Proof. By (3.11), for all $\rho \in \tilde{K}_1(x, \bar{\mathcal{O}})$ and $\lambda > 0$ small enough, we must have

$$\varphi(t_0, x_0) = v_*(t_0, x_0) \geq e^{-\lambda \delta(\rho)} v_*(t_0, x_0 e^{\lambda \rho}) \geq e^{-\lambda \delta(\rho)} \varphi(t_0, x_0 e^{\lambda \rho}) \ .$$

Thus, dividing by λ and sending λ to 0 leads to the required result. □

Remark 6.1. Assume that $\mathbf{H}_{\mathcal{O}}$ holds and that for all $(t_0, x_0) \in \bar{D}^*$ and φ as in Proposition 6.1, we have

$$\mathcal{H} \varphi(t_0, x_0) \geq 0 \ .$$

Let (t_0, x_0) and φ be as in Proposition 6.1 with $x_0 \in \partial \mathcal{O}^*$. Recall from $\mathbf{H}_{\mathcal{O}}$ the definition of the function d and observe that (t_0, x_0) is also a local minimum of $(v_* - \varphi)(t, x) + \varepsilon^{-1} d(x)$ on $\bar{D}^*$ for all $\varepsilon > 0$. Thus, if the above assertion is true, $\varphi - \varepsilon^{-1} d$ must satisfy

$$\delta(\rho) v_*(t_0, x_0) - \rho' \mathrm{diag}\,[x_0] \left(D\varphi(t_0, x_0) - \varepsilon^{-1} Dd(x_0) \right) \geq 0 \quad \text{for all} \ \ \rho \in \tilde{K}_1 \ .$$

Now observe that for $\rho \in \tilde{K}_1 \setminus \tilde{K}_1(x_0, \bar{\mathcal{O}})$, there is a sequence of positive parameters $\lambda_n \to 0$ such that $d(x_0 e^{\lambda_n \rho}) < 0 = d(x_0)$ for all n; recall (3.7). This implies that $\rho' \mathrm{diag}\,[x_0]\, Dd(x_0) < 0$. Hence, sending $\varepsilon \to 0$ in the above inequality leads to a contradiction if $\tilde{K}_1 \setminus \tilde{K}_1(x_0, \bar{\mathcal{O}}) \neq \emptyset$.

PROPOSITION 6.2. *Let $(t_0, x_0) \in D$ and $\varphi \in C^2(\bar{D}^*)$ be such that (t_0, x_0) is a local minimum on $\bar{D}^*$ of $v_* - \varphi$ satisfying $(v_* - \varphi)(t_0, x_0) = 0$. Then*

$$-\mathcal{L}\varphi(t_0, x_0) \geq 0 \,. \tag{6.1}$$

Proof. The proof is standard. Let V be a bounded open neighborhood of (t_0, x_0) such that (t_0, x_0) is a minimum on $\bar{V} \cap \bar{D}^*$ of $v_* - \varphi$ and let $(t_n, x_n)_n$ be a sequence in $V \cap D$ such that $(t_n, x_n) \to (t_0, x_0)$ and $v(t_n, x_n) \to v_*(t_0, x_0)$. For ease of notation we write $(\tau_n, X^n) = (\tau_{t_n,x_n}, X_{t_n,x_n})$. Given a sequence $(\eta_n)_n$ of positive numbers such that $t_n + \eta_n < T$ for all n, we set

$$\theta_n := \inf\{s \in [t_n, T] \ : \ (s, X^n(s)) \notin V \cap D\} \wedge (t_n + \eta_n) \,.$$

Since $0 \in \tilde{K}$, (2.13), the assumption $g \geq 0$ (see (2.7)) and the inequality $v_* \geq \varphi$ on V imply that

$$v(t_n, x_n) \geq \mathbb{E}\left[\varphi\left(\theta_n, X^n_{\theta_n}\right) \mathbf{1}_{\theta_n < \tau_n}\right] \,.$$

Set $\epsilon_n := v(t_n, x_n) - \varphi(t_n, x_n)$ and observe that ϵ_n converges to 0 as n goes to infinity. Moreover, it follows from Itô's lemma that

$$\epsilon_n \geq \mathbb{E}\left[\int_{t_n}^{\theta_n} \mathcal{L}\varphi(s, X^n(s)) ds \; \mathbf{1}_{\theta_n < \tau_n}\right] \,. \tag{6.2}$$

Using standard estimates, we then observe that

$$\liminf_{n\to\infty} \mathbb{E}\left[\eta_n^{-1} \int_{t_n}^{\theta_n} \mathcal{L}\varphi(s, X^n(s)) ds \; \mathbf{1}_{\theta_n < \tau_n}\right] \geq \mathcal{L}\varphi(t_0, x_0)$$

whenever $\eta_n \to 0$. Thus, choosing $(\eta_n)_n$ such that $\epsilon_n/\eta_n \to 0$ and using (6.2) leads to the required result. □

PROPOSITION 6.3. *Assume that $\mathbf{H}_{\tilde{K}}$ and $\mathbf{H}_g$ hold. Then $v_* \geq \hat{g}$ on $\partial_x D^*$.*

Proof.

1. We first prove that for all $(t_0, x_0) \in \partial_x D^*$ and $\varphi \in C^2(\bar{D}^*)$ such that

$$0 = (v_* - \varphi)(t_0, x_0) \ = \ \min_{\bar{D}^*} (\text{strict})(v_* - \varphi) \,,$$

we have

$$\max\{v_*(t_0, x_0) - g(t_0, x_0) \ ; \ -\mathcal{L}\varphi(t_0, x_0)\} \geq 0 \,. \tag{6.3}$$

Assume to the contrary that

$$\max\{\varphi(t_0, x_0) - g(t_0, x_0) \ ; \ -\mathcal{L}\varphi(t_0, x_0)\} \leq -2\varepsilon \tag{6.4}$$

for some $\varepsilon > 0$. Let $(t_n, x_n)_n$ be a sequence in D converging to (t_0, x_0) such that

$$v(t_n, x_n) \to v_*(t_0, x_0) \,.$$

By (2.2) and $\mathbf{H}_g$, there is an open ball B centered on (t_0, x_0) such that

$$-\mathcal{L}\varphi \leq 0 \ \text{ on } B \cap \bar{D}^* \qquad \text{and} \qquad \varphi - g \leq -\varepsilon \ \text{ on } B \cap \partial_x D^* \,. \tag{6.5}$$

Obviously, we can assume that $(t_n, x_n) \in B$. Set $(\tau_n, X^n) = (\tau_{t_n,x_n} X_{t_n,x_n})$ and let θ_n be the first exit time of $(X^n(s))_{s\geq t_n}$ from B. Observing that $\xi := \min_{\partial B\cap\bar{D}}(v_* - \varphi) > 0$, using Itô's lemma and (6.5) one obtains

$$\begin{aligned}\varphi(t_n, x_n) &\leq \mathbb{E}\left[\varphi\left(\tau_n \wedge \theta_n, X^n(\tau^n \wedge \theta^n)\right)\right] \\ &\leq -(\varepsilon \wedge \xi) + \mathbb{E}\left[g\left(\tau_n, X^n(\tau^n)\right)\mathbf{1}_{\tau_n\leq\theta_n} + v\left(\theta_n, X^n(\theta^n)\right)\mathbf{1}_{\tau_n>\theta_n}\right] .\end{aligned}$$

Since $(\varphi(t_n, x_n) - v(t_n, x_n)) \to 0$ and $0 \in \tilde{K}$, this leads to a contradiction of (2.13) for n large enough.

2. We now prove that $v_*(t_0, x_0) \geq g(t_0, x_0)$ for all $(t_0, x_0) \in \partial_x D^*$. To see this, we assume to the contrary that

$$v_*(t_0, x_0) < g(t_0, x_0) \tag{6.6}$$

for some $(t_0, x_0) \in \partial_x D^*$ and work toward a contradiction of (6.3). Let $\varphi \in C^2(\bar{D}^*)$ be such that

$$0 = (v_* - \varphi)(t_0, x_0) \;=\; \min_{\bar{D}^*}(\text{strict})(v_* - \varphi) .$$

For $\varepsilon > 0$, define ϕ^ε on $\bar{D}^*$ by

$$\phi^\varepsilon(t, x) = \varphi(t, x) - \left(d(x) - \frac{d(x)^2}{\varepsilon}\right) ,$$

where d is defined in $\mathbf{H}_{\mathcal{O}}$. Since $d(x) - \frac{d(x)^2}{\varepsilon} > 0$ when $0 < d(x) < \varepsilon$, it follows that (t_0, x_0) is a strict local minimum of $(v_* - \phi^\varepsilon)$ for each $\varepsilon > 0$. By (6.3) and (6.6), we must therefore have

$$-\mathcal{L}\varphi(t_0, x_0) + \mathrm{Tr}\left[a(t_0, x_0)D^2 d(x_0)\right] - \frac{1}{\varepsilon}\mathrm{Tr}\left[a(t_0, x_0)Dd(x_0)Dd(x_0)'\right] \geq 0 ,$$

which leads to a contradiction of (2.2) when ε tends to 0.

3. In view of step 2 and the definition of $\hat{g}$ in (3.5), (3.11) concludes the proof. □

PROPOSITION 6.4. *Assume that* $\mathbf{H}_{\tilde{K}}$ *and* $\mathbf{H}_g$ *hold. Then* $v_*(T, \cdot) \geq \hat{g}(T, \cdot)$ *on* $\bar{\mathcal{O}}^*$.

Proof. Fix $x_0 \in \bar{\mathcal{O}}^*$ and let $(t_n, x_n)_n$ be a sequence in D converging to (T, x_0) such that $v(t_n, x_n) \to v_*(T, x_0)$. Set $(\tau_n, X^n) = (\tau_{t_n,x_n}, X_{t_n,x_n})$. Since σ is bounded (see (i) of (2.2)), one easily checks that $(\tau_n, X^n(\tau_n)) \to (T, x_0)$ $\mathbb{P}$-a.s., after possibly passing to a subsequence. In view of $\mathbf{H}_g$, it follows that

$$\liminf_{n\to\infty}\left(g(\tau_n, X^n(\tau_n))\mathbf{1}_{\tau_n<T} + g(T, X^n(T))\mathbf{1}_{\tau_n=T}\right) \geq g(T, x_0) .$$

Since $g \geq 0$ by assumption and $0 \in \tilde{\mathcal{K}}$, it follows from Fatou's lemma and (2.11) that $v_*(T, x_0) \geq g(T, x_0)$. The proof is concluded by using (3.11) and recalling the definition of $\hat{g}(T, \cdot)$ in (3.3). □

6.2. Subsolution property. In view of Propositions 6.1, 6.2, 6.3, and 6.4, we already know that v_* is a supersolution of $\mathcal{B}_{\mathrm{d}}\varphi = 0$ on $\bar{D}^*$. To conclude the proof of (i) of Theorem 3.1, it remains to show that v^* is a subsolution of $\mathcal{B}\varphi = 0$ on $\bar{D}^*$. This is a consequence of Propositions 6.5, 6.6, and 6.7 below.

PROPOSITION 6.5. *Let* $(t_0, x_0) \in D$ *and* $\varphi \in C^2(\bar{D}^*)$ *be such that* (t_0, x_0) *is a local maximum on* $\bar{D}^*$ *of* $v^* - \varphi$ *satisfying* $(v^* - \varphi)(t_0, x_0) = 0$. *Then*

$$\min\left\{-\mathcal{L}\varphi(t_0, x_0)\ ;\ \mathcal{H}\varphi(t_0, x_0)\right\} \leq 0 . \tag{6.7}$$

Proof. The proof is standard. We assume that

$$G(t_0,x_0) := \inf_{\rho\in\tilde{K}} \{-\mathcal{L}\varphi(t_0,x_0) + \delta(\rho)\varphi(t_0,x_0) - \rho' \mathrm{diag}\,[x_0]\, D\varphi(t_0,x_0)\} > 0, \tag{6.8}$$

and work towards a contradiction. If (6.8) holds, then it follows from (i) of (2.2) that there exists some $\alpha > 0$ such that

$$G(t,x) > 0 \quad \text{for all } (t,x) \in B_0 := B(t_0,\alpha) \times B(x_0,\alpha) \subset D\ . \tag{6.9}$$

Let $(t_n,x_n)_{n\geq 0}$ be a sequence in B_0 such that $(t_n,x_n) \to (t_0,x_0)$ and $v(t_n,x_n) \to v^*(t_0,x_0)$. Observe that $\beta_n := \varphi(t_n,x_n) - v(t_n,x_n) \to 0$. Set $X^n = X_{t_n,x_n}$ and define the stopping times

$$\theta_n := T \wedge \inf\{s \in [t_n,T] \ :\ (s,X^n(s)) \notin B_0\}\ .$$

Let $\partial_p B_0 = [t_0,t_0+\alpha]\times\partial B(x_0,\alpha) \cup \{t_0+\alpha\}\times\bar{B}(x_0,\alpha)$ denote the parabolic boundary of B_0 and observe that

$$0 \ > \ -\zeta := \sup_{(t,x)\in\partial_p B_0} (v^* - \varphi)(t,x)\ .$$

Then we deduce from Itô's lemma applied on φ, (6.9), Girsanov's theorem (see the discussion in section 2.2), and the above assertion that

$$v(t_n,x_n) + \beta_n \geq \zeta + \sup_{\vartheta\in\tilde{\mathcal{K}}} \mathbb{E}^\vartheta \left[\mathcal{E}^\vartheta_{\theta_n} v(\theta_n, X^n(\theta_n))\right]\ .$$

Since by construction $\theta_n < \tau_{t_n,x_n}$ and $\beta_n \to 0$, we obtain a contradiction of (2.13). □

Proposition 6.6. *Assume that* $\mathbf{H}_{\mathcal{O}}$ *and* $\mathbf{H}_g$ *hold. Let* $(t_0,x_0) \in \partial_x D^*$ *and* $\varphi \in C^2(\bar{D}^*)$ *be such that* (t_0,x_0) *is a local maximum on* $\bar{D}^*$ *of* $v_* - \varphi$ *satisfying* $(v_* - \varphi)(t_0,x_0) = 0$. *Then*

$$\min\{v^*(t_0,x_0) - \hat{g}(t_0,x_0)\ ;\ \mathcal{H}\varphi(t_0,x_0)\} \leq 0\ .$$

Proof.

1. By using similar arguments as in the proof of Proposition 6.5, we first obtain that

$$\min\{v^*(t_0,x_0) - g(t_0,x_0)\ ;\ -\mathcal{L}\varphi(t_0,x_0)\ ;\ \mathcal{H}\varphi(t_0,x_0)\} \leq 0\ . \tag{6.10}$$

2. We now proceed by contradiction as in step 2 of the proof of Proposition 6.3 to show that

$$\min\{v^*(t_0,x_0) - g(t_0,x_0)\ ;\ \mathcal{H}\varphi(t_0,x_0)\} \leq 0\ .$$

As usual, we can assume that (t_0,x_0) is a strict local maximum of $v^* - \varphi$ on $\bar{D}^*$. Assume that for some $\eta > 0$,

$$\min\left\{v^*(t_0,x_0) - g(t_0,x_0)\ ;\ \inf_{\rho\in\tilde{K}_1} \delta(\rho)v^*(t_0,x_0) - \rho' \mathrm{diag}\,[x_0]\, D\varphi(t_0,x_0)\right\} > \eta.$$

Let $\lambda > 0$ be a fixed parameter to be chosen later and for $\varepsilon > 0$ set on $\bar{D}^*$

$$\phi^\varepsilon(t,x) = \varphi(t,x) + \lambda d(x) - \frac{d^2(x)}{\varepsilon}\ ,$$

where d is defined in $\mathbf{H}_{\mathcal{O}}$. For $x \in \bar{O}^*$ such that $d(x) < \varepsilon\lambda$ we have $\lambda d(x) - \frac{d^2(x)}{\varepsilon} \geq 0$. It follows that (t_0, x_0) is a local maximum of $v^* - \phi^\varepsilon$. Moreover,

$$\min\left\{ v^*(t_0,x_0) - g(t_0,x_0) \; ; \; \inf_{\rho\in\tilde{K}_1} \delta(\rho)v^*(t_0,x_0) - \rho' \mathrm{diag}\,[x_0]\, D\phi^\varepsilon(t_0,x_0) \right\} > 0,$$

for $\lambda > 0$ small enough since $d(x_0) = 0$ and therefore $D\phi^\varepsilon(t_0,x_0) = D\varphi(t_0,x_0) + \lambda Dd(x_0) - 2Dd(x_0)d(x_0)/\varepsilon = D\varphi(t_0,x_0) + \lambda Dd(x_0)$. Thus, it follows from step 1 that we must have

$$-\mathcal{L}(\varphi(t_0,x_0) + \lambda d(x_0)) + \frac{1}{\varepsilon}\mathrm{Tr}\left[a(t_0,x_0)Dd(x_0)Dd(x_0)'\right] \leq 0 \; .$$

Sending $\varepsilon \to 0$ leads to a contradiction of (i) of (2.2). □

PROPOSITION 6.7. *Assume that* $\mathbf{H}_g$ *holds. Then* $v^*(T,\cdot) \leq \hat{g}(T,\cdot)$ *on* $\bar{\mathcal{O}}^*$.

Proof.

1. Let $(t_n, x_n)_n$ be a sequence in D which converges to (T, x_0) and such that $v(t_n,x_n) \to v^*(T,x_0)$. Set $(\tau_n, X^n) = (\tau_{t_n,x_n}, X_{t_n,x_n})$. By the dual formulation (2.11), there is some $\vartheta^n \in \tilde{\mathcal{K}}$ such that

$$v(t_n,x_n) \leq \mathbb{E}^{\vartheta^n}\left[e^{-\int_{t_n}^{\tau_n}\delta(\vartheta_s^n)ds} g(\tau_n, X^n(\tau_n)) \right] + n^{-1} \; .$$

Since $\tilde{K}$ is a convex cone, δ is sublinear, and $g \geq 0$, it follows that

$$\begin{aligned} e^{-\int_{t_n}^{\tau_n}\delta(\vartheta_s^n)ds} g(\tau_n, X^n(\tau_n)) &\leq e^{-\delta(\int_{t_n}^{\tau_n}\vartheta_s^n ds)} g(\tau_n, X^n(\tau_n)) \\ &\leq \sup_{t_n\leq t\leq T} \hat{g}\left(t, X^n(t) e^{-\int_{t_n}^t \vartheta_s^n ds}\right) \end{aligned}$$

by definition of $\hat{g}$ in (3.3)–(3.5). In view of the above inequalities and the definition of (t_n, x_n), it remains to show that

$$\limsup_{n\to\infty} \mathbb{E}^{\vartheta^n}\left[\sup_{t_n\leq t\leq T} \hat{g}\left(t, Z^n(t)\right) \right] \leq \hat{g}(T,x_0) \; , \tag{6.11}$$

where $Z^n := X^n e^{-\int_{t_n}^{\cdot}\vartheta_s^n ds}$ solves on $[t_n, T]$

$$dZ^n(t) = \mathrm{diag}\,[Z^n(t)]\,\sigma(t,X^n(t))dW_t^n \; , \; Z^n(t_n) = x_n \; ,$$

and W^n is a standard Brownian motion under $\mathbb{Q}^{\vartheta^n}$, recall the discussion of section 2.2. Using the boundedness assumption on σ (see (2.2)), we deduce from standard arguments that there is a constant $C > 0$ independent of n such that

$$\mathbb{E}^{\vartheta^n}\left[\sup_{t_n\leq t\leq T} |Z^n(t) - x_0| \right] \leq C\left(|x_n - x_0| + (T-t_n)^{1/2} \right) \; .$$

We shall prove in step 2 that for each $\varepsilon > 0$ there is a Lipschitz function Ψ_ε such that $|\hat{g}(T,x_0) - \Psi_\varepsilon(T,x_0)| \leq \varepsilon$ and $\Psi_\varepsilon \geq \hat{g}$. It follows that, for each ε, we can find some finite $K_\varepsilon > 0$ such that

$$\begin{aligned} \limsup_{n\to\infty} \mathbb{E}^{\vartheta^n}\left[\sup_{t_n\leq t\leq T} \hat{g}\left(t, Z^n(t)\right) \right] &\leq \limsup_{n\to\infty} \mathbb{E}^{\vartheta^n}\left[\sup_{t_n\leq t\leq T} \Psi_\varepsilon\left(t, Z^n(t)\right) \right] \\ &\leq \Psi_\varepsilon(T,x_0) + \limsup_{n\to\infty} K_\varepsilon\left(|x_n - x_0| + (T-t_n)^{1/2} \right) \\ &= \Psi_\varepsilon(T,x_0) \; . \end{aligned}$$

By definition of Ψ_ε this implies that

$$\limsup_{n\to\infty} \mathbb{E}^{\vartheta^n}\left[\sup_{t_n\le t\le T} \hat{g}\left(t, Z^n(t)\right)\right] \le \hat{g}(T,x_0)+\varepsilon\ ,$$

and the proof of (6.11) is concluded by sending ε to 0.

2. We conclude this proof by constructing the sequence of functions $(\Psi_\varepsilon)_{\varepsilon>0}$. For $(t,x)\in[0,T]\times(0,\infty)^d$, we define

$$G_k(t,x) = \sup_{(s,z)\in[0,T]\times(0,\infty)^d} \left[\hat{g}(s,z) - k\left(|s-t|+|z-x|\right)\right],\ k\ge 1\ .$$

Clearly, $G_k\ge\hat{g}$ and G_k is k-Lipschitz. Moreover, taking k large enough, it follows from the linear growth and upper-semicontinuity assumptions on $\hat{g}$ (see $\mathbf{H}_g$) that for all $(t,x)\in[0,T]\times(0,\infty)^d$, the maximum is attained in the above definition by some $(t_k(t,x),x_k(t,x))$. In particular,

$$G_k(t,x) = \hat{g}(t_k(t,x),x_k(t,x)) - k\left(|t_k(t,x)-t|+|x_k(t,x)-x|\right) \ge \hat{g}(t,x)\ .$$

Using the linear growth of $\hat{g}$ again, we deduce that $(t_k(t,x),x_k(t,x))\to(t,x)$ as $k\to\infty$ after possibly passing to a subsequence. Since $\hat{g}$ is upper-semicontinuous, this also implies that

$$\hat{g}(T,x_0)\ge \limsup_{k\to\infty}\hat{g}(t_k(T,x_0),x_k(T,x_0)) \ \ge\ \limsup_{k\to\infty} G_k(T,x_0)\ge \hat{g}(T,x_0)\ .$$

We can then choose k_ε such that $|G_{k_\varepsilon}(T,x_0)-\hat{g}(T,x_0)|\le\varepsilon$ and set $\Psi_\varepsilon := G_{k_\varepsilon}$. □

6.3. Characterization of v_* as the smallest supersolution. In this section, we prove that $v=v_*$ on D and that v_* is the smallest supersolution of (3.8).

To this end, we introduce a sequence of approximating control problems as follows. For all $\eta\ge1$, we define $\tilde{K}_\eta$ as the set of elements $\rho\in\tilde{K}$ such that $|\rho|\le\eta$ and $\tilde{\mathcal{K}}_\eta$ as the set of elements $\vartheta\in\tilde{\mathcal{K}}$ that take values in $\tilde{K}_\eta$. We then define on $\bar{D}^*$

$$w_\eta(t,x) = \sup_{\vartheta\in\tilde{\mathcal{K}}_\eta} \mathbb{E}^\vartheta\left[\mathcal{E}^\vartheta_\tau g\left(\tau_{t,x}, X_{t,x}(\tau_{t,x})\right)\right]\ . \tag{6.12}$$

It is clear that w_η is a nondecreasing sequence, and it follows directly from Theorem 2.1 and the definition of $\tilde{\mathcal{K}}$ that

$$\lim_{\eta\to\infty}\uparrow w_\eta(t,x) = v(t,x) \quad \text{for all}\ \ (t,x)\in\bar{D}^*\ . \tag{6.13}$$

For $\eta\ge1$, let us introduce the operator $\mathcal{G}_\eta$ defined for smooth functions by

$$\mathcal{G}_\eta\varphi(t,x) := \min_{\rho\in\tilde{K}_\eta}\left\{-\mathcal{L}\varphi(t,x)+\delta(\rho)\varphi(t,x)-\rho'\mathrm{diag}\,[x]\,D\varphi(t,x)\right\}\ .$$

PROPOSITION 6.8. *Let the conditions $\mathbf{H}_g$ and $\mathbf{H}_\mathcal{O}$ hold. Then, for all $\eta\ge1$, w^*_η is a viscosity subsolution on D of*

$$\mathcal{G}_\eta\varphi(t_0,x_0)=0\ . \tag{6.14}$$

Moreover, $w^*_\eta\le\hat{g}$ on $\partial_x D^*\cup\partial_T D^*$.

Proof. The proof is standard. Set $\varphi\in C^2(D)$ and let (t_0,x_0) be a strict global maximizer of $w^*_\eta-\varphi$ on $\bar{D}^*$ such that $(w^*_\eta-\varphi)(t_0,x_0)=0$.

1. If $(t_0, x_0) \in D$, then the result follows from the same arguments as in the proof of Proposition 6.5.
2. Arguing as in Proposition 6.5 again, we deduce that

$$\min\left\{w_\eta^*(t_0,x_0) - \hat{g}(t_0,x_0)\ ,\ \mathcal{G}_\eta\varphi(t_0,x_0)\right\} \le 0$$

if $(t_0, x_0) \in \partial_x D^*$. The required result is then obtained by arguing as in step 2 of the proof of Proposition 6.6.
3. Since $w_\eta^* \le v^*$, the inequality $w_\eta^*(T,\cdot) \le \hat{g}(T,\cdot)$ follows from Proposition 6.7. □

PROPOSITION 6.9. *Assume that* $\mathbf{H}_g$ *holds. Let* u *(resp.,* w*) be a viscosity subsolution (resp., supersolution) of* (6.14) *on* D *satisfying the growth condition* (3.10)*. If* $u \le w$ *on* $\partial_x D^* \cup \partial_T D^*$*, then* $u \le w$ *on* $\bar{D}^*$*.*

Proof.

1. Given $\kappa > 0$, we set $\tilde{u}(t,x) = e^{\kappa t}u(t,x)$ and $\tilde{w}(t,x) = e^{\kappa t}w(t,x)$ so that $\tilde{u}$ and $\tilde{v}$ are, respectively, sub- and supersolutions of

$$\tilde{\mathcal{G}}_\eta\varphi(t,x) := \min_{\rho\in\tilde{K}_\eta}\left\{(\kappa+\delta(\rho))\varphi(t,x) - \mathcal{L}^\rho\varphi(t,x)\right\} \ =\ 0\ ,$$

where for $\rho \in \tilde{K}$

$$\mathcal{L}^\rho\varphi(t,x) := \mathcal{L}\varphi(t,x) + \rho'\mathrm{diag}\,[x]\,D\varphi(t,x)\ .$$

Recall the definition of $\bar{\gamma}$ in $\mathbf{H}_g$ and set

$$\gamma = 2\bar{\gamma} \in \mathbb{R}^d_+, \tilde{\gamma} = (2,\dots,2) \in (0,\infty)^d\ . \tag{6.15}$$

Define on $\bar{D}^*$

$$\beta(t,x) := e^{\tau(T-t)}\left(1 + x^\gamma + x^{\tilde{\gamma}}\right).$$

Observing that

$$\frac{\partial}{\partial t}\beta(t,x) = -\tau\beta(t,x), \mathrm{diag}\,[x]\,D\beta(t,x) = e^{\tau(T-t)}\left(x^\gamma\gamma + x^{\tilde{\gamma}}\tilde{\gamma}\right)\ ,$$
$$\mathrm{Tr}\left[a(t,x)D^2\beta(t,x)\right] = e^{\tau(T-t)}\left(x^\gamma\mathrm{Tr}\left[\sigma\sigma'(t,x)M\right] + x^{\tilde{\gamma}}\mathrm{Tr}\left[\sigma\sigma'(t,x)\tilde{M}\right]\right)$$

with $M := [\gamma^i(\gamma^i - 1)\mathbf{1}_{i=j} + \gamma^i\gamma^j\mathbf{1}_{i\neq j}]_{ij}$ and $\tilde{M}$ defined similarly, it follows from (i) of (2.2) and the compactness of $\tilde{K}_\eta$ that we can find $\tau > 0$ such that

$$\tilde{\mathcal{G}}_\eta\beta(t,x) \ge 0 \quad \text{on } \bar{D}^*\ . \tag{6.16}$$

2. We now argue by contradiction and assume that

$$\sup_{\bar{D}^*}(\tilde{u} - \tilde{w}) > 0\ .$$

2.1. In view of the growth condition on $\tilde{u}$, $\tilde{w}$ and (6.15), we then have

$$0 < 2m := \sup_{\bar{D}^*}(\tilde{u} - \tilde{w} - 2\alpha\beta) < \infty \tag{6.17}$$

for $\alpha > 0$ small enough. For $x \in \bar{D}^*$, set

$$f(x) = \sum_{i=1}^{d} (x^i)^{-2} \,. \tag{6.18}$$

Combining the growth condition on $\tilde{u}$, $\tilde{w}$ with (6.15) and the definition of f implies that, for each $\varepsilon > 0$, the upper-semicontinuous function

$$\Phi^\varepsilon := \tilde{u} - \tilde{w} - 2(\alpha\beta + \varepsilon f)$$

admits a maximum $(t_\varepsilon, x_\varepsilon)$ on $\bar{D}^*$. By (6.17), we can choose ε small enough so that

$$\Phi^\varepsilon(t_\varepsilon, x_\varepsilon) \geq m > 0 \,. \tag{6.19}$$

Let $(t_0^\varepsilon, x_0^\varepsilon)$ be a sequence in D such that $\Phi^\varepsilon(t_0^\varepsilon, x_0^\varepsilon) \to 2m$. By (6.17) and the definition of $(t_\varepsilon, x_\varepsilon)$, we have

$$\begin{aligned}
\liminf_{\varepsilon\to 0} \; (2m - 2\varepsilon f(x_\varepsilon)) &\geq \liminf_{\varepsilon\to 0} \; (\tilde{u} - \tilde{w} - 2(\alpha\beta + \varepsilon f))(t_\varepsilon, x_\varepsilon) \\
&\geq \lim_{\varepsilon\to 0} \; (\tilde{u} - \tilde{w} - 2(\alpha\beta + \varepsilon f))(t_0^\varepsilon, x_0^\varepsilon) \\
&= 2m \,.
\end{aligned}$$

This shows that

$$\limsup_{\varepsilon\to 0} \; \varepsilon f(x_\varepsilon) = \limsup_{\varepsilon\to 0} \; \varepsilon \sum_{i=1}^{d} (x_\varepsilon^i)^{-2} = 0 \,,$$

which, by (i) of (2.2) and the compactness of $\tilde{K}_\eta$, implies

$$\limsup_{\varepsilon\to 0} \; \sup_{\rho \in \tilde{K}_\eta} \; \varepsilon \left(|f(x_\varepsilon)| + |\mathcal{L}^\rho f(x_\varepsilon)| \right) = 0 \,. \tag{6.20}$$

2.2. For $(t, x) \in [0, T] \times \mathbb{R}^d$, set $G^\varepsilon(t, x) = |t - t_\varepsilon|^4 + |x - x_\varepsilon|^4$. Given $n > 0$, it follows from similar arguments to those above that the map

$$\begin{aligned}
\Phi_n^\varepsilon(t, x, y) := \tilde{u}(t, x) - \tilde{w}(t, y) - \frac{n}{2}|x - y|^2 - \alpha \left(\beta(t, x) + \beta(t, y) \right) \\
- \; \varepsilon \left(f(x) + f(y) + G^\varepsilon(t, x) \right)
\end{aligned}$$

also admits a maximum point $(t_n^\varepsilon, x_n^\varepsilon, y_n^\varepsilon) \in \bar{D}^*$ which necessarily satisfies

$$\Phi_n^\varepsilon(t_n^\varepsilon, x_n^\varepsilon, y_n^\varepsilon) \geq \Phi_n^\varepsilon(t_\varepsilon, x_\varepsilon, x_\varepsilon) = \Phi^\varepsilon(t_\varepsilon, x_\varepsilon) \geq m > 0 \,. \tag{6.21}$$

Using the growth assumption on u and w, (6.15), and the definition of f again, one easily checks that this implies that the sequence $(t_n^\varepsilon, x_n^\varepsilon, y_n^\varepsilon)_n$ is bounded and therefore converges, after possibly passing to a subsequence. Moreover, (6.21) implies that $n|x_n^\varepsilon - y_n^\varepsilon|^2 + \varepsilon f(x_n^\varepsilon)$ is bounded. Thus, there is $(\bar{t}_\varepsilon, \bar{x}_\varepsilon) \in \bar{D}^*$ such that $(t_n^\varepsilon, x_n^\varepsilon, y_n^\varepsilon) \to (\bar{t}_\varepsilon, \bar{x}_\varepsilon)$ and, by the definition of $(t_\varepsilon, x_\varepsilon)$ and (6.21), we must have

$$\begin{aligned}
\Phi^\varepsilon(t_\varepsilon, x_\varepsilon) &\geq \Phi^\varepsilon(\bar{t}_\varepsilon, \bar{x}_\varepsilon) \\
&\geq \limsup_{n\to\infty} \left(\Phi^\varepsilon(\bar{t}_\varepsilon, \bar{x}_\varepsilon) - \frac{n}{2}|x_n^\varepsilon - y_n^\varepsilon|^2 - \varepsilon G^\varepsilon(t_n^\varepsilon, x_n^\varepsilon) \right) \\
&\geq \Phi^\varepsilon(t_\varepsilon, x_\varepsilon) \,.
\end{aligned}$$

This shows that, up to a subsequence,

$$(t_n^\varepsilon, x_n^\varepsilon) \to (t_\varepsilon, x_\varepsilon) \in \bar{D}^* \ , \ \Phi_n^\varepsilon(t_n^\varepsilon, x_n^\varepsilon, y_n^\varepsilon) \to \Phi^\varepsilon(t_\varepsilon, x_\varepsilon) \quad \text{and} \quad n|x_n^\varepsilon - y_n^\varepsilon|^2 \to 0 \tag{6.22}$$

as $n \to \infty$.

3. Since the upper-semicontinuous function $u - w$ is nonpositive on $\partial_x D^* \cup \partial_T D^*$, it follows from (6.19) that $(t_\varepsilon, x_\varepsilon) \in D$ and that we may assume that $(t_n^\varepsilon, x_n^\varepsilon, y_n^\varepsilon) \in [0,T) \times \mathcal{O}^2$ for each $n > 0$. Using Ishii's lemma and following standard arguments (see [5, Theorem 8.3] and the discussion after [5, Theorem 3.2]) we deduce from the viscosity property of $\tilde{u}$ and $\tilde{w}$ that for some $\hat{\rho}_n^\varepsilon$ in the compact set $\tilde{K}_\eta$

$$\begin{aligned} 0 \le\ & (\kappa + \delta(\hat{\rho}_n^\varepsilon))(\tilde{w}(t_n^\varepsilon, y_n^\varepsilon) - \tilde{u}(t_n^\varepsilon, x_n^\varepsilon)) + \frac{1}{2}\mathrm{Tr}\,[a(t_n^\varepsilon, x_n^\varepsilon)A_n^\varepsilon - a(t_n^\varepsilon, y_n^\varepsilon)B_n^\varepsilon] \\ & + (\hat{\rho}_n^\varepsilon)'\mathrm{diag}\,[x_n^\varepsilon - y_n^\varepsilon]\, q_n^\varepsilon \\ & + \left\{ \mathcal{L}^{\hat{\rho}_n^\varepsilon}(\alpha\beta + \varepsilon[f + G^\varepsilon])(t_n^\varepsilon, x_n^\varepsilon) + \mathcal{L}^{\hat{\rho}_n^\varepsilon}(\alpha\beta + \varepsilon f)(t_n^\varepsilon, y_n^\varepsilon) \right\} , \end{aligned}$$

where

$$q_n^\varepsilon := n(x_n^\varepsilon - y_n^\varepsilon) \tag{6.23}$$

and A_n^ε, B_n^ε are two symmetric matrices satisfying

$$-3n \begin{pmatrix} I_d & 0 \\ 0 & I_d \end{pmatrix} \le \begin{pmatrix} A_n^\varepsilon & 0 \\ 0 & -B_n^\varepsilon \end{pmatrix} \le 3n \begin{pmatrix} I_d & -I_d \\ -I_d & I_d \end{pmatrix} . \tag{6.24}$$

Using (6.16), (6.21), (6.22), (6.23), (6.24), and (i) of (2.2), we then deduce that

$$\begin{aligned} 0 \le\ & -m(\kappa + \delta(\hat{\rho}_n^\varepsilon)) + C\, n|x_n^\varepsilon - y_n^\varepsilon|^2 - \varepsilon(\kappa + \delta(\hat{\rho}_n^\varepsilon))\, \{(f + G^\varepsilon)(t_n^\varepsilon, x_n^\varepsilon) \\ & +\ f(y_n^\varepsilon)\} + \varepsilon \left\{ \mathcal{L}^{\hat{\rho}_n^\varepsilon}(f + G^\varepsilon)(t_n^\varepsilon, x_n^\varepsilon) + \mathcal{L}^{\hat{\rho}_n^\varepsilon} f(y_n^\varepsilon) \right\} \end{aligned}$$

for some $C > 0$ independent of n. Sending n to ∞, it follows from the compactness of $\tilde{K}_\eta$ and (6.22) that

$$0 \le -m(\kappa + \delta(\hat{\rho}^\varepsilon)) + 2\varepsilon \left\{ \mathcal{L}^{\hat{\rho}^\varepsilon} f(x_\varepsilon) - (\kappa + \delta(\hat{\rho}^\varepsilon)) f(x_\varepsilon) \right\}$$

for some $\hat{\rho}^\varepsilon \in \tilde{K}_\eta$. Sending ε to 0 and using (6.20) finally leads to a contradiction since $\kappa, m > 0$ and $\delta \ge 0$ by (2.9). □

We now conclude the proof of Theorem 3.1.

Proof of (ii) *and* (iii) *of Theorem* 3.1. Observe that a supersolution u of $\mathcal{B}_{\mathrm{d}}\varphi = 0$ on $\bar{D}^*$ is also a supersolution of (6.14) on D, and, by Proposition 6.8, satisfies $u \ge w_\eta$ on $\partial_x D^* \cup \partial_T D^*$ for all $\eta \ge 1$. In view of Proposition 6.9 and (6.13), it follows that $u \ge \lim_{\eta\to\infty} \uparrow w_\eta = v$ on D whenever u satisfies (3.10). In particular, since v_* is a supersolution of (3.8) satisfying (3.10) (see Proposition 3.1) we have $v_* \ge v$ so that $v_* = v \le u$ on D and $v_* \le u_*$ on $\bar{D}^*$. □

7. A uniqueness result. We now proceed with the proof of Theorem 3.2. It is an immediate consequence of Proposition 3.1, Theorem 3.1, and the following comparison result.

THEOREM 7.1. *Assume that the conditions of Theorem* 3.2 *hold. Let u be an upper-semicontinuous viscosity subsolution of $\mathcal{B}\varphi = 0$ on $\bar{D}^*$. Assume furthermore that u satisfies the growth condition* (3.10). *Then $u \le v_*$ on $\bar{D}^*$.*

Remark 7.1.

1. It will be clear from the proof that the above theorem can be stated as follows. Let u and w be, respectively, the sub- and supersolution of $\mathcal{B}\varphi = 0$ and $\mathcal{B}_{\rm d}\varphi = 0$ on $D \cup \partial_x D^*$ satisfying the growth condition (3.10). Assume further that w satisfies

   C: For all $(t,x) \in D \cup \partial_x D^*$ and $\rho \in \tilde{K}_1(x, \bar{\mathcal{O}})$ there exists $\lambda_0 > 0$ s.t. $\lambda \in [0, \lambda_0] \mapsto w(t, xe^{\lambda\rho})e^{-\lambda\delta(\rho)}$

   is nonincreasing.

   Then $u \le w$ on $\partial_T D^*$ implies $u \le w$ on $\bar{D}^*$.
2. One can actually show that any supersolution of $\mathcal{H}_{\rm d}\varphi = 0$ satisfies condition C. Since it is not useful for our main result, we do not provide the proof, which is rather long.
3. Combining the above assertions provides a general comparison result for super- and subsolutions of, respectively, $\mathcal{B}_{\rm d}\varphi = 0$ and $\mathcal{B}\varphi = 0$ on $D \cup \partial_x D^*$.

In order to prove Theorem 7.1, we need the following intermediate lemma.

LEMMA 7.1. *Assume that $\mathbf{H}_{\mathcal{O}}$ holds. Fix $x_0 \in \partial\mathcal{O}^*$. If $\rho \in \tilde{K}_1$ satisfies*

$$Dd(x_0)' \operatorname{diag}[x_0]\, \rho \;>\; 0\,,$$

then there exists some positive parameters r_0 and λ_0 such that $xe^{\lambda\rho} \in \mathcal{O}$ for all $x \in B(x_0, r_0) \cap \bar{\mathcal{O}}$ and $\lambda \in (0, \lambda_0)$.

Proof. Recall from $\mathbf{H}_{\mathcal{O}}$ that the function d is C^2 on a neighborhood of x_0. Thus, $Dd(x_0)' \operatorname{diag}[x_0]\, \rho > 0$ implies that for some $\delta_0, r_0 > 0$

$$Dd(\bar{x})' \operatorname{diag}[x]\, \rho \;\ge\; \delta_0 \quad \text{for all } \bar{x}, x \in B(x_0, r_0)\,. \tag{7.1}$$

Given that $xe^{\lambda\rho} - x = \lambda \operatorname{diag}[x]\, \rho + o(\lambda)$, we can fix some $\lambda_0 > 0$ such that, for all $x \in B(x_0, r_0/2)$ and $\lambda \in (0, \lambda_0)$,

$$[x, xe^{\lambda\rho}] \subset B(x_0, r_0) \quad \text{and} \quad |xe^{\lambda\rho} - x - \lambda \operatorname{diag}[x]\, \rho| < \frac{\lambda\delta_0/2}{1 + \max\limits_{x \in \bar{B}(x_0, r_0)} |Dd(x)|}. \tag{7.2}$$

Let x be in $B(x_0, r_0/2) \cap \bar{\mathcal{O}}$, so that $d(x) \ge 0$. Since d is C^1, for each $\lambda \in (0, \lambda_0)$ there exists $\bar{x} \in [x, xe^{\lambda\rho}] \subset B(x_0, r_0)$ such that

$$\begin{aligned} d(xe^{\lambda\rho}) &= d(x) + Dd(\bar{x})' \left(xe^{\lambda\rho} - x\right) \\ &= d(x) + \lambda Dd(\bar{x})' \operatorname{diag}[x]\, \rho + Dd(\bar{x})' \left[xe^{\lambda\rho} - x - \lambda \operatorname{diag}[x]\, \rho\right] \\ &\ge d(x) + \lambda \frac{\delta_0}{2} \;>\; 0\,, \end{aligned}$$

where the last inequality follows from (7.1) and (7.2). This shows that $xe^{\lambda\rho} \in \mathcal{O}$. □

Proof of Theorem 7.1. In order to avoid too many complications, we make the proof under the following assumption in place of $\mathbf{H}'$:

$\mathbf{H}''$: (i) There exists $\varrho > 1$ s.t. $\varrho\bar{\gamma} \in K \cap (0, \infty)^d$.
(ii) $0 \in \operatorname{int}(K)$.
(iii) For all $x \in \partial\mathcal{O}^*$ there exists $\rho \in \tilde{K}_1$ s.t. $Dd(x)' \operatorname{diag}[x]\, \rho > 0$.

We shall explain in the last step how to adapt this proof when $\bar{\mathcal{O}}$ is bounded but (i) of $\mathbf{H}''$ does not hold, or $0 \notin \mathrm{int}(K)$ but $\bar{\mathcal{O}} \cap \partial\mathbb{R}^d_+ = \emptyset$ and $\mathrm{int}(K) \neq \emptyset$.

1. Given some positive parameter κ, we introduce the functions $\tilde{u}(t,x) := e^{\kappa t} u(t,x)$, $\tilde{v}(t,x) := e^{\kappa t} v_*(t,x)$, and $\tilde{g}(t,x) := e^{\kappa t}\hat{g}(t,x)$. One easily checks that the function $\tilde{u}$ (resp., $\tilde{v}$) is a viscosity subsolution (resp., supersolution) of $\tilde{\mathcal{B}}\varphi = 0$ (resp., $\tilde{\mathcal{B}}_{\mathrm{d}}\varphi = 0$), where for a smooth function φ

$$\tilde{\mathcal{B}}\varphi = \begin{cases} \min\left\{\tilde{\mathcal{L}}\varphi\ ,\ \mathcal{H}\varphi\right\} & \text{on} \quad D\ , \\ \min\left\{\varphi - \tilde{g}\ ,\ \mathcal{H}\varphi\right\} & \text{on} \quad \partial_x D^*\ , \\ \varphi - \tilde{g} & \text{on} \quad \partial_T D^*\ , \end{cases}$$

$$\tilde{\mathcal{B}}_{\mathrm{d}}\varphi = \begin{cases} \tilde{\mathcal{B}}\varphi & \text{on} \quad D \cup \partial_T D^*\ , \\ \min\left\{\varphi - \tilde{g}\ ,\ \mathcal{H}_{\mathrm{d}}\varphi\right\} & \text{on} \quad \partial_x D^*\ , \end{cases}$$

and

$$\tilde{\mathcal{L}}\varphi := \kappa\varphi - \mathcal{L}\varphi\ .$$

Let $\varrho \in \mathbb{R}$ be as in $\mathbf{H}''$, i.e.,

$$\gamma := \varrho\bar{\gamma} \in K \cap (0,\infty)^d \ \text{ and } \ \varrho > 1\ . \tag{7.3}$$

Since $0 \in \mathrm{int}(K)$ by $\mathbf{H}''$, it follows from (2.9) and Remark 2.4 that the map defined by $\beta(t,x) = e^{\tau(T-t)}(1 + x^\gamma)$ on $\bar{D}^*$ satisfies

$$H\left(\beta(t,x), \mathrm{diag}\,[x]\, D\beta(t,x)\right) \geq c_K > 0 \quad \text{for all } (t,x) \in \bar{D}^*\ . \tag{7.4}$$

Moreover, by the same computations as in the proof of Proposition 6.9, one easily checks that we can choose τ large enough so that

$$\tilde{\mathcal{L}}\beta \geq 0 \quad \text{on } \bar{D}^*\ . \tag{7.5}$$

2. We argue by contradiction. We assume that

$$\sup_{\bar{D}^*}(u - v_*) > 0$$

and work towards a contradiction.

2.1. In this step, we follow the same construction as in the proof of Proposition 6.9. By the growth condition on $\tilde{u}$, $\tilde{v}$ and (7.3), we deduce that

$$0 < 2m := \sup_{\bar{D}^*}(\tilde{u} - \tilde{v} - 2\alpha\beta) < \infty \tag{7.6}$$

for $\alpha > 0$ small enough. Fix $\varepsilon > 0$ and let f be defined as in (6.18). Arguing as in the proof of Proposition 6.9, we obtain that

$$\Phi^\varepsilon := \tilde{u} - \tilde{v} - 2(\alpha\beta + \varepsilon f)$$

admits a maximum $(t_\varepsilon, x_\varepsilon)$ on $\bar{D}^*$, which, for $\varepsilon > 0$ small enough, satisfies

$$\Phi^\varepsilon(t_\varepsilon, x_\varepsilon) \geq m > 0\ . \tag{7.7}$$

Moreover, using the same arguments as in step 2.1 of the proof of Proposition 6.9, we obtain that

$$\limsup_{\varepsilon \to 0} \sup_{\rho \in \tilde{K}_1} \varepsilon\left(|f(x_\varepsilon)| + |\mathrm{diag}\,[x_\varepsilon]\, Df(x_\varepsilon)| + |\mathcal{L}f(x_\varepsilon)|\right) = 0\ . \tag{7.8}$$

Finally, since $\beta, f \geq 0$ and $v_*(T,\cdot) \geq u(T,\cdot)$, (7.7) implies that $t_\varepsilon < T$, i.e.,

$$(t_\varepsilon, x_\varepsilon) \in [0,T) \times \bar{\mathcal{O}}^* \,. \tag{7.9}$$

2.2. In the following, we fix $\rho_\varepsilon \in \tilde{K}_1$ such that

$$\begin{array}{rll} \rho_\varepsilon := 0 & \text{if} & x_\varepsilon \in \mathcal{O}\,, \\ Dd(x_\varepsilon)' \operatorname{diag}[x_\varepsilon]\, \rho_\varepsilon > 0 & \text{if} & x_\varepsilon \in \partial\mathcal{O}^*\,; \end{array} \tag{7.10}$$

see (iii) of $\mathbf{H}''$. By Lemma 7.1 and (3.11), we can fix r_ε, $\lambda_\varepsilon > 0$, such that

$$x e^{\lambda \rho_\varepsilon} \in \mathcal{O} \qquad \text{and} \qquad e^{-\lambda \delta(\rho_\varepsilon)} \tilde{v}(t, x e^{\lambda \rho_\varepsilon}) \leq \tilde{v}(t,x) \tag{7.11}$$

for all $t \in (t_\varepsilon - r_\varepsilon, t_\varepsilon + r_\varepsilon) \cap [0,T)$, $x \in B_\varepsilon := B(x_\varepsilon, r_\varepsilon) \cap \bar{\mathcal{O}}$, and $\lambda \in (0, \lambda_\varepsilon)$. For $n \geq 1$ and $\zeta \in (0,1)$, we then define the function $\Psi^\varepsilon_{n,\zeta}$ on $[0,T] \times (\bar{\mathcal{O}}^*)^2$ by

$$\begin{aligned} \Psi^\varepsilon_{n,\zeta}(t,x,y) := \Theta(t,x,y) - \varepsilon(f(x) + f(y)) - \zeta(|x - x_\varepsilon|^2 + |t - t_\varepsilon|^2) \\ - n^2 |x e^{\frac{\zeta}{n}\rho_\varepsilon} - y|^2, \end{aligned}$$

where

$$\Theta(t,x,y) := \tilde{u}(t,x) - \tilde{v}(t,y) - \alpha\left(\beta(t,x) + \beta(t,y)\right) \,.$$

It follows from (7.3) and the growth condition (3.10) satisfied by $\tilde{v}$ and $\tilde{u}$ that $\Psi^\varepsilon_{n,\zeta}$ attains its maximum at some $(t^\varepsilon_n,\, x^\varepsilon_n,\, y^\varepsilon_n) \in [0,T] \times (\bar{\mathcal{O}}^*)^2$. The inequality $\Psi^\varepsilon_{n,\zeta}(t^\varepsilon_n, x^\varepsilon_n, y^\varepsilon_n) \geq \Psi^\varepsilon_{n,\zeta}(t_\varepsilon, x_\varepsilon, x_\varepsilon e^{\frac{\zeta}{n}\rho_\varepsilon})$ implies that

$$\begin{aligned} \Theta(t^\varepsilon_n, x^\varepsilon_n, y^\varepsilon_n) \geq \Theta(t_\varepsilon, x_\varepsilon, x_\varepsilon e^{\frac{\zeta}{n}\rho_\varepsilon}) - \varepsilon\left(f(x_\varepsilon) + f(x_\varepsilon e^{\frac{\zeta}{n}\rho_\varepsilon})\right) \\ + n^2 |x^\varepsilon_n e^{\frac{\zeta}{n}\rho_\varepsilon} - y^\varepsilon_n|^2 + \zeta\left(|x^\varepsilon_n - x^\varepsilon|^2 + |t^\varepsilon_n - t_\varepsilon|^2\right) \\ + \varepsilon\left(f(x^\varepsilon_n) + f(y^\varepsilon_n)\right), \end{aligned}$$

which combined with the growth condition (3.10) and (7.3) shows that $n^2 |x^\varepsilon_n$ $e^{\frac{\zeta}{n}\rho_\varepsilon} - y^\varepsilon_n|^2 + f(x^\varepsilon_n)$ is bounded in n so that, up to a subsequence,

$$\text{(i)}\ x^\varepsilon_n e^{\frac{\zeta}{n}\rho_\varepsilon}, x^\varepsilon_n, y^\varepsilon_n \xrightarrow[n\to\infty]{} \bar{x}^\varepsilon \in \bar{\mathcal{O}}^* \qquad \text{and} \qquad t^\varepsilon_n \xrightarrow[n\to\infty]{} \bar{t}^\varepsilon \in [0,T]\,.$$

Let n be large enough so that $\frac{\zeta}{n} < \lambda_\varepsilon$. Recall from (7.11) that this implies that $\tilde{v}(t_\varepsilon, x_\varepsilon e^{\frac{\zeta}{n}\rho_\varepsilon}) \leq \tilde{v}(t_\varepsilon, x_\varepsilon) e^{\frac{\zeta}{n}\delta(\rho_\varepsilon)}$, which combined with the previous inequality yields

$$\begin{aligned} \Theta(t^\varepsilon_n, x^\varepsilon_n, y^\varepsilon_n) \geq \tilde{u}(t_\varepsilon, x_\varepsilon) - \tilde{v}(t_\varepsilon, x_\varepsilon) e^{\frac{\zeta}{n}\delta(\rho_\varepsilon)} - \alpha\left(\beta(t_\varepsilon, x_\varepsilon) + \beta(t_\varepsilon, x_\varepsilon e^{\frac{\zeta}{n}\rho_\varepsilon})\right) \\ - \varepsilon\left(f(x_\varepsilon) + f(x_\varepsilon e^{\frac{\zeta}{n}\rho_\varepsilon})\right) + n^2 |x^\varepsilon_n e^{\frac{\zeta}{n}\rho_\varepsilon} - y^\varepsilon_n|^2 \\ + \zeta\left(|x^\varepsilon_n - x_\varepsilon|^2 + |t^\varepsilon_n - t_\varepsilon|^2\right) + \varepsilon\left(f(x^\varepsilon_n) + f(y^\varepsilon_n)\right) \,. \end{aligned}$$

Sending $n \to \infty$ and using the maximum property of $(t_\varepsilon, x_\varepsilon)$, we get

$$\begin{aligned} 0 &\geq \Phi^\varepsilon(\bar{t}^\varepsilon, \bar{x}^\varepsilon) - \Phi^\varepsilon(t_\varepsilon, x_\varepsilon) \\ &\geq \limsup_{n\to\infty} \left(n^2 |x^\varepsilon_n e^{\frac{\zeta}{n}\rho_\varepsilon} - y^\varepsilon_n|^2 + \zeta\left(|x^\varepsilon_n - x_\varepsilon|^2 + |t^\varepsilon_n - t_\varepsilon|^2\right)\right) \,. \end{aligned}$$

Recalling (7.7) and (7.9), this shows that

(ii) $n^2|x_n^\varepsilon e^{\frac{\zeta}{n}\rho_\varepsilon} - y_n^\varepsilon|^2 + \zeta\left(|x_n^\varepsilon - x_\varepsilon|^2 + |t_n^\varepsilon - t_\varepsilon|^2\right) \xrightarrow[n\to\infty]{} 0$,

(iii) $\tilde{u}(t_n^\varepsilon, x_n^\varepsilon) - \tilde{v}(t_n^\varepsilon, y_n^\varepsilon) \xrightarrow[n\to\infty]{} (\tilde{u} - \tilde{v})(t_\varepsilon, x_\varepsilon) \geq m + 2\alpha\beta(t_\varepsilon, x_\varepsilon) + 2\varepsilon f(x_\varepsilon)$,

(iv) $(t_n^\varepsilon, x_n^\varepsilon) \in [0,T) \times \bar{\mathcal{O}}^*$ for n large enough.

3. From Theorem 8.3 in [5], we deduce that for each $\eta > 0$ there are real coefficients $b_{1,n}^\varepsilon$, $b_{2,n}^\varepsilon$ and symmetric matrices $\mathcal{X}_n^{\varepsilon,\eta}$ and $\mathcal{Y}_n^{\varepsilon,\eta}$ such that

$$\left(b_{1,n}^\varepsilon, p_n^\varepsilon, \mathcal{X}_n^{\varepsilon,\eta}\right) \in \bar{\mathcal{P}}_{\bar{\mathcal{O}}}^+ \tilde{u}(t_n^\varepsilon, x_n^\varepsilon) \text{ and } \left(-b_{2,n}^\varepsilon, q_n^\varepsilon, \mathcal{Y}_n^{\varepsilon,\eta}\right) \in \bar{\mathcal{P}}_{\bar{\mathcal{O}}}^- \tilde{v}(t_n^\varepsilon, y_n^\varepsilon)$$

—see [5] for the standard notations $\bar{\mathcal{P}}_{\bar{\mathcal{O}}}^+$ and $\bar{\mathcal{P}}_{\bar{\mathcal{O}}}^-$, where

$$p_n^\varepsilon := 2n^2(x_n^\varepsilon e^{\frac{\zeta}{n}\rho_\varepsilon} - y_n^\varepsilon)e^{\frac{\zeta}{n}\rho_\varepsilon} + 2\zeta(x_n^\varepsilon - x_\varepsilon) + \alpha\, , D\beta(t_n^\varepsilon, x_n^\varepsilon) + \varepsilon Df(x_n^\varepsilon)\, ,$$
$$q_n^\varepsilon := 2n^2(x_n^\varepsilon e^{\frac{\zeta}{n}\rho_\varepsilon} - y_n^\varepsilon) - \alpha D\beta(t_n^\varepsilon, y_n^\varepsilon) - \varepsilon Df(y_n^\varepsilon)$$

—and such that $b_{1,n}^\varepsilon$, $b_{2,n}^\varepsilon$, $\mathcal{X}_n^{\varepsilon,\eta}$, and $\mathcal{Y}_n^{\varepsilon,\eta}$ satisfy

$$\text{(7.12)} \quad \left\{ \begin{array}{c} b_{1,n}^\varepsilon + b_{2,n}^\varepsilon = 2\zeta(t_n^\varepsilon - t_\varepsilon) - \alpha\tau\left(\beta(t_n^\varepsilon, x_n^\varepsilon) + \beta(t_n^\varepsilon, y_n^\varepsilon)\right)\, , \\ \begin{pmatrix} \mathcal{X}_n^{\varepsilon,\eta} & 0 \\ 0 & -\mathcal{Y}_n^{\varepsilon,\eta} \end{pmatrix} \leq (A_n^\varepsilon + B_n^\varepsilon) + \eta(A_n^\varepsilon + B_n^\varepsilon)^2\, , \end{array} \right.$$

with

$$A_n^\varepsilon := \begin{pmatrix} 2n^2\, \mathrm{diag}[e^{2\frac{\zeta}{n}\rho_\varepsilon}] + 2\zeta I_d & -2n^2\, \mathrm{diag}[e^{\frac{\zeta}{n}\rho_\varepsilon}] \\ -2n^2\, \mathrm{diag}[e^{\frac{\zeta}{n}\rho_\varepsilon}] & 2n^2 I_d \end{pmatrix}\, ,$$
$$B_n^\varepsilon := \begin{pmatrix} \alpha D^2\beta(t_n^\varepsilon, x_n^\varepsilon) + \varepsilon D^2 f(x_n^\varepsilon) & 0 \\ 0 & \alpha D^2\beta(t_n^\varepsilon, y_n^\varepsilon) + \varepsilon D^2 f(y_n^\varepsilon) \end{pmatrix}\, .$$

3.1. We now show that, up to a subsequence,

$$y_n^\varepsilon \in \mathcal{O}\, . \tag{7.13}$$

In view of (ii), this is clearly true when $x_\varepsilon \in \mathcal{O}$. In the case $x_\varepsilon \in \partial\mathcal{O}$, we deduce from (ii) that

$$y_n^\varepsilon = x_n^\varepsilon e^{\frac{\zeta}{n}\rho_\varepsilon} + o(n^{-1}) \;=\; x_n^\varepsilon + \frac{\zeta}{n}\mathrm{diag}\,[x_n^\varepsilon]\,\rho_\varepsilon + o(n^{-1})\, .$$

This implies that, for some $\epsilon_n \to 0$,

$$d(y_n^\varepsilon) = d(x_n^\varepsilon) + \frac{\zeta}{n}\left(Dd(x_n^\varepsilon)'\mathrm{diag}\,[x_n^\varepsilon]\,\rho_\varepsilon + \epsilon_n\right)$$

so that (7.13) is a consequence of (7.10), the continuity of Dd, and (ii).

3.2. In this step, we show that there is a subsequence of $(t_n^\varepsilon, x_n^\varepsilon, y_n^\varepsilon)$ such that

$$\text{(7.14)}\ x_n^\varepsilon \in \mathcal{O} \qquad \text{and} \qquad \kappa\tilde{u}(t_n^\varepsilon, x_n^\varepsilon) - b_{1,n}^\varepsilon - \frac{1}{2}\mathrm{Tr}\left[a(t_n^\varepsilon, x_n^\varepsilon)\mathcal{X}_n^{\varepsilon,\eta}\right] \leq 0\, .$$

First observe that we cannot have $x_n^\varepsilon \in \partial\mathcal{O}^*$ and $\tilde{u}(t_n^\varepsilon, x_n^\varepsilon) \leq \tilde{g}(t_n^\varepsilon, x_n^\varepsilon)$ for all n. In view of (ii), this is obvious if $x_\varepsilon \in \mathcal{O}$. If $x_\varepsilon \in \partial\mathcal{O}^*$, it follows from (7.9)

and the viscosity property of $\tilde v$ that $\tilde v(t_\varepsilon, x_\varepsilon) \ge \tilde g(t_\varepsilon, x_\varepsilon)$. Since $\tilde g$ is upper-semicontinuous (see $\mathbf{H}_g$), this would imply that $\tilde u(t_n^\varepsilon, x_n^\varepsilon) \le \tilde v(t_n^\varepsilon, y_n^\varepsilon) + m/2$ for n large enough (see (ii)), thus leading to a contradiction to (iii) since $\beta, f \ge 0$. By (iv) and the viscosity subsolution property of $\tilde u$, we then deduce that either (7.14) holds or

$$H\left(\tilde u(t_n^\varepsilon, x_n^\varepsilon), \mathrm{diag}\,[x_n^\varepsilon]\, p_n^\varepsilon\right) \le 0\,. \tag{7.15}$$

Thus, it remains to prove that the above inequality leads to a contradiction. Using the supersolution property of $\tilde v$, (7.13), (ii)–(iii), and (2.9), we observe that (7.15) implies

$$\begin{aligned}
0 &\ge H\left(\tilde u(t_n^\varepsilon, x_n^\varepsilon), \mathrm{diag}\,[x_n^\varepsilon]\, p_n^\varepsilon\right) - H\left(\tilde v(t_n^\varepsilon, y_n^\varepsilon), \mathrm{diag}\,[y_n^\varepsilon]\, q_n^\varepsilon\right)\\
&\ge \alpha\left\{H\left(\beta(t_n^\varepsilon, x_n^\varepsilon), \mathrm{diag}\,[x_n^\varepsilon]\, D\beta(t_n^\varepsilon, x_n^\varepsilon)\right) + H\left(\beta(t_n^\varepsilon, y_n^\varepsilon), \mathrm{diag}\,[y_n^\varepsilon]\, D\beta(t_n^\varepsilon, y_n^\varepsilon)\right)\right\}\\
&+ \varepsilon\left\{H\left(f(x_n^\varepsilon), \mathrm{diag}\,[x_n^\varepsilon]\, Df(x_n^\varepsilon)\right) + H\left(f(y_n^\varepsilon), \mathrm{diag}\,[y_n^\varepsilon]\, Df(y_n^\varepsilon)\right)\right\}\\
&+ \inf_{\rho\in\tilde K_1} \delta(\rho)\left[\Theta(t_n^\varepsilon, x_n^\varepsilon, y_n^\varepsilon) - \varepsilon\left(f(x_n^\varepsilon) + f(y_n^\varepsilon)\right)\right]\\
&- \sup_{\rho\in\tilde K_1} \left[2n^2\rho'\mathrm{diag}\left[x_n^\varepsilon e^{\frac{\zeta}{n}\rho_\varepsilon} - y_n^\varepsilon\right]\left(x_n^\varepsilon e^{\frac{\zeta}{n}\rho_\varepsilon} - y_n^\varepsilon\right) + 2\zeta\rho'\mathrm{diag}\,[x_n^\varepsilon]\,(x_n^\varepsilon - x_\varepsilon)\right]\\
&\ge \inf_{\rho\in\tilde K_1} \delta(\rho)(m/2) + 2\alpha H(\beta(t_\varepsilon, x_\varepsilon), \mathrm{diag}\,[x_\varepsilon]\, D\beta(t_\varepsilon, x_\varepsilon))\\
&+ \epsilon_n + \varepsilon\left\{H\left(f(x_\varepsilon), \mathrm{diag}\,[x_\varepsilon]\, Df(x_\varepsilon)\right) + H\left(f(y_\varepsilon), \mathrm{diag}\,[y_\varepsilon]\, Df(y_\varepsilon)\right)\right\}\,,
\end{aligned}$$

where $\epsilon_n \to 0$ when $n \to \infty$, but depend on ε. Recalling (7.4) and (7.8), we get a contradiction for ε small and n large enough. This concludes the proof of (7.14).

3.3. We can now provide the required contradiction and conclude the proof. Let $\tilde\sigma$ be defined on $\bar D$ by $\tilde\sigma(t,x) = \mathrm{diag}\,[x]\,\sigma(t,x)$. By the viscosity supersolution property of $\tilde v$, (7.13), (7.14), and (7.12), $(t_n^\varepsilon, x_n^\varepsilon, y_n^\varepsilon)$ must satisfy

$$\begin{aligned}
\kappa\left(\tilde u(t_n^\varepsilon, x_n^\varepsilon) - \tilde v(t_n^\varepsilon, y_n^\varepsilon)\right) &\le b_{1,n}^\varepsilon + b_{2,n}^\varepsilon + \frac{1}{2}\mathrm{Tr}\left[a(t_n^\varepsilon, x_n^\varepsilon)\mathcal{X}_n^{\varepsilon,\eta} - a(t_n^\varepsilon, y_n^\varepsilon)\mathcal{Y}_n^{\varepsilon,\eta}\right]\\
&\le 2\zeta(t_n^\varepsilon - t_\varepsilon) - \alpha\tau\left(\beta(t_n^\varepsilon, x_n^\varepsilon) + \beta(t_n^\varepsilon, y_n^\varepsilon)\right)\\
&+ \frac{1}{2}\mathrm{Tr}\left[\Xi(t_n^\varepsilon, x_n^\varepsilon, y_n^\varepsilon)\left(A_n^\varepsilon + B_n^\varepsilon + \eta(A_n^\varepsilon + B_n^\varepsilon)^2\right)\right]\,,
\end{aligned}$$

where

$$\Xi(t_n^\varepsilon, x_n^\varepsilon, y_n^\varepsilon) := \begin{pmatrix} \tilde\sigma(t_n^\varepsilon, x_n^\varepsilon)\tilde\sigma'(t_n^\varepsilon, x_n^\varepsilon) & \tilde\sigma(t_n^\varepsilon, y_n^\varepsilon)\tilde\sigma'(t_n^\varepsilon, x_n^\varepsilon) \\ \tilde\sigma(t_n^\varepsilon, x_n^\varepsilon)\tilde\sigma'(t_n^\varepsilon, y_n^\varepsilon) & \tilde\sigma(t_n^\varepsilon, y_n^\varepsilon)\tilde\sigma'(t_n^\varepsilon, y_n^\varepsilon) \end{pmatrix}$$

is a nonnegative symmetric matrix. Using (ii)–(iii), (7.5), and (7.8), it follows that for ε small and n large enough

$$\begin{aligned}
\kappa\, m/2 &\le \kappa\left(\tilde u(t_n^\varepsilon, x_n^\varepsilon) - \tilde v(t_n^\varepsilon, y_n^\varepsilon) - (\alpha\beta + \varepsilon f)(t_n^\varepsilon, x_n^\varepsilon) - (\alpha\beta + \varepsilon f)(t_n^\varepsilon, y_n^\varepsilon)\right)\\
&\le 2\zeta(t_n^\varepsilon - t_\varepsilon) + \frac{1}{2}\mathrm{Tr}\left[\Xi(t_n^\varepsilon, x_n^\varepsilon, y_n^\varepsilon)\left(A_n^\varepsilon + \eta(A_n^\varepsilon + B_n^\varepsilon)^2\right)\right] + \theta(\varepsilon, n)\,,
\end{aligned}$$

where $\theta(\varepsilon, n)$ is independent of (η, ζ) and satisfies

$$\limsup_{\varepsilon\to 0}\limsup_{n\to\infty} |\theta(\varepsilon, n)| = 0\,. \tag{7.16}$$

Sending $\eta \to 0$ in the previous inequality provides

$$\kappa\, m/2 \le 2\zeta(t_n^\varepsilon - t_\varepsilon) + \frac{1}{2}\mathrm{Tr}\left[\Xi(t_n^\varepsilon, x_n^\varepsilon, y_n^\varepsilon)A_n^\varepsilon\right] + \theta(\varepsilon, n)\ ,$$

so that

$$\begin{aligned}\kappa\, m/2 \le{}& 2\zeta(t_n^\varepsilon - t_\varepsilon) + \zeta\mathrm{Tr}\left[\tilde\sigma(t_n^\varepsilon, x_n^\varepsilon)\tilde\sigma'(t_n^\varepsilon, x_n^\varepsilon)\right]\\ &+ n^2\left|\mathrm{diag}\left[x_n^\varepsilon e^{\frac{\zeta}{n}\rho_\varepsilon}\right]\sigma(t_n^\varepsilon, x_n^\varepsilon) - \mathrm{diag}\left[y_n^\varepsilon\right]\sigma(t_n^\varepsilon, y_n^\varepsilon)\right|^2 + \theta(\varepsilon, n)\ .\end{aligned}$$

Using (2.2), we now observe that

$$\begin{aligned}&\left|\mathrm{diag}\left[x_n^\varepsilon e^{\frac{\zeta}{n}\rho_\varepsilon}\right]\left(\sigma(t_n^\varepsilon, x_n^\varepsilon e^{\frac{\zeta}{n}\rho_\varepsilon}) - \sigma(t_n^\varepsilon, x_n^\varepsilon)\right)\right|\\ &\le \left|\mathrm{diag}\left[x_n^\varepsilon e^{\frac{\zeta}{n}\rho_\varepsilon}\right]\sigma(t_n^\varepsilon, x_n^\varepsilon e^{\frac{\zeta}{n}\rho_\varepsilon}) - \mathrm{diag}\left[x_n^\varepsilon\right]\sigma(t_n^\varepsilon, x_n^\varepsilon)\right|\\ &\quad + \left|\mathrm{diag}\left[x_n^\varepsilon e^{\frac{\zeta}{n}\rho_\varepsilon} - x_n^\varepsilon\right]\sigma(t_n^\varepsilon, x_n^\varepsilon)\right|\\ &\le C_\varepsilon\ \left|x_n^\varepsilon e^{\frac{\zeta}{n}\rho_\varepsilon} - x_n^\varepsilon\right|\\ &\le \zeta C_\varepsilon\ n^{-1}\ ,\end{aligned}$$

and

$$\left|\mathrm{diag}\left[x_n^\varepsilon e^{\frac{\zeta}{n}\rho_\varepsilon}\right]\sigma(t_n^\varepsilon, x_n^\varepsilon e^{\frac{\zeta}{n}\rho_\varepsilon}) - \mathrm{diag}\left[y_n^\varepsilon\right]\sigma(t_n^\varepsilon, y_n^\varepsilon)\right|^2 \le C_\varepsilon\ \left|x_n^\varepsilon e^{\frac{\zeta}{n}\rho_\varepsilon} - y_n^\varepsilon\right|^2\ ,$$

where $C_\varepsilon > 0$ denotes a generic constant independent of n and ζ. Plugging this into the previous inequality implies that there is some $C_\varepsilon > 0$ independent of n and ζ for which

$$\begin{aligned}\kappa\, m/2 \le{}& 2\zeta(t_n^\varepsilon - t_\varepsilon) + \zeta\mathrm{Tr}\left[\tilde\sigma'(t_n^\varepsilon, x_n^\varepsilon)\tilde\sigma(t_n^\varepsilon, x_n^\varepsilon)\right]\\ &+ C_\varepsilon\left(\zeta + n^2|x_n^\varepsilon e^{\frac{\zeta}{n}\rho_\varepsilon} - y_n^\varepsilon|^2\right) + \theta(\varepsilon, n).\end{aligned}$$

Finally, using (ii) and sending n to ∞ and then ζ to 0 in the last inequality implies

$$\kappa\, m/2 \le \limsup_{n\to\infty}\theta(\varepsilon, n)\ ,$$

which by (7.16) provides the required contradiction and concludes the proof.

4. We now explain how to adapt this proof to the alternative assumptions of $\mathbf{H}'$.

4.1. Observe that the penalty function β is introduced in order to obtain a finite supremum for $\tilde u - \tilde v - 2\alpha\beta$ and existence of an optimum for Φ^ε and $\Psi^\varepsilon_{n,\zeta}$. If $\bar{\mathcal{O}}$ is bounded, the introduction of such a penalty function is not required and we can reproduce the same proof with $\beta \equiv 0$ whenever $0 \in \mathrm{int}(K)$. Indeed, by Remark 2.4, $\inf_{\rho\in\tilde K_1}\delta(\rho) > 0$, so that we still obtain a contradiction at the end of step 3.2. The arguments of step 3.3 also work with $\beta \equiv 0$. The case where $0 \notin \mathrm{int}(K)$ is discussed below.

4.2. Similarly, the map f is introduced only to prevent the different maxima from taking values outside $\bar{\mathcal{O}}^*$. If $\bar{\mathcal{O}} \cap \partial\mathbb{R}^d_+ = \emptyset$, this penalty function is useless

and can be fixed to $f \equiv 0$. In this case, one can also fix some $\underline{\gamma} \in \text{int}(K)$, if nonempty, and add the term $e^{\tau(T-t)}x^{\underline{\gamma}}$ in the definition of β. Thus, β becomes $e^{\tau(T-t)}\,(1 + x^{\gamma} + x^{\underline{\gamma}})$ or $e^{\tau(T-t)}\,(1 + x^{\underline{\gamma}})$, depending on whether $\bar{\mathcal{O}}$ is bounded or not; see step 4.1. For fixed $\varepsilon > 0$, we deduce from Remark 2.4 and the fact that $\underline{\gamma} \in \text{int}(K)$ that $H(\beta(t,x), \text{diag}\,[x]\,D\beta(t,x)) > 0$. Since $f = 0$, there is no ε to send to 0 at the end of steps 3.2 and 3.3, and we obtain the same contradictions by simply sending n to ∞ and ζ to 0. □

QUASI-OPTIMAL ROBUST STABILIZATION OF CONTROL SYSTEMS*

CHRISTOPHE PRIEUR† AND EMMANUEL TRÉLAT‡

Abstract. In this paper, we investigate the problem of semiglobal minimal time robust stabilization of analytic control systems with controls entering linearly, by means of a hybrid state feedback law. It is shown that in the absence of minimal time singular trajectories, the solutions of the closed-loop system converge to the origin in quasi-minimal time (for a given bound on the controller) with a robustness property with respect to small measurement noise, external disturbances, and actuator noise.

Key words. hybrid feedback, robust stabilization, measurement errors, actuator noise, external disturbances, optimal control, singular trajectory, sub-Riemannian geometry

AMS subject classifications. 93B52, 93D15

DOI. 10.1137/050642629

1. Introduction.

Let m and n be two positive integers. Consider on $\mathbb{R}^n$ the control system

$$\dot{x}(t) = \sum_{i=1}^{m} u_i(t) f_i(x(t)), \tag{1.1}$$

where $f_1, \ldots, f_m$ are analytic vector fields on $\mathbb{R}^n$, and where the control function $u(\cdot) = (u_1(\cdot), \ldots, u_m(\cdot))$ satisfies the constraint

$$\sum_{i=1}^{m} u_i(t)^2 \leqslant 1. \tag{1.2}$$

All results of this paper still hold on a Riemannian analytic manifold of dimension n, which is connected and complete. However, for the sake of simplicity, our results are stated in $\mathbb{R}^n$. Let $\bar{x} \in \mathbb{R}^n$. The system (1.1), together with the constraint (1.2), is said to be *globally asymptotically stabilizable* at the point $\bar{x}$ if, for each point $x \in \mathbb{R}^n$, there exists a control law satisfying the constraint (1.2) such that the solution of (1.1) associated to this control law with the initial condition x tends to $\bar{x}$ as t tends to $+\infty$.

This asymptotic stabilization problem has a long history and has been widely investigated. Note that, due to *Brockett's condition* [16, Theorem 1 (iii)], if $m < n$, and if the vector fields $f_1, \ldots, f_m$ are independent, then there does not exist any continuous stabilizing feedback law for (1.1). However several control laws have been derived for such control systems (see, for instance, [8, 29] and the references therein).

The *robust asymptotic stabilization problem* is under current and active research. Many notions of controllers have been introduced to treat this problem, such as discontinuous sampling feedbacks [19, 45], time varying control laws [20, 21, 33, 34],

patchy feedbacks (as in [5]), and SRS feedbacks [43], enjoying different robustness properties depending on the errors under consideration.

In the present paper, we consider feedback laws having both discrete and continuous components, which generate closed-loop systems with *hybrid* terms (see, for instance, [11, 49]). Such feedback appeared first in [37] to stabilize nonlinear systems having a priori no discrete state. They consist in defining a *switching strategy* between several smooth control laws defined on a partition of the state space. Many results on the stabilization problem of nonlinear systems by means of hybrid controllers have been recently established (see, for instance, [14, 22, 25, 26, 30, 32, 35, 53]). The notion of solution, connected with the robustness problem, is by now well defined in the hybrid context (see [25, 39], among others). Specific conditions for the optimization can be found in the literature (see, e.g., [9, 24]).

The strategy of our paper is to combine a minimal time controller that is smooth on a part of the state space, and other controllers defined on the complement of this part, so as to provide a *quasi-minimal time hybrid controller* by defining a switching strategy between all control laws. The resulting hybrid law enjoys a quasi-minimal time property, and robustness with respect to (small) measurement noise, actuator errors, and external disturbances.

More precisely, in a first step, we consider the minimal time problem for the system (1.1) with the constraint (1.2) of steering a point $x \in \mathbb{R}^n$ to the point $\bar{x}$. Note that this problem is solvable as soon as the *Lie algebra rank condition* holds for the m-tuple of vector fields $(f_1, \dots, f_m)$. Of course, in general, it is impossible to compute explicitly the minimal time feedback controllers for this problem. Moreover, Brockett's condition implies that such control laws are not smooth whenever $m < n$ and the vector fields $f_1, \dots, f_m$ are independent. This raises the problem of the regularity of optimal feedback laws. The literature on this subject is immense. In an analytic setting, the problem of determining the analytic regularity of the minimal time function has been investigated in among others, [47]. For systems of the form (1.1), it follows from [1, 2, 50] that the minimal time function to $\bar{x}$ is *subanalytic*, provided there does not exist any nontrivial singular minimal time trajectory starting from $\bar{x}$ (see [27, 28] for a general definition of subanalytic sets). This assumption holds generically for systems (1.1), whenever $m \geqslant 3$ (see [18]). In particular, this function is analytic outside a stratified submanifold $\mathcal{S}$ of $\mathbb{R}^n$ of codimension greater than or equal to 1 (see [48]). As a consequence, outside this submanifold it is possible to provide an analytic minimal time feedback controller for the system (1.1), (1.2). This optimal controller gives rise to trajectories never crossing again the singular set $\mathcal{S}$.

Note that the analytic context is used so as to ensure stratification properties, which do not hold a priori if the system is smooth only. These properties are related to the notion of an *o-minimal category* (see [23]).

In a neighborhood of $\mathcal{S}$, we prove the existence of a set of controllers steering the system (1.1), (1.2) outside of this neighborhood in small time.

Then, in order to achieve a minimal time robust stabilization procedure, using a hybrid feedback law, we define a suitable switching strategy (more precisely, a hysteresis) between the minimal time feedback controller and other controllers defined in a neighborhood of $\mathcal{S}$. The resulting hybrid system has the following property: If the state is close to the singular submanifold $\mathcal{S}$, the feedback controller will push the state far enough from $\mathcal{S}$, in small time; if the state is not too close to $\mathcal{S}$, then the feedback controller will steer the system to $\bar{x}$ in minimal time. Hence, the stabilization is quasi-optimal and is proved to enjoy robustness properties.

Note that we thus give an alternative solution, in the context of hybrid systems using hysteresis, to a conjecture of [15, Conjecture 1, p. 101] concerning patchy feedbacks for smooth control systems.[1]

In a previous paper [41], this program was achieved on the so-called Brockett system, for which $n = 3$, $m = 2$, and, denoting $x = (x_1, x_2, x_3)$,

$$f_1 = \frac{\partial}{\partial x_1} + x_2 \frac{\partial}{\partial x_3}, \quad f_2 = \frac{\partial}{\partial x_2} - x_1 \frac{\partial}{\partial x_3}.$$

In this case, there does not exist any nontrivial singular trajectory, and the manifold $\mathcal{S}$ coincides with the axis $(0x_3)$. A simple explicit hybrid strategy was described. In contrast, in the present paper, we derive a general result that requires a countable number of components in the definition of the hysteresis hybrid feedback law.

The paper is organized as follows. In section 2, we first recall some facts about the minimal time problem for the system (1.1) with (1.2) and recall the definition of a singular trajectory. Then we give a notion of solution adapted to hybrid feedback laws and define the concept of stabilization via a minimal time hybrid feedback law. The main result, Theorem 2.10 in section 2.3, states that if there does not exist any nontrivial singular minimal time trajectory of (1.1), (1.2), starting from $\bar{x}$, then there exists a minimal time hybrid feedback law stabilizing semiglobally the point $\bar{x}$ for the system (1.1), (1.2). Section 2.4 describes the main ideas of the proof of the main result and, in particular, contains two key lemmas. Section 3 is then devoted to the detailed proof of Theorem 2.10 and gathers all technical aspects needed to deal with hybrid systems: the components of the hybrid feedback law and a switching strategy between both components are defined, and properties of the closed-loop system are investigated.

The results in this work were announced in [42].

2. Definitions and main result.

2.1. The minimal time problem. Consider the minimal time problem for the system (1.1) with the constraint (1.2).

Throughout the paper, we assume that the *Lie algebra rank condition* holds, that is, the Lie algebra spanned by the vector fields $f_1, \ldots, f_m$ is equal to $\mathbb{R}^n$, at every point x of $\mathbb{R}^n$.

It is well known that, under this condition, any two points of $\mathbb{R}^n$ can be joined by a minimal time trajectory of (1.1), (1.2).

Let $\bar{x} \in \mathbb{R}^n$ be fixed. We denote by $T_{\bar{x}}(x)$ the minimal time needed to steer the system (1.1) with the constraint (1.2) from a point $x \in \mathbb{R}^n$ to the point $\bar{x}$.

Remark 2.1. Obviously, the control function u associated to a minimal time trajectory of (1.1), (1.2), actually satisfies $\sum_{i=1}^{m} u_i^2 = 1$.

For $T > 0$, let $\mathcal{U}_T$ denote the (open) subset of $u(\cdot)$ in $L^\infty([0,T], \mathbb{R}^m)$ such that the solution of (1.1), starting from $\bar{x}$ and associated to a control $u(\cdot) \in \mathcal{U}_T$, is well defined on $[0,T]$. The mapping

$$\begin{array}{rccc} E_{\bar{x},T}: & \mathcal{U}_T & \longrightarrow & \mathbb{R}^n \\ & u(\cdot) & \longmapsto & x(T), \end{array}$$

[1] This conjecture on patchy feedbacks has been recently considered in [6]. In this preprint, written during the review process of the present work, the authors prove, using a penalization method, a general result on stabilization by means of patchy feedback of nonlinear control systems in quasi-minimal time.

which to a control $u(\cdot)$ associates the end-point $x(T)$ of the corresponding solution $x(\cdot)$ of (1.1) starting at $\bar{x}$, is called *end-point mapping* at the point $\bar{x}$, in time T; it is a smooth mapping.

DEFINITION 2.2. *A trajectory $x(\cdot)$ of (1.1), so that $x(0) = \bar{x}$, is said to be singular on $[0,T]$ if its associated control $u(\cdot)$ is a singular point of the end-point mapping $E_{\bar{x},T}$ (i.e., if the Fréchet derivative of $E_{\bar{x},T}$ at $u(\cdot)$ is not onto). The control $u(\cdot)$ is said to be singular.*

Remark 2.3. If $x(\cdot)$ is singular on $[0,T]$, then it is singular on $[t_0,t_1]$ for all $t_0,t_1 \in [0,T]$ such that $t_0 < t_1$.

Remark 2.4. It is a standard fact that the minimal time control problem for the system (1.1) with the constraint (1.2) is equivalent to the sub-Riemannian problem associated to the m-tuple of vector fields $(f_1,\dots,f_m)$ (see [10] for a general definition of a sub-Riemannian distance). In this context, there holds $T_{\bar{x}}(x) = d_{SR}(\bar{x},x)$, where d_{SR} is the sub-Riemannian distance. This implies that the functions $T_{\bar{x}}(\cdot)$ and $d_{SR}(\bar{x},\cdot)$ share the same regularity properties. In particular, the function $T_{\bar{x}}(\cdot)$ is continuous.

2.2. Class of controllers and notion of hybrid solution. Let $f : \mathbb{R}^n \times \mathbb{R}^m \to \mathbb{R}^n$ be defined by $f(x,u) = \sum_{i=1}^m u_i f_i(x)$. The system (1.1) is written as

$$\dot{x}(t) = f(x(t),u(t)). \tag{2.1}$$

Let $\bar{x} \in \mathbb{R}^n$ be fixed.

The controllers under consideration in this paper depend on the continuous state $x \in \mathbb{R}^n$ and also on a discrete variable $s_d \in \mathcal{N}$, where $\mathcal{N}$ is a nonempty subset of $\mathbb{N}$. According to the concept of a hybrid system of [25], we introduce the following definition.

DEFINITION 2.5. *A hybrid feedback is a 4-tuple (C,D,k,k_d), where*

- *C and D are subsets of $\mathbb{R}^n \times \mathcal{N}$;*
- *$k : \mathbb{R}^n \times \mathcal{N} \to \mathbb{R}^m$ is a function;*
- *$k_d : \mathbb{R}^n \times \mathcal{N} \to \mathcal{N}$ is a function.*

The sets C and D are, respectively, called the controlled continuous evolution set *and the* controlled discrete evolution set.

We next recall the notion of robustness to small noise (see [46]). Consider two functions e and d satisfying the following *regularity assumptions*:

$$\begin{aligned} &e(\cdot,\cdot), d(\cdot,\cdot) \in L^\infty_{loc}(\mathbb{R}^n \times [0,+\infty);\mathbb{R}^n),\\ &e(\cdot,t), d(\cdot,t) \in C^0(\mathbb{R}^n,\mathbb{R}^n)\ \forall t \in [0,+\infty). \end{aligned} \tag{2.2}$$

We introduce these functions as a measurement noise e and an external disturbance d.

Formally, the k-component of a hybrid feedback (k,k_d,C,D) governs the differential equation

$$\dot{x} = f(x,k(x+e)) + d \ \ \forall (x,s_d) \in C,$$

whereas the k_d-component governs the jump equation

$$s_d^+ = k_d(x,s_d) \ \ \forall (x,s_d) \in D.$$

The set C indicates where in the state space flow may occur, while the set D indicates where in the state space jumps may occur. The combination of this flow equation and this jump equation, under the perturbations e and d, is a perturbed hybrid system

$\mathcal{H}_{(e,d)}$, as considered, e.g., in [26]. We next provide a precise definition of the notion of solutions considered here.

This concept is well studied in the literature (see, e.g., [11, 14, 31, 38, 39, 49]). Here, we consider the notion of solution given in [25, 26].

DEFINITION 2.6. *Let* $S = \bigcup_{j=0}^{J-1} [t_j, t_{j+1}] \times \{j\}$, *where* $J \in \mathbb{N} \cup \{+\infty\}$ *and* $(x_0, s_0) \in \mathbb{R}^n \times \mathcal{N}$. *The domain* S *is said to be a hybrid time domain. A map* $(x, s_d) : S \to \mathbb{R}^n \times \mathcal{N}$ *is said to be a solution of* $\mathcal{H}_{(e,d)}$ *with the initial condition* (x_0, s_0) *if*

- *the map* x *is continuous on* S;
- *for every* j, $0 \leqslant j \leqslant J-1$, *the map* $x : t \in (t_j, t_{j+1}) \mapsto x(t, j)$ *is absolutely continuous;*
- *for every* j, $0 \leqslant j \leqslant J-1$, *and almost every* $t \geqslant 0$, $(t, j) \in S$, *we have*

$$(x(t,j) + e(x(t,j), t), s_d(t,j)) \in C \tag{2.3}$$

and

$$\dot{x}(t,j) = f(x(t), k(x(t,j) + e(x(t,j), t), s_d(t,j))) + d(x(t,j), t), \tag{2.4}$$

$$\dot{s}_d(t,j) = 0 \tag{2.5}$$

(where the dot stands for the derivative with respect to the time variable t*);*

- *for every* $(t, j) \in S$, $(t, j+1) \in S$, *we have*

$$(x(t,j) + e(x(t,j), t), s_d(t,j)) \in D \tag{2.6}$$

and

$$x(t, j+1) = x(t, j), \tag{2.7}$$

$$s_d(t, j+1) = k_d(x(t,j) + e(x(t,j), t), s_d(t,j)); \tag{2.8}$$

- $(x(0,0), s_d(0,0)) = (x_0, s_0)$.

In this context, we next define the concept of stabilization of (2.1) by a minimal time hybrid feedback law sharing a robustness property with respect to measurement noise and external disturbances. The usual Euclidean norm in $\mathbb{R}^n$ is denoted by $|\cdot|$, and the open ball centered at $\bar{x}$ with radius R is denoted $B(\bar{x}, R)$. Recall that a function of class $\mathcal{K}_\infty$ is a function δ: $[0, +\infty) \to [0, +\infty)$ which is continuous, increasing, and satisfies $\delta(0) = 0$ and $\lim_{R \to +\infty} \delta(R) = +\infty$.

As usual, the system is said to be complete if all solutions are maximally defined in $[0, +\infty)$ (see, e.g., [7]). More precisely, we have the following definition.

DEFINITION 2.7. *Let* $\rho : \mathbb{R}^n \to \mathbb{R}$ *be a continuous function satisfying*

$$\rho(x) > 0 \ \forall x \neq \bar{x}. \tag{2.9}$$

We say that the completeness assumption *for* ρ *holds if, for all* (e, d) *satisfying the regularity assumptions* (2.2), *and such that*

$$\sup_{[0,+\infty)} |e(x, \cdot)| \leqslant \rho(x), \ \operatorname{esssup}_{[0,+\infty)} |d(x, \cdot)| \leqslant \rho(x) \ \forall x \in \mathbb{R}^n, \tag{2.10}$$

for every $(x_0, s_0) \in \mathbb{R}^n \times \mathcal{N}$, *there exists a maximal solution on* $[0, +\infty)$ *of* $\mathcal{H}_{(e,d)}$ *starting from* (x_0, s_0).

Roughly speaking, the finite time convergence property means that all solutions reach $\bar{x}$ within finite time. A precise definition of this concept follows.

DEFINITION 2.8. *We say that the* uniform finite time convergence property *holds if there exists a continuous function* $\rho : \mathbb{R}^n \to \mathbb{R}$ *satisfying* (2.9)*, such that the completeness assumption for* ρ *holds, and if there exists a function* $\delta : [0, +\infty) \to [0, +\infty)$ *of class* $\mathcal{K}_\infty$ *such that, for every* $R > 0$*, there exists* $\tau = \tau(R) > 0$*, so that for all functions* e, d *satisfying the regularity assumptions* (2.2) *and inequalities* (2.10) *for this function* ρ*, for every* $x_0 \in B(\bar{x}, R)$*, and every* $s_0 \in \mathcal{N}$*, the maximal solution* (x, s_d) *of* $\mathcal{H}_{(e,d)}$ *starting from* (x_0, s_0) *satisfies*

$$|x(t, j) - \bar{x}| \leqslant \delta(R) \ \forall t \geqslant 0, \ (t, j) \in S, \tag{2.11}$$

and

$$x(t, j) = \bar{x} \ \forall t \geqslant \tau, \ (t, j) \in S. \tag{2.12}$$

We are now in a position to introduce our main definition. It deals with closed-loop systems whose trajectories converge to the equilibrium within quasi-minimal time and with a robustness property with respect to measurement noise and external disturbances.

DEFINITION 2.9. *The point* $\bar{x}$ *is said to be a* semiglobally quasi-minimal time robustly stabilizable equilibrium *for the system* (2.1) *if, for every* $\varepsilon > 0$ *and every compact subset* $K \subset \mathbb{R}^n$*, there exists a hybrid feedback law* (C, D, k, k_d) *satisfying the constraint*

$$\|k(x, s_d)\| \leqslant 1, \tag{2.13}$$

where $\|\cdot\|$ *stands for the Euclidean norm in* $\mathbb{R}^m$*, such that*

- *the uniform finite time convergence property holds;*
- *there exists a continuous function* $\rho_{\varepsilon,K} : \mathbb{R}^n \to \mathbb{R}$ *satisfying* (2.9) *for* $\rho = \rho_{\varepsilon,K}$*, such that, for every* $(x_0, s_0) \in K \times \mathcal{N}$*, all functions* e, d *satisfying the regularity assumptions* (2.2) *and inequalities* (2.10) *for* $\rho = \rho_{\varepsilon,K}$*, the maximal solution of* $\mathcal{H}_{(e,d)}$ *starting from* (x_0, s_0) *reaches* $\bar{x}$ *within time* $T_{\bar{x}}(x_0) + \varepsilon$*, where* $T_{\bar{x}}(x_0)$ *denotes the minimal time to steer the system* (2.1) *from* x_0 *to* $\bar{x}$*, under the constraint* $\|u\| \leqslant 1$*.*

2.3. Main result. The main result of this article is the following.

THEOREM 2.10. *Let* $\bar{x} \in \mathbb{R}^n$*. If there exists no nontrivial minimal time singular trajectory of* (1.1)*,* (1.2)*, starting from* $\bar{x}$*, then* $\bar{x}$ *is a semiglobally quasi-minimal time robustly stabilizable equilibrium for the system* (1.1)*, under the constraint* (1.2)*.*

Remark 2.11. The problem of global quasi-minimal time robust stabilization (i.e., $K = \mathbb{R}^n$ in Definition 2.9) cannot be achieved a priori because measurement noise may then accumulate and slow down the solution reaching $\bar{x}$ (compare with [15]).

Remark 2.12. The assumption of the absence of nontrivial singular minimizing trajectory is crucial. Notice the following facts, which show the relevance of this assumption:

- If $m \geqslant n$ and if the vector fields $f_1, \ldots, f_m$, are everywhere linearly independent, then there exists no singular trajectory. In this case, we are actually in the framework of Riemannian geometry (see Remark 2.4).
- Let $\mathcal{F}_m$ be the set of m-tuples of linearly independent vector fields $(f_1, \ldots, f_m)$, endowed with the C^∞ Whitney topology. If $m \geqslant 3$, there exists an open dense subset of $\mathcal{F}_m$, such that any control system of the form (1.1), associated to a m-tuple of this subset, admits no nontrivial singular minimizing trajectory

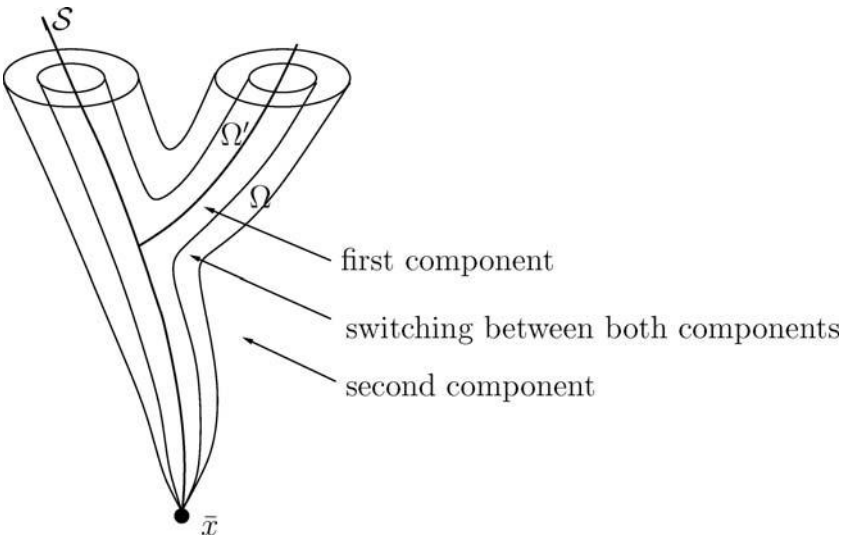

FIG. 2.1. *Switching strategy.*

(see [17, 18]; see also [2] for the existence of a dense set only). Hence generically the conclusion of Theorem 2.10 holds without assuming the absence of nontrivial singular minimizing trajectories.

- If there exist singular minimizing trajectories, then the conclusion on subanalyticity of the function T may fail (see [13, 50]), and we cannot a priori prove that the set $\mathcal{S}$ of singularities of T is a stratifiable manifold, which is the crucial fact in order to define a hybrid strategy.

2.4. Short description of the proof. The strategy of the proof of Theorem 2.10 is the following.

Under the assumption of the absence of nontrivial singular minimal time trajectory, the minimal time function $T_{\bar{x}}$ associated to the system (1.1), (1.2) is subanalytic, and hence is analytic outside a stratified submanifold $\mathcal{S}$ of $\mathbb{R}^n$, of codimension greater than or equal to one. Therefore, the corresponding minimal time feedback controller (further precisely defined in section 3.2.3) is continuous (even analytic) on $\mathbb{R}^n \setminus \mathcal{S}$ (see Figure 2.1). In a neighborhood of $\mathcal{S}$, it is therefore necessary to use other controllers, and then to define an adequate switching strategy.

More precisely, the proof of Theorem 2.10 relies on both of the following key lemmas.

LEMMA 2.13. *For every $\varepsilon > 0$, there exists a neighborhood Ω of $\mathcal{S}$ such that, for every stratum*[2] *M_i of $\mathcal{S}$, there exist a nonempty subset $\mathcal{N}_i$ of $\mathbb{N}$, a locally finite family $(\Omega_{i,p})_{p\in\mathcal{N}_i}$ of open subsets of Ω, a sequence of smooth controllers $u_{i,p}$ defined in a neighborhood of $\Omega_{i,p}$, satisfying $\|u_{i,p}\| \leqslant 1$, and there exists a continuous function $\rho_{i,p} : \mathbb{R}^n \to [0, +\infty)$ satisfying $\rho_{i,p}(x) > 0$ whenever $x \neq \bar{x}$, such that every solution of*

$$\dot{x}(t) = f(x(t), u_{i,p}(x(t) + e(x(t), t))) + d(x(t), t), \tag{2.14}$$

[2]Since $\mathcal{S}$ is a stratified submanifold of $\mathbb{R}^n$ of codimension greater than or equal to one, there exists a partition $(M_i)_{i\in\mathbb{N}}$ of $\mathcal{S}$, where M_i is a stratum, i.e., a locally closed submanifold of $\mathbb{R}^n$. Recall that if $M_i \cap \partial M_j \neq \emptyset$, then $M_i \subset M_j$ and $\dim(M_i) < \dim(M_j)$.

where $e, d : \mathbb{R}^n \times [0, +\infty) \to \mathbb{R}^n$ *are two functions satisfying the regularity assumptions* (2.2) *and*

$$\sup_{[0,+\infty)} |e(x,\cdot)| \leqslant \rho_{i,p}(x), \quad \operatorname{esssup}_{[0,+\infty)} |d(x,\cdot)| \leqslant \rho_{i,p}(x), \tag{2.15}$$

starting from $\Omega_{i,p}$ *and maximally defined on* $[0, T)$*, leaves* Ω *within time* ε*; moreover, there exists a function* $\delta_{i,p}$ *of class* $\mathcal{K}_\infty$ *such that, for every* $R > 0$*, every such solution starting from* $\Omega_{i,p} \cap B(\bar{x}, R)$ *satisfies*

$$|x(t) - \bar{x}| \leqslant \delta_{i,p}(R) \quad \forall t \in [0, T). \tag{2.16}$$

According to this lemma, in a neighborhood Ω of $\mathcal{S}$, there exist controllers steering the system outside Ω. Moreover, since this neighborhood can be chosen arbitrarily thin, the time ε needed for its traversing is arbitrarily small.

Outside Ω, the optimal controller is analytic. The following lemma shows that this controller shares an invariance property; in brief, it gives rise to trajectories never again crossing the singular set $\mathcal{S}$.

LEMMA 2.14. *For every neighborhood* Ω *of* $\mathcal{S} \setminus \{\bar{x}\}$ *in* $\mathbb{R}^n$*, there exists a neighborhood* Ω' *of* $\mathcal{S} \setminus \{\bar{x}\}$ *in* $\mathbb{R}^n$*, satisfying*

$$\Omega' \subsetneq \operatorname{clos}(\Omega') \subsetneq \Omega, \tag{2.17}$$

such that every trajectory of the closed-loop system (1.1) *with the optimal controller, starting from any point* $x \in \mathbb{R}^n \setminus \Omega$*, reaches* $\bar{x}$ *in minimal time, and is contained in* $\mathbb{R}^n \setminus \Omega'$*.*

Finally, our hybrid strategy is the following. For every $\varepsilon > 0$, there exists a neighborhood Ω of the singular set $\mathcal{S}$, and there exist controllers which steer the system outside this neighborhood in time less than ε. Outside Ω, there exists a continuous controller giving rise to trajectories never again crossing $\mathcal{S}$ and joining $\bar{x}$ in minimal time.

It is therefore necessary to define an adequate switching strategy connecting both controllers (see Figure 2.1). This is achieved in the context of hybrid systems, using a hysteresis strategy. The first component consists of controllers which are defined in Ω, and whose existence is stated in Lemma 2.13. The second component of the hysteresis is defined by the optimal controller, outside Ω. Both components are united using an hysteresis, by adding a dynamical discrete variable s_d and using a hybrid feedback law. With this resulting hybrid controller, the time needed to join $\bar{x}$, from any point x_0 of $\mathbb{R}^n$, is less than $T_{\bar{x}}(x_0) + \varepsilon$.

The next section, devoted to the detailed proof of Theorem 2.10, is organized as follows.

The first component of the hysteresis is defined in section 3.1, and Lemma 2.13 is proved.

Section 3.2 concerns the definition and properties of the second component of the hysteresis, defined by the minimal time controller. In section 3.2.1, we recall how to compute minimal time trajectories of the system (1.1), (1.2), using the Pontryagin maximum principle. We then provide in section 3.2.2 a crucial result on the cut locus (Proposition 3.6). The optimal feedback controller is defined in section 3.2.3; basic facts on subanalytic functions are recalled, permitting us to define the singular set $\mathcal{S}$. Invariance properties of this optimal controller are then investigated: Lemma 2.14 is proved in section 3.2.4; robustness properties are given and proved in section 3.2.5.

The hybrid controller is then defined in section 3.3. A definition of a hybrid control system, and properties of solutions, are given in sections 3.3.1 and 3.3.2. A

precise description of the switching strategy is provided in section 3.3.3. Theorem 2.10 is proved in section 3.4.

3. Proof of Theorem 2.10. In what follows, let $\bar{x} \in \mathbb{R}^n$ be fixed.

3.1. The first component of the hysteresis. The first component of the hysteresis consists of a set of controllers, defined in a neighborhood of $\mathcal{S}$, whose existence is stated in Lemma 2.13. Hereafter, we provide a proof of this lemma.

Proof of Lemma 2.13. First of all, recall that, on the one hand, the minimal time function coincides with the sub-Riemannian distance associated to the m-tuple $(f_1, \dots, f_m)$ (see Remark 2.4); on the other, since the Lie algebra rank condition holds, the topology defined by the sub-Riemannian distance d_{SR} coincides with the Euclidean topology of $\mathbb{R}^n$, and, since $\mathbb{R}^n$ is complete, any two points of $\mathbb{R}^n$ can be joined by a minimizing path (see [10]).

Let $\varepsilon > 0$ fixed. Since $\mathcal{S}$ is a stratified submanifold of $\mathbb{R}^n$, there exists a neighborhood Ω of $\mathcal{S}$ satisfying the following property: for every $y \in \mathcal{S}$, there exists $z \in \mathbb{R}^n \setminus \mathrm{clos}(\Omega)$ such that $d_{SR}(y, z) < \varepsilon$.

Consider a stratum M_i of $\mathcal{S}$. For every $y \in M_i$, let $z \in \mathbb{R}^n \setminus \mathrm{clos}(\Omega)$ such that $d_{SR}(y, z) < \varepsilon$. The Lie algebra rank condition implies that there exists an open-loop control $t \mapsto u_y(t)$, defined on $[0, T)$ for a $T > \varepsilon$, satisfying the constraint $\|u_y\| \leqslant 1$, such that the associated trajectory $x_y(\cdot)$ (which can be assumed to be one-to-one), solution of (1.1), starting from y, reaches z (and thus leaves $\mathrm{clos}(\Omega)$) within time ε. Using a density argument, the control u_y can, moreover, be chosen as a smooth function (see [10, Theorem 2.8, p. 21] for the proof of this statement). Since the trajectory is one-to-one, the open-loop control $t \mapsto u_y(t)$ can be considered as a feedback $t \mapsto u_y(x_y(t))$ along $x_y(\cdot)$. Consider a smooth extension of u_y on $\mathbb{R}^n$, still denoted u_y, satisfying the constraint $\|u_y(x)\| \leqslant 1$ for every $x \in \mathbb{R}^n$. By continuity, there exists a neighborhood Ω_y of y, and positive real numbers δ_y and ρ_y, such that every solution of

$$\dot{x}(t) = f(x(t), u_y(x(t) + e(x(t), t))) + d(x(t), t), \tag{3.1}$$

where $e, d : \mathbb{R}^n \times [0, +\infty) \to \mathbb{R}^n$ are two functions satisfying the regularity assumptions (2.2) and

$$\sup_{[0,+\infty)} |e(x, \cdot)| \leqslant \rho_y, \quad \operatorname{esssup}_{[0,+\infty)} |d(x, \cdot)| \leqslant \rho_y,$$

starting from Ω_y and maximally defined on $[0, T)$, leaves Ω within time ε; moreover,

$$|x(t) - \bar{x}| \leqslant \delta_y \ \forall t \in [0, T).$$

Repeat this construction for each $y \in M_i$.

Now, on the one hand, let $(y_p)_{p \in \mathcal{N}_i}$ be a sequence of points of M_i such that the family $(\Omega_{y_p})_{p \in \mathcal{N}_i}$ is a locally finite covering of M_i, where $\mathcal{N}_i$ is a subset of $\mathbb{N}$. Define $\Omega_{i,p} = \Omega_{y_p}$ and $u_{i,p} = u_{y_p}$.

On the other hand, the existence of a continuous function $\rho_{i,p} : \mathbb{R}^n \to [0, +\infty)$, satisfying $\rho_{i,p}(x) > 0$ whenever $x \neq x$, follows for the continuity of solutions with respect to disturbances. The existence of a function $\delta_{i,p}$ of class $\mathcal{K}_\infty$ such that (2.16) holds is obvious.

Repeat this construction for every stratum M_i of $\mathcal{S}$. Then the statement of the lemma follows. ∎

3.2. The second component of the hysteresis.

3.2.1. Computation of minimal time trajectories. Let $x_1 \in \mathbb{R}^n$, and let $x(\cdot)$ be a minimal time trajectory, associated to a control $u(\cdot)$, steering the system (1.1), (1.2), from $\bar{x}$ to x_1, in time $T = T_{\bar{x}}(x_1)$. According to Pontryagin's maximum principle (see [36]), the trajectory $x(\cdot)$ is the projection of an *extremal*, i.e., a triple $(x(\cdot), p(\cdot), u(\cdot))$ solution of the constrained Hamiltonian system

$$\dot{x}(t) = \frac{\partial H}{\partial p}(x(t), p(t), u(t)), \quad \dot{p}(t) = -\frac{\partial H}{\partial x}(x(t), p(t), u(t)),$$

$$H(x(t), p(t), p^0, u(t)) = \max_{\|v\| \leqslant 1} H(x(t), p(t), p^0, v),$$

almost everywhere on $[0, T]$, where

$$H(x, p, u) = \sum_{i=1}^{m} u_i \langle p, f_i(x) \rangle$$

is the *Hamiltonian* of the optimal control problem, and $p(\cdot)$ (called the *adjoint vector*) is an absolutely continuous mapping on $[0, T]$ such that $p(t) \in \mathbb{R}^n \setminus \{0\}$. Moreover, the function $t \mapsto \max_{\|v\| \leqslant 1} H(x(t), p(t), p^0, v)$ is Lipschitzian and everywhere constant on $[0, T]$. If this constant is not equal to zero, then the extremal is said to be *normal*; otherwise it is *abnormal*.

Remark 3.1. Any singular trajectory is the projection of an abnormal extremal, and conversely.

Controls associated to normal extremals can be computed as

$$u_i(t) = \frac{\langle p(t), f_i(x(t)) \rangle}{\sqrt{\sum_{j=1}^{m} \langle p(t), f_j(x(t)) \rangle^2}}, \ i = 1, \ldots, m. \tag{3.2}$$

Indeed, note that, by definition of normal extremals, the denominator of (3.2) cannot vanish. It follows that normal extremals are solutions of the Hamiltonian system

$$\dot{x}(t) = \frac{\partial H_1}{\partial p}(x(t), p(t)), \quad \dot{p}(t) = -\frac{\partial H_1}{\partial x}(x(t), p(t)), \tag{3.3}$$

where

$$H_1(x, p) = \sqrt{\sum_{i=1}^{m} \langle p, f_i(x) \rangle^2}.$$

Notice that $H_1(x(t), p(t))$ is constant, nonzero, along each normal extremal. Since $p(0)$ is defined up to a multiplicative scalar, it is usual to normalize it so that $H_1(x(t), p(t)) = 1$. Hence, we introduce the set

$$X = \{p_0 \in \mathbb{R}^n \mid H_1(\bar{x}, p_0) = 1\}.$$

It is a submanifold of $\mathbb{R}^n$ of codimension one, since $\frac{\partial H_1}{\partial p}(\bar{x}, p_0) = \dot{x}(0) \neq 0$ (see [12] for a similar construction in the general case). There exists a connected open subset

U of $[0,+\infty)\times X$ such that, for every $(t^*,p_0)\in X$, the differential system (3.3) has a well-defined smooth solution on $[0,t^*]$ such that $x(0)=\bar{x}$ and $p(0)=p_0$.

DEFINITION 3.2. *The smooth mapping*

$$\begin{array}{rccc}\exp_{\bar{x}}: & U & \longrightarrow & \mathbb{R}^n\\ & (t,p_0) & \longmapsto & x(t),\end{array}$$

where $(x(\cdot),p(\cdot))$ is the solution of the system (3.3) *such that $x(0)=\bar{x}$ and $p(0)=p_0\in X$, is called* exponential mapping *at the point $\bar{x}$.*

The exponential mapping parameterizes normal extremals. Note that the domain of $\exp_{\bar{x}}$ is a subset of $\mathbb{R}\times X$ which is locally diffeomorphic to $\mathbb{R}^n$ (since we are in the normal case).

DEFINITION 3.3. *A point $x\in\exp_{\bar{x}}(U)$ is said to be* conjugate *to $\bar{x}$ if it is a critical value of the mapping $\exp_{\bar{x}}$, i.e., if there exists $(t_c,p_0)\in U$ such that $x=\exp_{\bar{x}}(t_c,p_0)$ and the differential $d\exp_{\bar{x}}(t_c,p_0)$ is not onto. The* conjugate locus *of $\bar{x}$, denoted by $\mathcal{C}(\bar{x})$, is defined as the set of all points conjugate to $\bar{x}$.*

With the previous notation, define $\mathcal{C}_{min}(\bar{x})$ as the set of points $x\in\mathcal{C}(\bar{x})$ such that the trajectory $t\mapsto\exp_{\bar{x}}(t,p_0)$ is minimizing between $\bar{x}$ and x.

3.2.2. The cut locus. A standard definition is the following.

DEFINITION 3.4. *A point $x\in\mathbb{R}^n$ is not a* cut point *with respect to $\bar{x}$ if there exists a minimal time trajectory of* (1.1), (1.2), *joining $\bar{x}$ to x, which is the strict restriction of a minimal time trajectory starting from $\bar{x}$. The* cut locus *of $\bar{x}$, denoted by $\mathcal{L}(\bar{x})$, is defined as the set of all cut points with respect to $\bar{x}$.*

In other words, a cut point is a point at which a minimal time trajectory ceases to be optimal.

Remark 3.5. In the analytic case, it follows from the theory of conjugate points that every nonsingular minimal time trajectory ceases to be minimizing beyond its first conjugate point (see, for instance, [3, 13]). Hence, if there exists no singular minimal time trajectory starting from $\bar{x}$, then $\mathcal{C}_{min}(\bar{x})\subset\mathcal{L}(\bar{x})$.

The following result on the cut locus is crucial for the proof of Theorem 2.10.

PROPOSITION 3.6. *Assume that the vector fields $f_1,\dots,f_m$ are analytic, and that there exists no singular minimal time trajectory starting from $\bar{x}$. Then the set of points of $\mathbb{R}^n$ where the function $T_{\bar{x}}(\cdot)$ is not analytic is equal to the cut locus of $\bar{x}$, that is,*

$$\operatorname{Sing} T_{\bar{x}}(\cdot)=\mathcal{L}(\bar{x}). \tag{3.4}$$

Remark 3.7. Under the previous assumptions, one can prove that the set of points of $\mathbb{R}^n$ where $T_{\bar{x}}(\cdot)$ is analytic is equal to the set of points where $T_{\bar{x}}(\cdot)$ is of class C^1.

Proof. Let $x\in\mathbb{R}^n$ so that $T_{\bar{x}}(\cdot)$ is analytic at x. Then there exists a neighborhood V of x in $\mathbb{R}^n$ such that $T_{\bar{x}}(\cdot)$ is analytic on V. Let us prove that $x\notin\mathcal{L}(\bar{x})$. It follows from the maximum principle and the Hamilton–Jacobi theory (see [36]) that, for every $y\in V$, there exists a unique minimal time trajectory joining $\bar{x}$ to y having, moreover, a normal extremal lift $(x(\cdot),p(\cdot),u(\cdot))$ satisfying

$$p(T_{\bar{x}}(y))=\nabla T_{\bar{x}}(y)$$

(compare with [44, Proposition 2.3]). Set $U_1=\exp_{\bar{x}}^{-1}(V)$. It follows easily from the Cauchy–Lipschitz theorem that the mapping $\exp_{\bar{x}}$ is an analytic diffeomorphism from U_1 into V. Hence, obviously, the point x is not in the cut locus of $\bar{x}$.

Conversely, let $x \notin \mathcal{L}(\bar{x})$. To prove that $T_{\bar{x}}(\cdot)$ is analytic at x, we need the following two lemmas.

LEMMA 3.8. *The point x is not conjugate to $\bar{x}$ and is joined from $\bar{x}$ by a unique minimal time trajectory.*

Proof of Lemma 3.8. From the assumption of the absence of a singular minimal time trajectory, there exists a nonsingular minimal time trajectory joining $\bar{x}$ to x. From Remark 3.5, the point x is not conjugate to $\bar{x}$.

By contradiction, suppose that x is joined from $\bar{x}$ by at least two minimal time trajectories. By assumption, these two trajectories must admit normal extremal lifts. Since the structure is analytic, their junction at the point x is necessarily not smooth. This implies that both trajectories lose their optimality at the point x (indeed if not, there would exist a nonsmooth normal extremal, which is absurd), and thus $x \in \mathcal{L}(\bar{x})$. This is a contradiction. □

LEMMA 3.9. *There exists a neighborhood V of x in $\mathbb{R}^n$ such that every point $y \in V$ is not conjugate to $\bar{x}$, and there exists a unique (nonsingular) minimal time trajectory joining $\bar{x}$ to y.*

Proof of Lemma 3.9. Let $p_0 \in X$ so that $x = \exp_{\bar{x}}(T_{\bar{x}}(x), p_0)$. Since x is not conjugate to $\bar{x}$, the exponential mapping $\exp_{\bar{x}}$ is a diffeomorphism from a neighborhood U_1 of $(T_{\bar{x}}(x), p_0)$ in U into a neighborhood V of x in $\mathbb{R}^n$. Set $U_2 = \exp_{\bar{x}}^{-1}(V)$.

Let us prove that $\exp_{\bar{x}}$ is proper from U_2 into V. We argue by contradiction and suppose that there exists a sequence $(x_n)_{n\in\mathbb{N}}$ of points of V converging towards x, such that for each integer n there exists $p_n \in X$, satisfying $(T_{\bar{x}}(x_n), p_n) \in U_2$ and $x_n = \exp_{\bar{x}}(T_{\bar{x}}(x_n), p_n)$, such that $(p_n)_{n\in\mathbb{N}}$ is not bounded. It then follows from [51, Lemmas 4.8 and 4.9] (see also [52, Fact 1, p. 378]) that x is joined from $\bar{x}$ by a singular control u. In particular, x is conjugate to $\bar{x}$; this is a contradiction.

Therefore, the set $\{p \mid \exp_{\bar{x}}(T_{\bar{x}}(x), p) = x\}$ is compact in U_2. Moreover, since x is not conjugate to $\bar{x}$, this set has no cluster point, and thus is finite. As a consequence, up to reducing V, we assume that V is a connected open subset of $\exp_{\bar{x}}(U_2)$, and that U_2 is a finite union of disjoint connected open sets, all of which are diffeomorphic to V by the mapping $\exp_{\bar{x}}$. We infer that every point $y \in V$ is not conjugate to $\bar{x}$. Hence, the mapping $\exp_{\bar{x}}$ is a proper submersion from U_2 into V, and thus is a fibration with finite degree. Since, from Lemma 3.8, there exists a unique minimal time trajectory joining $\bar{x}$ to x, this degree is equal to one, that is, $\exp_{\bar{x}}$ is a diffeomorphism from U_2 into V. The conclusion follows. □

It follows from the previous lemma that $(T_{\bar{x}}(y), p_0) = \exp_{\bar{x}}^{-1}(y)$ for every $y \in V$, and hence $T_{\bar{x}}(\cdot)$ is analytic on V. □

3.2.3. Definition of the optimal controller. By assumption, there does not exist any nontrivial singular minimal time trajectory starting from $\bar{x}$. Under these assumptions, the function $T_{\bar{x}}(\cdot)$ is *subanalytic* outside $\bar{x}$ (see [1, 2, 50], combined with Remark 2.4).

For the sake of completeness, we recall below the definition of a subanalytic function (see [27, 28]) and some properties that are used in a crucial way in the present paper (see [48]).

Let M be a real analytic finite-dimensional manifold. A subset A of M is said to be *semianalytic* if and only if, for every $x \in M$, there exists a neighborhood U of x in M and $2pq$ analytic functions g_{ij}, h_{ij} $(1 \leqslant i \leqslant p$ and $1 \leqslant j \leqslant q)$, such that

$$A \cap U = \bigcup_{i=1}^{p} \{y \in U \mid g_{ij}(y) = 0 \text{ and } h_{ij}(y) > 0,\ j = 1, \dots, q\}.$$

Let SEM(M) denote the set of semianalytic subsets of M. The image of a semianalytic subset by a proper analytic mapping is not in general semianalytic, and thus this class has to be enlarged.

A subset A of M is said to be *subanalytic* if and only if, for every $x \in M$, there exist a neighborhood U of x in M and $2p$ couples $(\Phi_i^\delta, A_i^\delta)$ $(1 \leqslant i \leqslant p$ and $\delta = 1, 2)$, where $A_i^\delta \in SEM(M_i^\delta)$, and where the mappings $\Phi_i^\delta : M_i^\delta \to M$ are proper analytic, for real analytic manifolds M_i^δ, such that

$$A \cap U = \bigcup_{i=1}^{p} (\Phi_i^1(A_i^1) \backslash \Phi_i^2(A_i^2)).$$

Let SUB(M) denote the set of subanalytic subsets of M.

The subanalytic class is closed by union, intersection, complementary, inverse image by an analytic mapping, and image by a proper analytic mapping. In brief, the subanalytic class is *o-minimal* (see [23]). Moreover subanalytic sets are *stratifiable* in the following sense. A *stratum* of a differentiable manifold M is a locally closed submanifold of M. A locally finite partition $\mathcal{S}$ of M is a *stratification* of M if any $S \in \mathcal{S}$ is a stratum such that

$$\forall T \in \mathcal{S} \quad T \cap \partial S \neq \emptyset \Rightarrow T \subset \partial S \quad \text{and} \quad \dim T < \dim S.$$

Finally, a mapping $f : M \to N$ between two analytic manifolds is said to be *subanalytic* if its graph is a subanalytic subset of $M \times N$.

Let M be an analytic manifold, and let f be a subanalytic function on M. The *analytic singular support* of f is defined as the complement of the set of points x in M such that the restriction of f to some neighborhood of x is analytic. The following property is of great interest in the present paper (see [48]): the analytic singular support of f is subanalytic (and thus, in particular, is stratifiable). If f is, moreover, locally bounded on M, then it is of codimension greater than or equal to one.

Let us turn back to our problem. The function $T_{\bar{x}}(\cdot)$ is subanalytic outside $\bar{x}$, and, hence, its singular set $\mathcal{S} = \text{Sing } T_{\bar{x}}(\cdot)$ (i.e., the analytic singular support of $T_{\bar{x}}(\cdot)$) is a stratified submanifold of $\mathbb{R}^n$, of codimension greater than or equal to 1.

Remark 3.10. Note that the point $\bar{x}$ belongs to the adherence of $\mathcal{S}$ (see [1]).

Outside the singular set $\mathcal{S}$, it follows from the dynamic programming principle (see [36]) that the minimal time controllers steering a point $x \in \mathbb{R}^n \setminus \mathcal{S}$ to $\bar{x}$ are given by the closed-loop formula

$$u_i(x) = -\frac{\langle \nabla T_{\bar{x}}(x), f_i(x) \rangle}{\sqrt{\sum_{j=1}^m \langle \nabla T_{\bar{x}}(x), f_j(x) \rangle^2}}, \ i = 1, \ldots, m. \tag{3.5}$$

The objective is to construct neighborhoods of $\mathcal{S} \setminus \{\bar{x}\}$ in $\mathbb{R}^n$ whose complements share invariance properties for the optimal flow. This is the contents of Lemma 2.14, proved next.

3.2.4. Proof of Lemma 2.14. It suffices to prove that, for every compact subset K of $\mathbb{R}^n$ and for every neighborhood Ω of $\mathcal{S} \setminus \{\bar{x}\}$ in $\mathbb{R}^n$, there exists a neighborhood Ω' of $\mathcal{S} \setminus \{\bar{x}\}$ in $\mathbb{R}^n$, satisfying (2.17), such that every trajectory of the closed-loop system (1.1) with the optimal controller, joining a point $x \in (\mathbb{R}^n \setminus \Omega) \cap K$ to $\bar{x}$, is contained in $\mathbb{R}^n \setminus \Omega'$.

By definition of the cut locus, and using Proposition 3.6, every optimal trajectory joining a point $x \in (\mathbb{R}^n \setminus \Omega) \cap K$ to $\bar{x}$ does not intersect $\mathcal{S}$, and thus has a positive

distance to the set $\mathcal{S}$. Using the assumption of the absence of nontrivial singular minimizing trajectories starting from $\bar{x}$, a reasoning similar to the proof of Lemma 3.9 proves that the optimal flow joining points of the compact set $(\mathbb{R}^n \setminus \Omega) \cap K$ to $\bar{x}$ is parameterized by a compact set. Hence, there exists a positive real number $\delta > 0$ so that every optimal trajectory joining a point $x \in (\mathbb{R}^n \setminus \Omega) \cap K$ to $\bar{x}$ has a distance to the set $\mathcal{S}$ which is greater than or equal to δ. The existence of Ω' follows.

3.2.5. Robustness properties of the optimal controller. In this section, we prove robustness properties of the Carathéodory solutions of system (2.1) in closed-loop with this feedback optimal controller. Given $e, d : \mathbb{R}^n \times [0, +\infty) \to \mathbb{R}^n$, the perturbed system in closed-loop with the optimal controller (denoted u_{opt}) is

$$\dot{x}(t) = f(x(t), u_{opt}(x(t) + e(x(t), t))) + d(x(t), t). \tag{3.6}$$

Since the optimal controller is continuous outside the singular set $\mathcal{S}$, it enjoys a natural robustness property, stated below. In the next result, the notation $d(x, \mathcal{S})$ stands for the Euclidean distance from x to $\mathcal{S}$.

LEMMA 3.11. *There exist a continuous function $\rho_{opt} : \mathbb{R} \to \mathbb{R}$ satisfying*

$$\rho_{opt}(\xi) > 0 \ \forall \xi \neq 0 \tag{3.7}$$

and a continuous function $\delta_{opt} : [0, +\infty) \to [0, +\infty)$ of class $\mathcal{K}_\infty$ such that the following three properties hold:

- Robust Stability.
  For every neighborhood Ω of $\mathcal{S}$, there exists a neighborhood $\Omega' \subset \Omega$ of $\mathcal{S}$, such that, for all $e, d : \mathbb{R}^n \times [0, +\infty) \to \mathbb{R}^n$ satisfying the regularity assumptions (2.2) *and, for every $x \in \mathbb{R}^n$,*

  $$\sup_{[0,+\infty)} |e(x, \cdot)| \leqslant \rho_{opt}(d(x, \mathcal{S})), \ \operatorname{esssup}_{[0,+\infty)} |d(x, \cdot)| \leqslant \rho_{opt}(d(x, \mathcal{S})), \tag{3.8}$$

  and for every $x_0 \in \mathbb{R}^n \setminus \Omega$, there exists a unique Carathéodory solution $x(\cdot)$ of (3.6) *starting from x_0, maximally defined on $[0, +\infty)$, and satisfying $x(t) \in \mathbb{R}^n \setminus \Omega'$ for every $t > 0$.*
- Finite time convergence.
  For every $R > 0$, there exists $\tau_{opt} = \tau_{opt}(R) > 0$ such that, for all $e, d : \mathbb{R}^n \times [0, +\infty) \to \mathbb{R}^n$ satisfying the regularity assumptions (2.2) *and* (3.8)*, for every $x_0 \in \mathbb{R}^n$ with $|x_0 - \bar{x}| \leqslant R$, and every maximal solution $x(\cdot)$ of* (3.6) *starting from x_0, one has*

  $$|x(t) - \bar{x}| \leqslant \delta_{opt}(R) \ \forall t \geqslant 0, \tag{3.9}$$

  $$x(t) = \bar{x} \ \forall t \geqslant \tau_{opt}, \tag{3.10}$$

  and

  $$\|u_{opt}(x(t))\| \leqslant 1 \ \forall t \geqslant 0. \tag{3.11}$$

- Optimality.
  For every neighborhood Ω of $\mathcal{S}$, every $\varepsilon > 0$, and every compact subset K of $\mathbb{R}^n$, there exists a continuous function $\rho_{\varepsilon,K} : \mathbb{R}^n \to \mathbb{R}$ satisfying (2.9) *such*

that, for all $e, d : \mathbb{R}^n \times [0, +\infty) \to \mathbb{R}^n$ *satisfying the regularity assumptions* (2.2) *and*

$$\begin{aligned} &\sup_{[0,+\infty)}|e(x,\cdot)| \leqslant \min(\rho_{opt}(d(x,\mathcal{S})), \rho_{\varepsilon,K}(x)), \\ &\operatorname{esssup}_{[0,+\infty)}|d(x,\cdot)| \leqslant \min(\rho_{opt}(d(x,\mathcal{S}), \rho_{\varepsilon,K}(x)) \ \forall x \in \mathbb{R}^n, \end{aligned} \tag{3.12}$$

and for every $x_0 \in K \cap (\mathbb{R}^n \setminus \Omega)$*, the solution of* (3.6)*, starting from* x_0*, reaches* $\bar{x}$ *within time* $T_{\bar{x}}(x_0) + \varepsilon$*.*

Proof. Since Carathéodory conditions hold for the system (3.6), the existence of a unique Carathéodory solution of (3.6), for every initial condition, is ensured. Inequality (3.11) follows from the constraint (1.2). Since the optimal controller u_{opt} defined by (3.5) is continuous on $\mathbb{R}^n \setminus \mathcal{S}$, Lemma 2.14 implies the existence of $\rho_{opt} : \mathbb{R}^n \to [0, +\infty)$ so that the *robust stability* and the *finite time convergence* properties hold.

The so-called *optimality* property follows from the definition of u_{opt}, from the continuity of solutions with respect to disturbances, and from the compactness of the set of all solutions starting from $K \cup (\mathbb{R}^n \setminus \Omega)$. ∎

3.3. Definition of the hybrid feedback law. A switching strategy must be defined in order to connect the first component (optimal controller), and the second component (consisting of a set of controllers, stated in Lemma 2.13). The switching strategy is achieved by adding a dynamical discrete variable s_d and using a hybrid feedback law, described next.

3.3.1. A class of hybrid feedbacks. Let $\mathcal{F} = \{1, \dots, 6\}$, and let $\mathcal{N}$ be a countable set. In what follows, Greek letters refer to elements of $\mathcal{N}$. Fix ω as an element of $\mathcal{N}$. We emphasize that we do not introduce any order in $\mathcal{N}$.

Given a set-valued map $F : \mathbb{R}^n \rightrightarrows \mathbb{R}^n$, we define the solutions $x(\cdot)$ of the differential inclusion $\dot{x} \in F(x)$ as all absolutely continuous functions satisfying $\dot{x}(t) \in F(x(t))$ almost everywhere.

DEFINITION 3.12. *The family* $(\mathbb{R}^n \setminus \{\bar{x}\}, ((\Omega_{\alpha,l})_{l\in\mathcal{F}}, g_\alpha)_{\alpha\in\mathcal{N}})$ *is said to satisfy the property* $(\mathcal{P})$ *if*

1. *for every* $(\alpha, l) \in \mathcal{N} \times \mathcal{F}$*, the set* $\Omega_{\alpha,l}$ *is an open subset of* $\mathbb{R}^n$*;*
2. *for every* $\alpha \in \mathcal{N}$ *and every* $m > l \in \mathcal{F}$*,*

$$\Omega_{\alpha,l} \subsetneq \operatorname{clos}(\Omega_{\alpha,l}) \subsetneq \Omega_{\alpha,m}; \tag{3.13}$$

3. *for every* α *in* $\mathcal{N}$*,* g_α *is a smooth vector field, defined in a neighborhood of* $\operatorname{clos}(\Omega_{\alpha,6})$*, taking values in* $\mathbb{R}^n$*;*
4. *for every* $(\alpha, l) \in \mathcal{N} \times \mathcal{F}$*,* $l \leqslant 5$*, there exists a continuous function* $\rho_{\alpha,l} : \mathbb{R}^n \to [0, +\infty)$ *satisfying* $\rho_{\alpha,l}(x) \neq 0$ *whenever* $x \neq \bar{x}$ *such that every maximal solution* $x(\cdot)$ *of*

$$\dot{x} \in g_\alpha(x) + B(0, \rho_{\alpha,l}(x)), \tag{3.14}$$

defined on $[0, T)$ *and starting from* $\partial\Omega_{\alpha,l}$*, is such that*

$$x(t) \in \operatorname{clos}(\Omega_{\alpha,l+1}) \ \forall t \in [0, T);$$

5. *for every* $l \in \mathcal{F}$*, the sets* $(\Omega_{\alpha,l})_{\alpha\in\mathcal{N}}$ *form a locally finite covering of* $\mathbb{R}^n \setminus \{\bar{x}\}$*.*

Remark 3.13. Some observations are in order.

- First note that this notion is close to the notion of a family of nested patchy vector fields defined in [38]. However, note that, in general, the sets $(\Omega_{\alpha,l}, g_\alpha)$ may not be a patch as defined in [4, 38]. Indeed, due to property 4, the set $\Omega_{\alpha,l}$ may not be invariant for the system (3.14). Since the notion of a patch is one of the main ingredients of the proofs of [40], we cannot apply [40] directly, even though some notions are similar (see in particular Definition 3.14 below).
- To state our main result, we need a family of six nested patchy vector fields (see Remark 3.21 for comments on the necessity of six families). The patches 1, 2, 4, and 6 define the dynamics of the discrete component of our hybrid controller (see Definition 3.14 below). The patches 3 and 5 are used for technical reasons to handle the measurement noise.

We next define a class of hybrid controllers as those considered in section 2 (see also [40]).

DEFINITION 3.14. *Let $(\mathbb{R}^n \setminus \{\bar{x}\}, ((\Omega_{\alpha,l})_{l\in\mathcal{F}}, g_\alpha)_{\alpha\in\mathcal{N}})$ satisfy the property $(\mathcal{P})$ as in Definition* 3.12. *Assume that, for every α in $\mathcal{N}$, there exists a smooth function k_α defined in a neighborhood of $\Omega_{\alpha,6}$ and taking values in $\mathbb{R}^m$, such that, for every x in a neighborhood of $\Omega_{\alpha,6}$,*

$$g_\alpha(x) = f(x, k_\alpha(x)). \tag{3.15}$$

Set

$$D_1 = \Omega_{\omega,2}, \tag{3.16}$$

$$D_{\alpha,2} = \mathbb{R}^n \setminus \Omega_{\alpha,6}. \tag{3.17}$$

Let (C, D, k, k_d) be the hybrid feedback defined by

$$C = \{(x,\alpha) \mid x \in (\mathrm{clos}(\Omega_{\alpha,4}) \setminus \Omega_{\omega,1})\}, \tag{3.18}$$

$$D = \{(x,\alpha) \mid x \in D_1 \cup D_{\alpha,2}\}, \tag{3.19}$$

$$\begin{array}{rccll} k : \mathbb{R}^n \times \mathcal{N} & \to & \mathbb{R}^m & & \\ (x,\alpha) & \mapsto & k_\alpha(x) & \text{if} & x \in \Omega_{\alpha,6}, \\ & & 0 & \text{else}, & \end{array} \tag{3.20}$$

and

$$\begin{array}{rccll} k_d : \mathbb{R}^n \times \mathcal{N} & \rightrightarrows & \mathcal{N} & & \\ (x,\alpha) & \mapsto & \omega & \text{if } x \in \mathrm{clos}(\Omega_{\omega,1} \cap D_1) \text{ and if } x \notin D_{\alpha,2}, \\ & & \alpha' & \text{if } x \in \mathrm{clos}(\Omega_{\alpha',1} \cap D_{\alpha,2}). & \end{array} \tag{3.21}$$

The 4-tuple (C, D, k, k_d) is a hybrid feedback law on $\mathbb{R}^n$ as considered in section 2.2. *We denote by $\mathcal{H}_{(e,d)}$ the system* (2.1) *in closed-loop with such feedback with the perturbations e and d as measurement noise and external disturbance, respectively.*

In this definition, we do not use any order in $\mathcal{N}$. However, the element ω has a particular role in what follows, since it will refer to the optimal controller in the hybrid feedback law.

3.3.2. Properties of solutions. In this section, we investigate some properties of the solutions of the system in closed-loop with the hybrid feedback law defined above.

DEFINITION 3.15. *Let $\chi : \mathbb{R}^n \to \mathbb{R}$ be a continuous map such that $\chi(x) > 0$ for every $x \neq \bar{x}$.*

- *We say that χ is an admissible radius for the measurement noise if, for every $x \in \mathbb{R}^n$ and every $\alpha \in \mathcal{N}$, such that $x \in \Omega_{\alpha,6}$,*

$$\chi(x) < \frac{1}{2} \min_{l \in \{1,\dots,5\}} d(\mathbb{R}^n \setminus \Omega_{\alpha,l+1}, \Omega_{\alpha,l}). \tag{3.22}$$

- *We say that χ is an admissible radius for the external disturbances if, for every $x \in \mathbb{R}^n$, we have*

$$\chi(x) \leqslant \max_{(\alpha,l),\ x \in \Omega_{\alpha,l}} \rho_{\alpha,l}(x).$$

There exists an admissible radius for the measurement noise and for the external disturbances (note that, from (3.13), the right-hand side of inequality (3.22) is positive).

Consider an admissible radius χ for the measurement noise and the external disturbances. Let e and d be a measurement noise and an external disturbance respectively, such that, for all $(x,t) \in \mathbb{R}^n \times [0,+\infty)$,

$$e(x,t) \leqslant \chi(x), \quad d(x,t) \leqslant \chi(x). \tag{3.23}$$

The properties of the solutions of the system in closed-loop with the hybrid feedback law defined in Definition 3.14 are similar to those of [40]. Hence, we skip the proof of the following three lemmas, which do not use statement 4 of Definition 3.12 but only the definition of the hybrid feedback law.

LEMMA 3.16. *For all $(x_0, s_0) \in \mathbb{R}^n \times \mathcal{N}$, there exists a solution of $\mathcal{H}_{(e,d)}$ starting from (x_0, s_0).*

Recall that a Zeno solution is a complete solution whose domain of definition is bounded in the t-direction. A solution (x, s_d), defined on a hybrid domain S, is an instantaneous Zeno solution if there exist $t \geqslant 0$ and an infinite number of $j \in \mathbb{N}$ such that $(t,j) \in S$.

The Zeno solutions do not require a special treatment.

LEMMA 3.17. *There do not exist instantaneous Zeno solutions, although a finite number of switches may occur at the same time.*

We note, as usual, that maximal solutions of $\mathcal{H}_{(e,d)}$ blow up if their domain of definition is bounded. Since Zeno solutions are avoided, the blow-up phenomenon only concerns the t-direction of the domain of definition, and we get the following result (see also [25, Proposition 2.1]).

LEMMA 3.18. *Let (x, s_d) be a maximal solution of $\mathcal{H}_{(e,d)}$ defined on a hybrid time S. Suppose that the supremum T of S in the t-direction is finite. Then*

$$\limsup_{t \to T,\,(t,l) \in S} |x(t,l)| = +\infty.$$

We conclude this series of technical lemmas by studying the behavior of solutions between two jumps. For every $\alpha \in \mathcal{N}$, set

$$\begin{aligned} \tau_\alpha = \sup\big\{ T \mid x \text{ is a Carathéodory solution of } \dot{x} = f(x,k_\alpha) + B(0,\chi(x)) \\ \text{with } x(t) \in \Omega_{\alpha,6}\ \forall t \in [0,T) \big\}. \end{aligned} \tag{3.24}$$

Note that, at this stage, there may exist $\alpha \in \mathcal{N}$ such that $\tau_\alpha = +\infty$.

LEMMA 3.19. *Let (x, s_d) be a solution of $\mathcal{H}_{(e,d)}$ defined on a hybrid time domain S and starting in $(\mathbb{R}^n \setminus \{\bar{x}\}) \times \mathcal{N}$. Let T be the supremum in the t-direction of S. Then one of the two following cases may occur:*

- *Either there exists no positive jump time—more precisely, there exists* $\alpha \in \mathcal{N}$ *such that*
  1. *for almost every* $t \in (0,T)$ *and for every* l *such that* $(t,l) \in S$*, one has* $k(s_d(t,l)) = k_\alpha$*;*
  2. *for every* $t \in (0,T)$ *and every* l *such that* $(t,l) \in S$*, one has* $x(t,l) + e(x(t,l),t) \in \mathrm{clos}(\Omega_{\alpha,4}) \setminus \Omega_{\omega,1}$*;*
  3. *for all* $(t,l) \in S$*,* $t > 0$*, one has* $x(t,l) + e(x(t,l),t) \notin D$*, where* D *is defined by* (3.19)*;*
  4. *the inequality* $T < \tau_\alpha$ *holds;*
- *or there exists a unique positive jump time—more precisely, there exist* $\alpha \in \mathcal{N} \setminus \{\omega\}$ *and* $t_1 \in (0,T)$ *such that, letting* $t_0 = 0$*,* $t_2 = T$*,* $\alpha_0 = \alpha$*,* $\alpha_1 = \omega$*, for every* $j = 0,1$*, the following properties hold:*
  5. *for almost every* $t \in (t_j, t_{j+1})$ *and for every* l *such that* $(t,l) \in S$*, one has* $k(s_d(t,l)) = k_{\alpha_j}$*;*
  6. *for every* $t \in (t_0,t_1)$ *and every* l *such that* $(t,l) \in S$*, one has* $x(t,l) + e(x(t,l),t) \in \mathrm{clos}(\Omega_{\alpha,4}) \setminus \Omega_{\omega,1}$*;*
  7. *for every* t *in* (t_j, t_{j+1}) *and every* l *such that* $(t,l) \in S$*, one has* $x(t,l) + e(x(t,l),t) \notin D_{\alpha_j,2}$*, where* $D_{\alpha_j,2}$ *is defined by* (3.17)*;*
  8. *the inequality* $t_1 < \tau_{\alpha_j}$ *holds.*

Proof. Consider the sequence $(t_j)_{j \in \overline{m}}$ of jump times, i.e., the times such that $t_0 = 0$ and, for every $j \in \overline{m}$, $j \leqslant m-1$,

$$t_j \leqslant t_{j+1}, \tag{3.25}$$

$$(x(t_{j+1},j) + e(x(t_{j+1},j),t_{j+1}), s_d(t_{j+1},j)) \in D, \tag{3.26}$$

and

$$(x(t_{j+1},j+n_j) + e(x(t_{j+1},j),t_{j+1}), s_d(t_{j+1},j+n_j)) \in C, \tag{3.27}$$

where n_j is the finite number of instantaneous switches[3] (see Lemma 3.17). Let $\sigma : \mathbb{N} \to \mathbb{N}$ be an increasing function such that $t_{\sigma(j)} < t_{\sigma(j+1)}$.

Between two jumps, $s_d(t)$ is constant, and thus there exists a sequence (α_j) in $\mathcal{N}$ such that, for every $t \in (t_{\sigma(j)}, t_{\sigma(j+1)})$, except for a finite number of t, we have

$$s_d(t,\sigma(j)) = \alpha_j, \tag{3.28}$$

$$x \text{ is a Carathéodory solution of } \dot{x} = f(x,k_{\alpha_j}) + d \text{ on } (t_{\sigma(j)}, t_{\sigma(j+1)}), \tag{3.29}$$

and

$$k(s_d(t,\sigma(j))) = k_{\alpha_j}. \tag{3.30}$$

From (3.18), (3.27), and (3.28), we have, for every $t \in [t_{\sigma(j)}, t_{\sigma(j+1)}]$,

$$x(t,j) + e(x(t,j),t) \in \mathrm{clos}(\Omega_{\alpha_j,4}) \setminus \Omega_{\omega,1}. \tag{3.31}$$

Note that, from (3.30), (3.31), and statement 4 of Definition 3.12, for every $t > 0$ such that $t \in [t_{\sigma(j)}, t_{\sigma(j+1)}]$, one has

$$x(t,\sigma(j)) \notin D_{\alpha_j,2}. \tag{3.32}$$

[3]We emphasize that we may have jumps at time $t = 0$ (see also Remark 3.21).

Therefore, the positive jump time may occur only at time t_j where the point $x(t_j, l) + e(x(t_j, l), t_j)$ belongs to D_1. Thus, there exists at most one positive jump time. From (3.29) and (3.30), Statements 1 and 5 hold. Statements 2 and 6 are deduced from (3.31). Equation (3.32) implies Statements 3 and 7 Finally, Statements 4 and 8 are a consequence of (3.24) and (3.29). □

3.3.3. Definition of the hybrid feedback law, and switching strategy. We next define our hybrid feedback law. Let $\varepsilon > 0$ and K be a compact subset of $\mathbb{R}^n$. Let Ω be the neighborhood of $\mathcal{S}$ given by Lemma 2.13. For this neighborhood Ω, let $\Omega' \subset \Omega$ be the neighborhood of $\mathcal{S}$ yielded by Lemma 2.14.

Let $\mathcal{N}$ be the countable set defined by

$$\mathcal{N} = \{(i, p),\ i \in \mathbb{N},\ p \in \mathcal{N}_i\} \cup \{\omega\},$$

where ω is an element of $\mathbb{N} \times \mathbb{N}$, distinct from every (i, p), $i \in \mathbb{N}$, $p \in \mathcal{N}_i$.

We proceed in two steps. We first define k_α and $\Omega_{\alpha,l}$, where $\alpha \in \mathcal{N} \setminus \{\omega\}$ and $l \in \mathcal{F}$. Then we define k_ω and $\Omega_{\omega,l}$, where $l \in \mathcal{F}$.

1. Let $i \in \mathbb{N}$. Lemma 2.13, applied with the stratum M_i, implies the existence of a family of smooth controllers $(k_{i,p})_{p\in\mathcal{N}_i}$ satisfying the constraint (1.2) and of a family of neighborhoods $(\Omega_{i,p,7})_{p\in\mathcal{N}_i}$. The existence of the families $(\Omega_{i,p,1})_{p\in\mathcal{N}_i}, \dots, (\Omega_{i,p,6})_{p\in\mathcal{N}_i}$, satisfying

$$\Omega_{i,p,l} \subsetneq \operatorname{clos}(\Omega_{i,p,l}) \subsetneq \Omega_{i,p,m}$$

for every $m > l \in \mathcal{F}$, follows from a finite induction argument, using Lemma 2.13.

We have thus defined $k_{i,p}$ and $\Omega_{i,p,l}$, where $(i, p) \in \mathcal{N} \setminus \{\omega\}$ and $l \in \mathcal{F}$.

Remark 3.20. It follows from [1] that, near the point $\bar{x}$, the cut locus $\mathcal{S}$ is contained in a conic neighborhood $\mathcal{C}$ centered at $\bar{x}$ (as illustrated in Figure 2.1), the axis of the cone being transversal to the subspace $\operatorname{Span}\{f_1(\bar{x}), \dots, f_m(\bar{x})\}$. Moreover, we may modify slightly the previous construction, and assume that, near $\bar{x}$, the set $\bigcup_{\alpha\in\mathcal{N}\setminus\{\omega\},\ l\in\mathcal{F}} \Omega_{\alpha,l}$ is contained in this conic neighborhood.

2. It remains to define the sets $\Omega_{\omega,l}$, where $l \in \mathcal{F}$, and the controller k_ω. Let $\Omega_{\omega,1}$ be an open set of $\mathbb{R}^n$ containing $\mathbb{R}^n \setminus \bigcup_{\alpha\in\mathcal{N}\setminus\{\omega\}} \Omega_{\alpha,1}$ and contained in $\mathbb{R}^n \setminus \mathcal{S}$. From the previous remark, the point $\bar{x}$ belongs to $\operatorname{clos}(\Omega_{\omega,1})$. Lemma 2.14, applied with $\Omega = \mathbb{R}^n \setminus \operatorname{clos}(\Omega_{\omega,1})$, allows to define k_ω as k_{opt}, and Ω' a closed subset of $\mathbb{R}^n$ such that

$$\Omega' \subsetneq \Omega, \tag{3.33}$$

and such that Ω' is a neighborhood of $\mathcal{S}$. Set $\Omega_{\omega,2} = \mathbb{R}^n \setminus \Omega'$; it is an open subset of $\mathbb{R}^n$, contained in $\mathbb{R}^n \setminus \mathcal{S}$. Moreover, from (3.33), $\Omega_{\omega,1} \subsetneq \operatorname{clos}(\Omega_{\omega,1}) \subsetneq \Omega_{\omega,2}$. The existence of the sets $\Omega_{\omega,3}, \dots, \Omega_{\omega,6}$ follows from a finite induction argument, using Lemma 2.14. Moreover, from Lemma 3.11, we have the following property: for every $l \in \{1, \dots, 6\}$, for every $x_0 \in \Omega_{\omega,l}$, the unique Carathéodory solution $x(\cdot)$ of (3.6), with $x(0) = x_0$, satisfies $x(t) \in \Omega_{\omega,l+1}$ for every $t \geqslant 0$.

Therefore, $(\mathbb{R}^n \setminus \{\bar{x}\}, ((\Omega_{\alpha,l})_{l\in\mathcal{F}}, g_\alpha)_{\alpha\in\mathcal{N}})$ is a family satisfying the property $(\mathcal{P})$ as in Definition 3.12, where g_α is a function defined in a neighborhood of $\Omega_{\alpha,6}$ by $g_\alpha(x) = f(x, k_\alpha)$. The hybrid feedback law (C, D, k, k_d) is then defined according to Definition 3.14.

3.4. Proof of Theorem 2.10. Let $\varepsilon > 0$, and let K be a compact subset of $\mathbb{R}^n$. Consider the hybrid feedback law (C, D, k, k_d) defined previously. Let χ be an admissible radius for the external disturbances and the measurement noise (see Definition 3.15). We may reduce this function, and assume that, for every $\alpha \in \mathcal{N} \setminus \{\omega\}$,

$$\chi(x) \leqslant \rho_{opt}(d(x, \mathcal{S})) \quad \forall x \in \Omega_{\omega,6},$$
$$\chi(x) \leqslant \rho_\alpha(x) \quad \forall x \in \Omega_{\alpha,6}.$$

Note that, from the choice of the components of the hybrid feedback law, and from Lemmas 2.13 and 3.19, for every $\alpha \in \mathcal{N} \setminus \{\omega\}$, the constant τ_α defined by (3.24) is such that $\tau_\alpha < \varepsilon$.

Let us prove that the point $\bar{x}$ is a semiglobal quasi-minimal time robust stable equilibrium for the system (1.1) in closed-loop with the hybrid feedback law (C, D, k, k_d) as stated in Theorem 2.10.

Step 1: *Completeness and global stability.* Let $R > 0$ and $\delta : [0, +\infty) \to [0, +\infty)$ of class $\mathcal{K}_\infty$ be such that, for every $\alpha \in \mathcal{N}$ and every x, with $|x - \bar{x}| < R$ and $x \in \Omega_{\alpha,6}$, we have

$$\delta(R) \leqslant \delta_{opt}(\delta_\alpha(R)),$$

where the functions δ_α are defined in Lemma 2.13. Let e, d be two functions satisfying the regularity assumptions and (3.23). Let (x, s_d) be a maximal solution of $\mathcal{H}_{(e,d)}$ on a hybrid domain S with the initial condition (x_0, s_0), where $|x_0 - \bar{x}| < R$. From Lemmas 2.13, 3.11, and 3.19, we have, for every $(t, l) \in S$,

$$|x(t, l) - \bar{x}| \leqslant \delta(R). \tag{3.34}$$

Therefore, the conclusion of Lemma 3.18 cannot hold (since $\limsup_{t \to T, (t,l) \in S} |x(t, l)| \neq +\infty$), and thus the supremum T of S in the t-direction is infinite, and the maximality property follows. The stability property follows from (3.34).

Step 2: *Uniform finite time convergence property.* Let $x_0 \in B(\bar{x}, R)$, and $s_0 \in \mathcal{N}$. Let (x, s_d) denote the solution of $\mathcal{H}_{(e,d)}$ with the initial condition (x_0, s_0). If $x_0 = \bar{x}$, then, using (3.20) and the fact that $\chi(\bar{x}) = 0$, the solution remains at the point $\bar{x}$. We next assume that $x_0 \neq \bar{x}$. Let $\alpha_0 \in \mathcal{N}$ such that $x(\cdot)$ is a solution of $\dot{x} = f(x, k_{\alpha_0}(x)) + d$ on $(0, t_1)$ for a $t_1 > 0$ given by Lemma 3.19.

If $\alpha_0 = \omega$, then the feedback law under consideration coincides with the optimal controller and, from statement 3 of Lemma 3.19, there does not exist any switching time $t > 0$. Then, from Lemma 3.11, $x(\cdot)$ reaches $\bar{x}$ within time $T_{\bar{x}}(x_0) + \varepsilon$.

If $\alpha_0 \neq \omega$, then, from Lemmas 2.13 and 3.19, the solution $x(\cdot)$ leaves $\Omega_{\alpha_0,6}$ within time ε and then enters the set $\Omega_{\omega,4}$. Therefore, since $\tau_\alpha < \varepsilon$, $x(\cdot)$ reaches $\bar{x}$ within time $T_{\bar{x}}(x_1) + \varepsilon$, where x_1 denotes the point of $x(\cdot)$ when entering $\Omega_{\omega,4}$.

Let $\tau(R) = \max_{x \in \delta(R)} T(x) + \varepsilon$. With (3.34), we get (2.12) and the uniform finite time property. Note that, from Lemma 2.13, the constraint (2.13) is satisfied.

Step 3: *Quasi-optimality.* Let K be a compact subset of $\mathbb{R}^n$, and $(x_0, s_0) \in K \times \mathcal{N}$. Let $R > 0$ such that $K \subset B(0, R)$. From the previous arguments, two cases occur:

- The solution starting from (x_0, s_0) reaches $\bar{x}$ within time $T_{\bar{x}}(x_0) + \varepsilon$ whenever $\alpha_0 = \omega$.
- The solution starting from (x_0, s_0) reaches $\bar{x}$ within time $T_{\bar{x}}(x_1) + \varepsilon$, whenever $\alpha_0 \neq \omega$, where x_1 denotes the point of $x(\cdot)$ when entering $\Omega_{\omega,6}$. We may reduce the neighborhoods $\Omega_{\alpha,l}$, one has $|T_{\bar{x}}(x_0) - T_{\bar{x}}(x_1)| \leqslant \varepsilon$. Indeed, from Remark 2.4, the function $T_{\bar{x}}(\cdot)$ is uniformly continuous on the compact K.

Hence, the maximal solution starting from (x_0, s_0) reaches $\bar{x}$ within time $T_{\bar{x}}(x_0) + 2\varepsilon$. This is the quasi-optimality property.

Theorem 2.10 is proved.

Remark 3.21. We deduce from Lemma 3.19 and from the proof of Theorem 2.10 that the following two cases may occur:

- If $x_0 \in \Omega_{\omega,2}$, then the solutions (x, s_d) of $\mathcal{H}_{(e,d)}$ defined on the hybrid time domain S and with the initial condition (x_0, ω) satisfy $x(t,l) + e(x(t,l),t) \in \Omega_{\omega,4}$ for all $(t,l) \in S$.
- If $x_0 \in \Omega_{\alpha,2}$ for $\alpha \neq \omega$, then there exists a jump time $\bar{t} \geqslant 0$, $(\bar{t}, \bar{l}) \in S$ such that $x(\bar{t}, \bar{l}) + e(x(\bar{t}, \bar{l}), \bar{t}) \in \Omega_{\omega,2}$, and for all $(t,l) \in S$, $t \geqslant \bar{t}$, we have $x(t, \bar{l}) + e(x(t,l), t) \in \Omega_{\omega,4}$.

Hence, for every $x_0 \in \mathbb{R}^n \setminus \{\bar{x}\}$, by considering only the initial conditions (x_0, s_0) with $x_0 \in \Omega_{s_0,2}$, the solutions of $\mathcal{H}_{(e,d)}$ depend only on the sets $\Omega_{\alpha,2}$, $\Omega_{\alpha,3}$, and $\Omega_{\alpha,4}$ for some $\alpha \in \mathcal{N}$. In other words, for such initial conditions, we only need three nested families of open sets to state a quasi-optimality property. However, six nested families of open sets $(\Omega_{\alpha,l})_{\alpha\in\mathcal{N},\, l\in\mathcal{F}}$ are required to establish the quasi-optimality property stated in Theorem 2.10 *for all initial conditions* $(x_0, s_0) \in \mathbb{R}^n \setminus \{\bar{x}\} \times \mathcal{N}$, and *not only* for initial conditions $\{(x_0, s_0),\ x_0 \in \Omega_{s_0,2}\}$.

Since there is no restriction on the s_0 variable, a jump may occur at time $t = 0$ and the second claim of (3.21) is active for some initial conditions. We emphasize that Lemma 3.19 asserts that there exists at most one positive jump time, but another jump may occur at time $t = 0$.

Intuitively, two patches are required for defining both kinds of jumps: from the controllers built in Lemma 2.13 to the controller considered in Lemma 2.14, and conversely. The other four patches are used to define neighborhoods of these jump sets and to bound the admissible measurement noise (see Definition 3.15). This explains the necessity of considering at least six patches to establish our main result.

Acknowledgments. The authors are grateful to Ludovic Rifford for constructive comments, and to the reviewers for helpful suggestions about the presentation of this paper.

OUTPUT FEEDBACK POLE ASSIGNMENT FOR TRANSFER FUNCTIONS WITH SYMMETRIES*

UWE HELMKE†, JOACHIM ROSENTHAL‡, AND XIAOCHANG ALEX WANG§

Abstract. This paper studies the problem of pole assignment for symmetric and Hamiltonian transfer functions. A necessary and sufficient condition for pole assignment by complex symmetric output feedback transformations is given. Moreover, in the case where the McMillan degree coincides with the number of parameters appearing in the symmetric feedback transformations, we derive an explicit combinatorial formula for the number of pole assigning symmetric feedback gains. The proof uses intersection theory in projective space as well as a formula for the degree of the complex Lagrangian Grassmann manifold.

Key words. output feedback, pole placement, inverse eigenvalue problems, Lagrangian Grassmannian, symmetric or Hamiltonian realizations, degree of a projective variety

1. Introduction.

One of the best known inverse eigenvalue problems from linear system theory is that of pole assignment, i.e., finding a static output feedback gain for a given linear system such that the closed loop poles of the system coincide with a specified subset of the complex plane. Moreover, in the case of finitely many solutions, a formula for the number of pole assigning feedback transformations is desirable. Early contributions on the subject were obtained by, e.g., Davison and Wang [7] and Kimura [20], who derived sufficient conditions for the solvability. However, these conditions were far from being necessary as well. In a series of pioneering papers [16, 24, 25], Hermann and Martin applied tools from algebraic geometry to obtain necessary and sufficient conditions, valid for a generic class of systems and for *complex* feedback transformations. Their approach was based on the dominant morphism theorem [2, Chapter AG, section 17, Theorem 17.3] from complex algebraic geometry. A second breakthrough was subsequently made by Brockett and Byrnes [3], who used intersection theoretic arguments and the Schubert calculus on Grassmann manifolds to count the number of pole assigning complex feedback transformations. By refining these algebraic-geometric approaches of Hermann and Martin and Brockett and Byrnes, a number of fundamental contributions on the subject were made that finally led to a solution of the problem in the *real* case, with important contributions due to [8, 21, 29, 37, 38]. For an excellent survey paper on this subject, written from a control-theoretic point of view, see, e.g., [4]. More recently, various intersection theoretic tasks related to the Schubert calculus have been studied in the algebraic geometry literature; see, e.g., [12, 18, 34]. The focus of most of the investigations so far has been on the unstructured case, where no underlying symmetries

for the involved transfer function or for the associated feedback transformations are imposed. However, transfer functions with symmetries occur naturally in various application areas, such as in network theory or mechanics. For example, the transfer functions $G(s)$ of linear RLC-circuits, consisting solely of resistors, capacitors, and inductive elements, are symmetric; i.e., they satisfy $G(s)^\top = G(s)$. In mechanics, the transfer functions of linear Hamiltonian systems are characterized by the symmetry relation $G(-s)^\top = G(s)$, while second order mechanical systems of the form

$$M\ddot{x} = Nx + Bu, \quad y = B^\top x$$

yield symmetric Hamiltonian transfer functions, satisfying

$$G(s) = H(s^2), \quad H(s) = H(s)^\top;$$

see, e.g., [1, 5, 6, 9]. For such structured systems it is reasonable to restrict the class of admissible feedback transformations to those that preserve the symmetry properties of the transfer functions. Therefore the known results on pole placement on unstructured systems do not apply in these cases and instead require a new approach.

In this paper we start an investigation of the pole placement problem for $n \times n$ symmetric transfer functions $G(s) = G(s)^\top$, arising in electrical network theory, and Hamiltonian transfer functions. For both types of systems the natural class of admissible output feedback transformations are the symmetric ones $F = F^\top$, yielding a symmetric closed loop transfer function

$$G_F(s) := (I_n - G(s)F)^{-1}G(s).$$

As the number of free parameters occurring in the symmetric feedback matrices F is $n(n+1)/2$, a necessary condition for generic solvability of this output feedback problem is that the McMillan degree δ of the transfer function G satisfies $\delta \geq \binom{n+1}{2}$ in the symmetric case, and $\delta \geq n(n+1)$ in the Hamiltonian case. In fact, we show that generically for *complex* symmetric output feedback transformations this condition is also sufficient. Moreover, for the limit case $\delta = \binom{n+1}{2}$ (or $\delta = n(n+1)$), we derive an explicit combinatorial formula for the number of complex symmetric output feedback gains that place the poles at given points. Our formula coincides with that of the degree for the complex Lagrangian manifold, given in [36].

In the real case such complete results cannot be expected. In fact, the symmetry of the transfer functions then imposes a priori limitations for the possible pole locations of such systems. This has been observed in [23], where it is shown for symmetric transfer functions that—in the special case that the Cauchy index of G coincides with the McMillan degree—generically real symmetric output feedback pole assignability holds if and only if $n \geq \delta$. Of course, in most applications we have $n \leq \delta$, and therefore the description of the set of poles that can be achieved by real symmetric output feedback becomes a complicated and nontrivial task.

2. Complex symmetric and Hamiltonian realizations. In this section we recall some basic facts concerning complex symmetric and Hamiltonian transfer functions and associated signature symmetric and Hamiltonian realizations. Let $\mathbb{C}$ denote the field of complex numbers. A complex rational transfer function $G(s) \in \mathbb{C}(s)^{n\times n}$ of McMillan degree δ is called *symmetric or Hamiltonian, respectively,* if

$$G(s) = G(s)^\top \quad \text{or} \quad G(s) = G(-s)^\top, \quad \text{respectively,}$$

holds for all $s \in \mathbb{C}$. A *complex symmetric realization* is a linear system of the form

$$\dot{x} = Ax + Bu, \quad y = B^\top x,$$

where $A \in \mathbb{C}^{\delta\times\delta}$ is symmetric, i.e., $A^\top = A$, and $B \in \mathbb{C}^{\delta\times n}$. Similarly, a *Hamiltonian realization* is a linear system

$$\dot{x} = Ax + Bu, \quad y = Cx,$$

where $A \in \mathbb{C}^{\delta\times\delta}, B \in \mathbb{C}^{\delta\times n}, C \in \mathbb{C}^{n\times\delta}$ satisfies

$$AJ = (AJ)^\top, \quad C^\top = JB$$

and

$$\begin{bmatrix} 0 & I \\ -I & 0 \end{bmatrix}$$

denotes the standard symplectic form on $\mathbb{C}^{\delta\times\delta}$. In particular, Hamiltonian systems always have even McMillan degree δ.

Complex symmetric realizations are the natural class of realizations for complex symmetric transfer functions. In fact, they are the proper analogue of signature symmetric realizations of real rational transfer functions, appearing in network theory. Here a signature symmetric realization (A, B, C) is one that is symmetric relative to the bilinear form $I_{pq} := \mathrm{diag}(\mathrm{I_p}, -\mathrm{I_q})$; i.e., (A, B, C) satisfies $(AI_{pq})^\top = AI_{pq}, C^\top = I_{pq}B$. Such realizations always exist for real symmetric transfer functions G, and the integer $p - q$ coincides with the so-called Cauchy–Maslov index of G. If $q = 0$, then this definition coincides with the one above for symmetric realizations. In particularly, over $\mathbb{R}$, real symmetric realizations correspond to linear models of *RC*-networks, constructed entirely using capacitors and resistors. The real symmetric transfer functions defined by them are characterized by the property that the Cauchy–Maslov index coincides with the McMillan degree [1, 9, 14].

The following variant of the Kalman realization theorem is well known; see, e.g., [9, 10]. Recall that the complex orthogonal group $O(\delta, \mathbb{C})$ is the matrix group consisting of all complex $\delta \times \delta$ matrices S, satisfying $SS^\top = I_\delta$. Given any complex realization (A, B, C) of a symmetric transfer function $G(s) = C(sI - A)^{-1}B$, note that $(A^\top, C^\top, B^\top)$ is also a realization.

PROPOSITION 2.1. *Let $G(s) = G(s)^\top$ be an $n\times n$ strictly proper, complex rational transfer function of McMillan degree δ. Then the following hold:*

(1) *$G(s)$ has a controllable and observable complex symmetric realization*

$$(A, B, C) = (A^\top, C^\top, B^\top).$$

(2) *If (A_i, B_i, C_i), i=1, 2, are two controllable and observable complex symmetric realizations of $G(s)$, then there exists a unique complex orthogonal transformation $S \in O(\delta, \mathbb{C})$ such that $(A_2, B_2, C_2) = (SA_1S^{-1}, SB_1, C_1S^{-1})$.*

In the literature usually only the real case of the above result is proved, where the statement is actually slightly different due to the presence of signature symmetric realizations. In the complex case the result simplifies to the one given here. For the sake of completeness we include the proof; see also [10].

Proof. If (A, B, C) is a minimal realization of $G(s)$, then, by symmetry of G, $(A^\top, C^\top, B^\top)$ also is a minimal realization. Applying Kalman's realization theorem implies the existence of a unique invertible complex $\delta \times \delta$ matrix S with

$$(A^\top, C^\top, B^\top) = (SAS^{-1}, SB, CS^{-1}).$$

By transposing this equation and using the uniqueness of S we conclude that $S = S^\top$. It is a well-known fact from linear algebra that every complex symmetric invertible matrix has a representation $S = XX^\top$ by a complex invertible matrix X. Moreover, X is uniquely determined up to right factors XT, where $T \in O(\delta, \mathbb{C})$. Then (XAX^{-1}, XB, CX^{-1}) is a complex symmetric realization, which completes the proof. □

There is a similar realization theorem for Hamiltonian systems, for which we refer to the literature; see, e.g., [6, 9]. Static linear output feedback can be meaningfully defined for such systems only through symmetric gain matrices. Note that

$$\operatorname{adj}(sI - A) = s^{n-1}I + s^{n-2}(A - \operatorname{trace}(A)I) + \text{lower order terms.}$$

Thus, for symmetric A, the rational matrix

$$B^\top(sI - A - BFB^\top)^{-1}B = B^\top \frac{1}{\det(sI - A - BFB^\top)} \operatorname{adj}(sI - A - BFB^\top)B$$

is symmetric only if $B^\top BFB^\top B$ is symmetric. Therefore, if B has full column rank, an output feedback transformation

$$u = Fy + v$$

with the closed system

$$\dot{x} = (A + BFB^\top)x + Bu, \quad y = B^\top x$$

preserves the complex symmetry of the realizations if and only if $F = F^\top$. Thus we define two complex symmetric realizations (A_i, B_i, C_i), $i = 1, 2$, to be *symmetric output feedback equivalent* if and only if there exist $S \in O(\delta, \mathbb{C})$, $F = F^\top \in \mathbb{C}^{n\times n}$ with

$$(A_2, B_2, C_2) = (S(A_1 + B_1FB_1^\top)S^{-1}, SB_1, C_1S^{-1}).$$

Equivalently, they are symmetric output feedback equivalent if and only if the associated transfer functions satisfy

$$G_2(s) = (I_n - G_1(s)F)^{-1}G_1(s).$$

Similarly, output feedback for Hamiltonian systems

$$\dot{x} = (A + BFC)x + Bu, \quad y = Cx$$

preserves the Hamiltonian properties of the realization if and only if $F = F^\top$. Thus in both cases we have to focus on symmetric output feedback.

We note some elementary geometric properties of the set of complex symmetric transfer functions that will be important in the subsequent development; see, e.g., [6] for some of the details for the proof of the subsequent theorem. We omit a full proof as it would take us too far from the subject.

PROPOSITION 2.2. *Let $SRat_{\delta,n}(\mathbb{C})$ and $Ham_{\delta,n}(\mathbb{C})$, respectively, denote the sets of strictly proper, complex symmetric and Hamiltonian $n \times n$ transfer functions of McMillan degree δ. Then $SRat_{\delta,n}(\mathbb{C})$ and $Ham_{\delta,n}(\mathbb{C})$ are, respectively, a smooth complex manifold of complex dimension $\delta(n + 1)$ and dimension δn. Moreover, they are nonsingular irreducible quasi-affine varieties.*

In particular, there is a canonical notion of "genericity" for complex symmetric or Hamiltonian transfer functions. Explicitly, a property E of complex symmetric transfer functions is called generic if the set defined by E,

$$\{G \in SRat_{\delta,n}(\mathbb{C}) \mid G \text{ has property } E\},$$

is a Zariski open subset of $SRat_{\delta,m}(\mathbb{C})$. Equivalently, this also can be expressed in terms of complex symmetric realizations.

3. Main result. After these preliminaries we can now formulate and prove the main technical results of this paper. Let $G(s)$ be an $n \times n$ complex symmetric or Hamiltonian transfer function, i.e., $G(s)^\top = G(s)$ or $G(-s)^\top = G(s)$, respectively. Assume that $G(s)$ is strictly proper and has McMillan degree δ. The complex symmetric eigenvalue assignment problem then asks the following question.

PROBLEM 3.1. *For a given arbitrary monic polynomial $\varphi(s) \in \mathbb{C}[s]$ of degree δ ($\varphi(s) = \varphi(-s)$ is assumed to be* even *in the Hamiltonian case), is there an $n \times n$ complex symmetric matrix F such that the closed loop transfer function*

$$G_F(s) := (I_n - G(s)F)^{-1}G(s)$$

has the characteristic polynomial $\varphi(s)$, i.e., such that the poles of $G_F(s)$ are the zeros of $\varphi(s)$?

If for a particular symmetric (Hamiltonian) transfer function $G(s)$ Problem 3.1 has an affirmative answer, we will say that $G(s)$ is *pole assignable in the class of complex symmetric (Hamiltonian) feedback compensators.* We say that $G(s)$ is *generically pole assignable* if the problem is solvable for a generic choice of admissible polynomials $\varphi(s)$.

Similar to the situation of the static pole placement problem [3, 37] and the dynamic pole placement problem [28], Problem 3.1 turns out to be highly nonlinear, and techniques from algebraic geometry will be required to study the problem. The first main result is in the spirit of Hermann and Martin [16], by deriving a generic necessary and sufficient condition via the dominant morphism theorem.

We prove some lemmas first. Let $\pi(A) = (a_{11}, \ldots, a_{\delta\delta})$ be the projection onto the diagonal entries of an $\delta \times \delta$ matrix A. In what follows we will identify $\mathbb{C}^\delta$ with the complex vector space of row vectors. For any symmetric matrix L, define $\theta^L : O(\delta, \mathbb{C}) \to \mathbb{C}^\delta$ through

$$\theta^L(S) = \pi(SLS^{-1}).$$

As $O(\delta, \mathbb{C})$ is a Lie group, its tangent space at the identity matrix I is given by the Lie algebra of complex skew-symmetric matrices

$$so(\delta, \mathbb{C}) = \{X \in \mathbb{C}^{\delta\times\delta} \mid X + X^\top = 0\}.$$

Moreover, the Jacobian $d\theta_I^L$ of θ^L at I is given by

$$d\theta_I^L : so(\delta, \mathbb{C}) \to V, \qquad d\theta_I^L(X) = \pi(XL - LX),$$

where

$$V = \left\{ (x_1, \ldots, x_\delta) \in \mathbb{C}^\delta \mid \sum_1^\delta x_i = 0 \right\}.$$

For any $\delta \times \delta$ matrix L, the graph $\mathcal{G}(L)$ of L is defined as a graph with δ vertices such that there is a path from vertex i to vertex j if and only if the ijth entry of L is nonzero. It is a well-known fact from linear algebra that the graph $\mathcal{G}(L)$ is connected if and only if L is irreducible, i.e., if and only if there exists no permutation matrix P such that PLP^{-1} is block diagonal. We use this fact together with an idea developed in [15, Lemma 2.5] to prove the following equivalent characterization.

LEMMA 3.2. *The Jacobian $d\theta_I^L$ is surjective if and only if the associated graph $\mathcal{G}(L)$ is connected.*

Proof. By inspection, the derivative $d\theta_I^L$ is not surjective if and only if there exists a nonzero diagonal matrix Z of trace zero such that for all $X \in so(\delta, \mathbb{C})$

$$\text{trace}(Z(XL - LX)) = \text{trace}((LZ - ZL)X) = 0.$$

By symmetry of L, Z we have $LZ - ZL \in so(\delta, \mathbb{C})$. Since the trace function defines a nondegenerate bilinear form on $so(\delta, \mathbb{C})$, the condition $\text{trace}((LZ - ZL)X) = 0$ is equivalent to $LZ = ZL$. Since Z is a nonzero diagonal matrix of trace zero, there is a permutation matrix P such that $\hat{Z} := PZP^{-1} = \text{block diag}(a_1 I_1, \ldots, a_k I_k)$ with $k \geq 2$ and a_i's distinct. Let $\hat{L} = PLP^{-1}$. Then $LZ = ZL$ is equivalent to $\hat{L}\hat{Z} = \hat{Z}\hat{L}$, which is equivalent to $\hat{L}$ being block diagonal. But from the above remark this is equivalent to the graph $\mathcal{G}(L)$ being disconnected. The result follows. ∎

LEMMA 3.3. *Let L be a nonzero complex symmetric matrix such that $\pi(L) = 0$. Then there is a family of orthogonal matrices $S(\epsilon) \in O(\delta, \mathbb{C})$, $\epsilon \geq 0$, with $S(0) = I$ such that the matrix $\hat{L}(\epsilon) := S(\epsilon)LS(\epsilon)^{-1}$ has the properties that $\pi(\hat{L}(\epsilon)) = 0$ and $d\varphi_I^{\hat{L}(\epsilon)}$ is surjective for all $\epsilon \in (0, \pi/2)$.*

Proof. If $\mathcal{G}(L)$ is connected, then by the previous lemma the choice $S(\epsilon) := I$ does the job. Thus it suffices to prove that $\mathcal{G}(L)$ not connected implies that then we can find a family of transformations $S(\epsilon)$ such that $\pi(S(\epsilon)LS(\epsilon)^{-1}) = 0$ and the largest connected subgraph of $\mathcal{G}(S(\epsilon)LS(\epsilon)^{-1})$ contains more vertices than that of $\mathcal{G}(L)$ for all $0 < \epsilon < \pi/2$.

Note that $\pi(L) = 0$ and $L \neq 0$ imply that the largest connected subgraph of $\mathcal{G}(L)$ must contain at least 2 vertices. Assume that the largest connected subgraph of $\mathcal{G}(L)$ contains k vertices, $2 \leq k < \delta$. Without loss of generality, assume

$$L = \begin{bmatrix} L_1 & 0 \\ 0 & L_2 \end{bmatrix},$$

where the graph of the $k \times k$ submatrix L_1 is connected. Write

$$L_1 = \begin{bmatrix} L_{11} & \alpha \\ \alpha^\top & 0 \end{bmatrix} \text{ and } L_2 = \begin{bmatrix} 0 & \beta^\top \\ \beta & L_{22} \end{bmatrix},$$

where L_{11} and L_{22} are sizes $(k-1)\times(k-1)$ and $(\delta-k-1)\times(\delta-k-1)$, respectively. By irreducibility of L_1 we have $\alpha \neq 0$. Thus L has the form

$$\begin{bmatrix} L_{11} & \alpha & 0 & 0 \\ \alpha^\top & 0 & 0 & 0 \\ 0 & 0 & 0 & \beta^\top \\ 0 & 0 & \beta & L_{22} \end{bmatrix}.$$

Let

$$S(\epsilon) = \begin{bmatrix} I_{(k-1)\times(k-1)} & 0 & 0 & 0 \\ 0 & \cos\epsilon & -\sin\epsilon & 0 \\ 0 & \sin\epsilon & \cos\epsilon & 0 \\ 0 & 0 & 0 & I_{(\delta-k-1)\times(\delta-k-1)} \end{bmatrix}.$$

Then

$$S(\epsilon)LS^{-1}(\epsilon) = \begin{bmatrix} L_{11} & (\cos\epsilon)\alpha & (\sin\epsilon)\alpha & 0 \\ (\cos\epsilon)\alpha^\top & 0 & 0 & (-\sin\epsilon)\beta^\top \\ (\sin\epsilon)\alpha^\top & 0 & 0 & (\cos\epsilon)\beta^\top \\ 0 & (-\sin\epsilon)\beta & (\cos\epsilon)\beta & L_{22} \end{bmatrix}.$$

For the graph $\mathcal{G}(S(\epsilon)LS^{-1}(\epsilon))$ with $0 < \epsilon < \pi/2$, the vertices $\{1,\dots,k\}$ are still connected and the vertex $k+1$ is symmetrically connected to at least one of the first k vertices. Thus the vertices $\{1,\dots,k+1\}$ are connected. □

LEMMA 3.4. *Let $\mathcal{L}$ be a linear subspace of complex symmetric matrices of dimension δ, and $\mathcal{L} \not\subset sl(\delta,\mathbb{C})$. Then there exists an orthogonal matrix $S \in O(\delta,\mathbb{C})$ such that $\pi\mid_{S\mathcal{L}S^{-1}}$ is one to one, and onto.*

Proof. The proof goes by recursively constructing a basis $\{L_1,\dots,L_\delta\}$ of $\mathcal{L}$ such that $\{\pi(SL_1S^{-1}),\dots,\pi(SL_\delta S^{-1})\}$ are linearly independent for a suitable complex orthogonal matrix $S \in O(\delta,\mathbb{C})$. First note that we can modify any basis of $\mathcal{L}$ into a basis $\mathcal{L}^{(1)} := \{L_1,\dots,L_\delta\}$ of $\mathcal{L}$ such that $L_1 \notin sl(\delta,\mathbb{C})$ and $L_i \in sl(\delta,\mathbb{C})$ for $i = 2,\dots,\delta$. In fact, if $\{K_1,\dots,K_\delta\}$ denotes any basis of $\mathcal{L}$ with $\operatorname{trace}(K_1) \neq 0$, then $\{L_1 := K_1, L_2 := K_2 - c_2K_1,\dots,L_\delta := K_\delta - c_\delta K_1\}$, $c_i := \operatorname{trace}(K_i)/\operatorname{trace}(K_1)$, is as desired. By construction of L_1, we have $\pi(L_1) \neq 0$.

Let $\{L_1,\dots,L_\delta\}$ be a basis of $\mathcal{L}$ such that $L_1 \notin sl(\delta,\mathbb{C})$ and $L_i \in sl(\delta,\mathbb{C})$ for $i = 2,\dots,\delta$. Then $\dim \operatorname{span}\{\pi(L_1),\dots,\pi(L_\delta)\} := k \geq 1$. If $k < \delta$, then by reordering the indices we can assume that $\{\pi(L_1),\dots,\pi(L_k)\}$ are linearly independent and

$$\pi(L_j) = \sum_{i=1}^{k} c_{ij}\pi(L_i) \text{ for } j = k+1,\dots,\delta.$$

By replacing L_j with $L_j - \sum_{i=1}^{k} c_{ij}L_i$, we can further assume that $\pi(L_j) = 0$ for $j = k+1,\dots,\delta$. It is thus sufficient to show that if there is an orthogonal matrix $\hat{S}$ such that the matrices $\{M_j := \hat{S}L_j\hat{S}^{-1}, j = 1,\dots,\delta\}$ have the property that $\{\pi(M_1),\dots,\pi(M_k)\}$ are linearly independent and $\pi(M_j) = 0$, $j = k+1,\dots,\delta$, for some $k < n$, then we can find an orthogonal S such that

$$\{\pi(SM_1S^{-1}),\dots,\pi(SM_kS^{-1}),\pi(SM_{k+1}S^{-1})\}$$

are linearly independent.

By Lemma 3.3, there exists $S_\epsilon \in O(\delta,\mathbb{C})$ arbitrarily close to the identity matrix such that $\pi(S_\epsilon M_1 S_\epsilon^{-1}),\dots,\pi(S_\epsilon M_k S_\epsilon^{-1})$ are linearly independent and the graph $\mathcal{G}(S_\epsilon M_{k+1} S_\epsilon^{-1})$ is connected. By replacing M_i with $S_\epsilon M_i S_\epsilon^{-1}$, we can assume further that $d\theta_I^{M_{k+1}}$ is onto V. Then there exists a skew-symmetric matrix X such that

$$\pi(XM_{k+1} - M_{k+1}X) \notin \operatorname{span}\{\pi(M_1),\dots,\pi(M_k)\}.$$

Let

$$S(\epsilon) = \exp(\epsilon X).$$

Then $S(\epsilon)$ is orthogonal for all ϵ, and

$$S(\epsilon) = I + \epsilon X + \text{higher order terms}.$$

The Taylor series expansions of $\{\pi(S(\epsilon)M_iS(\epsilon)^{-1})\}$ have the forms

$$\pi(S(\epsilon)M_iS(\epsilon)^{-1}) = \pi(M_i) + \beta_i(\epsilon), \quad i = 1, \ldots, k,$$

and

$$\pi(S(\epsilon)M_{k+1}S(\epsilon)^{-1}) = \epsilon\left(\pi(XM_{k+1} - M_{k+1}X) + \beta_{k+1}(\epsilon)\right),$$

where $\beta_i(\epsilon)$ are continuous with respect to ϵ and $\beta_i(\epsilon) \to 0$ as $\epsilon \to 0$ for $i = 1, \ldots, k+1$. Since $\{\pi(M_1), \ldots, \pi(M_k), \pi(XM_{k+1} - M_{k+1}X)\}$ are linearly independent, for sufficient small $\epsilon > 0$, $\{\pi(M_1) + \beta_1(\epsilon), \ldots, \pi(M_k) + \beta_k(\epsilon), \pi(XM_{k+1} - M_{k+1}X) + \beta_{k+1}(\epsilon)\}$ are also linearly independent; i.e.,

$$\{\pi(S(\epsilon)M_1S(\epsilon)^{-1}, \ldots, \pi(S(\epsilon)M_kS(\epsilon)^{-1}, \pi(S(\epsilon)M_{k+1}S(\epsilon)^{-1}\}$$

are linearly independent. □

THEOREM 3.5. *If $G(s)$ is a symmetric (or Hamiltonian) transfer function of McMillan degree $\delta > \binom{n+1}{2}$ (or $\delta > n(n+1)$), then $G(s)$ is not pole assignable in the class of (real or) complex symmetric feedback compensators.*

When $\delta \leq \binom{n+1}{2}$ (or $\delta \leq n(n+1)$), then there is a generic set of $n \times n$ symmetric (or Hamiltonian) transfer functions of degree δ which are generically pole assignable via complex symmetric feedback compensators.

Proof. We give only a sketch of the proof, as the arguments based on the dominant morphism theorem are well known from [16, 24]. Note, however, that there is a serious gap in the proof of [24] for the pole placement result on Hamiltonian systems because it is not proved that the set of generically pole assignable Hamiltonian systems is nonempty. In fact, a construction of such an example is not completely trivial and depends on our previous lemmas.

The first claim follows immediately from a standard dimension argument, as the vector space $\mathrm{Sym}(n)$ of complex $n \times n$ symmetric matrices has dimension $\binom{n+1}{2}$. For the second claim we note that the set of generically pole assignable systems is a Zariski open subset of the nonsingular, irreducible quasi-affine variety of symmetric or Hamiltonian transfer functions, respectively. Therefore we need only show that this Zariski open subset is nonempty. By the dominant morphism theorem, it suffices to find one system whose Jacobian of the pole placement map at one point is onto.

Note, by the Newton formula, that the coefficients of the characteristic polynomial $\det(sI - A) = s^\delta + \alpha_{\delta-1}s^{\delta-1} + \cdots + \alpha_1 s + \alpha_0$ are related to the traces of powers of A as follows:

$$\begin{aligned}
\alpha_{\delta-1} &= -\operatorname{trace}(A),\\
\alpha_{\delta-2} &= -\frac{1}{2}(\operatorname{trace}(A^2) + \alpha_{\delta-1}\operatorname{trace}(A)),\\
&\vdots\\
\alpha_0 &= -\frac{1}{\delta}(\operatorname{trace}(A^\delta) + \alpha_{\delta-1}\operatorname{trace}(A^{\delta-1}) + \cdots + \alpha_1\operatorname{trace}(A)).
\end{aligned}$$

Therefore for the case of symmetric transfer functions, the pole placement map is equivalent to the map

$$\begin{array}{rccc}
\phi: & \mathrm{Sym}(n) & \longrightarrow & \mathbb{C}^\delta\\
& F & \longmapsto & (\operatorname{trace}(A + BFB^\top), \ldots, \operatorname{trace}(A + BFB^\top)^\delta),
\end{array} \tag{3.1}$$

and its Jacobian at 0 is given by

$$d\phi_0(F) = (\operatorname{trace}(BFB^\top), 2\operatorname{trace}(ABFB^\top), \ldots, \delta \operatorname{trace}(A^{\delta-1}BFB^\top)).$$

For the case of Hamiltonian transfer functions, since $JAJ = A^\top$ and $J^2 = -I$, we have $(-1)^{k-1}JA^kJ = (A^k)^\top$ for $k = 1, 2, \ldots$, which implies that the characteristic polynomial of A is even and

$$\operatorname{trace}(A^k) = 0 \text{ holds for all odd } k\text{'s}.$$

Therefore the pole placement map is equivalent to the map

(3.2)

$$\begin{array}{rccc} \psi: & \operatorname{Sym}(n) & \longrightarrow & \mathbb{C}^{\delta/2} \\ & F & \longmapsto & (\operatorname{trace}(A+BFC)^2, \operatorname{trace}(A+BFC)^4, \ldots, \operatorname{trace}(A+BFC)^\delta), \end{array}$$

and its Jacobian at 0 is given by

$$d\psi_0(F) = (2\operatorname{trace}(ABFC), 4\operatorname{trace}(A^3BFC) \ldots, \delta \operatorname{trace}(A^{\delta-1}BFC)).$$

We first consider the case of symmetric transfer functions. Let B be any real nonzero matrix and $\mathcal{L} = \{BFB^\top \mid F \in \operatorname{Sym}(n)\}$. Then $\mathcal{L} \not\subset sl(\delta, \mathbb{C})$ and $\dim\mathcal{L} \geq \delta$. By Lemma 3.4 there exists an orthogonal matrix $S \in O(\delta, \mathbb{C})$ such that $\pi|_{S\mathcal{L}S^{-1}}$ is surjective. Let $D = \operatorname{diag}(1, 2, \ldots, \delta)$ and $A = S^{-1}DS$. Then

$$\begin{aligned} d\phi_0(F) &= (\operatorname{trace}(BFB^\top), 2\operatorname{trace}(ABFB^\top), \ldots, \delta \operatorname{trace}(A^{\delta-1}BFB^\top)) \\ &= (\operatorname{trace}(SBFB^\top S^{-1}), 2\operatorname{trace}(DSBFB^\top S^{-1}), \ldots, \delta \operatorname{trace}(D^{\delta-1}SBFB^\top S^{-1})) \\ &= \pi(SBFB^\top S^{-1})V, \end{aligned}$$

where

$$V = \begin{bmatrix} 1 & 1 & \cdots & 1 \\ 1 & 2 & \cdots & 2^{\delta-1} \\ \vdots & \vdots & & \vdots \\ 1 & \delta & \cdots & \delta^{\delta-1} \end{bmatrix} \begin{bmatrix} 1 & 0 & \cdots & 0 \\ 0 & 2 & \cdots & 0 \\ \vdots & \vdots & & \vdots \\ 0 & 0 & \cdots & \delta \end{bmatrix}.$$

Since $\pi|_{S\mathcal{L}S^{-1}}$ is surjective and V is nonsingular, $d\phi_0$ is onto.

For the case of Hamiltonian transfer functions, let

$$B = \begin{bmatrix} 0 \\ B_1 \end{bmatrix} \text{ and } C = \begin{bmatrix} B_1^\top & 0 \end{bmatrix},$$

where B_1 is any real nonzero $\frac{\delta}{2} \times n$ matrix and $\mathcal{L} = \{B_1FB_1^\top \mid F \in \operatorname{Sym}(n)\}$. Then $\mathcal{L} \not\subset sl(\delta/2, \mathbb{C})$. By Lemma 3.4 there exists an orthogonal matrix $S_1 \in O(\delta/2, \mathbb{C})$ such that $\pi : S_1\mathcal{L}S_1^{-1} \mapsto \mathbb{C}^{\frac{\delta}{2}}$ is surjective. Let $D_1 = \operatorname{diag}(1, 2, \ldots, \delta/2)$,

$$S = \begin{bmatrix} S_1 & 0 \\ 0 & S_1 \end{bmatrix}, \quad D = \begin{bmatrix} 0 & D_1 \\ D_1 & 0 \end{bmatrix},$$

and $A = S^{-1}DS$. Note that D and S are Hamiltonian and symplectic matrices, respectively. In particular, A is Hamiltonian. Then

$$\begin{aligned} d\psi_0(F) &= (2\operatorname{trace}(ABFC), 4\operatorname{trace}(A^3BFC), \ldots, \delta \operatorname{trace}(A^{\delta-1}BFC)) \\ &= (2\operatorname{trace}(DSBFCS^{-1}), 4\operatorname{trace}(D^3SBFCS^{-1}), \ldots, \delta \operatorname{trace}(D^{\delta-1}SBFCS^{-1})) \\ &= (2\operatorname{trace}(D_1S_1B_1FB_1^\top S_1^{-1}), \ldots, \delta \operatorname{trace}(D_1^{\delta-1}S_1B_1FB_1^\top S_1^{-1})) \\ &= \pi(S_1B_1FB_1^\top S_1^{-1})U, \end{aligned}$$

where

$$U = \begin{bmatrix} 1 & 1 & \cdots & 1 \\ 2 & 2^3 & \cdots & 2^{\delta-1} \\ \vdots & \vdots & & \vdots \\ \frac{\delta}{2} & \left(\frac{\delta}{2}\right)^3 & \cdots & \left(\frac{\delta}{2}\right)^{\delta-1} \end{bmatrix} \begin{bmatrix} 2 & 0 & \cdots & 0 \\ 0 & 4 & \cdots & 0 \\ \vdots & \vdots & & \vdots \\ 0 & 0 & \cdots & \delta \end{bmatrix}.$$

Since $\pi|_{S_1 B_1 F B_1^\top S_1^{-1}}$ is surjective and U is nonsingular, $d\psi_0$ is onto. □

The second main theorem in this paper deals with the limit case $\delta = \binom{n+1}{2}$, where we can prove a more precise statement.

THEOREM 3.6. *Let $\delta = \binom{n+1}{2}$ in the symmetric case, and $\delta = n(n+1)$ for Hamiltonian systems. Then for a generic set of $n \times n$ symmetric (or Hamiltonian) transfer functions of degree δ, the number of pole assigning complex symmetric feedback compensators is finite, and when counted with multiplicities there are exactly*

$$d(n) := 2^{\binom{n}{2}} \frac{\binom{n+1}{2}!\ 1!\ 2!\ \cdots\ (n-1)!}{1!\ 3!\ \cdots\ (2n-1)!} = \frac{\binom{n+1}{2}!}{\prod_{i=0}^{n-1} (2\,i+1)^{n-i}} \tag{3.3}$$

many symmetric compensators as solution.

One immediately computes $d(1) = 1$, $d(2) = 2$, $d(3) = 2^4$, $d(4) = 3 \cdot 2^8$, $d(5) = 11 \cdot 13 \cdot 2^{11}$, and $d(6) = 13 \cdot 17 \cdot 19 \cdot 2^{18}$. The integer sequence $d(n)$ is sequence A005118 in Sloane's data bank of integer sequences [33]. The sequence has several combinatorial and geometric interpretations. For the context of this paper it will be important that $d(n)$ is equal to the degree of the Lagrangian Grassmannian, the projective variety of all maximal isotropic subspaces in a complex vector space of dimension $2n$.

As for the Grassmann variety, classical Schubert calculus [30] (see [11, Chapter 14] for a modern treatment of Schubert calculus) provides the tools to compute the degree of the Lagrangian Grassmannian. An explicit formula for the integers $d(n)$ was probably first given by Hiller [17], who computed

$$d(n) = \begin{cases} 2^{\binom{n}{2}} \frac{\binom{n+1}{2}!\ 2!\ 4!\ \cdots\ (n-2)!}{(n+1)1!\ (n+3)!\ \cdots\ (2n-1)!} & \text{if } n \text{ is even,} \\ 2^{\binom{n}{2}} \frac{\binom{n+1}{2}!\ 2!\ 4!\ \cdots\ (n-2)!}{(n+1)1!\ (n+3)!\ \cdots\ (2n-1)!} & \text{if } n \text{ is odd.} \end{cases} \tag{3.4}$$

The hard combinatorial work to derive formula (3.4) is actually due to Schur [31]. It has been pointed out by Totaro [36] that $d(n)$ is equal to the Kostka number $K_{\lambda,(1^N)}$, where λ is the partition $\lambda = (n, n-1, \ldots, 1)$ and $N = \binom{n+1}{2}$. Totaro derived an explicit formula for more general Kostka numbers, and Totaro's formula specializes to formula (3.3). Readers interested in combinatorial aspects of Kostka numbers should consult the book by Macdonald [22].

It can be seen from the formulas that $d(n)$ is always even, except for $n = 1$. This is related to the fact that the symmetric output feedback pole placement problem is *not* generically solvable over the reals. Actually, more can be said about $d(n)$. The sequence

$$\tilde{d}(n) := d(n) 2^{-\binom{n}{2}}$$

is the degree of the spinor variety, the complex projective variety $SO(2n+1)/U(n)$ [17]; in particular, $\tilde{d}(n)$ represents an integer sequence again. The sequence $\tilde{d}(n)$ appears under the number A003121 in Sloane's data bank [33].

The proof of Theorem 3.6 will occupy the rest of this section. The proof will necessitate a geometric reformulation and several technical lemmas.

First we will describe the closed loop characteristic equation in a slightly more convenient way. Consider a left coprime factorization $D^{-1}(s)N(s) = G(s)$ of the symmetric or Hamiltonian transfer function $G(s)$. Let $F \in \mathrm{Sym}(n)$ be an $n \times n$ complex symmetric matrix. When the feedback law $y = -Fu + v$ is applied, then up to a constant factor the characteristic polynomial $\varphi(s)$ is also equal to

$$\det \begin{bmatrix} D(s) & N(s) \\ F & I_n \end{bmatrix}. \tag{3.5}$$

The vector space $\mathrm{Sym}(n)$ describing the set of $n \times n$ complex symmetric matrices is not very well suited to invoking strong theorems from algebraic geometry and intersection theory [11], as these usually require compactness assumptions on the underlying spaces. A similar difficulty exists for the static output pole placement problem. Brockett and Byrnes showed in [3] how to translate the static pole placement problem into a geometric problem. This then resulted in an intersection problem on a compact Grassmann variety, and methods from classical Schubert calculus [30, 35] could be invoked.

We will follow this compactification strategy for Problem 3.1 as well. This will lead us to an intersection problem on some projective variety. In order to do so we therefore need a good compactification of $\mathrm{Sym}(n)$. For this identify the row span $\mathrm{rowsp}\,[F\ I_n]$ of any symmetric matrix F with an element of the Grassmann variety $\mathrm{Grass}(n, \mathbb{C}^{2n})$. Using the Plücker embedding

$$\mathrm{Grass}(n, \mathbb{C}^{2n}) \longrightarrow \mathbb{P}\left(\wedge^n \mathbb{C}^{2n}\right) = \mathbb{P}^N, \quad N = \binom{2n}{n} - 1,$$

we can then identify $\mathrm{Sym}(n)$ with a quasi-projective subset of the complex projective variety $\mathbb{P}^N$.

Definition 3.7. The algebraic closure of the set

$$\{\mathrm{rowsp}\,[F\ I_n] \mid F \in \mathrm{Sym}(n)\}$$

is called the *complex Lagrangian Grassmann manifold*. It will be denoted by $\mathbb{L}G(n)$.

It is well known that $\mathbb{L}G(n)$ is a smooth projective variety of dimension $\binom{n+1}{2}$, the dimension of $\mathrm{Sym}(n)$. Note that every element in $\mathbb{L}G(n)$ can be simply represented by a subspace of the form $\mathrm{rowsp}\,[F_1\ F_2]$, where $F_1(F_2)^\top$ is a symmetric matrix, i.e., $F_1(F_2)^\top = F_2(F_1)^\top$. The elements of $\mathbb{L}G(n)$ are thus exactly the Lagrangian subspaces of $\mathbb{C}^{2n}$. The subspace $\mathrm{rowsp}\,[F_1\ F_2]$ coincides with the subspace $\mathrm{rowsp}\,[S\ I_n]$ associated with an element S of $\mathrm{Sym}(n)$ if and only if F_2 is invertible. Moreover, then $S = (F_2)^{-1}F_1$. When F_2 is singular one can still define a characteristic polynomial through

$$\varphi(s) := \det \begin{bmatrix} D(s) & N(s) \\ F_1 & F_2 \end{bmatrix}. \tag{3.6}$$

Note that in the Hamiltonian case, $\varphi(s)$ is necessarily even; i.e.,

$$\varphi(s) = \varphi(-s).$$

Let $f_i,\ i = 0, \ldots, N$, be the Plücker coordinates of $\operatorname{rowsp}[F_1\ F_2]$. In terms of the Plücker coordinates the characteristic equation can then be written as

$$\det \begin{bmatrix} D(s) & N(s) \\ F_1 & F_2 \end{bmatrix} = \sum_{i=0}^{N} p_i(s) f_i, \tag{3.7}$$

where $p_i(s)$ is the cofactor of f_i in the determinant (3.7).

Let $\mathcal{Z} \subset \mathbb{P}^N$ be the linear subspace defined by

$$\mathcal{Z} = \left\{ z \in \mathbb{P}^N \,|\, \sum_{i=0}^{N} p_i(s) z_i = 0 \right\}. \tag{3.8}$$

Following [19, 27, 28, 37] we identify a closed loop characteristic polynomial $\varphi(s)$ with a point in $\mathbb{P}^\delta$. In analogy to the situation of the static pole placement problem considered in [3, 37] (compare also with [28, section 5]), one has a well-defined characteristic map

$$\begin{array}{rccc} \chi: & \mathbb{L}G(n) - \mathcal{Z} & \longrightarrow & \mathbb{P}^\delta \\ & \operatorname{rowsp}[F_1\ F_2] & \longmapsto & \sum_{i=0}^{N} f_i p_i(s) \end{array} \tag{3.9}$$

in the complex symmetric case and

$$\begin{array}{rccc} \chi': & \mathbb{L}G(n) - \mathcal{Z} & \longrightarrow & \mathbb{P}^{\delta/2} \\ & \operatorname{rowsp}[F_1\ F_2] & \longmapsto & \text{even part of } \sum_{i=0}^{N} f_i p_i(s) \end{array} \tag{3.10}$$

in the Hamiltonian case. In the latter case the reduction in dimension of the projective space arises due to the evenness of the closed loop characteristic polynomial, so that in the second map only the coefficients of the even terms of $\sum_{i=0}^{N} f_i p_i(s)$ appear.

Recall the notion of degree of a variety [13, Chapter I, section 7] and the notion of a central projection (see [32, Chapter I, section 4]). The geometric properties of the map χ are as follows.

THEOREM 3.8. *The maps χ, χ' define central projections. In particular, if $\mathcal{Z} \cap \mathbb{L}G(n) = \emptyset$ and $\dim \mathbb{L}G(n) = \binom{n+1}{2} = \delta$, then χ is surjective, and there are $\deg \mathbb{L}G(n)$ many preimages (counted with multiplicity) for each point in $\mathbb{P}^\delta$, where $\deg \mathbb{L}G(n)$ is the degree of the Lagrangian manifold $\mathbb{L}G(n)$ in $\mathbb{P}^N$. Similarly, if $\dim \mathbb{L}G(n) = \binom{n+1}{2} = \delta/2$, then χ' is surjective with exactly $\deg \mathbb{L}G(n)$ many preimage points in each fiber.*

Proof. By definition (see, e.g., [26, 32]), χ represents a central projection of $\mathbb{L}G(n)$ *from the center* $\mathcal{Z}$ *to* $\mathbb{P}^\delta$. When $\mathcal{Z} \cap \mathbb{L}G(n) = \emptyset$ and $\dim \mathbb{L}G(n) = \binom{n+1}{2} = \delta$, then χ is a finite morphism [32, Chapter I, section 5, Theorem 7] and onto of degree $\deg \mathbb{L}G(n)$ [26, Corollary 5.6]. Similar argument can be applied to χ'. ∎

The set $\mathcal{Z} \cap \mathbb{L}G(n)$ is sometimes referred to as the *base locus*. The interesting part of the theorem occurs when the base locus $\mathcal{Z} \cap \mathbb{L}G(n) = \emptyset$ since in this situation very specific information on the number of solutions is provided. If $\mathcal{Z} \cap \mathbb{L}G(n) = \emptyset$ and $\binom{n+1}{2} = \delta$ (or $n(n+1) = \delta$), then one says that χ (or χ') describes a *finite morphism* from the projective variety $\mathbb{L}G(n)$ onto the projective space $\mathbb{P}^\delta$ (or $\mathbb{P}^{\delta/2}$).

This last situation is most desirable, and this motivates the following definition.

DEFINITION 3.9. A particular symmetric transfer function $G(s)$ is called *nondegenerate* if $\mathcal{Z} \cap \mathbb{L}G(n) = \emptyset$. A system which is not nondegenerate will be called degenerate.

In terms of matrices a symmetric transfer function $G(s) = D(s)^{-1}N(s)$ is degenerate as soon as there is a Lagrangian subspace $\operatorname{rowsp}[F_1\ F_2] \in \mathbb{L}G(n)$, such that

$$\det \begin{bmatrix} D(s) & N(s) \\ F_1 & F_2 \end{bmatrix} = 0.$$

In more geometric language this means that the Hermann–Martin curve [25] defined by $\operatorname{rowsp}[D(s)\ N(s)]$ is fully contained in a Lagrangian hyperplane defined by $\operatorname{rowsp}[F_1\ F_2]$. In the study of the static pole placement problem [3] and the dynamic pole placement problem [28], definitions analogous to Definition 3.9 played an important role.

The next lemmas give specific information as to under which conditions $\mathcal{Z} \cap \mathbb{L}G(n) = \emptyset$, i.e., under which conditions a symmetric transfer function is nondegenerate. Similar results were crucial in proving the pole placement results in [3, 19, 28].

LEMMA 3.10. *If $\delta < \binom{n+1}{2} = \dim \mathbb{L}G(n)$, then every $n \times n$ symmetric transfer function of McMillan degree δ is degenerate. Similarly, any $n \times n$ Hamiltonian transfer function of McMillan degree δ is degenerate if $\delta < n(n+1) = 2 \dim \mathbb{L}G(n)$.*

Proof. $\dim \mathcal{Z} \geq N - \delta - 1$ as $\mathcal{Z}$ is defined by $\delta + 1$ linear equations ($\delta/2 + 1$ in the Hamiltonian case). If $\dim \mathbb{L}G(n) > \delta$ (or $\dim \mathbb{L}G(n) > \delta/2$ in the Hamiltonian case), then $\mathcal{Z} \cap \mathbb{L}G(n)$ is nonempty by the (projective) dimension theorem (see, e.g., [13, Chapter I, Theorem 7.2]). ∎

LEMMA 3.11. *If $\delta = \binom{n+1}{2} = \dim \mathbb{L}G(n)$ (or $\delta = n(n+1)$), then a generic set of $n \times n$ symmetric (or Hamiltonian) transfer functions of McMillan degree δ is nondegenerate.*

Proof. Let $\mathcal{Q}$ be the set of all $n \times n$ symmetric transfer functions of McMillan degree n. $\mathcal{Q}$ can be given the structure of a quasi-projective variety. For this, recall the definition of the projective variety $K^{\delta}_{n,n}$ that was introduced in [28] and which compactifies the set of all $n \times n$ transfer functions of McMillan degree δ. An element (Hermann–Martin curve) $\operatorname{rowsp}[D(s)\ N(s)] \in K^{\delta}_{n,n}$ describes an element of $\mathcal{Q}$ as soon as $\deg \det D(s) = \delta$ and $D(s)N(s)^{\top} = N(s)D(s)^{\top}$. The last condition translates into some linear conditions to be satisfied among the Plücker coordinates of $K^{\delta}_{n,n}$. The resulting subvariety of $K^{\delta}_{n,n}$ constitutes a natural compactification of $\mathcal{Q}$, and $\mathcal{Q}$ itself is a quasi-projective subset.

Consider now the coincidence set

$$\mathcal{S} := \left\{ (D(s)^{-1}N(s);\ F_1, F_2) \in \mathcal{Q} \times \mathbb{L}G(n) \mid \det \begin{bmatrix} D(s) & N(s) \\ F_1 & F_2 \end{bmatrix} = 0 \right\}.$$

Since $\mathbb{L}G(n)$ is projective, the projection onto $\mathcal{Q}$ is an algebraic set by the main theorem of elimination theory (see, e.g., [26]). The set of nondegenerate systems therefore forms a Zariski open subset of $\mathcal{Q}$. We have shown the result if we can exhibit one $n \times n$ transfer function of McMillan degree $\binom{n+1}{2}$ which is nondegenerate. The next lemma gives such an example, and the claim therefore follows. Note that the previous arguments run in a completely similar manner for the Hamiltonian case, and it therefore remains to construct one example as well. However, the symmetric Hamiltonian transfer function $G(s^2)$ is exactly such an example. ∎

LEMMA 3.12. *The symmetric transfer function*

$$G(s) := \begin{bmatrix} \frac{1}{s} & & & \\ & \frac{1}{s^2} & & \\ & & \ddots & \\ & & & \frac{1}{s^n} \end{bmatrix}$$

is nondegenerate.

Proof. First it is clear that $G(s)$ has McMillan degree $\delta = \binom{n+1}{2}$ and that

$$[D(s)\ N(s)] = \left[\begin{array}{cccc|cccc} s & & & & 1 & & & \\ & s^2 & & & & 1 & & \\ & & \ddots & & & & \ddots & \\ & & & s^n & & & & 1 \end{array}\right]$$

forms a left coprime factorization of $G(s)$. Let

$$R := \begin{bmatrix} & & & 1 \\ & & \iddots & \\ & \iddots & & \\ 1 & & & \end{bmatrix}$$

and assume by contradiction that $G(s)$ is degenerate. Then there exists rowsp $[F_1\ F_2] \in \mathbb{L}G(n)$, such that

$$0 = \det \begin{bmatrix} D(s) & N(s) \\ F_1 & F_2 \end{bmatrix} = \det \begin{bmatrix} D(s) & N(s)R \\ F_1 & F_2R \end{bmatrix}. \tag{3.11}$$

Let $S \in Gl_n$ be the matrix which transforms the $n \times 2n$ matrix $[F_1\ F_2R]$ into row reduced echelon form, i.e.,

$$[(SF_1)\ \ (SF_2R)] = \begin{bmatrix} * & \cdots & * & 1 & 0 & \cdots & 0 & 0 & \cdots & 0 & \cdots & 0 & 0 & 0 & \cdots & 0 \\ * & \cdots & * & 0 & * & \cdots & * & 1 & \cdots & 0 & \cdots & 0 & 0 & 0 & \cdots & 0 \\ \vdots & & \vdots & \vdots & \vdots & & \vdots & \vdots & & \vdots & & \vdots & \vdots & \vdots & & \vdots \\ * & \cdots & * & 0 & * & \cdots & * & 0 & \cdots & * & \cdots & * & 1 & 0 & \cdots & 0 \end{bmatrix} =: [\tilde{F}_1\ \ \tilde{F}_2]. \tag{3.12}$$

Let

$$i_1 < \cdots i_k \le n < i_{k+1} < \cdots i_n \le 2n$$

be the pivot indices. We claim that the first k pivot indices determine the last $n-k$ pivot indices uniquely. For this let $\hat{i}_1 < \cdots < \hat{i}_{n-k}$ be the complementary indices of the indices $\{i_1, \ldots i_k\}$ inside the set $\{1, \ldots, n\}$. Then we claim that

$$\begin{aligned} i_{k+1} &= 2n - \hat{i}_{n-k} + 1 \\ &\vdots \\ i_n &= 2n - \hat{i}_1 + 1. \end{aligned}$$

Indeed, if this is not the case, then it follows that $\tilde{F}_1 R (\tilde{F}_2)^\top$ cannot be symmetric for any choice of values in the row reduced echelon form (3.12). On the other hand, the matrix $\tilde{F}_1 R (\tilde{F}_2)^\top$ has to be symmetric since by assumption $F_1 (F_2)^\top$ is symmetric.

The indices $i_1, \ldots, i_n$ describe the maximal Plücker coordinate (with regard to the Bruhat order) of rowsp $[F_1\ \ F_2R]$ which is nonzero, and the corresponding cofactor of $[D(s)\ \ N(s)R]$ is computed as $\pm s^\alpha$, where $\alpha = \sum_{\ell=1}^{n-k} \hat{i}_\ell$. In general there are other full-size minors (Plücker coordinates) of $[D(s)\ \ N(s)R]$ which have the form $\pm s^\alpha$. All

other Plücker coordinates with this value, however, are not comparable with regard to the Bruhat order, and since $i_1, \ldots, i_n$ was the maximal nonzero Plücker coordinate of rowsp $[F_1 \;\; F_2 R]$, it follows that the determinant expansion in (3.11) cannot be zero. This is a contradiction, and it follows that $G(s)$ is nondegenerate. □

Remark 3.13. For the static pole placement problem Brockett and Byrnes [3] showed that the osculating normal curve

$$\text{rowsp} \begin{bmatrix} 1 & s & s^2 & \ldots & \ldots & s^{m+p-1} \\ 0 & 1 & 2s & \ldots & \ldots & \binom{m+p-1}{1} s^{m+p-2} \\ \vdots & & \ddots & & & \vdots \\ 0 & \ldots & 0 & 1 & \ldots & \binom{m+p-1}{m-1} s^p \end{bmatrix} \in \text{Grass}(m, \mathbb{K}^{m+p})$$

is nondegenerate. Also in this situation the Plücker coordinates have the simple form $\pm s^\beta$, where $\beta = \sum_{\ell=1}^{m} i_\ell - \ell$ and there are no two Plücker coordinates which are comparable in the Bruhat order and give rise to the same monomial s^β.

We have now all pieces together in order to prove the main result.

Proof of Theorem 3.6. Without loss of generality we focus on the case of symmetric transfer functions. The arguments for the Hamiltonian case run in a completely similar manner. Note, however, that the closed loop characteristic polynomial of a Hamiltonian system is always an *even* polynomial. Therefore our definition of generic pole assignability for Hamiltonian systems restricts to the space of even polynomials. Since the dimension of the space of even monic polynomials of degree δ is $\delta/2$, the appropriate condition for Hamiltonian systems is $\delta/2 \leq \binom{n+1}{2}$. With these comments in mind, we return to the proof for symmetric transfer functions.

When $\delta > \binom{n+1}{2}$, then a simple dimension argument shows that the image of the characteristic map χ described in (3.9) has dimension at most $\binom{n+1}{2}$ and therefore there is a Zariski open set in $\mathbb{P}^\delta$ not in the image of χ.

When $\delta = \binom{n+1}{2}$, then Lemmas 3.11 and 3.12 show that there is a generic set of $n \times n$ symmetric transfer functions of McMillan degree δ which are nondegenerate. The characteristic map (3.9) therefore has no base locus, and every point in the image of χ has $\deg \mathbb{L}G(n)$ preimage points when counted with multiplicities. The degree of the variety $\mathbb{L}G(n)$ was recently computed by Totaro [36] and resulted in the number (3.3).

A priori the geometric formulation only predicts $\deg \mathbb{L}G(n)$ many solutions inside $\mathbb{L}G(n)$, and it is not clear if all these solutions correspond to regular feedback laws of the form $u = -Fy + v$. If $G(s)$ is a strictly proper symmetric transfer function, then this is indeed the case and the same argument applies as in [3]. □

STABILITY AND STABILIZATION OF CONTINUOUS-TIME SWITCHED LINEAR SYSTEMS*

JOSÉ C. GEROMEL† AND PATRIZIO COLANERI‡

Abstract. This paper addresses two strategies for the stabilization of continuous-time, switched linear systems. The first one is of open loop nature (trajectory independent) and is based on the determination of a minimum dwell time by means of a family of quadratic Lyapunov functions. The relevant point on dwell time calculation is that the proposed stability condition does not require the Lyapunov function to be uniformly decreasing at every switching time. The second one is of closed loop nature (trajectory dependent) and is designed from the solution of what we call Lyapunov–Metzler inequalities from which the stability condition (including chattering) is expressed. Being nonconvex, a more conservative but simpler-to-solve version of the Lyapunov–Metzler inequalities is provided. The theoretical results are illustrated by means of examples.

1. Introduction.

This paper aims to provide new results on stability analysis and stabilizing control synthesis for a continuous-time, switched linear system of the general form

$$\dot{x}(t) = A_{\sigma(t)}x(t)\ ,\ x(0) = x_0, \tag{1}$$

defined for all $t \geq 0$, where $x(t) \in \mathbb{R}^n$ is the state, $\sigma(t)$ is the switching rule, and x_0 is the initial condition. Considering a set of matrices $A_i \in \mathbb{R}^{n\times n}$, $i = 1, \ldots, N$, be given, the switching rule $\sigma(t)$, for each $t \geq 0$, is such that

$$A_{\sigma(t)} \in \{A_1, \ldots, A_N\}, \tag{2}$$

where it is clear that this model naturally imposes a discontinuity on $A_{\sigma(t)}$ since this matrix must jump instantaneously from A_i to A_j for some $i \neq j = 1, \ldots, N$ once switching occurs. In other words, $A_{\sigma(t)}$ is constrained to jump among the N vertices of the matrix polytope $\{A_1, \ldots, A_N\}$.

Stability of continuous-time switched linear systems has been addressed by several authors [3], [5], [11], [12], [14], [16], [17], [18], [20] and [23]. While the survey papers [5] and [17] give a complete and detailed description on the problems arising in this area, the recent paper [11], dealing with extensions of LaSalle's invariance principle, provides an interesting discussion on a collection of results on uniform stability of switched systems. The themes dealt with in the present paper have their roots in the conference paper [9].

Generally speaking, when $\sigma(\cdot)$ is state independent, that is, when it is an a priori piecewise constant signal, the reported stability conditions are obtained using a family of symmetric and positive definite matrices $\{P_1, \ldots, P_N\}$, each one associated to the correspondent matrix of the set $\{A_1, \ldots, A_N\}$ such that a Lyapunov function $v(x(t))$ is nonincreasing for all $t \geq 0$; see [11]. In this paper, for minimum dwell time design preserving global stability it is assumed that each matrix of the set $\{A_1, \ldots, A_N\}$ is asymptotically stable but the above mentioned nonincreasing condition on the Lyapunov function is relaxed. It is replaced by the weaker condition that at every switching time t_k the sequence $v(x(t_k))$, for $k = 0, \ldots, \infty$, converges uniformly to zero. In some instances, our design procedure for the determination of the minimum dwell time, based on a quadratic guaranteed cost, is related to the results of [22] assuming further that the switching rule is not a priori given but can be taken arbitrarily, among the feasible ones; see [8]. For comparison purposes, a simple second-order example is solved, and it is shown that the estimation of the minimum dwell time provided in this paper is sensibly better than the one obtained from the classical result of [18] and the well-known *average dwell time stability* condition provided in [16], [10], and the references therein. The results obtained in this context have some resemblance with those achieved in [21], where the characterization of the exponential growth rate of switched systems is provided. However, much work is needed to establish the possible links between these two approaches.

For switched systems with $\sigma(\cdot)$ being state dependent, the stability condition is expressed in terms of a set of inequalities that we call *Lyapunov–Metzler inequalities* because the variables involved are a set of symmetric and positive definite matrices $\{P_1, \ldots, P_N\}$ and a Metzler matrix Π. The point to be noticed is that our asymptotic stability condition does not require any stability property associated to each individual matrix of the set $\{A_1, \ldots, A_N\}$ and it contains as a special case the quadratic stability condition. An important point of our main result is that it includes the stability of possible sliding modes, a fact that in the particular case $N = 2$ was observed in [16]. It is also important to stress that in [20] we can find some stability results related to the same problem (without the analysis of sliding modes) but restricted to the special case $N = 2$, which does not require the formalism based on the Lyapunov–Metzler inequalities introduced here. In our general case, the price to be paid, however, is the nonconvex nature of the the Lyapunov–Metzler inequalities being thus difficult to solve numerically. From this previous result, a more conservative but easier-to-solve asymptotic stability condition is proposed.

As a final remark, notice that the dwell time calculation provided in the first part of the paper also suggests a way to solve the state-feedback stabilization problem for a input-driven switched system characterized by the pairs (A_i, B_i). Under mild assumptions it is possible to design matrices K_i so as to stabilize the closed-loop systems $A_i + B_i K_i$. Hence, one can compute an upper bound of the dwell time to establish the time duration of the associated piecewise-constant control law. Notice that the general problem of minimization of the dwell time as a function of the design local control laws K_i is still open.

The paper is organized as follows. In section 2, time-switching control is analyzed. The switching rule $\sigma(t)$ is considered piecewise constant and a minimum dwell time preserving stability is determined. Section 3 is entirely devoted to state-switching control where the goal is to design a function $u(\cdot)$ such that the system (1) is globally asymptotically stable with the switching rule $\sigma(t) = u(x(t))$. Section 4 concludes the paper.

The notation used throughout is standard. Capital letters denote matrices, small letters denote vectors, and small Greek letters denote scalars. For matrices or vectors, $(')$ indicates transpose. For symmetric matrices, $X > 0$ (≥ 0) indicates that X is positive definite (positive semidefinite), and $\lambda_{min}(X)$, $\lambda_{max}(X)$ denote its minimum and maximum eigenvalue, respectively. The sets of real and natural numbers are denoted by $\mathbb{R}$ and $\mathbb{N}$, respectively. The $\mathcal{L}_2$ squared norm of $x(t) \in \mathbb{R}^n$ defined for all $t \geq 0$ equals $\|x(t)\|_2^2 = \int_0^\infty x(t)'x(t)dt$; see [4].

2. Time-switching control. This section is entirely dedicated to the design of a time-switching control law for the switched linear system defined by the model (1) and (2) where it is assumed that each matrix of the set $\{A_1, \ldots, A_N\}$ is asymptotically stable. The problem under consideration can be stated as follows. Determine a minimum dwell time $T_* > 0$ such that the equilibrium point $x = 0$ of the system (1) is globally asymptotically stable with the time switching control

$$\sigma(t) = i \in \{1, \ldots, N\}, \qquad t \in [t_k, t_{k+1}), \tag{3}$$

where t_k and t_{k+1} are successive switching times satisfying $t_{k+1} - t_k \geq T_*$ for all $k \in \mathbb{N}$ and the index $i \in \{1, \ldots, N\}$ selected at each instant of time $t \geq 0$ is arbitrary. Hence, asymptotic stability is preserved whenever $\sigma(t)$ remains unchanged for a period of time greater or equal to the minimum dwell time T_*. The next theorem provides the theoretical basis toward a possible solution of this problem by characterizing an upper bound for T_*. It uses the concept of multiple Lyapunov function with the innovation that the classical nonincreasing assumption at switching times is no longer needed.

THEOREM 1. *Assume that for some $T > 0$, there exists a collection of positive definite matrices $\{P_1, \ldots, P_N\}$ of compatible dimensions such that*

$$A_i'P_i + P_iA_i < 0 \quad \forall\ i = 1, \ldots, N \tag{4}$$

and

$$e^{A_i'T}P_je^{A_iT} - P_i < 0 \quad \forall\ i \neq j = 1, \ldots, N. \tag{5}$$

The time-switching control (3) *with $t_{k+1} - t_k \geq T$ makes the equilibrium solution $x = 0$ of* (1) *globally asymptotically stable.*

Proof. Consider, in accordance to (3), that $\sigma(t) = i \in \{1, \ldots, N\}$ for all $t \in [t_k, t_{k+1})$, where $t_{k+1} = t_k + T_k$ with $T_k \geq T > 0$, and that at $t = t_{k+1}$ the time-switching control jumps to $\sigma(t) = j \in \{1, \ldots, N\}$; otherwise the result trivially follows. From (4), it is seen that for all $t \in [t_k, t_{k+1})$, the time derivative of the Lyapunov function $v(x(t)) = x(t)'P_{\sigma(t)}x(t)$ along an arbitrary trajectory of (1) satisfies

$$\begin{aligned} \dot{v}(x(t)) &= x(t)'(A_i'P_i + P_iA_i)x(t) \\ &< 0, \end{aligned} \tag{6}$$

which enables us to conclude that there exist scalars $\alpha > 0$ and $\beta > 0$ such that

$$\|x(t)\|^2 \leq \beta e^{-\alpha(t-t_k)}v(x(t_k)) \quad \forall t \in [t_k, t_{k+1}). \tag{7}$$

On the other hand, using the inequalities (5) we have

$$\begin{aligned} v(x(t_{k+1})) &= x(t_{k+1})' P_j x(t_{k+1}) \\ &= x(t_k)' e^{A_i' T_k} P_j e^{A_i T_k} x(t_k) \\ &< x(t_k)' e^{A_i'(T_k - T)} P_i e^{A_i (T_k - T)} x(t_k) \\ &< x(t_k)' P_i x(t_k) \\ &< v(x(t_k)), \end{aligned} \tag{8}$$

where the second inequality holds from the fact that for every $\tau = T_k - T \geq 0$ it is true that $e^{A_i'\tau} P_i e^{A_i \tau} \leq P_i$. The consequence is that there exists $\mu \in (0,1)$ such that

$$v(x(t_k)) \leq \mu^k v(x_0) \quad \forall k \in \mathbb{N}, \tag{9}$$

which together with (7) implies that the equilibrium solution $x = 0$ of (1) is globally asymptotically stable. □

This result deserves some comments. First, it is simple to determine the scalars α, β and μ such that (7) and (9) hold. Indeed, assuming that $\{P_1, \ldots P_N\}$ satisfy the conditions of Theorem 1, then from (4) there exists $\epsilon > 0$ such that $A_i' P_i + P_i A_i' \leq -\epsilon I$ for all $i = 1, \ldots, N$ yielding $\alpha = \epsilon / \max_i \lambda_{max}(P_i) > 0$ and $\beta = 1/\min_i \lambda_{min}(P_i) > 0$. Furthermore, from (5) there exists $0 < \mu < 1$ such that $e^{A_i' T} P_j e^{A_i T} \leq \mu P_i$ for all $i \neq j = 1, \ldots, N$ leading to $v(x(t_{k+1})) \leq \mu v(x(t_k))$ and consequently (9). Second, since all matrices of the set $\{A_1, \ldots, A_N\}$ are supposed to be asymptotically stable, the constraints (4) are always feasible and the constraints (5) are satisfied when $T > 0$ is taken large enough. Third, assuming that matrices $A_1, \ldots, A_N$ are quadratically stable, which is the same as saying that they share a positive definite matrix P such that

$$A_i' P + P A_i < 0 \quad \forall i = 1, \ldots, N, \tag{10}$$

then the inequality (5) is satisfied for $P_1 = \cdots = P_N = P$ for any $T > 0$, meaning that even in the case the switching policy (3) jumps from i to j arbitrarily fast, the asymptotic stability is preserved. Hence, Theorem 1 contains, as a particular case, the quadratic stability condition. Finally, with $T > 0$ fixed it is always possible to define a time-switching control strategy (3) such that $A_{\sigma(t)}$ is periodic. As a consequence, a necessary condition for the feasibility of constraints (4) and (5) is

$$\theta(T) := \max_{q=1,\ldots,n} \left| \lambda_q \left(\prod_{p=1}^{N} e^{B_p T} \right) \right| < 1, \tag{11}$$

where $\lambda_q(\cdot)$ denotes a generic eigenvalue of $(\cdot)$ and $\{B_1, \ldots, B_N\}$ are matrices corresponding to any permutation among those of the set $\{A_1, \ldots, A_N\}$. However, since (3) may produce nonperiodic policies as well, the necessary condition (11) for the existence of a feasible solution to inequalities (4)–(5) generally does not meet sufficiency. In what follows, this aspect will be illustrated by means of an example.

Remark 1 (multiple Lyapunov functions). The important concept of multiple Lyapunov functions introduced in [3] is largely used in switching systems analysis; see also [11, 16]. In the present context, consider the family of Lyapunov functions $V_i(x(t)) = x(t)' P_i x(t)$ valid in each time interval such that $\sigma(t) = i$ for all $i = 1, \ldots, N$. From Theorem 3.1 of [16], the switched system (1) is globally asymptotically

stable whenever each Lyapunov function satisfies $V_i(x(t_q)) < V_i(x(t_p))$, where $\sigma(t_q) = \sigma(t_p) = i$ for every switching times $t_p < t_q$. For dwell time calculation, the use of this stability condition is not simple because it is difficult to impose the decreasing property for each function $V_i(\cdot)$ at nonsuccessive switching times. In Theorem 1 this constraint is replaced by $V_j(x(t_{k+1})) < V_i(x(t_k))$, where t_k and t_{k+1} are successive switching times such that $\sigma(t_k) = i$ and $\sigma(t_{k+1}) = j$. See [3] for a general discussion of these conditions applied to nonlinear switching systems. In [21], a similar stability condition is obtained based on the characterization of the exponential growth rate of switched systems.

From the previous result, an upper bound for the minimum dwell time T_* can be computed by taking the minimum value of T satisfying the conditions of Theorem 1. Hence, it can be calculated with no great difficulty from the optimal solution of the optimization problem[1]

$$\min_{T>0, P_1>0, \ldots, P_N>0} \{T \ : \ (4) \text{ and } (5)\}, \tag{12}$$

which, for each $T > 0$ fixed, reduces to a convex programming problem with linear matrix inequality constraints that can be handled by any LMI solver available in the literature to date; see [2] for an important study on systems and LMIs. A line search procedure is then used to deal with the scalar variable $T > 0$.

Finally, it is possible to generalize the result of Theorem 1 to define a guaranteed cost-to-go from an arbitrary initial point to the origin, associated to the stabilizing time-switching rule (3) with $t_{k+1} - t_k \geq T$ for any fixed $T > 0$. To this end, we make the assumption that $\mathcal{T} > 0$ is known such that $t_{k+1} - t_k \leq \mathcal{T}$ for all $k \in \mathbb{N}$. Clearly, these quantities are related through $\mathcal{T} \geq T \geq T_*$, where the second inequality assures global stability.

THEOREM 2. *Let $Q \geq 0 \in \mathbb{R}^{n\times n}$ and $\mathcal{T} \geq T > 0$ be given. Define the set of symmetric, nonnegative definite matrices*

$$R_i := \int_0^{\mathcal{T}} e^{A_i' t} Q e^{A_i t} dt, \qquad i = 1, \ldots, N. \tag{13}$$

Assume that there exists a collection of positive definite matrices $\{P_1, \ldots, P_N\}$ of compatible dimensions such that

$$A_i' P_i + P_i A_i + Q < 0 \ \ \forall\ i = 1, \ldots, N \tag{14}$$

and

$$e^{A_i' T} P_j e^{A_i T} - P_i + R_i < 0 \ \ \forall\ i \neq j = 1, \ldots, N. \tag{15}$$

The time-switching control (3) with $\mathcal{T} \geq t_{k+1} - t_k \geq T$ makes the equilibrium solution $x = 0$ of (1) globally asymptotically stable and

$$\int_0^{\infty} x(t)' Q x(t) dt < x_0' P_{\sigma(0)} x_0. \tag{16}$$

Proof. Since for $Q \geq 0$ and $\mathcal{T} \geq T > 0$ given, each matrix R_i defined in (13) is positive semidefinite and inequalities (14)–(15) are satisfied, then inequalities (4)–(5)

[1]This problem should be stated with inf instead of min. All feasible sets of problems expressed in terms of LMIs must be considered closed from the interior within a precision defined by the user.

are also satisfied. As a consequence, asymptotic stability follows from Theorem 1. On the other hand, using (13) together with the inequalities (14) and (15) we have that $P_i > R_i$ and

$$\begin{aligned} A_i'(P_i - R_i) + (P_i - R_i)A_i &< -Q - A_i'R_i - R_iA_i \\ &< -Q - \int_0^{\mathcal{T}} \frac{d}{dt} e^{A_i' t} Q e^{A_i t} dt \\ &< -e^{A_i'\mathcal{T}} Q e^{A_i \mathcal{T}} \\ &< 0 \end{aligned} \tag{17}$$

for all $i = 1, \ldots, N$. The important consequence of this calculation is that for each $i = 1, \ldots, N$ the inequality $e^{A_i'\tau}(P_i - R_i)e^{A_i\tau} \leq (P_i - R_i)$ holds for any $\tau \geq 0$. Using this property, taking into account the switching strategy (3) with $t_{k+1} - t_k = T_k \geq T$ and the inequalities (15) one obtains

$$\begin{aligned} v(x(t_{k+1})) &= x(t_{k+1})' P_j x(t_{k+1}) \\ &< x(t_k)' e^{A_i'(T_k - T)}(P_i - R_i) e^{A_i(T_k - T)} x(t_k) \\ &< x(t_k)'(P_i - R_i)x(t_k) \\ &< v(x(t_k)) - x(t_k)' R_{\sigma(t_k)} x(t_k), \end{aligned} \tag{18}$$

which summing up for all $k \in \mathbb{N}$ and taking into account that $\mathcal{T} \geq t_{k+1} - t_k$ allows us to write

$$\begin{aligned} \int_0^\infty x(t)' Q x(t) dt &= \sum_{k=0}^\infty \int_{t_k}^{t_{k+1}} x(t_k)' e^{A_i'(t - t_k)} Q e^{A_i(t - t_k)} x(t_k) dt \\ &\leq \sum_{k=0}^\infty x(t_k)' R_{\sigma(t_k)} x(t_k) \\ &< v(x_0), \end{aligned} \tag{19}$$

which proves the proposed theorem. □

It is interesting to observe that the conditions of Theorem 2 are feasible if and only if $\mathcal{T} \geq T \geq T_*$, and from (16) it is seen that a more accurate guaranteed cost is obtained whenever the value of $\mathcal{T}$ is chosen as small as possible. In addition, the choice $\mathcal{T} = +\infty$ enables us to conclude that the proposed time-switching rule (3) with $t_{k+1} - t_k \geq T_*$, makes the trajectory $y(t) = Q^{1/2}x(t), t \geq 0$, quadratically integrable. Theorem 2 admits the extreme situation $\mathcal{T} = T = +\infty$ for which no jump occurs and inequalities (14)–(15) are verified for

$$P_i = \int_0^\infty e^{A_i' t}(Q + \varepsilon I) e^{A_i t} dt > R_i \geq 0 \ , \ i = 1, \ldots, N \tag{20}$$

with $\varepsilon > 0$ arbitrary. When $\varepsilon > 0$ goes to zero, P_i goes to R_i and (16) becomes a well-known result. On the other hand, for $T > 0$ arbitrarily small and any $\mathcal{T} \geq T$, feasibility holds whenever the set of matrices $\{A_1, \ldots, A_N\}$ admits a common Lyapunov function.

Example 1. For illustration purposes of the theoretical results obtained so far, let us consider the example with $N = 2$ and matrices

$$A_1 = \begin{bmatrix} 0 & 1 \\ -10 & -1 \end{bmatrix}, \qquad A_2 = \begin{bmatrix} 0 & 1 \\ -0.1 & -0.5 \end{bmatrix}, \tag{21}$$

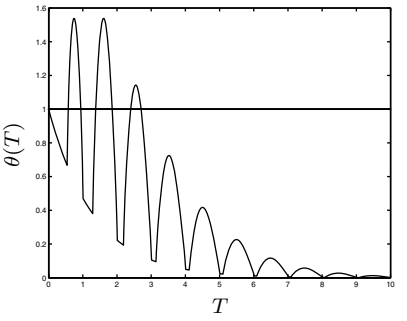

FIG. 1. *The function* $\theta(T)$.

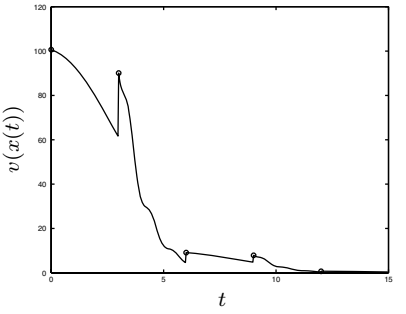

FIG. 2. *The Lyapunov function.*

which are not quadratically stable. First, from problem (12), we have calculated an upper bound for the minimum dwell time as being $T_* \leq 2.76$. To give an idea of its conservativeness we have calculated from the plot of Figure 1 the value $T_{per} = 2.71$ corresponding to the necessary condition for stability (11), arising from linear periodic systems. Both being very close indicates, for this simple example, a good precision on the determination of T_*. On the other hand, for comparison we have applied the classical result of [18] for the determination of an alternative upper bound for the minimum dwell time T_* given by $T_* \leq \max_{i=1,\ldots,N}\{T_i\}$, where

$$T_i = \inf_{\alpha>0,\beta>0} \left\{ \frac{\alpha}{\beta} \ : \ \|e^{A_i t}\| < e^{(\alpha-\beta t)} \quad \forall t \geq 0 \right\}. \tag{22}$$

For the matrices in (21), we have numerically determined $T_1 = 2.33$ and $T_2 = 6.66$, yielding an estimation for the minimum dwell time as being $T_* \leq 6.66$. Hence, in this particular example, the result provided by the solution of problem (12) is much more precise but at the expense of a more expressive computational effort. Moreover, using the method in [10] we have obtained the upper bound of the so-called average dwell time as being 16.5554, which is obviously greater than that obtained by our method.

Figure 2 has been constructed by simulation of system (1) with the time-switching rule (3), $t_{k+1} - t_k = 3.0$, initial conditions $x_0 = [1\ 1]'$, $\sigma(0) = 2$, and $Q = I$. The family of Lyapunov functions has been calculated from the optimal solution of the convex programming problem

$$\min_{P_1>0,\ldots,P_N>0} \max_{i=1,\ldots,N} \{x_0' P_i x_0 \ : \ (14) \text{ and } (15)\}, \tag{23}$$

which puts in evidence that a guaranteed cost can be determined for the worst case as far as the initial condition $\sigma(0)$ appearing in (16) is concerned. For $\mathcal{T} = T = 3.0$, we have obtained the minimum guaranteed cost equal to $\delta^* = 100.61$, valid for both initial conditions. As noted earlier, the Lyapunov function $v(x(t)) = x(t)'P_{\sigma(t)}x(t)$ goes to zero as t goes to infinity; however, it is not uniformly decreasing with respect to time. In Figure 2, due to the stability conditions of Theorem 2, the discontinuity points, marked with circles, defines a globally convergent sequence $v(x(t_k))$ for all $k \in \mathbb{N}$. Solving again problem (23) but for $\mathcal{T} = +\infty$ and $T = 3.0$, the minimum guaranteed cost increases to $\delta^* = 147.94$ as a consequence of allowing a more flexible switching rule (3) with $t_{k+1} - t_k \geq 3.0$.

The example above shows that there is a clear improvement on stability conditions, dwell time, and guaranteed cost calculations when compared to the results available in the literature to date; see [11], [18].

3. State-switching control. In this section, we consider once again the system (1) where the switching rule satisfies (2). The main difference from the previous section is that, presently, it is assumed that the state vector $x(t)$ is available for feedback for all $t \geq 0$. That is, our goal is to determine the function $u(\cdot) : \mathbb{R}^n \to \{1, \ldots, N\}$ such that

$$\sigma(t) = u(x(t)) \tag{24}$$

makes the equilibrium point $x = 0$ of (1) asymptotically stable. In this case, we do not assume that each matrix of the set $\{A_1, \ldots, A_N\}$ is asymptotically stable. To this end, let us define the simplex

$$\Lambda := \left\{ \lambda \in \mathbb{R}^N \ : \ \sum_{i=1}^{N} \lambda_i = 1 \ , \ \lambda_i \geq 0 \right\}, \tag{25}$$

which together with the set of positive definite matrices $\{P_1, \ldots, P_N\}$ enables us to introduce the following piecewise quadratic Lyapunov function:

$$v(x) := \min_{i=1,\ldots,N} x'P_i x = \min_{\lambda \in \Lambda} \left(\sum_{i=1}^{N} \lambda_i x'P_i x \right). \tag{26}$$

As it will be clear in what follows, this Lyapunov function is crucial to our purposes; see [1] and the references therein. However, it presents some difficulties to be handled, including the fact that it is not differentiable everywhere. To analyze this aspect, the set $I(x) = \{i : v(x) = x'P_i x\}$ plays a central role since $v(x)$ fails to be differentiable on $x \in \mathbb{R}^n$ such that $I(x)$ is composed of more than one element or, in other words, when the result of the minimization indicated in (26) is not unique, [19].

Before proceeding, let us recall the class of Metzler matrices denoted by $\mathcal{M}$ and consisting of all matrices $\Pi \in \mathbb{R}^{N \times N}$ with elements π_{ij}, such that

$$\pi_{ij} \geq 0 \ \forall i \neq j, \quad \sum_{i=1}^{N} \pi_{ij} = 0 \ \forall j. \tag{27}$$

It is clear that any $\Pi \in \mathcal{M}$ presents an eigenvalue at the origin of the complex plane since $c'\Pi = 0$, where $c' = [1 \ \cdots \ 1]$. In addition, it is well known from the Frobenius–Perron theorem that the eigenvector associated to the null eigenvalue of

Π is nonnegative, yielding the conclusion that there always exists $\lambda_\infty \in \Lambda$ such that $\Pi\lambda_\infty = 0$. The next theorem summarizes the main result of this section.

THEOREM 3. *Assume that there exist a set* $\{P_1, \ldots, P_N\}$ *of positive definite matrices and* $\Pi \in \mathcal{M}$ *satisfying the Lyapunov–Metzler inequalities*

$$A_i' P_i + P_i A_i + \sum_{j=1}^{N} \pi_{ji} P_j < 0, \qquad i = 1, \ldots, N. \tag{28}$$

The state-switching control (24) *with*

$$u(x(t)) = \arg \min_{i=1,\ldots,N} x(t)' P_i x(t) \tag{29}$$

makes the equilibrium solution $x = 0$ *of* (1) *globally asymptotically stable.*

Proof. It follows from the Lyapunov function (26), which, as we have said before, is not differentiable for all $t \geq 0$. For this reason we need to deal with the Dini derivative (see [7]):

$$D^+ v(x(t)) = \lim_{h \to 0^+} \sup \frac{v(x(t+h)) - v(x(t))}{h}. \tag{30}$$

Assume, in accordance to (29), that at an arbitrary $t \geq 0$, the state-switching control is given by $\sigma(t) = u(x(t)) = i$ for some $i \in I(x(t))$. Hence, from (30) and the system dynamic equation (1), applying the result of Theorem 1 of [15, p. 420] we have

$$\begin{aligned} D^+ v(x(t)) &= \lim_{h \to 0^+} \sup \frac{v(x(t) + hA_i x(t)) - v(x(t))}{h} \\ &= \min_{l \in I(x(t))} x(t)'(A_i' P_l + P_l A_i) x(t) \\ &\leq x(t)'(A_i' P_i + P_i A_i) x(t), \end{aligned} \tag{31}$$

where the inequality holds from the fact that $i \in I(x(t))$. Finally, remembering that (27) is valid for $\Pi \in \mathcal{M}$ and that $x(t)' P_j x(t) \geq x(t)' P_i x(t)$ for all $j \neq i = 1, \ldots, N$ once again due to the fact that $i \in I(x(t))$, using the Lyapunov–Metzler inequalities (28) one obtains

$$\begin{aligned} D^+ v(x(t)) &< -x(t)' \left(\sum_{j=1}^{N} \pi_{ji} P_j \right) x(t) \\ &< - \left(\sum_{j=1}^{N} \pi_{ji} \right) x(t)' P_i x(t) \\ &< 0, \end{aligned} \tag{32}$$

which proves the proposed theorem since the Lyapunov function $v(x(t))$ defined in (26) is radially unbounded. ∎

It is important to observe that Theorem 3 does not require the set $\{A_1, \ldots, A_N\}$ be exclusively composed of asymptotically stable matrices. Indeed, with $\Pi \in \mathcal{M}$, a necessary condition for the Lyapunov–Metzler inequalities to be feasible with respect to $\{P_1, \ldots, P_N\}$ is matrices $A_i + (\pi_{ii}/2)I$ for all $i = 1, \ldots, N$ be asymptotically stable. Since $\pi_{ii} \leq 0$ this condition does not imply the asymptotic stability of A_i. However,

an interesting case occurs when all matrices $\{A_1, \ldots, A_N\}$ are asymptotically stable, for which the choice $\Pi = 0$ is possible and the state-switching strategy proposed preserves stability. Furthermore, if the set $\{A_1, \ldots, A_N\}$ is quadratically stable, then the Lyapunov–Metzler inequalities admit a solution $P_1 = \cdots = P_N = P$ and $I(x(t)) = \{1, \ldots, N\}$ for all $t \geq 0$. In this classical but particular case, at any $t \geq 0$, the control law $u(x(t)) = i \in \{1, \ldots, N\}$ can be chosen arbitrarily and asymptotic stability is guaranteed. Hence, Theorem 3 contains as a particular case (since the Lyapunov–Metzler inequalities do not depend on Π anymore) the quadratic stability condition.

Remark 2 (chattering). Another important feature of Theorem 3 is that chattering in the switching, when it occurs, is always stable. Indeed, assume that $x \in \mathbb{R}^n$ belongs to a certain region $\mathcal{R}$ of the state space where the cardinality of $I(x)$ is greater than one. From the Lyapunov function (26) and the time derivative (31) a switching from any $i \in I(x)$ to some $j \in I(x)$ is possible only if $x'(A_i'P_j + P_jA_i)x \leq x'(A_i'P_i + P_iA_i)x < 0$, where the second inequality follows from (28). Hence, with scalars $\alpha_i \geq 0\ \forall i \in I(x)$ satisfying $\sum_{i \in I(x)} \alpha_i = 1$, we conclude that whenever $x \in \mathcal{R}$ the time derivative of the positive definite function $\nu(x) = x'P_jx$ is strictly negative along the trajectories of $\dot{x} = (\sum_{i \in I(x)} \alpha_i A_i)x$. From Filippov's definition this implies that the switched system is asymptotically stable. In the particular case characterized by $N = 2$, this aspect has already been treated in [16, pp. 70]. In [20] it is noted that a Lyapunov function like (26) but with min replaced by max does not exhibit this property, in which instance the chattering must be ruled out. In this sense, the numerical procedure proposed in [13] for the determination of a switching-state dependent control has to be further qualified to prevent chattering since when it occurs instability may be observed.

In the literature, the Lyapunov–Metzler inequalities with $\Pi \in \mathcal{M}$ fixed have been introduced to study the mean-square (MS) stability of Markov jump linear systems (MJLS). In that context, the Metzler matrix $\Pi = \Pi_0 \in \mathcal{M}$ is given and Π_0' represents the infinitesimal transition matrix of a Markov chain $\sigma(t)$ governing the dynamical system (1). In this respect, each component of the vector $\lambda(t) \in \Lambda$ is the probability of the Markov chain to be in the ith logical state and obeys the differential equation

$$\dot{\lambda}(t) = \Pi_0 \lambda(t)\ ,\ \lambda(0) = \lambda_0 \in \Lambda, \tag{33}$$

where the eigenvector $\lambda_\infty \in \Lambda$ associated to the null eigenvalue of Π_0 represents the stationary probability vector. Hence, using the fact that the stochastic system under consideration is said to be MS-stable if

$$\lim_{t \to +\infty} E(\|x(t)\|^2) = 0 \tag{34}$$

for any initial state $x(0)$ and any initial probability pattern $\lambda_0 \in \Lambda$, it has been shown (see, e.g., [6]) that the system is MS-stable if and only if there exists a set of positive definite matrices $\{P_1, \ldots, P_N\}$ satisfying the Lyapunov–Metzler inequalities (28) for $\Pi = \Pi_0$. Numerically speaking, this is a simple case, since (28) reduces to a set of linear matrix inequalities.

A relevant point to be discussed now concerns the existence of a solution of the Lyapunov–Metzler inequalities (28) with respect to the variables $\Pi \in \mathcal{M}$ and $\{P_1, \ldots, P_N\}$. Standard Kronecker calculus shows that for $\Pi \in \mathcal{M}$ fixed, a solution with respect to the remaining variables exists if and only if the Nn^2-dimensional

square matrix $\mathcal{J} := \mathcal{A} + \mathcal{BC}$ is asymptotically stable, where

$$\mathcal{A} = \begin{bmatrix} A_1' \oplus A_1' & 0 & \cdots & 0 \\ 0 & A_2' \oplus A_2' & \cdots & 0 \\ 0 & 0 & \ddots & 0 \\ 0 & 0 & \cdots & A_N' \oplus A_N' \end{bmatrix} \tag{35}$$

and

$$\mathcal{B} = \Pi' \begin{bmatrix} 0_{N-1} \\ I_{N-1} \end{bmatrix} \otimes I_{n^2}, \qquad \mathcal{C} = \begin{bmatrix} -1_{N-1} & I_{N-1} \end{bmatrix} \otimes I_{n^2}, \tag{36}$$

with the symbols $\oplus$ and $\otimes$ indicating the Kronecker sum and Kronecker product respectively,[2] 0_{N-1} denoting a row vector of $N-1$ zeros components, and 1_{N-1} denoting a column vector of $N-1$ ones components. Hence, the existence of a solution to (28) reduces to the existence of $\Pi \in \mathcal{M}$ rendering matrix $\mathcal{J}$ asymptotically stable. A possible approach to verify the existence of such a matrix is based on the observation that any $\alpha \geq 0$ and $\Pi \in \mathcal{M}$ implies $\alpha\Pi \in \mathcal{M}$, which from the introduction of this new degree of freedom makes possible to verify the existence of $\alpha \geq 0$ such that $\mathcal{J}(\alpha) := \mathcal{A} + \alpha\mathcal{BC}$ is asymptotically stable. Putting aside the situation in which all matrices $\{A_1, \ldots, A_N\}$ are asymptotically stable (making it possible to set $\alpha = 0$), let us consider the other extreme situation corresponding to $\alpha \to +\infty$. Simple determinant manipulations show that a certain number of eigenvalues goes to $-\infty$ while the other ones that remain finite, coincide with the *invariant zeros* of the triple $(\mathcal{A}, \mathcal{B}, \mathcal{C})$.

Fortunately, these invariant zeros can be determined with no great difficulty from the definition

$$\begin{bmatrix} \mu I - \mathcal{A} & \mathcal{B} \\ \mathcal{C} & 0 \end{bmatrix} \begin{bmatrix} \xi \\ \eta \end{bmatrix} = 0 \tag{37}$$

with the key observation that matrix $\mathcal{C}$, being constant, is independent of α and Π which imposes to the solution of $\mathcal{C}\xi = 0$ a vector of compatible dimension with the particular structure $\xi' = [x' \ \cdots \ x'], x \in \mathbb{R}^{n^2}$. In addition, taking $\lambda_\infty \in \Lambda$ such that $\Pi\lambda_\infty = 0$, multiplying each subequation above by $\lambda_{\infty i}$ and summing up, it follows that

$$\left(\mu I - \sum_{i=1}^{N} \lambda_{\infty i} A_i' \oplus A_i' \right) x = 0, \tag{38}$$

which can be rewritten as

$$\left(\mu I - A_{\lambda_\infty}' \oplus A_{\lambda_\infty}' \right) x = 0, \tag{39}$$

where $A_{\lambda_\infty} = \sum_{i=1}^{N} \lambda_{\infty i} A_i$. Therefore, as α goes to infinity, the eigenvalues of $\mathcal{J}(\alpha)$ that remain finite tend to the eigenvalues of $A_{\lambda_\infty}' \oplus A_{\lambda_\infty}'$ which are in the left-hand plane if and only if the eigenvalues of A_{λ_∞} are. This means that if there exists $\lambda_\infty \in \Lambda$

[2]While the Kronecker product is more or less standard, the sum requires a formal definition. In this respect we define the Kronecker sum of two matrices D and E as $D \oplus E = D \otimes I + I \otimes E$. It is important to recall that the eigenvalues of the Kronecker sum $D \oplus E$ are given by all sums of all eigenvalues of D and E.

such that A_{λ_∞} is asymptotically stable, then any $\Pi_0 \in \mathcal{M}$ satisfying $\Pi_0 \lambda_\infty = 0$ and α a sufficiently large positive number provide $\Pi = \alpha\Pi_0 \in \mathcal{M}$ such that the Lyapunov–Metzler inequalities are feasible with respect to the remaining variables $\{P_1, \ldots, P_N\}$.

Example 2. To illustrate the above point, let us consider a simple example with $N = 2$, the pair of matrices

$$A_1 = \begin{bmatrix} 0 & 1 \\ 2 & -9 \end{bmatrix}, \qquad A_2 = \begin{bmatrix} 0 & 1 \\ -2 & 8 \end{bmatrix}, \tag{40}$$

and

$$\Pi_0 = \begin{bmatrix} -0.51 & 0.49 \\ 0.51 & -0.49 \end{bmatrix} \in \mathcal{M}. \tag{41}$$

The eigenvector associated to the null eigenvalue of Π_0 is $\lambda_\infty' = [0.49 \;\; 0.51]$. We have determined numerically that the Lyapunov–Metzler inequalities (28) have a solution of the form $\Pi = \alpha\Pi_0$ for all $\alpha \geq 615.7374$, in accordance to the fact that the invariant zeros of the triple $(\mathcal{A}, \mathcal{B}, \mathcal{C})$ are $-0.33, -0.33, -0.33 \pm j0.226$, which, as discussed before, can alternatively be obtained from the eigenvalues of the asymptotically stable matrix $A_{\lambda_\infty} = 0.49A_1 + 0.51A_2$, taking all sums.

The existence of this particular solution to the inequalities (28) meets exactly the already classical stability condition provided in [16] and more recently in [24] as a particular case of switched nonlinear systems. In our present context, let us assume that there exits $\lambda_\infty \in \Lambda$ such that A_{λ_∞} is asymptotically stable, making possible the determination of $P > 0$ satisfying the Lyapunov inequality $A_{\lambda_\infty}' P + P A_{\lambda_\infty} < 0$. Hence, the switching rule (24) with

$$u(x(t)) = \arg \min_{i=1,\ldots,N} x(t)' \left(A_i' P + P A_i\right) x(t) \tag{42}$$

makes the equilibrium point $x = 0$ of the switched system (1) globally asymptotically stable. Indeed, considering the Lyapunov function $v(x(t)) = x(t)'Px(t)$ we have

$$\begin{aligned} \dot{v}(x(t)) &= x(t)' \left(A_{\sigma(t)}' P + P A_{\sigma(t)}\right) x(t) \\ &= \min_{i=1,\ldots,N} x(t)' \left(A_i' P + P A_i\right) x(t) \\ &= \min_{\lambda \in \Lambda} x(t)' \left(A_\lambda' P + P A_\lambda\right) x(t) \\ &\leq x(t)' \left(A_{\lambda_\infty}' P + P A_{\lambda_\infty}\right) x(t) \\ &< 0. \end{aligned} \tag{43}$$

It is important to keep in mind that if the set of matrices $\{A_1, \ldots, A_N\}$ does not admit A_λ asymptotically stable for some $\lambda \in \Lambda$, then the above stabilizing switching rule cannot be determined. In addition, even if it is known that there exists $\lambda \in \Lambda$ such that A_λ is asymptotically stable, the numerical determination of $\lambda \in \Lambda$ and $P > 0$ such that $A_\lambda' P + P A_\lambda < 0$ is not a simple task due to the nonlinear nature of this inequality. The Lyapunov–Metzler inequalities introduced in Theorem 3 suffer the same difficulty, but fortunately a simple numerical procedure based on line search can be settled to determine its solution. This aspect will be considered next. First, let us introduce a guaranteed quadratic cost associated to the proposed state switching control law (29).

LEMMA 1. *Let $Q \geq 0$ be given. Assume that there exist a set of positive definite matrices $\{P_1, \ldots, P_N\}$ and $\Pi \in \mathcal{M}$ satisfying the Lyapunov–Metzler inequalities*

$$A_i' P_i + P_i A_i + \sum_{j=1}^{N} \pi_{ji} P_j + Q < 0, \qquad i = 1, \ldots, N. \tag{44}$$

The state-switching control (24) *with $u(x(t))$ given by* (29) *makes the equilibrium solution $x = 0$ of* (1) *globally asymptotically stable and*

$$\int_0^\infty x(t)' Q x(t) dt < \min_{i=1,\ldots,N} x_0' P_i x_0. \tag{45}$$

Proof. The proof has the same pattern of the proof of Theorem 3. The Lyapunov function (26) and the Lyapunov–Metzler inequalities (44) yield

$$D^+ v(x(t)) < -x(t)' Q x(t), \tag{46}$$

which after integration gives

$$\begin{aligned} v(x(t)) - v(x(0)) &= \int_0^t D^+ v(x(\tau)) d\tau \\ &< -\int_0^t x(\tau)' Q x(\tau) d\tau \quad \forall t \geq 0, \end{aligned} \tag{47}$$

thus proving the proposed lemma since, due to the asymptotic stability, $v(x(t))$ goes to zero as t goes to infinity. □

The numerical determination, if any, of a solution of the Lyapunov–Metzler inequalities with respect to the variables $(\Pi, \{P_1, \ldots, P_N\})$ is not a simple task and certainly deserves additional attention. The main source of difficulty stems from its nonconvex nature due to the products of variables and so LMI solvers do not apply. Perhaps a point to be further investigated is that its particular structure with π_{ji} being scalars may help with the design of an interactive method based on relaxation.

In this paper we pursue an alternative route. The main idea is to obtain a simpler, although certainly more conservative, stability condition that can be expressed by means of LMIs and thus solvable by the machinery available in the literature to date. The next theorem shows that working with a subclass of Metzler matrices, characterized by having the same diagonal elements, this goal is accomplished.

THEOREM 4. *Let $Q \geq 0$ be given. Assume that there exist a set of positive definite matrices $\{P_1, \ldots, P_N\}$ and a scalar $\gamma > 0$ satisfying the modified Lyapunov–Metzler inequalities*

$$A_i' P_i + P_i A_i + \gamma(P_j - P_i) + Q < 0, \qquad j \neq i = 1, \ldots, N. \tag{48}$$

The state-switching control (24) *with $u(x(t))$ given by* (29) *makes the equilibrium solution $x = 0$ of* (1) *globally asymptotically stable and*

$$\int_0^\infty x(t)' Q x(t) dt < \sum_{i=1}^{N} x_0' P_i x_0. \tag{49}$$

Proof. The proof follows from the choice of $\Pi \in \mathcal{M}$ such that $\pi_{ii} = -\gamma$ and the remaining elements satisfying

$$\gamma^{-1} \sum_{j \neq i = 1}^{N} \pi_{ji} = 1 \tag{50}$$

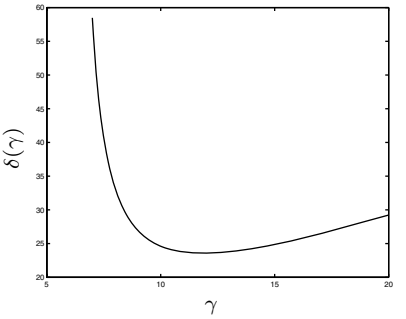

FIG. 3. *Guaranteed cost as a function of* γ.

for all $i = 1, \ldots, N$. Taking into account that $\pi_{ji} \geq 0$ for all $j \neq i = 1, \ldots, N$, multiplying (48) by π_{ji}, summing up for all $j \neq i = 1, \ldots, N$, and finally multiplying the result by $\gamma^{-1} > 0$ we obtain

$$\begin{aligned} A_i' P_i + P_i A_i + Q &< -\sum_{j \neq i = 1}^{N} \pi_{ji}(P_j - P_i) \\ &< -\sum_{j=1}^{N} \pi_{ji} P_j \end{aligned} \tag{51}$$

for all $i = 1, \ldots, N$, which are the Lyapunov–Metzler inequalities (44). From Lemma 1, the upper bound (45) holds, which trivially implies that (49) is verified. The proposed theorem is thus proved. □

The basic theoretical features of Theorem 3 and Lemma 1 are still present in Theorem 4. The most important is that the asymptotic stability of the set of matrices $\{A_1, \ldots, A_N\}$ is still not required. In addition, notice that the guaranteed cost (49) is clearly worse than the one provided by Lemma 1, but the former being convex makes it possible to solve the problem

$$\min_{\gamma > 0, P_1 > 0, \ldots, P_N > 0} \left\{ \sum_{i=1}^{N} x_0' P_i x_0 \ : \ (48) \right\} \tag{52}$$

by using LMI solvers and line search. The next example illustrates some aspects of the theoretical results obtained so far.

Example 3. Consider the system (1) with $N = 2$ and matrices $\{A_1, A_2\}$ given by

$$A_1 = \begin{bmatrix} 0 & 1 \\ 2 & -9 \end{bmatrix}, \qquad A_2 = \begin{bmatrix} 0 & 1 \\ -2 & 2 \end{bmatrix}, \tag{53}$$

which, as it can be easily verified by inspection, are both unstable. Considering $Q = I$ and the initial condition $x_0 = [1 \ 1]'$, problem (52) has been solved by line search fixing γ and minimizing its objective function, denoted by $\delta(\gamma)$, with respect to the remaining variables. Figure 3 shows the behavior of the function $\delta(\gamma)$ which enables us to determine its minimum value $\delta^* = 23.56$, corresponding to $\gamma^* = 11.80$. It is important to stress that, in this particular example, the function $\delta(\gamma)$ has a unique minimum. However, we do not have any evidence that this is a generic property valid

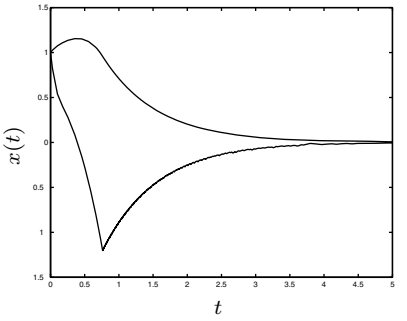

FIG. 4. *Time simulation of the state switching control.*

in all cases. Figure 4 shows the trajectories of the state variable $x(t) \in \mathbb{R}^2$ versus time for the system controlled by the state switching rule $\sigma(t) = u(x(t))$ given by (29) with the positive definite matrices

$$P_1 = \begin{bmatrix} 6.7196 & 1.6293 \\ 1.6293 & 1.0222 \end{bmatrix}, \qquad P_2 = \begin{bmatrix} 6.0825 & 2.1293 \\ 2.1293 & 2.2206 \end{bmatrix} \tag{54}$$

obtained from the optimal solution of problem (52). As it can be seen, the proposed control strategy is very effective in stabilizing the system under consideration.

4. Conclusion. In this paper we have introduced stability conditions for switched linear systems. They have been used for control synthesis of state-independent (open loop) and state-dependent (closed loop) switching rules. In both cases, the determination of a guaranteed cost associated to each control strategy has been addressed. Special attention has been devoted to the numerical solvability of the design problems by means of methods based on linear matrix inequalities.

Two issues deserve more attention. The first is related to the development of numerical algorithms for the solution of the Lyapunov–Metzler inequalities introduced in section 3. The second is the possible generalization of the stability conditions to cope with linear control design and guaranteed quadratic cost. Taking into account the nonlinear nature of the involved stability conditions, this point constitutes a real theoretical challenge.

Acknowledgment. The authors would like to thank the anonymous reviewers for many helpful comments and suggestions that certainly contributed to improve this paper.

GLOBAL SMOOTH SOLUTIONS AND EXPONENTIAL STABILITY FOR A NONLINEAR BEAM*

PENG-FEI YAO† AND GEORGE WEISS‡

Abstract. In this paper we consider a dynamical system with boundary input and output describing the bending vibrations of a quasi-linear beam, where the nonlinearity comes from Hooke's law. First we derive an existence result for short-time solutions of the system of equations. Then we show that the structure of the boundary input and output forces the system to admit global solutions at least when the initial data and the boundary input are small in a certain sense. In particular, we prove that the norm of the state of the system decays exponentially if the input becomes zero after a finite time (the input being zero can be understood as a boundary feedback).

Key words. quasi-linear beam, exponential stabilization, energy-preserving system, boundary input and output

1. Introduction and main results.

We consider a system modeling the bending vibrations of a nonlinear beam of length $L > 0$. Let ϕ denote the deflection of the beam and let M be the bending torque. Assuming unit mass density, from Segel and Handelman [12] we have

$$\phi_{tt} - \kappa\phi''_{tt} + M'' = 0, \quad x \in [0, L], \quad t > 0,$$

where $\kappa > 0$, $\sqrt{\kappa}$ is the radius of gyration, and the superscript "$'$" and the subscript t denote differentiation with respect to the variables x (space) and t (time), respectively. We assume that the constitutive law (Hooke's law) is nonlinear, determined by a smooth function σ, such that $M = \sigma(\phi'')$. The beam equation then becomes

$$\phi_{tt} - \kappa\phi''_{tt} + \sigma(\phi'')'' = 0, \quad x \in [0, L], \quad t > 0. \tag{1.1}$$

If $\sigma(x) = ax$, with $a > 0$, then the model is linear, called the *Rayleigh beam* in the literature. Recent papers dealing with the boundary stabilization of Rayleigh beams are Ammari, Liu, and Tucsnak [2], Guo, Wang, and Yung [7], and Weiss and Curtain [17].

Remark 1.1. We can derive (1.1) also from the calculus of variations. Let $T > 0$ be fixed. We define the *kinetic energy* of the beam at time $t \in [0, T]$ by $\mathbf{K}(\phi_t(\cdot, t))$, where the quadratic functional $\mathbf{K}$ is defined by

$$\mathbf{K}(\psi(\cdot, t)) = \frac{1}{2}\int_0^L \left[\psi^2(x, t) + \kappa\psi'^2(x, t)\right] \mathrm{d}x.$$

The *potential energy* of the beam at time t is defined as

$$\mathbf{P}(\phi(\cdot,t)) = \int_0^L F(\phi''(x,t))\,\mathrm{d}x,$$

where F is a smooth function such that $\frac{\mathrm{d}F(z)}{\mathrm{d}z} = \sigma(z)$. Then it is easy to check that the partial differential equation (1.1) is equivalent to the stationary point condition derived from Hamilton's principle

$$\frac{\mathrm{d}}{\mathrm{d}s}\int_0^T \mathbf{L}(\phi + sv, \phi_t + sv_t)\,\mathrm{d}t\,\Big|_{s=0} = 0 \quad \forall v \in C_0^\infty(Q_T),$$

where $\mathbf{L}(\phi,\psi) = \mathbf{K}(\psi) - \mathbf{P}(\phi)$ and $Q_T = (0,L)\times(0,T)$. Indeed, this follows from

$$\left\langle \frac{\partial \mathbf{L}}{\partial \phi}(\phi,\psi), v \right\rangle = -\langle \sigma(\phi''), v''\rangle, \quad \left\langle \frac{\partial \mathbf{L}}{\partial \psi}(\phi,\psi), v_t \right\rangle = \langle \psi, v_t\rangle + \kappa\langle \psi', v_t'\rangle,$$

where all the inner products are taken in $L^2(Q_T)$.

Suppose that the initial data are given by

$$\phi(x,0) = \phi^0(x), \quad \phi_t(x,0) = \phi^1(x), \quad x \in [0,L]. \tag{1.2}$$

We suppose that the right end of the beam is hinged, i.e.,

$$\phi(L,t) = \phi''(L,t) = 0, \tag{1.3}$$

and at the left end we have actuators and sensors, linked in a damping feedback mechanism, satisfying the equations

$$\begin{cases} 2b_1u_1(t) = \sigma(\phi''(0,t)) - b_1^2\phi_t'(0,t), \quad t \ge 0, \\ 2b_2u_2(t) = \left(\sigma(\phi'')\right)'(0,t) - \kappa\phi_{tt}'(0,t) + b_2^2\phi_t(0,t), \quad t \ge 0, \end{cases} \tag{1.4}$$

$$\begin{cases} 2b_1y_1(t) = \sigma(\phi''(0,t)) + b_1^2\phi_t'(0,t), \quad t \ge 0, \\ 2b_2y_2(t) = \left(\sigma(\phi'')\right)'(0,t) - \kappa\phi_{tt}'(0,t) - b_2^2\phi_t(0,t), \quad t \ge 0, \end{cases} \tag{1.5}$$

where $b_i > 0$ are constants for $i = 1, 2$, $u = (u_1, u_2)$ is the input function, and $y = (y_1, y_2)$ is the output function. The term $2b_1u_1(t)$ is an external torque acting at the left end of the beam, while $2b_2u_2(t)$ is an external transversal force acting at the same end. The term $\sigma(\phi''(0,t))$ is the total torque acting at $x = 0$, while $(\sigma(\phi''))'(0,t) - \kappa\phi_{tt}'(0,t)$ is the total transversal force at $x = 0$. The terms $-b_1^2\phi_t'(0,t)$ and $b_2^2\phi_t(0,t)$ represent the boundary feedback torque and force, respectively.

To guarantee that the system (1.1)–(1.5) is hyperbolic, we further assume that

$$\sigma(0) = 0, \quad \sigma'(z) > 0, \quad z \in (-\infty, \infty). \tag{1.6}$$

If we define the *total energy* of the system (1.1)–(1.5) by

$$\mathbf{E}(t) = \mathbf{K}(\phi_t(\cdot,t)) + \mathbf{P}(\phi(\cdot,t)),$$

where $\mathbf{K}$ and $\mathbf{P}$ are defined as in Remark 1.1, we obtain by a simple computation

$$\begin{aligned} \frac{\mathrm{d}\mathbf{E}(t)}{\mathrm{d}t} &= -\sigma(\phi''(0,t))\phi_t'(0,t) + [\sigma(\phi'')'(0,t) - \kappa\phi_{tt}'(0,t)]\phi_t(0,t) \\ &= |u(t)|^2 - |y(t)|^2. \end{aligned} \tag{1.7}$$

This formula expresses that the rate of change of the energy is equal to the power supplied to the system by the input minus the power taken out by the output. The balance equation (1.7) means that the system (1.1)–(1.5) is (scattering) *energy-preserving*. We refer to Staffans [14] and to Malinen, Staffans, and Weiss [11] for the theory of energy-preserving linear systems.

We define the positive smooth function $\mathcal{N} : (\sigma_-, \sigma_+) \to (0, \infty)$ by

$$\mathcal{N}(z) = \sigma'(\sigma^{-1}(z)), \tag{1.8}$$

where σ^{-1} is the inverse function of σ and

$$\sigma_\pm = \lim_{z \to \pm\infty} \sigma(z). \tag{1.9}$$

By the assumption (1.6), the above limits exist (they may be infinite) and

$$0 \in (\sigma_-, \sigma_+), \quad \lim_{z \to \sigma_\pm} \sigma^{-1}(z) = \pm\infty. \tag{1.10}$$

In the linear case ($\sigma(z) = az$) we have $\mathcal{N}(z) = a$, of course.

We introduce an equivalent system by the change of unknowns

$$\varphi = \sigma(\phi''), \quad \psi = \phi_t.$$

Then the system (1.1)–(1.5) becomes

$$\begin{cases} \varphi_t = \mathcal{N}(\varphi)\psi'', \\ \psi_t = \kappa\psi_t'' - \varphi'', \\ \varphi(x,0) = \varphi_0(x), \quad \psi(x,0) = \psi_0(x), \\ \varphi(L,t) = \psi(L,t) = \psi''(L,t) = 0, \end{cases} \tag{1.11}$$

with the input signal $u = (u_1, u_2)$ acting through

$$\begin{cases} 2b_1 u_1(t) = \varphi(0,t) - b_1^2\psi'(0,t), \\ 2b_2 u_2(t) = \varphi'(0,t) - \kappa\psi_t'(0,t) + b_2^2\psi(0,t), \end{cases} \tag{1.12}$$

and with the output signal $y = (y_1, y_2)$ defined by

$$\begin{cases} 2b_1 y_1(t) = \varphi(0,t) + b_1^2\psi'(0,t), \\ 2b_2 y_2(t) = \varphi'(0,t) - \kappa\psi_t'(0,t) - b_2^2\psi(0,t). \end{cases} \tag{1.13}$$

The initial functions of this new system are obtained from those in (1.2) by

$$\varphi_0 = \sigma(\phi^{0\prime\prime}), \qquad \psi_0 = \phi^1.$$

It is well known that smooth solutions of quasi-linear hyperbolic systems usually develop singularities after some time; see, for example, Klainerman and Majda [10]. However, since the structure of the boundary conditions (1.12) causes energy dissipation (as seen in (1.7)), we expect that the introduction of the boundary input (1.12) prevents the formation of singularities and assures the existence of a global smooth solution. In fact, such problems have been considered for the nonlinear string in Greenberg and Li [6], Slemrod [13], Alber and Cooper [1], and Yao [18].

The main aim of this paper is to study the existence of smooth short-time solutions and smooth global solutions of the nonlinear beam system (1.11)–(1.12) if the initial data φ_0, ψ_0 and the boundary input u are given. For short-time solutions, we use the results of Kato [8] to establish the existence of solutions of a certain linear system and then use an argument with contraction mappings from Dafermos and Hrusa [4] to obtain the existence. Due to the special structure of (1.12), some modifications are necessary in the energy estimates which are used in the fixed-point argument. For global solutions, we establish an estimate for the boundary trace by invoking some ideas from Alber and Cooper [1] and from Cirina [3]. Such an estimate is necessary for the global existence. In the linear case (where $\sigma(x) = ax$), boundary trace estimates are usually derived by the multiplier technique.

We mention that in the linear case our system fits into the framework of Weiss and Tucsnak [16] and [15], which guarantees that the system is well-posed and conservative (this property is stronger than "energy-preserving").

If $b_2 = 0$, the system (1.11)–(1.13) can be transformed into a quasi-linear string with an input-output structure at the boundary that has been studied in [18] (see Remark 4.2). Here we study only the case $b_2 > 0$.

Motivated by the structure of the function $\mathcal{N}$, we introduce the following concept. We say that a continuous function φ on $[0, L]$ satisfies the *σ-condition* if

$$\sigma_- < \inf_{x\in[0,L]} \varphi(x) \le \sup_{x\in[0,L]} \varphi(x) < \sigma_+, \tag{1.14}$$

where σ_-, σ_+ are as in (1.9). If $\sigma_\pm = \pm\infty$, then this condition is trivially true.

For short-time solutions, we have the following existence result.

THEOREM 1.1. *Suppose that $u = (u_1, u_2) \in C^3[0,\infty) \times C^2[0,\infty)$ and $(\varphi_0, \psi_0) \in H^2(0, L) \times H^3(0, L)$ satisfies the boundary conditions*

$$\varphi_0(L) = \psi_0(L) = \psi_0''(L) = 0 \tag{1.15}$$

and the compatibility conditions

$$\begin{cases} 2b_1u_1(0) = \varphi_0(0) - b_1^2\psi_0'(0), \\ 2b_2u_2(0) = 2b_1^{-1}\kappa u_{1t}(0) + \varphi_0'(0) - \kappa b_1^{-2}\mathcal{N}(\varphi_0(0))\psi_0''(0) + b_2^2\psi_0(0). \end{cases} \tag{1.16}$$

Furthermore, we assume that φ_0 satisfies the σ-condition (1.14).

Then there is a $T_0 > 0$ such that the problem (1.11)–(1.12) *admits a unique solution (φ, ψ) on $Q_{T_0} = (0, L) \times (0, T_0)$ satisfying*

$$\varphi \in \bigcap_{i=0}^{2} C^i\left([0, T_0]; H^{2-i}(0, L)\right), \quad \psi \in \bigcap_{i=0}^{3} C^i\left([0, T_0)]; H^{3-i}(0, L)\right), \tag{1.17}$$

where $H^0(0, L)$ stands for $L^2(0, L)$.

The proof of this theorem is given in section 3.

When the input u and the initial data (φ_0, ψ_0) are appropriately small, the solutions are global. To describe this, we introduce an energy-like function $\mathcal{E}$ as follows. Let (φ, ψ) be a solution of the system (1.11)–(1.12). For any multi-index $\alpha = (\alpha_1, \alpha_2) \in \{0, 1, 2, \dots\}^2$, we denote $|\alpha| = \alpha_1 + \alpha_2$. Define

$$\mathcal{E}(t) = [\varphi'(0, t)]^2 + \|\psi_{tt}'(\cdot, t)\|^2 + \sum_{|\alpha|\le 2} (\|\partial^\alpha\varphi(\cdot, t)\|^2 + \|\partial^\alpha\psi(\cdot, t)\|^2), \tag{1.18}$$

where $\partial^{(\alpha_1,\alpha_2)} = \left(\frac{\partial}{\partial x}\right)^{\alpha_1}\left(\frac{\partial}{\partial t}\right)^{\alpha_2}$ and $\|\cdot\|$ is the usual norm on $L^2(0, L)$.

For $u = (u_1, u_2) \in [H^2(0,T)]^2$, denote

$$\|u\|^2_{H^2(0,T)} = \int_0^T |u|_2^2(t)\,\mathrm{d}t, \qquad |u|_2^2(t) = |u(t)|^2 + |u_t(t)|^2 + |u_{tt}(t)|^2. \tag{1.19}$$

THEOREM 1.2. *Suppose that $u = (u_1, u_2) \in H^2(0,\infty) \times H^2(0,\infty)$ and the initial data $(\varphi_0, \psi_0) \in H^2(0,L) \times H^3(0,L)$ are such that the boundary conditions* (1.15) *and the compatibility conditions* (1.16) *hold. Then there are $\epsilon > 0$, $c_1 > 0$, $c_2 > 0$, $c_3 > 0$, independent of (φ_0, ψ_0) and u, such that if*

$$\mathcal{E}(0) + \|u\|^2_{H^2(0,\infty)} \le \epsilon, \tag{1.20}$$

then the problem (1.11)–(1.12) *has a unique solution (φ, ψ) on $Q_\infty = (0,L) \times (0,\infty)$ and*

$$\mathcal{E}(t) + c_1 \int_0^t \mathcal{E}(\tau)\mathrm{d}\tau \le c_2\mathcal{E}(0) + c_3\|u\|^2_{H^2(0,\infty)} \quad \forall\ t \ge 0. \tag{1.21}$$

Note that from (φ_0, ψ_0) we can compute $\partial^\alpha\varphi(\cdot,0)$ and $\partial^\alpha\psi(\cdot,0)$ by solving (1.11) at $t = 0$, so that also $\mathcal{E}(0)$ can be computed.

The above theorem will be proved in section 5.

COROLLARY 1.1. *Under the assumptions of Theorem* 1.2, *if* (1.20) *holds, then the solution (φ, ψ) of* (1.11)–(1.12) *and the output $y = (y_1, y_2)$ from* (1.13) *satisfy*

$$\varphi \in H^2(Q_\infty), \quad \psi \in H^2(Q_\infty) \cap H^{1,2}(Q_\infty), \quad y \in H^2(0,\infty) \times H^2(0,\infty), \tag{1.22}$$

where $H^{1,2}(Q_\infty)$ is the Sobolev space with the norm

$$\|\psi\|^2_{H^{1,2}(Q_\infty)} = \sum_{0\le i\le 1;\, 0\le j\le 2} \int_0^\infty \|\partial^{(i,j)}\psi(\cdot,t)\|^2\mathrm{d}t.$$

The following stability result will also be proved in section 5.

THEOREM 1.3. *Under the assumptions of Theorem* 1.2, *suppose that (φ_0, ψ_0) with u satisfy* (1.20). *If there is a $T_0 > 0$ such that*

$$u(t) = 0 \quad \forall\ t \ge T_0, \tag{1.23}$$

then there are $C > 0$ and $\epsilon_1 > 0$ such that

$$\mathcal{E}(t) \le Ce^{-\epsilon_1 t} \quad \forall t \ge 0. \tag{1.24}$$

This theorem shows that the energy-like function $\mathcal{E}(t)$ for the boundary feedback system corresponding to $u = 0$ decays exponentially.

Remark 1.2. We do not assume that φ_0 satisfies the σ-condition in Theorems 1.2, 1.3 and in Corollary 1.1, because for suitable ε, the small initial data assumption (1.20) implies this. Indeed,

$$\sup_{x\in[0,L]} |\varphi_0(x)| \le L^{\frac{1}{2}}\mathcal{E}^{\frac{1}{2}}(0) \le L^{\frac{1}{2}}\varepsilon^{\frac{1}{2}}.$$

Then the σ-condition is true if $0 < \varepsilon < L^{-1}\min\{\sigma_-^2, \sigma_+^2\}$.

2. Linear time-varying equations. Let $T > 0$ and let N be a function on $Q_T = (0, L) \times (0, T)$ such that

$$N \in \bigcap_{i=0}^{2} C^i\left([0, T]; H^{2-i}(0, L)\right)$$

and there are $N_0 > 0$, $N_1 > 0$ such that

$$N_0 \le N(x, t) \le N_1, \quad (x, t) \in Q_T. \tag{2.1}$$

Motivated by (1.11)–(1.12), we consider the linear dynamical system described by

$$\begin{cases} \varphi_t = N\psi'', \\ \psi_t = \kappa\psi_t'' - \varphi'', \\ \varphi(x, 0) = \varphi_0(x), \qquad \psi(x, 0) = \psi_0(x), \\ \varphi(L, t) = \psi(L, t) = \psi''(L, t) = 0, \\ 2b_1u_1(t) = \varphi(0, t) - b_1^2\psi'(0, t), \\ 2b_2u_2(t) = \varphi'(0, t) - \kappa\psi_t'(0, t) + b_2^2\psi(0, t). \end{cases} \tag{2.2}$$

We make a change of unknowns by

$$v = \varphi, \quad w = \psi + g \quad \text{on} \quad Q_T, \tag{2.3}$$

where g is a smooth function on Q_T satisfying the boundary conditions

$$g(L, t) = 0, \quad b_1g'(0, t) = 2u_1(t), \quad t \in [0, T]. \tag{2.4}$$

We shall specify later how to choose g in order to satisfy additional requirements. By (2.3)–(2.4), the system (2.2) becomes, for $(x, t) \in Q_T$,

$$\begin{cases} v_t - Nw'' = -Ng'', \\ w_t - \kappa w_t'' + v'' = g_t - \kappa g_t'', \\ v(x, 0) = \varphi_0(x), \quad w(x, 0) = \psi_0(x) + g(x, 0), \\ v(L, t) = w(L, t), \qquad w''(L, t) = g''(L, t), \\ v(0, t) - b_1^2w'(0, t) = 0, \\ v'(0, t) - \kappa w_t'(0, t) + b_2^2w(0, t) = 2b_2u_2(t) + b_2^2g(0, t) - \kappa g_t'(0, t). \end{cases} \tag{2.5}$$

Let us formulate the problem (2.5) in an appropriate Hilbert space. First we introduce the following space:

$$H = \{f \mid f \in H^1(0, L),\ f(L) = 0\}, \quad \langle f, p\rangle_H = \langle f, p\rangle + \kappa\langle f', p'\rangle,$$

where $\langle\cdot, \cdot\rangle$ is the usual inner product of $L^2(0, L)$. To rewrite the second equation in (2.5), we introduce an operator B_0: $L^2(0, L) \to H$ by

$$\langle p, f'\rangle = \langle B_0p, f\rangle_H \quad \forall\ p \in L^2(0, L),\ f \in H. \tag{2.6}$$

LEMMA 2.1. *The operator B_0 from* (2.6) *is an isomorphism between $L^2(0, L)$ and H. In addition, for every $p \in L^2(0, L)$,*

$$(B_0p)(x) = \langle p, q_0\rangle \cosh\sqrt{a}x + a\int_0^x p(s)\cosh\sqrt{a}(x - s)\mathrm{d}\,s, \tag{2.7}$$

where

$$a = \frac{1}{\kappa}, \quad q_0(x) = -\frac{a\cosh\sqrt{a}(L-x)}{\cosh\sqrt{a}L}. \tag{2.8}$$

In particular, $\frac{\partial}{\partial x}B_0$ *is bounded from* $L^2(0,L)$ *to itself, and for* $p \in L^2(0,L)$

$$\left(\frac{\partial}{\partial x}B_0 p\right)(x) = \sqrt{a}\langle p, q_0\rangle \sinh\sqrt{a}x + a^{\frac{3}{2}}\int_0^x p(s)\sinh\sqrt{a}(x-s)\mathrm{d}s + ap(x). \tag{2.9}$$

Proof. First, we assume that $p \in H^1(0,L)$. Denote $y = B_0 p$. From (2.6), integration by parts gives the problem

$$y - \kappa y'' = -p', \quad y'(0) = ap(0), \quad y(L) = 0.$$

Solving this problem, we obtain (2.7) with (2.8). Since $H^1(0,L)$ is dense in $L^2(0,L)$, (2.7) is actually true for all $p \in L^2(0,L)$. Differentiating (2.7) we obtain (2.9).

It is easy to check that B_0 is invertible and that B_0^{-1}: $H \to L^2(0,L)$ is given by

$$\left(B_0^{-1}f\right)(x) = \kappa f'(x) - \int_0^x f(s)\mathrm{d}s \quad \forall\ f \in H. \qquad \square$$

Let (v, w) be a smooth solution of the system (2.5). We multiply the second equation in (2.5) by a function $f \in H$ and integrate over $[0,L]$. Using integration by parts and (2.6) we obtain that for all $f \in H$,

$$\langle w_t, f\rangle_H = \langle B_0 v' + g_t, f\rangle_H + \left[v'(0,t)(t) - \kappa w_t'(0,t) + \kappa g_t'(0,t)\right] f(0).$$

Using the last equation in (2.5), this becomes

$$\langle w_t, f\rangle_H = \langle B_0 v' + g_t, f\rangle_H + \left[2b_2u_2(t) - b_2^2 w(0,t) + b_2^2 g(0,t)\right] f(0). \tag{2.10}$$

Let $q_1 \in H$ be such that

$$f(0) = \langle q_1, f\rangle_H \quad \forall\ f \in H. \tag{2.11}$$

It follows from (2.10) and (2.11) that

$$w_t = B_0 v' - b_2^2 w(0,t)q_1 + g_t + [2b_2u_2(t) + b_2^2 g(0,t)]q_1 \quad \text{in} \quad H.$$

Now the problem (2.5) becomes a problem on $L^2(0,L)\times H$:

$$\begin{cases} v_t = Nw'' - Ng'', \\ w_t = B_0 v' - b_2^2 w(0,t)q_1 + g_t + [2b_2u_2(t) + b_2^2 g(0,t)]q_1, \\ v(x,0) = \varphi_0(x), \quad w(x,0) = \psi_0(x) + g(x,0), \\ v(L,t) = w(L,t) = 0, \quad v(0,t) = b_1^2 w'(0,t). \end{cases} \tag{2.12}$$

We wish to solve (2.12) by applying the results of Kato [8, 9] in the space $\mathcal{H} = L^2(0,L)\times H$, with the inner product

$$\left\langle \begin{bmatrix} p \\ f \end{bmatrix}, \begin{bmatrix} \hat{p} \\ \hat{f} \end{bmatrix} \right\rangle_{\mathcal{H}} = \langle p, \hat{p}\rangle + \langle f, \hat{f}\rangle_H \quad \forall\ \begin{bmatrix} p \\ f \end{bmatrix}, \begin{bmatrix} \hat{p} \\ \hat{f} \end{bmatrix} \in \mathcal{H}.$$

To this end, we introduce a family of closed operators on $\mathcal{H}$ by

$$\mathcal{A}_0(t) = \begin{bmatrix} 0 & N\partial^2 \\ B_0\partial & -b_2^2 q_1 \Gamma_0 \end{bmatrix}, \quad 0 \le t \le T, \tag{2.13}$$

where $\partial = \frac{\partial}{\partial x}$, the linear functional Γ_0 is given by

$$\Gamma_0 f = f(0) \quad \forall\, f \in H,$$

and the domain of $\mathcal{A}_0(t)$ is

$$D(\mathcal{A}_0(t)) = \left\{ \begin{bmatrix} p \\ f \end{bmatrix} \in H^1(0,L) \times H^2(0,L) \;\middle|\; \begin{matrix} p(L) = f(L) = 0, \\ p(0) = b_1^2 f'(0) \end{matrix} \right\}. \tag{2.14}$$

Then the problem (2.12) can be written as an evolution equation on $\mathcal{H}$:

$$X_t(t) = \mathcal{A}_0(t)X(t) + \mathcal{F}_0(t), \quad X(0) = X_0, \tag{2.15}$$

with

$$X = \begin{bmatrix} v \\ w \end{bmatrix}, \quad \mathcal{F}_0(t) = \begin{bmatrix} -Ng'' \\ g_t + [2b_2u_2(t) + b_2^2 g(0,t)]q_1 \end{bmatrix}. \tag{2.16}$$

More precisely, the connection between (2.12) and (2.15) is as follows: Let

$$\mathcal{H}_1 = D(\mathcal{A}_0(t)), \tag{2.17}$$

which is a Hilbert space with the graph norm. This space is independent of t and for different t we get on it equivalent norms.

LEMMA 2.2. *If $X(\cdot) \in C^1([0,l];\mathcal{H}_1)$ is a solution of* (2.15)*, then its components (v,w) are a solution of* (2.12).

The proof of this lemma is by simple verification.

Note that $X(\cdot) \in C^1([0,T];\mathcal{H}_1)$ implies $X(t) \in H^1(0,L) \times H^3(0,L)$ for all $t \in [0,T]$. For less regular solutions of (2.15), some of the equations in (2.12) become meaningless. For example, if we only have $X(\cdot) \in C([0,T];\mathcal{H}_1)$, which is still rather smooth, then the last equation in (2.12) becomes meaningless.

Since the domain $D(\mathcal{A}_0(t))$ is independent of t (see (2.14)), the key of applying the work of Kato to our problem (2.15) is to show that $\{\,\mathcal{A}_0(t)\,|\,0 \le t \le T\,\}$ is a stable family on $\mathcal{H}$, in the sense of [8]. We recall that $\{\,\mathcal{A}_0(t)\,|\,0 \le t \le T\,\}$ is called a *stable family* if the following conditions hold:

(1) For each $t \in [0,T]$, $\mathcal{A}_0(t)$ is the generator of a C_0-semigroup.

(2) There are constants M, β (called the constants of stability) such that

$$\left\| \prod_{j=1}^{k} (\lambda - \mathcal{A}_0(t_j))^{-1} \right\| \le M(\lambda - \beta)^{-k}, \quad \lambda > \beta,$$

for any finite family $\{t_j\}$ with $0 \le t_1 \le \cdots \le t_k \le T$, $k \in \mathbb{N}$. Here, the product Π is time-ordered; i.e., a factor with larger t_j stands to the left of one with smaller t_j.

LEMMA 2.3. *Let $\mathcal{A}_0(t)$ be defined in* (2.13) *and* (2.14)*. For each t, $0 \le t \le T$, $\mathcal{A}_0(t)$ generates a C_0-semigroup on $\mathcal{H}$.*

Proof. For $t \in [0,T]$ we introduce a family of new inner products $\langle \cdot, \cdot \rangle_t$ on $\mathcal{H}$ which are equivalent to the old one, to show that $\mathcal{A}_0(t)$ is dissipative on $\mathcal{H}$:

$$\left\langle \begin{bmatrix} p \\ f \end{bmatrix}, \begin{bmatrix} \hat{p} \\ \hat{f} \end{bmatrix} \right\rangle_t = \langle N^{-1}(\cdot,t)p, \hat{p} \rangle + \langle f, \hat{f} \rangle_H \quad \forall \begin{bmatrix} p \\ f \end{bmatrix}, \begin{bmatrix} \hat{p} \\ \hat{f} \end{bmatrix} \in \mathcal{H}. \tag{2.18}$$

Since N satisfies (2.1), these new norms are equivalent to the old one.

Let $\left[\begin{smallmatrix} p \\ f \end{smallmatrix}\right] \in D(\mathcal{A}_0(t))$. It follows from (2.13), (2.14), and (2.18) that

$$\begin{aligned} \left\langle \mathcal{A}_0(t) \begin{bmatrix} p \\ f \end{bmatrix}, \begin{bmatrix} p \\ f \end{bmatrix} \right\rangle_t &= \left\langle \begin{bmatrix} Nf'' \\ B_0 p' - b_2^2 f(0) q_1 \end{bmatrix}, \begin{bmatrix} p \\ f \end{bmatrix} \right\rangle_t \\ &= \langle f'', p \rangle + \langle p', f' \rangle - b_2^2 f^2(0) = p f'|_0^L - b_2^2 f^2(0) \\ &= -b_1^2 f'^2(0) - b_2^2 f^2(0) \le 0. \end{aligned}$$

We want to show that $\mathcal{A}_0(t)$ is m-dissipative. For this, it is enough to show that also $\mathcal{A}_0^*(t)$ is dissipative, where $\mathcal{A}_0^*(t)$ is the adjoint operator of $\mathcal{A}_0(t)$ with respect to the inner product $\langle \cdot, \cdot \rangle_t$. A simple computation shows that

$$\mathcal{A}_0^*(t) = -\begin{bmatrix} 0 & N\partial^2 \\ B_0 \partial & b_2^2 q_1 \Gamma_0 \end{bmatrix},$$

$$D(\mathcal{A}_0^*(t)) = \left\{ \begin{bmatrix} p \\ f \end{bmatrix} \in H^1(0,L) \times H^2(0,L) \;\middle|\; \begin{array}{l} p(L) = f(L) = 0, \\ p(0) = -b_1^2 f'(0) \end{array} \right\}$$

and for all $\left[\begin{smallmatrix} p \\ f \end{smallmatrix}\right] \in D(\mathcal{A}_0^*(t))$,

$$\left\langle \mathcal{A}_0^*(t) \begin{bmatrix} p \\ f \end{bmatrix}, \begin{bmatrix} p \\ f \end{bmatrix} \right\rangle_t = -b_1^2 f'^2(0) - b_2^2 f^2(0) \le 0.$$

Thus, $\mathcal{A}_0(t)$ is m-dissipative. According to the Lumer–Phillips theorem, $\mathcal{A}_0(t)$ is the generator of a contraction semigroup on $\mathcal{H}$ (with respect to $\langle \cdot, \cdot \rangle_t$). ∎

LEMMA 2.4. *For any $t \in [0,T]$, $\{ \mathcal{A}_0(\tau) \,|\, 0 \le \tau \le T \}$ is a stable family with respect to the norm $\| \cdot \|_t$ (which corresponds to the inner product* (2.18)*) on $\mathcal{H}$.*

Proof. In view of Proposition 3.4 in [8] and Lemma 2.3 above, it suffices to verify that there exists $c > 0$ such that the following inequality holds:

$$\|\mathcal{X}\|_t / \|\mathcal{X}\|_s \le e^{c|t-s|} \qquad \forall\, \mathcal{X} = \begin{bmatrix} p \\ f \end{bmatrix} \in \mathcal{H},\ s,t \in [0,T]. \tag{2.19}$$

To this end, we take

$$c \ge \sup_{(x,t) \in Q_T} |N_t| N^{-1}$$

and set

$$h(t) = \left\| \begin{bmatrix} p \\ f \end{bmatrix} \right\|_t^2 = \langle N^{-1}(\cdot,t)p, p \rangle + \|f\|_H^2, \quad t \in [0,T].$$

Then

$$|h_t(t)| \le 2ch(t) \qquad \forall \begin{bmatrix} p \\ f \end{bmatrix} \in \mathcal{H}, \quad t \in [0,T].$$

This inequality implies that the function $h(t)e^{-2ct}$ is decreasing while $h(t)e^{2ct}$ is increasing for $t \in [0,T]$. Therefore, (2.19) is true. ∎

In order to have a solution $X(\cdot) \in C([0,T];\mathcal{H}_1)$ to the inhomogeneous system (2.15), it will suffice to choose $X_0 \in \mathcal{H}_1$ and a function g such that the inhomogeneous term $\mathcal{F}_0(\cdot) \in C([0,T];\mathcal{H}_1)$. For this, we consider the 3×3 matrix $\mathcal{B}$ defined by

$$\mathcal{B} = (e_2, e_3, e_1),$$

where (e_1, e_2, e_3) is the standard basis of the Euclidian space $\mathbb{R}^3$, and we take a function $\rho \in C^\infty[0,L]$ such that

$$\rho(x) = 1 \ \text{ for } \ x \le L/3, \qquad \rho(x) = 0 \ \text{ for } \ x \ge 2L/3. \tag{2.20}$$

LEMMA 2.5. *Assume that $u = (u_1, u_2) \in C^2[0,T] \times C^1[0,T]$. Using the notation $\mathcal{B}$ and ρ introduced above, there exists a function g of the form*

$$g(x,t) = \rho(x)\beta(t)\cdot e^{\mathcal{B}x}e_1, \quad (x,t) \in Q_T, \tag{2.21}$$

where $\beta(t) = [\beta_1(t)\ \beta_2(t)\ \beta_3(t)]$, such that g satisfies (2.4) *and $\mathcal{F}_0(\cdot) \in C([0,T];\mathcal{H}_1)$, where $\mathcal{F}_0(t)$ is given in* (2.16).

Proof. It follows from (2.20)–(2.21) that

$$\begin{cases} g(L,t) = g''(L,t) = 0, \\ g(0,t) = \beta_1(t), \quad g'(0,t) = \beta_2(t), \quad g''(0,t) = \beta_3(t). \end{cases}$$

On the other hand, from (2.14) and (2.16) we see that the conditions (2.4) and $\mathcal{F}_0(t) \in D(\mathcal{A}_0(t))$ for $t \in [0,T]$ will be satisfied if

$$\begin{cases} g(L,t) = g''(L,t) = 0, \qquad b_1 g'(0,t) = 2u_1(t), \\ N(0,t)g''(0,t) + q_1'(0)b_1^2 b_2^2 g(0,t) = -2b_1 u_{1t}(t) - 2q_1'(0)b_1^2 b_2 u_2(t). \end{cases}$$

This can be achieved if we set

$$\begin{cases} \beta_1(t) = 0, \qquad \beta_2(t) = 2b_1^{-1}u_1(t), \\ \beta_3(t) = -2b_1 N^{-1}(0,t)[u_{1t}(t) + q_1'(0)b_1 b_2 u_2(t)], \end{cases}$$

and moreover we then have $\mathcal{F}_0(\cdot) \in C([0,T];\mathcal{H}_1)$. ∎

Since $D(\mathcal{A}_0(t))$ is constant, by Theorem 7.1 of [8] (see also Remark 6.2 of the same paper), for any $X_0 \in \mathcal{H}_1$ and for $\mathcal{F}_0$ as in the last lemma, the problem (2.15) admits a unique solution $X(\cdot) \in C([0,T];\mathcal{H}_1)$. However, from here we cannot go back to the problem (2.2) through the change of unknowns (2.3), because the functions do not have enough somoothness to make sense of the boundary conditions.

For our purposes in this paper, we need the problem (2.2) to have solutions (φ, ψ) such that $\varphi \in C\big([0,T];H^2(0,L)\big)$ and $\psi \in C\big([0,T];H^3(0,L)\big)$. For this, we consider an evolutionary problem, like (2.15), on the space $(\mathcal{H}_1, \|\cdot\|_1)$ where $\mathcal{A}_0(t) : D(\mathcal{A}_0^2(t)) \to \mathcal{H}_1$ and $\mathcal{H}_1 = D(\mathcal{A}_0(t))$ with the graph norm. Using Lemma 2.1, a simple computation shows that $D(\mathcal{A}_0^2(t))$ consists of all the pairs $(v,w) \in H^2(0,L)\times H^3(0,L)$ satisfying the boundary conditions

$$v(L) = w(L) = w''(L) = 0, \quad v(0) = b_1^2 w'(0),$$

$$N(0,t)w''(0) = ab_1^2 v'(0) + ab_1^2 b_2^2 w(0).$$

The last boundary condition shows that $D(\mathcal{A}_0^2(t))$ depends on the time t. Thus, we would meet difficulty in verifying the assumptions of [8], [9], although the work of Kato does not assume that the domain is independent of time t.

We overcome the above difficulty as follows. Suppose that we have a solution X of the problem (2.15) such that

$$X(\cdot) \in C\left([0,T]; D(\mathcal{A}_0^2(t))\right). \tag{2.22}$$

After making a change of unknowns by

$$Y(t) = \mathcal{C}(t)X(t), \quad \mathcal{C}(t) = \lambda I - \mathcal{A}_0(t),$$

where λ is large enough, we observe that $Y(\cdot) \in C\left([0,T]; \mathcal{H}_1\right)$ satisfies

$$Y_t(t) = [\mathcal{A}_0(t) + \mathcal{C}_t(t)\mathcal{C}^{-1}(t)]Y(t) + \mathcal{C}(t)\mathcal{F}_0(t), \quad Y(0) = \mathcal{C}(0)X_0 \in \mathcal{H}_1. \tag{2.23}$$

Since the above argument is reversible, in order to obtain a solution to the problem (2.15) to satisfy (2.22), we need only solve the problem (2.23) in the space $\mathcal{H}$. This is achieved by the following two lemmas.

LEMMA 2.6. *For $t \in [0,T]$, $\mathcal{C}_t(t)\mathcal{C}^{-1}(t)$ is bounded from $\mathcal{H}$ to $\mathcal{H}$. Furthermore, for any $X \in \mathcal{H}$, $\mathcal{C}_t(\cdot)\mathcal{C}^{-1}(\cdot)X \in C([0,T];\mathcal{H})$.*

Proof. From the formula (2.13), we have

$$\mathcal{C}_t(t) = \begin{bmatrix} 0 & -N_t\partial^2 \\ 0 & 0 \end{bmatrix}. \tag{2.24}$$

Thus, if $X = \left[\begin{smallmatrix} v \\ w \end{smallmatrix}\right] \in D(\mathcal{A}_0(t))$, then (recalling the operators B_0 and Γ_0 introduced earlier in this section) we have that for all $t \in [0,T]$,

$$\begin{aligned} \|C_t(t)X\|_{\mathcal{H}}^2 &= \|N_t w''\|^2 \le c\|Nw''\|^2 \\ &\le c\left(\|Nw''\|^2 + \|B_0 v' - b_2^2\Gamma_0(w)q_1\|_H^2\right) = c\|\mathcal{A}_0(t)X\|_{\mathcal{H}}^2. \end{aligned} \tag{2.25}$$

Here, $c = \sup_{(x,t)\in Q_T} N_t^2 N^{-2}$, and the norm $\|\cdot\|_{\mathcal{H}}$ corresponds to the inner product defined before (2.13). Lemma 2.6 follows from (2.24) and (2.25). ∎

An argument similar to that for Lemma 2.5 yields the following lemma.

LEMMA 2.7. *Assume that $u = (u_1, u_2) \in C^2[0,T] \times C^1[0,T]$. There is a function g on Q_T that satisfies the conditions* (2.4) *such that*

$$\mathcal{C}(\cdot)\mathcal{F}_0(\cdot) \in C([0,T], \mathcal{H}_1),$$

where $\mathcal{F}_0(t)$ is defined in (2.16).

After we apply [8] to the problem (2.23) and go back all the way to the problem (2.2), we actually obtain the following theorem.

THEOREM 2.1. *Suppose that $T > 0$ and $u = (u_1, u_2) \in C^3[0,T] \times C^2[0,T]$. Assume that $(\varphi_0, \psi_0) \in H^2(0,L) \times H^3(0,L)$ satisfies the boundary conditions*

$$\varphi_0(L) = \psi_0(L) = \psi_0''(L) = 0$$

and the compatibility conditions

$$\begin{cases} 2b_1 u_1(0) = \varphi_0(0) - b_1^2\psi_0'(0), \\ 2b_2 u_2(0) = 2\kappa b_1^{-1} u_{1t}(0) + \varphi_0'(0) - \kappa b_1^{-2} N(0,0)\psi_0''(0) + b_2^2\psi_0(0). \end{cases} \tag{2.26}$$

Then the problem (2.2) *admits a unique solution* (φ, ψ) *satisfying*

$$\varphi \in \bigcap_{i=0}^{2} C^i\left([0,T]; H^{2-i}(0,L)\right), \quad \psi \in \bigcap_{i=0}^{3} C^i\left([0,T]; H^{3-i}(0,L)\right).$$

Remark 2.1. For an integer $k \geq 2$ the method for Theorem 2.1 can be used to find solutions to the problem (2.2) such that

$$\varphi \in \bigcap_{i=0}^{k} C^i\left([0,T]; H^{k-i}(0,L)\right), \quad \psi \in \bigcap_{i=0}^{k+1} C^i\left([0,T]; H^{k-i}(0,L)\right),$$

where, of course, more boundary conditions and more compatibility conditions for the initial data and the input function are needed.

3. Quasi-linear equations. In this section we use Theorem 2.1 and a fixed-point argument to establish the existence of solutions of the quasi-linear problem (1.11)–(1.12). To this end, we need to establish some energy estimates of the solutions to the linear problem (2.2), which is also useful when we derive the global solutions later.

Let $T > 0$ and $u = (u_1, u_2) \in C^3(0,T) \times C^2(0,T)$. Suppose that $(\varphi_0, \psi_0) \in H^2(0,L) \times H^3(0,L)$ satisfies the boundary conditions (1.15) and the compatibility conditions (1.16), and φ_0 satisfies the σ-condition (1.14). We fix constants $\xi_\pm \in \mathbb{R}$ with $\xi_- < 0 < \xi_+$ such that

$$\sigma_- < \xi_- < \inf_{x\in[0,L]} \varphi_0(x) \leq \sup_{x\in[0,L]} \varphi_0(x) < \xi_+ < \sigma_+, \tag{3.1}$$

where $\sigma_\pm$ are given by (1.9).

For $r, T > 0$, let $M(r, T, \xi_-, \xi_+)$ denote the set of all functions v defined on Q_T which satisfy

$$v \in \bigcap_{i=0}^{2} C^i\left([0,T]; H^{2-i}(0,L)\right),$$

$$\xi_- \leq v(x,t) \leq \xi_+, \quad (x,t) \in Q_T, \tag{3.2}$$

$$v(x,0) = \varphi_0(x), \quad v_t(x,0) = \sigma'(\sigma^{-1}(\varphi_0(x)))\psi_0''(x), \quad x \in [0,L], \tag{3.3}$$

$$v(L,t) = 0, \quad t \in [0,T],$$

$$\operatorname*{ess\,sup}_{t\in[0,T]} \mathbf{h}(v,t) \leq r^2, \tag{3.4}$$

where

$$\mathbf{h}(v,t) = v'^2(0,t) + \sum_{|\alpha|\leq 2} \|\partial^\alpha v\|^2. \tag{3.5}$$

In the above formula $\|\cdot\|$ denotes, as usual, the norm in $L^2(0,L)$. It follows from the trace theorem that $M(r, T, \xi_-, \xi_+)$ is nonempty if r is sufficiently large and T small. For example, if we let

$$v(x,t) = \varphi_0(x)\cos t + \sigma'(\sigma^{-1}(\varphi_0(x)))\psi_0''(x)\sin t,$$

then $v \in M(r, T, \xi_-, \xi_+)$ for r suitably large and T small. In the present section, we always make this assumption.

For any $v \in M(r, T, \xi_-, \xi_+)$, we consider the linear problem

$$\begin{cases} \eta(v)\varphi_t - \psi'' = 0, \\ \psi_t - \kappa\psi_t'' + \varphi'' = 0, \\ \varphi(x,0) = \varphi_0(x), \qquad \psi(x,0) = \psi_0(x), \\ \varphi(L,t) = \psi(L,t) = \psi''(L,t) = 0, \\ 2b_1u_1(t) = \varphi(0,t) - b_1^2\psi'(0,t), \\ 2b_2u_2(t) = \varphi'(0,t) - \kappa\psi_t'(0,t) + b_2^2\psi(0,t), \end{cases} \tag{3.6}$$

with the output

$$\begin{cases} 2b_1y_1(t) = \varphi(0,t) + b_1^2\psi'(0,t), \\ 2b_2y_2(t) = \varphi'(0,t) - \kappa\psi_t'(0,t) - b_2^2\psi(0,t), \end{cases}$$

where

$$\eta(z) = 1/\mathcal{N}(z), \quad z \in (\sigma_-, \sigma_+) \tag{3.7}$$

and $\mathcal{N}(\cdot)$ is defined in (1.8). Note that the assumptions (3.1) and (3.2) imply

$$0 < \inf_{\sigma^{-1}(\xi_-) \le \xi \le \sigma^{-1}(\xi_+)} \sigma'(\xi) \le \mathcal{N}(v(x,t)) \le \sup_{\sigma^{-1}(\xi_-) \le \xi \le \sigma^{-1}(\xi_+)} \sigma'(\xi) < \infty$$

for all $(x,t) \in Q_T$, so that there are $\eta_1 > 0$, $\eta_2 > 0$ such that

$$\eta_1 \le \eta(v) \le \eta_2 \quad \forall\, v \in M(r, T, \xi_-, \xi_+).$$

It is easy to check that for $v \in M(r, T, \xi_-, \xi_+)$ and $N = \mathcal{N}(v)$ the compatibility conditions (2.26) hold. By Theorem 2.1, for any $v \in M(r, T, \xi_-, \xi_+)$, the problem (3.6) has a unique solution (φ, ψ) with the regularity $\varphi \in \cap_{i=0}^{2} C([0,T]; H^{2-i}(0,L))$ and $\psi \in \cap_{i=0}^{3} C([0,T]; H^{3-i}(0,L))$. We denote by $\mathcal{K}$ the map which carries $v \in M(r, T, \xi_-, \xi_+)$ into φ, i.e.,

$$\mathcal{K}v = \varphi, \tag{3.8}$$

where (φ, ψ) is the solution of the problem (3.6). We establish an a priori estimate to show that $\mathcal{K}$ maps $M(r, T, \xi_-, \xi_+)$ into itself if r is sufficiently large and T is sufficiently small relative to r. We then equip $M(r, T, \xi_-, \xi_+)$ with the complete metric ρ defined by

$$\rho(v, \hat{v}) = \sup_{t \in [0,T]} \|v(\cdot, t) - \hat{v}(\cdot, t)\|$$

and show that $\mathcal{K}$ is a strict contraction if T is sufficiently small. Then the Banach fixed-point theorem implies that $\mathcal{K}$ has a fixed point which is obviously a solution to

the problem (1.11)–(1.12). We define, omitting to write $(\cdot, t)$ in many places,

$$\Gamma(t) = \frac{1}{2}\varphi'^2(0,t),$$

$$E_{00}(t) = \frac{1}{2}\left[\|\psi\|^2 + \kappa\|\psi'\|^2 + \langle\eta(v)\varphi,\, \varphi\rangle\right],$$

$$E_{10}(t) = \frac{1}{2}\left[\|\psi'\|^2 + \kappa\|\psi''\|^2 + \langle\eta(v)\varphi',\, \varphi'\rangle\right],$$

$$E_{01}(t) = \frac{1}{2}\left[\|\psi_t\|^2 + \kappa\|\psi_t'\|^2 + \langle\eta(v)\varphi_t,\, \varphi_t\rangle\right],$$

$$E_{20}(t) = \frac{1}{2}\left[\|\psi''\|^2 + \kappa\|\left(\eta(v)\varphi_t\right)'\|^2 + \langle\eta(v)\varphi'',\, \varphi''\rangle\right],$$

$$E_{02}(t) = \frac{1}{2}\left[\|\psi_{tt}\|^2 + \kappa\|\psi_{tt}'\|^2 + \langle\eta(v)\varphi_{tt},\, \varphi_{tt}\rangle\right].$$

Moreover, we set

$$\wp = b_1^2 + b_1^{-2} + b_2^2 + b_2^{-2},$$

$$\aleph(v,t) = 8\wp[(\kappa^2+1)(\eta(v(0,t))+1)^2 + 1] + 1,$$

$$\Pi(t) = \Gamma(t) + \sum_{i=1}^{2} E_{i0}(t) + \aleph(v,t)\sum_{i=0}^{2} E_{0i}(t). \tag{3.9}$$

Remark 3.1. It is clear that the function $\aleph(v,t)$ depends on the function $v(0,t)$. However, there are constants $c_1(\xi_-,\xi_+) > 0$, $c_2(\xi_-,\xi_+) > 0$, which depend only on ξ_-, ξ_+, such that for any function v satisfying the condition (3.2),

$$c_1(\xi_1,\xi_+) \le \aleph(v,t) \le c_2(\xi_-,\xi_+).$$

Similar estimates hold for $\Pi(t)$. Further estimates on $\aleph$ will be given in (3.27)–(3.29).

THEOREM 3.1. *Let ξ_-, ξ_+ be such that*

$$\sigma_- < \xi_- < 0 < \xi_+ < \sigma_+, \tag{3.10}$$

where $\sigma_\pm$ are given by (1.9). *Let $v \in \cap_{i=0}^{2} C^i\left([0,T]; H^{2-i}(0,L)\right)$ satisfy*

$$\xi_- \le v(x,t) \le \xi_+, \quad (x,t) \in Q_T, \tag{3.11}$$

and the boundary condition

$$v(L,t) = 0, \quad 0 \le t \le T.$$

Suppose that (φ,ψ) is the solution of the problem (3.6) *on $Q_T = (0,L)\times(0,T)$.*

Then there is a number $C(\xi_-,\xi_+) > 0$, which may depend on the constants ξ_-, ξ_+ but is independent of the initial data (φ_0,ψ_0), such that for $0 \le t \le T$

$$\frac{\mathrm{d}\Pi(t)}{\mathrm{d}t} \le C(\xi_-,\xi_+)|u|_2^2(t) - |y|_2^2(t) + C(\xi_-,\xi_+)\left[\mathbf{h}^{\frac{1}{2}}(v,t) + \mathbf{h}(v,t)\right]\Pi(t), \tag{3.12}$$

where $|u|_2(t)$ is defined by (1.19) *and $\mathbf{h}(v,t)$ is defined by* (3.5).

Remark 3.2. Here we use a special combination of $E_{ij}(t)$, as in the formula (3.9), to control the boundary terms to have the term $-|y|_2^2$ on the right-hand side of the inequality (3.12). We need the estimate (3.12) for the existence of local smooth solutions of the quasi-linear system, and it also plays a key role in the proof of the existence of global smooth solutions.

The proof of Theorem 3.1 is divided into several lemmas. We introduce the notation ∇ for the gradient of a function φ defined on Q_T, so that $\nabla\varphi = [\varphi'\ \varphi_t]$. We denote

$$|\nabla\varphi(\cdot,t)|_\infty = \sup_{x\in[0,L]}\{|\varphi'(x,t)|,\ |\varphi_t(x,t)|\}.$$

LEMMA 3.1. *Let* $v \in \cap_{i=0}^{2} C^i\left([0,T]; H^{2-i}(0,L)\right)$ *satisfy the condition* (3.11). *Suppose that* (φ,ψ) *is the solution to the problem* (3.6). *Then*

$$|\nabla\varphi(\cdot,t)|_\infty^2 \le 2(L+1)\cdot \mathbf{h}(\varphi,t), \quad t\in[0,T], \tag{3.13}$$

$$|\nabla v(\cdot,t)|_\infty^2 \le 2(L+1)L\cdot \mathbf{h}(v,t), \quad t\in[0,T]. \tag{3.14}$$

This follows from the boundary conditions. By the boundary structure of the system (3.6), a simple computation shows that the following lemma holds.

LEMMA 3.2. *With the notation from the previous lemma,*

$$\begin{cases} b_2\psi(0) = u_2 - y_2, \\ b_1\psi'(0) = y_1 - u_1, \\ \varphi(0) = b_1(y_1+u_1), \\ \varphi'(0) - \kappa\psi_t'(0) = b_2(y_2+u_2), \\ \varphi'(0) = \kappa b_1^{-1}(y_{1t}-u_{1t}) + b_2(u_2+y_2). \end{cases} \tag{3.15}$$

In the formulas (3.15) we have suppressed the variable t for the sake of simplicity; for example, $\psi(0) = \psi(0,t)$, $\varphi(0) = \varphi(0,t)$, and so on. We shall always make this omission if there is no danger of confusion.

Denote

$$\check{c}(\xi_-,\xi_+) = \inf_{\xi_-\le x\le\xi_+}\eta(x), \quad \hat{c}(\xi_-,\xi_+) = \sup_{\xi_-\le x\le\xi_+}\eta(x), \tag{3.16}$$

$$c_1(\xi_-,\xi_+) = \sup_{\xi_-\le x\le\xi}|\eta'(x)|, \quad c_2(\xi_-,\xi_+) = \sup_{\xi_-\le x\le\xi_+}|\eta''(x)|. \tag{3.17}$$

Since $[\xi_-,\xi_+]\subset(\sigma_-,\sigma_+)$, the formulas (1.8), (1.9), (1.10), and (3.7) imply that

$$0 < \check{c}(\xi_-,\xi_+) \le \hat{c}(\xi_-,\xi_+) < \infty, \quad c_1(\xi_-,\xi_+) < \infty, \quad c_2(\xi_-,\xi_+) < \infty.$$

LEMMA 3.3. *Let the assumptions in Theorem* 3.1 *hold. Then there exists a number* $C(\xi_-,\xi_+) > 0$, *which may depend on* ξ_- *and* ξ_+, *such that, for* $0\le t\le T$,

$$\frac{\mathrm{d}E_{00}(t)}{\mathrm{d}t} \le |u(t)|^2 - |y(t)|^2 + C(\xi_-,\xi_+)\mathbf{h}^{\frac{1}{2}}(v,t)E_{00}(t).$$

Proof. Using the systems (3.6), the formulas (3.15), (3.16), and (3.17), and integration by parts, we find (suppressing the notation for the dependence on t)

$$\begin{aligned}\frac{\mathrm{d}E_{00}}{\mathrm{d}t} &= \langle\psi,\psi_t\rangle + \kappa\langle\psi',\psi_t'\rangle + \langle\varphi,\psi''\rangle + \frac{1}{2}\langle\eta'(v)v_t\varphi,\varphi\rangle\\ &\le (u_2+y_2)b_2\psi(0) - (u_1+y_1)b_1\psi'(0) + c_1(\xi_-,\xi_+)|\nabla v|_\infty\|\varphi\|^2\\ &= |u|^2 - |y|^2 + c_1(\xi_-,\xi_+)|\nabla v|_\infty\|\varphi\|^2\\ &\le |u|^2 - |y|^2 + 2\check{c}^{-1}(\xi_-,\xi_+)c_1(\xi_-,\xi_+)[2(L+1)]^{1/2}\mathbf{h}^{\frac{1}{2}}(v)E_{00},\end{aligned}$$

where the inequality (3.14) was used. ∎

LEMMA 3.4. *Let the assumptions in Theorem* 3.1 *hold. Then there exists a number $C(\xi_-,\xi_+)>0$, which may depend on ξ_-, ξ_+, such that, for $0\le t\le T$,*

$$\frac{\mathrm{d}E_{01}(t)}{\mathrm{d}t} \le |u_t(t)|^2 - |y_t(t)|^2 + C(\xi_-,\xi_+)\mathbf{h}^{\frac{1}{2}}(v,t)E_{01}(t). \tag{3.18}$$

Proof. By differentiating the first and second equations in (3.6) with respect to the time t, we obtain

$$\begin{cases}\eta(v)\varphi_{tt} = \psi_t'' - \eta'(v)v_t\varphi_t,\\ \psi_{tt} - \kappa\psi_{tt}'' + \varphi_t'' = 0.\end{cases}$$

This together with (3.15) yields

$$\begin{aligned}\frac{\mathrm{d}E_{01}}{\mathrm{d}t} &= \langle\psi_t,\psi_{tt}\rangle + \kappa\langle\psi_t',\psi_{tt}'\rangle + \langle\eta(v)\varphi_t,\varphi_{tt}\rangle + \frac{1}{2}\langle\eta'(v)v_t\varphi_t,\varphi_t\rangle\\ &= \kappa\psi_t\psi_{tt}'|_0^L + \varphi_t\psi_t'|_0^L - \varphi_t'\psi_t|_0^L - \frac{1}{2}\langle\eta'(v)v_t\varphi_t,\varphi_t\rangle\\ &= |u_t|^2 - |y_t|^2 - \frac{1}{2}\langle\eta'(v)v_t\varphi_t,\varphi_t\rangle.\end{aligned}$$

The inequality (3.18) follows from here. ∎

LEMMA 3.5. *Let the assumptions of Theorem* 3.1 *hold. Then there exists a number $C(\xi_-,\xi_+)>0$, which depends on ξ_-, ξ_+, such that, for $0\le t\le T$,*

$$\frac{\mathrm{d}E_{02}(t)}{\mathrm{d}t} \le |u_{tt}(t)|^2 - |y_{tt}(t)|^2 + C(\xi_-,\xi_+)\left[\mathbf{h}^{\frac{1}{2}}(v,t) + \mathbf{h}(v,t)\right]\mathbf{h}(\varphi,t).$$

Proof. After we differentiate the first and second equations in (3.6) twice with respect to t, we obtain (suppressing the dependence on t in the notation)

$$\begin{cases}\eta(v)\varphi_{ttt} = \psi_{tt}'' - 2\eta'(v)v_t\varphi_{tt} - \eta'(v)v_{tt}\varphi_t - \eta''(v)v_t^2\varphi_t,\\ \psi_{ttt} - \kappa\psi_{ttt}'' + \varphi_{tt}'' = 0.\end{cases} \tag{3.19}$$

It follows from (3.19), (3.13), and (3.14) that

$$\left\langle\eta(v)\varphi_{ttt},\varphi_{tt}\right\rangle = \left\langle\psi_{tt}'',\varphi_{tt}\right\rangle + I_1, \tag{3.20}$$

where

$$\begin{aligned}I_1 &= \left\langle -2\eta'(v)v_t\varphi_{tt} - \eta'(v)v_{tt}\varphi_t - \eta''(v)v_t^2\varphi_t,\ \varphi_{tt}\right\rangle\\ &\le C(\xi_-,\xi_+)\left[|\nabla v|_\infty\|\varphi_{tt}\|^2 + \|v_{tt}\||\nabla\varphi|_\infty\|\varphi_{tt}\| + |\nabla v|_\infty^2\|\varphi_t\|\|\varphi_{tt}\|\right]\\ &\le C(\xi_-,\xi_+)\left[\mathbf{h}^{\frac{1}{2}}(v) + \mathbf{h}(v)\right]\mathbf{h}(\varphi).\end{aligned}$$

Using this and (3.19), (3.20), (3.15), we find

$$\begin{aligned}\frac{\mathrm{d}E_{02}}{\mathrm{d}t} &= \langle\psi_{ttt},\psi_{tt}\rangle + \kappa\langle\psi'_{ttt},\psi'_{tt}\rangle + \langle\eta(v)\varphi_{ttt},\varphi_{tt}\rangle + \frac{1}{2}\langle\eta'(v)v_t\varphi_{tt},\varphi_{tt}\rangle\\ &\le \kappa\psi_{tt}\psi'_{ttt}|_0^L + \varphi_{tt}\psi'_{tt}|_0^L - \varphi'_{tt}\psi_{tt}|_0^L + I_1 + C(\xi_-,\xi_+)|\nabla v|_\infty\mathbf{h}(\varphi)\\ &= [\varphi'(0)-\kappa\psi'_t(0)]_{tt}\,\psi_{tt}(0) - \varphi_{tt}(0)\psi'_{tt}(0) + I_1 + C(\xi_-,\xi_+)|\nabla v|_\infty\mathbf{h}(\varphi)\\ &= (u_{2tt}+y_{2tt})b_2\psi_{tt}(0) - (u_{1tt}+y_{1tt})b_1\psi'_{tt}(0) + I_1 + C(\xi_-,\xi_+)|\nabla v|_\infty\mathbf{h}(\varphi)\\ &\le |u_{tt}|^2 - |y_{tt}|^2 + C(\xi_-,\xi_+)\left[\mathbf{h}^{\frac12}(v)+\mathbf{h}(v)\right]\mathbf{h}(\varphi). \qquad \square\end{aligned}$$

For $u=(u_1,u_2)\in H^1(0,T)^2$, we define $|u|_1(t)$ by

$$|u|_1^2(t) = |u(t)|^2 + |u_t(t)|^2.$$

This is similar to the notation $|u|_2(t)$ introduced in (1.19).

LEMMA 3.6. *There exists a number $C(\xi_-,\xi_+)>0$, which depends only on ξ_-, ξ_+, such that, for $0\le t\le T$,*

$$\frac{\mathrm{d}E_{10}(t)}{\mathrm{d}t} \le \left[2\eta(v(0,t))(\kappa^2+1)+1\right]\wp\left[|u|_1^2(t)+|y|_1^2(t)\right] + C(\xi_-,\xi_+)\mathbf{h}^{\frac12}(v,t)E_{10}(t).$$

Proof. From the boundary conditions and the second equation of the system (3.6), it follows that

$$\varphi''(L)=0, \qquad \varphi''(0)-\kappa\psi''_t(0) = -\psi_t(0). \tag{3.21}$$

Using the first equation of the system (3.6), we obtain

$$\eta(v)\varphi'_t = [\eta(v)\varphi_t]' - \eta'(v)v'\varphi_t = \psi^{(3)} - \eta'(v)\eta^{-1}(v)v'\psi''. \tag{3.22}$$

Using (3.22), the second equation in (3.6), (3.21), and the first equation in (3.6),

$$\begin{aligned}\frac{\mathrm{d}E_{10}(t)}{\mathrm{d}t} &= \langle\psi'_t,\psi'\rangle + \kappa\langle\psi''_t,\psi''\rangle + \langle\eta(v)\varphi'_t,\varphi'\rangle + \frac12\langle\eta'(v)v_t\varphi',\varphi'\rangle\\ &= \kappa\psi'\psi''_t|_0^L + \varphi'\psi''|_0^L - \varphi''\psi'|_0^L + \left\langle\psi'_t - \kappa\psi_t^{(3)} + \varphi^{(3)},\,\psi'\right\rangle\\ &\quad - \left\langle\eta'(v)\eta^{-1}(v)v'\psi'',\,\varphi'\right\rangle + \frac12\langle\eta'(v)v_t\varphi',\varphi'\rangle\\ &\le -\psi_t(0)\psi'(0) - \eta(v(0))\varphi_t(0)\varphi'(0) + C(\xi_-,\xi_+)|\nabla v|_\infty E_{10}(t)\\ &\le \frac12\left[\psi_t^2(0)+\psi'^2(0)\right] + \frac12\eta(v(0))\left[\varphi_t^2(0)+\varphi'^2(0)\right] + C(\xi_-,\xi_+)|\nabla v|_\infty E_{10}(t).\end{aligned}$$

Moreover, a simple computation using (3.15) shows that

$$\begin{aligned}&\frac12\left[\psi_t^2(0)+\psi'^2(0)\right] + \frac12\eta(v(0))\left[\varphi_t^2(0)+\varphi'^2(0)\right]\\ &\qquad\le \left[2\eta(v(0))(\kappa^2+1)+1\right]\wp(|u|^2+|u_t|^2+|y|^2+|y_t|^2). \qquad \square\end{aligned}$$

LEMMA 3.7. *There exists a number $C(\xi_-,\xi_+)>0$, which depends only on ξ_-, ξ_+ such that, for $0\le t\le T$,*

$$\begin{aligned}\frac{\mathrm{d}E_{20}(t)}{\mathrm{d}t} \le{}& \left\{4\wp\left[(2\kappa^2+1)\eta^2(v(0,t))+1\right]+\eta(v(0,t))\right\}\left[|u|_2^2(t)+|y|_2^2(t)\right]\\ &+ C(\xi_-,\xi_+)\left[\mathbf{h}(v,t)+\mathbf{h}^{\frac12}(v,t)\right]\mathbf{h}(\varphi,t).\end{aligned}$$

Proof. Differentiating the first equation of (3.6) twice with respect to x gives

$$\eta(v)\varphi_t'' = \psi^{(4)} - 2\eta'(v)v'\varphi_t' - \eta'(v)v''\varphi_t - \eta''(v)v'^2\varphi_t.$$

This together with Lemma 3.1 then yields

$$\langle \eta(v)\varphi_t'', \varphi''\rangle = \left\langle \psi^{(4)}, \varphi''\right\rangle - I_0,$$

where

$$\begin{aligned} I_0 &= \left\langle 2\eta'(v)v'\varphi_t' + \eta'(v)v''\varphi_t + \eta''(v)v'^2\varphi_t,\ \varphi''\right\rangle \\ &\le C(\xi_-,\xi_+)\left[\mathbf{h}^{\frac{1}{2}}(v) + \mathbf{h}(v)\right]\mathbf{h}(\varphi). \end{aligned} \tag{3.23}$$

Next, noting that $(\eta(v)\varphi_t)' = \psi^{(3)}$, we obtain via integration by parts and the estimate (3.23) that

$$\begin{aligned} \frac{\mathrm{d}E_{20}}{\mathrm{d}t} &= \langle \psi'', \psi_t''\rangle + \kappa\left\langle \psi^{(3)}, \psi_t^{(3)}\right\rangle + \langle \eta(v)\varphi'', \varphi_t''\rangle + \frac{1}{2}\langle \eta'(v)v_t\varphi'', \varphi''\rangle \\ &\le \kappa\psi''\psi_t^{(3)}|_0^L + \varphi''\psi^{(3)}|_0^L - \varphi^{(3)}\psi''|_0^L + \left\langle \psi'',\ \psi_t'' - \kappa\psi_t^{(4)} + \varphi^{(4)}\right\rangle - I_0 \\ &= \left[\varphi^{(3)}(0) - \kappa\psi_t^{(3)}(0)\right]\psi''(0) - \varphi''(0)\psi^{(3)}(0) - I_0 \\ &= -\psi_t'(0)\psi''(0) - \varphi''(0)\psi^{(3)}(0) - I_0. \end{aligned} \tag{3.24}$$

From the formulas in (3.15) we see that

$$\begin{aligned} -\psi_t'(0)\psi''(0) &= -\psi_t'(0)\eta(v(0))\varphi_t(0) = -\eta(v(0))b_1\psi_t'(0)(y_{1t} + u_{1t}) \\ &= \eta(v(0))(u_{1t}^2 - y_{1t}^2). \end{aligned} \tag{3.25}$$

Let us estimate the term $-\varphi''(0)\psi^{(3)}(0)$. From the equations in (3.6) and the formulas in (3.15) we have

$$\begin{aligned} \varphi''(0) &= \kappa\psi_t''(0) - \psi_t(0) = \kappa(\eta(v)\varphi_t)_t(0) - \psi_t(0) \\ &= \kappa\eta'(v(0))v_t(0)\varphi_t(0) + \kappa b_1\eta(v(0))(u_{1tt} + y_{1tt}) - b_2^{-1}(u_{2t} - y_{2t}). \end{aligned}$$

It follows from here that

$$\varphi''^2(0) \le C(\xi_-,\xi_+)|\nabla\varphi|_\infty^2|\nabla v|_\infty^2 + 8[\kappa^2\eta^2(v(0)) + 1]\wp\left[u_{2t}^2 + y_{2t}^2 + u_{1tt}^2 + y_{1tt}^2\right]. \tag{3.26}$$

In addition, a similar computation gives the estimate

$$[\psi^{(3)}(0)]^2 \le C(\xi_-,\xi_+)|\nabla\varphi|_\infty^2|\nabla v|_\infty^2 + 8\eta^2(v(0))(\kappa^2+1)\wp\left[u_{1tt}^2 + y_{1tt}^2 + u_{2t}^2 + y_{2t}^2\right].$$

Combining this with (3.26), (3.25), (3.24), and (3.23) completes the proof. ∎

A similar computation proves the following lemma.

LEMMA 3.8.

$$\frac{\mathrm{d}\Gamma(t)}{\mathrm{d}t} \le 4(\kappa^2+1)\wp\left[|u|_2^2 + |y|_2^2\right].$$

Proof of Theorem 3.1. Under the assumption (3.11), there are $c(\xi_-,\xi_+) > 0$, $C(\xi_-,\xi_+) > 0$, which may depend on ξ_-,ξ_+ but are independent of the initial data and the input, such that, if v satisfies the condition (3.2), then

$$1 \le \aleph(v,t) \le C(\xi_-,\xi_+), \tag{3.27}$$

$$\left|\frac{\mathrm{d}\aleph(v,t)}{\mathrm{d}t}\right| \le C(\xi_-,\xi_+)\mathbf{h}^{\frac{1}{2}}(v,t), \tag{3.28}$$

$$\mathbf{h}(\varphi,t) \le C(\xi_-,\xi_+)\Pi(t) \tag{3.29}$$

for all $t \in [0,T]$. By summing up the differential inequalities from Lemmas 3.3–3.8 and using (3.27)–(3.29), we compute that for $t \in [0,T]$,

$$\begin{aligned}
\frac{\mathrm{d}\Pi(t)}{\mathrm{d}t} &= \frac{\mathrm{d}\Gamma(t)}{\mathrm{d}t} + \sum_{i=1}^{2}\frac{\mathrm{d}E_{i0}(t)}{\mathrm{d}t} + \aleph(v,t)\sum_{i=0}^{2}\frac{\mathrm{d}E_{0i}(t)}{\mathrm{d}t} + \frac{\mathrm{d}\aleph(v,t)}{\mathrm{d}t}\sum_{i=0}^{2}E_{0i}(t)\\
&\le [\aleph(v,t)-1]\left[|u|_2^2(t)+|y|_2^2(t)\right] + \aleph(v,t)\left[|u|_2^2(t)-|y|_2^2(t)\right]\\
&\quad + C(\xi_-,\xi_+)[\mathbf{h}(v,t)+\mathbf{h}^{\frac{1}{2}}(v,t)]\Pi(t)\\
&= [2\aleph(v,t)-1]|u|_2^2(t) - |y|_2^2(t) + C(\xi_-,\xi_+)\left[\mathbf{h}(v,t)+\mathbf{h}^{\frac{1}{2}}(v,t)\right]\Pi(t)\\
&\le C(\xi_-,\xi_+)|u|_2^2(t) - |y|_2^2(t) + C(\xi_-,\xi_+)\left[\mathbf{h}(v,t)+\mathbf{h}^{\frac{1}{2}}(v,t)\right]\Pi(t). \qquad \square
\end{aligned}$$

Proof of Theorem 1.1. Since φ_0 satisfies the σ-condition (1.14), we can fix constants ξ_-, ξ_+ such that the relations (3.1) and (3.10) are true.

Recall the notation $M(r,T,\xi_-,\xi_+)$ from the beginning of this section. Fix r large and T small such that $M(r,T,\xi_-,\xi_+)$ is nonempty. For any $v \in M(r,T,\xi_-,\xi_+)$, by Theorem 2.1, the condition (3.2) implies that the problem (3.6) has a unique solution (φ,ψ). We need to verify that $\varphi \in M(r,T,\xi_-,\xi_+)$ and the map $\mathcal{K}$, given by (3.8), is a strict contraction if r is sufficiently large and T is small.

By Theorem 3.1, there exists $C(\xi_-,\xi_+) > 0$ such that

$$\Pi(t) \le \Pi(0) + C(\xi_-,\xi_+)\|u\|^2_{H^2[0,T]} + C(\xi_-,\xi_+)\int_0^t \left[\mathbf{h}^{\frac{1}{2}}(v,\tau)+\mathbf{h}(v,\tau)\right]\Pi(\tau)\mathrm{d}\tau$$

for any $t \in [0,T]$. It follows from here, (3.29), and Gronwall's inequality that

$$\begin{aligned}
\mathbf{h}(\varphi,t) &\le C(\xi_-,\xi_+)\Pi(t)\\
&\le C(\xi_-,\xi_+)[\Pi(0)+C(\xi_-,\xi_+)\|u\|^2_{H^2[0,T]}]e^{C(\xi_-,\xi_+)\int_0^t[\mathbf{h}^{\frac{1}{2}}(v,\tau)+\mathbf{h}(v,\tau)]\mathrm{d}\tau}
\end{aligned} \tag{3.30}$$

for any $t \in [0,T]$. From the initial data (3.3) and the system (3.6), we can check that the constant $\Pi(0)$ is independent of the choice of $v \in M(r,T,\xi_-,\xi_+)$.

We now take $r_0 > r$ sufficiently large such that

$$r_0^2 \ge 2C(\xi_-,\xi_+)\left[\Pi(0)+C(\xi_-,\xi_+)\|u\|^2_{H^2[0,T]}\right].$$

It follows from (3.6), (3.4), (3.30), and the above estimate that

$$\mathbf{h}(\varphi,t) \le \frac{r_0^2}{2}e^{C(\xi_-,\xi_+)r_0(1+r_0)t}, \quad t \in [0,T],$$

for any $v \in M(r_0, T, \xi_-, \xi_+)$. Using this, we select $T_1 \in (0, T]$ such that for $t \in (0, T_1]$ we have

$$\operatorname*{ess\,sup}_{s \in [0,t]} \mathbf{h}(\varphi, s) \le r_0^2. \tag{3.31}$$

To find a $T_2 \in (0, T_1]$ such that $\varphi \in M(r_0, T_2, \xi_-, \xi_+)$, the only thing left to do is to verify that the condition (3.2) is satisfied by φ, since the conditions (3.3) are implied by the equations (3.6). In fact, by (3.31), for all $(x,t) \in Q_{T_1}$,

$$|\varphi(x,t) - \varphi_0(x)| = \left| \int_0^t \varphi_t(x,t) \mathrm{d}t \right| \le L^{1/2} \int_0^t \mathbf{h}^{\frac{1}{2}}(\varphi, s) \mathrm{d}s \le t L^{1/2} r_0.$$

Thus (3.2) is true for φ for small $T_2 \in (0, T_1]$, because of the assumption (3.1). With the above choice of r_0 and T_2, $\mathcal{K}$ maps $M(r_0, t, \xi_-, \xi_+)$ into itself for every $t \in (0, T_2]$.

Now we shall find a $T_3 \in (0, T_2]$ such that $\mathcal{K}$ is contractive from $M(r_0, T_3, \xi_-, \xi_+)$ to itself. Let $v_1, v_2 \in M(r_0, T_2, \xi_-, \xi_+)$ and set $\varphi_1 = \mathcal{K} v_1$, $\varphi_2 = \mathcal{K} v_2$, $v = v_1 - v_2$, $\varphi = \varphi_1 - \varphi_2$, $\psi = \psi_1 - \psi_2$. A simple computation shows that

$$\begin{cases} \eta(v_1)\varphi_t = \psi'' - [\eta(v_1) - \eta(v_2)]\varphi_{2t}, \\ \psi_t - \kappa \psi_t'' + \varphi'' = 0, \\ \varphi(x,0) = 0, \quad \psi(x,0) = 0, \\ \varphi(L,t) = \psi(L,t) = \psi''(L,t) = 0, \\ \varphi(0,t) - b_1^2 \psi'(0,t) = 0, \\ \varphi'(0,t) - \kappa \psi_t'(0,t) + b_2^2 \psi(0,t) = 0. \end{cases} \tag{3.32}$$

Denoting

$$\hat{E}_{00}(t) = \frac{1}{2} \left[\|\psi\|^2 + \kappa \|\psi'\|^2 + \langle \eta(v_1)\varphi, \varphi \rangle \right] \tag{3.33}$$

(where the argument $(\cdot, t)$ has been omitted in several places), from (3.32) we obtain

$$\begin{aligned} \frac{\mathrm{d}\hat{E}_{00}}{\mathrm{d}t} &= \kappa \psi \psi_t' |_0^L + \varphi \psi' |_0^L - \varphi' \psi |_0^L + I_2 \\ &= -b_2^2 \psi^2(0,t) - b_1^2 \psi'^2(0,t) + I_2 \le I_2, \end{aligned} \tag{3.34}$$

where

$$I_2 = \langle [\eta(v_2) - \eta(v_1)]\varphi_{2t}, \varphi \rangle + \frac{1}{2} \langle \eta'(v_1) v_{1t} \varphi, \varphi \rangle .$$

It follows from here and Lemma 3.1 that there exists a number $C(\xi_-, \xi_+) > 0$, which may depend on ξ_-, ξ_+, such that

$$\begin{aligned} |I_2| &\le C(\xi_-, \xi_+) \left[|\nabla \varphi_2|_\infty \|\varphi\| \|v_1 - v_2\| + |\nabla v_1|_\infty \|\varphi\|^2 \right] \\ &\le C(\xi_-, \xi_+) \left[\mathbf{h}^{\frac{1}{2}}(\varphi_2) \rho(\mathcal{K} v_1, \mathcal{K} v_2) \rho(v_1, v_2) + \mathbf{h}^{\frac{1}{2}}(v_1) \|\varphi\|^2 \right] \\ &\le C(\xi_-, \xi_+) \left[r_0 \rho(\mathcal{K} v_1, \mathcal{K} v_2) \rho(v_1, v_2) + \mathbf{h}^{\frac{1}{2}}(v_1) \|\varphi\|^2 \right], \end{aligned} \tag{3.35}$$

since $\varphi_2 = \mathcal{K} v_2 \in M(r_0, T_2, \xi_-, \xi_+)$. By virtue of (3.32), (3.33), (3.34), and (3.35),

for $T_3 \in (0, T_2]$ and for $t \in (0, T_3]$,

$$\|\varphi(\cdot,t)\|^2 \le C(\xi_-,\xi_+)\hat{E}_{00}(t) \le C(\xi_-,\xi_+)\int_0^t I_2(s)\mathrm{d}s$$

$$\le T_3 r_0 C(\xi_-,\xi_+)\rho(\mathcal{K}v_1,\mathcal{K}v_2)\rho(v_1,v_2) + C(\xi_-,\xi_+)\int_0^t \mathbf{h}^{\frac{1}{2}}(v_1,s)\|\varphi(\cdot,s)\|^2\mathrm{d}s.$$

Applying Gronwall's inequality to the last estimate yields

$$\|\varphi(\cdot,t)\|^2 \le T_3 r_0 C(\xi_-,\xi_+)\rho(\mathcal{K}v_1,\mathcal{K}v_2)\rho(v_1,v_2)e^{C(\xi_-,\xi_+)r_0T_3}$$

for all $t \in (0, T_3]$, where $T_3 \in (0, T_2]$. Since $\varphi = \mathcal{K}v_1 - \mathcal{K}v_2$,

$$\rho(\mathcal{K}v_1,\mathcal{K}v_2) \le T_3 r_0 C(\xi_-,\xi_+)\rho(v_1,v_2)e^{C(\xi_-,\xi_+)r_0T_3}, \quad T_3 \in (0,T_2].$$

The last inequality shows that $\mathcal{K}$ is strictly contractive if T_3 is sufficiently small. By the Banach fixed-point theorem, for $T_3 > 0$ sufficiently small $\mathcal{K}$ has a unique fixed point $\varphi \in M(r_0, T_3, \xi_-, \xi_+)$. Then (φ, ψ) is the desired solution of the system (1.11)–(1.12). □

Let (φ, ψ) be a solution of (1.11)–(1.12) on Q_T such that (1.17) holds. By the argument above, (φ, ψ) is the solution of the problem (3.6) on Q_T where $v = \varphi$. Thus, by the inequality (3.29), Theorem 3.1 can be rewritten as follows.

THEOREM 3.1*. *Let $T > 0$ and $\sigma_- < \xi_- < 0 < \xi_+ < \sigma_+$. There exists $C(\xi_-, \xi_+) > 0$, which depends on ξ_-, ξ_+ such that, if the solution (φ, ψ) of the problem (1.11)–(1.12) on Q_T satisfies $\xi_- \le \varphi \le \xi_+$, then for $0 \le t \le T$,*

$$\frac{\mathrm{d}\Pi(t)}{\mathrm{d}t} + |y|_2^2(t) \le C(\xi_-,\xi_+)|u|_2^2(t) + C(\xi_-,\xi_+)^2\left[\Pi^2(t) + \Pi^{3/2}(t)\right], \tag{3.36}$$

where $\Pi(t)$ is given by the formula (3.9) with $\aleph(v,t) = \aleph(\varphi,t)$.

4. Estimates of the boundary trace. Let $T > 0$ and $u = (u_1, u_2) \in H^2(0,T) \times H^2(0,T)$. Suppose that $(\varphi_0, \psi_0) \in H^2(0,L) \times H^3(0,L)$ satisfies the boundary conditions (1.15) and the compatibility conditions (1.16), where φ_0 satisfies the σ-condition (1.14). We assume that (φ, ψ) solves the problem (1.11)–(1.12) on $Q_T = (0,L)\times(0,T)$ such that the regularity (1.17) holds. Let $\xi_-, \xi_+ \in \mathbb{R}$ be such that

$$\sigma_- < \xi_- < 0 < \xi_+ < \sigma_+.$$

We define

$$T_{\xi_-,\xi_+} = L\kappa^{\frac{1}{2}} \sup_{\xi_- \le z \le \xi_+} \eta^{\frac{1}{2}}(z), \tag{4.1}$$

where (as usual) $\eta = 1/\mathcal{N}$ and $\mathcal{N}$ is defined in (1.8).

The purpose of this section is to prove the following theorem.

THEOREM 4.1. *Suppose that $\varsigma > 0$, $T > 3T_{\xi_-,\xi_+}$ and (φ, ψ) is a solution of the problem (1.11)–(1.12) on Q_T. Then there exists a number $C(\xi_-, \xi_+, \varsigma) > 0$, which depends on ξ_-, ξ_+ and ς such that, if (φ, ψ) satisfies*

$$\xi_- \le \varphi \le \xi_+, \quad \check{\mathcal{E}}_T \le \varsigma,$$

where

$$\check{\mathcal{E}}_T = \sup_{0\le t\le T} \mathcal{E}(t) \tag{4.2}$$

and $\mathcal{E}(t)$ *is defined by* (1.18)*, then for* $0 \le s \le t \le T$ *with* $t - s \ge 3T_{\xi_-,\xi_+}$,

$$\int_s^t \mathcal{E}(\tau)\mathrm{d}\tau \le C(\xi_-,\xi_+,\varsigma)\left(\|u\|^2_{H^2(s,t)} + \|y\|^2_{H^2(s,t)} + \int_s^t [\mathcal{E}^2(\tau) + \mathcal{E}^{\frac{3}{2}}(\tau)]\,\mathrm{d}\tau\right). \tag{4.3}$$

Remark 4.1. In fact, for any $\varepsilon > 0$, we can prove that the inequality (4.3) holds for $t - s \ge 2T_{\xi_-,\xi_+} + \varepsilon$, where the constant $C(\xi_-,\xi_+,\varsigma)$ may also depend on ε. In general, the conclusion of Theorem 4.1 is not true when $t - s < 2T_{\xi_-,\xi_+}$.

The proof of Theorem 4.1 is based on several lemmas below. Set

$$\vartheta = \begin{bmatrix}\varphi\\ \psi'\end{bmatrix}, \qquad A(\varphi) = \begin{bmatrix}0 & -\kappa\\ -\eta(\varphi) & 0\end{bmatrix}, \tag{4.4}$$

where $\eta(z) = 1/\mathcal{N}(z) = 1/\sigma'(\sigma^{-1}(z))$. We diagonalize $A(\varphi)$ as

$$SA(\varphi)S^{-1} = \begin{bmatrix}\kappa^{\frac{1}{2}}\eta^{\frac{1}{2}}(\varphi) & 0\\ 0 & -\kappa^{\frac{1}{2}}\eta^{\frac{1}{2}}(\varphi)\end{bmatrix},$$

where

$$S = \frac{1}{2}\begin{bmatrix}1 & -\kappa^{\frac{1}{2}}\eta^{-\frac{1}{2}}(\varphi)\\ 1 & \kappa^{\frac{1}{2}}\eta^{-\frac{1}{2}}(\varphi)\end{bmatrix}, \quad S^{-1} = \begin{bmatrix}1 & 1\\ -\kappa^{-\frac{1}{2}}\eta^{\frac{1}{2}}(\varphi) & \kappa^{-\frac{1}{2}}\eta^{\frac{1}{2}}(\varphi)\end{bmatrix}. \tag{4.5}$$

LEMMA 4.1. *Let* $\xi_- \le \varphi \le \xi_+$ *hold on* Q_T. *Let* $\vartheta = [\begin{smallmatrix}\varphi\\ \psi'\end{smallmatrix}]$, *where* (φ,ψ) *is the solution of the problem* (1.11)–(1.12). *Then*

$$A(\varphi)\vartheta_t + \vartheta' = \begin{bmatrix}\Lambda\varphi - \kappa b_2[u_2(t) + y_2(t)]q_1'\\ 0\end{bmatrix}, \quad (x,t) \in Q_T, \tag{4.6}$$

where

$$(\Lambda\varphi)(x) = a^{-1/2}\langle\varphi, q_0'\rangle \sinh a^{\frac{1}{2}}x - a\int_0^x \varphi(s)\cosh a^{\frac{1}{2}}(x-s)\mathrm{d}s. \tag{4.7}$$

Proof. From the second equation in (1.11), a computation as in (2.10) yields

$$\psi_t = B_0\varphi' - b_2^2\psi(0,t)q_1 + 2b_2u_2(t)q_1,$$

where B_0 is defined in Lemma 2.1 and q_1 by (2.11). We then employ (2.9), (2.8), and $b_2\psi(0,t) = u_2(t) - y_2(t)$ (see (3.15) with $\psi = w$) to obtain

$$\begin{aligned}\kappa\psi_t' &= \kappa\frac{\partial}{\partial x}B_0\varphi' - \kappa b_2^2\psi(0,t)q_1' + 2\kappa b_2u_2(t)q_1'\\ &= \varphi' + a^{-\frac{1}{2}}\langle\varphi', q_0\rangle\sinh a^{\frac{1}{2}}x + a^{\frac{1}{2}}\int_0^x \varphi'(s)\sinh a^{\frac{1}{2}}(x-s)\mathrm{d}s\\ &\quad - \kappa b_2^2\psi(0,t)q_1' + 2\kappa b_2u_2(t)q_1'\\ &= \varphi' - \Lambda\varphi + \kappa b_2[u_2(t) + y_2(t)]q_1'. \end{aligned} \tag{4.8}$$

The formula (4.6) follows from (4.8) and the first equation in (1.11). ∎

Remark 4.2. Assume for a moment that $b_2 = 0$. Using (4.8) we observe that, if we make the change of unknowns

$$\mu = \varphi, \qquad \nu = \psi',$$

then the problem (1.11)–(1.12) becomes

$$\begin{cases} \mu_t = \eta^{-1}(\mu)\nu', \\ \kappa\nu_t = \mu' - \Lambda(\mu), \\ \mu(x,0) = \varphi_0(x), \quad \nu(x,0) = \psi_0(x), \\ \mu(L,t) = 0, \end{cases} \tag{4.9}$$

with the input-output at $x = 0$:

$$\begin{cases} 2b_1 u_1(t) = \mu(0,t) - b_1^2\nu(0,t), \\ 2b_1 y_1(t) = \mu(0,t) + b_1^2\nu(0,t). \end{cases} \tag{4.10}$$

It is clear that the problem (4.9)–(4.10) represents a quasi-linear string with the input-output structure at the boundary. The existence of global solutions of the above problem has been studied in [18].

If $b_2 \neq 0$, then the term $\kappa[\mu'(0,t) - \kappa\nu_t'(0,t)]q_1'$ appears on the right-hand side of the second equation in (4.9), and this makes things quite different.

For $(x,t) \in Q_T$ let $\tau_i(s) = \tau_i(s;x,t)$ be the solutions of

$$\frac{\mathrm{d}\tau_i}{\mathrm{d}s} = \lambda_i(s,\tau_i), \qquad \tau_i(x;x,t) = t, \qquad i = 1,2, \tag{4.11}$$

where

$$\lambda_1(x,t) = \kappa^{\frac{1}{2}}\eta^{\frac{1}{2}}(\varphi(x,t)), \qquad \lambda_2(x,t) = -\kappa^{\frac{1}{2}}\eta^{\frac{1}{2}}(\varphi(x,t)).$$

Then $(s, \tau_i(s;x,t))$ are the forward and backward characteristics through (x,t), respectively, for $i = 1,2$. An argument similar to that in [1] implies the following lemma.

LEMMA 4.2. *For $i = 1,2$,*

$$\tau_i'(s;x,t) = -\lambda_i(x,t)\tau_{it}(s;x,t).$$

Suppose that $\xi_- \le \varphi \le \xi_+$ holds on Q_T. There exist numbers $C(\xi_-,\xi_+) > 0$ and $c(\xi_-,\xi_+) > 0$, which depend only on ξ_-, ξ_+ such that for $0 \le s \le x \le L$, $0 \le t \le T$,

$$e^{-c(\xi_-,\xi_+)\check{\mathcal{E}}_T^{\frac{1}{2}}} \le \tau_{it}(s;x,t) \le e^{c(\xi_-,\xi_+)\check{\mathcal{E}}_T^{\frac{1}{2}}} \tag{4.12}$$

and

$$C^{-1}(\xi_-,\xi_+)e^{-c(\xi_-,\xi_+)\check{\mathcal{E}}_T^{\frac{1}{2}}} \le |\tau_i'(s;x,t)| \le C(\xi_-,\xi_+)e^{c(\xi_-,\xi_+)\check{\mathcal{E}}_T^{\frac{1}{2}}},$$

where $\check{\mathcal{E}}$ is defined in (4.2).

LEMMA 4.3. *Assume that $\xi_- \le \varphi \le \xi_+$ holds on Q_T and let T_{ξ_-,ξ_+} be given by* (4.1). *Let $\omega \in H^1(Q_T) \times H^1(Q_T)$ such that*

$$A(\varphi)\omega_t + \omega' = \Psi(\varphi), \quad (x,t) \in Q_T, \tag{4.13}$$

where $A(\varphi)$ is defined in (4.4) *and $\Psi(\varphi)$ satisfies the estimate*

(4.14)
$$|\Psi(\varphi)| \le C(\xi_-,\xi_+)\left[|\Psi_0(\varphi)| + |\nabla\varphi|_\infty|\Psi_1(\varphi)| + |\nabla\varphi|_\infty^3 + |\nabla\varphi|_\infty^2 + |\nabla\varphi|_\infty|\omega|\right]$$

for $(x,t) \in Q_T$, where $\Psi_0(\varphi)$ and $\Psi_1(\varphi)$ (the components of $\Psi(\varphi)$) are functions determined by φ. Set

$$\Upsilon = S\omega, \tag{4.15}$$

where S is given in (4.5)*. Then there exist numbers $C(\xi_-,\xi_+) > 0$ and $c(\xi_-,\xi_+) > 0$, which depend only on ξ_-, ξ_+, such that for $2T_{\xi_-,\xi_+} \le t \le T$*

(4.16)
$$\int_0^t \|\Upsilon(\cdot,\tau)\|^2 \mathrm{d}\tau \le C(\xi_-,\xi_+)e^{c(\xi_-,\xi_+)\check{\mathcal{E}}_T^{\frac12}} \int_0^t \left[|\Upsilon(0,\varsigma)|^2 + |\Upsilon(L,\varsigma)|^2 + \Xi(\Upsilon)(\varsigma)\right]\mathrm{d}\varsigma,$$

where $\check{\mathcal{E}}_T$ is given in (4.2) *and*

$$\Xi(\Upsilon)(t) = \|\Psi_0(\varphi)(\cdot,t)\|^2 + \|\Psi_1(\varphi)(\cdot,t)\|^2$$

$$+ \left[|\nabla\varphi(\cdot,t)|_\infty^2 + |\nabla\varphi(\cdot,t)|_\infty\right]\|\Upsilon(\cdot,t)\|^2 + |\nabla\varphi(\cdot,t)|_\infty^4 + |\nabla\varphi(\cdot,t)|_\infty^3. \tag{4.17}$$

Furthermore, denoting the components of Υ by Υ_1, Υ_2, we have for $2T_{\xi_-,\xi_+} \le t \le T$,

$$\int_{T_\zeta}^t \Upsilon_1^2(L,\tau)\mathrm{d}\tau \le C(\xi_-,\xi_+)e^{c(\xi_-,\xi_+)\check{\mathcal{E}}_T^{\frac12}} \int_0^t \left[\Upsilon_1^2(0,\varsigma) + \Xi(\Upsilon)(\varsigma)\right]\mathrm{d}\varsigma, \tag{4.18}$$

$$\int_0^{T_\zeta} \Upsilon_2^2(L,\tau)\mathrm{d}\tau \le C(\xi_-,\xi_+)e^{c(\xi_-,\xi_+)\check{\mathcal{E}}_T^{\frac12}} \int_0^t \left[\Upsilon_2^2(0,\varsigma) + \Xi(\Upsilon)(\varsigma)\right]\mathrm{d}\varsigma. \tag{4.19}$$

Proof. From the formulas (4.13) and (4.15), a simple computation yields

$$SAS^{-1}\Upsilon_t + \Upsilon' = \Theta, \tag{4.20}$$

where

$$\Theta = \left(SAS^{-1}S_t + S'\right)S^{-1}\Upsilon + S\Psi(\varphi). \tag{4.21}$$

Thus we have from (4.20) that for $(x,t) \in Q_T$,

$$\kappa^{\frac12}\eta^{\frac12}(\varphi)\Upsilon_{1t} + \Upsilon_1' = \Theta\cdot e_1, \qquad -\kappa^{\frac12}\eta^{\frac12}(\varphi)\Upsilon_{2t} + \Upsilon_2' = \Theta\cdot e_2, \tag{4.22}$$

where $e_1 = (1,0)$ and $e_2 = (0,1)$.

Let $(x,t) \in Q_T$ be given. Using (4.22), we integrate Υ_1^2 along the forward characteristic $(s,\tau_1(s))$ from 0 to x to obtain

$$\begin{aligned}\Upsilon_1^2(x,t) &= \Upsilon_1^2(0,\tau_1(0;x,t)) + 2\int_0^x \Upsilon_1\frac{\mathrm{d}}{\mathrm{d}s}\Upsilon_1\,\mathrm{d}s \\ &= \Upsilon_1^2(0,\tau_1(0;x,t)) + 2\int_0^x (\Upsilon_1\Theta\cdot e_1)(s,\tau_1(s))\,\mathrm{d}s.\end{aligned} \tag{4.23}$$

On the other hand, from (4.21) and (4.14) we can derive that for $(x,t)\in Q_T$,

$$|\Theta|\le C(\xi_-,\xi_+)\left[|\Psi_0(\varphi)|+|\nabla\varphi|_\infty|\Psi_1(\varphi)|+|\nabla\varphi|_\infty^3+|\nabla\varphi|_\infty^2+|\nabla\varphi|_\infty|\Upsilon|\right].$$

By combining the above estimate with (4.23), we obtain

$$\Upsilon_1^2(x,t)\le\Upsilon_1^2(0,\tau_1(0;x,t))+C(\xi_-,\xi_+)\int_0^x f(s,\tau_1(s;x,t))\mathrm{d}\,s, \tag{4.24}$$

where

$$\begin{aligned}f(x,t)=&|\Upsilon_1(x,t)|\cdot|\Psi_0(\varphi)(x,t)|+|\Psi_1(\varphi)(x,t)|\cdot|\nabla\varphi(\cdot,t)|_\infty|\Upsilon_1(x,t)|\\&+\left[|\nabla\varphi(\cdot,t)|_\infty^2+|\nabla\varphi(\cdot,t)|_\infty\right]|\Upsilon(x,t)|^2+|\nabla\varphi(\cdot,t)|_\infty^3+|\nabla\varphi(\cdot,t)|_\infty^4.\end{aligned}$$

We now integrate both sides of (4.24) from T_{ξ_-,ξ_+} to t with respect to the time (denoted ν) and arrive at

$$\begin{aligned}\int_{T_{\xi_-,\xi_+}}^t\Upsilon_1^2(x,\nu)\,\mathrm{d}\,\nu\le&\int_{T_{\xi_-,\xi_+}}^t\Upsilon_1^2(0,\,\tau_1(0;x,\nu))\,\mathrm{d}\,\nu\\&+C(\xi_-,\xi_+)\int_0^x\int_{T_{\xi_-,\xi_+}}^t f(s,\tau_1(s;x,\nu))\mathrm{d}\nu\mathrm{d}\,s.\end{aligned}\tag{4.25}$$

Now we estimate the two terms on the right-hand side of (4.25) by a change of the integration variable. By the choice of the constant T_{ξ_-,ξ_+}, it is easy to see that

$$0\le\tau_1(s;x,t)\le t,\quad s\in[0,x],\ x\in[0,L],\ t\in[T_{\xi_-,\xi_+},T]. \tag{4.26}$$

For each fixed $s\in[0,x]$, we make a change of the integration variable by

$$\varsigma=\tau_1(s;x,t)$$

and use the inequalities (4.12) and (4.26) to obtain

$$\int_{T_{\xi_-,\xi_+}}^t f(s,\tau_1(s;x,\nu))\mathrm{d}\nu=\int_{\tau_1(s;x,T_{\xi_-,\xi_+})}^{\tau_1(s;x,t)}\frac{f(s,\varsigma)}{\tau_{1t}(s;x,\tau_1^{-1}(\varsigma))}\mathrm{d}\varsigma\le e^{c(\xi_-,\xi_+)\check{\mathcal{E}}_T^{\frac12}}\int_0^t f(s,\nu)\mathrm{d}\nu.$$

Similarly, we have

$$\int_{T_{\xi_-,\xi_+}}^t\Upsilon_1^2(0,\,\tau_1(0;x,\nu))\,\mathrm{d}\,\nu\le e^{c(\xi_-,\xi_+)\check{\mathcal{E}}_T^{\frac12}}\int_0^t\Upsilon_1^2(0,\nu)\mathrm{d}\nu.$$

We now substitute the last two inequalities into (4.25) and then integrate both sides from 0 to L with respect to the variable x to obtain

$$\begin{aligned}\int_{T_{\xi_-,\xi_+}}^t\|\Upsilon_1(\cdot,\nu)\|^2\mathrm{d}\nu\le&\,\varepsilon\int_0^t\|\Upsilon_1(\cdot,\nu)\|^2\mathrm{d}\nu\\&+C(\xi_-,\xi_+,\varepsilon)e^{c(\xi_-,\xi_+)\check{\mathcal{E}}_T^{\frac12}}\int_0^t\left[\Upsilon_1^2(0,\varsigma)+\Xi(\Upsilon)(\varsigma)\right]\mathrm{d}\,\varsigma,\end{aligned}\tag{4.27}$$

where we have used the inequality $|\Upsilon_1||\Psi_0(\varphi)|\le\epsilon|\Upsilon_1|^2+|\Psi_0(\varphi)|^2/4\epsilon$ for ε small.

Clearly, in order to obtain an estimate for $\int_0^t \|\Upsilon_1(\cdot,\nu)\|^2 \mathrm{d}\nu$, we have to estimate $\int_0^{T_{\xi_-,\xi_+}} \|\Upsilon_1(\cdot,\nu)\|^2 \mathrm{d}\nu$. To this end, we repeat the above process by using the forward characteristic $(s,\tau_1(s))$ again but this time on the segment $x \le s \le L$. We integrate $\Upsilon_1^2(s,\tau_1(s))$ from x to L and then we have

$$\Upsilon_1^2(x,t) \le \Upsilon_1^2(L,\tau_1(L;x,t)) + C(\xi_-,\xi_+)\int_0^L f(s,\tau_1(s;x,t))\mathrm{d}s. \tag{4.28}$$

From the choice of the T_{ξ_-,ξ_+} it is easy to see that

$$t \le \tau_1(s;x,t) \le \tau_1(L;x,t) \le T_{\xi_-,\xi_+} + t, \quad s \in [x,L],\ t \in [0,T].$$

We integrate both sides of (4.28) from 0 to T_{ξ_-,ξ_+} with respect to t. Noting that

$$\begin{aligned}\int_0^{T_{\xi_-,\xi_+}} \Upsilon_1^2(L,\tau_1(L;x,t))\mathrm{d}t &= \int_{\tau_1(L;x,0)}^{\tau_1(L;x,T_{\xi_-,\xi_+})} \Upsilon_1^2(L,\varsigma)\tau_{1t}^{-1}\mathrm{d}\varsigma \\ &\le e^{c(\xi_-,\xi_+)\check{\mathcal{E}}_T^{\frac{1}{2}}} \int_0^{2T_{\xi_-,\xi_+}} \Upsilon_1^2(L,t)\mathrm{d}t,\end{aligned}$$

a computation similar to that for the inequality (4.27) yields

$$\begin{aligned}\int_0^{T_{\xi_-,\xi_+}} \|\Upsilon_1(\cdot,t)\|^2\mathrm{d}t \le{}& \varepsilon\int_0^{2T_{\xi_-,\xi_+}} \|\Upsilon_1(\cdot,t)\|^2\mathrm{d}t \\ &+ C(\xi_-,\xi_+,\varepsilon)e^{c(\xi_-,\xi_+)\check{\mathcal{E}}_T^{\frac{1}{2}}} \int_0^{2T_{\xi_-,\xi_+}} [\Upsilon_1^2(L,\varsigma) + \Xi(\Upsilon)(\varsigma)]\mathrm{d}\varsigma.\end{aligned}$$

It follows from the above inequality and (4.27) that for $2T_{\xi_-,\xi_+} \le t \le T$,

$$\int_0^t \|\Upsilon_1(\cdot,\nu)\|^2\mathrm{d}t \le C(\xi_-,\xi_+)e^{c(\xi_-,\xi_+)\check{\mathcal{E}}_T^{\frac{1}{2}}} \int_0^t \left[\Upsilon_1^2(0,\varsigma) + \Upsilon_1^2(L,\varsigma) + \Xi(\Upsilon)(\varsigma)\right]\mathrm{d}\varsigma.$$

Now, we do the same thing along the backward characteristic $(s,\tau_2(s))$ and then we obtain an inequality which is the same as the last one if Υ_1 is changed into Υ_2. Therefore, addition of these two inequalities actually yields (4.16).

Next, we prove the inequalities (4.18) and (4.19). We go back to the inequality (4.24) and set $x = L$ in (4.24). Then we integrate both sides of (4.24) with respect to time from T_{ξ_-,ξ_+} to t to give the inequality (4.18). As to the inequality (4.19), we do the same thing on the backward characteristic $(s,\tau_2(s))$ $(0 \le s \le L)$. Noting the inequality

$$0 \le \tau_2(0;L,0) \le \tau_2(0;L,T_{\xi_-,\xi_+}) \le 2T_{\xi_-,\xi_+} \le t,$$

we obtain the inequality (4.19). □

LEMMA 4.4. *Assume that $\xi_- \le \varphi \le \xi_+$ holds on Q_T. If $T > 2T_{\xi_-,\xi_+}$, then there exist numbers $C(\xi_-,\xi_+) > 0$ and $c(\xi_-,\xi_+) > 0$, which depend only on ξ_-,ξ_+, such that for $2T_{\xi_-,\xi_+} \le t \le T$,*

$$\begin{aligned}\int_0^t \mathcal{E}(\tau)\mathrm{d}\tau \le{}& C(\xi_-,\xi_+)e^{c(\xi_-,\xi_+)\check{\mathcal{E}}_T^{\frac{1}{2}}} \left(\|u\|_{H^2(0,t)}^2 + \|y\|_{H^2(0,t)}^2\right) \\ &+ C(\xi_-,\xi_+)e^{c(\xi_-,\xi_+)\check{\mathcal{E}}_T^{\frac{1}{2}}} \int_0^t \left[\mathbf{h}(\Lambda\varphi,\tau) + \mathcal{E}^2(\tau) + \mathcal{E}^{\frac{3}{2}}(\tau)\right]\mathrm{d}\tau,\end{aligned} \tag{4.29}$$

where $\Lambda\varphi$ and $\mathbf{h}(\Lambda\varphi,\tau)$ are given by the formulas (4.7) *and* (3.5)*, respectively.*

Proof. Let (φ, ψ) be a solution of the problem (1.11)–(1.12). Take $\omega = \left[\begin{smallmatrix} \varphi \\ \psi' \end{smallmatrix}\right]$. The formula (4.6) yields

$$A(\varphi)\omega_t + \omega' = \Psi(\varphi),$$

where

$$\Psi(\varphi) = \begin{bmatrix} \Lambda\varphi - \kappa b_2[u_2(t) + y_2(t)]q_1' \\ 0 \end{bmatrix}. \tag{4.30}$$

Set $\Upsilon = S\omega$. Then the estimate (4.14) is trivially true for $\Psi(\varphi)$ with $\Psi_1(\varphi) = 0$.

From the boundary condition $\varphi(L,t) = 0$ in (1.11) and the formula for S in (4.5), we have

$$\Upsilon_1(L,t) + \Upsilon_2(L,t) = \varphi(L,t) = 0, \quad t \geq 0. \tag{4.31}$$

Applying the inequalities (4.18) and (4.19) to $\Upsilon = (\Upsilon_1, \Upsilon_2)$ and using (4.31) gives

$$\begin{aligned} \int_0^t |\Upsilon(L,\nu)|^2 \mathrm{d}\nu &= 2\int_0^{T_{\xi_-,\xi_+}} \Upsilon_2^2(L,\nu)\mathrm{d}\nu + 2\int_{T_{\xi_-,\xi_+}}^t \Upsilon_1^2(L,\nu)\mathrm{d}\nu \\ &\leq C(\xi_-,\xi_+)e^{c(\xi_-,\xi_+)\check{\mathcal{E}}_T^{\frac{1}{2}}} \int_0^t [|\Upsilon|^2(0,\nu) + \Xi(\Upsilon)(\nu)]\mathrm{d}\nu. \end{aligned}$$

Combining the above inequality and (4.16), we get for $2T_{\xi_-,\xi_+} \leq t \leq T$,

$$\int_0^t \|\Upsilon(\cdot,\nu)\|^2 \mathrm{d}\nu \leq C(\xi_-,\xi_+)e^{c(\xi_-,\xi_+)\check{\mathcal{E}}_T^{\frac{1}{2}}} \int_0^t \left[|\Upsilon(0,\nu)|^2 + \Xi(\Upsilon)(\nu)\right] \mathrm{d}\nu. \tag{4.32}$$

On the other hand, from (3.13), (4.17), and (4.30), we obtain

$$\Xi(\Upsilon)(t) \leq C(\xi_-,\xi_+)\left[u_2^2(t) + y_2^2(t) + \|\Lambda\varphi(\cdot,t)\|^2 + \mathcal{E}^2(t) + \mathcal{E}^{\frac{3}{2}}(t)\right] \tag{4.33}$$

for all $t \in [0,T]$. In addition, it is easy to check that

$$C_1(\xi_-,\xi_+)[\varphi^2(x,t) + \psi'^2(x,t)] \leq |\Upsilon(x,t)|^2 \leq C_2(\xi_-,\xi_+)[\varphi^2(x,t) + \psi'^2(x,t)]$$

for all $(x,t) \in Q_T$. Using the inequalities (4.33), (4.32) and the boundary values in (3.15), where $v = \varphi$, $w = \psi$, we then obtain

(4.34)

$$\begin{aligned} &\int_0^t \left[\|\varphi(\cdot,\nu)\|^2 + \|\psi'(\cdot,\nu)\|^2\right] \mathrm{d}\nu \\ &\quad \leq C(\xi_-,\xi_+)e^{c(\xi_-,\xi_+)\check{\mathcal{E}}_T^{\frac{1}{2}}} \int_0^t \left[|u(\nu)|^2 + |y(\nu)|^2 + \|\Lambda\varphi(\cdot,\nu)\|^2 + \mathcal{E}^2(\nu) + \mathcal{E}^{\frac{3}{2}}(\nu)\right] \mathrm{d}\nu. \end{aligned}$$

Next, we take $\omega = \left[\begin{smallmatrix} \varphi' \\ \psi'' \end{smallmatrix}\right]$. We differentiate (4.6) with respect to x, obtaining

$$A(\varphi)\omega_t + \omega' = \Psi(\varphi),$$

where, this time,

$$\Psi(\varphi) = \Psi_0(\varphi) - [A(\varphi)]'\vartheta_t,$$

$$\Psi_0(\varphi) = \begin{bmatrix} (\Lambda\varphi)' - \kappa b_2 \left[u_2(t) + y_2(t)\right] q_1'' \\ 0 \end{bmatrix}.$$

In order to apply Lemma 4.3 to $\Upsilon = S(\varphi', \psi'')$ this time, we have to find $\Psi_1(\varphi)$ such that the estimate (4.14) is true, where $\Psi(\varphi)$ is as above. In fact, using the identity (4.8) and $|\Lambda\varphi| \le C(\xi_-, \xi_+)|\nabla\varphi|_\infty$, we obtain (suppressing the variable t)

$$\begin{aligned}|\Psi(\varphi)| &\le C(\xi_-, \xi_+)\left[|\Psi_0(\varphi)| + |\nabla\varphi|_\infty(|\varphi_t| + |\psi_t'|)\right]\\ &\le C(\xi_-, \xi_+)\left[|\Psi_0(\varphi)| + |\nabla\varphi|_\infty|\Psi_1(\varphi)| + |\nabla\varphi|_\infty^2\right],\end{aligned}$$

where $\Psi_1(\varphi) = [u_2(t) + y_2(t)]q_1'$. Then a computation similar to that for (4.34) but this time with $\Upsilon = S(\varphi', \psi'')$ yields

$$\int_0^t \left[\|\varphi'(\cdot,\nu)\|^2 + \|\psi''(\cdot,\nu)\|^2\right]\mathrm{d}\nu$$

$$\le C(\xi_-, \xi_+)e^{c(\xi_-,\xi_+)\check{\mathcal{E}}_T^{\frac{1}{2}}}\int_0^t \left[\|(\Lambda\varphi)'(\cdot,\nu)\|^2 + |u|_1^2(\nu) + |y|_1^2(\nu) + \check{\mathcal{E}}^2(\nu) + \check{\mathcal{E}}^{\frac{3}{2}}(\nu)\right]\mathrm{d}\nu.$$

Similarly, when we apply Lemma 4.3 to $\Upsilon = S[\begin{smallmatrix}\varphi''\\ \psi'''\end{smallmatrix}]$, $\Upsilon = S[\begin{smallmatrix}\varphi_t\\ \psi_t'\end{smallmatrix}]$, and $\Upsilon = [\begin{smallmatrix}\varphi_{tt}\\ \psi_{tt}'\end{smallmatrix}]$, respectively, we get the corresponding estimates for $\int_0^t(\|\varphi''\|^2 + \|\varphi_t'\|^2)\mathrm{d}\nu$, $\int_0^t(\|\varphi_t\|^2 + \|\psi_t'\|^2)\mathrm{d}\nu$, and $\int_0^t(\|\varphi_{tt}\|^2 + \|\psi_{tt}'\|^2)\mathrm{d}\nu$, respectively. After we add all those inequalities together, we obtain (4.29). We omit the details here. □

Remark 4.3. To prove Theorem 4.1, our next step is to absorb the lower order term $\int_0^t \mathbf{h}(\Lambda\varphi, \tau)\mathrm{d}\tau$ in the inequality (4.29). Since the operator Λ: $L^2(Q_T) \to L^2(Q_T)$ (given by (4.7)) is compact, $\int_0^t \mathbf{h}(\Lambda\varphi, \tau)\mathrm{d}\tau$ is a lower order term with respect to the energy level $\int_0^t \mathcal{E}\mathrm{d}\tau$. This is shown by a compactness/uniqueness argument in the following lemma.

LEMMA 4.5. *Let $\xi_- \le \varphi \le \xi_+$ hold on $Q_{3T_{\xi_-,\xi_+}}$ and let $\varsigma > 0$ be given. Let T_{ξ_-,ξ_+} and $\check{\mathcal{E}}$ be defined by* (4.1) *and* (4.2)*, respectively. Suppose that (φ_0, ψ_0) and $u \in [H^2(0, 3T_{\xi_-,\xi_+})]^2$ are such that the solution of the system* (1.11)–(1.12) *satisfies*

$$\check{\mathcal{E}}_{3T_{\xi_-,\xi_+}} \le \varsigma.$$

Then there exists $C(\xi_-, \xi_+, \varsigma) > 0$, which may depend on ξ_-, ξ_+, and ς but is independent of the initial data (φ_0, ψ_0), such that

$$\begin{aligned}\int_0^{3T_{\xi_-,\xi_+}} \mathbf{h}(\Lambda\varphi, \nu)\mathrm{d}\nu \le\ & C(\xi_-, \xi_+, \varsigma)\left(\|u\|^2_{H^2(0,3T_{\xi_-,\xi_+})} + \|y\|^2_{H^2(0,3T_{\xi_-,\xi_+})}\right)\\ &+ C(\xi_-, \xi_+, \varsigma)\int_0^{3T_{\xi_-,\xi_+}} [\mathcal{E}^2(\nu) + \mathcal{E}^{\frac{3}{2}}(\nu)]\mathrm{d}\nu,\end{aligned}$$

where $\mathbf{h}(\Lambda\varphi, \nu)$ is given by the formula (3.5).

Proof. By contradiction, assume that the conclusion of the lemma does not hold. Then, there exist initial data $(\varphi_{0,n}, \psi_{0,n})$, an input u_n, and the corresponding solutions (φ_n, ψ_n) of (1.11)–(1.12) over $(0, 3T_{\xi_-,\xi_+})$ such that, denoting $\tau = 3T_{\xi_-,\xi_+}$,

$$\xi_- \le \varphi_n \le \xi_+, \quad \check{\mathcal{E}}_{n,\tau} \le \varsigma,$$

$$\frac{1}{n}\int_0^\tau \mathbf{h}(\Lambda\varphi_n, \nu)\mathrm{d}\nu \ge \|u_n\|^2_{H^2(0,\tau)} + \|y_n\|^2_{H^2(0,\tau)} + \int_0^\tau \left[\mathcal{E}_n^2(\nu) + \mathcal{E}_n^{\frac{3}{2}}(\nu)\right]\mathrm{d}\nu. \tag{4.35}$$

Since $\mathbf{h}(\Lambda\varphi_n,\nu)\le C(\xi_-,\xi_+)\check{\mathcal{E}}_{n,\tau}$,

$$\|u_n\|^2_{H^2(0,\tau)}+\|y_n\|^2_{H^2(0,\tau)}+\int_0^\tau\left[\mathcal{E}_n^2(\nu)+\mathcal{E}_n^{\frac{3}{2}}(\nu)\right]\mathrm{d}\,\nu\to 0,$$

which further implies

$$\|(\varphi_n,\psi_n)\|^2_{H^2(Q_\tau)}+\int_0^\tau[{\varphi_n'}^2(0,\nu)+\|\psi_{tt}'(\cdot,\nu)\|^2]\mathrm{d}\,\nu=\int_0^\tau\mathcal{E}_n(\nu)\mathrm{d}\,\nu\to 0, \tag{4.36}$$

$$\sup_{(x,t)\in Q_\tau}|\varphi_n(x,t)|\to 0. \tag{4.37}$$

Set

$$c_n^2=\int_0^\tau\mathbf{h}(\Lambda\varphi_n,\nu)\mathrm{d}\,\nu,\quad \rho_n=\frac{\varphi_n}{c_n},\quad \varrho_n=\frac{\psi_n}{c_n},\quad \mu_n=\frac{u_n}{c_n},\quad \nu_n=\frac{y_n}{c_n},$$

$$\mathcal{E}(\rho_n,\varrho_n)(t)={\rho'}_n^2(0,t)+\|\varrho_{ntt}'(\cdot,t)\|^2+\sum_{|\alpha|\le 2}\left[\|\partial^\alpha\rho_n(\cdot,t)\|^2+\|\partial^\alpha\varrho_n(\cdot,t)\|^2\right].$$

Then

$$\|\Lambda\rho_n\|^2_{H^2(Q_\tau)}+\int_0^\tau(\Lambda\rho_n')^2(0,t)\mathrm{d}\,t=\int_0^\tau\mathbf{h}(\Lambda\rho_n,t)\mathrm{d}\,t=1, \tag{4.38}$$

and by (4.35)

$$\|\mu_n\|^2_{H^2(0,\tau)}+\|\nu_n\|^2_{H^2(0,\tau)}+\frac{1}{c_n^2}\int_0^\tau\left[\mathcal{E}_n^2(t)+\mathcal{E}_n^{\frac{3}{2}}(t)\right]\mathrm{d}\,t\to 0. \tag{4.39}$$

We divide both sides of (4.29) by c_n^2 and use the relation (4.39) to see that the expressions below form a bounded sequence (indexed by n):

$$\|(\rho_n,\varrho_n)\|^2_{H^2(Q_\tau)}+\int_0^\tau\left[{\rho'}_n^2(0,t)+\|\varrho_{ntt}'(\cdot,t)\|^2\right]\mathrm{d}\,t=\int_0^\tau\mathcal{E}(\rho_n,\varrho_n)(t)\mathrm{d}t.$$

Since the operator Λ is compact, there are $\rho\in H^2(Q_\tau)$ and $\varrho\in H^{1,2}(Q_\tau)\cap H^2(Q_\tau)$ such that (by taking a subsequence)

$$\rho_n\to\rho\quad\text{weakly in } H^2(Q_\tau), \tag{4.40}$$

$$\Lambda\rho_n\to\Lambda\rho\quad\text{strongly in } H^2(Q_\tau), \tag{4.41}$$

$$\varrho_n\to\varrho\quad\text{weakly in } H^{1,2}(Q_\tau). \tag{4.42}$$

Moreover, it is easy to check that (ρ_n,ϱ_n) and φ_n satisfy for $(x,t)\in Q_\tau$

$$\begin{cases}\rho_{nt}=\mathcal{N}(\varphi_n)\varrho_n'',\\ \varrho_{nt}=\kappa\varrho_{nt}''-\rho_n'',\\ \rho_n(L,t)=\varrho_n(L,t)=\varrho_n''(L,t)=0,\\ \rho_n(0,t)=b_1[\mu_{n1}(t)+\nu_{1n}(t)],\\ \varrho_n'(0,t)=b_1^{-1}[\nu_{1n}(t)-\mu_{1n}(t)],\\ \rho_n'(0,t)-\kappa\varrho_{nt}'(0,t)=b_2[\mu_{2n}(t)+\nu_{2n}(t)],\\ \varrho_n(0,t)=b_2^{-1}[\mu_{n2}(t)-\nu_{2n}(t)].\end{cases} \tag{4.43}$$

Therefore, the relations (4.36), (4.37), (4.39), and (4.40)–(4.43) imply that

$$(\rho, \varrho) \in H^2(Q_\tau) \times [H^{1,2}(Q_\tau) \cap H^2(Q_\tau)]$$

solves the following linear boundary-value problem for $(x,t) \in Q_\tau$:

$$\begin{cases} \rho_t = \mathcal{N}(0)\varrho'', \\ \varrho_t = \kappa\varrho_t'' - \rho'', \\ \rho(L,t) = \varrho(L,t) = \varrho''(L,t) = 0, \\ \rho(0,t) = \varrho(0,t) = 0, \\ \rho'(0,t) = \varrho'(0,t) = 0. \end{cases} \tag{4.44}$$

However, since $\tau > 2T_{\xi_-,\xi_+}$ it is easy to check that the linear problem (4.44) has only the zero solution, i.e., $(\rho, \varrho) = 0$ on Q_τ. This is a contradiction, since (4.38) and (4.41) imply $\int_0^\tau \mathbf{h}(\Lambda\rho, t)\mathrm{d}t = 1$. □

Remark 4.4. To guarantee that the problem (4.44) has only the zero solution, it is enough to assume that (4.44) holds on Q_{T_0}, where $T_0 > 2T_{\xi_-,\xi_+}$.

Proof of Theorem 4.1. It suffices to prove the inequality (4.3) for $s = 0$. We use a trick from Feng and Feng [5]. From Lemma 4.4 we see that (4.3) is true for $s = 0$ if we can find $C(\xi_-, \xi_+, \varsigma) > 0$ such that for $3T_{\xi_-,\xi_+} \le t \le T$

$$\int_0^t \mathbf{h}(\Lambda\varphi, \nu)\mathrm{d}\nu \le C(\xi_-, \xi_+, \varsigma)\left[\|u\|^2_{H^2(0,t)} + \|y\|^2_{H^2(0,t)} + \int_0^t \left[\mathcal{E}^2(\nu) + \mathcal{E}^{\frac{3}{2}}(\nu)\right]\mathrm{d}\nu\right]. \tag{4.45}$$

In fact, for any $h > 0$, from Lemma 4.5 we have, denoting again $\tau = 3T_{\xi_-,\xi_+}$,

$$\begin{aligned} \int_h^{\tau+h} \mathbf{h}(\Lambda\varphi, t)\mathrm{d}t &= \int_0^\tau \mathbf{h}(\Lambda\varphi_h, t)\mathrm{d}t \\ &\le C(\xi_-, \xi_+, \varsigma)\left[\|u_h\|^2_{H^2(0,\tau)} + \|y_h\|^2_{H^2(0,\tau)} + \int_0^\tau \left[\mathcal{E}_h^2(t) + \mathcal{E}_h^{\frac{3}{2}}(t)\right]\mathrm{d}t\right] \\ &= C(\xi_-, \xi_+, \varsigma)\left[\|u\|^2_{H^2(h,\tau+h)} + \|y\|^2_{H^2(h,\tau+h)}\right] \\ &\quad + C(\xi_-, \xi_+, \varsigma)\int_h^{\tau+h} \left[\mathcal{E}^2(t) + \mathcal{E}^{\frac{3}{2}}(t)\right]\mathrm{d}t, \end{aligned} \tag{4.46}$$

where $\varphi_h(t) = \varphi(t+h)$, $u_h(t) = u(t+h)$, $y_h(t) = y(t+h)$, and $\mathcal{E}_h$ is defined by (1.18) with (φ_h, ψ_h) in place of (φ, ψ). Denote the right-hand side of (4.46) by $I(h, \tau+h)$. Then for $m\tau \le t \le (m+1)\tau$ with $m \ge 2$ an integer, we obtain

$$\begin{aligned} \int_0^t \mathbf{h}(\Lambda\varphi, \nu)\mathrm{d}\nu &\le \int_0^\tau \mathbf{h}(\Lambda\varphi, \nu)\mathrm{d}\nu + \cdots + \int_{(m-1)\tau}^{m\tau} \mathbf{h}(\Lambda\varphi, \nu)\mathrm{d}\nu + \int_{t-\tau}^t \mathbf{h}(\Lambda\varphi, \nu)\mathrm{d}\nu \\ &\le I(0,\tau) + \cdots + I((m-1)\tau,\, m\tau) + I(t-\tau,\ t) \le 2I(0,t), \end{aligned}$$

which is just the inequality (4.45). □

From the definitions (1.18) and (3.9), it is easy to check that if the solution (φ, ψ) of the system (1.11)–(1.12) satisfies $\xi_- \le \varphi \le \xi_+$, then there are $C_1(\xi_-, \xi_+) > 0$ and $C(\xi_-, \xi_+) > 0$ such that

$$C_1(\xi_-, \xi_+)\mathcal{E}(t) \le \Pi(t) \le C(\xi_-, \xi_+)\mathcal{E}(t), \quad 0 \le t \le T. \tag{4.47}$$

For convenience, we rewrite Theorem 4.1 as follows.

THEOREM 4.1*. *Suppose that* $\sigma_- < \xi_- < 0 < \xi_+ < \sigma_+$, $\varsigma > 0$, *and* $T > 3T_{\xi_-,\xi_+}$. *Then there exists a number* $C(\xi_-, \xi_+, \varsigma) > 0$, *which depends on* ξ_-, ξ_+ *and* ς, *such that if the solution* (φ, ψ) *of the system* (1.11)–(1.12) *satisfies the assumptions*

$$\xi_- \le \varphi \le \xi_+, \quad \sup_{0\le t\le T} \Pi(t) \le \varsigma,$$

then for $0 \le s \le t \le T$ *with* $t - s \ge 3T_{\xi_-,\xi_+}$,

$$\int_s^t \Pi(\nu)\mathrm{d}\nu \le C(\xi_-, \xi_+, \varsigma) \left[\|u\|^2_{H^2(s,t)} + \|y\|^2_{H^2(s,t)} + \int_s^t \left[\Pi^2(\nu) + \Pi^{\frac{3}{2}}(\nu)\right] \mathrm{d}\nu \right].$$

5. Global smooth solutions. In this section we establish the existence of the global smooth solutions and the exponential decay of the Sobolev norm for small initial data.

Let $u(t) = (u_1, u_2) \in H^2(0,\infty) \times H^2(0,\infty)$. Suppose that $(\varphi_0, \psi_0) \in H^2(0, L) \times H^3(0, L)$ satisfies the boundary conditions (1.15) and the compatibility conditions (1.16). We assume that (φ, ψ) solves the problem (1.11)–(1.12) on $Q_T = (0, L)\times(0, T)$ for some $T > 0$ such that the regularity (1.17) holds.

Throughout this section we fix ξ such that

$$\sigma_- < -\xi < 0 < \xi < \sigma_+.$$

We introduce some constants that we need later: Let $C(-\xi, \xi) > 0$ be given by Theorem 3.1*, (4.47), and (3.29) for $\xi_- = -\xi$ and $\xi_+ = \xi$. Set

$$\varsigma = \min\left\{1, \frac{1}{C(-\xi,\xi)}, \frac{\xi^2}{2LC(-\xi,\xi)}\right\}.$$

Let $C(-\xi, \xi, \varsigma)$ be given by Theorem 4.1* for $\xi_- = \xi$, $\xi_+ = \xi$, and the above ς. We then fix $\gamma > 0$ small such that

$$\varpi(\gamma) = C^{-1}(-\xi, \xi, \varsigma) - 2[2\gamma + \gamma^{\frac{1}{2}}] > 0, \tag{5.1}$$

$$c(\gamma) = \varpi - 2C(-\xi, \xi)[2\gamma + \gamma^{\frac{1}{2}}] > 0, \tag{5.2}$$

$$T_0(\gamma) = \frac{1}{2C(-\xi,\xi)\gamma^{\frac{1}{2}}} > 3T_{-\xi,\xi}, \tag{5.3}$$

where $T_{-\xi,\xi}$ is given by (4.11) for $\xi_- = \xi$ and $\xi_+ = \xi$.

Proof of Theorem 1.2. We fix

$$0 < \gamma < \varsigma/4 \tag{5.4}$$

such that the inequalities (5.1)–(5.3) hold.

We assume that the initial data (φ_0, ψ_0) and the input u are such that

$$\mathcal{E}(0) + \|u\|^2_{H^2(0,\infty)} < \min\left\{\frac{\xi^2}{2L}, \frac{\gamma}{C(-\xi,\xi)+1}\right\}, \tag{5.5}$$

where $\mathcal{E}(t)$ is given by (1.18).

Step I. We prove that, under the small initial condition (5.5), the problem (1.11)–(1.12) has global solutions. The condition (5.5) yields

$$\sup_{x\in[0,L]}|\varphi_0(x)| \le L^{\frac{1}{2}}\mathcal{E}^{\frac{1}{2}}(0) < \frac{\xi}{\sqrt{2}}, \tag{5.6}$$

which, by Theorem 1.1, implies that the short-time solution (φ,ψ) of the problem (1.11)–(1.12) exists. For $0\le s\le t$, set

$$h(s,t) = \Pi(t) + \|y\|^2_{H^2(s,t)},$$

$$g(s,t) = \Pi(s) + C(-\xi,\xi)\|u\|^2_{H^2(s,t)}. \tag{5.7}$$

By (4.47), (5.5), and (5.4), we have

$$g(0,\infty) \le C(-\xi,\xi)[\mathcal{E}(0) + \|u\|^2_{H^2(0,\infty)}] \le \gamma < \varsigma/4. \tag{5.8}$$

In particular, $\Pi(0)\le\varsigma/4$. This inequality together with (5.6) implies that the local solution must satisfy

$$-\xi\le\varphi\le\xi, \quad x\in[0,L], \quad \Pi(t)\le\varsigma, \tag{5.9}$$

for t in some interval $[0,\delta]$.

Let δ_0 be the largest number such that the estimates in (5.9) hold for $t\in[0,\delta_0)$. We shall prove that $\delta_0=\infty$ by contradiction. Then the problem (1.11)–(1.12) has global solutions under the small initial data condition (5.5).

Let $\delta_0<\infty$. Then (3.36) implies that for $t\in[0,\ \min\{\delta_0,T_0(\gamma)\}]$

$$\begin{aligned} h(0,t) &\le g(0,t) + C(-\xi,\xi)\int_0^t \Pi^{\frac{3}{2}}(\Pi^{\frac{1}{2}}+1)\mathrm{d}t \\ &\le g\left(0,\ \min\{\delta_0,T_0(\gamma)\}\right) + 2C(-\xi,\xi)\int_0^t h^{\frac{3}{2}}(0,t)\mathrm{d}t, \end{aligned} \tag{5.10}$$

since $g(0,\cdot)$ is increasing. By (5.8), we have

$$\min\{\delta_0,T_0(\gamma)\} \le T_0(\gamma) \le \frac{1}{2C(-\xi,\xi)g^{\frac{1}{2}}\left(0,\ \min\{\delta_0,T_0(\gamma)\}\right)}. \tag{5.11}$$

We obtain from (5.8), (5.10), and (5.11) that

$$\begin{aligned} \Pi(t) + \|y\|^2_{H^2(0,t)} &\le g\left(0,\ \min\{\delta_0,T_0(\gamma)\}\right)/[1 - tC(-\xi,\xi)g^{\frac{1}{2}}\left(0,\ \min\{\delta_0,T_0(\gamma)\}\right)]^2 \\ &\le 4g\left(0,\ \min\{\delta_0,T_0(\gamma)\}\right) \le 4\gamma < \varsigma \end{aligned} \tag{5.12}$$

for $0\le t\le\min\{\delta_0,T_0(\gamma)\}$.

We assume that $T_0(\gamma)\ge\delta_0$. Then the inequality (5.12) shows that $\Pi(t)\le 4\gamma<\varsigma$ holds for $0\le t\le\delta_0$, which gives, via (3.29),

$$\begin{aligned} \sup_{0\le x\le L}|\varphi(x,t)| &\le L^{\frac{1}{2}}\mathbf{h}^{\frac{1}{2}}(\varphi,t) \le [LC(-\xi,\xi)\Pi(t)]^{\frac{1}{2}} \\ &\le 2[LC(-\xi,\xi)]^{\frac{1}{2}}\gamma^{\frac{1}{2}} \le \frac{\xi}{\sqrt{2}}, \quad 0\le t\le\delta_0. \end{aligned}$$

Then the conditions (5.9) are true for $t \in [0, \delta_1)$ with $\delta_1 > \delta_0$. This is a contradiction. Thus, we obtain that $T_0(\gamma) < \delta_0$.

Now the inequality (5.12) implies

$$\Pi(t) \le 4\gamma, \quad 0 \le t \le T_0(\gamma). \tag{5.13}$$

We apply Theorem 4.1* to give for $T_0(\gamma) \ge t \ge 3T_{-\xi,\xi}$

$$\varpi \int_0^t \Pi(t)dt \le \|u\|^2_{H^2(0,t)} + \|y\|^2_{H^2(0,t)}. \tag{5.14}$$

We then add the inequalities (3.36) with $\xi_- = -\xi$, $\xi_+ = \xi$, and (5.14) to deduce from (5.13) that, for $3T_{-\xi,\xi} \le t \le T_0(\gamma)$,

$$\begin{aligned} &\Pi(t) + \varpi \int_0^t \Pi(\tau)\mathrm{d}\tau + \|y\|^2_{H^2(0,t)} \\ &\quad \le \Pi(0) + [C(-\xi,\xi)+1]\|u\|^2_{H^2(0,t)} + \|y\|^2_{H^2(0,t)} \\ &\quad\quad + 2C(-\xi,\xi)[2\gamma + \gamma^{\frac{1}{2}}] \int_0^t \Pi(\tau)\mathrm{d}\tau, \end{aligned} \tag{5.15}$$

that is,

$$\Pi(t) + c(\gamma) \int_0^t \Pi(\tau)d\tau \le \Pi(0) + [C(-\xi,\xi)+1]\,\|u\|^2_{H^2(0,t)}, \tag{5.16}$$

for $3T_{-\xi,\xi} \le t \le T_0(\gamma)$. From (5.7), (5.16), (4.47), and (5.5) we have

$$\begin{aligned} g\,(T_0(\gamma),\,\infty) &\le \Pi(0) + [C(-\xi,\xi)+1]\,\|u\|^2_{H^2(0,T_0(\gamma))} + C(-\xi,\xi)\|u\|^2_{H^2(T_0(\gamma),\infty)} \\ &\le \Pi(0) + [C(-\xi,\xi)+1]\,\|u\|^2_{H^2(0,\infty)} \\ &\le C(-\xi,\xi)\mathcal{E}(0) + [C(-\xi,\xi)+1]\,\|u\|^2_{H^2(0,\infty)} \le \gamma. \end{aligned}$$

Next, we restart the above procedure from $g\,(T_0(\gamma),\infty) < \gamma$ and using $T_0(\gamma) \le t \le 2T_0(\gamma)$ instead of $0 \le t \le T_0(\gamma)$ and we arrive at

$$2T_0(\gamma) < \delta_0.$$

If we continue, by induction we obtain that for any $k \in \mathbb{N}$,

$$kT_0(\gamma) < \delta_0.$$

This is also a contradiction.

Step II. By Step I, under the condition (5.5), the estimates (5.9) hold for all $t \in [0,\infty)$. In the interval $[0,\infty)$ we apply Theorems 3.1* and 4.1* and, by the extension from $[iT_0(\gamma),\ (i+1)T_0(\gamma)]$ to $[(i+1)T_0(\gamma),\ (i+2)T_0(\gamma)]$ for $i \ge 0$, obtain that the inequality (5.12) holds for all $t \in [0,\infty)$. Then, an argument similar to that for (5.16) yields that for $t \in [3T_{-\xi,\xi},\infty)$,

$$\Pi(t) + c(\gamma) \int_0^t \Pi(\tau)\mathrm{d}\tau \le \Pi(0) + [C(-\xi,\xi)+1]\,\|u\|^2_{H^2(0,t)}.$$

By (4.47), the proof is complete. ∎

Proof of Theorem 1.3. Let the input u satisfy

$$u(t) = 0 \quad \forall\, t \geq T_0.$$

We repeat the argument in the proof of Theorem 1.2 for $s \geq t \geq T_0$ to obtain that for $s \geq t \geq T_0$,

$$\Pi(s) + c(\gamma) \int_t^s \Pi(\tau) d\tau \leq \Pi(t) + [C(-\xi, \xi) + 1] \|u\|^2_{H^2(t,\infty)} = \Pi(t),$$

which yields

$$\Pi(t) \leq \Pi(T_0) e^{-c(\gamma)(t-T_0)} \qquad \forall\, t \geq T_0.$$

The decay rate estimate (1.24) is true because of the inequality (4.47). ∎

FROM DIFFERENTIAL CALCULUS TO 0-1 TOPOLOGICAL OPTIMIZATION*

MAATOUG HASSINE†, SOPHIE JAN‡, AND MOHAMED MASMOUDI‡

Abstract. The topological asymptotic expansion gives the variation of a cost function when a small hole is created in a domain. This approach leads to very powerful algorithms in topological optimization. Unfortunately, these asymptotic expansions are obtained with the use of complicated mathematical tools. The goal of this paper is to provide a straightforward way to derive a topological asymptotic expansion using a classical gradient. We will illustrate this general approach by some numerical experiments for the elasticity and the Stokes problems.

Key words. topological gradient, classical gradient, shape optimization, topological optimization, differential calculus

1. Introduction.

The topological sensitivity analysis consists of studying the variation of a cost function with respect to a modification of the topology of a domain, such as the inclusion of holes or insertion of obstacles. It also provides an asymptotic expansion of a cost function with respect to a finite perturbation of the physical properties in a small region of the domain.

In order to present the basic idea, let us consider a domain Ω of $\mathbb{R}^d$, $d = 1, 2, 3$, and a cost function $j(\Omega) = J(\Omega, u_\Omega)$ which is to be minimized. We denote by u_Ω the solution to a given PDE (partial differential equation) problem for $d = 2, 3$, or to a differential equation for $d = 1$, defined in Ω. For $\varepsilon > 0$, let $\Omega_\varepsilon = \Omega \backslash \overline{(x_0 + \varepsilon\omega)}$ be the domain obtained by removing a small part $\overline{(x_0 + \varepsilon\omega)}$ from Ω, where $x_0 \in \Omega$ and $\omega \subset \mathbb{R}^d$ is a fixed bounded domain containing the origin. Then, an asymptotic expansion of the function j is obtained in the following form:

$$j(\Omega_\varepsilon) = j(\Omega) + \rho(\varepsilon) g(x_0) + o(\rho(\varepsilon)),$$

where $\rho(\varepsilon)$ is a scalar positive function going to zero with ε. This expression is called the topological asymptotic expansion and g the topological gradient. The function g is very easy to compute. In order to minimize the cost function, the best location to insert a small hole in Ω is where g is negative. In fact if $g(x_0) < 0$, we have $j(\Omega_\varepsilon) < j(\Omega)$ for small ε. The function g can be used as a descent direction of the domain optimization process.

The optimality condition $g(x_0) \geq 0$ in the domain coincides with the one obtained by Buttazzo and Dal Maso [12] for the Laplace equation using the homogenization theory. The notion of topological asymptotic expansion allows us to build fast numerical algorithms that can solve a large class of problems in applications.

In structural mechanics the total energy variation with respect to the creation of a small hole is well known [25]. Schumacher [35] introduced the bubble method that

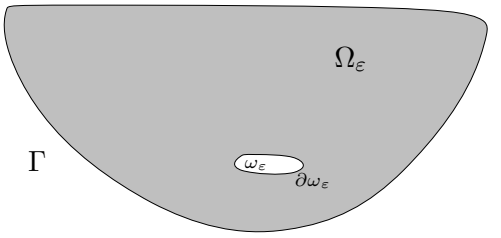

FIG. 1. *The perturbed domain* Ω_ε.

uses this energy variation for topological optimization. Then Sokołowski [36] extended this idea to more general cost functions using the adjoint approach but still with a Neumann boundary condition. A topological sensitivity framework allowing us to consider a Dirichlet condition on the boundary of the hole has been introduced in [29]. The key ideas in this work are to use a generalized Lagrangian method and a domain truncation technique to obtain a fixed functional space. The fundamental property of an adjoint method [13, 29] is to provide the variation of a function with respect to a parameter using a solution u_Ω and an adjoint state v_Ω which do not depend on the chosen parameters. From the numerical point of view, only two problems have to be solved to obtain $g(x)$ for all $x \in \Omega$. This observation leads to very efficient numerical algorithms. The work in [29] has been generalized to the elasticity equations in the case of arbitrarily shaped holes and a Neumann boundary condition [20].

Recently, similar results have been obtained using a Dirichlet boundary condition and noncircular holes in the Poisson equation [23], Stokes equations [24], quasi-Stokes equations [26], Helmholtz equations [8, 33], and Navier–Stokes equations [7]. One can remark that in all these papers the topological gradient has the same expression. Such a result can be interpreted by the fact that all these operators have the same principal part. It is proved that when J is an integral over the boundary, we have $g(x) = u_\Omega(x).v_\Omega(x)$. Others terms may appear if J involves ∇u_Ω at x.

The goal of this paper is to provide an easy way to obtain this type of topological sensitivity in the case of Dirichlet boundary conditions. We will show that it is possible, under weak assumptions, to derive topological asymptotic expansion using differential calculus. Also, when these hypotheses do not hold, the classical gradient [22, 28, 32, 34] provides a "topological descent direction." More precisely, let us consider the following elliptic problem:

$$-\mathrm{div}(\alpha\nabla u) + c\,u = F \text{ in } \Omega,$$

where α and c are two functions defined in Ω.

Let ω_ε be a small domain included in Ω (see Figure 1). We suppose that ω_ε has the form $\omega_\varepsilon = x_0 + \varepsilon\omega$, where $x_0 \in \Omega$, $\varepsilon > 0$, and where ω is a given fixed open and bounded domain of $\mathbb{R}^d$, containing the origin, whose boundary $\partial\omega$ is connected and of class $\mathcal{C}^1$. Our aim is to derive topological sensitivity information from the classical gradient with respect to α or c. If α goes to zero in ω_ε, for a given ε, the corresponding solution u_α tends to the solution u_ε of the following problem:

$$-\mathrm{div}(\alpha\nabla u_\varepsilon) + c\,u_\varepsilon = F \text{ in } \Omega_\varepsilon,$$

with a Neumann boundary condition $\partial_n u_\varepsilon = 0$ on $\partial\omega_\varepsilon$.

If c goes to infinity in ω_ε, for a given ε, the corresponding solution u_c tends to the solution u_ε of the following problem:

$$-\mathrm{div}(\alpha\nabla u_\varepsilon) + c\,u_\varepsilon = F \text{ in } \Omega_\varepsilon,$$

with a Dirichlet boundary condition $u_\varepsilon = 0$ on $\partial\omega_\varepsilon$. This reminds us of the well-known penalization technique used in the finite element method for the implementation of a Dirichlet condition.

We will show in subsection 2.1 that the gradient with respect to c is equal to the topological gradient in the case of a Dirichlet condition. To this end, we will consider a topological perturbation δc_ε of the form

$$\delta c_\varepsilon(x) = \begin{cases} \kappa \text{ if } x \in \omega_\varepsilon, \\ 0 \text{ if } x \in \Omega\backslash\overline{\omega_\varepsilon}, \end{cases}$$

where κ is a constant and $\varepsilon > 0$ is small enough.

This perturbation is small in $L^p(\Omega)$ for $1 \le p < +\infty$, and the variation $f(c + \delta c_\varepsilon) - f(c)$ of a given differentiable functional f defined on $L^p(\Omega)$ can be estimated by a classical gradient. But this result is not valid for the gradient with respect to α. We will give some counterexamples in subsections 2.2 and 2.3, where the classical gradient is not equal to the topological gradient but still provides a "topological descent direction." Some numerical results are given for the elasticity problem in section 3 and for the Stokes problem in section 4.

2. From classical gradient to topological sensitivity. Let $1 \le p < +\infty$. We denote by f a differentiable functional on $L^p(\Omega)$,

$$\begin{array}{ccc} f : L^p(\Omega) & \to & \mathbb{R}, \\ c & \mapsto & f(c), \end{array} \tag{2.1}$$

and we denote by g the Riesz representation of its differential $f'(c)$.

Then for all $\delta c \in L^p(\Omega)$, we have

$$f'(c)\delta c = \int_\Omega g(x)\,\delta c(x)dx.$$

Now, we wish to study the variation of the functional f with respect to a finite topological perturbation δc_ε of c.

We make the following assumptions.

HYPOTHESIS 2.1.

- *The function f is differentiable, and there exists a constant $\gamma_1 > 0$ such that*

$$\forall c \in L^p(\Omega), \quad \Big|f(c+\delta c) - f(c) - f'(c)\delta c\Big| \le \gamma_1 \|\delta c\|^2_{L^p(\Omega)} \quad \forall \delta c \in L^p(\Omega). \tag{2.2}$$

- *The function g is Lipschitz continuous, that is, there exists a constant $\gamma_2 > 0$ such that*

$$|g(x) - g(y)| \le \gamma_2 \|x - y\| \quad \forall\, x, y \in \Omega. \tag{2.3}$$

The following theorem gives the variation of f.

THEOREM 2.2. *If f is differentiable on $L^p(\Omega)$ with $1 \le p < 2$ and if Hypothesis 2.1 holds, then we have*

$$f(c + \delta c_\varepsilon) - f(c) = \kappa\rho(\varepsilon)g(x_0) + o\Big(\rho(\varepsilon)\Big), \tag{2.4}$$

where $\rho(\varepsilon) = meas(\omega_\varepsilon)$. The function g is called the topological gradient.

Proof. First, we have

$$|f(c+\delta c_\varepsilon) - f(c) - \kappa\rho(\varepsilon)g(x_0)| \leq |f(c+\delta c_\varepsilon) - f(c) - f'(c)\delta c_\varepsilon| + |f'(c)\delta c_\varepsilon - \kappa\rho(\varepsilon)g(x_0)|. \tag{2.5}$$

Thanks to (2.2), we derive

$$|f(c+\delta c_\varepsilon) - f(c) - f'(c)\delta c_\varepsilon| \leq \gamma_1 \|\delta c_\varepsilon\|^2_{L^p(\Omega)}.$$

Using the fact that $p < 2$, we obtain

$$\|\delta c_\varepsilon\|^2_{L^p(\Omega)} = \kappa^2(\rho(\varepsilon)^{1/p})^2 = \kappa^2\rho(\varepsilon)^{2/p} = o\Big(\rho(\varepsilon)\Big).$$

Therefore

$$|f(c+\delta c_\varepsilon) - f(c) - f'(c)\delta c_\varepsilon| = o\Big(\rho(\varepsilon)\Big). \tag{2.6}$$

For the second part in (2.5), we have

$$\left|\int_\Omega g(x)\,\delta c_\varepsilon(x)dx - \kappa\rho(\varepsilon)g(x_0)\right| = \left|\int_\Omega \Big(g(x) - g(x_0)\Big)\,\delta c_\varepsilon(x)dx\right|.$$

It follows from (2.3) that

$$\begin{aligned}\left|\int_\Omega g(x)\,\delta c_\varepsilon(x)dx - \kappa\rho(\varepsilon)g(x_0)\right| &\leq \gamma_2\int_\Omega \|x-x_0\|\,|\delta c_\varepsilon(x)|\,dx = \gamma_2\,|\kappa|\int_{\omega_\varepsilon}\|x-x_0\|\,dx \\ &\leq \gamma_2\,|\kappa|\,\varepsilon\rho(\varepsilon).\end{aligned} \tag{2.7}$$

Finally, using (2.5), (2.6), and (2.7), we deduce the desired result. ∎

2.1. The Dirichlet condition. Consider a Hilbert space $\mathcal{V} \subset H^1(\Omega)^d$. Let a be a bilinear, symmetric, continuous, and coercive form on $\mathcal{V}$, and let l be a linear and continuous form on $\mathcal{V}$; that is, there exist constants $M > 0$, $\gamma > 0$, and $L > 0$ such that

$$\begin{aligned} a(u\,,\,v) &\leq M\,\|u\|\,\|v\| && \forall u,\, v \in \mathcal{V},\\ a(u\,,\,u) &\geq \gamma\,\|u\|^2 && \forall u \in \mathcal{V},\\ l(v) &\leq L\,\|v\| && \forall v \in \mathcal{V}.\end{aligned}$$

For all $c \in L^p(\Omega)$, we denote by a_c the following bilinear form:

$$\begin{aligned} a_c:\quad \mathcal{V}\times\mathcal{V} &\longrightarrow \mathbb{R},\\ (u,v) &\longmapsto a_c(u,v) = a(u,v) + \int_\Omega c(x)u(x).v(x)dx.\end{aligned}$$

We have the following lemma.

LEMMA 2.3. *The map*

$$\begin{aligned} L^p(\Omega) &\longrightarrow \mathcal{L}_2(\mathcal{V}),\\ c &\longmapsto a_c\end{aligned} \tag{2.8}$$

is continuous for $p \geq 1$ if $d = 1$, for $p > 1$ if $d = 2$, and for $p \geq \frac{3}{2}$ if $d = 3$.

Proof. Thanks to Theorem IX.16 from Brezis [11], we know that $H^1(\Omega)^d \subset L^q(\Omega)^d$ for $1 \leq q \leq +\infty$ when $d = 1$, for $1 \leq q < +\infty$ when $d = 2$, and for $1 \leq q \leq 6$ when $d = 3$.

It is well known that if $u \in L^{p_1}(\Omega)$ and $v \in L^{p_2}(\Omega)$, the product $u.v \in L^p(\Omega)$ with $\frac{1}{p} = \frac{1}{p_1} + \frac{1}{p_2}$. So, for all u and v in $L^q(\Omega)^d$, the product $u.v$ belongs to $L^{q/2}(\Omega)$.

Since Ω is bounded, the map $c \mapsto a_c$ is continuous for

$$\frac{1}{p} + \frac{2}{q} \leq 1. \tag{2.9}$$

Then, combining (2.9) and the conditions on q for which we have $H^1(\Omega)^d \subset L^q(\Omega)^d$, we deduce that the map is continuous for $p \geq 1$ if $d = 1$, for $p > 1$ if $d = 2$, and for $p \geq \frac{3}{2}$ if $d = 3$. □

Next, we denote by $u_c \in \mathcal{V}$ the unique solution of the following variational problem:

$$a_c(u_c, v) = l(v) \quad \forall\, v \in \mathcal{V}, \tag{2.10}$$

and we consider the cost function f defined by

$$\begin{array}{rccc} f: & L^p(\Omega) & \longrightarrow & \mathbb{R}, \\ & c & \longmapsto & f(c) = J(u_c), \end{array}$$

where J is a given functional defined on the boundary of Ω.

If J is differentiable, using the Lagrangian method, one can prove that the function f is differentiable, and we have

$$f'(c)\delta c = \int_\Omega \delta c(x) u_c(x).v_c(x)dx \quad \forall \delta c \in L^p(\Omega), \tag{2.11}$$

where u_c is the solution to the direct problem (2.10) and $v_c \in \mathcal{V}$ is the solution to the associated adjoint problem

$$a_c(w, v_c) = -\frac{\partial J}{\partial u}(u_c)w \quad \forall w \in \mathcal{V}. \tag{2.12}$$

From relation (2.11), we deduce the Riesz representation g of the differential $f'(c)$:

$$g = u_c.v_c.$$

The regularity of g depends on that of the bilinear form a, the linear mapping l, and the functional J.

Let us now consider the following particular case:

$$c \equiv 0 \text{ and } \delta c = \delta c_\varepsilon.$$

Denoting $j(\varepsilon) = J(u_{\delta c_\varepsilon})$ and using Theorem 2.2, we deduce the following result.

PROPOSITION 2.4. *The cost function j has the following asymptotic expansion:*

$$j(\varepsilon) - j(0) = \kappa\, \rho(\varepsilon)\, u_0.v_0 + o(\rho(\varepsilon)). \tag{2.13}$$

When κ is large, the solution $u_{\delta c_\varepsilon}$ is close to zero in ω_ε. Using the penalization technique, this corresponds to a good approximation of the solution in $\Omega \backslash \overline{\omega_\varepsilon}$ with a Dirichlet condition on the boundary of the hole ω_ε. The topological gradient $g = u_0.v_0$ is exactly what we obtain by a much more complicated approach (see [7, 8, 19, 20, 23, 24, 26]).

2.2. Analytical examples. We consider here two one-dimensional examples for which the solution can be calculated explicitly. In the first, we give an example in which the classical gradient is equal to the topological gradient. In the second, we consider the case when the classical gradient and the topological one are different.

2.2.1. First example. Consider the following one-dimensional elliptic state equation:

$$\left\{\begin{array}{rcl} -u''(x)+c(x)u(x) &=& 0 \quad \text{for } x\in]0,1[,\\ u(0) &=& 0,\\ u'(1) &=& 1. \end{array}\right. \tag{2.14}$$

One can show that (2.14) have the following variational formulation:

$$\left\{\begin{array}{l} \text{find } u\in\mathcal{V} \text{ such that}\\ \displaystyle\int_0^1 u'(x)w'(x)dx+\int_0^1 c(x)u(x)w(x)dx=w(1) \quad \forall\, w\in\mathcal{V}, \end{array}\right. \tag{2.15}$$

where $\mathcal{V}=\{w\in H^1(\Omega): w(0)=0\}$.

If c is in $L^1([0,1])$, thanks to the Lax–Milgram theorem, problem (2.15) admits a unique solution. We denote this solution by u_c.

We now want to minimize the functional

$$\begin{array}{rccc} f: & L^1([0,1]) & \longrightarrow & \mathbb{R},\\ & c & \longmapsto & u_c(1). \end{array}$$

The associated Lagrangian is given by

$$L(c,u,w)=u(1)+\int_0^1 u'(x)w'(x)dx+\int_0^1 c(x)u(x)w(x)dx-w(1).$$

Using (2.15), we deduce

$$L(c,u_c,w)=f(c) \quad \forall w\in\mathcal{V}.$$

Therefore,

$$f'(c)\delta c=\frac{\partial L}{\partial c}(c,u_c,w)\delta c+\frac{\partial L}{\partial u}(c,u_c,w)\frac{\partial u_c}{\partial c}\delta c \quad \forall w\in\mathcal{V}.$$

We denote by v_c the solution to the adjoint problem

$$\frac{\partial L}{\partial u}(c,u_c,v_c)w=0 \quad \forall w\in\mathcal{V}.$$

Then, $v_c\in\mathcal{V}$ is a solution to

$$w(1)+\int_0^1 w'(x)v_c'(x)dx+\int_0^1 c(x)w(x)v_c(x)dx=0 \quad \forall w\in\mathcal{V}. \tag{2.16}$$

From (2.15) and (2.16), one can observe that $v_c=-u_c$.

Thus, we derive

$$f'(c)\delta c=\frac{\partial L}{\partial c}(c,u_c,v_c)\delta c=-\int_0^1 \delta c(x)\,u_c^2(x)dx.$$

Let δc_ε be the characteristic function of $[x_0, x_0+\varepsilon]$:

$$\delta c_\varepsilon = \begin{cases} 1 & \text{if } x \in [x_0, x_0+\varepsilon], \\ 0 & \text{elsewhere.} \end{cases}$$

Then, using Theorem 2.2, we derive

$$f(c+\delta c_\varepsilon) - f(c) = \varepsilon\Big(- u_c(x_0)^2\Big) + o(\varepsilon).$$

Recall that $j(\varepsilon) = J(u_{\delta c_\varepsilon}) = f(\delta c_\varepsilon)$.

In the particular case when $c \equiv 0$, the function j has the following asymptotic expansion:

$$j(\varepsilon) - j(0) = \varepsilon\Big(- u_0(x_0)^2\Big) + o(\varepsilon). \tag{2.17}$$

But, in this simple case, the solution of (2.14) can be calculated explicitly: we have $u_0(x) = x$, for all $x \in]0,1[$.

Equation (2.17) can thus be rewritten as

$$j(\varepsilon) - j(0) = \varepsilon(-x_0^2) + o(\varepsilon). \tag{2.18}$$

In the case when $c = \delta c_\varepsilon$, the solution $u_{\delta c_\varepsilon}$ is given by

$$u_{\delta c_\varepsilon}(x) = \begin{cases} \dfrac{2x}{(x_0+1)e^{\varepsilon} - (x_0-1)e^{-\varepsilon}} & \text{if } x \in [0, x_0], \\ \dfrac{(x_0+1)e^{x-x_0} + (x_0-1)e^{-(x-x_0)}}{(x_0+1)e^{\varepsilon} - (x_0-1)e^{-\varepsilon}} & \text{if } x \in [x_0, x_0+\varepsilon], \\ x - (x_0+\varepsilon) + \dfrac{(x_0+1)e^{\varepsilon} + (x_0-1)e^{-\varepsilon}}{(x_0+1)e^{\varepsilon} - (x_0-1)e^{-\varepsilon}} & \text{if } x \in [x_0+\varepsilon, 1]. \end{cases}$$

Therefore,

$$\begin{aligned} j(\varepsilon) - j(0) = u_{\delta c_\varepsilon}(1) - u_0(1) &= -(x_0+\varepsilon) + \frac{(x_0+1)e^{\varepsilon} + (x_0-1)e^{-\varepsilon}}{(x_0+1)e^{\varepsilon} - (x_0-1)e^{-\varepsilon}} \\ &= -x_0^2\varepsilon + (-1+x_0^2)x_0\varepsilon^2 + o(\varepsilon^2). \end{aligned}$$

We obtain the same result as in (2.18) which confirms that given by Theorem 2.2.

2.2.2. Second example. Let us consider the following problem:

$$\begin{cases} \Big(c(x)u'(x)\Big)' &= 0 \quad \text{for } x \in]0,1[, \\ u(0) &= 0, \\ c(1)u'(1) &= 1, \end{cases} \tag{2.19}$$

which admits the following variational formulation:

$$\text{find } u \in \mathcal{V} \text{ such that } \forall\, w \in \mathcal{V}, \quad \int_0^1 c(x)u'(x)w'(x)dx = w(1), \tag{2.20}$$

where $\mathcal{V} = \{w \in H^1(\Omega) : w(0) = 0\}$.

If c is in $L^\infty([0,1])$ and there exists $\gamma > 0$ such that $c \geq \gamma > 0$, thanks to the Lax–Milgram theorem, problem (2.20) admits a unique solution $u_c \in \mathcal{V}$.

Next, we want to minimize the following functional:

$$f: \begin{array}{ccc} L^\infty([0,1]) & \longrightarrow & \mathbb{R}, \\ c & \longmapsto & u_c(1). \end{array} \tag{2.21}$$

The associated Lagrangian is defined by

$$L(c,u,w) = u(1) + \int_0^1 c(x)u'(x)w'(x)dx - w(1).$$

Taking into account that u_c is the solution to (2.20), we have $L(c,u_c,w) = f(c)$ for all $w \in \mathcal{V}$. Therefore,

$$f'(c)\delta c = \frac{\partial L}{\partial c}(c,u_c,w)\delta c + \frac{\partial L}{\partial u}(c,u_c,w)\frac{\partial u_c}{\partial c}\delta c \quad \forall w \in \mathcal{V}.$$

Let $v_c \in \mathcal{V}$ be the solution to the associated adjoint problem; then v_c satisfies

$$\left\{ \begin{array}{l} v_c \in \mathcal{V}, \\ w(1) + \displaystyle\int_0^1 c(x)w'(x)v_c'(x)dx = 0 \quad \forall w \in \mathcal{V}. \end{array} \right. \tag{2.22}$$

As in the first example, from (2.20) and (2.22) we deduce that $v_c = -u_c$, which implies

$$f'(c)\delta c = \frac{\partial L}{\partial c}(c,u_c,v_c)\delta c = -\int_0^1 \delta c(x)\Big(u_c'(x)\Big)^2 dx.$$

As a consequence, the classical gradient is given by $g = -(u_c')^2$.

Let us consider the perturbation

$$\delta c_\varepsilon(x) = \left\{ \begin{array}{ll} \kappa & \text{if } x \in [x_0, x_0+\varepsilon], \\ 0 & \text{elsewhere,} \end{array} \right.$$

with $\kappa \in \mathbb{R}$ a fixed given constant.

As in the previous case, we can use analytic calculus.

Let c_0 be a constant in $\mathbb{R}$. Then if $c \equiv c_0$, the solution of (2.19) is given by $u_0(x) = \frac{x}{c_0}$.

If $c = c_0 + \delta c_\varepsilon$, the solution $u_{c_0+\delta c_\varepsilon}$ of (2.19) has the following expression

$$u_{c_0+\delta c_\varepsilon}(x) = \left\{ \begin{array}{ll} \dfrac{x}{c_0} & \text{if } x \in [0,x_0], \\ \dfrac{x-x_0}{c_0+\kappa} + \dfrac{x}{c_0} & \text{if } x \in [x_0, x_0+\varepsilon], \\ \dfrac{x-\varepsilon}{c_0} + \dfrac{\varepsilon}{c_0+\kappa} & \text{if } x \in [x_0+\varepsilon, 1]. \end{array} \right.$$

Therefore,

$$j(\varepsilon) - j(0) = f(c_0+\delta c_\varepsilon) - f(c_0) = \varepsilon\left(\frac{1}{c_0+\kappa} - \frac{1}{c_0}\right) = \frac{-\kappa\varepsilon}{c_0^2 + \kappa c_0}. \tag{2.23}$$

The assumptions of Theorem 2.2 are not satisfied in this case, since the map f (see (2.21)) is differentiable on $L^p([0,1])$ only for $p = +\infty$. But if they were, we should have

$$j(\varepsilon) - j(0) = -\frac{\kappa\varepsilon}{c_0^2} + o(\varepsilon). \tag{2.24}$$

Here is an example in which the classical gradient (2.24) is different from the topological gradient (2.23). These two expressions are close when κ is small, but this is no more the case when κ is close to $-c_0$. However, when $\kappa > -c_0$, both expressions have the same sign. Thus, the classical gradient could be seen as a "topological descent direction."

2.3. Another example: The Maxwell problem. We consider the Maxwell equations in a domain $\Omega \subset \mathbb{R}^3$ containing a small inhomogeneity ω_ε. We denote by H_ε the magnetic field. It is the solution to

$$\left\{ \begin{array}{ll} \nabla \times (\alpha_\varepsilon \nabla \times H_\varepsilon) + \beta_\varepsilon H_\varepsilon = 0 & \text{in } \Omega, \\ \alpha_\varepsilon (\nabla \times H_\varepsilon) \times \mathbf{n} = \phi & \text{on } \partial\Omega. \end{array} \right. \tag{2.25}$$

Here, $\mathbf{n}$ denotes the outward normal to $\partial\Omega$, and the functions α_ε and β_ε are given by

$$\alpha_\varepsilon = \left\{ \begin{array}{ll} \alpha_0 & \text{in } \Omega \backslash \overline{\omega_\varepsilon}, \\ \alpha_1 & \text{in } \omega_\varepsilon, \end{array} \right. \qquad \beta_\varepsilon = \left\{ \begin{array}{ll} \beta_0 & \text{in } \Omega \backslash \overline{\omega_\varepsilon}, \\ \beta_1 & \text{in } \omega_\varepsilon, \end{array} \right.$$

where α_0, α_1, β_0, and β_1 are positive constants.

A sensitivity analysis with respect to the presence of small inhomogeneities for the Maxwell equations is given in [4, 5, 6, 30]. A topological asymptotic expansion is derived in [30] when inserting a dielectric object and when creating a small hole. In the case of a spherical metallic object, it is proved that the topological gradient is given by

$$g(H_0, v_0) = \mathcal{R}e\Big(-2\nabla \times H_0 . \overline{\nabla \times v_0} + k^2 \, H_0 . \overline{v_0} \Big),$$

where $H_0 \in H(curl, \Omega) = \{u \in L^2(\Omega)^3;\ \nabla \times u \in L^2(\Omega)^3\}$ is the magnetic field in the absence of any inhomogeneities, v_0 is the solution to the associated adjoint problem, and k is the wave number. As we observe, the topological gradient $g(H_0, v_0)$ is not equal to the classical gradient $g_c(H_0, v_0) = \mathcal{R}e(-2\nabla \times H_0 . \overline{\nabla \times v_0})$. The reason for this is that $H(curl, \Omega)$ is a subset of $L^2(\Omega)^3$, but not a subset of $L^p(\Omega)^3$ for $p < 2$.

The numerical experiments that are performed in [30] show that it is possible to obtain satisfying results using the classical gradient instead of the topological one.

3. Application to the elasticity problem. The linear elasticity problem [17, 20] is described by the following system:

$$\left\{ \begin{array}{rcl} -\operatorname{div}\sigma(u) = & 0 & \text{in } \Omega, \\ \sigma(u).\mathbf{n} = & T_N & \text{in } \Gamma_N, \\ u = & 0 & \text{in } \Gamma_D, \end{array} \right. \tag{3.1}$$

where u is the displacement, $(\sigma_{ij})_{1 \le i,j \le d}$ $(d = 2, 3)$ is the stress tensor

$$\sigma_{ij}(u) = \lambda \operatorname{div} u \, \delta_{ij} + 2\mu \varepsilon_{ij}(u),$$

λ and μ are the Lamé coefficients, and $(\varepsilon_{ij})_{1 \le i,j \le d}$ is the strain tensor

$$\varepsilon_{ij}(u) = \frac{1}{2}\Big(\frac{\partial u_i}{\partial x_j} + \frac{\partial u_j}{\partial x_i} \Big), \quad 1 \le i, j \le d.$$

Here δ_{ij} is the Kronecker symbol, and $\mathbf{n}$ denotes the outward normal to the boundary $\partial\Omega = \Gamma_D \cup \Gamma_N$, where both Γ_D and Γ_N have a nonnegative Lebesgue

TABLE 1
Expressions of the topological gradient.

Boundary condition on $\partial\omega_\varepsilon$	Topological gradient g
2D Dirichlet	$-\dfrac{4\pi\mu(\mu+\eta)}{2\mu+\eta}\,u.v$
3D Dirichlet	$\dfrac{12\pi\mu(\lambda+2\mu)}{2\lambda+5\mu}\,u.v$
2D Neumann	$-\dfrac{\pi(\mu+\eta)}{2\eta\mu}\{4\mu\sigma(u):\varepsilon(v)+(\eta-2\mu)\ \mathrm{tr}\sigma(u)\ \mathrm{tr}\varepsilon(v)\}$
3D Neumann	$-\dfrac{\pi(\lambda+2\mu)}{\mu(9\lambda+14\mu)}\{20\mu\sigma(u):\varepsilon(v)+(3\lambda-2\mu)\ \mathrm{tr}\sigma(u)\ \mathrm{tr}\varepsilon(v)\}$

measure and $\Gamma_D \cap \Gamma_N = \emptyset$. Equations (3.1) describe the displacement u of an isotropic solid which is loaded by a surface traction T_N on Γ_N and which is clamped on Γ_D.

Structural optimization involves relaxed formulations, homogenization, and the level-set method (see, e.g., [1, 2, 3, 9, 16, 27, 31]). In the context of the topological sensitivity analysis, the asymptotic behavior of a design function with respect to the creation of a small hole ω_ε in Ω has been studied in [20]. In the case of a spherical hole, we present in Table 1 the different expressions of the topological sensitivity for the Dirichlet and Neumann boundary conditions in two and three dimensions, where v is the solution to the associated adjoint problem, $\mathrm{tr}\sigma = \sum_i \sigma_{ii}$ is the usual trace operator, and the parameter η is given by

$$\eta = \begin{cases} \dfrac{\mu(3\lambda+2\mu)}{\lambda+2\mu} & \text{plane stress,} \\ \lambda+\mu & \text{plane strain.} \end{cases}$$

One can observe that in both cases, the topological gradient $g(u,v)$ is not equal to the classical gradient, which is given by

$$g_c(u,v) = \sigma(u):\varepsilon(v).$$

However, we will show on a simple two-dimensional plane stress elasticity problem that it is possible to use the classical gradient as a "topological descent direction" in the optimization algorithm. For the sake of completeness, we recall briefly the optimization algorithm we use. For more details, one may consult [7, 8, 19, 20, 23, 24, 26, 33]). We apply an iterative process to build a sequence of geometries $(\Omega_k)_{k\geq 0}$ with $\Omega_0 = \Omega$. At the kth iteration, the topological gradient is denoted by g_k, and the new geometry Ω_{k+1} is defined by a level set curve of g_k.

THE ALGORITHM.

- Initialization: choose $\Omega_0 = \Omega$ and set $k = 0$.
- Repeat until $g_k \geq 0$ in Ω_k:
  - Solve (4.1) and its associated adjoint problem in Ω_k;
  - compute the topological sensitivity g_k;
  - set $\Omega_{k+1} = \{x \in \Omega_k, \quad g_k(x) \geq c_k\}$, where c_k is chosen in such a way that the cost function decreases as most as possible;
  - $k \longleftarrow k+1$.

This algorithm can be seen as a descent method, where the descent direction is determined by the topological sensitivity g_k and the step length is given by the volume variation $meas(\Omega_k \backslash \Omega_{k+1})$.

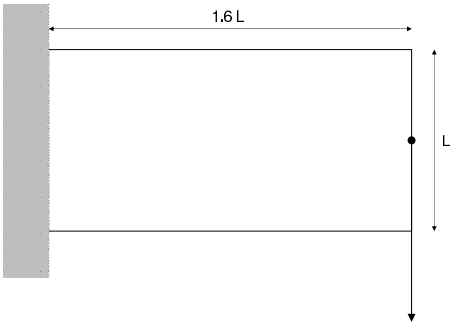

FIG. 2. *2D cantilever beam.*

The natural optimality condition is

$$g_k(x) \geq 0 \quad \forall x \in \Omega_k.$$

It coincides with the one obtained by Buttazzo and Dal Maso [12] for the Laplace equation using homogenization theory. In practice, some other stopping criteria can be successfully implemented, such as the material volume to be removed [14, 20, 23], the number of holes to be inserted [26], or the obstacles number to be detected [24].

We consider here the maximization of the compliance for a two-dimensional cantilever beam represented in Figure 2. The initial domain is a plain rectangle with one edge clamped, and a pointwise load is applied to the middle of the opposite edge. In the numerical results (Figures 3 and 4), 10% of the material is removed at each step, and the optimal domains are obtained when their volumes are less than 40% of the initial one; i.e., after nine iterations. One can observe that the results obtained with the classical gradient are not so different from those obtained with the topological expansion, and this is the case for various materials such as steel or concrete. The reason for this is that the difference between the topological gradient and the classical one is small.

Other numerical results on some structural shape optimization examples are presented in [20] that show also that it is possible to use the classical gradient as a "topological descent direction" in the optimization algorithm.

4. Application to the Stokes equations. In this section, we consider the Stokes equations case. Let Ω be a bounded domain of $\mathbb{R}^d$, $d = 2, 3$. We denote by Γ its boundary.

4.1. Formulation of the problem. The standard form of the Stokes equations describing the motion of an incompressible fluid in Ω is given by

$$\begin{aligned} -\nu\Delta u + \nabla p &= F \quad \text{in } \Omega, \\ \operatorname{div} u &= 0 \quad \text{in } \Omega, \\ u &= 0 \quad \text{on } \Gamma, \end{aligned} \tag{4.1}$$

where u is the velocity, p is the pressure, F is a given body force per unit of mass, and ν is the kinematic viscosity of the fluid.

One can show that the velocity u satisfies the following variational problem:

$$\begin{cases} \text{find } u \in \mathcal{V} \text{ such that} \\ \quad a(u, w) = l(w) \quad \forall w \in \mathcal{V}, \end{cases} \tag{4.2}$$

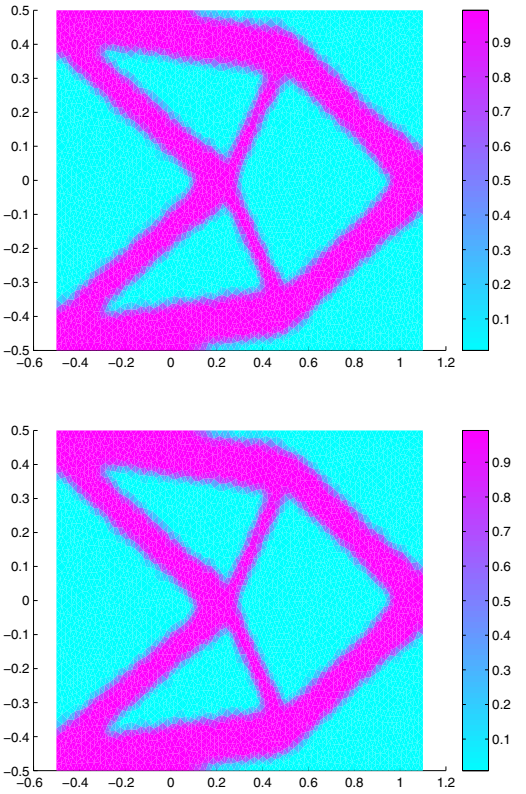

FIG. 3. *Comparison: density obtained by the topological algorithm using the classical gradient (top) and the topological one (bottom).*

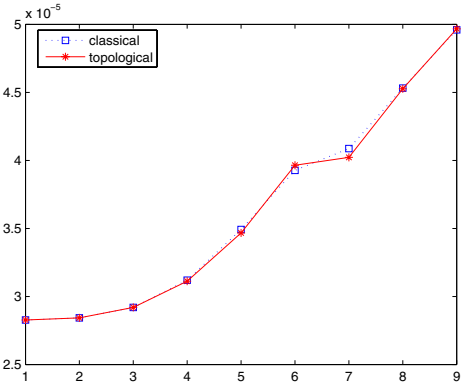

FIG. 4. *Evolution of the compliance with respect to the number of iterations using the classical (square) and the topological (star) gradients.*

with

$$\mathcal{V} = \Big\{ v \in H_0^1(\Omega)^d, \ \text{div } v = 0 \Big\},$$
$$a(v,w) = \nu \int_\Omega \nabla v \nabla w \ \text{dx} \quad \forall v, w \in \mathcal{V},$$
$$l(w) = \int_\Omega F\, w \ \text{dx} \quad \forall w \in \mathcal{V}.$$

It is easy to verify that $\mathcal{V} \subset H^1(\Omega)^d$ is a Hilbert space; a is a bilinear, symmetric, continuous, and coercive form on $\mathcal{V}$; and l is a linear and continuous form on $\mathcal{V}$.

In order to apply the tools presented in section 2, we consider the following penalized problem:

$$\begin{aligned} -\text{ div } (\nu \nabla u_\varepsilon) + \delta c_\varepsilon u_\varepsilon + \nabla p_\varepsilon &= F \quad \text{in } \Omega, \\ \text{div } u_\varepsilon &= 0 \quad \text{in } \Omega, \\ u_\varepsilon &= 0 \quad \text{on } \Gamma, \end{aligned} \tag{4.3}$$

where δc_ε is a piecewise constant function defined in Ω by

$$\delta c_\varepsilon = \begin{cases} \kappa \text{ if } x \in \omega_\varepsilon, \\ 0 \text{ if } x \in \Omega_\varepsilon, \end{cases}$$

with κ a positive constant and $\Omega_\varepsilon = \Omega \backslash \overline{\omega_\varepsilon}$.

Then, if κ goes to infinity in ω_ε, for a given ε, the corresponding solution u_ϵ converges to the solution of the following Stokes system:

$$\begin{aligned} -\nu \Delta u_\varepsilon + \nabla p_\varepsilon &= F \quad \text{in } \Omega_\varepsilon, \\ \text{div } u_\varepsilon &= 0 \quad \text{in } \Omega_\varepsilon, \\ u_\varepsilon &= 0 \quad \text{on } \Gamma, \end{aligned} \tag{4.4}$$

with a Dirichlet condition on the boundary of ω_ε:

$$u_\varepsilon = 0 \text{ on } \partial\omega_\varepsilon.$$

Consider now a cost function

$$j(\varepsilon) = J(u_\varepsilon) \in \mathbb{R},$$

where $u_\varepsilon \in \mathcal{V}$ is the solution to (4.3).

Using Proposition 2.4 (see (2.13)), we derive the asymptotic expansion for j. Then, if J is defined on the boundary of Ω, we have

$$j(\varepsilon) - j(0) = \kappa |\omega| \varepsilon^d u_0 . v_0 + o(\varepsilon^d),$$

where u_0 is the solution to (4.1) and v_0 is the solution to the associated adjoint problem.

Let us recall the topological asymptotic expansion obtained in [7, 24, 26]:

$$j(\varepsilon) - j(0) = m(\varepsilon) u_0 . v_0 + o(m(\varepsilon)).$$

When ω is the unit ball $B(x_0, 1)$, we have $\omega_\varepsilon = B(x_0, \varepsilon)$, and $m(\varepsilon)$ is given by

$$m(\varepsilon) = \begin{cases} \dfrac{-4\pi\nu}{\log(\varepsilon)} & \text{in two dimensions,} \\ \\ 6\pi\nu\varepsilon & \text{in three dimensions.} \end{cases}$$

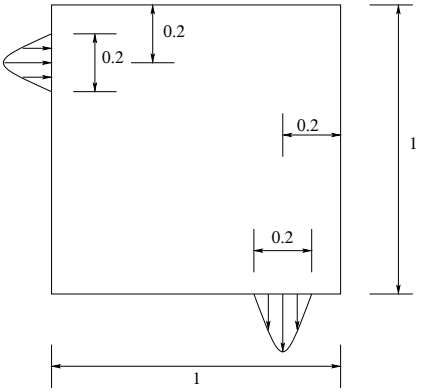

FIG. 5. *Design domain for the pipe bend example.*

We remark that the straightforward method gives the right topological gradient,

$$g(x) = u_0(x).v_0(x), \quad x \in \Omega.$$

From the numerical point of view, the behavior with respect to ε is not so important. In the following subsections, we give some numerical applications of this result.

4.2. Numerical results. Here, we limit ourselves to the two-dimensional case. As an application of the previous theoretical results, we consider in this subsection some engineering applications commonly found in the fluid mechanics literature. In the first part of this subsection we consider two numerical examples that were also considered in [10, 21]. In the second part, we deal with other interesting examples concerning the shape optimization of tubes in a cavity.

Our implementation is based on the topological optimization algorithm recalled in section 3. We proceed by iterations. At each step, we remove the zones in which the topological gradient g_k is nonpositive. In this test case, we stop the process when g_k is positive everywhere. The direct and the adjoint problems are discretized by a finite element method using a Reynolds number $Re = 100$. The computation of the approximate solution is achieved by the Uzawa algorithm.

4.2.1. A comparison. In order to test the advantage of our approach, we compare our results to those obtained in [10, 21]. We consider here two numerical examples. The first one is the pipe bend that is depicted in Figure 5. This test case is treated by Borrvall and Petersson in [10]. The second one is the double pipe shown in Figure 7. It was also considered by Borrvall and Petersson in [10] and recently by Guest and Prévost in [21]. The aim here is to obtain the optimal shape minimizing the dissipated power in the fluid. In both cases the inflow and the outflow conditions are of a prescribed parabolic flow profiles type.

Pipe bend example. We present in Figure 5 the design domain for the pipe bend example. Here the prescribed maximum flow velocity is equal to 1 at the inlet (left) and at the outlet (bottom). The inlet and outlet flows are shown in the figure, and velocity is prescribed to be zero elsewhere on the boundary of the domain. The results of this example are obtained in only three iterations. We present the geometries obtained during the optimization process in Figure 6. The optimal solution is nearly identical to those presented in [10]. However, we obtain this result in three iterations,

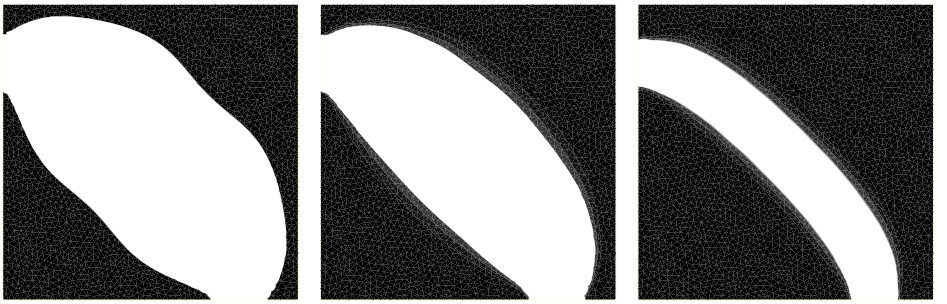

FIG. 6. *Geometries obtained during the optimization process.*

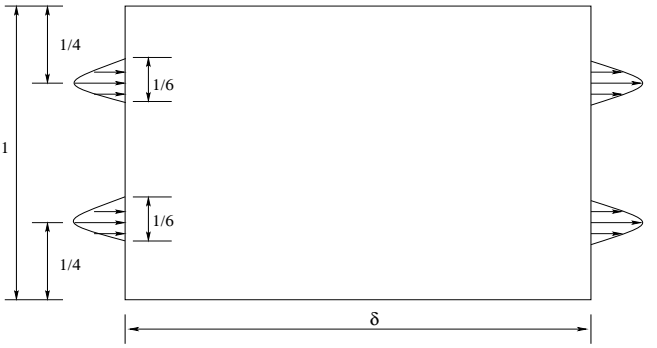

FIG. 7. *Design domain for the double pipe example.*

where Borrvall and Petersson needed more than sixty. As can be seen, we have a more torus-shaped pipe than in [10], like most pipe bends in fluid mechanics literature. It is stated in [21] that the solution in Borrvall and Petersson [10] contains regions of artificial material and does not sufficiently take into account the adherence condition.

Double pipe example. The design domain of this example is shown in Figure 7. The domain has two inlet and outlet flows, each with a maximum velocity equal to 1, and velocity is prescribed to be zero elsewhere on the boundary of the domain. The problem is solved using an 80×120 element mesh. We present here the solution obtained for the longer flow distances (e.g., $\delta = 1.5$). The optimal geometry is obtained using only five iterations (where Borrvall and Peterson needed more than sixty iterations). The geometries obtained during the optimization process are given in Figure 8. However, the two pipes join to form a single, wider pipe through the center of the domain. This design decreases the length of the fluid-solid interface, thereby decreasing the power lost. As can be seen, the optimal solution is identical to that obtained by Guest and Prévost [21], but it does not match that of Borrvall and Petersson [10]. As for the pipe bend example, the solution in [10] contains regions of artificial material and does not sufficiently take into account the adherence condition.

4.2.2. Shape optimization of tubes in a cavity. In this section we treat the shape optimization of tubes in a cavity. We consider an incompressible fluid in a cavity Ω having one inlet Γ_{in} and some outlets Γ_{out}^i, $i = 1, m$. (see Figure 9).

The aim here is to determine the optimal shape of the tubes that connect the inlet to the outlets of the cavity maximizing the outflow rate. It consists of inserting small obstacles in the cavity in order to maximize the outflow rate at Γ_{out}^i, $i = 1, m$.

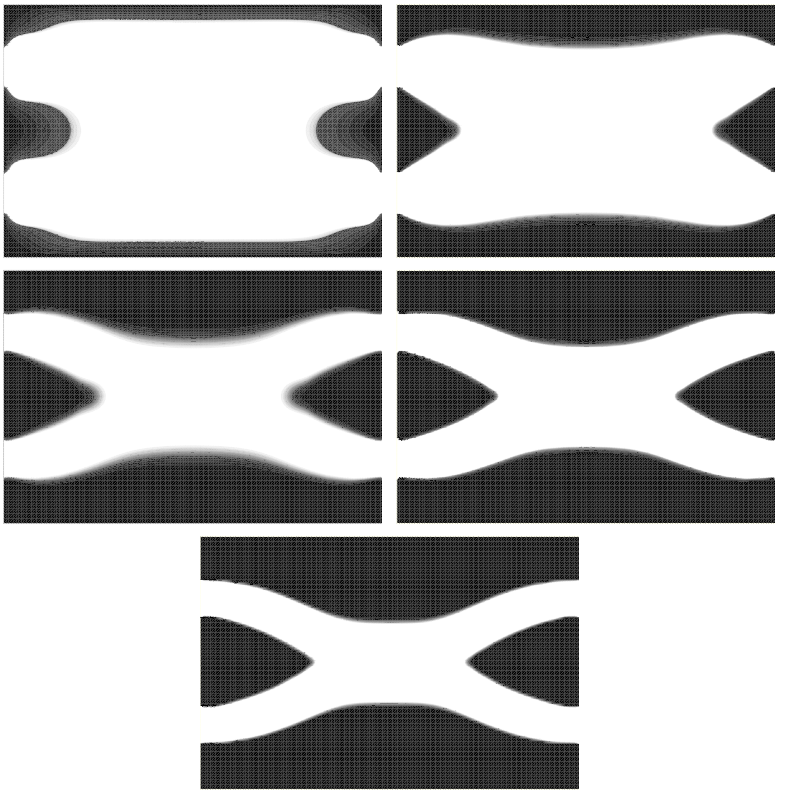

FIG. 8. *Geometries obtained during the optimization process (double pipe, $\delta = 1.5$).*

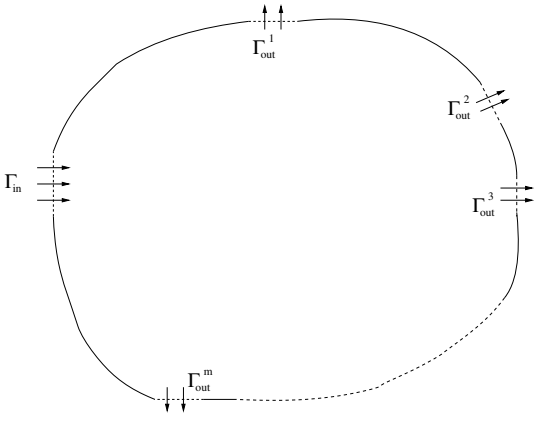

FIG. 9. *The cavity Ω.*

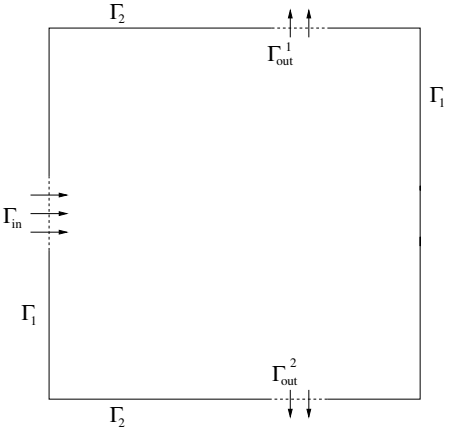

FIG. 10. *The initial geometry for the first test case.*

We assume that the flow satisfies the steady state Stokes equations

$$\begin{aligned} -\nu\Delta u + \nabla p &= 0 \quad \text{in } \Omega, \\ \text{div } u &= 0 \quad \text{in } \Omega. \end{aligned} \tag{4.5}$$

On the inlet Γ_{in} we define the normal component of the stress tensor,

$$\sigma(u).\mathbf{n} = \phi \text{ on } \Gamma_{in},$$

where $\sigma(u) = \nu(\nabla u + \nabla u^T) - pI$, I is the 2×2 identity matrix, and $\mathbf{n}$ denotes the outward normal to the boundary.

On the outlets, we use a free surface boundary condition

$$\sigma(u).\mathbf{n} = 0 \text{ on } \cup_{i=1}^{m} \Gamma_{out}^{i}.$$

The velocity is prescribed to be zero elsewhere on the boundary of the cavity.

The cost function measuring the outflow rate is given by

$$J(u) = \sum_{i=1}^{m} \int_{\Gamma_{out}^{i}} |u.\mathbf{n}| \text{ ds}.$$

4.2.3. First case: A cavity with one inlet and two outlets. We consider a cavity with one inlet and two outlets having the same section (see Figure 10).

The results of this case are given in Figures 11, 12, and 13. In Figure 11, we illustrate the variation of the outflow rate. The optimal design is presented in Figure 12. We present the topological gradient and the geometries obtained during the optimization process in Figure 13. The topological gradient corresponding to the initial geometry is shown in Figure 13(a). The topological gradient corresponding to the final geometry is presented in Figure 13(d). One can observe that the optimality condition is reached after only four iterations. Indeed, the topological gradient is almost positive everywhere (see Figure 13(d)) in the current domain ($g_4(x) \geq -8.5610^{-4}$ for all $x \in \Omega_4$).

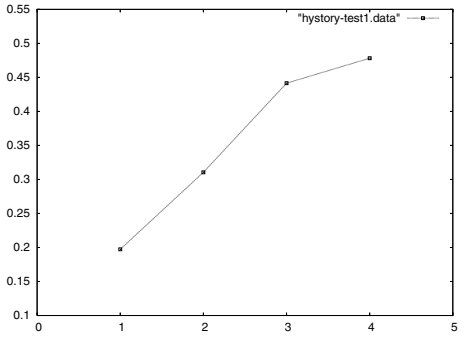

FIG. 11. *Variation of the outflow rate (first case).*

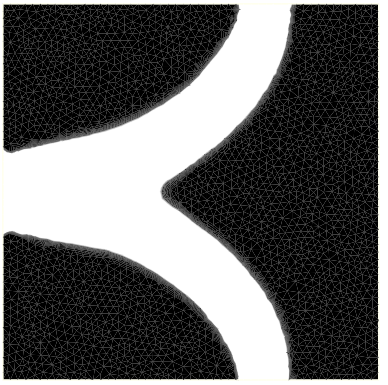

FIG. 12. *The optimal design (first case).*

4.2.4. Second case: A cavity with one inlet and three outlets. In the second case, we use a cavity with one inlet Γ_{in} and three outlets Γ_{out}^1, Γ_{out}^2, and Γ_{out}^3 (see Figure 14).

The results of this case are given in Figures 15, 16, and 17. As in the first case, we present the variation of the outflow rate in Figure 15 and the optimal design in Figure 16. The topological gradient and the geometries that we obtained during the optimization process are given in Figure 17. The topological gradient corresponding to the initial geometry is shown in Figure 17(a). The topological gradient corresponding to the final geometry is presented in Figure 17(d). As can be seen, the optimal solution is obtained using only four iterations.

4.2.5. Third case: A cavity with one inlet and three outlets (nonsymmetric case). We consider now a cavity with one inlet and three nonsymmetric outlets. The initial geometry is described in Figure 18. The obtained results are given in Figures 19, 20, and 21. As in the previous cases, we illustrate the variation of the outflow rate (see Figure 19), we present the optimal design (see Figure 20), and we give the topological gradient and the geometries that we obtained during the optimization process (see Figure 21). The initial geometry is given in Figure 21(a); the optimal one is given in Figure 21(d).

COPRIME FACTORIZATION AND DYNAMIC STABILIZATION OF TRANSFER FUNCTIONS*

KALLE M. MIKKOLA†

Abstract. It is known that a matrix-valued transfer function P has a stabilizing dynamic controller Q (i.e., $\left[\begin{smallmatrix} I & -Q \\ -P & I \end{smallmatrix}\right]^{-1} \in \mathrm{H}^\infty$) iff P has a right (or left) coprime factorization. We show that the same result is true in the operator-valued case. Thus, the standard Youla–Bongiorno parameterization applies to every dynamically stabilizable function. We then derive further equivalent conditions, one of them being that P has a stabilizing controller with internal loop; this and some others are new even in the scalar-valued case. We also establish certain related results. For example, we extend the classical results on coprime factorization and partial feedback (measurement-feedback) stabilization to nonrational transfer functions. All our results apply in both discrete- and continuous-time settings, except that in the latter it is not clear whether the controller Q can always be chosen so that it is "continuous-time proper" (holomorphic and bounded on a right half-plane) unless, e.g., $P(z) \to 0$ as $\operatorname{Re} z \to +\infty$.

Key words. dynamic stabilization, internal stabilization, right coprime factorization, measurement feedback, dynamic partial feedback, dynamically stabilizing controllers with internal loop, operator-valued transfer functions, infinite-dimensional systems

1. Introduction.

In this introductory section we present our main results for discrete-time transfer functions (those defined on a subset of the unit disc $\mathbb{D} := \{z \in \mathbb{C} \mid |z| < 1\}$). Corresponding results for continuous-time functions (those defined on the right half-plane) and others are given in section 7.

Let $\mathtt{U}$, $\mathtt{W}$, $\mathtt{Y}$, and $\mathtt{Z}$ be complex Hilbert spaces. By $\mathcal{B}(\mathtt{U},\mathtt{Y})$ we denote bounded linear operators $\mathtt{U} \to \mathtt{Y}$ and by $\mathrm{H}^\infty(\mathtt{U},\mathtt{Y})$ we denote bounded holomorphic functions $\mathbb{D} \to \mathcal{B}(\mathtt{U},\mathtt{Y})$ with supremum norm. We set $\mathcal{B}(\mathtt{U}) := \mathcal{B}(\mathtt{U},\mathtt{U})$, $\mathrm{H}^\infty(\mathtt{U}) := \mathrm{H}^\infty(\mathtt{U},\mathtt{U})$, $\mathcal{GB} := \{F \in \mathcal{B} \mid \text{there exists } F^{-1} \in \mathcal{B}\}$, and $\mathcal{G}\,\mathrm{H}^\infty := \{F \in \mathrm{H}^\infty \mid \text{there exists } F^{-1} \in \mathrm{H}^\infty\}$. By I or $I_{\mathtt{U}}$ we denote the identity operator $I \in \mathcal{B}(\mathtt{U})$ (or the corresponding constant function $I \in \mathrm{H}^\infty(\mathtt{U})$).

A holomorphic function P ("the plant") defined on a neighborhood of the origin is called *proper*. It is *strictly proper* if $P(0) = 0$. We identify a holomorphic function on a disc $r\mathbb{D} = \{z \in \mathbb{C} \mid |z| < r\}$ with its restriction to any open subset of $r\mathbb{D}$.

A proper $\mathcal{B}(\mathtt{Y},\mathtt{U})$-valued function Q is called a (dynamic feedback) *proper stabilizing controller* for a proper $\mathcal{B}(\mathtt{U},\mathtt{Y})$-valued function P if the "input-to-error" map $E : \left[\begin{smallmatrix} u_{\mathrm{in}} \\ y_{\mathrm{in}} \end{smallmatrix}\right] \mapsto \left[\begin{smallmatrix} u \\ y \end{smallmatrix}\right]$ in Figure 1.1 is in H^∞.[1] The map E is obviously given by

*Received by the editors October 3, 2005; accepted for publication (in revised form) July 12, 2006; published electronically January 8, 2007. This work was supported by the Academy of Finland under grant 203946 and by the Magnus Ehrnrooth Foundation.

†Helsinki University of Technology, Institute of Mathematics, P.O. Box 1100, FIN-02015 HUT, Espoo, Finland (Kalle.Mikkola@iki.fi).

[1]This means that some $E \in \mathrm{H}^\infty(\mathtt{U} \times \mathtt{Y})$ satisfies $E\left[\begin{smallmatrix} I & -Q \\ -P & I \end{smallmatrix}\right] = \left[\begin{smallmatrix} I & 0 \\ 0 & I \end{smallmatrix}\right] = \left[\begin{smallmatrix} I & -Q \\ -P & I \end{smallmatrix}\right] E$ on a neighborhood of 0. By a direct computation, (1.1) follows (on a neighborhood of 0). Recall that the inverse of a holomorphic operator-valued function is always holomorphic. (This kind of algebraic, function-theoretic and other well-known results used in this article can be found in our generality in [11, Appendices A and D].)

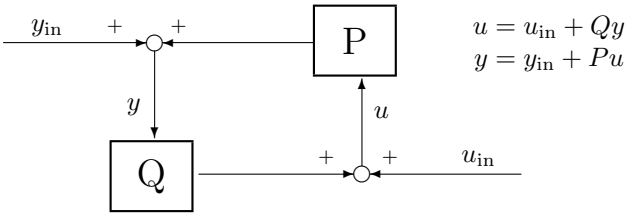

FIG. 1.1. *Controller Q for the transfer function P.*

$$E := \begin{bmatrix} I & -Q \\ -P & I \end{bmatrix}^{-1} = \begin{bmatrix} (I-QP)^{-1} & Q(I-PQ)^{-1} \\ P(I-QP)^{-1} & (I-PQ)^{-1} \end{bmatrix}. \tag{1.1}$$

(Observe that then P is also a proper stabilizing controller for Q.)

Two functions $M, N \in \mathrm{H}^\infty$ are called (Bézout) *r.c.* (right coprime) if $\left[\begin{smallmatrix} M \\ N \end{smallmatrix}\right]$ is left-invertible in H^∞, i.e., if there exist $\tilde{X}, \tilde{Y} \in \mathrm{H}^\infty$ satisfying the "Bézout identity"

$$\tilde{X}M - \tilde{Y}N \equiv I. \tag{1.2}$$

We call the factorization $P = NM^{-1}$ a *r.c.f.* (right coprime factorization) of P if $N \in \mathrm{H}^\infty(\mathtt{U}, \mathtt{Y})$ and $M \in \mathrm{H}^\infty(\mathtt{U})$ are r.c., $M(0) \in \mathcal{GB}$, and $P = NM^{-1}$ (near 0).

The following is our main result.

THEOREM 1.1 (dynamic feedback stabilization). *The following are equivalent for any proper $\mathcal{B}(\mathtt{U}, \mathtt{Y})$-valued function P:*

(i) *P has a strictly proper stabilizing controller.*
(ii) *P has a proper stabilizing controller.*
(iii) *P has a stabilizing controller with internal loop.*[2]
(iv) *P has a r.c.f.*
(v) *$\left[\begin{smallmatrix} P & 0 \\ 0 & I_{\mathtt{Z}} \end{smallmatrix}\right]$ has a r.c.f. for some (hence any) Hilbert space $\mathtt{Z}$.*

Assume that P has a r.c.f. $P = NM^{-1}$. Then $\left[\begin{smallmatrix} M \\ N \end{smallmatrix}\right] \in \mathrm{H}^\infty(\mathtt{U}, \mathtt{U} \times \mathtt{Y})$ can be extended to an invertible element of $\mathrm{H}^\infty(\mathtt{U} \times \mathtt{Y})$, say $\left[\begin{smallmatrix} M & Y \\ N & X \end{smallmatrix}\right]$. Denote its inverse by $\left[\begin{smallmatrix} \tilde{X} & -\tilde{Y} \\ -\tilde{N} & \tilde{M} \end{smallmatrix}\right] \in \mathrm{H}^\infty(\mathtt{U} \times \mathtt{Y})$. Then all stabilizing controllers for P are given by the Youla(–Bongiorno) parameterization[3]

$$Q = (Y + MV)(X + NV)^{-1} \qquad (= (\tilde{X} + V\tilde{N})^{-1}(\tilde{Y} + V\tilde{M})), \tag{1.3}$$

where $V \in \mathrm{H}^\infty(\mathtt{Y}, \mathtt{U})$ is arbitrary (the controller is proper iff $(X + NV)^{-1}$ is proper, or equivalently, iff $(\tilde{X} + V\tilde{N})^{-1}$ is proper). The map $V \mapsto Q$ is one-to-one.

If P is strictly proper, then all these controllers are proper.

Usually one excludes the values of the parameter V that make the controller (1.3) nonproper. However, sometimes only such controllers possess the properties that one would like to obtain in practical applications [4]. To also include such controllers, the

[2]These will be defined in section 3. They may be nonproper.

[3]For some functions P and V, the inverse $(X + NV)^{-1}$ in (1.3) need not exist at the origin (or anywhere; e.g., $\left[\begin{smallmatrix} M & Y \\ N & X \end{smallmatrix}\right] = \left[\begin{smallmatrix} 1 & 1 \\ 1 & 0 \end{smallmatrix}\right]$, $V = 0$). Even so, the "nonproper" controller (1.3) can be interpreted as a "stabilizing controller with internal loop," as described in section 3, where also properness is explained in detail. Nevertheless, for each P (and $\left[\begin{smallmatrix} M & Y \\ N & X \end{smallmatrix}\right]$), some $V \in \mathrm{H}^\infty$ makes $(X + NV)(0)$ invertible in $\mathcal{B}(\mathtt{Y})$. The parameterization (1.3) covers all stabilizing controllers with internal loop in the sense described in section 3. Moreover, every proper stabilizing controller equals exactly one of these Q on a neighborhood of the origin.

theory of "controllers with internal loop" (which cover both the proper and nonproper controllers) was developed in [32] and [4]. Also nonproper controllers with internal loop can be physically realized. In section 3 we shall define them and explain their relation to proper controllers.

Further necessary and sufficient conditions for (i) will be presented later, particularly in Theorem 2.1 and Proposition 2.2. One such condition is the existence of a stabilizable and detectable realization. Conditions (iii) and Theorem 2.1(ii') are weaker forms of (ii). Their equivalence to (ii) means that if P is dynamically stabilizable in any reasonable sense, then it is dynamically stabilizable in the standard sense (possibly by a different, nonequivalent controller).

By combining the above results with [27], [30], and [7], we obtain the following result.

COROLLARY 1.2 (matrix-valued case). *Assume that* $\dim \mathtt{U} < \infty$ *and* $\dim \mathtt{Y} < \infty$. *Then also the following conditions are equivalent to* (i) *of Theorem* 1.1 *for a proper* $\mathcal{B}(\mathtt{U},\mathtt{Y})$*-valued function* P*:*

(vi) P *has a stable (hence proper) stabilizing controller* ($Q \in \mathrm{H}^\infty(\mathtt{Y},\mathtt{U})$).

(vii) $P = NM^{-1}$, *where* $N, M \in \mathrm{H}^\infty$, $N^*N + M^*M \geq \epsilon I$ *on* $\mathbb{D}$, $\epsilon > 0$, *and* $\det M \not\equiv 0$.

(The corona condition in (vii) is not sufficient for coprimeness in the operator-valued case [26]. It is not known whether (vi) is necessary in general.)

For rational transfer functions, (i)–(vii) always hold, and also the rest of Theorem 1.1 is well known [6]. The study of corresponding results for nonrational functions started in the 1970s and soon became intensive. An introduction to coprime factorization and dynamic stabilization of infinite-dimensional systems can be found in, e.g., [5] or [31]. Several sufficient conditions for some of the conditions (i)–(v) have been established earlier, but our proof of the equivalence would not have been possible without the results in [23], [32], [11], [14], [2], and [16].

In the matrix-valued case, the implication (ii)⇒(iv) was independently established in [9] and [22] and the enhanced converse (iv)⇒(vi) in [27] (in the scalar-valued case, which is equivalent to the matrix-valued case, by [30, Theorem 3]; the exact statement can be found in [19]). The "Carleson corona theorem" (iv)⇔(vii) was extended to the matrix-valued case in [7] (see [28] for the operator-valued case, where (vii)⇒(iv) is not true without additional assumptions).

In the general case, the implication (iv)⇒(iii) was established in [32] and [4], and (iv)⇒(v) and (i)⇒(ii)⇒(iii) are trivial. The existence of $\left[\begin{smallmatrix} M & Y \\ N & X \end{smallmatrix}\right] \in \mathcal{G}\,\mathrm{H}^\infty(\mathtt{U}\times\mathtt{Y})$ is from [16] (based on [28] and [12]); the matrix-valued case is a well-known consequence of Tolokonnikov's lemma [25]. The Youla parameterization (including the "if" part of the properness of Q) is straightforward [4]. The "only if" part of properness, implications (iii)⇒(v)⇒(iv)⇒(i), and the strictly proper case are new (except that (iv)⇒(i) was already known in the matrix-valued case). The differences between continuous- and discrete-time results are otherwise insignificant, but properness and strict properness become more complicated in continuous time; see section 7 for details.

With certain other commutative unital rings in place of $\mathrm{H}^\infty(\mathbb{C})$, Theorem 1.1 becomes false. Related results for such settings are given by Quadrat [19], [18], [20] in the matrix-valued case.

In section 2 we present further conditions that are equivalent to (i), such as coprime factorization or stabilization with invertibility at some other $\alpha \in \mathbb{D}$ instead of 0. In section 3 we define controllers with internal loop, present corresponding details of Theorem 1.1, and develop related new results. The results in sections 2 and 3 are needed in the proof of Theorem 1.1, but they are also important by themselves.

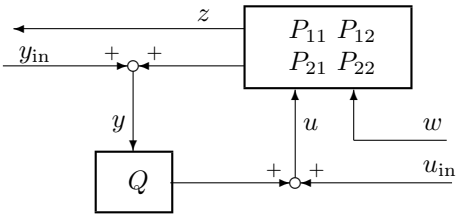

FIG. 1.2. *DPF-controller Q for P.*

In section 4 we present analogous results for "measurement feedback" or dynamic partial feedback, where the controller can use only a part of the output and can affect only a part of the input of $P = \left[\begin{smallmatrix} P_{11} & P_{12} \\ P_{21} & P_{22} \end{smallmatrix}\right]$, where $P(z) \in \mathcal{B}(\mathtt{U} \times \mathtt{W},\ \mathtt{Z} \times \mathtt{Y})$, as in Figure 1.2. We obtain direct generalizations of the classical results, such as those in [6] or [8]. In particular, we show that if P is stabilizable by dynamic partial feedback, then a $\mathcal{B}(\mathtt{Y}, \mathtt{U})$-valued controller Q stabilizes P by dynamic partial feedback iff it stabilizes P_{21} by dynamic feedback.

In section 5 we observe that practically all our results also hold for "power stabilization" (or "exponential stabilization" in the continuous-time setting of section 7), mutatis mutandis, where the "closed-loop" map (1.1) is required to be holomorphic on an open set that contains $\overline{\mathbb{D}}$. In section 6 we show that even if we allow the domain of Q to be an arbitrary region, we meet no ambiguity with holomorphic extensions and the identification of controllers.

In section 7 we establish our results in the continuous-time setting, where the properness notion is different. Proofs and some further results are given in the appendices.

In our generality, corresponding state-space results can be found in [33], [11], and [24] (and [32]), where many assumptions can be weakened, by our results. Robust stabilization with state-space results are given in [1]. Further state-space results will be presented in a subsequent article by the author.

2. Dynamic stabilization. In this section we show how any reasonable variants of the above conditions (i)–(v) are equivalent to (i). We also present realization-based conditions that are equivalent to (i).

In the matrix-valued case, as in (vii), one need not care where M or $\left[\begin{smallmatrix} I & -Q \\ -P & I \end{smallmatrix}\right]^{-1}$ is invertible, since it is invertible a.e. anyway (if it is invertible somewhere). In Theorem 2.1 we show that invertibility at any reasonable point is sufficient also in the operator-valued case. The definitions below are used to formulate these facts.

Let $\alpha \in \mathbb{D}$. We call NM^{-1} an *α-r.c.f. of P* if $N, M \in \mathrm{H}^\infty$ are r.c., $M(\alpha) \in \mathcal{GB}(\mathtt{U})$, and $NM^{-1} = P$ on a neighborhood of α. We call $\tilde{M}^{-1}\tilde{N}$ an *α-l.c.f. of P* if $\tilde{N}, \tilde{M} \in \mathrm{H}^\infty$ are *l.c.* (i.e., $\tilde{M}X - \tilde{N}Y = I$ for some $X, Y \in \mathrm{H}^\infty$), $\tilde{M}(\alpha) \in \mathcal{GB}(\mathtt{U})$, and $\tilde{M}^{-1}\tilde{N} = P$ on a neighborhood of α. We call $\left[\begin{smallmatrix} M & Y \\ N & X \end{smallmatrix}\right] \in \mathcal{G}\,\mathrm{H}^\infty(\mathtt{U} \times \mathtt{Y})$ an *α-d.c.f. of P* if $M(\alpha) \in \mathcal{GB}(\mathtt{U})$ and $P = NM^{-1}$ on a neighborhood of α (it follows that $P = NM^{-1}$ is an α-r.c.f. and $P = \tilde{M}^{-1}\tilde{N}$ is an α-l.c.f., where $\left[\begin{smallmatrix} \tilde{X} & -\tilde{Y} \\ -\tilde{N} & \tilde{M} \end{smallmatrix}\right] := \left[\begin{smallmatrix} M & Y \\ N & X \end{smallmatrix}\right]^{-1}$ [11]; conversely, any α-r.c.f. and α-l.c.f. can be extended to an α-d.c.f., by Lemma 3.4). A 0-d.c.f. (resp., 0-l.c.f.) is called a *d.c.f.* (resp., *l.c.f.*).

Now we can present further equivalent conditions (see section 3 for (iii')).

THEOREM 2.1 (dynamic feedback stabilization). *Assume that $\Omega_P \subset \mathbb{D}$ is open and connected, $P : \Omega_P \to \mathcal{B}(\mathtt{U}, \mathtt{Y})$ is holomorphic, and $0, \alpha, \beta \in \Omega_P$. Then the follow-*

ing conditions are equivalent to (iv) *of Theorem* 1.1*:*

(iv') *P has an α-r.c.f.*

(iv") *P has an α-l.c.f.*

(iv"') *P has an α-d.c.f.*

(ii') *For some open and connected $\Omega_Q \subset \Omega_P$ there exists a holomorphic function $Q : \Omega_Q \to \mathcal{B}(\mathtt{Y},\mathtt{U})$ such that $\left[\begin{smallmatrix} I & -Q \\ -P & I \end{smallmatrix}\right]^{-1} \in \mathrm{H}^\infty$.*

(ii") *For some neighborhood Ω_Q of α, condition* (ii') *holds with $Q(\alpha) = 0$.*

(iii') *P has a stabilizing canonical controller.*

Any α-r.c.f. of P is a β-r.c.f. of P. The same holds with "l.c.f." or "d.c.f." in place of "r.c.f."

Note that, by duality, we get "left results" from all "right results" of this article (because, e.g., $P = \tilde{M}^{-1}\tilde{N}$ is an α-l.c.f. iff $P^{\mathrm{d}} = \tilde{N}^{\mathrm{d}}(\tilde{M}^{\mathrm{d}})^{-1}$ is an $\bar{\alpha}$-r.c.f., where the *dual* P^{d} is defined by $P^{\mathrm{d}}(s) := P(\bar{s})^*$). See section 6 for further variants of (ii').

We recall the following from [16] (which contains the definitions of (viii)–(viii"')).

PROPOSITION 2.2 (realizations). *Assume that P is a proper $\mathcal{B}(\mathtt{U},\mathtt{Y})$-valued function. Then also the following are equivalent to* (i) *of Theorem* 1.1*:*

(viii) *P has a jointly stabilizable and detectable realization.*

(viii') *P has a stabilizable and detectable realization.*

(viii") *P has an output-stabilizable and input-detectable realization.*

(viii"') *P has a realization Σ such that Σ and its dual satisfy the finite cost condition.*

See [2] or [16] for an equivalent condition in terms of Riccati equations, which also yield a constructive formula for the r.c.f. The original proof of "(viii')⇒(iv)" is due to [2], and that of "(viii)⇔(iv"')" due to [23], both in continuous time.

By combining Proposition 2.2 and Theorem 1.1 with [11] one can obtain further equivalent conditions, such as having a dynamically stabilizable realization. For (continuous-time) exponential dynamic stabilization of realizations, the necessity of exponential stabilizability and detectability was shown in [33]; their sufficiency follows from [17] (or [33]), Remark 5.1, and Theorems 1.1 and 7.3.

Constructive formulae for doubly coprime factorizations in terms of realizations can be found in, e.g., [2], [3], and [11] under different assumptions; in [32], [11], and [1] formulae for stabilizing dynamic controllers are given. They also provide further historical remarks. For constructive formulae for mere r.c.f.'s, see also the end of section 7.

3. Controllers with internal loop. In this section we present certain results on controllers with internal loop and explain the rest of Theorem 1.1. As before, we work in the discrete-time setting, but we show in section 7 that practically everything below holds in the continuous-time setting too.

Controllers with internal loop were defined in [32] both to complete the theory of dynamic stabilization of nonrational transfer functions and to cover also the "short circuit control"-type applications. Their theory has been further developed in [4], [33], and [11]. As explained in [32] and [4], without them some aspects of the standard theory for finite-dimensional systems cannot be satisfactorily generalized to general infinite-dimensional systems. For example, the standard observer-based controller need not have a proper transfer function, but it can be identified with a proper 2×2-matrix-valued transfer function [32, Example 6.5], which has a well-posed realization. See also the rational SISO example at the end of this section.

We start this section from the definitions and then explain the correspondence to the proper controllers presented in the introduction.

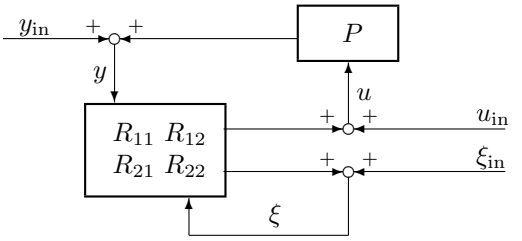

FIG. 3.1. *Controller R with internal loop for P.*

We say that R is a (possibly nonproper) *stabilizing controller with internal loop* for P if $R = \left[\begin{smallmatrix} R_{11} & R_{12} \\ R_{21} & R_{22} \end{smallmatrix}\right]$ is a proper $\mathcal{B}(\mathtt{Y} \times \Xi, \mathtt{U} \times \Xi)$-valued function for some Hilbert space Ξ and

$$(I - P^R)^{-1} \in \mathrm{H}^\infty(\mathtt{U} \times \mathtt{Y} \times \Xi), \quad \text{where } P^R = \begin{bmatrix} 0 & R_{11} & R_{12} \\ P & 0 & 0 \\ 0 & R_{21} & R_{22} \end{bmatrix}. \tag{3.1}$$

Note that $(I - P^R)^{-1}$ maps $\left[\begin{smallmatrix} u_{\text{in}} \\ y_{\text{in}} \\ \xi_{\text{in}} \end{smallmatrix}\right] \mapsto \left[\begin{smallmatrix} u \\ y \\ \xi \end{smallmatrix}\right]$ in Figure 3.1. Thus, R is stabilizing iff the maps $\left[\begin{smallmatrix} u_{\text{in}} \\ y_{\text{in}} \\ \xi_{\text{in}} \end{smallmatrix}\right] \mapsto \left[\begin{smallmatrix} u \\ y \\ \xi \end{smallmatrix}\right]$ are "well-posed and stable."

If $R = \left[\begin{smallmatrix} Q & 0 \\ 0 & 0 \end{smallmatrix}\right]$, then R is completely equivalent to the stabilizing controller Q. Thus, the proper controllers presented in the introduction essentially form a subset of the controllers with internal loop.

In general, R corresponds to "$R_{11} + R_{12}(I - R_{22})^{-1}R_{21}$" (cf. Lemma 3.2); this "function" need not be proper (we may even have $R_{22} \equiv I$). In the nonproper case the ξ-loop in Figure 3.1 becomes ill-posed if R is disconnected from P; i.e., physically one must connect R to P before closing the internal loop.

A nonproper controller is a proper controller for an extended system.

LEMMA 3.1. *A proper $\mathcal{B}(\mathtt{Y} \times \Xi, \mathtt{U} \times \Xi)$-valued function R is a stabilizing controller with internal loop for P iff R is a stabilizing controller for $P_I := \left[\begin{smallmatrix} P & 0 \\ 0 & I_\Xi \end{smallmatrix}\right]$.*

(This follows because $\left[\begin{smallmatrix} I & -R \\ -P_I & I \end{smallmatrix}\right]^{-1}$ consists of $(I - P^R)^{-1}$ and of some copies of its elements, as observed in [11, Proposition 7.2.5(c)]. An alternative proof is to observe that the equations that determine the latter reduce to those that determine the former. In fact, this is rather obvious, since I_Ξ corresponds to the identity feedthrough of ξ in Figure 3.1.)

Two stabilizing controllers with internal loop are considered *equivalent* for P iff they lead to the same closed-loop map $\left[\begin{smallmatrix} u_{\text{in}} \\ y_{\text{in}} \end{smallmatrix}\right] \mapsto \left[\begin{smallmatrix} u \\ y \end{smallmatrix}\right]$ (i.e., if the (1–2, 1–2)-blocks of corresponding $(I - P^R)^{-1}$'s are equal), even if the maps from ξ_{in} and the maps to ξ (i.e., those describing the internal loop in the controller) would differ.

In the lemma below we show that R corresponds to a proper controller Q iff the internal loop of R can be closed (while R is disconnected from P).

LEMMA 3.2 (proper R). *Assume that $R = \left[\begin{smallmatrix} R_{11} & R_{12} \\ R_{21} & R_{22} \end{smallmatrix}\right]$ is a stabilizing controller with internal loop for P.*

Then R is equivalent to a stabilizing controller with internal loop of form $\tilde{R} = \left[\begin{smallmatrix} Q & 0 \\ 0 & 0 \end{smallmatrix}\right]$ iff $I - R_{22}(0) \in \mathcal{GB}$. If $I - R_{22}(0) \in \mathcal{GB}$, then the unique solution is given by $Q = R_{11} + R_{12}(I - R_{22})^{-1}R_{21}$.

(Note that then $\left[\begin{smallmatrix} I & -Q \\ -P & I \end{smallmatrix}\right]^{-1} \in \mathrm{H}^\infty$, as in the introduction, and that if we close the internal loop of R, then its top-left block becomes $R_{11} + R_{12}(I - R_{22})^{-1}R_{21}$.)

Any such R is called a *proper* stabilizing controller (with internal loop) for P (and R is identified with Q). Since equivalence is an equivalence relation, R is equivalent to a proper stabilizing controller with internal loop iff R is proper, by Lemma 3.2.

If $Y \in \mathrm{H}^\infty(\mathtt{Y},\mathtt{U})$ and $X \in \mathrm{H}^\infty(\mathtt{U})$ are r.c., then $R := \left[\begin{smallmatrix} 0 & Y \\ I & I-X \end{smallmatrix}\right]$ is called a *canonical controller* (see [4] or [11]; in [11], the term controller with a coprime internal loop was used). Sometimes we denote it by YX^{-1}, as in the Youla parameterization (1.3) above. In particular, we say that YX^{-1} *stabilizes* P iff $\left[\begin{smallmatrix} 0 & Y \\ I & I-X \end{smallmatrix}\right]$ is a stabilizing controller with internal loop for P.

(If YX^{-1} is a stabilizing canonical controller for P, then it is equivalent to $\left[\begin{smallmatrix} 0 & I \\ \tilde{Y} & I-\tilde{X} \end{smallmatrix}\right]$ (or $\tilde{X}^{-1}\tilde{Y}$), where $\tilde{X}$ and $\tilde{Y}$ are obtained by $\left[\begin{smallmatrix} \tilde{X} & -\tilde{Y} \\ -\tilde{N} & \tilde{M} \end{smallmatrix}\right] := \left[\begin{smallmatrix} M & Y \\ N & X \end{smallmatrix}\right]^{-1}$ for any r.c.f. NM^{-1} of P, as one observes from Lemma 3.5 and its dual.)

Modulo equivalence, there are no other controllers than the canonical ones.

LEMMA 3.3 (equivalent canonical controller). *Let R be a stabilizing controller with internal loop for P. Then some stabilizing canonical controller $\tilde{X}^{-1}\tilde{Y}$ for P is equivalent to R (and so is one of form YX^{-1}).*

The Youla parameterization (1.3) gives all stabilizing canonical controllers for P. Here we have identified the canonical controllers that are equivalent (see above), i.e., the ones determined by $\left[\begin{smallmatrix} Y \\ X \end{smallmatrix}\right] V$ for a fixed r.c. pair $\left[\begin{smallmatrix} Y \\ X \end{smallmatrix}\right]$ and arbitrary $V \in \mathcal{G}\,\mathrm{H}^\infty(\mathtt{U})$. Any stabilizing controller with internal loop is equivalent to exactly one stabilizing canonical controller, so actually all stabilizing controllers with internal loop are covered by (1.3) modulo equivalence. In particular, this parameterization contains all proper stabilizing controllers, by Lemma 3.2. (Indeed, any proper stabilizing controller is equivalent to one of form $\tilde{R} := \left[\begin{smallmatrix} Q & 0 \\ 0 & 0 \end{smallmatrix}\right]$ and to a canonical controller $R := \left[\begin{smallmatrix} 0 & Y \\ I & I-X \end{smallmatrix}\right]$. By Lemma 3.2, $X(0) = I - R_{22}(0) \in \mathcal{GB}$ and $Q = YX^{-1}$.)

Since any r.c.f. and l.c.f. can be extended to a d.c.f. (Lemma 3.4), we can apply (1.3) when we have either.

A "Bézout identity" $\tilde{X}M - \tilde{Y}N = I$ (or $\tilde{M}X - \tilde{N}Y = I$) can always be extended to a d.c.f.

LEMMA 3.4 (r.c.f.→d.c.f.). *Let $M, N, \tilde{X}, \tilde{Y} \in \mathrm{H}^\infty$ be such that NM^{-1} is a $\mathcal{B}(\mathtt{U},\mathtt{Y})$-valued r.c.f. and $\tilde{X}M - \tilde{Y}N = I$. Then, for any l.c.f. $\tilde{M}^{-1}\tilde{N}$ of NM^{-1}, there exist $X, Y \in \mathrm{H}^\infty$ such that $\left[\begin{smallmatrix} M & Y \\ N & X \end{smallmatrix}\right] = \left[\begin{smallmatrix} \tilde{X} & -\tilde{Y} \\ -\tilde{N} & \tilde{M} \end{smallmatrix}\right]^{-1} \in \mathcal{G}\,\mathrm{H}^\infty(\mathtt{U}\times\mathtt{Y})$.*

(This follows from the proof of [23, Lemma 4.3(iii)]; observe from Theorem 2.1 that the l.c.f. necessarily exists.)

A canonical controller YX^{-1} stabilizes P iff $\left[\begin{smallmatrix} Y \\ X \end{smallmatrix}\right]$ can be extended to a d.c.f. of P. We state the dual result here.

LEMMA 3.5. *Let P be a proper $\mathcal{B}(\mathtt{U},\mathtt{Y})$-valued function and $R' = \left[\begin{smallmatrix} 0 & I \\ \tilde{Y} & I-\tilde{X} \end{smallmatrix}\right] \in \mathrm{H}^\infty(\mathtt{Y}\times\mathtt{U},\, \mathtt{U}\times\mathtt{U})$.*

Then R' is a stabilizing controller with internal loop for P iff for some (hence any) r.c.f. NM^{-1} of P we have $\tilde{X}M - \tilde{Y}N \in \mathcal{G}\,\mathrm{H}^\infty(\mathtt{U})$, or equivalently, iff P has a r.c.f. NM^{-1} such that $\tilde{X}M - \tilde{Y}N = I$.

Assume that R' is a stabilizing controller with internal loop for P. Then there exists a d.c.f. $\left[\begin{smallmatrix} M & Y \\ N & X \end{smallmatrix}\right] = \left[\begin{smallmatrix} \tilde{X} & -\tilde{Y} \\ -\tilde{N} & \tilde{M} \end{smallmatrix}\right]^{-1} \in \mathrm{H}^\infty(\mathtt{U}\times\mathtt{Y})$ of P with these particular $\tilde{X}$ and $\tilde{Y}$. Moreover, for any such d.c.f., we have

$$\begin{bmatrix} I & -R_{11} & -R_{12} \\ -P & I & 0 \\ 0 & -R_{21} & I-R_{22} \end{bmatrix}^{-1} = \begin{bmatrix} Y\tilde{N}+I & M\tilde{Y} & * \\ X\tilde{N} & N\tilde{Y}+I & * \\ * & * & * \end{bmatrix} = \begin{bmatrix} M\tilde{X} & Y\tilde{M} & * \\ N\tilde{X} & X\tilde{M} & * \\ * & * & * \end{bmatrix}, \tag{3.2}$$

where R is any stabilizing controller with internal loop that is equivalent to $\tilde{X}^{-1}\tilde{Y}$. If $R = \left[\begin{smallmatrix} 0 & I \\ \tilde{Y} & I-\tilde{X} \end{smallmatrix}\right]$, then

$$\begin{bmatrix} I & -R_{11} & -R_{12} \\ -P & I & 0 \\ 0 & -R_{21} & I-R_{22} \end{bmatrix}^{-1} = \begin{bmatrix} M\tilde{X} & M\tilde{Y} & M \\ N\tilde{X} & N\tilde{Y}+I & N \\ M\tilde{X}-I & M\tilde{Y} & M \end{bmatrix}. \tag{3.3}$$

(Thus, any such stabilizing R' is actually a canonical controller. However, also some noncanonical functions $R' = \left[\begin{smallmatrix} 0 & I \\ \tilde{Y} & I-\tilde{X} \end{smallmatrix}\right] \in \mathrm{H}^\infty$ do lead to (3.2), but the $*$'s (which denote unimportant entries) do not become stable unless $\tilde{X}$ and $\tilde{Y}$ are l.c.)

We record here an obvious consequence of the dual of Lemma 3.5.

COROLLARY 3.6. *Let P be a proper $\mathcal{B}(\mathtt{U},\mathtt{Y})$-valued function. If a canonical controller YX^{-1} stabilizes P, then P has a r.c.f. and any r.c.f. NM^{-1} of P satisfies $\left[\begin{smallmatrix} M & Y \\ N & X \end{smallmatrix}\right] \in \mathcal{G}\,\mathrm{H}^\infty$. Conversely, if there exists $\left[\begin{smallmatrix} M & Y \\ N & X \end{smallmatrix}\right] \in \mathcal{G}\,\mathrm{H}^\infty$ such that $M(0) \in \mathcal{GB}(\mathtt{U})$ and $P = NM^{-1}$, then YX^{-1} stabilizes P.*

If P is strictly proper, then the X in Corollary 3.6 is necessarily invertible at 0.

LEMMA 3.7. *If P is strictly proper, then any stabilizing controller with internal loop for P is proper.*

(This follows from Lemmata 3.2, 3.3, and 3.5, because $P(0) = 0 \;\Rightarrow\; N(0) = 0 \;\Rightarrow\; \tilde{X}(0)M(0) = I \;\Rightarrow\; \tilde{X}(0) = M(0)^{-1} \in \mathcal{GB}(\mathtt{U})$.)

Example. The function $P = NM^{-1} = (1-z)^{-1}$, where $N = 1$, $M = 1-z$, has the stabilizing controller $R := \left[\begin{smallmatrix} 0 & 1 \\ -1 & 1 \end{smallmatrix}\right]$ with internal loop (the canonical controller $\tilde{\mathscr{X}} = 0$, $\tilde{\mathscr{Y}} = -1$). Since $1 - R_{22}$ is nowhere invertible, this controller is not equivalent to any proper controller, by Lemma 3.2. However, by Theorem 1.1, there are also proper stabilizing controllers for P (e.g., $Q(z) = -z$). The continuous-time equivalent of this example was presented in [32, p. 6], where the nonproper controller was shown to be the natural engineering solution (short circuit tracking) for the problem.

Notes for section 3. The "if" part of Lemma 3.2 is from [32]. With the additional assumption that P has a d.c.f., Lemma 3.3 is contained in [4]. However, the proof in [4] is seven pages long, so we present a short, self-contained proof in Appendix A. Also most of Lemma 3.5 can be found in [4]. For further similar results, see [11]; for practical examples, see [32] and [4]. Lemma 3.7 becomes less obvious and even more important in the continuous-time setting of Theorem 7.3.

4. Partial feedback. In this section we treat *dynamic partial feedback (DPF)*, where the controller Q sees only a part of the output and can affect only a part of the input.

Throughout this section we assume that P is a proper $\mathcal{B}(\mathtt{U}\times\mathtt{W},\ \mathtt{Z}\times\mathtt{Y})$-valued function. A proper $\mathcal{B}(\mathtt{Y},\mathtt{U})$-valued function Q is called a *stabilizing DPF-controller* for P if $\left[\begin{smallmatrix} 0 & Q \\ 0 & 0 \end{smallmatrix}\right]$ is a stabilizing controller for P. This obviously corresponds to Figure 1.2. Analogously, a $\mathcal{B}(\mathtt{Y}\times\Xi,\ \mathtt{U}\times\Xi)$-valued proper function R is called a *stabilizing DPF-controller with internal loop* for P if

$$R_{\mathrm{DPF}} := \begin{bmatrix} 0 & R_{11} & R_{12} \\ 0 & 0 & 0 \\ 0 & R_{21} & R_{22} \end{bmatrix} \quad \text{(whose values lie in } (\mathtt{Z}\times\mathtt{Y}\times\Xi,\ \mathtt{U}\times\mathtt{W}\times\Xi)) \tag{4.1}$$

is a stabilizing controller with internal loop for P; see Figure 4.1. If such an R exists, then we call P *DPF-stabilizable* (with internal loop). (Further details are given in [11, section 7.3]. Observe that the [DPF-]controller $R = \left[\begin{smallmatrix} Q & 0 \\ 0 & 0 \end{smallmatrix}\right]$ with internal loop functions exactly as the [DPF-]controller Q; we identify the two.)

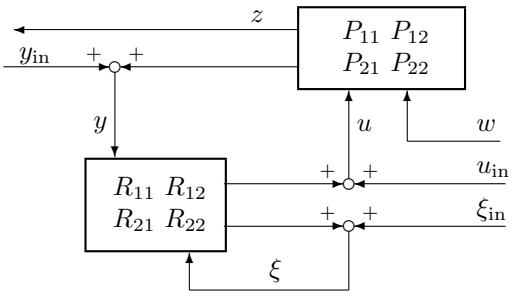

FIG. 4.1. *DPF-controller R with internal loop for P.*

We call two stabilizing controllers with internal loop for P (say, R and R') *equivalent* if they lead to same maps $u_{\text{in}}, y_{\text{in}} \mapsto u, y$ (or equivalently, to same maps $u_{\text{in}}, w, y_{\text{in}} \mapsto u, y, z$, or equivalently, if R_{DF} and R'_{DF} are equivalent for P, or equivalently, if R and R' are equivalent for P_{21}; see [11, Lemma 7.3.8] for this equivalence).

DPF is the standard setting in the general (four-block) H^∞ regulator problem (see [11, Chapter 12] for this general case with internal loops).

Note that the second input (column) of P is the exogenous input (or disturbance) and the first input (column) is the one connected to the controller output, not vice versa (both variants can be found in the literature; the other choice would move the I's out of the diagonal in Theorem 4.2 below).

With the aid the Theorem 1.1, we can derive the following two theorems, which are direct generalizations of well-known results for rational functions. The first theorem reduces DPF-stabilization problems to ordinary dynamic stabilization problems.

THEOREM 4.1 (P iff P_{21}). *Assume that P is DPF-stabilizable. Then a proper $\mathcal{B}(\mathtt{Y} \times \Xi, \mathtt{U} \times \Xi)$-valued function R is a stabilizing DPF-controller with internal loop for P iff R is a stabilizing controller with internal loop for P_{21}.*

In particular, a proper $\mathcal{B}(\mathtt{Y}, \mathtt{U})$-valued function Q is a stabilizing DPF-controller for P iff Q is a stabilizing controller for P_{21}. It also follows that every stabilizing DPF-controller with internal loop for P is equivalent to one of the canonical controllers (for P_{21}) given by the Youla parameterization.

Observe that $P_{21} : u \mapsto y - y_{\text{in}}$ is the control-to-measurement part of P.

A function is DPF-stabilizable iff it has a coprime factorization "through P_{21}."

THEOREM 4.2 (DPF). *The following are equivalent:*

(i) *P has a strictly proper stabilizing DPF-controller.*
(ii) *P has a proper stabilizing DPF-controller.*
(iii) *P has a stabilizing DPF-controller with internal loop.*
(iv) *P has a r.c.f. of the form $P = \left[\begin{smallmatrix} N_{11} & N_{12} \\ N_{21} & N_{22} \end{smallmatrix}\right] \left[\begin{smallmatrix} M_{11} & M_{12} \\ 0 & I \end{smallmatrix}\right]^{-1}$ such that N_{21} and M_{11} are r.c.*
(v) *P has a l.c.f. of the form $P = \left[\begin{smallmatrix} I & \tilde{M}_{12} \\ 0 & \tilde{M}_{22} \end{smallmatrix}\right]^{-1} \left[\begin{smallmatrix} \tilde{N}_{11} & \tilde{N}_{12} \\ \tilde{N}_{21} & \tilde{N}_{22} \end{smallmatrix}\right]$ such that $\tilde{N}_{21}$ and $\tilde{M}_{22}$ are l.c.*

Assume (iv) *and* (v). *Then $N_{21}M_{11}^{-1}$ is a r.c.f. of P_{21} and $\tilde{M}_{22}^{-1}\tilde{N}_{21}$ is a l.c.f. of P_{21}.*

(Thus, the above r.c.f. of P contains a r.c.f. of P_{21} that can be used for the Youla parameterization of all stabilizing DPF-controllers with internal loop for P, by Theorem 4.1.)

One can also derive sufficient conditions for DPF-stabilizability in terms of realizations. One sufficient condition is the power stabilizability and detectability of the subsystem corresponding to P_{21}; see [11, Lemma 7.3.6(c)] for details.

Notes for section 4. For rational matrix-valued functions, the above two theorems can be found in, e.g., [6] or [8]; most of them were extended to the Callier–Desoer class in [5].

If (iv) holds, then the stabilizing DPF-controllers for P are, modulo equivalence, exactly the canonical controllers $\tilde{X}^{-1}\tilde{Y}$ for any $\tilde{X}, \tilde{Y} \in \mathrm{H}^\infty$ such that $\tilde{X}M_{11} - \tilde{Y}N_{21} = I$, by Lemma 3.5. An equivalent characterization is those YX^{-1} for which $\left[\begin{smallmatrix} M_{11} & M_{12} & Y \\ M_{21} & M_{22} & 0 \\ N_{21} & N_{22} & X \end{smallmatrix}\right] \in \mathcal{G}\,\mathrm{H}^\infty(\mathtt{U} \times \mathtt{W} \times \mathtt{Y})$ for some (hence any) r.c.f. NM^{-1} of P [11, Lemma 7.3.22]. A third equivalent characterization is the Youla parameterization (for P_{21}). By Theorem 4.1, also all proper stabilizing DPF-controllers for P are contained in any of these (as in Theorem 1.1).

The coprimeness condition in (iv) cannot be weakened: the r.c.f. $P = NM^{-1} := \left[\begin{smallmatrix} 1 & 0 \\ 0 & 0 \end{smallmatrix}\right] \left[\begin{smallmatrix} (z+1)/(z+2) & 0 \\ 0 & 1 \end{smallmatrix}\right]^{-1}$ is of the form $\left[\begin{smallmatrix} * & * \\ * & * \end{smallmatrix}\right] \left[\begin{smallmatrix} * & * \\ 0 & I \end{smallmatrix}\right]^{-1}$ (hence P and P_{21} both have a d.c.f. and thus have stabilizing controllers), but yet P is not DPF-stabilizable with internal loop, since $P_{11} = (z+2)/(z+1)$ is unstable ($\notin \mathrm{H}^\infty$) and unaffected by any DPF-controller, because $P_{21} = 0$. However, if some P is DPF-stabilizable, then any r.c.f. of that P of the form $P = \left[\begin{smallmatrix} N_{11} & N_{12} \\ N_{21} & N_{22} \end{smallmatrix}\right] \left[\begin{smallmatrix} M_{11} & M_{12} \\ 0 & I \end{smallmatrix}\right]^{-1}$ has N_{21}, M_{11} r.c. [11, Corollary 7.3.17]. A corresponding continuous-time example is given by $P(s) = \left[\begin{smallmatrix} 1 & 0 \\ 0 & 0 \end{smallmatrix}\right] \left[\begin{smallmatrix} s/(s+1) & 0 \\ 0 & 1 \end{smallmatrix}\right]^{-1}$.

A rational right factorization is r.c. iff M has no other zeros than the poles of P. The coprimeness condition on N_{21} and M_{11} says that as we multiply the zeros of P away by M_{11}, we do not introduce to $N_{21} = P_{21}M_{11}$ any new zeros (in addition to those of P_{21}), i.e., that the poles of P are also poles of P_{21}. In other words, this says that the poles of P are visible through P_{21}; other kind of poles of P could not be stabilized by partial feedback having access to P_{21} only, as is the case in the above example $P = \left[\begin{smallmatrix} 1 & 0 \\ 0 & 0 \end{smallmatrix}\right] \left[\begin{smallmatrix} (z+1)/(z+2) & 0 \\ 0 & 1 \end{smallmatrix}\right]^{-1}$.

Using the above two theorems and the other results in this article, [16], and [14], one could generalize to nonrational functions also the other classical results, as presented in, e.g., [6] or [8]. Part of this can be found in [11], whose Hypothesis 7.3.15 holds iff P is DPF-stabilizable with internal loop, by Theorem 4.2. This simplifies section 7.3 of [11] significantly; similarly, Theorem 1.1 simplifies sections 7.1 and 7.2. Partially the same applies to state-space results.

5. Power stabilization. One sometimes wants to power-stabilize systems or transfer functions (or stabilize exponentially in the continuous-time setting). In this section we observe that the "power-variants" of our results hold and follow easily. (However, from the "power-variants" one cannot obtain the original results. Moreover, in the power stabilization of systems, there are some results whose nonpower-stabilization variants are false.)

We write $N \in \mathrm{H}^\infty_{\mathrm{power}}$ if $N(r\cdot) \in \mathrm{H}^\infty$ for some $r > 1$ (i.e., $N \in \mathrm{H}^\infty$ has a holomorphic extension to an open disc that contains $\overline{\mathbb{D}}$). We define *power*-variants of the following definitions by replacing H^∞ by $\mathrm{H}^\infty_{\mathrm{power}}$: r.c., l.c., r.c.f., l.c.f., d.c.f., α-r.c.f., α-l.c.f., α-d.c.f., stabilizing [DPF-]controller, stabilizing [DPF-]controller with internal loop, canonical controller, DPF-stabilizable. Thus, e.g., a d.c.f. $\left[\begin{smallmatrix} M & Y \\ N & X \end{smallmatrix}\right]$ is a *power-d.c.f.* iff $\left[\begin{smallmatrix} M & Y \\ N & X \end{smallmatrix}\right], \left[\begin{smallmatrix} M & Y \\ N & X \end{smallmatrix}\right]^{-1} \in \mathrm{H}^\infty_{\mathrm{power}}$, and Q is a *power-stabilizing* controller for P iff $\left[\begin{smallmatrix} I & -Q \\ -P & I \end{smallmatrix}\right]^{-1} \in \mathrm{H}^\infty_{\mathrm{power}}$.

REMARK 5.1 (power stabilization). *With the above "power-"concepts in place of the original ones and* $\mathrm{H}^\infty_{\mathrm{power}}$ *in place of* H^∞*, Theorem* 2.1*, Lemmata* A.5*,* A.10*, and* A.11*, and the results of sections* 1*,* 3*, and* 4 *hold.*

(Also the power form of Proposition 2.2 holds in the sense explained in [16].)

Proof. This follows easily from the original results. For example, if P has a power-stable r.c.f. NM^{-1}, then $P(r\cdot) = N(r\cdot)M(r\cdot)^{-1}$ is a r.c.f. for some $r > 1$; hence then $P(r\cdot)$ has a proper stabilizing controller $\tilde{Q}$, and hence $Q := \tilde{Q}(r^{-1}\cdot)$ is power-stabilizing for P (because $\left[\begin{smallmatrix} I & -Q \\ -P & I \end{smallmatrix}\right]^{-1} = \left[\begin{smallmatrix} I & -\tilde{Q} \\ -P(r\cdot) & I \end{smallmatrix}\right]^{-1}(r^{-1}\cdot) \in \mathrm{H}^\infty_{\mathrm{power}}$), by Theorem 1.1. ∎

Observe that a rational function is in H^∞ iff it does not have a pole in $\overline{\mathbb{D}}$, or equivalently, iff it is in $\mathrm{H}^\infty_{\mathrm{power}}$. Similarly, also finite-dimensional state-space stability coincides with state-space power stability. In the infinite-dimensional setting, both forms of stability are very popular.

6. Nonproper controller functions. In this section we study "stabilizing controllers" of the form of a possibly nonproper function. We also show that all such controllers are canonical controllers and explain how they relate to each other.

In the matrix-valued case, a factorization NM^{-1} is well defined everywhere on $\mathbb{D}$ except possibly for some isolated points (assuming that $M, N \in \mathrm{H}^\infty$, $\det M \not\equiv 0$). In the operator-valued case, one may easily end up with functions having disconnected domains. Moreover, in dynamic stabilization one often meets the question whether two functions can be identified when they coincide on the intersection of their domains.

We show that if a function Q stabilizes P in a reasonable sense, then $Q = YX^{-1}$, where YX^{-1} is a stabilizing canonical controller for P in the standard sense, and then YX^{-1} (on the subset of $\mathbb{D}$ where X^{-1} exists) is the maximal holomorphic extension of Q (within $\mathbb{D}$). A similar claim holds for P. It follows that any such function element of Q stabilizes any such function element of P (on the intersection of their domains) in the same sense.

LEMMA 6.1. *Let* $\Omega \subset \mathbb{D}$ *be open and let* $\alpha, \beta \in \Omega$*. Let* $P : \Omega \to \mathcal{B}(\mathtt{U}, \mathtt{Y})$ *and* $Q : \Omega \to \mathcal{B}(\mathtt{Y}, \mathtt{U})$*.*

Then some $E \in \mathrm{H}^\infty(\mathtt{Y} \times \mathtt{U})$ *satisfies* $E \left[\begin{smallmatrix} I & -Q \\ -P & I \end{smallmatrix}\right] = I = \left[\begin{smallmatrix} I & -Q \\ -P & I \end{smallmatrix}\right] E$ *on* Ω *iff there exists* $\left[\begin{smallmatrix} M & Y \\ N & X \end{smallmatrix}\right] \in \mathcal{G}\,\mathrm{H}^\infty(\mathtt{U}\times\mathtt{Y})$ *such that* $M(z), X(z) \in \mathcal{GB}$ *for all* $z \in \Omega$ *and* $P = NM^{-1}$ *and* $Q = YX^{-1}$ *on* Ω*.*

If such a quadruple $\left[\begin{smallmatrix} M & Y \\ N & X \end{smallmatrix}\right]$ *exists, and* $P = N_1M_1^{-1}$ *and* $Q = Y_1X_1^{-1}$ *are* α*-r.c.f.'s, then they are* β*-r.c.f.'s and* $\left[\begin{smallmatrix} M_1 & Y_1 \\ N_1 & X_1 \end{smallmatrix}\right] \in \mathcal{G}\,\mathrm{H}^\infty(\mathtt{U} \times \mathtt{Y})$*. Moreover, then any holomorphic extension (to a connected open subset of* $\mathbb{D}$*) of any restriction of* NM^{-1} *(to an open set) is a restriction of* NM^{-1} *(with domain* $\{z \in \mathbb{D} \mid M(z)^{-1}$ *exists*$\}$*).*

(Obviously, then $\left[\begin{smallmatrix} X & N \\ Y & M \end{smallmatrix}\right]$ is a β-d.c.f. of Q.)

We observed above that even if the domain of P and Q is not connected, a single d.c.f. applies at each component of the domain (if Q stabilizes P "at each component with the same inverse E"; otherwise the different components of P could be arbitrary). Moreover, there is no problem of extending P or Q holomorphically within the unit disc (the values of the functions at a certain point do not depend of the domain). This is an alternative proof of the fact that the function $P = \log$ (or any other function with different branches) is not dynamically stabilizable.

Next we define (possibly nonproper) stabilizing controller functions. Assume, for awhile, that $\Omega_P \subset \mathbb{D}$ is open and connected. Let $P : \Omega_P \to \mathcal{B}(\mathtt{U}, \mathtt{Y})$ be holomorphic. If $\Omega \subset \Omega_P$ is open and $Q : \Omega \to \mathcal{B}(\mathtt{Y}, \mathtt{U})$ is holomorphic, then we call Q a *stabilizing*

controller function for P if $\left[\begin{smallmatrix} I & -Q \\ -P & I \end{smallmatrix}\right]^{-1} \in \mathrm{H}^\infty$.[4] We define *stabilizing DPF-controller functions* analogously (i.e., we do not require them to be proper).

By Lemma 6.1, the above definitions are in a complete accordance with the old ones and any stabilizing controller function is a stabilizing canonical controller. In particular, the existence of a stabilizing controller function (for a proper function P) is equivalent to Theorem 1.1(i). However, not all canonical controllers are functions, as one observes from the example at the end of section 3.

7. Continuous-time results. In this section we shall show that almost all *DT* (discrete-time) results of the other sections also hold in their *CT* (continuous-time) forms, even if we use the standard CT properness (defined later). But first we record the following obvious consequence of the Riemann mapping theorem.

REMARK 7.1 (Cayley). *The results in sections* 1–4, *section* 6, *and Appendix* A *except Proposition* 2.2 *hold true even if we replace* $\mathbb{D}$ *by any simply connected open* $\mathbb{D}' \subsetneq \mathbb{C}$ *and the origin* 0 *by any* $\zeta \in \mathbb{D}'$.

(We shall often use this implicitly when referring to those results. In fact, many of these results would hold even if $\mathbb{D}'$ was not simply connected (some results would hold with essentially the same proof; some others could be reduced to the simply connected case if, e.g., $\mathbb{D}'$ is a finite union of simply connected open sets containing ζ).)

In the most important special case, where $\mathbb{D}' := \mathbb{C}^+$ and $\zeta \in \mathbb{C}^+$, we can use the "Cayley" mapping $f : s \mapsto \frac{\zeta - s}{\zeta + s}$ to map $\mathbb{C}^+ \to \mathbb{D}$ conformally with $\zeta \mapsto 0$. Then we can apply the earlier results to $P \circ f^{-1}$, $M \circ f^{-1}$, $N \circ f^{-1}$, etc. in place of P, M, N, etc.

In CT, the right half-plane $\mathbb{C}^+$ takes the role of $\mathbb{D}$. Therefore, for the rest of this section, we redefine some concepts (cf. Theorem 7.3).

DEFINITION 7.2 (CT forms). *Given* $\omega \in \mathbb{R}$ *we set* $\mathbb{C}^+_\omega := \{z \in \mathbb{C} \mid \operatorname{Re} z > \omega\}$, *and by* $\mathrm{H}^\infty_\omega(\mathtt{U}, \mathtt{Y})$ *we denote the Banach space of bounded holomorphic functions* $\mathbb{C}^+_\omega \to \mathcal{B}(\mathtt{U}, \mathtt{Y})$ *with the supremum norm.*

We call P proper *if* $P \in \mathrm{H}^\infty_\infty := \cup_{\omega \in \mathbb{R}} \mathrm{H}^\infty_\omega$, *i.e., if* P *is a bounded holomorphic function on some right half-plane. (We identify a holomorphic function on a right half-plane* $\mathbb{C}^+_\omega$ *with its restriction to any open subset of* $\mathbb{C}^+_\omega$.*) It is* strictly proper *if, in addition,* $P(z) \to 0$ *as* $\operatorname{Re} z \to +\infty$.[5] *We set* $\mathbb{C}^+ := \mathbb{C}^+_0$, $\mathrm{H}^\infty := \mathrm{H}^\infty_0$. *Moreover, in all definitions and results in the other sections, we replace* $\mathbb{D}$ *by* $\mathbb{C}^+$ *and invertibility at* 0 *by the existence of a proper inverse.*

(The main motivation for the above properness concept is that a function is proper iff it is the transfer function of a well-posed linear system [21].)

Thus, e.g., if $N, M \in \mathrm{H}^\infty$ are r.c., $M^{-1} \in \mathrm{H}^\infty_\infty(\mathtt{U})$ and $P = NM^{-1}$ (on a right half-plane), then we call $P = NM^{-1}$ an *r.c.f. of* P; similarly, if P and Q are proper and $\left[\begin{smallmatrix} I & -Q \\ -P & I \end{smallmatrix}\right]^{-1} \in \mathrm{H}^\infty$, then Q is a *proper stabilizing controller* for P. Recall that $(I - P^R)^{-1} \in \mathrm{H}^\infty$ in (3.1) means that $(I - P^R)^{-1}$ is the restriction of some element of H^∞, or equivalently, that some $E \in \mathrm{H}^\infty$ satisfies $E(I - P^R) = I = (I - P^R)E$ on some right half-plane (since P and R were assumed to be proper in (3.1)). If $I - R_{22}$ has a proper inverse, then we again (see below Lemma 3.2) identify R with the proper controller $R_{11} + R_{12}(I - R_{22})^{-1}R_{21}$.

---

[4] Naturally, this means that there exists $E \in \mathrm{H}^\infty$ such that $E\left[\begin{smallmatrix} I & -Q \\ -P & I \end{smallmatrix}\right] \equiv I \equiv \left[\begin{smallmatrix} I & -Q \\ -P & I \end{smallmatrix}\right] E$ on Ω. Note that if(f) $0 \in \Omega$, then this is equivalent to the definition of a proper stabilizing controller. Thus, "proper stabilizing controller function" means the same as "proper stabilizing controller."

[5] This means that for each $\epsilon > 0$ there exists $\omega_\epsilon \in \mathbb{R}$ such that $\|P(z)\| < \epsilon$ for all $z \in \mathbb{C}$ such that $\operatorname{Re} z > \omega_\epsilon$.

When N and M are r.c., $\alpha \in \mathbb{C}^+$, $M(\alpha) \in \mathcal{GB}(\mathtt{U})$, and $P = NM^{-1}$ on a neighborhood of α, we call $P = NM^{-1}$ an *α-r.c.f. of P*.

Next we define (possibly nonproper) stabilizing controller functions. Let, for awhile, $\Omega_P \subset \mathbb{C}^+$ be open and connected. Let $P : \Omega_P \to \mathcal{B}(\mathtt{U},\mathtt{Y})$ be holomorphic. If $\Omega \subset \Omega_P$ is open and $Q : \Omega \to \mathcal{B}(\mathtt{Y},\mathtt{U})$ is holomorphic, then we call Q a *stabilizing controller function for P* if $\left[\begin{smallmatrix} I & -Q \\ -P & I \end{smallmatrix}\right]^{-1} \in \mathrm{H}^\infty$.[6] We define *stabilizing DPF-controller functions* analogously (i.e., we do not require them to be proper, whereas we still require that a *stabilizing [DPF-]controller with internal loop* is determined by a proper function R, as above).

By the arguments of Remark 7.1, the corresponding DT comments (below Lemma 6.1) apply here too (with Theorem 7.4 in place of Theorem 1.1).

THEOREM 7.3 (CT forms). *Propositions* A.1 *and* A.2*, Lemmata* A.3*,* A.4*,* A.9*,* A.10*, and* A.11*, and the results in sections* 1–3 *and* 6 *hold in their CT forms too if we replace Theorem* 1.1 *(resp., Theorem* 2.1*, Lemma* 3.2*) by Theorem* 7.4 *(resp., Theorem* 7.5*, Lemma* 7.7*).*

See Theorem 7.8 (resp., Theorem 7.9, Remark 7.10) for Theorem 4.1 (resp., Theorem 4.2, Remark 5.1). See [16] for the CT definitions for Proposition 2.2.

The main theorem, Theorem 1.1, holds in its CT form too once we remove "[strictly] proper" from (i) and (ii). We write this explicitly below with a new condition (i).

THEOREM 7.4 (CT: Dynamic feedback stabilization). *Let P be a proper $\mathcal{B}(\mathtt{U},\mathtt{Y})$-valued function, i.e., $P \in \mathrm{H}^\infty_\omega(\mathtt{U},\mathtt{Y})$ for some $\omega \geq 0$. Let $\zeta \in \mathbb{C}^+_\omega$. Then the following are equivalent:*

(i) *There exists a holomorphic $\mathcal{B}(\mathtt{Y},\mathtt{U})$-valued function Q on a neighborhood of ζ such that $\left[\begin{smallmatrix} I & -Q \\ -P & I \end{smallmatrix}\right]^{-1} \in \mathrm{H}^\infty$.*
(ii) *P has a stabilizing controller function.*
(iii) *P has a stabilizing controller with internal loop.*
(iv) *P has a r.c.f.*
(v) *$\left[\begin{smallmatrix} P & 0 \\ 0 & I_{\mathtt{Z}} \end{smallmatrix}\right]$ has a r.c.f. for some (hence any) Hilbert space $\mathtt{Z}$.*

Assume that P has a r.c.f. $P = NM^{-1}$. Then $\left[\begin{smallmatrix} M \\ N \end{smallmatrix}\right] \in \mathrm{H}^\infty(\mathtt{U},\mathtt{U}\times\mathtt{Y})$ can be extended to an invertible element of $\mathrm{H}^\infty(\mathtt{U}\times\mathtt{Y})$, say $\left[\begin{smallmatrix} M & Y \\ N & X \end{smallmatrix}\right]$. Denote its inverse by $\left[\begin{smallmatrix} \tilde{X} & -\tilde{Y} \\ -\tilde{N} & \tilde{M} \end{smallmatrix}\right] \in \mathrm{H}^\infty(\mathtt{U}\times\mathtt{Y})$. Then all stabilizing controllers for P are given by the Youla(–Bongiorno) parameterization

$$Q = (Y + MV)(X + NV)^{-1} \qquad (= (\tilde{X} + V\tilde{N})^{-1}(\tilde{Y} + V\tilde{M})), \tag{7.1}$$

where $V \in \mathrm{H}^\infty(\mathtt{Y},\mathtt{U})$ is arbitrary (the controller is proper iff $(X + NV)^{-1}$ is proper, or equivalently, iff $(\tilde{X} + V\tilde{N})^{-1}$ is proper). The map $V \mapsto Q$ is one-to-one.

If P is strictly proper, then all these controllers are proper.

(Note that in PDE systems, the transfer function is usually strictly proper. That is also the case for well-posed systems having a bounded input or output operator and no feedthrough [13, Theorem 1.2].)

If, in Theorem 7.4, we set $\Omega_P := \mathbb{C}^+_\omega$ and fix some $\alpha, \beta \in \Omega_P$, then also the six conditions listed below become equivalent to (i).

THEOREM 7.5. *Assume that $\Omega_P \subset \mathbb{C}^+$ is open and connected and contains a right half-plane, $P : \Omega_P \to \mathcal{B}(\mathtt{U},\mathtt{Y})$ is holomorphic and proper, and $\alpha, \beta \in \Omega_P$.*

---

[6] Naturally, this means that there exists $E \in \mathrm{H}^\infty$ such that $E\left[\begin{smallmatrix} I & -Q \\ -P & I \end{smallmatrix}\right] \equiv I \equiv \left[\begin{smallmatrix} I & -Q \\ -P & I \end{smallmatrix}\right] E$ on Ω. Note that if(f) Ω contains a right half-plane and P and Q are proper, then this is equivalent to the definition of a proper stabilizing controller.

Then the conditions (ii'), (ii"), (iii'), (iv'), (iv"), *and* (iv"') *of Theorem* 2.1 *are equivalent to* (iv) *of Theorem* 7.4. *Moreover, then any* α*-r.c.f. of* P *is a* β*-r.c.f. of* P. *The same holds with "l.c.f." or "d.c.f." in place of "r.c.f."*

(See Proposition 2.2 and Corollary 1.2 for further equivalent conditions.)

Condition (ii") says that for any point α in the domain Ω_P of P, there exists a stabilizing controller function whose domain includes α. We do not know whether a proper stabilizing controller always exists even if we assume that P is proper. Naturally, a similar comment applies to Theorem 7.9. In the matrix-valued case, a proper stabilizing controller $Q \in \mathrm{H}^\infty$ exists, by Corollary 1.2(vi) (through Theorem 7.3). If P is strictly proper, then any stabilizing controller (with or without internal loop) for P is proper, by Lemma 3.7. Moreover, whenever P has a sufficiently regular right factorization, a strictly proper Q exists.

THEOREM 7.6 (CT: strictly proper Q). *Assume that* P *has a r.c.f. and that* $P = NM^{-1}$, *where* $N \in \mathrm{H}^\infty(\mathtt{U},\mathtt{Y})$, $M \in \mathrm{H}^\infty(\mathtt{U})$, *and* M^{-1} *is proper. If* $M(+\infty) := \lim_{\mathrm{Re}\, s \to +\infty} M(s)$ *exists, then there exists a strictly proper* Q *such that* $\left[\begin{smallmatrix} I & -Q \\ -P & I \end{smallmatrix}\right]^{-1} \in \mathrm{H}^\infty(\mathtt{Y} \times \mathtt{U})$.

(Note that this NM^{-1} need not be a r.c.f.; the existence of a r.c.f. is needed only for guaranteeing the existence of a stabilizing controller.)

A r.c.f. of P (if any exists) can be determined from the LQR Riccati equation for an output-stabilizable realization as the resulting closed-loop transfer function $\left[\begin{smallmatrix} N \\ M \end{smallmatrix}\right]$; see [2] or [14]. For sufficient regularity (for Theorem 7.6) of this particular factorization, many different assumptions can be found in the literature, such as the analytic semigroup setting of [10] or certain assumptions on the unboundedness of the control and/or observation operators [29], [11].

Next we rewrite Lemma 3.2, which says that a controller with internal loop is proper iff $(I - R_{22})^{-1}$ is proper.

LEMMA 7.7 (CT: proper R). *Assume that* $R = \left[\begin{smallmatrix} R_{11} & R_{12} \\ R_{21} & R_{22} \end{smallmatrix}\right]$ *is a stabilizing controller with internal loop for* P.

Then R *is equivalent to a stabilizing controller with internal loop of form* $\tilde{R} = \left[\begin{smallmatrix} Q & 0 \\ 0 & 0 \end{smallmatrix}\right]$ *iff* $(I - R_{22})^{-1} \in \mathrm{H}_\infty^\infty$. *If* $(I - R_{22})^{-1} \in \mathrm{H}_\infty^\infty$, *then the unique solution is given by* $Q = R_{11} + R_{12}(I - R_{22})^{-1}R_{21}$.

(This holds by the original proof (with H_∞^∞-invertibility in place of invertibility at the origin).)

As in Theorem 4.1, we can reduce DPF-stabilization problems to ordinary dynamic stabilization problems.

THEOREM 7.8 (CT: P iff P_{21}). *Assume that* P *is a proper* $\mathcal{B}(\mathtt{U} \times \mathtt{W},\ \mathtt{Z} \times \mathtt{Y})$*-valued DPF-stabilizable function. Then a proper* $\mathcal{B}(\mathtt{Y} \times \Xi, \mathtt{U} \times \Xi)$*-valued function* R *is a stabilizing DPF-controller with internal loop for* P *iff* R *is a stabilizing controller function with internal loop for* P_{21}.

Moreover, a $\mathcal{B}(\mathtt{Y},\mathtt{U})$*-valued function* Q *is a stabilizing DPF-controller function for* P *iff* Q *is a stabilizing controller fucntion for* P_{21}. *It also follows that every stabilizing DPF-controller with internal loop for* P *is equivalent to one of the canonical controllers (for* P_{21}*) given by the Youla parameterization.*

(Also Theorem 4.1 holds in this CT terminology (and vice versa); the only difference is that here we do not require Q to be proper.)

As in Theorem 4.2, a function P is DPF-stabilizable iff it has a coprime factorization "through P_{21}."

THEOREM 7.9 (CT: DPF). *The following are equivalent for a proper* $\mathcal{B}(\mathtt{U} \times \mathtt{W},\ \mathtt{Z} \times \mathtt{Y})$*-valued function* P*:*

(ii) *P has a stabilizing DPF-controller function.*

(iii) *P has a stabilizing DPF-controller with internal loop.*

(iv) *P has a r.c.f. of the form $P = \left[\begin{smallmatrix} N_{11} & N_{12} \\ N_{21} & N_{22} \end{smallmatrix}\right] \left[\begin{smallmatrix} M_{11} & M_{12} \\ 0 & I \end{smallmatrix}\right]^{-1}$ such that N_{21} and M_{11} are r.c.*

(v) *P has a l.c.f. of the form $P = \left[\begin{smallmatrix} I & \tilde{M}_{12} \\ 0 & \tilde{M}_{22} \end{smallmatrix}\right]^{-1} \left[\begin{smallmatrix} \tilde{N}_{11} & \tilde{N}_{12} \\ \tilde{N}_{21} & \tilde{N}_{22} \end{smallmatrix}\right]$ such that $\tilde{N}_{21}$ and $\tilde{M}_{22}$ are l.c.*

Assume (iv) *and* (v). *Then $N_{21}M_{11}^{-1}$ is a r.c.f. of P_{21} and $\tilde{M}_{22}^{-1}\tilde{N}_{21}$ is a l.c.f. of P_{21}.*

(The changes above are essentially the same as those in Theorem 7.4. Naturally, by Theorem 7.8, we could add a condition resembling Theorem 7.4(i).)

Also Remark 5.1 holds in CT, mutatis mutandis.

REMARK 7.10 (exponential stabilization). *Define the power concepts above Remark* 5.1 *with $\mathrm{H}^\infty_{\mathrm{exp}} := \cup_{\omega<0} \mathrm{H}^\infty_\omega$ in place of $\mathrm{H}^\infty_{\mathrm{power}}$.*

With such "power-"concepts in place of the original ones and $\mathrm{H}^\infty_{\mathrm{exp}}$ in place of H^∞, Theorems 7.4–7.6, *Lemma* 7.7, *Theorems* 7.8 *and* 7.9, *and the CT forms (see Definition* 7.2, *Theorem* 7.3, *and the text between them) of Corollary* 1.2, *Theorem* 2.1, *Lemmata* A.10 *and* A.11, *and the results of section* 3 *hold if we rewrite the CT form of Corollary* 1.2(vii) *as follows:*

(vii) *$P = NM^{-1}$, where $N, M \in \mathrm{H}^\infty_{\mathrm{exp}}$, $N^*N + M^*M \geq \epsilon I$ on $\mathbb{C}^+_{-\epsilon}$, $\epsilon > 0$, and $\det M \not\equiv 0$.*

(Also the "power form" of Proposition 2.2 holds in the sense explained in [15]. Thus, all results in sections 1–4 are covered with some slight modifications.)

In the CT terminology for the "power concepts" of section 5, one usually replaces the component "power-" by the word "exponential[ly]" (see, e.g., [24] or [11] for details).

Despite the "different properness and different power stability" in CT, the "same" results hold as in DT, with the exception that we do not guarantee the existence of a proper stabilizing [DPF-]controller in general (just in the three special cases mentioned below Theorem 7.5) and we made the slight "change" ($\mathbb{C}^+_{-\epsilon}$ instead of $\mathbb{C}^+$) in (vii) at the end of Remark 7.10.

Appendix A. Discrete-time proofs. In this appendix we shall prove all our nontrivial results except those of section 7. We start by showing that every dynamically stabilizable function has a r.c.f. For that purpose we need to recall part of [16], particularly the fact that any $\mathrm{H}^\infty / \mathrm{H}^\infty$ fraction can be written as a fraction of so-called weakly r.c. functions. This requires the following definitions.

If $N \in \mathrm{H}^\infty(\mathtt{U}, \mathtt{Y})$, $M \in \mathrm{H}^\infty(\mathtt{U})$, and $M(0) \in \mathcal{GB}(\mathtt{U})$, then we call NM^{-1} a *right factorization (of P*, if $P = NM^{-1}$ near 0). We call such a factorization a *weakly right coprime factorization (w.r.c.f.)* if, in addition,

$$\begin{bmatrix} N \\ M \end{bmatrix} f \in \mathrm{H}^2 \;\Rightarrow\; f \in \mathrm{H}^2 \tag{A.1}$$

for every proper $\mathtt{U}$-valued function f, i.e., if a holomorphic $\mathtt{U}$-valued function f defined on a neighborhood of 0 is a restriction of an element of $\mathrm{H}^2(\mathtt{U})$ whenever $\left[\begin{smallmatrix} N \\ M \end{smallmatrix}\right] f$ is a restriction of an element of $\mathrm{H}^2(\mathtt{Y} \times \mathtt{U})$.

We recall the following two propositions from [16].

PROPOSITION A.1 (w.r.c.f.). *A $\mathcal{B}(\mathtt{U}, \mathtt{Y})$-valued function P has a right factorization iff it has a w.r.c.f.*

Moreover, if $P = NM^{-1}$ is a w.r.c.f., then all right factorizations of P are parameterized by $P = (NV)(MV)^{-1}$, where $V \in \mathrm{H}^\infty(\mathtt{U})$ and V^{-1} is proper. The

w.r.c.f.'s are those for which $V^{-1} \in \mathrm{H}^\infty$ *too. In particular, if a function* P *has a r.c.f., then every w.r.c.f. of* P *is a r.c.f.*

PROPOSITION A.2. *If* NM^{-1} *is a w.r.c.f. with* $M \in \mathrm{H}^\infty(\mathtt{U})$, R *is a proper* $\mathcal{B}(\mathtt{Z},\mathtt{U})$*-valued function, and* $NR, MR \in \mathrm{H}^\infty$, *then* $R \in \mathrm{H}^\infty$.

LEMMA A.3. *If* $P = NM^{-1}$ *is a w.r.c.f. and* $(I-P)^{-1} \in \mathrm{H}^\infty$, *then* $(M-N)^{-1} \in \mathrm{H}^\infty$.

Proof. Since $I - P = (M - N)M^{-1}$, we have $M(M - N)^{-1} = (I - P)^{-1} \in \mathrm{H}^\infty$ and

$$\text{(A.2)}\quad N(M-N)^{-1} = NM^{-1}M(M-N)^{-1} = P(I-P)^{-1} = (I-P)^{-1} - I \in \mathrm{H}^\infty.$$

By Proposition A.2, it follows that $(M - N)^{-1} \in \mathrm{H}^\infty$. □

Now we are ready to prove the implication (ii)⇒(iv) in Theorem 1.1.

LEMMA A.4. *If* Q *is a proper stabilizing controller to a proper* $\mathcal{B}(\mathtt{U},\mathtt{Y})$*-valued function* P, *then* P *has a r.c.f.*

In the proof we take the factorizations (of P and Q) determined by (1.1), replace them by weakly coprime factorizations ($P = NM^{-1}$ and $Q = YX^{-1}$), and use Lemma A.3 to prove the invertibility of $\left[\begin{smallmatrix} M & Y \\ N & X \end{smallmatrix}\right]$ in H^∞.

Proof of Lemma A.4. By (1.1), $P = N_1 M_1^{-1}$, where $M_1 := (I - QP)^{-1} \in \mathrm{H}^\infty$ and $N_1 := PM_1 \in \mathrm{H}^\infty$. By Proposition A.1, P has a w.r.c.f. $P = NM^{-1}$. Similarly, Q has a w.r.c.f. $Q = YX^{-1}$. It obviously follows that

$$\text{(A.3)}\qquad \begin{bmatrix} 0 & Q \\ P & 0 \end{bmatrix} = \begin{bmatrix} 0 & Y \\ N & 0 \end{bmatrix} \begin{bmatrix} M & 0 \\ 0 & X \end{bmatrix}^{-1}$$

is a w.r.c.f. Since $\left(I - \left[\begin{smallmatrix} 0 & Q \\ P & 0 \end{smallmatrix}\right]\right)^{-1} \in \mathrm{H}^\infty$ (see (1.1)), it follows from Lemma A.3 that

$$\text{(A.4)}\qquad \left(\begin{bmatrix} M & 0 \\ 0 & X \end{bmatrix} - \begin{bmatrix} 0 & Y \\ N & 0 \end{bmatrix}\right)^{-1} = \begin{bmatrix} M & -Y \\ -N & X \end{bmatrix}^{-1} \in \mathrm{H}^\infty.$$

Therefore, $\left[\begin{smallmatrix} M & Y \\ N & X \end{smallmatrix}\right]^{-1} = \left(\left[\begin{smallmatrix} I & 0 \\ 0 & -I \end{smallmatrix}\right]\left[\begin{smallmatrix} M & -Y \\ -N & X \end{smallmatrix}\right]\left[\begin{smallmatrix} I & 0 \\ 0 & -I \end{smallmatrix}\right]\right)^{-1} \in \mathrm{H}^\infty$. □

(The main part of the above is essentially the proof of [11, Lemmata 7.1.5 and 6.6.6] with w.r.c.f.'s in place of r.c.f.'s.)

Next we observe that a r.c.f. can be extended to a d.c.f. that has $Y(0) = 0$ and $X(0) \in \mathcal{GB}$.

LEMMA A.5. *Let* NM^{-1} *be a* $\mathcal{B}(\mathtt{U},\mathtt{Y})$*-valued r.c.f. Then* NM^{-1} *has a d.c.f.* $\left[\begin{smallmatrix} M & Y \\ N & X \end{smallmatrix}\right] = \left[\begin{smallmatrix} \tilde{X} & -\tilde{Y} \\ -\tilde{N} & \tilde{M} \end{smallmatrix}\right]^{-1} \in \mathrm{H}^\infty(\mathtt{U} \times \mathtt{Y})$ *such that* $X(0), \tilde{X}(0), \tilde{M}(0) \in \mathcal{GB}$ *and* $Y(0) = 0$. *Moreover, the strictly proper function* $Q := YX^{-1} = \tilde{X}^{-1}\tilde{Y}$ *stabilizes* $P := NM^{-1}$ *in the sense that* $\left[\begin{smallmatrix} I & -Q \\ -P & I \end{smallmatrix}\right]^{-1} \in \mathrm{H}^\infty$. *Furthermore, we can have above* $X(0) = I = \tilde{M}(0)$ *(and* $\tilde{X}(0) = I = M(0)$ *if we replace* N *by* NV *and* M *by* MV, *where* $V := M(0) \in \mathcal{GB}(\mathtt{U})$*).*

Proof. By [16], we can extend the function $\left[\begin{smallmatrix} M \\ N \end{smallmatrix}\right]$ to a d.c.f. $\left[\begin{smallmatrix} M & Y_0 \\ N & X_0 \end{smallmatrix}\right]$. Set $\left[\begin{smallmatrix} M & Y_1 \\ N & X_1 \end{smallmatrix}\right] := \left[\begin{smallmatrix} M & Y_0 \\ N & X_0 \end{smallmatrix}\right]\left[\begin{smallmatrix} I & -M(0)^{-1}Y_0 \\ 0 & I \end{smallmatrix}\right]$ to have $Y_1(0) = 0$. It follows that $X_1(0)$ must be invertible. Set $\left[\begin{smallmatrix} M & Y \\ N & X \end{smallmatrix}\right] := \left[\begin{smallmatrix} M & Y_1 \\ N & X_1 \end{smallmatrix}\right]\left[\begin{smallmatrix} I & 0 \\ 0 & X_1(0)^{-1} \end{smallmatrix}\right]$ to have $X(0) = I$; hence $\left[\begin{smallmatrix} \tilde{X} & -\tilde{Y} \\ -\tilde{N} & \tilde{M} \end{smallmatrix}\right](0) = \left[\begin{smallmatrix} M(0)^{-1} & 0 \\ P(0) & I \end{smallmatrix}\right]$, where $P := NM^{-1}$ (and $\left[\begin{smallmatrix} \tilde{X} & -\tilde{Y} \\ -\tilde{N} & \tilde{M} \end{smallmatrix}\right] := \left[\begin{smallmatrix} M & Y \\ N & X \end{smallmatrix}\right]^{-1}$). The final claim obviously follows. One easily verifies that $\left[\begin{smallmatrix} I & -Q \\ -P & I \end{smallmatrix}\right]^{-1} = \left[\begin{smallmatrix} M\tilde{X} & Y\tilde{M} \\ N\tilde{X} & X\tilde{M} \end{smallmatrix}\right] = I$. □

LEMMA A.6. *Conditions* (i)–(v) *of Theorem* 1.1 *are equivalent.*

Proof. 1° (i), (ii), (iv), *and* (v): By Lemmata A.4 and A.5, (i), (ii), and (iv) are equivalent. If $P = NM^{-1}$ is a r.c.f., then obviously so is $\left[\begin{smallmatrix} P & 0 \\ 0 & I \end{smallmatrix}\right] = \left[\begin{smallmatrix} N & 0 \\ 0 & I \end{smallmatrix}\right] \left[\begin{smallmatrix} M & 0 \\ 0 & I \end{smallmatrix}\right]^{-1}$; thus, (iv) implies (v). Assume then (v). By Proposition 2.2, $\left[\begin{smallmatrix} P & 0 \\ 0 & I \end{smallmatrix}\right]$ has a realization $\tilde{\Sigma}$ that satisfies the finite cost condition and its dual. Remove the bottom row of $\tilde{\Sigma}$ to obtain a realization Σ of P that satisfies the finite cost condition and its dual (this follows very easily). By Proposition 2.2, this shows that P has a r.c.f.

2° (iii): Trivially, (i) implies (iii) (take $R := \left[\begin{smallmatrix} Q & 0 \\ 0 & 0 \end{smallmatrix}\right]$). If (iii) holds, then so does (v), by Lemmata 3.1 and A.4 (with $\left[\begin{smallmatrix} P & 0 \\ 0 & I \end{smallmatrix}\right]$ in place of P). ∎

The following is well known [24].

PROPOSITION A.7 (Schur decomposition). (a) *If* $A = B^{-1} \in \mathcal{GB}(\mathtt{X}_1 \times \mathtt{X}_2, \mathtt{Y}_1 \times \mathtt{Y}_2)$, *then* $A_{22} \in \mathcal{GB}(\mathtt{X}_2, \mathtt{Y}_2) \Leftrightarrow B_{11} \in \mathcal{GB}(\mathtt{Y}_1, \mathtt{X}_1) \Rightarrow B_{11}^{-1} = A_{11} - A_{12}A_{22}^{-1}A_{21}$.

(b) *If* $A \in \mathcal{B}(\mathtt{X}_1 \times \mathtt{X}_2,\ \mathtt{Y}_1 \times \mathtt{Y}_2)$ *and* $A_{22} \in \mathcal{GB}(\mathtt{X}_2, \mathtt{Y}_2)$, *then* $A \in \mathcal{GB} \Leftrightarrow A_{11} - A_{12}A_{22}^{-1}A_{21} \in \mathcal{GB}(\mathtt{X}_1, \mathtt{Y}_1)$.

Now we can prove the results of section 3.

Proof of Lemma 3.2. 1° Set

$$A := I - P^R = \left[\begin{array}{cc|c} I & -R_{11} & -R_{12} \\ -P & I & 0 \\ \hline 0 & -R_{21} & I - R_{22} \end{array}\right], \tag{A.5}$$

$B := A^{-1}$. Assume that $A_{22}(0) := I - R_{22}(0) \in \mathcal{GB}$. By Proposition A.7(a), $B_{11}^{-1} = A_{11} - A_{12}A_{22}^{-1}A_{21} = \left[\begin{smallmatrix} I & -Q \\ -P & I \end{smallmatrix}\right]$, where $Q := R_{11} - R_{12}(I - R_{22})^{-1}R_{21}$; hence $B_{11} = \tilde{B}_{11}$, where $\tilde{B} := (I - P^{\tilde{R}})^{-1}$, $\tilde{R} := \left[\begin{smallmatrix} Q & 0 \\ 0 & 0 \end{smallmatrix}\right]$. Thus, R and $\tilde{R}$ are "equivalent." But $\tilde{B}_{21} = 0$, $\tilde{B}_{12} = 0$, and $\tilde{B}_{22} = I$; hence $\tilde{B} \in \mathrm{H}^\infty$, so also $\tilde{R}$ is stabilizing.

2° Assume that R and $\tilde{R}$ are equivalent. Then we again have $B_{11} = \tilde{B}_{11}$. But $\tilde{B}_{11}^{-1} = \left[\begin{smallmatrix} I & -Q \\ -P & I \end{smallmatrix}\right]$ is proper; hence $B_{11}(0) \in \mathcal{GB}$. By Proposition A.7(a), this implies that $\mathcal{GB} \ni A_{22}(0) = I - R_{22}(0)$. ∎

Proof of Lemma 3.3. By Lemma A.6, P has a r.c.f. NM^{-1}. Set

$$T := \begin{bmatrix} T_{11} & T_{12} & T_{13} \\ T_{21} & T_{22} & T_{23} \\ T_{31} & T_{32} & T_{33} \end{bmatrix} := (I - P^R)^{-1}, \qquad \tilde{X} := M^{-1}T_{11}, \qquad \tilde{Y} := M^{-1}T_{12}. \tag{A.6}$$

Since $T(I - P^R) = I = (I - P^R)T$, we have (see (A.5)) $T_{11}I - T_{12}P = I$, $-PT_{11} + T_{21} = 0$, and $-PT_{12} + T_{22} = I$; hence $\tilde{X} - \tilde{Y}P = M^{-1}$, i.e., $\tilde{X}M - \tilde{Y}N = I$, and also $-N\tilde{X} + T_{21} = 0$, $-N\tilde{Y} + T_{22} = 0$. Thus, $N\tilde{X}, N\tilde{Y} \in \mathrm{H}^\infty$. But $M\tilde{X} = T_{11} \in \mathrm{H}^\infty$ and $M\tilde{Y} = T_{12} \in \mathrm{H}^\infty$; hence $\tilde{X}, \tilde{Y} \in \mathrm{H}^\infty$, by Proposition A.2, and hence $\tilde{X}$ and $\tilde{Y}$ are l.c. By duality (because R^{d} is stabilizing for P^{d}), we get X and Y. ∎

The following is a direct consequence of Proposition A.7.

LEMMA A.8. *Let* P *be* $\mathcal{B}(\mathtt{U}, \mathtt{Y})$*-valued and proper and let* $R = \left[\begin{smallmatrix} 0 & I \\ \tilde{Y} & I - \tilde{X} \end{smallmatrix}\right]$ *be* $\mathcal{B}(\mathtt{Y} \times \mathtt{U},\ \mathtt{Y} \times \mathtt{Y})$*-valued and proper. Then* $R(0) \in \mathcal{GB}$ *iff* $(\tilde{X} - \tilde{Y}P)(0) \in \mathcal{GB}$. *Moreover, if* $R(0) \in \mathcal{GB}$, *then (set* $M := (\tilde{X} - \tilde{Y}P)^{-1}$*)*

$$(I - P^R)^{-1} = \begin{bmatrix} I + M\tilde{Y}P & M\tilde{Y} & M \\ P(I + M\tilde{Y}P) & I + PM\tilde{Y} & PM \\ M\tilde{Y}P & M\tilde{Y} & M \end{bmatrix} = \begin{bmatrix} M\tilde{X} & M\tilde{Y} & M \\ PM\tilde{X} & I + PM\tilde{Y} & PM \\ M\tilde{X} - I & M\tilde{Y} & M \end{bmatrix}. \tag{A.7}$$

Proof of Lemma 3.5. 1° One easily verifies (3.3). By the definition of equivalence (and the equation $\left[\begin{smallmatrix} M & Y \\ N & X \end{smallmatrix}\right]\left[\begin{smallmatrix} \tilde{X} & -\tilde{Y} \\ -\tilde{N} & \tilde{M} \end{smallmatrix}\right] = I$), (3.2) follows.

2° If $P = NM^{-1}$ is a r.c.f., $\tilde{X}, \tilde{Y} \in \mathrm{H}^\infty$, and $\Delta := \tilde{X}M - \tilde{Y}N \in \mathcal{G}\mathrm{H}^\infty$ (by Proposition A.1, the same then holds for all r.c.f.'s of P), then $N_1 := N\Delta^{-1}$, $M_1 := M\Delta^{-1}$ form a r.c.f. of P and satisfy $\tilde{X}M_1 - \tilde{Y}N_1 = I$. By Lemma 3.4 and (3.3), only the "only if" from the first "iff" remains to be proved.

3° Assume that R' is stabilizing. By the proof of Lemma 3.3, R' is equivalent to $\tilde{X}_1^{-1}\tilde{Y}_1$, where $\tilde{X}_1, \tilde{Y}_1 \in \mathrm{H}^\infty$ and $\tilde{X}_1 M_1 - \tilde{Y}_1 N_1 = I$ for some r.c.f. $P = N_1 M_1^{-1}$. By (A.7) and the equivalence of R' to $\tilde{X}_1^{-1}\tilde{Y}_1$, we have $\begin{bmatrix} M_1\tilde{X}_1 & M_1\tilde{Y}_1 \end{bmatrix} = \begin{bmatrix} M\tilde{X} & M\tilde{Y} \end{bmatrix}$; hence $\tilde{X} = \Delta\tilde{X}_1$ and $\tilde{Y} = \Delta\tilde{Y}_1$, where

$$\Delta := M^{-1}M_1 = \tilde{X}M_1 - \tilde{Y}N_1 \in \mathrm{H}^\infty(\mathtt{U}) \tag{A.8}$$

(because $M^{-1} = \tilde{X} - \tilde{Y}P$). But $\Delta^{-1} = M_1^{-1}M$; hence $M_1\Delta^{-1} = M$ and $N_1\Delta^{-1} = PM$. Since $M, PM \in \mathrm{H}^\infty$, by (A.7), we have $\Delta^{-1} \in \mathrm{H}^\infty$, by Proposition A.2. Thus, $\tilde{X}M_1 - \tilde{Y}N_1 = \Delta \in \mathcal{G}\,\mathrm{H}^\infty$. □

Now we are ready to complete the proof of our main result.

Proof of Theorem 1.1. Lemma A.6 contains the equivalence. Assume then that $P = NM^{-1}$ is a r.c.f. By [16], $\left[\begin{smallmatrix} M \\ N \end{smallmatrix}\right]$ can be extended to a d.c.f. It obviously follows that $\tilde{M}(0) \in \mathcal{GB}$ and $P = \tilde{M}^{-1}\tilde{N}$ (see [11] or [24]). The Youla parameterization is essentially from [4, Theorem 5.5] or [11, Theorem 7.2.14] (and can easily be obtained from Lemmata 3.3 and 3.5). The claim on properness is from Lemma 3.2 and that on strict properness is from Lemma 3.7. □

Proof of Theorem 2.1. 1° If $P = NM^{-1}$ is an α-r.c.f. and $\tilde{X}M - \tilde{Y}N = I$, $\tilde{X}, \tilde{Y} \in \mathrm{H}^\infty$, then $\tilde{X} - \tilde{Y}P = M^{-1}$ near α, hence on Ω_P; hence then $P = NM^{-1}$ is a β-r.c.f. too. The rest of the last paragraph follows analogously.

2° (iii)–(iv"'): By 1°, (iv) and (iv') are equivalent. The implication (iv')⇒(iv"') is from Theorem 1.1 (and Remark 7.1) and the converse is trivial. By duality, we get (iv")⇔(iv"'). The equivalence of (iii) and (iii') follows from Lemma 3.3.

3° As in Remark 7.1, we observe that Theorem 1.1 holds with α in place of 0, so the equivalence of (ii") and (iv') follows from that of (i) and (iv). Similarly, if (ii') holds and $z \in \Omega_Q$, then P has a z-r.c.f.; hence then (iv) holds, by 1°. Trivially, (ii") implies (ii). □

Proof of Corollary 1.2. The implications (vi)⇒(ii) and (iv)⇒(vii) are trivial (take $\epsilon := 1/\|[\tilde{X} - \tilde{Y}]\|^2$). Implication (iv)⇒(vi) is from [19, Corollary 6.6] and (vii)⇒(iv') (see Theorem 2.1) holds for some suitable $\alpha \in \mathbb{D}$ by [7]. □

(In fact, (vii) is equivalent to (i)–(v) even if $\dim \mathtt{Y} = \infty$; it suffices that $\dim \mathtt{U} < \infty$.)

Next we need the following generalization of a classical result.

LEMMA A.9 (R stabilizes P_{21}). *If R is stabilizing DPF-controller with internal loop for P, then R is a stabilizing controller with internal loop for P_{21}.*

(This was shown rigorously in [11, Lemma 7.3.5], but this can be observed from Figure 4.1: For $w = 0$ the closed-loop equations obviously define the map $(I - (P_{21})^R)^{-1}$ (see (3.1)) if we ignore the equation for z; thus, $(I - (P_{21})^R)^{-1}$ is contained in the "DPF closed-loop map" $(I - P^{R_{\mathrm{DPF}}})^{-1} \in \mathrm{H}^\infty$ for P and R.)

Proof of Theorems 4.1 *and* 4.2. 1° We first note that if R DPF-stabilizes P with internal loop, then it stabilizes P_{21}, by Lemma A.9; hence then P_{21} has a d.c.f. and R is equivalent to a canonical controller, by Theorem 1.1.

2° (iii)⇒(iv): Let $\tilde{X}^{-1}\tilde{Y}$ be a canonical controller that DPF-stabilizes P. Then $\tilde{X}^{-1}\tilde{Y}$ stabilizes P_{21}. One can verify that $\left[\begin{smallmatrix}\tilde{X} & 0\\ 0 & I\end{smallmatrix}\right]^{-1}\left[\begin{smallmatrix}0 & \tilde{Y}\\ 0 & 0\end{smallmatrix}\right]$ is a canonical controller that stabilizes P (see [11, Lemma 7.3.10] for details). By Lemma 3.5 it follows that there exists a r.c.f. $P = NM^{-1}$ such that

$$\text{(A.9)}\qquad \begin{bmatrix} I & 0\\ 0 & I\end{bmatrix} = \begin{bmatrix}\tilde{X} & 0\\ 0 & I\end{bmatrix} M - \begin{bmatrix}0 & \tilde{Y}\\ 0 & 0\end{bmatrix} N = \begin{bmatrix}\tilde{X}M_{11} - \tilde{Y}N_{21} & \tilde{X}M_{12} - \tilde{Y}N_{22}\\ M_{21} & M_{22}\end{bmatrix};$$

in particular, $\tilde{X}M_{11} - \tilde{Y}N_{21} = I$, $M_{21} = 0$, and $M_{22} = I$, and hence (iv) holds.

3° (iv)⇒(iii): Assume (iv). By Lemma 3.5 and (A.9), $\tilde{X}^{-1}\tilde{Y}$ DPF-stabilizes P iff we have

$$\text{(A.10)}\qquad \begin{bmatrix}\tilde{X}M_{11} - \tilde{Y}N_{21} & \tilde{X}M_{12} - \tilde{Y}N_{22}\\ 0 & I\end{bmatrix} \in \mathcal{G}\,\mathrm{H}^\infty(\mathtt{U}\times\mathtt{W}),$$

or equivalently, $\tilde{X}M_{11} - \tilde{Y}N_{21} \in \mathcal{G}\,\mathrm{H}^\infty(\mathtt{U})$, or equivalently, iff the canonical controller $\tilde{X}^{-1}\tilde{Y}$ stabilizes $N_{21}M_{11}^{-1} = P_{21}$. By Theorem 1.1 (applied to P_{21}), such $\tilde{X}, \tilde{Y} \in \mathrm{H}^\infty$ do exist.

4° By duality, we get "(iii)⇔(v)"; hence (iii)–(v) are equivalent. Moreover, in 3° we observed that if (iv) holds, then a canonical controller DPF-stabilizes P iff it stabilizes P_{21}. By Theorem 1.1, all such canonical controllers are given by the Youla parameterization (1.3) and at least one of them is strictly proper; hence (i) and (ii) are equivalent to (iii). Moreover, by Lemmata A.9 and 3.3, any DPF-stabilizing controller with internal loop for P is equivalent to some canonical controller. Thus, both theorems have been established. □

In a r.c.f. $P = NM^{-1}$, the inverse M^{-1} has the same maximal domain as P.

LEMMA A.10. *If $P : \Omega \to \mathcal{B}(\mathtt{U},\mathtt{Y})$ is holomorphic, where $\Omega \subset \mathbb{D}$ is connected, and $P = NM^{-1}$ is a α-r.c.f. for some $\alpha \in \Omega$, then $P = NM^{-1}$ is a z-r.c.f. for every $z \in \Omega$.*

(Indeed, if $\tilde{X}M - \tilde{Y}N = I$, then $I = (\tilde{X} - \tilde{Y}P)M = M(\tilde{X} - \tilde{Y}P)$ near α, hence on Ω.)

Thus, then any connected holomorphic extension of P (within $\mathbb{D}$) is a restriction of NM^{-1}.

Next we conclude the same with a "possibly nonconnected Ω." For example, if NM^{-1} has an α_1-r.c.f. and an α_2-r.c.f., then these are the same (modulo a unit).

LEMMA A.11. *Let $\alpha_1, \alpha_2 \in \mathbb{D}$, $N \in \mathrm{H}^\infty(\mathtt{U},\mathtt{Y})$, $M \in \mathrm{H}^\infty(\mathtt{U})$, $M(\alpha_1), M(\alpha_2) \in \mathcal{GB}(\mathtt{U})$. Let $N_kM_k^{-1}$ be an α_k-r.c.f. of NM^{-1} ($k = 1, 2$). Then $\left[\begin{smallmatrix}N_2\\ M_2\end{smallmatrix}\right] = \left[\begin{smallmatrix}N_1\\ M_1\end{smallmatrix}\right] V$ for some $V \in \mathcal{G}\,\mathrm{H}^\infty(\mathtt{U})$; in particular, $N_1M_1^{-1}$ is also an α_2-r.c.f. of NM^{-1}.*

Proof. Set $F := \left[\begin{smallmatrix}N\\ M\end{smallmatrix}\right]$, $F_k := \left[\begin{smallmatrix}N_k\\ M_k\end{smallmatrix}\right]$, and pick $G_k \in \mathrm{H}^\infty$ such that $G_kF_k = I$ ($k = 1, 2$). By Proposition A.1 (and Remark 7.1), we have $F = F_kV_k$ for some $V_k \in \mathrm{H}^\infty(\mathtt{U})$ such that $V_k(\alpha_k) \in \mathcal{GB}(\mathtt{U})$ ($k = 1, 2$). Therefore $V_1 = G_1F_2V_2$ and $V_2 = G_2F_1V_1 = G_2F_1G_1F_2V_2$; hence $G_2F_1G_1F_2 = I$ near α_2, hence on $\mathbb{D}$. Similarly, $TS = I$, where $T := G_1F_2$, $S := G_2F_1$. But $F_2V_2 = F_1V_1 = F_1TV_2$; hence $F_2 = F_1T$ near α_2, hence on $\mathbb{D}$. Set $V := T$. □

Proof of Lemma 6.1. 1° *"If"*: Set $\left[\begin{smallmatrix}\tilde{X} & -\tilde{Y}\\ -\tilde{N} & \tilde{M}\end{smallmatrix}\right] := \left[\begin{smallmatrix}M & Y\\ N & X\end{smallmatrix}\right]^{-1}$. By (3.2) (and Remark 7.1 and Lemma 3.2), $\left[\begin{smallmatrix}I & -Q\\ -P & I\end{smallmatrix}\right]^{-1} = \left[\begin{smallmatrix}Y\tilde{N}+I & Y\tilde{M}\\ X\tilde{N} & X\tilde{M}\end{smallmatrix}\right] =: E$ on Ω.

2° *"Only if"*: By (1.1), $N_0, M_0 \in \mathrm{H}^\infty$, where $N_0 := P(I - QP)^{-1}$ and $M_0 = (I - QP)^{-1}$. Since $P = N_0M_0^{-1}$ on Ω, P has an α-r.c.f. and a β-r.c.f., by Lemma A.4 (cf. Remark 7.1). By Lemma A.11, any α-r.c.f. of P is a β-r.c.f. of P.

By Lemmata 3.3, 3.5, and 3.2, there exists an α-d.c.f. $\left[\begin{smallmatrix} M & Y \\ N & X \end{smallmatrix}\right] = \left[\begin{smallmatrix} \tilde{X} & -\tilde{Y} \\ -\tilde{N} & \tilde{M} \end{smallmatrix}\right]^{-1}$ of P such that $X(\alpha) \in \mathcal{GB}(\mathtt{Y})$ and $Q = YX^{-1}$ on a neighborhood of α. By the above, $\left[\begin{smallmatrix} M & Y \\ N & X \end{smallmatrix}\right]$ is also a β-d.c.f. of P. Exchange the roles of P and Q to observe that $Q = YX^{-1}$ is also a β-r.c.f. (in particular, $X(\beta) \in \mathcal{GB}(\mathtt{Y})$).

3° By Proposition A.1 (cf. Remark 7.1), $\left[\begin{smallmatrix} M_1 & Y_1 \\ N_1 & X_1 \end{smallmatrix}\right] = \left[\begin{smallmatrix} M & Y \\ N & X \end{smallmatrix}\right] \left[\begin{smallmatrix} V & 0 \\ 0 & V_Q \end{smallmatrix}\right]$ for some $V \in \mathcal{G}\,\mathrm{H}^\infty(\mathtt{U})$, $V_Q \in \mathcal{G}\,\mathrm{H}^\infty(\mathtt{Y})$; hence the claim on β-r.c.f.'s follows. The last claim now follows from Lemma A.10. ∎

Appendix B. Continuous-time proofs (for section 7). In this appendix we prove the results of section 7.

Proof of Remark 7.1. This is straightforward, but we give some examples below. For clarity, in this proof we add the prefix "$(\mathbb{D}', \zeta)$-" when we refer to the redefined terminology of Remark 7.1; otherwise we refer to the original DT terminology of sections 1–6.

By the Riemann mapping theorem, there exists a holomorphic function $f : \mathbb{D}' \to \mathbb{D}$ that has a holomorphic inverse and satisfies $f(\zeta) = 0$. Obviously, a function P' is $(\mathbb{D}', \zeta)$-proper (resp., $(\mathbb{D}', \zeta)$-H^∞) iff $P := P' \circ f^{-1}$ is proper (resp., H^∞). Moreover, a function Q is a proper stabilizing controller for P iff $Q' := Q \circ f$ is a $(\mathbb{D}', \zeta)$-proper stabilizing controller for $P \circ f = P'$, i.e., iff Q' is $(\mathbb{D}', \zeta)$-proper and $\left[\begin{smallmatrix} I & -Q' \\ -P' & I \end{smallmatrix}\right]^{-1}$ is a bounded holomorphic function on $\mathbb{D}'$ (because $\left[\begin{smallmatrix} I & -Q' \\ -P' & I \end{smallmatrix}\right]^{-1} = \left[\begin{smallmatrix} I & -Q \\ -P & I \end{smallmatrix}\right]^{-1} \circ f$ wherever either exists).

Similarly, also all other required old terminology is mapped to corresponding new $(\mathbb{D}', \zeta)$-terminology; hence all results mentioned in Remark 7.1 hold also for this new $(\mathbb{D}', \zeta)$-terminology.

For example, if a ζ-proper function P' has a $(\mathbb{D}', \zeta)$-proper stabilizing controller, then $P := P' \circ f^{-1}$ has a r.c.f. $P = NM^{-1}$, by Theorem 1.1; hence then P' has the r.c.f. $N'(M')^{-1}$ with $N' := N \circ f$, $M' := M \circ f$. ∎

The original proofs of all DT results apply in their CT forms too except that part of the proof of Theorem 1.1 would require additional details. Also Remark 7.1 (with some additional work) could be used to prove almost all CT results, but in some cases it becomes more cumbersome than the use of the original proofs, so we shall in each proof below select the simplest method.

From now on we use the CT terminology defined in Definition 7.2 and below it unless we explicitly use the prefix *DT-* (when referring to the original DT terminology of sections 1–6)) or the prefix ζ- (when referring to the terminology defined in Remark 7.1 for fixed $\zeta \in \mathbb{C}^+$ and $\mathbb{D}' := \mathbb{C}^+$). Thus, e.g., proper means H^∞_∞, but *DT-proper* (resp., ζ-*proper*) means holomorphic on a neighborhood of 0 (resp., ζ). Observe that in, e.g., ζ-*canonical controller* or ζ-H^∞ the prefix is redundant (but *DT*-H^∞ means holomorphic and bounded on $\mathbb{D}$, not on $\mathbb{C}^+$).

However, when referring to some result, we refer to its original form unless we use the prefix "CT-" or "ζ-". When we write, e.g., *CT-Corollary* 3.6, we refer to the CT-form of Corollary 3.6 that is established in Theorem 7.3 (its proof is given later below). Similarly, ζ-*Corollary* 3.6 refers to the form established in Remark 7.1 (with $\mathbb{D}' = \mathbb{C}^+$).

We shall often need the fact that the (CT) r.c.f.'s of a proper function are the same as its α-r.c.f.'s:

Lemma B.1 (α-r.c.f.). *Let $\omega \geq 0$, $P \in \mathrm{H}^\infty_\omega(\mathtt{U}, \mathtt{Y})$, and $\alpha \in \mathbb{C}^+_\omega$. Then an α-r.c.f. of P is a r.c.f., and a r.c.f. of P is an α-r.c.f. A similar claim obviously holds for l.c.f.'s and d.c.f.'s.*

Proof. If $\tilde{X}, \tilde{Y}, M, N \in \mathrm{H}^\infty$, $I = \tilde{X}M - \tilde{Y}N$ (on $\mathbb{C}^+$), and $NM^{-1} = P$ on a neighborhood Ω of α, then $I = (\tilde{X} - \tilde{Y}P)M$ on $\mathbb{C}_\omega^+$ and $M(\alpha)^{-1}$ exists; hence then $I = M(\tilde{X} - \tilde{Y}P)$ on a neighborhood of α, hence on $\mathbb{C}_\omega^+$ too, so then $P = NM^{-1}$ is a (CT) r.c.f. The converse is analogous. ∎

Proof of Theorem 7.5. As in the proof of Lemma B.1, we observe that also here α-r.c.f.'s coincide with r.c.f.'s. The rest of Theorem 7.5 is already contained in ζ-Theorem 2.1 (for any fixed $\zeta \in \Omega_P$). ∎

Proof of Theorem 7.4 *except CT-Lemma* 3.7. Pick $\omega \geq 0$ such that $P \in \mathrm{H}_\omega^\infty$, and set $\Omega_P := \mathbb{C}_\omega^+$ (and $\mathbb{D}' := \mathbb{C}^+$). Observe that a (CT) "canonical controller" is such also in terms of Remark 7.1 (when, e.g., $\zeta \in \mathbb{C}_\omega^+$).

1° The equivalence of (i)–(v) follows from Theorem 7.5 as follows: The equivalence "(iv)⇔(iv')" is contained in Theorem 7.5. For $\alpha = \zeta \in \mathbb{C}_\omega^+$, we get "(iv)⇔(v)" from "(iv)⇔(iv')" (twice) and ζ-Theorem 1.1 (P has a r.c.f. ⇔ it has a ζ-r.c.f. ⇔ $\left[\begin{smallmatrix} P & 0 \\ 0 & I \end{smallmatrix}\right]$ has a ζ-r.c.f. ⇔ $\left[\begin{smallmatrix} P & 0 \\ 0 & I \end{smallmatrix}\right]$ has a r.c.f.). Each of conditions (i) and (ii) is obviously equivalent to (ii') and/or (ii") (of Theorem 7.5). (iii') implies (iii); if (iii) holds, then P has a ζ-r.c.f. for some $\zeta \in \mathbb{C}_\omega^+$ (pick one in the definition of the controller), by ζ-Theorem 1.1(iii) and (iv); i.e., then (iv') holds (take $\alpha = \zeta$).

2° For any $\zeta \in \mathbb{C}_\omega^+$, we get the d.c.f. from ζ-Theorem 1.1 and Lemma B.1. Obviously, a canonical controller $\left[\begin{smallmatrix} 0 & Y \\ I & I-X \end{smallmatrix}\right]$ stabilizes P iff it ζ-stabilizes P (for some $\zeta \in \mathbb{C}_\omega^+$). A stabilizing controller $R \in \mathrm{H}_\infty^\infty$ with internal loop for P is a ζ-stabilizing controller with internal loop for P (for some $\zeta \in \mathbb{C}_\omega^+$), hence equivalent to a [ζ-]canonical controller, by ζ-Lemma 3.3, so the Youla parameterization claim holds (recall Lemma 7.7). ∎

Proof of Theorem 7.3. *All propositions*: The CT forms are given in [15].

Lemmata A.3, A.4, *and* 3.3: Use the original proofs.

Lemmata 3.4 *and* 3.5 *and Corollaries* 3.6 *and* 1.2: Use the original proofs, mutatis mutandis (see Definition 7.2).

Lemmata A.9, A.10, A.11, *and* 3.1: These follow easily from Remark 7.1.

Lemma 3.7: Pick a d.c.f. $\left[\begin{smallmatrix} M & Y \\ N & X \end{smallmatrix}\right] = \left[\begin{smallmatrix} \tilde{X} & -\tilde{Y} \\ -\tilde{N} & \tilde{M} \end{smallmatrix}\right]^{-1} \in \mathrm{H}^\infty(\mathtt{U} \times \mathtt{Y})$ of P. Pick $\omega' > 0$ such that $\|\tilde{X}(s) - M^{-1}(s)\| = \|\tilde{Y}(s)P(s)\| < 1/2\|M\|_{\mathrm{H}^\infty}$ for all $s \in \mathbb{C}_{\omega'}^+$ to have $\tilde{X}(s)^{-1}$ bounded on $\mathbb{C}_{\omega'}^+$. Thus, all canonical controllers are proper (see CT-Corollary 3.6). By CT-Lemmata 3.2 and 3.3, all stabilizing controllers with internal loop for P are proper.

Lemma 6.1: This follows easily from Remark 7.1 and Lemma B.1. ∎

Proof of Theorem 7.6. One easily verifies that $M(+\infty) \in \mathcal{GB}(\mathtt{U})$ [11, Proposition 6.3.1(c)]. Let $P = N_0 M_0^{-1}$ be a r.c.f. By CT-Proposition A.1, $\left[\begin{smallmatrix} N \\ M \end{smallmatrix}\right] = \left[\begin{smallmatrix} N_0 \\ M_0 \end{smallmatrix}\right] V$ for some $V \in \mathrm{H}^\infty$ such that V^{-1} is proper. Let $\left[\begin{smallmatrix} M_0 & Y \\ N_0 & X \end{smallmatrix}\right] \in \mathcal{G}\,\mathrm{H}^\infty(\mathtt{Y} \times \mathtt{U})$ (see Theorem 7.4) and set

(B.1)
$$\begin{bmatrix} M_0 & Y_0 \\ N_0 & X_0 \end{bmatrix} := \begin{bmatrix} M_0 & Y \\ N_0 & X \end{bmatrix} \begin{bmatrix} I & -VM(+\infty)^{-1}Y \\ 0 & I \end{bmatrix} = \begin{bmatrix} M_0 & (1 - MM(+\infty)^{-1})Y \\ N_0 & X - NM(+\infty)^{-1}Y \end{bmatrix}.$$

Set $\left[\begin{smallmatrix} \tilde{X} & -\tilde{Y} \\ -\tilde{N} & \tilde{M} \end{smallmatrix}\right] := \left[\begin{smallmatrix} M_0 & Y_0 \\ N_0 & X_0 \end{smallmatrix}\right]^{-1} \in \mathcal{G}\,\mathrm{H}^\infty$. Since $Y_0(+\infty) = 0$, the function $\tilde{M}X_0 = I - \tilde{N}Y_0$ is boundedly invertible on some right half-plane; hence so is X_0 (because so is $\tilde{M}$). Thus, $Q = Y_0 X_0^{-1}$ is strictly proper (and stabilizing, by Theorem 7.4). ∎

Proof of Theorem 7.9. The equivalence of (ii) and (iii) follows from Theorem 7.4 (and the definitions). The rest follows from ζ-Theorem 4.2 and Lemma B.1 for a suitable ζ. ∎

Proof of Theorem 7.8. From ζ-Theorem 4.1 (for some ζ in the domain of P and R) we observe that the first equivalence and the last claim hold.

If Q is a stabilizing DPF-controller function for P, then it is a [ζ-]stabilizing canonical controller for P_{21} given by the Youla parameterization (pick some ζ in the domain of Q), by ζ-Theorem 4.1. The same holds when Q is a stabilizing controller function for P_{21}, by Theorem 7.4. Therefore, the second equivalence in Theorem 7.8 follows from the first. □

Proof of Remark 7.10. In the proof of Remark 5.1, use $(\cdot - r)$ in place of $(r\cdot)$, for a suitable $r > 0$. □

SIMPLIFIED FORMULA FOR A CONTROLLER IN OPTIMAL CONTROL PROBLEMS*

JOVAN STEFANOVSKI†

Abstract. We derive a simplified frequency-domain formula for a controller transfer matrix for LQ optimal output feedback control of stochastic systems. For this purpose we apply a generalization of the Wiener–Hopf method. The generalization is characterized by the following three properties: (1) We generalize the usual operator $\{\cdot\}_+$ on rational matrices in the traditional Wiener–Hopf approach. The same algorithms as for computation of $\{\cdot\}_+$ are applicable to compute the new operator. (2) The matrices of the Youla–Kučera parametrization do not appear in the optimal controller transfer matrix $\mathbf{C}$ (they appear only in its derivation), even if the plant is unstable. (3) Unlike the traditional Wiener–Hopf method [D. C. Youla, H. A. Jabr, and J. J. Bongiorno, Jr., *IEEE Trans. Automat. Control*, AC-21 (1976), pp. 319–338], where the spectral factors in the two spectral factorizations are both stable and minimum phase, our spectral factors need to be minimum phase only. Finally, three state-space applications of the formula are presented.

Key words. parametrization of stabilizing controllers, Laplace transformation, Wiener–Hopf approach, partial fraction expansion, spectral factorization

1. Introduction.

Consider the system of Figure 1. This system is classical in control theory and practice and it originates from the problem of optimal tracking with rejection of disturbances in the presence of measurement noise, which is one of the most important control problems. The variable w represents the plant disturbances, v is measurement noise, and r is reference input (to-be-tracked signal).

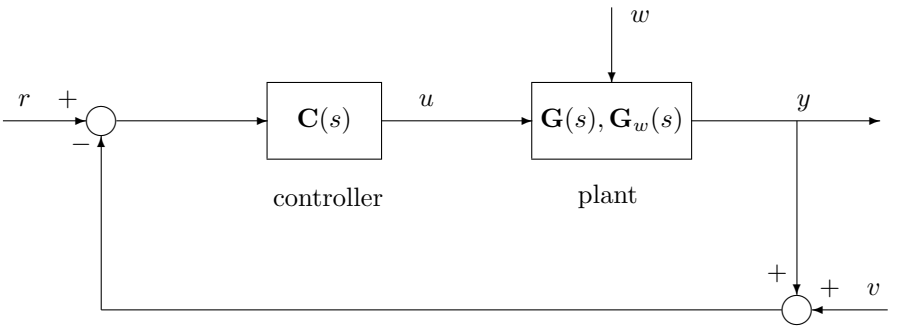

FIG. 1. *Control scheme for tracking and disturbance rejecting.*

The two approaches for linear quadratic (LQ) optimal control by output feedback are the time-domain approach, operating with state-space equations, and the frequency-domain approach, operating with polynomial and/or rational matrices.

The state-space approach (see [3], [13], and references therein), did not solve the optimization control problem for the system of Figure 1, where the spectral characteristics of the signals r, w, and v are arbitrary, because problems with colored

†Control & Informatics Division, JP "Streževo," 7000 Bitola, Republic of Macedonia (jovanstef@mt.net.mk).

measurement noise, problems with a singular covariance matrix of a white measurement noise, problems with a colored reference signal, problems with shape-deterministic inputs, and problems with frequency-dependent weighting functions are not close to the philosophy of this approach. In particular, the methodology of [3] and its generalization in [13] cannot directly solve our state-space applications presented in sections 4.1 and 4.3, because they require frequency-dependent spectral characteristics of inputs, or shape-deterministic inputs. The application in section 4.2 have zero matrix D_{12}, where the matrix D_{12} is defined in [3], but the algorithm of [3] requires $D_{12} = \left[\begin{smallmatrix} 0 \\ I \end{smallmatrix}\right]$.

The second approach, with polynomial and/or rational matrices (see [17], [8], [5], [2], [4], [6], [7], [11], and references therein), is based on solving a Wiener–Hopf problem in the frequency domain [17], and uses the parametrization of all stabilizing controllers, known in the control literature as Youla–Kučera parametrization [17], [5]. Unlike the state-space approach, this approach can handle colored input signals, frequency-dependent weighting matrices, shape-deterministic inputs, and any structure at infinity of the plant, so the general LQ optimization problem of the system of Figure 1 can be solved by the existing frequency-domain algorithms.

However, a disadvantage of the frequency-domain algorithms is that the matrices of the Youla–Kučera parametrization appear in the controller transfer matrix, so that it is quite complex, and unsuitable for large-scale systems because the pole-zero cancellation in the controller transfer matrix among its products cannot be done numerically in a reliable way. As a result, the controller order is greater than necessary, and, more important, if the cancellation among the products in $\mathbf{C}$ is not done correctly, the closed-loop system of Figure 1 can be unstable.[1]

On the other hand, given the optimal controller transfer matrix in the frequency domain, when state-space equations are employed, matrices of Youla–Kučera parametrization can be removed from the optimal controller transfer matrix. Two different approaches for this removal are presented in [10] and [14]. These results are satisfactory, from a viewpoint of practical controller construction, but the solved class of systems is limited. For example, in [10], the inputs are white noises (except the reference signal), having positive definite spectral densities, the weighting matrices in the minimizing criterion are also positive definite, the plant transfer matrices are strict proper, and the minimal realizations of $\mathbf{G}_w$ and $\mathbf{G}$ have the same poles.

In this work we solve the problem of obtaining a simplified controller transfer matrix (see (4.1)), which is free of the matrices of Youla–Kučera parametrization. This result allows us to solve, in respect to the cited results, more general optimal control problems.

Before we proceed with an explanation of our contribution, some remarks are in order.

Remarks on the notation and techniques used. All considered stochastic processes are stationary. By $\mathcal{E}\{\cdot\}$ we denote the mean value of a stochastic variable.

Vectors are denoted by lowercase symbols and matrices are denoted by uppercase symbols.

If $x(t)$ is a vector stochastic variable, then the matrix autocorrelation function is defined by $\Phi_{xx}(\tau) = \mathcal{E}\left\{x(t) \cdot x^{\mathrm{T}}(t-\tau)\right\}$.

By $\mathbf{\Phi}(s)$ we denote the two-sided Laplace transformation of a function $\Phi(t)$, i.e., $\mathbf{\Phi}(s) = \int_{-\infty}^{\infty} \Phi(t) e^{-st} \mathrm{d}t$, $\alpha_1 \leq \Re(s) \leq \alpha_2$, $\alpha_1 < 0 < \alpha_2$, where by $\Re(s)$ we denote the

[1] The matrices of the Youla–Kučera parametrization do not appear in the controller in Corollary 1 in [17], if the plant is stable.

real part of s, and the inverse Laplace transformation is $\Phi(t) = \frac{1}{2\pi i}\int_{-i\infty}^{i\infty} \mathbf{\Phi}(s)e^{st}\mathrm{d}s$. All considered functions of s are rational and with real coefficients. If not ambiguous, we shall omit the Laplace argument s in the functions.

Poles and zeros of a rational matrix are defined through its McMillan form.

The notation $\mathbf{\Phi}(s) \leq O(s^{\nu})$ means that no entry of $\mathbf{\Phi}$ grows faster than s^{ν} as $s \to \infty$. The rational matrix $\mathbf{\Phi}(s)$ is proper if $\mathbf{\Phi}(s) \leq O(1)$ and is strict proper if $\mathbf{\Phi}(s) \leq O(s^{-1})$. If $\mathbf{\Phi}_1 \leq O(s^{\nu_1})$ and $\mathbf{\Phi}_2 \leq O(s^{\nu_2})$, then $\mathbf{\Phi}_1\mathbf{\Phi}_2 \leq O(s^{\nu_1+\nu_2})$.

The transfer matrix $\mathbf{H}(s)$ is *stable* if $\mathbf{H}(s)$ is analytic in $\Re(s) \geq 0$. The transfer matrix $\mathbf{H}(s)$ is *minimum phase* if the zeros of $\mathbf{H}(s)$ are in $\Re(s) < 0$. Matrix A is stable if $(sI - A)^{-1}$ is stable.

If $\mathbf{\Phi}(s)$ is a rational matrix that is analytic on the imaginary axis, the integral $\int_{-i\infty}^{i\infty} \mathbf{\Phi}(s)\mathrm{d}s$ is finite if and only if $\mathbf{\Phi}(s) \leq O(s^{-2})$. If $\mathbf{\Phi}(s) \leq O(s^{-2})$ and $\mathbf{\Phi}$ is analytic in $\Re(s) \geq 0$ (or $\Re(s) \leq 0$), then $\int_{-i\infty}^{i\infty} \mathbf{\Phi}(s)\mathrm{d}s = 0$.

By $\mathrm{Tr}\{\cdot\}$ we denote the trace of a square matrix, and by the superscript T we denote the matrix transposition. By $\mathbf{H}^{\sim}$ we denote the matrix $\mathbf{H}^{\mathrm{T}}(-s)$. By $\mathbf{H}^{-\sim}$ we denote the matrix $(\mathbf{H}^{\sim})^{-1}$.

We introduce a generalization of the usual operators $\{\cdot\}_+$ and $\{\cdot\}_-$ [8], [17]. Let τ be a set of complex numbers and $\mathbf{\Phi}$ be a rational matrix. There exists a partial fraction expansion $\mathbf{\Phi} = \mathbf{\Phi}_\tau + \mathbf{\Phi}_\sigma$ such that the poles of $\mathbf{\Phi}_\tau$ are in τ, the poles of $\mathbf{\Phi}_\sigma$ are not in τ, and $\mathbf{\Phi}_\sigma$ is strict proper. Then we define the operators $\{\mathbf{\Phi}\}_\sigma = \mathbf{\Phi}_\sigma$ and $\{\mathbf{\Phi}\}_\tau = \mathbf{\Phi}_\tau$. If τ is the open right complex half-plane, then $\{\mathbf{\Phi}\}_+ = \{\mathbf{\Phi}\}_\sigma$.

The operators $\{\cdot\}_\sigma$ and $\{\cdot\}_\tau$ can be computed exactly as the operators $\{\cdot\}_+$ and $\{\cdot\}_-$, that is, by partial fraction expansion. □

To state the problem of the paper, consider the plant in Figure 1 with its proper transfer matrices $\mathbf{G}$ and $\mathbf{G}_w$, so that

$$\mathbf{y} = \mathbf{G}\mathbf{u} + \mathbf{G}_w\mathbf{w} \ .$$

Define the tracking error as $\mathbf{e} = \mathbf{r} - \mathbf{y}$. In respect to Figure 1, we have

$$\mathbf{e} = \mathbf{r} - \mathbf{y} = \mathbf{H}\mathbf{x} + (I - \mathbf{H})\mathbf{v} \ , \tag{1.1}$$

$$\mathbf{u} = \mathbf{C}\mathbf{H}(\mathbf{x} - \mathbf{v}) \ , \tag{1.2}$$

where $\mathbf{H}$ is the sensitivity matrix

$$\mathbf{H} = (I + \mathbf{G}\mathbf{C})^{-1} \ ,$$

and

$$\mathbf{x} = \mathbf{r} - \mathbf{G}_w\mathbf{w} \ . \tag{1.3}$$

We assume the following minimization criterion:

$$\begin{aligned} \mathcal{J} &= \mathcal{E}\left\{e^{\mathrm{T}}(t)Q_e e(t) + u^{\mathrm{T}}(t)Q_u u(t)\right\} \\ &= \mathrm{Tr}\left\{Q_e\Phi_{ee}(0)\right\} + \mathrm{Tr}\left\{Q_u\Phi_{uu}(0)\right\} \\ &= \frac{1}{2\pi i}\int_{-i\infty}^{i\infty} \left(\mathrm{Tr}\left\{Q_e\mathbf{\Phi}_{ee}\right\} + \mathrm{Tr}\left\{Q_u\mathbf{\Phi}_{uu}\right\}\right)\mathrm{d}s \ , \end{aligned} \tag{1.4}$$

where Q_e and Q_u are some positive semidefinite weighting matrices, for an unknown stabilizing controller.

We assume that the stochastic signals r, w, and v are pairwise stochastically independent and with spectral densities that are proper and positive semidefinite on the imaginary axis. We also allow shape-deterministic inputs r, w, and v (or parts of them) [1], [16].

We have

$$\mathbf{\Phi}_{ee} = \mathbf{H}\mathbf{\Phi}_{xx}\mathbf{H}^{\sim} + (I - \mathbf{H})\mathbf{\Phi}_{vv}(I - \mathbf{H})^{\sim} \ , \tag{1.5}$$

$$\mathbf{\Phi}_{xx} = \mathbf{\Phi}_{rr} + \mathbf{G}_w\mathbf{\Phi}_{ww}\mathbf{G}_w^{\sim} \ ,$$

$$\mathbf{\Phi}_{uu} = \mathbf{CH}(\mathbf{\Phi}_{xx} + \mathbf{\Phi}_{vv})(\mathbf{CH})^{\sim} \ . \tag{1.6}$$

The criterion (1.4) depends on the controller transfer matrix $\mathbf{C}$ nonquadratically. As usual, we shall transform the problem into an LQ problem, so that the criterion depends on the unknown rational matrix (Youla–Kučera parameter) quadratically. In section 2 we formulate a general theorem, which presents a solution of the above problem, and in section 3 we present the proof of the theorem. In section 4 we present three applications of the theorem, i.e., state-space solutions of optimal control problems.

2. Formulation of main result. Throughout this paper we assume the following.

ASSUMPTION 1. *The rational matrix $\mathbf{\Phi}_{xx}$ is strict proper.*

There are two reasons for such an assumption: (1) The criterion (1.4) can be finite only if $\operatorname{Tr}\{Q_e\mathbf{H}\mathbf{\Phi}_{xx}\mathbf{H}^{\sim}\} \le O(s^{-2})$. If $\mathbf{\Phi}_{xx}$ is only proper (not strict proper), having in mind that $\mathbf{H}$ can be only proper when dealing with proper controllers and plants, this condition is a constraint on optimal $\mathbf{C}$. Such a constrained optimization problem is not a topic of this paper. (2) There is not a physical meaning stating the reference signal r to contain white noise or impulsive shape-deterministic signal, when dealing with strict proper $\mathbf{G}_w\mathbf{\Phi}_{ww}\mathbf{G}_w^{\sim}$, as we do in our applications in section 4.

PROPOSITION 2.1. *Given a proper transfer matrix $\mathbf{G}$ without unstable hidden modes* [17], *and symmetric positive semidefinite matrices Q_u and Q_e, if Assumption* 2 *below holds, then there exist proper and stable rational matrices $\mathbf{\Psi}$, $\mathbf{\Theta}$, $\mathbf{U}$, $\mathbf{V}$, $\mathbf{\Psi}_1$, $\mathbf{\Theta}_1$, $\mathbf{U}_1$, and $\mathbf{V}_1$, of which $\mathbf{\Theta}$, $\mathbf{\Theta}_1$, $\mathbf{U}$, and $\mathbf{U}_1$ are biproper, and $\mathbf{V}$ and $\mathbf{V}_1$ are strict proper, such that*

$$\mathbf{G} = \mathbf{\Theta}_1^{-1}\mathbf{\Psi}_1 = \mathbf{\Psi}\mathbf{\Theta}^{-1} \ , \tag{2.1}$$

$$\begin{bmatrix} \mathbf{U} & \mathbf{V} \\ -\mathbf{\Psi}_1 & \mathbf{\Theta}_1 \end{bmatrix} \begin{bmatrix} \mathbf{\Theta} & -\mathbf{V}_1 \\ \mathbf{\Psi} & \mathbf{U}_1 \end{bmatrix} = \begin{bmatrix} \mathbf{\Theta} & -\mathbf{V}_1 \\ \mathbf{\Psi} & \mathbf{U}_1 \end{bmatrix} \begin{bmatrix} \mathbf{U} & \mathbf{V} \\ -\mathbf{\Psi}_1 & \mathbf{\Theta}_1 \end{bmatrix} = \begin{bmatrix} I & 0 \\ 0 & I \end{bmatrix} \ , \tag{2.2}$$

$$\mathbf{\Psi}^{\sim}Q_e\mathbf{\Psi} + \mathbf{\Theta}^{\sim}Q_u\mathbf{\Theta} = I \ . \tag{2.3}$$

If $\mathbf{G}$ is strict proper, then $\mathbf{\Psi}$ and $\mathbf{\Psi}_1$ are strict proper.

ASSUMPTION 2. *Rational matrix $Q_u + \mathbf{G}^{\sim}Q_e\mathbf{G}$ is biproper and without zeros on the imaginary axis.*

Proposition 2.1 is proved in [9], but for the case of positive definite matrices Q_u and Q_e.

The system of Figure 1 is internally stable if and only if the four transfer matrices $\mathbf{H}$, $\mathbf{HG}$, $\mathbf{CH}$, and $\mathbf{CHG}$ are proper and stable. A controller that stabilizes the system is called a stabilizing controller.

To represent the class of all stabilizing controllers [15], we consider plant transfer matrix $\mathbf{G}$, satisfying Assumption 2.

PROPOSITION 2.2. *A controller* $\mathbf{C}$ *is stabilizing if and only if there exists a proper and stable rational matrix* $\mathbf{S}$ *such that*

$$\mathbf{C} = \mathbf{\Theta W} \left(I - \mathbf{\Psi W}\right)^{-1} \ , \tag{2.4}$$

$$\det \left(I - \mathbf{\Psi W}\right) \not\equiv 0 \ , \tag{2.5}$$

where

$$\mathbf{W} = \mathbf{V} + \mathbf{S\Theta}_1 \ . \tag{2.6}$$

By Proposition 2.2, transfer matrices $\mathbf{H}$ and $\mathbf{CH}$ can be expressed as

$$\mathbf{H} = I - \mathbf{\Psi W} \ , \quad \mathbf{CH} = \mathbf{\Theta W} \ . \tag{2.7}$$

Equations (1.1) and (1.2), having in mind (1.3), are

$$\begin{bmatrix} \mathbf{y} \\ \mathbf{u} \end{bmatrix} = \begin{bmatrix} -\mathbf{H} & -\mathbf{HG}_w \\ \mathbf{CH} & \mathbf{CHG}_w \end{bmatrix} \begin{bmatrix} \mathbf{r} - \mathbf{v} \\ -\mathbf{w} \end{bmatrix} + \begin{bmatrix} \mathbf{r} - \mathbf{v} \\ 0 \end{bmatrix} \ ;$$

therefore, besides internal system stability, transfer matrices $\mathbf{HG}_w$ and $\mathbf{CHG}_w$ have to be also proper and stable. We satisfy that condition by assuming that the proper plant transfer matrix $\mathbf{G}_w$ is

$$\mathbf{G}_w = \mathbf{\Theta}_1^{-1} \mathbf{\Psi}_2 \tag{2.8}$$

for some proper stable rational matrix $\mathbf{\Psi}_2$. With (2.4), (2.6), and (2.8), it is easy to prove that transfer matrices $\mathbf{HG}_w$ and $\mathbf{CHG}_w$ are proper and stable.

Remark 2.1. If $\mathbf{G}$ is strict proper, by Proposition 2.2 we have that (1) every stabilizing controller is proper, and (2) the condition (2.5) is void. (See [15] also.)

In the following proposition we present conditions on the possible unstable inputs $\mathbf{r}$, $\mathbf{w}$, and $\mathbf{v}$ such that the outputs $\mathbf{e}$ and $\mathbf{u}$ are strict proper and stable. This result we apply when dealing with shape-deterministic inputs [1], [16], for example, when $\mathbf{r}$ or $\mathbf{w}$ includes step or ramp functions, the most important inputs in respect to tracking and disturbance rejection.

PROPOSITION 2.3. *Let* $\mathbf{C}$ *be a stabilizing controller of Proposition* 2.2*, parametrized by* $\mathbf{S}$*. A necessary and sufficient condition for* $\mathbf{u}$ *and* $\mathbf{e}$ *to be strict proper and stable is that* $\mathbf{\Theta}_1\mathbf{r} - \mathbf{\Psi}_2\mathbf{w}$ *and* $\mathbf{Wv}$ *are strict proper and stable.*

Since we do not impose constraints on optimal $\mathbf{W}$ (or on optimal $\mathbf{C}$) in this paper, and since we cannot count on cancellation of the unstable terms of $\mathbf{\Theta}_1\mathbf{r}$ and $\mathbf{\Psi}_2\mathbf{w}$ in $\mathbf{\Theta}_1\mathbf{r} - \mathbf{\Psi}_2\mathbf{w}$ because of uncertainty in $\mathbf{w}$, when dealing with shape-deterministic inputs r and/or w and/or v, we assume the following.

ASSUMPTION 3. *The rational functions* $\mathbf{\Theta}_1\mathbf{r}$*,* $\mathbf{\Psi}_2\mathbf{w}$*, and* $\mathbf{v}$ *are strict proper and stable.*

We also introduce the following.

ASSUMPTION 4. *There exists the spectral factorization*

$$\mathbf{\Phi}_{vv} + \mathbf{\Phi}_{xx} = \mathbf{\Phi}\mathbf{\Phi}^{\sim} \ ,$$

where $\mathbf{\Phi}$ *is nonsingular and minimum phase.*

If possible, we choose spectral factor $\mathbf{\Phi}$ so that the following holds.

ASSUMPTION 5. *Rational matrix* $\mathbf{\Theta}_1\mathbf{\Phi}$ *is stable and minimum phase.*

This condition is not hard to satisfy, at least for the purpose of our applications in section 4.

By Assumptions 3 and 4, rational matrix $\mathbf{\Phi}_{vv}\mathbf{\Phi}^{-\sim}$ does not have poles on the imaginary axis.

Denote by τ the union of the sets of poles of $\mathbf{\Psi}^{\sim}$, $\mathbf{\Theta}^{\sim}$, and unstable poles of $\mathbf{\Phi}_{vv}\mathbf{\Phi}^{-\sim}$. Introduce rational matrices $\mathbf{L}$, $\mathbf{L}_\sigma$, and $\mathbf{L}_\tau$ by

$$\mathbf{L} = \mathbf{\Psi}^{\sim} Q_e \mathbf{\Phi}_{xx} \mathbf{\Phi}^{-\sim} = \mathbf{L}_\sigma + \mathbf{L}_\tau \ , \quad \mathbf{L}_\sigma \stackrel{\text{def}}{=} \{\mathbf{L}\}_\sigma \ , \quad \mathbf{L}_\tau \stackrel{\text{def}}{=} \{\mathbf{L}\}_\tau \ . \tag{2.9}$$

THEOREM 2.4. *Suppose in addition to Assumptions* 1–5 *one has the following.*

ASSUMPTION 6. *No pole of* $\mathbf{\Phi}$ *belongs to* τ.

ASSUMPTION 7. $\mathbf{\Phi}^{-1} \leq O(s)$.

Then an optimal controller is given by (2.4)*, i.e.,*

$$\mathbf{C} = \mathbf{\Theta}\mathbf{W}\left(I - \mathbf{\Psi}\mathbf{W}\right)^{-1} \ , \tag{2.10}$$

where

$$\mathbf{W} = \mathbf{L}_\sigma \mathbf{\Phi}^{-1} \ , \tag{2.11}$$

under condition (2.5) *(which is void if* $\mathbf{G}$ *is strict proper).*

A consequence of Theorem 2.4 is the following.

COROLLARY 2.5. *Under Assumptions* 1–7*, if* v *is a white noise, then an optimal controller is given by* (2.10) *and* (2.11)*, where* $\mathbf{L}_\sigma$ *is given by*

$$\mathbf{L}_\sigma = \{\mathbf{\Psi}^{\sim} Q_e \mathbf{\Phi}\}_\sigma \ . \tag{2.12}$$

3. Proof of main result. We start with the following.

Proof of Proposition 2.1. Since $\mathbf{G}$ is proper, there exist matrices A, B, C, and D, with an (A, B) stabilizable pair and a (C, A) detectable pair, such that

$$\mathbf{G} = D + C(sI - A)^{-1}B \stackrel{\text{def}}{=} \left[\begin{array}{c|c} A & B \\ \hline C & D \end{array}\right] \ . \tag{3.1}$$

Define matrices

$$\begin{bmatrix} \mathbf{U} & \mathbf{V} \\ -\mathbf{\Psi}_1 & \mathbf{\Theta}_1 \end{bmatrix} = \left[\begin{array}{c|cc} A - FC & B - FD & F \\ \hline N_u K & N_u & 0 \\ -C & -D & I \end{array}\right] \ , \tag{3.2}$$

$$\begin{bmatrix} \mathbf{\Theta} & -\mathbf{V}_1 \\ \mathbf{\Psi} & \mathbf{U}_1 \end{bmatrix} = \left[\begin{array}{c|cc} A - BK & BN_u^{-1} & F \\ \hline -K & N_u^{-1} & 0 \\ C - DK & DN_u^{-1} & I \end{array}\right] \ , \tag{3.3}$$

where matrices N_u, K, and F are arbitrary with the properties that matrix N_u is nonsingular and matrices $A - BK$ and $A - FC$ are stable. It can be checked that identities (2.1) and (2.2) hold.

We shall choose matrices N_u and K so that (2.3) is satisfied.

By Assumption 2, matrix $Q_{u1} = Q_u + D^{\mathrm{T}} Q_e D$ is nonsingular, and rational matrix $Q_u + \mathbf{G}^{\sim} Q_e \mathbf{G}$ does not have zeros on the imaginary axis. The zeros of that rational

matrix are the same as the eigenvalues of the Hamiltonian matrix, associated with the following continuous time algebraic Riccati equation (CARE):

$$YA + A^{\mathrm{T}}Y - (YB + C^{\mathrm{T}}Q_eD)Q_{u1}^{-1}(B^{\mathrm{T}}Y + D^{\mathrm{T}}Q_eC) + C^{\mathrm{T}}Q_eC = 0 \ . \tag{3.4}$$

We shall use the following lemma [3].

LEMMA 3.1. *Consider CARE*

$$YA + A^{\mathrm{T}}Y - (YB + \Sigma_{12})\Sigma_{22}^{-1}(B^{\mathrm{T}}Y + \Sigma_{21}) + \Sigma_{11} = 0 \ , \tag{3.5}$$

where

$$\Sigma = \begin{bmatrix} \Sigma_{11} & \Sigma_{12} \\ \Sigma_{21} & \Sigma_{22} \end{bmatrix} = \Sigma^{\mathrm{T}} \ .$$

Sufficient conditions for existence of a stabilizing solution Y *of CARE* (3.5)*, i.e., such that matrix* $A - B\Sigma_{22}^{-1}(B^{\mathrm{T}}Y + \Sigma_{21})$ *is stable, are as follows:*

(i) $\Sigma \geq 0$*;*

(ii) *the Hamiltonian matrix associated with* (3.5) *does not have eigenvalues on the imaginary axis;*

(iii) *the matrix pair* (A, B) *is stabilizable.*

By Lemma 3.1, the conditions of the positive semidefiniteness of Q_e and Q_u, nonsingularity of Q_{u1}, absence of purely imaginary eigenvalues of the Hamiltonian matrix, and stabilizability of the pair (A, B) are sufficient for existence of a stabilizing solution Y of CARE (3.4), i.e., for the stability of matrix $A - BK$, where

$$K = Q_{u1}^{-1}(B^{\mathrm{T}}Y + D^{\mathrm{T}}Q_eC) \ . \tag{3.6}$$

Using (3.4), it is easy to check the following spectral factorization:

$$Q_u + \mathbf{G}^{\sim}Q_e\mathbf{G} = \mathbf{\Delta}^{\sim}\mathbf{\Delta} \ , \tag{3.7}$$

where

$$\mathbf{\Delta} = N_u(I + K\mathbf{\Omega}B) \ , \quad N_u^2 = Q_{u1} \ , \quad \mathbf{\Omega} = (sI - A)^{-1} \ . \tag{3.8}$$

Now define

$$\mathbf{\Theta} = \mathbf{\Delta}^{-1} = (I - K\mathbf{\Omega}_Y B)N_u^{-1} \ , \quad \mathbf{\Omega}_Y = (sI - A + BK)^{-1} \tag{3.9}$$

and

$$\mathbf{\Psi} = \mathbf{G}\mathbf{\Theta} = \left[D + (C - DK)\mathbf{\Omega}_Y B\right] N_u^{-1} \ . \tag{3.10}$$

These $\mathbf{\Psi}$ and $\mathbf{\Theta}$ coincide with $\mathbf{\Psi}$ and $\mathbf{\Theta}$ defined in (3.3). The identity (3.7) becomes (2.3). □

Proof of Proposition 2.3. Express, at first, $\mathbf{u}$ and $\mathbf{e}$:

$$\begin{aligned} \mathbf{u} &= \mathbf{C}\mathbf{H}(\mathbf{x} - \mathbf{v}) = \mathbf{\Theta}(\mathbf{V} + \mathbf{S}\mathbf{\Theta}_1)(\mathbf{x} - \mathbf{v}) \\ &= (\mathbf{V}_1\mathbf{\Theta}_1 + \mathbf{\Theta}\mathbf{S}\mathbf{\Theta}_1)(\mathbf{x} - \mathbf{v}) = (\mathbf{V}_1 + \mathbf{\Theta}\mathbf{S})\mathbf{\Theta}_1(\mathbf{x} - \mathbf{v}) \ , \\ \mathbf{e} &= \mathbf{H}(\mathbf{x} - \mathbf{v}) + \mathbf{v} = (I - \mathbf{\Psi}\mathbf{W})(\mathbf{x} - \mathbf{v}) + \mathbf{v} \\ &= (I - \mathbf{\Psi}\mathbf{V} - \mathbf{\Psi}\mathbf{S}\mathbf{\Theta}_1)(\mathbf{x} - \mathbf{v}) + \mathbf{v} = (\mathbf{U}_1 - \mathbf{\Psi}\mathbf{S})\mathbf{\Theta}_1(\mathbf{x} - \mathbf{v}) + \mathbf{v} \ . \end{aligned}$$

Further we have

$$\mathbf{Uu}-\mathbf{Ve}=\mathbf{U}(\mathbf{V}_1+\mathbf{\Theta S})\mathbf{\Theta}_1(\mathbf{x}-\mathbf{v})-\mathbf{V}(\mathbf{U}_1-\mathbf{\Psi S})\mathbf{\Theta}_1(\mathbf{x}-\mathbf{v})-\mathbf{Vv}$$

$$=\mathbf{S\Theta}_1(\mathbf{x}-\mathbf{v})-\mathbf{Vv}=\mathbf{S\Theta}_1\mathbf{x}-\mathbf{Wv}=\mathbf{S}(\mathbf{\Theta}_1\mathbf{r}-\mathbf{\Psi}_2\mathbf{w})-\mathbf{Wv}\ ,$$

$$\mathbf{\Psi}_1\mathbf{u}+\mathbf{\Theta}_1\mathbf{e}=\mathbf{\Psi}_1(\mathbf{V}_1+\mathbf{\Theta S})\mathbf{\Theta}_1(\mathbf{x}-\mathbf{v})+\mathbf{\Theta}_1(\mathbf{U}_1-\mathbf{\Psi S})\mathbf{\Theta}_1(\mathbf{x}-\mathbf{v})+\mathbf{\Theta}_1\mathbf{v}$$

$$=\mathbf{\Theta}_1(\mathbf{x}-\mathbf{v})+\mathbf{\Theta}_1\mathbf{v}=\mathbf{\Theta}_1\mathbf{x}=\mathbf{\Theta}_1\mathbf{r}-\mathbf{\Psi}_2\mathbf{w}\ ,$$

i.e.,

$$\begin{bmatrix}\mathbf{U} & \mathbf{V}\\ -\mathbf{\Psi}_1 & \mathbf{\Theta}_1\end{bmatrix}\begin{bmatrix}-\mathbf{u}\\ \mathbf{e}\end{bmatrix}=\begin{bmatrix}-\mathbf{S}(\mathbf{\Theta}_1\mathbf{r}-\mathbf{\Psi}_2\mathbf{w})+\mathbf{Wv}\\ \mathbf{\Theta}_1\mathbf{r}-\mathbf{\Psi}_2\mathbf{w}\end{bmatrix}\ .$$

Therefore, the necessity is proved. The sufficiency is obvious if we solve the above matrix system for $-\mathbf{u}$ and $\mathbf{e}$, using (2.2). □

Proof of Theorem 2.4. Rational matrix $\mathbf{L}$ (2.9) is strict proper. This fact easily follows by Assumptions 1 and 7.[2]

Introduce the rational matrix

$$\mathbf{K}=\mathbf{L}-\mathbf{V\Phi}=\mathbf{\Psi}^{\sim}Q_e\mathbf{\Phi}_{xx}\mathbf{\Phi}^{-\sim}-\mathbf{V\Phi}\ , \tag{3.11}$$

which is also strict proper, because $\mathbf{V}$ is strict proper.

To find another representation of $\mathbf{K}$ besides (3.11), which will be crucial in our proof, we use the equation

$$\mathbf{U\Theta}+\mathbf{V\Psi}=I \tag{3.12}$$

for $\mathbf{U}$ and $\mathbf{V}$, which is contained in (2.2). Having in mind that a particular solution of (3.12) for $\mathbf{U}$, $\mathbf{V}$, by (2.3), is $\mathbf{\Theta}^{\sim}Q_u$, $\mathbf{\Psi}^{\sim}Q_e$, the general solution of (3.12) is

$$\mathbf{U}=\mathbf{\Theta}^{\sim}Q_u-\mathbf{R\Psi}_1\ , \tag{3.13}$$

$$\mathbf{V}=\mathbf{\Psi}^{\sim}Q_e+\mathbf{R\Theta}_1\ , \tag{3.14}$$

where $\mathbf{R}$ is a rational matrix. Using the identities (3.13), (3.14), and (2.2), we obtain

$$\mathbf{R}=-\mathbf{\Psi}^{\sim}Q_e\mathbf{U}_1+\mathbf{\Theta}^{\sim}Q_u\mathbf{V}_1\ . \tag{3.15}$$

Conversely, it is easy to check that this $\mathbf{R}$ satisfies the pair of equations (3.13) and (3.14). So, we have

$$\mathbf{K}=\mathbf{\Psi}^{\sim}Q_e\mathbf{\Phi}_{xx}\mathbf{\Phi}^{-\sim}-\mathbf{V\Phi}=\mathbf{\Psi}^{\sim}Q_e\left(\mathbf{\Phi\Phi}^{\sim}-\mathbf{\Phi}_{vv}\right)\mathbf{\Phi}^{-\sim}-\left(\mathbf{\Psi}^{\sim}Q_e+\mathbf{R\Theta}_1\right)\mathbf{\Phi}$$

$$=-\mathbf{\Psi}^{\sim}Q_e\mathbf{\Phi}_{vv}\mathbf{\Phi}^{-\sim}-\mathbf{R\Theta}_1\mathbf{\Phi}$$

$$=-\mathbf{\Psi}^{\sim}Q_e\mathbf{\Phi}_{vv}\mathbf{\Phi}^{-\sim}-\left(-\mathbf{\Psi}^{\sim}Q_e\mathbf{U}_1+\mathbf{\Theta}^{\sim}Q_u\mathbf{V}_1\right)\mathbf{\Theta}_1\mathbf{\Phi}\ . \tag{3.16}$$

By (3.16), matrix $\mathbf{K}$ does not have purely imaginary poles.

[2]Rational matrix $\mathbf{L}$ is strict proper without Assumption 7 (see Remark 3.3).

Using matrix $\mathbf{K}$ defined in (3.11), and (1.5), (1.6), and (2.7), the integrand-function in the criterion (1.4) can be expressed as

$$\begin{aligned}
&\mathrm{Tr}\,\{Q_e\mathbf{\Phi}_{ee}\} + \mathrm{Tr}\,\{Q_u\mathbf{\Phi}_{uu}\} \\
&= \mathrm{Tr}\,\{Q_e\,[\mathbf{H}\mathbf{\Phi}_{xx}\mathbf{H}^{\sim} + (I-\mathbf{H})\mathbf{\Phi}_{vv}(I-\mathbf{H})^{\sim}]\} + \mathrm{Tr}\,\{Q_u\mathbf{CH}(\mathbf{\Phi}_{xx}+\mathbf{\Phi}_{vv})(\mathbf{CH})^{\sim}\} \\
&= \mathrm{Tr}\,\{Q_e\,[(I-\mathbf{\Psi}\mathbf{W})\mathbf{\Phi}_{xx}(I-\mathbf{W}^{\sim}\mathbf{\Psi}^{\sim}) + \mathbf{\Psi}\mathbf{W}\mathbf{\Phi}_{vv}\mathbf{W}^{\sim}\mathbf{\Psi}^{\sim}]\} \\
&\quad + \mathrm{Tr}\,\{Q_u\mathbf{\Theta}\mathbf{W}(\mathbf{\Phi}_{xx}+\mathbf{\Phi}_{vv})\mathbf{W}^{\sim}\mathbf{\Theta}^{\sim}\} \\
&= \mathrm{Tr}\,\{Q_e\,[\mathbf{\Phi}_{xx} - \mathbf{\Phi}_{xx}\mathbf{W}^{\sim}\mathbf{\Psi}^{\sim} - \mathbf{\Psi}\mathbf{W}\mathbf{\Phi}_{xx} + \mathbf{\Psi}\mathbf{W}(\mathbf{\Phi}_{xx}+\mathbf{\Phi}_{vv})\mathbf{W}^{\sim}\mathbf{\Psi}^{\sim}]\} \\
&\quad + \mathrm{Tr}\,\{Q_u\mathbf{\Theta}\mathbf{W}(\mathbf{\Phi}_{xx}+\mathbf{\Phi}_{vv})\mathbf{W}^{\sim}\mathbf{\Theta}^{\sim}\} \\
&= \mathrm{Tr}\,\{Q_e\,(\mathbf{\Phi}_{xx} - \mathbf{\Phi}_{xx}\mathbf{W}^{\sim}\mathbf{\Psi}^{\sim} - \mathbf{\Psi}\mathbf{W}\mathbf{\Phi}_{xx})\} \\
&\quad + \mathrm{Tr}\,\{(\mathbf{\Psi}^{\sim}Q_e\mathbf{\Psi} + \mathbf{\Theta}^{\sim}Q_u\mathbf{\Theta})\mathbf{W}(\mathbf{\Phi}_{xx}+\mathbf{\Phi}_{vv})\mathbf{W}^{\sim}\} \\
&= \mathrm{Tr}\,\{Q_e\mathbf{\Phi}_{xx}\} - \mathrm{Tr}\,\{\mathbf{L}\mathbf{\Phi}^{\sim}\mathbf{W}^{\sim}\} - \mathrm{Tr}\,\{\mathbf{W}\mathbf{\Phi}\mathbf{L}^{\sim}\} + \mathrm{Tr}\,\{\mathbf{W}\mathbf{\Phi}\mathbf{\Phi}^{\sim}\mathbf{W}^{\sim}\} \\
&= \mathrm{Tr}\,\{Q_e\mathbf{\Phi}_{xx}\} - \mathrm{Tr}\,\{\mathbf{L}\mathbf{L}^{\sim}\} + \mathrm{Tr}\,\left\{\left(\mathbf{W}-\mathbf{L}\mathbf{\Phi}^{-1}\right)\mathbf{\Phi}\mathbf{\Phi}^{\sim}\left(\mathbf{W}-\mathbf{L}\mathbf{\Phi}^{-1}\right)^{\sim}\right\} \\
&= \mathrm{Tr}\,\{Q_e\mathbf{\Phi}_{xx}\} - \mathrm{Tr}\,\{\mathbf{L}\mathbf{L}^{\sim}\} + \mathrm{Tr}\,\{(\mathbf{S}\mathbf{\Theta}_1\mathbf{\Phi}-\mathbf{K})\,(\mathbf{S}\mathbf{\Theta}_1\mathbf{\Phi}-\mathbf{K})^{\sim}\}\ , \qquad (3.17)
\end{aligned}$$

where identities (2.3) and $\mathbf{W}-\mathbf{L}\mathbf{\Phi}^{-1} = (\mathbf{S}\mathbf{\Theta}_1\mathbf{\Phi}-\mathbf{K})\mathbf{\Phi}^{-1}$ have been also used.

With respect to (3.17), we shall prove the following.

LEMMA 3.2. *Rational function* $\mathrm{Tr}\,\{Q_e\mathbf{\Phi}_{xx}\} - \mathrm{Tr}\,\{\mathbf{L}\mathbf{L}^{\sim}\}$ *is* $\leq O(s^{-2})$ *and does not have purely imaginary poles.*

Proof. The first property is obvious. Concerning the absence of purely imaginary poles, compute at first

$$\begin{aligned}
&\mathrm{Tr}\,\{Q_e\mathbf{\Phi}_{xx}\} - \mathrm{Tr}\,\{\mathbf{L}\mathbf{L}^{\sim}\} = \mathrm{Tr}\,\{Q_e(\mathbf{\Phi}\mathbf{\Phi}^{\sim} - \mathbf{\Phi}_{vv})\} - \mathrm{Tr}\,\{(\mathbf{K}+\mathbf{V}\mathbf{\Phi})(\mathbf{K}+\mathbf{V}\mathbf{\Phi})^{\sim}\} \\
&= \mathrm{Tr}\,\{(\mathbf{V}^{\sim}\mathbf{\Psi}^{\sim}Q_e + Q_e\mathbf{\Psi}\mathbf{V} - Q_e)\,\mathbf{\Phi}_{vv}\} - \mathrm{Tr}\,\{\mathbf{K}\mathbf{K}^{\sim}\} \\
&\quad + \mathrm{Tr}\,\{\mathbf{\Phi}^{\sim}\,(Q_e + \mathbf{V}^{\sim}\mathbf{R}\mathbf{\Theta}_1 + \mathbf{\Theta}_1^{\sim}\mathbf{R}^{\sim}\mathbf{V} - \mathbf{V}^{\sim}\mathbf{V})\,\mathbf{\Phi}\}\ , \qquad (3.18)
\end{aligned}$$

where expression (3.11) for $\mathbf{K}$ is used. The matrices in the first two traces of (3.18) do not have purely imaginary poles.

Concerning the matrix in the third trace of (3.18), we have

$$Q_e + \mathbf{V}^{\sim}\mathbf{R}\mathbf{\Theta}_1 + \mathbf{\Theta}_1^{\sim}\mathbf{R}^{\sim}\mathbf{V} - \mathbf{V}^{\sim}\mathbf{V} = \mathbf{Z} + \mathbf{\Theta}_1^{\sim}\mathbf{R}^{\sim}\mathbf{R}\mathbf{\Theta}_1\ , \qquad (3.19)$$

where identity (3.14) is used, and matrix $\mathbf{Z}$ by

$$\mathbf{Z} = Q_e - Q_e\mathbf{\Psi}\mathbf{\Psi}^{\sim}Q_e$$

is introduced. We shall prove that matrix $\mathbf{Z}$ can be represented as

$$\mathbf{Z} = \mathbf{\Theta}_1^{\sim}\hat{\mathbf{M}}\mathbf{\Theta}_1 \qquad (3.20)$$

for some matrix $\hat{\mathbf{M}}$ that does not have purely imaginary poles. Since matrices $\mathbf{\Theta}_1\mathbf{\Phi}$ and $\mathbf{R}$ (3.15) do not have purely imaginary poles, by (3.18) and (3.19) it will follow

that rational function $\mathrm{Tr}\{Q_e\mathbf{\Phi}_{xx}\} - \mathrm{Tr}\{\mathbf{L}\mathbf{L}^\sim\}$ does not have purely imaginary poles, as required.

Define matrix $\hat{\mathbf{G}}$, which is analytic on the imaginary axis, by

$$\hat{\mathbf{G}} = \begin{bmatrix} Q_u^{\frac{1}{2}}\mathbf{\Theta} \\ Q_e^{\frac{1}{2}}\mathbf{\Psi} \end{bmatrix} . \tag{3.21}$$

By $\hat{\mathbf{G}}^\sim\hat{\mathbf{G}} = I$, it has full column rank on the imaginary axis. Define matrix $\hat{\mathbf{Z}}$, which is analytic on the imaginary axis, by

$$\hat{\mathbf{Z}} = I - \hat{\mathbf{G}}\hat{\mathbf{G}}^\sim .$$

We have, on the imaginary axis $s = j\omega$,

$$0 \leq \begin{bmatrix} I \\ \hat{\mathbf{G}}^\sim \end{bmatrix} \begin{bmatrix} I, \hat{\mathbf{G}} \end{bmatrix} = \begin{bmatrix} I & \hat{\mathbf{G}} \\ \hat{\mathbf{G}}^\sim & I \end{bmatrix} \cong \begin{bmatrix} I - \hat{\mathbf{G}}\hat{\mathbf{G}}^\sim & 0 \\ 0 & I \end{bmatrix} = \begin{bmatrix} \hat{\mathbf{Z}} & 0 \\ 0 & I \end{bmatrix} ,$$

where $\cong$ stands for the congruency relation of hermitian matrices. Therefore, matrix $\hat{\mathbf{Z}}$ is positive semidefinite on the imaginary axis and of constant rank, and there exists its factorization

$$\hat{\mathbf{Z}} = \mathbf{Q}^\sim\mathbf{Q}$$

for some rational matrix $\mathbf{Q}$.

By $\hat{\mathbf{Z}}\hat{\mathbf{G}} = (I - \hat{\mathbf{G}}\hat{\mathbf{G}}^\sim)\hat{\mathbf{G}} = 0$, it follows that

$$\mathbf{Q}\hat{\mathbf{G}} = 0 . \tag{3.22}$$

We have

$$\mathbf{Z} = Q_e - Q_e\mathbf{\Psi}\mathbf{\Psi}^\sim Q_e = Q_e^{\frac{1}{2}} \left(I - [0, I]\hat{\mathbf{G}}\hat{\mathbf{G}}^\sim \begin{bmatrix} 0 \\ I \end{bmatrix} \right) Q_e^{\frac{1}{2}}$$

$$= Q_e^{\frac{1}{2}}[0, I]\hat{\mathbf{Z}} \begin{bmatrix} 0 \\ I \end{bmatrix} Q_e^{\frac{1}{2}} = Q_e^{\frac{1}{2}}[0, I]\mathbf{Q}^\sim\mathbf{Q} \begin{bmatrix} 0 \\ I \end{bmatrix} Q_e^{\frac{1}{2}} = Q_e^{\frac{1}{2}}\mathbf{Q}_2^\sim\mathbf{Q}_2 Q_e^{\frac{1}{2}} , \tag{3.23}$$

where matrix $\mathbf{Q}$ is partitioned on $\mathbf{Q} = [\mathbf{Q}_1, \mathbf{Q}_2]$,

It follows from (3.22), i.e.,

$$\mathbf{Q}_1 Q_u^{\frac{1}{2}}\mathbf{\Theta} + \mathbf{Q}_2 Q_e^{\frac{1}{2}}\mathbf{\Psi} = 0 ,$$

that

$$\mathbf{Q}_1 Q_u^{\frac{1}{2}} = -\mathbf{M}\mathbf{\Psi}_1 , \quad \mathbf{Q}_2 Q_e^{\frac{1}{2}} = \mathbf{M}\mathbf{\Theta}_1 \tag{3.24}$$

for some rational matrix $\mathbf{M}$, i.e.,

$$\mathbf{Q} \begin{bmatrix} Q_u^{\frac{1}{2}} & 0 \\ 0 & Q_e^{\frac{1}{2}} \end{bmatrix} = \mathbf{M} \begin{bmatrix} -\mathbf{\Psi}_1, & \mathbf{\Theta}_1 \end{bmatrix} .$$

By right multiplication of the above identity with the matrix $\left[\begin{smallmatrix} -\mathbf{V}_1 \\ \mathbf{U}_1 \end{smallmatrix} \right]$, using (2.2), we obtain

$$\mathbf{M} = \mathbf{Q} \begin{bmatrix} Q_u^{\frac{1}{2}} & 0 \\ 0 & Q_e^{\frac{1}{2}} \end{bmatrix} \begin{bmatrix} -\mathbf{V}_1 \\ \mathbf{U}_1 \end{bmatrix} .$$

Now define matrix $\hat{\mathbf{M}}$ by

$$\hat{\mathbf{M}} = \mathbf{M}^{\sim}\mathbf{M} = [-\mathbf{V}_1^{\sim}, \mathbf{U}_1^{\sim}] \begin{bmatrix} Q_u^{\frac{1}{2}} & 0 \\ 0 & Q_e^{\frac{1}{2}} \end{bmatrix} \hat{\mathbf{Z}} \begin{bmatrix} Q_u^{\frac{1}{2}} & 0 \\ 0 & Q_e^{\frac{1}{2}} \end{bmatrix} \begin{bmatrix} -\mathbf{V}_1 \\ \mathbf{U}_1 \end{bmatrix} .$$

Matrix $\hat{\mathbf{M}}$ does not have purely imaginary poles, and, by (3.23) and (3.24), identity (3.20) holds, as required. □

By (3.17), Lemma 3.2, and the fact that $\mathbf{K}$ is strict proper and without poles on the imaginary axis, criterion (1.4) is finite if and only if $\mathbf{S}\boldsymbol{\Theta}_1\boldsymbol{\Phi}$ is strict proper.

By (3.16), since $\boldsymbol{\Theta}_1\boldsymbol{\Phi}$ is stable, the unstable poles of $\mathbf{K}$ are contained in the union of the sets of poles of $\boldsymbol{\Psi}^{\sim}$, $\boldsymbol{\Theta}^{\sim}$, and the unstable poles of $\boldsymbol{\Phi}_{vv}\boldsymbol{\Phi}^{-\sim}$, i.e., the complex numbers in τ.

So, if we extract the poles in τ off the rational matrix $\mathbf{K}$ by partial fraction expansion, we shall obtain a stable rational matrix. Therefore, the rational matrix

$$\mathbf{K}_\sigma \stackrel{\text{def}}{=} \{\mathbf{K}\}_\sigma = \{\mathbf{L} - \mathbf{V}\boldsymbol{\Phi}\}_\sigma = \mathbf{L}_\sigma - \mathbf{V}\boldsymbol{\Phi} , \tag{3.25}$$

where we have used Assumption 6, is stable.

Further on, since matrices $\mathbf{S}$, $\boldsymbol{\Theta}_1\boldsymbol{\Phi}$, $\mathbf{K}_\sigma$, and $\mathbf{K}_\tau^{\sim}$ are stable and matrices $\mathbf{S}\boldsymbol{\Theta}_1\boldsymbol{\Phi}$, $\mathbf{K}_\sigma$, and $\mathbf{K}_\tau^{\sim}$ are strict proper, where $\mathbf{K}_\tau \stackrel{\text{def}}{=} \{\mathbf{K}\}_\tau$, we have

$$\int_{-i\infty}^{i\infty} (\mathbf{S}\boldsymbol{\Theta}_1\boldsymbol{\Phi} - \mathbf{K}_\sigma)\, \mathbf{K}_\tau^{\sim} \mathrm{d}s = 0 . \tag{3.26}$$

The integrand (3.17) can be expressed as

$$\begin{aligned} &\mathrm{Tr}\,\{Q_e\boldsymbol{\Phi}_{xx}\} - \mathrm{Tr}\,\{\mathbf{L}\mathbf{L}^{\sim}\} + \mathrm{Tr}\,\{(\mathbf{S}\boldsymbol{\Theta}_1\boldsymbol{\Phi} - \mathbf{K}_\sigma)\,(\mathbf{S}\boldsymbol{\Theta}_1\boldsymbol{\Phi} - \mathbf{K}_\sigma)^{\sim}\} \\ &\quad - \mathrm{Tr}\,\{(\mathbf{S}\boldsymbol{\Theta}_1\boldsymbol{\Phi} - \mathbf{K}_\sigma)\,\mathbf{K}_\tau^{\sim}\} - \mathrm{Tr}\,\{\mathbf{K}_\tau\,(\mathbf{S}\boldsymbol{\Theta}_1\Phi - \mathbf{K}_\sigma)^{\sim}\} + \mathrm{Tr}\,\{\mathbf{K}_\tau\mathbf{K}_\tau^{\sim}\} . \end{aligned}$$

Having in mind (3.26), it remains to integrate

$$\begin{aligned} &\mathrm{Tr}\,\{Q_e\boldsymbol{\Phi}_{xx}\} - \mathrm{Tr}\,\{\mathbf{L}\mathbf{L}^{\sim}\} + \mathrm{Tr}\,\{\mathbf{L}_\tau\mathbf{L}_\tau^{\sim}\} \\ &\quad + \mathrm{Tr}\,\{(\mathbf{S}\boldsymbol{\Theta}_1\boldsymbol{\Phi} - \mathbf{K}_\sigma)\,(\mathbf{S}\boldsymbol{\Theta}_1\boldsymbol{\Phi} - \mathbf{K}_\sigma)^{\sim}\} , \end{aligned} \tag{3.27}$$

where the identity $\mathbf{K}_\tau = \mathbf{L}_\tau$ has been used.

The integral of the function (3.27) is minimal if we take

$$\mathbf{S}\boldsymbol{\Theta}_1\boldsymbol{\Phi} - \mathbf{K}_\sigma = 0 .$$

The parameter-matrix

$$\mathbf{S} = \mathbf{K}_\sigma\boldsymbol{\Phi}^{-1}\boldsymbol{\Theta}_1^{-1} \tag{3.28}$$

is indeed proper (by Assumption 7) and stable (because rational matrix $\boldsymbol{\Theta}_1\boldsymbol{\Phi}$ is minimum phase).

Optimal $\mathbf{W}$ is also proper and stable, and, by (3.28) and (3.25),

$$\mathbf{W} = \mathbf{V} + \mathbf{S}\boldsymbol{\Theta}_1 = \mathbf{V} + \mathbf{K}_\sigma\boldsymbol{\Phi}^{-1} = \mathbf{V} + (\mathbf{L}_\sigma - \mathbf{V}\boldsymbol{\Phi})\,\boldsymbol{\Phi}^{-1} = \mathbf{L}_\sigma\boldsymbol{\Phi}^{-1} .$$

The finiteness of the criterion with optimal $\mathbf{C}$ follows by Lemma 3.2 and (3.27). □

Remark 3.1. By (3.27), the minimum of the criterion (1.4) is obtained by integrating $\mathrm{Tr}\{Q_e\mathbf{\Phi}_{xx}\} - \mathrm{Tr}\{\mathbf{L}\mathbf{L}^\sim\} + \mathrm{Tr}\{\mathbf{L}_\tau\mathbf{L}_\tau^\sim\}$. To compute the minumum, we can transform this problem into computing an $\mathcal{H}_2$ norm of possibly unstable transfer matrices. In applying such an algorithm, care must be taken to prevent existence of purely imaginary poles in the integrand-functions. For instance, if shape-deterministic inputs are present, the two functions $\mathrm{Tr}\{Q_e\mathbf{\Phi}_{xx}\}$ and $\mathrm{Tr}\{\mathbf{L}\mathbf{L}^\sim\}$ may have purely imaginary poles (although the function $\mathrm{Tr}\{Q_e\mathbf{\Phi}_{xx}\} - \mathrm{Tr}\{\mathbf{L}\mathbf{L}^\sim\}$ does not).

Remark 3.2. Assumptions 1, 3, and 5 are consistent. In particular, if r, w, and v are shape-deterministic signals satisfying Assumption 3, then $\mathbf{\Phi}_{xx} = \mathbf{\Phi}_{rr} + \mathbf{G}_w\mathbf{\Phi}_{ww}\mathbf{G}_w^\sim = \mathbf{\Theta}_1^{-1}(\mathbf{\Theta}_1\mathbf{\Phi}_{rr}\mathbf{\Theta}_1^\sim + \mathbf{\Psi}_2\mathbf{\Phi}_{ww}\mathbf{\Psi}_2^\sim)\mathbf{\Theta}_1^{-\sim}$ is strict proper. Conversely, if $\mathbf{\Phi}_{xx}$ is strict proper, then $\mathbf{\Theta}_1\mathbf{r}$ and $\mathbf{\Psi}_2\mathbf{w}$ are strict proper. Further on, under Assumption 3, from $\mathbf{\Theta}_1\mathbf{\Phi}\mathbf{\Phi}^\sim\mathbf{\Theta}_1^\sim = \mathbf{\Theta}_1\mathbf{\Phi}_{vv}\mathbf{\Theta}_1^\sim + \mathbf{\Theta}_1\mathbf{\Phi}_{rr}\mathbf{\Theta}_1^\sim + \mathbf{\Psi}_2\mathbf{\Phi}_{ww}\mathbf{\Psi}_2^\sim$, it follows that $\mathbf{\Theta}_1\mathbf{\Phi}$ does not have purely imaginary poles.

Remark 3.3. If we relax the definition of internal stability of the system of Figure 1 so that we do not impose properness of the four transfer matrices $\mathbf{H}$, $\mathbf{HG}$, $\mathbf{CH}$, and $\mathbf{CHG}$, and if we relax Assumption 3 so that we do not impose strict properness of $\mathbf{\Theta}_1\mathbf{r}$, $\mathbf{\Psi}_2\mathbf{w}$, and $\mathbf{v}$ when we deal with shape-deterministic inputs, we can generalize Theorem 2.4 so that we avoid Assumption 7. In this new optimal control problem, parameter-matrix $\mathbf{S}$ in (3.28) need not be proper.

To prove the generalization, it suffices to prove that matrix $\mathbf{L}$ is strict proper without Assumption 7. By (2.9), it suffices to prove that $\mathbf{\Phi}_{xx}\mathbf{\Phi}^{-\sim}$ is strict proper. Without loss of generality, assume that $\mathbf{\Phi}_{vv} = \mathbf{U}_v\mathbf{U}_v^\sim$ and $\mathbf{\Phi}_{xx} = \mathbf{U}_x\mathbf{U}_x^\sim$, for some possibly nonsquare proper matrices $\mathbf{U}_v$ and $\mathbf{U}_x$. Then

$$\mathbf{\Phi}_{vv} + \mathbf{\Phi}_{xx} = \mathbf{U}_v\mathbf{U}_v^\sim + \mathbf{U}_x\mathbf{U}_x^\sim = [\mathbf{U}_v, \mathbf{U}_x]\begin{bmatrix}\mathbf{U}_v^\sim \\ \mathbf{U}_x^\sim\end{bmatrix} = \mathbf{\Phi}\mathbf{\Phi}^\sim \ .$$

It follows that $\mathbf{\Phi}^{-1}[\mathbf{U}_v, \mathbf{U}_x]$ is proper and in particular, that $\mathbf{\Phi}^{-1}\mathbf{U}_x$ is proper. By the fact that $\mathbf{\Phi}_{xx} = \mathbf{U}_x\mathbf{U}_x^\sim$ is strict proper, $\mathbf{U}_x^\sim$ is strict proper. As a consequence, $\mathbf{\Phi}^{-1}\mathbf{\Phi}_{xx} = (\mathbf{\Phi}^{-1}\mathbf{U}_x)\mathbf{U}_x^\sim$ is strict proper.

Remark 3.4. Another generalization of Theorem 2.4 can be made by considering set τ being of as few elements as possible, but including all unstable poles of $\mathbf{K}$. Such a decrease in the number of elements of τ is required because of Assumption 6, and it does not affect $\mathbf{L}_\sigma$. If we consider the minimal τ, i.e., consisting of all unstable poles of $\mathbf{K}$, matrices $\mathbf{U}_1$ and $\mathbf{V}_1$ will appear in the controller transfer matrix implicitly. To compromise we assume that τ is a union of the sets of the poles of $\hat{\mathbf{G}}^\sim$ (3.21) and the unstable poles of $\mathbf{\Psi}^\sim Q_e\mathbf{\Phi}_{vv}\mathbf{\Phi}^{-\sim}$.

Remark 3.5. Concerning the satisfaction of Assumption 5, we could take a systematic approach to finding a stable and minimum phase factor $\mathbf{\Theta}_1\mathbf{\Phi}$ in the factorization $\mathbf{\Theta}_1\mathbf{\Phi}\mathbf{\Phi}^\sim\mathbf{\Theta}_1^\sim = \mathbf{\Theta}_1(\mathbf{\Phi}_{vv} + \mathbf{\Phi}_{rr})\mathbf{\Theta}_1^\sim + \mathbf{\Psi}_2\mathbf{\Phi}_{ww}\mathbf{\Psi}_2^\sim$, but we regard such an approach as more complex, at least when the plant is given by state-space equations, because matrices $\mathbf{\Theta}_1$ and $\mathbf{\Psi}_2$ will appear in the controller transfer matrix.

Proof of Corollary 2.5. We have

$$\begin{aligned}\mathbf{L}_\sigma &= \left\{\mathbf{\Psi}^\sim Q_e\mathbf{\Phi}_{xx}\mathbf{\Phi}^{-\sim}\right\}_\sigma = \left\{\mathbf{\Psi}^\sim Q_e\left(\mathbf{\Phi}\mathbf{\Phi}^\sim - \mathbf{\Phi}_{vv}\right)\mathbf{\Phi}^{-\sim}\right\}_\sigma \\ &= \left\{\mathbf{\Psi}^\sim Q_e\mathbf{\Phi}\right\}_\sigma - \left\{\mathbf{\Psi}^\sim Q_e\mathbf{\Phi}_{vv}\mathbf{\Phi}^{-\sim}\right\}_\sigma = \left\{\mathbf{\Psi}^\sim Q_e\mathbf{\Phi}\right\}_\sigma \ ,\end{aligned}$$

because rational matrix $\mathbf{\Psi}^\sim Q_e\mathbf{\Phi}_{vv}\mathbf{\Phi}^{-\sim}$ has its poles in τ. □

Example 3.1. This example illustrates the possibilities we have of satisfying Assumption 5. Let $\mathbf{G}$ be given by (3.1), $\mathbf{\Phi}_{ww} = 0$, $\mathbf{\Phi}_{rr} = 0$, and $\mathbf{\Phi}_{vv} = M =$

Const > 0. We have at least two possibilities: to take the constant matrix $\mathbf{\Phi} = N$, $N^2 = M$, or to take the matrix $\mathbf{\Phi} = (I + C\mathbf{\Omega}XC^{\mathrm{T}}M^{-1})N$, where $\mathbf{\Omega} = (sI - A)^{-1}$ and X is the stabilizing solution of CARE:

$$AX + XA^{\mathrm{T}} - XC^{\mathrm{T}}M^{-1}CX = 0 \ ,$$

i.e., a solution such that matrix $\mathbf{\Omega}_X = (sI - A + XC^{\mathrm{T}}M^{-1}C)^{-1}$ is stable. To achieve the property of minimum phase and stability of $\mathbf{\Theta}_1\mathbf{\Phi}$, we take the second solution. Indeed, by (3.2), we have $\mathbf{\Theta}_1 = I - C\mathbf{\Omega}_F F$, $\mathbf{\Omega}_F = (sI - A + FC)^{-1}$ and

$$\mathbf{\Theta}_1\mathbf{\Phi} = \left[I - C\mathbf{\Omega}_F(F - XC^{\mathrm{T}}M^{-1})\right] N \ ,$$

$$(\mathbf{\Theta}_1\mathbf{\Phi})^{-1} = N^{-1}\left[I + C\mathbf{\Omega}_X(F - XC^{\mathrm{T}}M^{-1})\right] \ .$$

Therefore, $\mathbf{\Theta}_1\mathbf{\Phi}$ is minimum phase and stable. Optimal controller $\mathbf{C}$ can be easily found (see section 4).

Example 3.2. This example illustrates that Assumption 6 cannot be avoided in general. Let $\mathbf{G} = (1+s)/(1-s)$, $Q_e = Q_u = 1$, $\mathbf{\Phi}_{vv} = 0$, $\mathbf{\Phi}_{xx} = 1/(1-s^2)$. We have that

$$\mathbf{\Psi} = \frac{1}{\sqrt{2}} \ , \quad \mathbf{\Delta} = \mathbf{\Theta}^{-1} = \sqrt{2}\frac{1+s}{1-s} \ , \quad \mathbf{\Theta}_1 = \mathbf{\Theta} \ , \quad \mathbf{\Phi} = \frac{1}{1-s} \ ;$$

hence $\tau = \{1\}$. Since $\mathbf{\Theta}_1\mathbf{\Phi} = \frac{1}{\sqrt{2}(1+s)}$, Assumption 5 is satisfied. By $\mathbf{L} = \frac{1}{\sqrt{2}(1-s)}$, it follows that $\mathbf{L}_\sigma = 0$, so application of (2.10) and (2.11) gives $\mathbf{C} = 0$. This controller renders the system unstable; hence it is not optimal. However, Assumption 6 is not satisfied because the pole at 1 of $\mathbf{\Phi}$ belongs to τ.

4. Applications. The first purpose of this section is to illustrate the application of the simplified formulas (2.10) and (2.11), in particular, to show how the new operator $\{\cdot\}_\sigma$ can be computed, and to show that Assumptions 1–7 are not unrealistic, especially the most important assumption that rational matrix $\mathbf{\Theta}_1\mathbf{\Phi}$ is stable and minimum phase. The other purpose of this section is to solve three important optimal control problems explicitly.

We assume the plant transfer matrix $\mathbf{G}$ given by (3.1), and the plant transfer matrix

$$\mathbf{G}_w = C(sI - A)^{-1}B_w = C\mathbf{\Omega}B_w \ .$$

These $\mathbf{G}$ and $\mathbf{G}_w$ are in the required forms (2.1) and (2.8), correspondingly, with $\mathbf{\Psi}_2 = C(sI - A + FC)^{-1}B_w$.

We shall use the following form of optimal controller (see (2.10) and (2.11)):

$$\mathbf{C} = \left(\mathbf{\Delta} - \mathbf{L}_\sigma\mathbf{\Phi}^{-1}\mathbf{G}\right)^{-1}\mathbf{L}_\sigma\mathbf{\Phi}^{-1} \ , \tag{4.1}$$

where matrix $\mathbf{\Delta} = \mathbf{\Theta}^{-1}$ is defined in (3.8).

4.1. Output zeroing: Colored measurement noise is present. In this subsection we assume the output zeroing case, i.e., $r = 0$, and white disturbance noise with $\mathbf{\Phi}_{ww} = W \geq 0$. We have

$$\mathbf{\Phi}_{xx} = C\mathbf{\Omega}S\mathbf{\Omega}^{\sim}C^{\mathrm{T}} \ , \quad S = B_w W B_w^{\mathrm{T}} \ .$$

Also we assume colored measurement noise with the following covariance matrix

$$\mathbf{\Phi}_{vv} = \mathbf{\Omega}_v V \mathbf{\Omega}_v^{\sim} \ , \quad \mathbf{\Omega}_v = (sI - A_v)^{-1} \ ,$$

for some stable matrix A_v and positive semidefinite V.

To apply Theorem 2.4, we have to solve the following spectral factorization:

$$\mathbf{\Phi}_{vv} + \mathbf{\Phi}_{xx} = C\mathbf{\Omega} S \mathbf{\Omega}^{\sim} C^{\mathrm{T}} + \mathbf{\Omega}_v V \mathbf{\Omega}_v^{\sim} = \mathbf{\Phi}\mathbf{\Phi}^{\sim} \ ,$$

where $\mathbf{\Phi}$ is minimum phase.

Since the rational matrix $\mathbf{\Omega}_v$ is minimum phase already, we can search $\mathbf{\Phi}$ in the form

$$\mathbf{\Phi} = \mathbf{\Omega}_v \mathbf{\Phi}_1 \ ,$$

where $\mathbf{\Phi}_1$ is a minimum phase spectral factor in the factorization

$$\mathbf{\Omega}_v^{-1} C \mathbf{\Omega} S \mathbf{\Omega}^{\sim} C^{\mathrm{T}} \mathbf{\Omega}_v^{-\sim} + V = \mathbf{\Phi}_1 \mathbf{\Phi}_1^{\sim} \ . \tag{4.2}$$

Having in mind the identity

$$\mathbf{\Omega}_v^{-1} C \mathbf{\Omega} = C + Q\mathbf{\Omega} \ , \quad Q = CA - A_v C \ , \tag{4.3}$$

the problem (4.2) transforms into

$$M + CS\mathbf{\Omega}^{\sim} Q^{\mathrm{T}} + Q\mathbf{\Omega} S C^{\mathrm{T}} + Q\mathbf{\Omega} S \mathbf{\Omega}^{\sim} Q^{\mathrm{T}} = \mathbf{\Phi}_1 \mathbf{\Phi}_1^{\sim} \ , \tag{4.4}$$

where

$$M = V + CSC^{\mathrm{T}} \ .$$

Using Assumption 7, we deduce that matrix M is positive definite. Introduce the matrix N by $N^2 = M$, and consider the following CARE:

$$XA^{\mathrm{T}} + AX + S - (SC^{\mathrm{T}} + XQ^{\mathrm{T}}) M^{-1} (CS + QX) = 0 \ .$$

To prove the existence of a stabilizing solution X of CARE, it suffices to prove that the matrix pair $(A^{\mathrm{T}}, Q^{\mathrm{T}})$ is stabilizable (see Lemma 3.1). We have, identically

$$\begin{bmatrix} sI - A_v & -C \\ 0 & I \end{bmatrix} \begin{bmatrix} C \\ sI - A \end{bmatrix} = \begin{bmatrix} Q \\ sI - A \end{bmatrix} \ .$$

Since the eigenvalues of matrix A_v are stable and matrix pair (C, A) is detectable, the pencil $\left[\begin{smallmatrix} Q \\ sI - A \end{smallmatrix}\right]$ has full column rank for every s, $\Re(s) \geq 0$; i.e., matrix pair $(A^{\mathrm{T}}, Q^{\mathrm{T}})$ is stabilizable.

The spectral factor $\mathbf{\Phi}_1$ in (4.4) is

$$\mathbf{\Phi}_1 = N + Q\mathbf{\Omega} \left(SC^{\mathrm{T}} + XQ^{\mathrm{T}} \right) M^{-1} N \ .$$

To check Assumption 5, write at first,

$$\mathbf{\Phi} = \mathbf{\Omega}_v \mathbf{\Phi}_1 = \mathbf{\Omega}_v \left[N + Q\mathbf{\Omega} (SC^{\mathrm{T}} + XQ^{\mathrm{T}}) M^{-1} N \right] = \mathbf{\Omega}_v N_1 + C\mathbf{\Omega} N_2 \ ,$$

where $N_2 = (SC^{\mathrm{T}} + XQ^{\mathrm{T}})M^{-1}N$, $N_1 = N - CN_2$. We have, by (3.2),

$$\begin{aligned}\boldsymbol{\Theta}_1\boldsymbol{\Phi} &= (I - C\boldsymbol{\Omega}_F F)(\boldsymbol{\Omega}_v N_1 + C\boldsymbol{\Omega} N_2)\\ &= \boldsymbol{\Omega}_v N_1 + C\boldsymbol{\Omega} N_2 - C\boldsymbol{\Omega}_F F\boldsymbol{\Omega}_v N_1 - C\boldsymbol{\Omega}_F FC\boldsymbol{\Omega} N_2\\ &= \boldsymbol{\Omega}_v N_1 + C\boldsymbol{\Omega} N_2 - C\boldsymbol{\Omega}_F F\boldsymbol{\Omega}_v N_1 - C(\boldsymbol{\Omega} - \boldsymbol{\Omega}_F)N_2\\ &= \boldsymbol{\Omega}_v N_1 - C\boldsymbol{\Omega}_F F\boldsymbol{\Omega}_v N_1 + C\boldsymbol{\Omega}_F N_2\ ,\end{aligned}$$

so, $\boldsymbol{\Theta}_1\boldsymbol{\Phi}$ is stable, because $\boldsymbol{\Omega}_F = (sI - A + FC)^{-1}$ is stable. To check that it is minimum phase, introduce the rational matrix $\boldsymbol{\Omega}_X = \left[sI - A + (SC^{\mathrm{T}} + XQ^{\mathrm{T}})M^{-1}Q\right]^{-1}$. The matrix identity

$$\boldsymbol{\Omega}_X(SC^{\mathrm{T}} + XQ^{\mathrm{T}})M^{-1}Q\boldsymbol{\Omega} = \boldsymbol{\Omega} - \boldsymbol{\Omega}_X \tag{4.5}$$

is easy to check. We have

$$\begin{aligned}(\boldsymbol{\Theta}_1\boldsymbol{\Phi})^{-1} = \boldsymbol{\Phi}^{-1}\boldsymbol{\Theta}_1^{-1} &= N^{-1}\left[I - Q\boldsymbol{\Omega}_X(SC^{\mathrm{T}} + XQ^{\mathrm{T}})M^{-1}\right]\boldsymbol{\Omega}_v^{-1}(I + C\boldsymbol{\Omega}F)\\ &= N^{-1}\left[I - Q\boldsymbol{\Omega}_X(SC^{\mathrm{T}} + XQ^{\mathrm{T}})M^{-1}\right](\boldsymbol{\Omega}_v^{-1} + CF + Q\boldsymbol{\Omega}F)\\ &= N^{-1}\left[I - Q\boldsymbol{\Omega}_X(SC^{\mathrm{T}} + XQ^{\mathrm{T}})M^{-1}\right](\boldsymbol{\Omega}_v^{-1} + CF) + N^{-1}Q\boldsymbol{\Omega}F - N^{-1}Q(\boldsymbol{\Omega} - \boldsymbol{\Omega}_X)F\\ &= N^{-1}\left[I - Q\boldsymbol{\Omega}_X(SC^{\mathrm{T}} + XQ^{\mathrm{T}})M^{-1}\right](\boldsymbol{\Omega}_v^{-1} + CF) + N^{-1}Q\boldsymbol{\Omega}_X F\ ,\end{aligned}$$

so, $\boldsymbol{\Theta}_1\boldsymbol{\Phi}$ is minimum phase.

From the identity $\boldsymbol{\Phi}_{vv}\boldsymbol{\Phi}^{-\sim} = \boldsymbol{\Omega}_v V\boldsymbol{\Omega}_v^{\sim}\boldsymbol{\Omega}_v^{-\sim}\boldsymbol{\Phi}_1^{-\sim} = \boldsymbol{\Omega}_v V\boldsymbol{\Phi}_1^{-\sim}$, it follows that the set τ consists of the poles of $\boldsymbol{\Omega}_X^{\sim}$ and $\boldsymbol{\Omega}_Y^{\sim}$, where $\boldsymbol{\Omega}_Y$ is given in (3.9).

To find optimal controller $\mathbf{C}$, at first compute, using (4.5),

$$\begin{aligned}&(C^{\mathrm{T}} + \boldsymbol{\Omega}^{\sim}Q^{\mathrm{T}})\left[I - M^{-1}(CS + QX)\boldsymbol{\Omega}_X^{\sim}Q^{\mathrm{T}}\right]\\ &= C^{\mathrm{T}} - C^{\mathrm{T}}M^{-1}(CS + QX)\boldsymbol{\Omega}_X^{\sim}Q^{\mathrm{T}} + \boldsymbol{\Omega}^{\sim}Q^{\mathrm{T}} - \boldsymbol{\Omega}^{\sim}Q^{\mathrm{T}}M^{-1}(CS + QX)\boldsymbol{\Omega}_X^{\sim}Q^{\mathrm{T}}\\ &= C^{\mathrm{T}} - C^{\mathrm{T}}M^{-1}(CS + QX)\boldsymbol{\Omega}_X^{\sim}Q^{\mathrm{T}} + \boldsymbol{\Omega}^{\sim}Q^{\mathrm{T}} - (\boldsymbol{\Omega}^{\sim} - \boldsymbol{\Omega}_X^{\sim})Q^{\mathrm{T}}\\ &= C^{\mathrm{T}} + \left[I - C^{\mathrm{T}}M^{-1}(CS + QX)\right]\boldsymbol{\Omega}_X^{\sim}Q^{\mathrm{T}}\ .\end{aligned} \tag{4.6}$$

Further on, using (4.6) and the matrix identity

$$\boldsymbol{\Omega}S\left[I - C^{\mathrm{T}}M^{-1}(CS + QX)\right]\boldsymbol{\Omega}_X^{\sim} = \boldsymbol{\Omega}X + X\boldsymbol{\Omega}_X^{\sim}\ ,$$

compute

$$\begin{aligned}&\boldsymbol{\Omega}S(C^{\mathrm{T}} + \boldsymbol{\Omega}^{\sim}Q^{\mathrm{T}})\left[I - M^{-1}(CS + QX)\boldsymbol{\Omega}_X^{\sim}Q^{\mathrm{T}}\right]\\ &= \boldsymbol{\Omega}SC^{\mathrm{T}} + \boldsymbol{\Omega}S\left[I - C^{\mathrm{T}}M^{-1}(CS + QX)\right]\boldsymbol{\Omega}_X^{\sim}Q^{\mathrm{T}}\\ &= \boldsymbol{\Omega}SC^{\mathrm{T}} + (\boldsymbol{\Omega}X + X\boldsymbol{\Omega}_X^{\sim})Q^{\mathrm{T}}\\ &= \boldsymbol{\Omega}(SC^{\mathrm{T}} + XQ^{\mathrm{T}}) + X\boldsymbol{\Omega}_X^{\sim}Q^{\mathrm{T}}\ .\end{aligned} \tag{4.7}$$

Using (3.10), (4.3), (4.7), and the matrix identity

$$\mathbf{\Omega}_Y^{\sim}(C^{\mathrm{T}} - K^{\mathrm{T}}D^{\mathrm{T}})Q_eC\mathbf{\Omega} = \mathbf{\Omega}_Y^{\sim}Y + Y\mathbf{\Omega}\ , \tag{4.8}$$

where Y, K, and $\mathbf{\Omega}_Y$ are given by (3.4), (3.6), and (3.9), we compute

$$\begin{aligned}
\mathbf{L} &= \mathbf{\Psi}^{\sim}Q_e\mathbf{\Phi}_{xx}\mathbf{\Phi}^{-\sim} \\
&= \left[DN_u^{-1} + (C - DK)\mathbf{\Omega}_Y BN_u^{-1}\right]^{\sim} Q_eC\mathbf{\Omega}S\mathbf{\Omega}^{\sim}C^{\mathrm{T}}\mathbf{\Omega}_v^{-\sim} \\
&\quad \cdot \left[I + Q\mathbf{\Omega}(SC^{\mathrm{T}} + XQ^{\mathrm{T}})M^{-1}\right]^{-\sim} N^{-1} \\
&= N_u^{-1}\left[D^{\mathrm{T}} + B^{\mathrm{T}}\mathbf{\Omega}_Y^{\sim}(C^{\mathrm{T}} - K^{\mathrm{T}}D^{\mathrm{T}})\right] Q_eC\mathbf{\Omega}S(C^{\mathrm{T}} + \mathbf{\Omega}^{\sim}Q^{\mathrm{T}}) \\
&\quad \cdot \left[I - M^{-1}(CS + QX)\mathbf{\Omega}_X^{\sim}Q^{\mathrm{T}}\right] N^{-1} \\
&= N_u^{-1}\left[D^{\mathrm{T}} + B^{\mathrm{T}}\mathbf{\Omega}_Y^{\sim}(C^{\mathrm{T}} - K^{\mathrm{T}}D^{\mathrm{T}})\right] Q_eC\left[\mathbf{\Omega}(SC^{\mathrm{T}} + XQ^{\mathrm{T}}) + X\mathbf{\Omega}_X^{\sim}Q^{\mathrm{T}}\right] N^{-1} \\
&= N_u^{-1}\left[D^{\mathrm{T}}Q_eC\mathbf{\Omega}(SC^{\mathrm{T}} + XQ^{\mathrm{T}}) + D^{\mathrm{T}}Q_eCX\mathbf{\Omega}_X^{\sim}Q^{\mathrm{T}}\right. \\
&\quad \left. + B^{\mathrm{T}}(\mathbf{\Omega}_Y^{\sim}Y + Y\mathbf{\Omega})(SC^{\mathrm{T}} + XQ^{\mathrm{T}}) + B^{\mathrm{T}}\mathbf{\Omega}_Y^{\sim}(C^{\mathrm{T}} - K^{\mathrm{T}}D^{\mathrm{T}})Q_eCX\mathbf{\Omega}_X^{\sim}Q^{\mathrm{T}}\right] N^{-1}\ .
\end{aligned}$$

Since the poles of $\mathbf{\Omega}_X^{\sim}$ and $\mathbf{\Omega}_Y^{\sim}$ belong to τ, we have

$$\mathbf{L}_\sigma = \left\{\mathbf{\Psi}^{\sim}Q_e\mathbf{\Phi}_{xx}\mathbf{\Phi}^{-\sim}\right\}_\sigma = N_uK\mathbf{\Omega}(SC^{\mathrm{T}} + XQ^{\mathrm{T}})N^{-1}\ .$$

To compute $\mathbf{W}$, we use the identity (4.5):

$$\begin{aligned}
\mathbf{W} &= \mathbf{L}_\sigma\mathbf{\Phi}^{-1} \\
&= N_uK\mathbf{\Omega}(SC^{\mathrm{T}} + XQ^{\mathrm{T}})M^{-1}\left[I - Q\mathbf{\Omega}_X(SC^{\mathrm{T}} + XQ^{\mathrm{T}})M^{-1}\right]\mathbf{\Omega}_v^{-1} \\
&= N_uK\left[\mathbf{\Omega}(SC^{\mathrm{T}} + XQ^{\mathrm{T}})M^{-1} - (\mathbf{\Omega} - \mathbf{\Omega}_X)(SC^{\mathrm{T}} + XQ^{\mathrm{T}})M^{-1}\right]\mathbf{\Omega}_v^{-1} \\
&= N_uK\mathbf{\Omega}_X(SC^{\mathrm{T}} + XQ^{\mathrm{T}})M^{-1}\mathbf{\Omega}_v^{-1}\ .
\end{aligned}$$

Further on, using identities (3.8), (4.3), and (4.5), we obtain

$$\begin{aligned}
N_u^{-1}(\mathbf{\Delta} - \mathbf{WG}) &= I + K\mathbf{\Omega}B - K\mathbf{\Omega}_X(SC^{\mathrm{T}} + XQ^{\mathrm{T}})M^{-1}\mathbf{\Omega}_v^{-1}(D + C\mathbf{\Omega}B) \\
&= I + K\mathbf{\Omega}B - K\mathbf{\Omega}_X(SC^{\mathrm{T}} + XQ^{\mathrm{T}})M^{-1}(\mathbf{\Omega}_v^{-1}D + CB + Q\mathbf{\Omega}B) \\
&= I + K\mathbf{\Omega}B - K\mathbf{\Omega}_X(SC^{\mathrm{T}} + XQ^{\mathrm{T}})M^{-1}(\mathbf{\Omega}_v^{-1}D + CB) - K(\mathbf{\Omega} - \mathbf{\Omega}_X)B \\
&= I + K\mathbf{\Omega}_X\left[B - (SC^{\mathrm{T}} + XQ^{\mathrm{T}})M^{-1}(\mathbf{\Omega}_v^{-1}D + CB)\right] \stackrel{\mathrm{def}}{=} I + K\mathbf{\Omega}_X\mathbf{H}_v\ .
\end{aligned}$$

Introduce the matrices

$$\begin{aligned}
E_1 &= I - (SC^{\mathrm{T}} + XQ^{\mathrm{T}})M^{-1}DK\ , \\
A_1 &= A - BK - (SC^{\mathrm{T}} + XQ^{\mathrm{T}})M^{-1}(Q + A_vDK - CBK)\ .
\end{aligned}$$

To achieve proper controller $\mathbf{C}$, assume that matrix E_1 is nonsingular; then we have, for optimal controller $\mathbf{C}$,

$$\begin{aligned}\mathbf{C} &= (\mathbf{\Delta} - \mathbf{WG})^{-1}\,\mathbf{W} \\ &= (I + K\mathbf{\Omega}_X\mathbf{H}_v)^{-1}\,K\mathbf{\Omega}_X(SC^{\mathrm{T}} + XQ^{\mathrm{T}})M^{-1}\mathbf{\Omega}_v^{-1} \\ &= K\left[sI - A + (SC^{\mathrm{T}} + XQ^{\mathrm{T}})M^{-1}Q + \mathbf{H}_vK\right]^{-1}(SC^{\mathrm{T}} + XQ^{\mathrm{T}})M^{-1}\mathbf{\Omega}_v^{-1} \\ &= K\left(sI - E_1^{-1}A_1\right)^{-1}E_1^{-1}(SC^{\mathrm{T}} + XQ^{\mathrm{T}})M^{-1}\mathbf{\Omega}_v^{-1} \\ &= D_{\mathbf{c}} + K\left(sI - E_1^{-1}A_1\right)^{-1}B_{\mathbf{c}}\ ,\end{aligned}$$

where

$$D_{\mathbf{c}} = KE_1^{-1}(SC^{\mathrm{T}} + XQ^{\mathrm{T}})M^{-1}\ ,\quad B_{\mathbf{c}} = E_1^{-1}\left[A_1D_{\mathbf{c}} - (SC^{\mathrm{T}} + XQ^{\mathrm{T}})M^{-1}A_v\right]\ .$$

The order of the controller is n.

Concerning Assumption 6, we shall give its interpretation for this particular application. The poles of $\mathbf{\Phi}$ are a union of the eigenvalues of A and eigenvalues of A_v, and the set τ is a union of the eigenvalues of $-(A - BK)$ and eigenvalues of $-\left[A - (SC^{\mathrm{T}} + XQ^{\mathrm{T}})M^{-1}Q\right]$. Therefore, Assumption 6 means that the unstable eigenvalues of A are not eigenvalues of $-(A - BK)$ and eigenvalues of $-\left[A - (SC^{\mathrm{T}} + XQ^{\mathrm{T}})M^{-1}Q\right]$.

4.2. Output zeroing: Measurement noise is absent. To apply Corollary 2.5 on case $r = 0$, $v = 0$, and white disturbance noise with $\mathbf{\Phi}_{ww} = W \geq 0$, the following spectral factorization requires

$$\mathbf{G}_wW\mathbf{G}_w^{\sim} = \mathbf{\Phi}\mathbf{\Phi}^{\sim}\ , \tag{4.9}$$

where $\mathbf{\Phi}$ is a minimum phase spectral factor. Since $\mathbf{G}_w$ is strict proper, the spectral factorization (4.9) is not obvious. Using Assumption 7, we deduce that matrix $CB_wWB_w^{\mathrm{T}}C^{\mathrm{T}}$ is positive definite. Without loss of generality, we assume matrix A in block-triangular form

$$A = \begin{bmatrix} A_1 & A_3 \\ 0 & A_2 \end{bmatrix}\ ,$$

where A_1 is a square matrix of dimension p, p being the number of outputs, and A_2 is a square matrix of dimension $n - p$. In addition, we assume the matrix C_1 is nonsingular, where

$$C = [C_1, C_2]\ ,\quad B_w = \begin{bmatrix} B_1 \\ B_2 \end{bmatrix}\ .$$

For reduction of the matrix A in the above form by orthogonal similarity transformation matrices, the QR-algorithm can be applied. We do not have additional requirements on the eigenvalues of the matrices A_1 and A_2. We have

$$\mathbf{G}_w = [C_1, C_2]\begin{bmatrix} \mathbf{\Omega}_1 & \mathbf{\Omega}_1A_3\mathbf{\Omega}_2 \\ 0 & \mathbf{\Omega}_2 \end{bmatrix}\begin{bmatrix} B_1 \\ B_2 \end{bmatrix} = C_1\mathbf{\Omega}_1B_1 + C_1\mathbf{\Omega}_1A_3\mathbf{\Omega}_2B_2 + C_2\mathbf{\Omega}_2B_2\ ,$$

where $\mathbf{\Omega}_1 = (sI - A_1)^{-1}$, $\mathbf{\Omega}_2 = (sI - A_2)^{-1}$. Introduce the matrices P and Q by $P = C_1^{-1}C_2$ and $Q = PA_2 - A_1P$. Then $\mathbf{\Omega}_1^{-1}C_1^{-1}C_2\mathbf{\Omega}_2 = P + Q\mathbf{\Omega}_2$ and

$$\mathbf{G}_w = C_1\mathbf{\Omega}_1 \left[B_1 + PB_2 + (A_3 + Q)\mathbf{\Omega}_2 B_2\right] \ .$$

The rational matrix $C_1\mathbf{\Omega}_1$ is minimum phase already; therefore it remains to factorize the rational matrix

$$\left[B_1 + PB_2 + (A_3 + Q)\mathbf{\Omega}_2 B_2\right] W \left[B_1 + PB_2 + (A_3 + Q)\mathbf{\Omega}_2 B_2\right]^{\sim} = \mathbf{\Phi}_1\mathbf{\Phi}_1^{\sim} \ ,$$

where $\mathbf{\Phi}_1$ is a minimum phase spectral factor. Since the matrix

$$M = (B_1 + PB_2)\, W\, (B_1 + PB_2)^{\mathrm{T}} = C_1^{-1}CB_wWB_w^{\mathrm{T}}C^{\mathrm{T}}C_1^{-\mathrm{T}}$$

is positive definite, we can introduce matrix N by $N^2 = M$, and the following CARE:

$$\left[B_2WB_1^{\mathrm{T}} + B_2WB_2^{\mathrm{T}}P^{\mathrm{T}} + X(A_3 + Q)^{\mathrm{T}}\right] M^{-1} \left[B_1WB_2^{\mathrm{T}} + PB_2WB_2^{\mathrm{T}} + (A_3 + Q)X\right]$$

$$- XA_2^{\mathrm{T}} - A_2X - B_2WB_2^{\mathrm{T}} = 0 \ .$$

We shall prove that it has a stabilizing solution X. For that purpose, having in mind Lemma 3.1, it suffices to prove that matrix pair $(A_2^{\mathrm{T}}, (A_3 + Q)^{\mathrm{T}})$ is stabilizable. The matrix pencil

$$\begin{bmatrix} C_1 & C_2 \\ sI - A_1 & -A_3 \\ 0 & sI - A_2 \end{bmatrix} \sim \begin{bmatrix} C_1 & 0 \\ sI - A_1 & -[A_3 + (sI - A_1)P] \\ 0 & sI - A_2 \end{bmatrix}$$

has full column rank, for every complex s, $\Re(s) \geq 0$, because the pair (C, A) is detectable, where $\sim$ stands for the strict equivalence relation of matrix pencils. Therefore, the matrix pencil

$$\begin{bmatrix} A_3 + (sI - A_1)P \\ sI - A_2 \end{bmatrix} \sim \begin{bmatrix} A_3 + PA_2 - A_1P \\ sI - A_2 \end{bmatrix} = \begin{bmatrix} A_3 + Q \\ sI - A_2 \end{bmatrix}$$

has full column rank for every s, $\Re(s) \geq 0$. Therefore matrix pair $(A_2^{\mathrm{T}}, (A_3 + Q)^{\mathrm{T}})$ is stabilizable.

The spectral factorization (4.9) is solved by

$$\mathbf{\Phi} = C_1\mathbf{\Omega}_1\mathbf{\Phi}_1 \ , \tag{4.10}$$

where

$$\mathbf{\Phi}_1 = N + (A_3 + Q)\mathbf{\Omega}_2 ZN \ , \tag{4.11}$$

$$Z = \left[B_2WB_1^{\mathrm{T}} + B_2WB_2^{\mathrm{T}}P^{\mathrm{T}} + X(A_3 + Q)^{\mathrm{T}}\right] M^{-1} \ .$$

It is easy to check that another form of $\mathbf{\Phi}$ is

$$\mathbf{\Phi} = C\mathbf{\Omega}U \ , \quad U = \begin{bmatrix} I - PZ \\ Z \end{bmatrix} N \ . \tag{4.12}$$

Having solved the factorization (4.9), we have to check Assumption 5. Concerning stability of $\mathbf{\Theta}_1\mathbf{\Phi}$, we have, by (3.2) and (4.12),

$$\mathbf{\Theta}_1\mathbf{\Phi} = (I - C\mathbf{\Omega}_F F)C\mathbf{\Omega}U = C\mathbf{\Omega}U - C\mathbf{\Omega}_F FC\mathbf{\Omega}U$$

$$= C\mathbf{\Omega}U - C(\mathbf{\Omega}_F - \mathbf{\Omega})U = C\mathbf{\Omega}_F U \ ,$$

where $\mathbf{\Omega}_F = (sI - A + FC)^{-1}$. Hence $\mathbf{\Theta}_1\mathbf{\Phi}$ is stable. Further on, $\mathbf{\Theta}_1\mathbf{\Phi}$ is minimum phase, because it has the same zeros as $C\mathbf{\Omega}U$.

Now, proceed with computation of $\mathbf{L}_\sigma$ in (2.12). We have, by (3.10), (4.12), (4.8), and (3.6),

$$\mathbf{L}_\sigma = \{\mathbf{\Psi}^{\sim} Q_e \mathbf{\Phi}\}_\sigma = \left\{N_u^{-1}\left[D^{\mathrm{T}} + B^{\mathrm{T}}\mathbf{\Omega}_Y^{\sim}(C^{\mathrm{T}} - K^{\mathrm{T}}D^{\mathrm{T}})\right] Q_e C\mathbf{\Omega}U\right\}_\sigma$$

$$= \left\{N_u^{-1}\left[D^{\mathrm{T}}Q_e C\mathbf{\Omega} + B^{\mathrm{T}}(\mathbf{\Omega}_Y^{\sim}Y + Y\mathbf{\Omega})\right] U\right\}_\sigma = N_u^{-1}(B^{\mathrm{T}}Y + D^{\mathrm{T}}Q_e C)\mathbf{\Omega}U$$

$$= N_u K\mathbf{\Omega}U \ ,$$

because the set τ consists of the poles of $\mathbf{\Omega}_Y^{\sim}$. Introduce matrix $\mathbf{\Omega}_X = [sI - A_2 + Z(A_3 + Q)]^{-1}$. We shall need the following three matrix identities:

$$\mathbf{\Omega}UN^{-1}(A_3 + Q)\mathbf{\Omega}_X = \mathbf{\Omega}C^{\perp} - C^{\perp}\mathbf{\Omega}_X \ ,$$

where

$$C^{\perp} = \begin{bmatrix} -P \\ I \end{bmatrix} \ ,$$

$$UN^{-1} - C^{\perp}Z = \begin{bmatrix} I \\ 0 \end{bmatrix} \ ,$$

and

$$\mathbf{\Omega}_X Z\mathbf{\Omega}_1^{-1} = Z + \mathbf{\Omega}_X R \ , \quad R = -ZA_1 + A_2 Z - Z(A_3 + Q)Z \ ,$$

which can be easily checked. We have

$$\mathbf{W} = \mathbf{L}_\sigma\mathbf{\Phi}^{-1} = N_u K\mathbf{\Omega}UN^{-1}\left[I + (A_3 + Q)\mathbf{\Omega}_2 Z\right]^{-1}\mathbf{\Omega}_1^{-1}C_1^{-1}$$

$$= N_u K\mathbf{\Omega}UN^{-1}\left[I - (A_3 + Q)\mathbf{\Omega}_X Z\right]\mathbf{\Omega}_1^{-1}C_1^{-1}$$

$$= N_u K\left[\mathbf{\Omega}UN^{-1} - \mathbf{\Omega}UN^{-1}(A_3 + Q)\mathbf{\Omega}_X Z\right]\mathbf{\Omega}_1^{-1}C_1^{-1}$$

$$= N_u K\left(\mathbf{\Omega}UN^{-1} - \mathbf{\Omega}C^{\perp}Z + C^{\perp}\mathbf{\Omega}_X Z\right)\mathbf{\Omega}_1^{-1}C_1^{-1}$$

$$= N_u K\left(\mathbf{\Omega}\begin{bmatrix} I \\ 0 \end{bmatrix} + C^{\perp}\mathbf{\Omega}_X Z\right)\mathbf{\Omega}_1^{-1}C_1^{-1}$$

$$= N_u K\left(\begin{bmatrix} I \\ 0 \end{bmatrix} + C^{\perp}\mathbf{\Omega}_X Z\mathbf{\Omega}_1^{-1}\right)C_1^{-1}$$

$$= N_u K\left(\begin{bmatrix} I \\ 0 \end{bmatrix} + C^{\perp}(Z + \mathbf{\Omega}_X R)\right)C_1^{-1}$$

$$= N_u K\left(U + C^{\perp}\mathbf{\Omega}_X RN\right)N^{-1}C_1^{-1} \ .$$

To find controller transfer matrix $\mathbf{C}$, we shall need the following two identities:

$$\mathbf{\Omega}_X R C_1^{-1} C \mathbf{\Omega} = \mathbf{\Omega}_X L - L\mathbf{\Omega} \ , \quad L = [Z,\ ZP - I] \ ,$$

and

$$I - UN^{-1}C_1^{-1}C + C^{\perp}L = 0 \ .$$

We have

$$\begin{aligned} & N_u^{-1}\left(\mathbf{\Delta} - \mathbf{WG}\right) \\ &= I + K\mathbf{\Omega}B - K\left(U + C^{\perp}\mathbf{\Omega}_X RN\right)N^{-1}C_1^{-1}(D + C\mathbf{\Omega}B) \\ &= I - KUN^{-1}C_1^{-1}D + K(I - UN^{-1}C_1^{-1}C)\mathbf{\Omega}B \\ &\quad - KC^{\perp}\mathbf{\Omega}_X RC_1^{-1}D - KC^{\perp}\mathbf{\Omega}_X RC_1^{-1}C\mathbf{\Omega}B \\ &= I - KUN^{-1}C_1^{-1}D - KC^{\perp}L\mathbf{\Omega}B - KC^{\perp}\mathbf{\Omega}_X RC_1^{-1}D - KC^{\perp}(\mathbf{\Omega}_X L - L\mathbf{\Omega})B \\ &= N_u^{-1}N_1 - KC^{\perp}\mathbf{\Omega}_X(RC_1^{-1}D + LB) \ , \end{aligned}$$

where $\mathbf{\Delta}$ is given by (3.8), and the matrix

$$\begin{aligned} N_1 &= N_u(I - KUN^{-1}C_1^{-1}D) \\ &= N_u^{-1}\left[Q_u + D^{\mathrm{T}}Q_e D - (B^{\mathrm{T}}Y + D^{\mathrm{T}}Q_e C)UN^{-1}C_1^{-1}D)\right] \\ &= N_u^{-1}(Q_u - B^{\mathrm{T}}YUN^{-1}C_1^{-1}D) \end{aligned}$$

has been introduced. To achieve proper controller $\mathbf{C}$, assume that N_1 is nonsingular and introduce the rational matrix

$$\mathbf{\Omega}_{XY} = \left[sI - A_2 + Z(A_3 + Q) - (RC_1^{-1}D + LB)N_1^{-1}N_u KC^{\perp}\right]^{-1} \ .$$

The last matrix identity we shall need is

$$\mathbf{\Omega}_{XY}(RC_1^{-1}D + LB)N_1^{-1}N_u KC^{\perp}\mathbf{\Omega}_X = \mathbf{\Omega}_{XY} - \mathbf{\Omega}_X \ .$$

We have

$$\begin{aligned} & \mathbf{C} = \left(\mathbf{\Delta} - \mathbf{WG}\right)^{-1}\mathbf{W} \\ &= N_1^{-1}\left[I + N_u KC^{\perp}\mathbf{\Omega}_{XY}(RC_1^{-1}D + LB)N_1^{-1}\right]N_u K(U + C^{\perp}\mathbf{\Omega}_X RN)N^{-1}C_1^{-1} \\ &= N_1^{-1}\big[N_u KU + N_u KC^{\perp}\mathbf{\Omega}_X RN + N_u KC^{\perp}\mathbf{\Omega}_{XY}(RC_1^{-1}D + LB)N_1^{-1}N_u KU \\ &\qquad + N_u KC^{\perp}(\mathbf{\Omega}_{XY} - \mathbf{\Omega}_X)RN\big]N^{-1}C_1^{-1} \\ &= N_1^{-1}N_u K\left\{U + C^{\perp}\mathbf{\Omega}_{XY}\left[RN + (RC_1^{-1}D + LB)N_1^{-1}N_u KU\right]\right\}N^{-1}C_1^{-1} \ . \end{aligned}$$

This is a state space realization of optimal controller $\mathbf{C}$. Note that its order is minimal, equal to $n - p$.

Concerning Assumption 6, we shall give its interpretation for this particular application. By (4.12), the poles of $\mathbf{\Phi}$ are the eigenvalues of A, and the set τ consists of the eigenvalues of $-(A - BK)$. Therefore, Assumption 6 means that the unstable eigenvalues of A are not eigenvalues of $-(A - BK)$.

Remark 4.1. In the above example we have assumed that rational matrix $\mathbf{G}_w W$ is right invertible. If it is not right invertible, under very general conditions, we can apply an observer of arbitrary pole distribution, in which the disturbance variable w is absent [12] (of minimal order $n - p$), and detect the state variable x arbitrarily fast.

4.3. Tracking: White measurement noise is present. In this subsection we assume white noises with $\mathbf{\Phi}_{vv} = M > 0$, $N^2 = M$, $\mathbf{\Phi}_{ww} = W \geq 0$, and $\mathbf{G}$ strict proper (i.e., $D = 0$ in (3.1)).

For some symmetric positive definite matrix H, let the spectral density of a shape-deterministic reference signal r be

$$\mathbf{\Phi}_{rr} = C_r \mathbf{\Omega}_r B_r H B_r^{\mathrm{T}} \mathbf{\Omega}_r^{\sim} C_r^{\mathrm{T}} \ , \quad \mathbf{\Omega}_r = (sI - A_r)^{-1} \ ,$$

where (A_r, B_r) and (C_r, A_r) are controllable and observable matrix pairs, correspondingly.

To solve the formulated optimal control problem, we shall apply Corollary 2.5.

By Assumption 1, the condition of stability of $\mathbf{\Theta}_1 \mathbf{r}$ has to be satisfied. We have

$$\begin{aligned} \mathbf{\Theta}_1 \mathbf{r} &= (I - C\mathbf{\Omega}_F F) C_r \mathbf{\Omega}_r B_r = C_r \mathbf{\Omega}_r B_r - C \mathbf{\Omega}_F F C_r \mathbf{\Omega}_r B_r \\ &= C_r \mathbf{\Omega}_r B_r - C(\mathbf{\Omega}_F U_r - U_r \mathbf{\Omega}_r) B_r = (C_r + C U_r) \mathbf{\Omega}_r B_r - C \mathbf{\Omega}_F U_r B_r \ , \end{aligned}$$

where U_r is a solution of the Sylvester equation

$$U_r A_r - (A - FC) U_r + F C_r = 0 \ . \tag{4.13}$$

If the pair (C, A) is observable, we can take the eigenvalues of $A - FC$ pairwise distinct of the eigenvalues of A_r; hence (4.13) has a solution for U_r. Since the pair (A_r, B_r) is controllable, from the condition of stability of $(C_r + CU_r)\mathbf{\Omega}_r B_r$, we obtain the condition of stability of $(C_r + CU_r)\mathbf{\Omega}_r$.

To find $\mathbf{\Phi}$, write

$$\begin{aligned} \mathbf{\Phi}_{vv} + \mathbf{\Phi}_{xx} &= M + \mathbf{\Phi}_{rr} + \mathbf{G}_w W \mathbf{G}_w^{\sim} \\ &\stackrel{\mathrm{def}}{=} M + \bar{C}(sI - \bar{A})^{-1} \bar{B} \bar{\Phi} \bar{B}^{\mathrm{T}} (-sI - \bar{A}^{\mathrm{T}})^{-1} \bar{C}^{\mathrm{T}} \\ &\stackrel{\mathrm{def}}{=} M + \bar{\mathbf{G}} \bar{\Phi} \bar{\mathbf{G}}^{\sim} = \mathbf{\Phi} \mathbf{\Phi}^{\sim} \ , \end{aligned}$$

where

$$\bar{C} = [C_r, C] \ , \quad \bar{A} = \begin{bmatrix} A_r & 0 \\ 0 & A \end{bmatrix} \ , \quad \bar{B} = \begin{bmatrix} B_r & 0 \\ 0 & B_w \end{bmatrix} \ , \quad \bar{\Phi} = \begin{bmatrix} H & 0 \\ 0 & W \end{bmatrix} \ ,$$

$$\bar{\mathbf{G}} = \bar{C}(sI - \bar{A})^{-1} \bar{B} \stackrel{\mathrm{def}}{=} \bar{C} \bar{\mathbf{\Omega}} \bar{B} \ .$$

We have

$$\mathbf{\Phi} = N + \bar{C} \bar{\mathbf{\Omega}} X \bar{C}^{\mathrm{T}} M^{-1} N \ , \tag{4.14}$$

and X is the stabilizing solution of CARE

$$\bar{A} X + X \bar{A}^{\mathrm{T}} - X \bar{C}^{\mathrm{T}} M^{-1} \bar{C} X + \bar{B} \bar{\Phi} \bar{B}^{\mathrm{T}} = 0 \ .$$

The stabilizing solution exists because, by Lemma 3.1, matrix pair (C_r, A_r) is observable and (C, A) is observable; i.e., matrix pair $(\bar{C}, \bar{A})$ is observable.

Consider the following Sylvester equation for the unknown matrix K_1:

$$K_1 A_r + (A - B Q_u^{-1} B^{\mathrm{T}} Y)^{\mathrm{T}} K_1 + C^{\mathrm{T}} Q_e C_r = 0 \ . \tag{4.15}$$

We shall prove that it has a solution. By (4.14), the poles of $\mathbf{\Phi}$ are a union of the eigenvalues of A and eigenvalues of A_r, and the set τ consists of the eigenvalues of $-(A-BK)$ and eigenvalues of $-(\hat{A}-X\hat{C}^{\mathrm{T}}M\hat{C})$. Therefore, Assumption 6 means that the unstable eigenvalues of A and unstable eigenvalues of A_r are not eigenvalues of $-(A-BK)$ and of $-(\hat{A}-X\hat{C}^{\mathrm{T}}M\hat{C})$. In particular, the eigenvalues of A_r and eigenvalues of $-(A-BK)^{\mathrm{T}}=-(A-BQ_u^{-1}B^{\mathrm{T}}Y)^{\mathrm{T}}$ are pairwise distinct; hence Sylvester equation (4.15) has a solution.

We shall need the matrix identity

$$\mathbf{\Omega}_Y^{\sim}C^{\mathrm{T}}Q_eC_r\mathbf{\Omega}_r=\mathbf{\Omega}_Y^{\sim}K_1+K_1\mathbf{\Omega}_r\ ,$$

where K_1 is the solution of Sylvester equation (4.15), and the identity (4.8) with $D=0$.

Compute

$$\begin{aligned}&\left\{\mathbf{\Omega}_Y^{\sim}C^{\mathrm{T}}Q_e\bar{C}\bar{\mathbf{\Omega}}\right\}_\sigma\\ &=\left[\mathbf{\Omega}_Y^{\sim}C^{\mathrm{T}}Q_eC_r\mathbf{\Omega}_r,\ \mathbf{\Omega}_Y^{\sim}C^{\mathrm{T}}Q_eC\mathbf{\Omega}\right]_\sigma=\left[\mathbf{\Omega}_Y^{\sim}K_1+K_1\mathbf{\Omega}_r,\ \mathbf{\Omega}_Y^{\sim}Y+Y\mathbf{\Omega}\right]_\sigma\\ &=[K_1\mathbf{\Omega}_r,\ Y\mathbf{\Omega}]=[K_1,Y]\begin{bmatrix}\mathbf{\Omega}_r & 0\\ 0 & \mathbf{\Omega}\end{bmatrix}=Z\bar{\mathbf{\Omega}}\ ,\end{aligned}$$

where $Z=[K_1,Y]$. Further we have

$$\begin{aligned}\mathbf{L}_\sigma=\{\mathbf{\Psi}^{\sim}Q_e\mathbf{\Phi}\}_\sigma&=\left\{N_u^{-1}B^{\mathrm{T}}\mathbf{\Omega}_Y^{\sim}C^{\mathrm{T}}Q_e\left(N+\bar{C}\bar{\mathbf{\Omega}}X\bar{C}^{\mathrm{T}}M^{-1}N\right)\right\}_\sigma\\ &=N_u^{-1}B^{\mathrm{T}}Z\bar{\mathbf{\Omega}}X\bar{C}^{\mathrm{T}}M^{-1}N\end{aligned}$$

and

$$\begin{aligned}\mathbf{W}=\mathbf{L}_\sigma\mathbf{\Phi}^{-1}&=N_u^{-1}B^{\mathrm{T}}Z\bar{\mathbf{\Omega}}X\bar{C}^{\mathrm{T}}M^{-1}\left(I+\bar{C}\bar{\mathbf{\Omega}}X\bar{C}^{\mathrm{T}}M^{-1}\right)^{-1}\\ &=N_u^{-1}B^{\mathrm{T}}Z\left(I+\bar{\mathbf{\Omega}}X\bar{C}^{\mathrm{T}}M^{-1}\bar{C}\right)^{-1}\bar{\mathbf{\Omega}}X\bar{C}^{\mathrm{T}}M^{-1}\\ &=N_u^{-1}B^{\mathrm{T}}Z\left(sI-\bar{A}+X\bar{C}^{\mathrm{T}}M^{-1}\bar{C}\right)^{-1}X\bar{C}^{\mathrm{T}}M^{-1}\\ &=N_u^{-1}B^{\mathrm{T}}Z\mathbf{\Omega}_XX\bar{C}^{\mathrm{T}}M^{-1}\ ,\end{aligned}$$

where $\mathbf{\Omega}_X=\left(sI-\bar{A}+X\bar{C}^{\mathrm{T}}M^{-1}\bar{C}\right)^{-1}$. It is easy to check that

$$\mathbf{\Omega}_XX\bar{C}^{\mathrm{T}}M^{-1}C\mathbf{\Omega}=L\mathbf{\Omega}-\mathbf{\Omega}_XL\ ,$$

where $L=\left[\begin{smallmatrix}0\\ I\end{smallmatrix}\right]$. Therefore

$$\begin{aligned}\mathbf{C}&=(\mathbf{\Delta}-\mathbf{WG})^{-1}\mathbf{W}\\ &=\left[N_u+N_uQ_u^{-1}B^{\mathrm{T}}Y\mathbf{\Omega}B-N_u^{-1}B^{\mathrm{T}}Z\mathbf{\Omega}_XX\bar{C}^{\mathrm{T}}M^{-1}C\mathbf{\Omega}B\right]^{-1}\mathbf{W}\\ &=\left[N_u+N_uQ_u^{-1}B^{\mathrm{T}}Y\mathbf{\Omega}B-N_u^{-1}B^{\mathrm{T}}Z(L\mathbf{\Omega}-\mathbf{\Omega}_XL)B\right]^{-1}\mathbf{W}\\ &=(I+Q_u^{-1}B^{\mathrm{T}}Z\mathbf{\Omega}_XLB)^{-1}Q_u^{-1}B^{\mathrm{T}}Z\mathbf{\Omega}_XX\bar{C}^{\mathrm{T}}M^{-1}\\ &=Q_u^{-1}B^{\mathrm{T}}Z(I+\mathbf{\Omega}_XLBQ_u^{-1}B^{\mathrm{T}}Z)^{-1}\mathbf{\Omega}_XX\bar{C}^{\mathrm{T}}M^{-1}\\ &=Q_u^{-1}B^{\mathrm{T}}Z(sI-\bar{A}+X\bar{C}^{\mathrm{T}}M^{-1}\bar{C}+LBQ_u^{-1}B^{\mathrm{T}}Z)^{-1}X\bar{C}^{\mathrm{T}}M^{-1}\ ,\end{aligned}$$

because $ZL = Y$. This is a state-space realization of optimal controller $\mathbf{C}$. Its order is $n + n_r$, where n_r is the dimension of the matrix A_r.

It remains to check Assumption 5. We have

$$\begin{aligned}\boldsymbol{\Theta}_1\boldsymbol{\Phi} &= (I - C\boldsymbol{\Omega}_F F)(N + \bar{C}\bar{\boldsymbol{\Omega}}X\bar{C}^{\mathrm{T}}M^{-1}N)\\ &= N + \bar{C}\bar{\boldsymbol{\Omega}}X\bar{C}^{\mathrm{T}}M^{-1}N - C\boldsymbol{\Omega}_F FN - C\boldsymbol{\Omega}_F F\bar{C}\bar{\boldsymbol{\Omega}}X\bar{C}^{\mathrm{T}}M^{-1}N\\ &= N + \bar{C}\bar{\boldsymbol{\Omega}}X\bar{C}^{\mathrm{T}}M^{-1}N - C\boldsymbol{\Omega}_F FN - C(\boldsymbol{\Omega}_F U - U\bar{\boldsymbol{\Omega}})X\bar{C}^{\mathrm{T}}M^{-1}N\ ,\end{aligned}$$

where $U = [U_r, -I]$. Further we have

$$\boldsymbol{\Theta}_1\boldsymbol{\Phi} = N + (C_r + CU_r)\boldsymbol{\Omega}_r[I, 0]X\bar{C}^{\mathrm{T}}M^{-1}N - C\boldsymbol{\Omega}_F(F + UX\bar{C}^{\mathrm{T}}M^{-1})N\ .$$

Since $(C_r + CU_r)\boldsymbol{\Omega}_r$ is stable, $\boldsymbol{\Theta}_1\boldsymbol{\Phi}$ is stable. Further we have

$$\begin{aligned}(\boldsymbol{\Theta}_1\boldsymbol{\Phi})^{-1} &= \boldsymbol{\Phi}^{-1}\boldsymbol{\Theta}_1^{-1} = N^{-1}(I - \bar{C}\boldsymbol{\Omega}_X X\bar{C}^{\mathrm{T}}M^{-1})(I + C\boldsymbol{\Omega}F)\\ &= N^{-1}\left[I + C\boldsymbol{\Omega}F - \bar{C}\boldsymbol{\Omega}_X X\bar{C}^{\mathrm{T}}M^{-1} - \bar{C}(L\boldsymbol{\Omega} - \boldsymbol{\Omega}_X L)F\right]\\ &= N^{-1}\left[I - \bar{C}\boldsymbol{\Omega}_X(X\bar{C}^{\mathrm{T}}M^{-1} - LF)\right]\ .\end{aligned}$$

Therefore, $\boldsymbol{\Theta}_1\boldsymbol{\Phi}$ is minimum phase.

Remark 4.2. It can be proved that the property $\boldsymbol{\Theta}_1\mathbf{r}$ being stable is independent of the matrix F in (3.2) and (3.3), introduced to define $\boldsymbol{\Theta}_1$.

Conclusions. We have presented solutions to an LQ output tracking controller in the presence of plant disturbances with or without measurement noise, in which matrices of Youla–Kučera parametrization do not appear. Further research can be as follows:

• Although matrices of Youla–Kučera parametrization are not present in the optimal controller transfer matrix, they are still present in the expression for the minimal value of the criterion (see (3.18) and (3.19)). On the other hand, if we deal with the LQG control problem, the minimal value of the criterion can be easily expressed in explicit form, without matrices of Youla–Kučera parametrization. Can it be expressed in a similar explicit form in general?

• Generalize the application from subsection 4.1 to consider $\boldsymbol{\Phi}_{vv} = V_1\boldsymbol{\Omega}_v V\boldsymbol{\Omega}_v^{\sim}V_1^{\mathrm{T}}$ for some matrix V_1. The augmentation method of subsection 4.3 can be applied, and then spectral factorization of strict proper matrices of subsection 4.2 can be applied.

Acknowledgment. The author is grateful to a reviewer for many helpful remarks.

ON THE PARAMETRIZATION OF ALL REGULARLY IMPLEMENTING AND STABILIZING CONTROLLERS*

C. PRAAGMAN†, H. L. TRENTELMAN‡, AND R. ZAVALA YOE‡

Abstract. In this paper we deal with problems of controller parametrization in the context of behavioral systems. Given a full plant behavior, a subbehavior of the manifest plant behavior is called *regularly implementable* if it can be achieved as the controlled behavior resulting from the interconnection of the full plant behavior with a suitable controller behavior, in such a way that the controller does not impose restrictions that are already present in the plant. We establish a parametrization of *all* controllers that regularly implement a given behavior. We also obtain a parametrization of all stabilizing controllers.

Key words. linear differential system behaviors, implementability, stabilization, parametrization of controllers, Youla parametrization

1. Introduction.

An important issue in the behavioral approach to control is that of *implementability*. The concept of implementability has been successfully applied to resolve a number of important synthesis problems in the behavioral approach, in particular the synthesis of dissipative systems [11] and the behavioral versions of the problems of pole placement and stabilization [2]. The concept was also studied in [3], for nD behaviors in [7], and for general behaviors in [8]. A nice overview can also be found in [1]. Implementability deals with the issue which system behaviors can be achieved ("implemented") by interconnecting a given system with a controller, and is thus concerned with the limits of performance of a given plant. In the behavioral framework this is made precise as follows. Given is a system behavior (plant) with two types of variables: the variable w to be controlled, and the variable c (the control variable) on which we are allowed to put restrictions. A controller for our plant behavior is an additional system behavior, called controller behavior. Interconnecting the plant with the controller simply means requiring c to be an element of the controller behavior. The space of all w trajectories that are possible after interconnecting the plant behavior with the controller behavior forms the so-called *manifest controlled behavior*. A behavior is called implementable (w.r.t. the given plant behavior) if it can be achieved as manifest controlled behavior in this way. In the contexts of synthesis of dissipative systems, pole placement, and stabilization, an important role is also played by *regular implementability*. A given behavior is called regularly implementable if it can be achieved by a controller behavior that does not impose restrictions on the control variable that are already present in the plant; equivalently, the number of outputs of the associated full controlled behavior is equal to the sum of the number of outputs of the plant and the number of outputs of the controller. In [11], for a given plant behavior a characterization was given of all implementable behaviors, and

in [2] a characterization was given of all regularly implementable behaviors. Once a given behavior is (regularly) implementable, it is important to know which controller behaviors implement it. In this paper we establish a parametrization of all controller behaviors that regularly implement a given behavior.

A controller is called a stabilizing controller if it regularly implements a stable behavior. In [2], conditions on the plant behavior were given for the existence of a stabilizing controller. Once a stabilizing controller exists, it is important to have a parametrization of all stabilizing controllers. In fact, a result of paramount importance in feedback control is the celebrated Youla parametrization of all stabilizing controllers; see [12] and [9]. In this paper we find a parametrization of all stabilizing controllers in the behavioral framework. In this framework, the parametrization problem was considered before in [4] for the so-called full interconnection case. Here, we resolve the general, partial interconnection case.

The outline of this paper is as follows. In section 2 we review the basic material on linear differential systems needed in this paper and some less known material on left and right minimal annihilators. In section 3 we formulate the main problems that we treat in this paper, the problems of parametrizing all regularly implementing controllers and all stabilizing controllers. We also give some motivating examples there. Section 4 deals with the special case of full interconnection. We review the basic facts on implementability by full interconnection and present a new condition for regular implementability. Next, we solve the problems of parametrizing all regularly implementing controllers and all stabilizing controllers, both for the full interconnection case. Section 5 solves the parametrization problem for the case that in the plant behavior the control variable is observable from the manifest variable. Next, in section 6, we reduce the general, nonobservable, case to the observable case by describing two reduction steps. Then, in section 7 we give a parametrization of all stabilizing controllers, first in the observable case, and next by reducing the general case to the observable case. Finally, in section 8, we provide a number of worked out examples to illustrate the theory of this paper.

In several places in this paper we denote by $\mathrm{col}(A, B)$ the matrix obtained by stacking A over B. A polynomial p is called Hurwitz if all its zeros are contained in the open left half complex plane $\mathbb{C}^- := \{\lambda \in \mathbb{C} \mid \mathrm{Re}(\lambda) < 0\}$. A square polynomial matrix P is called Hurwitz if $\det(P)$ is Hurwitz. Finally, we denote $\mathbb{C}^+ := \{\lambda \in \mathbb{C} \mid \mathrm{Re}(\lambda) \geq 0\}$.

2. Linear differential systems. In the behavioral approach to linear systems, a dynamical system is given by a triple $\Sigma = (\mathbb{R}, \mathbb{R}^q, \mathfrak{B})$, where $\mathbb{R}$ is the time axis, $\mathbb{R}^q$ is the signal space, and the behavior $\mathfrak{B}$ is a subset of $\mathfrak{C}^\infty(\mathbb{R}, \mathbb{R}^q)$ (the space of all infinitely often differentiable functions from $\mathbb{R}$ to $\mathbb{R}^q$) consisting of all solutions of a set of higher order, linear, constant coefficient differential equations. More precisely, there exists a real polynomial matrix R with q columns such that $\mathfrak{B} = \{w \in \mathfrak{C}^\infty(\mathbb{R}, \mathbb{R}^q) \mid R(\frac{\mathrm{d}}{\mathrm{d}t})w = 0\}$. Any such dynamical system Σ is called a *linear differential system*. The set of all linear differential systems with q variables is denoted by $\mathfrak{L}^q$. Since the behavior $\mathfrak{B}$ of the system Σ is the central item, we will speak mostly about the system $\mathfrak{B} \in \mathfrak{L}^q$ (instead of $\Sigma \in \mathfrak{L}^q$). Henceforth, in this paper we will suppress the notation $\frac{\mathrm{d}}{\mathrm{d}t}$ and write Rw instead of $R(\frac{\mathrm{d}}{\mathrm{d}t})w$.

The behavioral approach makes a distinction between the behavior as the space of all solutions to a set of (differential) equations and the set of equations itself. A set of equations in terms of which the behavior is defined is called a *representation* of the behavior. If a behavior $\mathfrak{B}$ is represented by $Rw = 0$, then we call this a kernel representation of $\mathfrak{B}$ and often write $\mathfrak{B} = \ker(R)$.

Suppose R has p rows. Then the kernel representation is said to be *minimal* if every other kernel representation of $\mathfrak{B}$ has at least p rows. A given kernel representation $\mathfrak{B} = \ker(R)$ is minimal if and only if the polynomial matrix R has full row rank (see [5, Theorem 3.6.4]). The number of rows in any minimal kernel representation of $\mathfrak{B}$ is denoted by $\mathfrak{p}(\mathfrak{B})$. This number is called the *output cardinality* of $\mathfrak{B}$. It corresponds to the number of outputs in any input/output representation of $\mathfrak{B}$ (see [5, section 3.3]).

A linear differential system is *defined* as the solution space $\mathfrak{B}$ of a differential equation of the form $Rw = 0$. However, such a system can have other representations as well. One of these is the image representation. Let M be a real polynomial matrix with q rows and, say, l columns. If

$$\mathfrak{B} = \{w \in \mathfrak{C}^\infty(\mathbb{R}, \mathbb{R}^q) \mid \text{ there exists } \ell \in \mathfrak{C}^\infty(\mathbb{R}, \mathbb{R}^l) \text{ such that } w = M\ell\},$$

then we call $w = M\ell$ an image representation of the system behavior $\mathfrak{B}$ and often write $\mathfrak{B} = \mathrm{im}(M)$. The linear differential system $\mathfrak{B}$ has an image representation if and only if it is *controllable* (see [5, Theorem 6.6.1]). If $\mathfrak{B} = \ker(R)$, then $\mathfrak{B}$ is controllable if and only if the rank of the complex matrix $R(\lambda)$ is independent of λ for $\lambda \in \mathbb{C}$. If $\mathfrak{B}$ is a linear differential system, then we denote by $\mathfrak{B}_{\mathrm{cont}}$ the largest controllable subbehavior of $\mathfrak{B}$ (see [5, Theorem 5.2.14]). The system $\mathfrak{B}$ is *stabilizable* if and only if the rank of $R(\lambda)$ is independent of λ for $\lambda \in \mathbb{C}^+$ (see [5, Theorem 5.2.30]).

We now recall the concepts of minimal (left and right) annihilator. If M is a polynomial matrix, then the polynomial matrix R is called *a minimal left annihilator* (MLA) of M if $\mathrm{im}(M) = \ker(R)$. Since, for any M, $\mathrm{im}(M)$ is a linear differential behavior (see [5, section 6.6]), and since every linear differential behavior has a kernel representation $\ker(R)$, every M has an MLA. For a given polynomial matrix R, the polynomial matrix M is called *a minimal right annihilator* (MRA) of R if $\mathrm{im}(M) = (\ker(R))_{\mathrm{cont}}$. Given R, the controllable part $(\ker(R))_{\mathrm{cont}}$ of $\ker(R)$ admits an image representation $\mathrm{im}(M)$ (see [5, Theorem 6.6.1]). Thus every R has an MRA.

In many places in this paper, we will use, for a given M, an MLA of R *with full row rank*. If the given M has full row rank, say q, then for consistency we *define* such a full row rank MLA as the "void" matrix R with 0 rows and q columns. Likewise we often use, for a given R, an MRA with the property that $M(\lambda)$ has full column rank for all λ. If R has full column rank q, we define such an M to be the void matrix with q rows and 0 columns. In that case, if K is a given matrix with q columns, then KM is again void. Finally, we use the convention that if R is void, with zero rows and q columns, then a full column rank MRA is given by the $q \times q$ identity matrix I_q.

Note that if R is a full row rank MLA, say of M, then automatically $R(\lambda)$ has full row rank for all $\lambda \in \mathbb{C}$. Indeed, if $\ker(R) = \mathrm{im}(M)$, then $\ker(R)$ is controllable so its rank is independent of λ. As an immediate consequence of this, if R is a full row rank MLA, then there exists a polynomial matrix R' such that $\mathrm{col}(R, R')$ is unimodular.

Next, we review some facts on observability. Suppose $\mathfrak{B} \in \mathfrak{L}^q$ with system variable $w = (w_1, w_2)$, where w_1 and w_2 take values in $\mathbb{R}^{q_1}$ and $\mathbb{R}^{q_2}$, respectively, $q = q_1 + q_2$. We call w_2 *observable from* w_1 if $(w_1, w_2), (w_1, w_2') \in \mathfrak{B}$ implies $w_2 = w_2'$. We call w_2 *detectable from* w_1 if $(w_1, w_2), (w_1, w_2') \in \mathfrak{B}$ implies $\lim_{t\to\infty}(w_2(t) - w_2'(t)) = 0$. If $\mathfrak{B}$ is represented by $R_1 w_1 + R_2 w_2 = 0$, then w_2 is observable from w_1 if and only if $R_2(\lambda)$ has full column rank for all $\lambda \in \mathbb{C}$ ([5, Theorem 5.3.3]). Also, w_2 is detectable from w_1 if and only if $R_2(\lambda)$ has full column rank for all $\lambda \in \mathbb{C}^+$ ([5, Theorem 5.3.17]).

We now review some facts on elimination. Again, let $\mathfrak{B} \in \mathfrak{L}^q$ with system variable $w = (w_1, w_2)$. Let P_{w_1} denote the projection onto the w_1-component. Then the set $P_{w_1}\mathfrak{B}$ of all w_1 for which there exists w_2 such that $(w_1, w_2) \in \mathfrak{B}$ is again a linear differential system. In this paper we denote $P_{w_1}\mathfrak{B}$ by $\mathfrak{B}_{w_1}$. We call $\mathfrak{B}_{w_1}$ the

system obtained by eliminating w_2 from $\mathfrak{B}$ ([5, section 6.2.2]). If $\mathfrak{B} = \ker(R_1 \;\; R_2)$, then a representation of $\mathfrak{B}_{w_1}$ is obtained as follows: choose a unimodular matrix V such that $VR_2 = \mathrm{col}(R_{12}, 0)$, with R_{12} full row rank, and conformably partition $VR_1 = \mathrm{col}(R_{11}, R_{21})$. Then $\mathfrak{B}_{w_1} = \ker(R_{21})$ (see [5, section 6.2.2]). This is due to the fact that R_{12} is a full row rank polynomial matrix, which therefore induces a surjective differential operator from $\mathfrak{C}^\infty(\mathbb{R}, \mathbb{R}^{q_2})$ to $\mathfrak{C}^\infty(\mathbb{R}, \mathbb{R}^r)$, with $r := \mathrm{rowdim}(R_{12})$.

Sometimes, system behaviors are represented by latent variable representations of the form $Rw = M\ell$, with *latent variable* ℓ. Of course, this equation represents the full behavior of all (w, ℓ) that satisfy the differential equation. The w-behavior $\mathfrak{B}$ obtained by eliminating ℓ from this full behavior is called the *manifest behavior* associated with this latent variable representation. On several occasions in this paper we need to compute the output cardinality $\mathtt{p}(\mathfrak{B})$ of this behavior in terms of the polynomial matrices R and M. It was shown in [2, Lemma 8], that $\mathtt{p}(\mathfrak{B}) = \mathrm{rank}(R, M) - \mathrm{rank}(M)$.

Finally, we recall some facts on autonomous systems. If the behavior $\mathfrak{B}$ has the property that $\mathtt{p}(\mathfrak{B}) = q$ (the number of variables; thus all variables are output), then we call $\mathfrak{B}$ *autonomous*. An autonomous system is called *stable* if $\lim_{t\to\infty} w(t) = 0$ for all $w \in \mathfrak{B}$ (see [5, section 7.2]).

3. Problem formulation. In this section we introduce the main problems that are considered in this paper. We first briefly review the relevant definitions on interconnection and implementability. For an extensive treatment, see [2]. Let $\mathcal{P}_{\mathrm{full}} \in \mathfrak{L}^{q+k}$ be a linear differential system, with system variable (w, c), where w takes its values in $\mathbb{R}^q$ and c in $\mathbb{R}^k$. The variables w should be interpreted as the variables to be controlled, and the variables c are those through which we can interconnect the plant to a controller and are called *the control variables*. Let $\mathcal{C} \in \mathfrak{L}^k$ be a controller behavior, with variable c.

DEFINITION 1. *The interconnection of* $\mathcal{P}_{\mathrm{full}}$ *and* $\mathcal{C}$ *through* c *is defined as the system behavior* $\mathcal{K}_{\mathrm{full}}(\mathcal{C}) \in \mathfrak{L}^{q+k}$*, given by* $\mathcal{K}_{\mathrm{full}}(\mathcal{C}) = \{(w, c) \mid (w, c) \in \mathcal{P}_{\mathrm{full}}$ *and* $c \in \mathcal{C}\}$*. This behavior is called* the full controlled behavior.

DEFINITION 2. *The interconnection of* $\mathcal{P}_{\mathrm{full}}$ *and* $\mathcal{C}$ *through* c *is called* regular *if the output cardinality of the full controlled behavior is the sum of the output cardinalities of the plant and the controller, i.e.,* $\mathtt{p}(\mathcal{K}_{\mathrm{full}}(\mathcal{C})) = \mathtt{p}(\mathcal{P}_{\mathrm{full}}) + \mathtt{p}(\mathcal{C})$.

This condition is equivalent to the following: $\mathcal{C}$ does not reimpose restrictions on $\mathcal{K}_{\mathrm{full}}(\mathcal{C})$ that are already present in $\mathcal{P}_{\mathrm{full}}$ (see also [7, Definition 3.1]).

DEFINITION 3. *The behavior* $(\mathcal{K}_{\mathrm{full}}(\mathcal{C}))_w \in \mathfrak{L}^q$ *that is obtained by eliminating* c *from* $\mathcal{K}_{\mathrm{full}}(\mathcal{C})$ *is called the* manifest controlled behavior.

Let $\mathcal{K} \in \mathfrak{L}^q$ be a given behavior, which should be interpreted as a "desired" behavior. A fundamental question is whether this $\mathcal{K}$ can be achieved as controlled behavior as stated in the following definition.

DEFINITION 4. *If there exists* $\mathcal{C} \in \mathfrak{L}^k$ *such that* $\mathcal{K} = (\mathcal{K}_{\mathrm{full}}(\mathcal{C}))_w$*, then* $\mathcal{K}$ *is called* implementable by partial interconnection (through c, w.r.t. $\mathcal{P}_{\mathrm{full}}$). *If there exists* $\mathcal{C} \in \mathfrak{L}^k$ *such that* $\mathcal{K} = (\mathcal{K}_{\mathrm{full}}(\mathcal{C}))_w$ *and* $\mathtt{p}(\mathcal{K}_{\mathrm{full}}(\mathcal{C})) = \mathtt{p}(\mathcal{P}_{\mathrm{full}}) + \mathtt{p}(\mathcal{C})$*, then we call* $\mathcal{K}$ regularly implementable by partial interconnection (through c, w.r.t. $\mathcal{P}_{\mathrm{full}}$).

Necessary and sufficient conditions for a given $\mathcal{K} \in \mathfrak{L}^q$ to be (regularly) implementable by partial interconnection have been obtained in [11] and [2]. We will review these conditions in section 5.

We now formulate the first main problem that we deal with in this paper. Let $\mathcal{P}_{\mathrm{full}} = \ker(R_1 \;\; R_2)$ be a minimal representation of the plant. Let $\mathcal{K} = \ker(K)$ be a minimal representation of the desired behavior. Then the problem is as follows: *give a*

parametrization, in terms of the polynomial matrices R_1, R_2 and K, of all *polynomial matrices C such that the controller* $\ker(C)$ *regularly implements $\mathcal{K}$.*

Example 5. Consider the plant behavior $\mathcal{P}_{\text{full}}$ with manifest variable $w = (w_1, w_2)$ and control variable $c = (c_1, c_2)$ represented by

$$\begin{aligned} w_1 + \dot{w}_2 + \dot{c}_1 + c_2 &= 0, \\ c_1 + c_2 &= 0. \end{aligned}$$

Clearly, $(\mathcal{P}_{\text{full}})_w = \mathfrak{C}^\infty(\mathbb{R}, \mathbb{R}^2)$. For the desired behavior $\mathcal{K}$ we take $\mathcal{K} = \{(w_1, w_2) \mid w_1 + \dot{w}_2 = 0\}$. The following controller regularly implements $\mathcal{K}$ through c: $\mathcal{C} = \{(c_1, c_2) \mid \dot{c}_1 + c_2 = 0\}$. Also every controller represented by $kc_1 + c_2 = 0$, with $k \neq 1$, regularly implements $\mathcal{K}$. We would like to find a parametrization of *all* 1×2 polynomial matrices $C(\xi) = (C_1(\xi) \quad C_2(\xi))$ such that $\mathcal{C} = \ker(C_1 \quad C_2)$ regularly implements $\mathcal{K}$.

We now recall the definition of a stabilizing controller (see [2, section 3]).

DEFINITION 6. *Let $\mathcal{P}_{\text{full}} \in \mathfrak{L}^{q+k}$. The controller $\mathcal{C} \in \mathfrak{L}^k$ is said to stabilize $\mathcal{P}_{\text{full}}$ through c if the manifest controlled behavior $(\mathcal{K}_{\text{full}}(\mathcal{C}))_w$ is stable and the interconnection of $\mathcal{P}_{\text{full}}$ and $\mathcal{C}$ is regular. The controller $\mathcal{C}$ is then called a* stabilizing controller.

The following result was shown in [2, Theorem 6].

PROPOSITION 7. *Let $\mathcal{P}_{\text{full}} \in \mathfrak{L}^{q+k}$. There exists a stabilizing controller $\mathcal{C}$ if and only if $(\mathcal{P}_{\text{full}})_w$ is stabilizable and in $\mathcal{P}_{\text{full}}$ w is detectable from c.*

We now formulate the second main problem that is solved in this paper. Let $\mathcal{P}_{\text{full}} = \ker(R_1 \quad R_2)$ be a minimal representation of the plant. Then the problem is as follows: *give a parametrization, in terms of the polynomial matrices R_1 and R_2, of* all *polynomial matrices C such that the controller* $\ker(C)$ *is a stabilizing controller.*

Example 8. Consider the full plant behavior $\mathcal{P}_{\text{full}}$ represented by

$$\begin{aligned} w_1 + \dot{w}_2 + \dot{c}_1 + c_2 &= 0, \\ w_2 + c_1 + c_2 &= 0, \\ \dot{c}_1 + c_1 + \dot{c}_2 + c_2 &= 0. \end{aligned}$$

A stabilizing controller is given by $\mathcal{C} = \{(c_1, c_2) \mid \dot{c}_2 + 2c_1 + c_2 = 0\}$. Indeed, by eliminating c from the full controlled behavior $\mathcal{K}_{\text{full}}(\mathcal{C})$ (as described in section 2) we find that $(\mathcal{K}_{\text{full}}(\mathcal{C}))_w = \ker(R)$, with

$$R(\xi) = \begin{pmatrix} 0 & \xi + 1 \\ -1 & 2 \end{pmatrix},$$

which is Hurwitz. Yet another class of stabilizing controllers is represented by $C(\xi) = (\xi(\xi + 1) + k, \xi + 1 + k)$, $k \in \mathbb{R}$. We want to find a parametrization of *all* 1×2 polynomial matrices $C(\xi)$ such that $\ker(C)$ is a stabilizing controller.

For the special case of full interconnection (see section 4), the problem of parametrizing all stabilizing controllers was considered earlier in [4]. Of course, in the context of feedback stabilization this parametrization problem dates back to the famous result of Youla [12].

4. Implementability and controller parametrization: The full interconnection case. In this section we treat the full interconnection case. First, we briefly review some facts on implementability and present a new condition for regular implementability. Then we establish a parametrization of all controllers that regularly implements a given behavior. Finally, we parametrize all stabilizing controllers.

Let $\mathcal{P} \in \mathfrak{L}^q$ be a plant behavior. A controller for $\mathcal{P}$ is a system behavior $\mathcal{C} \in \mathfrak{L}^q$. The *full interconnection* of $\mathcal{P}$ and $\mathcal{C}$ is defined as the system with behavior $\mathcal{P} \cap \mathcal{C}$. This *controlled behavior* is again an element of $\mathfrak{L}^q$. The full interconnection is called *regular* if $\mathfrak{p}(\mathcal{P} \cap \mathcal{C}) = \mathfrak{p}(\mathcal{P}) + \mathfrak{p}(\mathcal{C})$.

Let $\mathcal{K} \in \mathfrak{L}^q$ be a given behavior, to be interpreted as a "desired" behavior. If $\mathcal{K}$ can be achieved as controlled behavior, i.e., if there exists $\mathcal{C} \in \mathfrak{L}^q$ such that $\mathcal{K} = \mathcal{P} \cap \mathcal{C}$, then we call $\mathcal{K}$ *implementable by full interconnection* (w.r.t. $\mathcal{P}$). If $\mathcal{K}$ can be achieved by regular interconnection, i.e., if there exists $\mathcal{C}$ such that $\mathcal{K} = \mathcal{P} \cap \mathcal{C}$ and $\mathfrak{p}(\mathcal{P} \cap \mathcal{C}) = \mathfrak{p}(\mathcal{P}) + \mathfrak{p}(\mathcal{C})$, then we call $\mathcal{K}$ *regularly implementable by full interconnection*. Obviously, a given $\mathcal{K} \in \mathfrak{L}^q$ is implementable by full interconnection w.r.t. $\mathcal{P}$ if and only if $\mathcal{K} \subseteq \mathcal{P}$. Indeed, if $\mathcal{K} \subseteq \mathcal{P}$, then with "controller" $\mathcal{C} = \mathcal{K}$ we have $\mathcal{K} = \mathcal{P} \cap \mathcal{C}$. Thus, if $\mathcal{P} = \ker(R)$ and $\mathcal{K} = \ker(K)$ are minimal representations, then $\mathcal{K}$ is implementable w.r.t. $\mathcal{P}$ if and only if there exists a polynomial matrix F such that $R = FK$. The property of *regular* implementability turns out to be equivalent with the existence of such a polynomial matrix F with, in addition, $F(\lambda)$ full row rank for all λ, as stated in the following theorem.

THEOREM 9. *Let $\mathcal{P}, \mathcal{K} \in \mathfrak{L}^q$. Let $\mathcal{P} = \ker(R)$ and $\mathcal{K} = \ker(K)$ be minimal representations. Then the following statements are equivalent:*

1. *$\mathcal{K}$ is regularly implementable w.r.t. $\mathcal{P}$ by full interconnection.*
2. *There exists a polynomial matrix F with $F(\lambda)$ full row rank for all $\lambda \in \mathbb{C}$, such that $R = FK$.*
3. *$\mathcal{K} + \mathcal{P}_{\text{cont}} = \mathcal{P}$.*

Here, $\mathcal{P}_{\text{cont}}$ denotes the controllable part of $\mathcal{P}$.

Proof. The equivalence of statements 1 and 3 was proven in [2, Lemma 7]. We will only prove the equivalence of 1 and 2 here.

($1 \Rightarrow 2$) Let C be such that $\binom{R}{C} w = 0$ is a minimal representation of $\mathcal{K}$. Then there exists a unimodular U such that $\operatorname{col}(R, C) = UK$. This implies $R = FK$, with F consisting of the upper rows of U.

($2 \Rightarrow 1$) Assume $R = FK$. Let V be such that $\operatorname{col}(F, V)$ is unimodular. Define $C = VK$. Then $\binom{R}{C} w = 0$ is a minimal representation of $\mathcal{K}$, and thus $\mathcal{K}$ is regularly implemented by the controller $\mathcal{C} = \ker(C)$. ∎

From the above, for a given regularly implementable $\mathcal{K}$ it is easy to obtain a controller that regularly implements it. Indeed, if $R = FK$ with $F(\lambda)$ full row rank for all λ, let V be such that $\operatorname{col}(F, V)$ is unimodular. Then clearly the controller $\ker(VK)$ does the job. Note that this construction requires the representation $\mathcal{K} = \ker(K)$ to be minimal. In the subsequent development, in particular in section 5, we will need an expression in terms of K for a regularly implementing controller in the general case that K is *not* full row rank. This issue is dealt with in the following lemma.

LEMMA 10. *Let $\mathcal{P}, \mathcal{K} \in \mathfrak{L}^q$. Let K be such that $\mathcal{K} = \ker(K)$ (not necessarily minimal), and let R be such that $\mathcal{P} = \ker(R)$ is a minimal representation. Construct a polynomial matrix W as follows:*

1. *Let M be an MRA of R such that $M(\lambda)$ has full column rank for all $\lambda \in \mathbb{C}$;*
2. *Let Q be a full row rank MLA of KM;*
3. *Let W be a polynomial matrix such that $\operatorname{col}(Q, W)$ is unimodular.*

Then $\mathcal{K}$ is regularly implementable by full interconnection w.r.t. $\mathcal{P}$ if and only if

$$\begin{pmatrix} R \\ WK \end{pmatrix} w = 0 \tag{1}$$

is a minimal representation of $\mathcal{K}$. A controller that regularly implements $\mathcal{K}$ is then represented by the minimal representation $WKw = 0$.

Proof. Factor $R = DR_1$, with D square and nonsingular and $R_1(\lambda)$ full row rank for all λ. Then $\mathcal{P}_{\text{cont}} = \ker(R_1)$ (see [5, Theorem 5.2.14]). Let M^+ be a polynomial left inverse of M and R_1^+ a polynomial right inverse of R_1. Define $S := M^+(I - R_1^+R_1)$. By direct verification we then have $\left(\begin{smallmatrix} R_1 \\ S \end{smallmatrix}\right)(R_1^+ \;\; M) = I_q$. It follows that $R_1^+R_1 + MS = I_q$. We claim that there exists a polynomial matrix T such that $TR = QK$. In order to prove this, we show that $\ker(R) \subseteq \ker(QK)$. Indeed, let w be such that $Rw = 0$. Since $\mathcal{P} = \mathcal{K} + \mathcal{P}_{\text{cont}}$, there exist $w_1 \in \mathcal{K}$ and $w_2 \in \mathcal{P}_{\text{cont}}$ such that $w = w_1 + w_2$. Hence, since $w_2 \in \ker(R_1)$ and $QKM = 0$, $QKw = QKw_2 = QK(R_1^+R_1 + MS)w_2 = 0$. Next, note that

$$\begin{pmatrix} I_p & 0 \\ -T & Q \\ 0 & W \end{pmatrix} \begin{pmatrix} R \\ K \end{pmatrix} = \begin{pmatrix} R \\ 0 \\ WK \end{pmatrix}.$$

The leftmost matrix in this equation is unimodular. Thus we have that ($w \in \mathcal{K}$) if and only if ($Kw = 0$ and $Rw = 0$), which in turn is equivalent to ($WKw = 0$ and $Rw = 0$). This proves that (1) is indeed a kernel representation of $\mathcal{K}$.

Finally, we show that the representation (1) is minimal. Indeed,

$$\begin{pmatrix} R \\ WK \end{pmatrix} \begin{pmatrix} R_1^+ & M \end{pmatrix} = \begin{pmatrix} D & 0 \\ WKR_1^+ & WKM \end{pmatrix}.$$

It is easily seen that, by construction, WKM has full row rank. Since D is nonsingular, we conclude that $\text{col}(R, WK)$ must have full row rank as well. ∎

We now establish, for a given plant $\mathcal{P} \in \mathfrak{L}^q$ and a given regularly implementable behavior $\mathcal{K} \in \mathfrak{L}^q$, a parametrization of all controllers $\mathcal{C} \in \mathfrak{L}^q$ that regularly implement $\mathcal{K}$ by full interconnection. This problem was considered before in [4] for the case where the plant behavior $\mathcal{P}$ is controllable and the given subbehavior $\mathcal{K}$ is autonomous. Here, we will establish a parametrization for arbitrary $\mathcal{P}$ and arbitrary (regularly implementable) $\mathcal{K}$.

THEOREM 11. *Let $\mathcal{P} \in \mathfrak{L}^q$, with minimal representation $\mathcal{P} = \ker(R)$. Let $\mathcal{K} \in \mathfrak{L}^q$ be regularly implementable by full interconnection, and let $\mathcal{K} = \ker(K)$. Construct a polynomial matrix W as in Lemma 10. Then for any $\mathcal{C} \in \mathfrak{L}^q$, $\mathcal{C} = \ker(C)$, the following statements are equivalent:*

1. *$\mathcal{C} = \ker(C)$ is a minimal representation, and $\mathcal{C}$ regularly implements $\mathcal{K}$.*
2. *There exist a polynomial matrix F and a unimodular polynomial matrix U such that $C = FR + UWK$.*

Proof. (2 ⇒ 1) First note that since $\mathcal{K}$ is regularly implementable, by Lemma 10 the polynomial matrix $\text{col}(R, WK)$ has full row rank. Since

$$\begin{pmatrix} I_p & 0 \\ F & U \end{pmatrix} \begin{pmatrix} R \\ WK \end{pmatrix} = \begin{pmatrix} R \\ FR + UWK \end{pmatrix}, \tag{2}$$

this implies that also $C = FR + UWK$ has full row rank, so $Cw = 0$ is a minimal representation of $\mathcal{C}$. It also follows from (2) that $\mathcal{C}$ implements $\mathcal{K}$. Clearly, the interconnection of $\mathcal{P}$ and $\mathcal{C}$ is regular.

(1 ⇒ 2) Assume that C has full row rank and that $\mathcal{C}$ regularly implements $\mathcal{K}$. Then both

$$\begin{pmatrix} R \\ C \end{pmatrix} w = 0 \quad \text{and} \quad \begin{pmatrix} R \\ WK \end{pmatrix} w = 0$$

are minimal representations of $\mathcal{K}$. Consequently, there exists a unimodular polynomial matrix $V = \left(\begin{smallmatrix} V_{11} & V_{12} \\ V_{21} & V_{22} \end{smallmatrix}\right)$ such that $V\mathrm{col}(R, WK) = \mathrm{col}(R, C)$. This implies $R = V_{11}R + V_{12}WK$. Since $\mathrm{col}(R, WK)$ has full row rank, this yields $V_{11} = I_p$ and $V_{12} = 0$. It follows that V_{22} is unimodular. We also have $C = V_{21}R + V_{22}WK$. This completes the proof of the theorem. ∎

Note that since $\mathrm{col}(R, WK)$ has full row rank, the linear map $(F, U) \mapsto FR + UWK$ is one-one, so different parameters (F, U) yield different controllers C.

To conclude this section, we parametrize all controllers that stabilize a given plant behavior by full interconnection. The problem of stabilization by full interconnection is formulated as follows. Let $\mathcal{P} \in \mathfrak{L}^q$ be a given plant behavior. Find a controller behavior $\mathcal{C} \in \mathfrak{L}^q$ such that the controlled behavior $\mathcal{K} = \mathcal{P} \cap \mathcal{C}$ is autonomous and stable and the interconnection is regular. It was proved in [10] that such a stabilizing controller $\mathcal{C}$ exists if and only if $\mathcal{P}$ is stabilizable.

Let $\mathcal{P} = \ker(R)$ be a minimal representation. Assume that $\mathcal{P}$ is stabilizable; equivalently, $R(\lambda)$ has full row rank for all $\lambda \in \mathbb{C}^+ = \{\lambda \in \mathbb{C} \mid \mathrm{Re}(\lambda) \geq 0\}$. The following theorem yields a parametrization of all stabilizing controllers.

THEOREM 12. *Let $\mathcal{P} \in \mathfrak{L}^q$ be stabilizable. Let $\mathcal{P} = \ker(R)$ be a minimal representation, and let R_1 be such that $\ker(R_1)$ is a minimal representation of the controllable part $\mathcal{P}_{\mathrm{cont}}$ of $\mathcal{P}$. Let C_0 be such that $\mathrm{col}(R_1, C_0)$ is unimodular. Then for any $\mathcal{C} \in \mathfrak{L}^q$ with $\mathcal{C} = \ker(C)$ the following statements are equivalent:*

1. *$\mathcal{P} \cap \mathcal{C}$ is autonomous and stable, the interconnection is regular, and the representation $\mathcal{C} = \ker(C)$ is minimal.*
2. *There exist a polynomial matrix F and a Hurwitz polynomial matrix D such that $C = FR + DC_0$.*

Proof. By combining [5, Theorems 5.2.14 and 5.2.30], note that $R = D_1R_1$, with D_1 Hurwitz. ($2 \Rightarrow 1$) Assume that $C = FR + DC_0$. We have

$$\begin{pmatrix} R \\ C \end{pmatrix} = \begin{pmatrix} D_1 & 0 \\ FD_1 & D \end{pmatrix} \begin{pmatrix} R_1 \\ C_0 \end{pmatrix}.$$

This implies that $\mathrm{col}(R, C)$ has full row rank, so the interconnection of $\mathcal{P}$ and $\mathcal{C}$ is regular. Also, for some nonzero constant c, $\det \mathrm{col}(R, C) = c\det(D_1)\det(D)$, so the interconnection is autonomous and stable.

($1 \Rightarrow 2$) Since $\mathcal{P} \cap \mathcal{C}$ is stable and the interconnection is regular, $\mathrm{col}(R, C)$ is Hurwitz. Also, $\mathrm{col}(R_1, C_0)$ is unimodular, so there exist polynomial matrices F_{11}, F_{12}, F_{21}, and F_{22} such that

$$\begin{pmatrix} R \\ C \end{pmatrix} = \begin{pmatrix} F_{11} & F_{12} \\ F_{21} & F_{22} \end{pmatrix} \begin{pmatrix} R_1 \\ C_0 \end{pmatrix}.$$

This implies that $F_{11} = D_1$ and $F_{12} = 0$. The left-hand side of the above equation is Hurwitz, so F_{22} must be Hurwitz. The proof is completed by taking $F = F_{21}$ and $D = F_{22}$. ∎

The above result generalizes the result from [4] for controllable $\mathcal{P}$. If, in the above, we assume that $\mathcal{P}$ is controllable, then we can take $R = R_1$, and we recover the parametrization obtained in [4].

Remark 13. In the special case that the plant $\mathcal{P}$ to be stabilized is given together with an input/output partition $w = (y, u)$, our parametrization result of Theorem 12 specializes to the well-known Youla parametrization of all stabilizing controllers. For simplicity, assume that $\mathcal{P}$ is controllable. Assume that, in $\mathcal{P}$, G is the transfer matrix

from u to y. Let $P^{-1}Q$ be a left coprime factorization of G. Then $\mathcal{P} = \ker(P \quad -Q)$. Choose polynomial matrices X and Y such that

$$\begin{pmatrix} P & -Q \\ X & Y \end{pmatrix}$$

is unimodular. According to Theorem 12, a parametrization of all stabilizing controllers $\ker(Q_c \quad P_c)$ is given by $(Q_c \quad P_c) = F(P \quad -Q) + D(X \quad Y)$, where F is arbitrary polynomial and D is Hurwitz. In transfer matrix form this yields $C := -P_c^{-1}Q_c = -(DY - FQ)^{-1}(DX + FP) = -(Y - D^{-1}FQ)^{-1}(X + D^{-1}FP)$. Finally, denote $D^{-1}F$ by T, and let T vary over all proper stable rational matrices to obtain the original Youla parametrization $C = -(Y - TQ)^{-1}(X + TP)$ (see [12]).

5. All controllers that regularly implement a given behavior: The observable case. We now turn to the partial interconnection case. Let $\mathcal{P}_{\text{full}} \in \mathfrak{L}^{q+k}$, with system variable (w, c), where w takes its values in $\mathbb{R}^q$ and c in $\mathbb{R}^k$. In this section and the next we study the problem of parametrizing, for a given regularly implementable $\mathcal{K} \in \mathfrak{L}^q$, all controllers $\mathcal{C} \in \mathfrak{L}^k$ that regularly implement $\mathcal{K}$ through c w.r.t. $\mathcal{P}_{\text{full}}$. We first assume that in the full plant behavior $\mathcal{P}_{\text{full}}$, c is observable from w. Starting from this assumption, in the present section we establish a parametrization. Then, in the next section we will lift the observability assumption and describe a parametrization for the general case.

Implementability by *partial* interconnection was already defined in section 3. Necessary and sufficient conditions for a given $\mathcal{K} \in \mathfrak{L}^q$ to be (regularly) implementable by partial interconnection can be given in terms of the manifest plant behavior and hidden behavior associated with the full plant behavior $\mathcal{P}_{\text{full}}$, which are defined as follows.

DEFINITION 14. *The* manifest plant behavior *is the behavior* $(\mathcal{P}_{\text{full}})_w \in \mathfrak{L}^q$ *obtained from* $\mathcal{P}_{\text{full}}$ *by eliminating* c. *The* hidden behavior $\mathcal{N}$ *consists of those* w *trajectories that appear in* $\mathcal{P}_{\text{full}}$ *with* c *equal to zero, i.e.,* $\mathcal{N} = \{w \mid (w, 0) \in \mathcal{P}_{\text{full}}\}$.

Conditions for implementability and regular implementability were obtained in [11, Theorem 1] and [2, Theorem 4], respectively, as follows.

PROPOSITION 15.

1. $\mathcal{K} \in \mathfrak{L}^q$ *is implementable by partial interconnection through* c *w.r.t.* $\mathcal{P}_{\text{full}}$ *if and only if* $\mathcal{N} \subseteq \mathcal{K} \subseteq (\mathcal{P}_{\text{full}})_w$.
2. $\mathcal{K} \in \mathfrak{L}^q$ *is regularly implementable by partial interconnection through* c *w.r.t.* $\mathcal{P}_{\text{full}}$ *if and only if* $\mathcal{N} \subseteq \mathcal{K} \subseteq (\mathcal{P}_{\text{full}})_w$ *and* $\mathcal{K}$ *is regularly implementable w.r.t.* $(\mathcal{P}_{\text{full}})_w$ *by full interconnection.*

For a given $\mathcal{K} \in \mathfrak{L}^q$, an important role will be played by the subbehavior $\mathcal{L}_{\text{full}}(\mathcal{K})$ of $\mathcal{P}_{\text{full}}$ defined as the interconnection of $\mathcal{P}_{\text{full}}$ and $\mathcal{K}$ through w:

$$\mathcal{L}_{\text{full}}(\mathcal{K}) := \{(w, c) \in \mathcal{P}_{\text{full}} \mid w \in \mathcal{K}\}. \tag{3}$$

The proof of the following lemma is straightforward and is left to the reader.

LEMMA 16. *If* $\mathcal{K} \subseteq (\mathcal{P}_{\text{full}})_w$, *then* $(\mathcal{L}_{\text{full}}(\mathcal{K}))_w = \mathcal{K}$.

Now let $\mathcal{K} \in \mathfrak{L}^q$ be implementable through c w.r.t. $\mathcal{P}_{\text{full}}$. We first consider the problem of finding one controller $\mathcal{C} \in \mathfrak{L}^k$ that implements $\mathcal{K}$. We will derive a representation of one such controller in terms of representations of $\mathcal{P}_{\text{full}}$ and $\mathcal{K}$. Let $\mathcal{P}_{\text{full}} = \ker(R_1 \quad R_2)$ and $\mathcal{K} = \ker(K)$. Then clearly the behavior $\mathcal{L}_{\text{full}}(\mathcal{K})$ defined by (3) is represented by

$$\begin{pmatrix} R_1 & R_2 \\ K & 0 \end{pmatrix} \begin{pmatrix} w \\ c \end{pmatrix} = 0.$$

Note that the hidden behavior $\mathcal{N}$ is equal to $\ker(R_1)$. Since $\mathcal{N} \subseteq \mathcal{K}$ there exists a polynomial matrix F such that $K = FR_1$. Now define a controller behavior $\mathcal{C}^* \in \mathfrak{L}^k$ by

$$\mathcal{C}^* := \ker(FR_2). \tag{4}$$

This controller indeed implements $\mathcal{K}$, as shown in the following lemma.

LEMMA 17. $\mathcal{K} = (\mathcal{K}_{\text{full}}(\mathcal{C}^*))_w$.

Proof. We have

$$\begin{pmatrix} R_1 & R_2 \\ 0 & FR_2 \end{pmatrix} = \begin{pmatrix} I & 0 \\ F & -I \end{pmatrix} \begin{pmatrix} R_1 & R_2 \\ K & 0 \end{pmatrix}.$$

Hence $\mathcal{L}_{\text{full}}(\mathcal{K})$ is equal to the full controlled behavior $\mathcal{K}_{\text{full}}(\mathcal{C}^*)$. The conclusion then follows from Lemma 16. ∎

The following lemma states that if c is observable from w and if a given subbehavior of the manifest plant behavior is obtained by elimination of c from a subbehavior of $\mathcal{P}_{\text{full}}$, then this subbehavior of $\mathcal{P}_{\text{full}}$ is unique, as shown in the following lemma.

LEMMA 18. *Let $\mathcal{P}_{\text{full}} \in \mathfrak{L}^{q+k}$ with system variable (w, c). Assume that c is observable from w. Let $\mathcal{K}^1_{\text{full}}, \mathcal{K}^2_{\text{full}} \in \mathfrak{L}^{q+k}$ be subbehaviors of $\mathcal{P}_{\text{full}}$. Then we have $(\mathcal{K}^1_{\text{full}})_w = (\mathcal{K}^2_{\text{full}})_w$ if and only if $\mathcal{K}^1_{\text{full}} = \mathcal{K}^2_{\text{full}}$.*

Proof. Assume $(w, c) \in \mathcal{K}^1_{\text{full}}$. Then $w \in (\mathcal{K}^1_{\text{full}})_w = (\mathcal{K}^2_{\text{full}})_w$, so there exists c' such that $(w, c') \in \mathcal{K}^2_{\text{full}}$. Thus, $(0, c - c') = (w, c) - (w, c') \in \mathcal{P}_{\text{full}}$, so $c = c'$. It follows that $(w, c) \in \mathcal{K}^2_{\text{full}}$. ∎

LEMMA 19. *Let $\mathcal{P}_{\text{full}} \in \mathfrak{L}^{q+k}$ with system variable (w, c). Let $\mathcal{K} \in \mathfrak{L}^q$ be implementable through c w.r.t. $\mathcal{P}_{\text{full}}$. Let $\mathcal{C}$ be a controller such that $\mathcal{K} = (\mathcal{K}_{\text{full}}(\mathcal{C}))_w$. Then we have the following:*

1. *$\mathcal{K}_{\text{full}}(\mathcal{C}) \subseteq \mathcal{L}_{\text{full}}(\mathcal{K})$;*
2. *if c is observable from w, then $\mathcal{K}_{\text{full}}(\mathcal{C}) = \mathcal{L}_{\text{full}}(\mathcal{K})$.*

Proof. (1) If $(w, c) \in \mathcal{K}_{\text{full}}(\mathcal{C})$, then $w \in (\mathcal{K}_{\text{full}}(\mathcal{C}))_w = \mathcal{K}$. Also, $(w, c) \in \mathcal{P}_{\text{full}}$. It follows that $(w, c) \in \mathcal{L}_{\text{full}}(\mathcal{K})$. (2) By Lemma 16 $(\mathcal{K}_{\text{full}}(\mathcal{C}))_w = \mathcal{K} = (\mathcal{L}_{\text{full}}(\mathcal{K}))_w$. If c is observable from w, then this implies $\mathcal{K}_{\text{full}}(\mathcal{C}) = \mathcal{L}_{\text{full}}(\mathcal{K})$. ∎

For the special case that, in $\mathcal{P}_{\text{full}}$, c is observable from w, the following theorem reduces the problem of parametrizing all controllers that regularly implement $\mathcal{K}$ via interconnection through c w.r.t. $\mathcal{P}_{\text{full}}$ to that of parametrizing all controllers that regularly implement $(\mathcal{L}_{\text{full}}(\mathcal{K}))_c$ via *full interconnection* w.r.t. $(\mathcal{P}_{\text{full}})_c$ (see also [6, Prop. 1]).

THEOREM 20. *Let $\mathcal{P}_{\text{full}} \in \mathfrak{L}^{q+k}$ with system variable (w, c). Assume that c is observable from w. Let $\mathcal{K} \in \mathfrak{L}^q$ be regularly implementable through c. Let $\mathcal{L}_{\text{full}}(\mathcal{K})$ be the interconnection of $\mathcal{P}_{\text{full}}$ and $\mathcal{K}$ through w. Let $\mathcal{C} \in \mathfrak{L}^k$. Then the following two statements are equivalent:*

1. *$\mathcal{C}$ regularly implements $\mathcal{K}$ by interconnection through c.*
2. *$\mathcal{C}$ regularly implements $(\mathcal{L}_{\text{full}}(\mathcal{K}))_c$ via full interconnection w.r.t. $(\mathcal{P}_{\text{full}})_c$.*

Proof. Let $\mathcal{P}_{\text{full}} = \ker(R_1 \;\; R_2)$ be a minimal representation. Let V be unimodular such that $VR_1 = \text{col}(R_{11}, 0)$ with R_{11} full row rank. Partition $VR_2 = \text{col}(R_{12}, R_{22})$. Then $R_{22}c = 0$ is a minimal representation of $(\mathcal{P}_{\text{full}})_c$. $\mathcal{K}$ is implementable, so (using Lemma 19), there exists a polynomial matrix, say C^* (with C^* any polynomial matrix such that $\mathcal{C}^* = \ker(C^*)$ with $\mathcal{C}^*$ given by (4)), such that

$$\begin{pmatrix} R_{11} & R_{12} \\ 0 & R_{22} \\ 0 & C^* \end{pmatrix} \begin{pmatrix} w \\ c \end{pmatrix} = 0$$

is a kernel representation of $\mathfrak{L}_{\text{full}}(\mathcal{K})$. Hence a kernel representation of $(\mathfrak{L}_{\text{full}}(\mathcal{K}))_c$ is given by

$$\begin{pmatrix} R_{22} \\ C^* \end{pmatrix} c = 0. \tag{5}$$

$(1 \Rightarrow 2)$ Assume that $\mathcal{C}$ regularly implements $\mathcal{K}$; i.e., $(\mathcal{K}_{\text{full}}(\mathcal{C}))_w = \mathcal{K}$ and the interconnection is regular. Let $\mathcal{C} = \ker(C)$ be a minimal representation of $\mathcal{C}$. Then the polynomial matrix

$$\begin{pmatrix} R_{11} & R_{12} \\ 0 & R_{22} \\ 0 & C \end{pmatrix} \tag{6}$$

has full row rank and (by Lemma 19) represents $\mathfrak{L}_{\text{full}}(\mathcal{K})$. It is then immediate that $(\mathcal{P}_{\text{full}})_c \cap \mathcal{C} = (\mathfrak{L}_{\text{full}}(\mathcal{K}))_c$. Obviously, $\operatorname{col}(R_{22}, C)$ has full row rank, so the full interconnection of $(\mathcal{P}_{\text{full}})_c$ and $\mathcal{C}$ is regular.

$(2 \Rightarrow 1)$ Conversely, assume that $\mathcal{C}$ regularly implements $(\mathfrak{L}_{\text{full}}(\mathcal{K}))_c$ w.r.t. $(\mathcal{P}_{\text{full}})_c$ by full interconnection, and that $\mathcal{C} = \ker(C)$ is a minimal representation. Then $\binom{R_{22}}{C} c = 0$ is a minimal kernel representation of $(\mathfrak{L}_{\text{full}}(\mathcal{K}))_c$. Since (5) is also a kernel representation, it is easily seen that $\mathcal{K}_{\text{full}}(\mathcal{C}) = \mathfrak{L}_{\text{full}}(\mathcal{K})$, which, by Lemma 16, implies $(\mathcal{K}_{\text{full}}(\mathcal{C}))_w = (\mathfrak{L}_{\text{full}}(\mathcal{K}))_w = \mathcal{K}$. In addition, (6) has full row rank so the interconnection is regular. ∎

Finally, we arrive at the main result of this section. We establish, for the case that in $\mathcal{P}_{\text{full}}$ c is observable from w, a parametrization of all controllers that regularly implement a given $\mathcal{K}$ w.r.t. $\mathcal{P}_{\text{full}}$. The idea is to compute representations of $(\mathcal{P}_{\text{full}})_c$ and $(\mathfrak{L}_{\text{full}}(\mathcal{K}))_c$ and to parametrize all controllers that regularly implement $(\mathfrak{L}_{\text{full}}(\mathcal{K}))_c$ by full interconnection w.r.t. $(\mathcal{P}_{\text{full}})_c$ using Theorem 11. Then, by Theorem 20, this yields a parametrization of all controllers that regularly implemement $\mathcal{K}$ through c w.r.t. $\mathcal{P}_{\text{full}}$.

THEOREM 21. *Let $\mathcal{P}_{\text{full}} \in \mathfrak{L}^{q+k}$ with system variable (w, c) and c observable from w. Let $\mathcal{P}_{\text{full}} = \ker(R_1 \;\; R_2)$ be a minimal representation. Let $\mathcal{K} \in \mathfrak{L}^q$ be regularly implementable through c w.r.t. $\mathcal{P}_{\text{full}}$. Let $\mathcal{K} = \ker(K)$ be a minimal representation. Construct polynomial matrices V_1, V_2, F_1, and W as follows:*

1. *Let V_2 be a full row rank MLA of R_1.*
2. *Choose V_1 such that $\operatorname{col}(V_1, V_2)$ is unimodular.*
3. *Let M be an MRA of $V_2 R_2$ with $M(\lambda)$ full column rank for all λ.*
4. *Let F_1 be such that $K = F_1 V_1 R_1$.*
5. *Let Q be a full row rank MLA of $F_1 V_1 R_2 M$.*
6. *Choose W such that $\operatorname{col}(Q, W)$ is unimodular.*

Then for any $\mathcal{C} \in \mathfrak{L}^k$ with $\mathcal{C} = \ker(C)$, the following statements are equivalent:

1. *$\mathcal{C} = \ker(C)$ is a minimal representation and $\mathcal{C}$ regularly implements $\mathcal{K}$ through c w.r.t. $\mathcal{P}_{\text{full}}$.*
2. *There exist a polynomial matrix G and a unimodular U such that*

$$C = (UWF_1V_1 + GV_2)R_2.$$

Proof. V_2 is a full row rank MLA of R_1, so the unimodular matrix $V = \operatorname{col}(V_1, V_2)$ satisfies $VR_1 = \operatorname{col}(V_1R_1, 0)$ with V_1R_1 full row rank. Also $VR_2 = \operatorname{col}(V_1R_2, V_2R_2)$. Obviously, $(\mathcal{P}_{\text{full}})_c = \ker(V_2R_2)$ is a minimal representation, and the hidden behavior $\mathcal{N}$ is represented by $\ker(V_1R_1)$. Let F_1 be such that $K = F_1V_1R_1$ (such F_1 exists since

$\mathcal{N} \subseteq \mathcal{K}$). Then the controller $\ker(F_1V_1R_2)$ implements $\mathcal{K}$, so by Lemma 19 $\mathcal{L}_{\text{full}}(\mathcal{K})$ is represented by

$$\begin{pmatrix} V_1R_1 & V_1R_2 \\ 0 & V_2R_2 \\ 0 & F_1V_1R_2 \end{pmatrix} \begin{pmatrix} w \\ c \end{pmatrix} = 0;$$

thus $(\mathcal{L}_{\text{full}}(\mathcal{K}))_c = \ker\left(\begin{smallmatrix} V_2R_2 \\ F_1V_1R_2 \end{smallmatrix}\right)$. Now, M is an MRA of V_2R_2 so

$$\begin{pmatrix} V_2R_2 \\ F_1V_1R_2 \end{pmatrix} M = \begin{pmatrix} 0 \\ F_1V_1R_2M \end{pmatrix}.$$

Since Q is a full row rank MLA of $F_1V_1R_2M$, clearly $\left(\begin{smallmatrix} I & 0 \\ 0 & Q \end{smallmatrix}\right)$ is a full row rank MLA of $\left(\begin{smallmatrix} V_2R_2 \\ F_1V_1R_2M \end{smallmatrix}\right)$. If we choose W such that $\operatorname{col}(Q, W)$ is unimodular, then the matrix

$$\begin{pmatrix} I & 0 \\ 0 & Q \\ 0 & W \end{pmatrix}$$

is unimodular. By applying Theorem 11, a parametrization of all controllers that regularly implement $(\mathcal{L}_{\text{full}}(\mathcal{K}))_c$ by full interconnection w.r.t. $(\mathcal{P}_{\text{full}})_c$ is then given by $C = GV_2R_2 + U(0 \quad W)\left(\begin{smallmatrix} V_2R_2 \\ F_1V_1R_2 \end{smallmatrix}\right) = (GV_2 + UWF_1V_1)R_2$, where G ranges over all polynomial matrices and U ranges over all unimodular polynomial matrices, of course of suitable dimensions. Finally, by Theorem 20, the same parametrization holds for all controllers $\ker(C)$ that regularly implement $\mathcal{K}$ through c w.r.t. $\mathcal{P}_{\text{full}}$. ∎

6. Parametrization of all regular controllers: The nonobservable case. We now treat the nonobservable case. Consider the system $\mathcal{P}_{\text{full}}$ represented by $R_1w + R_2c = 0$. We no longer assume that c is observable from w, but show that the general case can be reduced to the observable case. This reduction requires two steps. First, we reduce the general case to the case that R_2 has full column rank, and next reduce the latter to the case that $R_2(\lambda)$ has full column rank for all λ, i.e., the observable case.

1. *Reduction to the case that R_2 has full column rank.* Let V be a unimodular matrix such that $R_2 = \begin{pmatrix} \tilde{R}_2 & 0 \end{pmatrix} V$, with $\tilde{R}_2$ full column rank k'. Define $\mathcal{P}'_{\text{full}} \in \mathfrak{L}^{q+k'}$ as the system (with control variable c') represented by $R_1w + \tilde{R}_2c' = 0$.
2. *Reduction to the observable case.* Assume now that in $\mathcal{P}_{\text{full}}$ the matrix R_2 has full column rank. Let L be a square, nonsingular polynomial matrix such that $R_2 = \tilde{R}_2L$, with $\tilde{R}_2(\lambda)$ full column rank for all $\lambda \in \mathbb{C}$. Using the Smith form of R_2 it is easily seen that this is always possible. Define $\mathcal{P}'_{\text{full}}$ as the system (with control variable c') represented by $R_1w + \tilde{R}_2c' = 0$. In the system $\mathcal{P}'_{\text{full}}$, c' is observable from w.

As it will turn out, in both reduction steps, $\mathcal{K} \in \mathfrak{L}^q$ is regularly implementable through c w.r.t. $\mathcal{P}_{\text{full}}$ if and only if it is regularly implementable through c' w.r.t. $\mathcal{P}'_{\text{full}}$. Also, every controller that regularly implements $\mathcal{K}$ w.r.t. $\mathcal{P}'_{\text{full}}$ will turn out to lead to a *set* of controllers that implement $\mathcal{K}$ w.r.t. $\mathcal{P}_{\text{full}}$. In the following two subsections, we will treat the two reduction steps separately.

6.1. Reduction to the case that R_2 has full column rank. In this subsection the parametrization problem for the original plant $\mathcal{P}_{\text{full}}$ is reduced to the parametrization problem for a plant $\mathcal{P}'_{\text{full}}$ in which the R_2-matrix has full column rank. In the following, let V be a unimodular matrix such that $R_2 = (\tilde{R}_2 \quad 0)V$, with $\tilde{R}_2$ full column rank $k' = \text{rank}(R_2)$. Define $\mathcal{P}'_{\text{full}}$ as the system represented by $R_1 w + \tilde{R}_2 c' = 0$.

THEOREM 22. *Let $\mathcal{K} \in \mathfrak{L}^q$. Then $\mathcal{K}$ is regularly implementable through c w.r.t. $\mathcal{P}_{\text{full}}$ if and only if $\mathcal{K}$ is regularly implementable through c' w.r.t. $\mathcal{P}'_{\text{full}}$. Let $\mathcal{C} \in \mathfrak{L}^k$, with $\mathcal{C} = \ker(C)$ a minimal representation. Then the following two statements are equivalent:*

1. *The controller $\mathcal{C}$ regularly implements $\mathcal{K}$ through c w.r.t. $\mathcal{P}_{\text{full}}$.*
2. *There exist a polynomial matrix C_{11}, polynomial matrices C_{12} and C_{21} of full row rank, and a unimodular matrix U such that*

$$C = U \begin{pmatrix} C_{11} & C_{12} \\ C_{21} & 0 \end{pmatrix} V \tag{7}$$

and such that the controller $\mathcal{C}_{21} = \ker(C_{21})$ regularly implements $\mathcal{K}$ through c' w.r.t. $\mathcal{P}'_{\text{full}}$.

Proof. We first prove the equivalence of statements 1 and 2. Partition $CV^{-1} = (C_1 \quad C_2)$ with the number of columns of C_1 equal to $k' = \text{rank}(R_2)$. Choose a unimodular matrix U such that $U^{-1}C_2 = \text{col}(C_{12}, 0)$ with C_{12} full row rank. Partition $U^{-1}C_1 = \text{col}(C_{11}, C_{21})$. Then we have

$$\mathcal{K}_{\text{full}}(\mathcal{C}) = \{(w, V^{-1}c') \mid (w, c') \in \ker(M)\}, \text{ where } M = \begin{pmatrix} R_1 & \tilde{R}_2 & 0 \\ 0 & C_{11} & C_{12} \\ 0 & C_{21} & 0 \end{pmatrix}.$$

Define $\mathcal{K}'_{\text{full}}(\mathcal{C}_{21}) := \{(w, c_1) \mid R_1 w + \tilde{R}_2 c_1 = 0 \text{ and } C_{21} c_1 = 0\}$, the full controlled behavior of $\mathcal{P}'_{\text{full}}$ using the controller $\mathcal{C}_{21} := \ker(C_{21})$. Using the full row rank of C_{12} we then have $(\mathcal{K}_{\text{full}}(\mathcal{C}))_w = (\ker(M))_w = (\mathcal{K}'_{\text{full}}(\mathcal{C}_{21}))_w$. From this we conclude that $\mathcal{C}$ implements $\mathcal{K}$ through c w.r.t. $\mathcal{P}_{\text{full}}$ if and only if $\mathcal{C}_{21}$ implements $\mathcal{K}$ through c' w.r.t. $\mathcal{P}'_{\text{full}}$. Furthermore, again by full row rank of C_{12}, regularity of either of the interconnections implies the same for the other one.

Finally, the statement that $\mathcal{K}$ is regularly implementable through c w.r.t. $\mathcal{P}_{\text{full}}$ if and only if $\mathcal{K}$ is regularly implementable through c' w.r.t. $\mathcal{P}'_{\text{full}}$ follows immediately from the equivalence of statements 1 and 2. ∎

6.2. Reduction to the observable case. In the previous subsection it was shown that our parametrization problem can be reduced to a problem for a plant behavior with R_2-matrix of full row rank. In the present subsection we reduce the full column rank case to the observable case. Let $\mathcal{P}_{\text{full}} = \ker(R_1 \quad R_2)$ be a minimal representation, with R_2 full column rank. Let L be square and nonsingular such that $R_2 = \tilde{R}_2 L$, with $\tilde{R}_2(\lambda)$ full column rank for all λ. Let $\mathcal{P}'_{\text{full}}$ be the (observable) system represented by $R_1 w + \tilde{R}_2 c' = 0$.

THEOREM 23. *Let $\mathcal{K} \in \mathfrak{L}^q$. Then $\mathcal{K}$ is regularly implementable through c w.r.t. $\mathcal{P}_{\text{full}}$ if and only if $\mathcal{K}$ is regularly implementable through c' w.r.t. $\mathcal{P}'_{\text{full}}$. Let $\mathcal{C} \in \mathfrak{L}^k$ with $\mathcal{C} = \ker(C)$ a minimal representation. Then the following two statements are equivalent:*

1. *The controller $\mathcal{C}$ regularly implements $\mathcal{K}$ through c w.r.t. $\mathcal{P}_{\text{full}}$.*

2. *The controller* $\mathcal{C}'$ *represented in latent variable representation (with latent variable* ℓ*) by*

$$\begin{pmatrix} I \\ 0 \end{pmatrix} c' = \begin{pmatrix} L \\ C \end{pmatrix} \ell \tag{8}$$

regularly implements $\mathcal{K}$ *through* c' *w.r.t.* $\mathcal{P}'_{\text{full}}$.

Proof. We first prove the equivalence of statements 1 and 2. The manifest controlled behavior resulting from the interconnection of $\mathcal{P}_{\text{full}}$ and $\mathcal{C}$ is equal to

$$(\mathcal{K}_{\text{full}}(\mathcal{C}))_w = \{w \mid \text{ there exists } c \text{ such that } R_1 w + \tilde{R}_2 L c = 0,\ Cc = 0\},$$

which, since L is nonsingular, equals

$$\{w \mid \text{ there exists } c', c \text{ such that } R_1 w + \tilde{R}_2 c' = 0,\ c' = Lc,\ Cc = 0\}.$$

The latter is equal to $(\mathcal{K}'_{\text{full}}(\mathcal{C}'))_w$, the manifest controlled behavior resulting from the interconnection of $\mathcal{P}'_{\text{full}}$ and $\mathcal{C}'$. Thus, $\mathcal{C}$ implements $\mathcal{K}$ w.r.t. $\mathcal{P}_{\text{full}}$ if and only if $\mathcal{C}'$ implements $\mathcal{K}$ w.r.t. $\mathcal{P}'_{\text{full}}$. Next, we prove that the interconnection of $\mathcal{P}_{\text{full}}$ and $\mathcal{C}$ is regular if and only if the interconnection of $\mathcal{P}'_{\text{full}}$ and $\mathcal{C}'$ is regular. Note that $\mathcal{K}'_{\text{full}}(\mathcal{C}')$ has latent variable representation

$$\begin{pmatrix} R_1 & \tilde{R}_2 \\ 0 & I \\ 0 & 0 \end{pmatrix} \begin{pmatrix} w \\ c' \end{pmatrix} = \begin{pmatrix} 0 \\ L \\ C \end{pmatrix} \ell.$$

Hence the output cardinality of $\mathcal{K}'_{\text{full}}(\mathcal{C}')$ equals

$$\mathfrak{p}(\mathcal{K}'_{\text{full}}(\mathcal{C}')) = \operatorname{rank} \begin{pmatrix} R_1 & \tilde{R}_2 & 0 \\ 0 & I & L \\ 0 & 0 & C \end{pmatrix} - \operatorname{rank} \begin{pmatrix} 0 \\ L \\ C \end{pmatrix}$$

(see [2, Lemma 8]). Using elementary row and column operations and the fact that L is nonsingular, this can be shown to be equal to $\operatorname{rank} \left(\begin{smallmatrix} R_1 & R_2 \\ 0 & C \end{smallmatrix}\right)$, which equals $\mathfrak{p}(\mathcal{K}_{\text{full}}(\mathcal{C}))$. Also, $\mathfrak{p}(\mathcal{C}') = \operatorname{rank} \left(\begin{smallmatrix} I & L \\ 0 & C \end{smallmatrix}\right) - \operatorname{rank} \left(\begin{smallmatrix} L \\ C \end{smallmatrix}\right) = \operatorname{rank}(C) = \mathfrak{p}(\mathcal{C})$. Finally, $\mathfrak{p}(\mathcal{P}_{\text{full}}) = \operatorname{rank}(R_1 \ \ R_2) = \operatorname{rank}(R_1 \ \ \tilde{R}_2) = \mathfrak{p}(\mathcal{P}'_{\text{full}})$. This proves our claim.

Again, the first statement of the theorem follows immediately from the equivalence of statements 1 and 2. ∎

According to this theorem, the controller $\mathcal{C} = \ker(C)$ works for $\mathcal{P}_{\text{full}}$ if and only if the controller $L\ker(C)$ (with control variable c') works for the observable system $\mathcal{P}'_{\text{full}}$. What we are looking for here is a parametrization of *all* such polynomial matrices C. The next theorem reduces the parametrization of these C's to the parametrization of all polynomial matrices C' such that $\ker(C')$ regularly implements $\mathcal{K}$ through c' w.r.t. $\mathcal{P}'_{\text{full}}$, which was already established in Theorem 21.

THEOREM 24. *Let* $\mathcal{P}_{\text{full}} = \ker(R_1 \ \ R_2)$ *be a minimal representation, with* R_2 *full column rank. Let* L *be square and nonsingular such that* $R_2 = \tilde{R}_2 L$*, with* $\tilde{R}_2(\lambda)$ *full column rank for all* λ*. Let* $\mathcal{P}'_{\text{full}}$ *be the (observable) system represented by* $R_1 w + \tilde{R}_2 c' = 0$*. Let* $\mathcal{C} \in \mathfrak{L}^k$ *with minimal representation* $\mathcal{C} = \ker(C)$*. Then for every* $\mathcal{K} \in \mathfrak{L}^q$ *that is regularly implementable through* c *w.r.t.* $\mathcal{P}_{\text{full}}$ *the following two statements are equivalent:*

1. *The controller* $\mathcal{C}$ *regularly implements* $\mathcal{K}$ *through* c *w.r.t.* $\mathcal{P}_{\text{full}}$.

2. *There exists a square, nonsingular polynomial matrix X and a full row rank polynomial matrix C' such that $C = X^{-1}C'L$, where $(C'(\lambda) \;\; X(\lambda))$ has full row rank for all $\lambda \in \mathbb{C}$ and the controller $\mathcal{C}' = \ker(C')$ regularly implements $\mathcal{K}$ through c' w.r.t. $\mathcal{P}'_{\text{full}}$.*

Proof. $(1 \Rightarrow 2)$ Let $\mathcal{C} = \ker(C)$ regularly implement $\mathcal{K}$ through c w.r.t. $\mathcal{P}_{\text{full}}$. By Theorem 23, the controller $L\ker(C)$ regularly implements $\mathcal{K}$ through c' w.r.t. $\mathcal{P}'_{\text{full}}$. Let

$$\begin{pmatrix} A & B \\ Y & X \end{pmatrix} \begin{pmatrix} L \\ C \end{pmatrix} = \begin{pmatrix} D \\ 0 \end{pmatrix}, \tag{9}$$

where the leftmost matrix is unimodular and D has full row rank. Obviously, this can always be done. We claim that $L\ker(C) = \ker(Y)$. Indeed, $(c' \in L\ker(C)) \Leftrightarrow$ (there exists ℓ such that $c' = L\ell$ and $C\ell = 0$) $\Leftrightarrow$ (there exists ℓ such that $\left(\begin{smallmatrix} A & B \\ Y & X \end{smallmatrix}\right)\left(\begin{smallmatrix} c' \\ 0 \end{smallmatrix}\right) = \left(\begin{smallmatrix} D \\ 0 \end{smallmatrix}\right)\ell$) $\Leftrightarrow (Yc' = 0)$. The last equivalence follows from the fact that D has full row rank, so it induces a surjective differential operator. Next, we prove that Y has full row rank. Let p be a polynomial row vector such that $pY = 0$. Since $YL + XC = 0$ and C has full row rank, we obtain $pX = 0$. Since $(Y \;\; X)$ has full row rank, this yields $p = 0$. In the same way it can be proved that X has full row rank.

Now define $C' := -Y$. Then the controller $\mathcal{C}' = \ker(C')$ regularly implements $\mathcal{K}$ through c' w.r.t. $\mathcal{P}'_{\text{full}}$. Of course, coming from a unimodular matrix, $(C'(\lambda) \;\; X(\lambda))$ has full row rank for all $\lambda \in \mathbb{C}$. We show that X is nonsingular. Since it has full row rank, it suffices to show that it is square. This follows immediately from (9):

$$\operatorname{rowdim}(X) = \operatorname{rowdim}(C) + \operatorname{rowdim}(L) - \operatorname{rank}(\operatorname{col}(L, C)).$$

Since L is nonsingular, $\operatorname{rank}(\operatorname{col}(L, C)) = \operatorname{rank}(L)$, so $\operatorname{rowdim}(X) = \operatorname{rowdim}(C)$. Of course, also $\operatorname{coldim}(X) = \operatorname{rowdim}(C)$, so X is square. Finally, we have $C = X^{-1}C'L$.

$(2 \Rightarrow 1)$ We will prove that $L\ker(C) = \ker(C')$. The implication will then follow from Theorem 23. Clearly, $-C'L + XC = 0$. Let A and B be polynomial matrices such that $\left(\begin{smallmatrix} A & B \\ -C' & X \end{smallmatrix}\right)$ is unimodular. Let D be defined by

$$\begin{pmatrix} A & B \\ -C' & X \end{pmatrix} \begin{pmatrix} L \\ C \end{pmatrix} = \begin{pmatrix} D \\ 0 \end{pmatrix}.$$

By the same argument as was used in the first part of this proof, it suffices to prove that D has full row rank. Indeed, using the fact that A is square, we have that $\operatorname{rank}(D) = \operatorname{rank}(\operatorname{col}(D, 0)) = \operatorname{rank}(\operatorname{col}(L, C)) = \operatorname{rank}(L) = \operatorname{rowdim}(L) = \operatorname{coldim}(A) = \operatorname{rowdim}(A) = \operatorname{rowdim}(D)$. ∎

Thus, for any given full row rank C' that works for the observable system $\mathcal{P}'_{\text{full}}$, a *set* of polynomial matrices C that work for $\mathcal{P}_{\text{full}}$ is obtained by dividing $C'L$ by those nonsingular polynomial matrices X that have the properties that $(C'(\lambda) \;\; X(\lambda))$ has full row rank for all λ, and the quotient $X^{-1}C'L$ is a polynomial matrix again.

7. All stabilizing controllers: The partial interconnection case. In this section we return to the stabilization problem. Whereas in Theorem 12 we gave a parametrization in the full interconnection case, we now solve the problem of parametrizing, for a given plant $\mathcal{P}_{\text{full}} = \ker(R_1 \;\; R_2)$, all stabilizing controllers (see section 3, Definition 6) for the case of partial interconnection. This is done along the same lines as the parametrization of all regularly implementing controllers: we first establish a parametrization under the condition that in $\mathcal{P}_{\text{full}}$ c is observable from

w. Then we lift the assumption and treat the general case. As already mentioned in section 3, necessary and sufficient conditions for the existence of a stabilizing controller for $\mathcal{P}_{\text{full}}$ are that $(\mathcal{P}_{\text{full}})_w$ is stabilizable and that w is detectable from c (see Proposition 7). For the observable case the following lemma is instrumental.

LEMMA 25. *Let $\mathcal{P}_{\text{full}} \in \mathfrak{L}^{q+k}$ with system variable (w, c). Assume that c is observable from w. Assume that $(\mathcal{P}_{\text{full}})_w$ is stabilizable and that w is detectable from c. Let $\mathcal{C} \in \mathfrak{L}^k$. Then the following two statements are equivalent:*

1. *$\mathcal{C}$ stabilizes $\mathcal{P}_{\text{full}}$ through c.*
2. *$\mathcal{C}$ stabilizes $(\mathcal{P}_{\text{full}})_c$ by full interconnection.*

Proof. $(1 \Rightarrow 2)$ $\mathcal{K} := (\mathcal{K}_{\text{full}}(\mathcal{C}))_w$ is stable and the interconnection is regular. Let $\mathcal{L}_{\text{full}}(\mathcal{K})$ be the interconnection of $\mathcal{P}_{\text{full}}$ and $\mathcal{K}$ through w. Then, by Lemma 19, $\mathcal{K}_{\text{full}}(\mathcal{C}) = \mathcal{L}_{\text{full}}(\mathcal{K})$. According to Theorem 20, $\mathcal{C}$ regularly implements $(\mathcal{L}_{\text{full}}(\mathcal{K}))_c$ by full interconnection with $(\mathcal{P}_{\text{full}})_c$. We claim that $(\mathcal{L}_{\text{full}}(\mathcal{K}))_c$ is stable. Indeed, let $c \in (\mathcal{L}_{\text{full}}(\mathcal{K}))_c$. There exists w such that $(w, c) \in \mathcal{L}_{\text{full}}(\mathcal{K}) \subseteq \mathcal{P}_{\text{full}}$. Let R_2^+ be a polynomial left-inverse of R_2. Then we have $c = -R_2^+ R_1 w$. Hence $c(t) \to 0$ $(t \to \infty)$ (note that the components of w are products of polynomials and stable exponentials).

$(2 \Rightarrow 1)$ Let $\mathcal{P}_{\text{full}} = \ker\left(\begin{smallmatrix} R_{11} & R_{12} \\ 0 & R_{22} \end{smallmatrix}\right)$ be a minimal representation, with R_{11} full row rank (see also the proof of Theorem 20). Then $(\mathcal{P}_{\text{full}})_c = \ker(R_{22})$ is a minimal representation. Represent $\mathcal{C} = \ker(C)$ minimally. Then $\operatorname{col}(R_{22}, C)$ is Hurwitz. Using this, together with the fact that R_{11} has full row rank, it is immediate that the interconnection of $\mathcal{P}_{\text{full}}$ and $\mathcal{C}$ is regular. We now prove that $(\mathcal{K}_{\text{full}}(\mathcal{C}))_w$ is stable. Let $w \in (\mathcal{K}_{\text{full}}(\mathcal{C}))_w$. There exists c such that $(w, c) \in \mathcal{K}_{\text{full}}(\mathcal{C})$ so $R_{11}w + R_{12}c = 0$ and $\left(\begin{smallmatrix} R_{22} \\ C \end{smallmatrix}\right)c = 0$. Thus, the components of c are products of polynomials and stable exponentials. Since w is detectable from c, $R_{11}(\lambda)$ has full column rank for all $\lambda \in \mathbb{C}^+$. This implies that $w(t) \to 0$ $(t \to \infty)$. ∎

The following theorem then gives a parametrization of all stabilizing controllers for the observable case.

COROLLARY 26. *Let $\mathcal{P}_{\text{full}} \in \mathfrak{L}^{q+k}$ satisfy the assumptions of Lemma 25. Let $\mathcal{P}_{\text{full}} = \ker(R_1 \;\; R_2)$ be a minimal representation. Construct polynomial matrices V_2, S, and C_0 as follows:*

1. *Let V_2 be a full row rank MLA of R_1.*
2. *Factorize $V_2 R_2 = TS$ with T square, nonsingular and $S(\lambda)$ full row rank for all $\lambda \in \mathbb{C}$.*
3. *Let C_0 be such that $\operatorname{col}(S, C_0)$ is unimodular.*

Then for any $\mathcal{C} \in \mathfrak{L}^k$ with $\mathcal{C} = \ker(C)$ the following statements are equivalent:

1. *$\mathcal{C}$ stabilizes $\mathcal{P}_{\text{full}}$ through c and the representation $\mathcal{C} = \ker(C)$ is minimal.*
2. *There exist a polynomial matrix F and a Hurwitz polynomial matrix D such that $C = FS + DC_0$.*

Proof. This is an immediate Corollary of Theorem 12 and Lemma 25. ∎

Thus we have obtained a parametrization of all stabilizing controllers for the observable case. In order to arrive at a parametrization for the general case, we can perform the same two reduction steps as in section 6. We will describe both steps separately now; the proofs are left to the reader.

The first step concerns the reduction of a general $\mathcal{P}_{\text{full}}$ to a full plant behavior $\mathcal{P}'_{\text{full}}$ with R_2-matrix full column rank. Let V be a unimodular matrix such that $R_2 = (\tilde{R}_2 \;\; 0)V$, with $\tilde{R}_2$ full column rank. Let $\mathcal{P}'_{\text{full}}$ be represented by $R_1 w + \tilde{R}_2 c' = 0$.

COROLLARY 27. *$(\mathcal{P}_{\text{full}})_w$ is stabilizable if and only if $(\mathcal{P}'_{\text{full}})_w$ is stabilizable, and in $\mathcal{P}_{\text{full}}$, w is detectable from c if and only in $\mathcal{P}'_{\text{full}}$, w is detectable from c'. Furthermore,*

if $\mathcal{C} \in \mathfrak{L}^k$ with minimal representation $\mathcal{C} = \ker(C)$, then the following two statements are equivalent:

1. *The controller $\mathcal{C}$ stabilizes $\mathcal{P}_{\text{full}}$ through c.*
2. *There exist a polynomial matrix C_{11}, polynomial matrices C_{12} and C_{21} of full row rank, and a unimodular matrix U such that*

$$C = U \begin{pmatrix} C_{11} & C_{12} \\ C_{21} & 0 \end{pmatrix} V, \tag{10}$$

and such that the controller $\mathcal{C}_{21} = \ker(C_{21})$ stabilizes $\mathcal{P}'_{\text{full}}$ through c'.

The next step concerns the reduction of a full plant behavior $\mathcal{P}_{\text{full}}$ with full column rank R_2-matrix to a behavior $\mathcal{P}'_{\text{full}}$ in which the control variable c' is observable from w. Let L be square, nonsingular, such that $R_2 = L\tilde{R}_2$, with $\tilde{R}_2(\lambda)$ full column rank for all λ. Let $\mathcal{P}'_{\text{full}}$ be represented by $R_1 w + \tilde{R}_2 c' = 0$.

COROLLARY 28. *$(\mathcal{P}_{\text{full}})_w$ is stabilizable if and only if $(\mathcal{P}'_{\text{full}})_w$ is stabilizable, and in $\mathcal{P}_{\text{full}}$, w is detectable from c if and only if in $\mathcal{P}'_{\text{full}}$, w is detectable from c'. Furthermore, for $\mathcal{C} \in \mathfrak{L}^k$ with minimal representation $\mathcal{C} = \ker(C)$, the following two statements are equivalent:*

1. *The controller $\mathcal{C}$ stabilizes $\mathcal{P}_{\text{full}}$ through c.*
2. *There exist a square, nonsingular polynomial matrix X and a full row rank polynomial matrix C' such that $C = X^{-1}C'L$, where $(C'(\lambda) \quad X(\lambda))$ has full row rank for all $\lambda \in \mathbb{C}$ and the controller $\mathcal{C}' = \ker(C')$ stabilizes $\mathcal{P}'_{\text{full}}$ through c'.*

8. Worked-out examples. In order to illustrate the theory developed in this paper, we now present some worked-out examples. The examples are those that were already presented in the problem formulation in section 3.

Example 29. Let $\mathcal{P}_{\text{full}}$ with manifest variable $w = (w_1, w_2)$ and control variable $c = (c_1, c_2)$ be represented by

$$\begin{aligned} w_1 + \dot{w}_2 + \dot{c}_1 + c_2 &= 0, \\ c_1 + c_2 &= 0. \end{aligned}$$

Clearly, $(\mathcal{P}_{\text{full}})_w = \mathfrak{C}^\infty(\mathbb{R}, \mathbb{R}^2)$. For $\mathcal{K}$ take the behavior represented by $w_1 + \dot{w}_2 = 0$. $\mathcal{K}$ is regularly implementable through (c_1, c_2) w.r.t. $\mathcal{P}_{\text{full}}$. We have

$$R_1(\xi) = \begin{pmatrix} 1 & \xi \\ 0 & 0 \end{pmatrix} \text{ and } R_2(\xi) = \begin{pmatrix} \xi & 1 \\ 1 & 1 \end{pmatrix}.$$

R_2 has full column rank. Factorize $R_2 = \tilde{R}_2 L$ with $\tilde{R}_2 = I_2$, the 2×2 identity matrix, and $L = R_2$. The resulting system $\mathcal{P}'_{\text{full}}$ represented by $R_2 w + \tilde{R}_2 c' = 0$ is observable. We first parametrize all controllers that regularly implement $\mathcal{K}$ w.r.t. $\mathcal{P}'_{\text{full}}$. For this, we perform the steps described in Theorem 21: $V_2 = (0, 1)$, $V_1 = (1, 0)$, $V_2\tilde{R}_2 = (0, 1)$, so $M = \text{col}(1, 0)$. Next, $V_1 R_1 = K = (1, \xi)$, so $F_1 = 1$. We have $F_1 V_1 \tilde{R}_2 M = 1$. Thus Q, as full row rank MLA of 1, is void. We take $W = 1$. A parametrization of all full row rank controller representations C' that regularly implement $\mathcal{K}$ w.r.t. $\mathcal{P}'_{\text{full}}$ is given by $C'(\xi) = (u, g(\xi))$, with $0 \neq u \in \mathbb{R}$ and g an arbitrary polynomial with real coefficients.

Next we parametrize all controllers C that regularly implement $\mathcal{K}$ w.r.t. the original full plant behavior $\mathcal{P}_{\text{full}}$. According to Theorem 24, for any choice of $u \neq 0$ and polynomial g, we should find all nonzero polynomials $x(\xi)$ that divide $C'L =$

$(u\xi + g(\xi), u + g(\xi))$ such that $(x(\lambda), u, g(\lambda)) \neq 0$ for all $\lambda \in \mathbb{C}$. Since $u \neq 0$, this constraint is automatically satisfied. Thus we need only compute all common factors $x(\xi)$ of the polynomials $u\xi + g(\xi)$ and $u + g(\xi)$. If $x(\xi)$ is such a common factor, then it must also divide the difference $u(\xi - 1)$. Hence there are two possibilities:

1. $g(1) \neq -u$. In this case $u\xi + g(\xi)$ and $u + g(\xi)$ are coprime. The only common factor is then $x(\xi) = 1$.
2. $g(1) = -u$. In this case $x(\xi) = \xi - 1$ is the only common factor.

Thus we find that a parametrization of all controllers that regularly implement $\mathcal{K}$ for $\mathcal{P}_{\text{full}}$ is given by $C(\xi) = (u\xi + g(\xi), u + g(\xi))$, $u \neq 0$ and g arbitrary polynomial, or $C(\xi) = (\frac{u\xi+g(\xi)}{\xi-1}, \frac{u+g(\xi)}{\xi-1})$, $u \neq 0$ and g arbitrary polynomial such that $g(1) = -u$. Since $g(1) = -u$ if and only if there exists a polynomial h such that $g(\xi) = -u + h(\xi)(\xi - 1)$, the latter is equivalent to $C(\xi) = (u + h(\xi), h(\xi))$, $u \neq 0$ and h arbitrary polynomial.

Example 30. Consider the full plant behavior $\mathcal{P}_{\text{full}}$ represented by

$$\begin{aligned} w_1 + \dot{w}_2 + \dot{c}_1 + c_2 &= 0, \\ w_2 + c_1 + c_2 &= 0, \\ \dot{c}_1 + c_1 + \dot{c}_2 + c_2 &= 0. \end{aligned}$$

We will parametrize all controllers $C(\frac{\mathrm{d}}{\mathrm{d}t})c = 0$ that stabilize $\mathcal{P}_{\text{full}}$ through c. We have

$$R_1 = \begin{pmatrix} 1 & \xi \\ 0 & 1 \\ 0 & 0 \end{pmatrix}, \; R_2 = \begin{pmatrix} \xi & 1 \\ 1 & 1 \\ \xi + 1 & \xi + 1 \end{pmatrix}, \; \tilde{R}_2 = \begin{pmatrix} 1 & 0 \\ 0 & 1 \\ 0 & \xi + 1 \end{pmatrix}, \; L = \begin{pmatrix} \xi & 1 \\ 1 & 1 \end{pmatrix}.$$

In $\mathcal{P}'_{\text{full}}$, represented by $R_1 w + \tilde{R}_2 c' = 0$, c' is observable from w. We first parametrize all controllers $C'(\frac{\mathrm{d}}{\mathrm{d}t})c' = 0$ that stabilize $\mathcal{P}'_{\text{full}}$. Performing the steps of Corollary 26, we obtain $V_2 = (0, 0, 1)$, $V_2\tilde{R}_2 = TS$ with $T(\xi) = \xi + 1$ and $S = (0, 1)$. Choose $C_0 = (1, 0)$. The required parametrization is then $C'(\xi) = (d(\xi), f(\xi))$ with d an arbitrary Hurwitz polynomial and f an arbitrary polynomial. We compute $C'(\xi)L(\xi) = (\xi d(\xi) + f(\xi), d(\xi) + f(\xi))$. A parametrization for the original plant $\mathcal{P}_{\text{full}}$ is obtained by computing, for any choice of d and f, all nonzero common factors $x(\xi)$ of the polynomials $\xi d(\xi) + f(\xi)$ and $d(\xi) + f(\xi)$ with the property that $(x(\lambda), d(\lambda), f(\lambda)) \neq 0$ for all λ. Let d and f be given, with d Hurwitz. If $x(\xi)$ is a common factor, then it is also a common factor of $(\xi - 1)d(\xi)$. Hence the following possibilities occur:

1. $x(\xi) = c$, constant, unequal to zero. These $x(\xi)$'s satisfy the requirements.
2. $x(\xi) = c(\xi - 1)$, with $c \neq 0$, equivalently, $d(1) + f(1) = 0$. Since d is Hurwitz, $d(1) \neq 0$, so we have $(x(1), d(1), f(1)) \neq 0$, and the rank condition holds.
3. $x(\xi)$ is not constant and divides $d(\xi)$. In this case there is λ such that $x(\lambda) = 0$ and $d(\lambda) = 0$. However, then also $f(\lambda) = 0$, violating the rank condition.

By applying Corollary 28, we conclude that a parametrization of all stabilizing controllers for $\mathcal{P}_{\text{full}}$ is given by $C(\xi) = (\xi d(\xi) + f(\xi), d(\xi) + f(\xi))$, with d Hurwitz polynomial, f arbitrary polynomial, or $C(\xi) = \frac{1}{\xi-1}(\xi d(\xi) + f(\xi), d(\xi) + f(\xi))$, with d Hurwitz polynomial and f polynomial such that $d(1) + f(1) = 0$.

Acknowledgment. The authors wish to thank one of the anonymous referees for contributions that have led to major improvements of parts of this paper, in particular of section 6.2.

ON THE INTERSECTION OF A CLARKE CONE WITH A BOLTYANSKII CONE*

ALBERTO BRESSAN†

Abstract. We provide an example of two closed sets $S_1, S_2 \subset \mathbb{R}^4$ such that $S_1 \cap S_2 = \{0\}$. Yet, at the origin, a Boltyanskii tangent cone C_1 to S_1 and the Clarke tangent cone C_2 to S_2 are strongly transversal. This settles a question originally proposed by H. Sussmann.

Key words. optimal control, necessary conditions, tangent cones

AMS subject classifications. 49K15, 49K05

DOI. 10.1137/060654852

1. Introduction.

Let $t \mapsto x^*(t)$ and $t \mapsto u^*(t)$ be, respectively, a trajectory and an optimal control for the Mayer problem

$$\begin{aligned} \text{minimize} \qquad & \varphi\big(x(T)\big) \\ \text{subject to} \qquad & \dot{x}(t) = f\big(t,\, x(t),\, u(t)\big) \\ \text{and} \qquad & x(0) = \bar{x}\,, \qquad x(T) \in S\,. \end{aligned}$$

Here $x \in \mathbb{R}^m$ is the state variable, while $u \in U \subseteq \mathbb{R}^m$ is the control variable.

A set of necessary conditions for optimality of the pair (x^*, u^*) is provided by the celebrated Pontryagin maximum principle (PMP), which provides one of the cornerstones of the mathematical theory of control [6]. In essence, these necessary conditions can be related to a separation property: On one hand, we have a set S_1 of "reachable points," i.e., points $x\big(T, u\big)$ that can be reached at the terminal time T by means of admissible controls $t \mapsto u(t) \in U$. On the other hand, we can consider a set S_2 of "profitable points," i.e., points that satisfy the terminal constraint $x \in S$ and achieve a lower cost $\varphi(x) \leq \varphi\big(x^*(T)\big)$, with equality holding only if $x = x^*(T)$.

Necessary conditions for optimality are then obtained by constructing a tangent cone C_1 to the set S_1 at the terminal point $x^*(T)$, and a tangent cone C_2 to S_2, also at $x^*(T)$. If these cones are transversal, under suitable assumptions one can conclude that the intersection $S_1 \cap S_2$ is nontrivial; i.e., it contains points other than $x^*(T)$. Hence, the pair (x^*, u^*) is not optimal. Reversing the argument, the optimality of the trajectory-control pair (x^*, u^*) implies that the tangent cones C_1 and C_2 are weakly separated. This provides an alternative way to state the PMP.

Subsequent work on the PMP has been aimed at deriving high order necessary conditions [4, 5] and at weakening the regularity assumptions [1, 2, 3, 7, 8, 9, 10, 11]. At present, two essentially different versions of the PMP can be found in the literature: one is based on the use of "Clarke tangent cones" [1, 2, 3], while the other relies on the concept of "Boltyanskii approximating cones" [7, 8, 9, 10, 11]. The precise definitions of these cones will be recalled in section 2. The following statements on the nontrivial

*Received by the editors March 22, 2006; accepted for publication (in revised form) August 30, 2006; published electronically January 12, 2007.

†Department of Mathematics, Penn State University, University Park, PA 16802 (bressan@math.psu.edu).

intersection are well known in the literature and provide the key ingredients in the two approaches.

(I) Assume $\bar{x} \in S_1 \cap S_2$ and let C_1 and C_2 be the Clarke tangent cones to S_1 and S_2, respectively, at the point $\bar{x}$. If C_1 and C_2 are strongly transversal, then the sets S_1 and S_2 have a nontrivial intersection. Indeed, $\bar{x}$ belongs to the closure of the set $(S_1 \cap S_2) \setminus \{\bar{x}\}$.

(II) Assume $\bar{x} \in S_1 \cap S_2$ and let C_1 and C_2 be Boltyanskii approximating cones to S_1 and S_2, respectively, at the point $\bar{x}$. If C_1 and C_2 are strongly transversal, then the sets S_1 and S_2 have a nontrivial intersection. Indeed, $\bar{x}$ belongs to the closure of the set $(S_1 \cap S_2) \setminus \{\bar{x}\}$.

It is interesting to speculate whether these two approaches can be combined into a single, more general PMP. To achieve this goal, one should introduce a new definition of "generalized tangent cone" such that the following hold:

(i) The Clarke tangent cone to a closed set S and all Boltyanskii approximating cones to S at a given point $\bar{x} \in S$ are "generalized tangent cones" in the sense of this new definition.

(ii) If two closed sets S_1 and S_2 have "generalized tangent cones" C_1, C_2 at a point $\bar{x}$, and if these two cones are strongly transversal, then the sets themselves have a nontrivial intersection. Namely, $\bar{x}$ belongs to the closure of $(S_1 \cap S_2) \setminus \{\bar{x}\}$.

In particular, if such a notion of generalized tangent cone did exist, the following question posed by H. Sussmann (see Conjecture 3.6.4 in [9]) should have a positive answer.

Let $n \geq 1$ and let S_1, S_2 be closed subsets of $\mathbb{R}^n$ such that $0 \in S_1 \cap S_2$. Assume that

- *C_1 is a Boltyanskii approximating cone to S_1 at 0;*
- *C_2 is the Clarke tangent cone to S_2 at 0;*
- *C_1 and C_2 are strongly transversal.*

Does this imply that 0 belongs to the closure of $(S_1 \cap S_2) \setminus \{0\}$?

In the present paper, however, we prove that this question has a negative answer in every space dimension $n \geq 4$. For the general theory of necessary conditions, our result implies that there are at least two noncomparable maximum principles, which cannot be unified by means of any new concept of tangent cone.

The remainder of the paper is organized as follows. In section 2 we review some basic definitions and discuss an example in space dimension $n = 3$. Our main counterexample is then given in section 3, where we construct two closed sets $S_1, S_2 \subset R^4$. At the origin, the Clarke tangent cone to S_1 and a Boltyanskii tangent cone to S_2 are strongly transversal. Yet, the two sets have a trivial intersection, namely, $S_1 \cap S_2 = \{0\}$.

Based on the present counterexample, the forthcoming paper by Sussmann [12] exhibits an optimal control problem and an optimal trajectory for which the usual conclusions of the PMP cannot be achieved if the Clarke tangent cone to the terminal set is used instead of a Boltyanskii approximating cone.

2. Preliminary analysis. For the reader's convenience, we first recall some basic definitions.

DEFINITION 1. *A nonempty set $C \subseteq \mathbb{R}^n$ is a cone if, whenever $v \in C$ and $r \geq 0$, it follows that $rv \in C$.*

DEFINITION 2. *Let $S \subseteq \mathbb{R}^n$. The Clarke tangent cone to a point $x \in S$ is the set of all vectors $v \in \mathbb{R}^n$ such that the following holds. For every sequence $x_k \to x$ with*

$x_k \in S$ for all $k \geq 1$, there exist a sequence $v_k \to v$ such that

$$\liminf_{h \to 0+} \frac{d\big(x_k + hv_k\,,\ S\big)}{h} = 0\,.$$

DEFINITION 3. *Given a set $S \subseteq \mathbb{R}^n$ and a point $x \in S$, we say that a closed convex cone $C \subseteq \mathbb{R}^n$ is a Boltyanskii approximating cone to S at x if there exists a continuous map $F : C \mapsto S$ such that*

$$\lim_{v \to 0,\, v \in C} \frac{F(v) - x - v}{|v|} = 0\,.$$

DEFINITION 4. *Two convex cones $C_1, C_2 \subseteq \mathbb{R}^n$ are strongly transversal if $C_1 \cap C_2 \neq \{0\}$ and, moreover,*

$$C_1 - C_2 \doteq \big\{v_1 - v_2\,;\quad v_1 \in C_1\,,\quad v_2 \in C_2\big\} = \mathbb{R}^n\,.$$

Before giving a counterexample in dimension $n = 4$, it is useful to see what can happen in dimension $n = 3$.

Consider $\mathbb{R}^3$ with coordinates t, x, y. Let $\phi : \mathbb{R} \mapsto [0, 1]$ be a $\mathcal{C}^\infty$ function such that

$$\begin{array}{ll} \phi(\xi) > 0 & \text{if}\ \ 0 < \xi < 1\,, \\ \phi(\xi) = 0 & \text{if}\ \ \xi \leq 0\ \ \text{or}\ \ \xi \geq 1\,. \end{array} \tag{1}$$

Consider a sequence of times t_m decreasing to zero, say $t_m = m^{-1}$. Moreover, choose a positive sequence ε_m decreasing to zero and a sequence of integers $N_m \to \infty$ such that

$$\frac{\varepsilon_m}{t_m} \to 0\,, \qquad\qquad \frac{\varepsilon_m}{t_{m-1} - t_m} \to 0\,, \tag{2}$$

$$t_{m-1} - t_m < \frac{t_m}{2N_m}\,. \tag{3}$$

We wish to construct two sets S_1, S_2 whose tangent cones at the origin will be

$$\begin{aligned} C_1 &= \big\{(t, x, y)\,;\quad t \geq 0,\quad x = 0\,,\quad |y| \leq t\,\big\}\,, \\ C_2 &= \big\{(t, x, y)\,;\quad t \geq 0,\quad y = 0\,,\quad |x| \leq t\big\}\,. \end{aligned}$$

To define S_2 we proceed as follows. For each $m \geq 1$ we divide the segment $[-t_m,\ t_m]$ into N_m equal parts. This is achieved by setting

$$x_{m,k} = -t_m + \frac{2kt_m}{N_m}$$

so that

$$-t_m = x_{m,0} < x_{m,1} < \cdots < x_{m,N_m} = t_m\,.$$

For $t \in [t_m,\ t_{m-1}]$ and $j = 1, \ldots, N_m$, define the spatial interval

$$I_{m,j}(t) \doteq \big[x_{m,j-1} - (t - t_m),\quad x_{m,j} + (t - t_m)\big]\,.$$

Notice that each of these closed intervals becomes wider as time increases. However, if the time interval $[t_m,\ t_{m-1}]$ is sufficiently short, so that (3) holds, then disjoint

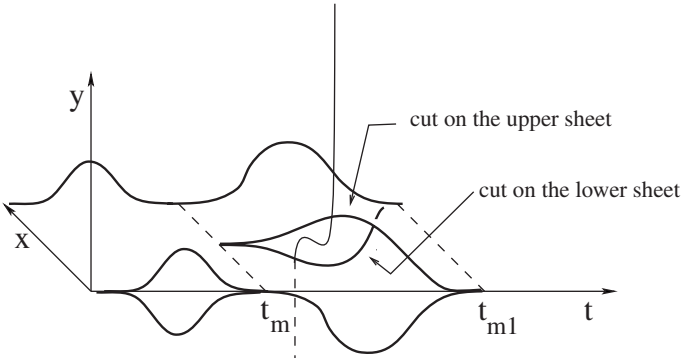

FIG. 1. *For $t \neq t_m$, a nearly vertical thread can pass through both sheets.*

intervals will not overlap for $t \in [t_m,\ t_{m-1}]$. More precisely

$$I_{m,j}(t) \cap I_{m,\ell}(t) = \emptyset \qquad \text{whenever} \quad \ell \geq j+2\,.$$

As S_2 we take the set

$$S_2 \doteq \bigcup_{m\geq 1} \left[\left\{ (t,x,y)\,;\ t\in[t_m,\ t_{m-1}]\,,\ x\in I_{m,j}\,,\ y = \varepsilon_m \phi\Big(\frac{t-t_m}{t_{m-1}-t_m}\Big) \quad j \text{ even} \right\} \right.$$
$$\left. \cup \left\{ (t,x,y)\,;\ t\in[t_m,\ t_{m-1}]\,,\ x\in I_{m,j}\,,\ y = -\varepsilon_m \phi\Big(\frac{t-t_m}{t_{m-1}-t_m}\Big) \quad j \text{ odd} \right\} \right].$$

If the numbers ε_m converge to zero fast enough, so that (2) holds, then the Clarke tangent cone to S_2 to the origin is precisely C_2.

We now consider whether is it possible to slightly deform the cone C_1, by means of a map

$$\varphi : (t,0,y) \mapsto \big(t,\ x(t,y), y\big)$$

with

$$\big|x(t,y)\big| = o\big(|t|\big)\,,$$

so that the image

$$S_1 \doteq \varphi(C_1)$$

intersects S_2 only at the origin.

Of course this is not possible. Indeed, at each time $t = t_m$ (with m sufficiently large) there must be an intersection. However, we notice that we could choose φ so that intersections occur only in arbitrarily small neighborhoods of the points $(t_m, 0, 0)$. Indeed, consider a time $\tau \notin \{t_1, t_2, t_3, \ldots\}$, say with $t_m < \tau < t_{m-1}$. The intersection of S_2 with the plane $\{t = \tau\}$ then consists of two sets of segments, at heights

$$y = \pm\varepsilon_m\, \phi\Big(\frac{\tau - t_m}{t_{m-1}-t_m}\Big).$$

One can thus deform a vertical line on the same plane so that no intersection occurs (Figure 1).

The construction performed in the previous example amounted to the creation of "pockets," which could be used by a vertical thread in order to cross both sheets

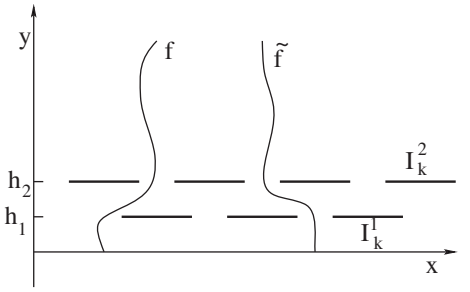

FIG. 2. *The functions $x = f(y)$ and $x = \tilde{f}(y)$ are not homotopic (avoiding the segments).*

without intersection. In dimension $n = 3$ this can be only partially successful, since the crossings at times $t = t_m$ ($m \geq 1$) cannot be avoided.

Performing a similar construction in dimension $n = 4$, however, one can completely remove any intersection (except at the origin), thus answering in the negative the question posed by Sussmann. The crucial difference between dimensions $n = 3$ and $n = 4$ is illustrated in the following remarks, which we regard as obvious.

Remark 1. Fix $\delta > \delta' > 0$ and $h_1 < h_2$. On the x-y plane, consider two countable sets of disjoint segments, all of length $2\delta'$:

$$I^1_k \doteq \Big\{(x,y)\,;\quad y = h_1\,,\quad \big|x - (2k)\delta\big| \leq \delta'\Big\}\,,$$
$$I^2_k \doteq \Big\{(x,y)\,;\quad y = h_2\,,\quad \big|x - (2k+1)\delta\big| \leq \delta'\Big\}\,.$$

If $x = f(y)$, $x = \tilde{f}(y)$ are two continuous functions whose graphs do not intersect any of the segments I^i_k, in general it is not possible to construct a homotopy preserving this property (Figure 2). In other words, there exists no continuous map $F : [0,1] \times \mathbb{R} \mapsto \mathbb{R}$ such that

$$F(0,x) = f(x)\,, \qquad\qquad F(1,x) = \tilde{f}(x),$$

and the graph of F does not intersect any of the segments I^i_k.

Remark 2. Fix $\delta > \delta' > 0$ and $h_1 < h_2 < h_3 < h_4$. In x-y-z space, consider four countable sets of disjoint squares, parallel to the x-y plane, located at four different heights $z = h_i$. These will all have side length $2\delta'$ and centers at points in the lattice $\delta\,\mathbb{Z}^2$:

$$Q^1_{jk} \doteq \Big\{(x,y,z)\,;\quad z = h_1\,,\quad \big|x - (2j)\delta\big| \leq \delta'\,,\quad \big|y - (2k)\delta\big| \leq \delta'\Big\}\,,$$
$$Q^2_{jk} \doteq \Big\{(x,y,z)\,;\quad z = h_2\,,\quad \big|x - (2j+1)\delta\big| \leq \delta'\,,\quad \big|y - (2k)\delta\big| \leq \delta'\Big\}\,,$$
$$Q^3_{jk} \doteq \Big\{(x,y,z)\,;\quad z = h_3\,,\quad \big|x - (2j)\delta\big| \leq \delta'\,,\quad \big|y - (2k+1)\delta\big| \leq \delta'\Big\}\,,$$
$$Q^4_{jk} \doteq \Big\{(x,y,z)\,;\quad z = h_4\,,\quad \big|x - (2j+1)\delta\big| \leq \delta'\,,\quad \big|y - (2k+1)\delta\big| \leq \delta'\Big\}\,.$$

Let now $(x,y) = f(z)$ and $(x,y) = \tilde{f}(z)$ be two continuous functions, whose graphs do not intersect any of the squares Q^i_{jk}. Then they are homotopic (Figure 3), i.e. we can now construct a continuous map $F : [0,1] \times \mathbb{R} \mapsto \mathbb{R}^2$ such that

$$F(0,z) = f(z)\,, \qquad\qquad F(1,z) = \tilde{f}(z),$$

and the graph of F does not intersect any of the squares Q^i_{jk}.

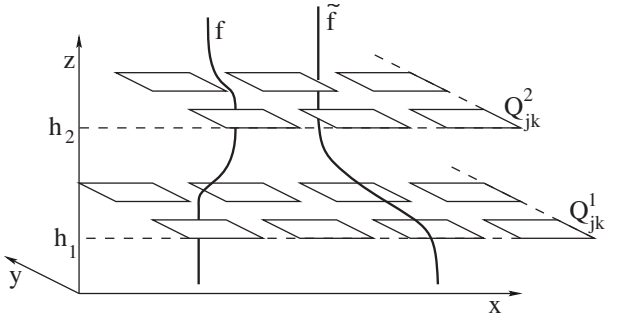

FIG. 3. *The functions $(x, y) = f(z)$ and $(x, y) = \tilde{f}(z)$ are homotopic (avoiding the squares).*

3. The four-dimensional counterexample. In the space $\mathbb{R}^4$ with coordinates (t, x, y, z) we will construct two closed sets S_1, S_2, having the origin as their only point in common. A Boltyanskii tangent cone to S_1 at the origin will be

$$C_1 \doteq \big\{(t, x, y, z)\,;\quad t \geq 0\,,\quad |z| \leq t\,,\quad x = y = 0\big\}\,,$$

while the Clarke tangent cone to S_2 at the origin will be

$$C_2 \doteq \big\{(t, x, y, z)\,;\quad t \geq 0\,,\quad z = 0\big\}\,.$$

The strong transversality of the two cones is thus clear.

We begin by constructing the set S_2. Define the decreasing sequence of times

$$t_m \doteq \frac{1}{m}\,. \tag{4}$$

Each time slice

$$S_2(\tau) \doteq S_2 \cap \{t = \tau\}$$

will be a subset of the x-y-z space $\mathbb{R}^3$ consisting of a finite union of square patches.

In addition to the function ϕ in (1), let $\tilde{\phi} : \mathbb{R} \mapsto [0, 1]$ be a $\mathcal{C}^\infty$ function such that

$$\begin{cases} \tilde{\phi}(\xi) > 0 & \text{if} \quad -1 < \xi < 1\,, \\ \tilde{\phi}(\xi) = 0 & \text{if} \quad \xi \leq -1 \quad \text{or} \quad \xi \geq 1\,. \end{cases} \tag{5}$$

Moreover, define the function

$$\delta(t, x) = t^6 \cdot \tilde{\phi}\Big(\frac{x}{t^{4/3}} - 2\cos\frac{\pi}{t}\Big)\,. \tag{6}$$

This will determine the separation in height between the four layers of squares. Notice that

$$\delta > 0 \qquad \Longleftrightarrow \qquad \Big|x - 2t^{4/3}\cos\frac{\pi}{t}\Big| < t^{4/3}. \tag{7}$$

Moreover,

$$\cos\frac{\pi}{t_m} = \cos m\pi = \begin{cases} 1 & \text{if} \quad m \text{ is even}, \\ -1 & \text{if} \quad m \text{ is odd}. \end{cases}$$

The region where $\delta > 0$ is depicted in Figure 4.

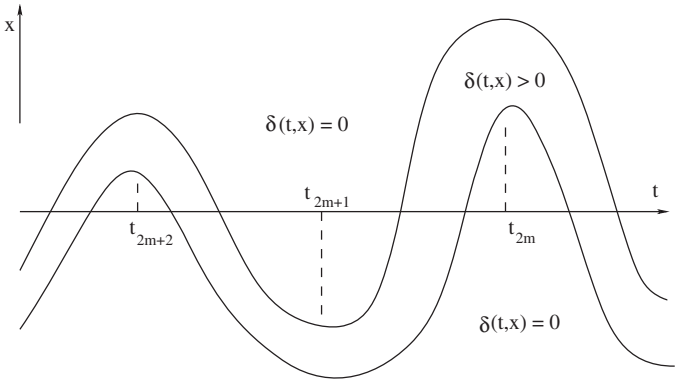

FIG. 4. *The region in the t-x plane where the sheets are separated.*

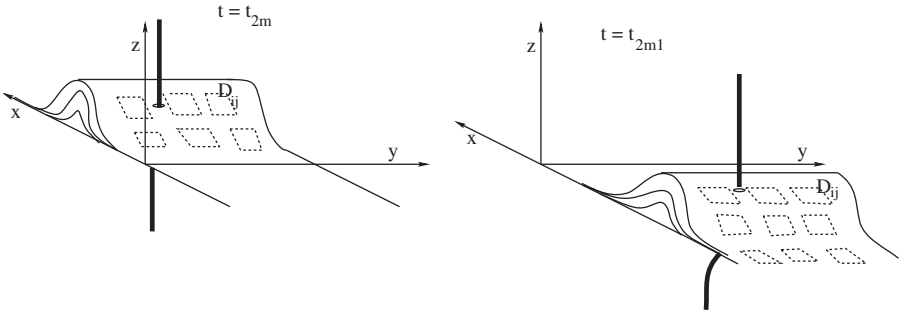

FIG. 5. *A thread crossing four sheets of fabric, without ever touching the square patches on them.*

Before writing down lengthy formulas, we explain the underlying idea in plain words.

KNITTING PROBLEM. *Consider four sheets of fabric spread over a horizontal table, the x-y plane (see Figure* 5*). At a given time t, the heights of the four sheets are given by the smooth functions*

$$z = i \cdot \delta(t, x), \qquad i = 0, 1, 2, 3,$$

where $\delta(t, x)$ *is as in* (6)*. On each of these sheets we single out finitely many square patches:* $A_{ij}(t)$ *on the first sheet,* $B_{ij}(t)$ *on the second,* C_{ij} *on the third, and* D_{ij} *on the fourth. Any two distinct* A_{ij} *do not intersect, and the same is true for* B_{ij}*,* C_{ij}*, and* D_{ij}*.*

We now want to pass an (almost vertical) thread through the four sheets of cloth, moving the thread continuously in time, without ever touching any of the square patches A_{ij}*,* B_{ij}*,* C_{ij}*, and* D_{ij}*. The crossing cannot take place on regions where the four sheets stick together (i.e., where* $\delta(t, x) = 0$*), because the vertical projections of all these patches cover the x-y plane. However, we can easily pass our thread through the four sheets, as long as the crossing takes place over a region of the x-y plane where the four sheets are separated, i.e., where* $\delta(t, x) > 0$*.*

We now specify details. At every time t, the projection of the set S_2^τ on the x-y plane is the entire plane. In x-y-z space, the time slice $S_2(\tau)$ consists of countably many square patches. The ones having centers at points with $x > 0$ will be treated separately from the ones having centers at points with $x < 0$.

(i) *Squares with centers with $x > 0$.* To define these squares, assume $t_{2m+1} \le \tau \le t_{2m-1}$. Divide the upper half-plane $\{(x,y)\,;\quad x \ge 0\}$ into squares of equal size, each with side of length t_{2m+1}/N_{2m+1}. The centers of these squares are located at the points

$$(x_i, y_j) \doteq \left(\frac{(i-\frac{1}{2})t_{2m+1}}{N_{2m+1}}\ ,\ \frac{(j-\frac{1}{2})t_{2m+1}}{N_{2m+1}} \right), \qquad i \ge 1\,,\quad j \in \mathbb{Z}\,.$$

We split these squares into four classes, depending on whether i, j are even or odd. For $\tau \in [t_{2m+1},\ t_{2m-1}]$ we then define

$$\begin{aligned}
A_{ij}(\tau) = \Big\{(\tau,x,y,z)\,;\quad & |x-x_i| \le \frac{t_{2m+1}}{2N_{2m+1}} + (\tau - t_{2m+1})\,,\\
& |y-y_j| \le \frac{t_{2m+1}}{2N_{2m+1}} + (\tau - t_{2m+1})\,,\quad z = 0\Big\}\,,\\
B_{ij}(\tau) = \Big\{(\tau,x,y,z)\,;\quad & |x-x_i| \le \frac{t_{2m+1}}{2N_{2m+1}} + (\tau - t_{2m+1})\,,\\
& |y-y_j| \le \frac{t_{2m+1}}{2N_{2m+1}} + (\tau - t_{2m+1})\,,\quad z = \delta(\tau,x)\Big\}\,,\\
C_{ij}(\tau) = \Big\{(\tau,x,y,z)\,;\quad & |x-x_i| \le \frac{t_{2m+1}}{2N_{2m+1}} + (\tau - t_{2m+1})\,,\\
& |y-y_j| \le \frac{t_{2m+1}}{2N_{2m+1}} + (\tau - t_{2m+1})\,,\quad z = 2\delta(\tau,x)\Big\}\,,\\
D_{ij}(\tau) = \Big\{(\tau,x,y,z)\,;\quad & |x-x_i| \le \frac{t_{2m+1}}{2N_{2m+1}} + (\tau - t_{2m+1})\,,\\
& |y-y_j| \le \frac{t_{2m+1}}{2N_{2m+1}} + (\tau - t_{2m+1})\,,\quad z = 3\delta(\tau,x)\Big\}\,,
\end{aligned}$$

and then

$$S_2^{(\mathrm{upper})}(\tau) \doteq \left(\bigcup_{\substack{i\ \text{even}\\ j\ \text{even}}} A_{ij}(\tau) \right) \cup \left(\bigcup_{\substack{i\ \text{odd}\\ j\ \text{even}}} B_{ij}(\tau) \right) \cup \left(\bigcup_{\substack{i\ \text{even}\\ j\ \text{odd}}} C_{ij}(\tau) \right) \cup \left(\bigcup_{\substack{i\ \text{odd}\\ j\ \text{odd}}} D_{ij}(\tau) \right).$$

We stress that here the union ranges over all couples of indices (i,j) with $i \ge 1$.

(ii) *Squares with centers with $x < 0$.* To define these squares, we now assume $\tau \in [t_{2m},\ t_{2m-2}]$. We divide the lower half-plane $\{(x,y)\,;\quad x \le 0\}$ into squares of equal size, each with side of length t_{2m}/N_{2m}. The centers of these squares are located at the points

$$(x_i, y_j) \doteq \left(\frac{(i-\frac{1}{2})t_{2m}}{N_{2m}}\ ,\ \frac{(j-\frac{1}{2})t_{2m}}{N_{2m}} \right), \qquad i \le 0\,,\quad j \in \mathbb{Z}\,.$$

These will not be confused with the previous ones because now $i \le 0$. We define

$$\begin{aligned}
A_{ij}(\tau) = \Big\{(\tau,x,y,z)\,;\quad & |x-x_i| \le \frac{t_{2m}}{2N_{2m}} + (\tau - t_{2m})\,,\\
& |y-y_j| \le \frac{t_{2m}}{2N_{2m}} + (\tau - t_{2m})\,,\quad z = 0\Big\}\,,
\end{aligned}$$

$$B_{ij}(\tau) = \Big\{(\tau,x,y,z)\,;\quad |x-x_i| \leq \frac{t_{2m}}{2N_{2m}} + (\tau - t_{2m})\,,$$
$$|y-y_j| \leq \frac{t_{2m}}{2N_{2m}} + (\tau - t_{2m})\,,\quad z = \delta(\tau,x)\Big\}\,,$$
$$C_{ij}(\tau) = \Big\{(\tau,x,y,z)\,;\quad |x-x_i| \leq \frac{t_{2m+1}}{2N_{2m}} + (\tau - t_{2m})\,,$$
$$|y-y_j| \leq \frac{t_{2m}}{2N_{2m}} + (\tau - t_{2m})\,,\quad z = 2\delta(\tau,x)\Big\}\,,$$
$$D_{ij}(\tau) = \Big\{(\tau,x,y,z)\,;\quad |x-x_i| \leq \frac{t_{2m}}{2N_{2m}} + (\tau - t_{2m})\,,$$
$$|y-y_j| \leq \frac{t_{2m}}{2N_{2m}} + (\tau - t_{2m})\,,\quad z = 3\delta(\tau,x)\Big\}$$

and then

$$S_2^{(\text{lower})}(\tau) \doteq \left(\bigcup_{\substack{i\ \text{even}\\ j\ \text{even}}} A_{ij}(\tau)\right) \cup \left(\bigcup_{\substack{i\ \text{odd}\\ j\ \text{even}}} B_{ij}(\tau)\right) \cup \left(\bigcup_{\substack{i\ \text{even}\\ j\ \text{odd}}} C_{ij}(\tau)\right) \cup \left(\bigcup_{\substack{i\ \text{odd}\\ j\ \text{odd}}} D_{ij}(\tau)\right).$$

In this case, the union ranges over all couples of indices (i,j) with $i \leq 0$.

Finally, we define

$$S_2(0) \doteq \Big\{(0,x,y,0)\,;\quad x,y \in \mathbb{R}\Big\}\,,$$
$$S_2(\tau) \doteq S_2^{(\text{upper})}(\tau) \cup S_2^{(\text{lower})}(\tau) \qquad \text{for}\quad \tau > 0\,,$$
$$S_2 \doteq \bigcup_{\tau \geq 0} S_2(\tau)\,.$$

Next, we claim that there exists a continuous function $\varphi : C_1 \mapsto \mathbb{R}^2$, say $(x,y) = \varphi(t,0,0,z)$, such that

$$\varphi(t,0,0,z) = o\big(|t|\big) \qquad \text{as } t \to 0\,,\quad (t,0,0,z) \in C_1\,,$$

and, moreover, the graph

$$S_1 \doteq \Big\{(t,x,y,z)\,;\quad (x,y) = \varphi(t,0,0,z)\,,\quad (t,0,0,z) \in C_1\Big\}$$

intersects the set S_2 only at the origin.

Intuitively, at each time $\tau > 0$ the one-dimensional set $S_1^\tau \doteq S_1 \cap \{t = \tau\}$ gives the position of the thread, which should not touch any of the square patches $A_{ij}(\tau)$, $B_{ij}(\tau)$, $C_{ij}(\tau)$, $D_{ij}(\tau)$ contained in $S_2(\tau)$.

In view of Remark 2, such a continuous function φ exists provided that

• the width of the region where $\delta(\tau,\cdot) > 0$ is much larger than the sides of the single paths $A_{ij}(\tau)$, $B_{ij}(\tau)$, $C_{ij}(\tau)$, $D_{ij}(\tau)$.

• square patches on the same sheet remain disjoint, i.e.,

$$\text{[length of a side]} < \text{[distance between two centers]}.$$

Since patches grow in time at unit rate, this last condition is a consequence of the inequalities

$$t_{2m-1} - t_{2m+1} < \frac{t_{2m-1}}{5N_{2m-1}}\,,\qquad t_{2m-2} - t_{2m} < \frac{t_{2m}}{5N_{2m}} \qquad (m \geq 1). \tag{8}$$

Finally, in order for the set S_2 to have C_2 as a Clarke tangent cone at the origin, we need

$$\frac{\partial}{\partial t}\,\delta(t,x)\to 0 \qquad \frac{\partial}{\partial x}\,\delta(t,x)\to 0 \qquad \text{as } \ t\to 0. \tag{9}$$

On the other hand, in order for the set S_1 to have C_1 as a Boltyanskii tangent cone at the origin, we need the following:

• The maximum size of the patches $A_{ij}(t)$, $B_{ij}(t)$, $C_{ij}(t)$, $D_{ij}(t)$ is $o(t)$ as $t\to 0$. Moreover,

$$\sup\ \big\{|x|\,;\ \ \delta(t,x)>0\big\}=o(t) \qquad \text{as } t\to 0.$$

It is not difficult to make choices such that all the above conditions are satisfied. Indeed,

$$t_{m-2}-t_m=\mathcal{O}(t_m^2)=o(t_m^{2-\varepsilon}).$$

Therefore, if we choose N_m so that

$$[\text{size of patches at time } t_m]\approx\frac{t_m}{N_m}\approx t_m^{3/2},$$

then conditions (8) will certainly hold. To fix the ideas, we will choose

$$\begin{cases} N_m \ \doteq m^{1/2} & \text{if } m \text{ is even}\,,\\ N_m \ \doteq 9m^{1/2} & \text{if } m \text{ is odd}\,. \end{cases} \tag{10}$$

By these choices, as $t\to 0$,

• the sizes of the patches are $\mathcal{O}(t^{3/2})$.

• the region where $\delta(t,\cdot)>0$, where the crossing can occur, is at a distance of $O(t^{4/3})$ from the x-axis.

Hence, we can construct the function $(x,y)=\varphi(t,z)$ such that

$$\big|\varphi(t,z)\big|=\mathcal{O}(t^{4/3}).$$

This guarantees that C_1 is indeed a Boltyanskii tangent cone to S_1 at the origin.

Finally, the factor t^6 on the right-hand side of (6) guarantees that the derivatives of $\delta(\cdot,\cdot)$ w.r.t. both t and x vanish as $t\to 0$. Hence, C_2 is the Clarke tangent cone to S_2. This completes the analysis.

Remark 3. Some additional words of explanation might be helpful. With reference to Figure 5, what is going on is the following. At time $t=t_m$, the four sheets are sticking together in the half-plane where $x\le 0$, but are separated in some region where $x>0$, (Figure 5, left).

We split the lower half-plane $\{x\le 0\}$ into four classes of square patches, of size length $\ell(t_{2m})=t_{2m}/N_{2m}=\mathcal{O}(t_{2m}^{2/3})$. These patches keep sticking together for $t>t_{2m}$ until δ becomes positive.

At time $t=t_{2m-1}$, all four sheets now coincide in the upper half-plane $\{x\ge 0\}$, but are separated in some region where $x<0$ (Figure 5, right). It is here that the thread can cross all sheets without intersecting any of the square patches.

The reader should notice that, on the interval $[t_{2m-1}\,,\ t_{2m-3}]$, sheets in the upper half-plane are split into square patches which are different from those defined during the previous time interval $[t_{2m+1}\,,\ t_{2m-1}]$. This different definition, however, does not introduce any discontinuity at the time $t=t_{2m-1}$. Indeed, since $\delta(t_{2m-1},x)=0$ for $x\ge 0$, all four sheets in the upper half-plane coincide. Therefore, it does not make

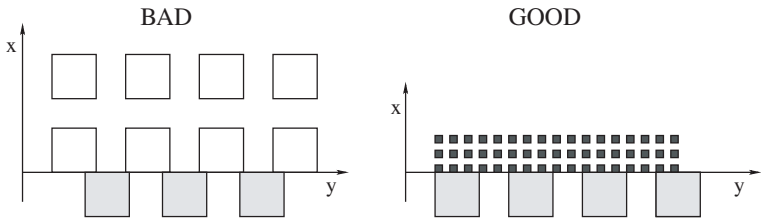

FIG. 6. *Choosing upper and lower squares of different sizes, we ensure that the complement set is connected.*

any difference to represent the set

$$S_2^{(\text{upper})}(t_{2m-1}) \doteq \Big\{(t_{2m-1}, x, y, z)\,;\quad x \geq 0\,,\quad z = 0\Big\}$$

as a union of squares of side length $\ell(t_{2m-1})$ rather than $\ell(t_{2m+1}) + 2(t_{2m-1} - t_{2m+1})$.

Remark 4. The factor "9" in (10) is motivated by a small technical detail. On the upper and lower half-planes $\{x > 0\}$ and $\{x < 0\}$ we usually have patches of different sizes, and centers on different lattice points, on one single sheet. Indeed, the sizes of upper squares are defined at the times t_{2m+1}, while the sizes of lower squares are determined at the times t_{2m}, for $m \geq 1$. In principle, on one of the sheets we may have a configuration as shown in Figure 6, left. This would prevent the thread from moving freely from the upper to the lower half-plane. This can be easily prevented by requiring that the lower squares be considerably larger that the upper ones, as in Figure 6, right.

ON THE INTERNAL MODEL STRUCTURE FOR INFINITE-DIMENSIONAL SYSTEMS: TWO COMMON CONTROLLER TYPES AND REPETITIVE CONTROL*

EERO IMMONEN†

Abstract. In this paper we shall extend and amplify the recent theory of controllers employing the so-called internal model structure. For exponentially stable closed loop control systems this structure has been shown in another paper to be necessary and sufficient for robust output regulation, also in infinite-dimensional spaces. Here we shall derive conditions under which two controller types occurring frequently in applications have the internal model structure. Under these conditions robust output regulation is achieved—also in infinite-dimensional spaces—if the closed loop system is sufficiently stable. In the case that the closed loop system is only strongly (but not exponentially) stable, it is sometimes possible to obtain conditional robustness. This means that asymptotic tracking/disturbance rejection is not destroyed by small perturbations so long as closed loop stability also persists. Our results allow for infinite-dimensional plants, controllers, and exogenous systems, and as an application of such a general setting we shall consider generalized repetitive control for exponentially stable infinite-dimensional SISO systems.

Key words. robust output regulation, infinite-dimensional linear systems, regulator equations, internal model principle, internal model structure

1. Introduction.

Although regulating the output of a given (linear time-invariant) plant is one of the central problems in control theory, this output regulation theory is rather useless in practice unless the controllers provide a degree of robustness. Robustness means fault tolerance; here we treat it so that small perturbations in some of the parameters of the plant, the controller, and the exogenous reference/disturbance signal generator should not affect closed loop stability and asymptotic tracking of the reference signals in the presence of disturbances. Such robust controllers have been subject to a considerable amount of research during the past three decades. The problem was solved for finite-dimensional systems by Davison [10], Davison and Goldenberg [11], Francis [13], Francis and Wonham [14], Sebakhy and Wonham [35], Wonham [40] and others in the 1970s. It seems that although many authors independently evolved their own design techniques, these methods can be quite generally grouped into two distinct categories: those employing estimates of the state of a coupled system containing the plant and the exosystem (see, e.g., [13]), and those employing dynamic error augmentation (see, e.g., [10]). Moreover, these two categories arise as special instances of the general robust output regulation paradigm for finite-dimensional systems: the celebrated internal model principle due to Francis and Wonham [14]. This principle asserts, roughly, that an error feedback controller which stabilizes the closed loop system also achieves robust output regulation if and only if the controller utilizes a suitably reduplicated copy of the maximal cyclic component of the exogenous system operator. For a survey of these (and related) results and the differences between the above two controller types the reader should consult

the article of Kwatny and Kalnitsky [27].

During the past few decades several authors have extended the theory cited above for infinite-dimensional plants and finite-dimensional exogenous systems. The finite-dimensional results of Davison [10] and Davison and Goldenberg [11] have been generalized by Pohjolainen [30, 31], Hämäläinen and Pohjolainen [17, 18], Ukai and Iwazumi [36], and others (see [19] for more detailed information). On the other hand, the finite-dimensional results of Francis [13] have been generalized to this setting, e.g., by Schumacher [34] and Byrnes et al. [6]. Interestingly enough, the existing infinite-dimensional generalizations of the theory of Francis do not seem to cover robustness issues. Moreover, while robustness does play a central role in some of the above generalizations of the results of Davison, none of these authors has studied the internal model principle for infinite-dimensional systems. In the author's view this is probably due to the fact that the principle, although easy to formulate in vague terms, is notoriously dependent on purely finite-dimensional concepts when formulated in precise terms [14].

In the papers cited above the exogenous signal generator is finite-dimensional. This means that the above theory is applicable in the case of simple reference/disturbance signals such as constants and sinusoids. However, the use of infinite-dimensional exogenous systems allows for the asymptotic tracking of arbitrary bounded uniformly continuous reference signals in the presence of disturbances of a similar type [4, 5, 21, 23, 24, 22]. The repetitive control scheme, which is a frequency domain–based error feedback control technique introduced by Hara et al. [15] (see also [39, 42, 43]) for the asymptotic tracking of periodic signals for finite-dimensional systems, furnishes a widespread example of the application of an infinite-dimensional exogenous system—the p-periodic signal generator. As a matter of fact, Yamamoto and Hara [43] have also proved an analogue of the internal model principle for repetitive control systems: stable asymptotic tracking necessitates the internal model $\frac{1}{1-e^{-sp}}$ of the exogenous signals in the closed loop system.

Only rather recently has the internal model principle been generalized for infinite-dimensional systems in the spirit of its original state space formulation [20]. This generalization (see section 3 below) employs purely operator theoretic concepts and is thus valid regardless of the dimensions of the state spaces of the plant, the controller, and the exogenous system. The core of this infinite-dimensional internal model principle lies in the observation that *any* closed loop error feedback control system, when properly stabilized, already contains the error zeroing dynamics. An appropriate choice of the controller's parameters resulting in the so-called internal model structure (see Definition 3.1) then realizes the desired dynamical behavior of output regulation. In particular, in finite dimensions, an error feedback controller containing a suitably controllable reduplication of the exogenous system dynamics has this internal model structure [20].

Whereas [20] presented a general robustness theory for infinite-dimensional systems without any regard to the choice of the controller's parameters, in this paper our purpose is to extend and amplify those results by establishing conditional robustness results for one member in each of the two aforementioned distinct regulator categories (for infinite-dimensional systems). Here conditional robustness means that asymptotic tracking and disturbance rejection are not destroyed by small perturbations so long as closed loop stability also persists; this is specified precisely in Definition 2.5. As a member of the first category we introduce (following [6, 22] closely) an infinite-dimensional generalization of a finite-dimensional controller of Francis [13]; we call this "type I controller" (see subsection 3.1 and in particular (3.13)). As a member of

the second category we introduce an infinite-dimensional generalization of the finite-dimensional controller (originally due to Davison [10]) studied in [16]; we call this "type II controller" (cf. subsection 3.2). We shall show that under certain assumptions both type I and type II controllers have the internal model structure. An application of the abstract results in [20] then immediately yields sufficient conditions for conditionally robust output regulation for these controllers. An important feature in our results is that they describe *how* these controllers achieve conditionally robust output regulation of bounded uniformly continuous exogenous signals for infinite-dimensional systems. Moreover, it turns out that we can design controllers achieving conditionally robust output regulation without relying on any purely finite-dimensional concepts, such as maximal cyclic components and rational canonical decompositions, so long as sufficient closed loop stability is achieved. To the author's knowledge this has not been possible before.

Although not all of our results are new—some finite-dimensional results of Davison and his coworkers have actually been generalized[1] for plants in the Callier–Desoer algebra [17] and subsequently for plants which are well-posed infinite-dimensional systems [32]—their presentation within the context of the infinite-dimensional internal model principle is new. Furthermore, our results explain in a novel way the function of the internal model principle in the robust output regulation of finite-dimensional systems. In particular, our framework provides a natural interpretation and generalization for the somewhat unintuitive (finite-dimensional) process of incorporating reduplications of the maximal cyclic component of the exosystem generator in the controller. On the other hand, the existing infinite-dimensional generalizations [6, 22, 34] of the theory of Francis [13] do not cover robustness issues; our results will cover robustness of the controllers in [6, 22] (type I).

One particularly interesting application for which the conditional robustness theory of this paper is suitable is repetitive control. In the classical repetitive control literature, e.g., [15, 42, 43], one invariably requires *exponential* stability of the closed loop system containing the plant and the infinite-dimensional internal model of the exogenous signals. Unfortunately this requirement can never be satisfied for any strictly proper finite-dimensional plant (see section V of [43] and Proposition 2 of [15]), so the scope of the classical repetitive control theory is somewhat limited. In this paper we shall apply the conditional robustness theory in a generalized repetitive control problem, where only *strong* closed loop stability and periodic tracking/rejection are required, and where the plant is a (possibly infinite-dimensional) exponentially stable single input–single output (SISO) system. We shall show that generalized repetitive control is possible provided that the corresponding feedforward regulator equations are solvable and provided that the reference/disturbance signals are smooth enough. In this SISO case the feedforward regulator equations can be solved using the methods of [24], provided that there are no transmission zeros at the complex frequencies $\frac{2\pi ni}{p}$, $n \in \mathbb{Z}$, of the exogenous signals; this is illustrated in an example in section 4. Moreover, conditional robustness allows us to dispense with certain severe stabilization problems present in a related earlier work [22]. A consequence of our results is that generalized repetitive control in the above sense is possible even for exponentially stable strictly proper finite-dimensional SISO plants (see section 4 for more details).

1.1. Notation. For Banach spaces E and F, $\mathcal{L}(E, F)$ denotes the space of bounded linear operators $E \to F$. The resolvent set of a closed linear operator

[1] The exosystems utilized in [17, 32] are still finite-dimensional, however.

$A : E \to F$ is denoted by $\rho(A)$, whereas $\sigma(A)$ denotes its spectrum. The point spectrum of A is denoted by $\sigma_p(A)$. $R(\lambda, A)$ denotes (whenever it exists) the resolvent operator $(\lambda I - A)^{-1}$. If $\widetilde{E}$ is a subspace of E, then $A|_{\widetilde{E}}$ denotes the restriction of A to $\widetilde{E}$. If $A : E \to E$ generates a strongly continuous (or C_0-) semigroup in E, then this semigroup is in general denoted by $T_A(t)$. We say that $T_A(t)$ is strongly stable if $\lim_{t\to\infty}\|T_A(t)x\| = 0$ for each $x \in E$. $T_A(t)$ is exponentially stable if $\|T_A(t)\| \le Me^{-\omega t}$ for some $M, \omega > 0$ and all $t \ge 0$. For the sake of brevity in these circumstances we sometimes say that A is strongly/exponentially stable. The inner product is denoted by $\langle\cdot,\cdot\rangle_E$, where the subscript E is occasionally included to clarify the space on which the inner product is defined.

2. The output regulation problem and robustness. In this section we recall the error feedback output regulation problem studied under various assumptions, e.g., in [6, 10, 13, 14, 22]. A solution of this problem amounts to designing a controller which employs error feedback to achieve stability of the closed loop (consisting of the plant and the controller) and asymptotic tracking of the reference signals under disturbances. Here asymptotic tracking means $e(t) = y(t) - y_{ref}(t) \to 0$ as $t \to \infty$, where $y(t)$ is the output of the plant and $y_{ref}(t)$ is the reference signal. In order to be more precise, we need to first define the plant and the exogenous system that generates the reference and disturbance signals.

2.1. The plant. We consider a plant described by the following (possibly infinite-dimensional) control system:

$$\dot{z}(t) = Az(t) + Bu(t) + \mathcal{U}_{dist}(t), \quad z(0) \in Z, \quad t \ge 0, \tag{2.1a}$$

$$y(t) = Cz(t) + Du(t), \quad t \ge 0. \tag{2.1b}$$

Here A generates a C_0-semigroup $T_A(t)$, $t \ge 0$, in a complex Banach space Z. The continuous input $u : \mathbb{R}_+ \to H$ and continuous output $y : \mathbb{R}_+ \to H$ take values in a complex Banach space H. The control operator $B \in \mathcal{L}(H, Z)$, the observation operator $C \in \mathcal{L}(Z, H)$, and the feedthrough operator $D \in \mathcal{L}(H)$. The continuous function $\mathcal{U}_{dist}$ is a disturbance (to be defined shortly). Equation (2.1a) is to be considered in the mild sense (see Curtain and Zwart [8]).

2.2. The exogenous system. It is a common (and mathematically convenient) assumption in control literature that the reference and disturbance signals in output regulation problems are generated by a so-called exogenous system. A common choice for an exogenous signal generator is a linear matrix differential equation with observation. Such an exosystem can handle the generation of simple signals—e.g., constants and sinusoids—but unfortunately signals which occur in practice are often more complex than this. Following the approach in [20, 21, 22, 23, 24], we shall next construct a possibly infinite-dimensional exogenous system which can generate general bounded uniformly continuous reference functions.

Let $\mathcal{H}$ be a Banach space which is continuously embedded in $BUC(\mathbb{R}, H)$, the space of bounded uniformly continuous H-valued functions on $\mathbb{R}$ endowed with the sup-norm ($\mathcal{H}$ need not have the sup-norm). In symbols, let $\mathcal{H} \hookrightarrow BUC(\mathbb{R}, H)$. We let $T_S(t)$ denote the shift C_0-group in $BUC(\mathbb{R}, H)$ defined as $T_S(t)f = f(\cdot + t)$; its infinitesimal generator is $S = \frac{d}{dx}$ with a suitable domain of definition $\mathcal{D}(S) \subset BUC(\mathbb{R}, H)$. If $\mathcal{H}$ is invariant for $T_S(t)$ and the restrictions $T_S(t)|_{\mathcal{H}}$ to $\mathcal{H}$ constitute an isometric C_0-group, we denote this by $\mathcal{H} \overset{s}{\hookrightarrow} BUC(\mathbb{R}, H)$. In this case the generator of $T_S(t)|_{\mathcal{H}}$ is denoted by $S|_{\mathcal{H}}$.

DEFINITION 2.1 (the exogenous system). *Let $\mathcal{H} \overset{s}{\hookrightarrow} BUC(\mathbb{R}, H)$, let $Q \in \mathcal{L}(\mathcal{H}, H)$ be an observation operator, and let $P \in \mathcal{L}(\mathcal{H}, Z)$ be a disturbance operator. The exogenous system generating the reference signals y_{ref} and the disturbance signals $\mathcal{U}_{dist}$ is defined on the state space $\mathcal{H}$ as*

$$\dot{w}(t) = S|_{\mathcal{H}} w(t), \quad w(0) = w_0 \in \mathcal{H}, \tag{2.2a}$$

$$y_{ref}(t) = Qw(t), \quad t \in \mathbb{R}, \tag{2.2b}$$

$$\mathcal{U}_{dist}(t) = Pw(t), \quad t \in \mathbb{R}, \tag{2.2c}$$

where (2.2a) *is to be considered in the mild sense* (*see Curtain and Zwart* [8]).

One particularly good choice is $Q = \delta_0$, where δ_0 is the point evaluation at the origin in $\mathcal{H}$, i.e., $\delta_0 f = f(0)$ for $f \in \mathcal{H}$. Clearly δ_0 is linear and $\|\delta_0 f\|_H = \|f(0)\|_H \le \|f\|_\infty \le c\|f\|_{\mathcal{H}}$ for some $c \ge 0$ (because $\mathcal{H} \hookrightarrow BUC(\mathbb{R}, H)$) and so $\delta_0 \in \mathcal{L}(\mathcal{H}, H)$. Moreover, $\delta_0 T_S(t)|_{\mathcal{H}} f = f(x+t)|_{x=0} = f(t)$ for every $f \in \mathcal{H}$ and $t \in \mathbb{R}$. Consequently, for $Q = \delta_0$, every reference signal y_{ref} in $\mathcal{H}$ (and only those) can be obtained from (2.2b) by choosing $w(0) = y_{ref}$. Although the choice $Q = \delta_0$ is sufficient for output regulation purposes [22], it turns out that for robustness considerations it is convenient to let Q vary in $\mathcal{L}(\mathcal{H}, H)$.

2.3. The error feedback output regulation problem and robustness. Our primary concern in this paper is to study robustness issues for the following output regulation problem [6, 10, 13, 14, 22].

DEFINITION 2.2. *The task in the error feedback regulation problem (EFRP) is to design an error feedback controller of the form*

$$\dot{x}(t) = Fx(t) + Ge(t), \quad x(0) \in X, \quad t \ge 0, \tag{2.3a}$$

$$u(t) = Jx(t) \tag{2.3b}$$

on some Banach state space X, where F generates a C_0-semigroup, $G \in \mathcal{L}(H, X)$, and $J \in \mathcal{L}(X, H)$. The controller must satisfy the following requirements:

1. *In the closed loop system for $t \ge 0$,*

$$\dot{z}(t) = Az(t) + BJx(t) + Pw(t), \tag{2.4a}$$

$$\dot{x}(t) = GCz(t) + (F + GDJ)x(t) - GQw(t), \tag{2.4b}$$

$$\dot{w}(t) = S|_{\mathcal{H}} w(t), \tag{2.4c}$$

$$e(t) = y(t) - y_{ref}(t) = Cz(t) + DJx(t) - Qw(t), \tag{2.4d}$$

   the semigroup $T_{\mathcal{A}}(t)$ generated by $\mathcal{A} = \left(\begin{smallmatrix} A & BJ \\ GC & F+GDJ \end{smallmatrix}\right)$ on $Z \times X$ is strongly stable (or, for brevity, $\mathcal{A}$ is strongly stable on $Z \times X$).
2. *The tracking error $e(t) \to 0$ as $t \to \infty$ for any initial conditions $z(0) \in Z$, $x(0) \in X$, and $w(0) \in \mathcal{H}$.*

The foundations of this paper are laid on the following result, first proved in [22].

THEOREM 2.3. *Let P and Q in the exosystem be fixed. Assume that F, G, and J in the controller* (2.3) *have been chosen such that the operator $\mathcal{A} = \left(\begin{smallmatrix} A & BJ \\ GC & F+GDJ \end{smallmatrix}\right)$ generates a strongly stable C_0-semigroup $T_{\mathcal{A}}(t)$ on $Z \times X$. If in addition there exist $\Pi \in \mathcal{L}(\mathcal{H}, Z)$ and $\Lambda \in \mathcal{L}(\mathcal{H}, X)$ such that $\Pi(\mathcal{D}(S|_{\mathcal{H}})) \subset \mathcal{D}(A)$ and $\Lambda(\mathcal{D}(S|_{\mathcal{H}})) \subset \mathcal{D}(F)$, and the following regulator equations are satisfied:*

$$A\Pi + BJ\Lambda + P = \Pi S|_{\mathcal{H}} \quad \text{in } \mathcal{D}(S|_{\mathcal{H}}), \tag{2.5a}$$

$$F\Lambda = \Lambda S|_{\mathcal{H}} \quad \text{in } \mathcal{D}(S|_{\mathcal{H}}), \tag{2.5b}$$

$$C\Pi + DJ\Lambda = Q \quad \text{in } \mathcal{H}, \tag{2.5c}$$

then with this triplet (F, G, J) the EFRP is solvable.

Explicit operators F, G, J which satisfy the conditions of Theorem 2.3 will be provided later in this paper (see also [6, 22]).

In our robustness analysis some (but not necessarily all) of the parameters A, B, C, D, G, J, P, and Q of the plant, the controller, and the exogenous system are subject to perturbations. Throughout this paper we assume that all perturbations are bounded, additive, and linear. For example, upon perturbation A may become $A + \Delta_A$, where $\Delta_A \in \mathcal{L}(Z)$. Furthermore, we assume that all perturbations to any one of the above operators are independent of the possible perturbations to the other operators in the above list. We then treat robustness in the following sense.

DEFINITION 2.4. *Output regulation is robust with respect to a set* $\Omega \subset \{A, B, C, D, G, J, P, Q\}$ *of parameters of the plant, the controller, and the exogenous system if the two conditions in Definition* 2.2 *hold in spite of sufficiently small perturbations in the elements of* Ω.

DEFINITION 2.5. *Output regulation is conditionally robust with respect to a set* $\Omega \subset \{A, B, C, D, G, J, P, Q\}$ *of parameters of the plant, the controller, and the exogenous system if all such small perturbations in the elements of* Ω *which preserve closed loop stability* (*i.e., condition* 1 *in Definition* 2.2) *also preserve asymptotic tracking* (*i.e., condition* 2 *in* Definition 2.2).

We point out that perturbations to F and $S|_{\mathcal{H}}$ are not permitted in our framework; this is in accordance with the corresponding finite-dimensional theory [13]. However, by varying $\mathcal{H}$ one can investigate robustness of output regulation for different classes of reference signals. On the other hand, perturbations to the parameters P and Q of the exogenous system never destroy closed loop stability. Hence such perturbations need not always be small for conditional robustness (see, e.g., Theorem 3.2). Finally, we point out that occasionally we must place additional structural requirements for the perturbations even for conditional robustness results (see section 4).

Remark 2.6. A potentially useful result in the study of conditional robustness is the following one due to Casarino and Piazzera [7]: Assuming that $\mathcal{A}$ generates a strongly stable C_0-semigroup on $Z \times X$, a sufficient condition that the perturbed closed loop operator $\mathcal{A} + \Delta_{\mathcal{A}}$, where $\Delta_{\mathcal{A}} \in \mathcal{L}(Z \times X)$,[2] still generates a strongly stable C_0-semigroup on $Z \times X$ is

$$\sup_{t \geq 0} \int_0^t \|\Delta_{\mathcal{A}} T_{\mathcal{A}}(s)\theta\| ds \leq C\|\theta\| \quad \forall \theta \in \mathcal{D}(\mathcal{A}), \quad 0 < C < 1. \tag{2.6}$$

Remark 2.7. If $T_{\mathcal{A}}(t)$ is exponentially stable, then bounded perturbations $\Delta_{\mathcal{A}}$ for which $\|\Delta_{\mathcal{A}}\|$ is sufficiently small do not destroy exponential stability of the closed loop system. Consequently for exponentially stable closed loop systems conditionally robust output regulation implies robust output regulation.

3. Conditionally robust regulation for two controllers. In this section we shall prove conditional robustness results for infinite-dimensional systems by utilizing type I and type II controllers. As mentioned in section 1, type I and type II controllers are representative members of the following two general regulator categories, respectively: those employing estimates of the state of the coupled system containing the plant and the exosystem (type I) and those employing dynamic error augmentation (type II). Our aim here is to (i) illustrate the abstract robustness theory—in particular the internal model structure—developed in [20]; (ii) prove new robustness

[2] In [7] the additive perturbation $\Delta_{\mathcal{A}}$ may actually be of the more general Miyadera–Voigt type.

results for control systems in infinite-dimensional spaces; and (iii) unify some existing robustness results using the abstract setting. To our knowledge conditional robustness (in the sense of Definition 2.5) of these two controller types has not been studied before.

We first recall some definitions from [20]. The linear Sylvester operator $\mathcal{T}_{F,S|_{\mathcal{H}}}$ is defined on a subspace of $\mathcal{L}(\mathcal{H},X)$ by

$$\mathcal{D}(\mathcal{T}_{F,S|_{\mathcal{H}}}) = \{\, \Lambda \in \mathcal{L}(\mathcal{H},X) \mid \Lambda(\mathcal{D}(S|_{\mathcal{H}})) \subset \mathcal{D}(F), \exists M \in \mathcal{L}(\mathcal{H},X) : \tag{3.1}$$
$$Mf = F\Lambda f - \Lambda S|_{\mathcal{H}} f \ \forall f \in \mathcal{D}(S|_{\mathcal{H}}) \,\},$$

$$\mathcal{T}_{F,S|_{\mathcal{H}}}\Lambda = M. \tag{3.2}$$

Definition 3.1 (internal model structure [20]). *The controller* (2.3) *has the internal model structure if the following implication holds:*

$$\forall \Lambda \in \mathcal{D}(\mathcal{T}_{F,S|_{\mathcal{H}}}), \forall \Delta \in \mathcal{L}(\mathcal{H},H) : \Lambda S|_{\mathcal{H}} = F\Lambda + G\Delta \text{ in } \mathcal{D}(S|_{\mathcal{H}}) \implies \Delta = 0. \tag{3.3}$$

The central idea behind the internal model structure is, roughly stated, the following. Suppose that F, G, and J in (2.3) have been fixed in such a way that the controller has the internal model structure. If, in addition, the closed loop system is "sufficiently" stable, then there always exist $\Pi \in \mathcal{L}(\mathcal{H},Z)$ and $\Lambda \in \mathcal{L}(\mathcal{H},X)$ such that the first regulator equation (2.5a) is satisfied *and* such that $\Lambda S|_{\mathcal{H}} = F\Lambda + G(C\Pi + DJ\Lambda - Q)$ in $\mathcal{D}(S|_{\mathcal{H}})$. This operator equation combines the second and third regulator equations (2.5b)–(2.5c), but the internal model structure ensures that we can separate them and thus satisfy all of the regulator equations (2.5). As a consequence of this, sufficient closed loop stability and the internal model structure together imply output regulation by Theorem 2.3. A glance at the appendix of [14] immediately reveals that this idea generalizes the finite-dimensional arguments of Francis and Wonham.

In [20] the author showed that under *exponential* closed loop stability (and certain additional assumptions) the internal model structure is both necessary and sufficient for *robust* output regulation. Moreover, the following result was essentially proved in [20]. It provides sufficient conditions for closed loop stability and internal model structure to yield (conditionally) robust output regulation. We choose to prove the result also here to emphasize the effect of the internal model structure: *Any* sufficiently stable closed loop error feedback control system already contains the error zeroing dynamics. If, in addition, the controller has the internal model structure, then the desirable dynamical behavior of output regulation is realized. It is remarkable that here the regulator equations (2.5) do not have to be explicitly solved as in, e.g., [22], where nonrobust output regulation was studied.

Theorem 3.2. *Let F, G, and J be chosen such that the closed loop operator $\mathcal{A}$ generates a strongly stable C_0-semigroup on $Z \times X$ and such that the controller has the internal model structure. Let A, B, C, D, and J be subject to perturbations and let $\mathcal{A}^p$, with $\mathcal{D}(\mathcal{A}^p) = \mathcal{D}(\mathcal{A})$, denote the perturbed closed loop operator. Then the following hold:*

1. *If for given $P \in \mathcal{L}(\mathcal{H},Z)$ and $Q \in \mathcal{L}(\mathcal{H},H)$ in the exosystem there exists $\Pi \in \mathcal{L}(\mathcal{H}, Z \times X)$ such that $\Pi(\mathcal{D}(S|_{\mathcal{H}})) \subset \mathcal{D}(\mathcal{A}^p)$ and $\Pi S|_{\mathcal{H}} = \mathcal{A}^p\Pi + \left(\begin{smallmatrix} P \\ -GQ \end{smallmatrix}\right)$ in $\mathcal{D}(S|_{\mathcal{H}})$, and if $\mathcal{A}^p$ is still strongly stable, then the EFRP is solved for these P, Q and the above perturbed closed loop parameters.*
2. *If for every $\mathcal{P} \in \mathcal{L}(\mathcal{H}, Z \times X)$ there exists a unique $\Pi \in \mathcal{L}(\mathcal{H}, Z \times X)$ such that $\Pi(\mathcal{D}(S|_{\mathcal{H}})) \subset \mathcal{D}(\mathcal{A})$ and $\Pi S|_{\mathcal{H}} = \mathcal{A}\Pi + \mathcal{P}$ in $\mathcal{D}(S|_{\mathcal{H}})$, then the controller*

achieves conditionally robust output regulation with respect to the above perturbed closed loop parameters for all $P \in \mathcal{L}(\mathcal{H}, Z)$ *and* $Q \in \mathcal{L}(\mathcal{H}, H)$.

3. *If* $\mathcal{A}$ *is exponentially stable, then the controller achieves robust output regulation with respect to the above perturbed closed loop parameters for all* $P \in \mathcal{L}(\mathcal{H}, Z)$ *and* $Q \in \mathcal{L}(\mathcal{H}, H)$.

Proof.

1. Let $P \in \mathcal{L}(\mathcal{H}, Z)$ and $Q \in \mathcal{L}(\mathcal{H}, H)$ be given, and set $\mathcal{P} = \left(\begin{smallmatrix} P \\ -GQ \end{smallmatrix}\right)$. Let $A^p = A + \Delta_A, B^p = B + \Delta_B, C^p = C + \Delta_C, D^p = D + \Delta_D, J^p = J + \Delta_J$, where the perturbations are bounded and linear on suitable spaces. By our assumption, there exists an operator $\left(\begin{smallmatrix} \Pi_1 \\ \Pi_2 \end{smallmatrix}\right) \in \mathcal{L}(\mathcal{H}, Z \times X)$ such that $\left(\begin{smallmatrix} \Pi_1 \\ \Pi_2 \end{smallmatrix}\right) S|_{\mathcal{H}} = \mathcal{A}^p \left(\begin{smallmatrix} \Pi_1 \\ \Pi_2 \end{smallmatrix}\right) + \mathcal{P}$ in $\mathcal{D}(S|_{\mathcal{H}})$, i.e.,

$$\begin{pmatrix} \Pi_1 \\ \Pi_2 \end{pmatrix} S|_{\mathcal{H}} = \begin{pmatrix} A^p & B^p J^p \\ GC^p & F + GD^p J^p \end{pmatrix} \begin{pmatrix} \Pi_1 \\ \Pi_2 \end{pmatrix} + \begin{pmatrix} P \\ -GQ \end{pmatrix} \quad \text{in } \mathcal{D}(S|_{\mathcal{H}}). \tag{3.4}$$

But this shows that $\Pi_2 S|_{\mathcal{H}} = F\Pi_2 + G(C^p\Pi_1 + D^p J^p \Pi_2 - Q)$ in $\mathcal{D}(S|_{\mathcal{H}})$, and since the controller has the internal model structure, ultimately $C^p\Pi_1 + D^p J^p \Pi_2 = Q$. Consequently the following regulator equations are satisfied:

$$A^p\Pi_1 + B^p J^p \Pi_2 + P = \Pi_1 S|_{\mathcal{H}} \quad \text{in } \mathcal{D}(S|_{\mathcal{H}}), \tag{3.5a}$$

$$F\Pi_2 = \Pi_2 S|_{\mathcal{H}} \quad \text{in } \mathcal{D}(S|_{\mathcal{H}}), \tag{3.5b}$$

$$C^p\Pi_1 + D^p J^p \Pi_2 = Q \quad \text{in } \mathcal{H}. \tag{3.5c}$$

According to Theorem 2.3 solvability of (3.5) and strong closed loop stability together imply output regulation.

2. Let $P \in \mathcal{L}(\mathcal{H}, Z)$ and $Q \in \mathcal{L}(\mathcal{H}, H)$ be arbitrary, and set $\mathcal{P} = \left(\begin{smallmatrix} P \\ -GQ \end{smallmatrix}\right)$. Let $A^p = A + \Delta_A, B^p = B + \Delta_B, C^p = C + \Delta_C, D^p = D + \Delta_D, J^p = J + \Delta_J$, where the perturbations are bounded and linear on suitable spaces. For conditional robustness, we assume that $\mathcal{A}^p$ is still the generator of a strongly stable C_0-semigroup. Define the linear Sylvester operator $\mathcal{T}_{\mathcal{A}, S|_{\mathcal{H}}}$ by

$$\mathcal{D}(\mathcal{T}_{\mathcal{A}, S|_{\mathcal{H}}}) = \{\Gamma \in \mathcal{L}(\mathcal{H}, Z \times X) \mid \Gamma(\mathcal{D}(S|_{\mathcal{H}})) \subset \mathcal{D}(\mathcal{A}), \exists Y \in \mathcal{L}(\mathcal{H}, Z \times X) :$$

$$Yf = \mathcal{A}\Gamma f - \Gamma S|_{\mathcal{H}} f \; \forall f \in \mathcal{D}(S|_{\mathcal{H}}) \}, \tag{3.6}$$

$$\mathcal{T}_{\mathcal{A}, S|_{\mathcal{H}}} \Gamma = Y. \tag{3.7}$$

By our assumptions, $\mathcal{T}_{\mathcal{A}, S|_{\mathcal{H}}}$ is a boundedly invertible closed operator [2]; consequently so is $\mathcal{T}_{\mathcal{A}^p, S|_{\mathcal{H}}}$ as long as the above perturbations to A, B, C, D, and J are small enough [26, p. 196]. Hence there exists a unique operator $\left(\begin{smallmatrix} \Pi_1 \\ \Pi_2 \end{smallmatrix}\right) \in \mathcal{L}(\mathcal{H}, Z \times X)$ such that $\left(\begin{smallmatrix} \Pi_1 \\ \Pi_2 \end{smallmatrix}\right) S|_{\mathcal{H}} = \mathcal{A}^p \left(\begin{smallmatrix} \Pi_1 \\ \Pi_2 \end{smallmatrix}\right) + \mathcal{P}$ in $\mathcal{D}(S|_{\mathcal{H}})$. The result now follows by item 1.

3. By [38] exponential stability of $\mathcal{A}$ implies that for every $\mathcal{P} \in \mathcal{L}(\mathcal{H}, Z \times X)$ there exists a unique $\Pi \in \mathcal{L}(\mathcal{H}, Z \times X)$ such that $\Pi(\mathcal{D}(S|_{\mathcal{H}})) \subset \mathcal{D}(\mathcal{A})$ and $\Pi S|_{\mathcal{H}} = \mathcal{A}\Pi + \mathcal{P}$ in $\mathcal{D}(S|_{\mathcal{H}})$ [37, 38]. Hence the conditions of item 2 are satisfied, and so we obtain conditionally robust output regulation with respect to A, B, C, D, and J for all P and Q. However, now all sufficiently small bounded perturbations to the closed loop operator $\mathcal{A}$ result in an operator $\mathcal{A}^p$, which still generates an exponentially stable semigroup. We thus deduce that the controller achieves robust output regulation with respect to A, B, C, D, and J for every P and Q. ∎

Remark 3.3. The above proof is based on solving the regulator equations (2.5) for the perturbed operators. Since these equations do not depend on G, in items 1–3 of Theorem 3.2 we also obtain (conditional) robustness with respect to G, because of the assumption that perturbations to the parameters can be considered independently of each other. From now on, perturbations to G are always justified by a similar reasoning and the assumption about independence of the perturbations.

Unique solvability of the Sylvester-type operator equation $\Pi S|_{\mathcal{H}} = \mathcal{A}\Pi + \mathcal{P}$ for each $\mathcal{P}$, which in Theorem 3.2 is shown to be crucial for conditional robustness, has been studied, e.g., in [2, 3, 37, 38]. We emphasize that in many instances this unique solvability can be deduced without explicitly calculating the solution operator Π. As mentioned above, this is the case, for example, whenever $\mathcal{A}$ is exponentially stable. Unfortunately, if $\mathcal{A}$ is only strongly stable, then this conclusion cannot be drawn. In fact, if $\mathcal{A}$ is strongly stable such that $\sigma(\mathcal{A}) \cap \sigma(S|_{\mathcal{H}}) \neq \emptyset$ (which is clearly possible), then the operator equation $\Pi S|_{\mathcal{H}} = \mathcal{A}\Pi + \mathcal{P}$ in $\mathcal{D}(S|_{\mathcal{H}})$ does not have a unique solution for every $\mathcal{P}$ [38]. On the other hand, in the case of finite-dimensional spaces Z and X, strong stability of $\mathcal{A}$ is equivalent to exponential stability of $\mathcal{A}$. Consequently, in finite dimensions, as soon as closed loop stability is achieved, the internal model structure guarantees robust output regulation without additional assumptions.

3.1. Conditional robustness results for type I controllers. In this subsection we shall explicitly specify the parameters of type I controllers in (3.13) and we shall show *how* one achieves (conditionally) robust output regulation using such controllers. The internal model structure will play a decisive role in our analysis. Before proving the results, however, we shall provide the reader with some essential background on the construction of type I controllers.

Type I controllers—as we call them in this paper—were introduced in a slightly different form in the finite-dimensional setup by Francis [13], where he presented the synthesis algorithm (SA) and its robust counterpart, the structurally stable synthesis algorithm (SSSA), for the solution of the output regulation problem. In the original paper, Francis [13] did not allow for perturbations in C and Q, but it has been shown in [20] that if the (finite-dimensional) EFRP of this paper is solved using the SSSA, then output regulation is robust with respect to C for an arbitrary Q as well. Byrnes et al. [6] have extended Francis's SA for infinite-dimensional plants, and this theory has subsequently been generalized for infinite-dimensional exogenous systems in [22]. However, as neither of the articles [6, 22] discusses robustness issues, the results of this subsection are new even for finite-dimensional exogenous systems.

In the original finite-dimensional setting of SSSA, robust controllers for the solution of the output regulation problem are constructed by employing $\dim(H)$-fold reduplications of the maximal cyclic component of the exosystem generator [13]. Here we shall employ a slightly different—and perhaps more intuitive—strategy in which none of the spaces has to be finite-dimensional; our idea is to embed the generator of a suitable translation group in the controller. In order to do this, we first embed the state space $\mathcal{H}$ of the exosystem continuously in a possibly larger space $\mathcal{G} \overset{s}{\hookrightarrow} BUC(\mathbb{R}, H)$ (we shall motivate this selection of $\mathcal{G}$ shortly). For every isolated point $i\omega \in \sigma(S|_{\mathcal{G}})$ we can then define the spectral projection by $P^{\mathcal{G}}_{i\omega} = \frac{1}{2\pi i} \oint_{i\omega} R(\lambda, S|_{\mathcal{G}}) d\lambda$ (and similarly for the isolated points of $\sigma(S|_{\mathcal{H}})$). We shall make the following standing assumptions, which hold throughout this subsection:

1. There is no feedthrough, i.e., $D = 0$.
2. The spectra $\sigma(S|_{\mathcal{H}}) = \sigma(S|_{\mathcal{G}})$ are discrete.

3. There exist $P \in \mathcal{L}(\mathcal{G}, Z)$ and $Q \in \mathcal{L}(\mathcal{G}, H)$ and $G = \left(\begin{smallmatrix} G_1 \\ G_2 \end{smallmatrix}\right) \in \mathcal{L}(H, Z \times \mathcal{G})$ such that $\left(\begin{smallmatrix} A & P \\ 0 & S|_{\mathcal{G}} \end{smallmatrix}\right) - \left(\begin{smallmatrix} G_1 \\ G_2 \end{smallmatrix}\right)\left(\begin{smallmatrix} C & -Q \end{smallmatrix}\right)$ generates a strongly stable C_0-semigroup on $Z \times \mathcal{G}$.
4. There exists $K \in \mathcal{L}(Z, H)$ such that $A + BK$ generates an exponentially stable C_0-semigroup on Z.
5. There exist $\Pi \in \mathcal{L}(\mathcal{G}, Z)$, such that $\Pi(\mathcal{D}(S|_{\mathcal{G}})) \subset \mathcal{D}(A)$, and $\Gamma \in \mathcal{L}(\mathcal{G}, H)$ satisfying the regulator equations

$$\Pi S|_{\mathcal{G}} = A\Pi + B\Gamma + P \quad \text{in } \mathcal{D}(S|_{\mathcal{G}}), \tag{3.8a}$$

$$Q = C\Pi \quad \text{in } \mathcal{G} \tag{3.8b}$$

6. For every $i\omega \in \sigma(S|_{\mathcal{G}})$ the operator $P^{\mathcal{G}}_{i\omega} G_2 : H \to \operatorname{ran}(P^{\mathcal{G}}_{i\omega})$ is injective.

Assumptions 1–5 are natural infinite-dimensional generalizations of those in the SSSA of Francis [13]; see also [22] for a discussion on how to satisfy assumption 3. However, assumption 6 requires additional justification. To this end we shall temporarily assume that $H = \mathbb{C}^N$ for some $N \in \mathbb{N}$. Then $\mathcal{G} \subset BUC(\mathbb{R}, \mathbb{C}^N)$ and $P^{\mathcal{G}}_{i\omega}$ maps $\mathcal{G}$ to $\{\, ae^{i\omega\cdot} \mid a \in \mathbb{C}^N \,\}$, which is an N-dimensional linear space. Since $G_2 : \mathbb{C}^N \to \mathcal{G}$, it is evident that $P^{\mathcal{G}}_{i\omega} G_2$ can be represented by an $N \times N$ matrix. In fact, each $f \in \mathbb{C}^N$ has the representation $f = \sum_{n=1}^N \langle f, e_n \rangle e_n$ in terms of the natural orthornormal basis for $\mathbb{C}^N$. Then, upon defining $\psi_n = G_2 e_n \in \mathcal{G}$ for each $1 \le n \le N$, we have

$$P^{\mathcal{G}}_{i\omega} G_2 f = \sum_{n=1}^N \langle f, e_n \rangle P^{\mathcal{G}}_{i\omega} \psi_n = \begin{pmatrix} P^{\mathcal{G}}_{i\omega}\psi_1 & \cdots & P^{\mathcal{G}}_{i\omega}\psi_N \end{pmatrix} \begin{pmatrix} \langle f, e_1 \rangle \\ \vdots \\ \langle f, e_N \rangle \end{pmatrix} \tag{3.9}$$

$$= e^{i\omega\cdot} \begin{pmatrix} \hat{\psi}_{11}(\omega) & \cdots & \hat{\psi}_{1N}(\omega) \\ \vdots & \vdots & \vdots \\ \hat{\psi}_{N1}(\omega) & \cdots & \hat{\psi}_{NN}(\omega) \end{pmatrix} \begin{pmatrix} \langle f, e_1 \rangle \\ \vdots \\ \langle f, e_N \rangle \end{pmatrix}, \tag{3.10}$$

where for each $1 \le n \le N$,

$$P^{\mathcal{G}}_{i\omega} \psi_n = \begin{pmatrix} \hat{\psi}_{1n}(\omega) \\ \vdots \\ \hat{\psi}_{Nn}(\omega) \end{pmatrix} e^{i\omega\cdot} \in \{\, ae^{i\omega\cdot} \mid a \in \mathbb{C}^N \,\} = \operatorname{ran}(P^{\mathcal{G}}_{i\omega}). \tag{3.11}$$

Consequently in order to meet assumption 6, the $N \times N$ matrix in (3.10) must be nonsingular for every $i\omega \in \sigma(S|_{\mathcal{G}})$. This requirement can often be met in practice because the functions $\psi_n = G_2 e_n$ can be chosen freely modulo assumption 3. In the SISO case ($N = 1$) it reduces to $\hat{\psi}_{11}(\omega) \neq 0$ for each $i\omega \in \sigma(S|_{\mathcal{G}})$. If the plant is SISO, if $\mathcal{G}$ is a Hilbert space, and if $S|_{\mathcal{G}}$ is a Riesz spectral operator[3] (see section 4 for a concrete example of such a situation), then $G_2 u = gu$ for some $g \in \mathcal{G}$ and all $u \in \mathbb{C}$. Moreover, in this case for each $i\omega \in \sigma(S|_{\mathcal{G}})$ we have $P^{\mathcal{G}}_{i\omega} G_2 = P^{\mathcal{G}}_{i\omega} g = \langle g, \phi_\omega \rangle_{\mathcal{G}} \theta_\omega$ for some eigenvector ϕ_ω of $S|_{\mathcal{G}}$; thus whenever $\langle g, \phi_\omega \rangle_{\mathcal{G}} \neq 0$ for each $i\omega \in \sigma(S|_{\mathcal{G}})$, the operator $P_{i\omega} G_2$ is injective. This condition, on the other hand, reduces to approximate controllability of the pair $(S|_{\mathcal{G}}, G_2)$ by Theorem 4.2.3 in [8].

We next drop the assumption $\dim(H) < \infty$ and explicitly specify the parameters F, G, and J of type I controllers in (3.13). Under assumptions 1–6 we can use an

[3] A Riesz-spectral operator on $\mathcal{G}$ is a closed operator whose spectrum consists of simple eigenvalues $\{\, \lambda_n \mid n \in \mathbb{Z} \,\}$, such that $\overline{\{\, \lambda_n \mid n \in \mathbb{Z} \,\}}$ is totally disconnected and such that the corresponding eigenvectors ϕ_ω constitute a Riesz basis (with biorthogonal vectors θ_ω) on $\mathcal{G}$ [8].

observer to generate an estimate $\Theta(t) = \left(\begin{smallmatrix}\theta_1(t)\\ \theta_2(t)\end{smallmatrix}\right)$ of the state $\left(\begin{smallmatrix}z(t)\\ w(t)\end{smallmatrix}\right)$ of the system

$$\begin{pmatrix}\dot z(t)\\ \dot w(t)\end{pmatrix} = \begin{pmatrix}A & P\\ 0 & S|_{\mathcal G}\end{pmatrix}\begin{pmatrix}z(t)\\ w(t)\end{pmatrix} + \begin{pmatrix}B\\ 0\end{pmatrix}u(t), \quad z(0)\in Z, \quad w(0)\in\mathcal G, \tag{3.12a}$$

$$e(t) = \begin{pmatrix}C & -Q\end{pmatrix}\begin{pmatrix}z(t)\\ w(t)\end{pmatrix} \tag{3.12b}$$

and then apply the control $u(t) = J\Theta(t) = J_1\theta_1(t) + J_2\theta_2(t)$, where $J_1 \in \mathcal L(Z,H)$ and $J_2 \in \mathcal L(\mathcal G, H)$ are chosen so that they solve a corresponding feedforward output regulation problem. This is the main idea in the construction of type I controllers [6, 13, 22]; the following new results validate this procedure and show that we obtain (conditionally) robust output regulation.

THEOREM 3.4. *Under assumptions* 1–6 *the dynamic type* I *controller*

$$\begin{aligned} F &= \begin{pmatrix}A+BK-G_1C & P+B(\Gamma-K\Pi)+G_1Q\\ -G_2C & S|_{\mathcal G}+G_2Q\end{pmatrix},\\ J &= \begin{pmatrix}K & \Gamma-K\Pi\end{pmatrix}, \quad G = \begin{pmatrix}G_1\\ G_2\end{pmatrix}\end{aligned} \tag{3.13}$$

on the state space $X = Z\times\mathcal G$ *has the internal model structure.*

Proof. Assume that $\Delta\in\mathcal L(\mathcal H,H)$ and $\Lambda = \left(\begin{smallmatrix}\Lambda_1\\ \Lambda_2\end{smallmatrix}\right) \in \mathcal D(\mathcal T_{F,S|_{\mathcal H}}) \subset \mathcal L(\mathcal H, X)$ are such that $\Lambda S|_{\mathcal H} = F\Lambda + G\Delta$ in $\mathcal D(S|_{\mathcal H})$. Then

$$\begin{pmatrix}\Lambda_1\\ \Lambda_2\end{pmatrix}S|_{\mathcal H} = \begin{pmatrix}A+BK-G_1C & P+B(\Gamma-K\Pi)+G_1Q\\ -G_2C & S|_{\mathcal G}+G_2Q\end{pmatrix}\begin{pmatrix}\Lambda_1\\ \Lambda_2\end{pmatrix} + \begin{pmatrix}G_1\\ G_2\end{pmatrix}\Delta \quad \text{in } \mathcal D(S|_{\mathcal H}), \tag{3.14}$$

whence $\Lambda_2 S|_{\mathcal H} = S|_{\mathcal G}\Lambda_2 + G_2(Q\Lambda_2 - C\Lambda_1 + \Delta)$ in $\mathcal D(S|_{\mathcal H})$.

By our assumptions and Gelfand's theorem [1, Cor. 4.4.8] the spectra $\sigma_p(S|_{\mathcal G}) = \sigma(S|_{\mathcal G}) = \sigma(S|_{\mathcal H}) = \sigma_p(S|_{\mathcal H})$. Moreover, as we define the spectral projections $P^{\mathcal H}_{i\omega} = \frac{1}{2\pi i}\oint_{i\omega} R(\lambda, S|_{\mathcal H})d\lambda$, it is true that $S|_{\mathcal F}P^{\mathcal F}_{i\omega} = i\omega P^{\mathcal F}_{i\omega} = P^{\mathcal F}_{i\omega}S|_{\mathcal F}$ for each $i\omega\in\sigma(S|_{\mathcal F})$, for $\mathcal F = \mathcal G, \mathcal H$. Applying projections on both sides of the equation $\Lambda_2 S|_{\mathcal H} = S|_{\mathcal G}\Lambda_2 + G_2(Q\Lambda_2 - C\Lambda_1 + \Delta)$ in $\mathcal D(S|_{\mathcal H})$ yields

$$0 = P^{\mathcal G}_{i\omega}[\Lambda_2 S|_{\mathcal H} - S|_{\mathcal G}\Lambda_2 - G_2(Q\Lambda_2 - C\Lambda_1+\Delta)]P^{\mathcal H}_{i\omega} = P^{\mathcal G}_{i\omega}G_2(Q\Lambda_2 - C\Lambda_1+\Delta)P^{\mathcal H}_{i\omega}. \tag{3.15}$$

But since $P^{\mathcal G}_{i\omega}G_2$ is injective, we must have $(Q\Lambda_2 - C\Lambda_1+\Delta)P^{\mathcal H}_{i\omega} = 0$ for every $i\omega\in\sigma(S|_{\mathcal H})$. Now since $T_S(t)|_{\mathcal H}$ is an isometric C_0-group, by [38, pp. 399–401] there exists a sequence $(\mathcal H_n)_{n\in\mathbb N}\subset\mathcal H$ of closed translation invariant (i.e., $T_S(t)|_{\mathcal H}$-invariant) subspaces such that $\mathcal H_n\subset\mathcal H_{n+1}$ for every $n\in\mathbb N$, $\sigma(S|_{\mathcal H_n})\subset\sigma(S|_{\mathcal H})$, $S_n = S|_{\mathcal H_n}\in\mathcal L(\mathcal H)$, and $\overline{\cup_{n\in\mathbb N}\mathcal H_n} = \mathcal H$. Moreover, we can choose $\mathcal H_n$ as the maximal invariant subspace on which $S|_{\mathcal H}$ is bounded and has a spectrum contained in (say) $[-in, in]$. Hence $S_n = \sum_{k\in I_n} i\omega_k P^{\mathcal H}_{i\omega_k}$ for some finite index set I_n and every $n\in\mathbb N$. Moreover, $\mathcal H_n = \operatorname{span}\{\, P^{\mathcal H}_{i\omega_k}f \mid f\in\mathcal H, k\in I_n\,\}$. Consequently $Q\Lambda_2 - C\Lambda_1+\Delta = 0$ on $\cup_{n\in\mathbb N}\mathcal H_n$. An extension by continuity gives $Q\Lambda_2 - C\Lambda_1+\Delta = 0$ on $\mathcal H$. Hence also $\Lambda_2 S|_{\mathcal H} = S|_{\mathcal G}\Lambda_2$ in $\mathcal D(S|_{\mathcal H})$.

On the other hand, by (3.14) we also have

$$\Lambda_1 S|_{\mathcal H} = (A+BK-G_1C)\Lambda_1 + (P+B(\Gamma-K\Pi)+G_1Q)\Lambda_2 + G_1\Delta \tag{3.16}$$

$$= (A+BK)\Lambda_1 + (P+B(\Gamma-K\Pi))\Lambda_2 + G_1(Q\Lambda_2 - C\Lambda_1+\Delta) \tag{3.17}$$

$$= (A+BK)\Lambda_1 + (P+B(\Gamma-K\Pi))\Lambda_2 \quad \text{in } \mathcal D(S|_{\mathcal H}). \tag{3.18}$$

Consequently $\left(\begin{smallmatrix}\Lambda_1\\ \Lambda_2\end{smallmatrix}\right)S|_{\mathcal{H}} = \left(\begin{smallmatrix}A+BK & B(\Gamma-K\Pi)+P\\ 0 & S|_{\mathcal{G}}\end{smallmatrix}\right)\left(\begin{smallmatrix}\Lambda_1\\ \Lambda_2\end{smallmatrix}\right)$ in $\mathcal{D}(S|_{\mathcal{H}})$. But since by our assumptions the regulator equations (3.8) are satisfied, we have

$$\begin{pmatrix} I & \Pi \\ 0 & I \end{pmatrix}\begin{pmatrix} A+BK & 0 \\ 0 & S|_{\mathcal{G}} \end{pmatrix}\begin{pmatrix} I & -\Pi \\ 0 & I \end{pmatrix} = \begin{pmatrix} A+BK & B(\Gamma-K\Pi)+P \\ 0 & S|_{\mathcal{G}} \end{pmatrix} \tag{3.19}$$

so that $\left(\begin{smallmatrix}I & -\Pi\\ 0 & I\end{smallmatrix}\right)\left(\begin{smallmatrix}\Lambda_1\\ \Lambda_2\end{smallmatrix}\right)S|_{\mathcal{H}} = \left(\begin{smallmatrix}A+BK & 0\\ 0 & S|_{\mathcal{G}}\end{smallmatrix}\right)\left(\begin{smallmatrix}I & -\Pi\\ 0 & I\end{smallmatrix}\right)\left(\begin{smallmatrix}\Lambda_1\\ \Lambda_2\end{smallmatrix}\right)$ in $\mathcal{D}(S|_{\mathcal{H}})$. Therefore $(\Lambda_1 - \Pi\Lambda_2)S|_{\mathcal{H}} = (A+BK)(\Lambda_1-\Pi\Lambda_2)$ in $\mathcal{D}(S|_{\mathcal{H}})$. But $A+BK$ is exponentially stable, so that the only operator $M \in \mathcal{L}(\mathcal{H}, Z)$ satisfying $MS|_{\mathcal{H}} = (A+BK)M$ in $\mathcal{D}(S|_{\mathcal{H}})$ is $M=0$. We thus have $\Lambda_1 = \Pi\Lambda_2$ in $\mathcal{H}$.

Finally, recall from the above that $Q\Lambda_2 - C\Lambda_1 + \Delta = 0$ in $\mathcal{H}$, so that by the regulator equations (3.8) we have $Q\Lambda_2 - C\Pi\Lambda_2 + \Delta = Q\Lambda_2 - Q\Lambda_2 + \Delta = \Delta = 0$. This shows that the controller has the internal model structure. ∎

COROLLARY 3.5. *Let assumptions* 1–6 *hold, and consider the type* I *controller* (3.13). *If for every* $\mathcal{P} \in \mathcal{L}(\mathcal{H}, Z\times X)$ *there exists a unique operator* $M \in \mathcal{L}(\mathcal{H}, Z\times X)$ *such that* $M(\mathcal{D}(S|_{\mathcal{H}})) \subset \mathcal{D}(\mathcal{A})$ *and* $MS|_{\mathcal{H}} = \mathcal{A}M + \mathcal{P}$ *in* $\mathcal{D}(S|_{\mathcal{H}})$, *then the controller* (3.13) *solves the EFRP. Moreover, output regulation is conditionally robust with respect to* $A, B, C, G,$ *and* J *regardless of* $P \in \mathcal{L}(\mathcal{H}, Z)$ *and* $Q \in \mathcal{L}(\mathcal{H}, H)$ *in the exosystem.*

Proof. Under assumptions 1–6 the controller (3.13) has the internal model structure by Theorem 3.4. We shall verify that the closed loop system is strongly stable and appeal to Theorem 3.2. Applying a similarity transform U given as

$$U = \begin{pmatrix} I & 0 & 0 \\ I & -I & 0 \\ 0 & 0 & -I \end{pmatrix} \tag{3.20}$$

on $Z\times Z\times\mathcal{G}$ to the closed loop operator $\mathcal{A}$ we obtain the operator $\widetilde{\mathcal{A}} = U\mathcal{A}U$ having the expression

$$\widetilde{\mathcal{A}} = \begin{pmatrix} A+BK & -BK & -B(\Gamma-K\Pi) \\ 0 & A-G_1C & P+G_1Q \\ 0 & -G_2C & S|_{\mathcal{G}}+G_2Q \end{pmatrix} := \begin{pmatrix} A+BK & \Delta \\ 0 & \mathcal{A}_s \end{pmatrix}. \tag{3.21}$$

By our assumption, $\mathcal{A}_s$ generates a strongly stable C_0-semigroup on X, and $A+BK$ generates an exponentially stable C_0-semigroup on Z. Clearly the C_0-semigroup generated by $\widetilde{\mathcal{A}}$ on $Z\times X$ is given by

$$T_{\widetilde{\mathcal{A}}}(t) = \begin{pmatrix} T_{A+BK}(t) & \int_0^t T_{A+BK}(t-s)\Delta T_{\mathcal{A}_s}(s)ds \\ 0 & T_{\mathcal{A}_s}(t) \end{pmatrix}. \tag{3.22}$$

Consequently $T_{\widetilde{\mathcal{A}}}(t)$ is strongly stable if

$$\lim_{t\to\infty}\int_0^t T_{A+BK}(t-s)\Delta T_{\mathcal{A}_s}(s)xds = 0 \quad \forall x\in X. \tag{3.23}$$

But (3.23) holds by Proposition 5.6.1 in [1]. This proves that also $T_{\mathcal{A}}(t)$ is strongly stable. ∎

COROLLARY 3.6. *Let assumptions* 1–6 *hold, and assume that the closed loop operator* $\mathcal{A}$ *employing the type* I *controller* (3.13) *generates an exponentially stable* C_0*-semigroup on* $Z\times X$. *Then output regulation is robust with respect to* $A, B, C, G,$ *and* J *regardless of* $P \in \mathcal{L}(\mathcal{H}, Z)$ *and* $Q \in \mathcal{L}(\mathcal{H}, H)$ *in the exosystem.*

In [6] (Theorem IV.2) Byrnes et al. have proved a complete characterization for the existence of a dynamic controller achieving (possibly nonrobust) output regulation for a given finite-dimensional exogenous system with fixed operators P and Q. They also employed controllers analogous to (3.13), but in their setting the closed loop system is exponentially stable; hence Corollary 3.6 above reveals that if G_2 is chosen appropriately, then the controller does not need to be changed if the operators P and Q in the exosystem are changed. Moreover, Corollary 3.6 proves that in this case output regulation is in fact robust with respect to certain parameters.

We emphasize that in the case of finite-dimensional spaces $\mathcal{G}$ and H, the differential operator $S|_{\mathcal{G}}$ can be represented by a diagonal matrix S_0. Moreover, it is easy to see that S_0 is similar to a matrix containing a $\dim(H)$-fold copy of the maximal cyclic component of S_0. Hence the above robustness results are in accordance with the corresponding finite-dimensional theory [13]. Moreover, they provide a natural interpretation and generalization for the somewhat unintuitive process of incorporating copies of maximal cyclic components of S_0 into the controller, which in the finite-dimensional setting is well known to guarantee robust output regulation under closed loop stability [10, 13, 14, 27, 40].

We also point out that it is convenient to allow for $\mathcal{H} \hookrightarrow \mathcal{G}$, because then $\mathcal{H}$ and $\mathcal{G}$ may also have different topologies. This turns out to be important in the verification of the conditions of Theorem 3.2. In fact, we shall see in Section 4 that although it may not be possible to solve $\Pi S|_{\mathcal{H}} = \mathcal{A}\Pi + \mathcal{P}$ in $\mathcal{D}(S|_{\mathcal{H}})$ uniquely for every $\mathcal{P} \in \mathcal{L}(\mathcal{H}, Z \times X)$, as required in Corollary 3.5, sometimes it is possible to solve $\Pi S|_{\mathcal{H}} = \mathcal{A}\Pi + \mathcal{P}$ in $\mathcal{D}(S|_{\mathcal{H}})$ for every $\mathcal{P} \in \mathcal{L}(\mathcal{G}, Z \times X) \subset \mathcal{L}(\mathcal{H}, Z \times X)$. This anomalous situation occurs, however, only if the closed loop system is not exponentially stable. If $\mathcal{A}$ generates an exponentially stable C_0-semigroup, then the equation $\Pi S|_{\mathcal{H}} = \mathcal{A}\Pi + \mathcal{P}$ in $\mathcal{D}(S|_{\mathcal{H}})$ has a unique solution regardless of $\mathcal{H} \hookrightarrow BUC(\mathbb{R}, H)$ and $\mathcal{P} \in \mathcal{L}(\mathcal{H}, Z \times X)$ [38].

We conclude this subsection with an example of error feedback control for a one-dimensional heat equation. The example below is essentially Example VI.2 of [6] (which is why we omit some details). Byrnes et al. [6] have constructed a controller which achieves output regulation of a sinusoidal reference signal in the disturbance-free case; below we shall show that their controller is also robust. In the following example we have $\mathcal{G} = \mathcal{H}$ and $S|_{\mathcal{G}} = S|_{\mathcal{H}}$.

Example 3.7. Consider a disturbance-free controlled one-dimensional heat equation on the interval $[0, 1]$ with Neumann boundary conditions: $\frac{\partial z(x,t)}{\partial t} = \frac{\partial^2 z(x,t)}{\partial^2 x} + Bu(t)$, $\frac{\partial z(0,t)}{\partial x} = \frac{\partial z(1,t)}{\partial x} = 0$, $z(x, 0) = \psi(x)$. The output is given as $y(t) = Cz(t)$. The bounded control operator $B : \mathbb{C} \to L^2(0, 1)$ is defined by $Bu = b(x)u$, with $b(x) = 2\chi_{[\frac{1}{2},1]}(x)$. Here $\chi_{[\epsilon,\delta]}(x)$ denotes the characteristic function of the interval $[\epsilon, \delta]$. The bounded observation operator $C : L^2(0, 1) \to \mathbb{C}$ is defined by $C\psi = \int_0^1 c(x)\psi(x)dx$, with $c(x) = 2\chi_{[0,\frac{1}{2}]}(x)$.

It is well known how to put this system in the form (2.1) with $D = 0$, $P = 0$ [6, 8, 23]. In [6] (Example VI.2) Byrnes et al. designed a dynamic error feedback controller (2.3) such that the plant can asymptotically track the reference signal $y_{ref}(t) = M \sin(\gamma t)$, with $M, \gamma > 0$. They used the exosystem $\dot{w}_0(t) = Sw_0(t)$ with $S = \left(\begin{smallmatrix} 0 & \gamma \\ -\gamma & 0 \end{smallmatrix}\right)$, $w_0(0) = \left(\begin{smallmatrix} 0 \\ M \end{smallmatrix}\right)$, $Q_0 = \left(\begin{smallmatrix} 1 & 0 \end{smallmatrix}\right)$ to generate $y_{ref}(t)$. After an application of the similarity transformation $U = \left(\begin{smallmatrix} i & -i \\ 1 & 1 \end{smallmatrix}\right)$ this exosystem becomes

(3.24)

$$\dot{w}(t) = S|_{\mathcal{H}} w(t) = \begin{pmatrix} \dot{w}_1(t) \\ \dot{w}_2(t) \end{pmatrix} = \begin{pmatrix} -i\gamma & 0 \\ 0 & i\gamma \end{pmatrix} \begin{pmatrix} w_1(t) \\ w_2(t) \end{pmatrix}, \quad Q = \begin{pmatrix} i & -i \end{pmatrix}, \quad w(0) = \begin{pmatrix} \frac{1}{2}M \\ \frac{1}{2}M \end{pmatrix},$$

which is now isomorphic to the desired form (2.2) on the state space $\mathcal{H} = \operatorname{span}\{e^{-i\gamma\cdot}\} \oplus \operatorname{span}\{e^{i\gamma\cdot}\}$. For example, in this basis the above initial condition is $w(0) = \frac{1}{2}M(e^{-i\gamma\cdot} + e^{i\gamma\cdot})$.

For the above plant Byrnes et al. [6] have solved the regulator equations $\Pi_0 S = A\Pi_0 + B\Gamma_0$ and $C\Pi_0 = Q_0$ for Π_0 and Γ_0. Since $S|_{\mathcal{H}} = U^{-1}SU$ and $Q = Q_0 U$, we readily see that $\Pi = \Pi_0 U$ and $\Gamma = \Gamma_0 U$ solve the regulator equations (3.8). We may then let

$$
\begin{aligned}
F &= \begin{pmatrix} A + BK - G_1 C & B(\Gamma - K\Pi) + G_1 Q \\ -G_2 C & S|_{\mathcal{H}} + G_2 Q \end{pmatrix}, \\
&= \begin{pmatrix} K & \Gamma - K\Pi \end{pmatrix}, \quad \text{and} \quad G = \begin{pmatrix} G_1 \\ G_2 \end{pmatrix},
\end{aligned} \tag{3.25}
$$

where $G_2 = U^{-1}G_2^0$, and $G_0 = \left(\begin{smallmatrix} G_1 \\ G_2^0 \end{smallmatrix}\right)$ is the same exponentially stabilizing output injection for the pair $\left(\left(\begin{smallmatrix} A & 0 \\ 0 & S \end{smallmatrix}\right), \left(\begin{smallmatrix} C & -Q_0 \end{smallmatrix}\right)\right)$ and K is the same exponentially stabilizing state feedback for the pair (A, B) used in [6]. These choices lead to an exponentially stable closed loop system operator $\mathcal{A}$, which is also similar to the one in Example VI.2 of [6]. In fact,

$$
\begin{aligned}
&\begin{pmatrix} A & BJ \\ GC & F \end{pmatrix} \\
&= \begin{pmatrix} I & 0 & 0 \\ 0 & I & 0 \\ 0 & 0 & U^{-1} \end{pmatrix} \begin{pmatrix} A & BK & B(\Gamma_0 - K\Pi_0) \\ G_1 C & A + BK - G_1 C & B(\Gamma_0 - K\Pi_0) + G_1 Q_0 \\ G_2^0 C & -G_2^0 C & S + G_2^0 Q_0 \end{pmatrix} \begin{pmatrix} I & 0 & 0 \\ 0 & I & 0 \\ 0 & 0 & U \end{pmatrix}.
\end{aligned} \tag{3.26}
$$

According to Corollary 3.6, in order to obtain robust output regulation, we need only verify that $P_{i\omega}^{\mathcal{H}} G_2$ is injective for $\omega = \pm\gamma$. But since Byrnes et al. [6] chose $G_2^0 = \left(\begin{smallmatrix} -3 \\ -3 \end{smallmatrix}\right)$, we obtain $G_2 = U^{-1}G_2^0 = \frac{3}{2}\left(\begin{smallmatrix} i-1 \\ -i-1 \end{smallmatrix}\right)$. Since neither component of G_2 is zero, $P_{i\omega}^{\mathcal{H}} G_2$ is injective for $\omega = \pm\gamma$. Consequently, output regulation is robust with respect to A, B, C, G, and J regardless of $P \in \mathcal{L}(\mathcal{H}, Z)$ and $Q \in \mathcal{L}(\mathcal{H}, \mathbb{C})$ in the exosystem. Observe that these operators P, Q need not coincide with those inside F (cf. (3.13)), and that robustness allows for asymptotic tracking *and* disturbance rejection (only tracking is considered in [6]).

3.2. Conditional robustness results for type II controllers. In this subsection we shall explicitly specify the parameters of type II controllers in (3.32), and we shall prove conditional robustness results for such controllers by utilizing the concept of internal model structure. Before proving any results, however, we shall provide the reader with some background on the construction of type II controllers.

Recall that a type II controller is a specific (possibly infinite-dimensional) representative member of the general regulator category in which dynamic error augmentation is employed. Type II controllers—as we call them in this paper—were originally introduced in a slightly different form in the finite-dimensional setup by Davison [10]. Davison's arguments, which proved robustness of the controllers, were based on calculations of the steady state time response of the closed loop system, and they have subsequently been somewhat simplified by Huang [16]. A key element in the proofs is that the controllers employ $\dim(H)$-fold reduplications of the exosystem generator in a suitably transformed form. Davison's robust output regulation theory has also been generalized for infinite-dimensional plants and finite-dimensional exogenous

systems, e.g., in [18, 31, 36]. However, to the author's knowledge type II controllers for infinite-dimensional exogenous systems have not been studied before.

Type II controllers are often designed in two phases [16]. In the first phase, a type II *state feedback* controller is designed in order to achieve robust output regulation. In the second phase, the parameters of this state feedback controller are utilized in the design of a dynamic type II controller which does not employ state feedback. In order to illustrate this procedure, let us consider the controller

$$\dot{x}(t) = Fx(t) + Ge(t), \quad x(0) \in X, \quad t \geq 0, \tag{3.27a}$$

$$u(t) = K_1 z(t) + Jx(t), \tag{3.27b}$$

which also employs a state feedback $K_1 \in \mathcal{L}(Z, H)$ from the plant. Let $\mathcal{H} \hookrightarrow \mathcal{G} \overset{s}{\hookrightarrow} BUC(\mathbb{R}, H)$, and assume the following throughout this subsection:

(a) The spectra $\sigma(S|_{\mathcal{H}}) = \sigma(S|_{\mathcal{G}})$ are discrete.

(b) There exist $K_1 \in \mathcal{L}(H, Z)$, $K_2 \in \mathcal{L}(\mathcal{G}, H)$, and $G_0 \in \mathcal{L}(H, \mathcal{G})$ such that $\mathcal{A}_0 = \left(\begin{smallmatrix} A+BK_1 & BK_2 \\ G_0(C+DK_1) & S|_{\mathcal{G}}+G_0DK_2 \end{smallmatrix}\right)$ generates a strongly stable C_0-semigroup on $Z \times \mathcal{G}$.

(c) For every $i\omega \in \sigma(S|_{\mathcal{G}})$ the operator $P^{\mathcal{G}}_{i\omega}G_0 : H \to \operatorname{ran}(P^{\mathcal{G}}_{i\omega})$ is injective (see subsection 3.1 for the notation).

Under the above assumptions we can specify $X = \mathcal{G}, F = S|_{\mathcal{G}}, G = G_0$, and $J = K_2$ in (3.27). We thus obtain the following controller, which we call the type II state feedback controller:

$$\dot{x}(t) = S|_{\mathcal{G}}x(t) + G_0e(t), \quad x(0) \in \mathcal{G}, \tag{3.28a}$$

$$u(t) = K_1 z(t) + K_2 x(t). \tag{3.28b}$$

We shall next establish conditions under which this state feedback controller solves the EFRP for a plant, where A is replaced with $A + BK_1$ and C is replaced with $C + DK_1$. Of course, this replacement procedure is just a compact way of showing that the state feedback controller (3.28) achieves closed loop stability and asymptotic tracking of the reference signals in the presence of disturbances for the plant (2.1).

THEOREM 3.8. *Let assumptions* (a)–(c) *hold, and consider a plant in which A is replaced with $A + BK_1$ and C is replaced with $C + DK_1$. Set $X = \mathcal{G}$ with $F = S|_{\mathcal{G}}$, $G = G_0$, $J = K_2$. Then the resulting dynamic controller (F, G, J) has the internal model structure.*

Proof. The proof that $\Lambda S|_{\mathcal{H}} = S|_{\mathcal{G}}\Lambda + G_0\Delta$ in $\mathcal{D}(S|_{\mathcal{H}})$ implies $\Delta = 0$ is carried out analogously to the proof of Theorem 3.4 using Gelfand's theorem, the injectivity of $P^{\mathcal{G}}_{i\omega}G_0$, and the decomposition of $\mathcal{H}$ to the closed translation-invariant subspaces $\mathcal{H}_n$, with $\mathcal{H} = \overline{\cup_{n\in\mathbb{N}}\mathcal{H}_n}$. ∎

COROLLARY 3.9. *Let assumptions* (a)–(c) *hold, and consider a plant in which A is replaced with $A + BK_1$ and C is replaced with $C + DK_1$. If, in addition, for every $\mathcal{P} \in \mathcal{L}(\mathcal{H}, Z\times X)$ there exists a unique $\Pi \in \mathcal{L}(\mathcal{H}, Z\times X)$ such that $\Pi(\mathcal{D}(S|_{\mathcal{H}})) \subset \mathcal{D}(\mathcal{A}_0)$ and $\Pi S|_{\mathcal{H}} = \mathcal{A}_0\Pi + \mathcal{P}$ in $\mathcal{D}(S|_{\mathcal{H}})$, then the controller of Theorem* 3.8 *achieves a conditionally robust output regulation with respect to the operators A, B, C, D, K_1, K_2, and G_0 for all $P \in \mathcal{L}(\mathcal{H}, Z)$ and $Q \in \mathcal{L}(\mathcal{H}, H)$.*

Proof. Let $P \in \mathcal{L}(\mathcal{H}, Z)$ and $Q \in \mathcal{L}(\mathcal{H}, H)$ be arbitrary, and set $\mathcal{P} = \left(\begin{smallmatrix} P \\ -G_0Q \end{smallmatrix}\right)$. As in the proof of Theorem 3.2 we deduce that (after possibly applying small bounded perturbations to the parameters A, B, C, D, K_1, K_2) there exists a unique operator

$\left(\begin{smallmatrix}\Pi\\ \Lambda\end{smallmatrix}\right) \in \mathcal{L}(\mathcal{H}, Z\times\mathcal{G})$ such that $\left(\begin{smallmatrix}\Pi\\ \Lambda\end{smallmatrix}\right)S|_{\mathcal{H}} = \mathcal{A}_0\left(\begin{smallmatrix}\Pi\\ \Lambda\end{smallmatrix}\right) + \mathcal{P}$ in $\mathcal{D}(S|_{\mathcal{H}})$, i.e.,

$$\begin{pmatrix}\Pi\\ \Lambda\end{pmatrix} S|_{\mathcal{H}} = \begin{pmatrix} A+BK_1 & BK_2\\ G_0(C+DK_1) & S|_{\mathcal{G}}+G_0DK_2\end{pmatrix}\begin{pmatrix}\Pi\\ \Lambda\end{pmatrix} + \begin{pmatrix} P\\ -G_0Q\end{pmatrix} \quad \text{in } \mathcal{D}(S|_{\mathcal{H}}). \tag{3.29}$$

But this shows that $\Pi S|_{\mathcal{H}} = (A+BK_1)\Pi + BK_2\Lambda + P$ and $\Lambda S|_{\mathcal{H}} = S|_{\mathcal{G}}\Lambda + G_0[(C+DK_1)\Pi + DK_2\Lambda - Q]$ in $\mathcal{D}(S|_{\mathcal{H}})$. Since by Theorem 3.8 the controller has the internal model structure, we must have that $(C+DK_1)\Pi + DK_2\Lambda - Q = 0$ in $\mathcal{H}$ and $\Lambda S|_{\mathcal{H}} = S|_{\mathcal{G}}\Lambda$ in $\mathcal{D}(S|_{\mathcal{H}})$. The result now follows from Theorem 2.3 because by our assumptions the closed loop operator $\mathcal{A} = \mathcal{A}_0$ generates a strongly stable C_0-semigroup and because the regulator equations (2.5) have a solution. ∎

COROLLARY 3.10. *Let assumptions* (a)–(c) *hold, and consider a plant in which* A *is replaced with* $A+BK_1$ *and* C *is replaced with* $C+DK_1$. *If, in addition,* $\mathcal{A}_0$ *is exponentially stable, then the controller of Theorem* 3.8 *achieves a robust output regulation with respect to the operators* A, B, C, D, K_1, K_2, *and* G_0 *for all* $P \in \mathcal{L}(\mathcal{H}, Z)$ *and* $Q \in \mathcal{L}(\mathcal{H}, H)$.

Before turning to the construction of dynamic controllers (2.3), which do not involve state feedback from the plant, namely the type II controllers, we show how the operators K_1, K_2, and G_0 above could be chosen such that assumption 2 is satisfied.

PROPOSITION 3.11. *Assume that there exist* $K \in \mathcal{L}(H, Z)$, $K_2 \in \mathcal{L}(\mathcal{G}, H)$, *and* $L \in \mathcal{L}(H, \mathcal{G})$ *such that* either $A+BK$ *generates an exponentially stable* C_0*-semigroup on* Z *and* $S|_{\mathcal{G}} + LK_2$ *generates a strongly stable* C_0*-semigroup on* $\mathcal{G}$ or $A+BK$ *generates a strongly stable* C_0*-semigroup on* Z *and* $S|_{\mathcal{G}} + LK_2$ *generates an exponentially stable* C_0*-semigroup on* $\mathcal{G}$. *If there exist* $G_0 \in \mathcal{L}(H, \mathcal{G})$ *and* $\Pi \in \mathcal{L}(Z, \mathcal{G})$ *such that* $\Pi(\mathcal{D}(A)) \subset \mathcal{D}(S|_{\mathcal{G}})$ *and*

$$S|_{\mathcal{G}}\Pi = \Pi(A+BK) + G_0(C+DK) \quad \text{in } \mathcal{D}(A), \tag{3.30a}$$

$$L = \Pi B + G_0 D \quad \text{in } H, \tag{3.30b}$$

then for $K_1 = K + K_2\Pi$ *the operator* $\mathcal{A}_0 = \left(\begin{smallmatrix} A+BK_1 & BK_2\\ G_0(C+DK_1) & S|_{\mathcal{G}}+G_0DK_2\end{smallmatrix}\right)$ *generates a strongly stable* C_0*-semigroup on* $Z\times\mathcal{G}$.

Proof. With the above choices we have $\mathcal{A}_0 = \left(\begin{smallmatrix} A+B(K+K_2\Pi) & BK_2\\ G_0(C+D[K+K_2\Pi]) & S|_{\mathcal{G}}+G_0DK_2\end{smallmatrix}\right)$. Then a direct calculation shows that

$$\begin{pmatrix} I & 0\\ \Pi & I\end{pmatrix}\begin{pmatrix} A+B(K+K_2\Pi) & BK_2\\ G_0(C+D[K+K_2\Pi]) & S|_{\mathcal{G}}+G_0DK_2\end{pmatrix}\begin{pmatrix} I & 0\\ -\Pi & I\end{pmatrix} = \begin{pmatrix} A+BK & BK_2\\ 0 & S|_{\mathcal{G}}+LK_2\end{pmatrix}, \tag{3.31}$$

which shows (see Theorem 5.1.2 and Proposition 5.6.4 in [1]) that $\mathcal{A}_0$ generates a strongly stable C_0-semigroup. ∎

Remark 3.12. If in Proposition 3.11 both $A+BK$ and $S|_{\mathcal{G}} + LK_2$ generate exponentially stable C_0-semigroups, then the closed loop system operator $\mathcal{A}_0$ is also exponentially stable. In fact, if we let $\|T_{A+BK}(t)\| \le M_1 e^{-\omega_1 t}$ and $\|T_{S|_{\mathcal{G}}+LK_2}(t)\| \le M_2 e^{-\omega_2 t}$ for all $t \ge 0$ and if, without loss of generality, we assume $\omega_2 \ge \omega_1 > 0$, then for all $y \in \mathcal{G}$ we have $\|\int_0^t T_{A+BK}(t-s)BK_2T_{S|_{\mathcal{G}}+LK_2}(s)yds\| \le M_1M_2\|BK_2\|\|y\|e^{-\omega_1 t}$ $\int_0^t e^{(\omega_1-\omega_2)s}ds$, which decays to 0 exponentially fast as $t\to\infty$.

We emphasize that state feedback makes it possible to treat plants in which (A, B) is only strongly stabilizable. For an alternative approach for strong stabilization of the closed loop system using Riccati equations we refer the reader to [9].

Now that we have presented type II state feedback controllers (3.28) which achieve (conditionally) robust output regulation, we turn to the construction of a dynamic

type II controller (2.3) which does not involve state feedback from the plant. In addition to assumptions (a)–(c) we shall need the following assumption:

(d) There exists $L \in \mathcal{L}(H,Z)$ such that $A-LC$ generates an exponentially stable C_0-semigroup on Z.

A dynamic type II controller (2.3) employing the parameters of the above state feedback controller is specified by the following parameters:

$$F=\begin{pmatrix} A+BK_1-L(C+DK_1) & (B-LD)K_2 \\ 0 & S|_{\mathcal{G}} \end{pmatrix}, \quad J=\begin{pmatrix} K_1 & K_2 \end{pmatrix}, \quad \text{and} \quad G=\begin{pmatrix} L \\ G_0 \end{pmatrix}. \tag{3.32}$$

It is clear that under the above assumptions the type II controller (3.32) has the internal model structure. The following result presents conditions under which we also achieve conditionally robust output regulation.

THEOREM 3.13. *Let assumptions* (a)–(d) *hold and assume that for every* $\mathcal{P} \in \mathcal{L}(\mathcal{H}, Z\times X)$ *there exists a unique* $\Pi \in \mathcal{L}(\mathcal{H}, Z\times X)$ *such that* $\Pi(\mathcal{D}(S|_{\mathcal{H}})) \subset \mathcal{D}(\mathcal{A})$ *and* $\Pi S|_{\mathcal{H}} = \mathcal{A}\Pi + \mathcal{P}$ *in* $\mathcal{D}(S|_{\mathcal{H}})$. *Then the type* II *controller* (3.32) *solves the EFRP. Moreover, output regulation is conditionally robust with respect to* $A, B, C, D, G,$ *and* J *regardless of* $P \in \mathcal{L}(\mathcal{H}, Z)$ *and* $Q \in \mathcal{L}(\mathcal{H}, H)$.

Proof. Since clearly the controller (3.32) has the internal model structure, according to Theorem 3.2 it is sufficient to prove that the closed loop system is strongly stable. With $F, G,$ and J as in (3.32), the closed loop system operator becomes

$$\mathcal{A} = \begin{pmatrix} A & BJ \\ GC & F+GDJ \end{pmatrix} = \begin{pmatrix} A & BK_1 & BK_2 \\ LC & A+BK_1-LC & BK_2 \\ G_0C & G_0DK_1 & S|_{\mathcal{H}}+G_0DK_2 \end{pmatrix}. \tag{3.33}$$

Applying the similarity transform U given as

$$U = \begin{pmatrix} I & -I & 0 \\ 0 & I & 0 \\ 0 & 0 & I \end{pmatrix}, \tag{3.34}$$

we see that $\mathcal{A}$ is similar to the operator $\widetilde{\mathcal{A}} = U\mathcal{A}U^{-1}$ having the expression

$$\widetilde{\mathcal{A}} = \begin{pmatrix} A-LC & 0 & 0 \\ LC & A+BK_1 & BK_2 \\ G_0C & G_0(C+DK_1) & S|_{\mathcal{H}}+G_0DK_2 \end{pmatrix}, \tag{3.35}$$

which by our assumptions generates a strongly stable C_0-semigroup on $Z\times X$ (use, e.g., Proposition 5.6.1 in [1]). This proves that also the similar closed loop semigroup $T_{\mathcal{A}}(t)$ is strongly stable. □

COROLLARY 3.14. *Let assumptions* (a)–(d) *hold and assume that the closed loop operator* $\mathcal{A}$ *generates an exponentially stable* C_0*-semigroup on* $Z\times X$. *Then the type* II *controller* (3.32) *solves the EFRP. Moreover, output regulation is robust with respect to* $A, B, C, D, G,$ *and* J *regardless of* $P \in \mathcal{L}(\mathcal{H}, Z)$ *and* $Q \in \mathcal{L}(\mathcal{H}, H)$.

Remark 3.15. To the author's knowledge, besides that of Ukai and Iwazumi [36], no work on type II controllers allowing for strongly stable closed loop operator has been reported, even for finite-dimensional exosystems. Ukai and Iwazumi essentially constructed type II controllers for infinite-dimensional systems on reflexive spaces and finite-dimensional exosystems, and in their work the closed loop system does not have to be exponentially stable.

We conclude this subsection with an example of regulation of finite-dimensional signals for a weakly damped string of unit length. In this case the plant (and hence also the closed loop system) is only strongly stable. The obtained type II state feedback controller is finite-dimensional, and it achieves conditionally robust output regulation.

Example 3.16. A model for a weakly damped string of unit length, with clamped ends, is (see [29])

$$\frac{\partial^2 v(x,t)}{\partial t^2} + M\frac{\partial v(x,t)}{\partial t} = \frac{\partial^2 v(x,t)}{\partial x^2} \quad \text{for } t \geq 0 \quad \text{and} \quad 0 \leq x \leq 1, \tag{3.36a}$$

$$v(0,t) = v(1,t) = 0 \quad \text{for } t \geq 0. \tag{3.36b}$$

Here M is a damping operator which will be defined shortly. We define the operator U by $Uv = -\frac{\partial^2 v}{\partial x^2}$ with $\mathcal{D}(U) = \{\, v \in H^2(0,1) \mid v(0) = v(1) = 0 \,\}$, where $H^2(0,1)$ denotes the standard Sobolev space on the unit interval. It can be shown that U has eigenvalues $\lambda_k = k^2\pi^2$, $k = 1, 2, \ldots$, and the corresponding eigenvectors $\phi_k(x) = \sqrt{2}\sin(k\pi x)$ constitute an orthonormal basis in $L^2(0,1)$ [29].

The damping operator M is defined by $Mv = \epsilon\langle m, v\rangle_{L^2(0,1)} m$, where $\epsilon > 0$ and

$$m = \sum_{k=1}^{\infty} \gamma_k \phi_k \tag{3.37}$$

with γ_k satisfying $0 < |\gamma_k| \leq \frac{d}{\sqrt{\lambda_k}}$ (for example, $\gamma_k = \frac{1}{k}$) for some $d > 0$. Next we define the Hilbert space $Z = L^2(0,1) \times L^2(0,1)$ with the natural inner product $\langle \cdot, \cdot \rangle$, and introduce

$$z(t) = \begin{pmatrix} U^{\frac{1}{2}} v(x,t) \\ \frac{\partial v(x,t)}{\partial t} \end{pmatrix}, \quad \text{and} \quad A = \begin{pmatrix} 0 & U^{\frac{1}{2}} \\ -U^{\frac{1}{2}} & M \end{pmatrix}. \tag{3.38}$$

Then (3.36) can be rewritten as $\dot{z}(t) = Az(t)$, $z(0) \in Z$, and it can be shown (see [29] and the references therein) that A generates a strongly (but not exponentially) stable C_0-semigroup $T_A(t)$ on Z. Moreover, all eigenvalues ν_k of A have negative real part, and the corresponding eigenvectors $(\psi_k)_k$ form a Riesz basis in Z. Consequently $\sigma(A) \cap i\mathbb{R} = \emptyset$, because for every $\omega \in \mathbb{R}$ and every index k the elements $R(i\omega, A)\psi_k = \int_0^\infty e^{-i\omega t} T_A(t)\psi_k dt = \int_0^\infty e^{(-i\omega+\nu_k)t}\psi_k dt$ exist in Z.

Consider then application of distributed control and observation to system (3.36) in the following sense. For a control operator $B \in \mathcal{L}(\mathbb{C}, Z)$ and an observation operator $C \in \mathcal{L}(Z, \mathbb{C})$ the SISO plant is given as

$$\dot{z}(t) = Az(t) + Bu(t), \quad z(0) \in Z, \quad t \geq 0, \tag{3.39a}$$

$$y(t) = Cz(t), \quad t \geq 0. \tag{3.39b}$$

Let the exogenous system (i.e., $\mathcal{H}$) be finite-dimensional, let $(\theta_n)_{n\in I}$ be the (finite) orthonormal basis for $\mathcal{H}$ corresponding to the eigenvectors of $S|_{\mathcal{H}}$, and assume that $S|_{\mathcal{H}} + LK_2$ is exponentially stable for some operators $L \in \mathcal{L}(\mathbb{C}, \mathcal{H})$ and $K_2 \in \mathcal{L}(\mathcal{H}, \mathbb{C})$. Assume in addition that $G_0 \in \mathcal{L}(\mathbb{C}, \mathcal{H})$ can be chosen such that $G_0 u = g_0 u$ for all $u \in \mathbb{C}$, with $g_0 \in \mathcal{H}$ and $\langle g_0, \theta_n\rangle_{\mathcal{H}} \neq 0$ for each $n \in I$, and such that the following regulator equations are satisfied:

$$S|_{\mathcal{H}}\Pi = \Pi A + G_0 C \quad \text{in } \mathcal{D}(A), \tag{3.40a}$$

$$\Pi B = L \quad \text{in } H \tag{3.40b}$$

for some $\Pi \in \mathcal{L}(Z, \mathcal{H})$ (we point out that by taking adjoints these equations can be solved for the adjoint operator of Π using the methods of [6]). In particular, by the skew-adjointness of $S|_{\mathcal{H}}$, the operators Π and G_0 must be chosen such that for every $n \in I$

$$\Pi^* \theta_n = R(-iw_n, A^*) C^* G_0^* \theta_n, \tag{3.41a}$$

$$L^* \theta_n = B^* R(-iw_n, A^*) C^* G_0^* \theta_n. \tag{3.41b}$$

If, in particular, $L = \delta_0^*$ as in the above, and if $B^* R(-iw_n, A^*) C^* \neq 0$ for all $n \in I$ (i.e., there are no transmission zeros on $\sigma(S|_{\mathcal{H}})$), then suitable operators Π and G_0, with $\langle g_0, \theta_n \rangle_{\mathcal{H}} \neq 0$ for each $n \in I$, are readily found by taking operator adjoints and by using the fact that θ_n is an orthonormal basis for $\mathcal{H}$.

A suitable state feedback controller is then given on the state space $X = \mathcal{H}$ by

$$\dot{x}_0(t) = S|_{\mathcal{H}} x_0(t) + G_0 e(t), \quad x_0(0) \in \mathcal{H}, \tag{3.42a}$$

$$u(t) = K_2 \Pi z(t) + K_2 x_0(t). \tag{3.42b}$$

In fact, the resulting closed loop system operator $\mathcal{A}_0 = \left(\begin{smallmatrix} A + BK_2\Pi & BK_2 \\ G_0 C & S|_{\mathcal{H}} \end{smallmatrix} \right)$ satisfies

$$\begin{pmatrix} I & 0 \\ \Pi & I \end{pmatrix} \begin{pmatrix} A + BK_2\Pi & BK_2 \\ G_0 C & S|_{\mathcal{H}} \end{pmatrix} \begin{pmatrix} I & 0 \\ -\Pi & I \end{pmatrix} = \begin{pmatrix} A & BK_2 \\ 0 & S|_{\mathcal{H}} + LK_2 \end{pmatrix}, \tag{3.43}$$

and hence it is strongly stable on $Z \times X$. Moreover, $\sigma(\mathcal{A}_0) \cap i\mathbb{R} = \emptyset$, because $\sigma(A) \cap i\mathbb{R} = \emptyset$ and $\sigma(S|_{\mathcal{H}} + LK_2) \cap i\mathbb{R} = \emptyset$, so that by the finite-dimensionality of the exogenous system for every $\mathcal{P} \in \mathcal{L}(\mathcal{H}, Z \times X)$ there exists a unique $Y \in \mathcal{L}(\mathcal{H}, Z \times X)$ such that $\operatorname{ran}(Y) \subset \mathcal{D}(\mathcal{A}_0)$ and $YS|_{\mathcal{H}} = \mathcal{A}_0 Y + \mathcal{P}$ in $\mathcal{H}$ [2, 38]. Corollary 3.9 shows that the controller (3.42) achieves conditionally robust output regulation with respect to A, B, C, Π, K_2, and G_0 for all $P \in \mathcal{L}(\mathcal{H}, Z)$ and $Q \in \mathcal{L}(\mathcal{H}, \mathbb{C})$.

4. Generalized repetitive control for exponentially stable SISO systems. In this section we shall focus on an important application, namely, generalized repetitive control, in which the goal is to achieve strong closed loop stability and asymptotic tracking/rejection of p-periodic reference and disturbance signals for some fixed $p > 0$ and for infinite-dimensional plants. Although such exogenous signals are rather simple, they must be generated using an infinite-dimensional linear exogenous system (2.2); otherwise we would be bound to deal with trigonometric polynomials only. Consequently, the well-known results on output regulation for finite-dimensional exogenous systems, e.g., those in [6], do not apply.

From [15, 22, 39, 42, 43] it is evident that one of the biggest obstacles in the design of repetitive controllers is that the closed loop system is often difficult to stabilize. In fact, Hara et al. [15] proved that repetitive controllers can never be designed (in the classical sense) for strictly proper finite-dimensional plants (e.g., A is exponentially stable and $D = 0$), because the requirement for exponential closed loop stability cannot be satisfied. In [22] the authors solved generalized repetitive control problems also for strictly proper infinite-dimensional systems using type I controllers. However, certain rather severe stabilizability problems are also present in [22]: In particular, for a *fixed* $P \in \mathcal{L}(\mathcal{G}, Z)$ and a *fixed* $Q \in \mathcal{L}(\mathcal{G}, H)$ the existence of $G = \left(\begin{smallmatrix} G_1 \\ G_2 \end{smallmatrix} \right) \in \mathcal{L}(H, Z \times \mathcal{G})$, for which $\left(\begin{smallmatrix} A & P \\ 0 & S|_{\mathcal{G}} \end{smallmatrix} \right) - \left(\begin{smallmatrix} G_1 \\ G_2 \end{smallmatrix} \right) \left(C \ -Q \right)$ generates a strongly stable C_0-semigroup on $Z \times \mathcal{G}$, is not trivial for an infinite-dimensional $\mathcal{G}$. This was required in [22] (see assumption 3 in subsection 3.1 and the discussion in [22]).

In this section we shall show that the above stabilizability problem of [22] can be partially solved using the conditional robustness theory of this paper. We shall design a type I controller for generalized repetitive control in such a way that the closed loop system is stabilized for certain simple operators P and Q contained in the operator F of (2.3) and (3.13) (see also assumption 3 of subsection 3.1). The conditional robustness theory then guarantees that the *same fixed* controller also achieves output regulation for *different* operators P and Q in the exosystem. Thus, robustness allows us—to a degree—to dispense with the problem in [22] of stabilizing the closed loop control system. Moreover, as opposed to [22], here the disturbances can be genuinely unmeasurable: Apart from the fact that we require sufficient continuity for the disturbance operator P (see Theorem 4.6 below), this operator P in the exosystem need not be explicitly known.

We assume the following throughout this section.

ASSUMPTION 4.1. *The plant is a SISO system, i.e., $H = \mathbb{C}$, the operator A generates an exponentially stable C_0-semigroup, $D = 0$, and $\mathcal{G} = H^\alpha_{per}(0,p)$ for some $\alpha > \frac{1}{2}$ (this is the standard Sobolev space of α-differentiable p-periodic functions* [25]*).*

We remark that the assumption that there is no feedthrough in the plant, i.e., $D = 0$, is deliberate: We aim to show that, contrary to the view in [15], conditionally robust regulation of periodic signals is possible even in this case if we do not require exponential closed loop stability but only strong closed loop stability. This is a key difference between the classical repetitive control problems [15, 39, 43] and the generalized repetitive control problems that we study.

We begin the controller design process by stabilizing the exogenous system for an appropriate Q. Recall from [24, 25] that $\mathcal{G} = H^\alpha_{per}(0,p)$ is a Hilbert space; its inner product is denoted by $\langle\cdot,\cdot\rangle$ and it is defined by $\langle f,g\rangle = \sum_{n\in\mathbb{Z}}(1+\omega_n^2)^\alpha \hat{f}_n\overline{\hat{g}_n}$, where $\hat{f}_n$ and $\hat{g}_n$ are ordinary L^2-Fourier coefficients and $\omega_n = \frac{2\pi n}{p}$. Moreover, every $f \in H^\alpha_{per}(0,p)$, $\alpha > \frac{1}{2}$, has the uniformly convergent Fourier series expansion $f(t) = \sum_{n\in\mathbb{Z}} \hat{f}_n e^{i\omega_n t} = \sum_{n\in\mathbb{Z}}\langle f,\phi_n\rangle\phi_n$, where the Fourier coefficients satisfy $\sum_{n\in\mathbb{Z}}(1+\omega_n^2)^\alpha|\hat{f}_n|^2 < \infty$, and $(\phi_n)_{n\in\mathbb{Z}}$ denotes the orthonormal basis of (weighted) exponentials $c_n e^{i\omega_n\cdot} = \frac{e^{i\omega_n\cdot}}{(\sqrt{1+\omega_n^2})^\alpha}$ in $H^\alpha_{per}(0,p)$.

LEMMA 4.2. *The space $\mathcal{G} \overset{s}{\hookrightarrow} BUC(\mathbb{R},\mathbb{C})$ and $T_S(t)|_{\mathcal{G}} f = \sum_{n\in\mathbb{Z}} e^{i\omega_n t}\langle f,\phi_n\rangle\phi_n$ for every $t \in \mathbb{R}$ and every $f \in \mathcal{G}$. Moreover, $S|_{\mathcal{G}}$ is a Riesz-spectral operator on $\mathcal{G}$ and $S|_{\mathcal{G}} = \sum_{n\in\mathbb{Z}} i\omega_n\langle\cdot,\phi_n\rangle\phi_n$, with $\mathcal{D}(S|_{\mathcal{G}}) = \{\, f \in \mathcal{G} \mid \sum_{n\in\mathbb{Z}}\omega_n^2|\langle f,\phi_n\rangle|^2 < \infty \,\}$.*

Proof. It is clear that $\mathcal{G} \hookrightarrow BUC(\mathbb{R},\mathbb{C})$ (see, e.g., Theorem 3.195 in [25]) and that the left shift operators $T_S(t)$ are isometries on $\mathcal{G}$ leaving this space invariant. The (semi)group property and strong continuity of $T_S(t)|_{\mathcal{G}}$ are easy to verify, so that $\mathcal{G} \overset{s}{\hookrightarrow} BUC(\mathbb{R},\mathbb{C})$. Since the elements of the orthonormal basis (ϕ_n) for $\mathcal{G}$ satisfy $\phi_n(\cdot) = c_n e^{i\omega_n\cdot}$ for $c_n = \frac{1}{(\sqrt{1+\omega_n^2})^\alpha}$ and every $n \in \mathbb{Z}$, it is also evident that $T_S(t)|_{\mathcal{G}}\phi_n = e^{i\omega_n t}\phi_n$ for each $t \in \mathbb{R}$. Hence $T_S(t)|_{\mathcal{G}} f = T_S(t)|_{\mathcal{G}}\sum_{n\in Z}\langle f,\phi_n\rangle\phi_n = \sum_{n\in Z}\langle f,\phi_n\rangle T_S(t)|_{\mathcal{G}}\phi_n = \sum_{n\in Z} e^{i\omega_n t}\langle f,\phi_n\rangle\phi_n$ for each $f \in \mathcal{G}$. That $S|_{\mathcal{G}}$ is a Riesz-spectral operator is evident; the spectrum of $S|_{\mathcal{G}}$ consists of the simple eigenvalues $\{\, i\omega_n \mid n \in \mathbb{Z} \,\}$ (whose closure is obviously totally disconnected). Moreover, the corresponding eigenvectors ϕ_n constitute an orthonormal (hence Riesz) basis in $\mathcal{G}$. The expression of $S|_{\mathcal{G}}$ follows from Theorem 2.3.5 in [8]. ∎

We are now ready to prove the following stabilization result, where δ_0 denotes the (bounded and linear) point evaluation operator on $\mathcal{G}$ centered at the origin.

LEMMA 4.3. *Let $\gamma > \alpha + \frac{1}{2}$. Then there exists $L \in \mathcal{L}(\mathbb{C}, \mathcal{G})$ such that*

1. *$S|_{\mathcal{G}} + L\delta_0$ generates a strongly stable C_0-semigroup on $\mathcal{G}$;*
2. *the resolvent satisfies $\|R(i\omega_n, S|_{\mathcal{G}} + L\delta_0)\| \le C'(\sqrt{1+\omega_n^2})^{\gamma}$ for some $C' > 0$ and every $n \in \mathbb{Z}$;*
3. *there exists a unique $l \in \mathcal{G}$ such that $Lu = lu$ for every $u \in \mathbb{C}$ and $\langle l, \phi_n \rangle \neq 0$ for every $n \in \mathbb{Z}$.*

Proof.

1. We shall first employ the theory of Xu and Sallet [41] to find $L \in \mathcal{L}(\mathbb{C}, \mathcal{G})$ such that $S|^*_{\mathcal{G}} + \delta_0^* L^*$ generates a strongly stable C_0-semigroup (here and elsewhere the superscript * denotes the operator adjoint). To this end, we need to show that the standing assumptions $H1 - H3$ in [41] are satisfied.
   First of all, $H1$ amounts to verifying that $S|^*_{\mathcal{G}}$ has compact resolvents and a simple spectrum. Clearly whenever $\lambda > 0$ we have $R(\lambda, S|_{\mathcal{G}}) = \sum_{n\in\mathbb{Z}} \frac{\langle \cdot, \phi_n\rangle \phi_n}{\lambda - i\omega_n}$. Since $\omega_n = \frac{2\pi n}{p}$, the resolvent $R(\lambda, S|_{\mathcal{G}})$ is a uniform limit of finite-rank operators and hence is compact. Moreover, the spectrum of $S|_{\mathcal{G}}$ consists of the simple eigenvalues $i\omega_n$, $n \in \mathbb{Z}$. Since $S|^*_{\mathcal{G}} = -S|_{\mathcal{G}}$, hypothesis $H1$ in [41] is satisfied.
   Second, $H2$ amounts to showing that $\mathcal{D}(S|_{\mathcal{G}})$ is a Hilbert space in the graph norm and that δ_0^* (when interpreted as an input element) satisfies $\delta_0^* \in \mathcal{D}(S|_{\mathcal{G}})'$ (the topological dual of $\mathcal{D}(S|_{\mathcal{G}})$). The first assertion is evident, and the second assertion follows from the boundedness of δ_0^*.
   Finally, in order to meet assumption $H3$ in [41] the eigenvectors ϕ_n of $S|^*_{\mathcal{G}}$ need to form a Riesz basis in $\mathcal{G}$, $\langle \phi_n, \delta_0^* \rangle \neq 0$ for each $n \in \mathbb{Z}$, and there must exist a positive constant M such that

$$\sum_{n\in\mathbb{Z}} \left| \frac{\langle \phi_n, \delta_0^* \rangle}{\lambda + i\omega_n} \right|^2 \le M \quad \text{and} \quad \sup_{m\in\mathbb{Z}} \sum_{n\neq m} \left| \frac{\langle \phi_n, \delta_0^* \rangle}{-i\omega_m + i\omega_n} \right|^2 \le M \tag{4.1}$$

   whenever the distance from λ to $\sigma(S|_{\mathcal{H}})$ is at least $\frac{2\pi}{3p}$. Now the eigenvectors ϕ_n of $S|^*_{\mathcal{G}} = -S|_{\mathcal{G}}$ constitute an orthonormal (hence Riesz) basis in $\mathcal{G}$. Moreover, since $\phi_n(\cdot) = c_n e^{i\omega_n \cdot}$, with $c_n = \frac{1}{(\sqrt{1+\omega_n^2})^{\alpha}}$, for each $f \in \mathcal{G}$ we have $\delta_0 f = f(0) = \sum_{n\in\mathbb{Z}} \langle f, \phi_n \rangle \phi_n(0) = \sum_{n\in\mathbb{Z}} c_n \langle f, \phi_n \rangle = \langle f, \sum_{n\in\mathbb{Z}} c_n \phi_n \rangle$, so that the adjoint of δ_0 satisfies $\delta_0^* u = u \sum_{n\in\mathbb{Z}} c_n \phi_n$ for every $u \in \mathbb{C}$. Obviously then $\langle \phi_n, \delta_0^* \rangle = c_n \neq 0$ for every $n \in \mathbb{Z}$. Moreover, for λ as in the above, we have

$$\sum_{n\in\mathbb{Z}} \left| \frac{\langle \phi_n, \delta_0^* \rangle}{\lambda + i\omega_n} \right|^2 \le \frac{9p^2}{4\pi^2} \sum_{n\in\mathbb{Z}} |c_n|^2 = \frac{9p^2}{4\pi^2} \sum_{n\in\mathbb{Z}} (1+\omega_n^2)^{-\alpha} = M < \infty \tag{4.2}$$

   and

$$\sup_{m\in\mathbb{Z}} \sum_{n\neq m} \left| \frac{\langle \phi_n, \delta_0^* \rangle}{-i\omega_m + i\omega_n} \right|^2 = \sup_{m\in\mathbb{Z}} \sum_{n\neq m} \left| \frac{c_n}{\frac{2\pi i}{p}(n-m)} \right|^2 \le \frac{p^2}{4\pi^2} \sum_{n\in\mathbb{Z}} (1+\omega_n^2)^{-\alpha} < M. \tag{4.3}$$

   In conclusion, the assumptions $H1$–$H3$ in [41] are satisfied.

Let $\gamma > \alpha + \frac{1}{2}$, and set $\mu_n = -i\omega_n - \frac{1}{(\sqrt{1+\omega_n^2})^\gamma}$ for every $n \in \mathbb{Z}$. We next design a feedback $L^* \in \mathcal{L}(\mathcal{G}, \mathbb{C})$ such that it assigns the spectrum $\sigma(S|_{\mathcal{G}}^* - \delta_0^* L^*) = \{\, \mu_n \mid n \in \mathbb{Z} \,\} \subset \{\, z \in \mathbb{C} \mid \Re(z) < 0 \,\}$. If we can accomplish this, then $S|_{\mathcal{G}}^* - \delta_0^* L^*$ generates a strongly stable C_0-semigroup on $\mathcal{G}$. In fact, the operator $S|_{\mathcal{G}}^* + \delta_0^* L^*$ is regular spectral [41]; i.e., it has compact resolvents and its eigenvectors $(\theta_n)_{n\in\mathbb{Z}}$, with $(S|_{\mathcal{G}}^* + \delta_0^* L^*)\theta_n = \mu_n \theta_n$ for every $n \in \mathbb{Z}$, constitute a Riesz basis in $\mathcal{G}$. Hence the C_0-semigroup $T_{S|_{\mathcal{G}}^* + \delta_0^* L^*}(t)$ is uniformly bounded; strong stability follows from the Arendt–Batty–Lyubich–Vu theorem (see, e.g., Theorem V.2.21 in [12]) because $S|_{\mathcal{G}}^* + \delta_0^* L^*$ has no spectrum on $i\mathbb{R}$. In order to show that such an L^* indeed exists, we aim to apply Theorem 1 in [41]. To this end, we observe that the assigned spectral points μ_n satisfy the necessary condition (3) on page 522 of [41]:

$$\sum_{n\in\mathbb{Z}} \left| \frac{\mu_n + i\omega_n}{\langle \phi_n, \delta_0^* \rangle} \right|^2 = \sum_{n\in\mathbb{Z}} \left| \frac{1}{c_n} \frac{1}{\left(\sqrt{1+\omega_n^2}\right)^\gamma} \right|^2 = \sum_{n\in\mathbb{Z}} \left| \left(\sqrt{1+\omega_n^2}\right)^{\alpha-\gamma} \right|^2 = \sum_{n\in\mathbb{Z}} (1+\omega_n^2)^{\alpha-\gamma} < \infty.$$

Theorem 1 in [41] now implies that the claim follows for the particular choice of $L^* = \langle \cdot, l \rangle$, where $l \in \mathcal{G}$ is given by

(4.4)
$$l = \sum_{n\in\mathbb{Z}} l_n \phi_n, \quad \text{where } \overline{l_n} = -\frac{\left(\sqrt{1+\omega_n^2}\right)^\alpha}{\left(\sqrt{1+\omega_n^2}\right)^\gamma} \prod_{k=-\infty, k\neq n}^{\infty} \frac{-i\omega_n + i\omega_k + \left(\sqrt{1+\omega_k^2}\right)^{-\gamma}}{-i\omega_n + i\omega_k}.$$

Our final task in item 1 is to show that the adjoint $S|_{\mathcal{G}} + L\delta_0$ is also the generator of a strongly stable C_0-semigroup on $\mathcal{G}$. Clearly $S|_{\mathcal{G}} + L\delta_0$ generates at least a weakly stable C_0-semigroup on $\mathcal{G}$. Since $S|_{\mathcal{G}}$ has compact resolvents, so has $S|_{\mathcal{G}} + L\delta_0$ (see [12, p. 159]). For such semigroup generators, weak stability implies strong stability (see Proposition 3.21 in [28]).

2. According to Theorem 1 in [41] the operator $S|_{\mathcal{G}}^* + \delta_0^* L^*$ above is regular spectral; i.e., it has compact resolvents and its eigenvectors $(\theta_n)_{n\in\mathbb{Z}}$, with $(S|_{\mathcal{G}}^* + \delta_0^* L^*)\theta_n = \mu_n \theta_n$ for every $n \in \mathbb{Z}$, constitute a Riesz basis in $\mathcal{G}$. We remark that the eigenvalues $(\mu_n)_{n\in\mathbb{Z}}$ of $S|_{\mathcal{G}}^* + \delta_0^* L^*$ need not be simple in general. Let $(\psi_n)_{n\in\mathbb{Z}}$ denote the sequence in $\mathcal{G}$ which is biorthogonal to $(\theta_n)_{n\in\mathbb{Z}}$ [8]. Whenever $\lambda \neq \mu_n$ for each $n \in \mathbb{Z}$ we have $(\lambda I - S|_{\mathcal{G}}^* - \delta_0^* L^*)\theta_n = (\lambda - \mu_n)\theta_n$, whence $R(\lambda, S|_{\mathcal{G}}^* + \delta_0^* L^*)\theta_n = \frac{1}{\lambda - \mu_n}\theta_n$, and so for every such $\lambda \in \mathbb{C}$,

$$R(\lambda, S|_{\mathcal{G}}^* + \delta_0^* L^*) f = \sum_{n\in\mathbb{Z}} \frac{\langle f, \psi_n \rangle \theta_n}{\lambda - \mu_n} \quad \forall f \in \mathcal{G}. \tag{4.5}$$

For every $m \in \mathbb{Z}$ we may now estimate using the well-known properties of Riesz bases [8] as follows:

(4.6)

$$\|R(-i\omega_m, S|_{\mathcal{G}}^* + \delta_0^* L^*)f\|^2 = \left\| \sum_{n\in\mathbb{Z}} \frac{\langle f, \psi_n\rangle \theta_n}{-i\omega_m - \mu_n} \right\|^2 \le D' \sum_{n\in\mathbb{Z}} \left| \frac{\langle f, \psi_n\rangle}{-i\omega_m - \mu_n} \right|^2$$

$$= D' \left[\sum_{n\in I_m} \left| \frac{\langle f, \psi_n\rangle}{-i\omega_m - \mu_m} \right|^2 + \sum_{n\notin I_m} \left| \frac{\langle f, \psi_n\rangle}{-i\omega_m - \mu_n} \right|^2 \right] \tag{4.7}$$

$$\le D' \left[(1+\omega_m^2)^\gamma \sum_{n\in\mathbb{Z}} |\langle f, \psi_n\rangle|^2 + c' \sum_{n\in\mathbb{Z}} |\langle f, \psi_n\rangle|^2 \right] \tag{4.8}$$

$$\le C'^2 (1+\omega_m^2)^\gamma \|f\|^2, \tag{4.9}$$

where I_m is the finite (cf. Corollary IV.1.19 in [12]) multiplicity of the eigenvalue μ_m, and c', D', C' are positive constants. This shows that $\|R(-i\omega_n, S|_{\mathcal{G}}^* + \delta_0^* L^*)\| \le C' \left(\sqrt{1+\omega_n^2}\right)^\gamma$ for each $n \in \mathbb{Z}$. But according to Lemmas A.3.65 and A.3.60 in [8], $\|R(i\omega_n, S|_{\mathcal{G}} + L\delta_0)\| = \|R(-i\omega_n, S|_{\mathcal{G}}^* + \delta_0^* L^*)\| \le C' \left(\sqrt{1+\omega_n^2}\right)^\gamma$ for each $n \in \mathbb{Z}$.

3. If we choose L^* according to (4.4), then evidently $Lu = lu$ for the unique $l \in \mathcal{G}$. Moreover, $\langle \phi_n, l\rangle = \overline{l_n}$ for each $n \in \mathbb{Z}$. Now by Theorem 1 in [41] we have

$$\lim_{M,N\to\infty} \frac{\mu_n + i\omega_n}{c_n} \prod_{k=-M, k\ne n}^{N} \frac{-i\omega_n + i\omega_k + \frac{1}{\left(l\sqrt{1+\omega_k^2}\right)^\gamma}}{-i\omega_n + i\omega_k} \tag{4.10}$$

$$= \frac{\mu_n + i\omega_n}{c_n} \lim_{M,N\to\infty} \prod_{k=-M, k\ne n}^{N} \left[1 + \frac{1}{i(\omega_k - \omega_n)\left(\sqrt{1+\omega_k^2}\right)^\gamma} \right]$$

$$= \overline{l_n}. \tag{4.11}$$

Since

$$\left| \prod_{k=-M, k\ne n}^{N} \left[1 + \frac{1}{i(\omega_k - \omega_n)\left(\sqrt{1+\omega_k^2}\right)^\gamma} \right] \right|$$

$$= \prod_{k=-M, k\ne n}^{N} \left| 1 - \frac{i}{(\omega_k - \omega_n)\left(\sqrt{1+\omega_k^2}\right)^\gamma} \right| > 1$$

for every $M, N \in \mathbb{N}$, the above infinite product cannot converge to 0. Hence we have $l_n \ne 0$ for each $n \in \mathbb{Z}$. □

Remark 4.4. The stabilizing operator L is actually constructed in the above proof; see (4.4).

Remark 4.5. Strong stability is the best we can achieve in Lemma 4.3. In fact, since $S|_{\mathcal{G}}$ generates an isometric C_0-group on an infinite-dimensional space, $S|_{\mathcal{G}} + \Delta$ is not exponentially stable for any compact perturbation $\Delta \in \mathcal{L}(\mathcal{G})$ (cf. Corollary 3.58 in [28]).

The following is the main result of this section.

THEOREM 4.6. *Let $\mathcal{G}$ and L be as in Lemma 4.3. Let $\beta > \gamma + \alpha + \epsilon$ for arbitrary $\epsilon > \frac{1}{2}$ and set $\mathcal{H} = H^\beta_{per}(0, p)$. Assume that there exist $\Pi \in \mathcal{L}(\mathcal{G}, Z)$ and $\Gamma \in \mathcal{L}(\mathcal{G}, \mathbb{C})$ such that $\Pi(\mathcal{D}(S|_{\mathcal{G}})) \subset \mathcal{D}(A)$ and the following (feedforward) regulator equations are*

satisfied:

$$A\Pi + B\Gamma = \Pi S|_{\mathcal{G}} \quad \text{in } \mathcal{D}(S|_{\mathcal{G}}), \tag{4.12a}$$

$$C\Pi = \delta_0 \quad \text{in } \mathcal{G}. \tag{4.12b}$$

Let $X = Z \times \mathcal{G}$, *and set* $F = \left(\begin{smallmatrix} A & B\Gamma \\ -LC & S|_{\mathcal{G}} + L\delta_0 \end{smallmatrix}\right)$, $J = (0\ \Gamma)$, *and* $G = \left(\begin{smallmatrix} 0 \\ L \end{smallmatrix}\right)$. *Then this type* I *controller solves the EFRP for every* $P \in \mathcal{L}(\mathcal{G}, Z)$ *and each* $Q \in \mathcal{L}(\mathcal{G}, \mathbb{C})$.

Proof. Consider the closed loop operator

$$\mathcal{A} = \begin{pmatrix} A & BJ \\ GC & F \end{pmatrix} = \begin{pmatrix} A & 0 & B\Gamma \\ 0 & A & B\Gamma \\ LC & -LC & S|_{\mathcal{G}} + L\delta_0 \end{pmatrix}. \tag{4.13}$$

Applying the similarity transform U given as

$$U = \begin{pmatrix} I & 0 & 0 \\ I & -I & 0 \\ 0 & 0 & -I \end{pmatrix} \tag{4.14}$$

on $Z \times X = Z \times Z \times \mathcal{G}$ to $\mathcal{A}$ we obtain the operator $\widetilde{\mathcal{A}} = U\mathcal{A}U$ having the expression

$$\widetilde{\mathcal{A}} = \begin{pmatrix} A & 0 & -B\Gamma \\ 0 & A & 0 \\ 0 & -LC & S|_{\mathcal{G}} + L\delta_0 \end{pmatrix} := \begin{pmatrix} A & \Delta \\ 0 & \mathcal{A}_s \end{pmatrix}. \tag{4.15}$$

By Lemma 4.3, $S|_{\mathcal{G}} + L\delta_0$ generates a strongly stable C_0-semigroup on $\mathcal{G}$. Since in addition A generates an exponentially stable C_0-semigroup on Z, the semigroup generated by $\mathcal{A}_s$ on $Z \times \mathcal{G}$ is strongly stable (use, e.g., Proposition 5.6.1 in [1]). The same reasoning shows that the C_0-semigroup generated by $\widetilde{\mathcal{A}}$ on $Z \times X$ is strongly stable. Consequently so is the similar semigroup generated by $\mathcal{A}$ on $Z \times X$.

Let $\mathcal{P} \in \mathcal{L}(\mathcal{G}, Z \times Z \times \mathcal{G}) \subset \mathcal{L}(\mathcal{H}, Z \times Z \times \mathcal{G})$ be arbitrary. We show that the equation $\Pi S|_{\mathcal{H}} = \widetilde{\mathcal{A}}\Pi + \mathcal{P}$ in $\mathcal{D}(S|_{\mathcal{H}})$ has a solution $\Pi \in \mathcal{L}(\mathcal{H}, Z \times Z \times \mathcal{G})$ and apply Theorem 3.2 to obtain the desired result. Now $\Pi S|_{\mathcal{H}} = \widetilde{\mathcal{A}}\Pi + \mathcal{P}$ in $\mathcal{D}(S|_{\mathcal{H}})$ reads

$$\begin{pmatrix} \Pi_1 \\ \Pi_2 \\ \Pi_3 \end{pmatrix} S|_{\mathcal{H}} = \begin{pmatrix} A & 0 & -B\Gamma \\ 0 & A & 0 \\ 0 & -LC & S|_{\mathcal{G}} + L\delta_0 \end{pmatrix} \begin{pmatrix} \Pi_1 \\ \Pi_2 \\ \Pi_3 \end{pmatrix} + \begin{pmatrix} P_1 \\ P_2 \\ P_3 \end{pmatrix} \quad \text{in } \mathcal{D}(S|_{\mathcal{H}}), \tag{4.16}$$

where Π_i, $i = 1, 2, 3$, denote the components of Π and P_i, $i = 1, 2, 3$, denote the components of $\mathcal{P}$. Now $P_2 \in \mathcal{L}(\mathcal{G}, Z) \subset \mathcal{L}(\mathcal{H}, Z)$, and by exponential stability of A there exists a unique $\Pi_2 \in \mathcal{L}(\mathcal{G}, Z)$ for which $\Pi_2 S|_{\mathcal{G}} = A\Pi_2 + P_2$ in $\mathcal{D}(S|_{\mathcal{G}})$. Since $\mathcal{H} \hookrightarrow \mathcal{G}$, the same operator $\Pi_2 \in \mathcal{L}(\mathcal{H}, Z)$ satisfies $\Pi_2 S|_{\mathcal{H}} = A\Pi_2 + P_2$ in $\mathcal{D}(S|_{\mathcal{H}})$. It suffices to show that $\Pi_3 \in \mathcal{L}(\mathcal{H}, \mathcal{G})$ exists such that $\Pi_3 S|_{\mathcal{H}} = (S|_{\mathcal{G}} + L\delta_0)\Pi_3 + P_3 - LC\Pi_2$ in $\mathcal{D}(S|_{\mathcal{H}})$, because then exponential stability of A also guarantees the existence and uniqueness of $\Pi_1 \in \mathcal{L}(\mathcal{H}, Z)$ such that $\Pi_1 S|_{\mathcal{H}} = A\Pi_1 + P_1 - B\Gamma\Pi_3$ in $\mathcal{D}(S|_{\mathcal{H}})$.

Let $\Delta = P_3 - LC\Pi_2 \in \mathcal{L}(\mathcal{G})$. Recall that (ϕ_n) is an orthonormal basis for $\mathcal{G}$. By Lemmas 4.2 and 4.3, $S|_{\mathcal{H}}\phi_n = S|_{\mathcal{G}}\phi_n = i\omega_n\phi_n$ for every $n \in \mathbb{Z}$ and $\sigma(S|_{\mathcal{G}} + L\delta_0) \cap i\mathbb{R} = \emptyset$. Hence we have for each $n \in \mathbb{Z}$ that $\Pi_3 S|_{\mathcal{H}}\phi_n = (S|_{\mathcal{G}} + L\delta_0)\Pi_3\phi_n + \Delta\phi_n$ if and only if $\Pi_3\phi_n = R(i\omega_n, S|_{\mathcal{G}} + L\delta_0)\Delta\phi_n$. Define the linear operator $\Pi_3 : \mathcal{D}(\Pi_3) \subset \mathcal{G} \to \mathcal{G}$ by

$$\Pi_3 f = \sum_{n \in \mathbb{Z}} \langle f, \phi_n \rangle R(i\omega_n, S|_{\mathcal{G}} + L\delta_0)\Delta\phi_n \quad \forall f \in \mathcal{D}(\Pi_3) = \mathcal{H}. \tag{4.17}$$

Now for some $C', k > 0$, and every $f \in \mathcal{H}$ we have by the Schwartz inequality and Lemma 4.3 that

$$\|\Pi_3 f\|_{\mathcal{G}} \le \sum_{n\in\mathbb{Z}} |\langle f, \phi_n\rangle| \|R(i\omega_n, S|_{\mathcal{G}} + L\delta_0)\|_{\mathcal{L}(\mathcal{G})} \|\Delta\|_{\mathcal{L}(\mathcal{G})} \|\phi_n\|_{\mathcal{G}} \tag{4.18}$$

$$= \|\Delta\|_{\mathcal{L}(\mathcal{G})} \sum_{n\in\mathbb{Z}} |\hat{f}_n| \Big(\sqrt{1+\omega_n^2}\Big)^{\alpha} \|R(i\omega_n, S|_{\mathcal{G}} + L\delta_0)\|_{\mathcal{L}(\mathcal{G})} \tag{4.19}$$

$$\le C' \|\Delta\|_{\mathcal{L}(\mathcal{G})} \sum_{n\in\mathbb{Z}} |\hat{f}_n| \Big(\sqrt{1+\omega_n^2}\Big)^{\alpha} \Big(\sqrt{1+\omega_n^2}\Big)^{\gamma} \tag{4.20}$$

$$\le C' \|\Delta\|_{\mathcal{L}(\mathcal{G})} \sqrt{\sum_{n\in\mathbb{Z}} |\hat{f}_n|^2 (1+\omega_n^2)^{\beta}} \sqrt{\sum_{n\in\mathbb{Z}} \frac{(1+\omega_n^2)^{\gamma+\alpha}}{(1+\omega_n^2)^{\beta}}} < k\|f\|_{\mathcal{H}}, \tag{4.21}$$

whence $\Pi_3 \in \mathcal{L}(\mathcal{H}, \mathcal{G})$. Using the closedness of $S|_{\mathcal{G}} + L\delta_0$ and arguments similar to the above it is straightforward to show that $\Pi_3(\mathcal{D}(S|_{\mathcal{H}})) \subset \mathcal{D}(S|_{\mathcal{G}} + L\delta_0)$ and that $\Pi_3 S|_{\mathcal{H}} f = (S|_{\mathcal{G}} + L\delta_0)\Pi_3 f + (P_3 - LC\Pi_2)f$ for each $f \in \mathcal{D}(S|_{\mathcal{H}})$.

By the above, the equation $\Pi S|_{\mathcal{H}} = \widetilde{\mathcal{A}}\Pi + \mathcal{P}$ in $\mathcal{D}(S|_{\mathcal{H}})$ has a solution for every $\mathcal{P} \in \mathcal{L}(\mathcal{G}, Z \times Z \times \mathcal{G})$. But then also the equation $\Pi S|_{\mathcal{H}} = \mathcal{A}\Pi + \mathcal{P}$ in $\mathcal{D}(S|_{\mathcal{H}})$ has a solution for every such $\mathcal{P}$, because $\widetilde{\mathcal{A}} = U\mathcal{A}U$ and U is boundedly invertible. Now for each $P \in \mathcal{L}(\mathcal{G}, Z) \subset \mathcal{L}(\mathcal{H}, Z)$ and $Q \in \mathcal{L}(\mathcal{G}, \mathbb{C}) \subset \mathcal{L}(\mathcal{H}, \mathbb{C})$ we have $\mathcal{P} = \left(\begin{smallmatrix} P \\ -GQ \end{smallmatrix}\right) \in \mathcal{L}(\mathcal{G}, Z \times X)$, and so condition 1 in Theorem 3.2 is satisfied for $\mathcal{A}^p = \mathcal{A}$.

In order to be able to apply Theorem 3.2, we still need to verify that the controller has the internal model structure. This is easy to do by mimicking the proof of Theorem 3.4 together with property 3 in Lemma 4.3. □

Remark 4.7. It is crucial in the above proof that we appeal only to Theorem 3.2 to achieve output regulation if the closed loop system contains a copy of the exogenous system operator, which is stabilized on a larger space $\mathcal{G} = H^{\alpha}_{per}(0, p)$ than the space $\mathcal{H} = H^{\beta}_{per}(0, p)$ on which we require output regulation. This peculiarity is purely a consequence of the lack of exponential closed loop stability.

Remark 4.8. It has been shown in [24] that the solvability of the regulator equations (4.12) is a necessary and sufficient condition for the existence of a simpler feedforward controller achieving output regulation in the disturbance-free case. The results of [21, 24] also immediately show that under the assumptions of this section and under the assumption that the plant does not have transmission zeros on $\sigma(S|_{\mathcal{G}})$ the regulator equations (4.12) have solutions $\Pi \in \mathcal{L}(\mathcal{G}, Z)$ and $\Gamma \in \mathcal{L}(\mathcal{G}, \mathbb{C})$ if and only if the periodic signals in $\mathcal{G}$ are smooth enough to satisfy $\sum_{n\in\mathbb{Z}} |H(i\omega_n)|^{-2}(1 + \omega_n^2)^{-\alpha} < \infty$. Explicit solutions of the regulator equations (4.12) for this case have been constructed in [24]; see also Example 4.10.

Remark 4.9. It is easy to see from the above proof that for each $\mathcal{P} \in \mathcal{L}(\mathcal{G}, Z \times X)$ the solution of $\Pi S|_{\mathcal{H}} = \mathcal{A}\Pi + \mathcal{P}$ in $\mathcal{D}(S|_{\mathcal{H}})$ is actually unique. Based on the arguments in Theorem 3.2 we suspect that the above controller also possesses a degree of conditional robustness with respect to some perturbations in the parameters of the plant and the controller. However, we cannot conclude conditional robustness directly using Theorem 3.2. This is because $0 \in \overline{\sigma(S|_{\mathcal{G}} + L\delta_0) - \sigma(S|_{\mathcal{H}})}$, which, by [2], implies that the equation $\Pi_3 S|_{\mathcal{H}} = (S|_{\mathcal{G}} + L\delta_0)\Pi_3 + \Delta$ in $\mathcal{D}(S|_{\mathcal{H}})$ does not have a unique solution for each $\Delta \in \mathcal{L}(\mathcal{H}, \mathcal{G})$. Hence we can solve only the equation $\Pi S|_{\mathcal{H}} = \mathcal{A}\Pi + \mathcal{P}$ for $\mathcal{P} \in \mathcal{L}(\mathcal{G}, Z \times X) \subset \mathcal{L}(\mathcal{H}, Z \times X)$.

We conclude this section with an example which illustrates the use of Theorem 4.6.

Example 4.10. Let $a > 0$, $r \neq 0$, $\tau_1 > \tau_2 > 0$, and consider the scalar delay

differential equation

$$\dot{x}(t) = -ax(t) - b\big[x(t-\tau_1) + x(t-\tau_2)\big] + u(t) + \mathcal{U}_{dist}(t), \tag{4.22a}$$

$$y(t) = rx(t), \quad t \geq 0, \tag{4.22b}$$

which was also studied in [22, 24] for possibly nonrobust controllers. As in [22, 24], our aim here is to study asymptotic tracking of reference signals in the Sobolev spaces $\mathcal{H} = H^\beta_{per}(0,p)$ for some $p > 0$ and $\beta > \frac{1}{2}$. However, here we can utilize Theorem 4.6 to also obtain a degree of conditional robustness for large enough values of β, i.e., for sufficiently smooth reference signals.

Taking into account initial conditions for $x(\cdot)$, the pair (4.22) can be formulated as a plant of the form (2.1) in which $D = 0$ [8]. Moreover, it can be shown (see, e.g., [8, Lem. 4.3.9]) that the transfer function $H(s) = CR(s,A)B$ of this plant is given by

$$H(s) = \frac{r}{s + a + b(e^{-s\tau_1} + e^{-s\tau_2})} \tag{4.23}$$

for those $s \in \mathbb{C}$ at which the denominator is not equal to zero.

The semigroup generated by A is exponentially stable if and only if $s+a+b(e^{-s\tau_1} + e^{-s\tau_2}) \neq 0$ for all $s \in \{\, z \in \mathbb{C} \mid \Re(z) \geq 0 \,\}$ [8, Thm. 5.1.7]. Ruan and Wei [33] have given a complete characterization (in terms of a, b, τ_1, and τ_2) of those instances in which all roots of equation $s + a + b(e^{-s\tau_1} + e^{-s\tau_2}) = 0$ have negative real parts. In their characterization, the parameter b lies on an interval (b_0^-, b_0^+). We assume that the semigroup generated by A is exponentially stable. By the above discussion, we then have $i\omega_n = i\frac{2\pi n}{p} \in \rho(A)$ and $H(i\omega_n) \neq 0$ for every $n \in \mathbb{Z}$.

Let $\mathcal{G} = H^\alpha_{per}(0,p)$ for $\alpha = \frac{5}{3}$ (we need $\alpha > \frac{3}{2}$ by the results of [24]). We can now easily solve the feedforward regulator equations (4.12) for $\Pi \in \mathcal{L}(\mathcal{G}, Z)$ and $\Gamma \in \mathcal{L}(\mathcal{G}, \mathbb{C})$ using the method of [24]. In fact, clearly $\sum_{n=-\infty}^{\infty} |H(i\omega_n)^{-1}|^2(1+\omega_n^2)^{-\alpha} < \infty$. Then by the Schwartz inequality, exponential stability of A, and the Riemann–Lebesgue lemma (cf. [24]) the following operators are in $\mathcal{L}(\mathcal{G}, \mathbb{C})$ and $\mathcal{L}(\mathcal{G}, Z)$, respectively:

$$\Gamma y = \sum_{n\in\mathbb{Z}} y_n \frac{\delta_0 \phi_n}{H(i\omega_n)} = \sum_{n\in\mathbb{Z}} \frac{\hat{y}_n}{H(i\omega_n)} \quad \forall y \in \mathcal{G}, \tag{4.24}$$

$$\Pi y = \sum_{n\in\mathbb{Z}} y_n R(i\omega_n, A)B\Gamma\phi_n = \sum_{n\in\mathbb{Z}} \hat{y}_n \frac{R(i\omega_n, A)B}{H(i\omega_n)} \quad \forall y \in \mathcal{G}. \tag{4.25}$$

Here $(\phi_n)_{n\in\mathbb{Z}}$ is the natural orthonormal basis of weighted exponentials for $\mathcal{G}$, y_n is the nth Fourier coefficient of $y \in \mathcal{G}$ with respect to this basis, and $\hat{y}_n$ is the nth L^2-Fourier coefficient of y (recall that $\sum_{n=-\infty}^{\infty} |\hat{y}_n|^2(1+\omega_n^2)^\alpha < \infty$). It is straight-forward to verify using the unique Fourier series description of the elements in $\mathcal{G}$ that these two operators Π and Γ also satisfy the regulator equations (4.12) (see [24] for more details).

Let the stabilizing operator L be as in Lemma 4.3 for $\gamma = \alpha+1$. Then by Theorem 4.6 the dynamic type I controller (2.3) with $X = Z \times \mathcal{G}$ and with parameters

$$F = \begin{pmatrix} A & B\Gamma \\ -LC & S|_{\mathcal{G}} + L\delta_0 \end{pmatrix}, \quad J = \begin{pmatrix} 0 & \Gamma \end{pmatrix}, \quad \text{and} \quad G = \begin{pmatrix} 0 \\ L \end{pmatrix} \tag{4.26}$$

achieves the asymptotic tracking of all reference signals in $\mathcal{H} = H^\beta_{per}(0,p)$ for (say) $\beta > 5$ (take $Q = \delta_0 \in \mathcal{L}(\mathcal{H}, \mathbb{C}) \cap \mathcal{L}(\mathcal{G}, \mathbb{C})$ in Theorem 4.6 and argue as in subsection

2.2 to see this). Moreover, here we simultaneously also achieve rejection of possibly unknown (i.e., P need not be known) p-periodic disturbances, whereas only tracking was achieved in [22].

5. Conclusions and future work. In this paper we showed that two controller types encountered frequently in practice achieve conditionally robust output regulation by employing the so-called internal model structure, a concept introduced recently in another paper. Our results are valid also for infinite-dimensional plants, controllers, and exogenous systems, and we have presented an example of such a general situation, namely, repetitive control of an exponentially stable SISO plant. The general conditional robustness theory for the two controller types is new for infinite-dimensional systems, but it also unifies and simplifies the treatment of these controllers in the finite-dimensional case.

We have restricted our attention to the case in which the plant has bounded control and observation operators. In the future it would be interesting to see if the results of this paper can also be generalized for unbounded control and observation operators in the plant. This would allow for boundary control and observation. On the other hand, it is well known that unbounded feedback can yield better stabilizability than bounded feedback; in particular, it is sometimes possible to uniformly shift an infinite number of eigenvalues from the imaginary axis to the open left half plane. Consequently, by allowing for unbounded control/observation operators also in the controller it might be possible to obtain better closed loop stability properties and thus better robustness properties. This would be especially useful in repetitive control, where exponential stabilization of the closed loop system using only compact feedback operators is impossible. Other interesting directions for future research include unbounded perturbations in the system parameters, and quantitative robustness analysis describing how small the perturbations must be in order to guarantee conditionally robust output regulation.

Acknowledgments. The author is indebted to Prof. Seppo Pohjolainen and Dr. Timo Hämäläinen for numerous helpful discussions concerning this article. The author also thanks the anonymous referees for their constructive criticism and useful suggestions for improving the paper.

WEIGHTED ADMISSIBILITY AND WELLPOSEDNESS OF LINEAR SYSTEMS IN BANACH SPACES*

BERNHARD H. HAAK† AND PEER CHR. KUNSTMANN†

Abstract. We study linear control systems in infinite-dimensional Banach spaces governed by analytic semigroups. For $p \in [1, \infty]$ and $\alpha \in \mathbb{R}$ we introduce the notion of L^p-admissibility of type α for unbounded observation and control operators. Generalizing earlier work by Le Merdy [*J. London Math. Soc.* (2), 67 (2003), pp. 715–738] and Haak and Le Merdy [*Houston J. Math.*, 31 (2005), pp. 1153–1167], we give conditions under which L^p-admissibility of type α is characterized by boundedness conditions which are similar to those in the well-known Weiss conjecture. We also study L^p-wellposedness of type α for the full system. Here we use recent ideas due to Prüss and Simonett [*Arch. Math. (Basel)*, 82 (2004), pp. 415–431]. Our results are illustrated by a controlled heat equation with boundary control and boundary observation where we take Lebesgue and Besov spaces as state space. This extends the considerations in [C. I. Byrnes et al., *J. Dynam. Control Systems*, 8 (2002), pp. 341–370] to non-Hilbertian settings and to $p \neq 2$.

Key words. control theory, linear systems, admissibility, H^∞-calculus, square-function estimates

1. Introduction and main theorems.

We are concerned with linear control systems of the form

$$\left\{ \begin{array}{lcll} x'(t) + Ax(t) & = & Bu(t) & (t > 0), \\ x(0) & = & x_0, & \\ y(t) & = & Cx(t) & (t > 0), \end{array} \right. \tag{1.1}$$

where $-A$ is the generator of a strongly continuous semigroup $(T(\cdot))$ in a Banach space X. The function $x(\cdot)$ takes values in X, and the functions $u(\cdot)$ and $y(\cdot)$ take values in Banach spaces U and Y, respectively. The control operator B is an unbounded operator from U to X, and the observation operator C is an unbounded operator from X to Y. We refer, e.g., to [25, 28, 32, 31].

A commonly used minimal assumption on B and C is that C is bounded $X_1(A) \to Y$ and B is bounded $U \to X_{-1}(A)$, where $X_1(A)$ denotes the domain $D(A)$ of A equipped with the graph norm, and $X_{-1}(A)$ denotes the completion of $(X, \|R(\lambda_0, A)\cdot\|_X)$ with λ_0 in the resolvent set $\rho(A)$ of A (cf., e.g., [9, sect. II.5]). Note that for $\lambda_0 \in \rho(A)$, the norm $\|(\lambda_0 - A)\cdot\|_X$ on $X_1(A)$ is equivalent to the graph norm of A. The semigroup $T(\cdot)$ has an extension to a strongly continuous semigroup $T_{-1}(\cdot)$ on $X_{-1} := X_{-1}(A)$ whose generator A_{-1} is an extension of A (cf. [9, sect. II.5]). These extensions are needed to give a precise meaning to compositions involving the operator B.

Now let $\mathcal{X} := C([0, \infty), X)$ and, for each $\tau > 0$, $\mathcal{X}_\tau = C([0, \tau], X)$. Suppose that we are given spaces $\mathcal{Y}$ of functions $\mathbb{R}_+ \to Y$ and $\mathcal{U}$ of functions $\mathbb{R}_+ \to U$ with restrictions $\mathcal{Y}_\tau$, $\mathcal{U}_\tau$ to $[0, \tau]$, $\tau > 0$, respectively. Then the system (1.1) is called

†Mathematisches Institut I, Universität Karlsruhe, Englerstraße 2, 76128 Karlsruhe, Germany (Bernhard.Haak@math.uni-karlsruhe.de, Peer.Kunstmann@math.uni-karlsruhe.de).

wellposed if, for each $\tau > 0$, state and output of the system (1.1) depend continuously on initial state and input, i.e., if the mapping

$$X \times \mathcal{U}_\tau \to X \times \mathcal{Y}_\tau, \quad (x_0, u(\cdot)) \mapsto (x(\tau), y(\cdot))$$

is continuous. Since for $t > 0$ the solution to (1.1) has the (formal) representation

$$\big(x(t), y(t)\big) = \left(T(t)x_0 + \int_0^t T(s)Bu(t-s)\,ds,\ CT(t)x_0 + C\int_0^t T(s)Bu(t-s)\,ds \right),$$

and $T(\cdot)$ is strongly continuous, this means continuity of the three maps

$$\Psi_\tau : \begin{cases} X \to \mathcal{Y}_\tau, \\ x_0 \mapsto CT(\cdot)x_0, \end{cases} \quad \Phi_\tau : \begin{cases} \mathcal{U}_\tau \to X, \\ u \mapsto T_{-1}(\cdot)B * u, \end{cases} \quad \text{and} \quad \mathcal{F}_\tau : \begin{cases} \mathcal{U}_\tau \to \mathcal{Y}_\tau, \\ u \mapsto CT_{-1}(\cdot)B * u, \end{cases}$$

where $*$ denotes convolution. Requiring continuity of these maps leads to the notions of *admissibility* for the observation operator C, for the control operator B, respectively, and the notion of *wellposedness* for the input-output map $\mathcal{F}_\tau$ of system (1.1).

In case of uniformly exponentially stable semigroups and $\mathcal{Y}_\tau = L^p([0,\tau], Y)$ and $\mathcal{U}_\tau = L^p([0,\tau], U)$, one may also consider wellposedness on $\mathbb{R}_+ = (0,\infty)$, i.e., the spaces $\mathcal{Y} = L^p(\mathbb{R}_+, Y)$ and $\mathcal{U} = L^p(\mathbb{R}_+, U)$ and continuity of the maps

$$\Psi : \begin{cases} X \to \mathcal{Y}, \\ x_0 \mapsto CT(\cdot)x_0, \end{cases} \quad \Phi : \begin{cases} \mathcal{U}_\tau \to X, \\ u \mapsto \displaystyle\int_0^\infty T_{-1}(t)Bu(t)\,dt, \end{cases} \quad \text{and} \quad \mathcal{F} : \begin{cases} \mathcal{U} \to \mathcal{Y}, \\ u \mapsto CT_{-1}(\cdot)B * u. \end{cases}$$

Notice that in the second mapping the convolution is replaced by an integration of the semigroup against the right-hand side (cf. [31] and Remark 1.4).

If X, Y, and U are Hilbert spaces, it is natural to take $\mathcal{Y} = L^2(\mathbb{R}_+, Y)$ and $\mathcal{U} = L^2(\mathbb{R}_+, U)$ (cf. [15, 31, 32]). In the Banach space case one can consider $\mathcal{Y} = L^p(\mathbb{R}_+, Y)$ and $\mathcal{U} = L^p(\mathbb{R}_+, U)$, where $p \in [1,\infty]$ (cf. [8, 15, 27, 31]). For the case $p = 2$, the notion of *α-admissibility* for observation and control operators was introduced in [12] meaning that the L^2-space on $\mathbb{R}_+$ with values in Y or U, respectively, is taken with respect to a polynomial weight on $\mathbb{R}_+$. In this paper, we will extend that notion for observation operators from L^2-norms to L^p-norms with $p \in [1,\infty]$. For control operators our definition differs from that given in [12] (cf. Remarks 1.2 and 1.4). Furthermore, we will introduce and study the new notion of *L^p-wellposedness of type α* for the system (1.1). For a short discussion on our motivation we refer to Theorem 1.16 and Remark 1.18.

The main basic question in modeling a given system in order to obtain a wellposed system of the form (1.1) is, of course, how to check for admissibility of the operators C and B and the wellposedness of the input-output map $\mathcal{F}$. For Hilbert spaces X, Y, U, the well-known *Weiss conjecture* (cf. [15, 33]) relates L^2-admissibility on $\mathbb{R}_+$ of C and B to boundedness of

$$W_C := \{\lambda^{1/2} C(\lambda + A)^{-1} :\ \lambda > 0\} \subseteq B(X, Y) \qquad \text{and}$$
$$W_B := \{\lambda^{1/2} (\lambda + A_{-1})^{-1} B :\ \lambda > 0\} \subseteq B(U, X),$$

respectively. Assuming that $T(\cdot)$ is bounded analytic and that $A^{1/2}$ is L^2-admissible for A, boundedness of W_C actually characterizes L^2-admissibility of C. (See [20] for this result and a detailed discussion of the Weiss conjecture.) In [12], this characterization was extended to cover the case of L^2-admissibility of type α for a certain range of α.

For $\omega \in (0,\pi)$, let $S(\omega) := \{z \in \mathbb{C}\setminus\{0\} : |\arg z| < \omega\}$ and let $S(0) := (0,\infty)$. We recall that a *sectorial operator A of type* $\omega \in [0,\pi)$ in a Banach space X is a closed linear operator A satisfying $\sigma(A) \subseteq \overline{S(\omega)}$ and, for any $\nu \in (\omega,\pi)$,

$$\sup\{\|\lambda R(\lambda,A)\| : |\arg\lambda| \geq \nu\} < \infty.$$

Observe that $-A$ generates a bounded analytic semigroup in X if and only if A is a densely defined sectorial operator in X of type $< \pi/2$. Moreover, we recall that a sectorial operator with dense range is actually injective (cf. [22, Thm. 3.8]). Occasionally we shall use fractional powers of sectorial operators or their functional calculus. We refer to, e.g., [13, 19, 21].

L^p-admissibility of type α. In this paper, we assume that A is a densely defined sectorial operator of type $< \pi/2$ with dense range, and we characterize L^p–admissibility of type α for observation and control operators, the range of values of α depending on $p \in [1,\infty]$. For a fixed $p \in [1,\infty]$ we denote by p' the dual exponent given by $1/p + 1/p' = 1$. To formulate our first definition we introduce, for any $k \in \mathbb{N}$ and a given generator $-A$ of a bounded strongly continuous semigroup $T(\cdot)$ in X, the spaces $X_k := X_k(A)$, which are $\mathcal{D}(A^k)$ equipped with the norm $\|(\mathrm{Id}+A)^k\cdot\|_X$, and $X_{-k} := X_{-k}(A)$, which is the completion of X with respect to the norm $\|(\mathrm{Id}+A)^{-k}\cdot\|_X$. Observe that $1 \in \rho(-A)$ and that replacing $\mathrm{Id}+A$ by $\lambda_0 + A$ in these expressions leads to equivalent norms whenever $\lambda_0 \in \rho(-A)$ (again, we refer to [9, sect. II.5]). The semigroup $T(\cdot)$ has an extension to a bounded strongly continuous semigroup $T_{-k}(\cdot)$ on X_{-k} whose generator A_{-k} is an extension of the operator A.

We denote, for $\alpha \in \mathbb{R}$ and intervals $I \subseteq \mathbb{R}_+$,

$$L^p_\alpha(I,X) := \big\{f : I \to X :\ t \mapsto t^\alpha f(t) \in L^p(I,X)\big\}.$$

The space $L^p_\alpha(\mathbb{R}_+,X)$ is abbreviated $L^p_\alpha(X)$.

Definition 1.1. *Let X,U,Y be Banach spaces and for some $k \in \mathbb{N}$ let $C \in B(X_k,Y)$ and $B \in B(U,X_{-k})$. Given $p \in [1,\infty]$ and a bounded analytic semigroup $T(\cdot)$ on X,*

(a) *C is called* finite-time L^p-admissible of type $\alpha > -1/p$ *if for any $\tau > 0$ there is a constant $M_\tau > 0$ such that for all $x \in X_k$ we have*

$$\big\|t \mapsto CT(t)x\big\|_{L^p_\alpha([0,\tau],Y)} \leq M_\tau \|x\|_X; \tag{1.2}$$

(b) *B is called* finite-time L^p-admissible of type $\alpha < 1/p'$ *(or $\alpha \leq 0$ for $p = 1$) if for any $\tau > 0$ there is a constant $K_\tau > 0$ such that for all $u \in L^p_\alpha((0,\tau),U)$ we have*

$$\big\|T_{-k}B * u\big\|_{L^\infty((0,\tau),X)} \leq K_\tau \|u\|_{L^p_\alpha((0,\tau),U)}. \tag{1.3}$$

If the above estimates hold with constants M_τ and K_τ that can be chosen independently of $\tau > 0$, the operators B and C are called (infinite-time) L^p-admissible of type α.

Remark 1.2. In part (b) of the definition, inequality (1.3) means the estimate $\operatorname{ess\,sup}_{t\in(0,\tau)} \|\Phi_t(u)\|_X \leq K_\tau \|u\|_{L^p_\alpha((0,\tau),U)}$. This seems to be better suited when dealing with weighted spaces than requiring just $\|\Phi_\tau(u)\|_X \leq K_\tau \|u\|_{L^p_\alpha((0,\tau),U)}$.

Notice that our definition differs from that in [12]: for observation operators, L^2-admissibility of type α is called 2α-admissibility there. For control operators, our definition is different from the notion studied in [12]. This is due to the application

to nonlinear problems in Theorem 1.16. See also Remark 1.4 for a study of both notions.

LEMMA 1.3. *The notion of finite-time L^p-admissibility of type α for A is independent of the underlying interval $[0,\tau]$ in the definition.*

If the semigroup is uniformly exponentially stable and $\alpha \geq 0$ or $p = \infty$, finite-time L^p-admissibility of type α for control operators is equivalent to (infinite-time) L^p-admissibility of type α. For observation operators this is true for all α. Moreover, an observation operator C is (infinite-time) L^p-admissible of type α of A if and only if

$$\left(\int_0^\infty \|t^\alpha CT(t)x\|^p \, dt\right)^{1/p} \leq M_{\tau,\alpha}\|x\| \tag{1.4}$$

holds.

Notice that the requirement $\alpha \geq 0$ or $p = \infty$ in the above equivalence assertion for control operators is necessary. We provide a short counterexample in case $\alpha < 0$ in Example 3.1.

Remark 1.4 (dualization). Let X, Y be reflexive Banach spaces and $p \in (1,\infty)$ and assume that $C \in B(X_1, Y)$ is L^p-admissible of type α for A on $\mathbb{R}_+$. Then, for $u \in L^{p'}_{-\alpha}(\mathbb{R}_+, Y')$,

$$\begin{aligned}\big\langle t \mapsto CT(t)x, u\big\rangle_{L^p_\alpha \times L^{p'}_{-\alpha}} &= \int_0^\infty \big\langle t^\alpha CT(t)x, t^{-\alpha}u(t)\big\rangle_{Y\times Y'} \, dt \\ &= \left\langle x \int_0^\infty T(t)'C'u(t)\, dt X \times X' \right\rangle.\end{aligned}$$

One can therefore consider the following dual condition to (1.4), which was introduced in [12]:

$$\left\| \int_0^\infty T(t)Bu(t)\, dt \right\|_X \leq K\|u\|_{L^p_{-\alpha}(\mathbb{R}_+,U)}, \tag{1.5}$$

where the integral is considered as a Pettis integral in X_{-k} taking values in X. Notice that in case $\alpha \neq 0$ the reflection $R_\tau u = u(\tau - \cdot)$ is not bounded on $L^p_\alpha([0,\tau])$. Therefore, one cannot hope that (1.5) might be equivalent to infinite-time L^p-admissibility of type α unless $\alpha = 0$. We shall see in Theorem 1.8 that condition (1.5) is indeed a stronger notion than L^p-admissibility of type α. However, for $\alpha > 0$, L^p-admissibility of an observation operator C *implies* L^p-admissibility of C' on X' by Theorem 1.8.

L^p_*-estimates and the real interpolation method. As mentioned above, the crucial condition in [20] (besides $T(\cdot)$ being bounded and analytic) for the Weiss conjecture to hold was that $A^{1/2}$ is admissible for A, i.e., the existence of a constant $L > 0$ such that

$$\int_0^\infty \big\|A^{1/2}T(t)x\big\|^2 \, dt = \int_0^\infty \big\|(tA)^{1/2}T(t)x\big\|^2 \, \tfrac{dt}{t} = \big\|\psi(tA)x\big\|^2_{L^2(\mathbb{R}_+,dt/t,X)} \leq L\|x\|^2_X,$$

where $\psi(z) = z^{1/2}e^{-z}$. In our situation this corresponds to

$$\begin{aligned}\int_0^\infty \big\|t^\alpha A^{\alpha+1/p}T(t)x\big\|^p \, dt &= \int_0^\infty \big\|(tA)^{\alpha+1/p}T(t)x\big\|^p \, \tfrac{dt}{t} \\ &= \big\|\psi(tA)x\big\|^p_{L^p(\mathbb{R}_+,dt/t,X)} \leq \widetilde{L}\|x\|^p_X\end{aligned} \tag{1.6}$$

for $\psi(z) = z^{\alpha+1/p}\exp(-z)$. We denote $L^p_*(\mathbb{R}_+, X) := L^p(\mathbb{R}_+, dt/t, X)$. It is known that the property of a sectorial operator A of type ω on a Banach space X to satisfy an estimate $\|\psi(\cdot A)x\|_{L^p_*(\mathbb{R}_+,Y)} \le L\|x\|_X$ does not depend upon the particular choice of the function $\psi \in H^\infty_0(S(\nu))\backslash\{0\}$, $\nu > \omega$, where

$$H^\infty_0(S(\nu)) = \big\{ f \in H^\infty(S(\nu)) :\ \exists c, s > 0 :\ \big|f(z)\big| \le c\,\tfrac{|z|^s}{1+|z|^{2s}} \big\};$$

see [22, Thm. 5], [2, Thm. 4.1], [14, Thm. 4.3], or [13, Thm. 6.4.3]. Therefore, we say that A *satisfies* L^p_**-estimates on* X if (1.6) holds.

Let A be a densely defined sectorial operator of type ω with dense range on X. Let $\mathbb{X} := (X, \|A(I+A)^{-2}\cdot\|)^\sim$. For some holomorphic function ψ on $S(\nu)$, $\nu > \omega$ and $\theta \in (-1, 1)$ such that $z^{-\theta}\psi(z) \in H^\infty_0(S(\nu))\backslash\{0\}$ consider the space

$$X_{\theta,\psi,p} := \big\{ x \in \mathbb{X} :\ t^{-\theta}\psi(tA)x \in L^p_*(\mathbb{R}_+, X) \big\}.$$

Since $X_{\theta,\psi,p}$ does not depend on $\psi \in H^\infty_0(S(\nu))\backslash\{0\}$ (see above), we write for short $X_{\theta,p} := X_{\theta,\psi,p}$. Resorting to the space $\mathbb{X}$ in this setting allows explicitly that $X_{\theta,p}$ may be a larger space than X. For the background of this construction we refer, e.g., to [18], [11, sect. 2] or [13, Chap. 6.3]. Notice that in this terminology L^p_*-estimates for A read as $X \hookrightarrow X_{0,p}$. These spaces are strongly connected to real interpolation spaces between the homogeneous spaces $\dot X_{-1}$ and $\dot X_1$. Here, for $\sigma \in \mathbb{Z}$, we denote by $\dot X_\sigma := \dot X_\sigma(A)$ the completion of the space $\mathcal{D}(A^\sigma)$ with respect to the homogeneous norm $\|A^\sigma\cdot\|_X$. We refer to [17], [19, sect. 15], [11], or [14] for more details on these spaces. Observe that—due to our assumptions—the space $\mathcal{D}(A^\sigma)$ is dense in X and that $\dot X_\sigma = X_\sigma$ in case $0 \in \rho(A)$. With these notations the following result holds true. (See [2] for the case $p = 2$ and [13, Thm. 6.4.6], [14, Thm. 5.2] for the general case.)

THEOREM 1.5. *Let X be a Banach space and A be a densely defined sectorial operator of type ω with dense range on X. Then*

$$\big(\dot X_{-1}(A), \dot X_1(A)\big)_{\theta,p} = X_{2\theta-1,p}$$

for all $\theta \in (0,1)$ and $p \in [1,\infty]$.

Remark 1.6. In the situation of the above theorem, A has L^p_*-estimates if and only if $X \hookrightarrow \big(\dot X_{-1}(A), \dot X_1(A)\big)_{1/2,p}$. This can be used to establish L^p_*-estimates for given operators in concrete cases, as we will show in section 2.

We start our main results with the following characterizations of L^p-admissibility of type α for observation and control operators that extend the results in [12].

THEOREM 1.7. *Let $p \in [1,\infty]$ and A be a densely defined sectorial operator of type $\omega < \pi/2$ with dense range on X. Let $C \in B(X_k, Y)$ be an observation operator for some $k \ge 1$. Let $\alpha \in (-1/p, k - 1/p)$ and consider the set*

$$W_C := \big\{ \lambda^{k-\alpha-1/p}\, C(\lambda + A)^{-k} :\ \lambda > 0 \big\} \subseteq B(X, Y). \tag{1.7}$$

Then the following assertions hold:

(a) *If C is L^p-admissible of type α for A, then W_C is bounded in $B(X,Y)$.*
(b) *If A satisfies L^p_*-estimates and W_C is bounded in $B(X,Y)$, then C is L^p-admissible of type α for A.*

Notice that for the operator $C := A^{\alpha+1/p}$, the set W_C in (1.7) is bounded, whence the assumption of L^p_*-estimates in the above characterization cannot be improved (cf. (1.6)).

THEOREM 1.8. *Let $p \in [1,\infty]$ and A be a densely defined sectorial operator of type $\omega < \pi/2$ with dense range on X. Let $B \in B(U, X_{-k})$ be a control operator for some $k \geq 1$ and let $\alpha \in (1/p' - k, 1/p')$ and consider the set*

$$W_B := \left\{ \lambda^{k+\alpha-1/p'} (\lambda + A_{-k})^{-k} B : \ \lambda > 0 \right\} \subseteq B(U, X). \tag{1.8}$$

Then the following assertions hold:

(a) *If B is L^p-admissible of type α for A, then W_B is bounded.*
(b) *If W_B is bounded and $\alpha > 0$ (for $p > 1$) or $\alpha = 0$ (for $p = 1$), then B is L^p-admissible of type α for A.*
(a)′ *If the dual condition* (1.5) *holds, then W_B is bounded.*
(b)′ *If $p < \infty$ and W_B is bounded and the adjoint operator A' satisfies $L^{p'}_*$-estimates, then* (1.5) *holds.*

As mentioned above, in case $\alpha = 0$, L^p-admissibility of type α and (1.5) are equivalent. In particular, a modified Weiss conjecture on control operators holds for $p = 1$.

Also the boundedness conditions on the sets W_C and W_B in (1.7) and (1.8) may be characterized by real interpolation methods. In fact, they are conditions on the *domain* of (a continuous extension of) the observation operator C and the *range* of the control operator B, respectively. This way of viewing the boundedness conditions on W_C and W_B, respectively, is not new for control operators (cf. [33]) under the supplementary assumption of $0 \in \varrho(A)$. The general equivalence for observation and control operators was first studied in [11]. The proof of the following is very similar to the arguments used there and is thus omitted.

THEOREM 1.9. *Let A be an injective sectorial operator on the Banach space X, and let $k \in \mathbb{N}$. Let $C \in B(X_k, Y)$ and $B \in B(U, X_{-k})$ be bounded operators, where U, Y are Banach spaces, and let $\theta \in (0,1)$. Then the following equivalences hold true:*

(a) $\sup_{0<\lambda<\infty} \|\lambda^{k\theta}(\lambda + A_{-k})^{-k} B\|_{U\to X} < \infty$ *if and only if $B : U \to X_{-k}$ is bounded in the norm $U \to (\dot{X}_{-k}, X)_{\theta,\infty}$.*
(b) $\sup_{0<\lambda<\infty} \|\lambda^{k(1-\theta)} C(\lambda + A)^{-k}\|_{X\to Y} < \infty$ *if and only if $C : X_k \to Y$ is bounded in the norm $(X, \dot{X}_k)_{\theta,1} \to Y$.*

Remark 1.10. Of course, if for some $k \in \mathbb{N}$, $C \in B(X_k, Y)$ and if the operators $\lambda^{k(1-?)} C(\lambda + A)^{-k}$, $\lambda > 0$, are uniformly bounded, then for any $n \in \mathbb{N}_0$, $C \in B(X_{k+n}, Y)$ the operators $\lambda^{n+k(1-?)} C(\lambda + A)^{-k-n}$, $\lambda > 0$, are uniformly bounded by the sectoriality of A. However, by reiteration (cf. [29, Thm. 1.10.2]),

$$\left(X, \dot{X}_k\right)_{\theta,1} = \left(X, \dot{X}_{k+n}\right)_{\sigma,1}$$

for $\sigma = \frac{n+k(1-\theta)}{k+n}$, whence the assertions of Theorem 1.9 do not depend on the question, for which $k \in \mathbb{N}$ the given boundedness conditions are satisfied. The same arguments apply to the conditions on control operators.

Wellposedness of the full system. We now study the full system (1.1) for $\mathcal{Y} = L^p_\alpha(\mathbb{R}_+, Y)$ and $\mathcal{U} = L^p_\alpha(\mathbb{R}_+, U)$.

DEFINITION 1.11. *Let X, U, Y be Banach spaces and let $k \in \mathbb{N}$, $p \in [1,\infty]$ and $\alpha \in (-1/p, 1/p')$. Let $T(\cdot)$ be a bounded analytic semigroup on X generated by $-A$. Then the system* (1.1) *is called L^p-*wellposed of type α *if $C \in B(X_k, Y)$ and $B \in B(U, X_{-k})$ are L^p-admissible of type α, and $\mathcal{F}^\alpha : L^p_\alpha(U) \to L^p_\alpha(Y)$, $\mathcal{F}^\alpha u = CT_{-k}(\cdot)B * u$ is bounded.*

If we have finite-time L^p-admissibility of type α of B and C on $I := [0,\tau]$ and if $\mathcal{F}^\alpha_\tau : L^p_\alpha(I, U) \to L^p_\alpha(I, Y)$ is bounded, we call the system *finite-time L^p-wellposed of*

type α. By resorting to $(e^{-\omega t}T(t))$ we may then assume $0 \in \varrho(A)$. The next lemma shows that the only possible singularity of the convolution kernel of $\mathcal{F}_\tau$ is at $t = 0$, whence the notion of finite-time L^p-wellposedness of type α does not depend on $\tau > 0$.

Notice that by analyticity of the semigroup $T(\cdot)$, we have $T_{-k}(t)X_{-k} \subseteq X_k$ for $t > 0$. Therefore the convolution kernel $CT_{-k}(\cdot)B$ of $\mathcal{F}^\alpha$ is a well-defined bounded operator from U to Y. (See the next lemma for norm estimates.) From Theorems 1.7, 1.8, and 1.9 we know that L^p-admissibility of type α of B and C yields $(X, \dot{X}_k)_{\theta,1} \hookrightarrow \mathcal{D}(C)$ and $\mathcal{R}(B) \subseteq (X, \dot{X}_{-k})_{\sigma,\infty}$ for $\theta = (\alpha + 1/p)/k$ and $\sigma = (1/p' - \alpha)/k$. Notice that $k(\sigma + \theta) = 1$. The next lemma is well known to specialists. We use it for $q = 1$ and $r = \infty$ and provide a proof in section 3.

LEMMA 1.12. *Let X be a Banach space and $T(\cdot)$ be a bounded analytic semigroup on X. Let $k \in \mathbb{N}$ and $\sigma, \theta \in (0,1)$ such that $k(\sigma + \theta) = 1$. Let $q, r \in [1, \infty]$ and $Z := (X, \dot{X}_k)_{\theta,q}$ and $W := (\dot{X}_{-k}, X)_{1-\sigma,r}$. Then, there exists a constant $M > 0$ such that $\|T(t)\|_{W \to Z} \le M/t$ for all $t > 0$.*

To sum up the above considerations: whenever C and B are L^p-admissible of type α, we have $\|CT(t)B\|_{U \to Y} \le M/t$ for $t > 0$ for some constant $M > 0$. A corresponding condition in the following theorem seems thus very natural.

THEOREM 1.13. *Let $p \in (1, \infty)$, $\alpha \in (-1/p, 1/p')$, and $k \in \mathbb{N}$. Let X, U, Y be Banach spaces and let $T(\cdot)$ be a bounded analytic semigroup on X, $C \in B(X_k, Y)$ and $B \in B(U, X_{-k})$ such that $\|CT(t)B\|_{U \to Y} \le M/t$. Then $\mathcal{F}^\alpha := CT(\cdot)B*$ is bounded $L^p_\alpha(U) \to L^p_\alpha(Y)$ if and only if $\mathcal{F} = \mathcal{F}^0$ is bounded $L^p(U) \to L^p(Y)$.*

The above theorem is basically a reformulation of [24, Thm. 2.4]. However, our proof also allows negative values of α. It relies on the following result.

PROPOSITION 1.14. *Let $p \in (1, \infty)$ and $\alpha < 1 - 1/p$. Let U, Y be Banach spaces and suppose that $K \in C(\mathbb{R}_+, B(U, Y))$ satisfies $\|K(t)\| \le M/t$ for some $M > 0$. Let*

$$(Tf)(t) := \int_0^t K(t-s)\left[\left(\frac{t}{s}\right)^\alpha - 1\right] f(s)\, ds, \qquad f \in L^p(\mathbb{R}_+, X).$$

Then $T \in B(L^p(\mathbb{R}_+, X), L^p(\mathbb{R}_+, Y))$ with norm bound cM where $c = c(p, \alpha)$.

We shortly discuss boundedness of $\mathcal{F}$ for $\alpha = 0$. Suppose that $C : Z \to Y$ and $B : U \to W$ are bounded, where Z and W are Banach spaces satisfying $X_1 \subseteq Z \subseteq X$ and $X \subseteq W \subseteq X_{-1}$. Suppose further that the restriction A_W of A_{-1} to W is sectorial with $\mathcal{D}(A_W) = Z$ (equivalent norms). Then $CT(\cdot)B* : L^p(U) \to L^p(Y)$ is bounded if $T(\cdot)* : L^p(W) \to L^p(Z)$ is bounded. But it is well known that the latter is equivalent to A_W having the property of *maximal L^p-regularity*. (We refer to [1, 6, 7, 19, 30] for this relation, the problem of maximal regularity, characterization results, and further references on the subject.) Thus we have obtained the next theorem.

THEOREM 1.15. *Let $p \in (1, \infty)$ and W be a Banach space $X \subseteq W \subseteq X_{-1}$ such that A_W has maximal L^p-regularity. Let $C : Z \to Y$ and $B : U \to W$ be bounded where Z denotes $\mathcal{D}(A_W)$ equipped with the graph norm. Then $\mathcal{F}^\alpha$ is bounded $L^p_\alpha(U) \to L^p_\alpha(Y)$ for any $\alpha \in (-1/p, 1/p')$.*

Our results can be used to establish existence and uniqueness of solutions to some nonlinear systems in feedback form. Let $p \in (1, \infty)$, let X, U, Y be Banach spaces, and let $x_0 \in X$. Let $F : X \to B(Y, U)$ be a Lipschitz-continuous operator-valued function, let A, B, C be linear operators such that $-A_0 := -(A - BF(x_0)C)$ generates an analytic semigroup $T(\cdot)$ in X and such that B and C are finite-time

L^p-admissible of type α for A_0. We consider the closed loop system

$$\left\{\begin{array}{lcl} x'(t)+Ax(t) &=& Bu(t),\\ x(0) &=& x_0,\\ y(t) &=& Cx(t),\\ u(t) &=& F(x(t))\,y(t) \end{array}\right. \tag{1.9}$$

on $[0,\tau]$, which we rewrite as

$$\left\{\begin{array}{lcll} x'(t)+A_0x(t) &=& B\big(F(x(t))-F(x_0)\big)\,Cx(t), & t\in[0,\tau],\\ x(0) &=& x_0. & \end{array}\right. \tag{1.10}$$

We are interested in mild solutions of (1.10), i.e., solutions of

$$x = T(\cdot)x_0 + T*B\big(F(x)-F(x_0)\big)\,Cx \quad \text{on } [0,\tau]. \tag{1.11}$$

The following result shall also be proved in section 3.

THEOREM 1.16. *Assume in addition to the preceding assumptions that $Z\hookrightarrow X$ is a Banach space such that the system corresponding to (A_0,B,Id_Z) is finite-time L^p-wellposed of type α and that $C\in B(Z,Y)$. Then there exists $\tau=\tau(x_0)>0$ such that* (1.9) *has a unique mild solution $x\in C([0,\tau],X)\cap L^p_\alpha([0,\tau],Z)$.*

Remark 1.17. The reason for introducing the space Z here is that $x\mapsto Cx$ may not induce a closed operator from $C([0,\tau],X)$ into $L^p_\alpha([0,\tau],Y)$. If C is closed as an operator from X to Y, then we can replace $C([0,\tau],X)\cap L^p_\alpha([0,\tau],Z)$ by $\{x\in C([0,\tau],X) : x(t)\in D(C) \text{ a.e., } Cx\in L^p_\alpha([0,\tau],Y)\}$ in the assertion, and the assumption on the space Z is not needed.

Remark 1.18. Our results on L^p-admissibility of type α and L^p-wellposedness of type α give more flexibility in the choice of Banach spaces X, U, and Y for the modeling of a given problem. This is important for the study of nonlinear systems via fixed point arguments, e.g., via Theorem 1.16, where an appropriate choice of α allows us to choose state spaces X as function spaces with little regularity (cf. also [24, Rem. 3.3(b)]). For the example of the controlled heat equation that we study in section 2 we refer to Remarks 2.11 and 2.12, where we describe how to obtain state spaces with negative smoothness index by suitable choices of α. In Example 2.14 we give an application of Theorem 1.16 in a nonlinear feedback situation. We mention in this context that Besov spaces of negative order have become relevant as spaces for initial values in the study of other nonlinear partial differential problems, e.g., Navier–Stokes equations (cf. [5]).

In the next section we provide examples and applications of our results. In section 3 we give proofs of the results presented so far.

2. Example: A controlled heat equation. In this section we illustrate our results with a controlled heat equation. In [4], the problem was studied in the state space $X=L^2(\Omega)$ and for $\alpha=0$. Below we discuss Lebesgue and Besov spaces.

Let $\Omega\subset\mathbb{R}^n$ be a bounded domain with boundary $\partial\Omega\in C^\infty$. Denote the outer normal unit vector on $\partial\Omega$ by $\nu:\partial\Omega\to\mathbb{R}^n$. We consider the problem

$$\left\{\begin{array}{lcl} x'(t)-\Delta x(t) &=& 0 \quad (t>0),\\ \frac{\partial x(t)}{\partial\nu}\big|_{\partial\Omega} &=& u(t) \quad (t>0),\\ x(0) &=& x_0,\\ y(t) &=& x(t)\big|_{\partial\Omega} \quad (t>0), \end{array}\right. \tag{2.1}$$

where $x(\cdot)$ takes values in some function space X. The functions $u(\cdot)$ and $y(\cdot)$ take values in function spaces on the boundary. For the modeling we follow closely [4] and set $A := -\Delta$ with Neumann boundary condition. In the state spaces we shall consider below, the operator A is sectorial of type 0, but not injective. We aim for finite-time L^c-admissibility of type γ for observation operators and finite-time L^b-admissibility of type β for control operators, where $b, c \in [1, \infty]$. Sufficient for this is $L^{b/c}$-admissibility of type β/γ on $\mathbb{R}_+$ for $\mathrm{Id} + A$. In order to use our characterizations of admissibility, we assume

$$\beta \in \left(-1/b, 1/b'\right) \quad \text{and} \quad \gamma \in \left(-1/c, 1/c'\right).$$

We start with the L^q-case.

The L^q-case. Consider $X := L^q(\Omega)$, $1 < q < \infty$. Due to the smoothness of $\partial\Omega$, we then have $\mathcal{D}(A) = \{x \in W^2_q(\Omega) : \frac{\partial x}{\partial \nu}\big|_{\partial\Omega} = 0\}$ and $-A$ generates a bounded analytic semigroup. To ensure L^c_*-estimates, we have to impose

$$\begin{aligned} X \hookrightarrow \left(\dot{X}_{-1}(\mathrm{Id}+A), \dot{X}_1(\mathrm{Id}+A)\right)_{1/2,c} &= \left(X_{-1}(A), X_1(A)\right)_{1/2,c} \\ &= \left(X_{-\delta}(A), X_\delta(A)\right)_{1/2,c}, \end{aligned} \tag{2.2}$$

where the last equality holds for any $\delta > 0$ by reiteration. In the case $X = L^q(\Omega)$, we have $X_\delta = H^{2\delta}_q(\Omega)$ for small $\delta > 0$ (cf. [26]) and $X_{-\delta} = H^{-2\delta}_q(\Omega)$ by dualization. Therefore, L^c_*-estimates for $\mathrm{Id} + A$ on $L^q(\Omega)$ are equivalent to the continuous embedding $L^q(\Omega) \hookrightarrow B^0_{q,c}(\Omega)$ (cf. [29, Thms. 2.4.1, 4.3.1]). We use the following lemma, which is proved in section 3.

LEMMA 2.1. *Let $\Omega \subset \mathbb{R}^n$ be a bounded domain with boundary $\partial\Omega \in C^\infty$. If $p, q \in [1, \infty]$, we have $L^q(\Omega) \hookrightarrow B^0_{q,p}(\Omega)$ if and only if $p \geq \max(2, q)$.*

For an application of Theorem 1.7 for L^c-admissibility of C in $X = L^q(\Omega)$ we thus need $c \geq \max(2, q)$. For an application of Theorem 1.8 for L^b-admissibility of B in $X = L^q(\Omega)$ in case $\beta = 0$, we also need $L^{b'}_*$-estimates for $(I+A)'$ on X'. By the arguments above these are equivalent to $L^{q'}(\Omega) \hookrightarrow B^0_{q',b'}(\Omega)$, which means by Lemma 2.1 that for $\beta = 0$, we have to suppose $b \leq \min(q, 2)$. Obviously, if $\beta = 0$, then application of both Theorems 1.7 and 1.8 for $b = c$ would require $b = c = q = 2$ and we are back in the Hilbert space situation. We shall come back to this below.

Admissibility. Denoting the Dirichlet trace operator $\gamma_0 : x \mapsto x\big|_{\partial\Omega}$ by C we are looking for a space Y on $\partial\Omega$ such that $C : \mathcal{D}(A) \to Y$ is L^c-admissible of type γ for $\mathrm{Id} + A$. If $c \geq \max(2, q)$, then $\mathrm{Id} + A$ has L^c_*-estimates and we know by Theorem 1.7 that L^c-admissibility of type γ of $C : \mathcal{D}(A) \to Y$ is equivalent to uniform boundedness of the operators

$$\lambda^{1-\gamma-1/c} C(\lambda + \mathrm{Id} + A)^{-1}, \quad \lambda > 0.$$

By Theorem 1.9 this is equivalent to C having a continuous extension to the Banach space Z, where

$$\begin{aligned} Z &:= \left(X, \dot{X}_k(\mathrm{Id}+A)\right)_{\gamma+1/c,1} \\ &= \left(X, X_k(A)\right)_{\gamma+1/c,1} \\ &\overset{(*)}{=} \begin{cases} B^s_{q,1}(\Omega) & \text{if } s < 1 + 1/q, \\ \{x \in B^s_{q,1}(\Omega) : \ \frac{\partial x}{d\nu}\big|_{\partial\Omega} = 0\} & \text{if } s > 1 + 1/q, \end{cases} \end{aligned}$$

where $s = 2\gamma + 2/c$. For equality $(*)$ we refer to [29, Thm. 4.3.3] or [10, Thm. 3.5]. It is known that γ_0 is bounded from $B^s_{q,1}(\Omega)$ to $B^{s-1/q}_{q,1}(\partial\Omega)$ if $s > 1/q$ (cf. [29, Thm. 4.7.1]). We thus have almost proved the following proposition.

PROPOSITION 2.2. *Let $\gamma \in \mathbb{R}$, $c \in [1,\infty]$, and $q \in (1,\infty)$ satisfy $c \geq \max(q,2)$ and $2\gamma + 2/c \in (1/q, 1+1/q)$, and let Y be a Banach space and $X = L^q(\Omega)$. Then $\gamma_0 : \mathcal{D}(A) \to Y$ is L^c-admissible of type γ for $Id + A$ if and only if $B^{2\gamma+2/c-1/q}_{q,1}(\partial\Omega) \hookrightarrow Y$.*

Proof. Let $s := 2\gamma + 2/c$. The arguments above show that $B^{s-1/q}_{q,1}(\partial\Omega) \hookrightarrow Y$ is sufficient. To prove necessity we compose $\gamma_0 : B^s_{q,1}(\Omega) \to Y$ with a continuous extension operator $E_0 : B^{s-1/q}_{q,1}(\partial\Omega) \to B^s_{q,1}(\Omega)$ such that $\gamma_0 E_0 = Id$ (cf. [29, Thm. 4.7.1]). ∎

Remark 2.3. The upper bound $2\gamma + 2/c < 1 + 1/q$ appears only for simplicity of formulation. The calculation of the space Z above indicates how to proceed in other cases.

To obtain the representation of the control operator B we follow again ideas in [4] and multiply the state equation in (2.1) with a fixed function $v \in C^\infty(\overline{\Omega})$. Then, integrating by parts gives

$$\langle x'(t), v\rangle_\Omega + \langle \nabla x(t), \nabla v\rangle_\Omega = \int_{\partial\Omega} u(t) v \, d\sigma,$$

where $\langle\cdot,\cdot\rangle_\Omega$ denotes the usual duality pairing on $L^q(\Omega) \times L^{q'}(\Omega)$ and σ denotes the surface measure on $\Gamma := \partial\Omega$. Denoting extensions of the usual $L^q(\Gamma) \times L^{q'}(\Gamma)$-duality by $\langle\cdot,\cdot\rangle_\Gamma$ we thus have

$$\int_{\partial\Omega} u(t) v \, d\sigma = \langle u(t), \gamma_0 v\rangle_\Gamma,$$

which means that $B = \gamma_0'$ if we identify $X_{-1}(A)$ with the dual space of $(X')_1(A')$. Notice that $A' = -\Delta$ with Neumann boundary conditions in $X' = L^{q'}(\Omega)$.

We are interested in L^b-admissibility of type β for $\gamma_0' : U \to X_{-1}$ and $\mathrm{Id} + A$ in $X = L^q(\Omega)$. Assuming $b \leq \min(q,2)$ in case $\beta = 0$ we may use Theorem 1.8 and only have to check boundedness of $\gamma_0' : U \to W$, where the extrapolation space W is given by

$$\begin{aligned} W &= (\dot{X}_{-1}(\mathrm{Id} + A), X)_{\beta+1/b,\infty} = (X_{-1}, X)_{\beta+1/b,\infty} \\ &= \big(\big((X')_1, X'\big)_{\beta+1/b,1}\big)' = \big(\big(X', (X')_1\big)_{1-(\beta+1/b),1}\big)' \end{aligned}$$

(cf. [3, sect. 3.7]). As we have seen above, we have

$$(X', (X')_1)_{1-(\beta+1/b),1} = B^{2-2\beta-2/b}_{q',1}(\Omega)$$

for $2 - 2\beta - 2/b < 1 + 1/q' = 2 - 1/q$. Now $\gamma_0 : B^{2-2\beta-2/b}_{q',1}(\Omega) \to B^{2-2\beta-2/b-1/q'}_{q',1}(\partial\Omega)$ is continuous for $2 - 2\beta - 2/b > 1/q' = 1 - 1/q$ and $\partial\Omega$ is without boundary; hence $(B^s_{q',1}(\partial\Omega))' = B^{-s}_{q,\infty}(\partial\Omega)$. Thus we have proved one implication in the following proposition.

PROPOSITION 2.4. *Let $\beta \in \mathbb{R}$, $b \in [1,\infty]$, and $q \in (1,\infty)$ satisfy $2/b + 2\beta \in (1/q, 1+1/q)$. If $\beta = 0$, assume in addition $b \leq \min(q,2)$. Let U be a Banach space and $X = L^q(\Omega)$. Then $\gamma_0' : U \to X_{-1}$ is L^b-admissible of type β for $Id + A$ if and only if $U \hookrightarrow B^{2/b+2\beta-1-1/q}_{q,\infty}(\partial\Omega)$.*

For the remaining implication we make use of E_0', where E_0 is the extension map from the proof of Proposition 2.2.

Wellposedness of the full system. We study L^p-wellposedness of type α in finite time for the system (2.1) in the state space $X = L^q(\Omega)$, where $\alpha \in \mathbb{R}$, $p \in [1,\infty]$ and $q \in (1,\infty)$. Hence we have $c = b = p$ and $\gamma = \beta = \alpha$ in the admissibility situations above. Again, it is sufficient to study infinite-time L^p-admissibility of type α for $Id + A$. The assumptions of Propositions 2.2 and 2.4 lead, for $\alpha \neq 0$, to the restrictions $p \geq \max(q,2)$ and $2\alpha + \frac{2}{p} \in (\frac{1}{q}, 1 + \frac{1}{q})$, and for $\alpha = 0$ to the restriction $p = q = 2$.

For $p = q = 2$ we thus can state the following result extending the case $\alpha = 0$, $r = 2$, considered in [4].

PROPOSITION 2.5. *Let $|\alpha| < \frac{1}{4}$, $r \in [1,\infty]$, and $X = L^2(\Omega)$. Let Y and U be Banach spaces on $\partial\Omega$ such that $B^{2\alpha+\frac{1}{2}}_{2,r}(\partial\Omega) \hookrightarrow Y$ and $U \hookrightarrow B^{2\alpha-\frac{1}{2}}_{2,r}(\partial\Omega)$. Then the system (2.1) is L^2-wellposed of type α.*

Proof. By Propositions 2.2 and 2.4, C and B are L^p-admissible of type α for $\mathrm{Id} + A$. Notice that the semigroup associated to $\mathrm{Id} + A$ is $S(t) := e^{-t}T(t)$.

Since $B = \gamma_0 : B^{2\alpha+\frac{1}{2}}_{2,r}(\partial\Omega) \to \widetilde{W} := (X_{-1}, X)_{\beta+\frac{1}{b},r} = (X_{-1}, X)_{\alpha+\frac{1}{2},r}$ (recall $\beta = \alpha$ and $b = p = 2$) and $C = \gamma_0 : \widetilde{Z} \to B^{2\alpha+\frac{1}{2}}_{2,r}(\partial\Omega)$, where $\widetilde{Z} := B^{2\alpha+1}_{2,r}(\Omega) = (X, X_1)_{\alpha+\frac{1}{2},r}$, it suffices to prove that $S(\cdot)* : L^p_\alpha(\mathbb{R}_+, \widetilde{W}) \to L^p_\alpha(\mathbb{R}_+, \widetilde{Z})$. Theorem 1.13 applies by $|\alpha| < \frac{1}{4} < \frac{1}{2}$. Now notice that $\widetilde{Z} = \mathcal{D}(A_{\widetilde{W}})$. Hence we are left to check that $A_{\widetilde{W}}$ has maximal L^p-regularity in $\widetilde{W}$ which holds by [6, Thm. 4.7]. ∎

With essentially the same arguments we can study problem (2.1) in state spaces $X = H^\delta_q(\Omega)$ where we restrict to $\delta \in (-\frac{1}{q'}, \frac{1}{q})$ and are thus not bothered by additional boundary conditions. Here we have $X_1 = \mathcal{D}(A) = \{x \in H^{2+\delta}_q(\Omega) : \frac{\partial x}{\partial \nu}|_{\partial\Omega} = 0\}$, and a repetition of the arguments above yields for the corresponding interpolation spaces $Z = B^{\delta+2(\alpha+\frac{1}{p})}_{q,1}(\Omega)$ if $\delta + 2(\alpha + \frac{1}{p}) < 1 + \frac{1}{q}$ and $W = (B^{2-\delta-2(\alpha+\frac{1}{p})}_{q',1}(\Omega))'$ if $2 - \delta - 2(\alpha + \frac{1}{p}) < 1 + \frac{1}{q'}$, i.e., if $\frac{1}{q} < \delta + 2(\alpha + \frac{1}{p})$. Thus we obtain the next proposition.

PROPOSITION 2.6. *Let $q \in (1,\infty)$ and $p \in [1,\infty]$ satisfy $p \geq \max(2,q)$. Let $\delta \in (-\frac{1}{q'}, \frac{1}{q})$, and $\delta + 2(\alpha + \frac{1}{p}) \in (\frac{1}{q}, 1 + \frac{1}{q})$, where $\alpha \neq 0$. Let $X = H^\delta_q(\Omega)$ and let Y and U be Banach spaces on $\partial\Omega$.*

(a) *The operator $C = \gamma_0 : \mathcal{D}(A) \to Y$ is L^p-admissible of type α for $Id + A$ if and only if $B^{\delta+2(\alpha+\frac{1}{p})-\frac{1}{q}}_{q,1}(\partial\Omega) \hookrightarrow Y$.*

(b) *The operator $B = \gamma_0' : U \to X_{-1}$ is L^p-admissible of type α for $Id + A$ if and only if $U \hookrightarrow B^{\delta+2(\alpha+\frac{1}{p})-\frac{1}{q}-1}_{q,\infty}(\partial\Omega)$.*

(c) *Let $r \in [1,\infty]$ and $B^{\delta+2(\alpha+\frac{1}{p})-\frac{1}{q}}_{q,r}(\partial\Omega) \hookrightarrow Y$ and $U \hookrightarrow B^{\delta+2(\alpha+\frac{1}{p})-\frac{1}{q}-1}_{q,r}(\partial\Omega)$. Then the system (2.1) is finite-time L^p-wellposed of type α.*

Observe that the assumptions imply $\alpha + \frac{1}{p} \in (0,1)$.

We see that δ may be chosen arbitrarily close to $-\frac{1}{q'}$ by taking p large and adjusting α. Moreover, one still has free choice of $r \in [1,\infty]$.

The Besov space case. We continue the study of (2.1), but now we take as state space the Besov space $X := B^0_{q,v}(\Omega)$, where $1 < q, v < \infty$ are fixed. Again we put $A := -\Delta$ with homogeneous Neumann boundary conditions; i.e., A has domain $\mathcal{D}(A) = \{x \in B^2_{q,v}(\Omega) : \frac{\partial x}{\partial \nu}\big|_{\partial\Omega} = 0\}$. As in the L^q-case, $-A$ generates a bounded analytic semigroup in X.

Admissibility. Still denoting by γ_0 the Dirichlet trace on $\partial\Omega$, we study L^c-admissibility of type γ for $C = \gamma_0$ and L^b-admissibility of type β for $B = \gamma_0'$, where $\beta, \gamma \in \mathbb{R}$ and $b, c \in [1,\infty]$.

First we note that $\big(X_{-1}, X_1\big)_{1/2,c} = B^0_{q,c}(\Omega)$, whence $\mathrm{Id} + A$ has L^c_*-estimates on X if and only if $B^0_{q,v}(\Omega) \hookrightarrow B^0_{q,c}(\Omega)$ which is equivalent to $c \geq v$. Notice that this condition does not depend on q. If $c \geq v$, then the characterizing Theorem 1.7 applies, and L^c-admissibility of type γ of the observation operator $C = \gamma_0$ may be checked by verifying the boundedness condition on the set W_C. Again, we use Theorem 1.9 and find that, for $2\gamma + 2/c < 1 + 1/q$, W_C is bounded if and only if γ_0 has a continuous extension to the very same Banach space

$$Z = B^{2\gamma+2/c}_{q,1}(\Omega)$$

we calculated above. Hence the proof of the following can be done as in the case $X = L^q(\Omega)$.

PROPOSITION 2.7. *Let $\gamma \in \mathbb{R}$, $c \in [1,\infty]$, and $q, v \in (1,\infty)$ satisfy $c \geq v$ and $2\gamma + 2/c \in (1/q, 1+1/q)$. Let Y be a Banach space and $X = B^0_{q,v}(\Omega)$. Then $\gamma_0 : \mathcal{D}(A) \to Y$ is L^c-admissible of type γ for $Id + A$ if and only if $B^{2\gamma+2/c-1/q}_{q,1}(\partial\Omega) \hookrightarrow Y$.*

We turn to L^b-admissibility of type β for $B = \gamma_0'$. For an application of Theorem 1.8 in $X = B^0_{q,v}(\Omega)$ in case $\beta = 0$ we need $L^{b'}_*$-estimates for $(\mathrm{Id} + A)'$, which are, by the argument above, equivalent to $b \leq v$. This yields the next proposition.

PROPOSITION 2.8. *Let $\beta \in \mathbb{R}$, $b \in [1,\infty]$, and $q, v \in (1,\infty)$ satisfy $2/b + 2\beta \in (1/q, 1 + 1/q)$. Assume additionally $b \leq v$ if $\beta = 0$. Let U be a Banach space and $X = B^0_{q,v}(\Omega)$. Then $\gamma_0' : U \to X_{-1}$ is L^b-admissible of type β for $Id + A$ if and only if $U \hookrightarrow B^{2/b+2\beta-1-1/q}_{q,\infty}(\partial\Omega)$.*

Wellposedness of the full system. We study L^p-wellposedness of type α for the system (2.1) where $\alpha \in \mathbb{R}$, $p \in [1,\infty]$ and the state space $X = B^0_{q,v}(\Omega)$ with $q, v \in (1,\infty)$. Again we have $c = b = p$ and $\gamma = \beta = \alpha$ in the admissibility situations above. The assumptions of Propositions 2.7 and 2.8 now lead, for $\alpha \neq 0$, to the restrictions $p \geq v$ and $2\alpha + 2/p \in (1/q, 1 + 1/q)$. In case $\alpha = 0$ we are led to $p = v$. For example, if $p = q$, then we are led to $2\alpha \in (-1/q, 1/q')$, which, for $q = 2$, corresponds to the condition $|\alpha| < 1/4$ in Proposition 2.5 (recall $L^2(\Omega) = B^0_{2,2}(\Omega)$). By the arguments used above we hence obtain the next proposition.

PROPOSITION 2.9. *Let $\alpha \in \mathbb{R}$, $p \in (1,\infty)$, and $q \in (1,\infty)$ satisfy $2\alpha + 2/p \in (1/q, 1 + 1/q)$. Let $X = B^0_{q,p}(\Omega)$ and let Y and U be Banach spaces on $\partial\Omega$ such that $B^{2\alpha+2/p-1/q}_{q,p}(\partial\Omega) \hookrightarrow Y$ and $U \hookrightarrow B^{2/p+2\alpha-1-1/q}_{q,p}(\partial\Omega)$. Then the system (2.1) is finite-time L^p-wellposed of type α.*

Proof. The proof is similar to the case $X = L^q(\Omega)$. We check here that Theorem 1.13 applies, i.e., that $\alpha \in (-1/p, 1/p')$. The condition on α in the assumption may be rephrased as $\alpha \in (1/2q - 1/p,\ 1/2 + 1/2q - 1/p)$. In particular $\alpha > 1/2q - 1/p \geq -1/p$ and $\alpha < 1/2 + 1/2q - 1/p \leq 1 - 1/p$. ∎

We also give an analogue of Proposition 2.6 for Besov spaces, e.g., for state spaces $X = B^\delta_{q,p}(\Omega)$, where $q, p \in (1,\infty)$, and we restrict to $\delta \in (-1/q', 1/q)$ for the same reasons as before.

PROPOSITION 2.10. *Let $q, p \in (1,\infty)$, $\delta \in (-1/q', 1/q)$, $2\alpha + 2/p + \delta \in (1/q, 1 + 1/q)$, and $X = B^\delta_{q,p}(\Omega)$. Let Y and U be Banach spaces on $\partial\Omega$.*

(a) *The operator $C = \gamma_0 : \mathcal{D}(A) \to Y$ is L^p-admissible of type α for $Id + A$ if and only if $B^{2\alpha+2/p+\delta-1/q}_{q,1}(\partial\Omega) \hookrightarrow Y$.*

(b) *The operator $B = \gamma_0' : U \to X_{-1}$ is L^p-admissible of type $-\alpha$ for $Id + A$ if and only if $U \hookrightarrow B^{2\alpha+2/p+\delta-1-1/q}_{q,\infty}(\partial\Omega)$.*

(c) *Let* $r \in [1,\infty]$ *and* $B^{2\alpha+2/p+\delta-1/q}_{2,r}(\partial\Omega) \hookrightarrow Y$ *and* $U \hookrightarrow B^{2\alpha+2/p+\delta-1-1/q}_{2,r}(\partial\Omega)$. *Then the system* (2.1) *is finite-time* L^p*-wellposed of type* α.

Discussion. We discuss our results for the system (2.1) by starting from $Y := B^s_{q,r}(\partial\Omega)$ and $U := B^{s-1}_{q,r}(\partial\Omega)$, where $s \in (0,1)$, $q \in (1,\infty)$, and $r \in [1,\infty]$ are fixed. We now look for α, p, and a state space X such that (2.1) is L^p-wellposed of type α. This should be compared with the situation studied in [4], where $p = q = r = 2$, $\alpha = 0$, $s = 1/2$, and $X = L^2(\Omega)$.

Remark 2.11. In case $q = 2$, we may take $p = 2$ and $X = H^\delta_2(\Omega)$, where the restrictions may be read off Proposition 2.6: $2\alpha + \delta + 1/2 = s$ and $|\delta| < 1/2$. Thus we see that a suitable choice of α always allows us to have δ arbitrarily close to $-1/2$. In particular this applies to the "classical" case $s = 1/2$, where the restriction $\alpha = 0$ forces $\delta = 0$ and $X = L^2(\Omega)$.

Remark 2.12. For general $q \in (1,\infty)$, we may apply Proposition 2.10 and take $X = B^\delta_{q,p}(\Omega)$ under the restrictions $s = 2\alpha + 2/p + \delta - 1/q$ and $\delta \in (-1/q', 1/q)$. We see that taking p arbitrarily large and δ arbitrarily close to $-1/q'$, we still obtain finite-time L^p-wellposedness of type α for the system with state space $X = B^\delta_{q,p}(\Omega)$ by adjusting α. Observe that the state space $X = H^\delta_q(\Omega)$ would have required the additional restriction $p \geq \max(2,q)$ for $\alpha \neq 0$.

Remark 2.13. We let $s = 1/2$ and $U := H_2^{-1/2}(\partial\Omega)$, $Y := H_2^{1/2}(\partial\Omega)$; i.e., we take $q = r = 2$ in the situation discussed above. Then, for $\delta \in (-1/2, 1/2)$ and $X = B^\delta_{2,p}(\Omega)$, we have that (2.1) is finite-time L^p-wellposed of type α if $\delta = 1 - 2(\alpha + 1/p)$. The restrictions are $p \in (1,\infty)$ and $\alpha + 1/p \in (1/4, 3/4)$. This means, in other words, that for $\epsilon \in (0,1)$, $p \in [2,\infty)$, and $X = B^{-1/2+\epsilon}_{2,p}(\Omega)$, the system (2.1) is finite-time L^p-wellposed of type $\alpha = 3/4 - \epsilon/2 - 1/p$.

Now we consider a nonlinear feedback in the setting of the above remark.

Example 2.14. Since $Y = H_2^{1/2}(\partial\Omega) \hookrightarrow L^{\frac{2n-2}{n-2}}(\partial\Omega)$ and since $L^{2-2/n}(\partial\Omega) \hookrightarrow H_2^{-1/2}(\partial\Omega)$, Hölder's inequality yields that any $g \in L^{n-1}(\partial\Omega)$ induces a bounded multiplication operator $Y \to U$, $y \mapsto g \cdot y$. We take a smooth open subset Ω_0 with $\overline{\Omega_0} \subset \Omega$, e.g., a small ball, and let $\psi(x) := \int_{\Omega_0} x(\omega)\, d\omega = \langle x, 1_{\Omega_0}\rangle$ for $x \in X$. Observe that $\psi \in X'$ for all spaces X mentioned above (cf. [29]). Taking a Lipschitz-continuous function $f : \mathbb{R} \to \mathbb{R}$, we let $F(x)y := f(\psi(x))\, g \cdot y$. Then $F : X \to B(Y,U)$ is Lipschitz-continuous. We interpret $x \mapsto \psi(x)$ as a distributed measurement in Ω affecting via $f(\psi(x))$ the intensity of the linear feedback $y \mapsto g \cdot y$.

For $\epsilon \in (0,1)$, $p \in [2,\infty)$, $X = B^{-1/2+\epsilon}_{2,p}(\Omega)$, and $\alpha = 3/4 - \epsilon/2 - 1/p$ we take $x_0 \in X$ satisfying (for simplicity) $f(\psi(x_0)) = 0$ and show that Theorem 1.16 applies. We have $F(x_0) = 0$; hence $A_0 = A$. We take $Z = H^1_2(\Omega)$ whence by an application of Theorem 1.7 and Theorem 1.9, Id_Z is finite-time L^p-admissible of type α (cf. [29, Rem. 2.8.1]).

Since $B = \gamma_0' : H_2^{-1/2}(\partial\Omega) \to (H^1_2(\Omega))' =: W$ is bounded and $\mathrm{Id} + A$ has maximal L^p-regularity in W we obtain by Remark 1.4 and Theorem 1.13 that the system (A_0, B, Id_Z) is L^p-wellposed of type α in finite time. Hence we may apply Theorem 1.16 and obtain that the nonlinear system

$$\left\{\begin{array}{lcll} x'(t) - \Delta x(t) & = & 0, & t \in [0,\tau], \\ x(0) & = & x_0, & \\ \frac{\partial x(t)}{\partial \nu} & = & f\left(\int\limits_{\Omega_0} x(t)\, d\omega\right) g \cdot x(t)|_{\partial\Omega} & \end{array}\right. \tag{2.3}$$

has, for some $\tau(x_0) > 0$, a unique mild solution $x(\cdot)$ in the space $C([0,\tau], B_{2,p}^{-1/2+\epsilon}(\Omega)) \cap L^p_\alpha([0,\tau], H^1_2(\Omega))$. This means that we obtain solutions also for rather rough initial data x_0.

In the example above we made the assumption $f(\psi(x_0)) = 0$ for simplicity. For initial data x_0 with $f(\psi(x_0)) \neq 0$ one may resort to perturbation results in [11].

3. Proofs. Finite-time admissibility of type α.

Proof of Lemma 1.3. Assume C to be finite-time L^p-admissible of type α for A. For $b \geq 0$ we then have

$$\begin{aligned}\left(\int_{b+\tau/2}^{b+\tau} \|t^\alpha CT(t)x\|^p\,dt\right)^{1/p} &= \left(\int_{\tau/2}^{\tau} \|s^\alpha (1+\tfrac{b}{s})^\alpha CT(s)T(b)x\|^p\,dt\right)^{1/p}\\ &\leq \left(\int_0^\tau \|s^\alpha CT(s)T(b)x\|^p\,dt\right)^{1/p} \max((1+\tfrac{2b}{\tau})^\alpha, 1)\\ &\leq M_\tau \,\|T(b)x\|\, \max((1+\tfrac{2b}{\tau})^\alpha, 1).\end{aligned}$$

If $T(\cdot)$ is uniformly exponentially stable, i.e., if there are $c, \epsilon > 0$ such that $\|T(t)\| \leq c\,e^{-\epsilon t}$, $t \geq 0$, then we obtain for $b = (k-1)\tau/2$ and $k \in \mathbb{N}_0$,

$$\left(\int_{k\tau/2}^{(k+1)\tau/2} \|t^\alpha CT(t)x\|^p\,dt\right)^{1/p} \leq c\,M_\tau\, \max((1+\tfrac{2b}{\tau})^\alpha, 1)\, e^{-\epsilon(k-1)\tau/2}\|x\|.$$

Thus (1.4) holds.

A similar reasoning shows that the notion of finite-time L^p-admissibility of type α for control operators is independent of τ: let $a = \tau/2$ and $b = 3/2\,\tau$. Since

$$\int_0^b T(b-s)Bu(s)\,ds \leq T(a)\int_0^\tau T(\tau-s)Bu(s)\,ds + \int_a^\tau T(\tau-s)Bu(s+a)\,ds,$$

L^p-admissibility of type α on $[0,\tau]$ gives for $p < \infty$

$$\begin{aligned}\left\|\int_0^b T(b-s)Bu(s)\,ds\right\| &\leq K_\tau\|T(a)\|\,\|u\|_{L^p_\alpha([0,\tau])} + K_\tau\|\mathbb{1}_{[a,\tau]}(\cdot)u(a+\cdot)\|_{L^p_\alpha([0,\tau])}\\ &\leq K_\tau\|T(a)\|\,\|u\|_{L^p_\alpha([0,\tau])} + K_\tau\widetilde{c}_\alpha\,\|u\|_{L^p_\alpha([\tau,b])}\\ &\leq K_\tau\big(\widetilde{c}_\alpha + \|T(\tau/2)\|\big)\,\|u\|_{L^p_\alpha([0,b])},\end{aligned}$$

where $\widetilde{c}_\alpha = \max\big((\frac{1}{2})^\alpha, (\frac{2}{3})^\alpha\big)$ does not depend on τ. In case $p = \infty$, we obtain the same estimate with $\widetilde{c}_\alpha = 1$ by directly regarding the first line of the above inequalities. Thus, B is L^p-admissible of type α on $[0, 3/2\,\tau]$ as required. An iteration of the argument shows that

$$K_{(3/2)^n\tau} \leq K_\tau(\widetilde{c}_\alpha)^n \prod_{j=1}^n \big(1 + \widetilde{c}_\alpha^{-1}\|T(3\tau(\tfrac{3}{2})^j)\|\big).$$

If $T(\cdot)$ is uniformly exponentially stable and if $\alpha \geq 0$ or if $p = \infty$, the left-hand side of the above inequality is bounded since $\sum_{j\geq 1}\exp(-3\epsilon\tau(\tfrac{3}{2})^j) < \infty$ and $|\widetilde{c}_\alpha| \leq 1$. □

If $\alpha < 0$ and $p < \infty$, equivalence of finite-time and infinite-time L^p-admissibility of type α fails in general.

Example 3.1. Take $U = X = \mathbb{C}$, $-\alpha = \beta > 0$, and $T(t) = e^{-\epsilon t}$. Then, for any $\tau > 0$,

$$|T * u(\tau)| \le \|u\|_{L^p_\alpha(0,\tau)} \|e^{-\epsilon(\cdot)}\|_{L^{p'}_\beta(0,\tau)} \le c_{p'} \tau^{\beta + 1/p'} \|u\|_{L^p_\alpha(0,\tau)},$$

and the identity is finite-time L^p-admissible of type α.

On the other hand, letting $u_k := \mathbb{1}_{[k,k+1]} e^{-\epsilon(\cdot - k)}$ for $k \in \mathbb{N}$, we have $\|u_k\|_{L^p_\alpha} \le k^{-\beta} \|u_k\|_{L^p} = c k^{-\beta}$ and for $\delta \in (0,1]$,

$$(T * u_k)(k+\delta) = \int_k^{k+\delta} e^{-\epsilon(k+\delta-s)}\, e^{-\epsilon(s-k)}\, ds = \delta e^{-\epsilon\delta}.$$

Hence the identity is not infinite-time L^p-admissible of type α.

Characterization of L^p-admissibility of type α. In the proof of Theorems 1.7 and 1.8 we make use of the following lemma.

LEMMA 3.2 (see [12, Lem. 4.1]). *Let $\sigma \in (0,\pi)$, let $\varphi \in H^\infty_0(S(\sigma))$, and let $m \ge 1$ be an integer. There exist a function $f \in H^\infty_0(S(\sigma))$ and a constant $a \in \mathbb{C}$ such that*

$$\varphi(z) = z^m f^{(m)}(z) + a \frac{z^m}{(1+z)^{m+1}}, \qquad z \in S(\sigma). \tag{3.1}$$

Furthermore, if $\delta, \epsilon \in (0,1)$ are positive numbers such that

$$|\varphi(z)| = O(|z|^{-\delta}) \quad \text{at } \infty \qquad \text{and} \qquad |\varphi(z)| = O(|z|^{\epsilon}) \quad \text{at } 0,$$

then f can be chosen so that we also have $|f(z)| = O(|z|^{-\delta})$ at ∞ and $|f(z)| = O(|z|^{\epsilon})$ at 0.

Proof of Theorem 1.7. (a) Notice that for any $\lambda \in \mathbb{C}$ with positive real part and for any $x \in X$, we have

$$(\lambda + A)^{-k} x = \frac{1}{(k-1)!} \int_0^\infty t^{k-1} e^{-\lambda t} T(t) x \, dt.$$

For $x \in X_k = \mathcal{D}(A^k)$, the integrand $t \mapsto t^{k-1} e^{-\lambda k} T(t)x$ belongs to $L^1(\mathbb{R}_+, X_k)$, and so continuity of C on X_k shows

$$C(\lambda + A)^{-k} x = \frac{1}{(k-1)!} \int_0^\infty t^{k-1} e^{-\lambda t} C T(t) x \, dt.$$

By Hölder's inequality we thus have for $x \in X_k$

$$\begin{aligned}
& \big\| C(\lambda + A)^{-k} x \big\| \\
\le\ & \frac{1}{(k-1)!} \int_0^\infty \big\| t^\alpha C T(t) x \big\| t^{k-1-\alpha} e^{-Re(\lambda)\, t}\, dt \\
\le\ & \frac{1}{(k-1)!} \Big\| t \mapsto t^\alpha C T(t) x \Big\|_{L^p(\mathbb{R}_+, Y)} \left(\int_0^\infty t^{(k-1-\alpha)p'} e^{-Re(\lambda) p'\, t}\, dt \right)^{1/p'} \\
\overset{s = Re(\lambda) p'\, t}{\le}\ & \frac{M}{(k-1)!} \|x\|_X \Big((p' \mathrm{Re}(\lambda))^{-1-(k-1-\alpha)p'} \Gamma\big(1 + (k-1-\alpha)p'\big) \Big)^{1/p'} \\
=\ & K \mathrm{Re}(\lambda)^{-k+\alpha+1/p}\, \|x\|_X,
\end{aligned}$$

where Γ is the usual Gamma function and the number K depends only on k, p, and the admissibility constant M. By density of X_k in X this shows the first assertion.

(b) Without loss of generality we may assume $k \geq 2$ since by sectoriality of A, whenever W_C is bounded for some $k \in \mathbb{N}$, it is also bounded when k is replaced by $k+1$ (see Remark 1.10). We make use of the (unbounded) operator A^{-1} that is densely defined on the range of A. We set $F_k(z) := z^{k-1}e^{-z}$. Then for any $x \in X_k$ and any $t > 0$, we have

$$t^\alpha CT(t)x = t^{\alpha-k+1}CA^{-k+1}F_k(tA)x. \tag{3.2}$$

For some $\epsilon \in (0,1)$ that we will specify later, consider the decomposition $F_k(z) = \varphi(z)\psi(z)$, where

$$\varphi(z) = z^\epsilon(1+z)^{-1} \qquad \text{and} \qquad \psi(z) = z^{k-1-\epsilon}(1+z)e^{-z}. \tag{3.3}$$

Note that $\psi \in H_0^\infty(S(\theta))$ for any $\theta < \frac{\pi}{2}$, whereas $\varphi \in H_0^\infty(S(\sigma))$ for any $\sigma < \pi$. By (3.2), we have

$$\int_0^\infty \|t^\alpha CT(t)x\|_Y^p dt \leq \int_0^\infty \| \underbrace{\left[t^{\alpha+1/p-k+1}CA^{-k+1}\psi(tA)\right]}_{=:K(t)} t^{-1/p}\varphi(tA)x\|_X^p \, dt.$$

Now we will show that the operator family $K(t)$, $t > 0$, is uniformly bounded. Once this is done, the assertion of the theorem follows immediately from the assumed L^p_*-estimate for A (cf. (1.6)).

We fix $\sigma \in (\omega, \pi)$ and apply Lemma 3.2 to ψ with $m = k-1$ and $\delta = 1-\epsilon$. Let $f \in H_0^\infty(S(\sigma))$ denote the corresponding function satisfying (3.1). Note that according to that equation, $z \mapsto z^{k-1}f^{(k-1)}(z)$ belongs to $H_0^\infty(S(\sigma))$. Let $\theta = \theta_\sigma$ for some $\theta \in (\omega, \sigma)$ and let Γ denote the positively orientated boundary of $S(\theta)$. Then, as in the proof of [12, Thm. 4.2] the following representation formula for x in the dense subspace $Z := ran(A^{k-1}(I+A)^{-k})$ holds:

$$CA^{-k+1}[z^{k-1}f^{(k-1)}(z)](tA)x = \tfrac{(k-1)!}{2\pi i}\int_\Gamma f(\lambda)t^{k-1}\, CR(\lambda, tA)^k x \, d\lambda, \quad t > 0. \tag{3.4}$$

For $\lambda \in \Gamma$, by the resolvent equation we have

$$\lambda^{k-\alpha-1/p}CR(\lambda,A)^k = |\lambda|^{k-\alpha-1/p}C(|\lambda|+A)^{-k}\left[2\cosh(\pm\theta/2)\lambda R(\lambda,A) - I\right]^k, \tag{3.5}$$

and thus $\lambda^{k-\alpha-1/p}CR(z,A)^k$ is uniformly bounded by sectoriality of A. Now, by the representation (3.4),

$$K(t) = \tfrac{(k-1)!}{2\pi i}\int_\Gamma t^{\alpha+1/p}f(\lambda)\, CR(\lambda,tA)^k x\, d\lambda + at^{\alpha+1/p}C(I+tA)^{-k}$$

on Z. Next we show that for an appropriately chosen $\epsilon \in (0,1)$, $K(t) \in B(X,Y)$ and moreover the operators $K(t)$ are uniformly bounded for $t > 0$. To this end, write

$$\begin{aligned} K(t) = \tfrac{(k-1)!}{2\pi i}\int_\Gamma f(\lambda)\lambda^{1-k+\alpha+1/p}\left[\left(\tfrac{\lambda}{t}\right)^{k-\alpha-1/p} CR(\tfrac{\lambda}{t},A)^k x\right]\tfrac{d\lambda}{\lambda} \\ + a\left[\left(\tfrac{1}{t}\right)^{k-\alpha-1/p} C(\tfrac{1}{t}+A)^{-k}\right]. \end{aligned}$$

By our assumption (1.7) and scaling invariance of Γ and the measure $d\lambda/\lambda$ we obtain that $K(t)$ is uniformly bounded, provided that the integral

$$\int_\Gamma \big|f(\lambda)\big|\big|\lambda\big|^{-k+\alpha+1/p}\, d|\lambda|$$

is finite. By the estimates in Lemma 3.2 we know that $f \in O(|z|^{k-1-\epsilon})$ at zero and $f \in O(|z|^{-n})$ for any $n \in \mathbb{N}$ at infinity. Therefore the above integral is finite if

$$k - 1 - \epsilon - k + \alpha + 1/p > -1, \quad \text{i.e., if} \quad \epsilon < \alpha + 1/p.$$

This, however, due to our assumption on α, may always be satisfied by an appropriate choice of $\epsilon \in (0,1)$, and the proof is done. □

To analyze L^p-admissibility for control operators, assume that $\|T_{-k}(t)B\|_{U\to X} \le Mt^{-\gamma}$ for some $\gamma \in \mathbb{R}$. For $t > 0$ fixed we thus have

$$\begin{aligned}\left\|\int_0^t T(t-s)Bu(s)\,ds\right\|_X &\le \int_0^t \big\|T(t-s)B\big\|_{U\to X}\, s^{-\alpha}\, \|s^\alpha u(s)\|_U\, ds \\ &\le c\int_0^t (t-s)^{-\gamma} s^{-\alpha} \|s^\alpha u(s)\|_U\, ds.\end{aligned}$$

Let $k_{\alpha,\gamma}(t,s) = \mathbb{1}_{(0,t)}(s)(t-s)^{-\gamma}s^{-\alpha}$ for $s,t \in (0,\tau)$. Thus the study of the kernel $k_{\alpha,\gamma}$ which may or may not induce a bounded integral operator $K_{\alpha,\gamma} : L^p(0,\tau) \to L^\infty(0,\tau)$ gives a sufficient criterion for (in)finite-time L^p-admissibility of type α of control operators.

For $p = 1$, $K_{\alpha,\gamma}$ is bounded if and only if $k_{\alpha,\gamma}$ is uniformly bounded, which, for finite τ, is equivalent to $\gamma \le 0$ and $\alpha \le 0$. In this case we have

$$\|K_{\alpha,\gamma}\|_{L^\infty(0,\tau)\to L^\infty(0,\tau)} = \|k_{\alpha,\gamma}\|_\infty = \frac{|\alpha|^{|\alpha|}|\gamma|^{|\gamma|}}{|\alpha+\gamma|^{|\alpha+\gamma|}}\,\tau^{|\alpha+\gamma|}.$$

For $\tau = \infty$, $k_{\alpha,\gamma}$ is uniformly bounded if and only if $\alpha = \gamma = 0$.

For $p > 1$ we use Hölder's inequality and obtain

$$\begin{aligned}\int_0^t k_{\alpha,\gamma}(t,s)|f(s)|\,ds &\le \left(\int_0^t \big(k_{\alpha,\gamma}(t,s)\big)^{p'}\,ds\right)^{1/p'} \|f\|_p \\ \text{(subst. } s = t\sigma) &= \left(t^{1-(\gamma+\alpha)p'}\int_0^1 (1-\sigma)^{-\gamma p'}\sigma^{-\alpha p'}\,d\sigma\right)^{1/p'} \|f\|_p.\end{aligned}$$

Convergence of the integral in the last line is equivalent to $\gamma < 1/p'$ and $\alpha < 1/p'$. Taking the sup over $t \in (0,\tau)$ we see that, for finite τ,

$$\|K_{\alpha,\gamma}\|_{L^p(0,\tau)\to L^\infty(0,\tau)} \le c_{\alpha,\gamma,p}\tau^{1/p'-(\gamma+\alpha)}$$

provided that $\gamma < 1/p'$, $\alpha < 1/p'$, and $\gamma + \alpha \le 1/p'$, whereas, for $\tau = \infty$,

$$\|K_{\alpha,\gamma}\|_{L^p(0,\infty)\to L^\infty(0,\infty)} \le c_{\alpha,\gamma,p}$$

provided that $\gamma + 1/p < 1$, $\alpha + 1/p < 1$, and $\gamma + \alpha + 1/p = 1$. Since, in fact (cf. [16]),

$$\|K_{\alpha,\gamma}\|_{L^p(0,\tau)\to L^\infty(0,\tau)} = \sup_{t\in(0,\tau)} \|k_{\alpha,\gamma}(t,\cdot)\|_{L^{p'}(0,\tau)},$$

we have just proved the following result.

PROPOSITION 3.3. *The operator $K_{\alpha,\gamma}$ is bounded $L^p(0,\tau) \to L^\infty(0,\tau)$ if and only one of the following conditions holds:*

$$\begin{array}{lllll} \text{(i)} & p=1, & \tau<\infty, & \alpha\le 0, & \gamma\le 0, \\ \text{(ii)} & p=1, & \tau=\infty, & \alpha=0, & \gamma=0, \\ \text{(iii)} & p>1, & \tau<\infty, & \alpha+1/p<1, & \gamma+1/p<1, \quad \alpha+\gamma+1/p\le 1, \\ \text{(iv)} & p>1, & \tau=\infty, & \alpha+1/p<1, & \gamma+1/p<1, \quad \alpha+\gamma+1/p=1. \end{array} \tag{3.6}$$

Observe that condition (iv) *implies $\alpha>0$ and $\gamma>0$.*

Proof of Theorem 1.8. (a) Consider for $t>0$ the function $u(s) := \mathbb{1}_{(t/2,t)}(s)u_0$. Then

$$\left\|\int_0^t T(t-s)Bu(s)\,ds\right\|_X = \left\|\int_{t/2}^t AT(t-s)Bu(s)\,ds\right\|_{\dot X_{-1}} = \big\|\,[T(t)-T(t/2)]Bu_0\big\|_{\dot X_{-1}}.$$

We have $\|u\|_{L^p_\alpha([0,t],U)} = \frac{1}{1+\alpha p}\big(\frac{t}{2}\big)^{\alpha+1/p}$. Let $f(z) := \exp(z)-\exp(z/2)$. Notice that the function $z \mapsto z^{-\alpha-1/p} f(z) \in H_0^\infty(S(\sigma))$ for all $\sigma < \pi/2$, so Theorem 1.5 applies. We obtain

$$\begin{aligned} \mathcal{R}(B) &\subseteq \big((\dot X(A_{-1}))_{-1}, (\dot X(A_{-1}))_1\big)_{1/2(\alpha+1/p+1),\infty} \\ &= \big(\dot X_{-2}, X\big)_{1/2(\alpha+1/p+1),\infty} = \big(\dot X_{-k}, X\big)_{1-\theta,\infty} \end{aligned}$$

with $\theta = 1/k\,(1/p'-\alpha)$, $k\in\mathbb{N}$. The claim now follows from Theorem 1.9.

(b) By Theorem 1.9, boundedness of W_B is equivalent to $B: U \to (\dot X_{-k}, X)_{\theta,\infty}$ with $\theta = 1+1/k\,(\alpha-1/p')$. By analyticity of the semigroup this implies $\|T(t)B\| \le ct^{-\gamma}$ with $\gamma = 1/p'-\alpha$ (cf. the arguments in the proof of Lemma 1.12). Hence, if in addition to the assumptions of the theorem, $\alpha>0$ in case $p>1$ (or $p=1$ in case $\alpha=0$, respectively), Proposition 3.3 gives the claim.

(a)′ Let (1.5) hold. For $\mathrm{Re}(\lambda)>0$ and $u\in U$ we have

$$(\lambda + A_{-k})^{-k} Bu = \frac{1}{(k-1)!}\int_0^\infty t^{k-1} e^{-\lambda t} T_{-k}(t)Bu\,dt.$$

Then, by assumption

$$\begin{aligned} &\big\|\mathrm{Re}(\lambda)^{k+\alpha-1/p'}\,(\lambda+A)^{-k-1}Bu\big\| \\ &\le \tfrac{1}{(k-1)!}\left\|\int_0^\infty t^{k-1}\mathrm{Re}(\lambda)^{k+\alpha-1/p'}\,e^{-\lambda t}T_{-k}(t)Bu\,dt\right\| \\ &= \tfrac{1}{(k-1)!}\left\|\int_0^\infty T_{-k}(t)B\big[t^{k-1}\mathrm{Re}(\lambda)^{k+\alpha-1/p'}\,e^{-\lambda t}\otimes u\big]\,dt\right\| \\ &\le \tfrac{K}{(k-1)!}\big\|h_\lambda(t)\otimes u\big\|_{L^p_\alpha(\mathbb{R}_+,U)} \le \widetilde K\|u\|_U. \end{aligned}$$

Here the uniform boundedness of the functions $h_\lambda(t) := \mathrm{Re}(\lambda)^{k+\alpha-1/p'}\,t^{k-1}e^{-\lambda t}$, $\lambda>0$, in $L^p_\alpha(\mathbb{R}_+)$ is shown similar to the proof of Theorem 1.7.

(b)′ Without loss of generality we assume $k\ge 2$. We proceed in two steps.

Step 1. To show the existence of the integral in (1.5), we choose some $x'\in(X_{-k})'$, $x'\ne 0$. Notice that $(X_{-k})'$ may be identified with $(X')_k$, that is, the domain $\mathcal{D}((A')^k)$ with graph norm. We consider

$$\int_0^\infty \big|\langle T_{-k}(t)Bu(t), x'\rangle\big|\,dt = \int_0^\infty \big|\langle t^{-k+1}A^{-k+1}(tA)^{k-1}T_{-k}(t)Bu(t), x'\rangle\big|\,dt.$$

As we did in the proof of Theorem 1.7, we decompose $F_k(z) = z^{k-1}e^{-z}$ as $F_k(z) = \varphi(z)\psi(z)$ with φ, ψ as in (3.3). We obtain

$$\int_0^\infty \big|\langle T_{-k}(t)Bu(t), x'\rangle\big|\,dt = \int_0^\infty \big|\langle t^{-k+1}A_{-k}^{-k+1}\varphi(tA_{-k})\psi(tA_{-k})Bu(t), x'\rangle\big|\,dt.$$

Notice that by sectoriality of A, the operators $A_{-k}(\mu + A_{-k})^{-1}$, $\mu > 0$, are uniformly bounded. Moreover, $\lim_{\mu\to 0+} A_{-k}(\mu + A_{-k})^{-1}Bu = Bu$ in X_{-k} since A_{-k} has dense range in X. Therefore, applying Fatou's lemma and writing $B_\mu := A_{-k}(\mu+A_{-k})^{-1}B$, we have

$$\begin{aligned}&\int_0^\infty \big|\langle T_{-k}(t)Bu(t), x'\rangle\big|\,dt\\ &\le \liminf_{\mu\to 0+} \int_0^\infty \big|\langle t^{-k+1}A_{-k}^{-k+1}\varphi(tA_{-k})\psi(tA_{-k})B_\mu u(t), x'\rangle\big|\,dt.\end{aligned}$$

Notice that $\psi(tA_{-k})Bu(t) \in \mathcal{D}(A_{-k}^{-k+1+\epsilon})$, whereas $\psi(tA_{-k})B_\mu u(t) \in \mathcal{D}(A_{-k}^{-k+\epsilon})$. This observation allows us to interchange the operators $\varphi(tA_{-k})$ and A_{-k}^{-k+1} as follows:

$$\begin{aligned}&= \liminf_{\mu\to 0+} \int_0^\infty \big|\langle \varphi(tA_{-k})t^{-k+1}A_{-k}^{-k+1}\psi(tA_{-k})B_\mu u(t), x'\rangle\big|\,dt\\ &= \liminf_{\mu\to 0+} \int_0^\infty \big|\langle t^{1+1/p'-k}A_{-k}^{-k}\psi(tA_{-k})B_\mu u(t), t^{-1/p'}\varphi(tA_{-k})'x'\rangle\big|\,dt\\ &\le \liminf_{\mu\to 0+} \Big\| t \mapsto \underbrace{\big[t^{1/p'-\alpha-k+1}A_{-k}^{-k-1}\psi(tA_{-k})B_\mu\big]}_{=:L_\mu(t)} t^\alpha u(t)\Big\|_{L^p(\mathbb{R}_+,X)} \big\|\varphi(tA')x'\big\|_{L^{p'}(\mathbb{R}_+,\frac{dt}{t},X')}.\end{aligned}$$

Notice that by assumption on A', the $L^{p'}$-norm has an estimate against the norm of x', whence the existence of the integral is proved if we show the uniform boundedness of the operators $L_\mu(t)$ for $t > 0$ and $\mu > 0$. This step is very similar to the proof of uniform boundedness of the family $K(t)$, $t > 0$, in the proof of Theorem 1.7: we apply Lemma 3.2 with $m = k - 1$ to the function $\psi(z)$ and obtain for fixed $t > 0$

$$\begin{aligned}&A_{-k}^{-k+1}\psi(tA_{-k})B_\mu u(t)\\ =\ &\tfrac{(k-1)!}{2\pi i}\int_\Gamma f(\lambda)t^{k-1}R(\lambda, tA_{-k})^k B_\mu u(t)\,d\lambda + at^{k-1}(I + tA_{-k})^{-k}B_\mu u(t).\end{aligned}$$

Now for $u \in U$ write

$$\begin{aligned}L_\mu(t)u &= \tfrac{(k-1)!}{2\pi i}\int_\Gamma f(\lambda)t^{1/p'-\alpha}R(\lambda, tA_{-k})^k B_\mu u\,d\lambda + at^{1/p'-\alpha}(I + tA_{-k})^{-k}B_\mu u(t)\\ &= \tfrac{(k-1)!}{2\pi i}\int_\Gamma f(\lambda)\lambda^{-k-\alpha+1/p'}\left[A_{-k}(\mu+A_{-k})^{-1}\right]\left[\left(\tfrac{\lambda}{t}\right)^{k+\alpha-1/p'+1} R(\tfrac{\lambda}{t}, A_{-k})^k B\right] u\,\tfrac{d\lambda}{\lambda}\\ &\quad + a\left[A_{-k}(\mu+A_{-k})^{-1}\right]\left[\left(\tfrac{1}{t}\right)^{k+\alpha-1/p'}(\tfrac{1}{t} + A_{-k})^{-k}B\right] u.\end{aligned}$$

Therefore, by the assumption (1.8) and a similar calculation to (3.5) the set $\{L_\mu(t) : t > 0,\ \mu > 0\}$ is bounded in $B(U, X)$ provided that the integral

$$\int_\Gamma \big|f(\lambda)\big|\,|\lambda|^{-k-\alpha+1/p'}\,d|\lambda|$$

is finite. Since $f \in O(|z|^{k-1-\epsilon})$ in zero and $f \in O(|z|^{-n})$ for any $n \in \mathbb{N}$, this boils down to

$$k - 1 - \epsilon - k - \alpha + 1/p' > -1, \quad \text{i.e., to} \quad \alpha < 1/p' - \epsilon,$$

which, due to our assumption on α, always may be satisfied by some $\epsilon \in (0,1)$.

Step 2. Now let $x' \in X'$. We show that $t \mapsto \langle T(t)Bu(t), x'\rangle \in L^1(\mathbb{R}_+)$ with a norm estimate against $K'\|u\|_{L^p_\alpha(R_+,U)}\|x'\|_{X'}$. To this end we first notice that by analyticity of the semigroup, $T_{-k}(t)Bu(t) \in X$ for $t > 0$. Moreover, for t positive, $T_{-k}(t)Bu(t) = \lim_{\epsilon\to 0} T_{-k}(t+\epsilon)Bu(t)$ in X. Therefore, Fatou's lemma yields

$$\int_0^\infty \big|\langle T_{-k}(t)Bu(t), x'\rangle\big|\,dt \le \liminf_{\epsilon\to 0} \int_0^\infty \big|\langle T_{-k}(t)Bu(t), T_{-k}(\epsilon)'x'\rangle\big|\,dt.$$

Notice that $y'_\epsilon := T_{-k}(\epsilon)'x' \in \mathcal{D}((A')^k)$ and by Step 1,

$$\int_0^\infty \big|\langle T(t)Bu(t), y'_\epsilon\rangle\big|\,dt \le K\|u\|_{L^p_\alpha}\|y'_\epsilon\|_{X'}.$$

Since $\|T_{-k}(\epsilon)'x'\| \le K_0\|x'\|$ the integral $\int_0^\infty T(t)Bu(t)\,dt$ exists as a Pettis integral in X. The above argumentation shows that we have a bounded linear mapping $\Phi : L^p(\mathbb{R}_+, U) \to X''$, $\Phi(u) = \int_0^\infty T_{-k}(t)Bu(t)\,dt$. If u is a step function with compact support that does not contain zero, the integral in question even exists as a Bochner integral. In this case, it takes values in X by analyticity of the semigroup $T(\cdot)$. Since such step functions are dense in $L^p(\mathbb{R}_+, U)$ (recall $p < \infty$) we obtain $\mathcal{R}\Phi \subseteq X$ and thus Φ is necessarily bounded from $L^p(\mathbb{R}_+, U)$ to X. This finishes our proof. ∎

Regularity and wellposedness.

Proof of Lemma 1.12. It is not hard to see that for bounded analytic semigroups and $k \in \mathbb{N}$, $\|t^k A^k T(t)\| \le c_k < \infty$. Indeed, by the elementary functional calculus for sectorial operators (cf. [21]) and substituting $tz = \lambda$ one has

$$\begin{aligned}\big\|(tA)^k T(t)\big\| &= \left\| \tfrac{1}{2\pi i} \int_\Gamma (tz)^k e^{-tz} R(z, A)\,dz \right\| \\ &\le M \int_\Gamma |tz|^k e^{-t\,\mathrm{Re}(z)}\, \tfrac{|dz|}{|z|} = M \int_\Gamma |\lambda|^k e^{-\ \mathrm{Re}\ \lambda}\, \tfrac{|d\lambda|}{|\lambda|} =: c_k < \infty.\end{aligned}$$

This shows $\|T(t)\|_{X\to \dot X_k} \le c_k t^{-k}$, $t > 0$. On the other hand, clearly $\|T(t)\|_{X\to X} \le c_0$, $t \ge 0$. By real interpolation we obtain immediately $\|T(t)\|_{X\to Z} \le k_1 t^{-\theta k}$. Similarly, considering $\dot X_{-k}$ and X in place of X and $\dot X_k$, one obtains $\|T(t)\|_{W\to X} \le k_2 t^{-\sigma k}$. Both estimates together give the claim by the semigroup property. ∎

Proof of Proposition 1.14. Let $\phi(s) := \big|(1+s)^\alpha - 1\big|$. Then

$$\|(Tf)(t)\|_Y \le M \int_0^t \tfrac{1}{t-s}\phi(\tfrac{t-s}{s})\|f(s)\|_U\,ds,$$

whence T is pointwise bounded by a multiple of the scalar integral operator

$$(\widetilde{T}u)(t) := \int_0^t \tfrac{1}{t-s}\phi(\tfrac{t-s}{s})u(s)\,ds,$$

which has the kernel $k(t,s) = \mathbb{1}_{[0,t]}(s)\frac{1}{t-s}\phi(\frac{t-s}{s})$. Notice that, substituting $s = t\sigma$,

$$\big\|k(t,\cdot)\big\|_{p'}^{p'} = \int_0^t \left|\frac{(1+\frac{t-s}{s})^\alpha - 1}{t-s}\right|^{p'} ds = t^{1-p'} \int_0^1 \left|\frac{\sigma^{-\alpha}-1}{\sigma-1}\right|^{p'} d\sigma \le t^{1-p'}\widetilde{c},$$

where $\widetilde{c} = \widetilde{c}(p,\alpha) < \infty$ since letting $g(\sigma) := \sigma^{-\alpha}$, the limit for $\sigma \to 1$ equals $g'(1) = -\alpha$. It follows by Hölder's inequality that $|\widetilde{T}u(t)| \le cM\|u\|_p t^{-1/p}$ (notice $(1-p')/p' = -1/p$). Therefore,

$$\lambda\,\mu\big(\{t>0:\ |\widetilde{T}u(t)|\ge\lambda\}\big)^{1/p} \le \lambda\,\mu\big(\{t>0:\ M\|u\|_p t^{-1/p}\ge\lambda\}\big)^{1/p} = M\|u\|_p,$$

showing that $\widetilde{T}$ is of weak type (p,p) for every $p\in(1,\infty)$. By Marcinkiewicz interpolation, $\widetilde{T}$ is bounded on $L^p(\mathbb{R}_+)$ for $p\in(1,\infty)$, which implies the assertion. □

Proof of Theorem 1.13. Let $\mathcal{F}$ denote the convolution operator acting $L^p(\mathbb{R}_+,U) \to L^p(\mathbb{R}_+,Y)$ and $\mathcal{F}^\alpha$ denote the same operator acting $L^p_\alpha(\mathbb{R}_+,U) \to L^p_\alpha(\mathbb{R}_+,Y)$. Further let $\Phi_\alpha : L^p_\alpha(\mathbb{R}_+,\cdot) \to L^p(\mathbb{R}_+,\cdot)$ be the canonical isometric isomorphism given by $(\Phi_\alpha f)(t) := t^\alpha f(t)$. Then $T := \Phi_\alpha \mathcal{F}^\alpha \Phi_\alpha^{-1} - \mathcal{F}$ satisfies

$$(Tu)(t) = \int_0^t \big[\big(\tfrac{t}{s}\big)^\alpha - 1\big] K(t-s)\,u(s)\,ds$$

with $K(t-s) = CT(t-s)B$. By analyticity of the semigroup, $K\in C(\mathbb{R}_+, B(U,Y))$ and by hypothesis $\|K(t)\| \le M/t$. Therefore, Proposition 1.14 applies and yields boundedness of $T : L^p(\mathbb{R}_+,U) \to L^p(\mathbb{R}_+,Y)$. Hence $\mathcal{F}$ is bounded if and only if $\mathcal{F}^\alpha$ is. □

Proof of Theorem 1.16. We let $v := T(\cdot)x_0$ and denote, for $\rho,\tau>0$ to be fixed later,

$$\Sigma_{\rho,\tau} = \{x\in C([0,\tau],X)\cap L^p_\alpha([0,\tau],Z) : x(0)=x_0, \|x-w\|_\Sigma \le \rho\},$$

where $\|x\|_\Sigma := \max\{\|x\|_{C([0,\tau],X)}, \|x\|_{L^p_\alpha([0,\tau],Z)}\}$. Observe that we dropped τ in notation of the norm and that $\Sigma_{\rho,\tau}$ is complete for the metric induced by $\|x\|_\Sigma$. We let $\Gamma x := v + T(\cdot) * B(F(x)-F(x_0))Cx$ for $x\in\Sigma_{\rho,\tau}$ and shall choose ρ and τ such that Γ is a contraction on $\Sigma_{\rho,\tau}$. Then Banach's fixed point theorem ends the proofs.

If f is a simple function with values in U with compact support in $(0,\tau)$, then by analyticity of the semigroup $T(\cdot)B * f$ is a continuous, X-valued function. Since such functions are dense in $L^p_\alpha(U)$ (recall $p<\infty$), $T(\cdot)B*$ maps $L^p_\alpha(U)$ boundedly into $C([0,\tau],X)$. We let $c_v(\tau) := \|v-x_0\|_{C([0,\tau],X)}$ and $l_v(\tau) := \|v\|_{L^p_\alpha([0,\tau],Z)}$. In the following we shall drop the time interval in the norms. The assumptions imply that $\|T(\cdot)B*u\|_\Sigma \le K\|u\|_{L^p_\alpha(U)}$ for some $K>0$. We write L for the Lipschitz-constant of the function F. Then we have, for $x\in\Sigma_{\rho,\tau}$,

$$\begin{aligned}
\|\Gamma x - v\|_\Sigma &\le K\|(F(x)-F(x_0))Cx\|_{L^p_\alpha(U)}\\
&\le KL\|C\|\|x-x_0\|_{L^\infty(X)}\|x\|_{L^p_\alpha(Z)}\\
&\le KL\|C\|(\|x-v\|_{C(X)} + \|v-x_0\|_{C(X)})(\|x-v\|_{L^p_\alpha(Z)} + \|v\|_{L^p_\alpha(Z)})\\
&\le KL\|C\|(\rho + c_v(\tau))(\rho + l_v(\tau)).
\end{aligned}$$

Similarly, we obtain, for $x,\tilde{x}\in\Sigma_{\rho,\tau}$,

$$\begin{aligned}
\|\Gamma x - \Gamma\tilde{x}\|_\Sigma &\le K\|(F(x)-F(x_0))Cx - (F(\tilde{x})-F(x_0))C\tilde{x}\|_{L^p_\alpha(U)}\\
&\le K(\|(F(x)-F(x_0))C(x-\tilde{x})\|_{L^p_\alpha(U)} + \|(F(x)-F(\tilde{x}))C\tilde{x}\|_{L^p_\alpha(U)})\\
&\le KL\|C\|(\|x-x_0\|_{L^\infty(X)}\|x-\tilde{x}\|_{L^p_\alpha(Z)} + \|x-\tilde{x}\|_{C(X)}\|\tilde{x}\|_{L^p_\alpha(Z)})\\
&\le KL\|C\|(\rho + c_v(\tau) + \rho + l_v(\tau))\|x-\tilde{x}\|_\Sigma.
\end{aligned}$$

Now we choose $\rho > 0$ such that $\eta := 4KL\|C\|\rho < 1$ and then $\tau > 0$ such that $\max\{c_v(\tau), l_v(\tau)\} \le \rho$. Thus we obtain

$$\|\Gamma x - v\|_\Sigma \le \eta\rho < \rho \quad \text{and} \quad \|\Gamma x - \Gamma\tilde{x}\|_\Sigma \le \eta\|x - \tilde{x}\|_\Sigma$$

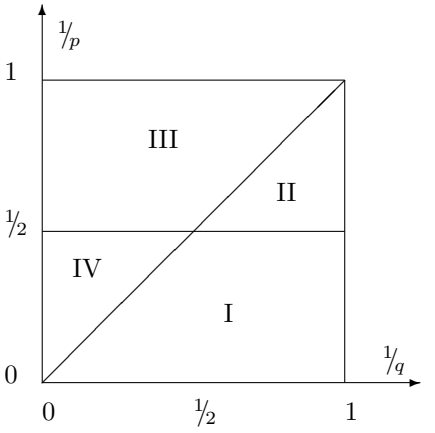
for $x, \tilde{x} \in \Sigma_{\rho,\tau}$, as desired. □

L^q-spaces and Besov spaces.

Proof of Lemma 2.1. The definition of Besov and Triebel–Lizorkin spaces together with Minkowski's inequality yield, for any $s \in \mathbb{R}$,

$$\begin{aligned} &B^s_{q,p}(\Omega) \hookrightarrow F^s_{q,p}(\Omega) \quad \text{provided that } q \ge p \text{ and} \\ &F^s_{q,p}(\Omega) \hookrightarrow B^s_{q,p}(\Omega) \quad \text{provided that } q \le p. \end{aligned}$$

This will be used in what follows. First we show the "if" part; that is, we show $L^q(\Omega) \hookrightarrow B^0_{q,p}(\Omega)$ in the case $p \ge \max(2, q)$, that is, $(1/q, 1/p) \in$ I, where area I is as depicted below. By the above embeddings of Besov and Triebel–Lizorkin spaces, $L^q(\Omega) = F^0_{q,2}(\Omega) \hookrightarrow F^0_{q,p} \hookrightarrow B^0_{q,p}$.



Next, we consider the case $(1/q, 1/p) \in$ III, that is, $p \le \min(q, 2)$ and $(p, q) \ne (2, 2)$. If $p \le 2 \le q$ and if $p < q$, we have

$$B^0_{q,p}(\Omega) \hookrightarrow B^0_{q,2} \underset{\neq}{\hookrightarrow} F^0_{q,2}(\Omega) = L^q(\Omega),$$

and if $p, q < 2$ and $p \le q$, we have

$$B^0_{q,p}(\Omega) \hookrightarrow F^0_{q,p}(\Omega) \underset{\neq}{\hookrightarrow} F^0_{q,2}(\Omega) = L^q(\Omega).$$

Therefore, obviously $L^q(\Omega) \not\hookleftarrow B^0_{q,p}(\Omega)$.

For counterexamples in areas II and IV we construct specific functions $f \in L^q$ by wavelet decompositions (cf. [23]) that show why the Besov norm cannot be estimated by the L^q-norm.

Let Λ be the set of all points $\lambda = 2^{-j}k + 2^{-j-1}\epsilon$, where $j \in \mathbb{Z}$, $k \in \mathbb{Z}^n$, and $0 \ne \epsilon \in \{0, 1\}^n$. Then every $\lambda \in \Lambda$ corresponds to unique j, k, and ϵ. Let Q_λ be the dyadic cube defined by $Q_\lambda := \{x \in \mathbb{R}^n : \ 2^j x - k \in [0, 1)^n\}$. Finally, by [23, Thm. III.8.1] choose some 1-regular wavelet basis (ψ_λ) with compact support. Then supp $\psi_\lambda \subset cQ_\lambda$ for some $c > 0$. We let $\Lambda' := \{\lambda \in \Lambda : \text{ supp } \psi_\lambda \subset \Omega\}$.

First we treat $(1/q, 1/p)$ in area II, that is, $q < p < 2$. By [23, Thm. VI.2.1], for $f = \sum_\lambda \alpha(\lambda)\psi_\lambda(x)$ in $L^q(\mathbb{R}^n)$, we have equivalence

$$\|f\|_{L^q} \sim \left\| \left(\sum_{\lambda\in\Lambda} |\alpha(\lambda)|^2 |Q_\lambda|^{-1} \mathbb{1}_{Q_\lambda} \right)^{1/2} \right\|_{L^q}. \tag{3.7}$$

In the following, it will be sufficient to consider only functions f that decompose in a finite sum. If $Q \subset \Omega$ for some $Q = Q_{\lambda_0}$, $\lambda_0 \in \Lambda'$, set $\alpha(\cdot)$ such that only dyadic subcubes of Q are considered in the above summation: if Q_λ belongs to the jth dyadic subdivision of Q, then let $\alpha(\lambda) := \alpha_j$; otherwise let $\alpha(\alpha) := 0$. Then the expression on the right-hand side of (3.7) L^q-norm of f simplifies to

$$\left\| \left(\sum_{j=0}^{N} \sum_{\Lambda'_j} \left|\alpha(\lambda)\right|^2 \mathbb{1}_{Q_\lambda} \right)^{1/2} \right\|_{L^q} = \left|Q\right|^{1/q} \left(\sum_{j=0}^{N} |\alpha_j|^2 \right)^{1/2}.$$

On the left-hand side, an equivalent $B^0_{q,p}$-norm of $f = \sum_\lambda \alpha(\lambda)\psi_\lambda(x)$ is given by

$$\|f\|_{B^0_{q,p}} \sim \left(\sum_{j=0}^{N} \left(\left(\sum_{\lambda\in\Lambda'_j} \left|\alpha(\lambda)\right|^q \right)^{1/q} 2^{-nj(1/q-1/2)} \right)^p \right)^{1/p}; \tag{3.8}$$

see [23, VI.10.5]. But, for $\lambda \in \Lambda'_j$ such that $Q_\lambda \subset Q$, $|\alpha(\lambda)| = |\alpha_j| 2^{jn/q}$, whence

$$\|f\|_{B^0_{q,p}} \sim \left(\sum_{j=0}^{N} |\alpha_j| 2^{njp/2} \right)^{1/p}.$$

Therefore, setting $\alpha_j := 2^{njp/2}$ for $j = 0, \dots, N$ and letting $N \to \infty$ reveals that $L^q(\Omega) \hookrightarrow B^0_{q,p}$ implies $p \geq 2$.

Finally, consider the case IV, that is, $q > 2$ and $2 < p < q$. If we set the wavelet coefficients $\alpha(\lambda)$ of f in (3.7) such that the cubes in $\{Q(\lambda) : \alpha(\lambda) \neq 0\}$ are piecewise disjoint, then

$$\begin{aligned}
\|f\|_q \sim \left\| \left(\sum_{\lambda\in\Lambda} |\alpha(\lambda)|^2 |Q_\lambda|^{-1} \mathbb{1}_{Q_\lambda} \right)^{1/2} \right\|_{L^q} &= \left\| \sum_{\lambda\in\Lambda} |\alpha(\lambda)| |Q_\lambda|^{-1/2} \mathbb{1}_{Q_\lambda} \right\|_{L^q} \\
&= \left(\sum_{\lambda\in\Lambda} |\alpha(\lambda)|^q |Q_\lambda|^{-q/2} |Q_\lambda| \right)^{1/q} \\
&= \left(\sum_j \left(\left(\sum_{\lambda\in\Lambda_j} |\alpha(\lambda)|^q \right)^{1/q} |Q_\lambda|^{1/q-1/2} \right)^q \right)^{1/q}.
\end{aligned}$$

On the left-hand side, notice that $|Q_\lambda| = 2^{-nj}$. Thus, comparing the L^q-norm of f with the equivalent $B^0_{q,p}$-norm given by (3.8), we find $L^q(\Omega) \hookrightarrow B^0_{q,p}(\Omega)$ requires $q \geq p$, contradicting the assumption $p < q$. □

CONJUGATE POINTS IN FORMATION CONSTRAINED OPTIMAL MULTI-AGENT COORDINATION: A CASE STUDY*

JIANGHAI HU†, MARIA PRANDINI‡, AND CLAIRE TOMLIN§

Abstract. In this paper, an optimal coordinated motion planning problem for multiple agents subject to constraints on the admissible formation patterns is formulated. Solutions to the problem are reinterpreted as distance minimizing geodesics on a certain manifold with boundary. A geodesic on this manifold may fail to be a solution for different reasons. In particular, if a geodesic possesses conjugate points, then it will no longer be distance minimizing beyond its first conjugate point. We study a particular instance of the formation constrained optimal coordinated motion problem, where a number of initially aligned agents tries to switch positions by rotating around their common centroid. The complete set of conjugate points of a geodesic naturally associated with this problem is characterized analytically. This allows us to prove that the geodesic will not correspond to an optimal coordinated motion when the angle of rotation exceeds a threshold that decreases to zero as the number of agents increases. Moreover, infinitesimal perturbations that improve the performance of the geodesic after it passes the conjugate points are also determined, which, interestingly, are characterized by a certain family of orthogonal polynomials.

Key words. conjugate point, multi-agent coordination, geodesics, orthogonal polynomials

1. Introduction.

Multi-agent coordinated motion planning problems arise in various contexts, such as air traffic management (ATM) [12, 21], robotics [3], and unmanned aerial vehicles (UAVs) [17, 20, 22]. In most cases, certain separation constraints between the agents have to be guaranteed due to physical, safety, or efficiency reasons. For example, in ATM systems, aircraft flying at the same altitude are required to maintain a minimal horizontal separation of 5 nautical miles in en-route airspace and 3 nautical miles when close to airports. When multiple mobile robots are performing a coordinated task such as lifting a common object, specific formations have to be kept by the robots throughout the operation. For UAVs, flying in formation may reduce the fuel expenditure and the communication power needed for information exchange.

In this paper, we formulate an optimal coordinated motion planning problem for multiple agents under formation constraints. We consider all the coordinated motions that can lead a group of agents from given initial positions to given destination positions within a certain time horizon, while satisfying the additional constraint that the formation patterns of the agents belong to a prescribed subset. Among the coordinated motions in this restricted set, we try to find the ones that minimize a weighted sum of the energy functions of each individual agent's motions, with the weights

representing agent priorities. In our problem formulation, we use simple kinetic models for the agent dynamics and consider only holonomic constraints, as opposed to the numerous works dealing with nonholonomic constraints (e.g. [2, 11, 19]). See, for example, [5, 13, 15] for relevant work on the problems of stable and optimal coordinated control of vehicle formations.

A geometric interpretation of the considered optimal coordinated motion planning problem is given in this paper. According to this interpretation, a solution to the problem is a shortest curve with constant speed between two fixed points in a certain manifold with boundary, where the boundary is determined by the feasible formation patterns. Being a shortest curve between two points, which can be far away from each other, such a *globally* distance minimizing curve is obviously also a *locally* distance minimizing curve, i.e., a curve whose sufficiently short segments are distance-minimizing between their respective end points. Locally distance minimizing curves parameterized with constant speed are called *geodesics*. Thus a solution to the problem necessarily corresponds to a geodesic of the manifold.

Conversely, however, for various reasons a geodesic of the manifold may fail to be globally distance minimizing, thus failing to solve the problem. One of the reasons is the occurrence of conjugate points. Traveling along a geodesic from a fixed starting point, a conjugate point occurs at a point where there exists a nontrivial Jacobi field along the geodesic vanishing at both the starting point and that particular point [4], or less rigorously, where there exists infinitesimally more than one geodesic connecting the starting point to that point. For a simple example, consider the sphere. Geodesics on the sphere are great circles; and conjugate points along a great circle occur at the antipodal point of its starting point. It is a well-known fact in Riemannian geometry that a geodesic will not be distance minimizing once it passes its first conjugate point [4], as one can then infinitesimally perturb it to obtain a shorter curve with the same end points. In the sphere example, when a great circle extends beyond two antipodal points, a shorter curve between its starting and ending points can be found by following the intersection of the sphere with any codimensional one plane passing through the two points. The aim of this paper is to study, through a concrete example, the loss of optimality due to the existence of conjugate points in the multiagent coordination problem, which so far has been largely ignored in the literature.

It is in general difficult, if not impossible, to characterize the conjugate points of a geodesic analytically. In this paper, we shall focus on a special instance of the formation constrained optimal coordination problem, namely, a group of initially aligned agents switching positions by rotating around their common centroid. We shall show that the conjugate points of a geodesic that arises naturally as a candidate solution to this particular problem admit nice analytic formulae. We shall also determine the infinitesimal perturbations that can shorten the geodesic with various efficiencies, once it passes its conjugate points, and characterize them using a certain family of orthogonal polynomials. A geometric interpretation of our results is that they characterize how far a curve traveling along the outer edge of a (high-dimensional) donut-shaped state space can be extended before it is no longer distance minimizing. Another interesting interpretation of our results can be given with reference to a mechanical model of a multisegment snake-like robot that needs to rotate, moving between two completely stretched configurations. If the angle of rotation exceeds a certain threshold, then the motion corresponding to the robot rotating around its center of mass at constant angular velocity, with all of its segments constantly aligned in a straight line, will not be energy minimizing. More efficient motions can be found by "folding" the snake in various ways.

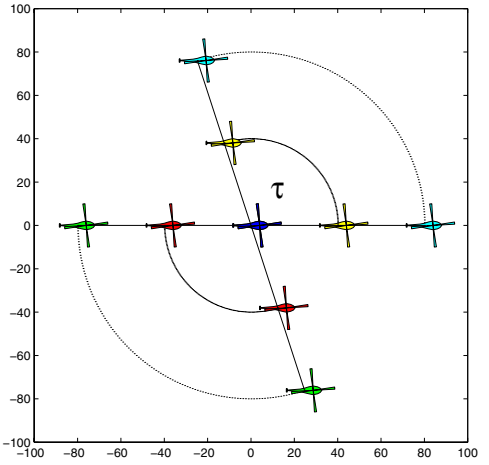

FIG. 1.1. *A five-agent example.*

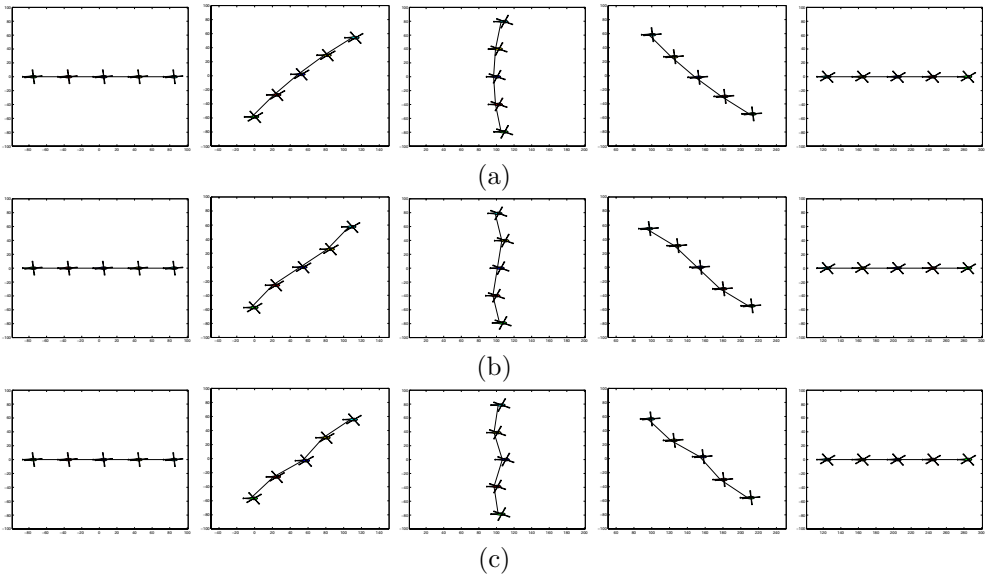

FIG. 1.2. *Three joint maneuvers with increasingly lower cost than the one shown in Figure* 1.1 *when* $\tau = \pi$. *Top row: maneuver* (a)*; middle row: maneuver* (b)*; bottom row: maneuver* (c). *From left to right: snapshots at times* $t = 0, \frac{1}{4}, \frac{1}{2}, \frac{3}{4}, 1$, *respectively.*

As a preview of the results and a specific example, see Figure 1.1, where five helicopters initially flying in a straight line try to reach new positions by rotating counterclockwise around their centroid, i.e., the middle helicopter, at the same angular velocity during the time period $[0, 1]$ (thus the five helicopters form a straight line at all times). The results in this paper will show that this joint maneuver is optimal in terms of minimizing a cost function defined as the sum of energy of an individual helicopter's maneuvers only if the angle τ of rotation is small, and that it is not optimal if $\tau > \frac{\pi}{3}$. Indeed, if for example $\tau = \pi$, then we can find better maneuvers than the one in Figure 1.1. We plot in the three rows of Figure 1.2 three such maneuvers, where in each row the five figures from left to right represent the snapshots of the

maneuver at times $t = 0, \frac{1}{4}, \frac{1}{2}, \frac{3}{4}, 1$, respectively. In terms of performance, we will show that maneuver (c) is the best; maneuver (a) is the worst of the three, but still better than the original one in Figure 1.1.

A related work [7] studies the simpler problem of optimal collision avoidance—with no formation constraints. Avoidance maneuvers are formally classified into homotopy types, and the optimal ones are characterized by local and global conditions obtained through a variational analysis approach based on a geometric interpretation of a joint maneuver as a braid. In [7, sect. 3.6], a special instance of the case study investigated in this paper, with only three agents involved in the coordinated maneuver, was presented as an example to show that optimal solutions within a homotopy type are not unique.

The results proved in the present paper represent a highly nontrivial extension of those in the example of [7] to the general case of k (possibly larger than 3) agents and contain contributions that go far beyond the scope of [7]. First of all, formation constraints play a central role in the optimal coordination problem studied here, whereas in [7] they are only marginally treated in the example of section 3.6. Second, as the number k of agents increases beyond 3, computing the conjugate points becomes a markedly more difficult task because (i) many intermediate results, such as the inverse Riemannian metric, the Christoffel symbols, and the curvature tensors, are no longer directly computable; (ii) the Jacobi equation that one needs to solve is of the form $\ddot{x} = -Bx$ with $B \in \mathbb{R}^{(k-1)\times(k-1)}$, and for $k > 3$ it cannot be reduced to a scalar ODE as in [7, sect. 3.6], thus necessitating the spectrum decomposition of B; and (iii) the perturbed solutions with better performance after passing the conjugate points are now multidimensional instead of one-dimensional. Lastly, some completely new results are obtained in this paper, such as that the first conjugate point along the candidate solution occurs at a distance that decreases to zero at the rate of $\frac{1}{k}$ as the number k of agents grows to infinity, and that the infinitesimal perturbation that can improve the performance of the candidate solution after it passes the conjugate points can be described by a family of orthogonal polynomials of order $k-1$, called the ultraspherical polynomials.

This paper is organized as follows. In section 2 the formation patterns of a group of agents are defined and the problem of formation constrained optimal multi-agent coordination is formulated. In section 3 the conjugate points of the geodesic naturally arising in a particular instance of the problem are characterized analytically. Infinitesimal perturbations that improve the performance of the geodesic beyond its conjugate points are also determined. Finally, some conclusions are drawn in section 4.

2. Formation constrained optimal multi-agent coordination. In this section we formulate the problem of formation constrained optimal multi-agent coordination and describe some properties of its solutions that will be useful in the next section. For simplicity, the problem is formulated in Euclidean spaces. See [9] for an extension of the results to general Riemannian manifolds with a group of symmetries.

2.1. Problem formulation. We first introduce some notions. Let $\mathbb{R}^n$ be the Euclidean space with the standard Euclidean metric. Denote by $\langle q_i \rangle_{i=1}^k = (q_1, \ldots, q_k)$ an (ordered) k-tuple of points in $\mathbb{R}^n$ for some positive integer k. We say that $\langle q_i \rangle_{i=1}^k$ satisfies the *r-separation condition* for some $r > 0$ if $d(q_i, q_j) = \|q_i - q_j\| \geq r$ for all $i \neq j$, i.e., if the minimum pairwise distance among the k points is at least r.

With each k-tuple $\langle q_i \rangle_{i=1}^k$ satisfying the r-separation constraint we associate an undirected graph $(\mathcal{V}, \mathcal{E})$ with a set of vertices $\mathcal{V} = \{1, \ldots, k\}$ and a set of edges $\mathcal{E} = \{(i,j) : \|q_i - q_j\| = r\}$. We call $(\mathcal{V}, \mathcal{E})$ the *formation pattern* of the k-tuple

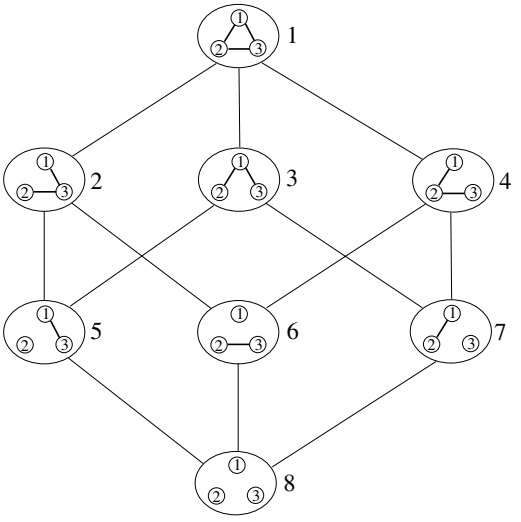

FIG. 2.1. *A graphical representation of $\mathcal{F}$ in the cases $n = 2$ and $k = 3$. Eight feasible formation patterns are represented by eight nodes. There is a line segment upward from node $(\mathcal{V}, \mathcal{E}_1)$ to node $(\mathcal{V}, \mathcal{E}_2)$ if and only if $(\mathcal{V}, \mathcal{E}_1) \prec (\mathcal{V}, \mathcal{E}_2)$ and no other $(\mathcal{V}, \mathcal{E}) \in \mathcal{F}$ satisfies $(\mathcal{V}, \mathcal{E}_1) \prec (\mathcal{V}, \mathcal{E}) \prec (\mathcal{V}, \mathcal{E}_2)$.*

$\langle q_i \rangle_{i=1}^k$. Denote by $\mathcal{F}$ the set of (*feasible*) formation patterns, i.e., the set of all undirected graphs $(\mathcal{V}, \mathcal{E})$ associated with k-tuples of points satisfying the r-separation condition. A partial order $\prec$ can be defined on $\mathcal{F}$ so that two formation patterns satisfy $(\mathcal{V}, \mathcal{E}_1) \prec (\mathcal{V}, \mathcal{E}_2)$ if and only if $(\mathcal{V}, \mathcal{E}_1)$ is a subgraph of $(\mathcal{V}, \mathcal{E}_2)$. A graphical representation of $\mathcal{F}$ with this partial order relation is shown in Figure 2.1 in the cases $n = 2$ and $k = 3$.

REMARK 1. *For given n, r, and k, all graphs with k vertices are not feasible formation patterns, i.e., are not the formation patterns of a k-tuple of points in $\mathbb{R}^n$ satisfying the r-separation condition. For example, if $n = 2$ and $k = 4$, the complete graph with four vertices and edges between each pair of them is not the formation pattern of any $\langle q_i \rangle_{i=1}^4$ satisfying the r-separation condition, regardless of r. Characterizing the set $\mathcal{F}$ of all feasible formation patterns for general n, r, and k remains a challenging problem.*

Consider k agents moving in $\mathbb{R}^n$. Suppose that they start at time 0 from the initial positions $a_1, \ldots, a_k \in \mathbb{R}^n$ and must reach the destination positions $b_1, \ldots, b_k \in \mathbb{R}^n$ at time t_f, respectively. We assume that both $\langle a_i \rangle_{i=1}^k$ and $\langle b_i \rangle_{i=1}^k$ satisfy the r-separation condition. Denote the joint trajectory of the agents by a k-tuple of curves $\gamma = \langle \gamma_i \rangle_{i=1}^k$, where the trajectory of agent i during the time interval $[0, t_f]$ is modeled as a continuous and piecewise C^1 curve $\gamma_i : [0, t_f] \to \mathbb{R}^n$ such that $\gamma_i(0) = a_i$ and $\gamma_i(t_f) = b_i$. The joint trajectory γ is said to be *collision-free* if for all $t \in [0, t_f]$ the k-tuple $\langle \gamma_i(t) \rangle_{i=1}^k$ satisfies the r-separation condition, or equivalently, if the distance between any two agents is at least r at all times during $[0, t_f]$. For a collision-free joint trajectory γ, its formation pattern at time $t \in [0, t_f]$ is the formation pattern of the k-tuple of points $\langle \gamma_i(t) \rangle_{i=1}^k$, which is time varying.

Define the cost of the joint trajectory γ as

$$J(\gamma) = \sum_{i=1}^{k} \mu_i E(\gamma_i), \tag{2.1}$$

where $\mu_1, \dots, \mu_k$ are positive numbers representing the priorities of the agents, and

$$E(\gamma_i) = \frac{1}{2}\int_0^{t_f} \|\dot{\gamma}_i(t)\|^2\, dt \tag{2.2}$$

is the standard energy of the trajectory γ_i as a curve in $\mathbb{R}^n$, for $i = 1, \dots, k$. If we denote by $L(\gamma_i) = \int_0^{t_f} \|\dot{\gamma}_i(t)\|\, dt$ the arc length of γ_i, then by the Cauchy–Schwarz inequality [14], $E(\gamma_i) \geq \frac{1}{2}L^2(\gamma_i)/t_f$, where the equality holds if and only if $\|\dot{\gamma}_i(t)\|$ is constant for $t \in [0, t_f]$.

Based on the introduced notions, the problem of optimal formation constrained coordinated motions for k agents moving in $\mathbb{R}^n$ can be formulated as follows.

PROBLEM 1 (optimal formation constrained coordination (OFC)). *Among all the collision-free joint trajectories $\gamma = \langle \gamma_i \rangle_{i=1}^k$ that start from $\langle a_i \rangle_{i=1}^k$ at time 0 and end at $\langle b_i \rangle_{i=1}^k$ at time t_f, find the ones that minimize the cost $J(\gamma)$ and satisfy the constraint that the formation pattern of γ at any time $t \in [0, t_f]$ belongs to some prescribed subset $\tilde{\mathcal{F}}$ of $\mathcal{F}$. Here we assume that $\tilde{\mathcal{F}}$ contains the formation patterns of both $\langle a_i \rangle_{i=1}^k$ and $\langle b_i \rangle_{i=1}^k$.*

If $\tilde{\mathcal{F}} = \mathcal{F}$, i.e., all formation patterns are allowed, the resulting OFC problem is also called the optimal collision avoidance (OCA) problem, which has important implication in the ATM application [21].

As an example, in Figure 2.1, one can choose $\tilde{\mathcal{F}}$ to consist of formation patterns 1, 2, 3, and 4, thus requiring that every two agents "contact" each other either directly or indirectly via the third agent at all time instants. This makes sense in practical situations, where the three agents have to share some common data and where information exchange is possible only at the minimum allowed distance. As another example, $\tilde{\mathcal{F}}$ can be chosen to consist of formation patterns 1, 3, 4, and 7. In this case, agent 1 and agent 2 are required to be bound together during the whole time interval $[0, t_f]$; thus the OFC problem can be viewed as the OCA problem between agent 3 and this two-agent group.

2.2. Geometric interpretation. The OFC problem can be interpreted in the following geometric way.

Each k-tuple $\langle q_i \rangle_{i=1}^k$ of points in $\mathbb{R}^n$ corresponds to a single point $q = (q_1, \dots, q_k)$ in $\mathbb{R}^{nk} = \mathbb{R}^n \times \cdots \times \mathbb{R}^n$ (k times). Thus each joint trajectory $\gamma = \langle \gamma_i \rangle_{i=1}^k$ of the k agents corresponds to a curve γ in $\mathbb{R}^{nk}$ starting from the point $a = (a_1, \dots, a_k)$ at time 0 and ending at the point $b = (b_1, \dots, b_k)$ at time t_f. The collision-free condition is equivalent to γ avoiding the obstacle

$$W \triangleq \cup_{i \neq j} \{(q_1, \dots, q_k) \in \mathbb{R}^{nk} : \|q_i - q_j\| < r\}, \tag{2.3}$$

or equivalently, γ being a curve in the set $\mathbb{R}^{nk} \setminus W$. With the formation constraint $\tilde{\mathcal{F}}$, a solution γ to the OFC problem is further restricted to lie in a subset $X_{\tilde{\mathcal{F}}}$ of $\mathbb{R}^{nk} \setminus W$. Indeed, corresponding to each allowed formation pattern $(\mathcal{V}, \mathcal{E})$ in $\tilde{\mathcal{F}}$, the feasible set of γ is a submanifold (cell) $X_{(\mathcal{V},\mathcal{E})}$ of $\mathbb{R}^{nk} \setminus W$ of proper dimension: the less edges (i.e., distance constraints) in $(\mathcal{V}, \mathcal{E})$, the higher the dimension of the cell $X_{(\mathcal{V},\mathcal{E})}$. For example, the cell corresponding to the "free" formation pattern that consists of no edges is the interior of $\mathbb{R}^{nk} \setminus W$ and has the highest possible dimension nk. Thus the feasible set of the solution γ to the OFC problem is the union of all such cells: $X_{\tilde{\mathcal{F}}} = \cup_{(\mathcal{V},\mathcal{E}) \in \tilde{\mathcal{F}}} X_{(\mathcal{V},\mathcal{E})}$. In order for γ to be a solution to the OFC problem, γ as a curve in $\mathbb{R}^{nk}$ must lie in $X_{\tilde{\mathcal{F}}}$.

As a subset of $\mathbb{R}^{nk}$, $X_{\tilde{\mathcal{F}}}$ inherits a Riemannian metric from the standard one on $\mathbb{R}^{nk}$ after properly scaling its coordinate axes according to $\langle \mu_i \rangle_{i=1}^k$. For a solution γ to the OFC problem, its cost $J(\gamma)$ defined in (2.1) is nothing but the energy of γ as a curve in $X_{\tilde{\mathcal{F}}}$ under this inherited metric. In particular, if $\mu_1 = \cdots = \mu_k = 1$, $J(\gamma)$ is the standard energy of γ as a curve in $\mathbb{R}^{nk}$. Thus the OFC problem is equivalent to finding the energy minimizing curves connecting a and b in $X_{\tilde{\mathcal{F}}}$. It is well known in Riemannian geometry [16] (see also the discussion after (2.2)) that such curves are necessarily the shortest curves in $X_{\tilde{\mathcal{F}}}$ between a and b parameterized with constant speed. Therefore, solving the OFC problem is equivalent to finding the geodesics from a to b in $X_{\tilde{\mathcal{F}}}$ that are also globally distance minimizing.

REMARK 2. *Solutions to the OFC problem may not exist. The OCA problem of two agents on a line trying to switch positions is one such example. The geometric interpretation of the OFC problem allows us to easily formulate conditions for its feasibility. In general, to ensure the existence of solutions, it is sufficient (though not necessary) to require that the set $X_{\tilde{\mathcal{F}}}$ be closed and that a and b lie in the same connected component of $X_{\tilde{\mathcal{F}}}$. The first requirement translates into the following property of $\tilde{\mathcal{F}}$: For each $(\mathcal{V}, \mathcal{E}) \in \tilde{\mathcal{F}}$, any formation pattern $(\mathcal{V}, \mathcal{E}_1)$ such that $(\mathcal{V}, \mathcal{E}) \prec (\mathcal{V}, \mathcal{E}_1)$ is also an element of $\tilde{\mathcal{F}}$. The second requirement is satisfied if there exists at least one collision-free joint trajectory $\langle \gamma_i \rangle_{i=1}^k$ from a to b whose formation pattern is in $\tilde{\mathcal{F}}$ at all times.*

2.3. Conservation law for the solutions. We now describe some properties of the solutions to the OFC problem that will be used in the next sections.

PROPOSITION 1. *Suppose that the joint trajectory $\gamma = \langle \gamma_i \rangle_{i=1}^k$ is a solution to the OFC problem. Then the quantities*

$$\sum_{i=1}^k \mu_i \dot{\gamma}_i(t), \quad \sum_{i=1}^k \mu_i \big(\gamma_i(t)\dot{\gamma}_i^T(t) - \dot{\gamma}_i(t)\gamma_i^T(t)\big) \tag{2.4}$$

are constant for all $t \in [0, t_f]$.

Note that in this paper an element in $\mathbb{R}^n$ is regarded by default as a column vector; thus the second quantity in (2.4) is an n-by-n matrix.

If one thinks of each agent i as a point in $\mathbb{R}^n$ with mass μ_i, then Proposition 1 implies that the linear and (generalized) angular momenta of the k-point mass system are conserved along the solutions to the OFC problem. The proof of this proposition can be found in, e.g., [6], and, for the case of general Riemannian manifolds with a group of symmetries, in [9]. Thus we omit the proof here.

One implication of Proposition 1 is that, if both a and b are μ-aligned in the sense that $\sum_{i=1}^k \mu_i a_i = \sum_{i=1}^k \mu_i b_i = 0$, then so is any k-tuple $\langle \gamma_i(t) \rangle_{i=1}^k$, $t \in [0, t_f]$, for a solution $\gamma = \langle \gamma_i \rangle_{i=1}^k$ to the OFC problem, namely,

$$\sum_{i=1}^k \mu_i \gamma_i \equiv 0.$$

Hence in the μ-aligned case the solution γ as a curve in $\mathbb{R}^{nk}$ must lie in a subspace

$$V = \left\{ (q_1, \ldots, q_k) \in \mathbb{R}^{nk} : \sum_{i=1}^k \mu_i q_i = 0 \right\}$$

of $\mathbb{R}^{nk}$. This reduces the dimension of the state space by n.

3. An interesting example. Consider the OFC problem on $\mathbb{R}^2$ with the k agents having the same priority $\mu_1 = \cdots = \mu_k = 1$ and the minimal allowed separation $r = 1$. Suppose that the starting positions $\langle a_i \rangle_{i=1}^k$ of the agents are given by $\langle (\frac{2i-k-1}{2}, 0) \rangle_{i=1}^k$. In other words, at time $t = 0$, the k agents are aligned on the x-axis with a common centroid at the origin and with consecutive agents at the minimal allowed separation. For each $t \geq 0$, denote by $R_t : \mathbb{R}^2 \to \mathbb{R}^2$ the counterclockwise rotation of $\mathbb{R}^2$ by an angle t in radians. Suppose that the destination positions are $\langle b_i \rangle_{i=1}^k = \langle R_{t_f}(a_i) \rangle_{i=1}^k$. Both the initial and destination positions have the same formation pattern $(\mathcal{V}, \mathcal{E})$, where $\mathcal{V} = \{1, \ldots, k\}$ and $\mathcal{E} = \{(i, i+1) : i = 1, \ldots, k-1\}$. We choose the admissible formation pattern set $\tilde{\mathcal{F}}$ to consist of this formation pattern only. Therefore, in considering the OFC problem, we require that agents i and $i+1$ be kept at constant distance r throughout $[0, t_f]$ for $i = 1, \ldots, k-1$, and all other pairs of agents maintain a distance greater than r.

Since $\langle a_i \rangle_{i=1}^k$ and $\langle b_i \rangle_{i=1}^k$ are μ-aligned, by the discussion after Proposition 1 in section 2.3, a solution $\gamma = \langle \gamma_i \rangle_{i=1}^k$ to the above OFC problem satisfies $\sum_{i=1}^k \gamma_i \equiv 0$. Thus γ as a curve in $\mathbb{R}^{2k} \setminus W$ lies in the subspace $V = \{(q_1, \ldots, q_k) \in \mathbb{R}^{2k} : \sum_{i=1}^k q_i = 0\}$. Furthermore, due to the admissible formation pattern set $\tilde{\mathcal{F}}$, γ belongs to the subset $X_{\tilde{\mathcal{F}}}$ of $(\mathbb{R}^{2k} \setminus W) \cap V$ given by

$$X_{\tilde{\mathcal{F}}} = \Bigg\{ (q_1, \ldots, q_k) \in \mathbb{R}^{2k} : \|q_i - q_{i+1}\| = 1, i = 1, 2, \ldots, k-1, \\ \|q_i - q_j\| > 1 \ \forall j > i+1, \text{ and } \sum_{i=1}^k q_i = 0 \Bigg\}. \tag{3.1}$$

Therefore, according to section 2.2, the solutions to the OFC problem are the distance minimizing geodesics in $X_{\tilde{\mathcal{F}}}$ connecting $a = (a_1, \ldots, a_k)$ to $b = (b_1, \ldots, b_k)$.

In this section, we shall consider $\gamma^* = \langle R_t(a_i) \rangle_{i=1}^k$, $t \in [0, t_f]$, as a natural candidate solution to the above OFC problem.[1] Under the motions specified by γ^*, the k agents rotate counterclockwise at a constant unit angular velocity around the origin from their starting to their destination positions. We shall show that $\langle R_t(a_i) \rangle_{i=1}^k$, $t \geq 0$, is a geodesic in $X_{\tilde{\mathcal{F}}}$; thus γ^* is optimal for t_f small enough. We shall also show that the first conjugate point along this geodesic occurs at $\langle R_{\tau_k}(a_i) \rangle_{i=1}^k$ for some time τ_k, implying that γ^* is no longer optimal if $t_f > \tau_k$. We shall derive the analytical expression of τ_k and show that $\tau_k \sim \frac{1}{k} \to 0$ as $k \to \infty$.

3.1. Geometry of the manifold $X_{\tilde{\mathcal{F}}}$. We start by constructing a convenient coordinate system on $X_{\tilde{\mathcal{F}}}$ and then proceed to derive the geometry of $X_{\tilde{\mathcal{F}}}$ as a submanifold of $\mathbb{R}^{2k}$ in this coordinate system, such as its Riemannian metric, its covariant derivatives, and its curvature tensors. A general reference on Riemannian geometry can be found in [4].

First of all, $X_{\tilde{\mathcal{F}}}$ is a $(k-1)$-dimensional smooth submanifold of $\mathbb{R}^{2k}$ and admits global coordinates $(\theta_1, \ldots, \theta_{k-1})$, where θ_i is the angle $q_{i+1} - q_i \in \mathbb{R}^2$ makes with respect to the positive x-axis (see Figure 3.1). The coordinate map $f : (\theta_1, \ldots, \theta_{k-1}) \mapsto (q_1, \ldots, q_k) \in X_{\tilde{\mathcal{F}}}$ is defined by

$$q_i = q_1 + \sum_{j=1}^{i-1} \begin{bmatrix} \cos\theta_j \\ \sin\theta_j \end{bmatrix}, \quad i = 2, \ldots, k, \tag{3.2}$$

[1] In the following, γ^* is also sometimes used to denote the whole curve $\langle R_t(a_i) \rangle_{i=1}^k$, $t \geq 0$. In such cases, its meaning should be clear from the context.

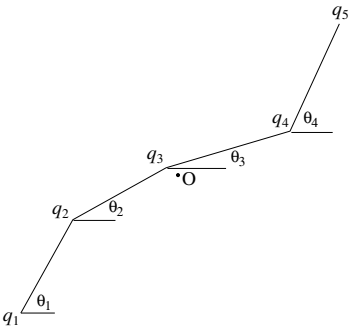

FIG. 3.1. *Coordinates of the manifold $X_{\tilde{\mathcal{F}}}$ when $k = 5$.*

where q_1 is chosen such that $\sum_{i=1}^{k} q_i = 0$, namely,

$$q_1 = -\frac{1}{k}\sum_{j=1}^{k-1}(k-j)\begin{bmatrix}\cos\theta_j\\ \sin\theta_j\end{bmatrix}. \tag{3.3}$$

In these coordinates, γ^* corresponds to $\theta_i(t) = t$, $t \in [0, t_f]$, $i = 1, \ldots, k-1$.

At any $q \in X_{\tilde{\mathcal{F}}}$, $\frac{\partial}{\partial\theta_1}, \ldots, \frac{\partial}{\partial\theta_{k-1}}$ form a basis of $T_q X_{\tilde{\mathcal{F}}}$. In this basis, the Riemannian metric $\langle\cdot,\cdot\rangle$ that $X_{\tilde{\mathcal{F}}}$ inherits from $\mathbb{R}^{2k}$ as a submanifold can be computed as

$$g_{ij} \triangleq \left\langle \frac{\partial}{\partial\theta_i}, \frac{\partial}{\partial\theta_j} \right\rangle = \left\langle \frac{\partial f}{\partial\theta_i}, \frac{\partial f}{\partial\theta_j} \right\rangle_{\mathbb{R}^{2k}}, \quad 1 \le i, j \le k-1. \tag{3.4}$$

Here f is the map defined in (3.2) and (3.3), and each $\frac{\partial f}{\partial\theta_i}$ is a vector in $\mathbb{R}^{2k}$. $\langle\cdot,\cdot\rangle_{\mathbb{R}^{2k}}$ is the standard inner product on $\mathbb{R}^{2k}$. With this definition of metric, the map f becomes an isometry, and the cost of a joint trajectory γ of the k-agent system given by (2.1) can be expressed in two equivalent ways: In $(q_1, \ldots, q_k)$ coordinates it is

$$J(\gamma) = \frac{1}{2}\int_0^{t_f} \sum_{i=1}^{k} \|\dot{q}_i\|^2\, dt,$$

and in $(\theta_1, \ldots, \theta_{k-1})$ coordinates it is

$$J(\gamma) = \frac{1}{2}\int_0^{t_f} \left\langle \sum_{i=1}^{k-1}\dot{\theta}_i\frac{\partial}{\partial\theta_i}, \sum_{i=1}^{k-1}\dot{\theta}_i\frac{\partial}{\partial\theta_i} \right\rangle dt = \frac{1}{2}\int_0^{t_f} \sum_{i,j=1}^{k-1} g_{ij}\dot{\theta}_i\dot{\theta}_j\, dt.$$

After some careful computation, (3.4) in our case yields

$$g_{ij} = \Delta_{ij}\cos(\theta_i - \theta_j),$$

where Δ_{ij} are constants given by

$$\Delta_{ij} = \begin{cases} \frac{i(k-j)}{k} & \text{if } i \le j, \\ \frac{(k-i)j}{k} & \text{if } i > j. \end{cases} \tag{3.5}$$

Denote by $(g^{ij})_{1\le i,j\le k-1}$ the inverse matrix of $(g_{ij})_{1\le i,j\le k-1}$.

REMARK 3. *For a general configuration $(\theta_1, \dots, \theta_{k-1})$, the metric g defined above may become degenerate; i.e., the inverse matrix of $(g_{ij})_{1\le i,j\le k-1}$ may not exist. This is the case, for example, when $\theta_i - \theta_{i+1} = \pi$ for some $i = 1, \dots, k-2$. However, due to the condition that $\|q_i - q_j\| > 1$ for $j > i+1$ in the definition (3.1) of $X_{\tilde{\mathcal{F}}}$, this degeneracy will not be encountered by configurations in $X_{\tilde{\mathcal{F}}}$.*

The following lemma can be verified directly.

LEMMA 1. *Let $\Delta = (\Delta_{ij})_{1\le i,j\le k-1} \in \mathbb{R}^{(k-1)\times(k-1)}$ be the symmetric matrix with components Δ_{ij} defined in (3.5). Then*

$$\Delta^{-1} = \begin{bmatrix} 2 & -1 & & & \\ -1 & 2 & -1 & & \\ & \ddots & \ddots & \ddots & \\ & & -1 & 2 & -1 \\ & & & -1 & 2 \end{bmatrix}.$$

With the Riemannian metric g defined above, the covariant derivative with respect to the Levi–Civita connection on $X_{\tilde{\mathcal{F}}}$ is given by [4]:

$$\nabla_{\frac{\partial}{\partial\theta_i}} \frac{\partial}{\partial\theta_j} = \sum_{m=1}^{k-1} \Gamma_{ij}^m \frac{\partial}{\partial\theta_m}, \tag{3.6}$$

where Γ_{ij}^m are the Christoffel symbols defined as

$$\Gamma_{ij}^m = \frac{1}{2} \sum_{l=1}^{k-1} \left\{ \frac{\partial g_{jl}}{\partial\theta_i} + \frac{\partial g_{li}}{\partial\theta_j} - \frac{\partial g_{ij}}{\partial\theta_l} \right\} g^{lm}, \quad 1 \le i, j, m \le k-1.$$

A curve γ in $X_{\tilde{\mathcal{F}}}$ is a geodesic if and only if $\nabla_{\dot\gamma}\dot\gamma \equiv 0$. By definition (3.6), this equation, also called the geodesic equation, can be written in the $(\theta_1, \dots, \theta_{k-1})$ coordinates as a group of second order differential equations:

$$\ddot\theta_m = -\sum_{i,j=1}^{k-1} \Gamma_{ij}^m \dot\theta_i \dot\theta_j, \quad m = 1, \dots, k-1. \tag{3.7}$$

In our case, we can compute that, for $1 \le i, j, m \le k-1$,

$$\Gamma_{ij}^m = \begin{cases} 0 & \text{if } i \ne j, \\ \sum_{l=1}^{k-1} \Delta_{il} \sin(\theta_l - \theta_i) g^{lm} & \text{if } i = j. \end{cases} \tag{3.8}$$

Notice that along γ^* we have $\theta_1 = \cdots = \theta_{k-1}$. Therefore, we have the following.

LEMMA 2. *Along γ^* we have $\Gamma_{ij}^m = 0$ for all i, j, m; hence $\nabla_{\frac{\partial}{\partial\theta_i}} \frac{\partial}{\partial\theta_j} = 0$ for all i, j.*

Since $\dot\gamma^* = \frac{\partial}{\partial\theta_1} + \cdots + \frac{\partial}{\partial\theta_{k-1}}$, by Lemma 2 and the linearity of covariant derivatives,

$$\nabla_{\dot\gamma^*} \frac{\partial}{\partial\theta_j} = \nabla_{\sum_{i=1}^{k-1} \frac{\partial}{\partial\theta_i}} \frac{\partial}{\partial\theta_j} = \sum_{i=1}^{k-1} \nabla_{\frac{\partial}{\partial\theta_i}} \frac{\partial}{\partial\theta_j} = 0, \quad j = 1, \dots, k-1. \tag{3.9}$$

Thus

$$\nabla_{\dot\gamma^*}\dot\gamma^* = \nabla_{\dot\gamma^*} \sum_{j=1}^{k-1} \frac{\partial}{\partial\theta_j} = \sum_{j=1}^{k-1} \nabla_{\dot\gamma^*} \frac{\partial}{\partial\theta_j} = 0,$$

which is exactly the condition for γ^* to be a geodesic in $X_{\tilde{\mathcal{F}}}$. Alternatively, since $\Gamma_{ij}^m = 0$ along γ^*, the geodesic equation (3.7) reduces to $\ddot{\theta}_m = 0$, $m = 1, \ldots, k-1$, which are trivially satisfied by $\gamma^*(t)$ with coordinates $\theta_i(t) = t$, $i = 1, \ldots, k-1$, $t \in [0, t_f]$.

COROLLARY 1. *γ^* is a geodesic in $X_{\tilde{\mathcal{F}}}$.*

Since by definition a geodesic is locally distance minimizing, we conclude that γ^* is a solution to the OFC problem for t_f small enough.

3.2. Conjugate points along γ^*. To characterize the conjugate points of γ^*, we need to calculate the curvature of $X_{\tilde{\mathcal{F}}}$. The curvature tensor of $X_{\tilde{\mathcal{F}}}$ is given by [4]

$$R\left(\frac{\partial}{\partial\theta_i}, \frac{\partial}{\partial\theta_j}\right)\frac{\partial}{\partial\theta_l} = \sum_{m=1}^{k-1} R_{ijl}^m \frac{\partial}{\partial\theta_m}, \tag{3.10}$$

where R_{ijl}^m are defined from the Christoffel symbols as

$$R_{ijl}^m = \sum_{\beta=1}^{k-1} \Gamma_{il}^\beta \Gamma_{j\beta}^m - \sum_{\beta=1}^{k-1} \Gamma_{jl}^\beta \Gamma_{i\beta}^m + \frac{\partial \Gamma_{il}^m}{\partial\theta_j} - \frac{\partial \Gamma_{jl}^m}{\partial\theta_i}, \quad 1 \le i, j, l,\ m \le k-1. \tag{3.11}$$

A Jacobi field X along γ^* is a vector field along γ^* satisfying the Jacobi equation

$$\nabla_{\dot{\gamma}^*}\nabla_{\dot{\gamma}^*} X + R(\dot{\gamma}^*, X)\dot{\gamma}^* = 0. \tag{3.12}$$

A conjugate point $\gamma^*(\tau)$ along γ^* occurs at time $t = \tau$ if there is a nontrivial Jacobi field X along γ^* that vanishes at both times 0 and τ, i.e., $X(0) = X(\tau) = 0$. In the following, we shall characterize the conjugate points of γ^* starting from $\gamma^*(0) = a$.

Write an arbitrary vector field X along γ^* in coordinates as

$$X = \sum_{i=1}^{k-1} x_i \frac{\partial}{\partial\theta_i} \tag{3.13}$$

for some C^2 functions $x_i : [0, t_f] \to \mathbb{R}$. Note that here for simplicity we drop the time t in the above expression, following the convention in [4]. The explicit form for the vector field X should be $X(t) = \sum_{i=1}^{k-1} x_i(t) \frac{\partial}{\partial\theta_i}\big|_{\gamma^*(t)}$, $t \in [0, t_f]$. Equation (3.13) thus represents X as a vector $x = (x_1, \ldots, x_{k-1})$ in $\mathbb{R}^{k-1}$ that varies with time $t \in [0, t_f]$.

By (3.9) and the property of covariant derivatives, we have

$$\nabla_{\dot{\gamma}^*} X = \nabla_{\dot{\gamma}^*} \sum_{m=1}^{k-1} x_m \frac{\partial}{\partial\theta_m} = \sum_{m=1}^{k-1} \left(x_m \nabla_{\dot{\gamma}^*} \frac{\partial}{\partial\theta_m} + \dot{x}_m \frac{\partial}{\partial\theta_m} \right) = \sum_{m=1}^{k-1} \dot{x}_m \frac{\partial}{\partial\theta_m},$$

and similarly,

$$\nabla_{\dot{\gamma}^*}\nabla_{\dot{\gamma}^*} X = \sum_{m=1}^{k-1} \ddot{x}_m \frac{\partial}{\partial\theta_m}.$$

On the other hand, since R defined in (3.10) is a trilinear tensor, by expansion we have

$$R(\dot{\gamma}^*, X)\dot{\gamma}^* = \sum_{i,j,l,m=1}^{k-1} R_{ijl}^m x_j \frac{\partial}{\partial\theta_m}.$$

So the Jacobi equation (3.12) along γ^* is reduced to

$$\sum_{m=1}^{k-1}\left(\ddot{x}_m+\sum_{i,j,l=1}^{k-1}R^m_{ijl}x_j\right)\frac{\partial}{\partial\theta_m}=0,$$

or equivalently, to the following group of second order differential equations on $\mathbb{R}^{k-1}$:

$$\ddot{x}_m+\sum_{i,j,l=1}^{k-1}R^m_{ijl}x_j=0,\quad m=1,\dots,k-1. \tag{3.14}$$

Equations (3.14) can be written in matrix form as

$$\ddot{x}+B_kx=0, \tag{3.15}$$

where $B_k=(b_{mj})_{1\le m,j\le k-1}\in\mathbb{R}^{(k-1)\times(k-1)}$ is a constant matrix whose component on the mth row and jth column is defined by

$$b_{mj}=\sum_{i,l=1}^{k-1}R^m_{ijl}.$$

In Appendix A we will prove the following simple expression for B_k.

LEMMA 3. *Define* $\Lambda\triangleq\operatorname{diag}(\frac{k-1}{2},\dots,\frac{i(k-i)}{2},\dots,\frac{k-1}{2})_{1\le i\le k-1}\in\mathbb{R}^{(k-1)\times(k-1)}$. *Then*

$$B_k=\Delta^{-1}\Lambda-I_k, \tag{3.16}$$

where I_k *is the* $(k-1)$*-by-*$(k-1)$ *identity matrix.*

REMARK 4. B_k *is a constant matrix independent of* t *since the metric of* $X_{\tilde{\mathcal{F}}}$ *is homogeneous along* γ^*, *or more precisely, for each* $\tau>0$, *the map* $(q_1,\dots,q_k)\in X_{\tilde{\mathcal{F}}}\mapsto(R_\tau(q_1),\dots,R_\tau(q_k))\in X_{\tilde{\mathcal{F}}}$ *is an isometry of* $X_{\tilde{\mathcal{F}}}$ *mapping* $\gamma^*(t)$ *to* $\gamma^*(t+\tau)$, *whose differential map takes* $\frac{\partial}{\partial\theta_i}\big|_{\gamma^*(t)}$ *to* $\frac{\partial}{\partial\theta_i}\big|_{\gamma^*(t+\tau)}$ *for each* $i=1,\dots,k-1$.

The solutions of the Jacobi equation (3.15) are closely related to the spectral decomposition of B_k. To compute the eigenvalues of B_k, define a matrix

$$U\triangleq\begin{bmatrix}u_1&\cdots&u_{k-1}\end{bmatrix}$$

whose column vectors u_j for $j=1,\dots,k-1$ are given by

$$u_j=\left[\left(\frac{2-k}{k}\right)^{j-1},\dots,\left(\frac{2i-k}{k}\right)^{j-1},\dots,\left(\frac{k-2}{k}\right)^{j-1}\right]^T\in\mathbb{R}^{k-1}. \tag{3.17}$$

U is a Vandermonde matrix and hence nonsingular.

The following lemma can be verified directly.

LEMMA 4. *For each* $j=1,\dots,k-1$,

$$\Delta^{-1}\Lambda u_j=\frac{j(j+1)}{2}u_j+\textit{linear combination of } u_1,\dots,u_{j-1}. \tag{3.18}$$

In matrix form, (3.18) is equivalent to $\Delta^{-1}\Lambda U=U\Sigma$, i.e., $U^{-1}\Delta^{-1}\Lambda U=\Sigma$, where Σ is an upper triangular matrix whose elements on the main diagonal are

$\frac{j(j+1)}{2}$, $j = 1, \ldots, k-1$. Thus $\Delta^{-1}\Lambda$ and Σ have the same set of eigenvalues. As a result, we have the following.

COROLLARY 2. *B_k has $k-1$ distinctive eigenvalues $\lambda_j = \frac{j(j+1)}{2} - 1$ for $j = 1, \ldots, k-1$.*

Denote by v_j an eigenvector of $\Delta^{-1}\Lambda$ corresponding to the eigenvalue $\lambda_j + 1$, i.e.,

$$\Delta^{-1}\Lambda v_j = (\lambda_j + 1)v_j = \frac{j(j+1)}{2}\, v_j, \tag{3.19}$$

for $j = 1, \ldots, k-1$. Then by (3.16) v_j is also an eigenvector of B_k corresponding to the eigenvalue λ_j. Lemma 4 and (3.17) imply that v_j is of the form

$$v_j = \left[P_j\left(\frac{2-k}{k}\right), \ldots, P_j\left(\frac{2i-k}{k}\right), \ldots, P_j\left(\frac{k-2}{k}\right)\right]^T \tag{3.20}$$

for some nontrivial polynomial P_j of degree $j-1$.

In Appendix B, we shall derive from (3.19) and (3.20) the general condition (B.3) on the polynomials P_j and prove that P_j are the discrete version of some orthogonal polynomials called the *ultraspherical* (or *Gegenbauer*) polynomials $C_{j-1}^{(\alpha)}$ with parameter $\alpha = \frac{3}{2}$. In particular, P_j is an even polynomial when j is odd, and an odd polynomial when j is even [1].

Using condition (B.3), one can determine the first few P_j (up to a scaling factor):

$$P_1(x) = 1, \quad P_2(x) = 3x, \quad P_3(x) = 5x^2 - \left(1 - \frac{4}{k^2}\right), \quad P_4(x) = 7x^3 + \left(\frac{20}{k^2} - 3\right)x.$$

The first few v_j can then be obtained by (3.20). Therefore, we have the next lemma.

LEMMA 5. *B_k has the following eigenvectors:*

- $v_1 = [1, \ldots, 1]^T$ *for* $\lambda_1 = 0$;
- $v_2 = [2-k, \ldots, 2i-k, \ldots, k-2]^T$ *for* $\lambda_2 = 2$;
- $v_3 = [4k^2 - 20k + 24, \ldots, 5(2i-k)^2 - k^2 + 4, \ldots, 4k^2 - 20k + 24]^T$ *for* $\lambda_3 = 5$.

REMARK 5. *B_k has an eigenvalue 0 with the corresponding eigenvector $[1, \ldots, 1]^T$ as a consequence of the fact that $\dot{\gamma}^* = \frac{\partial}{\partial\theta_1} + \cdots + \frac{\partial}{\partial\theta_{k-1}}$ is parallel along γ^*.*

For large values of j, the expression of the polynomial P_j can be quite complicated. Fortunately, one can verify directly the following lemma.

LEMMA 6. *B_k has the following eigenvectors:*

- $v_{k-2} = [(2-k)\binom{k}{1}, \ldots, (-1)^{i+1}(2i-k)\binom{k}{i}, \ldots, (-1)^k(k-2)\binom{k}{k-1}]^T$ *for* $\lambda_{k-2} = \frac{(k-1)(k-2)}{2} - 1$;
- $v_{k-1} = [\binom{k}{1}, \ldots, (-1)^{i+1}\binom{k}{i}, \ldots, (-1)^k\binom{k}{k-1}]^T$ *for* $\lambda_{k-1} = \frac{k(k-1)}{2} - 1$.

Lemmas 5 and 6 together give the eigenvectors of B_k corresponding to a few of its smallest and largest eigenvalues.

The eigenvectors $v_1, \ldots, v_{k-1}$ of B_k form a basis of $\mathbb{R}^{k-1}$. We can then express x in this basis as $x = \sum_{j=1}^{k-1} y_j v_j$, so that the Jacobi equation (3.15) becomes

$$\ddot{y}_j + \lambda_j y_j = 0, \quad 1 \le j \le k-1.$$

Assume that X, hence x, vanishes at $t = 0$. Then $y_1(0) = \cdots = y_{k-1}(0) = 0$. Nontrivial solutions to the above equations with $y_j(0) = 0$, $1 \le j \le k-1$, are

$$\begin{aligned} y_1(t) &= c_1 t, \\ y_j(t) &= c_j \sin(t\sqrt{\lambda_j}), \quad j = 2, \ldots, k-1, \end{aligned}$$

for some constants $c_1, \dots, c_{k-1}$ not identically zero. Conjugate points are encountered at those time epochs $\tau > 0$, where $y_j(\tau) = 0$ for all j. This is possible only if $c_1 = 0$ and τ is an integer multiple of $\pi/\sqrt{\lambda_j}$ for some $j \in \{2, \dots, k-1\}$. Therefore, we have the next theorem.

THEOREM 1. *The set of conjugate points along γ^* is*

$$\{\gamma^*(\tau) : \tau = m\pi/\sqrt{\lambda_j} \text{ for some } m \in \mathbb{N} \text{ and some } j \in \{2, \dots, k-1\}, \tau \le t_f\}.$$

The first conjugate point along γ^* occurs at time

$$\tau_k \triangleq \frac{\pi}{\sqrt{\lambda_{k-1}}} = \frac{\pi\sqrt{2}}{\sqrt{(k-2)(k+1)}}. \tag{3.21}$$

A geodesic is no longer distance minimizing beyond its first conjugate point. Thus we have the following.

COROLLARY 3. *γ^* is not a solution to the OFC problem if $t_f > \tau_k$.*

Note that $\tau_k \sim \frac{1}{k}$ as $k \to \infty$. The result for the case $k = 3$ was first proved in [7].

REMARK 6. *Traveling along a geodesic emitting from a fixed starting point, the last point for which the corresponding geodesic segment remains distance minimizing is called a* cut point [4]. *Along the geodesic a cut point is either the first conjugate point, or the first point that is connected by at least two distinct (possibly far way from each other) geodesics to the starting point. In the latter case, the cut point is encountered before the first conjugate point. In our case we conjecture that the cut point along γ^* coincides with the first conjugate point, or in other words, γ^* is an optimal solution to the OFC problem for all t_f up to τ_k.*

3.3. Infinitesimal perturbations beyond the conjugate points. We now show how shorter curves than γ^* with the same end points look, at least infinitesimally, once γ^* surpasses its conjugate points.

Let $\{\gamma_s^*\}_{-\epsilon<s<\epsilon}$ be a C^∞ proper variation of γ^* in $X_{\tilde{\mathcal{F}}}$ with variation field

$$X \triangleq \frac{\partial \gamma_s^*}{\partial s}\Big|_{s=0},$$

which is a vector field along γ^*. For each s, define $E(s)$ as the energy of γ_s^* in $X_{\tilde{\mathcal{F}}}$, which coincides with the cost function of the joint trajectory corresponding to γ_s^*. By the variation of energy formulas [10], $E'(0) = 0$ since γ^* is a geodesic, and

$$E''(0) = -\int_0^{t_f} \langle X, \nabla_{\dot\gamma^*}\nabla_{\dot\gamma^*}X + R(\dot\gamma^*, X)\dot\gamma^*\rangle \, dt.$$

Write $X = \sum_{i=1}^{k-1} x_i \frac{\partial}{\partial\theta_i}$ in the basis $\frac{\partial}{\partial\theta_1}, \dots, \frac{\partial}{\partial\theta_{k-1}}$ along γ^*. Since $\{\gamma_s^*\}_{-\epsilon<s<\epsilon}$ is a proper variation, vector $x = (x_1, \dots, x_{k-1})$ vanishes at times 0 and t_f. In this coordinate system, the above equation reduces to

$$E''(0) = -\int_0^{t_f} x^T \Delta(\ddot{x} + B_k x) \, dt.$$

Suppose now that $t_f > \pi/\sqrt{\lambda_j}$ for some $j \in \{2, \dots, k-1\}$. Then, by choosing $\{\gamma_s^*\}_{-\epsilon<s<\epsilon}$ such that $x(t) = v_j \sin(\pi t/t_f)$, where we recall that v_j is an eigenvector of B_k associated with the eigenvalue λ_j, we have

$$E''(0) = -\left(\lambda_j - \frac{\pi^2}{t_f^2}\right)(v_j^T \Delta v_j)\int_0^{t_f} \sin^2\left(\frac{\pi t}{t_f}\right) dt < 0, \tag{3.22}$$

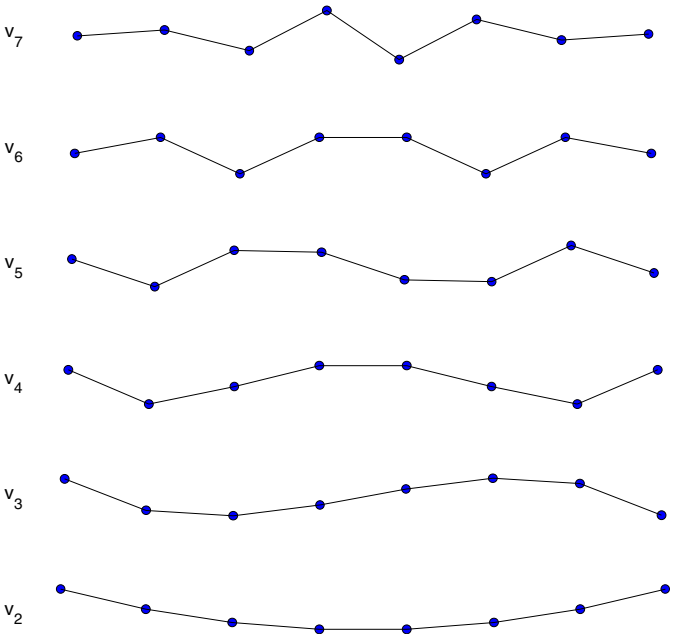

FIG. 3.2. *Perturbed shapes corresponding to* v_l, $l = 2, \ldots, k-1$, *when* $k = 8$.

since $v_j^T \Delta v_j > 0$ and $\lambda_j - \pi^2/t_f^2 > 0$. Therefore, γ_s^* is shorter than γ^* for sufficiently small s.

To sum up, the above analysis shows that if $t_f > \pi/\sqrt{\lambda_j}$ for some $j \in \{2, \ldots, k-1\}$, a solution better than γ^* can be obtained by infinitesimally perturbing γ^* in such a way that, at each $t \in [0, t_f]$, $(\theta_1, \ldots, \theta_{k-1})$ is incremented by an amount of $v_j \sin(\pi t/t_f) ds$. The linked-rod system (snake) formed by connecting successive agents will then assume a shape determined by the signs of the components of v_j. For example, the alternating signs of the components of v_{k-1} indicate a perturbation, where the $k-1$ rods are first folded into a saw-like shape during the first half of the time interval $[0, t_f]$, with the degree of folding of each rod depending on its position (in fact, proportional to $\binom{k}{l}$ for the lth rod from the edge, $l = 1, \ldots, k-1$), and then straightened up during the latter half of the time interval. In contrast, v_2 indicates that the $k-1$ rods bend into a bow-like shape, whereas the shape specified by v_{k-2} is a mixing (product) of the bending specified by v_2 and the folding specified by v_{k-1}. The maximal perturbation occurs at $t = t_f/2$. Figure 3.2 plots the various shapes of the linked-rod system at time $t = t_f/2$ caused by the perturbations $v_j \sin(\pi t/t_f)$ when $k = 8$. Note that these shapes have been rotated to align with the x-axis.

The efficiency of the perturbations specified by different v_j, provided that $t_f > \pi/\sqrt{\lambda_j}$, can be studied by comparing the respective $E''(0)$ under the requirement that $\int_0^{t_f} \|X\|^2 \, dt$ be constant. Since $\int_0^{t_f} \|X\|^2 \, dt = (v_j^T \Delta v_j) \int_0^{t_f} \sin^2(\pi t/t_f) \, dt$, we can conclude by (3.22) that the larger the eigenvalue λ_j, the more efficient the perturbation specified by its corresponding eigenvector v_j. This implies that the most efficient perturbation is the one given by v_{k-1}.

4. Conclusions. In this paper, we formulate the optimal formation constrained multi-agent coordination problem and give a geometric interpretation of its solutions

as geodesics in a certain manifold. We study an instance of the problem and characterize analytically the conjugate points of a geodesic proposed as a candidate solution. We conclude that this geodesic is optimal for sufficiently close starting and destination positions, but no longer optimal after surpassing its first conjugate point, which occurs from the starting position at a distance that decreases to zero at the same rate as $1/k$ as the number k of agents increases. In this case, infinitesimally better coordinated motions are determined. We show that the analytical forms of these motions can be derived from a certain family of orthogonal polynomials.

Appendix A. Proof of Lemma 3. In this proof, all terms in the equations, such as R^m_{ijl}, the Christoffel symbols, and their derivatives, are evaluated along γ^*, for which $\theta_1 = \cdots = \theta_{k-1}$ and the conclusion of Lemma 2 holds. Thus (3.11) becomes

$$R^m_{ijl} = \frac{\partial \Gamma^m_{il}}{\partial \theta_j} - \frac{\partial \Gamma^m_{jl}}{\partial \theta_i}, \quad i,j,l,m \in \{1,\dots,k-1\},$$

and for each $1 \le m, j \le k-1$,

$$b_{mj} = \sum_{i,l} R^m_{ijl} = \sum_{i,l} \frac{\partial \Gamma^m_{il}}{\partial \theta_j} - \sum_{i,l} \frac{\partial \Gamma^m_{jl}}{\partial \theta_i} = \sum_i \frac{\partial \Gamma^m_{ii}}{\partial \theta_j} - \sum_i \frac{\partial \Gamma^m_{jj}}{\partial \theta_i}, \tag{A.1}$$

where the summations are all from 1 to $k-1$. The first term can be simplified to

$$\begin{aligned}\sum_i \frac{\partial \Gamma^m_{ii}}{\partial \theta_j} &= \sum_{i\neq j} \frac{\partial \Gamma^m_{ii}}{\partial \theta_j} + \frac{\partial \Gamma^m_{jj}}{\partial \theta_j} \\ &= \sum_{i\neq j} \frac{\partial}{\partial \theta_j}\left[\sum_l \Delta_{il}\sin(\theta_l - \theta_i) g^{lm}\right] + \frac{\partial}{\partial \theta_j}\left[\sum_{l\neq j} \Delta_{jl}\sin(\theta_l - \theta_j) g^{lm}\right] \\ &= \sum_{i\neq j} \Delta_{ij} g^{jm} - \sum_{l\neq j} \Delta_{jl} g^{lm},\end{aligned}$$

where we have used the fact that $\theta_1 = \cdots = \theta_{k-1}$ on γ^*. Similarly,

$$\begin{aligned}\sum_i \frac{\partial \Gamma^m_{jj}}{\partial \theta_i} &= \sum_{i\neq j} \frac{\partial}{\partial \theta_i}\left[\sum_l \Delta_{jl}\sin(\theta_l - \theta_j) g^{lm}\right] + \frac{\partial}{\partial \theta_j}\left[\sum_{l\neq j} \Delta_{jl}\sin(\theta_l - \theta_j) g^{lm}\right] \\ &= \sum_{i\neq j} \Delta_{ji} g^{im} - \sum_{l\neq j} \Delta_{jl} g^{lm}.\end{aligned}$$

Hence (A.1) can be rewritten as

$$b_{mj} = \sum_{i\neq j} \Delta_{ij} g^{jm} - \sum_{i\neq j} \Delta_{ji} g^{im} = \Big(\sum_i \Delta_{ij}\Big) g^{jm} - \sum_i \Delta_{ji} g^{im}.$$

Since $g_{ji} = \Delta_{ji}$ on γ^*, $\sum_i \Delta_{ji} g^{im} = \sum_i g_{ji} g^{im} = \delta_{mj}$ by the definition of g^{im}. Moreover, $\sum_i \Delta_{ij} = \sum_{i\le j} \frac{i(k-j)}{2} + \sum_{i>j} \frac{(k-i)j}{2} = \frac{j(k-j)}{2}$. Therefore,

$$b_{mj} = \frac{j(k-j)}{2} g^{jm} - \delta_{mj} = \frac{j(k-j)}{2} g^{mj} - \delta_{mj} \tag{A.2}$$

by the symmetry of g^{mj}. Note that, on γ^*, $(g^{mj})_{1\le m,j\le k-1} = [(g_{mj})_{1\le m,j\le k-1}]^{-1} = \Delta^{-1}$. So (A.2) is exactly the desired conclusion.

Appendix B. Computation of polynomials P_j. In this appendix we shall derive the expressions of the polynomials P_j in (3.20) and prove that they belong to a certain family of orthogonal polynomials.

Fix a $j \in \{1, \dots, k-1\}$. Recall that the polynomial P_j is defined in (3.20), where v_j is given in (3.19). By substituting (3.20) into (3.19) and using Lemma 1, we have

$$-\frac{1}{2}(i-1)(k-i+1)P_j\left(\frac{2i-2-k}{k}\right) + i(k-i)P_j\left(\frac{2i-k}{k}\right)$$

$$-\frac{1}{2}(i+1)(k-i-1)P_j\left(\frac{2i+2-k}{k}\right) = \frac{j(j+1)}{2}P_j\left(\frac{2i-k}{k}\right)$$

for $i = 1, \dots, k-1$. This is equivalent to

$$\nabla^2_{2/k}[(1-x^2)P_j(x)] = -j(j+1)P_j(x) \tag{B.1}$$

for $x = \frac{2i-k}{k}$, $i = 1, \dots, k-1$. Here, for $h > 0$, ∇^2_h denotes the operator

$$\nabla^2_h[P(x)] = \frac{1}{h^2}[-2P(x) + P(x-h) + P(x+h)], \tag{B.2}$$

which is a difference approximate of $P''(x)$ with step size h. ∇^2_h maps a polynomial $P(x)$ of degree $m \geq 2$ to a polynomial of degree $m-2$. Thus in (B.1) both sides are polynomials of degree $j-1 \leq k-2$. Since the equality (B.1) holds for $k-1$ distinct values of x, it holds for all x. To sum up, P_j satisfies the following condition:

$$\nabla^2_{2/k}[(1-x^2)P_j(x)] = -j(j+1)P_j(x) \quad \forall x \in \mathbb{R}. \tag{B.3}$$

Note that $\nabla^2_h[P(x)] \to P''(x)$ as $h \to 0$. Therefore, for large k, the above condition can be approximated by

$$(1-x^2)P_j''(x) - 4xP_j'(x) + (j-1)(j+2)P_j(x) = 0.$$

The polynomial solution to this differential equation is called the $(j-1)$th *ultraspherical* (or *Gegenbauer*) *polynomial* $C^{(\alpha)}_{j-1}(x)$ with parameter $\alpha = \frac{3}{2}$ [1, p. 781]. The polynomials $C^{(3/2)}_{j-1}(x)$ obtained for different $j \geq 1$ are orthogonal on $[-1, 1]$ with respect to the weight function $1-x^2$, i.e., $\int_{-1}^{1}(1-x^2)C^{(3/2)}_l(x)C^{(3/2)}_j(x)\,dx = 0$ for $l \neq j$ (see [18]). Since $P_j(x)$ tends to $C^{(3/2)}_{j-1}(x)$ as $k \to \infty$, we expect that the polynomials $P_j(x)$, $j = 1, \dots, k-1$, are "approximately" orthogonal with respect to $1-x^2$ on $[-1, 1]$ as well. Indeed, a discrete version of this orthogonality condition holds:

$$\sum_{x=\frac{2i-k}{k},\, i=1,\dots,k-1} (1-x^2)P_l(x)P_j(x) = 0 \quad \text{for } l, j \in \{1, \dots, k-1\},\ l \neq j. \tag{B.4}$$

Condition (B.4) can be easily proved as follows. Observe that

$$\sum_{x=\frac{2i-k}{k},\, i=1,\dots,k-1} (1-x^2)P_l(x)P_j(x) = \frac{8}{k^2}v_l^T \Lambda\, v_j.$$

Thus we need only to show that $v_l^T \Lambda\, v_j = 0$ for $l \neq j$, or equivalently, that $V^T \Lambda V$ is diagonal, where V is the matrix defined as $V = \begin{bmatrix} v_1 & \cdots & v_{k-1} \end{bmatrix}$. Equation (3.19) implies that $\Lambda V = \Delta V \Omega$, where $\Omega = \mathrm{diag}(\lambda_1 + 1, \ldots, \lambda_i + 1, \ldots, \lambda_{k-1} + 1)$. Thus $V^T \Lambda V = (V^T \Delta V)\Omega$. Note that the left-hand side $V^T \Lambda V$ is a symmetric matrix, while the right-hand side is the product of a symmetric matrix $V^T \Delta V$ and a diagonal matrix Ω with distinct diagonal elements. In order for them to be equal, we must have that both $V^T \Lambda V$ and $V^T \Delta V$ are diagonal matrices. The diagonality of $V^T \Lambda V$ implies condition (B.4), and the diagonality of $V^T \Delta V$ implies that the tangent vectors represented by v_j, $j = 1, \ldots, k-1$, at any point on γ^* are orthogonal.

Acknowledgment. The first author would like to thank Alan Weinstein for his helpful comments and discussions on the results of this paper.

CHARACTERIZATION OF DELAY-INDEPENDENT STABILITY AND DELAY INTERFERENCE PHENOMENA*

WIM MICHIELS† AND SILVIU-IULIAN NICULESCU‡

Abstract. The problem of the asymptotic stability independent of delays for a class of linear systems including multiple delays is addressed. Both cases where the delays are allowed to vary independently of each other and where they are restricted to a one-dimensional subspace of the delay-parameter space are considered. It the latter case it turns out that the resulting dependency between the delays (rationally independent, rationally dependent, commensurate) plays an important role. The stability conditions are expressed in terms of the spectral properties of some appropriate complex matrices. As a consequence of the stability study, a complete characterization of the delay interference phenomenon is given. Furthermore, a connection is established with the stability theory for continuous-time delay-difference equations, subjected to delay perturbations. Various illustrative examples complete the paper.

1. Introduction.

We address the asymptotic stability in the delay-parameter space of the linear system

$$\dot{x}(t) = A_0 x(t) + \sum_{i=1}^{m} A_i x(t-\tau_i), \tag{1.1}$$

where $A_i \in \mathbb{R}^{n\times n},\ i = 0,\dots,m$, are given system matrices and $\tau_i \geq 0,\ i = 1,\dots,m$, are delay constants.

The subject of delay-independent stability of the zero solution of (1.1), that is, asymptotic stability guaranteed for all delay values, received a lot of attention in the literature starting in the 1980s. Without being exhaustive, we cite some of the approaches proposed to handle the problem: two-variable criteria [12, 13], matrix pencil techniques [3, 20], frequency-sweeping tests [5, 4], and finite-dimensional LMI conditions derived by using some appropriate quadratic Lyapunov–Krasovskii functionals [2]. For further discussions and references, see, for instance, [24, 8, 21, 6]. Essentially, in most such existing criteria for delay-independent stability and, more generally, in work on characterizing and computing stability regions in the delay-parameter space, the delays are *either* allowed to vary completely independently of each other *or* they are restricted to be commensurate (multiples of the same number).

The latter implies a relation of the form

$$(\tau_1, \dots, \tau_m) = \tau_0\ (n_1, \dots, n_m), \quad n_i \in \mathbb{N},\ i = 1, \dots, m, \tag{1.2}$$

where $n_1, \dots, n_m$ are fixed and $\tau_0 \in \mathbb{R}_+$ is the free parameter. Geometrically, the parameterization (1.2) corresponds to a particular *ray* or direction in the complete delay-parameter space.

In this paper we study the eigenvalue distribution of a collection of complex matrices, derived from the delay system (1.1). Among others, this leads us to new necessary and sufficient conditions for delay-independent stability. The criteria cover both the case where all delays vary independently of each other and the case where they are restricted to *an arbitrary* ray in the delay-parameter space, more precisely,

$$(\tau_1, \dots, \tau_m) = \tau_0\ (r_1, \dots, r_m), \quad r_i \in \mathbb{R}_+,\ i = 1, \dots, m, \tag{1.3}$$

with $\tau_0 \in \mathbb{R}_+$ being once again the free parameter. The relaxation from (1.2) to (1.3) has the following consequences:

1. It allows us to make assertions about *delay-independent stability* when the ray under consideration consists of delay values with *any type of interdependence* (commensurate, rationally (in)dependent delays). This interdependency turns out to be important.
2. A study of the *sensitivity* of delay-independent stability *along a ray* w.r.t. changes of the direction (determined by the r_i in (1.3)) becomes possible. Among others, it leads us to a complete characterization of the so-called *delay interference phenomenon*, that is, the presence of delay-independent stability along a particular ray, which is not robust against arbitrarily small perturbations of the direction of the ray.

Due to the fragility of delay-independent stability properties (note that they involve a *noncompact* set of delay values), these issues are nontrivial and deserve special attention, as we shall see. They have, however, barely been treated in the literature, excepting some contributions on the interference phenomenon and related topics [16, 17, 5, 15, 22].

To the best of the authors' knowledge, the notion of delay interference[1] was first mentioned by MacDonald [17] (see also [16]), where a second-order system including two delays is shown to be subjected to delay interference if it has the following property: delay-independent stability if the delays are equal, and delay-dependent stability with respect to each delay if the other is equal to zero. A further example (scalar system including two delays) of delay interference can be found in [5]. This is also discussed in [15] and [22], where some characterizations regarding interference are given (a frequency-sweeping test combined with a matrix pencil condition in [22], a sector characterization in [15]). As we shall discuss at the end of section 5, these results appear as corollaries of the general theory developed throughout the paper.

The paper is organized as follows. Some definitions, notations, and assumptions are presented in the next section. Section 3 contains preliminary results, in support of section 4, which is devoted to the main results (delay-independent stability and interference characterizations). In section 5 some illustrative examples are presented and discussed. In section 6 the main results are connected with the stability theory

[1] In physics, interference represents the combination of two or more wave motions to form a resultant wave in which the displacement is reinforced or canceled.

of continuous-time delay-difference equations. Finally, some concluding remarks end the paper. The appendices contain some background material.

2. Notation, definitions, and assumptions. The following notation is used:

$\mathbb{C}$	set of complex numbers
$\mathbb{C}_-,\ \mathbb{C}_+$	open left half-plane, open right half-plane
$d(\rho, E),\quad \rho \in \mathbb{C},\ E \subseteq \mathbb{C}$	$\inf_{t\in E} \lvert\rho - t\rvert$
$D(E, F),\quad E, F \subseteq \mathbb{C}$	$\sup_{\rho\in E} d(\rho, F)$
$D_h(E, F),\quad E, F \subseteq \mathbb{C}$	$\max\{D(E, F), D(F, E)\}$, Hausdorff distance
ϕ	empty set
j	imaginary unit, $j = \sqrt{-1}$
$\mathbb{N}$	set of natural numbers, includes zero
$\mathbb{Q}$	set of rational numbers
$\mathbb{R}$	set of real numbers
$\mathbb{R}_+$	$\{r \in \mathbb{R} :\ r \geq 0\}$.
$\Re(\lambda), \Im(\lambda),\quad \lambda \in \mathbb{C}$	real and imaginary part of λ
$\vec{r} \in \mathbb{R}^m, \vec{n} \in \mathbb{N}^m, \ldots$	short notation for $(r_1, \ldots, r_m), (n_1, \ldots, n_m), \ldots$
$\Sigma(A)$	spectrum of the matrix A
$\mathbb{Z}$	set of integer numbers
$\bar{E}$	closure of the set E
$\mathcal{P}(E)$	power set of E, set of all subsets
$H(\lambda;\ \vec{\tau})$	characteristic function of (1.1), $\det(\lambda I - A_0 - \sum_{i=1}^m A_i e^{-\lambda\tau_i})$
$\lVert x\rVert, x \in \mathbb{R}^n$	Euclidean norm of x
$\mathcal{B}_+^m$	$\{\vec{r} \in \mathbb{R}_+^m :\ \lVert\vec{r}\rVert = 1\}$

Given a direction $(r_1, \ldots, r_m) \in \mathcal{B}_+^m$ in the delay-parameter space, we define the associated *ray*, $\mathcal{T}(\vec{r})$, as follows.

DEFINITION 2.1. *For $\vec{r} \in \mathcal{B}_+^m$, let $\mathcal{T}(\vec{r}) := \{\tau_0\ \vec{r} :\ \tau_0 \in \mathbb{R}_+\}$.*

As we address delay-independent stability properties for both cases where all delays vary independently of each other, and where they are restricted to a particular ray, we will from now on consequently use the following terminology, to avoid confusion.

DEFINITION 2.2. *The system* (1.1) *is delay-independent stable if and only if its zero solution is asymptotically stable for all $\vec{\tau} \in \mathbb{R}_+^m$.*

DEFINITION 2.3. *The ray $\mathcal{T}(\vec{r})$ is stable if and only if the zero solution of* (1.1) *is asymptotically stable for all $\vec{\tau} \in \mathcal{T}(\vec{r})$.*

Regarding delay interference we have the next definition.

DEFINITION 2.4. *A stable ray $\mathcal{T}(\vec{r})$ is subjected to the delay interference phenomenon if and only if for all $\epsilon > 0$ there exists a $\vec{s} \in \mathcal{B}_+^m$ with $\lVert\vec{r} - \vec{s}\rVert < \epsilon$ such that the ray $\mathcal{T}(\vec{s})$ is not stable.*

Recall that the zero solution of (1.1) is asymptotically stable if and only if all its *characteristic roots*, the zeros of

$$H(\lambda;\ \vec{\tau}) = \det\left(\lambda I - A_0 - \sum_{i=1}^{m} A_i e^{-\lambda\tau_i}\right),$$

are in the open left half-plane. See, for instance, [14] for stability definitions and their relation with the location of the characteristic roots.

The following technical assumption will be made throughout the paper.

Assumption 2.5.

$$\det\left(A_0 + \sum_{i=1}^{m} A_i\right) \neq 0.$$

Note that if this assumption is not satisfied, we have

$$\forall \vec{\tau} \in \mathbb{R}_+^m \quad H(0;\ \vec{\tau}) = 0,$$

which implies that the zero solution is not asymptotically stable, whatever the values of the delays. As the article is devoted to characterizations of delay-independent stability, the assumption can be made without losing generality.

3. Preliminaries. The following sets and quantities will play a major role in the characterization of delay-independent stability and the interference phenomenon.

DEFINITION 3.1. *Let*

$$\mathbb{W} = \bigcup_{\vec{\theta}\in[0,\ 2\pi]^m} \Sigma\left(A_0 + \textstyle\sum_{i=1}^{m} A_i e^{-j\theta_i}\right),$$

$$\alpha_0 = \sup\left\{\Re(\lambda) :\ \lambda \in \mathbb{W}\right\},$$

and for $\vec{r} \in \mathcal{B}_+^m$, *let*

$$\mathbb{V}(\vec{r}) = \bigcup_{\theta\geq 0} \Sigma\left(A_0 + \textstyle\sum_{i=1}^{m} A_i e^{-j\theta r_i}\right),$$

$$\alpha(\vec{r}) = \sup\left\{\Re(\lambda) :\ \lambda \in \mathbb{V}(\vec{r})\right\}.$$

It directly follows that

$$\begin{aligned} \forall \vec{r} \in \mathbb{B}_+^m \quad & \overline{\mathbb{V}(\vec{r})} \subseteq \mathbb{W}, \\ & \alpha(\vec{r}) \leq \alpha_0. \end{aligned} \tag{3.1}$$

As we shall see the relations (3.1) can be strict ($\subset$, resp., $<$). However, if the components of $\vec{r}$ are rationally independent,[2] then the next proposition applies.

PROPOSITION 3.2. *If the components of* $\vec{r}$ *are rationally independent, then*

$$\overline{\mathbb{V}(\vec{r})} = \mathbb{W}, \quad \alpha(\vec{r}) = \alpha_0.$$

Proof. Since $\mathbb{V}(\vec{r}) \subseteq \mathbb{W}$ and $\mathbb{W}$ is closed, it remains to prove for the first statement that every element of W can be approximated arbitrarily well with elements from $\mathbb{V}(\vec{r})$.

For any $\tilde{\lambda} \in \mathbb{W}$ there exists a $\vec{\theta} \in [0,\ 2\pi]^m$ such that $\tilde{\lambda}$ is a zero of the polynomial

$$p(\lambda) := \det\left(\lambda I - A_0 - \sum_{i=1}^{m} A_i e^{-j\theta_i}\right).$$

Since the delays $\vec{r}$ are rationally independent, we can apply Kronecker's theorem [11, Theorem 444], which leads to the following: for all $n \geq 1$, there exists a $k_n > 0$ such that

$$\left|e^{-j\theta_i} - e^{-jk_n r_i}\right| < \frac{1}{n}, \quad i = 1, \ldots, m.$$

[2]See Appendix B for definitions regarding the interdependency of numbers.

It follows that the set of polynomials $\{p_n(\lambda)\}_{n\geq 1}$, where

$$p_n(\lambda) := \det\left(\lambda I - A_0 - \sum_{i=1}^{m} A_i e^{-jk_n r_i}\right),$$

uniformly converges to $p(\lambda)$ on compact sets. Applying Theorem A1 of [18], a variant of Rouché's theorem, yields the following: for all $\epsilon > 0$, there exists a $\bar{n} \geq 0$ such that for all $n \geq \bar{n}$, p_n has a zero λ_n satisfying $|\lambda_n - \tilde{\lambda}| < \epsilon$. Since for any n the zeros of p_n are contained in $\mathbb{V}(\vec{r})$ the proof the first statement is complete. The second statement is a direct corollary of the first. □

Next, with $\mathcal{B}_+^m$ equipped with the Euclidean norm and $\mathcal{P}(\mathbb{C})$ with the Hausdorff metric, we address the continuity of the functions $\mathbb{V}(\cdot)$ and $\alpha(\cdot)$; see Appendix A for precise definitions. As we illustrate at the end of the section, these functions in general are not continuous at each point; however, the following weaker property holds.

PROPOSITION 3.3. *The function* $\mathbb{V} : \mathcal{B}_+^m \to \mathcal{P}(\mathbb{C}),\ \vec{r} \mapsto \mathbb{V}(\vec{r})$ *is lower semicontinuous at each* $\vec{r} \in \mathcal{B}_+^m$.

Proof. We prove lower semicontinuity of $\mathbb{V}(\cdot)$ at an arbitrary point $\vec{s} \in \mathcal{B}_+^m$.

Fix $\epsilon > 0$. Put a grid on the complex plane, whose lines are parallel to the real or imaginary axis and equally spaced with $\epsilon/4$ in both directions. This partitions the complex plane into disjunct squares. If the closure of such a square has a nonempty intersection with $\mathbb{V}(\vec{s})$, we assign a complex number to it, obtained by sampling exactly one point from the intersection. Let the set $\mathcal{G}_\epsilon$ be defined as a collection of all these samples. Since $\mathbb{V}(\vec{r})$ is bounded we have $\mathrm{card}(\mathcal{G}_\epsilon) < \infty$, and by construction,

$$\forall v \in \mathbb{V}(\vec{s}) \quad d(v, \mathcal{G}_\epsilon) < \epsilon/2. \tag{3.2}$$

Next, take any point $g \in \mathcal{G}_\epsilon$. By definition, there exists a $\tilde{\theta} > 0$ such that the matrix $A_0 + \sum_{i=1}^m A_i e^{-j\tilde{\theta}s_i}$ has a characteristic root equal to g. From continuity properties of the characteristic roots, there exists a $\delta > 0$ such that for all $\vec{r} \in \mathcal{B}_+^m$ with $\|\vec{r} - \vec{s}\| < \delta$, the matrix $A_0 + \sum_{i=1}^m A_i e^{-j\tilde{\theta}r_i}$ has an eigenvalue, say, λ, which satisfies $|\lambda - g| < \epsilon/2$. This can be repeated for all points of $\mathcal{G}_\epsilon$, and, since the cardinality of this set is finite, we can choose the threshold δ *independently* of $g \in \mathcal{G}_\epsilon$. Hence, we obtain

$$\exists \delta > 0\ \forall g \in \mathcal{G}_\epsilon\ \forall \vec{r} \in \mathcal{B}_+^m \quad \|\vec{r} - \vec{s}\| < \delta \Rightarrow d(g, \mathbb{V}(\vec{r})) < \epsilon/2. \tag{3.3}$$

The combination of (3.2) and (3.3) results in

$$\exists \delta > 0\ \forall v \in \mathbb{V}(\vec{s})\ \forall \vec{r} \in \mathcal{B}_+^m \quad \|\vec{r} - \vec{s}\| < \delta \Rightarrow d(v, \mathbb{V}(\vec{r})) < \epsilon. \tag{3.4}$$

Since the above analysis can be repeated for any $\epsilon > 0$, we end up with

$$\forall \epsilon > 0\ \exists \delta > 0 \quad \forall \vec{r} \in \mathcal{B}_+^m \quad \|\vec{r} - \vec{s}\| < \delta \Rightarrow D(\mathbb{V}(\vec{s}), \mathbb{V}(\vec{r})) \leq \epsilon, \tag{3.5}$$

that is, lower semicontinuity of $\mathbb{V}$ at $\vec{s}$. □

COROLLARY 3.4. *The function* $\alpha : \mathcal{B}_+^m \to \mathbb{R},\ \vec{r} \mapsto \alpha(\vec{r})$ *is lower semicontinuous at each* $\vec{r} \in \mathcal{B}_+^m$.

By combining Propositions 3.2 and 3.3 with relations (3.1) we arrive at a stronger result at rationally independent $\vec{r}$, as follows.

PROPOSITION 3.5. *The function* $\mathbb{V} : \mathcal{B}_+^m \to \mathcal{P}(\mathbb{C}),\ \vec{r} \mapsto \mathbb{V}(\vec{r})$ *is continuous at rationally independent* $\vec{r}$. *The function* $\alpha : \mathcal{B}_+^m \to \mathbb{R},\ \vec{r} \mapsto \alpha(\vec{r})$ *is continuous at rationally independent* $\vec{r}$.

We illustrate the above concepts and properties with the equation

$$\dot{x}(t) = -1.3x(t) - x(t-\tau_1) - \frac{1}{2}x(t-\tau_2), \tag{3.6}$$

for which we have

$$\mathbb{W} = \bigcup_{(\theta_1,\theta_2)\in[0,\ 2\pi]^2} \left(-1.3 - e^{-j\theta_1} - \tfrac{1}{2}e^{-j\theta_2}\right) = \left\{\lambda \in \mathbb{C} :\ \tfrac{1}{2} \le |\lambda + 1.3| \le \tfrac{3}{2}\right\},$$
$$\mathbb{V}(\vec{r}) = \bigcup_{\theta\ge 0} \left(-1.3 - e^{-jr_1\theta} - \tfrac{1}{2}e^{-jr_2\theta}\right).$$

In Figure 1 we show the set $\mathbb{V}(\vec{r})$ for some values of $\vec{r}$. We also indicate the boundaries of $\mathbb{W}$. When the components of $\vec{r}$ are commensurate, $\mathbb{V}(\vec{r})$ forms a closed curve. In all the cases displayed we have $\alpha(\vec{r}) < \alpha_0$ and $\overline{\mathbb{V}(\vec{r})} \subset \mathbb{W}$ (strict relations). *Discontinuities* of the function $\vec{r} \mapsto \mathbb{V}(\vec{r})$ occur at all rationally dependent $\vec{r}$. To illustrate the mechanism, let us first compare the cases (a) and (f). Ratio $r_2/r_1 = 1.9$ can be seen as a perturbation of $r_2/r_1 = 2$ and, although the components of $\vec{r}$ are still commensurate, they are more independent, since the coprime numbers 19 and 10 (having ratio 1.9) are larger than 2 and 1 (having ratio 2). As a consequence, the curve

$$\theta \ge 0 \mapsto -1.3 - e^{-j\theta} - \frac{1}{2}e^{-j\frac{r_2}{r_1}\theta} \tag{3.7}$$

with $r_2/r_1 = 1.9$ only closes at $\theta = 20\pi$ when θ is increased from zero (instead of $\theta = 2\pi$ for $r_2/r_1 = 2$), and a larger portion of $\mathbb{W}$ is covered by $\mathbb{V}(\vec{r})$. This is clearly visible in subplot (f), where we have also depicted the values of (3.7) for $\theta \in [0,\ 2\pi]$ (bold part of curve). Next, if $r_2/r_1 = 2$ would be perturbed instead to an irrational value, such as $2 - \pi/n, n \ge 2$, then the corresponding curve $\mathbb{V}(\vec{r})$ would never close and its points would densely fill $\mathbb{W}$, as follows from Proposition 3.2. Since n can be taken arbitrarily large, the perturbation can be taken arbitrarily small.

4. Main results. Step by step we characterize the stability of the zero solution of (1.1) in the delay parameters, in terms of the sets $\mathbb{V}(\cdot)$ and $\mathbb{W}$. The main results will be stated in Theorems 4.1, 4.5, and 4.7, and they will be summarized in Table 2.

We first recall some properties of the characteristic roots of (1.1), which are needed in the subsequent analysis. The number of characteristic roots in any right half-plane is finite. Furthermore, the function

$$g :\ \mathbb{R}_+^m \to \mathbb{R},\ \vec{\tau} \mapsto g(\vec{\tau}) = \max_{\lambda\in\mathbb{C}} \{\Re(\lambda) :\ H(\lambda;\ \vec{\tau}) = 0\} \tag{4.1}$$

is continuous [21]. As a consequence, if the zero solution of (1.1) is asymptotically stable for some delay values but the system is not delay-independent stable, then there exist delay values for which the rightmost characteristic roots are *on the imaginary axis*.

Necessary and sufficient conditions for delay-independent stability are expressed by the following theorem.

THEOREM 4.1. *The system* (1.1) *is delay-independent stable if and only if*

$$\mathbb{W} \subset (\mathbb{C}_- \cup \{0\}). \tag{4.2}$$

Proof. Both implications are proved by *contradiction*.

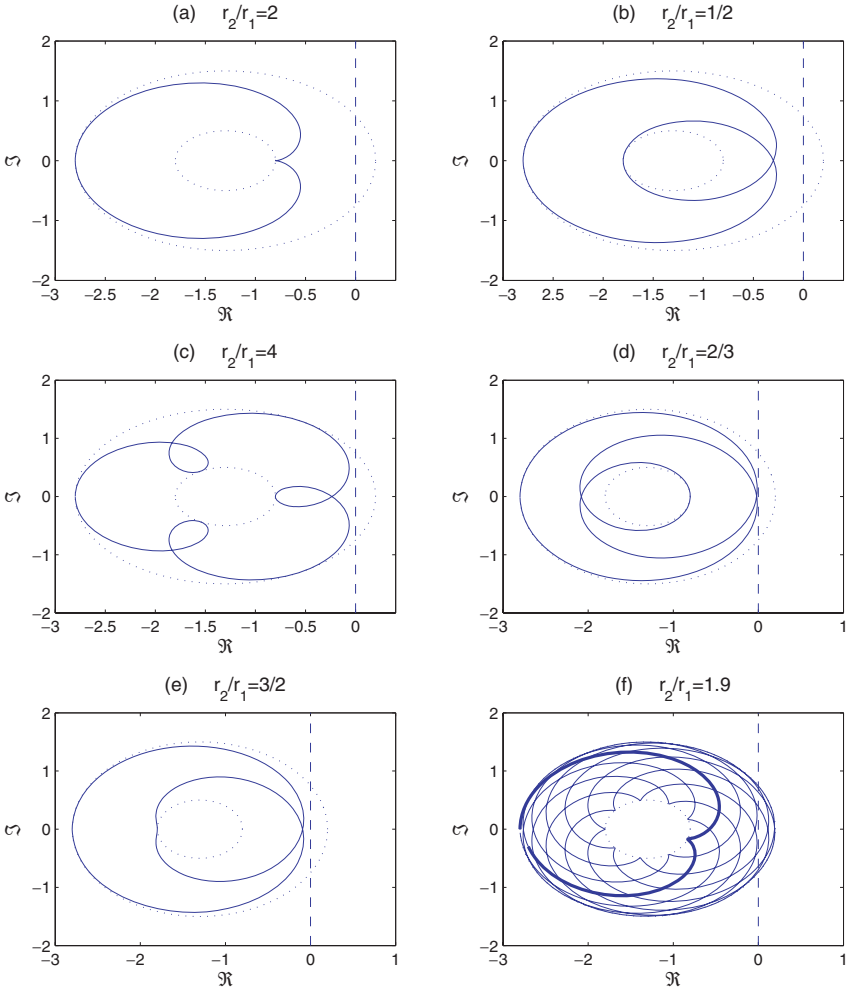

FIG. 1. *The set* $\mathbb{V}(\vec{r})$ *for the system* (3.6)*, for different values of* $\vec{r}$ *(solid curves). The dotted curves are the boundaries of* $\mathbb{W}$*.*

$\Rightarrow$ Assume that $\mathbb{W} \not\subset (\mathbb{C}_- \cup \{0\})$. We distinguish between two cases, as follows.

Case 1. $\mathbb{W}$ contains an element $j\omega,\ \omega \neq 0$, i.e., there exists a $\vec{\theta} \in [0,\ 2\pi]^m$ such that

$$\det\left(j\omega I - A_0 - \sum_{i=1}^{m} A_i e^{-j\theta_i}\right) = 0.$$

It follows that $H(j\omega;\ \vec{\tau}_0) = 0$, where

$$\vec{\tau}_0 = \left(\frac{\theta_1}{\omega}, \ldots, \frac{\theta_m}{\omega}\right).$$

This contradicts the delay-independent stability.

Case 2. $\mathbb{W}$ contains an element $\tilde{\lambda} \in \mathbb{C}_+$. Hence, there exists a $\vec{\theta_0} \in [0,\ 2\pi]^m$ such that

$$A_0 + \sum_{i=1}^{m} A_i e^{-j\theta_i} \tag{4.3}$$

has a characteristic root $\tilde{\lambda}$ for $\vec{\theta} = \vec{\theta_0}$. If $\vec{\theta} \in \mathbb{R}_+^m$ is varied continuously (w.r.t. the Euclidean norm) from $\vec{\theta_0}$ to $(k_1 2\pi, \ldots, k_m 2\pi)$, for some $\vec{k} \in \mathbb{N}^m$, the spectrum of the matrix (4.3) continuously changes (w.r.t. the Hausdorff metric) to the spectrum of $A_0 + \sum_{i=1}^m A_i$. If the latter matrix is not Hurwitz, we have a contradiction (instability for all delays equal to zero). If not, it implies that $\mathbb{W} \cap \mathbb{C}_+$ is not separated from the imaginary axis, and we are the situation described with Case 1.

$\Leftarrow$ Assume that (1.1) is not delay-independent stable. In the case where $A_0 + \sum_{i=1}^m A_i$ is not Hurwitz, this matrix has a characteristic root in the closed right half-plane, different from zero (Assumption 2.5), and we already have a contradiction since $\Sigma(A_0 + \sum_{i=1}^m A_i) \subseteq \mathbb{W}$. In the other case, the system (1.1) is asymptotically stable for all delays equal to zero and, by the continuity of (4.1), there must be characteristic roots on the imaginary axis for some delay values, i.e.,

$$\exists \omega > 0\ \exists \vec{\tau}_0 \in \mathbb{R}_+^m \quad H(j\omega;\ \vec{\tau}_0) = 0.$$

It follows that $j\omega \in \mathbb{W}$ and we have a contradiction. ∎

Remark 4.2. For a delay-independent stable system, the condition $0 \notin \mathbb{W}$, respectively, $0 \in \mathbb{W}$, is referred to in the literature as *strong*, respectively, *weak*, delay-independent stability (see [2, 21] and the references therein), notions which are related to stability properties of some associated 2D system.

The stability of a ray $\mathcal{T}(\vec{r})$ can be characterized in an analogous way, as follows.

PROPOSITION 4.3. *The ray $\mathcal{T}(\vec{r})$ is stable if and only if*

$$\mathbb{V}(\vec{r}) \subset (\mathbb{C}_- \cup \{0\})\,. \tag{4.4}$$

Proof. The proof is similar to the proof of Theorem 4.1. ∎

The next proposition states that if the system (1.1) is not delay-independent stable, then it is always prone to the delay interference phenomenon.

PROPOSITION 4.4. *Assume that $\mathbb{W} \not\subset (\mathbb{C}_- \cup \{0\})$. If a ray $\mathcal{T}(\vec{r})$ is stable, then it is subjected to the delay interference phenomenon.*

Proof. From the assumption $\mathbb{W} \not\subset (\mathbb{C}_- \cup \{0\})$ it follows that (1.1) is not delay-independent stable. So there exist delay values $\vec{\tau} \in \mathbb{R}_+^m$ and a frequency $\omega > 0$ such that $H(j\omega; \vec{\tau}) = 0$. For any given $\vec{k} \in \mathbb{N}^m,\ \vec{k} \neq 0$, this implies that $H(j\omega; \vec{\tau}(n)) = 0$ for all $n \in \mathbb{N}$, where

$$\vec{\tau}(n) = \left(\tau_1 + k_1 n\ \frac{2\pi}{\omega}, \ldots, \tau_m + k_m n\ \frac{2\pi}{\omega}\right). \tag{4.5}$$

Therefore, the ray

$$\mathcal{T}\left(\frac{\vec{\tau}(n)}{\|\vec{\tau}(n)\|}\right)$$

is unstable for all $n \in \mathbb{N}$. From

$$\lim_{n\to\infty} \frac{\vec{\tau}(n)}{\|\vec{\tau}(n)\|} = \frac{\vec{k}}{\|\vec{k}\|}$$

and the fact that this analysis can be repeated for every nonzero $\vec{k} \in \mathbb{N}^m$, it follows that every ray $\mathcal{T}(\vec{r})$ where $\vec{r}$ has *commensurate* components becomes unstable when applying certain infinitesimal perturbations to $\vec{r}$.

If the components of $\vec{r}$ are noncommensurate, then there exist infinitesimal $\delta\vec{r}$ such that $\vec{r} + \delta\vec{r}$ has commensurate components ($\mathbb{Q}^m$ is dense in $\mathbb{R}^m$), and the above arguments can be repeated. This completes the proof. ∎

Combining the previous results for the case where $\mathbb{W}$ has a nonempty intersection with the open right half-plane yields the following.

THEOREM 4.5. *Assume that* $\mathbb{W} \cap \mathbb{C}_+ \neq \phi$. *Then the following hold:*

1. *If the components of* $\vec{r}$ *are rationally independent, then the ray* $\mathcal{T}(\vec{r})$ *is unstable.*
2. *If the ray* $\mathcal{T}(\vec{r})$ *is stable, then it is subjected to the delay interference phenomenon.*
3. *The set* $\left\{\vec{r} \in \mathcal{B}_+^m : \ \mathcal{T}(\vec{r}) \text{ stable}\right\}$ *is nowhere dense in* $\mathcal{B}_+^m$.

Proof. If the components of $\vec{r}$ are rationally independent, then $\overline{\mathbb{V}(\vec{r})} = \mathbb{W}$ by Proposition 3.2. A combination with the assumption of the theorem leads to $\mathbb{V}(\vec{r}) \cap \mathbb{C}_+ \neq \phi$. Applying Proposition 4.3 then yields the first assertion.

The second assertion can be proven in two different ways. It directly follows from Proposition 4.4, whose proof mainly relies on the invariance property (4.5). Alternatively, let $\vec{r} \in \mathbb{R}_+^m$ be such that $\mathcal{T}(\vec{r})$ is stable. Following from the density of the rationally independent numbers in $\mathbb{C}^m$, there exist arbitrarily small perturbations $\delta\vec{r} \in \mathbb{R}_+^m$ such that $\vec{r}+\delta\vec{r}$ has rationally independent components. By the first assertion of the theorem, the ray $\mathcal{T}((\vec{r} + \delta\vec{r})/(\|\vec{r} + \delta\vec{r}\|))$ is unstable. This implies that $\mathcal{T}(\vec{r})$ is subjected to the delay interference phenomenon.

The third assertion follows from Propositions 3.2 and 3.3 and Proposition 4.3. ∎

Under the assumption of the previous theorem, we comment on the detection of *stable* rays $\mathcal{T}(\vec{r})$ (if any), *without* the explicit computation of stability/instability regions of (1.1) in the delay-parameter space. From Theorem 4.5, the components of $\vec{r}$ cannot be rationally independent. By Proposition 4.3, we have to search for values for which $\mathbb{V}(\vec{r}) \subset (\mathbb{C}_- \cup \{0\})$, whereas we have $\mathbb{W} \cap \mathbb{C}_+ \neq \phi$ and $\mathbb{V}(\vec{r}) \subseteq \mathbb{W}$. Thus, values of $\vec{r}$, for which $\mathbb{V}(\vec{r})$ doesn't cover $\mathbb{W}$ very well, are good candidates. Following from Propositions 3.2 and 3.3, such values must be characterized by a large dependence, for instance, $\vec{r} = \vec{n}/\|\vec{n}\|$, with $\vec{n} \in \mathbb{N}^m$ and $\|\vec{n}\|$ small. To fix the ideas, we pick up the example (3.6), which satisfies $\mathbb{W} \cap \mathbb{C}_+ \neq \phi$ since $\alpha_0 = 0.2$. Table 1 displays the corresponding values of $\alpha(\vec{r})$, for rationally dependent $\vec{r}$. It becomes apparent that stable rays correspond to

$$(n_1, n_2) \in \{(1,0),\ (0,1),\ (1,2),\ (1,4),\ (2,1),\ (2,3),\ (3,2)\}\,. \tag{4.6}$$

Notice that for five of these cases the set $\mathbb{V}(\vec{r})$ is depicted in Figure 1, subplots (a) to (e).

Finally, we look at the special case, where $\mathbb{W} \not\subset (\mathbb{C}_- \cup \{0\})$ but still lies in the *closed* left half-plane. But first we prove the following lemma.

LEMMA 4.6. *Assume that* (1.1) *has a characteristic root in* $\mathbb{C}_+$ *for some delay values. Then* $\mathbb{W} \cap \mathbb{C}_+ \neq \phi$.

Proof. Inspired by the proof of Lemma 2.2 in [10], we use an approximation and a continuation argument.

TABLE 1
Values of $\alpha(\vec{r})$, where $\vec{r} = (n_1,\ n_2)/\sqrt{n_1^2 + n_2^2}$, computed for the system (3.6).

$\vdots$										
n_2										

Let $\vec{\tau}$ be delay values, for which (1.1) has a characteristic root $\tilde{\lambda} \in \mathbb{C}_+$, i.e.,

$$\det\left\{\tilde{\lambda}I - A_0 - \sum_{i=1}^{m} A_i e^{-\tilde{\lambda}\tau_i}\right\} = 0. \tag{4.7}$$

Without losing generality we may assume that the components of $\vec{\tau}$ are commensurate,[3] and we can set

$$\vec{\tau} = \tau_0\left(\frac{p_1}{q}, \ldots, \frac{p_m}{q}\right), \quad p_i \in \mathbb{N},\ i = 1, \ldots, m, \quad q \in \mathbb{N}.$$

Then (4.7) can be written as

$$\det\left\{\tilde{\lambda}I - A_0 - \sum_{i=1}^{m} A_i \mu_0^{p_i}\right\} = 0, \tag{4.8}$$

where

$$\mu_0 = e^{-\frac{\tilde{\lambda}\tau_0}{q}}.$$

From (4.8) it follows that the polynomial

$$p(\mu; k) := \det\left\{k\tilde{\lambda}I - A_0 - \sum_{i=1}^{m} A_i\ \mu^{p_i}\right\}, \tag{4.9}$$

parameterized by $k \in [1, \infty)$, satisfies $p(\mu_0; 1) = 0$. By definition we have $|\mu_0| < 1$. Obviously, as $k \to \infty$, *all* zeros of (4.9) must become unbounded. From this and the continuity of the zeros w.r.t. k, there must be a pair $(\tilde{k}, \tilde{\mu})$ with $\tilde{k} > 1$ and $|\tilde{\mu}| = 1$ such that

$$\det\left\{\tilde{k}\tilde{\lambda}I - A_0 - \sum_{i=1}^{m} A_i\ \tilde{\mu}^{p_i}\right\} = 0.$$

[3]If not, they can be made commensurate by adding perturbations, which can be chosen sufficiently small, such that characteristic roots in $\mathbb{C}_+$ are maintained.

TABLE 2
Characterization of stability of the steady-state solution of (1.1) *along rays in the delay parameter space, as a function of* $\mathbb{W}$ *and* $\mathbb{V}(\cdot)$.

<table>
<tr><th>$\mathbb{W} \subset (\mathbb{C}_- \cup \{0\})$</th><th>$\mathbb{W} \not\subset (\mathbb{C}_- \cup \{0\})$ and

</table>

This means that $\tilde{k}\tilde{\lambda} \in \mathbb{W}$ and, consequently, $\mathbb{W} \cap \mathbb{C}_+ \neq \phi$. ∎

The combination of Theorem 4.1, Proposition 4.4, and Lemma 4.6 results in the next theorem.

THEOREM 4.7. *Assume that* $\mathbb{W} \cap \mathbb{C}_+ = \phi$ *and* $\mathbb{W} \not\subset (\mathbb{C}_- \cup \{0\})$. *Then there exist delay values for which* (1.1) *has characteristic roots on the imaginary axis, while there are no delay values for which* (1.1) *has characteristic roots in* $\mathbb{C}_+$. *Every stable ray is subjected to the delay interference phenomenon.*

The main results of this section are summarized in Table 2. The cases $\mathbb{W} \cap \mathbb{C}_+ \neq \phi$ and $\mathbb{W} \subset (\mathbb{C}_- \cup \{0\})$ with $0 \notin \mathbb{W}$ are generic. The other cases, where the rightmost elements of $\mathbb{W}$ are on the imaginary axis, characterize situations where a system is on the edge of loosing or acquiring delay-independent stability. Recall that this analysis has been performed under Assumption 2.5, which can be checked a priori. (If the assumption is not satisfied, then there exist no values of $\vec{\tau}$ for which the zero solution of (1.1) is asymptotically stable.)

To conclude, we briefly discuss some existing results related to the interference phenomenon. In [15] it is shown that delay-independent stability is equivalent to asymptotic stability for all delay values lying in a nontrivial sector in the delay-parameter space, and to the robustness of stability of a ray, consisting of commensurate delay values, w.r.t. small perturbations of the direction (see [15] for precise formulations). Note that the latter two statements imply the existence of a stable ray, which is not subjected to the interference phenomenon. Given a stable ray, the additional condition to have interference of [17] (delay-dependent stability when one of the (two) delays is set to zero) and of [22] (frequency-sweeping test) are in fact conditions for the presence of characteristic roots on the imaginary axis for some delay values, thus conditions for *not* having delay-independent stability. In this way, the above cited results are a direct corollary of the fact that a system is *either* delay-independent stable *or* every stable ray is subjected to the delay interference phenomenon; see Table 2.

5. Illustrations. We present two examples, which together illustrate all results and phenomena described in the previous sections. Besides the delays, the examples will exhibit another parameter. This allows us to illustrate, in addition, two scenarios for the transition between delay-independent stability and delay-dependent stability: one via weak delay-independent stability, the other via the case $\mathbb{W} \not\subset (\mathbb{C}_- \cup \{0\})$, $\mathbb{W} \cap \mathbb{C}_+ = \phi$.

As a first example we consider

$$\dot{x}(t) = -ax(t) - x(t-\tau_1) - \frac{1}{2}x(t-\tau_2), \tag{5.1}$$

where $a \in \mathbb{R}$ is a parameter. We have

$$\mathbb{W} = \left\{ \lambda \in \mathbb{C} : \ \frac{1}{2} \leq |\lambda + a| \leq \frac{3}{2} \right\}.$$

According to Table 2 the zero solution of (5.1) is delay-independent stable if and only if $a \geq \frac{3}{2}$. For $a > \frac{3}{2}$ we have strong delay-independent stability, and for $a = \frac{3}{2}$ we have weak delay-independent stability. For $a < \frac{3}{2}$ we are directly in the case $\mathbb{W} \cap \mathbb{C}_+ \neq \phi$.

For $a = 1.3$ the system reduces to (3.6), for which the analysis in the previous section and Table 1 shows that there are seven stable rays, characterized by $\vec{r} = \vec{n}/\|\vec{n}\|$, with $\vec{n}$ given by (4.6). Such an analysis can easily be repeated for other values of a, since a change of this parameter, say, δa, affects only the sets $\mathbb{W}$ and $\mathbb{V}(\vec{r})$ by a shift along the real axis of $-\delta a$, while the numerical values of Table 1 change accordingly with $-\delta a$. For $a = 1$, there are only three stable rays left, characterized by

$$(n_1, n_2) \in \{(1,0),\ (0,1),\ (1,2)\}, \tag{5.2}$$

and for $a < -0.5$ all rays are unstable.

In Figure 2 we show the complete stability/instability regions of (5.1) in the delay-parameter space,[4] for $a = 1$ and $a = 1.3$. The solid lines correspond to delay values for which there are characteristic roots on the imaginary axis. The dashed lines indicate the stable rays. Notice that small perturbations of their slope lead to intersections with the solid curves, a consequence of the delay interference phenomenon. As $a \to 1.5$, we have in fact a scenario toward delay-independent stability, characterized by an increase of the number of stable rays. That number becomes arbitrarily large when getting arbitrarily closed to the bifurcation value $a = 1.5$, for which we have weak delay-independent stability.

Next, we analyze the system

$$\dot{x}(t) = A_0 x(t) + A_1 x(t - \tau_1) + A_2 x(t - \tau_2), \tag{5.3}$$

where

$$A_0 = \begin{bmatrix} 0 & 1 \\ a - a^2 - \frac{5}{4} & 2a - 1 \end{bmatrix}, \quad A_1 = \begin{bmatrix} 0 & 0 \\ \frac{1}{5} & 0 \end{bmatrix}, \quad A_2 = \begin{bmatrix} 0 & 0 \\ -\frac{4}{5} & 0 \end{bmatrix} \tag{5.4}$$

and $a \in \mathbb{R}$ is a parameter. The corresponding set $\mathbb{W}$ is depicted in Figure 3. A change of parameter a results once again in a shift of this set along the real axis.

For $a < 0$ the system is strongly delay-independent stable and for $a > 0$ we have $\mathbb{W} \cap \mathbb{C}_+ \neq \phi$; see Table 2. For the intermediate value, $a = 0$, we are in the special case where the assumptions of Theorem 4.7 are satisfied.

In Figure 4, we plot the stability region in the (τ_1, τ_2)-space for $a = 1/16$ and $a = 0$. In the first case there are three stable rays, determined by $\vec{r} = \vec{n}/\|\vec{n}\|$, with

$$\vec{n} \in \{(1,0),\ (1,1),\ (4,1)\}.$$

These directions can also be obtained directly by constructing a table similar to Table 1. As $a \to 0+$, all closed curves in the (τ_1, τ_2)-space, corresponding to charac-

[4]The stability crossing curves were computed as Hopf bifurcation curves with the package DDE-BIFTOOL [7], thereby exploiting (frequency-dependent) invariance properties w.r.t. delay shifts. Other approaches are described in [9] and [23].

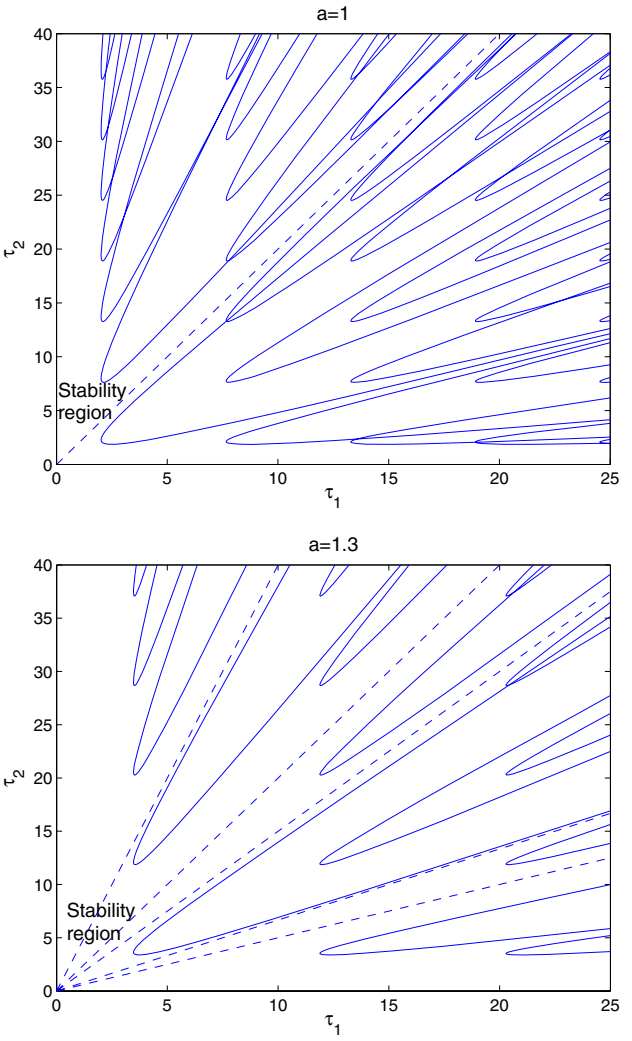

FIG. 2. *Stability/instability regions of the zero solution of* (5.1) *in the* (τ_1, τ_2)*-space, for* $a = 1$ *(top) and* $a = 1.3$ *(bottom). For* $a = 1$*, the directions of the stable rays (dashed lines) are given by* (5.2)*, for* $a = 1.3$ *by* (4.6)*. For* $a \geq 1.5$ *the systems is delay-independent stable.*

teristic roots on the imaginary axis, shrink, and at the limit $a = 0$, where Theorem 4.7 applies, they have collapsed to equally spaced points. For such delay values, which can be computed analytically as

$$(\tau_1, \tau_2) = \left(\frac{10\pi}{3\sqrt{3}} + k\frac{4\pi}{\sqrt{3}}, \frac{4\pi}{3\sqrt{3}} + l\frac{4\pi}{\sqrt{3}} \right), \quad k, l \in \mathbb{N}, \tag{5.5}$$

the system has characteristic roots on the imaginary axis (more precisely, $\pm j\sqrt{3}/2$), but for all other delay values its zero solution is asymptotically stable. This is illustrated in Figure 5, where the real parts of the rightmost characteristic roots are displayed along a particular ray, containing some of the points (5.5).

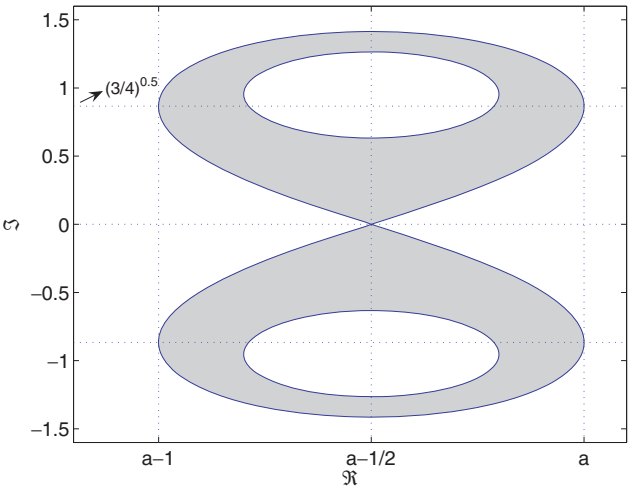

FIG. 3. *The set* $\mathbb{W}$*, corresponding to the system* (5.3)–(5.4)*, is shaded.*

Notice that for the limit case, $a = 0$, the number of unstable rays is infinite but *countable*, since the unstable rays have to contain at least one of the points (5.5). Hence, they are characterized by a slope

$$\frac{r_2}{r_1} = \frac{2+6l}{5+6k},\ k, l \in \mathbb{N},$$

being rational numbers. This leads to a paradox: for $a = 0$ all rays $\mathcal{T}(\vec{r})$, with r_2/r_1 irrational, are stable, whereas for any $a > 0$, they are unstable (since $\mathbb{W} \cap \mathbb{C}_+ \neq \phi$ and Theorem 4.5 applies). The explanation is as follows: for all rationally independent $\vec{r}$ and every value of a, we have for the example

$$\begin{aligned} &\alpha(\vec{r}) = \alpha_0, \\ &\Re(\lambda) < \alpha_0 \quad \forall \lambda \in \mathbb{V}(\vec{r}). \end{aligned}$$

Consequently, $\mathbb{V}(\vec{r})$ intersects the closed right half-plane if $\alpha_0 > 0$ but not if $\alpha_0 = 0$.

6. Relation with the stability of continuous-time delay-difference equations. We relate the results of the previous sections with stability conditions for continuous-time delay-difference equations of the form

$$x(t) - \sum_{i=1}^{m} A_i x(t - r_i) = 0, \tag{6.1}$$

which are discussed in, e.g., [10, 19, 18] and the references therein.

We assume that $\det(I - \sum_{i=1}^{m} A_i) \neq 0$, which prevents a characteristic root at zero for all $\vec{r} \in \mathbb{R}_+^m$. Then the stability conditions for the zero solution of (6.1) from [10, Theorem 2.2 and Corollary 2.2] can be rephrased as displayed in Table 3.

A comparison between Tables 2 and Table 3 reveals a strong correspondence between the stability of the zero solution of (1.1) along rays in the delay space

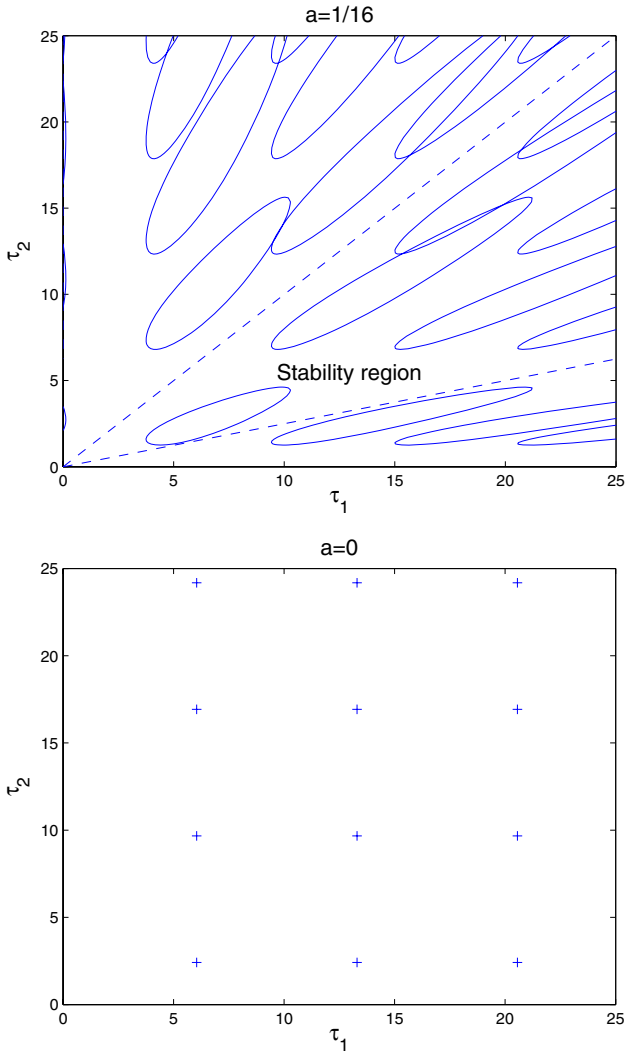

FIG. 4. *Stability/instability regions of the zero solution of* (5.3)–(5.4) *in the* (τ_1, τ_2)*-space, for* $a = 1/16$ *(top) and* $a = 0$ *(bottom).*

and the stability of the zero solution of (6.1). This correspondence is described in Table 4.

7. Concluding remarks. A complete characterization of delay-independent stability, stability of rays in the delay-parameter space, and the delay interference phenomenon was made. The results were illustrated with numerical examples. In addition, scenarios for the transition between delay-dependent stability and delay-independent stability were shown, and the correspondence with the stability theory for delay-difference equations was outlined.

It is worthwhile to mention that the stability results for rays in the delay-parameter space can easily be extended toward higher dimensional subspaces. For instance, asymptotic stability for all delay values lying in a subspace spanned by $\vec{r}^{(1)} \in \mathcal{B}_+^m$ and

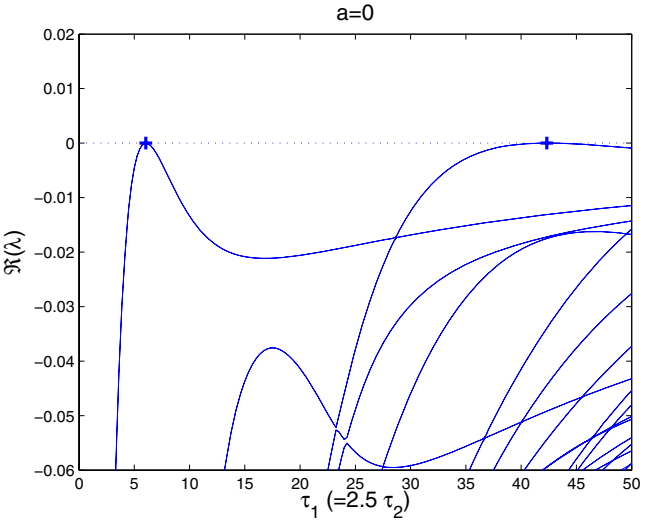

FIG. 5. *Real parts of the rightmost characteristic roots of the system* (5.3)–(5.4) *with* $a = 0$*, for delay values along the ray* $\mathcal{T}(5/\sqrt{29}, 2/\sqrt{29})$.

TABLE 3

Conditions for the stability of the zero solution of (6.1). *The set* $\mathbb{W}$ *is defined as in Definition* 3.1*, with* A_0 *set to zero.*

$\mathbb{W} \subset \{\lambda \in \mathbb{C} : \ \lvert\lambda\rvert < 1\}$	$\sup\{\lvert\lambda\rvert : \ \lambda \in \mathbb{W}\} > 1$
asympt. stable for all values of $\vec{r}$	not asympt. stable for all values of $\vec{r}$
	if $\vec{r}$ is stabilizing, then there exist infinitesimal perturbations on $\vec{r}$ which destroy stability $\equiv$ not strongly stable
	unstable for rationally independent $\vec{r}$

$\vec{r}^{(2)} \in \mathcal{B}_+^m$ will be determined by the position of the set

$$\bigcup_{\theta_1,\theta_2 \geq 0} \Sigma \left(A_0 + \sum_{i=1}^m A_i e^{-j\left(\theta_1 r_i^{(1)} + \theta_2 r_i^{(2)}\right)} \right) \subseteq \mathbb{W}.$$

Furthermore, the study of the sets $\mathbb{W}$ and $\mathbb{V}(\cdot)$ does not only lead to a powerful tool for characterizing delay-independent stability properties. Note, for instance, that the intersection of $\mathbb{W}$ with the imaginary axis contains all possible values where characteristic roots can cross the imaginary axis when the delays are varied. Actually, from these values and/or the corresponding parameters, that is, $\vec{\theta}$ in Definition 3.1, detailed information can be retrieved about the geometry of the stability crossing curves/(hyper)surfaces in the delay-parameter space, thereby generalizing the results from [9].

Appendix A. Continuity properties. Throughout the paper we encounter functions from $\mathcal{B}_+^m \subset \mathbb{R}^m$ to $\mathbb{R}$ and from $\mathcal{B}_+^m$ to $\mathcal{P}(\mathbb{C})$. We assume that $\mathbb{R}^m$ is equipped with the Euclidean norm and $\mathcal{P}(\mathbb{C})$ with the Hausdorff metric.

A function $f : \mathcal{B}_+^m \to \mathbb{R}$ is lower semicontinuous, respectively, upper semicontinuous, at $\vec{s}$ if and only if (see, for instance, [1])

$$\forall \epsilon > 0 \ \exists \delta > 0 \ \ \forall \vec{r} \in \mathcal{B}_+^m \ \ \|\vec{r} - \vec{s}\| < \delta \Rightarrow f(\vec{r}) - f(\vec{s}) > -\epsilon,$$

TABLE 4
The similarity between the stability of the zero solution of (1.1) *along rays in the delay space, and the stability of the zero solution of* (6.1).

Equation (1.1)	$\rightsquigarrow$	Equation (6.1)
relation of $\mathbb{W}$ w.r.t. imaginary axis	$\rightsquigarrow$	relation of $\mathbb{W}$ w.r.t. unit circle
direction $\vec{r}$ in delay space	$\rightsquigarrow$	nominal delay value $\vec{r}$
(un)stable ray $\mathcal{T}(\vec{r})$	$\rightsquigarrow$	(de)stabilizing delay value $\vec{r}$
stable ray subjected to the delay interference phenomenon	$\rightsquigarrow$	stability for nominal $\vec{r}$ destroyed by infinitesimal perturbations on $\vec{r}$

respectively,

$$\forall \epsilon > 0 \ \exists \delta > 0 \ \ \forall \vec{r} \in \mathcal{B}_+^m \ \ \|\vec{r} - \vec{s}\| < \delta \Rightarrow f(\vec{r}) - f(\vec{s}) < \epsilon.$$

It is continuous at $\vec{s}$ when it is both upper and lower semicontinuous at $\vec{s}$.

A function $f : \mathcal{B}_+^m \to \mathcal{P}(\mathbb{C})$ is lower semicontinuous at $\vec{s}$ if and only if

$$\forall \epsilon > 0 \ \exists \delta > 0 \ \ \forall \vec{r} \in \mathcal{B}_+^m \ \ \|\vec{r} - \vec{s}\| < \delta \Rightarrow D(f(\vec{s}), f(\vec{r})) < \epsilon.$$

When replacing $D(f(\vec{s}), f(\vec{r}))$ with $D(f(\vec{r}), f(\vec{s}))$, respectively, $D_h(f(\vec{s}), f(\vec{r}))$, we have upper semicontinuity, respectively, continuity, at $\vec{s}$.

Appendix B. Interdependency of numbers. The real numbers $r_1, r_2, \ldots, r_m$ are *rationally independent* if and only if

$$\sum_{i=1}^{m} z_i r_i = 0, \quad z_i \in \mathbb{Z},$$

implies $z_i = 0, \ \ i = 1, \ldots, m$. For example, two numbers are rationally independent if and only if their ratio is an irrational number.

If the real numbers $r_1, \ldots r_m$ are *rationally dependent* (that is, not rationally independent), then there always exists an integer $p < m$ and a matrix $\Gamma \in \mathbb{Z}^{m \times p}$ of full column rank such that

$$\begin{bmatrix} r_1 \\ \vdots \\ r_m \end{bmatrix} = \Gamma \begin{bmatrix} s_1 \\ \vdots \\ s_p \end{bmatrix},$$

with the numbers $s_1, \ldots, s_p$ rationally independent. Thus, rationally dependent numbers depend on a smaller number of rationally independent numbers. In the special case where $p = 1$, the numbers $r_1, \ldots, r_m$ are called *commensurate*, as they are all multiples of the same number.

For example, the numbers 1, π and $\exp(1)$ are rationally independent, the numbers $1, 2$, and $5/3$ commensurate. The numbers 1, π and $1 + \pi$ are rationally dependent, yet not commensurate, as

$$\begin{bmatrix} 1 \\ \pi \\ 1+\pi \end{bmatrix} = \begin{bmatrix} 1 & 0 \\ 0 & 1 \\ 1 & 1 \end{bmatrix} \begin{bmatrix} 1 \\ \pi \end{bmatrix},$$

with 1 and π rationally independent.

Acknowledgments. The authors would like to thank the associate editor and the anonymous reviewers for the careful reading of the manuscript and the careful comments.

ON MARKOV GAMES WITH AVERAGE REWARD CRITERION AND WEAKLY CONTINUOUS TRANSITION PROBABILITIES*

HEINZ-UWE KÜENLE†

Abstract. In this paper we consider two-person zero-sum stochastic games with the average reward criterion and Borel state and action spaces. A geometric drift condition is assumed. We show that the optimality (Shapley) equation has a unique solution if the transition probability function is weakly continuous, the stage reward is lower semicontinuous, and the set-valued mappings of admissible actions satisfy some semicontinuity assumptions. Furthermore, the minimizing player has an optimal stationary strategy and the maximizing player has an ε-optimal stationary strategy for every $\varepsilon > 0$.

Key words. zero-sum Markov games, average reward criterion, weakly continuous transition probabilities, optimality equation

DOI. 10.1137/040617303

1. Introduction.

This paper deals with two-person zero-sum stochastic games with average payoff criterion and unbounded reward function. As in related papers (see, for instance, [1], [2], [5], [7], [11], [13]), we make some stochastic stability assumptions. For the existence of the value and of optimal or ε-optimal strategies further assumptions are necessary. In the literature especially (semi-)continuity and compactness conditions are known. Concerning discounted Markov games or Markov games with finite horizon, two classes of such conditions are considered. In the one class the transition probability function is strongly continuous, in the other class it is weakly continuous. But in all the papers cited above only the case of strongly continuous transition probabilities is investigated. The reason may be that there are some difficulties in considering stochastic games with weakly continuous transition probabilities under the average reward criterion. On the other hand, in many applications the transition probabilities are weakly, not strongly, continuous. Jaśkiewicz and Nowak [3] were the first to treat stochastic games with average payoff criterion, unbounded rewards, stochastic stability conditions, and weakly continuous transition probabilities. They assume continuity of the reward function and of the set-valued mappings of admissible actions and prove the existence of the value of the game and of optimal stationary strategies using a vanishing discount factor approach. But the question of the existence of a solution of the optimality (Shapley) equation is not completely answered in their paper.

In this paper we use the same stochastic stability conditions. However, we assume only that the reward function is lower semicontinuous, the set-valued mapping of admissible actions of the maximizing player is lower semicontinuous (and complete-valued), and that of the minimizing player is upper semicontinuous (and compact-valued). We show that the optimality equation has a unique solution, the game has a value, the minimizing player has an optimal stationary strategy, and the maximizing player has an ε-optimal stationary strategy for every $\varepsilon > 0$.

The main ideas of our proof are the following. First we substitute a certain Borel measurable function δ in the stochastic stability conditions (which is the generalization of the indicator function of a small set (in the sense of [8])) by an upper semicontinuous function. Then we introduce a parametrized family of operators and show that there are parameters for which these operators have lower semicontinuous fixed points. Finally, we prove that there is one such parameter for which the solution of the fixed point equation defines a solution of the optimality equation.

This proof can be considered as a modification of the proofs in [5] and [7]. We remark that in the case of strongly continuous transition function another fixed point approach is given by Vega-Amaya [13]. But if δ is not continuous, then Vega-Amaya's approach as well as the original approach in [5] and [7] does not work in the case of weakly continuous transition probability function, since the operators used do not map the corresponding sets of lower semicontinuous functions into itself.

The paper is organized as follows. In section 2 we introduce the Markov game model. Section 3 contains our assumptions and some preliminary results. In section 4 we present the main result and its proof.

2. The Markov game model. For a metric space Y we denote by $\mathfrak{B}_Y$ the σ-algebra of all Borel subsets of Y and by $P(Y)$ the family of all probability measures on $\mathfrak{B}_Y$. If Y is a Borel subset of a complete separable metric space, endowed with $\mathfrak{B}_Y$, then Y is called a Borel space. Measurability of a function on Y stands for $\mathfrak{B}_Y$-measurability.

We study two-person zero-sum stochastic games

$$\mathcal{M} = (X, A, B, K_A, K_B, p, r),$$

whereby

1. X is the *state space* and A and B are the *action spaces* for players 1 and 2. All three sets are assumed to be Borel spaces.
2. K_A and K_B are the *constraint sets*, which are Borel subsets of $X \times A$ and $X \times B$. For each state $x \in X$, the set

$$A(x) := \{a \in A : (x, a) \in K_A\}$$

represents the *set of admissible actions* for player 1 in state x and is assumed to be nonempty. Analogously, we define $B(x)$ as the (nonempty) *set of admissible actions* for player 2 in state x. The set

$$K := \{(x, a, b) : x \in X, a \in A(x), b \in B(x)\}$$

is a Borel subset of $X \times A \times B$ (see [9]).
3. p is a Borel measurable transition probability from K to X, the *law of motion.*
4. $r : K \to \mathbb{R}$ is a Borel measurable function from K to $\mathbb{R}$, the *reward function* for player 1.

We can describe the situation of a zero-sum Markov game as follows. At any discrete time point $n = 0, 1, 2, \ldots$, the game is in state $x \in X$. Both players simultaneously decide for actions $a \in A(x)$ and $b \in B(x)$. Player 1 receives a reward $r(x, a, b)$, while player 2 has to pay an amount of $r(x, a, b)$. At the beginning of the next period $n + 1$ the game is in a state x', chosen according to the probability distribution $p(\cdot|x, a, b)$. The goal of player 1 is to maximize his reward, while player 2 wants to minimize his costs.

Let $H_n = K^n \times X$. An element $h_n \in H_n$ is called the *history* of the game up to time n.

A sequence $\pi = (\pi_0, \pi_1, \dots)$ is a *strategy* for player 1 if each π_n is a transition probability from H_n to A, and $\pi_n(A(x_n)|x_0, a_0, b_0, \dots, x_n) = 1$ for all n. The class of all strategies for player 1 will be denoted by Π. Analogously, we define $\mathbf{P}$ as the class of all strategies for player 2. We assume $\Pi \neq \emptyset$ and $\mathbf{P} \neq \emptyset$, which follows from the assumptions to be given later.

A Borel measurable transition probability f from X to A with $f(A(x)|x) = 1$ for all $x \in X$ is called a *Markovian decision rule (of the first player)*. The set of all Markovian decision rules for the first player is denoted $\mathbf{F}$. For $f \in \mathbf{F}$, we write $f(x)$ for the probability measure on $A(x)$ with $f(x)(D) = f(D|x)$ for all Borel sets $D \subseteq A(x)$. A sequence $\pi = (f_0, f_1, \dots)$ with $f_n \in \mathbf{F}$ for all n is a *Markovian strategy* for player 1. If additionally $f_n = f$ for some $f \in \mathbf{F}$ and all n, $\pi = (f, f, \dots) =: f^\infty$ is a *stationary* strategy for player 1. Hence, the set of all stationary strategies for player 1 can be identified by $\mathbf{F}$. Similarly, we define $\mathbf{G}$ as the set of all Markovian decision rules for the second player (transition probabilities g from X to B with $g(B(x)|x) = 1$ for all $x \in X$) which can be identified by the set of all stationary strategies of this player.

Let us consider the space $\Omega := (X \times A \times B)^\infty$, endowed with the product σ-algebra $\mathcal{F}$. It follows from the Ionescu–Tulcea theorem that there exists a suitable probability measure $P_x^{\pi\rho}$ and a stochastic process $\{X_n, A_n, B_n\}$ on $(\Omega, \mathcal{F})$ for every pair $(\pi, \rho) \in \Pi \times \mathbf{P}$ and each initial state $x = x_0 \in X$. Here, the random variables X_n, A_n, B_n represent the state and the actions of players 1 and 2 in stage n. Let $E_x^{\pi\rho}$ be the expectation operator with respect to $P_x^{\pi\rho}$. Then, for a pair $\pi \in \Pi, \rho \in \mathbf{P}$ of strategies, the *total expected n-stage reward* for player 1 is

$$J_n(x, \pi, \rho) := E_x^{\pi\rho}\left[\sum_{m=0}^{n-1} r(X_m, A_m, B_m)\right]$$

if the expectation exists. The *expected average reward* for player 1 is

$$J(x, \pi, \rho) := \liminf_{n\to\infty} J_n(x, \pi, \rho)/n.$$

We define the *lower value* and the *upper value* of the game by

$$v_l(x) := \sup_{\pi\in\Pi} \inf_{\rho\in\mathbf{P}} J(x, \pi, \rho) \qquad \text{and} \qquad v_u(x) := \inf_{\rho\in\mathbf{P}} \sup_{\pi\in\Pi} J(x, \pi, \rho).$$

Obviously, there is always $v_l(x) \leq v_u(x)$ for all $x \in X$. If the equality $v_l(x) = v_u(x)$ holds for all $x \in X$, the common function is called the *value* v of the game.

Assume that v exists and let $\varepsilon \geq 0$. Then a strategy $\pi^* \in \Pi$ is called *ε-optimal* for player 1 if

$$\inf_{\rho\in\mathbf{P}} J(x, \pi^*, \rho) \geq v(x) - \varepsilon$$

for all $x \in X$ and similarly a strategy $\rho^* \in \mathbf{P}$ is *ε-optimal* for player 2 if

$$\sup_{\pi\in\Pi} J(x, \pi, \rho^*) \leq v(x) + \varepsilon$$

for all $x \in X$. As is usual, 0-optimal strategies are called *optimal*.

3. Assumptions and preliminary results. Let Y and Z be metric spaces and $\Gamma : Y \to \mathfrak{B}_Z$ a set-valued mapping. Γ is called lower (upper) semicontinuous if $\{y \in Y : \Gamma(y) \cap S \neq \emptyset\}$ is open (closed) for every open (closed) subset of $S \subseteq Z$. Γ is called continuous if Γ is lower (l.s.c) and upper semicontinuous (u.s.c).

A real function $v : Y \to \mathbb{R}$ is called l.s.c. if for every $r \in \mathbb{R}$ the set $\{y \in Y : v(y) > r\}$ is open. v is called u.s.c. if $-v$ is l.s.c. Clearly, a semicontinuous function is Borel measurable.

A transition probability q from Y to Z is called weakly continuous if $\int_Z u(z)q(dz|\cdot)$ is continuous on Y for every bounded continuous function $u : Z \to \mathbb{R}$.

We now formulate our main assumptions.

Assumption 3.1.

A1. $A(\cdot)$ is l.s.c. $A(x)$ is complete for every $x \in X$.

A2. $B(\cdot)$ is u.s.c. $B(x)$ is compact for every $x \in X$.

A3. r is l.s.c.

A4. p is weakly continuous.

A5. There is a continuous function $W : X \to [1, \infty)$, a Borel measurable function $\delta : K \to [0, 1]$ with $\delta \not\equiv 0$, a probability measure $\mu \in P(X)$, and constants $\alpha \in (0, 1)$, $\beta > 0$, such that

(a) $\sup_{(x,a,b)\in K} \frac{|r(x,a,b)|}{W(x)} < \infty$,

(b) $\int_X W(\xi)p(d\xi|\cdot)$ is continuous on K,

(c) $\int_X W(\xi)p(d\xi|x, a, b) \leq \alpha W(x) + \beta\delta(x, a, b)$ for each $(x, a, b) \in K$,

(d) $\delta(\cdot)\mu(D) \leq p(D|\cdot)$ for each Borel set $D \subseteq X$.

We remark that under A1 and A2 the strategy sets $\mathbf{F}$ and $\mathbf{G}$ are not empty. (See Lemma 2.1. and Lemma 2.2. in [10], for instance.)

Furthermore, A5(c) and A5(d) imply $\int_X W(\xi)\mu(d\xi) < \infty$, because there is $(x_0, a_0, b_0) \in K$ with $\delta(x_0, a_0, b_0) > 0$. Hence,

$$\begin{aligned}\int_X W(\xi)\mu(d\xi) &\leq \frac{1}{\delta(x_0, a_0, b_0)} \int_X W(\xi)p(d\xi|x_0, a_0, b_0) \\ &\leq \frac{1}{\delta(x_0, a_0, b_0)}(\alpha W(x_0) + \beta\delta(x_0, a_0, b_0)) < \infty.\end{aligned}$$

Let $w : K \to \mathbb{R}$ be a measurable function for which $w(x, \cdot)$ is bounded from below for all $x \in X$. For $\nu_1 \in P(A(x))$, $\nu_2 \in P(B(x))$ we set

$$w(x, \nu_1, \nu_2) := \int_{A(x)} \int_{B(x)} w(x, a, b)\nu_2(db)\nu_1(da) \tag{3.1}$$

and $w_{fg}(x) := w(x, f(x), g(x))$ for each pair $f \in \mathbf{F}$, $g \in \mathbf{G}$. Especially,

$$p(D|x, \nu_1, \nu_2) := \int_{A(x)} \int_{B(x)} p(D|x, a, b)\nu_2(db)\nu_1(da)$$

and $p_{fg}(D|x) := p(D|x, f(x), g(x))$ for any $D \in \mathfrak{B}_X$, $\nu_1 \in P(A(x))$, $\nu_2 \in P(B(x))$, $f \in \mathbf{F}$, $g \in \mathbf{G}$.

We denote by V the function $V : X \to \mathbb{R}$ with $V(x) := W(x) + \beta$ for each $x \in X$. For a function $u : X \to \mathbb{R}$ we define $\|u\|_V := \sup_{x\in X} \frac{|u(x)|}{V(x)}$.

Let $\mathcal{V}$ be the set of all real Borel measurable functions u with finite $\|u\|_V$. $\mathcal{V}$ is a Banach space.

Let Y and Z be metric spaces, q a substochastic kernel from Y to Z, and u a measurable function on $Y \times Z$. We denote by $qu(y)$ the integral

$$qu(y) := \int_Z u(y,z)q(dz|y) \tag{3.2}$$

(if it exists for all $y \in Y$). Then we can consider q also as an operator which maps corresponding sets of measurable functions on $Y \times Z$ into the set of measurable functions on Y.

We then have

$$pv(x,a,b) = \int_X v(\xi)p(d\xi|x,a,b)$$

for each $v \in \mathcal{V}$ and $(x,a,b) \in K$ and

$$\mu v = \int_X v(\xi)\mu(d\xi).$$

The operators p and μ are well defined on $\mathcal{V}$ since the assumptions A5(a) and A5(c) hold.

Let $\mathcal{C}$ be the set of all nonnegative bounded continuous functions u on X with $\mu u > 0$. We put

$$\zeta(x,a,b) := \inf_{u\in\mathcal{C}} \frac{pu(x,a,b)}{\mu u}.$$

Obviously, $\delta \le \zeta \le 1$. The following lemma shows that we can replace δ by the u.s.c. function ζ.

LEMMA 3.2. *Let* A4 *and* A5 *hold.*

(a) ζ *is u.s.c.*

(b)

$$\int_X W(\xi)p(d\xi|x,a,b) \le \alpha W(x) + \beta\zeta(x,a,b) \text{ for each } (x,a,b) \in K. \tag{3.3}$$

(c)

$$\zeta(\cdot)\mu(D) \le p(D|\cdot) \text{ for each } D \in \mathfrak{B}_X. \tag{3.4}$$

Proof.

(a) Assumption A4 implies the continuity of pu for $u \in \mathcal{C}$. From the properties of semicontinuous functions it follows that the infimum of an arbitrary nonempty set of continuous functions is u.s.c.

(b) This inequality follows from $\delta \le \zeta$.

(c) Let U be an open subset of X and I_U the indicator function of U. Since I_U is l.s.c., there is a sequence of bounded continuous functions $(w_n)_{n\in\mathbb{N}}$ with $w_n \nearrow I_U$. (See, for instance, Lemma 5.1. in [10]). We can assume $w_n \ge 0$, because for a continuous function w the function $\max\{w,0\}$ is also continuous. From

$$\zeta(x,a,b)\mu w_n \le pw_n(x,a,b)$$

it follows then by the monotone convergence theorem that

$$\zeta(x,a,b)\mu(U) \le p(U|x,a,b)$$

for all $(x,a,b) \in K$.

Because X is a Borel subset of a metric space, every probability measure on $\mathfrak{B}_X$ is regular. (See, for instance, Lemma 1.16 in [4].) That means especially

$$\mu(D) = \inf\{\mu(U) : \ D \subseteq U, \ U \text{ open}\}$$

and

$$p(D|x,a,b) = \inf\{p(U|x,a,b) : \ D \subseteq U, \ U \text{ open}\}$$

for all $D \in \mathfrak{B}_X$. It follows (3.4). □

We now put

$$P(D|x,a,b) := p(D|x,a,b) - \zeta(x,a,b)\mu(D)$$

for all $D \in \mathfrak{B}_X$, $(x,a,b) \in K$. It follows from (3.4) that P is a substochastic kernel. The operator P according to (3.2) is then well defined on $\mathcal{V}$. It holds that $Pv = pv - \zeta \cdot \mu v$ for $v \in \mathcal{V}$.

We set

$$\lambda := \frac{\alpha + \beta}{1 + \beta}.$$

Obviously, $\alpha < \lambda < 1$. The following properties play an essential role in our approach.

LEMMA 3.3. *Let* A4 *and* A5 *hold.*

(a) *P is isotonic.*

(b) *$0 \le PV(x,a,b) \le \lambda V(x)$ for all $(x,a,b) \in K$.*

Proof.

(a) $Pv_1 \le Pv_2$ for $v_1 \le v_2$ for $v_1, v_2 \in \mathcal{V}$ follows immediately from Lemma 3.2(c).

(b) It holds that

$$\beta = \lambda - \alpha + \lambda\beta \le (\lambda - \alpha)W + \lambda\beta \tag{3.5}$$

and

$$\beta \le \mu V. \tag{3.6}$$

It follows that

$$\begin{aligned} pV &= pW + \beta \\ &\le \alpha W + \beta\zeta + \beta \quad \text{(see (3.3))} \\ &\le \alpha W + \zeta\mu V + (\lambda - \alpha)W + \lambda\beta \quad \text{(see (3.5) and (3.6))} \\ &= \lambda V + \zeta\mu V. \end{aligned}$$

This yields $PV \le \lambda V$. $PV \ge 0$ follows from (a). □

Let $\tilde{\mathcal{V}}$ be the set of all l.s.c. functions from $\mathcal{V}$. $\tilde{\mathcal{V}}$ is complete. To establish this fact, we consider a Cauchy sequence (v_n) with $v_n \in \tilde{\mathcal{V}}$ and put $v^* := \lim_{n\to\infty} v_n \in \mathcal{V}$. The sequence (u_n) with $u_n := v_n - \|v^* - v_n\|_V V$ has the properties $u_n \in \tilde{\mathcal{V}}$, $u_n \le v^*$, and $u_n \to v^*$. Hence, $v^* = \sup_{n\in\mathbb{N}} u_n \in \tilde{\mathcal{V}}$.

The following minimax selection theorem is a slight modification of Nowak's Theorem 5.1. in [10]. Similar results can be found also in [6] and [12].

LEMMA 3.4. *Let assumptions* A1 *and* A2 *be satisfied. Let $u : K \to \mathbb{R}$ be an l.s.c. function with $\sup_{(x,a,b)\in K} \frac{|u(x,a,b)|}{V(x)} < \infty$ and $v(x) := \sup_{f\in\mathbf{F}} \inf_{g\in\mathbf{G}} u(x, f(x), g(x))$*

for all $x \in X$. Then it holds that

(a) $v \in \tilde{\mathcal{V}}$,

(b) $v(x) = \inf_{g\in\mathbf{G}} \sup_{f\in\mathbf{F}} u(x, f(x), g(x))$ *for all* $x \in X$,

(c) *there is* $g^* \in \mathbf{G}$ *with* $v(x) = \sup_{f\in\mathbf{F}} u(x, f(x), g^*(x))$ *for all* $x \in X$,

(d) *for every* $\varepsilon > 0$ *there is* $f_\varepsilon \in \mathbf{F}$ *with* $v(x) - \varepsilon \le \inf_{g\in\mathbf{G}} u(x, f_\varepsilon(x), g(x))$ *for all* $x \in X$.

Proof. There is $c \in \mathbb{R}$ with $u' := u + cV > 0$. Hence, u' is l.s.c. and bounded from below. Then (a)–(c) follow directly from Theorem 5.1 in [10]. To show (d), Nowak [10] assumes that u is also bounded from above. But it is easy to see that his proof works also under our assumption $\sup_{(x,a,b)\in K} \frac{|u(x,a,b)|}{V(x)} < \infty$. ∎

4. Main result. In this section we will prove our main result, namely, that under Assumption 3.1 the optimality equation has a solution $(h^*, v^*) \in \mathbb{R} \times \tilde{\mathcal{V}}$, where h^* is unique and v^* is unique up to an additive constant. Furthermore, we show that h^* is the value of the game, the first player has an ε-optimal stationary strategy for every $\varepsilon > 0$, and the second player has an optimal stationary strategy.

THEOREM 4.1. *Let Assumption* 3.1 *be satisfied. Then the following hold.*

(a) *The optimality equation*

$$v(x) + h = \sup_{f\in\mathbf{F}} \inf_{g\in\mathbf{G}} \left\{ r_{fg}(x) + \int_X v(\xi) p_{fg}(d\xi|x) \right\} \quad \text{for all } x \in X \tag{4.1}$$

has a solution $(h^*, v^*) \in \mathbb{R} \times \tilde{\mathcal{V}}$.

(b) *There is a Markovian decision rule* $g^* \in \mathbf{G}$ *and, for every* $\varepsilon > 0$, *a Markovian decision rule* $f_\varepsilon \in \mathbf{F}$, *with*

$$\begin{aligned} v^*(x) + h^* &= \sup_{f\in\mathbf{F}} \left\{ r_{fg^*}(x) + \int_X v^*(\xi) p_{fg^*}(d\xi|x) \right\} \\ &\le \inf_{g\in\mathbf{G}} \left\{ r_{f_\varepsilon g}(x) + \int_X v^*(\xi) p_{f_\varepsilon g}(d\xi|x) \right\} + \varepsilon \end{aligned} \tag{4.2}$$

for all $x \in X$.

(c) f_ε^∞ *is an* ε*-optimal strategy of the first player and* $g^{*\infty}$ *is an optimal strategy of the second player.*

(d) h^* *is the value of the game for every solution* $(h^*, v^*) \in \mathbb{R} \times \tilde{\mathcal{V}}$ *of* (4.1).

(e) v^* *is unique in* $\tilde{\mathcal{V}}$ *up to additive constants.*

Before we prove Theorem 4.1 we will show some auxiliary results. But let us introduce first two further operators. In this section it is assumed that Assumption 3.1 is satisfied, which implies that the following operators are well defined. We set

$$T_{fg}^\eta v := r_{fg} - (1 - \zeta_{fg})\eta + P_{fg} v$$

and

$$LT^\eta v(x) := \sup_{f\in\mathbf{F}} \inf_{g\in\mathbf{G}} T_{fg}^\eta v(x)$$

for all $f \in \mathbf{F}$, $g \in \mathbf{G}$, $v \in \mathcal{V}$, $x \in X$, and $\eta \in \mathbb{R}$.

We remark that it holds that $T_{fg}^\eta v = [T^\eta v]_{fg}$ in the sense of (3.1).

The proof of the next lemma can be omitted since it follows immediately from Lemma 3.3 by standard methods.

LEMMA 4.2. *Fix an arbitrary* $\eta \in \mathbb{R}$.

(a) T^η_{fg} *is contractive in* $\mathcal{V}$, *which means* $T^\eta_{fg}\mathcal{V} \subseteq \mathcal{V}$, *and for all* $u, v \in \mathcal{V}$, $f \in \mathbf{F}$, *and* $g \in \mathbf{G}$ *it holds*

$$\|T^\eta_{fg}u - T^\eta_{fg}v\|_V \le \lambda\|u - v\|_V.$$

(b) *For all* $u, v \in \mathcal{V}$ *it holds*

$$\|LT^\eta u - LT^\eta v\|_V \le \lambda\|u - v\|_V.$$

(c) T^η_{fg} *and* LT^η *are isotonic.*

We remark that we have $LT^\eta\tilde{\mathcal{V}} \subseteq \tilde{\mathcal{V}}$ for continuous ζ, which means that in this case LT^η is contractive in $\tilde{\mathcal{V}}$ and the idea of the proof in [5] works also under the above assumptions. But the assumption of continuous ζ seems very strong. (See also the corresponding remarks in [3].) Therefore, we have to modify the proof in [5]. We will first find a set $\check{H} \subseteq \mathbb{R}$ and for every $\eta \in \check{H}$ a complete set $\check{\mathcal{V}}_\eta \subseteq \mathcal{V}$ with $LT^\eta\check{\mathcal{V}}_\eta \subseteq \check{\mathcal{V}}_\eta$. Hence, LT^η is contractive in $\check{\mathcal{V}}_\eta$ and has a unique fixed point $v^*_\eta \in \check{\mathcal{V}}_\eta$. Then we will show that there is an $\eta^* \in \check{H}$ such that $(\eta^*, v^*_{\eta^*})$ is a solution of the optimality equation.

The next lemma gives a condition under which $LT^\eta v \in \tilde{\mathcal{V}}$ for $v \in \tilde{\mathcal{V}}$.

LEMMA 4.3. $LT^\eta v \in \tilde{\mathcal{V}}$ *for every* $v \in \tilde{\mathcal{V}}$ *and* $\eta \in \mathbb{R}$ *with* $\mu v \ge \eta$.

Proof. Let

$$u(x,a,b) := r(x,a,b) + \int_X v(\xi)p(d\xi|x,a,b) - \eta + (\eta - \mu v)\zeta(x,a,b)$$

for all $(x,a,b) \in K$. It is well known that for weakly continuous p the integral $\int_X v'(\xi)p(d\xi|\cdot)$ is l.s.c. if v' is l.s.c. and bounded from below. (See, e.g., Lemma 5.3. in [10].) Setting $v' := v + \|v\|_V V$ we see also that u is l.s.c. The statement follows then by Lemma 3.4. □

Let $v \in \tilde{\mathcal{V}}$. We set

$$\check{L}T^\eta v := \begin{cases} LT^\eta v & \text{if } \eta \le \mu v, \\ -\infty & \text{if } \eta > \mu v, \end{cases}$$

where $-\infty$ means a numerical function identical with $-\infty$. Especially, $\check{L}T^\eta(-\infty) := -\infty$. From Lemma 4.3 it follows that we can consider $\check{L}T^\eta$ as an operator $\check{L}T^\eta : \tilde{\mathcal{V}} \cup \{-\infty\} \to \tilde{\mathcal{V}} \cup \{-\infty\}$.

LEMMA 4.4. *Let* $c := \sup_{(x,a,b)\in K} \frac{|r(x,a,b)|}{V(x)}$, $C := -c(1-\lambda)^{-1}$, *and* $\eta := C\mu V$. *If* $u_0 \equiv 0$ *and* $u_n = \check{L}T^\eta u_{n-1}$ *for* $n \ge 1$, *then* $u_n \ge CV$ *and* $\mu u_n \ge \eta$ *for all* $n \in \mathbb{N}$.

Proof. Assume that $u_{n-1} \in \tilde{\mathcal{V}}$ and $u_{n-1} \ge CV$. Then $u_n \in \tilde{\mathcal{V}}$, and

$$\begin{aligned} u_n = LT^\eta u_{n-1} &\ge \sup_{f\in\mathbf{F}} \inf_{g\in\mathbf{G}} \{-cV - \eta(1-\zeta_{fg}) + P_{fg}(-c(1-\lambda)^{-1}V)\} \\ &\ge \sup_{f\in\mathbf{F}} \inf_{g\in\mathbf{G}} \{-cV - c(1-\lambda)^{-1}P_{fg}V\} \\ &\ge -c(1+\lambda(1-\lambda)^{-1})V = CV. \end{aligned}$$

Hence, $\mu u_n \ge C\mu V = \eta$.

We now get the statement by mathematical induction. □

This lemma allows us now to define the aforementioned sets $\check{H}$ and $\check{\mathcal{V}}_\eta$. We put

$$\check{\mathcal{V}}_\eta := \{v \in \tilde{\mathcal{V}} : [\check{L}T^\eta]^n v > -\infty \text{ for every } n \in \mathbb{N}\} \text{ and } \check{H} := \{\eta \in \mathbb{R} : \check{\mathcal{V}}_\eta \neq \emptyset\}.$$

From Lemma 4.4 it follows that $\check{H} \neq \emptyset$.

We now show an inequality which will be helpful to prove the next lemmas.

LEMMA 4.5. *Let* $u_0, u_0' \in \tilde{\mathcal{V}}$, $\eta, \eta' \in \mathbb{R}$. *If* $u_n := [\check{L}T^\eta]^n u_0 > -\infty$, $u_n' := [\check{L}T^{\eta'}]^n u_0' > -\infty$, *then*

$$\|u_n - u_n'\|_V \leq \lambda^n \|u_0 - u_0'\|_V + \frac{1}{1-\lambda}|\eta - \eta'|.$$

Proof. It follows from the definition of $\check{L}T^\eta$ and from Lemma 4.3 $\eta \leq \mu u_{k-1}$, $\eta' \leq \mu u_{k-1}'$, and $u_k, u_k' \in \tilde{\mathcal{V}}$ for $1 \leq k \leq n$. Hence, $u_k = LT^\eta u_{k-1}$ and $u_k' = LT^{\eta'} u_{k-1}'$ for $1 \leq k \leq n$.

Assume that

$$u_{k-1} \leq u_{k-1}' + \lambda^{k-1}\|u_0 - u_0'\|_V V + \frac{1}{1-\lambda}|\eta - \eta'|V.$$

Then we get by means of Lemma 3.3 for all $f \in \mathbf{F}$, $g \in \mathbf{G}$,

$$\begin{aligned} T_{fg}^\eta u_{k-1} &= r_{fg} - \eta(1 - \zeta_{fg}) + P_{fg} u_{k-1} \\ &= r_{fg} - \eta'(1 - \zeta_{fg}) + P_{fg} u_{k-1}' + (\eta' - \eta)(1 - \zeta_{fg}) + P_{fg}(u_{k-1} - u_{k-1}') \\ &\leq T_{fg}^{\eta'} u_{k-1}' + |\eta' - \eta|V + \lambda^{k-1}\|u_0 - u_0'\|_V \lambda V + \frac{\lambda}{1-\lambda}|\eta' - \eta|V \\ &= T_{fg}^{\eta'} u_{k-1}' + \lambda^k \|u_0 - u_0'\|_V V + \frac{1}{1-\lambda}|\eta' - \eta|V. \end{aligned}$$

Hence,

$$\begin{aligned} u_k = LT^\eta u_{k-1} &\leq LT^{\eta'} u_{k-1}' + \lambda^k \|u_0 - u_0'\|_V V + \frac{1}{1-\lambda}|\eta' - \eta|V \\ &= u_k' + \lambda^k \|u_0 - u_0'\|_V V + \frac{1}{1-\lambda}|\eta' - \eta|V. \end{aligned}$$

By mathematical induction it follows

$$u_n \leq u_n' + \lambda^n \|u_0 - u_0'\|_V V + \frac{1}{1-\lambda}|\eta' - \eta|V.$$

Because we can exchange u_n and u_n', we obtain the statement from this inequality. ∎

LEMMA 4.6. $\check{\mathcal{V}}_\eta$ *is complete for every* $\eta \in \check{H}$.

Proof. Let (u_n) be a Cauchy sequence in $\check{\mathcal{V}}_\eta$. Since $\tilde{\mathcal{V}}$ is complete, there is $u^* \in \tilde{\mathcal{V}}$ with $\lim_{n\to\infty} u_n = u^*$.

From $\mu u_n \geq \eta$ it follows $\mu u^* \geq \eta$ by the dominated convergence theorem. Let $v_k := [\check{L}T^\eta]^k u^*$. Assume that there is $N \in \mathbb{N}$ with $\mu v_{N-1} \geq \eta$, $\gamma := \eta - \mu v_N > 0$. We consider $n_0 \in \mathbb{N}$ with $\|u_{n_0} - u^*\|_V \leq \frac{\gamma}{2\mu V}$. For $w_k := [LT^\eta]^k u_{n_0}$ we get, from Lemma 4.5,

$$\|v_N - w_N\|_V \leq \lambda^N \|u^* - u_{n_0}\|_V \leq \frac{\gamma}{2\mu V}.$$

Hence,

$$\eta - \mu w_N \geq \eta - \mu v_N - \frac{\gamma}{2\mu V}\mu V = \gamma - \frac{\gamma}{2} = \frac{\gamma}{2} > 0,$$

which contradicts $u_{n_0} \in \check{\mathcal{V}}_\eta$.

Therefore, $\mu v_n \geq \eta$ for all $n \in \mathbb{N}$. This implies $u^* \in \check{\mathcal{V}}_\eta$, and the completeness of $\check{\mathcal{V}}_\eta$. □

LEMMA 4.7. *For $\eta \in \check{H}$, the operator LT^η has in $\check{\mathcal{V}}_\eta$ a unique fixed point.*

Proof. $\check{\mathcal{V}}_\eta \neq \emptyset$, $\check{\mathcal{V}}_\eta$ is complete (see Lemma 4.6), and $LT^\eta \check{\mathcal{V}}_\eta \subseteq \check{\mathcal{V}}_\eta$. Furthermore, LT^η is contractive in $\check{\mathcal{V}}_\eta$ (see Lemma 4.2). Then the statement follows by Banach's fixed point theorem. □

By means of the following two lemmas we will construct suitable $\eta^* \in \mathbb{R}$ and $v^* \in \check{\mathcal{V}}$, and finally we will show that (η^*, v^*) is a solution of the optimality equation. We denote the unique fixed point of LT^η in $\check{\mathcal{V}}_\eta$ by v^*_η.

LEMMA 4.8. *Let $\eta \in \check{H}$. Then it holds for all $\eta' \in \check{H}$ with $\eta \leq \eta'$*

(a) $v^*_\eta \geq v^*_{\eta'}$,

(b) $\eta' \leq \mu v^*_\eta$.

Proof.

(a) Let $\eta, \eta' \in \check{H}$. For $u \geq u'$ with $\mu u' \geq \eta'$ we have $\mu u \geq \mu u' \geq \eta' \geq \eta$. Then we get by Lemma 4.2

$$v := LT^\eta u \geq LT^\eta u' \geq LT^{\eta'} u' =: v'.$$

Hence, if $\mu v' \geq \eta'$, then $\mu v \geq \eta$. Therefore, if $u_0 \in \check{\mathcal{V}}_{\eta'}$, then $u_0 \in \check{\mathcal{V}}_\eta$. For $u_0 \in \check{\mathcal{V}}_{\eta'}$ we then have

$$v^*_{\eta'} = \lim_{n\to\infty} [LT^{\eta'}]^n u_0 \leq \lim_{n\to\infty} [LT^\eta]^n u_0 = v^*_\eta.$$

(b) For an arbitrary $\eta \in \check{H}$ we have for all $\eta' \in \check{H}$ with $\eta \leq \eta'$

$$\eta' \leq \mu v^*_{\eta'} \leq \mu v^*_\eta.$$

Therefore, μv^*_η is an upper bound for $\check{H}$. □

LEMMA 4.9. *For $\eta^* := \sup \check{H}$, $v^* := \inf_{\eta \in \check{H}} v^*_\eta$, it holds that $\mu v^* = \eta^*$. Furthermore, $\lim_{\eta \nearrow \eta^*} \|v^*_\eta - v^*\|_V = 0$ and $v^* \in \tilde{\mathcal{V}}$.*

Proof. From Lemma 4.8(b) it follows that $\mu v^* \geq \eta^*$ by the monotone convergence theorem. Let $\varepsilon := \mu v^* - \eta^*$.

Assume $\varepsilon > 0$. Let $\gamma := \varepsilon \frac{1-\lambda}{4\mu V} > 0$. It holds that $\gamma \leq \frac{\varepsilon}{4}$. Let $\eta := \eta^* - \gamma$, $\eta' := \eta^* + \gamma$. Then $\eta \in \check{H}$ and $\eta' = \mu v^* - \varepsilon + \gamma \leq \mu v^* \leq \mu v^*_\eta$. Let $u_n := [\check{L}T^{\eta'}]^n v^*_\eta$. If $\mu u_k \geq \eta'$ for all $k < n$, then it follows from Lemma 4.5 that

$$\|u_n - v^*_\eta\|_V \leq \frac{1}{1-\lambda}|\eta - \eta'| = \frac{2}{1-\lambda}\gamma.$$

Hence,

$$u_n \geq v^*_\eta - \frac{2}{1-\lambda}\gamma V.$$

Then, it follows

$$\mu u_n \geq \mu v^*_\eta - \frac{2}{1-\lambda}\gamma\mu V = \mu v^*_\eta - \frac{\varepsilon}{2} \geq \mu v^* - \frac{\varepsilon}{2} = \eta^* + \varepsilon - \frac{\varepsilon}{2} \geq \eta^* + \gamma = \eta'.$$

By mathematical induction we get $\mu u_n \geq \eta'$ for all $n \in \mathbb{N}$. That means $\eta' \in \check{H}$, which contradicts $\eta^* := \sup \check{H}$. Hence, $\mu v^* = \eta^*$.

For $\eta_n \nearrow \eta^*$ we have $v^*_{\eta_n} \searrow v^*$ (see Lemma 4.8). From Lemma 4.5 it follows that $(v^*_{\eta_n})$ is a Cauchy sequence. Then $v^* \in \tilde{\mathcal{V}}$, since $\tilde{\mathcal{V}}$ is complete. □

Now we are ready to prove Theorem 4.1. Especially, we will show that (η^*, v^*) is a solution of the optimality equation. We remark that we will not use $\eta^* \in \check{H}$ and $v^* = v^*_{\eta^*}$ in this proof. We will, however, derive these facts later (see Corollary 4.10).

Proof of Theorem 4.1. Let v^*, η^* as in Lemma 4.9 and (η_n) a sequence with $\eta_n \in \check{H}$ and $\lim_{n\to\infty} \eta_n = \eta^*$. Then it follows from Lemma 4.9 $\lim_{n\to\infty} \|v^*_{\eta_n} - v^*\|_V = 0$. We get for all $f \in \mathbf{F}$, $g \in \mathbf{G}$, by Lemma 3.3,

$$\begin{aligned} r_{fg} - \eta^* + p_{fg}v^* &= r_{fg} - (1-\zeta_{fg})\eta^* + p_{fg}v^* - \zeta_{fg}\mu v^* \\ &= r_{fg} - (1-\zeta_{fg})\eta^* + P_{fg}v^* \\ &= r_{fg} - (1-\zeta_{fg})\eta_n + P_{fg}v^*_{\eta_n} + (1-\zeta_{fg})(\eta_n - \eta^*) + P_{fg}(v^* - v^*_{\eta_n}) \\ &\leq r_{fg} - (1-\zeta_{fg})\eta_n + P_{fg}v^*_{\eta_n} + |\eta_n - \eta^*| + \lambda\|v^*_{\eta_n} - v^*\|_V V \\ &= T^{\eta_n}_{fg} v^*_{\eta_n} + |\eta_n - \eta^*| + \lambda\|v^*_{\eta_n} - v^*\|_V V, \end{aligned}$$

and analogously

$$r_{fg} - \eta^* + p_{fg}v^* \geq T^{\eta_n}_{fg} v^*_{\eta_n} - |\eta_n - \eta^*| - \lambda\|v^*_{\eta_n} - v^*\|_V V.$$

Therefore,

$$\begin{aligned} & v^*_{\eta_n}(x) - |\eta_n - \eta^*| - \lambda\|v^*_{\eta_n} - v^*\|_V V(x) \\ &= LT^{\eta_n} v^*_{\eta_n}(x) - |\eta_n - \eta^*| - \lambda\|v^*_{\eta_n} - v^*\|_V V(x) \\ &\leq \sup_{f\in\mathbf{F}} \inf_{g\in\mathbf{G}} \left\{ r_{fg}(x) + \int_X v^*(\xi) p_{fg}(d\xi|x) \right\} - \eta^* \\ &\leq LT^{\eta_n} v^*_{\eta_n}(x) + |\eta_n - \eta^*| + \lambda\|v^*_{\eta_n} - v^*\|_V V(x) \\ &= v^*_{\eta_n}(x) + |\eta_n - \eta^*| + \lambda\|v^*_{\eta_n} - v^*\|_V V(x) \end{aligned}$$

for all $x \in X$. For $n \to \infty$, it follows that

$$v^*(x) = \sup_{f\in\mathbf{F}} \inf_{g\in\mathbf{G}} \left\{ r_{fg}(x) + \int_X v^*(\xi) p_{fg}(d\xi|x) \right\} - \eta^*$$

for all $x \in X$. Hence, (η^*, v^*) is a solution of the optimality equation.

For every solution $(h^*, v^*) \in \mathbb{R} \times \tilde{\mathcal{V}}$ of the optimality equation (4.1) we obtain the existence of $g^* \in \mathbf{G}$ and $f_\varepsilon \in \mathbf{F}$ with (4.2) by Lemma 3.4. The proof of (d) uses standard arguments (see, for instance, [5]). The proof of (e) is also similar to the proof in [5]. Let $(\eta^*, \tilde{v})) \in \mathbb{R} \times \tilde{\mathcal{V}}$ an arbitrary solution of (4.1). We set $\tilde{u}(x) := \tilde{v}(x) + \eta^* - \int_X \tilde{v}(\xi)\mu(d\xi)$ for all $x \in X$. Then $(\eta^*, \tilde{u}) \in \mathbb{R} \times \tilde{\mathcal{V}}$ and $(\eta^*, \tilde{u})$ is

also a solution of (4.1). It follows that

$$\begin{aligned}\tilde{u}(x) &= \sup_{f\in\mathbf{F}}\inf_{g\in\mathbf{G}}\left\{r_{fg}(x)-(1-\zeta_{fg}(x))\eta^*+\int_X \tilde{u}(\xi)p_{fg}(d\xi|x)-\zeta_{fg}(x)\eta^*\right\}\\ &= \sup_{f\in\mathbf{F}}\inf_{g\in\mathbf{G}}\left\{r_{fg}(x)-(1-\zeta_{fg}(x))\eta^*+\int_X \tilde{u}(\xi)P_{fg}(d\xi|x)\right.\\ &\qquad \left.+\zeta_{fg}(x)\int_X \tilde{u}(\xi)\mu(d\xi)-\zeta_{fg}(x)\eta^*\right\}\\ &= \sup_{f\in\mathbf{F}}\inf_{g\in\mathbf{G}}\left\{r_{fg}(x)-(1-\zeta_{fg}(x))\eta^*+\int_X \tilde{u}(\xi)P_{fg}(d\xi|x)\right\}\end{aligned}$$

for all $x\in X$. Hence, $\tilde{u}$ is a solution of the fixed point equation

$$u = LT^{\eta^*}u.$$

Since this fixed point equation has only one solution (see Lemma 4.2(b)), we obtain the statement.

Finally, we present some properties of the set $\check{H}$ and the fixed points of the operators LT^η for $\eta\in\check{H}$.

COROLLARY 4.10. *Let v^*, η^* as in Lemma 4.9.*

(a) *v^* is the unique solution of the fixed point equation $v = LT^{\eta^*}v$. Hence, $v^* = v^*_{\eta^*}$.*

(b) *$\check{H} = (-\infty, \eta^*]$*

(c) *$(v^*_\eta)_{\eta\in\check{H}}$ is continuous (left-continuous at η^*) in the V-norm $\|\cdot\|_V$.*

(d) *For $\eta\in\check{H}$ it holds that $\mu v^*_\eta = \eta$ if and only if $\eta = \eta^*$.*

Proof.

(a) If we choose $\tilde{v} = v^*$ in the proof of Theorem 4.1, we then get $\tilde{u} = v^*$.

(b) $\eta^*\in\check{H}$ follows from (a). $\eta\le\eta^*$ implies $v^* = LT^{\eta^*}v^* \le LT^\eta v^*$. By mathematical induction we then get $[\check{L}T^\eta v^*]^n = [LT^\eta v^*]^n \ge v^* > -\infty$ for all $n\in\mathbb{N}$. Therefore, $v^*\in\check{\mathcal{V}}_\eta$ and $\eta\in\check{H}$.

(c) See Lemma 4.5.

(d) See Lemmas 4.8 and 4.9. □

5. Conclusions. This paper deals with two-person zero-sum stochastic games with the average reward criterion and Borel state and action spaces under a geometric drift condition. We assume that the law of motion p is weakly continuous, the reward function r is l.s.c., the set-valued mapping A of admissible actions of the maximizing player is l.s.c (and complete-valued), and the set-valued mapping B of admissible actions of the minimizing player is u.s.c. (and compact-valued). It is shown that the optimality equation has a unique solution, the game has a value, the minimizing player has an optimal stationary strategy, and the maximizing player has an ε-optimal stationary strategy for every $\varepsilon > 0$.

In contrast to this, the assumptions in the paper of Jaśkiewicz and Nowak [3] are more restrictive. It is required that r, A, and B are continuous and that the probability measure μ and the function δ in the geometric drift condition satisfy the additional property $\int_X \inf_{a\in A(x)}\inf_{b\in B(x)}\delta(x,a,b)\mu(dx) > 0$. Under these conditions it is proved that both players have optimal stationary strategies. But it is only shown that the optimality equation holds almost everywhere in respect of a maximal irreducibility measure (whose existence must be assumed).

We remark that it is not difficult to derive the existence of an optimal stationary strategy of the maximizing player from our results if r, A, and B are continuous. It is sufficient to consider a Markov game with $-r$ instead of r.

Acknowledgments. The author wishes to thank an associate editor and the anonymous referees for many helpful comments. One of the referees provided a very detailed review and proposed various modifications to improve the paper. He also suggested the inclusion of Corollary 4.10.

CONVERGENT NUMERICAL SCHEME FOR SINGULAR STOCHASTIC CONTROL WITH STATE CONSTRAINTS IN A PORTFOLIO SELECTION PROBLEM*

AMARJIT BUDHIRAJA† AND KEVIN ROSS†

Abstract. We consider a singular stochastic control problem with state constraints that arises in problems of optimal consumption and investment under transaction costs. Numerical approximations for the value function using the Markov chain approximation method of Kushner and Dupuis are studied. The main result of the paper shows that the value function of the Markov decision problem (MDP) corresponding to the approximating controlled Markov chain converges to that of the original stochastic control problem as various parameters in the approximation approach suitable limits. All our convergence arguments are probabilistic; the main assumption that we make is that the value function be finite and continuous. In particular, uniqueness of the solutions of the associated HJB equations is neither needed nor available (in the generality under which the problem is considered). Specific features of the problem that make the convergence analysis nontrivial include unboundedness of the state and control space and the cost function; degeneracies in the dynamics; mixed boundary (Dirichlet–Neumann) conditions; and presence of both singular and absolutely continuous controls in the dynamics. Finally, schemes for computing the value function and optimal control policies for the MDP are presented and illustrated with a numerical study.

1. Introduction.

Singular control is an important and challenging class of problems in stochastic control theory. Roughly speaking, by singular control we mean that the control terms in the dynamics of the state process need not be absolutely continuous with respect to the Lebesgue measure and are only required to have paths of bounded variation. The Hamilton–Jacobi–Bellman (HJB) equations for such problems, which are variational inequalities with gradient constraints, are typically quite hard to work with. Despite the fact that over the past 20 years there has been a significant development in the theory of weak and viscosity solutions of HJB equations for such diffusion control problems (cf. [5, 26, 4, 15, 22, 29]), the existence/uniqueness and regularity theory for this class of PDEs is not well understood. In view of the various applications in mathematical finance (cf. [11]) and stochastic networks (cf. [12]) that lead to singular control, it is particularly important to develop methods for numerical approximations for such control problems.

Over the last 30 years, Kushner, Dupuis, and coworkers (cf. [19] and references therein) have developed a powerful machinery, the so-called Markov chain approximation method, for a wide spectrum of computational problems in stochastic control theory. This probabilistic approach has two main advantages. First, approximation with a Markov chain allows one to use physical insights derived from the dynamics

of the controlled diffusion in obtaining a stable approximation scheme. Second, the Markov chain approximation method does not require the smoothness of the cost or value function, nor does it rely on the uniqueness properties of the associated HJB equations. This is a particularly significant advantage in problems where the PDE theory for the associated HJB equations is hard to tackle.

In this work we study a problem of optimal consumption and portfolio selection with proportional transaction costs that has been studied by several authors [24, 6, 29, 23, 31]. The basic problem can be described as follows. Consider a single investor who has two instruments available for investment: a risk-free asset such as a bank account, which pays a fixed interest rate $r > 0$, and a risky asset, such as a stock, whose price evolution is modeled via a geometric Brownian motion with a mean value of return $b > r$ and constant volatility $\sigma > 0$. We assume that the investor may buy or sell stock continuously over time in not necessarily integer valued quantities. The investor is assumed to consume wealth at some time-dependent rate $C(t)$, and without loss of generality we assume that the consumption is deducted from the bank account. The investor may instantaneously transfer money from the bank account to stock, and vice versa, by paying a proportional transaction cost; namely, there are $\lambda \in (0, \infty)$ and $\mu \in (0, 1)$ such that the investor pays λ times the amount moved from the bank account to stock as a transaction fee, and similarly, he pays μ times the amount moved from stock to the bank account as a transaction fee. All transaction fees are charged from the bank account. The basic constraint on the consumption control C and the portfolio selection control, denoted (M, N), is that the investor must be solvent at all times. More precisely, if $X(t)$ and $Y(t)$ represent the amount of investment in the bank account and the stock, respectively, at time t, then we require $(X(t), Y(t)) \in \mathbb{S}$ for all $t \geq 0$, where

$$\mathbb{S} \doteq \{(x, y) \in \mathbb{R}^2 : x + (1 + \lambda)y \geq 0 \text{ and } x + (1 - \mu)y \geq 0\}.$$

These solvency constraints ensure that at all times the investor has sufficient wealth to settle any obligations due to selling stock short (the first inequality) or borrowing from the bank account (the second inequality). The goal of the investor is to maximize the expected total discounted utility of consumption, $\mathbb{E}\int_0^\infty e^{-\beta t} f(C(t))dt$, where $\beta \in (0, \infty)$ is the discount factor and the utility function $f : [0, \infty) \to [0, \infty)$ is a continuous function satisfying $f(0) = 0$. The condition $f(0) = 0$ can be relaxed if f is nondecreasing and $f(0) > -\infty$ by replacing f with $f - f(0)$.

In the absence of transaction costs, Merton proved in the classical paper [25] that when the utility function is $f(c) = c^p/p, p < 1, p \neq 0$ or $f(c) = \log c$ (note that the latter utility function does not satisfy the conditions of the current paper) the investor's optimal policy is to keep a constant proportion of total wealth in the risky asset and to consume at a rate proportional to total wealth. (For a simple and self-contained treatment, see [6]). This "Merton line" target can always be achieved since transactions can be made continuously and instantaneously without affecting wealth. However, when transaction costs apply, such a policy results in immediate bankruptcy. Magill and Constantinides first conjectured in [24] that there must exist a "no-transaction region" taking the form of a wedge in the wealth space. When wealth is inside this region, consumption is the only control that can be exercised. Purchase or sale of stock occurs only when the wealth attempts to exit the no-transaction region. The formal arguments of [24] were put on a rigorous footing by Davis and Norman in [6] for the cases $f(c) = c^p/p$ and $f(c) = \log c$. In their work, under suitable conditions on model parameters, the free boundary problem associated with optimal

consumption in the presence of proportional transaction costs is solved explicitly, and C^2 regularity of the value function is established. The authors show that the (optimal) no-transaction region is a wedge; in particular, the optimal policy is to exercise the minimal amount of trading necessary to keep wealth inside the no-transaction region. Inside the region, consumption occurs at a finite rate. In [29] Shreve and Soner consider the same problem as in [6] but with conditions on the model parameters that are weaker and much more explicit. Once more, regularity properties of the value function and the associated free boundary are proved. A more general utility function, which satisfies suitable smoothness, concavity and growth properties, was considered in [31]. Using viscosity solution methods, the authors sketch a proof for unique solvability of the associated HJB equation by the value function. A finite difference approximation scheme for approximating the value function is introduced; however, convergence of the proposed scheme for the portfolio selection problem is not proved. The authors do provide results from several numerical studies which identify near optimal control policies and the (numerical) free boundary.

In the current work, we do not impose any concavity, smoothness, or growth conditions on the utility function; the key condition (Condition 2.1) that we require is that the value function is finite and continuous. In particular, we do not claim or use the fact that the value function is the unique solution of the associated HJB equation. The main goal of the study is to obtain convergent numerical approximations for the value function. The basic approach, as in [19], is to introduce a Markov decision problem (MDP) for an approximating, finite state, discrete time, controlled Markov chain. The main result of the paper (Theorem 5.12) shows that the value function of the MDP converges to the value function of the original singular control problem as various parameters in the approximation approach their limits suitably. In section 6 we use the approximating MDP to obtain computational schemes for obtaining near optimal control policies. The key result of this section is Lemma 6.1, which allows us to characterize the value function and optimal control policies via the solution of suitable dynamic programming equations (see Theorem 6.2). Finally, in section 7 results from a numerical study using the algorithm of section 6 are described. In particular, Figure 2 shows the numerical no-transaction region and the associated (numerical) free boundary obtained by an implementation of the algorithm.

The only paper (to the best of our knowledge) that carries out a complete convergence analysis for a numerical scheme for a singular control problem is [20]. Although several ideas developed in [20] are crucial to the ideas in the current paper, there are key differences in the model that make our analysis substantially delicate. First, the above paper considers a queuing problem with "finite buffers" which essentially means that the state space and control space are bounded. In the current study we first have to suitably approximate the original unbounded model by one in which the consumption control and the state space are bounded. This two stage approximation procedure is carried out in Propositions 2.2 and 2.4. This is the only place where the assumption on the continuity of the value function (Condition 2.1) is used. Next, in contrast to [20], in addition to singular control terms, we also have an absolutely continuous control term (consumption control) that appears in a nonlinear fashion in the cost (reward) criterion through the utility function f. This requires us to introduce the relaxed formulation for the stochastic control problem in order to carry out the convergence analysis. Lemma 5.1 ensures that the relaxed formulation does not change the value function of the control problem. The next substantial difficulty in our analysis is the state constraint feature of the dynamics. Although in [20] also the state is constrained to be in a bounded polyhedral region, that can be easily handled

by introducing the so-called "Skorohod map." In the current model the directions of control, which do not point inward into the state space (see Figure 1), do not allow for a similar reduction. However, one useful feature of the dynamics (see (1)) is that once the state of the system reaches the boundary of $\mathbb{S}$, the only admissible control corresponds to moving the state process instantaneously to the origin and keeping it there at all times. This observation allows us to convert an infinite horizon cost to an exit time criterion (see (2)–(4)). This reformulation makes some aspects of the convergence analysis simpler; however, the degeneracies in the state dynamics make the treatment of convergence properties of exit times quite subtle. To see the basic difficulty, consider the following simple example. Let ξ_n be a sequence of positive reals such that $\xi_n \to 0$ as $n \to \infty$. Let x_n be the solution of the ODE $\dot{x} = x$ with initial condition ξ_n and x be the solution of the same ODE with 0 initial condition. Clearly $x_n \to x$ uniformly on compacts; however, if $\tau_n \doteq \inf\{t|x_n(t) = 0\}$ and $\tau \doteq \inf\{t|x(t) = 0\}$, then clearly $\tau_n \not\to \tau$. In other words, convergence of processes in general need not imply the convergence of the corresponding exit times. The issue is especially problematic when, as is the case for the controlled dynamics considered in this paper, the diffusion coefficients in the state dynamics are not uniformly nondegenerate. This is another key difference between the current model and the problem studied in [20].

One of the major obstacles in proving the convergence of the value function of a sequence of approximating discrete MDPs to the value of the original singular control problem is proving the tightness of the sequence of singular control terms in the Skorohod $D[0, \infty)$ space. A powerful technique for bypassing this tightness issue, based on suitable stretching of a time scale, was introduced in [20]. Although such time transformation ideas go back to the work of Meyer and Zheng [27] (see also Kurtz [18]), the papers [20, 21] were the first to use such ideas in stochastic control problems. A similar technique was also recently used in [3]. A key ingredient to this technique is the uniform moment estimate obtained in Lemma 4.4. In [20] such a moment estimate follows easily from the form of the cost function where a strictly positive proportional cost is incurred for exercising the singular control. In the current problem there is no direct contribution to the (cost) reward function from the singular control term and, as a result, the proof of this uniform estimate becomes more involved. Roughly speaking, the main idea of the proof is that a controller cannot make too much use of a singular control without pushing the process to the boundary of the domain.

The paper is organized as follows. In section 2 we give a precise formulation of the control problem of interest. We also present here two propositions (Propositions 2.2 and 2.4) which allow approximation of the original control problem by one with a bounded state space and bounded consumption actions. Section 3 introduces the discrete MDP that approximates the original singular control problem, and section 4 defines the continuous time interpolations and the time transformation that are key to the convergence analysis. In section 5 we present the main convergence result that establishes the convergence of the value function of the MDP to that of the original singular control problem. Section 6 is devoted to computational methods for the MDP. A key result here is Lemma 6.1 which allows, via Theorems 6.2 and 6.3, iterative methods for computation of the value function and optimal control policies for the MDP. In problems with only absolutely continuous controls, estimates of the form in Lemma 6.1 are straightforward consequences of a contraction property that follows from the strictly positive discount factor in the cost (cf. Chapter 6 of [19]). However, for singular control problems, due to the instantaneous nature of the control, such contraction estimates are typically unavailable. Here, once again, we

use the special feature of the dynamics, which says that excessive use of the singular control will rapidly bring the process to the boundary, in obtaining such an estimate. In section 7 we present results from a numerical study of the algorithm. Finally, the appendix contains proofs of the more technical results.

The following notation will be used in the paper. Given a Polish space E, $D_E \equiv D([0,\infty) : E)$ will denote the space of paths that are right-continuous with left limits (RCLL) on $[0,\infty)$ taking values in E, endowed with the usual Skorohod topology. For an RCLL path $\{\xi(t)\}$, the jump at $t > 0$ will be denoted by $\delta\xi(t)$. As a convention we take $\delta\xi(0) \doteq \xi(0)$. For a sequence of random variables $\{\xi_n\}_{n\geq 0}$, we will use the notation $\delta\xi_n$ for the increment $\xi_{n+1} - \xi_n$. For a point $x \in \mathbb{R}^k$ and a set $G \in \mathbb{R}^k$, $\mathrm{dist}(x, G)$ will denote the distance of x from $\overline{G}$. The Borel sigma field for a metric space E will be denoted by $\mathcal{B}(E)$.

2. Optimal consumption and portfolio selection with transaction costs. We begin with a precise mathematical formulation of the optimal consumption and investment problem described in the previous section. Let $(\Omega, \mathcal{F}, \mathbb{P})$ be a probability space on which is given a filtration $\{\mathcal{F}_t\}_{t\geq 0}$ satisfying the usual hypothesis. Let W be a real-valued $\{\mathcal{F}_t\}$-Brownian motion. We will denote the probability system $(\Omega, \mathcal{F}, \mathbb{P}, \{\mathcal{F}_t\}, W)$ by Φ. The Wiener process represents the source of uncertainty of the risky asset. The state process, which represents the wealth of the investor, is a controlled Markov process $Z \equiv (X, Y)$ given on the above probability system via the equations

$$\begin{aligned} dX(t) &= (rX(t) - C(t))dt - (1+\lambda)dM(t) + (1-\mu)dN(t), \\ dY(t) &= bY(t)dt + \sigma Y(t)dW(t) + dM(t) - dN(t), \end{aligned} \tag{1}$$

with initial condition $X(0-) = x, Y(0-) = y$, where $z \doteq (x, y) \in \mathbb{S}$. Here C is an $\{\mathcal{F}_t\}$-progressively measurable process such that for all $t \in [0,\infty)$, $C(t) \geq 0$ a.s. and $\mathbb{E}\int_0^t e^{-rs}C(s)ds < \infty$. Also, M and N are $\{\mathcal{F}_t\}$-adapted, nondecreasing, RCLL processes satisfying $M(0) \geq 0$ and $N(0) \geq 0$ a.s. The processes X and Y represent the amounts invested in the bond and the stock, respectively; $M(t), N(t)$ denote the cumulative purchases and sales of stock, respectively, over $[0, t]$. The process C represents the consumption of the investor. The processes C, M, and N are the control processes. Since M and N are not required to be absolutely continuous (with respect to the Lebesgue measure), they are referred to as singular controls. Denote by $\mathcal{A}(\Phi, z) \equiv \mathcal{A}(z)$ the set of "admissible controls," i.e., all $U \equiv (C, M, N)$ of the form described above. Let $\partial\mathbb{S}$ denote the boundary of $\mathbb{S}$. From the dynamical description of Z it follows that if $z \in \partial\mathbb{S}$, then the only control that keeps the investor solvent takes Z to the origin instantly and keeps it there at all times (see Figure 1).

Recall the utility function f in the introduction. Since $f(0) = 0$, one can reformulate the state constraint control problem on an infinite time horizon described in the introduction to an exit time control problem, as follows. For $z \in \mathbb{S}$ and $U \in \mathcal{A}(z)$, let $\tau \equiv \tau(z, U)$ be defined as

$$\tau \doteq \inf\{t \in [0,\infty) : Z(t) \notin \mathbb{S}^o\}, \tag{2}$$

where Z is the controlled process corresponding to initial condition z and control U. Define the cost, $J(z, U)$, for using the control U by

$$J(z, U) \doteq \mathbb{E}\int_{[0,\tau)} e^{-\beta t} f(C(t))dt. \tag{3}$$

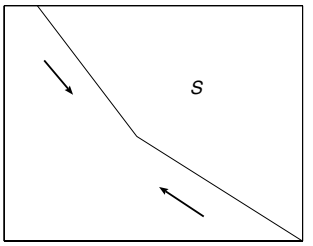

FIG. 1. *State space and singular control directions.*

The value function of the control problem is then given by

$$V(z) = \sup_{\Phi} \sup_{U \in \mathcal{A}(z)} J(z, U), \tag{4}$$

where the outside supremum is over all probability systems Φ. The following will be a standing assumption in this work.

CONDITION 2.1. *For all $z \in \mathbb{S}$, $V(z) < \infty$ and $V : \mathbb{S} \to \mathbb{R}_+$ is a continuous map.*

We refer the reader to [16, 29, 31] for some sufficient conditions needed for the above assumption to hold.

State and control space truncation. In order to develop numerical methods for computing $V(z)$, we will need to first approximate the control problem by an analogous control problem with a bounded state space and control set. We now present the convergence result, which says that the value function of the "truncated control problem" converges to V as the truncation parameters approach their limits. We begin by considering the control space truncation.

For $p \in (0, \infty)$, let $\mathcal{A}_p(\Phi, z) \equiv \mathcal{A}_p(z)$ be the subset of $\mathcal{A}(z)$ consisting of $U = (C, M, N)$, which satisfy $0 \le C(t) \le p$, for all $t \ge 0$ a.s. Define $V_p(z)$ by replacing $\mathcal{A}(z)$ with $\mathcal{A}_p(z)$ in (4). The following is the first convergence result.

PROPOSITION 2.2. *V_p converges to V, uniformly on compact subsets of $\mathbb{S}$, as $p \to \infty$.*

Proof. We first establish pointwise convergence, i.e., $V_p(z) \to V(z)$ as $p \to \infty$. Since $V_p(z) \le V(z)$, it suffices to show that, for all $z \in \mathbb{S}$,

$$\liminf_{p \to \infty} V_p(z) \ge V(z).$$

Fix $\epsilon > 0$ and choose an "ϵ-optimal control," i.e., $U_\epsilon \in \mathcal{A}(z)$ such that $V(z) - \epsilon < J(z, U_\epsilon)$. Suppose τ_ϵ is the associated exit time from $\mathbb{S}^o$. Define a control $\tilde{U}_p \equiv (\tilde{C}_p, \tilde{M}_p, \tilde{N}_p)$ by $\tilde{C}_p(t) \doteq C_\epsilon(t) \wedge p$, $\tilde{M}_p(t) \doteq M_\epsilon(t)$, $\tilde{N}_p(t) \doteq N_\epsilon(t)$, $t \ge 0$. It follows from the fact that $\tilde{C}_p \le C_\epsilon$ and standard comparison results for solutions of stochastic differential equations (cf. Proposition 5.2.18 of [17]) that the wealth process under control $\tilde{U}_p$ is never less than the wealth process under control U_ϵ. In particular, denoting by τ_p the exit time from $\mathbb{S}^o$ by the controlled process corresponding to the control $\tilde{U}_p$, we have $\tau_p \ge \tau_\epsilon$. Combining this with the observations that $\tilde{C}_p(t) \uparrow C_\epsilon(t)$ as $p \to \infty$ a.s. for all $t \ge 0$ and f is continuous, we have from Fatou's lemma

$$\liminf_{p \to \infty} J(z, \tilde{U}_p) \ge \liminf_{p \to \infty} \mathbb{E} \int_{[0, \tau_\epsilon)} e^{-\beta t} f(\tilde{C}_p(t)) dt \ge \mathbb{E} \int_{[0, \tau_\epsilon)} e^{-\beta t} f(C_\epsilon(t)) dt \ge V(z) - \epsilon.$$

Since $\epsilon > 0$ is arbitrary, the pointwise convergence of V_p to V follows. Next we show that for each p, V_p is lower semicontinuous (l.s.c.). Fix $z \in \mathbb{S}$ and let $\mathbb{S} \ni z_n \to z$ as $n \to \infty$. To prove that V_p is l.s.c. it suffices to show that

$$\liminf_{n\to\infty} V_p(z_n) \geq V_p(z). \tag{5}$$

Fix $\epsilon > 0$ and let $U_\epsilon = (C_\epsilon, M_\epsilon, N_\epsilon) \in \mathcal{A}_p(z)$ be an ϵ-optimal control, i.e., $V_p(z) - \epsilon < J(z, U_\epsilon)$. Let Z_ϵ be the controlled process according to U_ϵ and define τ_ϵ via (2) with Z replaced by Z_ϵ. Define $U_n \equiv (C_n, M_n, N_n)$ as $C_n \doteq C_\epsilon$, $M_n(t) \doteq M_\epsilon(t)1_{t<\tau_\epsilon} + M_n^* 1_{t\geq\tau_\epsilon}$, $N_n(t) \doteq N_\epsilon(t)1_{t<\tau_\epsilon} + N_n^* 1_{t\geq\tau_\epsilon}$, where $M_n^*, N_n^* \geq 0$ are chosen so that the controlled process Z_n corresponding to U_n and initial condition z_n satisfies $Z_n(\tau_\epsilon) \notin \mathbb{S}^o$. (Note that, clearly, $U_n \in \mathcal{A}_p(z_n)$.) This ensures that $\tau_n \doteq \inf\{t : Z_n(t) \notin \mathbb{S}^o\}$ is at most τ_ϵ. Note that on the set $\{\tau_\epsilon = \infty\}$, we have $U_n(t) = U_\epsilon(t)$ for all $t \geq 0$. We claim that on the set $\{\tau_\epsilon < \infty\}$ we have $\liminf_{n\to\infty} \tau_n \geq \tau_\epsilon$ a.s., which implies $\tau_n \to \tau_\epsilon$ a.s. as $n \to \infty$ on the set $\{\tau_\epsilon < \infty\}$. To see the claim, suppose that $\liminf \tau_n < \tau_\epsilon - \delta$ for some $\delta > 0$. Then there exists $N_0 \geq 1$ such that $\tau_n < \tau_\epsilon - \delta/2$ for all $n \geq N_0$. Also, from the choice of the control U_n we see that, for all $\delta > 0$ and $L \in (0, \infty)$, $\sup_{0\leq t\leq(\tau_\epsilon-\delta/2)\wedge L} |Z_n(t) - Z(t)| \to 0$ in probability as $n \to \infty$. Combining this with the fact that $Z_n(\tau_n) \notin \mathbb{S}^o$, we have that $Z(t) \notin \mathbb{S}^o$ for some $t \leq \tau_\epsilon - \delta/2$. However, this contradicts the definition of τ_ϵ. Thus we have shown $\tau_n \to \tau_\epsilon$ a.s. on the set $\{\tau_\epsilon < \infty\}$.

Next, recalling the choice of U_ϵ and that $C_\epsilon(t) = C_n(t)$ for all $t \geq 0$ on the set $\{\tau_\epsilon = \infty\}$, we have

$$\begin{aligned} V_p(z) - V_p(z_n) &\leq J(z, U_\epsilon) - J(z_n, U_n) + \epsilon \\ &= \mathbb{E}\Big[1_{\{\tau_\epsilon<\infty\}} \int_{[\tau_n,\tau_\epsilon)} e^{-\beta t}(f(C_\epsilon(t)) - f(C_n(t)))dt\Big] + \epsilon \\ &\leq f_*(p)\mathbb{E}\Big[1_{\{\tau_\epsilon<\infty\}} \int_{[\tau_n,\tau_\epsilon)} e^{-\beta t}dt\Big] + \epsilon, \end{aligned}$$

where $f_*(p) \doteq \sup_{0\leq c\leq p} f(c) < \infty$. Since $\tau_n \to \tau_\epsilon$ a.s. on the set $\{\tau_\epsilon < \infty\}$, the first term on the right in the last line above approaches 0 as $n \to \infty$. Inequality (5) now follows from the above display on taking $n \to \infty$ and then $\epsilon \to 0$. Finally, note that for each z, $V(z) - V_p(z) \downarrow 0$. The result now follows from Dini's theorem (cf. Theorem M8 in [1]). □

Next, we consider the truncation of the state space. The reduction will be achieved by replacing the original dynamical system given by (1) with one which evolves exactly as before in the interior of some compact domain but is instantaneously reflected back when the controlled process is about to exit the domain. The reflection mechanism is made precise via the notion of a Skorohod map. We begin with the following definition. Fix $\ell \in (0, \infty)$.

DEFINITION 2.3. *Let $\phi \in \mathcal{D} \doteq D([0, \infty) : \mathbb{R}^2)$ be such that $\phi(0) \in (-\infty, \ell] \times (-\infty, \ell]$. We will denote the space of all such ϕ by $\mathcal{D}_0$. We say a pair $(\psi, \eta) \in \mathcal{D} \times \mathcal{D}$ solves the Skorohod problem (SP) for ϕ in $(-\infty, \ell] \times (-\infty, \ell]$, with normal reflection, if the following hold:*

(i) $\psi(0) = \phi(0)$.

(ii) $\psi(t) = \phi(t) - \eta(t)$, $t \in (0, \infty)$.

(iii) $\psi(t) \in (-\infty, \ell] \times (-\infty, \ell]$ *for all* $t \geq 0$.

(iv) $\eta(\cdot)$ *is componentwise nondecreasing.*

(v) $\eta_i(t) = \int_{(0,t]} 1_{\{\psi_i(t)=\ell\}} d\eta_i(t)$, $i = 1, 2$, *where* $\eta(t) = (\eta_1(t), \eta_2(t))'$, $\psi(t) = (\psi_1(t), \psi_2(t))'$.

It is well known (cf. [7, 13]) that for every $\phi \in \mathcal{D}_0$, there is a unique solution (ψ, η) to the above SP. We will write $\psi = \Gamma(\phi)$ and refer to the map $\Gamma : \mathcal{D}_0 \to \mathcal{D}_0$ as the Skorohod map. The following Lipschitz property (cf. [7]) is quite useful in various estimates. There exists $\kappa \in (0, \infty)$, independent of ℓ, such that, for all $\phi_1, \phi_2 \in \mathcal{D}_0$,

$$|\Gamma(\phi_1) - \Gamma(\phi_2)|_T^* \le \kappa |\phi_1 - \phi_2|_T^*, \ T \in (0, \infty). \tag{6}$$

We will now introduce the modified constrained dynamics of the controlled Markov process. Set $\mathbb{S}_\ell \doteq \mathbb{S} \cap (-\infty, \ell] \times (-\infty, \ell]$. Let $Z_\ell \equiv (X_\ell, Y_\ell)$ solve the following system of equations:

$$\begin{aligned} dX_\ell(t) &= (rX_\ell(t) - C(t))dt - (1+\lambda)dM(t) + (1-\mu)dN(t) - dR_1(t), \\ dY_\ell(t) &= bY_\ell(t)dt + \sigma Y_\ell(t)dW(t) + dM(t) - dN(t) - dR_2(t), \end{aligned} \tag{7}$$

where $Z_\ell(0-) = z$, $U \equiv (C, M, N) \in \mathcal{A}_p(z)$, $z = (x, y) \in \mathbb{S}_\ell$, and $R = (R_1, R_2)'$ is a componentwise nondecreasing, RCLL, $\{\mathcal{F}_t\}$-adapted process satisfying

$$\int_0^\infty 1_{\{X_\ell(t)<\ell\}} dR_1(t) = 0, \quad \int_0^\infty 1_{\{Y_\ell(t)<\ell\}} dR_2(t) = 0. \tag{8}$$

The unique solvability of (7) and (8) follows from the Lipschitz continuity property (6) of the Skorohod map and the usual Picard iteration method. Define τ_ℓ and $J_\ell(z, U)$ as in (2) and (3) with Z replaced by Z_ℓ in (2) and τ replaced by τ_ℓ in (3). Define $V_{\ell,p}$ as

$$V_{\ell,p}(z) = \sup_{\Phi} \sup_{U \in \mathcal{A}_p(\Phi, z)} J_\ell(z, U). \tag{9}$$

The following is the second convergence result of this section.

PROPOSITION 2.4. *For all* $p \in (0, \infty)$, $V_{\ell,p}$ *converges to* V_p, *uniformly on compact subsets of* $\mathbb{S}$, *as* $\ell \to \infty$.

Proof. Let $Z \equiv (X, Y)$ be as in (1) and τ as in (2), with $C \equiv 0$. It is easy to check that for each $T \in (0, \infty)$ and compact subset $\mathbb{S}_0 \subset \mathbb{S}$, there exists $\Lambda \equiv \Lambda(T) \in (0, \infty)$ such that

$$\sup_{\Phi} \sup_{(M,N)} \sup_{z \in \mathbb{S}_0} \mathbb{E} \sup_{0 \le t \le T \wedge \tau} (X^+(t) + Y^+(t)) \le \Lambda,$$

where the supremum is taken over all $\{\mathcal{F}(t)\}$-adapted, nondecreasing, RCLL processes M and N such that $M(0) \ge 0$, $N(0) \ge 0$, and over all systems Φ. Thus in particular we have that

$$\sup_{\ell} \sup_{\Phi} \sup_{U \in \mathcal{A}_p(\Phi, z)} \sup_{z \in \mathbb{S}_0} \mathbb{E} \sup_{0 \le t \le T \wedge \tau_\ell} (X_\ell^+(t) + Y_\ell^+(t)) \le \Lambda, \tag{10}$$

where $Z_\ell \equiv (X_\ell, Y_\ell)$ are as defined in (7), and τ_ℓ is as introduced below (8).

Fix $\delta > 0$. Let $z \in \mathbb{S}_0$ and $\epsilon > 0$ be arbitrary. Let Φ and $U \in \mathcal{A}_p(z, \Phi)$ be such that $V_{\ell,p}(z) \le J_\ell(z, U) + \epsilon$. Choose $T \in (0, \infty)$ such that $f_*(p)e^{-\beta T}/T < \epsilon$. Then $V_{\ell,p}(z) \le \mathbb{E} \int_0^{T \wedge \tau_\ell} e^{-\beta t} f(C(t))dt + 2\epsilon$.

Choose $\ell_0 \equiv \ell_0(\delta)$ such that $\ell_0 > (\Lambda f_*(p))/(\delta\beta)$. Define

$$A_{\ell_0} \doteq \left\{ \omega : \sup_{0 \le t \le T \wedge \tau_\ell} (X_\ell^+(t) + Y_\ell^+(t)) > \ell_0 \right\}.$$

Then

$$\mathbb{E}\int_0^{T\wedge\tau_\ell} e^{-\beta t} f(C(t))dt$$
$$= \mathbb{E}\left[1_{A_{\ell_0}} \int_0^{T\wedge\tau_\ell} e^{-\beta t} f(C(t))dt\right] + \mathbb{E}\left[1_{A^c_{\ell_0}} \int_0^{T\wedge\tau_\ell} e^{-\beta t} f(C(t))dt\right]. \tag{11}$$

It follows from Markov's inequality and (10) that $\mathbb{P}[A_{\ell_0}] \le \Lambda/\ell_0$. Thus the first integral on the right side of (11) is bounded by $(f_*(p)/\beta)\mathbb{P}[A_{\ell_0}] \le \delta$. Next, for $\ell \ge \ell_0$, on the set $A^c_{\ell_0}$, $Z_\ell(\cdot \wedge T \wedge \tau_\ell) = Z(\cdot \wedge T \wedge \tau_\ell)$. In particular, $T \wedge \tau \ge T \wedge \tau_\ell$. Thus

$$\mathbb{E}\left[1_{A^c_{\ell_0}} \int_0^{T\wedge\tau_\ell} e^{-\beta t} f(C(t))dt\right] \le \mathbb{E}\left[\int_0^{T\wedge\tau} e^{-\beta t} f(C(t))dt\right] \le V_p(z).$$

Combining the above bounds, we have $V_{\ell,p}(z) \le V_p(z)+\delta+2\epsilon$. Since $\epsilon > 0$ is arbitrary, we have that, for all $\ell \ge \ell_0$ and $z \in \mathbb{S}_0$, $V_{\ell,p}(z) \le V_p(z) + \delta$. It is easily seen that the roles of V_p and $V_{\ell,p}$ can be interchanged in the above argument. Thus we have that, given $\delta > 0$, there exists an ℓ_0 such that $|V_{\ell,p}(z) - V_p(z)| \le \delta$ if $\ell > \ell_0$, for all $z \in \mathbb{S}_0$. Since $\mathbb{S}_0$ is an arbitrary compact subset of $\mathbb{S}$, the result follows. □

COROLLARY 2.5. *For all* $z \in \mathbb{S}$, $\lim_{p\to\infty} \lim_{\ell\to\infty} V_{\ell,p}(z) = V(z)$.

3. An approximating Markov decision problem. In this section we will present the Markov decision problem whose value function approximates $V_{\ell,p}$. Since throughout this section ℓ, p will be fixed, we will drop them from the notation: $V_{\ell,p}, \tau_\ell, J_\ell, \mathcal{A}_p(z)$ and $Z_\ell \equiv (X_\ell, Y_\ell)$. We will introduce a discrete time, discrete state controlled Markov chain to approximate the continuous time process given by (7).

Fix $h > 0$ and define the two-dimensional h-grid, $L^h \doteq \{(jh, kh) : -\infty < j, k < +\infty\}$. The symbol h denotes the approximation parameter, and as h approaches 0, a suitable interpolation of the controlled Markov chain, to be introduced below, "approaches" a controlled diffusion process of the form in (7). We will assume for simplicity that ℓ is an integer multiple of h.

A natural definition of the state space for the approximating chain is $\mathbb{S}^h_\ell \doteq \mathbb{S}_\ell \cap L^h$. However, due to reflection terms in the dynamics of the controlled process, it is convenient to consider a slightly "enlarged" state space, namely, $\mathbb{S}^{h+}_\ell \doteq \mathbb{S}_{\ell+h} \cap L^h$. The "solvency boundary" and reflecting boundary of the space $\mathbb{S}^{h+}_\ell$ are defined, respectively, as

$$\partial^h \doteq \{(x, y) \in \mathbb{S}^{h+}_\ell : x + (1 + \lambda)y \le h(1 + \lambda), \text{ or } x + (1 - \mu)y \le h\}$$
$$\partial^h_{\mathrm{R}} \doteq \{(x, y) \in \mathbb{S}^{h+}_\ell : x = \ell + h, \text{ or } y = \ell + h\}.$$

Let $\{Z^h_n, n = 0, 1, 2, \dots\}$ be a discrete time controlled Markov chain with state space $\mathbb{S}^{h+}_\ell$, with $Z^h_n = (X^h_n, Y^h_n)$. The transition probabilities will be defined so that the chain's evolution law well approximates the local behavior of the controlled diffusion (7). For each n, the increments of the chain δZ^h_n will approximate exactly one of the following dynamical descriptions:

- "Controlled diffusion step": $(rX_t - C_t, bY_t)'dt + (0, \sigma)'dW_t$.
- "Purchase control step": $(-(1 + \lambda), 1)'dM_t$.
- "Sales control step": $(1 - \mu, -1)'dN_t$.
- "Reflection step": dR_t.

Each of these steps is described precisely in what follows. We also introduce a family of "interpolation intervals" $\{\Delta^h, h > 0\}$ used in defining the approximating cost function and in the convergence arguments. For each pair $(z, c) \in \mathbb{S}_\ell^{h+} \times [0, p]$ we first define a family $\tilde{\Delta}^h(z, c)$. For the controlled diffusion steps, if the state of the chain is z and the exercised consumption control is c, Δ^h will be taken to be $\tilde{\Delta}^h(z, c)$; whereas for singular control steps and reflection steps, Δ^h will be taken to be 0. This reflects the fact that for the controlled diffusion (7), reflection and singular control terms can change the state instantaneously. Suitable conditions on $\tilde{\Delta}^h(z, c)$ needed to obtain convergence of the continuous time interpolated processes to corresponding controlled diffusions are introduced below.

Controlled diffusion steps and local consistency. By a controlled diffusion step we mean that the Markov chain evolves according to a transition law which is "locally consistent" in the sense of [19], with a (controlled) diffusion given as

$$d\tilde{X}(t) = (r\tilde{X}(t) - C(t))dt,\ d\tilde{Y}(t) = b\tilde{Y}(t)dt + \sigma\tilde{Y}(t)dW(t).$$

Formally, given $h > 0$, we choose for each $c \in [0, p]$ and $z \in \mathbb{S}_\ell^{h+} \setminus \partial^h$ a probability measure $q_h^{(0)}(z, c, d\tilde{z})$ on L^h, along with an interpolation interval $\tilde{\Delta}^h(z, c)$, which satisfies the following local consistency conditions for some $\rho > 0$:

$$m_0(z, c) \doteq \int_{L^h} (\tilde{z} - z) q_h^{(0)}(z, c, d\tilde{z}) = \begin{pmatrix} rx - c \\ by \end{pmatrix} \tilde{\Delta}^h(z, c) + O(h^\rho \tilde{\Delta}^h(z, c)), \tag{12}$$

$$\begin{aligned} \sigma_0(z, c) &\doteq \int_{L^h} (\tilde{z} - z - m_0(z, c))(\tilde{z} - z - m_0(z, c))' q_h^{(0)}(z, c, d\tilde{z}) \\ &= \begin{pmatrix} 0 & 0 \\ 0 & |\sigma y|^2 \end{pmatrix} \tilde{\Delta}^h(z, c) + O(h^\rho \tilde{\Delta}^h(z, c)). \end{aligned} \tag{13}$$

In the above displays, $\tilde{z} = (\tilde{x}, \tilde{y})$, and throughout, by the symbol $O(k)$ we will mean an expression which is bounded above by $\alpha|k|$, where α is a constant depending only on the coefficients of the model and the truncation parameters ℓ, p. In addition we assume that there exists $\zeta \in (0, \infty)$ such that $q_h^{(0)}(z, c, B_{\zeta h}(z)) = 1$ for all $c \in [0, p]$ and $h > 0$, where $B_{\zeta h}(z)$ is a ball of radius ζh centered at z. The interpolation intervals are required to satisfy

$$\tilde{\Delta}_*^h \doteq \sup_{z,c} \tilde{\Delta}^h(z, c) \to 0 \text{ as } h \to 0,\ \inf_{z,c} \tilde{\Delta}^h(z, c) > 0 \text{ for each } h > 0, \tag{14}$$

where the sup and inf in the above displays are taken over all $(z, c) \in \mathbb{S}_\ell^{h+} \times [0, p]$. For the sake of specificity we make the following choice for $q_h^{(0)}$. Let $Q(x, y) \equiv Q^h(x, y) \doteq hr|x| + hp + hb|y| + \sigma^2 y^2$. Define for all $(x, y) \in \mathbb{S}_\ell^{h+} \setminus \partial^h$

$$\begin{aligned} q_h^{(0)}((x, y), c, (x + h, y)) &\doteq \frac{hrx^+}{Q(x, y)}, \quad q_h^{(0)}((x, y), c, (x - h, y)) \doteq \frac{hrx^- + hc}{Q(x, y)}, \\ q_h^{(0)}((x, y), c, (x, y + h)) &\doteq \frac{hby^+ + \frac{1}{2}\sigma^2 y^2}{Q(x, y)}, \quad q_h^{(0)}((x, y), c, (x, y - h)) \doteq \frac{hby^- + \frac{1}{2}\sigma^2 y^2}{Q(x, y)}, \\ q_h^{(0)}((x, y), c, (x, y)) &\doteq \frac{h(p - c)}{Q(x, y)}, \\ \tilde{\Delta}^h(z, c) &\doteq \frac{h^2}{Q(x, y)}. \end{aligned} \tag{15}$$

It is easy to check that $q_h^{(0)}, \tilde{\Delta}^h$ defined above satisfy (12), (13), and (14).

Singular control steps. The singular control terms in the controlled diffusion are the nondecreasing RCLL processes M and N. The process M pushes the state process in the direction $v_1 = (-(1+\lambda), 1)'$, whereas N pushes the state process in the direction $v_2 = ((1-\mu), -1)'$. For the approximating chain we will assume that at most one among the sales control and purchase control are exercised at any given time instant and that the magnitude of the corresponding displacement is $O(h)$. In order to capture the "singular" behavior of the limit diffusion—namely, the feature that the state process can instantaneously be displaced by large amounts—we will take the interpolation interval for all singular control steps in the approximating chain to be 0.

In order to obtain weak convergence of the interpolated chain to the controlled diffusion, we need to ensure that the control directions match asymptotically those for the physical problem. More precisely, given $h > 0$ we define for each $z \in \mathbb{S}_\ell^{h+}$ two probability measures $q_h^{(i)}(z, d\tilde{z}), i = 1, 2$, on L^h as follows. For states $(x, y) \in \mathbb{S}_\ell^{h+} \setminus \partial^h$,

$$q_h^{(1)}((x,y),(x-h,y)) = \lambda/(\lambda+1), q_h^{(1)}((x,y),(x-h,y+h)) = 1/(\lambda+1); \tag{16}$$

$$q_h^{(2)}((x,y),(x,y-h)) = \mu, q_h^{(2)}((x,y),(x+h,y-h)) = 1-\mu. \tag{17}$$

It is easy to check that $q_h^{(1)}$ and $q_h^{(2)}$ introduced above satisfy the following consistency conditions:

$$m_i(z) \doteq \int_{L^h} (\tilde{z} - z) q_h^{(i)}(z, d\tilde{z}) = h v_i, \tag{18}$$

$$\sigma_i(z) \doteq \int_{L^h} (\tilde{z} - z - m_i(z))(\tilde{z} - z - m_i(z))' q_h^{(i)}(z, d\tilde{z}) = O(h^2). \tag{19}$$

Reflection steps. We will define a transition kernel that with probability 1 moves a state in ∂_{R}^h to some state in $\mathbb{S}_\ell^h$. Once more, since reflection in the diffusion control problem occurs instantaneously, we take the interpolation interval at reflection steps to be 0. Since the directions of reflection in the diffusion control problem are normal, a natural choice of the transition kernel for reflection step is as follows for $z \in \partial_{\mathrm{R}}^h$:

$$q_h^{(3)}((\ell+h,y),(\ell,y)) = 1, \quad q_h^{(3)}((x,\ell+h),(x,\ell)) = 1, \quad q_h^{(3)}((\ell+h,\ell+h),(\ell,\ell)) = 1. \tag{20}$$

For $z \notin \partial_{\mathrm{R}}^h$, $q_h^{(3)}(z, \cdot)$ can be defined arbitrarily. It will be seen from the definition of admissible controls given below that for such states, the definition of $q_h^{(3)}$ is immaterial.

The controlled Markov chain. As described above, the control at each step is first specified by the choice of an action: controlled diffusion, singular control, or reflection. Therefore, we define a sequence of control actions $\{I_n^h, n = 0, 1, 2, \dots\}$ with $I_n^h = 0, 1, 2, 3$ if the nth step in the chain is a controlled diffusion step, purchase control step, sales control step, or reflection step, respectively. In the case of a controlled diffusion step, the magnitude of the consumption control must also be specified. Consequently, the space of controls is given by $\mathcal{U} \doteq \{0, 1, 2, 3\} \times [0, p]$.

The probability measures associated with each of the control actions will now be combined into a single probability measure for use in defining the controlled Markov chain. For each $z \in \mathbb{S}_\ell^{h+} \setminus \partial^h, u \in \mathcal{U}$ $(u = (i, c))$, we define a probability measure

$p_h(z,u,d\tilde{z})$ on L^h by

$$p_h(z,u,d\tilde{z}) = q_h^{(0)}(z,c,d\tilde{z})1_{\{i=0\}} + q_h^{(i)}(z,d\tilde{z})1_{\{i\in\{1,2,3\}\}}. \tag{21}$$

The definition of the transition function for $z \in \partial^h$ is not important since in the analysis of the control problem the chain will be stopped the first time it hits ∂^h. For the sake of specificity we set $p_h(z,u,z) = 1$ for all $z \in \partial^h$ and $u \in \mathcal{U}$.

We are now ready to specify the controlled Markov chains. Given a sequence $U^h = \{U_n^h, n = 0,1,2,\dots\}$ (where $U_n^h = (I_n^h, C_n^h)$) of $\mathcal{U}$-valued random variables we construct a controlled Markov chain $\{Z_n^h, n = 0,1,2,\dots\}$ with initial condition $z_h = (x_h, y_h) \in \mathbb{S}_\ell^{h+}$ and state space $\mathbb{S}_\ell^{h+}$, as follows:

$$Z_0^h = z_h, \;\; \mathbb{P}[Z_{n+1}^h \in E|\mathcal{F}_n^h] = p_h(Z_n^h, U_n^h, E), \;\; n \geq 0, \;\; E \in \mathcal{B}(\mathbb{S}_\ell^{h+}), \tag{22}$$

where $\mathcal{F}_n^h = \sigma\{Z_0^h,\dots,Z_n^h,U_0^h,\dots,U_n^h\}$. The following definition of admissible controls ensures that $Z_n^h \in \mathbb{S}_\ell^{h+}$ for all n, and so the definition in (22) is meaningful.

DEFINITION 3.1. *The control sequence $U^h = \{U_n^h, n = 0,1,2,\dots\}$ is said to be admissible for the initial condition z_h, and $\{Z_n^h\}$ ($\{Z_n^h, U_n^h\}$) is called the corresponding controlled Markov chain (respectively, controlled pair) if*

1. *U_n^h is $\sigma\{Z_0^h,\dots,Z_n^h,U_0^h,\dots,U_{n-1}^h\}$-adapted.*
2. *$\mathbb{P}[I_n^h = 3|Z_n^h \in \mathbb{S}_\ell^h] = 0$ and $\mathbb{P}[I_n^h = 3|Z_n^h \in \partial_R^h \setminus \partial^h] = 1$ for all n.*
3. *Condition (22) holds.*

The class of all admissible control sequences for initial state z_h will be denoted by $\mathcal{A}^h(z_h)$.

We also define for each $z \in \mathbb{S}_\ell^{h+}$ and $u = (i,c) \in \mathcal{U}$ the interpolation intervals

$$\Delta^h(z,u) = \tilde{\Delta}^h(z,c)1_{\{i=0\}}. \tag{23}$$

For an admissible pair $\{Z_n^h, U_n^h\}$, we denote the associated sequence of interpolation intervals $\Delta^h(Z_n^h, U_n^h)$ by $\{\Delta_n^h, n = 0,1,2,\dots\}$. Define, $t_0^h \doteq 0$ and $t_n^h \doteq \sum_{i=0}^{n-1} \Delta_i^h$ for $n \geq 1$.

MDP for the chain. Given an admissible pair $\{Z_n^h, U_n^h\}$ let $\eta_h \doteq \inf\{n : Z_n^h \in \partial^h\}$. The cost function for the controlled Markov chain is defined as

$$J^h(z_h, U^h) = \mathbb{E}\sum_{n=0}^{\eta_h - 1} e^{-\beta t_n^h} f(C_n^h)\left(\frac{1 - e^{-\beta\Delta_n^h}}{\beta}\right). \tag{24}$$

Note that we have used the factor $(1 - e^{-\beta\Delta_n^h})/\beta$ rather than the more intuitive (and asymptotically equivalent) Δ_n^h. This somewhat simplifies the convergence proofs without affecting the limiting results. The value function of the MDP is defined as

$$V^h(z_h) = \sup_{U^h \in \mathcal{A}^h(z_h)} J^h(z_h, U^h). \tag{25}$$

4. Continuous time interpolation and time rescaling. One of the main goals of the study is to show that the value function of the MDP defined in (25) converges, as $h \to 0$, to the value function of the limit diffusion control problem. This convergence result allows for the computation of near optimal policies for the diffusion control problem introduced below (6) by numerically solving the above MDP. We next introduce the continuous time interpolation and time rescaling techniques that will be used in the proof of our main convergence result.

The continuous time interpolations of various processes will be constructed to be piecewise constant on the time intervals $[t_n^h, t_{n+1}^h)$, $n \geq 0$. For use in this construction we define $n^h(t) \doteq \max\{n : t_n^h \leq t\}$, $t \geq 0$. Note that $n^h(t)$ is an $\{\mathcal{F}_n^h\}$-stopping time. Setting $\mathcal{F}^h(t) \doteq \mathcal{F}_{n^h(t)}^h$ we obtain a continuous time filtration $\{\mathcal{F}^h(t), t \geq 0\}$. Define $U^h(t) \doteq U_{n^h(t)}^h, t \geq 0$. Also, define the continuous time processes associated with the controlled diffusion steps as follows. First, let $B_0^h = 0$ and $S_0^h = 0$ and define for $n \geq 1$,

$$B_n^h \doteq \sum_{k=0}^{n\wedge\eta_h - 1} \mathbb{E}[\delta Z_k^h | \mathcal{F}_k^h] 1_{\{I_k^h = 0\}}, \quad S_n^h \doteq \sum_{k=0}^{n\wedge\eta_h - 1} \Big(\delta Z_k^h - \mathbb{E}[\delta Z_k^h | \mathcal{F}_k^h]\Big) 1_{\{I_k^h = 0\}}. \tag{26}$$

Define the continuous time process B^h by setting $B^h(0) \doteq 0$ and $B^h(t) \doteq B_{n^h(t)}^h$ for $t > 0$. The process S^h is defined in a similar manner. We define the interpolations associated with the purchase control and sales control as follows. Let $M_0^h = 0, N_0^h = 0$, $E_{i,0}^h = 0$, $i = 1, 2$, and define for $n \geq 1$,

$$M_n^h \doteq \sum_{k=0}^{n\wedge\eta_h - 1} h 1_{\{I_k^h = 1\}}, \quad N_n^h \doteq \sum_{k=0}^{n\wedge\eta_h - 1} h 1_{\{I_k^h = 2\}}, \quad E_{i,n}^h \doteq \sum_{k=0}^{n\wedge\eta_h - 1} (\delta Z_k^h - h v_i) 1_{\{I_k^h = i\}}.$$

The continuous time processes M^h and N^h are defined as $M^h(0) \doteq 0, N^h(0) \doteq 0$ and $M^h(t) \doteq M_{n^h(t)}^h, N^h(t) \doteq N_{n^h(t)}^h$ for $t \geq 0$. The processes E_1^h and E_2^h are defined analogously. The continuous time process associated with reflection is defined as follows. If $n^h(t) = 0$, define $R^h(t) = 0$; otherwise let

$$R^h(t) \doteq - \sum_{k=0}^{n^h(t)-1} \delta Z_k^h 1_{\{I_k^h = 3\}}. \tag{27}$$

We define the continuous time interpolation Z^h of the controlled Markov chain Z_n^h introduced in Definition 3.1 by $Z^h(t) \doteq Z_{n^h(t)}^h$, $t \geq 0$. The following representation for $Z^h(t)$ is easily verified:

$$Z^h(t) = z_h + B^h(t) + S^h(t) + v_1 M^h(t) + v_2 N^h(t) + E_1^h(t) + E_2^h(t) - R^h(t), \ t \geq 0. \tag{28}$$

Also, it follows from condition (12) that on the set $\{I_n^h = 0, \eta_h > n\}$,

$$\mathbb{E}[\delta Z_n^h | \mathcal{F}_n^h] = \begin{pmatrix} r X_n^h - C_n^h \\ b Y_n^h \end{pmatrix} \Delta^h(Z_n^h, 0, C_n^h) + O(h^\rho \Delta^h(Z_n^h, 0, C_n^h)) \text{ a.s.}$$

This fact, together with the piecewise constant nature of the processes, yields

$$B^h(t) = \int_0^{t\wedge\tau^h} \begin{pmatrix} r X^h(s) - C^h(s) \\ b Y^h(s) \end{pmatrix} ds + \delta_1^h(t), \tag{29}$$

where $\tau^h \doteq t_{\eta_h}^h$ and δ_1^h is an $\{\mathcal{F}^h(t)\}$-adapted process which, in view of (14), satisfies for all $t \geq 0$ and $m \geq 1$,

$$\sup_{0 \leq s \leq t} \mathbb{E}|\delta_1^h(s)|^m \to 0 \text{ as } h \to 0.$$

A similar calculation gives the following representation of the cost function (24):

$$J^h(z_h, U^h) = \mathbb{E}\int_{[0,\tau^h]} e^{-\beta t} f(C^h(t))dt. \tag{30}$$

Time rescaling. A common approach for proving the convergence of V^h to V as $h \to 0$ is to begin by showing that the collection $\{(Z^h(\cdot), \tau^h), h \geq 0\}$ is tight and then characterize the subsequential weak limits suitably. However, for problems with singular controls, showing the tightness of the above family becomes problematic since, in general, the processes $\{(M^h(\cdot), N^h(\cdot)), h \geq 0\}$ may fail to be tight. A powerful method for handling this tightness issue was introduced by Martins and Kushner [21]. The basic idea is to suitably stretch out the time scale so that the various processes involved in the convergence analysis, in the new time scale, are tight; carry out the weak convergence analysis with the rescaled processes; and finally, revert back to the original time scale to argue the convergence of V^h to V.

We now introduce the time rescaling that will be used in our study. The rescaled time increments, $\{\hat{\Delta}_n^h, n = 0, 1, 2, \dots\}$, are defined as $\hat{\Delta}_n^h \doteq \Delta_n^h 1_{\{I_n^h=0\}} + h1_{\{I_n^h \in \{1,2\}\}}$. Define $\hat{t}_0^h \doteq 0$ and $\hat{t}_n^h \doteq \sum_{i=0}^{n-1} \hat{\Delta}_i^h$ for $n \geq 1$.

DEFINITION 4.1. *The rescaled time process $\hat{T}^h(t)$ is the unique continuous nondecreasing process satisfying the following:* (1) $\hat{T}^h(0) = 0$*;* (2) *the derivative of $\hat{T}^h(t)$ is* 1 *for $t \in (\hat{t}_n^h, \hat{t}_{n+1}^h)$ if $I_n^h = 0$;* (3) *the derivative of $\hat{T}^h(t)$ for $t \in (\hat{t}_n^h, \hat{t}_{n+1}^h)$ is* 0 *if $I_n^h = 1, 2, 3$.*

It is easy to check that $\hat{T}^h(\hat{t}_n^h) = t_n^h$ and that $\hat{T}^h(\hat{t}_{n+1}^h) - \hat{T}^h(\hat{t}_n^h) = \Delta_n^h$. Let $\hat{n}^h(t) \doteq \max\{n : \hat{t}_n^h \leq t\}$, $t \geq 0$. Using the observation that every reflection step must be followed by either a singular control step or a diffusion control step, it follows that $\hat{n}^h(t)$ is a bounded $\{\mathcal{F}_n^h\}$-stopping time, with bound

$$\hat{n}^h(t) \leq 2\left(\frac{t}{h} + \frac{t}{\inf_{z,c} \hat{\Delta}^h(z, 0, c)}\right) < \infty. \tag{31}$$

Define the continuous time filtration $\{\hat{\mathcal{F}}^h(t), t \geq 0\}$ by setting $\hat{\mathcal{F}}^h(t) \doteq \mathcal{F}_{\hat{n}^h(t)}$.

The rescaled processes (denoted with a $\hat{}$) are defined in a manner similar to the processes defined below (26) with appropriate adjustments to the time variable. For example, we define $\hat{B}^h(0) = 0$ and $\hat{B}^h(t) \doteq B^h_{\hat{n}^h(t)}$ if $\hat{n}^h(t) > 0$. We define the processes $\hat{U}^h(t)$, $\hat{S}^h(t)$, $\hat{M}^h(t)$, $\hat{N}^h(t)$, $\hat{E}_1^h(t)$, $\hat{E}_2^h$, $\hat{R}^h(t)$, $\hat{Z}^h(t)$ analogously (that is, by replacing $n^h(t)$ with $\hat{n}^h(t)$ in the definitions below (26)). Then we have the following rescaled version of (28):

$$\hat{Z}^h(t) = z_h + \hat{B}^h(t) + \hat{S}^h(t) + v_1\hat{M}^h(t) + v_2\hat{N}^h(t) + \hat{E}_1^h(t) + \hat{E}_2^h - \hat{R}^h(t). \tag{32}$$

Remark 4.2. From the definition of $\hat{T}^h(t)$ if follows that $\hat{n}^h(t) = n^h(\hat{T}^h(t))$. This equality yields a straightforward relationship between the original interpolated processes and the rescaled processes. For example, $\hat{B}^h(t) = B^h(\hat{T}^h(t))$. Similar equations hold between $U^h(t)$, $S^h(t)$, $M^h(t)$, $N^h(t)$, $E_1^h(t)$, E_2^h, $R^h(t)$, $Z^h(t)$, and their corresponding rescaled versions.

Using the fact that $\hat{T}^h(\hat{t}_{n+1}^h) - \hat{T}^h(\hat{t}_n^h) = \Delta_n^h$, which is 0 for singular control and reflection steps, a calculation similar to that which produced (29) yields

$$\hat{B}^h(t) = \int_0^{t\wedge\hat{\tau}_1^h} \begin{pmatrix} r\hat{X}^h(s) - \hat{C}^h(s) \\ b\hat{Y}^h(s) \end{pmatrix} d\hat{T}^h(s) + \hat{\delta}_1^h(t), \tag{33}$$

where $\hat{\tau}_1^h \doteq \inf\{t : \hat{Z}^h(t) \in \partial^h\}$ and $\hat{\delta}_1^h$ is an $\{\hat{\mathcal{F}}^h(t)\}$-adapted process satisfying, for all $m \geq 1$,

$$\mathbb{E} \sup_{0\leq s\leq t} |\hat{\delta}_1^h(s)|^m \to 0 \text{ as } h \to 0. \tag{34}$$

We now state several lemmas related to the time rescaling. The following "change of variables" formula (cf. Theorem IV.3.45 in [28]) will be used several times in our analysis.

LEMMA 4.3. *Let $\hat{G} : [0,\infty) \to [0,\infty)$ be a continuous and nondecreasing function. Suppose that $\hat{G}(t) \to \infty$ as $t \to \infty$. Define the inverse $G : [0,\infty) \to [0,\infty)$ as $G(t) = \inf\{s : \hat{G}(s) > t\}$. Then for all bounded and measurable functions $g : [0,\infty) \to [0,\infty)$,*

$$\int_{[0,G(t)]} g(s)d\hat{G}(s) = \int_{[0,t]} g(G(s))ds. \tag{35}$$

The following lemma is at the heart of the time transformation idea. It ensures that the weak limits of $\hat{T}^h(t)$ increase to ∞ as $t \to \infty$ and thus makes reverting back to the original time scale, in the limit, possible (see Theorem 5.6). The proof of the lemma is contained in the appendix.

LEMMA 4.4. *Let $\{U_n^h, n = 0, 1, 2, \dots\}_{h>0}$ be a family of admissible control sequences. Then for all $t \geq 0$,*

$$\sup_h \mathbb{E}|M^h(t) + N^h(t)| < \infty. \tag{36}$$

An important consequence of the above lemma is the following.

LEMMA 4.5. *There exists an $h_0 \in (0,\infty)$ such that for all $h < h_0$, $\hat{T}^h(t) \to \infty$ with probability 1 as $t \to \infty$.*

Proof. Since $\tilde{\Delta}_*^h \to 0$ as $h \to 0$, we can find an h_0 such that $\tilde{\Delta}_*^h < 1$ for all $h < h_0$. We will argue via contradiction. Suppose $h < h_0$ and $\mathbb{P}[\sup_{t\geq 0} \hat{T}^h(t) < \infty] > 0$. Then there exist $\epsilon > 0$ and $T_0 > 0$ such that

$$\mathbb{P}\left[\sup_{t\geq 0} \hat{T}^h(t) < T_0 - 1\right] > \epsilon. \tag{37}$$

Using Lemma 4.4 we can find a K large enough so that

$$\mathbb{P}[M^h(T_0) \geq K] \leq \frac{\mathbb{E}M^h(T_0)}{K} < \frac{\epsilon}{4}, \;\; \mathbb{P}[N^h(T_0) \geq K] \leq \frac{\mathbb{E}N^h(T_0)}{K} < \frac{\epsilon}{4}.$$

We will now show that

$$\mathbb{P}[\hat{T}^h(T_0 + 2K) < T_0 - 1] \leq \frac{\epsilon}{2}. \tag{38}$$

This will lead to a contradiction in view of (37) and hence prove the lemma. Note that

$$\begin{aligned}
&\mathbb{P}[\hat{T}^h(T_0 + 2K) < T_0 - 1] \\
&\quad \leq \mathbb{P}[\hat{T}^h(T_0 + M^h(T_0) + N^h(T_0)) < T_0 - 1, M^h(T_0) < K, N^h(T_0) < K] \\
&\quad +\mathbb{P}[M^h(T_0) \geq K] + \mathbb{P}[N^h(T_0) \geq K] \\
&\quad \leq \mathbb{P}[\hat{T}^h(T_0 + M^h(T_0) + N^h(T_0)) < T_0 - 1] + \frac{\epsilon}{4} + \frac{\epsilon}{4}. \qquad (39)
\end{aligned}$$

Furthermore, for each fixed t, $t+M^h(t)+N^h(t) \geq \sum_{k=0}^{n^h(t)-1}(\Delta_k^h 1_{\{I_k^h=0\}}+h1_{\{I_k^h=1,2\}})$. Since $\hat{T}^h$ is nondecreasing and $\hat{T}^h(\hat{t}_n^h)=t_n^h$,

$$\hat{T}^h\left(t+M^h(t)+N^h(t)\right) \geq \hat{T}^h\left(\sum_{k=0}^{n^h(t)-1}\left(\Delta_k^h 1_{\{I_k^h=0\}}+h1_{\{I_k^h=1,2\}}\right)\right)$$
$$= \hat{T}^h(\hat{t}^h_{n^h(t)}) = t^h_{n^h(t)} = \sum_{k=0}^{n^h(t)-1}\Delta_k^h 1_{\{I_k^h=0\}} \geq t-\tilde{\Delta}_*^h.$$

The last inequality above is a consequence of the inequalities $\sum_{k=0}^{n^h(t)-1}\Delta_k^h 1_{\{I_k^h=0\}} \leq t \leq \sum_{k=0}^{n^h(t)}\Delta_k^h 1_{\{I_k^h=0\}}$. Recalling that $\tilde{\Delta}_*^h<1$, we see that $\hat{T}^h(t+M^h(t)+N^h(t)) \geq t-1$ for all $t\geq 0$. Using this inequality in (39) proves (38) and hence we have the result. □

Let $T^h(t) \doteq \inf\{s : \hat{T}^h(s) > t\}$. Observe that $\hat{T}^h(T^h(t))=t$ and that, due to Lemma 4.5, $T^h(t)<\infty$ a.s. for all $t\geq 0$. Define $\hat{\tau}^h \doteq T^h(\tau^h)$.

LEMMA 4.6. *For $z_h \in \mathbb{S}_\ell^{h+}$ and $\{U_n^h\} \in \mathcal{A}^h(z_h)$,*

$$J^h(z_h,U^h) = \mathbb{E}\int_{[0,\hat{\tau}_1^h]} e^{-\beta\hat{T}^h(t)} f(\hat{C}^h(t))d\hat{T}^h(t).$$

Proof. Note that

$$\hat{\tau}_1^h = \inf\{t : \hat{Z}^h(t)\in\partial^h\} \;=\; \inf\{t : Z^h(\hat{T}^h(t))\in\partial^h\} \;=\; \inf\{t : \hat{T}^h(t)\geq\tau^h\}.$$

If $\tau^h=\infty$, then clearly $\hat{\tau}_1^h=\infty$. Suppose $\tau^h<\infty$. Then the above display shows that $\hat{\tau}_1^h = T^h(\tau^h-)$. Also, clearly $\hat{T}^h$ is constant over the interval $(T^h(\tau^h-), T^h(\tau^h)]$. The result now follows from (30) and Lemma 4.3. □

5. Main convergence result. In this section we show that $V^h(z_h)$ converges to $V(z)$ whenever $z_h \to z$. The basic approach will be as follows. First, we establish tightness of the continuous time (rescaled) processes defined in the previous section and characterize their subsequential limits. Then we define a time transformation for the limit processes to revert back to the original scale. We will show that the time transformed versions of the limit processes have the same laws as those of the various processes in the diffusion control problem. Using this characterization result we will show that, given a sequence of admissible controls $\{U^h, h>0\}$, the lim sup of the corresponding cost functions is bounded above by the cost for an admissible control for the diffusion control problem. This will establish that $\limsup_{h\to 0} V^h(z_h) \leq V(z)$ whenever $z_h \to z$. Finally, we prove convergence of the value functions by proving the reverse inequality. The main idea of this proof is to select a near optimal control for the limit diffusion control problem and to construct from this an admissible control for the controlled Markov chain which is asymptotically near optimal.

We begin by introducing the following "relaxed control" formulation which arises naturally in the weak convergence arguments for convergence of the cost functions.

Relaxed control formulation. Let $\tilde{\mathcal{M}}$ denote the space of all Borel measures ϑ on $[0,p]\times[0,\infty)$ such that if $\vartheta(d\alpha,dt)=\vartheta_t(d\alpha)\nu(dt)$, then (i) ϑ_t is a probability measure on $[0,p]$ for ν-almost every t, and (ii) $\nu(a,b]\leq b-a$ for all $0\leq a\leq b<\infty$. Let $\mathcal{M}$ be the subset of $\tilde{\mathcal{M}}$ consisting of ϑ that satisfy, for all $t\geq 0$, $\vartheta([0,p]\times[0,t])=t$. Given a probability system Φ and initial condition $z\in\mathbb{S}_\ell$, let $\bar{\mathcal{A}}_p(\Phi,z)$ be the set of

all processes $\bar{U} \equiv (m, M, N)$, where M and N are as introduced below (1), $m \in \mathcal{M}$ a.s., and $m(A \times [0,t])$ is $\{\mathcal{F}_t\}$-adapted for all $t \in [0,\infty)$, $A \in \mathcal{B}[0,p]$. Set $C(t) \doteq \int_{[0,p]} \alpha m_t(d\alpha)$, where m_t, a probability measure on $[0,p]$, is defined by the relation $m(d\alpha, dt) = m_t(d\alpha)dt$.

Let Z be defined via (7) with (C, M, N) as above and τ be given by (2). Define for $\bar{U} \in \bar{\mathcal{A}}_p(\Phi, z)$,

$$\bar{J}(z, \bar{U}) \doteq \mathbb{E} \int_{[0,p]\times[0,\tau)} e^{-\beta t} f(\alpha) m(d\alpha, dt),$$

and let

$$\bar{V}(z) \doteq \sup_{\Phi} \sup_{\bar{U} \in \bar{\mathcal{A}}(\Phi, z)} \bar{J}(z, \bar{U}).$$

The following lemma establishes the equivalence between the relaxed control formulation and the precise control formulation. The proof is contained in the appendix.

LEMMA 5.1. *For all* $z \in \mathbb{S}$, $\bar{V}(z) = V(z)$.

The space $\tilde{\mathcal{M}}$ can be metrized using the Prohorov metric in the usual way (see pages 263–264 of [19]). Furthermore, with this metric, $\tilde{\mathcal{M}}$ is a compact space, and a sequence $\vartheta_n \in \tilde{\mathcal{M}}$ converges to ϑ if and only if for all continuous functions ψ on $[0,p] \times [0,\infty)$ with compact support,

$$\int_{[0,p]\times[0,\infty)} \psi(\alpha, t) m_n(d\alpha, dt) \to \int_{[0,p]\times[0,\infty)} \psi(\alpha, t) m(d\alpha, dt). \tag{40}$$

We now define $\tilde{\mathcal{M}}$-valued random variables $\hat{m}^h$ by the relation

$$\hat{m}^h(A \times [0,t]) \doteq \int_{[0,t]} 1_A(\hat{C}^h(s)) d\hat{T}^h(s), \quad A \in \mathcal{B}([0,p]), t \in [0,\infty).$$

Noting that the right side above is equal to $\int_{[0,t]} (\int_A \delta_{\hat{C}^h(s)}(d\alpha)) d\hat{T}^h(s)$, where δ_x is the probability measure concentrated at x, we can write $\hat{m}^h(d\alpha, dt)$ as $\hat{m}^h_t(d\alpha)\hat{\nu}^h(dt)$, where $\hat{m}^h_t$ and $\hat{\nu}^h$ are given by $\hat{m}^h_t(A) = \delta_{\hat{C}^h(t)}(A)$, $\hat{\nu}^h(a,b] = \hat{T}^h(b) - \hat{T}^h(a)$ for $A \in \mathcal{B}([0,p])$ and $0 \le a \le b < \infty$.

Convergence of the time rescaled processes. Recall the definitions and notation, found in section 4, relating to the continuous time interpolated processes and the corresponding rescaled versions. We begin by showing that the processes $\hat{E}^h_1$ and $\hat{E}^h_2$ converge weakly to the 0 process as $h \to 0$.

LEMMA 5.2. *Let* $\hat{E}^h_i, i = 1, 2$, *be as defined above* (27). *Then* $\hat{E}^h_i$ *converges in probability to* 0 *in* $D([0,\infty) : \mathbb{R}^2)$.

Proof. The local consistency condition (18) and property (22) imply that $E^h_{i,n}$ is an $\{\mathcal{F}^h_n\}$-martingale. As $\hat{n}^h(t)$ is a bounded stopping time (cf. (31)) and the increments of $E^h_{i,n}$ are bounded, it follows from the optional sampling theorem that the continuous time process $\hat{E}^h_i(t)$ is an $\{\hat{\mathcal{F}}^h(t)\}$-martingale, the trace of the quadratic variation of which is given by $\mathrm{Tr}\langle \hat{E}^h_i \rangle(t) = \sum_{k=0}^{\hat{n}^h(t)\wedge\eta_h - 1} \mathbb{E}[|\delta z^h_k - h v_i|^2 1_{\{I^h_k = i\}} | \mathcal{F}^h_{k-1}]$. Finally, applying Doob's inequality, (19), and the observation that the maximum number of steps of either singular control in the first $\hat{n}^h(t)$ steps is t/h, we have for $i = 1, 2$, $\mathbb{E}[\sup_{s\le t} |\hat{E}^h_i(s)|]^2 \le 4\mathbb{E}\mathrm{Tr}\langle \hat{E}^h_1 \rangle(t) \le O(h^2)(t/h) = O(h)$. The result now follows. ∎

Define the process $\hat{A}^h$ by $\hat{A}^h(t) \doteq \int_{[0,t)} \hat{C}^h(s) d\hat{T}^h(s)$. Let $\bar{\mathbb{R}}$ denote the one point compactification of $\mathbb{R}$. The following proposition gives the tightness of the various time rescaled processes. The proof is similar to that of Theorem 5.3 of [20] and is therefore omitted.

PROPOSITION 5.3. *Let $\hat{H}^h \doteq (\hat{Z}^h, \hat{T}^h, \hat{A}^h, \hat{M}^h, \hat{N}^h, \hat{R}^h, \hat{B}^h, \hat{S}^h)$. Then the family $\{(\hat{H}^h, \hat{\tau}_1^h, \hat{m}^h), h > 0\}$ is tight in $D([0,\infty) : E) \times \bar{\mathbb{R}} \times \mathcal{M}$, where $E = \mathbb{S}_\ell^{h+} \times \mathbb{R}_+^6 \times \mathbb{R}^4$.*

We now turn our attention to characterizing subsequential limit points of the family $\{(\hat{H}^h, \hat{\tau}_1^h, \hat{m}^h), h > 0\}$. Suppose that the initial condition sequence $\{z_h\}$ converges to some $z \in \mathbb{S}_\ell$. Slightly abusing notation, let h index a weakly convergent subsequence of $(\hat{H}^h, \hat{\tau}_1^h, \hat{m}^h)$ with weak limit, $(\hat{H}, \hat{\tau}_1, \hat{m})$, where $\hat{H} \doteq (\hat{Z}, \hat{T}, \hat{A}, \hat{M}, \hat{N}, \hat{R}, \hat{B}, \hat{S})$, given on some probability space $(\Omega, \mathcal{F}, \mathbb{P})$. Let $\hat{\mathcal{F}}^*(t) \doteq \sigma(\hat{H}(s), \hat{m}(A \times [0,s)) | A \in \mathcal{B}([0,p]), 0 \le s \le t)$, and let $\hat{\mathcal{F}}(t) \doteq \hat{\mathcal{F}}^*(t+) \vee \mathcal{N}$, where $\mathcal{N}$ denotes the collection of all $\mathbb{P}$-null sets.

THEOREM 5.4. *The limit point $(\hat{H}, \hat{\tau}_1, \hat{m})$ has the following properties.*

1. *$\hat{T}$ is nondecreasing and Lipschitz continuous with Lipschitz coefficient 1.*
2. *There exists an $\{\hat{\mathcal{F}}(t)\}$-progressively measurable process $\hat{C}$ with $\hat{C}(t) \in [0,p]$ for all $t \ge 0$, such that*

$$\hat{B}(t) = \int_0^{t \wedge \hat{\tau}_1} \begin{pmatrix} r\hat{X}(s) - \hat{C}(s) \\ b\hat{Y}(s) \end{pmatrix} d\hat{T}(s). \tag{41}$$

3. *$\hat{S}_1(t) = 0$, for all $t \ge 0$, and $\hat{S}_2$ is a continuous $\{\hat{\mathcal{F}}(t)\}$-martingale with quadratic variation $\langle \hat{S}_2 \rangle_t = \int_0^t |\sigma \hat{Y}(s)|^2 d\hat{T}(s), t \ge 0$.*
4. *$\hat{M}$ and $\hat{N}$ are nondecreasing and continuous.*
5. *$\hat{R}$ is a vector of nondecreasing continuous processes which satisfy*

$$\int_0^\infty 1_{\{\hat{X}(t) < \ell\}} d\hat{R}_1(t) = 0, \quad \int_0^\infty 1_{\{\hat{Y}(t) < \ell\}} d\hat{R}_2(t) = 0. \tag{42}$$

6. *$\hat{Z}$ is a continuous process satisfying $\mathbb{P}[\hat{Z}(t) \in S_\ell] = 1$ for all $t \ge 0$ and*

$$\hat{Z}(t) = z + \hat{B}(t) + \hat{S}(t) + v_1 \hat{M}(t) + v_2 \hat{N}(t) - \hat{R}(t). \tag{43}$$

7. *Writing $\hat{m}(d\alpha, dt)$ as $\hat{m}_t(d\alpha)\hat{\nu}(dt)$ we have $\hat{\nu}(a,b] = \hat{T}(b) - \hat{T}(a)$, $0 \le a \le b < \infty$.*
8. *$\hat{C}(t) = \int_{[0,p]} \alpha \hat{m}_t(d\alpha)$ for $\hat{\nu}$-almost every $t \in [0,\infty)$.*

Proof. By appealing to the Skorohod representation theorem and by relabeling the convergent subsequence, we can assume without loss of generality that $\hat{H}^h \to \hat{H}$ a.s. The fact that the process $\hat{T}$ is nondecreasing and Lipschitz continuous with Lipschitz coefficient 1 follows easily from similar properties for $\hat{T}^h$. Since $|\hat{A}^h(t) - \hat{A}^h(s)| \le p|\hat{T}^h(t) - \hat{T}^h(s)|$ it follows that $\hat{A}$ is absolutely continuous with respect to $\hat{T}$. Therefore there exists a $[0,p]$-valued process $\hat{C}$, progressively measurable with respect to $\{\hat{\mathcal{F}}^*(t)\}$ such that $\hat{A}(t) = \int_0^t \hat{C}(s) d\hat{T}(s)$. This fact, together with $(\hat{Z}^h, \hat{T}^h) \to (\hat{Z}, \hat{T})$ a.s. and an application of the dominated convergence theorem, yields 2. We next show that $\hat{S}$ has continuous paths. First, note that by local consistency ((12), (13)) there exists $\zeta \in (0,\infty)$ such that for all $u \ge 0, h \ge 0$ $j(\hat{S}^h, u) \doteq \sup_{t \le u} |\hat{S}^h(t) - \hat{S}^h(t-)| \le 2\zeta h$. Thus for h small enough, $j(\hat{S}^h) \doteq \int_0^\infty e^{-u}(j(\hat{S}^h, u) \wedge 1) du \le 2\zeta h$. Therefore, by Theorem 3.10.2 in [9] the limiting process $\hat{S}$ has continuous paths. One can check

that the quadratic variation of $\hat{S}^h$, which is an $\{\hat{\mathcal{F}}^h(t)\}$-martingale, is given by

$$\langle \hat{S}^h \rangle(t) = \begin{pmatrix} 0 & 0 \\ 0 & 1 \end{pmatrix} \int_0^{t \wedge \hat{\tau}_1^h} |\sigma \hat{Y}^h(s)|^2 d\hat{T}^h(s) + \hat{\delta}_2^h(t), \tag{44}$$

where due to (14) and using (31) the process $\hat{\delta}_2^h$ satisfies for all $m \geq 1$,

$$\mathbb{E} \sup_{s \leq t} |\hat{\delta}_2^h(s)|^m \to 0 \text{ as } h \to 0.$$

From (44) it follows that $\hat{S}_1(t) = 0$ for all $t \geq 0$. From (44) and the Burkholder–Gundy inequalities we also have

$$\mathbb{E}|\hat{S}_2^h(t)|^4 \leq \alpha \left[T^2 + \mathbb{E} \sup_{0 \leq u \leq t} |\hat{\delta}_2^h(u)|^2 \right].$$

Thus the family $\{(\hat{S}_2^h(t))^2, h > 0\}$ is uniformly integrable. A standard argument (cf. pages 1457–1458 in [20]) shows that $\hat{S}_2$ is an $\{\hat{\mathcal{F}}_t\}$-martingale with quadratic variation as given in 3. Part 4 is immediate on noting that $\hat{M}^h, \hat{N}^h$ are nondecreasing, and since the maximum number of purchase or sales steps over $(\hat{n}^h(t), \hat{n}^h(t+s))$ is $s/h + 1$,

$$|\hat{M}^h(t+s) - \hat{M}^h(t)| \leq s + h, \;\; |\hat{N}^h(t+s) - \hat{N}^h(t)| \leq s + h.$$

From Definition 3.1(3) it follows that (42) holds with $(\hat{X}, \hat{Y}, \hat{R})$ replaced by $(\hat{X}^h, \hat{Y}^h, \hat{R}^h)$. Also clearly $\hat{Z}^h \in (-\infty, \ell] \times (-\infty, \ell]$. Parts 5 and 6 are now immediate consequences of (32) and continuity properties of the Skorohod map (see (6)). Next, write $\hat{m}(d\alpha, dt)$ as $\hat{m}_t(d\alpha)\hat{\nu}(dt)$. Since $\hat{m}^h([0,p],(a,b]) = \hat{T}^h(b) - \hat{T}^h(a)$ for $0 \leq a \leq b < \infty$, taking limits yields $\hat{\nu}(a,b] = \hat{T}(b) - \hat{T}(a)$. This proves part 7. Part 8 is immediate from the representation $\int_{(a,b]} \hat{C}^h(s) d\hat{T}^h(s) = \int_{(a,b] \times [0,p]} \alpha \hat{m}^h(d\alpha, ds)$, $0 \leq a \leq b < \infty$ and the fact that (see the proof of part 2) $\int_{(a,b]} \hat{C}^h(s) d\hat{T}^h(s)$ converges to $\int_{(a,b]} \hat{C}(s) d\hat{T}(s)$. □

Time inversion. We now define an inverse time transformation that will revert the limit processes back to the original time scale. We will see that the time inverted processes lead to an admissible control pair for the diffusion control problem in (7)–(9). The key step in returning to the original time scale is the following result analogous to Lemma 4.5.

LEMMA 5.5. *$\hat{T}(t) \to \infty$ with probability 1 as $t \to \infty$.*

Proof. We will argue via contradiction. Suppose $\mathbb{P}[\sup_{t \geq 0} \hat{T}(t) < \infty] > 0$. Then there exist $\epsilon > 0$ and $T_0 > 0$ such that

$$\mathbb{P}\left[\sup_{t \geq 0} \hat{T}(t) < T_0 - 1 \right] > \epsilon. \tag{45}$$

As in the proof of Lemma 4.5 we can find a $K \in (0, \infty)$ such that $\liminf_{h \to 0} \mathbb{P}[\hat{T}^h(T_0 + 2K) < T_0 - 1] \leq \epsilon/2$. The weak convergence $\hat{T}^h \Rightarrow \hat{T}$ now implies $\mathbb{P}[\hat{T}(T_0 + 2K) < T_0 - 1] \leq \epsilon/2$. This contradicts (45), and hence the result follows. □

Let T be the inverse of $\hat{T}$, defined as $T(t) \doteq \inf\{s : \hat{T}(s) > t\}$. From Lemma 5.5 it follows that $T(t) < \infty$ a.s. for all $t \geq 0$. Since $\hat{T}(t)$ is nondecreasing and continuous,

it follows that $T(t)$ is nondecreasing and right-continuous. Also note the following properties for all $t \geq 0$:

$$T(t) \geq t, \quad \hat{T}(T(t)) = t, \quad T(\hat{T}(t)) \geq t,$$
$$T(t) \uparrow \infty \text{ as } t \uparrow \infty, \quad T(t) < \infty \text{ a.s.}, \quad \hat{T}(s) \in [0,t] \Leftrightarrow s \in [0, T(t)]. \tag{46}$$

Let $\hat{H}$ be as in Theorem 5.4. Define $H(t) \doteq \hat{H}(T(t))$. We will use similar notation for the various components of H; for example, $Z(t) \doteq \hat{Z}(T(t))$, etc. Let $\tau_1 \doteq \hat{T}(\hat{\tau}_1)$. Then by (43), for $t \geq 0$,

$$Z(t) = z + B(t) + S(t) + v_1 M(t) + v_2 N(t) - R(t). \tag{47}$$

Before characterizing the various terms in (47) we note that for $t \geq 0$, $\{T(s) < t\} = \{\hat{T}(t) > s\} \in \hat{\mathcal{F}}(t)$ since $\hat{T}(t)$ is $\hat{\mathcal{F}}(t)$-measurable. Therefore, since $\hat{\mathcal{F}}(t)$ is right-continuous, $T(s)$ is an $\{\hat{\mathcal{F}}(t)\}$-stopping time for each $s \geq 0$. Let $\mathcal{F}_0(t) \doteq \hat{\mathcal{F}}(T(t))$ and note that $H(t) \doteq \hat{H}(T(t))$ and $m(A \times [0,t]) \doteq \hat{m}(A \times [0, T(t)])$ are $\mathcal{F}_0(t)$-measurable. Define $\mathcal{F}(t) \doteq \sigma(H(s), m(A \times [0,s]) : A \in \mathcal{B}([0,p]), 0 \leq s \leq t)$. Then $\mathcal{F}(t) \subseteq \mathcal{F}_0(t)$.

THEOREM 5.6. *The processes in* (47) *have the following properties.*

1. $B(t) = \int_0^{t\wedge\tau_1} \binom{rX(s) - C(s)}{bY(s)} ds$.
2. $S_1 \equiv 0$ *and* S_2 *is a continuous* $\{\mathcal{F}_0(t)\}$*-martingale with quadratic variation*

$$\langle S_2 \rangle(t) = \int_0^{t\wedge\tau_1} |\sigma Y(s)|^2 ds. \tag{48}$$

There exists an enlargement of the probability space $(\Omega, \mathcal{F}, \mathbb{P})$ *and of the filtration* $\{\mathcal{F}_0(t)\}$ *that supports a Wiener process* W*, which is a martingale with respect to the enlarged filtration and such that*

$$S_2(t) = \int_0^{t\wedge\tau_1} \sigma Y(s) dW(s). \tag{49}$$

3. *The process* C *is* $\{\mathcal{F}_0(t)\}$*-progressively measurable with* $C(t) \in [0,p]$ *a.s. for all* $t \geq 0$*. In addition,* $M(0), N(0) \geq 0$ *and the processes* M *and* N *are right-continuous, nondecreasing, and* $\{\mathcal{F}_0(t)\}$*-adapted. Hence defining* $\Phi \doteq (\Omega, \mathcal{F}, \mathbb{P}, \{\mathcal{F}_0(t)\}, W)$ *we have* $U \equiv (C, M, N) \in \mathcal{A}_p(\Phi, z)$.
4. *For all* $t \geq 0$*,* $Z(t) \in (-\infty, \ell] \times (-\infty, \ell]$ *a.s., R is a vector of nondecreasing right-continuous processes, and the representation* (7) *holds with* (X_ℓ, Y_ℓ, Z_ℓ) *there replaced by* (X, Y, Z).

Remark 5.7. Note that Theorem 5.6 does not prove that (Z, R) is a solution to the Skorohod problem introduced in Definition 2.3, since in general (8) may fail to hold for the process R. However, note that if (Z^*, R^*) is the solution of (7) and (8) with $U = (C, M, N)$ as in part 3 of Theorem 5.6, then by classical comparison results for (reflected) stochastic differential equations one can show that $Z^*(t) \geq Z(t)$ for all t a.s., and so $\tau^* \geq \tau$ where τ is as in (2) and τ^* is defined by the right side of (2) with Z replaced by Z^*. This in particular shows that

$$\int_{[0,p]\times[0,\tau]} e^{-\beta t} f(\alpha) dm_t(d\alpha) dt \leq \int_{[0,p]\times[0,\tau^*]} e^{-\beta t} f(\alpha) dm_t(d\alpha) dt. \tag{50}$$

Proof of Theorem 5.6. Part 1 is an immediate consequence of Theorem 5.4(2) and Lemma 4.3 on noting that

$$\int 1_{[T(\tau_1-),T(\tau_1)]} d\hat{T}(s) = 0 \text{ a.s.} \tag{51}$$

Clearly, $S_1(t) \doteq \hat{S}_1(T(t)) \equiv 0$ a.s. From Theorem 5.4 we have that $\{\hat{S}_2(t), \hat{\mathcal{F}}(t)\}$ is a continuous martingale. Thus for all $n \geq 1$, $\mathbb{E}[\hat{S}_2(T(t) \wedge n)|\hat{\mathcal{F}}(T(s))] = \hat{S}_2(T(s) \wedge n)$ a.s. Also as $\hat{S}_2$ has continuous paths and $T(t) < \infty$ a.s., we have as $n \to \infty$ for all $t \geq 0$, $\hat{S}_2(T(t) \wedge n) \to \hat{S}_2(T(t)) = S_2(t)$ a.s. Furthermore, from Theorem 5.4, part 3, there exists $\alpha \in (0, \infty)$ such that $\mathbb{E}|\hat{S}_2(T(t) \wedge n)|^2 \leq \alpha t$ for all $t \geq 0, n \in \mathbb{N}$. Hence, for each fixed t, the family $\{\hat{S}_2(T(t) \wedge n), n \geq 1\}$ is uniformly integrable and therefore $\hat{S}_2(T(t) \wedge n) \to \hat{S}_2(T(t))$ in L^1. Taking limits as $n \to \infty$, it follows that $\mathbb{E}[\hat{S}_2(T(t))|\hat{\mathcal{F}}(T(s))] = \hat{S}_2(T(s))$, that is, $\mathbb{E}[S_2(t)|\mathcal{F}_0(s)] = S_2(s)$. This proves that $\{S_2(t), \mathcal{F}_0(t)\}$ is a martingale. Although T in general may fail to be continuous, $S_2(\cdot) \doteq \hat{S}_2(T(\cdot))$ has continuous paths a.s. This is a consequence of the fact that $\{S_2^h(\cdot)\}_{h>0}$ is tight in $D([0, \infty))$, and an argument similar to that for $\{\hat{S}_2^h\}$ in the proof of Theorem 5.4 shows that any weak limit point, $\tilde{S}_2$, of $\{S_2^h\}$ must have continuous paths a.s. Also, since $\hat{S}_2^h(\cdot) = S_2^h(\hat{T}^h(\cdot))$, we must have that if $(\tilde{S}_2, \hat{S}_2, \hat{T})$ is a limit point of the tight sequence $(S_2^h, \hat{S}_2^h, \hat{T}^h)$, then $\hat{S}_2(t) = \tilde{S}_2(\hat{T}(t))$, and thus from (46), $S(t) \doteq \hat{S}_2(T(t)) = \tilde{S}_2(t)$. Thus we have shown that S_2 is a continuous $\mathcal{F}_0(t)$-martingale. We next consider its quadratic variation. By the Burkholder–Davis–Gundy inequalities (cf. Theorem 3.3.28 in [17]) there exists a constant α independent of n such that

$$\mathbb{E}[|\hat{S}_2^2(T(t) \wedge n)|^2] \leq \mathbb{E}\left[\left(\sup_{0 \leq s \leq T(t)} |\hat{S}_2(s \wedge n)|\right)^4\right] \leq \alpha(\alpha_1^2 t^2).$$

Thus the families $\{\hat{S}_2^2(T(t) \wedge n), n \geq 1\}$ and $\{\langle \hat{S}_2 \rangle(T(t) \wedge n), n \geq 1\}$ are uniformly integrable for each fixed $t \geq 0$. Since $\hat{S}_2^2$ (respectively, $\langle \hat{S}_2 \rangle$) has continuous paths and $T(t) < \infty$ a.s. $\hat{S}^2(T(t) \wedge n) \to \hat{S}_2^2(T(t))$ (respectively, $\langle \hat{S}_2 \rangle(T(t) \wedge n) \to \langle \hat{S}_2 \rangle(T(t))$) a.s. as $n \to \infty$. By the uniform integrability, this convergence also holds in the L^1 sense. Thus

$$\mathbb{E}[\hat{S}_2^2(T(t) \wedge n) - \langle \hat{S}_2 \rangle(T(t) \wedge n)|\hat{\mathcal{F}}(T(s))] \to \mathbb{E}[\hat{S}_2^2(T(t)) - \langle \hat{S}_2 \rangle(T(t))|\hat{\mathcal{F}}(T(s))]. \tag{52}$$

The above relation and the fact that $\hat{S}_2^2 - \langle \hat{S}_2 \rangle$ is an $\hat{\mathcal{F}}_t$-martingale now show that $\mathbb{E}[S_2^2(t) - \langle \hat{S} \rangle(T(t))|\mathcal{F}_0(s)] = S_2^2(s) - \langle \hat{S} \rangle(T(s))$. Thus the quadratic variation of S_2 is given by $\langle S_2 \rangle(t) = \langle \hat{S}_2 \rangle(T(t))$. The representation (48) now follows on using Theorem 5.4, Lemma 4.3, and (51). By the martingale representation theorem (e.g., Theorem 3.4.2 in [17]) it now follows that there exists a one-dimensional Brownian motion W, possibly defined on an enlarged probability space, that is, a martingale with respect to an enlargement of the filtration $\{\mathcal{F}_0(t)\}$ and is such that (49) holds.

The $\{\mathcal{F}_0(t)\}$-progressive measurability (respectively, adaptedness) of C (respectively, M and N) follows from the $\{\hat{\mathcal{F}}(t)\}$-progressive measurability of $\hat{C}$ (respectively, adaptedness of $\hat{M}$ and $\hat{N}$). Also, since $\hat{C}$ takes values in $[0, p]$, the same is true of C. Right continuity of M and N is a consequence of the fact that $\hat{M}$ and $\hat{N}$ are continuous and T is right continuous. This proves 3. Part 4 is once more an immediate consequence of Theorem 5.4 (part (5)) and Lemma 4.3. □

Until now the parameters ℓ, p have been fixed and thus excluded from the notation. It is convenient to include these parameters in the notation for the remainder of this section.

Convergence of the value functions. Let $z \in \mathbb{S}_\ell$ and let $\{z_h, h > 0\}$ be a sequence with $z_h \in \mathbb{S}_\ell^h$ such that $z_h \to z$ as $h \to 0$. Recall the definitions of $V_{\ell,p}(z)$ in (9) and $V^h(z_h)$ in (25). Our main goal in this section is to show that $V^h(z_h) \to V_{\ell,p}(z)$ as $h \to 0$. We begin with the following proposition.

PROPOSITION 5.8. *Let $\{z_h\}, z$ be as above. Then* $\limsup_{h\to 0} V^h(z_h) \le V_{\ell,p}(z)$.

Proof. Fix for each $h > 0$ an admissible control sequence for the initial condition z_h, $U^h \equiv \{U_n^h, n \ge 1\} \in \mathcal{A}^h(z_h)$. Recall the definition of $J^h(z_h, U^h)$ in (24). In order to prove the proposition it suffices to show that

$$\limsup_{h\to 0} J^h(z_h, U^h) \le V_{\ell,p}(z). \tag{53}$$

Using Lemma 4.6 and boundedness of f, we can find, for each $\epsilon \in (0,\infty)$, a $c \equiv c(\epsilon) \in (0,\infty)$ such that

$$J^h(z_h, U^h) \le \mathbb{E}\int_{[0,\hat\tau_1^h \wedge c]\times[0,p]} e^{-\beta \hat T^h(t)} f(\alpha)\hat m^h(d\alpha, dt) + \frac{\epsilon}{2}. \tag{54}$$

Let $(\hat H^h, \hat\tau_1^h, \hat m^h)$ be as in Proposition 5.3 and $(\hat H, \hat\tau_1, \hat m)$ be one of its weak limit points. Once more, as in the proof of Theorem 5.4 we can assume, by relabeling and appealing to the Skorohod representation theorem, that $(\hat H^h, \hat\tau_1^h, \hat m^h) \to (\hat H, \hat\tau_1, \hat m)$ a.s. Taking limits as $h \to 0$ in (54), we have

$$\limsup_{h\to 0} J^h(z_h, U^h) \le \mathbb{E}\int_{[0,p]\times[0,\hat\tau_1\wedge c]} e^{-\beta \hat T(t)} f(\alpha)\hat m(d\alpha, dt) + \frac{\epsilon}{2}.$$

As $\epsilon > 0$ and $c = c(\epsilon)$ are arbitrary,

$$\limsup_{h\to 0} J^h(z_h, U^h) \le \mathbb{E}\int_{[0,p]\times[0,\hat\tau_1]} e^{-\beta \hat T(t)} f(\alpha)\hat m(d\alpha, dt). \tag{55}$$

Let, as before, $\hat\tau \doteq \inf\{t \ge 0 : \hat Z(t) \notin \mathbb{S}^o\}$. Recall that $\hat\tau_1 \ge \hat\tau$. Then clearly

$$\begin{aligned}&\mathbb{E}\left[1_{\{\hat\tau=\infty\}}\int_{[0,p]\times[0,\hat\tau_1]} e^{-\beta \hat T(t)} f(\alpha)\hat m(d\alpha, dt)\right]\\ &\quad= \mathbb{E}\left[1_{\{\hat\tau=\infty\}}\int_{[0,p]\times[0,\hat\tau]} e^{-\beta \hat T(t)} f(\alpha)\hat m(d\alpha, dt)\right].\end{aligned} \tag{56}$$

Now suppose that $\hat\tau < \infty$. Let τ^* denote the first point of increase of $\hat T$ in $[\hat\tau, \hat\tau_1]$. More precisely, let $\tau^* \doteq \inf\{t \in [\hat\tau, \infty) : \hat T(t+\delta) > \hat T(t) \text{ for all } \delta > 0\} \wedge \hat\tau_1$. Note that

$$\begin{aligned}&\mathbb{E}\left[1_{\{\hat\tau<\infty\}}\int_{(\hat\tau,\hat\tau_1]} e^{-\beta \hat T(t)}\left(\int_{[0,p]} f(\alpha) d\hat m_t(d\alpha)\right) d\hat T(t)\right]\\ &\quad= \mathbb{E}\left[1_{\{\hat\tau<\infty\}}\int_{[\tau^*,\hat\tau_1]} e^{-\beta \hat T(t)}\left(\int_{[0,p]} f(\alpha) d\hat m_t(d\alpha)\right) d\hat T(t)\right].\end{aligned} \tag{57}$$

We now show that the above quantity is equal to 0. Consider the evolution of the process $\hat Z$ over the interval $[\hat\tau, \tau^*]$. By definition, $\hat Z(\hat\tau) \notin \mathbb{S}^o$. Since $\hat T$ is constant over

this time interval, we see from Theorem 5.4(2),(3) that $\hat{B}_1$ and $\hat{S}$ are both constant over this interval, and since neither v_1 nor v_2 can push the process into the interior of $\mathbb{S}$, we see that $\hat{Z}(\tau^*) \notin \mathbb{S}^o$. Define $s^* \doteq \hat{T}(\tau^*)$. Since τ^* is a point of increase of $\hat{T}$ we have $T(s^*) = T(\hat{T}(\tau^*)) = \tau^*$. Thus $Z(s^*) = \hat{Z}(\tau^*) \notin \mathbb{S}^o$, where Z is defined by (47). Consider first the case $Z(s^*) \neq 0$; then from (48), $\langle S_2 \rangle$ is strictly increasing at s^*. From this it follows that for all $\delta > 0$ there exists $s_\delta \in [s^*, s^* + \delta]$ such that $\text{dist}(Z(s_\delta), \mathbb{S}) > 0$, i.e., $\text{dist}(\hat{Z}(T(s_\delta)), \mathbb{S}) > 0$. Now since $\mathbb{S}^h \to \mathbb{S}$ and $\hat{Z}^h \to \hat{Z}$ as $h \to 0$ we have $\text{dist}(\hat{Z}^h(T(s_\delta)), \mathbb{S}^h) > 0$ for all h small enough. Therefore, by definition of $\hat{\tau}_1^h$ we must have $\hat{\tau}_1^h \leq T(s_\delta)$ for all h small enough. This implies $\hat{\tau}_1 \leq T(s_\delta)$. Now, taking $\delta \to 0$ and using the right continuity of T at s^* it follows that $\hat{\tau}_1 \leq T(s^*) = \tau^*$. Hence the quantity in (57) is equal to 0.

Finally, consider the case when $Z(s^*) = 0$ (and $\hat{\tau} < \infty$). Let $s^{**} \doteq \inf\{s > s^* | Z(s^*) \neq 0\}$. From the dynamics of Z (see (47)) it follows that for every $\delta > 0$, there exists $s_\delta \in [s^{**}, s^{**} + \delta]$ such that $\text{dist}(Z(s_\delta), \mathbb{S}) > 0$. Arguing as before, we have $\hat{\tau}_1 \leq T(s^{**})$. Define $m_t(d\alpha) \doteq \hat{m}_{T(t)}(d\alpha)$ for $t \geq 0$. Since $C(t) = 0$ for $t \in [s^*, s^{**}]$ we get that $m_t = \delta_0$ for t in this interval. Thus since $f(0) = 0$, we have $\int_{[0,p]} f(\alpha) dm_t(d\alpha) = 0$ for all $t \in [s^*, s^{**}]$. Combining this with the fact that $[\tau^*, \hat{\tau}_1] \subset [T(s^*), T(s^{**})]$ we now see that the expression in (57) is 0. Thus

$$\begin{aligned} &\mathbb{E}\left[1_{\{\hat{\tau}<\infty\}} \int_{[0,p]\times[0,\hat{\tau}_1]} e^{-\beta \hat{T}(t)} f(\alpha) \hat{m}(d\alpha, dt)\right] \\ &= \mathbb{E}\left[1_{\{\hat{\tau}<\infty\}} \int_{[0,p]\times[0,\hat{\tau}]} e^{-\beta \hat{T}(t)} f(\alpha) \hat{m}(d\alpha, dt)\right]. \end{aligned} \tag{58}$$

Combining (55), (56), and (58) we now get

$$\limsup_{h\to 0} J^h(z_h, U^h) \leq \mathbb{E} \int_{[0,\hat{\tau}]} e^{-\beta \hat{T}(t)} \left(\int_{[0,p]} f(\alpha) d\hat{m}_t(d\alpha) \right) d\hat{T}(t).$$

We next consider the time inversion. Recall that $\tau \doteq \inf\{t : Z(t) \notin \mathbb{S}^o\}$. Note that $\tau \geq \hat{T}(\hat{\tau})$. Using this inequality and Lemma 4.3 we have

$$\mathbb{E} \int_{[0,\hat{\tau}]} e^{-\beta \hat{T}(t)} \left(\int_{[0,p]} f(\alpha) d\hat{m}_t(d\alpha) \right) d\hat{T}(t) \leq \mathbb{E} \int_{[0,\tau]} e^{-\beta t} \left(\int_{[0,p]} f(\alpha) dm_t(d\alpha) \right) dt.$$

Inequality (53) now follows from the above inequality and Remark 5.7. □

We now proceed to the proof of the reverse inequality

$$\liminf_{h\to 0} V^h(z_h) \geq V_{\ell,p}(z). \tag{59}$$

We begin with the following lemma which allows us to restrict our attention to controls that have several simplifying features. The proof is contained in the appendix. Recall the definition of an admissible control above Proposition 2.2 and the corresponding cost defined above (9).

LEMMA 5.9. *Let Φ be a probability system and $U \in \mathcal{A}_p(\Phi, z)$ be a control with corresponding cost function $J_\ell(z, U)$. Then for any $\delta > 0$ there exists $U_\delta \in \mathcal{A}_p(\Phi, z)$ such that $|J_\ell(z, U) - J_\ell(z, U_\delta)| < \delta$ and U_δ satisfies the following:*

1. *There exists $T \in (0, \infty)$ such that $M_\delta(t) = M_\delta(T), N_\delta(t) = N_\delta(T)$, and $C_\delta(t) = 0$ for all $t \geq T$.*

2. *There exists* $L \in (0,\infty)$ *such that*

$$\sup_{0\le t<\infty}\sup_{\omega}(M_\delta(t\wedge\tau,\omega)+N_\delta(t\wedge\tau,\omega))\le L.$$

3. *There exist* $\eta,\theta\in(0,\infty)$ *and* $K\in\mathbb{N}$ *such that* $C(t),M(t),N(t)$ *take values in the finite set* $\{k\eta : k=0,1,2,\dots,K\}$. *Furthermore,* $C,M,$ *and* N *are piecewise constant with possible time points of change being* $\{0,\theta,2\theta,3\theta,\dots\}$.
4. *There exists a* $\gamma\in(0,\infty)$ *such that* θ *is an integer multiple of* γ *and the chosen control* $U=(C,M,N)$ *satisfies the following equality for* $m\ge 1$*:*

$$\begin{aligned}&\mathbb{P}[(C(m\theta),\delta M(m\theta),\delta N(m\theta))=k\eta|U(s),s<m\theta;W(s),s\le m\theta]\\&\quad=\mathbb{P}[(C(m\theta),\delta M(m\theta),\delta N(m\theta))=k\eta|U(n\theta),n<m;W(l\gamma),l\gamma\le m\theta],\end{aligned}\tag{60}$$

where $k=(k_1,k_2,k_3)$ *and* k_1,k_2,k_3 *are integers, at most one of which is nonzero.*
5. *Denoting for* $m\ge 1$, $\Psi(m)\doteq\{C(n\theta),\delta M(n\theta),\delta N(n\theta),n<m\}$, $\mathcal{W}(m)\doteq\{W(l\gamma),l\gamma\le m\theta\}$, *and* $k\doteq(k_1,k_2,k_3)$, *rewrite the above probability as*

$$\begin{aligned}&\mathbb{P}[C(m\theta)=k_1\eta,\delta M(m\theta)=k_2\eta,\delta N(m\theta)=k_3\eta|\Psi(m),\mathcal{W}(m)]\\&\quad\doteq q_{m,k}(\Psi(m),z,\mathcal{W}(m)).\end{aligned}\tag{61}$$

Denote $\mathbb{P}[U(0)=(k_1\eta,k_2\eta,k_3\eta)]$ *by* $q_{0,k}(z)$. *For each* $m\ge 0$, *the function* $q_{m,k}$ *can be chosen so that the function* $(z,w)\to q_{m,k}(\psi,z,w)$ *is continuous for every* ψ.

Construction of asymptotically near optimal admissible controls for the MDP. Fix a probability system Φ, $z\in\mathbb{S}_\ell$, and a sequence $\{z_h\}$ such that $z_h\in\mathbb{S}^h$ and $z_h\to z$ as $h\to 0$. Let $\epsilon>0$ be arbitrary. Let $U\in\mathcal{A}_p(\Phi,z)$ be such that U satisfies properties 1–5 of Lemma 5.9 and $V_{\ell,p}(z)-\epsilon\le J_\ell(z,U)$. For each $h>0$, we construct from U an admissible control sequence $\{U_n^h,n\ge 0\}$ for the MDP in Definition 3.1 with initial condition z_h such that the cost for U^h asymptotically agrees with the cost of U. We outline below the main steps in the construction of such a control sequence. Let $\mathcal{K}\doteq\{(k_1,k_2,k_3) : k_i=0,1,\dots,K; i=1,2,3$ such that at most one of k_1,k_2,k_3 is positive$\}$.

Step 1. We begin by taking a random draw, denoted by $\kappa=(\kappa_1,\kappa_2,\kappa_3)$, from the probability distribution $\{q_{0,k}(z_h),k\in\mathcal{K}\}$. Set $\tilde{U}_0^h=\kappa\eta$, $Z_0^h=z_h$, and $\Psi^h(1)\doteq\tilde{U}_0^h$. Also set $\tilde{n}_0=0$. Note that at most one of κ_2 and κ_3 will be nonzero. If both κ_2 and κ_3 are 0, set $n_1=0$, skip Step 2 below and go to Step 3. Otherwise proceed to Step 2.

Step 2(A). Recall the kernel p_h defined in (21). If $\kappa_2>0$, let $U_0^h=(1,0)$ and take a random draw, denoted by Z_1^h, from $p_h(Z_0^h,U_0^h,d\tilde{z})$. We express this as "the chain takes a purchase control step." If $Z_1^h\in\partial_{\mathrm{R}}^h$, we set $U_1^h=(3,0)$ and draw Z_2^h from $p_h(Z_1^h,U_1^h,d\tilde{z})$; i.e., the chain takes a reflection step. Otherwise set $U_1^h=(1,0)$ and draw Z_2^h from $p_h(Z_1^h,U_1^h,d\tilde{z})$. Define (U_n^h,Z_n^h), $n=1,2,\dots$, recursively by taking either a purchase control step or, if needed, a reflection step, until a total of $[\kappa_2\eta/h]$ purchase control steps have been taken. Denote by n_1 the index of the state after the last purchase control has been exercised.

Step 2(B). If $\kappa_3>0$, let $U_0^h=(2,0)$ (that is, the chain takes a sales control step) and proceed as in Step 2(A) above, alternating sales control steps and reflection

steps (when needed) until $[\kappa_3\eta/h]$ sales control steps have been taken. Again, let n_1 denote the index of the state after the last sales control has been exercised.

Step 3. If $Z^h_{n_1} \in \partial^h_{\mathrm{R}}$, set $U^h_{n_1} = (3,0)$, and the chain takes a reflection step. Otherwise set $U^h_{n_1} = (0, \kappa_1\eta)$ and draw $Z^h_{n_1+1}$ from $p_h(Z^h_{n_1}, U^h_{n_1}, d\tilde{z})$; i.e., the chain takes a diffusion step with $c = \kappa_1\eta$. Let t^h_n be as defined below (23). Define $(U^h_n, Z^h_{n+1}, n = n_1, n_1+1, n_1+2, \ldots, \tilde{n}_1 - 1$ recursively, where $\tilde{n}_1 \doteq \inf\{n : t^h_n \geq \theta\}$, as follows. If $Z^h_n \in \partial^h_{\mathrm{R}}$, set $U^h_n = (3,0)$; otherwise set it to be $(0, \kappa_1\eta)$. Draw Z^h_{n+1} from $p_h(Z^h_n, U^h_n, d\tilde{z})$.

Step 4. Next we define the "pre-Wiener process" that is needed to obtain the control at the next step. Let $\{\nu_n, n \geq 1\}$ be an independent, identically distributed (i.i.d.) sequence of $N(0,1)$ random variables, independent of $(U^h_n, Z^h_{n+1})_{n=0}^{\tilde{n}_1-1}$. Define S^h_n for $n \leq \tilde{n}_1 - 1$ as in (26); here we consider only the second component $S^h_{n,2}$. Set $\mathcal{S}^h_0 \equiv 0$, and for $\tilde{n}_0 < n \leq \tilde{n}_1 - 1$,

$$\mathcal{S}^h_n \doteq \frac{S^h_{n+1,2} - S^h_{n,2}}{\sigma Y^h_n} 1_{\{|Y^h_n| \neq 0\}} + \nu_n \sqrt{\Delta^h_n} 1_{\{|Y^h_n| = 0\}}.$$

Next define $W^h_{\tilde{n}_0} = 0$ and $W^h_n \doteq W^h_{\tilde{n}_0} + \sum_{i=0}^{n-1} \mathcal{S}^h_i$. Now define for $0 \leq t \leq \theta$,

$$W^h(t) \doteq W^h_{n^h(t)} - W^h_{\tilde{n}_0}. \tag{62}$$

Finally, define $\mathcal{W}^h(1) \doteq \{W^h(l\gamma), l \in \mathbb{N}_0, l\gamma \leq \theta\}$.

Step 5. Suppose we have, for $j = 1, \ldots, m$, defined $\tilde{n}_j \doteq \inf\{n : t^h_n \geq j\theta\}$; (Z^h_{n+1}, U^h_n), $n = 0, 1, \ldots, \tilde{n}_j - 1$; $\Psi^h(j)$; and $\mathcal{W}^h(j)$. Consider now the case $j = m+1$. Take a random draw, denoted once more by $\kappa = (\kappa_1, \kappa_2, \kappa_3)$, from $\{q_{m,k}(\Psi^h(m), z_h, \mathcal{W}^h(m)),\ k \in \mathcal{K}\}$. Set $\tilde{U}^h_m = \kappa\eta$ and $\Psi^h(m+1) = (\tilde{U}^h_0, \ldots, \tilde{U}^h_m)$. Follow Step 2 with $\tilde{U}^h_0$ replaced by $\tilde{U}^h_m$ and the starting index of U^h replaced with $\tilde{n}_m$. Denote by n_{m+1} the index of the state obtained after the last singular control step in Step 2. Follow Step 3 with n_1 replaced by n_{m+1}. Let $\tilde{n}_{m+1} = \inf\{n : t^h_n \geq (m+1)\theta\}$. This defines $(Z^h_{n+1}, U^h_n), i = 0, 1, \ldots, \tilde{n}_{m+1} - 1$. Define $W^h(t) - W^h(m\theta)$, for $t \in [m\theta, (m+1)\theta)$, by the right side of (62) as in Step 4 with $\tilde{n}_0, \tilde{n}_1$ replaced by $\tilde{n}_m, \tilde{n}_{m+1}$, respectively. Now set $\mathcal{W}^h(m+1) \doteq \{W^h(l\gamma), l \in \mathbb{N}, l\gamma \leq (m+1)\theta\}$.

Noting that $\tilde{n}_m$ is strictly increasing in m, we obtain the controlled chain $\{(Z^h_n, U^h_n)$, $n = 0, 1, 2, \ldots\}$ via the recursion:

$$(\{(Z^h_{n+1}, U^h_n)\}_{n=0}^{\tilde{n}_m-1}, \Psi^h(m), \mathcal{W}^h(m)) \to (\{(Z^h_{n+1}, U^h_n)\}_{n=0}^{\tilde{n}_{m+1}-1}, \Psi^h(m+1), \mathcal{W}^h(m+1)).$$

The main step in the proof of (59) is showing that if interpolated processes (Z^h, U^h) using the above control sequence are defined as below (25) and W^h is defined by (62), then as $h \to 0$,

$$(Z^h, U^h, W^h) \text{ converges weakly in } D([0,\infty) : \mathbb{R}^5) \text{ to } (Z, U, W), \tag{63}$$

where W is a standard Brownian motion and Z is defined by (7) with the initial condition $Z(0-) = z$. This convergence is established by proving convergence over the period $[j\theta, (j+1)\theta)$ for each j in a recursive manner. Note that given the initial condition $Z(j\theta-) = z$ and the control value $U(j\theta) = k\eta$, the dynamics of Z for $t \in [j\theta, (j+1)\theta)$ are particularly simple and are given as

$$\begin{aligned} X(t) &= x + (1-\mu)\kappa_3\eta - (1+\lambda)\kappa_2\eta + \int_{j\theta}^t (rX(s) - \kappa_1\eta)ds, \\ Y(t) &= y + \kappa_2\eta - \kappa_3\eta + \int_{j\theta}^t bY(s)ds + \int_{j\theta}^t \sigma Y(s)dW(s). \end{aligned} \tag{64}$$

The following lemma provides the convergence of (Z^h, U^h, W^h) over one fixed period $[j\theta, (j+1)\theta)$ given the initial data at $j\theta$. The proof follows via straightforward weak convergence arguments and thus is omitted.

LEMMA 5.10. *Fix $z \in \mathbb{S}_\ell$ and let $k = (k_1, k_2, k_3) \in \mathcal{K}$. Let $(Z(t), W(t))$ given on some probability system Φ be defined for $t \in [0, \theta]$ by (7) with $Z(0-) = z$ and $(C(t), M(t), N(t)) = k\eta$ for $t \in [0, \theta]$. Consider a sequence $\{z_h\}$ such that $z_h \in \mathbb{S}^h$ and $z_h \to z$ as $h \to 0$. Define $\tilde{n}_1$ and the sequence $\{U_n^h, Z_n^h\}_{n=0}^{\tilde{n}_1}$ via Steps 2 and 3 and $\{S_n^h, W_n^h\}_{n=0}^{\tilde{n}_1}$ by Step 4. Let $\{\delta_h\}$ be a sequence of nonnegative reals such that $\delta_h \to 0$ as $h \to 0$. Define, for $t \in [0, \theta]$, the interpolated process (Z^h, W^h, U^h, E^h) as before (see (62) and below (26)) with the change that $\Delta^h(Z_0^h, U_0^h)$ is replaced with $\delta_h + \Delta^h(Z_0^h, U_0^h)$. Denote the laws of (Z^h, W^h, U^h) and (Z, W, U) on $D([0, \theta] : \mathbb{R}^5)$ by Π_h^{k,δ_h} and Π^k, respectively. Then $\Pi_h^{k,\delta_h} \to \Pi^k$ as $h \to 0$.*

In the following proposition we show that the cost, $J^h(z_h, U^h)$, corresponding to the above constructed control sequence, converges to $J_\ell(z, U)$ as $h \to 0$. The desired inequality in (59) then follows since $V^h(z_h) \geq J^h(z_h, U^h)$, $J_\ell(z, U) \geq V_{\ell,p}(z) - \epsilon$,and $\epsilon > 0$ is arbitrary.

PROPOSITION 5.11. *Let $\epsilon > 0$ be arbitrary and fix $z \in \mathbb{S}_\ell$. Let Φ be a probability system and $U \equiv U(\epsilon) \in \mathcal{A}_p(\Phi, z)$ be such that U satisfies properties 1–5 of Lemma 5.9 and $V_{\ell,p}(z) - \epsilon \leq J_\ell(z, U)$. Let, for each $h > 0$, $\{U_n^h\}$ be an admissible control sequence as constructed via Steps 1–5 above. Then $J^h(z_h, U^h) \to J_\ell(z, U)$ as $h \to 0$, and consequently (59) holds.*

Proof. For $t \geq 0$, let $n^h(t), Z^h(t), M^h(t), N^h(t), C^h(t)$ be as defined below (25). Define $U^h \equiv (M^h, N^h, C^h)$ and let W^h be as in (62). We begin by establishing (63). Define for $j \in \mathbb{N}_0$ and $t \in [0, \theta)$,

$$U_j^h(t) \doteq U^h(t + j\theta),\ Z_j^h(t) \doteq Z^h(t + j\theta),\ W_j^h(t) \doteq W^h(t + j\theta) - W^h(j\theta),$$

and set $(U_j^h(\theta), Z_j^h(\theta), W_j^h(\theta)) = (U_j^h(\theta-), Z_j^h(\theta-), W_j^h(\theta-))$. Define processes U_j, Z_j, W_j, $j \in \mathbb{N}_0$, in a similar manner. Recall the sequence $\{U_j^h\}$ constructed above Lemma 5.10 and let $\zeta_j^h \doteq (\tilde{U}_j^h, U_j^h, W_j^h, Z_j^h)$, $\zeta_j \doteq (\tilde{U}_j, U_j, W_j, Z_j)$, where $\tilde{U}_j \doteq (C(j\theta), \delta M(j\theta), \delta N(j\theta))$, $j \in \mathbb{N}_0$. Due to the piecewise constant feature of the control U, in order to prove (63), it suffices to show that

$$\text{for all } n \in \mathbb{N}_0,\ \Upsilon_h^n \doteq \{\zeta_j^h\}_{j=0}^n \text{ converges weakly to } \Upsilon \doteq \{\zeta_j\}_{j=0}^n \text{ as } h \to 0. \tag{65}$$

We will prove (65) via induction (on n). The case $n = 0$ is immediate from Lemma 5.10 and continuity of the kernel $q_{0,k}$ on noting that for $k \in \mathcal{K}$ and $E \in \mathcal{B}(D([0, \theta], \mathbb{R}^5)$,

$$\mathbb{P}(\tilde{U}_0^h = k\eta, (U_0^h, W_0^h, Z_0^h) \in E) = q_{0,k}(z_h)\Pi_h^{k,0}(E),$$
$$\mathbb{P}(\tilde{U}_0 = k\eta, (U_0, W_0, Z_0) \in E) = q_{0,k}(z)\Pi^k(E).$$

Suppose now that (65) holds for $n = 0, \ldots, m$ and consider the case $n = m + 1$. Denote the law of Υ_n^h, Υ_n by ϖ_n^h and ϖ, respectively. By the induction hypothesis, $\varpi_m^h \to \varpi_m$ as $h \to 0$. Furthermore, ϖ_{m+1}^h can be expanded in terms of ϖ_m^h as follows:

$$d\varpi_{m+1}^h(\upsilon_{m+1}) = \sum_{k \in \mathcal{K}} q_{m+1,k}(z_h, \tilde{u}^{*,m}, w^{*,m}) \Pi_h^{k,\delta_h(\upsilon_m)}(\varsigma_{m+1}) d\varpi_m^h(\upsilon_m), \tag{66}$$

where $\upsilon_m = \{\varsigma_j\}_{j=0}^m$; $\varsigma_j = (\tilde{u}_j, u_j, w_j, z_j)$; $\tilde{u}_j = k\eta, k \in \mathcal{K}$; $(u_j, w_j, z_j) \in D([0, \theta] : \mathbb{R}^5)$; $\tilde{u}^{*,m} = \{\tilde{u}_j\}_{j=0}^m$; $w^{*,m} = \{w_j(l\gamma), l \in \mathbb{N}, l\gamma \leq \theta\}_{j=0}^m$; and δ_h is a measurable map from the state space of Υ_m to $[0, 1]$ satisfying $0 \leq \delta_h(\upsilon_m) \leq \tilde{\Delta}_*^h$.

From the continuity properties of the kernel $\{q_{m+1,k}\}$ and the weak convergence of ϖ_m to ϖ, we have for all continuous and bounded functions F_1, F_2 defined on suitable spaces, as $h \to 0$,

$$\int F_1(\upsilon_m) \sum_{k\in\mathcal{K}} q_{m+1,k}(z, \tilde{u}^{*,m}, w^{*,m}) \left(\int F_2(\zeta_{m+1}) d\Pi^k(\zeta_{m+1}) \right) d\varpi_m^h(\upsilon_m)$$

$$\to \int F_1(\upsilon_m) \sum_{k\in\mathcal{K}} q_{m+1,k}(z, \tilde{u}^{*,m}, w^{*,m}) \left(\int F_2(\zeta_{m+1}) d\Pi^k(\zeta_{m+1}) \right) d\varpi_m(\upsilon_m). \tag{67}$$

Next, from Lemma 5.10, for all sequences $\{\delta_h\}$ converging to 0 and compact sets E (of Euclidean space of appropriate dimension), as $h \to 0$,

$$\sup_{k\in\mathcal{K}, \tilde{u}^{*,m}\in\eta\mathcal{K}^{m+1}, w^{*,m}\in E} \left| \int F_2(\zeta_{m+1}) q_{m+1,k}(z_h, \tilde{u}^{*,m}, w^{*,m}) d\Pi_h^{k,\delta_h}(\zeta_{m+1}) \right.$$

$$\left. - \int F_2(\zeta_{m+1}) q_{m+1,k}(z_h, \tilde{u}^{*,m}, w^{*,m}) d\Pi^k(\zeta_{m+1}) \right| \to 0. \tag{68}$$

The weak convergence of ϖ_{m+1}^h to ϖ_{m+1} now follows on combining (66), (67), and (68). This proves (63).

We now address convergence of the cost functions. First, let T be as in Lemma 5.9. Recall $\eta^h = \inf\{n \geq 0 : Z_n^h \in \partial^h\}$ and $\tau^h = t_{\eta^h}^h$. Note that $\tau^h = \inf\{t \geq 0 : Z^h(t) \in \partial^h\}$ due to the piecewise constant nature of $Z^h(t)$.

Let $\tau = \inf\{t \geq 0 : Z(t) \notin \mathbb{S}^o\}$. It can be shown in a manner similar to that used in the proof of Lemma 5.1 that $\tau^h \to \tau$ as $h \to 0$ on the set $\{\tau = \infty\}$. Also, on the set $\{\tau < \infty\}$ for every $\delta > 0$ there exists $t \in [\tau, \tau + \delta)$ and $\epsilon > 0$ such that $\mathrm{dist}(Z(t), \mathbb{S}) > \epsilon$. Furthermore, $|Z^h(t) - Z(t)|$ uniformly on $[0, T]$ and $\partial^h \to \partial\mathbb{S}$ as $h \to 0$. Together these three facts imply $\tau^h \wedge T \to \tau \wedge T$ as $h \to 0$. Therefore, since $(z_h, Z^h, U^h, W^h, \tau^h) \to (z, Z, U, W, \tau)$, by the dominated convergence theorem,

$$J^h(z_h, U^h) = \mathbb{E} \int_{[0,\tau^h\wedge T)} e^{-\beta t} f(C^h(t)) dt \to \mathbb{E} \int_{[0,\tau\wedge T)} e^{-\beta t} f(C(t)) dt = J_\ell(z, U). \qquad \square$$

Combining Corollary 2.5 and Propositions 5.8 and 5.11 we have the following theorem.

THEOREM 5.12. *Let $z \in \mathbb{S}$ and let $\{z_h, h > 0\}$ be a sequence with $z_h \in \mathbb{S}_\ell^h$ such that $z_h \to z$ as $h \to 0$. Then $\lim_{p\to\infty} \lim_{\ell\to\infty} \lim_{h\to 0} V^h(z^h) = \lim_{p\to\infty} \lim_{\ell\to\infty} V_{\ell,p}(z) = V(z)$.*

6. Computational methods for the MDP. The convergence results in the previous section ensure that for small values of h, the MDP defined in section 3 provides a good approximation to the diffusion control problem defined in section 2. In this section we outline the numerical methods for solving the MDP. Specifically, we provide the algorithm through which we compute the value function (25) and the associated optimal control for each initial state $z_h \in \mathbb{S}_\ell^h$. In practice, we fix a value of h and use the associated MDP to provide approximations to the diffusion control problem. Thus, for the remainder of the section, we will take h as a fixed value and suppress it in the notation.

Specifying the controlled Markov chain. In section 3, we specified a choice of transition probabilities and interpolation intervals which satisfy the local consistency criteria; see (15)–(17) and (20). Many variations of this choice are possible; when

specifying the particular controlled Markov chain, consideration must be given to the numerical implementation. For example, note that neither the denominators of the probabilities nor the interpolation intervals in (15) depend on the value of c. This was accomplished by allowing the self-transition (x, y) to (x, y). Also, we have separated the pure diffusion effects from the effects of the consumption control. That is, as consumption always decreases wealth, we associate it with only the transition from (x, y) to $(x - h, y)$. Recall that $\Delta(z, u) = 0$ for all z if $u = (3, c)$; that is, the interpolation interval is 0 if reflection occurs. Hence, using (24), a reflection step incurs no cost and thus $V(\ell + h, y) = V(\ell, y), V(x, \ell + h) = V(x, \ell)$. It is a consequence of Definition 3.1 that $\mathbb{P}[I_n = 3 | Z_n \in \partial_{\mathrm{R}} \setminus \partial^h] = 1$ for all n; that is, reflection is the only admissible action for states in the reflecting boundary. Therefore, by adjusting the transition probabilities associated with the diffusion and singular controls, it is possible to eliminate states in the reflecting boundary without affecting the cost function. This modification helps in speeding up the convergence of the numerical scheme.

In what follows, we will assume that the reflecting boundary states have been eliminated and the appropriate adjustments to the transition probabilities made. Thus, the state space of the controlled Markov chain used in the numerical schemes is given by $\mathbb{S}_{\mathrm{MDP}} \doteq \mathbb{S}_\ell^{h+} \setminus \partial_{\mathrm{R}}$, and the control space is $\mathcal{U}_{\mathrm{MDP}} \doteq \{0, 1, 2\} \times [0, p]$.

Dynamic programming equation. Let $U \equiv \{U_n, n = 0, 1, 2, \dots\}$ be an admissible control sequence (see Definition 3.1) for the MDP with state space $\mathbb{S}_{\mathrm{MDP}}$, control space $\mathcal{U}_{\mathrm{MDP}}$, and initial state z. For the numerical methods it is convenient to work with the cost function

$$J(z, U) = \mathbb{E} \sum_{n=0}^{\eta-1} e^{-\beta t_n} f(C_n) \tilde{\Delta}(Z_n, C_n) 1_{\{I_n = 0\}}, \tag{69}$$

which is asymptotically equivalent to (24). Recall that the value function is given as $V(z) = \sup_{U \in \mathcal{A}(z)} J(z, U)$.

We now present the dynamic programming equation that characterizes the value function. We begin by introducing the class of feedback controls. A *feedback control* is a measurable function $\mathbf{u} : \mathbb{S}_{\mathrm{MDP}} \to \mathcal{U}_{\mathrm{MDP}}$. We write $\mathbf{u} = (\mathbf{i}, \mathbf{c})$, where $\mathbf{i}$ and $\mathbf{c}$ are the two coordinates of the function $\mathbf{u}$. Using such a function one can construct an admissible control pair (Z_n, U_n) recursively by setting $Z_0 = z_0$, $U_n = \mathbf{u}(Z_n), n \geq 0$, and

$$\mathbb{P}[Z_{n+1} \in \cdot | Z_0, \dots, Z_n, U_0, \dots, U_n] = p(Z_n, U_n, \cdot).$$

With an abuse of terminology we will refer to this sequence $\{U_n\}$ as a feedback control as well. Note that $U_n \equiv (I_n, C_n) = (\mathbf{i}(Z_n), \mathbf{c}(Z_n))$.

If $U = \{U_n, n = 0, 1, 2, \dots\}$ is a feedback control, then one can easily check that the pair (Z_n, U_n) is a Markov chain, from which it follows that for all $z \in \mathbb{S}_{\mathrm{MDP}}$,

$$J(z, U) = \sum_{\tilde{z} \in \mathbb{S}_{\mathrm{MDP}}} r(z, \mathbf{u}(z), \tilde{z}) J(\tilde{z}, U) + f(\mathbf{c}(z)) \Delta^h(z, \mathbf{u}(z)), \tag{70}$$

where $r(z, \mathbf{u}(z), \tilde{z}) = e^{-\beta \Delta(z, \mathbf{u}(z))} p(z, \mathbf{u}(z), \tilde{z})$. Observing that $J(z, U) = 0$ for all $z \in \partial^h$, the summation above can be taken over $\tilde{z} \in \mathbb{S}^* \doteq \mathbb{S}_{\mathrm{MDP}} \setminus \partial^h$.

We can write the above equality in matrix form as follows. Let $|\mathbb{S}^*| = s$ and fix an ordering of all the states in $\mathbb{S}^*$, i.e., $\mathbb{S}^* = \{z_1, \dots, z_s\}$. Let $F(\mathbf{u})$ be an $s \times 1$ vector

whose ith entry is $f(\mathbf{c}(z_i))\Delta(z_i,\mathbf{u}(z_i)), i=1,\dots,s$. Let $R(\mathbf{u})$ be the $s\times s$ matrix with the (i,j)th entry as $r(z_i,\mathbf{u}(z_i),z_j)$. Finally, let $J(\mathbf{u})$ be the $s\times 1$ vector with the ith entry being $J(z_i,U)$. Then using these matrices, (70) can be written as

$$J(\mathbf{u}) = R(\mathbf{u})J(\mathbf{u}) + F(\mathbf{u}). \tag{71}$$

Next, for $u\in\mathcal{U}_{\mathrm{MDP}}$ let $R(u)$ be the $s\times s$ matrix with (i,j)th entry $r(z_i,u,z_j)$. From standard arguments (cf. section 5.8 in [19]) it follows that the value function V satisfies the following dynamic programming equation:

$$V = \sup_{u\in\mathcal{U}_{\mathrm{MDP}}} R(u)V + F(u), \tag{72}$$

where in the above equation V is interpreted as an $s\times 1$ vector whose ith entry is $V(z_i)$, and the supremum on the right-hand side above is taken row by row.

The following contraction property is central in the characterization of the value function via the dynamic programming equation in (72). The proof of the following lemma relies on the fact that the cost is of the discounted form with a strictly positive discount factor at all diffusion control steps, and although the discount is zero for singular control steps, such steps tend to push the process towards the boundary of the domain and thus cannot occur "too often."

LEMMA 6.1. *For all feedback controls* $\mathbf{u}$, $R^n(\mathbf{u})\to 0$ *as* $n\to\infty$.

Proof. Let $\mathbf{u}$ be a feedback control and denote $R^n(\mathbf{u})$ by simply R^n with entries r^n_{ij}, $i,j=1,\dots,s$. It suffices to show $\sum_{j=1}^s r^n_{ij}\to 0$ as $n\to\infty$, for each $i=1,\dots,s$.

Let (Z_n,U_n) be the controlled Markov chain associated with feedback control $\mathbf{u}$ and a transition kernel as defined in section 3 with the modifications discussed in this section, and let $\Delta_k\equiv\Delta(Z_k,U_k)$ be the associated interpolation intervals. Let $\eta\doteq\inf\{n: Z_n\in\partial^h\}$. A simple calculation yields for all $i=1,\dots,s$:

$$\sum_{j=1}^s r^n_{ij} = \mathbb{E}_i\left[e^{-\beta\sum_{k=0}^{n-1}\Delta_k}\sum_{j=1}^s 1_{\{Z_n=z_j\}}\right],$$

where $\mathbb{E}_i$ denotes the expectation given that $Z_0=z_i$.

Since the states in ∂^h are not included in $\mathbb{S}^*$ and $p(z,\mathbf{u}(z),z)=1$ for $z\in\partial^h$, we have $1_{\{Z_n=z_j\}}=0$ for $j=1,\dots,s$ when $n\ge\eta$. Thus we have

$$\sum_{j=1}^s r^n_{ij} = \mathbb{E}_i\left[1_{\{n<\eta\}}\sum_{j=1}^s e^{-\beta\sum_{k=0}^{n-1}\Delta_k}1_{\{Z_n=z_j\}}\right]. \tag{73}$$

Fix $a\in\mathbb{Z}_+$; conditions on a will be specified later. Define

$$\tilde{d}\doteq\#\{\theta\in\{1,2,\dots,[n/a]\}: U_m=(0,\cdot)\text{ for some } m\in[(\theta-1)a,\theta a)\}.$$

Set $\tilde{d}'=[n/a]-\tilde{d}$. The integer a is used to group the steps of the chain from 1 to n together into intervals. The quantity $\tilde{d}$, ($\tilde{d}'$) counts the number of such intervals with at least one diffusion step (respectively, no diffusion steps). By (14) there is a $\delta>0$ such that $\Delta_n\ge\delta$ for all diffusion steps (i.e., all n such that $U_n=(0,\cdot)$). Also, recall that $\Delta_n=0$ if step n is not a diffusion step. Combining these observations, we have

$$\mathbb{E}_i\left[1_{\{n<\eta\}}e^{-\beta\sum_{k=0}^{n-1}\Delta_k}\sum_{j=1}^s 1_{\{Z_n=z_j\}}\right] \le e^{-\beta\frac{\delta}{4}[\frac{n}{a}]} + \mathbb{E}_i\left[1_{\{n<\eta\}}1_{\{\tilde{d}'>\frac{3}{4}[\frac{n}{a}]\}}\right]. \tag{74}$$

We will utilize the behavior of the singular controls to bound the second term on the right-hand side of the line above. Let $E_1, E_2, \ldots, E_{\tilde{d}'}$ denote the intervals containing no diffusion steps, each of size a. Let K_d denote the number of purchase control steps in E_d; then $a - K_d$ is the number of sales control steps in E_d. Due to the finiteness of the state space, the maximum number of successive transitions to the left is bounded; in particular, it is bounded by $B \doteq 2(\ell/h+1)$. Similarly, B is a bound on the maximum number of downward transitions in a row. From (17) we see that each sales control always pushes the chain downward. Thus the application of too many sales controls in a row will cause the chain to hit the boundary. However, by (16) a purchase control potentially pushes the chain upward. Similarly, a purchase control always pushes the chain to the left, while a sales control has the potential to push the chain to the right. Thus in order to avoid hitting the boundary, the number of sales controls must be properly balanced by the number of purchase controls. More precisely, if $n < \eta$, we must have $|K_d - (a - K_d)| < B$; that is, $(a-B)/2 < K_d < (a+b)/2,\ d = 1, \ldots, \tilde{d}'$. For $m \in E_d$ define $\tilde{L}_m \doteq 1_{\{Z_{m+1} - Z_m = (-h,0)', U_m = (1,0)\}}$. The random variable $\tilde{L}_m$ indicates if the chain moves strictly to the left at step m given that a purchase control is applied. Since on E_d there are no diffusion steps and movement to the left is possible only at purchase control steps, the number of increments δZ_k equal to $(-h, 0)'$ on E_d is given by $\sum_{m \in E_d} \tilde{L}_m \doteq L_d$.

Let ϵ be chosen to satisfy $0 < \epsilon < p/2$. Recall that at a purchase control step the chain moves to the left with probability $q \doteq \lambda/(1+\lambda)$. Thus by Cramer's theorem (see Theorem 2.1.24 in [8]) there exists a $\kappa \equiv \kappa(\epsilon)$ such that

$$\mathbb{P}[L_d < K_d(q-\epsilon)] \le \mathbb{P}\left[\left|\frac{L_d}{K_d} - q\right| > \epsilon\right] \le e^{-K_d\kappa} \le e^{-\kappa(a-B)/2}, \tag{75}$$

where the last inequality follows from the bound on K_d. We claim that for each $d = 1, \ldots, \tilde{d}'$, $\{\eta < n\} \cap \{L_d > qK_d/2\} = \emptyset$. To see the claim suppose that $L_d > qK_d/2$. Then the number of upward steps ($\delta Z_k = (\cdot, h)'$) in E_d, given by $K_d - L_d$, is at most $(1 - q/2)K_d$. The number of downward steps ($\delta Z_k = (\cdot, -h)'$) in E_d equals the number of sales control steps, $a - K_d$. Thus using the bounds on K_d, we have

$$\#\{\text{down steps in } E_d\} - \#\{\text{up steps in } E_d\} \ge a - K_d - (1-q/2)K_d \ \ge\ aq/4 - (1+q/4)B,$$

which is greater than B for $a > B(4+q)/q$. Henceforth fix such an a. On the other hand, on the set $\{\eta < n\}$ we must have $|\#\{\text{down steps in } E_d\} - \#\{\text{up steps in } E_d\}| < B$; otherwise, the chain would hit the boundary. This leads to a contradiction and thus the claim holds. Combining this with (75) we have that

$$\begin{aligned}
\mathbb{E}_i\left[1_{\{n<\eta\}} 1_{\{\tilde{d}' > \frac{3}{4}[\frac{n}{a}]\}}\right] &= \mathbb{E}_i\left[1_{\{n<\eta, \tilde{d}' > \frac{3}{4}[\frac{n}{a}]\}} \prod_{d=1}^{\tilde{d}'} 1_{\{L_d \le qK_d/2\}}\right] \\
&\le \mathbb{E}_i\left[\prod_{d=1}^{\frac{3}{4}[\frac{n}{a}]} 1_{\{L_d \le qK_d/2\}}\right] \\
&\le e^{-\kappa \frac{a-B}{2} \frac{3}{4}[\frac{n}{a}]}.
\end{aligned}$$

Finally, by (73), (74), and the above, we have $\sum_{j=1}^{s} r_{ij}^n \le e^{-\beta \frac{\delta}{4}[\frac{n}{a}]} + e^{-\kappa \frac{a-B}{2} \frac{3}{4}[\frac{n}{a}]}$. The result now follows on noting that the term on the right approaches 0 as $n \to \infty$. □

An immediate consequence of the lemma (cf. section 2.3 of [19]) is the following.

THEOREM 6.2. *For any feedback control* $\mathbf{u}$, $J(\mathbf{u})$ *is the unique solution to the equation* $v = R(\mathbf{u})v + F(\mathbf{u})$. *Furthermore, the value function* $\{V(z), z \in \mathbb{S}^*\}$ *defined below* (69) *is the unique solution of* (72). *Denoting the* arg max *for the ith row maximization on the right side of* (72) *by* $\mathbf{u}(z_i)$ *and the control sequence corresponding to the feedback control* $\mathbf{u}$ *by* $U = \{U_n, n = 0, 1, 2, \dots\}$, *we have that* U *is an optimal control, i.e.,* $J(z, U) = V(z)$ *for all* $z \in \mathbb{S}^*$.

From the above theorem it follows that in order to compute the value function and the optimal control it suffices to solve (72).

Numerical methods. We will use classical iterative methods to find the optimal control by solving the dynamic programming equation (72). A sketch of the algorithm is provided here. Details can be found in Chapter 6 of [19].

The following theorem provides the basis for the numerical approximation of the optimal control. We refer the reader to Theorem 6.2.1 in [19] for a proof.

THEOREM 6.3. *Let* $\mathbf{u}_0$ *be a feedback control. Define a sequence of feedback controls* $\{\mathbf{u}_n, n \geq 1\}$ *and costs* $\{J(\mathbf{u}_n), n \geq 1\}$ *recursively as follows. Given* $\mathbf{u}_n$, *define*

$$J(\mathbf{u}_n) = R(\mathbf{u}_n)J(\mathbf{u}_n) + F(\mathbf{u}_n), \tag{76}$$

$$\mathbf{u}_{n+1} \doteq \arg\max_{u \in \mathcal{U}_{\mathrm{MDP}}} R(u)J(\mathbf{u}_n) + F(u), \tag{77}$$

where the arg max *on the right-hand side is computed row by row. Then* $J(\mathbf{u}_n) \to V$ *as* $n \to \infty$.

Given some control, (77) provides a way of "updating" the control in the search for the optimal control. However, this requires solving (76) to obtain the cost associated with the given control. Finding an exact solution to this equation can be numerically intensive since it involves the inversion of an $s \times s$ matrix. Thus we use instead an approximation to the cost function $J(\mathbf{u}_n)$ in (77). The following theorem provides a method for obtaining such an approximation. We refer the reader to Theorem 6.2.2 in [19] for the proof.

THEOREM 6.4. *Let* $\mathbf{u}$ *be an admissible feedback control. Then for any initial* $s \times 1$ *vector* $\tilde{J}_0$, *the sequence defined recursively by*

$$\tilde{J}_{n+1} = R(\mathbf{u})\tilde{J}_n + F(\mathbf{u}) \tag{78}$$

converges to $J(\mathbf{u})$.

The numerical method for finding the optimal control is obtained by combining Theorems 6.3 and 6.4 as follows.

Policy iteration: Having determined an approximation to $J(\mathbf{u}_n)$, denoted as $\tilde{J}(\mathbf{u}_n)$, one obtains $\mathbf{u}_{n+1}$ by solving the minimization problem in (77) by replacing $J(\mathbf{u}_n)$ there with $\tilde{J}(\mathbf{u}_n)$.

Value iteration: Given $\mathbf{u}_n$, iterate (78) a large number of times (say, m) with $R(\mathbf{u})$ there replaced by $R(\mathbf{u}_n)$ and initial value $\tilde{J}_0$ replaced by $\tilde{J}(\mathbf{u}_{n-1})$. Set $\tilde{J}(\mathbf{u}_n) \doteq \tilde{J}_m$.

The numerical algorithm alternates between policy iterations and value iterations until some suitable stopping criterion is met. Several modifications of (78) are often used to improve numerical efficiency; see section 6.2.4 of [19] for details.

7. Numerical study. We now present the results of a small pilot study using the method described in section 6. We consider one of the examples in [31]. As in that reference, we set $r = 0.07$, $b = 0.12$, $\sigma = 0.40$, and $\beta = 0.10$. We consider the case $\lambda = \mu = 0.01$ and the utility function $f(c) = 2\sqrt{c}$. We take $\ell = 10$ as in [31] and $p = 10$. The discretization parameter is taken to be $h = 0.25$. (Note that [31] uses $h = 0.025$.)

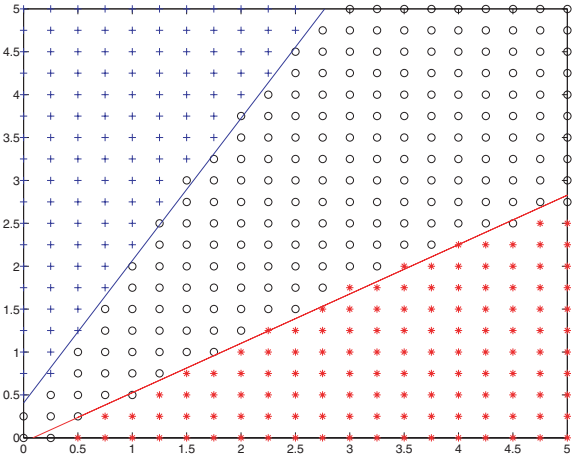

FIG. 2. *Numerically computed optimal control.*

To implement the numerical algorithm, we choose an initial feedback control matrix $\mathbf{u}_0$ given by, for $z \in \mathbb{S}^*$,

$$\mathbf{u}_0(z) = \begin{cases} (0,p), & x \geq 0, y \geq 0, \\ (1,0), & x \geq 0, y < 0, \\ (2,0), & \text{otherwise.} \end{cases}$$

Based on this control, the no-transaction region is the first quadrant of $\mathbb{R}^2$, and we always exercise the maximum amount of possible consumption. For $z \in \mathbb{S}^*$ we take $\tilde{J}_0(z)$ to be 75% of the value function computed in the absence of transaction costs; see equation (2.5) in [6].

We ran the algorithm described in the previous section. Figure 2 displays the first quadrant of the state space and illustrates the optimal control for this region. We see that the no-transaction region looks roughly like a cone. Consumption states are represented by the circles, purchase states by the plus signs, and sales states by the asterisks. The estimated boundaries of the no-transaction region (the solid lines in the figure) are given by the lines $y = 0.575x - 0.050$ (the boundary of the "buy" region) and $y = 1.659x + 0.405$ (the boundary of the "sell" region). The estimated sell boundary of the no-transaction region is similar to that obtained by Tourin and Zariphopoulou (see Figure 1 in [31]). However, the slope of our buy boundary appears to be lower than the slope illustrated in Figure 1 of [31]. A possible reason for this could be the difference in the discretization parameter. We used $h = 0.25$ to produce the test results provided here. Within the no-transaction region, consumption remains at a fairly constant percentage of wealth, 11.5%, which is very close to the constant percentage of consumption in the case of no-transaction costs (see Theorem 2.1 in [6]). We also compare the value function computed by the algorithm versus the value function in the case of no-transaction costs (again, see Theorem 2.1 in [6]). In general, the optimal value for an initial state computed in the presence of transaction costs is roughly 97% of the optimal value for the same state in the absence of transaction costs. However, when the initial wealth is small, this percentage tends to be lower (roughly 80%–90%).

8. Appendix. This section contains the proofs of Lemmas 4.4, 5.1, and 5.9. We refer the reader to the corresponding sections for the relevant notation and definitions.

Proof of Lemma 4.4. Without loss of generality, assume $h \in (0,1)$. Define

$$Y_i^h(t) \doteq \sum_{k=0}^{n^h(t)\wedge\eta_h-1} \delta Z_k^h 1_{\{I_k^h=i\}}, \quad n_i^h(t) \doteq \sum_{k=0}^{n^h(t)\wedge\eta_h-1} 1_{\{I_k^h=i\}}, \ i=1,2.$$

Writing $Y_i^h \equiv (Y_{i,1}^h, Y_{i,2}^h)'$, it follows from (16) and (17) that

$$\mathbb{E}Y_{1,2}^h(t) = h\frac{1}{1+\lambda}\mathbb{E}[n_1^h(t)], \ \ \mathbb{E}Y_{2,1}^h(t) = h(1-\mu)\mathbb{E}[n_2^h(t)].$$

A straightforward calculation shows $|B^h(t)| \le c_1(1+t)$ and $\mathbb{E}|S^h(t)| \le c_2(1+t)$, where the constants c_1, c_2 are independent of h and t. From (16), (17) we see that $hn_1^h(t) = M^h(t) = Y_{1,1}^h(t)$ and $hn_2^h(t) = N^h(t) = Y_{2,2}^h(t)$. Thus from (28) there is $\tilde{c}_1 \in (0,\infty)$ such that

$$hn_1^h(t) \le \tilde{c}_1(1+t) + |S_1^h(t)| + Y_{2,1}^h(t), \ hn_2^h(t) \le \tilde{c}_1(1+t) + |S_2^h(t)| + Y_{1,2}^h(t). \tag{79}$$

Combining the above inequalities we have, for some $c_3 \in (0,\infty)$, $h\mathbb{E}[n_1^h(t)] \le c_3(1+t) + h(1-\mu)\mathbb{E}[n_2^h(t)]$ and $h\mathbb{E}[n_2^h(t)] \le c_3(1+t) + h\mathbb{E}[n_1^h(t)]/(1+\lambda)$. It follows that $h\mathbb{E}[n_1^h(t)]$ and $h\mathbb{E}[n_2^h(t)]$ are "close" to each other. More precisely, there exist constants $\alpha \ge 1$, $c_4 > 0$, $L_0 > 0$ such that for $L \ge L_0$,

$$h(\mathbb{E}[n_1^h(t)] \vee \mathbb{E}[n_2^h(t)]) > L \Rightarrow h(\mathbb{E}[n_1^h(t)] \wedge \mathbb{E}[n_2^h(t)]) > \alpha L - c_4.$$

In particular, we have $\sup_h h\mathbb{E}[n_1^h(t)] = \infty$ if and only if $\sup_h h\mathbb{E}[n_2^h(t)] = \infty$. Now suppose $\sup_h h\mathbb{E}[n_1^h(t)] = \infty$ and $\sup_h h\mathbb{E}[n_2^h(t)] = \infty$. By Cramer's theorem (see Theorem 2.1.24 in [8]), for all $\delta > 0$ there exists a constant $c(\delta) \in (0,\infty)$ such that for all $k_0 \in \mathbb{N}_0$ and $h > 0$,

$$\max\Big\{\mathbb{P}[|Y_{2,1}^h - h(1-\mu)n_2^h(t)| > \delta h n_2^h(t), n_2^h(t) = k_0], \\ \mathbb{P}[|Y_{1,2}^h - h(1/(1+\lambda))n_1^h(t)| > \delta h n_1^h(t), n_1^h(t) = k_0]\Big\} \le c(\delta)e^{-k_0 c(\delta)}.$$

Choose δ such that $\mu + \delta < 1$ and $1/(1+\lambda) - \delta > 0$ (which is possible since $\mu \in (0,1)$ and $\lambda \in (0,\infty)$). Define $\alpha_1 = 1 - (1-\mu-\delta)(1/(1+\lambda)-\delta) < 1$ and $\theta = \alpha_1/4$. Fix $\epsilon \in (0,1)$ and choose K large enough so that

$$\frac{c(\delta)}{1-e^{-c(\delta)}}e^{-c(\delta)(K+1)} < \frac{\epsilon}{8} \ \text{ and } \ \frac{c_2(1+t)}{\theta K - \tilde{c}_1(1+t)} < \frac{\epsilon}{8}. \tag{80}$$

Since by assumption, $\sup_h h\mathbb{E}[n_1^h(t)] = \sup_h h\mathbb{E}[n_2^h(t)] = \infty$, there exists $h' \le 1$ such that

$$\mathbb{P}\left[n_1^{h'}(t) > \frac{K}{h'}, n_2^{h'}(t) > \frac{K}{h'}\right] > \epsilon. \tag{81}$$

Then for all $t \geq 0$,

$$\begin{aligned}
&\mathbb{P}\left[|Y_{2,1}^{h'}(t) - h'(1-\mu)n_2^{h'}(t)| > \delta h' n_2^{h'}(t), n_2^{h'}(t) > \frac{K}{h'}\right] \\
&= \sum_{j=[K/h']+1}^{\infty} \mathbb{P}[|Y_{2,1}^{h'}(t) - h'(1-\mu)n_2^{h'}(t)| > \delta h' n_2^{h'}(t), n_2^{h'}(t) = j] \\
&\leq \sum_{j=[K/h']+1}^{\infty} c(\delta)e^{-c(\delta)j} \quad = \frac{c(\delta)}{1-e^{-c(\delta)}} e^{-c(\delta)([\frac{K}{h'}]+1)} < \frac{\epsilon}{8},
\end{aligned}$$

where the last inequality follows from the choice of K in (80). Similarly, $\mathbb{P}[|Y_{1,2}^{h'}(t) - \frac{h'}{1+\lambda} n_1^{h'}(t)| > \delta h' n_1^{h'}(t), n_1^{h'}(t) > \frac{K}{h'}] < \frac{\epsilon}{8}$. Hence, in view of (81) we have

$$\begin{aligned}
\mathbb{P}\Bigg[&\min\{n_1^{h'}(t), n_2^{h'}(t)\} > \frac{K}{h'}\ ,\ |Y_{2,1}^{h'}(t) - h'(1-\mu)n_2^{h'}(t)| \leq \delta h' n_2^{h'}(t), \\
&\left|Y_{1,2}^{h'}(t) - \frac{h'}{1+\lambda} n_1^{h'}(t)\right| \leq \delta h' n_1^{h'}(t)\Bigg] > \frac{\epsilon}{2}.
\end{aligned}$$

Let E denote the event in the equation above. From (79) and (80),

$$\begin{aligned}
\mathbb{P}[h' n_1^{h'}(t) - Y_{2,1}^{h'}(t) \geq \theta K] &\leq \mathbb{P}[|S_1^{h'}(t)| \geq \theta K - \tilde{c}_1(1+t)] \\
&\leq \frac{\mathbb{E}|S_1^{h'}(t)|}{\theta K - \tilde{c}_1(1+t)} \\
&\leq \frac{c_2(1+t)}{\theta K - \tilde{c}_1(1+t)} < \frac{\epsilon}{8}.
\end{aligned}$$

Similarly, $\mathbb{P}[h' n_2^{h'}(t) - Y_{1,2}^{h'}(t) \geq \theta K] < \frac{\epsilon}{8}$. Thus

$$\begin{aligned}
\frac{\epsilon}{2} < \mathbb{P}[E] &\leq \mathbb{P}[E, h' n_1^{h'}(t) - Y_{2,1}^{h'}(t) < \theta K, h' n_2^{h'}(t) - Y_{1,2}^{h'}(t) < \theta K] \\
&\quad + \mathbb{P}[h' n_1^{h'}(t) - Y_{2,1}^{h'}(t) \geq \theta K] + \mathbb{P}[h' n_2^{h'}(t) - Y_{1,2}^{h'}(t) \geq \theta K] \\
&\leq \mathbb{P}[\tilde{E}] + \frac{\epsilon}{8} + \frac{\epsilon}{8},
\end{aligned}$$

where $\tilde{E}$ is the event in the first term on the right side above. It follows that $\mathbb{P}[\tilde{E}] > \epsilon/4$ and thus $\tilde{E}$ is nonempty. Now for any $\omega \in \tilde{E}$, we have from the definition of $\tilde{E}$ that

$$h' n_1^{h'}(t) - h'(1-\mu-\delta)n_2^{h'}(t) < \theta K, \ \ h' n_2^{h'}(t) - h'(1/(1+\lambda) - \delta) n_1^{h'}(t) < \theta K.$$

A straightforward calculation using these inequalities shows that for such ω,

$$h' n_1^{h'}(t) \leq \frac{2\theta}{1 - (1-\mu-\delta)(1/(1+\lambda) - \delta)} K = \frac{K}{2}.$$

However, this contradicts the fact that $h' n_1^{h'}(t) > K$ on $\tilde{E}$. Thus we must have $\sup_h h\mathbb{E}[n_1^h(t)] < \infty$, $\sup_h h\mathbb{E}[n_2^h(t)] < \infty$. The result now follows on recalling that $M^h(t) = h n_1^h(t)$ and $N^h(t) = h n_2^h(t)$. □

Proof of Lemma 5.1. The inequality $V(z) \leq \bar{V}(z)$ is immediate since every exact control can be expressed as a relaxed control. Consider now the reverse inequality.

Let Φ be a probability system and $\bar{U} = (\bar{m}, M, N) \in \bar{\mathcal{A}}(\Phi, z)$ be such that $\bar{V}(z) \leq \bar{J}(z, \bar{U}) + \epsilon$. From the boundedness of the cost function it follows that, without loss of generality, we can assume that there is a $T \in (0, \infty)$ such that $M(t) = M(t \wedge T)$ and $N(t) = N(t \wedge T)$ for all $t \in (0, \infty)$, and $\bar{m}_t(d\alpha) = \delta_p$ for all $t \geq T$. Also, T can be chosen large enough so that $f_*(p)e^{-\beta T}/\beta < \epsilon$.

Let Z be defined via (7) with $C(t) \doteq \int_{[0,p]} \alpha \bar{m}_t(d\alpha)$, and τ as before. Then

$$\bar{J}(z, \bar{U}) \leq \mathbb{E} \int_{[0,p]\times[0,T\wedge\tau)} e^{-\beta t} f(\alpha) m(d\alpha, dt) + \epsilon. \tag{82}$$

Also, by modifying m, M, and N if needed, we can assume that

$$M(t) = M(T \wedge \tau), \;\; N(t) = N(T \wedge \tau), \text{ and } \bar{m}_t(d\alpha) = \delta_p \text{ for all } t \geq T \wedge \tau. \tag{83}$$

Following the proof of Theorem 1.2.1 in [2] one can show that there exists a sequence of exact controls $C_n \in \mathcal{A}_p(\Phi, z)$ which satisfy

$$\sup_{0\leq t\leq T_1} \left| \int_{[0,p]\times[0,t]} e^{-\beta t} f(\alpha) m(d\alpha, dt) - \int_{[0,t]} e^{-\beta t} f(C_n(t)) dt \right| \to 0 \text{ a.s., and} \tag{84}$$

$$\sup_{0\leq t\leq T_1} \left| \int_{[0,t]} (C_n(s) - C(s)) ds \right| \to 0 \text{ a.s.} \tag{85}$$

as $n \to \infty$ for all $T_1 \in (0, \infty)$. In fact the cited theorem shows that, for each n, C_n can be chosen such that it takes values in a finite set and there is a sequence $0 < t_1^n < t_2^n \cdots$ such that C_n is constant over $[t_k^n, t_{k+1}^n)$ for all $k \in \mathbb{N}_0$.

Let Z_n be defined via (7) with C replaced by C_n and with M and N as introduced above. A straightforward application of Gronwall's inequality and (85) shows that for each $T_1 \in (0, \infty)$, there is a $c \equiv c(T_1) \in (0, \infty)$ such that

$$\sup_{0\leq t\leq T_1} \mathbb{E}|Z_n(t) - Z(t)| \leq c \sup_{0\leq t\leq T_1} \mathbb{E} \left| \int_{[0,t]} (C_n(s) - C(s)) ds \right|. \tag{86}$$

Hence $Z_n \to Z$, in probability, uniformly on $[0, T]$.

If $\tau = \infty$, $Z(t) \in \mathbb{S}^o$ for all $t \geq 0$. Thus, (86) implies that there exists N_0 such that if $n > N_0$, then $Z_n(t) \in \mathbb{S}^o$ for all $t \geq 0$, and therefore $\tau_n = \infty$ for all $n > N_0$. Then clearly $\tau_n \to \tau$ a.s. as $n \to \infty$ on the set $\{\tau = \infty\}$. Next note that, a.s. on the set $\{\tau < \infty\}$ and for every $\delta > 0$, there exist $t \in [\tau, \tau + \delta)$ and $\epsilon > 0$ such that $\text{dist}(Z(t), \mathbb{S}) > \epsilon$. This is because, in view of (83), $Z(\tau + t)$, $t \geq 0$, is described via (7) with initial condition $Z(\tau)$ and $M \equiv N \equiv 0$. If $Z(\tau) = 0$, the property is satisfied trivially since $C(t) = p$ for all $t \geq \tau$. Otherwise, the property follows from a standard argument based on the law of the iterated logarithm for Brownian motion (cf. pages 260–261 in [19]). This, along with the convergence of Z_n to Z, shows that $\tau_n \doteq \inf\{t : Z_n(t) \notin \mathbb{S}^o\}$ converges to τ a.s. as $n \to \infty$. In proving this statement we also use the observation that if $Z(t-) \notin \mathbb{S}$, then $Z(t) \notin \mathbb{S}$. Thus $\tau_n \wedge T \to \tau \wedge T$. Combining these observations with (84), we obtain

$$\mathbb{E} \int_{[0,\tau_n\wedge T]} e^{-\beta t} f(C_n(t)) dt \to \mathbb{E} \int_{[0,p]\times[0,\tau\wedge T]} e^{-\beta t} f(\alpha) m(d\alpha, dt). \tag{87}$$

The result now follows on using this observation in (82). □

Proof of Lemma 5.9. Let $\epsilon > 0$ be arbitrary and let $T \in (0,\infty)$ be such that $f_*(p)e^{-\beta T}/\beta < \epsilon$. Consider $\tilde{U} = (\tilde{C}, \tilde{M}, \tilde{N})$ given by $\tilde{C}(t) = C(t)1_{t<T}$, $\tilde{M}(t) = M(t\wedge T)$, and $\tilde{N}(t) = N(t\wedge T)$, $t \geq 0$. Clearly $\tilde{U} \in \mathcal{A}_p(z)$, and it is easy to check that $|J_\ell(z,U) - J_\ell(z,\tilde{U})| < \epsilon$. This proves 1. Henceforth we will assume, without loss of generality, that 1 holds for U in the statement of the lemma. Using (7) and the bounds on the state and control space, it is easy to show $\sup_{0\leq t\leq T}[M(t\wedge\tau,\omega)+N(t\wedge\tau,\omega)] \leq c_1 + c_2 \sup_{0\leq t\leq T}|W(t)|$, where c_1 and c_2 are nonnegative constants that may depend on T. Let $L \in (0,\infty)$ be large enough so that $c_2\mathbb{E}\sup_{0\leq t\leq T}|W(t)|/(L-c_1) < \epsilon$. Define $\tilde{U}$ by $\tilde{C} \equiv C$, $\tilde{M}(t) \doteq M(t)\wedge L$, $\tilde{N}(t) \doteq N(t)\wedge L$. Let $\tilde{Z}$ be the corresponding controlled process and $\tilde{\tau}$ the corresponding hitting time. Let T be as in part 1, and define $A \doteq \{\sup_{0\leq t\leq T}[M(t\wedge\tau)+N(t\wedge\tau)] < L\}$. Then

$$J_\ell(z,\tilde{U}) = \mathbb{E}\left[1_A \int_{[0,\tilde{\tau}]} e^{-\beta t} f(\tilde{C}(t))dt\right] + \mathbb{E}\left[1_{A^c}\int_{[0,\tilde{\tau}]} e^{-\beta t} f(\tilde{C}(t))dt\right]. \tag{88}$$

Using the bound on f, the choice of L, and Markov's inequality, the second term on the right side of the above inequality is bounded by ϵ. Also, since on the set A, $M(t) < L$ and $N(t) < L$ for all $t \leq \tau\wedge T$, we have that the evolution of $\tilde{Z}$ is the same as that of Z. Therefore $\tilde{\tau}$ in the first expression on the right side of (88) can be replaced with τ. This shows that $|J_\ell(z,\tilde{U}) - J_\ell(z,U)| \leq 2\epsilon$ and hence 2 follows.

We now consider 3. Let $U \equiv (C,M,N)$ be an admissible control satisfying properties 1 and 2 and let Z be the solution to (7) under (C,M,N) defined on some probability system. Following Theorem 1.2.1 of [2] (see comments below (85)) we can assume without loss of generality that C takes values in a finite set, is RCLL, and piecewise constant with finitely many points of change over $[0,T]$. We also assume without loss of generality (by modifying controls if needed) that $M(t) = M(t\wedge\tau)$, $N(t) = N(t\wedge\tau)$, and $C(t) = C(t)1_{t<\tau} + p1_{t\geq\tau}$. Fix $\eta,\theta \in (0,\infty)$ and define the piecewise constant processes $C_{\eta,\theta}$, $M_{\eta,\theta}$, and $N_{\eta,\theta}$ as follows. For $m = 0$, define $M_{\eta,\theta}(m\theta) = M_{\eta,\theta}(0) = k\eta$ if $M(0) \in [k\eta, k\eta+\eta)$. For $m \geq 1$, set $\delta M_{\eta,\theta}(m\theta) = k\eta$ if $M(m\theta) - M(m\theta-\theta) \in [k\eta, k\eta+\eta)$. By property 2, we need only consider the finite set $\{k\eta : k = 0,1,2,\ldots,K\}$, where K is some positive integer. Then let $M_{\eta,\theta}(t) = M_{\eta,\theta}(m\theta)$ for $t \in [m\theta, m\theta+\theta)$. Define $N_{\eta,\theta}$ analogously based on N. Define $C_{\eta,\theta}(m\theta) = k\eta$ if $C(m\theta) \in [k\eta, k\eta+\eta)$ and $C_{\eta,\theta}(t) = C_{\eta,\theta}(m\theta)$ for $t \in [m\theta, m\theta+\theta)$. The constructed process $U_{\eta,\theta} \equiv (C_{\eta,\theta}, M_{\eta,\theta}, N_{\eta,\theta})$ is an admissible control. Let $Z_{\eta,\theta}$ denote the solution to (7) under this control, defined on some probability system, and let $\tau_{\eta,\theta}$ denote the first time this process exits $\mathbb{S}^o_\ell$. Choose a sequence (η_k,θ_k) such that $\eta_k,\theta_k \to 0$ as $k\to\infty$. Denote Z_{η_k,θ_k} by Z_k. Similar abbreviations are used for $U_{\eta_k,\theta_k}, \tau_{\eta_k,\theta_k}$. One can easily check that $(Z_k,U_k) \to (Z,U)$ in $D([0,T],\mathbb{R}^2\times[0,p]\times[0,L]\times[0,L])$ (in probability) as $k\to\infty$. If $\tau = \infty$, the uniform convergence $Z_k \to Z$ implies that there exists K_0 such that for all $k > K_0$ we have $Z_k(t) \in \mathbb{S}^o$ for all $t \geq 0$, and thus $\tau_k = \infty$ for all $k > K_0$. Therefore $\tau_k \to \tau$ a.s. as $k\to\infty$ on the set $\{\tau = \infty\}$. Next note that, a.s. on the set $\{\tau < \infty\}$, for every $\delta > 0$ there exists $t \in [\tau, \tau+\delta)$ and $\epsilon > 0$ such that $\mathrm{dist}(Z(t),\mathbb{S}) > \epsilon$. This is because, on this set, by our choice of U, $Z(\tau+t)$, $t \geq 0$, is described via (7) with $M \equiv N \equiv 0$ and initial condition $Z(\tau)$. In the case $Z(\tau) = 0$ the property is satisfied trivially since $C(t) = p$ for all $t \geq \tau$. Otherwise, the property follows from an argument analogous to the proof of Theorem 9.4.3 of [19] (see pp. 260–261). Next, recalling that $Z_k \to Z$, $Z(t)$ is continuous for all $t \geq \tau$ and the observation that $Z(\tau-) \in (\mathbb{S}^o_\ell)^c \Rightarrow Z(\tau) \in (\mathbb{S}^o_\ell)^c$,

we conclude $\tau_k \wedge T \to \tau \wedge T$ in probability. The convergence of $J(z, U_k)$ to $J(z, U)$ now follows. This proves 3.

The proofs of 4 and 5 are quite standard and we provide only a sketch; the reader is referred to the proof of Theorem 10.3.1 of [19] (pages 285–287) for details. Assume that U satisfies properties 1–3, and let $\gamma > 0$. Part 4 is essentially a consequence of the martingale convergence theorem on noting that the σ-fields $\mathcal{G}_\gamma \doteq \sigma\{U(n\theta), n < m; W(l\gamma), l\gamma \leq, \theta\}$ increase to the σ-field $\mathcal{G} \doteq \sigma\{U(n\theta), n < m; W(s), s \leq, \theta\}$ as $\gamma \downarrow 0$. The main idea is to define controls U_γ and controlled processes Z_γ recursively over intervals $[m\theta, (m+1)\theta)$ by using the right side of (60) in defining the law of U_γ over $[m\theta, (m+1)\theta)$. Proving the weak convergence of (Z_γ, C_γ) to (Z, C) is straightforward. The convergence of hitting times is argued as in the proof of part 3. Finally, part 5 is proved by convolving $q_{m,k}$, defined in (61), in the (z, w) variables by a parametrized family of mollifiers and arguing weak convergence of the resulting controlled pair to (Z, C) as the mollifying parameter approaches a suitable limit. Convergence of stopping times is argued, once more, as in 3. □

PERFORMANCE RECOVERY IN DIGITAL IMPLEMENTATION OF ANALOGUE SYSTEMS*

GUOFENG ZHANG†, TONGWEN CHEN‡, AND XIANG CHEN§

Abstract. In this paper, the *generalized* bilinear transformation (GBT) is proposed. Compared with the traditional bilinear, zero-order hold (ZOH) and first-order hold transformations, one advantage of GBT is that it may convert unstable poles (zeros) to stable poles (zeros). It is proved that controllability and observability are invariant under GBT. After that, it is shown that the performance of a sampled-data system obtained via GBT approaches that of the analogue system as the underlying sampling period goes to zero. Performance studied here is characterized in terms of internal stability and ℓ_p induced norms for all $1 \leq p \leq \infty$. This results extends the main results in [G. Zhang and T. Chen, *Dyn. Contin. Discrete Impuls. Syst. Ser. B Appl. Algorithms, Suppl.*, 2003, pp. 28–33] and [G. Zhang and T. Chen, *Automatica J. IFAC*, 40 (2004), pp. 327–330] from SISO to MIMO and also removes the limitation on the "A" matrix of the system. Finally, an example is employed to compare digital implementations via GBT and the ZOH transformation.

Key words. fractional-order hold transformation, generalized bilinear transformation, graph metric, Hankel singular values, performance recovery, unstable zeros

1. Introduction.

Sampling a continuous-time system is a fundamental problem in a variety of scientific areas, such as computer control, system identification, and signal processing. It is becoming even more conspicuous in light of the huge success of computer-aided processing and networking [1], [2], [6], [13], [22], [23], [18], [24], [35], [17]. There are many intriguing problems related to sampling. This paper focuses on the problem of performance recovery in digital implementation of analogue systems. Consider the continuous-time closed-loop system Σ_1 shown in Figure 1.1, where W is a finite-dimensional linear time-invariant (FDLTI) stable block, and both G and K are FDLTI. Suppose that Σ_1 is internally stable [6, p. 241] and also satisfies some input-output performance specifications. Now conduct a digital implementation as in Figure 1.2 by using K_h obtained via some discretization method, with h being the underlying sampling period. For convenience, we denote the system in Figure 1.2 by Σ_2. Note that Σ_2 is a sampled-data control system. Within this set-up, the following question could be raised: Under what condition will Σ_2 also be internally stable and have similar input-output properties as those of Σ_1?

This problem has been studied extensively in recent years. In Chen and Francis [5], [6], an upper bound for the sampling period h is derived, for which the sampled-data control system Σ_2 is ℓ_p input-output stable; furthermore, it is shown that performance of Σ_2 converges to that of Σ_1 as h approaches zero. The digital implementation

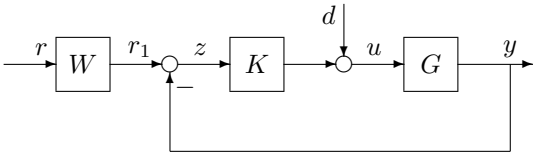

FIG. 1.1. Σ_1: *analogue system.*

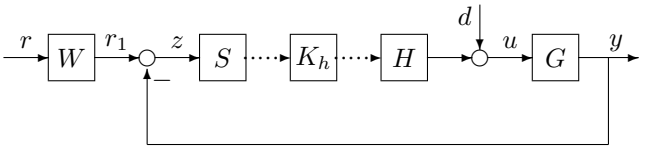

FIG. 1.2. Σ_2: *digital implementation of* Σ_1.

of an analogue controller will generally degrade the performance of the closed-loop system. Two examples are given in [21] to illustrate how this degradation is quantified as a function of the underlying sampling period. Some sufficient conditions that guarantee uniform-in-time input-output performance convergence of sampled-data control systems are proposed in [28]. A new discretization method is proposed in [16] based on the principle of controller approximation, where an upper bound is derived to ensure closed-loop stability. Quite contrary to the above, Oishi [25] illustrates via concrete examples that, in some circumstances, even as the sampling period tends to zero, the best sampled-data closed-loop performance may not necessarily converge to the best analogue closed-loop performance.

All the above results are derived for digital implementation of analogue systems via the step-invariant transformation (the zero-order hold (ZOH) equivalent). Let K_d and K_{bt} denote two different versions of K_h, obtained via the step-invariant and bilinear transformations respectively. By showing that the ℓ_p induced norm of $K_d - K_{bt}$ approaches zero for all $1 \le p \le \infty$ as h goes to zero, Zhang and Chen [38] and [39] proved that performance recovery of digital implementation of Σ_1 via the bilinear transformation still holds. However, it is assumed in [38] and [39] that G in Figure 1.1 is a single-input–single-output (SISO) stable block, and furthermore, the "A" matrix is diagonalizable with all real eigenvalues. Actually, the result holds for $p = \infty$ no matter whether G is multi-input–multi-output (MIMO) or G is diagonalizable with all real eigenvalues. One of the main purposes of this paper is to generalize the results in [38] and [39] to the cases of $1 \le p < \infty$. The remainder of this paper is outlined as follows.

In section 2, we propose the generalized bilinear transformation (GBT) that contains the (traditional) bilinear transformation as a special case. Denoting the resulting digital controller by K_{gbt}, we explore the relation between the poles and zeros of K and K_{gbt}. One advantage of the GBT is that it may be able to convert unstable zeros or poles to stable zeros or poles. This is quite desirable since unstable zeros and poles always impose various limitations on system performance [7], [15], [27], [44], process identification algorithms [19], [30], network communication bandwidth [33], [11], and stability of networked control systems [40]. Then we show that controllability, as well as observability, is preserved under the GBT. More important, the GBT provides a class of discretizations. When control engineers have some practical digital implementation problem at hand, instead of only the ZOH, first-order hold,

or traditional bilinear transformations, now they have infinite many choices at their disposal. Therefore, for a specified control performance, he may select a particular discretization method by tuning the parameter in the GBT. Clearly, this new degree of freedom will enhance the capability of a control engineer.

In section 3, we investigate the limiting behavior of K_{gbt}. More specifically, we prove the following result: Given K stable, the ℓ_p induced norm of $K_{gbt} - K_d$ approaches zero for all $1 \leq p \leq \infty$ as the underlying sampling period h tends to zero. This result holds no matter whether K is SISO or MIMO, thus generalizing Theorem 1 in [39]. This result plays a key role in the development in section 4.

Based on the results in section 3, we establish in section 4 that all existing stability and performance results for the step-invariant transformation (the ZOH equivalent) can be translated into those for the GBT. Using the methods proposed in this paper, limiting properties and performance recovery of other types of digital implementations such as the Al-Alaoui transformation can be dealt with in a similar way.

Section 5 is a case study. An example is used to compare digital implementations of analogue systems via the ZOH transformation and the GBT. It demonstrates that GBT converts some unstable system zeros (poles) to stable ones, therefore bringing in a closed-loop system which has much less performance limitations than that using ZOH.

Our main purpose in this paper is to show performance recovery in digital implementations of analogue systems via the GBT in fast sampling. However, it is worthwhile to point out that in some circumstance fast sampling is dangerous. For example, if a quantizer of fixed sensitivity is inserted into a control loop consisting of a system and an unstable controller, the simulation in [3] demonstrates that system performance will grow *unbounded* as the sampling period goes to zero. Hence, in the framework of network-based control, where signal quantization is prevalent, very fast sampling will in general degrade control performance [20]. This understanding warn us that we should be careful in choosing a suitable sampling period when dealing with practical problems.

Finally, some words about notation. The norm symbol $\|\cdot\|$ represents the Euclidean norm if $\cdot$ is a vector, or its largest singular value if $\cdot$ is a matrix; $\|\cdot\|_{\ell_p}$ is the ℓ_p norm if applied to a vector and is the ℓ_p induced norm if applied to a system. Following the convention, for a discrete-time transfer function $H(z)$ with a state-space realization (A, B, C, D), define

$$\left[\begin{array}{c|c} A & B \\ \hline C & D \end{array}\right] := D + C(zI - A)^{-1}B.$$

2. GBT. The bilinear transformation is motivated by considering the trapezoidal approximation of an integrator. Given an integrator $1/s$ with input u and output y, the trapezoidal approximation of

$$y(kh + h) = y(kh) + \int_{kh}^{kh+h} u(\tau)d\tau \tag{2.1}$$

is

$$y\left(kh + h\right) = y\left(kh\right) + h\frac{u\left(kh + h\right) + u\left(kh\right)}{2};$$

i.e., the integral is approximated by the average value of $u(kh + h)$ and $u(kh)$. Now we approximate the integral in (2.1) using some other combination of $u(kh + h)$ and

$u(kh)$. More specifically, consider

$$y(kh+h) = y(kh) + h(\alpha u(kh+h) + (1-\alpha)u(kh)), \tag{2.2}$$

where $\alpha \in (0,1)$. The transfer function of (2.2) is (in z transform)

$$\frac{y(z)}{u(z)} = h\frac{\alpha z + (1-\alpha)}{z-1}.$$

This motivates us to introduce the GBT

$$\frac{1}{s} = h\frac{\alpha z + (1-\alpha)}{z-1},$$

that is,

$$s = \frac{1}{h}\frac{z-1}{\alpha z + (1-\alpha)}. \tag{2.3}$$

Therefore, under the generalized bilinear transformation, the continuous-time transfer function $K(s)$ in Figure 1.1 is mapped to $K_{gbt}(z)$, where

$$K_{gbt}(z) = K\left(\frac{1}{h}\frac{z-1}{\alpha z + (1-\alpha)}\right). \tag{2.4}$$

In terms of state-space data, take a minimal realization for $K(s)$, namely, (A,B,C,D), and assume $A \in \mathbb{R}^{n\times n}$, $B \in \mathbb{R}^{n\times m}$, $C \in \mathbb{R}^{p\times n}$, $D \in \mathbb{R}^{p\times m}$; it is straightforward to derive that $K_{gbt}(z)$ has a state-space model $(A_{gbt}, B_{gbt}, C_{gbt}, D_{gbt})$ with

$$A_{gbt} = (I-\alpha hA)^{-1}(I+(1-\alpha)hA), \quad B_{gbt} = (1-\alpha)(I-\alpha hA)^{-1}hB,$$
$$C_{gbt} = C\left(I + \frac{\alpha}{1-\alpha}A_{gbt}\right), \quad D_{gbt} = D + \frac{\alpha}{1-\alpha}CB_{gbt}.$$

When $\alpha = 1/2$, we recover the traditional bilinear transformation. In what follows, without loss of generality, it is assumed that the matrix B is of full column rank, i.e., $\operatorname{rank}(B) = m$.

(Conversely, given a discrete-time system $K_{gbt}(z)$ with state-space data $(A_{gbt}, B_{gbt}, C_{gbt}, D_{gbt})$, one can also get a continuous-time system K, one of whose state-space realizations is

$$A = -\Omega(I - A_{gbt}),\ B = \Omega B_{gbt},\ C = C_{gbt}(I + \alpha h\Omega(I - A_{gbt})),$$
$$D = D_{gbt} - C_{gbt}\alpha h\Omega B_{gbt},$$

where $\Omega = ((1-\alpha)hI + \alpha hA_{gbt})^{-1}$.)

In what follows we study properties of the generalized bilinear transformation. Let us first look at poles and invariant zeros. Equation (2.3) yields

$$z = \frac{1+(1-\alpha)hs}{1-\alpha hs}. \tag{2.5}$$

Hence, if s is an eigenvalue of the matrix A, then z in (2.5) is that of A_{gbt}. The same is true for invariant zeros [43]. Actually we have a stronger conclusion.

THEOREM 2.1. *If s is an invariant zero of K, then z in* (2.5) *is an invariant zero of K_{gbt}. Furthermore, if $D = 0$, then $z = -\frac{1-\alpha}{\alpha}$ is also a zero of K_{gbt}.*

Proof. We begin with the first part. Let s be an invariant zero of K. Then there exist $0 \neq x \in \mathbb{R}^n$ and $u \in \mathbb{R}^m$ such that

$$\begin{aligned} (A - sI)\, x + Bu &= 0, \\ Cx + Du &= 0. \end{aligned} \tag{2.6}$$

It suffices to show that

$$\begin{aligned} (A_{gbt} - zI)\, \tilde{x} + B_{gbt}\tilde{u} &= 0, \\ C_{gbt}\tilde{x} + D_{gbt}\tilde{u} &= 0, \end{aligned} \tag{2.7}$$

where

$$\tilde{u} = u, \quad \tilde{x} = \frac{1}{1 + \frac{\alpha}{1-\alpha} z} x. \tag{2.8}$$

In terms of (2.8), the left-hand side of (2.7) is equivalent to

$$\begin{aligned} (A_{gbt} - zI)\, \tilde{x} + B_{gbt}\tilde{u} &= \left((I - \alpha hA)^{-1} (I + (1-\alpha)hA) - zI \right) \tilde{x} \\ &\quad + (1-\alpha) (I - \alpha hA)^{-1} hB\tilde{u} \\ &= (I - \alpha hA)^{-1} \left\{ (I + (1-\alpha)hA - (I - \alpha hA)\, z)\, \tilde{x} + (1-\alpha)hBu \right\}, \\ C_{gbt}\tilde{x} + D_{gbt}\tilde{u} &= C \left(I + \frac{\alpha}{1-\alpha} A_{gbt} \right) \tilde{x} + \left(D + \frac{\alpha}{1-\alpha} C B_{gbt} \right) \tilde{u} \\ &= C\tilde{x} + Du \\ &\quad + \frac{\alpha}{1-\alpha} C (I - \alpha hA)^{-1} \left\{ (I + (1-\alpha)hA)\, \tilde{x} + (1-\alpha)hBu \right\}. \end{aligned} \tag{2.9}$$

Rewriting (2.6) as $Bu = (sI - A)\, x$, $-Cx = Du$, and substituting it into the first equation of (2.9), we have

$$\begin{aligned} &(A_{gbt} - zI)\, \tilde{x} + B_{gbt}\tilde{u} \\ &\quad = (I - \alpha hA)^{-1} \left\{ (I + (1-\alpha)hA - (I - \alpha hA)\, z)\, \tilde{x} + (1-\alpha)h\, (sI - A)\, x \right\} \\ &\quad = (I - \alpha hA)^{-1} \left\{ (I + (1-\alpha)hA)\, \tilde{x} + (1-\alpha)h\, (sI - A)\, x - (I - \alpha hA)\, z\tilde{x} \right\}. \end{aligned}$$

Therefore, we need only to show that

$$(I + (1-\alpha)hA)\, \tilde{x} + (1-\alpha)h\, (sI - A)\, x = (I - \alpha hA)\, z\tilde{x} \tag{2.10}$$

and

$$\begin{aligned} &C\tilde{x} + Du + \frac{\alpha}{1-\alpha} C (I - \alpha hA)^{-1} \left\{ (I + (1-\alpha)hA)\, \tilde{x} + (1-\alpha)hBu \right\} \\ &= C (\tilde{x} - x) + \frac{\alpha}{1-\alpha} C (I - \alpha hA)^{-1} \left\{ (I + (1-\alpha)hA)\, \tilde{x} + (1-\alpha)h\, (sI - A)\, x \right\} = 0. \end{aligned} \tag{2.11}$$

Clearly, $\tilde{x}$ in (2.8) satisfies (2.10). In light of this, the left-hand side of (2.11) is converted to

$$\begin{aligned} &C\tilde{x} + Du + \frac{\alpha}{1-\alpha} C (I - \alpha hA)^{-1} \left\{ (I + (1-\alpha)hA)\, \tilde{x} + (1-\alpha)hBu \right\} \\ &= C (\tilde{x} - x) + \frac{\alpha}{1-\alpha} C (I - \alpha hA)^{-1} (I - \alpha hA)\, z\tilde{x} = C (\tilde{x} - x) + \frac{\alpha}{1-\alpha} Cz\tilde{x} \\ &= C \left(\left(1 + \frac{\alpha}{1-\alpha} z \right) \tilde{x} - x \right) = 0. \end{aligned}$$

In summary, (2.7) holds.

Next, assuming $D = 0$, we prove the second part of the theorem. Since $D = 0$, (2.7) becomes

$$\begin{aligned} (A_{gbt} - zI)\,\tilde{x} + B_{gbt}\tilde{u} &= 0, \\ C\left(I + \frac{\alpha}{1-\alpha}A_{gbt}\right)\tilde{x} + \frac{\alpha}{1-\alpha}CB_{gbt}\tilde{u} &= 0, \end{aligned} \tag{2.12}$$

which yields

$$C\left[1 + \frac{\alpha}{1-\alpha}z\right]\tilde{x} = 0. \tag{2.13}$$

Clearly, $z = -\frac{1-\alpha}{\alpha}$ satisfies (2.13). Substitution of it into (2.12) gives rise to

$$\begin{aligned} (A_{gbt} - zI)\tilde{x} + B_{gbt}\tilde{u} &= 0, \\ \tilde{x} &= zhB\tilde{u}. \end{aligned} \tag{2.14}$$

Because B is of full column rank, the dimension of $span(B)$, namely, the space spanned by the column vectors of B, is m. Hence, there exist vectors $\tilde{u}_1, \ldots, \tilde{u}_m$ in $\mathbb{R}^m$ such that $B\tilde{u}_1, \ldots, B\tilde{u}_m$ constitute a basis of $span(B)$. Define $\tilde{x}_i$ via the second equation of (2.14), $i = 1, \ldots, n-m$. Then $(\tilde{x}_i, \tilde{u}_i)$, $(i = 1, \ldots, n-m)$ are solutions to (2.14) for $z = -\frac{1-\alpha}{\alpha}$. The theorem is proved. □

Remark 1. When $D = 0$, $s = \infty$ is actually a zero of K. By (2.5), $z = -(1-\alpha)/\alpha$ is indeed the corresponding zero of K_{gbt}. In this regard, Theorem 2.1 tells us that the generalized bilinear transformation may generate new zeros which have no *finite* counterparts in the continuous-time domain. Following conventional notation, we call these zeros *discretization zeros*. Similarly, given a finite zero in the continuous-time domain, a finite zero in the discrete-time domain can be obtained via (2.5). We call such zeros *intrinsic zeros*. Suppose that K is a SISO system whose transfer function has relative degree $n - m > 0$ (note that in this case, $D = 0$). If K is discretized via the step-invariant transformation, it is proved in [1] that if $n - m > 2$, some discretization zero(s) will become unstable at a sufficiently small sampling period h. Even when $n - m = 2$, as $h \to 0$, the unique discretization zero approaches the point $(-1, 0)$ on the plane from outside the unit disk under a certain condition (Theorem 5 in [14]). As to the first-order hold transformation, for $n - m \geq 2$, there are unstable discretization limiting zeros for sufficiently small h (Theorem 9 in [14]). As for the traditional bilinear transformation, namely, $\alpha = 1/2$ in (2.4), Theorem 2.1 indicates that there are $n-m$ discretization zeros at $(-1, 0)$ on the plane, so the resulting discrete-time system is at most marginally stable. However, for $\alpha \in (1/2, 1)$, $z = -\frac{1-\alpha}{\alpha}$ is within the unit circle, implying stable discretization zeros. It is worth noting that discretization zeros are independent of the sampling period for the generalized bilinear transformation. Therefore, as far as system zeros are concerned, the generalized bilinear transformation with $\alpha \in (1/2, 1)$ is the best.

In the following, we investigate the stability of poles (resp., zeros) of the discrete-time system K_{gbt} obtained from the continuous-time system K. Suppose that $s = a + jb$ is a pole (resp., zero) of K, where $j = \sqrt{-1}$. Then by (2.5), we have

$$\left|\frac{1 + (1-\alpha)hs}{1 - \alpha hs}\right| < 1 \Leftrightarrow (1 + ah(1-\alpha))^2 + h^2b^2(1-\alpha)^2 < (1 - a\alpha h)^2 + b^2h^2\alpha^2,$$

which is equivalent to

$$\frac{2a}{a^2+b^2} < (2\alpha - 1)\, h. \tag{2.15}$$

We have the following observations.

1. When $\alpha = 1/2$, the GBT reduces to the traditional bilinear transformation. In this case, inequality (2.15) always holds, provided that $a < 0$; i.e., the traditional bilinear transformation maps stable poles (resp., zeros) of K to stable poles (resp., zeros) of K_{gbt}. If $D = 0$, Remark 1 shows that discretization zeros are at $(-1, 0)$ on the plane.
2. When $\alpha \in (0, 1/2)$, $(2\alpha - 1) < 0$. Hence, for such a value of α, the resulting GBT may map a stable pole (resp., zero) of K to an unstable pole (resp., zero) of K_{gbt}. If $D = 0$, discretization zeros lie outside the unit circle, thus leading to a nonminimum phase discrete-time system.
3. When $\alpha \in (1/2, 1)$, $(2\alpha - 1) > 0$. Hence, for such a value of α, the resulting generalized bilinear transformation may map an unstable pole (resp., zero) of K to a stable pole (resp., zero) of K_{gbt}. If $D = 0$, discretization zeros are all stable.

Now we see that the traditional bilinear transformation stands in the middle of the GBT; on the one side lie transformations that may convert a stable zero (resp., pole) to an unstable pole (resp., zero) (for $0 < \alpha < 1/2$); on the other side stand transformations that may transform an unstable pole (resp., zero) to a stable zero (resp., pole) (for $1/2 < \alpha < 1$). As is well known, unstable zeros or poles are generally undesirable in a control system because they always impose various kinds of limitations on system performance, such as frequency-dependent constraints on the complementary sensitivity function of discrete-time systems [7], the achievable transient performance of tracking and rejection to disturbances applied to the plant output in some servomechanism problem [27], a discrete-time loop transfer recovery procedure [44], and optimal prediction and estimation algorithms for stochastic models [19], [30]. Therefore, it is always desirable to avoid unstable poles and zeros. In this regard, the generalized bilinear transformation with $1/2 < \alpha < 1$ has advantages over the traditional bilinear transformation ($\alpha = 1/2$) because it may be able to eliminate unstable zeros or poles of an analogue systems provided that the sampling period is not too small, which is always the case in practice, as is commented on in section 1. Moreover, in light of Theorem 2.1, discretization zeros generated via the GBT with $1/2 < \alpha < 1$ are all stable, which is also an advantage over the traditional bilinear transformation. Actually, some other types of bilinear transformations have been used in the literature. For instance, in [4], a general bilinear relationship is applied to the problem of deriving discrete analogues of continuous singular perturbation and direct truncation model reduction. We remark that a similar application can be done for the GBT presented in this paper.

Because controllability and observability are two fundamental properties of any control system, in the following we establish that the generalized bilinear transformation preserve these two features.

THEOREM 2.2. *Assume that $\alpha \in (0, 1)$. K is controllable (resp., observable) if and only if K_{gbt} is controllable (resp., observable).*

Proof. We first prove preservation of observability by contradiction. Suppose that K_{gbt} is not observable; then there exist a nonzero vector $w \in \mathbb{R}^n$ and a scalar $z \in \mathbb{R}$

such that

$$A_{gbt}w = zw \tag{2.16}$$

and

$$C_{gbt}w = 0. \tag{2.17}$$

There are two possible cases as follows.

Case 1($z = 0$). In this case, (2.16) is equivalent to

$$A_{gbt}w = 0. \tag{2.18}$$

Substituting it into (2.17), we have $Cw = 0$. According to (2.18), $(I + (1-\alpha)hA)\, w = 0$, that is, $(A - \frac{1}{(\alpha-1)h}I)w = 0$. Clearly, $x = w \neq 0$ and $s = \frac{1}{(\alpha-1)h}$ satisfy $Ax = sx$ and $Cx = 0$.

Case 2($z \neq 0$). In this case, define $x = (I + \frac{\alpha}{1-\alpha}A_{gbt})w$. Then $Cx = 0$. However, we need to verify that $x \neq 0$. If $x = 0$, then $w = -\frac{\alpha}{1-\alpha}A_{gbt}w$. Combining it with (2.16), we have $(1 + \frac{\alpha z}{1-\alpha})A_{gbt}w = 0$. Since $A_{gbt}w \neq 0$ (otherwise $z = 0$), $1 + \frac{\alpha z}{1-\alpha} = 0$, i.e., $z = \frac{\alpha-1}{\alpha}$. According to (2.16), $(I + (1-\alpha)hA)\, w = z(I - \alpha hA)w = \frac{\alpha-1}{\alpha}(I - \alpha hA)w$, which implies $w = 0$ and contradicts our hypothesis. As a consequence, $x \neq 0$. Define $s = \frac{1}{h}\frac{z-1}{1-\alpha+\alpha h}$. Then it is straightforward to verify that $Ax = sx$ and $Cx = 0$.

The "sufficient" part can be proved by reverting the preceding procedure. Consequently the case of observability is proved. Preservation of controllability can be readily proved in a similar way. □

Remark 2. We have studied such properties of the GBT as the mapping of zeros and poles and preservation of controllability and observability. Certainly, there are more to be investigated. For example, Chen and Weller [9] studied the problem of how the finite and infinite zero structures, as well as invertibility structures, of a general continuous-time LTI multivariable system are mapped to those of its discrete-time counterpart under the bilinear transformation. Similar results can be drawn for the GBT.

Remark 3. From our point of view, the real significance of GBT is that it induces a class of controller discretizations. The parameter α provides an extra degree of freedom in the course of digital implementation of analogue controllers. Therefore, it is possible for a designer to utilize α to achieve better control performance. For example, it is now possible to adjust α to assign the poles of the digital controller to some prespecified place. Take step tracking as another example. For a sampled-data system obtained by approximating the analogue controller via either the step-invariant transformation or the bilinear transformation, it is well known that it is step-tracking if and only if the analogue system is step-tracking. However, due to digital approximation, the transient response in the sampled-data system is worse than that of the analogue system. Transient response is primarily determined by closed-loop poles. Hence, with the aid of GBT, we may expect better transient response by choosing α carefully. In summary, there are a lot of issues to be investigated regarding GBT. Due to space limitation, in what follows we discuss only one type of performance, namely, performance recovery characterized by ℓ_p induced norms of systems. In section 3, we show that the ℓ_p induced norms of $K_d - K_{gbt}$ approach zero as the sampling period h goes to zero. Then based on this result, in section 4 we prove performance recovery in digital implementation of analogue systems via the GBT.

3. Convergence in ℓ_p induced norms. Given an analogue system K with a state-space realization (A, B, C, D), its step-invariant transformation K_d has a state-space realization $K_d(z) = (A_d, B_d, C, D)$, where

$$A_d = e^{Ah}, \quad B_d = \int_0^h e^{A\tau} d\tau B.$$

In this section, assuming that K is stable, we investigate the convergence properties between K_d and K_{gbt} in terms of ℓ_p induced norms when the sampling period h goes to zero. Some preliminaries are necessary for further development.

LEMMA 3.1. *Assume that the pair (A, B) is stabilizable. Then there exists a constant matrix F such that $A+BF$ and $\frac{1}{1-\alpha}A+BF$ ($\alpha \in (0,1)$) are all asymptotically stable.*

Proof. Since (A, B) is stabilizable, it is well known that there exists a positive definite matrix P such that

$$A'P + PA - PBB'P < 0.$$

Define $F = -\frac{1}{2}\frac{1}{1-\alpha}B'P$. It can be verified that

$$(A + BF)' P + P (A + BF) \le A'P + PA - PBB'P < 0$$

and

$$\left(\frac{1}{1-\alpha}A + BF\right)' P + P\left(\frac{1}{1-\alpha}A + BF\right) = \frac{1}{1-\alpha}(A'P + PA - PBB'P) < 0.$$

By the Lyapunov theorem, $A + BF$ and $\frac{1}{1-\alpha}A + BF$ are both asymptotically stable. □

LEMMA 3.2. *If $A+BF$ is asymptotically stable (in continuous time), $A_d + B_dF$, $A_{gbt} + B_{gbt}F$, and $A_{gbt} + \frac{1}{1-\alpha}B_{gbt}F$ are all asymptotically stable (in discrete time) for sufficiently small h.*

Proof. The stability of $A_d + B_dF$ can be proved using the power series. Observe that

$$\begin{aligned} A_d + B_dF &= e^{Ah} + \int_0^h e^{A\tau} d\tau BF \\ &= e^{Ah} + \left(hI + \frac{1}{2}Ah^2 + o(h^2)\right) BF \\ &= I + h(A + BF) + o(h), \end{aligned}$$

where $o(h)$ satisfies $\lim_{h\to 0} \frac{o(h)}{h} = 0$. Because $A + BF$ is asymptotically stable, so is $A_d + B_dF$ for sufficiently small h. To prove the stability of $A_{gbt} + B_{gbt}F$, in addition to the power series, Lemma 3.1 is also required. Observe that

$$\begin{aligned} A_{gbt} + B_{gbt}F &= (I - \alpha hA)^{-1} (I + (1-\alpha)hA) + (1-\alpha)h (I - \alpha hA)^{-1} BF \\ &= (I - \alpha hA)^{-1} (I + (1-\alpha)h(A + BF)) \\ &= (I + \alpha hA + o(h)) (I + (1-\alpha)h(A + BF)) \\ &= I + h(A + (1-\alpha)BF) + o(h) \\ &= I + (1-\alpha)h\left(\frac{1}{1-\alpha}A + BF\right) + o(h). \end{aligned}$$

Coupling this with Lemma 3.1 yields the asymptotic stability of $(\frac{1}{1-\alpha}A + BF)$ for sufficiently small h. Hence, $A_{gbt} + B_{gbt}F$ is asymptotically stable for sufficiently small h. Finally, we show the asymptotic stability of $A_{gbt} + \frac{1}{1-\alpha}B_{gbt}F$. Observe that

$$\begin{aligned} A_{gbt} + \frac{1}{1-\alpha}B_{gbt}F &= (I - \alpha hA)^{-1}(I + (1-\alpha)hA) + (I - \alpha hA)^{-1} hBF \\ &= (I - \alpha hA)^{-1}(I - \alpha hA + h(A + BF)) \\ &= I + (I - \alpha hA)^{-1} h(A + BF) \\ &= I + (I + \alpha hA + o(h))\, h(A + BF) \\ &= I + h(A + BF) + o(h). \end{aligned}$$

As a consequence, $A_{gbt} + \frac{1}{1-\alpha}B_{gbt}F$ is asymptotically stable. □

Now we have a set-up for the following lemma that is crucial in further development.

LEMMA 3.3. *In the graph metric* [34], [26], $K_d - K_{gbt}$ *converges to zero as the sampling period* h *goes to zero.*

This result can be easily derived based on the above two lemmas as well as the proof of Theorem 2 in [39] by replacing

$$\begin{bmatrix} M_{bt}(z) \\ N_{bt}(z) \end{bmatrix} = \left[\begin{array}{c|c} A_{bt} + 2B_{bt}F & B_{bt} \\ \hline 2F & I \\ \hline C_{bt} + 2D_{bt}F & D_{bt} \end{array}\right]$$

with

$$\begin{bmatrix} M_{gbt}(z) \\ N_{gbt}(z) \end{bmatrix} = \left[\begin{array}{c|c} A_{bt} + \frac{1}{1-\alpha}B_{gbt}F & B_{gbt} \\ \hline \frac{1}{1-\alpha}F & I \\ \hline C_{gbt} + \frac{1}{1-\alpha}D_{gbt}F & D_{gbt} \end{array}\right]$$

for a right coprime factorization of $K_{gbt} = N_{gbt}(M_{gbt})^{-1}$.

If K is asymptotically stable and $\alpha \in (1/2, 1)$, then it follows from Lemma 3.2 that both K_d and K_{gbt} are asymptotically stable. In this case, the graph metric induces the same topology as that induced by the H_∞ norm. We have the following.

COROLLARY 3.4. *If* K *is stable and* $\alpha \in (1/2, 1)$, $\lim_{h\to 0^+} \|K_d(z) - K_{gbt}(z)\|_{\ell_2} = 0$.

With the aid of Corollary 3.4, we are now in a position to prove the main result of this section.

THEOREM 3.5. *Assume that* K *is stable and* $\alpha \in (1/2, 1)$. *Then*

$$\lim_{h\to 0^+} \|K_d - K_{gbt}\|_{\ell_p} = 0$$

for all $1 \le p \le \infty$.

Proof. Observe that

$$K_d(z) - K_{gbt}(z) = \left[\begin{array}{cc|c} A_d & 0 & B_d \\ 0 & A_{gbt} & B_{gbt} \\ \hline C & -C_{gbt} & -\alpha hC(I - \alpha hA)^{-1}B \end{array}\right].$$

Let

$$K_{cl}(z) := \left[\begin{array}{cc|c} A_d & 0 & B_d \\ 0 & A_{gbt} & B_{gbt} \\ \hline C & -C_{gbt} & 0 \end{array}\right], \quad D_{cl} := -\alpha hC(I - \alpha hA)^{-1}B.$$

Then

$$K_d(z) - K_{gbt}(z) = K_{cl}(z) + D_{cl}.$$

By Corollary 3.4,

$$\lim_{h\to 0^+} \|K_{cl}(z)\|_{\ell_2} = 0.$$

Let the Hankel singular values of $K_{cl}(z)$ be $\sigma_H^h = \{\sigma_1^h, \cdots, \sigma_N^h\}$, where $\sigma_1^h \geq \cdots \geq \sigma_N^h \geq 0$. According to the discrete-time counterpart of Theorem 7.8 in [43], we have

$$\|K_{cl}(z)\|_{\ell_1} \leq 2\sum_{k=1}^{N} \sigma_i^h \leq 2N\sigma_1^h.$$

As a result,

$$\lim_{h\to 0^+} \|K_{cl}(z)\|_{\ell_1} = 0.$$

Clearly, $D_{cl} \to 0$ as $h \to 0$. Therefore

$$\lim_{h\to 0^+} \|K_d(z) - K_{gbt}(z)\|_{\ell_1} = 0.$$

Furthermore, according to the discrete-time version of Theorem 9.1.2 in [6],

$$\|K_d - K_{gbt}\|_{\ell_p} \leq \|K_d - K_{gbt}\|_{\ell_1} \quad \text{for all } 1 \leq p \leq \infty.$$

The result is proved. □

Remark 4. The above theorem is applicable to MIMO systems. The restriction of the "A" matrix being diagonalizable with all real eigenvalues in [39] is also removed. Thus it generalizes Theorem 1 of [39]. In this way, along with Theorem 9.4.1 in [6], if the step-invariant or GBT is applied to an analogue system, internal stability as well as other performance specifications of the analogue system can be recovered as the sampling period tends to zero. This is the topic of the next section.

Remark 5. As commented before, when $\alpha = 1/2$, the GBT in (2.4) reduces to the traditional one. For convenience, we denote it by K_{bt}. It can be shown that $K(s)$ and $K_{bt}(z)$ have the same Hankel singular values. Unfortunately, the GBT does not enjoy this nice property.

4. Performance recovery. In this section, we discuss an application of Theorem 3.5. It is well known that internal stability of an analogue control system can be recovered if the controller is implemented via the step-invariant transformation. Similar results can be proved for other types of performance specifications. More concretely, consider the feedback system Σ_1 in Figure 1.1. Now we perform digital implementation using the step-invariant transformation; then K_h in Figure 1.2 becomes K_d. Assume that both G and K_d are FDLTI and strictly causal. Furthermore, suppose that W is FDLTI, strictly causal, and stable, introduced as a prefilter before the sampler for later digital implementation. This closed-loop system is said to be *internally stable* [6] if the mapping

$$\begin{bmatrix} I & G \\ -K & I \end{bmatrix}^{-1} : \begin{bmatrix} r \\ d \end{bmatrix} \longmapsto \begin{bmatrix} z \\ u \end{bmatrix}$$

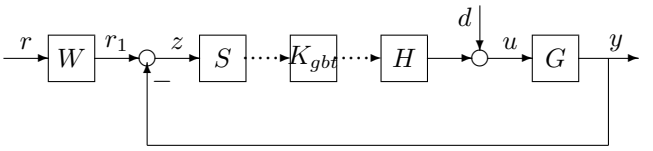

FIG. 4.1. *Digital system* Σ_3 *via the GBT.*

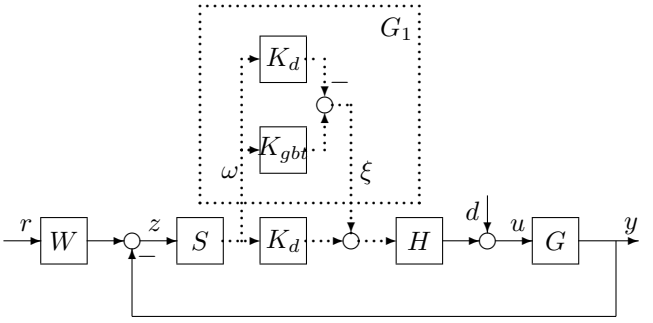

FIG. 4.2. *The equivalent system of* Σ_3.

is bounded $\mathcal{L}_2(\mathbb{R}_+) \to \mathcal{L}_2(\mathbb{R}_+)$.

The following proposition will be used later.

PROPOSITION 4.1 (see [6]). *Suppose that* Σ_1 *is internally stable and satisfies* $\sup_{\|r\|_{\ell_p}\le 1} \|z\|_{\ell_p} < \epsilon$, *for some* $\epsilon > 0$. *Then*

(a) Σ_2 *is internally stable as* $h \to 0$;

(b) $\sup_{\|r\|_{\ell_p}\le 1} \|z\|_{\ell_p} < \epsilon$ *as* $h \to 0$.

If we replace K_d in Figure 1.2 with K_{gbt}, then we get another sampled-data system, Σ_3, as shown in Figure 4.1. We have the following result that is the counterpart of Proposition 4.1.

THEOREM 4.2. *This pertains to the configuration of Figure* 4.1. *Suppose that* Σ_1 *is internally stable and satisfies* $\sup_{\|r\|_{\ell_p}\le 1} \|z\|_p < \epsilon$ *for some* $\epsilon > 0$. *Furthermore, assume that* K *is strictly causal and stable. Then*

(a) Σ_3 *is internally stable as* $h \to 0$;

(b) $\sup_{\|r\|_{\ell_p}\le 1} \|z\|_{\ell_p} < \epsilon$ *as* $h \to 0$.

In order to prove this theorem, we observe the following fact: Let G be a stable, FDLTI, discrete-time system. Then

$$\|G\|_{\ell_p} \le \|G\|_{\ell_1} \quad \text{for all } p \in \mathbb{N} \cup \infty. \tag{4.1}$$

We can now proceed with the proof of Theorem 4.2.

Proof. First we reconfigure system Σ_3 in the way shown in Figure 4.2. The system G_1 can be viewed as a perturbation to the system under it, which is exactly system Σ_2 in Figure 1.2. Therefore, if the norm from ω to ξ tends to zero as $h \to 0$, then according to the small gain theorem, we can ascertain that system Σ_3 is internally stable. Hence, the problem is reduced to showing property (b) for system Σ_3. For that, and in view of (4.1), it is sufficient to show $\lim_{h\to 0} \|G_1\|_{\ell_1} = 0$, which is given by Theorem 3.5. ∎

5. Discussion on performance limitations of digital implementations of analogue systems. In this section, we discuss digital implementation of analogue systems with examples. If an analogue plant $G(s)$ is preceded by a zero-order holder and followed by an ideal sampler, then one gets its discrete-time counterpart, $G_d(z)$. Now suppose there is a certain holder as well as some sampler such that the discrete-time version of $G(s)$ is $G_{gbt}(z)$ obtained via (2.4), i.e., the GBT is physically implementable. Next, we will employ an example to compare these two implementations in terms of various performance limitations of closed-loop systems, such as limitations of feedback control given by Bode or Poisson integrals as well as bandwidth limitations and quantization in network-based control or communication.

Suppose that we have a continuous-time system $G(s)$ whose transfer function is

$$G(s) = \frac{s^3 - 3s + 12s - 10}{s^4 - 10s^3 - 7s^2 + 64s + 60}.$$

$G(s)$ has three unstable zeros: $z_1 = 1 + 3i$, $z_2 = 1 + 3i$, and $z_3 = 1$, where $i = \sqrt{-1}$. The poles of $G(s)$ are $p_1 = 10$, $p_2 = 3$, $p_3 = -2$, and $p_4 = -1$. Note that the first two are unstable. Let the sampling period be $h = 0.5$. Assume that $G_d(z)$ is the discretization of $G(z)$ via the ZOH transformation, and $G_{gbt}(z)$ is that of $G(z)$ via a GBT at $\alpha = 7/8$. Then

$$G_d(z) = \frac{12.76z^3 - 46.34z^2 + 75.95z - 63.65}{z^3 - 153.9z^3 + 814.3z^2 - 682.2z + 148.4}$$

and

$$G_{gbt}(z) = \frac{0.1765z^4 - 0.3691z^3 + 0.1594z^2 - 0.1595z - 0.02719}{z^4 + 3.163z^3 - 2.656z^2 - 0.744z + 0.5568}.$$

It is easy to see that the zeros of $G_d(z)$ are

$$z_1^d = 0.8779 + 1.3742i,\ z_2^d = 0.8779 - 1.3742i,\ z_3^d = 1.8761,$$

and its poles are

$$p_1^d = 148.4132,\ p_2^d = 4.4817,\ p_3^d = 0.6065,\ p_4^d = 0.3679.$$

Hence, $G_d(z)$ has three unstable zeros. Note that the relative degree of $G(s)$ is 1; thus there are no discretization zeros [1]. $G_d(z)$ has two unstable poles, too. The zeros of $G_{gbt}(z)$ are

$$z_1^{gbt} = 1.8889,\ z_2^{gbt} = -0.1429,\ z_3^{gbt} = 0.1724 + 0.7356i,\ z_4^{gbt} = 0.1724 - 0.7356i,$$

and its poles are

$$p_1^{gbt} = -3.8000,\ p_2^{gbt} = -0.4815,\ p_3^{gbt} = 0.4667,\ p_4^{gbt} = 0.6522.$$

It is worthwhile to observe that $z_2^{gbt} = -0.1429$ is a discretization zero, i.e., $-\frac{1-\alpha}{\alpha} = -\frac{1-7/8}{7/8} = -1/7 \approx -0.1429$ corresponding to the zero at ∞ as indicated by Theorem 2.1. $G_{gbt}(z)$ has one unstable zero as well as one unstable pole. In the following, we will compare $G_d(z)$ and $G_{gbt}(z)$ in terms of performance limitations, such as those characterized by sensitivity and complementary sensitivity functions as well as bandwidth requirement in network-based control.

The benefit of feedback is that it compensates for the influence of various sources of uncertainties and disturbances. For example, a sensitivity function quantifies a system's ability to attenuate output disturbance, while a complementary sensitivity function describes a system's ability to attenuate noise response as well as maintain stability robustness. Such performance limitations can be characterized by Bode and Poisson integrals of sensitivity and complementary sensitivity functions. Due to their fundamental importance, in what follows we compare G_d and G_{gbt} in this respect.

First we discuss G_{gbt}. It is easy to show that G_{gbt} is stabilizable by a strictly proper stable controller, F, so to speak (see p. 115 of [6] for one choice of such a controller). Hence, the resulting open-loop transfer function $G_{gbt}F$ is strictly proper too. In light of this, according to Theorem 2 of [36] (resp., Theorem 3.3 of [8]), the Bode integral of the sensitivity function from $-\pi$ to π is $2\pi \cdot (log(p_1^{gbt})) \approx 2\pi \cdot 1.3350 \approx 8.3881$. As to G_d, it is not easy to find directly a strictly proper stable controller M that ensures stability of the closed-loop system. However, by mapping G_d into the continuous-time domain via the traditional bilinear transformation, one can use Theorem 1 in [37] to design a strictly proper stable controller, say M. Indeed, the procedure described by Corollary 3 in [37] can be implemented to find such a controller. Therefore, the open-loop transfer function G_dM is also strictly proper, and its unstable poles are given uniquely by G_d. According to Theorem 2 of [36] (resp., Theorem 3.3 of [8]), the Bode integral of the sensitivity function from $-\pi$ to π is around 40.8407, which is much bigger than that of the sensitivity function $G_{gbt}F$. Due to space limitation, we omit the calculation of Bode integrals for complementary functions of G_dM and $G_{gbt}F$. We also omit the Poisson integrals for the sensitivity function and the complementary function of G_dM as well as those of $G_{gbt}F$ (interested readers may follow the discussions on pages 74–83 of [29]). However, our calculation shows that those performance limitations for G_{gbt} are much less severe than those of G_d because of the unstable poles and zeros structures.

Signal quantization is widely adopted in network-based control. Given a plant G, quantization of state space of G will surely affect the control law to be designed. Insofar as state feedback is concerned, unstable poles turn out to determine primarily the quantization of the system state space. For example, it is shown in [10] that the presence of unstable poles causes nonexistence of a stabilizing state feedback law under any fixed state quantization. A new network data transmission strategy has recently been proposed, and its dynamics have been analyzed in depth in [40], [41], and [42], where it is proved that the presence of unstable poles leads to no stabilizing feedback laws under this new networked control scheme. In [12], a parameter ρ is employed to describe the coarseness of quantization. In general, the smaller ρ is, the coarser the quantization is. Coarser quantization indicates that less control effort is required. Now we compare the optimal ρ values for both cases of the ZOH and GBT transformations. According to Theorem 2.2 of [12], the coarsest quantizer ρ associated with $G_d(z)$ is 0.6266, while that of $G_{gbt}(z)$ is 0.5833. Therefore quantization for $G_{gbt}(z)$ can be coarser, signifying less control effort.

Furthermore, a Bode integral formula has been generalized to the case of networked control systems. For example, in a Gaussian network, it is shown in [11] that the Bode integral is equal to some average directed information [32] that describes the required transmission rate of a stable communication scheme (Theorem 4.6 of [11]). It turns out that the Bode integral for the sensitivity function is given by unstable poles of the plant to be controlled via the network. More concretely, for $G_d(z)$, this

quantity is

$$\ln\left(p_1^d\right) + \ln\left(p_2^d\right) = 6.5000,$$

while that of $G_{gbt}(z)$ is

$$\ln\left(p_1^{gbt}\right) = 1.3350.$$

Clearly, a lower transmission rate is required if the original continuous-time plant G is implemented via the generalized bilinear transformation with $\alpha = 7/8$. Interestingly, it is shown [33], [31] that the above value is also the minimal bandwidth required to guarantee the asymptotic observability and asymptotic stabilizability of a discrete-time linear system in network-based control, which are argued to be two fundamentally important concepts in network-based control.

6. Conclusion. In this paper, we have proposed the generalized bilinear transformation (GBT). We have proved that GBT preserves both controllability and observability. We have shown that, compared with the traditional bilinear transformation, as well as the zero-order hold (ZOH) transformation, one advantage of GBT is its ability to convert unstable poles (resp., zeros) to stable poles (resp., zeros). We have also proved that GBT and ZOH converge to one another as the sampling period goes to zero in the sense of ℓ_p induced norms for all $1 \leq p \leq \infty$. Finally, we have established performance recovery of digital implementations of continuous-time systems via GBT. We hope that the brief discussion of the GBT in this paper can lay the groundwork for a subsequent study of its possible applications in the fields of digital and network-based control, and signal processing.

PATHWISE STOCHASTIC CONTROL PROBLEMS AND STOCHASTIC HJB EQUATIONS*

RAINER BUCKDAHN† AND JIN MA‡

Abstract. In this paper we study a class of *pathwise stochastic control problems* in which the optimality is allowed to depend on the paths of exogenous noise (or information). Such a phenomenon can be illustrated by considering a particular investor who wants to take advantage of certain extra information but in a completely legal manner. We show that such a control problem may not even have a "minimizing sequence," but nevertheless the (Bellman) dynamical programming principle still holds. We then show that the corresponding Hamilton–Jacobi–Bellman equation is a stochastic partial differential equation, as was predicted by Lion and Souganidis [*C. R. Acad. Sci. Paris Sér. I Math.*, 327 (1998), pp. 735–741]. Our main device is a Doss–Sussmann-type transformation introduced in our previous work [*Stochastic Process. Appl.*, 93 (2001), pp. 181–204] and [*Stochastic Process. Appl.*, 93 (2001), pp. 205–228]. With the help of such a transformation we reduce the pathwise control problem to a more standard relaxed control problem, from which we are able to verify that the value function of the pathwise stochastic control problem is the unique stochastic viscosity solution to this stochastic partial differential equation, in the sense of [*Stochastic Process. Appl.*, 93 (2001), pp. 181–204] and [*Stochastic Process. Appl.*, 93 (2001), pp. 205–228].

1. Introduction.

In this paper we are interested in the so-called *pathwise stochastic control problem*, originally proposed by P.-L. Lions and Souganidis [13]. A version of such a problem can be described by the following example of optimazation problem in finance, in which the underlying risky asset follows a "hidden Markovian" stochastic volatility model:

$$\begin{cases} dS_t = S_t[\mu(t,S_t)dt + \widehat{\sigma}(Y_t)dW_t], \\ dY_t = h(t,Y_t)dt + \sigma_1(t,Y_t)dW_t + \sigma_2(t,Y_t)\circ dB_t, \\ S_0 = \xi, Y_0 = y. \end{cases} \tag{1.1}$$

where W and B are two independent Brownian motions, S_t is the asset value at t, and $\widehat{\sigma}(Y)$ is the volatility process. Here the Stratonovic differential $\circ dB$ in (1.1) is used to simplify our future discussion; it can be replaced by an Itô-type integral if needed.

We note that the extra noise B in (1.1) can be thought of as some extra information that cannot be detected in the market in general, but is available to the particular investor. The problem then is to show how this investor can take advantage of such extra information to optimize his/her utility, but by taking actions that are

completely "legal," in the sense that the investor has to choose the optimal strategy in the usual class of the admissible portfolios.

Mathematically, we can formulate such an optimization problem for this investor as follows. First recall that if the short rate of the riskless asset in this market is $\{r_t,\ t \geq 0\}$, and we assume that the (self-financing) portfolios $\{\pi_t,\ t \geq 0\}$ are all the $\{\mathcal{F}_t^W\}$-progressively measurable, square-integrable processes, then the dynamics of the wealth process, $\{\mathcal{V}_t, t \geq 0\}$, of the investor satisfies the SDE

$$\begin{cases} d\mathcal{V}_t = [r_t\mathcal{V}_t + \pi_t(\mu(t,S_t) - r_t)]dt + \pi_t\widehat{\sigma}(Y_t)dW_t, \\ \mathcal{V}_0 = v. \end{cases} \tag{1.2}$$

Next, denoting $\{\mathcal{F}_t^B\}_{t\geq 0}$ to be the filtration generated by B, we define the following "cost functional" (given the extra information):

$$J(\pi) = E\left\{H(\mathcal{V}_T) + \int_0^T \ell(t,\mathcal{V}_t,\pi_t)dt\Big|\mathcal{F}_T^B\right\}. \tag{1.3}$$

Clearly, the purpose of conditioning on $\mathcal{F}_T^B$ means that we are seeking optimization given all the possible extra information (some of them might be anticipating!), while the restriction that all strategies are $\{\mathcal{F}_t^W\}$-adapted indicates that they are completely "legal."

To make (1.2) and (1.3) fit more into a stochastic control framework, we combine (1.1) and (1.2) as follows. Define $X \triangleq (Y,S,\mathcal{V})^T$ and

$$\begin{aligned} b(t,X_t,\pi_t) &\triangleq [h(t,Y_t), \mu(t,S_t)S_t, r_t\mathcal{V}_t + \pi_t(\mu(t,S_t) - r_t)]^T, \\ \sigma(t,X_t,\pi_t) &\triangleq [\sigma_1(t,Y_t), \hat{\sigma}(Y_t)S_t, \hat{\sigma}(Y_t)\pi_t]^T, \\ \theta(t,X_t) &\triangleq [\sigma_2(t,Y_t), 0, 0]^T. \end{aligned}$$

Then the new "state" process X satisfies the following SDE:

$$\begin{cases} dX_t = b(t,X_t,\pi_t)dt + \sigma(t,X_t,\pi_t)dW_t + \theta(t,X_t)\circ dB_t, \\ X_s = (y,\xi,v)^T, \end{cases} \qquad 0 \leq s \leq t \leq T, \tag{1.4}$$

and cost functional (1.3) can be rewritten as

$$J(s,(y,\xi,v);\pi) = E_{s,(y,\xi,v)}\left\{H(X_T) + \int_s^T \ell(t,X_t,\pi_t)dt\Big|\mathcal{F}_T^B\right\}. \tag{1.5}$$

Our *pathwise stochastic control problem* is then to minimize the cost functional (1.5) over the set of "admissible controls" $\mathcal{A}$, which is by definition all the $\{\mathcal{F}_t^W\}$-adapted strategies. The value function of this stochastic control problem is defined by

$$V(s,(y,\xi,v)) = \operatorname*{essinf}_{\pi\in\mathcal{A}} J(s,(y,\xi,v)). \tag{1.6}$$

Here the essential infimum should be understood as one with respect to the indexed family of random variables (see, e.g., [5, 7] or [10, Appendix A]; detailed definition will be given in section 2).

At this point we would like to point out that the pathwise stochastic control problem of this kind was one of the motivations for the study of the "stochastic

viscosity solution" for fully nonlinear stochastic PDEs (see Lions and Souganidis [13]). However, while it has long been predicted that the Hamilton–Jacobi–Bellman (HJB) equation for such stochastic control problem is a fully nonlinear stochastic PDE, to date the mathematical content of this problem has not been fully explored. One of the main purposes of this paper is to try to establish a rigorous framework for the pathwise stochastic control problem and provide some necessary machinery for future study. It turns out that many of them are interesting in their own right. Among other things, we shall prove the Bellman dynamic programming principle in this particular situation, from which we then prove that the value function is a *stochastic viscosity* solution of a stochastic HJB equation, in the sense of our previous works (see Buckdahn and Ma [2, 3]). It should be noted that the special measurability issue involved in the "legality" of our admissible controls has not been studied before.

We should note that the pathwise control problem defined above is quite different from a standard stochastic control problem, or even those with partial observations (see, e.g., Bensoussan [1]). The most essential difference is that the cost functional is now a random field instead of a deterministic function, and therefore so is the value function. Consequently, the usual infimum (or supremum) involved in the optimization problem should naturally be replaced by the "essential infimum" (or "essential supremum"). Such a seemingly "routine" change, together with the "legality" requirements for the admissible controls, turns out to be the source of many substantial difficulties, both from a mathematical point of view and from the control theoretical point of view. In fact, in the appendix we shall provide an example which shows that in general there does not exist a minimizing sequence for our pathwise stochastic control problem. The lack of such a sequence seems to be fatal for the dynamic programming method. To overcome this difficulty we introduce an intermediate stochastic control problem (called the "wider-sense" control problem in what follows), in which the stochastic integral against the Brownian motion B is eliminated. We show that this wider-sense control problem is in some sense equivalent to a traditional stochastic control problem, and we can use it as a bridge to reach our goal.

Another immediate problem is the stochastic HJB equation itself, mainly in various forms of measurability issues including the definition of the stochastic integration (one should appreciate the fact that an HJB equation is always "backward"!). One of the main reasons that we insist on using the Stratonovic stochastic integral with regard to the Brownian motion B is that it is "insensitive" to the direction of integration, as we can show. Finally, we would like to remark that the notion of stochastic viscosity solutions has been studied by Lions and Souganidis [12, 13, 14, 15] and Buckdahn and Ma [2, 3, 4]. The definition of the stochastic viscosity solution in this paper is consistent with our previous works, with slight modifications to suit the present situation. We note that such a modification will not alter the uniqueness result from [3].

The rest of the paper is organized as follows. In section 2 we formulate the problem more formally and provide some necessary preliminaries. In section 3 we introduce some wider-sense control problems and establish some properties and relationship among them. Section 4 is devoted to a proof of the Bellman principle. Finally, in section 5 we prove that the value function of the corresponding wider-sense control problem is the viscosity solution to a randomized HJB equations, and in section 6 we extend the result to the original problem.

2. Problem formulation and preliminaries. In this section we give a detailed formulation of our pathwise control problem. Let $W = (W^1, \dots, W^d)$ and $B = (B^1, \dots, B^m)$ be two independent, standard Brownian motions defined on some

complete probability space $(\Omega, \mathcal{F}, P)$, and let $T > 0$ be a given finite time horizon. We denote $\mathbf{F}^W = \{\mathcal{F}_t^W\}_{t\in[0,T]}$ and $\mathbf{F}^B = \{\mathcal{F}_t^B\}_{t\in[0,T]}$ to be the two filtrations generated by W and B, respectively, and augmented by the P-null sets in $\mathcal{F}$ so that they satisfy the *usual hypotheses* (see, e.g., [16]). The following two filtrations will be frequently used in the future:

$$\begin{cases} \mathbf{F} = \{\mathcal{F}_t\}_{t\in[0,T]} \triangleq \{\mathcal{F}_t^W \vee \mathcal{F}_t^B\}_{t\in[0,T]} = \mathbf{F}^W \vee \mathbf{F}^B, \\ \mathbf{G} = \{\mathcal{G}_t\}_{t\in[0,T]} \triangleq \{\mathcal{F}_t^W \vee \mathcal{F}_T^B\}_{t\in[0,T]} = \mathbf{F}^W \vee \mathcal{F}_T^B. \end{cases} \tag{2.1}$$

Here, for two σ-fields $\mathcal{F}$ and $\mathcal{G}$, $\mathcal{F} \vee \mathcal{G}$ denotes $\sigma(\mathcal{F} \cup \mathcal{G})$ as usual. The meaning for those involving filtrations is obvious.

Throughout this paper we let $\mathbb{E}$ be a generic Euclidean space, with inner product $\langle \cdot, \cdot \rangle$ and norm $|\cdot|$. We denote $C^k(\mathbb{E}; \mathbb{E}_1)$ to be the usual space of $\mathbb{E}_1$-valued, k-times continuously differentiable functions defined on $\mathbb{E}$. Furthermore, we denote $C_b^k(\mathbb{E}; \mathbb{E}_1) \subset C^k(\mathbb{E}; \mathbb{E}_1)$ to be all functions that have uniformly bounded partial derivatives and $C_p^k(\mathbb{E}; \mathbb{E}_1) \subset C^k(\mathbb{E}; \mathbb{E}_1)$ to be all functions whose partial derivatives are of at most polynomial growth. The spaces $C^{k,\ell}([0,T] \times \mathbb{E}; \mathbb{E}_1)$, $C_b^{k,\ell}([0,T] \times \mathbb{E}; \mathbb{E}_1)$, $C_p^{k,\ell}([0,T] \times \mathbb{E}; \mathbb{E}_1)$ are defined similarly. Finally, if $\mathbb{E}_1 = \mathbb{R}$, we shall omit $\mathbb{E}_1$ in the notation above.

Now let $\mathbb{B}$ be a generic Banach space and $\mathbf{H} = \{\mathcal{H}_t\}_{t\in[0,T]}$ a generic Filtration on $(\Omega, \mathcal{F}, P)$. We shall denote the following:

- For any $1 \le p < \infty$, $L^p(\mathbf{H}, [0,T]; \mathbb{B})$ denotes all $\mathbb{B}$-valued, $\mathbf{H}$-progressively measurable processes ψ, such that $E\int_0^T \|\psi_t\|_{\mathbb{B}}^p dt < \infty$. In particular, we denote $L^0(\mathbf{H}, [0,T]; \mathbb{B})$ to be all $\mathbb{B}$-valued, $\mathbf{H}$-progressively measurable processes and $L^\infty(\mathbf{H}, [0,T]; \mathbb{B})$ to be a subset of $L^0(\mathbf{H}, [0,T]; \mathbb{B})$ in which all processes are uniformly bounded.
- For any $1 \le p < \infty$, $L_{loc}^p(\mathbf{H}, [0,T] \times \mathbb{E}; \mathbb{E}_1)$ denotes the space of all $\mathbb{E}_1$-valued random fields η defined on $[0,T] \times \Omega \times \mathbb{E}$, such that for fixed $x \in \mathbb{E}$, the mapping $(t, \omega) \mapsto \eta(t, \omega, x)$ is $\mathbf{H}$-progressively measurable, and that $E\int_0^T |\eta(t, \cdot, x)|^p dt < \infty$. In particular, we denote $L_{loc}^p(\mathbf{H}, [0,T]; C^k(\mathbb{E}, \mathbb{E}_1))$ to be all $C^k(\mathbb{E}, \mathbb{E}_1)$-valued, $\mathbf{H}$-progressively measurable random fields η such that η and all the partial derivatives $D_{x_i}\eta$ are elements of $L_{loc}^p(\mathbf{H}, [0,T] \times \mathbb{E}; \mathbb{E}_1)$.
- $C^{k,\ell}(\mathbf{H}, [0,T] \times \mathbb{E}; \mathbb{E}_1)$ (resp., $C_b^{k,\ell}(\mathbf{H}, [0,T] \times \mathbb{E}; \mathbb{E}_1)$, $C_p^{k,\ell}(\mathbf{H}, [0,T] \times \mathbb{E}; \mathbb{E}_1)$) denotes the space of all $\mathbb{E}_1$-valued random fields φ, defined on $[0,T] \times \Omega \times \mathbb{E}$ such that for P-a.e. $\omega \in \Omega$, $\varphi(\cdot, \omega, \cdot) \in C^{k,\ell}([0,T] \times \mathbb{E}; \mathbb{E}_1)$ (resp., $C_b^{k,\ell}([0,T] \times \mathbb{E}; \mathbb{E}_1)$, $C_p^{k,\ell}([0,T] \times \mathbb{E}; \mathbb{E}_1)$), and that for fixed $x \in \mathbb{E}$, the process $\varphi(\cdot, \cdot, x)$ is $\mathbf{H}$-progressively measurable.
- $\mathcal{M}_{0,T}(\mathbf{H})$ denotes all the $\mathbf{H}$-stopping times τ such that $0 \le \tau \le T$, P-a.s., and $\mathcal{M}_{0,\infty}(\mathbf{H})$ denotes all $\mathbf{H}$-stopping times that are almost surely finite.

To formulate our control problem let us first specify the *admissible control* sets. Let U be a compact metric space. We denote $\mathcal{A}$ to be the set of all $\mathbf{F}^W$-progressively measurable processes $\alpha : [0,T] \times \Omega \to U$, and denote $\widetilde{\mathcal{A}}$ to be the set of all $\mathbf{G}$-progressively measurable processes $\beta : [0,T] \times \Omega \to U$. We shall refer to the elements in $\mathcal{A}$ as the admissible controls and those in $\widetilde{\mathcal{A}}$ as the *admissible controls in a wider sense.*

For $(t,x) \in [0,T] \times \mathbb{R}^n$ and $\alpha \in \mathcal{A}$, let us consider the following controlled stochastic system: for $0 \le s \le t \le T$,

$$X_t = x + \int_s^t b(r, X_r, \alpha_r)\, dr + \int_s^t \sigma(r, X_r, \alpha_r)\, dW_r + \int_s^t \theta(r, X_r) \circ dB_r. \tag{2.2}$$

The solution of SDE (2.2) will be denoted by $X^{\alpha,s,x}$. The superscripts $^{(\alpha,s,x)}$ will often be dropped for notational simplicity if the context is clear.

The *cost functional* of the pathwise control problems is defined by

$$J(\alpha;s,x)\stackrel{\Delta}{=}E\left\{H(X_T^{\alpha,s,x})+\int_s^T \ell(t,X_t^{\alpha,s,x},\alpha_t)dt\Big|\mathcal{F}_T^B\right\}, \tag{2.3}$$

where $(s,x)\in[0,T]\times\mathbb{R}^n$, and $\alpha\in\mathcal{A}$, and the *value function* is defined by

$$V(s,x)\stackrel{\Delta}{=}\operatorname*{essinf}_{\alpha\in\mathcal{A}} J(\alpha,s,x). \tag{2.4}$$

We note that the definition of essential infimum for a family of nonnegative random variables can be found in [7] and [10, Appendix A]; we recast it here for ready reference.

DEFINITION 2.1. *Let $\mathcal{X}$ be a nonempty family of nonnegative random variables defined on a probability space $(\Omega,\mathcal{F},P)$. The essential infimum of $\mathcal{X}$, denoted by* essinf $\mathcal{X}$*, is a random variable X^* satisfying the folowing:*

(i) *for all $X\in\mathcal{X}$, $X^*\le X$, P-a.s.; and*

(ii) *if Y is a random variable such that $Y\le X$ for all $X\in\mathcal{X}$, then $Y\le X^*$, P-a.s.*

Throughout this paper we shall make use of the following standing assumptions:

(H1) The functions $b:\mathbb{R}^n\times U\mapsto\mathbb{R}^n$, $\sigma:\mathbb{R}^n\times U\mapsto\mathbb{R}^{n\times d}$ are bounded, uniformly continuous, and uniformly Lipschitz with respect to $x\in\mathbb{R}^n$, uniformly in $u\in U$.

(H2) The function θ belongs to $C^4_{\ell,b}(\mathbb{R}^n;\mathbb{R}^{n\times m})$.

(H3) The function $H:\mathbb{R}^n\mapsto\mathbb{R}$ is uniformly bounded and continuous.

The Lipschitz constants in (H1)–(H3) will be denoted by a generic one $K>0$.

We would like to remark here that in (2.4) the value function $V(\cdot,\cdot)$ is obtained by taking an "essinf" instead of an "inf" as in the usual stochastic control problem. Such a change on the one hand is necessary due to the randomness of the cost functionals, as it is often seen in optimization problems involving random objectives (see, e.g., [10]); it does, on the other hand, generate a great deal of subtleties to the otherwise standard control problem. In fact, in the Appendix we shall provide a counterexample which shows that with such an "essinf" one does not even have a "minimizing sequence" to the control problem. This gives rise to some substantial difficulties in proving the dynamic programming principle, as well as in deriving the stochastic HJB equations. We will show how to get around of this difficulty by studying the related "wider-sense control problems" in section 4.

We should also note that since we do not require any "nondegeneracy" condition on the coefficient σ (or $\sigma\sigma^T$) in this framework, we can apply a standard treatment to reduce the system to a time-homogeneous one and to eliminate the running cost ℓ in (2.3) by adding the extra states

$$X_t^0=t\qquad\text{and}\qquad X_t^{n+1}=\int_s^t \ell(r,X_r,\alpha_r)dr.$$

For example, in this case the cost functional can be written as

$$J(\alpha;s,(s,x,0))=E\{\widetilde{H}(X_T^{\alpha,s,(s,x,0)})\big|\mathcal{F}_T^B\},$$

where $\widetilde{H}(x^0,x,x^{n+1})=H(x)+x^{n+1}$. Therefore, in the rest of the paper we shall

consider the following simplified version of (2.2), (2.3), and (2.4):

$$X_t = x + \int_s^t b\,(X_r, \alpha_r)\,dr + \int_s^t \sigma\,(X_r, \alpha_r)\,dW_r + \int_s^t \theta\,(X_r) \circ dB_r, \tag{2.5}$$

$$J(\alpha; s, x) \triangleq E\left\{H(X_T^{\alpha,s,x})\middle|\mathcal{F}_T^B\right\}, \tag{2.6}$$

and

$$V(s, x) \triangleq \operatorname*{essinf}_{\alpha\in\mathcal{A}} J(\alpha, s, x). \tag{2.7}$$

To conclude this section we remark that under (H1) and (H2), for any admissible control $\alpha \in \mathcal{A}$ the SDE (2.2) has a unique ($\mathbf{F}$-adapted) solution. But if $\alpha \in \widetilde{\mathcal{A}}$, the situation would be much more complicated, although it could be made sensible if we allow the integral $\int \theta(X_r) \circ dB_r$ to be the anticipating Stratonovic integral. But we shall avoid such complexity by introducing the wider-sense problems. Finally, we note that the value function defined by (2.7) is an $\mathcal{F}_T^B$-measurable random field. We shall prove that it is indeed $\mathcal{F}_{s,T}^B$-measurable for any $s \in [0, T]$, and hence the stochastic HJB equation, which is "backwardly" defined (given the terminal condition at time T), would simply be a time-reversed stochastic PDE in the usual sense.

3. A Doss–Sussmann-type transformation. In this section we introduce the first step towards our wider-sense control problem. In light of the idea of "stochastic characteristics" (cf. Lions and Souganidis [12, 13, 14, 15]) and/or "Doss–Sussmann" transformation (cf. Buckdahn and Ma [2, 3, 4]), we would like to remove the stochastic integral "$\int \theta(X) \circ dB$" so it becomes less "problematic." We note that such a step is essential in the study of stochastic viscosity solutions as well.

We proceed as follows. First consider the following SDE with parameters: for any $0 \le s \le T$, and $z \in \mathbb{R}^n$,

$$\eta_t^s(z) = z + \int_s^t \theta(\eta_r^s(z)) \circ dB_r \qquad s \le t \le T. \tag{3.1}$$

We note that this SDE can be converted easily into the following "Itô form":

$$\eta_t^s(z) = z + \int_s^t \theta(\eta_r^s(z))dB_r + \frac{1}{2}\int_s^t [D_x\theta \otimes \theta](\eta_r^s(z))dr, \qquad s \le t \le T. \tag{3.2}$$

Here $[D_x\theta \otimes \theta]$ denotes the product of the tensor $D_x\theta$ and the matrix θ, defined by

$$[D_x\theta \otimes \theta]_i \triangleq \sum_{j=1}^m \sum_{k=1}^n \frac{\partial\theta^{ij}}{\partial x^k}\theta^{kj} = \operatorname{tr}\{[D_x\theta^i]\theta^T\}, \qquad i = 1, \dots, n, \tag{3.3}$$

where θ^i is the ith row vector of the matrix θ. We note that in this paper the dimensions of the Brownian motion are not essential. Thus, to simplify notation, in what follows we shall assume $m = 1$. Thus the tensor product is simplified to the usual matrix product: $D\theta \otimes \theta = [D\theta]\theta$.

Next, we note that the stochastic flow $z \mapsto \eta_t^s(z)$ is a diffeomorphism for all $s \le t \le T$, P-a.s., and

$$D_z\eta_t^s(z) = I + \int_s^t D_z\eta_r^s(z) D\theta(\eta_r^s(z)) \circ dB_r, \quad s \le t \le T. \tag{3.4}$$

Consequently, $[D_z\eta_t^s]^{-1}(\cdot)$ exists; and it can be shown (see, e.g., [2]) that the inverse flow of $\eta_t^s(\cdot)$, denoted by $\zeta_t^s(\cdot)$, exists and satisfies the first order stochastic PDE:

$$\zeta_t^s(z) = z - \int_s^t D_z\zeta_r^s(z)\theta(z)\circ dB_r, \qquad 0\le s\le t\le T,\ z\in\mathbb{R}^n, \tag{3.5}$$

and it holds that $\eta_t^s(\zeta_t^s(z)) = \zeta_t^s(\eta_t^s(z)) = z$ for $0\le s\le t\le T$, $z\in\mathbb{R}^n$, P-a.s. Let us now define the following random fields: for $(t,z,u)\in[0,T]\times\mathbb{R}^n\times U$,

$$\widetilde{\sigma}(t,z,u) \triangleq [D_z\eta_t^0(z)]^{-1}\sigma(\eta_t^0(z),u); \tag{3.6}$$

$$\begin{aligned}\widetilde{b}(t,z,u) \triangleq [D_z\eta_t^0(z)]^{-1}\Big\{ & b(\eta_t^0(z),u)\\ & -\frac{1}{2}\mathrm{tr}\left\{[D_z\eta_t^0(z)]^{-1}\sigma\sigma^T(\eta_t^0(z),u)[(D_z\eta_t^0(z))^T]^{-1}[D_{zz}^2\eta_t^0(z)]\right\}\Big\}.\end{aligned} \tag{3.7}$$

Clearly, $\widetilde{b}$ and $\widetilde{\sigma}$ are $\mathbf{F}$-progressively measurable. The following lemma is essential.

LEMMA 3.1. *Assume* (H1) *and* (H2). *Then for any* $0<\gamma<\frac{1}{12}$, *there exist a sequence of* $\mathbf{F}^B$*-stopping times* $0\le\tau_1\le\tau_2\le\cdots\le\tau_\ell\le\cdots$ *satisfying* $P\{\tau_\ell = T\}\uparrow 1$, *as* $\ell\to\infty$, *and some constant* $C>0$, *depending only on the coefficients* b, σ, *and* θ, *such that for all* $\ell\ge 1$ *and* $t\in[0,T]$, $z,z'\in\mathbb{R}^n$, *and* $u\in U$, *it holds* P*-a.s. on* $\{\tau_\ell = T\}$ *that*

$$\begin{aligned}|\widetilde{\sigma}(t,z,u)| &\le C\ell(1+|z|^2)^\gamma \le C\ell(1+|z|);\\ |\widetilde{b}(t,z,u)| &\le C\ell^4(1+|z|^2)^{4\gamma} \le C\ell^4(1+|z|);\\ |\widetilde{\sigma}(t,z,u)-\widetilde{\sigma}(t,z',u)| &\le C\ell^3(1+|z|^2+|z'|^2)^{3\gamma}|z-z'|\\ &\le C\ell^3(1+|z|+|z'|)|z-z'|;\\ |\widetilde{b}(t,z,u)-\widetilde{b}(t,z',u)| &\le C\ell^6(1+|z|^2+|z'|^2)^{6\gamma}|z-z'|\\ &\le C\ell^6(1+|z|+|z'|)|z-z'|.\end{aligned}$$

Proof. First, let $\mathbb{E}$ be any Euclidean space, and let $f\in L^2_{loc}(\mathbf{G};[0,T],C^1(\mathbb{R}^n;\mathbb{E}))$ (that is, $f(t,\omega,\cdot)\in C^1(\mathbb{R}^n;\mathbb{E})$, and all components of f and D_zf belong to the space $L^2(\mathbf{G};[0,T]\times\mathbb{R}^n;\mathbb{E})$). For any constant $\gamma>0$ and $p\ge 2\vee n$, we can apply the Sobolev imbedding theorem (cf. section 7.10 of [9]), the Burkholder–Gundy–Davis inequality, and the Hölder inequality to conclude that there exists a constant $C_{p,\gamma}>0$ (which we allow to vary from line to line) such that, for all $s\in[0,T]$,

$$\begin{aligned}&E\left\{\sup_{\substack{t\in[s,T]\\ z\in\mathbb{R}^n}}\left[(1+|z|^2)^{-\gamma}\Big|\int_s^t f(r,z)dB_r\Big|\right]^2\right\}\\ &\le C_{p,\gamma}E\left\{\sup_{t\in[s,T]}\int_{\mathbb{R}^n}(1+|z|^2)^{-p\gamma}\left\{\Big|\int_s^t f(r,z)dB_r\Big|^p+\Big|\int_s^t D_zf(r,z)dB_r\Big|^p\right\}dz\right\}^{\frac{2}{p}}\\ &\le C_{p,\gamma}\left\{\int_{\mathbb{R}^n}(1+|z|^2)^{-p\gamma}\left\{E\left[\sup_{t\in[s,T]}\Big|\int_s^t f(r,z)dB_r\Big|^p\right]\right.\right.\\ &\qquad\left.\left.+E\left[\sup_{t\in[s,T]}\Big|\int_s^t D_zf(r,z)dB_r\Big|^p\right]\right\}dz\right\}^{\frac{2}{p}}\\ &\le C_{p,\gamma}\left\{\int_{\mathbb{R}^n}(1+|z|^2)^{-p\gamma}\left\{E\left[\int_s^T|f(r,z)|^2\,dr\right]^{\frac{p}{2}}+E\left[\int_s^T|D_zf(r,z)|^2\,dr\right]^{\frac{p}{2}}\right\}dz\right\}^{\frac{2}{p}}.\end{aligned} \tag{3.8}$$

Here we note that, as we pointed out before, if $\mathbb{E} = \mathbb{R}^{n\times m}$, then $D_z f$ should be understood as a "tensor." But such a notational complexity does not cause any substantial difficulty; therefore to simply presentation in the rest of the proof we consider only the case $n = m = 1$.

Now, differentiating (3.1) twice we have, for $s \le t \le T$,

$$D_z\eta_t^s(z) = 1 + \int_s^t \theta'(\eta_r^s(z))D_z\eta_r^s(z) \circ dB_r,$$
$$D_z^2\eta_t^s(z) = \int_s^t \{D_z^2\eta_r^s(z)\theta'(\eta_r^s(z)) + \theta''(\eta_r^s(z))[D_z\eta_t^s(z)]^2\} \circ dB_r.$$

Here and in what follows D_z^k denotes the kth derivative of the flow $z \mapsto \eta_t^s(z)$. Thus, noting assumption (H2) it is readily seen that for any $q \ge 2$,

$$E\left\{\sup_{t\in[s,T]} \left(|D_z\eta_t^s(z)|^q + |D_z^2\eta_t^s(z)|^q\right)\right\} \le \widetilde{C}_q \qquad \forall z \in \mathbb{R}^n. \tag{3.9}$$

Setting $f(s,\cdot,z) = \theta'(\eta_t^s(z))D_z\eta_t^s(z)$ in (3.8) and using (3.9) we obtain that

$$\begin{aligned} &E\left\{\sup_{\substack{t\in[s,T]\\ z\in\mathbb{R}^n}} \left[\left(1+|z|^2\right)^{-\gamma} \left|\int_s^t \theta'(\eta_t^s(z))D_z\eta_t^s(z)dB_r\right|\right]^2\right\} \\ &\le C_{p,\gamma}\left\{\int_{\mathbb{R}^n}(1+|z|^2)^{-p\gamma}\left[E\left(\int_s^T \left|\theta'(\eta_r^s(z))\right|^2 dr\right)^p\right]^{1/2} dz\right\}^{2/p} \\ &\quad + C_{p,\gamma}\left\{\int_{\mathbb{R}^n}(1+|z|^2)^{-p\gamma}\left[E\left(\int_s^T \left|\theta''(\eta_r^s(z))\right|^2 dr\right)^p\right]^{1/2} dz\right\}^{2/p} \\ &\le C_{p,\gamma}\left\{\int_{\mathbb{R}^n}(1+|z|^2)^{-p\gamma}dz\right\}^{2/p} \le C_{p,\gamma}, \end{aligned} \tag{3.10}$$

provided $2p\gamma > 1$. Moreover, from (H2) we also have

$$E\left\{\sup_{\substack{t\in[s,T]\\ z\in\mathbb{R}^n}} \left[\left(1+|z|^2\right)^{-\gamma} \left|\int_s^t [\theta'\theta]'(\eta_r^s(z))D_z\eta_r^s(z)dr\right|\right]^2\right\} \le C_{p,\gamma}. \tag{3.11}$$

This, together with (3.10), gives that

$$E\left\{\sup_{\substack{t\in[s,T]\\ z\in\mathbb{R}^n}} \left[(1+|z|^2)^{-\gamma}\left|\int_s^t \theta'(\eta_r^s(z))D_z\eta_r^s(z) \circ dB_r\right|\right]^2\right\} \le C_{p,\gamma}, \tag{3.12}$$

and consequently

$$E\left\{\sup_{\substack{t\in[s,T]\\ z\in\mathbb{R}^n}} \left[\left(1+|z|^2\right)^{-\gamma} |D_z\eta_t^s(z)|\right]^2\right\} \le C_{p,\gamma}. \tag{3.13}$$

Repeating the similar argument one also shows that, for all $\gamma > 0$ and $2p\gamma > 1$, there is some constant $C_{p,\gamma} > 0$ such that

$$E\left\{\sup_{\substack{s\in[t,T]\\ z\in R^n}}\left[(1+|z|^2)^{-\gamma}\left\{|[D_z\eta_t^s]^{-1}(z)|+|D_z^2\eta_t^s(z)|+|D_z^3\eta_t^s(z)|\right\}\right]^2\right\}\le C_{p,\gamma}. \tag{3.14}$$

We now fix $0 < \gamma < 1/12$, and define a sequence of $\mathbf{F}$-stopping times: for $\ell \ge 1$,

$$\tau_\ell \stackrel{\triangle}{=} \inf\left\{s\ge 0:\sup_{z\in\mathbb{R}^n}(1+|z|^2)^{-\gamma}\left[|[D_z\eta_s^0]^{-1}(z)|+\sum_{i=1}^3|D_z^i\eta_s^0(z)|\right]>\ell\right\}\wedge T. \tag{3.15}$$

Clearly, by virtue of (3.13) and (3.14), this sequence of stopping times $\{\tau_\ell\}$ satisfies the following properties:

(i) $0 \le \tau_1 \le \tau_2 \le \cdots$;
(ii) $\{\tau_\ell = T\} \uparrow \Omega$, P-a.s., as $\ell \to +\infty$;
(iii) for each $s \in [t, \tau_\ell)$, $z \in \mathbb{R}^n$, and $\ell \ge 1$, it holds P-a.s. that

$$|[D_z\eta_s^0]^{-1}(z)|+|D_z\eta_s^0(z)|+|D_z^2\eta_s^0(z)|+|D_z^3\eta_s^0(z)|\le \ell(1+|z|^2)^\gamma. \tag{3.16}$$

We can now easily derive the desired properties of $\widetilde{\sigma}$ and $\widetilde{b}$ by combining the definitions (3.6), (3.7) and the estimate (3.16), proving the lemma. □

A direct consequence of Lemma 3.1 is that we can now consider the following "transformed" control system of (2.2). Note that W and B are independent, and W is a $\mathbf{G}$-Brownian motion as well. Also, since both $\widetilde{b}$ and $\widetilde{\sigma}$ are $\mathbf{G}$-progressively measurable random fields, for any β in the wider-sense admissible control set $\widetilde{\mathcal{A}}$ the following SDE is well-defined:

$$F_t^{s,x,\beta} = x + \int_s^t \widetilde{b}(r, F_r^{s,x,\beta}, \beta_r)dr + \int_s^t \widetilde{\sigma}(r, F_r^{s,x,\beta}, \beta_r)dW_r, \qquad t\in[s,T]. \tag{3.17}$$

The following result validates the name "Doss–Sussmann transformation."

LEMMA 3.2. *Assume* (H1) *and* (H2). *Let* $\{\eta_t^s(z) : (t,z) \in [s,T]\times\mathbb{R}^n\}$ *be the stochastic flow given by* (3.1) *or* (3.2), $\{X_t^{s,x,\alpha} : t \in [s,T]\}$ *the solution of the SDE* (2.5), *and* $\{F_t^{s,x,\beta} : t \in [s,T]\}$ *the solution of* (3.17). *Then the following hold:*

(i) *For each* $\alpha \in \mathcal{A}$, *the solution* $F^{s,x,\alpha}$ *is* $\mathbf{F}$*-progressively measurable. Moreover, it holds that*

$$\eta_t^s(F_t^{s,x,\alpha}) = X_t^{s,\eta_s^0(x),\alpha}, \qquad t\in[s,T],\ P\text{-a.s.},$$

or, equivalently, $\eta_t^s(F_t^{s,\zeta_s^0(x),\alpha}) = X_t^{s,x,\alpha}$, $t\in[s,T]$, P*-a.s.*

(ii) *For each* $\beta \in \widetilde{\mathcal{A}}$, *we define* $X_t^{s,x,\beta} \stackrel{\triangle}{=} \eta_t^s(F_t^{s,\zeta_s^0(x),\beta})$, $t\in[s,T]$. *Then there exists a sequence of* $\mathbf{F}$*-stopping times* $\{\tau_\ell\}_{\ell\ge1}$ *with* $P\{\tau_\ell = T\}\uparrow 1$, *such that*

$$\sup_{\beta\in\widetilde{A}} E\left\{\sup_{t\in[s,\tau_\ell]}\left(\left|X_t^{s,x,\beta}\right|^p+\left|X_t^{s,\eta_s^0(x),\beta}\right|^p\right)\right\}<+\infty \quad \forall\ p\ge1.$$

Proof. Again, we shall assume $n = 1$ to simplify the presentation. The higher-dimensional case can be treated in exactly the same way without substantial difficulties.

(i) Let $\alpha \in \mathcal{A}$, and denote $F_t^\alpha = F_t^{s,x,\alpha}$ and $\eta_t = \eta_t^0$, $t \geq s$, for simplicity. Define $X_t^\alpha = \eta_t(F_t^\alpha)$, $t \geq s$. Applying the Itô–Ventzell formula (cf., e.g., [11]) in a differential form we get, for $t \in [s,T]$,

$$\begin{aligned}
dX_t^\alpha &= d\eta_t(F_t^\alpha) + D_z\eta_t(F_t^\alpha)dF_t^\alpha + \frac{1}{2}D_z^2\eta_t(F_t^\alpha)d[F^\alpha]_t \\
&= \theta(\eta_t(F_t^\alpha)) \circ dB_t + D_z\eta_t(F_t^\alpha)\widetilde{\sigma}(t,F_t^\alpha,\alpha_t)dW_t + D_z\eta_t(F_t^\alpha)\widetilde{b}(t,F_t^\alpha,\alpha_t)dt \\
&\quad + \frac{1}{2}D_z^2\eta_t(F_t^\alpha)|\widetilde{\sigma}(t,F^\alpha,\alpha_t)|^2dt \\
&= \theta(\eta_t(F_t^\alpha)) \circ dB_t + \sigma(\eta_t(F_t^\alpha),\alpha_t)dW_t \\
&\quad + \left\{ b(\eta_t(F_t^\alpha),\alpha_t) - \frac{1}{2}\left[\left| [D_z\eta_t(F_t^\alpha)]^{-1} \right|^2 |\sigma(\eta_t(F_t^\alpha),\alpha_t)|^2 D_z^2\eta_t(F_t^\alpha) \right] \right\} dt \\
&\quad + \frac{1}{2}\left| [D_z\eta_t(F_t^\alpha)]^{-1} \right|^2 |\sigma(\eta_t(F_t^\alpha),\alpha_t)|^2 D_z^2\eta_t(F_s^\alpha)dt \\
&= \theta(X_t^\alpha) \circ dB_t + \sigma(X_t^\alpha,\alpha_t)dW_t + b(X_t^\alpha,\alpha_t)dt.
\end{aligned}$$

Furthermore, at $t = s$, one has $X_s^\alpha = \eta_s^0(F_s^{s,x,\alpha}) = \eta_s^0(x)$. Thus by uniqueness of the SDE one must have $X^\alpha \equiv X^{s,\eta_s^0(z),\alpha}$.

(ii) We now let $\beta \in \widetilde{\mathcal{A}}$, and define $X_s^\beta = \eta_t(F_t^\beta)$, $t \in [s,T]$. Note that for all $(t,z) \in [s,T] \times \mathbb{R}^n$ we can write

$$\eta_t(z) = \eta_t(0) + \int_0^1 D_z\eta_t(\theta z)d\theta.$$

One can easily show, thanks to Lemma 3.1, that for all $\gamma > 0$, there exists an increasing sequence of $\mathbb{F}$-stopping times $(\tau_\ell)_{\ell \geq 1}$ with $P\{\tau_\ell = T\} \uparrow 1$, as $\ell \to \infty$, such that all the estimates of Lemma 3.1 are satisfied, and it holds furthermore that

$$|\eta_s(z)|^2 \leq \ell\left(1 + |z|^{2+\gamma}\right), \qquad s \in [t,\tau_\ell],\ z \in \mathbb{R}^n,\ P\text{-a.s.}$$

Consequently, we see that the unique $\mathbb{G}$-adapted solution F^β of (3.17) must satisfy

$$E\left\{ \sup_{s\in[t,\tau_\ell]} |F_s^\beta|^p \right\} < +\infty \qquad \forall\ p > 1.$$

Finally, it is readily seen that $X_t^\beta = \eta_t(F_t^\beta)$, $t \in [s,T]$, is a $\mathbb{G}$-adapted continuous process and it satisfies that $E\{\sup_{s\in[t,\tau_\ell]} |X_s^\beta|^p\} < +\infty$ for all $p > 1$. The other estimate is similar. The proof is complete. □

4. Wider-sense control problems. In this section we introduce two types of wider-sense stochastic control problems which will help us attack the original pathwise control problem. We begin by considering the state equation after the Doss–Sussmann transformation:

$$F_t^\beta = x + \int_s^t \widetilde{\sigma}(r,F_r^\beta,\beta_r)dW_r + \int_s^t \widetilde{b}(r,F_r^\beta,\beta_r)dr, \quad s \in [t,T], \tag{4.1}$$

where $\beta \in \widetilde{\mathcal{A}}$. Lemma 3.1 guarantees the well-posedness of this SDE, and Lemma 3.2 enables us to rewrite the cost functional (2.6) as

$$J(s,x;\alpha) = E\left\{H\left(X_T^{s,x,\alpha}\right)\middle|\, \mathcal{F}_T^B\right\} = E\left\{H\left(\eta_T^0(F_T^{s,\zeta_0^s(x),\alpha})\right)\middle|\, \mathcal{F}_T^B\right\}, \qquad P\text{-a.s.},$$

for all $\alpha \in \mathcal{A}$. Let us now define the following two new "cost functionals":

$$\widetilde{J}(s,x,\beta) = E\{H(\eta_T^0(F_T^{s,x,\beta}))|\mathcal{F}_T^B\}, \qquad \beta \in \widetilde{\mathcal{A}}, \tag{4.2}$$

and

$$\widehat{J}(s,x,\beta) = E\{\widetilde{J}(s,x,\beta)\} = E\{H(\eta_T^0(F_T^{s,x,\beta}))\}, \quad \beta \in \widetilde{\mathcal{A}}. \tag{4.3}$$

Then Lemma 3.2(i) tells us that

$$\widetilde{J}(s,x,\alpha) = J(s,\eta_s^0(x),\alpha) \qquad \forall \alpha \in \mathcal{A}. \tag{4.4}$$

In other words $\widetilde{J}$ is in some sense an "extension" of J to the wider-sense admissible control set $\widetilde{\mathcal{A}}$. The following two "wider-sense" stochastic control problems are the building blocks of our method.

Wider-sense control problem I (WSCP-I).

- State: $F^{s,x,\beta}$, $\beta \in \widetilde{\mathcal{A}}$.
- Cost functional: $\widetilde{J}(s,x;\beta)$, $\beta \in \widetilde{\mathcal{A}}$.
- Value function:

$$\widetilde{V}(t,x) = \operatorname*{essinf}_{\beta \in \widetilde{\mathcal{A}}} \widetilde{J}(t,x,\beta). \tag{4.5}$$

Remark 4.1. (i) The main purpose of introducing WSCP-I is to remove the "problematic" term involving the Brownian motion B from the state equation. However, a closer look at the cost functional and the value function should lead to the understanding that it is still a far cry from a standard stochastic control problem. For example, the cost functional not only still contains a conditional expectation, the terminal cost function is actually random (via the flow $\eta_\cdot^0$). As a consequence the value function $\widetilde{V}(s,x)$ is still a random field(!), and thus the "pathwise" nature of the problem remains.

(ii) Although the value function in WSCP-I still involves an "essinf," this time it is much more benign than the original one. The main difference is that in this case there do exist minimizing sequences to this problem.

We make a further modification to completely eliminate the "pathwise" nature of the control problem.

Wider-sense control problem II (WSCP-II).

- State: $F^{s,x,\beta}$, $\beta \in \widetilde{\mathcal{A}}$.
- Cost functional: $\widehat{J}(s,x;\beta)$, $\beta \in \widetilde{\mathcal{A}}$.
- Value function:

$$\widehat{V}(s,x) = \inf_{\beta \in \widetilde{\mathcal{A}}} \widehat{J}(s,x,\beta). \tag{4.6}$$

It is readily seen that WSCP-II looks almost like a standard stochastic control problem, except for the form of the terminal cost function (it is still random via the flow η^0). But it is much easier to handle than the previous two control problems. In the rest of this section we analyze the relationship among the two wider-sense stochastic control problems and the original pathwise control problem.

We begin by observing some more or less obvious facts. First, it is clear that for any $\beta \in \widetilde{\mathcal{A}}$, it holds that

$$E\{\widetilde{V}(s,x)\} = E\left\{\operatorname*{essinf}_{\beta \in \widetilde{\mathcal{A}}} \widetilde{J}(s,x;\beta)\right\} \le E\{\widetilde{J}(s,x;\beta)\}.$$

Thus we must have

$$E\{\widetilde{V}(s,x)\} \le \hat{V}(s,x), \qquad (s,x) \in [0,T] \times \mathbb{R}^n. \tag{4.7}$$

Next, from (4.4) we see that for all $\alpha \in \mathcal{A}$ and $(s,x) \in [0,T] \times \mathbb{R}^n$, it holds that

$$V(s,\eta_s^0(x)) = \operatorname*{essinf}_{\alpha\in\mathcal{A}} J(s,\eta_s^0(x);\alpha) = \operatorname*{essinf}_{\alpha\in\mathcal{A}} \widetilde{J}(s,x;\alpha) \ge \widetilde{V}(s,x). \tag{4.8}$$

We now give the main result of this section. Among other things, we show that the equalities in (4.7) and (4.8) both hold, and we construct a minimizing sequence for WSCP-I, which is essential for our future discussion.

THEOREM 4.2. *Assume* (H1)–(H3). *Then the following statements hold:*

(i) $\widetilde{V}(s,x) = V(s,\eta_s^0(x))$, *for all* $(s,x) \in [0,T] \times \mathbb{R}^n$, P-*a.s.*

(ii) *There exists some sequence* $\{\beta^k\}_{k\ge1} \subset \widetilde{\mathcal{A}}$ *such that*

$$\widetilde{V}(s,x) = \lim_{k\to\infty} \downarrow \widetilde{J}(s,x;\beta^k), \qquad P\text{-a.s.}$$

Here and in what follows " $\lim\downarrow$*" stands for the monotone decreasing limit.*

(iii) $E\{\widetilde{V}(s,x)\} = \widehat{V}(s,x)$ *for all* $(s,x) \in [0,T] \times \mathbb{R}^n$.

Proof. (i) From (4.8) we know that $\widetilde{V}(s,x) \le V(s,\eta_s^0(x))$. We need only show the reverse inequality. To this end, consider a subset $\widetilde{\mathcal{A}}_0 \subset \widetilde{\mathcal{A}}$ that consists of all elements of the form

$$\beta_t(\omega) = \sum_{1\le i,j\le N} u_{i,j} \mathbf{1}_{[t_{i-1},t_i)\times(A_{i,j}\cap B_{i,j})}(t,\omega), \qquad 0 \le s \le t,$$

where $N \ge 1$, $s = t_0 < t_1 < \cdots < t_N = T$, $u_{i,j} \in U$, $A_{i,j} \in \mathcal{F}_{t_{i-1}}^W$, $B_{i,j} \in \mathcal{F}_T^B$ with $B_{i,j} \cap B_{i,k} = \emptyset$ for $j \ne k$, and $\cup_{j=1}^N B_{i,j} = \Omega$.

It is not hard to check that $\widetilde{\mathcal{A}}_0$ is a dense subset of $\widetilde{\mathcal{A}}$ in the space $L^2([s,T]\times\Omega;U)$. That is, for any $\beta \in \widetilde{\mathcal{A}}$ one can find a sequence $(\beta^\ell)_{\ell\ge1} \subset \widetilde{\mathcal{A}}_0$ such that

$$E\left\{\int_s^T |\beta_r - \beta_r^\ell|^2 dr\right\} \to 0 \qquad \text{as } \ell \to \infty.$$

It follows that $\{F^{s,x,\beta^\ell}\}_{\ell\ge1}$ converges to $F^{s,x,\beta}$ in $L^0(\Omega;C([0,T];\mathbb{R}^n))$ as $\ell \to \infty$, thanks to Lemma 3.1, and that $\widetilde{J}(s,x;\beta^\ell) \to \widetilde{J}(s,x,\beta)$, in probability, as $\ell \to \infty$. Consequently, one has $\operatorname{essinf}_\ell \widetilde{J}(s,x;\beta^\ell) \le \widetilde{J}(s,x;\beta)$, P-a.s., and thus it suffices to show that

$$V(s,\eta_s^0(x)) \le \widetilde{J}(s,x;\beta) \qquad \forall\ \beta \in \widetilde{\mathcal{A}}_0. \tag{4.9}$$

To this end, we fix arbitrarily a $\beta \in \widetilde{\mathcal{A}}_0$. Denote by Λ the set of all finite sequences $\lambda = \{\lambda_i\}_{1\le i\le N}$, where λ_i's take values in the finite set $\{1,2,\dots,N\}$. For each $\lambda \in \Lambda$, we denote $B_\lambda = \cap_{i=1}^N B_{i,\lambda_i}$, and

$$\alpha_t^\lambda(\omega) = \sum_{1\le i\le N} \mathbf{1}_{[t_{i-1},t_i)}(t) u_{i,\lambda_i} \mathbf{1}_{A_{i,\lambda_i}}(\omega), \qquad (t,\omega) \in [s,T]\times\Omega.$$

Then it is readily seen that all B_λ's are $\mathcal{F}_T^B$-measurable sets, and all α^λ's are elements of the original admissible control set $\mathcal{A}$(!).

Now let us rewrite β as follows:

$$\beta_t(\omega) = \sum_{\lambda\in\Lambda} \alpha_t^\lambda(\omega)\mathbf{1}_{B_\lambda}(\omega), \qquad (t,\omega)\in[s,T]\times\Omega.$$

Observe that $\sum_{\lambda\in\Lambda} B_\lambda = \Omega$, and the SDE (4.1) does not contain a stochastic integral with respect to the Brownian motion B. Using the total probability formula and the uniqueness of solution to the SDE, one can show that the following decomposition holds:

$$F_t^{s,x,\beta} = \sum_{\lambda\in\Lambda} F_t^{s,x,\alpha^\lambda}\mathbf{1}_{B_\lambda}, \qquad t\in[s,T],\ P\text{-a.s.}$$

Similarly, applying the same arguments and noting Lemma 3.2(i) we also have

$$\eta_t^0(F_t^{s,x,\beta}) = \eta_t^0\left(\sum_{\lambda\in\Lambda} F_t^{s,x,\alpha^\lambda}\mathbf{1}_{B_\lambda}\right) = \sum_{\lambda\in\Lambda}\eta_t^0(F_t^{s,x,\alpha^\lambda})\mathbf{1}_{B_\lambda} = \sum_{\lambda\in\Lambda} X_t^{s,\eta^0(x),\alpha^\lambda}\mathbf{1}_{B_\lambda}$$

for all $t\in[s,T]$. Therefore, we have

$$\begin{aligned}\widetilde{J}(s,x,\beta) &= E\left\{H\Big(\eta_T^0(F_T^{s,x,\beta})\Big)\Big|\mathcal{F}_T^B\right\} = \sum_{\lambda\in\Lambda} E\left\{H(X_T^{s,\eta_s^0(x),\alpha^\lambda})\Big|\mathcal{F}_T^B\right\}\mathbf{1}_{B_\lambda}\\ &= \sum_{\lambda\in\Lambda} J(s,\eta^0(x),\alpha^\lambda)\mathbf{1}_{B_\lambda} \geq V(s,\eta^0(x)),\end{aligned}$$

proving (4.9), whence (i).

(ii) Let $(s,x)\in[0,T]\times\mathbb{R}^n$ be fixed. We first choose a sequence $\{\widetilde{\beta}^k\}_{k\geq1}\subset\widetilde{\mathcal{A}}$ such that

$$\widetilde{V}(s,x) = \operatorname*{essinf}_{k\geq1}\widetilde{J}(s,x;\widetilde{\beta}^k).$$

To do this, we borrow the idea of [8]. For any $\varepsilon>0$, define

$$\delta = \inf_{\{\beta^k\}\subset\widetilde{\mathcal{A}}} P\left\{\widetilde{V}(s,x)\leq\operatorname*{essinf}_{k\geq1}\widetilde{J}(s,x;\beta^k)-\varepsilon\right\}. \tag{4.10}$$

(Note that the infimum above is taken over all the sequences $\{\beta^k\}$ in $\widetilde{\mathcal{A}}$!) We claim the following two facts:

(a) the infimum in (4.10) is always attained, and

(b) $\delta=0$.

To prove (a), we first use the definition of "inf" to find, for $n=1,2,\ldots$, sequences $\{\beta^{n,k}\}_{k\geq1}$, $n=1,2,\ldots$, such that

$$\delta\leq P\left\{\widetilde{V}(s,x)\leq\operatorname*{essinf}_{k\geq1}\widetilde{J}(s,x;\beta^{n,k})-\varepsilon\right\}<\delta+\frac{1}{n}.$$

Let us consider the sequence $\{\beta^{n,k}\}_{n\geq1,k\geq1}$, and denote

$$\begin{aligned}A_\varepsilon^n &\triangleq \left\{\omega:\widetilde{V}(s,x)\leq\operatorname*{essinf}_{k\geq1}\widetilde{J}(s,x;\beta^{n,k})-\varepsilon\right\};\\ \bar{A}_\varepsilon &\triangleq \left\{\omega:\widetilde{V}(s,x)\leq\operatorname*{essinf}_{n\geq1,k\geq1}\widetilde{J}(s,x;\beta^{n,k})-\varepsilon\right\}.\end{aligned}$$

Then it is easily seen that $\bar{A}_\varepsilon \subseteq A^n_\varepsilon$ for all n. This, together with the definition of δ, leads to

$$\delta \le P\{\bar{A}_\varepsilon\} \le P\{A^n_\varepsilon\} = P\left\{\widetilde{V}(s,x) \le \operatorname*{essinf}_{k\ge 1} \widetilde{J}(s,x;\beta^{n,k}) - \varepsilon\right\} < \delta + \frac{1}{n}$$

for all $n \ge 1$. Letting $n \to \infty$ we obtain that

$$\delta = P\left\{\widetilde{V}(s,x) \le \operatorname*{essinf}_{n\ge 1,k\ge 1} \widetilde{J}(s,x;\beta^{n,k}) - \varepsilon\right\}.$$

This proves (a).

(b) By a rearrangement of indices let us denote the minimizer in part (a) by $\{\widetilde{\beta}^k\}_{k\ge 1}$. For any $\varepsilon > 0$ and $\beta \in \widetilde{\mathcal{A}}$ we denote

$$\bar{A}_\varepsilon \triangleq \left\{\widetilde{V}(s,x) \le \operatorname*{essinf}_{k\ge 1} \widetilde{J}(s,x;\widetilde{\beta}^k) - \varepsilon\right\}, \qquad A_\varepsilon(\beta) \triangleq \left\{\widetilde{V}(s,x) \le \widetilde{J}(s,x;\beta) - \varepsilon\right\}.$$

Suppose that $P(\bar{A}_\varepsilon) = \delta > 0$. Then we claim that for each $\varepsilon > 0$ there exists a $\bar{\beta} \in \widetilde{\mathcal{A}}$ such that

$$P\{\bar{A}_\varepsilon \setminus A_{\frac{\varepsilon}{2}}(\bar{\beta})\} > 0. \tag{4.11}$$

Indeed, if for all $\beta \in \widetilde{\mathcal{A}}$ one has $P\{\bar{A}_\varepsilon \setminus A_{\frac{\varepsilon}{2}}(\beta)\} = 0$, then for all $\beta \in \widetilde{\mathcal{A}}$ one must have

$$\widetilde{V}(s,x) + \frac{\varepsilon}{2}\mathbf{1}_{\bar{A}_\varepsilon} \le \widetilde{J}(s,x;\beta), \qquad P\text{-a.s.}$$

But then it follows that

$$\widetilde{V}(s,x) + \frac{\varepsilon}{2}\mathbf{1}_{\bar{A}_\varepsilon} \le \operatorname*{essinf}_{\beta\in\widetilde{\mathcal{A}}} \widetilde{J}(s,x;\beta) = \widetilde{V}(s,x), \qquad P\text{-a.s.},$$

contradicting $P(\bar{A}_\varepsilon) = \delta > 0$. Hence (4.11) must hold, and consequently

$$\begin{aligned} P\left\{\widetilde{V}(s,x) \le \widetilde{J}(s,x;\bar{\beta}) \wedge \operatorname*{essinf}_{k\ge 1} \widetilde{J}(s,x;\widetilde{\beta}^k) - \varepsilon\right\} &\le P\{\bar{A}_e \cap A_\varepsilon(\bar{\beta})\} \\ &\le P\{\bar{A}_e \cap A_{\frac{\varepsilon}{2}}(\bar{\beta})\} = P\{\bar{A}_\varepsilon\} - P\{\bar{A}_\varepsilon \setminus A_{\frac{\varepsilon}{2}}(\bar{\beta})\} < \delta. \end{aligned} \tag{4.12}$$

Let us now modify the sequence $\{\widetilde{\beta}^k\}$ slightly: define

$$\bar{\beta}^\kappa \triangleq \begin{cases} \widetilde{\beta}^k & \text{on } \{\widetilde{J}(s,x;\widetilde{\beta}^k) \le \widetilde{J}(s,x;\bar{\beta})\}, \\ \bar{\beta} & \text{on } \{\widetilde{J}(s,x;\widetilde{\beta}^k) > \widetilde{J}(s,x;\bar{\beta})\}, \end{cases} \qquad k \ge 1. \tag{4.13}$$

Since $J(s,x,\bar{\beta})$ and $J(s,x,\widetilde{\beta}^k)$'s are all $\mathcal{F}^B_T$-measurable, $\{\bar{\beta}^k\}_{k\ge 1} \subset \widetilde{\mathcal{A}}$. Furthermore, by definition it is readily seen that

$$\widetilde{J}(s,x;\bar{\beta}^k) \le \widetilde{J}(s,x;\bar{\beta}) \wedge \widetilde{J}(s,x;\widetilde{\beta}^k) \qquad \forall k \ge 1.$$

Thus, using (4.12) we obtain that

$$P\left\{\widetilde{V}(s,x) \le \operatorname*{essinf}_{k\ge 1} \widetilde{J}(s,x;\bar{\beta}^k) - \varepsilon\right\} < \delta.$$

This contradicts the definition of δ, proving (b).

To conclude the proof we use a similar technique to construct the desired minimizing sequence inductively as follows. Let $\beta^1 = \widetilde{\beta}^1$, and for $k \geq 2$, we define

$$\beta^\kappa \triangleq \begin{cases} \widetilde{\beta}^k & \text{on } \{\widetilde{J}(s,x;\widetilde{\beta}^k) \leq \widetilde{J}(s,x;\beta^{k-1})\}, \\ \beta^{k-1} & \text{on } \{\widetilde{J}(s,x;\widetilde{\beta}^k) > \widetilde{J}(s,x;\beta^{k-1})\}, \end{cases} \qquad k \geq 1. \tag{4.14}$$

Again, we have $\{\beta^k\}_{k\geq 1} \subset \widetilde{\mathcal{A}}$ and $\widetilde{J}(s,x;\beta^k) \leq \widetilde{J}(s,x;\beta^{k-1}) \wedge \widetilde{J}(s,x;\widetilde{\beta}^k)$ for all $k \geq 1$. Consequently, we have

$$\lim_{k\to\infty} \downarrow \widetilde{J}(s,x;\beta^k) \leq \operatorname*{essinf}_{k\geq 1} \widetilde{J}(s,x;\widetilde{\beta}^k) = \widetilde{V}(s,x).$$

Finally, that $\widetilde{V}(s,x) \leq \lim_{k\to\infty} \downarrow \widetilde{J}(s,x;\beta^k)$ is obvious. We proved (ii).

(iii) is a direct consequence of (ii). Thus proof is complete. □

We remark that part (ii) in Theorem 4.2 provides us the first version of a "minimizing sequence"(!). As we can see, the construction of such a sequence depends heavily on $\widetilde{J}$, hence $\mathcal{F}_T^B$-measurable. Thus the wider-sense admissible class $\widetilde{\mathcal{A}}$ is essential. The counterexample in the appendix shows that this cannot be relaxed.

To end this section let us take a brief look at the existence of optimal control. Note that WSCP-II is now a rather standard optimal control problem; therefore with a possible change of probability space, one should always be able to find an optimal control, at least in a "relaxed" form (cf., e.g., El Karoui, Nguyen, and Jeanblanc-Picqué [8]). We do not pursue this issue here due to the length of the paper. However, we give the following corollary of Theorem 4.2 that more or less explains the benefit of introducing the wider-sense controls.

COROLLARY 4.3. *Assume* (H1)–(H3). *Then any optimal control β^* for the WSCP-*II *is also an optimal control for WSCP-*I. *That is, if for $(s,x) \in [0,T] \times \mathbb{R}^n$, $\beta^* \in \widetilde{\mathcal{A}}$ is such that $\widehat{V}(s,x) = \widehat{J}(s,x;\beta^*)$, then it must hold that*

$$\widetilde{V}(s,x) = \widetilde{J}(s,x;\beta^*), \qquad P\text{-a.s.}$$

Proof. Let $\beta^* \in \widetilde{\mathcal{A}}$ be an optimal control for WSCP-II, that is, $\widehat{V}(s,x) = \widehat{J}(s,x,\beta^*)$. We show that it actually holds that

$$\widetilde{J}(s,x,\beta^*) \leq \widetilde{J}(s,x,\beta) \qquad \forall\ \beta \in \widetilde{\mathcal{A}}. \tag{4.15}$$

To see this let $\beta \in \widetilde{\mathcal{A}}$ be arbitrary. We define, as before, a new control $\widetilde{\beta}$ be such that

$$\widetilde{\beta} = \beta \mathbf{1}_{\{\widetilde{J}(s,x,\beta) < \widetilde{J}(s,x,\beta*)\}} + \beta^* \mathbf{1}_{\{\widetilde{J}(s,x,\beta) \geq \widetilde{J}(s,x,\beta^*)\}}.$$

Again, we have $\widetilde{\beta} \in \widetilde{\mathcal{A}}$, and the optimality of β^* leads to

$$\begin{aligned} E[\widetilde{J}(s,x,\beta^*)] &\leq E[\widetilde{J}(s,x,\widetilde{\beta})] \\ &= E\left[\widetilde{J}(s,x,\beta)\mathbf{1}_{\{\widetilde{J}(s,x,\beta) < \widetilde{J}(s,x,\beta^*)\}} + \widetilde{J}(s,x,\beta^*)\mathbf{1}_{\{\widetilde{J}(s,x,\beta) \geq \widetilde{J}(s,x,\beta^*)\}}\right], \end{aligned}$$

or, equivalently, $E[(\widetilde{J}(s,x,\beta) - \widetilde{J}(s,x,\beta^*))\mathbf{1}_{\{\widetilde{J}(s,x,\beta) < \widetilde{J}(s,x,\beta^*)\}}] \geq 0$. Thus we obtain that $P\{\widetilde{J}(s,x,\beta) < \widetilde{J}(s,x,\beta^*)\} = 0$, proving (4.15), whence the corollary. □

5. Properties of the value function $\widetilde{V}$. In this section we take a closer look at the value function of WSCP-I, $\widetilde{V}(s,x)$. To be more precise we would like to derive some finer results on its measurability as well as regularity, as a random field. These properties will be important for us to derive the Bellman principle, and ultimately the stochastic HJB equation.

First note that by definition we know immediately that $\widetilde{V}(s,x)$ is $\mathcal{F}_T^B$-measurable for all $(s,x)\in[0,T]\times\mathbb{R}^n$, and therefore it is $\mathbf{G}$-progressively measurable. On the other hand, note that

$$\begin{aligned}\widetilde{J}(s,x,\beta) &= E\left\{H(\eta_T^0(F_T^{s,x,\beta})\Big|\mathcal{F}_T^B\right\} = E\left\{E\left\{H\left(\eta_T^0(F_T^{s,x,\beta})\right)\Big|\mathcal{G}_s\right\}\Big|\mathcal{F}_T^B\right\}\\ &\geq E\left\{\operatorname*{essinf}_{\beta\in\widetilde{\mathcal{A}}} E\left\{H\Big(\eta_T^0(F_T^{s,x,\beta})\Big)\Big|\mathcal{G}_s\right\}\Big|\mathcal{F}_T^B\right\}.\end{aligned}$$

Therefore we can only have

$$\widetilde{V}(s,x)\geq E\left\{\operatorname*{essinf}_{\beta\in\widetilde{\mathcal{A}}} E\left\{H\Big(\eta_T^0(F_T^{s,x,\beta})\Big)\Big|\mathcal{G}_s\right\}\Big|\mathcal{F}_T^B\right\}.$$

Let us first establish a stronger result than the relation above and construct another version of minimizing sequence, which is essential for us to derive the Bellman principle.

THEOREM 5.1. *Assume* (H1)–(H3). *For all* $(s,x)\in[0,T]\times\mathbb{R}^n$, *there exists a sequence* $\{\beta^k\}\subset\widetilde{\mathcal{A}}$, *such that*

$$\widetilde{V}(s,x)=\operatorname*{essinf}_{\beta\in\widetilde{\mathcal{A}}} E\left\{H\left(\eta_T^0(F_T^{s,x,\beta})\right)\Big|\mathcal{G}_s\right\}=\lim_{k\to\infty}\downarrow E\left\{H\left(\eta_T^0(F_T^{s,x,\beta^k})\right)\Big|\mathcal{G}_s\right\},\ P\text{-a.s.}$$

Proof. We first show that, for any $(s,x)\in[0,T]\times\mathbb{R}^n$,

$$\widetilde{V}(s,x)\leq\operatorname*{essinf}_{\beta\in\widetilde{\mathcal{A}}} E\left\{H(\eta_T^0(F_T^{s,x,\beta}))\Big|\mathcal{G}_s\right\},\qquad P\text{-a.s.}\tag{5.1}$$

To this end, we fix $(s,x)\in[0,T]\times\mathbb{R}^n$ and $\beta\in\widetilde{\mathcal{A}}$, and construct a special sequence $\{\beta^k\}_{k\geq1}$ that approximates β in $L^2([0,T]\times\Omega)$. We proceed as follows. First, let us denote for each $k\geq1$ and $0\leq a<b\leq T$

$$D_k^{a,b}\triangleq\left\{a+\frac{i}{2^k}(b-a):i=0,1,2,\dots,2^k\right\},$$

and denote the generic elements of $D_k^{a,b}$ to be $t_i^{k,a,b}$ $(=a+\frac{i}{2^k}(b-a))$, $i=0,1,2,\dots,2^k$. To simplify notation we shall denote $D_k^a=D_k^{0,a}$, and $t_i^{k,a}=t_i^{k,0,a}$ for $a\in[0,T]$. Finally we define $D_k=D_k^s\cup D_k^{s,T}$.

Now consider the probability space $([0,T]\times\Omega,\mathcal{P},\mu)$, where $\mathcal{P}$ is the $\mathbf{G}$-predictable σ-field on $[0,T]\times\Omega$ and $\mu(dtd\omega)=\frac{1}{T}dtP(d\omega)$. Let $\mathcal{G}_t^s\triangleq\sigma\{W_r-W_s,\ r\in[s,t]\}\vee\mathcal{F}_T^B$, $t\geq s$, and introduce the following σ-fields:

$$\begin{aligned}\mathcal{G}_\ell^{k,s}&\triangleq\sigma\{\Delta W_{t_i^{k,s}},\ \Delta B_{t_j^{k,T}}:\ 0\leq i\leq\ell-1;\ 0\leq j\leq2^k-1\},\\ \widetilde{\mathcal{G}}_\ell^{k,s,T}&\triangleq\sigma\{\Delta W_{t_i^{k,s}},\ \Delta W_{t_{i'}^{k,s,T}},\ \Delta B_{t_j^{k,T}}:\ 0\leq i'\leq\ell-1;\ 0\leq i,j\leq2^k-1\}.\end{aligned}$$

where $\Delta\xi_{t_i^{k,a,b}} \triangleq \xi_{t_{i+1}^{k,a,b}} - \xi_{t_i^{k,a,b}}$, $\xi = W, B$. Now let

$$\mathcal{P}_k \triangleq \sigma\left\{(t_\ell^{k,s}, t_{\ell+1}^{k,s}] \times A_\ell;\ (t_\ell^{k,s,T}, t_{\ell+1}^{k,s,T}] \times \widetilde{A}_\ell :\ A_\ell \in \mathcal{G}_\ell^{k,s},\ \widetilde{A}_\ell \in \widetilde{\mathcal{G}}_\ell^{k,s,T}\right\}.$$

It is then clear that $\{\mathcal{P}_k\}_{k\geq 1}$ is an increasing family of σ-fields, and $\mathcal{P}_k \uparrow \mathcal{P}$ as $k \to \infty$ (cf., e.g., Dellacherie and Meyer [6]). Furthermore, if we define $\beta^k \triangleq E^\mu\{\beta|\mathcal{P}_k\}$, then we must have $\beta^k \in \widetilde{\mathcal{A}}$, and $\beta^k \to \beta$ in $L^2([0,T]\times\Omega)$ as $k \to \infty$. Consequently, possibly along a subsequence (we may again denote it by $\{\beta^k\}$), one has

$$E\left\{H(\eta_T^0(F_T^{s,x,\beta^k}))\Big|\mathcal{G}_s\right\} \to E\left\{H(\eta_T^0(F_T^{s,x,\beta}))\Big|\mathcal{G}_s\right\}, \qquad P\text{-a.s.} \quad \text{as } k \to \infty.$$

Now let us use the sequence $\{\beta^k\}$ to prove (5.1). First note that by a monotone-class argument and the structure of the σ-fields $\mathcal{P}_k$'s, it can be shown that the processes β^k's have the following representations:

$$\beta_t^k(\omega) = \gamma^k(t, W_{t_1^{k,s}}(\omega), W_{t_2^{k,s}}(\omega), \dots, W_{t_{2^k-1}^{k,s}}(\omega), \omega), \qquad (t,\omega) \in [0,T]\times\Omega,$$

where, for $y = (y_1, \dots, y_{2^k}) \in \mathbb{R}^{2^k d}$,

$$\begin{aligned}\gamma^k(t,y,\omega) = &\sum_{\ell=0}^{2^k-1} f_{k,\ell}(y1, \dots, y_\ell, B_{t_1^{k,T}}(\omega), \dots, B_{t_{2^k-1}^{k,T}}(\omega))\mathbf{1}_{(t_\ell^{k,s}, t_{\ell+1}^{k,s}]}(t)\\ &+ \sum_{\ell=0}^{2^k-1} g_{k,\ell}(y, W_{t_1^{t,s,T}}, \dots, W_{t_{2^k-1}^{k,s,T}}(\omega), B_{t_1^{k,T}}(\omega), B_{t_{2^k-1}^{k,T}}(\omega))\mathbf{1}_{(t_\ell^{k,s,T}, t_{\ell+1}^{k,s,T}]}(t),\end{aligned}$$

where $f_{k,\ell} : \mathbb{R}^{\ell d} \times \mathbb{R}^{2^k m} \mapsto U$ and $g_{k,\ell} : \mathbb{R}^{2^k d} \times \mathbb{R}^{\ell d} \times \mathbb{R}^{2^k m} \mapsto U$ are Borel measurable functions. Note that $\gamma^k : [0,T]\times\mathbb{R}^{2^k d}\times\Omega \mapsto \mathbb{R}^n$ is a $\mathbf{G}^s$-progressive random field (that is, for each $y \in \mathbb{R}^{2^k n}$, the mapping $(t,\omega) \mapsto \gamma^k(t,y,\omega)$ is $\mathcal{G}_t^s$-progressively measurable). We see that for each $y \in \mathbb{R}^{2^k d}$, the random variable $H(\eta_T^0(F_T^{s,x,\gamma^k(y,\cdot)}))$ is independent of $\mathcal{F}_s^W$. Therefore,

$$\begin{aligned}E\left\{H\left(\eta_T^0(F_T^{s,x,\beta})\right)\Big|\mathcal{G}_s\right\} &\geq \operatorname*{essinf}_{k\geq 1} E\left\{H\left(\eta_T^0(F_T^{s,x,\beta^k})\right)\Big|\mathcal{G}_s\right\}\\ &\geq \operatorname*{essinf}_{k\geq 1}\inf_{y\in\mathbb{R}^{2^k d}} E\left\{H\left(\eta_T^0(F_T^{s,x,\gamma^k(y,\cdot)})\right)\Big|\mathcal{G}_s\right\}\\ &= \operatorname*{essinf}_{k\geq 1}\inf_{y\in\mathbb{R}^{2^k d}} E\left\{H\left(\eta_T^0(F_T^{s,x,\gamma^k(y,\cdot)})\right)\Big|\mathcal{F}_T^B\right\}\\ &\geq \operatorname*{essinf}_{\beta\in\widetilde{\mathcal{A}}} E\left\{H\left(\eta_T^0(F_T^{s,x,\beta})\right)\Big|\mathcal{F}_T^B\right\} = \widetilde{V}(s,x), \qquad P\text{-a.s.}\end{aligned}$$

We now prove the reversed inequality of (5.1) and construct another "minimizing sequence." In fact we will show that there exists a sequence $\{\beta^k\} \subset \widetilde{\mathcal{A}}$ such that

$$\widetilde{V}(s,x) = \lim_{k\to\infty} \downarrow E\left\{H\left(\eta_T^0(F_T^{s,x,\beta^k})\right)\Big|\mathcal{G}_s\right\}, \qquad P\text{-a.s.} \tag{5.2}$$

Since the right side above is obviously no less than $\operatorname{essinf}_{\beta\in\widetilde{\mathcal{A}}} E\{H(\eta_T^0(F_T^{s,x,\beta}))|\mathcal{G}_s\}$, the reversed inequality of (5.1), whence the theorem, will follow.

To construct the desired minimizing sequence, let us first choose a sequence $\{\hat\beta^k\}_{k\ge1}\subset\widetilde{\mathcal{A}}$ such that $\widetilde V(s,x)=\lim_{k\to\infty}\downarrow\widetilde J(s,x,\hat\beta^k)$, P-a.s., thanks to Theorem 4.2(ii), and then modify it as follows. Let $\beta^1\triangleq\hat\beta^1$, and for $k\ge2$, we denote recursively that

$$A^k\triangleq\Big\{E\Big\{H\Big(\eta_T^0(F_T^{s,x,\hat\beta^k})\Big)\Big|\mathcal{G}_s\Big\}\le E\Big\{H\Big(\eta_T^0(F_T^{s,x,\beta^{k-1}})\Big)\Big|\mathcal{G}_s\Big\}\Big\},$$

and define, for $(t,\omega)\in[s,T]\times\Omega$,

$$\beta_t^k(\omega)=\hat\beta_t^k(\omega)\mathbf{1}_{([s,T]\times A^k)\cup([0,s]\times\Omega)}(t,\omega)+\beta_t^{k-1}(\omega)\mathbf{1}_{[s,T]\times[A^k]^c}(t,\omega).$$

Then obviously $\{\beta^k\}_{k\ge1}\subset\widetilde A$, since A^k's are all $\mathbf{G}$-progressively measurable. Further, it holds that

$$H\Big(\eta_T^0(F_T^{s,x,\beta^k})\Big)=H\Big(\eta_T^0(F_T^{s,x,\hat\beta^k})\Big)\mathbf{1}_{A^k}+H\Big(\eta_T^0(F_T^{s,x,\beta^{k-1}})\Big)\mathbf{1}_{(A^k)^c}.$$

Therefore, we have

$$E\Big\{H\Big(\eta_T^0(F_T^{s,x,\beta^k})\Big)\Big|\mathcal{G}_s\Big\}\le E\Big\{H\Big(\eta_T^0(F_T^{s,x,\hat\beta^k})\Big)\Big|\mathcal{G}_s\Big\}\wedge E\Big\{H\Big(\eta_T^0(F_T^{s,x,\beta^{k-1}})\Big)\Big|\mathcal{G}_s\Big\}. \tag{5.3}$$

Consequently, the sequence $\{E\{H(\eta_T^0(F^{s,x,\beta^k}))|\mathcal{G}_s\}:k\ge1\}$ is monotone decreasing, and by (5.1),

$$\widetilde V(s,x)\le\lim_{k\to\infty}\downarrow E\Big\{H\Big(\eta_T^0(F_T^{t,x,\beta^k})\Big)\Big|\mathcal{G}_s\Big\},\qquad P\text{-a.s.} \tag{5.4}$$

But on the other hand, noting the definition of $\{\hat\beta^k\}_{k\ge1}$, the fact (5.3), and applying the monotone convergence theorem, we also have

$$\begin{aligned}
&E[\widetilde V(s,x)]=E\Big\{\lim_{k\to\infty}\downarrow\widetilde J(s,x,\hat\beta^k)\Big\}=\lim_{k\to\infty}\downarrow E\{\widetilde J(s,x,\hat\beta^k)\}\\
&=\lim_{k\to\infty}\downarrow E\Big\{E\Big\{H\Big(\eta_T^0(F_T^{s,x,\hat\beta^k})\Big)\Big|\mathcal{G}_s\Big\}\Big\}\ge\lim_{k\to\infty}\downarrow E\Big\{E\Big\{H\Big(\eta_T^0(F_T^{s,x,\beta^k})\Big)\Big|\mathcal{G}_s\Big\}\Big\}\\
&=E\Big\{\lim_{k\to\infty}\downarrow E\Big\{H\Big(\eta_T^0(F_T^{s,x,\beta^k})\Big)\Big|\mathcal{G}_s\Big\}\Big\}.
\end{aligned}$$

This, together with (5.4), leads to (5.2), completing the proof. □

We now turn to the regularity of the value function $\widetilde V(s,x)$. It is well understood that in a standard stochastic control problem the value function is usually (locally) Lipschitz in the spatial variable, and Hölder-1/2 in the temporal variable. We will show in the next theorem that this is in principle still true, but with a slight modification.

We first give a lemma that concerns the solution $F^{s,x,\beta}$ of the SDE (3.17). Let us begin by recalling Lemma 3.1 and the sequence of $\mathcal{F}_T^B$-measurable random times (whence $\mathbf{G}$-stopping times!) $\{\tau_\ell\}_{\ell\ge1}$ there (see (3.15)):

$$\tau_\ell=\inf\left\{s\ge0:\sup_{z\in\mathbb{R}^n}(1+|z|^2)^{-\gamma}\left(\Big|[D_z\eta_s^0(z)]^{-1}\Big|+\sum_{i=1}^3\Big|D_z^i\eta_s^0(z)\Big|\right)>\ell\right\}\wedge T, \tag{5.5}$$

for $\ell=1,2,\dots$. We can localize $F^{s,x,\beta}$ even further: for any $M>0$, and fixed $(s,x)\in[0,T]\times\mathbb{R}^n$ and $\beta\in\widetilde{\mathcal{A}}$, we define

$$\tau_{\ell,M}^{s,x,\beta}=\inf\Big\{t\ge s:|F_t^{s,x,\beta}|>M,\ \tau_\ell=T\Big\}\wedge T. \tag{5.6}$$

Then it is clear that $\tau_{\ell,M}^{s,x,\beta}$ is again a $\mathbf{G}$-stopping time. We have the following lemma.

LEMMA 5.2. *Assume* (H1)—H(3). *Then, for any $p \geq 1$ and $\ell \geq 1$, there exists a constant $C_{\ell,p} > 0$ such that for any $(s,x),(s',x') \in [0,T] \times \mathbb{R}^n$, $\beta \in \widetilde{\mathcal{A}}$, and $M > 0$, it holds P-a.s. on the set $\{\tau_\ell = T\}$ that*

$$E\Big\{ \sup_{t\in[s,T]} |F_t^{s,x,\beta}|^p \Big| \mathcal{G}_s \Big\} \leq C_{\ell,p}(1+|x|^p); \tag{5.7}$$

$$P\Big\{ \tau_{\ell,M}^{s,x,\beta} < M \Big| \mathcal{G}_s \Big\} \leq \frac{1}{M^p} E\Big\{ \sup_{t\in[s,T]} |F_t^{s,x,\beta}|^p \Big| \mathcal{G}_s \Big\} \leq C_{\ell,p} \frac{(1+|x|^p)}{M^p}; \tag{5.8}$$

$$E\Big\{ \sup_{s\leq t\leq \tau_{\ell,M}^{s,x,\beta}\wedge\tau_{\ell,M}^{s,x',\beta}} |F_t^{s,x,\beta} - F_t^{s,x',\beta}|^p \Big| \mathcal{G}_s \Big\} \leq C_{\ell,p} e^{M^p} |x-x'|^p; \tag{5.9}$$

$$E\Big\{ \sup_{s\leq t\leq \tau_{\ell,M}^{s,x,\beta}\wedge\tau_{\ell,M}^{s',x,\beta}} |F_t^{s,x,\beta} - F_t^{s',x,\beta}|^p \Big| \mathcal{G}_s \Big\} \leq C_{\ell,p} e^{M^p} (1+|x|^p) |s-s'|^{\frac{p}{2}}. \tag{5.10}$$

Proof. Note that all the following discussions are restricted to the set $\{\tau_\ell = T\}$. By virtue of the (localized) Lipschitz conditions and the linear growth properties of the coefficients $\widetilde{b}$ and $\widetilde{\sigma}$, thanks to Lemma 3.1, the estimates (5.7), (5.9), and (5.10) follow easily from some standard arguments for SDEs. Further, the estimate (5.8) is a direct consequence of definition (5.6), Chebyshev's inequality, and (5.7). We leave the details to the reader. □

The second main result of this section is the following. One should note that the parameter $\varepsilon > 0$ makes our result different from similar ones in standard stochastic control theory.

THEOREM 5.3. *Assume* (H1)–(H3). *Then, for any $\ell \geq 1$, $R > 0$, and $\varepsilon > 0$, there exists a $C_{\ell,R,\varepsilon} > 0$, such that for all $(s,x),(s',x') \in [0,T] \times \mathbb{B}_R^n$, it holds P-a.s. on $\{\tau_\ell = T\}$ that*

$$|\widetilde{V}(s,x) - \widetilde{V}(s',x')| \leq \varepsilon + C_{\ell,R,\varepsilon} \|H\|_\infty (|s-s'|^{\frac{1}{2}} + |x-x'|). \tag{5.11}$$

Here $\mathbb{B}_R^n \triangleq \{z \in \mathbb{R}^n : |z| \leq R\}$, and $\|\cdot\|_\infty$ is the sup-norm of $L^\infty(\mathbb{R}^n)$.

Proof. We first fix $R > 0$ and let $(s,x),(s',x') \in [0,T] \times \mathbb{B}_R^n$ be arbitrarily given. Then by Theorem 5.1 we can choose a sequence $\{\beta^k\}_{k\geq 1}$ such that

$$\widetilde{V}(s,x) = \lim_{k\to\infty} \downarrow E\Big\{ H\Big(\eta_T^0(F_T^{s,x,\beta^k})\Big) \Big| \mathcal{G}_s \Big\}, \qquad P\text{-a.s.} \tag{5.12}$$

Since H is uniformly continuous by (H3), for any $\varepsilon > 0$ we can find $\delta > 0$ such that

$$|H(z) - H(z')| < \frac{\varepsilon}{4}, \qquad \text{whenever } |z-z'| < \delta. \tag{5.13}$$

Now fix ℓ such that $P\{\tau_\ell = T\} > 0$. For each $M > 0$ and $k > 0$, we recall the stopping times defined by (5.6) and denote, for simplicity, that

$$\tau_{k,M} \triangleq \tau_{\ell,M}^{s,x,\beta^k}, \qquad \tau'_{k,M} \triangleq \tau_{\ell,M}^{s,x',\beta^k}, \qquad \tau''_{k,M} \triangleq \tau_{\ell,M}^{s',x',\beta^k},$$

and define $\bar{\tau}_{k,M} \triangleq \tau_{k,M} \wedge \tau'_{k,M} \wedge \tau''_{k,M}$. Then using (5.8) (with $p=2$) we have

$$P\{\bar{\tau}_{k,M} < T | \mathcal{G}_{s\wedge s'}\} \leq \frac{1}{M^2} C_{\ell,2}(1+|x|^2+|x'|^2) \leq C_{\ell,2} \frac{(1+2R^2)}{M^2}. \tag{5.14}$$

Bearing in mind that $\widetilde{V}(s,x)$ is $\mathcal{F}_T^B$-measurable, and $\mathcal{F}_T^B \subset \mathcal{G}_t$ for all $t \geq 0$, we can easily check that the minimizing sequence in Theorem 5.1 also satisfies

$$\widetilde{V}(s,x) = \lim_{k\to\infty} \downarrow E\left\{H\Big(\eta_T^0(F_T^{s,x,\beta^k})\Big)\Big|\mathcal{G}_{s\wedge s'}\right\}, \qquad P\text{-a.s.}$$

On the other hand, we observe that

$$\widetilde{V}(s',x') = \operatorname*{essinf}_{\beta\in\widetilde{\mathcal{A}}} E\left\{H\Big(\eta_T^0(F_T^{s',x',\beta})\Big)\Big|\mathcal{G}_{s\wedge s'}\right\}, \qquad P\text{-a.s.}$$

Keeping these in mind we now define

$$A_{\varepsilon,\ell}^k = \left\{\tau_\ell = T; \widetilde{V}(s,x) \geq E\left\{H\Big(\eta_T^0(F_T^{s,x,\beta^k})\Big)\Big|\mathcal{G}_{s\wedge s'}\right\} - \frac{\varepsilon}{4}\right\}.$$

Then $\lim_{k\to\infty} P\{A_{\varepsilon,\ell}^k\} = P\{\tau_\ell = T\} > 0$, and hence $P\{A_{\varepsilon,\ell}^k\} > 0$ for k large enough. Also, on the set $A_{\varepsilon,\ell}^k$ we have

$$\begin{aligned}(5.15)\qquad &\widetilde{V}(s',x') - \widetilde{V}(s,x)\\ &\leq \frac{\varepsilon}{4} + \left|E\left\{H\Big(\eta_T^0(F_T^{s',x',\beta^k})\Big)\Big|\mathcal{G}_{s\wedge s'}\right\} - E\left\{H\Big(\eta_T^0(F_T^{s,x,\beta^k})\Big)\Big|\mathcal{G}_{s\wedge s'}\right\}\right|\end{aligned}$$

We now analyze the right-hand side above. Again let us simplify the notation a little bit. Denote

$$\begin{aligned}&\Delta F_T^k \triangleq F_T^{s',x',\beta^k} - F_T^{s,x,\beta^k}, \quad \Delta\eta(F_T^k) \triangleq \eta_T^0(F_T^{s',x',\beta^k}) - \eta_T^0(F_T^{s,x,\beta^k}),\\ &\Delta H(\eta(F_T^k)) \triangleq H\left(\eta_T^0(F_T^{s',x',\beta^k})\right) - H\left(\eta_T^0(F_T^{s,x,\beta^k})\right).\end{aligned}$$

Recalling the definition of $\bar{\tau}_{k,M}$ and δ we see that the second term on the right-hand side of (5.15) becomes

$$\begin{aligned}&\left|E\left\{\Delta H(\eta(F_T^k))\Big|\mathcal{G}_{s\wedge s'}\right\}\right|\\ &= \left|E\left\{\Delta H(\eta(F_T^k))\mathbf{1}_{\{\bar{\tau}_{k,M}<T\}}\Big|\mathcal{G}_{s\wedge s'}\right\} + E\left\{\Delta H(\eta(F_T^k))\mathbf{1}_{\{\bar{\tau}_{k,M}=T\}}\Big|\mathcal{G}_{s\wedge s'}\right\}\right|\\ &\leq E\left\{\left|\Delta H(\eta(F_T^k))\right|\mathbf{1}_{\{\bar{\tau}_{k,M}<T\}}\Big|\mathcal{G}_{s\wedge s'}\right\} + E\left\{\left|\Delta H(\eta(F_T^k))\right|\mathbf{1}_{\{|\Delta\eta(F_T^k)|<\delta,\bar{\tau}_{k,M}=T\}}\Big|\mathcal{G}_{s\wedge s'}\right\}\\ &\quad + E\left\{\left|\Delta H(\eta(F_T^k))\right|\mathbf{1}_{\{|\Delta\eta(F_T^k)|\geq\delta,\bar{\tau}_{k,M}=T\}}\Big|\mathcal{G}_{s\wedge s'}\right\} = I_1 + I_2 + I_3,\end{aligned}$$

(5.16)

where I_1, I_2, and I_3 are defined in an obvious way. Clearly, by (5.14) we see that

$$\begin{aligned}I_1 &= E\left\{\left|\Delta H(\eta(F_T^k))\right|\mathbf{1}_{\{\bar{\tau}_{k,M}<T\}}\Big|\mathcal{G}_{s\wedge s'}\right\} \leq 2\|H\|_\infty P\left\{\bar{\tau}_{k,M} < T\Big|\mathcal{G}_{s\wedge s'}\right\}\\ &\leq C_{\ell,2}\frac{1+2R^2}{M^2}2\|H\|_\infty. \qquad (5.17)\end{aligned}$$

Also, in light of (5.13) we see that $|\Delta H(\eta(F_T^k))| < \frac{\varepsilon}{4}$ on the set $\{|\Delta\eta(F_T^k)| < \delta\}$, which implies that

$$I_2 = E\left\{\left|\Delta H(\eta(F_T^k))\right|\mathbf{1}_{\{|\Delta\eta(F_T^k)|<\delta,\bar{\tau}_{k,M}=T\}}\Big|\mathcal{G}_{s\wedge s'}\right\} < \frac{\varepsilon}{4}. \qquad (5.18)$$

Now, first applying the Chebyshev inequality and then applying Lemma 5.2 with $p=1$, we have, P-a.s. on $\{\tau_\ell = T\}$,

$$\begin{aligned} I_3 &= E\left\{\left|\Delta H(\eta(F_T^k))\right| \mathbf{1}_{\{|\Delta\eta(F_T^k)|\geq\delta,\bar\tau_{k,M}=T\}}\Big|\mathcal{G}_{s\wedge s'}\right\} \\ &\leq 2\|H\|_\infty P\left\{|\Delta\eta(F_T^k)|\geq\delta,\bar\tau_{k,M}=T\Big|\mathcal{G}_{s\wedge s'}\right\} \qquad (5.19)\\ &\leq \frac{2}{\delta}\|H\|_\infty E\left\{\ell\left(1+|F_T^{s',x',\beta^k}|+|F_T^{s,x,\beta^k}|\right)|\Delta F_T^k|\mathbf{1}_{\{\bar\tau_{k,M}=T\}}\Big|\mathcal{G}_{s\wedge s'}\right\} \\ &\leq \frac{2(1+2M)\ell}{\delta}\|H\|_\infty E\left\{|F_{\bar\tau^k}^{s,x,\beta^k}-F_{\bar\tau^k}^{s,x',\beta^k}|+|F_{\bar\tau^k}^{s',x',\beta^k}-F_{\bar\tau^k}^{s,x',\beta^k}|\Big|\mathcal{G}_{s\wedge s'}\right\} \\ &\leq \frac{2(1+2M)C_{\ell,1}\ell e^M(1+R)}{\delta}\|H\|_\infty(|s-s'|^{\frac12}+|x-x'|). \end{aligned}$$

Plugging (5.16)–(5.19) into (5.15) we see that on the set $A_{\varepsilon,\ell}^k$ one has

$$\begin{aligned} \widetilde V(s',x')-\widetilde V(s,x) &< \frac{\varepsilon}{2}+C_{\ell,2}\frac{1+2R^2}{M^2}2\|H\|_\infty \\ &\quad+\frac{2(1+2M)C_{\ell,1}\ell e^M(1+R)}{\delta}\|H\|_\infty(|s-s'|^{\frac12}+|x-x'|). \end{aligned} \qquad (5.20)$$

We note that since $\{\tau_\ell = T\} = \cup_{k\geq1}A_{\varepsilon,\ell}^k$, (5.20) actually holds on the set $\{\tau_\ell = T\}$.

To conclude, for fixed $\varepsilon>0$, $\ell>0$, and $R>0$, we first choose $\delta=\delta(\varepsilon)>0$ such that (5.13) holds, and then choose $M = M_{\ell,R,\varepsilon} > 2\sqrt{C_{\ell,2}(1+2R^2)\|H\|_\infty/\varepsilon}$. Denoting

$$C_{\ell,R,\varepsilon} \triangleq \frac{2(1+2M)C_{\ell,1}\ell e^M(1+R)}{\delta(\varepsilon)},$$

it is then easily seen that (5.20) becomes

$$\widetilde V(s',x')-\widetilde V(s,x) < \varepsilon + C_{\ell,R,\varepsilon}\|H\|_\infty(|s-s'|^{\frac12}+|x-x'|), \quad P\text{-a.s. on } \{\tau_\ell=T\}.$$

Reversing the role of (s,x) and (s',x'), we have proved the theorem. □

A closer look at the proof of Theorem 5.3 would lead to the following dependence result for the wider-sense state process $X_t^{s,x,\beta}=\eta_t^0(F_t^{s,x,\beta})$, $t\in[s,T]$, $\beta\in\widetilde{\mathcal{A}}$.

COROLLARY 5.4. *Assume* (H1)–(H3). *Then for any $\ell\geq1$, $R>0$, and $\varepsilon>0$ there exists some constant $C_{\ell,R,\varepsilon}>0$, depending only on ℓ, R, and ε, such that for all $\beta\in\widetilde{\mathcal{A}}$ and all $(s,x),(s',x')\in[0,T]\times\mathbb{R}^n$ with $x,x'\in\mathbb{B}_R$, it holds P-a.s. on $\{\tau_\ell=T\}$ that*

$$\left|E\left\{X_T^{s',x',\beta}-X_T^{s,x,\beta}\Big|\mathcal{G}_{s\wedge s'}\right\}\right| \leq \varepsilon + C_{\ell,R,\varepsilon}((|s-s'|^{\frac12}+|x-x'|). \qquad (5.21)$$

Proof. Noting that $X_T^{s,x,\beta}=\eta_T^0(F_T^{s,x,\beta})$, the proof follows from similar arguments of Theorem 5.3. We leave it to the interested reader. □

To conclude this section we note that Theorem 5.3 does not provide us the usual regularity of the value function (that is, Lipschitz in x, and Hölder-1/2 in s). In fact, as a random field, even the following property of $\widetilde V(\cdot,\cdot)$ is not completely trivial.

THEOREM 5.5. *Assume* (H1)–(H3). *The random field $\widetilde V(s,x)$ possesses a continuous version on $[0,T]\times\mathbb{R}^n$.*

Proof. We would like to construct a P-null exceptional set beyond which the function $(s,x)\mapsto\widetilde V(s,x,\omega)$ is continuous for all fixed ω.

To this end, let us denote $\mathbf{Q}$ to be all the rationals in $\mathbb{R}$. Denote also $\mathbf{Q}_+^* = \mathbf{Q}\cap(0,\infty)$ and $\mathbf{Q}_T = \mathbf{Q}\cap[0,T]$. The notation for the n-dimensional version $\mathbf{Q}^n \subset \mathbb{R}^n$ is defined in an obvious way.

For $\ell \geq 1$ we define the following subset of Ω:

$$\Omega_\ell \stackrel{\triangle}{=} \bigcap_{\substack{R\in\mathbf{Q}_+^*\\ \varepsilon\in\mathbf{Q}_+^*}} \{\tau_\ell = T \text{ and (5.11) holds for all } (s,x),(s',x') \in \mathbf{Q}_T \times \mathbb{B}_R^n \cap \mathbf{Q}^n\},$$

$$\widetilde{\Omega} = \cup_{\ell=1}^\infty \Omega_\ell.$$

Applying Theorem 5.3 we see that for fixed $\ell > 0$, $R > 0$, and $\varepsilon > 0$, (5.11) holds P-a.s. on the set $\{\tau_\ell = T\}$. In other words, one must have $\Omega_\ell \subseteq \{\tau_\ell = T\}$ and $P\{\{\tau_\ell = T\} \setminus \Omega_\ell\} = 0$ for all ℓ. Since $\cup_{\ell=1}^\infty \{\tau_\ell = T\} = \Omega$, modulo a P-null set, one has

$$\Omega \setminus \widetilde{\Omega} \subseteq \bigcup_{\ell=1}^\infty \{\{\tau_\ell = T\} \setminus \Omega_\ell\}, \qquad \text{almost surely.}$$

It then follows that $P\{\widetilde{\Omega}\} = 1$.

Now let us fix $\omega \in \widetilde{\Omega}$. By (5.11) we see that the mapping $(s,x) \mapsto \widetilde{V}(s,x,\omega)$ is continuous on $\mathbf{Q}_T \times \mathbf{Q}^n$. For general $(s,x) \in [0,T]\times\mathbb{R}^n$, we choose a sequence $\{(s_k,x_k)\}_{k\geq 1} \subset \mathbf{Q}_T \times \mathbf{Q}^n$, such that $(s_k,x_k) \to (s,x)$, as $k \to \infty$. Applying (5.11) again we see that $\{\widetilde{V}(s_k,x_k)\}_{k\geq 1}$ is Cauchy, and we can define the limit by $\bar{V}(s,x,\omega)$ and show that it is independent of the choice of the sequence $\{(s_k,x_k)\}$. Now define a random field

$$\bar{V}(s,x,\omega) = \begin{cases} \lim\limits_{k\to\infty} \widetilde{V}(s_k,x_k,\omega), & \mathbf{Q}_T \times \mathbf{Q}^n \ni (s_k,x_k) \to (s,x),\ \omega \in \widetilde{\Omega}, \\ 0, & \omega \in \Omega \setminus \widetilde{\Omega}. \end{cases}$$

Then, using a standard "3ε-argument," one shows that $\bar{V}$ is continuous on $[0,T]\times\mathbb{R}^n$ for all $\omega \in \widetilde{\Omega}$. It remains to verify that $\bar{V}$ is a version of $\widetilde{V}$. But by continuity of $\bar{V}$ we need only check that $\bar{V}$ is a modification of $\widetilde{V}$. To wit, for any $(s,x) \in [0,T]\times\mathbb{R}^n$, it holds that $\bar{V}(s,x) = \widetilde{V}(s,x)$, P-a.s. But by virtue of Theorem 5.3 and the definition of $\bar{V}$ one can check that for fixed (s,x) and any sequence $\{(s_k,x_k)\}_{k\geq 1} \subset \mathbf{Q}_T \times \mathbf{Q}^n$ such that $(s_k,x_k) \to (s,x)$, it must hold that

$$\widetilde{V}(s,x) = \lim_{k\to\infty} \widetilde{V}(s_k,x_k) = \bar{V}(s,x), \qquad P\text{-a.s.}$$

We leave the details to the readers. The proof is now complete. □

6. The Bellman principle. We are now ready to establish the first fundamental result of this paper— the "Bellman principle" of dynamic programming for the wider-sense control problem. We should note that our reduction of the original problem to problems WSCP-I and WSCP-II enables us to find different versions of minimizing sequences, which will be essential in our discussions in this section.

Our main result of this section is the following.

THEOREM 6.1 (Bellman principle). *Assume* (H1)–(H3). *For any* $(s,x) \in [0,T)\times\mathbb{R}^n$ *and* $h > 0$ *such that* $0 \leq s \leq s+h \leq T$, *it holds that*

$$\widetilde{V}(s,x) = \operatorname*{essinf}_{\beta\in\widetilde{A}} E\left\{\widetilde{V}(s+h, F_{s+h}^{s,x,\beta})\Big|\mathcal{G}_s\right\}, \qquad P\text{-a.s.}$$

The proof of Theorem 6.1 is rather lengthy, so we will split it into two lemmas, each taking care of one direction of the inequality, and each using a special technique.

LEMMA 6.2. *Assume* (H1)–(H3). *For all* $(s,x) \in [0,T) \times \mathbb{R}^n$, $h > 0$ *such that* $s+h \le T$, *it holds that*

$$\widetilde{V}(s,x) \le \operatorname*{essinf}_{\beta \in \widetilde{\mathcal{A}}} E\left\{ \widetilde{V}(s+h, F_{s+h}^{s,x,\beta}) \Big| \mathcal{G}_s \right\}. \tag{6.1}$$

Proof. Clearly, we need only show that for all $(s,x) \in [0,T) \times \mathbb{R}^n$, $h > 0$ such that $s+h \le T$, and $\beta \in \widetilde{A}$, it holds that

$$\widetilde{V}(s,x) \le E\left\{ \widetilde{V}(s+h, F_{s+h}^{s,x,\beta}) \Big| \mathcal{G}_s \right\}, \qquad P\text{-a.s.} \tag{6.2}$$

The proof depends heavily on the estimates established in Theorem 5.3. First let us fix $\ell > 0$ and $\varepsilon > 0$, and let $0 \le s < s+h \le T$ and $x \in \mathbb{R}^n$ be given and fixed as well. Applying Lemma 5.2 and the Chebyshev inequality, we have, for any $R > 0$, P-a.s. on $\{\tau_\ell = T\}$,

$$P\left\{ |F_{s+h}^{s,x,\beta}| > R \Big| \mathcal{G}_t \right\} \le \frac{1}{R^2} E\left\{ \sup_{t \in [s,T]} |F_t^{s,x,\beta}|^2 \Big| \mathcal{G}_t \right\} \le \frac{C_{\ell,2}}{R^2}(1+|x|^2).$$

Let us now fix $R = R_{\ell,x,\varepsilon} > \sqrt{C_{\ell,2}(1+|x|^2)\|H\|_\infty/\varepsilon}$, so that

$$P\left\{ |F_{s+h}^{s,x,\beta}| > R \Big| \mathcal{G}_s \right\} < \left(\frac{\varepsilon}{\|H\|_\infty} \right) \wedge \varepsilon, \quad P\text{-a.s. on } \{\tau_\ell = T\}. \tag{6.3}$$

Next, following the main ideas of the proof of Theorem 5.3, we can find a constant $C_{\ell,R,\varepsilon}$ such that for all $y, y' \in \mathbb{B}_R^n$, it holds almost surely on $\{\tau_\ell = T\}$ that

$$\begin{aligned} &\left| E\left\{ H\Big(\eta_T^0(F_T^{s+h,y,\beta})\Big) \Big| \mathcal{G}_{s+h} \right\} - E\left\{ H\Big(\eta_T^0(F_T^{s+h,y',\beta})\Big) \Big| \mathcal{G}_{s+h} \right\} \right| \\ &\qquad \le \frac{\varepsilon}{2} + C_{\ell,R,\varepsilon}\|H\|_\infty |y-y'| \end{aligned} \tag{6.4}$$

and

$$\left| \widetilde{V}(s+h,y) - \widetilde{V}(s+h,y') \right| \le \frac{\varepsilon}{2} + C_{\ell,R,\varepsilon}\|H\|_\infty |y-y'|. \tag{6.5}$$

Now let us fix $\delta = \delta_{\ell,x,\varepsilon} < \frac{\varepsilon}{2C_{\ell,R,\varepsilon}\|H\|_\infty}$, and choose a finite set of open balls $\{\mathcal{O}_\delta(y^k)\}_{k=1}^N$, centered at y^k's and with radius δ such that it covers the (compact) ball $\mathbb{B}_R^n$. That is, $\mathbb{B}_R^n \subset \bigcup_{k=1}^N \mathcal{O}_\delta(y^k)$. Clearly, on the set $\{\tau_\ell = T\}$, whenever $y \in \mathcal{O}_\delta(y^k)$ we have

$$\left| E\left\{ H\Big(\eta_T^0(F_T^{s+h,y,\beta})\Big) \Big| \mathcal{G}_{s+h} \right\} - E\left\{ H\Big(\eta_T^0(F_T^{s+h,y^k,\beta})\Big) \Big| \mathcal{G}_{s+h} \right\} \right| < \varepsilon \tag{6.6}$$

and

$$\left| \widetilde{V}(s+h,y) - \widetilde{V}((s+h,y^k)) \right| < \varepsilon. \tag{6.7}$$

Furthermore, we define a partition of $\mathbb{B}_R^n$ as follows:

$$\Gamma_{R,1} \stackrel{\triangle}{=} \mathcal{O}_\delta(y^1) \cap \mathbb{B}_R^n; \qquad \Gamma_{R,k} \stackrel{\triangle}{=} \left(\mathcal{O}_\delta(y^k) \setminus \bigcup_{l=1}^{k-1} \mathcal{O}_\delta(y^l) \right) \bigcap \mathbb{B}_R^n, \qquad k > 1.$$

Thus it follows from (6.7) that, for any $\beta \in \widetilde{\mathcal{A}}$, P-a.s. on $\{|F^{s,x,\beta}_{s+h}| \le R, \tau_\ell = T\}$,

$$\begin{aligned}\widetilde{V}(s+h, F^{s,x,\beta}_{s+h}) &= \sum_{k=1}^{N} \widetilde{V}(s+h, F^{s,x,\beta}_{s+h}) \mathbf{1}_{\Gamma_{R,k}}(F^{s,x,\beta}_{s+h}) \\ &\ge \sum_{k=1}^{N} \widetilde{V}(s+h, y^k) \mathbf{1}_{\Gamma_{R,k}}(F^{s,x,\beta}_{s+h}) - \varepsilon.\end{aligned} \tag{6.8}$$

Now for each k we apply Theorem 5.1 (or, in particular, (5.2)) to find a $\beta^k \in \widetilde{\mathcal{A}}$ such that the set

$$A_{\varepsilon,k} \stackrel{\triangle}{=} \left\{\omega : \widetilde{V}(s+h, y^k, \omega) < E\left\{H\Big(\eta^0_T(F^{s+h,y^k,\beta^k}_T)\Big)\Big|\mathcal{G}_{s+h}\right\}(\omega) - \varepsilon\right\}$$

satisfies $P(A_{\varepsilon,k}) \le 2^{-k}\varepsilon$. Next, define

$$\widetilde{A}_{\ell,\varepsilon,k} \stackrel{\triangle}{=} \{|F^{s,x,\beta}_{s+h}| \le R, \tau_\ell = T\} \cap A^c_{\varepsilon,k} \quad \text{and} \quad \widetilde{\Omega}_{\ell,\varepsilon} \stackrel{\triangle}{=} \bigcap_{k=1}^{N} \widetilde{A}_{\ell,\varepsilon,k}. \tag{6.9}$$

Then

$$\begin{aligned}P\{\widetilde{\Omega}^c_{\ell,\varepsilon}\} &\le P\left\{\{\tau_\ell < T\} \cup \{|F^{s,x,\beta}_{s+h}| > R, \tau_\ell = T\} \cup \left(\bigcup_{k=1}^{N} A_{\varepsilon,k}\right)\right\} \\ &\le P\{\tau_\ell < T\} + P\{|F^{s,x,\beta}_{s+h}| > R, \tau_\ell = T\} + \sum_{k=1}^{N} P(A_{\varepsilon,k}) \\ &\le P\{\tau_\ell < T\} + 2\varepsilon \to 0 \qquad \text{as } \ell \uparrow \infty \text{ and } \varepsilon \downarrow 0.\end{aligned} \tag{6.10}$$

Let us now restrict ourselves to the set $\widetilde{\Omega}_{\ell,\varepsilon}$. Clearly, almost surely on $\widetilde{\Omega}_{\ell,\varepsilon}$ we have

$$\widetilde{V}(s+h, y^k) \ge E\left\{H\Big(\eta^0_T(F^{s+h,y^k,\beta^k}_T)\Big)\Big|\mathcal{G}_{s+h}\right\} - \varepsilon.$$

Thus on the set $\widetilde{\Omega}_{\ell,\varepsilon} \in \mathcal{G}_{s+h}$ the estimate (6.8) can further be written as

$$\widetilde{V}(s+h, F^{s,x,\beta}_{s+h}) \ge \sum_{k=1}^{N} E\left\{H\Big(\eta^0_T(F^{s+h,y^k,\beta^k}_T)\Big)\Big|\mathcal{G}_{s+h}\right\} \mathbf{1}_{\{F^{s,x,\beta}_{s+h} \in \Gamma_{R,k}\}} - 2\varepsilon. \tag{6.11}$$

Now let $\beta \in \widetilde{\mathcal{A}}$ be any control. We modify β as follows: for $(t,\omega) \in [s,T] \times \Omega$,

$$\widetilde{\beta}_t(\omega) = \begin{cases} \beta^k_t(\omega) & \text{if } t \ge s+h, \omega \in \{\tau_\ell = T\} \cap \{F^{s,x,\beta}_{s+h} \in \Gamma_{R,k}\},\ 1 \le k \le N, \\ \beta_t(\omega) & \text{otherwise.} \end{cases}$$

Then clearly $\widetilde{\beta} \in \widetilde{\mathcal{A}}$ as well, and, moreover, the pathwise uniqueness of SDE (3.17), together with the estimate (6.6), shows that for each k, P-a.s. on $\{\tau_\ell = T\}$,

$$\begin{aligned}&E\left\{H\Big(\eta^0_T(F^{s,x,\widetilde{\beta}}_T)\Big)\Big|\mathcal{G}_{s+h}\right\} \mathbf{1}_{\{F^{s,x,\beta}_{s+h} \in \Gamma_{R,k}\}} \\ &= E\left\{H\Big(\eta^0_T(F^{s+h,F^{s,x,\beta}_{s+h},\beta^k}_T)\Big)\mathbf{1}_{\{F^{s,x,\beta}_{s+h} \in \Gamma_{R,k}\}}\Big|\mathcal{G}_{s+h}\right\} \\ &\le E\left\{H\Big(\eta^0_T(F^{s+h,y^k,\beta^k}_T)\Big)\mathbf{1}_{\{F^{s,x,\beta}_{s+h} \in \Gamma_{R,k}\}}\Big|\mathcal{G}_{s+h}\right\} + \varepsilon \mathbf{1}_{\{F^{s,x,\beta}_{s+h} \in \Gamma_{R,k}\}}.\end{aligned} \tag{6.12}$$

Thus, noting that $\cup_{k=1}^N \Gamma_{R,k} = \mathbb{B}_R^n$, we can continue from (6.11) to get

$$\begin{aligned}
&\widetilde{V}(s+h, F_{s+h}^{s,x,\beta}) \\
&\geq \sum_{k=1}^N E\left\{ H\Big(\eta_T^0(F_T^{s,x,\widetilde{\beta}})\Big) \mathbf{1}_{\{F_{s+h}^{s,x,\beta} \in \Gamma_{R,k}\}} \Big| \mathcal{G}_{s+h} \right\} - 2\varepsilon - \varepsilon \sum_{k=1}^N \mathbf{1}_{\{F_{s+h}^{s,x,\beta} \in \Gamma_{R,k}\}} \\
&= E\left\{ H\Big(\eta_T^0(F_T^{s,x,\widetilde{\beta}})\Big) \Big| \mathcal{G}_{s+h} \right\} \sum_{k=1}^N \mathbf{1}_{\{F_{s+h}^{s,x,\beta} \in \Gamma_{R,k}\}} - 2\varepsilon - \varepsilon \sum_{k=1}^N \mathbf{1}_{\{F_{s+h}^{s,x,\beta} \in \Gamma_{R,k}\}} \\
&= \left[E\left\{ H\Big(\eta_T^0(F_T^{s,x,\widetilde{\beta}})\Big) \Big| \mathcal{G}_{s+h} \right\} - \varepsilon \right] - 2\varepsilon = E\left\{ H\Big(\eta_T^0(F_T^{s,x,\widetilde{\beta}})\Big) \Big| \mathcal{G}_{s+h} \right\} - 3\varepsilon.
\end{aligned}$$

Note that the above inequality holds only on the $\widetilde{\Omega}_{\ell,\varepsilon}$. Taking conditional expectation $E\{\cdot|\mathcal{G}_s\}$ over $\widetilde{\Omega}_{\ell,\varepsilon} \in \mathcal{G}_{s+h}$ on both sides, we have

$$\begin{aligned}
&E\left\{ \widetilde{V}(s+h, F_{s+h}^{s,x,\beta}) \Big| \mathcal{G}_s \right\} \geq E\left\{ \widetilde{V}(s+h, F_{s+h}^{s,x,\beta}) \mathbf{1}_{\widetilde{\Omega}_{\ell,\varepsilon}} \Big| \mathcal{G}_s \right\} \\
&\geq E\left\{ H\Big(\eta_T^0(F_T^{s,x,\widetilde{\beta}})\Big) \mathbf{1}_{\widetilde{\Omega}_{\ell,\varepsilon}} \Big| \mathcal{G}_s \right\} - 3\varepsilon = E\left\{ H\Big(\eta_T^0(F_T^{s,x,\widetilde{\beta}})\Big) [1 - \mathbf{1}_{\widetilde{\Omega}_{\ell,\varepsilon}^c}] \Big| \mathcal{G}_s \right\} - 3\varepsilon \\
&\geq E\left\{ H\Big(\eta_T^0(F_T^{s,x,\widetilde{\beta}})\Big) \Big| \mathcal{G}_s \right\} - \|H\|_\infty P\{\widetilde{\Omega}_{\ell,\varepsilon}^c | \mathcal{G}_s\} - 3\varepsilon \\
&\geq \widetilde{V}(s,x) - \|H\|_\infty P\{\widetilde{\Omega}_{\ell,\varepsilon}^c | \mathcal{G}_s\} - 3\varepsilon.
\end{aligned}$$

Letting $\ell \to \infty$ and then $\varepsilon \downarrow 0$, we obtain (6.2), whence (6.1). □

The next lemma will show the reversed inequality.

LEMMA 6.3. *Assume* (H1)–(H3). *Then, for all* $(s,x) \in [0,T) \times \mathbb{R}^n$, *and* $s+h \leq T$,

$$\widetilde{V}(s,x) \geq \operatorname*{essinf}_{\beta \in \widetilde{\mathcal{A}}} E\left\{ \widetilde{V}(s+h, F_{s+h}^{s,x,\beta}) \Big| \mathcal{G}_s \right\}. \tag{6.13}$$

Proof. This time we shall prove that for all $(s,x) \in [0,T) \times \mathbb{R}^n$, and $s+h \leq T$, there exists a sequence $\{\beta^k\} \subset \widetilde{A}$, such that

$$\widetilde{V}(s,x) = \lim_{k \to \infty} \downarrow E\left\{ \widetilde{V}(s+h, F_{s+h}^{s,x,\beta^k}) \Big| \mathcal{G}_s \right\}, \qquad P\text{-a.s.} \tag{6.14}$$

We note that this "minimizing sequence" is different from all the previous ones, and that (6.13) follows from (6.14) trivially.

To prove (6.14), we fix $(s,x) \in [0,T) \times \mathbb{R}^n$ and $h > 0$ such that $s+h \leq T$. First applying Theorem 5.1 we know that there exists a sequence $\{\beta^k\} \subset \widetilde{\mathcal{A}}$ such that

$$\widetilde{V}(s,x) = \lim_{k \to \infty} \downarrow E\left\{ H\Big(\eta_T^0(F_T^{s,x,\beta^k})\Big) \Big| \mathcal{G}_s \right\}.$$

Next, applying Lemma 6.2 we have

$$\begin{aligned}
\widetilde{V}(s,x) &\leq E\left\{ \widetilde{V}(s+h, F_{s+h}^{s,x,\beta^k}) \Big| \mathcal{G}_s \right\} \\
&\leq E\left\{ E\Big\{ H\Big(\eta_T^0\Big(F_T^{s+h, F_{s+h}^{s,x,\beta^k}, \beta^k}\Big)\Big) \Big| \mathcal{G}_{s+h} \Big\} \Big| \mathcal{G}_s \right\} \\
&= E\left\{ H\Big(\eta_T^0(F_T^{s,x,\beta^k})\Big) \Big| \mathcal{G}_s \right\}, \qquad P - \text{a.s., } \forall k \geq 1.
\end{aligned} \tag{6.15}$$

We will use the by now standard technique to modify the sequence $\{\beta^k\}$ to derive the desired minimizing sequence. Let $\widetilde{\beta}^1 = \beta^1$. For $k > 1$, we define, for $t \in [s, T]$,

$$\widetilde{\beta}_t^k = \begin{cases} \beta_t^k & \text{on } \left\{ E\Big\{ \widetilde{V}(s+h, F_{s+h}^{s,x,\beta^k}) \Big| \mathcal{G}_s \Big\} \le E\Big\{ \widetilde{V}(s+h, F_{s+h}^{s,x,\widetilde{\beta}^{k-1}}) \Big| \mathcal{G}_s \Big\} \right\}, \\ \widetilde{\beta}_t^{k-1} & \text{otherwise,} \end{cases}$$

and set $\widetilde{\beta}_t^k \equiv \widetilde{\beta}_t^1$ for all k for $t \in [0, s)$. Then, clearly $\{\widetilde{\beta}^k\} \subset \widetilde{\mathcal{A}}$, and for all $k \ge 1$, one has

$$\begin{aligned} & E\left\{ \widetilde{V}(s+h, F_{s+h}^{s,x,\widetilde{\beta}^k}) \Big| \mathcal{G}_s \right\} \\ & \le E\left\{ \widetilde{V}(s+h, F_{s+h}^{s,x,\widetilde{\beta}^{k-1}}) \Big| \mathcal{G}_s \right\} \wedge E\left\{ \widetilde{V}(s+h, F_{s+h}^{s,x,\beta^k}) \Big| \mathcal{G}_s \right\} \\ & \le E\left\{ \widetilde{V}(s+h, F_{s+h}^{s,x,\widetilde{\beta}^{k-1}}) \Big| \mathcal{G}_s \right\} \wedge E\left\{ H\Big(\eta_T^0(F_T^{s,x,\beta^k}) \Big) \Big| \mathcal{G}_s \right\}, \qquad P\text{-a.s.} \end{aligned}$$

Consequently we have

$$\begin{aligned} \widetilde{V}(s,x) & \le \lim_{k\to\infty} \downarrow E\left\{ \widetilde{V}(s+h, F_{s+h}^{s,x,\widetilde{\beta}^k}) \Big| \mathcal{G}_s \right\} \\ & \le \lim_{k\to\infty} \downarrow E\left\{ H\Big(\eta_T^0(F_T^{s,x,\beta^k}) \Big) \Big| \mathcal{G}_s \right\} = \widetilde{V}(s,x), \end{aligned}$$

thanks to Theorem 5.1 again. This proves the lemma. □

Remark 6.4. By modifying the proof slightly one can easily show that the Bellman principle (Theorem 6.1) also holds if the initial states (s, x) and the increment h are replaced by $\mathcal{F}_T^B$-measurable random variables, since $\mathcal{F}_T^B \subset \mathcal{G}_t$ for all $t \ge 0$. In particular, if (s, x) is replaced by $\mathcal{F}_T^B$-measurable random variables (τ, ξ) and $h > 0$ remains a deterministic constant, then we make the convention that $\tau + h = (\tau + h) \wedge T$.

7. Stochastic HJB equation. In this section we shall derive two versions of the stochastic HJB equations: one for the value function of WSCP-I and the other for the original pathwise control problem.

7.1. HJB equation for WSCP-I. We first consider the HJB equation for the value function $\widetilde{V}$. Let us denote

$$\widetilde{\mathcal{L}}_{s,x,u} \triangleq \frac{1}{2} \mathrm{tr}\left\{ \widetilde{\sigma}\widetilde{\sigma}^T(s,x,u) D_{xx}^2 \right\} + \widetilde{b}(t,x,u) D_x.$$

Note that in the above the coefficients $\widetilde{b}$ and $\widetilde{\sigma}$ are $\mathcal{F}_T^B$-measurable random fields, and thus $\widetilde{\mathcal{L}}$ is a "random" differential operator. We then consider the following (random) PDE:

$$\begin{cases} -\dfrac{\partial v}{\partial s}(s,x) - \operatorname*{essinf}_{u\in U} [\widetilde{\mathcal{L}}_{s,x,u} v](s,x) = 0, & (s,x) \in [0,T] \times \mathbb{R}^n; \\ \\ v(T,x) = H\left(\eta_T^0(x) \right), & x \in \mathbb{R}^n. \end{cases} \tag{7.1}$$

We should note that since this randomized PDE does not involve any stochastic integrals, it could be studied in an ω-wise manner. However, the "adaptedness" nature

of the random field is by no means obvious from such a treatment. As an alternative, in what follows we shall consider the random PDE as a special (degenerate) stochastic PDE with a time reversal, and introduce a definition of "stochastic viscosity solution" of this equation that is in the spirit of Buckdahn and Ma [2, 3, 4].

DEFINITION 7.1. *A continuous, $\mathcal{B}([0,T]\times\mathbb{R}^n)\otimes\mathcal{F}_T^B$-measurable random field v is a stochastic viscosity subsolution (resp., supersolution) if*

(i) $v(T,x)\le$ *(resp.,* $\ge$*)* $H\left(\eta_T^0(x)\right)$, $x\in\mathbb{R}^n$;

(ii) *for all* $\tau\in L^0_{\mathcal{F}_T^B}(\Omega;[0,T])$, $\xi\in L^2_{\mathcal{F}_T^B}(\Omega;\mathbb{R}^n)$, *and* $\varphi\in C^{1,2}_{\mathcal{F}_T^B}([0,T]\times\mathbb{R}^n)$, *it holds that*

$$-\frac{\partial\varphi}{\partial s}(\tau,\xi)-\operatorname*{essinf}_{u\in U}[\widetilde{\mathcal{L}}_{\tau,\xi,u}\varphi](\tau,\xi)\le 0\quad\textit{(resp., }\ge 0\textit{)}, \tag{7.2}$$

on the (ω-)set $\{v-\varphi$ *achieves a local maximum (resp., minimum) at* $(\tau,\xi)\}\in\mathcal{F}_T^B$.

A random field v is called a stochastic viscosity solution if it is both a stochastic subsolution and a stochastic supersolution.

We remark here that the main difference between Definition 7.1 and those of [2, 3, 4], besides the time reversal, is that in [2, 3, 4] we require τ to be a stopping time and ξ to be an $\mathcal{F}_\tau^B$-measurable random variable. Due to the special structure here we assume only that τ is an $\mathcal{F}_T^B$-measurable random time. But one should appreciate again that any $\mathcal{F}_T^B$-measurable random time τ is a $\mathbf{G}$-stopping time!

Our first main result of this section is the following theorem.

THEOREM 7.2. *Assume* (H1)—(H3). *The value function $\widetilde{V}$ is a stochastic viscosity solution of* (7.1) *in the sense of Definition* 7.1. *Furthermore, the solution is unique in the class $C_{\mathcal{F}_T^B}([0,T]\times\mathbb{R}^n)$.*

Proof. We first show that $\widetilde{V}$ is a subsolution. Let $\tau\in L^0_{\mathcal{F}_T^B}(\Omega;[0,T])$, $\xi\in L^2_{\mathcal{F}_T^B}(\Omega;\mathbb{R}^n)$, and $\varphi\in C^{1,2}_{\mathcal{F}_T^B}([0,T]\times\mathbb{R}^n)$ be given. We assume that the set

$$\Gamma=\Gamma^{\tau,\xi}\triangleq\{\widetilde{V}-\varphi\text{ achieves a local maximum at }(\tau,\xi)\}$$

satisfies $P(\Gamma)>0$ (for otherwise there is nothing to prove).

We begin by the following "localization" procedure. First, let $\{\tau_\ell\}$ be the sequence of $\mathbf{G}$-stopping times defined by (3.15). We can then choose $\ell>0$ and $\varepsilon>0$ such that the set

$$\Gamma_{\ell,\varepsilon}\triangleq\{\widetilde{V}-\varphi\text{ achieves in }\mathbb{B}_\varepsilon^{n+1}(\tau,\xi)\text{ its maximum at }(\tau,\xi),\quad\tau_\ell=T\} \tag{7.3}$$

also satisfies $P(\Gamma_{\ell,\varepsilon})>0$, where $\mathbb{B}_\varepsilon^{n+1}(s,x)$ denotes the (closed) ball in $\mathbb{R}^{n+1}$ centered at (s,x) with radius ε.

Next, noting that the random fields $\widetilde{V}$ and φ are both $\mathcal{B}([0,T]\times\mathbb{R}^n)\otimes\mathcal{F}_T^B$-measurable, and $\widetilde{V}$ is uniformly bounded (by $\|H\|_\infty$!), we can modify the value of φ outside of $\mathbb{B}_{\varepsilon/2}^{n+1}(\tau,\xi)$ so that φ is uniformly bounded,

$$P\Big\{\sup_{(s,x)\in[0,T]\times\mathbb{R}^n}\Big[|D_t\varphi(s,x)|+|D_x\varphi(s,x)|+|D^2_{xx}\varphi(s,x)|\Big]<\infty\Big\}=1,$$

and $\Gamma_{\ell,\varepsilon}\subset\{(\tau,\xi)\in\operatorname{argmax}\{\widetilde{V}-\varphi\}\}\cap\{\tau_\ell=T\}$. Consequently, we can find $\rho>0$ small enough, and a set $\Gamma^\rho_{\ell,\varepsilon}\in\mathcal{F}_T^B$, such that

(i) $P(\Gamma^\rho_{\ell,\varepsilon})>P(\Gamma_{\ell,\varepsilon})-\rho>0$;

(ii) $\Gamma^{\rho}_{\ell,\varepsilon} \subseteq \{(\tau,\xi) \in \operatorname{argmax}\{\widetilde{V} - \varphi\}\} \cap \{\tau_\ell = T\}$;

(iii) $D_t\varphi(\tau,\xi)$, $D_x\varphi(\tau,\xi)$, $D^2_{xx}\varphi(\tau,\xi)$ are all bounded on $\Gamma^{\rho}_{\ell,\varepsilon}$.

Now let us recall from Remark 6.4 that the Bellman principle (Theorem 6.1) can be extended to the case where the initial state (τ,ξ) is a pair of $\mathcal{F}^B_T$-measurable random variables (with the convention that $\tau+h = (\tau+h)\wedge T$). Thus, for any $h>0$ and $\beta_s \equiv u \in U$ we can apply such a version of Theorem 6.1 and Itô's formula to get the following: on the set $\Gamma^{\rho}_{\ell,\varepsilon}$,

$$
\begin{aligned}
0 &\le \frac{1}{h} E\left\{ \widetilde{V}(\tau+h, F^{\tau,\xi,\beta}_{\tau+h}) - \widetilde{V}(\tau,\xi) \Big| \mathcal{G}_\tau \right\} \le \frac{1}{h} E\left\{ \varphi(\tau+h, F^{\tau,\xi,\beta}_{\tau+h}) - \varphi(\tau,\xi) \Big| \mathcal{G}_\tau \right\} \\
&= \frac{1}{h} E\left\{ \int_\tau^{\tau+h} \left[\partial_t + \widetilde{\mathcal{L}}_{s, F^{\tau,\xi,\beta}_s, u} \right] \varphi(s, F^{\tau,\xi,\beta}_s) ds \Big| \mathcal{G}_\tau \right\} \qquad (7.4) \\
&\le \left[\partial_t + \widetilde{\mathcal{L}}_{\tau,\xi,u} \right] \varphi(\tau,\xi) + r_{\tau,\xi}(h),
\end{aligned}
$$

where

$$
r_{\tau,\xi}(h) \stackrel{\triangle}{=} E\left\{ \sup_{s\in[\tau,\tau+h]} \left| \left[\partial_t + \widetilde{\mathcal{L}}_{s, F^{\tau,\xi,\beta}_s, u} \right] \varphi(s, F^{\tau,\xi,\beta}_s) - \left[\partial_t + \widetilde{\mathcal{L}}_{\tau,\xi,u} \right] \varphi(\tau,\xi) \right| \Big| \mathcal{G}_\tau \right\}.
$$

Note that $\Gamma^{\rho}_{\ell,\varepsilon} \subset \{\tau_\ell = T\}$, and applying Lemma 3.1 and 3.2(ii) we have, on the set $\Gamma^{\rho}_{\ell,\varepsilon}$,

$$
\begin{aligned}
&E\left\{ \sup_{s\in[\tau,T]} |(\partial_t + \widetilde{\mathcal{L}}_{s, F^{\tau,\xi,\beta}_s, u})\varphi(s, F^{\tau,\xi,\beta}_s) \right\} \\
&\le C\Big(1 + E\Big\{ \sup_{s\in[\tau,T]} (|\widetilde{\sigma}(s, F^{\tau,\xi,\beta}_s, u)|^2 + |\widetilde{b}(s, F^{\tau,\xi,\beta}_s, u)|) \Big\} \Big) \\
&\le C\ell^2 \Big(1 + E\Big\{ \sup_{s\in[\tau,T]} |F^{\tau,\xi,\beta}_s|^2 \Big\} \Big) < \infty.
\end{aligned}
$$

Thus, applying the dominated convergence theorem we see that $\lim_{h\downarrow 0} r_{\tau,\xi}(h) = 0$, in probability, on the set $\Gamma^{\rho}_{\ell,\varepsilon}$, and (7.4) leads to

$$
\operatorname*{essinf}_{u\in U} \left[\partial_t + \widetilde{\mathcal{L}}_{\tau,\xi,u} \right] \varphi(\tau,\xi) \ge 0, \qquad P\text{-a.s. on the set } \Gamma^{\rho}_{\ell,\varepsilon}.
$$

Therefore, first letting $\rho \to 0$, then $\varepsilon \to 0$, and then $\ell \to \infty$, we obtain that

$$
-\operatorname*{essinf}_{u\in U} \left[\partial_t + \widetilde{\mathcal{L}}_{\tau,\xi,u} \right] \varphi(\tau,\xi) \le 0, \quad P\text{-a.s. on } \Gamma.
$$

In other words, $\widetilde{V}$ is a stochastic subsolution.

The proof that $\widetilde{V}$ is also a supersolution is a little more involved. We again fix $\tau \in L^0_{\mathcal{F}^B_T}(\Omega;[0,T])$, $\xi \in L^2_{\mathcal{F}^B_T}(\Omega;\mathbb{R}^n)$ and $\varphi \in C^{1,2}_{\mathcal{F}^B_T}([0,T]\times\mathbb{R}^n)$. Also, for any $\varepsilon>0$, $\ell>0$, $\rho>0$, we again find $\Gamma^{\rho}_{\ell,\varepsilon}$ that satisfies (i)–(iii) before, with "max" being replaced by "min."

To derive the desired inequality, we argue slightly differently. First we modify Lemma 6.3 to obtain a sequence $\{\beta^k\} \subset \widetilde{\mathcal{A}}$ such that (6.14) holds for the $\mathcal{F}^B_T$-measurable pair (τ,ξ) and $0<h\ll 1$, that is,

$$
\widetilde{V}(\tau,\xi) = \lim_{k\to\infty} \downarrow E\left\{ \widetilde{V}(\tau+h, F^{\tau,\xi,\beta^k}_{\tau+h}) \Big| \mathcal{G}_\tau \right\}, \quad P\text{-a.s.}
$$

Here we note that the convention $\tau + h = (\tau + h) \wedge T$ is used again and that the sequence $\{\beta^k\}$ may depend on h. Let us denote, for fixed $h > 0$ and each $k \geq 1$,

$$A_h^k \triangleq \left\{\omega : E\left\{\widetilde{V}(\tau + h, F_{\tau+h}^{\tau,\xi,\beta^k})\Big|\, \mathcal{G}_\tau\right\}(\omega) - \widetilde{V}(\tau, \xi, \omega) \leq h^2\right\}.$$

Then by definition of $\{\beta^k\}$ we have $\lim_{k\to\infty} P\{\Omega \setminus A_h^k\} = 0$. Since $P(\Gamma_{\ell,e}^\rho) > 0$, we must also have $\lim_{k\to\infty} P\{A_h^k \cap \Gamma_{\ell,\varepsilon}^\rho\} = P(\Gamma_{\ell,e}^\rho) > 0$.

Now, using the definition of φ and applying Itô's formula, one has, P-a.s. on the set $A_h^k \cap \Gamma_{\ell,\varepsilon}^\rho$,

$$\begin{aligned} h &\geq \frac{1}{h} E\left\{\widetilde{V}(\tau + h, F_{\tau+h}^{\tau,\xi,\beta^k}) - \widetilde{V}(\tau, \xi)\Big|\, \mathcal{G}_\tau\right\} \\ &\geq \frac{1}{h} E\left\{\varphi(\tau + h, F_{\tau+h}^{\tau,\xi,\beta^k}) - \varphi(\tau, \xi)\Big|\, \mathcal{G}_\tau\right\} \\ &= \frac{1}{h} E\left\{\int_\tau^{\tau+h} \Big(\partial_t + \widetilde{\mathcal{L}}_{s,F_s^{\tau,\xi,\beta^k},\beta^k}\Big)\varphi(s, F_s^{\tau,\xi,\beta^k})ds\,\Big|\, \mathcal{G}_\tau\right\} \qquad (7.5) \\ &\geq \operatorname*{essinf}_{u\in U}\Big[\partial_t + \widetilde{\mathcal{L}}_{\tau,\xi,u}\Big]\varphi(\tau, \xi) - \widetilde{r}_{\tau,\xi}(h), \end{aligned}$$

where

$$\widetilde{r}_{\tau,\xi}(h) \triangleq \sup_{k\geq 1} E\left\{\sup_{s\in[\tau,\tau+h]}\left|\Big[\partial_t + \widetilde{\mathcal{L}}_{s,F_s^{\tau,\xi,\beta^k},\beta_s^k}\Big]\varphi(s, F_s^{\tau,\xi,\beta^k}) - \Big[\partial_t + \widetilde{\mathcal{L}}_{\tau,\xi,\beta_s^k}\Big]\varphi(\tau, \xi)\right|\Big|\, \mathcal{G}_\tau\right\}.$$

Let us now denote $\Psi = (\partial_t\varphi, D_x\varphi, D_{xx}^2\varphi)$ and for fixed (τ, ξ),

$$G_{\tau,\xi}^k(s) \triangleq |\widetilde{\sigma}\widetilde{\sigma}^T(s, \xi, \beta_s^k) - \widetilde{\sigma}\widetilde{\sigma}^T(\tau, \xi, \beta_s^k)| + |\widetilde{b}(s, \xi, \beta_s^k) - \widetilde{b}(\tau, \xi, \beta_s^k)|, \qquad s \in [0, T].$$

Clearly, Ψ is bounded and continuous on $\Gamma_{\ell,\varepsilon}^\rho$. Furthermore, a tedious but straightforward argument using Lemmas 3.1 and 5.2 ((5.7) in particular) and the Chebyshev inequality, one can show that for any $h > 0, k \geq 1$, and $\delta > 0$, there exists a constant $C_{\ell,\varepsilon,\rho} > 0$ such that, P-a.s., on $\Gamma_{\ell,\varepsilon}^\rho$, it holds that

$$\begin{aligned} &E\left\{\sup_{s\in[\tau,\tau+h]}\Big[\partial_t + \widetilde{\mathcal{L}}_{s,F_s^{\tau,\xi,\beta^k},\beta_s^k}\Big]\varphi(s, F_s^{\tau,\xi,\beta^k}) - \Big[\partial_t + \widetilde{\mathcal{L}}_{\tau,\xi,\beta_s^k}\Big]\varphi(\tau, \xi)\Big|\mathcal{G}_\tau\right\} \\ &\leq C_{\ell,\varepsilon,\rho}\left(1 + \frac{1}{\delta^2}\right)\big(1 + |\xi|^4\big)\left\{\sup_{\substack{s\in[\tau,\tau+h],\\ |x|\leq\delta}} |\Psi(s, \xi + x) - \Psi(\tau, \xi)| + \sup_{\tau\leq s\leq\tau+h} E\{G_{\tau,\xi}^k(s)|\mathcal{G}_\tau\}\right\}. \end{aligned}$$

Consequently, for all $h > 0, \delta > 0$, it holds, P-a.s. on $\Gamma_{\ell,\varepsilon}^\rho$ that

$$\begin{aligned} \widetilde{r}_{\tau,\xi}(h) &\leq C_{\ell,\varepsilon\rho}\left(1 + \frac{1}{\delta^2}\right)(1 + |\xi|^4) \\ &\quad \times \left\{\sup_{\substack{s\in[\tau,\tau+h],\\ |x|\leq\delta}} |\Psi(s, \xi + x) - \Psi(\tau, \xi)|\right\} + \sup_{\substack{s\in[\tau,\tau+h]\\ k\geq 1}} E\{G_{\tau,\xi}^k(s)|\mathcal{G}_\tau\}\right\}. \end{aligned}$$

Now from the definition of $\widetilde{\sigma}$ and $\widetilde{b}$ ((3.6) and (3.7)) and the assumption (H1) we see that $G_{\tau,\xi}^k(s)$ is continuous in s, uniformly in k. Thus applying the dominated convergence theorem we have

$$\lim_{h\downarrow 0} \sup_{s\in[\tau,\tau+h],k\geq 1} E\{G_{\tau,\xi}^k(s)|\mathcal{G}_\tau\} = 0, \qquad P\text{-a.s.}$$

It then follows that $\widetilde{r}_{\tau,\xi}(h) \to 0$, P-a.s. on $\Gamma^{\rho}_{\ell,\varepsilon}$ as $h \downarrow 0$. In other words, we obtain

$$\operatorname*{essinf}_{u\in U}\left[\partial_t + \widetilde{\mathcal{L}}_{\tau,\xi,u}\right]\varphi(\tau,\xi) \le 0, \qquad P\text{-a.s. on } \Gamma^{\rho}_{\ell,\varepsilon}.$$

Again, first sending $\rho \to 0$, then $\varepsilon \to 0$, and then $\ell \to \infty$, we obtain that

$$-\operatorname*{essinf}_{u\in U}\left[\partial_t + \widetilde{\mathcal{L}}_{\tau,\xi,u}\right]\varphi(\tau,\xi) \ge 0, \quad P\text{-a.s.}$$

That is, $\widetilde{V}$ is a stochastic viscosity supersolution of (7.1).

To conclude, note that the uniqueness of the viscosity solution can be proved by following the almost identical idea of Buckdahn and Ma [3], with even easier arguments since in the present case there is no "martingale" term in the degenerated stochastic PDF (7.1). The proof is complete. □

7.2. HJB equation for the original control problem. We now turn to our last objective of this paper: to derive the stochastic HJB equation for the original value function V. The idea is straightforward, that is, we shall apply the "inverse" Doss–Sussmann transformation and see what will happen to the stochastic HJB equation (7.1). We first observe the following simple fact: if $\varphi \in C^{1,2}_{\mathcal{F}^B_T}([0,T]\times R^n)$, then by the Itô–Ventzell formula (cf., e.g., Kunita [11]), one has (recall the process $\{\zeta^s_t\}$ from (3.5))

$$\begin{aligned} d[\varphi(t,\zeta^0_t(x))] &= \frac{\partial\varphi}{\partial t}(t,\zeta^0_t(x))dt + (D_x\varphi)(t,\zeta^0_t(x))\circ d\zeta^0_t(x) \\ &= \frac{\partial\varphi}{\partial t}(t,\zeta^0_t(x))dt - (D_x\varphi)\,(t,\zeta^0_t(x))D_z\zeta^0_t(x)\theta(x)\circ dB_t \\ &= \frac{\partial\varphi}{\partial t}(t,\zeta^0_t(x))dt - D_x[\varphi(t,\zeta^0_t(x))]\theta(x)\circ dB_t. \end{aligned} \tag{7.6}$$

Now recall from Theorem 4.2(i) that $\widetilde{V}(s,x) = V(s,\eta^0_s(x))$, and hence $V(s,x) = \widetilde{V}(s,\zeta^0_s(x))$. Thus if $\widetilde{V} \in C^{1,2}_{\mathcal{F}^B_T}$, then in light of (7.6) we should have

$$dV(s,x) = d[\widetilde{V}(s,\zeta^0_s(x))] = \frac{\partial\widetilde{V}}{\partial t}(t,\zeta^0_s(x))ds - D_x[\widetilde{V}(t,\zeta^0_s(x))]\theta(x)\circ dB_s. \tag{7.7}$$

Combining (7.1) for $\widetilde{V}$ and relation (7.7) we can then formally write down the stochastic HJB equation for the original value function V:

$$\begin{cases} dV(s,x) + \operatorname*{essinf}_{u\in U}[\mathcal{L}_{x,u}V](s,x)ds + D_xV(s,x)\theta(x)\circ dB_s = 0, \\ \qquad\qquad\qquad\qquad\qquad\qquad\qquad\qquad (s,x)\in[0,T)\times\mathbb{R}^n, \\ V(T,x) = H(x), \qquad x\in\mathbb{R}^n. \end{cases} \tag{7.8}$$

Again, we remark that this stochastic PDE is a "terminal value" problem; therefore it would become a complicated issue if we were to seek an $\{\mathcal{F}^B_t\}$-adapted solution. However, the following modification of the definition of stochastic viscosity solution for the stochastic PDE (7.8) given in [2, 3, 4] proves sufficient for our purpose.

DEFINITION 7.3. *A random field $v \in C_{\mathcal{F}^B_T}([0,T]\times\mathbb{R}^n)$ is said to be a (stochastic) viscosity subsolution (resp., supersolution) of equation* (7.8) *if*

(i) *$v(T,x) \le$ (resp., $\ge$) $H(x)$ for all $x\in\mathbb{R}^n$;*

(ii) *for any* $(\tau,\xi)\in L^2(\mathcal{F}_T^B;[0,T]\times\mathbb{R}^n)$, *and* $\varphi\in C^{1,2}_{\mathcal{F}_T^B}([0,T]\times\mathbb{R}^n)$, *it holds that*

$$-\frac{\partial\varphi}{\partial t}\left(\tau,\zeta_s^0(\xi)\right)\leq \text{(resp., }\geq)\operatorname*{essinf}_{u\in U}\mathcal{L}_{\tau,\xi,u}\left[\varphi(\tau,\zeta_\tau^0(\cdot))\right](\xi),$$

P-a.s. on the set

$$\Gamma^\varphi_{\tau,\xi}\stackrel{\triangle}{=}\{\omega:(\tau(\omega),\xi(\omega))\in \operatorname{argmax}_{loc}[v(s,x,\omega)-\varphi(s,\zeta_0^s(x),\omega)]\ \text{(resp., } \operatorname{argmin}_{loc})\}$$

We have the following theorem.

THEOREM 7.4. *Assume* (H1)–(H3). *Then the value function* V *is the unique stochastic viscosity solution of* (7.8).

Proof. Having proved Theorem 7.2, we need only prove the following equivalence relation: a random field $v\in C_{\mathcal{F}_T^B}([0,T]\times\mathbb{R}^n)$ is a stochastic viscosity subsolution (resp., supersolution) of the stochastic HJB equation (7.8) if and only if

$$\widetilde{v}(t.x)=v(t,\eta_t^0(x)),\qquad (t,x)\in[0,T]\times\mathbb{R}^n,$$

is a stochastic viscosity subsolution (supersolution) of the (random) HJB equation (7.1).

To this end, we observe that for any given $(\tau,\xi)\in L^2(\mathcal{F}_T^B;[0,T]\times\mathbb{R}^n)$ and $\varphi\in C^{1,2}_{\mathcal{F}_T^B}([0,T]\times\mathbb{R}^n\}$,

$$\begin{aligned}\Gamma^\varphi_{\tau,\xi}&=\{\omega:(\tau(\omega),\xi(\omega))\in\operatorname{argmax}_{loc}[v(s,x,\omega)-\varphi(s,\zeta_s^0(x),\omega)]\}\\&=\{\omega:(\tau(\omega),\zeta_\tau^0(\xi)(\omega))\in\operatorname{argmax}_{loc}[v(s,\eta_s^0(x),\omega)-\varphi(s,x,\omega)]\}\\&=\{\omega:(\tau(\omega),\zeta_\tau^0(\xi)(\omega))\in\operatorname{argmax}_{loc}[\widetilde{v}(s,x,\omega)-\varphi(s,x,\omega)]\}.\end{aligned}$$

On the other hand, it is easy to check that

$$\mathcal{L}_{x,u}[\varphi(t,\zeta_t^0(\cdot))](x)=(\widetilde{\mathcal{L}}_{t,\zeta_t^0(x),u}\varphi)(t,\zeta_t^0(x))\qquad\forall(t,x,u)\in[0,T]\times\mathbb{R}^n\times U;$$

we see that $\widetilde{v}$ is a viscosity subsolution of equation (7.1) if and only if for all $(\tau,\xi)\in L^2(\mathcal{F}_T^B;[0,T]\times\mathbb{R}^n)$ and $\varphi\in C^{1,2}_{\mathcal{F}_T^B}([0,T]\times\mathbb{R}^n\}$, it holds, P-a.s. on the set $\Gamma^\varphi_{\tau,\xi}$, that

$$-\left[\left(\frac{\partial}{\partial t}+\operatorname*{essinf}_{u\in U}\widetilde{\mathcal{L}}_{\tau,\zeta_\tau^0(\xi),u}\right)\varphi\right](\tau,\zeta_\tau^0(\xi))\leq 0.$$

But this amounts to saying that for any such given (τ,ξ) and φ, it holds, P-a.s. on $\Gamma^\varphi_{\tau,\xi}$, that

$$-\frac{\partial\varphi}{\partial t}\left(\tau,\zeta_0^s\left(\xi\right)\right)\leq\operatorname*{essinf}_{u\in U}\mathcal{L}_{\tau,\xi,u}\left[\varphi\left(\tau,\zeta_0^\tau(\cdot)\right)\right](\xi).$$

But by Definition 7.3 it shows exactly that v is a stochastic viscosity subsolution of (7.8). The proof for the supersolutions is analogous. Thus the theorem follows from Theorem 7.2. □

8. Appendix (a counterexample). We give an example showing that the original pathwise stochastic control problem does not possess any minimizing sequence in $\mathcal{A}$. Let us assume that $n=1$, $U=[0,1]$, and $(s,x)=(0,0)$. Assume also that

$b(t,x,u) \equiv u$, $\sigma \equiv 0$, and $\theta(x) \equiv x$. Finally, let $H(x) = |x-1|$. That is, the system dynamics is

$$\begin{cases} dX_t^\alpha = \alpha_t dt + X_t^\alpha \circ dB_t, & t \in [0,T], \\ X_0^\alpha = 0. \end{cases}$$

Furthermore, the Doss–Sussmann transformation is $\eta_t^0(z) = z + \int_0^t \eta_r^0(z) \circ dB_r$, which can be solved explicitly as $\eta_t^0(z) = ze^{B_t}$, $t \in [0,T]$. Therefore, the "transformed" coefficients are $\widetilde{\sigma} \equiv 0$ and $\widetilde{b}(t,z,u) = \left[D_z \eta_t^0(z)\right]^{-1} b(\eta_t^0(z),u) = e^{-B_t}u$; and the "transformed" system equation becomes

$$dF_t^\beta = \widetilde{b}(t, F_t^\beta, \beta_t)dt = e^{-B_t}\beta_t dt, \qquad \beta \in \widetilde{A},$$

which can also be solved explicitly as $F_t^\beta = \int_0^t e^{-B_r}\beta_r dr$. Consequently we have $\eta_T^0(F_T^\beta) = \int_0^T e^{B_T - B_r}\beta_r dr$.

We can now easily check that, at $(s,x) = (0,0)$,

$$V(0,0) = \widetilde{V}(0,0) = \operatorname*{essinf}_{\beta \in \widetilde{A}} E\left\{ |\eta_T^0(F_T^\beta) - 1| \,\middle|\, \mathcal{F}_T^B \right\} = \left[1 - \int_0^T e^{B_T - B_r} dr\right]^+,$$

with a wider sense optimal control being

$$\beta_t^* = \begin{cases} \left(\int_0^T e^{B_T - B_r} dr\right)^{-1} & \text{on } \left\{\int_0^T e^{B_T - B_r} dr > 1\right\}, \\ \\ 1 & \text{on } \left\{\int_0^T e^{B_T - B_r} dr \le 1\right\}. \end{cases}$$

We should note that such an optimal control is unique on the set $\{\int_0^T e^{B_T - B_r} dr \le 1\}$.

On the other hand, we observe that if $\alpha \in \mathcal{A}$, then so is $E[\alpha]$, and by Jensen's inequality we have

$$\begin{aligned} J(0,0;\alpha) &= E\left\{ \left| \int_0^T e^{B_T - B_r}\alpha_r dr - 1 \right| \middle| \mathcal{F}_T^B \right\} \ge \left| \int_0^T e^{B_T - B_r} E[\alpha_r] dr - 1 \right| \\ &= J(0,0,E[\alpha]) \ge V(0,0). \end{aligned}$$

Now let us assume that there exists a minimizing sequence $\{\alpha^k\}_{k \ge 1} \subset \mathcal{A}$. Then it holds, P-a.s., that $\lim_{k\to\infty} J(0,0;\alpha^k) = V(0,0)$. But the above argument shows that

$$J(0,0,E[\alpha^k]) = \left| \int_0^T e^{B_T - B_r} E[\alpha_r^k] dr - 1 \right| \longrightarrow V(0,0) = \left[1 - \int_0^T e^{B_T - B_r} dr\right]^+ \tag{8.1}$$

as well. Since $0 \le E[\alpha_t^k] \le 1$ for all t, we see that on the set $\{\int_0^t e^{B_T - B_t} dr \le 1\}$ it must hold that

$$\int_0^T e^{B_T - B_r} E[\alpha_r^k] dr \longrightarrow \int_0^T e^{B_T - B_r} dr \qquad \text{as } k \to \infty,$$

or, equivalently, $\int_0^T e^{B_T - B_r}[1 - E[\alpha_r^k]] dr \to 0$, on $\{\int_0^t e^{B_T - B_t} dr \le 1\}$. But again notice that $0 \le E[\alpha_t^k] \le 1$, which implies that $E[\alpha_\cdot^k] \longrightarrow 1$, as $k \to \infty$ in (Lebesgue)

measure, and consequently one must have

$$\left|\int_0^T e^{B_T-B_r}E[\alpha_r^k]dr-1\right| \longrightarrow \left|\int_0^T e^{B_T-B_r}dr-1\right|, \quad P\text{-a.s.}$$

Since

$$\left|\int_0^T e^{B_T-B_r}dr-1\right| > V(0,0) \qquad \text{on} \quad \left\{\int_0^T e^{B_T-B_r}dr>1\right\},$$

and $P\{\int_0^T e^{B_T-B_r}dr>1\}>0$, we obtain that

$$\lim_{k\to\infty} J(0,0,E[\alpha^k]) = \left|\int_0^T e^{B_T-B_r}dr-1\right| > V(0,0) \qquad \text{on } \left\{\int_0^T e^{B_T-B_r}dr>1\right\}.$$

This contradicts (8.1). Therefore such a minimizing sequence cannot exist.

ADAPTIVE DIGITAL CONTROL OF HAMMERSTEIN NONLINEAR SYSTEMS WITH LIMITED OUTPUT SAMPLING*

FENG DING†, TONGWEN CHEN‡, AND ZENTA IWAI§

Abstract. This paper is motivated by the practical control considerations that nonlinearity is abundant in industrial processes and output sampling rates are often limited due to hardware constraints. In particular, for a Hammerstein nonlinear sampled-data system in which the output sampling period is an integer multiple of the input updating period, we derive, by using a polynomial transformation technique, a mathematical model which is suitable for parameter estimation with dual-rate measurement data. Further, we present an adaptive control scheme for such a dual-rate nonlinear system; the parameter estimation–based adaptive algorithm can achieve virtually asymptotically optimal control and ensure that the closed-loop system is stable and globally convergent. The simulation results are included.

Key words. Hammerstein systems, sampled-data systems, multirate modeling, self-tuning regulator, adaptive control, dual-rate systems, convergence properties, least squares methods

1. Introduction.

This paper focuses on adaptive control problems of a class of nonlinear systems, namely, Hammerstein nonlinear systems, with limited output sampling frequencies; in particular, the Hammerstein systems of interest have output sampling periods which are integer multiples of input updating periods. These systems are sometimes referred to as *dual-rate sampled-data systems*. Such slow output sampled systems often arise in industry due to hard limits on sensoring devices; see the industrial processes described in, e.g., [26, 31, 34]. Without assuming knowledge of the nonlinear model involved, our main idea in this work is to perform closed-loop adaptive control through an online identification scheme, which estimates the parameters of the nonlinear model by making use of only the available dual-rate data.

In the identification area of nonlinear systems, there exists a large amount of research exploring different approaches; see, e.g., [3, 4, 5, 6, 35, 36, 37]. Vörös presented a recursive half-substitution algorithm for discontinuous nonlinear systems [36]. For Hammerstein–Wiener nonlinear models, Bai reported a two-stage identification algorithm based on the recursive least squares and the singular value decomposition [3] and a blind identification approach [5]. Recently, Cerone and Regruto derived the parameter error bounds in the Hammerstein models [8] by assuming that the output measurement error was bounded; Ding and Chen developed an iterative method

and a recursive least squares identification method for Hammerstein nonlinear autoregression and moving average with exogenous input (ARMAX) systems [12]. In this paper, we will extend the noniterative method of Chang and Luus [7] for Hammerstein models to present a parameter estimation–based adaptive algorithm for Hammerstein nonlinear *dual-rate* systems.

In the field of adaptive control of linear dual-rate systems, Albertos, Salt, and Tormero studied adaptive control schemes for dual-rate systems [1]; Ishitobi, Kawanaka, and Nishi presented a least squares–based self-tuning control algorithm [28]; and Kanniah, Malik, and Hope proposed a control algorithm based on a parameterized model with its autoregression (AR) coefficients corresponding to the fast sampling rate and the moving average (MA) coefficients to the slow sampling rate [29]. Though these are earlier contributions in this area, the reported adaptive control schemes have two main limitations as follows (in view of the goal in our work):

- First, the prediction and control were both based on the slow sampling rate; the desired fast-rate system performance could not be achieved in these schemes in design, and there might be poor intersample behavior even if the behavior at the slow sampling instants is acceptable.
- Second, these schemes used *linear* models as the primary assumption; for nonlinear Hammerstein models, which capture a wide class of industrial systems and processes, new research is required.

In order to overcome the two limitations for dual-rate Hammerstein models, we develop an estimation scheme to obtain *fast-rate* models which can be used to implement an adaptive control law updated at the *fast rate*, even if the output is sampled at a relatively slow rate.

To the best of our knowledge, few contributions have addressed such adaptive control problems involving Hammerstein nonlinear dual-rate systems, especially the convergence problem of the algorithms involved, which are the focus of this work. Therefore, the objective of this paper is to extend the control scheme of dual-rate systems in [10] to the nonlinear case, in particular, in the following ways:

- By a polynomial transformation technique, derive models suitable for dual-rate identification of Hammerstein nonlinear sampled-data systems.
- Based on the models derived, propose a parameter estimation–based adaptive control scheme.
- Study the convergence properties of the proposed adaptive control algorithms.

Briefly, the paper is organized as follows. Section 2 introduces the problem formulation related to Hammerstein nonlinear dual-rate systems and an adaptive control scheme. Section 3 uses a polynomial transformation technique to derive a suitable mathematical model and present an adaptive control algorithm based on parameter estimation. Sections 4 and 5 analyze the output tracking performance and global stability of the closed-loop systems under the proposed adaptive control. Section 6 presents an illustrative example demonstrating the effectiveness of the proposed algorithm. Finally, section 7 offers some concluding remarks.

2. Problem formulation. In many chemical processes [26, 31, 34], due to hardware sensoring constraints, only infrequent and scarce output sampling is available; but the input updating can be achieved by actuators and digital computers at relatively fast speeds [10, 11, 30]. This gives rise to a class of *dual-rate* systems in which the input updating rate is an integer multiple of the output sampling rate. This paper focuses on adaptive control of a class of Hammerstein nonlinear dual-rate sampled-data systems—a static nonlinearity $f(\cdot)$ followed by a linear dynamic subsystem $G(z)$,

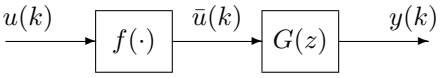

FIG. 1. *A Hammerstein nonlinear system.*

as depicted in Figure 1, where $u(k)$ is the system input, the inner variable $\bar{u}(k)$ is the output of the nonlinear block (unmeasurable), $y(k)$ is the system output but is available only every qth sampling instant, q being a positive integer ($q > 1$). Thus, the available input-output data set consists of

- $\{u(k) : \ k = 0, 1, 2, \dots\}$ at the fast rate, and
- $\{y(kq) : \ k = 0, 1, 2, \dots\}$ at the slow rate.

Here, we refer to the unavailable intersample outputs, $y(kq+j)$, $j = 1, 2, \dots, q-1$, as the *missing* output samples, and to $\{u(k), y(kq)\}$ as the *dual-rate* measurement data.

Often the static nonlinear part in the Hammerstein model is assumed to be a polynomial of a known order m in the input as follows (see, e.g., [7, 22, 33]):

$$\bar{u}(k) = c_1 u(k) + c_2 u^2(k) + \cdots + c_m u^m(k),$$

or, more generally, to be a nonlinear function of a known basis $(\gamma_1, \gamma_2, \dots, \gamma_m)$ as follows [8]:

$$(1) \quad \bar{u}(k) = f(u(k)) = c_1\gamma_1(u(k)) + c_2\gamma_2(u(k)) + \cdots + c_m\gamma_m(u(k)) = \sum_{i=1}^{m} c_i\gamma_i(u(k)),$$

where the c_i's are unknown parameters. Of course, the nonlinearity considered here also covers cubic spline nonlinearity [9], support vector machines [23, 24], and piecewise linear functions with discontinuities [35, 36], in addition to the single-parameter nonlinearities [4]. The linear block is a time-invariant system (at the fast rate) with a known order n and takes the following real-rational form:

$$(2) \qquad y(k) = \frac{B(z)}{A(z)}\,\bar{u}(k), \ G(z) := \frac{B(z)}{A(z)}$$

with

$$A(z) = 1 + a_1 z^{-1} + a_2 z^{-2} + \cdots + a_n z^{-n},$$
$$B(z) = b_1 z^{-1} + b_2 z^{-2} + \cdots + b_n z^{-n}.$$

Here, z^{-1} represents a unit backward shift operator at the fast rate, $z^{-1}u(k) = u(k-1)$, and $G(z)$ is the transfer function of the linear dynamical part with one unit delay.

Notice that in the characterization of the Hammerstein model shown in Figure 1, $f(u)$ and $G(z)$ are actually not unique from the identification point of view. Any pair $(cf(u), G(z)/c)$ for some nonzero and finite constant c would produce identical input and output measurements. In other words, none of the identification schemes can distinguish between $(f(u), G(z))$ and $(cf(u), G(z)/c)$. Therefore, to get a unique parameterization, without loss of generality, one of the gains of $f(u)$ and $G(z)$ has to be fixed. There are several ways to normalize the gains [3, 8, 22]. Here, we adopt the assumption used in [5, 22]: The first coefficient of the function $f(\cdot)$ equals 1; i.e., $c_1 = 1$. (In case $c_1 = 0$, one can use any nonzero c_i and normalize it to 1.)

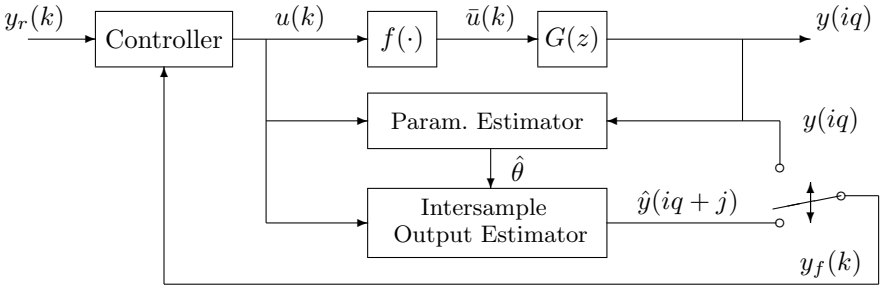

FIG. 2. *The adaptive control scheme* ($j = 1, 2, \ldots, q-1$).

For dual-rate sampled-data control systems, we expect that the control law be updated at the fast rate even if the output is sampled at the slow rate. To implement this, the adaptive control scheme we propose is shown in Figure 2, where $y_r(k)$ denotes a deterministic reference input or desired output signal. The control scheme makes use of a parameter estimator, or an identification algorithm, which generates online the estimates $\hat{\theta}$ of the unknown system parameters based on the dual-rate data $\{u(k), y(kq)\}$; based on $\hat{\theta}$, and thus the fast-rate model, and the input $u(k)$, the intersample (missing) outputs $\hat{y}$ are estimated—see the intersample output estimator in Figure 2. In order to feed back to the controller a fast rate signal $y_f(k)$, representing the output $y(k)$, we use the slow sampled output $y(iq)$ at every q period, giving $y(0)$, $y(q)$, and $y(2q)$, etc., and use the estimated output $\hat{y}(iq+j)$ to fill in the missing samples in $y(k)$. Hence in Figure 2, $y_f(k)$ connects to $y(iq)$ at times $k = iq$, and connects to $\hat{y}(iq+j)$ at $k = iq+j$, $j = 1, 2, \ldots, (q-1)$; thus the output of the switch, $y_f(k)$, is a fast rate signal. The operation of the periodic switch can be expressed in the following equation:

$$y_f(k) = \begin{cases} y(iq), & k = iq, \\ \hat{y}(iq+j), & k = iq+j,\ j = 1, 2, \ldots, (q-1). \end{cases} \tag{3}$$

To summarize, the dual-rate adaptive control scheme uses a fast single-rate controller and a periodic switch. It is conceptually simple, easy to implement in digital computers, and practical for industry.

In connection with Figure 2, the objectives of this paper can be restated more clearly as follows:

- Establish a dual-rate model which is suitable for identification using the given dual-rate data.
- Propose an algorithm to estimate the intersample outputs $\{y(kq+j) :\ j = 1, 2, \ldots, (q-1)\}$.
- Design an adaptive controller so that the output $y(k)$ tracks the given desired output $y_r(k)$ by minimizing the tracking error criterion given by

$$J[u(k)] = [y_f(k+1) - y_r(k+1)]^2 \tag{4}$$

for deterministic systems, or

$$J[u(k)] = \mathrm{E}\{[y_f(k+1) - y_r(k+1)]^2 | \mathcal{F}_{k-1}\} \tag{5}$$

for stochastic systems, and study the properties of the closed-loop system.

Here, $\{\mathcal{F}_k\}$ is the σ algebra sequence generated by the observations up to and including time k.

3. Control algorithm description. Let us introduce some notation first. The symbol I stands for an identity matrix of appropriate dimensions. The superscript T denotes the matrix transpose. For a square matrix X, $|X| = \det[X]$ represents the determinant; $\lambda_i[X]$ denotes the ith eigenvalue of X; and $\lambda_{\max}[X]$ and $\lambda_{\min}[X]$ represent the maximum and minimum eigenvalues of X, respectively. The norm of a matrix M is defined by $\|M\|^2 = \mathrm{tr}[MM^{\mathrm{T}}]$. The notation $\mathbf{1}_n$ denotes an n-dimensional column vector whose elements are all 1; $f(k) = o(g(k))$ represents $f(k)/g(k) \to 0$ as $k \to \infty$; for $g(k) \geq 0$, we write $f(k) = O(g(k))$ or $f(k) \sim g(k)$ if there exists a positive constant δ_1 such that $|f(k)| \leq \delta_1 g(k)$.

The model in (1)–(2) is not suitable for dual-rate adaptive control because it would involve the unavailable outputs $\{y(kq+j) : \ j = 1, 2, \ldots, (q-1)\}$. To obtain a model that we can use directly on the dual-rate data, by a polynomial transformation technique, $G(z)$ can be converted into a form so that the denominator is a polynomial in z^{-q} instead of z^{-1}.

For a general discussion, let the roots of $A(z)$ be z_i to get

$$A(z) = \prod_{i=1}^{n}(1 - z_i z^{-1}).$$

Define

$$\phi_q(z) := \prod_{i=1}^{n}(1 + z_i z^{-1} + z_i^2 z^{-2} + \cdots + z_i^{q-1} z^{-q+1}) = \prod_{i=1}^{n} \frac{1 - z_i^q z^{-q}}{1 - z_i z^{-1}}.$$

Multiplying the numerator and denominator of $G(z)$ by $\phi_q(z)$ and using the polynomial transformation formula [27, 32],

$$1 - x^q = (1 - x)(1 + x + x^2 + \cdots + x^{q-1}),$$

we get a new model:

$$P(z) = \frac{B(z)\phi_q(z)}{A(z)\phi_q(z)} =: \frac{\beta(z)}{\alpha(z)},$$

or

$$\alpha(z)y(k) = \beta(z)\bar{u}(k) \tag{6}$$

with

$$\alpha(z) = 1 + \alpha_1 z^{-q} + \alpha_2 z^{-2q} + \cdots + \alpha_n z^{-qn},$$
$$\beta(z) = \beta_1 z^{-1} + \beta_2 z^{-2} + \cdots + \beta_{qn} z^{-qn}.$$

Equation (6) has the advantage that the denominator is a polynomial of z^{-q}; arising from here is a recursive equation using only slowly sampled outputs. The control algorithm we propose later for dual-rate systems will be based on this model, which does not involve the unavailable intersample outputs.

From the model in (6), we easily get the recursive equation:

$$\begin{aligned} y(k) &= -\sum_{i=1}^{n} \alpha_i y(k - iq) + \sum_{i=1}^{qn} \beta_i \bar{u}(k - i) \\ &= -\sum_{i=1}^{n} \alpha_i y(k - iq) + \sum_{i=1}^{qn} \beta_i \sum_{j=1}^{m} c_j \gamma_j(u(k - i)). \end{aligned}$$

Define the parameter vector θ and information vector $\varphi(k)$ as

$$\theta = \begin{bmatrix} \boldsymbol{\alpha} \\ \boldsymbol{\beta} \\ c_2\boldsymbol{\beta} \\ \vdots \\ c_m\boldsymbol{\beta} \end{bmatrix} \in \mathbb{R}^{n_0}, \quad \varphi(k-1) = \begin{bmatrix} -y(k-q) \\ -y(k-2q) \\ \vdots \\ -y(k-nq) \\ \psi(k-1) \end{bmatrix} \in \mathbb{R}^{n_0}, \ n_0 := (mq+1)n,$$

$$\boldsymbol{\alpha} = \begin{bmatrix} \alpha_1 \\ \alpha_2 \\ \vdots \\ \alpha_n \end{bmatrix} \in \mathbb{R}^n, \quad \boldsymbol{\beta} = \begin{bmatrix} \beta_1 \\ \beta_2 \\ \vdots \\ \beta_{qn} \end{bmatrix} \in \mathbb{R}^{qn}, \quad \boldsymbol{c} = \begin{bmatrix} c_2 \\ c_3 \\ \vdots \\ c_m \end{bmatrix} \in \mathbb{R}^{m-1},$$

$$\psi(k-1) = \begin{bmatrix} \psi_1(k-1) \\ \psi_2(k-1) \\ \vdots \\ \psi_m(k-1) \end{bmatrix} \in \mathbb{R}^{mqn},$$

$$\psi_j(k-1) = \begin{bmatrix} \gamma_j(u(k-1)) \\ \gamma_j(u(k-2)) \\ \vdots \\ \gamma_j(u(k-nq)) \end{bmatrix} \in \mathbb{R}^{qn}, \ j = 1, 2, \ldots, m.$$

Then we have

$$y(k) = \varphi^{\mathrm{T}}(k-1)\theta. \tag{7}$$

Notice that if k is an integer multiple of q, then $\varphi(k-1)$ uses only available dual-rate data—only the past measurement outputs (slow rate) and inputs (fast rate).

From here, we can see that the number of parameters will be greatly increased after the parameterization of nonlinear systems with dual-rate sampling; this will lead to increased computational complexity, which may be reduced by using the hierarchical identification scheme [13, 14, 15, 16, 17, 18].

Let $y_r(k)$ be a desired output signal; define the output tracking error

$$\xi(k+1) = y(k+1) - y_r(k+1).$$

In the deterministic case, if the control signal $u(k)$ is chosen according to the equation $y_r(k+1) = \varphi^{\mathrm{T}}(k)\theta$ obtained by minimizing the criterion function in (4), then the tracking error $\xi(k+1)$ approaches zero asymptotically.

For stochastic systems, based on the model in (7), introducing a zero-mean white noise disturbance term $v(k)$, we have

$$y(k) = \varphi^{\mathrm{T}}(k-1)\theta + v(k). \tag{8}$$

Let $\hat{\theta}$ be the estimate of unknown parameter vector θ; then $\hat{y}(k+1) = \varphi^{\mathrm{T}}(k)\hat{\theta}$ is the output prediction, which is computed by the intersample output estimator in Figure 2. According to the certainty equivalence principle [25], or minimizing the criterion function in (5), the control law takes the following form:

$$y_r(k+1) = \varphi^{\mathrm{T}}(k)\hat{\theta}. \tag{9}$$

Replacing k in (8) with kq gives

$$y(kq) = \varphi^{\mathrm{T}}(kq-1)\theta + v(kq). \tag{10}$$

Then the recursive least squares algorithm may be used to produce the estimate $\hat{\theta}(kq)$ of θ at current time kq, and the algorithm is as follows:

$$\hat{\theta}(kq) = \hat{\theta}(kq-q) + P(kq)\varphi(kq-1)e(kq), \tag{11}$$

$$e(kq) = [y(kq) - \varphi^{\mathrm{T}}(kq-1)\hat{\theta}(kq-q)], \tag{12}$$

$$\hat{\theta}(i) = \hat{\theta}(kq),\ i = kq, kq+1, \ldots, kq+q-1, \tag{13}$$

$$P^{-1}(kq) = P^{-1}(kq-q) + \varphi(kq-1)\varphi^{\mathrm{T}}(kq-1), \tag{14}$$

$$\hat{\theta}(kq) = [\hat{\theta}_1(kq),\ \hat{\theta}_2(kq), \ldots,\ \hat{\theta}_{n_0}(kq)]^{\mathrm{T}}. \tag{15}$$

Based on (9), the control law is given by

$$\varphi^{\mathrm{T}}(kq+j)\hat{\theta}(kq) = y_r(kq+1+j),\quad j = 0, 1, \ldots, q-1. \tag{16}$$

To initialize the control algorithm in (11)–(16), we take $P(0) = p_0 I$, with p_0 normally a large positive number, e.g., $p_0 = 10^6$, and $\hat{\theta}(0) = \hat{\theta}_0$ some small real vector, e.g., $\hat{\theta}(0) = \mathbf{1}_{n_0}/p_0$. Notice that the parameter estimate $\hat{\theta}$ is updated every q (fast) samples, namely, at the slow rate, as is the covariance matrix P; in between the slow samples, we simply hold $\hat{\theta}$ unchanged. Thus, every time $\hat{\theta}$ is updated, we have q new input samples and one new output sample.

Defining the gain vector

$$L(kq) := P(kq)\varphi(kq-1)$$

and applying the matrix inversion lemma

$$(A+BC)^{-1} = A^{-1} - A^{-1}B(I+CA^{-1}B)^{-1}CA^{-1}$$

to (14), it is easy to get that the covariance matrix P can be updated as follows:

$$P(kq) = [I - L(kq)\varphi^{\mathrm{T}}(kq-1)]P(kq-q),$$
$$L(kq) = \frac{P(kq-q)\varphi(kq-1)}{1+\varphi^{\mathrm{T}}(kq-1)P(kq-q)\varphi(kq-1)}.$$

Note $c_1 = 1$; the estimates

$$\hat{\boldsymbol{\alpha}}(kq) = [\hat{\alpha}_1(kq),\ \hat{\alpha}_2(kq), \ldots,\ \hat{\alpha}_n(kq)]^{\mathrm{T}},$$
$$\hat{\boldsymbol{\beta}}(kq) = [\hat{\beta}_1(kq),\ \hat{\beta}_2(kq), \ldots,\ \hat{\beta}_{qn}(kq)]^{\mathrm{T}}$$

of $\boldsymbol{\alpha}$ and $\boldsymbol{\beta}$ can be read from the first n and second qn entries of $\hat{\theta}(kq)$, respectively. Let

$$\hat{\boldsymbol{c}}(kq) = [\hat{c}_2(kq),\ \hat{c}_3(kq), \ldots,\ \hat{c}_m(kq)]^{\mathrm{T}}$$

be the estimate of $\boldsymbol{c}$. Referring to the definition of θ, we get that the estimates of c_j, $j = 2, 3, \ldots, m$, may be computed by

$$\hat{c}_j = \frac{\hat{\theta}_{n+(j-1)qn+i}(kq)}{\hat{\beta}_i(kq)},\ j = 2, 3, \ldots, m;\ i = 1, 2, \ldots, qn.$$

From here, we can see that there is considerable redundancy in determination of each coefficient $\hat{c}_j$ in the nonlinear function $f(\cdot)$, since for each c_j we have qn estimates $\hat{c}_j$ for $i = 1, 2, \ldots, n$. Because we do not need such n estimates for $\hat{c}_j$, one simple way is to take their average as the estimate of c_j [12], i.e.,

$$\hat{c}_j(kq) = \frac{1}{qn} \sum_{i=1}^{qn} \frac{\hat{\theta}_{n+(j-1)qn+i}(kq)}{\hat{\beta}_i(kq)}, \ j = 2, 3, \ldots, m.$$

Of course, the singular value decomposition technique or least squares optimization methods can also be used to find the estimate of $\boldsymbol{c}$ [3, 7].

The control signal $u(kq + j)$ in (16) may be obtained by solving the following nonlinear equation:

$$\begin{aligned} (17) \qquad & \sum_{i=1}^{n} \hat{\theta}_i(kq) y(kq + j + 1 - iq) + \sum_{l=1}^{m} \sum_{i=1}^{nq} \hat{\theta}_{n+(l-1)qn+i}(kq) \gamma_l(u(kq + j + 1 - i)) \\ & = y_r(kq + j + 1), \qquad j = 0, 1, \ldots, q - 1. \end{aligned}$$

Here, a difficulty arises because over the interval $[kq, kq + q)$, except for $j = q - 1$, the expression on the right-hand side of the above equation contains the future and past missing outputs $y(kq + j + 1 - iq)$. So it looks impossible to compute the control law by (17) and to realize the algorithm in (11)–(16). Our solution is based on the adaptive control scheme stated in section 2—these unknown outputs $y(kq + j)$ in (17) are replaced by their estimates $\hat{y}(kq + j)$. Hence we have

$$\begin{aligned} (18) \qquad & \sum_{i=1}^{n} \hat{\theta}_i(kq) \hat{y}(kq + j + 1 - iq) + \sum_{l=1}^{m} \sum_{i=1}^{nq} \hat{\theta}_{n+(l-1)qn+i}(kq) \gamma_l(u(kq + j + 1 - i)) \\ & = y_r(kq + j + 1) \end{aligned}$$

or

$$\begin{aligned} & \sum_{l=1}^{m} \hat{\theta}_{n+(l-1)qn+1}(kq) \gamma_l(u(kq + j)) = y_r(kq + j + 1) - \sum_{i=1}^{n} \hat{\theta}_i(kq) \hat{y}(kq + j + 1 - iq) \\ (19) \qquad & - \sum_{l=1}^{m} \sum_{i=2}^{nq} \hat{\theta}_{n+(l-1)qn+i}(kq) \gamma_l(u(kq + j + 1 - i)), \qquad j = 0, 1, \ldots, q - 2. \end{aligned}$$

In fact, it is only when $j = q - 1$ that the control term $u(kq + j)$ does not involve the missing outputs and can be generated by

$$\begin{aligned} & \sum_{l=1}^{m} \hat{\theta}_{n+(l-1)qn+1}(kq) \gamma_l(u(kq + q - 1)) = y_r(kq + q) - \sum_{i=1}^{n} \hat{\theta}_i(kq) \hat{y}(kq + q - iq) \\ (20) \qquad & - \sum_{l=1}^{m} \sum_{i=2}^{nq} \hat{\theta}_{n+(l-1)qn+i}(kq) \gamma_l(u(kq + q - i)). \end{aligned}$$

In our adaptive control algorithm in (11)–(16) (or (11)–(15), (19), and (20)), based on the parameter estimation, the control signal $u(k)$ is computed by the model inverse of the Hammerstein model defined in (1) and (2) using past inputs $u(k - j)$ for $j = 1, 2, \ldots$, the current output $y(k)$ ($\hat{y}(k)$), past outputs $y(k - j)$ ($\hat{y}(k - j)$) for

$j = 1, 2, \ldots$, and desired output $y_r(k+1)$ (for one-step-ahead self-tuning control) as k increases, and the input $u(k)$ is made to drive the system output at time $k+1$ to the target value $y_r(k+1)$. In order to ensure that the input signal is bounded, this model inverse must be stable; thus the inverse of the nonlinearity $f(\cdot)$ must exist (i.e., the nonlinearity $f(\cdot)$ must be invertible) and $G(z)$ is minimum phase, exactly as in the case of linear models. The control signal $u(k)$ is also determined by using the following approach. Assuming $b_1 \neq 0$ or $\beta \neq 0$, we compute the control signal $u(k)$ by

$$u(kq+j) = \hat{f}^{-1}(\bar{u}(kq+j)),\ i = 0, 1, 2, \ldots, q-1, \tag{21}$$

where $\hat{f}^{-1}(\cdot)$ is the inverse of the estimated nonlinear function $\hat{f}(\cdot)$ defined by

$$\begin{aligned}\bar{u}(kq+j) = \hat{f}(u(kq+j)) = \gamma_1(u(kq+j)) + \hat{c}_2(kq)\gamma_2(u(kq+j)) \\ + \cdots + \hat{c}_m(kq)\gamma_m(u(kq+j)),\end{aligned} \tag{22}$$

and the intermediate signal $\bar{u}(k)$ is obtained from the inverse of the linear model, i.e.,

$$\begin{aligned}\bar{u}(kq+j) = \frac{1}{\hat{\beta}_1(kq)}\Bigg[y_r(kq+j+1) + \sum_{i=1}^{n}\hat{\alpha}_i(kq)\hat{y}(kq+j+1-iq) \\ - \sum_{i=2}^{nq}\hat{\beta}_i(kq)u(kq+j-i+1)\Bigg],\quad j = 0, 1, \ldots, q-2,\end{aligned}$$

$$\begin{aligned}\bar{u}(kq+q-1) = \frac{1}{\hat{\beta}_1(kq)}\Bigg[y_r(kq+q) + \sum_{i=1}^{n}\hat{\alpha}_i(kq)y(kq+q-iq) \\ - \sum_{i=2}^{nq}\hat{\beta}_i(kq)u(kq+j-i+1)\Bigg].\end{aligned}$$

The above two control law equations contain only $nq+n$ parameters (less than $mqn+n$ parameters); however, this increased computation is still tolerable and affordable.

Due to the nonlinear function $f(\cdot)$, the control signal $u(k)$ in (22) is usually solved by numerical methods.

The following assumption is required and is also reasonable: Given $\bar{u}(k)$, there exists a $u(k)$ satisfying (1). Note that we do not require that $u(k)$ be *uniquely* determined by given $\bar{u}(k)$, because all such $u(k)$'s produce the same $\bar{u}(k)$, which does not affect our output tracking performance.

4. Output tracking performance. Let us first introduce some definitions and assumptions. The sequence $\{v(k), \mathcal{F}_k\}$ is assumed to be a martingale difference sequence defined on a probability space $\{\Omega, \mathcal{F}, P\}$, where $\{\mathcal{F}_k\}$ is the σ algebra sequence generated by the observations up to and including time k [25]. The noise sequence $\{v(k)\}$ satisfies the following conditions:

(A1) $\mathrm{E}[v(k)|\mathcal{F}_{k-1}] = 0$ a.s.;

(A2) $\mathrm{E}[v^2(k)|\mathcal{F}_{k-1}] = \sigma^2(k) \leq \bar{\sigma}^2 < \infty$ a.s.;

(A3) $\limsup_{k\to\infty}\frac{1}{k}\sum_{i=1}^{k}v^2(i) \leq \bar{\sigma}^2 < \infty$ a.s.

That is, $\{v(k)\}$ is an independent random noise sequence with zero mean and bounded time-varying variance.

Define

$$r(kq) := \mathrm{tr}[P^{-1}(kq)],\ r(0) := \frac{n_0}{p_0}.$$

It follows easily that

$$\begin{aligned} r(kq) &= \lambda_1[P^{-1}(kq)] + \lambda_2[P^{-1}(kq)] + \cdots + \lambda_{n_0}[P^{-1}(kq)] \\ &\le n_0\lambda_{\max}[P^{-1}(kq)], \\ |P^{-1}(kq)| &= \lambda_1[P^{-1}(kq)]\lambda_2[P^{-1}(kq)]\cdots\lambda_{n_0}[P^{-1}(kq)] \\ &\le \lambda_{\max}^{n_0}[P^{-1}(kq)] \le r^{n_0}(kq), \\ \ln|P^{-1}(kq)| &= O(\ln r(kq)). \end{aligned} \tag{23}$$

In order to study the output tracking performance of the adaptive control algorithm proposed earlier, the following lemma is required.

LEMMA 1. *For the algorithm in* (11)–(16)*, the following inequality holds:*

$$\sum_{i=1}^{\infty} \frac{\varphi^{\mathrm{T}}(iq-1)P(iq)\varphi(iq-1)}{\{\ln r(iq)\}^c} < \infty \ \textit{a.s. for any}\ \ c > 1.$$

Proof. From the definition of $P(kq)$, we have

$$\begin{aligned} P^{-1}(iq-q) &= P^{-1}(iq) - \varphi(iq-1)\varphi^{\mathrm{T}}(iq-1) \\ &= P^{-1}(iq)[I - P(iq)\varphi(iq-1)\varphi^{\mathrm{T}}(iq-1)]. \end{aligned}$$

Taking determinants on both sides gives

$$\begin{aligned} |P^{-1}(iq-q)| &= |P^{-1}(kq)||I - P(kq)\varphi(kq-1)\varphi^{\mathrm{T}}(kq-1)| \\ &= |P^{-1}(iq)|[1 - \varphi^{\mathrm{T}}(iq-1)P(iq)\varphi(iq-1)]. \end{aligned}$$

Thus,

$$\varphi^{\mathrm{T}}(iq-1)P(iq)\varphi(iq-1) = \frac{|P^{-1}(iq)| - |P^{-1}(iq-q)|}{|P^{-1}(iq)|}. \tag{24}$$

Noting that $|P^{-1}(iq)|$ is a nondecreasing function of i, dividing both sides of (24) by $\{\ln r(kq)\}^c$ gives

$$\begin{aligned} \sum_{i=1}^{\infty} \frac{\varphi^{\mathrm{T}}(iq-1)P(iq)\varphi(iq-1)}{\{\ln r(iq)\}^c} &= \sum_{i=1}^{\infty} \frac{|P^{-1}(iq)| - |P^{-1}(iq-q)|}{|P^{-1}(iq)|\{\ln r(iq)\}^c} \\ &\le n_0^c \sum_{i=1}^{\infty} \frac{|P^{-1}(iq)| - |P^{-1}(iq-q)|}{|P^{-1}(iq)|\{\ln|P^{-1}(iq)|\}^c} \\ &= n_0^c \sum_{i=1}^{\infty} \int_{|P^{-1}(iq-q)|}^{|P^{-1}(iq)|} \frac{\mathrm{d}x}{|P^{-1}(iq)|\{\ln|P^{-1}(iq)|\}^c} \\ &\le n_0^c \sum_{i=1}^{\infty} \int_{|P^{-1}(iq-q)|}^{|P^{-1}(iq)|} \frac{\mathrm{d}x}{x(\ln x)^c} \end{aligned}$$

$$
\begin{aligned}
&= n_0^c \int_{|P^{-1}(0)|}^{|P^{-1}(\infty)|} \frac{\mathrm{d}x}{x(\ln x)^c} \\
&= \frac{-n_0^c}{c-1} \cdot \frac{1}{\{\ln x\}^{c-1}} \Big|_{|P^{-1}(0)|}^{|P^{-1}(\infty)|} \\
&= \frac{n_0^c}{c-1} \left[\frac{1}{\{\ln |P^{-1}(0)|\}^{c-1}} - \frac{1}{\{\ln |P^{-1}(\infty)|\}^{c-1}} \right] \\
&< \infty \text{ a.s., } c > 1. \qquad \square
\end{aligned}
$$

We shall prove the main results of this paper by formulating a martingale process as in [13, 14, 19, 21] and by using stochastic process theory and the martingale convergence theorem (Lemma D.5.3 in [25]).

THEOREM 2. *For the system in* (10)*, assume that* (A1)–(A3) *hold,* $B(z)$ *is stable, and the reference input* $y_r(k)$ *is bounded in the sense of*

$$\text{(A4)} \quad |y_r(k)| < \infty.$$

Then the adaptive control algorithm in (11)–(17) *guarantees that the output tracking error at the output sampling instants has the property of minimum variance, i.e.,*

$$\lim_{k\to\infty} \frac{1}{k} \sum_{i=1}^{k} [y_r(iq) - y(iq) + v(iq)]^2 = 0 \ \ a.s.;$$

$$\limsup_{k\to\infty} \frac{1}{k} \sum_{i=1}^{k} \mathrm{E}\{[y_f(iq) - y_r(iq)]^2 | \mathcal{F}_{iq-1}\} \le \bar{\sigma}^2 < \infty \ \ a.s.$$

Proof. Define the parameter estimation error vector as

$$\tilde{\theta}(kq) = \hat{\theta}(kq) - \theta.$$

Using (10) and (11), we have

$$
\begin{aligned}
\tilde{\theta}(kq) &= \tilde{\theta}(kq-q) + P(kq)\varphi(kq-1)[\varphi^{\mathrm{T}}(kq-1)\theta + v(kq) - \varphi^{\mathrm{T}}(kq-1)\hat{\theta}(kq-q)] \\
&:= \tilde{\theta}(kq-q) + P(kq)\varphi(kq-1)[-\tilde{y}(kq) + v(kq)], \qquad (25)
\end{aligned}
$$

where

$$\tilde{y}(kq) := \varphi^{\mathrm{T}}(kq-1)\tilde{\theta}(kq-q) = \varphi^{\mathrm{T}}(kq-1)\hat{\theta}(kq-q) - \varphi^{\mathrm{T}}(kq-1)\theta. \qquad (26)$$

By using (10) and (16), it follows that

$$\tilde{y}(kq) = y_r(kq) - y(kq) + v(kq).$$

Define a nonnegative definite function

$$V(kq) = \tilde{\theta}^{\mathrm{T}}(kq)P^{-1}(kq)\tilde{\theta}(kq).$$

Using (10), (25), and (26), we have

$$
\begin{aligned}
V(kq) &= \tilde{\theta}^{\mathrm{T}}(kq-q)P^{-1}(kq)\tilde{\theta}(kq-q) + 2\tilde{\theta}^{\mathrm{T}}(kq-q)\varphi(kq-1)[-\tilde{y}(kq) + v(kq)] \\
&\quad + \varphi^{\mathrm{T}}(kq-1)P(kq)\varphi(kq-1)[-\tilde{y}(kq) + v(kq)]^2 \\
&= \tilde{\theta}^{\mathrm{T}}(kq-q)[P^{-1}(kq-q) + \varphi^{\mathrm{T}}(kq-1)\varphi(kq-1)]\tilde{\theta}(kq-q) \\
&\quad + 2\tilde{y}(kq)[-\tilde{y}(kq) + v(kq)] + \varphi^{\mathrm{T}}(kq-1)P(kq)\varphi(kq-1)[-\tilde{y}(kq) + v(kq)]^2 \\
&= V(kq-q) - [1 - \varphi^{\mathrm{T}}(kq-1)P(kq)\varphi(kq-1)]\tilde{y}^2(kq) \\
&\quad + \varphi^{\mathrm{T}}(kq-1)P(kq)\varphi(kq-1)v^2(kq) \\
&\quad + 2[1 - \varphi^{\mathrm{T}}(kq-1)P(kq)\varphi(kq-1)]\tilde{y}(kq)v(kq). \qquad (27)
\end{aligned}
$$

Noting that $\tilde{y}(kq)$, $\varphi^{\mathrm{T}}(kq-1)P(kq)\varphi(kq-1)$ are uncorrelated with $v(kq)$ and are $\mathcal{F}_{kq-1}$-measurable, taking the conditional expectation on both sides of (27) with respect to $\mathcal{F}_{kq-1}$ and using (A1)–(A2) give

$$\begin{aligned}\mathrm{E}[V(kq)|\mathcal{F}_{kq-1}] \le V(kq-q) &- [1-\varphi^{\mathrm{T}}(kq-1)P(kq)\varphi(kq-1)]\tilde{y}^2(kq)\\ &+2\varphi^{\mathrm{T}}(kq-1)P(kq)\varphi(kq-1)\bar{\sigma}^2.\end{aligned}$$

Let

$$W(kq) := \frac{V(kq)}{[\ln r(kq)||]^c},\ c>1.$$

Noting that $\ln r(kq)$ is nondecreasing, we have

$$\begin{aligned}\mathrm{E}[W(kq)|\mathcal{F}_{kq-1}] &\le \frac{V(kq-q)}{[\ln r(kq)]^c} - \frac{1-\varphi^{\mathrm{T}}(kq-1)P(kq)\varphi(kq-1)}{[\ln r(kq)]^c}\ \tilde{y}^2(kq)\\ &\quad+\frac{2\varphi^{\mathrm{T}}(kq-1)P(kq)\varphi(kq-1)}{[\ln r(kq)]^c}\ \bar{\sigma}^2\\ &\le W(kq-q) - \frac{1-\varphi^{\mathrm{T}}(kq-1)P(kq)\varphi(kq-1)}{[\ln r(kq)]^c}\ \tilde{y}^2(kq)\\ &\quad+\frac{2\varphi^{\mathrm{T}}(kq-1)P(kq)\varphi(kq-1)}{[\ln r(kq)]^c}\ \bar{\sigma}^2. \qquad (28)\end{aligned}$$

In terms of Lemma 1, we can see that the sum of the last right-hand term of (28) for k from $k=1$ to $k=\infty$ is finite. Since

$$1-\varphi^{\mathrm{T}}(kq-1)P(kq)\varphi(kq-1) = [1+\varphi^{\mathrm{T}}(kq-1)P(kq-q)\varphi(kq-1)]^{-1} \ge 0,$$

applying the martingale convergence theorem (Lemma D.5.3 in [25]) to (28), we conclude that $W(kq)$ converges a.s. to a finite random variable, say, W_0; i.e.,

$$W(kq) = \frac{V(kq)}{[\ln r(kq)]^c} \to W_0 < \infty \text{ a.s., or } V(kq) = O([\ln r(kq)]^c) \text{ a.s.},$$

and also

$$\sum_{k=1}^{\infty} \frac{1-\varphi^{\mathrm{T}}(kq-1)P(kq)\varphi(kq-1)}{[\ln r(kq)]^c}\ \tilde{y}^2(kq) < \infty \text{ a.s.}$$

Due to $\varphi^{\mathrm{T}}(kq-1)P(kq)\varphi(kq-1) = o(1)$, we have

$$\sum_{i=1}^{\infty} \frac{\tilde{y}^2(iq)}{[\ln r(iq)]^c} < \infty \text{ a.s.} \qquad (29)$$

As $r(kq)\to\infty$, using the Kronecker lemma (Lemma D.5.5 in [25]) yields

$$\lim_{k\to\infty} \frac{1}{[\ln r(kq)]^c} \sum_{i=1}^{k}\ \tilde{y}^2(iq) = 0 \text{ a.s.}$$

Since $[\ln r(kq)]^c = o(r(kq))$, we have

$$\lim_{k\to\infty} \frac{k}{r(kq)}\ \frac{1}{k}\sum_{i=1}^{k}\ \tilde{y}^2(iq) = 0 \text{ a.s.} \qquad (30)$$

Since $B(z)$ is stable, applying Lemma B.3.3 in [25] to (10) and using (A3) yields

$$\frac{1}{k}\sum_{i=1}^{k} u^2(iq) \le \frac{c_1}{k}\sum_{i=1}^{k} y^2(iq) + c_2 \text{ a.s.},$$

where c_i represent finite positive constants. According to the definitions of $r(kq)$ and $\varphi(kq)$, it is not difficult to get

$$\begin{aligned}\frac{r(kq)}{k} &\le \frac{c_3}{k}\sum_{i=1}^{k} y^2(iq) + c_4 \\ &= \frac{c_3}{k}\sum_{i=1}^{k} [y_r(iq) - \tilde{y}(iq) + v(iq)]^2 + c_4 \\ &\le \frac{c_5}{k}\sum_{i=1}^{k} \tilde{y}^2(iq) + c_6 \text{ a.s.}\end{aligned}$$

Thus, from (30)

$$0 = \lim_{k\to\infty} \frac{\frac{1}{k}\sum_{i=1}^{k} \tilde{y}^2(iq)}{\frac{r(kq)}{k}} \ge \lim_{k\to\infty} \frac{\frac{1}{k}\sum_{i=1}^{k} \tilde{y}^2(iq)}{\frac{c_5}{k}\sum_{i=1}^{k} \tilde{y}^2(iq) + c_6} \ge 0 \text{ a.s.},$$

and hence

$$\lim_{k\to\infty} \frac{1}{k}\sum_{i=1}^{k} \tilde{y}^2(iq) = 0 \text{ a.s.},$$

or

$$\lim_{k\to\infty} \frac{1}{k}\sum_{i=1}^{k} [y_r(iq) - y(iq) + v(iq)]^2 = 0 \text{ a.s.} \tag{31}$$

Since

$$\begin{aligned}&\mathrm{E}\{[y_r(kq) - y(kq) + v(kq)]^2 | \mathcal{F}_{kq-1}\} \\ &\quad = \mathrm{E}[(y_r(kq) - y(kq))^2 + 2y_r(kq)v(kq) - 2y(kq)v(kq) + v^2(kq) | \mathcal{F}_{kq-1}] \\ &\quad = \mathrm{E}[(y_r(kq) - y(kq))^2 | \mathcal{F}_{kq-1}] + 0 - 2\sigma^2(kq) + \sigma^2(kq) \\ &\quad = \mathrm{E}[(y_r(kq) - y(kq))^2 | \mathcal{F}_{kq-1}] - \sigma^2(kq) \text{ a.s.},\end{aligned}$$

and $y_f(kq) = y(kq)$ at the output sampling instants, we have

$$\begin{aligned}\limsup_{k\to\infty} \frac{1}{k}\sum_{i=1}^{k} \mathrm{E}\{[y_f(iq) - y_r(iq)]^2 | \mathcal{F}_{iq-1}\} &= \limsup_{k\to\infty} \frac{1}{k}\sum_{i=1}^{k} \mathrm{E}\{[y(iq) - y_r(iq)]^2 | \mathcal{F}_{iq-1}\} \\ &= \limsup_{k\to\infty} \frac{1}{k}\sum_{i=1}^{k} \sigma^2(iq) \le \bar{\sigma}^2 \text{ a.s.}\end{aligned}$$

This proves Theorem 2. □

Since single-rate systems belong to a special class of dual-rate systems with $q = 1$, the results in Theorem 2 still hold for single-rate Hammerstein nonlinear systems, which, to the best of our knowledge, have not even been reported in the literature before.

5. Global convergence. In this section, we analyze global stability properties of the closed-loop system under the adaptive control proposed earlier.

From (3) and (10), we have

$$y_f(kq) = y(kq) = \varphi^{\mathrm{T}}(kq-1)\theta + v(kq), \tag{32}$$

$$y_f(kq+j) = \hat{y}(kq+j), \quad j = 1, 2, \ldots, q-1. \tag{33}$$

From Figure 2 and (10), since $v(kq)$ is a "white" noise, the best estimates of all missing output $y(kq+j)$ are given by

$$\hat{y}(kq+j+1) = \hat{\varphi}^{\mathrm{T}}(kq+j)\hat{\theta}(kq), \quad j = 0, 1, \ldots, q-2,$$

with

$$\hat{\varphi}(kq+j) = \begin{bmatrix} -\hat{y}(kq+j+1-q) \\ -\hat{y}(kq+j+1-2q) \\ \vdots \\ -\hat{y}(kq+j+1-nq) \\ \psi(kq+j) \end{bmatrix} \in \mathbb{R}^{n_0}, \ \psi(kq+j) = \begin{bmatrix} \psi_1(kq+j) \\ \psi_2(kq+j) \\ \vdots \\ \psi_m(kq+j) \end{bmatrix} \in \mathbb{R}^{mqn},$$

$$\psi_i(kq+j) = \begin{bmatrix} \gamma_i(u(kq+j)) \\ \gamma_i(u(kq+j-1)) \\ \vdots \\ \gamma_i(u(kq+j+1-nq)) \end{bmatrix} \in \mathbb{R}^{qn}, \ i = 1, 2, \ldots, m.$$

The missing output estimates $\hat{y}(kq+j)$ can also be computed from the recursive equation:

$$\begin{aligned} \hat{y}(kq+j+1) = &-\sum_{i=1}^{n} \hat{\theta}_i(kq)\hat{y}(kq+j+1-iq) \\ &+ \sum_{l=1}^{m}\sum_{i=1}^{nq} \hat{\theta}_{n+(l-1)qn+i}(kq)\gamma_l(u(kq+j+1-i)), \\ &j = 0, 1, \ldots, q-2. \end{aligned} \tag{34}$$

Comparing (18) with (34), we find that the missing intersample output estimates $\hat{y}(kq+j)$, $j = 1, 2, \ldots, q-1$, equal the desired outputs $y_r(kq+j)$; so we have

$$y_r(kq+j) = \hat{y}(kq+j) = \hat{\varphi}^{\mathrm{T}}(kq+j)\hat{\theta}(kq), \quad j = 1, 2, \ldots, q-1, \tag{35}$$

$$\hat{\varphi}(kq+j) = \begin{bmatrix} -y_r(kq+j+1-q) \\ -y_r(kq+j+1-2q) \\ \vdots \\ -y_r(kq+j+1-nq) \\ \psi(kq+j) \end{bmatrix}. \tag{36}$$

It is easy to understand that the unknown intersample outputs $y(kq+j)$ are replaced by the desired outputs $y_r(kq+j)$ because our goal is to make $y(k)$ track $y_r(k)$. Hence, combining (20) with (35)–(36) generates the control signal sequence $\{u(kq+j)$,

$j = 0, 1, \ldots, q-1\}$ based on the parameter estimates $\hat{\theta}(kq)$ obtained. Thus, the following theorem is easily established.

THEOREM 3. *Assume that the conditions of Theorem* 2 *hold, $A(z)$ and $B(z)$ both are stable, and $f(\cdot)$ is invertible. Then the adaptive control algorithm in* (11)–(15), (19), *and* (20) *ensures that the closed-loop system is stable and globally convergent with probability* 1*; moreover,*

- *the input and output variables are uniformly bounded, i.e.,*

$$\limsup_{k\to\infty} \frac{1}{k} \sum_{i=1}^{k} [u^2(i) + y^2(i) + y_f^2(i)] < \infty \ a.s.;$$

- *the average output tracking error is less than or equal to $\bar{\sigma}^2/q$, i.e.,*

$$\limsup_{k\to\infty} \frac{1}{k} \sum_{i=1}^{k} \mathrm{E}\{[y_f(i) - y_r(i)]^2 | \mathcal{F}_{i-1}\} \le \frac{\bar{\sigma}^2}{q} \ a.s.$$

Proof. Since $y_r(k)$ is bounded, from Theorem 2 and condition (A3), it is easy to get that the outputs $y(kq)$ at the output sampling instants are uniformly bounded, i.e.,

$$\limsup_{k\to\infty} \frac{1}{k} \sum_{i=1}^{k} y^2(iq) \le \delta_y < \infty \text{ a.s.}$$

Also, the intersample output estimates $\hat{y}(kq+j)$, $j = 1, 2, \ldots, (q-1)$, satisfy

$$\hat{y}(kq+j) = y_r(kq+j), \quad j = 1, 2, \ldots, q-1.$$

So $y_f(kq+j)$ is bounded. According to (32) and (33), $y_f(k)$ is bounded. Since $A(z)$ and $B(z)$ are stable, so are $\alpha(z)$ and $\beta(z)$, and $u(k)$ is bounded in terms of Lemma B.3.3 in [25]. Hence we have

$$\limsup_{k\to\infty} \frac{1}{k} \sum_{i=1}^{k} u^2(i) < \infty \text{ a.s.}, \qquad \limsup_{k\to\infty} \frac{1}{k} \sum_{i=1}^{k} y^2(i) < \infty \text{ a.s.},$$

$$\limsup_{k\to\infty} \frac{1}{k} \sum_{i=1}^{k} y_f^2(i) < \infty \text{ a.s.},$$

which means that all the input and output variables are uniformly bounded. Also,

$$\limsup_{k\to\infty} \frac{1}{k} \sum_{i=1}^{k} \mathrm{E}\{[y_f(i) - y_r(i)]^2 | \mathcal{F}_{i-1}\} = \limsup_{k\to\infty} \frac{1}{kq} \sum_{i=1}^{k} \mathrm{E}\{[y(iq) - y_r(iq)]^2 | \mathcal{F}_{iq-1}\}$$

$$+ \limsup_{k\to\infty} \frac{1}{kq} \sum_{j=1}^{q-1} \sum_{i=1}^{k} \mathrm{E}\{[\hat{y}(iq+j) - y_r(iq+j)]^2 | \mathcal{F}_{iq+j-1}\}.$$

Since $y_f(i) = \hat{y}(i) = y_r(i)$ at the missing output sampling instants, the last term on the right-hand side is zero, and the first term is no more than $\bar{\sigma}^2/q$ from Theorem 2. This proves Theorem 3. □

Theorems 2 and 3 indicate that the proposed adaptive control scheme in the dual-rate setting can achieve the property of minimum variance at the output sampling instants. Between the output sampling instants, we have $\hat{y}_f(kq+j) = \hat{y}(kq+j) = y_r(kq+j)$, $j = 1, 2, \ldots, q-1$. The control scheme here is easily extended to non-

minimum phase cases by defining a new weighted criterion:

$$J[u(k)] = \mathrm{E}\{[P(z)y_f(k+d) - Q(z)y_r(k+d)]^2 + [R(z)u(k)]^2 | \mathcal{F}_{k-1}\}.$$

Here, $P(z)$, $Q(z)$, and $R(z)$ are polynomials in z^{-1}.

If the single-rate system considered is an AR model with exogenous input (ARX model), then by the model transform, the noise model should be $\phi_q(z)v(k)$ instead of $v(t)$. This leads to an ARMAX model. In this case, we may use the recursive extended least squares algorithm in [25] to estimate the parameters.

The persistent excitation condition is required for the convergence of the parameter estimation. Like in linear single-rate cases [25], adaptive control algorithms do not guarantee the convergence of the parameter estimation to their true values.

In order to avoid generating $u(k)$ with too large magnitudes, for a given small positive ε, if $|\hat{\beta}_1(kq)| < \varepsilon$, we take $\hat{\beta}_1(kq) = \mathrm{sgn}[\hat{\beta}_1(kq)]\varepsilon$, where the sign function is defined by

$$\mathrm{sgn}(x) = \begin{cases} 1 & x \geq 0, \\ 0 & x < 0. \end{cases}$$

6. Example. In this section, we illustrate the results reported with simulation examples, including an experimental water level system.

Example 1. For the Hammerstein nonlinear model shown in Figure 1, we select the dual-rate sampling ratio as $q = 2$, the fast-rate discrete-time (dynamic) model $G(z)$ as a second-order one with

$$G(z) = \frac{B(z)}{A(z)} = \frac{0.412z^{-1} + 0.309z^{-2}}{1 - 1.60z^{-1} + 0.80z^{-2}},$$

and the static nonlinear function $f(\cdot)$ as

$$\bar{u}(k) = f(u(k)) = c_1u(k) + c_2u^2(k) + c_3u^3(k) = u(k) + 0.5u^2(k) + 0.25u^3(k).$$

We choose the noise sequence $\{v(k)\}$ to be a white noise sequence with zero mean and variance $\bar{\sigma}^2 = 0.05^2$ and the desired output to be

$$y_r(400i + j) = (-1)^{i+1}, \quad i = 0, 1, 2, \ldots; \quad j = 1, 2, \ldots, 400.$$

The adaptive control algorithm in section 3 is applied to this system. The system output $y(k)$ and the desired output $y_r(k)$ are shown in Figure 3 with $q = 2$. Figure 4 with $q = 1$ is the simulated results of the Åström–Wittenmark self-tuning regulator (A–W STR) suitable for single-rate systems [2].

From Figures 3 and 4, we can see that the control algorithm proposed in this paper can achieve both less and more stationary average tracking errors than the A–W STR algorithm. This is due to $\hat{y}(kq + j) - y_r(kq + j) = 0$, $j = 1, 2, \ldots, q - 1$, between output sampling instants. Thus, the closed-loop tracking performance is satisfactory. This confirms the results reported earlier.

Example 2. This example is a computer-controlled experimental water tank system at the University of Alberta, and is shown in Figure 5. In this system, the manipulated variable is the position of the inlet water valve, denoted $u(t)$; the measured variable is the water level in the tank, denoted $y(t)$; the inner variable, namely, the water flow rate $\bar{u}(t)$ (the output of the water valve) is not measured. The map from $u(t)$ to $\bar{u}(t)$ is nonlinear and can be approximated by a third-order polynomial,

$$\bar{u}(t) = c_1u(t) + c_2u^2(t) + c_3u^3(t)$$

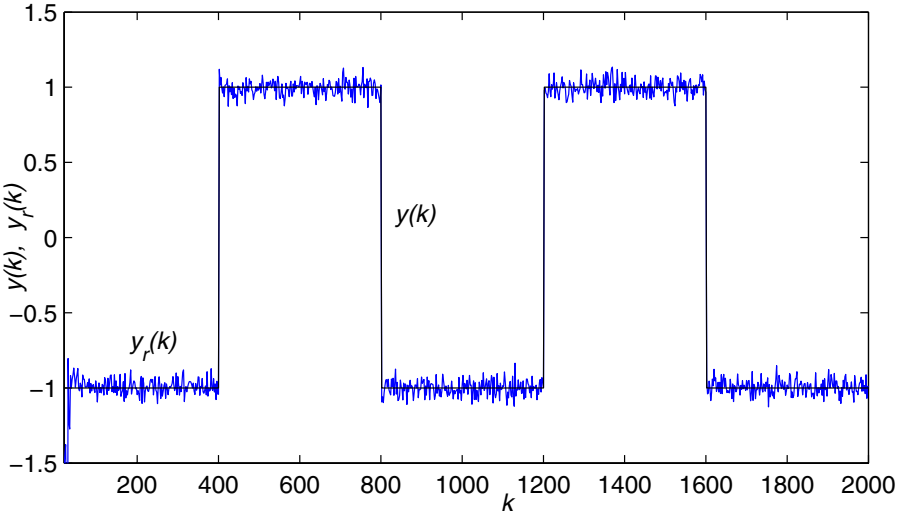

FIG. 3. $y(k)$ *and* $y_r(k)$ *versus* k $(q = 2)$.

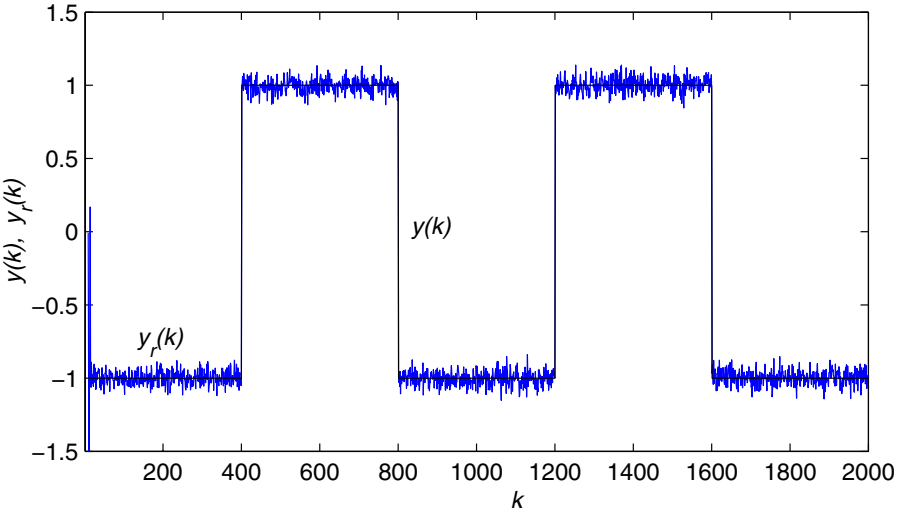

FIG. 4. $y(k)$ *and* $y_r(k)$ *versus* k $(q = 1)$.

(keeping the first few terms in the Taylor series expansion). For our study, the input $u(t)$ is updated every $h = 40$ s to get $u(k)$, and the output $y(t)$ is sampled every $qh = 80$ s (hence $q = 2$), yielding $y(kq)$. Around an operating point, we use a random binary sequence generated by MATLAB as the input signal. By data correlation analysis on the collected input-output data, we determined that the model order associated with $G(z)$ from $\bar{u}(k)$ to $y(k)$ is 2 with a delay of 2 samples, and hence $G(z)$ has the form of

$$G(z) = \frac{b_2 z^{-2} + b_3 z^{-3}}{1 + a_1 z^{-1} + a_2 z^{-2}}.$$

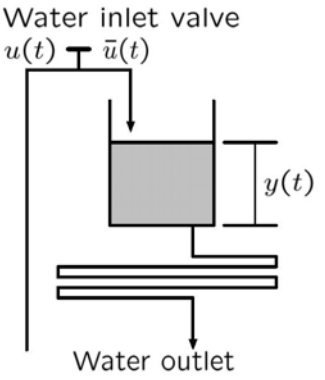

FIG. 5. *Experimental setup of a water tank.*

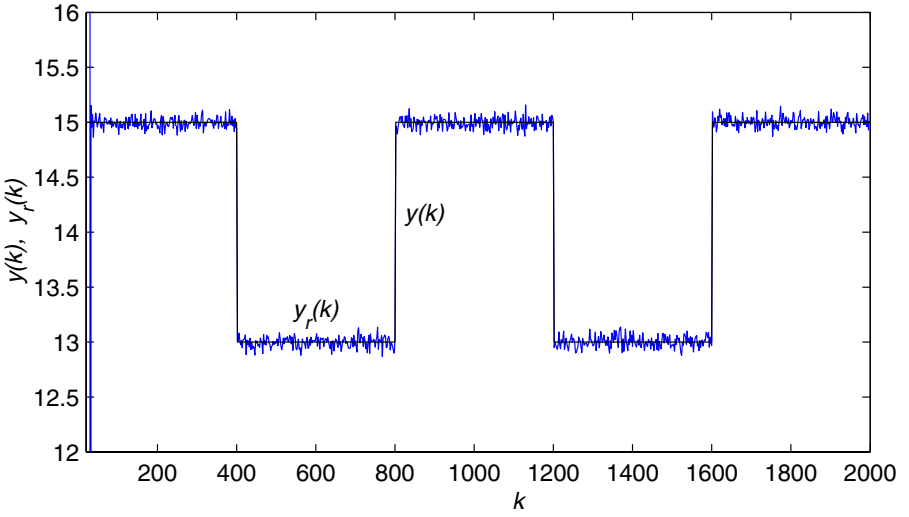

FIG. 6. *$y(k)$ and $y_r(k)$ versus k ($q = 2$).*

Using the polynomial transform, we estimated the new model from $\bar{u}(k)$ to $y(kq)$ as follows:

$$P(z) = \frac{\beta(z)}{\alpha(z)} = \frac{0.92691z^{-2} + 0.83503z^{-3} - 0.65555z^{-4} - 0.66384z^{-5}}{1 - 1.55795z^{-2} + 0.60728z^{-4}}.$$

The parameters of $P(z)$ were obtained by the dual-rate least squares algorithm in (11)–(15); see [20]. Similarly, we took $\{v(k)\}$ to be a white noise sequence with zero mean and variance $\bar{\sigma}^2 = 0.05^2$ and the desired output to be

$$y_r(400i + j) = 14 + (-1)^i, \quad i = 0, 1, 2, \ldots; \quad j = 1, 2, \ldots, 400.$$

Here, $y_r(k) = 14$ is the operating point. The adaptive control algorithm in section 3 was applied to this water tank system. The system output $y(k)$ and the desired output $y_r(k)$ are shown in Figure 6. From Figure 6, we conclude that satisfactory tracking performance has been achieved, and this shows that the algorithm reported is effective.

7. Conclusions. An adaptive control algorithm for Hammerstein nonlinear sampled-data systems with *limited* (slow) output sampling is presented based on only *slow-rate* output measurement data; the algorithm generates a relatively fast-rate control signal from an online parameter identification routine which estimates fast-rate models for Hammerstein systems involving dynamic linear blocks and static nonlinear blocks. Performance analysis in the stochastic framework indicates that the proposed control algorithm can achieve a desired tracking control objective under certain conditions. The simulation results also validate the theoretical findings.

OUTPUT STABILIZATION VIA NONLINEAR LUENBERGER OBSERVERS*

L. MARCONI†, L. PRALY‡, AND A. ISIDORI§

Abstract. The present paper addresses the problem of the existence of an (output) feedback law that asymptotically steers to zero prescribed outputs, while keeping all state variables bounded, for any initial conditions in a given compact set. The problem can be viewed as an extension of the classical problem of semiglobally stabilizing the trajectories of a controlled system to a compact set. The problem also encompasses a version of the classical problem of output regulation. Under only a *weak minimum phase* assumption, it is shown that there exists a controller solving the problem at hand. The paper is deliberately focused on theoretical results regarding the existence of such a controller. Practical aspects involving the design and the implementation of the controller are left to a forthcoming work.

Key words. output stabilization, nonlinear output regulation, nonlinear observers, Lyapunov functions, nonminimum-phase systems, robust control

1. Introduction.

The problem of controlling a system in such a way that some prescribed outputs converge to zero while all other state variables remain bounded is a relevant problem in control theory. It includes, as special cases, the problem of asymptotic stabilization of a fixed equilibrium point and the problem of asymptotic stabilization of a fixed invariant set. It also includes design problems in which some selected variables are required to asymptotically track (or to asymptotically reject) certain signals generated by an independent autonomous system. Problems of this kind, usually referred to as problems of "output regulation," have been extensively studied in the past for linear systems (see [10, 18, 17]) as well as, beginning with the seminal work [23], for nonlinear systems. As a matter of fact, these problems can be viewed as problems in which a "regulated" output of an "augmented system" (a system consisting of the controlled plant and the exogenous system generator) must be asymptotically steered to zero while all other state variables are kept bounded. As pointed out in [23], for instance, the basic challenges in a problem of this type are to create an invariant set on which the desired regulated output vanishes, and to render this set asymptotically attractive.

Even though paper [23] is limited in scope (the design method suggested therein being only meant to secure local, and nonrobust, regulation about an equilibrium point) it has the merit of highlighting a few basic concepts and ideas which shaped all subsequent developments in this area of research. These ideas include the fundamental link between the problem in question and the notion of "zero dynamics" (a concept introduced and studied earlier by the same authors), the necessity of the existence of

a (controlled) invariant set on which the desired regulated output vanishes, and an embryo of design philosophy based on the idea of making this invariant set locally (and exponentially) attractive.

In the past 15 years, the design philosophy of [23] was extended in several directions. One clear need was to move from "local" to "nonlocal" convergence, a goal which was pursued, for instance, in [25, 21, 30, 5], where different approaches (at increasing levels of generality) have been proposed. Another concern was to obtain design methods which are insensitive, or even robust, with respect to model uncertainties. This issue was originally addressed in [20], where it was shown how, under appropriate hypotheses, the property of (local) asymptotic regulation can be made robust with respect to plant parameter variations, extending in this way a celebrated property of linear regulators.

In the presence of plant parameter variations, the challenge is to design a (parameter-independent) controller in such a way that the closed-loop system possesses a (possibly parameter *dependent*) attractive invariant set on which the regulated output vanishes. The two issues of forcing the existence of such an invariant set and of making the invariant set (locally or nonlocally) attractive are of course interlaced, and this is precisely what, in the past, has determined the various scenarios under which different solutions to the problem have been proposed. In the paper [20], for instance, a solution was achieved by assuming that the set of all feed-forward controls which force the regulated output to be identically zero had to be generated by a single (parameter-independent) *linear* system. This assumption was weakened in [12], in [11], and subsequently in [6], where it was replaced with the assumption that the controls in question are generated by a single (parameter-independent) *nonlinear* system, uniformly observable in the sense of [19].

The crucial observation that made the advances in [6] and [11] possible was the realization that the two issues of forcing the existence of an invariant set (on which the regulated variable vanishes) and of making the invariant set attractive are intimately related to, and actually can be cast as, the problem of designing a (nonlinear) *observer*. As a matter of fact, the design method suggested in [6] was based almost entirely on the construction of a nonlinear "high-gain" observer following the methods of Gauthier and Kupka [19], while the design method suggested in [11] was based almost entirely on the construction of a nonlinear adaptive observer following the methods of Bastin and Gevers [3] and Marino and Tomei [24].

Having realized that the design of observers is instrumental in the design of controllers which solve the problem in question, researchers came to the idea of examining whether alternative options, in the design of observers, could be of some help in weakening the assumptions even further. This turns out to be true, as shown in the present paper, in the case when we adopt the approach to the design of nonlinear observers outlined by Kazantis and Kravaris [27] and further pursued by Kreisselmeier and Engel [28], Krener and Xiao [26], and Andrieu and Praly [1].

While in all earlier contributions it was assumed that the controls which force the regulated output to be identically zero could be interpreted as outputs of a (in general, nonlinear) system having special observability properties (which eventually became part of the controller), a crucial property highlighted in the proof of Theorem 3 of [1] shows that no assumption of this kind is actually needed. The controls in question can *always* be generated by means of a system of appropriate dimension whose dynamics are linear but whose output map is a nonlinear (and, in general, only continuous but not necessarily locally Lipschitzian) map. Once this system is embedded in the controller, boundedness of all closed-loop trajectories and convergence to the desired

invariant set can be guaranteed, as in the earlier contributions [6] and [11], by a somewhat standard paradigm which blends practical stabilization with a small-gain property for feedback interconnection of systems which are input-to-state stable (with restrictions).

The purpose of this paper is to provide a complete proof of how the results of [1] can be exploited for the design of a controller solving the problem, and also to show how some technical hypotheses used in the asymptotic analysis of [7] can be totally removed, yielding in this way a general theory cast only on a very simple and meaningful assumption. This paper is deliberately meant to present only those theoretical results needed to show the *existence* of the solution of the problem in question. Issues related to practical aspects involving constructive design and implementation will be dealt with in a forthcoming work.

The paper is organized as follows. In the next section the main framework under which the problem is solved is presented and discussed. Then section 3 presents an outline of the main results concerning the existence of the output feedback regulator. Section 4 concludes the paper with some with final remarks. Technical proofs of the results in section 3 are postponed to Appendices A and B.

Notation. For $x \in \mathbb{R}^n$, $|x|$ denotes the Euclidean norm, and for $\mathcal{C}$ a closed subset of $\mathbb{R}^n$, $|x|_{\mathcal{C}} = \min_{y\in\mathcal{C}} |x-y|$ denotes the distance of x from $\mathcal{C}$. For $\mathcal{S}$ a subset of $\mathbb{R}^n$, $\operatorname{cl}\mathcal{S}$ and $\operatorname{int}\mathcal{S}$ are the closure of $\mathcal{S}$ and the interior of $\mathcal{S}$, respectively, and $\partial\mathcal{S}$ its boundary. For the smooth[1] dynamical system $\dot{x} = f(x)$, the value at time t of the solution passing through x_0 at time $t = 0$ will be written as $x(t, x_0)$. The more compact notation $x(t)$ will be used instead of $x(t, x_0)$, when the initial condition is clear from the context. A set $\mathcal{S}$ is said to be forward (backward) invariant for $\dot{x} = f(x)$ if each $x_0 \in \mathcal{S}$, $x(t, x_0) \in \mathcal{S}$ for all $t \geq 0$ ($t \leq 0$). The set is invariant if it is backward and forward invariant. For a locally Lipschitz function $V(t)$ we define Dini's derivative of V at t as

$$D^+V(t) = \lim_{h\to 0^+} \sup \frac{1}{h}[V(t+h) - V(t)].$$

By extension, when $V(t)$ is obtained by evaluating V along a solution $x(t, x_0)$, we denote also

$$D^+V(x_0) = \lim_{h\to 0^+} \sup \frac{1}{h}[V(x(h, x_0)) - V(x_0)]. \tag{1}$$

Note that if $\limsup = \lim$, this is simply $L_fV(x_0)$, the Lie derivative at x_0 of V along f.

2. The framework.

2.1. The problem of output stabilization and the main result.

We consider in what follows a nonlinear *single input–single output* smooth system described by[2]

$$\begin{aligned} \dot{z} &= f(z, y), \\ \dot{y} &= q(z, y) + u \end{aligned} \tag{2}$$

[1] In this paper, "smooth" means "differentiable a sufficiently large number of times" so that all of what we write makes sense.

[2] System (2) is described in the well-known *normal form* with relative degree 1 (see [22]). As discussed in section 2.2, the case of systems in normal form with a higher relative degree can be dealt with in the proposed framework.

with state $(z, y) \in \mathbb{R}^n \times \mathbb{R}$, *measured output* y, and *control input* $u \in \mathbb{R}$, and with initial conditions $(z(0), y(0))$ ranging in a known arbitrary compact set $Z \times \Xi \subset \mathbb{R}^n \times \mathbb{R}$. Associated with (2) there is a *controlled* output $e \in \mathbb{R}^p$ expressed as

$$e = h(z, y) \tag{3}$$

in which $h : \mathbb{R}^n \times \mathbb{R} \to \mathbb{R}^p$ is a smooth function.

For system (2)–(3) the problem of semiglobal (with respect to $Z \times \Xi$) output stabilization is defined as follows. Find, if possible, a dynamic output feedback controller of the form

$$\begin{aligned} \dot{\eta} &= \varphi(\eta, y), \\ u &= \varrho(\eta, y) \end{aligned} \tag{4}$$

with state $\eta \in \mathbb{R}^\nu$ and a compact set $M \subset \mathbb{R}^\nu$ such that, in the associated closed-loop system

$$\begin{aligned} \dot{z} &= f(z, y), \\ \dot{y} &= q(z, y) + \varrho(\eta, y), \\ \dot{\eta} &= \varphi(\eta, y), \\ e &= h(z, y), \end{aligned} \tag{5}$$

the positive orbit of $Z \times \Xi \times M$ is bounded and, for each $(z(0), y(0), \eta(0)) \in Z \times \Xi \times M$,

$$\lim_{t \to \infty} e(t) = 0.$$

The problem at issue will be solved only under the following *weak minimum-phase* assumption which requires that system

$$\dot{z} = f(z, 0), \tag{6}$$

representing the zero dynamics of (2) associated with the input u and output y, has a compact attractor which is asymptotically stable. In more precise terms the assumption in question is formulated as follows.

Assumption. There exists a compact set $\mathcal{A} \subset \mathbb{R}^n$ such that

(a_1) the set $\mathcal{A}$ is locally asymptotically stable[3] for system (6) with a domain of attraction $\mathcal{D} \supset Z$;

(a_2) $h(z, 0) = 0$ for all $z \in \mathcal{A}$.

Comments on this assumption and on the proposed framework are postponed until after the next theorem, which presents the main result of the paper.

THEOREM 1. *There exists an $m > 0$, a controllable pair $(F, G) \in \mathbb{R}^{m \times m} \times \mathbb{R}^{m \times 1}$, a continuous function $\gamma : \mathbb{R}^m \to \mathbb{R}$, and for any compact set $M \subset \mathbb{R}^m$, a continuous function $\kappa : \mathbb{R}^p \to \mathbb{R}$, such that the controller*

$$\begin{aligned} \dot{\eta} &= F\eta + Gu, \qquad \eta(0) \in M, \\ u &= \gamma(\eta) + v, \\ v &= \kappa(y) \end{aligned} \tag{7}$$

solves the problem of semiglobal (with respect to $Z \times \Xi$) output stabilization.

[3]Refer to Appendix A for precise definitions regarding the notion of asymptotic stability.

2.2. Remarks on the framework and the result. The framework presented above deals with problems which can be viewed as problems of "external stabilization" of nonlinear systems, namely, problems in which the goal is to steer to zero only a few selected *external* variables, represented in the current framework by the controlled outputs e, while all other variables are simply kept bounded. In this respect the method can be used to handle systems in which there are uncontrollable internal motions that are not necessarily converging to an equilibrium but remain otherwise bounded.

The main idea pursued in the present paper to solve the problem at hand is to extend "high-gain" control paradigms, conventionally used to stabilize a minimum-phase system with respect to an equilibrium point (see [8, 33]), to the case of compact attractors. In this respect assumption (a_1) can be interpreted as a "weak" version of classical minimum-phase hypotheses for the case in which the asymptotic behavior of the zero dynamics (6) is not constrained to being an equilibrium but rather is allowed to be governed by complex bounded dynamics. Clearly, to take advantage of the fact that the trajectories of (6) with initial conditions in Z, as required in part (a_1) of the assumption, are attracted by a compact set $\mathcal{A}$, it would be desirable to have, asymptotically, y converging to zero. Of course since the controlled variable e is required to asymptotically decay to 0, it is also appropriate to assume, as done in (a_2), that $h(z,0)$ vanishes on $\mathcal{A}$. If this were to occur, in fact, then also the controlled variable e would converge to zero, and the problem would be solved. To make y converge to zero, one might wish to appeal to (somewhat standard) "high-gain" arguments and design a control law of the form $u = -ky$. However, it is well known (see, e.g., [33]) that to have y asymptotically converging to zero in a "high-gain" scheme, it is somewhat necessary that the "coupling" term $q(z,y)$ between the upper and the lower subsystem of (2) asymptotically vanishes. More specifically, it is necessary that $q(z,0)$ vanish on the set $\mathcal{A}$ to which the state z of the upper subsystem converges if y decays to zero. Now, in general, there is no guarantee that $q(z,0)$ would vanish on $\mathcal{A}$, and this is why a more elaborate controller has to be synthesized. As a matter of fact, the main result of the paper is that a suitable *dynamic* controller ensures that a property of this kind is achieved.

For the sake of simplicity, we have chosen to illustrate our theory in the case of a system of the form (2), which is rather special for a number of reasons. As a matter of fact, this system has relative degree 1 between the control input u and the measured output y, its "high-frequency gain" is equal to 1, and the dynamics (6) is assumed to possess a compact attractor which is asymptotically stable. However, the main result of the paper lends itself to the synthesis of regulators for more general classes of systems. A natural way in which assumption (a_1) can be weakened consists of viewing y as a "virtual control" of

$$\dot{z} = f(z,y)$$

and assuming the existence of a map $\alpha : \mathbb{R}^n \to \mathbb{R}$ and a compact set $\mathcal{A}$ such that

(a_1') the set $\mathcal{A}$ is locally asymptotically stable for

$$\dot{z} = f(z,\alpha(z))$$

with a domain of attraction $\mathcal{D} \supset Z$,

(a_2') $h(z,\alpha(z)) = 0$ for all $z \in \mathcal{A}$.

If this is the case, in fact, the change of variable $\tilde{y} = y - \alpha(z)$ transforms system (2) into a system in which assumptions (a_1) and (a_2) are fulfilled. The result of Theorem 1 can therefore be used, provided that the variable $\tilde{y}$ is available for feedback.

An extension of this kind is useful in handling cases of systems having relative degree $r > 1$ between the control input u and the measured output y. Consider, to this end, the case of a plant modeled by equations of the form

$$\begin{aligned} \dot{z}_1 &= f(z_1, Cz_2), \\ \dot{z}_2 &= Az_2 + B\zeta, \\ \dot{\zeta} &= q(z_1, z_2, \zeta) + u, \end{aligned} \tag{8}$$

in which $z_1 \in \mathbb{R}^{n-r+1}$, $z_2 \in \mathbb{R}^{r-1}$, $y \in \mathbb{R}$, and A, B, C is a triplet in "prime" form, with measured output

$$y = Cz_2 \tag{9}$$

and controlled output

$$e = h(z_1, z_2, \zeta). \tag{10}$$

Let $Z = Z_1 \times Z_2$ be the prescribed compact set of initial conditions for (z_1, z_2) and suppose there exists a compact set $\mathcal{A}_1$ which is locally asymptotically stable for

$$\dot{z}_1 = f(z_1, 0),$$

with a domain of attraction $\mathcal{D}_1 \supset Z_1$, and such that

$$h(z_1, 0, 0) = 0 \qquad \forall z_1 \in \mathcal{A}_1. \tag{11}$$

If this is the case, the problem of steering e to zero while keeping all internal states bounded can be easily handled in the following way. Standard backstepping arguments (see, e.g., [4] and also [11]) show the existence of matrix K such that, in the system

$$\begin{aligned} \dot{z}_1 &= f(z_1, Cz_2), \\ \dot{z}_2 &= Az_2 + BKz_2, \end{aligned} \tag{12}$$

the compact set $\mathcal{A} = \{(z_1, z_2) : z_1 \in \mathcal{A}_1,\ z_2 = 0\}$ is locally asymptotically stable for (12) with a domain of attraction $\mathcal{D} \supset Z_1 \times Z_2$. Thus, by letting $z = \mathrm{col}(z_1, z_2)$ and $\alpha(z) = Kz_2$, by virtue of (11), it turns out that assumptions (a'_1) and (a'_2) above are fulfilled by system (12) with controlled output (10). This, in view of the previous discussion, guarantees the existence of a controller solving the problem at hand provided that the variable $\tilde{y} := \zeta - Kz_2$ is available for feedback. In particular, since $\mathrm{col}(z_2, \zeta) = (y, \dot{y}, \ldots, y^{(r-1)})$, Theorem 1 guarantees the existence of a *partial state feedback* controller, namely, a controller relying not only on the knowledge of the measured output (9) but also on all its first $r-1$ derivatives with respect to time. This is not a restriction, though, because—as shown, for instance, in [14] and [33]—as long as convergence from a compact set of initial conditions is sought, all components of $\mathrm{col}(z_2, \zeta)$ can always be estimated by means of an "approximate" observer driven only by its first component Cz_2, namely, the actual measured output y.

Finally, it is worth noting that all the results presented in the paper could be generalized to treat the case in which the "high-frequency gain," which is assumed to be unitary in (2), is a generic sign-definite function of the state, namely, the case in which the dynamics of y in (2) is described by

$$\dot{y} = q(z, y) + b(z, y)u \tag{13}$$

with $b(z, y) \geq \underline{b}$ for some known $\underline{b} > 0$. Details on how this can be accomplished are rather straightforward and are not deliberately presented here, as they would only add notational complications without any extra conceptual value.

2.3. Output regulation. A special case covered by the previous setup is the one in which system (2)–(3) is described by equations of the form

$$\begin{array}{rcl} \dot{z}_1 & = & f_1(z_1), \\ \dot{z}_2 & = & f_2(z_1, z_2, y), \\ \dot{y} & = & q(z_1, z_2, y) + u, \\ e & = & h(z_1, z_2, y), \end{array} \tag{14}$$

i.e., a system with "triangular" zero dynamics. In this case, it is clear that the dynamics of z_1 is a totally *autonomous* dynamics, which can be viewed as an "exogenous" signal generator. This is the way in which the classical problem of *output regulation* is usually cast (see [23]). Depending on the control scenario, the variable z_1 may assume different meanings. It may represent exogenous disturbances to be rejected and/or references to be tracked. It may also contain a set of (constant or time-varying) uncertain parameters affecting the controlled plant.

In this context, it is important to note that the proposed framework encompasses a number of problems which have been recently addressed (see, among others, [25, 31, 11, 5, 4, 12]), all relying upon various versions of the so-called "minimum-phase" and "immersion" assumptions.

More specifically, as far as the assumption of "minimum-phase" is concerned, all the aforementioned works require that the dynamics

$$\begin{array}{rcl} \dot{z}_1 & = & f_1(z_1), \\ \dot{z}_2 & = & f_2(z_1, z_2, 0), \end{array} \tag{15}$$

with $z_1 \in \mathbb{R}^s$, $z_2 \in \mathbb{R}^{n-s}$, possess some stability property. For instance, in [31] the assumption in question is the existence of a differentiable map $\pi : \mathbb{R}^s \to \mathbb{R}^{n-r}$ whose graph

$$\mathcal{A} = \{(z_1, z_2) \in \mathbb{R}^s \times \mathbb{R}^{n-r} \ : \ z_2 = \pi(z_1)\}$$

is invariant and locally exponentially stable for (15), uniformly with respect to the exogenous variable z_1, with a domain of attraction containing the assigned compact set of initial conditions and such that

$$h(z_1, z_2, 0) = 0 \qquad \forall\, (z_1,\, z_2) \in \mathcal{A}.$$

This assumption has been substantially weakened in [5] (see also [6] and [4]) by simply asking that the positive orbit of the set of initial conditions under the flow of (15) be bounded (which is, in turn, equivalent to the existence of a compact set $\mathcal{A}$, having the properties indicated above, which is the graph of a *set-valued* map π). Of course, it is apparent that all these cases fit into the framework presented in section 2.1.

Furthermore, the framework presented in the actual literature, where the problems of output regulation are usually tackled, requires an additional assumption commonly referred to as the "immersion" assumption. The latter refers to system (15) with output $q(z_1, z_2, 0)$ which is required to be immersed into a system with prescribed properties. To mention a few of these properties, typical assumptions required immersion into a linear observable system (see [20, 31, 30]), or into a nonlinear system in canonical observability form (see [6]), or into a nonlinear system in adaptive observability form (see [11]).

Remarkably, this additional assumption is not present in the framework proposed in this work. In this respect the important conceptual result proved in Theorem 1 is that no "immersion" assumption is, in principle, necessary for the problem of output regulation to be solvable.

3. Main results.

3.1. The basic approach. In this section we overview the main steps which will be followed to prove Theorem 1. Technical proofs of the results given here are presented in Appendix B.

We consider the closed-loop system (2), (7) which, after the change of coordinates

$$\eta \to x = \eta - Gy,$$

can be rewritten as

$$\begin{aligned} \dot{z} &= f_0(z) + f_1(z,y), \\ \dot{x} &= Fx - Gq_0(z) - Gq_1(z,y) + FGy, \\ \dot{y} &= q_0(z) + q_1(z,y) + \gamma(x + Gy) + v, \end{aligned} \tag{16}$$

in which

$$f_0(z) := f(z,0), \qquad q_0(z) := q(z,0) \tag{17}$$

and

$$\begin{aligned} f_1(z,y) &:= f(z,y) - f(z,0), \\ q_1(z,y) &:= q(z,y) - q(z,0). \end{aligned}$$

Observe that we have $f_1(z,0) \equiv 0$ and $q_1(z,0) \equiv 0$ for all $z \in \mathbb{R}^n$.

Remark. In the case when the y dynamic is described by (13) (namely, the system does not have unitary "high-frequency gain"), it turns out that the change of coordinates to be considered is of the form

$$\eta \to x = \eta - G \int_0^y \frac{1}{b(z,s)}\, ds,$$

which is well defined as $b(z,y) \geq \underline{b} > 0$. In this case the resulting system exhibits all the crucial properties of (16) on which the forthcoming stability analysis is based, with, in particular, the function $q_0(z)$ defined as $q_0(z) = q(z,0)/b(z,0)$.

In what follows, system (16) is seen as a system with input v, output y, and initial conditions contained in a set of the form $Z \times X \times C$ in which $X \subset \mathbb{R}^m$ and $C \subset \mathbb{R}$ are compact sets dependent on Ξ and M. A controller of the form (7) solves the problem at issue if, for some map $\kappa : \mathbb{R}^n \to \mathbb{R}^n$, the control law $v = \kappa(y)$ is such that all trajectories of (16) originating from $Z \times X \times C$ are bounded and

$$\lim_{t\to\infty} y(t) = 0, \qquad \lim_{t\to\infty} |z(t)|_{\mathcal{A}} = 0. \tag{18}$$

As a matter of fact, since systems (2), (7), and (16) are diffeomorphic, boundedness of the trajectories of (16) with initial conditions in $Z \times X \times C$ implies boundedness of the trajectories of (2), (7) originating from $Z \times \Xi \times M$. Furthermore, by virtue of assumption (a_2), since $h(\cdot)$ is a continuous function, condition (18) implies also that $\lim_{t\to\infty} e(t) = 0$, namely, that the problem of semiglobal output stabilization is solved.

By virtue of this fact, in the following we focus our attention on system (16), and we prove that (16) controlled by $v = \kappa(y)$ has bounded trajectories and that (18) holds. To this end, for notational convenience, denote

$$p = \mathrm{col}(z,x)$$

and rewrite system (16) in the more compact form

$$\begin{aligned} \dot{p} &= M(p) + N(p, y), \\ \dot{y} &= H(p) + K(p, y) + v, \end{aligned} \tag{19}$$

in which $M(\cdot)$ and $H(\cdot)$ are defined as

$$M(p) = \begin{pmatrix} f_0(z) \\ Fx - Gq_0(z) \end{pmatrix} \tag{20}$$

and

$$H(p) = q_0(z) + \gamma(x), \tag{21}$$

and $N(\cdot)$ and $K(\cdot)$ are therefore suitable smooth remainder functions which satisfy necessarily $N(p, 0) = 0$ and $K(p, 0) = 0$ for all p. Consistently set $P = Z \times X$ so that the initial conditions of (19) range in $P \times C$. System (19) is recognized as a system in normal form with relative degree one (with respect to input v and output y) and zero dynamics given by

$$\dot{p} = M(p). \tag{22}$$

Thus, following consolidated knowledge about stabilization of *minimum-phase* nonlinear systems (see [8, 2, 33]), the capability of stabilizing (19) by output feedback is expected to strongly rely upon asymptotic properties of the zero dynamics (22). This is confirmed by the next two results showing that the existence of an asymptotically stable attractor for system (22) is sufficient to achieve boundedness of trajectories and *practical* stabilization (Theorem 2), which becomes *asymptotic* if the function $H(\cdot)$ vanishes on the attractor (Theorem 3). These results, which in the context of this paper represent building blocks for proving Theorem 1, are interesting on their own, as they represent an extension of well-known stabilization paradigms for systems with equilibria (see [33]) to the case of systems of the form (19), with zero dynamics (22) possessing compact attractors. For precise definitions of asymptotic and exponential stability used in the statement of the theorems, the reader is referred to Appendix A.

THEOREM 2. *Consider system* (19) *with* $M(\cdot)$ *and* $N(\cdot)$ *at least locally Lipschitz functions and* $H(\cdot)$ *and* $K(\cdot)$ *at least continuous functions. Let the initial conditions be in* $P \times C$. *Assume that system* (22) *has a compact attractor* $\mathcal{B}$ *which is asymptotically stable with a domain of attraction* $\mathcal{D} \supset P$. *Then for all* $\epsilon > 0$ *there exists a* $\kappa^\star > 0$ *such that for all* $\kappa \geq \kappa^\star$ *the trajectories of* (19) *with* $v = -\kappa y$ *are bounded and* $\limsup_{t\to\infty} |y(t)| \leq \epsilon$ *and* $\limsup_{t\to\infty} |p(t)|_{\mathcal{B}} \leq \epsilon$.

THEOREM 3. *In addition to the hypotheses of the previous theorem, assume that* $H(p)|_{\mathcal{B}} = 0$. *Then there exists a continuous function* $\kappa : \mathbb{R} \to \mathbb{R}$ *such that the trajectories of* (19) *with* $v = \kappa(y)$ *are bounded and* $\lim_{t\to\infty} y(t) = 0$ *and* $\lim_{t\to\infty} |p(t)|_{\mathcal{B}} = 0$. *If, additionally,* $H(\cdot)$ *and* $K(\cdot)$ *are locally Lipschitz and the set* $\mathcal{B}$ *is also locally exponentially stable for* (22), *then there exists* $\kappa^\star > 0$ *such that for all* $\kappa \geq \kappa^\star$ *the same properties hold with* $v = -\kappa y$.

For the proofs of these theorems the reader is referred to sections B.1 and B.2, respectively.

Motivated by these results (and in particular by Theorem 3), we turn our attention to the study of the zero dynamics (22) (with $M(\cdot)$ as in (20)) and to the function $H(\cdot)$ in (21) by looking for the existence of a pair (F, G) and a function $\gamma(\cdot)$ which guarantee the basic requirements behind Theorem 3 with, in particular, $H(p)|_{\mathcal{B}} = 0$. Details in this direction are presented in the next subsection.

3.2. The properties of the "core subsystem" (22). The crucial result which will be proved in this part is that, under the assumption presented in section 2.1, there is a choice of the pair (F, G) and of the map $\gamma(\cdot)$ which guarantee the existence of an asymptotically stable compact attractor $\mathcal{B}$ for (22), on which the function $H(\cdot)$ in (21) vanishes. Moreover the projection of $\mathcal{B}$ on the z coordinates coincides with $\mathcal{A}$. In view of the arguments discussed in the previous subsection, this, along with an appropriate choice of $\kappa(\cdot)$ whose existence is claimed in Theorem 3, substantially proves Theorem 1.

The result in question is proved in the next three propositions. To this end, note that the core subsystem (22) in the original coordinates (z, x) is expressed as

$$\begin{aligned} \dot{z} &= f_0(z), \\ \dot{x} &= Fx - Gq_0(z) \end{aligned} \tag{23}$$

with an initial condition in $Z \times X$. The first proposition is related to the first basic requirement behind Theorem 2, namely, the existence of a locally asymptotically stable attractor for (23).

More precisely, under the only requirement, which is that F be a Hurwitz matrix, we show the existence of a set which is *forward invariant* and *locally asymptotically stable* for (23). The set in question is described by the graph of a map.

PROPOSITION 1. *Consider system* (23) *with the z-subsystem satisfying assumption* (a_1)*, and let* (F, G) *be any pair with* F *Hurwitz. Then*

(i) *there exists at least one continuous map* $\tau : \mathbb{R}^n \to \mathbb{R}^m$ *such that the set*

$$\text{graph}(\tau|_{\mathcal{A}}) := \{(z, x) \in \mathcal{A} \times \mathbb{R}^m \ : \ x = \tau(z)\} \tag{24}$$

is forward invariant for (23)*.*

(ii) *the set* $\text{graph}(\tau|_{\mathcal{A}})$ *is locally asymptotically stable for* (23) *with a domain of attraction containing* $Z \times X$*. Furthermore, the set in question is also locally exponentially stable for* (23) *if* $\mathcal{A}$ *is such for* (6)*.*

The proof of this proposition can be found in section B.3.

Remark. Indeed, there might be many different continuous maps τ having property (i) of Proposition 1. However, it turns out that if $\mathcal{A}_0$ is any compact *subset* of $\mathcal{A}$ which is also *backward invariant* for (6), then for each $z \in \mathcal{A}_0$ there is one and only one $x_z \in \mathbb{R}^m$ such that the set $\bigcup_{z \in \mathcal{A}_0} \{(z, x_z)\}$ is invariant for (23). In particular,

$$x_z = -\int_{-\infty}^{0} e^{-Fs} G q_0(z(s, z)) ds,$$

where $z(s, z)$ denotes the value at time $t = s$ of the solution of $\dot{z} = f_0(z)$ passing through $z \in \mathcal{A}_0$ at time $t = 0$ (see [11]).

The second crucial requirement imposed by Theorem 3 is that the function $H(\cdot)$ in (21) vanishes on the asymptotically stable attractor $\text{graph}(\tau|_{\mathcal{A}})$. Here is where the precise choices of the pair (F, G) and of the map $\gamma(\cdot)$ play a role. In particular note that, by definition of $H(\cdot)$ in (21) and of $\text{graph}(\tau|_{\mathcal{A}})$ in (24), it turns out that

$$H(p)|_{\text{graph}(\tau|_{\mathcal{A}})} = (q_0(z) + \gamma \circ \tau(z))|_{\mathcal{A}}, \tag{25}$$

from which it is apparent that $\gamma(\cdot)$ should be chosen to satisfy $\gamma \circ \tau(z) = -q_0(z)$ for all z in $\mathcal{A}$. It is easy to realize that the possibility of choosing $\gamma(\cdot)$ in this way

is intimately related to the fact that the map τ satisfies the *partial* (*with respect to* $q_0(\cdot)$) *injectivity condition*

$$\tau(z_1) = \tau(z_2) \qquad \Rightarrow \qquad q_0(z_1) = q_0(z_2) \qquad \forall\, z_1, z_2 \in \mathcal{A}. \tag{26}$$

In this respect it is interesting to note that what this condition says is that we need only to reconstruct the value of $q_0(z)$ as a function of z from the knowledge of $\tau(z)$ and not the whole state z (see also the remark at the end of the subsection).

As τ is dependent on the pair (F, G), the next natural point to be addressed is if there exists a choice of (F, G) yielding the desired property for $\tau(\cdot)$. To this end is devoted the next proposition which claims that, indeed, there exists a suitable choice of (F, G), with F Hurwitz, such that the associated map $\tau(\cdot)$ satisfies the required partial injectivity condition. Besides other technical constraints on the choice of F, which will be better detailed in the proof of the Proposition 2, the main requirement on F is given by its dimension, which is required to be sufficiently large with respect to the dimension of z.

PROPOSITION 2. *Set*

$$m = 2 + 2n.$$

Then there exist a controllable pair $(F, G) \in \mathbb{R}^{m\times m} \times \mathbb{R}^{m\times 1}$*, with* F *a Hurwitz matrix, and a class-*$\mathcal{K}$ *function* $\varrho : \mathbb{R}^+ \to \mathbb{R}^+$ *such that*

$$|q_0(z_1) - q_0(z_2)| \leq \varrho(|\tau(z_1) - \tau(z_2)|) \qquad \forall\, z_1, z_2 \in \mathcal{A} \tag{27}$$

in which $\tau(\cdot)$ *is a map (associated with* F*) having the properties indicated in Proposition* 1*.*

For the proof of this proposition the reader is referred to section B.4.

Remark. Going through the proof of the previous proposition, it turns out that the pair (F, G) can be chosen as any $(2n + 2)$-dimensional real representation of the $(n + 1)$-dimensional complex pair (F_c, G_c), with $F_c = \operatorname{diag}(\lambda_1, \ldots, \lambda_{r+1})$, $G_c = (g_1, \ldots, g_{r+1})^{\mathrm{T}}$ in which g_i are arbitrary nonzero real numbers and λ_i are $n+1$ complex numbers taken arbitrarily outside a set of zero Lebesgue measure and with real part smaller than ℓ, a real number related to the Lipschitz constant of $f_0(\cdot)$ (see Proposition 4).

It turns out that the injectivity property (27) is a sufficient condition for the map $\gamma(\cdot)$ to exist. This is formalized in the following final proposition, proved in section B.5, which states that if (27) holds, then there exists a map $\gamma(\cdot)$ which makes $H(\cdot)$ vanish on the attractor $\operatorname{graph}(\tau|_{\mathcal{A}})$. The map $\gamma(\cdot)$ can be claimed, in general, to be only continuous. It is also Lipschitz in the special case in which the class-$\mathcal{K}$ function $\varrho(\cdot)$ in (27) is Lipschitz.

PROPOSITION 3. *Let* $\tau(\cdot)$ *be a continuous map satisfying* (27) *with* $\mathcal{A}$ *a closed set. Then there exists a continuous map* $\gamma : \mathbb{R}^m \to \mathbb{R}$ *such that*

$$q_0(z) + \gamma \circ \tau(z) = 0 \qquad \forall\, z \in \mathcal{A}. \tag{28}$$

If, in addition, the function $\varrho(\cdot)$ *in* (27) *is linearly bounded at the origin, then the map* γ *is Lipschitz.*

Combining the results of all the previous propositions, it appears that it is sufficient to choose the pair (F, G) of suitable dimension (with F Hurwitz) according to Proposition 2 and to choose $\gamma(\cdot)$ in order to satisfy relation (28). In fact, by doing

so we are guaranteed that the compact set $\mathcal{B} = \text{graph}(\tau|_{\mathcal{A}})$ is locally asymptotically stable for (23) with the map (21) which is vanishing on $\mathcal{B}$. This, indeed, makes it possible to apply Theorem 3 and to prove the existence of a continuous function $\kappa(\cdot)$, completing in this way the synthesis of the controller.

Remark. The reader who is familiar with recent developments in the theory of nonlinear state observers will find it interesting to compare the previous results with the design method proposed by Kazantzis and Kravaris in [27] and pursued in [28], [26], and [1]. In the framework of [27], system (23) can be identified with the cascade of an "observed" system $\dot{z} = f_0(z)$ with output $y_z = q_0(z)$ driving an "observer" $\dot{x} = Fx - Gy_z$. If the map $\tau(\cdot)$ has a left inverse $\tau_\ell^{-1}(\cdot)$, the observer in question provides a state estimate $\hat{z} = \tau_\ell^{-1}(x)$. Such a left-inverse, as shown in [1], always exists provided that the dimension of x is sufficiently large, if the pair (f_0, q_0) has appropriate *observability* properties. In the present context of output stabilization, though, left invertibility of $\tau(\cdot)$ is not needed. In fact, what the controller is expected to do is reproduce only the output $q_0(z(t))$ and not the full state $z(t)$ of the "observed system." This motivates the absence of observability hypotheses on the pair (f_0, q_0).

4. Conclusions. This paper is focused on the existence of an output feedback law that asymptotically steers to zero a given controlled variable, while keeping all state variables bounded, for any initial conditions in a fixed compact set. The proposed framework encompasses and extends a number of existing results in the fields of output feedback stabilization and output regulation of nonlinear systems. The main assumption under which the theory is developed is the existence of a state feedback control law able to achieve boundedness of the trajectories of the zero dynamics of the controlled plant. In this sense the result presented here is applicable for a wide class of nonminimum-phase nonlinear systems not tractable in existing frameworks. In the paper only results regarding the existence of the controller solving the problem at hand have been presented, while practical aspects involving its design and implementation are left to a forthcoming work.

Appendix A. Converse Lyapunov result. Consider a system of the form

$$\dot{p} = f(p), \qquad p \in \mathbb{R}^n, \tag{29}$$

in which $f(p)$ is a C^k (with k sufficiently large) function, with an initial condition ranging over a fixed *compact* set P. For system (29) assume the existence of a compact set $\mathcal{B} \subset \mathbb{R}^n$ which is asymptotically stable for (29), with a domain of attraction $\mathcal{D} \supset P$. More precisely, by setting

$$|p|_{\mathcal{B}/\mathcal{D}} = \left(1 + \frac{1}{|p|_{\partial\,\text{cl}\,\mathcal{D}}}\right) |p|_{\mathcal{B}},$$

we assume that the set $\mathcal{B}$ satisfies the following two properties:[4]

Uniform stability: There exists a class-$\mathcal{K}$ function φ such that for any $\alpha > 0$,

$$|p_0|_{\mathcal{B}/\mathcal{D}} \leq \alpha \qquad \Rightarrow \qquad |p(t, p_0)|_{\mathcal{B}/\mathcal{D}} \leq \varphi(\alpha) \quad \forall\, t \geq 0.$$

Uniform attractivity: There exists a continuous function $T : \mathbb{R}^+ \times \mathbb{R}^+ \to \mathbb{R}^+$ such that for any $\alpha > 0$ and $\epsilon > 0$,

$$|p_0|_{\mathcal{B}/\mathcal{D}} \leq \alpha \qquad \Rightarrow \qquad |p(t, p_0)|_{\mathcal{B}/\mathcal{D}} \leq \epsilon \quad \forall\, t \geq T(\alpha, \epsilon).$$

[4]In these properties the adjective "uniform" refers to independence with respect to a particular point p in a compact set $|p|_{\mathcal{B}\setminus\mathcal{D}} \leq c$.

We say that $\mathcal{B}$ is also *locally exponentially stable* for (29) if there exist $M \geq 1$, $\lambda > 0$, and $c_0 > 0$ such that

$$|p_0|_{\mathcal{B}/\mathcal{D}} \leq c_0 \qquad \Rightarrow \qquad |p(t,p_0)|_{\mathcal{B}/\mathcal{D}} \leq Me^{-\lambda t}|p_0|_{\mathcal{B}/\mathcal{D}}.$$

In this framework it is possible to formulate the following converse Lyapunov result which claims the existence of a *locally Lipschitz* Lyapunov function vanishing on the attractor. The result is not formally proved, as it can be easily deduced by the arguments presented in [34] (see in particular Theorem 22.5 and the related Theorems 22.1 and 19.2 in the quoted reference).

THEOREM 4. *Under the above uniform stability and uniform attractivity conditions, there exists a continuous function $V : \mathcal{D} \to \mathbb{R}$ with the following properties:*

(a) *There exist class-$\mathcal{K}_\infty$ functions $\underline{a}(\cdot), \overline{a}(\cdot)$ such that*

$$\underline{a}(|p|_{\mathcal{B}/\mathcal{D}}) \leq V(p) \leq \overline{a}(|p|_{\mathcal{B}/\mathcal{D}}) \qquad \forall\, p \in \mathcal{D};$$

(b) *there exists $c > 0$ such that*

$$D^+V(p) \leq -cV(p) \qquad \forall\, p \in \mathcal{D};$$

(c) *for all $\alpha > 0$ there exists $L_\alpha > 0$ such that for all $p_1, p_2 \in \mathcal{D}$ such that $|p_1|_{\mathcal{B}/\mathcal{D}} \leq \alpha$, $|p_2|_{\mathcal{B}/\mathcal{D}} \leq \alpha$, the following holds:*

$$|V(p_1) - V(p_2)| \leq L_\alpha |p_1 - p_2|.$$

If $\mathcal{B}$ is also locally exponentially stable for (29)*, then property* (a) *holds with $\underline{a}(\cdot), \overline{a}(\cdot)$ linear near the origin.*

With this result at hand, it is also possible to formulate a local input-to-state stability result for system (29) forced by an external signal. This is formalized in the next lemma.

LEMMA 1. *Let $x : \mathbb{R}_+ \to \mathbb{R}^m$ be a C^0 function. Consider the system*

$$\dot{p} = f(p) + \ell(p, x(t)) \tag{30}$$

in which $p \in \mathbb{R}^n$ and $\ell(p,0) = 0$ for all $p \in \mathbb{R}^n$. The functions $f(\cdot), \ell(\cdot)$ are C^1. Suppose that system (29) *satisfies the above uniform stability and uniform attractivity conditions. Then there exist functions $\beta(\cdot,\cdot)$ and $\gamma(\cdot)$, respectively, of class $\mathcal{KL}$ and $\mathcal{K}$, and a $d^* > 0$ such that if*

$$|p_0|_{\mathcal{B}} \leq d^* \qquad \text{and} \qquad |x(t)| \leq d^* \quad \forall\, t \geq 0, \tag{31}$$

then the right maximal interval of definition of $p(t,p_0)$ is $[0, +\infty)$, and we have

$$|p(t,p_0)|_{\mathcal{B}} \leq \max\left\{\beta(|p_0|_{\mathcal{B}}, t)\,,\, \gamma\left(\max_{\tau\in[0,t]}|x(\tau)|\right)\right\} \qquad \forall\, t \geq 0. \tag{32}$$

If the set $\mathcal{B}$ is also locally exponentially stable for (29)*, then there exist $N > 1$, $k > 0$, and $\bar{\gamma} > 0$ such that* (32) *can be modified to read*

$$|p(t,p_0)|_{\mathcal{B}} \leq Ne^{-kt}|p_0|_{\mathcal{B}} + \bar{\gamma} \max_{\tau\in[0,t]}|x(\tau)| \qquad \forall\, t \geq 0. \tag{33}$$

Proof. Pick $\beta > 0$ such that if $|p|_{\mathcal{B}} \leq \beta$, then $p \in \mathcal{D}$, and note that there exists $d_\beta > 1$ such that for all p satisfying $|p|_{\mathcal{B}} \leq \beta$,

$$|p|_{\mathcal{B}/\mathcal{D}} \leq d_\beta |p|_{\mathcal{B}}. \tag{34}$$

Pick $d^* > 0$ arbitrarily for the time being but more specifically later on. As $\ell(\cdot)$ is differentiable and $\ell(p,0) = 0$, there is an $\hat{\ell} > 0$ such that for all $|p|_{\mathcal{B}} \leq \beta$ and $|x| \leq d^*$,

$$|\ell(p,x)| \leq \hat{\ell}|x|.$$

So consider the Lyapunov function V given by Theorem 4. By using properties (b) and (c) of this theorem, setting $\alpha = d_\beta \beta$, we obtain for system (30), as long as $|p_1|_{\mathcal{B}} < \beta$ and $|x| \leq d^*$,

$$\begin{aligned} D^+V(p_1,x) &= \limsup_{h\to 0^+} \frac{1}{h}[V(p(h,p_1)) - V(p_1)] \\ &= \limsup_{h\to 0^+} \frac{1}{h}[V(p_1 + hf(p_1) + h\ell(p,x)) - V(p_1)] \\ &\leq \limsup_{h\to 0^+} \frac{1}{h}[V(p_1 + hf(p_1) + h\ell(p_1,x)) - V(p_1 + hf(p_1))] \\ &\qquad + \limsup_{h\to 0^+} \frac{1}{h}[V(p_1 + hf(p_1)) - V(p_1)] \\ &\leq \limsup_{h\to 0^+} \frac{1}{h} L_\alpha h\ell(p_1,x) - cV(p_1) \leq L_\alpha \hat{\ell}|x| - cV(p_1). \end{aligned} \tag{35}$$

Now assume (31) holds. Let $p(t,p_0)$, abbreviated $p(t)$, be the corresponding solution of (30). Let $[0,T_0)$ be its right maximal interval of definition when restricted to take values in the open set $\{p : |p|_{\mathcal{B}} < \beta\}$. Equation (35) holds for $p_1 = p(t)$ and all t in $[0,T_0)$. This implies

$$V(p(t)) \leq e^{-c(t-t_0)}V(p_0) + \frac{L_\alpha \hat{\ell}}{c} \max_{\tau\in[0,t]} |x(\tau)| \qquad \forall t \in [0,T_0). \tag{36}$$

This, in view of property (a) in Theorem 4, yields

$$|p(t)|_{\mathcal{B}} \leq |p(t)|_{\mathcal{B}/\mathcal{D}} \leq \underline{a}^{-1}(2e^{-ct}\,\overline{a}(|p_0|_{\mathcal{B}/\mathcal{D}})) + \underline{a}^{-1}\left(2\frac{L_\alpha \hat{\ell}}{c} \max_{\tau\in[0,t]} |x(\tau)|\right) \quad \forall t \in [0,T_0). \tag{37}$$

By using (34), it follows that if d^* is chosen so that

$$d^\star \leq \min\left\{ \frac{c}{2L_\alpha \hat{\ell}}\, \underline{a}\left(\frac{\beta}{3}\right), \frac{1}{d_\beta}\, \overline{a}^{-1}\left(\frac{1}{2}\, \underline{a}\left(\frac{\beta}{3}\right)\right)\right\}$$

we have

$$|p(t)|_{\mathcal{B}} < \beta \qquad \forall t \in [0,T_0).$$

From the definition of T_0, it must be infinite. So we have established that (37) holds for all $t \geq 0$ if (31) is satisfied. This proves the first part of the result. The second part of the result, namely, that under exponential stability the bound (33) holds, follows immediately by (37) by using the fact that the functions $\underline{a}(\cdot)$ and $\overline{a}(\cdot)$ can be linear near the origin. □

Appendix B. Proofs.

B.1. Proof of Theorem 2. The feedback interconnection (19) can be studied by means of arguments which are quite similar to those used in [22] to prove some of the main stabilization results of [33]. In doing this, we take advantage of the converse Theorem 4 presented in Appendix A.

Let $V : \mathcal{D} \to \mathbb{R}$ be the function given by Theorem 4. Pick a number $a > 0$ such that $C \subset B_a := \{y \in \mathbb{R} : |y| \leq a\}$ and $P \subset V^{-1}([0, a])$ (which is possible because of property (a) in Theorem 4). Define

$$\hat{c} = \max_{(p,y) \in V^{-1}([0,a+1]) \times B_{a+1}} |H(p) + K(p, y)|.$$

Also, since $N(p, y)$ is locally Lipschitz and vanishes at $y = 0$, there is a number $\hat{n}$ such that

$$|N(p, y)| \leq \hat{n}|y| \qquad \forall (p, y) \in V^{-1}([0, a + 1]) \times B_{a+1}.$$

Finally, by property (c) in Theorem 4, there is a number L_V such that

$$|V(p_1) - V(p_2)| \leq L_V |p_1 - p_2| \qquad \forall (p_1, p_2) \in V^{-1}([0, a + 1])^2.$$

Then, by choosing $v = -ky$ in the y-dynamics in (19), we get (see notation (1))

$$D^+|y| \leq -\kappa|y| + \hat{c} \qquad \forall (p, y) \in V^{-1}([0, a + 1]) \times B_{a+1}. \tag{38}$$

Also, by following along the same lines as in (35), we get

$$D^+V(p) \leq L_V \hat{n}|y| - cV(p) \qquad \forall (p, y) \in V^{-1}([0, a + 1]) \times B_{a+1}. \tag{39}$$

So now consider a solution $(p(t), y(t))$ issued from a point in $P \times C \subset V^{-1}([0, a]) \times B_a$. Let $[0, T_1)$ be its right maximal interval of definition when restricted to take values in the open set $\operatorname{int}\big(V^{-1}([0, a + 1]) \times B_{a+1}\big)$. It follows that both (38) and (39) hold for $(p(t), y(t))$ when t is in $[0, T_1)$. They give successively, for all t in $[0, T_1)$,

$$\begin{aligned}
|y(t)| &\leq e^{-\kappa t}\, a + \frac{\hat{c}}{\kappa}\left(1 - e^{-\kappa t}\right), \\
V(p(t)) &\leq e^{-ct}\, a + L_V \hat{n} \left(\frac{\hat{c}}{\kappa} \frac{1 - e^{-ct}}{c} + \frac{e^{-ct} - e^{-\kappa t}}{\kappa - c} \left[a - \frac{\hat{c}}{\kappa} \right] \right) \\
&\leq a + L_V \hat{n} \left(\frac{\hat{c}}{c\kappa} + \frac{a}{\kappa - c} \right).
\end{aligned}$$

Hence, by selecting κ to satisfy

$$\kappa > \max \left\{ 2\hat{c}, (c + 3aL_V \hat{n}), \frac{3L_V \hat{n} \hat{c}}{c} \right\},$$

we get, for all t in $[0, T_1)$,

$$|y(t)| \leq a + \frac{1}{2} \quad \text{and} \quad V(p(t)) \leq a + \frac{2}{3}.$$

This says that the solution remains in $V^{-1}([0, a + \frac{2}{3}]) \times B_{a+\frac{1}{2}}$. So from its definition, T_1 is infinite. Then, from (38), we get

$$\limsup_{t \to +\infty} |y(t)| \leq \frac{\hat{c}}{\kappa}.$$

With (39), this in turn implies

$$\limsup_{t \to +\infty} V(p(t)) \leq \frac{L_V \hat{n} \hat{c}}{\kappa}.$$

In view of property (a) in Theorem 4, the latter yields

$$\limsup_{t\to+\infty} |p(t)|_{\mathcal{B}} \le \underline{a}^{-1}\left(\frac{L_V \hat{n}\hat{c}}{\kappa}\right).$$

So the conclusion of Theorem 2 holds if we further impose that κ satisfies

$$\kappa > \max\left\{\frac{\hat{c}}{\epsilon}, \frac{L_V \hat{n}\hat{c}}{\underline{a}(\epsilon)}\right\}. \qquad \square$$

B.2. Proof of Theorem 3. The proof of this result follows by standard small-gain arguments. Let $\kappa(y) = -\alpha(y)$, where $\alpha(\cdot)$ is a continuous function such that $\alpha(0) = 0$ and $y\alpha(y) > 0$ for all $y \neq 0$. By mimicking the proof of Theorem 2 it is possible to show that for any $\epsilon > 0$ there exist a $\kappa^\star > 0$ and a $T > 0$ such that, if $|\alpha(|y|)| \ge \kappa^\star |y|$, then each trajectory of the closed-loop system issuing from the compact set $P \times C$ satisfies

$$|p(t)|_{\mathcal{B}} \le 2\epsilon \quad \text{and} \quad |y(t)| \le 2\epsilon \quad \forall\, t \ge T.$$

Observe that Lemma 1 applies to the p-component of the closed-loop solution. So let $d^\star$ be given by this lemma. By picking ϵ above satisfying $2\epsilon \le d^\star$, and by applying Lemma 1 to the p-component by picking the initial condition at time $t = T$, we obtain

$$|p(t)|_{\mathcal{B}} \le \max\left\{\beta(|p(T)|_{\mathcal{B}}, t-T)\,,\, \gamma\left(\max_{\tau\in[T,t]} |y(\tau)|\right)\right\} \qquad \forall\, t \ge T. \tag{40}$$

With the properties of the functions H and K, there exist class-$\mathcal{K}$ functions $\varrho_h(\cdot)$ and $\varrho_q(\cdot)$ such that

$$|H(p)| \le \varrho_h(|p|_{\mathcal{B}}), \qquad |K(p,y)| \le \varrho_k(|y|).$$

Clearly $\varrho_h(\cdot)$ and $\varrho_k(\cdot)$ can be taken linearly bounded at the origin if $H(\cdot)$ and $K(\cdot)$ are locally Lipschitz. We obtain, for all (p, y),

$$D^+|y| \;\le\; \varrho_h(|p|_{\mathcal{B}}) + \varrho_k(|y|) - |\alpha(y)|.$$

So let us choose $\alpha(\cdot)$ so that

$$|\alpha(y)| \ge 3\max\{\varrho_h(\bar{\gamma}^{-1}(|y|)),\, \varrho_k(|y|),\, \kappa^\star|y|\} + |y|, \tag{41}$$

where $\bar{\gamma}(\cdot)$ is a class-$\mathcal{K}$ function such that $\bar{\gamma}\circ\gamma(s) < s$ for all $s \in \mathbb{R}^+$ with γ given by Lemma 1 (see (32)). This gives

$$D^+|y| \;\le\; -|y| + \left[\varrho_h(|p|_{\mathcal{B}}) - \varrho_h(\bar{\gamma}^{-1}(|y|))\right].$$

So for the closed-loop solution, we get

$$|y(t)| \;\le\; \max\left\{\exp(-(t-T))|y(T)|\,,\, \sup_{s\in[T,t)} \bar{\gamma}(|p(s)|_{\mathcal{B}})\right\}$$

for all $t \ge T$. From this and (40) the first claim of the theorem follows by small-gain arguments. To prove the second claim of the theorem note that, if $H(\cdot)$ and $K(\cdot)$ are locally Lipschitz, the functions $\varrho_h(\cdot)$ and $\varrho_k(\cdot)$ in (41) can be taken as linear. Furthermore, by (33) in Lemma 1, the function $\bar{\gamma}(\cdot)$ also can be taken as linear. From this the claim directly follows by the previous arguments. $\square$

B.3. Proof of Proposition 1. Let $\mathcal{O}(Z)$ denote the positive orbit of Z under the flow of

$$\dot{z} = f_0(z), \tag{42}$$

namely,

$$\mathcal{O}(Z) = \mathrm{cl}\left\{ \bigcup_{t\geq 0} z(t, z_0) \ : \ z_0 \in Z \right\}.$$

The set $\mathcal{O}(Z)$ is a bounded and forward invariant set for (42), such that $\mathcal{A} \subset \mathcal{O}(Z)$. Moreover let $\hat{\mathcal{O}}(Z)$ be a compact strict superset of $\mathcal{O}(Z)$ such that $\hat{\mathcal{O}}(Z) \subset \mathcal{D}$, and define the system

$$\dot{\hat{z}} = a_0(\hat{z}) f_0(\hat{z}) \tag{43}$$

in which $a(\hat{z}) : \mathbb{R}^n \to \mathbb{R}$ is any bounded smooth function such that

$$a_0(\hat{z}) = \begin{cases} 1, & \hat{z} \in \mathcal{O}(Z), \\ 0, & \hat{z} \in \mathbb{R}^n \setminus \hat{\mathcal{O}}(Z). \end{cases}$$

Let $\hat{z}(t, z_0)$ and $z(t, z_0)$ denote the flows of (43) and (42), respectively, and note that, as a consequence of the fact that $\mathcal{O}(Z)$ is forward invariant and that systems (42) and (43) agree on $\mathcal{O}(Z)$, it turns out that

$$\hat{z}(t, z_0) = z(t, z_0) \qquad \forall\ z_0 \in \mathcal{O}(Z) \text{ and } t \geq 0. \tag{44}$$

Moreover note that for any $\hat{z}_0 \in \mathbb{R}^n$, (43) has a unique solution $\hat{z}(t, \hat{z}_0)$ which is defined and bounded on $t \in (-\infty, \infty)$.

Define now

$$\begin{array}{rcccl} \tau & : & \mathbb{R}^n & \to & \mathbb{R}^m, \\ & & z & \mapsto & \displaystyle\int_{-\infty}^{0} e^{-Fs} G q_0(\hat{z}(s, z)) ds, \end{array} \tag{45}$$

which, as a consequence of the fact that F is Hurwitz and $q_0(\hat{z}(s, z))$ is bounded and continuous in z for any $s \in \mathbb{R}$, is a well-defined *continuous* map. We show now that $\mathrm{graph}(\tau|_{\mathcal{A}}) = \{(z, \xi) \in \mathcal{A} \times \mathbb{R}^m : x = \tau(z)\}$ is a forward invariant set for (23). Pick $z_0 \in \mathcal{A}$ and $x_0 \in \mathbb{R}^m$, let $(z(t, z_0), x(t, z_0, x_0))$ denote the value at time t of the solution of (23) passing through (z_0, x_0) at time $t = 0$, and note that for all $t \geq 0$ (using (44)),

$$\begin{array}{rcl} x(t, z_0, \tau(z_0)) & = & e^{Ft}\tau(z_0) + \displaystyle\int_0^t e^{F(t-s)} G q_0(z(s, z_0)) ds \\ & = & e^{Ft} \displaystyle\int_{-\infty}^{0} e^{-Fs} G q_0(\hat{z}(s, z_0)) ds + \int_0^t e^{F(t-s)} G q_0(z(s, z_0)) ds \\ & = & \displaystyle\int_{-\infty}^{t} e^{F(t-s)} G q_0(\hat{z}(s, z_0)) ds = \int_{-\infty}^{0} e^{-Fs} G q_0(\hat{z}(s+t, z_0)) ds \\ & = & \tau(\hat{z}(t, z_0)) = \tau(z(t, z_0)). \end{array} \tag{46}$$

This, along with the fact that $\mathcal{A}$ is forward invariant for (42) and is a subset of $\mathcal{O}(Z)$, proves that $\mathrm{graph}(\tau|_{\mathcal{A}})$ is *forward invariant* for (23).

We now prove item (ii) of the proposition. To this end note that, by (46), it follows that

$$L_{a_0 f_0}\tau(z) = F\tau(z) - Gq_0(z)$$

for all $z \in \mathcal{A}$. Defining $\tilde{x} := x - \tau(z)$, the previous relation yields that $\dot{\tilde{x}}(t) = F\tilde{x}(t)$ for all $t \geq 0$ and for all initial states $x_0 \in \mathbb{R}^m$ and $z_0 \in \mathcal{A}$. This, the fact that F is Hurwitz, and that $\mathcal{A}$ is locally asymptotically (exponentially) stable for (42) immediately yield the desired result. □

B.4. Proof of Proposition 2. The result will be proved by taking the "complex" pair

$$F = \mathrm{diag}(\lambda_1, \ldots, \lambda_{n+1}), \qquad G = (g, \ldots, g)^{\mathrm{T}} \tag{47}$$

in which $\lambda_i \in \mathbb{C}_\ell = \{\lambda \in \mathbb{C} : \mathrm{Re}\,\lambda < -\ell\}$, $i = 1, \ldots, n+1$, $\ell > 0$, and $g \neq 0$. Once we prove the result for the $(n+1)$-dimensional pair in (47), the claim of the proposition follows by taking any $(2n+2)$-dimensional "real" representation of (47).

By bearing in mind the definition of the map τ in (45) note that, as a consequence of the choice of F and G in (47), it turns out that

$$\tau(z) = \begin{pmatrix} \tau_{\lambda_1}(z) & \tau_{\lambda_2}(z) & \cdots & \tau_{\lambda_{n+1}}(z) \end{pmatrix}^{\mathrm{T}}, \qquad \tau_{\lambda_i}(z) = \int_{-\infty}^{0} e^{-\lambda_i s}\, g\, q_0(\hat{z}(s,z))ds. \tag{48}$$

We will prove next that there exists an $\ell > 0$ such that by arbitrarily choosing λ_i, $i = 1, \ldots, n+1$, in $\mathbb{C}_\ell \setminus S$, where S is a set of zero Lebesgue measure, the map τ is such that

$$\tau(z_1) = \tau(z_2) \qquad \Rightarrow \qquad q_0(z_1) = q_0(z_2) \qquad \forall\, z_1, z_2 \in \mathbb{R}^n. \tag{49}$$

More precisely we will prove that, having defined

$$\Upsilon = \{(z_1, z_2) \in \mathbb{R}^n \times \mathbb{R}^n \ : \ q_0(z_1) \neq q_0(z_2)\},$$

the set

$$S = \{(\lambda_1, \ldots, \lambda_{n+1}) \in \mathbb{C}_\ell^{n+1} \ : \ \exists\, (z_1, z_2) \in \Upsilon \ : \ \tau_{\lambda_i}(z_1) = \tau_{\lambda_i}(z_2) \quad \forall\, i = 1, \ldots, n+1\} \tag{50}$$

has a zero Lebesgue measure in $\mathbb{C}^{n+1}$ for a proper choice of ℓ. To this end the following theorem, proved in a more general setting in [1] (see also [9]), plays a crucial role.

THEOREM 5. *Let Ω and Υ be open subsets of $\mathbb{C}$ and $\mathbb{R}^{2n}$, respectively. Let $(\varpi, \lambda) \in \Upsilon \times \Omega \mapsto \delta_\tau(\varpi, \lambda) \in \mathbb{C}$ be a function which is holomorphic in λ for each $\varpi \in \Upsilon$ and C^1 for each $\lambda \in \Omega$. If, for each pair $\varpi \in \Upsilon$, the function $\lambda \mapsto \delta_\tau(\varpi, \lambda)$ is not identically zero on Ω, then the set*

$$S = \bigcup_{\varpi \in \Upsilon} \{(\lambda_1, \ldots, \lambda_{n+1}) \in \Omega^{n+1} \quad : \quad \delta_\tau(\varpi, \lambda_1) = \cdots = \delta_\tau(\varpi, \lambda_{n+1}) = 0\}$$

has a zero Lebesgue measure in $\mathbb{C}^{n+1}$.

To apply this theorem to our context we first observe the following.

PROPOSITION 4. *There exists an $\ell > 0$ such that for all $\lambda_i \in \mathbb{C}_\ell$, $i = 1, \ldots, n+1$, the map $\tau(\cdot)$ in (48) is C^1.*

Proof of Proposition 4. The map $\tau(\cdot)$ in (48) is C^1 if functions $e^{-\lambda_i s}\, g\, \partial q_0(\hat{z}(s,z))/\partial z$, $i = 1, \ldots, n+1$, are integrable on $s \in (-\infty, 0]$ for all $z \in \mathbb{R}^n$ (see [16]). Consider the expansion

$$\frac{\partial q_0(\hat{z}(s,z))}{\partial z} = \left[\frac{\partial q_0}{\partial z}\right]_{[z=\hat{z}(s,z)]} \frac{\partial \hat{z}(s,z)}{\partial z}.$$

By definition, there is a number M such that $|\hat{z}(s,z)| \leq M$ for all $s \leq 0$ and all $z \in \mathbb{R}^n$. This, along with the fact that $q_0(z)$ is C^1, shows that the first factor is bounded on $(-\infty, 0] \times \mathbb{R}^n$. As for the second factor, bearing in mind the notation introduced in section B.3, observe that

$$\frac{d}{ds}\frac{\partial \hat{z}(s,z)}{\partial z} = \left[\frac{\partial a_0(z) f_0(z)}{\partial z}\right]_{[z=\hat{z}(s,z)]} \frac{\partial \hat{z}(s,z)}{\partial z}.$$

Letting

$$\bar{f} = \max_{z \in \mathbb{R}^n} \frac{\partial a_0(z) f_0(z)}{\partial z},$$

we obtain

$$\left|\frac{\partial \hat{z}(s,z)}{\partial z}\right| \leq e^{\bar{f}|s|}$$

for all s and for all $z \in \mathbb{R}^n$. From this, the result immediately follows with $\ell = \bar{f}$. ∎

Now set $\varpi := (z_1, z_2)$ and

$$\delta_\tau(\varpi, \lambda) = \int_{-\infty}^{0} e^{-\lambda s}\, g\, [q_0(\hat{z}(s,z_1)) - q_0(\hat{z}(s,z_2))]\, ds = \tau_\lambda(z_1) - \tau_\lambda(z_2).$$

This function is C^1 in $\varpi \in \mathbb{R}^n \times \mathbb{R}^n$ and is holomorphic in $\lambda \in \mathbb{C}_\ell$ for every $\varpi \in \mathbb{R}^n \times \mathbb{R}^n$ (see [29, Chap. 19, p. 367]). Moreover as

$$\int_{-\infty}^{0} e^{-as}\, |g\, q_0(\hat{z}(s,z_1)) - g\, q_0(\hat{z}(s,z_2))\,|^2\, ds < +\infty$$

for all $\varpi \in \mathbb{R}^n \times \mathbb{R}^n$ and for all $a < 0$, the Plancherel theorem can be invoked to obtain

$$\frac{1}{2\pi}\int_{-\infty}^{\infty} |\delta_\tau(\varpi, a+is)|^2 ds = \int_{-\infty}^{0} e^{-2as}\, |g\, q_0(\hat{z}(s,z_1)) - g\, q_0(\hat{z}(s,z_2))\,|^2\, ds \tag{51}$$

for all $a < 0$ and for all $\varpi \in \mathbb{R}^n \times \mathbb{R}^n$.

Now note that, for $\varpi = (z_1, z_2) \in \Upsilon$, we have $q_0(z_1) \neq q_0(z_2)$, and by continuity of flow with respect to time, there exists a time $t_1 < 0$ such that

$$|g\, q_0(\hat{z}(s,z_1)) - g\, q_0(\hat{z}(s,z_2))| > 0 \qquad \forall\, s \in (t_1, 0]$$

which, combined with (51), yields

$$\int_{-\infty}^{\infty} |\delta_\tau(\varpi, a+is)|^2 ds > 0.$$

This implies that, for each $\varpi \in \Upsilon$, the function $\lambda \mapsto \delta_\tau(\varpi, \lambda)$ is not identically zero on $\mathbb{C}_\ell$. Hence Theorem 5 can be applied to obtain the desired result, namely, that the set (50) has a zero Lebesgue measure.

By this result we are guaranteed that by arbitrarily picking $n+1$ complex eigenvalues in $\mathbb{C}_\ell \setminus S$ (with ℓ dictated by Proposition 4) of F defined in (47), condition (49) is satisfied. From this it is easy to show that there exists a class-$\mathcal{K}$ function satisfying (27). Define

$$\varphi(s) = \sup_{\substack{|\tau(z_1)-\tau(z_2)|\le s \\ z_1,z_2\in\mathcal{A}}} |q_0(z_1) - q_0(z_2)|.$$

This function is increasing and, as a consequence of (49), $\varphi(0) = 0$. Moreover it is possible to prove that $\varphi(s)$ is continuous at $s = 0$. Suppose that it is not; namely, as $\varphi(\cdot)$ is increasing and $\varphi(0) = 0$, suppose that there exists a $\varphi^\star > 0$ such that $\lim_{s\to 0^+} \varphi(s) = \varphi^\star$. This implies that there exist sequences $\{z_{1n}\}, \{z_{2n}\}$ in $\mathcal{A}$, such that $|q_0(z_{1n}) - q_0(z_{2n})| \ge \varphi^\star/2$ and $|\tau(z_{1n}) - \tau(z_{2n})| < 1/n$ for any $n \in \mathbb{N}$. But, as $\mathcal{A}$ is bounded, there are subsequences of $\{z_{1n}\}$, $\{z_{2n}\}$ which, for $n \to \infty$, converge to $z_1^\star$, $z_2^\star$, respectively. As $\tau(\cdot)$ and $q_0(\cdot)$ are continuous, $\tau(z_1^\star) - \tau(z_2^\star) = 0$ and $|q_0(z_1^\star) - q_0(z_2^\star)| \ge \varphi^\star/2$, which contradict (49). Hence, $\varphi(s)$ is continuous at $s = 0$. With this result at hand, define the candidate class-$\mathcal{K}$ function

$$\varrho(s) = \frac{1}{s}\int_s^{2s} \varphi(\sigma)d\sigma \; + \; s$$

which satisfies

$$\varphi(s) \le \varrho(s). \tag{52}$$

By construction this function is continuous for all $s > 0$ and, as $\varphi(s)$ is continuous at $s = 0$ and by (52), it is also continuous at $s = 0$. Moreover since, by definition of $\varphi(\cdot)$,

$$\varphi(|\tau(z_1) - \tau(z_2)|) \ge |q_0(z_1) - q_0(z_2)| \qquad \forall\, z_1, z_2 \in \mathcal{A},$$

it turns out that (52) yields

$$|q_0(z_1) - q_0(z_2)| \le \varphi(|\tau(z_1) - \tau(z_2)|) \le \varrho(|\tau(z_1) - \tau(z_2)|) \qquad \forall\, z_1, z_2 \in \mathcal{A},$$

namely, (27) is satisfied. This concludes the proof of Proposition 2. □

B.5. Proof of Proposition 3. By the result of the previous proposition we know that

$$\tau(z_1) = \tau(z_2) \qquad \Rightarrow \qquad q_0(z_1) = q_0(z_2) \qquad \forall\, z_1, z_2 \in \mathcal{A}.$$

For any $x \in \tau(\mathcal{A})$, let $[x] = \{z \in \mathcal{A} : \tau(z) = x\}$. The previous property shows that the map $q_0(\cdot)$ is constant on $[x]$. As a consequence, there is a well-defined function $\gamma_0 : \tau(\mathcal{A}) \to \mathbb{R}$ such that

$$\gamma_0(\tau(z)) = -q_0(z) \qquad \forall z \in \mathcal{A}.$$

In fact, the value $\gamma_0(x)$ at any $x \in \tau(\mathcal{A})$ is simply defined by taking any $z \in [x]$ and setting $\gamma_0(x) := -q_0(z)$. Moreover by (27), the map in question is also continuous.

Now note that, as $\mathcal{A}$ is compact and $\tau(\cdot)$ and $q_0(\cdot)$ are continuous maps, $\tau(\mathcal{A}) \subset \mathbb{R}^m$ and $q_0(\mathcal{A}) \subset \mathbb{R}$ are compact sets. From this, Tietze's extension theorem (see, for instance, Theorem VII.5.1 in [13]) can be invoked to claim the existence of a continuous map $\gamma : \mathbb{R}^m \to \mathbb{R}$ which agrees with γ_0 on $\tau(\mathcal{A})$. This implies that $q_0(z) + \gamma \circ \tau(z) = 0$ for all $z \in \mathcal{A}$ and proves the first claim of the proposition.

Furthermore, if $\varrho(\cdot)$ is linearly bounded at the origin, by compactness arguments it is possible to claim the existence of a positive $\bar{\varrho}$ such that $|q_0(z_1) - q_0(z_2)| \leq \bar{\varrho}|\tau(z_1) - \tau(z_2)|$. It follows that γ_0 is a Lipschitz function on $\tau(\mathcal{A})$. From this, the Kirszbraun theorem (see, for instance, Theorem 2.10.43 in [15]) yields the existence of a Lipschitz map $\gamma : \mathbb{R}^m \to \mathbb{R}$, with Lipschitz constant ϱ, which agrees with γ_0 on $\tau(\mathcal{A})$. This completes the proof of the proposition. □

DYNAMIC PROGRAMMING FOR ERGODIC CONTROL OF MARKOV CHAINS UNDER PARTIAL OBSERVATIONS: A CORRECTION*

VIVEK S. BORKAR†

Abstract. A gap in the author's work on dynamic programming for ergodic control of partially observed Markov chains [V. S. Borkar, *SIAM J. Control Optim.*, 39 (2000), pp. 673–681] is pointed out and a correction is provided.

Key words. controlled Markov chains, ergodic control, partial observations, dynamic programming

DOI. 10.1137/05064610X

1. Introduction. Huizen Yu of MIT has pointed out a subtle gap in [1] having to do with the definition of wide sense admissible controls in control of partially observed Markov processes. The error is in the handling of Lemma 3.1 of [1]. We explain this in the next section in the context of [1] and present a corrected proof of Lemma 3.1 in section 3. The ideas of [1] were applied to a specific control problem in [4]. The results were extended to Markov processes with a Euclidean state space in [2], [3], taking a slightly modified approach. This will be commented upon later.

2. Wide sense admissibility. The framework of [1] is a controlled Markov chain $\{X_n\}$ on a finite state space S with an associated control process $\{Z_n\}$ taking values in a compact metric control space A and an associated observations process $\{Y_n\}$ taking values in a finite observation space W. The transition mechanism is

$$P(X_{n+1}=i, Y_{n+1}=j | X_m, Y_m, Z_m, m \le n) = p(X_n, Z_n, i, j) \tag{1}$$

for $n \ge 0, i \in S, j \in W$, where $p : S \times A \times S \times W \to [0,1]$ is a continuous "transition probability" function satisfying $\sum_{i,j} p(k,u,i,j) = 1, k \in S, u \in A$. X_0 has a known distribution π_0. We follow the common convention that (Y_0, Z_0) are independent of X_0. The aim is to minimize the ergodic cost

$$\limsup_{n\to\infty} \frac{1}{n} \sum_{m=0}^{n-1} E[h(X_m, Z_m)]$$

for a prescribed $h \in C(S \times A)$ over $\{Z_n\}$ adapted to $\sigma(Y_m, m \le n), n \ge 0$, the so-called *strict sense admissible controls*. [1] introduces a relaxation of this class to the larger class of *wide sense admissible controls* defined as follows. On a possibly augmented probability space, $\{X_n\}$ above may be viewed as being given by the dynamics

$$X_{n+1} = F(X_n, Z_n, \xi_n) \tag{2}$$

for $\{\xi_n\}$ independently and identically distributed (i.i.d.) uniformly distributed on $[0,1]$ and F a measurable map $S \times A \times [0,1] \to S$ that depends on the function $p(\cdot)$ above. Suppose (X_n, Y_n, Z_n, ξ_n) are defined on a probability space $(\Omega, \mathcal{F}, \bar{P})$ such that there is another probability measure P_0 on $(\Omega, \mathcal{F})$ with the following properties:

*Received by the editors November 25, 2005; accepted for publication (in revised form) July 17, 2006; published electronically February 20, 2007.
http://www.siam.org/journals/sicon/45-6/64610.html
†School of Technology and Computer Science, Tata Institute of Fundamental Research, Homi Bhabha Road, Mumbai 400005, India (borkar@tifr.res.in).

1. Under P_0, $\{Y_n\}$ is i.i.d. uniform on W and independent of $X_0, \{\xi_n\}$, and furthermore $\{Z_n, Y_0, \ldots, Y_n\}$ is independent of $\{\xi_m\}, X_0, \{Y_i, i > n\}$ $\forall n$.
2. If $\bar{P}_n, P_{0n}$ are restrictions of $\bar{P}, P_0$, resp., to $\sigma(X_0; Y_m, m \leq n; \xi_m, Z_m, m < n)$ for $n \geq 1$, then $\bar{P}_n \ll P_{0n}$ with

$$\frac{d\bar{P}_n}{dP_{0n}} = \Pi_{m=0}^{n-1} \frac{p(X_m, Z_m, X_{m+1}, Y_{m+1})}{\bar{p}(X_m, Z_m, X_{m+1})(1/d)},$$

where $d = |W|$ and $\bar{p}(i, z, j) = \sum_y p(i, z, j, y)$ $\forall i, z, j$.

Then we say that $\{Z_n\}$ is *wide sense admissible*. This includes strict sense admissible controls. The wide sense admissible control is in effect prescribed by the joint law ϕ of $(\{Y_n\}, \{Z_n\})$ under P_0. Hence it can be identified with this ϕ. Let Φ denote the set of wide sense admissible controls, i.e., of ϕ as above. The "vanishing discount" argument used later in [1] requires that we consider a pair of state-observation processes $\{\hat{X}_n, \hat{Y}_n\}$ and $\{\tilde{X}_n, \tilde{Y}_n\}$ on the same probability space with a *common* control process $\{Z_n\}$ that is wide sense admissible for both, and corresponds to a prescribed ϕ for one of them, say the latter. The way [1] tried to achieve this is as follows:

1. Given initial distributions $\hat{\pi}_0, \tilde{\pi}_0$ on S, consider

$$\hat{\Omega} = S \times S \times [0,1]^\infty \times [0,1]^\infty \times W^\infty \times A^\infty \times W^\infty$$

with the product σ-field $\hat{\mathcal{F}}$ and the probability measure

$$\begin{aligned} &\hat{P}_0(d\hat{x} \times d\tilde{x} \times d\hat{u}^\infty \times d\tilde{u}^\infty \times d\tilde{y}^\infty \times dz^\infty \times d\hat{y}^\infty) \\ &\qquad = \Gamma(d\hat{x}d\tilde{x})\ell_1^\infty(d\hat{u}^\infty)\ell_1^\infty(d\tilde{u}^\infty)\phi(d\tilde{y}^\infty, dz^\infty)\ell_2^\infty(d\hat{y}^\infty), \end{aligned} \tag{3}$$

where,

- ℓ_1, ℓ_2 are uniform distributions on $[0,1], W$, resp.,
- $\Gamma(d\hat{x} \times S) = \hat{\pi}_0(d\hat{x}), \Gamma(S \times d\tilde{x}) = \tilde{\pi}_0(d\tilde{x})$, and
- if $\phi \approx$ the law of $(Y_0', Y_1', Y_2', \ldots; Z_0', Z_1', Z_2', \ldots)$, then
  (†) $\{Y_n'\}$ are i.i.d. uniform on W and for each n, $Y_m', m > n$, is independent of $Z_m', m \leq n; Y_k', k < n$.

Condition (†) is effectively the wide sense admissibility condition of $\{Z_n\}$ for $(\{\tilde{X}_n\}, \{\tilde{Y}_n\})$. It should be noted that the definition of (3) in [1] uses $\Gamma(d\hat{x}, d\tilde{x}) = \hat{\pi}_0(d\hat{x})\tilde{\pi}_0(\tilde{x})$, i.e., the two initial conditions are independent under $\hat{P}_0$, but a dependence is introduced later on in [1].

2. Define random variables $(\hat{X}_0, \tilde{X}_0, \{\hat{\xi}_n\}, \{\tilde{\xi}_n\}, \{\tilde{Y}_n\}, \{Z_n\}, \{\hat{Y}_n\})$ canonically on this probability space so that their joint law is $\hat{P}_0$. (Thus, for example, $\hat{X}_0([\hat{x}, \tilde{x}, \hat{u}^\infty, \tilde{u}^\infty, \tilde{y}^\infty, z^\infty, \hat{y}^\infty]) = \hat{x}$.)
3. Generate $\{\hat{X}_n\}, \{\tilde{X}_n\}$ from $(\hat{X}_0, \{Z_n\}, \{\hat{\xi}_n\}), (\tilde{X}_0, \{Z_n\}, \{\tilde{\xi}_n\})$, resp., by using (2).
4. Change measure to $\hat{P}$ as follows: If $\hat{P}_n, \hat{P}_{0n}$ are the restrictions of $\hat{P}, \hat{P}_0$, resp., to $\mathcal{G}_n \triangleq \sigma(\hat{X}_0, \tilde{X}_0; \hat{\xi}_m, \tilde{\xi}_m, Z_m, m < n; \hat{Y}_m, \tilde{Y}_m, m \leq n)$ for $n \geq 0$, then $\hat{P}_n \ll \hat{P}_{0n}$ with

$$\begin{aligned} \frac{d\hat{P}_n}{d\hat{P}_{0n}} &= \Lambda_n \\ &\triangleq \Pi_{m=0}^{n-1} \left(\frac{p(\hat{X}_m, Z_m, \hat{X}_{m+1}, \hat{Y}_{m+1})}{\bar{p}(\hat{X}_m, Z_m, \hat{X}_{m+1})(1/d)} \right) \left(\frac{p(\tilde{X}_m, Z_m, \tilde{X}_{m+1}, \tilde{Y}_{m+1})}{\bar{p}(\tilde{X}_m, Z_m, \tilde{X}_{m+1})(1/d)} \right). \end{aligned} \tag{4}$$

Let $E_0[\ \cdot\ ]$ denote the expectation under $\hat{P}_0$. Lemma 3.1 of [1] claims that under $\hat{P}$, $\{\hat{X}_n, \hat{Y}_n\}, \{\tilde{X}_n, \tilde{Y}_n\}$ are two state-observation pairs with a common control $\{Z_n\}$ wide sense admissible for both. This is far from obvious. While $\{Z_n\}$ is clearly wide sense admissible for $\{\tilde{X}_n, \tilde{Y}_n\}$, it is not obviously so for $\{\hat{X}_n, \hat{Y}_n\}$. This is because, while

$$E_0\left[\frac{d\hat{P}_n}{d\hat{P}_{0n}}\middle| \tilde{X}_m, \tilde{Y}_m, m \le n; Z_m, m < n\right] \tag{5}$$

does equal

$$\Lambda_{2n} \triangleq \Pi_{m=0}^{n-1}\left(\frac{p(\tilde{X}_m, Z_m, \tilde{X}_{m+1}, \tilde{Y}_{m+1})}{\bar{p}(\tilde{X}_m, Z_m, \tilde{X}_{m+1})(1/d)}\right),$$

its counterpart

$$E_0\left[\frac{d\hat{P}_n}{d\hat{P}_{0n}}\middle| \hat{X}_m, \hat{Y}_m, m \le n; Z_m, m < n\right] \tag{6}$$

need not equal

$$\Lambda_{1n} \triangleq \Pi_{m=0}^{n-1}\left(\frac{p(\hat{X}_m, Z_m, \hat{X}_{m+1}, \hat{Y}_{m+1})}{\bar{p}(\hat{X}_m, Z_m, \hat{X}_{m+1})(1/d)}\right).$$

It is, however, of the form

$$\hat{\Lambda}_{1n} \triangleq \Pi_{m=0}^{n-1}\left(\frac{p(\hat{X}_m, Z_m, \hat{X}_{m+1}, \hat{Y}_{m+1})}{\bar{p}(\hat{X}_m, Z_m, \hat{X}_{m+1})(1/d)}\right)\zeta_n.$$

Here ζ_n is an a.s. positive random variable of the form

$$\zeta_n = \psi_n(\hat{X}_0, Z_0, \ldots, Z_{n-1})$$

for a suitable measurable function ψ_n, and is independent of $\{\hat{\xi}_k\}$ and $\{\hat{Y}_m, m \ge n\}$ under $\hat{P}_0$.

3. The correction. In order to set this right, we need the following additional assumption:

$$p(i, u, j, k) > 0\ \forall k \text{ whenever } \bar{p}(i, u, j) > 0. \tag{7}$$

In particular, this implies that the ratio $p(i, u, j, k)/(\bar{p}(i, u, j)(1/d))$ is strictly positive when defined. The following example (due to Huizen Yu) shows that some condition like this will be necessary to obtain a state-independent optimal cost for the partially observed control problem.

Example. Let $S = \{1, 2, 3, 4\}$, $A = \{a, b\}$, $W = \{q, r\}$, and let the following transition probabilities hold:

$$p(1, u, 1, q) = \frac{1}{2} \ = \ p(1, u, 2, r)\ \forall u,$$

$$p(1, u, k, \ell) = 0 \ \text{ otherwise},$$

$$p(3, u, 3, q) = \frac{1}{2} \ = \ p(3, u, 4, r)\ \forall u,$$

$$p(3,u,k,\ell) = 0 \ \text{ otherwise},$$
$$p(2,u,3,q) = 1 \ \forall u,$$
$$p(2,u,k,\ell) = 0 \ \text{ otherwise},$$
$$p(4,u,1,q) = 1 \ \forall u,$$
$$p(4,u,k,\ell) = 0 \ \text{ otherwise}.$$

The costs are $h(1,a) = 1 = h(3,b)$ and $h(i,u) = 0$ for all other choices of i,u. Let $[z]$ denote a string of the type "$zzz\cdots z$" of a random finite length. It is easy to see that if the initial law is the Dirac measure at 1, then the state trajectory is $[1],2,[3],4,[1],2,[3],4,\ldots$, with the output trajectory $[q],r,[q],r,\ldots$, with matching lengths, so that the former is exactly recovered from the latter. In other words, the process $\{\pi_n\}$ of conditional laws of X_n given $\sigma(Y_m, m \le n)$ for $n \ge 0$ remains Dirac. Similarly if the initial law is a Dirac measure at 3, the state process is exactly known from the observations. A similar reasoning applies if the initial laws are Dirac at 2 or 4. In particular, the set of Dirac measures is invariant for the nonlinear filter, which recursively generates $\{\pi_n\}$. The optimal cost is zero in all these cases, as we can choose control b in state 1 and a in state 3. On the other hand, if the initial law is $\pi'(\{1\}) = \pi'(\{3\}) = \frac{1}{2}$, then $\{\pi_n\}$ is of the form $[\pi'],\pi'',[\pi'],\pi'',\ldots$, where $\pi''(\{2\}) = \pi''(\{4\}) = \frac{1}{2}$. A similar statement holds if the initial law is π'' instead. Thus $\{\pi',\pi''\}$ is also invariant for the nonlinear filter. In this case the optimal cost will be strictly positive: when $\pi_n = \pi'$, choosing a with probability q and b with probability $1-q$ will yield a cost of $\frac{1}{2}$ regardless of the choice of q. Note that the transition probabilities of $\{X_n\}$ are independent of the control and the resulting state process is an irreducible aperiodic, and therefore ergodic, Markov chain. But the resulting process of conditional laws is a nonergodic Markov process.

The correction is as follows: We replace (3) by

$$\begin{aligned}&\hat{P}_0(d\hat{x}\times d\tilde{x}\times d\hat{u}^\infty\times d\tilde{u}^\infty\times d\tilde{y}^\infty\times dz^\infty\times d\hat{y}^\infty)\\ &\qquad = \hat{\pi}(d\hat{x})\tilde{\pi}(d\tilde{x})\ell_1^\infty(d\hat{u}^\infty)\ell_1^\infty(d\tilde{u}^\infty)\phi(d\tilde{y}^\infty,dz^\infty)\ell_2^\infty(d\hat{y}^\infty),\end{aligned} \tag{8}$$

and (4) by

$$\begin{aligned}\frac{d\hat{P}_n}{d\hat{P}_{0n}} &= \frac{\Gamma(\{(\hat{X}_0,\tilde{X}_0)\})}{\hat{\pi}(\{\hat{X}_0\})\tilde{\pi}(\{\tilde{X}_0\})}\\ &\quad\times\Pi_{m=0}^{n-1}\left(\frac{p(\hat{X}_m,Z_m,\hat{X}_{m+1},\hat{Y}_{m+1})}{\bar{p}(\hat{X}_m,Z_m,\hat{X}_{m+1})(1/d)}\right)\left(\frac{p(\tilde{X}_m,Z_m,\tilde{X}_{m+1},\tilde{Y}_{m+1})}{\bar{p}(\tilde{X}_m,Z_m,\tilde{X}_{m+1})(1/d)}\right).\end{aligned} \tag{9}$$

Define yet another probability measure $\bar{P}_0$ as follows: If $\bar{P}_{0n} \triangleq$ the restriction of $\bar{P}_0$ to $\mathcal{G}_n$, then

$$\frac{d\bar{P}_{0n}}{d\hat{P}_{0n}} = \Pi_{m=0}^{n-1}\left(\frac{p(\tilde{X}_m,Z_m,\tilde{X}_{m+1},\tilde{Y}_{m+1})}{\bar{p}(\tilde{X}_m,Z_m,\tilde{X}_{m+1})(1/d)}\right).$$

Then, using (7), we have

$$\frac{d\hat{P}_n}{d\bar{P}_{0n}} = \frac{\Gamma(\{(\hat{X}_0,\tilde{X}_0)\})}{\hat{\pi}(\{\hat{X}_0\})\tilde{\pi}(\{\tilde{X}_0\})}\Pi_{m=0}^{n-1}\left(\frac{p(\hat{X}_m,Z_m,\hat{X}_{m+1},\hat{Y}_{m+1})}{\bar{p}(\hat{X}_m,Z_m,\hat{X}_{m+1})(1/d)}\right),$$

and under $\bar{P}_0$, $\{\hat{Y}_n\}$ is i.i.d. uniform on W and independent of $\hat{X}_0, \{\hat{\xi}_n\}$, and furthermore $\{Z_n, \hat{Y}_0, \ldots, \hat{Y}_n\}$ is independent of $\{\hat{\xi}_m\}, \hat{X}_0, \{\hat{Y}_i, i > n\}$ $\forall n$. This establishes the wide sense admissibility of $\{Z_n\}$ for $\{(\hat{X}_n, \hat{Y}_n)\}$ and completes the proof of Lemma 3.1 of [1].

Let $\tau = \min\{n \geq 0 : \hat{X}_n = \tilde{X}_n, \hat{Y}_n = \tilde{Y}_n\}$. As in [1], we assume that

$$M \stackrel{\Delta}{=} \sup E[\tau] < \infty, \tag{10}$$

where the supremum is over all Γ and all wide sense admissible $\{Z_n\}$. Let $\{Z_n\}$ above be chosen to be optimal for the α-discounted cost when the initial law is $\hat{\pi}$. Also define

$$\begin{aligned}
X_n^* &\stackrel{\Delta}{=} \tilde{X}_n I\{n \leq \tau\} + \hat{X}_n I\{n > \tau\},\\
\bar{X}_n &\stackrel{\Delta}{=} \hat{X}_n I\{n \leq \tau\} + \tilde{X}_n I\{n > \tau\},\\
Y_n^* &\stackrel{\Delta}{=} \tilde{Y}_n I\{n \leq \tau\} + \hat{Y}_n I\{n > \tau\},\\
\bar{Y}_n &\stackrel{\Delta}{=} \hat{Y}_n I\{n \leq \tau\} + \tilde{Y}_n I\{n > \tau\},\\
\xi_n^* &\stackrel{\Delta}{=} \tilde{\xi}_n I\{n \leq \tau\} + \hat{\xi}_n I\{n > \tau\},\\
\bar{\xi}_n &\stackrel{\Delta}{=} \hat{\xi}_n I\{n \leq \tau\} + \tilde{\xi}_n I\{n > \tau\}.
\end{aligned}$$

Note that

- $\{\bar{\xi}_n, \xi_n^*\}$ are i.i.d. uniform and independent of $\hat{X}_0, \tilde{X}_0$ under both $\hat{P}, \hat{P}_0$;
- under $\hat{P}_0$, $\{\bar{Y}_n\}, \{Y_n^*\}$ are i.i.d. uniform and independent of $\{\bar{\xi}_n\}$, $\{\xi_n^*\}$, $\hat{X}_0$, $\tilde{X}_0$;
- under $\hat{P}_0$, $\{Z_n, \bar{Y}_0, \ldots, \bar{Y}_n\}$ (resp., $\{Z_n, Y_0^*, \ldots, Y_n^*\}$) for each n is independent of $\bar{Y}_m, m > n, \{\bar{\xi}_k\}$ (resp., $Y_m^*, m > n, \{\xi_k^*\}$);
- $\{\bar{X}_n\}$ (resp., $\{X_n^*\}$) are generated recursively by (2) from $(\hat{X}_0, \{\bar{\xi}_n\}, \{Z_n\})$ (resp., $(\tilde{X}_0, \{\xi_n^*\}, \{Z_n\})$).

Furthermore, one verifies that

$$\begin{aligned}
\frac{d\hat{P}_n}{d\hat{P}_{0n}} \stackrel{\Delta}{=} & \frac{\Gamma(\{(\bar{X}_0, X_0^*)\})}{\hat{\pi}(\{\bar{X}_0\})\tilde{\pi}(\{X_0^*\})} \Pi_{m=0}^{n-1} \frac{p(\bar{X}_m, Z_m, \bar{X}_{m+1}, \bar{Y}_{m+1})}{\bar{p}(\bar{X}_m, Z_m, \bar{X}_{m+1})(1/d)}\\
& \times \Pi_{m=0}^{n-1} \frac{p(X_m^*, Z_m, X_{m+1}^*, Y_{m+1}^*)}{\bar{p}(X_m^*, Z_m, X_{m+1}^*)(1/d)}
\end{aligned}$$

for $n \geq 1$. In particular, this shows by the same arguments as above that $(\{\bar{X}_n\}, \{\bar{Y}_n\}, \{Z_n\})$ as well as $(\{X_n^*\}, \{Y_n^*\}, \{Z_n\})$ are state-observation-control triples for which $\{Z_n\}$ is simultaneously wide sense admissible. The rest follows exactly as in [1], leading to Theorems 4.1 and 4.2 of [1], in particular the dynamic programming equation for ergodic control given by (4.1) there. Theorem 4.1 (ii) of [1] yields the existence of an optimal wide sense admissible control $\{Z_n\}$ of the form $Z_n = v(\pi_n), n \geq 0$, for some measurable $v(\cdot)$, where $\pi_n \stackrel{\Delta}{=}$ the regular conditional law of X_n given $Y_m, Z_m, m \leq n$. Plugging this back into (2.4) of [1] (which is the recursive nonlinear filter describing the evolution of $\{\pi_n\}$), one inductively sees that this control is in fact strict sense admissible. This implies that the value function remains unchanged if we move from strict sense admissible over to wide sense admissible controls, and thus justifies the above relaxation.

In the corresponding developments for Euclidean state space worked out in [2], [3], the counterpart of (7) is already assumed. (In fact, it is available free for the sampled nondegenerate diffusions considered later in [2] and [3].) The coupling time τ gets replaced by a "coupling time at the pseudo-atom." In this case, however, $\Gamma(d\hat{x}d\tilde{x})$ need not be absolutely continuous with respect to $\hat{\pi}(d\hat{x})\tilde{\pi}(d\tilde{x})$ in general. But the approach taken in [3] works with independent initial conditions and therefore does not run into this difficulty.

Acknowledgments. I thank Aristotle Arapostathis, Amarjit Budhiraja, and Huizen Yu for extensive discussions.
