \bullet & \bullet & \bullet & \bullet & \bullet \\ A^TZ & A^TY + C_y^TF^T & Z & Y & \bullet & \bullet & \bullet & \bullet \\ B^TZ & B^TY + D_y^TF^T & \mathbf{0} & \mathbf{0} & \mu\mathbf{I} & \bullet & \bullet & \bullet \\ \mathbf{0} & G & C_z - RC_y - L & C_z - RC_y & D_z - RD_y & \mu\mathbf{I} - E & \bullet & \bullet \\ \mathbf{0} & \mathbf{0} & \gamma RC_y + \gamma L & \gamma RC_y & \gamma RD_y & \mathbf{0} & E & \bullet \\ \mathbf{0} & \mathbf{0} & \gamma FC_y + \gamma Q & \gamma FC_y & \gamma FD_y & \mathbf{0} & G^T & H \end{bmatrix} > 0,$$

has a feasible solution, then the nominal filter $\mathcal{F}_0$ given in (30) *is such that*

$$\|H_{we}(z; \mathcal{F}_0 + \Delta_{\mathcal{F}})\|_\infty \le \rho_\infty(\mathcal{F}_0) := \mu \quad \forall \Delta_{\mathcal{F}} \in \mathbb{F}_{\mathcal{R}}(\mathcal{F}_0), \tag{34}$$

where $\mathbb{F}_{\mathcal{R}}(\mathcal{F}_0)$ is defined with the scaling matrix $\mathcal{R}$ given by (32).

Proof. This proof follows the same pattern as the proof of Theorem 1 and is thus omitted. □

The constraints stated in Theorems 1 and 2 are all LMI. The scalar μ can be used to define the guaranteed cost function (22). The global optimal solution to the guaranteed cost problem (21) can be obtained by minimizing the scalar μ subject to the given LMI.

It is interesting to observe that under the assumption that the scaling matrix $\mathcal{R}$ is a free variable, the filter provided by Theorem 1 shares with the one proposed

in [17] the property that its state space realization is irrelevant as far as the upper bound of the estimation error is concerned. As in Lemmas 1 and 2, the state space parameterization of the optimal filter obtained in Theorems 1 and 2 can be arbitrarily chosen by changing the matrices U and V. However, notice that, from (32), the choice of V does affect the multiplier $\mathcal{R}$. For instance, for the particular choice $V = \mathbf{I}$, the sets $\mathbb{F}_{\mathcal{R}}(\mathcal{F}_0) \equiv \mathbb{F}_{\mathcal{S}\mathcal{R}\mathcal{S}^T}(\mathcal{K}_0)$. Due to the coupling condition (32), this property does not remain valid when the scaling matrix is fixed. This special case is treated in detail in the following paragraphs.

When $\mathcal{R}$ is a given constant matrix, the variable V, which is associated with the choice of filter realization, becomes part of the optimization variables by the relation (32). In general, the introduction of (32) in the form of a constraint in the optimization design problem destroys the desired convexity properties. However, in the important case when $\mathcal{R}$ is a given matrix with the block diagonal structure

$$\bar{\mathcal{R}} = \begin{bmatrix} \bar{\mathcal{R}}_1 & \mathbf{0} \\ \mathbf{0} & \bar{\mathcal{R}}_2 \end{bmatrix}, \tag{35}$$

one can show that convexity is preserved, still leading to an LMI design problem. In this case, which is possibly the most meaningful for modeling implementation uncertainty, the following corollaries to Theorems 1 and 2 apply.

COROLLARY 3. *Let $\bar{\mathcal{R}}$ be partitioned as in* (35)*. If there exist a positive scalar λ, matrix $\mathcal{K}_0$, partitioned as in* (8)*, and symmetric matrices Y, Z, W, E, H such that the LMI* (27)–(29) *with the additional linear constraints*

$$E = \lambda \bar{\mathcal{R}}_1, \quad G = \mathbf{0}, \tag{36}$$

have a feasible solution, then the nominal filter $\mathcal{F}_0$ given in (30) *with*

$$V = \lambda^{-1/2} H^{1/2} \bar{\mathcal{R}}_2^{-1/2}$$

is such that $\|H_{we}(z; \mathcal{F}_0 + \Delta_{\mathcal{F}})\|_2^2 \leq \rho_2(\mathcal{F}_0) := \mu$ for all $\Delta_{\mathcal{F}} \in \mathbb{F}_{\bar{\mathcal{R}}}(\mathcal{F}_0)$.

COROLLARY 4. *Let $\bar{\mathcal{R}}$ be partitioned as in* (35)*. If there exist a positive scalar λ, matrix $\mathcal{K}_0$, partitioned as in* (8)*, and symmetric matrices Y, Z, E, H such that the LMI* (33) *with the additional linear constraints* (36) *has a feasible solution, then the nominal filter $\mathcal{F}_0$ given in* (30) *with $V = \lambda^{-1/2} H^{1/2} \bar{\mathcal{R}}_2^{-1/2}$ is such that $\|H_{we}(z; \mathcal{F}_0 + \Delta_{\mathcal{F}})\|_\infty \leq \rho_\infty(\mathcal{F}_0) := \mu$ for all $\Delta_{\mathcal{F}} \in \mathbb{F}_{\bar{\mathcal{R}}}(\mathcal{F}_0)$.*

Proof. Corollaries 3 and 4 can be proved in the same way. If $\mathcal{R} = \lambda \bar{\mathcal{R}}$, given in (35), then from (32) and (36) we have that

$$V^{-1} H V^{-T} = \lambda \bar{\mathcal{R}}_2,$$

which is satisfied by the choice of $V = \lambda^{-1/2} H^{1/2} \bar{\mathcal{R}}_2^{-1/2}$. Also notice that $\mathbb{F}_{\bar{\mathcal{R}}}(\mathcal{F}_0) = \mathbb{F}_{\lambda \bar{\mathcal{R}}}(\mathcal{F}_0)$. ∎

In Corollaries 3 and 4, the matrix V (and, consequently, matrix U) is automatically chosen by the optimization problem and cannot be picked by the designer, as in Theorems 1 and 2. This implies that the state space realization of the optimal filter is obtained as a result of the optimization procedure. In this sense, Theorems 1 and 2 simultaneously design the optimal filter transfer function *and* its realization. This result is in accordance with the well-known fact that some realizations of the same filter transfer function can be better than others for implementation [1, 2].

Also notice that, as in [17, 15], all of the above results can be shown to reduce to the standard Kalman filter and to the central H_∞ filter when $\gamma = 0$. In fact, with

$\gamma = 0$ the scaling matrices E, G, and H can be set arbitrarily close to zero, reducing these inequalities to the ones given in [17].

An interesting comment on the technical device used to prove Theorems 1 and 2 is that, to the authors' knowledge, it is the first time that a filtering or control robustness property has been derived directly from the transformed inequalities given in Lemmas 1 and 2. The robustness analysis was performed with respect to the transformed set of filter parameters $\mathcal{K}$ instead of the actual filter parameters $\mathcal{F}$. Working with the transformed parameters $\mathcal{K}$ instead of $\mathcal{F}$ was the key that permitted us to both incorporate and keep the scaling matrix $\mathcal{R}$ as an extra variable in the obtained design inequalities.

5. Extension to plant parameter uncertainty. In this section the assumption that the plant parameters are exactly known is relaxed. Following [17], the plant parameters, collected in the matrix

$$\mathcal{M} := \begin{bmatrix} A & B \\ C_z & D_z \\ C_y & D_y \end{bmatrix}, \tag{37}$$

are allowed to be unknown but to belong to the convex hull of N given extreme matrices (see [22]). That is,

$$\mathcal{M} \in \mathbb{M} := \operatorname{co}\left\{ \mathcal{M}_i := \begin{bmatrix} A_i & (B)_i \\ (C_z)_i & (D_z)_i \\ (C_y)_i & (D_y)_i \end{bmatrix}, \quad i = 1, \dots, N \right\}. \tag{38}$$

The goal is to derive design procedures that enable one to take into account the filter parameter uncertainty as well as the plant parameter uncertainty. This can be done by defining guaranteed cost functions that satisfy the general inequality

$$\|H_{we}(z; \mathcal{F}_0 + \Delta_{\mathcal{F}}, \mathcal{M})\|_p \le \rho_p(\mathcal{F}_0) \qquad \forall\, \Delta_{\mathcal{F}} \in \mathbb{F}_{\mathcal{R}}(\mathcal{F}_0) \quad \forall\, \mathcal{M} \in \mathbb{M}. \tag{39}$$

In the case of plant parametric uncertainty, the uncertain transfer function $H_{we}(z; \mathcal{F}_0 + \Delta_{\mathcal{F}}, \mathcal{M})$ depends on both the filter perturbation $\Delta_{\mathcal{F}}$ and the uncertain plant parameters $\mathcal{M}$. The guaranteed cost ρ_p provides an upper bound to the H_p norm of $H_{we}(z; \mathcal{F}_0 + \Delta_{\mathcal{F}}, \mathcal{M})$, which holds for all $\Delta_{\mathcal{F}} \in \mathbb{F}_{\mathcal{R}}(\mathcal{F}_0)$ *and* all $\mathcal{M} \in \mathbb{M}$. Following [17, 22], a guaranteed cost function ρ_2 can be built by generating N copies of the LMI (27)–(29) whose plant parameters correspond to those of $\mathcal{M}_i$, $i = 1, \dots, N$. The same procedure can be applied to generate ρ_∞ from appropriate versions of the inequalities given in Theorem 2.

The rationale behind this procedure is that the LMI (27)–(29) and (33) are all affine on the parameters of the uncertain matrix $\mathcal{M}$. Therefore, a convex combination of feasible inequalities (27)–(29) and (33) can be used to generate appropriate feasible inequalities for each $M \in \mathbb{M}$ (see [17, 22]). It is also straightforward to generate robust filtering conditions, which use a parameter dependent Lyapunov function to test stability following the methods of [18, 19]. The derivation of these extensions and the corresponding LMI conditions are left to the interested reader.

6. Numerical example. Consider the system in the form (1)–(3) with matrices

$$\left[\begin{array}{c|c} A & B \\ \hline C_z & D_z \\ \hline C_y & D_y \end{array}\right] = \left[\begin{array}{cc|ccc} 0.8 & 0.9 & 1 & 0 & 0 \\ 0.3 & -0.5 & 0 & 1 & 0 \\ \hline 1 & 1 & 0 & 0 & 0 \\ \hline 1 & 0 & 0 & 0 & 1 \end{array}\right].$$

TABLE 1

Design II	1.39	1.94	3.29	1.68	3.67	5.65	7.00	0.00	0.00

In the next sections we will design filters $\mathcal{F}_0$ to minimize an upper bound to the H_p norm, $p = \{2, \infty\}$, of $H_{we}(z; \mathcal{F}_0 + \Delta_{\mathcal{F}})$, where $\Delta_{\mathcal{F}} \in \mathbb{F}_{\mathcal{R}}(\mathcal{F}_0)$ for the values of $\gamma = \{0.01, 0.05, 0.1\}$.

6.1. H_2 filtering. A standard stationary Kalman filter has been designed to serve as a template for the H_2 filtering design. The transfer function $\mathcal{F}_{\mathrm{K}}(z)$ of the Kalman filter is given by

$$\mathcal{F}_{\mathrm{K}}(z) = \frac{0.58z(z+0.96)}{(z-0.38)(z+0.52)}.$$

The following two H_2 filter design methods have been tried:

Design I: Minimize μ subject to the LMI (27)–(29) with a full variable scaling $\mathcal{R}$ (Theorem 1).

Design II: Minimize μ subject to the LMI (27)–(29) and the linear constraint (36) with a fixed scaling $\bar{\mathcal{R}} = \mathbf{I}$ (Corollary 3).

The transfer functions of Designs I and II are given in Table 1. These filters are associated with the performance measures given in Table 2. In this table the "Nominal cost" is the H_2 norm of $H_{we}(z; \mathcal{F}_0)$, and the "Guaranteed cost" is the square root of the value of μ obtained by solving the problems in Theorem 1 and Corollary 3. The "Round-off gain" shown in the third column of Table 2 is a measure that has not been directly optimized by solving the design problems of this paper. It was computed after determining the minimal round-off gain realizations for the designed filters according to [2, 5].

It is important to notice that the solution of the problems in Theorem 1 and Corollary 3 implies the simultaneous design of a filter realization. Moreover, if one is to use these results to compare performance with a given filter realization $\mathcal{F}$, it is necessary to impose an additional constraint relating $\mathcal{F}$ and $\mathcal{K}$. As noted before, such a relationship is nonlinear and destroys the convexity of the problem. For these reasons, and to be able to compare our results with other techniques, we have arbitrarily chosen $V = \mathbf{I}$, in which case the relationship between $\mathcal{F}$ and $\mathcal{K}$ becomes linear. This is, in a certain sense, equivalent to fixing the admissible filter realizations. Additionally, it also implies $\mathbb{F}_{\mathcal{R}}(\mathcal{F}_0) \equiv \mathbb{F}_{\mathcal{S}\mathcal{R}\mathcal{S}^T}(\mathcal{K}_0)$, which seems to be an appropriate choice for comparing a given realization to one obtained by the methods proposed in this paper.

TABLE 3
H_∞ filter transfer functions.

γ	0.01	0.05	0.1
Design III	$\frac{0.72(z+1.09)}{z+0.24}$	$\frac{1.16(z+0.57)}{z+0.51}$	$\frac{1.20(z+0.13)}{z+0.13}$
Design IV	$\frac{0.85(z+0.93)}{z+0.36}$	$\frac{1.11(z+0.73)}{z+0.60}$	$\frac{1.17(z+0.70)}{z+0.65}$

Using this idea, we have computed guaranteed cost for the standard Kalman filter. However, no results are shown in the table since the LMI in Theorem 1 and Corollary 3 become infeasible for $\gamma = 3.3\times10^{-4}$ and $\gamma = 1.2\times10^{-4}$, respectively. This is evidence of the importance of allowing the optimization to freely tune the filter realization.

Also notice that the optimal round-off gain realizations of the filters produced by Designs I and II have lower round-off gains than the optimal coordinates of the Kalman filter, although this measure of performance has not been directly optimized. This asserts the effectiveness of the uncertainty domain $\mathbb{F}_{\mathcal{R}}(\mathcal{F}_0)$ in producing *non-fragile* filters.

It is interesting to try to interpret the effect of the parameter perturbation on the performance measures and in the filter transfer functions. From Table 1, one can notice that, as the parameter uncertainty increases, the filter transfer function tends to a constant, with no dynamics. This trend can help explain why the round-off gains have decreased accordingly in Table 2. This effect is even accentuated in Design II, where the filter optimization has fewer parameters with which to play. It seems interesting that, to maximize the performance in the presence of an increasing implementation uncertainty, the designed filter has been made simpler by the design procedure.

6.2. H_∞ filtering. This time we have designed a standard H_∞ filter to serve as a template for the H_∞ filtering design. The transfer function $\mathcal{F}_{\rm H}(z)$ of the standard H_∞ filter is given by

$$\mathcal{F}_{\rm H}(z) = \frac{0.76(z+1.02)}{(z+0.29)}.$$

It is interesting to notice that the standard optimal H_∞ filter design already presents a pole-zero cancellation. In fact, this feature will be present in all designed filters. As before, two H_∞ filter design methods have been tried as follows:

Design III: Minimize μ subject to the LMI (33) with a full variable scaling $\mathcal{R}$ (Theorem 2).

Design IV: Minimize μ subject to the LMI (33) and the linear constraint (36) with a fixed scaling $\bar{\mathcal{R}} = \mathbf{I}$ (Corollary 4).

The transfer functions of Designs III and IV are given in Table 3 and their performance measures in Table 4. The guaranteed costs for the standard H_∞ filter have been computed by setting $V = \mathbf{I}$ and solving the design LMI for the given realization. The costs in the first line corresponds to the case when the scaling $\mathcal{R}$ has been optimized, whereas the costs in the second line have been obtained with $\bar{\mathcal{R}} = \mathbf{I}$.

The same trends observed in the H_2 filter design appear in the H_∞ design. Notice especially the tendency to simplify the filter by reducing it to a constant scaling. Interestingly enough, this tendency now appears more accentuated in Design III,

TABLE 4
H_∞ filtering performance.

	Nominal cost			Guaranteed cost			Round-off gain		
γ	0.01	0.05	0.1	0.01	0.05	0.1	0.01	0.05	0.1
H_∞	1.44	1.44	1.44	1.96 13.67	5.19 178.8	11.64 593.5	6.98	6.98	6.98
Design III	1.56	3.61	5.63	1.66	3.93	7.28	10.88	1.14	0.07
Design IV	1.68	3.67	5.65	1.75	4.89	7.82	7.00	0.00	0.00

TABLE 5
Actual H_2 filtering performance for the example in section 6.1.

γ	0.01	0.05	0.1
Kalman	1.36	1.55	2.13
Design II	1.42	2.05	3.59

where the scaling $\mathcal{R}$ has been allowed to be optimized. Notice again a significant reduction in the round-off gain.

6.3. Estimating conservativeness. In the previous section, the performances of the designed filters have been evaluated with respect to guaranteed cost functions, which are upper bounds to the norm of the filtering error system. In this section we attempt to access the filter performance by directly evaluating an estimate of the actual error system norms. The idea is to estimate the conservativeness of the method and to evaluate its practical usefulness. We restrict our attention to the case of H_2 filtering design with $\mathcal{R} = \mathbf{I}$.

For each filter design $\mathcal{F}_0$, we randomly generate a number of perturbation matrices $\Delta_{\mathcal{F}_j}$, $j = 1, \ldots, M$, in $\mathbb{F}_\mathcal{R}(\mathcal{F}_0)$. The following procedure was used in this generation:

1. Generate a square matrix Δ_j, with the same number of rows as in $\mathcal{F}_0$, where all entries are normally distributed random real numbers with zero mean and unitary variance.
2. Compute $\Delta_{\mathcal{F}j} = \frac{\gamma}{\|\Delta_j\|}\Delta_j\mathcal{F}_0$ and $\mathcal{F}_j = \mathcal{F}_0 + \Delta_{\mathcal{F}j}$.
3. If $\mathcal{F}_j$ is asymptotically stable, set $\sigma_j = \|H_{we}(z; \mathcal{F}_j)\|_2$; otherwise set $\sigma_j = \infty$.

All filter perturbations generated by the above procedure are guaranteed to be in the boundary of the set $\mathbb{F}_\mathcal{R}(\mathcal{F}_0)$, and an estimate of the error system norm can be computed as

$$\bar{\sigma} := \max_{j=1,\ldots,M} \sigma_j \approx \sup_{\Delta_\mathcal{F} \in \mathbb{F}_\mathcal{R}(\mathcal{F}_0)} \|H_{we}(z; \mathcal{F}_0 + \Delta_\mathcal{F})\|_2.$$

Strictly speaking, $\bar{\sigma}$ provides a lower bound to the error system norm, which serves as a good approximation for the worst case norm as M becomes large. In our experiments we have set $M = 1000$.

We start by evaluating the problem described in section 6.1. The results of the above numerical experiment applied to the filters previously labelled Kalman and Design II are shown in Table 5 for several values of γ. Note that the performance of Design II is, as expected, always below the designed guaranteed cost but, surprisingly, above the performance of the nominal Kalman filter design. We credit this apparently surprising behavior to a relative insensitivity of this particular example to variations on the filter parameters, rather than to an overconservativeness of our approach. We try to support this claim in the following paragraphs.

TABLE 6
Actual H_2 filtering performance for the second example in section 6.3.

	$\bar{\sigma}$		
γ	0.01	0.05	0.1
Kalman	1.30	∞	∞
Corollary 3	1.28	1.35	1.43

The previous example might leave the impression that the proposed design procedure produces robust filters at the expense of sacrificing performance; this impression is possibly due to the implicit conservativeness in the design inequalities. In order to show that the proposed procedure can indeed lead to efficient robust designs, we consider another simple example with

$$\left[\begin{array}{c|c} A & B \\ \hline C_z & D_z \\ \hline C_y & D_y \end{array}\right] = \left[\begin{array}{ccc|cc} 0 & 1 & 0 & 0 & 0 \\ 0 & 0 & 1 & 0 & 0 \\ -0.5 & 0.5 & 0.1 & 1 & 0 \\ \hline 1 & 0 & 0 & 0 & 0 \\ \hline -0.5 & 0.25 & 0.5 & 0 & 1 \end{array}\right].$$

For the above example, the Kalman filter has a nominal performance of $\|H_{we}(z;\mathcal{F}_0)\|_2 = 1.28$. The results of the above numerical experiment applied to the Kalman filter for several values of γ are shown in the first row of Table 6. These results show that the Kalman filter is extremely sensitive to parameter variations: a relative perturbation of size $\gamma = 0.01$ already implies some loss of performance but, more important, for higher values of γ, the Kalman filter becomes unstable (indicated as an infinite cost). This highly sensitive system seems to provide a better benchmark for our design methodology. After computing the robust filters using Corollary 3, we run the numerical experiment and obtain the performance estimate shown in the second row of Table 6. In this example, the design procedure not only produced a filter, which performs as efficiently as the nominal Kalman filter for $\gamma = 0.01$, but also produced robust filters for $\gamma = 0.05$ and $\gamma = 0.1$, which were able to withstand large parameter perturbations without becoming unstable and without sacrificing too much performance.

In the above example, an aspect that might have contributed to the sensitivity of the Kalman filter to parameter variations is the increased order of the filter. Generally speaking, it seems natural to expect that state space realizations of filters become more sensitive to parameter variations as the order of the filter (and the associated matrix dimensions) increases. In order to verify this trend we modify the system used in section 6.1 to augment its order. More specifically, we introduce a delay on the measurement signal $y(k)$. This produces the third order system

$$\left[\begin{array}{c|c} A & B \\ \hline C_z & D_z \\ \hline C_y & D_y \end{array}\right] = \left[\begin{array}{ccc|ccc} 0.8 & 0.9 & 0 & 1 & 0 & 0 \\ 0.3 & -0.5 & 0 & 0 & 1 & 0 \\ 1 & 0 & 0 & 0 & 0 & 0 \\ \hline 1 & 1 & 0 & 0 & 0 & 0 \\ \hline 0 & 0 & 1 & 0 & 0 & 1 \end{array}\right].$$

Due to the introduction of the delay on the measurement, the Kalman filter now has a nominal performance of $\|H_{we}(z;\mathcal{F}_0)\|_2 = 1.72$.

Table 7 shows the results of the numerical experiment performed on both the nominal Kalman filter design and the filters produced by Corollary 3. Note that now

TABLE 7
Actual H_2 filtering performance for the example in section 6.1 with a measurement delay.

	$\bar{\sigma}$		
γ	0.01	0.05	0.1
Kalman	1.74	2.16	3.70
Corollary 3	1.75	2.15	3.62

the performances of the Kalman filter and the robust filter designed for $\gamma = 0.01$ are practically the same, whereas Corollary 3 produces filters that perform better than the Kalman filter for values of γ greater than 0.05. These results agree with the statement that we should expect the Kalman filter to become more sensitive to parameter variations as the order of the filter increases, in which case the procedure we have proposed provides an effective way to design robust filters.

Finally, note that the main source of conservatism in this design comes from the fact that the guaranteed cost functions we have used evaluate performance with respect to parameter perturbations $\Delta_{\mathcal{F}} \in \mathbb{F}_{\mathcal{R}}(\mathcal{F}_0)$, which are allowed to vary with time. Indeed, this explains the gap between the (time-varying) guaranteed cost values in Table 2 and the (time-invariant) values of $\bar{\sigma}$ in Table 5.

7. Conclusions. A new procedure has been proposed for designing filters which are robust in the presence of perturbations on the filter parameters. The filters are obtained by minimizing guaranteed H_2 and H_∞ cost functions developed by confining the filter parametric uncertainty in a region defined by a quadratic inequality. The size of this uncertainty region depends on the size of the filter parameters, and the maximum allowed parametric perturbation is specified as a percentage of the size of the filter gains. Both the transfer function and the realization of the robust filter are simultaneously designed. The optimization problems to be solved have constraints specified in terms of LMI, whose global optimal solutions can be determined using convex programming. The numerical examples suggest that the proposed technique may produce filters with reduced round-off noise gain, although this performance measure is not directly optimized in the design process.

STATE-SPACE FORMULAS FOR THE NEHARI–TAKAGI PROBLEM FOR NONEXPONENTIALLY STABLE INFINITE-DIMENSIONAL SYSTEMS*

JOSEPH A. BALL†, KALLE M. MIKKOLA‡, AND AMOL J. SASANE§

Abstract. We obtain state-space formulas for the solution of the Nehari–Takagi/suboptimal Hankel norm approximation problem for infinite-dimensional systems with a nonexponentially stable generator, via the method of J-spectral factorization. We make key use of a purely frequency-domain solution of the problem.

Key words. Nehari–Takagi problem, infinite-dimensional systems, state-space formulas

1. Introduction.

The Hankel norm approximation problem has received a lot of attention, both in the mathematical and engineering literature (see Adamjan, Arov, and Kreĭn [1], Ball and Helton [4], Ball and Ran [7], Glover [19], and Doyle, Glover, and Zhou [17]). Its importance in control theory is due to its connections with the model reduction problem (see [19]).

In order to state the suboptimal Hankel norm approximation problem, we will need a few preliminaries. First we recall the definition of the (frequency-domain) Hankel operator corresponding to a symbol $G \in L_\infty(i\mathbb{R}, \mathbb{C}^{p\times m})$ and the definition of its singular values. Let $\mathbb{C}_+ := \{s \in \mathbb{C} \mid \mathrm{Re}(s) > 0\}$ and $\mathbb{C}_- := \{s \in \mathbb{C} \mid \mathrm{Re}(s) < 0\}$.

Let $H_2(\mathbb{C}_+, \mathbb{C}^k)$ denote the set of all analytic functions $f : \mathbb{C}_+ \to \mathbb{C}^k$ such that

$$\|f\|_2 := \sup_{\zeta>0} \left(\frac{1}{2\pi} \int_{-\infty}^{\infty} \|f(\zeta + i\omega)\|^2 d\omega \right)^{\frac{1}{2}} < \infty.$$

Analogously one defines $H_2(\mathbb{C}_-, \mathbb{C}^k)$. For $G \in L_\infty(i\mathbb{R}, \mathbb{C}^{p\times m})$ we define the *Hankel operator with symbol* G, denoted by H_G, acting from $H_2(\mathbb{C}_-, \mathbb{C}^m)$ to $H_2(\mathbb{C}_+, \mathbb{C}^p)$, as follows:

$$H_G f = P_{H_2(\mathbb{C}_+, \mathbb{C}^p)}(M_G f) \quad \text{for } f \in H_2(\mathbb{C}_-, \mathbb{C}^m),$$

where M_G is the multiplication map on $L_2(i\mathbb{R}, \mathbb{C}^m)$ induced by G, and $P_{H_2(\mathbb{C}_+, \mathbb{C}^p)}$ is the orthogonal projection operator from $L_2(i\mathbb{R}, \mathbb{C}^p)$ onto $H_2(\mathbb{C}_+, \mathbb{C}^p)$. The Hankel operator is bounded, that is, $H_G \in \mathcal{L}(H_2(\mathbb{C}_-, \mathbb{C}^m), H_2(\mathbb{C}_+, \mathbb{C}^p))$.

Now we recall the notion of singular values of a bounded linear operator from a Hilbert space $\mathcal{H}_1$ to a Hilbert space $\mathcal{H}_2$. For $k \in \{1, 2, \dots\}$ the kth *singular value*

(denoted by $\sigma_k(\mathtt{H})$) of an operator $\mathtt{H} \in \mathcal{L}(\mathcal{H}_1, \mathcal{H}_2)$ is defined to be the distance with respect to the norm in $\mathcal{L}(\mathcal{H}_1, \mathcal{H}_2)$ of $\mathtt{H}$ from the set of operators in $\mathcal{L}(\mathcal{H}_1, \mathcal{H}_2)$ of rank at most $k-1$. Thus $\sigma_1(\mathtt{H}) = \|\mathtt{H}\|$, and $\sigma_1(\mathtt{H}) \geq \sigma_2(\mathtt{H}) \geq \sigma_3(\mathtt{H}) \geq \cdots \geq 0$. For $G \in L_\infty(i\mathbb{R}, \mathbb{C}^{p\times m})$, we refer to the singular values of H_G simply as the *Hankel singular values of* G.

Let $H_{\infty,k}(\mathbb{C}_-, \mathbb{C}^{p\times m})$ denote the set of all $p \times m$ matrix-valued functions K of a complex variable defined in the open left half-plane such that $K = G_{\mathtt{f}} + F$, where F is an element in $H_\infty(\mathbb{C}_-, \mathbb{C}^{p\times \mathtt{m}})$ and $G_{\mathtt{f}}$ is the transfer function of a finite-dimensional system with order at most k, with all its poles in the open left half-plane. The set $H_{\infty,k}(\mathbb{C}_-, \mathbb{C}^{p\times m})$ is a subset of $L_\infty(i\mathbb{R}, \mathbb{C}^{p\times m})$.

We recall the following well-known result of Adamjan, Arov, and Kreĭn [1], adapted here to the right half-plane setting: If $G \in L_\infty(i\mathbb{R}, \mathbb{C}^{p\times m})$, then

$$\inf_{K\in H_{\infty,k}(\mathbb{C}_-,\mathbb{C}^{p\times m})} \|G(i\cdot) + K(i\cdot)\|_\infty = \sigma_{k+1}(G).$$

We are now ready to give the statement of the suboptimal Hankel norm approximation problem, which is also known as the *Nehari–Takagi problem*. The *suboptimal Hankel norm approximation problem* is the following: Let $G(i\cdot) \in L_\infty(\mathbb{R}, \mathbb{C}^{p\times m})$. If $\sigma_{k+1} < \sigma < \sigma_k$, then find $K \in H_{\infty,k}(\mathbb{C}_-, \mathbb{C}^{p\times m})$ such that $\|G(i\cdot) + K(i\cdot)\|_\infty \leq \sigma$. In fact, the authors of [1], working with Schmidt pairs of the Hankel operator, also gave a linear-fractional description for the set of all solutions of the suboptimal Hankel norm approximation problem; later work of Ball and Helton [4] obtained such a linear-fractional description, but via an indefinite-metric Beurling–Lax theorem combined with some Kreĭn-space projective geometry.

Now suppose that G is in fact the transfer function of some well-posed linear system; that is, G is not simply an L_∞ function, but it has the special form $G(s) = C(sI - A)^{-1}B$, where (A, B, C) are the generators of the system. Then by a *state-space solution* to the suboptimal Hankel norm approximation problem we mean a K given explicitly in terms of the A, B, C operators. For the case of rational $G(s)$ with system-generators (A, B, C) equal to finite matrices, a state-space solution of the Hankel norm approximation problem has been obtained by Kung and Lin [29], Glover [19], Ball and Ran [7], and Ball, Gohberg, and Rodman [3, Chapter 20].

In Curtain and Sasane [14, 13], state-space solutions to the suboptimal Hankel norm approximation problem were given for two classes of infinite-dimensional state-linear systems, but under the assumption that A generates an *exponentially* stable, strongly continuous semigroup. Recall that a semigroup $\{T(t)\}_{t\geq 0}$ on a Hilbert space X is said to be exponentially stable if there exist positive constants M and ϵ such that

$$\|T(t)\| \leq Me^{-\epsilon t} \quad \text{for all } \ t \geq 0.$$

However, there exists an important class of systems with a transfer function $G \in H_\infty(\mathbb{C}_-, \mathbb{C}^{p\times m})$ for which A does not generate an exponentially stable semigroup (see, for example, Oostveen [33]), for example, if A is the generator of a *strongly stable semigroup*, that is, a semigroup satisfying

$$T(t)x \to 0 \ \text{ as } \ t \to \infty \quad \text{for all } \ x \in X.$$

Roughly speaking, the rate of convergence to zero is not uniform but depends on the choice of the element in the Hilbert space. An elementary example of a semigroup

which is strongly stable but not exponentially stable is given by e^{tA} on ℓ_2, where

$$A = \begin{bmatrix} -1 & & & & \\ & -\frac{1}{2} & & & \\ & & -\frac{1}{3} & & \\ & & & \ddots & \end{bmatrix} \in \mathcal{L}(\ell_2).$$

In this article, we consider an even weaker notion of stability, the so-called *nonexponentially stable semigroup*, namely, a semigroup whose generator has a nonnegative growth bound. Clearly this class encompasses both strongly stable semigroups and (hence surely) exponentially stable semigroups; thus we emphasize that the prefix "non" is really short for "not necessarily."

Earlier work on the problem for infinite-dimensional systems includes the work of Curtain and Ran [12], which handled the case of Pritchard–Salamon systems, and of Glover, Curtain, and Partington [20], where approximating solutions to the optimal Hankel norm approximation problem were obtained without assuming exponential stability, but only for the case that the Hankel operator is nuclear, a rather strong assumption. In this paper, we give solutions to the suboptimal Hankel norm approximation problem for infinite-dimensional systems having a nonexponentially stable semigroup. Our solution depends on a preliminary result which obtains the linear-fractional parameterization of the set of all solutions in purely frequency-domain terms via the solution Θ of a certain J-spectral factorization problem. The fact that Θ may be unbounded in our general setting makes the analysis much more delicate. We give three proofs of this key frequency-domain result in order to point out the close connections with results already existing in the literature. The first proof shows how the result can be reduced to the result of Adamjan, Arov, and Kreĭn in [1]. The second proof revisits the proof of Ball and Helton [4] with special care given to the details required to handle the general case where Θ may be unbounded. The third proof revisits the homotopy argument appearing in [3, 40]. The standard homotopy argument works well in case the coefficients of the linear-fractional parameterization and the free parameter are continuous up to the boundary. We show how an approximation argument can be used to reduce the general case here to the classical situation, at least for the proof that every admissible free parameter leads to a solution of the Nehari–Takagi problem. The proof that any solution of the Nehari–Takagi problem necessarily is of the linear-fractional form follows the ideas appearing in the second proof.

The outline of the paper is as follows. In section 2, we give the key frequency-domain result (the reduction of the parameterization of the set of all solutions of the suboptimal Hankel norm approximation problem to solving a certain J-spectral factorization problem), along with our three proofs of this result. In section 3 we use this frequency-domain result to parameterize all solutions to the suboptimal Hankel norm approximation problem for infinite-dimensional state-space systems for which the generator is not necessarily exponentially stable. Finally in the last section, we give state-space solutions for well-posed linear systems by applying the result in section 3 to the associated reciprocal system.

2. The key frequency-domain result.

THEOREM 2.1. *Let $G \in H_\infty(\mathbb{C}_+, \mathbb{C}^{p\times m})$ and let $H_G\colon H_2(\mathbb{C}_-, \mathbb{C}^m) \mapsto H_2(\mathbb{C}_+, \mathbb{C}^p)$ denote the corresponding Hankel operator, with the singular values $\sigma_1 \geq \sigma_2 \geq \cdots (\geq 0)$. Suppose that $\sigma_k > \sigma > \sigma_{k+1}$. Then there exists a matrix function $\Lambda\colon \mathbb{C}_- \mapsto$*

$\mathbb{C}^{(p+m)\times(p+m)}$, *uniquely determined up to a* $(p+m)\times(p+m)$*-matrix right constant factor* U *satisfying* $U^*\left[\begin{smallmatrix} I_p & 0 \\ 0 & -I_m \end{smallmatrix}\right]U = \left[\begin{smallmatrix} I_p & 0 \\ 0 & -I_m \end{smallmatrix}\right]$, *such that*

S1. $\Lambda(i\omega)^*\left[\begin{smallmatrix} I_p & 0 \\ 0 & -I_m \end{smallmatrix}\right]\Lambda(i\omega) = \left[\begin{smallmatrix} I_p & G(i\omega) \\ 0 & I_m \end{smallmatrix}\right]^*\left[\begin{smallmatrix} I_p & 0 \\ 0 & -\sigma^2 I_m \end{smallmatrix}\right]\left[\begin{smallmatrix} I_p & G(i\omega) \\ 0 & I_m \end{smallmatrix}\right]$ *for* $\omega \in \mathbb{R}$;

S2. $\frac{1}{\cdot - 1}\Lambda \in H_2(\mathbb{C}_-, \mathbb{C}^{(p+m)\times(p+m)})$;

S3. Λ *is invertible* (*i.e., there exists a* $V\colon \mathbb{C}_- \mapsto \mathbb{C}^{(p+m)\times(p+m)}$ *such that* $\Lambda(s)V(s) = I_{p+m}$ *for* $s \in \mathbb{C}_-$) *and* $\frac{1}{\cdot - 1}V \in H_2(\mathbb{C}_-, \mathbb{C}^{(p+m)\times(p+m)})$.

Define

$$\Theta(i\omega)\left(= \begin{bmatrix} \Theta_{11}(i\omega) & \Theta_{12}(i\omega) \\ \Theta_{21}(i\omega) & \Theta_{22}(i\omega) \end{bmatrix}\right) = \begin{bmatrix} I_p & G(i\omega) \\ 0 & I_m \end{bmatrix} V(i\omega) \quad \text{for } \omega \in \mathbb{R}.$$

Then we have the following: $K\colon \mathbb{C}_- \mapsto \mathbb{C}^{p\times m}$ *such that* $K \in H_{\infty,k}(\mathbb{C}_-, \mathbb{C}^{p\times m})$ *and* $\|G(i\cdot) + K(i\cdot)\|_\infty \le \sigma$ *if and only if*

(2.1)
$$G(i\omega) + K(i\omega) = (\Theta_{11}(i\omega)Q(i\omega) + \Theta_{12}(i\omega))(\Theta_{21}(i\omega)Q(i\omega) + \Theta_{22}(i\omega))^{-1} \quad \text{for } \omega \in \mathbb{R}$$

for some $Q\colon \mathbb{C}_- \mapsto \mathbb{C}^{p\times m}$ *such that* $Q \in H_\infty(\mathbb{C}_-, \mathbb{C}^{p\times m})$ *and* $\|Q(i\cdot)\|_\infty \le 1$.

For the application of Theorem 2.1 in section 3, we note that a sufficient condition for the validity of S2 is the existence of a constant $\Lambda(\infty) \in \mathbb{C}^{(p+m)\times(p+m)}$ such that $\Lambda - \Lambda(\infty) \in H_2(\mathbb{C}_-, \mathbb{C}^{(p+m)\times(p+m)})$.

By using the transformation

$$f(s) \mapsto \widetilde{f}(z) := f\left(\frac{1-z}{1+z}\right)$$

and observing (via the Jacobi change-of-variable formula) that

$$\int_{\mathbb{T}} |\widetilde{f}(z)|^2 \, |dz| = \int_{i\mathbb{R}} |f(s)|^2 \, \frac{|ds|}{1+|s|^2},$$

we see that Theorem 2.1 is exactly equivalent to the following discrete-time version. Here $\mathbb{D}$ denotes the unit disk, $\mathbb{D}_e$ denotes the exterior of the unit disk (including the point at infinity), and $\mathbb{T}$ denotes the unit torus (equal to the boundary of $\mathbb{D}$).

THEOREM 2.2. *Let* $G \in H_\infty(\mathbb{D}_e)$ *and let* $H_G\colon H_2(\mathbb{D}, \mathbb{C}^m) \mapsto H_2(\mathbb{D}, \mathbb{C}^p)^\perp$ *be the associated Hankel operator, with singular values* $\sigma_1 \ge \sigma_2 \ge \cdots (\ge 0)$. *Suppose that* $\sigma_k > \sigma > \sigma_{k+1}$. *Then there exists a unique matrix function* $\Lambda\colon \mathbb{D} \mapsto \mathbb{C}^{(p+m)\times(p+m)}$, *uniquely determined up to a* $(p+m)\times(p+m)$*-matrix right constant factor* U *satisfying* $U^*\left[\begin{smallmatrix} I_p & 0 \\ 0 & -I_m \end{smallmatrix}\right]U = \left[\begin{smallmatrix} I_p & 0 \\ 0 & -I_m \end{smallmatrix}\right]$, *such that*

S′1. $\Lambda(\zeta)^*\left[\begin{smallmatrix} I_p & 0 \\ 0 & -I_m \end{smallmatrix}\right]\Lambda(\zeta) = \left[\begin{smallmatrix} I_p & G(\zeta) \\ 0 & I_m \end{smallmatrix}\right]^*\left[\begin{smallmatrix} I_p & 0 \\ 0 & -\sigma^2 I_m \end{smallmatrix}\right]\left[\begin{smallmatrix} I_p & G(\zeta) \\ 0 & I_m \end{smallmatrix}\right]$ *for* $\zeta \in \mathbb{T}$;

S′2. $\Lambda \in H_2(\mathbb{D}, \mathbb{C}^{(p+m)\times(p+m)})$;

S′3. Λ *is invertible* (*i.e., there exists a* $V\colon \mathbb{D} \mapsto \mathbb{C}^{(p+m)\times(p+m)}$ *such that* $\Lambda(z)V(z) = I_{p+m}$ *for* $z \in \mathbb{D}$) *and* $V \in H_2(\mathbb{D}, \mathbb{C}^{(p+m)\times(p+m)})$.

Define

$$\Theta(\zeta)\left(= \begin{bmatrix} \Theta_{11}(\zeta) & \Theta_{12}(\zeta) \\ \Theta_{21}(\zeta) & \Theta_{22}(\zeta) \end{bmatrix}\right) = \begin{bmatrix} I_p & G(\zeta) \\ 0 & I_m \end{bmatrix} V(\zeta) \quad \text{for } \zeta \in \mathbb{T}. \tag{2.2}$$

Then we have the following: $K\colon \mathbb{D} \mapsto \mathbb{C}^{p\times m}$ *is such that* $K \in H_{\infty,k}(\mathbb{D}, \mathbb{C}^{p\times m})$ *and* $\|(G+K)|_{\mathbb{T}}\|_\infty \le \sigma$ *if and only if*

$$G(\zeta) + K(\zeta) = (\Theta_{11}(\zeta)Q(\zeta) + \Theta_{12}(\zeta))(\Theta_{21}(\zeta)Q(\zeta) + \Theta_{22}(\zeta))^{-1} \quad \text{for } \zeta \in \mathbb{T} \tag{2.3}$$

for some $Q\colon \mathbb{D} \mapsto \mathbb{C}^{p\times m}$ *such that* $Q \in H_\infty(\mathbb{D}, \mathbb{C}^{p\times m})$ *and* $\|Q\|_\infty \le 1$.

We next indicate several proofs of Theorem 2.2 based on various different points of view. We first need to lay out a few preliminaries.

2.1. Preliminaries. For p and m positive integers we let $\mathbb{C}^{p\times m}$ be the space of complex $p \times m$ matrices M with norm $\|M\|$ equal to the induced operator norm:

$$\|M\| = \sup_{x\in\mathbb{C}^m:\ \|x\|_2\le 1} \|Mx\|_2,$$

where $\|x\|_2$ is the standard Euclidean 2-norm on $\mathbb{C}^m$. The trace norm $\mathrm{Tr}(M)$ of a $p \times m$ matrix M is defined by

$$\mathrm{Tr}(M) = \mathrm{tr}(M^*M)^{1/2},$$

where the *trace* $\mathrm{tr}(A)$ of an $m \times m$ matrix A is defined by

$$\mathrm{tr}(A) = \sum_{k=1}^{p} \langle Ae_k, e_k\rangle,$$

where $\{e_1, \dots, e_n\}$ is any orthonormal basis for $\mathbb{C}^p$—a good reference for the natural infinite-dimensional setting for this material is [21, Chapter VII]. We let $L_\infty(\mathbb{T}, \mathbb{C}^{p\times m})$ denote the space of measurable $p \times m$ matrix-valued functions on the unit circle $\mathbb{T}$ with finite essential supremum (supremum up to sets of measure zero) norm uniformly bounded:

$$\|F\|_\infty = \operatorname*{ess\text{-}sup}_{\zeta\in\mathbb{T}} \|F(\zeta)\| < \infty.$$

We let $L_1(\mathbb{T}, \mathbb{C}^{m\times p})$ be the space of measurable $m \times p$ matrix-valued functions f on $\mathbb{T}$ with integrable trace norm:

$$\|f\|_1 = \frac{1}{2\pi}\int_{\mathbb{T}} \mathrm{Tr}(f(\zeta))|d\zeta|.$$

It is well known (see, e.g., [38, page 197]) that the Banach space $L_\infty(\mathbb{T}, \mathbb{C}^{p\times m})$ can be identified as the dual of the Banach space $L_1(\mathbb{T}, \mathbb{C}^{m\times p})$ under the duality pairing

$$[F, f] = \frac{1}{2\pi}\int_{\mathbb{T}} \mathrm{tr}(F(\zeta)f(\zeta))\ d|\zeta| \quad \text{for } F \in L_\infty(\mathbb{T}, \mathbb{C}^{p\times m}) \text{ and } f \in L_1(\mathbb{T}, \mathbb{C}^{m\times p}).$$

Therefore, in addition to its norm topology, $L_\infty(\mathbb{T}, \mathbb{C}^{p\times m})$ carries a *weak-$*$ topology* induced by its duality with respect to $L_1(\mathbb{T}, \mathbb{C}^{p\times m})$. We shall have use of the following facts concerning this weak-$*$ topology.

Proposition 2.3.

(1) *A subspace $\mathcal{S}$ of $L_\infty(\mathbb{T}, \mathbb{C}^{p\times m})$ is closed in the weak-$*$ topology of $L_\infty(\mathbb{T}, \mathbb{C}^{p\times m})$ if and only if whenever $\{F_n\}_{n=1,2,\dots}$ is a sequence of elements of $\mathcal{S}$ converging weak-$*$ to $F \in L_\infty(\mathbb{T}, \mathbb{C}^{p\times m})$, then in fact $F \in \mathcal{S}$.*

(2) *Suppose that $\{F_n\}_{n=1,2,\dots}$ is a sequence of elements of $L_\infty(\mathbb{T}, \mathbb{C}^{p\times m})$ converging* pointwise boundedly *to the element $F \in L_\infty(\mathbb{T}, \mathbb{C}^{p\times m})$, i.e.,*

$$\lim_{n\to\infty} F_n(\zeta) = F(\zeta) \quad \text{for almost all } \zeta \in \mathbb{T}, \text{ and}$$
$$\|F_n(\zeta)\| \le M \quad \text{for some } M < \infty \text{ for all } n = 1, 2, \dots.$$

Then F_n converges to F in the weak-$*$ topology of $L_\infty(\mathbb{T}, \mathbb{C}^{p\times m})$.

Proof. By the Kreĭn–Šmulian theorem (see [42, Theorem 10.1, page 173]), a subspace $\mathcal{S}$ of $L_\infty(\mathbb{T}, \mathbb{C}^{p\times m})$ (or more generally, a convex subset) is weak-$*$ closed if and only if $\mathcal{S}\cap\{F\colon \|F\|_\infty \le r\}$ is weak-$*$ closed for each $r > 0$. Since $\mathcal{S}$ is a subspace, by homogeneity it suffices to consider only the case $r = 1$. As $L_\infty(\mathbb{T}, \mathbb{C}^{p\times m})$ is the dual of the *separable* space $L_1(\mathbb{T}, \mathbb{C}^{m\times p})$, it follows that the weak-$*$ topology on the unit ball of $L_\infty(\mathbb{T}, \mathbb{C}^{p\times m})$ is metrizable (see [18, Theorem 102, page 174]). Hence, to show that $\mathcal{S}$ is closed in the weak-$*$ topology, it suffices to show that $\mathcal{S}$ is closed under sequential weak-$*$ limits as asserted. This proves part (1) of Proposition 2.3.

Suppose now that $\{F_n\}_{n=1,2,\dots}$ is a sequence of elements of $L_\infty(\mathbb{T}, \mathbb{C}^{p\times m})$ converging pointwise boundedly to F. To show that F_n converges to F in the weak-$*$ topology, we must show that

$$\lim_{n\to\infty}[F_n, f] = \lim_{n\to\infty}\frac{1}{2\pi}\int_{\mathbb{T}}\operatorname{tr}(F_n(\zeta)f(\zeta))|d\zeta| = \frac{1}{2\pi}\int_{\mathbb{T}}\operatorname{tr}(F(\zeta)f(\zeta))|d\zeta| \tag{2.4}$$

for each choice of $f \in L_1(\mathbb{T}, \mathbb{C}^{m\times p})$. Note that the assumptions imply that

$$\lim_{n\to\infty}\operatorname{tr}(F_n(\zeta)f(\zeta)) = \operatorname{tr}(F_n(\zeta)f(\zeta)) \quad \text{for almost all } \zeta \in \mathbb{T}.$$

By the standard trace estimate

$$|\operatorname{tr}(AB)| \le \operatorname{Tr}(AB) \le \|A\|\operatorname{Tr}(B),$$

we have

$$|\operatorname{tr}(F_n(\zeta)f(\zeta))| \le \|F_n(\zeta)\|\operatorname{Tr}(f(\zeta)) \le M\operatorname{Tr}(f(\zeta)),$$

where $M\operatorname{Tr}(f(\cdot))$ is integrable by the definition of $f \in L_1(\mathbb{T}, \mathbb{C}^{p\times m})$. It now follows from the Lebesgue dominated convergence theorem (see, e.g., [37, Theorem 16, page 91]) that (2.4) follows as required. This completes the proof of part (2) of Proposition 2.3. ∎

The subspace $H_\infty(\mathbb{D}, \mathbb{C}^{p\times m})$ can be viewed as the subspace of $L_\infty(\mathbb{D}, \mathbb{C}^{p\times m})$ consisting of functions $F \in L_\infty(\mathbb{T}, \mathbb{C}^{p\times m})$ such that the Fourier coefficients of negative index vanish:

$$\frac{1}{2\pi}\int_{\mathbb{T}}F(\zeta)\zeta^n|d\zeta| = 0 \quad \text{for } n = -1, -2, \dots.$$

The subspace $H_\infty(\mathbb{D}, \mathbb{C}^{p\times m})$ can also be viewed (via identification through nontangential-limit boundary values) as the space of analytic $p \times m$ matrix-valued functions on the unit disk which are uniformly bounded there:

$$\|F\|_\infty = \sup_{z\in\mathbb{D}}\|F(z)\| < \infty.$$

We define $H_{\infty,k}(\mathbb{D}, \mathbb{C}^{p\times m})$ as consisting of all elements G of $L_\infty(\mathbb{T}, \mathbb{C}^{p\times m})$ for which the associated Hankel operator $H_G\colon H_2(\mathbb{D}, \mathbb{C}^m) \mapsto H_2(\mathbb{D}, \mathbb{C}^p)^\perp$ given by

$$H_G\colon f \mapsto P_{H_2(\mathbb{D},\mathbb{C}^p)^\perp}M_G|_{H_2(\mathbb{D},\mathbb{C}^m)}$$

has rank equal to k. Here M_G denotes the multiplication operator associated with G. Equivalently, the *Hankel matrix*

$$[H_G] = \begin{bmatrix} g_{-1} & g_{-2} & g_{-3} & \cdots \\ g_{-2} & g_{-3} & g_{-4} & \cdots \\ g_{-3} & g_{-4} & g_{-5} & \cdots \\ \vdots & \vdots & \vdots & \end{bmatrix} : \ell^2(\mathbb{Z}_+, \mathbb{C}^m) \mapsto \ell^2(\mathbb{Z}_+, \mathbb{C}^p)$$

based on the Fourier coefficients for G,

$$G(z) \sim \sum_{n=-\infty}^{\infty} g_n z^n \quad \text{for } z \in \mathbb{T},$$

has rank equal to k. In what follows we shall use the following result.

PROPOSITION 2.4. *For a given $k \in \{0, 1, 2, \dots\}$, the set*

$$\bigcup_{k' \,:\, k' \le k} H_{\infty,k'}(\mathbb{D}, \mathbb{C}^{p\times m})$$

is closed in the weak-$*$ topology of $L_\infty(\mathbb{T}, \mathbb{C}^{p\times m})$.

Proof. Let us suppose that $G_n \in H_{\infty,k'}(\mathbb{D}, \mathbb{C}^{p\times m})$ for some $k' \le k$ for all $n = 1, 2, \dots$, and that G_n converges to $G \in L_\infty(\mathbb{T}, \mathbb{C}^{p\times m})$ in the weak-$*$ topology. By part (1) of Proposition 2.3, Proposition 2.4 follows if we are able to show that necessarily the limit G is again in $\bigcup_{k' \,:\, k' \le k} H_{\infty,k'}(\mathbb{D}, \mathbb{C}^{p\times m})$. For $f \in H_2(\mathbb{D}, \mathbb{C}^m)$ and $g \in H_2(\mathbb{D}, \mathbb{C}^p)^\perp$ we then have

$$\begin{aligned} \langle H_{G_n} f, g\rangle_{H_2^\perp} &= \frac{1}{2\pi}\int_{\mathbb{T}} g(\zeta)^* G_n(\zeta) f(\zeta) |d\zeta| \\ &= \frac{1}{2\pi}\int_{\mathbb{T}} \operatorname{tr}\left(G_n(\zeta) f(\zeta) g(\zeta)^*\right) |d\zeta|. \end{aligned} \tag{2.5}$$

As $f(\zeta)g(\zeta)^* \in L_1(\mathbb{T}, \mathbb{C}^{m\times p})$ and G_n converges weak-$*$ to G by assumption, we conclude from (2.5) that

$$\begin{aligned} \lim_{n\to\infty} \langle H_{G_n} f, g\rangle_{H_2^\perp} &= \frac{1}{2\pi}\int_{\mathbb{T}} \operatorname{tr}\left(G(\zeta) f(\zeta) g(\zeta)^*\right) |d\zeta| \\ &= \langle H_G f, g\rangle_{H_2^\perp}, \end{aligned} \tag{2.6}$$

i.e., H_{G_n} *converges to* H_G *in the weak operator topology of* $\mathcal{L}(H_2(\mathbb{D}, \mathbb{C}^m), H_2(\mathbb{D}, \mathbb{C}^p)^\perp)$. The fact that $G_n \in H_{\infty,k'}(\mathbb{D}, \mathbb{C}^{p\times m})$ with $k' \le k$ means that

$$\det[\langle H_{G_n} e_j, f_\ell\rangle_{H_2^\perp}]_{j,l=1,\dots,k+1} = 0 \tag{2.7}$$

for all $n = 1, 2, 3, \dots$ for any choice of $k+1$ linearly independent vectors $\{e_1, \dots, e_{k+1}\}$ in $H_2(\mathbb{D}, \mathbb{C}^m)$ and $k+1$ linearly independent vectors $\{f_1, \dots, f_{k+1}\}$ in $H_2(\mathbb{D}, \mathbb{C}^p)^\perp$. Using (2.5) and taking limits in (2.7) then implies that

$$\det[\langle H_G e_j, f_l\rangle_{H_2^\perp}]_{j,l=1,\dots,k+1} = 0 \tag{2.8}$$

for all such $\{e_1, \dots, e_{k+1}\}$ and $\{f_1, \dots, f_{+1}\}$. This then implies that H_G has rank at most k, or, by definition, $G \in H_{\infty,k'}(\mathbb{D}, \mathbb{C}^{p\times m})$ for some $k' \le k$. ∎

Sometimes it is of interest to focus on the "unit ball" of $H_{\infty,k}(\mathbb{D}, \mathbb{C}^{p\times m})$, namely, the set of functions $G \in H_{\infty,k}(\mathbb{D}, \mathbb{C}^{p\times m})$ with $\|G\|_\infty \le 1$. This class is often given a special name, namely, the *generalized Schur class of index* k, denoted as $\mathcal{S}_k(\mathbb{D}, \mathbb{C}^{p\times m})$. The following result concerning the class $\mathcal{S}_k(\mathbb{D}, \mathbb{C}^{p\times m})$ originates in the work of Kreĭn and Langer (see [27, 28]).

PROPOSITION 2.5. *Let $G \in L^\infty(\mathbb{T}, \mathbb{C}^{p\times m})$. Then the following are equivalent:*

(1) $G \in \mathcal{S}_k(\mathbb{D}, \mathbb{C}^{p\times m})$.

(2) *G has a factorization $G = F \cdot B^{-1}$, where F is in $H_\infty(\mathbb{D}, \mathbb{C}^{p\times m})$ with $\|F\|_\infty \leq 1$ and B is an $m \times m$ Blaschke–Potapov product of degree k, and no such representation $G = f' \cdot B'^{-1}$ is possible with B' an $m \times m$ matrix Blaschke–Potapov product of degree $k' < k$.*

(3) *G has meromorphic continuation to $\mathbb{D}$ and, for any choice of vectors $x_1, \ldots, x_N \in \mathbb{C}^p$, points $z_1, \ldots, z_N \in \Omega_G$ (where $\Omega_G \subset \mathbb{D}$ is the domain of analyticity for G), and $N = 1, 2, 3, \ldots$, the Hermitian matrix*

$$\left[\frac{x_i^* x_j - x_i^* G(z_i) G(z_j)^* x_j}{1 - z_i \overline{z_j}}\right] \tag{2.9}$$

has at most k negative eigenvalues, and there is at least one choice of $x_1, \ldots, x_N$, $z_1, \ldots, z_N$, and N for which (2.9) has exactly k negative eigenvalues.

We shall also need an asymptotic version of the maximum modulus theorem for the generalized Schur class $\mathcal{S}_k(\mathbb{D}, \mathbb{C}^{p\times m})$ (with $k < \infty$).

PROPOSITION 2.6. *Suppose G is in the generalized Schur class $\mathcal{S}_k(\mathbb{D}, \mathbb{C}^{p\times m})$, where $k < \infty$, and let $s > 1$. Then there exists an $r < 1$ so that*

$$z \in \mathbb{D}, \quad r < |z| < 1 \Rightarrow z \in \Omega_G, \quad \text{and} \quad \|G(z)\| \leq s.$$

Proof. Let $G = F \cdot B^{-1}$ be the Kreĭn–Langer factorization G and suppose that we are given a number $s > 1$. As $F \in H_\infty(\mathbb{D}, \mathbb{C}^{p\times m})$ with $\|F\|_\infty \leq 1$, we have $\|F(z)\| \leq 1$ for all $z \in \mathbb{D}$ by the maximum modulus theorem for H_∞. As B is a finite matrix Blaschke–Potapov product, B is uniformly continuous on the closed disk $\overline{\mathbb{D}}$, and B^{-1} is uniformly continuous on any annulus $\mathbb{A}_r = \{z \colon r \leq |z| \leq 1\}$ which misses the zeros of B. As B^{-1} has norm 1 on the unit circle, we can therefore guarantee that $\|B^{-1}(z)\| \leq s$ (for any preassigned $s > 1$) as long as we restrict to an annulus $\mathbb{A}_r$ with r sufficiently close to 1. The result now follows. ∎

We also need the following elementary result.

PROPOSITION 2.7. *Suppose that $G \in H_\infty(\mathbb{D}_e, \mathbb{C}^{p\times m})$ with Hankel singular values $\sigma_1 \geq \sigma_2 \geq \cdots (\geq 0)$. If $Q \in H_{\infty,k}(\mathbb{D}, \mathbb{C}^{p\times m})$, then $\|G + Q\|_\infty \geq \sigma_{k+1}$.*

Proof. The Hankel singular values are characterized by

$$\sigma_{k+1}(H_G) = \inf_{X \colon \operatorname{rank} X \leq k} \|H_G - X\|,$$

where X here is an operator from $H_2(\mathbb{D}, \mathbb{C}^m)$ to $H_2(\mathbb{D}, \mathbb{C}^p)$ (see, e.g., [21, Chapter VI, Theorem 1.5, page 98]). In particular, if $K \in H_{\infty,k}(\mathbb{D}, \mathbb{C}^{p\times m})$, then $X = H_K$ has rank equal to k. Hence

$$\|G + K\|_\infty \geq \|H_{G+K}\|_{op} = \|H_G + H_K\|_{op} \geq \inf_{X \colon \operatorname{rank} X \leq k} \|H_G + X\|_{op} = \sigma_{k+1},$$

and the assertion follows. ∎

2.2. Existence of Λ and Θ in Theorem 2.2. In this section we point out some general considerations which guarantee the existence of a function $\Lambda \colon \mathbb{D} \mapsto \mathbb{C}^{(p+m)\times(p+m)}$ satisfying conditions S′1, S′2, and S′3. It then remains to prove that such a Λ leads to a parameterization of the set of all solutions of the Nehari–Takagi problem as in Theorem 2.2. In practice, it then remains to compute Λ (and Θ) in some explicit form in terms of known parameters in the application; this is what we do in section 3 (for the setting of the left half-plane rather than of the unit disk), where $G(s) = C(sI - A)^{-1}B$ is assumed to be the transfer function of a continuous-time linear system having certain (nonexponential) stability properties.

First we need to make a few general observations. The invertibility of $H_G^*H_G - \sigma^2 I$ on $L_2(\mathbb{T}, \mathbb{C}^m)$ is equivalent to σ being in the resolvent set of $[H_G^*H_G]^{1/2}$, i.e., of σ being in a gap of the spectrum of $[H_G^*H_G]^{1/2}$. It is well known that the singular values $\sigma_1 > \sigma_2 > \cdots$ of H_G consist of the points of the spectrum of $[H_G^*H_G]^{1/2}$ which are isolated eigenvalues of finite multiplicity positioned to the right of the continuous spectrum. The condition that σ is in a gap between Hankel singular values implies in particular that σ is in a gap of the spectrum of $[H_G^*H_G]^{1/2}$, and hence implies the invertibility of $H_G^*H_G - \sigma^2 I$ on $L_2(\mathbb{T}, \mathbb{C}^m)$. Further details on singular values in general are given in Lemma 6.2 in Appendix B. For a given matrix function $G \in L_\infty(\mathbb{T}, \mathbb{C}^{p\times m})$, in addition to the notation $H_G\colon H_2(\mathbb{D}, \mathbb{C}^m) \mapsto H_2(\mathbb{D}, \mathbb{C}^p)^\perp$ for the Hankel operator $H_G\colon f \mapsto P_{H_2(\mathbb{D},\mathbb{C}^p)^\perp}(G \cdot f)$ associated with G, we let $T_G\colon H_2(\mathbb{D}, \mathbb{C}^m) \mapsto H_2(\mathbb{D}, \mathbb{C}^p)$ denote the *Toeplitz operator* associated with G,

$$T_G\colon f \mapsto P_{H_2(\mathbb{D},\mathbb{C}^p)}(G \cdot f) \quad \text{for } f \in H_2(\mathbb{D}, \mathbb{C}^m),$$

and we let $M_G\colon L_2(\mathbb{T}, \mathbb{C}^m) \mapsto L_2(\mathbb{T}, \mathbb{C}^p)$ denote the *multiplication* (sometimes also called the *Laurent*) *operator* associated with G,

$$M_G\colon f \mapsto G \cdot f.$$

The next proposition gives a number of conditions equivalent to the invertibility of $H_G^*H_G - \sigma^2 I$ on $H_2(\mathbb{D}, \mathbb{C}^m)$.

PROPOSITION 2.8. *Let $G \in L_\infty(\mathbb{T}, \mathbb{C}^{p\times m})$ and set $A = \left[\begin{smallmatrix} I & G \\ 0 & I \end{smallmatrix}\right] \in L_\infty(\mathbb{T}, \mathbb{C}^{(p+m)\times(p+m)})$. Then the following conditions are equivalent:*

(1) *$H_G^*H_G - \sigma^2 I$ is invertible.*
(2) *The Toeplitz operator $T_{A^*J_\sigma A}$ is invertible on $H_2(\mathbb{D}, \mathbb{C}^{p+m})$.*
(3) *The singular integral operator $S := M_{A^*J_\sigma A}P_{H_2(\mathbb{D},\mathbb{C}^{p+m})} + P_{H_2(\mathbb{D},\mathbb{C}^{p+m})^\perp}$ is invertible on $L_2(\mathbb{T}, \mathbb{C}^m)$.*

Proof. To see that (1) $\Rightarrow$ (2), note that

$$A^*J_\sigma A = \begin{bmatrix} I_p & G \\ 0 & I_m \end{bmatrix}^* \begin{bmatrix} I_p & 0 \\ 0 & -\sigma^2 I_m \end{bmatrix} \begin{bmatrix} I_p & G \\ 0 & I_m \end{bmatrix} = \begin{bmatrix} I_p & G \\ G^* & G^*G - \sigma^2 I_m \end{bmatrix}.$$

Taking Schur complements, we see that invertibility of $T_{A^*J_\sigma A}$ is equivalent to invertibility of

$$\begin{aligned} T_{G^*G-\sigma^2 I_m} - T_{G^*}T_G &= P_{H_2}\left(M_{G^*}M_G - M_{G^*}P_{H_2}M_G\right)|_{H_2} - \sigma^2 I_{H_2} \\ &= P_{H_2}M_{G^*}P_{H_2^\perp}M_G|_{H_2} - \sigma^2 I_{H_2} \\ &= H_G^*H_G - \sigma^2 I_{H_2}, \end{aligned}$$

and (1) $\iff$ (2) follows.

If we decompose $L_2(\mathbb{C}^{p+m})$ in the form $L_2(\mathbb{C}^{p+m}) = \left[\begin{smallmatrix} H_2(\mathbb{D},\mathbb{C}^{p+m}) \\ H_2(\mathbb{D},\mathbb{C}^{p+m})^\perp \end{smallmatrix}\right]$, then the singular integral operator $S := M_{A^*J_\sigma A}P_{H_2} + P_{H_2^\perp}$ has the operator-block representation

$$S = \begin{bmatrix} T_{A^*J_\sigma A} & 0 \\ H_{A^*J_\sigma A} & I_{H_2^\perp} \end{bmatrix}.$$

From the triangular form of this block operator matrix, we see (2) $\iff$ (3). ∎

Theorem VII.2.1 combined with Theorem VIII.4.1 from [10], adapted to our setting, gives the following.

THEOREM 2.9 (see [10, Theorem VII.2.1 and Theorem VIII.4.1] or [31]). *Let $G \in L_\infty(\mathbb{D}, \mathbb{C}^{p\times m})$. Then the following are equivalent:*

(1) *Any of the equivalent conditions* (1), (2), *or* (3) *in Proposition* 2.8 *holds.*
(2) *There exists a function* $\Lambda \in H_2(\mathbb{D}, \mathbb{C}^{(p+m)\times(p+m)})$ *meeting the conditions* S′1, S′2, *and* S′3 *of Theorem* 2.2 *and satisfying the additional condition:* The operator $M_V P_{H_2} M_\Lambda$ $(= M_{\Lambda^{-1}} P_{H_2} M_\Lambda)$ defines a bounded projection operator on $L_2(\mathbb{T}, \mathbb{C}^{p+m})$. *Moreover,* Λ *is uniquely determined up to a* $(p+m)\times(p+m)$*-matrix right constant factor* U *satisfying* $U^* \left[\begin{smallmatrix} I_p & 0 \\ 0 & -I_m \end{smallmatrix}\right] U = \left[\begin{smallmatrix} I_p & 0 \\ 0 & -I_m \end{smallmatrix}\right]$.

We point out that in fact conditions S′1, S′2, and S′3 already determine Λ uniquely up to a constant (without the additional condition on the boundedness of $M_V P_{H_2} M_\Lambda$). Indeed if Λ and Λ' satisfy S′1, S′2, and S′3, then $\Lambda\Lambda'^{-1}(z)$ is analytic on $\mathbb{D}$ and satisfies

$$(\Lambda\Lambda'^{-1})^*(\zeta) \begin{bmatrix} I_p & 0 \\ 0 & -I_m \end{bmatrix} (\Lambda\Lambda'^{-1})(\zeta) = \begin{bmatrix} I_p & 0 \\ 0 & -I_m \end{bmatrix} \quad \text{for } \zeta \in \mathbb{T}. \tag{2.10}$$

We then use the formula $\left[\begin{smallmatrix} I_p & 0 \\ 0 & -I_m \end{smallmatrix}\right] (\Lambda\Lambda'^{-1})^{*-1}(1/\overline{z}) \left[\begin{smallmatrix} I_p & 0 \\ 0 & -I_m \end{smallmatrix}\right]$ to analytically continue $\Lambda\Lambda'^{-1}$ to the exterior of the unit disk. From (2.10) we see that the nontangential boundary values from outside the disk agree with the nontangential boundary values from inside the disk. By using Lemma 6.6 from [32, page 223], we see that the analytic continuation passes through the unit circle as well. Then by Liouville's theorem we see that $\Lambda\Lambda'^{-1}$ must be an invertible constant matrix U. Since Λ and Λ' both satisfy S′1, we see next that the constant matrix U must also satisfy $U^* \left[\begin{smallmatrix} I_p & 0 \\ 0 & -I_m \end{smallmatrix}\right] U = \left[\begin{smallmatrix} I_p & 0 \\ 0 & -I_m \end{smallmatrix}\right]$.

We remark that the version of Theorem 2.9 as formulated in [10] uses the invertibility of the singular integral operator (condition (3) in Proposition 2.8) as the operator theory condition equivalent to the existence of the so-called canonical generalized factorization with respect to L_2.

2.3. Proof of Theorem 2.2 via the Adamjan–Arov–Kreĭn (AAK) theorem. The following result of Adamjan, Arov, and Kreĭn (see [1]) also gives a parameterization of the set of all solutions of the (discrete-time) Nehari–Takagi problem under the assumption that $\sigma_k > \sigma > \sigma_{k+1}$. A thorough recent treatment of the AAK approach can be found in Peller [34].

THEOREM 2.10. *Let* $G \in H_\infty(\mathbb{D}_e)$ *and let* $H_G \colon H_2(\mathbb{D}, \mathbb{C}^m) \mapsto H_2(\mathbb{D}, \mathbb{C}^p)^\perp$ *be the associated Hankel operator, with singular values* $\sigma_1 \geq \sigma_2 \geq \cdots (\geq 0)$. *Suppose that* $\sigma_k > \sigma > \sigma_{k+1}$. *Define*

$$\Theta(\zeta) = \begin{bmatrix} \Theta_{11}(\zeta) & \Theta_{12}(\zeta) \\ \Theta_{21}(\zeta) & \Theta_{22}(\zeta) \end{bmatrix} \in L_2(\mathbb{T}, \mathbb{C}^{(p+m)\times(p+m)})$$

by (*viewed as an operator from* $\mathbb{C}^{p+m}$ *into* $L_2(\mathbb{T}, \mathbb{C}^{p+m})$)

$$\Theta = \begin{bmatrix} \zeta \cdot Z_* e_*^* \gamma_* & H_G Z e^* \gamma \\ \zeta \cdot H_G^* Z_* e_*^* \gamma_* & Z e^* \gamma \end{bmatrix}, \tag{2.11}$$

where $e_* \colon L^2(\mathbb{T}, \mathbb{C}^p) \mapsto \mathbb{C}^p$, $e \colon L^2(\mathbb{T}, \mathbb{C}^m) \mapsto \mathbb{C}^m$, $Z \colon H_2(\mathbb{D}, \mathbb{C}^m) \mapsto H_2(\mathbb{D}, \mathbb{C}^m)$, $Z_* \colon H_2(\mathbb{D}, \mathbb{C}^p) \mapsto H_2(\mathbb{D}, \mathbb{C}^p)$, $\gamma \colon \mathbb{C}^m \mapsto \mathbb{C}^m$, *and* $\gamma_* \colon \mathbb{C}^p \mapsto \mathbb{C}^p$ *are given by*

$$\begin{aligned} &e_* \colon \textstyle\sum_{j=-\infty}^{\infty} \zeta^j f_j \mapsto f_{-1}, && e \colon \textstyle\sum_{j=-\infty}^{\infty} \zeta^j g_j \mapsto g_0, \\ &Z = (I - \sigma^{-2} H_G^* H_G)^{-1}, && Z_* = (I - \sigma^{-2} H_G H_G^*)^{-1}, \\ &\gamma = (e Z e^*)^{-1/2}, && \gamma_* = (e_* Z_* e_*^*)^{-1/2}. \end{aligned}$$

Then the conclusion of Theorem 2.2 *holds with* Θ *given by* (2.11) *rather than by* (2.2).

In [4] it is argued that one way to compute a function $\Theta \in L_2(\mathbb{D}, \mathbb{C}^{(p+m)\times(p+m)})$ meeting the requirement in Theorem 2.2 is as follows: Θ should satisfy the conditions

C′1. $\Theta(\zeta)^*\left[\begin{smallmatrix} I_p & 0 \\ 0 & -\sigma^2 I_m \end{smallmatrix}\right]\Theta(\zeta) = \left[\begin{smallmatrix} I_p & 0 \\ 0 & I_q \end{smallmatrix}\right]$ and

C′2. the columns of Θ should form a basis for the "wandering subspace" $\mathcal{L}$ associated with the problem

$$\Theta \cdot \mathbb{C}^{p+m} = \mathcal{L} := \mathcal{M} \ominus_{J_\sigma} \zeta \cdot \mathcal{M},$$

where we have set

$$\mathcal{M} := \begin{bmatrix} I_p & G \\ 0 & I_m \end{bmatrix} \cdot H_2(\mathbb{D}, \mathbb{C}^{p+m})$$

and where the notation $\ominus_{J_\sigma}$ refers to the orthogonal difference in the indefinite inner product $\langle \cdot, \cdot \rangle_{J_\sigma}$ on $L_2(\mathbb{T}, \mathbb{C}^{p+m})$ induced by J_σ:

$$\langle f, g \rangle_{J_\sigma} = \frac{1}{2\pi} \int_{\mathbb{T}} \langle J_\sigma f(\zeta), g(\zeta) \rangle_{\mathbb{C}^{p+m}} \, |d\zeta|.$$

In fact, this construction is very close to that in [10] for the construction of Wiener–Hopf factors under the assumption that the associated singular integral operator is invertible as discussed in section 2.2. Furthermore, in [2] it is verified that Θ as defined in (2.11) meets the criteria C′1 and C′2. In this way we have a proof of Theorem 2.2 which ultimately rests on the main result from [1].

2.4. Proof of Theorem 2.2 via Kreĭn-space projective geometry: The Ball–Helton approach. This approach, originating in [4] (see also [39] and [2]), relies on a projective geometry of Kreĭn spaces. The method is reasonably straightforward in case the spectral factor Λ and its inverse V are bounded (and hence also Θ is bounded), but there are some extra complications for the general case. Since these extra complications remained a little obscure in the original exposition [4], we now revisit the ideas there in an attempt to make them more accessible for the system-theory community. For basic background concerning Kreĭn spaces, we refer to [9].

We first observe that the space $L_2(\mathbb{T}, \mathbb{C}^{p+m})$ is a Kreĭn space in the J_σ inner product given by

$$\langle f, g \rangle_{J_\sigma} = \frac{1}{2\pi} \int_{\mathbb{T}} \langle J_\sigma f(\zeta), g(\zeta) \rangle_{\mathbb{C}^{p+m}} \, |d\zeta|.$$

A key role is played by the subspace $\mathcal{M}$ given by

$$\mathcal{M} = \begin{bmatrix} I & G \\ 0 & I \end{bmatrix} \cdot H_2(\mathbb{D}, \mathbb{C}^{p+m}) \subset L_2(\mathbb{T}, \mathbb{C}^{p+m}). \tag{2.12}$$

In general a subspace $\mathcal{M}$ of a Kreĭn space $\mathcal{K}$ is said to be *regular* if it has a good orthogonal complement in the Kreĭn space inner product (i.e., if $\mathcal{K} = \mathcal{M} \dot{+} \mathcal{M}^{[\perp]}$, where $\dot{+}$ indicates direct-sum decomposition), where $\mathcal{M}^{[\perp]}$ indicates the orthogonal complement in the indefinite Kreĭn space inner product. We have the following characterization of when the subspace $\mathcal{M}$ given by (2.12) is a regular subspace of the Kreĭn spaces $(L_2(\mathbb{T}, \mathbb{C}^{p+m}), \langle \cdot, \cdot \rangle_{J_\sigma})$.

PROPOSITION 2.11. *The subspace $\mathcal{M}$ given by* (2.12) *is a regular subspace of the Kreĭn space $(L_2(\mathbb{T}, \mathbb{C}^{p+m}), \langle \cdot, \cdot \rangle_{J_\sigma})$ if and only if any one of the equivalent conditions in Proposition* 2.8 *holds.*

Proof. Note that, for $f, g \in H_2(\mathbb{D}, \mathbb{C}^{p+m})$, we have

$$\left\langle \begin{bmatrix} I_p & G \\ 0 & I_m \end{bmatrix} f, g \right\rangle_{J_\sigma} = \left\langle J_\sigma \begin{bmatrix} I_p & G \\ 0 & I_m \end{bmatrix} f, g \right\rangle_{L_2(\mathbb{T}, \mathbb{C}^{p+m})} = \langle T_{A^* J_\sigma A} f, g \rangle_{L_2(\mathbb{T}, \mathbb{C}^{p+m})},$$

where $A = \left[\begin{smallmatrix} I & G \\ 0 & I \end{smallmatrix}\right]$ is as in Proposition 2.8. Thus the map $U\colon f \mapsto \left[\begin{smallmatrix} I_p & G \\ 0 & I_m \end{smallmatrix}\right] \cdot f$ is unitary from $H_2(\mathbb{D}, \mathbb{C}^{p+m})$ with the inner product induced by the Toeplitz operator $T_{A^* J_\sigma A}$ to $\mathcal{M}$ with the inner product induced by J_σ. A standard fact concerning Kreĭn spaces (see, e.g., [9]) is that a subspace of a Kreĭn space $\mathcal{K}$ is regular if and only if it is itself a Kreĭn space in the inner product inherited from $\mathcal{K}$. In the case at hand, by the indefinite-metric unitary property of U, this happens if and only if $H_2(\mathbb{T}, \mathbb{C}^{p+m})$ is a Kreĭn space in the inner product induced by $T_{A^* J_\sigma A}$; this in turn is equivalent to the invertibility of the Toeplitz operator $T_{A^* J_\sigma A}$, i.e., condition (2) in Proposition 2.8. Proposition 2.11 now follows. ∎

When $\mathcal{M}$ is a regular subspace of $(L_2(\mathbb{T}, \mathbb{C}^{p+m}), \langle \cdot, \cdot \rangle_{J_\sigma})$, we denote by $P_{\mathcal{M}}$ the projection of $L_2(\mathbb{T}, \mathbb{C}^{p+m})$ onto $\mathcal{M}$ along $\mathcal{M}^{[\perp]}$. Then $P_{\mathcal{M}}$ is bounded as an operator on $L_2(\mathbb{T}, \mathbb{C}^{p+m})$ and is self-adjoint in the J_σ-inner product:

$$\langle P_{\mathcal{M}} f, g \rangle_{J_\sigma} = \langle f, P_{\mathcal{M}} g \rangle_{J_\sigma}.$$

A key result from [4] is that when $\mathcal{M}$ is regular, then $\mathcal{M}$ has the following Beurling–Lax-type representation.

THEOREM 2.12 (see [4, 5]). *Assume that the subspace $\mathcal{M}$ as in* (2.12) *is a regular subspace of $(L_2(\mathbb{T}, \mathbb{C}^{p+m}), \langle \cdot, \cdot \rangle_{J_\sigma})$. Then there is a matrix function $\Theta \in L_2(\mathbb{T}, \mathbb{C}^{p+m})$ such that*

(1) *$\mathcal{M} = L_2(\mathbb{T}, \mathbb{C}^{p+m})$-closure of $\Theta \cdot H_\infty(\mathbb{D}, \mathbb{C}^{p+m})$;*
(2) *$\Theta(\zeta)^* J_\sigma \Theta(\zeta) = J_1 := \left[\begin{smallmatrix} I_p & 0 \\ 0 & -I_m \end{smallmatrix}\right]$ for almost all $\zeta \in \mathbb{T}$;*
(3) *the operator $M_\Theta P_{H_2(\mathbb{D}, \mathbb{C}^{p+m})} M_\Theta^{-1}$ defines a bounded operator, namely, the J_σ-orthogonal projection $P_{\mathcal{M}}$ of $L_2(\mathbb{T}, \mathbb{C}^{p+m})$ onto $\mathcal{M}$ along $\mathcal{M}^{[\perp]}$.*

Moreover, Θ is uniquely determined up to a constant J-unitary factor on the right, and in principle can be computed from the (J_1, J_σ)-unitary property (2) *above, along with the condition that*

$$\Theta \cdot \mathbb{C}^{p+m} = \mathcal{M} \ominus_{J_\sigma} \zeta \cdot \mathcal{M}.$$

Alternatively, Θ arises as $\Theta = \left[\begin{smallmatrix} I_p & G \\ 0 & I_m \end{smallmatrix}\right] V$, where $V = \Lambda^{-1}$ and Λ is the spectral factor for $A^* J_\sigma A$ as in Theorem 2.9.

Remark 2.13. Note that if we set $A = \left[\begin{smallmatrix} I_p & G \\ 0 & I_m \end{smallmatrix}\right]$ (with then $A^{-1} = \left[\begin{smallmatrix} I_p & -G \\ 0 & I_m \end{smallmatrix}\right]$), we have

$$M_\Theta P_{H_2(\mathbb{D}, \mathbb{C}^{p+m})} M_{\Theta^{-1}} = M_A M_V P_{H_2(\mathbb{D}, \mathbb{C}^{p+m})} M_\Lambda M_A^{-1},$$

where M_A and its inverse M_A^{-1} are bounded on $L_2(\mathbb{T}, \mathbb{C}^{p+m})$. In this way we see that the last part of condition (2) in Theorem 2.9 fits with condition (3) in Theorem 2.12.

The next step is to reformulate the Nehari–Takagi problem itself in terms of a certain graph subspace of $L_2(\mathbb{T}, \mathbb{C}^{p+m})$ instead of in terms of the matrix function $K \in H_{\infty,k}(\mathbb{T}, \mathbb{C}^{p \times m})$. We shall work with the Kreĭn–Langer representation for an element K of $H_{\infty,k}(\mathbb{D}, \mathbb{C}^{p \times m})$. Specifically, a matrix function $K \in L_\infty(\mathbb{T}, \mathbb{C}^{p \times m})$ is in the class $H_{\infty,k}(\mathbb{D}, \mathbb{C}^{p \times m})$ if and only if K has a representation as $K = F \cdot B^{-1}$, where $F \in H_\infty(\mathbb{D}, \mathbb{C}^{p \times m})$ and $B \in H_\infty(\mathbb{D}, \mathbb{C}^{m \times m})$ is a Blaschke–Potapov product of degree k, and k is the smallest nonnegative integer for which such a representation is possible. Then we have the following reformulation of the Nehari–Takagi problem.

PROPOSITION 2.14 (see [4, 2]). *The angle-operator–graph correspondence induces a one-to-one correspondence between solutions $K \in H_{\infty,k'}(\mathbb{D}, \mathbb{C}^{p \times m})$ of the Nehari–Takagi problem with datum $G \in L_\infty(\mathbb{T}, \mathbb{C}^{p \times m})$ and with index $k' \le k$, on the one*

hand, and subspaces $\mathcal{G}$ of the Kreĭn space

$$\mathcal{K} = \left(\begin{bmatrix} L_2(\mathbb{T}, \mathbb{C}^p) \\ H_2(\mathbb{D}, \mathbb{C}^m) \end{bmatrix}, \langle \cdot, \cdot \rangle_{J_\sigma} \right) \tag{2.13}$$

such that

(1) $\mathcal{G} \subset \mathcal{M} := \left[\begin{smallmatrix} I_p & 0 \\ 0 & I_m \end{smallmatrix} \right] \cdot H_2(\mathbb{D}, \mathbb{C}^{p+m})$,

(2) $\mathcal{G}$ *has codimension* k *in a maximal negative subspace of* $\mathcal{K}$, *and*

(3) $\mathcal{G}$ *is shift invariant, i.e.,* $\zeta \cdot \mathcal{G} \subset \mathcal{G}$,

on the other hand, as follows. If $K \in H_{\infty,k'}(\mathbb{D}, \mathbb{C}^{p\times m})$ *has a representation as* $K = FB^{-1}$, *with* $F \in H_\infty(\mathbb{D}, \mathbb{C}^{p\times m})$ *and with* $B \in H_\infty(\mathbb{D}, \mathbb{C}^{m\times m})$ *a Blaschke–Potapov product of degree* k, *and is such that* $\|G + K\|_\infty \le \sigma$, *and if we set*

$$\mathcal{G}_K = \begin{bmatrix} G + K \\ I \end{bmatrix} B \cdot H_2(\mathbb{T}, \mathbb{C}^{p\times m}) = \begin{bmatrix} GB + F \\ B \end{bmatrix} \cdot H_2(\mathbb{D}, \mathbb{C}^{p\times m}), \tag{2.14}$$

then $\mathcal{G}_K$ *satisfies conditions* (1), (2), *and* (3) *listed above. Conversely, if* $\mathcal{G}$ *satisfies conditions* (1), (2), *and* (3) *listed above, then necessarily there is a* $K \in H_{\infty,k'}(\mathbb{D}, \mathbb{C}^{p\times m})$ *with* $k' \le k$ *and with* $K = FB^{-1}$ *for a Blaschke–Potapov product of degree* k' *such that* $\|G + K\|_\infty \le \sigma$ *and* $\mathcal{G}$ *has the form* $\mathcal{G}_K$ *as in* (2.14).

Proof. We defer the proof to Appendix A (see section 5.1). ∎

The next step is to note the geometric significance of the fact that $\sigma_k > \sigma > \sigma_{k+1}$.

PROPOSITION 2.15. *Assume that* $G \in L_\infty(\mathbb{T}, \mathbb{C}^{p\times m})$ *has Hankel singular values* $\sigma_1 \ge \sigma_2 \ge \cdots$ *with* $\sigma_k > \sigma > \sigma_{k+1}$, *and define subspaces* $\mathcal{M}$ *and* $\mathcal{K}$ *of* $L_2(\mathbb{T}, \mathbb{C}^{p+m})$ *as in* (2.12) *and* (2.13). *Then* $\mathcal{M}$ *is a regular subspace of* $\mathcal{K}$, *and the* J_σ*-orthogonal complement* $\mathcal{K} \ominus_{J_\sigma} \mathcal{M}$ *of* $\mathcal{M}$ *inside* $\mathcal{K}$ *has* k *negative squares.*

Proof. One can compute that the relative J_σ-orthogonal complement $\mathcal{K} \ominus_{J_\sigma} \mathcal{M}$ is given by

$$\mathcal{K} \ominus_{J_\sigma} \mathcal{M} = \begin{bmatrix} I \\ \sigma^{-2} H_G^* \end{bmatrix} H_2(\mathbb{D}, \mathbb{C}^p)^\perp.$$

Hence, the negative signature of $\mathcal{K} \ominus_{J_\sigma} \mathcal{M}$ is equal to the number of negative eigenvalues of the self-adjoint operator

$$\begin{bmatrix} I & \sigma^{-2} H_G \end{bmatrix} \begin{bmatrix} I_p & 0 \\ 0 & -\sigma^2 I_m \end{bmatrix} \begin{bmatrix} I \\ \sigma^{-2} H_G^* \end{bmatrix} = I - \sigma^{-2} H_G H_G^*.$$

From the definition of singular values, we see that this quantity in turn is equal to k if $\sigma_k > \sigma > \sigma_{k+1}$, and the assertion follows. ∎

Proposition 2.15 enables us to adjust Proposition 2.14 to a more useful form as follows.

PROPOSITION 2.16. *Assume that* $G \in L_\infty(\mathbb{T}, \mathbb{C}^{p\times m})$ *has Hankel singular values* $\sigma_1 \ge \sigma_2 \ge \cdots$ *satisfying* $\sigma_k > \sigma > \sigma_{k+1}$ *as in Proposition* 2.15. *Then the angle-operator–graph correspondence as sketched in Proposition* 2.14 *induces a one-to-one correspondence between solutions* $K \in H_{\infty,k}(\mathbb{D}, \mathbb{C}^{p\times m})$ *of the Nehari–Takagi problem with datum* $G \in L_\infty(\mathbb{T}, \mathbb{C}^{p\times m})$ *and with index* k, *on the one hand, and subspaces* $\mathcal{G}$ *of the Kreĭn space* $\mathcal{K}$ *as in* (2.13) *such that*

(1) $\mathcal{G} \subset \mathcal{M} := \left[\begin{smallmatrix} I_p & G \\ 0 & I_m \end{smallmatrix} \right] \cdot H_2(\mathbb{D}, \mathbb{C}^{p+m})$,

(2) $\mathcal{G}$ *is a maximal negative subspace as a subspace of* $\mathcal{M}$*, and*
(3) $\mathcal{G}$ *is shift invariant, i.e.,* $\zeta \cdot \mathcal{G} \subset \mathcal{G}$*,*
on the other hand.

Proof. We defer the proof to Appendix A (see section 5.2). ∎

Proposition 2.16 reduces the description of all solutions K of the Nehari–Takagi problem to a description of all shift-invariant subspaces $\mathcal{G}$ of $\mathcal{M}$ which are maximal negative as a subspace of $\mathcal{M}$. The next proposition gives a characterization of these subspaces; it is at this point that we use the Beurling–Lax representation of $\mathcal{M}$ given in Theorem 2.12.

PROPOSITION 2.17. *Assume that* $K \in L_\infty(\mathbb{T}, \mathbb{C}^{p\times m})$ *with Hankel singular values* $\sigma_1 > \sigma_2 > \cdots$ *satisfying* $\sigma_k > \sigma > \sigma_{k+1}$ *as in Proposition* 2.16*. As in* (2.12)*, let* $\mathcal{M}$ *be considered as a Kreĭn space in the* J_σ*-inner product, and let* $\Theta \in L_2(\mathbb{T}, \mathbb{C}^{p\times m})$ *be the* J_σ*-Beurling–Lax representer for* $\mathcal{M}$ *as in Theorem* 2.12*. Then a subspace* $\mathcal{G}$ *of* $\mathcal{M}$ *satisfies conditions* (1)*,* (2)*, and* (3) *in Proposition* 2.16 *if and only if there is a matrix function* $Q \in H_\infty(\mathbb{T}, \mathbb{C}^{p\times m})$ *such that*

$$\mathcal{G} = L_2(\mathbb{T}, \mathbb{C}^{p+m})\text{-closure of } \Theta \begin{bmatrix} Q \\ I \end{bmatrix} \cdot H_\infty(\mathbb{D}, \mathbb{C}^m) \tag{2.15}$$

for a uniquely determined matrix function $Q \in H_\infty(\mathbb{D}, \mathbb{C}^{p\times m})$ *with* $\|Q\|_\infty \le 1$*.*

Proof. The proof is deferred to Appendix A (see section 5.3). ∎

We are now ready to put all the pieces together to complete the proof of Theorem 2.2

Proof of Theorem 2.2. By combining Propositions 2.14 and 2.16 with Proposition 2.17, we see that K solves the Nehari–Takagi problem if and only if K has a Kreĭn–Langer factorization $Q = FB^{-1}$ (where $F \in H_\infty(\mathbb{D}, \mathbb{C}^{p\times m})$ and $B \in H_\infty(\mathbb{D}, \mathbb{C}^{m\times m})$ is a Blaschke–Potapov product of degree k) such that

$$\begin{bmatrix} G+K \\ I_m \end{bmatrix} B \cdot H_2(\mathbb{D}, \mathbb{C}^m) \cap \Theta \cdot H_\infty(\mathbb{D}, \mathbb{C}^{p+m}) = \Theta \begin{bmatrix} Q \\ I_m \end{bmatrix} \cdot H_\infty(\mathbb{D}, \mathbb{C}^m)$$

for a uniquely determined $Q \in H_\infty(\mathbb{D}, \mathbb{C}^{p\times m})$ with $\|Q\|_\infty \le 1$. In particular, we see that for each of the standard basis vectors $e_1, \ldots, e_m$ in $\mathbb{C}^m$ there must be corresponding vector functions $f_1, \ldots, f_m \in BH_2(\mathbb{D}, \mathbb{C}^m)$ so that

$$\begin{bmatrix} G+K \\ I_m \end{bmatrix} f_j = \Theta \begin{bmatrix} Q \\ I_m \end{bmatrix} e_j,$$

or, in operator form,

$$\begin{bmatrix} G+K \\ I_m \end{bmatrix} F = \begin{bmatrix} \Theta_{11}Q + \Theta_{12} \\ \Theta_{21}Q + \Theta_{22} \end{bmatrix}.$$

From the bottom component we read off that $F = \Theta_{21}Q + \Theta_{22}$; then the top component gives

$$(G+K)(\Theta_{21}Q + \Theta_{22}) = \Theta_{11}Q + \Theta_{12}.$$

Once we confirm that $F(\zeta)^{-1} = (\Theta_{21}(\zeta)Q(\zeta) + \Theta_{22}(\zeta))^{-1}$ makes sense for almost all $\zeta \in \mathbb{T}$, we can solve for $G+K$ and arrive at the formula (2.3) for $G+K$. As all the analysis is necessary and sufficient, this will then complete the proof of Theorem 2.2.

We can see that $\Theta_{21}(\zeta)Q(\zeta) + \Theta_{22}(\zeta)$ is invertible for almost all $\zeta \in \mathbb{T}$ by the following geometric argument; for those readers who would prefer an analytic argument, we also give an analytic proof of the same point in the next section. By our construction we have that the linear manifold

$$\begin{bmatrix} G+K \\ I_m \end{bmatrix} F \cdot H_\infty(\mathbb{D}, \mathbb{C}^m)$$

is dense in a shift-invariant subspace $\mathcal{G}_{G+K}$ of $\mathcal{K} = \left[\begin{smallmatrix} L_2(\mathbb{T},\mathbb{C}^p) \\ H_2(\mathbb{D},\mathbb{C}^m) \end{smallmatrix}\right]$ which has codimension k in a maximal J_σ-negative subspace of $\mathcal{K}$. By the angle-operator–graph correspondence for J_σ-negative subspaces, equivalently $\|G+K\|_\infty \le \sigma$ and the L_2-closure of $FH_\infty(\mathbb{D}, \mathbb{C}^m)$ has the form $BH_2(\mathbb{D}, \mathbb{C}^m)$ for a Blaschke–Potapov product in $H_\infty(\mathbb{D}, \mathbb{C}^{m\times m})$ of degree k. For this to occur, it is necessarily the case that $\det F(\zeta) \neq 0$ for almost all $\zeta \in \mathbb{T}$. The proof of Theorem 2.2 (via Kreĭn-space projective geometry) is now complete. □

2.5. Proof of Theorem 2.2 via a winding number argument. It is also possible to bypass the Kreĭn-space geometry ideas and give a more analytic, less geometric proof for most of the content of Theorem 2.2, as we now show. The main idea for this approach comes from [6]; it can also be considered as a purely frequency-domain version of the state-space solution given in [3] for the rational case. One key point of Theorem 2.2 is that every solution of the Nehar–Takagi problem arises from a contractive H_∞-free parameter via the linear-fractional map; for the proof of this part we translate the ideas from the Grassmannian approach to the more analytic setting here.

The starting point for this alternative derivation is still the Beurling–Lax representation for the subspace $\mathcal{M}$ given in Theorem 2.12. Under the assumption that $\mathcal{M}$ is a *regular* subspace of $(L_2(\mathbb{T}, \mathbb{C}^{p+m}), \langle\cdot,\cdot\rangle_{J_\sigma})$, we know that $L_2(\mathbb{T}, \mathbb{C}^{p+m})$ has a direct sum decomposition

$$L_2(\mathbb{T}, \mathbb{C}^{p+m}) = \mathcal{M}^{[\perp]} \dot{+} \mathcal{M},$$

and hence there is a bounded projection operator $P_{\mathcal{M}}$ from $L_2(\mathbb{T}, \mathbb{C}^{p+m})$ onto $\mathcal{M}$ along the J_σ-orthogonal complement $\mathcal{M}^{[\perp]}$ of $\mathcal{M}$. In addition, in this setup the projection operator $P_{\mathcal{M}}$ is J_σ-self-adjoint in the sense that

$$\langle P_{\mathcal{M}} f, g\rangle_{J_\sigma} = \langle f, P_{\mathcal{M}} g\rangle_{J_\sigma} \quad \text{for all } f, g \in L_2(\mathbb{T}, \mathbb{C}^{p+m}).$$

In addition, we shall have use for the operator $P_-^* P_{\mathcal{M}} P_-$ on $H_2(\mathbb{D}, \mathbb{C}^m)$, where we have set

$$P_- = \begin{bmatrix} 0_{p\times m} \\ I_m \end{bmatrix} : H_2(\mathbb{D}, \mathbb{C}^m) \mapsto L_2(\mathbb{T}, \mathbb{C}^{p+m}).$$

Note that then

$$P_-^* = \begin{bmatrix} 0_{m\times p} & P_{H_2(\mathbb{D},\mathbb{C}^m)} \end{bmatrix} : L_2(\mathbb{T}, \mathbb{C}^{p+m}) \mapsto H_2(\mathbb{D}, \mathbb{C}^m).$$

PROPOSITION 2.18. *Assume that $\mathcal{M}$ as in* (2.12) *is regular and that $\mathcal{M}$ has the J_σ-Beurling–Lax representation $\mathcal{M} = L_2$-closure of $\Theta \cdot H_\infty(\mathbb{D}, \mathbb{C}^{p+m})$ as in Theorem* 2.12. *Then the following hold:*

(1) *J_σ-orthogonal projection of $L_2(\mathbb{T},\mathbb{C}^{p+m})$ onto $\mathcal{M}$ can be computed either in terms of G as*

$$P_{\mathcal{M}} = \begin{bmatrix} P_{H_2(\mathbb{D},\mathbb{C}^p)} & 0 \\ 0 & 0 \end{bmatrix} + \begin{bmatrix} H_G \\ I \end{bmatrix} \left(H_G^* H_G - \sigma^2 I_m\right)^{-1} \begin{bmatrix} H_G^* & -\sigma^2 I_m \end{bmatrix} \tag{2.16}$$

or in terms of Θ as

$$P_{\mathcal{M}} = M_\Theta P_{H_2(\mathbb{D},\mathbb{C}^{p+m})} M_\Theta^{-1}. \tag{2.17}$$

(2) *The operator $P_-^* P_{\mathcal{M}} P_-$ can be expressed in two ways:*

$$P_-^* P_{\mathcal{M}} P_- = -\sigma^2 (H_G^* H_G - \sigma^2 I_m)^{-1} \tag{2.18}$$

$$= -\sigma^2 M_{[\Theta_{21}\ \Theta_{22}]} P_{H_2(\mathbb{D},\mathbb{C}^{p+m})} M_{[\Theta_{21}\ -\Theta_{22}]^*}. \tag{2.19}$$

(3) *The number k of negative eigenvalues of the self-adjoint operator $P_-^* P_{\mathcal{M}} P_-$ on $H_2(\mathbb{D},\mathbb{C}^m)$ can be expressed either as*

$$k = \text{ the number of Hankel singular values } > \sigma \tag{2.20}$$

or as the number of negative squares of the kernel

$$\frac{\Theta_{22}(z)\Theta_{22}(w)^* - \Theta_{21}(z)\Theta_{21}(w)^*}{1 - z\overline{w}}. \tag{2.21}$$

Consequently, the matrix function $\Theta_{22}^{-1}\Theta_{21} \in H_{\infty,k}(\mathbb{D},\mathbb{C}^{m\times p})$ with $\|\Theta_{22}^{-1} \cdot \Theta_{21}\|_\infty \le 1$, and Θ_{22} has outer-inner factorization $\Theta_{22} = F \cdot B$, where $F \in H_2(\mathbb{D},\mathbb{C}^{m\times m})$ is outer and $B \in H_\infty(\mathbb{D},\mathbb{C}^{m\times m})$ is a Blaschke–Potapov product of degree k.

Proof. To prove (2.16) note that $\mathcal{M}$ has J_σ-orthogonal decomposition

$$\mathcal{M} = \begin{bmatrix} H_2(\mathbb{D},\mathbb{C}^p) \\ 0 \end{bmatrix} \oplus_{J_\sigma} \begin{bmatrix} H_G \\ I_m \end{bmatrix} H_2(\mathbb{D},\mathbb{C}^m). \tag{2.22}$$

The J_σ-orthogonal projection onto $\operatorname{im}\left[\begin{smallmatrix} H_G \\ I_m \end{smallmatrix}\right]$ can be computed as

$$P_{\operatorname{im}\left[\begin{smallmatrix} H_G \\ I_m \end{smallmatrix}\right]} = \begin{bmatrix} H_G \\ I_m \end{bmatrix} \left(\begin{bmatrix} H_G \\ I \end{bmatrix}^{[*]} \begin{bmatrix} H_G \\ I_m \end{bmatrix} \right)^{-1} \begin{bmatrix} H_G \\ I \end{bmatrix}^{[*]}. \tag{2.23}$$

Here we view $\left[\begin{smallmatrix} H_G \\ I_m \end{smallmatrix}\right]$ as an operator acting from $H_2(\mathbb{D},\mathbb{C}^m)$ with the standard Hilbert space inner product into $L_2(\mathbb{T},\mathbb{C}^{p+m})$ with the J_σ-inner product. Hence

$$\begin{bmatrix} H_G \\ I_m \end{bmatrix}^{[*]} = \begin{bmatrix} H_G \\ I_m \end{bmatrix}^* J_\sigma = \begin{bmatrix} H_G^* & -\sigma^2 I \end{bmatrix}. \tag{2.24}$$

Substituting (2.24) into (2.23) and using (2.22) then gives the formula (2.16) for $P_{\mathcal{M}}$.

Formula (2.17) for $P_{\mathcal{M}}$ was already noted as condition (3) of Theorem 2.12.

Formula (2.18) now follows upon multiplying (2.16) on the left by $[0\ \ P_{H_2(\mathbb{D},\mathbb{C}^m)}]$ and on the right by $\left[\begin{smallmatrix} 0 \\ I_m \end{smallmatrix}\right]$ (considered as acting from $H_2(\mathbb{D},\mathbb{C}^m)$ into $L_2(\mathbb{T},\mathbb{C}^{p+m})$).

Formula (2.20) for the number of negative eigenvalues of $P_-^* P_{\mathcal{M}} P_-$ can now be read off immediately from formula (2.18) for $P_- P_{\mathcal{M}} P_-$. To get formula (2.21) for the number of negative eigenvalues of $P_-^* P_{\mathcal{M}} P_-$, we use (2.19) to compute, where we set

$k_w(\zeta) = \frac{1}{1-\zeta\overline{w}}$ equal to the kernel function for $H_2(\mathbb{D},\mathbb{C})$, for any $w_1,\dots,w_N \in \mathbb{D}$ and $x_1,\dots,x_N \in \mathbb{C}^m$,

$$\begin{aligned}
&\left\langle P_- P_{\mathcal{M}} P_- \left(\sum_{j=1}^N k_{w_j} x_j \right), \sum_{i=1}^N k_{w_i} x_i \right\rangle_{H_2(\mathbb{D},\mathbb{C}^m)} \\
&\quad = -\sigma^2 \sum_{i,j=1}^N \left\langle \left(M_{\Theta_{21}} P_{H_2} M_{\Theta_{21}^*} - M_{\Theta_{22}} P_{H_2} M_{\Theta_{22}^*} \right) k_{w_j} x_j, k_{w_i} x_i \right\rangle_{H_2(\mathbb{D},\mathbb{C}^m)} \\
&\quad = -\sigma^2 \sum_{i,j=1}^N x_i^* \frac{\Theta_{21}(w_i)\Theta_{21}(w_j)^* - \Theta_{22}(w_i)\Theta_{22}(w_j)^*}{1 - w_i\overline{w_j}} x_j.
\end{aligned}$$

By the density of the span of the kernel functions $\{k_w x \colon w \in \mathbb{D},\ x \in \mathbb{C}^m\}$, the formula (2.21) for the number of negative eigenvalues for $P_-^* P_{\mathcal{M}} P_-$ now follows.

Finally, from the (J, J_σ)-unitary property of Θ we know that $\Theta(\zeta)^{-1} = J_1 \Theta(\zeta)^* J_\sigma$ for almost all $\zeta \in \mathbb{T}$, and hence

$$\Theta(\zeta) J_1 \Theta(\zeta)^* = J_{\sigma^{-1}}.$$

In particular,

$$\Theta_{21}(\zeta)\Theta_{21}(\zeta)^* - \Theta_{22}(\zeta)\Theta_{22}(\zeta)^* = -\sigma^{-2} I_m$$

or

$$\Theta_{22}(\zeta)\Theta_{22}(\zeta)^* = \Theta_{21}(\zeta)\Theta_{21}(\zeta)^* + \sigma^{-2} I_m \geq \sigma^{-2} I_m \tag{2.25}$$

for almost all $\zeta \in \mathbb{T}$. Hence, for all such ζ, $\Theta_{22}(\zeta)$ is invertible and

$$0 \leq \Theta_{22}(\zeta)^{-1}\Theta_{21}(\zeta)\Theta_{21}(\zeta)^*\Theta_{22}(\zeta)^{*-1} = I_m - \sigma^{-2}\Theta_{22}(\zeta)^{-1}\Theta_{22}(\zeta)^{*-1} \leq I_m. \tag{2.26}$$

We conclude that $\Theta_{22}^{-1}\Theta_{21} \in L_\infty(\mathbb{T}, \mathbb{C}^{m\times p})$ with $\|\Theta_{22}^{-1}\Theta_{21}\| \leq 1$. Moreover, by conjugating the kernel in (2.21) by Θ_{22}^{-1} (multiplying by $\Theta_{22}(z)^{-1}$ on the left and by $\Theta_{22}(w)^{*-1}$ on the right for the generic sets of z and w for which these are defined), we see that the kernel

$$\frac{I_m - (\Theta_{22}^{-1}\Theta_{21})(z)(\Theta_{22}^{-1}\Theta_{21})(w)^*}{1 - z\overline{w}}$$

also has k negative squares on $\mathbb{D}\times\mathbb{D}$, i.e., $\Theta_{22}^{-1}\Theta_{21} \in H_{\infty,k}(\mathbb{D}, \mathbb{C}^{m\times p})$ with $\|\Theta_{22}^{-1}\Theta_{21}\|_\infty \leq 1$. Thus $\Theta_{22}^{-1}\Theta_{21}$ has a left Kreĭn–Langer factorization $\Theta_{22}^{-1}\Theta_{21} = B^{-1}F$ with B an $m \times m$ Blaschke–Potapov product of degree k and $F \in H_\infty(\mathbb{D}, \mathbb{C}^{m\times p})$. From the fact that $\mathcal{M} = L_2$-closure of $\Theta \cdot H_\infty(\mathbb{D}, \mathbb{C}^{m+p})$ and the fact that $\begin{bmatrix} 0 & I_m \end{bmatrix} \mathcal{M} \subset H_2(\mathbb{D}, \mathbb{C}^m)$, we see that the matrix entries of both Θ_{21} and Θ_{22} are in H_2. From $\Theta_{22}^{-1}\Theta_{21} = B^{-1}F$ we conclude that Θ_{22} must have outer-inner factorization of the form $\Theta_{22} = \Theta_{22,o} \cdot B$ with $\Theta_{22,o} \in H_2(\mathbb{D}, \mathbb{C}^{m\times m})$ outer and $B \in H_\infty(\mathbb{D}, \mathbb{C}^{m\times m})$ a Blaschke–Potapov product of degree k. This completes the proof of Proposition 2.18. □

Winding number proof of Theorem 2.2. Suppose that $Q \in H_\infty(\mathbb{D}, \mathbb{C}^{p\times m})$ with $\|Q\|_\infty \leq 1$. From (2.25) and (2.26) we see that $\Theta_{22}(\zeta)$ is invertible and that $\|(\Theta_{22}^{-1}\Theta_{21})(\zeta)\| < 1$ for almost all $\zeta \in \mathbb{T}$. Hence the quantity

$$\Theta_{21}(\zeta)Q(\zeta) + \Theta_{22}(\zeta) = \Theta_{22}(\zeta)(I_m + \Theta_{22}(\zeta)^{-1}\Theta_{21}(\zeta)Q(\zeta))$$

is invertible for almost all $\zeta \in \mathbb{T}$. We may then define a $p \times m$ matrix-valued function K on $\mathbb{T}$ by

$$K = (V_{11}Q + V_{12})(\Theta_{21}Q + \Theta_{22})^{-1}. \tag{2.27}$$

We verify that $K \in L_\infty(\mathbb{T}, \mathbb{C}^{p\times m})$ and in fact that $\|G + K\|_\infty \le \sigma$ as follows. Note that

$$\begin{aligned}\begin{bmatrix} G+K \\ I_m \end{bmatrix}(\Theta_{21}Q + \Theta_{22}) &= \begin{bmatrix} I_p & G \\ 0 & I_m \end{bmatrix}\begin{bmatrix} K \\ I_m \end{bmatrix}(\Theta_{21}Q + \Theta_{22}) = \begin{bmatrix} I_p & G \\ 0 & I_m \end{bmatrix}\begin{bmatrix} V_{11}Q + V_{12} \\ \Theta_{21}Q + \Theta_{22} \end{bmatrix} \\ &= \begin{bmatrix} I_p & G \\ 0 & I_m \end{bmatrix} V \begin{bmatrix} Q \\ I_m \end{bmatrix} = \Theta \begin{bmatrix} Q \\ I_m \end{bmatrix}. \end{aligned} \tag{2.28}$$

(Here we use that $\left[\begin{smallmatrix} I_p & G \\ 0 & I_m \end{smallmatrix}\right] \cdot V = \Theta$ and thus also $\begin{bmatrix} V_{21} & V_{22} \end{bmatrix} = \begin{bmatrix} \Theta_{21} & \Theta_{22} \end{bmatrix}$.) Consequently, considering the various expressions below as functions on $\mathbb{T}$, we have

$$\begin{aligned}(G+K)^*(G+K) - \sigma^2 I_m &= \begin{bmatrix} (G+K)^* & I_m \end{bmatrix} J_\sigma \begin{bmatrix} G+K \\ I_m \end{bmatrix} \\ &= (\Theta_{21}Q + \Theta_{22})^{*-1} \begin{bmatrix} Q^* & I_m \end{bmatrix} \Theta^* J_\sigma \Theta \begin{bmatrix} Q \\ I_M \end{bmatrix} (\Theta_{21}Q + \Theta_{22})^{-1} \\ &= (\Theta_{21}Q + \Theta_{22})^{*-1}(Q^*Q - I_m)(\Theta_{21}Q + \Theta_{22})^{-1} \le 0, \end{aligned}$$

where the last step follows from the assumption that $\|Q\|_\infty \le 1$. In particular, it follows that

$$\|K\|_\infty \le \sigma + \|G\|_\infty \text{ whenever } K = (V_{11}Q + V_{12})(\Theta_{21}Q + \Theta_{22})^{-1} \text{ with } \|Q\|_\infty \le 1. \tag{2.29}$$

Moreover, from (2.28) we see that $G + K$ is given in terms of Q, as in (2.3).

For the discussion in this paragraph we consider the special case $\|Q\|_\infty < 1$; in the end we shall use this special case to arrive at the general case by an approximation argument. We observed at the end of the proof of Proposition 2.18 that the matrix entries of Θ_{21} and Θ_{22} are all in H_2, and by Proposition 2.18 we know that Θ_{22} has outer-inner factorization $\Theta_{22} = F \cdot B$ with F outer and the inner factor B equal to a Blaschke–Potapov product of degree k. For any function f analytic on the disk $\mathbb{D}$ (with possibly finitely many exceptional points), set $f_r(z) = f(rz)$ for each $r < 1$. Then $\Theta_{22,r}$ still has the form $F_r' \cdot B_r'$ with F_r' outer and B_r' a Blaschke–Potapov product of degree k, as long as we take $r < 1$ sufficiently close to 1. Moreover, by Proposition 2.6, we know that there is an $r_0 < 1$ such that, for all r subject to $r_0 \le r < 1$, we have $\|\Theta_{22,r}^{-1}\Theta_{21,r}\|_\infty \le \frac{1}{2}(1 + \|Q\|_\infty^{-1})$, with the consequence that

$$\begin{aligned}\|\Theta_{22,r}^{-1}\Theta_{21,r}Q_r\|_\infty &\le \frac{1}{2}\|Q_r\|_\infty(1 + \|Q\|_\infty^{-1}) \\ &\le \frac{1}{2}(\|Q\|_\infty + 1) < 1 \quad \text{for all } r_0 \le r < 1. \end{aligned} \tag{2.30}$$

By the Neumann series estimate, it follows that $(I + \Theta_{22,r}^{-1}\Theta_{21,r}Q_r)$ is invertible in $L_\infty(\mathbb{T}, \mathbb{C}^{m\times m})$ with

$$\|(I + \Theta_{22,r}^{-1}\Theta_{21,r}Q_r)^{-1}\|_\infty \le \frac{1}{1 - \frac{1}{2}(1 + \|Q\|_\infty)} = \frac{2}{1 - \|Q\|_\infty}. \tag{2.31}$$

Another consequence of the estimate (2.30) is that the determinant of $(I+\Theta_{22,r}^{-1}\Theta_{21,r}Q_r)$ has winding number around the unit circle equal to zero. As $\det\Theta_{22,r}=\det(F_r')\cdot\det B_r'$ has winding number equal to k (since F_r' is outer and B_r' is a matrix Blaschke–Potapov product of degree k), it follows that the determinant of

$$\Theta_{21,r}Q_r+\Theta_{22,r}=\Theta_{22,r}\left(\Theta_{22,r}^{-1}\Theta_{21,r}Q_r+I_m\right)$$

has winding number equal to k around the unit circle. As $\Theta_{21,r}Q_r+\Theta_{22,r}$ is in the disk algebra (analytic on the open disk and continuous on the closed disk), we conclude that $(\Theta_{21,r}Q_r+\Theta_{22,r})^{-1}$ is in $H_{\infty,k}(\mathbb{D},\mathbb{C}^{m\times m})$.

We now return to the case of a general $Q\in H_\infty(\mathbb{D},\mathbb{C}^{p\times m})$ with $\|Q\|\le 1$. Let s be a number with $0<s<1$. Then the above analysis applies to the situation where we have $s\cdot Q$ in place of Q. Thus

$$\|(\Theta_{22,r}^{-1}\Theta_{21,r}(sQ_r)+I)^{-1}\|_\infty\le\frac{2}{1-s\|Q\|_\infty}\le\frac{2}{1-s} \tag{2.32}$$

for all $r<1$ sufficiently close to 1. Also, from (2.26) we read off that $\|\Theta_{22}^{-1}\|_\infty\le\sigma$; by Proposition 2.6 we then have $\|\Theta_{22,r}^{-1}\|_\infty\le\sigma+\epsilon$ for any given $\epsilon>0$ as long as we take $r<1$ sufficiently close to 1. Hence, for all $r<1$ but sufficiently close to 1, we have

$$\begin{aligned}\|(\Theta_{21,r}(sQ_r)+\Theta_{22,r})^{-1}\|_\infty&=\|(\Theta_{22,r}^{-1}\Theta_{21,r}(sQ_r)+I)^{-1}\Theta_{22,r}^{-1}\|_\infty\\&\le\left(\frac{2}{1-s}\right)\cdot(\sigma+\epsilon)<\infty.\end{aligned}$$

We conclude that $(\Theta_{21,r}(sQ_r)+\Theta_{22,r})^{-1}$ converges pointwise boundedly, and hence, by part (2) of Proposition 2.3, also in the $L_\infty(\mathbb{T},\mathbb{C}^{m\times m})$-weak-$*$ topology, to $(\Theta_{21}(sQ)+\Theta_{22})^{-1}$ as $r\to 1$. As we have seen above, each $(\Theta_{21,r}(sQ_r)+\Theta_{22,r})^{-1}$ is in $H_{\infty,k}(\mathbb{D},\mathbb{C}^{m\times m})$. By Proposition 2.4, we conclude that $(\Theta_{21}(sQ)+\Theta_{22})^{-1}\in H_{\infty,k'}(\mathbb{D},\mathbb{C}^{m\times m})$ with $k'\le k$. But then $K_s:=(V_{11}(sQ)+V_{12})(\Theta_{21}(sQ)+\Theta_{22})^{-1}$ is in $(H_2(\mathbb{D},\mathbb{C}^{p\times m})\cdot H_{\infty,k'})\cap L_\infty$, and hence is in fact in $H_{\infty,k'}(\mathbb{D},\mathbb{C}^{p\times m})$ for some $k'\le k$. By (2.29), we know that $\|K_s\|_\infty\le\sigma+\|G\|_\infty$ for all $s<1$. Hence, by another application of part (2) of Proposition 2.3 combined with Proposition 2.4, we may let $s\to 1$ and conclude that $K=(V_{11}Q+V_{12})(\Theta_{21}Q+\Theta_{22})^{-1}$ is in $H_{\infty,k'}(\mathbb{D},\mathbb{C}^{p\times m})$ for some $k'\le k$. Since we have already verified that $\|G+K\|_\infty\le\sigma$ and we know by Proposition 2.7 that k is the smallest possible index for a solution to the Nehari–Takagi problem to exist for level σ if $\sigma_k>\sigma>\sigma_{k+1}$, we conclude that necessarily $k'=k$. We have now verified that the formula (2.3) provides a solution K to the Nehari–Takagi problem as asserted in Theorem 2.2.

Conversely, suppose that $K\in H_{\infty,k}(\mathbb{D},\mathbb{C}^{p\times m})$ provides a solution of the Nehari–Takagi problem. Then K has a Kreĭn–Langer factorization $K=F'B'^{-1}$, where $F'\in H_\infty(\mathbb{D},\mathbb{C}^{p+m})$ and $B'\in H_\infty(\mathbb{D},\mathbb{C}^{m\times m})$ is a Blaschke–Potapov product of degree k. Then

$$\begin{aligned}\begin{bmatrix}G+K\\I_m\end{bmatrix}B'&=\begin{bmatrix}I_p&G\\0&I_m\end{bmatrix}\begin{bmatrix}K\\I_m\end{bmatrix}B'\\&=\Theta\cdot\Lambda\cdot\begin{bmatrix}F'\\B'\end{bmatrix}\\&=\Theta\cdot\begin{bmatrix}\Lambda_{11}F'+\Lambda_{12}B'\\\Lambda_{21}F'+\Lambda_{22}B'\end{bmatrix}=:\Theta\cdot\begin{bmatrix}Q_1\\Q_2\end{bmatrix},\end{aligned} \tag{2.33}$$

where $Q_1 := \Lambda_{11}F' + \Lambda_{12}B' \in H_2(\mathbb{D}, \mathbb{C}^{p\times m})$ and $Q_2 := \Lambda_{21}F' + \Lambda_{22}B' \in H_2(\mathbb{D}, \mathbb{C}^{m\times m})$. Since $\|G + K\|_\infty \le \sigma$ by assumption,

$$\begin{aligned} 0 &\ge B'^* \left((G+K)^*(G+K) - \sigma^2 I_m\right) B' \\ &= B'^* \begin{bmatrix} (G+K)^* & I_m \end{bmatrix} J_\sigma \begin{bmatrix} G+K \\ I_m \end{bmatrix} B' \\ &= \begin{bmatrix} Q_1^* & Q_2^* \end{bmatrix} \Theta^* J_\sigma \Theta \begin{bmatrix} Q_1 \\ Q_2 \end{bmatrix} \\ &= Q_1^* Q_1 - Q_2^* Q_2 \end{aligned} \tag{2.34}$$

a.e. on $\mathbb{T}$. We conclude that

$$Q_2(\zeta)x(\zeta) = 0 \Rightarrow Q_1(\zeta)x(\zeta) = 0. \tag{2.35}$$

From the definition of Q_1 and Q_2 in (2.33) we see that

$$B' = \Theta_{21}Q_1 + \Theta_{22}Q_2. \tag{2.36}$$

Hence (2.35) forces $B'(\zeta)x(\zeta) = 0$ as well, and hence $x(\zeta) = 0$ for almost all $\zeta \in \mathbb{T}$. We conclude that $Q_2(\zeta)$ is invertible a.e. on $\mathbb{T}$ and $Q(\zeta) := Q_1(\zeta)Q_2(\zeta)^{-1}$ makes sense. The calculation (2.34) then implies that $\|Q\|_\infty \le 1$, while (2.33) shows that we recover $G + K$ from Q as in the representation (2.3).

It remains to show that $Q \in H_\infty(\mathbb{D}, \mathbb{C}^{p\times m})$. For this piece of the argument we borrow some ideas from the Grassmannian approach. If $Q_2H_\infty(\mathbb{C}, \mathbb{C}^m)$ is not dense in $H_2(\mathbb{D}, \mathbb{C}^m)$, we may choose a nonzero $h_0 \in H_\infty(\mathbb{D}, \mathbb{C}^m)$ lying in $H_2(\mathbb{D}, \mathbb{C}^m) \ominus \overline{Q_2H_\infty(\mathbb{D}, \mathbb{C}^m)}$. Then

$$\begin{bmatrix} 0 \\ h_0 \end{bmatrix} \perp_{J_1} \begin{bmatrix} Q_1 \\ Q_2 \end{bmatrix} H_\infty(\mathbb{D}, \mathbb{C}^m).$$

Since $\Theta^* J_\sigma \Theta = J_1$ on $\mathbb{T}$, it then follows that

$$\Theta \begin{bmatrix} 0 \\ h_0 \end{bmatrix} = \begin{bmatrix} \Theta_{12}h_0 \\ \Theta_{22}h_0 \end{bmatrix} \perp_{J_\sigma} \Theta \begin{bmatrix} Q_1 \\ Q_2 \end{bmatrix} H_\infty(\mathbb{D}, \mathbb{C}^m) = \begin{bmatrix} G+K \\ I_m \end{bmatrix} B'H_\infty(\mathbb{D}, \mathbb{C}^m) \text{ (by (2.33))}.$$

Hence

$$\|\Theta_{12}h_0 + (G+K)B'h\|_2^2 \le \|\Theta_{22}h_0 + B'h\|_2^2$$

for all $h \in H_2(\mathbb{D}, \mathbb{C}^m)$. Therefore there is a contraction operator X from $\mathcal{D}_0 := \operatorname{span}\{\Theta_{22}h_0\} + B'H_2(\mathbb{D}, \mathbb{C}^m)$ into $L_2(\mathbb{T}, \mathbb{C}^p)$ such that

$$\begin{bmatrix} X \\ I_m \end{bmatrix} (h_0 + B'h) = \begin{bmatrix} \Theta_{12}h_0 \\ \Theta_{22}h_0 \end{bmatrix} + \begin{bmatrix} G+K \\ I_m \end{bmatrix} B'h \in \begin{bmatrix} I_p & G \\ 0 & I_m \end{bmatrix} H_2(\mathbb{D}, \mathbb{C}^{p+m}) \tag{2.37}$$

for all $h \in H_2(\mathbb{D}, \mathbb{C}^m)$. Note that $\left[\begin{smallmatrix} I_p & G \\ 0 & I_m \end{smallmatrix}\right] H_2(\mathbb{D}, \mathbb{C}^{p+m})$ has a J_σ-orthogonal splitting

$$\begin{bmatrix} I_p & G \\ 0 & I_m \end{bmatrix} H_2(\mathbb{D}, \mathbb{C}^{p+m}) = \begin{bmatrix} H_2(\mathbb{D}, \mathbb{C}^p) \\ \{0\} \end{bmatrix} \oplus_{J_\sigma} \begin{bmatrix} H_G \\ I_m \end{bmatrix} \mathcal{E}_+ \oplus_{J_\sigma} \begin{bmatrix} H_G \\ I_m \end{bmatrix} \mathcal{E}_-, \tag{2.38}$$

where $\mathcal{E}_+ = \operatorname{im} E((\sigma, +\infty))$ and $\mathcal{E}_- = \operatorname{im} E([0, \sigma))$ and where we have set $E(\cdot)$ equal to the spectral projection for the self-adjoint operator $(H_G^* H_G)^{1/2}$. Note that the first

two direct summands in (2.38) are uniformly J_σ-positive, while the last is uniformly J_σ-negative. As $\|X\| \le 1$, the equality (2.37) forces the existence of a subspace $\mathcal{E}_-^0$ of $\mathcal{E}_-$ so that

$$\begin{bmatrix} X \\ I_m \end{bmatrix} \mathcal{D}_0 = \left\{ \begin{bmatrix} Y_2 e \\ 0 \end{bmatrix} + \begin{bmatrix} H_G \\ I_m \end{bmatrix} Y_1 e + \begin{bmatrix} H_G \\ I_m \end{bmatrix} e \colon e \in \mathcal{E}_-^0 \right\} \tag{2.39}$$

for operators $Y_1 \colon \mathcal{E}_-^0 \mapsto \mathcal{E}_+$ and $Y_2 \colon \mathcal{E}_-^0 \mapsto H_2(\mathbb{D}, \mathbb{C}^p)$. In particular,

$$\mathcal{D}_0 = \{Y_1 e + e \colon e \in \mathcal{E}_-^0\}. \tag{2.40}$$

But the subspace $\mathcal{D}_0 = \operatorname{span}\{\Theta_{22} h_0\} + B' H_2(\mathbb{D}, \mathbb{C}^m)$ has codimension $k-1$ in $H_2(\mathbb{D}, \mathbb{C}^m)$, while the subspace on the right in (2.40) has the same codimension in $H_2(\mathbb{D}, \mathbb{C}^m)$ as does $\mathcal{E}_-^0$. As $\mathcal{E}_-^0$ is a subspace of $\mathcal{E}_-$ which has codimension k in $H_2(\mathbb{D}, \mathbb{C}^m)$, we conclude that the right-hand side of (2.40) has codimension at most k in $H_2(\mathbb{D}, \mathbb{C}^m)$. In this way we arrive at a contradiction and conclude that necessarily Q_2 is outer. It now follows that $Q = Q_1 Q_2^{-1}$ is of bounded type with no inner factor in the denominator. This together with $Q \in L_\infty(\mathbb{T}, \mathbb{C}^{p\times m})$ gives us finally that $Q \in H_\infty(\mathbb{D}, \mathbb{C}^{p\times m})$, as wanted. ∎

Remark 2.19. *The band method.* A very flexible method for solving a variety of interpolation and extension problems which has evolved into increasing levels of sophistication over the past two decades is the so-called *band method* (see [22] for an excellent overview and [35] for one of the latest variations). Recent work (see [26]) enhances this abstract scheme to handle the Nehari–Takagi problem ($\sigma_{k+1} < \sigma < \sigma_k$ with $k \ge 1$) rather than merely the suboptimal Nehari problem ($\sigma_1 < \sigma$). However, the core of the method involves solving equations in a Wiener-like algebra; this limitation forces the spectral factor Λ and its inverse $\Lambda^{-1} = V$ (in the discrete-time setting) to be in $H_\infty(\mathbb{D}, \mathbb{C}^{(p+m)\times(p+m)})$ rather than merely in $H_2(\mathbb{D}, \mathbb{C}^{(p+m)\times(p+m)})$. A remaining open issue appears to be the extension of this abstract framework to include the situation studied in this paper.

3. State-space solutions. Let X be an arbitrary Hilbert space, and let A be the infinitesimal generator of a strongly continuous semigroup $\{T(t)\}_{t\ge 0}$. Let $B \in \mathcal{L}(\mathbb{C}^m, X)$, $C \in \mathcal{L}(X, \mathbb{C}^p)$. Assume that the triple (A, B, C) satisfies

A1. $B^*(\cdot I - A^*)^{-1} x \in H_2(\mathbb{C}_+, \mathbb{C}^m)$ (input stable),

A2. $C(\cdot I - A)^{-1} x \in H_2(\mathbb{C}_+, \mathbb{C}^p)$ (output stable),

A3. $C(\cdot I - A)^{-1} B u \in H_\infty(\mathbb{C}_+, \mathbb{C}^p)$ (input-output stable)

for all $x \in X$, $u \in \mathbb{C}^m$. Condition A3 holds if and only if $\mathcal{D} \in \mathcal{L}(L^2(\mathbb{R}_+; \mathbb{C}^m), L^2(\mathbb{R}_+; \mathbb{C}^p))$, where

$$(\mathcal{D}u)(t) = C \int_0^t T(t-s) B u(s)\, ds \quad (u \in L^2(\mathbb{R}_+; \mathbb{C}^m)). \tag{3.1}$$

Equation (3.1) is equivalent to $\widehat{\mathcal{D}u} = G\widehat{u}$, where $G(s) := C(sI - A)^{-1} B$ and $\widehat{u}$ denotes the Laplace transform of u ($\widehat{u}(s) := \int_0^\infty \mathrm{e}^{-st} u(t)\, du$). It is well known that $\|\mathcal{D}\| = \|G\|_{H_\infty}$. By Plancherel's theorem (and the closed graph theorem), A2 means that $\mathcal{C} : X \to L^2(\mathbb{R}_+; \mathbb{C}^p)$ is bounded, where $(\mathcal{C}x)(t) := CT(t)x$, $t \ge 0$. Hence it also follows that $L_C := \mathcal{C}^*\mathcal{C} \in \mathcal{L}(X)$. Similarly, A1 implies that $\mathcal{B}^{\mathrm{d}} : X \to L^2(\mathbb{R}_+; \mathbb{C}^m)$ is bounded, where $(\mathcal{B}^{\mathrm{d}} x)(t) := B^* T(t)^* x$, $t \ge 0$. Thus, $L_B := \mathcal{B}\mathcal{B}^* \in \mathcal{L}(X)$, where $\mathcal{B}^* := \mathcal{R}\mathcal{B}^{\mathrm{d}}$, $(\mathcal{R}f)(t) := f(-t)$ (the reflection). (See, for instance, Curtain and Zwart [16] or Mikkola [30] for details.)

It is easy to see that if the system is *exponentially stable* (that is, there are $\epsilon > 0$, $M < \infty$ such that $\|T(t)\|_{\mathcal{L}(X)} \leq M\mathrm{e}^{-\epsilon t}$ for all $t > 0$), then A1–A3 are satisfied (and $\overline{\mathbb{C}_+} \subset \rho(A)$). However, there are several important systems that are not exponentially stable but for which A1–A3 hold. In this section we shall derive the state-space formulas for the factors Λ and V for such systems; we use the additional assumption that the open right half-plane $\mathbb{C}_+$ is contained in the resolvent set $\rho(A)$, but this assumption can be relaxed (for example, a zero-measurable spectrum on each vertical line on $\mathbb{C}_+$ is not a problem; see Remark 3.4 below).

In Lemma 3.1 below we show that if A1–A3 hold, then the systems $(A, -, B^*L_C)$ and $(A^*, -, CL_B)$ are output stable, that is, $B^*L_CT \in \mathcal{L}(X, L^2(\mathbb{R}_+; \mathbb{C}^m))$, $CL_BT^* \in \mathcal{L}(X, L^2(\mathbb{R}_+; \mathbb{C}^p))$. We use the following notation:

$$(\pi_+ f)(t) := \begin{cases} f(t) & \text{if } t \geq 0, \\ 0 & \text{if } t < 0, \end{cases} \quad \text{and} \quad \mathcal{D}^{\mathrm{d}} := \mathcal{R}\mathcal{D}^*\mathcal{R}$$

is the input-output map of (A^*, C^*, B^*) (see [30, Lemma 6.2.9(b)]).

LEMMA 3.1. *If* A1*,* A2*, and* A3 *hold, then* $\pi_+\mathcal{D}^*\mathcal{C}x = B^*L_CT(\cdot)x$ *and* $\mathcal{R}\pi_-\mathcal{D}\mathcal{B}^*x = \pi_+(\mathcal{D}^{\mathrm{d}})^*\mathcal{B}^{\mathrm{d}}x = CL_BT(\cdot)^*x$ *for each* $x \in X$*. In particular, there is* $M < \infty$ *such that* $\|B^*L_C(\cdot I - A)^{-1}x\|_{H_2(\mathbb{C}_+,\mathbb{C}^m)} \leq M\|x\|_X$ *and* $\|CL_B(\cdot I - A^*)^{-1}x\|_{H_2(\mathbb{C}_+,\mathbb{C}^p)} \leq M\|x\|_X$ *for all* $x \in X$*.*

Proof. By Lemma 4.2.6 of [33], we have $\pi_+\mathcal{D}^*\mathcal{C}x = B^*L_CTx$ (everywhere, by continuity). The first inequality is obtained from Plancherel's theorem with $M := \|\mathcal{D}\| \max\{\|\mathcal{C}\|, \|\mathcal{B}\|\}$. Applying the above to (A^*, C^*, B^*), we obtain the second equality and inequality (because $\|(\mathcal{D}^{\mathrm{d}})^*\| = \|\mathcal{D}^{\mathrm{d}}\| = \|B^*(\cdot I - A^*)^{-1}C^*\|_\infty = \|G^*\|_\infty = \|G\|_\infty = \|\mathcal{D}\|$). ∎

Now we are ready to give the state-space formulas for the factors Λ and V. The case where $\overline{\mathbb{C}_+} \subset \rho(A)$ is simple, and the general case will be reduced to that by using the results given in section 6.

LEMMA 3.2. *Assume that the triple* (A, B, C) *satisfies* A1*,* A2*,* A3 *and that* $\mathbb{C}_+ \subset \rho(A)$*. Let* $G(s) = C(sI - A)^{-1}B$ *be the associated transfer function, with associated Hankel singular values* $\sigma_1 \geq \sigma_2 \geq \cdots$*, and let* σ *be such that* $\sigma_{k+1} < \sigma < \sigma_k$*. Let* Λ *be defined as follows:*

(3.2)
$$\Lambda(s) = \begin{bmatrix} I_p & 0 \\ 0 & \sigma I_m \end{bmatrix} + \frac{1}{\sigma^2}\begin{bmatrix} -CL_B \\ \sigma B^* \end{bmatrix}\left(I - \frac{1}{\sigma^2}L_CL_B\right)^{-1}(sI + A^*)^{-1}\begin{bmatrix} C^* & L_CB \end{bmatrix},$$

$s \in \mathbb{C}_-$*. Then* Λ *has the following properties:*

(1) $\Lambda(i\omega)^*\left[\begin{smallmatrix} I_p & 0 \\ 0 & -I_m \end{smallmatrix}\right]\Lambda(i\omega) = \left[\begin{smallmatrix} I_p & G(i\omega) \\ 0 & I_m \end{smallmatrix}\right]^*\left[\begin{smallmatrix} I_p & 0 \\ 0 & -\sigma^2 I_m \end{smallmatrix}\right]\left[\begin{smallmatrix} I_p & G(i\omega) \\ 0 & I_m \end{smallmatrix}\right]$ *for almost all* $\omega \in \mathbb{R}$*.*

(2) $\Lambda(s)$ *is invertible for each* $s \in \mathbb{C}_-$*, and its inverse is given by*

(3.3)
$$V(s) = \begin{bmatrix} I_p & 0 \\ 0 & \frac{1}{\sigma}I_m \end{bmatrix} - \frac{1}{\sigma^2}\begin{bmatrix} -CL_B \\ \sigma B^* \end{bmatrix}(sI + A^*)^{-1}\left(I - \frac{1}{\sigma^2}L_CL_B\right)^{-1}\begin{bmatrix} C^* & \frac{1}{\sigma}L_CB \end{bmatrix},$$

$s \in \mathbb{C}_-$*.*

(3) $\Lambda(\cdot) - \left[\begin{smallmatrix} I_p & 0 \\ 0 & \sigma I_m \end{smallmatrix}\right] \in H_2(\mathbb{C}_-, \mathbb{C}^{(p+m)\times(p+m)})$*.*

(4) $V(\cdot) - \left[\begin{smallmatrix} I_p & 0 \\ 0 & \frac{1}{\sigma}I_m \end{smallmatrix}\right] \in H_2(\mathbb{C}_-, \mathbb{C}^{(p+m)\times(p+m)})$*.*

Proof. 1° *Case* $\overline{\mathbb{C}_+} \subset \rho(A)$*:* The proofs of parts (1) and (2) go in a way similar to the suboptimal Nehari problem addressed in Curtain and Zwart [16, section 8.3].

The new part is to show that parts (3) and (4) hold. Set

$$\widehat{g}(s) := \begin{bmatrix} C \\ B^*L_C \end{bmatrix} (sI - A)^{-1} \quad (s \in \rho(A)). \tag{3.4}$$

By Lemma 3.1, we have $\widehat{g}x \in H_2(\mathbb{C}_+, \mathbb{C}^{p+m})$ for all $x \in X$, and so

$$\widehat{f} := \widehat{g}\left(I - \frac{1}{\sigma^2} L_B L_C\right)^{-1} \begin{bmatrix} -L_B C^* \\ \sigma B \end{bmatrix} \tag{3.5}$$

satisfies $\widehat{f}z \in H_2(\mathbb{C}_+, \mathbb{C}^{p+m})$ for all $z \in \mathbb{C}^{p+m}$. Thus $\widehat{f} \in H_2(\mathbb{C}_+, \mathbb{C}^{(p+m)\times(p+m)})$. Since $-\widehat{f}(-\bar{s})^* = \Lambda(s) - \left[\begin{smallmatrix} I_p & 0 \\ 0 & \sigma I_m \end{smallmatrix}\right]$, we obtain that (3) holds.

Part (4) can be proved in an analogous way.

2° *The general case* $\mathbb{C}_+ \subset \rho(A)$*:* The proof in 1° establishes (2)–(4). However, (1) is more complicated: Now (3.2) defines Λ on $\mathbb{C}_-$ only, and on $i\mathbb{R}$ it is defined a.e. as the radial (or nontangential) limit or, equivalently, as the Fourier (Laplace) transform of the inverse Laplace transform of Λ. This follows from (3) (see below).

Nevertheless, the triple $(A-\epsilon, B, C)$ satisfies the assumptions of 1° (cf. Lemma 6.1). Therefore, the corresponding functions Λ_ϵ and G_ϵ satisfy (1) in place of Λ and G. (Note that $G_\epsilon(i\omega) := C(i\omega I - (A-\epsilon))^{-1}B = G(i\omega + \epsilon)$.) Repeat (3.4) and (3.5) with $\widehat{g}_\epsilon, \widehat{f}_\epsilon, A-\epsilon, L_{C,\epsilon}, L_{B,\epsilon}$ in place of $\widehat{g}, \widehat{f}, A, L_C, L_B$, respectively.

By (2) and (3) of Lemma 6.1 (and Lemma A.3.1(j3) of Mikkola [30]), we have $g_\epsilon x := \pi_+ \left[\begin{smallmatrix} I \\ \mathcal{D}_\epsilon^* \end{smallmatrix}\right] \mathcal{C}_\epsilon x \to \pi_+ \left[\begin{smallmatrix} I \\ \mathcal{D}^* \end{smallmatrix}\right] \mathcal{C}x$ in $L^2(\mathbb{R}_+; \mathbb{C}^{p+m})$, and so $\widehat{g}_\epsilon x \to \widehat{g}x$ in $L^2(i\mathbb{R}; \mathbb{C}^{p+m})$, as $\epsilon \to 0+$, for all $x \in X$. Therefore, $\widehat{f}_\epsilon z \to \widehat{f}z$ in $L^2(i\mathbb{R}; \mathbb{C}^{p+m})$ for all $z \in \mathbb{C}^{p+m}$ (here we also need (7) and (4) of Lemma 6.1); hence a subsequence converges a.e. on $i\mathbb{R}$. But, similarly, $G_\epsilon(i\omega)z = G(i\omega + \epsilon)z \to G(i\omega)z$, as $\epsilon \to 0+$, for almost every $\omega \in \mathbb{R}$, for each $z \in \mathbb{C}^{p+m}$ (use the standard H^∞ boundary function result, such as Theorem 3.3.1(c1) of Mikkola [30]).

We already noted above that $\langle \Lambda_\epsilon(i\omega)\tilde{z}, \left[\begin{smallmatrix} I_p & 0 \\ 0 & -I_m \end{smallmatrix}\right] \Lambda_\epsilon(i\omega)z \rangle = \left\langle \left[\begin{smallmatrix} I_p & G_\epsilon(i\omega) \\ 0 & I_m \end{smallmatrix}\right] \tilde{z}, \left[\begin{smallmatrix} I_p & 0 \\ 0 & -\sigma^2 I_m \end{smallmatrix}\right] \left[\begin{smallmatrix} I_p & G_\epsilon(i\omega) \\ 0 & I_m \end{smallmatrix}\right] z \right\rangle$ for almost every $\omega \in \mathbb{R}$, for any $z, \tilde{z} \in \mathbb{C}^{p+m}$. By the above, we can remove the ϵ's (just let $\epsilon \to 0$). Since $\mathbb{C}^{p+m}$ has a finite basis, (1) holds. ∎

In light of Lemma 3.2, we now obtain our main theorem by invoking the key frequency-domain result, namely, Theorem 2.1. The following theorem gives explicit formulas (in terms of the state-space parameters) for all solutions to the suboptimal Hankel norm approximation problem in the case of infinite-dimensional systems which do not necessarily have an exponentially stable semigroup.

THEOREM 3.3. *Assume that the triple* (A, B, C) *satisfies* A1, A2, A3 *and that* $\mathbb{C}_+ \subset \rho(A)$*. Let* $G(s) = C(sI - A)^{-1}B$ *be the associated transfer function, and let the Hankel singular values be denoted by* $\sigma_1 \geq \sigma_2 \geq \cdots$*. Suppose that* σ *is such that* $\sigma_{k+1} < \sigma < \sigma_k$*, and let* V *be given by* (3.3)*.*

Then K *is such that* $K(\cdot) \in H_{\infty,k}(\mathbb{C}_-, \mathbb{C}^{p\times m})$ *and* $\|G(i\cdot) + K(i\cdot)\|_\infty \leq \sigma$ *if and only if* K *is given by* $K(i\omega) = (V_{11}(i\omega)Q(i\omega)+V_{12}(i\omega))(V_{21}(i\omega)Q(i\omega)+V_{22}(i\omega))^{-1}, \omega \in \mathbb{R}$*, for some* $Q \in H_\infty(\mathbb{C}_-, \mathbb{C}^{p\times m})$ *such that* $\|Q\|_\infty \leq 1$*.*

This follows from Theorem 2.1 and Lemma 3.2.

Remark 3.4.

(a) The assumption $\mathbb{C}_+ \subset \rho(A)$ can be weakened in all our results, including the above. Indeed, it suffices that, for instance, the Lebesgue measure of $\{r+\omega i \in \sigma(A) : \omega \in \mathbb{R}\}$ is zero for all small $r > 0$, as one can verify from the proofs.

(b) Finally, we remark that in Chapter 6 of Sasane [40], using another approach, state-space formulas were given in the nonexponentially stable case. However, these were in terms of the parameters of the shifted system Σ_ϵ and only guaranteed that, for a small enough shift, they are also solutions to the original system. Also, while only the existence of some solutions was demonstrated in [40], here we give a complete parameterization of *all* solutions.

4. An application to the case of well-posed linear systems. Finally, in this last section we give an application of Theorem 3.3 to obtain state-space formulas for the suboptimal Hankel norm approximation problem for *well-posed* linear systems. This was done using the idea of reciprocal systems in Curtain and Sasane [15], but there, instead of Theorem 3.3, a weaker result from Chapter 6 of Sasane [40] (which was mentioned in Remark 3.4) was used. Here, using Theorem 3.3, we obtain a different solution to the problem, where, as opposed to Curtain and Sasane [15], we now obtain a parameterization of the set of *all* solutions to the suboptimal Hankel norm approximation problem for well-posed linear systems.

We consider the suboptimal Hankel norm approximation problem for a well-posed linear system Σ on a Hilbert space X, with input space $\mathbb{C}^m$, output space $\mathbb{C}^p$, generating operators A, B, C, semigroup $\{T(t)\}_{t\geq 0}$, and transfer function G, under the following assumptions:

B1. $0 \in \rho(A)$ and $\mathbb{C}_+ \subset \rho(A)$.

B2. Σ is input-stable.

B3. Σ is output-stable.

B4. $G \in H_\infty(\mathbb{C}_+, \mathbb{C}^{p\times m})$.

(Condition B1 can be relaxed; for example, it suffices to assume that $0 \in \rho(A)$ and $\sigma(A) \cap \mathbb{C}_+$ is at most countable (see Remark 3.4(a)). Moreover, instead of $0 \in \rho(A)$ it suffices to assume that $ir \in \rho(A)$ for some $r \in \mathbb{R}$, but then one must replace A by $A - ir$ in the formulas, so that the new G equals the old $G(ir + \cdot)$.)

The *reciprocal system* of such a well-posed linear system is defined as the well-posed linear system Σ_r with the bounded generating operators $A^{-1}, A^{-1}B, -CA^{-1}$. In Curtain and Sasane [15], it was established that if Σ satisfies B1–B4 above, then its reciprocal system is such that

1. A1, A2, A3 from the previous section are satisfied;
2. $\mathbb{C}_+ \subset \rho(A^{-1})$;
3. the controllability and observability Gramians of Σ_r are the same as the controllability and observability Gramians of Σ;
4. $K_r \in H_{\infty,k}(\mathbb{C}_-; \mathbb{C}^{p\times m})$ is a solution to the suboptimal Hankel norm approximation problem of the reciprocal system Σ_r if and only if

$$K(s) := K_r\left(\frac{1}{s}\right) - G(0) \quad \text{for } s \in \mathbb{C}_- \tag{4.1}$$

is a solution[1] to the suboptimal Hankel norm approximation problem of the original system Σ.

[1]Note that from equation (4.1), it follows that $K \in H_{\infty,k}(C_-, \mathbb{C}^{p\times m})$ if and only if $K_r \in H_{\infty,k}(C_-, \mathbb{C}^{p\times m})$.

In light of these remarks, we have thus proved the following theorem.

THEOREM 4.1. *Suppose that the well-posed linear system Σ with transfer function G satisfies assumptions* B1–B4. *Let σ be such that $\sigma_{k+1} < \sigma < \sigma_k$, where $\sigma_1 \geq \sigma_2 \geq \cdots$ are the Hankel singular values of G. Let V be given by*

$$V(s) = \begin{bmatrix} I_p & 0 \\ 0 & \frac{1}{\sigma} I_m \end{bmatrix} - \frac{1}{\sigma^2} \begin{bmatrix} CA^{-1}L_B \\ \sigma(A^{-1}B)^* \end{bmatrix} \big(s + (A^{-1})^*\big)^{-1} \left(I - \frac{1}{\sigma^2} L_C L_B\right)^{-1} \cdot \begin{bmatrix} -(CA^{-1})^* & \frac{1}{\sigma} L_C B A^{-1} \end{bmatrix},$$

$s \in \mathbb{C}_-$, where L_B and L_C denote the controllability Gramian and the observability Gramian, respectively, of the system Σ, and $N_\sigma := (I - \frac{1}{\sigma^2} L_B L_C)^{-1}$. Then $K \in H_{\infty,k}(\mathbb{C}_-, \mathbb{C}^{p\times m})$ satisfies $\|G(i\cdot) + K(i\cdot)\|_\infty \leq \sigma$ if and only if

$$K(s) = K_r\left(\frac{1}{s}\right) - G(0),$$

where $K_r(i\omega) = (V_{11}(i\omega)Q(i\omega) + V_{12}(i\omega))(V_{21}(i\omega)Q(i\omega) + V_{22}(i\omega))^{-1}$, $\omega \in \mathbb{R}$, for some $Q \in H_\infty(\mathbb{C}_-, \mathbb{C}^{p\times m})$ such that $\|Q\|_\infty \leq 1$.

This solves the suboptimal Hankel norm approximation problem for well-posed linear systems.

5. Appendix A. In this appendix we present the proofs that were deferred in section 2.

5.1. Proof of Proposition 2.14.

Proof. Suppose that the matrix-valued function K has a Kreĭn–Langer factorization $K = F \cdot B^{-1}$ with $F \in H_\infty(\mathbb{D}, \mathbb{C}^{p\times m})$ and with $B \in H_\infty(\mathbb{D}, \mathbb{C}^{m\times m})$ a Blaschke–Potapov function of degree k. Then the graph of the multiplication operator M_{G+K} restricted to the subspace $B \cdot H_2(\mathbb{D}, \mathbb{C}^m)$ satisfies

$$\begin{aligned} \mathcal{G}_{M_{G+K}} &:= \begin{bmatrix} G+K \\ I \end{bmatrix} BH_2(\mathbb{D}, \mathbb{C}^m) \\ &= \begin{bmatrix} I & G \\ 0 & I \end{bmatrix} \begin{bmatrix} K \\ I \end{bmatrix} BH_2(\mathbb{D}, \mathbb{C}^m) \\ &\subset \begin{bmatrix} I & G \\ 0 & I \end{bmatrix} H_2(\mathbb{D}, \mathbb{C}^{m+p}) =: \mathcal{M}. \end{aligned} \tag{5.1}$$

If also $\|G+K\|_\infty \leq \sigma$, then we see that $\mathcal{G}_{G+K}$ is a *negative subspace* in the Kreĭn-space inner product

$$\langle f, g\rangle_{J_\sigma} = \frac{1}{2\pi} \int_{\mathbb{T}} \langle J_\sigma f(\zeta), g(\zeta)\rangle_{\mathbb{C}^{m+p}} \, |d\zeta|$$

on $L_2(\mathbb{T}, \mathbb{C}^{m+p})$; i.e., each function $f \in \mathcal{G}_{M_{G+K}}$ has negative J_σ-self-inner product

$$\langle f, f\rangle_{J_\sigma} \leq 0 \quad \text{for } f \in \mathcal{G}_{M_{G+K}}. \tag{5.2}$$

Since $B \cdot H_2(\mathbb{D}, \mathbb{C}^m)$ has codimension k in $H_2(\mathbb{D}, \mathbb{C}^m)$, we see in addition that $\mathcal{G}_{M_{G+K}}$ *has codimension k in a maximal negative subspace of the Kreĭn space* $\mathcal{K} := \big(\left[\begin{smallmatrix} L_2(\mathbb{T}, \mathbb{C}^p) \\ H_2(\mathbb{D}, \mathbb{C}^m) \end{smallmatrix}\right], \langle\cdot,\cdot\rangle_{J_\sigma}\big)$. In addition, since $\mathcal{G} := \mathcal{G}_{G+K}$ is the graph of a multiplication operator M_{G+K}, we see that $\mathcal{G}$ *is invariant for the shift operator* $M_\zeta \colon f(\zeta) \mapsto \zeta f(\zeta)$. We have

thus verified the following: *If $K = FB^{-1}$ is a solution of the Nehari–Takagi problem, then the subspace $\mathcal{G} = \mathcal{G}_{G+K} := \left[\begin{smallmatrix} G+K \\ I \end{smallmatrix}\right] \cdot B \cdot H_2(\mathbb{D}, \mathbb{C}^m)$ (where B is the Blaschke–Potapov product of degree k chosen so that $K \cdot B \in H_\infty(\mathbb{D}, \mathbb{C}^{p\times m})$) satisfies conditions* (1)–(3) *in the statement of Proposition* 2.14.

Conversely, if $\mathcal{G}$ is a subspace of $\mathcal{K}$ which satisfies conditions (1)–(3) in Proposition 2.14, one can reverse the steps and come up with a $K \in H_{\infty,k'}(\mathbb{D}, \mathbb{C}^{p+m})$ ($k' \le k$) which solves the Nehari–Takagi problem as follows. Since $\mathcal{G}$ is a negative subspace in the J_σ-inner product, $\mathcal{G}$ necessarily has the form of a graph space

$$\mathcal{G} = \begin{bmatrix} X \\ I \end{bmatrix} \mathcal{D}(X),$$

where the angle operator $X\colon \mathcal{D}(X) \mapsto L_2(\mathbb{T}, \mathbb{C}^p)$ has domain $\mathcal{D}(X) \subset H_2(\mathbb{D}, \mathbb{C}^m)$ and norm $\|X\| \le \sigma$. Since $\mathcal{G}$ has codimension k in a maximal negative subspace, necessarily $\dim H_2(\mathbb{D}, \mathbb{C}^m) \ominus \mathcal{D}(X) = k$. Since $\mathcal{G}$ is shift invariant, we have

$$\begin{bmatrix} M_\zeta X \\ M_\zeta \end{bmatrix} \mathcal{D}(X) \subset \begin{bmatrix} X \\ I \end{bmatrix} \mathcal{D}(X).$$

Hence $\mathcal{D}(X)$ is shift invariant, and

$$M_\zeta X x = X M_\zeta x \quad \text{for } x \in \mathcal{D}(X).$$

But then, by the Beurling–Lax theorem, $\mathcal{D}(X)$ has the form $\mathcal{D}(X) = B \cdot H_2(\mathbb{D}, \mathbb{C}^m)$ for a Blaschke–Potapov factor of degree k, and the rule

$$X\colon \zeta^{-n} Bh \mapsto \zeta^{-n} X(Bh)$$

(for $h \in H_2(\mathbb{D}, \mathbb{C}^m)$ and $n = 0, 1, 2, \dots$) extends X to an operator, still called X, defined on the dense subset $\cup_{n=0}^\infty \zeta^{-n} B H_2(\mathbb{D}, \mathbb{C}^m)$ of $L_2(\mathbb{T}, \mathbb{C}^m)$, still with norm $\|X\| \le \sigma$, such that $X M_\zeta = M_\zeta X$. This forces X to be a multiplication operator $X = M_{G+K}$ for some matrix function $K \in L_\infty(\mathbb{T}, \mathbb{C}^{p+m})$ with $\|G + K\|_\infty \le \sigma$. From the fact that $\mathcal{G} \subset \mathcal{M}$, we have

$$\begin{bmatrix} G+K \\ I \end{bmatrix} B H_2(\mathbb{D}, \mathbb{C}^m) \subset \begin{bmatrix} I & G \\ 0 & I \end{bmatrix} H_2(\mathbb{D}, \mathbb{C}^m),$$

i.e.,

$$\begin{bmatrix} I & G \\ 0 & I \end{bmatrix}^{-1} \begin{bmatrix} G+K \\ I \end{bmatrix} B H_2(\mathbb{D}, \mathbb{C}^m) = \begin{bmatrix} K \\ I \end{bmatrix} B H_2(\mathbb{D}, \mathbb{C}^m) \subset H_2(\mathbb{D}, \mathbb{C}^{p+m}).$$

In particular, $K \cdot B$ maps $H_2(\mathbb{D}, \mathbb{C}^m)$ into $H_2(\mathbb{D}, \mathbb{C}^p)$, and we see that $F\colon = K \cdot B \in H_\infty(\mathbb{D}, \mathbb{C}^{p\times m})$. But then $K = F \cdot B^{-1}$ has the Kreĭn–Langer factorization form required to be in the class $H_{\infty,k'}(\mathbb{D}, \mathbb{C}^{p\times m})$ for k' at most k. Proposition 2.14 now follows. □

5.2. Proof of Proposition 2.16.

Proof. By Proposition 2.7, since $\sigma_k > \sigma > \sigma_{k+1}$ we know that the existence of a solution $K \in H_{\infty,k'}(\mathbb{D}, \mathbb{C}^{p\times m})$ with $k' \le k$ forces $k' = k$. This combined with the result in Proposition 2.14 implies that the only content to be added by Proposition 2.16 is that, under the hypothesis that $\sigma_k > \sigma > \sigma_{k+1}$, *a subspace $\mathcal{G}$ of $\mathcal{M}$ is $\mathcal{M}$-maximal negative* (i.e., maximal as a negative subspace contained in $\mathcal{M}$) *if and only*

if $\mathcal{G} \subset \mathcal{M}$ has codimension k in a $\mathcal{K}$-maximal negative subspace $\widetilde{\mathcal{G}}$ of $\mathcal{K}$. One can see this general principle as follows. As $\mathcal{M}$ is regular, $\mathcal{M}$ has a fundamental decomposition $\mathcal{M} = \mathcal{M}_+ \dot{+} \mathcal{M}_-$, where $\mathcal{M}_+$ is a uniformly positive subspace and $\mathcal{M}_-$ is a uniformly negative subspace in the Kreĭn-space inner product $\langle \cdot, \cdot \rangle_{J_\sigma}$. As $\mathcal{M}^{[\perp]}$ is also regular, $\mathcal{M}^{[\perp]}$ also has a fundamental decomposition as $\mathcal{M}^{[\perp]} = \mathcal{P} \dot{+} \mathcal{N}$, where $\mathcal{P}$ is uniformly positive and $\mathcal{N}$ is uniformly negative. We note also that, as a consequence of Proposition 2.15, $\dim \mathcal{N} = k$. Then $\mathcal{K} = \mathcal{K}_+ \dot{+} \mathcal{K}_-$ is a fundamental decomposition for $\mathcal{K}$, where

$$\mathcal{K}_+ = \mathcal{M}_+ \dot{+} \mathcal{P}, \qquad \mathcal{K}_- = \mathcal{M}_- \dot{+} \mathcal{N}.$$

By the angle-operator–graph correspondence, $\mathcal{M}$-maximal negative subspaces of $\mathcal{M}$ are of the form

$$\mathcal{G} = \{Xx + x \colon x \in \mathcal{M}_-\},$$

where X is a Hilbert space contraction operator from $(\mathcal{M}_-, -\langle \cdot, \cdot \rangle_{J_\sigma})$ into $(\mathcal{M}_+, \langle \cdot, \cdot \rangle_{J_\sigma})$. Similarly, $\mathcal{K}$-maximal negative subspaces of $\mathcal{K}$ are of the form

$$\widetilde{\mathcal{G}} = \{\widetilde{X}x + x \colon x \in \mathcal{K}_- = \mathcal{M}_- \dot{+} \mathcal{N}\},$$

where $\widetilde{X}$ is a contraction operator from $(\mathcal{K}_-, -\langle \cdot, \cdot \rangle_{J_\sigma})$ into $(\mathcal{K}_+ = \mathcal{M}_+ \dot{+} \mathcal{P}, \langle \cdot, \cdot \rangle_{J_\sigma})$. From this model, it is clear that $\mathcal{M}$-maximal negative subspaces of $\mathcal{M}$ match up exactly with those subspaces of $\mathcal{M}$ which have codimension k in a $\mathcal{K}$-maximal negative subspace of $\mathcal{K}$. This completes the proof of Proposition 2.16. ∎

5.3. Proof of Proposition 2.17. The proof of Proposition 2.17 requires a preliminary lemma.

LEMMA 5.1. *Suppose that $R \in H_2(\mathbb{D}, \mathbb{C}^{p+m})$ is outer and that $\mathcal{G}$ is a closed, shift-invariant subspace of $H_2(\mathbb{D}, \mathbb{C}^{p+m})$. Then $\mathcal{G} \cap R \cdot H_\infty(\mathbb{D}, \mathbb{C}^{p+m})$ is dense in $\mathcal{G}$.*

Proof. Let $g \in \mathcal{G}$. For $n = 1, 2, \ldots$ choose scalar outer functions r_n so that

$$|r_n(\zeta)| = \min\left\{ \frac{n}{\|R(\zeta)^{-1} g(\zeta)\|}, 1 \right\} \quad \text{for almost all } \zeta \in \mathbb{T}.$$

Then $g_n := r_n \cdot g \in \mathcal{G}$ since $\mathcal{G}$ is shift invariant. Since $\|R^{-1}(\zeta) g_n(\zeta)\| \le n$ for almost all $\zeta \in \mathbb{T}$, by construction, we see that $g_n \in R \cdot H_\infty(\mathbb{D}, \mathbb{C}^{p+n})$. Finally, since $|r_n(\zeta)| \le 1$ for almost all $\zeta \in \mathbb{T}$ and $g \in H_2(\mathbb{D}, \mathbb{C}^{p+m})$, we see that $\{g_n\}$ converges to g as $n \to \infty$ in $H_2(\mathbb{D}, \mathbb{C}^{p+m})$, and the lemma follows. ∎

Proof of Proposition 2.17. Suppose first that $\mathcal{G} \subset \mathcal{M}$ is maximal negative as a subspace of $\mathcal{M}$ in the J_σ-inner product. Then $\mathcal{G}$ has the form $\mathcal{G} = \left[\begin{smallmatrix} I_p & G \\ 0 & I_m \end{smallmatrix}\right] \cdot \mathcal{G}'$, where $\mathcal{G}'$ is a closed shift-invariant subspace of $H_2(\mathbb{D}, \mathbb{C}^{p+m})$. By Lemma 5.1 we know that $\mathcal{G}' \cap V \cdot H_\infty(\mathbb{D}, \mathbb{C}^{p+m})$ is dense in $\mathcal{G}'$. Multiplication by $\left[\begin{smallmatrix} I_p & G \\ 0 & I_m \end{smallmatrix}\right]$ then gives that $\mathcal{G} \cap \Theta \cdot H_\infty(\mathbb{D}, \mathbb{C}^{p+m})$ is dense in $\mathcal{G}$. We may write $\mathcal{G} \cap \Theta \cdot H_\infty(\mathbb{D}, \mathbb{C}^{p+m})$ in the form

$$\mathcal{G} \cap \Theta \cdot H_\infty(\mathbb{D}, \mathbb{C}^{p+m}) = \Theta \cdot \mathcal{G}_1,$$

where $\mathcal{G}_1 \subset H_\infty(\mathbb{D}, \mathbb{C}^{p+m})$.

We assert that $\mathcal{G}_1$ *is weak-$*$ closed in* $H_\infty(\mathbb{D}, \mathbb{C}^{p+m})$. By part (1) of Proposition 2.3, it suffices to consider a sequence $\{h_n\}_{n=1,2,\ldots}$ of elements of $\mathcal{G}_1$ convergent in the weak-$*$ topology to an element h of $L_\infty(\mathbb{D}, \mathbb{C}^{p+m})$ and prove that in fact $h \in \mathcal{G}_1$, i.e., that $\Theta h \in \mathcal{G} \cap \Theta \cdot H_\infty(\mathbb{D}, \mathbb{C}^{p+m})$. From the characterization of $H_\infty(\mathbb{D}, \mathbb{C}^{p+m})$

as that subspace of $L_\infty(\mathbb{T},\mathbb{C}^{m+p})$ consisting of functions F for which all the Fourier coefficients of negative index vanish,

$$\frac{1}{2\pi}\int_{\mathbb{T}} F(\zeta)\overline{\zeta}^n|d\zeta| = 0 \quad \text{for } n=-1,-2,\dots,$$

it is easily seen that $H_\infty(\mathbb{D},\mathbb{C}^{p+m})$ is weak-$*$ closed in $L_\infty(\mathbb{T},\mathbb{C}^{p+m})$ and hence $h \in H_\infty(\mathbb{D},\mathbb{C}^{p+m})$. It therefore remains only to show that $\Theta h \in \mathcal{G}$. For this purpose note that, for any $k \in L_2(\mathbb{T},\mathbb{C}^{p+m})$,

$$\langle \Theta h_n, k\rangle_{L_2} = \frac{1}{2\pi}\int_{\mathbb{T}} k(\zeta)^*\Theta h_n(\zeta)k(\zeta)|d\zeta|. \tag{5.3}$$

As $k^*\Theta \in L_2(\mathbb{T},\mathbb{C}^{1\times(m+n)}) \subset L_1(\mathbb{T},\mathbb{C}^{1\times(m+n)})$ and h_n is assumed to converge to h in the weak-$*$ topology of $L_\infty(\mathbb{T},\mathbb{C}^{(m+n)\times 1})$, we may take limits in (5.3) to get

$$\lim_{n\to\infty}\langle \Theta h_n, k\rangle_{L_2} = \langle \Theta h, k\rangle_{L_2} \quad \text{for each } k \in L_2(\mathbb{T},\mathbb{C}^{p+m}); \tag{5.4}$$

i.e., Θh_n converges to Θh in the weak topology on $L_2(\mathbb{T},\mathbb{C}^{p+m})$. As $\Theta h_n \in \mathcal{G}$ for each n and as norm-closed subspaces of a Hilbert space are also closed in the weak topology (see [42, Theorem 6.3, page 158]), it follows that $\Theta h \in \mathcal{G}$ as wanted. We conclude that $\mathcal{G}_1$ *is weak-$*$ closed as asserted.*

By the Beurling–Lax theorem for weak-$*$ closed subspaces of $H_\infty(\mathbb{D},\mathbb{C}^{m+p})$ (see, e.g., [41] or [25, page 25] for the scalar case), there is a matrix inner function $\psi = \left[\begin{smallmatrix}\psi_1\\ \psi_2\end{smallmatrix}\right]$ in $H_\infty(\mathbb{D},\mathbb{C}^{(p+m)\times m_1})$ (for some $m_1 \le m+p$) so that

$$\mathcal{G}_1 = \begin{bmatrix}\psi_1\\ \psi_2\end{bmatrix} H_\infty(\mathbb{D},\mathbb{C}^{m_1}). \tag{5.5}$$

The inner property of ψ means that

$$\psi_1(\zeta)^*\psi_1(\zeta) + \psi_2(\zeta)^*\psi_2(\zeta) = I_{m'} \quad \text{for almost all } \zeta \in \mathbb{T}. \tag{5.6}$$

From the fact that $\mathcal{G}_1$ is J_1-negative we then also get

$$\psi_1(\zeta)^*\psi_1(\zeta) - \psi_2(\zeta)^*\psi_2(\zeta) \le 0 \quad \text{for almost all } \zeta \in \mathbb{T}. \tag{5.7}$$

Hence, if we set $Q(\zeta) = \psi_2(\zeta)\psi_1(\zeta)^\ddagger$, where $\psi_2(\zeta)^\ddagger$ is the left Moore–Penrose generalized inverse of $\psi_2(\zeta)$,

$$\psi_2(\zeta)^\ddagger \colon c \mapsto \begin{cases} 0 & \text{if } c \perp \operatorname{im}\psi_2(\zeta),\\ c' & \text{if } c = \psi_2(\zeta)c', \end{cases} \tag{5.8}$$

then $Q(\zeta)$ defines a contraction operator from $\mathbb{C}^m$ into $\mathbb{C}^p$ for almost all $\zeta \in \mathbb{T}$, and we can rewrite (5.5) as

$$\mathcal{G}_1 = \begin{bmatrix} Q\\ I_m\end{bmatrix}\psi_2 H_\infty(\mathbb{D},\mathbb{C}^{m_1}). \tag{5.9}$$

We next argue that $\psi_2 H_\infty(\mathbb{D},\mathbb{C}^{m_1})$ *is weak-$*$ closed in* $H_\infty(\mathbb{D},\mathbb{C}^m)$. Indeed, suppose that $\psi_2 h_n$ converges in the L_∞-weak-$*$ topology to an element $k \in L_\infty$. Then the computation (for each $g \in L_1(\mathbb{T},\mathbb{C}^p)$)

$$[\psi_1 h_n, g] = [Q\psi_2 h_n, g] = [\psi_2 h_n, Q^* g] \to [k, Q^* g] = [Qk, g]$$

shows that $\psi_1 h_n$ tends weak-$*$ to Qk. (Here we let $[\cdot,\cdot]$ denote the duality pairing

$$[F,f]=\frac{1}{2\pi}\int_{\mathbb{T}} f(\zeta)^* F(\zeta)|d\zeta| \quad \text{for } F\in L_\infty(\mathbb{T},\mathbb{C}^{m'}) \text{ and } f\in L_1(\mathbb{T},\mathbb{C}^{m'})$$

between $L_\infty(\mathbb{T},\mathbb{C}^{m'})$ and $L_1(\mathbb{T},\mathbb{C}^{m'})$ for any fixed choice of m', and we use that $Q^*\cdot g\in L_1(\mathbb{T},\mathbb{C}^m)$ for any $g\in L_1(\mathbb{T},\mathbb{C}^p)$ since $Q(\zeta)$ is contractive a.e.) We conclude that

$$\begin{bmatrix}\psi_1\\ \psi_2\end{bmatrix} h_n \to \begin{bmatrix}Q\\ I_m\end{bmatrix} k$$

in the weak-$*$ topology. As $\mathcal{G}_1$ is closed in the weak-$*$ topology, it follows that $\left[\begin{smallmatrix}Q\\ I_m\end{smallmatrix}\right]k\in\mathcal{G}_1$, and hence, in particular, $k\in\psi_2 H_\infty(\mathbb{D},\mathbb{C}^{m_1})$. We conclude that $\psi_2 H_\infty(\mathbb{D},\mathbb{C}^{m_1})$ *is closed in the weak-$*$ topology as wanted.*

We next argue that in fact

$$\psi_2 H_\infty(\mathbb{D},\mathbb{C}^{m'})=H_\infty(\mathbb{D},\mathbb{C}^m). \tag{5.10}$$

Indeed, via a second application of the Beurling–Lax theorem for weak-$*$ closed subspaces of vector-valued H_∞, by the fact established in the previous paragraph it follows that there is an $m\times m'$ matrix inner function ϕ so that $\psi_2 H_\infty(\mathbb{D},\mathbb{C}^{m'})=\phi H_\infty(\mathbb{D},\mathbb{C}^{m'})$. If $m'<m$ (or more generally, if $\phi H_\infty(\mathbb{D},\mathbb{C}^{m'})$ does not fill up all of $H_\infty(\mathbb{D},\mathbb{C}^m)$), then we may choose a nonzero vector $f\in(H_2(\mathbb{D},\mathbb{C}^m)\ominus\psi H_2(\mathbb{D},\mathbb{C}^{m'}))\cap H_\infty(\mathbb{D},\mathbb{C}^m)$ so that the L_2-closure of $M_\Theta\cdot\left(\operatorname{span}\left[\begin{smallmatrix}0\\ f\end{smallmatrix}\right]+\mathcal{G}_1\right)$ is a larger negative subspace of $\mathcal{M}$ which includes $\mathcal{G}$ as a subspace. As $\mathcal{G}$ is assumed to be maximal negative in $\mathcal{M}$, this leads to a contradiction, and we conclude that $m'=m$ and ϕ is a unitary constant. We have now arrived at

$$\mathcal{G}\cap\Theta\cdot H_\infty(\mathbb{D},\mathbb{C}^{p+m})=\Theta\begin{bmatrix}Q\\ I\end{bmatrix}\cdot H_\infty(\mathbb{D},\mathbb{C}^m).$$

Taking closures in this identity gives the representation (2.15) for the shift-invariant subspace $\mathcal{G}$ assumed to be maximal negative in $\mathcal{M}$.

Conversely, suppose that $Q\in H_\infty(\mathbb{D},\mathbb{C}^{p\times m})$ with $\|Q\|_\infty\le 1$ and we define $\mathcal{G}\subset L_2(\mathbb{T},\mathbb{C}^{p\times m})$ by (2.15). From the factorization $\left[\begin{smallmatrix}I_p & G\\ 0 & I_m\end{smallmatrix}\right]=\Theta\cdot\Lambda$, where Λ and $V=\Lambda^{-1}$ are in $H_2(\mathbb{D},\mathbb{C}^{(p+m)\times(p+m)})$, it is clear that $\mathcal{G}\subset\mathcal{M}:=\left[\begin{smallmatrix}I_p & G\\ 0 & I_m\end{smallmatrix}\right]\cdot H_2(\mathbb{D},\mathbb{C}^{p+m})$. Since $\|Q\|_\infty\le 1$ and Θ is (J_1,J_σ)-unitary on $\mathbb{T}$, we see that necessarily $\mathcal{G}$ is negative in the J_σ-inner product. If $\mathcal{G}'$ is a J_σ-negative subspace with $\mathcal{G}\subset\mathcal{G}'\subset\mathcal{M}$, then by the same argument as in the first part of the proof we know that

$$\mathcal{G}'\cap\Theta\cdot H_\infty(\mathbb{D},\mathbb{C}^{p+m})=\mathcal{G}'_1$$

for some weak-$*$ closed subspace $\mathcal{G}'_1$ of $H_\infty(\mathbb{D},\mathbb{C}^{p+m})$. The (J_1,J_σ)-unitary property of Θ and the fact that $\mathcal{G}'$ is J_σ-negative then force $\mathcal{G}'_1$ to be J_1-negative. Hence $\mathcal{G}'_1$ can contain no elements of the form $\left[\begin{smallmatrix}h\\ 0\end{smallmatrix}\right]$ with $h\in H_\infty(\mathbb{D},\mathbb{C}^p)$ nonzero. We conclude that $\mathcal{G}'_1$ is a graph space; i.e., there is an operator X mapping some domain $\mathcal{D}(X)\subset H_\infty(\mathbb{D},\mathbb{C}^m)$ into $H_\infty(\mathbb{D},\mathbb{C}^p)$ so that $\mathcal{G}'_1=\left[\begin{smallmatrix}X\\ I_m\end{smallmatrix}\right]\mathcal{D}(X)$. Since $\mathcal{G}'\supset\mathcal{G}$, we see next that $\mathcal{G}'_1\supset\mathcal{G}_1$, i.e.,

$$\begin{bmatrix}X\\ I_m\end{bmatrix}\mathcal{D}(X)\supset\begin{bmatrix}Q\\ I_m\end{bmatrix}H_\infty(\mathbb{D},\mathbb{C}^m).$$

As $\mathcal{D}(X)\subset H_\infty(\mathbb{D},\mathbb{C}^m)$, we must have $\mathcal{D}(X)=H_\infty(\mathbb{D},\mathbb{C}^m)$, X is the operator of multiplication by Q, and $\mathcal{G}=\mathcal{G}'$ is $\mathcal{M}$-maximal negative. This concludes the proof of Proposition 2.17. ∎

6. Appendix B. In this appendix we present the proofs that were deferred in section 3.

To prove Lemma 3.2(1) we want to study how the operators determined by "shifted" triple $(A-\epsilon, B, C)$ converge to those determined by (A, B, C), as $\epsilon \to 0+$. For the shifted system, the semigroup is denoted by $\{T_\epsilon(t)\}_{t\geq 0}$, the controllability map is denoted by $\mathcal{C}_\epsilon$, and the controllability Gramian $\mathcal{C}_\epsilon^*\mathcal{C}_\epsilon$ is abbreviated by $L_{C,\epsilon}$; similarly, one uses the notation $\mathcal{B}_\epsilon^*, L_{B,\epsilon}, \mathcal{D}_\epsilon$, etc. Since the functions in A1, A2, and A3 are shifted to the left $(C(sI-(A-\epsilon I))^{-1}x = C((s+\epsilon)I-A)^{-1}x$, etc.), the assumptions A1–A3 hold a fortiori. Some further claims are straightforward, while others are more complicated.

LEMMA 6.1. *Assume that the triple (A, B, C) satisfies* A1*,* A2*, and* A3*. Then, with the above notation, as $\epsilon \to 0+$, we have the following for all $k \in \{1, 2, 3, \dots\}$, $t \geq 0$, $x \in X$, $u \in L^2(\mathbb{R}_+; \mathbb{C}^m)$, $y \in L^2(\mathbb{R}_+; \mathbb{C}^p)$:*

(1) $T_\epsilon(t) = \mathrm{e}^{-\epsilon t}T(t)$, $\mathcal{C}_\epsilon x = \mathrm{e}^{-\epsilon\cdot}\mathcal{C}x$, *and* $\mathcal{D}_\epsilon u = \mathrm{e}^{-\epsilon\cdot}\mathcal{D}\mathrm{e}^{\epsilon\cdot}u$.

(2) $\|\mathcal{C}_\epsilon\| \leq \|\mathcal{C}\|$ *and* $\|\mathcal{C}_\epsilon x_\epsilon - \mathcal{C}x\|_2 \to 0$ *whenever* $\|x_\epsilon - x\|_X \to 0$.

(3) $\|\mathcal{D}_\epsilon\| \leq \|\mathcal{D}\|$ *and* $\|\mathcal{D}_\epsilon^* y_\epsilon - \mathcal{D}^* y\|_2 \to 0$ *whenever* $\|y_\epsilon - y\|_2 \to 0$.

(4) $\|L_{C,\epsilon}\| \leq \|L_C\|$, $\|L_{B,\epsilon}\| \leq \|L_B\|$, $L_{C,\epsilon}x \to L_C x$, *and* $L_{B,\epsilon}x \to L_B x$.

(5) σ_k *is the* k*th singular value of* $\Gamma := \mathcal{C}\mathcal{B}$.

(6) $\sigma_{k,\epsilon} \to \sigma_k-$, *where* $\sigma_{k,\epsilon}$ *is the* k*th singular value of* $\Gamma_\epsilon := \mathcal{C}_\epsilon\mathcal{B}_\epsilon$.

(7) *Let* $\sigma_k > \sigma > \sigma_{k+1}$. *Then there are* $\epsilon_0 > 0$ *and* $M_0 < \infty$ *such that* $N_{\sigma,\epsilon} := (I - \sigma^{-2}L_{B,\epsilon}L_{C,\epsilon})^{-1}$ *exists and* $\|N_{\sigma,\epsilon}\| \leq M_0$ *for all* $\epsilon \in (0, \epsilon_0)$. *Moreover,* $N_{\sigma,\epsilon}x \to N_\sigma x$.

Proof. (1) This is straightforward.

(2) By (1), we have $\|\mathcal{C}_\epsilon\| \leq \|\mathcal{C}\|$. Obviously, $\|\mathcal{C}_\epsilon x - \mathcal{C}x\|_2 \to 0$. Since $\mathcal{C}_\epsilon x_\epsilon - \mathcal{C}x = \mathcal{C}_\epsilon(x_\epsilon - x) + (\mathcal{C}_\epsilon - \mathcal{C})x$, we obtain that (2) holds.

(3) We have $\widehat{\mathcal{D}_\epsilon u}(s) = (G(\cdot)u(\cdot-\epsilon))(s+\epsilon) = G(\epsilon+s)u(s)$, i.e., $G_\epsilon = G(\epsilon+\cdot)$. Therefore, $\|G_\epsilon\|_\infty \leq \|G\|_\infty$ and $G_\epsilon^* y_0 \to G^* y_0$ a.e. on $i\mathbb{R}$, for any $y_0 \in \mathbb{C}^p$ (see, e.g., Theorem 3.3.1(c1) of [30]). Consequently, $G_\epsilon^*\widehat{y} \to G^*\widehat{y}$ in $L^2(i\mathbb{R}; \mathbb{C}^m)$ for any $\widehat{y} \in L^2(i\mathbb{R}; \mathbb{C}^p)$, by the dominated convergence theorem. By Plancherel's theorem, this means that $\mathcal{D}_\epsilon^* y \to \mathcal{D}^* y$ for any $y \in L^2(\mathbb{R}; \mathbb{C}^m)$. Because the functions $\mathcal{D}_\epsilon^*$ are uniformly bounded, (3) also holds.

(4) We have

$$\|L_{C,\epsilon}\| = \sup_{\|x\|\leq 1}\langle x, L_{C,\epsilon}x\rangle = \sup_{\|x\|\leq 1}\|\mathcal{C}_\epsilon x\|_{L_2}^2 \leq \sup_{\|x\|\leq 1}\|\mathcal{C}x\|_{L_2}^2 = \sup_{\|x\|\leq 1}\langle x, L_C x\rangle = \|L_C\|.$$

Moreover, $\langle x, (L_C - L_{C,\epsilon})x\rangle = \int_0^\infty (1-\mathrm{e}^{-2\epsilon t})|(\mathcal{C}x)(t)|^2\,dt \to 0$. By duality (i.e., (A^*, C^*, B^*) in place of (A, B, C)), we obtain the claims for L_B.

(5) By Plancherel's theorem, H_G and Γ are isomorphic (see [16, Lemma 8.2.3(c), page 397]).

(6) Define $(S_\epsilon f)(t) = \mathrm{e}^{-\epsilon t}f$ $(\epsilon \in \mathbb{R})$. For any $f \in L^2(\mathbb{R}; \mathbb{C}^n)$, $n \geq 1$, we have $S_\epsilon f \to f$ in L^2 as $\epsilon \to 0$. Moreover, $\|S_\epsilon f\| \leq \|f\|$ (respectively, $\|S_{-\epsilon}f\| \leq \|f\|$) if $f = 0$ on $\mathbb{R}_-$ (respectively, $\mathbb{R}_+$). Therefore, $\Gamma_\epsilon^*\Gamma_\epsilon u \to \Gamma^*\Gamma u$ for each $u \in L^2(\mathbb{R}_-; \mathbb{C}^m)$ (see Mikkola [30, Lemma A.3.1(j3)] and note that $\mathcal{C}_\epsilon = S_\epsilon\mathcal{C}$, $\mathcal{B}_\epsilon = \mathcal{B}S_\epsilon$). Thus, we get $\liminf_{\epsilon\to 0+}\sigma_{k,\epsilon} \geq \sigma_k$ from Lemma 6.3.

Conversely, if $\operatorname{rank} K \leq k-1$, then $\operatorname{rank} K_\epsilon \leq k-1$, where $K_\epsilon := S_\epsilon K S_{-\epsilon}$, and $\|\Gamma_\epsilon - K_\epsilon\| = \|S_\epsilon(\Gamma - K)S_{-\epsilon}\| \leq \|\Gamma - K\|$. Hence $\sigma_{k+1,\epsilon} \leq \sigma_{k+1}$. Similarly, we observe that $\sigma_{k+1,\epsilon} \leq \sigma_{k+1,\epsilon'}$ when $\epsilon > \epsilon' > 0$.

(7) Let δ be as in Lemma 6.2(2), and choose ϵ_0 so that $\sigma_{l,\epsilon}^2 - \sigma_l^2 < \delta/2$ for $l = k$, $k+1$, and $\epsilon \in (0, \epsilon_0)$ (use (6)). Then Lemma 6.2(2) implies that $\|(\sigma^2 I - \Gamma_\epsilon^*\Gamma_\epsilon)^{-1}\| \leq 2/\delta$,

that is, that $\|(I-\sigma^{-2}\Gamma_\epsilon^*\Gamma_\epsilon)^{-1}\| \le 2\sigma^2/\delta$, for $\epsilon \in (0,\epsilon_0)$. Apply $(I-ST)^{-1} = I + S(I-TS)^{-1}T$ to $T = \sigma^{-2}\mathcal{B}_\epsilon^*$, $S := \mathcal{C}_\epsilon^*\mathcal{C}_\epsilon\mathcal{B}_\epsilon$ to obtain the inequality in (7) for $M_0 := 1+2\sigma^2\|\mathcal{C}\|\|\mathcal{B}\|/\delta$ (use (2) and its dual). The last claim follows from the others and (4) (see (j3)–(j5) of Lemma A.3.1 of Mikkola [30]). ∎

In the above we have used the following two lemmas. In the first one we present some sort of a singular value decomposition with k largest singular values on the diagonal and a small operator on the bottom-right corner.

LEMMA 6.2 (partial singular value decomposition). *Assume that $\{\sigma_k\}$ are the singular values of $S \in \mathcal{L}(X,Y)$ and X,Y are Hilbert spaces.*

(1) *For any $k \in \{0,1,2,\dots\}$, there is a k-dimensional subspace $X_k \subset X$ such that $S^*S = \operatorname{diag}(\sigma_1^2,\dots,\sigma_k^2;T)$ on $X_k \times X_k^\perp = X$, $\|T\| = \sigma_{k+1}^2$.*

(2) *We have $\sigma^2 \in \rho(S^*S)$ and $\|(\sigma^2 - S^*S)^{-1}\| \le \delta^{-1}$, where $\delta := \min\{\sigma_k^2 - \sigma^2, \sigma^2 - \sigma_{k+1}^2\}$.*

Claim (1) follows from pp. 212–213 of [21], alternatively, by using a resolution of the identity of S^*S. Claim (2) follows, because $(\sigma^2 - S^*S)^{-1} = \operatorname{diag}((\sigma_1^2-\sigma^2)^{-1},\dots,(\sigma_k^2-\sigma^2)^{-1};(\sigma^2-T)^{-1})$. Recall that $\sigma_k := \inf\{\|S-K\| : K \in \mathcal{L}(X,Y), \operatorname{rank} K \le k-1\} = \inf_{\dim M \le k-1}\|SP_{M^\perp}\|$, where $P_{M^\perp}$ is the orthogonal projection $X \to M^\perp$.

LEMMA 6.3 ($\liminf_n \sigma_{k,n} \ge \sigma_k$). *Let $S_n, S \in \mathcal{L}(X,Y)$ for all n, and let $S_n^*S_nx \to S^*Sx$ for all $x \in X$, where X,Y are Hilbert spaces. Then $\liminf_{n\to\infty}\sigma_{k,n} \ge \sigma_k$, where $\sigma_{k,n}$ is the kth singular value of S_n $(n \in \mathbb{N})$.*

Proof. Given $\epsilon > 0$, choose N such that $\|(S_n^*S_n - S^*S)P\| < \epsilon$ for all $n \ge N$, where $P : X \to X_{k-1}$ is the orthogonal projection and X_{k-1} is as in Lemma 6.2.

We obviously have $\sigma_k = \inf_{\dim M \le k-1}\|SP_{M^\perp}\|$, where $P_{M^\perp}$ is the orthogonal projection $X \to M^\perp$. But if $\dim M \le k-2$, then there is $x \in M^\perp \cap X_{k-1}$ such that $\|x\| = 1$ (otherwise we would have $X_{k-1} \subset \operatorname{Ker}(P_{M^\perp}) = M$). Then $\|S_nx\| = \langle Px, S_n^*S_nPx\rangle \ge \langle x, S^*Sx\rangle - \epsilon \ge \sigma_k - \epsilon$. ∎

Acknowledgments. The authors would like to thank Professor Ruth Curtain of the Department of Mathematics, University of Groningen, The Netherlands, and the anonymous referees for useful comments on the previous draft, which led to improvements in the exposition.

INSTANTANEOUS CLOSED LOOP CONTROL OF THE NAVIER–STOKES SYSTEM*

M. HINZE†

Abstract. Instantaneous control is applied to the control of the instationary Navier–Stokes system. This control technique is closely related to receding horizon control and allows for an interpretation as suboptimal closed loop controller, whose parameters may be adjusted so as to stabilize the nonlinear equation under consideration. Besides stability analysis for the distributed control case, numerical examples for the continuous and discrete-in-time control laws are presented.

Key words. optimal control, instantaneous control, closed loop control, Navier–Stokes equations

DOI. 10.1137/S036301290241246X

1. Introduction.

This research is devoted to the study of instantaneous control applied to the instationary Navier–Stokes system. It thereby builds upon and extends results of [14] for the Burgers equation, where a comprehensive discussion of the method also can be found.

In primal variables the Navier–Stokes system can be written in the form

$$\text{(D)} \qquad \begin{cases} y_t - \nu\Delta y + (y\nabla)y + \nabla p = \mathcal{B}u & \text{in } Q, \\ -\operatorname{div} y = 0 & \text{in } Q, \\ y = 0 & \text{on } (0,T)\times\partial\Omega, \\ y(0) = \phi & \text{in } \Omega. \end{cases}$$

Here $\nu := 1/\mathrm{Re}$ denotes the viscosity parameter, with Re denoting the Reynolds number. Furthermore, $Q := (0,T)\times\Omega$, with $\Omega \subset \mathbb{R}^2$ denoting an open bounded domain and $T > 0$ the time horizon. The control target is to match the given desired state z in the $L^2(Q)$-sense by adjusting the body force $\mathcal{B}u$ in an appropriate manner. Above, $\mathcal{B}$ denotes an abstract control extension operator which maps controls of an abstract Hilbert space $\mathcal{U}$ to admissible right-hand sides of the Navier–Stokes system (D). In this context the method of instantaneous control serves a dual purpose—to construct a closed loop feedback control law which steers the system state y to z for t tending to ∞, and to compute open loop control policies which (hopefully) approximate optimal open loop control strategies, i.e. solutions of

$$\text{(P)} \qquad \begin{cases} \min J(y,u) = \dfrac{1}{2}\displaystyle\int_0^T \int_\Omega |y-z|^2 dx\, dt + \frac{\alpha}{2}\int_0^T |u|_{\mathcal{U}}^2\, dt \\ \text{s.t. (D).} \end{cases}$$

Optimal control problems for the Navier–Stokes system of the form of (P) are mathematically and numerically well understood [1, 2, 9, 13]. For (P) instantaneous control

*Received by the editors July 31, 2002; accepted for publication (in revised form) December 6, 2004; published electronically August 31, 2005.
http://www.siam.org/journals/sicon/44-2/41246.html
†Technische Universität Dresden, Institut für Numerische Mathematik, Zellescher Weg 12-14, D-01062 Dresden, Germany (hinze@math.tu-dresden.de).

may be regarded as a suboptimal control approach which provides control policies on the time horizon $(0, T)$. However, as is shown in [14], instantaneous control may be regarded as nonlinear feedback control policy, and it is the main aim of this work to extend the stability analysis presented there to the Navier–Stokes system.

Instantaneous control works as follows. The uncontrolled Navier–Stokes equations are discretized with respect to time. Then, at selected time slices an instantaneous version of the cost functional is approximately minimized w.r.t. a stationary quasi-Navier–Stokes system, whose structure depends on the chosen time-discretization method. The control obtained is used to steer the system to the next time slice, where the procedure is repeated.

Instantaneous control therefore is closely related to receding horizon control (rhc) or model predictive control (mpc) with finite time horizon [7, 21, 22]. It was applied to control the Burgers equation with stochastic forcing in [5] and was also successfully applied to compute suboptimal controls for a great variety of fluid mechanical control problems [3, 4, 10, 12, 19, 20], and in the recent past it was also applied as a real-time control approach to the cooling of steel [25]. Linear body force feedback control for the Navier–Stokes system is investigated in [8, 17, 18].

As far as the author knows there are only a few stability investigations for the application of the method to the control of infinite-dimensional systems [14, 16].

In the present work the results obtained in [14] are extended to the instationary Navier–Stokes system in two spatial dimensions. While for the continuous control policies developed in [14] similar stability properties can be proved as in the case of the Burgers equation, for the discrete controllers developed there only conditional stability can be shown for the Navier–Stokes system (Theorems 4.4 and 4.5). This motivates the construction of a slightly modified control policy, for which unconditional stability is proved in Theorem 4.7. The main results of the present work can be summarized as follows.

Main results.

1. Given a sufficiently smooth desired state z, instantaneous control of the instationary Navier–Stokes system can be regarded as time discretization of a closed loop feedback policy K that steers the system exponentially fast to z, i.e., with S denoting the Stokes operator and $b(y)$ the nonlinearity of the Navier–Stokes equations

$$y_t + \nu S y + b(y) = K(y),$$

the solution of this system satisfying $|y(t) - z(t)|_{H^1} \leq c \exp(-\gamma t)$ with some positive constants c and γ (Theorems 4.1 and 4.2).

2. Instantaneous control may be regarded as a discrete-in-time feedback policy that steers the dynamical system exponentially fast to the desired state z, provided that either $z(0)$ is sufficiently close to the initial value ϕ or the viscosity parameter ν is sufficiently large (Theorems 4.4 and 4.5).

3. Instantaneous control gives rise to a discrete-in-time feedback policy that steers the dynamical system exponentially fast to the desired state z (Theorem 4.7).

The paper is organized as follows. In section 2 an appropriate functional analytic framework is introduced and preliminary results are collected. In section 3 the derivation of the instantaneous control approach, the formulation of the algorithm, and its interpretation as nonlinear continuous and discrete-in-time feedback control policy are sketched. The results in this part of the work are similar to those in [14] and are stated for the convenience of the reader. In section 4 both exponential stability of the continuous controllers and conditional exponential stability of the discrete controllers

are shown. To obtain these results in consequence of the nonlinearity in the Navier–Stokes system a more subtle analysis is necessary than for the Burgers equation in [14]. Moreover, a slightly modified discrete controller is proposed for which unconditional exponential stability is proved. Finally, in section 5 numerical examples are presented, which illustrate the theoretical results and also compare the feedback policy on a time horizon $[0,T]$ to the corresponding optimal open loop control strategy for (P).

Throughout this work c and C denote global generic constants whose dependencies are mentioned when necessary.

2. Preliminaries. Set $V = \{v \in H_0^1(\Omega)^2,\ \operatorname{div} v = 0\}$, $H = \operatorname{clos}_{L^2(\Omega)^2}\{v \in C_0^\infty(\Omega)^2,\ \operatorname{div} v = 0\}$ and identify the Hilbert space H with its dual H'. On H the common inner product is used, and V is endowed with the inner product

$$(\varphi,\psi)_V = (\nabla\varphi,\nabla\psi)_H \quad \text{for } \varphi,\psi \in V.$$

Moreover, with Z denoting a Hilbert space, $L^p(Z)$ $(1 \le p \le \infty)$ denotes the space of measurable abstract functions $\varphi : (0,T) \to Z$, which are p-integrable $(1 \le p < \infty)$ or essentially bounded on $(0,T)$ $(p = \infty)$, respectively.

As control space, $L^2(\mathcal{U})$ is taken, where $\mathcal{U}$ denotes the Hilbert space of abstract controls. The space $\mathcal{U}$ also is identified with its dual. Furthermore,

$$\mathcal{B} : \mathcal{U} \to V' \tag{2.1}$$

denotes the control extension operator, which is assumed to be bounded. In order to formulate the weak form of the instationary Navier–Stokes equations, let $W := W(V) = \{\varphi \in L^2(V) : \varphi_t \in L^2(V')\}$ supplied with the common inner product. Further, introduce

$$b(u,v,w) := \int_\Omega (u\cdot\nabla)vw\,dx.$$

Then from [24],

$$b(u,v,w) \le C \begin{cases} |u|_H^{\frac12}|u|_V^{\frac12}|v|_H^{\frac12}|v|_V^{\frac12}|w|_V & \forall u,v,w \in V, \\ |u|_H^{\frac12}|u|_V^{\frac12}|v|_V^{\frac12}|\Delta v|_H^{\frac12}|w|_H & \forall u \in V,\ v \in V \cap H^2(\Omega)^2,\ w \in H, \\ |u|_H|v|_V|w|_H^{\frac12}|\Delta w|_H^{\frac12} & \forall u \in H,\ v \in V,\ w \in V \cap H^2(\Omega)^2, \\ |u|_H^{\frac12}|\Delta u|_H^{\frac12}|v|_V|w|_H & \forall u \in V \cap H^2(\Omega)^2,\ v \in V,\ w \in H, \end{cases} \tag{2.2}$$

with a positive constant C, which for the uppermost estimate can be chosen as $C = \sqrt{2}$ [23, Chap. III, eq. (3.55)]. Moreover, for $y \in L^2(V)$ the function $b(y)$ defined by

$$\langle b(y), v\rangle_{V',V} := -b(y,y,v) \quad \forall\, v \in V \tag{2.3}$$

is an element of V' for almost all $t \in (0,T)$ and $b(y) \in L^1(V)$. Now let $P : L^2(\Omega)^2 \to H$ denote the Leray projector [6, Remark 1.10]. Then, the Stokes operator S is given by

$$S : \mathcal{D}(S) \subset H \to H, \qquad S := -P\Delta, \qquad \mathcal{D}(S) = H^2(\Omega)^2 \cap V.$$

Further define

$$A := \nu S$$

and denote by B the solution operator of

$$v + hAv = f \text{ in } V', \tag{2.4}$$

where $f \in V'$ is given. The operator B is linear, bounded, and self-adjoint, and there holds $B^{-1} = I + hA$.

In this setting the Navier–Stokes system (D) may be rewritten as the Burgers equation in the space V,

$$\begin{aligned} y_t + Ay &= b(y) + \mathcal{B}u, \\ y(0) &= \phi, \end{aligned}$$

where the nonlinearity $b(y)$ is defined in (2.3). The derivation and also the interpretation of instantaneous control for the Navier–Stokes system in the following therefore are abutted to the exposition in [14].

Let $X = W \times L^2(\mathcal{U})$ and $Y = L^2(V') \times H$. Introducing the operator $e : X \to Y$ by

$$e(y,u) = (e_1(y,u), e_2(y,u)) = (y_t - \nu\Delta y - b(y) - \mathcal{B}u, y(0) - \phi),$$

the Navier–Stokes system (D) can be expressed in the form $e(y,u) = 0$ in Y, and the optimal control problem (P) can be regarded as a minimization problem with equality constraints:

$$\text{minimize } J(y,u) \quad \text{s.t.} \quad e(y,u) = 0.$$

Among other things, it is shown in [13] that this problem admits a solution $(y^*, u^*) \in X$ and that both J and e are infinitely continuously Fréchet-differentiable.

Young's inequality

$$ab \le \delta a^2 + \frac{1}{4\delta} b^2 \quad \forall\ a, b \ge 0,\ \delta > 0, \tag{2.5}$$

and the following lemmas are frequently used in the proofs of the main theorems.

LEMMA 2.1. *For $y \in V$ let $w := By$. Then $w \in V \cap H^3(\Omega)^2$ and $Sw \in V$. Moreover,*

$$|w|_H^2 \ge |y|_H^2 - 2\nu h |y|_V^2. \tag{2.6}$$

Further, let $z := B((y\nabla)y) = Bb(y)$. Then $z \in V$ and

$$|z|_H^2 \le \frac{1}{2\nu h} |y|_H^2 |y|_V^2. \tag{2.7}$$

Proof. By the definition of the operator B the regularity claim for w follows from [23, Chap. I, Prop. 2.3]. Thus, $Sw \in H^1(\Omega)^2$ [6, Remark 1.10] and, since $y \in V$, $Sw \in V$. Therefore, Sw can be utilized as test function in the equation

$$w + hAw = y.$$

This gives

$$|w|_V^2 + \nu h |Sw|_H^2 = \int_\Omega \nabla w \nabla y \, dx \Rightarrow |w|_V^2 + 2\nu h |Sw|_H^2 \le |y|_V^2.$$

Furthermore, using y as test function, the latter estimate leads to

$$|y|_H^2 = \int_\Omega yw + \nu h \nabla y \nabla w \, dx \le \frac{1}{2}|y|_H^2 + \frac{1}{2}|w|_H^2 + h\nu |y|_V |w|_V \le \frac{1}{2}|y|_H^2 + \frac{1}{2}|w|_H^2 + h\nu |y|_V^2,$$

which gives the first claim.

To prove the second claim take z as test function in the equation

$$z + hAz = b(y).$$

This gives, using the first estimate of (2.2) and Young's inequality (2.5) with $\delta = \nu h$,

$$|z|_H^2 + \nu h |z|_V^2 \le |b(y)|_{V'} |z|_V \le \sqrt{2} |y|_H |y|_V |z|_V \le \frac{1}{2\nu h} |y|_H^2 |y|_V^2 + \nu h |z|_V^2,$$

which completes the proof of the lemma. □

LEMMA 2.2. *Let $y \in V$, $\kappa := By$, and $\tau := B\kappa$. Then*

$$\int_\Omega ByBSy \, dx = |y|_V^2 - \nu h \int_\Omega (S\kappa + S\tau) Sy \, dx$$

and

$$|S\tau|_H^2, |S\kappa|_H^2 \le \frac{1}{4\nu h} |y|_V^2. \tag{2.8}$$

Proof. The definition of κ and τ implies $\kappa \in H^3(\Omega)^2 \cap V$, $\tau \in H^5(\Omega)^2 \cap V$. Moreover, $S\kappa$ and $S\tau$ are elements of V. Integration by parts gives the first part of the claim. To obtain the second claim, test the equation for κ with $S\kappa$. This gives

$$|\kappa|_V^2 + \nu h |S\kappa|_H^2 \le |y|_V |\kappa|_V \le \begin{cases} \frac{1}{4}|y|_V^2 + |\kappa|_V^2 \\ \frac{1}{2}|y|_V^2 + \frac{1}{2}|\kappa|_V^2, \end{cases}$$

where Young's inequality (2.5) was used for the upper estimate with $\delta = 1$, and for the lower estimate with $\delta = \frac{1}{2}$. Since the same estimate holds with κ replaced by τ and y replaced by κ, and $|\kappa|_V \le |y|_V$ by the lower estimate, the lemma is proved. □

3. Instantaneous control strategy. For $m \in \mathbb{N}$ an equidistant discretization of the time interval $(0, T)$ is defined by $h = \frac{T}{m}$ and $t_k = kh$, $k = 0, 1, \dots, m$. Instantaneous versions of the cost functional J in (P) are given by

$$J^k : V \times \mathcal{U} \to \mathbb{R}, \qquad (y, u) \mapsto \frac{1}{2} \, |y - z^k|_H^2 + \frac{\alpha}{2} \, |u|_{\mathcal{U}}^2,$$

where

$$z^k = \frac{1}{h} \int_{t_k - \frac{h}{2}}^{t_k + \frac{h}{2}} z(s, \cdot) ds \tag{3.1}$$

and $z(t,\cdot) = 0$ for $t > T$. Finally, for $k = 1, \dots, m$ and $i = 1, 2$, introduce the operators $e_i^k : V \times \mathcal{U} \to V'$ by

$$e_1^k(y,u) = (I + hA)y - hb(y^{k-1}) - y^{k-1} - \mathcal{B}u,$$

and for later purposes also

$$e_2^k(y,u) = (I + hA)y - hb(y) - y^{k-1} - \mathcal{B}u,$$

where y^{k-1} denotes the state at the previous time slice.

The instantaneous optimal control problem for the semi-implicit time integration is given by

$$(\mathrm{P}^k) \qquad \text{minimize } J^k(y,u) \quad \text{s.t.} \quad e_1^k(y,u) = 0 \text{ in } V',$$

where $y^0 = \phi$. The initial value ϕ now is required to be an element of the space V. For given y^{k-1}, a pair (y^k, u^k) satisfies the subsidiary condition $e_1^k(y,u) = 0$ in V' if and only if

$$\nu h(y^k, \varphi)_V + (y^k, \varphi)_H = (y^{k-1}, \varphi)_H + \langle \mathcal{B}u^k + hb(y^{k-1}), \varphi \rangle_{V',V} \quad \forall \varphi \in V. \tag{3.2}$$

Since $\phi \in V$ holds, the right-hand side in this linear equation defines a bounded linear functional on V. Thus, for every $u^k \in \mathcal{U}$, (3.2) admits a unique solution $y^k \in V$ which satisfies the a priori estimate

$$|y^k|_V \le \frac{C}{\nu h} \left(|y^{k-1}|_H + h|y^{k-1}|^2{}_V + |u^k|_{\mathcal{U}} \right).$$

Since J^k is quadratic and e_1^k is linear, every problem (P^k), $k = 1, \dots, m$, admits a unique solution $(y_*^k, u_*^k) \in V \times \mathcal{U}$ which in fact defines a minimum for (P^k). Furthermore, the unique Lagrange multiplier $\lambda_*^k \in V$ together with the solution (y_*^k, u_*^k) satisfies the first-order necessary optimality conditions (note that A is self-adjoint)

$$(I + hA)y = \mathcal{B}u + y^{k-1} + hb(y^{k-1}), \tag{3.3a}$$

$$(I + hA)\lambda = -(y - z^k), \tag{3.3b}$$

$$\alpha u - \mathcal{B}^\star \lambda = 0. \tag{3.3c}$$

The optimal control problem (P^k) is equivalent to the unconstrained minimization of the functional

$$\hat{J}^k(u) = J^k(y(u), u)$$

over $\mathcal{U}$, where for a control $u \in \mathcal{U}$ the state $y(u) \in V$ is given as the unique solution to (3.2). The gradient of $\hat{J}^k$ at u is given by

$$\nabla \hat{J}^k(u) = \alpha u - \mathcal{B}^\star \lambda,$$

where for given u the function λ is obtained by first solving the linear quasi-Stokes problem (3.3a) for the state y and then solving (3.3b) for λ.

Remark 3.1. If one uses implicit time integration in problem (P^k), i.e., in the subsidiary condition the operator e_1^k is replaced by e_2^k, the adjoint equation (3.3b) alters to

$$(I + hA)\lambda - b'(y)^\star \lambda = -(y - z^k). \tag{3.4}$$

Into this equation the state y enters in two different fashions: first as observation $-(y - z^k)$, and second as coefficient in the nonlinearity $b'(y)^\star$. Since the gradient $\nabla \hat{J}^k(u)$ at a control u depends on λ, in the present case it depends on the observation $y^k - z^k$ and also on the whole state y^k in terms of the derivative of b. The structure of (3.4) is retained also in the case of boundary observation, where the observation enters as boundary condition into the adjoint equation, but the whole state y^k again enters as a coefficient function. As a consequence, computation of gradient information for $\hat{J}^k$ in the present case cannot be based on observations alone.

On the other hand, the adjoint equation (3.3b) depends only on the observation $y^k - z^k$. Therefore, gradient information for the functional $\hat{J}^k$ is available utilizing the observations only. In the particular case of boundary observation no information of the state in the whole computational domain is needed at all.

3.1. The algorithm. Instead of solving (P^k) exactly, the instantaneous control strategy provides only approximate solutions to this problem through applying one step of the steepest descent method with stepsize $\rho > 0$. The control obtained in this way is used to steer the system to the next time slice. With the gradient of the functional $\hat{J}^k$ available, this procedure in algorithmic form can be formulated as follows.

ALGORITHM 1 (instantaneous control).

1. Set $y^0 = \phi$, $k = 0$ and $t^0 = 0$.
2. Given an initial control u_0^k, solve
$$(I + hA)y = y^k + hb(y^k) + \mathcal{B}u_0^k,$$
$$(I + hA)\lambda = -(y - z^k).$$
3. Set $\nabla \hat{J}(u_0^k) = \alpha u_0^k - \mathcal{B}^\star \lambda$.
4. Given $\rho > 0$, set $u^{k+1} = u_0^k - \rho \nabla \hat{J}(u_0^k)$.
5. Solve
$$(I + hA)y^{k+1} = y^k + hb(y^k) + \mathcal{B}u^{k+1}.$$
6. Set $t_{k+1} = t_k + h$, $k = k + 1$. If $t_k < T$ goto 2.

Here, $\hat{J} = \hat{J}^k$. The choice of the stepsize ρ in step 4 of the algorithm is crucial. Since (P^k) is quadratic with linear constraints, the optimal choice ρ^* can be computed exactly and in the present situation is given by

$$\rho^* = -\frac{(y(u) - z, y(d))_H + \alpha(u, d)_{\mathcal{U}}}{|y(d)|_H^2 + \alpha|d|_{\mathcal{U}}^2} = \frac{|d|_{\mathcal{U}}^2}{|y(d)|_H^2 + \alpha|d|_{\mathcal{U}}^2} \le \frac{1}{\alpha}, \tag{3.5}$$

where $d = -\nabla \hat{J}(u)$. The computation of ρ^* requires only the computation of the auxiliary function $y(d)$.

It is shown in [11, 14] that Algorithm 1 allows the interpretation as a nonlinear discrete-in-time suboptimal closed loop control method, which turns out to be the stable time discretization of some continuous closed loop controller. For the convenience of the reader these results for the Navier–Stokes system are summarized in the following subsection. To simplify the exposition from here onward, $\mathcal{U} = V'$ and, thus, $\mathcal{B} = I$ are assumed. This choice is justified by the fact that in many applications of distributed control applied to systems governed by parabolic equations, the operator $\mathcal{B}$ defined in (2.1) plays the role of an extension operator.

3.2. Feedback control laws. It is shown in [11, Theorem 5.4.1], [14, Theorem 3] that Algorithm 1 allows the following interpretation.

THEOREM 3.2.

(i) *For $u_0^k = 0$ Algorithm 1 is equivalent to the semi-implicit time discretization with discretization stepsize h,*

(3.6)
$$(I + hA)y^{k+1} = y^k + hb(y^k) - \rho BB(y^k - z^k) - h\rho BB(b(y^k) - Az^k), \quad y^0 = \phi,$$

of the dynamical system

$$\dot{y} + Ay - b(y) = K(y) \quad \text{in } L^2(V') \quad \text{and} \quad y(0) = \phi, \tag{3.7}$$

where

$$K(y) = -\frac{\rho}{h}BB(y - z) - \rho BB(b(y) - Az). \tag{3.8}$$

(ii) *Choosing the initial control u_0^k in Algorithm 1 as the solution of*

$$\left(I - \frac{\rho}{1 - \rho\alpha}BB\right)u_0^k = \frac{1}{1 - \rho\alpha}\left(z^{k+1} - z^k + Az^{k+1} - b(z^k) + \rho BB(b(z^k) - Az^k)\right),$$

the algorithm is equivalent to

$$\begin{aligned}(I + hA)w^{j+1} = w^j + h(b(y^j) - b(z^j)) - \rho BBw^j \\ -\rho hBB(b(y^j) - b(z^j)), \quad w^0 = \phi - z(0),\end{aligned} \tag{3.9}$$

where $w := y - z$. The related continuous system is given by

$$y_t + Ay - b(y) = K(y) \quad \text{in } L^2(V') \quad \text{and} \quad y(0) = \phi, \tag{3.10}$$

where

$$K(y) = -\frac{\rho}{h}BB(y - z) - \rho BB(b(y) - b(z)) + z_t + Az - b(z). \tag{3.11}$$

It is now clear that the nonlinear operators K defined in (3.8) and (3.11), respectively, can be interpreted as nonlinear closed loop control policies for the Navier–Stokes equations. In this context it is important to note that the discretization stepsize h and the descent parameter ρ in the gradient step of Algorithm 1 in the continuous case may now be regarded as parameters defining the controller.

The discrete counterpart to (3.11) will frequently be used in what follows. It is given by

$$K^D(y) = -\frac{\rho}{h}BB(y - z^j) - \rho BB(b(y) - b(z^j)) + \frac{z^{j+1} - z^j}{h} + Az^{j+1} - b(z^j). \tag{3.12}$$

Unless otherwise stipulated, the following assumption holds from here onward.

Assumption 3.3. $0 \neq \phi \in V$, and $z \in H^{2,1}(Q)$.

Note that this assumption on the desired state z in particular implies that $z(0)$ is meaningful. Moreover, $z(0) \in V$.

4. Existence, uniqueness, and stability of solutions. In this section existence, uniqueness, stability, and regularity of a solution to (3.10) are discussed. The boundary $\partial\Omega$ is assumed to be as smooth as required by the existence and regularity results for the Stokes and quasi-Stokes problems considered in the proofs of the theorems below; see [23, Chap. I, Prop. 2.3]. It follows from the a priori estimates to be derived that the stabilized system (3.10) admits a unique solution. Moreover,

the H- and V-norms of difference $w = y - z$ decay exponentially with rate $-\frac{\rho}{h}$. To achieve these results the range of ρ has to be adapted to the size of $|z|^2_{L^\infty(H)}$. For this purpose set $d_H := 2|\phi - z(0)|^2_H$ and let the range of ρ be implicitly defined by

$$0 < \rho \le \rho_1 := \min\left(\rho_0, \frac{\nu^2}{2\nu^2 + \exp\left(\frac{4+\rho}{\nu}|z|^2_{L^2(V)}\right) d_H + |z|^2_{L^\infty(H)}}\right). \tag{4.1}$$

THEOREM 4.1. *Let $0 < \rho \le \rho_1$ with ρ_1 from (4.1) and let $h > 0$ be fixed. Further, let $\phi \in H$ and $z \in W$. Then (3.10) for every $T > 0$ admits a unique solution $y \in W$, and the difference $w = y - z$ satisfies*

$$\begin{cases} |w|^2_H \le C\,(\nu, |z|_W)\, e^{-\frac{\rho}{h}t} & \forall\, t \in [0,T], \\ |w|^2_{L^\infty(H)} \le C\,(\nu, |z|_W), & \\ |w|^2_{L^2(V)} \le C\,(\nu, |z|_W), & \text{and} \\ |w_t|^2_{L^2(V')} \le C\,(\nu, |z|_W)\left\{1 + \frac{\rho}{h}\right\}, & \end{cases} \tag{4.2}$$

where $C(\nu, |z|_W)$ is a positive constant independent of ρ and h.

Proof. Existence of a solution can be proved using a Galerkin ansatz in combination with the estimates derived below; compare [11, 14]. Uniqueness also follows from these estimates. To prove (4.2) use w as test function in the variational formulation of (3.10). This leads to

$$\begin{aligned} &\frac{d}{dt}|w|^2_H + \nu|w|^2_V + \frac{\rho}{h}|Bw|^2_H \\ &\quad = \int_\Omega ((w\nabla)w + (z\nabla)w + (w\nabla)z)w\,dx \\ &\qquad -\rho\int_\Omega (B((w\nabla)w + (z\nabla)w + (w\nabla)z))Bw\,dx = (i) + \cdots + (vi). \end{aligned}$$

Since $(i) = (ii) = 0$, it remains to estimate the terms $(iii), (iv), (v)$, and (vi) in order to derive a differential inequality for $y - z$. To begin, estimate, using Young's inequality and (2.7),

$$\begin{aligned} (iii) &\le \frac{\nu}{2}|w|^2_V + \frac{2}{\nu}|z|^2_V|w|^2_H, \\ (iv) \le \rho h|B((w\nabla)w)|^2_H + \frac{\rho}{4h}|Bw|^2_H &\le \frac{\rho}{2\nu}|w|^2_H|w|^2_V + \frac{\rho}{4h}|Bw|^2_H, \\ (v) + (vi) &\le \rho h\left\{|B((w\nabla)z)|^2_H + |B((z\nabla)w)|^2_H\right\} + \frac{\rho}{4h}|Bw|^2_H \\ &\le \frac{\rho}{4h}|Bw|^2_H + \frac{\rho}{2\nu}\left\{|w|^2_V|z|^2_H + |z|^2_V|w|^2_H\right\}, \end{aligned}$$

and apply estimate (2.6). This leads to

$$\frac{1}{2}\frac{d}{dt}|w|^2_H + \left(\nu\left(\frac{1}{2} - \rho\right) - \frac{\rho}{2\nu}\left(|w|^2_H + |z|^2_{L^\infty(H)}\right)\right)|w|^2_V + \frac{\rho}{2h}|w|^2_H \le \frac{4+\rho}{2\nu}|z|^2_V|w|^2_H.$$

Since ρ satisfies (4.1), $\nu(\frac{1}{2} - \rho) - \frac{\rho}{2\nu}(\exp(\frac{4+\rho}{\nu}|z|^2_{L^2(V)})d_H + |z|^2_{L^\infty(H)}) > 0$. For ρ in this range standard arguments yield

$$\begin{aligned} &\frac{1}{2}\frac{d}{dt}|w|^2_H + \left(\nu\left(\frac{1}{2} - \rho\right) - \frac{\rho}{2\nu}\left(\exp\left(\frac{4+\rho}{\nu}|z|^2_{L^2(V)}\right) d_H + |z|^2_{L^\infty(H)}\right)\right) \\ &\qquad \times |w|^2_V + \frac{\rho}{2h}|w|^2_H \le \frac{4+\rho}{2\nu}|z|^2_V|w|^2_H. \end{aligned} \tag{4.3}$$

Since the right-hand side in (4.3) is integrable, a further Gronwall argument gives the desired result. Note that the estimate for w_t is a direct consequence of the second and third estimates in (4.2). □

A similar result holds for the decay w.r.t. the V-norm of w. Now let the range of ρ be implicitly defined by the relation

$$0 < \rho \le \rho_2 := \min\left(\rho_0, \frac{1}{2}\frac{\nu^2}{2\nu^2 + 3\exp\left(\frac{4+\rho}{\nu}|z|^2_{L^2(V)}\right) d_H + 3|z|^2_{L^\infty(H)}}\right). \tag{4.4}$$

THEOREM 4.2. *Let ρ satisfy* (4.4) *and let y be the unique solution of* (3.10). *Then $y \in H^{2,1}(Q)$, and $w = y - z$ satisfies*

$$\begin{aligned}
&|w|^2_V \le C\left(\nu, |z|_{H^{2,1}(Q)}\right) e^{-\frac{\rho}{h}t} && \forall\, t \in [0,T],\\
&|w|^2_{L^\infty(V)} \le C\left(\nu, |z|_{H^{2,1}(Q)}\right),\\
&|w|^2_{L^2(H^2(\Omega)^2 \cap V)} \le C\left(\nu, |z|_{H^{2,1}(Q)}\right), && \text{and}\\
&|w_t|^2_{L^2(H)} \le C\left(\nu, |z|_{H^{2,1}(Q)}\right)\left\{1 + \frac{\rho}{h}\right\},
\end{aligned}$$

where $C(\nu, |z|_{H^{2,1}(Q)})$ is a positive constant independent of ρ and h.

Proof. Use Sw as test function in (3.10). This leads to

$$\begin{aligned}
&\frac{1}{2}\frac{d}{dt}|w|^2_V + \nu|Sw|^2_H + \int_\Omega ((y\nabla)y - (z\nabla)z)\, Sw\, dx\\
&\quad = -\frac{\rho}{h}\int_\Omega BwBSw\, dx - \rho\int_\Omega B((y\nabla)y - (z\nabla)z)BSw\, dx.
\end{aligned}$$

Relation (4.4) implies $1 - \rho - \frac{3\rho}{\nu^2}(\exp(\frac{4+\rho}{\nu}|z|^2_{L^2(V)})d_H + |z|^2_{L^\infty(H)}) \ge \frac{1}{2}$. Restricting ρ to this range, similar to the derivation of (4.3) after several applications of (2.2), (2.8), Lemma 2.2, and Young's inequality, one ends up with

$$\begin{aligned}
&\frac{1}{2}\frac{d}{dt}|w|^2_V + \frac{\nu}{2}|Sw|^2_H + \frac{\rho}{h}\left(1 - \rho - \frac{3\rho}{\nu^2}\left(\exp\left(\frac{4+\rho}{\nu}|z|^2_{L^2(V)}\right) d_H + |z|^2_{L^\infty(H)}\right)\right)|w|^2_V\\
&\quad \le C_\nu\left\{|w|^2_H|w|^2_V + |z|_H|Sz|_H + |z|^2_V + |z|^4_V\right\}|w|^2_V.
\end{aligned} \tag{4.5}$$

Since the right-hand side in (4.5) is integrable, a Gronwall argument gives the desired result. □

4.1. Stability of discrete controllers. First the stability properties of the instantaneous control procedure (3.9) are investigated. As will be shown, stability for a certain parameter range of h and ρ can be ensured only by requiring additionally either largeness of the viscosity parameter ν or smallness of $\phi - z(0)$. As is shown in [14], these restrictions do not apply when the procedure is applied to the instationary Burgers equation. Secondly, a slightly modified version of the controller (3.12) is applied to the fully implicit Euler discretization of the Navier–Stokes system. It turns out that the resulting discrete-in-time system for $w = y - z$ is unconditionally stable. Note that fully implicit discretization of the state is a realistic situation, since the discrete controller is applied to stabilize a physical system which is described by the

Navier–Stokes equations. Therefore, the choice of the discretization procedure for the uncontrolled state need not be linked to the discrete controller.

Throughout this section it is assumed that the following assumption holds.

Assumption 4.3. In addition to Assumption 3.3, let $z \in C([0,T]; H^{1,\infty}(\Omega)^2 \cap V)$.

In a preparatory step, an inequality relating the H-norms of $w = y^{j+1} - z^{j+1}$ and $v = y^j - z^j$ is derived, and $z := z^j$, $j \in \mathbb{N}$. To begin, test (3.9) with w. This gives

$$\begin{aligned} &\frac{1}{2}|w|_H^2 - \frac{1}{2}|v|_H^2 + \frac{1}{2}|w-v|_H^2 + \nu h|w|_V^2 \\ &\quad = h\int_\Omega \left((v\nabla)v + (z^j\nabla)v + (v\nabla)z^j\right) w\,dx - \rho\int_\Omega BvBw\,dx \\ &\qquad -\rho h\int_\Omega B\left((v\nabla)v + (z^j\nabla)v + (v\nabla)z^j\right) Bw\,dx = (i) + \cdots + (vii). \end{aligned} \tag{4.6}$$

Estimating, using (2.2),

$$|B((v\nabla)v)|_H^2 \le \frac{1}{2\nu h}|v|_H^2|v|_V^2$$

from Lemma 2.1 and Young's inequality yields

$$\begin{aligned} (i) &\le \frac{\nu h}{4}|w|_V^2 + \frac{2h}{\nu}|v|_H^2|v|_V^2, \\ (ii) &\le \frac{\nu h}{4}|w|_V^2 + \frac{|z|_\infty^2 h}{\nu}|v|_H^2, \\ (iii) &\le \frac{h}{2}|w|_H^2 + \frac{|z|_{1,\infty}^2 h}{2}|v|_H^2, \\ (iv) &= -\rho\int_\Omega |Bw|^2 dx - \rho\int_\Omega B(v-w)Bw \le \frac{\rho}{2}(\rho-1)|Bw|_H^2 + \frac{1}{2}|v-w|_H^2, \\ (v) &= -\rho h\int_\Omega B\left((v\nabla)v\right)Bw\,dx \le \frac{3\rho h}{2\nu(1-\rho)}|v|_H^2|v|_V^2 + \frac{\rho}{12}(1-\rho)|Bw|_H^2, \end{aligned}$$

and finally

$$\begin{aligned} (vi) + (vii) &= -\rho h\int_\Omega B\left((v\nabla)z^j + (z^j\nabla)v\right)Bw\,dx \\ &\le \left\{\frac{3\rho h^2|z|_{1,\infty}^2}{1-\rho} + \frac{3\rho h|z|_\infty^2}{4(1-\rho)\nu}\right\}|v|_H^2 + \frac{\rho(1-\rho)}{6}|Bw|_H^2. \end{aligned}$$

Now introduce

$$c_1(\rho,h) := \frac{1}{2} + \frac{\rho}{4}(1-\rho) - \frac{h}{2}$$

and

$$\begin{aligned} c_2^j(\rho,h,z) := \frac{1}{2} &+ \left[\frac{2h}{\nu} + \frac{3h\rho}{2\nu(1-\rho)}\right]|v|_V^2 \\ &+ \underbrace{\left[\frac{|z|_{1,\infty}^2 h}{2} + \frac{|z|_\infty^2 h}{\nu} + \frac{3\rho h^2|z|_{1,\infty}^2}{1-\rho} + \frac{3\rho h|z|_\infty^2}{(1-\rho)4\nu}\right]}_{=:\tilde{c}_2(h,\rho,z)}. \end{aligned}$$

With this notation the estimates above and Lemma 2.1 together with (4.6) give

$$c_1(\rho,h)|w|_H^2 - c_2^j(\rho,h,z)|v|_H^2 + \frac{\nu h}{2}(1-\rho+\rho^2)|w|_V^2 \le 0. \tag{4.7}$$

THEOREM 4.4 (conditional H-norm stability of instantaneous control). *Let $w^j := y^j - z^j$, where y^j denotes the iterates obtained by* (3.9). *Then*

$$\forall \rho \in (0,1)\ \exists h^*(\rho),\ 0<\kappa<1\ \forall j \in \mathbb{N} : |w^{j+1}|_H^2 \le \kappa^j |w^0|_H^2,$$

provided $0 < h \le h^*(\rho)$ and

$$crit := \frac{4-\rho}{\nu^2(1-\rho)(1-\rho+\rho^2)}|w^0|_H^2$$

is sufficiently small.

Proof. Fixing $\rho \in (0,1)$, define

$$\hat{c}_2(\rho,h,z) := \frac{1}{2} + crit + \tilde{c}_2(\rho,h,z)$$

and argue by induction as follows.

1. Set $j=0$, and choose $h_0 = h_0(\rho)$ and *crit* so small that for all $0 < h \le h_0$
   (a) $\hat{c}_2(\rho,h,z) \le 1$ and $c_2^0(\rho,h,z) \le 1$,
   (b) $\frac{\hat{c}_2(\rho,h,z)}{c_1(\rho,h)} = \kappa_1 < 1$, and
   (c) $\frac{c_2^0(\rho,h,z)}{c_1(\rho,h)} = \kappa_2 < 1$

hold. This is possible, since for $\rho \in (0,1)$ the term $\frac{\rho}{4}(1-\rho)$ in the definition of $c_1(\rho,h)$ is positive. Define $\kappa := \max(\kappa_1,\kappa_2)$. Then (4.7) implies

$$|w^1|_H^2 \le \kappa |w^0|_H^2$$

and

$$|w^1|_V^2 \le \frac{2}{\nu h(1-\rho+\rho^2)}|w^0|_H^2 = \frac{2}{\nu h(1-\rho+\rho^2)}\kappa^0|w^0|_H^2.$$

2. Now assume that for $j \in \mathbb{N}$
   (a) $|w^j|_H^2 \le \kappa^j |w^0|_H^2$ and
   (b) $|w^j|_V^2 \le \frac{2}{\nu h(1-\rho+\rho^2)}\kappa^{j-1}|w^0|_H^2$

hold true.

3. Then conclude from (4.7) that

$$\begin{aligned} c_2^j(\rho,h,z) &= \frac{1}{2} + \left[\frac{2h}{\nu} + \frac{3h\rho}{2\nu(1-\rho)}\right]|w^j|_V^2 + \tilde{c}_2(\rho,h,z) \\ &\le \frac{1}{2} + \left[\frac{2h}{\nu} + \frac{3h\rho}{2\nu(1-\rho)}\right]\frac{2}{\nu h(1-\rho+\rho^2)}\kappa^{j-1}|w^0|_H^2 + \tilde{c}_2(\rho,h,z) \\ &\le \frac{1}{2} + crit + \tilde{c}_2(\rho,h,z) = \hat{c}_2(\rho,h,z). \end{aligned}$$

Thus, a further application of (4.7) implies

$$|w^{j+1}|_H^2 \le \frac{c_2^j(\rho,h,z)}{c_1(\rho,h)}|w^j|_H^2 \le \frac{\hat{c}_2(\rho,h,z)}{c_1(\rho,h)}|w^j|_H^2 \le \kappa^{j+1}|w^0|_H^2$$

and

$$|w^{j+1}|_V^2 \le \frac{2}{\nu h(1-\rho+\rho^2)}c_2^j(\rho,h,z)|w^j|_H^2 \le \frac{2}{\nu h(1-\rho+\rho^2)}\kappa^j|w^0|_H^2,$$

which completes the proof of Theorem 4.4. ∎

The last estimate of the previous proof also yields stability with respect to the V-norm.

THEOREM 4.5 (conditional V-norm stability of instantaneous control).

$$\forall \rho \in (0,1)\ \exists h^*(\rho),\ 0<\kappa<1\ \forall j\in\mathbb{N},\ 0<h\le h^*: |w^j|_V \le \frac{2}{\nu h(1-\rho+\rho^2)}\kappa^{j-1}|w^0|_H,$$

provided

$$crit := \frac{4-\rho}{\nu^2(1-\rho)(1-\rho+\rho^2)}|w^0|_H^2$$

is sufficiently small.

Remark 4.6. The smallness of *crit* in Theorems 4.4 and 4.5 is a condition either on the smallness of the initial difference between state and desired state or on the smallness of the Reynolds number of the fluid. It has to be required since there are no better estimates available for the term (i) in (4.6). The term (v) in (4.6) could be estimated in a slightly different way to obtain a ρ^2 in front of $|v|_V^2$ (see the proof of the next theorem) and therefore could be reduced by decreasing ρ. However, for (i) in (4.6) there is no further knob to fix its size. For the Burgers equation the situation is much more comfortable at this stage. Due to the continuous embedding $H^1 \hookrightarrow L^\infty$ and the well-known L^2-H^1 interpolation estimate for L^∞ functions in one spatial dimension, one has

$$h\int_\Omega vv'w\,dx \le \frac{\nu h}{4}|w|_V^2 + h^{1-2\alpha}|w|_H^2 + h^{1+2\alpha}\frac{1}{2\sqrt{\nu}}|w|_V^2|w|_H^2 \quad \forall\ \alpha\in(0,1).$$

Following the lines of the proof of Theorem 4.4 one can now conclude that the smallness requirement on *crit* may be dropped provided ρ is sufficiently small, since the power of h in the last addend on the right-hand side of this estimate is larger than one. For more details see [14].

Finally, a discrete-in-time control policy for the Navier–Stokes system is considered which is unconditionally stable. Let

(4.8)
$$K^D(y) = -\frac{\rho}{h}BB(y-z^j) - \rho BB(b(y)-b(z^j)) + \frac{z^{j+1}-z^j}{h} + Az^{j+1} - b(z^{j+1}),$$

and consider the following discretization of (3.10):

$$\frac{y^{j+1}-y^j}{h} + Ay^{j+1} - b(y^{j+1}) = K^D(y^j), \quad j=0,1,\dots \quad \text{and} \quad y^0=\phi. \tag{4.9}$$

There holds the following theorem.

THEOREM 4.7 (H- and V-norm stability of (4.8)). *Let $w^j := y^j - z^j$. There exists some $\rho^*\in(0,1)$ such that for every $0<\rho\le\rho^*$ there exist an $h^*(\rho)>0$ and a positive $\kappa<1$ such that for all $j\in\mathbb{N}$*

$$|w^j|_H^2 \le \kappa^j|w^0|_H^2 \quad \textit{and}$$

$$|w^j|_V^2 \le \frac{2}{\nu h(1-\frac{2}{3}\rho+\frac{2}{3}\rho^2)}\kappa^{j-1}|w^0|_H^2,$$

provided $0<h\le h^*(\rho)$.

Proof. During the proof again let $v = y^j - z^j$, $w = y^{j+1} - z^{j+1}$ and test (4.9) with w. This leads to

$$\begin{aligned}
&\frac{1}{2}|w|_H^2 - \frac{1}{2}|v|_H^2 + \frac{1}{2}|w-v|_H^2 + h\nu|w|_V^2 \\
&\quad = h\int_\Omega \left((w\nabla)w + (z^j\nabla)w + (w\nabla)z^j\right) w\,dx - \rho\int_\Omega BvBw\,dx \\
&\quad\quad -\rho h\int_\Omega B\left((v\nabla)v + (z^j\nabla)v + (v\nabla)z^j\right) Bw\,dx \\
&\quad = (i)' + (ii)' + (iii)' + (iv) + (v)' + (vi) + (vii),
\end{aligned} \tag{4.10}$$

where (iv), (vi), and (vii) are defined in (4.6). There holds $(i)' = (ii)' = 0$, and $(iii)'$ can be estimated as

$$(iii)' \le \frac{\nu h}{2}|w|_V^2 + \frac{h}{\nu}|z|_V^2|w|_H^2.$$

Utilizing the estimate $|BBw|_V \le |w|_V$, one obtains

$$(v)' \le \frac{\nu h}{3}|w|_V^2 + \frac{3\rho^2 h}{2\nu}|v|_H^2|v|_V^2.$$

The remaining addenda can be estimated as above. Now introduce

$$c_1(\rho,h,z) := \frac{1}{2} + \frac{\rho}{3}(1-\rho) - \frac{2h}{\nu}|z|_{L^\infty(V)}^2 - \frac{h}{2}$$

and

$$c_2^j(\rho,h,z) := \frac{1}{2} + \frac{3\rho^2 h}{2\nu}|v|_V^2 + \underbrace{\left[\frac{3\rho h^2|z|_{1,\infty}^2}{1-\rho} + \frac{3\rho h|z|_\infty^2}{4(1-\rho)\nu}\right]}_{=:\tilde{c}_2(h,\rho,z)}.$$

With this notation and the estimates above, one concludes from (4.10) that

$$c_1(\rho,h,z)|w|_H^2 - c_2^j(\rho,h,z)|v|_H^2 + \frac{\nu h}{2}\left(1 - \frac{2}{3}\rho + \frac{2}{3}\rho^2\right)|w|_V^2 \le 0. \tag{4.11}$$

Now define

$$\hat{c}_2(\rho,h,z) := \frac{1}{2} + \frac{3\rho^2}{\nu^2(1-\frac{2}{3}\rho+\frac{2}{3}\rho^2)}|w^0|_H^2 + \tilde{c}_2(\rho,h,z)$$

and proceed as follows.

1. Choose $\rho^* \in (0,1)$ such that

$$\frac{3\rho}{\nu^2(1-\frac{2}{3}\rho+\frac{2}{3}\rho^2)}|w^0|_H^2 \le \frac{1}{6}(1-\rho) \quad \forall\,\rho\in(0,\rho^*]. \tag{4.12}$$

2. Fix $\rho \in (0,\rho^*]$ and choose $h^* = h^*(\rho) > 0$ such that
   (a) $\tilde{c}_2(h,\rho,z) \le \frac{1}{4}$,
   (b) $\frac{3\rho^2 h}{2\nu}|w^0|_V^2 \le \frac{1}{4}$,
   (c) $\frac{h}{2} + \frac{2h}{\nu}|z|_{L^\infty(V)}^2 + \tilde{c}_2(h,\rho,z) < \frac{\rho}{6}(1-\rho)$, and
   (d) $\frac{c_2^0(\rho,h,z)}{c_1(\rho,h,z)} \le \kappa_1 < 1$

hold for all h in the interval $(0,h^*]$. Let $h \in (0,h^*]$.

3. Now conclude from (4.12) and $\rho \in (0,1)$ that

$$\frac{3\rho^2}{\nu^2(1-\frac{2}{3}\rho+\frac{2}{3}\rho^2)}|w^0|_H^2 \le \frac{\rho}{6}(1-\rho) < \frac{1}{4},$$

which together with (c) implies that

$$\hat{c}_2(\rho,h,z) < 1 \quad \text{and} \quad \frac{\hat{c}_2(\rho,h,z)}{c_1(\rho,h,z)} \le \kappa_2 < 1.$$

Furthermore, (a) and (b) give $c_2^0(\rho,h,z) \le 1$, so that with (4.11)

$$|w^1|_V^2 \le \frac{2c_2^0(\rho,h,z)}{\nu h(1-\frac{2}{3}\rho+\frac{2}{3}\rho^2)}|w^0|_H^2 \le \frac{2}{\nu h(1-\frac{2}{3}\rho+\frac{2}{3}\rho^2)}\kappa^0|w^0|^2.$$

4. Now assume that for $j \in \mathbb{N}$
   (a) $|w^j|_H^2 \le \kappa^j|w^0|_H^2$ and
   (b) $|w^j|_V^2 \le \frac{2}{\nu h(1-\frac{2}{3}\rho+\frac{2}{3}\rho^2)}\kappa^{j-1}|w^0|_H^2$

hold true, where $\kappa := \max(\kappa_1,\kappa_2) < 1$.

5. Then conclude from (b) that

$$\begin{aligned} c_2^j(\rho,h,z) &= \frac{1}{2} + \frac{3h\rho^2}{2\nu}|w^j|_V^2 + \tilde{c}_2(\rho,h,z) \\ &\le \frac{1}{2} + \frac{3h\rho^2}{2\nu}\frac{2}{\nu h(1-\frac{2}{3}\rho+\frac{2}{3}\rho^2)}\kappa^{j-1}|w^0|_H^2 + \tilde{c}_2(\rho,h,z) \\ &\le \hat{c}_2(\rho,h,z). \end{aligned}$$

Thus, utilizing (4.11) one more time gives

$$|w^{j+1}|_H^2 \le \frac{c_2^j(\rho,h,z)}{c_1(\rho,h,z)}|w^j|_H^2 \le \frac{\hat{c}_2(\rho,h,z)}{c_1(\rho,h,z)}|w^j|_H^2 \le \kappa^{j+1}|w^0|_H^2$$

and

$$|w^{j+1}|_V^2 \le \frac{2}{\nu h(1-\frac{2}{3}\rho+\frac{2}{3}\rho^2)}c_2^j(\rho,h,z)|w^j|_H^2 \le \frac{2}{\nu h(1-\frac{2}{3}\rho+\frac{2}{3}\rho^2)}\kappa^j|w^0|_H^2,$$

which completes the proof of Theorem 4.7. ∎

Remark 4.8.

1. In the discrete scheme (4.9) all local quantities are discretized implicitly, and nonlocal quantities explicitly.

2. The proof of Theorem 4.7 is constructive. Estimates of ρ^* and $h^*(\rho)$ therefore can be deduced from (4.12) and 2(a)–(d) of the proof of the theorem, respectively.

3. Note further that the conditions on ρ in (4.1), (4.4) are satisfied for the stepsize of (3.5), provided the parameter α is chosen sufficiently large.

5. Numerical validation. Here the results obtained in the previous sections are numerically validated. In order to value the performance of the feedback operators (3.11) and (3.12), the numerical example is taken from [16]. As is demonstrated below the instantaneous controller presented here steers the H-norm and the V-norm

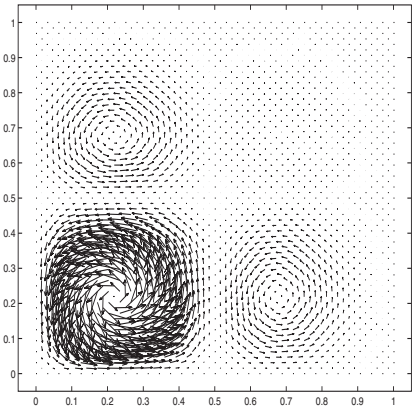

FIG. 1. *Desired flow at* $T = 2$.

of the difference $y - z$ to zero with exponential decay. This seems to be a more stable performance than that reported by Hou and Yan in [16] for their $(1, 1)$-rhc (i.e., control horizon length coincides with time stepsize). The instantaneous controls are compared to the optimal control, and it turns out that instantaneous controls give a much better reduction of the control gain but at significantly higher overall costs.

The control problem considered here is of tracking type and is given by (P) with cost functional

$$J(y,u) := \frac{1}{2}\int_Q |y-z|^2 dx\,dt + \frac{\alpha}{2}\int_Q |u|^2 dx\,dt$$

and control space $\mathcal{U} := L^2(\Omega)^2$, with $\mathcal{B}$ denoting the injection from U into V'. The initial value of the uncontrolled flow is chosen as

$$y(x,0) = e\begin{bmatrix}(\cos 2\pi x_1 - 1)\sin 2\pi x_2\\ -(\cos 2\pi x_2 - 1)\sin 2\pi x_1\end{bmatrix}$$

with e denoting the Euler number, and the desired state is time dependent and given by

$$z(t,x) = \begin{bmatrix}\varphi_{x_2}(t,x_1,x_2)\\ -\varphi_{x_1}(t,x_1,x_2)\end{bmatrix},$$

where φ is defined through the stream function

$$\varphi(t,x_1,x_2) = \theta(t,x_1)\theta(t,x_2)$$

with

$$\theta(t,y) = (1-y)^2(1-\cos 2k\pi t), \quad y \in [0,1].$$

For the results presented, $\alpha = 1.e-2$, $k = 1$, and the time interval is chosen as $[0, 2]$, i.e., $T = 2$. For the discretization in time, an equidistant grid with width $\delta t = 0.01$ is used, and for the spatial discretization, the Taylor–Hood finite element [15] is used on a grid containing 1024 triangles with 2113 velocity nodes and 545 pressure nodes. The number of unknowns in the discretized control problem therefore has the magnitude 1.65×10^6, including the primal, adjoint, and control variables.

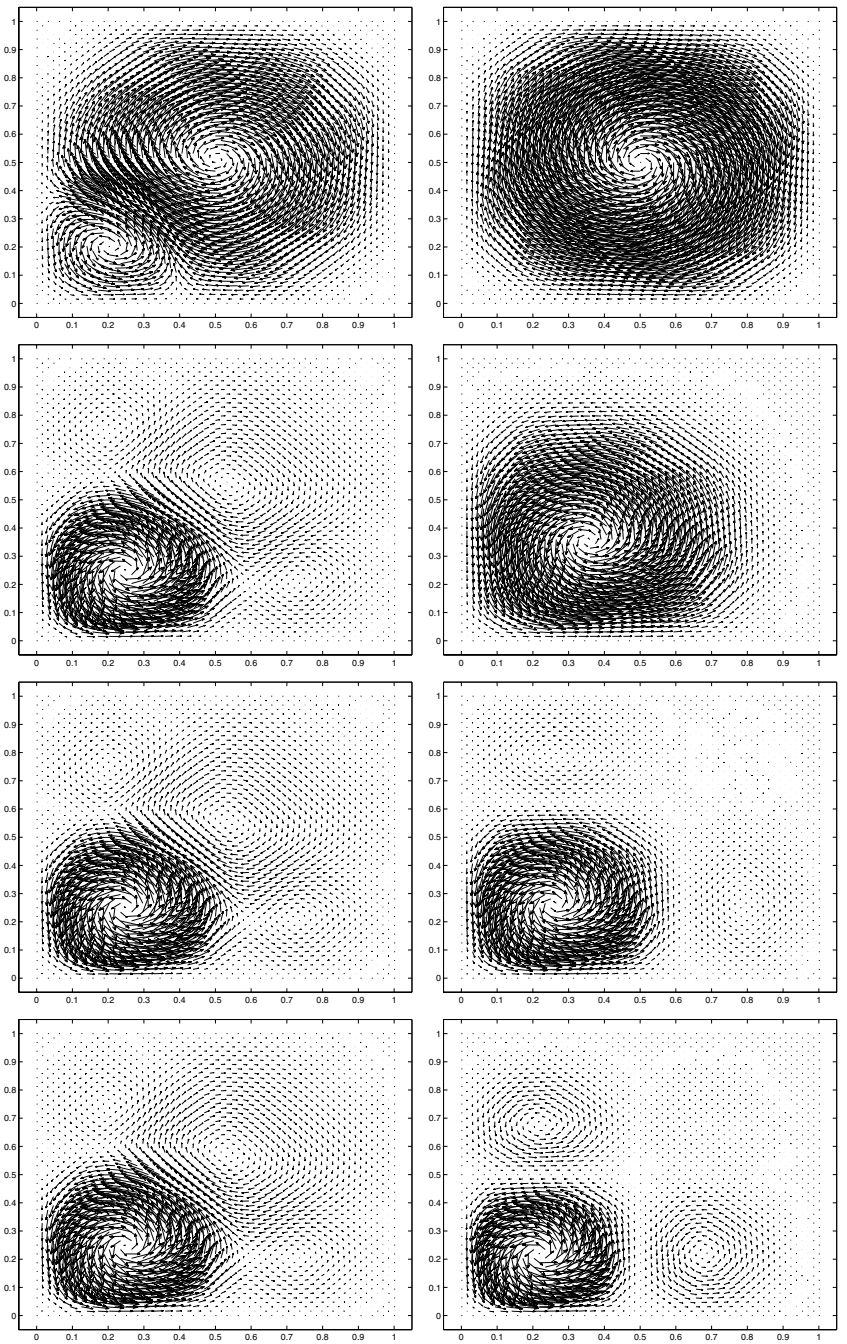

FIG. 2. *Optimally controlled (left) versus instantaneously controlled flows for* $t = 0.1, 1, 1.6, 2$.

In Figure 1 the desired flow at $T = 2$ is shown. It forms four cells with opposite flow directions near the cell borders.

In Figure 2 the evolution of the optimally controlled flow computed with Newton's method (see [11, 13] for computational details) and the instantaneously controlled flow

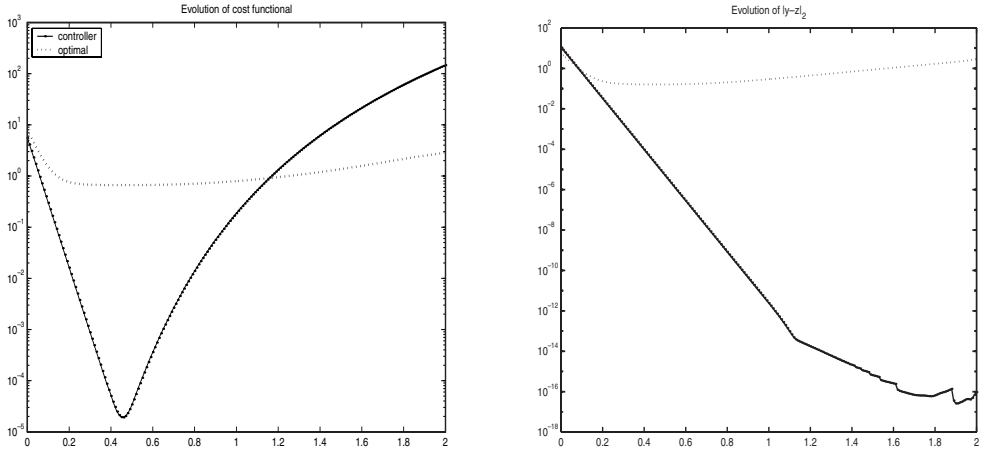

FIG. 3. *Evolution of cost (left) and control gain for* $h = 0.01$ *and* $\rho = 0.1$.

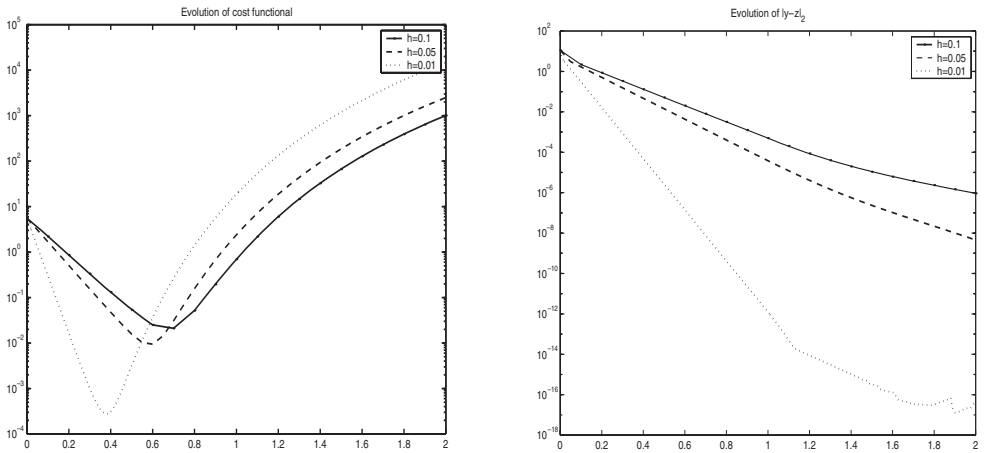

FIG. 4. *Evolution of cost (left) and control gain for* $\rho = 0.1$ *and* $h = 0.01, 0.05, 0.1$.

are illustrated at selected time instances. The costs are compared in Figure 3. For the instantaneous control strategy they become larger with increasing time. This is due to the increasing dynamics of the desired state. As is expected, the optimal control strategy equidistributes the costs over the time horizon, whereas instantaneous control at every time instance tries to match the desired state. This is also illustrated by the evolution in Figure 2.

For $\nu = 1/\mathrm{Re} = 1/10$ and $\gamma = 1.e-2$, the numerical computation of the optimal control takes about 45 minutes of cpu-time on a DEC-ALPHA^{TM} station 500. The instantaneous feedback controller takes about 2 minutes to compute a control function on the time horizon $[0, 2]$.

In Figure 4 the evolution of the L^2-cost for the instantaneous control law is shown for $\rho = 0.1$ and different values of h. In Figure 5, $h = 0.1$ is fixed, and the evolution of the control gain in the L^2- and H^1-norms for different values of ρ is shown. Exponential decay is observed, and thus the theoretical results of Theorems 4.1, 4.2, 4.4, and 4.5 are confirmed.

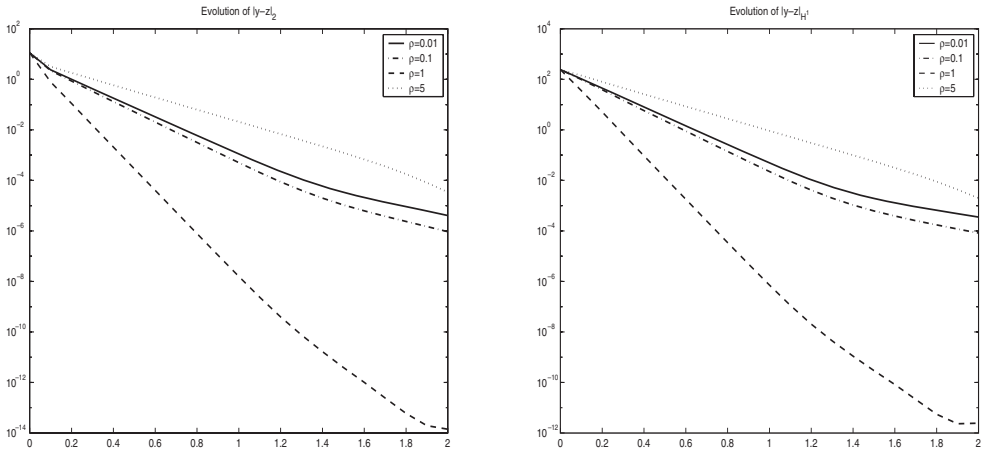

FIG. 5. *Evolution of control gain in L^2-norm (left) and H^1-norm for $h = 0.1$ and $\rho = 0.01, 0.1, 1, 5$.*

MULTIRATE STABILIZATION OF LINEAR MULTIPLE SENSOR SYSTEMS VIA LIMITED CAPACITY COMMUNICATION CHANNELS*

ALEXEY S. MATVEEV† AND ANDREY V. SAVKIN‡

Abstract. The paper addresses a feedback stabilization problem involving bit-rate communication capacity constraints. A discrete-time partially observed linear system is studied. Unlike classic theory, the signals from multiple sensors are transmitted to the controller over separate finite capacity communication channels. The sensors do not have constant access to the channels, and the channels are not perfect: the messages incur time-varying transmission delays and may be corrupted or lost. However, we suppose that the time-average number of bits per sample period that can be successfully transmitted over the channel during a time interval converges to a certain limit as the length of the interval becomes large. Necessary and sufficient conditions for stabilizability are established. They give the tightest lower bounds on the channel capacities for which stabilization is possible. An algorithm for stabilization is also presented.

Key words. networked control systems, finite data rate, communication constraints, stabilizability

1. Introduction.

The standard assumption in classical control theory is that data transmission required by the algorithm can be performed with infinite precision. However, due to the growth in communication technology, it is becoming more common to employ digital finite capacity networks for the exchange of information between plant components. Examples concern complex dynamical processes like advanced aircraft, spacecraft, automotive, industrial and defense systems, arrays of microactuators, and power control in mobile communication. Bandwidth communication constraints are often major obstacles to control system design by means of classical theory. For instance, as was shown in [24], the design of control systems for platoons of underwater vehicles strongly highlights the need for control strategies that address explicitly the bandwidth limitation on communication between vehicles, which is severely restricted underwater. All these emerging applications motivate development of a new chapter of control theory that deals with networked systems and combines the control and communication issues, taking into account all the limitations on communication between sensors, controllers, and actuators.

Recently there was a good deal of research activity in this field. Starting with [4] and continuing with [1, 2, 3, 7, 8, 13, 15, 16, 17, 19, 22, 25, 27], various control schemes were proposed for stabilization via a limited capacity channel. The smallest data rate above in which stabilization is possible was derived in [19, 20, 25, 27] in various settings. However, up to now, only networks with the simplest topology, which involve only one "sensor-controller" and "controller-actuator" channel, and perfect,

i.e., noiseless and undelayed, communication were mainly considered. However, many modern control systems are implemented in a distributed fashion, which results in a less trivial topology with multiple sensors, controllers, and actuators communicating over a serial network. Various time delays in transmission are characteristic for such networks, and nonconstant access to the channel is typical [13].

In this paper, we also study a stabilization problem via quantized state feedback for a linear time-invariant partially observed system. However, we consider a multichannel communication between the multiple sensors and the controller, where each sensor is served by its own finite capacity channel and there is no information exchange between the sensors. There is also no feedback communication between the sensors and the controller, and the sensors have no access to the control. The objective is to establish first, the tightest lower bounds on the capacities of the channels for which the stabilization is possible and second, the rate of exponential stability that is achievable for given capacities obeying those bounds. To this end, we obtain necessary and sufficient conditions for stabilizability. In the particular case where the channels are perfect and the system is detectable via each sensor, these conditions formally come to those from [19, 20]. Thus we show that in this case, multiple noncommunicating sensors and channels with separate capacity constraints may be treated as a single sensor and a single channel with a united constraint, respectively. However, employing multiple sensors usually means that there are problems with detectability by means of a single sensor, and then the model with nondetecting sensors is often a good option.

Another crucial point is that we do not assume the channels to be perfect. Sensor signals may incur independent and time-varying delays and arrive at the controller out of order. There may be periods when the sensor is denied access to the channel. Transmitted data may be corrupted or even lost. However, we assume that the communication noise is compensated and so ultimately reveals itself only in the form of decay of the channel information capacity. For example, employing error correcting block codes [10, Chap. 12] means that the channel must be partly engaged in transmission of redundant check symbols, which decreases the average amount of carried primal messages from the sensors. We suppose that error correction is the function of the channel, i.e., the corresponding coder and decoder are given and considered as parts of what is termed "channel." The key assumption is that the time-average number of bits per sample period that can be successfully transmitted across the channel during a time interval converges to what we call the transmission capacity as the length of the interval becomes large. The stabilizability region is given in terms of these capacities. Note that bounded communication delays do not influence them and thus the region, though they affect the design of the stabilizing controller.

Stabilization with limited information feedback was studied in the presence of transmission delays in [27]. Unlike the current paper, the transmission time required to transfer one bit was assumed constant, the continuous time linear plant and the network with the simplest topology and constant access channels were considered, and conditions for nonasymptotic stability but a weaker property called containability were established.

Stabilization of multiple sensor systems via perfect (instantaneous and noiseless) channels was discussed in [25] under the assumption that the control is known at the sensor sites. In fact, a particular recurrent (i.e., changed according to a fixed rule as time progresses) stabilization scheme was examined. It is based on scaled quantization by means of special quantizers. Ideas coherent with Slepian–Wolf encoding of data

from correlated sources were also employed. It was established when the system can be stabilized via such a scheme. The answer is given in terms of the controller parameters called the rate vectors. They are tuples of naturals each being the number of the quantizer levels with respect to a certain state coordinate. These conditions can be reformulated in terms of the capacities of the channels. Then the criterion for stabilizability via the above scheme reduces to solvability of some linear system of inequalities in integers. The arguments from [25] also presuppose that the system is reducible to the real-diagonal form so that any "mode" is in a simple relation with any sensor. The latter means that the mode either does not affect the sensor outputs or can be completely determined from these outputs.[1]

In this paper, we show that there exist stabilizible systems, which, however, cannot be stabilized by means of the aforementioned control scheme. Moreover, insufficient are all schemes that merely have some features in common with that one (see section 9).[2] This stresses that stabilizability should be tested in the class of all controllers with a given information pattern. Such an analysis is offered in this paper. This gives rise to an additional trouble in the form of a gap between necessary and sufficient conditions, where all and specific controllers proposed in this paper are concerned, respectively. To fill this gap, not only time averaging but also convex duality techniques are employed. Contrary to [25], the final criterion is given in terms of only the plant and channels parameters. This criterion strictly improves that from [25].

We consider the case where the system is not necessarily reducible to a diagonal form. It is shown that nontrivial Jordan blocks may make it impossible to disintegrate the system into state-independent subsystems each in simple relations with the sensors. To treat this case, we employ sequential stabilization based on triangular decomposition into state-dependant subsystems. They are stabilized successively. In doing so, their interinfluence is interpreted as an exogenous disturbance, and ideas related to those from [6, 22] as well as [2, 19, 20, 25] are employed. Points of novelty concern an account for transmission delays and disturbances decaying at a known rate. Unlike the previous works, no other characteristics of the disturbance (e.g., an upper bound) are assumed to be known. Apart from state-dependency, the subsystems are also dependant via control. Since it is common, the control aimed to stabilize a particular subsystem may disturb the others. We offer a method to cope with this problem. Note that this issue was not addressed in [25]. Finally, contrary to [25], we consider the case when the sensors have no access to the control: there is no feedback communication between them and the decoder.

The paper is organized as follows. We first illustrate the problem statement and the main result by an example in section 2. The general problem statement is given in section 3. Section 4 offers basic definitions, assumptions, and notations. The main result is presented in section 5. Its proof is given in sections 7 and 8, where necessary and sufficient conditions for stabilizability are, respectively, justified. In section 6, the main result is applied to the example from section 2. The concluding section 9 comments on an important assumption imposed in this paper.

2. Example. We first illustrate the class of problems to be studied by an example.

[1] The arguments from [25] do not really require the diagonal form. However, the assumption that the system can be decomposed into independent subsystems each in simple relations with sensors seems to be crucial.

[2] For example, stabilization results from a control scheme, which is not recurrent but is cyclic (i.e., periodically varies in time).

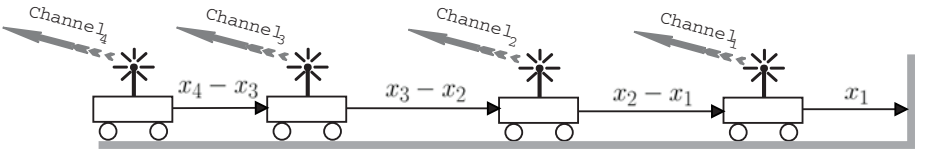

FIG. 2.1. *Platoon of autonomous vehicles.*

We consider a platoon composed of k vehicles moving along a line and enumerated from right to left. The dynamics of the platoon are uncoupled, and the vehicles are described by the equations

$$\dot{x}_i = v_i, \quad \dot{v}_i = u_i, \quad i = 1, \dots, k, \tag{2.1}$$

where x_i is the position of the ith vehicle, v_i is its velocity, and u_i is the control input. Each vehicle is equipped with a sensor giving the distance $y_i = x_i - x_{i-1}$ from it to the preceding one for $i \geq 2$ and the position $y_1 = x_1$ for $i = 1$. It is also endowed with a digital communication channel over which the measurement y_i is sent to the central controller. To this end, the sensor signals are sampled with a period $\Delta > 0$. This channel is delayed, nonstationary, and lossy and transmits on average $\mathfrak{c}_i > 0$ bits per sample period. Employing the data that arrives over all channels, the central controller produces the control inputs for all vehicles at the sample times. The objective is to stabilize the platoon motion about a given constant-velocity trajectory: $v_i = v_i^0, x_i(t) = x_i^0 + v_i^0 t \ \forall i$. This situation is illustrated in Figure 2.1 for $k = 4$. In this context, we pose the following questions:

1. *What is the minimum rate of the information transmission for which stabilization is possible?*
2. *Which rate of stability can be achieved for channels with given capacities* $\mathfrak{c}_j$ *and sample period* Δ*?*

More precisely, we are interested in the rate μ at which the platoon is able to approach the following desired trajectory:

$$|v_i(t) - v_i^0| \leq K_{v,i}\mu^{t/\Delta}, \qquad |x_i(t) - x_i^0 - v_i^0 t| \leq K_{x,i}\mu^{t/\Delta}.$$

As will be shown in section 6, stabilization of the platoon is possible for any capacities $\mathfrak{c}_i > 0$ and at any rate $\mu > \mu^0 := \sqrt{2}^{\,-\mathfrak{c}_{\min}}$, where $\mathfrak{c}_{\min} := \min_{i=1,\dots,k} \mathfrak{c}_i$. At the same time, no rate $\mu < \mu^0$ is achievable.

Now consider another situation where the sensor system accommodated by each vehicle is able to give the distances to $l < k$ vehicles to the right, as well as to l vehicles to the left. Then the platoon motion remains stabilizable for any capacities

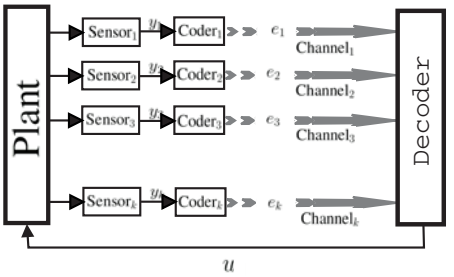

FIG. 3.1. *Feedback control by means of communication channels.*

$\mathfrak{c}_i$. However, the above threshold stability rate μ^0 is changed: $\mu^0 = \sqrt{2}^{\,-\mathfrak{c}_{k,l}}$. Here

$$\mathfrak{c}_{k,l} := \min\left\{\mathfrak{c}_{k,l}^{(1)}, \mathfrak{c}_{k,l}^{(2)}, \mathfrak{c}_{k,l}^{(3)}\right\} \quad \text{if} \quad 2l \geq k, \quad \text{and} \quad \mathfrak{c}_{k,l} := \min\left\{\mathfrak{c}_{k,l}^{(4)}, \mathfrak{c}_{k,l}^{(5)}, \mathfrak{c}_{k,l}^{(6)}\right\} \quad \text{if} \quad 2l < k, \quad \text{where} \tag{2.2}$$

$$\mathfrak{c}_{k,l}^{(1)} := \min_{i=1,\dots,k-l} \frac{1}{i}\sum_{j=1}^{i} \mathfrak{c}_j, \quad \mathfrak{c}_{k,l}^{(2)} := \frac{1}{k}\sum_{j=1}^{k} \mathfrak{c}_j, \quad \mathfrak{c}_{k,l}^{(3)} := \min_{i=l+1,\dots,k-1} \frac{1}{k-i}\sum_{j=i+1}^{k} \mathfrak{c}_j,$$

$$\mathfrak{c}_{k,l}^{(4)} := \min_{i=1,\dots,l+1} \frac{1}{i}\sum_{j=1}^{i} \mathfrak{c}_j, \quad \mathfrak{c}_{k,l}^{(5)} := \min_{i=l+2,\dots,k-l} \mathfrak{c}_i, \quad \mathfrak{c}_{k,l}^{(6)} := \min_{i=k-l,\dots,k-1} \frac{1}{k-i}\sum_{j=i+1}^{k} \mathfrak{c}_j.$$

The objective of this paper is to develop a general theory that enables one to obtain results like these.

3. General problem statement. We consider linear discrete-time multiple sensor systems of the form

$$\boldsymbol{x}(t+1) = A\boldsymbol{x}(t) + B\boldsymbol{u}(t); \qquad \boldsymbol{x}(0) = \boldsymbol{x}_0; \tag{3.1}$$

$$\boldsymbol{y}_j(t) = C_j\boldsymbol{x}(t), \qquad j = 1, \dots, k. \tag{3.2}$$

Here $\boldsymbol{x} \in \mathbb{R}^n$ is the state, $\boldsymbol{u} \in \mathbb{R}^{n_u}$ is the control, and $\boldsymbol{y}_j \in \mathbb{R}^{n_{y,j}}$ is the output of the jth sensor. The system is unstable: there is an eigenvalue λ of the matrix A with $|\lambda| \geq 1$. The objective is to stabilize the plant: $\boldsymbol{x}(t) \xrightarrow{t\to\infty} 0$.

We consider a remote control setup. Each sensor is served by its own communication channel capable of transmitting signals from a finite *alphabet* $\mathfrak{E}_j$. Over this channel, the jth *coder* sends a message $e_j(t) \in \mathfrak{E}_j$ based on the prior measurements

$$e_j(t) = \mathcal{E}_j[t, \boldsymbol{y}_j(0), \dots, \boldsymbol{y}_j(t)]. \tag{3.3}$$

On the basis of the data $\overline{\boldsymbol{e}}(t)$ received over all channels up to the current time t, the *decoder* selects the control

$$\boldsymbol{u}(t) = \mathcal{U}\left[t, \overline{\boldsymbol{e}}(t)\right]. \tag{3.4}$$

In the situation illustrated in Figure 3.1, the *networked controller* is constituted by the decoder and the set of coders

$$\mathcal{NC} := \left[\mathcal{E}_1(\cdot), \dots, \mathcal{E}_k(\cdot), \mathcal{U}(\cdot)\right]. \tag{3.5}$$

Transmitted messages incur delays and may be lost: the message sent at time t arrives at the decoder at the discrete time $t+\tau_j(t) \geq t$, where $\tau_j(t) := \infty$ if it is lost. So the data available to the decoder at time t is

$$\overline{\boldsymbol{e}}(t) := \big[\overline{\boldsymbol{e}}_1(t), \dots, \overline{\boldsymbol{e}}_k(t)\big], \quad \text{where} \quad \overline{\boldsymbol{e}}_j(t) := \big[e_j(\theta_1), \dots, e_j(\theta_{\sigma_j})\big] \tag{3.6}$$

is the data that arrived via the jth channel by the time t: $\{\theta_1 < \theta_2 < \dots < \theta_{\sigma_j}\} = \{\theta = 0, 1, \dots : \theta + \tau_j(\theta) \leq t\}$.

The main question to be considered is what is the minimum rate of the information exchange in the system for which stabilization is possible? In other words, we look for necessary and sufficient conditions for stabilizability expressed in terms of the channels *transmission capacities* $\mathfrak{c}_1, \dots, \mathfrak{c}_k$, along with the plant-sensors parameters A, B, C_j. Roughly speaking, such a capacity is the average number of bits transmitted over the channel during the sample period, despite the losses and delays.

4. Definitions, notations, and assumptions. It should be remarked that there may be a difference between the number of bits that happen to reach the decoder thanks to occasional favorable circumstances and the number of bits that can be successfully transmitted under any circumstances. In fact, these numbers give rise to two concepts of capacity. The first and second of these are concerned with the necessary and sufficient conditions for stabilizability, respectively. To simplify matters, we postulate that these capacities coincide: the discrepancy between those numbers is considerably less than the time of a long experiment.

We also consider the case where there is an uncertainty about the channel. Specifically, its *regime of operation* given by the distribution of integer transmission delays $\tau_j(t)$ over time t may not be known in advance. However, we suppose that it satisfies certain assumptions, and the designer of the controller is aware of some lower and upper bounds for the number of bits transmitted across the channel during a time interval of a given duration.

To understand the details, we start with the following.

DEFINITION 4.1. *We say that a message is* transmitted within a time interval $[t_0 : t_1]$ *if it departs and arrives at times* t *and* $t+\tau_j(t)$ *from this interval:* $t, t+\tau_j(t) \in [t_0 : t_1]$.

The *length* or *duration* of a discrete time interval $[t_0 : t_1]$ is defined to be $t_1 - t_0$.

ASSUMPTION 4.1. *For each channel, there exist two integer functions* $b_j^-(r)$ *and* $b_j^+(r)$ *of time* r *such that*

1. *no more than* $b_j^+(r)$ *bits are brought by the transmissions that occur within any time interval of length* r*;*
2. *given a time interval of duration* r*, there exists a way to transmit without losses and errors no less than* $b_j^-(r)$ *bits of information within this interval;*
3. *as the length* r *of the time interval increases, the averaged numbers* $b_j^+(r)/r$ *and* $b_j^-(r)/r$ *converge to a common limit* $\mathfrak{c}_j$ *called the* transmission capacity *of the channel*

$$\mathfrak{c}_j = \lim_{r\to\infty} \frac{b_j^-(r)}{r} = \lim_{r\to\infty} \frac{b_j^+(r)}{r}. \tag{4.1}$$

Claim 1 means that $p_j(t_0, t_1) \cdot \log_2 N_j \leq b_j^+(t_1 - t_0)$. Here $p_j(t_0, t_1)$ and N_j denote the numbers of messages transmitted in fact during the time interval $[t_0 : t_1]$ and the size of the channel alphabet, respectively. Note that each message from this alphabet carries $\log_2 N_j$ bits. In claim 2, the "way" is constituted by encoding and

decoding rules. The former translates b-bit words $\boldsymbol{\beta} = (\beta_1, \dots, \beta_b), \beta_i = 0, 1$, into sequences of messages $e \in \mathfrak{E}_j$ sent consecutively during the interval at hand. The decoder transforms the sequence of messages that arrived within this interval into a b-bit word $\boldsymbol{\beta}'$. The overall transmission must be errorless: $\boldsymbol{\beta}' = \boldsymbol{\beta}$.

We suppose that the designer of the controller is aware of these rules, along with the functions $b_j^-(r), b_j^+(r)$. A regime of the channel operation $\{\tau_j(\cdot)\}$ compatible with these data is said to be *possible*.

Now we offer two examples of channels satisfying Assumption 4.1. Other such examples can be found in [18].

Noiseless instantaneous channel. The channel is constantly accessible; any transmission is successful and instantaneous $\tau_j(t) = 0$. Then $b_j^-(r) = \lfloor (r+1) \cdot \log_2 N_j \rfloor, b_j^+(r) = \lceil (r+1) \cdot \log_2 N_j \rceil$, and $\mathfrak{c}_j = \log_2 N_j$.

Noiseless delayed channel. Now suppose that in the previous example, the transmission time is nonzero, is not known in advance, but is bounded $0 \le \tau_j(t) \le \tau_j^+$ by a known constant. The messages do not overtake each other. Then $b_j^-(r) = \lfloor (r - \tau_j^+ + 1) \cdot \log_2 N_j \rfloor$ if $r \ge \tau_j^+$ and $b_j^-(r) = 0$, otherwise $b_j^+(r) = \lceil (r+1) \cdot \log_2 N_j \rceil$ and $\mathfrak{c}_j = \log_2 N_j$.

Now we introduce two concepts of stabilizability: weak and strong ones.

DEFINITION 4.2. *The system is said to be* stabilizable *if some networked controller makes all trajectories converging to zero* $\boldsymbol{x}(t) \xrightarrow{t \to \infty} 0$ *for at least one possible regime of channels operation.*

DEFINITION 4.3. *We say that a networked controller* uniformly exponentially stabilizes *the system* at the rate $\mu \in (0, 1)$ *if the corresponding trajectories obey the inequalities*

$$|\boldsymbol{x}(t)| \le K_x \mu^t, \quad |\boldsymbol{u}(t)| \le K_u \mu^t \qquad \forall t = 0, 1, 2, \dots \tag{4.2}$$

whenever $|\boldsymbol{x}_0| \le K_0$. *This must be true irrespective of the regime of channels operation, provided it is possible. The constants* K_x *and* K_u *may depend on* K_0 *but must not depend on time* t *and this regime.*

DEFINITION 4.4. *The system is said to be* uniformly exponentially stabilizable at the rate $\mu \in (0, 1)$ *if there exists a networked controller that uniformly exponentially stabilizes the system at this rate.*

Note that this controller may depend on μ, along with $b_j^+(\cdot), b_j^-(\cdot)$ and A, B, C_j.

DEFINITION 4.5. *The system uniformly exponentially stabilizable at some rate* $\mu \in (0, 1)$ *is said to be* uniformly exponentially stabilizable. *The infimum value of* μ *is called the* rate of exponential stabilizability.

4.1. General notations. $\mathbf{mes}$—the Lebesgue measure; B_x^d—the open ball centered at x with the radius d; $\det \mathcal{A}$—the determinant of the operator $\mathcal{A}$ in a finite dimensional linear space; $\sigma(\mathcal{A})$—the spectrum of $\mathcal{A}$; $\sigma^+(\mathcal{A}) := \{\lambda \in \sigma(\mathcal{A}) : |\lambda| \ge 1\}$; $\sigma^-(\mathcal{A}) := \sigma(\mathcal{A}) \setminus \sigma^+(\mathcal{A})$; $M_\sigma = M_\sigma(\mathcal{A})$—the invariant subspace of $\mathcal{A}$ related to the spectrum set $\sigma \subset \sigma(\mathcal{A})$; $M_{st}(\mathcal{A}) := M_{\sigma^-(\mathcal{A})}$; $M_{unst}(\mathcal{A}) := M_{\sigma^+(\mathcal{A})}$; $\mathcal{A}|_L$—the operator $\mathcal{A}$ acting in its invariant subspace L; $\lceil z \rceil := \min\{i = 0, \pm 1, \pm 2, \dots : i \ge z\}, \lfloor z \rfloor := \max\{i = 0, \pm 1, \pm 2, \dots : i \le z\}$.

4.2. Assumptions about the system (3.1), (3.2).

ASSUMPTION 4.2. *The pair* (A, B) *is stabilizable.*

The next assumption concerns the subspaces that are not observed and detected,

respectively, by a given sensor:

(4.3)
$$L_j^{-obs} := \{\boldsymbol{x} \in \mathbb{R}^n : C_j A^\nu \boldsymbol{x} = 0 \quad \forall \nu = 0, \dots, n-1\}, \qquad L_j^- := M_{unst}(A) \cap L_j^{-obs}.$$

To state this assumption, we introduce the following.

DEFINITION 4.6. *A spectral set $\sigma \subset \sigma(A)$ is said to be* elementary *if it consists of either one real eigenvalue or a couple of conjugate complex ones.*

ASSUMPTION 4.3. *Let $\sigma \subset \sigma^+(A)$ be any elementary set that gives rise to more than one real Jordan block. Consider the subspace $L_j^- \cap M_\sigma$ of states $\boldsymbol{x} \in M_\sigma$ ignored by the jth sensor. Then the variety of all these subspaces $j = 1, \dots, k$ has the atomic structure: the space M_σ can be decomposed into a direct sum of "atom" subspaces M_σ^i, $i = 1, \dots, m_\sigma$, so that any $L_j^- \cap M_\sigma$ is the sum of several "atoms" (the sum over the empty set is $\{0\}$):*

$$L_j^-(\sigma) := L_j^- \cap M_\sigma = \oplus_{i \in I(j)} M_\sigma^i, \qquad \text{where} \quad I(j) \subset [1 : m_\sigma]. \tag{4.4}$$

If the set σ gives rise to only one real Jordan block, this assumption is necessarily true (see Lemma 8.2).

Assumption 4.3 is technical, imposed to meet the paper length limitation, and will be commented on in section 9. A typical example of the situation forbidden by this assumption is as follows:

$$\boldsymbol{x}(t+1) = \lambda \boldsymbol{x}(t) + \boldsymbol{u}(t) \in \mathbb{R}^2, \quad y_1(t) = x_1(t), \quad y_2(t) = x_2(t), \quad y_3(t) = x_1(t) - x_2(t), \quad \lambda > 1, \tag{4.5}$$

where $\boldsymbol{x} = (x_1, x_2)$. Indeed, here the invariant subspaces nondetectable by the sensors are $L_1^- = \{\boldsymbol{x} : x_1 = 0\}, L_2^- = \{\boldsymbol{x} : x_2 = 0\}$, and $L_3^- = \{\boldsymbol{x} : x_1 = x_2\}$. It is easy to see that $\mathbb{R}^2$ cannot be decomposed into a direct sum of "atom" subspaces M^i so that its special partial sums give each space L_i^-, as is required by Assumption 4.3. Anyhow, this assumption holds if any eigenvalue $\lambda : |\lambda| \geq 1$ gives rise to only one real Jordan block, or each of the sensors detects or ignores any of the above subspaces M_σ completely: either $M_\sigma \cap L_j^- = \{0\}$ or $M_\sigma \subset L_j^-$.

5. The main result. For any group of sensors $J \subset [1 : k]$, we introduce the space of states

$$L(J) := \bigcap_{j \in J} L_j^- \tag{5.1}$$

nondetectable by this group. (We recall that L_j^- is given by (4.3).) For consistency, we assign $M_{unst}(A)$ to the empty group. Gathering $L = L(J)$ except for $L = \{0\}$ over all groups of sensors J gives rise to a set $\mathfrak{L} = \{L\}$. Its size may be less than the number of all such groups since different groups may produce a common space $L(J)$.

Now we are in a position to state the main result of the paper.

THEOREM 5.1. *Suppose that Assumptions* 4.1–4.3 *hold. Then the following two statements are equivalent:*

1. *The system* (3.1), (3.2) *is uniformly exponentially stabilizable (see Definition* 4.5*);*

2. *For every subspace* (5.1) $L \in \mathfrak{L}$ *constituted by all states nondetectable by a certain group of sensors,*

(5.2)
$$\log_2 |\det A|_L| < \sum_{j \notin J(L)} \mathfrak{c}_j, \ \textit{where} \quad J(L) := \{j = 1, \dots, k : C_j x = 0 \quad \forall x \in L\}.$$

Here the sum is over the sensors that do not completely ignore the subspace L *at hand, and* $\mathfrak{c}_j$ *is the transmission capacity* (4.1) *of the* j*th channel.*

If the equivalent claims 1 *and* 2 *are true, the rate* μ^0 *of exponential stabilizability of the system is given by*

$$\log_2 \mu^0 = \max_{L \in \mathfrak{L}} \frac{1}{\mathbf{dim} L} \left(\log_2 |\det A|_L| - \sum_{j \notin J(L)} \mathfrak{c}_j \right). \tag{5.3}$$

A stabilizing networked controller will be constructed in section 8. We note that it uses only a finite and fixed number of recent observations $\boldsymbol{y}_j$ and messages e_j in (3.3) and (3.4), respectively.

As was shown in [20], the quantity $\log_2 |\det A|_L|$ from (5.2) represents the unit time increment of the number of bits required to describe to a particular accuracy the state of the open-loop system (3.1) considered on the invariant subspace L. More precisely, if the initial state $\boldsymbol{x}_0$ is randomly distributed over the subspace L in accordance with a certain probability density and $\boldsymbol{u}(t) \equiv 0$, the differential entropy $H[\boldsymbol{x}(t)]$ (see, e.g., [5] for the definition) of the state $\boldsymbol{x}(t)$ evolves as follows: $H[\boldsymbol{x}(t+1)] = H[\boldsymbol{x}(t)] + \log_2 |\det A|_L|$. At the same time, the right-hand side of (5.2) can be interpreted as the joint capacity of all channels except for those carrying no information about the state $\boldsymbol{x} \in L$. (The latter serve the sensors that completely ignore such states $C_j \boldsymbol{x} = 0 \ \forall \boldsymbol{x} \in L$.) Thus the condition (5.2) means that the amount of information concerning the state $\boldsymbol{x} \in L$ that the decoder may receive over all channels for the unit time exceeds the unit time growth of the number of bits required to describe the state to a particular accuracy. It must be noted here that some of the bits counted on the right-hand side in (5.2) characterize the state $\boldsymbol{x} \in L$ only partly. They correspond to any sensor whose outputs are not sufficient to reconstruct the entire state $\boldsymbol{x} \in L$. Moreover all the sensors may be of such a kind. Nevertheless, when inequalities (5.2) are taken for all subspaces L (or in other words, groups of sensors), they constitute a sufficient and necessary criterion for stabilizability.

Remark 5.1. The conditions (5.2) imply that the system is detectable via the entire set of the sensors.

Indeed, otherwise (5.2) fails to be true for $L := \bigcap_{j=1}^{k} L_j^- \neq \{0\}$ since the sum over the empty set is defined to be 0.

Remark 5.2. If the system is detectable by each sensor $L_j^- = \{0\} \ \forall j$, the set $\mathfrak{L}$ contains only one space $M_{unst} := M_{unst}(A)$ and so the condition 2 reduces to only one inequality,

$$\log_2 |A|_{M_{unst}}| < \mathfrak{c} := \sum_{j=1}^{k} \mathfrak{c}_j.$$

The sum $\mathfrak{c}$ can be interpreted as the capacity of the channel composed of all the channels at hand. So the inequality is in a harmony with those from [11, 14, 19, 20, 25] concerning the case of one channel.

In general, the number of inequalities (5.2) does not exceed 2^k (the total number of all groups of sensors). It also does not exceed the number N of "unstable" invariant subspaces. (If any eigenvalue $\lambda : |\lambda| \geq 1$ gives rise to only one Jordan block, then $N \leq 2^n - 1$.) Generally speaking, relations (5.2) are not independent. However, revealing "superfluous" inequalities is usually a much harder task than direct verification of the entire inequality set (5.2).

Remark 5.3. Whenever the system is stabilizable in the sense of Definition 4.2, the set of nonstrict inequalities (5.2) holds. Moreover, if the second limit in (4.1) is approached quickly enough, e.g.,

$$\left| \frac{b_j^+(r)}{r} - \mathfrak{c}_j \right| \leq \frac{\text{const}}{r},$$

the strict inequalities (5.2) are necessary for the weak stabilizability introduced by Definition 4.2. Then Theorem 5.1 ensures that this stabilizability implies the strong one described by Definitions 4.4 and 4.5.

The necessity of inequalities (5.2) can be complemented by the following fact. Whenever one of the inequalities strictly violates (i.e., $>$ occurs instead of $<$ in (5.2)), the state $\boldsymbol{x}(t)$ exponentially diverges from zero for almost all (with respect to the Lebesgue measure) initial states $\boldsymbol{x}_0 \in \mathbb{R}^n$, irrespective of which networked controller is employed.

We do not prove these remarks since they are not utilized further.

Remark 5.4. The implication $1 \Rightarrow 2$ remains true even if Assumption 4.3 is dropped.

This easily follows from the proof of this implication presented in section 7.

The proof of Theorem 5.1 is given in sections 7 and 8. In section 7, we prove its necessity part $1 \Rightarrow 2$. The converse $1 \Leftarrow 2$ is established in section 8, where formula (5.3) is also justified.

6. Application of Theorem 5.1 to the example from section 2. In this section, we justify the statements from section 2. We recall that they concern a platoon of k vehicles described by (2.1). Each of them is equipped with a sensor giving the distance $y_i = x_i - x_{i-1}$ from it to the preceding vehicle for $i \geq 2$ and the position $y_1 = x_1$ for $i = 1$. It is also served by a communication channel with the transmission capacity $\mathfrak{c}_i > 0$ carrying signals to the controller with the sample period $\Delta > 0$. The objective is to stabilize the platoon motion about a given constant-velocity trajectory: $v_i = v_i^0, x_i(t) = x_i^0 + v_i^0 t \ \forall i$.

The substitution of the variables $v_i := v_i - v_i^0, x_i := x_i - x_i^0 - v_i^0 t$ keeps the dynamics equations unchanged and shapes the control goal into $x_i = 0, v_i = 0$. To put the problem into the framework adopted in this paper, we consider the trajectory only at sampling times: $x_i(\tau) := x_i(\tau\Delta), v_i(\tau) := v_i(\tau\Delta), u_i(\tau) := u_i(\tau\Delta + 0)$. Then

$$(6.1)\quad x_i(\tau+1) = x_i(\tau) + \Delta \cdot v_i(\tau) + \frac{\Delta^2}{2} u_i(\tau), \quad v_i(\tau+1) = v_i(\tau) + \Delta \cdot u_i(\tau),$$
$$y_i(\tau) = x_i(\tau) - x_{i-1}(\tau),$$

where $x_0 := 0$. Now $A = \mathbf{diag}(A_1, \dots, A_k)$, $A_i = \mathcal{A} = \left(\begin{smallmatrix} 1 & \Delta \\ 0 & 1 \end{smallmatrix}\right)$. So the system has only one eigenvalue 1, which gives rise to k Jordan blocks. The nonobservable and nondetectable subspaces (4.3) are identical and equal,

$$L_j^- = \{\mathfrak{x} := (z_1, w_1, \dots, z_k, w_k) : z_j = 0, w_j = 0\}, \text{ where } z_i := x_i - x_{i-1}, w_i := v_i - v_{i-1}$$

for $i \geq 2$ and $z_1 := x_1, w_1 := v_1$. Assumption 4.3 holds with $M^i_\sigma := \{\mathfrak{x} : z_j = 0, w_j = 0\ \forall j \neq i\}, i = 1, \dots, k$; Assumption 4.2 is immediate from (6.1). Since $|\det A|_L| = 1$ for any invariant subspace L, Theorem 5.1 guarantees that *the platoon is uniformly exponentially stabilizable under arbitrary transmission capacities* $\mathfrak{c}_i > 0$.

To determine the rate of stabilizability μ^0, note that the states nondetectable by (maybe, empty) group $\mathcal{J} \subset [1:k]$ of sensors constitute the subspace $L(\mathcal{J}) := \{\mathfrak{x} : z_j = 0, w_j = 0\ \forall j \in \mathcal{J}\}$. Since $\mathbf{dim} L(\mathcal{J}) = 2(k - |\mathcal{J}|)$, where $|\mathcal{J}|$ is the size of $\mathcal{J}$, relation (5.3) shapes into

$$\log_2 \mu^0 = \max_{\mathcal{J}} \frac{1}{2(k-|\mathcal{J}|)} \left(-\sum_{j \notin \mathcal{J}} \mathfrak{c}_j \right) = -\frac{1}{2} \mathfrak{c}_{\min}, \quad \text{where} \quad \mathfrak{c}_{\min} := \min_{j=1,\dots,k} \mathfrak{c}_j. \tag{6.2}$$

Thus *the rate of the platoon exponential stabilizability equals* $\sqrt{2}^{\,-\mathfrak{c}_{\min}}$ *per sample period*.

Now consider the situation where the sensor system accommodated by each vehicle gives the distances to $l < k$ vehicles to the right, as well as to l vehicles to the left. (We suppose that there is an imaginary vehicle numbered by 0 and staying at the origin.) Then

$$L^-_j = \Big\{ \mathfrak{x} : z_i = 0, w_i = 0 \quad \forall i = \max\{j - l + 1, 1\}, \dots, \min\{j + l, k\} \Big\}.$$

Assumption 4.3 remains true with the same subspaces M^i_σ, and the platoon evidently remains uniformly exponentially stabilizable. What can be said about the rate of stabilizability? Now the collection $\mathfrak{L}$ consists of spaces $L(\mathcal{J})$ related to sets $\mathcal{J}$ which along with any element $j \in \mathcal{J}$, contain a certain interval of the form $[i - l + 1 : i + l] \cap [1:k] \ni j, i = 1, \dots, k$. Furthermore, such sets are said to be *wide*. To proceed, we consider separately two cases.

1. Let $2l \geq k$. Then any two such intervals contain a common point. It follows that apart from $\mathcal{J} = \emptyset$, the wide sets $\mathcal{J}$ are intervals of the form $[1:i], i \geq l+1$, or $[i:k], i \leq k-l+1$. By retracing (6.2), we see that $\mu^0 = \sqrt{2}^{\,-\mathfrak{c}_{k,l}}$, where $\mathfrak{c}_{k,l}$ is given by (2.2).

2. Now let $2l < k$. Then the sets

$$[1:i-1] \cup [i+1:k], i = l+2, \dots, k-l, \quad [i:k], i = 2, \dots, l+2, \quad [1:i], i = k-l, \dots, k-1,$$

are wide. By restricting the maximum in (6.2) to only these sets $\mathcal{J}$, we see that $\mu^0 \geq \sqrt{2}^{\,-\mathfrak{c}_{k,l}}$, where $\mathfrak{c}_{k,l}$ is given by (2.2). In fact, $\mu^0 = \sqrt{2}^{\,-\mathfrak{c}_{k,l}}$. To prove this, it suffices to show that

$$\frac{1}{k - |\mathcal{J}|} \sum_{j \notin \mathcal{J}} \mathfrak{c}_j \geq \mathfrak{c}_{k,l} \tag{6.3}$$

for any wide set $\mathcal{J}$. To this end, we put $i_- := \min\{j : j \in \mathcal{J}\}$ and $i_+ := \max\{j : j \in \mathcal{J}\}$. Then $i_- \leq l+1 \Rightarrow [i_- : l+1] \subset \mathcal{J}$ and $i_+ \geq k-l+1 \Rightarrow [k-l+1 : i_+] \subset \mathcal{J}$ by the definition of the wide set. Hence $\{j : j \notin \mathcal{J}\} = \mathcal{J}_1 \cup \dots \cup \mathcal{J}_s$, where the sets $\mathcal{J}_\nu$ are pairwise disjoint and any of them either contains only one index, $\mathcal{J}_\nu = \{i\}, i = l+2, \dots, k-l$, or $\mathcal{J}_\nu = [1:i], i = 1, \dots, l+1$, or $\mathcal{J}_\nu = [i:k], i = k-l+1, \dots, k$. By (2.2), $1/|\mathcal{J}_\nu| \sum_{j \in \mathcal{J}_\nu} \mathfrak{c}_j \geq \mathfrak{c}_{k,l}$. This implies (6.3) as follows:

$$\frac{1}{k - |\mathcal{J}|} \sum_{j \notin \mathcal{J}} \mathfrak{c}_j = \frac{1}{k - |\mathcal{J}|} \sum_{\nu=1}^{s} |\mathcal{J}_\nu| \frac{1}{|\mathcal{J}_\nu|} \sum_{j \in \mathcal{J}_\nu} \mathfrak{c}_j \geq \mathfrak{c}_{k,l}.$$

7. Inequalities (5.2) as necessary conditions for stabilizability. The current and next sections contain the proof of Theorem 5.1. For technical reasons which will become clear soon, we extend the class of systems

$$\boldsymbol{x}(t+1) = A\boldsymbol{x}(t) + \mathcal{B}[t, \boldsymbol{u}(0), \dots, \boldsymbol{u}(t)], \tag{7.1}$$

where $\mathcal{B}(\cdot)$ is a given function. We also generalize on them a fact well known for the systems (3.1) (see [11, 20, 25]).

LEMMA 7.1. *Suppose that there is only one channel $k = 1$. Then $\log_2 |\det A| < \mathfrak{c} := \mathfrak{c}_1$ whenever the system (7.1) is uniformly exponentially stabilizable.*

Proof. Let some networked controller uniformly exponentially stabilize the system. Then

$$|\boldsymbol{x}(t)| \le K\mu^t \quad \forall t = 01, 2, \dots \quad \text{whenever} \quad |\boldsymbol{x}_0| < 1, \quad \text{where} \quad \mu \in (0, 1). \tag{7.2}$$

Thanks to 1 of Assumption 4.1, no more than $b_1^+(t)$ bits arrive at the decoder by time t. So in the formula

$$\boldsymbol{x}(t) = A^t\boldsymbol{x}_0 - \boldsymbol{\omega}(t), \quad \boldsymbol{\omega}(t) := -\sum_{\nu=0}^{t-1} A^{t-1-\nu}\mathcal{B}\big[\nu, \boldsymbol{u}(0), \dots, \boldsymbol{u}(\nu)\big] \tag{7.3}$$

$\overset{(3.4),(3.6)}{=\!=} \mathcal{V}[t, \overline{\boldsymbol{e}}(t)]$, the tuple $\overline{\boldsymbol{e}}(t)$ and the vector $\boldsymbol{\omega}(t)$ take values from some sets each containing no more than $2^{b_1^+(t)}$ elements and not depending on the initial state $\boldsymbol{x}_0$. So (7.2) means that the image $A^tB_0^1$ of the unit ball can be covered by the union of no more than $2^{b_1^+(t)}$ balls of the form $B^{K\mu^t}_{\boldsymbol{\omega}(t)}$. Hence

$$|\det A|^t \,\mathbf{mes}\, B_0^1 = \mathbf{mes}\,\big[A^tB_0^1\big] \le 2^{b_1^+(t)}\,\mathbf{mes}\, B_0^{K\mu^t} = 2^{b_1^+(t)}\mu^{nt}K^n\,\mathbf{mes}\, B_0^1$$
$$\Downarrow$$
$$\log_2|\det A| \le \frac{b_1^+(t)}{t} + n\log_2\mu + \frac{n\log_2 K}{t}.$$

Letting $t \to \infty$ and taking into account 3 of Assumption 4.1 and the inequality $\mu < 1$ completes the proof. □

Lemma 7.1 evidently remains true if the regime of channel operation (given by $\tau_1(\cdot)$) is known in advance.

To prove (5.2), we revert to the system (3.1) and pick a subspace $L \in \mathfrak{L}$ constituted by the states not detectable by a certain group of sensors. Then we restrict ourselves to trajectories $\{\boldsymbol{x}(t)\}$ starting at $\boldsymbol{x}_0 \in L$ and apply Lemma 7.1 to them. More precisely, we take into account that $\{\boldsymbol{x}(t)\}$ may leave L due to controls, and consider $\boldsymbol{x}_L(t) := \pi\boldsymbol{x}(t)$. Here π is an arbitrarily chosen projector from $\mathbb{R}^n$ onto L. By applying formula (7.3) to the system (3.1), it is easy to check that the evolution of $\boldsymbol{x}_L$ is governed by the equations of the form (7.1),

$$\boldsymbol{x}_L(t+1) = A|_L\boldsymbol{x}_L(t) + \pi B\boldsymbol{u}(t) + \sum_{i=0}^{t-1}(\pi A - A\pi)A^{t-1-i}B\boldsymbol{u}(i),\ \boldsymbol{x}_L(t) \in L,\ \boldsymbol{x}_L(0) = \boldsymbol{x}_0. \tag{7.4}$$

(The first equation simplifies if $\pi A = A\pi$. However, such a projector π exists if and only if there exists an A-invariant subspace that is complementary to L, which is not

true in general.) We interpret (7.4) as equations of an auxiliary system and equip it with the sensor

$$\boldsymbol{y}_L(t) = C_{J^c}\boldsymbol{x}_L(t). \tag{7.5}$$

Here $J^c := \{j : j \notin J\}$ is the complement to the set $J = \{j : C_j\boldsymbol{x} = 0\ \forall \boldsymbol{x} \in L\}$ of sensors ignoring the subspace L. Furthermore, for $I \subset [1:k]$, the symbol C_I denotes the block matrix that results from arranging the blocks C_j with $j \in I$ into a column. (For any entities v_j enumerated by $j \in [1:k]$, the symbol v_I is defined likewise.) We also suppose that all channels with $j \notin J$ are commissioned to transmit $\boldsymbol{y}_L$.

The sum on the right-hand side of (5.2) equals the capacity of the union of these channels. Hence (5.2) follows from Lemma 7.1 applied to the system (7.4), (7.5). To complete the proof, it suffices to show that this system is stabilizable whenever the original one (3.1), (3.2) can be stabilized. In doing so, one must cope with the fact that the trajectory of the original closed-loop system (3.1)–(3.4) may leave the subspace L. So the observations (3.2) and (7.5) may differ. Moreover, the sensors omitted in (7.5) may see the state $\boldsymbol{x}(t)$ for $t \geq 1$. It should be shown that they are yet useless and can be dropped.

LEMMA 7.2. *Let the system* (3.1), (3.2) *be exponentially stabilized by some networked controller, and the regime of channels operation be known in advance. Then the system* (7.4), (7.5) *is also exponentially stabilizable.*

Proof. We first show that for $\boldsymbol{x}_0 \in L$, the process in the original closed-loop system obeys the relations

$$\begin{aligned} e_J(t) = \mathcal{E}'_j\big[t, \overline{e}_{J^c}(t-1)\big], \quad \boldsymbol{y}_J(t) = \mathcal{Y}'\big[t, \overline{e}_{J^c}(t-1)\big], \\ \boldsymbol{y}_{J^c}(t) = \boldsymbol{y}_L(t) + \mathcal{Y}''\big[t, \overline{e}_{J^c}(t-1)\big]. \end{aligned} \tag{7.6}$$

We recall that the data $\overline{e}_j(t)$ that arrived via the jth channel by time t is given by (3.6). The observation $\boldsymbol{y}_L(t)$ is defined by (7.4) and (7.5) for the sequence of controls $\boldsymbol{u}(t)$ identical to that driving the original system.

For $t = 0$, we have $\boldsymbol{x}(0) \in L \Rightarrow \boldsymbol{y}_J(0) = 0$ and $\boldsymbol{y}_{J^c}(0) = \boldsymbol{y}_L(0)$, and (7.6) with $t = 0$ follows from (3.3). Now suppose that (7.6) with $t := \theta$ holds for all $\theta \leq t$. Then $\overline{e}_J(\theta) = \overline{\mathcal{E}}'\big[\theta, \overline{e}_{J^c}(t-1)\big]$ and so

$$\overline{e}(\theta) = \big[\overline{e}_J(\theta), \overline{e}_{J^c}(\theta)\big] = \overline{\mathcal{E}}\big[\theta, \overline{e}_{J^c}(t)\big] \overset{(3.4)}{\Longrightarrow} \boldsymbol{u}(\theta) = \mathcal{U}'\big[\theta, \overline{e}_{J^c}(t)\big], \qquad \theta \leq t. \tag{7.7}$$

Now we invoke (7.3) and note that $\boldsymbol{x}_0 \in L \Rightarrow A^{t+1}\boldsymbol{x}_0 \in L \Rightarrow C_J A^{t+1}\boldsymbol{x}_0 = 0and(I - \pi)A^{t+1}\boldsymbol{x}_0 = 0$:

$$\begin{aligned} \boldsymbol{y}_J(t+1) &= \underbrace{C_J A^{t+1}\boldsymbol{x}_0}_{=0} + \sum_{\theta=0}^{t} C_J A^{t-\theta} B\boldsymbol{u}(\theta) =: \mathcal{Y}'\big[t+1, \overline{e}_{J^c}(t)\big], \\ \boldsymbol{y}_{J^c}(t+1) - \boldsymbol{y}_L(t+1) &= C_{J^c}\big[\boldsymbol{x}(t+1) - \pi\boldsymbol{x}(t+1)\big] = \underbrace{C_{J^c}(I-\pi)A^{t+1}\boldsymbol{x}_0}_{=0} \\ &\quad + C_{J^c}\sum_{\theta=0}^{t}(I-\pi)A^{t-\theta}B\boldsymbol{u}(\theta) =: \mathcal{Y}''\big[t+1, \overline{e}_{J^c}(t)\big], \end{aligned}$$

i.e., the last two relations from (7.6) do hold with $t := t+1$. Then the first relation follows from (3.3).

It follows from (3.3) and (7.6) that the signal $e_{J^c}(t)$ is determined by the prior measurements from (7.5),

$$e_{J^c}(t) = \mathcal{E}_L[t, \boldsymbol{y}_L(0), \dots, \boldsymbol{y}_L(t)].$$

Now we interpret this as the equation of the coder, and the last relation from (7.7) (where $\theta := t$) as that of the decoder for the system (7.4), (7.5). By the foregoing, this coder-decoder pair generates the trajectory $\pi\boldsymbol{x}(t), \boldsymbol{u}(t), t = 0, 1, \dots$, where $\boldsymbol{x}(t), \boldsymbol{u}(t)$ is the trajectory of the original closed-loop system. So the inequalities (4.2) are inherited by the system (7.4), (7.5), which completes the proof. □

As was remarked, the part 1 ⇒ 2 of Theorem 5.1 is immediate from Lemmas 7.1 and 7.2.

8. Inequalities (5.2) as sufficient conditions for stabilizability. From now on, we suppose that 2 of Theorem 5.1 holds. We also assume, until otherwise stated, that *the system* (3.1) *has no stable modes*. In the general case, a stabilizing controller will be obtained by applying that presented below to the unstable part of the system.

To stabilize the system, we employ the scaled quantization scheme (see, e.g., [2, 12, 14, 19, 20, 22, 23, 25]). It was mainly developed for only one channel and is stated briefly as follows. Both coder and decoder compute a common upper bound δ of the current state norm $|\boldsymbol{x}| := \max_i |x_i|$. They are also given a partition of the unit ball into m balls (cubes) with small radii $\le \sigma(m)$. The number m matches the channel capacity so that the serial number of the cube can be communicated to the decoder. The coder determines the current state from the observations and notifies the decoder which cube contains this state divided by δ. Since the decoder knows δ, it thus becomes aware of a ball B with the radius $\le \delta\sigma(m)$ containing the current state. Then it selects a control that drives the system from the center of this ball to zero. The ball itself is expanded due to the unstable dynamics of the system and transformed into a set $D_+(B)$ centered about zero: $D_+(B) \subset B_0^\rho$. So the radius ρ can be taken as a new upper bound δ. Here $\rho \le \delta\sigma(m)\alpha$, where α characterizes the expansion rate of the system. If $\sigma(m)\alpha < 1$, the bound δ is thus improved $\delta := \delta\sigma(m)\alpha < \delta$ and by continuing likewise, driven to zero $\delta \to 0$, along with the state $\boldsymbol{x}$.

In the context of this paper, a problem with the above scheme is that no coder may be aware of the entire state $\boldsymbol{x}$. So a natural idea [25] is to disintegrate the system (3.1) into subsystems each observable by some sensor. Then each subsystem can be stabilized by following the above lines, provided the stability condition $\sigma(m)\alpha < 1$ holds for it. In fact, this condition means that there is a way to communicate a sufficiently large amount of information from the subsystem to the decoder: the smaller the radius $\sigma(m)$, the larger the size m of the partition, and so the larger the number of bits required to describe which of m cubes contains the state.

No channel in itself may meet the above stability condition. At the same time, this condition may be met if several channels are commissioned to transmit information about a given subsystem. Then each channel may carry only a part of this information, whereas the decoder assembles these parts and thus gets the entire message. Certainly, these channels must be chosen among those serving the sensors that observe the subsystem at hand.

Since a given sensor may observe several subsystems, the above scheme means that each channel must transmit a set of messages each concerning a particular subsystem. This gives rise to the question: is it possible to distribute the required information about any particular subsystem over parallel channels in such a way that the total amount of information carried via every channel meets its capacity? It will be shown

via convex duality arguments that the answer is in the affirmative whenever 2 of Theorem 5.1 holds.

Another problem is how to use a sensor observing the subsystem only partly. Certainly, this problem does not hold if there are no such sensors and subsystems: the state of each subsystem either is completely determined from or does not affect the outputs of any given sensor. Decomposition into a set of such subsystems is possible. However, in general, these subsystems are dependant. First, the control is common. Second, Jordan blocks may entail an unavoidable interinfluence between the states of subsystems. Now we illustrate this by an example.

Example. Consider the system whose dynamical matrix is a standard Jordan block,

(8.1)
$$\begin{array}{rcccccccc} x_1(t+1) & = & \lambda x_1(t) & + & 0 & + & b_1^* u(t) & & y_1(t)=x_1(t) \\ x_2(t+1) & = & \lambda x_2(t) & + & x_1(t) & + & b_2^* u(t) & & y_2(t)=x_2(t) \\ & & & & \vdots & & & , & \vdots \\ x_d(t+1) & = & \lambda x_d(t) & + & x_{d-1}(t) & + & b_d^* u(t) & & y_d(t)=x_d(t) \end{array} \quad , \qquad |\lambda|>1.$$

The unobservable subspaces of the sensors are, respectively,

$$L_1^- := \{\boldsymbol{x} : x_1 = 0\}, \quad L_2^- = \{\boldsymbol{x} : x_1 = x_2 = 0\}, \dots, L_{d-1}^- = \{\boldsymbol{x} : x_1 = \dots = x_{d-1} = 0\},$$
$$L_d^- = \{0\}.$$

There are no other invariant subspaces (see Lemma 8.2 below), so this system cannot be decomposed into subsystems with independent open-loop dynamics. At the same time, any sensor except for the last one observes the state $\boldsymbol{x}$ only partly. So to exclude such a partial vision, disintegration into state-dependant subsystems is unavoidable.

To deal with them, we employ sequential stabilization. We define the sth subsystem as that described in the sth row from (8.1). Its state is x_s. Then we stabilize the first subsystem, which is independent of the other ones. This makes x_1 exponentially decaying. In the equations of the second subsystem, we interpret x_1 as an exogenous disturbance. By constructing a device stabilizing this subsystem under any exponentially vanishing disturbances, we make x_2 exponentially decaying. The entire system is stabilized by continuing likewise.

These arguments, however, do not take into account that the control affects all subsystems and some of them may be unstabilizable (though the entire system is controllable). For example, the subsystems with $s \geq 2$ are unstabilizable if $b_1 = 1, b_2 = \dots b_d = 0$ in (8.1). These obstacles can be easily overcome via increasing the sample period.

Indeed, let us pick $r = 1, 2, \dots$. The state $\boldsymbol{x}_i := \boldsymbol{x}(ir)$ evolves as follows:

$$\boldsymbol{x}_{i+1} = A^r \boldsymbol{x}_i + \mathfrak{B}\boldsymbol{U}^{\,i}, \tag{8.2}$$

(8.3)
$$\text{where} \quad \boldsymbol{U}^{\,i} := \big[\boldsymbol{u}(ir), \boldsymbol{u}(ir+1), \dots, \boldsymbol{u}(ir+r-1)\big] \quad \text{and} \quad \mathfrak{B}\boldsymbol{U} := \sum_{j=0}^{r-1} A^{r-1-j} B \boldsymbol{u}_j$$

is the state to which the control program $\boldsymbol{U} = \big[\boldsymbol{u}_0, \dots, \boldsymbol{u}_{r-1}\big]$ drives the system at time $t = r$ from $\boldsymbol{x}(0) = 0$. Since the system (3.1) with no stable modes is controllable

by Assumption 4.2, the operator $\mathfrak{B}$ is onto if $r > n$. Related to the decomposition of the system $\boldsymbol{x} = (\boldsymbol{x}^1, \dots, \boldsymbol{x}^d)$ is a block partition $\mathfrak{B}\boldsymbol{U} = \left[\mathfrak{B}_1\boldsymbol{U}, \dots, \mathfrak{B}_d\boldsymbol{U}\right]$. Since all operators $\mathfrak{B}_s$ have full rank, any subsystem is controllable. Moreover, any control action $\boldsymbol{y} = \mathfrak{B}_s\boldsymbol{U}$ in the sth subsystem can be implemented by a control $\boldsymbol{U}$ that does not disturb the other subsystems, $\mathfrak{B}_j\boldsymbol{U} = 0\ \forall j \neq s$.

Summarizing, we adopt the following plan of proving the sufficiency part of Theorem 5.1.

1. We decompose the system so that, for any given sensor, the state of each subsystem either does not affect or is determined from the sensor outputs and second, the decomposition is triangular. The latter permits us to employ the sequential stabilization approach.
2. We increase the sample period and, for each subsystem, offer a class of networked controllers stabilizing it under any exponentially decaying disturbance. In doing so, we assume that the coder is aware of the current state at any sample time $t = ir$, and there is a way to transmit as much information as desired from the coder to the decoder. Then we find the controller for which the information traffic is minimal.
3. We show that if all subsystems are equipped with the above controllers, the entire system is stabilized.
4. We obtain conditions under which the entire set of these controllers can be implemented on the basis of real channels and sensors. These conditions are not constructive and require that a linear system of inequalities be solvable in integers.
5. By employing convex duality arguments, we show that these conditions are equivalent to (5.2).

8.1. Decomposition of the system. Now we perform step 1 of the plan of proving the sufficiency part of Theorem 5.1.

PROPOSITION 8.1. *Suppose that the system* (3.1) *has no stable modes. Then after a proper one-to-one linear transformation and partition of the state*

$$\boldsymbol{x} = (\boldsymbol{x}^1, \dots, \boldsymbol{x}^d) \tag{8.4}$$

into several blocks $\boldsymbol{x}^s \in \mathbb{R}^{n_s}$ *interpreted as the states of subsystems, the following statements hold:*

1. *The unobservable subspace* (4.3) $L_j^{-obs} = L_j^-$ *of any sensor is composed of several blocks,*

$$L_j^- = \{\boldsymbol{x} : \boldsymbol{x}^s = 0\ \forall s \in O_j\}, \qquad \text{where} \quad O_j \subset [1:d].$$

2. *The block representation of the dynamics equations* (3.1) *is lower triangular,*

$$\boldsymbol{x}^s(t+1) = \sum_{i=1}^{s} A_{si}\boldsymbol{x}^i(t) + B_s\boldsymbol{u}(t), \qquad s = 1, \dots, d. \tag{8.5}$$

By 1, the states $\boldsymbol{x}^s$ of subsystems $s \notin O_j$ do not affect the outputs of the jth sensor, whereas the states $\boldsymbol{x}^s$ with $s \in O_j$ are uniquely determined from these outputs.

To prove the proposition, we start with two technical facts.

LEMMA 8.2. *Assumption* 4.3 *holds for any elementary spectral set* σ.

Proof. It suffices to prove the lemma assuming that the set σ gives rise to only one real Jordan block. We put $M := M_\sigma, A_\sigma := A|_M$ and note that $\det[\lambda I - A_\sigma] = \varphi(\lambda)^p$, where the polynomial φ is irreducible over the field of real numbers. By employing the basis in M reducing A_σ to the real Jordan form, it is easy to see that the formula $\mathcal{L}(\nu) := \ker\left[\varphi(A_\sigma)\right]^\nu$ produces $(p+1)$ distinct $\{0\} = \mathcal{L}(0) \subset \mathcal{L}(1) \subset \cdots \subset \mathcal{L}(p) = M$ invariant subspaces and $\mathbf{dim}\mathcal{L}(\nu) = \nu \deg\varphi$. We are going to show that there are no other invariant subspaces.

Indeed let L be such a subspace and ψ be the minimal annihilating polynomial of L. Then ψ is a divisor of φ^p and so $\psi = \varphi^\nu, \nu = 0, \dots, p$. Hence $L \subset \ker\left[\varphi(A_\sigma)\right]^\nu = \mathcal{L}(\nu)$. At the same time, Theorem 2 of [9, p. 180] implies that $\mathbf{dim}L = \deg\psi$. Thus $\mathbf{dim}L = \nu, \deg\varphi = \mathbf{dim}\mathcal{L}(\nu)$, and so $L = \mathcal{L}(\nu)$.

As a result, we see that all invariant subspaces $L_j^- \cap M_\sigma$ are among $\mathcal{L}(0), \dots, \mathcal{L}(p)$. It remains to pick $M_\sigma^1 := \mathcal{L}(1), m_\sigma := p$, and for $i = 2, \dots, p$, choose M_σ^i so that $\mathcal{L}(i-1) \oplus M_\sigma^i = \mathcal{L}(i)$. □

The next lemma plays the key role in the proof of Proposition 8.1.

LEMMA 8.3. *In Assumption* 4.3*, the atoms $M_\sigma^i, i = 1, \dots, m_\sigma$, can be chosen so that all partial direct sums $M_\sigma^1 \oplus \cdots \oplus M_\sigma^i, i = 1, \dots, m_\sigma$, are A-invariant.*

Proof. We consider the set of atoms with the minimal size m_σ. We also introduce the undetectable subspaces $L_j := L_j^- \cap M_\sigma$ of M_σ, then form all their intersections $L^\cap = L_{j^1} \cap \cdots \cap L_{j^p}$, and then all algebraic sums (not necessarily direct) of such intersections $L^\Sigma = L_{i^1}^\cap + \cdots + L_{i^r}^\cap$. Here p, r and the subspaces $L_{j^\nu}, L_{i^\mu}^\cap$ are chosen arbitrarily. Let $\mathfrak{M}$ denote the set of all L^Σ. It is clear that (1) any space $L \in \mathfrak{M}$ is invariant and decomposed into a direct sum of several atoms, (2) $L \in \mathfrak{M} \Rightarrow L \cap L_j \in \mathfrak{M} \forall j$, (3) $M_\sigma \in \mathfrak{M}$, (4) $L', L'' \in \mathfrak{M} \Rightarrow L' + L'' \in \mathfrak{M}$, and (5) the set $\mathfrak{M}$ is finite. Now we pick a minimal element $L_{\min}$ among $L \in \mathfrak{M}, L \neq \{0\}$, i.e., such that $L \subset L_{\min}$ and $L \in \mathfrak{M}$ and $L \neq \{0\} \Rightarrow L = L_{\min}$. By trying here $L := L_{\min} \cap L_j$, we see that either $L_{\min} \subset L_j$ or $L_{\min} \cap L_j = \{0\}$. Hence any L_j contains either all atoms constituting $L_{\min}$ or none of them. So these atoms can be replaced by their sum in Assumption 4.3. Since the number of all atoms is minimal, the only concern is $L_{\min} = M_\sigma^\nu$. By permuting the atoms, we set $\nu = 1$. Then the claim of the lemma holds for $i = 1$ by (1).

Now let $L_{\min}$ denote a minimal element among $L \in \mathfrak{M}, L \supset M_\sigma^1, L \neq M_\sigma^1$. By (2) and (4), $L := M_\sigma^1 + L_j \cap L_{\min} \in \mathfrak{M}$. So the minimum property yields that either $L = M_\sigma^1$ or $L_{\min} \subset L$. In terms of the decomposition from (1) $L_{\min} = M_\sigma^1 \oplus M_{\min} \in \mathfrak{M}$ (where $M_{\min}$ is the sum of several atoms), this means that either $M_{\min} \cap L_j = \{0\}$ or $M_{\min} \subset L_j$. Like above, this implies that $M_{\min}$ consists of only one atom M_σ^ν. By permuting the atoms, we set $\nu = 2$ and make the claim of the lemma true for $i = 2$ by (1). The proof is completed by continuing likewise. □

Proof of Proposition 8.1. We decompose the spectrum $\sigma(A) = \sigma^1 \cup \cdots \cup \sigma^p$ into the union of disjoint elementary sets. Then $\mathbb{R}^n = M_{\sigma^1} \oplus \cdots \oplus M_{\sigma^p}$, and any invariant subspace L_j^- is decomposed $L_j^- = L_j^-(1) \oplus \cdots \oplus L_j^-(p)$ into invariant subspaces $L_j^-(\nu) := L_j^- \cap M_{\sigma^\nu}$. So it suffices to show that, for any ν, there exist linear coordinates in M_{σ^ν} and their block partition for which any subspace $L_j^-(\nu), j = 1, \dots, k$, is the direct sum of several "blocks" and the operator $A|_{M_{\sigma^\nu}}$ has a lower triangular form with respect to this partition. These blocks $\boldsymbol{z}^i$ are in fact given by Lemma 8.3: $\boldsymbol{z}^i \in M_{\sigma^\nu}^{m_{\sigma^\nu}-i+1}$. More precisely, it suffices to pick a basis in each subspace $M_{\sigma^\nu}^i, i = 1, \dots, m_{\sigma^\nu}$, unite them to produce a basis in M_{σ^ν}, and then consider the coordinates with respect to this basis and their partition that corresponds to the partition $\boldsymbol{z} = \boldsymbol{z}^1 + \cdots + \boldsymbol{z}^{m_{\sigma^\nu}}$ of $\boldsymbol{z}$ into $\boldsymbol{z}^i \in M_{\sigma^\nu}^{m_{\sigma^\nu}-i+1}$.

8.2. Separate stabilization of subsystems. In this subsection, we pick an integer parameter r and focus attention only on the states at times $\tau_i = i \cdot r$. The evolution of these states is given by (8.2), which evidently inherits the lower triangular structure from (8.5),

$$\boldsymbol{x}^s_{i+1} = \sum_{\nu=1}^{s} A^{(r)}_{s\nu} \boldsymbol{x}^\nu_i + \mathfrak{B}_s \boldsymbol{U}_i \tag{8.6}$$

for $s = 1, \dots, d$. Here $\boldsymbol{x}^s_i := \boldsymbol{x}^s(\tau_i), \boldsymbol{U}_i = \big[\boldsymbol{u}(\tau_i), \dots, \boldsymbol{u}(\tau_i + r - 1)\big]$, and the diagonal coefficients from (8.6) are the rth powers of matching coefficients from (8.5), $A^{(r)}_{ss} = A^r_{ss}$. The *sth subsystem* is described by the following equations:

$$\boldsymbol{x}^s_{i+1} = A^r_{ss} \boldsymbol{x}^s_i + \mathfrak{B}_s \boldsymbol{U}_i + \boldsymbol{\xi}_{s,i}, \qquad i = 0, 1, \dots . \tag{8.7}$$

Here in accordance with (8.6),

$$\boldsymbol{\xi}_{s,i} = 0 \quad \text{for} \quad s = 1 \quad \text{and} \qquad \boldsymbol{\xi}_{s,i}(t) = \sum_{\nu=1}^{s-1} A^{(r)}_{s\nu} \boldsymbol{x}^\nu_i \quad \text{otherwise.} \tag{8.8}$$

In this subsection, we ignore this rule and interpret $\boldsymbol{\xi}_{s,i}$ as an exogenous disturbance. This permits us to study each subsystem independently of the others. We also suppose that the disturbance decays at a known rate ρ_ξ,

$$|\boldsymbol{\xi}_{s,i}| \le K_\xi \rho^i_\xi, \qquad \rho_\xi \in [0, 1), \quad i = 0, 1, \dots, \tag{8.9}$$

whereas K_ξ is unknown, and offer a controller that stabilizes the sth subsystem under all such disturbances. In doing so, we assume that the current state $\boldsymbol{x}^s_i$ is measured on-line. The proposed controller uses only finitely many bits of information about $\boldsymbol{x}^s_i$.

It will be mainly based on the ideas from [2, 12, 14, 19, 20, 22, 23, 25]. A novelty concerns two points. First, we consider the case where the transmission of the above bits to the decoder takes some time (specifically, r units of time). This implies complements to the stabilization scheme, e.g., the need to quantize not the current state but the state prognosis. Second, we take into account exogenous disturbances decaying at a known rate.

We start with introducing components of which the coder and decoder will be assembled.

Quantizer. An m-level *quantizer* $\mathfrak{Q}^s$ in $\mathbb{R}^{n_s}$ is a partition of the unit ball $B^1_0 \subset \mathbb{R}^{n_s}$ with respect to some norm $|\cdot|$ into m disjoint sets $Q_1, \dots, Q_m$ each equipped with a *centroid* $\boldsymbol{q}^{Q_i} \in Q_i$. Such a quantizer associates any vector $\boldsymbol{x}^s \in Q_i$ with its *quantized value* $\mathfrak{Q}^s(\boldsymbol{x}^s) := \boldsymbol{q}^{Q_i}$ and any vector $\boldsymbol{x}^s \notin B^1_0$ with an alarm symbol ✠.

Definition 8.4. *The quantizer $\mathfrak{Q}^s$ is said to be* r-contracted *(for the sth subsystem) if*

$$A^r_{ss}\big(Q - \boldsymbol{q}^Q\big) \subset \rho_{\mathfrak{Q}^s} B^1_0 \quad \forall Q = Q_i,\ i = 1, \dots, m, \qquad \textit{where} \quad \rho_{\mathfrak{Q}^s} \in (0, 1). \tag{8.10}$$

Deadbeat stabilizer. This is a linear transformation $\mathfrak{S}$ of an initial state $\boldsymbol{x}^s_0$ into a control program $\boldsymbol{U}$ that drives the unperturbed $\boldsymbol{\xi}_{s,i} \equiv 0$ subsystem (8.7) to zero,

$$0 = \boldsymbol{x}^s_1 (= \boldsymbol{x}^s(r)) = A^r_{ss} \boldsymbol{x}^s_0 + \mathfrak{B}_s \boldsymbol{U} \quad \text{for} \quad \boldsymbol{U} := \mathfrak{S} \boldsymbol{x}^s_0 \quad \text{and any} \quad \boldsymbol{x}^s_0. \tag{8.11}$$

It is supposed that a contracted quantizer and deadbeat stabilizer are given. Furthermore, we show that they do exist.

Parameters. Apart from r, the controller employs two more parameters ρ and γ. They are chosen so that

$$r > n, \qquad \gamma > \|A_{ss}\|^r, \qquad \text{and} \qquad 1 > \rho > \max\{\rho_\xi, \rho_{\mathfrak{O}^s}\}, \tag{8.12}$$

where A_{ss}, ρ_ξ, and $\rho_{\mathfrak{O}^s}$ are taken from (8.5), (8.9), and (8.10), respectively.

Both coder and decoder compute controls $\boldsymbol{U}^{\,c}_i$, $\boldsymbol{U}^{\,d}_i$ and upper bounds δ^c_i, δ^d_i for the state norm $|\boldsymbol{x}^s_i|$, respectively. Actually, acting upon the plant is the control $\boldsymbol{U}^{\,d}_i$. The initial bounds are common: $\delta^c_0 = \delta^d_0 = \delta_0$. (The inequality $\delta_0 \geq |x^s_0|$ may be violated.) At any time $\tau_i = ir$, the coder selects a finite-bit message based on $\boldsymbol{x}^s_i$. This message is sent to the decoder and arrives by time τ_{i+1}. Specifically, the coder and decoder act as follows.

The *s*th coder (at the times $t = \tau_i, i = 1, 2, \dots$).

c.1. Proceeding from the current state $\boldsymbol{x}^s_i$, computes the state prognosis for the time $t = \tau_{i+1}$,

$$\widehat{\boldsymbol{x}}^s_{i+1} := A^r_{ss}\boldsymbol{x}^s_i + \mathfrak{B}_s\boldsymbol{U}^{\,c}_i; \tag{8.13}$$

c.2. Employs the r-contracted quantizer $\mathfrak{Q}^s$ to compute the quantized value $\boldsymbol{q}_i$ of the scaled state at $t = \tau_{i+1}$,

$$\boldsymbol{\varepsilon}_i := \big[\delta^c_i\big]^{-1}\widehat{\boldsymbol{x}}^s_{i+1}, \qquad \boldsymbol{q}_i := \mathfrak{Q}^s\big[\boldsymbol{\varepsilon}_i\big]; \tag{8.14}$$

c.3. Encodes this quantized value $\boldsymbol{q}_i$ for transmission and sends it to the decoder;

c.4. Computes the next control program by means of the deadbeat stabilizer $\mathfrak{S}$ and corrects the upper bound,

$$\boldsymbol{U}^{\,c}_{i+1} := \mathfrak{S}\big[\delta^c_i \overset{\star}{\boldsymbol{q}}_i\big], \qquad \delta^c_{i+1} := \delta^c_i \times \langle \boldsymbol{q}_i\rangle_{\rho,\gamma}, \qquad \text{where} \tag{8.15}$$

$$\overset{\star}{\boldsymbol{q}} := \begin{cases} \boldsymbol{q} & \text{if } \boldsymbol{q} \neq \maltese, \\ 0 & \text{otherwise,} \end{cases} \qquad \langle q\rangle_{\rho,\gamma} := \begin{cases} \rho & \text{if } q \neq \maltese, \\ \gamma & \text{otherwise.} \end{cases} \tag{8.16}$$

The *s*th decoder (at the times $t = \tau_i, i = 2, 3, \dots$).

d.1. Decodes the newly received data and thus acquires $\boldsymbol{q}_{i-1}$;

d.2. Computes the current control program and corrects the upper bound,

$$\boldsymbol{U}^{\,d}_i := \mathfrak{S}\big[\delta^d_i \overset{\star}{\boldsymbol{q}}_{i-1}\big], \qquad \delta^d_{i+1} := \delta^d_i \times \big\langle \boldsymbol{q}_{i-1}\big\rangle_{\rho,\gamma}. \tag{8.17}$$

For definiteness, the initial control programs $\boldsymbol{U}^{\,c}_0, \boldsymbol{U}^{\,d}_0, \boldsymbol{U}^{\,c}_1, \boldsymbol{U}^{\,d}_1$ are taken to be zero.

We introduced separate controls $\boldsymbol{U}^{\,c}_i, \boldsymbol{U}^{\,d}_i$ and bounds δ^c_i, δ^d_i to stress that the coder and decoder compute them independently. However, it easily follows from (8.15), (8.17) and induction on i that they in fact coincide,

$$\delta^d_i = \delta^c_{i-1}, \qquad \boldsymbol{U}^{\,d}_i = \boldsymbol{U}^{\,c}_i, \qquad i = 1, 2, \dots . \tag{8.18}$$

The second relation implies that the error in the state prognosis (8.13) is equal to the disturbance from (8.7),

$$\widehat{\boldsymbol{x}}^s_{i+1} = \boldsymbol{x}^s_{i+1} - \boldsymbol{\xi}_{s,i}. \tag{8.19}$$

Stabilizing properties of the offered controller are revealed by the following main result of the subsection.

PROPOSITION 8.5. *Suppose that the disturbance in the sth subsystem* (8.7) *satisfies* (8.9) *and that* (8.12) *holds. Then the above coder-decoder pair uniformly exponentially stabilizes this subsystem,*

$$|\boldsymbol{x}_i^s| \le \mathcal{K}_x\rho^i, \quad |\boldsymbol{U}_i^d| \le \mathcal{K}_u\rho^i \quad \forall i = 0,1,2,\dots \qquad \text{whenever} \quad |\boldsymbol{x}_0^s| \le K_0. \tag{8.20}$$

Here ρ is the parameter of the controller and the constants $\mathcal{K}_x, \mathcal{K}_u$ may depend on K_ξ from (8.9) *and K_0.*

The proof of this proposition consists of several lemmas. We start with rough estimates of concerned variables.

LEMMA 8.6. *The following inequalities hold for all $i = 1,2,\dots, h = 0,1,\dots,$ and $p \ge h$:*

$$\begin{aligned} &\delta_0\rho^{i-1} \le \delta_i^c \le \delta_0\gamma^{i-1}, \quad |\boldsymbol{U}_i^d| \le \|\mathfrak{S}\|\delta_{i-1}^c, \\ &|\boldsymbol{x}_p^s| \le \|A_{ss}\|^{r(p-h)}\Big[|\boldsymbol{x}_h^s| + K'_\xi\rho_\xi^h\Big] + K_\gamma\gamma^p|\mathfrak{I}(p,h)|, \end{aligned} \tag{8.21}$$

where $|\mathfrak{I}(p,h)|$ is the size of the set $\mathfrak{I}(p,h) := \{j = h,\dots,p-1 : j \ge 2 \;\&\; \boldsymbol{q}_{j-1} \ne \maltese\}$, $K'_\xi := K_\xi/(\|A_{ss}\|^r - 1)$, and the constant K_γ does not depend on $\boldsymbol{x}_0, i, h, p, K_\xi$.

Proof. The first formula is immediate from (8.15) and (8.16) since $\rho < 1 < \gamma$ by (8.12). The second one results from (8.17) and (8.18) since $|\overset{\star}{\boldsymbol{q}}| \le 1$ due to (8.16). To prove the last formula, we first note that $\boldsymbol{U}_j^d = 0\,\forall j \notin \mathfrak{I}(p,h), h \le j \le p-1$, by (8.17) and (8.16). Hence

$$\begin{aligned} |x_p^s| &\overset{(8.7)}{=\!=} \left|A_{ss}^{r(p-h)}x_h^s + \sum_{j=h}^{p-1} A_{ss}^{r(p-1-j)}\Big[\mathfrak{B}_s\boldsymbol{U}_j^d + \boldsymbol{\xi}_{s,j}\Big]\right| \\ &\overset{(8.9)}{\le} \|A_{ss}\|^{r(p-h)}|x_h^s| + \|\mathfrak{B}_s\|\|\mathfrak{S}\|\delta_0 \sum_{j\in\mathfrak{I}(p,h)} \underbrace{\|A_{ss}\|^{r(p-1-j)}}_{\le\gamma^{p-1-j}\text{by (8.12)}}\gamma^{j-2} \\ &\quad + K_\xi\sum_{j=h}^{p-1}\|A_{ss}\|^{r(p-1-j)} \underbrace{\rho_\xi^j}_{\le\rho_\xi^h\text{by (8.9)}} \\ &\le \|A_{ss}\|^{r(p-h)}|x_h^s| + \|\mathfrak{B}_s\|\|\mathfrak{S}\|\delta_0|\mathfrak{I}(p,h)|\gamma^{p-3} + K_\xi\rho_\xi^h\frac{\|A_{ss}\|^{r(p-h)}-1}{\|A_{ss}\|^r - 1}, \end{aligned}$$

which yields the last formula from (8.21). ∎

To prove stability, it suffices to show that δ_i^c are true bounds for the state prognosis $|\widehat{\boldsymbol{x}}_{i+1}^s| \le \delta_i^c$ for all large i. Indeed, then $|\boldsymbol{\varepsilon}_i| \le 1\ \forall i \approx \infty$ by (8.14). Hence (8.15) and (8.16) ensure that the bound δ_i^c and thus $\widehat{\boldsymbol{x}}_{i+1}^s$ decay exponentially $\delta_{i+1}^c = \rho\delta_i^c$ for $i \approx \infty$. Then so does the state $\boldsymbol{x}_{i+1}^s$ thanks to (8.9) and (8.19), i.e., the system is stable. We start by showing that even if the bound δ_i^c is incorrect for some i, it becomes true later.

LEMMA 8.7. *For any K_0, K_ξ, and i_0, there exists an integer $p_0 \ge i_0$ such that the bound δ_i^c is correct $|\widehat{\boldsymbol{x}}_{i+1}^s| \le \delta_i^c$ for at least one index $i \in [i_0 : p_0]$ whenever $|\boldsymbol{x}_0^s| \le K_0$ and* (8.9) *holds.*

Proof. The letter $\mathcal{K}$ (with possible indices) is used to denote a constant that depends on K_0, K_ξ but not $\boldsymbol{x}_0^s$ and $\boldsymbol{\xi}_{s,i}$. By putting $h := 0$ and the estimate $|\mathfrak{I}(p,h)| \le p - h$ into the last inequality from (8.21), we see that

$$|\boldsymbol{x}_{p+1}^s| \le \mathcal{K}^{(p)} \quad \text{whenever } |\boldsymbol{x}_0^s| \le K_0 \text{ and (8.9) holds.} \tag{8.22}$$

Now suppose that the bound δ_i^c is incorrect for all i from some interval $[i_0 : i_1]$ with the left end i_0. To estimate i_1, we note that $\mathfrak{I}(p,i) = \emptyset$ for $i := i_0 + 1$ and $p := i_1 + 1$ due to (8.14). So the last inequality from (8.21) yields

$$\begin{aligned}
|\boldsymbol{x}_{i_1+1}^s| &\le \|A_{ss}\|^{r(i_1-i_0)}\Big[\mathcal{K}^{(i_0+1)} + K'_\xi \rho_\xi^{i_0+1}\Big]; |\widehat{\boldsymbol{x}}_{i_1+1}^s| \overset{(8.19)}{=\!=} |\boldsymbol{x}_{i_1+1}^s - \boldsymbol{\xi}_{s,i_1}| \\
&\overset{(8.9)}{\le} \|A_{ss}\|^{r(i_1-i_0)}\Big[\mathcal{K}^{(i_0+1)} + K'_\xi \rho_\xi^{i_0+1}\Big] + K_\xi \rho_\xi^{i_1} \\
&\overset{\rho_\xi<1}{\le} \|A_{ss}\|^{r(i_1-i_0)}\Big[\mathcal{K}^{(i_0+1)} + K'_\xi\Big] + K_\xi \overset{1\le\|A_{ss}\|}{\le} \big(\mathcal{K}^{(i_0+1)} + K'_\xi + K_\xi\big)\|A_{ss}\|^{r(i_1-i_0)}.
\end{aligned}$$

At the same time, (8.15) and (8.16) entail that $\delta_{i+1}^c = \gamma \delta_i^c$ for $i \in [i_0 : i_1]$. So $\delta_{i_1}^c = \gamma^{i_1-i_0}\delta_{i_0}^c \ge \gamma^{i_1-i_0}\rho^{i_0-1}\delta_0$, where the last inequality is based on (8.21). Since the bound $\delta_{i_1}^c$ is incorrect, it follows that

$$1 \le \frac{|\widehat{\boldsymbol{x}}_{i_1+1}^s|}{\delta_{i_1}^c} \le \left(\frac{\|A_{ss}\|^r}{\gamma}\right)^{i_1-i_0} \frac{\mathcal{K}^{(i_0+1)} + K'_\xi + K_\xi}{\rho^{i_0-1}\delta_0}.$$

By invoking the second relation from (8.12), we conclude that

$$i_1 \le i_0 + \nu, \quad \text{where} \quad \nu := \left\lfloor \frac{\log_2(\mathcal{K}^{(i_0+1)} + K'_\xi + K_\xi) - (i_0-1)\log_2\rho - \log_2\delta_0}{\log_2\gamma - r\log_2\|A_{ss}\|} \right\rfloor.$$

So one may pick $p_0 := i_0 + 1 + \max\{\nu, 0\}$. The claim of the lemma remains true with the same p_0 if the interval $[i_0 : i_1]$ does not exist, because the bound $\delta_{i_0}^c$ is correct. ∎

The next lemma in fact completes the proof of Proposition 8.5.

LEMMA 8.8. *Suppose that $|\boldsymbol{x}_0^s| \le K_0$ and (8.9) holds. Whenever the bound δ_i^c becomes correct $|\widehat{\boldsymbol{x}}_{i+1}^s| \le \delta_i^c$, it is kept true afterwards, provided that $i \ge i_0$. Here i_0 is taken so that*

$$\frac{\rho_{\mathfrak{O}^s}}{\rho} + \frac{\|A_{ss}\|^r K_\xi}{\delta_0}\left(\frac{\rho_\xi}{\rho}\right)^i < 1 \qquad \forall i \ge i_0. \tag{8.23}$$

Remark 8.1. Such an i_0 exists due to the last inequality from (8.12).

Proof of Lemma 8.8. By (8.14), $|\boldsymbol{\varepsilon}_i| \le 1$. So (8.14), (8.15), and (8.16) imply that

$$\boldsymbol{\varepsilon}_i \in Q, \quad \boldsymbol{q}_i = \boldsymbol{q}^Q \quad \text{for some} \quad Q \in \{Q_1, \dots, Q_m\}; \quad \boldsymbol{U}_{i+1}^c = \mathfrak{S}\big[\delta_i^c \boldsymbol{q}_i\big], \quad \delta_{i+1}^c = \rho\delta_i^c, \tag{8.24}$$

where Q_j are the level sets of the quantizer. By (8.11), the third relation yields $\delta_i^c A_{ss}^r \boldsymbol{q}_i + \mathfrak{B}_s \boldsymbol{U}_{i+1}^c = 0$. Hence

$$\begin{aligned}
\big(\delta_{i+1}^c\big)^{-1}\big|\widehat{\boldsymbol{x}}_{i+2}^s\big| &\overset{(8.13)}{=\!=} \big(\delta_{i+1}^c\big)^{-1}\big|A_{ss}^r \boldsymbol{x}_{i+1}^s + \mathfrak{B}_s \boldsymbol{U}_{i+1}^c\big| = \big(\delta_{i+1}^c\big)^{-1}\big|A_{ss}^r \boldsymbol{x}_{i+1}^s - \delta_i^c A_{ss}^r \boldsymbol{q}_i\big| \\
&\overset{(8.19)}{=\!=} \big(\delta_{i+1}^c\big)^{-1}\big|A_{ss}^r\big[\widehat{\boldsymbol{x}}_{i+1}^s + \boldsymbol{\xi}_{s,i}\big] - \delta_i^c A_{ss}^r \boldsymbol{q}_i\big| \overset{(8.14)}{\le} \frac{\delta_i^c}{\delta_{i+1}^c}\big|A_{ss}^r\big[\boldsymbol{\varepsilon}_i - \boldsymbol{q}_i\big]\big| + \big(\delta_{i+1}^c\big)^{-1}\big|A_{ss}^r \boldsymbol{\xi}_{s,i}\big|.
\end{aligned}$$

It follows from (8.10) and the first two relations in (8.24) that $\left|A_{ss}^r\left[\boldsymbol{\varepsilon}_i - \boldsymbol{q}_i\right]\right| \le \rho_{\mathfrak{O}^s}$. We proceed by invoking (8.9) and the last relation from (8.24), along with the first inequality from (8.21),

$$\left(\delta_{i+1}^c\right)^{-1}\left|\widehat{\boldsymbol{x}}_{i+2}^s\right| \le \frac{\rho_{\mathfrak{O}^s}}{\rho} + \|A_{ss}\|^r K_\xi \frac{\rho_\xi^i}{\delta_{i+1}^c} \le \frac{\rho_{\mathfrak{O}^s}}{\rho} + \frac{\|A_{ss}\|^r K_\xi}{\delta_0}\left(\frac{\rho_\xi}{\rho}\right)^i \overset{(8.23)}{<} 1.$$

Thus the bound δ_{i+1}^c is true, which completes the proof. □

Proof of Proposition 8.5. Consider the number p_0 from Lemma 8.7, where i_0 is taken from Lemma 8.8. By these lemmas, the bound δ_i^c is true $|\widehat{\boldsymbol{x}}_{i+1}^c| \le \delta_i^c \forall i \ge p_0$. Then $\delta_{i+1}^c = \rho\delta_i^c\ \forall i \ge p_0$ thanks to (8.14), (8.15), and (8.16). With regard to the first relation from (8.21), we see that $\delta_i^c \le \delta_0\gamma^i\ i \le p_0, \delta_i^c = \delta_{p_0}^c\rho^{i-p_0} \le \delta_0\big(\gamma/\rho\big)^{p_0}\rho^i\ i \ge p_0$ and so $\delta_i^c \le \mathcal{K}_\delta\rho^i\ \forall i$, where $\mathcal{K}_\delta := \delta_0\big(\gamma/\rho\big)^{p_0}$. This and the second formula from (8.21) give the second inequality in (8.20). To prove the first one, we note that

$$\left|\boldsymbol{x}_{i+1}^c\right| \overset{(8.19)}{=\!=} \left|\widehat{\boldsymbol{x}}_{i+1}^c + \boldsymbol{\xi}_{s,i}\right| \overset{(8.9)}{\le} \delta_i^c + K_\xi\rho_\xi^i \overset{(8.12)}{\le} \mathcal{K}_x^0\rho^{i+1} \quad \forall i \ge p_0,$$
$$\text{where} \quad \mathcal{K}_x^0 := \rho^{-1}\left(\mathcal{K}_\delta + K_\xi\right).$$

For $i \le p_0 + 1$, inequality (8.22) yields $|\boldsymbol{x}_i^c| \le \mathcal{K}^{(i)} \le \mathcal{K}' := \max_{j=0,\dots,p_0+1}\mathcal{K}^{(j)}$. Thus the first inequality in (8.20) does hold with $K_x := \max\{\mathcal{K}_x^0; \mathcal{K}'\rho^{-p_0-1}\}$. □

8.3. Existence of a contracted quantizer and deadbeat stabilizer. To implement the proposed scheme, the state $\boldsymbol{x}_i^s$ should be determined at a certain site, which may be only the site of a sensor. Then the quantized value $\boldsymbol{q}_i = \mathfrak{O}^s(\boldsymbol{x}_i^s)$ should be communicated for r units of time to the decoder. Since the capacities of the channels serving the sensors are limited, we are interested in minimizing the number b of communicated bits. This number is that $b = \lceil\log(m+1)\rceil$ required to describe a quantized value (including the alarm one ✠) for the m-level quantizer $\mathfrak{O}^s$. Thus finding an r-contracted quantizer with the minimum number of levels m is of interest.

Now we establish tight lower and upper bounds for this number.

LEMMA 8.9. *For any m-level r-contracted* (8.10) *quantizer, $m > |\det A_{ss}|^r$. This inequality is sufficient up to a polynomial factor. In other words, there is a polynomial $\varphi_s(\cdot)$ (depending on A_{ss}) such that for any $r = 1, 2, \dots$ there exists an r-contracted quantizer $\mathfrak{O}^s$ with the number of levels*

$$m_s \le \varphi_s(r)|\det A_{ss}|^r. \tag{8.25}$$

Proof. Necessity. Due to (8.10), $|\det A_{ss}|^r\,\mathbf{mes}\,(Q_i) = |\det A_{ss}|^r\,\mathbf{mes}\,[Q_i - q^{Q_i}] = \mathbf{mes}\left[A_{ss}^r(Q_i - q^{Q_i})\right] \le \rho_{\mathfrak{O}^s}^{n_s}\,\mathbf{mes}\,B_0^1 < \mathbf{mes}\,B_0^1$. Summing over i gives $m > |\det A_{ss}|^r$.

Sufficiency. Note first that whenever the claim is true for two matrices A'_{ss} and A''_{ss}, it is also true for the block matrix $\left(\begin{smallmatrix} A'_{ss} & 0 \\ 0 & A''_{ss}\end{smallmatrix}\right)$. By employing the canonical Jordan form of A_{ss}, this reduces the proof to the case where the matrix is a real Jordan block. Let n_s denote its size, λ its eigenvalue, and $\omega := |\lambda|$. As follows from, e.g., [26, Lemma 3.1, p. 64], $\Xi(r) := \omega^{-r}\varphi(r)^{-1}A_{ss}^r \to 0$ as $r \to \infty$ for some polynomial $\varphi(\cdot)$. So $\|\Xi(r)\| < \rho < 1$ for $r \approx \infty$. Here $\|\cdot\|$ is the operator norm associated with the norm $|\boldsymbol{z}| := \max_i |z_i|$ in $\mathbb{R}^{n_s} = \{\boldsymbol{z} = (z_1, \dots, z_{n_s})\}$. Multiplying the polynomial $\varphi(r)$ by a sufficiently large scalar factor makes the inequality $\|\Xi(r)\| < \rho$ true for all r. Now consider the uniform quantizer $\mathfrak{O}^s$ partitioning the unit ball B_0^1 into $m_s := k^{n_s}$

balls Q_i of radius $\frac{1}{k}$, where $k := \lceil \omega^r \varphi(r) \rceil$. The centroid q^{Q_i} is the center of the ball Q_i. Then

$$\|\Xi(r)\| < \rho \Rightarrow \Xi(r)[Q_i - q^{Q_i}] \subset \rho[Q_i - q^{Q_i}] = \frac{\rho}{k} B_0^1 \Rightarrow A^r[Q_i - q^{Q_i}] \subset \rho \frac{\omega^r \varphi(r)}{k} B_0^1 \subset \rho B_0^1.$$

Thus the quantizer is r-contracted. It remains to note that

$$m_s = k^{n_s} \le [\omega^r \varphi(r) + 1]^{n_s} \le 2^{n_s - 1} \Big([\omega^r \varphi(r)]^{n_s} + 1 \Big) = 2^{n_s - 1} \Big(|\det A_{ss}|^r \varphi(r)^{n_s} + 1 \Big)$$
$$\overset{1 \le |\det A_{ss}|}{\le} 2^{n_s - 1} |\det A_{ss}|^r \Big[\varphi(r)^{n_s} + 1 \Big].$$

Thus (8.25) does hold with $\varphi_s(r) := 2^{n_s - 1}[\varphi(r)^{n_s} + 1]$. □

When all subsystems are equipped with the proposed controllers, the stability of a particular subsystem may be violated by the controllers serving the other subsystems since the control is common. To avoid this, it suffices to choose the controls in such a way that they influence only the subsystem for which they are intended. For the basic (unit) sample period, this may be impossible. Now we show that this can be done if the sample period r is properly increased: the controls generated for a given subsystem do not affect the other ones at times $t = i \cdot r, i = 0, 1, \dots$.

Common controls give rise to another trouble. As was remarked, the sth coder will be implemented at the sites of sensors observing the sth subsystem. To compute the states $\boldsymbol{x}_i^s = \boldsymbol{x}^s(\tau_i)$ utilized by this coder, not only the observations but also controls must be known at these sites. However, the sth coder may know the control only partly. It is aware of its own summand in the overall control, which is the sum of the controls generated for all subsystems. At the same time, it is not able to determine the summands based on the modes $\boldsymbol{x}^j$ invisible at its site. To overcome this obstacle, it suffices to note that the controls must be known for only n times t preceding τ_i. So it suffices to ensure that all controllers produce zero controls at these times.

Now we show that deadbeat stabilizers with the above properties do exist.

LEMMA 8.10. *Whenever $r > n$, a deadbeat stabilizer for the sth subsystem exists. Moreover, it can be chosen so that it generates control programs $\boldsymbol{U} = (\boldsymbol{u}_0, \dots, \boldsymbol{u}_{r-1})$ vanishing since the time $t = n$, i.e., $\boldsymbol{u}_n = \dots = \boldsymbol{u}_{r-1} = 0$, and does not disturb the other subsystems, i.e., $\mathfrak{B}_j \boldsymbol{U} = 0$ for $j \ne s$, $\boldsymbol{U} = \mathfrak{S}\boldsymbol{x}^s$, and any $\boldsymbol{x}^s$.*

Proof. By (8.11), a deadbeat stabilizer is the right inverse to the operator $\mathfrak{D}\boldsymbol{U} := -A_{ss}^{-r} \mathfrak{B}_s \boldsymbol{U}$. In (8.2), $\mathfrak{B}\boldsymbol{U}$ is the state to which the control program $\boldsymbol{U}$ drives the system (3.1) at time $t = r$ from $\boldsymbol{x}(0) = 0$. By assumption, this system has no stable modes. So it is controllable thanks to Assumption 4.2. It follows that the operator $\mathfrak{B}$ is onto. Moreover, $\mathfrak{B}|_M$ is onto, where $M := \{\boldsymbol{U} : \boldsymbol{u}_n = \dots = \boldsymbol{u}_{r-1} = 0\}$. Indeed for any $\boldsymbol{x}$, it suffices to pick the control program $\boldsymbol{u}_0, \dots, \boldsymbol{u}_{n-1}$ that drives the system from 0 at $t = 0$ to $A^{n-r}\boldsymbol{x}$ at $t = n$ and extend it by zeros to form $\boldsymbol{U} \in M$. Then evidently $\mathfrak{B}\boldsymbol{U} = \boldsymbol{x}$. Now consider $\boldsymbol{x}$ such that in (8.4) all blocks are zeros except for $\boldsymbol{x}^s \in \mathbb{R}^{n_s}$. Since this block can be chosen arbitrarily, it follows that the operator $\mathfrak{B}_s$ maps $L := \{\boldsymbol{U} \in M : \mathfrak{B}_j \boldsymbol{U} = 0 \, \forall j \ne s\}$ onto $\mathbb{R}^{n_s}$. So evidently does $\mathfrak{D}$. It remains to define $\mathfrak{S}$ as the right inverse to $\mathfrak{D}|L$. □

8.4. Stabilization of the entire system. Now we study the set of all subsystems in their actual connection. So the disturbance in (8.7) is given by (8.8). We pick $r > n$ and suppose that the following claims hold for any s:

A1. *The block $\boldsymbol{x}^s(\tau_i)$ of the state can be determined at any time $\tau_i = i \cdot r$ at a certain site* (called the sth site)*;*

A2. *The sth coder from subsection* 8.2 *is implemented at this site;*

A3. *There is a way to communicate the quantized value* $\boldsymbol{q}_i^s$ *generated by the sth coder at the step* **c.3** *to the decoder site during the time interval* $[\tau_i : \tau_{i+1})$.

Note that the sth coder is driven by only the sequence of states $\boldsymbol{x}_i^s = \boldsymbol{x}^s(\tau_i)$. So A1 makes A2 possible. In A3, considered is the site where the actual decoder (see Figure 3.1) must be situated. The sth decoder from subsection 8.2 is implemented at this site for all s. This is possible since it is driven only by the sequence of quantized values $\boldsymbol{q}_i^s, i = 0, 1, \dots$. Each decoder produces its own sequence of controls $\boldsymbol{U}_i^d = \big[\boldsymbol{u}^s(ir), \boldsymbol{u}^s(ir+1), \dots, \boldsymbol{u}^s(ir+r-1)\big]$. These sequences are summed over all decoders to produce the control sequence acting upon the plant:

$$\boldsymbol{u}(t) := \boldsymbol{u}^1(t) + \boldsymbol{u}^2(t) + \cdots + \boldsymbol{u}^d(t).$$

To complete the description of the coders, a quantizer, deadbeat stabilizer, and parameters r, γ, ρ should be chosen for each coder. The parameter $r > n$ is already picked. For any subsystem s, the quantizer and stabilizer are taken from Lemmas 8.9 and 8.10, respectively. The parameter $\gamma = \gamma_s$ is chosen to satisfy the second relation from (8.12). As for the third relation, it is indefinite under the circumstances since ρ_ξ from (8.9) is not given. So now we pick the parameter $\rho = \rho_s$ in another way. It is chosen successively for $s = 1, 2, \dots, d$ and so that

(8.26)
$$\rho_1 > \rho_{\mathfrak{Q}^1}, \quad \rho_2 > \max\{\rho_{\mathfrak{Q}^2}; \rho_1\}, \quad \rho_3 > \max\{\rho_{\mathfrak{Q}^3}; \rho_2\}, \dots, 1 > \rho_d > \max\{\rho_{\mathfrak{Q}^d}; \rho_{d-1}\},$$

where $\rho_{\mathfrak{Q}^s}$ is taken from (8.10). Stabilizing properties of this control scheme are described by the following.

PROPOSITION 8.11. *Suppose that assumptions* A1–A3 *hold. Then the proposed networked controller uniformly exponentially stabilizes the entire system* (3.1) *at the rate* $\mu = \rho_d^{1/r}$.

We preface the proof of this proposition with a simple technical fact.

LEMMA 8.12. *Suppose that a trajectory of the system* (3.1) *satisfies the estimates*

$$|\boldsymbol{x}_i| \le \mathcal{K}_x \rho^i, \quad |\boldsymbol{U}_i| \le \mathcal{K}_u \rho^i, \qquad i = 0, 1, 2, \dots, \tag{8.27}$$

where $\boldsymbol{x}_i := \boldsymbol{x}(\tau_i), \rho \in [0, 1), \tau_i := i \cdot r$, *and* $\boldsymbol{U}_i := [\boldsymbol{u}(\tau_i), \boldsymbol{u}(\tau_i + 1), \dots, \boldsymbol{u}(\tau_i + r - 1)]$. *Then* (4.2) *holds, where* $\mu := \rho^{1/r}$ *and the constants* K_x, K_u *are determined by* $\mathcal{K}_x, \mathcal{K}_u, \rho$ *(for a given system).*

Proof. Whenever $t \in [\tau_i : \tau_{i+1})$, we have $\rho^i = \mu^{\tau_i} = \mu^{\tau_i - t}\mu^t \le \mu^{-r}\mu^t = \rho^{-1}\mu^t$. So $|\boldsymbol{u}(t)| \le |\boldsymbol{U}_i| \le \mathcal{K}_u\rho^i \le \mathcal{K}_u\rho^{-1}\mu^t$, i.e., the second inequality from (4.2) does hold. We denote $\varkappa := 1 + \|A\|$. Then

$$\begin{aligned}
|\boldsymbol{x}(t)| = \left| A^{t-\tau_i}\boldsymbol{x}(\tau_i) + \sum_{j=\tau_i}^{t-1} A^{t-1-j} B\boldsymbol{u}(j) \right| &\le \|A\|^{t-\tau_i}|\boldsymbol{x}(\tau_i)| + \sum_{j=\tau_i}^{t-1} \|A\|^{t-1-j}\|B\||\boldsymbol{u}(j)| \\
&\le \left[\|A\|^{t-\tau_i} + \|B\| \sum_{j=\tau_i}^{t-1} \|A\|^{t-1-j} \right] \times [|\boldsymbol{x}(\tau_i)| + |\boldsymbol{U}_i|] \\
&\le \left[\varkappa^r + \|B\| \sum_{j=\tau_i}^{\tau_{i+1}-1} \varkappa^{\tau_{i+1}-1-j} \right] [\mathcal{K}_x + \mathcal{K}_u]\, \rho^i,
\end{aligned}$$

where $\rho^i \le \rho^{-1}\mu^t$. By the index substitution $j := \tau_i + \nu$ in the last sum, we see that (4.2) is true. □

Proof of Proposition 8.11. Suppose that $|\boldsymbol{x}(0)| \le K_0$, where K_0 is given. The controls $\boldsymbol{u}^s$ with $s \ge 2$ do not disturb the first block $\boldsymbol{x}_i^1 := \boldsymbol{x}^1(\tau_i)$ of the state at times $\tau_i = i \cdot r$ by the choice of the deadbeat stabilizers. So this block $\boldsymbol{x}_i^1, i = 0, 1, \dots,$ evolves just as in the first subsystem (8.7) driven by the first coder and decoder and perturbed by the noise $\boldsymbol{\xi}_{1,i}$, which is zero by (8.8). Then Proposition 8.5 and the first inequality from (8.26) imply that the first subsystem $s = 1$ is uniformly exponentially stabilized (8.20) at the rate $\rho := \rho_1$. This and (8.8) imply that the noise $\boldsymbol{\xi}_{2,i}$ in the second subsystem (8.7) (where $s = 2$) exponentially decays (8.9) at the rate ρ_1. Now we retrace the above arguments with respect to this subsystem and employ the second relation from (8.26). As a result, we establish that this subsystem is stabilized at the rate ρ_2, i.e., (8.20) holds for $s = 2$ and $\rho := \rho_2$. By continuing likewise, we see that for any s, inequalities (8.20) are true with $\rho := \rho_s$ and proper constants $\mathcal{K}_x, \mathcal{K}_u$ (depending on s) whenever $|\boldsymbol{x}(0)| \le K_0$. Since $\rho_d \ge \rho_s \, \forall s$ by (8.26), it follows that (8.27) holds with $\rho := \rho_d$ and some constants $\mathcal{K}_x, \mathcal{K}_u$ depending on K_0. Lemma 8.12 and Definition 4.3 complete the proof. □

8.5. Analysis of Assumptions A1 and A3. Our next goal is to show that these assumptions stated in the previous subsection are satisfied whenever $r > 2n$ and (5.2) holds. This in fact will complete the proof of Theorem 5.1. In this subsection, we perform the first step to this end.

We start with assumption A1. By 1 of Proposition 8.1, the unobservable subspace (4.3) $L_j^{-obs} = L_j^-$ of the jth sensor is composed of several blocks $\boldsymbol{x}^s, s \notin O_j$, of the state (8.4). These blocks do not affect its outputs y_j, whereas all other blocks $\boldsymbol{x}^s, s \in O_j$, can be determined from these outputs.

LEMMA 8.13. *Whenever $r > 2n$, assumption* A1 *holds. For any s, the site of any sensor j with $O_j \ni s$ can be taken as the sth site in* A1.

Proof. We recall that the deadbeat stabilizers were taken from Lemma 8.10. So they produce control programs $\boldsymbol{U} = (\boldsymbol{u}_0, \dots, \boldsymbol{u}_{r-1})$ with zeros $\boldsymbol{u}_i = 0$ at any place $i \ge n$. For $r > 2n$, this means that the corresponding control sequence $u(t), t = 0, 1, \dots,$ vanishes $u(t) = 0$ for at least n times t preceding each $\tau_i = i \cdot r, i = 0, 1, \dots$. It remains to invoke the remarks prefacing Lemma 8.10. □

Now we turn to an analysis of A3. We recall that in A3, the value $\boldsymbol{q}_i^s$ is given by an m_s level quantizer $\mathfrak{Q}^s$. Description of such a value (which may equal ✠) requires $b_s = \lceil \log_2(m_s + 1) \rceil$ bits. This number may exceed the capacity of the channel that serves any particular sensor j observing the block $\boldsymbol{x}^s$. So we employ all such channels. Specifically, the following scheme of transmission $\boldsymbol{q}_i^s$ to the decoder site is used for each subsystem $s = 1, \dots, d$:

- T1. The sth coder is implemented at the sites of all sensors j observing the state $\boldsymbol{x}^s$, i.e., such that $s \in O_j$;
- T2. By employing a common encoding rule, the value $\boldsymbol{q}_i^s$ produced at each of these sites is then transformed into a b_s-bit sequence $\boldsymbol{\beta}_i^s = (\beta_1, \beta_2, \dots, \beta_{b_s})$ of binary digits $\beta_\nu = 0, 1$;
- T3. By applying a common rule, this sequence $\boldsymbol{\beta}$ is split into several subsequences $\boldsymbol{\beta}_i^{s,j}$ each associated with one of the concerned sensors j, i.e., such that $s \in O_j$;
- T4. Each of these sensors j sends only its own subsequence $\boldsymbol{\beta}_i^{s,j}$ over the attached channel to the decoder site;
- T5. At the decoder site, the required value $\boldsymbol{q}_i^s$ is reconstructed by reversing the rules from T2 and T3.

We assume that the rules from T2 and T3 do not change as i progresses and are known at the decoder site. Furthermore, the rule from T2 is lossless: the value $\boldsymbol{q}_i^s$ can be reconstructed from $\boldsymbol{\beta}$. This makes T5 possible.

The above scheme means that several binary words $\boldsymbol{\beta}_i^{s,j}, s \in O_j$, must be transmitted over the common jth channel during any time interval $[\tau_i : \tau_{i+1})$ of duration $r-1$. By 2 of Assumption 4.1, this is possible if the total length of these words does not exceed $b_j^-(r-1)$. Now we denote by b_{sj} the number of bits in $\boldsymbol{\beta}_i^{s,j}$ whenever $s \in O_j$ and put $b_{sj} := 0$ otherwise. Summarizing, we arrive at the following lemma.

LEMMA 8.14. *Assumption* A3 *is satisfied whenever there exist nonnegative integer numbers $b_{sj}, s = 1, \dots, d$, $j = 1, \dots, k$, such that the following relations hold:*

$$\sum_{j=1}^{k} b_{sj} = b_s = \lceil \log_2(m_s + 1) \rceil \ \forall s, \quad \sum_{s=1}^{d} b_{sj} \le b_j^-(r-1) \ \forall j, \quad \textit{and} \quad b_{sj} = 0 \ \textit{whenever} \quad s \notin O_j. \tag{8.28}$$

Here k and d are the numbers of sensors and subsystems, respectively, m_s is the number of levels for the r-contracted quantizer taken from Lemma 8.9*, whereas $b_j^-(\cdot)$ and O_j are taken from* 2 *of Assumption* 4.1 *and* 1 *of Proposition* 8.1*, respectively.*

8.6. Inconstructive sufficient conditions for stabilizability. These conditions are immediate from Proposition 8.11 combined with Lemmas 8.13 and 8.14.

PROPOSITION 8.15. *Suppose that the following system of relations*

$$\log_2 |\det A_{ss}| < \sum_{j=1}^{k} \alpha_{sj} \ \forall s, \quad \sum_{s=1}^{d} \alpha_{sj} < \mathfrak{c}_j \ \forall j, \quad \alpha_{sj} \ge 0 \ \forall s, j, \quad \alpha_{sj} = 0 \ \textit{whenever} \ s \notin O_j \tag{8.29}$$

is solvable in real numbers α_{sj}. Here A_{ss} is taken from 2 *of Proposition* 8.1 *and $\mathfrak{c}_j$ is the transmission capacity* (4.1) *of the jth channel. Then the system* (3.1), (3.2) *is uniformly exponentially stabilizable.*

Proof. It suffices to show that for all large r, the system (8.28) is solvable in nonnegative integers b_{sj}. Indeed such an r can be clearly chosen so that $r > 2n$. Then Lemmas 8.13 and 8.14 ensure that assumptions A1 and A3 from subsection 8.4 hold, whereas A2 $\Leftarrow$ A1. In A2, the parameters of the sth coder are chosen as was indicated in that subsection. Proposition 8.11 completes the proof. □

We note first that in (8.28), the first relation can be replaced by the inequality

$$\sum_{j=1}^{k} b_{sj} \ge \lceil \log_2(m_s + 1) \rceil. \tag{8.30}$$

Indeed, if after this the system is solvable, than a solution for the original relation can be obtained by properly decreasing the nonnegative integers b_{sj}. Specifically, they are decreased to satisfy the first relation from (8.28), which may only enhance the second relation and keep the third relation true.

We are going to show that a solution is given by $b_{sj} := \lfloor r \cdot \alpha_{sj} \rfloor$, provided $r \approx \infty$.

Indeed the third relation in (8.28) follows from the last one in (8.29). Furthermore,

$$\frac{1}{r}\sum_{j=1}^{k} b_{sj} \xrightarrow{r\to\infty} \sum_{j=1}^{k} \alpha_{sj} \overset{(8.29)}{=\!=} \log_2|\det A_{ss}| + \varkappa_s, \text{ where } \varkappa_s > 0,$$

$$\frac{1}{r}\lceil\log_2(m_s+1)\rceil \le \frac{1}{r}\left[\log_2(m_s+1)+1\right]$$

$$\overset{(8.25)}{\le} \frac{1}{r}\left[\log_2\left(\varphi_s(r)|\det A_{ss}|^r+1\right)+1\right] \xrightarrow{r\to\infty} \log_2|\det A_{ss}|.$$

It follows that (8.30) does hold for all $r \approx \infty$. Likewise,

$$\frac{1}{r}\sum_{s=1}^{d} b_{sj} \xrightarrow{r\to\infty} \sum_{s=1}^{d} \alpha_{sj} \overset{(8.29)}{=\!=} \mathfrak{c}_j - \eta_j, \text{ where } \eta_j > 0, \qquad \frac{b_j^-(r-1)}{r} \xrightarrow{(4.1)} \mathfrak{c}_j \text{ as } r\to\infty.$$

Thus the second relation from (8.28) is also true for all $r \approx \infty$. □

8.7. Convex duality and a criterion for the system (8.29) to be solvable. Now we in fact perform the final step in the proof of the sufficiency part of Theorem 5.1 by justifying the following claim.

PROPOSITION 8.16. *The system* (8.29) *is solvable in real numbers* α_{sj} *if and only if* 2 *of Theorem* 5.1 *holds.*

Then by invoking Proposition 8.15, we arrive at the following corollary.

COROLLARY 8.1. *Whenever the system* (3.1) *has no stable modes,* 2 *of Theorem* 5.1 *implies* 1.

We preface the proof of Proposition 8.16 with a useful reformulation of 2 from Theorem 5.1 in terms of the decomposition from Proposition 8.1.

LEMMA 8.17. *Along with the sets* O_j *from* 1 *of Proposition* 8.1, *consider all their unions* $O = \bigcup_{j\in J} O_j$, *where* J *ranges over all groups of sensors. (The union of the empty group of sets* O_j *is included and interpreted as the empty set.) Then* 2 *of Theorem* 5.1 *is true if and only if for any such a union* $O \neq [1:d]$,

$$\sum_{s\notin O} \log_2|\det A_{ss}| < \sum_{j:O_j\not\subset O} \mathfrak{c}_j. \tag{8.31}$$

Proof. Due to 1 of Proposition 8.1, the sets (5.1) $L = \bigcap_{j\in J} L_j^-$ have the form

$$L = \{\boldsymbol{x} : \boldsymbol{x}^s = 0 \ \forall s \in O\}, \qquad \text{where} \quad O = \bigcup_{j\in J} O_j.$$

So (8.5) implies $\det A_L = \prod_{s\notin O} \det A_{ss}$. Hence the left-hand sides in (5.2) and (8.31) coincide. It remains to note that so do the right-hand ones since in (5.2) $J(L) = \{j : O_j \subset O\}$ owing to (4.3), (5.1), and 1 of Proposition 8.1.

Proof of Proposition 8.16. *Necessity.* Suppose that (8.29) has a solution α_{sj}. Then

$$\sum_{s\notin O} \log_2|\det A_{ss}| \overset{(8.29)}{<} \sum_{s\notin O}\sum_{j=1}^{k} \alpha_{sj} = \sum_{j=1}^{k}\sum_{s\notin O} \alpha_{sj} \overset{(8.29)}{=\!=} \sum_{j:O_j\not\subset O}\sum_{s\notin O} \alpha_{sj} \le \sum_{j:O_j\not\subset O}\sum_{s=1}^{d} \alpha_{sj}$$

$$\overset{(8.29)}{<} \sum_{j:O_j\not\subset O} \mathfrak{c}_j,$$

i.e., (8.31) holds. By Lemma 8.17, so does (5.2).

Sufficiency. Now suppose that 2 of Theorem 5.1 is true. By Lemma 8.17, this means that (8.31) holds for the union O of any sets O_j, provided $O \neq [1:d]$. It should be shown that (8.29) is solvable in real numbers α_{sj}.

Suppose the contrary. Then the following convex polyhedra in the space of matrices $\alpha = (\alpha_{sj})$ are disjoint:

$$C_1 := \left\{ \alpha : \log_2 |\det A_{ss}| < \sum_{j=1}^{k} \alpha_{sj} \ \forall s \right\},$$

$$C_2 := \left\{ \alpha : \sum_{s=1}^{d} \alpha_{sj} < \mathfrak{c}_j \ \forall j, \alpha_{sj} \geq 0 \ \forall s, j, \alpha_{sj} = 0 \text{ if } s \notin O_j \right\}.$$

Hence they are separated by a hyperplane: there exists a nonzero matrix $\gamma = (\gamma_{sj})$ such that

$$\inf_{\alpha \in C_1} \sum_{s,j} \gamma_{sj} \alpha_{sj} \geq \sup_{\alpha \in C_2} \sum_{s,j} \gamma_{sj} \alpha_{sj}. \tag{8.32}$$

The definition of C_1 implies that

$$\inf_{\alpha \in C_1} \sum_{s,j} \gamma_{sj} \alpha_{sj} = \sum_{s=1}^{d} \inf_{(\alpha_j): \sum_{j=1}^{k} \alpha_j > \log_2 |\det A_{ss}|} \sum_{j=1}^{k} \gamma_{sj} \alpha_j.$$

The infimum on the right is that of a linear functional over a half-space of (α_j) bounded by a hyperplane with the normal $(1, \dots, 1)$. This infimum is finite only if the functional is generated by a vector colinear with the normal. So $\gamma_{sj} = \theta_s \ \forall j$ for some $\theta_s \geq 0$ and $\sum_s \theta_s > 0$. It follows that

$$\inf_{\alpha \in C_1} \sum_{s,j} \gamma_{sj} \alpha_{sj} = \sum_{s=1}^{d} \theta_s \log_2 |\det A_{ss}|.$$

At the same time, the definition of C_2 implies that

$$\sup_{\alpha \in C_2} \sum_{s,j} \gamma_{sj} \alpha_{sj} = \sup_{\substack{\alpha_{sj} \geq 0, \sum_s \alpha_{sj} < \mathfrak{c}_j, \\ s \notin O_j \Rightarrow \alpha_{sj} = 0}} \sum_{sj} \theta_s \alpha_{sj} = \sum_{j=1}^{k} \max_{\alpha_s \geq 0, \sum_s \alpha_s \leq \mathfrak{c}_j} \sum_{s \in O_j} \theta_s \alpha_s$$

$$= \sum_{j=1}^{k} \mathfrak{c}_j \max_{s \in O_j} \theta_s.$$

By (8.32), the cone $K := \{\theta = (\theta_1, \dots, \theta_d) \in \mathbb{R}^d : \theta_s \geq 0\}$ contains a nonzero solution of the inequality

$$\sum_{s=1}^{d} \theta_s \log_2 |\det A_{ss}| \geq \sum_{j=1}^{k} \mathfrak{c}_j \max_{s \in O_j} \theta_s. \tag{8.33}$$

This cone can be partitioned into a finite number of convex polyhedral subcones such that the right-hand side of (8.33) is linear on any subcone. It follows that (8.33) must

be satisfied on some extreme ray of some subcone. Any of them is bounded by a finite number of hyperplanes, each described by an equation of the form either $\theta_\nu = 0$ or $\theta_\mu = \theta_\nu$, where $\nu \neq \mu$ and $\nu, \mu \in O_j$ for some j. This implies [21, p. 104] that the extreme ray is described by a finite system of such equations, which determines its solution uniquely up to multiplication by a scalar. It is easy to see that the solution of such a system looks as follows: $\theta_s = \theta$ whenever $s \notin \mathcal{O}$, and $\theta_s = 0$ otherwise. Here $\mathcal{O} \subset [1:d]$ is some set, $\mathcal{O} \neq [1:d]$. For vectors on the above extreme ray, we have $\theta > 0$, and (8.33) shapes into

$$\sum_{s \notin \mathcal{O}} \log_2 |\det A_{ss}| \geq \sum_{j: O_j \not\subset \mathcal{O}} \mathfrak{c}_j.$$

Changing $\mathcal{O} := O := \bigcup_{j: O_j \subset \mathcal{O}} O_j$ does not alter the right-hand side, possibly increases the left-hand one, and thus keeps the inequality true, in violation of (8.31). The contradiction obtained proves that the system (8.29) is solvable in real numbers α_{sj}. □

8.8. Proof of Theorem 5.1. It was shown in section 7 that $1 \Rightarrow 2$. The converse $2 \Rightarrow 1$ is given by Corollary 8.1 if the system (3.1) has no stable modes. Thus it remains to drop the last requirement and prove (5.3).

To achieve the first objective, we consider the system (3.1) with both unstable and stable modes that satisfies 2. It is clear that it suffices to stabilize only its unstable part,

(8.34)
$$x_+(t+1) = A_+ x_+(t) + \pi_+ B u(t), \qquad x_+(0) := \pi_+ x_0 \in L_+, \qquad y_+(t) = C x_+(t).$$

Here $L_+ := M_{unst}(A)$ and $L_- := M_{st}(A)$ are the invariant subspaces of A related to the unstable and stable parts of its spectrum, π_+ and π_- are the projectors onto L_+ parallel to L_- and vice versa, respectively, and $A_\pm := A|_{L_\pm}$. Thanks to the second relation from (4.3), 2 still holds for the system (8.34). By the foregoing, this system can be uniformly exponentially stabilized by some networked controller. While constructing it, we employ the parameter $r > 2n$. Now we apply this controller to the primal system (3.1). In doing so, the proof of possibility of T1 from subsection 8.5 must be revisited. Indeed the sth coder can be implemented at the jth sensor site (where $s \in O_j$) only if $\boldsymbol{x}^s(\tau_i), \tau_i := i \cdot r$ can be determined there. Formerly this was done on the base of the past measurements from (8.34). Now we must employ the observations from (3.1). This is possible due to (4.3) and 1 of Proposition 8.1 since the dynamics of the system (3.1) is free $u(t) = 0$ at least n time steps before τ_i.

By Definition 4.3, there exists $\mu \in [0, 1)$ such that whenever a constant K_0 is given and $|\boldsymbol{x}_0| \leq K_0$,

$$|\pi_+ \boldsymbol{x}(t)| \leq K_x^+ \mu^t, \quad |\boldsymbol{u}(t)| \leq K_u \mu^t \qquad \forall t = 0, 1, 2, \dots .$$

The evolution of $\boldsymbol{x}_-(t) := \pi_- \boldsymbol{x}(t)$ is described by the first two equations from (8.34), where the index $_+$ is switched to $_-$. Since the operator A_- is stable and the controls $\boldsymbol{u}(t)$ exponentially decay, so do the states $|\boldsymbol{x}_-(t)| \leq K_x^- \rho^t$. Here $\rho \in (0, 1)$ does not depend on K_0. Since $|\boldsymbol{x}(t)| = |\boldsymbol{x}_-(t) + \boldsymbol{x}_+(t)| \leq |\boldsymbol{x}_-(t)| + |\boldsymbol{x}_+(t)|$, increasing $\mu := \max\{\mu, \rho\}$ yields (4.2). Definitions 4.3 and 4.4 complete the proof of 1 from Theorem 5.1.

It remains to justify (5.3). To this end, we note that the transformation $z(t) := \mu^{-t} x(t), v(t) := \mu^{-t} u(t)$ establishes a one-to-one correspondence between the trajectories $\{x(t), u(t)\}$ and $\{z(t), v(t)\}$ of the systems given by (3.1) and the equation

$z(t+1) = \mu^{-1}Az(t) + \mu^{-1}Bv(t)$, respectively. We equip the latter with the sensors $\widetilde{y}_j = C_j z, j = 1, \dots, k$. It easily follows from Definitions 4.3 and 4.4 that the initial system is uniformly exponentially stabilizable at a rate $\mu' \in (0, \mu)$ if and only if the second system is uniformly exponentially stabilizable. By applying the $1 \Leftrightarrow 2$ part of Theorem 5.1 to it, we get

$$-\mathbf{dim}L \cdot \log_2 \mu + \log_2 |\det A|_L|$$

$$< \sum_{j \not\in J(L)} \mathfrak{c}_j \ \forall L \in \mathfrak{L} \Rightarrow \log_2 \mu > \max_{L \in \in \mathfrak{L}} \frac{1}{\mathbf{dim}L} \left(\log_2 |\det A|_L| - \sum_{j \not\in J(L)} \mathfrak{c}_j \right).$$

To arrive at (5.3), it remains to note that the rate of exponential stabilizability μ^0 is the infimum of all such μ.

9. Comments on Assumption 4.3. Now we explain why it has such a big impact on the controller design. We also briefly discuss ideas underlying such a design in the case where this assumption does not hold.

To start with, we illuminate the role of Assumption 4.3. A "subsystem" (arising from (8.4)) is said to be in a *simple relation* with the jth sensor if it either does affect this sensor or its state can be uniquely determined from the sensor outputs. The simplest case in stabilization of a multiple sensor system is where the system can be decomposed into independent subsystems each in a simple relation with any sensor. In general, this is impossible. As was shown, a nontrivial Jordan block may form a barrier to decomposition into independent subsystems. The example (4.5) proves that it may be still worse: the system cannot be disintegrated into (even dependent) subsystems each in simple relations with sensors. Assumption 4.3 in fact describes when this worst case does not occur.

So if this assumption is violated, unavoidable is the situation where some sensor partly observes some subsystem: its state cannot be determined on the site of this sensor though the sensor signals contain information about this state. Then an additional problem arises: how to utilize this information in the coding-decoding scheme for stabilization purposes? As will be shown, the answer requires the revision of some basic principles on which the design of such schemes was based up to now. In this paper, this is omitted due to space limitations.

To come into details, we pick natural $\mathfrak{c}$ and real $\lambda \approx \sqrt{2}^{3\mathfrak{c}}, \lambda < \sqrt{2}^{3\mathfrak{c}}$ numbers and revert to the example (4.5),

$$\boldsymbol{x}(t+1) = \lambda \boldsymbol{x}(t) + \boldsymbol{u}(t) \in \mathbb{R}^2, \quad y_1(t) = x_1(t), \quad y_2(t) = x_2(t), \quad y_3(t) = x_1(t) - x_2(t), \quad t = 0, 1, \dots, \tag{9.1}$$

where $\boldsymbol{x} = (x_1, x_2)$. Any of three channels transmits $\mathfrak{c}$ bits per unit time without delays and losses, i.e., $\mathfrak{c}_1 = \mathfrak{c}_2 = \mathfrak{c}_3 = \mathfrak{c}$. The necessary conditions for stabilizability (5.2) take the form $\lambda < \sqrt{2}^{3\mathfrak{c}}$ and are satisfied.

Assumption 4.3 clearly does not hold: one of the sensors observes a certain subsystem only partly for any decomposition of the system (9.1).For example, consider the natural decomposition $\boldsymbol{x} = (x_1, x_2)$, where x_1 and x_2 are interpreted as the states of the subsystems. They are in simple relations with the first and second sensors. However, they are not in such relations with the third one. Indeed the state x_i influences its outputs $y_3 = x_1 - x_2$ but cannot be determined on the basis of them. Moreover,

the only linear coordinate (i.e., function) of the state that can be determined on the site of the third sensor is its output y_3 (up to a scalar factor). Likewise, the first and second sensors permit us to find only x_1 and x_2, respectively. This conclusion holds for any decomposition.

Now we are going to show that though *the system* (9.1) *is stabilizable, it cannot be stabilized by a controller with the following features*, which are characteristic for the most known relevant controllers:

1. Not only the "mode" y_i but also its upper (maybe incorrect) bound δ_i is determined at the sensor site;
2. The state $\boldsymbol{x}$ and these bounds in fact constitute the state of the closed-loop system, which is time-invariant;
3. At the decoder site, the information about the "mode" $y_i(t)$ comes to its quantized scaled value $e_i(t) = \mathfrak{Q}_i[\delta_i(t)^{-1}y_i(t)]$ given by a static quantizer $\mathfrak{Q}_i(\cdot)$ with convex level sets and the number m_i of levels matching $m_i \le 2^{\mathfrak{c}} - 1$ the channel capacity;
4. The next bound $\delta_i(t+1)$ is determined from $\delta_i(t)$ and the knowledge of whether $e_i(t) = \maltese$ or not;
5. Whenever all bounds are true $\delta_i(t) \ge |y_i(t)|\,\forall i$, they remain true afterwards.

It is clear that these features mainly concern the coding algorithm.

Remark 9.1. In [25], a specific class of networked controllers was proposed for stabilization of multiple sensor systems. Since those controllers satisfy 1–5, they are unable to stabilize some stabilizable systems, e.g., the system (9.1). In [25], it was established when a system can yet be stabilized by a controller from this class. The corresponding results are formulated as criteria for "stabilizability" with no reference to the class. This does not seem a good idea because then some actually stabilizable systems are in fact classified as "unstabilizable."

LEMMA 9.1. *Let* $\mathfrak{c} \ge 2$ *and a networked controller satisfying* 1–5 *be given. Then the closed-loop system* (9.1) *is neither stable nor dissipative:* $\limsup_{t\to\infty}\sup_{\boldsymbol{x}_0\in B_0^\delta}|\boldsymbol{x}(t)| = \infty$ *for all* $\delta > 0$ *and initial bounds* $\delta_i^0 > 0$.

Proof. By 2 and 4, $\delta_i(t+1) = \mathcal{D}_i[\delta_i(t)]$ whenever $e_i(t) \ne \maltese$. We are going to estimate $\mathcal{D}_i(\cdot)$ from below. Due to 3, any quantizer $\mathfrak{Q}_i$ is related to a partition of the interval $[-1,1]$ into m_i subintervals (level sets) $\Delta_1^{(i)},\dots,\Delta_{m_i}^{(i)}$, $\Delta_j^{(i)} = [\alpha_j^{(i)},\beta_j^{(i)}]$. Since $m_i \le 2^{\mathfrak{c}} - 1$, one of them has the length $\beta_{j^i}^{(i)} - \alpha_{j^i}^{(i)} \ge 2\cdot 2^{-\mathfrak{c}}$. Now we pick $\delta > 0$, set the initial bounds $\delta_1(0) = \delta_2(0) = \delta, \delta_3(0) = 2\delta$, and note that all initial states from the segment $S := \{\boldsymbol{x}_0 = (\delta\alpha_{j^1}^{(1)} + \theta, \delta\alpha_{j^2}^{(2)} + \theta) : 0 \le \theta \le 2\delta 2^{-\mathfrak{c}}\}$ give rise to common outputs for each quantizer $i = 1,2,3$ at $t = 0$. So they give rise to a common control $\boldsymbol{u}(0) = (u_1, u_2)$. For all these states, the above initial bounds are correct. Then 5 ensures that for $i = 1, 2$

$$\delta_i(1) = \mathcal{D}_i[\delta_i(0)] = \mathcal{D}_i[\delta] \ge |y_i(1)| = |\lambda x_i(0) + u_i|.$$

Here $\lambda x_i(0) + u_i$ runs over an interval of length $\ge 2\lambda\delta 2^{-\mathfrak{c}}$ as $\boldsymbol{x}_0$ ranges over S. Hence

$$\mathcal{D}_i(\delta) \ge \lambda\delta 2^{-\mathfrak{c}} \tag{9.2}$$

for $i = 1, 2$. This inequality is extended on $i = 3$ by putting $\delta_1(0) = \delta_3(0) = \delta, \delta_2(0) = 2\delta, S := \{\boldsymbol{x}_0 = (\delta\alpha_{j^1}^{(1)} + \theta, \delta\alpha_{j^1}^{(1)} - \delta\alpha_{j^3}^{(3)}) : 0 \le \theta \le 2\delta 2^{-\mathfrak{c}}\}$ and retracing the above arguments.

Now we suppose that for some $\delta_i^0 > 0$ and $\delta > 0$ the conclusion of the lemma violates $c := \sup|\boldsymbol{x}(t)| < \infty$, where sup is over $\boldsymbol{x}_0 \in B_0^\delta$ and all t. By decreasing δ, one

can ensure that $\delta < \min\{\delta_1^0, \delta_2^0, \frac{1}{2}\delta_3^0\}$. Then for all initial states $\boldsymbol{x}_0 \in B_0^\delta$, the bounds δ_i are correct for $t = 0$. Thanks to 4 and 5, they remain correct for all t and common for all $\boldsymbol{x}_0 \in B_0^\delta$. Then (9.2) yields $\delta_i(t) \geq \delta \left(\frac{\lambda}{2^{\mathfrak{c}}}\right)^t$. Here $\lambda \approx \sqrt{2}^{3\mathfrak{c}}$. So $\delta_i(t) \to \infty$ as $t \to \infty$. As a result, the interval $[-2c, 2c]$ is covered by at most two intervals $\delta_i(t)\Delta_j^{(i)}$ for each $i = 1, 2, 3$, provided t is large enough. Since $|\boldsymbol{x}(t)| \leq c \Rightarrow |y_i(t)| \leq 2c, i = 1, 2, 3$, this and 3 mean that for $\boldsymbol{x}_0 \in B_0^\delta$ each $\mathfrak{Q}_i$ in fact acts as a binary quantizer at any large time. Thus the decoder receives in fact no more than one bit of information about processes with $\boldsymbol{x}_0 \in B_0^\delta$ via each channel. By treating three channels as one and retracing the arguments from the proof of Lemma 7.1 (see also [20, 25, 11]), we arrive at the necessary conditions for dissipativity $\lambda^2 \leq 2^3 \Leftrightarrow \lambda \leq 2^{3/2}$. At the same time, $\mathfrak{c} \geq 2$ and $\lambda \approx \sqrt{2}^{3\mathfrak{c}} > 2^{3/2}$. The contradiction obtained proves the lemma. □

Now we show that nevertheless *the system* (9.1) *is stabilizable*. The stabilizing controller lacks properties 2 and 3. It employs a 2-periodic quantization scheme applied to not only scaled but also shifted observations. We give only a sketch of the proof and focus on the main part of the stabilization process. It starts when a correct upper bound of the state norm is found via successive multiplying by a sufficiently large factor (see, e.g., subsection 8.2).

Each coder computes a number $\delta_i(t)$, and the decoder duplicates these computations. The meaning of the numbers and actions of the controller are different for odd and even times t. To explain them, we put $N := 2^{\mathfrak{c}}$.

At *odd* times, $\delta_1(t) = \delta_2(t), \delta_3(t) = \delta_1(t) + \delta_2(t)$, $\boldsymbol{x}(t) \in M(t) := \{\boldsymbol{x} : -\delta_i(t) \leq y_i < \delta_i(t), i = 1, 2\}$ and

1. For $i = 1, 2$, the ith coder determines which interval $[\mu_{j'}^{(i)}, \mu_{j'+1}^{(i)})$, $\mu_{j'}^{(i)} := j'\frac{2\delta_i(t)}{N}, j' = 0, \ldots, N-1$, contains $\overline{y}_i(t) := y_i(t) + \delta_i(t)$, and notifies the decoder about its serial number $j' = j^{(i)}$;
2. For $i = 3$, the coder (a) finds which interval $[\omega_j, \omega_{j+1}), \omega_j := j\frac{\delta_i(t)}{N}$ contains $\overline{y}_i(t)$, (b) notifies the decoder which subinterval $[\omega_j^{(\nu)}, \omega_j^{(\nu+1)})$, $\omega_j^{(\nu)} := \omega_j + \nu\frac{\omega_{j+1}-\omega_j}{N-2}$, $\nu = 0, \ldots, N-3$, contains $\overline{y}_i(t)$, and (c) uses the remaining bit to make the decoder aware of whether j is odd or even.

It is easy to see that $(j^{(1)} + j_*^{(2)})\frac{\delta_3(t)}{N} < \overline{y}_3(t) < (j^{(1)} + j_*^{(2)} + 2)\frac{\delta_3(t)}{N}$, where $j_*^{(2)} := N - j^{(2)} - 1$. So either $j = j^{(1)} + j_*^{(2)}$ or $j = j^{(1)} + j_*^{(2)} + 1$. Hence j can be found from $j^{(1)}, j^{(2)}$ and the information from (c).

3. From $j^{(1)}$, the decoder finds the strip $\{\boldsymbol{x} : y_1 \in -\delta_1(t) + [\mu_{j^{(1)}}^{(1)}, \mu_{j^{(1)}+1}^{(1)})\}$ that contains $\boldsymbol{x}(t)$. By reconstructing j and using ν, it finds another such strip $\{\boldsymbol{x} : y_3 \in -\delta_3(t) + [\omega_j^{(\nu)}, \omega_j^{(\nu+1)})\}$. Then the decoder selects a control driving the system from the center of the intersection of the strips to zero.

As a result, $\boldsymbol{x}(t+1) \in M(t+1) := \{\boldsymbol{x} : -\boldsymbol{\varepsilon}' \leq y_1 < \boldsymbol{\varepsilon}', -\boldsymbol{\varepsilon}'' \leq y_3 < \boldsymbol{\varepsilon}''\}$, where $\boldsymbol{\varepsilon}' := \lambda\delta_1(t)N^{-1} \approx \delta_1(t)2^{3/2\mathfrak{c}}2^{-\mathfrak{c}} = \delta_1(t)2^{\mathfrak{c}/2} > \delta_1(t)$ and $\boldsymbol{\varepsilon}'' := \lambda\delta_1(t)[N(N-2)]^{-1} \approx \delta_1(t)2^{\mathfrak{c}/2}(2^{\mathfrak{c}} - 1)^{-1} \leq 2\delta_1(t)2^{-\mathfrak{c}/2} < \delta_3(t)$ for $\mathfrak{c} \geq 2$. Thus, for one step, the domain $M(t) \ni \boldsymbol{x}(t)$ is stretched in one direction and tightened in the other.

4. The ith coder defines the next number δ_i as the bound for y_i when $\boldsymbol{x} \in M(t+1)$, i.e., $\delta_1(t+1) := \lambda N^{-1}\delta_i(t), \delta_3(t+1) := \frac{1}{2}\lambda\delta_3(t)[N(N-2)]^{-1}$, and $\delta_2(t+1) := \lambda\delta_2(t)N^{-1}[1 + (N-2)^{-1}]$.

At *even* times, $\delta_3(t) = \frac{\delta_1(t)}{N-2}, \delta_2(t) = \delta_1(t) + \delta_3(t), \boldsymbol{x}(t) \in M(t) = \{\boldsymbol{x} : -\delta_i(t) \leq y_i < \delta_i(t), i = 1, 3\}$, and

5. The operation 1 is carried out by the first and third coders $i = 1, 3$, and 2 is

done by the second one $i = 2$ with ω_j altered: $\omega_j := j\frac{4\delta_2(t)}{N}$.

The definitions of $j^{(1)}, j^{(3)}$ and j from 1 and 2, respectively, imply that $j^{(1)}, j^{(3)} \in [0 : N-1]$ and

$$-\delta_2(t) + \tfrac{2\delta_2(t)}{N}\left[j^{(1)} + \tfrac{N-1-j^{(3)}-j^{(1)}}{N-1}\right] < y_2 < -\delta_2(t) + \tfrac{2\delta_2(t)}{N}\left[j^{(1)} + \tfrac{N-1-j^{(3)}-j^{(1)}}{N-1}\right] + \tfrac{2\delta_2(t)}{N} \quad \Downarrow$$

$$-\delta_2(t) + \tfrac{2\delta_2(t)}{N}(j^{(1)} - 1) < y_2 < -\delta_2(t) + \tfrac{2\delta_2(t)}{N}(j^{(1)} + 2),$$

whereas $-\delta_2(t) + \frac{4\delta_2(t)}{N} j \le y_2 < -\delta_2(t) + \frac{4\delta_2(t)}{N}(j+1)$. It follows that either $j = j^{(1)}/2$ or $j = j^{(1)}/2 - 1$ if $j^{(1)}$ is even, and either $j = (j^{(1)} - 1)/2$ or $j = (j^{(1)} - 1)/2 + 1$ if $j^{(1)}$ is odd. Thus the number j can be found by the decoder on the basis of $j^{(1)}$ and the information from 2.c).

6. The decoder finds two strips containing $\boldsymbol{x}(t)$. The first of them is $\{\boldsymbol{x} : y_3 \in -\delta_3(t) + [\mu^{(3)}_{j^{(3)}}, \mu^{(3)}_{j^{(3)}+3})\}$, and the second one is $\{\boldsymbol{x} : y_2 \in -\delta_2(t) + [\omega^{(\nu)}_j, \omega^{(\nu+1)}_j)\}$. Then the decoder selects a control driving the system from the center of the intersection of the strips to zero.

As a result, $\boldsymbol{x}(t+1) \in M'(t+1) := \{\boldsymbol{x} : -\boldsymbol{\varepsilon}' \le y_3 < \boldsymbol{\varepsilon}', -\boldsymbol{\varepsilon}'' \le y_2 < \boldsymbol{\varepsilon}''\}$, where $\boldsymbol{\varepsilon}' := \lambda\delta_3(t)N^{-1}$ and $\boldsymbol{\varepsilon}'' := 1/2[\omega^{(\nu+1)}_j - \omega^{(\nu)}_j] = 2\lambda\delta_2(t)[N(N-2)]^{-1} = 2\lambda\delta_3(t)(N-1)[N(N-2)]^{-1} \le 3\lambda\delta_3(t)N^{-1}$ (since $N = 2^{\mathfrak{c}}$ and $\mathfrak{c} \ge 2$). The set $M'(t+1)$ is covered by the square $M(t+1) := \{\boldsymbol{x} : |x_1|, |x_2| \le 3\lambda\delta_3(t)N^{-1}\}$.

7. The numbers δ_i are updated so that $\delta_1 = \delta_2$ become the half length of the edge of $M(t+1)$ and $\delta_3 = \delta_1 + \delta_2$, i.e., $\delta_1(t+1) := 3\lambda\delta_1(t)[N(N-2)]^{-1}, \delta_2(t+1) := 3\lambda\delta_2(t)[N(N-1)]^{-1}, \delta_3(t+1) := 6\lambda\delta_3(t)N^{-1}$.

Now observe that for two steps, the square $M(t) \ni \boldsymbol{x}(t)$ with the edge $2\delta_1(t)$ (where t is odd) is transformed into the square $M(t+2)$ with the edge $2\delta_1(t) \times \frac{3\lambda^2}{N^2(N-2)}$. So if $\frac{3\lambda^2}{N^2(N-2)} < 1 \Leftrightarrow \lambda < 2^{3/2\mathfrak{c}}\sqrt{1/3(1-2^{1-\mathfrak{c}})}$, the system is stabilized. The last inequality is a bit worse than the necessary condition for stabilizability $\lambda < 2^{3/2\mathfrak{c}}$. This gap can be discarded by increasing the sample period to r time units. Indeed, this "transforms" λ into λ^r, N into N^r, and the sufficient condition $\lambda < 2^{3/2\mathfrak{c}}\sqrt{1/3(1-2^{1-\mathfrak{c}})}$ for stabilizability into $\lambda^r < 2^{3/2r\mathfrak{c}}\sqrt{1/3(1-2^{1-r\mathfrak{c}})} \Leftrightarrow \lambda < 2^{3/2\mathfrak{c}}[1/3(1-2^{1-r\mathfrak{c}})]^{2/r}$. The latter reduces to $\lambda < 2^{3/2\mathfrak{c}}$ as $r \to \infty$.

Thus even for a very simple system, violation of Assumption 4.3 complicates the coding-decoding scheme. We consider the study of the general case where this assumption does not hold as a topic of separate research.
