RETRIEVING LÉVY PROCESSES FROM OPTION PRICES: REGULARIZATION OF AN ILL-POSED INVERSE PROBLEM*

RAMA CONT† AND PETER TANKOV‡

Abstract. We propose a stable nonparametric method for constructing an option pricing model of exponential Lévy type, consistent with a given data set of option prices. After demonstrating the ill-posedness of the usual and least squares version of this inverse problem, we suggest to regularize the calibration problem by reformulating it as the problem of finding an exponential Lévy model that minimizes the sum of the pricing error and the relative entropy with respect to a prior exponential Lévy model. We prove the existence of solutions for the regularized problem and show that it yields solutions which are continuous with respect to the data, stable with respect to the choice of prior, and which converge to the minimum entropy least squares solution of the initial problem when the noise level in the data vanishes.

Key words. inverse problem, entropy, Lévy process, jump process, model calibration, option pricing, regularization, ill-posed problem

1. Introduction.

The specification of an arbitrage-free option pricing model on a time horizon T_∞ involves the choice of a *risk-neutral* measure [25]: a probability measure Q on the set Ω of possible trajectories $\{S_t\}_{t\in[0,T_\infty]}$ of the underlying asset such that the discounted asset price $e^{-rt}S_t$ is a martingale (where r is the discount rate). Such a probability measure Q then specifies a pricing rule which attributes to an option with terminal payoff H_T at T the value $C(H_T) = e^{-rT}E^Q[H_T]$. For example, the value under the pricing rule Q of a call option with strike K and maturity T is given by $e^{-rT}E^Q[(S_T - K)^+]$. Given that data sets of option prices have become increasingly available, a common approach for selecting the pricing model is to choose, given option prices $(C(H^i))_{i\in I}$ with maturities T_i payoffs H^i, a risk-neutral measure Q compatible with the observed market prices, i.e., such that $C(H^i) = e^{-rT_i}E^Q[H^i]$. This *inverse problem* of determining a pricing model Q verifying these constraints is known as the "model calibration" problem. The number of observed options can be large ($\simeq$ 100–200 for index options) and the Black–Scholes model has to be replaced with models with richer structure such as nonlinear diffusion models [18] or models with jumps [13]. The inverse problem is ill-posed in these settings [14, 33] and various methods have been proposed for solving it in a stable manner, mostly in the framework of diffusion models [1, 4, 5, 6, 9, 16, 18, 26, 28, 32, 33].

Given the ill-posed nature of the inverse problem, an extra criterion must be used to select a model compatible with observed option prices. The use of *relative entropy* as a model selection criterion has solid theoretical foundations [17] and has been investigated by many authors in the context of option pricing.

The notion of minimal entropy martingale measure (MEMM)—the pricing measure Q that minimizes the relative entropy with respect to a reference probability P—has been investigated by many authors [22, 19, 29]. However, option prices computed using the MEMM are in general not consistent with the market-quoted prices of traded European options and can lead to arbitrage opportunities with respect to market-traded options.

The notion of minimal entropy distribution consistent with observed market prices was introduced in a static framework in [4, 3, 35]; given prices of call options $\{C_M(T_i, K_i)\}_{i\in I}$ and a prior distribution P on scenarios, it is obtained by minimizing relative entropy over all probability measures $Q \sim P$ such that

$$C_M(T_i, K_i) = E^Q[e^{-rT_i}(S_{T_i} - K_i)^+] \quad \text{for } i \in I. \tag{1.1}$$

This approach is based on relative entropy minimization under constraints [17] and yields a computable result. It was extended to the case of stochastic processes by the weighted Monte Carlo method of Avellaneda et al. [5], but the martingale property is not taken into account since it would yield an infinite number of constraints [30]. As a result, derivative prices computed with the weighted Monte Carlo algorithm may contain arbitrage opportunities, especially when applied to forward start contracts.

Goll and Rüschendorf [24] consider the notion of consistent (or calibrated) MEMM (CMEMM), defined as the solution of

$$I(Q^*|P) = \min_{Q\in\mathcal{M}^*} I(Q|P),$$

where the minimum is taken over all martingale measures $Q \sim P$ verifying (1.1). While this notion seems to conciliate the advantages of the MEMM and Avellaneda's entropy minimization under constraints, no algorithm is proposed in [24] to compute the CMEMM. In fact, the notion of CMEMM does not in general preserve the structure of the prior—e.g., the Markov property—and it may be difficult to represent.[1]

We also note that such model selection methods based on relative entropy are not convenient when dealing with one-dimensional diffusion models since as soon as the model has a diffusion coefficient different from the prior their measures become singular and the relative entropy is infinite.

In this paper we show that the shortcomings of the above approaches can be overcome by enlarging the class of models to include processes with jumps and using relative entropy as a regularization criterion rather than a selection criterion. On one hand, introducing jumps in the prior model allows us to obtain a large class of equivalent martingale measures which also have finite relative entropy with respect to the prior, avoiding the singularity which arises in diffusion models. On the other hand, by restricting the class of pricing models to exponential Lévy models—where the risk-neutral dynamics of the logarithm of the stock price is given by a Lévy process—we are able to go beyond a simple existence result and obtain a computable alternative to the CMEMM. Also, unlike the weighted Monte Carlo approach, our approach yields as a solution a continuous-time price process whose discounted value is a martingale. Finally, the use of regularization yields a stable solution to the inverse problem for which a computational approach is possible [14].

The relation between the option prices and the parameters of the process (its Lévy measure) being nonlinear, we face a nonlinear, infinite-dimensional inverse problem.

[1] In particular, if X is a Lévy process under the prior P, it will in general no longer be a Lévy process under a consistent MEMM.

After demonstrating the ill-posedness of the usual and least squares version of this inverse problem, we show that it can be regularized by using as a penalization term the relative entropy with respect to a prior exponential Lévy model. We show that our approach yields solutions which are continuous with respect to the data, stable with respect to the choice of prior, and which converge to the minimum entropy least squares solution of the initial problem.

Unlike linear inverse problems for which general results on regularization methods and their convergence properties are available [20], nonlinear inverse problems have been explored less systematically. Our study is an example of rigorous analysis of regularization using entropy for a nonlinear, infinite-dimensional inverse problem. Previous results on regularization using entropy have been obtained in a Banach space setting [21] by mapping the problem to a Tikhonov regularization problem. Using probabilistic methods, we are able to use a direct approach and extend these results to the spaces of probability measures considered here.

The paper is structured as follows. Section 2 recalls basic facts about Lévy processes and exponential Lévy models. In section 3 we formulate the calibration problem as that of finding a martingale measure Q, consistent with market-quoted prices of traded options, under which the logarithm of the stock price process remains a Lévy process. We show that both this problem and its least squares version are ill-posed: a solution need not exist and, when it exists, may be unstable with respect to perturbations in the data. Section 4 discusses relative entropy in the case of Lévy processes and its use as a criterion for selecting solutions, and introduces the notion of minimum entropy least squares solution. In section 5 we formulate the regularized version of the calibration problem, show that it always admits a solution depending continuously on market data, discuss conditions for the solutions to be equivalent martingale measures, and formulate conditions under which they converge to the minimum entropy least squares solutions as the noise level in the data goes to zero.

In section 6 we show that the solutions of the regularized calibration problem are stable with respect to small perturbations of the prior measure. The solutions of the regularized calibration problem with any prior measure can thus be approximated (in the weak sense) by the solutions of regularized problems with discretized priors, which has implications for the discretization and the numerical solution of the regularized calibration problem, further discussed in [14]. In the appendix we discuss some properties of relative entropy in the case of Lévy processes.

2. Definitions and notation. Consider a time horizon $T_\infty < \infty$ and denote by Ω the space of real-valued cadlag functions on $[0, T_\infty]$, equipped with the Skorokhod topology [27]. The time horizon T_∞ must be chosen finite since we will work with the class of Lévy processes absolutely continuous with respect to a given Lévy process, and on an infinite time interval this class is trivial since in this case absolute continuity of Lévy processes is equivalent to identity in law [27, Theorem IV.4.39]. Unless otherwise mentioned, X is the coordinate process: for every $\omega \in \Omega$, $X_t(\omega) := \omega(t)$. $\mathcal{F}$ is the smallest σ-field, for which the mappings $\omega \in \Omega \mapsto \omega(s)$ are measurable for all $s \in [0, T_\infty]$ and for any $t \in [0, T_\infty]$, and $(\mathcal{F}_t)$ is the natural filtration of $(X_t)_{t\in[0,T_\infty]}$. Weak convergence of measures will be denoted by $\Rightarrow$.

Lévy processes. A Lévy process $\{X_t\}_{t\geq 0}$ on $(\Omega, \mathcal{F}, P)$ is a stochastic process with stationary independent increments satisfying $X_0 = 0$. The characteristic function of X_t has the following form, called the Lévy–Khinchin representation [34]:

$$E[e^{izX_t}] = e^{t\psi(z)} \text{ with } \psi(z) = -\frac{1}{2}Az^2 + i\gamma z + \int_{-\infty}^{\infty} (e^{izx} - 1 - izh(x))\nu(dx), \tag{2.1}$$

where $A \geq 0$ is the unit variance of the Brownian motion part of the Lévy process, $\gamma \in \mathbb{R}$, ν is a positive measure on $\mathbb{R}$ verifying $\nu(\{0\}) = 0$ and

$$\int_{-\infty}^{\infty} (x^2 \wedge 1)\nu(dx) < \infty,$$

and h is the truncation function: any bounded measurable function $\mathbb{R} \to \mathbb{R}$ such that $h(x) \equiv x$ on a neighborhood of zero. The most common choice of truncation function is $h(x) = x1_{|x|\leq 1}$ but sometimes in this paper we will need h to be continuous. The triplet (A, ν, γ) is called the characteristic triplet of X with respect to the truncation function h.

Model setup. We consider exponential Lévy models, where the stock price S_t is modeled, under a *risk-neutral measure* Q [25], as the exponential of a Lévy process:

$$S_t = S_0 e^{rt+X_t}, \tag{2.2}$$

where r is the interest rate. Since Q is a risk-neutral probability measure, e^{X_t} must be a martingale. It follows from (2.1) that this is the case if and only if

$$\frac{A}{2} + \gamma + \int_{-\infty}^{\infty} (e^x - 1 - h(x))\nu(dx) = 0. \tag{2.3}$$

Under Q call option prices can be evaluated as discounted expectations of terminal payoffs:

$$C^Q(T, K) = e^{-rT} E^Q[(S_T - K)^+] = e^{-rT} E^Q[(S_0 e^{rT+X_T} - K)^+]. \tag{2.4}$$

Notation. In what follows $\mathcal{P}(\Omega)$ denotes the set of probability measures (stochastic processes) on $(\Omega, \mathcal{F})$, $\mathcal{L}$ denotes the set of all probability measures $P \in \mathcal{P}(\Omega)$ under which the coordinate process X is a Lévy process, and $\mathcal{M}$ stands for the set of all probability measures $P \in \mathcal{P}(\Omega)$, under which $\exp(X_t)$ is a martingale. $\mathcal{L}_{NA}$ is the set of all probability measures $P \in \mathcal{L}$ corresponding to arbitrage-free exponential Lévy models, that is, to Lévy processes that are not almost surely increasing nor almost surely decreasing. Furthermore, for $B > 0$ we define

$$\mathcal{L}_B^+ = \{P \in \mathcal{L},\ P[\Delta X_t \leq B\ \forall t \in [0, T_\infty]\ ] = 1\ \},$$

the set of Lévy processes with jumps bounded from above by B.

The following lemma shows the usefulness of the above definitions.

LEMMA 2.1. *The set $\mathcal{M} \cap \mathcal{L}_B^+$ is weakly closed for every $B > 0$.*

Proof. Let $\{Q_n\}_{n=1}^{\infty} \subset \mathcal{M} \cap \mathcal{L}_B^+$ with characteristic triplets (A_n, ν_n, γ_n) with respect to a continuous truncation function h and let Q be a Lévy process with characteristic triplet (A, ν, γ) with respect to h, such that $Q_n \Rightarrow Q$. Note that the limit in distribution of a sequence of Lévy processes is necessarily a Lévy process; due to convergence of characteristic functions, the limiting process must have stationary and independent increments. Define a function f by

$$f(x) := \begin{cases} 0, & x \leq B, \\ 1, & x \geq 2B, \\ \frac{x-B}{B} & B < x < 2B. \end{cases}$$

By Corollary VII.3.6 in [27], $\int_{-\infty}^{\infty} f(x)\nu(dx) = \lim_{n\to\infty} \int_{-\infty}^{\infty} f(x)\nu_n(dx) = 0$, which implies that the jumps of Q are bounded by B. Define

$$g(x) := \begin{cases} e^x - 1 - h(x) - \frac{1}{2}h^2(x), & x \leq B, \\ e^B - 1 - h(B) - \frac{1}{2}h^2(B), & x > B. \end{cases}$$

Then, once again by Corollary VII.3.6 in [27] and because Q_n satisfies the martingale condition (2.3) for every n,

$$\gamma + \frac{A}{2} + \int_{-\infty}^{\infty} (e^x - 1 - h(x))\nu(dx) = \gamma + \frac{A + \int_{-\infty}^{\infty} h^2(x)\nu(dx)}{2} + \int_{-\infty}^{\infty} g(x)\nu(dx)$$
$$= \lim_{n\to\infty} \left\{ \gamma_n + \frac{A_n + \int_{-\infty}^{\infty} h^2(x)\nu_n(dx)}{2} + \int_{-\infty}^{\infty} g(x)\nu_n(dx) \right\} = 0,$$

which shows that Q also satisfies the condition (2.3). □

3. The calibration problem and its least squares formulation. Suppose first that the market data C_M are consistent with the class of exponential Lévy models. This is, for example, the case when the market pricing rule is an exponential Lévy model but can hold more generally since many models may give the same prices for a given set of European options. For instance one can construct, using Dupire's formula [18], a diffusion model that gives the same prices, for a set of European options, as a given exp-Lévy model [12]. Using the notation defined in the preceding section, the calibration problem assumes the following form.

PROBLEM 1 (calibration with equality constraints). *Given prices of call options* $\{C_M(T_i, K_i)\}_{i\in I}$*, find an arbitrage-free exponential Lévy model* $Q^* \in \mathcal{M} \cap \mathcal{L}$ *such that*

$$\forall i \in I, \quad C^{Q^*}(T_i, K_i) = C_M(T_i, K_i). \tag{3.1}$$

When the market data are not consistent with the class of exponential Lévy models, the exact calibration problem may not have a solution. In this case one may consider an approximate solution: instead of reproducing the market option prices exactly, one may look for a Lévy triplet which reproduces them in a least squares sense. Let w be a probability measure on $[0, T_\infty] \times [0, \infty)$ (the weighting measure, determining the relative importance of different data points). An option data set is defined as a mapping $C : [0, T_\infty] \times [0, \infty) \to [0, \infty)$ and the data sets that coincide w-almost everywhere are considered identical. One can introduce a norm on option data sets via

$$\|C\|_w^2 := \int_{[0,T_\infty]\times[0,\infty)} C(T, K)^2 w(dT \times dK). \tag{3.2}$$

The quadratic pricing error in model Q is then given by $\|C_M - C^Q\|_w^2$. If the number of constraints is finite, then $w = \sum_{i=1}^N w_i \delta_{(T_i,K_i)}(dT \times dK)$ (with, e.g., N constraints), where $\{w_i\}_{1\le i\le N}$ are positive weights that sum up to one. Therefore, in this case

$$\|C_M - C^Q\|_w^2 = \sum_{i=1}^N w_i (C_M(T_i, K_i) - C^Q(T_i, K_i))^2. \tag{3.3}$$

The following lemma establishes some useful properties of the pricing error functional.

LEMMA 3.1. *The pricing error functional* $Q \mapsto \|C_M - C^Q\|_w^2$ *is uniformly bounded and weakly continuous on* $\mathcal{M} \cap \mathcal{L}$.

Proof. From (2.4), $C^Q(T, K) \le S_0$. Absence of arbitrage in the market implies that the market option prices satisfy the same condition. Therefore, $(C_M(T, K) - C^Q(T, K))^2 \le S_0^2$ and, since w is a probability measure, $\|C_M - C^Q\|_w^2 \le S_0^2$.

Let $\{Q_n\}_{n\geq 1} \subset \mathcal{M}\cap\mathcal{L}$ and $Q \in \mathcal{M}\cap\mathcal{L}$ be such that $Q_n \Rightarrow Q$. For all T, K,

$$\begin{aligned}\lim_n C^{Q_n}(T,K) &= e^{-rT}\lim_n E^{Q_n}[(S_0e^{rT+X_T}-K)^+]\\ &= e^{-rT}\lim_n E^{Q_n}[S_0e^{rT+X_T}-K] + e^{-rT}\lim_n E^{Q_n}[(K-S_0e^{rT+X_T})^+]\\ &= S_0 - Ke^{-rT} + e^{-rT}E^Q[(K-S_0e^{rT+X_T})^+] = C^Q(T,K).\end{aligned}$$

Therefore, by the dominated convergence theorem, $\|C_M - C^{Q_n}\|_w^2 \to \|C_M - C^Q\|_w^2$. □

The calibration problem now takes the following form.

PROBLEM 2 (least squares calibration problem). *Given prices C_M of call options, find $Q^* \in \mathcal{M}\cap\mathcal{L}$ such that*

$$\|C_M - C^{Q^*}\|_w^2 = \inf_{Q\in\mathcal{M}\cap\mathcal{L}} \|C_M - C^Q\|_w^2. \tag{3.4}$$

In what follows, any such Q^* will be called a least squares solution and the set of all least squares solutions will be denoted by $\mathrm{LSS}(C_M)$.

Several authors [2, 8] have used least squares formulations similar to (3.4) for calibrating parametric models without taking into account that the least squares calibration problem is ill-posed in several ways:

Lack of identification. Option prices are only available for a finite number of strikes (typically between 10 and 100) and knowing the prices of a finite number of options is not sufficient to reconstruct the Lévy process. This problem is discussed in detail in [14, 36].

Absence of solution. In some cases even the least squares problem may not admit a solution, as shown by the following (artificial) example.

Example 3.1. Suppose that $S_0 = 1$, there are no interest rates or dividends, and the (equally weighted) market data consist of the following two observations:

$$C_M(T=1, K=1) = 1 - e^{-\lambda} \quad \text{and} \quad C_M(T=1, K=e^{\lambda}) = 0, \tag{3.5}$$

with some $\lambda > 0$. It is easy to see that these prices are, for example, compatible with the (martingale) asset price process $S_t = e^{\lambda t}1_{t\leq\tau_1}$, where τ_1 is the time of the first jump of a Poisson process with intensity λ. We will show that if the market data are given by (3.5), the calibration problem (3.4) does not admit a solution.

Equation (2.4) implies that in every risk-neutral model Q, for fixed T, $C^Q(T,K)$ is a convex function of K and that $C^Q(T, K=0) = 1$. The only convex function which satisfies this equality and passes through the market data points (3.5) is given by $C(T=1,K) = (1-Ke^{-\lambda})^+$. Therefore, in every arbitrage-free model that is an exact solution of the calibration problem with market data (3.5), for every $K \geq 0$, $P[S_1 \leq K] = e^{-\lambda}1_{K\leq e^{\lambda}}$. Since in an exponential Lévy model $P[S_1 > 0] = 1$, there is no risk-neutral exponential Lévy model for which $\|C_M - C^Q\|_w = 0$.

On the other hand, $\inf_{Q\in\mathcal{M}\cap\mathcal{L}} \|C_M - C^Q\|_w^2 = 0$. Indeed, let $\{N_t\}_{t\geq 0}$ be a Poisson process with intensity λ. Then for every n, the process

$$X_t^n := -nN_t + \lambda t(1-e^{-n}) \tag{3.6}$$

belongs to $\mathcal{M}\cap\mathcal{L}$ and

$$\lim_{n\to\infty} E[(e^{X_t^n}-K)^+] = \lim_{n\to\infty}\sum_{k=0}^{\infty} e^{-\lambda t}\frac{(\lambda t)^k}{k!}\left(e^{-nk+\lambda t(1-e^{-n})}-K\right)^+ = (1-Ke^{-\lambda t})^+.$$

We have shown that $\inf_{Q\in\mathcal{M}\cap\mathcal{L}} \|C_M - C^Q\|^2 = 0$ and that for no Lévy process $Q \in \mathcal{M}\cap\mathcal{L}$, $\|C_M - C^Q\|^2 = 0$. Thus the calibration problem (3.4) does not admit a solution.

Lack of continuity of solutions with respect to market data. Market option prices are typically defined up to a bid-ask spread and the prices used for calibration may therefore be subject to perturbations of this order. If the solution of the calibration problem is not continuous with respect to market data, these small errors may dramatically alter the result of calibration, rendering it useless. In addition, in absence of continuity small daily changes in prices could lead to large variations of calibrated parameters and of quantities computed using these parameters, such as prices of exotic options.

When the calibration problem has more than one solution, care should be taken in defining continuity. In what follows, we will use the following definition [7, 20].

DEFINITION 3.2 (continuity with respect to data). *The solutions of a calibration problem are said to depend continuously on input data at the point C_M if for every sequence of data sets $\{C_M^n\}_{n\geq 0}$ such that $\|C_M^n - C_M\|_w \xrightarrow[n\to\infty]{} 0$; if, for every n, Q_n is a solution of the calibration problem with data C_M^n, then*

1. *$\{Q_n\}_{n\geq 1}$ has a weakly convergent subsequence $\{Q_{n_m}\}_{m\geq 1}$.*
2. *The limit Q of every weakly convergent subsequence of $\{Q_n\}_{n\geq 1}$ is a solution of the calibration problem with data C_M.*

If the solution of the calibration problem with the limiting data C_M is unique, this definition reduces to the standard definition of continuity, because in this case every subsequence of $\{Q_n\}$ has a further subsequence converging towards Q, which implies $Q_n \Rightarrow Q$.

Remark 3.1. Note that the above definition can accommodate the presence of random errors ("noise") in the data. In this case the observational error can be described by a separate probability space $(\Omega_0, \mathcal{E}, p_0)$. The continuity property must then be interpreted as almost-sure continuity with respect to the law p_0 of the observational errors: for every (random) sequence $\{C_M^n\}_{n\geq 0}$ such that $\|C_M^n - C_M\|_w \xrightarrow[n\to\infty]{} 0$ almost surely, any sequence of solutions with data $\{C_M^n\}_{n\geq 0}$ must verify the properties of Definition 3.2 p_0-almost surely.

It is easy to construct an example of market data leading to a least squares calibration problem (3.4) that does not satisfy the above definition.

Example 3.2. Assume $S_0 = 1$, no interest rates or dividends, and observations given by a single option price:

$$C_M^n(T=1, K=1) = E[(e^{X_1^n} - 1)^+] \quad \text{for } n \geq 1 \quad \text{and} \quad C_M(T=1, K=1) = 1 - e^{-\lambda},$$

where X_t^n is defined by (3.6) and $\lambda > 0$. Then $\|C_M^n - C_M\|_w \xrightarrow[n\to\infty]{} 0$ and X_t^n is a solution for data C_M^n, but the sequence $\{X_t^n\}$ has no convergent subsequence (cf. Corollary VII.3.6 in [27]).

In addition to these theoretical obstacles, even if a solution exists, it may be difficult to compute numerically since, as shown in [14, 36], the pricing error $\|C_M - C^Q\|^2$ is typically nonconvex and can have many local minima, preventing a gradient-based minimization algorithm from finding the solution.

4. Relative entropy as a selection criterion. When constraints given by option prices do not determine the exponential Lévy model completely, additional information may be introduced into the problem by specifying a *prior model*: we start from a reference Lévy process P and look for the solution of the problem (3.4) that has the smallest relative entropy with respect to P. For two probabilities P and Q on the same measurable space $(\Omega, \mathcal{F})$, the relative entropy of Q with respect to P

is defined by

$$I(Q|P) = \begin{cases} E^P\left[\frac{dQ}{dP}\log\frac{dQ}{dP}\right] & \text{if } Q \ll P, \\ \infty & \text{otherwise,} \end{cases} \tag{4.1}$$

where by convention $x \log x = 0$ when $x = 0$. We define $I_T(Q|P) := I(Q|_{\mathcal{F}_T}|P|_{\mathcal{F}_T})$.

Problem 3 (minimum entropy least squares calibration problem). *Given prices C_M of call options and a prior Lévy process P, find a least squares solution $Q^* \in \mathrm{LSS}(C_M)$, such that*

$$I(Q^*|P) = \inf_{Q\in\mathrm{LSS}(C_M)} I(Q|P). \tag{4.2}$$

In what follows, any such Q^* will be called a minimum entropy least squares solution (MELSS) and the set of all such solutions will be denoted by $\mathrm{MELSS}(C_M)$.

P reflects a priori knowledge about the nature of possible trajectories of the underlying asset and their probabilities of occurrence. A natural choice of prior, ensuring absence of arbitrage in the calibrated model, is an exponential Lévy model estimated from the time series of returns. Whether this choice is adopted or not does not affect our discussion below. Other possible ways to choose the prior model in practice are discussed in [14], which also gives an empirical analysis of the effect of the choice of prior on the solution of the calibration problem.

The choice of relative entropy as a method for selection of solutions of the calibration problem is driven by the following considerations:

- Relative entropy can be interpreted as a (pseudo-)distance to the prior P: it is convex, nonnegative functional of Q for fixed P, and equal to zero if and only if $\frac{dQ}{dP} = 1$ P-a.s. To see this, observe that

$$E^P\left[\frac{dQ}{dP}\log\frac{dQ}{dP}\right] = E^P\left[\frac{dQ}{dP}\log\frac{dQ}{dP} - \frac{dQ}{dP} + 1\right],$$

  and that $z \log z - z + 1$ is a convex nonnegative function of z, equal to zero if and only if $z = 1$.
- Relative entropy for Lévy processes is easily expressed in terms of their characteristic triplets (see Theorem A.1).
- Relative entropy has an information-theoretic interpretation and has been repeatedly used for model selection in finance (see section 1).

Using relative entropy for the selection of solutions removes, to some extent, the identification problem of least squares calibration. Whereas in the least squares case this was an important nuisance, now, if two measures reproduce market option prices with the same precision and have the same entropy relative to the prior, this means that both measures are compatible with all the available information. Knowledge of many such probability measures instead of one may be seen as an advantage, because it allows us to estimate model risk and provide confidence intervals for the prices of exotic options [12]. However, the calibration problem (4.2) remains ill-posed: since the minimization of entropy is done over the results of least squares calibration, problem (4.2) may only admit a solution if problem (3.4) does. Also, $\mathrm{LSS}(C_M)$ is not necessarily a compact set, so even if it is nonempty, (4.2) may not have a solution. Other undesirable properties such as absence of continuity and numerical instability are also inherited from the least squares approach.

The MELSS does not always exist, but if the prior is chosen correctly such that (3.4) admits a solution with finite relative entropy with respect to the prior, then MELSSs will also exist.

LEMMA 4.1. *Let $P \in \mathcal{L}_{NA} \cap \mathcal{L}_B^+$ for some $B > 0$ and assume problem* (3.4) *admits a solution Q^+ with $I(Q^+|P) = C < \infty$. Then problem* (4.2) *admits a solution.*

Proof. Under the condition of the lemma, it is clear that the solution Q^* of problem (4.2), if it exists, satisfies $I(Q^*|P) \leq C$. This entails that $Q^* \ll P$, which means by Theorem IV.4.39 in [27] that $Q^* \in \mathcal{L}_B^+$. Therefore, Q^* belongs to the set

$$\mathcal{L}_B^+ \cap \{Q \in \mathcal{M} \cap \mathcal{L} : \|C^Q - C_M\| = \|C^{Q^+} - C_M\|\} \cap \{Q \in \mathcal{L} : I(Q|P) \leq C\}. \tag{4.3}$$

Lemma A.2 and the Prohorov's theorem entail that the level set $\{Q \in \mathcal{L} : I(Q|P) \leq C\}$ is relatively weakly compact. On the other hand, by Corollary A.4, $I(Q|P)$ is weakly lower semicontinuous with respect to Q for fixed P. Therefore, the set $\{Q \in \mathcal{P}(\Omega) : I(Q|P) \leq C\}$ is weakly closed, and since by Lemma 2.1 $\mathcal{M} \cap \mathcal{L}_B^+$ is also weakly closed, the set $\mathcal{M} \cap \mathcal{L}_B^+ \cap \{Q \in \mathcal{L} : I(Q|P) \leq C\}$ is weakly compact. Lemma 3.1 then implies that the set (4.3) is also weakly compact. Since $I(Q|P)$ is weakly lower semicontinuous, it reaches its minimum on this set. □

Remark 4.1. It is essential for our analysis that the model has discontinuous trajectories, i.e., the prior P corresponds to a process with jumps, not a diffusion process. If P corresponds to the law of a Markovian diffusion model, then the set of processes which have both the martingale property and finite entropy with respect to P is reduced to a single element and the solution to 4.2 is trivial (this follows, e.g., from Theorem IV.4.39 in [27]).

5. Regularization using relative entropy. As observed in [14] and in section 4, problem (4.2) is ill-posed and hard to solve numerically. In particular its solutions, when they exist, may not be stable with respect to perturbations of market data. If we do not know the prices C_M exactly but only dispose of observations C_M^δ with $||C_M^\delta - C_M||_w \leq \delta$ and want to construct an approximation to MELSS(C_M), it is not a good idea to solve problem (4.2) with the noisy data C_M^δ because MELSS(C_M^δ) may be very different from MELSS(C_M). We therefore need to regularize the problem (4.2), that is, construct a family of continuous "regularization operators" $\{R_\alpha\}_{\alpha>0}$, where α is the regularization parameter such that $R_\alpha(C_M^\delta)$ converges to an MELSS as the noise level δ tends to zero if an appropriate parameter choice rule $\delta \mapsto \alpha(\delta)$ is used [20]. The approximation to MELSS(C_M) using the noisy data C_M^δ is then given by $R_\alpha(C_M^\delta)$ with an appropriate choice of α.

Following a classical approach to regularization of ill-posed problems [20, 4], we regularize (4.2) by using the relative entropy as a penalization term:

$$J_\alpha(Q) = \|C_M^\delta - C^Q\|_w^2 + \alpha I(Q|P), \tag{5.1}$$

where α is the regularization parameter. We then solve the following optimization problem.

PROBLEM 4 (regularized calibration problem). *Given prices C_M of call options, a prior Lévy process P, and a regularization parameter $\alpha > 0$, find $Q^* \in \mathcal{M} \cap \mathcal{L}$ such that*

$$J_\alpha(Q^*) = \inf_{Q \in \mathcal{M} \cap \mathcal{L}} J_\alpha(Q). \tag{5.2}$$

Problem (5.2) can be thought of in two ways:

- If the MELSS with the true data C_M exists, (5.2) allows us to construct a stable approximation of this solution using the noisy data.
- If the MELSS$(C_M) = \emptyset$, either because the set of least squares solutions is empty or because the least squares solutions are incompatible with the prior, the regularized problem (5.2) allows us to achieve, in a stable manner, a trade-off between matching the constraints and the prior information.

In the rest of this section we study the regularized calibration problem. Under our standing hypothesis that the prior Lévy process has jumps bounded from above and corresponds to an arbitrage-free market ($P \in \mathcal{L}_{NA} \cap \mathcal{L}_B^+$), we show that the regularized calibration problem always admits a solution that depends continuously on the market data. In addition, we give a sufficient condition on the prior P for the solution to be an *equivalent* martingale measure and show how the regularization parameter α must be chosen depending on the noise level δ if the regularized solutions are to converge to the solutions of the minimum entropy least squares calibration problem (4.2).

5.1. Existence of solutions. The following result shows that, unlike the exact or the least squares formulations, the regularized inverse problem always admits a solution.

THEOREM 5.1. *Let $P \in \mathcal{L}_{NA} \cap \mathcal{L}_B^+$ for some $B > 0$. Then the calibration problem* (5.2) *has a solution $Q^* \in \mathcal{M} \cap \mathcal{L}_B^+$.*

Proof. By Lemma A.5, there exists $Q^0 \in \mathcal{M} \cap \mathcal{L}$ with $I(Q^0|P) < \infty$. The solution, if it exists, must belong to the level set $L_{J_\alpha(Q^0)} := \{Q \in \mathcal{L} : I(Q|P) \leq J_\alpha(Q^0)\}$. Since $J_\alpha(Q^0) = \|C_M - C^{Q^0}\|_w^2 + I(Q^0|P) < \infty$, by Lemma A.2 $L_{J_\alpha(Q^0)}$ is tight and, by Prohorov's theorem, weakly relatively compact. Corollary A.4 entails that $I(Q|P)$ is weakly lower semicontinuous with respect to Q. Therefore, $\{Q \in \mathcal{P}(\Omega) : I(Q|P) \leq J_\alpha(Q^0)\}$ is weakly closed, and since by Lemma 2.1 $\mathcal{M} \cap \mathcal{L}_B^+$ is weakly closed, $\mathcal{M} \cap \mathcal{L}_B^+ \cap L_{J_\alpha(Q^0)}$ is weakly compact. Moreover, by Lemma 3.1 the squared pricing error is weakly continuous, which entails that $J_\alpha(Q)$ is weakly lower semicontinuous. Therefore, $J_\alpha(Q)$ achieves its minimum value on $\mathcal{M} \cap \mathcal{L}_B^+ \cap L_{J_\alpha(Q^0)}$, which proves the theorem. □

Since $P \in \mathcal{L}_B^+$ (i.e., with jumps of X bounded from above P-a.s.), solutions Q are also in $\mathcal{L}_B^+$. This may seem a limitation if the data is generated by a Lévy process with jumps unbounded from above. This case is unlikely in financial applications; the form of Lévy densities found empirically in [14] gives little evidence for large upward jumps. Even in the theoretical case where the observed option prices are generated by an exponential-Lévy model with jumps unbounded from above, the localization estimates in [15, Proposition 4.2.] show that we can reproduce such prices with a Lévy process in $\mathcal{L}_B^+$ by choosing B large enough.

Since every solution Q^* of the regularized calibration problem (5.2) has finite relative entropy with respect to the prior P, necessarily $Q^* \ll P$. However, Q^* need not in general be equivalent to the prior. When the prior corresponds to the "objective" probability measure, absence of arbitrage is guaranteed if options are priced using an *equivalent* martingale measure [25]. The following theorem gives a sufficient condition for this equivalence.

THEOREM 5.2. *Let $P \in \mathcal{L}_{NA} \cap \mathcal{L}_B^+$ and assume the characteristic function Φ_T^P of P satisfies*

$$\int_{-\infty}^{\infty} |\Phi_T^P(u)| du < \infty \tag{5.3}$$

for some $T < T_0$, where T_0 is the shortest maturity, present in the market data. Then every solution Q^* of the calibration problem (5.2) *satisfies $Q^* \sim P$.*

Remark 5.1. Condition (5.3) implies that the prior Lévy process has a continuous density at time T and all subsequent times. Two important examples of processes satisfying the condition (5.3) for all T are

- processes with nonzero Gaussian component ($A > 0$).
- processes with stablelike behavior of small jumps, that is, processes whose Lévy measure satisfies

$$\exists \beta \in (0,2), \quad \liminf_{\varepsilon \downarrow 0} \varepsilon^{-\beta} \int_{-\varepsilon}^{\varepsilon} |x|^2 \nu(dx) > 0. \tag{5.4}$$

  For a proof, see [34, Proposition 28.3]. This class includes tempered stable processes [13] with $\alpha_+ > 0$ and/or $\alpha_- > 0$.

To prove Theorem 5.2 we will use the following lemma.

LEMMA 5.3. *Let $P \in \mathcal{M} \cap \mathcal{L}_B^+$ with characteristic triplet (A, ν, γ) and characteristic exponent ψ. There exists $C < \infty$ such that*

$$\left| \frac{\psi(v-i)}{(v-i)v} \right| \le C \quad \forall v \in \mathbb{R}.$$

Proof. From the Lévy–Khinchin formula and (2.3),

$$\psi(v-i) = -\frac{1}{2} A v (v-i) + \int_{-\infty}^{\infty} (e^{i(v-i)x} + iv - e^x - ive^x) \nu(dx). \tag{5.5}$$

Observe first that

$$e^{i(v-i)x} + iv - e^x - ive^x = iv(xe^x + 1 - e^x) + \frac{\theta v^2 x^2 e^x}{2} \quad \text{for some } \theta \text{ with } |\theta| \le 1.$$

Therefore, for all v with $|v| \ge 2$,

$$\left| \frac{e^{i(v-i)x} + iv - e^x - ive^x}{(v-i)v} \right| \le xe^x + 1 - e^x + x^2 e^x. \tag{5.6}$$

On the other hand,

$$\begin{aligned} \frac{e^{i(v-i)x} + iv - e^x - ive^x}{(v-i)v} &= \frac{ie^x(e^{ivx} - 1)}{v} - \frac{i(e^{i(v-i)x} - 1)}{v-i} \\ &= -xe^x - \frac{ivx^2}{2} e^{\theta_1 ivx} + x + \frac{i(v-i)x^2}{2} e^{\theta_2 i(v-i)x} \end{aligned}$$

with some $\theta_1, \theta_2 \in [0,1]$. Therefore, for all v with $|v| \le 2$,

$$\left| \frac{e^{i(v-i)x} + iv - e^x - ive^x}{(v-i)v} \right| \le x(1-e^x) + \frac{x^2}{2}(v + \sqrt{1+v^2} e^x) \le x(1-e^x) + x^2(1+2e^x). \tag{5.7}$$

Since the support of ν is bounded from above, the right-hand sides of (5.6) and (5.7) are ν-integrable and the proof of the lemma is completed. □

Proof of Theorem 5.2. Let Q^* be a solution of (5.2) with prior P. By Lemma A.5, there exists $Q^0 \in \mathcal{M} \cap \mathcal{L}$ such that $Q^0 \sim P$. Denote the characteristic triplet of Q^* by (A, ν^*, γ^*) and that of Q^0 by (A, ν^0, γ^0).

Let Q_x be a Lévy process with characteristic triplet $(A, x\nu^0 + (1-x)\nu^*, x\gamma^0 + (1-x)\gamma^*)$. From the linearity of the martingale condition (2.3), it follows that for all $x \in [0,1]$, $Q_x \in \mathcal{M} \cap \mathcal{L}$. Since Q^* realizes the minimum of $J_\alpha(Q)$, necessarily $J_\alpha(Q_x) - J_\alpha(Q^*) \geq 0$ for all $x \in [0,1]$. Our strategy for proving the theorem is first to show that $\frac{\|C_M - C^{Q_x}\|^2 - \|C_M - C^{Q^*}\|^2}{x}$ is bounded as $x \to 0$ and then to show that if $\frac{I(Q_x|P) - I(Q^*|P)}{x}$ is bounded from below as $x \to 0$, necessarily $Q^* \sim P$.

The first step is to prove that the characteristic function Φ^* of Q^* satisfies the condition (5.3) for some $T < T_0$. If $A > 0$, this is trivial. Assume that $A = 0$. In this case, $|\Phi^*_T(u)| = \exp(T\int_{-\infty}^{\infty}(\cos(ux)-1)\nu^*(dx))$. Denote $\frac{d\nu^*}{d\nu^P} := \phi^*$. Since $Q^* \ll P$, by Theorem IV.4.39 in [27], $\int_{-\infty}^{\infty}(\sqrt{\phi^*(x)}-1)^2\nu^P(dx) \leq K < \infty$ for some constant K. Therefore, there exists another constant $C > 0$ such that

$$\int_{\{\phi^*(x)>C\}} (1-\cos(ux))|\phi^* - 1|\nu^P(dx) < C$$

uniformly on u. For all $r > 0$,

$$\begin{aligned}\int_{-\infty}^{\infty}(1-\cos(ux))|\phi^*-1|\nu^P(dx) &\leq C + \int_{\{\phi^*(x)\leq C\}}(1-\cos(ux))|\phi^*-1|\nu^P(dx)\\ &\leq C + \frac{r}{2}\int_{\{\phi^*(x)\leq C\}}(1-\cos(ux))^2\nu^P(dx) + \frac{1}{2r}\int_{\{\phi^*(x)\leq C\}}(\phi^*-1)^2\nu^P(dx)\\ &\leq C + r\int_{-\infty}^{\infty}(1-\cos(ux))\nu^P(dx) + \frac{K(\sqrt{C}+1)^2}{2r}.\end{aligned}$$

This implies

$$\int_{-\infty}^{\infty}(\cos(ux)-1)\nu^*(dx) \leq (1+r)\int_{-\infty}^{\infty}(\cos(ux)-1)\nu^P(dx) + C + \frac{K(\sqrt{C}+1)^2}{2r}$$

for all $r > 0$. Therefore, if the characteristic function of P satisfies the condition (5.3) for some T, the characteristic function of Q^* will satisfy it for every $T' > T$.

Since $P \in \mathcal{L}_{NA} \cap \mathcal{L}^+_B$, $Q_x \in \mathcal{M} \cap \mathcal{L}^+_B$ for all $x \in [0,1]$. Therefore, condition (11.15) in [13] is satisfied and option prices can be computed using equation (11.20) of [13]:[2]

$$\begin{aligned}C^{Q_x}(T,K) &= (1 - Ke^{-rT})^+\\ &\quad + \frac{1}{2\pi}\int_{-\infty}^{\infty} e^{-iv\log K + ivrT}\frac{\exp(T(1-x)\psi^*(v-i) + Tx\psi^0(v-i)) - 1}{iv(1+iv)}dv,\end{aligned}$$

where ψ^0 and ψ^* denote the characteristic exponents of Q_0 and Q^*. It follows that

$$\begin{aligned}&\frac{C^{Q_x}(T,K) - C^{Q^*}(T,K)}{x}\\ &\qquad = \frac{1}{2\pi}\int_{-\infty}^{\infty} e^{-iv\log K + ivrT}\frac{e^{T(1-x)\psi^*(v-i) + Tx\psi^0(v-i)} - e^{T\psi^*(v-i)}}{iv(1+iv)x}dv.\end{aligned}$$

[2]This method for option pricing by Fourier transform is originally due to Carr and Madan [10].

Since $\Re\psi^0(v-i) \le 0$ and $\Re\psi^*(v-i) \le 0$ for all $v \in \mathbb{R}$, Lemma 5.3 implies

$$\left| e^{-iv\log K + ivrT} \frac{e^{T(1-x)\psi^*(v-i)+Tx\psi^0(v-i)} - e^{T\psi^*(v-i)}}{iv(1+iv)x} \right| \le T\frac{|e^{T(1-x)\psi^*(v-i)}||\psi^0(v-i)-\psi^*(v-i)|}{|v(1+iv)|} \le T|e^{T(1-x)\psi^*(v-i)}|C'$$

for some constant C'. From the dominated convergence theorem and since Q^* satisfies (5.3), $\frac{\partial C^{Q_x}(T,K)}{\partial x}|_{x=0}$ exists and is bounded uniformly on T and K in the market data set. This in turn means that $\frac{\|C_M - C^{Q_x}\|^2 - \|C_M - C^{Q^*}\|^2}{x}$ is bounded as $x \to 0$. To complete the proof, it remains to show that if $\frac{I(Q_x|P)-I(Q^*|P)}{x}$ is bounded from below as $x \to 0$, necessarily $Q^* \sim P$. Using the convexity (with respect to ν^Q and γ^Q) of the two terms in the expression (A.1) for relative entropy, we have

$$\begin{aligned}
&\frac{I(Q_x|P) - I(Q^*|P)}{x} \\
&= \frac{T_\infty}{2Ax}\left\{x\gamma^0 + (1-x)\gamma^* - \gamma^P - \int_{|z|\le 1} z(x\nu^0 + (1-x)\nu^* - \nu^P)(dz)\right\}^2 1_{A\neq 0} \\
&\quad - \frac{T_\infty}{2Ax}\left\{\gamma^* - \gamma^P - \int_{|z|\le 1} z(\nu^* - \nu^P)(dz)\right\}^2 1_{A\neq 0} \\
&\quad + \frac{T_\infty}{x}\int_{-\infty}^{\infty}\{(x\phi^0 + (1-x)\phi^*)\log(x\phi^0 + (1-x)\phi^*) - x\phi^0 - (1-x)\phi^* + 1\}\nu^P(dz) \\
&\quad - \frac{T_\infty}{x}\int_{-\infty}^{\infty}\{\phi^*\log(\phi^*) - \phi^* + 1\}\nu^P(dz) \\
&\le \frac{T_\infty}{2A}\left\{\gamma^0 - \gamma^P - \int_{|z|\le 1} z(\nu^0 - \nu^P)(dz)\right\}^2 1_{A\neq 0} \\
&\quad - \frac{T_\infty}{2A}\left\{\gamma^* - \gamma^P - \int_{|z|\le 1} z(\nu^* - \nu^P)(dz)\right\}^2 1_{A\neq 0} \\
&\quad + T_\infty\int_{\{\phi^*>0\}}\{\phi^0\log(\phi^0) - \phi^0 + 1\}\nu^P(dz) - T_\infty\int_{\{\phi^*>0\}}\{\phi^*\log(\phi^*) - \phi^* + 1\}\nu^P(dz) \\
&\quad + T_\infty\int_{\{\phi^*=0\}}\{\phi^0\log(x\phi^0) - \phi^0\}\nu^P(dz) \le I(Q_0|P) + T_\infty\int_{\{\phi^*=0\}}(\phi_0\log x - 1)\nu^P(dz).
\end{aligned}$$

Since $J_\alpha(Q_x) - J_\alpha(Q^*) \ge 0$, this expression must be bounded from below. Therefore, because $\phi_0 > 0$, necessarily $\nu^P(\{\phi^* = 0\}) = 0$ and Theorem IV.4.39 in [27] entails that $P \ll Q^*$. □

5.2. Continuity of solutions with respect to data.

THEOREM 5.4 (continuity of solutions with respect to data). *Let $\{C_M^n\}_{n\ge 1}$ and C_M be data sets of option prices such that*

$$\|C_M^n - C_M\|_w \underset{n\to\infty}{\to} 0.$$

Let $P \in \mathcal{L}_{NA} \cap \mathcal{L}_B^+$, $\alpha > 0$, and for each n let Q_n be a solution of the calibration problem (5.2) with data C_M^n, prior Lévy process P, and regularization parameter α.

Then $\{Q_n\}_{n\geq 1}$ has a subsequence converging weakly to $Q^* \in \mathcal{M} \cap \mathcal{L}_B^+$, and the limit of every converging subsequence of $\{Q_n\}_{n\geq 1}$ is a solution of calibration problem (5.2) *with data C_M, prior P, and regularization parameter α.*

Proof. By Lemma A.5, there exists $Q^0 \in \mathcal{M} \cap \mathcal{L}$ with $I(Q^0|P) < \infty$. Since, by Lemma 3.1, $\|C^{Q^0} - C_M^n\|^2 \leq S_0^2$ for all n, $\alpha I(Q_n|P) \leq S_0^2 + \alpha I(Q^0|P)$ for all n. Therefore, by Lemmas 2.1 and A.2 and Prohorov's theorem, $\{Q_n\}_{n\geq 1}$ is weakly relatively compact. Together with Lemma 2.1 this proves the first part of the theorem. □

Choose any subsequence of $\{Q_n\}_{n\geq 1}$ converging weakly to $Q^* \in \mathcal{M} \cap \mathcal{L}_B^+$. To simplify notation, this subsequence is denoted again by $\{Q_n\}_{n\geq 1}$. The triangle inequality and Lemma 3.1 imply that

$$\|C^{Q_n} - C_M^n\|^2 \xrightarrow[n\to\infty]{} \|C^{Q^*} - C_M\|^2. \tag{5.8}$$

Since, by Lemma A.3, the relative entropy functional is weakly lower semicontinuous with respect to Q, for every $Q \in \mathcal{M} \cap \mathcal{L}_B^+$,

$$\begin{aligned}
\|C^{Q^*} - C_M\|^2 + \alpha I(Q^*|P) &\leq \liminf_n \{\|C^{Q_n} - C_M^n\|^2 + \alpha I(Q_n|P)\} \\
&\leq \liminf_n \{\|C^{Q} - C_M^n\|^2 + \alpha I(Q|P)\} \\
&= \lim_n \|C^{Q} - C_M^n\|^2 + \alpha I(Q|P) \\
&= \|C^{Q} - C_M\|^2 + \alpha I(Q|P),
\end{aligned}$$

where the second inequality follows from the fact that Q_n is the solution of the calibration problem with data C_M^n and the last line follows from the triangle inequality.

5.3. Convergence to MELSSs. The convergence analysis of regularization methods for inverse problems usually involves the study of the solution of the regularized problem as the noise level δ vanishes, the regularization parameter being chosen as a function $\alpha(\delta)$ of the noise level using some parameter choice rule. The following result gives conditions on the parameter choice rule $\delta \mapsto \alpha(\delta)$ under which the solutions of the regularized problem (5.2) converge to MELSSs defined by (4.2).

THEOREM 5.5. *Let $\{C_M^\delta\}$ be a family of data sets of option prices such that $\|C_M - C_M^\delta\| \leq \delta$, let $P \in \mathcal{L}_{NA} \cap \mathcal{L}_B^+$, and assume there exists a solution Q of problem* (3.4) *with data C_M (a least squares solution) such that $I(Q|P) < \infty$.*

In the case where the constraints are attainable, i.e., $\|C^Q - C_M\| = 0$, let $\alpha(\delta)$ be such that $\alpha(\delta) \to 0$ and $\frac{\delta^2}{\alpha(\delta)} \to 0$ as $\delta \to 0$. Otherwise, let $\alpha(\delta)$ be such that $\alpha(\delta) \to 0$ and $\frac{\delta}{\alpha(\delta)} \to 0$ as $\delta \to 0$.

Then every sequence $\{Q^{\delta_k}\}$, where $\delta_k \to 0$ and Q^{δ_k} is a solution of problem (5.2) *with data $C_M^{\delta_k}$, prior P, and regularization parameter $\alpha(\delta_k)$, has a weakly convergent subsequence. The limit of every convergent subsequence is a solution of problem* (4.2) *with data C_M and prior P. If the MELSS is unique (MELSS$(C_M) = \{Q^+\}$), then*

$$Q^\delta \underset{\delta\to 0}{\Rightarrow} Q^+.$$

Proof. By Lemma 4.1, there exists at least one MELSS with data C_M and prior P, with finite relative entropy with respect to the prior. Let $Q^+ \in \text{MELSS}(C_M)$. Since Q^{δ_k} is the solution of the regularized problem, for every k,

$$\|C^{Q^{\delta_k}} - C_M^{\delta_k}\|^2 + \alpha(\delta_k) I(Q^{\delta_k}|P) \leq \|C^{Q^+} - C_M^{\delta_k}\|^2 + \alpha(\delta_k) I(Q^+|P).$$

Using the fact that for every $r > 0$ and for every $x, y \in \mathbb{R}$,

$$(1-r)x^2 + (1-1/r)y^2 \le (x+y)^2 \le (1+r)x^2 + (1+1/r)y^2,$$

we obtain that

$$(1-r)\|C^{Q^{\delta_k}} - C_M\|^2 + \alpha(\delta_k) I(Q^{\delta_k}|P) \le (1+r)\|C^{Q^+} - C_M\|^2 + \frac{2\delta_k^2}{r} + \alpha(\delta_k) I(Q^+|P), \tag{5.9}$$

and since $Q^+ \in \mathrm{LSS}(C_M)$, this implies for all $r \in (0,1)$ that

$$\alpha(\delta_k) I(Q^{\delta_k}|P) \le 2r\|C^{Q^+} - C_M\|^2 + \frac{2\delta_k^2}{r} + \alpha(\delta_k) I(Q^+|P). \tag{5.10}$$

If the constraints are met exactly, $\|C^{Q^+} - C_M\| = 0$, and with the choice $r = 1/2$, the above expression yields

$$I(Q^{\delta_k}|P) \le \frac{4\delta_k^2}{\alpha(\delta_k)} + I(Q^+|P).$$

Since, by the theorem's statement, in the case of exact constraints $\frac{\delta_k^2}{\alpha(\delta_k)} \to 0$, this implies

$$\limsup_k \{I(Q^{\delta_k}|P)\} \le I(Q^+|P). \tag{5.11}$$

If $\|C^{Q^+} - C_M\| > 0$ (misspecified model), then the right-hand side of (5.10) achieves its maximum when $r = \delta_k \|C^{Q^+} - C_M\|^{-1}$, in which case we obtain

$$I(Q^{\delta_k}|P) \le \frac{4\delta_k}{\alpha(\delta_k)}\|C^{Q^+} - C_M\| + I(Q^+|P).$$

Since in the case of approximate constraints $\frac{\delta_k}{\alpha(\delta_k)} \to 0$, we obtain (5.11) once again.

Inequality (5.11) implies in particular that $I(Q^{\delta_k}|P)$ is uniformly bounded, which proves, by Lemmas A.2 and 2.1, that $\{Q^{\delta_k}\}$ is relatively weakly compact in $\mathcal{M} \cap \mathcal{L}_B^+$.

Choose a subsequence of $\{Q^{\delta_k}\}$ converging weakly to $Q^* \in \mathcal{M} \cap \mathcal{L}_B^+$. To simplify notation, this subsequence is denoted again by $\{Q^{\delta_k}\}_{k \ge 1}$. Substituting $r = \delta$ into (5.9) and making k tend to infinity shows that

$$\limsup_k \|C^{Q^{\delta_k}} - C_M\|^2 \le \|C^{Q^+} - C_M\|^2.$$

Together with Lemma 3.1 this implies that

$$\|C^{Q^*} - C_M\|^2 \le \|C^{Q^+} - C_M\|^2;$$

hence Q^* is a least squares solution. By weak lower semicontinuity of I (cf. Lemma A.3) and using (5.11),

$$I(Q^*|P) \le \liminf_k I(Q^{\delta_k}|P) \le \limsup_k I(Q^{\delta_k}|P) \le I(Q^+|P),$$

which means that $Q^* \in \text{MELSS}(C_M)$. The last assertion of the theorem follows from the fact that in this case every subsequence of $\{Q^{\delta_k}\}$ has a further subsequence converging toward Q^+. □

Remark 5.2 (random errors). In line with Remark 3.1, it is irrelevant whether the noise in the data is "deterministic" or "random," as long the error level δ is interpreted as a worst-case error level, i.e., an almost-sure bound on the error:

$$\mathbb{P}_0(||C_M^\delta - C_M|| \le \delta) = 1. \tag{5.12}$$

In this case, Theorem 5.5 holds for random errors, convergence being interpreted as almost-sure convergence with respect to the law $\mathbb{P}_0$ of the errors.

6. Stability with respect to the prior. If we choose a prior Lévy process P with a finite number of jump sizes (sometimes called *simple* Lévy processes),

$$\nu^P = \sum_{k=0}^{M-1} p_k \delta_{\{x_k\}}(dx), \tag{6.1}$$

then the solution Q satisfies $Q \ll P$ by Theorem IV.4.39 in [27]. Thus the corresponding Lévy measure ν^Q satisfies $\nu^Q \ll \nu^P$ and is of the form

$$\nu^Q = \sum_{k=0}^{M-1} q_k \delta_{\{x_k\}}(dx). \tag{6.2}$$

The calibration problem (5.2) is then a finite-dimensional optimization problem and can be solved using a numerical optimization algorithm [14]. The advantage of this method is that we are simply solving (5.2) with a specific choice of prior, so all results of section 5 hold. Numerical methods for solving this problem are discussed in the companion paper [14]. Here we will complement these results by a theorem showing that the solution of a calibration problem with any prior can be approximated (in the weak sense) by a sequence of solutions of calibration problems with simple Lévy processes as priors. We start by showing that every Lévy process can be approximated by simple Lévy processes of the form (6.1).

LEMMA 6.1. *Let P be a Lévy process with characteristic triplet (A, ν, γ) with respect to a continuous truncation function h; for every n, let P_n be a Lévy process with characteristic triplet (A, ν_n, γ) (with respect to h), where*

$$\nu_n := \sum_{k=1}^{2n} \delta_{\{x_k\}}(dx) \frac{\mu([x_k - 1/\sqrt{n}, x_k + 1/\sqrt{n}))}{1 \wedge x_k^2},$$

$x_k := (2(k-n)-1)/\sqrt{n}$, and μ is a (positive and finite) measure on $\mathbb{R}$, defined by $\mu(B) := \int_B (1 \wedge x^2)\nu(dx)$ for all $B \in \mathcal{B}(\mathbb{R})$. Then $P_n \Rightarrow P$.

Proof. For a function $f \in C_b(\mathbb{R})$, define

$$f_n(x) := \begin{cases} 0, & x \ge 2\sqrt{n}, \\ 0, & x < -2\sqrt{n}, \\ f(x_i), & x \in [x_i - 1/\sqrt{n}, x_i + 1/\sqrt{n}) \quad \text{with } 1 \le i \le 2n. \end{cases}$$

Then $\int (1 \wedge x^2) f(x) \nu_n(dx) = \int f_n(x)\mu(dx)$. Since $f(x)$ is continuous, $f_n(x) \xrightarrow{n\to\infty} f(x)$ for all x and since f is bounded, the dominated convergence theorem implies

$$\lim_n \int (1 \wedge x^2) f(x) \nu_n(dx) = \lim_n \int f_n(x)\mu(dx) = \int (1 \wedge x^2) f(x)\nu(dx). \tag{6.3}$$

With $f(x) \equiv \frac{h^2(x)}{1 \wedge x^2}$ the above yields

$$\int h^2(x)\nu_n(dx) \overset{n\to\infty}{\to} \int h^2(x)\nu(dx).$$

On the other hand, for every $g \in C_b(\mathbb{R})$ such that $g(x) \equiv 0$ on a neighborhood of 0, $f(x) := \frac{g(x)}{1\wedge x^2}$ belongs to $C_b(\mathbb{R})$. Therefore, from (6.3), $\lim_n \int g(x)\nu_n(dx) = \int g(x)\nu(dx)$ and by Corollary VII.3.6 in [27], $P_n \Rightarrow P$. □

To compute numerically the solution of the calibration problem (5.2) with a given prior P, we can construct, using Lemma 6.1, an approximating sequence $\{P_n\}$ of simple Lévy processes such that $P_n \Rightarrow P$. Problem (5.2) with P replaced by P_n is then a finite-dimensional optimization problem that can be solved. The resulting sequence $\{Q_n\}$ of solutions will converge, as shown in the following theorem, to a solution of the calibration problem with prior P.

THEOREM 6.2. *Let $P, \{P_n\}_{n\geq 1} \subset \mathcal{L}_{NA} \cap \mathcal{L}_B^+$ such that $P_n \Rightarrow P$. Let $\alpha > 0$, let C_M be a data set of option prices, and for each $n \geq 1$ let Q_n be a solution of the calibration problem* (5.2) *with prior P_n, regularization parameter α, and data C_M. Denote the characteristic triplet (with respect to a continuous truncation function h) of P_n by $(A_n, \nu_n^P, \gamma_n^P)$ and that of P by (A, ν^P, γ^P). If $A_n \to A > 0$, then the sequence $\{Q_n\}_{n\geq 1}$ has a weakly convergent subsequence and the limit of every weakly convergent subsequence of $\{Q_n\}_{n\geq 1}$ is a solution of the calibration problem* (5.2) *with prior P.*

Proof. By Lemma A.5, there exists $C < \infty$ such that for every n one can find $\tilde{Q}_n \in \mathcal{M} \cap \mathcal{L}$ with $I(\tilde{Q}_n|P_n) \leq C$. Since $\|C^{\tilde{Q}_n} - C_M\|_w^2 \leq S_0^2$ for every n and Q_n is the solution of the calibration problem, $I(Q_n|P_n) \leq S_0^2/\alpha + C < \infty$ for every n. Therefore, by Lemma A.2, $\{Q_n\}$ is tight and, by Prohorov's theorem and Lemma 2.1, weakly relatively compact in $\mathcal{M} \cap \mathcal{L}_B^+$. Choose a subsequence of $\{Q_n\}$ converging weakly to $Q \in \mathcal{M} \cap \mathcal{L}_B^+$. To simplify notation, this subsequence is also denoted by $\{Q_n\}_{n\geq 1}$. It remains to show that Q is indeed a solution of (5.2). We can parameterize the characteristic triplet of any $Q^\phi \in \mathcal{M} \cap \mathcal{L}$ with $I(Q|P) < \infty$ as

$$\left(A, \phi\nu^P, \gamma^\phi := -\frac{A}{2} - \int_{-\infty}^{\infty} (e^x - 1 - h(x))\phi\nu^P(dx)\right),$$

where $\phi \in L^1(\ (|x|^2 \wedge 1)\nu^P(dx)\ )$, $\phi \geq 0$. To prove that Q is a solution of (5.2), we need to establish that

$$\|C^Q - C_M\|_w^2 + \alpha I(Q, P) \leq \|C^{Q^\phi} - C_M\|_w^2 + \alpha I(Q^\phi|P). \tag{6.4}$$

This will be shown in three steps.

Step 1. Let $C_b^{(k)}(\mathbb{R})$ denote the set of continuous bounded functions $\phi : \mathbb{R} \to \mathbb{R}$ equal to k on some neighborhood of 0: for each $\phi \in C_b^{(k)}(\mathbb{R})$ there exists $\delta > 0$ with $\phi(x) = k$ for all $x : |x| < \delta$. The first step is to prove (6.4) for every $\phi \in C_b^{(1)}$. Choose one such ϕ and let Q_n^ϕ denote an element of $\mathcal{M} \cap \mathcal{L}$ with triplet

$$\left(A_n, \phi\nu_n^P, \gamma_n^\phi := -\frac{A_n}{2} - \int_{-\infty}^{\infty} (e^x - 1 - h(x))\phi\nu_n^P(dx)\right).$$

Corollary VII.3.6 in [27] and the fact that $P_n \Rightarrow P$ imply that $Q_n^\phi \Rightarrow Q^\phi$, and therefore by Lemma 3.1,

$$\lim_n \|C^{Q_n^\phi} - C_M\|_w^2 = \|C^{Q^\phi} - C_M\|_w^2.$$

Moreover, $\phi \log \phi + 1 - \phi \in C_b^{(0)}(\mathbb{R})$ and $h(\phi - 1) \in C_b^{(0)}(\mathbb{R})$. Therefore, using once again Corollary VII.3.6 in [27], we obtain (here, we use the hypothesis $\lim A_n = A > 0$)

$$\lim_n I(Q_n^\phi | P_n) = \lim_n \frac{T_\infty}{2A_n} \left\{ \gamma_n^\phi - \gamma_n^P - \int_{-\infty}^{\infty} h(x)(\phi - 1)\nu_n^P(dx) \right\}^2 1_{A_n \neq 0} + \lim_n T_\infty \int_{-\infty}^{\infty} (\phi \log \phi + 1 - \phi)\nu_n^P(dx) = I(Q^\phi | P).$$

Lemma A.3 entails that

$$I(Q, P) \leq \liminf_n I(Q_n, P_n), \tag{6.5}$$

and since, by Lemma 3.1, the pricing error is weakly continuous, we have, using the optimality of Q_n,

$$\begin{aligned} \|C^Q - C_M\|_w^2 + \alpha I(Q, P) &\leq \liminf_n \{\|C^{Q_n} - C_M\|_w^2 + \alpha I(Q_n, P_n)\} \\ &\leq \liminf_n \{\|C^{Q_n^\phi} - C_M\|_w^2 + \alpha I(Q_n^\phi, P_n)\} = \|C^{Q^\phi} - C_M\|_w^2 + \alpha I(Q^\phi, P). \end{aligned} \tag{6.6}$$

This proves (6.4) for all $\phi \in C_b^{(1)}(\mathbb{R})$.

Step 2. Let $\phi \in L^1((|x|^2 \wedge 1)\nu^P)$ such that $\phi \geq 0$ and $|\phi(x) - 1| \leq C(|x| \wedge 1)$ for every $x \in \mathbb{R}$. Then there exists a sequence $\{\phi_n\} \subset C_b^{(1)}(\mathbb{R})$ such that $\phi_n \to \phi$ ν^P-a.e. and $|\phi_n(x) - 1| \leq C(|x| \wedge 1)$ for every n and every $x \in \mathbb{R}$. Then by Step 1,

$$\|C^Q - C_M\|_w^2 + \alpha I(Q, P) \leq \|C^{Q^{\phi_n}} - C_M\|_w^2 + \alpha I(Q^{\phi_n}, P) \quad \forall n. \tag{6.7}$$

Using the dominated convergence theorem and Corollary VII.3.6 in [27] yields that $Q^{\phi_n} \Rightarrow Q^\phi$. Since $|h(x)(\phi_n - 1)| \leq Ch(x)(|x| \wedge 1)$ and

$$\phi_n \log \phi_n + 1 - \phi_n \leq (\phi_n - 1)^2 \leq C^2(|x|^2 \wedge 1),$$

the dominated convergence theorem yields

$$\lim_n I(Q^{\phi_n} | P_n) = \lim_n \frac{T_\infty}{2A} \left\{ \gamma^{\phi_n} - \gamma^P - \int_{-\infty}^{\infty} h(x)(\phi_n - 1)\nu^P(dx) \right\}^2 1_{A \neq 0} + \lim_n T_\infty \int_{-\infty}^{\infty} (\phi_n \log \phi_n + 1 - \phi_n)\nu^P(dx) = I(Q^\phi | P).$$

Therefore, by passing to the limit $n \to \infty$ in (6.7), we obtain that (6.4) holds for every $\phi \in L^1((|x|^2 \wedge 1)\nu^P)$ such that $\phi \geq 0$ and $|\phi(x) - 1| \leq C(|x| \wedge 1)$.

Step 3. Let us now choose a nonnegative $\phi \in L^1((|x|^2 \wedge 1)\nu^P)$. Without loss of generality, we can assume $I(Q^\phi | P) < \infty$. Let

$$\phi_n(x) = \begin{cases} 1 - n(|x| \wedge 1), & \phi(x) < 1 - n(|x| \wedge 1), \\ 1 + n(|x| \wedge 1), & \phi(x) > 1 + n(|x| \wedge 1), \\ \phi(x) & \text{otherwise.} \end{cases}$$

Then $\phi_n \leq \phi \vee 1$ and, once again, the dominated convergence theorem and Corollary VII.3.6 in [27] entail that $Q^{\phi_n} \Rightarrow Q^\phi$. Since $|h(x)(\phi_n - 1)| \leq |h(x)(\phi - 1)|$ and $\phi_n \log \phi_n + 1 - \phi_n \leq \phi \log \phi + 1 - \phi$, again by dominated convergence we obtain that

$\lim_n I(Q^{\phi_n}|P_n) = I(Q^\phi|P)$ and by passage to the limit $n \to \infty$ in (6.7), (6.4) holds for all $\phi \in L^1((|x|^2 \wedge 1)\nu^P)$ with $\phi \geq 0$, which completes the proof of the theorem. □

Another implication of the above theorem is that small changes in the prior Lévy process lead to small changes in the solution: the solution is not very sensitive to minor errors in the determination of the prior measure. This result confirms the empirical observations made in [14].

7. Conclusion. We have proposed here a stable method for constructing an option pricing model of exponential Lévy type, consistent with a given data set of option prices. Our approach is based on the regularization of the calibration problem using the relative entropy with respect to a prior exp-Lévy model as penalization term. The regularization restores existence and stability of solutions; the use of relative entropy links our approach to previous work using relative entropy as a criterion for selection of pricing rules. This technique is readily amenable to numerical implementation, as shown in [14], where empirical applications to financial data are also discussed.

The problem studied here is an example of regularization of a nonlinear, infinite-dimensional inverse problem with noisy data. The above results may also be useful for other nonlinear inverse problems where positivity constraints on the unknown parameter make regularization by relative entropy suitable.

Finally, although we have considered the setting of Lévy processes, this approach can also be adapted to other models with jumps—such as stochastic volatility models with jumps (see [13, Chapter 15] for a review)—where the jump structure is described by a Lévy measure to be retrieved from observations.

Appendix A. Relative entropy for Lévy processes. In this appendix we explicitly compute the relative entropy of two Lévy processes in terms of their characteristic triplets and establish some properties of the relative entropy viewed as a functional on Lévy processes. Under additional assumptions the relative entropy of two Lévy processes was computed in [11] in the case where Q is equivalent to P and the Lévy process has finite exponential moments under P and in [30] in the case where $\log \frac{d\nu^Q}{d\nu^P}$ is bounded. We give here an elementary proof valid for all Lévy processes.

THEOREM A.1 (relative entropy of Lévy processes). *Let $\{X_t\}_{t\geq 0}$ be a real-valued Lévy process on $(\Omega, \mathcal{F}, Q)$ and on $(\Omega, \mathcal{F}, P)$ with respective characteristic triplets (A_Q, ν_Q, γ_Q) and (A_P, ν_P, γ_P). Suppose that $Q \ll P$ (by Theorem* IV.4.39 *in* [27], *this implies that $A^Q = A^P$ and $\nu^Q \ll \nu^P$) and denote $A := A_Q = A_P$. Then for every time horizon $T \leq T_\infty$ the relative entropy of $Q|_{\mathcal{F}_T}$ with respect to $P|_{\mathcal{F}_T}$ can be computed as follows:*

$$I_T(Q|P) = I(Q|_{\mathcal{F}_T}|P|_{\mathcal{F}_T}) = \frac{T}{2A}\left\{\gamma^Q - \gamma^P - \int_{-1}^{1} x(\nu^Q - \nu^P)(dx)\right\}^2 1_{A\neq 0} + T\int_{-\infty}^{\infty}\left(\frac{d\nu^Q}{d\nu^P}\log\frac{d\nu^Q}{d\nu^P} + 1 - \frac{d\nu^Q}{d\nu^P}\right)\nu^P(dx). \tag{A.1}$$

Proof. Let $\{X_t^c\}_{t\geq 0}$ be the continuous martingale part of X under P (a Brownian motion), μ be the jump measure of X, and $\phi := \frac{d\nu^Q}{d\nu^P}$. From [27, Theorem III.5.19], the density process $Z_t := \frac{dQ|_{\mathcal{F}_t}}{dP|_{\mathcal{F}_t}}$ is the Doléans-Dade exponential of the Lévy process $\{N_t\}_{t\geq 0}$ defined by

$$N_t := \beta X_t^c + \int_{[0,t]\times\mathbb{R}} (\phi(x) - 1)\{\mu(ds \times dx) - ds\, \nu^P(dx)\},$$

where β is given by

$$\beta = \begin{cases} \frac{1}{A}\{\gamma^Q - \gamma^P - \int_{|x|\le 1} x(\phi(x)-1)\nu^P(dx)\} & \text{if } A > 0, \\ 0 & \text{otherwise.} \end{cases}$$

Choose $0 < \varepsilon < 1$ and let $I := \{x : \varepsilon \le \phi(x) \le \varepsilon^{-1}\}$. We split N_t into two independent martingales:

$$N'_t := \beta X^c_t + \int_{[0,t]\times I} (\phi(x)-1)\{\mu(ds\times dx) - ds\,\nu^P(dx)\} \quad \text{and}$$

$$N''_t := \int_{[0,t]\times(\mathbb{R}\setminus I)} (\phi(x)-1)\{\mu(ds\times dx) - ds\,\nu^P(dx)\}.$$

Since N' and N'' never jump together, $[N', N'']_t = 0$ and $\mathcal{E}(N'+N'')_t = \mathcal{E}(N')_t\mathcal{E}(N'')_t$ (cf. equation II.8.19 in [27]). Moreover, since N' and N'' are Lévy processes and martingales, their stochastic exponentials are also martingales (Proposition 8.23 in [13]). Therefore,

$$\begin{aligned} I_T(Q|P) &= E^P[Z_T \log Z_T] \\ &= E^P[\mathcal{E}(N')_T\mathcal{E}(N'')_T \log \mathcal{E}(N')_T] + E^P[\mathcal{E}(N')_T\mathcal{E}(N'')_T \log \mathcal{E}(N'')_T] \\ &= E^P[\mathcal{E}(N')_T \log \mathcal{E}(N')_T] + E^P[\mathcal{E}(N'')_T \log \mathcal{E}(N'')_T] \end{aligned} \tag{A.2}$$

if these expectations exist.

Since $\Delta N'_t > -1$ a.s., $\mathcal{E}(N')_t$ is almost surely positive. Therefore, from Lemma 5.8 in [23], $U_t := \log \mathcal{E}(N')_t$ is a Lévy process with the following characteristic triplet:

$$\begin{aligned} A^U &= \beta^2 A, \\ \nu^U(B) &= \nu^P(I \cap \{x : \log\phi(x) \in B\})\ \forall B \in \mathcal{B}(\mathbb{R}), \\ \gamma^U &= -\frac{\beta^2 A}{2} - \int_{-\infty}^{\infty} (e^x - 1 - x1_{|x|\le 1})\nu^U(dx). \end{aligned}$$

This implies that U has bounded jumps and all exponential moments. Therefore, $E[U_T e^{U_T}] < \infty$ and can be computed as follows:

$$\begin{aligned} E^P[U_T e^{U_T}] &= -i\frac{d}{dz}E^P[e^{izU_T}]|_{z=-i} = -iT\psi'(-i)E^P[e^{U_T}] = -iT\psi'(-i) \\ &= T\left(A^U + \gamma^U + \int_{-\infty}^{\infty}(xe^x - x1_{|x|\le 1})\nu^U(dx)\right) \\ &= \frac{\beta^2 AT}{2} + T\int_I (\phi(x)\log\phi(x) + 1 - \phi(x))\nu^P(dx). \end{aligned} \tag{A.3}$$

It remains to compute $E^P[\mathcal{E}(N'')_T \log \mathcal{E}(N'')_T]$. Since N'' is a compound Poisson process, $\mathcal{E}(N'')_t = e^{bt}\prod_{s\le t}(1+\Delta N''_s)$, where $b = \int_{\mathbb{R}\setminus I}(1-\phi(x))\nu^P(dx)$. Let ν'' be the Lévy measure of N'' and λ its jump intensity. Then

$$\mathcal{E}(N'')_T \log \mathcal{E}(N'')_T = bT\mathcal{E}(N'')_T + e^{bT}\prod_{s\le T}(1+\Delta N''_s)\sum_{s\le T}\log(1+\Delta N''_s)$$

and

$$\begin{aligned} &E^P[\mathcal{E}(N'')_T \log \mathcal{E}(N'')_T] \\ &\quad = bT + e^{bT}\sum_{k=0}^{\infty} e^{-\lambda T}\frac{(\lambda T)^k}{k!} E\left[\prod_{s\le T}(1+\Delta N''_s)\sum_{s\le T}\log(1+\Delta N''_s) | k \text{ jumps}\right]. \end{aligned}$$

Since, under the condition that N'' jumps exactly k times in the interval $[0,T]$, the jump sizes are independent and identically distributed, we find, denoting the generic jump size by $\Delta N''$,

$$\begin{aligned}
&E^P[\mathcal{E}(N'')_T \log \mathcal{E}(N'')_T] \\
&\quad = bT + e^{bT} \sum_{k=0}^{\infty} e^{-\lambda T} \frac{(\lambda T)^k}{k!} k E[1+\Delta N'']^{k-1} E[(1+\Delta N'')\log(1+\Delta N'')] \\
&\quad = bT + \lambda T E[(1+\Delta N'')\log(1+\Delta N'')] \\
&\quad = bT + T\int_{-\infty}^{\infty} (1+x)\log(1+x)\nu''(dx) \\
&\quad = T\int_{\mathbb{R}\setminus I} (\phi(x)\log\phi(x) + 1 - \phi(x))\nu^P(dx).
\end{aligned}$$

In particular, $E^P[\mathcal{E}(N'')_T \log \mathcal{E}(N'')_T]$ is finite if and only if the integral in the last line is finite. Combining the above expression with (A.3) and (A.2) finishes the proof. □

LEMMA A.2. *Let $P, \{P_n\}_{n\geq 1} \subset \mathcal{L}_B^+$ for some $B > 0$, such that $P_n \Rightarrow P$. Then for every $r > 0$, the level set $L_r := \{Q \in \mathcal{L} : I(Q|P_n) \leq r \text{ for some } n\}$ is tight.*

Proof. For every $Q \in L_r$, choose any element of $\{P_n\}_{n\geq 1}$ for which $I(Q|P_Q) \leq r$ and denote it by P_Q. The characteristic triplet of Q is denoted by (A^Q, ν^Q, γ^Q) and that of P_Q by $(A^{P_Q}, \nu^{P_Q}, \gamma^{P_Q})$. In addition, we define $\phi^Q := \frac{d\nu^Q}{d\nu^{P_Q}}$. From Theorem A.1,

$$\int_{-\infty}^{\infty} (\phi^Q(x)\log\phi^Q(x) + 1 - \phi^Q(x))\nu^{P_Q}(dx) \leq r/T_\infty.$$

Therefore, for u sufficiently large,

$$\int_{\{\phi^Q > u\}} \phi^Q \nu^{P_Q}(dx) \leq \int_{\{\phi^Q > u\}} \frac{2\phi^Q[\phi^Q\log\phi^Q + 1 - \phi^Q]\nu^{P_Q}(dx)}{\phi^Q\log\phi^Q} \leq \frac{2r}{T_\infty \log u},$$

which entails that for u sufficiently large,

$$\int_{\{\phi^Q > u\}} \nu^Q(dx) \leq \frac{2r}{T_\infty \log u}$$

uniformly with respect to $Q \in L_r$. Let $\varepsilon > 0$ and choose u such that $\int_{\{\phi^Q>u\}} \nu^Q(dx) \leq \varepsilon/2$ for every $Q \in L_r$. By Corollary VII.3.6 in [27],

$$\int_{-\infty}^{\infty} f(x)\nu^{P_n}(dx) \to \int_{-\infty}^{\infty} f(x)\nu^P(dx)$$

for every continuous bounded function f that is identically zero on a neighborhood of zero. Since the measures ν^P and ν^{P_n} for all $n \geq 1$ are finite outside a neighborhood of zero and $P_n \Rightarrow P$, we can choose a compact K such that $\nu^{P_n}(\mathbb{R}\setminus K) \leq \varepsilon/2u$ for every n. Then

$$\nu^Q(\mathbb{R}\setminus K) = \int_{(\mathbb{R}\setminus K)\cap\{\phi^Q\leq u\}} \phi^Q\nu^{P_Q}(dx) + \int_{(\mathbb{R}\setminus K)\cap\{\phi^Q>u\}} \nu^Q(dx) \leq \varepsilon. \tag{A.4}$$

It is easy to check by computing derivatives that for every $u > 0$, on the set $\{x : \phi^Q(x) \leq u\}$,

$$(\phi^Q - 1)^2 \leq 2u(\phi^Q\log\phi^Q + 1 - \phi^Q).$$

Therefore, for u sufficiently large and for all $Q \in L_r$,

$$\begin{aligned}
&\left|\int_{|x|\le 1} x(\phi^Q - 1)\nu^{P_Q}(dx)\right| \\
&\quad\le \left|\int_{|x|\le 1,\ \phi^Q \le u} x(\phi^Q - 1)\nu^{P_Q}(dx)\right| + \left|\int_{|x|\le 1,\ \phi^Q > u} x(\phi^Q - 1)\nu^{P_Q}(dx)\right| \\
&\quad\le \int_{|x|\le 1} x^2\nu^{P_Q}(dx) + \int_{|x|\le 1,\ \phi^Q \le u} (\phi^Q - 1)^2\nu^{P_Q}(dx) + 2\int_{\phi^Q > u} \phi^Q\nu^{P_Q}(dx) \\
&\quad\le \int_{|x|\le 1} x^2\nu^{P_Q}(dx) + 2u\int_{-\infty}^{\infty} (\phi^Q \log\phi^Q + 1 - \phi^Q)\nu^{P_Q}(dx) + \frac{4r}{T_\infty \log u} \\
&\quad\le \int_{|x|\le 1} x^2\nu^{P_Q}(dx) + \frac{3ru}{T_\infty}. \qquad \text{(A.5)}
\end{aligned}$$

By Proposition VI.4.18 in [27], the tightness of $\{P_n\}_{n\ge 1}$ implies that

$$A^{P_n} + \int_{|x|\le 1} x^2\nu^{P_n}(dx) \qquad \text{(A.6)}$$

is bounded uniformly on n, which means that the right-hand side of (A.5) is bounded uniformly with respect to $Q \in L_r$. From Theorem IV.4.39 in [27], $A^Q = A^{P_Q}$ for all $Q \in L_r$ because for the relative entropy to be finite, necessarily $Q \ll P_Q$. Theorem A.1 then implies that

$$\left\{\gamma^Q - \gamma^P - \int_{-1}^{1} x(\nu^Q - \nu^P)(dx)\right\}^2 \le \frac{2A^{P_Q} r}{T_\infty}.$$

From (A.6), A^{P_n} is bounded uniformly on n. Therefore, inequality (A.5) shows that $|\gamma^Q|$ is bounded uniformly with respect to Q. For u sufficiently large,

$$\begin{aligned}
A^Q + \int_{-\infty}^{\infty} (x^2 \wedge 1)\phi^Q\nu^{P_Q}(dx) &\le A^Q + u\int_{\phi^Q \le u} (x^2 \wedge 1)\nu^{P_Q}(dx) \\
&\quad + \int_{\phi^Q > u} \phi^Q\nu^{P_Q}(dx) \le A^{P_Q} + u\int_{-\infty}^{\infty} (x^2 \wedge 1)\nu^{P_Q}(dx) + \frac{2r}{T_\infty \log u}
\end{aligned} \qquad \text{(A.7)}$$

and (A.6) implies that the right-hand side is bounded uniformly with respect to $Q \in L_r$. By Proposition VI.4.18 in [27], (A.4), (A.7), and the fact that $|\gamma^Q|$ is bounded uniformly with respect to Q entail that the set L_r is tight. □

LEMMA A.3. *Let Q and P be two probability measures on $(\Omega, \mathcal{F})$. Then*

$$I(Q|P) = \sup_{f \in C_b(\Omega)} \left\{\int_\Omega f dQ - \int_\Omega (e^f - 1)dP\right\}, \qquad \text{(A.8)}$$

where $C_b(\Omega)$ is space of bounded continuous functions on Ω.

Proof. Observe that

$$\phi(x) = \begin{cases} x\log x + 1 - x, & x > 0, \\ \infty, & x \le 0, \end{cases}$$

and $\phi^*(y) = e^y - 1$ are proper convex functions on $\mathbb{R}$, conjugate to each other, and apply Corollary 2 in [31, p. 538]. □

COROLLARY A.4. *The relative entropy functional $I(Q|P)$ is weakly lower semi-continuous with respect to Q for fixed P.*

LEMMA A.5. *Let $P, \{P_n\}_{n\geq 1} \subset \mathcal{L}_{NA} \cap \mathcal{L}_B^+$ for some $B > 0$ such that $P_n \Rightarrow P$. There exists a sequence $\{Q_n\}_{n\geq 1} \subset \mathcal{M} \cap \mathcal{L}_B^+$ with $Q_n \sim P_n$ for every n and a constant $C < \infty$ such that $I(Q_n|P_n) \leq C$ for every n.*

Proof. Let $h : \mathbb{R} \to \mathbb{R}$ be a continuous truncation function. For $n \geq 1$, let (A_n, ν_n, γ_n) be the characteristic triplet of P_n with respect to h and let

$$f(\beta, P_n) := \gamma_n + \left(\frac{1}{2} + \beta\right) A_n + \int_{-\infty}^{\infty} \left\{(e^x - 1)e^{\beta(e^x-1)} - h(x)\right\} \nu_n(dx).$$

The first step is to show that for every n, there exists a unique β_n such that $f(\beta_n, P_n) = 0$ and that the sequence $\{\beta_n\}_{n\geq 1}$ is bounded.

Since for every n, $P_n \in \mathcal{L}_B^+$, the dominated convergence theorem yields

$$f'_\beta(\beta, P_n) = A_n + \int_{-\infty}^{\infty} (e^x - 1)^2 e^{\beta(e^x-1)} \nu_n(dx) > 0,$$

and since $P_n \in \mathcal{L}_{NA}$, the Lévy process (X, P_n) is not a.s. increasing or a.s. decreasing, which means that at least one of the following conditions holds:

1. $A_n > 0$,
2. $\nu_n((-\infty, 0)) > 0$ and $\nu_n(0, \infty) > 0$,
3. $A_n = 0$, $\nu_n((-\infty, 0)) = 0$ and $\gamma_n - \int_{-\infty}^{\infty} h(x)\nu_n(dx) < 0$,
4. $A_n = 0$, $\nu_n((0, \infty)) = 0$ and $\gamma_n - \int_{-\infty}^{\infty} h(x)\nu_n(dx) > 0$.

Since $f'_\beta(\beta, P_n) \geq A_n + \min(\int_{-\infty}^{0} (e^x - 1)^2 \nu_n(dx), \int_0^{\infty} (e^x - 1)^2 \nu_n(dx))$, if conditions 1 or 2 above hold, $f'_\beta(\beta, P_n)$ is bounded from below by a positive constant and therefore

$$\exists! \beta_n : f(\beta_n, P_n) = 0. \tag{A.9}$$

If condition 3 above holds, $\lim_{\beta\to-\infty} f(\beta, P_n) = \gamma_n - \int_{-\infty}^{\infty} h(x)\nu_n(dx) < 0$ and $\lim_{\beta\to\infty} f(\beta, P_n) = \infty$, which means that (A.9) also holds. The case when condition 4 above is satisfied may be treated similarly.

Let us now show that the sequence $\{\beta_n\}_{n\geq 1}$ is bounded. Rewrite $f(\beta, P_n)$ as

$$\begin{aligned} f(\beta, P_n) := \gamma_n + \left(\frac{1}{2} + \beta\right) \left(A_n + \int_{-\infty}^{\infty} h^2(x)\nu_n(dx)\right) \\ + \int_{-\infty}^{\infty} \left\{(e^x - 1)e^{\beta(e^x-1)} - h(x) - \left(\frac{1}{2} + \beta\right) h^2(x)\right\} \nu_n(dx). \end{aligned} \tag{A.10}$$

Since $(e^x - 1)e^{\beta(e^x-1)} - x - \left(\frac{1}{2} + \beta\right) x^2 = o(|x|^2)$ and the integrand in the last term of (A.10) is bounded on $(-\infty, B]$, by Corollary VII.3.6 in [27], for every β, $\lim_n f(\beta, P_n) = f(\beta, P)$.

Since P also belongs to $\mathcal{L}_B^+ \cap \mathcal{L}_{NA}$, by the same argument as above, there exists a unique β^* such that $f(\beta, P) = 0$ and $f'_\beta(\beta^*, P) > 0$. This means that there exist $\varepsilon > 0$ and finite constants $\beta_- < \beta^*$ and $\beta^+ > \beta^*$ such that $f(\beta_-, P) < -\varepsilon$ and $f(\beta_+, P) > \varepsilon$. One can then find N such that for all $n \geq N$, $f(\beta_-, P_n) < -\varepsilon/2$ and $f(\beta_+, P_n) > \varepsilon/2$, which means that $\beta_n \in [\beta_-, \beta_+]$ and the sequence $\{\beta_n\}$ is bounded. Let (X, Q_n) be the Lévy process with characteristic triplet (with respect to h)

$$\begin{aligned} A_n^Q &= A_n, \qquad \nu_n^Q = e^{\beta_n(e^x-1)}\nu_n, \\ \gamma_n^Q &= \gamma_n + A_n\beta_n + \int_{-\infty}^{\infty} h(x)(e^{\beta(e^x-1)} - 1)\nu_n(dx). \end{aligned}$$

The measure Q_n is in fact the minimal entropy martingale measure for P_n [29], but this result is not used here. From Theorem A.1,

(A.11)
$$I(Q_n|P_n) = -T\left\{\frac{\beta_n}{2}(1+\beta_n)A_n + \beta_n\gamma_n + \int_{-\infty}^{\infty}\{e^{\beta_n(e^x-1)} - 1 - \beta_n h(x)\}\nu_n(dx)\right\}.$$

To show that the sequence $\{I(Q_n|P_n)\}_{n\geq 1}$ is bounded, observe that for

$$\forall x \in [-1,1], \quad \left|e^{\beta(e^x-1)} - 1 - \beta x\right| \leq \beta e^{\beta(e-1)+1}(1+\beta e)|x|^2,$$
$$\forall x \leq B, \quad \left|e^{\beta(e^x-1)} - 1 - \beta x 1_{|x|\leq 1}\right| \leq \beta e^{\beta(e^B+1)} + 1 + \beta B.$$

The uniform boundedness of the sequence of relative entropies now follows from (A.11) and Theorem VI.4.18 in [27]. □

DISTANCE TO UNCONTROLLABILITY FOR CONVEX PROCESSES*

ADRIAN LEWIS†, RENÉ HENRION‡, AND ALBERTO SEEGER§

Abstract. The classical study of controllability of linear systems assumes unconstrained control inputs. The "distance to uncontrollability" measures the size of the smallest perturbation to the matrix description of the system rendering it uncontrollable and is a key measure of system robustness. We extend the standard theory of this measure of controllability to the case where the control input must satisfy given linear inequalities. Specifically, we consider the control of differential inclusions, concentrating on the particular case where the control input takes values in a given convex cone.

Key words. convex processes, controllability, rank condition, uncontrollable modes, adjoint processes, cone-constrained controls, distance to uncontrollability

1. Introduction.

Classical linear control theory concerns a system of the form

$$\dot{x}(t) = Ax(t) + Bu(t), \tag{1.1}$$

where, at each time t, the state vector $x(t)$ lies in the space $\mathbb{R}^n$, the input control $u(t)$ lies in the space $\mathbb{R}^m$, and the given matrices A and B are real and of appropriate dimensions. A key question is controllability—whether x can be steered from the origin to an arbitrary point in the state space. To fix the ideas, suppose the input function $u(\cdot)$ is taken from

$$\mathcal{U} = \left\{ u : [0,T] \to \mathbb{R}^m \mid \int_0^T |u(t)|dt < \infty \right\},$$

the space of integrable functions over a prescribed time interval $[0,T]$. The associated trajectory

$$t \mapsto x_{u,A,B}(t) = \int_0^t e^{(t-s)A} Bu(s)ds$$

is then an element of the function space

$$\mathcal{X} = \{x : [0,T] \to \mathbb{R}^n \mid x \text{ is absolutely continuous}\}.$$

Controllability of the linear system (1.1), or equivalently of the pair (A,B), simply means that

$$\left\{ x_{u,A,B}(T) \mid u \in \mathcal{U} \right\} = \mathbb{R}^n.$$

For convenience, we see (A, B) not just as a pair of matrices but also as an element of $\mathcal{L}(\mathbb{R}^{n+m}, \mathbb{R}^n)$, the space of linear maps from $\mathbb{R}^{n+m}$ to $\mathbb{R}^n$. Spaces of this type are equipped with the operator (or spectral) norm, which we denote by $\|\cdot\|$. Norms in standard Euclidean spaces are denoted simply by $|\cdot|$. To avoid a possible misunderstanding, let us be more explicit:

$$\|(A, B)\| = \sup_{|(s,w)|=1} |As + Bw|.$$

As pointed out by Lee and Markus [25], the set

$$\Xi = \{(A, B) \in \mathcal{L}(\mathbb{R}^{n+m}, \mathbb{R}^n) \mid \text{the system (1.1) is uncontrollable}\}$$

is closed. This fact prompted Paige [27] to introduce the number

$$\mu(A, B) = \inf_{(C,D)\in\Xi} \|(A, B) - (C, D)\| \tag{1.2}$$

as measure for the "degree of controllability" of a given (A, B). The number (1.2) indicates how much we need to perturb the system (1.1) in order to destroy its controllability.

The problem of estimating (1.2) is of importance for control theorists and engineers alike. In section 3 we review what has been done already in connection with the evaluation of Paige's distance function $\mu : \mathcal{L}(\mathbb{R}^{n+m}, \mathbb{R}^n) \to \mathbb{R}$. We also clarify a point that remained a bit obscure until now, namely, the difference between real and complex controllability.

The purpose of our work is to go beyond the traditional context of the unconstrained linear model (1.1). As shown in section 5, the discussion becomes more involved when the input function $u(\cdot)$ is subject to constraints. New concepts and tools are needed to handle this more general situation. Sections 7 and 8 are devoted to the controllability analysis of dynamical systems described by convex processes.

The notation that we employ is for the most part standard; however, a partial list is provided for the reader's convenience:

$\mathrm{Im}L = \{Ls \mid s \in \mathbb{R}^n\}$ (range of an operator L defined on $\mathbb{R}^n$),

$\mathrm{Ker}L = \{s \in \mathbb{R}^n \mid Ls = 0\}$ (nullspace of an operator L defined on $\mathbb{R}^n$),

$\mathrm{dist}[z, \Gamma] = \inf_{\gamma\in\Gamma}|z-\gamma|$ (distance from z to the set Γ),

$\mathrm{span}K = K-K$ (space spanned by the cone $K \subset \mathbb{R}^n$),

$\mathrm{lin}K = K\cap -K$ (lineality space of the cone $K \subset \mathbb{R}^n$),

$K^+ = \{q \in \mathbb{R}^n \mid q^T s \geq 0 \ \forall s \in K\}$ (dual cone of $K \subset \mathbb{R}^n$),

$S^\perp = \{q \in \mathbb{R}^n \mid q^T s = 0 \ \forall s \in S\}$ (orthogonal space of $S \subset \mathbb{R}^n$),

$\mathrm{gr}\mathcal{F} = \{(s, v) \in \mathbb{R}^n \times \mathbb{R}^n \mid v \in \mathcal{F}(s)\}$ (graph of a process $\mathcal{F} : \mathbb{R}^n \rightrightarrows \mathbb{R}^n$),

$\mathrm{dom}\mathcal{F} = \{s \in \mathbb{R}^n \mid \mathcal{F}(s) \neq \emptyset\}$ (domain of a process $\mathcal{F} : \mathbb{R}^n \rightrightarrows \mathbb{R}^n$),

$\mathrm{Im}\mathcal{F} = \cup_{s\in\mathbb{R}^n} \mathcal{F}(s)$ (image of a process $\mathcal{F} : \mathbb{R}^n \rightrightarrows \mathbb{R}^n$).

2. The reduction lemma. Controllability is a linear-algebraic property of the matrix pair (A, B), and in this framework, the problem of computing the distance to uncontrollability is a matrix distance problem. As is often the case for such problems, rank-one perturbations are important. We capture the essential idea in the following abstract linear algebra result that plays a ubiquitous role throughout this work. The notation x^T indicates the transpose of the column vector x.

LEMMA 2.1 (reduction lemma). *Let $\Gamma \subset \mathbb{R}^p$ be a nonempty set, $x \in \mathbb{R}^n$ a nonzero vector, $y \in \mathbb{R}^p$, and $F \in \mathcal{L}(\mathbb{R}^n, \mathbb{R}^p)$. Then,*

$$\inf_{\substack{E \in \mathcal{L}(\mathbb{R}^n, \mathbb{R}^p) \\ Ex - y \in \Gamma}} \|E - F\| \;=\; \frac{1}{|x|}\, \mathrm{dist}[Fx - y, \Gamma]. \tag{2.1}$$

Furthermore, if γ is a point in Γ at minimal distance from $Fx - y$, then

$$E = F + \frac{1}{|x|^2}\,(y - Fx + \gamma)x^T \tag{2.2}$$

achieves the infimum on the left-hand side of (2.1).

Proof. Denote by α the term on the left-hand side of (2.1). Then,

$$\begin{aligned}
\alpha = \inf_{\substack{E \in \mathcal{L}(\mathbb{R}^n, \mathbb{R}^p) \\ Ex - y \in \Gamma}} \sup_{|s|=1} |(E - F)s| \;&\geq\; \inf_{\substack{E \in \mathcal{L}(\mathbb{R}^n, \mathbb{R}^p) \\ Ex - y \in \Gamma}} \left| (E - F)\left(\frac{x}{|x|}\right)\right| \\
\geq \frac{1}{|x|} \inf_{\substack{E \in \mathcal{L}(\mathbb{R}^n, \mathbb{R}^p) \\ Ex - y \in \Gamma}} |(Ex - y) - (Fx - y)| \;&\geq\; \frac{1}{|x|}\, \mathrm{dist}[Fx - y, \Gamma].
\end{aligned}$$

To prove the reverse inequality, we find a sequence $\{\gamma_\nu\}_{\nu \in \mathbb{N}}$ in Γ such that

$$|Fx - y - \gamma_\nu| \leq \mathrm{dist}[Fx - y, \Gamma] + \nu^{-1} \quad \forall \nu \in \mathbb{N}.$$

(Recall that Γ is not assumed to be closed.) The corresponding linear map

$$E_\nu = F + \frac{1}{|x|^2}\,(y - Fx + \gamma_\nu)x^T$$

satisfies $E_\nu x - y \in \Gamma$, and therefore

$$\begin{aligned}
\alpha \leq \|E_\nu - F\| = \frac{1}{|x|^2} \sup_{|s|=1} |(y - Fx + \gamma_\nu)x^T s| \\
\leq \frac{|y - Fx + \gamma_\nu|}{|x|} \;\leq\; \frac{\mathrm{dist}[Fx - y, \Gamma] + \nu^{-1}}{|x|}.
\end{aligned}$$

We now let $\nu \to \infty$ and arrive at the desired conclusion. The second part of the lemma is obtained by working with γ instead of the minimizing sequence $\{\gamma_\nu\}_{\nu \in \mathbb{N}}$. ∎

What formula (2.1) says is that our complicated approximation problem in the space $(\mathcal{L}(\mathbb{R}^n, \mathbb{R}^p), \|\cdot\|)$ can be reduced to a simpler approximation problem over the Euclidean space $(\mathbb{R}^p, |\cdot|)$.

3. The unconstrained linear model. Paige's measure of controllability (1.2), while rather natural, is not the most amenable to analysis. We therefore begin our exposition by discussing the easier case first analyzed by Paige, allowing the pair (A, B) to have *complex* entries. Most of the material presented in this section is well known,

but we take the opportunity to clarify some common points of confusion. The original Paige measure of controllability is the distance function $\mu_{\text{complex}} : \mathcal{L}(\mathbb{C}^{n+m}, \mathbb{C}^n) \to \mathbb{R}$ defined by

$$\mu_{\text{complex}}(A,B) = \inf_{\substack{(C,D)\ \text{uncontrollable} \\ (C,D)\in\mathcal{L}(\mathbb{C}^{n+m},\mathbb{C}^n)}} \|(A,B)-(C,D)\|. \tag{3.1}$$

A celebrated result due to Eising [9] asserts that

$$\mu_{\text{complex}}(A,B) = \inf_{z\in\mathbb{C}} \sigma_{\min}[A - zI, B], \tag{3.2}$$

where the term on the right-hand side concerns the minimization of the smallest singular value of the rectangular matrix $[A - zI, B]$ with respect to the complex scalar z. This minimization problem has been extensively studied in the last years (cf. [6, 10, 11, 14, 17]), so we don't indulge in this matter. Suffice it to say that the Eising formula has its root in the Hautus [16] characterization of controllability:

$$(A,B) \text{ is controllable} \quad\Longleftrightarrow\quad \operatorname{rank}[A - zI, B] = n \quad \forall z \in \mathbb{C}.$$

We would like to stress the fact that in this paper we are going to work with control systems described only in terms of real entries. The field of complex numbers is ill adjusted when it comes to conically constrained control systems or, more generally, with convex processes.

As shown by Gracia and de Hoyos [15], even if (A, B) has real entries, the uncontrollable (C, D) achieving the infimum in (3.1) may well have complex entries. The "real" Paige function (1.2) is not just the restriction of μ_{complex} to the real field. The question of estimating the real Paige function can be answered in at least two different ways.

3.1. The approach of DeCarlo and Wicks. In what follows, we identify the set

$$\mathcal{O}(r,n) = \{Q \in \mathcal{L}(\mathbb{R}^r, \mathbb{R}^n) \mid Q^TQ = I\}$$

with the collection of orthonormal matrices of size $n \times r$. The following variational formula involves a minimization over the collection of orthonormal matrices having at most two columns.

Proposition 3.1 (see DeCarlo and Wicks [8]). *Consider a controllable operator $(A, B) \in \mathcal{L}(\mathbb{R}^{n+m}, \mathbb{R}^n)$. Then, one has*

$$\mu(A,B) = \inf_{Q\in\mathcal{O}(1,n)\cup\mathcal{O}(2,n)} \|(Q^TA(I-QQ^T), Q^TB)\|. \tag{3.3}$$

From a computational point of view, formula (3.3) is not very satisfactory because it involves a minimization problem over a complicated set of matrices. Notice that (3.3) can be written in the form

$$\mu(A,B) = \min\{\mu_1(A,B),\ \mu_2(A,B)\},$$

where the term

$$\begin{aligned}\mu_1(A,B) = \inf_{Q\in\mathcal{O}(1,n)} \|(Q^TA(I-QQ^T), Q^TB)\| &= \inf_{|q|=1} \left[|(I-qq^T)A^Tq|^2 + |B^Tq|^2\right]^{1/2} \\ = \inf_{|q|=1}\inf_{\lambda\in\mathbb{R}} \left[|A^Tq-\lambda q|^2 + |B^Tq|^2\right]^{1/2} &= \inf_{\lambda\in\mathbb{R}} \sigma_{\min}[A-\lambda I, B]\end{aligned}$$

is rather easy to evaluate, but the computation of

$$\mu_2(A,B) = \inf_{Q\in\mathcal{O}(2,n)} \|(Q^TA(I-QQ^T), Q^TB)\|$$

remains a difficult task. As observed in [15], the term $\mu_1(A,B)$ is not necessarily equal to $\mu(A,B)$. As a general rule, it is only an upper bound.

3.2. The approach of Hu and Davison. An alternative formula for estimating the real Paige function has been suggested by Hu and Davison [19, 20]. In the proposition stated below, the symbols $\mathcal{R}W$ and $\mathcal{I}W$ refer, respectively, to the real part and the imaginary part of a complex linear map $W \in \mathcal{L}(\mathbb{C}^{n+m}, \mathbb{C}^n)$. The notation $\mathrm{sssv}(E)$ stands for the second-smallest singular value of the matrix E.

PROPOSITION 3.2 (see Hu and Davison [19, 20]). *Consider a controllable operator* $(A,B) \in \mathcal{L}(\mathbb{R}^{n+m}, \mathbb{R}^n)$. *Then,*

$$\mu(A,B) = \inf_{z\in\mathbb{C}} \sup_{\gamma\in]0,1]} \mathrm{sssv}\left(\begin{bmatrix} \mathcal{R}W_z & -\gamma\mathcal{I}W_z \\ \gamma^{-1}\mathcal{I}W_z & \mathcal{R}W_z \end{bmatrix}\right) \tag{3.4}$$

with $W_z = [A - zI, B]$.

Paradoxically, the evaluation of the real Paige function is much more involved than the evaluation of the complex counterpart. This should not be very surprising, however, for readers who have encountered a similar phenomenon while comparing the real stability radius of a matrix to the complex one. (See the survey paper of Hinrichsen and Pritchard [18].)

3.3. Partial perturbations. The case of perturbations in the pair (A,B) is the most popular one, but other situations could be considered as well. It may happen, for instance, that only the component A is subject to perturbations. The partial index

$$\partial_A\mu(A,B) = \inf_{\substack{C\in\mathcal{L}(\mathbb{R}^n,\mathbb{R}^n) \\ (C,B) \text{ uncontrollable}}} \|A-C\|$$

indicates how much one needs to perturb the first component of (A,B) in order to produce a pair which is uncontrollable. A similar interpretation must be given to the number

$$\partial_B\mu(A,B) = \inf_{\substack{D\in\mathcal{L}(\mathbb{R}^m,\mathbb{R}^n) \\ (A,D) \text{ uncontrollable}}} \|B-D\|.$$

Later on, these indices are used in the more general context of cone-constrained linear systems (section 5) and control systems governed by convex processes (section 7).

4. Incorporating linear constraints on the input function. Our aim in this work is to extend the classical theory of the distance to uncontrollability to the case where the control u is constrained. As a first, easy but illuminating, step, let us consider the case of linear equality constraints. The works of DeCarlo and Wicks [8] and Hu and Davison [19, 20] can both be extended to the case of a linear system with linear constraints on the input function:

$$\begin{cases} \dot{x}(t) = Ax(t) + Bu(t), \\ u(t) \in S. \end{cases} \tag{4.1}$$

Controllability for the model (4.1) simply means that $\{x_{u,A,B}(T) \mid u \in \mathcal{U}_S\} = \mathbb{R}^n$, with

$$\mathcal{U}_S = \{u \in \mathcal{U} \mid u(t) \in S \text{ a.e. on } [0,T]\}.$$

For convenience, we introduce the notation

$$\Xi(S) = \{(A,B) \in \mathcal{L}(\mathbb{R}^{n+m}, \mathbb{R}^n) \mid \text{the system (4.1) is uncontrollable}\}.$$

THEOREM 4.1 (transfer theorem). *Let S be an r-dimensional subspace of $\mathbb{R}^m$. Then, the index of controllability*

$$\mu_S(A,B) = \inf_{(C,D)\in\Xi(S)} \|(A,B) - (C,D)\| \tag{4.2}$$

for the model (4.1) *is given simply by*

$$\mu_S(A,B) = \mu(A,BQ), \tag{4.3}$$

where $Q \in \mathcal{L}(\mathbb{R}^r, \mathbb{R}^m)$ is any orthonormal map having S as range.

Proof. The subspace S can be represented as the range of a certain orthonormal map $Q \in \mathcal{L}(\mathbb{R}^r, \mathbb{R}^m)$. By writing the input u in the form $u(t) = Qw(t)$, we arrive at a linear control problem

$$\dot{x}(t) = Ax(t) + BQw(t), \tag{4.4}$$

where the input function w is chosen without restrictions. It is not difficult to see that (4.1) is controllable if and only if the pair (A, BQ) is controllable. This simple but important fact is at the origin of formula (4.3). First, one can write

$$\|(A,B) - (C,D)\| \geq \|(A,BQ) - (C,DQ)\| \qquad \forall (C,D) \in \mathcal{L}(\mathbb{R}^{n+m}, \mathbb{R}^n)$$

because Q is orthonormal. Thus,

$$\begin{aligned} \mu_S(A,B) &\geq \inf_{\substack{(C,D)\in\mathcal{L}(\mathbb{R}^{n+m},\mathbb{R}^n) \\ (C,DQ) \text{ uncontrollable}}} \|(A,BQ) - (C,DQ)\| \\ &\geq \inf_{\substack{(C,Y)\in\mathcal{L}(\mathbb{R}^{n+r},\mathbb{R}^n) \\ (C,Y) \text{ uncontrollable}}} \|(A,BQ) - (C,Y)\| \;=\; \mu(A,BQ). \end{aligned}$$

For the proof of the reverse inequality $\mu_S(A,B) \leq \mu(A,BQ)$, pick up any solution (C^*, Y^*) to the minimization problem

$$\begin{cases} \text{minimize } \|(A,BQ) - (C,Y)\|, \\ (C,Y) \in \mathcal{L}(\mathbb{R}^{n+r}, \mathbb{R}^n) \text{ uncontrollable.} \end{cases} \tag{4.5}$$

Since the map $D \in \mathcal{L}(\mathbb{R}^m, \mathbb{R}^n) \mapsto DQ \in \mathcal{L}(\mathbb{R}^r, \mathbb{R}^n)$ is surjective, one can write

$$\mu(A,BQ) = \inf_{\substack{D\in\mathcal{L}(\mathbb{R}^m,\mathbb{R}^n) \\ DQ=Y^*}} \|(A,BQ) - (C^*,DQ)\|. \tag{4.6}$$

We now construct a $D^* \in \mathcal{L}(\mathbb{R}^m, \mathbb{R}^n)$ such that

$$D^*Q = Y^* \text{ and } \|(A,BQ) - (C^*, D^*Q)\| = \|(A,B) - (C^*,D^*)\|. \tag{4.7}$$

To see that this is possible, take an orthonormal map $V \in \mathcal{L}(\mathbb{R}^{m-r}, \mathbb{R}^m)$ such that $\mathrm{Im}V = S^\perp$, and define

$$D^* = Y^*Q^T + BVV^T.$$

With this particular choice, one has

$$\begin{aligned} D^*Q &= Y^*Q^TQ + BVV^TQ = Y^*, \\ D^*V &= Y^*Q^TV + BVV^TV = BV. \end{aligned}$$

Hence,

$$\begin{aligned} \|(A,B) - (C^*,D^*)\| &= \sup_{|(s,w)|\le 1} |(A-C^*)s + (B-D^*)w| \\ &= \sup_{|(s,\gamma_1,\gamma_2)|\le 1} |(A-C^*)s + (B-D^*)(Q\gamma_1 + V\gamma_2)| \\ &= \sup_{|(s,\gamma_1)|\le 1} |(A-C^*)s + (B-D^*)Q\gamma_1| \ = \|(A,BQ) - (C^*,D^*Q)\|. \end{aligned}$$

Notice that $(C^*, D^*) \in \Xi(S)$. The combination of (4.6) and (4.7) produces then the desired inequality, completing the proof in this way. □

Remark. The proof technique of the transfer theorem tells us, in fact, how to construct an operator (C^*, D^*) achieving the infimum (4.2) in the definition of $\mu_S(A,B)$. Everything boils down to solving the easier and well-understood minimization problem (4.5).

We end this section with a proposition concerning the partial indices

$$\partial_A\mu_S(A,B) = \inf_{\substack{C\in\mathcal{L}(\mathbb{R}^n,\mathbb{R}^n)\\(C,B)\in\Xi(S)}} \|A-C\|,$$

$$\partial_B\mu_S(A,B) = \inf_{\substack{D\in\mathcal{L}(\mathbb{R}^m,\mathbb{R}^n)\\(A,D)\in\Xi(S)}} \|B-D\|.$$

As was done in the transfer theorem, it is possible to get rid again of the linear contraint set S.

PROPOSITION 4.2. *Suppose that S is an r-dimensional subspace of $\mathbb{R}^m$ and that $Q \in \mathcal{L}(\mathbb{R}^r, \mathbb{R}^m)$ is an orthonormal map having S as range. Then,*

$$\partial_A\mu_S(A,B) = \partial_A\mu(A,BQ) \quad \textit{and} \quad \partial_B\mu_S(A,B) = \partial_B\mu(A,BQ). \tag{4.8}$$

Proof. We take into account the transformation $u(t) = Qw(t)$ that leads to the unconstrained control system (4.4). One can show straightforwardly the first equality in (4.8), as well as

$$\partial_B\mu_S(A,B) \ge \inf_{\substack{D\in\mathcal{L}(\mathbb{R}^m,\mathbb{R}^n)\\(A,DQ)\text{ uncontrollable}}} \|BQ-DQ\| \ \ge \ \partial_B\mu(A,BQ).$$

For the proof of the reverse inequality $\partial_B\mu_S(A,B) \le \partial_B\mu(A,BQ)$, pick up any solution Y^* to the problem

$$\begin{cases} \text{minimize } \|BQ-Y\| \text{ with respect to} \\ Y \in \mathcal{L}(\mathbb{R}^r,\mathbb{R}^n) \text{ such that } (A,Y) \text{ is uncontrollable,} \end{cases}$$

and observe that

$$\partial_B \mu(A, BQ) = \inf_{\substack{D \in \mathcal{L}(\mathbb{R}^m, \mathbb{R}^n) \\ DQ = Y^*}} \|BQ - DQ\|.$$

It suffices then to construct a $D^* \in \mathcal{L}(\mathbb{R}^m, \mathbb{R}^n)$ such that

$$D^*Q = Y^* \quad \text{and} \quad \|BQ - D^*Q\| = \|B - D^*\|.$$

The construction of D^* and the remaining part of the proof is as in Theorem 4.1. □

5. The cone-constrained linear model. In the previous section we saw that restricting controls to take values in a subspace presents no substantial technical difficulties to the classical theory of controllability. In this section we take the next natural step: conical constraints. The problem of controlling a linear system by using positive inputs has been recognized as an important one since the pioneering works of Brammer [5] and Korobov [22] (see also Son [32]).

5.1. Preliminaries. The model under consideration in this section is

$$\left\{ \begin{array}{l} \dot{x}(t) = Ax(t) + Bu(t), \\ u(t) \in P, \end{array} \right. \tag{5.1}$$

where the closed convex cone P is regarded as the set of "positive" elements in $\mathbb{R}^m$. (Typically, P is the positive orthant of $\mathbb{R}^m$.)

Controllability for the model (5.1) is defined in a similar way as before, except that now the contraint set is not the subspace S but the cone P. Controllability of (5.1) implies, of course, controllability of the relaxed control problem

$$\left\{ \begin{array}{l} \dot{x}(t) = Ax(t) + Bu(t), \\ u(t) \in \text{span}P. \end{array} \right. \tag{5.2}$$

Relaxation is a convenient device to be back in a linear setting, where simple and nice controllability tests are available. In what follows, we use the notation

$$\ll A, B, P \gg = B(P) + AB(P) + \cdots + A^{n-1}B(P),$$

where addition of sets is understood in the usual Minkowski sense, and powers of $A \in \mathcal{L}(\mathbb{R}^n, \mathbb{R}^n)$ correspond to iterated compositions. Since P is a convex cone, the set $\ll A, B, P \gg$ is also a convex cone and

$$\text{span} \ll A, B, P \gg \; = \; \ll A, B, \text{span}P \gg \; = \; \{\mathcal{C}^{A,B}\gamma : \gamma \in [\text{span}P]^n\}$$

with $\mathcal{C}^{A,B} = [B, AB, \ldots, A^{n-1}B]$ denoting the controllability matrix associated to the pair (A, B). If one represents the space span$P$ as the range of a linear map $Q \in \mathcal{L}(\mathbb{R}^r, \mathbb{R}^m)$, with $r = \dim[\text{span}P]$, then

$$\text{span} \ll A, B, P \gg \; = \; \text{Im}\, \mathcal{C}^{A,BQ}.$$

PROPOSITION 5.1. *The following three conditions are equivalent:*

(i) *the relaxed system* (5.2) *is controllable,*
(ii) $\ll A, B, P \gg$ *spans the whole space* $\mathbb{R}^n$*,*
(iii) $\mathcal{C}^{A,BQ}$ *has full rank.*

Proof. This result is surely well known since it is an obvious extension of Kalman's controllability theorem [21]. □

Unfortunately, the relaxation (or linearization) mechanism $P \mapsto \text{span}P$ destroys part of the information contained in the original model (5.1). For recovering the information that is lost, we introduce the concept of "unilateral uncontrollable mode."

DEFINITION 5.2. *One says that $\lambda \in \mathbb{R}$ is an uncontrollable mode of (A, B) relative to P if*

$$\text{Im}(A - \lambda I) + B(P) \neq \mathbb{R}^n. \tag{5.3}$$

Such an uncontrollable mode λ is declared unilateral if $\text{Im}(A-\lambda I)+B(P)$ *has nonempty interior; otherwise it is declared bilateral.*

If the relaxed system (5.2) is controllable, then we should not worry about the existence of uncontrollable modes of the bilateral type. In fact, one has the next lemma.

LEMMA 5.3. *Suppose that $\ll A, B, P \gg$ spans $\mathbb{R}^n$. Then, (A, B) doesn't have bilateral uncontrollable modes relative to P.*

Proof. This corresponds to a particular case of a more general result stated in section 7, namely, Proposition 7.9. □

That $\ll A, B, P \gg$ spans $\mathbb{R}^n$ doesn't rule out, however, the existence of uncontrollable modes of the unilateral type. This is an important point that deserves to be stressed.

THEOREM 5.4. *Controllability of the cone-constrained linear model* (5.1) *is equivalent to the combination of the following two conditions:*

(i) $\ll A, B, P \gg$ *spans* $\mathbb{R}^n$,

(ii) (A, B) *has no unilateral uncontrollable mode relative to* P.

Proof. According to Brammer [5], controllability of (5.1) is equivalent to the combination of (i) and

$$\left\{ \begin{array}{l} \text{the matrix } A^T \text{ has no (real) eigenvalue with} \\ \text{associated eigenvector in the cone } [B(P)]^+. \end{array} \right. \tag{5.4}$$

Since

$$[B(P)]^+ = \{q \in \mathbb{R}^n \mid B^T q \in P^+\},$$

Brammer's condition (5.4) is just another way of saying that (A, B) has no uncontrollable mode relative to P. Due to Lemma 5.3, bilateral uncontrollable modes can be taken out of the discussion. Indeed, these modes are excluded by the property (i). □

5.2. Divide and conquer. As shown in the above theorem, controllability of a cone-constrained linear model is a concept that can be broken into two different pieces. The first piece is a sort of generalized Kalman's rank condition. It takes into account the span of the cone P, but not the cone itself. This condition is purely linear in the sense that it doesn't recognize the "conic" part of P. The second piece takes care of the possible gap between the cone P and its span. In line with this observation, we split the set

$$\Xi(P) = \{(A, B) \in \mathcal{L}(\mathbb{R}^{n+m}, \mathbb{R}^n) \mid \text{the system (5.1) is uncontrollable}\}$$

in two different components:

$$\Xi^{\text{rank}}(P) = \{(A,B) \in \mathcal{L}(\mathbb{R}^{n+m}, \mathbb{R}^n) \mid \text{span} \ll A, B, P \gg \neq \mathbb{R}^n\},$$
$$\Xi^{\text{uni}}(P) = \{(A,B) \in \mathcal{L}(\mathbb{R}^{n+m}, \mathbb{R}^n) \mid \sigma_P^{\text{uni}}(A,B) \neq \emptyset\}.$$

The notation $\sigma_P^{\text{uni}}(A,B)$ refers, of course, to the set of all unilateral uncontrollable modes of (A,B) relative to P. Since

$$\Xi(P) = \Xi^{\text{rank}}(P) \cup \Xi^{\text{uni}}(P),$$

the index of controllability

$$\mu_P(A,B) = \inf_{(C,D)\in\Xi(P)} \|(A,B) - (C,D)\|$$

for the cone-constrained model (5.1) can be computed by using the rule

$$\mu_P(A,B) = \min\{\mu_P^{\text{rank}}(A,B), \mu_P^{\text{uni}}(A,B)\},$$

where the component indices $\mu_P^{\text{rank}}(A,B)$ and $\mu_P^{\text{uni}}(A,B)$ are defined in an obvious manner.

The evaluation of μ_P^{rank} is the "easy" part of the job. What we have to do is to adjust Hu–Davison's formula to the linearly constrained control system (5.2).

PROPOSITION 5.5. *Let P be an r-dimensional closed convex cone in $\mathbb{R}^m$. Let $Q \in \mathcal{L}(\mathbb{R}^r, \mathbb{R}^m)$ be any orthonormal map such that* span $P =$ Im Q. *Consider an operator $(A,B) \in \mathcal{L}(\mathbb{R}^{n+m}, \mathbb{R}^n)$ such that $\ll A, B, P \gg$ spans $\mathbb{R}^n$. Then,*

$$\mu_P^{\text{rank}}(A,B) = \inf_{z\in\mathbb{C}} \sup_{\gamma\in]0,1]} \text{sssv}\left(\begin{bmatrix} \mathcal{R}W_z & -\gamma\mathcal{I}W_z \\ \gamma^{-1}\mathcal{I}W_z & \mathcal{R}W_z \end{bmatrix}\right) \tag{5.5}$$

with $W_z = [A - zI, BQ]$.

Proof. By definition, μ_P^{rank} is the distance function to the set $\Xi^{\text{rank}}(P)$. Since

$$\mu_P^{\text{rank}}(A,B) = \mu_{\text{span}P}(A,B),$$

it suffices to combine Theorem 4.1 and Proposition 3.2. □

The evaluation of μ_P^{uni} falls beyond the context of Hu–Davison's formula. We no longer seem able to use arguments in the realm of standard linear algebra. The number

$$\mu_P^{\text{uni}}(A,B) = \inf_{(C,D)\in\Xi^{\text{uni}}(P)} \|(A,B) - (C,D)\| \tag{5.6}$$

indicates how much we need to perturb the pair (A,B) if we wish to produce a unilateral uncontrollable mode.

Before trying to compute this number, let us say a few additional words on the set $\Xi^{\text{uni}}(P)$. In the very definition of this set, we use implicitly the expression

$$P^{\oplus} = P^+ \backslash \text{lin}(P^+).$$

We don't know if there is already a name for $P^{\oplus}$, so we call it the pseudo-dual cone of P. Without loss of generality we may suppose that P is not a subspace. If P were a subspace, then $P^{\oplus}$ would be empty, and $\Xi^{\text{uni}}(P)$ would be empty as well. Observe that the cone $P^{\oplus}$ is convex but not necessarily closed.

LEMMA 5.6. *Consider a closed convex cone K in some arbitrary Euclidean space. If K is not a subspace, then one has* $\mathrm{cl}[K\backslash \mathrm{lin}\, K] = K$ *and also* $\mathrm{cl}[K^{\oplus}] = K^{+}$.

Proof. We prove only $K \subset \mathrm{cl}[K\backslash \mathrm{lin} K]$, the reverse inclusion being trivial. Take $c \in K$. Suppose that $c \in \mathrm{lin}(K)$; otherwise we are done. Since K is not a subspace, we can pick up some $c^* \in K\backslash \mathrm{lin} K$ and form

$$c_\alpha = (1-\alpha)c + \alpha c^* \quad \text{with} \quad \alpha \in]0,1[.$$

Since c and c^* are in K, so is the convex combination c_α. The equality

$$c^* = \alpha^{-1} c_\alpha - \alpha^{-1}(1-\alpha)c$$

implies that c_α doesn't belong to $\mathrm{lin}(K)$. Hence, $c_\alpha \in K\backslash \mathrm{lin} K$. The desired conclusion is obtained by letting $\alpha \to 0^+$. □

LEMMA 5.7. *Suppose that P is a closed convex cone but not a subspace. Then,*

$$(C,D) \in \Xi^{\mathrm{uni}}(P) \iff \left\{ \begin{array}{l} \text{one can find } \lambda \in \mathbb{R} \text{ and a unit vector } q \\ \text{such that } C^T q = \lambda q \ \text{ and } D^T q \in P^{\oplus}. \end{array} \right.$$

Proof. The proof is not difficult, and therefore it is omitted. □

PROPOSITION 5.8. *Suppose that P is a closed convex cone but not a subspace. Then, the index* (5.6) *admits the characterization*

$$\mu_P^{\mathrm{uni}}(A,B) = \inf_{\substack{\lambda \in \mathbb{R} \\ |q|=1}} \Big[|A^T q - \lambda q|^2 + \mathrm{dist}^2[B^T q, P^+] \Big]^{1/2}. \tag{5.7}$$

Proof. By using Lemma 5.7, one gets

$$\mu_P^{\mathrm{uni}}(A,B) = \inf_{(C,D)} \ \inf_{\substack{\lambda \in \mathbb{R}, |q|=1 \\ C^T q = \lambda q,\ D^T q \in P^{\oplus}}} \|(A,B)-(C,D)\| \ = \ \inf_{\lambda \in \mathbb{R}, |q|=1} \Psi_{A,B}(\lambda, q)$$

with

$$\Psi_{A,B}(\lambda,q) \ = \ \inf_{\substack{(C,D) \in \mathcal{L}(\mathbb{R}^{n+m}, \mathbb{R}^n) \\ C^T q = \lambda q,\ D^T q \in P^{\oplus}}} \|(A,B)-(C,D)\|.$$

A simple matter of computation shows that

$$\begin{aligned} \Psi_{A,B}(\lambda,q) \ &= \ \inf_{\substack{(C,D) \in \mathcal{L}(\mathbb{R}^{n+m}, \mathbb{R}^n) \\ (C^T - \lambda I)q = 0,\ D^T q \in P^{\oplus}}} \left\| \begin{bmatrix} C^T - \lambda I \\ D^T \end{bmatrix} - \begin{bmatrix} A^T - \lambda I \\ B^T \end{bmatrix} \right\| \\ &= \ \inf_{X,Y} \left\| \begin{bmatrix} X \\ Y \end{bmatrix} - \begin{bmatrix} A^T - \lambda I \\ B^T \end{bmatrix} \right\|, \end{aligned}$$

where the last infimum is taken with respect to

$$\begin{bmatrix} X \\ Y \end{bmatrix} \in \mathcal{L}(\mathbb{R}^n, \mathbb{R}^{n+m}) \quad \text{such that} \quad \begin{bmatrix} X \\ Y \end{bmatrix} q \in \begin{bmatrix} 0 \\ P^{\oplus} \end{bmatrix}.$$

The reduction lemma yields

$$\Psi_{A,B}(\lambda,q) = \mathrm{dist}\left[\begin{bmatrix} A^T - \lambda I \\ B^T \end{bmatrix} q, \begin{bmatrix} 0 \\ P^{\oplus} \end{bmatrix} \right],$$

and therefore

$$\mu_P^{\mathrm{uni}}(A,B) = \inf_{\substack{\lambda \in \mathbb{R} \\ |q|=1}} \Big[|A^T q - \lambda q|^2 + \mathrm{dist}^2[B^T q, P^{\oplus}] \Big]^{1/2}.$$

But, due to Lemma 5.6, one can change $P^{\oplus}$ by P^+. □

6. Partial perturbations of cone-constrained linear models. Analogously to our earlier discussion of partial perturbations, we might wish to consider perturbing only the matrix A in measuring the distance to uncontrollability of the cone-contrained linear model (5.1). The techniques of the previous section extend in a straightforward manner. The nonnegative real number

$$\partial_A \mu_P^{\text{uni}}(A,B) = \inf_{\substack{C\in\mathcal{L}(\mathbb{R}^n,\mathbb{R}^n)\\ \sigma_P^{uni}(C,B)\neq\emptyset}} \|A-C\|$$

indicates how much one needs to perturb the first component of (A,B) in order to produce a unilateral uncontrollable mode relative to P. A similar interpretation must be given to the number

$$\partial_B \mu_P^{\text{uni}}(A,B) = \inf_{\substack{D\in\mathcal{L}(\mathbb{R}^m,\mathbb{R}^n)\\ \sigma_P^{uni}(A,D)\neq\emptyset}} \|B-D\|.$$

In the next proposition we provide the reader with a recipe for computing these partial indices.

PROPOSITION 6.1. *Suppose that P is a closed convex cone but not a subspace. Then,*

$$\partial_A \mu_P^{\text{uni}}(A,B) = \inf_{\substack{\lambda\in\mathbb{R},|q|=1\\ B^Tq\in P^+}} |A^Tq-\lambda q| \tag{6.1}$$

and

$$\partial_B \mu_P^{\text{uni}}(A,B) = \inf_{\substack{\lambda\in\mathbb{R},|q|=1\\ A^Tq=\lambda q}} \operatorname{dist}[B^Tq,P^+]. \tag{6.2}$$

Proof. Both formulas are obtained by employing a similar proof technique as in Proposition 5.8. By way of example, let us write

$$\partial_A \mu_P^{\text{uni}}(A,B) = \inf_{C\in\mathcal{L}(\mathbb{R}^n,\mathbb{R}^n)} \inf_{\substack{\lambda\in\mathbb{R},|q|=1\\ C^Tq=\lambda q,\ q\in[B(P)]^\oplus}} \|A-C\| \ = \inf_{\substack{\lambda\in\mathbb{R},|q|=1\\ q\in[B(P)]^\oplus}} \Psi_A(\lambda,q) \tag{6.3}$$

with

$$\Psi_A(\lambda,q) \ = \inf_{\substack{C\in\mathcal{L}(\mathbb{R}^n,\mathbb{R}^n)\\ C^Tq=\lambda q,}} \|A-C\| \ = \inf_{\substack{X\in\mathcal{L}(\mathbb{R}^n,\mathbb{R}^n)\\ Xq=0}} \|X-(A^T-\lambda I)\| \ = |A^Tq-\lambda q|.$$

The last equality is obtained, of course, by applying the reduction lemma. Notice that due to Lemma 5.6 and a continuity argument, the last infimum in (6.3) can be written with $[B(P)]^+$ instead of $[B(P)]^\oplus$. □

The partial indices $\partial_A \mu_P^{\text{rank}}$ and $\partial_B \mu_P^{\text{rank}}$ are defined in an obvious manner:

$$\partial_A \mu_P^{\text{rank}}(A,B) \ = \ \partial_A \mu_{\text{span}P}(A,B) = \inf_{\substack{C\in\mathcal{L}(\mathbb{R}^n,\mathbb{R}^n)\\ \ll C,B,\text{span}P\gg\neq\mathbb{R}^n}} \|A-C\|,$$

$$\partial_B \mu_P^{\text{rank}}(A,B) \ = \ \partial_B \mu_{\text{span}P}(A,B) = \inf_{\substack{D\in\mathcal{L}(\mathbb{R}^m,\mathbb{R}^n)\\ \ll A,D,\text{span}P\gg\neq\mathbb{R}^n}} \|B-D\|.$$

The computation of these indices can be carried out with the help of the transfer formulas established in Proposition 4.2.

7. Controllability of convex processes. We can consider the control models we have studied so far in a slightly different light, as controlling differential inclusions of the form $\dot{x} \in Ax + K$ for convex cones K. In the model (5.1), for example, $K = BP$. In this section we broaden this perspective, considering the controllability of a differential inclusion

$$\dot{x}(t) \in \mathcal{F}(x(t)) \tag{7.1}$$

whose right-hand side is a strict closed convex processes $\mathcal{F} : \mathbb{R}^n \rightrightarrows \mathbb{R}^n$. That $\mathcal{F}$ is a closed convex process simply means that

$$\mathrm{gr}\mathcal{F} = \{(s, v) \in \mathbb{R}^n \times \mathbb{R}^n \mid v \in \mathcal{F}(s)\}$$

is a closed convex cone. Saying that $\mathcal{F}$ is strict is a short way of indicating that $\mathcal{F}$ is nonempty-valued everywhere, that is to say, $\mathcal{F}(s) \neq \emptyset$ for any $s \in \mathbb{R}^n$.

DEFINITION 7.1. *A strict convex process $\mathcal{F} : \mathbb{R}^n \rightrightarrows \mathbb{R}^n$ is said to be controllable if the corresponding reachable set*

$$\mathit{Reach}(\mathcal{F}) = \{x(T) \mid x \in \mathcal{X} \text{ solves } (7.1) \text{ and } x(0) = 0\}$$

is the whole space $\mathbb{R}^n$.

7.1. Characterizing controllability. We know exactly what controllability of $\mathcal{F}$ means in terms of the trajectories of its associated differential inclusion, but it would be helpful to have at our disposal some simple algebraic criteria for checking this property. This topic has been handled in a brilliant manner by Aubin, Frankowska and Olech in their 1986 paper [3]. Their contribution admits, however, a certain number of improvements. To put everything in the right perspective, let us start by recalling two algebraic concepts for an arbitrary convex process. The first concept emerges as an extension of the classical rank condition of Kalman.

DEFINITION 7.2. *A convex process $\mathcal{F} : \mathbb{R}^n \rightrightarrows \mathbb{R}^n$ is said to be reproducing if*

$$\text{there is an integer } k \geq 1 \text{ such that } \mathcal{F}^k(0) \text{ spans } \mathbb{R}^n, \tag{7.2}$$

where the kth power $\mathcal{F}^k = \mathcal{F} \circ \cdots \circ \mathcal{F}$ (k-fold) is understood as an iterated composition in the multivalued sense.

We shall say some extra words on the reproducibility or rank condition (7.2) in a moment. The second concept is an extension of Definition 5.2.

DEFINITION 7.3. *The number $\lambda \in \mathbb{R}$ is called an uncontrollable mode of the convex process $\mathcal{F} : \mathbb{R}^n \rightrightarrows \mathbb{R}^n$ if $\mathcal{F} - \lambda I$ is not surjective, that is, if $\mathrm{Im}[\mathcal{F} - \lambda I] \neq \mathbb{R}^n$. The set of uncontrollable modes of $\mathcal{F}$ is denoted by $\sigma(\mathcal{F})$.*

These are the basic ingredients to state the following theorem.

THEOREM 7.4 (see Aubin, Frankowska, and Olech, [3]). *Let $\mathcal{F} : \mathbb{R}^n \rightrightarrows \mathbb{R}^n$ be a strict closed convex process. Then,*

$$\mathcal{F} \text{ is controllable} \iff \mathcal{F} \text{ is reproducing and has no uncontrollable modes.}$$

We mention two ways of rendering this beautiful result even more attractive. First, there is a simple way to characterize the reproducibility condition (7.2). The proposition stated below seems to be new, so we prove it in detail. We rely on two auxiliary lemmas.

LEMMA 7.5. *Consider a strict convex process $\mathcal{F} : \mathbb{R}^n \rightrightarrows \mathbb{R}^n$ and an integer $k \geq 1$. If the spans of the cones $\mathcal{F}^{k-1}(0)$ and $\mathcal{F}^k(0)$ coincide, then so do the spans of the cones $\mathcal{F}^j(0)$ for exponents $j = k-1, k, k+1, \ldots$.*

Proof. By induction, it suffices to prove the case $j = k+1$. In this case, if the result fails, there is a vector v in the cone $\mathcal{F}^{k+1}(0)$ outside the span of the cone $\mathcal{F}^k(0)$. Choose a vector s in $\mathcal{F}^k(0)$ with $v \in \mathcal{F}(s)$ and a vector w in the relative interior of the cone $\mathcal{F}^{k-1}(0)$. Since s lies in the span of the cone $\mathcal{F}^{k-1}(0)$, the vector $bw + s$ lies in $\mathcal{F}^{k-1}(0)$ for some real $b > 0$ sufficiently large. Since $\mathcal{F}$ is strict, there is a vector z in $\mathcal{F}(w)$ (and hence in $\mathcal{F}^k(0)$). Since the graph of $\mathcal{F}$ is a convex cone, the vector $bz + v$ lies in $\mathcal{F}(bw + s)$, and hence in $\mathcal{F}^k(0)$, contradicting the fact that v lies outside the span of $\mathcal{F}^k(0)$. □

LEMMA 7.6. *Suppose that $\mathcal{F} : \mathbb{R}^n \rightrightarrows \mathbb{R}^n$ is a strict convex process. Then the interiors of the cones $\mathcal{F}^k(0)$ (for exponents $k = n, n+1, \ldots$) are either all empty or all nonempty.*

Proof. The spans of the cones $\mathcal{F}^k(0)$ (for exponents $k = 1, 2, \ldots$) are an increasing sequence of linear subspaces. The previous result implies that equality of two successive elements of the sequence entails constancy thereafter. Hence, by counting dimension, the sequence is constant after at most n elements. The result now follows, since a convex cone has nonempty interior if and only if it spans the whole space. □

Remark. One can construct an easy example showing that $\mathcal{F}^{n+1}(0)$ need not be equal to $\mathcal{F}^n(0)$. Consider, for instance, $n = 2$ and a convex process $\mathcal{F} : \mathbb{R}^2 \to \mathbb{R}^2$ of the form $\mathcal{F}(s) = As + K$, with

$$A = \begin{bmatrix} \cos\theta & \sin\theta \\ -\sin\theta & \cos\theta \end{bmatrix}, \quad K = \mathbb{R}_+ \begin{bmatrix} 1 \\ 0 \end{bmatrix}.$$

The angle $\theta > 0$ is chosen small enough. Since K is a ray and A is a rotation matrix, the set

$$\mathcal{F}^k(0) = K + A(K) + \cdots + A^{k-1}(K)$$

reduces to the convex cone generated by the vectors

$$\begin{bmatrix} 1 \\ 0 \end{bmatrix}, \quad \begin{bmatrix} \cos((k-1)\theta) \\ \sin((k-1)\theta) \end{bmatrix}.$$

This happens as long as $(k-1)\theta \leq \pi$, that is, $k \leq 1 + \pi/\theta$. It is only after $k > 1 + \pi/\theta$ that $\mathcal{F}^k(0) = \mathbb{R}^2$ becomes constant. Observe that $1 + \pi/\theta$ goes to infinity as $\theta \to 0^+$, so one can adjust this example to cover the case of an arbitrary power n.

PROPOSITION 7.7. *A strict convex process $\mathcal{F} : \mathbb{R}^n \rightrightarrows \mathbb{R}^n$ is reproducing if and only if $\mathcal{F}^n(0)$ spans $\mathbb{R}^n$.*

Proof. This follows from the last lemma. □

The second improvement in the presentation of Theorem 7.4 has to do with the nature of uncontrollable modes. The elements of $\sigma(\mathcal{F})$ can be partioned into two different categories. One says that $\lambda \in \sigma(\mathcal{F})$ is of the unilateral type if $\mathrm{Im}[\mathcal{F} - \lambda I]$ has nonempty interior; otherwise, it is declared of the bilateral type. In short, one has a partition

$$\sigma(\mathcal{F}) = \sigma^{\mathrm{uni}}(\mathcal{F}) \cup \sigma^{\mathrm{bi}}(\mathcal{F}),$$

where the notation is self-explanatory.

The different types of uncontrollability modes are perhaps better understood if we characterize them in terms of the adjoint process of F. Recall that the *adjoint* (or transpose) of the convex process $\mathcal{F} : \mathbb{R}^n \rightrightarrows \mathbb{R}^n$ is the convex process $\mathcal{F}^* : \mathbb{R}^n \rightrightarrows \mathbb{R}^n$ defined by

$$\mathrm{gr}\mathcal{F}^* = \{(q,p) \in \mathbb{R}^n \times \mathbb{R}^n \mid (-p,q) \in [\mathrm{gr}\mathcal{F}]^+\},$$

that is,

$$(q,p) \in \mathrm{gr}\mathcal{F}^* \iff \langle p,s\rangle \leq \langle q,v\rangle \quad \forall (s,v) \in \mathrm{gr}\mathcal{F}.$$

We assume that the reader is familiar with this transposition mechanism [2, 4, 29]. As observed already in Proposition 2.4 of [30], the convex cone $\mathrm{Im}[\mathcal{F} - \lambda I]$ is related to

$$(\mathcal{F}^* - \lambda I)^{-1}(0) = \{q \in \mathbb{R}^n \mid \lambda q \in \mathcal{F}^*(q)\}$$

by means of the duality formula

$$(\mathcal{F}^* - \lambda I)^{-1}(0) = [\mathrm{Im}(\mathcal{F} - \lambda I)]^+ . \tag{7.3}$$

As a consequence of (7.3), it is clear that an uncontrollable mode of $\mathcal{F}$ is exactly the same thing as an eigenvalue of $\mathcal{F}^*$. In short,

$$\sigma(\mathcal{F}) = \Lambda(\mathcal{F}^*) \tag{7.4}$$

with

$$\Lambda(\mathcal{F}^*) = \{\lambda \in \mathbb{R} \mid \lambda q \in \mathcal{F}^*(q) \ \text{ for some } \ q \neq 0\}$$

denoting the (point) spectrum of $\mathcal{F}^*$. General information on point spectra of convex processes can be found, for instance, in [1, 23, 24]. For bilateral uncontrollable modes, one has the next lemma.

LEMMA 7.8. *Consider a convex process $\mathcal{F} : \mathbb{R}^n \rightrightarrows \mathbb{R}^n$. For $\lambda \in \mathbb{R}$, the following three conditions are equivalent:*

(i) *λ is a bilateral uncontrollable mode of $\mathcal{F}$,*

(ii) *the convex cone $(\mathcal{F}^* - \lambda I)^{-1}(0)$ contains a line,*

(iii) *there is a unit vector $q \in \mathbb{R}^n$ such that $\lambda q \in \mathcal{F}^*(q)$ and $-\lambda q \in \mathcal{F}^*(-q)$.*

Proof. The equivalence between (ii) and (iii) is straightforward. The equivalence between (i) and (ii) is again a consequence of the duality formula (7.3). □

Remark. A vector q as in Lemma 7.8 (iii) is called a bilateral eigenvector of $\mathcal{F}^*$. The concept of bilateral eigenvector is used by Gajardo and Seeger [13] in connection with the asymptotic stability analysis of discrete-time evolution systems governed by convex processes.

PROPOSITION 7.9. *For a strict convex process $\mathcal{F} : \mathbb{R}^n \rightrightarrows \mathbb{R}^n$, one has the implication*

$$\sigma^{\mathrm{bi}}(\mathcal{F}) \neq \emptyset \quad \Longrightarrow \quad \mathrm{int}[\mathcal{F}^k(0)] = \emptyset \quad \forall k \geq 1.$$

In particular, if a strict convex process $\mathcal{F} : \mathbb{R}^n \rightrightarrows \mathbb{R}^n$ is reproducing, then it has no bilateral uncontrollable modes.

Proof. Take $\lambda \in \sigma^{\mathrm{bi}}(\mathcal{F})$. By Lemma 7.8, there is a unit vector $q \in \mathbb{R}^n$ such that

$$\lambda q \in \mathcal{F}^*(q), \quad -\lambda q \in \mathcal{F}^*(-q). \tag{7.5}$$

We claim that for every $k \in \mathbb{N}$, one has

$$\lambda^k q \in (\mathcal{F}^*)^k(q), \quad -\lambda^k q \in (\mathcal{F}^*)^k(-q). \tag{7.6}$$

The proof is carried out by using an induction argument. The case $k = 1$ corresponds to (7.5). Suppose that (7.6) is true for a given k, and let us examine the situation for $k + 1$. One has

$$(\mathcal{F}^*)^{k+1}(q) = \mathcal{F}^*[(\mathcal{F}^*)^k(q)] = \cup_{z\in(\mathcal{F}^*)^k(q)}\mathcal{F}^*(z) \supset \mathcal{F}^*(\lambda^k q),$$

and similarly

$$(\mathcal{F}^*)^{k+1}(-q) = \mathcal{F}^*[(\mathcal{F}^*)^k(-q)] = \cup_{z\in(\mathcal{F}^*)^k(-q)}\mathcal{F}^*(z) \supset \mathcal{F}^*(-\lambda^k q).$$

We now use the fact that $\mathcal{F}^*$ is positively homogeneous. If $\lambda^k \geq 0$, then one can write

$$\lambda^k \mathcal{F}^*(q) \subset (\mathcal{F}^*)^{k+1}(q), \quad \lambda^k \mathcal{F}^*(-q) \subset (\mathcal{F}^*)^{k+1}(-q).$$

If $\lambda^k < 0$, then one gets

$$-\lambda^k \mathcal{F}^*(-q) \subset (\mathcal{F}^*)^{k+1}(q), \quad -\lambda^k \mathcal{F}^*(q) \subset (\mathcal{F}^*)^{k+1}(-q).$$

In either case, one obtains

$$\lambda^{k+1} q \in (\mathcal{F}^*)^{k+1}(q), \quad -\lambda^{k+1} q \in (\mathcal{F}^*)^{k+1}(-q),$$

proving in this way our claim. In fact, we don't use the full power of (7.6). We just observe that

$$q \in \mathrm{dom}(\mathcal{F}^*)^k \cap -\mathrm{dom}(\mathcal{F}^*)^k,$$

that is, $\mathrm{dom}(\mathcal{F}^*)^k$ is a convex cone containing a line. By invoking the duality formula

$$[\mathcal{F}^k(0)]^+ = \mathrm{dom}(\mathcal{F}^*)^k$$

of Phat [28, Prop. 2.5], we conclude that $\mathcal{F}^k(0)$ has empty interior. □

In view of Propositions 7.7 and 7.9, the Aubin–Frankowska–Olech controllability theorem can be reformulated in the following form.

COROLLARY 7.10. *Suppose that $\mathcal{F} : \mathbb{R}^n \rightrightarrows \mathbb{R}^n$ is a strict closed convex process. Then,*

$$\mathcal{F} \textit{ is controllable } \iff \mathcal{F}^n(0) \textit{ spans } \mathbb{R}^n \textit{ and } \sigma^{\mathrm{uni}}(\mathcal{F}) \textit{ is empty}$$

7.2. Checking reproducibility. Deviating momentarily from the main stream of the discussion, we make some comments concerning the concept of reproducibility.

The relaxation mechanism (5.2) introduced in section 5.1 can be extended to the framework of a differential inclusion whose right-hand side is a general convex process.

DEFINITION 7.11. *The linear relaxation of a convex process $\mathcal{F} : \mathbb{R}^n \rightrightarrows \mathbb{R}^n$ is defined as the multivalued operator $\mathcal{F}^{rel} : \mathbb{R}^n \rightrightarrows \mathbb{R}^n$ whose graph is given by*

$$\mathrm{gr}\mathcal{F}^{rel} = \mathrm{gr}\mathcal{F} - \mathrm{gr}\mathcal{F}.$$

Said in another way, the graph of $\mathcal{F}^{rel}$ is the linear subspace spanned by the convex cone $\mathrm{gr}\mathcal{F}$.

A more explicit formula for $\mathcal{F}^{\rm rel}$ is given by

$$\mathcal{F}^{\rm rel}(s) = \bigcup_{s_2 - s_1 = s} \mathcal{F}(s_2) - \mathcal{F}(s_1) \qquad \forall s \in \mathbb{R}^n. \tag{7.7}$$

By construction, the multivalued operator $\mathcal{F}^{\rm rel}$ is linear in the sense that

$$\mathcal{F}^{\rm rel}(\alpha_1 s_1 + \alpha_2 s_2) = \alpha_1 \mathcal{F}^{\rm rel}(s_1) + \alpha_2 \mathcal{F}^{\rm rel}(s_2)$$

$\forall s_1, s_2 \in {\rm dom}\mathcal{F}^{\rm rel}$ and nonzero $\alpha_1, \alpha_2 \in \mathbb{R}$. (That $\alpha_1, \alpha_2 \in \mathbb{R}$ are nonzero scalars is of importance and should not be neglected.) General information on the theory of linear multivalued operators can be found in the book by Cross [7].

We declare the differential inclusion

$$\dot{x}(t) \in \mathcal{F}^{\rm rel}(x(t)) \tag{7.8}$$

as being the relaxed version of the control model (7.1). As we shall see in the next theorem, reproducibility of $\mathcal{F}$ is equivalent to controllability of (7.8). First, we state the next lemma.

LEMMA 7.12. *For a strict closed convex process $\mathcal{F} : \mathbb{R}^n \rightrightarrows \mathbb{R}^n$, one has*

(i) $\mathcal{F}(s_2) - \mathcal{F}(s_1) \subset \mathcal{F}(s_2 - s_1) - \mathcal{F}(0) \quad \forall s_1, s_2 \in \mathbb{R}^n$,
(ii) $\mathcal{F}^{\rm rel}(s) \subset \mathcal{F}(s) - \mathcal{F}(0) \quad \forall s \in \mathbb{R}^n$,
(iii) $\mathcal{F}(s) \subset \mathcal{F}^{\rm rel}(s) \quad \forall s \in \mathbb{R}^n$,
(iv) $(\mathcal{F}^{\rm rel})^k(0) = {\rm span}\mathcal{F}^k(0) \quad \forall k \in \mathbb{N}$.

Proof. For proving part (i), take $s_1, s_2 \in \mathbb{R}^n$ and $v \in \mathcal{F}(s_2) - \mathcal{F}(s_1)$. Write

$$v = v_2 - v_1 \quad \text{with} \quad v_1 \in \mathcal{F}(s_1), v_2 \in \mathcal{F}(s_2).$$

By strictness of $\mathcal{F}$, we can find some element w in $\mathcal{F}(-s_1)$. Since the graph of $\mathcal{F}$ is a convex cone, it follows that

$$v_1 + w \in \mathcal{F}(0), \quad v_2 + w \in \mathcal{F}(s_2 - s_1).$$

Hence,

$$v = (v_2 + w) - (v_1 + w) \ \in \mathcal{F}(s_2 - s_1) - \mathcal{F}(0).$$

Part (ii) follows immediately from (i) and formula (7.7). Part (iii) is trivial because ${\rm gr}\mathcal{F} \subset {\rm gr}\mathcal{F}^{\rm rel}$. The proof of (iv) is more subtle and is based on an induction argument. For $k = 1$, the result is true because the equality

$$\mathcal{F}^{\rm rel}(0) = {\rm span}\mathcal{F}(0)$$

is obtained by combining (ii) and (iii). Suppose the announced formula is true for a given k. For $k+1$, one gets

$$(\mathcal{F}^{\rm rel})^{k+1}(0) = \bigcup_{v \in (\mathcal{F}^{\rm rel})^k(0)} \mathcal{F}^{\rm rel}(v) = \bigcup_{v \in {\rm span}\mathcal{F}^k(0)} \mathcal{F}^{\rm rel}(v) = \bigcup_{v_1, v_2 \in \mathcal{F}^k(0)} \mathcal{F}^{\rm rel}(v_2 - v_1)$$
$$= \bigcup_{v_1, v_2 \in \mathcal{F}^k(0)} \Big\{ \mathcal{F}^{\rm rel}(v_2) - \mathcal{F}^{\rm rel}(v_1) \Big\} \subset \bigcup_{v_1, v_2 \in \mathcal{F}^k(0)} \Big\{ [\mathcal{F}(v_2) - \mathcal{F}(0)] - [\mathcal{F}(v_1) - \mathcal{F}(0)] \Big\}.$$

Therefore,

$$(\mathcal{F}^{\rm rel})^{k+1}(0) \subset [\mathcal{F}(\mathcal{F}^k(0)) - \mathcal{F}(0)] - [\mathcal{F}(\mathcal{F}^k(0)) - \mathcal{F}(0)] = {\rm span}\mathcal{F}^{k+1}(0) + {\rm span}\mathcal{F}(0).$$

The subspace $\mathrm{span}\mathcal{F}(0)$ can be dropped from the last sum because it is contained in $\mathrm{span}\mathcal{F}^{k+1}(0)$. We have proved in this way the inclusion $(\mathcal{F}^{\mathrm{rel}})^{k+1}(0) \subset \mathrm{span}\mathcal{F}^{k+1}(0)$. The reverse inclusion is trivial because the convex cone $\mathcal{F}^{k+1}(0)$ is smaller than the linear space $(\mathcal{F}^{\mathrm{rel}})^{k+1}(0)$. □

LEMMA 7.13. *Let $\mathcal{F} : \mathbb{R}^n \rightrightarrows \mathbb{R}^n$ be a strict closed convex process. Then, $\mathcal{F}^{\mathrm{rel}}$ admits the representation*

$$\mathcal{F}^{\mathrm{rel}}(s) = A^{\mathcal{F}}s + S^{\mathcal{F}} \qquad \forall s \in \mathbb{R}^n, \tag{7.9}$$

where $S^{\mathcal{F}} = \mathrm{span}\mathcal{F}(0)$, and $A^{\mathcal{F}} \in \mathcal{L}(\mathbb{R}^n, \mathbb{R}^n)$ is defined by

$$A^{\mathcal{F}}s = \pi^{\mathcal{F}}[\mathcal{F}^{\mathrm{rel}}(s)] \tag{7.10}$$

with $\pi^{\mathcal{F}} : \mathbb{R}^n \to \mathbb{R}^n$ denoting the orthogonal projection onto $[\mathrm{span}\mathcal{F}(0)]^{\perp}$.

Proof. It must be observed that $\pi^{\mathcal{F}}[\mathcal{F}^{\mathrm{rel}}(s)]$ is indeed a singleton. To see this, take $y_1, y_2 \in \pi^{\mathcal{F}}[\mathcal{F}^{\mathrm{rel}}(s)]$ and write

$$y_1 = \pi^{\mathcal{F}}(v_1), \quad y_2 = \pi^{\mathcal{F}}(v_2) \quad \text{with } v_1, v_2 \in \mathcal{F}^{\mathrm{rel}}(s).$$

Hence,

$$y_1 - y_2 = \pi^{\mathcal{F}}(v_1) - \pi^{\mathcal{F}}(v_2) = \pi^{\mathcal{F}}(v_1 - v_2) = 0,$$

the last equality being due to the fact that

$$v_1 - v_2 \in \mathcal{F}^{\mathrm{rel}}(s) - \mathcal{F}^{\mathrm{rel}}(s) = \mathcal{F}^{\mathrm{rel}}(0) = \mathrm{span}\mathcal{F}(0).$$

Checking the linearity of the single-valued operator $A^{\mathcal{F}}$ is essentially a matter of exploiting the linearity of the multivalued operator $\mathcal{F}^{\mathrm{rel}}$. The details are omitted. Finally, we check the representation formula (7.9). Take $s \in \mathbb{R}^n$ and $y \in A^{\mathcal{F}}s + S^{\mathcal{F}}$. Thus,

$$y = q_1 + \pi^{\mathcal{F}}(v) \quad \text{with } q_1 \in S^{\mathcal{F}},\ v \in \mathcal{F}^{\mathrm{rel}}(s).$$

Since $q_2 = v - \pi^{\mathcal{F}}(v) \in S^{\mathcal{F}}$, it follows that

$$y = q_1 - q_2 + v \in S^{\mathcal{F}} + \mathcal{F}^{\mathrm{rel}}(s) = \mathcal{F}^{\mathrm{rel}}(0) + \mathcal{F}^{\mathrm{rel}}(s) \subset \mathcal{F}^{\mathrm{rel}}(s).$$

Conversely, take $y \in \mathcal{F}^{\mathrm{rel}}(s)$. Since $y - \pi^{\mathcal{F}}(y) \in S^{\mathcal{F}}$, it follows that

$$y = \pi^{\mathcal{F}}(y) + [y - \pi^{\mathcal{F}}(y)] \in A^{\mathcal{F}}s + S^{\mathcal{F}}. \qquad \square$$

Remark. The operator $A^{\mathcal{F}}$ used to represent $\mathcal{F}^{\mathrm{rel}}$ is not unique. In fact, one has $\mathcal{F}^{\mathrm{rel}}(\cdot) = A(\cdot) + S^{\mathcal{F}}$ for any $A \in \mathcal{L}(\mathbb{R}^n, \mathbb{R}^n)$ with $\mathrm{Im}(A - A^{\mathcal{F}}) \subset S^{\mathcal{F}}$. Such A is called a linear selector of $\mathcal{F}^{\mathrm{rel}}$. We declare $A^{\mathcal{F}}$ to be the standard linear selector of $\mathcal{F}^{\mathrm{rel}}$.

In view of Lemma 7.13, the relaxed version of the differential inclusion (7.1) can be written in the form

$$\begin{cases} \dot{x}(t) = A^{\mathcal{F}}x(t) + u(t), \\ u(t) \in S^{\mathcal{F}}, \end{cases} \tag{7.11}$$

a model that is well understood by now. Such linearly constrained control problem can also be written in the unconstrained form

$$\begin{cases} \dot{x}(t) = A^{\mathcal{F}}x(t) + Qw(t), \\ w(t) \in \mathbb{R}^r, \end{cases} \tag{7.12}$$

where r is the dimension of $S^{\mathcal{F}}$, and $Q \in \mathcal{L}(\mathbb{R}^r, \mathbb{R}^n)$ is any orthonormal map such that $\mathrm{Im}Q = S^{\mathcal{F}}$.

THEOREM 7.14. *For a strict closed convex process $\mathcal{F} : \mathbb{R}^n \rightrightarrows \mathbb{R}^n$, the following five conditions are equivalent:*

(i) *$\mathcal{F}$ is reproducing,*
(ii) *$\mathcal{F}^{\mathrm{rel}}$ is reproducing,*
(iii) *the system (7.11) is controllable,*
(iv) *$(A^{\mathcal{F}}, Q)$ is controllable for some $Q \in \mathcal{O}(r,n)$ such that $\mathrm{Im}\, Q = S^{\mathcal{F}}$,*
(v) *$(A^{\mathcal{F}}, Q)$ is controllable for every $Q \in \mathcal{O}(r,n)$ such that $\mathrm{Im}\, Q = S^{\mathcal{F}}$.*

Proof. The equivalence between (i) and (ii) is a consequence of Lemma 7.12(iv). From the controllability theory of linear systems, we know that the conditions (iii), (iv), and (v) are all equivalent to (ii). □

8. Additive versus hybrid perturbations. Equipped with the characterizations of controllability of process differential inclusions we explored in the previous section, we can now return to our central topic of measuring the degree of controllability. Robustness of controllability for a system like (7.1) is a topic that has been studied by Naselli-Ricceri [26], Tuan [33], and Lavilledieu and Seeger [24]. Here we go beyond the qualitative analysis carried out by these authors and focus attention on the quantitative aspect. We want to measure how much we need to perturb the system (7.1) in order to destroy its controllability.

8.1. Additive perturbations. The simplest way to perturb the differential inclusion (7.1) is to add a linear map $L \in \mathcal{L}(\mathbb{R}^n, \mathbb{R}^n)$ to the reference or nominal operator $\mathcal{F}$. The perturbed system

$$\dot{x}(t) \in (\mathcal{F} + L)(x(t)) \tag{8.1}$$

may no longer be controllable if the perturbation L is too severe. The index

$$\mu_{\mathrm{add}}(\mathcal{F}) = \inf_{\substack{L \in \mathcal{L}(\mathbb{R}^n, \mathbb{R}^n) \\ \mathcal{F}+L \text{ uncontrollable}}} \|L\| \tag{8.2}$$

speaks by itself and doesn't need further explanation. In line with the "divide and conquer" strategy adopted in this work, we write

$$\mu_{\mathrm{add}}(\mathcal{F}) = \min\{\mu^{\mathrm{rank}}_{\mathrm{add}}(\mathcal{F}), \mu^{\mathrm{uni}}_{\mathrm{add}}(\mathcal{F})\},$$

where

$$\mu^{\mathrm{rank}}_{\mathrm{add}}(\mathcal{F}) = \inf_{\substack{L \in \mathcal{L}(\mathbb{R}^n, \mathbb{R}^n) \\ \mathcal{F}+L \text{ irreproducing}}} \|L\| \tag{8.3}$$

measures the distance to irreproducibility, and

$$\mu^{\mathrm{uni}}_{\mathrm{add}}(\mathcal{F}) = \inf_{\substack{L \in \mathcal{L}(\mathbb{R}^n, \mathbb{R}^n) \\ \sigma^{\mathrm{uni}}(\mathcal{F}+L) \neq \emptyset}} \|L\| \tag{8.4}$$

indicates how much we need to perturb $\mathcal{F}$ in order to produce a unilateral uncontrollable mode.

In the proof of the theorem stated below, we use the notation $\mathcal{F}^{\odot}$ to indicate the *pseudo-adjoint* of the convex process $\mathcal{F} : \mathbb{R}^n \rightrightarrows \mathbb{R}^n$. By definition, $\mathcal{F}^{\odot} : \mathbb{R}^n \rightrightarrows \mathbb{R}^n$ is the convex process given by $\mathrm{gr}\mathcal{F}^{\odot} = \mathrm{gr}\mathcal{F}^* \backslash \mathrm{lin}[\mathrm{gr}\mathcal{F}^*]$, or, more explicitly,

$$\mathcal{F}^{\odot}(q) = \mathcal{F}^*(q) \backslash -\mathcal{F}^*(-q) \quad \forall q \in \mathbb{R}^n.$$

THEOREM 8.1. *Suppose that $\mathcal{F} : \mathbb{R}^n \rightrightarrows \mathbb{R}^n$ is a strict closed convex process. Then,*

$$\mu^{\rm uni}_{\rm add}(\mathcal{F}) = \begin{cases} \inf\limits_{\substack{\lambda\in\mathbb{R}\\ |q|=1}} {\rm dist}[\lambda q, \mathcal{F}^*(q)] & \text{if } {\rm gr}\mathcal{F} \text{ is not a subspace},\\ \infty & \text{otherwise.}\end{cases} \tag{8.5}$$

On the other hand,

$$\mu^{\rm rank}_{\rm add}(\mathcal{F}) = \partial_A \mu(A^{\mathcal{F}}, Q) \tag{8.6}$$

with $Q \in \mathcal{O}(r,n)$ such that Im $Q = {\rm span}\mathcal{F}(0)$ *and $A^{\mathcal{F}}$ denoting the standard linear selector of $\mathcal{F}^{\rm rel}$.*

Proof. The formula (8.5) is based on the fact that $\sigma^{\rm uni}(\mathcal{F}+L) \neq \emptyset$ if and only if there exist a scalar $\lambda \in \mathbb{R}$ and a unit vector $q \in \mathbb{R}^n$ such that

$$\begin{cases} \lambda q \in \mathcal{F}^*(q) + L^T q,\\ -\lambda q \notin \mathcal{F}^*(-q) - L^T q.\end{cases}$$

The above condition can be written in the more compact form $L^T q - \lambda q \in -\mathcal{F}^{\odot}(q)$. Hence,

$$\mu^{\rm uni}_{\rm add}(\mathcal{F}) = \inf_{\substack{\lambda\in\mathbb{R}\\ |q|=1}} \inf_{\substack{L\in\mathcal{L}(\mathbb{R}^n,\mathbb{R}^n)\\ L^T q-\lambda q\in-\mathcal{F}^{\odot}(q)}} \|L\|.$$

By applying the reduction lemma, one obtains

$$\mu^{\rm uni}_{\rm add}(\mathcal{F}) = \inf_{\substack{\lambda\in\mathbb{R}\\ |q|=1}} {\rm dist}[\lambda q, \mathcal{F}^{\odot}(q)]. \tag{8.7}$$

Both terms in (8.7) are equal to ∞ if ${\rm gr}\mathcal{F}$ is a subspace. Suppose then that ${\rm gr}\mathcal{F}$ is not a subspace. Since $\mathcal{F}$ is a strict closed convex process, it follows that $\mathcal{F}^*(0) = \{0\}$. Hence,

$$\mathcal{F}^*(q) + \mathcal{F}^*(-q) \subset \{0\}.$$

From this relation, one can see that

$${\rm dom}\mathcal{F}^{\odot} = {\rm dom}\mathcal{F}^* \backslash {\rm lin}[{\rm dom}\mathcal{F}^*] \quad \text{and} \quad \mathcal{F}^{\odot}(q) = \mathcal{F}^*(q) \ \ \forall q \in {\rm dom}\mathcal{F}^{\odot}.$$

It has to be shown that, for arbitrary $\lambda \in \mathbb{R}$ and unit vector $q \in {\rm dom}\mathcal{F}^*$, one has

$${\rm dist}[\lambda q, \mathcal{F}^*(q)] \geq \mu^{\rm uni}_{\rm add}(\mathcal{F}).$$

To do this, we take into account (8.7) and the following two facts. First, due to Lemma 5.6, every unit vector in ${\rm dom}\mathcal{F}^*$ can be obtained as limit of a sequence of unit vectors taken from ${\rm dom}\mathcal{F}^* \backslash {\rm lin}[{\rm dom}\mathcal{F}^*]$. Second, since $\mathcal{F}$ is strict, $\mathcal{F}^*$ maps bounded sets to bounded sets and $\mathcal{F}^*$ is single-valued over ${\rm lin}[{\rm dom}\mathcal{F}^*]$ (cf. Corollary 2.5.8 in [2]). As far as (8.6) is concerned, one follows a similar proof technique as in the more general situation discussed in Theorem 8.3. □

8.2. Hybrid perturbations. Perturbing a differential inclusion by adding a linear map to the right-hand side is not the most general perturbational scheme that one may consider. In fact, a perturbational scheme of the additive type is poorly suited to deal with a large number of important situations occurring in practice. To

see this, just think of the particular case of the unconstrained linear control problem (1.1). This model can be represented in terms of the convex process $\mathcal{F}_{A,B} : \mathbb{R}^n \rightrightarrows \mathbb{R}^n$ given by

$$\mathcal{F}_{A,B}(s) = As + \mathrm{Im}B.$$

By adding a linear map $L \in \mathcal{L}(\mathbb{R}^n, \mathbb{R}^n)$ to the convex process $\mathcal{F}_{A,B}$ one recovers a perturbed system

$$\dot{x}(t) = (A + L)x(t) + Bu(t)$$

for which the B component remains unaffected. A more sophisticated operation must be carried out on $\mathcal{F}_{A,B}$ if one wishes to incorporate perturbations in the B component as well.

The concept of hybrid perturbation is based on the simultaneous use of two linear maps, say, $M \in \mathcal{L}(\mathbb{R}^n, \mathbb{R}^n)$ and $L \in \mathcal{L}(\mathbb{R}^n, \mathbb{R}^n)$, the first acting in an multiplicative way and the second in a additive way. The new convex process

$$s \in \mathbb{R}^n \mapsto [M \circ \mathcal{F} + L](s) = M(\mathcal{F}(s)) + Ls$$

is viewed as a perturbed version of $\mathcal{F}$. Of course, perturbation doesn't occur if one takes $(M, L) = (I, 0)$. All this is for saying that

$$\mu_{\mathrm{hyb}}(\mathcal{F}) = \inf_{\substack{M,L \in \mathcal{L}(\mathbb{R}^n, \mathbb{R}^n) \\ M \circ \mathcal{F} + L \text{ uncontrollable}}} \|(M, L) - (I, 0)\| \tag{8.8}$$

is a reasonable candidate for measuring the degree of controllability of $\mathcal{F}$. Observe, incidentally, that hybrid perturbations preserve the strictness of $\mathcal{F}$.

We follow once more our old habit of thought and decompose (8.8) in the form

$$\mu_{\mathrm{hyb}}(\mathcal{F}) = \min\{\mu^{\mathrm{rank}}_{\mathrm{hyb}}(\mathcal{F}), \mu^{\mathrm{uni}}_{\mathrm{hyb}}(\mathcal{F})\}$$

with $\mu^{\mathrm{rank}}_{\mathrm{hyb}}(\mathcal{F})$ and $\mu^{\mathrm{uni}}_{\mathrm{hyb}}(\mathcal{F})$ being defined in an obvious way.

THEOREM 8.2. *Suppose that $\mathcal{F} : \mathbb{R}^n \rightrightarrows \mathbb{R}^n$ is a strict closed convex process. Then, one has*

$$\mu^{\mathrm{uni}}_{\mathrm{hyb}}(\mathcal{F}) = \begin{cases} \inf_{\substack{\lambda \in \mathbb{R}, \\ |q|=1}} \mathrm{dist}[(q, \lambda q), \mathrm{gr}\mathcal{F}^*] & \text{if } \mathrm{gr}\mathcal{F} \text{ is not a subspace,} \\ \infty & \text{otherwise.} \end{cases} \tag{8.9}$$

Proof. We consider only the case when $\mathrm{gr}\mathcal{F}$ is not a subspace, the other case being trivial. For any $M, L \in \mathcal{L}(\mathbb{R}^n, \mathbb{R}^n)$, one has $(M \circ \mathcal{F} + L)^* = \mathcal{F}^* \circ M^T + L^T$. Hence, $\sigma^{\mathrm{uni}}(M \circ \mathcal{F} + L) \neq \emptyset$ if and only if there exist a scalar $\lambda \in \mathbb{R}$ and a unit vector $q \in \mathbb{R}^n$ such that

$$\begin{cases} \lambda q \in \mathcal{F}^*(M^T q) + L^T q, \\ -\lambda q \notin \mathcal{F}^*(-M^T q) - L^T q. \end{cases}$$

This can be written in the form

$$(L^T q - \lambda q, M^T q) \in (\mathrm{gr}\mathcal{F})^{\oplus}$$

with $(\mathrm{gr}\mathcal{F})^{\oplus}$ denoting the pseudo-dual of the convex cone $\mathrm{gr}\mathcal{F}$. Hence,

$$\mu^{\mathrm{uni}}_{\mathrm{hyb}}(\mathcal{F}) = \inf_{\substack{\lambda \in \mathbb{R}, \\ |q|=1}} \inf_{\substack{M,L \in \mathcal{L}(\mathbb{R}^n, \mathbb{R}^n) \\ (L^T q - \lambda q, M^T q) \in (\mathrm{gr}\mathcal{F})^{\oplus}}} \|(M, L) - (I, 0)\| = \inf_{\substack{\lambda \in \mathbb{R}, \\ |q|=1}} \inf_{X,Y} \left\| \begin{bmatrix} X \\ Y \end{bmatrix} - \begin{bmatrix} 0 \\ I \end{bmatrix} \right\|,$$

where the last infimum is taken with respect to

$$\begin{bmatrix} X \\ Y \end{bmatrix} \in \mathcal{L}(\mathbb{R}^n, \mathbb{R}^{n+m}) \quad \text{such that} \quad \begin{bmatrix} X \\ Y \end{bmatrix} q - \begin{bmatrix} \lambda q \\ 0 \end{bmatrix} \in (\mathrm{gr}\mathcal{F})^{\oplus}.$$

The reduction lemma yields

$$\mu^{\mathrm{uni}}_{\mathrm{hyb}}(\mathcal{F}) = \inf_{\substack{\lambda\in\mathbb{R},\\ |q|=1}} \mathrm{dist}[(-\lambda q, q), (\mathrm{gr}\mathcal{F})^{\oplus}] = \inf_{\substack{\lambda\in\mathbb{R},\\ |q|=1}} \mathrm{dist}[(-\lambda q, q), (\mathrm{gr}\mathcal{F})^{+}],$$

from which one gets the announced result. □

THEOREM 8.3. *Suppose that $\mathcal{F} : \mathbb{R}^n \rightrightarrows \mathbb{R}^n$ is a strict closed convex process. Then,*

$$\mu^{\mathrm{rank}}_{\mathrm{hyb}}(\mathcal{F}) = \inf_{\substack{M,L\in\mathcal{L}(\mathbb{R}^n,\mathbb{R}^n)\\ (MA+L,MQ)\ \text{uncontrollable}}} \|(M, L) - (I, 0)\| \tag{8.10}$$

with $Q \in \mathcal{O}(r, n)$ such that $\mathrm{Im}\, Q = \mathrm{span}\mathcal{F}(0)$ *and A denoting any linear selector of $\mathcal{F}^{\mathrm{rel}}$.*

Proof. One can show that for any $M, L \in \mathcal{L}(\mathbb{R}^n, \mathbb{R}^n)$, one has the identity

$$\mathrm{gr}(M \circ \mathcal{F} + L) - \mathrm{gr}(M \circ \mathcal{F} + L) = \mathrm{gr}(M \circ \mathcal{F}^{\mathrm{rel}} + L),$$

and therefore $(M \circ \mathcal{F} + L)^{\mathrm{rel}} = M \circ \mathcal{F}^{\mathrm{rel}} + L$. By combining this fact and Theorem 7.14, one sees that

$$\begin{aligned} M \circ \mathcal{F} + L \text{ is irreproducing} &\iff (M \circ \mathcal{F} + L)^{\mathrm{rel}} \text{ is irreproducing} \\ &\iff M \circ \mathcal{F}^{\mathrm{rel}} + L \text{ is irreproducing} \\ &\iff (MA + L, MQ) \text{ is uncontrollable.} \end{aligned}$$

This proves, of course, the announced formula. □

We end this section by showing how to evaluate the hybrid indices μ^{uni}_{hyb} and $\mu^{\mathrm{rank}}_{hyb}$ in the particular case of a convex process $\mathcal{F}^P_{A,B} : \mathbb{R}^n \rightrightarrows \mathbb{R}^n$ given by

$$\mathcal{F}^P_{A,B}(s) = As + B(P).$$

This choice may seem very peculiar, but, in fact, it is one of the most prominent examples in the general theory of convex processes. Observe that the cone-constrained model (5.1) can be written in the form of a differential inclusion whose right-hand side is $\mathcal{F}^P_{A,B}$. For the sake of completeness, we mention that the class

$$\mathcal{H}_P = \{\mathcal{F}^P_{A,B} \mid (A, B) \in \mathcal{L}(\mathbb{R}^{n+m}, \mathbb{R}^n)\}$$

is stable with respect to hybrid perturbations. Indeed, one can write the identity

$$M \circ \mathcal{F}^P_{A,B} + L = \mathcal{F}^P_{C,D},$$

where the pairs (A, B) and (C, D) are related through the transformation formulas

$$C = MA + L, \quad D = MB.$$

Observe that the perturbation (M, L) that brings (A, B) to (C, D) is given by

$$M = D(B^TB)^{-1}B^T, \quad L = C - D(B^TB)^{-1}B^TA. \tag{8.11}$$

For writing (8.11) we are implicitly assuming that the transpose of $B \in \mathcal{L}(\mathbb{R}^m, \mathbb{R}^n)$ is surjective because otherwise $B^T B$ is not invertible. In the context of our cone-constrained control problem (5.1), surjectivity of B^T can be assumed without loss of generality. It is interesting to note that seemingly more general types of perturbations like pointwise or graphical addition of convex processes do not even allow to recover the class $\mathcal{H}_p$ introduced above.

COROLLARY 8.4. *Let $P \subset \mathbb{R}^m$ be a closed convex cone but not a subspace. Then,*

$$\mu^{\rm uni}_{\rm hyb}(\mathcal{F}^P_{A,B}) = \inf_{\substack{\lambda\in\mathbb{R}\\ |q|=1}} \inf_{B^Th\in P^+} \Big[|A^Th-\lambda q|^2 + |h-q|^2\Big]^{1/2}. \tag{8.12}$$

Proof. An easy calculation shows that

$$\mathrm{gr}(\mathcal{F}^P_{A,B})^* = \{(h,p) \mid B^Th \in P^+,\ p = A^Th\}.$$

It suffices now to apply the general formula (8.9). □

We mention in passing that (8.12) can also be obtained by writing

$$\begin{aligned}\mu^{\rm uni}_{\rm hyb}(\mathcal{F}^P_{A,B}) &= \inf_{\substack{M,L\in\mathcal{L}(\mathbb{R}^n,\mathbb{R}^n)\\ \sigma^{uni}(M\circ\mathcal{F}^P_{A,B}+L)\neq\emptyset}} \|(M,L)-(I,0)\| \\ &= \inf_{\substack{M,L\in\mathcal{L}(\mathbb{R}^n,\mathbb{R}^n),\lambda\in\mathbb{R},|q|=1\\ A^TM^Tq+L^Tq=\lambda q,\ B^TM^Tq\in P^\oplus}} \|(M,L)-(I,0)\|\end{aligned}$$

and then applying the reduction lemma. This alternative method, however, requires some additional simplificatory work.

COROLLARY 8.5. *Let $(A,B) \in \mathcal{L}(\mathbb{R}^{n+m}, \mathbb{R}^n)$ and $P \subset \mathbb{R}^m$ be a closed convex cone. Take any $Q \in \mathcal{O}(r,n)$ such that* $\mathrm{Im}\, Q = \mathrm{span}\, B(P)$. *Then,*

$$\mu^{\rm rank}_{\rm hyb}(\mathcal{F}^P_{A,B}) = \inf_{\substack{M,L\in\mathcal{L}(\mathbb{R}^n,\mathbb{R}^n)\\ (MA+L,MQ)\ \text{uncontrollable}}} \|(M,L)-(I,0)\|. \tag{8.13}$$

Proof. It suffices to apply Theorem 8.3, keeping in mind that the relaxed version of $\mathcal{F}^P_{A,B}$ is given by $[\mathcal{F}^P_{A,B}]^{\rm rel}(\cdot) = A(\cdot) + \mathrm{span}B(P)$. □

9. By way of conclusion. This paper is about measuring the distance to uncontrollability in cone-constrained linear control problems or, more generally, in control problems described by convex processes. We have adopted the strategy of splitting the analysis into two separate components. One part of our study consists in measuring the distance to irreproducibility. The term *reproducibility* refers to a suitable generalization of Kalman's rank condition. The second part of our study consists in measuring the distance to unilateral modality (i.e., existence of unilateral uncontrollable modes). It is in this part of our study that the conic aspect of the data (convex cones, convex processes, etc.) comes into the picture. Bilateral uncontrollable modes belong to the realm of classical linear algebra and therefore they are left aside (in fact, they are implicitly incorporated in the analysis of reproducibility).

The formulas for measuring the distance to unilateral modality were obtained by exploiting the reduction lemma. There is a different approach which consists in exploiting the concept of ε-eigenvalue for multivalued operators. Following Gajardo and Seeger [12], we denote by

$$\Lambda_\varepsilon(\mathcal{F}^*) = \{\lambda \in \mathbb{R} \mid \exists (q,p) \in \mathrm{gr}\mathcal{F}^* \text{with } q \neq 0, \text{ such that } |p-\lambda q| \leq \varepsilon|q|\}$$

the set of ε-eigenvalues of $\mathcal{F}^*$. For practical purposes, it is important to estimate the smallest value of $\varepsilon \in \mathbb{R}_+$ that guarantees the nonvacuity of $\Lambda_\varepsilon(\mathcal{F}^*)$. This smallest value is called the spectral threshold of $\mathcal{F}^*$. As established in [12], the equality

$$\inf\{\varepsilon \in \mathbb{R}_+ \mid \Lambda_\varepsilon(\mathcal{F}^*) \neq \emptyset\} = \inf_{\substack{\lambda \in \mathbb{R} \\ |q|=1}} \operatorname{dist}[\lambda q, \mathcal{F}^*(q)] \tag{9.1}$$

holds, in particular, when $\mathcal{F}$ is a strict closed convex process. Formula (9.1) gives us an alternative interpretation of the index $\mu^{\text{uni}}_{\text{add}}(\mathcal{F})$ when $\text{gr}\mathcal{F}$ is not a subspace (cf. Theorem 8.1).

Remark. When $\text{gr}\mathcal{F}$ is not a subspace, both expressions in (9.1) serve not only to measure the distance to unilateral modality but also to modality in general (i.e., existence of uncontrollable modes without specification of their nature). This observation is quite subtle because, in general, the sets $\sigma^{\text{uni}}(\mathcal{F})$ and $\sigma(\mathcal{F})$ don't coincide.

As far as the hybrid index $\mu^{\text{uni}}_{\text{hyb}}(\mathcal{F})$ is concerned, we see now appearing an expression of the form

$$\Psi_{\mathcal{F}^*}(\lambda) = \inf_{|q|=1} \operatorname{dist}[(q, \lambda q), gr\mathcal{F}^*] \tag{9.2}$$

which has to be minimized with respect to $\lambda \in \mathbb{R}$. The function $\Psi_{\mathcal{F}^*}$ is used by Seeger [31] in connection with the upper stabilization of the point-spectral set-valued mapping Λ. Observe that in a finite dimensional setting, one has

$$\Lambda(\mathcal{F}^*) = \{\lambda \in \mathbb{R} \mid \Psi_{\mathcal{F}^*}(\lambda) = 0\}.$$

In an infinite dimensional setting, the above equality is no longer true. As shown in [31], the roots of $\Psi_{\mathcal{F}^*}$ produce a set which may be much larger than $\Lambda(\mathcal{F}^*)$ (one gets the so-called approximate or stabilized spectrum of $\mathcal{F}^*$). This observation is just to warn the reader that some of our results (for instance, Theorem 8.2) do not extend to an infinite dimensional setting, unless important modifications are incorporated. Infinite dimensionality introduces various complications that are not addressed in the present work.

BIAS OPTIMALITY FOR CONTINUOUS-TIME CONTROLLED MARKOV CHAINS*

TOMÁS PRIETO-RUMEAU† AND ONÉSIMO HERNÁNDEZ-LERMA‡

Abstract. In this paper we give conditions for the existence of bias optimal policies in a class of continuous-time controlled Markov chains with unbounded reward and transition rates. Several characterizations of bias optimality are proposed. We also introduce new sets of conditions ensuring uniform exponential ergodicity of continuous-time controlled Markov chains.

Key words. continuous-time controlled Markov chain (or Markov decision process), average reward (or gain) criterion, Poisson equation, bias optimality, exponential ergodicity

AMS subject classifications. 93E20, 90C40, 60J27

DOI. 10.1137/S036301290343432

1. Introduction.

The long-run average reward or *gain* is one of the most widely used optimality criteria for stochastic control processes, in particular in applications to manufacturing processes, computer systems, and telecommunication networks, to name just a few [10, 11, 12, 13, 14, 15, 16, 17, 18, 19, 26, 28, 32]. However, as it is only concerned with the asymptotic behavior of the process it turns out to be extremely underselective. For instance, to be a little more precise, suppose that $J_T(f)$ denotes the expected total reward during the time interval $[0, T]$, when using a control policy f, and let

$$g(f) := \liminf_{T\to\infty} \frac{1}{T} J_T(f)$$

be the corresponding gain. Then if f and f' are two policies such that

$$J_T(f) = J_T(f') + T^\theta \tag{1.1}$$

for all $T > 0$ and some $\theta \in (0, 1)$, we have two policies that yield the *same gain* although their finite-horizon rewards are quite different. Thus the average reward criterion is "underselective" because it does not distinguish between policies such as f and f'.

To avoid such a behavior we have to restrict ourselves to "better" classes of policies. In this paper we first impose conditions under which the finite-horizon rewards of stationary policies are necessarily of the form

$$J_T(f) = T \cdot g(f) + h_f(\cdot) + e(f, T), \tag{1.2}$$

where $h_f(\cdot)$ is the so-called *bias* of f and $e(f, T)$ is a residual term converging to 0 as $T \to \infty$. Therefore, if f and f' are two stationary policies with the same gain, then

instead of (1.1) we now get

$$J_T(f) - J_T(f') = h_f(\cdot) - h_{f'}(\cdot) + [e(f,T) - e(f',T)].$$

If in addition $h_f(\cdot) \geq h_{f'}(\cdot)$, then the policy f, which has the larger bias, will eventually "overtake" f' in the sense that for any given $\varepsilon > 0$,

$$J_T(f) \geq J_T(f') - \varepsilon$$

for all T sufficiently large. In other words, maximizing the bias functions, within the class of gain optimal policies, allows us to take the policy with the larger growth.

The main objective for this paper is to make precise the ideas expressed in the previous paragraph for a class of continuous-time controlled Markov chains (CMCs), also known as Markov decision processes. Hence, starting with the set $\mathbb{F}$ of all stationary policies, we give conditions for the existence of subclasses

$$\mathbb{F}_{ao} \supseteq \mathbb{F}_{ca} \supseteq \mathbb{F}_{bias}, \tag{1.3}$$

which are, respectively, the class of stationary *average optimal* policies, the class of *canonical* policies, and the class of *bias optimal* policies. Our main goal is to show that $\mathbb{F}_{bias}$ is nonempty and to characterize the policies in it. It should be noted that the inclusions in (1.3) can all be *proper*. For instance, Guo and Liu [11] show an average optimal policy which is *not* canonical, whereas our Example 3.7 gives a canonical policy which is *not* bias optimal. Similar examples for discrete-time CMCs can be seen in [12, 15, 18, 19, 26], for instance.

The concept of bias optimality, which was introduced by Veinott [30], has been extensively studied for *discrete-time* CMCs—see, for instance, [2, 15, 16, 17, 18, 19, 26], and their references. However, to the best of our knowledge, this is the first paper dealing with the *continuous-time* case—although it is implicit in Puterman's work [25] for controlled diffusions in compact intervals. It should also be noted that in our control model a control action can be taken at *any* time $t \geq 0$ (as opposed to at certain times) and, therefore, our CMC cannot be reduced to a discrete-time problem.

Our point of departure to study bias optimality is the average reward optimality equation for continuous-time CMCs. This optimality equation was established by Guo and Hernández-Lerma in [10] under a uniform exponential ergodic property of the continuous-time CMC. The authors propose irreducibility and monotonicity conditions ensuring that the model is uniformly exponentially ergodic; see [10, Assumption C]. In this paper, we propose an alternative sufficient condition for uniform ergodicity, namely, we replace Assumption C in [10] with a uniform integrability condition. This result is of valuable interest by itself and not just in the context of average or bias optimality.

The remainder of our paper is organized as follows. In section 2 we introduce the control model we will be dealing with, paying particular attention to its ergodic properties. Our main results are stated in section 3. For expositional clarity, the proofs of the results in sections 2 and 3 are postponed to sections 4 and 5, respectively. Section 6 states the final conclusions and mentions some interesting open issues.

2. Model definition and ergodic properties.

The control model. The control model we are concerned with is

$$\{S, (A(i), i \in S), q_{ij}(a), r(i,a)\}, \tag{2.1}$$

where S is the *state space*, a denumerable set. Without loss of generality we will assume that $S = \{0, 1, 2, \ldots\}$, the set of nonnegative integers. Furthermore, $A(i)$ is a Borel space which stands for the set of *admissible control actions* in the state $i \in S$. Let $\mathcal{B}(A(i))$ be the Borel σ-algebra of subsets of $A(i)$, and $K := \{(i, a) : i \in S, a \in A(i)\}$. The numbers $q_{ij}(a)$, for $(i, a) \in K$ and $j \in S$ are the system's *transition rates* and so they satisfy that $q_{ij}(a) \geq 0$ if $j \neq i$. Moreover, the matrix $[q_{ij}(a)]$ is supposed to be *conservative*, i.e.,

$$\sum_{j \in S} q_{ij}(a) = 0 \quad \text{for all } (i, a) \in K, \tag{2.2}$$

and *stable*, which means that

$$q(i) := \sup_{a \in A(i)} [-q_{ii}(a)] < \infty \quad \text{for } i \in S. \tag{2.3}$$

In addition, $q_{ij}(a)$ is measurable in $a \in A(i)$ for each fixed $i, j \in S$. Finally, $r : K \to \mathbb{R}$ denotes the *reward rate* and is assumed to be measurable in $a \in A(i)$ for each fixed $i \in S$. (As $r(i, a)$ is allowed to take positive and negative values, it can be interpreted as a *cost rate* rather than a "reward.")

Control policies. Let $A := \cup_{i \in S} A(i)$. A function $f : S \to A$ is called a *decision function* if $f(i)$ is in $A(i)$ for all $i \in S$. The set of all such functions is denoted by $\mathbb{F}$. Now let Φ_m be the family of functions $\varphi_t(B|i)$ such that

- for each $i \in S$ and $t \geq 0$, $B \mapsto \varphi_t(B|i)$ is a probability measure on $\mathcal{B}(A(i))$, and
- for each $i \in S$ and $B \in \mathcal{B}(A(i))$, $t \mapsto \varphi_t(B|i)$ is a Lebesgue measurable function on $[0, \infty)$.

A family $\varphi = \{\varphi_t, t \geq 0\}$ in Φ_m is called a *randomized Markov policy*. If in addition there is a function $f \in \mathbb{F}$ such that $\varphi_t(\cdot|i)$ is concentrated at $f(i)$ for all $i \in S$ and $t \geq 0$, then φ is said to be a (deterministic) *stationary policy* and it is identified with f. In other words, we will identify the family $\mathbb{F}$ of decision functions with the family of stationary policies.

Notation. For each $\varphi = \{\varphi_t, t \geq 0\} \in \Phi_m$, i and j in S, and $t \geq 0$, we write

$$r(t, i, \varphi) := \int_{A(i)} r(i, a) \varphi_t(da|i), \tag{2.4}$$

$$q_{ij}(t, \varphi) := \int_{A(i)} q_{ij}(a) \varphi_t(da|i) \tag{2.5}$$

whenever these integrals are well defined. For a stationary policy $\varphi = f \in \mathbb{F}$, (2.4) and (2.5) reduce to $r(i, f) := r(i, f(i))$ and $q_{ij}(f) := q_{ij}(f(i))$, respectively.

DEFINITION 2.1. *A randomized Markov policy $\varphi \in \Phi_m$ is said to be* admissible *if $q_{ij}(t, \varphi)$ is continuous in t for each fixed $i, j \in S$. We shall denote by Φ_{ad} the family of all such policies.*

Observe that Φ_{ad} contains $\mathbb{F}$. The continuity of the transition rates is a standard assumption, e.g., [7, 9, 10]. It allows us to derive the transition function of the system from its transition rates. More precisely, for each $\varphi \in \Phi_{ad}$, the matrix $Q(t, \varphi) := [q_{ij}(t, \varphi)]$ is easily seen to be conservative and stable and, therefore, there exists a *Q-process*—that is, a possibly substochastic and nonhomogeneous transition function—with transition rates $q_{ij}(t, \varphi)$. To ensure the existence of a regular (stochastic) transition function $p^{\varphi}(s, i, t, j)$ and an associated Markov process $\{x^{\varphi}(t)\}$, we will borrow the following "drift" condition from [10].

Assumption A. There exists a sequence $\{S_m, m \geq 1\}$ of subsets of S, a non-decreasing function $w \geq 1$ on S, and constants $b \geq 0$, $c > 0$, and $M > 0$ such that

(a) $S_m \uparrow S$ and $\sup_{i \in S_m} q(i) < \infty$ for each $m \geq 1$;
(b) $\inf_{j \notin S_m} w(j) \to +\infty$ as $m \to \infty$;
(c) $\sum_{j \in S} q_{ij}(a) w(j) \leq -cw(i) + b\delta_{i0}$ for all $(i, a) \in K$, where δ_{ij} denotes the Kronecker delta;
(d) $|r(i, a)| \leq Mw(i)$ for all $(i, a) \in K$.

See Remark 2.1 in [10] for a discussion of Assumption A, in particular, its connection to similar conditions in the previous literature, e.g., Anderson [1] and Lund, Meyn, and Tweedie [20]. On the other hand, Assumption A guarantees that the long-run average reward in (2.7) is finite-valued. To state this we need some notation.

For each initial state $i \in S$ at time $s \geq 0$ and $\varphi \in \Phi_{ad}$, we denote by $P^{\varphi}_{s,i}$ and $E^{\varphi}_{s,i}$ the probability measure determined by $p^{\varphi}(s, i, t, j)$ and the corresponding expectation operator. If $s = 0$, we write $E^{\varphi}_{0,i}$ as E^{φ}_{i} and $p^{\varphi}(0, i, t, j)$ as $p^{\varphi}(i, t, j)$.

DEFINITION 2.2. *For each $\varphi \in \Phi_{ad}$, $i \in S$ and $T \geq 0$, let*

$$J_T(i, \varphi) := E^{\varphi}_{i} \left[\int_0^T r(t, x(t), \varphi) dt \right]. \tag{2.6}$$

The long-run average reward—*also known as the* gain—*of φ is given by*

$$J(i, \varphi) := \liminf_{T \to \infty} \frac{1}{T} J_T(i, \varphi). \tag{2.7}$$

The function

$$J^*(i) := \sup_{\varphi \in \Phi_{ad}} J(i, \varphi) \quad \textit{for } i \in S$$

is referred to as the optimal gain *or* optimal average reward. *A policy $\varphi^* \in \Phi_{ad}$ is said to be* average optimal *if $J(i, \varphi^*) = J^*(i)$ for all $i \in S$.*

Remark 2.3. Observe that in (2.6) the Markov process is not denoted $\{x^{\varphi}(t)\}$. The reason for this is that $P^{\varphi}_{s,i}$ is a probability measure over the set of all sample paths $\{x(t)\} \in S^{[0,\infty)}$ and thus writing, for instance, $E^{\varphi}_{s,i}[x^{\varphi}(t)]$ is redundant.

Under Assumption A, for each $f \in \mathbb{F}$ the corresponding Markov process $\{x^f(t)\}$ is nonexplosive [21, Theorem 2.1] and positive Harris recurrent and, further, it has a unique invariant probability measure μ_f for which

$$\mu_f(w) := \sum_{j \in S} w(j) \mu_f(j) < \infty; \tag{2.8}$$

see [21, Theorem 4.2]. Moreover, the gain or reward in (2.7) turns out to be a constant $J(\cdot, f) \equiv g(f)$ independent of the initial state $i \in S$ given by

$$g(f) = \lim_{T \to \infty} \frac{1}{T} J_T(i, f) = \sum_{j \in S} r(j, f) \mu_f(j) \quad \text{for } i \in S. \tag{2.9}$$

Our next assumption states the standard continuity-compactness conditions (see Assumption B in [10]).

Assumption B. For each $i, j \in S$

(a) $A(i)$ is compact, and

(b) $r(i,a)$, $q_{ij}(a)$, and $\sum_{j\in S} q_{ij}(a)w(j)$ are upper semicontinuous in $a \in A(i)$, where w is the function in Assumption A.

(c) There exists a nonnegative function w' on S and constants $b' \geq 0$, $c' > 0$, $M' > 0$ such that

$$q(i)w(i) \leq M'w'(i) \quad \text{and} \quad \sum_{j\in S} q_{ij}(a)w'(j) \leq c'w'(i) + b'$$

for all $(i,a) \in K$.

To state our last assumption, we need some notation. Let $w(\cdot) \geq 1$ be as in Assumption A. The *w-norm* of a function $u : S \to \mathbb{R}$ is defined as

$$||u||_w := \sup_{i\in S} \frac{|u(i)|}{w(i)}.$$

We shall denote by $B_w(S)$ the Banach space of functions on S with finite w-norm.

Assumption C.

(a) For each $f \in \mathbb{F}$, the Markov process $\{x^f(t)\}$ is irreducible; that is, given a pair of states $i \neq j$ there exists a set of distinct states $i = i_1, \ldots, i_m = j$ such that

$$\prod_{k=1}^{m-1} q_{i_k i_{k+1}}(f) > 0.$$

(b) The CMC model is *w-exponentially ergodic*; that is, there exist constants $\delta > 0$ and $R \geq 0$ such that

$$\sup_{f\in\mathbb{F}} |E_i^f u(x(t)) - \mu_f(u)| \leq Re^{-\delta t}||u||_w w(i) \tag{2.10}$$

for all $i \in S$, $u \in B_w(S)$, and $t \geq 0$, where $\mu_f(u) := \sum_{j\in S} u(j)\mu_f(j)$.

Assumption C(b) seems to be difficult to verify in practice. For noncontrolled Markov processes, several approaches yield exponential ergodicity; see, e.g., [3, 6, 20, 21, 29]. Also, there exist conditions ensuring uniform ergodicity of discrete-time controlled Markov chains; see [5], for instance. However, except for the paper [10], very little has been done for controlled continuous-time Markov chains.

Next, we propose two different sets of sufficient conditions for Assumption C(b). The first, stated in Theorem 2.4, is taken from [10]. (See, in particular, its connection to the monotonicity conditions in [20].)

THEOREM 2.4. *Suppose that Assumptions A(a)–(c) and C(a) are satisfied and, in addition, that*

(i) *for every $i, k \in S$ (where $k \neq i+1$) and for each $f \in \mathbb{F}$,*

$$\sum_{j\geq k} q_{ij}(f) \leq \sum_{j\geq k} q_{i+1,j}(f);$$

(ii) *for every $f \in \mathbb{F}$ and $j > i > 0$, there exist nonzero distinct states $i = i_1, \ldots, i_m \geq j$ such that*

$$\prod_{k=1}^{m-1} q_{i_k i_{k+1}}(f) > 0.$$

Then, Assumption C(b) holds with $\delta = c$, the constant in Assumption A(c).

For a proof, we refer to [10, 20]. Condition (i) in Theorem 2.4 imposes that for each $f \in \mathbb{F}$, the Markov process $\{x^f(t)\}$ is stochastically monotone, whereas condition (ii) means that for every $f \in \mathbb{F}$, we can "travel" with positive probability from state i to the set $\{j, j+1, \ldots\}$ (with $j > i > 0$) without passing through $\{0\}$.

Our next result, rather than the monotonicity conditions in Theorem 2.4, imposes a uniform integrability assumption.

THEOREM 2.5. *Suppose that Assumptions A(a)–(c), B(a), and C(a) are satisfied. Suppose also that for every $i, j \in S$, the function $a \mapsto q_{ij}(a)$ is continuous on $A(i)$ (cf. Assumption B(b)) and that*

$$\lim_{k\to\infty} \sup_{f\in\mathbb{F}} \left\{ \sum_{j=k}^{\infty} p^f(i,t,j) w(j) \right\} = 0 \quad \text{for every } i \in S \text{ and } t \geq 0. \tag{2.11}$$

Then, Assumption C(b) holds.

Observe that by [10, Lemma 3.2], the condition (2.11) holds for every single $f \in \mathbb{F}$. The proof of Theorem 2.5, which is based on the discrete-time ergodicity results in [5], is given in section 4. See Remark 4.7 for an equivalent formulation of (2.11).

Assumptions A, B, and C are supposed to hold throughout the following.

3. Main results. For expositional convenience, in this section we state Theorems 3.3, 3.6, 3.8 and 3.9 but their proofs are postponed to section 5.

Canonical policies. Let $\mathbb{F}_{ao} \subseteq \mathbb{F}$ be the family of stationary average optimal policies. Under Assumptions A, B, and C, the set $\mathbb{F}_{ao}$ is nonempty; see [10]. Actually, its subset $\mathbb{F}_{ca}$ defined next is also nonempty.

DEFINITION 3.1.

(a) *A pair (g^*, h^*) consisting of a constant $g^* \in \mathbb{R}$ and a function $h^* \in B_w(S)$ is said to be a* solution of the average reward optimality equation (*AROE*) *if*

$$g^* = \max_{a\in A(i)} \left[r(i,a) + \sum_{j\in S} q_{ij}(a) h^*(j) \right] \quad \text{for all } i \in S. \tag{3.1}$$

(b) *If $f^* \in \mathbb{F}$ is such that $f^*(i) \in A(i)$ attains the maximum in* (3.1) *for all $i \in S$, that is,*

$$g^* = r(i, f^*) + \sum_{j\in S} q_{ij}(f^*) h^*(j) \quad \text{for } i \in S, \tag{3.2}$$

then f^* is called a canonical policy*, and, furthermore, (g^*, h^*, f^*) is called a* canonical triplet*. The set of canonical policies is denoted $\mathbb{F}_{ca}$.*

Remark 3.2. If (g^*, h^*) is a solution of the AROE, it is easily seen that g^* is unique (see (3.3) below). However, as a consequence of (2.2), h^* can be replaced with $h^* + z$ for any constant z. In fact, as in the proof of Proposition 3.5, it can be shown that h^* is unique up to additive constants.

As in [10, Theorem 4.1], our standing assumptions guarantee the existence of a canonical triplet (g^*, h^*, f^*). Moreover,

$$g^* = J^*(i) = J(i, f^*) \quad \text{for } i \in S, \tag{3.3}$$

which means that g^* is the optimal gain and that f^* is average optimal; hence

$$\mathbb{F}_{ca} \subseteq \mathbb{F}_{ao}. \tag{3.4}$$

In general, the inclusion in (3.4) can be proper; in other words, there can be average optimal policies which are *not* canonical—see Guo and Liu [11], for instance. However, under our Assumptions A, B, and C, the following Theorem 3.3 states that in fact the *equality* holds in (3.4).

THEOREM 3.3. *A stationary policy is canonical if and only if it is average optimal, that is,* $\mathbb{F}_{ca} = \mathbb{F}_{ao}$.

The Poisson equation. For each stationary policy $f \in \mathbb{F}$, we define the *bias* of f as

$$h_f(i) := \int_0^\infty [E_i^f r(x(t), f) - g(f)]dt \quad \text{for } i \in S. \tag{3.5}$$

By (2.10) and Assumptions A(d) and C(b),

$$|E_i^f r(x(t), f) - g(f)| \le RMw(i)e^{-\delta t} \quad \text{for all } t \ge 0$$

and so

$$|h_f(i)| \le \delta^{-1} RMw(i) \quad \text{for } i \in S. \tag{3.6}$$

It follows that h_f is in $B_w(S)$ and also that its w-norm is *uniformly bounded* in $f \in \mathbb{F}$ because

$$||h_f||_w \le \delta^{-1} RM \quad \text{for every } f \in \mathbb{F}.$$

We also get the following.

PROPOSITION 3.4. *For each* $f \in \mathbb{F}$, *the pair* $(g(f), h_f)$ *is the unique solution of the so-called* Poisson equation

$$g(f) = r(i, f) + \sum_{j \in S} q_{ij}(f) h_f(j) \quad \textit{for } i \in S \tag{3.7}$$

for which the μ_f*-expectation of the bias* h_f *is zero:*

$$\sum_{j \in S} h_f(j)\mu_f(j) = 0. \tag{3.8}$$

Proof. For a proof of (3.7) see, for instance, Theorem 5.2(ii) in [4] or Lemma 5.1 in [10]. To obtain (3.8) first note that, by (3.6) and (2.8), h_f is indeed μ_f-integrable. Then in (3.5) choose the distribution of the inital state to be μ_f, and so (3.8) follows from a direct calculation.

To prove uniqueness we will use the fact that, by (2.10),

$$\lim_{t \to \infty} \frac{1}{t} E_i^f [u(x(t))] = 0 \tag{3.9}$$

for all $f \in \mathbb{F}$, $i \in S$, and $u \in B_w(S)$. We will also use the notation

$$(Q^f h)(i) := \sum_{j \in S} q_{ij}(f) h(j). \tag{3.10}$$

Now, for $k = 1, 2$, let $(g_k, h_k) \in \mathbb{R} \times B_w(S)$ be a solution of (3.7), (3.8). Then for each $k = 1, 2$, Dynkin's formula

$$E_i^f h_k(x(t)) = h_k(i) + E_i^f \left[\int_0^t (Q^f h_k)(x(s))ds \right] \tag{3.11}$$

together with (3.7) and (2.6) yields

$$E_i^f h_k(x(t)) = h_k(i) + t \cdot g_k - J_t(i, f). \tag{3.12}$$

Multiplying both sides by $1/t$ and letting $t \to \infty$, it follows from (3.9) and (2.9) that

$$g_1 = g_2 = g(f).$$

It only remains to show that $h_1 = h_2$. Let $u := h_1 - h_2$. Substracting the Poisson equation (3.7) for (g_2, h_2) from the corresponding equation for (g_1, h_1) we get that

$$(Q^f u)(i) = 0 \quad \text{for } i \in S. \tag{3.13}$$

Therefore, using Dynkin's formula (3.11) with u in lieu of h_k we see that u is *harmonic*, that is,

$$u(i) = E_i^f u(x(t)) = \sum_{j \in S} p^f(i, t, j) u(j) \quad \text{for } t \geq 0.$$

Thus, letting $t \to \infty$, (2.10) and (3.8) give

$$u(i) = \mu_f(u) = \mu_f(h_1) - \mu_f(h_2) = 0 \quad \text{for all } i \in S, \tag{3.14}$$

that is, $h_1(\cdot) = h_2(\cdot)$. □

Now let $f \in \mathbb{F}_{ao}$ be an average optimal policy. Then, by Theorem 3.3, f is canonical and, therefore, it satisfies (3.2), i.e.,

$$g^* = r(i, f) + \sum_{j \in S} q_{ij}(f) h^*(j).$$

On the other hand, since $g(f) = g^*$, the Poisson equation (3.7) for f becomes

$$g^* = r(i, f) + \sum_{j \in S} q_{ij}(f) h_f(j),$$

and so substracting the last two equalities we conclude that $u := h^* - h_f$ satisfies (3.13). This implies that u is harmonic and, as in (3.14), we conclude that $u = h^* - h_f = \mu_f(h^*) - \mu_f(h_f) = \mu_f(h^*)$. We can summarize this as follows.

PROPOSITION 3.5. *If $f \in \mathbb{F}$ is average optimal, then its bias h_f and any function h^* in the AROE* (3.1) *are equal up to an additive constant; in fact*

$$h_f(i) = h^*(i) - \mu_f(h^*) \quad \textit{for } i \in S. \tag{3.15}$$

The next theorem provides an interesting characterization of a canonical triplet. We shall need a little notation first. In addition to the finite-horizon reward in (2.6), we consider the reward functional

$$J_T(i, s, \varphi, h) := E_{s,i}^{\varphi} \left[\int_s^T r(t, x(t), \varphi) dt + h(x(T)) \right]$$

for each $i \in S$, $0 \leq s \leq T$, $\varphi \in \Phi_{ad}$, and $h \in B_w(S)$. The corresponding optimal reward function is

$$J_T^*(i, s, h) := \sup_{\varphi \in \Phi_{ad}} J_T(i, s, \varphi, h). \tag{3.16}$$

A policy attaining the supremum in (3.16) for all $i \in S$ and a given $s \in [0, T]$ will be called *optimal for the finite-horizon control problem over* $[s, T]$ *with terminal payoff* h.

THEOREM 3.6. *$(g^*, h^*, f^*) \in \mathbb{R} \times B_w(S) \times \mathbb{F}$ is a canonical triplet if and only if for all $i \in S$ and $0 \le s \le T$,*

(i) $J_T^*(i, s, h^*) = (T - s)g^* + h^*(i)$, *and*

(ii) $J_T^*(i, s, h^*) = J_T(i, s, f^*, h^*)$, *i.e., f^* is optimal for the finite-horizon control problem over $[s, T]$ with terminal payoff h^*.*

The characterization of a canonical triplet in Theorem 3.6 is essentially the same as the one proposed by Yushkevich [33] (see also [14] or [15]) for *discrete-time* CMCs.

Bias optimality. The function $\hat{h} \in B_w(S)$ defined as

$$\hat{h}(i) := \sup_{f \in \mathbb{F}_{ao}} h_f(i) \quad \text{for } i \in S \tag{3.17}$$

is called the *optimal bias function*. (By (3.6), $\hat{h}$ is indeed in $B_w(S)$.) A stationary average optimal policy $\hat{f}$ is said to be *bias optimal* if it attains the maximum in (3.17), i.e.,

$$h_{\hat{f}}(i) = \hat{h}(i) \quad \text{for } i \in S.$$

We shall denote by $\mathbb{F}_{bias}$ the family of bias optimal policies. By definition of bias optimality, $\mathbb{F}_{bias}$ is a subset of $\mathbb{F}_{ao} = \mathbb{F}_{ca}$, and in general the inclusion is *strict*: the following simple example shows an average optimal policy which is *not* bias optimal. Other examples are given by Lewis and Puterman [18, 19] and Haviv and Puterman [12].

Example 3.7. Consider a control model as in (2.1) with components

$$S = \{1, 2\},\ A(1) = \{1\},\ A(2) = \{1, 2\},$$

$$q_{11}(1) = -2,\ q_{22}(1) = -1,\ q_{22}(2) = -2,$$

$$r(1, 1) = 4,\ r(2, 1) = 1,\ r(2, 2) = 0.$$

There are two stationary policies f_1, f_2, with $f_1(2) = 1$, $f_2(2) = 2$. Moreover, the corresponding gain and bias functions are

$$g(f_1) = g(f_2) = 2 \quad \text{and} \quad h_{f_1}(\cdot) = \begin{pmatrix} 2/3 \\ -1/3 \end{pmatrix},\ h_{f_2}(\cdot) = \begin{pmatrix} 1/2 \\ -1/2 \end{pmatrix}.$$

Hence both policies have the same gain and they are average optimal [10, Theorem 4.1] but only f_1 is bias optimal.

The following result states the existence of bias optimal policies as well as a useful "growth sensitive" characterization (b_3) of bias optimality.

THEOREM 3.8. *Under Assumptions A, B, and C,*

(a) *There exists a bias optimal policy—that is, $\mathbb{F}_{bias}$ is nonempty.*

(b) *The following statements are equivalent:*

(b_1) *$\hat{f} \in \mathbb{F}$ is bias optimal.*

(b_2) *$\hat{f} \in \mathbb{F}$ is a canonical policy and $\mu_{\hat{f}}(\hat{h}) = 0$.*

(b_3) *$\hat{f} \in \mathbb{F}$ is* weakly overtaking optimal *in $\mathbb{F}$, that is,*

$$\liminf_{T \to \infty} [J_T(i, \hat{f}) - J_T(i, f)] \ge 0 \quad \textit{for every } i \in S \textit{ and } f \in \mathbb{F}. \tag{3.18}$$

More explicitly, (3.18) states that for every $\varepsilon > 0$ there exists $T_\varepsilon = T_\varepsilon(i, \hat{f}, f)$ such that

$$J_T(i, \hat{f}) \geq J_T(i, f) - \varepsilon \quad \text{for } T \geq T_\varepsilon. \tag{3.19}$$

(If (3.19) holds for $\varepsilon = 0$, it is said that $\hat{f}$ *overtakes* f, a concept that can be traced back to Ramsey [27]. The weaker form in (3.18) is due to Gale [8] and von Weizsäcker [31].)

To conclude this section we shall introduce another characterization of bias optimality related to (b_2) in Theorem 3.8 and the AROE (3.1).

A pair $(g^*, u) \in \mathbb{R} \times B_w(S)$ is said to verify the *bias optimality equations* if (g^*, u) is a solution of the AROE, i.e.,

$$g^* = \max_{a \in A(i)} \left[r(i,a) + \sum_{j \in S} q_{ij}(a) u(j) \right] \quad \text{for } i \in S, \tag{3.20}$$

and in addition there exists $v \in B_w(S)$ such that

$$u(i) = \max_{a \in A^*(i)} \left[\sum_{j \in S} q_{ij}(a) v(j) \right] \quad \text{for } i \in S, \tag{3.21}$$

where $A^*(i)$ is the set of actions $a \in A(i)$ attaining the maximum in (3.20).

THEOREM 3.9. *$(g^*, \hat{h})$ is the unique pair that verifies the bias optimality equations. Moreover, a policy $f \in \mathbb{F}$ is bias optimal if and only if for all $i \in S$, $f(i)$ attains the maximum in the two equations* (3.20), (3.21).

Remark 3.10. As in (3.12), from Dynkin's formula and the Poisson equation (3.7) we have

$$J_T(i, f) = T \cdot g(f) + h_f(i) - E_i^f h_f(x(T)) \quad \text{for } f \in \mathbb{F},\ i \in S, \text{ and } T \geq 0.$$

This fact and (2.10) yield

$$\sup_{f \in \mathbb{F}} ||J_T(\cdot, f) - T \cdot g(f) - h_f(\cdot)||_w = \mathrm{O}(e^{-\delta T}).$$

This shows that the rate of convergence to zero of the residual term in (1.2) is uniformly exponential.

4. Proof of Theorem 2.5. Throughout this section, we assume that the hypotheses of Theorem 2.5 are verified, namely, Assumptions A(a)–(c), B(a), and C(a), the continuity of the transition rates, and the uniform integrability condition (2.11). To prove Theorem 2.5, we will consider a discretization of the Markov control process; in other words, we will deal with a "skeleton" CMC. We suppose that the system is observed at times $0, \Delta, 2\Delta, \ldots$, where, for the moment, $\Delta > 0$ is left unspecified.

In the next paragraphs, we make important remarks with regard to the discretization of the continuous-time CMC.

Topology of the action spaces. If the state of the system is i at time $k\Delta$, then the action chosen at i at time $k\Delta$ *does not* suffice to determine the state of the system at time $(k+1)\Delta$. The reason for this is that the process can move to any state $j \in S$ between times $k\Delta$ and $(k+1)\Delta$; as a consequence, we must specify the action chosen not only at i, but at *every* state $j \in S$.

This means that when dealing with the discretized CMC, the set of available actions at the state $i \in S$ is $\mathbb{F}$ instead of $A(i)$. (We are focusing on stationary strategies.) This is not a real problem because $\mathbb{F}$ is metrizable and compact with the topology of componentwise convergence, i.e., $f_n \to f$ if $f_n(i) \to f(i)$ for every $i \in S$; see the paragraph after Assumption 2.1 in [5, p. 541].

Definition of the skeleton CMC. The above paragraph implies that the corresponding skeleton CMC is defined by the following elements:

- the denumerable state space $S = \{0, 1, 2, \ldots\}$,
- the action space $\mathbb{F}$, a compact metric space, which is the same for every state $i \in S$, and
- the transition probabilities $p^f(i, \Delta, j)$, for $\Delta > 0$, $i, j \in S$, and $f \in \mathbb{F}$.

As we are mainly concerned with ergodic properties of Markov processes, the definition of the corresponding reward function is not relevant.

Observe that a deterministic stationary strategy for the skeleton CMC does not correspond to a deterministic stationary strategy for the continuous-time CMC; indeed, the chosen action (in $\mathbb{F}$) would depend on the state of the system at the times $k\Delta$ and, therefore, it would not be stationary (in the continuous-time sense). Hence, in the discrete-time model, we will deal with a subclass of deterministic stationary strategies, namely, we will consider *constant* deterministic stationary strategies, that is, the *same* action $f \in \mathbb{F}$ is chosen at *every* state $i \in S$.

Our plan is as follows. Uniform ergodicity has been proved for discrete-time CMCs in Key Theorem II [5, p. 544]. (For ease of reference, we state this result here in Theorem 4.1.) In Propositions 4.5, 4.6, and 4.9, we propose conditions under which the hypotheses of Theorem 4.1 are verified by the skeleton CMC model. Then, we will prove Theorem 2.5.

THEOREM 4.1. *Suppose that for some $\Delta > 0$, the skeleton CMC verifies the following properties:*

(i) *For every i and j in S, the function*

$$f \mapsto p^f(i, \Delta, j)$$

is continuous on $\mathbb{F}$.

(ii) *For every i in S, the function*

$$f \mapsto \sum_{j \in S} p^f(i, \Delta, j) w(j)$$

is continuous on $\mathbb{F}$.

(iii) *There exists a constant $\gamma < 1$ such that*

$$\sum_{j=1}^{\infty} p^f(i, \Delta, j) w(j) \le \gamma w(i)$$

for every $f \in \mathbb{F}$ and $i \in S$.

Then, there exist constants $H > 0$ and $\beta < 1$ such that

$$\sum_{j \in S} \left| p^f(i, k\Delta, j) - \mu_f(j) \right| w(j) \le H\beta^k w(i) \quad \text{and} \quad \sum_{j \in S} p^f(i, \Delta, j) w(j) \le H w(i)$$

for every $i \in S$, $k \ge 0$ integer, and $f \in \mathbb{F}$. (Recall that μ_f is the invariant probability measure of $\{x^f(t)\}$.)

Proof. For every $f \in \mathbb{F}$, the Markov chain $\{x^f(k\Delta)\}_{k\geq 0}$ is irreducible and aperiodic (recall Assumption C(a)) and, therefore, the stated result directly follows from Key Theorem II in [5, p. 544]. □

Next, we are going to prove that condition (i) in Theorem 4.1 is verified for every $\Delta > 0$. First, we will show it for a model with *bounded* transition rates, and then this will be extended to a model with unbounded transition rates.

We give some previous definitions. Define the 1-norm of the real-valued vector $z := \{z(k)\}_{k\in S}$ as the supremum norm, that is, $||z||_1 := \sup_{k\in S} |z(k)|$. Let $C(1) := \{z \in \mathbb{R}^S : ||z||_1 \leq 1\} \subseteq B_w(S)$. For a given $f \in \mathbb{F}$, recall that the operator Q^f was defined in (3.10) as

$$(Q^f z)(i) := \sum_{k\in S} q_{ik}(f)z(k) \quad \text{for } i \in S,$$

where $z = \{z(k)\}_{k\in S}$.

LEMMA 4.2. *Suppose* $\sup_{i\in S} q(i) =: q < \infty$. *Then, the following results hold.*

(i) *For each* $f \in \mathbb{F}$, Q^f *is a linear operator on* $B_w(S)$ *that satisfies*

$$||Q^f z||_w \leq (q + b)||z||_w, \tag{4.1}$$

where b *is as in Assumption A.*

(ii) *If the sequence* $\{f_n\}_{n\in\mathbb{N}} \subseteq \mathbb{F}$ *converges to* $f \in \mathbb{F}$, *then*

$$\lim_{n\to\infty} \sup_{z\in C(1)} \{||Q^{f_n} z - Q^f z||_w\} = 0.$$

(iii) *If the sequence* $\{z_n\}_{n\in\mathbb{N}} \subseteq C(1)$ *converges pointwise to* $z \in C(1)$, *i.e.,* $z_n(k) \to z(k)$ *for every* $k \in S$, *then*

$$\lim_{n\to\infty} ||Q^f z_n - Q^f z||_w = 0 \quad \textit{for every } f \in \mathbb{F}.$$

Proof. The proof of this lemma is straightforward and we omit it. However, it is worth noting that the following is needed in the proof:

$$\lim_{k\to\infty} \sup_{a\in A(i)} \left\{ \sum_{j=k}^{\infty} q_{ij}(a) \right\} = 0 \quad \text{for every } i \in S,$$

and this result is derived from Dini's theorem. □

Suppose that $f \in \mathbb{F}$ and $j \in S$ are given. Define $z^f(t) \in C(1)$ (we do not make j explicit in the notation) as

$$(z^f(t))(i) := p^f(i, t, j) \quad \text{for } i \in S \text{ and } t \geq 0.$$

LEMMA 4.3. *Suppose that* $\sup_{i\in S} q(i) =: q < \infty$. *Then,*

(i) *For every* $f \in \mathbb{F}$ *and* $j \in S$, *the function* $t \mapsto z^f(t)$ *is* $C^1[0, \infty)$ *and it is a solution of the differential equation*

$$\frac{d}{dt} z^f(t) = Q^f z^f(t) \quad \textit{for } t \geq 0, \tag{4.2}$$

where continuity and differentiability are understood to be in the w*-norm* (*and* not *in a componentwise sense*).

(ii) *For every* $t \geq 0$ *and* $i, j \in S$, $f \mapsto p^f(i, t, j)$ *is continuous on* $\mathbb{F}$.

Proof of (i). Observe that the equality (4.2) corresponds to Kolmogorov's backward equations, which are known to hold in a *componentwise* sense. The fact that $t \mapsto z^f(t)$ is $C^1[0,\infty)$ in the w-norm and that (4.2) holds in the w-norm is deduced from Lemma 4.2(iii), and we skip the details. □

Proof of (ii). It is well known that

$$||y(t)|| \le ||y(0)|| + \int_0^t ||y'(s)||ds \quad \text{for } t \ge 0, \tag{4.3}$$

where y is a $C^1[0,\infty)$ function on a Banach space.

Fix an arbitrary $f \in \mathbb{F}$ and a sequence $\{f_n\}_{n\in\mathbb{N}} \subseteq \mathbb{F}$ that converges to f. By part (i) of this lemma and (4.3),

$$||z^{f_n}(t) - z^f(t)||_w \le \int_0^t ||Q^{f_n} z^{f_n}(s) - Q^f z^f(s)||_w ds \quad \text{for } t \ge 0. \tag{4.4}$$

On the other hand, $||Q^{f_n} z^{f_n}(s) - Q^f z^f(s)||_w$ is bounded by

$$||Q^{f_n} z^{f_n}(s) - Q^{f_n} z^f(s)||_w + ||Q^{f_n} z^f(s) - Q^f z^f(s)||_w,$$

which, by (4.1), is less than or equal to

$$(q+b)||z^{f_n}(s) - z^f(s)||_w + ||Q^{f_n} z^f(s) - Q^f z^f(s)||_w.$$

Now, by Lemma 4.2(ii), given $\varepsilon > 0$ there exists N (not depending on $s \ge 0$) such that

$$||Q^{f_n} z^f(s) - Q^f z^f(s)||_w \le \varepsilon \quad \text{for } n \ge N \text{ and every } s \ge 0.$$

Combining these bounds with (4.4), we deduce that

$$||z^{f_n}(t) - z^f(t)||_w \le (q+b) \int_0^t ||z^{f_n}(s) - z^f(s)||_w ds + \varepsilon t \quad \text{for } n \ge N \text{ and } t \ge 0.$$

Hence, applying Gronwall's inequality, we have that

$$||z^{f_n}(t) - z^f(t)||_w \le \varepsilon T e^{(q+b)T} \quad \text{for } n \ge N \text{ and } 0 \le t \le T,$$

where $T > 0$ is arbitrary. In particular,

$$|p^{f_n}(i,t,j) - p^f(i,t,j)| \le w(i)\varepsilon T e^{(q+b)T} \quad \text{for } n \ge N,$$

thus showing that $f \mapsto p^f(i,t,j)$ is continuous on $\mathbb{F}$, as we wanted to prove. □

Now we drop the boundedness hypothesis on the transition rates made in Lemmas 4.2 and 4.3. Given a state $m \in S$ and $f \in \mathbb{F}$, let

$$T_m := \min_{s\ge 0}\{x^f(s) \ge m\}.$$

Define then the Markov process $\{x_m^f(t)\}$ as

$$x_m^f(t) := x^f(t \wedge T_m)$$

(where "$\wedge$" stands for *minimum*). The transition probabilities of $\{x_m^f\}$ are denoted $p_m^f(i,t,j)$ for $t \ge 0$ and $i, j \in S$.

LEMMA 4.4. *For arbitrary $i, j \in S$ and $t \geq 0$,*

$$\lim_{m\to\infty} \sup_{f\in\mathbb{F}} \{|p^f(i,t,j) - p^f_m(i,t,j)|\} = 0.$$

(*Notice that we do not assume* $\sup_{i\in S} q(i) < \infty$.)

Proof. We have that

$$\begin{aligned} p^f(i,t,j) - p^f_m(i,t,j) &= E^f_i \left[I\{x^f(t) = j\} - I\{x^f_m(t) = j\} \right] \\ &= E^f_i \left[I\{t \geq T_m\} (I\{x^f(t) = j\} - I\{x^f_m(t) = j\}) \right], \end{aligned}$$

where $I\{\cdot\}$ denotes the indicator function. Hence,

$$|p^f(i,t,j) - p^f_m(i,t,j)| \leq 2P^f_{0,i}\{t \geq T_m\}. \tag{4.5}$$

(Recall the notation introduced in section 2.) We also have that

$$\begin{aligned} \{t \geq T_m\} &= \left\{ \sup_{0\leq s\leq t} \{x^f(s)\} \geq m \right\} \\ &\subseteq \left\{ \sup_{0\leq s\leq t} \{w(x^f(s))e^{-bs}\} \geq w(m)e^{-bt} \right\}, \end{aligned}$$

where the constant $b \geq 0$ is taken from Assumption A. Thus, from the nonexplosion condition CD0 in [21, p. 524] and Theorem 2.1 in [21], we deduce that

$$P^f_{0,i}\{t \geq T_m\} \leq w(i)e^{bt}/w(m)$$

(it is important to note that this bound is uniform in $f \in \mathbb{F}$ because the drift constants in [21, condition CD0] do not depend on f), which, together with (4.5), yields that

$$\sup_{f\in\mathbb{F}}\{|p^f(i,t,j) - p^f_m(i,t,j)|\} \leq 2w(i)e^{bt}/w(m).$$

Letting $m \to \infty$ in this expression proves the lemma. □

Now we can show that condition (i) in Theorem 4.1 holds.

PROPOSITION 4.5. *For every $t \geq 0$, and $i, j \in S$ fixed, the function*

$$f \mapsto p^f(i,t,j)$$

is continuous on $\mathbb{F}$.

Proof. Observe that the process $\{x^f_m(t)\}$ verifies the hypotheses of Lemma 4.3 because its transition rates are bounded by $\sup_{0\leq i<m} q(i)$, and then, for fixed $i, j, m \in S$ and $t \geq 0$, $f \mapsto p^f_m(i,t,j)$ is continuous on $\mathbb{F}$. The continuity of $f \mapsto p^f(i,t,j)$ is now a straightforward consequence of Lemma 4.4. □

Condition (ii) in Theorem 4.1, stated in Proposition 4.6, is now easily derived from condition (2.11), and the proof is omitted.

PROPOSITION 4.6. *If condition* (2.11) *is satisfied, then for every $t \geq 0$ and $i \in S$ fixed, the function*

$$f \mapsto \sum_{j\in S} p^f(i,t,j)w(j)$$

is continuous on $\mathbb{F}$.

Remark 4.7. Observe that, taking into account the result of Proposition 4.5, it follows that the uniform integrability condition (2.11) and the continuity of $f \mapsto \sum_{j\in S} p^f(i,t,j)w(j)$ are in fact equivalent. Indeed, the continuous functions

$$f \mapsto \sum_{j=0}^{k} p^f(i,t,j)w(j)$$

form an increasing sequence that converges to the continuous function

$$f \mapsto \sum_{j\in S} p^f(i,t,j)w(j).$$

Hence, by Dini's theorem, convergence is uniform on $\mathbb{F}$, and then (2.11) follows.

Remark 4.8. It could seem that

$$f \mapsto \sum_{j\in S} q_{ij}(f)w(j) \text{ is continuous} \tag{4.6}$$

is the continuous-time version of the discrete-time condition in Theorem 4.1(ii)

$$f \mapsto \sum_{j\in S} p^f(i,t,j)w(j) \text{ is continuous.} \tag{4.7}$$

However, this is not true because (4.6) takes into account only the first transition when starting from state $i \in S$, while (4.7) includes all the transitions that occured in the time interval $[0,t]$.

The following result establishes condition (iii) in Theorem 4.1.

PROPOSITION 4.9. *There exists* $\Delta > 0$ *such that*

$$\sum_{j=1}^{\infty} p^f(i,t,j)w(j) \le e^{-ct/2}w(i)$$

for every $i \in S$, $0 \le t \le \Delta$, *and* $f \in \mathbb{F}$, *where* c *is as in Assumption A.*

Proof. From the drift condition in Assumption A

$$\sum_{j=0}^{\infty} q_{ij}(a)w(j) \le -cw(i) + b\delta_{i0} \quad \text{for every } i \in S \text{ and } a \in A(i),$$

and using Dynkin's formula, we obtain (see, e.g., [6, equation 31])

$$\sum_{j=0}^{\infty} p^f(i,t,j)w(j) \le e^{-ct}w(i) + be^{-ct}\int_0^t p^f(i,s,0)e^{cs}ds, \tag{4.8}$$

which holds for every $f \in \mathbb{F}$, $i \in S$, and $t \ge 0$. The inequality (4.8) may be rewritten as

$$\sum_{j=1}^{\infty} p^f(i,t,j)w(j) \le e^{-ct/2}w(i)R(t,i,f),$$

where

$$R(t,i,f) := e^{-ct/2}\left(1 + \frac{b}{w(i)}\int_0^t p^f(i,s,0)e^{cs}ds - \frac{w(0)}{w(i)}p^f(i,t,0)e^{ct}\right).$$

Hence, to prove the proposition, it suffices to show that there exists $\Delta > 0$ such that $R(t,i,f) \leq 1$ or, equivalently,

$$\frac{b}{w(i)} \int_0^t p^f(i,s,0) e^{cs} ds - \frac{w(0)}{w(i)} p^f(i,t,0) e^{ct} \leq e^{ct/2} - 1 \tag{4.9}$$

for every $0 \leq t \leq \Delta$, $i \in S$, and $f \in \mathbb{F}$. We will proceed in two steps, depending on whether $i = 0$ or $i > 0$.

Case $i = 0$. Proving (4.9) for $i = 0$ is equivalent to show that

$$\frac{b}{w(0)} \int_0^t p^f(0,s,0) e^{cs} ds - p^f(0,t,0) e^{ct} \leq e^{ct/2} - 1,$$

and it suffices that

$$p^f(0,t,0) e^{ct} \geq \frac{b}{w(0)} \int_0^t p^f(0,s,0) e^{cs} ds.$$

Observe now that

$$p^f(0,s,0) e^{cs} \leq e^{ct} \quad \text{and} \quad p^f(0,t,0) \geq e^{-q(0)t}$$

(see (2.3) for the definition of $q(0)$) for every $0 \leq s \leq t$ and $f \in \mathbb{F}$. Hence, choosing $\Delta_1 > 0$ such that

$$e^{-q(0)t} \geq \frac{b}{w(0)} t \quad \text{for } 0 \leq t \leq \Delta_1$$

yields

$$R(t,0,f) \leq 1 \quad \text{for } 0 \leq t \leq \Delta_1 \text{ and } f \in \mathbb{F}.$$

Case $i > 0$. We will show that for $i \geq 1$,

$$\frac{b}{w(i)} \int_0^t p^f(i,s,0) e^{cs} ds \leq e^{ct/2} - 1. \tag{4.10}$$

Note that $e^{ct/2} - 1 \geq ct/2$ and that $\int_0^t p^f(i,s,0) e^{cs} ds \leq t e^{ct}$. As a consequence, there exists some $I \geq 1$ (not depending on f) such that

$$\frac{b}{w(i)} e^{ct} \leq \frac{c}{2} \quad \text{for } 0 \leq t \leq \Delta_1 \text{ and } i > I.$$

Therefore, $R(t,i,f) \leq 1$ for every $0 \leq t \leq \Delta_1$, $i > I$, and $f \in \mathbb{F}$.
In case $1 \leq i \leq I$, observe that

$$p^f(i,s,0) \leq 1 - e^{q_{ii}(f)s} \leq -q_{ii}(f)s \leq q(i)s.$$

Thus, in order to establish (4.10), it is enough to prove that

$$\frac{b e^{ct} q(i) t^2}{2 w(i)} \leq ct/2,$$

which is verified for every $1 \leq i \leq I$, $f \in \mathbb{F}$, and $0 \leq t \leq \Delta_2$, provided that $\Delta_2 > 0$ is small enough.

To conclude, we have proved that $R(t,i,f) \le 1$ for every $0 \le t \le \min\{\Delta_1, \Delta_2\}$, $i \in S$ and $f \in \mathbb{F}$. □

Remark 4.10. The term $e^{-ct/2}$ in the statement of Proposition 4.9 can be replaced with $e^{-\alpha t}$ for any $0 < \alpha < c$, and the proof would be the same.

Finally, we can prove our main result.

Proof of Theorem 2.5. Choosing $\Delta > 0$ as in Proposition 4.9, it follows from Propositions 4.5, 4.6, and 4.9 that conditions (i), (ii), and (iii) in Theorem 4.1 are verified by the skeleton CMC.

Hence, given arbitrary $t \ge 0$, let $0 \le s < \Delta$ and $k \ge 0$ integer satisfy $t = k\Delta + s$. If $i \in S$, $u \in B_w(S)$, and $f \in \mathbb{F}$,

$$\begin{aligned} |E_i^f u(x(t)) - \mu_f(u)| &= \left| \sum_{j \in S} (p^f(i,t,j) - \mu^f(j)) u(j) \right| \\ &\le ||u||_w \sum_{j \in S} w(j) |p^f(i,t,j) - \mu^f(j)| \\ &= ||u||_w \sum_{j \in S} w(j) \left| \sum_{i' \in S} p^f(i,s,i') (p^f(i',k\Delta,j) - \mu^f(j)) \right|, \end{aligned}$$

where we use the Chapman–Kolmogorov equation. Hence,

$$\begin{aligned} |E_i^f u(x(t)) - \mu_f(u)| &\le ||u||_w \sum_{i' \in S} p^f(i,s,i') \sum_{j \in S} w(j) |p^f(i',k\Delta,j) - \mu^f(j)| \\ &\le H\beta^k ||u||_w \sum_{i' \in S} p^f(i,s,i') w(i') \\ &\le H\beta^{-1} (\beta^{1/\Delta})^t ||u||_w \sum_{i' \in S} p^f(i,s,i') w(i') \end{aligned}$$

for some constants H and $\beta < 1$ (see Theorem 4.1). Finally, [10, Lemma 3.2] yields that

$$|E_i^f u(x(t)) - \mu_f(u)| \le H\beta^{-1} (\beta^{1/\Delta})^t ||u||_w (1 + b/c) w(i),$$

where the constants b and c come from Assumption A, thus showing that the uniform w-ergodic property holds, letting

$$R := H\beta^{-1}(1 + b/c) \quad \text{and} \quad \delta := -(\log \beta)/\Delta$$

in Assumption C(b). □

5. Proof of theorems in section 3.

Proof of Theorem 3.3. By (3.4), we only need to show that $\mathbb{F}_{ao} \subseteq \mathbb{F}_{ca}$. Let $f \in \mathbb{F}$ be average optimal, so that (by (2.9) and (3.3)) $g(f) = g^*$. Recalling the Poisson equation (3.7), and if (g^*, h^*) is a solution of the AROE (3.1), then for all $i \in S$,

$$\begin{aligned} g^* &= r(i,f) + \sum_{j \in S} q_{ij}(f) h_f(j) \\ &= \max_{a \in A(i)} \left[r(i,a) + \sum_{j \in S} q_{ij}(a) h^*(j) \right] \\ &\ge r(i,f) + \sum_{j \in S} q_{ij}(f) h^*(j), \end{aligned}$$

and thus, with the notation introduced in (3.13),

$$(Q^f(h_f - h^*))(i) \geq 0 \quad \text{for } i \in S.$$

Using Dynkin's formula, the above yields $E_i^f[h_f(x(t)) - h^*(x(t))] \geq h_f(i) - h^*(i)$, and letting $t \to \infty$ we obtain

$$\mu_f(h_f - h^*) \geq h_f - h^*.$$

Since $\mu_f(h_f - h^*)$ is finite, it follows that there exists a constant $z \in \mathbb{R}$ such that

$$h_f(i) = h^*(i) + z \tag{5.1}$$

for all i in a set of μ_f-probability one, and thus (5.1) holds for every $i \in S$ because the Markov process $\{x^f(t)\}$ is irreducible (recall Assumption C(a)). Finally, as a consequence of Remark 3.2, the pair (g^*, h_f) is a solution of the AROE (3.1), and then

$$\begin{aligned} g^* &= \max_{a \in A(i)} \left[r(i,a) + \sum_{j \in S} q_{ij}(a) h_f(j) \right] \\ &\geq r(i,f) + \sum_{j \in S} q_{ij}(f) h_f(j) = g^* \quad \text{(by (3.7))}. \end{aligned}$$

Hence f is canonical. □

Proof of Theorem 3.6. Let (g^*, h^*, f^*) be a canonical triplet. We will first show that the expressions on the right-hand sides of (i) and (ii) coincide, i.e.,

$$J_T(i, s, f^*, h^*) = (T - s)g^* + h^*(i). \tag{5.2}$$

Indeed, in (3.11)–(3.12) replace $[0, t]$ and (g_k, h_k, f) with $[s, T]$ and (g^*, h^*, f^*), respectively, to obtain (via (3.2))

$$E_{s,i}^{f^*} h^*(x(T)) = h^*(i) + (T - s) \cdot g^* - J_T(i, s, f^*, 0).$$

Thus, rearranging terms we get (5.2).

Now let $v(i, s) := (T - s)g^* + h^*(i)$ for $i \in S$ and $0 \leq s \leq T$, and note that $v(\cdot, s)$ is in $B_w(S)$. Given $f \in \mathbb{F}$, let L^f be the *extended generator* of the state (Markov) process $\{x^f(t), t \geq 0\}$ (see, e.g., [13, p. 2]). Then we obviously have

$$(L^f v)(i, s) = -g^* + \sum_{j \in S} q_{ij}(f) h^*(j)$$

and, therefore,

$$r(i, f) + (L^f v)(i, s) \leq 0 \quad \text{for all } i \in S \text{ and } 0 \leq s \leq T \tag{5.3}$$

with equality if $f = f^*$. Hence, since we also have $v(i, T) = h^*(i)$, we conclude from (5.3) and (3.1)–(3.2) that $v(i, s)$ satisfies the dynamic programming equation for the control problem (3.16) with terminal payoff h^*, namely,

$$\max_{f \in \mathbb{F}} [r(i, f) + (L^f v)(i, s)] = 0 \quad \text{for all } i \in S \text{ and } 0 \leq s \leq T,$$

with boundary condition $v(i,T) = h^*(i)$ for all $i \in S$. Therefore, by a standard dynamic programming "verification theorem" (see [13, Theorem 5.1], for instance), $v(i,s)$ is the control problem's value function (3.16) with $h = h^*$, i.e.,

$$v(i,s) = J_T^*(i,s,h^*).$$

Hence from the definition of $v(i,s)$ and (5.2) we obtain (i), (ii).

Conversely, suppose that (i) and (ii) hold. Given $f \in \mathbb{F}$ we have

$$J_T(i,f) \le Tg^* + h^*(i) - E_i^f h^*(x(T)) \quad \text{for each } i \in S$$

with equality if $f = f^*$. Multiplying by $1/T$ and letting $T \to \infty$ in the above inequality, and also recalling (3.9), we derive that $g(f) \le g^*$ for all $f \in F$ and $g(f^*) = g^*$. Therefore, g^* is the optimal gain and the stationary policy f^* is average optimal. Hence there exists a function $\tilde{h} \in B_w(S)$ such that $(g^*, \tilde{h})$ is a solution of the AROE (3.1), i.e.,

$$g^* = \max_{a \in A(i)} \left[r(i,a) + \sum_{j \in S} q_{ij}(a) \tilde{h}(j) \right] \quad \text{for } i \in S, \tag{5.4}$$

and, by Theorem 3.3, f^* attains the maximum in (5.4) so that, from the proof of Proposition 3.4, h_{f^*} and $\tilde{h}$ differ by a constant. Also, as mentioned above,

$$J_T(i,f^*) = Tg^* + h^*(i) - E_i^{f^*} h^*(x(T)) \quad \text{for } i \in S$$

and, again from the proof of Proposition 3.4, we know that

$$J_T(i,f^*) = Tg^* + h_{f^*}(i) - E_i^{f^*} h_{f^*}(x(T)) \quad \text{for } i \in S.$$

Substracting these equations and letting $T \to \infty$ we derive that h^* and h_{f^*} differ by a constant. This fact, together with (2.2), allows us to replace $\tilde{h}$ with h^* in (5.4):

$$g^* = \max_{a \in A(i)} \left[r(i,a) + \sum_{j \in S} q_{ij}(a) h^*(j) \right] \quad \text{for } i \in S,$$

and we also have

$$g^* = r(i,f^*) + \sum_{j \in S} q_{ij}(f^*) h^*(j) \quad \text{for } i \in S.$$

Hence, (g^*, h^*, f^*) is a canonical triplet. □

Proof of Theorem 3.8. (a) Using (3.15) we may rewrite (3.17) as

$$\hat{h}(i) = h^*(i) + \sup_{f \in \mathbb{F}_{ao}} \left[\sum_{j \in S} -h^*(j) \right] \mu_f(j). \tag{5.5}$$

Therefore, finding bias optimal policies reduces to an average reward problem with reward rate

$$r'(i,a) := -h^*(i) \tag{5.6}$$

and for which, by (5.5), the maximization is over $\mathbb{F}_{ao} = \mathbb{F}_{ca}$. Observe that if $A^*(i)$ is as in (3.21), then a policy f is in $\mathbb{F}_{ca}$ if and only if $f(i) \in A^*(i)$ for all $i \in S$; in other words, f satisfies (3.2). Hence, instead of the control model (2.1) we now consider

$$\mathcal{M} := \{S, (A^*(i), i \in S), q_{ij}(a), r'(i,a)\} \tag{5.7}$$

with r' as in (5.6). Now, by Assumption B, $A^*(i)$ is a (nonempty) compact subset of $A(i)$ and, on the other hand, r' satisfies Assumption A(d) because h^* is in $B_w(S)$. Thus $\mathcal{M}$ satisfies Assumptions A, B, and C, and so the set of corresponding stationary average optimal policies, which is the same as $\mathbb{F}_{bias}$, is nonempty.

(b) To prove the equivalence of (b_1) and (b_2), suppose first that $\hat{f}$ is bias optimal. Then, by definition, $\hat{f}$ is canonical and

$$h_{\hat{f}}(\cdot) = \hat{h}(\cdot).$$

Thus, integration with respect to $\mu_{\hat{f}}$ gives $\mu_{\hat{f}}(\hat{h}) = 0$; that is, (b_1) implies (b_2). Conversely, suppose that (i) $\hat{f}$ is canonical, and (ii) $\mu_{\hat{f}}(\hat{h}) = 0$. By (i), $\hat{f}$ satisfies (3.2), i.e.,

$$g^* = r(i, \hat{f}) + \sum_{j \in S} q_{ij}(\hat{f}) h^*(j),$$

which can be written as

$$g(\hat{f}) = r(i, \hat{f}) + \sum_{j \in S} q_{ij}(\hat{f}) \hat{h}(j),$$

because $g^* = g(\hat{f})$ and the functions h^* and $\hat{h}$ differ by only a constant—see (5.5). Thus, (ii) and Proposition 3.4 imply that $\hat{h} = h_{\hat{f}}$, and (b_1) follows.

$(b_1) \Leftrightarrow (b_3)$. From Remark 3.10,

$$J_T(i,f) = T \cdot g(f) + h_f(i) - E_i^f h_f(x(T))$$

for all $f \in \mathbb{F}$, $i \in S$, and $T > 0$ with $E_i^f h_f(x(T)) \to 0$ as $T \to \infty$. Therefore, if $\hat{f} \in \mathbb{F}$ is any other stationary policy we obtain

$$\begin{aligned} J_T(i,\hat{f}) - J_T(i,f) &= T \cdot [g(\hat{f}) - g(f)] \\ &\quad + h_{\hat{f}}(i) - h_f(i) - (E_i^{\hat{f}} h_{\hat{f}}(x(T)) - E_i^f h_f(x(T))). \end{aligned} \tag{5.8}$$

To prove that (b_1) implies (b_3) suppose that $\hat{f}$ is bias optimal. Then for any $f \in \mathbb{F}$, either $g(\hat{f}) = g^* > g(f)$ or $g(\hat{f}) = g(f)$ and $h_{\hat{f}}(\cdot) = \hat{h}(\cdot) \geq h_f(\cdot)$, and so letting $T \to \infty$ in (5.8) we get (3.18).

To prove the converse, suppose that $\hat{f}$ satisfies (3.18) and that $\hat{f}$ is not bias optimal. If $f \in \mathbb{F}$ is a bias optimal policy, then $g(f) > g(\hat{f})$ or $g(f) = g(\hat{f})$ (that is, $\hat{f}$ is average optimal) and $h_f(i) > h_{\hat{f}}(i)$ for all $i \in S$, as a consequence of Proposition 3.5. In both cases

$$\lim_{T \to \infty} [J_T(i,f) - J_T(i,\hat{f})] > 0,$$

contradicting (3.18). □

Proof of Theorem 3.9. First, let us rewrite (5.5) as

$$\hat{h}(\cdot) = h^*(\cdot) + \hat{g}, \quad \text{with } \hat{g} := \sup_{f \in \mathbb{F}_{ao}} \mu_f(-h^*), \tag{5.9}$$

and let $A^*(i)$ be as in (3.21). It then follows that the AROE (3.1) can be expressed as

$$g^* = \max_{a \in A(i)} \left[r(i,a) + \sum_{j \in S} q_{ij}(a) \hat{h}(j) \right] \quad \text{for } i \in S; \tag{5.10}$$

that is, $(g^*, \hat{h})$ satisfies the *first* bias optimality equation (3.20). Now let $v \in B_w(S)$ be such that $(\hat{g}, v)$ is a *solution of the AROE for the average control model* $\mathcal{M}$ in (5.7), so that [as in (3.1)]

$$\begin{aligned} \hat{g} &= \max_{a \in A^*(i)} \left[-h^*(i) + \sum_{j \in S} q_{ij}(a) v(j) \right] \\ &= -h^*(i) + \max_{a \in A^*(i)} \sum_{j \in S} q_{ij}(a) v(j). \end{aligned}$$

Equivalently, by (5.9),

$$\hat{h}(i) = \max_{a \in A^*(i)} \sum_{j \in S} q_{ij}(a) v(j) \quad \text{for } i \in S, \tag{5.11}$$

which means that $(g^*, \hat{h})$ also satisfies the *second* bias optimality equation (3.21). Moreover (recall Remark 3.2), from (5.9)–(5.11) it follows that g^* and $\hat{h}$ form the unique pair that satisfies the bias optimality equations.

Finally, observe that a stationary policy $f \in \mathbb{F}$ attains the maximum in both (5.10) and (5.11) if and only if f is canonical (by (5.10)) and $\mu_f(\hat{h}) = 0$ (by (5.11)). Therefore, the last statement of Theorem 3.9 follows from the equivalence of (b_1) and (b_2) in Theorem 3.8. □

6. Concluding remarks. In the previous sections we presented an essentially self-contained analysis of the bias optimality criterion for a class of continuous-time CMCs with possibly unbounded reward and transition rates. Our hypotheses allow us to obtain not only the existence of bias optimal policies but also some interesting characterizations. For instance, (3.18)–(3.19) show that among the class of average optimal policies, those with the optimal bias are basically those for which the expected total reward grows faster. In contrast, the characterization in Theorem 3.9 gives that a bias optimal policy is one that lexicographically maximizes the vector criterion $(g(f), h_f)$.

These characterizations together with the relations obtained in [23] between average reward optimality and some "discount-sensitive" criteria give a quite complete picture of what bias optimality is about.

However, there remain many open problems. For instance, the proofs of our results are greatly simplified by the fact that the state space of the CMC is a *countable* set. The obvious question then is, can our results be extended to other classes of continuous-time controlled Markov processes (CMPs), for example, diffusions, general jump processes, and so on?

Finally, it would be interesting to consider some of the problems above for continuous-time *Markov games* rather than CMPs. For instance, there are some connections between average and discounted criteria [22] for discrete-time games that could be naturally extended to the continuous-time case. One should be careful, however, because some results for CMPs cannot be extrapolated to stochastic games. For example, the equivalence between bias optimality and weak overtaking optimality that has been proved in Theorem 3.8 for control problems does not hold for stochastic games [24], thus exhibiting a (perhaps unexpected) discrepancy between control and games models.

UNIQUENESS RESULTS FOR SECOND-ORDER BELLMAN–ISAACS EQUATIONS UNDER QUADRATIC GROWTH ASSUMPTIONS AND APPLICATIONS*

FRANCESCA DA LIO† AND OLIVIER LEY‡

Abstract. In this paper, we prove a comparison result between semicontinuous viscosity sub- and supersolutions growing at most quadratically of second-order degenerate parabolic Hamilton–Jacobi–Bellman and Isaacs equations. As an application, we characterize the value function of a finite horizon stochastic control problem with unbounded controls as the unique viscosity solution of the corresponding dynamic programming equation.

Key words. degenerate parabolic equations, nonlinear Hamilton–Jacobi equations, nonlinear Isaacs equations, viscosity solutions, unbounded solutions, maximum principle, linear quadratic problems.

1. Introduction.

In this paper, we are interested in the second-order equation

$$\begin{cases} \dfrac{\partial w}{\partial t} + H(x,t,Dw,D^2w) + G(x,t,Dw,D^2w) = 0 & \text{in } \mathbb{R}^N \times (0,T), \\ w(x,0) = \psi(x) & \text{in } \mathbb{R}^N, \end{cases} \tag{1.1}$$

where $N \geq 1$, $T > 0$, the unknown w is a real-valued function defined in $\mathbb{R}^N \times [0,T]$, Dw and D^2w denote, respectively, its gradient and Hessian matrix, and ψ is a given initial condition. The Hamiltonians $H, G : \mathbb{R}^N \times [0,T] \times \mathbb{R}^N \times \mathcal{S}_N(\mathbb{R}) \to \mathbb{R}$ are continuous in all their variables and have the form

$$H(x,t,p,X) = \inf_{\alpha \in A} \left\{ \langle b(x,t,\alpha), p \rangle + \ell(x,t,\alpha) - \operatorname{Tr}\left[\sigma(x,t,\alpha)\sigma^T(x,t,\alpha)X\right] \right\} \tag{1.2}$$

and

$$G(x,t,p,X) = \sup_{\beta \in B} \left\{ -\langle g(x,t,\beta), p \rangle - f(x,t,\beta) - \operatorname{Tr}\left[c(x,t,\beta)c^T(x,t,\beta)X\right] \right\}. \tag{1.3}$$

This kind of equation is of particular interest for applications since it relies on differential game theory (Isaacs equations) or on deterministic and stochastic control problems when either $H \equiv 0$ or $G \equiv 0$ (Hamilton–Jacobi–Bellman equations).

Notations and precise assumptions are given in section 2 but we point out that we allow one of the control set A or B to be unbounded and the solutions to (1.1) may have quadratic growth. Our model case is the well-known stochastic linear quadratic

problem. We refer to Bensoussan [10], Fleming and Rishel [18], Fleming and Soner [19], Øksendal [38], Yong and Zhou [41], and the references therein for an overview and to Examples 2.2 and 3.1 below. This problem can be described as follows. Let $(\Omega, \mathcal{F}, (\mathcal{F}_t)_{t\geq 0}, P)$ be a filtered probability space and let $(W_t)_t$ be an $\mathcal{F}_t$-adapted standard M-Brownian motion. The control set is $A = \mathbb{R}^k$ for some $k > 0$ and we consider the linear stochastic differential equation

$$\begin{cases} dX_s = [A(s)X_s + B(s)\alpha_s]ds + [C(s)X_s + D(s)]dW_s \quad \text{for } t \leq s \leq T, \\ X_t = x, \end{cases}$$

where $\alpha_s \in \mathcal{A}_t$, the set of A-valued $\mathcal{F}_t$-progressively measurable controls and the adapted process X_s is the solution. The linear quadratic problem consists in minimizing the quadratic cost

$$V(x,t) = \inf_{\alpha_s \in \mathcal{A}_t} \mathrm{E}\left\{ \int_t^T [\langle X_s, Q(s)X_s\rangle + R|\alpha_s|^2]\, ds + \langle X_T, SX_T\rangle \right\}, \tag{1.4}$$

where $A(\cdot), B(\cdot), C(\cdot), D(\cdot), Q(\cdot)$, and S are deterministic matrix-valued functions of suitable size and $R > 0$ to simplify the presentation. The Hamilton–Jacobi equation associated to this problem is

$$\begin{cases} -\dfrac{\partial w}{\partial t} - \langle A(t)x, Dw\rangle - \langle x, Q(t)x\rangle + \dfrac{1}{4R}|B(t)^T Dw|^2 - \mathrm{Tr}\left[a(x,t)D^2 w\right] = 0, \\ w(x,T) = \langle x, Sx\rangle, \end{cases} \tag{1.5}$$

where $a(x,t) = (C(t)x + D(t))(C(t)x + D(t))^T/2$. Note that this equation is of type (1.1) (with $G \equiv 0$) since

$$\frac{1}{4R}|B(t)^T Dw|^2 = \sup_{\alpha \in \mathbb{R}^k} \Big\{ -\langle B(t)\alpha, Dw\rangle - R|\alpha|^2 \Big\}. \tag{1.6}$$

In this paper, we are concerned with two issues about this problem.

The first question relies on the partial differential equation (1.5). We note that the quadratic cost with unbounded controls leads to a quadratic term with respect to the gradient variable. From the terminal condition, we expect the solutions have quadratic growth. Moreover, the diffusion matrix may be degenerate. Therefore, we cannot hope to obtain smooth solutions in general. We need to consider weak solutions, namely, viscosity solutions. (We refer the reader who is not familiar with this notion of solutions to Crandall, Ishii and Lions [15], Fleming and Soner [19], Bardi and Capuzzo Dolcetta [3], and Barles [6], and all the references therein). We obtain the existence of a unique continuous viscosity solution for (1.5) and for a large class of equations of type (1.1) (see Theorem 2.1 and Corollary 2.1).

We point out that the results obtained in this paper are beyond the classical comparison results for viscosity solutions (see, e.g., [15]) because of the growth of both the solutions and the Hamiltonians. In fact, most of the comparison results in the literature require that either the solutions are uniformly continuous or the Hamiltonian is uniformly continuous with respect to the gradient uniformly in the x variable. (In our case this amounts to assuming that both controls sets are compact.) Let us mention that uniqueness and existence problems for a class of first-order Hamiltonians corresponding to unbounded control sets and under assumptions including deterministic

linear quadratic problems have been addressed by several authors; see, e.g., the book by Bensoussan [10], the papers of Alvarez [2], Bardi and Da Lio [4], Cannarsa and Da Prato [12], and Rampazzo and Sartori [40] in the case of convex operators, and the papers of Da Lio and McEneaney [16] and Ishii [22] for more general operators. As for second-order Hamiltonians under quadratic growth assumptions, Ito [23] obtained the existence of locally Lipschitz solutions to particular equations of the form (1.1) under more regularity conditions on the data, by establishing a priori estimates on the solutions, whereas Crandall and Lions in [14] proved a uniqueness result for very particular operators depending only on the Hessian matrix of the solution. Kobylanski [26] studied equations with the same kind of quadratic nonlinearity in the gradient as ours, but her existence and uniqueness results hold in the class of bounded viscosity solutions. Finally, one can find existence and uniqueness results for viscosity solutions which may have a quadratic growth in [7] for quasilinear degenerate parabolic equations.

The second question we deal with in this paper concerns the link between the control problem (1.4) and equation (1.5). The rigorous connection between the Hamilton–Jacobi–Bellman and optimal control is usually performed by means of a principle of optimality. For deterministic control problems which lead to a first-order Hamilton–Jacobi equation, see Bardi and Capuzzo Dolcetta [3] and Barles [6]; for the connections between stochastic control problems and second-order Hamilton–Jacobi–Bellmann equations see Fleming and Rishel [18], Krylov [27], Lions [31, 32, 33], Fleming and Soner [19], Yong and Zhou [41, Theorem 3.3], and the references therein.

However, for stochastic differential equations with unbounded controls as in stochastic linear quadratic problems, additional difficulties arise. Some results in this direction were obtained for infinite horizon problems, in the deterministic case by Barles [5] and in the stochastic case by Alvarez [1]. In this paper, we characterize the value function (1.4) as the unique solution of (1.5). Actually, our results apply for a larger class of unbounded stochastic control problems

$$V(x,t) = \inf_{\alpha_s \in \mathcal{A}_t} \mathrm{E}\left\{ \int_t^T \ell(X_s, s, \alpha_s)\, ds + \psi(X_T) \right\}, \tag{1.7}$$

where the process X_s is governed by

$$\begin{cases} dX_s = b(X_s, s, \alpha_s)ds + \sigma(X_s, s, \alpha_s)dW_s, \\ X_t = x, \end{cases} \tag{1.8}$$

where A is a possibly unbounded subset of a normed linear space and all the data are continuous with the following restricted growths: b grows at most linearly with respect to both the control and the state, σ grows at most linearly with respect to the state and is bounded in the control variable, ψ can have a quadratic growth, and ℓ grows at most quadratically with respect to both the control and the state with a coercitivity assumption

$$\ell(x, \alpha, t) \geq \frac{\nu}{2}|\alpha|^2 - C(1 + |x|^2). \tag{1.9}$$

In this case, the Hamilton–Jacobi equation looks like (1.1) with $G \equiv 0$. (See section 3 for details.) Because of the unbounded framework, the use of an optimality principle to establish the connection between the control problem and the equation is more delicate than usual. Thus we follow another strategy which consists in comparing

directly the value function with the unique solution of the Hamilton–Jacobi equation as long as this latter exists (see Theorem 3.1).

It is worth noticing that, surprisingly, for the general stochastic linear problem, it is not even clear how to give sense to the partial differential equation associated to the stochastic control problem! For instance, consider again the above linear quadratic problem where $\sigma(x,t,\alpha) = C(t)x + D(t)$ is replaced by $C(t)x + D(t)\alpha$ which depends now both on the state and the control. Taking $A, C, Q \equiv 0$ and $B, R, D \equiv 1$ to simplify, the Hamiltonian in (1.5) becomes

$$\sup_{\alpha\in\mathbb{R}^k}\left\{-\langle\alpha, Dw\rangle - |\alpha|^2 - \frac{|\alpha|^2}{2}\Delta w\right\}, \tag{1.10}$$

which is $+\infty$ as soon as $\Delta w \le -2$. The connection between the control problem and the equation in this case was already investigated (see Yong and Zhou [41] and the references therein). The results need a priori knowledges about the value function. (The value function and its derivatives are supposed to remain in the domain of the Hamiltonian.) We do not consider the case when σ is unbounded in the control variable in this paper; this is the aim of a future work. When finishing this paper, we learned that Krylov [28] succeeded in treating the general stochastic linear regulator. But his assumptions are designed to solve this latter problem (the data are supposed to be polynomials of degree 1 or degree 2 in (x,α)) and the proofs rely heavily on the particular form of the data.

Another important example of equations of type (1.1) where concave and convex Hamiltonians appear is the first-order equation

$$\frac{\partial w}{\partial t} + \min_{\alpha\in\mathbb{R}^k}\left\{\frac{\gamma^2}{2}|\alpha|^2 - \langle\sigma(x)\alpha, Dw\rangle\right\} + \max_{\beta\in B}\{-\langle g(x,\beta), Dw\rangle - f(x,\beta)\} = 0 \tag{1.11}$$

in $\mathbb{R}^N \times (0,T)$. This kind of equation is related to the so-called H_∞-Robust control problem. This problem can be seen as a deterministic differential game. See Example 3.3 and McEneaney [34, 35, 36], Nagai [37], and the references therein for details.

Finally, we point out that one of the main fields of application of these types of equations and problems is mathematical finance; see, e.g., Lamberton and Lapeyre [29], Fleming and Soner [19], Øksendal [38], and the references therein for an introduction. For recent papers which deal with equations we are interested in, see Pham [39] and Benth and Karlsen [11] (see Example 3.2).

Let us now describe how the paper is organized.

Section 2 is devoted to the study of (1.1). More precisely, we prove a uniqueness result for (1.1) in the set of continuous functions growing at most quadratically in the state variable under the assumption that either A or B is an unbounded control set, the functions b, g and ℓ, f grow, respectively, at most linearly and quadratically with respect to both the control and the state. Instead the functions σ, c are assumed to grow at most linearly with respect to the state and bounded in the control variable.

One of the main tools within the theory of viscosity solutions to obtain a uniqueness result is to show a comparison result between viscosity upper semicontinuous subsolutions and lower semicontinuous supersolutions to (1.1); see Theorem 2.1. Indeed, the existence and the uniqueness (Corollary 2.1) follow as a by-product of the comparison result and Perron's method of Ishii [21]. However, under our general assumptions one cannot expect the existence of a solution for all times, as Example 2.2 shows.

The method we use in proving the comparison Theorem 2.1 is similar in spirit to the one applied by Ishii in [22] in the case of first-order Hamilton–Jacobi equations and it is based on a kind of linearization procedure of the equation. Roughly speaking, it consists of three main steps: (1) one computes the equations satisfied by $\Psi_\mu = U - \mu V$ (U, V being, respectively, the sub- and supersolution of the original pde and $0 < \mu < 1$ a parameter); (2) for all $R > 0$ one constructs a strict supersolution χ_R^μ of the linearized equation such that $\chi_R^\mu(x,t) \to 0$ as $R \to \infty$; (3) one shows that $\Psi_\mu(x,t) \le \chi_R^\mu(x,t)$ and then one concludes by letting first $R \to \infty$ and then $\mu \to 1$.

In section 3, we give applications to finite horizon stochastic control problems previously mentioned and we provide some examples.

In section 4, we deal with particular cases where both controls are unbounded but H (or G) is "predominant" in $H + G$ (see Remark 2.2 and Theorem 4.1). For instance, we are able to deal with equations of the form

$$\frac{\partial w}{\partial t} - \frac{|\Sigma_1(x)Dw|^2}{2} + \frac{|\Sigma_2(x)Dw|^2}{2} = 0 \quad \text{in } \mathbb{R}^N \times (0,T),$$

where Σ_1, Σ_2 are $N \times k$ matrices, which corresponds to the case $\alpha, \beta \in \mathbb{R}^k$, $\sigma \equiv c \equiv 0$, $b(x,t,\alpha) = \Sigma_1(x)\alpha$, $g(x,t,\beta) = \Sigma_2(x)\beta$, and $\ell(x,t,\alpha) = |\alpha|^2/2$, $f(x,t,\beta) = |\beta|^2/2$ in (1.2) and (1.3). The comparison result applies if either $(\Sigma_1\Sigma_1^T)(x) > (\Sigma_2\Sigma_2^T)(x)$ or $(\Sigma_1\Sigma_1^T)(x) < (\Sigma_2\Sigma_2^T)(x)$.

When neither H nor G is predominant, the problem seems to be very difficult and our only result takes place in dimension $N = 1$: we have comparison for

$$\frac{\partial w}{\partial t} + h(x,t)|Dw|^2 = 0 \quad \text{in } \mathbb{R}^N \times (0,T), \tag{1.12}$$

where the function h may change sign (see (A5) for details). Finally, we point out that assumptions and proofs in section 4 essentially differ from those of Theorem 2.1 (see Remark 4.1).

2. Comparison result for the Hamilton–Jacobi equation (1.1). In order to give precise assumptions on (1.1) and (1.2), (1.3), we need to introduce some notation. For all integers $N, M \ge 1$ we denote by $\mathcal{M}_{N,M}(\mathbb{R})$ (respectively, $\mathcal{S}_N(\mathbb{R})$, $\mathcal{S}_N^+(\mathbb{R})$) the set of real $N \times M$ matrices (respectively, real symmetric matrices, real symmetric nonnegative $N \times N$ matrices). All the norms which appear in the sequel are denoted by $|\cdot|$. The standard Euclidean inner product in $\mathbb{R}^N$ is written $\langle \cdot, \cdot \rangle$. We recall that a modulus of continuity $m : \mathbb{R} \to \mathbb{R}^+$ is a nondecreasing continuous function such that $m(0) = 0$. Finally, $B(x,r) = \{y \in \mathbb{R}^N : |x - y| < r\}$ is the open ball of center x and radius $r > 0$.

We list the basic assumptions on H, G and ψ. We assume that there exist positive constants $\bar{C}$ and ν such that

(A1) (assumptions on H given by (1.2)):

(i) A is a subset of a separable complete normed space. The main point here is the possible unboundedness of A. Therefore, to emphasize this property in what follows, we take $A = \mathbb{R}^k$ for some $k \ge 1$ (see Remark 2.1 above);

(ii) $b \in C(\mathbb{R}^N \times [0,T] \times \mathbb{R}^k; \mathbb{R}^N)$ satisfying for $x, y \in \mathbb{R}^N, t \in [0,T], \alpha \in \mathbb{R}^k$,

$$|b(x,t,\alpha) - b(y,t,\alpha)| \le \bar{C}(1 + |\alpha|)|x - y|,$$
$$|b(x,t,\alpha)| \le \bar{C}(1 + |x| + |\alpha|);$$

(iii) $\ell \in C(\mathbb{R}^N \times [0,T] \times \mathbb{R}^k; \mathbb{R})$ satisfying for $x \in \mathbb{R}^N, t \in [0,T], \alpha \in \mathbb{R}^k$,

$$\bar{C}(1+|x|^2+|\alpha|^2) \geq \ell(x,t,\alpha) \geq \frac{\nu}{2}|\alpha|^2 + \ell_0(x,t,\alpha) \text{ with } \ell_0(x,t,\alpha) \geq -\bar{C}(1+|x|^2),$$

and for every $R > 0$, there exists a modulus of continuity m_R such that for all $x, y \in B(0,R), t \in [0,T], \alpha \in \mathbb{R}^k$,

$$|\ell(x,t,\alpha) - \ell(y,t,\alpha)| \leq (1+|\alpha|^2)\, m_R(|x-y|); \tag{2.1}$$

(iv) $\sigma \in C(\mathbb{R}^N \times [0,T] \times \mathbb{R}^k; \mathcal{M}_{N,M}(\mathbb{R}))$ is locally Lipschitz continuous with respect to x uniformly for $(t,\alpha) \in [0,T] \times \mathbb{R}^k$ and satisfies for every $x \in \mathbb{R}^N,\ t \in [0,T],\ \alpha \in \mathbb{R}^k$,

$$|\sigma(x,t,\alpha)| \leq \bar{C}(1+|x|).$$

(A2) (assumptions on G given by (1.3)):

(i) B is a bounded subset of a normed space;

(ii) $g \in C(\mathbb{R}^N \times [0,T] \times B; \mathbb{R}^N)$ is locally Lipschitz continuous with respect to x uniformly for $(t,\beta) \in [0,T] \times B$ and satisfies for every $x \in \mathbb{R}^N,\ t \in [0,T],\ \beta \in B$,

$$|g(x,t,\beta)| \leq \bar{C}(1+|x|);$$

(iii) $f \in C(\mathbb{R}^N \times [0,T] \times B; \mathbb{R})$ is locally uniformly continuous with respect to x uniformly in $(t,\beta) \in [0,T] \times B$ and satisfies for every $x \in \mathbb{R}^N,\ t \in [0,T],\ \beta \in B$,

$$|f(x,t,\beta)| \leq \bar{C}(1+|x|^2);$$

(iv) $c \in C(\mathbb{R}^N \times [0,T] \times B; \mathcal{M}_{N,M}(\mathbb{R}))$ is locally Lipschitz continuous with respect to x uniformly for $(t,\beta) \in [0,T] \times B$ and satisfies for every $x \in \mathbb{R}^N,\ t \in [0,T],\ \beta \in B$,

$$|c(x,t,\beta)| \leq \bar{C}(1+|x|).$$

(A3) (assumptions on the initial condition ψ):
$\psi \in C(\mathbb{R}^N; \mathbb{R})$ and

$$|\psi(x)| \leq \bar{C}(1+|x|^2) \quad \text{for every } x \in \mathbb{R}^N.$$

Remark 2.1. (i) Concerning (A1)(i), we choose to take $A = \mathbb{R}^k$ in this section to emphasize the possible unboundedness of A in the notation. Indeed, the calculations when A is any subset of a complete separable normed space are the same and are based on the following inequality: for every $\rho > 0, \gamma \in \mathbb{R}$,

$$\inf_{\alpha \in A} \left\{\rho|\alpha|^2 + \gamma|\alpha|\right\} = \inf_{\alpha \in A} \left\{ \left(\sqrt{\rho}|\alpha|^2 + \frac{\gamma}{2\sqrt{\rho}}\right)^2 - \frac{\gamma^2}{4\rho} \right\} \geq -\frac{\gamma^2}{4\rho}. \tag{2.2}$$

(ii) Note that with respect to the gradient variable, H is a concave function and G is a convex function. Under Assumptions (A1) and (A2), classical computations show that H and G are continuous in all their variables.

Example 2.1. The typical case we have in mind is when H is quadratic in the gradient variable, for instance, $A = \mathbb{R}^k$, $\ell(x,t,\alpha) = |\alpha|^2/2$, $\sigma \equiv 0$, and $b(x,t,\alpha) =$

$a(x)\alpha$, where $a \in C(\mathbb{R}^N; \mathcal{M}_{N,k}(\mathbb{R}))$ is locally Lipschitz continuous and bounded for all $x \in \mathbb{R}^N$. It leads to

$$H(x,p) = \inf_{\alpha\in\mathbb{R}^k} \left\{ \langle a(x)\alpha, p\rangle + \frac{|\alpha|^2}{2} \right\} = -\frac{|a(x)^T p|^2}{2}. \tag{2.3}$$

This particular example is treated both in Ishii [22] and in Da Lio and McEneaney [16] in the case of first-order Hamilton–Jacobi–Bellman equations under more restrictive assumptions than ours. In particular, a has to be a nonsingular matrix in [22]. See also section 4 for some further comments.

For any $O \subseteq \mathbb{R}^K$, we denote by $USC(O)$ the set of upper semicontinuous functions in O and by $LSC(O)$ the set of lower semicontinuous functions in O.

The main result of this section is the following theorem.

THEOREM 2.1. *Assume* (A1)–(A3). *Let* $U \in USC(\mathbb{R}^N \times [0,T])$ *be a viscosity subsolution of* (1.1) *and* $V \in LSC(\mathbb{R}^N \times [0,T])$ *be a viscosity supersolution of* (1.1). *Suppose that* U *and* V *have quadratic growth, i.e., there exists* $\hat{C} > 0$ *such that for all* $x \in \mathbb{R}^N$, $t \in [0,T]$,

$$|U(x,t)|,\ |V(x,t)| \le \hat{C}(1+|x|^2). \tag{2.4}$$

Then $U \le V$ *in* $\mathbb{R}^N \times [0,T]$.

The question of the existence of a continuous solution to (1.1) is not completely obvious. In the framework of viscosity solutions, existence is usually obtained as a consequence of the comparison principle by means of Perron's method as soon as we can build a sub- and a supersolution to the problem. Here, the comparison principle is proved in the class of functions satisfying the quadratic growth condition (2.4). Therefore, to perform the above program of existence, we need to be able to build quadratic sub- and supersolutions to (1.1). In general one can expect to build such sub- and supersolutions only for a short time. (See the following lemma and Corollary 2.1.) In Example 2.2, we see that solutions may not exist for all time.

LEMMA 2.1. *Assume* (A1)–(A3). *If* $K \ge \bar{C} + 1$ *and* ρ *are large enough, then* $\underline{u}(x,t) = -K\mathrm{e}^{\rho t}(1+|x|^2)$ *is a viscosity subsolution of* (1.1) *in* $\mathbb{R}^N \times [0,T]$ *and there exists* $0 < \tau \le T$ *such that* $\overline{u}(x,t) = K\mathrm{e}^{\rho t}(1+|x|^2)$ *is a viscosity supersolution of* (1.1) *in* $\mathbb{R}^N \times [0,\tau]$.

Proof of Lemma 2.1. We only verify that $\overline{u}$ is a supersolution (the proof that $\underline{u}$ is a subsolution being similar and simpler). Since $K \ge \bar{C} + 1$, we have $\overline{u}(x,0) = K(1+|x|^2) \ge \psi(x)$. Moreover, since $\overline{u}$ is smooth and using (A1), (A2), and (2.2), we have

$$\begin{aligned}
&\frac{\partial \overline{u}}{\partial t} + H(x,t,D\overline{u},D^2\overline{u}) + G(x,t,D\overline{u},D^2\overline{u}) \\
&= K\rho\mathrm{e}^{\rho t}(1+|x|^2) + H(x,t,2K\mathrm{e}^{\rho t}x, 2K\mathrm{e}^{\rho t}Id) + G(x,t,2K\mathrm{e}^{\rho t}x, 2K\mathrm{e}^{\rho t}Id) \\
&\ge K\rho\mathrm{e}^{\rho t}(1+|x|^2) + \inf_{\alpha\in\mathbb{R}^k} \Big\{ -\bar{C}(1+|x|+|\alpha|)\}2K\mathrm{e}^{\rho t}|x| + \frac{\nu}{2}|\alpha|^2 \\
&\qquad\qquad - \bar{C}(1+|x|^2) - \bar{C}^2(1+|x|)^2 2K\mathrm{e}^{\rho t} \Big\} \\
&\qquad + \sup_{\beta\in B} \{ -\bar{C}(1+|x|)2K\mathrm{e}^{\rho t}|x| - \bar{C}(1+|x|^2) - \bar{C}^2(1+|x|)^2 2K\mathrm{e}^{\rho t} \} \\
&\ge K\rho\mathrm{e}^{\rho t}(1+|x|^2) - K(10\bar{C} + 12\bar{C}^2)\mathrm{e}^{\rho t}(1+|x|^2) + \inf_{\alpha\in\mathbb{R}^k} \Big\{ -2K\bar{C}\mathrm{e}^{\rho t}|x||\alpha| + \frac{\nu}{2}|\alpha|^2 \Big\} \\
&\ge \left[\rho - 10\bar{C} - 12\bar{C}^2 - \frac{2\bar{C}^2 K\mathrm{e}^{\rho t}}{\nu} \right] K\mathrm{e}^{\rho t}(1+|x|^2).
\end{aligned}$$

We notice that if $t\rho \leq 1$ and $\rho > 0$ is large enough, then the quantity between the brackets is nonnegative. Hence the result follows with $0 < \tau = 1/\rho$. □

As explained above, Theorem 2.1 together with Perron's method implies the following result. We omit its proof since it is standard.

COROLLARY 2.1. *Assume* (A1)–(A3). *Then there is* $\tau > 0$ *such that there exists a unique continuous viscosity solution of* (1.1) *in* $\mathbb{R}^N \times [0,\tau]$ *satisfying the growth condition* (2.4).

Remark 2.2. (i) For global existence results under further regularity assumptions on the data see [23]. For a case where blowup in finite time occurs, see Example 2.2.

(ii) Theorem 2.1 and Corollary 2.1 hold when replacing "inf" by "sup" and "ℓ" by "$-\ell$" in H or/and "sup" by "inf" and "f" by "$-f$" in G. To adapt the proofs, one can use the change of function $w' := -w$ or to consider $\mu U - V$ instead of $U - \mu V$ in the proof of Theorem 2.1. Therefore it is possible to deal either with unbounded controls in the sup in order to have a convex quadratic Hamiltonian or to deal with unbounded control in the inf in order to have a concave quadratic Hamiltonian.

(iii) Up to replace t by $T - t$, all our results hold for

$$\text{(2.5)} \qquad \begin{cases} -\dfrac{\partial w}{\partial t} + H(x,t,Dw,D^2w) + G(x,t,Dw,D^2w) = 0 & \text{in } \mathbb{R}^N \times (0,T), \\ w(x,T) = \psi(x) & \text{in } \mathbb{R}^N. \end{cases}$$

This latter equation with terminal condition is the one which arises usually in control theory; see Example 2.2 and section 3.

(iv) In this section, we are not able to consider the case when both α in H and β in G are unbounded controls. Roughly speaking, a reason is that unbounded controls lead to quadratic Hamiltonians. When both controls are unbounded, we then obtain two quadratic-type Hamiltonians, a concave and a convex one. Let us explain the difficulty on a model case where

$$H(x,p) = \inf_{\alpha\in\mathbb{R}^k} \left\{ \langle a_1(x)\alpha, p\rangle + \frac{|\alpha|^2}{2} \right\} = -\frac{|a_1(x)^T p|^2}{2},$$
$$G(x,p) = \sup_{\beta\in\mathbb{R}^k} \left\{ \langle a_2(x)\beta, p\rangle - \frac{|\beta|^2}{2} \right\} = \frac{|a_2(x)^T p|^2}{2},$$

where $a_1, a_2 \in C(\mathbb{R}^N; \mathcal{M}_{N,k}(\mathbb{R}))$ are locally Lipschitz continuous and bounded. The difficulty to treat such a case is related to our strategy of proof which relies on a kind of linearization procedure (see Lemma 2.2 and its proof). In this simple case, this linearization uses in a crucial way the convex inequality

$$\frac{|p|^2}{\mu} - |q|^2 \geq -\frac{|p-q|^2}{1-\mu} \quad \text{for all } p,q \in \mathbb{R}^N \text{ and } 0 < \mu < 1,$$

which does not work at the same time for a concave and a convex Hamiltonian. Of course, in this simple case, there are alternative ways to solve the problem: we have

$$\text{(2.6)} \qquad H(x,p) + G(x,p) = \frac{1}{2}\langle (a_1+a_2)(a_2-a_1)^T p, p\rangle,$$

then we can apply Theorem 2.1 to H given by 2.6 to add some assumptions on a_1 or a_2 (for instance, $(a_1+a_2)(a_2-a_1)^T$ is a nonnegative symmetric matrix with a locally Lipschitz squareroot). In section 4, we provide another approach to solving such equations (see Theorem 4.1 and Remark 4.1).

Example 2.2 (a deterministic linear quadratic control problem). Linear quadratic control problems (see also section 3 for stochastic linear quadratic control problems) are the typical examples we have in mind since they lead to Hamilton–Jacobi equations with quadratic terms. On the other hand, the value function can blow up in finite time. Consider the control problem (in dimension 1 for sake of simplicity)

$$\begin{cases} dX_s = \alpha_s\, ds, \quad s \in [t,T],\ 0 \le t \le T, \\ X_t = x \in \mathbb{R}, \end{cases}$$

where the control $\alpha \in \mathcal{A}_t := L^2([t,T];\mathbb{R})$ and the value function is given by

$$V(x,t) = \inf_{\alpha \in \mathcal{A}_t} \left\{ \rho \int_t^T (|\alpha_s|^2 + |X_s|^2)\, ds - |X_T|^2 \right\} \quad \text{for some } \rho > 0.$$

Then the value function, when it is finite, is the unique viscosity solution of the Hamilton–Jacobi equation of type (1.1) which reads

$$\begin{cases} -w_t + \frac{1}{4\rho}|w_x|^2 = \rho x^2 & \text{in } \mathbb{R} \times (0,T), \\ w(x,T) = -x^2. \end{cases} \tag{2.7}$$

(See Theorem 3.1 for a proof of this result.) Looking for a solution w under the form $w(x,t) = \varphi(t)x^2$, we obtain that φ is a solution of the differential equation

$$-\varphi' + \frac{\varphi^2}{\rho} = \rho \ \text{ in } (0,T), \qquad \varphi(T) = -1. \tag{2.8}$$

We distinguish two cases.

Case 1. If $\rho \ge 1$, then the solution of (2.8) is defined in the whole interval $[0,T]$ for all $T > 0$ and is given by

$$\varphi(t) = \rho\, \frac{(\rho-1)\mathrm{e}^{2(T-t)} - (\rho+1)}{(\rho-1)\mathrm{e}^{2(T-t)} + \rho + 1}, \tag{2.9}$$

which is a function decreasing from $\varphi(0)$ to -1. Therefore (2.7) admits a unique viscosity solution in $\mathbb{R} \times [0,T]$ which is the value function of the control problem

$$V(x,t) = \varphi(t)x^2.$$

Note that if $\rho > 1$ and $T > \ln((\rho+1)/(\rho-1))/2$, then $\varphi(0) > 0$. It follows that the value function satisfies (2.4) but is neither bounded from above nor bounded from below.

Case 2. If $0 < \rho < 1$ and $T > \ln((1+\rho)/(1-\rho))/2$, then the solution of (2.8) is given by (2.9) in $(\bar\tau, T]$, where

$$\bar\tau := T - \frac{1}{2}\ln\left(\frac{1+\rho}{1-\rho}\right),$$

and blows up at $t = \bar\tau$. Therefore we have existence for (2.7) only in $\mathbb{R} \times (\bar\tau, T]$.

Proof of Theorem 2.1. We divide the proof of the theorem into two steps.

Step 1. We first assume that $\ell_0 \ge 0$, $f \le 0$, and $\psi \le 0$ in (A1), (A2), and (A3).

The proof is based on the two following lemmas, whose proofs are postponed.

LEMMA 2.2 (linearization of (1.1)). *Let $0 < \mu < 1$ and set $\Psi = U - \mu V$. Suppose $\ell_0 \geq 0$, $f \leq 0$ and $\psi \leq 0$. Then Ψ is a USC viscosity subsolution of*

$$\mathcal{L}[w] := \frac{\partial w}{\partial t} - \frac{\bar{C}^2}{2\nu(1-\mu)}|Dw|^2 - 2\bar{C}(1+|x|)|Dw|$$

$$- \sup_{\alpha\in\mathbb{R}^k} \mathrm{Tr}\left[\sigma(x,t,\alpha)\sigma^T(x,t,\alpha)D^2w\right] - \sup_{\beta\in B} \mathrm{Tr}\left[c(x,t,\beta)c^T(x,t,\beta)D^2w\right] = 0 \tag{2.10}$$

in $\mathbb{R}^N \times (0,T)$, with the initial condition

$$w(\cdot,0) \leq (1-\mu)\psi \leq 0. \tag{2.11}$$

LEMMA 2.3. *Consider the parabolic problem*

$$\begin{cases} \varphi_t - r^2\varphi_{rr} - r\varphi_r = 0 & \text{in } [0,+\infty)\times(0,T], \\ \varphi(r,0) = \varphi_R(r) & \text{in } [0,+\infty), \end{cases} \tag{2.12}$$

where $\varphi_R(r) = \max\{0, r-R\}$ for some $R > 0$. Then (2.12) has a unique solution $\varphi \in C([0,+\infty)\times[0,T]) \cap C^\infty([0,+\infty)\times(0,T])$ such that for all $t \in (0,T]$, $\varphi(\cdot,t)$ is positive, nondecreasing, and convex in $[0,+\infty)$. Moreover, for every $(r,t) \in [0,+\infty)\times(0,T]$,

$$\varphi(r,t) \geq \varphi_R(r), \quad 0 \leq \varphi_r(r,t) \leq \mathrm{e}^T \quad \text{and} \quad \varphi(r,t) \underset{R\to+\infty}{\longrightarrow} 0. \tag{2.13}$$

Let $\Phi(x,t) = \varphi(C(1+|x|^2)\mathrm{e}^{Lt}, Mt) + \eta t$, where φ is given by Lemma 2.3, L, M, η are positive constants to be determined, and $C > \max\{\bar{C}, \hat{C}\}$, where $\bar{C}$ and $\hat{C}$ are the constants appearing in the assumptions.

Claim. We can choose the constants L and M such that Φ is a strict supersolution of (2.10) at least in $\mathbb{R}^N \times (0,\tau]$ for small τ.

To prove the claim, we have to show that $\mathcal{L}[\Phi] > 0$ in $\mathbb{R}^N \times (0,\tau]$ for some $\tau > 0$. The function $\Phi \in C(\mathbb{R}^N \times [0,T]) \cap C^\infty(\mathbb{R}^N \times (0,T])$ and we have, for $t > 0$,

$$\Phi_t = \eta + LC(1+|x|^2)\mathrm{e}^{Lt}\varphi_r + M\varphi_t, \quad D\Phi = 2Cx\mathrm{e}^{Lt}\varphi_r,$$
$$\text{and } D^2\Phi = 2C\,Id\,\mathrm{e}^{Lt}\varphi_r + 4C^2\mathrm{e}^{2Lt}\varphi_{rr}\, x\otimes x.$$

Using (A1) and (A2), for all $(x,t) \in \mathbb{R}^N \times (0,T]$, we get

$$\mathcal{L}[\Phi] \geq \eta + LC(1+|x|^2)\mathrm{e}^{Lt}\varphi_r + M\varphi_t - \frac{\bar{C}^2}{2\nu(1-\mu)}|2Cx\mathrm{e}^{Lt}\varphi_r|^2$$
$$- 2\bar{C}(1+|x|)|2Cx\mathrm{e}^{Lt}\varphi_r| - 2\bar{C}^2(1+|x|)^2|2C\,Id\,\mathrm{e}^{Lt}\varphi_r + 4C^2\mathrm{e}^{2Lt}x\otimes x\,\varphi_{rr}|.$$

Setting $r = C(1+|x|^2)\mathrm{e}^{Lt}$ and since $C > \bar{C}$, we obtain

$$\mathcal{L}[\Phi] \geq \eta + M\varphi_t - 16C^2r^2\varphi_{rr} - 8C(C+1)r\varphi_r + \left(L - \frac{2C^3\mathrm{e}^{Lt}\varphi_r}{\nu(1-\mu)}\right) r\varphi_r.$$

Our aim is to fix the parameters M and L in order to make $\mathcal{L}[\Phi]$ positive.

We first choose $M > 16C^2 + 8C$. Since φ is a solution of (2.12) (Lemma 2.3), we obtain

$$\mathcal{L}[\Phi] > \eta + \left(L - \frac{2C^3\mathrm{e}^{Lt}\varphi_r}{\nu(1-\mu)}\right) r\varphi_r. \tag{2.14}$$

Then, taking $L > \frac{2C^3 \mathrm{e}^{T+1}}{\nu(1-\mu)}$, we get $\mathcal{L}[\Phi] > \eta > 0$ for all $x \in \mathbb{R}^N$ and $t \in (0, \tau]$, where $\tau = 1/L$. This proves the claim.

We continue by considering

$$\max_{\mathbb{R}^N \times [0,\tau]} \{\Psi - \Phi\}, \tag{2.15}$$

where Ψ is the function defined in Lemma 2.2 which is a viscosity subsolution of (2.10) and Φ is the strict supersolution of (2.10) in $\mathbb{R}^N \times (0, \tau]$ we built above.

From (2.13), we have $\Phi(x,t) \geq C(1+|x|^2) > \bar{C}(1+|x|^2) \geq \Psi(x,t)$ for $|x| \geq R$. It follows that the maximum (2.15) is achieved at a point $(\bar{x}, \bar{t}) \in \mathbb{R}^N \times [0, \tau]$. We claim that $\bar{t} = 0$. Indeed, suppose by contradiction that $\bar{t} > 0$. Then since Ψ is a viscosity subsolution of (2.10), by taking Φ as a test function, we would have $\mathcal{L}[\Phi](\bar{x}, \bar{t}) \leq 0$, which contradicts the fact that Φ is a strict supersolution.

Thus, for all $(x,t) \in \mathbb{R}^N \times [0, \tau]$,

$$\Psi(x,t) - \Phi(x,t) \leq \Psi(\bar{x}, 0) - \Phi(\bar{x}, 0) \leq (1-\mu)\psi(\bar{x}),$$

where the last inequality follows from (2.11) and the fact that $\Phi \geq 0$. Since we assumed that ψ is nonpositive, for every $(x,t) \in \mathbb{R}^N \times [0, \tau]$, we have $\Psi(x,t) \leq \Phi(x,t)$. Letting η go to 0 and R to $+\infty$, we get by Lemma 2.3, $\Psi \leq 0$ in $\mathbb{R}^N \times [0, \tau]$.

By a step-by-step argument, we prove that $\Psi \leq 0$ in $\mathbb{R}^N \times [0, T]$. Therefore $\Psi = U - \mu V \leq 0$ in $\mathbb{R}^N \times [0, T]$. Letting μ go to 1, we obtain $U \leq V$ as well, which concludes Step 1.

Step 2. *The general case.* The idea is to reduce to the first case by a suitable change of function (see Ishii [22]). Suppose that w is a solution of (1.1). Then, a straightforward computation shows that $\bar{w}(x,t) = w(x,t) - C(1+|x|^2)\mathrm{e}^{\rho t}$ for $C > \bar{C}, \hat{C}$ and $\rho > 0$ is a solution of

$$\begin{cases} \bar{w}_t + \inf\limits_{\alpha \in \mathbb{R}^k} \left\{ \langle b(x,t,\alpha), D\bar{w} \rangle + \bar{\ell}(x,t,\alpha) - \operatorname{Tr}\left[\sigma(x,t,\alpha)\sigma^T(x,t,\alpha) D^2 \bar{w}\right] \right\} \\ \qquad + \sup\limits_{\beta \in B} \left\{ -\langle g(x,t,\beta), D\bar{w} \rangle - \bar{f}(x,t,\beta) - \operatorname{Tr}\left[c(x,t,\beta)c^T(x,t,\beta) D^2 \bar{w}\right] \right\} = 0, \\ \bar{w}(x,0) = \psi(x) - C(1+|x|^2), \end{cases} \tag{2.16}$$

where

$$\begin{aligned} \bar{\ell}(x,t,\alpha) &= \ell(x,t,\alpha) + 2C\mathrm{e}^{\rho t}\langle b(x,t,\alpha), x \rangle - 2C\mathrm{e}^{\rho t} \operatorname{Tr}\left[\sigma(x,t,\alpha)\sigma^T(x,t,\alpha)\right] \\ &\qquad + \frac{1}{2} C\rho \mathrm{e}^{\rho t}(1+|x|^2), \\ \bar{f}(x,t,\beta) &= f(x,t,\beta) + 2C\mathrm{e}^{\rho t}\langle g(x,t,\beta), x \rangle + 2C\mathrm{e}^{\rho t} \operatorname{Tr}\left[c(x,t,\beta)c^T(x,t,\beta)\right] \\ &\qquad - \frac{1}{2} C\rho \mathrm{e}^{\rho t}(1+|x|^2). \end{aligned}$$

We observe that $\bar{\ell}$ and $\bar{f}$ still satisfy, respectively, assumptions (A1)(iii) and (A2)(iii). Moreover from (A3), we can choose $C > \bar{C}$ in order that $\bar{\psi} \leq 0$.

Next we show that if $\rho > 0$ is chosen in a suitable way, then $\bar{\ell}(x,t,\alpha) \geq \bar{\nu}|\alpha|^2/2$ for all $(x,t,\alpha) \in \mathbb{R}^N \times [0, 1/\rho] \times \mathbb{R}^k$ and $f(x,t,\beta) \leq 0$ for all $(x,t,\beta) \in \mathbb{R}^N \times [0, 1/\rho] \times B$.

Indeed, for all $(x,t,\alpha) \in \mathbb{R}^N \times [0,1/\rho] \times \mathbb{R}^k$ by (A1) we have

$$\begin{aligned}\bar{\ell}(x,t,\alpha) &\geq \frac{\nu}{2}|\alpha|^2 - \bar{C}(1+|x|^2) - 2C\bar{C}\mathrm{e}^{\rho t}(1+|x|+|\alpha|)|x| - 2C\bar{C}^2\mathrm{e}^{\rho t}(1+|x|)^2 \\ &\quad + \frac{1}{2}C\rho\mathrm{e}^{\rho t}(1+|x|^2) \\ &\geq \frac{\nu}{2}|\alpha|^2 - (\bar{C}+4C\bar{C}+4C\bar{C}^2)\mathrm{e}^{\rho t}(1+|x|^2) - 2C\bar{C}\mathrm{e}^{\rho t}|\alpha||x| \\ &\quad + \frac{1}{2}C\rho\mathrm{e}^{\rho t}(1+|x|^2).\end{aligned}$$

But

$$2C\bar{C}\mathrm{e}^{\rho t}|\alpha||x| \leq \frac{\nu}{4}|\alpha|^2 + \frac{16C^2\bar{C}^2\mathrm{e}^{2\rho t}}{\nu}|x|^2\,.$$

Therefore, by choosing

$$\rho > 2\frac{\bar{C}}{C} + 8\bar{C} + 8\bar{C}^2 + \frac{32C\bar{C}^2\mathrm{e}}{\nu}, \tag{2.17}$$

we have

$$\bar{\ell}(x,t,\alpha) \geq \frac{\nu}{4}|\alpha|^2 \quad \text{for all } (x,t,\alpha) \in \mathbb{R}^N \times [0,1/\rho] \times \mathbb{R}^k,$$

which is the desired estimate with $\bar{\nu} = \nu/2 > 0$ and $\ell_0 \equiv 0$.

The next step consists in choosing ρ such that $\bar{f} \leq 0$. Using (A2), the same kind of calculation as above shows that taking

$$\rho > 8(\bar{C}+\bar{C}^2) + 2 \tag{2.18}$$

ensures $\bar{f} \leq 0$.

Finally, if we choose $C > \bar{C}$ and ρ as the maximum of the two quantities appearing in (2.17) and (2.18), we are in the framework of Step 1 in $\mathbb{R}^N \times [0,\rho]$. Setting $\bar{U} = U - C(1+|x|^2)\mathrm{e}^{\rho t}$ and $\bar{V} = V - C(1+|x|^2)\mathrm{e}^{\rho t}$, from Step 1 we get $\bar{U} \leq \bar{V}$ in $\mathbb{R}^N \times [0,1/\rho]$; thus $U \leq V$ in $\mathbb{R}^N \times [0,1/\rho]$. Then by a step-by-step argument we obtain the comparison in $\mathbb{R}^N \times [0,T]$. □

Remark 2.3. A key fact in the proof to build a strict supersolution of (2.10) is to use a function which is the solution of the auxiliary—and simpler—pde (2.12). This idea comes from mathematical finance to deal with equations related to the Blake and Scholes formula. See, for instance, Lamberton and Lapeyre [29] and Barles et al. [8].

We turn to the proof of Lemmas 2.2 and 2.3.

Proof of Lemma 2.2. For $0 < \mu < 1$, let $\tilde{V} = \mu V$ and $\Psi = U - \tilde{V}$. We divide the proof into steps.

Step 1. *A new equation for* $\tilde{V}$. It is not difficult to see that if V is a supersolution of (1.1), then $\tilde{V}$ is a supersolution of

$$\begin{aligned}&\tilde{V}_t + \mu\, H\left(x,t,\frac{D\tilde{V}}{\mu},\frac{D^2\tilde{V}}{\mu}\right) + \mu\, G\left(x,t,\frac{D\tilde{V}}{\mu},\frac{D^2\tilde{V}}{\mu}\right) \geq 0 \quad \text{in } \mathbb{R}^N \times (0,T), \\ &\tilde{V}(x,0) \geq \mu\,\psi(x) \qquad\qquad \text{in } \mathbb{R}^N.\end{aligned} \tag{2.19}$$

Step 2. *Viscosity inequalities for* U *and* $\tilde{V}$. This step is classical in viscosity theory. Let $\varphi \in C^2(\mathbb{R}^N \times (0,T])$ and $(\bar{x},\bar{t}) \in \mathbb{R}^N \times (0,T]$ be a local maximum of $\Psi - \varphi$. We

can assume that this maximum is strict in the same ball $\overline{B}(\bar{x},r)\times[\bar{t}-r,\bar{t}+r]$ (see [6] or [3]). Let

$$\Theta(x,y,t)=\varphi(x,t)+\frac{|x-y|^2}{\varepsilon^2}$$

and consider

$$M_\varepsilon:=\max_{x,y\in\overline{B}(\bar{x},r),\,t\in[\bar{t}-r,\bar{t}+r]}\{U(x,t)-\tilde{V}(y,t)-\Theta(x,y,t)\}.$$

This maximum is achieved at a point $(x_\varepsilon,y_\varepsilon,t_\varepsilon)$ and, since the maximum is strict, we know [6], [3] that

$$\frac{|x_\varepsilon-y_\varepsilon|^2}{\varepsilon^2}\to 0\quad\text{as }\varepsilon\to 0$$

and

$$M_\varepsilon=U(x_\varepsilon,t_\varepsilon)-\tilde{V}(y_\varepsilon,t_\varepsilon)-\Theta(x_\varepsilon,y_\varepsilon,t_\varepsilon)\longrightarrow U(\bar{x},\bar{t})-\tilde{V}(\bar{x},\bar{t})-\varphi(\bar{x},\bar{t})=\Psi(\bar{x},\bar{t})-\varphi(\bar{x},\bar{t}).$$

This means that at the limit $\varepsilon\to 0$, we obtain some information on $\Psi-\varphi$ at $(\bar{x},\bar{t})$ which will provide the new equation for Ψ. Before that, we can take Θ as a test function to use the fact that U is a subsolution and $\tilde{V}$ a supersolution. Indeed, $(x,t)\in\overline{B}(\bar{x},r)\times[\bar{t}-r,\bar{t}+r]\mapsto U(x,t)-\tilde{V}(y_\varepsilon,t)-\Theta(x,y_\varepsilon,t)$ achieves its maximum at $(x_\varepsilon,t_\varepsilon)$ and $(y,t)\in\overline{B}(\bar{x},r)\times[\bar{t}-r,\bar{t}+r]\mapsto -U(x_\varepsilon,t)+\tilde{V}(y,t)+\Theta(x_\varepsilon,y,t)$ achieves its minimum at $(y_\varepsilon,t_\varepsilon)$. Thus, by Theorem 8.3 in the user's guide [15], for every $\rho>0$, there exist $a_1,a_2\in\mathbb{R}$ and $X,Y\in\mathcal{S}_N$ such that

$$(a_1,D_x\Theta(x_\varepsilon,y_\varepsilon,t_\varepsilon),X)\in\bar{\mathcal{P}}^{2,+}(U)(x_\varepsilon,t_\varepsilon),(a_2,-D_y\Theta(x_\varepsilon,y_\varepsilon,t_\varepsilon),Y)\in\bar{\mathcal{P}}^{2,-}(\tilde{V})(y_\varepsilon,t_\varepsilon),$$

$a_1-a_2=\Theta_t(x_\varepsilon,y_\varepsilon,t_\varepsilon)=\varphi_t(x_\varepsilon,t_\varepsilon)$ and

$$-\left(\frac{1}{\rho}+|M|\right)I\le\begin{pmatrix}X&0\\0&-Y\end{pmatrix}\le M+\rho M^2,\quad\text{where } M=D^2\Theta(x_\varepsilon,y_\varepsilon,t_\varepsilon).\tag{2.20}$$

Setting $p_\varepsilon=2\dfrac{x_\varepsilon-y_\varepsilon}{\varepsilon^2}$, we have

$$D_x\Theta(x_\varepsilon,y_\varepsilon,t_\varepsilon)=p_\varepsilon+D\varphi(x_\varepsilon,t_\varepsilon)\quad\text{and}\quad D_y\Theta(x_\varepsilon,y_\varepsilon,t_\varepsilon)=-p_\varepsilon,$$

and

$$M=\begin{pmatrix}D^2\varphi(x_\varepsilon,t_\varepsilon)+2I/\varepsilon^2&-2I/\varepsilon^2\\-2I/\varepsilon^2&2I/\varepsilon^2\end{pmatrix}.$$

Thus, from (2.20), it follows

$$\langle Xp,p\rangle-\langle Yq,q\rangle\le\langle D^2\varphi(x_\varepsilon,t_\varepsilon)p,p\rangle+\frac{2}{\varepsilon^2}|p-q|^2+m\left(\frac{\rho}{\varepsilon^4}\right),\tag{2.21}$$

where m is a modulus of continuity which is independent of ρ and ε. In what follows, m will always denote a generic modulus of continuity independent of ρ and ε.

Writing the subsolution viscosity inequality for U and the supersolution inequality for $\tilde{V}$ by means of the semijets and subtracting the inequalities, we obtain

$$\begin{aligned}\varphi_t(x_\varepsilon,t_\varepsilon)+H\big(x_\varepsilon,t_\varepsilon,D\varphi(x_\varepsilon,t_\varepsilon)+p_\varepsilon,X\big)-\mu\,H\left(y_\varepsilon,t_\varepsilon,\frac{p_\varepsilon}{\mu},\frac{Y}{\mu}\right)\\ +G\big(x_\varepsilon,t_\varepsilon,D\varphi(x_\varepsilon,t_\varepsilon)+p_\varepsilon,X\big)-\mu\,G\left(y_\varepsilon,t_\varepsilon,\frac{p_\varepsilon}{\mu},\frac{Y}{\mu}\right)\le 0.\end{aligned}\tag{2.22}$$

Step 3. *Estimate of* $\mathcal{G}:=G\big(x_\varepsilon,t_\varepsilon,D\varphi(x_\varepsilon,t_\varepsilon)+p_\varepsilon,X\big)-\mu\,G\big(y_\varepsilon,t_\varepsilon,\frac{p_\varepsilon}{\mu},\frac{Y}{\mu}\big)$. For simplicity, we set

$$c(x_\varepsilon,t_\varepsilon,\beta)=c_x\quad\text{and}\quad c(y_\varepsilon,t_\varepsilon,\beta)=c_y.$$

We have

$$\begin{aligned}\mathcal{G}&=\sup_{\beta\in B}\left\{-\langle g(x_\varepsilon,t_\varepsilon,\beta),D\varphi(x_\varepsilon,t_\varepsilon)+p_\varepsilon\rangle-f(x_\varepsilon,t_\varepsilon,\beta)-\operatorname{Tr}\left[c_xc_x^TX\right]\right\}\\ &\quad-\sup_{\beta\in B}\left\{-\langle g(y_\varepsilon,t_\varepsilon,\beta),p_\varepsilon\rangle-\mu f(y_\varepsilon,t_\varepsilon,\beta)-\operatorname{Tr}\left[c_yc_y^TY\right]\right\}\\ &\ge\inf_{\beta\in B}\left\{\langle g(y_\varepsilon,t_\varepsilon,\beta)-g(x_\varepsilon,t_\varepsilon,\beta),p_\varepsilon\rangle-\langle g(x_\varepsilon,t_\varepsilon,\beta),D\varphi(x_\varepsilon,t_\varepsilon)\rangle\right.\\ &\qquad\left.-(1-\mu)f(y_\varepsilon,t_\varepsilon,\beta)+f(y_\varepsilon,t_\varepsilon,\beta)-f(x_\varepsilon,t_\varepsilon,\beta)-\operatorname{Tr}\left[c_xc_x^TX-c_yc_y^TY\right]\right\}.\end{aligned}$$

From (A2), if $L_{g,r}$ is the Lipschitz constant of g in $\overline{B}(\bar{x},r)\times[\bar{t}-r,\bar{t}+r]$, then we have

$$\langle g(y_\varepsilon,t_\varepsilon,\beta)-g(x_\varepsilon,t_\varepsilon,\beta),p_\varepsilon\rangle\le L_{g,r}|y_\varepsilon-x_\varepsilon||p_\varepsilon|\le 2L_{g,r}\frac{|y_\varepsilon-x_\varepsilon|^2}{\varepsilon^2}=m(\varepsilon)$$

and

$$-\langle g(x_\varepsilon,t_\varepsilon,\beta),D\varphi(x_\varepsilon,t_\varepsilon)\rangle\ge-\bar{C}(1+|x_\varepsilon|)|D\varphi(x_\varepsilon,t_\varepsilon)|.$$

By assumption, $f\le 0$ thus $-(1-\mu)f(y_\varepsilon,t_\varepsilon,\beta)\ge 0$. Again from (A2) it follows that

$$f(y_\varepsilon,t_\varepsilon,\beta)-f(x_\varepsilon,t_\varepsilon,\beta)\ge-m(|y_\varepsilon-x_\varepsilon|).$$

Let us denote by $(e_i)_{1\le i\le N}$ the canonical basis of $\mathbb{R}^N$. By using (2.21), we obtain

$$\begin{aligned}\operatorname{Tr}\left[c_xc_x^TX-c_yc_y^TY\right]&=\sum_{i=1}^N\langle Xc_xe_i,c_xe_i\rangle-\langle Yc_ye_i,c_ye_i\rangle\\ &\le\operatorname{Tr}\left[c_xc_x^TD^2\varphi(x_\varepsilon,t_\varepsilon)\right]+\frac{2}{\varepsilon^2}|c_x-c_y|^2+m\left(\frac{\rho}{\varepsilon^4}\right)\\ &\le\operatorname{Tr}\left[c_xc_x^TD^2\varphi(x_\varepsilon,t_\varepsilon)\right]+2L_{c,r}^2\frac{|x_\varepsilon-y_\varepsilon|^2}{\varepsilon^2}+m\left(\frac{\rho}{\varepsilon^4}\right)\\ &\le\operatorname{Tr}\left[c_xc_x^TD^2\varphi(x_\varepsilon,t_\varepsilon)\right]+m(\varepsilon)+m\left(\frac{\rho}{\varepsilon^4}\right),\end{aligned}$$

where $L_{c,r}$ is a Lipschitz constant for c in $\bar{B}(x,r)$. Hence, since all the moduli are independent of ε, ρ and the control, we have

$$\begin{aligned}\mathcal{G}\ge-\bar{C}(1+|x_\varepsilon|)|D\varphi(x_\varepsilon,t_\varepsilon)|+\inf_{\beta\in B}\left\{-\operatorname{Tr}\left[c(x_\varepsilon,t_\varepsilon,\beta)c(x_\varepsilon,t_\varepsilon,\beta)^TD^2\varphi(x_\varepsilon,t_\varepsilon)\right]\right\}\\ +m(\varepsilon)+m\left(\frac{\rho}{\varepsilon^4}\right).\end{aligned}$$

Step 4. *Estimate of* $\mathcal{H} := H\big(x_\varepsilon, t_\varepsilon, D\varphi(x_\varepsilon,t_\varepsilon)+p_\varepsilon, X\big) - \mu\, H\big(y_\varepsilon, t_\varepsilon, \frac{p_\varepsilon}{\mu}, \frac{Y}{\mu}\big)$. With the same notation as in Step 3, we have

$$\begin{aligned}\mathcal{H} \geq \inf_{\alpha\in\mathbb{R}^k}\{&\langle b(x_\varepsilon,t_\varepsilon,\alpha)-b(y_\varepsilon,t_\varepsilon,\alpha),p_\varepsilon\rangle + \langle b(x_\varepsilon,t_\varepsilon,\alpha), D\varphi(x_\varepsilon,t_\varepsilon)\rangle\\ &+(1-\mu)\ell(y_\varepsilon,t_\varepsilon,\alpha)+\ell(x_\varepsilon,t_\varepsilon,\alpha)-\ell(y_\varepsilon,t_\varepsilon,\alpha)-\operatorname{Tr}\left[\sigma_x\sigma_x^T X-\sigma_y\sigma_y^T Y\right]\}.\end{aligned}$$

From (A1) these estimates follow:

$$\langle b(x_\varepsilon,t_\varepsilon,\alpha)-b(y_\varepsilon,t_\varepsilon,\alpha),p_\varepsilon\rangle \geq -\bar{C}(1+|\alpha|)|x_\varepsilon-y_\varepsilon||p_\varepsilon| \geq -\bar{C}|\alpha|m(\varepsilon)+m(\varepsilon),$$

$$\langle b(x_\varepsilon,t_\varepsilon,\alpha), D\varphi(x_\varepsilon,t_\varepsilon)\rangle \geq -\bar{C}(1+|x_\varepsilon|)|D\varphi(x_\varepsilon,t_\varepsilon)| - \bar{C}|\alpha||D\varphi(x_\varepsilon,t_\varepsilon)|,$$

$$\ell(x_\varepsilon,t_\varepsilon,\alpha)-\ell(y_\varepsilon,t_\varepsilon,\alpha) \geq -(1+|\alpha|^2)m_r(|x_\varepsilon-y_\varepsilon|) \geq -|\alpha|^2 m(\varepsilon)+m(\varepsilon),$$

$$(1-\mu)\ell(y_\varepsilon,t_\varepsilon,\alpha) \geq (1-\mu)\left(\frac{\nu}{2}|\alpha|^2+\ell_0(x,t,\alpha)\right) \geq \frac{\nu(1-\mu)}{2}|\alpha|^2,$$

where the last inequality follows from the fact that by assumption, $\ell_0(x,t,\alpha)\geq 0$.

By proceeding exactly as in Step 3 one can show that

$$\operatorname{Tr}\left[\sigma_x\sigma_x^T X-\sigma_y\sigma_y^T Y\right] \leq \operatorname{Tr}\left[\sigma_x\sigma_x^T D^2\varphi(x_\varepsilon,t_\varepsilon)\right]+m(\varepsilon)+m\left(\frac{\rho}{\varepsilon^4}\right), \tag{2.23}$$

where m is independent of α. Thus, using (2.2), we have

$$\begin{aligned}\mathcal{H} \geq &\inf_{\alpha\in\mathbb{R}^k}\left\{\left(\frac{\nu(1-\mu)}{2}+m(\varepsilon)\right)|\alpha|^2-\bar{C}(|D\varphi(x_\varepsilon,t_\varepsilon)|+m(\varepsilon))|\alpha|\right\}\\ &+\inf_{\alpha\in\mathbb{R}^k}\left\{-\operatorname{Tr}\left[\sigma(x_\varepsilon,t_\varepsilon,\alpha)\sigma(x_\varepsilon,t_\varepsilon,\alpha)^T D^2\varphi(x_\varepsilon,t_\varepsilon)\right]\right\}\\ &-\bar{C}(1+|x_\varepsilon|)|D\varphi(x_\varepsilon,t_\varepsilon)|+m(\varepsilon)+m\left(\frac{\rho}{\varepsilon^4}\right)\\ \geq &-\frac{(\bar{C}|D\varphi(x_\varepsilon,t_\varepsilon)|+m(\varepsilon))^2}{2\nu(1-\mu)+m(\varepsilon)}-\bar{C}(1+|x_\varepsilon|)|D\varphi(x_\varepsilon,t_\varepsilon)|\\ &+\inf_{\alpha\in\mathbb{R}^k}\left\{-\operatorname{Tr}\left[\sigma(x_\varepsilon,t_\varepsilon,\alpha)\sigma(x_\varepsilon,t_\varepsilon,\alpha)^T D^2\varphi(x_\varepsilon,t_\varepsilon)\right]\right\}+m(\varepsilon)+m\left(\frac{\rho}{\varepsilon^4}\right).\end{aligned} \tag{2.24}$$

Step 5. Finally, from (2.22), (2.23), and (2.24), letting first ρ go to 0 and then sending ε to 0, we obtain

$$\begin{aligned}\mathcal{L}[\varphi](\bar{x},\bar{t}) = \varphi_t(\bar{x},\bar{t}) &- \frac{\bar{C}^2}{2\nu(1-\mu)}|D\varphi(\bar{x},\bar{t})|^2-2\bar{C}(1+|\bar{x}|)|D\varphi(\bar{x},\bar{t})|\\ &+\inf_{\alpha\in\mathbb{R}^k}\left\{-\operatorname{Tr}\left[\sigma(\bar{x},\bar{t},\alpha)\sigma(\bar{x},\bar{t},\alpha)^T D^2\varphi(\bar{x},\bar{t})\right]\right\}\\ &+\inf_{\beta\in B}\left\{-\operatorname{Tr}\left[c(\bar{x},\bar{t},\beta)c(\bar{x},\bar{t},\beta)^T D^2\varphi(\bar{x},\bar{t})\right]\right\}\leq 0,\end{aligned}$$

which means exactly that Ψ is a subsolution of (2.10). □

Proof of Lemma 2.3. Set $\chi(s,t)=\varphi(\mathrm{e}^s,t)$ for $(s,t)\in\mathbb{R}\times[0,+\infty)$. A straightforward calculation shows that φ satisfies (2.12) if and only if χ is a solution of the heat equation

$$\begin{cases}\chi_t-\chi_{ss}=0 & \text{in } \mathbb{R}\times(0,T),\\ \chi(s,0)=\varphi_R(\mathrm{e}^s) & \text{in } \mathbb{R}.\end{cases} \tag{2.25}$$

Since the initial data satisfy the growth estimate $|\chi(s,0)| < \mathrm{e}^{s^2}$, by classical results on the heat equation (John [24], Evans [17]), we know there exists a unique classical solution $\chi \in C(\mathbb{R}\times[0,T]) \times C^\infty(\mathbb{R}\times(0,T])$ of (2.25). It is given by the representation formula: for every $(s,t) \in \mathbb{R}\times[0,T]$,

$$\chi(s,t) = \frac{1}{\sqrt{4\pi t}} \int_{\mathbb{R}} \mathrm{e}^{-\frac{(s-y)^2}{4t}} \varphi_R(\mathrm{e}^y)\, dy = \frac{1}{\sqrt{4\pi t}} \int_{\log R}^{+\infty} \mathrm{e}^{-\frac{(s-y)^2}{4t}} (\mathrm{e}^y - R)\, dy. \tag{2.26}$$

From the above formula, it follows $\chi(s,t) > 0$ for all $(s,t) \in \mathbb{R}\times(0,T]$. Let $h > 0$. We have $\varphi_R(\mathrm{e}^s) \le \varphi_R(\mathrm{e}^{s+h})$ for all $s \in \mathbb{R}$. Since $\chi(\cdot + h, \cdot)$ is a solution of (2.25) with initial data $\varphi_R(\mathrm{e}^{s+h})$, by the maximum principle, we obtain $\chi(s,t) \le \chi(s+h,t)$. This proves that χ is nondecreasing with respect to s. It follows that $\varphi(r,t) = \chi(\log r, t)$ is the unique solution of (2.12) and $\varphi \in C([0,+\infty)\times[0,T]) \cap C^\infty((0,+\infty)\times(0,T])$ is positive and nondecreasing. Moreover, if the initial data are convex, we know that the solution of a quasi-linear equation like (2.12) is convex in the space variable for every time (see, e.g., Giga et al. [20]). Thus $\varphi(\cdot,t)$ is convex in $[0,+\infty)$ for all $t \in [0,T]$.

It remains to prove the estimates (2.13). Noticing that $\varphi_R(\mathrm{e}^s) \le \mathrm{e}^s$ and that $(s,t) \mapsto \varphi_R(\mathrm{e}^s)$ and $(s,t) \mapsto \mathrm{e}^{s+t}$ are respectively sub- and supersolution (in the viscosity sense, for example) of (2.25), by the maximum principle, we obtain $\varphi_R(\mathrm{e}^s) \le \chi(s,t) \le \mathrm{e}^{s+t} \le \mathrm{e}^{s+T}$ for $(s,t) \in \mathbb{R}\times[0,T]$. It follows

$$\varphi_R(r) \le \varphi(r,t) \le \mathrm{e}^T r \quad \text{for } (r,t) \in [0,+\infty]\times[0,T]. \tag{2.27}$$

This gives the first estimate. To prove the second estimate, we note that $\varphi(\cdot,t)$ is a convex nondecreasing function satisfying (2.27). It follows $0 \le \varphi_r(r,t) \le \mathrm{e}^T$ for $(r,t) \in [0,+\infty]\times(0,T]$. The last assertion is obvious, using the dominated convergence theorem in (2.26). It completes the proof of the lemma. □

3. Applications. This section is divided into two parts. In the first part we consider a finite horizon unbounded stochastic control problem and we characterize the value function as the unique viscosity solution of the corresponding dynamic programming equation, which is a particular case of (1.1). In the second part we list some concrete examples of model cases to which the results of section 1 can be applied.

3.1. Unbounded stochastic control problems. Let $(\Omega, \mathcal{F}, (\mathcal{F}_t)_{t\ge0}, P)$ be a filtered probability space, W_t be an $\mathcal{F}_t$-adapted standard M-Brownian motion such that $W_0 = 0$ a.s., and let A be a subset of a separable normed space (possibly unbounded). We consider a *finite horizon unbounded stochastic control problem* for controlled diffusion processes $X_s^{t,x}$ whose dynamic is governed by a stochastic differential equation of the form

$$\begin{cases} dX_s^{t,x} = b(X_s^{t,x}, s, \alpha_s)ds + \sigma(X_s^{t,x}, s, \alpha_s)dW_s, & s \in (t,T),\ 0 \le t \le T, \\ X_t^{t,x} = x \in \mathbb{R}^N, \end{cases} \tag{3.1}$$

where the control $\alpha_s \in A$, $b\colon \mathbb{R}^N \times \mathbb{R} \times A \to \mathbb{R}^N$ is a continuous vector field and σ is a continuous real $N \times M$ matrix. The payoff to be minimized is

$$J(t,x,\alpha) = \mathrm{E}_{tx}\left\{ \int_t^T \ell(X_s^{t,x}, s, \alpha_s)\, ds + \psi(X_T^{t,x}) \right\},$$

where E_{tx} is the expectation with respect to the event $X_t^{t,x} = x$, the functions $\ell : \mathbb{R}^N \times [0,T] \times A \to \mathbb{R}$ and $\psi : \mathbb{R}^N \to \mathbb{R}$ are continuous, $\alpha_s \in \mathcal{A}_t$, the set of A-valued

$\mathcal{F}_t$-progressively measurable controls such that

$$\mathrm{E}_{tx}\left(\int_t^T |\alpha_s|^2\, ds\right) < +\infty, \tag{3.2}$$

and $X_s^{t,x}$ is the solution of (3.1). The value function is defined by

$$V(x,t) = \inf_{\alpha_s \in \mathcal{A}_t} J(t,x,\alpha_s). \tag{3.3}$$

At least formally, the dynamic programming equation associated to this control problem is

$$-\frac{\partial w}{\partial t} + \sup_{\alpha\in A}\left\{-\langle b(x,t,\alpha), Dw\rangle - \ell(x,t,\alpha) - \frac{1}{2}\mathrm{Tr}\left(\sigma(x,t,\alpha)\sigma(x,t,\alpha)^T D^2 w\right)\right\} = 0 \tag{3.4}$$

in $\mathbb{R}^N \times (0,T)$, with the terminal value condition $w(x,T) = \psi(x)$.

Our main goal is to characterize the value function V as the unique continuous viscosity solution of (3.4) with the terminal value condition $V(x,T) = \psi(x)$. We recall that the fact that the value function is a viscosity solution of (3.4) is in general obtained by a direct use of the dynamic programming principle. Since we are in an unbounded control framework, the proof of the dynamic programming principle is rather delicate, and thus we follow another strategy which consists in comparing directly V with the unique viscosity solution U of (3.4) obtained by Corollary 2.1 when this latter exists.

We make the following assumptions on the data.

(S0) A is a subset (possibly unbounded) of a separable complete normed space.

(S1) $b \in C(\mathbb{R}^N \times [0,T] \times A; \mathbb{R}^N)$ and there exists $\bar{C} > 0$ such that for all $x, y \in \mathbb{R}^N$, $t \in [0,T]$, and $\alpha \in A$ we have

$$|b(x,t,\alpha) - b(y,t,\alpha)| \le \bar{C}|x-y|,$$
$$|b(x,t,\alpha)| \le \bar{C}(1+|x|+|\alpha|);$$

(S2) $\sigma \in C(\mathbb{R}^N \times [0,T] \times A; \mathcal{M}_{N,M})$ and there exists $\bar{C} > 0$ such that for all $x, y \in \mathbb{R}^N$, $t \in [0,T]$ and $\alpha \in A$ we have

$$|\sigma(x,t,\alpha) - \sigma(y,t,\alpha)| \le \bar{C}|x-y|,$$
$$|\sigma(x,t,\alpha)| \le \bar{C}(1+|x|).$$

Moreover we assume that ℓ and ψ satisfy, respectively, (A1)(iii) and (A3).

We first observe that under the current assumptions (S1) and (S2) on b and σ, for any control $\alpha \in \mathcal{A}_t$ satifying (3.2) and any random variable Z such that $\mathrm{E}[Z] < \infty$, there exists a unique strong solution of the stochastic differential equation (3.1) which satisfies

$$\mathrm{E}\left\{\sup_{t\le s\le T} |X_s^{t,Z}|^2\right\} < \infty$$

(see, e.g., Appendix D in [19]). Moreover, we have better estimates on the trajectories of (3.1).

LEMMA 3.1. *Assume* (S0), (S1), *and* (S2). *For every* $(x,t) \in \mathbb{R}^N \times [0,T]$ *and every* $\alpha_s \in \mathcal{A}_t$, *the solution* $X_s^{t,x}$ *of* (3.1) *corresponding to* α_s *satisfies the following properties:*

(i) *there exists a constant $C > 0$ such that*

$$\mathrm{E}_{tx}\left\{\sup_{t\le s\le T}|X_s^{t,x}|^2\right\} \le \left(|x|^2 + C(T-t) + C\mathrm{E}_{tx}\int_t^T |\alpha_s|^2\,ds\right)\mathrm{e}^{C(T-t)}\ ; \tag{3.5}$$

(ii) *there exists $C_{x,\alpha} > 0$ which depends on x and on the control α_s such that for all $s, s' \in [t,T]$,*

$$\mathrm{E}_{tx}\{|X_s^{t,x} - X_{s'}^{t,x}|\} \le C_{x,\alpha}|s-s'|^{1/2}. \tag{3.6}$$

In particular for all $\tau \in [t,T]$ we have

$$\mathrm{E}_{tx}\left\{\sup_{t\le s\le \tau}|X_s^{t,x} - x|\right\} \le C_{x,\alpha}|\tau|^{1/2}. \tag{3.7}$$

Proof of Lemma 3.1. We start by proving (i). Let us take an increasing sequence of C^2 functions $\varphi_R : \mathbb{R}_+ \to \mathbb{R}_+$ such that for all $R > 0$, $\varphi_R'(r) = 0$ if $r > 2R$, $\varphi_R''(r) \le 0$ and $\varphi_R(r) \uparrow r$, $\varphi_R'(r) \uparrow 1$, as $R \to +\infty$. By applying Ito's formula to the process $\varphi_R(|X_s^{t,x}|^2)$, for a.e. $t \le \tau \le T$, we have (dropping the argument of φ_R and its derivatives)

$$\begin{aligned}\varphi_R(|X_\tau^{t,x}|^2) &= \varphi_R(|x|^2) + \int_t^\tau 2\varphi_R'\langle X_s^{t,x}, b(X_s^{t,x},s,\alpha_s)\rangle\,ds\\ &\quad + \int_t^\tau \left(\varphi_R'\mathrm{Tr}[\sigma\sigma^T(X_s^{t,x},s,\alpha_s)] + 2\varphi_R''|\sigma^T(X_s^{t,x},s,\alpha_s)X_s^{t,x}|^2\right)ds\\ &\quad + \int_t^\tau 2\varphi_R'\langle X_s^{t,x}, \sigma(X_s^{t,x},s,\alpha_s)dW_s\rangle.\end{aligned} \tag{3.8}$$

By using the current assumptions on b and σ the following estimate holds:

$$\begin{aligned}&\int_t^\tau \left(2\varphi_R'\langle X_s^{t,x}, b(X_s^{t,x},s,\alpha_s)\rangle + \varphi_R'\mathrm{Tr}[\sigma\sigma^T(X_s^{t,x},s,\alpha_s)]\right.\\ &\qquad \left. + 2\,\varphi_R''|\sigma^T(X_s^{t,x},s,\alpha_s)X_s^{t,x}|^2\right)ds\\ &\le 2C\int_t^\tau \varphi_R'|X_s^{t,x}|(1+|X_s^{t,x}|+|\alpha_s|)\,ds + C\int_t^\tau \varphi_R'(1+|X_s^{t,x}|^2)\,ds \quad \text{a.s.},\end{aligned}$$

where the constant C depends on neither the control α_s nor on R. Moreover, we observe that since $\varphi_R' = 0$ for $t > 2R$ we have

$$\mathrm{E}_{tx}\left\{\int_t^\tau |\varphi_R'\langle X_s^{t,x}, \sigma(X_s,s,\alpha_s)\rangle|^2\,ds\right\} < +\infty,$$

hence the expectation of the stochastic integral is zero. By taking the expectation in (3.9) and applying Fubini's theorem we obtain

$$\mathrm{E}_{tx}\{\varphi_R(|X_\tau^{t,x}|^2)\} \le \varphi_R(|x|^2) + C\int_t^\tau \mathrm{E}_{tx}\{\varphi_R'[2+5|X_s^{t,x}|^2 + |\alpha_s|^2]\}\,ds.$$

Since φ_R, φ_R' are increasing sequences, we can apply Levi's theorem. Therefore by letting $R \to \infty$ we obtain, for every $t \le \tau \le T$,

$$\begin{aligned}\mathrm{E}_{tx}\{|X_\tau^{t,x}|^2\} &\le |x|^2 + C\int_t^\tau \mathrm{E}_{tx}\{2+5|X_s^{t,x}|^2 + |\alpha_s|^2\}\,ds\\ &\le |x|^2 + 5C\int_t^\tau \mathrm{E}_{tx}|X_s^{t,x}|^2\,ds + C\mathrm{E}_{tx}\left\{\int_t^\tau |\alpha_s|^2\,ds\right\} + 2C(T-t).\end{aligned}$$

Applying Gronwall's inequality we obtain

$$\mathrm{E}_{tx}\{|X_\tau^{t,x}|^2\} \le \left(|x|^2 + 2C(T-t) + C\,\mathrm{E}_{tx}\left\{\int_t^T |\alpha_s|^2\,ds\right\}\right) \mathrm{e}^{5C(T-t)}.$$

We conclude by Doob's maximal inequality (see, e.g., [25]).

The proof of (ii) is an extension of the one in the Appendix D in [19] and we leave it to the reader. □

PROPOSITION 3.1. *Assume* (S0), (S1), (S2), (A1)(iii) *for* ℓ *and* (A3) *for* ψ. *Then there exists* $0 \le \tau < T$ *such that the value function* V *is finite and satisfies the quadratic growth condition* (2.4) *in* $\mathbb{R}^N \times [\tau, T]$.

Proof of Proposition 3.1. We aim to show that if the constants $\rho, C > 0$ are large enough, then there exists $\tau > 0$ depending on ρ such that $|V(x,t)| \le C(1+|x|^2)\mathrm{e}^{\rho(T-t)}$ for all $(x,t) \in \mathbb{R}^N \times [\tau, T]$. The upper estimate is obtained by majorizing directly the value function with the cost functional corresponding to a constant control and using the estimates of the trajectories in Lemma 3.1. The most difficult is to prove the estimate from below since V is defined by an infimum. To this purpose we take any control $\alpha_s \in \mathcal{A}_t$. By applying Ito's formula to the process $(1+|X_s^{t,x}|^2)\mathrm{e}^{\rho(t-s)}$, $X_s^{t,x}$ being the trajectory corresponding to α_s, we have the following estimate:

$$\begin{aligned} d[(1+|X_s^{t,x}|^2)\mathrm{e}^{\rho(T-s)}] &= -\rho\mathrm{e}^{\rho(T-s)}(1+|X_s^{t,x}|^2)ds + \mathrm{e}^{\rho(T-s)}\mathrm{Tr}\,(\sigma\sigma^T(X_s^{t,x},s,\alpha_s))ds \\ &\quad + 2\mathrm{e}^{\rho(T-s)}\langle X_s^{t,x}, b(X_s^{t,x},s,\alpha_s)ds + \sigma(X_s^{t,x},s,\alpha_s)dW_s\rangle. \end{aligned} \tag{3.9}$$

Integrating both sides of (3.9) from t to T and taking the expectation we get

$$\begin{aligned} \mathrm{E}_{tx}\{1+|X_T^{t,x}|^2\} - (1+|x|^2)\mathrm{e}^{\rho(T-t)} = \mathrm{E}_{tx}\Bigg\{\int_t^T \Big(&-\rho(1+|X_s^{t,x}|^2) \\ &+ 2\langle X_s^{t,x}, b(X_s^{t,x},s,\alpha_s)\rangle \\ &+ \mathrm{Tr}(\sigma\sigma^T(X_s,s,\alpha_s)\Big)\mathrm{e}^{\rho(T-s)}\,ds\Bigg\}. \end{aligned} \tag{3.10}$$

We notice that in the above estimate we supposed that the expectation of the stochastic integral is zero. This is false in general but we can overcome such a difficulty by an approximation argument which is similar to the one used in the proof of Lemma 3.1. Now for any ε-optimal control α_s for $V(x,t)$, by using (3.10), we get

$$\begin{aligned} &V(x,t) + C(1+|x|^2)\mathrm{e}^{\rho(T-t)} + \varepsilon \\ &\quad \ge \mathrm{E}_{tx}\left\{\int_t^T \Big(\ell(X_s^{t,x},s,\alpha_s) - 2C\mathrm{e}^{\rho(T-s)}\langle X_s^{t,x}, b(X_s^{t,x},s,\alpha_s)\rangle \right. \\ &\qquad - C\mathrm{e}^{\rho(T-s)}\mathrm{Tr}(\sigma\sigma^T(X_s^{t,x},s,\alpha_s)) + \rho\mathrm{e}^{\rho(T-s)}C(1+|X_s|^2)\Big)\,ds \\ &\qquad \left. + \psi(X_T^{t,x}) + C(1+|X_T^{t,x}|^2)\right\} \\ &\quad = \mathrm{E}_{tx}\left\{\int_t^T \bar{\ell}(X_s^{t,x},s,\alpha_s)\,ds + \bar{\psi}(X_T^{t,x})\right\}, \end{aligned}$$

where $\bar\ell(x,t,\alpha) := \ell(x,t,\alpha) - 2C\mathrm{e}^{\rho(T-t)}\langle b(x,t,\alpha),x\rangle - 2C\mathrm{e}^{\rho(T-t)}\mathrm{Tr}\,a(x,t,\alpha) + C\rho\mathrm{e}^{\rho(T-t)}(1+|x|^2)$ and $\bar\psi(x) := \psi(x) + C(1+|x|^2)$. By analogous arguments as those used in section 2 one can see that for $\rho, C > 0$ large enough there is $\tau > 0$ such that $\bar\ell$ and $\bar\psi$ are nonnegative in $\mathbb{R}^N \times [\tau, T]$. Thus we can conclude since ε is arbitrary. □

Remark 3.1. If ℓ, ψ are bounded from below, namely, they satisfy, for some $C > 0$, the two conditions $\ell(x,t,\alpha) \ge \nu|\alpha|^2 - C$ and $\psi(x) \ge -C$, then V is finite and satisfies the growth condition (2.4) in $\mathbb{R}^N \times [0,T]$ (i.e., for all time).

Next we prove that V is the unique viscosity solution of (3.4). We start with the following proposition.

PROPOSITION 3.2. *Under the assumptions of Proposition* 3.1 *we have*

(i) (*superoptimality principle*) *for all* $t \in (\tau, T]$ *and* $0 < h \le T - t$ *and for all stopping time* $t \le \theta \le T$, *we have*

(3.11)
$$V(x,t) \ge \inf_{\alpha_s \in \mathcal{A}_t} \mathrm{E}_{tx}\left\{\int_t^{(t+h)\wedge\theta} \ell(X_s^{t,x}, s, \alpha_s)\,ds + V_*(X^{t,x}_{(t+h)\wedge\theta}, (t+h)\wedge\theta)\right\};$$

(ii) *the function* V *is a supersolution of* (3.4) *in* $\mathbb{R}^N \times [\tau, T]$.

Proof of Proposition 3.2. The proof of (i) is a standard routine and we refer the reader, for instance, to [41]. The opposite inequality is more delicate; see Krylov [27, 28].

We turn to the proof of (ii), showing that the superoptimality principle implies that V_* is a viscosity supersolution of (3.4). Let $\phi \in C^2(\mathbb{R}^N \times [0,T])$ and $(\bar x, \bar t) \in \mathbb{R}^N \times (\tau, T)$ be a local minimum of $V_* - \phi$. We can assume that $V_*(\bar x, \bar t) = \phi(\bar x, \bar t)$ and that the maximum is strict, i.e., $V_*(x,t) > \phi(x,t)$ for all $(x,t) \in \bar B(\bar x, \varepsilon) \times [\bar t - \varepsilon, \bar t + \varepsilon]$ with $(x,t) \ne (\bar x, \bar t)$ (see [3] or [6]). We assume by contradiction that there exists $\delta_\varepsilon > 0$ such that for all $(x,t) \in \bar B(\bar x, \varepsilon) \times [\bar t - \varepsilon, \bar t + \varepsilon]$, we have

(3.12)
$$-\phi_t(x,t) + \sup_{\alpha\in A}\left\{-\langle b(x,t,\alpha), D\phi(x,t)\rangle - \ell(x,t,\alpha) - \mathrm{Tr}\left[\frac{1}{2}\sigma\sigma^T(x,t,\alpha)D^2\phi(x,t)\right]\right\} \le -\delta_\varepsilon.$$

Since $(\bar x, \bar t)$ is a strict minimum of $V_* - \phi$, it follows that there exists η_ε such that

$$V_*(x,t) \ge \phi(x,t) + \eta_\varepsilon \quad \text{for all } (x,t) \in \partial B(\bar x, \varepsilon) \times [\bar t - \varepsilon, \bar t + \varepsilon]. \tag{3.13}$$

From now on, we fix $0 < h < \varepsilon/2$ such that $h\delta_\varepsilon < \eta_\varepsilon$. Let us denote by $\tau_{t,x}$ the exit time of the trajectory $X_s^{t,x}$ from the ball $B(\bar x, \varepsilon)$. We first observe that by the continuity of the trajectory (see Lemma 3.1), we have $\tau_{t,x} > t$ for all $(x,t) \in B(\bar x, \varepsilon) \times [0,T)$. For every $(x,t) \in B(\bar x, \varepsilon) \times (\bar t - \varepsilon/2, \bar t + \varepsilon/2)$, there exists a control $\alpha_s \in \mathcal{A}_t$ such that

$$V(x,t) + \frac{\delta_\varepsilon h}{2} \ge \mathrm{E}_{tx}\left\{\int_t^{(t+h)\wedge\tau_{t,x}} \ell(X_s^{t,x}, s, \alpha_s)\,ds + V_*(X^{t,x}_{(t+h)\wedge\tau_{t,x}}, (t+h)\wedge\tau_{t,x})\right\}.$$

Since $V_* \ge \phi$ in $\bar B(\bar x, \varepsilon) \times [\bar t - \varepsilon, \bar t + \varepsilon]$, if $\tau_{t,x} < t + h$, then, from (3.13), we have

$$V_*(X^{t,x}_{(t+h)\wedge\tau_{t,x}}, (t+h)\wedge\tau_{t,x}) \ge \phi(X^{t,x}_{\tau_{t,x}}, \tau_{t,x}) + \eta_\varepsilon.$$

Therefore the following estimate holds:

$$
\begin{aligned}
V(x,t)+\frac{\delta_\varepsilon h}{2} &\geq \mathrm{E}_{tx}\left\{\left[\int_t^{\tau_{t,x}} \ell(X_s^{t,x},s,\alpha_s)\,ds+\phi(X_{\tau_{t,x}}^{t,x},\tau_{t,x})+\eta_\varepsilon\right]1_{\{\tau_{t,x}<t+h\}}\right\}\\
&\quad+\mathrm{E}_{tx}\left\{\left[\int_t^{t+h} \ell(X_s^{t,x},s,\alpha_s)\,ds+\phi(X_{t+h}^{t,x},t+h)\right]1_{\{\tau_{t,x}\geq t+h\}}\right\}\\
&\geq \mathrm{E}_{tx}\Big\{[I(\tau_{t,x})+\eta_\varepsilon]1_{\{\tau_{t,x}<t+h\}}\Big\}+\mathrm{E}_{tx}\Big\{I(t+h)1_{\{\tau_{t,x}\geq t+h\}}\Big\}, \qquad (3.14)
\end{aligned}
$$

where for all $\tau'>0$

$$
I(\tau')=\int_t^{\tau'} \ell(X_s^{t,x},s,\alpha_s)\,ds+\phi(X_{\tau'}^{t,x},\tau').
$$

Applying Ito's formula to the process $\phi(X_{\tau'}^{t,x},\tau')$, we obtain

$$
\begin{aligned}
I(\tau')=\int_t^{\tau'}&\Big(\ell(X_s^{t,x},s,\alpha_s)+\phi_t(X_s^{t,x},s)+\langle D\phi(X_s^{t,x},s),b(X_s^{t,x},s,\alpha_s)\rangle\\
&+\frac{1}{2}\mathrm{Tr}\left[\sigma\sigma^T(X_s^{t,x},s,\alpha_s)D^2\phi\right]\Big)\,ds\\
&+\phi(x,t)+\int_t^{\tau'}\langle D\phi(X_s^{t,x},s),\sigma(X_s^{t,x},s,\alpha_s)dW_s\rangle \quad \text{a.s.}
\end{aligned}
$$

Note that the expectation of the above stochastic integral is zero for $\tau'\in[t,t+\varepsilon]$.

Now we can estimate the two last terms in (3.14). For the first term, we have

$$
\begin{aligned}
&\mathrm{E}_{tx}\Big\{[I(\tau_{t,x})+\eta_\varepsilon]1_{\{\tau_{t,x}<t+h\}}\Big\}\\
&\geq -\mathrm{E}_{tx}\left\{\left[\int_t^{\tau_{t,x}}\Big(-\phi_t(X_s^{t,x},s)+\sup_{\alpha\in A}\{-\ell(X_s^{t,x},s,\alpha)-\langle D\phi(X_s^{t,x},s),b(X_s^{t,x},s,\alpha)\rangle\right.\right.\\
&\qquad\left.\left.-\frac{1}{2}\mathrm{Tr}\left[\sigma\sigma^T(X_s^{t,x},s,\alpha)D^2\phi\right]\}\Big)\,ds-\phi(x,t)-\eta_\varepsilon\right]1_{\{\tau_{t,x}<t+h\}}\right\}.
\end{aligned}
$$

Since $X_s^{t,x}\in B(\bar{x},\varepsilon)$ when $s\leq\tau_{t,x}$ and since $t+h<\bar{t}+\varepsilon$, from (3.12), we get

$$
\begin{aligned}
\mathrm{E}_{tx}\Big\{[I(\tau_{t,x})+\eta_\varepsilon]1_{\{\tau_{t,x}<t+h\}}\Big\} &\geq -\mathrm{E}_{tx}\left\{\left[\int_t^{\tau_{t,x}}(-\delta_\varepsilon)\,ds-\phi(x,t)-\eta_\varepsilon\right]1_{\{\tau_{t,x}<t+h\}}\right\}\\
&\geq \delta_\varepsilon\mathrm{E}_{tx}\left[(\tau_{t,x}-t)1_{\{\tau_{t,x}<t+h\}}\right]\\
&\quad+(\eta_\varepsilon+\phi(x,t))P(\{\tau_{t,x}<t+h\})\\
&\geq (\eta_\varepsilon+\phi(x,t))P(\{\tau_{t,x}<t+h\}). \qquad (3.15)
\end{aligned}
$$

For the second term, we proceed in the same way, noting that if $\tau_{t,x}\geq t+h$, then for all $t\leq s\leq t+h$, $X_s^{t,x}\in B(\bar{x},\varepsilon)$, and it allows us to apply (3.12). More precisely we

have

(3.16)

$$
\begin{aligned}
&\mathrm{E}_{tx}\Big\{I(t+h)1_{\{\tau_{t,x}\geq t+h\}}\Big\}\\
&\quad\geq -\mathrm{E}_{tx}\left\{\left[\int_t^{t+h}\Big(-\phi_t(X_s^{t,x},s)+\sup_{\alpha\in A}\{-\ell(X_s^{t,x},s,\alpha)-\langle D\phi(X_s^{t,x},s),b(X_s^{t,x},s,\alpha)\rangle\right.\right.\\
&\qquad\left.\left.-\frac{1}{2}\mathrm{Tr}\,[\sigma\sigma^T(X_s^{t,x},s,\alpha)D^2\phi]\}\Big)\,ds-\phi(x,t)\right]1_{\{\tau_{t,x}\geq t+h\}}\right\}\\
&\quad\geq(\delta_\varepsilon h+\phi(x,t))P(\{\tau_{t,x}\geq t+h\}).
\end{aligned}
$$

Combining (3.14), (3.15), and (3.16), we get

$$
\begin{aligned}
V(x,t)+\frac{\delta_\varepsilon h}{2}&\geq\eta_\varepsilon P(\{\tau_{t,x}<t+h\})+\delta_\varepsilon h\,P(\{\tau_{t,x}\geq t+h\})\\
&\quad+\phi(x,t)\left[P(\{\tau_{t,x}<t+h\})+P(\{\tau_{t,x}\geq t+h\})\right].
\end{aligned}
$$

Since $\eta_\varepsilon>\delta_\varepsilon h$ and $P(\{\tau_{t,x}<t+h\})+P(\{\tau_{t,x}\geq t+h\})=1$, we get

$$
V(x,t)\geq\phi(x,t)+\frac{\delta_\varepsilon h}{2}.
$$

The above inequality is valid for all $(x,t)\in B(\bar{x},\varepsilon)\times(\bar{t}-\varepsilon/2,\bar{t}+\varepsilon/2)$, and thus we have

$$
\liminf_{(x,t)\to(\bar{x},\bar{t})}V(x,t)=V_*(\bar{x},\bar{t})\geq\phi(\bar{x},\bar{t})+\frac{\delta_\varepsilon h}{2},
$$

which is a contradiction with the choice of ϕ. □

THEOREM 3.1. *Under the assumptions of Proposition* 3.1*, the function V is the unique continuous viscosity solution of* (3.4) *in* $\mathbb{R}^N\times[\tau,T]$.

Proof of Theorem 3.1. Let U be the unique solution of (3.4) in $\mathbb{R}^N\times[\tau,T]$ such that $U(x,T)=\psi(x)$ given by Theorem 2.1. Our goal is to prove that $V\equiv U$ in $\mathbb{R}^N\times[\tau,T]$. The inequality $U\leq V_*$ follows by combining Proposition 3.2 and Theorem 2.1. To show that $V^*\leq U$ in $\mathbb{R}^N\times[\tau,T]$, we proceed as follows.

Step 1. We consider the functions $\widetilde{V}(x,t):=V(x,t)-C(1+|x|^2)\mathrm{e}^{\rho(T-t)}$ and $\widetilde{U}(x,t):=U(x,t)-C(1+|x|^2)\mathrm{e}^{\rho(T-t)}$. As it is proved in Step 2 of the proof of Theorem 2.1, $\widetilde{U}$ is the unique solution of

(3.17)

$$
\begin{cases}
-w_t+\sup_{\alpha\in A}\left\{-\frac{1}{2}\mathrm{Tr}(\sigma\sigma^T(x,t,\alpha)D^2w)-\langle b(x,t,\alpha),Dw\rangle-\bar{\ell}(x,t,\alpha)\right\}=0 \text{ in } \mathbb{R}^N\times(\tau,T),\\
w(x,T)=\bar{\psi}(x),
\end{cases}
$$

where $\bar{\ell}(x,t,\alpha):=\ell(x,t,\alpha)+2C\mathrm{e}^{\rho(T-t)}\langle b(x,t,\alpha),x\rangle+C\mathrm{e}^{\rho(T-t)}\mathrm{Tr}\,\sigma\sigma^T(x,t,\alpha)$ $-C\rho\mathrm{e}^{\rho(T-t)}(1+|x|^2)$ and $\bar{\psi}(x):=\psi(x)-C(1+|x|^2)$.

Step 2. Claim: for all $(x,t)\in\mathbb{R}^N\times[\tau,T]$, $\widetilde{V}$ satisfies

$$
\widetilde{V}(x,t)\leq\inf_{\alpha_s\in\mathcal{A}_t}\mathrm{E}_{tx}\left\{\int_t^T\bar{\ell}(X_s,s,\alpha_s)\,ds+\bar{\psi}(X_t)\right\}. \tag{3.18}
$$

To prove the claim let us take any $\alpha_s \in \mathcal{A}_t$. Arguing exactly as in the proof of Proposition 3.1, from (3.10), we have

$$\begin{aligned}\widetilde{V}(x,t) \le \mathrm{E}_{tx}\Bigg\{\int_t^T \Big(&\ell(X_s^{x,t},s,\alpha_s) + 2\mathrm{e}^{\rho(T-s)}\langle X_s^{x,t}, b(X_s^{x,t},t,\alpha_s)\rangle \\ &+ \mathrm{e}^{\rho(T-s)}\,\mathrm{Tr}(\sigma\sigma^T(X_s^{x,t},s,\alpha_s)) - \rho\mathrm{e}^{\rho(T-s)}(1+|X_s^{x,t}|^2)\Big)\,ds + \psi(X_T^{x,t}) \\ &- C(1+|X_T^{x,t}|^2)\Bigg\} \\ = \mathrm{E}_{tx}\Bigg\{\int_t^T &\bar{\ell}(X_s^{x,t},s,\alpha_s)\,ds + \bar{\psi}(X_T^{x,t})\Bigg\}.\end{aligned}$$

Since α_s is arbitrary we get (3.18) and prove the claim.

Step 3. Choose $C, \rho > 0$ large enough so that for all $(x,t,\alpha) \in \mathbb{R}^N \times [\tau,T] \times A$, we have

$$\begin{aligned}-\widetilde{C}\mathrm{e}^{2\rho(T-t)}(1+|x|^2) + \frac{\nu}{4}|\alpha|^2 \le \bar{\ell}(x,t,\alpha) \le -C\mathrm{e}^{\rho(T-t)}(1+|x|^2) + C\mathrm{e}^{\rho(T-t)}(1+|\alpha|^2), \\ -2C(1+|x|^2) \le \bar{\psi}(x) \le 0,\end{aligned}$$

where $\widetilde{C}$ depends only on C and ν. For all real $R > 0$ and all integer $n > 0$, we set $A_n := \{\alpha \in A : |\alpha| \le n\}$, $\bar{\ell}_R(x,t,\alpha) := \max\{\bar{\ell}(x,t,\alpha), -R\}$ and $\bar{\psi}_R(x,t) := \max\{\bar{\psi}(x,t), -R\}$. We observe that $\bar{\ell}_R \colon \mathbb{R}^N \times [\tau,T] \times A_n \to \mathbb{R}$ is bounded and uniformly continuous in $x \in \mathbb{R}^N$ uniformly with respect to $(t,\alpha) \in [\tau,T] \times A_n$ and $\psi_R \colon \mathbb{R}^N \to \mathbb{R}$ is bounded and uniformly continuous in $\mathbb{R}^N$. Set

$$\begin{aligned}\bar{H}(x,t,p,X) &:= \sup_{\alpha\in A}\left\{-\frac{1}{2}\mathrm{Tr}(\sigma\sigma^T(x,t,\alpha)X) - \langle b(x,t,\alpha),p\rangle - \bar{\ell}(x,t,\alpha)\right\}, \\ H_n^R(x,t,p,X) &:= \sup_{\alpha\in A_n}\left\{-\frac{1}{2}\mathrm{Tr}(\sigma\sigma^T(x,t,\alpha)X) - \langle b(x,t,\alpha),p\rangle - \bar{\ell}_R(x,t,\alpha)\right\}\end{aligned}$$

and define

$$V_n^R(x,t) = \inf_{\alpha_s\in\mathcal{A}_t^n} \mathrm{E}_{tx}\left\{\int_t^T \bar{\ell}_R(X_s^{x,t},s,\alpha_s)\,ds + \bar{\psi}_R(X_T^{x,t})\right\},$$

where $\mathcal{A}_t^n$ is the set of A_n-valued $\mathcal{F}_t$-progressively measurable controls such that (3.2) holds. The function V_n^R is now the value function of a stochastic control problem with bounded controls and uniformly continuous datas b, σ, $\bar{\ell}_R$, and $\bar{\psi}_R$. These assumptions enter the framework of Yong and Zhou [41]. We deduce that V_n^R is the unique continuous viscosity solution of

$$-\frac{\partial V_n^R}{\partial t} + H_n^R(x,t,DV_n^R,D^2V_n^R) = 0 \ \text{ in } \mathbb{R}^N \times (\tau,T), \tag{3.19}$$

with terminal condition $V_n^R(x,T) = \bar{\psi}_R(x)$ in $\mathbb{R}^N$. Moreover, for all compact subsets $K \subset \mathbb{R}^N$ there exists $M > 0$ independent on R and n such that $||V_n^R||_\infty \le M$ in $K \times [\tau,T]$. Indeed, take any constant control $\alpha_s = \bar{\alpha} \in A_1$, by definition of V_n^R for all

$R, n > 0$ and for every $(x,t) \in \mathbb{R}^N \times [\tau, T]$ we have

$$V_n^R(x,t) \le \mathrm{E}_{tx}\left\{\int_t^T \bar{\ell}_R(X_s^{x,t}, s, \bar{\alpha})\, ds + \bar{\psi}_R(X_T^{x,t})\right\}$$
$$\le \int_t^T C\mathrm{e}^{\rho(T-s)}(1+\bar{\alpha}^2)\, ds \le \frac{C}{\rho}\mathrm{e}^{\rho(T-t)}(1+\bar{\alpha}^2),$$

and on the other hand we have $V_n^R(x,t) \ge \widetilde{V}(x,t) \ge -\widetilde{C}\mathrm{e}^{2\rho(T-t)}(1+|x|^2)$.

Finally one can readily see that H_n^R converges locally uniformly to $\bar{H}$ as $n, R \to \infty$. Thus by applying the half-relaxed limits method (see Barles and Perthame [9]), the functions

$$\overline{V}(x,t) = \limsup{}^* V_n^R(x,t) = \limsup_{\substack{(y,s)\to(x,t)\\ n,R\to+\infty}} V_n^R(y,s)$$
$$\text{and } \ \underline{V}(x,t) = \liminf{}^* V_n^R(x,t) = \liminf_{\substack{(y,s)\to(x,t)\\ n,R\to+\infty}} V_n^R(y,s)$$

are, respectively, viscosity sub- and supersolution of (3.17). Theorem 2.1 yields $\overline{V}(x,t) \le \widetilde{U}(x,t) \le \underline{V}(x,t)$. On the other hand by construction we have also $\widetilde{V}^*(x,t) \le \limsup^* V_n^R(x,t)$. It follows $\widetilde{V}^*(x,t) \le \widetilde{U}(x,t)$ and we can conclude. □

3.2. Some examples.

Example 3.1. A model case we have in mind is the so-called stochastic linear regulator problem which is a stochastic perturbation of the deterministic linear quadratic problem. In this case, the stochastic differential (3.1) is linear and reads

$$dX_s^{t,x} = [B(s)X_s^{t,x} + C(s)\alpha_s]ds + \sum_j [C_j(s)X_s^{t,x} + D_j(s)]dW_s^j$$

and the expected total cost to minimized is

$$J(x,t,\alpha_s) = \mathrm{E}_{tx}\left\{\int_t^T [\langle X_s^{t,x}, Q(s)X_s^{t,x}\rangle + \langle \alpha_s, R(s)\alpha_s\rangle]\, ds + \langle X_T^{t,x}, GX_T^{t,x}\rangle\right\}.$$

The previous results apply if the functions $B(\cdot), C(\cdot), C_j(\cdot), D_j(\cdot), Q(\cdot), R(\cdot)$, and G are deterministic continuous matrix-valued functions of suitable size and if $R(s)$ is a positive definite symmetric matrix. Deterministic and stochastic linear quadratic problems were extensively studied. For a survey we refer for instance to the books of Bensoussan [10], Fleming and Rishel [18], Fleming and Soner [19], Øksendal [38], and Yong and Zhou [41] and references therein.

Example 3.2. Equations of the type (3.4) are largely considered in mathematical finance. See the introductory books quoted in the introduction or Pham [39]. In particular, recently Benth and Karlsen [11] studied the following semilinear elliptic partial equation

$$-w_t - \frac{1}{2}\beta^2 w_{xx} + F(x, w_x) = 0 \qquad \text{in } \mathbb{R}\times(0,T) \tag{3.20}$$

with the final condition $w(x,T) = 0$. The nonlinear function F is given by

$$F(x,p) = \frac{1}{2}\delta^2 p^2 - \left\{\alpha(x) - \frac{\mu(x)\beta\rho}{\sigma(x)}\right\} p - \frac{\mu^2(x)}{\sigma^2(x)},$$

where δ, β, ρ are real constant and $\alpha(x)$ and $\dfrac{\mu}{\sigma}(x)$ are C^1 functions satisfying

$$|\alpha(x)|, \left|\frac{\mu}{\sigma}(x)\right| \leq C|x| \quad \text{for all } x \in \mathbb{R}.$$

Their main motivation is to determine via the solution of (3.20) the minimal entropy martingale measure in stochastic market. The conditions they assume on data fall within the assumptions of section 2.

Example 3.3. Another application of the results obtained in section 2 is given by the finite time-horizon risk-sensitive limit problem for nonlinear systems. In the stochastic risk-sensitive problem, (3.1) reads

$$dX_s^{t,x,\varepsilon} = g(X_s^{t,x,\varepsilon}, \beta_s)\, dt + \sqrt{\frac{\varepsilon}{\gamma^2}} c(X_s^{t,x,\varepsilon})\, dW_s, \tag{3.21}$$

where $X_s^{t,x,\varepsilon} \in \mathbb{R}^N$ depends on the parameter $\varepsilon > 0$, g represents the nominal dynamics with control $\beta_s \in B$, a compact normed space, and c is an $N \times k$-valued diffusion coefficient, ε is a measure of the risk-sensitivity and γ is the disturbance attenuation level. The cost criterion is of the form

$$J^\varepsilon(x,t,\beta_s) = \mathrm{E} \exp\left\{\frac{1}{\varepsilon}\left[\int_t^T f(X_s^{t,x,\varepsilon}, \beta_s)\, dt + \psi(X_T^{t,x,\varepsilon})\right]\right\} \tag{3.22}$$

and the value function is

$$V^\varepsilon(x,t) \quad = \inf_{\beta_s \in \mathcal{B}_t} \varepsilon \log J^\varepsilon(x,t,\beta_s) = \varepsilon \log \inf_{\beta_s \in \mathcal{B}_t} J^\varepsilon(x,t,\beta_s), \tag{3.23}$$

where $\mathcal{B}_t$ is the set of B-valued, $\mathcal{F}_t$-progressively measurable controls such that there exists a strong solution to (3.21). The dynamic programming equation associated to this problem is

(3.24)
$$\begin{cases} -\dfrac{\partial w}{\partial t} - \dfrac{1}{2\gamma^2}\langle Dw, a(x) Dw\rangle + \tilde{G}(x, Dw) - \dfrac{\varepsilon}{2\gamma^2}\mathrm{Tr}(a(x) D^2 w) = 0 \quad \text{in } \mathbb{R}^N \times [\tau, T], \\ w(x,T) = \psi(x), \end{cases}$$

where $a(x) = c(x)c(x)^T$ and

$$\tilde{G}(x,p) = \max_{\beta \in B}\{\langle -g(x,\beta), p\rangle - f(x,\beta)\}.$$

We note that

$$-\frac{1}{2\gamma^2}\langle p, a(x) p\rangle = \min_{\alpha \in \mathbb{R}^k}\left\{\frac{\gamma^2}{2}|\alpha|^2 - \langle c(x)\alpha, p\rangle\right\}. \tag{3.25}$$

In [16] it is shown that as $\varepsilon \downarrow 0$ (i.e., as the problem becomes infinitely risk averse), the value function of the risk-sensitive problem converges to that of an H_∞ robust control problem. This problem can be considered as a differential game with the cost functional

$$J(x,t,\alpha,\beta) = \int_t^T \Big(f(y_x(s), \beta_s) - \frac{\gamma^2}{2}|\alpha_s|^2\Big) ds + \psi(y_x(T)), \tag{3.26}$$

where $\alpha_s \in \mathcal{A}_t := L^2([t,T],\mathbb{R}^k)$ is the control of the maximizing player, $\beta_s \in \mathcal{B}_t := \{\text{measurable functions } [t,T] \to B\}$ is the control of the minimizing player, and $y_x(\cdot)$ is the unique solution of the following dynamical system

$$\begin{cases} y'(s) = g(y(s),\beta_s) + c(y(s))\alpha_s, \\ y(t) = x. \end{cases}$$

Note that we switch notation from X_t to $y(t)$ to emphasize that the paths are now (deterministic) solutions of ordinary differential equations rather than (stochastic) solutions of stochastic differential equations. The dynamic programing equation associated to the robust control problem is a first-order equation given by

$$-\frac{\partial w}{\partial t} + \min_{\alpha\in\mathbb{R}^k}\left\{\frac{\gamma^2}{2}|\alpha|^2 - \langle c(x)\alpha, Dw\rangle\right\} + \tilde{G}(x,Dw) = 0 \ \text{ in } \mathbb{R}^N \times (\tau,T) \tag{3.27}$$

with the terminal condition $w(T,x) = \psi(x)$. One of the key tools to get this convergence result is the uniqueness property for (3.27). In Da Lio and McEneaney [16], the authors characterized the value function of the H_∞ control as the unique solution to (3.27) in the set of locally Lipschitz continuous functions growing at most quadratically with respect to the state variable. Moreover, the uniqueness result in [16] is obtained by using representation formulas of locally Lipschitz solutions of (3.27). We remark that the comparison theorem, Theorem 2.1, not only improves the uniqueness result for (3.27) obtained in [16] (in the sense it holds in a larger class of functions) but it also should allow us to prove the convergence result in [16] under weaker assumptions, only the equiboundedness estimates of the solutions of (3.24) being enough by means of the half-relaxed limit method.

4. Study of related equations. In this section we focus our attention on Hamilton–Jacobi equations of the form

$$\begin{cases} \dfrac{\partial w}{\partial t} + \langle \Sigma(x,t)Dw, Dw\rangle + G(x,t,Dw,D^2w) = 0 & \text{in } \mathbb{R}^N \times (0,T), \\ w(x,0) = \psi(x) & \text{in } \mathbb{R}^N, \end{cases} \tag{4.1}$$

where $\Sigma(x,t) \in \mathcal{M}_N(\mathbb{R})$ and G is given by (1.3) and

$$\begin{cases} \dfrac{\partial w}{\partial t} + h(x)|Dw|^2 = 0 & \text{in } \mathbb{R}^N \times (0,T), \\ w(x,0) = \psi(x) & \text{in } \mathbb{R}^N, \end{cases} \tag{4.2}$$

where $h : \mathbb{R}^N \to \mathbb{R}$. Our aim is to investigate comparison (and existence) results for (4.1) and (4.2) under assumptions which include Hamiltonians like (2.6) in Remark 2.2(iii) (see Remark 4.1 for further comments). More precisely, we introduce two new assumptions:

(A4) $\Sigma \in C(\mathbb{R}^N \times [0,T]; \mathcal{S}_N^+(\mathbb{R}))$ and for all $x \in \mathbb{R}^N, t \in [0,T]$,

$$0 < \Sigma(x,t) \quad \text{and} \quad |\Sigma(x,t)| \le \bar{C}.$$

(A5) $h \in C(\mathbb{R}^N;\mathbb{R})$, $h \in W^{2,\infty}(\tilde{\Gamma})$, where $\tilde{\Gamma}$ is an open neighborhood of $\Gamma := \{x \in \mathbb{R}^N : h(x) = 0\}$ and for all $x \in \Gamma$,

$$Dh(x) = 0.$$

THEOREM 4.1. *Assume* (A2), (A3) *and* (A4) (*respectively,* (A3) *and* (A5)). *Let* $U \in USC(\mathbb{R}^N \times [0,T])$ *be a viscosity subsolution of* (4.1) (*respectively,* (4.2)) *and* $V \in LSC(\mathbb{R}^N \times [0,T])$ *be a viscosity supersolution of* (4.1) (*respectively,* (4.2)) *satisfying the quadratic growth condition* (2.4). *Then* $U \leq V$ *in* $\mathbb{R}^N \times [0,T]$.

The question of existence faces the same problems as in section 2. We have existence and uniqueness of a continuous viscosity solution for (4.1) and (4.2) in the class of functions with quadratic growth at least for short time (as in Corollary 2.1). But solutions can blow up in finite time.

Before giving the proof of the theorem, we give some comments on the equations and the assumptions.

Remark 4.1. (i) In the same way as in Remark 2.2, the above results hold replacing Σ by $-\Sigma$ in (4.1) and h by $-h$ in (4.2) and when dealing with terminal data in both equations.

(ii) Coming back to Remark 2.2(iii), we note $(a_1+a_2)(a_2-a_1)^T$ is not necessarily symmetric in (2.6), whereas we assume Σ to be symmetric in (A4) (and h is real-valued and therefore symmetric in (A5)). This is not a restriction of generality since comparison for (4.1) with Σ symmetric implies obviously a comparison for (4.1) for any matrix Σ, using that, for any $\Sigma \in \mathcal{M}_N(\mathbb{R})$, $(\Sigma + \Sigma^T)/2 \in \mathcal{S}_N(\mathbb{R})$.

(iii) Coming back to Remark 2.2(iv) again, we see that (A4) corresponds to the case where the convex Hamiltonian is predominant with respect to the concave one in (1.1) with (2.6). Assumption (A5) corresponds to (2.6) when a_1 and a_2 are real valued but h is allowed to change its sign. For example, we have comparison for

$$w_t + \phi(x)^3 |Dw|^2 = 0,$$

where $\phi \in C^2(\mathbb{R}^N;\mathbb{R})$ is any bounded function. Let us compare (1.12) with first-order Hamilton–Jacobi equations whose Hamilonians are Lipschitz continuous both in the state and gradient variables, or, to make it simple, with the Eikonal equation

$$\frac{\partial w}{\partial t} + a(x)|Dw| = 0 \quad \text{in } \mathbb{R}^N \times (0,T),$$

where a is Lipschitz continuous function. We know [13], [30] we have existence and uniqueness of a continuous viscosity solution for any continuous initial data without any restriction on the growth. In this case, the sign of a does not play any role, whereas it seems to be the case for the sign of h in (1.12). We would like to know if comparison for (1.12) is true under weaker assumptions than (A5) and in dimension $N > 1$ (i.e., when Σ is neither positive nor negative definite in (4.1)).

(iv) There are some links between Theorem 2.1 and Theorem 4.1. Nevertheless we point out that if (1.1) under assumptions of section 2 is naturally associated with a control problem, this is not necessarily the case under the assumptions of the current section. To be more precise, let us compare (1.1) with H given by (2.3) and (4.1) under (A4). The matrix a can be singular in (2.3), whereas we impose the nondegeneracy condition $\Sigma > 0$ in (4.1). The counterpart is that the regularity assumption with respect to x on Σ is weaker (Σ is supposed to be merely continuous) than the locally Lipschitz regularity we assume for a. Therefore (4.1) does not enter in the framework of section 2 in general. A natural consequence is that proofs differ: in both proofs of Theorem 2.1 and 4.1, the main argument is a kind of linearization procedure, but while in the proof of Theorem 2.1 we use essentially the convexity (or concavity) of the operator corresponding to the unbounded control set, here we use the locally Lipschitz continuity of the Hamiltonian with respect to the gradient uniformly in the state variable.

(v) Note that we are able to deal with a second-order term in (4.1) but not in (4.2).

Proof of Theorem 4.1. We divide the proof into two parts, corresponding, respectively, to the case of (4.1) and (4.2). The main argument in both proofs is a kind of linearization procedure as the one of Lemma 2.2. The rest of the proof is close to the one of Theorem 2.1.

Part 1. We assume (A2), (A3), and (A4).

The estimates of G are exactly the same than in Lemma 2.2 so, for sake of simplicity, we choose to take $G \equiv 0$. The linearization procedure is the subject of the following lemma, whose proof is postponed to the end of the section.

LEMMA 4.1. *Let* $0 < \lambda < 1$ *and set* $\Psi = \lambda U - V$. *Then* Ψ *is a USC viscosity subsolution of*

$$\begin{cases} \dfrac{\partial w}{\partial t} - \dfrac{2\bar{C}}{1-\lambda}|Dw|^2 \le 0 & \text{in } \mathbb{R}^N \times (0,T), \\ w(x,0) \le (\lambda - 1)\psi(x) & \text{in } \mathbb{R}^N. \end{cases} \tag{4.3}$$

If $\psi \ge 0$, then it follows $\Psi(x,0) \le 0$ in $\mathbb{R}^N$ and using the above lemma with the same supersolution as in the proof of Theorem 2.1, we obtain $\Psi \le 0$ in $\mathbb{R}^N \times [0,T]$. Note that the boundedness of Σ (see (A4)) is crucial to build the supersolution. In the particular case when $G = 0$, we can also choose a simpler supersolution such as, for instance,

$$(x,t) \mapsto K\frac{[(|x| - R)^+]^2}{1 - Lt} + \eta t, \quad K, L, R, \eta > 0. \tag{4.4}$$

Letting λ go to 1, we conclude that $U \le V$ in $\mathbb{R}^N \times [0,T]$.

It remains to prove that we can assume $\psi \ge 0$ without loss of generality. To this end we use an argument similar to the one of Step 2 in the proof of Theorem 2.1: let $\bar{U} = U + M(1+|x|^2)\mathrm{e}^{\rho t}$, $\bar{V} = V + M(1+|x|^2)\mathrm{e}^{\rho t}$, for some positive constants M and ρ and set $\bar{\Psi} = \lambda\bar{U} - \bar{V}$. We can easily prove that for $\rho > 16M^2\bar{C}\mathrm{e}$, $\bar{\Psi}$ is a subsolution of (4.3) (with a larger constant $4\bar{C}$ instead of $2\bar{C}$) in $\mathbb{R}^N \times (0,\tau]$ for $\tau = 1/\rho$. Moreover, $\bar{\Psi}(x,0) \le (\lambda - 1)(\psi(x) + M(1+|x|^2)\mathrm{e}^{\rho t}) \le 0$ for M sufficiently large (since ψ has quadratic growth). Letting λ go to 1, it follows that $U \le V$ in $\mathbb{R}^N \times [0,\tau]$ and we conclude by a step-by-step argument.

Part 2. We assume (A3) and (A5).

Set $\Omega^+ = \{x \in \mathbb{R}^N : h(x) > 0\}$ and $\Omega^- = \{x \in \mathbb{R}^N : h(x) < 0\}$ which are open subsets of $\mathbb{R}^N$. Define $\bar{\Psi} = \lambda\bar{U} - \bar{V}$ for $0 < \lambda < 1$, $\bar{U} = U + M(1+|x|^2)\mathrm{e}^{\rho t}$ and $\bar{V} = V + M(1+|x|^2)\mathrm{e}^{\rho t}$ with M larger than the constants which appear in (A3) and in the growth condition (2.4). Arguing as in Lemma 4.1 and noticing that all arguments are local, we obtain that $\bar{\Psi}$ is a subsolution in Ω^+ of the same kind of equation as (4.3), namely,

$$\begin{cases} \dfrac{\partial w}{\partial t} - \dfrac{C}{1-\lambda}|Dw|^2 \le 0 & \text{in } \Omega^+ \times (0,\tau), \\ w(x,0) \le 0 & \text{in } \Omega^+, \end{cases} \tag{4.5}$$

for some constant $C = 16\,||h||_\infty$, $\rho > 4MC\mathrm{e}$, and $\tau = 1/\rho > 0$ which are independent of λ. Note that $\bar{\Psi}(\cdot,0) \le 0$ in $\mathbb{R}^N$ because of the choice of M.

The sign of $\bar{\Psi}$ on Γ is the subject of the following lemma the proof of which uses (A5) and is postponed.

LEMMA 4.2. *For all* $x \in \Gamma,\ t \in [0,T]$, *we have* $U(x,t) \le \psi(x) \le V(x,t)$.

Noticing that $\{\Gamma, \Omega^+, \Omega^-\}$ is a partition of $\mathbb{R}^N$, we set

$$\hat{\Psi} := \begin{cases} \sup\{\bar{\Psi}, 0\} & \text{in } (\Gamma \cup \Omega^+) \times [0,T], \\ 0 & \text{in } \Omega^- \times [0,T]. \end{cases}$$

From the lemma, $\bar{\Psi} \le 0$ in $\Gamma \times [0,T]$. Therefore the function $\hat{\Psi}$ is continuous in $\mathbb{R}^N \times (0,T)$. Moreover, we claim that $\hat{\Psi}$ is a subsolution of (4.5) in $\mathbb{R}^N \times (0,\tau)$. This claim is clearly true in $\Omega^- \times (0,T)$ (since 0 is clearly a subsolution) and in $\Omega^+ \times (0,\tau)$ (since $\hat{\Psi}$ is the supremum of two subsolutions). It remains to prove the result on Γ. Let $\varphi \in C^1(\mathbb{R}^N \times (0,\tau))$ such that $\hat{\Psi} - \varphi$ achieves a local maximum at a point $(\bar{x},\bar{t}) \in \Gamma \times (0,\tau)$. Let (x,t) be in a neighborhood of $(\bar{x},\bar{t})$. If $x \in \Gamma \cup \Omega^+$, then $0 \le \hat{\Psi}(x,t)$, and if $x \in \Omega^-$, then $0 = \hat{\Psi}(x,t)$. In any case, $(0-\varphi)(x,t) \le (\hat{\Psi}-\varphi)(x,t) \le (\hat{\Psi}-\varphi)(\bar{x},\bar{t})$. But $\hat{\Psi}(\bar{x},\bar{t}) \le 0$ since $(\bar{x},\bar{t}) \in \Gamma \times (0,\tau)$. Therefore $(\bar{x},\bar{t})$ is a local maximum of $0-\varphi$ which ends the proof of the claim. The initial condition $\hat{\Psi} \le 0$ in $\mathbb{R}^N \times \{0\}$ is trivially satisfied. From the comparison principle proved in Part 1 (for example, using (4.4) as a supersolution), we obtain $\hat{\Psi} \le 0$ in $\mathbb{R}^N \times [0,\tau]$. Since τ does not depend on λ, we can send λ to 1. We obtain $U \le V$ in $(\Gamma \cup \Omega^+) \times [0,\tau]$. We conclude in $(\Gamma \cup \Omega^+) \times [0,T]$ by a step-by-step procedure.

Repeating the same kind of arguments replacing Ω^+ by Ω^- and $\bar{\Psi}$ by $U - M(1+|x|^2)\mathrm{e}^{\rho t} - \mu(V - M(1+|x|^2)\mathrm{e}^{\rho t})$, $0 < \mu < 1$, we obtain that $U - V \le 0$ in $(\Gamma \cup \Omega^-) \times [0,T]$, which ends the proof. □

Proof of Lemma 4.1. We proceed as in the proof of Lemma 2.2. We can assume that $G \equiv 0$ since the computations with G are exactly the same than in Lemma 2.2.

Note first that λU is an USC subsolution of

$$\text{(4.6)} \qquad \begin{cases} \dfrac{\partial w}{\partial t} + \dfrac{1}{\lambda}\langle \Sigma(x,t) Dw, Dw\rangle \le 0 & \text{in } \mathbb{R}^N \times (0,T), \\ w(x,0) \le \lambda\psi(x) & \text{in } \mathbb{R}^N. \end{cases}$$

Let $\varphi \in C(\mathbb{R}^N \times [0,T])$ and suppose that $\Psi - \varphi$ reaches a strict local maximum at $(\bar{x},\bar{t}) \in \mathbb{R}^N \times (0,T]$ in some compact subset $K \subset \mathbb{R}^N \times (0,T]$. We have

$$\max_{(x,t)(y,t)\in K} \left\{ \lambda U(x,t) - V(y,t) - \varphi\left(\frac{x+y}{2}, t\right) - \frac{|x-y|^2}{\varepsilon^2} \right\} \underset{\varepsilon \downarrow 0}{\longrightarrow} \Psi(\bar{x},\bar{t}) - \varphi(\bar{x},\bar{t}).$$

The above maximum is achieved at some point $(x_\varepsilon, y_\varepsilon, t_\varepsilon)$. Writing the viscosity inequalities and subtracting them, we obtain

$$\begin{aligned} &\varphi_t\left(\frac{x_\varepsilon + y_\varepsilon}{2}, t_\varepsilon\right) + \frac{1}{\lambda}\left\langle \Sigma(x_\varepsilon, t_\varepsilon)\left(\frac{1}{2} D\varphi\left(\frac{x_\varepsilon + y_\varepsilon}{2}, t_\varepsilon\right) + 2\frac{x_\varepsilon - y_\varepsilon}{\varepsilon^2}\right),\right. \\ &\left. \frac{1}{2} D\varphi\left(\frac{x_\varepsilon + y_\varepsilon}{2}, t_\varepsilon\right) + 2\frac{x_\varepsilon - y_\varepsilon}{\varepsilon^2}\right\rangle \\ &- \left\langle \Sigma(y_\varepsilon, t_\varepsilon)\left(-\frac{1}{2} D\varphi\left(\frac{x_\varepsilon + y_\varepsilon}{2}, t_\varepsilon\right) + 2\frac{x_\varepsilon - y_\varepsilon}{\varepsilon^2}\right),\right. \\ &\left. -\frac{1}{2} D\varphi\left(\frac{x_\varepsilon + y_\varepsilon}{2}, t_\varepsilon\right) + 2\frac{x_\varepsilon - y_\varepsilon}{\varepsilon^2}\right\rangle \le 0. \end{aligned}$$

In what follows, we omit writing the dependence in t_ε and the point $((x_\varepsilon + y_\varepsilon)/2, t_\varepsilon)$ in the derivatives of φ. Set $p_\varepsilon = 2(x_\varepsilon - y_\varepsilon)/\varepsilon^2$, $p_x = D\varphi/2 + p_\varepsilon$, and $p_y = -D\varphi/2 + p_\varepsilon$.

We have

$$\begin{aligned}0 &\geq \varphi_t + \frac{1}{\lambda}\langle\Sigma(x_\varepsilon)p_x, p_x\rangle - \langle\Sigma(y_\varepsilon)p_y, p_y\rangle\\ &\geq \varphi_t + \left(\frac{1}{\lambda} - 1\right)\langle\Sigma(x_\varepsilon)p_x, p_x\rangle + \langle(\Sigma(x_\varepsilon) - \Sigma(y_\varepsilon))p_x, p_x\rangle + \langle\Sigma(y_\varepsilon)p_x, p_x\rangle\\ &\quad -\langle\Sigma(y_\varepsilon)p_y, p_y\rangle\\ &\geq \varphi_t + \left(\frac{1}{\lambda} - 1\right)\langle\Sigma(x_\varepsilon)p_x, p_x\rangle - m_K(|x_\varepsilon - y_\varepsilon|)|p_x|^2 + \langle\Sigma(y_\varepsilon)p_x, p_x\rangle - \langle\Sigma(y_\varepsilon)p_y, p_y\rangle,\end{aligned}$$

where m_K is a modulus of continuity for Σ in the compact subset K. Since $\Sigma(y_\varepsilon)$ is a symmetric matrix, we have

$$\begin{aligned}\langle\Sigma(y_\varepsilon)p_x, p_x\rangle - \langle\Sigma(y_\varepsilon)p_y, p_y\rangle &= \langle\Sigma(y_\varepsilon)(p_x + p_y), p_x - p_y\rangle = 2\,\langle\Sigma(y_\varepsilon)p_\varepsilon, D\varphi\rangle\\ &= -\langle\Sigma(y_\varepsilon)D\varphi, D\varphi\rangle + 2\,\langle\Sigma(y_\varepsilon)p_x, D\varphi\rangle.\end{aligned}$$

For any $\alpha > 0$, denoting by $\sqrt{\Sigma(y_\varepsilon)}$ the positive symmetric squareroot of the positive symmetric matrix $\Sigma(y_\varepsilon)$, we get

$$\begin{aligned}2\langle\Sigma(y_\varepsilon)p_x, D\varphi\rangle = 2\langle\sqrt{\Sigma(y_\varepsilon)}p_x, \sqrt{\Sigma(y_\varepsilon)}D\varphi\rangle &\leq \alpha\langle\Sigma(y_\varepsilon)D\varphi, D\varphi\rangle + \frac{1}{\alpha}\langle\Sigma(y_\varepsilon)p_x, p_x\rangle\\ &\leq \alpha\langle\Sigma(y_\varepsilon)D\varphi, D\varphi\rangle + \frac{1}{\alpha}\langle\Sigma(x_\varepsilon)p_x, p_x\rangle + \frac{1}{\alpha}\langle m_K(|x_\varepsilon - y_\varepsilon|)p_x, p_x\rangle.\end{aligned}$$

It follows

$$\begin{aligned}0 \geq \varphi_t + \left\langle\left[\left(\frac{1}{\lambda} - 1 - \frac{1}{\alpha}\right)\Sigma(x_\varepsilon) - \left(1 + \frac{1}{\alpha}\right)m_K(|x_\varepsilon - y_\varepsilon|)Id\right]p_x, p_x\right\rangle\\ - (1+\alpha)\langle\Sigma(y_\varepsilon)D\varphi, D\varphi\rangle.\end{aligned}$$

Take $\alpha = \frac{2\lambda}{(1-\lambda)} > 0$ in order to have $\frac{1}{\lambda} - 1 - \frac{1}{\alpha} = \frac{1}{2}(\frac{1}{\lambda} - 1) > 0$. We recall that $\Sigma > 0$ by (A4); hence for ε small enough the above scalar product is nonnegative. Thus

$$0 \geq \varphi_t - (1+\alpha)\langle\Sigma(y_\varepsilon, t_\varepsilon)D\varphi, D\varphi\rangle = \varphi_t - \frac{1+\lambda}{1-\lambda}\langle\Sigma(y_\varepsilon, t_\varepsilon)D\varphi, D\varphi\rangle.$$

Letting ε go to 0, we get

$$0 \geq \varphi_t(\bar{x}, \bar{t}) - \frac{2}{1-\lambda}\langle\Sigma(\bar{x}, \bar{t})D\varphi(\bar{x}, \bar{t}), D\varphi(\bar{x}, \bar{t})\rangle,$$

which proves the result. □

Proof of Lemma 4.2. We make the proof for U, the second inequality being similar. Let $x_0 \in \Gamma$ and consider, for $\eta > 0$,

$$\sup_{t\in[0,T]}\{U(x_0, t) - \eta t\}.$$

This supremum is achieved at a point $t_0 \in [0, T]$ and we can assume, up to subtract $|t - t_0|^2$, that it is a strict local maximum. Consider, for $\varepsilon > 0$,

$$\sup_{\bar{B}(x_0,1)\times[0,T]}\left\{U(x, t) - \frac{|x - x_0|^2}{\varepsilon^2} - \eta t\right\}.$$

This supremum is achieved at a point $(x_\varepsilon, t_\varepsilon)$ and it is easy to see that $(x_\varepsilon, t_\varepsilon) \to (x_0, t_0)$ when $\varepsilon \to 0$.

Suppose that $t_\varepsilon > 0$. It allows us to write the viscosity inequality for the subsolution U at $(x_\varepsilon, t_\varepsilon)$ and we get

$$\eta + h(x_\varepsilon)\left|2\frac{x_\varepsilon - x_0}{\varepsilon^2}\right|^2 \leq 0. \tag{4.7}$$

Since $h \in W^{2,\infty}$ in a neighborhood of Γ, we can write a Taylor expansion of h at x_0 for ε small enough

$$h(x_\varepsilon) = h(x_0) + \langle Dh(x_0), x_\varepsilon - x_0\rangle + \frac{1}{2}\langle D^2h(x_0)(x_\varepsilon - x_0), x_\varepsilon - x_0\rangle + o(|x_\varepsilon - x_0|^2).$$

From (4.7) and (A5), it follows

$$\eta - (2C + m(|x_\varepsilon - x_0|^2))\left(\frac{|x_\varepsilon - x_0|^2}{\varepsilon^2}\right)^2 \leq 0,$$

where m is a modulus of continuity. Since $|x_\varepsilon - x_0|^2/\varepsilon^2 \to 0$ as $\varepsilon \to 0$, we obtain a contradiction for small ε.

Therefore $t_\varepsilon = 0$ for ε small enough. It follows that for all $(x,t) \in \bar{B}(x_0,1)\times[0,T]$, we have

$$U(x,t) - \frac{|x - x_0|^2}{\varepsilon^2} - \eta t \leq U(x_\varepsilon, 0) - \frac{|x_\varepsilon - x_0|^2}{\varepsilon^2} \leq \psi(x_\varepsilon).$$

Setting $x = x_0$ and sending ε and then η to 0, we obtain the conclusion. □

MINIMUM DISTANCE TO THE RANGE OF A BANDED LOWER TRIANGULAR TOEPLITZ OPERATOR IN ℓ^1 AND APPLICATION IN ℓ^1-OPTIMAL CONTROL*

ZDENĚK HURÁK†, ALBRECHT BÖTTCHER‡, AND MICHAEL ŠEBEK§

Abstract. The subject of the paper is the best approximation in ℓ^1 of a given infinite sequence by sequences in the range of a given banded lower-triangular Toeplitz operator. Necessary and sufficient conditions for the existence of a minimizing solution are established and a numerical algorithm for finding such a solution is designed and theoretically founded. It is also shown that an optimal error sequence is only finitely nonzero. The relevancy of the problem in systems theory is outlined and numerical examples are presented.

Key words. Toeplitz operator, banded, lower-triangular, range, minimum distance problem, ℓ^1-optimal control

1. Introduction. This paper concerns the problem of finding the distance between a given sequence in ℓ^1 and the range of a given infinite lower-triangular Toeplitz band matrix on ℓ^1. Our research was motivated by recent attempts [7], [8], [9], [15], [17], [18] to solve the standard ℓ^1-optimal control problem [24] without using interpolation. The approach of the present paper follows the line of reasoning pursued by Dahleh and Pearson in their seminal paper [10], which launched a hunt for reliable procedures for ℓ^1-optimal control design, but the problem is posed in a different setting, which leads to a different numerical algorithm. Using new theoretical tools, we establish (the already known) necessary and sufficient conditions for the solvability of the problem and design a new numerical algorithm for finding a solution. The convergence of this algorithm is rigorously proved. In essence, our approach shares the spirit of polynomial methods with Casavola's approach [7], [8], [9] in that we formulate the problem using equations with polynomials and power series. In contrast to previous work, which used interpolation techniques (see [11] for a detailed exposition) relying on the solution of numerically ill-conditioned Vandermonde systems, our algorithm is based on finding optimal solutions of overdetermined but numerically better behaved Toeplitz systems. Compared to Casavola's polynomial approach, ours does not introduce any new *structural* parameter (a term coined by Casavola) for the optimization and the Diophantine equation $AX + Y = B$ in the ring of *stable* functions is attacked directly using powerful results from Toeplitz operator theory. The rigorousness of this paper might perhaps seem unnecessary for control of single-input-single-output (SISO) plants, because it is well known that the design of an ℓ^1-optimal controller

simply consists in designing a dead-beat controller minimizing the sum of the absolute values of the closed-loop impulse response and that hence not much space is left for innovations. But the theoretical rigorousness pays back in that the extension to the multiple-input-multiple-output (MIMO) case is straightforward; preliminary achievements have recently been presented by the authors in [16].

2. Statement of the problem. We start with some standard definitions [4], [5], [6]. The Wiener algebra W is the Banach algebra of all complex-valued functions on the complex unit circle $\mathbf{T}$ with absolutely convergent Fourier series. Thus, a function $a : \mathbf{T} \to \mathbf{C}$ belongs to W if and only if

$$a(t) = \sum_{j=-\infty}^{\infty} a_j t^j \quad (t = e^{i\theta} \in \mathbf{T}), \quad \|a\|_W := \sum_{j=-\infty}^{\infty} |a_j| < \infty.$$

Wiener's theorem states that if $a \in W$ has no zeros on $\mathbf{T}$, then $1/a$ is also in W. For $a \in W$, the infinite Toeplitz matrix $T(a)$ and the finite Toeplitz matrices $T_k(a)$ are defined by $T(a) = (a_{i-j})_{i,j=1}^{\infty}$ and $T_k(a) = (a_{i-j})_{i,j=1}^{k}$, respectively.

We denote by c_0 the set of all real-valued sequences $x = \{x_j\}_{j=1}^{\infty}$ with $|x_j| \to 0$ as $j \to \infty$ and by ℓ^1 the set of all real-valued sequences $x = \{x_j\}_{j=1}^{\infty}$ satisfying $\sum_{j=1}^{\infty} |x_j| < \infty$. The sets c_0 and ℓ^1 are real Banach spaces under the norms $\|x\|_\infty = \sup_{j\geq 1} |x_j|$ and $\|x\|_1 = \sum_{j=1}^{\infty} |x_j|$, respectively. Moreover, ℓ^1 is the dual space of c_0, $\ell^1 = c_0^*$, under the pairing $\langle z, b\rangle = \sum_{j=1}^{\infty} z_j b_j$, $\{z_j\} \in c_0$, $\{b_j\} \in \ell^1$.

Given a Banach space X, we let $\mathcal{B}(X)$ stand for the Banach algebra of all bounded linear operators on X. For $A \in \mathcal{B}(X)$, the norm $\|A\|_{\mathcal{B}(X)}$ is $\sup \|Ax\|$, the supremum over all $x \in X$ with $\|x\| \leq 1$, and the range and null space of A are defined by $\mathcal{R}(A) = A(X)$ and $N(A) = \{x \in X : Ax = 0\}$.

Let $a \in W$ and suppose the Fourier coefficients of a are all real. Then the infinite Toeplitz matrix $T(a)$ induces a bounded linear operator on c_0 and ℓ^1 via

$$(T(a)x)_i = \sum_{j=1}^{\infty} a_{i-j} x_j \quad (j \geq 1).$$

For $j \in \mathbf{Z}$, define the function χ_j by $\chi_j(t) = t^j$ $(t \in \mathbf{T})$. The operators $T(\chi_1)$ and $T(\chi_{-1})$ are the forward and backward shifts acting by the rules

$$T(\chi_1) : \{x_1, x_2, x_3, \ldots\} \mapsto \{0, x_1, x_2, \ldots\},$$
$$T(\chi_{-1}) : \{x_1, x_2, x_3, \ldots\} \mapsto \{x_2, x_3, x_4, \ldots\}.$$

Clearly, $T(a) = \sum_{j=-\infty}^{\infty} a_j T(\chi_j)$. This implies that $\|T(a)\|_{\mathcal{B}(c_0)} = \|T(a)\|_{\mathcal{B}(\ell^1)} = \|a\|_W$. The adjoint operator of $T(a) : c_0 \to c_0$ is the operator $T(\overline{a}) : \ell^1 \to \ell^1$, where $\overline{a}(t) = \sum_{j=-\infty}^{\infty} a_j t^{-j}$ $(t = e^{i\theta} \in \mathbf{T})$.

Throughout this paper we suppose that $a_+(t) = a_0 + a_1 t + \cdots + a_n t^n$ with real numbers $a_0, a_1, \ldots, a_n$ and with $a_n \neq 0$. Clearly, $T(a_+)$ is a banded lower-triangular Toeplitz matrix, while $T(\overline{a}_+)$ is a banded upper-triangular Toeplitz matrix. We always think of $T(a_+)$ as acting on ℓ^1 and always consider $T(\overline{a}_+)$ as an operator on c_0. Thus, $T(a_+)$ is the adjoint of $T(\overline{a}_+)$.

This paper concerns the following problem of finding the distance between some given real sequence with finite sum of absolute values and the range of a banded lower triangular Toeplitz operator in ℓ^1 space. Given $b \in \ell^1$, determine the distance

$$d := \operatorname{dist}_{\ell^1}(b, \mathcal{R}(T(a_+))) := \inf_{m \in \mathcal{R}(T(a_+))} \|b - m\|_1,$$

find out whether there is an $m_0 \in \mathcal{R}(T(a_+))$ with $\|b - m_0\|_1 = d$, and if yes, compute such an m_0. Note that once m_0 is available, we can easily solve the lower-triangular system $T(a_+)x_0 = m_0$ to get x_0.

3. Two results from functional analysis. We will employ the following two theorems (whose proofs can be found in [21, pp. 121, 156]). Recall that the annihilator $M^\perp$ of a set $M \subset X$ is defined as $M^\perp = \{b \in X^* : \langle z, b\rangle = 0 \text{ for all } z \text{ in } M\}$. Furthermore, two elements $z \in X$ and $b \in X^*$ are said to be aligned if the equality $\|z\|\,\|b\| = \langle z, b\rangle$ holds.

THEOREM 3.1. *Let M be a linear subset of a real normed space X and let $b \in X^*$. Then*

$$\inf_{m \in M^\perp} \|b - m\| = \sup_{z \in M, \|z\| \le 1} \langle z, b\rangle. \tag{3.1}$$

The infimum in (3.1) *is always attained at some $m_0 \in M^\perp$. If the supremum in* (3.1) *is achieved for some $z_0 \in M$ with $\|z_0\| \le 1$, then z_0 and $b - m_0$ are aligned.*

THEOREM 3.2. *Let X be a Banach space and $A \in \mathcal{B}(X)$. Then $\mathcal{R}(A)$ is closed if and only if $\mathcal{R}(A^*)$ is closed, in which case $\mathcal{R}(A^*) = [N(A)]^\perp$.*

4. Toeplitz operators. The product of two Toeplitz operators is in general not a Toeplitz operator. However, this happens in certain special cases. Let W_+ and W_- denote the functions in W whose Fourier coefficients with negative and positive indices vanish, respectively. Thus, if $c_\pm \in W_\pm$, then $T(c_-)$ and $T(c_+)$ are upper and lower triangular, respectively. It is easily seen by direct inspection that if $c_- \in W_-$, $f \in W$, $c_+ \in W_+$, then

$$T(c_-)T(f)T(c_+) = T(c_- f c_+). \tag{4.1}$$

The following results are known to specialists (see, e.g., [4] and [12]). We include the proofs for the reader's convenience.

PROPOSITION 4.1. *The range $\mathcal{R}(T(a_+))$ is a closed subset of ℓ^1 if and only if a_+ has no zeros on $\mathbf{T}$.*

Proof. If a_+ has no zeros on $\mathbf{T}$, then a_+^{-1} belongs to W and has real Fourier coefficients. From (4.1) we obtain that $T(a_+^{-1})T(a_+) = I$. Thus, $T(a_+)$ has a bounded left inverse, which implies that the range of $T(a_+)$ is closed (see, e.g., [12, section I.1.2]).

Now suppose $a_+(\tau) = 0$ for some $\tau \in \mathbf{T}$. Contrary to what we want, we assume that $\mathcal{R}(T(a_+))$ is a closed subset of ℓ^1. We denote by $\ell^1(\mathbf{C})$ the complex Banach space of all complex-valued sequences $x = \{x_j\}_{j=1}^\infty$ for which $\|x\|_1 = \sum_{j=1}^\infty |x_j| < \infty$. The range of $T(a_+)$ on $\ell^1(\mathbf{C})$ is $\mathcal{R}(T(a_+)) + i\mathcal{R}(T(a_+))$, which is closed whenever $\mathcal{R}(T(a_+))$ is closed. From Theorem 3.2 we now infer that $T(\overline{a}_+) : c_0(\mathbf{C}) \to c_0(\mathbf{C})$ has closed range, where $c_0(\mathbf{C})$ is defined in analogy to $\ell^1(\mathbf{C})$. The operator $T(\overline{a}_+)$ is upper-triangular, and it is easily seen that the range of every nonzero upper-triangular Toeplitz operator contains all finitely supported sequences. Consequently, $T(\overline{a}_+)$ must be surjective. We may write

$$\begin{aligned}\overline{a}_+(t) = a(1/t) &= a_0 + a_1\frac{1}{t} + \cdots + a_n\frac{1}{t^n} \\ &= a_n\left(\frac{1}{t} - \tau\right)\left(\frac{1}{t} - z_1\right)\cdots\left(\frac{1}{t} - z_{n-1}\right) = a_n(\chi_{-1}(t) - \tau)d(t).\end{aligned}$$

Since $T(\overline{a}_+) = T(\chi_{-1}-\tau)T(d)$ by (4.1), the operator $T(\chi_{-1}-\tau)$ is surjective together with $T(\overline{a}_+)$. The equation $T(\chi_{-1}-\tau)z = 0$ is satisfied if and only if $z_j = \tau^{j-1}z_1$ ($j \geq 1$), and this is a sequence in $c_0(\mathbf{C})$ only for $z_1 = 0$. Thus, $T(\overline{a}_+)$ is injective on $c_0(\mathbf{C})$. In summary, $T(\chi_{-1}-\tau)$ is invertible on $c_0(\mathbf{C})$. It follows that $T(\chi_1 - 1/\tau)$ is invertible on $\ell^1(\mathbf{C})$. But the solution of $T(\chi_1 - 1/\tau)x = \{1, 0, 0, \ldots\}$ is $x_j = -\tau^j$ ($j \geq 1$), which is not in $\ell^1(\mathbf{C})$. This contradiction proves that $\mathcal{R}(T(a_+))$ cannot be closed. □

The function $a_+(z) = a_0 + a_1 z + \cdots + a_n z^n$ is defined for all $z \in \mathbf{C}$.

PROPOSITION 4.2. *If a_+ has no zeros on $\mathbf{T}$, then the dimension of $N(T(\overline{a}_+))$ in c_0 is equal to the number of zeros of a_+ in the open unit disk $\mathbf{D} := \{z \in \mathbf{C} : |z| < 1\}$.*

Proof. Let a_+ have $\varkappa$ zeros $\delta_1, \ldots, \delta_\varkappa$ in $\mathbf{D}$ and $n - \varkappa$ zeros $\mu_1, \ldots, \mu_{n-\varkappa}$ in $\mathbf{C} \setminus (\mathbf{D} \cup \mathbf{T})$. We then have

$$\begin{aligned}\overline{a}_+(t) = a_+(1/t) &= a_n \prod_{k=1}^{n-\varkappa} \left(\frac{1}{t} - \mu_k\right) \prod_{j=1}^{\varkappa} \left(\frac{1}{t} - \delta_j\right) \\ &= \gamma t^{-\varkappa} \prod_{k=1}^{n-\varkappa} \left(1 - \frac{1}{\mu_k t}\right) \prod_{j=1}^{\varkappa} (1 - \delta_j t)\end{aligned}$$

with $\gamma = a_n(-\mu_1)\ldots(-\mu_{n-\varkappa})$. We consider $T(\overline{a}_+)$ on $c_0(\mathbf{C})$. Let N be the null space of $T(\overline{a}_+)$ on c_0. Then $N + iN$ is the null space of $T(\overline{a}_+)$ on $c_0(\mathbf{C})$. From (4.1) we obtain that

$$T(\overline{a}_+) = \gamma T(\chi_{-\varkappa}) \prod_{k=1}^{n-\varkappa} \left(I - \frac{1}{\mu_k} T(\chi_{-1})\right) \prod_{j=1}^{\varkappa} (I - \delta_j T(\chi_1)).$$

Since $\|(1/\mu_k)T(\chi_{-1})\| = 1/|\mu_k| < 1$ and $\|\delta_j T(\chi_1)\| = |\delta_j| < 1$, we conclude that the operators $I - (1/\mu_k)T(\chi_{-1})$ and $I - \delta_j T(\chi_1)$ are all invertible. Consequently, the dimension of $N + iN$ is the dimension of the null space of $T(\chi_{-\varkappa})$ on $c_0(\mathbf{C})$. It follows that the dimension of $N + iN$ over $\mathbf{C}$ is $\varkappa$, which implies that the dimension of N over $\mathbf{R}$ is also $\varkappa$. □

5. Existence of the solution. Here is our result on the solvability of the problem posed in section 2. This result states that for some sequence b in ℓ^1 and a polynomial a_+, there is a real sequence in the range of the Toeplitz operator generated by a_+ that minimizes distance to b if and only if the polynomial has no zeros on the unit circle. The error sequence then has a finite number of nonzero terms only.

THEOREM 5.1. *The problem*

$$\|b - m\|_1 = \operatorname{dist}_{\ell^1}(b, \mathcal{R}(T(a_+))) =: d \tag{5.1}$$

has a solution $m_0 \in \mathcal{R}(T(a_+))$ for every $b \in \ell^1$ if and only if a_+ has no zeros on $\mathbf{T}$. If $a_+(t) \neq 0$ for $t \in \mathbf{T}$, then for every $b \in \ell^1$ there exists a $z_0 \in N(T(\overline{a}_+))$ such that

$$\|z_0\|_\infty \leq 1 \quad \text{and} \quad d = \langle z_0, b\rangle = \sup_{z \in N(T(\overline{a}_+)), \|z\|_\infty \leq 1} \langle z, b\rangle, \tag{5.2}$$

and if $m_0 \in \mathcal{R}(T(a_+))$ is any sequence satisfying (5.1)*, then the sequence $b - m_0$ has only finitely many nonzero terms.*

Proof. If a_+ has a zero on $\mathbf{T}$, then $\mathcal{R}(T(a_+))$ is not closed due to Proposition 4.1 and hence (5.1) has no solution $m_0 \in \mathcal{R}(T(a_+))$ if b is in the closure of $\mathcal{R}(T(a_+))$ but not in $\mathcal{R}(T(a_+))$.

Now suppose that a_+ has no zeros on $\mathbf{T}$. Then $\mathcal{R}(T(a_+))$ is closed by Proposition 4.1. From Theorem 3.2 we deduce that $\mathcal{R}(T(a_+)) = [N(T(\overline{a}_+))]^\perp$. The existence of an $m_0 \in \mathcal{R}(T(a_+))$ satisfying (5.1) then follows from Theorem 3.1. This theorem also yields the equality

$$d = \sup_{z \in N(T(\overline{a}_+)), \|z\|_\infty \le 1} \langle z, b \rangle,$$

and since $\{z \in N(T(\overline{a}_+)) : \|z\|_\infty \le 1\}$ is compact by virtue of Proposition 4.2 and the map $z \mapsto \langle z, b\rangle$ is continuous, we conclude that the supremum is attained at some $z_0 \in N(T(\overline{a}_+))$ with $\|z_0\|_\infty \le 1$.

The last assertion of the theorem is trivial for $d = 0$. So let $d > 0$, which implies that $\|z_0\|_\infty > 0$. The sequences $b - m_0$ and z_0 are aligned by Theorem 3.1. Consequently, with $b - m_0 = \{e_j\}_{j=1}^\infty$ and $z_0 = \{z_j\}_{j=1}^\infty$,

$$\sum_{j=1}^\infty z_j e_j = \|z_0\|_\infty \sum_{j=1}^\infty |e_j|. \tag{5.3}$$

As $\{z_j\} \in c_0$, there is a j_0 such that $|z_j| < \|z_0\|_\infty$ for all $j \ge j_0$. From (5.3) we infer that $e_j = 0$ for $j \ge j_0$. □

6. Finite sections of Toeplitz operators. In this section, we quote two known theorems that will be needed when proving the convergence of and giving an error estimate for our numerical algorithm. For $k \ge 1$, we denote by P_k the projection on ℓ^1 and c_0 that acts by the rule

$$P_k : \{x_1, x_2, x_3, \ldots\} \mapsto \{x_1, \ldots, x_k, 0, 0, \ldots\}.$$

We identify $\mathcal{R}(P_k)$ and $\mathbf{R}^k$, and hence we may think of vectors in $\mathbf{R}^k$ as elements of ℓ^1 or c_0. The following theorem was established by Reich [23] and Baxter [1]. Full proofs are also in [4, section 3.3] and [12, section II.2].

THEOREM 6.1. *If $f \in W$ and $T(f)$ is invertible on ℓ^1, then the matrices $T_k(f)$ are invertible for all sufficiently large k and $T_k^{-1}(f)P_k y$ converges in ℓ^1 to $T^{-1}(f)y$ for every $y \in \ell^1$.*

The next theorem can be proved using the asymptotic inverses presented in [4, section 3.5] or [6, section 2.3].

THEOREM 6.2. *Let f be a Laurent polynomial, that is, suppose f has only finitely many nonzero Fourier coefficients, and let $T(f)$ be invertible on ℓ^1. Fix a natural number $\varkappa$. Then there exist a natural number k_0 and constants $\alpha > 0$ and $C < \infty$ such that*

$$\|P_\varkappa T_k^{-1}(f) - P_\varkappa T^{-1}(f)\|_{\mathcal{B}(\ell^1)} = \|T_k^{-1}(\overline{f})P_\varkappa - T^{-1}(\overline{f})P_\varkappa\|_{\mathcal{B}(c_0)} \le C\, e^{-\alpha k}$$

for all $k \ge k_0$.

7. Numerical algorithm. Fix $b \in \ell^1$ and a_+ as above. Suppose a_+ has exactly $\varkappa$ zeros in $\mathbf{D}$ and no zeros on $\mathbf{T}$. If $k \geq \varkappa + 1$, the operator $P_k T(a_+) P_{k-\varkappa}$ may be identified with a $k \times (k-\varkappa)$ matrix. The system $P_k T(a_+) P_{k-\varkappa} x^{(k)} = P_k b$ is overdetermined for $\varkappa \geq 1$. However, we can find an $x_0^{(k)} \in \mathbf{R}^{k-\varkappa}$ such that the residue

$$\|P_k T(a_+) P_{k-\varkappa} x^{(k)} - P_k b\|_1 \tag{7.1}$$

assumes its minimum at $x^{(k)} = x_0^{(k)}$. Let $d = \operatorname{dist}_{\ell^1}(b, \mathcal{R}(T(a_+)))$ and let d_k be the minimal value of (7.1). The following theorem reveals that d_k converges to d exponentially fast.

THEOREM 7.1. *There are constants $E < \infty$ and $\beta > 0$ such that $|d_k - d| \leq E\, e^{-\beta k}$ for all $k \geq 1$.*

Proof. Put $f(t) = t^{-\varkappa} a_+(t) = t^{-\varkappa}(a_0 + a_1 t + \cdots + a_n t^n)$. We claim that $T(f)$ is invertible on ℓ^1. Indeed, the proof of Proposition 4.2 shows that

$$T(\overline{f}) = \gamma \prod_{k=1}^{n-\varkappa} \left(I - \frac{1}{\mu_k} T(\chi_{-1}) \right) \prod_{j=1}^{\varkappa} (I - \delta_j T(\chi_1))$$

with all operators on the right being invertible on $c_0(\mathbf{C})$. It follows that $T(\overline{f})$ is invertible on c_0 and hence that $T(f)$ is invertible on ℓ^1.

From (4.1) we deduce that $T(a_+) = T(f)T(\chi_\varkappa)$. Let $x^{(k)} = \{x_1^{(k)}, \ldots, x_{k-\varkappa}^{(k)}, 0, \ldots\}$ and define $w^{(k)} \in \mathcal{R}(P_k)$ by

$$w^{(k)} = \{\underbrace{0, \ldots, 0}_{\varkappa}, x_1^{(k)}, \ldots, x_{k-\varkappa}^{(k)}, 0, \ldots\}.$$

Let Q_k be given on ℓ^1 and c_0 by $Q_k = I - P_k$, that is,

$$Q_k : \{x_1, x_2, x_3, \ldots\} \mapsto \{0, \ldots, 0, x_{k+1}, x_{k+2}, \ldots\}.$$

We have $P_{k-\varkappa} x^{(k)} = T(\chi_{-\varkappa}) P_k w^{(k)}$, and since $T(\chi_{-\varkappa}) T(\chi_\varkappa) = Q_k$ and $Q_\varkappa P_k = P_k Q_\varkappa$, we get

$$\begin{aligned} &\|P_k b - P_k T(a_+) P_{k-\varkappa} x^{(k)}\|_1 = \|P_k b - P_k T(f) T(\chi_\varkappa) T(\chi_{-\varkappa}) P_k w^{(k)}\|_1 \\ &= \|P_k b - P_k T(f) P_k Q_\varkappa w^{(k)}\|_1 = \|P_k b - T_k(f) Q_\varkappa w^{(k)}\|_1. \end{aligned} \tag{7.2}$$

The minimum of (7.2) as $w^{(k)}$ ranges over $\mathbf{R}^k$ is d_k, and the minimum is attained at the $w_0^{(k)}$ corresponding to any $x_0^{(k)}$ that minimizes (7.1). Hence, by Theorems 3.1 and 3.2,

$$d_k = \sup_{z \in N(Q_\varkappa T_k(\overline{f})), \|z\|_\infty \leq 1} \langle z, P_k b \rangle. \tag{7.3}$$

Theorem 6.1 implies that there is a k_0 such that the matrices $T_k(f)$ are invertible for all $k \geq k_0$. Let $k \geq k_0$. We have $Q_\varkappa T_k(\overline{f}) z = 0$ if and only if there is a $y \in \mathbf{R}^\varkappa$ such that $T_k(\overline{f}) z = P_\varkappa y$ or, equivalently, $z = T_k^{-1}(\overline{f}) P_\varkappa y$. (Note that $T_k(\overline{f})$ is simply the transpose of $T_k(f)$). From (7.3) we therefore obtain

$$\begin{aligned} d_k &= \sup_{z = T_k^{-1}(\overline{f}) P_\varkappa y, \|z\|_\infty \leq 1} \langle z, P_k b \rangle \\ &= \sup_{\|T_k^{-1}(\overline{f}) P_\varkappa y\|_\infty \leq 1} \langle T_k^{-1}(\overline{f}) P_\varkappa y, P_k b \rangle \\ &= \sup_{\|T_k^{-1}(\overline{f}) P_\varkappa y\|_\infty \leq 1} \langle P_\varkappa y, P_\varkappa T_k^{-1}(f) P_k b \rangle. \end{aligned}$$

Put $\mathcal{M}_k = \{y \in \mathbf{R}^\varkappa : \|T_k^{-1}(\overline{f})P_\varkappa y\|_\infty \le 1\}$ and define $\varphi_k : \mathcal{M}_k \to \mathbf{R}$ by $\varphi_k(y) = \langle y, P_\varkappa T_k^{-1}(f)P_k b\rangle$. Then

$$d_k = \sup_{y\in\mathcal{M}_k} \varphi_k(y).$$

From Theorem 5.1 we know that

$$d = \sup_{z\in N(T(\overline{a}_+)),\|z\|_\infty\le 1} \langle z, b\rangle.$$

As $T(\overline{a}_+) = T(\chi_{-\varkappa})T(\overline{f})$, the equation $T(\overline{a}_+)z = 0$ is equivalent to the equation $T(\chi_{-\varkappa})T(\overline{f})f = 0$, that is, to the existence of a $y \in \mathbf{R}^\varkappa$ such that $z = T^{-1}(\overline{f})P_\varkappa y$. It follows that

$$\begin{aligned} d &= \sup_{z=T^{-1}(\overline{f})P_\varkappa y,\|z\|_\infty\le 1} \langle z, b\rangle \\ &= \sup_{\|T^{-1}(\overline{f})P_\varkappa y\|_\infty\le 1} \langle T^{-1}(\overline{f})P_\varkappa y, b\rangle \\ &= \sup_{\|T^{-1}(\overline{f})P_\varkappa y\|_\infty\le 1} \langle P_\varkappa y, P_\varkappa T^{-1}(f)b\rangle = \sup_{y\in\mathcal{M}} \varphi(y), \end{aligned}$$

where $\mathcal{M} = \{y \in \mathbf{R}^\varkappa : \|T^{-1}(\overline{f})P_\varkappa y\|_\infty \le 1\}$ and $\varphi : \mathcal{M} \to \mathbf{R}$ is given by $\varphi(y) = \langle y, P_\varkappa T^{-1}(f)b\rangle$. By Theorem 6.2,

$$\varphi_k(y) = \sum_{j=1}^{\varkappa} \gamma_j(k)y_j, \quad \varphi(y) = \sum_{j=1}^{\varkappa} \gamma_j y_j,$$

where $\gamma_j(k)$ converges to γ_j exponentially fast as $k \to \infty$. We remark that if $y \in \mathcal{M}_k$, then

$$\begin{aligned} \|P_\varkappa y\|_\infty &\le \|P_k T(\overline{f})P_k\|_{\mathcal{B}(c_0)}\|T_k^{-1}(\overline{f})P_\varkappa y\|_\infty \\ &\le \|f\|_W\|T_k^{-1}(\overline{f})P_\varkappa y\|_\infty \le \|f\|_W. \end{aligned}$$

Analogously, $\|P_\varkappa y\|_\infty \le \|f\|_W$ for $y \in \mathcal{M}$.

Now take $y_0 = (y_1^{(0)}, \dots, y_\varkappa^{(0)}) \in \mathcal{M}$ so that $\varphi(y_0) = d$. Theorem 6.2 yields

$$\begin{aligned} \|T_k^{-1}(\overline{f})P_\varkappa y_0\|_\infty &\le \|T^{-1}(\overline{f})P_\varkappa y_0\|_\infty + \|T_k^{-1}(\overline{f})P_\varkappa y_0 - T^{-1}(\overline{f})P_\varkappa y_0\|_\infty \\ &\le 1 + C\,e^{-\alpha k}\|P_\varkappa y_0\|_\infty \le 1 + C\,e^{-\alpha k}\|f\|_W =: 1 + \sigma_k. \end{aligned}$$

Thus, $(1+\sigma_k)^{-1}y_0 \in \mathcal{M}_k$. This implies that

$$d_k \ge \varphi_k[(1+\sigma_k)^{-1}y_0] = (1+\sigma_k)^{-1}\sum_{j=1}^{\varkappa} \gamma_j(k)y_j^{(0)}.$$

Since $\{\gamma_j(k) - \gamma_j\}_{k=1}^\infty$ is exponentially decaying for each j, we have

$$\sum_{j=1}^{\varkappa} \gamma_j(k)y_j^{(0)} \ge \sum_{j=1}^{\varkappa} \gamma_j y_j^{(0)} - \tau_k = d - \tau_k$$

with some exponentially decaying sequence $\{\tau_k\}$. In summary, we have shown that $(1+\sigma_k)d_k \geq d - \tau_k$, which gives

$$d - d_k \leq \sigma_k d_k + \tau_k \leq \sigma_k \|b\|_1 + \tau_k. \tag{7.4}$$

Again taking into account that $\{\gamma_j(k) - \gamma_j\}_{k=1}^{\infty}$ is exponentially decaying for each j and using that $\|P_\varkappa y\|_\infty \leq \|f\|_W$ for all $y \in \mathcal{M}_k$, we obtain

$$d_k = \sup_{y\in\mathcal{M}_k} \sum_{j=1}^{\varkappa} \gamma_j(k) y_j \leq \sup_{y\in\mathcal{M}_k} \sum_{j=1}^{\varkappa} \gamma_j y_j + \varrho_k$$

with an exponentially decaying sequence $\{\varrho_k\}$. For $y \in \mathcal{M}_k$, Theorem 6.2 gives

$$\begin{aligned}\|T^{-1}(\overline{f})P_\varkappa y\|_\infty &\leq \|T_k^{-1}(\overline{f})P_\varkappa y\|_\infty + \|T^{-1}(\overline{f})P_\varkappa y - T_k^{-1}(\overline{f})P_\varkappa y\|_\infty \\ &\leq 1 + C\,e^{-\alpha k}\|P_\varkappa y\|_\infty \leq 1 + C\,e^{-\alpha k}\|f\|_W =: 1 + \sigma_k,\end{aligned}$$

and therefore $(1+\sigma_k)^{-1}y \in \mathcal{M}$. It follows that

$$\begin{aligned}d_k &\leq \sup_{(1+\sigma_k)^{-1}y\in\mathcal{M}} \sum_{j=1}^{\varkappa} \gamma_j y_j + \varrho_k = \sup_{v\in\mathcal{M}} \sum_{j=1}^{\varkappa} \gamma_j \cdot (1+\sigma_k) v_j + \varrho_k \\ &= (1+\sigma_k) \sup_{v\in\mathcal{M}} \varphi(v) + \varrho_k \leq (1+\sigma_k)d + \varrho_k,\end{aligned}$$

whence

$$d_k - d \leq \sigma_k d + \varrho_k. \tag{7.5}$$

Combining (7.4) and (7.5) we arrive at the assertion. □

COROLLARY 7.2. *For each $k \geq 1$, let $x_0^{(k)} \in \mathcal{R}(P_{k-\varkappa})$ be an element at which (7.1) attains its minimum d_k. If $k_i \to \infty$ and $\{x_0^{(k_i)}\}_{i=1}^{\infty}$ is any sequence that converges in ℓ^1 to some $x_0 \in \ell^1$, then $\|b - T(a_+)x_0\|_1 = d$.*

Proof. If $\|P_{k_i}b - P_{k_i}T(a_+)P_{k_i-\varkappa}x_0^{(k_i)}\|_1 = d_{k_i}$ and $x_0^{(k_i)} \to x$ as $i \to \infty$, then $\|b - T(a_+)x_0\|_1 = d$ because $d_{k_i} \to d$ by Theorem 7.1. □

8. Error estimate. In practice, we have an $x_0^{(k)}$ with

$$\|P_k b - P_k T(a_+) P_{k-\varkappa} x_0^{(k)}\|_1 = d_k,$$

and $\widetilde{m}_0 = T(a_+)P_{k-\varkappa}x_0^{(k)}$ is taken as an approximate solution. The question is, how far is $\|b - \widetilde{m}_0\|_1$ away from the optimal value d? We have

$$\begin{aligned}\|b - \widetilde{m}_0\|_1 \leq{}& \|b - P_k b\|_1 + \|P_k b - P_k T(a_+) P_{k-\varkappa} x_0^{(k)}\|_1 \\ &+ \|P_k T(a_+) P_{k-\varkappa} x_0^{(k)} - T(a_+) P_{k-\varkappa} x_0^{(k)}\|_1.\end{aligned} \tag{8.1}$$

Clearly, $\|b - P_k b\|_1 = \|Q_k b\|_1 = o(1)$ is given a priori. The second term on the right of (8.1) is just d_k. Let $x_i^{(k)}$ $(i = 1, \ldots, k-\varkappa)$ denote the components of $x_0^{(k)}$. The

vector in the third term on the right of (8.1) is

$$-Q_k T(a_+) P_{k-\varkappa} x_0^{(k)} = - \begin{pmatrix} a_k & \dots & a_{\varkappa+1} \\ a_{k+1} & \dots & a_{\varkappa+2} \\ \vdots & & \vdots \end{pmatrix} \begin{pmatrix} x_1^{(k)} \\ \vdots \\ x_{k-\varkappa}^{(k)} \end{pmatrix}$$

$$= - \begin{pmatrix} 0 & \dots & 0 & a_n & a_{n-1} & \dots & a_{\varkappa+1} \\ 0 & \dots & 0 & 0 & a_n & \dots & a_{\varkappa+2} \\ \vdots & & \vdots & \vdots & \vdots & & \vdots \\ 0 & \dots & 0 & 0 & 0 & \dots & a_n \end{pmatrix} \begin{pmatrix} x_1^{(k)} \\ \vdots \\ x_{k-\varkappa}^{(k)} \end{pmatrix},$$

which implies that

$$\|Q_k T(a_+) P_{k-\varkappa} x_0^{(k)}\|_1 \le (|a_{\varkappa+1}| + \dots + |a_n|) \left(|x_{k-n+1}^{(k)}| + \dots + |x_{k-\varkappa}^{(k)}| \right)$$
$$\le \|a_+\|_W \, \|Q_{k-n} x_0^{(k)}\|_1.$$

The vector $x_0^{(k)}$ is available and $\|Q_{k-n} x_0^{(k)}\|_1$ is the ℓ^1 norm of the last $n-\varkappa$ components of $x_0^{(k)}$. If k is large, then the last $n-\varkappa$ components of $x_0^{(k)}$ are expected to be small. In summary, (8.1) and Theorem 7.1 yield

$$\|b - \widetilde{m}_0\|_1 \le \|Q_k b\|_1 + \|a_+\|_W \, \|Q_{k-n} x_0^{(k)}\|_1 + d + \text{ exponentially small term.}$$

If $\varkappa = n$, then $-Q_k T(a_+) P_{k-\varkappa} x_0^{(k)} = 0$, and hence we even have

$$\|b - \widetilde{m}_0\|_1 \le \|Q_k b\|_1 + d + \text{ exponentially small term.}$$

Finally, if $\varkappa = n$ and b is finitely supported, then

$$\|b - \widetilde{m}_0\|_1 \le d + \text{ exponentially small term.}$$

9. Numerical example. The following example illustrates the algorithm described above. We consider the banded lower triangular Toeplitz matrix $T(a_+)$ with the symbol

$$a_+(t) = -0.1224 - 0.2906t + 0.7122t^2 + 2.7983t^3 + 2.9168t^4 + t^5$$

and we are looking for a sequence $x \in \ell^1$ minimizing $\|b - T(a_+)x\|_1$ for the right-hand side

$$b = \{1.8645, -0.3398, -1.1398, -0.2111, 1.1902, -1.1162, 0, 0, \dots\}.$$

The five zeros of the polynomial $a_+(t)$ are all inside the open unit disk. Thus, we can proceed as in section 7 with $\varkappa = 5$. (Notice that the algorithm of section 7 would be applicable to $\varkappa < 5$ as well.) Accordingly, we approximate $T(a_+)$ by the finite matrices $A_k = P_{5+k} T(a_+) P_k$ $(k = 1, 2, \dots)$. For example,

$$A_3 = \begin{pmatrix} -0.1224 & 0 & 0 \\ -0.2906 & -0.1224 & 0 \\ 0.7122 & -0.2906 & -0.1224 \\ 2.7983 & 0.7122 & -0.2906 \\ 2.9168 & 2.7983 & 0.7122 \\ 1 & 2.9168 & 2.7983 \\ 0 & 1 & 2.9168 \\ 0 & 0 & 1 \end{pmatrix}.$$

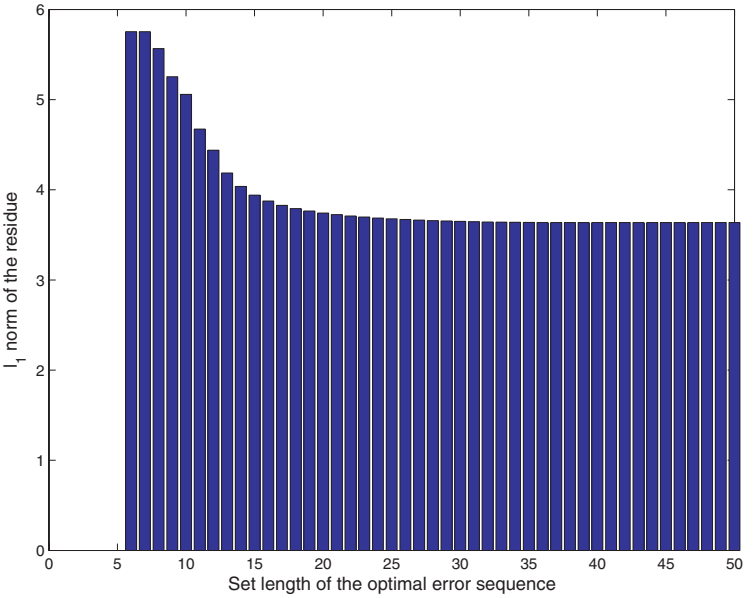

FIG. 9.1. *Evolvement of the ℓ^1-norm of the residue with increasing set length of the optimal error sequence.*

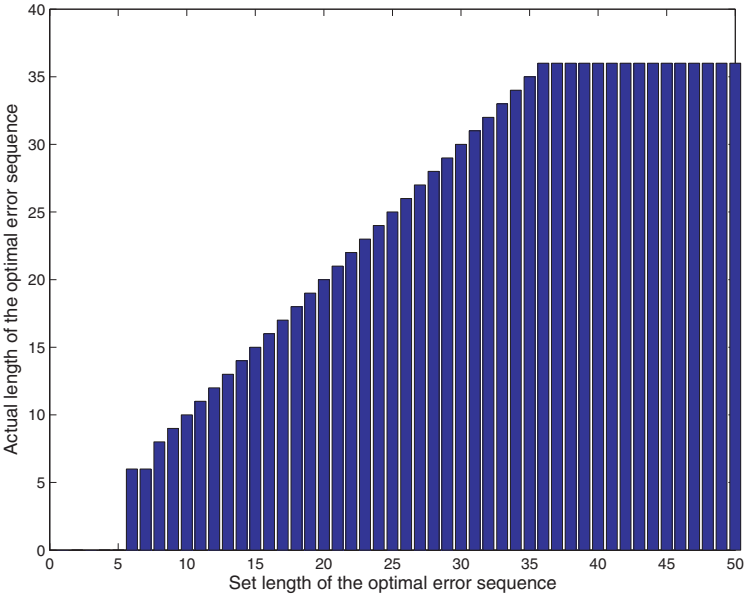

FIG. 9.2. *Evolvement of the actual length of the optimal error sequence with increasing set length of the optimal error sequence.*

Solving the corresponding overdetermined linear system for a solution minimizing the ℓ_1-norm of the residue (using a general LP solver) and repeating this for increasing index k, we obtain Figures 9.1 and 9.2. In Figure 9.1 we nicely see the exponentially fast stabilization of the objective function (that is, the number d_k or, equivalently, the ℓ^1-norm of the residuum) predicted by Theorem 7.1. Figure 9.2 reveals that for

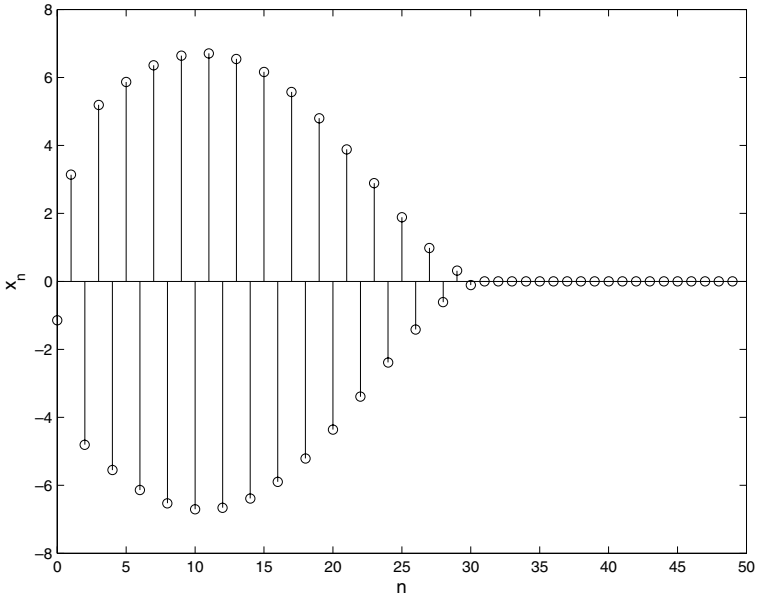

FIG. 9.3. *A sequence $x \in \ell_1$ minimizing $\|b - T(a_+)x\|_1$.*

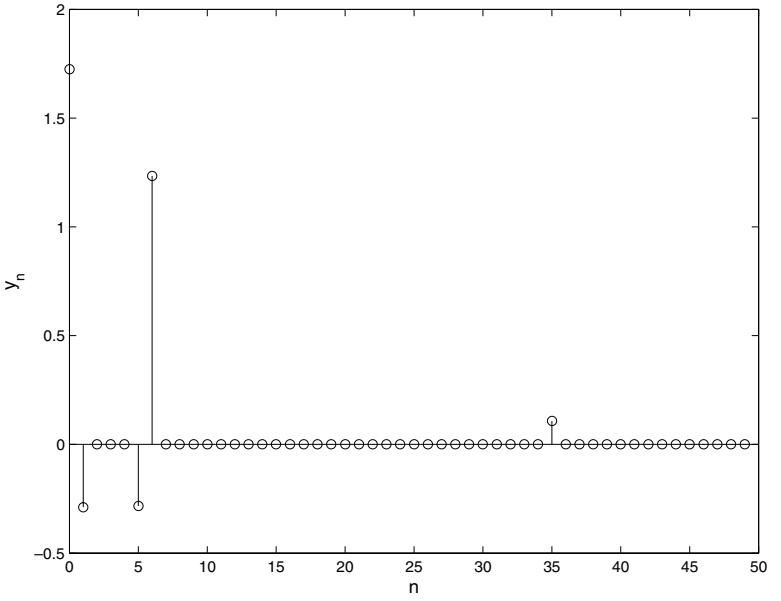

FIG. 9.4. *The optimal error sequence (residue) $y = b - T(a_+)x$.*

$k - \varkappa \geq 36$ the number of nonzero terms in $P_{k-\varkappa}x_0^{(k)}$ is no longer increasing. Thus, although we offer more and more space to the approximate optimal solution sequence $P_{k-\varkappa}x_0^{(k)}$, its actual length settles at 36.

Figures 9.3 and 9.4 show an optimal solution x and the residue sequence $y = b - T(a_+)x$. The very small number of nonzero terms in Figure 9.4 is a mystery we cannot yet explain.

10. Improvement of conditioning. Both our Toeplitz approach and the Vandermonde interpolation approach of [10] lead to linear systems of equations. These can be tackled by invoking an LP solver. Numerical experiments show that the condition numbers of the matrices emerging in our algorithm are much smaller than those of the matrices that result from interpolation. To give a concrete example, consider the task of finding the distance between a given $b \in \ell^1$ and the range of the Toeplitz operator $T(a_+)$ with $a_+(t)$ having its 10 roots equally distributed in the interval $[0.5, 0.9]$, that is, $a_+(t) = 0.0238 - 0.3520t + 2.3334t^2 - 9.1302t^3 + 23.3525t^4 - 40.7975t^5 + 49.3052t^6 - 40.7037t^7 + 21.9685t^8 - 7t^9 + t^{10}$. Let us set the length of the approximate optimal error sequence to 13. The 2-norm condition number, that is, the ratio of the largest and the smallest singular value, of the 10×13 Vandermonde matrix V_{13} built from the roots of $a_+(t)$ equals $\kappa(V_{13}) = 9.5458 \cdot 10^9$. In contrast to this, the 2-norm condition number of the matrix $A_{13} = P_{13}T(a_+)P_3$ is $\kappa(A_{13}) = 14.948$. To make a general conclusion, Vandermonde systems are known to be extremely ill-conditioned unless the roots are distributed along the unit circle. Analytical expressions for the conditioning of some common distributions are in [13, p. 418]. Similar analytical results for Toeplitz systems are not known to the authors.

11. Application to ℓ^1-optimal control. In compliance with control engineering, we now use the variable λ instead of t. (The variables λ, d, and z^{-1} are more common in control theory literature than t. The variable t is dominating in Toeplitz operators theory but it could be confused with time.) It is well known [19] that the achievable internally stable closed-loop maps $y(\lambda)$ of a standard feedback connection are parametrized by $y(\lambda) = b(\lambda) - a(\lambda)x(\lambda)$, where $a(\lambda)$, $b(\lambda)$, $x(\lambda)$, $y(\lambda)$ are power series with coefficient sequences in ℓ^1, $a(\lambda)$ and $b(\lambda)$ are given, and $x(\lambda)$, which is also called the Youla–Kučera parameter, is unknown. For finite-dimensional systems, $a(\lambda)$ is actually a polynomial. A principal task of ℓ^1-control is to design a stabilizing controller that minimizes the ℓ^1-norm of the coefficient sequence of $y(\lambda)$. This controller will guarantee optimal attenuation of peaks in the error signal $y(\lambda)$ because the Wiener norm of $y(\lambda)$ ($= \ell^1$-norm of its coefficient sequence) is equal to the ℓ^∞-induced operator norm of the closed-loop system [24].

Any stabilizing controller is determined by its Youla–Kučera parameter $x(\lambda)$. As the coefficient sequence of $a(\lambda)x(\lambda)$ results from that of $x(\lambda)$ by the action of an infinite lower-triangular Toeplitz band matrix, the problem of designing an optimal controller leads to the minimum distance problem between a given sequence $b \in \ell^1$ and the range $\mathcal{R}(T(a))$ of the infinite lower-triangular Toeplitz matrix $T(a)$ in ℓ^1. A concrete design procedure will be exemplified in the next section.

A noteworthy feature of the approach proposed here is that the Youla–Kučera parameter is explicitly computed and that, consequently, there is no need to extract a controller from the optimal closed-loop transfer function.

12. A concrete ℓ^1-optimal control design. We consider the standard feedback configuration of Figure 12.1 with a discrete-time plant $G(\lambda)$. Our aim is to construct a stabilizing discrete-time controller $C(\lambda)$ that minimizes the Wiener norm of the sensitivity function of the closed-loop system, that is, of the transfer function $1/(1 + C(\lambda)G(\lambda))$ between the disturbance and the error or, equivalently, the ℓ^1 norm of the impulse response.

We suppose that the plant is given as the quotient of two polynomials $p(\lambda)$ and $q(\lambda)$ without common zeros and with no zeros on the unit circle, $G(\lambda) = p(\lambda)/q(\lambda)$.

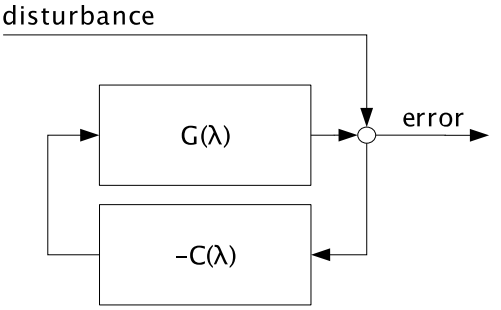

FIG. 12.1. *Standard feedback control configuration.*

The Youla–Kučera parametrization of all stabilizing controllers is

$$C(\lambda) = \frac{v(\lambda) + q(\lambda)x(\lambda)}{w(\lambda) - p(\lambda)x(\lambda)}, \tag{12.1}$$

where $v(\lambda), w(\lambda)$ are polynomials determined by $G(\lambda)$ and $x(\lambda)$ is a function we can freely choose in the Wiener algebra. The entire procedure can be done in four steps.

Step 1. Find stable-unstable factorizations $p(\lambda) = p_s(\lambda)p_u(\lambda)$ and $q(\lambda) = q_s(\lambda)q_u(\lambda)$. Here the indices s and u label polynomials with all zeros inside and outside the unit circle, respectively. Efficient algorithms for stable-unstable factorization are known (see, e.g., [3] and the references cited therein). In particular, reliable FFT-based algorithms are available from [2], [14].

Step 2. Find polynomials $x_0(\lambda)$ and $y_0(\lambda)$ satisfying the Diophantine equation $q(\lambda)x_0(\lambda) + p(\lambda)y_0(\lambda) = 1$. This problem can be conveniently solved using the polynomial toolbox [20].

Step 3. The polynomials $v(\lambda), w(\lambda)$ in (12.1) are

$$v(\lambda) = q_u(\lambda)p_u(\lambda)y_0(\lambda), \quad w(\lambda) = q_u(\lambda)p_u(\lambda)x_0(\lambda).$$

Step 4. Inserting the result of Step 3 in (12.1) we obtain

$$\frac{1}{1+CG} = \frac{1}{1 + \dfrac{q_u p_u y_0 + qx}{q_u p_u y x_0 - px}\,\dfrac{p}{q}} = \frac{qq_u p_u x_0 - qpx}{q_u p_u (qx_0 + py_0)},$$

which equals $qx_0 - q_s p_s x$ by virtue of Step 2. Thus, the final task is to minimize $\|y(\lambda)\|_W = \|q(\lambda)x_0(\lambda) - q_s(\lambda)p_s(\lambda)x(\lambda)\|_W$ or, in terms of the coefficient sequences, to minimize $\|y\|_1 = \|b - T(a_+)x\|_1$, where $b \in \ell^1$ is the coefficient sequence of $q(\lambda)x_0(\lambda)$ and $a_+(\lambda) = q_s(\lambda)p_s(\lambda)$. This problem can be solved using the algorithm of section 7. The desired optimal controller is given by (12.1) with $v(\lambda), w(\lambda)$ from Step 3 and $x(\lambda)$ from Step 4.

To have a numerical example, let

$$G(\lambda) = \frac{p(\lambda)}{q(\lambda)} = \frac{-45\lambda - 132\lambda^2 + 9\lambda^3}{-20 - 48\lambda + 5\lambda^2}.$$

The above procedure yields the Youla–Kučera parameter $x(\lambda) = 0.1321 - 0.0052\lambda$, the sensitivity function $y(\lambda) = 1.0000 - 12.5000\lambda - 37.5000\lambda^2$, and the optimal controller

$$C(\lambda) = \frac{-41.6667 + 4.1667\lambda}{-7.5000 + 113.0000\lambda - 7.5000\lambda^2}.$$

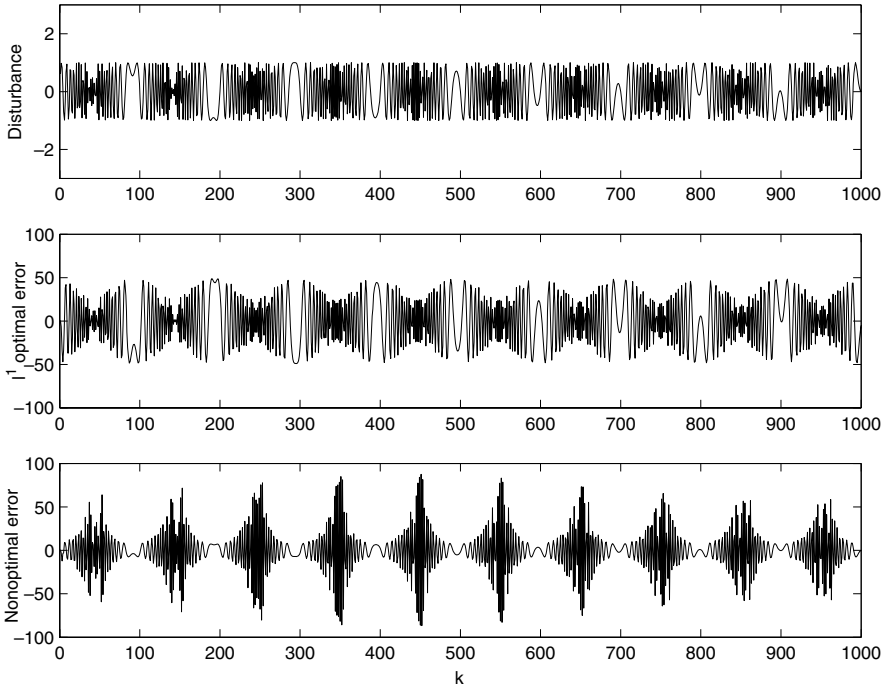

FIG. 12.2. *Simulation of a disturbance rejection with ℓ^1-optimal and nonoptimal controllers.*

A simulation result is shown in Figure 12.2. The horizontal axis represents the discrete time k. The disturbance is only known to be bounded in magnitude. The response of the closed-loop system to a disturbance bounded in magnitude by 1 is compared for the ℓ^1-optimal controller computed above and some random stabilizing controller. Note that with more sophisticated (optimal) controllers like LQG, $\mathcal{H}_2$-, and $\mathcal{H}_\infty$-optimal controllers the difference will not necessarily be this striking, as the system norms in finite-dimensional spaces are equivalent and, loosely speaking, minimizing some norm causes all the other norms to be small as well.

13. Conclusions. This paper contains an analysis of the problem of finding the minimum distance to the range of a banded lower-triangular Toeplitz operator in ℓ^1. Necessary and sufficient conditions for the existence of a minimizing sequence in ℓ^1 are established. It is shown that the optimal error sequences is finitely nonzero. The application of this result in ℓ^1-optimal control is outlined. The paper presents an alternative formulation and a new approach to the well known problem, putting it into operator-theoretic framework and leading to more reliable numerical algorithms.

It is demonstrated by an example that in some situations the interpolation approach may lead to highly ill-conditioned linear systems while the method proposed does not suffer from this unpleasant circumstance. Another striking feature of the present approach is that the (stable) optimal Youla–Kučera parameter is returned as a direct outcome of the linear optimization, so that there is no need for any numerically tricky extraction of an optimal controller from the closed-loop transfer function. Within the interpolation framework, a solution to the truncated problem does not necessarily yield an achievable stable closed-loop transfer function. Hence the controller obtained from it need not stabilize the plant. These complications are more

pronounced in the general MIMO case when only suboptimal solutions can be obtained.

The authors admit that the paper might seem unnecessarily tough to read, but the motivation for this high level of abstraction and rigorousness was to attract researchers from outside the field control theory, especially from operator theory. For instance, at this moment it is not known how to get an estimate of the length of the optimal error sequence (however, it is known that this length is data dependent [22]). Also, it is not known how to build a finite-dimensional approximation to the dual problem such that its optimal solutions are feasible for the original dual problem. This is a vital issue for the development of general primal-dual solvers. The extension of the analysis presented here to operators on vector-valued infinite sequences is very attractive in connection with practical applications, because it would enable control of systems with more than one control/disturbing input and more than one measured and/or regulated input. Some progress recently has been made by the authors, and preliminary results on the straightforward extension to rectangular block Toeplitz operators including analysis of existence, uniqueness, and convergence were presented in [16]. The present paper can be regarded as a building block for this extension.

ALGEBRAIC RICCATI EQUATION AND J-SPECTRAL FACTORIZATION FOR $\mathcal{H}_\infty$ SMOOTHING AND DECONVOLUTION*

PATRIZIO COLANERI† AND AUGUSTO FERRANTE‡

Abstract. This paper deals with a general steady-state estimation problem in the $\mathcal{H}_\infty$ setting. The existence of the stabilizing solution of the related algebraic Riccati equation (ARE) and of the solution of the associated J-spectral factorization problem is investigated. The existence of such solutions is well established if the prescribed attenuation level γ is larger than γ_f (the infimum of the values of γ for which a *causal* estimator with attenuation level γ exists). We consider the case when $\gamma \leq \gamma_f$ and show that the stabilizing solution of the ARE still exists (except for a finite number of values of γ) as long as a fixed-lag acausal estimator (smoother) does. The stabilizing solution of the ARE may be employed to derive a state-space realization of a minimum-phase J-spectral factor of the J-spectrum associated with the estimation problem. This J-spectral factor may be used, in turn, to compute the minimum-lag smoothing estimator. Some of the aspects of the J-spectral factorization problem and the properties of its solutions are discussed in correspondence to the (finite number of) values of γ for which the stabilizing solution of the ARE does not exist.

1. Introduction and problem statement.

Consider the discrete-time linear system

$$x_{k+1} = Ax_k + Bw_k, \tag{1.1a}$$

$$y_k = Cx_k + Dw_k, \tag{1.1b}$$

$$z_k = Lx_k + Mw_k, \tag{1.1c}$$

where $x_k \in \mathbb{R}^n$ and $y_k \in \mathbb{R}^p$ are the state and the measurement output vector, respectively, and $w_k \in \mathbb{R}^m$ is the vector of inputs and disturbances. The to-be-estimated signal $z_k \in \mathbb{R}^l$ is an unaccessible linear combination of the state and the input. This is very general and includes, as particular cases, the *state-filtering* problem ($L = I$ and $M = 0$) and the *deconvolution* problem ($L = 0$ and $M = I$). See section 1.3 for a brief discussion and references on these problems.

Let $F(z)$ be the transfer function of a causal filter driven by the observations y_k whose output $\hat{z}_k$ is an estimate of z_k, and let $e_k := z_k - \hat{z}_k$. The infinite-horizon $\mathcal{H}_\infty$ *filtering problem* consists in designing an estimator $F(z)$ guaranteeing a prescribed level of attenuation γ between the ℓ_2-norm of w_k and the ℓ_2-norm of the estimation error e_k. Introducing the transfer functions

$$H_1(z) := C(zI - A)^{-1}B + D, \tag{1.2a}$$

$$H_2(z) := L(zI - A)^{-1}B + M, \tag{1.2b}$$

this problem is equivalent to that of finding a stable causal transfer function $F(z)$ such that

$$F(z)H_1(z) - H_2(z) \in \mathcal{RH}_\infty, \qquad \|F(z)H_1(z) - H_2(z)\|_\infty < \gamma, \tag{1.3}$$

where $\mathcal{RH}_\infty$ denotes the space of real rational matrix functions whose poles lie all in $\{z \in \mathbb{C} : \ |z| < 1\}$. $\mathcal{RH}_\infty$ is endowed with the infinity norm associating with any $G(z) \in \mathcal{RH}_\infty$, $\|G(z)\|_\infty = \sup_{|z|=1} \|G(z)\|$ with $\|G(z)\|$ being the largest singular value of $G(z)$ for each given z.

The $\mathcal{H}_\infty$ *fixed-lag smoothing problem with preview horizon of length* N (or N-*lag smoothing problem*) may be defined as the problem of estimating (in the $\mathcal{H}_\infty$ framework) the signal z_k given the observations up to time $k + N$, $N \geq 0$. In other words, the only difference with the filtering problem is that the transfer function of the estimator is not required to be causal but has to be of the form $E(z) = z^N F(z)$ with $F(z)$ being stable and causal. This may be easily reformulated as the problem of finding a stable causal transfer function $F(z)$ such that

$$F(z)H_1(z) - H_{2,N}(z) \in \mathcal{RH}_\infty, \qquad \|F(z)H_1(z) - H_{2,N}(z)\|_\infty < \gamma \tag{1.4}$$

with

$$H_{2,N}(z) := z^{-N} H_2(z). \tag{1.5}$$

For a general overview on $\mathcal{H}_\infty$ estimation see to [19, 21] and references therein. For the continuous time version of the $\mathcal{H}_\infty$ smoothing problem see [18].

Assumptions. Let[1]

$$B_1 := B(I - D^\top (DD^\top)^{-1} D), \qquad F := A - BD^\top (DD^\top)^{-1} C. \tag{1.6}$$

We make the following standard assumptions:

$$DD^\top > 0, \tag{1.7a}$$

$$(A, C) \text{ is detectable}, \tag{1.7b}$$

$$(F, B_1) \text{ is reachable}, \tag{1.7c}$$

$$F \text{ is invertible}. \tag{1.7d}$$

Moreover, if $MD^\top \neq 0$, we define the auxiliary signal $\xi_k := z_k - MD^\top (DD^\top)^{-1} y_k = \widetilde{L} x_k + \widetilde{M} w_k$ with $\widetilde{L} := L - MD^\top (DD^\top)^{-1} C$ and $\widetilde{M} := M - MD^\top (DD^\top)^{-1} D$ and observe that, since ξ is obtained from z by subtracting a linear combination of the observed signal y, the estimations of z and ξ are equivalent problems (i.e., the estimation error is the same). In addition, a simple computation shows that $\widetilde{M} D^\top = 0$. Hence, without loss of generality, we assume

$$MD^\top = 0 \tag{1.7e}$$

so that the following identity holds:

$$BM^\top = B_1 M^\top. \tag{1.8}$$

Eventually, notice that neither A nor F is assumed to be stable.

[1] We denote by $M^\top$ the transpose of a matrix M.

From the point of view of the motivating $\mathcal{H}_\infty$ estimation problem, we mention that assumptions (1.7a) and (1.7d) do not impair loss of generality. In fact if (1.7a) is not satisfied we may resort to a Silverman transfomation (see [6]) that, employing a spectral interactor matrix, yields an equivalent problem in which $DD^\top > 0$. If (1.7d) is not satisfied, we may perform a preliminary feedback transformation, as described in [5], and obtain an equivalent problem, in which (1.7d) is satisfied.

1.1. *J*-spectral factorization. For a real transfer matrix function $G(z)$, we define $G\tilde{}(z) := G^\top(z^{-1})$. Let

$$H(z) := \begin{bmatrix} H_1(z) & 0 \\ H_2(z) & I_l \end{bmatrix} = \begin{bmatrix} C \\ L \end{bmatrix} (zI - A)^{-1}[B \mid 0\,] + \begin{bmatrix} D & 0 \\ M & I_l \end{bmatrix} \tag{1.9}$$

and $J_{i,j}(\gamma) := \operatorname{diag}\{I_i, -\gamma^2 I_j\}$. (We shall simply write J and I, instead of $J_{i,j}(\gamma)$ and I_i, when there is no risk of confusion.) The transfer function

$$\Psi(z) := H(z)J_{m,l}(\gamma)H\tilde{}(z) = \begin{bmatrix} \Psi_{11}(z) & \Psi_{12}(z) \\ \Psi_{12}\tilde{}(z) & \Psi_{22}(z) \end{bmatrix} \tag{1.10}$$

with

$$\Psi_{11}(z) := H_1(z)H_1\tilde{}(z), \quad \Psi_{12}(z) := H_1(z)H_2\tilde{}(z), \quad \Psi_{22}(z) := H_2(z)H_2\tilde{}(z) - \gamma^2 I \tag{1.11}$$

is called the *J-spectrum* of the system. A *square J-spectral factor* of $\Psi(z)$ is a square matrix function $\Omega(z)$ such that

$$\Omega(z)J_{p,l}(\gamma)\Omega\tilde{}(z) = \Psi(z). \tag{1.12}$$

A square J-spectral factor is said to be *minimum phase* if all its zeros lay in the open unit disk.[2] See [10] and references therein for further details on J-spectral factorization.

The estimation problem is strictly related to the existence of a J-spectral factor. Precisely, the existence of an estimator with prescribed attenuation level γ is equivalent to the existence of a minimum phase J-spectral factor of $\Psi(z)$ having a realization with the same state matrix A and the same output matrix $[C^\top \mid L^\top]^\top$ of the realization (1.9) of $H(z)$; see [3]. Once obtained such a spectral factor, a simple constructive procedure (described in [3]) furnishes a class of estimators $F(z)$ satisfying (1.3).

1.2. Algebraic Riccati equation. Let

$$H_0 := \begin{bmatrix} C \\ L \end{bmatrix}, \quad J_0 := \begin{bmatrix} D \\ M \end{bmatrix}, \quad J_1 := J_0 J_0^\top - \begin{bmatrix} 0 & 0 \\ 0 & \gamma^2 I \end{bmatrix} = \begin{bmatrix} DD^\top & DM^\top \\ MD^\top & MM^\top - \gamma^2 I \end{bmatrix} \tag{1.13}$$

and consider the algebraic Riccati equation (ARE)

$$\Delta = A\Delta A^\top + BB^\top - (A\Delta H_0^\top + BJ_0^\top)(J_1 + H_0\Delta H_0^\top)^{-1}(H_0\Delta A^\top + J_0 B^\top). \tag{1.14}$$

[2] Notice that in some papers and books the definition of minimum phase requires the stability of the spectral factor. Here, since neither A nor F is assumed to be "stable," we are not interested in stable J-spectral factors and we adopt the definition of phase minimality given above.

It is well known (see, e.g., [21]) that the existence of a proper stable filter $F(z)$ satisfying (1.3) is equivalent to the existence of a *symmetric*, *positive definite*, *stabilizing*, *feasible* solution of (1.14), i.e., a solution $\Delta_f = \Delta_f^\top > 0$ such that

$$A_f := A - (A\Delta_f H_0^\top + BJ_0^\top)(J_1 + H_0\Delta_f H_0^\top)^{-1}H_0 \tag{1.15}$$

is stable and $J_1 + H_0\Delta_f H_0^\top$ has the same inertia of $J_{p,l}(\gamma)$. In passing, notice that as long as $(DD^\top + C\Delta_f C^\top) > 0$, the latter condition (feasibility) may be written in the form

$$\gamma^2 I - MM^\top - L\Delta_f L^\top + L\Delta_f C^\top (DD^\top + C\Delta_f C^\top)^{-1} C\Delta_f L^\top > 0. \tag{1.16}$$

If we now define

$$\gamma_f := \inf\{\gamma : \text{ there exists a proper stable filter } F(z) \text{ satisfying (1.3)}\}, \tag{1.17}$$

it is clear that (1.14) admits a feasible symmetric positive semidefinite stabilizing solution if and only if $\gamma > \gamma_f$.

If this is the case, there exists a square J-spectral factor of $\Psi(z)$ having all zeros in the open unit disk and satisfying the stability conditions described in [3, Theorem 3.1], ensuring the existence of a proper stable filter $F(z)$.

On the other hand, it is also well known that there exists a value γ_0 such that for $\gamma < \gamma_0$, the ARE (1.14) does not admit any symmetric solution satisfying the feasibility condition and hence $\Psi(z)$ does not admit any minimal square J-spectral factor, namely, a J-spectral factor having the last possible McMillan degree. The constant γ_0 has the following interpretation from the J-spectral factorization point of view. A necessary condition for the existence of a square spectral factor is that $\Psi(e^{j\omega})$ has p positive eigenvalues and l negative eigenvalues for all $\omega \in (-\pi, \pi]$. Since under the present assumptions $\Psi_{11}(e^{j\omega}) > 0$ for all $\omega \in (-\pi, \pi]$, this condition is equivalent to the negative definiteness of the Schur complement

$$S(z) := \Psi_{22}(z) - \Psi_{12}\tilde{}(z)[\Psi_{11}(z)]^{-1}\Psi_{12}(z) \tag{1.18}$$

on the unit circle, i.e., to

$$S(e^{j\omega}) < 0, \qquad \omega \in (-\pi, \pi]. \tag{1.19}$$

By employing (1.11), we may write $S(z)$ as $S(z) = W(z) - \gamma^2 I$ with

$$\begin{aligned} W(z) &:= H_2(z)H_2\tilde{}(z) - H_2(z)H_1\tilde{}(z)[H_1(z)H_1\tilde{}(z)]^{-1}H_1(z)H_2\tilde{}(z) \\ &= H_2(z)[I - H_1\tilde{}(z)[H_1(z)H_1\tilde{}(z)]^{-1}H_1(z)]H_2\tilde{}(z). \end{aligned} \tag{1.20}$$

It is now easy to see that (1.19) is satified for γ sufficiently large: γ_0 is the infimum of the values of γ for which (1.19) is satisfied, i.e., γ_0^2 is the $\mathcal{L}_\infty$ norm of $W(z)$:

$$\gamma_0^2 = \|W(z)\|_\infty. \tag{1.21}$$

For a general overview on the connections between ARE and spectral and J-spectral factorization see [11, 12, 17, 1, 15] and references therein.

Remark 1.1. From the estimation problem point of view, the constant γ_0 is the infimum of the values of γ for which there exists a fixed-lag smoother (for some preview horizon N) achieving the attenuation level γ. To see this, first recall that under

the detectability assumption of the pair (A, C), without any loss of generality, one can assume from the very beginning the stability of $H_1(z)$ and $H_2(z)$ and transform the given problem in a unilateral model matching problem in a new stable free filter parameter [21]. Now, let $V_1(z)$ be a square spectral factor of $H_1(z)$. A simple computation shows that

$$\|F(z)H_1(z) - H_2(z)\|_\infty^2 = \|F(z)V_1(z) - H_2(z)H_1^\sim(z)V_1^\sim(z)^{-1}\|_\infty^2 + \|W(z)\|_\infty. \tag{1.22}$$

Hence, the attenuation level cannot be lower than γ_0 and this infimum value is achieved by the acausal estimator

$$F_\infty(z) = H_2(z)H_1^\sim(z)\left(H_1(z)H_1^\sim(z)\right)^{-1} = \sum_{i=-\infty}^{\infty} F_i z^i. \tag{1.23}$$

Now the question arises of how to construct a stable fixed-lag smoother when an attenuation level $\gamma > \gamma_0$ is prescribed. This problem can be solved directly from expression (1.22) by taking a finite length expansion of the anticausal part of $F_\infty(z)$ given by (1.23). Indeed, let

$$F_N(z) = F_\infty(z) - \sum_{i=N+1}^{\infty} F_i z^i.$$

If $F_N(z)$ is the (N steps acausal, yet stable) estimator so constructed, then

$$\begin{aligned}\|F_N(z)H_1(z) - H_2(z)\|_\infty^2 &\le \gamma_0^2 + \left\| \sum_{i=N+1}^{\infty} F_i z^i V_1(z) \right\|_\infty^2 \\ &\le \gamma_0^2 + \left(\sum_{i=N+1}^{\infty} \|F_i\| \right)^2 \|H_1(z)\|_\infty^2\end{aligned}$$

can be rendered arbitrarily close to γ_0^2 by selecting a sufficiently large N. The estimator can be realized from the relevant factor following the results in [3] or directly from the solution of a suitable Riccati equation as described in [20].

1.3. Contribution of the paper. In this paper, we investigate the existence of a feasible stabilizing solution of (1.14) and the existence and the construction of a minimum phase square J-spectral factor $\Omega(z)$ for values of γ in the interval $(\gamma_0, \gamma_f]$. Clearly, for such values of γ the filter cannot exist, but there exists a fixed-lag smoother associated with a certain preview horizon length N achieving the desired attenuation level. As shown in [5], the computation of the stabilizing solution Δ of (1.14) and of the corresponding J-spectral factor $\Omega(z)$ are crucial steps to obtain efficiently the minimum-lag smoothing filter achieving the desired attenuation level. Notably, the solution Δ can be directly used to initialize an iterative algorithm to work out a minimum-lag central smoother; see [13, 2].

The contribution of the present paper is to prove that for $\gamma \in (\gamma_0, \gamma_f]$, equation (1.14) still admits a stabilizing feasible solution except for a finite number (at most $2[n + \mathrm{rank}(M)]$) of values of γ. This result generalizes a result in [4] where it was assumed that $DD^\top = I$, $M = 0$, and $DB^\top = 0$. While removing the assumption $DD^\top = I$ impairs only slightly longer formulas, the presence of the matrix M gives rise to a much more difficult problem. Also, the presence of the matrix M implies that

having assumed (1.7e) we cannot assume $DB^\top = 0$ (only one of the two conditions (1.7e) and $DB^\top = 0$ can be assumed without loss of generality) and this adds some other technical difficulties to the problem. On the other hand the estimation problem becomes much more interesting and of practical importance if we consider the presence of the matrix M. Indeed, in this case, not only can we attack deconvolution problems for the importance of which we refer to [9] and references therein, but we can, more generally, address the problem of estimating an arbitrary linear combination of input and state vectors; see the discussion in [7] for the practical importance of the latter problem.

1.4. Paper organization. In section 2 we analyze some auxiliary spectral factorization problems and the corresponding AREs. In section 3 we show that for generic values of γ, the antistabilizing solution of an ARE considered in section 2 is nonsingular. Such preliminary results are employed in section 4, where we prove our main result on the existence of a stabilizing feasible solution of (1.14). In section 5 we explicitly derive a minimum phase J-spectral factor of $\Psi(z)$. In section 6 we analyze some of the issues arising in correspondence of the values of γ for which we cannot guarantee the existence of the stabilizing solution of (1.14) and we discuss some peculiar aspects of the J-spectral factorization.

2. Preliminary spectral factorizations and auxiliary AREs. In this section we compute a state-space realization of a spectral factor $T(z)$ of $W(z)$ defined in (1.20) and a spectral factorization of $-S(z) = \gamma^2 I - W(z)$. These factorizations are related to the stabilizing solutions of a pair of coupled AREs. These solutions will be used to compute the solution (and hence to prove constructively its existence) of a third ARE that is strictly related to (1.14). This procedure will be carried over through various steps.

2.1. Computation of a square spectral factor of $H_1(z)H_1^\sim(z)$. Consider the following standard filtering ARE:

$$P = APA^\top + BB^\top - (APC^\top + BD^\top)(DD^\top + CPC^\top)^{-1}(CPA^\top + DB^\top). \tag{2.1}$$

By assumptions (1.7b) and (1.7c), it admits a positive definite stabilizing solution $P_s = P_s^\top > 0$. Such a solution corresponds to spectral factorization of $H_1(z)H_1^\sim(z)$. In fact, by defining

$$D_1 := (DD^\top + CP_sC^\top)^{1/2}, \qquad G_1 := (AP_sC^\top + BD^\top)D_1^{-1}, \tag{2.2}$$

it is easy to check (see [12]) that

$$H_1(z)H_1^\sim(z) = V_1(z)V_1^\sim(z) \tag{2.3}$$

with

$$V_1(z) := C(zI - A)^{-1}G_1 + D_1. \tag{2.4}$$

2.2. Computation of $V_1(z)^{-1}H_1(z)$. First notice that

$$V_1(z)^{-1} = D_1^{-1} - D_1^{-1}C(zI - \Gamma)^{-1}G_1D_1^{-1} \tag{2.5}$$

with

$$\Gamma := A - G_1D_1^{-1}C \tag{2.6}$$

being the closed-loop matrix corresponding to the stabilizing solution P_s of the ARE (2.1) (so that all the eigenvalues of Γ lay in the open unit disk).

Then we have

$$\begin{aligned} V_2(z) &:= V_1(z)^{-1}H_1(z) \\ &= D_1^{-1}C(zI-A)^{-1}B - D_1^{-1}C(zI-\Gamma)^{-1}G_1D_1^{-1}D + D_1^{-1}D \\ &\quad -D_1^{-1}C(zI-\Gamma)^{-1}\underbrace{G_1D_1^{-1}C}_{(zI-\Gamma)-(zI-A)}(zI-A)^{-1}B \\ &= D_1^{-1}C(zI-\Gamma)^{-1}(B-G_1D_1^{-1}D) + D_1^{-1}D \\ &= C_2(zI-\Gamma)^{-1}G_2 + D_2 \end{aligned} \tag{2.7}$$

with

$$C_2 := D_1^{-1}C, \qquad G_2 := B - G_1D_1^{-1}D, \qquad D_2 := D_1^{-1}D. \tag{2.8}$$

2.3. Computation of $V_2(z)H_2^{\sim}(z)$. We have

$$\begin{aligned} V_2(z)H_2^{\sim}(z) &= [C_2(zI-\Gamma)^{-1}G_2 + D_2][B^\top(z^{-1}I-A^\top)^{-1}L^\top + M^\top] \\ &= C_2(zI-\Gamma)^{-1}G_2M^\top + D_2B^\top(z^{-1}I-A^\top)^{-1}L^\top + D_2M^\top \\ &\quad + C_2(zI-\Gamma)^{-1}G_2B^\top(z^{-1}I-A^\top)^{-1}L^\top. \end{aligned} \tag{2.9}$$

Taking the ARE (2.1) into account, it is easy to check that

$$G_2B^\top = P_s - \Gamma P_sA^\top, \tag{2.10}$$

which may be easily rewritten in the form

$$G_2B^\top = (zI-\Gamma)P_s(z^{-1}I-A^\top) + (zI-\Gamma)P_sA^\top + \Gamma P_s(z^{-1}I-A^\top). \tag{2.11}$$

Plugging this expression in (2.9) we get

$$V_2(z)H_2^{\sim}(z) = C_2(zI-\Gamma)^{-1}G_3 + G_1^\top(z^{-1}I-A^\top)^{-1}L^\top + D_3 \tag{2.12}$$

with $G_3 := \Gamma P_sL^\top + G_2M^\top$ and $D_3 := C_2P_sL^\top + D_2M^\top$ or, taking into account that $DM^\top = 0$,

$$G_3 = \Gamma P_sL^\top + BM^\top, \qquad D_3 = C_2P_sL^\top \tag{2.13}$$

2.4. Computation of $H_2(z)H_1^{\sim}(z)[H_1(z)H_1^{\sim}(z)]^{-1}H_1(z)H_2^{\sim}(z)$. It is clear that $H_2(z)H_1^{\sim}(z)[H_1(z)H_1^{\sim}(z)]^{-1}H_1(z)H_2^{\sim}(z) = H_2(z)V_2^{\sim}(z)V_2(z)H_2^{\sim}(z)$. We have

$$\begin{aligned} H_2(z)V_2^{\sim}(z)V_2(z)H_2^{\sim}(z) &= D_3^\top D_3 + G_3^\top(z^{-1}I-\Gamma^\top)^{-1}C_2^\top C_2(zI-\Gamma)^{-1}G_3 \\ &\quad + D_3^\top C_2(zI-\Gamma)^{-1}G_3 + D_3^\top G_1^\top(z^{-1}I-A^\top)^{-1}L^\top \\ &\quad + [D_3^\top C_2(zI-\Gamma)^{-1}G_3 + D_3^\top G_1^\top(z^{-1}I-A^\top)^{-1}L^\top]^{\sim} \\ &\quad + L(zI-A)^{-1}G_1C_2(zI-\Gamma)^{-1}G_3 \\ &\quad + [L(zI-A)^{-1}G_1C_2(zI-\Gamma)^{-1}G_3]^{\sim} \\ &\quad + L(zI-A)^{-1}G_1G_1^\top(z^{-1}I-A^\top)^{-1}L^\top. \end{aligned} \tag{2.14}$$

The last three terms of such expression may be expanded as follows: first taking into account that

$$G_1C_2 = G_1D_1^{-1}C = A - \Gamma = (zI - \Gamma) - (zI - A) \tag{2.15}$$

we have

$$L(zI - A)^{-1}G_1C_2(zI - \Gamma)^{-1}G_3 = L(zI - A)^{-1}G_3 - L(zI - \Gamma)^{-1}G_3. \tag{2.16}$$

Second, taking into account the ARE (2.1), we have

$$\begin{aligned} G_1G_1^\top = AP_sA^\top - P_s + BB^\top = BB^\top - (zI - A)P_s(z^{-1}I - A^\top) - (zI - A)P_sA^\top \\ -AP_s(z^{-1}I - A^\top) \end{aligned} \tag{2.17}$$

so that

$$\begin{aligned} L(zI-A)^{-1}G_1G_1^\top(z^{-1}I-A^\top)^{-1}L^\top \\ = L(zI - A)^{-1}BB^\top(z^{-1}I - A^\top)^{-1}L^\top - LP_sL^\top \\ - L(zI - A)^{-1}AP_sL^\top - LP_sA^\top(z^{-1}I - A^\top)^{-1}L^\top. \end{aligned} \tag{2.18}$$

2.5. Computation of $W(z)$. From the definition (1.20) of $W(z)$ it follows that

$$W(z) = H_2(z)\tilde{H_2}(z) - H_2(z)\tilde{V_2}(z)V_2(z)\tilde{H_2}(z). \tag{2.19}$$

Moreover, by computing $H_2(z)\tilde{H_2}(z)$, we get the following expression:

$$\begin{aligned} H_2(z)\tilde{H_2}(z) = L(zI - A)^{-1}BB^\top(z^{-1}I - A^\top)^{-1}L^\top + MM^\top \\ + L(zI - A)^{-1}BM^\top + [L(zI - A)^{-1}BM^\top]\tilde{}. \end{aligned} \tag{2.20}$$

By subtracting (2.14) from (2.20), taking (2.16), (2.18), and (2.19) into account, we get

$$\begin{aligned} W(z) = (L - D_3^\top C_2)(zI - \Gamma)^{-1}G_3 + [(L - D_3^\top C_2)(zI - \Gamma)^{-1}G_3]\tilde{} \\ - G_3^\top(z^{-1}I - \Gamma^\top)^{-1}C_2^\top C_2(zI - \Gamma)^{-1}G_3 + LP_sL^\top + MM^\top - D_3^\top D_3 \\ + L(zI - A)^{-1}(BM^\top - G_1D_3 + AP_sL^\top - G_3) \\ + [L(zI - A)^{-1}(BM^\top - G_1D_3 + AP_sL^\top - G_3)]\tilde{}. \end{aligned} \tag{2.21}$$

We now prove that $BM^\top - G_1D_3 + AP_sL^\top - G_3 = 0$, so that the last two terms of the latter expression vanish. We have

$$\begin{aligned} BM^\top - G_1D_3 + AP_sL^\top - G_3 \\ = BM^\top - \underbrace{G_1C_2}_{A-\Gamma}P_sL^\top + AP_sL^\top - \Gamma P_sL^\top - BM^\top = 0. \end{aligned} \tag{2.22}$$

2.6. Spectral factorization of $W(z)$. To factorize $W(z)$ we first need to rewrite the term

$$G_3^\top(z^{-1}I - \Gamma^\top)^{-1}C_2^\top C_2(zI - \Gamma)^{-1}G_3.$$

To this aim we derive a new expression for $C_2^\top C_2$. Standard computations show that the solution P_s of the ARE (2.1) satisfies the following identity [15, p. 271]:

$$P_s = FP_sF^\top - FP_sC^\top(CP_sC^\top + DD^\top)^{-1}CP_sF^\top + B_1B_1^\top, \tag{2.23}$$

where F and B_1 are defined in (1.6). We also have

$$\begin{aligned}\Gamma &= A - G_1 D_1^{-1} C = F + [BD^\top (DD^\top)^{-1} D_1^2 - AP_s C^\top - BD^\top] D_1^{-1} C_2 \\ &= F - FP_s C^\top D_1^{-1} C_2 = F - FP_s C_2^\top C_2 \\ &= F(I - P_s C_2^\top C_2) \end{aligned} \tag{2.24}$$

so that (2.23) may be rewritten in the form

$$P_s - B_1 B_1^\top = \Gamma P_s F^\top = F P_s \Gamma^\top. \tag{2.25}$$

From $DD^\top > 0$ and $P_s > 0$ it easily follows that $(I - P_s C_2^\top C_2) = P_s(P_s^{-1} - C^\top (CP_s C^\top + DD^\top)^{-1} C)$ is nonsingular (in fact, $(P_s^{-1} - C^\top (CP_s C^\top + DD^\top)^{-1} C) > 0$). Thus Γ, and hence $FP_s\Gamma^\top$, are nonsingular so that the left-hand side of (2.25) is nonsingular as well, and we have

$$(P_s - B_1 B_1^\top)^{-1} = \Gamma^{-\top} P_s^{-1} F^{-1}, \tag{2.26}$$

which may be rewritten as

$$P_s^{-1} = \Gamma^\top (P_s - B_1 B_1^\top)^{-1} F, \tag{2.27}$$

and, by multiplying on the right side by $(I - P_s C_2^\top C_2)$,

$$P_s^{-1}(I - P_s C_2^\top C_2) = \Gamma^\top (P_s - B_1 B_1^\top)^{-1} \Gamma. \tag{2.28}$$

Therefore

$$C_2^\top C_2 = P_s^{-1} - \Gamma^\top (P_s - B_1 B_1^\top)^{-1} \Gamma \tag{2.29a}$$

$$= P_s^{-1} - \Gamma^\top P_s^{-1} \Gamma - \Gamma^\top P_s^{-1} B_1 V^{-1} B_1^\top P_s^{-1} \Gamma \tag{2.29b}$$

$$\begin{aligned} &= (z^{-1} I - \Gamma^\top) P_s^{-1} (zI - \Gamma) + \Gamma^\top P_s^{-1} (zI - \Gamma) + (z^{-1} I - \Gamma^\top) P_s^{-1} \Gamma \\ &\quad - \Gamma^\top P_s^{-1} B_1 V^{-1} B_1^\top P_s^{-1} \Gamma, \end{aligned} \tag{2.29c}$$

where

$$V := I - B_1^\top P_s^{-1} B_1. \tag{2.30}$$

Notice that

$$P_s^{-1} - C_2^\top C_2 = P_s^{-1} - C^\top (DD^\top + CP_s C^\top)^{-1} C = P_s^{-1} [P_s^{-1} + C^\top (DD^\top)^{-1} C]^{-1} P_s^{-1} > 0 \tag{2.31}$$

so that from (2.29a) it follows that $P_s - B_1 B_1^\top > 0$, which, together with the positive definiteness of P_s, implies that V is positive definite as well.

Plugging in the expression in the right-hand side of (2.29c) in place of $C_2^\top C_2$ in the third term of (2.21), we get

$$\begin{aligned} W(z) = {} & (L - D_3^\top C_2 - G_3^\top P_s^{-1} \Gamma)(zI - \Gamma)^{-1} G_3 \\ & + [(L - D_3^\top C_2 - G_3^\top P_s^{-1} \Gamma)(zI - \Gamma)^{-1} G_3]^\sim \\ & + G_3^\top (z^{-1} I - \Gamma^\top)^{-1} \Gamma^\top P_s^{-1} B_1 V^{-1} B_1^\top P_s^{-1} \Gamma (zI - \Gamma)^{-1} G_3 \\ & + L P_s L^\top + M M^\top - D_3^\top D_3 - G_3^\top P_s^{-1} G_3. \end{aligned} \tag{2.32}$$

Now we are ready to prove that the following spectral factorization of $W(z)$ holds:

$$W(z) = T(z) T^\sim(z), \tag{2.33}$$

where

$$T(z) := [-G_3^\top (z^{-1}I - \Gamma^\top)^{-1}\Gamma^\top P_s^{-1}B_1 - G_3^\top P_s^{-1}B_1 + M]V^{-1/2}. \tag{2.34}$$

To this aim it is sufficient to show that

$$\begin{aligned}(M - G_3^\top P_s^{-1}B_1)V^{-1}(M - G_3^\top P_s^{-1}B_1)^\top \\ - (LP_sL^\top + MM^\top - D_3^\top D_3 - G_3^\top P_s^{-1}G_3) = 0\end{aligned} \tag{2.35}$$

and

$$\Gamma^\top P_s^{-1}B_1V^{-1}(M - G_3^\top P_s^{-1}B_1)^\top + (L - D_3^\top C_2 - G_3^\top P_s^{-1}\Gamma)^\top = 0. \tag{2.36}$$

As for (2.35) notice that

$$M - G_3^\top P_s^{-1}B_1 = M - LP_s\Gamma^\top P_s^{-1}B_1 - MB_1^\top P_s^{-1}B_1 = MV - LP_s\Gamma^\top P_s^{-1}B_1 \tag{2.37}$$

so that, taking (1.8) into account, we may expand the left-hand side of (2.35) as

$$\begin{aligned}&MVM^\top - MB_1^\top P_s^{-1}\Gamma P_sL^\top - (MB_1^\top P_s^{-1}\Gamma P_sL^\top)^\top \\ &+ LP_s\Gamma^\top P_s^{-1}B_1V^{-1}B_1^\top P_s^{-1}\Gamma P_sL^\top - LP_sL^\top - MM^\top \\ &+ LP_sC_2^\top C_2P_sL^\top + LP_s\Gamma^\top P_s^{-1}\Gamma P_sL^\top + MB_1^\top P_s^{-1}B_1M^\top \\ &+ MB_1^\top P_s^{-1}\Gamma P_sL^\top + (MB_1^\top P_s^{-1}\Gamma P_sL^\top)^\top \\ &= LP_s(\Gamma^\top P_s^{-1}B_1V^{-1}B_1^\top P_s^{-1}\Gamma - P_s^{-1} + C_2^\top C_2 + \Gamma^\top P_s^{-1}\Gamma)P_sL^\top = 0,\end{aligned} \tag{2.38}$$

where the latter equality follows from the expression (2.29b) for $C_2^\top C_2$.

Similarly, we may expand the left-hand side of (2.36) as

$$\begin{aligned}&L^\top - C_2^\top C_2P_sL^\top - \Gamma^\top P_s^{-1}\Gamma P_sL^\top - \Gamma^\top P_s^{-1}B_1V^{-1}B_1^\top P_s^{-1}\Gamma P_sL^\top \\ &= (P_s^{-1} - C_2^\top C_2 - \Gamma^\top P_s^{-1}\Gamma - \Gamma^\top P_s^{-1}B_1V^{-1}B_1^\top P_s^{-1}\Gamma)P_sL^\top = 0.\end{aligned} \tag{2.39}$$

We now rewrite $T(z)$ in a more convenient form. Notice that

$$(z^{-1}I - \Gamma^\top)^{-1} = -\Gamma^{-\top} - \Gamma^{-\top}(zI - \Gamma^{-\top})^{-1}\Gamma^{-\top}$$

so that

$$\begin{aligned}T(z) &= [G_3^\top\Gamma^{-\top}(zI - \Gamma^{-\top})^{-1}P_s^{-1}B_1 + M]V^{-1/2} \\ &= [G_3^\top\Gamma^{-\top}P_s^{-1}(zI - P_s\Gamma^{-\top}P_s^{-1})^{-1}B_1 + M]V^{-1/2} \\ &= L_1(zI - F_a)^{-1}B_1V^{-1/2} + MV^{-1/2}\end{aligned} \tag{2.40}$$

with

$$L_1 := G_3^\top\Gamma^{-\top}P_s^{-1} = L + MB_1^\top\Gamma^{-\top}P_s^{-1}, \qquad F_a := P_s\Gamma^{-\top}P_s^{-1}. \tag{2.41}$$

Notice that since Γ is stable, F_a is antistable. As a direct consequence of (2.26) we have the following relation that will be useful in what follows:

$$F_a = (I - B_1B_1^\top P_s^{-1})^{-1}F. \tag{2.42}$$

2.7. Spectral factorization of $-S(z)$. We have

$$-S(z) = \gamma^2 I - W(z) = \gamma^2 I - T(z)T^{\sim}(z).$$

As we have done for the factorization in section 2.1 consider the following ARE for the spectral factorization of $-S(z)$:

$$X = F_a X F_a^\top - B_1 V^{-1} B_1^\top - (F_a X L_1^\top - B_1 V^{-1} M^\top)(R + L_1 X L_1^\top)^{-1}(L_1 X F_a^\top - M V^{-1} B_1^\top) \tag{2.43}$$

with

$$R := \gamma^2 I - M V^{-1} M^\top. \tag{2.44}$$

In view of (1.21), we have $\|T(z)\|_\infty < \gamma$ for any $\gamma > \gamma_0$ so that as a consequence of a generalized version of the discrete-time bounded real lemma (see [8, Theorem 2.1]), (2.43) admits a stabilizing solution, namely, a solution $X_s = X_s^\top$ such that

$$\Gamma_a := F_a - (F_a X_s L_1^\top - B_1 V^{-1} M^\top)(R + L_1 X_s L_1^\top)^{-1} L_1 \tag{2.45}$$

is a stability matrix; moreover $(R + L_1 X_s L_1^\top) > 0$ and the function

$$T_1(z) := [I + L_1(zI - F_a)^{-1}(F_a X_s L_1^\top - B_1 V^{-1} M^\top)(R + L_1 X_s L_1^\top)^{-1}](R + L_1 X_s L_1^\top)^{1/2} \tag{2.46}$$

is a square spectral factor of $-S(z) = \gamma^2 I_l - W(z)$, namely, it is a square matrix function such that $-S(z) = T_1(z)T_1^{\sim}(z)$. Moreover, the numerator matrix of $T_1(z)$ is given by (2.45) and hence $[T_1(z)]^{-1}$ is stable.

We now show that X_s is positive definite. In fact, since $(R + L_1 X_s L_1^\top) > 0$, we have

$$X_s \le F_a X_s F_a^\top - B_1 V^{-1} B_1^\top. \tag{2.47}$$

But (F, B_1) is, by assumption, reachable, (F_a, B_1) is such (because F_a is obtained from F by state feedback as it is apparent from (2.42)), and then also $(F_a, B_1 V^{-1/2})$ is reachable. Therefore, since F_a is antistable, a standard Lyapunov argument, shows that $X_s > 0$.

2.8. The ARE for $P_s^{-1} - X_s^{-1}$. Define

$$R_1 := I - \frac{M^\top M}{\gamma^2} \tag{2.48}$$

and

$$F_y := A - B J_0' J_1^{-1} H_0, \tag{2.49}$$

where J_0, J_1, H_0 are defined in (1.13). Notice that F_y is well defined if and only if J_1 is nonsingular or, equivalently, if and only if R_1 is nonsingular. Let

$$\mathcal{G}_1 := \{\gamma > \gamma_0 : \text{ at least one of the matrices } R,\ R_1,\ \text{and } F_y,\ \text{is singular}\}. \tag{2.50}$$

Remark 2.1. Notice that since F_y may be written in the form

$$F_y = F - B_1 M^\top (M M^\top - \gamma^2 I)^{-1} L, \tag{2.51}$$

where F is nonsingular, $\mathcal{G}_1$ contains a finite number of points. More precisely, it contains, at most, $n + 2\,\mathrm{rank}(M)$ points.

We consider now the following ARE:

$$\begin{aligned} Y = F^\top Y F + \left(F^\top Y B_1 + \frac{L^\top M}{\gamma^2}\right)(R_1 - B_1^\top Y B_1)^{-1}\left(B_1^\top Y F + \frac{M^\top L}{\gamma^2}\right) \\ - C^\top (DD^\top)^{-1} C + \frac{L^\top L}{\gamma^2} \end{aligned} \tag{2.52}$$

and prove that it admits a solution that can be explicitely computed. To this aim we need a technical lemma.

LEMMA 2.1. *Let $\gamma > \gamma_0$ and $\gamma \notin \mathcal{G}_1$ and define*

$$F_1 := F_a + B_1 V^{-1} M^\top R^{-1} L_1. \tag{2.53}$$

Then the following relation holds:

$$X_s^{-1} = F_1^\top X_s^{-1}(I - B_1 R_1^{-1} B_1^\top (P_s^{-1} - X_s^{-1}))^{-1} F_y - L_1^\top R^{-1} L_1. \tag{2.54}$$

Proof. First we establish the following useful identity:

$$F_y = (I - B_1 R_1^{-1} B_1^\top P_s^{-1}) F_1. \tag{2.55}$$

To show identity (2.55), we write F_1 in the form

$$\begin{aligned} F_1 &= (I + B_1 V^{-1} M^\top R^{-1} M B_1^\top P_s^{-1}) F_a + B_1 V^{-1} M^\top R^{-1} L \\ &= (I + B_1 V^{-1} M^\top R^{-1} M B_1^\top P_s^{-1})(I - B_1 B_1^\top P_s^{-1})^{-1} F + B_1 V^{-1} M^\top R^{-1} L, \end{aligned} \tag{2.56}$$

which gives

$$\begin{aligned} &(I - B_1 R_1^{-1} B_1^\top P_s^{-1}) F_1 \\ &= (I - B_1 R_1^{-1} B_1^\top P_s^{-1})(I + B_1 V^{-1} M^\top R^{-1} M B_1^\top P_s^{-1})(I - B_1 B_1^\top P_s^{-1})^{-1} F \\ &\quad + (I - B_1 R_1^{-1} B_1^\top P_s^{-1}) B_1 V^{-1} M^\top R^{-1} L, \end{aligned} \tag{2.57}$$

so that, taking (2.51) into account, it is sufficient to prove that

$$(I - B_1 R_1^{-1} B_1^\top P_s^{-1})(I + B_1 V^{-1} M^\top R^{-1} M B_1^\top P_s^{-1})(I - B_1 B_1^\top P_s^{-1})^{-1} = I \tag{2.58}$$

and

$$(I - B_1 R_1^{-1} B_1^\top P_s^{-1}) B_1 V^{-1} M^\top R^{-1} = -B_1 M^\top (M M^\top - \gamma^2 I)^{-1}. \tag{2.59}$$

As for (2.58), we have

$$\begin{aligned} &(I - B_1 R_1^{-1} B_1^\top P_s^{-1})(I + B_1 V^{-1} M^\top R^{-1} M B_1^\top P_s^{-1})(I - B_1 B_1^\top P_s^{-1})^{-1} \\ &= (I - B_1 R_1^{-1} B_1^\top P_s^{-1})(I - B_1 B_1^\top P_s^{-1} + B_1 (I + V^{-1} M^\top R^{-1} M) B_1^\top P_s^{-1})(I - B_1 B_1^\top P_s^{-1})^{-1} \\ &= (I - B_1 R_1^{-1} B_1^\top P_s^{-1})\left[I - B_1 B_1^\top P_s^{-1} + B_1 \left(V - \frac{M^\top M}{\gamma^2}\right)^{-1} V B_1^\top P_s^{-1}\right](I - B_1 B_1^\top P_s^{-1})^{-1} \\ &= (I - B_1 R_1^{-1} B_1^\top P_s^{-1})\left[I + B_1 \left(V - \frac{M^\top M}{\gamma^2}\right)^{-1} V B_1^\top P_s^{-1}(I - B_1 B_1^\top P_s^{-1})^{-1}\right] \\ &= (I - B_1 R_1^{-1} B_1^\top P_s^{-1})\left[I + B_1 \left(V - \frac{M^\top M}{\gamma^2}\right)^{-1} B_1^\top P_s^{-1}\right] \\ &= (I - B_1 R_1^{-1} B_1^\top P_s^{-1})(I - B_1 R_1^{-1} B_1^\top P_s^{-1})^{-1} = I. \end{aligned} \tag{2.60}$$

As for (2.59), we have

$$\begin{aligned}(I - B_1R_1^{-1}B_1^\top P_s^{-1})B_1V^{-1}M^\top R^{-1} &= B_1(I - R_1^{-1}B_1^\top P_s^{-1}B_1)V^{-1}M^\top R^{-1}\\ &= B_1R_1^{-1}\underbrace{(R_1 - B_1^\top P_s^{-1}B_1)}_{V-\frac{M^\top M}{\gamma^2}}V^{-1}M^\top R^{-1}\\ &= B_1R_1^{-1}M^\top\left(I - \frac{MV^{-1}M^\top}{\gamma^2}\right)R^{-1}\\ &= -B_1M^\top(MM^\top - \gamma^2 I)^{-1}. \qquad (2.61)\end{aligned}$$

Since X_s is a solution of the ARE (2.43), as a direct consequence of standard equivalence of Riccati equations [15, p. 271], we have the following identity:

$$X_s = F_1X_sF_1^\top - F_1X_sL_1^\top(L_1X_sL_1^\top + R)^{-1}L_1X_sF_1^\top - B_1\left(V - \frac{M^\top M}{\gamma^2}\right)^{-1}B_1^\top \qquad (2.62)$$

with F_1 being defined in (2.53). The closed-loop matrix may thus be written in the form

$$\Gamma_a = F_1 - F_1X_sL_1^\top(L_1X_sL_1^\top + R)^{-1}L_1 = F_1(I + X_sL_1^\top R^{-1}L_1)^{-1}. \qquad (2.63)$$

Notice that $V - \frac{M^\top M}{\gamma^2}$ is nonsingular because V and R are such. In the same way, $X_s^{-1}+L_1^\top R^{-1}L_1$, and hence $(I+X_sL_1^\top R^{-1}L_1)$, are nonsingular because X_s, $L_1X_sL_1^\top + R$, and R are such. From (2.62) we easily get

$$X_s + B_1\left(V - \frac{M^\top M}{\gamma^2}\right)^{-1}B_1^\top = F_1(X_s - X_sL_1^\top(L_1X_sL_1^\top + R)^{-1}L_1X_s)F_1^\top. \qquad (2.64)$$

As an immediate consequence of (2.55) we have that F_1 is nonsingular, so that the right-hand side of (2.64) (which may be written in the form $F_1(I+X_sL_1^\top R^{-1}L_1)^{-1}F_1^\top$) is nonsingular. Hence $X_s + B_1(V - \frac{M^\top M}{\gamma^2})^{-1}B_1^\top$ is nonsingular as well and then $\frac{M^\top M}{\gamma^2} - V - B_1^\top X_s^{-1}B_1 = -\left(R_1 - B_1^\top(P_s^{-1} - X_s^{-1})B_1\right)$ is such. (Actually, a more detailed analysis allows to conclude that $\left(R_1 - B_1^\top(P_s^{-1} - X_s^{-1})B_1\right) > 0$.) Then we have

$$\left[X_s + B_1\left(V - \frac{M^\top M}{\gamma^2}\right)^{-1}B_1^\top\right]^{-1} = [F_1(X_s - X_sL_1^\top(L_1X_sL_1^\top + R)^{-1}L_1X_s)F_1^\top]^{-1}, \qquad (2.65)$$

which yields

$$X_s^{-1} + X_s^{-1}B_1\left(\frac{M^\top M}{\gamma^2} - V - B_1^\top X_s^{-1}B_1\right)^{-1}B_1^\top X_s^{-1} = F_1^{-\top}(X_s^{-1} + L_1^\top R^{-1}L_1)F_1^{-1} \qquad (2.66)$$

and hence

$$X_s^{-1} = F_1^\top X_s^{-1}F_1 - F_1^\top X_s^{-1}B_1\left(R_1 - B_1^\top(P_s^{-1} - X_s^{-1})B_1\right)^{-1}B_1^\top X_s^{-1}F_1 - L_1^\top R^{-1}L_1 \qquad (2.67a)$$

$$= F_1^\top X_s^{-1}(I - B_1R_1^{-1}B_1^\top(P_s^{-1} - X_s^{-1}))^{-1}(I - B_1R_1^{-1}B_1^\top P_s^{-1})F_1 - L_1^\top R^{-1}L_1. \qquad (2.67b)$$

Finally, by plugging (2.55) in (2.67b) we obtain (2.54). □

PROPOSITION 2.1. *Let $\gamma > \gamma_0$ and $\gamma \notin \mathcal{G}_1$. Then the ARE* (2.52) *admits the (necessarily unique) antistabilizing solution. In fact, such solution is given by*[3]

$$Y_a := P_s^{-1} - X_s^{-1}. \tag{2.68}$$

Proof. We have to show that when $Y = Y_a$, (2.52) is an identity and that all the eigenvalues of

$$\Gamma_y := F - B_1(B_1^\top Y_a B_1 - R_1)^{-1}\left(B_1^\top Y_a F + \frac{M^\top L}{\gamma^2}\right) \tag{2.69}$$

lay in $\{z \in \mathbb{C} : \ |z| > 1\}$.

We first prove that Y_a is a solution of the ARE

$$Y = F_y^\top Y F_y + F_y^\top Y B_1(R_1 - B_1^\top Y B_1)^{-1}B_1^\top Y F_y - H_0^\top J_1^{-1} H_0. \tag{2.70}$$

From (2.23) we get

$$(P_s - B_1 B_1^\top)^{-1} = F^{-\top}(P_s - P_s C^\top (C P_s C^\top + DD^\top)^{-1} C P_s)^{-1} F^{-1}, \tag{2.71}$$

which, using the same procedure that lead to (2.67a), yields

$$P_s^{-1} = F^\top P_s^{-1} F - F^\top P_s^{-1} B_1 (B_1^\top P_s^{-1} B_1 - I)^{-1} B_1^\top P_s^{-1} F - C^\top (DD^\top)^{-1} C, \tag{2.72}$$

which, taking (2.42) into account, may be also written in the form

$$P_s^{-1} = F_a^\top P_s^{-1} F - C^\top (DD^\top)^{-1} C \tag{2.73}$$

and, finally, in the form

$$P_s^{-1} = F_1^\top P_s^{-1} F_y + F_a^\top P_s^{-1}(F - F_y) - (F_1 - F_a)^\top P_s^{-1} F_y - C^\top (DD^\top)^{-1} C. \tag{2.74}$$

By subtracting (2.54) from (2.74) we now get

$$Y_a = F_1^\top [P_s^{-1} - X_s^{-1}(I - B_1 R_1^{-1} B_1^\top Y_a)^{-1}] F_y + R_2 \tag{2.75}$$

with

$$R_2 := F_a^\top P_s^{-1}(F - F_y) - (F_1 - F_a)^\top P_s^{-1} F_y - C^\top (DD^\top)^{-1} C + L_1^\top R^{-1} L_1. \tag{2.76}$$

We may rewrite (2.75) as follows:

$$\begin{aligned} Y_a &= F_1^\top [(Y_a - P_s^{-1} B_1 R_1^{-1} B_1^\top Y_a)(I - B_1 R_1^{-1} B_1^\top Y_a)^{-1}] F_y + R_2 \\ &= F_1^\top (I - P_s^{-1} B_1 R_1^{-1} B_1^\top) Y_a (I - B_1 R_1^{-1} B_1^\top Y_a)^{-1} F_y + R_2 \\ &= F_y^\top Y_a (I - B_1 R_1^{-1} B_1^\top Y_a)^{-1} F_y + R_2 \\ &= F_y^\top Y_a F_y + F_y^\top Y_a B_1 (R_1 - B_1^\top Y_a B_1)^{-1} B_1^\top Y_a F_y + R_2, \end{aligned} \tag{2.77}$$

where we have taken (2.55) into account.

[3] We shall denote such a solution by $Y_a(\gamma)$ when we want to stress its dependence upon γ.

To prove that Y_a is a solution of the ARE (2.70), it remains only to show that

$$R_2 = -H_0^\top J_1^{-1} H_0. \tag{2.78}$$

Indeed, taking into account (2.51), (2.53), and the first of (2.41), we have

$$\begin{aligned}
&R_2 + H_0^\top J_1^{-1} H_0 \\
&= F_a^\top P_s^{-1}(F - F_y) - (F_1 - F_a)^\top P_s^{-1} F_y + L_1^\top R^{-1} L_1 + L^\top (MM^\top - \gamma^2 I)^{-1} L \\
&= F_a^\top P_s^{-1} B_1 M^\top (MM^\top - \gamma^2 I)^{-1} L - L_1^\top R^{-1} M V^{-1} B_1^\top P_s^{-1} F \\
&\quad + L_1^\top R^{-1} M \underbrace{V^{-1} B_1^\top P_s^{-1} B_1}_{V^{-1} - I} M^\top (MM^\top - \gamma^2 I)^{-1} L \\
&\quad + L_1^\top R^{-1} L_1 + L^\top (MM^\top - \gamma^2 I)^{-1} L \\
&= F_a^\top P_s^{-1} B_1 M^\top (MM^\top - \gamma^2 I)^{-1} L - L_1^\top R^{-1} M V^{-1} B_1^\top P_s^{-1} F \\
&\quad + L_1^\top R^{-1} \underbrace{M V^{-1} M^\top}_{-R + \gamma^2 I} (MM^\top - \gamma^2 I)^{-1} L \\
&\quad - L_1^\top R^{-1} \underbrace{MM^\top}_{(MM^\top - \gamma^2 I) + \gamma^2 I} (MM^\top - \gamma^2 I)^{-1} L \\
&\quad + L_1^\top R^{-1} L_1 + L^\top (MM^\top - \gamma^2 I)^{-1} L \\
&= F_a^\top P_s^{-1} B_1 M^\top (MM^\top - \gamma^2 I)^{-1} L - L_1^\top R^{-1} M V^{-1} B_1^\top P_s^{-1} F \\
&\quad + \underbrace{(L^\top - L_1^\top)}_{-F_a^\top P_s^{-1} B_1 M^\top} (MM^\top - \gamma^2 I)^{-1} L + L_1^\top R^{-1} \underbrace{(L_1 - L)}_{M B_1^\top P_s^{-1} F_a} \\
&= L_1^\top R^{-1} M (B_1^\top P_s^{-1} F_a - V^{-1} B_1^\top P_s^{-1} F) \\
&= L_1^\top R^{-1} M (B_1^\top P_s^{-1} F_a - B_1^\top P_s^{-1} \underbrace{(I - B_1 B_1^\top P_s^{-1})^{-1} F}_{F_a}) = 0.
\end{aligned} \tag{2.79}$$

We now prove that Y_a is a solution of (2.52) as well. In fact, we have

$$\begin{aligned}
F_y &= F - B_1 M^\top (MM^\top - \gamma^2 I)^{-1} L = F + B_1 M^\top \left(\frac{I}{\gamma^2} + \frac{M R_1^{-1} M^\top}{\gamma^4} \right) L \\
&= F + B_1 R_1^{-1} \frac{M^\top L}{\gamma^2}
\end{aligned} \tag{2.80}$$

and

$$\begin{aligned}
H_0^\top J_1^{-1} H_0 &= C^\top (DD^\top)^{-1} C + L^\top (MM^\top - \gamma^2 I)^{-1} L \\
&= C^\top (DD^\top)^{-1} C - \frac{L^\top L}{\gamma^2} - \frac{L^\top M}{\gamma^2} R_1^{-1} \frac{M^\top L}{\gamma^2}
\end{aligned} \tag{2.81}$$

so that, by using standard manipulations [15, p. 271], (2.70) may be rewritten in the form (2.52).

It remains to prove that the solution Y_a is indeed antistabilizing, i.e., that all the eigenvalues of Γ_y lay in $\{z \in \mathbb{C} : \ |z| > 1\}$. Notice that Γ_y may be written in the form

$$\Gamma_y = F_y + B_1 (R_1 - B_1^\top Y_a B_1)^{-1} B_1^\top Y_a F_y = (I - B_1 R_1^{-1} B_1^\top Y_a)^{-1} F_y. \tag{2.82}$$

Moreover, we rewrite (2.54) in the form

$$X_s^{-1} + L_1^\top R^{-1} L_1 = F_1^\top X_s^{-1} \Gamma_y, \tag{2.83}$$

which, together with (2.63) yields

$$I = X_s(I + L_1^\top R^{-1} L_1 X_s)^{-1} F_1^\top X_s^{-1} \Gamma_y = X_s \Gamma_a^\top X_s^{-1} \Gamma_y, \tag{2.84}$$

so that Γ_y is clearly antistable. □

3. A monotonicity result. In this section we prove that the values of γ for which $Y_a(\gamma)$ is singular are finitely many. This will be usefull in order to prove existence of the stabilizing solution of (1.14).

PROPOSITION 3.1. *Let $Y_a(\gamma)$ be as in* (2.68). *The set*

$$\mathcal{G}_2 := \{\gamma > \gamma_0 : \ Y_a(\gamma) \text{ is singular}\} \tag{3.1}$$

contains, at most, n points.

Proof. The solution X_s of (2.43) is a continuous function of γ and its first derivative with respect to γ^2 exists and is continuous; see, e.g., [15, Theorem 14.2.2]. Since P_s does not depend on γ, the derivative $\frac{dY_a}{d\gamma^2}$ exists and is continuos as well. Consider an open set $\mathcal{I} = (a, b)$ such that $a \geq \gamma_0$, $b > a$ (possibly $b = \infty$) and $\mathcal{I} \cap \mathcal{G}_1 = \emptyset$. (Notice that the set $\{\gamma \in \mathbb{R} : \ \gamma > \gamma_0\}$ may be written as the union of a finite number of sets of this form and of a finite number of isolated points.) For $\gamma \in \mathcal{I}$, we may take derivatives in both sides of (2.52) and, by defining

$$Y_\gamma := \frac{dY_a}{d\gamma^2}, \tag{3.2}$$

we get

$$\begin{aligned}
Y_\gamma = {} & F^\top Y_\gamma F - \left(F^\top Y_\gamma B_1 - \frac{L^\top M}{\gamma^4}\right)(R_1 - B_1^\top Y_a B_1)^{-1}\left(B_1^\top Y_a F + \frac{M^\top L}{\gamma^2}\right) \\
& - \left(F^\top Y_a B_1 + \frac{L^\top M}{\gamma^2}\right)(R_1 - B_1^\top Y_a B_1)^{-1}\left(B_1^\top Y_\gamma F - \frac{M^\top L}{\gamma^4}\right) \\
& - \left(F^\top Y_a B_1 + \frac{L^\top M}{\gamma^2}\right)(R_1 - B_1^\top Y_a B_1)^{-1}\frac{M^\top M}{\gamma^4} \\
& \quad (R_1 - B_1^\top Y_a B_1)^{-1}\left(B_1^\top Y_a F + \frac{M^\top L}{\gamma^2}\right) \\
& + \left(F^\top Y_a B_1 + \frac{L^\top M}{\gamma^2}\right)(R_1 - B_1^\top Y_a B_1)^{-1} B_1^\top Y_\gamma B_1 \\
& \quad (R_1 - B_1^\top Y_a B_1)^{-1}\left(B_1^\top Y_a F + \frac{M^\top L}{\gamma^2}\right) \\
& - \frac{L^\top L}{\gamma^4}
\end{aligned} \tag{3.3}$$

and, taking (2.69) into account,

$$Y_\gamma = \Gamma_y^\top Y_\gamma \Gamma_y - \frac{L_2^\top L_2}{\gamma^4} \tag{3.4}$$

with

$$L_2 := L - M(R_1 - B_1^\top Y_a B_1)^{-1}\left(B_1^\top Y_a F + \frac{M^\top L}{\gamma^2}\right). \tag{3.5}$$

Taking (2.82) into account, we may rewrite (2.70) (with $Y + Y_a$) in the form

$$Y_a = \Gamma_y^\top Y_a \Gamma_y - \Gamma_y^\top Y_a B_1 R_1^{-1} B_1^\top Y_a \Gamma_y - H_0^\top J_1^{-1} H_0. \tag{3.6}$$

Define

$$Z := Y_a + \gamma^2 Y_\gamma. \tag{3.7}$$

By adding (3.4) multiplied by γ^2 to (3.6), we get

$$Z = \Gamma_y^\top Z \Gamma_y - \Gamma_y^\top Y_a B_1 R_1^{-1} B_1^\top Y_a \Gamma_y - H_0^\top J_1^{-1} H_0 - \frac{L_2^\top L_2}{\gamma^2}. \tag{3.8}$$

By taking into account the definitions (2.69) and (3.5) of Γ_y and L_2, respectively, and identity (2.81), it is not difficult to see that

$$-\Gamma_y^\top Y_a B_1 R_1^{-1} B_1^\top Y_a \Gamma_y - H_0^\top J_1^{-1} H_0 - \frac{L_2^\top L_2}{\gamma^2} = -C_1^\top C_1 - C^\top (DD^\top)^{-1} C \tag{3.9}$$

with

$$C_1 := (R_1 - B_1^\top Y_a B_1)^{-1} \left(B_1^\top Y_a F + \frac{M^\top L}{\gamma^2} \right). \tag{3.10}$$

Therefore, Z satisfies

$$Z = \Gamma_y^\top Z \Gamma_y - C_1^\top C_1 - C^\top (DD^\top)^{-1} C. \tag{3.11}$$

Notice that since Γ_y is antistable, (3.4) and (3.11) imply that

$$Y_\gamma \geq 0, \tag{3.12a}$$

$$Z \geq 0. \tag{3.12b}$$

Moreover, by multiplying (3.4) and (3.11) on the left side by $\Gamma_y^{-\top}$ and on the right side by Γ_y^{-1}, it is easy to see that both $\ker Y_\gamma$ and $\ker Z$ are invariant for Γ_y^{-1} and hence for Γ_y. Then

$$\ker Y_\gamma \subseteq \ker L_2 \tag{3.13}$$

and

$$\ker Z \subseteq \ker \begin{bmatrix} C_1 \\ C \end{bmatrix}. \tag{3.14}$$

Therefore,

$$\mathcal{K} := \ker \begin{bmatrix} Y_a \\ Y_\gamma \end{bmatrix} = \ker \begin{bmatrix} Z \\ Y_\gamma \end{bmatrix} \tag{3.15}$$

is Γ_y-invariant and satisfies

$$\mathcal{K} \subseteq \ker \begin{bmatrix} C \\ C_1 \\ L_2 \end{bmatrix}. \tag{3.16}$$

We now prove that $\mathcal{K} = \{0\}$. To this end it is sufficient to show that

$$\ker \begin{bmatrix} \Gamma_y - \lambda I \\ C \\ C_1 \\ L_2 \end{bmatrix} = \{0\} \quad \forall \lambda \in \mathbb{C}. \tag{3.17}$$

Assume by contradiction that there exist $v \neq 0$ and $\lambda \in \mathbb{C}$ such that

$$\begin{bmatrix} \Gamma_y - \lambda I \\ C \\ C_1 \\ L_2 \end{bmatrix} v = 0. \tag{3.18}$$

Then, since Γ_y is antistable, $|\lambda| > 1$. Moreover, the definitions (1.6) of F and (2.69) of Γ_y yield

$$\Gamma_y = A - BD^\top (DD^\top)^{-1} C - B_1 C_1 \tag{3.19}$$

so that $\Gamma_y v = Av$ and we get

$$\begin{bmatrix} A - \lambda I \\ C \end{bmatrix} v = 0, \quad |\lambda| > 1, \tag{3.20}$$

which is in contradiction with detectability of the pair (A, C). Therefore $\mathcal{K} = 0$ and then, when one eigenvalue of Y_a (that is a continuous function of Y_a and hence of γ) is zero, its derivative with respect to γ is positive. Thus, if $Y_a(\bar\gamma)$ is singular and (counting with multiplicity) has, say, k_+ positive, k_0 zero, and k_- negative eigenvalues, then there exists a positive value δ such that $Y_a(\gamma)$ has k_+ positive and $k_0 + k_-$ negative eigenvalues for $\gamma \in (\bar\gamma - \delta, \bar\gamma)$ and $k_+ + k_0$ positive and k_- negative eigenvalues for $\gamma \in (\bar\gamma, \bar\gamma + \delta)$. Clearly, this may happen for, at most, n different values of γ.

So far we have assumed that $\gamma \in \mathcal{I}$. As already observed, the set $\{\gamma \in \mathbb{R} : \ \gamma > \gamma_0\}$ may be written as the union of a finite number of sets of the same type of $\mathcal{I}$ and of a finite number of values of γ. In correspondence of such values, Y_a remains a continuous function of γ so that we can extend the conclusion to the whole set $\{\gamma \in \mathbb{R} : \ \gamma > \gamma_0\}$. □

4. Existence of a stabilizing solution of the ARE (1.14). Next we show that when Y_a is nonsingular, then Y_a^{-1} is the (necessarily unique) stabilizing solution of (1.14), so that, in view of Propositions 2.1 and 3.1, we get that, except for a finite number of values of $\gamma > \gamma_0$, the ARE (1.14) admits the stabilizing solution. We shall prove in the next section that such solution is also feasible.

Consider the set $\mathcal{G}_1 \cup \mathcal{G}_2$ and observe that it contains, at most, $2[n + \operatorname{rank}(M)]$ points. Then, the set of *regular* values of γ defined as

$$\mathcal{G}_r := \{\gamma > \gamma_0 : \ \gamma \notin \mathcal{G}_1 \cup \mathcal{G}_2\} \tag{4.1}$$

is generic in $\{\gamma \in \mathbb{R} : \ \gamma > \gamma_0\}$.

The following theorem is our main result.

THEOREM 4.1. *Let $\gamma \in \mathcal{G}_r$ and let $Y_a(\gamma)$ be the corresponding antistabilizing solution of* (2.52). *Then* (1.14) *admits a unique symmetric stabilizing solution. Such solution is given by*

$$\Delta_s = Y_a^{-1}. \tag{4.2}$$

Proof. As shown in Proposition 2.1, Y_a is a solution of (2.70) so that we have

$$\begin{aligned} Y_a + H_0^\top J_1^{-1} H_0 &= F_y^\top Y_a F_y + F_y^\top Y_a B_1 (R_1 - B_1^\top Y_a B_1)^{-1} B_1^\top Y_a F_y \\ &= F_y^\top (Y_a + Y_a B_1 (R_1 - B_1^\top Y_a B_1)^{-1} B_1^\top Y_a) F_y. \end{aligned} \tag{4.3}$$

Since $\gamma \in \mathcal{G}_r$, Y_a, R_1 and $(R_1 - B_1^\top Y_a B_1)$ are nonsingular so that $Y_a + Y_a B_1 (R_1 - B_1^\top Y_a B_1)^{-1} B_1^\top Y_a$ is such. Moreover, F_y is nonsingular so that the left-hand side of (4.3) is nonsingular and the same procedure that led to (2.67a) gives

$$Y_a^{-1} = F_y Y_a^{-1} F_y^\top - F_y Y_a^{-1} H_0^\top (J_1 + H_0 Y_a^{-1} H_0^\top)^{-1} H_0 Y_a^{-1} F_y^\top + B_1 R_1^{-1} B_1^\top, \tag{4.4}$$

which, taking (4.2) into account, yields, after some standard manipulations [15, p. 271]

$$\Delta_s = A \Delta_s A^\top + B B^\top - (A \Delta_s H_0^\top + B J_0^\top)(J_1 + H_0 \Delta_s H_0^\top)^{-1} (H_0 \Delta_s A^\top + J_0 B^\top). \tag{4.5}$$

It remains to show that

$$\Gamma_s := A - (A \Delta_s H_0^\top + B J_0^\top)(J_1 + H_0 \Delta_s H_0^\top)^{-1} H_0 = F_y - F_y \Delta_s H_0^\top (J_1 + H_0 \Delta_s H_0^\top)^{-1} H_0 \tag{4.6}$$

is stable. To this aim we rewrite (4.4) in the form

$$Y_a^{-1} - B_1 R_1^{-1} B_1^\top = \Gamma_s Y_a^{-1} F_y^\top, \tag{4.7}$$

which, taking (2.82) into account, yields

$$I = \Gamma_s Y_a^{-1} F_y^\top (Y_a^{-1} - B_1 R_1^{-1} B_1^\top)^{-1} = \Gamma_s Y_a^{-1} \Gamma_y^\top Y_a, \tag{4.8}$$

so that, since Γ_y is antistable, Γ_s is stable. □

Remark 4.1. It is worth noticing that the computation of the stabilizing solution of the Riccati equation (1.14) can be numerically obtained by resorting to standard routines available in most control packages without the need of computing the solution the auxiliary Riccati equations (2.1) and (2.43). Indeed, those Riccati equations were only instrumental to the purpose of proving the existence of the stabilizing solution of (1.14).

5. Construction of the minimum phase J-spectral factor and $\mathcal{H}_\infty$ estimator design. The following important theorem gives a constructive procedure to obtain, from the solution Δ_s, a minimum-phase J-spectral factor of $\Psi(z)$ having a realization with the same state matrix A and the same output matrix H_0 of the realization (1.9) of $H(z)$.

THEOREM 5.1. *Let*

$$\gamma \in \mathcal{G}_r \tag{5.1}$$

and let Δ_s be the corresponding stabilizing solution of equation (1.14). *Then,*

1. *The solution Δ_s is feasible, i.e., $J_1 + H_0 \Delta_s H_0^\top$ has the same inertia of $J_{p,l}(\gamma)$ and hence there exists a nonsingular matrix Λ such that*

$$\Lambda J_{p,l}(\gamma) \Lambda^\top = J_1 + H_0 \Delta_s H_0^\top. \tag{5.2}$$

2. *The transfer matrix*

$$\Omega_s(z) := H_0(zI - A)^{-1}(A\Delta_s H_0^\top + BJ_0^\top)(J_1 + H_0\Delta_s H_0^\top)^{-1}\Lambda + \Lambda \tag{5.3}$$

is a square J-spectral factor of the J-spectral density $\Psi(z)$.

3. *All the zeros of $\Omega_s(z)$ lay in the open unit disk, i.e., $\Omega_s(z)^{-1}$ is stable.*

Proof. The proof of this theorem may be obtained following the same lines of Theorem 4.1 in [4]. □

We recall from [3] that there is a simple procedure that, from $\Omega_s(z)$, furnishes a realization of an $\mathcal{H}_\infty$ smoothing filter with attenuation level γ.

6. The critical values of γ: A peculiar feature of the J-spectral factorization. In this section, we analyze the ARE (1.14) and the associated J-spectral factorization problem in the case when $\gamma \in \mathcal{G}_s := \mathcal{G}_1 \cup \mathcal{G}_2$. To this aim we write the set $\mathcal{G}_s$ as the union of disjoint sets $\mathcal{G}_s = \mathcal{G}_1' \cup \mathcal{G}_2$ with $\mathcal{G}_1' := \mathcal{G}_1 \cap \overline{\mathcal{G}_2}$ (usually $\mathcal{G}_1' = \mathcal{G}_1$) and we consider the cases $\gamma \in \mathcal{G}_1'$ and $\gamma \in \mathcal{G}_2$ separately.

For $\gamma \in \mathcal{G}_1'$, $Y_a(\gamma)$ is still nonsingular and we can define $\Delta_s := Y_a(\gamma)^{-1}$. In all the manifold examples that we have worked out, it turns out that, even for $\gamma \in \mathcal{G}_1'$, Δ_s defined in this way continues to be the stabilizing solution of (1.14). This leads us to conjecture that Theorem 4.1 holds (possibly with the Moore–Penrose pseudoinverse in place of the inverse in the ARE (1.14)) for all $\gamma \in \mathcal{G}_r \cup \mathcal{G}_1'$. In view of continutity, to prove this generalization it would be sufficient to show that for $\gamma \in \mathcal{G}_1'$, $(J_1 + H_0\Delta_s H_0^\top)$ is invertible or (using the pseudoinverse in place of the inverse) that $(A\Delta_s H_0^\top + BJ_0^\top)(J_1 + H_0\Delta_s H_0^\top)^\sharp(H_0\Delta_s A^\top + J_0 B^\top)$ is a continuous function of γ for each $\gamma \in \mathcal{G}_1'$.

Much more interesting is the behavior associated with $\gamma \in \mathcal{G}_2$. In this case, as shown in the following example, the ARE does not admit a stabilizing solution nor does the J-spectral density admit a minimum phase J-spectral factor having a realization with state matrix equal to A. This is a peculiar (and in the authors' opinion, rather counterintuitive) feature of the J-spectral factorization. In fact, in the standard (positive) spectral factorization this phenomenon cannot occur.

Let us consider the following very simple example: $A = 2$, $C = L = 1$, $B = [1 \mid 0]$, $D = [0 \mid 1]$, and $M = [0 \mid 0]$. In this case $W(z)$ defined in (1.20) is given by

$$W(z) = \frac{1}{2(3 - z - z^{-1})} \tag{6.1}$$

so that

$$\gamma_0^2 = \sup_{\vartheta} \left| \frac{1}{2(3 - 2\cos(\vartheta))} \right| = \frac{1}{2}. \tag{6.2}$$

Moreover, the stabilizing solution of the ARE (2.1) is easily computed to be $P_s = 2 + \sqrt{5}$ and the ARE (2.43) assumes the form

$$X^2 + \left(\frac{3 + \sqrt{5} - \gamma^2(10 + 6\sqrt{5})}{4} \right) X + \gamma^2 \left(\frac{3 + \sqrt{5}}{4} \right) = 0, \tag{6.3}$$

whose stabilizing solution $X_s(\gamma)$ equals P_s for $\gamma = 1$. Moreover, $X_s(\gamma) > P_s$ for $\gamma > 1$ and $X_s(\gamma) < P_s$ for $\gamma < 1$. Thus, in this case, $\mathcal{G}_2 = \{1\}$. The ARE (1.14) assumes the form

$$3\Delta + 1 - \frac{4\Delta^2}{\Delta(1 - \gamma^2) - \gamma^2}(1 - \gamma^2) = 0. \tag{6.4}$$

For $\gamma < 1$, (6.4) admits a negative stabilizing solution Δ_s that tends to $-\infty$ as $\gamma \to 1_-$. For $\gamma > 1$, (6.4) admits a positive stabilizing solution Δ_s that tends to $+\infty$ as $\gamma \to 1_+$.

For $\gamma = 1$, the order of such equation collapses and the stabilizing solution does not exist any more: the only solution is $\Delta_a = -1/3$ and the corresponding closed-loop matrix is $A - 0 = A = 2$. Notice that $\Delta_a = -1/3$ is feasible. In fact

$$J_1 + H_0 \Delta_a H_0^\top = \frac{1}{3} \begin{bmatrix} 2 & -1 \\ -1 & -4 \end{bmatrix} \tag{6.5}$$

has a positive and a negative eigenvalue so that there exists a matrix Λ such that[4]

$$J_1 + H_0 \Delta_a H_0^\top = \Lambda J_{1,1}(1) \Lambda^\top. \tag{6.6}$$

The same computation used in the proof of Theorem 5.1 shows that

$$\begin{aligned} \Omega_a(z) &:= H_0(zI - A)^{-1}(A\Delta_a H_0^\top + B J_0^\top)(J_1 + H_0 \Delta_a H_0^\top)^{-1}\Lambda + \Lambda \\ &= \begin{bmatrix} 1 \\ 1 \end{bmatrix} (z-2)^{-1} \left[-\frac{2}{3} \mid \frac{2}{3} \right] \Lambda + \Lambda \end{aligned} \tag{6.7}$$

is a J-spectral factor of the J-spectrum $\Psi(z)$ that, in this case, is given by

$$\Psi(z) = \begin{bmatrix} \frac{1}{(z-2)(z^{-1}-2)} + 1 & \frac{1}{(z-2)(z^{-1}-2)} \\ \frac{1}{(z-2)(z^{-1}-2)} & \frac{1}{(z-2)(z^{-1}-2)} - 1 \end{bmatrix}. \tag{6.8}$$

The numerator matrix of $\Omega_a(z)$ is $2 - \left[-\frac{2}{3} \mid \frac{2}{3} \right] \Lambda\Lambda^{-1} \left[\begin{smallmatrix} 1 \\ 1 \end{smallmatrix} \right] = 2$: the unique zero of $\Omega_a(z)$ lies outside the closed unit disk. (Such an $\Omega_a(z)$ is said to be a *maximum phase* J-spectral factor.) The set of all J-spectral factors of $\Psi(z)$ having a realization with state matrix $A = 2$ may be obtained as follows. We set

$$\Omega(z) = \begin{bmatrix} h_1 \\ h_2 \end{bmatrix} (z-2)^{-1} [g_1 \mid g_2] + \begin{bmatrix} d_{11} & d_{12} \\ d_{21} & d_{22} \end{bmatrix} \tag{6.9}$$

and impose

$$\Omega(z) J_{1,1}(1) \widetilde{\Omega}(z) = \Psi(z). \tag{6.10}$$

The corresponding solutions, up to a noninteresting change of basis in the state space, may be parametrizied as follows:

$$\Omega(z) = \begin{bmatrix} 1 \\ 1 \end{bmatrix} (z-2)^{-1} [g \mid \pm g] + \begin{bmatrix} \frac{-2-3\,g^2}{6\,g} & \pm\frac{2-3\,g^2}{6\,g} \\ \frac{-1+3\,g^2}{3\,g} & \pm\frac{1+3\,g^2}{3\,g} \end{bmatrix}, \qquad g \in \mathbb{R} \setminus \{0\}, \tag{6.11}$$

which is readily seen to be equal to the right-hand side of (6.7) as Λ varies among the solutions of (6.6). In conclusion, we have produced a maximum-phase J-spectral

[4]The set of solutions of (6.6) may be parametrized as

$$\Lambda = \begin{bmatrix} \frac{-2-3\,g^2}{6\,g} & \pm\frac{2-3\,g^2}{6\,g} \\ \frac{-1+3\,g^2}{3\,g} & \pm\frac{1+3\,g^2}{3\,g} \end{bmatrix}, g \in \mathbb{R} \setminus \{0\}$$

(where the $\pm$ signs are either both $+$ or both $-$).

factor and have shown that the corresponding minimum-phase one (i.e., a minimum-phase J-spectral factor having a realization with the same state-space matrix) does not exist. This is a very peculiar behavior that has no counterpart in the regular spectral factorization.

Notice that to obtain (6.11) we have imposed the McMillan degree[5] of $\Omega(z)$ to be equal to 1 or, equivalently, we have restricted our search to *minimal* J-spectral factors, namely, J-spectral factors having the last possible McMillan degree. (Such McMillan degree is clearly equal to one-half of the McMillan degree of the J-spectrum $\Psi(z)$.) See [16] for a discussion on the minimality of spectral factors. It is interesting to observe that extending the search to nonminimal J-spectral factors (i.e., J-spectral factors having larger McMillan degree), a minimum-phase J-spectral factor having a unique pole in $z = 2$ does exist. Indeed, it is not difficult to check that

$$\Omega_m(z) = (zI_2 - 2I_2)^{-1} \begin{bmatrix} \frac{-11}{2\sqrt{2}} & \frac{-3}{2\sqrt{2}} \\ -\frac{1}{\sqrt{2}} & \frac{3}{\sqrt{2}} \end{bmatrix} + \begin{bmatrix} \frac{-5\sqrt{2}}{3} & \frac{-\sqrt{2}}{3} \\ \frac{-1}{3\sqrt{2}} & \frac{7}{3\sqrt{2}} \end{bmatrix} \tag{6.12}$$

is a minimal realization of a J-spectral factor of $\Psi(z)$. As $H(z)$, $\Omega_m(z)$ has a unique pole in $z = 2$ and the corresponding numerator matrix

$$2I_2 - \begin{bmatrix} \frac{-11}{2\sqrt{2}} & \frac{-3}{2\sqrt{2}} \\ -\frac{1}{\sqrt{2}} & \frac{3}{\sqrt{2}} \end{bmatrix} \begin{bmatrix} \frac{-5\sqrt{2}}{3} & \frac{-\sqrt{2}}{3} \\ \frac{-1}{3\sqrt{2}} & \frac{7}{3\sqrt{2}} \end{bmatrix}^{-1} = \begin{bmatrix} \frac{1}{3} & \frac{1}{6} \\ -\frac{1}{6} & \frac{2}{3} \end{bmatrix} \tag{6.13}$$

has a unique eigenvalue (of multiplicity 2) in $z = 1/2$. Again, this fact has no counterpart in classical spectral factorization.

Eventually, notice that these discrepancies between J-spectral factorization and classical spectral factorization are associated to very particular J-spectra. In fact they may occur only for a finite number of values of γ.

6.1. Example with $\gamma \in \mathcal{G}_r$. In the following we consider the previous example in the case when $\gamma_0 < \gamma < \gamma_f$ and $\gamma \in \mathcal{G}_r$. We design a smoothing filter starting from the stabilizing solution Δ_s of (1.14). Let $\gamma^2 = 3/4$. The stabilizing solution Δ_s is then given by $-4 - \sqrt{13}$ and the corresponding J-spectral factor is given by

$$\Omega_s(z) = \left[\begin{array}{c} 1 \\ 1 \end{array}\right] (z-2)^{-1} \left[\begin{array}{c|c} 2.942 & 6.374 \end{array}\right] + \begin{bmatrix} -0.3124 & 2.99 \\ 0.2785 & 3.353 \end{bmatrix}. \tag{6.14}$$

From $\Omega_s(z)$, by following the procedure described in [3], we easily get the following transfer function of a 1-step lag smoother,

$$S_1(z) = z[0.2063(z - 0.02824)^{-1}2.958 + 0.1906], \tag{6.15}$$

and it is easy to check that

$$\|S_1(z)H_1(z) - H_2(z)\| = 0.8383 < \gamma \simeq 0.8660. \tag{6.16}$$

7. Conclusions. In this paper a general J-spectral factorization problem was considered and its relation with the existence of the stabilizing solution of the associated Riccati equation was investigated. The stabilizing solution depends on a positive

[5]We recall that the *McMillan degree* of a rational proper matrix function $P(z)$ is the state-space dimension of a minimal realization of $P(z)$; see [14] for more details.

parameter which represents the prescribed attenuation level for the underlying estimation problem. We have shown that the stabilizing solution of the ARE still exists (except for a finite number of values of γ) as long as a fixed-lag acausal estimator (smoother) does. A few aspects of the J-spectral factorization problem and the properties of its solutions are discussed in correspondence to the (finite number of) values of γ for which the stabilizing solution of the ARE does not exist.

SOME CONTROLLABILITY RESULTS FOR THE N-DIMENSIONAL NAVIER–STOKES AND BOUSSINESQ SYSTEMS WITH $N-1$ SCALAR CONTROLS*

ENRIQUE FERNÁNDEZ-CARA†, SERGIO GUERRERO†, OLEG YU. IMANUVILOV‡, AND JEAN-PIERRE PUEL§

Abstract. In this paper we deal with some controllability problems for systems of the Navier–Stokes and Boussinesq kind with distributed controls supported in small sets. Our main aim is to control N-dimensional systems ($N+1$ scalar unknowns in the case of the Navier–Stokes equations) with $N-1$ scalar control functions. In a first step, we present some global Carleman estimates for suitable adjoint problems of linearized Navier–Stokes and Boussinesq systems. In this way, we obtain null controllability properties for these systems. Then, we deduce results concerning the local exact controllability to the trajectories. We also present (global) null controllability results for some (truncated) approximations of the Navier–Stokes equations.

Key words. Navier–Stokes system, exact controllability, Carleman inequalities

1. Introduction and examples.

Let $\Omega \subset \mathbf{R}^N$ ($N = 2$ or 3) be a bounded connected open set whose boundary $\partial\Omega$ is regular enough (for instance of class C^2). Let $\mathcal{O} \subset \Omega$ be a (small) nonempty open subset and let $T > 0$. We will use the notation $Q = \Omega \times (0,T)$ and $\Sigma = \partial\Omega \times (0,T)$ and we will denote by $n(x)$ the outward unit normal to Ω at the point $x \in \partial\Omega$.

On the other hand, we will denote by C, C_1, C_2, ... various positive constants (usually depending on Ω and $\mathcal{O}$).

We will be concerned with the following controlled Navier–Stokes and Boussinesq systems:

$$\begin{cases} y_t - \Delta y + (y\cdot\nabla)y + \nabla p = v1_{\mathcal{O}}, \quad \nabla\cdot y = 0 & \text{in } Q,\\ y = 0 & \text{on } \Sigma,\\ y(0) = y^0 & \text{in } \Omega \end{cases} \tag{1}$$

and

$$\begin{cases} y_t - \Delta y + (y\cdot\nabla)y + \nabla p = v1_{\mathcal{O}} + \theta\, e_N, \quad \nabla\cdot y = 0 & \text{in } Q,\\ \theta_t - \Delta\theta + y\cdot\nabla\theta = h1_{\mathcal{O}} & \text{in } Q,\\ y = 0, \quad \theta = 0 & \text{on } \Sigma,\\ y(0) = y^0, \quad \theta(0) = \theta^0 & \text{in } \Omega \end{cases} \tag{2}$$

(in both dimensions $N = 2$ and $N = 3$).

For $N=2$, we will also consider the following approximation of the Navier–Stokes system with boundary conditions of the Navier kind:

$$\begin{cases} y_t - \Delta y + (y\cdot\nabla)\mathbf{T}_M(y) + \nabla p = v1_{\mathcal{O}}, \quad \nabla\cdot y = 0 & \text{in } Q,\\ y\cdot n = 0, \quad \nabla\times y = 0 & \text{on } \Sigma,\\ y(0) = y^0 & \text{in } \Omega, \end{cases} \tag{3}$$

where $M>0$, $\mathbf{T}_M(y) = (T_M(y_1), T_M(y_2))$ and T_M is given by

$$T_M(s) = \begin{cases} -M & \text{if } s \le -M,\\ s & \text{if } -M \le s \le M,\\ M & \text{if } s \ge M. \end{cases}$$

In systems (1), (2) and (3), $v = v(x,t)$ and $h = h(x,t)$ stand for the control functions. They act during the whole time interval $(0,T)$ over the set $\mathcal{O}$. The symbol $1_{\mathcal{O}}$ stands for the characteristic function of $\mathcal{O}$ and e_N is the Nth vector of the canonical basis of $\mathbf{R}^N$.

The controllability of Navier–Stokes systems has been the objective of considerable work over the last years. Up to our knowledge, the strongest results have been given in [7], where a strategy based on the methods in [13] and [14] has been followed. Recently, the techniques in [7] have been adapted in [12] to cover Boussinesq systems (see also [3], [4], [8] and [10] for other results).

This paper can be viewed as a continuation of [7]. We will present some new results which show that the N-dimensional systems (1) and (2) can be controlled, at least under some geometrical assumptions, with only $N-1$ scalar controls in $L^2(\mathcal{O}\times(0,T))$. In particular, the Boussinesq system (2) in dimension $N=2$ can be controlled by an action performed only on the temperature equation. We will also prove that the two-dimensional system (3) can be controlled with controls of the form $v1_{\mathcal{O}}$ where v is the curl of a function in $L^2(0,T;H^1(\mathcal{O}))$.

In this paper, we will have to impose some regularity assumptions on the initial data. To this purpose, we introduce the spaces H, E and V, with

$$H = \{w \in L^2(\Omega)^N : \nabla\cdot w = 0 \text{ in } \Omega,\ w\cdot n = 0 \text{ on } \partial\Omega\}, \tag{4}$$

$$E = \begin{cases} H & \text{if } N=2,\\ L^4(\Omega)^3 \cap H & \text{if } N=3 \end{cases}$$

and

$$V = \{w \in H_0^1(\Omega)^N : \nabla\cdot w = 0 \text{ in } \Omega\}.$$

For system (1), we will assume that the control region $\mathcal{O}$ is adjacent to the boundary $\partial\Omega$ (see assumption (11) below) and we will deal with the *local exact controllability to the trajectories*. More precisely, our task will be to prove that, for any bounded and sufficiently regular solution $(\overline{y},\overline{p})$ of the uncontrolled Navier–Stokes equations

$$\begin{cases} \overline{y}_t - \Delta\overline{y} + (\overline{y}\cdot\nabla)\overline{y} + \nabla\overline{p} = 0, \quad \nabla\cdot\overline{y} = 0 & \text{in } Q,\\ \overline{y} = 0 & \text{on } \Sigma,\\ \overline{y}(0) = \overline{y}^0 & \text{in } \Omega, \end{cases} \tag{5}$$

there exists $\delta > 0$ such that, whenever $y^0 \in E$ and

$$\|y^0 - \overline{y}^0\|_E \leq \delta,$$

we can find L^2 controls v with $v_k \equiv 0$ for at least one k and associated states (y, p) satisfying

$$y(T) = \overline{y}(T) \text{ in } \Omega. \tag{6}$$

Notice that, under these circumstances, after time $t = T$ we can switch off the control and let the system follow the "ideal" trajectory $(\overline{y}, \overline{p})$.

For the Boussinesq system (2), we will assume that $\mathcal{O}$ is adjacent to $\partial\Omega$ near a point x^0 such that $n_k(x^0) \neq 0$ for some $k < N$. We will also be concerned with the local exact controllability to the trajectories. Now, a trajectory is a bounded and sufficiently regular solution $(\overline{y}, \overline{p}, \overline{\theta})$ of

$$\begin{cases} \overline{y}_t - \Delta\overline{y} + (\overline{y} \cdot \nabla)\overline{y} + \nabla\overline{p} = \overline{\theta}\, e_N, \quad \nabla \cdot \overline{y} = 0 & \text{in } Q, \\ \overline{\theta}_t - \Delta\overline{\theta} + \overline{y} \cdot \nabla\overline{\theta} = 0 & \text{in } Q, \\ \overline{y} = 0, \quad \overline{\theta} = 0 & \text{on } \Sigma, \\ \overline{y}(0) = \overline{y}^0, \quad \overline{\theta}(0) = \overline{\theta}^0 & \text{in } \Omega. \end{cases} \tag{7}$$

The goal will be to prove that there exists $\delta > 0$ such that, whenever $(y^0, \theta^0) \in E \times L^2(\Omega)$ and

$$\|(y^0, \theta^0) - (\overline{y}^0, \overline{\theta}^0)\|_{E \times L^2} \leq \delta,$$

we can find L^2 controls v and h with $v_k \equiv v_N \equiv 0$ and associated states (y, p, θ) satisfying

$$y(T) = \overline{y}(T) \text{ and } \theta(T) = \overline{\theta}(T) \text{ in } \Omega. \tag{8}$$

In this context, the results established in [12] will be fundamental.

Notice that, in particular, when $N = 2$, we try to control the whole system (2) with just one scalar control h.

As far as (3) is concerned, our goal will be to prove the *(global) null controllability*. That is to say, for each $y^0 \in H$, we will try to find controls of the form $v1_{\mathcal{O}}$, where v belongs to the Hilbert space

$$W = \{\nabla \times z = (\partial_2 z, -\partial_1 z) : z \in L^2(0, T; H^1(\mathcal{O}))\}, \tag{9}$$

such that the associated solutions (y, p) satisfy

$$y(T) = 0 \text{ in } \Omega. \tag{10}$$

Approximate controllability results have been established for analogous systems in [4].

Observe that in this system the boundary conditions are of the Navier kind as in [3] (for their physical meaning, see, for instance, [11]). This and the fact that $N = 2$ will be essential in the arguments presented below.

Similarly to the previous situation, an extension by zero of the control after time $t = T$ will keep (y, p) at rest.

As mentioned above, some hypotheses will be imposed on the control domain and the trajectories. More precisely, we will frequently assume that

$$\exists x^0 \in \partial\Omega,\ \exists \varepsilon > 0 \text{ such that } \overline{\mathcal{O}} \cap \partial\Omega \supset B(x^0;\varepsilon) \cap \partial\Omega \tag{11}$$

($B(x^0;\varepsilon)$ is the ball centered at x^0 of radius ε),

$$\overline{y} \in L^\infty(Q)^N, \quad \overline{y}_t \in L^2(0,T;L^\sigma(\Omega)^N) \quad \begin{pmatrix} \sigma > 1 & \text{if } N = 2 \\ \sigma > 6/5 & \text{if } N = 3 \end{pmatrix} \tag{12}$$

and

$$\overline{\theta} \in L^\infty(Q), \quad \overline{\theta}_t \in L^2(0,T;L^\sigma(\Omega)) \quad \begin{pmatrix} \sigma > 1 & \text{if } N = 2 \\ \sigma > 6/5 & \text{if } N = 3 \end{pmatrix}. \tag{13}$$

Let us now present our main results in a precise form. The first one concerns the local exact controllability to the trajectories of system (1).

THEOREM 1. *Assume that $\mathcal{O}$ satisfies* (11). *Then, for any $T > 0$,* (1) *is locally exactly controllable at time T to the trajectories $(\overline{y}, \overline{p})$ satisfying* (12) *with controls $v \in L^2(\mathcal{O} \times (0,T))^N$ having one component identically zero.*

The second main result concerns the controllability of (2).

THEOREM 2. *Assume that $\mathcal{O}$ satisfies* (11) *with $n_k(x^0) \neq 0$ for some $k < N$. Then, for any $T > 0$,* (2) *is locally exactly controllable at time T to the trajectories $(\overline{y}, \overline{p}, \overline{\theta})$ satisfying* (12)–(13) *with L^2 controls v and h such that $v_k \equiv v_N \equiv 0$. In particular, if $N = 2$, we have local exact controllability to the trajectories with controls $v \equiv 0$ and $h \in L^2(\mathcal{O} \times (0,T))$.*

The last main result we present in this paper follows in Theorem 3.

THEOREM 3. *Let $N = 2$. Then, for any $T > 0$ and any $M > 0$,* (3) *is null controllable at time T with controls of the form $v1_{\mathcal{O}}$, where $v \in W$.*

For the proofs of these results, following a standard approach, we will first deduce null controllability results for suitable linearized versions of (1), (2) and (3), namely,

$$\begin{cases} y_t - \Delta y + (\overline{y} \cdot \nabla) y + (y \cdot \nabla)\overline{y} + \nabla p = f + v1_{\mathcal{O}}, \quad \nabla \cdot y = 0 & \text{in } Q, \\ y = 0 & \text{on } \Sigma, \\ y(0) = y^0 & \text{in } \Omega, \end{cases} \tag{14}$$

$$\begin{cases} y_t - \Delta y + (\overline{y} \cdot \nabla) y + (y \cdot \nabla)\overline{y} + \nabla p = f + v1_{\mathcal{O}} + \theta\, e_N & \text{in } Q, \\ \nabla \cdot y = 0 & \text{in } Q, \\ \theta_t - \Delta\theta + \overline{y} \cdot \nabla\theta + y \cdot \nabla\overline{\theta} = k + h1_{\mathcal{O}} & \text{in } Q, \\ y = 0, \quad \theta = 0 & \text{on } \Sigma, \\ y(0) = y^0, \quad \theta(0) = \theta^0 & \text{in } \Omega \end{cases} \tag{15}$$

and

$$\begin{cases} y_t - \Delta y + (y \cdot \nabla)\overline{y} + \nabla p = v1_{\mathcal{O}}, \quad \nabla \cdot y = 0 & \text{in } Q, \\ y \cdot n = 0, \quad \nabla \times y = 0 & \text{on } \Sigma, \\ y(0) = y^0 & \text{in } \Omega. \end{cases} \tag{16}$$

Then, appropriate arguments will be used to deduce the controllability of the nonlinear systems (1)–(3).

Remark 1. When $N = 3$, it is very natural to ask whether a result similar to Theorem 1 holds with controls having two zero components. In general, the answer is no. In fact, it seems difficult to identify the open sets Ω and $\mathcal{O}$ such that one has null controllability for all $T > 0$ with controls of this kind. This is unknown even for the classical Stokes equations for which, up to now, the only known results concern *approximate controllability*; see [16].

Remark 2. Assume that $N = 2$. The arguments in [7] implicitly show that, under hypotheses (12), we can find controls $v1_{\mathcal{O}}$ with $v \in W$ such that the associated solutions to (1) satisfy $y(T) = \overline{y}(T)$. Observe that the assumption (11) on the control domain is not necessary here.

This paper is organized as follows. We will first establish all the technical results needed in this work in section 2. Section 3 will deal with null controllability results for the linear control systems (14)–(16). Finally, the proofs of Theorems 1, 2 and 3 will be given in section 4.

2. Some previous results. In this section we will establish all the technical results needed in this paper. More precisely, we will present and prove the required *Carleman estimates* for the backward systems (19), (20) and (21), given below.

To do this, let us first introduce some weight functions:

$$\alpha(x,t) = \frac{e^{5/4\lambda m\|\eta^0\|_\infty} - e^{\lambda(m\|\eta^0\|_\infty + \eta^0(x))}}{t^4(T-t)^4},$$

$$\xi(x,t) = \frac{e^{\lambda(m\|\eta^0\|_\infty + \eta^0(x))}}{t^4(T-t)^4},$$

$$\widehat{\alpha}(t) = \min_{x\in\overline{\Omega}} \alpha(x,t) = \frac{e^{5/4\lambda m\|\eta^0\|_\infty} - e^{\lambda(m+1)\,\|\eta^0\|_\infty}}{t^4(T-t)^4}, \tag{17}$$

$$\alpha^*(t) = \max_{x\in\overline{\Omega}} \alpha(x,t) = \frac{e^{5/4\lambda m\|\eta^0\|_\infty} - e^{\lambda m\|\eta^0\|_\infty}}{t^4(T-t)^4},$$

$$\widehat{\xi}(t) = \max_{x\in\overline{\Omega}} \xi(x,t) = \frac{e^{\lambda(m+1)\|\eta^0\|_\infty}}{t^4(T-t)^4}, \quad \xi^*(t) = \min_{x\in\overline{\Omega}} \xi(x,t) = \frac{e^{\lambda m\|\eta^0\|_\infty}}{t^4(T-t)^4},$$

where $m > 4$ is a fixed real number. Here, η^0 is a function verifying

$$\eta^0 \in C^2(\overline{\Omega}), \quad |\nabla\eta^0| > 0 \text{ in } \overline{\Omega\setminus\mathcal{O}_0}, \quad \eta^0 > 0 \text{ in } \Omega \text{ and } \eta^0 \equiv 0 \text{ on } \partial\Omega \tag{18}$$

with $\mathcal{O}_0$ a nonempty open subset of $\mathcal{O}$ that will be determined below. For any $\mathcal{O}_0$, the existence of such a function η^0 is proved in [9]. Note that these weights have already been used in [7] and [12].

We will be dealing in this section with the adjoint systems to (14) and (15), that is to say,

$$\begin{cases} -\varphi_t - \Delta\varphi - (D\varphi)\,\overline{y} + \nabla\pi = g, \quad \nabla\cdot\varphi = 0 & \text{in } Q, \\ \varphi = 0 & \text{on } \Sigma, \\ \varphi(T) = \varphi^0 & \text{in } \Omega \end{cases} \tag{19}$$

and

$$
(20)\qquad \begin{cases} -\varphi_t - \Delta\varphi - (D\varphi)\,\overline{y} + \nabla\pi = g + \overline{\theta}\,\nabla\psi, \quad \nabla\cdot\varphi = 0 & \text{in } Q,\\ -\psi_t - \Delta\psi - \overline{y}\cdot\nabla\psi = q + \varphi_N & \text{in } Q,\\ \varphi = 0, \quad \psi = 0 & \text{on } \Sigma,\\ \varphi(T) = \varphi^0, \quad \psi(T) = \psi^0 & \text{in } \Omega \end{cases}
$$

(where $D\varphi = \nabla\varphi + \nabla\varphi^t$) as well as with the adjoint system of $\omega := \nabla\times y$ (where y is the solution of (16)), which is

$$
(21)\qquad \begin{cases} -\rho_t - \Delta\rho - \nabla\times((\overline{y}\cdot\nabla\times)\nabla\gamma) = 0, \quad \Delta\gamma = \rho & \text{in } Q,\\ \gamma = 0, \quad \rho = 0 & \text{on } \Sigma,\\ \rho(T) = \rho^0 & \text{in } \Omega. \end{cases}
$$

Here, $g \in L^2(Q)^N$, $q \in L^2(Q)$, $\varphi^0 \in H$, $\psi^0 \in L^2(\Omega)$ and $\rho^0 \in H^{-1}(\Omega)$ (of course, φ_N stands for the last component of the vector field φ).

2.1. New Carleman estimates for system (19). We will establish some new Carleman estimates for the solutions of (19). We will assume that $\mathcal{O}$ and $\overline{y}$ satisfy (11)–(12). To fix ideas, we will also assume for the moment that $N = 3$ and $n_1(x^0) \neq 0$ (x^0 appears in assumption (11)).

The desired Carleman inequalities will have the form

$$
I(\varphi) \le C\left(\iint_Q \rho_1^2\,|g|^2\,dx\,dt + \iint_{\mathcal{O}\times(0,T)} \rho_2^2\left(|\varphi_2|^2 + |\varphi_3|^2\right)\,dx\,dt\right),
$$

where $I(\varphi)$ contains global weighted integrals of $|\varphi|^2$, $|\nabla\varphi|^2$, etc. and ρ_1 and ρ_2 are appropriate weights that vanish exponentially as $t \to T$. This will suffice to prove in section 3 the null controllability of (14) with controls $v1_{\mathcal{O}}$ satisfying $v_1 \equiv 0$.

LEMMA 1. *Assume that $N = 3$, $n_1(x^0) \neq 0$ and $\mathcal{O}$ and $\overline{y}$ verify* (11)–(12). *Then there exists a positive constant C such that, for any $g \in L^2(Q)^3$ and any $\varphi^0 \in H$, the associated solution to* (19) *satisfies:*

$$
(22)\qquad \begin{cases} I(\varphi) := \displaystyle\iint_Q e^{\frac{-2\overline{\alpha}}{t^4(T-t)^4}}\,t^{-12}(T-t)^{-12}\,|\varphi|^2\,dx\,dt\\ \qquad + \displaystyle\iint_Q e^{\frac{-2\overline{\alpha}}{t^4(T-t)^4}}\,t^{-4}(T-t)^{-4}\,|\nabla\varphi|^2)\,dx\,dt\\ \qquad + \displaystyle\iint_Q e^{\frac{-2\overline{\alpha}}{t^4(T-t)^4}}\,t^{4}(T-t)^{4}\,\left(|\Delta\varphi|^2 + |\varphi_t|^2\right)\,dx\,dt\\ \qquad \le C\left(\displaystyle\iint_Q e^{\frac{-4\boldsymbol{\alpha}+2\overline{\alpha}}{t^4(T-t)^4}}t^{-30}(T-t)^{-30}\,|g|^2\,dx\,dt\right.\\ \qquad \left. + \displaystyle\iint_{\mathcal{O}\times(0,T)} e^{\frac{-16\boldsymbol{\alpha}+14\overline{\alpha}}{t^4(T-t)^4}}\,t^{-132}(T-t)^{-132}\,(|\varphi_2|^2 + |\varphi_3|^2)\,dx\,dt\right). \end{cases}
$$

Here, $\overline{\alpha}$ and $\widetilde{\alpha}$ are constants only depending on Ω, $\mathcal{O}$, T and $\overline{y}$ satisfying $0 < \widetilde{\alpha} < \overline{\alpha}$ and $8\widetilde{\alpha} - 7\overline{\alpha} > 0$.

Proof. Let us first recall a Carleman inequality for the solutions of (19) which has been proved in [7] whenever (12) is fulfilled:

$$
\begin{aligned}
& s^3\lambda^4 \iint_Q e^{-2s\alpha}\xi^3|\varphi|^2\,dx\,dt + s\lambda^2 \iint_Q e^{-2s\alpha}\xi|\nabla\varphi|^2\,dx\,dt \\
& \quad +s^{-1}\iint_Q e^{-2s\alpha}\xi^{-1}\left(|\varphi_t|^2+|\Delta\varphi|^2\right)dx\,dt \\
& \quad \le C_0(1+T^2)\left(s^{15/2}\lambda^{20}\iint_Q e^{-4sb+2s\alpha^*}\widehat{\xi}^{15/2}|g|^2\,dx\,dt\right. \\
& \quad \left. +s^{16}\lambda^{40}\iint_{\mathcal{O}_0\times(0,T)} e^{-8sb+6s\alpha^*}\widehat{\xi}^{16}|\varphi|^2\,dx\,dt\right).
\end{aligned}
\tag{23}
$$

Here, $s \ge s_0$ and $\lambda \ge \lambda_0$ are arbitrarily large and C_0, s_0 and λ_0 are suitable constants depending on Ω, $\mathcal{O}_0$, T and $\overline{y}$; see Theorem 1 in [7].

Recall that an inequality like (23) had already been proved in [13] using stronger properties on $\overline{y}$ than (12).

It is immediate from (23) that, for some C_1, $\overline{\alpha}$ and $\widetilde{\alpha}$ depending on Ω, $\mathcal{O}_0$, T and $\overline{y}$, we have:

$$
\left\{
\begin{array}{l}
\displaystyle\iint_Q e^{\frac{-2\overline{\alpha}}{t^4(T-t)^4}}\left(t^{-12}(T-t)^{-12}\,|\varphi|^2+t^{-4}(T-t)^{-4}\,|\nabla\varphi|^2\right)dx\,dt \\
\displaystyle\quad +\iint_Q e^{\frac{-2\overline{\alpha}}{t^4(T-t)^4}}\,t^4(T-t)^4\,\left(|\Delta\varphi|^2+|\varphi_t|^2\right)dx\,dt \\
\displaystyle\quad \le C_1\left(\iint_Q e^{\frac{-4b+2\overline{\alpha}}{t^4(T-t)^4}}\,t^{-30}(T-t)^{-30}\,|g|^2\,dx\,dt\right. \\
\displaystyle\quad \left. +\iint_{\mathcal{O}_0\times(0,T)} e^{\frac{-8b+6\overline{\alpha}}{t^4(T-t)^4}}\,t^{-64}(T-t)^{-64}\,|\varphi|^2\,dx\,dt\right).
\end{array}
\right.
\tag{24}
$$

Indeed, it suffices to choose

$$
\left\{
\begin{array}{l}
\overline{\alpha} = s_0\left(e^{5/4\lambda_0 m\|\eta^0\|_\infty}-e^{\lambda_0 m\|\eta^0\|_\infty}\right), \\
\widetilde{\alpha} = s_0\left(e^{5/4\lambda_0 m\|\eta^0\|_\infty}-e^{\lambda_0 (m+1)\|\eta^0\|_\infty}\right)
\end{array}
\right.
\tag{25}
$$

and $C_1 = C_0(1+T^2)s_0^{17}\lambda_0^{40}e^{17\lambda_0(m+1)\|\eta^0\|_\infty}$. Notice that $0<\widetilde{\alpha}<\overline{\alpha}$. Moreover, it can be assumed that $8\widetilde{\alpha}-7\overline{\alpha}>0$ (it suffices to notice that λ_0 is large enough in (25)).

We will apply (24) for the open set $\mathcal{O}_0 \subset \mathcal{O}$ defined as follows. We choose $\kappa>0$ such that

$$
n_1(x) \ne 0 \quad \forall x \in B(x^0;\kappa)\cap\partial\mathcal{O}\cap\partial\Omega
$$

and we denote this set by Γ_κ. Then, we define

$$
\mathcal{O}_0 = \{x\in\Omega : x = w+\tau\,e_1,\ w\in\Gamma_\kappa,\ |\tau|<\tau^0\},
\tag{26}
$$

with $\kappa, \tau^0 > 0$ small enough so that we still have

$$
\mathcal{O}_0 \subset \mathcal{O} \quad \text{and} \quad d_0 := \operatorname{dist}(\overline{\mathcal{O}_0}, \partial\mathcal{O}\cap\Omega) > 0.
\tag{27}
$$

Observe that, with this choice, each $P \in \mathcal{O}_0$ verifies that one of the two points where the straight line $\{P + \mathbf{R}\, e_1\}$ intersects $\partial\Omega$ belongs to $\partial\mathcal{O}_0$.

Once $\mathcal{O}_0$ is defined, we apply inequality (24) in this open set and we try to bound the term

$$\iint_{\mathcal{O}_0\times(0,T)} e^{\frac{-8\mathbf{a}+6\overline{\alpha}}{t^4(T-t)^4}}\, t^{-64}(T-t)^{-64}\,|\varphi_1|^2\,dx\,dt$$

in terms of local integrals of φ_2 and φ_3.

To this end, for each $(x,t) \in \mathcal{O}_0 \times (0,T)$ we denote by $l(x,t)$ (resp., $\widetilde{l}(x,t)$) the segment that starts from (x,t) with direction e_1 in the positive (resp. negative) sense and ends at $\partial\mathcal{O}_0$. Then, since φ is divergence-free, it is not difficult to see that

$$\varphi_1(x,t) = \int_{l(x,t)} (\partial_2\varphi_2 + \partial_3\varphi_3)(y_1, x_2, x_3, t)\,dy_1$$

for each $(x,t) \in \mathcal{O}_0 \times (0,T)$. For simplicity, let us introduce the notation

$$\beta(t) = e^{\frac{-8\mathbf{a}+6\overline{\alpha}}{t^4(T-t)^4}}\, t^{-64}(T-t)^{-64} \quad \forall t \in (0,T).$$

Applying at this point Hölder's inequality and Fubini's formula, we obtain

$$\begin{aligned}
&\iint_{\mathcal{O}_0\times(0,T)} \beta(t)\,|\varphi_1|^2\,dx\,dt \\
&\quad\le C_2 \iint_{\mathcal{O}_0\times(0,T)} \beta(t) \left(\int_{l(x,t)} (|\partial_2\varphi_2|^2 + |\partial_3\varphi_3|^2)\,dy_1\right) dx\,dt \\
&\quad= C_2 \iint_{\mathcal{O}_0\times(0,T)} (|\partial_2\varphi_2|^2 + |\partial_3\varphi_3|^2) \left(\int_{\widetilde{l}(y_1)} \beta(t)\,dx_1\right) dy_1\,dx_2\,dx_3\,dt \\
&\quad\le C_3 \iint_{\mathcal{O}_0\times(0,T)} \beta(t)(|\partial_2\varphi_2|^2 + |\partial_3\varphi_3|^2)\,dx\,dt,
\end{aligned} \tag{28}$$

where $\widetilde{l}(y_1)$ stands for the segment $\widetilde{l}(y_1, x_2, x_3, t)$. Then, we introduce a function $\zeta \in C^2(\overline{\mathcal{O}})$ such that

$$\zeta \equiv 1 \text{ in } \mathcal{O}_0, \quad 0 \le \zeta \le 1$$

and $\zeta(x) = 0$ at any point $x \in \mathcal{O}$ satisfying $\operatorname{dist}(x, \partial\mathcal{O} \cap \Omega) \le d_0/2$ (d_0 was defined in (27)). This and the fact that $\varphi|_\Sigma \equiv 0$ imply

$$\begin{aligned}
\iint_{\mathcal{O}_0\times(0,T)} \beta(t)\,|\partial_i\varphi_i|^2\,dx\,dt &\le \iint_{\mathcal{O}\times(0,T)} \zeta\,\beta(t)\,|\partial_i\varphi_i|^2\,dx\,dt \\
&= \frac{1}{2}\iint_{\mathcal{O}\times(0,T)} \partial_{ii}^2\zeta\,\beta(t)\,|\varphi_i|^2\,dx\,dt - \iint_{\mathcal{O}\times(0,T)} \zeta\,\beta(t)\,\partial_{ii}^2\varphi_i\,\varphi_i\,dx\,dt
\end{aligned}$$

for $i = 2, 3$. Finally, in view of Young's inequality and regularity estimates for φ_i in

Ω ($\varphi_i \in H^2(\Omega)$ and $\|\varphi_i\|_{H^2} \leq C\|\Delta\varphi_i\|_{L^2}$), we also have:

$$\begin{aligned}
&\iint_{\mathcal{O}_0\times(0,T)} \beta(t)\,|\partial_i\varphi_i|^2\,dx\,dt \\
&\leq C_4 \iint_{\mathcal{O}\times(0,T)} e^{\frac{-16\mathbf{a}+14\overline{\alpha}}{t^4(T-t)^4}}\, t^{-132}(T-t)^{-132}\,|\varphi_i|^2\,dx\,dt \\
&+\frac{1}{2C_1C_3}\iint_Q e^{\frac{-2\overline{\alpha}}{t^4(T-t)^4}}\, t^4(T-t)^4\,|\Delta\varphi_i|^2\,dx\,dt,
\end{aligned}$$

which, combined with (24) and (28), yields (22). □

Let us now present another Carleman inequality for (19) with weight functions not vanishing at time $t = 0$.

LEMMA 2. *Assume that $N = 3$, $n_1(x^0) \neq 0$ and $\mathcal{O}$ and $\overline{y}$ verify (11)–(12). Then there exist positive constants C, $\overline{\alpha}$ and $\widetilde{\alpha}$ with $0 < \widetilde{\alpha} < \overline{\alpha}$ and $8\widetilde{\alpha} - 7\overline{\alpha} > 0$ depending on Ω, $\mathcal{O}$, T and $\overline{y}$ such that, for any $g \in L^2(Q)^3$ and any $\varphi^0 \in H$, the associated solution to (19) satisfies:*

$$\left\{\begin{array}{l}
\displaystyle\iint_Q e^{\frac{-2\overline{\alpha}}{\ell(t)^4}}\left(\ell(t)^{-12}\,|\varphi|^2 + \ell(t)^{-4}\,|\nabla\varphi|^2\right)\,dx\,dt \\
\displaystyle\quad \leq C\left(\iint_Q e^{\frac{-4\mathbf{a}+2\overline{\alpha}}{\ell(t)^4}}\,\ell(t)^{-30}\,|g|^2\,dx\,dt\right. \\
\displaystyle\quad \left.+\iint_{\mathcal{O}\times(0,T)} e^{\frac{-16\mathbf{a}+14\overline{\alpha}}{\ell(t)^4}}\,\ell(t)^{-132}\,(|\varphi_2|^2+|\varphi_3|^2)\,dx\,dt\right),
\end{array}\right. \tag{29}$$

where ℓ is the C^1 function given by

$$\ell(t) = \left\{\begin{array}{ll} \dfrac{T^2}{4} & \text{for } 0 \leq t \leq T/2, \\ t(T-t) & \text{for } T/2 \leq t \leq T. \end{array}\right. \tag{30}$$

To prove (29), it suffices to use (22) and the classical parabolic estimates for the Stokes system satisfied by φ. The argument has already been used in [9], [13] and [7] in several similar situations, so we omit it for simplicity.

For completeness, let us state the similar result that can be established when $N = 2$. Here, we assume again that $n_1(x^0) \neq 0$.

LEMMA 3. *Assume that $N = 2$, $n_1(x^0) \neq 0$ and $\mathcal{O}$ and $\overline{y}$ verify (11)–(12). Then there exist positive constants C, $\overline{\alpha}$ and $\widetilde{\alpha}$ with $0 < \widetilde{\alpha} < \overline{\alpha}$ and $8\widetilde{\alpha} - 7\overline{\alpha} > 0$ depending on Ω, $\mathcal{O}$, T and $\overline{y}$ such that, for any $g \in L^2(Q)^2$ and any $\varphi^0 \in H$, the associated solution to (19) satisfies:*

$$\left\{\begin{array}{l}
\displaystyle\iint_Q e^{\frac{-2\overline{\alpha}}{\ell(t)^4}}\left(\ell(t)^{-12}\,|\varphi|^2 + \ell(t)^{-4}\,|\nabla\varphi|^2\right)\,dx\,dt \\
\displaystyle\quad \leq C\left(\iint_Q e^{\frac{-4\mathbf{a}+2\overline{\alpha}}{\ell(t)^4}}\,\ell(t)^{-30}\,|g|^2\,dx\,dt\right. \\
\displaystyle\quad \left.+\iint_{\mathcal{O}\times(0,T)} e^{\frac{-16\mathbf{a}+14\overline{\alpha}}{\ell(t)^4}}\,\ell(t)^{-132}\,|\varphi_2|^2\,dx\,dt\right),
\end{array}\right. \tag{31}$$

where ℓ is the function given by (30).

2.2. New Carleman estimates for system (20). We will establish suitable Carleman inequalities for the solutions of (20). To this end, our approach will be similar to the one in subsection 2.1.

Thus, we will assume again that $N=3$ and $n_1(x^0)\neq 0$ and we will prove an estimate of the form

$$K(\varphi,\psi)\leq C\left(\iint_Q \rho_3^2\left(|g|^2+|q|^2\right)dx\,dt+\iint_{\mathcal{O}\times(0,T)}\rho_4^2\left(|\varphi_2|^2+|\psi|^2\right)\,dx\,dt\right),$$

where $K(\varphi,\psi)=I(\varphi)+I(\psi)$ ($I(\varphi)$ has been given in (22)) and ρ_3 and ρ_4 are appropriate weights. This will be used in section 3 to find controls $v1_{\mathcal{O}}$ and $h1_{\mathcal{O}}$ with $v_1\equiv v_3\equiv 0$ leading to the null controllability of (15).

LEMMA 4. *Assume that $N=3$, $n_1(x^0)\neq 0$ and $\mathcal{O}$ and $(\overline{y},\overline{\theta})$ satisfy* (11)–(13). *Then, there exist positive constants C, $\overline{\alpha}$ and $\widetilde{\alpha}$ depending on Ω, $\mathcal{O}$, T, $\overline{y}$ and $\overline{\theta}$ with $0<\widetilde{\alpha}<\overline{\alpha}$ and $16\widetilde{\alpha}-15\overline{\alpha}>0$ such that, for any $g\in L^2(Q)^3$, $q\in L^2(Q)$, $\varphi^0\in H$ and $\psi^0\in L^2(\Omega)$, the associated solution to* (20) *satisfies:*

$$\left\{\begin{array}{l} I(\varphi)+I(\psi)\leq C\left(\displaystyle\iint_Q e^{\frac{-4\boldsymbol{a}+2\widetilde{\alpha}}{t^4(T-t)^4}}t^{-30}(T-t)^{-30}\,|g|^2\,dx\,dt\right.\\ \qquad+\displaystyle\iint_Q e^{\frac{-32\boldsymbol{a}+30\overline{\alpha}}{t^4(T-t)^4}}\,t^{-252}(T-t)^{-252}\,|q|^2\,dx\,dt\\ \qquad+\displaystyle\iint_{\mathcal{O}\times(0,T)} e^{\frac{-16\boldsymbol{a}+14\overline{\alpha}}{t^4(T-t)^4}}\,t^{-132}(T-t)^{-132}\,|\varphi_2|^2\,dx\,dt\\ \qquad\left.+\displaystyle\iint_{\mathcal{O}\times(0,T)} e^{\frac{-32\boldsymbol{a}+30\overline{\alpha}}{t^4(T-t)^4}}\,t^{-268}(T-t)^{-268}\,|\psi|^2\,dx\,dt\right).\end{array}\right. \tag{32}$$

Proof. Let us first recall a Carleman inequality for the solutions of (20) which has recently been proved in [12] (Proposition 1) whenever (12)–(13) are fulfilled:

$$\begin{array}{l} s^3\lambda^4\displaystyle\iint_Q e^{-2s\alpha}\xi^3(|\varphi|^2+|\psi|^2)\,dx\,dt\\ +s\lambda^2\displaystyle\iint_Q e^{-2s\alpha}\xi(|\nabla\varphi|^2+|\nabla\psi|^2)\,dx\,dt\\ +s^{-1}\displaystyle\iint_Q e^{-2s\alpha}\xi^{-1}\left(|\varphi_t|^2+|\psi_t|^2+|\Delta\varphi|^2+|\Delta\psi|^2\right)dx\,dt\\ \leq C_5(1+T^2)\left(s^{15/2}\lambda^{24}\displaystyle\iint_Q e^{-4s\boldsymbol{b}+2s\alpha^*}\widehat{\xi}^{15/2}(|g|^2+|q|^2)\,dx\,dt\right.\\ \left.+s^{16}\lambda^{48}\displaystyle\iint_{\mathcal{O}_0\times(0,T)} e^{-8s\boldsymbol{b}+6s\alpha^*}\widehat{\xi}^{16}(|\varphi|^2+|\psi|^2)\,dx\,dt\right).\end{array} \tag{33}$$

Here, $s\geq s_1$ and $\lambda\geq\lambda_1$ are arbitrarily large and C_5, s_1 and λ_1 are suitable constants depending on Ω, $\mathcal{O}_0$, T, $\overline{y}$ and $\overline{\theta}$; see Proposition 1 in [12]. The proof of this inequality follows the same arguments employed in [7] to prove (23) and can be achieved without any further regularity on $\overline{y}$ or $\overline{\theta}$.

It is clear from (33) that, for some C_6, $\overline{\alpha}$ and $\widetilde{\alpha}$ depending on Ω, $\mathcal{O}_0$, T, $\overline{y}$ and $\overline{\theta}$, we have:

$$
\begin{aligned}
&\iint_Q e^{\frac{-2\overline{\alpha}}{t^4(T-t)^4}} t^{-12}(T-t)^{-12}\left(|\varphi|^2+|\psi|^2\right)dx\,dt\\
&+\iint_Q e^{\frac{-2\overline{\alpha}}{t^4(T-t)^4}} t^{-4}(T-t)^{-4}\left(|\nabla\varphi|^2+|\nabla\psi|^2\right)dx\,dt\\
&+\iint_Q e^{\frac{-2\overline{\alpha}}{t^4(T-t)^4}}\, t^4(T-t)^4\,\left(|\Delta\varphi|^2+|\Delta\psi|^2+|\varphi_t|^2+|\psi_t|^2\right)dx\,dt\\
&\le C_6\left(\iint_Q e^{\frac{-4\mathbf{a}+2\overline{\alpha}}{t^4(T-t)^4}} t^{-30}(T-t)^{-30}\left(|g|^2+|q|^2\right)dx\,dt\right.\\
&\left.+\iint_{\mathcal{O}_0\times(0,T)} e^{\frac{-8\mathbf{a}+6\overline{\alpha}}{t^4(T-t)^4}}\, t^{-64}(T-t)^{-64}\left(|\varphi|^2+|\psi|^2\right)dx\,dt\right).
\end{aligned}
\tag{34}
$$

Indeed, it suffices to take $\overline{\alpha}$ and $\widetilde{\alpha}$ as in (25) and

$$C_6 = C_5(1+T^2)s_1^{17}\lambda_1^{48}e^{17\lambda_1(m+1)\|\eta^0\|_\infty}.$$

We thus obtain $0<\widetilde{\alpha}<\overline{\alpha}$ and, noticing that λ_1 is large enough, $16\widetilde{\alpha}-15\overline{\alpha}>0$.

We apply (34) for the open set $\mathcal{O}_0$ defined in (26). Then we can argue as in subsection 2.1 and deduce that

$$
\begin{aligned}
&\iint_{\mathcal{O}_0\times(0,T)} e^{\frac{-8\mathbf{a}+6\overline{\alpha}}{t^4(T-t)^4}}\, t^{-64}(T-t)^{-64}\,|\varphi_1|^2\,dx\,dt\\
&\le C_7\iint_{\mathcal{O}_1\times(0,T)} e^{\frac{-16\mathbf{a}+14\overline{\alpha}}{t^4(T-t)^4}} t^{-132}(T-t)^{-132}\left(|\varphi_2|^2+|\varphi_3|^2\right)dx\,dt\\
&+\varepsilon\iint_Q e^{\frac{-2\overline{\alpha}}{t^4(T-t)^4}} t^4(T-t)^4\left(|\Delta\varphi_2|^2+|\Delta\varphi_3|^2\right)dx\,dt,
\end{aligned}
$$

where $\mathcal{O}_1$ is an appropriate nonempty open set verifying

$$\mathcal{O}_0\subset\mathcal{O}_1\subset\mathcal{O},\quad d_1:=\operatorname{dist}(\overline{\mathcal{O}_1},\partial\mathcal{O}\cap\Omega)>0.$$

This inequality combined with (34) yields:

$$
\begin{aligned}
&\iint_Q e^{\frac{-2\overline{\alpha}}{t^4(T-t)^4}} t^{-12}(T-t)^{-12}\left(|\varphi|^2+|\psi|^2\right)dx\,dt\\
&+\iint_Q e^{\frac{-2\overline{\alpha}}{t^4(T-t)^4}} t^{-4}(T-t)^{-4}\left(|\nabla\varphi|^2+|\nabla\psi|^2\right)dx\,dt\\
&+\iint_Q e^{\frac{-2\overline{\alpha}}{t^4(T-t)^4}}\, t^4(T-t)^4\,\left(|\Delta\varphi|^2+|\Delta\psi|^2+|\varphi_t|^2+|\psi_t|^2\right)dx\,dt\\
&\le C_8\left(\iint_Q e^{\frac{-4\mathbf{a}+2\overline{\alpha}}{t^4(T-t)^4}} t^{-30}(T-t)^{-30}\left(|g|^2+|q|^2\right)dx\,dt\right.\\
&+\iint_{\mathcal{O}_1\times(0,T)} e^{\frac{-16\mathbf{a}+14\overline{\alpha}}{t^4(T-t)^4}}\, t^{-132}(T-t)^{-132}\left(|\varphi_2|^2+|\varphi_3|^2\right)dx\,dt\\
&\left.+\iint_{\mathcal{O}\times(0,T)} e^{\frac{-8\mathbf{a}+6\overline{\alpha}}{t^4(T-t)^4}}\, t^{-64}(T-t)^{-64}\,|\psi|^2\,dx\,dt\right).
\end{aligned}
\tag{35}
$$

Our last task will be to estimate the integral

$$\iint_{\mathcal{O}_1\times(0,T)} e^{\frac{-16\boldsymbol{\alpha}+14\overline{\alpha}}{t^4(T-t)^4}}\, t^{-132}(T-t)^{-132}\,|\varphi_3|^2\,dx\,dt$$

in terms of $\varepsilon I(\varphi_3)$ and local integrals of ψ and q. To do this, we set

$$\beta_1(t) = e^{\frac{-16\boldsymbol{\alpha}+14\overline{\alpha}}{t^4(T-t)^4}}\, t^{-132}(T-t)^{-132}$$

and we introduce a function $\zeta_0 \in C^2(\overline{\mathcal{O}})$ such that

$$\zeta_0 \equiv 1 \text{ in } \mathcal{O}_1, \quad 0 \le \zeta \le 1$$

and $\zeta_0(x) = 0$ at any point $x \in \mathcal{O}$ satisfying $\operatorname{dist}(x, \partial\mathcal{O} \cap \Omega) \le d_1/2$. From the differential equation satisfied by ψ (see (20)), we have

$$\begin{aligned}\iint_{\mathcal{O}_1\times(0,T)} \beta_1(t)\,|\varphi_3|^2\,dx\,dt &\le \iint_{\mathcal{O}\times(0,T)} \beta_1(t)\,\zeta_0\,|\varphi_3|^2\,dx\,dt\\ &= \iint_{\mathcal{O}\times(0,T)} \beta_1(t)\,\zeta_0\,\varphi_3(-\psi_t - \Delta\psi - \overline{y}\cdot\nabla\psi - q)\,dx\,dt.\end{aligned} \tag{36}$$

To end the proof, we perform integrations by parts in the last integral and pass all the derivatives from ψ to φ_3.

First, we integrate by parts in time taking into account that $\beta_1(0) = \beta_1(T) = 0$:

$$\begin{aligned}&-\iint_{\mathcal{O}\times(0,T)} \beta_1(t)\,\zeta_0\,\varphi_3\,\psi_t\,dx\,dt\\ &\quad= \iint_{\mathcal{O}\times(0,T)} \beta_{1,t}(t)\,\zeta_0\,\varphi_3\,\psi\,dx\,dt + \iint_{\mathcal{O}\times(0,T)} \beta_1(t)\,\zeta_0\,\varphi_{3,t}\,\psi\,dx\,dt\\ &\quad\le \varepsilon I(\varphi_3) + C_9(\varepsilon)\iint_{\mathcal{O}\times(0,T)} e^{\frac{-32\boldsymbol{\alpha}+30\overline{\alpha}}{t^4(T-t)^4}}\, t^{-268}(T-t)^{-268}\,|\psi|^2\,dx\,dt.\end{aligned} \tag{37}$$

Next, we integrate by parts twice in space. Here, we use the properties of the cut-off function ζ and the Dirichlet boundary conditions for φ_3 and ψ:

$$\begin{aligned}&-\iint_{\mathcal{O}\times(0,T)} \beta_1(t)\,\zeta_0\,\varphi_3\,\Delta\psi\,dx\,dt\\ &\quad= \iint_{\mathcal{O}\times(0,T)} \beta_1(t)\,(-\Delta\zeta_0\,\varphi_3 - 2\nabla\zeta_0\cdot\nabla\varphi_3 - \zeta_0\,\Delta\varphi_3)\,\psi\,dx\,dt\\ &\quad\le \varepsilon I(\varphi_3) + C_{10}(\varepsilon)\iint_{\mathcal{O}\times(0,T)} e^{\frac{-32\boldsymbol{\alpha}+30\overline{\alpha}}{t^4(T-t)^4}}\, t^{-268}(T-t)^{-268}\,|\psi|^2\,dx\,dt.\end{aligned} \tag{38}$$

We also integrate by parts in the third term with respect to x and we use the incompressibility condition on $\overline{y}$:

$$\begin{aligned}&-\iint_{\mathcal{O}\times(0,T)} \beta_1(t)\,\zeta_0\,\varphi_3\,\overline{y}\cdot\nabla\psi\,dx\,dt\\ &\quad= \iint_{\mathcal{O}\times(0,T)} \beta_1(t)\,\overline{y}\cdot(\varphi_3\,\nabla\zeta + \zeta\,\nabla\varphi_3)\psi\,dx\,dt\\ &\quad\le \varepsilon I(\varphi_3) + C_{11}(\varepsilon)\iint_{\mathcal{O}\times(0,T)} e^{\frac{-32\boldsymbol{\alpha}+30\overline{\alpha}}{t^4(T-t)^4}}\, t^{-260}(T-t)^{-260}\,|\psi|^2\,dx\,dt.\end{aligned} \tag{39}$$

We finally apply Young's inequality in the last term and we have:

$$
\begin{aligned}
&-\iint_{\mathcal{O}\times(0,T)} \beta_1(t)\,\zeta\,\varphi_3\,q\,dx\,dt \\
&\qquad \le \varepsilon I(\varphi_3) + C_{12}(\varepsilon)\iint_{\mathcal{O}\times(0,T)} e^{\frac{-32\mathbf{a}+30\overline{\alpha}}{t^4(T-t)^4}}\,t^{-252}(T-t)^{-252}\,|q|^2\,dx\,dt.
\end{aligned}
\tag{40}
$$

From (35), (36) and (37)–(40), it is easy to deduce the desired inequality (32). □

Arguing as in subsection 2.1, that is to say, combining the previous result and the classical energy estimates satisfied by φ and ψ, we can deduce the following Carleman inequality.

LEMMA 5. *Assume that $N = 3$, $n_1(x^0) \neq 0$ and $\mathcal{O}$ and $(\overline{y}, \overline{\theta})$ satisfy* (11)–(13). *Then, there exist positive constants C, $\overline{\alpha}$ and $\widetilde{\alpha}$ depending on Ω, $\mathcal{O}$, T, $\overline{y}$ and $\overline{\theta}$ with $0 < \widetilde{\alpha} < \overline{\alpha}$ and $16\widetilde{\alpha} - 15\overline{\alpha} > 0$ such that, for any $g \in L^2(Q)^3$, $q \in L^2(Q)$, $\varphi^0 \in H$ and $\psi^0 \in L^2(\Omega)$, the associated solution to* (20) *satisfies:*

$$
\left\{
\begin{aligned}
&\iint_Q e^{\frac{-2\overline{\alpha}}{\ell(t)^4}}\left(\ell(t)^{-12}\left(|\varphi|^2 + |\psi|^2\right) + \ell(t)^{-4}\left(|\nabla\varphi|^2 + |\nabla\psi|^2\right)\right)dx\,dt \\
&\qquad \le C\left(\iint_Q e^{\frac{-4\mathbf{a}+2\overline{\alpha}}{\ell(t)^4}}\,\ell(t)^{-30}\,|g|^2\,dx\,dt\right. \\
&\qquad + \iint_Q e^{\frac{-32\mathbf{a}+30\overline{\alpha}}{\ell(t)^4}}\,\ell(t)^{-252}\,|q|^2\,dx\,dt \\
&\qquad + \iint_{\mathcal{O}\times(0,T)} e^{\frac{-16\mathbf{a}+14\overline{\alpha}}{\ell(t)^4}}\,\ell(t)^{-132}\,|\varphi_2|^2\,dx\,dt \\
&\qquad \left. + \iint_{\mathcal{O}\times(0,T)} e^{\frac{-32\mathbf{a}+30\overline{\alpha}}{\ell(t)^4}}\,\ell(t)^{-268}\,|\psi|^2\,dx\,dt\right),
\end{aligned}
\right.
\tag{41}
$$

where the function ℓ was defined in (30).

The similar result that can be established when $N = 2$ follows.

LEMMA 6. *Assume that $N = 2$, $n_1(x^0) \neq 0$ and $\mathcal{O}$ and $(\overline{y}, \overline{\theta})$ satisfy* (11)–(13). *Then, there exist positive constants C, $\overline{\alpha}$ and $\widetilde{\alpha}$ depending on Ω, $\mathcal{O}$, T, $\overline{y}$ and $\overline{\theta}$ with $0 < \widetilde{\alpha} < \overline{\alpha}$ and $16\widetilde{\alpha} - 15\overline{\alpha} > 0$ such that, for any $g \in L^2(Q)^2$, $q \in L^2(Q)$, $\varphi^0 \in H$ and $\psi^0 \in L^2(\Omega)$, the associated solution to* (20) *satisfies:*

$$
\left\{
\begin{aligned}
&\iint_Q e^{\frac{-2\overline{\alpha}}{\ell(t)^4}}\left(\ell(t)^{-12}\left(|\varphi|^2 + |\psi|^2\right) + \ell(t)^{-4}\left(|\nabla\varphi|^2 + |\nabla\psi|^2\right)\right)dx\,dt \\
&\qquad \le C\left(\iint_Q e^{\frac{-4\mathbf{a}+2\overline{\alpha}}{\ell(t)^4}}\,\ell(t)^{-30}\,|g|^2\,dx\,dt\right. \\
&\qquad + \iint_Q e^{\frac{-32\mathbf{a}+30\overline{\alpha}}{\ell(t)^4}}\,\ell(t)^{-252}\,|q|^2\,dx\,dt \\
&\qquad \left. + \iint_{\mathcal{O}\times(0,T)} e^{\frac{-32\mathbf{a}+30\overline{\alpha}}{\ell(t)^4}}\,\ell(t)^{-268}\,|\psi|^2\,dx\,dt\right).
\end{aligned}
\right.
\tag{42}
$$

2.3. An observability estimate for system (21). We will prove an observability estimate for the system

$$\begin{cases} -\rho_t - \Delta\rho - \nabla\times((\overline{y}\cdot\nabla\times)\nabla\gamma) = 0, \quad \Delta\gamma = \rho & \text{in } Q,\\ \gamma = 0, \quad \rho = 0 & \text{on } \Sigma,\\ \rho(T) = \rho^0 & \text{in } \Omega. \end{cases} \tag{43}$$

This estimate will be implied by a Carleman inequality of the form

$$S(\nabla\gamma) \le C \iint_{\mathcal{O}\times(0,T)} |\nabla\gamma|^2\, dx\, dt,$$

where $S(\nabla\gamma)$ contains several global weighted integrals involving $\nabla\gamma$ (see (44)).

LEMMA 7. *Assume that $N = 2$ and $\overline{y} \in L^\infty(Q)^2$. There exist three positive constants C, $\overline{s}$ and $\overline{\lambda}$ depending on Ω, $\mathcal{O}$, T and $\overline{y}$ such that, for any $\rho^0 \in H^{-1}(\Omega)$, the associated solution to* (43) *satisfies:*

$$\begin{cases} S(\nabla\gamma) := s^4\lambda^4 \iint_Q e^{-2s\alpha}\,\xi^4|\nabla\gamma|^2\, dx\, dt \\ \qquad\qquad +s\lambda^2 \iint_Q e^{-2s\alpha}\,\xi|\nabla\rho|^2\, dx\, dt + s^3\lambda^4 \iint_Q e^{-2s\alpha}\xi^3|\rho|^2\, dx\, dt \\ \qquad\qquad \le C\, s^5\lambda^6 \iint_{\mathcal{O}\times(0,T)} e^{-2s\alpha}\xi^5|\nabla\gamma|^2\, dx\, dt, \end{cases} \tag{44}$$

for any $s \ge \overline{s}$ and any $\lambda \ge \overline{\lambda}$. Recall that α and ξ were defined in (17).

Proof. For the proof, s_j and λ_j ($j \ge 2$) will denote various positive constants that can eventually depend on Ω, $\mathcal{O}$, T and $\overline{y}$.

Let $\mathcal{O}_0$ be a nonempty open set satisfying $\mathcal{O}_0 \subset\subset \mathcal{O}$ and let us apply to ρ a Carleman inequality for parabolic systems with right-hand sides in $L^2(0,T;H^{-1}(\Omega))$, originally proved in [15] (this version can be found in Lemma 2.1 of [6]):

$$\begin{aligned} &s\lambda^2 \iint_Q e^{-2s\alpha}\,\xi|\nabla\rho|^2\, dx\, dt + s^3\lambda^4 \iint_Q e^{-2s\alpha}\xi^3|\rho|^2\, dx\, dt \\ &\qquad \le C_{13}\left(s^2\lambda^2\|\overline{y}\|_\infty^2 \iint_Q e^{-2s\alpha}\xi^2|\nabla(\nabla\times\gamma)|^2\, dx\, dt\right. \\ &\qquad\quad \left. +s^3\lambda^4 \iint_{\mathcal{O}_0\times(0,T)} e^{-2s\alpha}\xi^3|\rho|^2\, dx\, dt\right), \end{aligned} \tag{45}$$

for any $s \ge s_2$ and $\lambda \ge \overline{\lambda}_2$.

Observe that, here, the assumption $\rho^0 \in H^{-1}(\Omega)$ may seem too weak to apply this result. Indeed, (45) can be proved as in [15] whenever $\rho \in C^1(\overline{Q})$ and, by a continuity argument, also for the solutions of problem (43) for which the left-hand side of (45) is finite. This is our case, since one can ensure that $\rho \in L^2(Q)$ as soon as $\rho^0 \in H^{-1}(\Omega)$ (for instance, taking into account the definition of ρ as the solution by transposition of (43)).

Once (45) has been justified, let us first estimate the last integral in its right-hand side. Thus, let $\zeta \in C^2(\overline{\mathcal{O}})$ be a cut-off function satisfying

$$\zeta \equiv 1 \text{ in } \mathcal{O}_0, \quad 0 \le \zeta \le 1 \quad \text{and} \quad \zeta = 0 \text{ on } \partial\mathcal{O}.$$

We have:

$$
\begin{aligned}
s^3\lambda^4 \iint_{\mathcal{O}_0\times(0,T)} e^{-2s\alpha}\xi^3|\Delta\gamma|^2\,dx\,dt &\le s^3\lambda^4 \iint_{\mathcal{O}\times(0,T)} \zeta\, e^{-2s\alpha}\xi^3|\Delta\gamma|^2\,dx\,dt \\
&= -s^3\lambda^4 \iint_{\mathcal{O}\times(0,T)} e^{-2s\alpha}\xi^3(\nabla\zeta\cdot\nabla\gamma)\Delta\gamma\,dx\,dt \\
&\quad -3s^3\lambda^5 \iint_{\mathcal{O}\times(0,T)} \zeta\, e^{-2s\alpha}\xi^3(\nabla\eta^0\cdot\nabla\gamma)\Delta\gamma\,dx\,dt \\
&\quad +2s^4\lambda^5 \iint_{\mathcal{O}\times(0,T)} \zeta\, e^{-2s\alpha}\xi^4(\nabla\eta^0\cdot\nabla\gamma)\Delta\gamma\,dx\,dt \\
&\quad -s^3\lambda^4 \iint_{\mathcal{O}\times(0,T)} \zeta\, e^{-2s\alpha}\xi^3(\nabla\Delta\gamma\cdot\nabla\gamma)\,dx\,dt.
\end{aligned}
$$

Now, we apply Young's inequality several times and we obtain

$$
\begin{aligned}
&s^3\lambda^4 \iint_{\mathcal{O}_0\times(0,T)} e^{-2s\alpha}\xi^3|\Delta\gamma|^2\,dx\,dt \\
&\le C_{14}(\varepsilon)\, s^5\lambda^6 \iint_{\mathcal{O}\times(0,T)} e^{-2s\alpha}\xi^5|\nabla\gamma|^2\,dx\,dt \\
&+\varepsilon\left(s^3\lambda^4 \iint_Q e^{-2s\alpha}\xi^3|\Delta\gamma|^2\,dx\,dt + s\lambda^2 \iint_Q e^{-2s\alpha}\xi|\nabla\Delta\gamma|^2\,dx\,dt\right),
\end{aligned}
$$

for $s \ge s_3$ and $\lambda \ge \lambda_3$ and for any small positive constant ε. Combining this, the fact that $\rho = \Delta\gamma$, and (45), we get

$$
\begin{aligned}
&s\lambda^2 \iint_Q e^{-2s\alpha}\,\xi|\nabla\rho|^2\,dx\,dt + s^3\lambda^4 \iint_Q e^{-2s\alpha}\xi^3|\rho|^2\,dx\,dt \\
&\qquad \le C_{15}\left(s^2\lambda^2\|\overline{y}\|_\infty^2 \iint_Q e^{-2s\alpha}\xi^2|\nabla(\nabla\times\gamma)|^2\,dx\,dt\right. \\
&\qquad\quad \left. +s^5\lambda^6 \iint_{\mathcal{O}\times(0,T)} e^{-2s\alpha}\xi^5|\nabla\gamma|^2\,dx\,dt\right)
\end{aligned} \tag{46}
$$

for any $s \ge s_4$ and $\lambda \ge \lambda_4$.

Finally, we are going to estimate the first integral in the right-hand side of (45). To this end, let us notice that, for $j = 1$ and 2 and almost every $t \in (0,T)$, the function $\partial_j\gamma(t)$ satisfies:

$$
\Delta(\partial_j\gamma)(t) = \partial_j\rho(t) \ \text{ in } \Omega.
$$

Let us apply the main result in [14] to $\partial_j\gamma$. This yields the existence of two numbers $\widetilde{\tau} > 1$ and $\widetilde{\lambda} > 1$ such that

$$
\begin{aligned}
&\tau^4\lambda^4 \int_\Omega e^{2\tau\eta}\eta^4|\partial_j\gamma|^2(t)\,dx + \tau^2\lambda^2 \int_\Omega e^{2\tau\eta}\eta^2|\nabla(\partial_j\gamma)|^2(t)\,dx \\
&\le C_{16}\left(\tau \int_\Omega e^{2\tau\eta}\eta|\partial_j\rho|^2(t)\,dx + \tau^4\lambda^4 \int_{\mathcal{O}} e^{2\tau\eta}\eta^4|\partial_j\gamma|^2(t)\,dx\right. \\
&\quad \left. +\tau^{5/2}\lambda^2\, e^{2\tau}\|\partial_j\gamma(t)\|^2_{H^{1/2}(\partial\Omega)}\right)
\end{aligned} \tag{47}
$$

for $\tau \geq \widetilde{\tau}$ and $\lambda \geq \widetilde{\lambda}$. Here, we have introduced the function η, with

$$\eta(x) = e^{\lambda \eta^0(x)}.$$

In fact, the inequality one can find in [14] contains local integrals of $|\partial_j \gamma|^2$ and $|\nabla(\partial_j \gamma)|^2$ in the right-hand side. But it can be written for a smaller set $\mathcal{O}' \subset\subset \mathcal{O}$. Using localizing arguments together with the fact that we actually have a global weighted integral of $|\Delta(\partial_j \gamma)|^2$ in the left-hand side, (47) is easily found.

Following the same steps of [7], we set

$$\tau = \frac{s}{t^4(T-t)^4}\, e^{\lambda\, m \|\eta^0\|_\infty},$$

we multiply (47) by

$$\exp\left\{-2s\frac{e^{5/4\lambda m\|\eta^0\|_\infty}}{t^4(T-t)^4}\right\}$$

and we integrate in time over $(0,T)$. This gives

$$\begin{aligned}
&s^4\lambda^4 \iint_Q e^{-2s\alpha}\xi^4|\partial_j\gamma|^2\,dx\,dt + s^2\lambda^2 \iint_Q e^{-2s\alpha}\xi^2|\nabla(\partial_j\gamma)|^2\,dx\,dt \\
&\quad \leq C_{17}\left(s\iint_Q e^{-2s\alpha}\xi|\partial_j\rho|^2\,dx\,dt + s^4\lambda^4 \iint_{\mathcal{O}\times(0,T)} e^{-2s\alpha}\xi^4|\partial_j\gamma|^2\,dx\,dt\right. \\
&\quad \left. + s^{5/2}\lambda^2 \int_0^T e^{-2s\alpha^*}(\xi^*)^{5/2}\|\partial_j\gamma\|^2_{H^{1/2}(\partial\Omega)}\right)
\end{aligned}$$

for $s \geq s_5$ and $\lambda \geq \widetilde{\lambda}$. Combining this estimate and (46), we have

$$\begin{aligned}
&s^4\lambda^4 \iint_Q e^{-2s\alpha}\xi^4|\partial_j\gamma|^2\,dx\,dt + s\lambda^2 \iint_Q e^{-2s\alpha}\,\xi|\nabla\rho|^2\,dx\,dt \\
&\quad + s^3\lambda^4 \iint_Q e^{-2s\alpha}\xi^3|\rho|^2\,dx\,dt \leq C_{18}\left(s^{5/2}\lambda^2\int_0^T e^{-2s\alpha^*}(\xi^*)^{5/2}\|\partial_j\gamma\|^2_{H^{1/2}(\partial\Omega)}\right. \\
&\quad \left. + s^5\lambda^6 \iint_{\mathcal{O}\times(0,T)} e^{-2s\alpha}\xi^5|\nabla\gamma|^2\,dx\,dt\right)
\end{aligned}$$

for any $s \geq s_6$ and $\lambda \geq \lambda_5$. On the other hand, the boundary term can readily be bounded using the continuity of the trace operator:

$$\|\partial_j\gamma(t)\|^2_{H^{1/2}(\partial\Omega)} \leq C_{19}(\|\partial_j\gamma(t)\|^2_{L^2} + \|\nabla(\partial_j\gamma)(t)\|^2_{L^2}).$$

Furthermore, since $\gamma|_\Sigma \equiv 0$, we know that there exists a positive constant C_{20} such that

$$\|\nabla(\partial_j\gamma)(t)\|_{L^2} \leq C_{20}\|\Delta\gamma(t)\|_{L^2} \quad \text{a.e. in } (0,T) \text{ for } j = 1,2.$$

Consequently,

$$\begin{aligned}
&s^4\lambda^4 \iint_Q e^{-2s\alpha}\xi^4|\partial_j\gamma|^2\,dx\,dt + s\lambda^2 \iint_Q e^{-2s\alpha}\,\xi|\nabla\rho|^2\,dx\,dt \\
&\quad + s^3\lambda^4 \iint_Q e^{-2s\alpha}\xi^3|\rho|^2\,dx\,dt \leq C_{21}\, s^5\lambda^6 \iint_{\mathcal{O}\times(0,T)} e^{-2s\alpha}\xi^5|\nabla\gamma|^2\,dx\,dt
\end{aligned}$$

for $s \geq s_6$.

This implies (44) and ends the proof of Lemma 7. □

Remark 3. An almost immediate consequence of the Carleman estimate (44) is the following observability inequality:

$$\|(\nabla\gamma)(0)\|^2_{L^2} \le C \iint_{\mathcal{O}\times(0,T)} |\nabla\gamma|^2 \, dx\, dt. \tag{48}$$

Proof. All comes to prove a dissipation result for the L^2 norm of $\nabla\gamma$. Indeed, if we can prove that

$$\|\nabla\gamma(t_1)\|^2_{L^2} \le C\|\nabla\gamma(t_2)\|^2_{L^2} \quad \forall 0 \le t_1 < t_2 \le T, \tag{49}$$

then using the properties of the weight function $e^{-2s\alpha}$ and estimate (44), we readily deduce (48).

Thus, we multiply the equation in (43) by $-\gamma$ and we integrate in Ω. Taking into account that γ and ρ vanish on $\partial\Omega$, this yields:

$$-\frac{1}{2}\frac{d}{dt}\int_\Omega |\nabla\gamma|^2\, dx + \int_\Omega |\Delta\gamma|^2\, dx - \int_\Omega ((\overline{y}\cdot\nabla\times)\nabla\gamma)\cdot\nabla\times\gamma\, dx = 0,$$

from which the dissipation estimate (49) follows. □

In fact, this is what will be used in section 3 to prove the null controllability of system (16).

3. Null controllability of the linearized systems (14), (15) and (16).

3.1. Null controllability of (14). We are dealing here with the following system:

$$\begin{cases} y_t - \Delta y + (\overline{y}\cdot\nabla)y + (y\cdot\nabla)\overline{y} + \nabla p = f + v1_{\mathcal{O}}, \quad \nabla\cdot y = 0 & \text{in } Q,\\ y = 0 & \text{on } \Sigma,\\ y(0) = y^0 & \text{in } \Omega, \end{cases} \tag{50}$$

where $\mathcal{O}$ satisfies (11) and $\overline{y}$ satisfies (12). Our goal will be to find a control v such that $y(T) = 0$ in Ω.

Let us introduce some weight functions:

$$\beta_2(t) = \exp\left\{\frac{\overline{\alpha}}{\ell(t)^4}\right\}\ell(t)^6, \quad \beta_3(t) = \exp\left\{\frac{2\widetilde{\alpha}-\overline{\alpha}}{\ell(t)^4}\right\}\ell(t)^{15}$$

and

$$\beta_4(t) = \exp\left\{\frac{8\widetilde{\alpha}-7\overline{\alpha}}{\ell(t)^4}\right\}\ell(t)^{66}$$

(recall that ℓ was defined in (30)), where $\overline{\alpha}$ and $\widetilde{\alpha}$ are the constants provided by Lemma 2 when $N = 3$ and Lemma 3 when $N = 2$. Recall that, in particular, $0 < \widetilde{\alpha} < \overline{\alpha}$ and $8\widetilde{\alpha} - 7\overline{\alpha} > 0$.

Of course, we will need some specific conditions on f and y^0 to get the null controllability of (50). We will use the arguments in [7].

Thus, let us set

$$Ly = y_t - \Delta y + (\overline{y},\nabla)y + (y,\nabla)\overline{y} \tag{51}$$

and let us introduce the spaces

$$E_2 = \{(y,p,v) : (y,v) \in E_0,\ \ell^{-4}\beta_2(Ly + \nabla p - v1_{\mathcal{O}}) \in L^2(0,T;H^{-1}(\Omega)^2)\}$$

when $N = 2$ and

$$E_3 = \{(y,p,v) : (y,v) \in E_0,\ \ell^{-2}\beta_2^{1/2} y \in L^4(0,T;L^{12}(\Omega)^3),\\ \ell^{-4}\beta_2(Ly + \nabla p - v1_{\mathcal{O}}) \in L^2(0,T;W^{-1,6}(\Omega)^3)\}$$

when $N = 3$, where

$$E_0 = \{(y,v) : \beta_3\, y,\ \beta_4\, v1_{\mathcal{O}} \in L^2(Q)^N,\ v_1 \equiv 0,\\ \ell^{-2}\beta_2^{1/2} y \in L^2(0,T;V) \cap L^\infty(0,T;H)\}.$$

It is clear that E_N is a Banach space for the norm $\|\cdot\|_{E_N}$, where

$$\|(y,p,v)\|_{E_2} = \Big(\|\beta_3\, y\|^2_{L^2} + \|\beta_4\, v1_{\mathcal{O}}\|^2_{L^2} + \|\ell^{-2}\beta_2^{1/2} y\|^2_{L^2(0,T;V)}\\ + \|\ell^{-2}\beta_2^{1/2} y\|^2_{L^\infty(0,T;H)} + \|\ell^{-4}\beta_2(Ly + \nabla p - v1_{\mathcal{O}})\|^2_{L^2(0,T;H^{-1})}\Big)^{1/2}$$

and

$$\|(y,p,v)\|_{E_3} = \Big(\|\beta_3\, y\|^2_{L^2} + \|\beta_4\, v1_{\mathcal{O}}\|^2_{L^2} + \|\ell^{-2}\beta_2^{1/2} y\|^2_{L^2(0,T;V)}\\ + \|\ell^{-2}\beta_2^{1/2} y\|^2_{L^\infty(0,T;H)} + \|\ell^{-2}\beta_2^{1/2}\, y\|^2_{L^4(0,T;L^{12})}\\ + \|\ell^{-4}\beta_2(Ly + \nabla p - v1_{\mathcal{O}})\|^2_{L^2(0,T;W^{-1,6})}\Big)^{1/2}.$$

Remark 4. The spaces E_j $(j = 0, 2, 3)$ are natural spaces where solutions of the null controllability of (50) must be found in order to preserve these properties for the nonlinear term $(y \cdot \nabla)y$. More details are provided in subsection 4.1.

PROPOSITION 1. *Assume that $n_1(x^0) \neq 0$ and $\mathcal{O}$ and $\overline{y}$ verify* (11)–(12). *Let $y^0 \in E$ and let us assume that*

$$\ell^{-4}\beta_2 f \in \begin{cases} L^2(0,T;H^{-1}(\Omega)^2) & \text{if } N = 2,\\ L^2(0,T;W^{-1,6}(\Omega)^3) & \text{if } N = 3. \end{cases}$$

Then, we can find a control v such that the associated solution (y,p) to (50) *satisfies $(y,p,v) \in E_N$. In particular, $v_1 \equiv 0$ and $y(T) = 0$.*

Sketch of the proof. The proof of this proposition is very similar to the one of Proposition 2 in [7], so we will just give the main ideas. For simplicity, we will only consider the case $N = 3$. When $N = 2$, the proof is even easier.

Following the arguments in [9] and [13], let us introduce the auxiliary optimal control problem

$$\begin{cases} \inf\ \dfrac{1}{2}\left(\displaystyle\iint_Q |\beta_3\, y|^2 dxdt + \iint_{\mathcal{O}\times(0,T)} |\beta_4\, v|^2 dxdt\right)\\ \text{subject to } v \in L^2(Q)^3,\ \text{supp } v \subset \mathcal{O}\times(0,T),\ v_1 \equiv 0 \text{ and}\\ \qquad \begin{cases} Ly + \nabla p = f + v1_{\mathcal{O}} & \text{in } Q,\\ \nabla \cdot y = 0 & \text{in } Q,\\ y = 0 & \text{on } \Sigma,\\ y(0) = y^0, \quad y(T) = 0 & \text{in } \Omega. \end{cases} \end{cases} \tag{52}$$

Notice that a solution $(\widehat{y},\widehat{p},\widehat{v})$ to (52) is a good candidate to satisfy $(\widehat{y},\widehat{p},\widehat{v}) \in E_3$.

For the moment, let us assume that (52) possesses a solution $(\widehat{y},\widehat{p},\widehat{v})$. Then, by virtue of Lagrange's principle, there must exist dual variables $\widehat{z}$ and $\widehat{q}$ such that

$$\left\{\begin{array}{ll} \widehat{y}=\beta_3^{-2}(L^*\widehat{z}+\nabla\widehat{q}), \quad \nabla\cdot\widehat{z}=0 & \text{in } Q,\\ \widehat{v}_1\equiv 0, \quad \widehat{v}_i=-\beta_4^{-2}\,\widehat{z}_i \quad (i=2,3) & \text{in } \mathcal{O}\times(0,T),\\ \widehat{z}=0 & \text{on } \Sigma, \end{array}\right. \tag{53}$$

where L^* is the adjoint operator of L, i.e.,

$$L^*z=-z_t-\Delta z-(Dz)\,\overline{y}.$$

At least formally, the couple $(\widehat{z},\widehat{q})$ satisfies

$$a((\widehat{z},\widehat{q}),(w,h))=\langle G,(w,h)\rangle \quad \forall (w,h)\in P_0, \tag{54}$$

where P_0 is the space

$$P_0=\{(w,h)\in C^2(\overline{Q})^4 : \nabla\cdot w=0,\ w=0 \text{ on } \Sigma,\ \int_{\mathcal{O}} h(x,t)\,dx=0\}$$

and we have used the notation

$$\begin{aligned} a((\widehat{z},\widehat{q}),(w,h))=&\iint_Q \beta_3^{-2}\,(L^*\widehat{z}+\nabla\widehat{q})\cdot(L^*w+\nabla h)\,dx\,dt\\ &+\iint_{\mathcal{O}\times(0,T)}\beta_4^{-2}\,(\widehat{z}_2\,w_2+\widehat{z}_3\,w_3)\,dx\,dt \end{aligned}$$

and

$$\langle G,(w,h)\rangle=\int_0^T \langle f(t),w(t)\rangle_{H^{-1},H_0^1}\,dt+\int_\Omega y^0\cdot w(0)\,dx.$$

Conversely, if we are able to "solve" (54) and then use (53) to define $(\widehat{y},\widehat{p},\widehat{v})$, we will probably have found a solution to (52).

Thus, let us consider the linear space P_0. It is clear that $a(\cdot\,,\cdot):P_0\times P_0\mapsto\mathbf{R}$ is a symmetric, definite positive bilinear form on P_0. We will denote by P the completion of P_0 for the norm induced by $a(\cdot\,,\cdot)$. Then $a(\cdot\,,\cdot)$ is well-defined, continuous and again definite positive on P. Furthermore, in view of the Carleman estimate (29), the linear form $(w,h)\mapsto\langle G,(w,h)\rangle$ is well-defined and continuous on P. Hence, from Lax-Milgram's lemma, we deduce that the variational problem

$$\left\{\begin{array}{l} a((\widehat{z},\widehat{q}),(w,h))=\langle G,(w,h)\rangle\\ \forall (w,h)\in P, \quad (\widehat{z},\widehat{q})\in P, \end{array}\right. \tag{55}$$

possesses exactly one solution $(\widehat{z},\widehat{q})$.

Let $\widehat{y}$ and $\widehat{v}$ be given by (53). Then, it is readily seen that they verify

$$\iint_Q \beta_3^2|\widehat{y}|^2dx\,dt+\iint_{\mathcal{O}\times(0,T)}\beta_4^2|\widehat{v}|^2dx\,dt<+\infty$$

and, also, that $\widehat{y}$ is, together with some pressure $\widehat{p}$, the weak solution (belonging to $L^2(0,T;V)\cap L^\infty(0,T;H)$) of the Stokes system in (52) for $v=\widehat{v}$.

In order to prove that $(\widehat{y},\widehat{p},\widehat{v})\in E_3$, it only remains to check that $\ell^{-2}\,\beta_2^{1/2}\,\widehat{y}$ is, together with $\ell^{-2}\,\beta_2^{1/2}\,\widehat{p}$, a weak solution of a Stokes problem of the kind (50) with a right-hand side in $L^2(0,T;W^{-1,6}(\Omega)^3)$ that belongs to $L^4(0,T;L^{12}(\Omega)^3)$. To this end, we define the functions $y^*=\ell^{-2}\,\beta_2^{1/2}\,\widehat{y}$, $p^*=\ell^{-2}\,\beta_2^{1/2}\,\widehat{p}$ and $f^*=\ell^{-2}\,\beta_2^{1/2}(f+\widehat{v}1_{\mathcal{O}})$. Then (y^*,p^*) satisfies

$$\left\{\begin{array}{ll} Ly^*+\nabla p^*=f^*+(\ell^{-2}\beta_2^{-1/2})_t\,\widehat{y},\quad \nabla\cdot y^*=0 & \text{in } Q,\\ y^*=0 & \text{on } \Sigma,\\ y^*(0)=\ell^{-2}(0)\beta_2^{1/2}(0)y^0 & \text{in } \Omega. \end{array}\right. \tag{56}$$

From the fact that $f^*\in L^2(0,T;H^{-1}(\Omega)^3)$ and $y^0\in H$, we have indeed

$$y^*\in L^2(0,T;V)\cap L^\infty(0,T;H).$$

Finally, we deduce that $y^*\in L^4(0,T;L^{12}(\Omega)^3)$ from Lemma 2 in [7]. This ends the sketch of the proof of Proposition 1. □

3.2. Null controllability of system (15). We will establish the null controllability of the linear system

$$\left\{\begin{array}{ll} y_t-\Delta y+(\overline{y}\cdot\nabla)y+(y\cdot\nabla)\overline{y}+\nabla p=f+v1_{\mathcal{O}}+\theta\,e_N & \text{in } Q,\\ \nabla\cdot y=0 & \text{in } Q,\\ \theta_t-\Delta\theta+\overline{y}\cdot\nabla\theta+y\cdot\nabla\overline{\theta}=k+h1_{\mathcal{O}} & \text{in } Q,\\ y=0,\quad \theta=0 & \text{on } \Sigma,\\ y(0)=y^0,\quad \theta(0)=\theta^0 & \text{in } \Omega, \end{array}\right. \tag{57}$$

where $\mathcal{O}$ satisfies (11) and $\overline{y}$ and $\overline{\theta}$ satisfy (12) and (13), for suitable right-hand sides f and k.

The arguments we present here are completely analogous to those in [12] and subsection 3.1 of this paper, so that we will only give a sketch. Thus, we restrict ourselves again to the three-dimensional case with $n_1(x^0)\neq 0$.

Let us introduce the weight functions

$$\beta_5(t)=\exp\left\{\frac{\overline{\alpha}}{\ell(t)^4}\right\}\ell(t)^6,\quad \beta_6(t)=\exp\left\{\frac{2\widetilde{\alpha}-\overline{\alpha}}{\ell(t)^4}\right\}\ell(t)^{15},$$

$$\beta_7(t)=\exp\left\{\frac{16\widetilde{\alpha}-15\overline{\alpha}}{\ell(t)^4}\right\}\ell(t)^{126},\quad \beta_8(t)=\exp\left\{\frac{8\widetilde{\alpha}-7\overline{\alpha}}{\ell(t)^4}\right\}\ell(t)^{66}$$

and

$$\beta_9(t)=\exp\left\{\frac{16\widetilde{\alpha}-15\overline{\alpha}}{\ell(t)^4}\right\}\ell(t)^{134},$$

where the constants $\overline{\alpha}$ and $\widetilde{\alpha}$ are furnished by Lemma 5 when $N=3$ and Lemma 6 when $N=2$ (and, in particular, $0<\widetilde{\alpha}<\overline{\alpha}$ and $16\widetilde{\alpha}-15\overline{\alpha}>0$).

Let us set

$$P\theta=\theta_t-\Delta\theta+\overline{y}\cdot\nabla\theta \tag{58}$$

and let us introduce the spaces

$$\begin{aligned}\widetilde{E}_2 = \{&(y,p,\theta,v,h) : (y,\theta,v,h) \in \widetilde{E}_0,\\ &\ell^{-4}\beta_5(Ly + \nabla p - v1_{\mathcal{O}}) \in L^2(0,T;H^{-1}(\Omega)^2),\\ &\ell^{-4}\beta_5(P\theta + y\cdot\nabla\overline{\theta} - h1_{\mathcal{O}}) \in L^2(0,T;H^{-1}(\Omega))\}\end{aligned}$$

when $N = 2$ and

$$\begin{aligned}\widetilde{E}_3 = \{&(y,p,\theta,v,h) : (y,\theta,v,h) \in \widetilde{E}_0,\\ &\ell^{-2}\beta_5^{1/2} y \in L^4(0,T;L^{12}(\Omega)^3),\\ &\ell^{-4}\beta_5(Ly + \nabla p - v1_{\mathcal{O}}) \in L^2(0,T;W^{-1,6}(\Omega)^3),\\ &\ell^{-4}\beta_5(P\theta + y\cdot\nabla\overline{\theta} - h1_{\mathcal{O}}) \in L^2(0,T;H^{-1}(\Omega))\}\end{aligned}$$

when $N = 3$, where

$$\begin{aligned}\widetilde{E}_0 = \{&(y,\theta,v,h) : (\beta_6\, y)_i,\ \beta_7\,\theta,\ (\beta_8\, v1_{\mathcal{O}})_i,\ \beta_9\, h1_{\mathcal{O}} \in L^2(Q)\ (1\le i\le N),\\ &v_1 \equiv v_N \equiv 0,\ \ell^{-2}\beta_5^{1/2} y \in L^2(0,T;V)\cap L^\infty(0,T;H),\\ &\ell^{-2}\beta_5^{1/2}\theta \in L^2(0,T;H_0^1(\Omega))\cap L^\infty(0,T;L^2(\Omega))\}.\end{aligned}$$

It can be readily seen now that $\widetilde{E}_0$, $\widetilde{E}_2$ and $\widetilde{E}_3$ are Banach spaces for the norms

$$\begin{aligned}\|(y,\theta,v,h)\|_{\widetilde{E}_0} = \big(&\|\beta_6\, y\|^2_{L^2} + \|\beta_7\,\theta\|^2_{L^2} + \|\beta_8\, v\|^2_{L^2}\\ &+\|\beta_9\, h\|^2_{L^2} + \|\ell^{-2}\beta_5^{1/2} y\|^2_{L^2(0,T;V)} + \|\ell^{-2}\beta_5^{1/2} y\|^2_{L^\infty(0,T;H)}\\ &+\|\ell^{-2}\beta_5^{1/2}\theta\|^2_{L^2(0,T;H_0^1)} + \|\ell^{-2}\beta_5^{1/2}\theta\|^2_{L^\infty(0,T;L^2)}\big)^{1/2},\\ \|(y,p,\theta,v,h)\|_{\widetilde{E}_2} = \Big(&\|(y,\theta,v,h)\|^2_{\widetilde{E}_0}\\ &+\|\ell^{-4}\beta_5(Ly+\nabla p - v1_{\mathcal{O}})\|^2_{L^2(0,T;H^{-1})}\\ &+\|\ell^{-4}\beta_5(P\theta + y\cdot\nabla\overline{\theta} - h1_{\mathcal{O}})\|^2_{L^2(0,T;H^{-1})}\Big)^{1/2}\end{aligned}$$

and

$$\begin{aligned}\|(y,p,\theta,v,h)\|_{\widetilde{E}_3} = \Big(&\|(y,\theta,v,h)\|^2_{\widetilde{E}_0} + \|\ell^{-2}\beta_5^{1/2} y\|^2_{L^4(0,T;L^{12})}\\ &+\|\ell^{-4}\beta_5(Ly+\nabla p - v1_{\mathcal{O}})\|^2_{L^2(0,T;W^{-1,6})}\\ &+\|\ell^{-4}\beta_5(P\theta + y\cdot\nabla\overline{\theta} - h1_{\mathcal{O}})\|^2_{L^2(0,T;H^{-1})}\Big)^{1/2}.\end{aligned}$$

PROPOSITION 2. *Assume that $n_1(x^0)\neq 0$ and $\mathcal{O}$ and $(\overline{y},\overline{\theta})$ satisfy* (11)–(13). *Let $y^0 \in E$, $\theta^0 \in L^2(\Omega)$ and let us assume that*

$$\ell^{-4}\beta_1(f,k) \in \begin{cases} L^2(0,T;H^{-1}(\Omega)^2)\times L^2(0,T;H^{-1}(\Omega)) & \text{if } N=2,\\ L^2(0,T;W^{-1,6}(\Omega)^3)\times L^2(0,T;H^{-1}(\Omega)) & \text{if } N=3.\end{cases}$$

Then, we can find controls v and h such that the associated solution to (57) *satisfies $(y,p,\theta,v,h)\in\widetilde{E}_N$. In particular, $v_1\equiv v_N\equiv 0$ and $y(T)=\theta(T)=0$.*

We omit the proof of this proposition, since it is essentially the same as the one of Proposition 2 in [12] and follows the steps of Proposition 1 above. As we have already indicated, the main ideas come from [13].

3.3. Null controllability of system (16). We will prove the null controllability of the linear system

$$\begin{cases} y_t - \Delta y + (y\cdot\nabla)\overline{y} + \nabla p = v1_{\mathcal{O}}, \quad \nabla\cdot y = 0 & \text{in } Q,\\ y\cdot n = 0, \quad \nabla\times y = 0 & \text{on } \Sigma,\\ y(0) = y^0 & \text{in } \Omega, \end{cases} \tag{59}$$

where $N=2$ and $\overline{y}\in L^\infty(Q)^2$.

For this purpose, we first rewrite this system using the streamline-vorticity formulation. Thus, setting $\omega = \nabla\times y$, we have

$$\begin{cases} \omega_t - \Delta\omega + \nabla\times((\nabla\times\psi\cdot\nabla)\overline{y}) = \nabla\times(v1_{\mathcal{O}}), \quad \Delta\psi = \omega & \text{in } Q,\\ \psi = 0, \quad \omega = 0 & \text{on } \Sigma,\\ \omega(0) = \nabla\times y^0 & \text{in } \Omega. \end{cases} \tag{60}$$

PROPOSITION 3. *Assume that $y^0\in H$ and $\overline{y}\in L^\infty(Q)^2$. Then, there exists a constant $C(\Omega,\mathcal{O},T)>0$ and controls $v1_{\mathcal{O}}$ with $v\in W$ (W was defined in* (9)*), such that*

$$\|v\|_{L^2} \le C\|y^0\|_H \tag{61}$$

and the associated solutions of (59) *satisfy*

$$y\in L^2(0,T;H^1(\Omega)^2)\cap C^0([0,T];L^2(\Omega)^2), \quad y_t\in L^2(0,T;H^{-1}(\Omega)^2), \tag{62}$$

and $y(T)=0$, with

$$\|y\|_{L^2(0,T;H^1)} + \|y\|_{C^0([0,T];L^2)} + \|y_t\|_{L^2(0,T;H^{-1})} \le C\|y^0\|_H. \tag{63}$$

Proof. We first establish the null controllability property for y. This can be done in several ways. One of them is the following. We first define for each $\varepsilon>0$ the functional

$$\begin{cases} J_\varepsilon(\gamma^0) = \dfrac{1}{2}\displaystyle\iint_{\mathcal{O}\times(0,T)} |\nabla\times\gamma|^2\,dx\,dt + \varepsilon\|\nabla\gamma^0\|_{L^2} + ((\nabla\times\gamma)(0), y^0)_{L^2}\\ \forall\gamma^0\in H_0^1(\Omega), \end{cases}$$

where γ is given by (43) with $\rho^0 = \Delta\gamma^0\in H^{-1}(\Omega)$.

It is not difficult to see from the observability inequality (48) that this functional possesses a unique minimizer $\gamma_\varepsilon^0\in H_0^1(\Omega)$ (see Proposition 2.1 in [5]). Now, from the necessary conditions for J_ε to reach a minimum, we have

$$\begin{aligned} &\iint_Q ((\nabla\times\gamma_\varepsilon)1_{\mathcal{O}})\cdot(\nabla\times\gamma)\,dx\,dt + \varepsilon\Big(\frac{\nabla\times\gamma_\varepsilon^0}{\|\nabla\times\gamma_\varepsilon^0\|_{L^2}}, \nabla\times\gamma^0\Big)_{L^2}\\ &\quad + ((\nabla\times\gamma)(0), y^0)_{L^2} = 0 \quad \forall\gamma^0\in H_0^1(\Omega). \end{aligned} \tag{64}$$

Thus, setting $v_\varepsilon = (\nabla\times\gamma_\varepsilon)1_{\mathcal{O}}$ and putting $\gamma^0=\gamma_\varepsilon^0$, we find from (48) and (64) that (61) holds for v_ε for some C independent of ε:

$$\|\nabla\times\gamma_\varepsilon\|_{L^2(\mathcal{O}\times(0,T))^2} = \|v_\varepsilon\|_{L^2(\mathcal{O}\times(0,T))^2} \le C. \tag{65}$$

Let us denote by $(\omega_\varepsilon, \psi_\varepsilon)$ the solution to (60) for $v = v_\varepsilon$. Then, taking into account the systems satisfied by (ρ, γ) and $(\omega_\varepsilon, \psi_\varepsilon)$, we deduce that

$$\iint_Q \nabla \times (v_\varepsilon 1_{\mathcal{O}})\, \gamma \, dx\, dt + (\nabla \times \gamma^0, (\nabla \times \psi_\varepsilon)(T))_{L^2} - ((\nabla \times \gamma)(0), y^0)_{L^2} = 0 \quad \forall \gamma^0 \in H_0^1(\Omega).$$

Combining this and (64), we obtain

$$\|(\nabla \times \psi_\varepsilon)(T)\|_{L^2} \leq \varepsilon. \tag{66}$$

From (65) and (66) written for each $\varepsilon > 0$, we deduce that, at least for a subsequence, $v_\varepsilon \to v$ weakly in $L^2(\mathcal{O} \times (0,T))^2$, where the control $v1_{\mathcal{O}}$ is such that the corresponding solution (ω, ψ) to (60) satisfies

$$(\nabla \times \psi)(T) = y(T) = 0 \quad \text{in } \Omega.$$

Since $v \in L^2(\mathcal{O} \times (0,T))^2$ and $\nabla \cdot v = 0$ in $\mathcal{O} \times (0,T)$, we necessarily have $v \in W$ (from De Rham's lemma applied to $(v_2, -v_1)$).

In order to obtain the desired regularity for y, we will consider again the equations satisfied by ψ and ω and we will check that

$$\psi \in L^2(0,T; H^2(\Omega)) \cap C^0([0,T]; H_0^1(\Omega)) \ \text{ and } \ \psi_t \in L^2(Q), \tag{67}$$

with appropriate estimates.

For simplicity, we will only present the estimates. The rigorous argument relies on introducing a standard Galerkin approximation of (60) with a "special" basis of $H_0^1(\Omega)$ (more precisely, the basis formed by the eigenfunctions of the Laplacian-Dirichlet operator in Ω) and deducing for the associated approximate solutions the estimates below.

Thus, let us multiply the first equation in (60) by ψ and let us integrate by parts. We find that

$$\frac{1}{2}\int_\Omega |\nabla\psi(t)|^2\, dx + \int_0^t\int_\Omega |\Delta\psi|^2\, dx\, d\tau = \int_0^t\int_{\mathcal{O}} v \cdot (\nabla \times \psi)\, dx\, d\tau - \int_0^t\int_\Omega (((\nabla \times \psi), \nabla)\, \overline{y}) \cdot (\nabla \times \psi)\, dx\, d\tau + \frac{1}{2}\|(\nabla\psi)(0)\|_{L^2}^2$$

for all $t \in (0,T)$. If we integrate by parts in the last integral, we also have

$$-\int_0^t\int_\Omega (((\nabla \times \psi) \cdot \nabla)\, \overline{y}) \cdot (\nabla \times \psi)\, dx\, d\tau = \int_0^t\int_\Omega ((\nabla \times \psi) \cdot \nabla)(\nabla \times \psi) \cdot \overline{y}\, dx\, d\tau.$$

Since $\psi|_\Sigma \equiv 0$, we deduce that

$$\psi \in L^2(0,T; H^2(\Omega)) \cap L^\infty(0,T; H_0^1(\Omega)) \tag{68}$$

and

$$\|\psi\|_{L^2(0,T;H^2)} + \|\psi\|_{L^\infty(0,T;H_0^1)} \leq C\|y^0\|_{L^2}. \tag{69}$$

Now, let us introduce for each t the function $\psi^*(t) = \Delta^{-1}\psi_t(t)$, i.e., the solution to

$$\begin{cases} -\Delta\psi^*(t) = \psi_t(t) & \text{in } \Omega \\ \psi^*(t) = 0 & \text{on } \partial\Omega. \end{cases}$$

Observe that, whenever $\psi_t(t) \in L^2(\Omega)$, this function satisfies $\psi^*(t) \in H^2(\Omega) \cap H_0^1(\Omega)$ and

$$\|\psi^*(t)\|_{H^2} \leq C\|\psi_t(t)\|_{L^2}. \tag{70}$$

Then, we multiply the first equation of (60) by ψ^* and we integrate by parts. This gives

$$\iint_Q |\psi_t|^2\,dx\,dt = \iint_Q (\Delta\psi)\,\psi_t\,dx\,dt - \iint_Q ((\nabla\times\psi)\cdot\nabla)(\nabla\times\psi^*)\cdot\overline{y}\,dx\,dt + \iint_{\mathcal{O}\times(0,T)} v\cdot(\nabla\times\psi^*)\,dx\,dt.$$

Using that $v \in L^2(Q)^2$ and we already have (69) and (70), we conclude that $\psi_t \in L^2(Q)$ and

$$\|\psi_t\|_{L^2} \leq C\|y^0\|_{L^2}. \tag{71}$$

From (69) and (71), we immediately obtain (67), (62) and (63).

This ends the proof of Proposition 3. □

4. Proofs of the controllability results for the nonlinear systems. In this last section, we will give the proofs of Theorems 1, 2 and 3. For the proofs of Theorems 1 and 2 we employ an inverse mapping theorem, while a fixed point argument is used for Theorem 3.

4.1. Proof of Theorem 1. We also follow here the steps in [7].

Thus, we set $y = \overline{y} + z$ and $p = \overline{p} + \chi$ and we use these identities in (1). Taking into account that $(\overline{y}, \overline{p})$ solves (5), we find:

$$\begin{cases} Lz + (z\cdot\nabla)z + \nabla\chi = v1_{\mathcal{O}}, \quad \nabla\cdot z = 0 & \text{in } Q, \\ z = 0 & \text{on } \Sigma, \\ z(0) = y^0 - \overline{y}^0 & \text{in } \Omega \end{cases} \tag{72}$$

(recall that L was defined in (51)).

This way, we have reduced our problem to a local null controllability result for the solution (z, χ) to the *nonlinear* problem (72).

We will use the following inverse mapping theorem (see [1]).

THEOREM 4. *Let B_1 and B_2 be two Banach spaces and let $\mathcal{A} : B_1 \mapsto B_2$ satisfy $\mathcal{A} \in C^1(B_1; B_2)$. Assume that $b_0 \in B_1$, $\mathcal{A}(b_0) = d_0$ and also that $\mathcal{A}'(b_0) : B_1 \mapsto B_2$ is surjective. Then there exists $\delta > 0$ such that, for every $d \in B_2$ satisfying $\|d - d_0\|_{B_2} < \delta$, there exists a solution of the equation*

$$\mathcal{A}(b) = d, \quad b \in B_1.$$

We will apply this result with $B_1 = E_N$,

$$B_2 = \begin{cases} L^2(\ell^{-4}\beta_2; 0, T; H^{-1}(\Omega)^2) \times H & \text{if } N = 2, \\ L^2(\ell^{-4}\beta_2; 0, T; W^{-1,6}(\Omega)^3) \times (H \cap L^4(\Omega)^3) & \text{if } N = 3 \end{cases}$$

and

$$\mathcal{A}(z, \chi, v) = (Lz + (z \cdot \nabla)z + \nabla\chi - v1_{\mathcal{O}}, z(0)) \quad \forall (z, \chi, v) \in E_N.$$

From the facts that $\ell^{-2}\beta_2^{1/2} y \in L^4(0, T; L^{12}(\Omega)^3)$ and $\mathcal{A}$ is bilinear, it is not difficult to check that $\mathcal{A} \in C^1(B_1; B_2)$; more details can be found in [13] or [7].

Let b_0 be the origin in B_1. Notice that $\mathcal{A}'(0,0,0) : B_1 \mapsto B_2$ is given by

$$\mathcal{A}'(0,0,0)(z, \chi, v) = (Lz + \nabla\chi - v1_{\mathcal{O}}, z(0)) \quad \forall (z, \chi, v) \in E_N$$

and is surjective, in view of the null controllability result for (14) given in Proposition 1.

Consequently, we can indeed apply theorem 4 with these data and there exists $\delta > 0$ such that, if $\|z(0)\|_E \leq \delta$, then we find a control v satisfying $v_1 \equiv 0$ such that the associated solution to (72) verifies $z(T) = 0$ in Ω.

This concludes the proof of Theorem 1.

4.2. Proof of Theorem 2. Again, we follow here the ideas of [12].

Therefore, we set $y = \overline{y} + z$, $p = \overline{p} + \chi$ and $\theta = \overline{\theta} + \rho$, so from (2) and (7), we find:

$$(73) \qquad \begin{cases} Lz + (z \cdot \nabla)z + \nabla\chi = v1_{\mathcal{O}} + \rho\, e_N, \quad \nabla \cdot z = 0 & \text{in } Q, \\ P\rho + (z \cdot \nabla)\rho + z \cdot \nabla\overline{\theta} = h1_{\mathcal{O}} & \text{in } Q, \\ z = 0, \quad \rho = 0 & \text{on } \Sigma, \\ z(0) = y^0 - \overline{y}^0, \quad \rho(0) = \theta^0 - \overline{\theta}(0) & \text{in } \Omega \end{cases}$$

(L and P were respectively defined in (51) and (58)).

We are thus led to prove the local null controllability of (73). To this end, we will use again Theorem 4, which was presented in subsection 4.1. Using the same notation as there, we set $B_1 = \widetilde{E}_N$,

$$B_2 = L^2(\ell^{-4}\beta_5; 0, T; H^{-1}(\Omega)^3) \times H \times L^2(\Omega)$$

if $N = 2$ and

$$B_2 = L^2(\ell^{-4}\beta_5; 0, T; W^{-1,6}(\Omega)^3 \times H^{-1}(\Omega)) \times (L^4(\Omega)^3 \cap H) \times L^2(\Omega)$$

if $N = 3$.

Let us introduce $\mathcal{A}$, with

$$\mathcal{A}(z, \chi, \rho, v, h) = (\mathcal{A}_1(z, \chi, \rho, v), \mathcal{A}_2(z, \rho, h), z(0), \rho(0)),$$

$$\mathcal{A}_1(z, \chi, \rho, v) = Lz + (z \cdot \nabla)z + \nabla\chi - v1_{\mathcal{O}} - \rho e_N$$

and

$$\mathcal{A}_2(z, \rho, h) = P\rho + (z \cdot \nabla)\rho + z \cdot \nabla\overline{\theta} - h1_{\mathcal{O}}$$

for every $(z, \chi, \rho, v, h) \in \widetilde{E}_N$.

Using the fact that $\ell^{-2}\beta_5^{1/2} z \in L^4(0,T;L^{12}(\Omega)^3)$, it can be checked that $\mathcal{A}_1$ is C^1. Then, since $\ell^{-2}\beta_5^{1/2}\rho \in L^2(0,T;H^1(\Omega)) \cap L^\infty(0,T;L^2(\Omega))$ and this space is continuously embedded in $L^4(0,T;L^3(\Omega))$, we deduce that

$$\ell^{-4}\beta_5(z,\nabla)\rho = \nabla\cdot(z\,\rho) \in L^2(0,T;W^{-1,12/5}(\Omega)) \subset L^2(0,T;H^{-1}(\Omega))$$

and, consequently, $\mathcal{A}$ is well-defined and satisfies $\mathcal{A} \in C^1(B_1;B_2)$.

The fact that $\mathcal{A}'(0,0,0,0,0) : B_1 \longmapsto B_2$ is surjective is an immediate consequence of the result given in Proposition 2.

As a conclusion, we can apply Theorem 4 and the null controllability for system (73) holds.

4.3. Proof of Theorem 3. Let us recall the nonlinear system we are dealing with:

$$\begin{cases} y_t - \Delta y + (y\cdot\nabla)\mathbf{T}_M(y) + \nabla p = v1_{\mathcal{O}} & \text{in } Q,\\ \nabla\cdot y = 0 & \text{in } Q,\\ y\cdot n = 0, \quad \nabla\times y = 0 & \text{on } \Sigma,\\ y(0) = y^0 & \text{in } \Omega. \end{cases}$$

In this case, we are going to apply Kakutani's fixed point theorem (see, for instance, [2]).

THEOREM 5. *Let Z be a Banach space and let $\Lambda : Z \mapsto Z$ be a set-valued mapping satisfying the following assumptions:*

- *$\Lambda(z)$ is a nonempty closed convex set of Z for every $z \in Z$.*
- *There exists a convex compact set $K \subset Z$ such that $\Lambda(K) \subset K$.*
- *Λ is upper-hemicontinuous in Z, i.e., for each $\sigma \in Z'$ the single-valued mapping*

$$z \mapsto \sup_{y\in\Lambda(z)} \langle \sigma, y\rangle_{Z',Z} \tag{74}$$

is upper-semicontinuous.

Then Λ possesses a fixed point in the set K, i.e., there exists $z \in K$ such that $z \in \Lambda(z)$.

In order to apply this result, we set $Z = L^2(Q)^2$ and, for each $z \in Z$, we consider the following system:

$$\begin{cases} y_t - \Delta y + (y\cdot\nabla)\mathbf{T}_M(z) + \nabla p = v1_{\mathcal{O}} & \text{in } Q,\\ \nabla\cdot y = 0 & \text{in } Q,\\ y\cdot n = 0, \quad \nabla\times y = 0 & \text{on } \Sigma,\\ y(0) = y^0 & \text{in } \Omega. \end{cases} \tag{75}$$

Then, for each $z \in Z$, we denote by $A(z)$ the set of controls $v1_{\mathcal{O}}$ with $v \in W$ that drive system (75) to zero and satisfy (61). Finally, our set-valued mapping is given as follows: for each $z \in Z$, $\Lambda(z)$ is the set of functions y that solve, together with some p, the linear system (75) corresponding to a control $v \in A(z)$.

Let us check that the assumptions of Theorem 5 are satisfied in this setting. The first one holds easily, so we omit the proof. Next, the estimates (62) and (63) tell us that the whole space Z is actually mapped into a compact set.

Let us finally see that Λ is upper-hemicontinuous in Z. Assume that $\sigma \in Z'$ and let $\{z_n\}$ be a sequence in Z such that $z_n \to z$ in Z. We have to prove that

$$\limsup_{n\to\infty} \sup_{y\in\Lambda(z_n)} \langle \sigma, y\rangle_{Z',Z} \leq \sup_{y\in\Lambda(z)} \langle \sigma, y\rangle_{Z',Z}. \tag{76}$$

Let us choose a subsequence $\{z_{n'}\}$ such that

$$\limsup_{n\to\infty} \sup_{y\in\Lambda(z_n)} \langle \sigma, y\rangle_{Z',Z} = \lim_{n'\to\infty} \sup_{y\in\Lambda(z_{n'})} \langle \sigma, y\rangle_{Z',Z}. \tag{77}$$

From the fact that $\Lambda(z_{n'})$ is a compact set of Z, for each n' we have

$$\sup_{y\in\Lambda(z_{n'})} \langle \sigma, y\rangle_{Z',Z} = \langle \sigma, y_{n'}\rangle_{Z',Z}$$

for some $y_{n'} \in \Lambda(z_{n'})$. Obviously, it can be assumed that

$$z_{n'}(x,t) \to z(x,t) \text{ a.e. } (x,t) \in Q \tag{78}$$

and

$$v_{n'} \rightharpoonup v \text{ weakly in } L^2(Q)^2 \tag{79}$$

with $v \in A(z)$. Furthermore, since all the $y_{n'}$ belong to a fixed compact set, we can also assume that

$$y_{n'} \to y \text{ in } Z$$

(after extraction of a subsequence). This, together with (77)–(79) implies that $y \in \Lambda(z)$, since we have a Stokes system with a right-hand side weakly converging in L^2 and a coefficient converging almost everywhere. As a conclusion, (76) holds and the proof of Theorem 3 is achieved.

STABILITY ANALYSIS OF DETERMINISTIC AND STOCHASTIC SWITCHED SYSTEMS VIA A COMPARISON PRINCIPLE AND MULTIPLE LYAPUNOV FUNCTIONS*

DEBASISH CHATTERJEE† AND DANIEL LIBERZON†

Abstract. This paper presents a general framework for analyzing stability of nonlinear switched systems, by combining the method of multiple Lyapunov functions with a suitably adapted comparison principle in the context of stability in terms of two measures. For deterministic switched systems, this leads to a unification of representative existing results and an improvement upon the current scope of the method of multiple Lyapunov functions. For switched systems perturbed by white noise, we develop new results which may be viewed as natural stochastic counterparts of the deterministic ones. In particular, we study stability of deterministic and stochastic switched systems under average dwell-time switching.

Key words. switched systems, stability analysis, stochastic stability, multiple Lyapunov functions, comparison principle, two measures

1. Introduction.

A family of continuous-time systems, together with a *switching signal* that chooses an *active subsystem* from the family at every instant of time, constitute a *switched system* [30]. Compared to *hybrid systems* [44], which currently are the focus of a large and growing interdisciplinary area of research, switched systems enable a more abstract modeling of continuous time systems with isolated switching events, which is suitable from a control-theoretic viewpoint. The abstraction is the result of modeling the switching signal as a purely time-dependent function, regardless of the mechanism of its generation. However, results obtained in this framework are then applicable to more specific hybrid systems; see, e.g., [18, 30] for a discussion. This paper is concerned with stability analysis of switched systems whose continuous dynamics are described by ordinary or stochastic differential equations.

Stability analysis by Lyapunov's direct method, in the simplest case of a single system, involves seeking a positive definite function of the states—called a Lyapunov function—that decreases along solution trajectories; see, e.g., [13, 22] for details. In case of switched systems, there are essentially two approaches to analyzing stability using Lyapunov's direct method; one involves investigating the existence of a *common Lyapunov function*, and the other utilizes *multiple Lyapunov functions*; see, e.g., [30, Chapters 2, 3] for an extensive account. The former approach is usually more challenging, although once a common Lyapunov function is found, the subsequent analysis is simple. The latter approach is usually more amenable to applications; typically, to check stability, one needs to allocate one Lyapunov function to each subsystem, trace through the sequence of values of these functions at switching instants, and verify certain monotonicity requirements on this sequence. We elaborate further on this method below.

The *comparison principle* [22, 28] helps in stability analysis by acting upon Lyapunov's direct method. It characterizes the time evolution of a Lyapunov function along system trajectories in terms of the solution of a scalar differential equation—the *comparison system*. The stability characteristics of the original higher dimensional system can then be inferred from those of the comparison system.

Our purpose is to establish a framework for stability analysis of (a) deterministic and (b) stochastic switched systems, by combining the method of multiple Lyapunov functions with the comparison principle. Specific motivations and contributions are elaborated below.

Deterministic switched systems. Stability analysis of deterministic switched systems using multiple Lyapunov functions first appeared in [37] and has evolved over a series of articles, for instance, [6, 19, 38]. The basic idea behind this method is to utilize stability properties of individual subsystems to infer stability properties of a switched system, thereby characterizing switching signals that ensure stability. A typical result, e.g., [30, Theorem 3.1], involves verifying two conditions to check global asymptotic stability of a switched system: first, each Lyapunov function is to monotonically decay when the corresponding subsystem is active, and second, the sequence formed by the values of each Lyapunov function at the instants when the corresponding subsystem becomes active is to be monotonically decreasing. (Henceforth we shall refer to this as the *fixed-index monotonicity condition*.) The verification of the second condition apparently requires quantitative knowledge of system trajectories. However, in situations where the switching is triggered by the state crossing some switching surfaces, on which the values of relevant Lyapunov functions match, the second condition follows if the first holds. Also, slow switching with a suitable *dwell-time* (see, e.g., [30]) allows each Lyapunov function to decay sufficiently before a switching occurs, thereby satisfying the second condition. A generalization of dwell-time switching is provided by the scheme of *average dwell-time switching* [16], which has proved to be a fruitful analysis tool in supervisory control; see [30, Chapter 6] and the references therein. This scheme requires that the number of switches over an arbitrary time interval should increase at most linearly with the length of the interval but places no specific restrictions on monotonicity of Lyapunov function values at switching instants (thereby allowing violation of the second condition above). We know that under suitable hypotheses, average dwell-time switching guarantees global asymptotic stability of a switched system [16], but the original proof of this result (provided in [30, Chapter 3]) does not utilize Lyapunov functions alone. We propose an alternative approach to stability analysis, based on the observation that a time trace of Lyapunov functions corresponding to active subsystems, in a typical trajectory of a switched system, shows impulsive behavior. Trajectories of suitable scalar impulsive differential equations may be used to generate such traces and are thus natural choices for comparison systems (cf. [29, 42], where impulsive comparison systems were utilized in stability analysis of impulsive differential equations). By employing various types of impulsive differential equations as comparison systems, in our results we relax the fixed-index sequence monotonicity condition, allowing oscillations and overshoots in the sequence, and also letting unstable subsystems participate in the dynamics. Additionally, our proofs retain conventional characteristics of Lyapunov's direct method in the context of switched systems, without resorting to independent arguments as in the proof of the average dwell-time result [16]. We propose our results on deterministic switched systems in section 2.

Stochastic switched systems. There is an enormous body of literature considering effects of noise and disturbances in systems, particularly from control and communication viewpoint; see, e.g., [7, 24, 34, 45]. The use of Lyapunov functions in stability analysis of stochastic systems is a classical idea, discussed extensively in [1, 11, 14, 25, 46]. The literature on stability of stochastic *switched* systems—constituted by subsystems perturbed by a standard Wiener process—is much less extensive compared to that on deterministic switched systems. In recent times, modeling and analysis of stochastic hybrid systems have appeared in, e.g., [17, 20]. Ergodic control of switched diffusion processes appears in [12]; stabilization methods that involve arguments similar to multiple Lyapunov functions appear in [2]. Some straightforward results involving common Lyapunov functions for stochastic switched systems may be found in [8]. We propose a framework for stochastic stability analysis by utilizing statistical estimates of Lyapunov functions at switching instants and during active periods of each subsystem. We consider some general stability definitions, for instance, global asymptotic stability in the mean and global asymptotic stability in probability, and employ the method of multiple Lyapunov functions adapted to the stochastic context. Much like the deterministic case, in a typical trajectory of a stochastic switched system, a time trace of expected values of Lyapunov functions corresponding to active subsystems shows impulsive behavior. We utilize impulsive differential equations as comparison systems to build a general framework for stability analysis of stochastic switched systems. This allows for very general behavior of the expected values of Lyapunov functions corresponding to active subsystems between switching intervals. In particular, replacing the fixed-index sequence monotonicity condition in the deterministic case with a stochastic analogue involving statistical estimates of Lyapunov functions at switching instants, we obtain a natural stochastic counterpart of [30, Theorem 3.1]. In addition, our results provide sufficient conditions for global asymptotic stability in the mean under average dwell-time switching and some more specific hypotheses. We propose our results on stochastic switched systems in section 3.

The concept of *stability analysis in terms of two measures* generalizes analysis of the norm of the state vector to analysis of the behavior of more general functions of the states; see, e.g., [29, 35]. We incorporate stability analysis in terms of two measures in the framework that we build for switched systems and gain greater flexibility for our results.

We study representative notions of deterministic and stochastic stability for a reasonably large class of switched systems. Naturally, not every type of stability can be described here. However, the framework of stability analysis we propose is applicable, as it stands, to more general stability notions, as will be indicated subsequently at appropriate places.

Some Notations. For notational convenience and brevity, we adopt the following conventions. For M_1, M_2, M_3 subsets of Euclidean space, let $\mathrm{C}[M_1, M_2]$ denote the set of all continuous functions $f : M_1 \longrightarrow M_2$, and $\mathrm{C}^1[M_1, M_2]$ denote the set of all continuously differentiable functions $f : M_1 \longrightarrow M_2$. We also use $\mathrm{C}^{1,2}[M_1 \times M_2, M_3]$ to denote the set of functions $f : M_1 \times M_2 \longrightarrow M_3$ that are continuously differentiable once and twice in the first and second arguments, respectively. We denote by $|\cdot|$ the standard Euclidean norm and by $\mathbb{R}_{\geqslant 0}$ the interval $[0, \infty[$. As usual, $\circ$ between two functions denotes their composition.

We say that a function $\alpha \in \mathrm{C}[\mathbb{R}_{\geqslant 0}, \mathbb{R}_{\geqslant 0}]$ is of class $\mathcal{K}$ if α is strictly increasing with $\alpha(0) = 0$, is of class $\mathcal{K}_\infty$ if in addition $\alpha(r) \to \infty$ as $r \to \infty$; and we write $\alpha \in \mathcal{K}$

and $\alpha \in \mathcal{K}_\infty$, respectively. A function $\beta \in \mathrm{C}\big[\mathbb{R}^2_{\geqslant 0}, \mathbb{R}_{\geqslant 0}\big]$ is said to be of class $\mathcal{KL}$ if $\beta(\cdot, t)$ is a function of class $\mathcal{K}$ for every fixed t and $\beta(r, t) \to 0$ as $t \to \infty$ for every fixed r; and we write $\beta \in \mathcal{KL}$.

2. Deterministic switched systems. In this section, we study stability of deterministic switched nonlinear nonautonomous systems. In section 2.1, we describe a switched system and the stability notions that we study and define the comparison systems that we employ in our analysis. We propose our comparison theorem for deterministic switched systems in section 2.2 and illustrate it in sections 2.3 and 2.4. We discuss two other stability notions in section 2.5 that are different from Lyapunov stability and demonstrate that their analysis can be similarly carried out in the proposed framework.

2.1. Preliminaries.

System description and stability definitions. We consider a family of nonlinear nonautonomous systems,

$$\dot{x} = f_p(t, x), \qquad p \in \mathcal{P}, \tag{2.1}$$

where $x \in \mathbb{R}^n$, $\mathcal{P}$ is an index set, $f_p \in \mathrm{C}[\mathbb{R}_{\geqslant 0} \times \mathbb{R}^n, \mathbb{R}^n]$ is a vector field measurable in the first argument and locally Lipschitz in the second (see, e.g., [41] for further details), $f_p(\cdot, 0) \equiv 0$, for every $p \in \mathcal{P}$. Let there exist a piecewise constant function (continuous from the right by convention) $\sigma : \mathbb{R}_{\geqslant 0} \longrightarrow \mathcal{P}$, which specifies at every time t the index $\sigma(t) = p \in \mathcal{P}$ of the active subsystem. A *switched system* generated by the family (2.1) and such a *switching signal* σ is

$$\dot{x} = f_\sigma(t, x), \qquad x(t_0) = x_0, \quad t \geqslant t_0, \tag{2.2}$$

where $t_0 \in \mathbb{R}_{\geqslant 0}$. It is assumed that there is no jump in the state x at the switching instants and that there is a finite number of switches on every bounded interval of time. We denote the switching instants by τ_i, $i = 1, 2, \ldots$, $\tau_0 := t_0$, and the sequence $\{\tau_i\}_{i \geqslant 0}$ is strictly increasing. The *solution of* (2.2) *as a function of time* t*, interpreted in the sense of Carathéodory, initialized at a given pair* (t_0, x_0)*, and under a given switching signal* σ, is denoted by $x(t)$.

To perform analysis in terms of two measures, we utilize functions belonging to the class defined by

$$\Gamma := \left\{ h \in \mathrm{C}[\mathbb{R}_{\geqslant 0} \times \mathbb{R}^n, \mathbb{R}_{\geqslant 0}] \;\middle|\; \inf_{(t,x)} h(t, x) = 0 \right\}. \tag{2.3}$$

We focus on the following notion of stability in terms of two measures; see, e.g., [29] for further details on other related concepts of stability. This stability definition coincides in spirit with the class $\mathcal{KL}$ stability defined for differential inclusions in the paper [43], where the authors consider autonomous systems on an extended state space.

Definition 2.1. *Let* $h^\circ, h \in \Gamma$. *The switched system* (2.2) *is said to be* (h°, h)-globally uniformly asymptotically stable ((h°, h)-GUAS) *if there exists a class* $\mathcal{KL}$ *function* β *such that for every* $(t_0, x_0) \in \mathbb{R}_{\geqslant 0} \times \mathbb{R}^n$*, the inequality*

$$h(t, x(t)) \leqslant \beta(h^\circ(t_0, x_0), t - t_0) \qquad \forall\, t \geqslant t_0 \tag{2.4}$$

holds.

In this paper we consider stability notions that are uniform with respect to the initial time t_0, e.g., global uniform asymptotic stability. The occurrences of "uniform" in the sequel convey this particular sense. In contrast, in much of the existing literature "uniform" global asymptotic stability is used to signify uniformity over a class of switching signals; see, e.g., [30]. In situations where there is uniformity in this sense, it will be explicitly indicated at appropriate places.

Remark 2.2. Under the special case of $h^\circ(t,x) = h(t,x) = |x|$, we recover usual *global uniform asymptotic stability* (GUAS), and for autonomous systems the corresponding specializations lead to *global asymptotic stability* (GAS); see, e.g., [22] for further details on GUAS and GAS. Other examples include stability with respect to arbitrary "tubes" in $\mathbb{R}_{\geqslant 0} \times \mathbb{R}^n$ with the measures h°, h being the Hausdorff point-to-set distances, stability of prescribed motion $x_{\mathrm{r}}(\cdot)$ measured by $h^\circ(t,x) = h(t,x) := |x(t) - x_{\mathrm{r}}(t)|$, and partial stability. More examples may be found in [29].

Remark 2.3. The (h°, h)-GUAS property can be rephrased in traditional $\varepsilon - \delta$ form as follows. The (h°, h)-GUAS property expressed by (2.4) holds if and only if the following properties hold simultaneously:

(S1) ((h°, h)-uniform Lyapunov stability) there exists a class $\mathcal{K}_\infty$ function δ such that for every $\varepsilon > 0$ and $t_0 \in \mathbb{R}_{\geqslant 0}$, we have $h^\circ(t_0, x_0) < \delta(\varepsilon) \implies h(t, x(t)) < \varepsilon \quad \forall\, t \geqslant t_0$;

(S2) ((h°, h)-uniform global asymptotic convergence) for every $r, \varepsilon > 0$, there exists a number $T(r,\varepsilon) \geqslant 0$ such that for every $t_0 \in \mathbb{R}_{\geqslant 0}$, we have $h^\circ(t_0, x_0) < r \implies h(t, x(t)) < \varepsilon \quad \forall\, t \geqslant t_0 + T(r,\varepsilon)$.

A similar equivalence is established in [43, Proposition 1]; the proof of the above can be easily constructed from the proof of this proposition, and for completeness is provided in section A.

We introduce properties that will later be required from Lyapunov functions, cf. [29]. Let $V \in \mathrm{C}\big[\mathbb{R}_{\geqslant 0} \times \mathbb{R}^n, \mathbb{R}_{\geqslant 0}\big]$. The function V is said to be *h-positive definite* if for $(t,x) \in \mathbb{R}_{\geqslant 0} \times \mathbb{R}^n$ there exists a function $\alpha_1 \in \mathcal{K}_\infty$ such that $\alpha_1 \circ h(t,x) \leqslant V(t,x)$, and *$h^\circ$-decrescent* if for $(t,x) \in \mathbb{R}_{\geqslant 0} \times \mathbb{R}^n$ there exists a function $\alpha_2 \in \mathcal{K}_\infty$ such that $V(t,x) \leqslant \alpha_2 \circ h^\circ(t,x)$. In results that follow, we shall require a family of functions $\{V_p \mid p \in \mathcal{P}\}$ to be *$\mathcal{P}$-uniformly h-positive definite and h° decrescent*; i.e., there exist functions $\alpha_1, \alpha_2 \in \mathcal{K}_\infty$ such that we have

$$\alpha_1 \circ h(t,x) \leqslant V_p(t,x) \leqslant \alpha_2 \circ h^\circ(t,x) \qquad \forall\, (t,x) \in \mathbb{R}_{\geqslant 0} \times \mathbb{R}^n, \quad \forall\, p \in \mathcal{P}. \tag{2.5}$$

With h° and h specialized to Euclidean norms, usual positive definiteness and decrescence of V_p are recovered.

Remark 2.4. We point out that if $\mathcal{P}$ is finite, or if $\mathcal{P}$ is compact and suitable continuity assumptions hold true, then (2.5) is no loss of generality.

In this section, we present our results in the absence of classical differentiability assumptions, and the directional upper right Dini derivative is utilized. For example, along the vector field of a member with index p of the family of systems (2.1) the derivative of a function $V_p \in \mathrm{C}[\mathbb{R}_{\geqslant 0} \times \mathbb{R}^n, \mathbb{R}_{\geqslant 0}]$ is defined as

$$\mathrm{D}^+_{f_p} V_p(t,x) := \limsup_{\epsilon \downarrow 0} \frac{1}{\epsilon} \big(V_p(t+\epsilon, x + \epsilon f_p(t,x)) - V_p(t,x) \big);$$

for further details, see, e.g., [10]. We require that the functions V_p, $p \in \mathcal{P}$ are locally Lipschitz in the second argument.

Remark 2.5. For continuously differentiable functions, the upper right Dini derivative derivative reduces to the ordinary derivative. In particular, we note that

for $V_p \in \mathrm{C}^1[\mathbb{R}_{\geqslant 0} \times \mathbb{R}^n, \mathbb{R}_{\geqslant 0}]$, the expression simplifies to

$$\mathrm{D}_{f_p} V_p(t,x) = \frac{\mathrm{d}}{\mathrm{d}t} V_p(t,x) = \left(\frac{\partial V_p}{\partial t} + \frac{\partial V_p}{\partial x} f_p \right)(t,x),$$

which is the total derivative of V_p along solutions of the system with index p in the family (2.1).

Comparison systems and deterministic comparison principle. Let the switched system (2.2) be given, and for a given switching signal σ, let $\{\tau_i\}_{i \geqslant 1}$ be the sequence of switching instants. Let $\mathbb{R}^n \times \mathcal{P} \ni (x,p) \longmapsto y(x,p) \in \mathbb{R}_{\geqslant 0}$ be a function continuous in x. We consider scalar nonlinear nonautonomous impulsive differential equations of the type

$$(2.6) \quad \begin{cases} \dot{\xi} = \phi(t,\xi), \quad t \neq \tau_i, \\ \xi(\tau_i) = \psi_i\left(\xi\left(\tau_i^-\right), y\left(x(\tau_i), \sigma(\tau_i)\right)\right), \end{cases} \qquad \xi(t_0) = \xi_0 \geqslant 0, \quad i \geqslant 1, \quad t \geqslant t_0,$$

where $\xi \in \mathbb{R}$, the field $\phi \in \mathrm{C}\big[\mathbb{R}^2_{\geqslant 0}, \mathbb{R}\big]$ and the *reset map* $\psi_i \in \mathrm{C}\big[\mathbb{R}^2_{\geqslant 0}, \mathbb{R}_{\geqslant 0}\big]$ are such that $\phi(\cdot,0) \equiv 0$ and $\psi_i(0,\cdot) \equiv 0$, $t_0 \in \mathbb{R}_{\geqslant 0}$, τ_i, $i = 1,2,\ldots$, are the instants of the impulses, $\tau_0 := t_0$, *the sequence* $\{\tau_i\}_{i \geqslant 1}$ *is identified with the sequence of switching instants generated by* σ. Systems of the type (2.6) are utilized as *comparison systems*, as well as various special cases—with or without impulses, time-variation, and y. In this paper we shall not be utilizing time-varying ϕ; an example of this may be found in [9].

We denote by $\xi(t)$ *the solution* (2.6) *as a function of time, with the sequence* $\{\tau_i\}_{i \geqslant 0}$ *specified, and initialized at* (t_0, ξ_0). In all cases, we shall tacitly assume the existence of a unique solution to differential equations of the type (2.6). If there are multiple solutions, however, the results hold true with the largest solution in place of the (unique) solution of the comparison systems.

The GUAS property of equations of the type (2.6) is defined similarly to Definition 2.1, with h°, h specialized to the scalar norm. Formally, a system of the type (2.6), with a given sequence $\{\tau_i\}_{i \geqslant 0}$, is said to be *globally uniformly asymptotically stable* (GUAS) if there exists a function $\beta_\xi \in \mathcal{KL}$ such that for every $(t_0, \xi_0) \in \mathbb{R}_{\geqslant 0} \times \mathbb{R}_{\geqslant 0}$ the inequality

$$(2.7) \qquad |\xi(t)| \leqslant \beta_\xi(|\xi_0|, t - t_0) \qquad \forall\, t \geqslant t_0$$

holds. The properties required from ϕ and ψ_i in (2.6) ensure that $\xi(\cdot) \geqslant 0$; we shall therefore omit the absolute values on ξ in the sequel.

Remark 2.6. Remark 2.3 still applies if a system of the type (2.6) replaces (2.2), with h°, h specialized to the scalar norm.

The need to compare different Lyapunov functions at switching instants, which is inherent in the multiple Lyapunov functions method, prompts us to have a function y of the system states in the reset equation of a comparison system of the type (2.6). This function will be utilized in the construction of a suitable comparison system that will render [30, Theorem 3.1] a special case of our Theorem 2.8. For yet other applications, y will not be required.

The following well-known comparison lemma for nonswitched deterministic systems is needed for subsequent developments in this section; see, e.g., [28] for a proof.

LEMMA 2.7. *Consider the system with index* p *in the family* (2.1). *Suppose that there exist a function* $V_p \in \mathrm{C}[\mathbb{R}_{\geqslant 0} \times \mathbb{R}^n, \mathbb{R}_{\geqslant 0}]$ *and a comparison system*

$$\Sigma: \quad \dot{\xi} = \phi(t,\xi), \qquad \xi(t_0) = \xi_0 \geqslant 0, \quad t \geqslant t_0,$$

such that $\forall (t,x) \in \mathbb{R}_{\geqslant 0} \times \mathbb{R}^n$, *the differential inequality*

$$\mathrm{D}^+_{f_p} V_p(t,x) \leqslant \phi(t, V_p(t,x)) \tag{2.8}$$

holds. Then $V_p(\tau, x(\tau)) \leqslant \xi(\tau)$ *implies* $V_p(t,x(t)) \leqslant \xi(t) \quad \forall\, t \geqslant \tau$, *where* $x(t)$ *and* $\xi(t)$ *are the solutions of the system with index* p *in* (2.1) *and* Σ, *respectively.*

2.2. Comparison theorem for deterministic switched systems. The following result establishes a general framework for testing stability of deterministic switched systems using multiple Lyapunov functions and a comparison system.

THEOREM 2.8. *Consider the switched system* (2.2) *with a fixed switching signal* σ *generating a sequence of switching instants* $\{\tau_i\}_{i \geqslant 1}$, *and two functions* $h^\circ, h \in \Gamma$. *Suppose that there exist functions* $\alpha_1, \alpha_2 \in \mathcal{K}_\infty$, $V_p \in \mathrm{C}[\mathbb{R}_{\geqslant 0} \times \mathbb{R}^n, \mathbb{R}_{\geqslant 0}]$, $p \in \mathcal{P}$, *locally Lipschitz in the second argument, and a system* Σ *of the type* (2.6), *such that*

(i) *the family* $\{V_p \mid p \in \mathcal{P}\}$ *is* $\mathcal{P}$*-uniformly* h*-positive definite and* h°*-decrescent in the sense of* (2.5);

(ii) $\forall\, (t,x) \in \mathbb{R}_{\geqslant 0} \times \mathbb{R}^n$ *and* $\forall\, p \in \mathcal{P}$, *we have* $\mathrm{D}^+_{f_p} V_p(t,x) \leqslant \phi(t, V_p(t,x))$;

(iii) $\forall\, (t_0, x_0) \in \mathbb{R}_{\geqslant 0} \times \mathbb{R}^n$, *there exists* $\xi_0 \in \mathbb{R}_{\geqslant 0}$ *such that* $V_{\sigma(\tau_i)}(\tau_i, x(\tau_i)) \leqslant \xi(\tau_i)$ $\forall\, i \geqslant 0$, *where* $x(t)$ *and* $\xi(t)$ *are the corresponding solutions of* (2.2) *and* Σ, *respectively;*

(iv) Σ *is* GUAS *in the sense of* (2.7).

Then (2.2) *is* (h°, h)-GUAS *in the sense of* Definition 2.1.

Proof. Consider the interval $[\tau_\ell, \tau_{\ell+1}[$, with ℓ an arbitrary nonnegative integer. From hypotheses (iii) and (ii), and Lemma 2.7 applied with $\tau = \tau_\ell$, we have

$$V_{\sigma(\tau_\ell)}(t, x(t)) \leqslant \xi(t) \qquad \forall\, t \in [\tau_\ell, \tau_{\ell+1}[.$$

The above estimate in conjunction with hypothesis (iv) leads to

$$V_{\sigma(\tau_\ell)}(t, x(t)) \leqslant \xi(t) \leqslant \beta_\xi(\xi_0, t - t_0) \qquad \forall\, t \in [\tau_\ell, \tau_{\ell+1}[.$$

In view of hypothesis (i), we have

$$\alpha_1 \circ h(t, x(t)) \leqslant \beta_\xi(\alpha_2 \circ h^\circ(t_0, x_0), t - t_0) \qquad \forall\, t \in [\tau_\ell, \tau_{\ell+1}[. \tag{2.9}$$

With $\beta(r,s) := \alpha_1^{-1} \circ \beta_\xi(\alpha_2(r), s)$, the estimate in (2.9) is equivalent to

$$h(t, x(t)) \leqslant \beta(h^\circ(t_0, x_0), t - t_0) \qquad \forall\, t \in [\tau_\ell, \tau_{\ell+1}[.$$

Clearly $\beta \in \mathcal{KL}$. The arbitrariness of ℓ implies that

$$h(t, x(t)) \leqslant \beta(h^\circ(t_0, x_0), t - t_0) \qquad \forall\, t \geqslant t_0.$$

The (h°, h)-GUAS property of (2.2) follows. ∎

Theorem 2.8 does not provide a direct method for analyzing stability of a given switched system; we need to look for a suitable comparison system and check its stability properties first. We will now demonstrate how to proceed with such a scheme of analysis and how our framework stands in relation to existing results involving multiple Lyapunov functions. In section 2.3, we generalize [30, Theorem 3.1] in terms of two measures, which involves verification of a fixed-index sequence monotonicity condition to establish the (h°, h)-GUAS property of a switched system. The comparison system utilized in the proof makes use of quantitative information of system trajectories. In section 2.4 we construct comparison systems to rederive the sufficient conditions for GUAS of switched system under average dwell-time switching given in [30, Theorem 3.2] or [16]. Although the fixed-index sequence monotonicity condition is violated, the comparison framework of Theorem 2.8 works; also we do not require explicit information of system trajectories.

2.3. Stability under fixed-index sequence monotonicity condition. For this subsection, we let $\mathcal{P}$ be a finite set of N elements.

COROLLARY 2.9. *Consider the switched system* (2.2) *and* $h^\circ, h \in \Gamma$. *Suppose that there exist functions* $\alpha_1, \alpha_2 \in \mathcal{K}_\infty$, $\rho, U \in \mathcal{K}$, α *positive definite,* $V_p \in \mathrm{C}[\mathbb{R}_{\geqslant 0} \times \mathbb{R}^n, \mathbb{R}_{\geqslant 0}]$ *for each* $p \in \mathcal{P}$ *locally Lipschitz in the second argument, such that*

(i) *the family* $\{V_p \mid p \in \mathcal{P}\}$ *is* $\mathcal{P}$*-uniformly* h*-positive definite and* h°*-decrescent in the sense of* (2.5)*;*

(ii) $\forall\, (t,x) \in \mathbb{R}_{\geqslant 0} \times \mathbb{R}^n$ *and* $\forall\, p \in \mathcal{P}$, *we have* $\mathrm{D}^+_{f_p} V_p(t,x) \leqslant -\alpha \circ h^\circ(t,x)$*;*

(iii) *for every pair of switching time* (τ_i, τ_j), $i < j$ *such that* $\sigma(\tau_i) = \sigma(\tau_j) = p \in \mathcal{P}$ *and* $\sigma(\tau_k) \neq p$ *for* $\tau_i < \tau_k < \tau_j$, *the inequality*

$$V_p(\tau_j, x(\tau_j)) - V_p(\tau_i, x(\tau_i)) \leqslant -U \circ h^\circ(\tau_i, x(\tau_i)) \tag{2.10}$$

holds, where $x(t)$ *is the solution of* (2.2) *initialized at* (t_0, x_0)*;*

(iv) $\forall\, (t,x) \in \mathbb{R}_{\geqslant 0} \times \mathbb{R}^n$, *we have* $\alpha_2 \circ h^\circ(t,x) \leqslant \rho \circ \alpha_1 \circ h(t,x)$.

Then (2.2) *is* (h°, h)-GUAS.

Proof. We define a candidate impulsive differential comparison system of the type (2.6):

$$\Sigma: \quad \begin{cases} \dot{\xi} = -\alpha \circ \alpha_2^{-1}(\xi), & t \neq \tau_i, \\ \xi(\tau_i) = V_{\sigma(\tau_i)}(\tau_i, x(\tau_i)), & \end{cases} \qquad i \geqslant 0, \quad t \geqslant t_0. \tag{2.11}$$

By its very definition, Σ satisfies hypotheses (ii)–(iii) of Theorem 2.8. Hypothesis (i) of Theorem 2.8 is satisfied by our hypothesis (i). To verify hypothesis (iv) of Theorem 2.8, we shall first prove uniform Lyapunov stability of Σ and then prove its global uniform asymptotic convergence, in view of Remark 2.6.

Consider the interval $[\tau_0, \tau_1[$. From hypothesis (ii) we have

$$V_{\sigma(\tau_0)}(\tau_1, x(\tau_1)) \leqslant V_{\sigma(\tau_0)}(\tau_0, x(\tau_0)).$$

Combining with hypothesis (i), we reach

$$\alpha_1 \circ h(\tau_1, x(\tau_1)) \leqslant \alpha_2 \circ h^\circ(t_0, x_0). \tag{2.12}$$

For every $p \in \mathcal{P}$, we have from hypothesis (i)

$$V_p(\tau_1, x(\tau_1)) \leqslant \alpha_2 \circ h^\circ(\tau_1, x(\tau_1)),$$

and therefore by hypothesis (iv),

$$V_p(\tau_1, x(\tau_1)) \leqslant \rho \circ \alpha_1 \circ h(\tau_1, x(\tau_1)).$$

In view of (2.12), we get

$$V_p(\tau_1, x(\tau_1)) \leqslant \rho \circ \alpha_2 \circ h^\circ(t_0, x_0). \tag{2.13}$$

Consider now the interval $[\tau_1, \tau_2[$. From hypothesis (ii) we have

$$V_{\sigma(\tau_1)}(\tau_2, x(\tau_2)) \leqslant V_{\sigma(\tau_1)}(\tau_1, x(\tau_1)).$$

Combining with hypothesis (i) and applying (2.13) with $p = \sigma(\tau_2)$, we get

$$\alpha_1 \circ h(\tau_2, x(\tau_2)) \leqslant \rho \circ \alpha_2 \circ h^\circ(t_0, x_0). \tag{2.14}$$

Now, for all $p \in \mathcal{P}$, we have

$$V_p(\tau_2, x(\tau_2)) \leqslant \alpha_2 \circ h^\circ(\tau_2, x(\tau_2)),$$

so by hypothesis (iv),

$$V_p(\tau_2, x(\tau_2)) \leqslant \rho \circ \alpha_1 \circ h(\tau_2, x(\tau_2)).$$

Now (2.14) gives

$$V_p(\tau_2, x(\tau_2)) \leqslant \rho \circ \rho \circ \alpha_2 \circ h^\circ(t_0, x_0).$$

It is not difficult to see that the worst-case situation for maximum possible overshoot of the function V_σ occurs when the switching signal σ visits every element of the set $\mathcal{P}$ without repetition until $\mathcal{P}$ is exhausted. Let $\tau_{j^\star}$ be the first switching instant after all the subsystems that participate in the dynamics have become active at least once since initialization at $t = t_0$. Define the function

$$\rho^j := \underbrace{\rho \circ \ldots \circ \rho}_{j \text{ times}}.$$

From the above computations, it is easy to see that

$$\xi(\tau_{j^\star}) = V_{\sigma(\tau_{j^\star})}(\tau_{j^\star}, x(\tau_{j^\star})) \leqslant \rho^{\mathrm{N}-1} \circ \alpha_2 \circ h^\circ(t_0, x_0).$$

Clearly $\rho^{\mathrm{N}-1} \in \mathcal{K}$. Define the function

$$\gamma(\cdot) := \max\left\{\alpha_2(\cdot), \rho \circ \alpha_2(\cdot), \ldots, \rho^{\mathrm{N}-1} \circ \alpha_2(\cdot)\right\}.$$

From (2.10) it follows that $\xi(t) \leqslant \gamma \circ h^\circ(t_0, x_0)\, \forall\, t \geqslant t_0$. Therefore, by hypothesis (i) and the definition of ξ_0 in (2.11),

$$\xi(t) \leqslant \gamma \circ \alpha_1^{-1}(\xi_0) \qquad \forall\, t \geqslant t_0. \tag{2.15}$$

It remains to prove uniform global asymptotic convergence of Σ.

We distinguish two cases.

Case 1. *Switching stops in finite time.* Since σ eventually attains a constant value, say, from the κth switching instant, it follows that there are no impulses after $t = \tau_\kappa$. That is to say, the system (2.11) becomes an autonomous scalar ordinary differential equation after $t = \tau_\kappa$, with negative right-hand side for nonzero $\xi(\tau_\kappa)$. Therefore, $\xi(t)$ monotonically decreases to $0\, \forall\, t \geqslant \tau_\kappa$. In conjunction with (2.15) which shows uniform Lyapunov stability of Σ, we conclude that (2.11) is GUAS. Theorem 2.8 now guarantees that (2.2) is (h°, h)-GUAS.

Case 2. *Switching continues indefinitely.* Consider the restatement of the inequality (2.10) with $\xi(\tau_i)$ as defined in (2.11)

$$\begin{aligned}\xi(\tau_j) - \xi(\tau_i) &\leqslant -U \circ h^\circ(\tau_i, x(\tau_i)) \\ &\leqslant -U \circ \alpha_2^{-1} \circ V_p(\tau_i, x(\tau_i)) \\ &= -U \circ \alpha_2^{-1} \circ \xi(\tau_i).\end{aligned}$$

The pair (τ_i, τ_j) satisfies the condition in hypothesis (iii). Clearly, $\{\xi(\tau_i)\}_{\{i \geqslant 0 | \sigma(\tau_i) = p\}}$ is a positive (for nonzero x_0) monotonically decreasing sequence and must attain a limit, say, $c \geqslant 0$. If $c \neq 0$, then

$$\xi(\tau_j) - \xi(\tau_i) \leqslant -U \circ \alpha_2^{-1}(c)$$

for all (τ_i, τ_j) satisfying hypothesis (iii), which means that for some large enough j, say, j', $\xi(\tau_{j'}) < 0$. In view of (2.11) this means $V_{\sigma(\tau_{j'})}(\tau_{j'}, x(\tau_{j'})) < 0$, contradicting the hypothesis. Therefore, the subsequence $\{\xi(\tau_i)\}_{\{i \geqslant 0 | \sigma(\tau_i) = p\}}$ attains the limit 0 as $i \uparrow \infty$. For all time t between any two switching instants (τ_i, τ_j) satisfying hypothesis (iii), there is a uniform bound on $\xi(t)$ given by (2.15). For each $p \in \mathcal{P}$, the subsequence $\{\xi(\tau_i)\}_{\{i \geqslant 0 | \sigma(\tau_i) = p\}}$ attains the limiting value of 0, implying global asymptotic convergence. Combining with Lyapunov stability proved in (2.15) above, we conclude that Σ is GUAS.

By Theorem 2.8 now we conclude that (2.2) is (h°, h)-GUAS. □

Remark 2.10. We note that in the above proof, Σ makes explicit use of state information of (2.2)—in the notation of (2.6), we use

$$\psi_i\left(\xi\left(\tau_i^-\right), y(x(\tau_i), \sigma(\tau_i))\right) = V_{\sigma(\tau_i)}(\tau_i, x(\tau_i))$$

in the reset equation of Σ. On the other hand, $\xi(\tau_i^-)$ is not utilized.

Remark 2.11. Hypothesis (iv) in Corollary 2.9 essentially is a technical requirement to ensure that the measure h is nontrivial. This guarantees that the different Lyapunov functions at switching instants can be estimated from the initial condition. For $h^\circ(t, x) = h(t, x) = |x|$, this property is automatic (just let $\rho := \alpha_2 \circ \alpha_1^{-1}$), and then Corollary 2.9 becomes identical to [30, Theorem 3.1].

2.4. Stability under average dwell-time switching. In this subsection we rederive an existing result on global asymptotic stability under average dwell-time switching via our Theorem 2.8. We no longer retain the assumption that $\mathcal{P}$ is finite. Although we specialize to Euclidean norms and autonomous switched systems—to be able to use the aforesaid result in situ—the analysis can be readily generalized to two measures and nonautonomous switched systems.

Let us consider the autonomous switched system

$$\dot{x} = f_\sigma(x), \qquad x(t_0) = x_0, \quad t \geqslant t_0, \tag{2.16}$$

where $x \in \mathbb{R}^n$, $f_p \in \mathrm{C}[\mathbb{R}^n, \mathbb{R}^n]$ is locally Lipschitz for every $p \in \mathcal{P}$, $f_p(0) = 0$. The switching signal σ is said to have *average dwell-time* $\tau_a > 0$ [16] if there exists a positive number $N_\circ$ such that the number of switches $N_\sigma(T, t)$ on the interval $[t, T[$ satisfies

$$N_\sigma(T, t) \leqslant N_\circ + \frac{T - t}{\tau_a} \qquad \forall\, T \geqslant t \geqslant t_0. \tag{2.17}$$

We investigate the conditions on the average dwell-time of the switching signal σ such that (2.16) is GAS. The available result is as follows. (For a detailed discussion and proof, see, e.g., [30, Theorem 3.2].)

THEOREM 2.12 (see [16]). *Consider the switched system* (2.16). *Let there exist functions* $V_p \in \mathrm{C}^1[\mathbb{R}^n, \mathbb{R}_{\geqslant 0}]$ *for every* $p \in \mathcal{P}$, $\alpha_1, \alpha_2 \in \mathcal{K}_\infty$ *and a positive number* $\lambda_\circ$ *such that*

$$\alpha_1(|x|) \leqslant V_p(x) \leqslant \alpha_2(|x|) \qquad \forall\, p \in \mathcal{P} \tag{2.18}$$

and

$$\frac{\partial V_p}{\partial x}(x) f_p(x) \leqslant -\lambda_\circ V_p(x) \qquad \forall\, x \in \mathbb{R}^n. \tag{2.19}$$

Suppose also that there exists a positive constant μ such that

$$V_p(x) \leqslant \mu V_q(x) \qquad \forall\, x \in \mathbb{R}^n, \quad \forall\, p, q \in \mathcal{P}. \tag{2.20}$$

Then (2.16) *is* GAS *for every switching signal σ with average dwell-time $\tau_a > \frac{\ln \mu}{\lambda_\circ}$.*

Remark 2.13. The condition (2.20) imposes a restriction on permissible Lyapunov functions. Since this is a global result, it does not hold if, for example, some of the Lyapunov functions are quadratic and some others are quartic. Also, in view of interchangeability of p and q in (2.20), it follows that $\mu > 1$, excluding the trivial case of $\mu = 1$, which implies that there is a *common Lyapunov function* for the switched system [30].

For a fixed index $p \in \mathcal{P}$, the values of the Lyapunov function V_p at every switching instant τ_j with $\sigma(\tau_j) = p$ form a sequence $\{V_p(x(\tau_j))\}_{\{j \geqslant 0 | \sigma(\tau_j) = p\}}$. As discussed in section 1, results like [30, Theorem 3.1] provide sufficient conditions for stability of the switched system under the assumption that the sequences $\{V_p(x(\tau_j))\}_{\{j \geqslant 0 | \sigma(\tau_j) = p\}}$ are monotonically decreasing for every $p \in \mathcal{P}$. But σ with an average dwell-time permits overshoots and oscillations in each of these sequences; thus [30, Theorem 3.1] is inapplicable. We mentioned in section 1 that currently the problem is tackled by independent arguments utilizing auxiliary functions, as in [30]; the proof does not utilize the Lyapunov functions alone. In the framework of Theorem 2.8, we can dispense with such auxiliary functions and easily rederive Theorem 2.12, as we now demonstrate.

To the end of this subsection, we assume that the hypotheses of Theorem 2.12 hold.

An impulsive differential equation as a comparison system. Consider an impulsive differential system of the type (2.6) with

$$\psi_i\left(\xi\left(\tau_i^-\right), y(x(\tau_i), \sigma(\tau_i))\right) := \mu \xi(\tau_i^-), \quad i \geqslant 1, \quad \mu > 0,$$

as the reset equation and

$$\phi(t, \xi) := -\lambda_\circ \xi, \quad \lambda_\circ > 0.$$

The complete system stands as

$$\Sigma' : \quad \begin{cases} \dot{\xi} = -\lambda_\circ \xi, & t \neq \tau_i, \\ \xi(\tau_i) = \mu \xi(\tau_i^-), & \mu > 0, \end{cases} \qquad \xi(t_0) = V_{\sigma(t_0)}(x_0), \quad i \geqslant 1, \quad t \geqslant t_0. \tag{2.21}$$

From (2.18) it follows that hypothesis (i) of Theorem 2.8 is satisfied with $h^\circ(t, x) = h(t, x) = |x|$. Further, from (2.19) and (2.20) together with the initial condition in (2.21), it follows that hypotheses (ii) and (iii) of Theorem 2.8 are satisfied, respectively. Now we investigate stability of Σ'.

Let $T > 0$ be arbitrary. Consider the evolution of the system (2.21) from $t = t_0$ through $t = T$. Let there be $N_\sigma(T, t_0)$ switches on this interval, and let $\nu := N_\sigma(T, t)$, where $N_\sigma(T, t)$ is as defined in (2.17)

$$\xi(\tau_{i+1}^-) = \xi(\tau_i) \mathrm{e}^{-\lambda_\circ(\tau_{i+1} - \tau_i)}, \quad 0 \leqslant i \leqslant \nu,$$

and

$$\xi(T) = \xi(\tau_\nu) \mathrm{e}^{-2\lambda_\circ(T - \tau_\nu)}.$$

Combining with the reset equation of Σ' and iterating over i, it follows that

$$\xi(T) = \xi(t_0)\mu^{\nu}\mathrm{e}^{-\lambda_\circ(T-t_0)}. \tag{2.22}$$

Using the definition of ν, (2.22) leads to

$$\xi(T) = \xi(t_0)\mu^{N_\circ}\mathrm{e}^{\lambda_\circ t_0}\mathrm{e}^{-(\lambda_\circ - \ln\mu/\tau_a)T}. \tag{2.23}$$

To ensure $\xi(T) \to 0$ as $T \uparrow \infty$, it is sufficient to have $\tau_a > \frac{\ln\mu}{\lambda_\circ}$. This guarantees the convergence of the impulsive differential system (2.21) to zero as time increases to infinity. Stability of Σ' follows directly from (2.23)—the estimate $\xi(t) \leqslant \xi(t_0)\mu^{N_\circ}\mathrm{e}^{\lambda_\circ t_0}$ holds if $\tau_a > \frac{\ln\mu}{\tau_a}$. We conclude that Σ' is GAS, considering Remark 2.6. Therefore, hypothesis (iv) of Theorem 2.8 is also satisfied.

Intuitively,

- the minimum rate of decay of the Lyapunov function corresponding to each active subsystem is captured by the continuous dynamics of Σ'; and
- the maximum jump in the values of two Lyapunov functions corresponding to two consecutively active subsystems is captured by the reset equation of Σ'.

We conclude that by Theorem 2.8 the switched system (2.16) is GAS for switching signals with $\tau_a > \frac{\ln\mu}{\lambda_\circ}$.

An ordinary differential equation as a comparison system. Consider the following scalar autonomous differential equation, a special case of (2.6), for a candidate comparison system:

$$\Sigma'' : \quad \dot{\xi} = \left(\frac{\ln\mu}{\tau_a} - \lambda_\circ\right)\xi, \qquad \xi(t_0) = \mu^{N_\circ}\mathrm{e}^{\lambda_\circ t_0}V_{\sigma(t_0)}(x_0), \quad t \geqslant t_0. \tag{2.24}$$

The solution of Σ'' is

$$\xi(t) = \mu^{N_\circ}V_{\sigma(t_0)}(x_0)\mathrm{e}^{-(\lambda_\circ - \ln\mu/\tau_a)(t-t_0)} \qquad \forall\, t \geqslant t_0. \tag{2.25}$$

Let average dwell-time of σ be τ_a, and $\nu := N_\sigma(T, t_0)$ be the number of switches on $[t_0, T[$. Considering the least rate of decay for Lyapunov functions corresponding to active subsystems, we have for an arbitrary $T \geqslant 0$,

$$V_{\sigma(\tau_i)}(x(\tau_i^-)) \leqslant V_{\sigma(\tau_i)}(x(\tau_i))\mathrm{e}^{-\lambda_\circ(\tau_{i+1}-\tau_i)}, \quad 0 \leqslant i \leqslant \nu,$$

and

$$V_{\sigma(\tau_\nu)}(x(T)) \leqslant V_{\sigma(\tau_\nu)}(x(T))\mathrm{e}^{-\lambda_\circ(T-\tau_\nu)}.$$

Combining with (2.20) at switching instants and iterating over i, we reach the estimate

$$V_{\sigma(\tau_\nu)}(x(T)) \leqslant \mu^{\nu}V_{\sigma(t_0)}(x_0)\mathrm{e}^{-\lambda_\circ T} = \mu^{N_\circ}\mathrm{e}^{\lambda_\circ t_0}V_{\sigma(t_0)}(x_0)\mathrm{e}^{-(\lambda_\circ - \ln\mu/\tau_a)T}. \tag{2.26}$$

Clearly, $\lambda_\circ > \frac{\ln\mu}{\tau_a}$ ensures global asymptotic stability of Σ''. By Theorem 2.8 with $h^\circ(t,x) = h(t,x) = |x|$, it follows that (2.16) is GAS for switching signals with $\tau_a > \frac{\ln\mu}{\lambda_\circ}$.

From (2.18) it follows that hypothesis (i) of Theorem 2.8 is satisfied with $h^\circ(t,x) = h(t,x) = |x|$. Further, from the discussion above, it follows that hypotheses (ii)–(iv) of Theorem 2.8 are also satisfied

Intuitively,

- the initial condition of Σ'' captures the maximum possible overshoot in V_σ—this corresponds to the situation when all $N_\circ$ switches occur very close to $t = t_0$;
- $\xi(\cdot)$ forms an envelope of the sequence $\left\{V_{\sigma(\tau_i)}(x(\tau_i))\right\}_{i\geqslant 0}$ over the interval $[t_0, T]$.

We conclude that by Theorem 2.8 the switched system (2.16) is GAS for switching signals with $\tau_a > \frac{\ln \mu}{\lambda_\circ}$. This agrees with the assertion of Theorem 2.12.

Remark 2.14. We note that in contrast to (2.11), the comparison systems (2.21) and (2.24) do not utilize state information in the function y directly. However (2.21) utilizes $\xi(\tau_i^-)$ in the reset equation; cf. Remark 2.10.

Remark 2.15. It is easy to see from (2.22) and (2.25) that for switching signals with average dwell-time bounded away from $\frac{\ln \mu}{\lambda_\circ}$, we have GAS of (2.16). For instance, for $\lambda \in \,]0, \lambda_\circ[$ if $\tau_a \geqslant \frac{\ln \mu}{\lambda_\circ - \lambda}$, then the GAS property of (2.16) follows. Under this situation, (2.16) is GAS *uniformly* over all switching signals with $\tau_a \geqslant \frac{\ln \mu}{\lambda_\circ - \lambda}$. In prevailing literature, (2.16) is said to be *globally "uniformly" asymptotically stable* over all such switching signals.

Our comparison-based approach enables us to work with simple scalar differential equations which provide upper bounds of Lyapunov functions, rather than analyze the complicated evolution of the Lyapunov functions themselves. This provides new insights into average dwell-time switching, as is illustrated above, and moreover we can derive new switching rules that extend average dwell-time, as the following two remarks illustrate.

Remark 2.16. Let $N_\sigma(T, t)$ denote the number of switches on the interval $[t, T[$. As another illustration of Theorem 2.8, consider the switched system (2.2), and suppose that there exist functions $\alpha_1, \alpha_2 \in \mathcal{K}_\infty$, $V_p \in \mathrm{C}[\mathbb{R}_{\geqslant 0} \times \mathbb{R}^n, \mathbb{R}_{\geqslant 0}]$, $p \in \mathcal{P}$, and real numbers $m > 1, \lambda_\circ > 0, \mu > 1$, such that

(i) the family $\{V_p \mid p \in \mathcal{P}\}$ is $\mathcal{P}$-uniformly h-positive definite and h°-decrescent in the sense of (2.5);
(ii) $\forall\, (t, x) \in \mathbb{R}_{\geqslant 0} \times \mathbb{R}^n$ and $\forall\, p \in \mathcal{P}$, we have $\mathrm{D}^+_{f_p} V_p(t, x) \leqslant -\lambda_\circ V_p^m(t, x)$;
(iii) $\forall\, (t, x) \in \mathbb{R}_{\geqslant 0} \times \mathbb{R}^n$ and $\forall\, p, q \in \mathcal{P}$, we have $V_p(t, x) \leqslant \mu V_q(t, x)$.

Let us find conditions on $N_\sigma(T, t_0)$ such that (2.2) is (h°, h)-GUAS.

Consider the impulsive differential system of the type (2.6):

$$\overline{\Sigma}: \quad \begin{cases} \dot{\xi} = -\lambda_\circ \xi^m, & t \neq \tau_i, \\ \xi(\tau_i) = \mu \xi(\tau_i^-), & \mu > 0, \end{cases} \qquad \xi(t_0) = V_{\sigma(t_0)}(x(t_0)), \quad i \geqslant 1, \quad t \geqslant t_0.$$

A straightforward analysis leads to

$$\xi(T) = \frac{\mu^{N_\sigma(T,t_0)} \xi(t_0)}{\left(1 + \lambda_\circ (m-1)(\xi(t_0))^{m-1} \left(\sum_{i=1}^{N_\sigma(T,t_0)+1} \mu^{(m-1)(i-1)} (\tau_i - \tau_{i-1})\right)\right)^{1/(m-1)}},$$

where we let $\tau_{N_\sigma(T,t_0)+1} := T$. Since $\mu > 1$, we obtain

$$\xi(T) \leqslant \frac{\mu^{N_\sigma(T,t_0)} \xi(t_0)}{\left(1 + \lambda_\circ (m-1)(\xi(t_0))^{m-1} (T - t_0)\right)^{1/(m-1)}}.$$

A little calculation shows that if there exists $\epsilon > 0$ and $K > 0$ such that

(2.27)
$$N_\sigma(T, t_0) \leqslant \frac{1}{\ln \mu} \ln \left(\frac{K \left(1 + \lambda_\circ (m-1) \left(\alpha_2 \circ h^\circ(t_0, x_0)\right)^{m-1} (T - t_0)\right)^{\left(\frac{1}{m-1} - \epsilon\right)}}{\alpha_2 \circ h^\circ(t_0, x_0)} \right),$$

then $\overline{\Sigma}$ is GUAS. Just as in the case of Σ' and Σ'' above, it is easy to verify that the hypotheses of Theorem 2.8 hold with $\Sigma = \overline{\Sigma}$. It then follows by Theorem 2.8 that (2.2) is (h°, h)-GUAS. Note that unlike the case of average dwell-time, the switching law in (2.27) that guarantees (h°, h)-GUAS of (2.2) depends on the initial conditions (t_0, x_0).

Remark 2.17. In the context of Theorem 2.8, it is not necessary to assume that each subsystem in the family (2.1) is (h°, h)-GUAS for the switched system (2.2) to be (h°, h)-GUAS. This is evident from hypothesis (ii), which does not require ϕ to be negative definite in the second argument. It is possible that none of the individual subsystems is (h°, h)-GUAS but the switched system is, provided each subsystem is active for a small enough time.

For instance, consider the switched system (2.16) and suppose that switching is such that the number of switches $N_\sigma(T, t_0)$ on the interval $[t_0, T[$ is given by

$$N_\sigma(T, t_0) \geqslant \frac{T - t_0}{\delta_a} - N_\circ, \tag{2.28}$$

where $N_\circ, \delta_a > 0$. Such switching signals were called "reverse average dwell-time switching signals" in [15]. Let there exist functions $\alpha_1, \alpha_2 \in \mathcal{K}_\infty$, $V_p \in \mathrm{C}^1[\mathbb{R}^n, \mathbb{R}_{\geqslant 0}]$, $p \in \mathcal{P}$, and real numbers $\mu' \in]0, 1[$ and $\lambda_\circ > 0$, such that

(i) the estimate (2.18) holds;
(ii) $\frac{\partial V_p}{\partial x} f_p(x) \leqslant \lambda_\circ V_p(x) \qquad \forall\, x \in \mathbb{R}^n, \quad \forall\, p \in \mathcal{P}$;
(iii) $V_{\sigma(\tau_i)}(x(\tau_i)) \leqslant \mu' V_{\sigma(\tau_i^-)}(x(\tau_i^-)) \quad \forall\, i \geqslant 1$;
(iv) $\delta_a < -\ln \mu' / \lambda_\circ$.

Then (2.16) is GAS. Indeed, consider the comparison system

$$\widetilde{\Sigma}: \quad \begin{cases} \dot{\xi} = \lambda_\circ \xi, & t \neq \tau_i, \\ \xi(\tau_i) = \mu' \xi(\tau_i^-), \end{cases} \qquad \xi(t_0) = V_{\sigma(t_0)}(t_0, x_0), \quad i \geqslant 1, \quad t \geqslant t_0. \tag{2.29}$$

It is easy to see that hypothesis (i) with $h^\circ(t, x) = h(t, x) = |x|$, and hypotheses (ii) and (iii) of Theorem 2.8 are satisfied. Following the constructions for Σ' in (2.21) above, it is not difficult to show that the solution of $\widetilde{\Sigma}$ is given by

$$\xi(T) = (\mu')^{N_\circ} V_{\sigma(t_0)}(x(t_0)) \mathrm{e}^{(\lambda_\circ + \ln \mu'/\delta_a)(T - t_0)}, \tag{2.30}$$

where $T > t_0$. Clearly, from (2.30) it follows that $\widetilde{\Sigma}$ is GAS if $\lambda_\circ + \ln \mu'/\delta_a < 0$. In other words, if the condition (iv) above holds, hypothesis (iv) of Theorem 2.8 is also satisfied; Theorem 2.8 now guarantees that (2.16) is GAS. However, this situation is admittedly restrictive; the condition (iii) above holds only under special situations.

Remark 2.18. Consider a hybrid system described by a partition of its continuous state space into regions via fixed switching surfaces (*guards*) and fixed continuous dynamics in each region [30, 44]. Every trajectory of such a hybrid system corresponding to a fixed initial condition can be realized as a trajectory of the switched system (2.2),

for a suitable time-dependent switching signal σ. For hybrid system trajectories corresponding to different initial conditions, the resulting switching signals are in general different, and stability properties of the corresponding switched system realizations are different. Therefore, we cannot conclude stability of the hybrid system from stability of the associated switched system. However, it is possible to conclude stability of the hybrid system from the switched system provided we have uniform stability with respect to a suitable class of switching signals—namely, the class of switching signals obtained from the hybrid system by varying its initial condition.

We have stated our Theorem 2.8 for a fixed switching signal σ; no uniformity with respect to σ is claimed. However, we have noted in Remark 2.15 that under specific hypotheses, we do have uniform stability over the class of switching signals with sufficiently large average dwell-time. It turns out that in supervisory control algorithms based on state-dependent hysteresis switching (utilizing guards with memory), the switching signal is effectively constrained to precisely such a class, thereby ensuring uniform stability; see, e.g., [30] and the references therein. Identification of other useful classes of switching signals for which we can conclude stability for hybrid systems in this way remains to be studied.

2.5. Remarks on other stability notions. Although not covered by the results presented so far, the comparison framework of Theorem 2.8 is general enough to describe various other stability behavior. The classical comparison principle has been successfully applied to describe *strict stability*, *total stability*, *practical stability*, and *finite time stability*, among others. The idea has also been applied in the context of partial, impulsive, stochastic, and functional differential equations and integral equations; see [29] for further details. In this subsection we study two other notions of stability of switched systems in our framework of Theorem 2.8, namely, uniform practical stability and finite time stability.

Practical stability. We briefly study one representative notion of practical stability, defined below; see, e.g., [27] for other definitions and details.

DEFINITION 2.19. *Let $h^\circ, h \in \Gamma$ and the pair (λ, A), $\lambda \in]0, A[$ be given. The system* (2.2) *is said to be* (h°, h)-uniformly practically stable with respect to (λ, A) *if for every $t_0 \in \mathbb{R}_{\geqslant 0}$, the property*

$$h^\circ(t_0, x_0) < \lambda \implies h(t, x(t)) < A \qquad \forall\, t \geqslant t_0 \tag{2.31}$$

holds for all solutions of (2.2).

With h°, h specialized to Euclidean norms, we recover usual uniform practical stability.

Remark 2.20. Uniform practical stability of impulsive differential equations of the type (2.6), for a given sequence $\{\tau_i\}_{i\geqslant 0}$, is identical to Definition 2.19, with h°, h specialized to absolute values.

The following result, which we state without proof, provides sufficient conditions for (h°, h) uniform practical stability of the switched system (2.2) with respect to a given pair (λ, A); see [9] for a proof. In section 3.5 we state and prove a stochastic version of this result. We define the "open tube" (or cylinder) of radius $r > 0$ in terms of a measure $h \in \Gamma$ to be the set

$$\mathcal{B}(h, r) = \{(t, x) \in \mathbb{R}_{\geqslant 0} \times \mathbb{R}^n \mid h(t, x) < r\}.$$

PROPOSITION 2.21. *Consider the switched system* (2.2) *with a given σ, $h^\circ, h \in \Gamma$, and let the pair (λ, A), $\lambda \in]0, A[$ be given. Suppose that there exist functions $\alpha_1, \alpha_2 \in$*

$\mathcal{K}_\infty$, $V_p \in \mathrm{C}\big[\mathcal{B}(h,A) \cap \big((\mathbb{R}_{\geqslant 0} \times \mathbb{R}^n) \backslash \mathcal{B}(h^\circ, \lambda)\big),\ \mathbb{R}_{\geqslant 0}\big]$ *for each* $p \in \mathcal{P}$ *locally Lipschitz in the second argument, and a system* Σ *of the type* (2.6)*, such that*

(i) *the family* $\{V_p \mid p \in \mathcal{P}\}$ *is* $\mathcal{P}$*-uniformly* h*-positive definite and* h°*-decrescent in the sense of* (2.5)*;*

(ii) $\forall\, (t,x) \in \mathcal{B}(h,A) \cap \big((\mathbb{R}_{\geqslant 0} \times \mathbb{R}^n) \backslash \mathcal{B}(h^\circ, \lambda)\big)$ *and* $\forall\, p \in \mathcal{P}$*, we have* $\mathrm{D}^+_{f_p} V_p(t,x) \leqslant \phi(t, V_p(t,x))$*;*

(iii) $V_{\sigma(\tau_i)}(\tau_i, x(\tau_i)) \leqslant \xi(\tau_i) \quad \forall\, i \geqslant 0$*, where* $x(t)$ *and* $\xi(t)$ *are solutions of* (2.2) *and* Σ*, respectively;*

(iv) Σ *is uniformly practically stable with respect to* $(\alpha_2(\lambda), \alpha_1(A))$.

Then (2.2) *is* (h°, h)*-uniformly practically stable with respect to* (λ, A).

Finite time stability. We provide sufficient conditions for *finite time stability* in case of autonomous switched systems only. The definition of finite-time stability in terms of two measures is proposed in Definition 2.22; for further details on finite-time stability with Euclidean norms, see [3].

For autonomous switched systems, we specialize the class of functions Γ in (2.3) to the corresponding autonomous version $\Gamma_a := \{h \in \mathrm{C}[\mathbb{R}^n, \mathbb{R}_{\geqslant 0}] \mid \inf_x h(x) = 0\}$. For simplicity, we only consider special cases of h° and h below.

Definition 2.22. *Let* $h^\circ, h \in \Gamma_a$ *such that* $\ker h^\circ = \ker h = \{0\}$ *and* h°, h *are positive definite, radially unbounded. The switched system* (2.16) *is said to be* (h°, h)-finite time stable *if for every* $\varepsilon > 0$ *the following two properties hold simultaneously:*

- *The finite time convergence property holds; i.e., there exists a function* $T : \mathbb{R}^n \backslash \{0\} \longrightarrow \mathbb{R}_{>0}$ *called the settling time function such that for every* $x_0 \in \mathbb{R}^n \backslash \{0\}$*,* $x(t)$ *is defined on the interval* $[0, T(x_0)[$ *with* $x(t) \in \mathbb{R}^n \backslash \{0\}$ *and* $\lim_{t \uparrow T(x_0)} x(t) = 0$*, where* $x(t)$ *is the solution of* (2.16) *with initial condition* x_0.
- *Lyapunov stability holds; i.e., there exists a function* $\delta \in \mathcal{K}_\infty$ *such that* $h^\circ(x_0) < \delta(\varepsilon) \implies h \circ x(t) < \varepsilon \quad \forall\, t \in [0, T(x_0)[$.

With h°, h specialized to Euclidean norms, we recover finite time stability in the sense of [3].

Remark 2.23. Finite time stability of impulsive differential equations of the type (2.6) is identical to Definition 2.22, with h°, h specialized to absolute values.

Proposition 2.24. *Consider the switched system* (2.2) *with a given* σ*, and* $h^\circ, h \in \Gamma_a$*. Suppose that there exist functions* $\alpha_1, \alpha_2 \in \mathcal{K}_\infty$*, locally Lipschitz* $V_p \in \mathrm{C}[\mathbb{R}^n, \mathbb{R}_{\geqslant 0}]$ *for each* $p \in \mathcal{P}$ *and a system* Σ *of the type* (2.6)*, such that*

(i) $\forall\, x \in \mathbb{R}^n$ *and* $\forall\, p \in \mathcal{P}$*, we have* $\alpha_1 \circ h(x) \leqslant V_p(x) \leqslant \alpha_2 \circ h^\circ(x)$*;*

(ii) $\forall\, x \in \mathbb{R}^n$ *and* $\forall\, p \in \mathcal{P}$*, we have* $\mathrm{D}^+_{f_p} V_p(x) \leqslant \phi(t, V_p(x))$*;*

(iii) $\forall\, x_0 \in \mathbb{R}^n$*, there exists* $\xi_0 \in \mathbb{R}_{\geqslant 0}$ *such that* $V_{\sigma(\tau_i)}(\tau_i, x(\tau_i)) \leqslant \xi(\tau_i) \quad \forall\, i \geqslant 0$*, where* $x(t)$ *and* $\xi(t)$ *are the corresponding solutions of* (2.16) *and* Σ*, respectively;*

(iv) Σ *is finite time stable.*

Then (2.16) *is finite time stable.*

The proof of this Proposition is not difficult and is omitted.

3. Stochastic switched systems. In this section, we study stability of stochastic switched nonlinear nonautonomous systems of the Itô type. In section 3.1, we describe a stochastic switched system and define the notions of stability that we study. We propose our comparison theorem for stochastic switched systems in section 3.2 and illustrate it in sections 3.3 and 3.4. We discuss two other stability notions in section 3.5 and demonstrate that their analysis can be similarly carried out in the framework of the proposed results.

3.1. Preliminaries.

System description and stability definitions. Let $\mathbf{\Omega} := (\Omega, \mathcal{F}, \mathsf{P})$ be a complete probability space, where Ω is the sample space, $\mathcal{F}$ is the Borel σ-algebra on Ω, and P is a probability measure on the measurable space $(\Omega, \mathcal{F})$.

We consider a family of nonlinear nonautonomous Itô systems,

$$\mathrm{d}x = f_p(t,x)\mathrm{d}t + G_p(t,x)\mathrm{d}w, \qquad p \in \mathcal{P}, \tag{3.1}$$

where $x \in \mathbb{R}^n$, $\mathcal{P}$ is an index set, $f_p \in \mathrm{C}[\mathbb{R}_{\geqslant 0} \times \mathbb{R}^n, \mathbb{R}^n]$ is a vector field, $G_p \in \mathrm{C}[\mathbb{R}_{\geqslant 0} \times \mathbb{R}^n, \mathbb{R}^{n\times m}]$ is a diffusion rate matrix function, $f_p(\cdot, 0) \equiv 0$ and $G_p(\cdot, 0) \equiv 0$ for every $p \in \mathcal{P}$, w is an m-dimensional normalized Wiener process defined on the probability space $\mathbf{\Omega}$, and $\mathrm{d}x$ is a stochastic differential of x. We assume that f_p and G_p are smooth enough to ensure existence and uniqueness of the corresponding solution process; for precise conditions see, e.g., [36]. A *switched system* generated by the family (3.1) and a *switching signal* σ, defined similarly to section 2.1, is

$$\mathrm{d}x = f_\sigma(t,x)\mathrm{d}t + G_\sigma(t,x)\mathrm{d}w, \qquad x(t_0) = x_0, \quad t \geqslant t_0, \tag{3.2}$$

where $t_0 \in \mathbb{R}_{\geqslant 0}$. It is assumed, just as in section 2.1, that there is no jump in the state x at the switching instants, and there is a finite number of switches on every bounded interval of time. We denote the switching instants by τ_i, $i = 1, 2, \ldots$, with $\tau_0 := t_0$, and the sequence $\{\tau_i\}_{i\geqslant 0}$ is strictly increasing. The *solution process of* (3.2) *as a function of time* t*, initialized at a given pair* (t_0, x_0)*, and under a given switching signal* σ, is denoted by $x(t)$. In what follows, expected values at the (deterministic) initial condition are to be identified with their actual values; see also Remark 3.3.

Let $|x|_q := (\mathsf{E}[|x|^q])^{1/q}$ denote the qth mean of a random variable x defined on $\mathbf{\Omega}$. We will have occasion to use *Jensen's inequality*: if $\varphi \in \mathrm{C}[\mathbb{R}^n, \mathbb{R}]$ is concave and x is a random variable on $\mathbf{\Omega}$, then $\mathsf{E}[\varphi(x)] \leqslant \varphi(\mathsf{E}[x])$. Also, we need *Chebyshev's inequality*: for $\varepsilon > 0$, $\psi \in \mathrm{C}[\mathbb{R}^n, \mathbb{R}_{\geqslant 0}]$, x a random variable on $\mathbf{\Omega}$, we have $\mathsf{P}[\psi(x) \geqslant \varepsilon] \leqslant \mathsf{E}[\psi(x)]\,/\varepsilon$.

Consider the system with index p in the family (3.1). Let $V \in \mathrm{C}^{1,2}[\mathbb{R}_{\geqslant 0} \times \mathbb{R}^n, \mathbb{R}_{\geqslant 0}]$. By Itô's formula we have the stochastic differential of V as

$$\mathrm{d}V(t,x) = \mathscr{L}_p V(t,x)\mathrm{d}t + V_x(t,x)G_p(t,x)\mathrm{d}w(t),$$

where

$$\mathscr{L}_p V(t,x) := V_t(t,x) + V_x(t,x)f_p(t,x) + \frac{1}{2}\operatorname{tr}\left(V_{xx}(t,x)G_p(t,x)G_p^{\mathrm{T}}(t,x)\right) \tag{3.3}$$

is the *infinitesimal generator* for the system with index p in (3.1) acting on the function V, and V_t, V_x, V_{xx} denote the partial differentials of $V(t,x)$ with respect to t, x, and twice with respect to x, respectively, and tr denotes the trace of a matrix; see, e.g., [14].

We focus on the following two general notions of stochastic stability in terms of two measures, which belong to the set Γ in (2.3).

Definition 3.1. *Let* $h^\circ, h \in \Gamma$. *The stochastic switched system* (3.2) *is said to be* (h°, h)-globally uniformly asymptotically stable in the mean ((h°, h)-GUAS-M) *if there exists a function* $\beta \in \mathcal{KL}$ *such that for every* $(t_0, x_0) \in \mathbb{R}_{\geqslant 0} \times \mathbb{R}^n$*, the inequality*

$$\mathsf{E}[h(t, x(t))] \leqslant \beta(h^\circ(t_0, x_0), t - t_0) \qquad \forall\, t \geqslant t_0 \tag{3.4}$$

holds.

DEFINITION 3.2. *The stochastic switched system* (3.2) *is said to be* (h°, h)-globally uniformly asymptotically stable in probability ((h°, h)-GUAS-P) *if for every* $\eta \in]0,1[$, *there exists a function* $\beta \in \mathcal{KL}$ *such that for every* $(t_0, x_0) \in \mathbb{R}_{\geqslant 0} \times \mathbb{R}^n$, *the inequality*

$$\mathsf{P}\Big[h(t, x(t)) \geqslant \beta(h^\circ(t_0, x_0), t - t_0)\Big] < \eta \qquad \forall\, t \geqslant t_0 \tag{3.5}$$

holds.

Remark 3.3. We have stated our stability definitions in terms of deterministic initial condition. However, the results of this section hold true for the general case of stochastic initial condition as well. For instance, if we consider replacing $h^\circ(t_0, x_0)$ with $\mathsf{E}[h^\circ(t_0, x_0)]$ or $h^\circ(t_0, \mathsf{E}[x_0])$ in either (3.4) or (3.5), all the results hold true, with minor straightforward modifications in the proofs.

Remark 3.4. The (h°, h)-GUAS-M property is equivalent to the simultaneous verification of the following properties:

(SM1) there exists a class $\mathcal{K}_\infty$ function δ such that for every $\varepsilon > 0$, $t_0 \in \mathbb{R}_{\geqslant 0}$, we have $h^\circ(t_0, x_0) < \delta(\varepsilon) \implies \mathsf{E}[h(t, x(t))] < \varepsilon \quad \forall\, t \geqslant t_0$;

(SM2) for every $r, \varepsilon > 0$, there exists a number $T(r, \varepsilon) \geqslant 0$ such that for every $t_0 \in \mathbb{R}_{\geqslant 0}$, we have $h^\circ(t_0, x_0) < r \implies \mathsf{E}[h(t, x(t))] < \varepsilon \quad \forall\, t \geqslant t_0 + T(r, \varepsilon)$.

The proof follows directly from the proof of the equivalence in Remark 2.3 presented in Appendix A, with $\mathsf{E}[h(t, x(t))]$ replacing $h(t, x(t))$.

The (h°, h)-GUAS-P property is equivalent to the simultaneous verification of the following properties:

(WP1) for every $\eta' \in]0,1[$, there exists a function $\delta \in \mathcal{K}_\infty$ such that for every $\varepsilon > 0$, $t_0 \in \mathbb{R}_{\geqslant 0}$, we have $h^\circ(t_0, x_0) < \delta(\varepsilon) \implies \mathsf{P}[h(t, x(t)) \geqslant \varepsilon] < \eta' \quad \forall\, t \geqslant t_0$; and

(WP2) for every $\eta'' \in]0,1[$, $r, \varepsilon' > 0$, there exists a number $T(r, \varepsilon) \geqslant 0$ such that for every $t_0 \in \mathbb{R}_{\geqslant 0}$, we have $h^\circ(t_0, x_0) < r \implies \mathsf{P}[h(t, x(t)) \geqslant \varepsilon'] < \eta'' \quad \forall\, t \geqslant t_0 + T(r, \varepsilon')$.

Establishing this equivalence takes some more work; an outline may be found at the end of Appendix B.

Remark 3.5. We recover a notion essentially equivalent to *global uniform asymptotic stability in the qth mean* (GUAS-M$_q$) from Definition 3.1 with $h^\circ(t, x) = h(t, x) = |x|^q$, $q \geqslant 1$; see, e.g., [14]. With the same h° and h, Definition 3.2 yields *global uniform asymptotic stability in probability* (GUAS-P) in the sense of [23].

Remark 3.6. The (h°, h)-GUAS-P property of (3.2) follows from its (h°, h)-GUAS-M property. To see this, pick $\eta \in]0,1[$ and let there exist a function $\beta \in \mathcal{KL}$ such that (3.4) is satisfied. Consider a second function $\overline{\beta} \in \mathcal{KL}$ such that $\overline{\beta}(r, s) > \beta(r, s)/\eta$ for all $(r, s) \in \mathbb{R}^2_{\geqslant 0}$. Utilizing Chebyshev's inequality, we now have for every $t \geqslant t_0$

$$\begin{aligned}\mathsf{P}\big[h(t, x(t)) \geqslant \overline{\beta}(h^\circ(t_0, x_0), t - t_0)\big] &\leqslant \frac{\mathsf{E}[h(t, x(t))]}{\overline{\beta}(h^\circ(t_0, x_0), t - t_0)} \\ &\leqslant \frac{\beta(h^\circ(t_0, x_0), t - t_0)}{\overline{\beta}(h^\circ(t_0, x_0), t - t_0)} < \eta,\end{aligned}$$

which is the (h°, h)-GUAS-P property.

Comparison systems and stochastic comparison principle. We utilize the comparison system (2.6); see section 2.1 for the definitions. We need the following stochastic version of the comparison principle; see, e.g., [26] for a proof, where the authors also consider stochastic comparison systems.

LEMMA 3.7. *Consider the stochastic system with index p in the family* (3.1). *Suppose that there exist a function $V \in \mathrm{C}^{1,2}[\mathbb{R}_{\geqslant 0} \times \mathbb{R}^n, \mathbb{R}_{\geqslant 0}]$ and a comparison system*

$$\Sigma : \quad \dot{\xi} = \phi(t, \xi), \qquad \xi(t_0) = \xi_0 \geqslant 0, \quad t \geqslant t_0,$$

where ϕ is concave in the second argument, such that for all $(t, x) \in \mathbb{R}_{\geqslant 0} \times \mathbb{R}^n$, the differential inequality

$$\mathscr{L}_p V(t, x) \leqslant \phi(t, V(t, x))$$

is valid. Then $\mathsf{E}[V(\tau, x(\tau))] \leqslant \xi(\tau)$ implies $\mathsf{E}[V(t, x(t))] \leqslant \xi(t) \quad \forall\, t \geqslant \tau$, where $x(t)$ and $\xi(t)$ are the solution process of the system with index p in (3.1) *and the solution of Σ, respectively.*

3.2. Comparison theorem for stochastic switched systems. The following result establishes a general framework for testing stability of stochastic switched systems using multiple Lyapunov functions and a comparison system.

THEOREM 3.8. *Consider the stochastic switched system* (3.2) *with a fixed switching signal σ generating a sequence of switching instants $\{\tau_i\}_{i \geqslant 1}$ and two functions $h^\circ, h \in \Gamma$. Suppose that there exist functions $\alpha_1, \alpha_2 \in \mathcal{K}_\infty$, $V_p \in \mathrm{C}^{1,2}[\mathbb{R}_{\geqslant 0} \times \mathbb{R}^n, \mathbb{R}_{\geqslant 0}]$ for each $p \in \mathcal{P}$, and a system Σ of the type* (2.6), *such that*

(i) *α_1 is convex, and ϕ is concave in the second argument;*
(ii) *the family $\{V_p \mid p \in \mathcal{P}\}$ is $\mathcal{P}$-uniformly h-positive definite and h°-decrescent in the sense of* (2.5)*;*
(iii) *$\forall\, (t, x) \in \mathbb{R}_{\geqslant 0} \times \mathbb{R}^n$ and $\forall\, p \in \mathcal{P}$, the estimate $\mathscr{L}_p V_p(t, x) \leqslant \phi(t, V_p(t, x))$ holds;*
(iv) *$\forall\, (t_0, x_0) \in \mathbb{R}_{\geqslant 0} \times \mathbb{R}^n$, there exists $\xi_0 \in \mathbb{R}_{\geqslant 0}$ such that $\mathsf{E}\big[V_{\sigma(\tau_i)}(\tau_i, x(\tau_i))\big] \leqslant \xi(\tau_i)$ for all $i \geqslant 0$, where $x(t)$ and $\xi(t)$ are the solution process of* (3.2) *and the solution of Σ, respectively, for these initial conditions;*
(v) *Σ is* GUAS *in the sense of* (2.7).

Then (3.2) *is (h°, h)-*GUAS-M *in the sense of Definition* 3.1.

Proof. Consider the interval $[\tau_\ell, \tau_{\ell+1}[$, with ℓ an arbitrary nonnegative integer. Combining hypotheses (iv), (iii), and (i), and Lemma 3.7 with $\tau = \tau_\ell$, we have

$$\mathsf{E}\big[V_{\sigma(\tau_\ell)}(t, x(t))\big] \leqslant \xi(t) \qquad \forall\, t \in [\tau_\ell, \tau_{\ell+1}[.$$

The above estimate, in conjunction with hypothesis (v) and (2.7), yields

$$\mathsf{E}\big[V_{\sigma(\tau_\ell)}(t, x(t))\big] \leqslant \beta_\xi(\xi_0, t - t_0) \qquad \forall\, t \in [\tau_\ell, \tau_{\ell+1}[. \tag{3.6}$$

The function α_1 being convex by hypothesis (i), taking expectations and using Jensen's inequality in (2.5) and considering (3.6), we reach the estimate

$$\alpha_1 \circ \mathsf{E}[h(t, x(t))] \leqslant \beta_\xi(\xi_0, t - t_0) \qquad \forall\, t \in [\tau_\ell, \tau_{\ell+1}[. \tag{3.7}$$

The arbitrariness of ℓ in (3.7) leads to

$$\mathsf{E}[h(t, x(t))] \leqslant \beta(h^\circ(t_0, x_0), t - t_0) \qquad \forall\, t \geqslant t_0,$$

where $\beta(r, s) := \alpha_1^{-1} \circ \beta_\xi(\alpha_2(r), s)$. The function β being of class $\mathcal{KL}$, it follows that (3.2) is (h°, h)-GUAS-M. ∎

The following obvious Corollary, which we merely state, follows almost immediately from Theorem 3.8 in the light of Remark 3.6.

COROLLARY 3.9. *Suppose that the hypotheses of Theorem* 3.8 *hold true. Then* (3.2) *is* (h°, h)-GUAS-P *in the sense of* (3.5).

Remark 3.10. The hypothesis on convexity of α_1 in Corollary 3.9 actually is not necessary for (h°, h)-GUAS-P of (3.2). In Theorem 3.24 we will prove a stronger property without this convexity assumption, which will imply the (h°, h)-GUAS-P property of (3.2). For the moment, however, we shall work with (h°, h)-GUAS-M.

Theorem 3.8, like its deterministic counterpart Theorem 2.8, does not provide a direct method for analyzing stability of a given stochastic switched system. We will now demonstrate how to proceed with such a scheme of analysis and propose a few more specific results. In section 3.3 we provide sufficient conditions for (h°, h)-GUAS-M under a fixed-index sequence monotonicity condition. The comparison system utilized in the proof of this result utilizes quantitative information of system trajectories. In section 3.4 we provide sufficient conditions for GUAS-M_q of a stochastic switched system under average dwell-time switching, where the fixed-index sequence monotonicity assumption imposed in section 3.3 is violated. We construct two comparison systems that do not require quantitative information of system trajectories.

3.3. Stochastic stability under fixed-index sequence monotonicity condition. For this subsection we let $\mathcal{P}$ be a finite set with N elements. The following result provides a stochastic version of Corollary 2.9.

COROLLARY 3.11. *Consider the stochastic switched system* (3.2) *and* $h^\circ, h \in \Gamma$. *Suppose there exist functions* $\alpha, \alpha_1, \alpha_2, \rho, U \in \mathcal{K}_\infty$, $V_p \in \mathrm{C}^{1,2}[\mathbb{R}_{\geqslant 0} \times \mathbb{R}^n, \mathbb{R}_{\geqslant 0}]$ *for each* $p \in \mathcal{P}$, *such that*

(i) α_1, $\alpha \circ \alpha_2^{-1}$ *and* $U \circ \alpha_2^{-1}$ *are convex, and* ρ *is concave;*
(ii) *the family* $\{V_p \mid p \in \mathcal{P}\}$ *is* $\mathcal{P}$*-uniformly* h*-positive definite and* h°*-decrescent in the sense of* (2.5);
(iii) $\forall\, (t,x) \in \mathbb{R}_{\geqslant 0} \times \mathbb{R}^n$ *and* $\forall\, p \in \mathcal{P}$, *we have* $\mathscr{L}_p V_p(t,x) \leqslant -\alpha \circ h^\circ(t,x)$;
(iv) *for every pair of switching times* (τ_i, τ_j), $i < j$ *such that* $\sigma(\tau_i) = \sigma(\tau_j) = p$ *and* $\sigma(\tau_k) \neq p$ *for* $\tau_i < \tau_k < \tau_j$, *the inequality*

$$\mathsf{E}[V_p(\tau_j, x(\tau_j))] - \mathsf{E}[V_p(\tau_i, x(\tau_i))] \leqslant -\mathsf{E}[U \circ h^\circ(\tau_i, x(\tau_i))] \tag{3.8}$$

holds, where $x(t)$ *is the solution process of* (3.2) *initialized at* (t_0, x_0);
(v) $\forall\, (t,x) \in \mathbb{R}_{\geqslant 0} \times \mathbb{R}^n$, *we have* $\alpha_2 \circ h^\circ(t,x) \leqslant \rho \circ \alpha_1 \circ h(t,x)$.

Then (3.2) *is* (h°, h)-GUAS-M.

Proof. We define a candidate impulsive differential comparison system of the type (2.6):

$$\Sigma: \quad \begin{cases} \dot{\xi} = -\alpha \circ \alpha_2^{-1}(\xi), & t \neq \tau_i, \\ \xi(\tau_i) = \mathsf{E}\left[V_{\sigma(\tau_i)}(\tau_i, x(\tau_i))\right], & \end{cases} \qquad i \geqslant 0, \quad t \geqslant t_0. \tag{3.9}$$

By its very definition, Σ satisfies hypotheses (iii)–(iv) of Theorem 3.8. Hypotheses (i)–(ii) of Theorem 3.8 are satisfied by our hypotheses (i)–(ii). To verify hypothesis (v) of Theorem 3.8, we shall first prove Lyapunov stability of Σ and then prove its global asymptotic convergence, in view of Remark 2.6.

Consider the time interval $[\tau_0, \tau_1[$. From hypothesis (iii), we have

$$\mathsf{E}\left[V_{\sigma(\tau_0)}(\tau_1, x(\tau_1))\right] \leqslant \mathsf{E}\left[V_{\sigma(\tau_0)}(\tau_0, x_0)\right].$$

Combining with hypothesis (ii), using Jensen's inequality we reach

$$\mathsf{E}[\alpha_1(h(\tau_1, x(\tau_1)))] \leqslant \alpha_2 \circ h^\circ(t_0, x_0). \tag{3.10}$$

For every $p \in \mathcal{P}$, we have from hypothesis (i)

$$\mathsf{E}[V_p(\tau_1, x(\tau_1))] \leqslant \mathsf{E}[\alpha_2 \circ h^\circ(\tau_1, x(\tau_1))]\,,$$

and therefore by hypothesis (v),

$$\mathsf{E}[V_p(\tau_1, x(\tau_1))] \leqslant \mathsf{E}[\rho \circ \alpha_1 \circ h(\tau_1, x(\tau_1))]\,. \tag{3.11}$$

In view of hypothesis (ii), we apply Jensen's inequality to (3.11) and use hypothesis (ii) to get

$$\mathsf{E}[V_p(\tau_1, x(\tau_1))] \leqslant \rho(\mathsf{E}[\alpha_1 \circ h(\tau_1, x(\tau_1))]) \leqslant \rho \circ \alpha_2 \circ h^\circ(t_0, x_0). \tag{3.12}$$

Consider now the interval $[\tau_1, \tau_2[$. From hypothesis (iii) we have

$$\mathsf{E}\big[V_{\sigma(\tau_1)}(\tau_2, x(\tau_2))\big] \leqslant \mathsf{E}\big[V_{\sigma(\tau_1)}(\tau_1, x(\tau_1))\big]\,.$$

Combining with hypothesis (ii) and applying (3.12) with $p = \sigma(\tau_2)$, we get

$$\mathsf{E}[\alpha_1 \circ h(\tau_2, x(\tau_2))] \leqslant \rho \circ \alpha_2 \circ h^\circ(t_0, x_0). \tag{3.13}$$

For all $p \in \mathcal{P}$, we have

$$\mathsf{E}[V_p(\tau_2, x(\tau_2))] \leqslant \mathsf{E}[\alpha_2 \circ h^\circ(\tau_2, x(\tau_2))]\,,$$

so by hypothesis (iv) and Jensen's inequality we get

$$\mathsf{E}[V_p(\tau_2, x(\tau_2))] \leqslant \rho(\mathsf{E}[\alpha_1 \circ h(\tau_2, x(\tau_2))]).$$

Now (3.12) gives

$$\mathsf{E}[V_p(\tau_2, x(\tau_2))] \leqslant \rho \circ \rho \circ \alpha_2 \circ h^\circ(t_0, x_0).$$

It is not difficult to see that the worst-case situation for maximum possible overshoot of the function $\mathsf{E}[V_\sigma]$ occurs when the switching signal σ visits every element of the set $\mathcal{P}$ without repetition until $\mathcal{P}$ is exhausted. Let $\tau_{j^\star}$ be the first switching instant after all the subsystems that participate in the dynamics have become active at least once since initialization at $t = t_0$. From the above computations, it is easy to see that, with

$$\rho^j := \underbrace{\rho \circ \ldots \circ \rho}_{j \text{ times}},$$

the estimate

$$\xi(\tau_{j^\star}) \leqslant \rho^{\mathrm{N}-1} \circ \alpha_2 \circ h^\circ(t_0, x_0),$$

is valid. Define the function

$$\gamma(\cdot) := \max\left\{\alpha_2(\cdot), \rho \circ \alpha_2(\cdot), \ldots, \rho^{\mathrm{N}-1} \circ \alpha_2(\cdot)\right\}.$$

From the above arguments and (3.8), it follows that $\xi(t) \leqslant \gamma \circ h^\circ(t_0, x_0)$. In view of the definition of ξ_0 and hypothesis (ii), this leads to

$$\xi(t) \leqslant \gamma \circ \alpha_1^{-1}(\xi_0) \qquad \forall\, t \geqslant t_0. \tag{3.14}$$

It remains to prove uniform global asymptotic convergence of Σ.

We distinguish two cases.

Case 1. *Switching stops in finite time.* Since σ eventually becomes constant from the κth switching instant, it follows that there are no impulses after $t = \tau_\kappa$. Therefore, the system (3.9) becomes an autonomous scalar ordinary differential equation after $t = \tau_\kappa$, with negative right-hand side for nonzero $\xi(\tau_\kappa)$. It follows that $\xi(t)$ monotonically decreases to 0 for all $t \geqslant \tau_\kappa$. From (3.14) uniform Lyapunov stability of Σ follows. Thus, (3.9) is GUAS. Theorem 3.8 now guarantees that (3.2) is (h°, h)-GUAS-M.

Case 2. *Switching continues indefinitely.* Consider the restatement of the inequality (3.8) with $\xi(\tau_i)$ as in (3.9)

$$\begin{aligned}\xi(\tau_j) - \xi(\tau_i) &\leqslant -\mathsf{E}[U \circ h^\circ(\tau_i, x(\tau_i))] = -\mathsf{E}\left[U \circ \alpha_2^{-1} \circ \alpha_2 \circ h^\circ(\tau_i, x(\tau_i))\right] \\ &\leqslant -U \circ \alpha_2^{-1}\left(\mathsf{E}[\alpha_2 \circ h^\circ(\tau_i, x(\tau_i))]\right),\end{aligned}$$

where we have utilized Jensen's inequality and convexity of $U \circ \alpha_2^{-1}$ in hypothesis (i). The infinite sequence $\{\xi(\tau_i)\}_{\{i \geqslant 0 | \sigma(\tau_i) = p\}}$ is monotonically nonincreasing and therefore must attain a limit, say, $c \geqslant 0$. Taking limits as $i \uparrow \infty$ on both sides of (3.8), we have

$$c - c \leqslant - \lim_{\substack{i \uparrow \infty \\ \sigma(\tau_i) = p}} U \circ \alpha_2^{-1}\left(\mathsf{E}[\alpha_2 \circ h^\circ(\tau_i, x(\tau_i))]\right),$$

which leads to

$$\lim_{\substack{i \uparrow \infty \\ \sigma(\tau_i) = p}} \mathsf{E}[\alpha_2 \circ h^\circ(\tau_i, x(\tau_i))] = 0.$$

Considering hypothesis (ii) and the reset equation in (3.9), we have

$$\lim_{\substack{i \uparrow \infty \\ \sigma(\tau_i) = p}} \xi(\tau_i) = \lim_{\substack{i \uparrow \infty, \\ \sigma(\tau_i) = p}} \mathsf{E}\left[V_{\sigma(\tau_i)}(\tau_i, x(\tau_i))\right] = 0. \tag{3.15}$$

Combining (3.14) and (3.15), we conclude that (3.9) is GUAS.

By Theorem 3.8, there exists a function $\beta \in \mathcal{KL}$ such that

$$\mathsf{E}[h(t, x(t))] \leqslant \beta(h^\circ(t_0, x_0), t - t_0) \qquad \forall\, t \geqslant t_0,$$

and we conclude that (3.2) is (h°, h)-GUAS-M. □

Remark 3.12. We note that in the above proof, Σ makes explicit use of state information of (3.2)—in the notation of (2.6), we use

$$\psi_i\left(\xi\left(\tau_i^-\right), y(x(\tau_i), \sigma(\tau_i))\right) = \mathsf{E}\left[V_{\sigma(\tau_i)}(\tau_i, x(\tau_i))\right]$$

in the reset equation. However, $\xi(\tau_i^-)$ is not utilized; cf. Remark 2.10.

Remark 3.13. For Euclidean norms, the function $\rho \in \mathcal{K}_\infty$ always exists if the function $\alpha_2 \circ \alpha_1^{-1}$ is concave (cf. Remark 2.11). Also, if α_1, α_2, ρ, and U are quadratic, as is typically the case for linear systems, hypothesis (i) is always satisfied.

Remark 3.14. It readily follows that for autonomous switched stochastic systems and h°, h specialized to Euclidean norms, Corollary 3.11 gives global asymptotic stability in the mean. Corollary 3.9 then implies global asymptotic stability in probability, which is derived in [8] without the aid of the comparison framework.

3.4. Stochastic stability under average dwell-time switching. In this subsection we investigate conditions on the average dwell-time τ_a of a switching signal such that (3.2) has the GUAS-M$_q$ property. We no longer retain the assumption that $\mathcal{P}$ is finite. We specialize to Euclidean norms for simplicity and propose the following result, which may be regarded as a stochastic counterpart of Theorem 2.12. A generalization of Theorem 3.15 to two measures and nonautonomous stochastic switched systems is readily done.

Let us consider the autonomous stochastic switched system

$$\mathrm{d}x = f_\sigma(x)\mathrm{d}t + G_\sigma(x)\mathrm{d}w, \qquad x(t_0) = x_0, \quad t \geqslant t_0, \tag{3.16}$$

where $x \in \mathbb{R}^n$, $f_p \in \mathrm{C}[\mathbb{R}^n, \mathbb{R}^n]$, $G_p \in \mathrm{C}[\mathbb{R}^n, \mathbb{R}^{n\times m}]$, $f_p(0) = 0$, $G_p(0) = 0$ for every $p \in \mathcal{P}$, w is an m-dimensional Wiener process on the probability space $\mathbf{\Omega}$. We assume that f_p and G_p are smooth enough to ensure existence and uniqueness of the corresponding solution processes for every $p \in \mathcal{P}$; see, e.g., [36] for precise conditions.

We need the definition of average dwell-time from (2.17) for the following result.

THEOREM 3.15. *Consider the switched system* (3.2)*. Suppose that there exist functions $\alpha_1, \alpha_2 \in \mathcal{K}_\infty$, $V_p \in \mathrm{C}^1[\mathbb{R}^n, \mathbb{R}_{\geqslant 0}]$ for each $p \in \mathcal{P}$, and a positive number $\lambda_\circ$ such that*

$$\alpha_1(|x|^q) \leqslant V_p(x) \leqslant \alpha_2(|x|^q) \qquad \forall\, x \in \mathbb{R}^n \tag{3.17}$$

with α_1 convex, $q \geqslant 1$, and

$$\mathscr{L}_p V_p(x) \leqslant -\lambda_\circ V_p(x) \qquad \forall\, x \in \mathbb{R}^n. \tag{3.18}$$

Suppose also that there exists a positive constant μ such that for each $t \in \mathbb{R}_{\geqslant 0}$,

$$V_{p_1}(x) \leqslant \mu V_{p_2}(x) \qquad \forall\, x \in \mathbb{R}^n, \quad \forall\, p_1, p_2 \in \mathcal{P}. \tag{3.19}$$

Then (3.2) *is* GUAS-M$_q$ *for every switching signal σ with average dwell-time $\tau_a > \frac{\ln \mu}{\lambda_\circ}$.*

For a single system, (3.18) is a condition that implies global exponential stability in the qth mean [14], under an additional condition of $\alpha_i(r) = k_i r$, $i = 1, 2$. Theorem 3.15 is particularly simple for autonomous linear stochastic switched systems as we now show.

Consider a stochastic switched autonomous linear system

$$\mathrm{d}x = A_\sigma x\mathrm{d}t + B_\sigma x\mathrm{d}w_t, \qquad x(0) = x_0, \quad t \geqslant 0, \tag{3.20}$$

where $\sigma(t) \in \mathcal{P}$, $x \in \mathbb{R}^n$, $A_p, B_p \in \mathbb{R}^{n\times n}$, w is a scalar normalized Wiener process. For quadratic Lyapunov functions $V_p(x) = x^{\mathrm{T}} P_p x$, where P_p, $p \in \mathcal{P}$ is a positive definite symmetric matrix, with the aid of (3.3) the condition (3.18) simplifies to

$$A_p^{\mathrm{T}} P_p + P_p A_p + B_p P_p B_p^{\mathrm{T}} + \lambda_\circ P_p \leqslant 0, \tag{3.21}$$

which is a linear matrix inequality. To get the quadratic Lyapunov functions V_p, it is necessary to solve (3.21) for each $p \in \mathcal{P}$; see [5] for related methods of solution of such linear matrix inequalities, and see [14] for a discussion on quadratic Lyapunov functions in stability analysis of stochastic linear systems. Note that (3.19) is automatically satisfied if we can find such $V_p = x^{\mathrm{T}} P_p x$, with P_p satisfying (3.21).

We provide two different proofs of Theorem 3.15 to illustrate the versatility of our comparison framework.

An impulsive differential equation as a comparison system.

Proof. Consider an impulsive differential system of the type (2.6) with

$$\psi_i\left(\xi\left(\tau_i^-\right), y(x(\tau_i), \sigma(\tau_i))\right) = \mu\xi(\tau_i^-), \quad i \geqslant 1, \quad \mu > 0,$$

as the reset equation, and

$$\phi(t, \xi) = -\lambda_\circ \xi, \quad \lambda_\circ > 0.$$

Note that concavity of ϕ with respect to ξ is trivially satisfied. The complete system stands as

$$\Sigma' : \quad \begin{cases} \dot{\xi} = -\lambda_\circ \xi, & t \neq \tau_i, \\ \xi(\tau_i) = \mu\xi(\tau_i^-), & \mu > 0, \end{cases} \qquad \xi(t_0) = V_{\sigma(t_0)}(x_0), \quad i \geqslant 1, \quad t \geqslant t_0. \tag{3.22}$$

This system Σ' is the same as (2.21). From (3.17) it follows that hypothesis (ii) of Theorem 3.8 is satisfied with $h^\circ(t, x) = h(t, x) = |x|^q$. Further, from (3.18) and (3.19) together with the initial condition in (3.22), it follows that hypotheses (iii) and (iv) of Theorem 3.8 are satisfied, respectively.

Intuitively,

- the minimum rate of decay of the expected values of Lyapunov functions corresponding to each active subsystem is captured by the vector field of Σ'; and
- the maximum jump in the values of two Lyapunov functions corresponding to two consecutively active subsystems is captured by the reset equation of Σ' (since from (3.19) it follows that $\mathsf{E}[V_{p_1}(x(\tau_i))] \leqslant \mu\mathsf{E}\big[V_{p_2}(x(\tau_i^-))\big]$ for every $i \geqslant 1$, as in section 2.4, $\mu \geqslant 1$).

As in section 2.4, with $\tau_a > \frac{\ln \mu}{\lambda_\circ}$ the GUAS property of Σ' follows, which verifies hypothesis (v) of Theorem 3.8. In view of Remark 3.5, by Theorem 3.8 we conclude that (3.2) is GUAS-M$_q$. □

An ordinary differential equation as a comparison system.

Proof. Consider the following scalar autonomous system as a candidate comparison system:

$$\Sigma'' : \quad \dot{\xi} = \left(\frac{\ln \mu}{\tau_a} - \lambda_\circ\right)\xi, \qquad \xi(t_0) = \mu^{N_\circ} \mathrm{e}^{\lambda_\circ t_0} V_{\sigma(t_0)}(x_0), \quad t \geqslant t_0, \tag{3.23}$$

Note that concavity of the vector field of Σ'' with respect to ξ is trivially satisfied. Let the average dwell-time of σ be τ_a, and let $\nu := N_\sigma(T, t_0)$. Considering the least rate of decay of the expected values of Lyapunov functions corresponding to each active subsystem given by (3.18), we have for an arbitrary $T \geqslant 0$,

$$\mathsf{E}\big[V_{\sigma(\tau_i)}(x(\tau_{i+1}^-))\big] \leqslant \mathsf{E}\big[V_{\sigma(\tau_i)}(x(\tau_i))\big]\, \mathrm{e}^{-\lambda_\circ(\tau_{i+1} - \tau_i)}, \quad 0 \leqslant i \leqslant \nu,$$

and

$$\mathsf{E}\big[V_{\sigma(\tau_\nu)}(x(T))\big] \leqslant \mathsf{E}\big[V_{\sigma(\tau_\nu)}(x(\tau_\nu))\big]\, \mathrm{e}^{-\lambda_\circ(T - \tau_\nu)}.$$

Combining with the reset equation, we have

$$\mathsf{E}\big[V_{\sigma(\tau_\nu)}(x(T))\big] \leqslant \mu^\nu V_{\sigma(t_0)}(x_0) \mathrm{e}^{-\lambda_\circ(T - t_0)}.$$

The solution ξ of (3.23) is identical to (2.25). From (3.17) it follows that hypothesis (ii) of Theorem 3.8 is satisfied with $h^\circ(t,x) = h(t,x) = |x|^q$. Further, from (3.18) and (3.19) together with the initial condition in (3.23), it follows that hypotheses (iii) and (iv) of Theorem 3.8 are satisfied, respectively.

Intuitively,

- the initial condition of Σ'' captures the maximum possible overshoot in $\mathsf{E}[V_\sigma]$—this corresponds to the situation when all $N_\circ$ switches occur very close to $t = t_0$;
- $\xi(\cdot)$ forms an envelope of the sequence $\big\{\mathsf{E}\big[V_{\sigma(\tau_i)}(x(\tau_i))\big]\big\}_{i\geqslant 0}$ over the interval $[t_0, T]$.

As in section 2.4, $\lambda_\circ > \frac{\ln\mu}{\tau_a}$ ensures global uniform asymptotic stability of Σ''; this verifies Theorem 3.8 hypothesis (v). It follows that by Theorem 3.8, (3.2) is GUAS-M$_q$ for switching signals with $\tau_a > \frac{\ln\mu}{\lambda_\circ}$ in view of Remark 3.5. □

Remark 3.16. We note that in contrast to (3.9), the comparison systems (3.22) and (3.23) do not utilize state information in the form of the function y directly; cf. Remark 3.12.

Remark 3.17. From the solutions of (3.22) and (3.23) it is clear that for $\tau_a > \frac{\ln\mu}{\lambda_\circ}$, GUAS of Σ' and Σ'' are ensured, which in turn imply that (2.2) is GUAS-M$_q$. In other words, the GUAS-M$_q$ property of (3.2) is "uniform" over all switching signals with $\tau_a > \frac{\ln\mu}{\lambda_\circ}$. We therefore say that (3.2) is *globally "uniformly" asymptotically stable in the qth mean* over all such switching signals; see also Remark 2.15.

Remark 3.18. What we stated in Remark 2.17 for deterministic switched systems carries over to the stochastic case quite easily; it is not difficult to show that in the context of Theorem 3.8, under suitable hypotheses each subsystem may be exponentially unstable while the switched system (3.2) remains (h°, h)-GUAS-M$_q$.

Namely, consider the stochastic switched system (3.2), and suppose that σ is such that $N_\sigma(t, t_0)$ obeys (2.28) for some $N_\circ, \delta_a > 0$. Let there exist functions $\alpha_1, \alpha_2 \in \mathcal{K}_\infty$, $V_p \in \mathrm{C}^1[\mathbb{R}^n, \mathbb{R}_{\geqslant 0}]$, $p \in \mathcal{P}$, and real numbers $\mu' \in]0,1[$ and $\lambda_\circ > 0$, such that

(i) the estimate (3.17) holds;
(ii) $\forall\, x \in \mathbb{R}_{\geqslant 0} \times \mathbb{R}^n$ and $\forall\, p \in \mathcal{P}$, we have $\mathscr{L}_p V_p(x) \leqslant \lambda_\circ V_p(x)$;
(iii) $\mathsf{E}\big[V_{\sigma(\tau_i)}(x(\tau_i))\big] \leqslant \mu' \mathsf{E}\Big[V_{\sigma(\tau_i^-)}(x(\tau_i^-))\Big] \quad \forall\, i \geqslant 1$;
(iv) $\delta_a < -\ln\mu'/\lambda_\circ$.

Then (3.2) is GUAS-M$_q$.

It may be verified that the comparison system $\widetilde{\Sigma}$ in (2.29) is a suitable comparison system under the above hypotheses, and the assertion follows from Theorem 3.8.

Remark 3.19. We mentioned in Remark 2.18 that for a system with state-dependent switching, in general we cannot conclude stability for more than one initial condition from the associated switched system (2.2). The situation is more complicated in the case of a hybrid system with continuous dynamics perturbed by a Wiener process; now the switching signals σ corresponding to different trajectories are different even for a fixed initial condition, making direct analysis of such a system difficult. The switched system (3.2) provides for simpler stability analysis for a fixed initial condition, but once again we cannot conclude stability of the hybrid system under variations in initial conditions from stability of the switched system. Theorem 3.8 is stated without any claim of uniformity with respect to initial conditions. However, in Theorem 3.15 we obtained uniform stability of a switched system perturbed by a Wiener process over the class of σ defined by a suitable average dwell-time, without taking into account an underlying hybrid system. This class of signals is potentially

useful for hybrid systems where variations in the initial condition preserve average dwell-time switching; see [39] for some results in this direction.

3.5. Remarks on other stability notions. In this subsection we study two notions of stochastic stability of switched systems, different from the ones considered so far, and utilize the framework of Theorem 3.8.

Stochastic practical stability. Stochastic practical stability is concerned with practical stability of systems perturbed by a Wiener process with respect to prespecified domains in the state space. We briefly study a representative notion of stochastic practical stability below; see [40] for a version of the definition for nonswitched systems and with $h^\circ(t,x) = h(t,x) = |x|^q$.

DEFINITION 3.20. *Let $h^\circ, h \in \Gamma$ and the pair (λ, A), $\lambda \in]0, A[$ be given. The stochastic switched system (3.2) is said to be (h°, h)*-uniformly practically stable in the mean with respect to (λ, A) *if for every $t_0 \in \mathbb{R}_{\geqslant 0}$, the property*

$$h^\circ(t_0, x_0) < \lambda \implies \mathsf{E}[h(t, x(t))] < A \qquad \forall\, t \geqslant t_0 \tag{3.24}$$

holds for all solution processes.

The following result provides sufficient conditions for (h°, h)-uniform practical stability of (3.2) in the mean with respect to a given pair (λ, A).

PROPOSITION 3.21. *Consider the stochastic switched system (3.2) with a given σ, $h^\circ, h \in \Gamma$, and let the pair (λ, A), $\lambda \in]0, A[$ be given. Suppose that there exist functions $\alpha_1, \alpha_2 \in \mathcal{K}_\infty$, $V_p \in \mathrm{C}^{1,2}\big[\mathcal{B}(h, A) \cap \big((\mathbb{R}_{\geqslant 0} \times \mathbb{R}^n) \setminus \mathcal{B}(h^\circ, \lambda)\big), \mathbb{R}_{\geqslant 0}\big]$ for each $p \in \mathcal{P}$, and a system Σ of the type (2.6), such that*

(i) *α_1 is convex, and ϕ is concave in the second argument;*

(ii) *the family $\{V_p \mid p \in \mathcal{P}\}$ is $\mathcal{P}$-uniformly h-positive definite and h°-decrescent in the sense of (2.5);*

(iii) *$\forall\, (t, x) \in \mathcal{B}(h, A) \cap \big((\mathbb{R}_{\geqslant 0} \times \mathbb{R}^n) \setminus \mathcal{B}(h^\circ, \lambda)\big)$ and $\forall\, p \in \mathcal{P}$, we have $\mathscr{L}_p V_p(t, x) \leqslant \phi(t, V_p(t, x))$;*

(iv) *$\forall\, (t_0, x_0) \in \mathbb{R}_{\geqslant 0} \times \mathbb{R}^n$, there exists $\xi_0 \in \mathbb{R}_{\geqslant 0}$ such that $\mathsf{E}\big[V_{\sigma(\tau_i)}(\tau_i, x(\tau_i))\big] \leqslant \xi(\tau_i)$ for all $i \geqslant 0$, where $x(t)$ and $\xi(t)$ are the solution process of (3.2) and the solution of Σ, respectively, for these initial conditions;*

(v) *Σ is uniformly practically stable with respect to $(\alpha_2(\lambda), \alpha_1(A))$.*

Then (3.2) is (h°, h)-uniformly practically stable in the mean with respect to (λ, A).

Proof. In view of Remark 2.20, the uniform practical stability of Σ with respect to $(\alpha_2(\lambda), \alpha_1(A))$ implies that for every $t_0 \in \mathbb{R}_{\geqslant 0}$,

$$\xi_0 < \alpha_2(\lambda) \implies \xi(t) < \alpha_1(A) \qquad \forall\, t \geqslant t_0. \tag{3.25}$$

Select and arbitrary x_0 such that $h^\circ(t_0, x_0) < \lambda$, and pick $\xi_0 = \alpha_2 \circ h^\circ(t_0, x_0)$ and an arbitrary nonnegative integer ℓ. From hypothesis (iv) and Lemma 3.7 at time $\tau = \tau_\ell$, we have

$$\mathsf{E}\big[V_{\sigma(\tau_\ell)}(\tau_\ell, x(\tau_\ell))\big] \leqslant \xi(t) \qquad \forall\, t \in [\tau_\ell, \tau_{\ell+1}[. \tag{3.26}$$

Combining (3.26) with (3.25) over the time interval $[\tau_\ell, \tau_{\ell+1}[$, and using hypothesis (iii), we have

$$\mathsf{E}[\alpha_1 \circ h(t, x(t))] < \alpha_1(A) \qquad \forall\, t \in [\tau_\ell, \tau_{\ell+1}[. \tag{3.27}$$

Since α_1 is convex by hypothesis (i), by Jensen's inequality in (3.27), we reach

$$\alpha_1(\mathsf{E}[h(t, x(t))]) < \alpha_1(A) \qquad \forall\, t \in [\tau_\ell, \tau_{\ell+1}[. \tag{3.28}$$

The inequality (3.28), together with the arbitrariness of ℓ, indicate that (3.24) holds. The (h°, h)-uniform practical stability in the mean of (3.2) with respect to (λ, A) follows. □

Strong global uniform asymptotic stability in probability. We present a stronger version of global asymptotic stability in probability below; see, e.g., [33] for a version of the definition for nonswitched systems and Euclidean norms.

DEFINITION 3.22. *Let $h^\circ, h \in \Gamma$. The stochastic switched system* (3.2) *is said to be* (h°, h)-strongly globally uniformly asymptotically stable in probability ((h°, h)-SGUAS-P) *if for every $\eta \in]0,1[$, there exists a function $\beta \in \mathcal{KL}$ such that for every $(t_0, x_0) \in \mathbb{R}_{\geqslant 0} \times \mathbb{R}^n$, the inequality*

$$\mathsf{P}\left[\sup_{t \geqslant t_0} h(t, x(t)) \geqslant \beta(h^\circ(t_0, x_0), t - t_0)\right] < \eta \tag{3.29}$$

holds.

LEMMA 3.23. *The (h°, h)-*SGUAS-P *property is equivalent to the simultaneous verification of the following two properties:*

(SP1) *for every $\eta' \in]0,1[$, there exists a function $\delta \in \mathcal{K}_\infty$ such that for every $\varepsilon > 0$ and $t_0 \in \mathbb{R}_{\geqslant 0}$, we have*

$$h^\circ(t_0, x_0) < \delta(\varepsilon) \implies \mathsf{P}\left[\sup_{t \geqslant t_0} h(t, x(t)) \geqslant \varepsilon\right] < \eta'; \tag{3.30}$$

(SP2) *for every $\eta'' \in]0,1[$, $r, \varepsilon' > 0$, there exists a number $\widetilde{T}(r, \varepsilon') > 0$ such that for every $t_0 \in \mathbb{R}_{\geqslant 0}$, we have*

$$h^\circ(t_0, x_0) < r \implies \mathsf{P}\left[\sup_{t \geqslant t_0 + \widetilde{T}(r, \varepsilon')} h(t, x(t)) \geqslant \varepsilon'\right] < \eta''. \tag{3.31}$$

A proof of this result is provided in Appendix B.

It is clear that the (h°, h)-SGUAS-P property is stronger than the (h°, h)-GUAS-P property. However, the same hypotheses as those of Corollary 3.9 ensure this stronger property, as we prove below. In fact, the hypotheses can be slightly weaker—we can do away with the convexity assumption of α_1 in Theorem 3.8.

THEOREM 3.24. *Suppose the hypotheses of Theorem* 3.8 *hold true, with α_1 not necessarily convex. Then* (3.2) *is* (h°, h)-SGUAS-P.

Proof. In view of Lemma 3.23 it suffices to prove (SP1)–(SP2). We first prove (SP1). Let $\eta' \in]0,1[$ and $\varepsilon > 0$ be given. Since Σ is GUAS by hypothesis (v), in view of Remark 2.6 there exists a function $\delta_\xi \in \mathcal{K}_\infty$ such that for every $t_0 \in \mathbb{R}_{\geqslant 0}$, we have

$$\xi_0 < \delta_\xi(\eta' \alpha_1(\varepsilon)) \implies \xi(t) < \eta' \alpha_1(\varepsilon) \qquad \forall\, t \geqslant t_0.$$

Let $\delta(\cdot) := \alpha_2^{-1} \circ \delta_\xi(\eta' \alpha_1(\cdot))$, where we have suppressed the dependence of δ on η', which is implied. Choose an arbitrary x_0 such that $h^\circ(t_0, x_0) < \delta(\varepsilon)$ and let $\xi_0 := \alpha_2 \circ h^\circ(t_0, x_0)$. Then from hypotheses (iii), (iv) and Lemma 3.7, it follows that

$$\mathsf{E}\big[V_{\sigma(t)}(t, x(t))\big] \leqslant \xi(t) < \eta' \alpha_1(\varepsilon) \qquad \forall\, t \geqslant t_0. \tag{3.32}$$

Claim 1. We have $\mathsf{P}[\sup_{t \geqslant t_0} h(t, x(t)) \geqslant \varepsilon] < \eta'$.

Indeed, let τ_ε be the first exit time of $x(t)$ from $\mathcal{B}(h,\varepsilon)$, i.e., $\tau_\varepsilon := \inf\{t \geqslant t_0 \mid h(t,x(t)) \geqslant \varepsilon\} \leqslant \infty$. Therefore, from (3.32), we have

$$\mathsf{E}\big[V_{\sigma(\tau_\varepsilon\wedge t)}(\tau_\varepsilon \wedge t, x(\tau_\varepsilon \wedge t))\big] < \eta'\alpha_1(\varepsilon) \qquad \forall\, t \geqslant t_0. \tag{3.33}$$

Fix an arbitrary $t' > t_0$. We have from (3.33),

$$\eta'\alpha_1(\varepsilon) > \mathsf{E}\big[V_{\sigma(\tau_\varepsilon\wedge t')}(\tau_\varepsilon \wedge t', x(\tau_\varepsilon \wedge t'))\big] \geqslant \mathsf{E}\big[\mathbf{1}_{\{\tau_\varepsilon \leqslant t'\}} V_{\sigma(\tau_\varepsilon)}(\tau_\varepsilon, x(\tau_\varepsilon))\big], \tag{3.34}$$

where $\mathbf{1}_{\{\cdot\}}$ is the indicator function. From hypothesis (ii) and the definition of τ_ε, it follows that

$$\mathsf{E}\big[\mathbf{1}_{\{\tau_\varepsilon \leqslant t'\}} V_{\sigma(\tau_\varepsilon)}(\tau_\varepsilon, x(\tau_\varepsilon))\big] \geqslant \mathsf{E}\big[\mathbf{1}_{\{\tau_\varepsilon \leqslant t'\}} \alpha_1 \circ h(\tau_\varepsilon, x(\tau_\varepsilon))\big] = \mathsf{P}[\tau_\varepsilon \leqslant t']\, \alpha_1(\varepsilon). \tag{3.35}$$

Combining (3.34) and (3.35) we get $\eta'\alpha_1(\varepsilon) > \alpha_1(\varepsilon)\mathsf{P}[\tau_\varepsilon \leqslant t']$, and considering the definition of τ_ε, this leads to

$$\mathsf{P}\left[\sup_{t\in[t_0,t']} h(t,x(t)) \geqslant \varepsilon\right] < \eta'.$$

Since $t' > t_0$ is arbitrary, we have

$$\mathsf{P}\left[\sup_{t\geqslant t_0} h(t,x(t)) \geqslant \varepsilon\right] < \eta',$$

whence Claim 1 is verified. The (SP1) property (3.30) of (3.2) follows.

We now sketch the proof of (SP2), which is very similar to the proof of (SP1). Let $\eta'' \in]0,1[$ and $r, \varepsilon' > 0$ be given. Since Σ is GUAS by hypothesis (v), in view of Remark 2.6 there exists a number $T(\alpha_2(r), \eta''\alpha_1(\varepsilon')) \geqslant 0$ such that for every $t_0 \in \mathbb{R}_{\geqslant 0}$ we have

$$\xi_0 < \alpha_2(r) \implies \xi(t) < \eta''\alpha_1(\varepsilon') \qquad \forall\, t \geqslant t_0 + T(\alpha_2(r), \eta''\alpha_1(\varepsilon')).$$

Choose x_0 such that $h^\circ(t_0,x_0) < r$ and let $\xi_0 := \alpha_2 \circ h^\circ(t_0,x_0)$. Then from hypotheses (iii), (iv) and Lemma 3.7, it follows that

$$\mathsf{E}\big[V_{\sigma(t)}(t,x(t))\big] \leqslant \xi(t) < \eta''\alpha_1(\varepsilon') \qquad \forall\, t \geqslant t_0 + T(\alpha_2(r), \eta''\alpha_1(\varepsilon')). \tag{3.36}$$

Claim 2. We have $\mathsf{P}\left[\sup_{t\geqslant t_0 + T(\alpha_2(r),\eta''\alpha_1(\varepsilon'))} h(t,x(t)) \geqslant \varepsilon'\right] < \eta''$.

Indeed, defining $\tau_{\varepsilon'} := \inf\{t \geqslant t_0 + T(\alpha_2(r), \eta''\alpha_1(\varepsilon')) \mid h(t,x(t)) \geqslant \varepsilon'\} \leqslant \infty$, and following the steps of the above proof of (SP1) with τ'_ε replacing τ_ε, for an arbitrary $t'' > t_0 + T(\alpha_2(r), \eta''\alpha_1(\varepsilon'))$, we obtain

$$\eta''\alpha_1(\varepsilon') > \mathsf{E}\big[V_{\sigma(\tau_{\varepsilon'}\wedge t'')}(\tau_{\varepsilon'} \wedge t'', x(\tau_{\varepsilon'} \wedge t''))\big] \geqslant \mathsf{E}\big[\mathbf{1}_{\{\tau_{\varepsilon'} \leqslant t''\}} V_{\sigma(\tau_{\varepsilon'})}(\tau_{\varepsilon'}, x(\tau_{\varepsilon'}))\big].$$

This leads to $\eta''\alpha_1(\varepsilon') > \mathsf{P}[\tau_{\varepsilon'} \leqslant t'']\, \alpha_1(\varepsilon')$. Since t'' is arbitrary, by the definition of $\tau_{\varepsilon'}$ we get

$$\mathsf{P}\left[\sup_{t\geqslant t_0 + \widetilde{T}(r,\varepsilon')} h(t,x(t)) \geqslant \varepsilon'\right] < \eta'',$$

where $\widetilde{T}(r,\varepsilon') := T(\alpha_2(r), \eta''\alpha_1(\varepsilon'))$, suppressing the dependence on η'', which is implied. This verifies Claim 2, and hence the (SP2) property (3.31) of (3.2).

We conclude that (3.2) is (h°, h)-SGUAS-P. □

Since (h°, h)-SGUAS-P implies (h°, h)-GUAS-P, we obtain the (h°, h)-GUAS-P property of (3.2) without the necessity of α_1 being convex; cf. Remark 3.10. See also [23] for a proof of the GUAS-P property of a single stochastic system without the convexity assumption on α_1.

4. Conclusion. We have established a general framework for stability analysis of deterministic and stochastic switched systems. In section 2 we have unified representative existing results on deterministic switched systems and provided illustrations of how we can improve upon the scope of applicability of Lyapunov's second method to switched systems. In section 3 we have established new results on stability of stochastic switched systems. We have carried out analysis in terms of two measures and demonstrated how our framework applies to various stability notions. To conclude, we make the following comments with an eye toward possible future work.

In this paper we have considered disturbances in the form of a Wiener process affecting the states of a switched system, and we have not paid attention to the mechanism of switching signal generation. A common way to generate a switching signal, which has received a lot of attention in recent literature, is via a Markov chain with state space $\mathcal{P}$; see, e.g., [2, 4, 21]. In situations where both Markovian switching and a Wiener process are present, we have to keep in mind two different probability spaces in general: one that generates the disturbances, and the other which governs the Markovian switching. Some results on stability analysis of piecewise deterministic systems with Markovian switching are under development by the authors and will be presented separately.

Although we have utilized only scalar Lyapunov functions in this paper, there can be a parallel development utilizing *vector Lyapunov functions*. For details on this method, see, e.g., [32] and also [29] for an extensive development and discussion on vector Lyapunov functions used in conjunction with analysis using two measures.

A suitably modified version of the comparison framework can be used for systems with inputs also; details for the case of input-to-state stability of switched systems will be reported elsewhere.

Appendix A. Equivalence of definitions of (h°, h)-GUAS.

Proof of the claim in Remark 2.3. *Sufficiency.* Assume that the (S1) property holds. With a fixed $\varepsilon > 0$ we have

$$h^\circ(t_0, x_0) \leqslant \delta(\varepsilon) \implies h(t, x(t)) \leqslant \varepsilon \qquad \forall\, t \geqslant t_0,$$

and the above implication holds uniformly over t_0. Defining the function $\varphi \in \mathcal{K}_\infty$ such that $\varphi(\cdot) := \delta^{-1}(\cdot)$, it follows that

$$h(t, x(t)) \leqslant \varphi \circ h^\circ(t_0, x_0) \qquad \forall\, t \geqslant t_0, \tag{A.1}$$

since $\varepsilon > 0$ is arbitrary.

Now we assume that the (S2) property holds.

A straightforward generalization of [31, Lemma 3.1] leads to the existence of a family of mappings $\{T_r\}_{r>0}$ with the properties

- for every fixed $r > 0$, $T_r \in \mathrm{C}[\mathbb{R}_{>0}, \mathbb{R}_{>0}]$ is surjective and strictly decreasing, and
- for every fixed $\varepsilon > 0$, $T_r(\varepsilon)$ is strictly increasing with r and $\lim_{r\uparrow\infty} T_r(\varepsilon) = \infty$,

such that $h^\circ(t_0, x_0) < r$ implies $h(t, x(t)) < \varepsilon \quad \forall\, t \geqslant t_0 + T_r(\varepsilon)$.

Let $\psi_r(\cdot) := T_r^{-1}(\cdot),\ r \in]0, \infty[$. Then $\psi_r \in \mathrm{C}[\mathbb{R}_{>0}, \mathbb{R}_{>0}]$ is surjective and strictly decreasing. We write $\psi_r(0) = \infty$, considering $\lim_{t \downarrow 0} \psi_r(t) = \infty$.

Claim. For $h^\circ(t_0, x_0) < r$ we have $h(t, x(t)) \leqslant \psi_r(t)$ for $t \geqslant t_0$.

Proof. It follows from the definition of T_r that for an arbitrary $r, \varepsilon > 0$,

$$h^\circ(t_0, x_0) < r \implies h(t, x(t)) < \varepsilon \qquad \forall\, t \geqslant t_0 + T_r(\varepsilon).$$

Since $t - t_0 = T_r \circ \psi_r(t - t_0)$, for $t > t_0$, we have $h(t, x(t)) < \psi_r(t - t_0)$. Combining this and $\psi_r(0) = \infty$, the validity of the claim follows.

For arbitrary $s, t \in \mathbb{R}_{\geqslant 0}$, let

$$\overline{\psi}(s, t) := \min \left\{ \varphi(s), \inf_{r \in\,]s, \infty[} \psi_r(t) \right\}.$$

By definition of φ and the above claim, for every $(t_0, x_0) \in \mathbb{R}_{\geqslant 0} \times \mathbb{R}^n$,

$$h(t, x(t)) \leqslant \overline{\psi}(h^\circ(t_0, x_0), t - t_0) \qquad \forall\, t \geqslant t_0.$$

The function $\overline{\psi}$ need not be of class $\mathcal{KL}$, so we majorize it as follows. By definition, $\overline{\psi}(\cdot, t)$ is a nondecreasing function and for some fixed s, $\overline{\psi}(s, t) \to 0$ as $t \uparrow \infty$. Define

$$\widetilde{\psi}(s, t) := \int_s^{s+1} \overline{\psi}(v, t) \mathrm{d}v + \frac{s}{(1 + s)(1 + t - t_0)}.$$

It is straightforward to prove that

- $\widetilde{\psi}(s, t)$ is increasing with s for every $t \in \mathbb{R}_{\geqslant 0}$,
- $\widetilde{\psi}(s, t)$ decreases to 0 as $t \uparrow \infty$ for every fixed $s \in \mathbb{R}_{\geqslant 0}$, and
- $\widetilde{\psi}(s, t) \geqslant \overline{\psi}(s, t)$.

Then defining $\beta(s, t) := \sqrt{\varphi(s) \widetilde{\psi}(s, t)}$, it follows that for an arbitrary $(t_0, x_0) \in \mathbb{R}_{\geqslant 0} \times \mathbb{R}^n$,

$$h(t, x(t)) \leqslant \sqrt{\big(\varphi \circ h^\circ(t_0, x_0)\big)\, \big(\overline{\psi}(h^\circ(t_0, x_0), t - t_0)\big)} \leqslant \beta(h^\circ(t_0, x_0), t - t_0) \qquad \forall\, t \geqslant t_0.$$

The proof of sufficiency is complete.

Necessity.

- To see (S1), consider the inequality (2.4) at the initial condition. We recover a class $\mathcal{K}_\infty$ function $\beta(\cdot, 0) =: \gamma(\cdot)$ relating h° and h as $h(t, x) \leqslant \gamma \circ h^\circ(t, x)$ for all $(t, x) \in \mathbb{R}_{\geqslant 0} \times \mathbb{R}^n$. Now for $\varepsilon > 0$, consider $\delta(\cdot) = \gamma^{-1}(\cdot)$.
- To see (S2), consider $r, \varepsilon > 0$ given and the existence of T follows from the property of the class $\mathcal{KL}$ function β.

The proof of necessity is complete. □

Appendix B. Equivalence of definitions of (h°, h)-SGUAS-P.

Proof of Lemma 3.23. First we show that (h°, h)-SGUAS-P implies (SP1)–(SP2).

We note that by the (h°, h)-SGUAS-P property, there exists a function $\beta \in \mathcal{KL}$ such that (3.29) holds. Let $\eta', \eta'' \in]0, 1[$, $r, \varepsilon, \varepsilon' > 0$ and $t_0 \in \mathbb{R}_{\geqslant 0}$ be given. We choose $\eta = \eta' \wedge \eta''$. From the deterministic equivalence claimed in Remark 2.3, we have two numbers $\delta(\varepsilon) > 0$ and $T(r, \varepsilon') \geqslant 0$ such that from the condition $\sup_{t \geqslant t_0} h(t, x(t)) < \beta(h^\circ(t_0, x_0), t - t_0)$ we get

(i) $h^\circ(t_0, x_0) < \delta(\varepsilon) \implies \sup_{t \geqslant t_0} h(t, x(t)) < \varepsilon$, and

(ii) $h^\circ(t_0, x_0) < r \implies \sup_{t \geqslant t_0 + T(r, \varepsilon')} h(t, x(t)) < \varepsilon'$.

Choose $x_0 \in \mathbb{R}^n$ such that $h^\circ(t_0, x_0) < \delta(\varepsilon) \wedge r$. Define the sets

$$\begin{aligned} \Omega'_t &:= \big\{h(t, x(t)) < \varepsilon\big\}, \\ \Omega''_t &:= \big\{h(t, x(t)) < \varepsilon'\big\} \cup \big\{t < t_0 + T(r, \varepsilon')\big\}. \end{aligned} \tag{B.1}$$

Note that the set $\big\{t < t_0 + T(r, \varepsilon')\big\}$ merely ensures that the probability measure of the set $\big\{h(t, x(t)) < \varepsilon'\big\}$ is meaningful only after $t \geqslant t_0 + T(r, \varepsilon')$, which is what we need. In the light of (i)–(ii) and the definitions in (B.1), we know that (3.29) implies that $\mathsf{P}[\cap_{t \geqslant t_0} (\Omega'_t \cap \Omega''_t)] \geqslant 1 - \eta$. But by our choice of η, this means that $\mathsf{P}[\cap_{t \geqslant t_0} (\Omega'_t \cap \Omega''_t)] \geqslant (1-\eta') \vee (1-\eta'')$. Therefore, $\mathsf{P}[\cap_{t \geqslant t_0} \Omega'_t] \geqslant 1-\eta'$ and $\mathsf{P}[\cap_{t \geqslant t_0} \Omega''_t] \geqslant 1 - \eta''$, which are the properties (SP1) and (SP2) in (3.30) and (3.31), respectively.

Now we show that (SP1)–(SP2) implies (h°, h)-SGUAS-P.

Let $\eta \in]0, 1[$, $r, \varepsilon, \varepsilon' > 0$ and $t_0 \in \mathbb{R}_{\geqslant 0}$ be given. We choose $\eta' = \eta'' = \eta/2$. From (SP1)–(SP2), we get two numbers $\delta(\varepsilon) > 0$ and $T(r, \varepsilon') \geqslant 0$. Choose x_0 such that $h^\circ(t_0, x_0) < \delta(\varepsilon) \wedge r$. Using the definitions of Ω'_t and Ω''_t in (B.1), from (3.30) and (3.31) we have $\mathsf{P}[\cap_{t \geqslant t_0} \Omega'_t] \geqslant 1 - \eta/2$, and $\mathsf{P}[\cap_{t \geqslant t_0} \Omega''_t] \geqslant 1 - \eta/2$. We know that for $A, B \subset \Omega$ such that $\mathsf{P}[A] \geqslant 1 - \eta/2$ and $\mathsf{P}[B] \geqslant 1 - \eta/2$, we have $\mathsf{P}[A \cap B] \geqslant 1 - \eta$. (This follows from the simple observation that $1 \geqslant \mathsf{P}[A \cup B] = \mathsf{P}[A] + \mathsf{P}[B] - \mathsf{P}[A \cap B]$.) It follows that $\mathsf{P}[\cap_{t \geqslant t_0} (\Omega'_t \cap \Omega''_t)] \geqslant 1 - \eta$, which is just

$$\mathsf{P}\left[\left\{\sup_{t \geqslant t_0} h(t, x(t)) < \varepsilon\right\} \bigcap \left\{\sup_{t \geqslant t_0 + T(r, \varepsilon')} h(t, x(t)) < \varepsilon'\right\}\right] \geqslant 1 - \eta.$$

In view of Remark 2.3 and (i)–(ii) above, since $r, \varepsilon, \varepsilon' > 0$ were arbitrary, it follows that there exists a function $\beta \in \mathcal{KL}$ such that $\mathsf{P}\big[\sup_{t \geqslant t_0} h(t, x(t)) < \beta(h^\circ(t_0, x_0), t - t_0)\big] \geqslant 1 - \eta$, which is the (h°, h)-SGUAS-P property (3.29). □

We remark that with little alteration of the above proof we obtain the equivalence of the definitions of (h°, h)-GUAS-P claimed in Remark 3.4. Indeed, for arbitrary fixed $t > t_0$, we need to eliminate the intersections of the sets Ω'_t and Ω''_t over $t \geqslant t_0$ in the equations above to establish the equivalence for time t. Since t is an arbitrary choice, we can conclude the validity of the result for every $t \geqslant t_0$.

Acknowledgments. We are indebted to S. P. Meyn for sharing with us his vision and discernment on stochastic stability. We thank A. D. Teel and V. Lakshmikantham for providing valuable insights on stability analysis in terms of two measures at various junctures.

RECEDING HORIZON CONTROL WITH INCOMPLETE OBSERVATIONS*

KAZUFUMI ITO† AND KARL KUNISCH‡

Abstract. To overcome the difficulties related to the computational requirements for solving the optimality systems for optimal control problems on long time horizons, receding horizon techniques provide an important alternative. Rather than finding the optimal solution, a suboptimal control is obtained which achieves the design objective with significantly less computational effort. Moreover, the obtained control can be interpreted as a state feedback control. In this work we continue our analysis of receding horizon strategies, considering the situation when only partial state observations are available. The receding horizon strategy is combined with a state estimator framework. A linear quadratic Gaussian design based on a linearization procedure is proposed and its asymptotic performance is analyzed for systems with nonlinear dynamics. Numerical examples validate the proposed methodology.

Key words. receding horizon control, incomplete observations, dynamic compensator

1. Introduction.

We consider the optimal control problem of minimizing the performance index subject to a nonlinear control system:

$$\min \int_0^{T_\infty} f^0(x(t), u(t))\, dt, \tag{1.1}$$

where

$$\frac{d}{dt}x(t) = f(x(t)) + Bu(t) \quad \text{for} \quad t > 0, \tag{1.2}$$

$$x(0) = x_0, \tag{1.3}$$

for some $T_\infty \in (0, \infty]$ and $x_0 \in R^n$. In order to present our approach without the technical difficulties associated to infinite dimensional control systems, we assume here that the state space is finite dimensional. We refer to $x(\cdot)$ and $u(\cdot)$ as state and control functions with $x(t) \in R^n$ and $u(t) \in R^m$. Under appropriate conditions, (1.1)–(1.3) admit a solution which satisfies the minimum principle

$$\begin{cases} \frac{d}{dt}x(t) = H_p(x(t), u(t), p(t)),\ x(0) = x_0, \\ \frac{d}{dt}p(t) = -H_x(x(t), u(t), p(t)),\ p(T_\infty) = 0, \\ u(t) = \arg\min_{u \in R^m}\ H(x(t), u, p(t)), \end{cases} \tag{1.4}$$

where H is the Hamiltonian defined by $H(x,u,p) = f^0(x,u) + p \cdot (f(x) + Bu)$. The coupled system of two-point boundary value problems with initial condition for the primal equation and terminal condition for the adjoint equation represents a significant challenge for numerical computations in case the dimension n of the state or the time horizon T_∞ are large. It has therefore been the focus of many research efforts. An alternative approach consists in constructing the feedback solution based on Bellman's dynamic programming principle. Again, due to computational costs, this is tractable only for very limited examples.

One of the possibilities to overcome these difficulties is given by time-domain decomposition based on receding horizon formulations [ABQRW, GPM]. Receding horizon techniques have proved to be effective numerically both for optimal control problems governed by ordinary (e.g., [CA, JYH, K, MM, PND, SMR]) and by partial differential equations, e.g., in the form of the instantaneous control technique for problems in fluid mechanics [B, CHK, CTMC, HV].

To briefly explain the strategy let $0 = T_0 < T_1 \cdots < T_\infty$ describe a grid on $[0, T_\infty)$ and let $T \geq \max\{T_{i+1} - T_i : i = 0, \dots\}$. If $T > T_{i+1} - T_i$, we have overlapping domains. The receding horizon optimal control problem involves the successive finite horizon optimal control problems on $[T_i, T_i + T]$,

$$\min \int_{T_i}^{T_i+T} f^0(x(t), u(t))\, dt + G(x(T_i + T)), \tag{1.5}$$

subject to

$$\frac{d}{dt}x(t) = f(x(t)) + Bu(t),\ t \in [T_i, T_i + T], \tag{1.6}$$

$$x(T_i) = x^*(T_i) \text{ if } i \geq 1 \text{ and } x(0) = x_0 \text{ for } i = 0, \tag{1.7}$$

where x^* is the solution to the auxiliary problem on $[T_{i-1}, T_{i-1} + T]$.

The solution on $[0, T_\infty)$ is obtained by concatenation of the solutions on $[T_i, T_{i+1}]$ for $i = 0, \dots$. If the terminal cost G is chosen as a control Liapunov function, then the asymptotic stability and the performance estimate of the receding horizon synthesis are established in [IK1] in case (1.2) is posed in a finite dimensional state space, and in [IK2] for infinite dimensional state spaces. For example, if G is selected as the optimal value function for (1.1)–(1.3) on the infinite horizon, then the optimal pair (x^*, u^*) for the receding horizon control (1.5)–(1.8) is optimal for the original problem (1.1)–(1.3) on the infinite horizon. In general, G plays the role of a look-ahead term in the sense that it stabilizes the receding horizon synthesis and provides a good suboptimal control law for the given performance (1.1). Since it is impractical to assume that the optimal value functional is known we constructed in [IK1] and [IK2] control Liapunov functions for diverse classes of problems which are based on Liapunov or Riccati equations. For the numerical example of section 5 we select G as the solution to an associated Riccati equation.

If $x(T_i)$ is observed, then the receding horizon control technique is a state feedback method since the control on $[T_i, T_{i+1}]$ is determined as a function of the state $x^*(T_i)$. If the optimal pair $(x^*(t), u^*(t)),\ t \in [T_i, T_i + T]$ is shifted by $-T_i$ it satisfies the two-point boundary value problem (1.4) on the interval $[0, T]$ with the terminal condition $p(T) = G_x(x(T))$ and initial condition $x(0) = x^*(T_i)$.

In this paper we address the state estimator problem for the receding horizon technique. We shall also allow for additive noise in the system dynamics as well as

in the observation process and we admit uncertainty in the initial condition. The nonlinear time-independent control system with additive unmodeled disturbance is given by

$$\begin{cases} \frac{d}{dt}x(t) = f(x(t)) + Bu(t) + d(t) \ \text{ for } \ t > 0, \\ x(0) = x_0, \end{cases} \tag{1.8}$$

where $d(t)$ is an unknown disturbance process. The observation process providing partial observations $y(t) \in R^p$ of the state $x(t)$ is assumed to be of the form

$$y(t) = Cx(t) + n(t), \tag{1.9}$$

where $C \in \mathbb{R}^{p\times n}$ and $n(t)$ is a measurement noise process. The output feedback law will utilize the open loop optimal control u^* with associated optimal state x^* on the interval $[T_i, T_{i+1}]$ computed from (1.5) and (1.6). The initial condition for the computation of x^* is taken to be

$$x(0) = x_0 + \eta_0,$$

where η_0 denotes the uncertainty in the initial condition for $i = 0$, and then it is chosen as the state of the estimator, which will be introduced below, at time T_i, if $i \geq 1$. This can be considered as a preprocessing step for the construction of the feedback law, and in view of the fact that receding time horizon T is considered to be small compared to T_∞ it is considered to be comparatively cheap.

Once x^* is computed on $[T_i, T_i + T]$, the output feedback law is chosen to be of the form

$$u(t) = u^*(t) - B^T\Pi(w(t) - x^*(t)), \quad t \in [T_i, T_{i+1}), \tag{1.10}$$

where w denotes the state of the compensator. The construction of the feedback gain $B^T\Pi$ will be specified below. Suggested from linear quadratic Gaussian (LQG) design, the compensator is based on (1.10) together with the state estimator dynamics of the form

$$\frac{dw}{dt} = f'(\bar{x})(w(t) - x^*(t)) + f(x^*(t)) + Bu(t) + \Sigma C^T(y(t) - Cw(t)), \tag{1.11}$$

$$w(T_i) = w(T_i^-) \text{ for } i = 1, 2, \ldots, \text{ and } w(0) = x_0 + \eta_0, \tag{1.12}$$

for the state estimator $w(t)$, where $w(T_i^-)$ denotes the value of the estimator on $[T_{i-1}, T_{i-1} + T]$ at T_i and $f'(\bar{x})$ is the Jacobian of f at a reference state $\bar{x}$. This reference state $\bar{x}$ is selected on the basis of the optimal pair (x^*, u^*) on $[T_i, T_i + T]$, for example,

$$\bar{x} = \frac{1}{T}\int_{T_i}^{T_i+T} x^*(t)\,dt \quad \text{or} \quad \bar{x} = x^*(T_i + T). \tag{1.13}$$

The feedback synthesis (1.10)–(1.12) performs tracking of (1.8) to the optimal pair (x^*, u^*) on $[T_i, T_i+T]$ under the uncertainty of the initial condition, observation noise and an additive disturbance in the system dynamics. As described in section 2, our tracking method is based on the linearization of the nonlinearity f at the reference

state $\bar{x}$. The control gain $B^T\Pi$ and the filter gain ΣC^T will be constructed by two LQG Riccati equations, which we specify in section 2.

For our stability analysis of the output feedback synthesis (1.11)–(1.13) it is not necessary that (x^*, u^*) is assumed to be the optimal pair for the receding horizon control on $[T_i, T_i + T]$. It is only required that x^* is a stable trajectory of (1.2) corresponding to a given control u^*. However, if G is selected as a control Liapunov function, then the global stability and performance estimate of the receding control are established in [IK1]. Thus, we assume (x^*, u^*) is the optimal pair for the receding horizon control on each horizon $[T_i, T_i+T]$ and the corresponding (1.11)–(1.13) defines our proposed output feedback synthesis for (1.1)–(1.3).

The stability analysis and performance estimates for the proposed procedure are given in section 2. In section 3 the asymptotic behavior of the overall closed-loop system (1.8), with feedback control given by (1.10) and (1.11), is discussed. Our analysis uses the Liapunov stability arguments. In section 4 we briefly address a modification of the proposed method based on an H^∞-synthesis. Numerical examples that illustrate the feasibility of combining the receding horizon strategy with state estimator dynamics are given in section 5, by means of stabilization and tracking problems for the Burgers equation.

The controlled Burgers equation is an infinite dimensional system which, after discretization, is of the form considered in (1.2). In fact, while our analysis is carried out for finite dimensional systems, the proposed concepts can be extended to infinite dimensional systems. The details, however, require further research.

2. LQG design. In this section we describe the construction of the feedback and filters gains for (1.10) and (1.11). Subsequently we establish the stability and the performance estimate for the compensator dynamics (1.10), (1.11) based on the LQG design on a single time horizon $[0, T]$. The iterative procedure on the sequence of time horizons $[T_i, T_{i+1}]$ will be considered in section 3. The Jacobian of f at $x \in \mathbb{R}^n$ will be denoted by $A(x) = f'(x)$ and in particular we set

$$A = f'(\bar{x}).$$

We assume that

$$(A, B, C) \text{ is stabilizable and detectable.} \tag{2.1}$$

Consider the controlled linear equation, which results from linearizing f at $x^*(t)$ and subsequently replacing $x^*(t)$ by $\bar{x}$:

$$\begin{cases} \frac{d}{dt}(\hat{x}(t) - x^*(t)) = A(\hat{x}(t) - x^*(t)) + B(u(t) - u^*(t)) + d(t), \\ \hat{x}(0) = x_0 + \eta_0, \end{cases} \tag{2.2}$$

where $d(t)$ is the disturbance process. We shall further comment on the choice of the linearized equation in Remark 2.2. Let $Q \in \mathbb{R}^{n\times n}$ denote a positive definite matrix and consider the tracking problem to the pair (x^*, u^*):

$$\begin{cases} \min \frac{1}{2}\int_0^\infty ((\hat{x}(t) - x^*(t))^T Q(\hat{x}(t) - x^*(t)) + |u(t) - u^*(t)|^2)dt \\ \text{subject to (2.2) over } \ u \in L^2(0, \infty; \mathbb{R}^m). \end{cases} \tag{2.3}$$

Throughout this paper we use $|x|^2 = (x, x)$ to denote the square of the Euclidean norm of a vector x and $\|A\|$ for the subordinate matrix norm. Here (x, y) stands

for the dot product of vectors x, y which will at times also be denotes by $x^T y$. Let $V\colon \mathbb{R}^n \to \mathbb{R}^+$ denote the value functional associated to (2.3). It can be shown that

$$V(x) = \frac{1}{2}(x - x^*)^T \Pi (x - x^*) + v^T (x - x^*) + c,$$

where c is a constant, and the symmetric positive definite matrix $\Pi \in R^{n\times n}$ and $v \in R^n$ satisfy

$$\begin{cases} A^T \Pi + \Pi A - \Pi B B^T \Pi + Q = 0, \\ (A - B B^T \Pi)^T v + \Pi d = 0, \end{cases} \tag{2.4}$$

where we assume that the disturbance is constant in time. The optimal feedback loop control for (2.3) is given by

$$u = u^*(t) - B^T(\Pi(\hat{x}(t) - x^*(t)) + v). \tag{2.5}$$

Since we consider unknown, unmodeled disturbance $d = d(t)$ we do not include the feedforward input v in the feedback form (1.10).

Turning to the estimator we use the (Kalman) filter gain ΣC^T based on the linear system (A, C), where $\Sigma \in \mathbb{R}^{n\times n}$ is the positive definite solution to

$$A\Sigma + \Sigma A^T - \Sigma C^T C \Sigma + R = 0, \tag{2.6}$$

with $R \in R^{n\times n}$ a positive definite matrix. This results in the following equations for the compensator

$$\frac{dw}{dt} = A(\bar{x})(w(t) - x^*(t)) + f(x^*(t)) + Bu(t) + \Sigma C^T (y(t) - Cw(t)), \tag{2.7}$$

$$w(0) = x_0 + \eta_0 \tag{2.8}$$

and the associated feedback law

$$u(t) = u^*(t) - B^T \Pi (w(t) - x^*(t)). \tag{2.9}$$

Note that (2.1) guarantees the existence of Π and Σ with the specified properties. Moreover the spectra of $A - B B^T \Pi$ and $A - \Sigma C^T C$ are strictly contained in the left half of the complex plane. We henceforth assume that

$$d \in L^1_{loc}(0, \infty; R^n), \text{ and } n \in L^1_{loc}(0, \infty; R^p).$$

We further assume the existence of solutions x and w to (1.8) and (2.7), (2.8) on $[0, T]$ for every $u \in L^1(0, T; R^m)$, where y is given by (1.9).

PROPOSITION 2.1. *Let $W(x) = \frac{1}{2} x^T \Pi x$. For $t \in [0, T]$ we have*

$$\begin{aligned} \frac{d}{dt} W(x(t) - x^*(t)) = &-\frac{1}{2}(|B^T \Pi (x(t) - x^*(t))|^2 + (Q(x(t) - x^*(t)), x(t) - x^*(t))) \\ &+ (d(t) + r(x(t), x^*(t)), \Pi(x(t) - x^*(t))) + (B^T \Pi (x(t) - w(t)), B^T \Pi (x(t) - x^*(t))), \end{aligned}$$

where

$$r(x, x^*) = f(x) - f(x^*) - A(\bar{x})(x - x^*),$$

x is the solution to (1.8) *with u given in* (2.9)*, and x^* is the solution to* (1.6) *with the optimal open loop control u^*.*

Proof. Using (1.6) and (1.8) we have

$$\frac{d}{dt}(x(t)-x^*(t)) = A(x(t)-x^*(t)) - BB^T\Pi(x(t)-x^*(t))$$

$$+ BB^T\Pi(x(t)-w(t)) + d(t) + r(x(t),x^*(t)).$$

Thus,

$$\frac{d}{dt}W(x(t)-x^*(t)) = ((A-BB^T\Pi)(x(t)-x^*(t)) + BB^T\Pi(x(t)-w(t))$$

$$+ d(t) + r(x(t),x^*(t)), \Pi(x(t)-x^*(t))$$

and the proposition follows from the fact that

$$((A-BB^T\Pi)x,\Pi x) = -\frac{1}{2}\,(|B^T\Pi x|^2 + (Qx,x)). \qquad \square$$

PROPOSITION 2.2. *Let $\tilde{W}(z) = \frac{1}{2}\, z^T\Sigma^{-1}z$. For $t\in[0,T]$ we have*

$$\frac{d}{dt}\tilde{W}(x(t)-w(t)) = -\frac{1}{2}(|C(x(t)-w(t))|^2 + (R\Sigma^{-1}(x(t)-w(t)),\Sigma^{-1}(x(t)-w(t)))$$

$$+ (r(x(t),x^*(t)) + d(t), \Sigma^{-1}(x(t)-w(t))) - (n(t), C(x(t)-w(t)),$$

where x and w are the solutions to (1.8) *and* (2.7) *for some $u\in L^2(0,T;R^m)$.*

Proof. From (1.8) and (2.7) we have

$$\frac{d}{dt}(x(t)-w(t)) = A(x(t)-w(t)) + r(x(t),x^*(t)) + d(t) - \Sigma\, C^T(C(x(t)-w(t)) + n(t)),$$

and hence

$$\frac{d}{dt}\tilde{W}(x(t)-w(t)) = ((A-\Sigma C^TC)(x(t)-w(t))$$

$$+ r(x(t),x^*) + d(t) - \Sigma\, C^Tn(t), \Sigma^{-1}(x(t)-w(t))).$$

Thus the proposition follows from the fact that

$$((A-\Sigma C^TC)z,\Sigma^{-1}z) = -\frac{1}{2}\,(|Cz|^2 + (R\Sigma^{-1}z,\Sigma^{-1}z)). \qquad \square$$

To quantify the performance of the compensator we set

$$E(t) = (x(t)-x^*(t),\Pi(x(t)-x^*(t)))^{1/2} + (x(t)-w(t),\Sigma^{-1}(x(t)-w(t)))^{1/2}.$$

Note that $E(t) = (W(x(t)-x^*(t)) + \tilde{W}(x(t)-w(t)))^{1/2}$. We further introduce positive constants $\alpha_1,\ \alpha_2$ and $\beta_1,\ \beta_2$ such that

$$\alpha_1\, I \le \Pi \le \alpha_2\, I, \qquad \beta_1\, I \le \Sigma^{-1} \le \beta_2\, I, \tag{2.10}$$

where I is the identity matrix on R^n. We shall require the following assumptions: there exists $\omega > 0$ such that

$$\begin{aligned}\frac{1}{2}(|B^T\Pi x|^2 + (Qx,x) + |Cz|^2 + (R\Sigma^{-1}z, \Sigma^{-1}z))\\ - (B^T\Pi\Sigma\,\Sigma^{-1}z, B^T\Pi x) \geq \omega\,(W(x) + \tilde{W}(z)) \text{ for all } x,z \in R^n,\end{aligned} \tag{2.11}$$

and

$$E(0) \leq \frac{\delta}{2} \text{ and } |x^*(t) - \bar{x}| \leq \delta \text{ on } [0,T] \text{ for some } \delta > 0. \tag{2.12}$$

Turning to the effect of the nonlinearity we observe that

$$r(x,x^*) = f(x) - f(x^*) - A(x^*)(x - x^*) + (A(x^*) - A(\bar{x}))(x - x^*).$$

We assume that there exist a constant L such that

$$|r(x,x^*)| \leq L\,(|x^* - \bar{x}| + |x - x^*|)\,|x - x^*| \text{ for all } x, x^* \in \mathcal{S}, \tag{2.13}$$

where $\mathcal{S} = \{x \in R^n : |x - \bar{x}| \leq \delta(1 + \frac{1}{\sqrt{\alpha_1}})\}$. We shall further assume that

$$\tilde{\omega} = \omega - L\delta\,\frac{\sqrt{\alpha_1} + 1}{\alpha_1}\,\frac{\sqrt{\alpha_2} + \sqrt{\alpha_2 + \beta_2}}{2} > 0. \tag{2.14}$$

This requirement is trivially satisfied if f is linear. Let us define

$$\rho(t) = \sqrt{\alpha_2 + \beta_2}\,|d(t)| + \frac{1}{\sqrt{\beta_1}}\,\|C\||n(t)|.$$

We require the following smallness condition on the noise processes:

$$\int_0^t e^{-\tilde{\omega}(t-s)}\rho(s)\,ds < \frac{\delta}{2} \quad \text{for all } t \in [0,T]. \tag{2.15}$$

THEOREM 2.1. *If* (2.12) *and the stability conditions* (2.11), (2.13), (2.14) *and the smallness condition on the noise processes* (2.15) *are satisfied, then*

$$E(t) \leq e^{-\tilde{\omega}t}\,E(0) + \int_0^t e^{-\tilde{\omega}(t-s)}\rho(s)\,ds \tag{2.16}$$

holds for all $t \in [0,T]$.

Proof. Due to (2.12) there exists τ such that

$$E(\tau) \leq \delta \text{ on } [0,\tau].$$

Note that $\sqrt{\alpha_1}|x(t) - x^*(t)| \leq E(t)$ and therefore $x(t) \in \mathcal{S}$ for $t \in [0,\tau]$. Set $X(t) = |x(t) - x^*(t)|_\Pi$ and $Y(t) = |x(t) - w(t)|_{\Sigma^{-1}}$. Suppressing the dependence on t we obtain by (2.12), (2.13) that

$$\begin{aligned}&(r(x,x^*), \Pi(x - x^*)) + (r(x,x^*), \Sigma^{-1}(x - w))\\ &\leq L\delta\,\frac{\sqrt{\alpha_1} + 1}{\alpha_1}(\sqrt{\alpha_2}X^2 + \sqrt{\beta_2}XY)\\ &\leq L\delta\,\frac{\sqrt{\alpha_1} + 1}{\alpha_1}\,\frac{\sqrt{\alpha_2} + \sqrt{\alpha_2 + \beta_2}}{2}\,(X^2 + Y^2) \text{ for } t \in [0,\tau].\end{aligned}$$

Since

$$E(t)\frac{d}{dt}E(t) = \frac{d}{dt}(W(x(t)-x^*(t)) + \tilde{W}(x(t)-w(t))),$$

we find by Proposition 2.1, 2.2, with u given in (2.9), and (2.11), (2.13), (2.14) that

$$\frac{d}{dt}(W(x-x^*) + \tilde{W}(x-w))$$

$$\leq -\omega(W(x-x^*) + \tilde{W}(x-w)) + (d + r(x,x^*), \Pi(x-x^*) + \Sigma^{-1}(x-w)) - (n, C(x-w))$$

$$\leq -\tilde{\omega}(W(x-x^*) + \tilde{W}(x-w)) + (d, \Pi(x-x^*)) + (d, \Sigma^{-1}(x-w)) - (n, C(x-w))$$

$$\leq -\tilde{\omega}(W(x-x^*) + \tilde{W}(x-w)) + \rho(t)(W(x-x^*) + \tilde{W}(x-w))^{1/2}.$$

Consequently

$$\frac{d}{dt}E(t) \leq -\tilde{\omega}E(t) + \rho(t).$$

This implies (2.16) on $[0,\tau]$.

By (2.15) and continuity of $t \to \int_0^t e^{-\omega(t-s)}\rho(s)ds$ there exists $\alpha \in (0,1)$ such that

$$\int_0^t e^{-\tilde{\omega}(t-s)}\rho(s)ds \leq \frac{\alpha\delta}{2} \text{ for all } t \in [0,T],$$

and consequently

$$E(t) < \frac{\delta}{2}(1+\alpha) \text{ for all } t \in [0,\tau]. \tag{2.17}$$

A continuation argument implies that (2.16) and (2.17) hold on $[0,T]$. In fact, if (2.17) holds on $[0,T]$, then (2.16) can be continued from $[0,\tau]$ to $[0,T]$. Assuming that (2.17) is not valid on $[0,T]$, let $\tilde{\tau}$ denote the smallest value in $(0,T)$ such that $E(\tilde{\tau}) = \frac{\delta}{2}(1+\alpha)$. Then repeating the argument leading to (2.16) it can be shown that there exists $\epsilon > 0$ such that (2.16) holds in $[0,\tilde{\tau}+\epsilon]$. This implies $E(\tilde{\tau}+\epsilon) < \frac{\delta}{2}(1+\alpha)$, which is a contradiction. Thus (2.17) holds on $[0,T]$. □

Remark 2.1. Concerning assumption (2.12), we note that the indefinite term $-(B^T\Pi\Sigma\Sigma^{-1}, B^T\Pi x)$ can be estimated by

$$-(B^T\Pi\Sigma\Sigma^{-1}z, B^T\Pi x) \geq -\frac{1}{2\alpha}|B^T\Pi\Sigma\Sigma^{-1}z|^2 - \frac{\alpha}{2}|B^T\Pi x|^2$$

and the terms on the right-hand side can be combined with (Qx,x) and $(R\Sigma^{-1}z, \Sigma^{-1}z)$, and $\alpha > 0$ appropriately chosen, to check for (2.12). However, since Π and Σ depend nonlinearly on Q and R, respectively, we must check the validity of (2.12) for any given system. We have done so numerically for our test examples.

Remark 2.2. The linear equation (2.2) as a basis for the construction of the compensator is well suited for our purposes. Other choices are briefly indicated.

1. Linearizing (1.8) at $\bar{x}$ results in

$$\frac{d}{dt}(\hat{x}(t)-\bar{x}) = f(\bar{x}) + A(\hat{x}(t)-\bar{x}) + B(u(t)-u^*(t)) + d(t).$$

The resulting Riccati synthesis is of the form (2.4) with d replaced by $d+f(\bar{x})$. Since d is unknown it cannot be used for the construction of the estimator, and $f(\bar{x})$ remains as a known bias term. It necessitates to modify W to be $W(x) = \frac{1}{2}x^T\Pi x + x^T v$, with the bias v changing from one horizon to the next.

2. It is also possible to employ the time varying linearization

$$\begin{cases} \frac{d}{dt}(\hat{x}(t) - x^*(t)) = A(t)(\hat{x}(t) - x^*(t)) + B(u - u^*(t)) + \tilde{n}(t), \\ \\ \hat{x} = x_0, \end{cases} \tag{2.18}$$

where $A(t) = A(x^*(t))$ and use the corresponding time-varying gains $B^T\Pi(t)$ and $\Sigma(t)C^T$ determined by

$$\frac{d}{dt}\Pi(t) + A(t)^T\Pi(t) + \Pi(t)A(t) - \Pi(t)BB^T\Pi(t) + Q = 0$$

and

$$\frac{d}{dt}\Sigma(t) - A(t)\Sigma(t) - \Sigma(t)A(t)^T + \Sigma(t)BB^T\Sigma(t) - R = 0.$$

One can adapt our analysis and establish an error estimate analogous to (2.16) assuming that $\omega > 0$ and L are independent of $t \in [0, T]$.

3. Asymptotic performance of a closed-loop system. We will apply Theorem 2.1 repeatedly on the intervals $[T_i, T_i + T]$. Let us briefly recall the procedure. The open loop solution x^* to (1.5)–(1.7) is computed on $[T_i, T_{i+1}]$, and based on it $\bar{x}$ is determined; see (1.13). To refer to a specific horizon we henceforth use $\bar{x}_{T_i}$ for $\bar{x}$. This determines $A(\bar{x}_{T_i})$ and allows us to compute $\Pi = \Pi(\bar{x}_{T_i})$ and $\Sigma = \Sigma(\bar{x}_{T_i})$ as solutions to the corresponding Riccati equations. The compensator can then be defined on the basis of (1.10)–(1.12). To simplify the following discussion we assume that $T_{i+1} - T_i = T$ for all i. We shall assume that

$$E(0) \le \frac{\delta}{2} \text{ and } |x^*(t) - \bar{x}| \le \delta \text{ on } [T_i, T_{i+1}] \text{ for all } i = 0, \dots \tag{3.1}$$

and that (2.10) and (2.11) hold uniformly on all horizons $[T_i, T_{i+1}]$. In view of the continuity of $x \to A(x)$, we have continuity of $x \to \Pi(x)$ and $x \to \Sigma(x)$. Due to these properties and the fact that the open loop control x^* is typically guaranteed to be continuous and bounded on $[0, \infty)$ (see, e.g., [IK1]), assumptions (2.10), (2.11), and (3.1) are natural ones. As $\bar{x}_{T_i}$ changes from one horizon to the next, so does $\mathcal{S} = \mathcal{S}_{T_i}$ in (2.13). We assume that (2.13) holds uniformly for all horizons as well and that

$$\int_0^t e^{-\tilde{\omega}(t-s)}\rho(s + T_i)\, ds < \frac{\delta}{2} \text{ for } t \in [0, T] \text{ and all } i = 0, 1 \dots. \tag{3.2}$$

Finally we require that

$$\int_0^T e^{-\tilde{\omega}(T-t)}\, \rho(T_i + t)\, dt \le \frac{\delta}{2}(1 - e^{-\tilde{\omega}T}) \text{ for } i = 0, 1 \dots. \tag{3.3}$$

These assumptions imply that

$$E(t) \le e^{-\tilde{\omega}\,(t-T_i)}E(T_i) + \int_0^{t-T_i} e^{-\tilde{\omega}(t-T_i-s)}\, \rho(T_i + s)\, ds \text{ for } t \in [T_i, T_{i+1}] \tag{3.4}$$

for every i, provided that $E(T_i) \leq \frac{\delta}{2}$. Note that (3.3), (3.4) imply

$$E(T_{i+1}) \leq e^{-\tilde{\omega}\,T}\,E(T_i) + \frac{\delta}{2}(1 - e^{-\tilde{\omega}T}) \leq \frac{\delta}{2},$$

and hence by induction $E(T_i) \leq \frac{\delta}{2}$ for all i.

THEOREM 3.1. *If* (3.1)–(3.3) *hold and* (2.10), (2.11), *and* (2.13) *are satisfied uniformly, then*

$$E(t) \leq e^{-\tilde{\omega}\,(t-T_i)}E(T_i) + \int_0^{t-T_i} e^{-\tilde{\omega}(t-T_i-s)}\,\rho(T_i+s)\,ds$$

for $t \in [T_i, T_{i+1}]$ *and all* i. *In particular this implies*

$$E(t) \leq e^{-\tilde{\omega}t}E(0) + \int_0^t e^{-\tilde{\omega}(t-s)}\rho(s)\,ds \text{ for all } t > 0.$$

Note that on each horizon $[T_i, T_{i+1}]$ we must have $|x^*(t) - \bar{x}| \leq \delta$ on $[0, T]$. This may necessitate to take T smaller than $T_{i+1} - T_i$ to ensure that $|x^*(t) - \bar{x}| \leq \delta$ on $[T_i, T_i + T]$. In this case, we can further partition the interval $[T_i, T_{i+1}]$ into subintervals and use consecutive linearization on each subinterval so that the condition is satisfied. The extreme case of this procedure results in the time-varying synthesis as in Remark 2.2.

Concerning the condition $|x^*(t) - \bar{x}| \leq \delta$ we can use an alternative approach motivated by the H^∞ Riccati equation. This will be discussed in the next section.

4. H^∞ Riccati synthesis. In this section we present a modification of the approach proposed in section 1 motivated by H^∞ synthesis. We assume that there exists an attenuation bound $\gamma > 0$ such that

$$A^T\Pi + \Pi\,A - \Pi\left(B\,B^T - \frac{1}{\gamma}I\right)\Pi + \frac{1}{\gamma}I + Q = 0 \tag{4.1}$$

has a positive definite solution Π and

$$A\Sigma + \Sigma A^T - \Sigma\left(C^TC - \frac{1}{\gamma}I\right)\Sigma + \frac{1}{\gamma}I + R = 0 \tag{4.2}$$

has a positive definite solution Σ, where again $A = f'(\bar{x})$. These Riccati equations are similar to those used in the equivalence between H^∞ controllers and linear quadratic zero-some differential games where in our case u and w are the two players [BB]. In the following proposition x and w denote the solutions to (1.8) and (2.7)with u given in (2.9) and x^* is the solution to (1.6) with the optimal open loop control u^*.

PROPOSITION 4.1. *For* $t \in [0, T]$ *we have*

$$\begin{aligned}
&\frac{d}{dt}W(x - x^*)\\
&= -\tfrac{1}{2}(|B^T\Pi(x - x^*)|^2 + (Q(x - x^*), x - x^*) + \tfrac{1}{\gamma}\,|\Pi(x - x^*)|^2 + \tfrac{1}{\gamma}|x - x^*|^2)\\
&\qquad + (r(x, x^*) + d, \Pi(x - x^*)) + (B^T\Pi(x - w), B^T\Pi(x - x^*))
\end{aligned}$$

and

$$\frac{d}{dt}\tilde{W}(x-w)$$
$$= -\frac{1}{2}(|C(x-w)|^2 + (R\Sigma^{-1}(x-w), \Sigma^{-1}(x-w)) + \frac{1}{\gamma}|x-w|^2 + \frac{1}{\gamma}|\Sigma^{-1}(x-w)|^2)$$
$$+(r(x,x^*)+d, \Sigma^{-1}(x-w)) - (n, C(x-w)),$$

where

$$r(x,x^*) = f(x) - f(x^*) - A(\bar{x})(x-x^*),$$

and the dependence of the variables on t is suppressed.

Proof. The proposition follows from the proofs of Propositions 2.1 and 2.2 observing that

$$((A - BB^T\Pi)x, \Pi x) = -\frac{1}{2}\left(|B^T\Pi x|^2 + (Qx,x) + \frac{1}{\gamma}|x|^2 + \frac{1}{\gamma}|\Pi x|^2\right),$$

and

$$((A - \Sigma C^T C)z, \Sigma^{-1}z) = -\frac{1}{2}\left(|Cz|^2 + (R\Sigma^{-1}z, \Sigma^{-1}z) + \frac{1}{\gamma}|z|^2 + \frac{1}{\gamma}|\Sigma^{-1}z|^2\right). \qquad \square$$

Since

$$r(x(t), x^*(t)) = \left(\int_0^1 A(x^*(t) + \theta(x(t) - x^*(t)))\, d\theta - A\right)(x(t) - x^*(t)),$$

we can observe that the assumption

$$\left\|\int_0^1 A(x^*(t) + \theta(x(t) - x^*(t)))\, d\theta - A\right\| \leq \frac{1}{\sqrt{2}\gamma} \text{ for all } t \in [0,T] \tag{4.3}$$

implies that

$$(r(x(t), x^*(t)), \Pi(x(t) - x^*(t))) \leq \frac{1}{2\gamma}\left(|\Pi(x(t) - x^*(t))|^2 + \frac{1}{2}\,|x(t) - x^*(t)|^2\right), \tag{4.4}$$

and

$$(r(x(t), x^*(t)), \Sigma^{-1}(x(t) - x^*(t))) \leq \frac{1}{2\gamma}\left(|\Sigma^{-1}(x(t) - w(t))|^2 + \frac{1}{2}\,|x(t) - x^*(t)|^2\right) \tag{4.5}$$

Using (2.11) and (4.4), (4.5) we find

$$\frac{d}{dt}(W(x-x^*)+\tilde{W}(x-w))$$

$$\leq -\omega(W(x-x^*)+\tilde{W}(x-w))+(d+r(x,x^*),\Pi(x-x^*)+\Sigma^{-1}(x-w))-(n,C(x-w))$$

$$-\frac{1}{2\gamma}(|\Pi(x-x^*)|^2+|x-x^*|^2+|x-w|^2+|\Sigma^{-1}(x-w)|^2)$$

$$\leq -\omega(W(x-x^*)+\tilde{W}(x-w))+\rho(t)(W(x-x^*)+\tilde{W}(x-w))^{1/2}$$

$$+\frac{1}{2\gamma}(|\Pi(x-x^*)|^2+|x-x^*|^2+|\Sigma^{-1}(x-w)|^2)$$

$$-\frac{1}{2\gamma}(|\Pi(x-x^*)|^2+|x-x^*|^2+|x-w|^2+|\Sigma^{-1}(x-w)|^2),$$

where $\rho(t)$ was defined below (2.14). Hence it follows that

$$\frac{d}{dt}(W(x-x^*)+\tilde{W}(x-w)) \leq -\omega(W(x-x^*)+\tilde{W}(x-w))+\rho(t)((W(x-x^*)+\tilde{W}(x-w)))^{\frac{1}{2}},$$

and therefore

$$\frac{d}{dt}E(t) \leq -\omega E(t)+\rho(t).$$

We can summarize the above developments in the following result.

THEOREM 4.1. *If* (4.3) *and* (4.2) *admit solutions for* $\gamma > 0$ *and* (2.10), (2.11), (4.3) *hold on* $[0,T]$, *then*

$$E(t) \leq e^{-\omega t}E(0)+\int_0^t e^{-\omega(t-s)}\,\rho(s)\,ds \text{ for } t\in[0,T]. \tag{4.6}$$

If the assumptions hold uniformly on all intervals, then (4.6) *holds for all* $t\in[0,\infty)$.

5. Numerical examples. We validate the proposed approach by means of a class of optimal control problems for the Burgers equation

$$\min\ \frac{1}{2}\int_0^{T_\infty}|y(t)-z(t)|^2_{L^2(\Omega)}dt\ +\ \frac{\sigma}{2}\int_0^{T_\infty}|u(t)|^2_{L^2(\tilde{\Omega})}dt \tag{5.1}$$

subject to $u\in L^2(\tilde{\Omega})$ and

$$\begin{cases} \frac{d}{dt}\,y(t,x)=\nu\,y_xx(t,x)-y\cdot y_x(t,x)+Bu(t,x)+d(t,x), & t>0,\\ y(t,0)=y(t,1)=0, & t>0,\\ y(0,x)=\varphi(x), & x\in(0,1), \end{cases} \tag{5.2}$$

where $y(t)=y(t,x)$, $x\in\Omega=(0,1)$, and ν and σ are positive constants. Here the initial condition $\varphi\in L^2(\Omega)$, the control domain $\tilde{\Omega}$ is a subset of Ω, and B is the extension-by-zero-operator from $\tilde{\Omega}$ to Ω. Finally d represents noise to the system and the observation data are supposed to be of the form

$$\hat{y}(t)=C_{\hat{\Omega}}\,y(t)+n(t), \tag{5.3}$$

where C is the restriction operator from Ω to $\hat{\Omega}$ with $\hat{\Omega}$ a subset of Ω, and n stands for observation noise. We further need to specify the operators G for the terminal weight in the receding horizon cost (1.5), the tracking weight Q in (2.3) and the operator R in the Kalman filter equation. We shall set

$$R = r\,I \quad \text{and} \quad Q = q\,I. \tag{5.4}$$

After several tests G was taken to be 0 for stabilization problems ($z = 0$) and as a scalar multiple of $\frac{1}{2}(x, \Pi x)$, where Π is the nonnegative solution of the algebraic Riccati equation (2.4) with $A = -\nu\,\partial_{xx}$ for tracking problems with $z \neq 0$. In this way G does not depend on the specific receding horizon level and can be computed during the initialization phase. Choosing G instead as $G(x) = \alpha\,|x|^2$ resulted in longer computing times and less favorable tracking properties.

The spatial discretization was done by the standard Galerkin scheme applied to (5.2) based on the basis of linear finite elements with meshsize dx. The ordinary differential equations resulting from (5.2) and (2.2), (2.7) were solved with an implicit Euler scheme with stepsize dt, while resolving the nonlinearities by Newton's method. The resulting linear systems were solved by inexact GMRES iterations. Unless specified otherwise we took

$$\nu = .01, \quad dt = .05, \quad dx = .025,$$

and for the receding horizon, $T = .5$. Further, unless quoted otherwise we chose $\Omega = \tilde{\Omega} = \hat{\Omega}$, $q = 10^{-5}$, and $r = 10^3$. For Example 1 we took $\sigma = .0175$ and for Example 2 we calculated with $\sigma = 10^{-3}$. The MATLAB-routine CARE was used to solve the algebraic Riccati equations. Below, $\hat{J}$ denotes the tracking part of the cost in (5.1). Noise was simulated by choosing uniformly distributed random numbers in the interval $[-\delta, \delta]$. It was added to the spatial-temporal grid points for either d or n representing disturbance to the equation and noise in the observation, respectively. Analogously, noise in the initial data φ was simulated by adding random numbers in $[-\delta, \delta]$ to the values of φ at the spatial grid points. The initial condition for (5.2) on receding horizon intervals with $i \geq 2$ was chosen as the state of the estimator at time T_i.

EXAMPLE 5.1 (stabilization). *Here we choose*

$$\varphi(x) = \begin{cases} 5 \sin 2\pi x & \text{on } (0, \frac{1}{2}], \\ 0 & \text{on } (\frac{1}{2}, 1), \end{cases}$$

and $z = 0$. Further $T^\infty = 5$, $T = 0.5$, $T_i = iT$ so that we have 10 receding horizon intervals. The uncontrolled solution is depicted in Figure 5.1. For Figures 5.2–5.4 we chose $n = 0$ (no observation noise) and simulated disturbances to the system with noise level $\delta = 10$ for d. The result for Figure 5.2 shows an open-loop solution, i.e., first we compute the open-loop optimal control u^* to (5.1)–(5.2), with $d = 0$, and then use the optimal open-loop control u^* against the noisy Burgers equation with $d = 10$. Figure 5.3 is for the full observation case, obtained with the state estimator procedure introduced in section 1, with $\hat{\Omega} = \tilde{\Omega} = \Omega$. For Figure 5.4 we test a partial observation case, i.e., we chose the control domain $\tilde{\Omega} = (0, \frac{1}{2})$ and the observation domain $\hat{\Omega} = (\frac{1}{2}, 1)$. Thus control and observation domain are non-overlapping. It should be noted that the hyperbolic nature of the Burgers equation is such that information moves from smaller to larger x-values. Figures 5.5 and 5.6 show

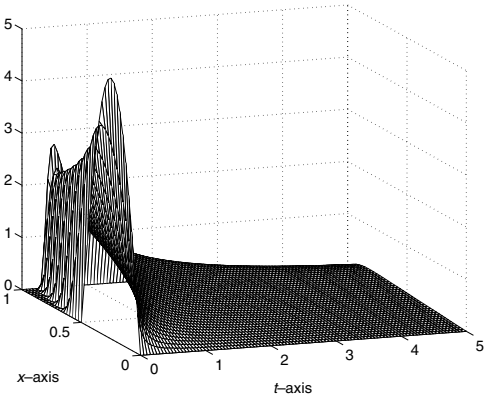

FIG. 5.1. *Uncontrolled solution, no noise.*

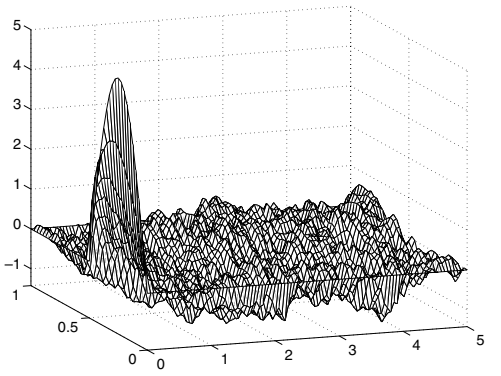

FIG. 5.2. *Open-loop controlled solution.*

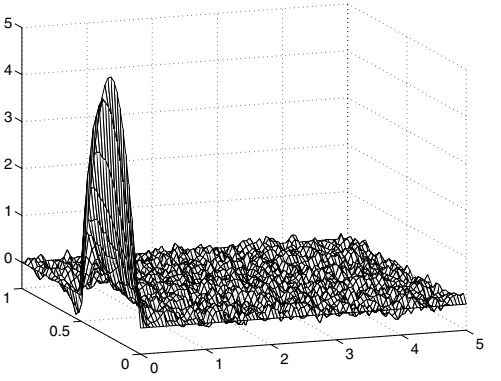

FIG. 5.3. *Estimator closed loop.*

results for the noisy observation case and we take again $\tilde{\Omega} = (0, \frac{1}{2})$ *and* $\hat{\Omega} = (\frac{1}{2}, 1)$*, i.e., the control and observation domains, which are as those used for Figure* 5.4*. Figure* 5.5 *disturbance to the equation was set* $d = 0$*, while now the observation data were taken to be noisy with noise level* $\delta = 10$ *for* n*. For Figure* 5.6 *noise was added to the initial condition* ($\delta = 5$) *and to the observation data* ($\delta = 10$).

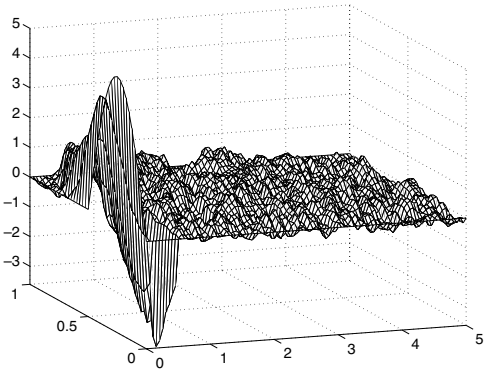

FIG. 5.4. *Partial control and observation domain.*

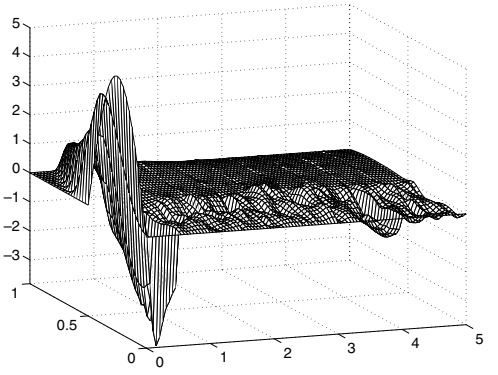

FIG. 5.5. *Noise in observation.*

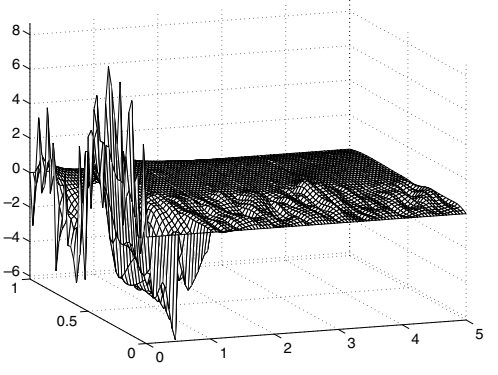

FIG. 5.6. *Noise in observation and initial condition.*

The run-times depend slightly on the random numbers that enter in d *or* n*. Typical times for Figures* 5.3–5.6 *are* 16 *to* 17 *units, whereas the run-time for Figure* 5.2*, which uses the open-loop optimal control on the complete interval* $[0, T^{\infty}]$*, is* 181 *units. The stabilization value for Figure* 5.2 *is* $\hat{J} = .540$*, whereas it is only* $\hat{J} = .146$ *for Figure* 5.3*. In Table* 1 *we give the stabilization values* $\hat{J}_{-}$ *for the results of Figures* 5.2–5.6 *on* $[0.5, 5]$*, i.e., for the receding horizon intervals* 2–10*.*

TABLE 1
$\hat{J}_-$.

Fig 5.2	Fig 5.3	Fig 5.4	Fig 5.5	Fig 5.6

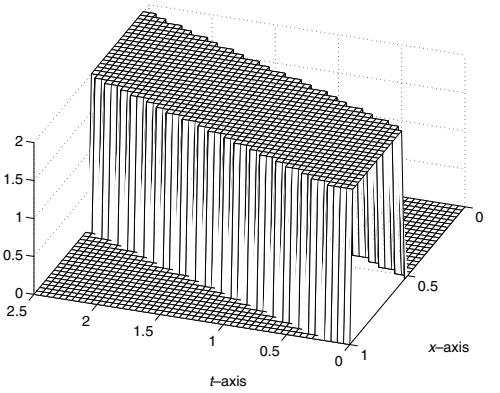

FIG. 5.7. *Desired state.*

We ran all tests with five randomly chosen initializations of the random number generator. In Table 1 we report the range of obtained values for $\hat{J}_-$. We can conclude that the receding horizon strategy combined with the dynamic observer introduced in section 1 attenuates noise significantly better than the open-loop controlled system; compare column 1 in Table 1 to columns 2–4. The computing times for the receding horizon strategy are much shorter than for the open-loop optimal control on the complete time interval. Finally the strategy can cope with partial observations.

EXAMPLE 5.2 (tracking). *Here we set the initial condition as*

$$\varphi(x) = \begin{cases} 1 & \text{on } (0, \frac{1}{2}], \\ 0 & \text{on } (\frac{1}{2}, 1), \end{cases}$$

and the target z as the characteristic function of the set $\{(t,x)\colon 2.5-5x < t < 5-5x$, $x \in (0,1)\}$; see Figure 5.7. *Further $T^\infty = 2.5$, $T = 0.5$, $T_i = iT$ so that we have five receding horizon intervals. Note that the uncontrolled solution of the Burgers equation would transport the jump at $x = \frac{1}{2}$ toward increasing x as t increases, while decreasing its height. Also, the desired state z moves into the direction which is opposite to the one of the characteristics of the Burgers equation. Thus this example can be considered as a challenging one. For the results presented here we took the control domain as $\tilde{\Omega} = \Omega$. The noise levels are* 5 *for disturbance to the equation and* 10 *for observation noise and disturbance to the initial condition. If noise is not mentioned, then it is set equal to* 0. *The random number generator is initialized at the same seed, independently for disturbances and observations.*

In Figures 5.8 *and* 5.9 *we show the open-loop and the full-observation ($\hat{\Omega} = \Omega$) closed-loop results, each with disturbances to the equation. Figures* 5.10 *and* 5.11 *show partial observation results with the observation domain $\hat{\Omega} = (1/4, 1)$ for nonzero disturbance d and nonzero observation noise n, respectively. Figure* 5.12 *provides the result for the case with the partial observation on $\hat{\Omega} = (1/4, 1)$, $d = 0$, and noise*

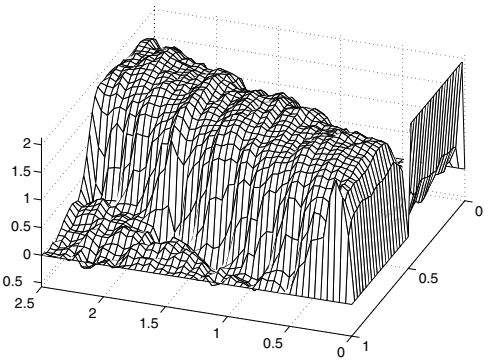

FIG. 5.8. *Open-loop controlled solution.*

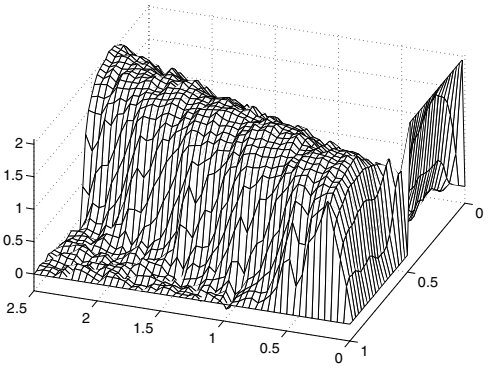

FIG. 5.9. *Estimator closed loop.*

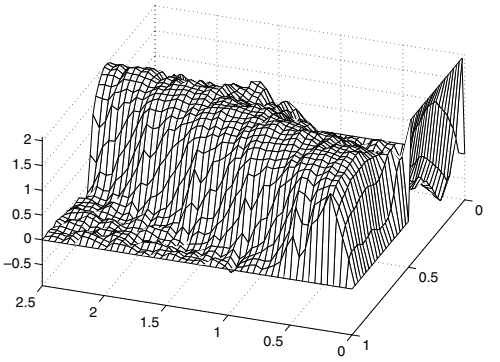

FIG. 5.10. *Estimator closed loop, partial obseration.*

entering to the observations as well as the initial condition. The tracking costs for Figures 5.8–5.12 *are given in Table* 2.

For Figure 5.8 *we again computed the open-loop optimal control from* $[0, T^{\infty}]$ *and applied it to the perturbed Burgers equation. The computing time for Figure* 5.8 *is* 56 *units, whereas for the other figures it is* 16.3 *to* 20 *units. Thus the ratio of the computing times for the open-loop control on* $[0, T^{\infty}]$ *and the receding horizon*

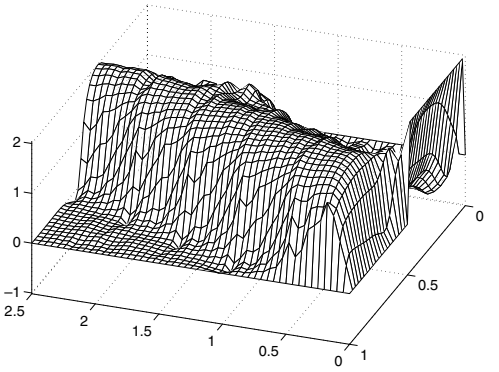

FIG. 5.11. *Estimator, noise in data.*

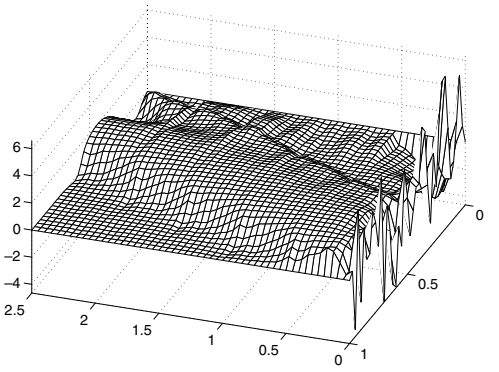

FIG. 5.12. *Noise in data and initial condition.*

TABLE 2
$\hat{J}$.

controls is less favorable than for Example 5.1. *This is because the resulting two-point boundary value problems are less well-conditioned as a consequence of the terminal weight* $G \neq 0$.

We also tested with smaller observation domain $\hat{\Omega}$ *and obtained comparable results. Reducing the control domain* $\tilde{\Omega}$ *results in a significant increase of* $\hat{J}$ *due to the challenging nature of the problem. For example, for the settings of Figure* 5.10, *if* $\tilde{\Omega} = (0, .8)$, *then* $\hat{J} = .490$.

6. Conclusion. The receding horizon technique is a sequential time-domain decomposition method to reduce the computational requirements for solving the optimality systems on long time horizons. The obtained controls on each receding horizon can be interpreted as a state feedback control. In this paper we developed a compensator design in the context of receding horizon control when only partial state observations are available. The receding horizon synthesis was combined with the state estimator dynamics. An LQG design based on a linearization procedure was

used and its asymptotic performance was analyzed for nonlinear systems with disturbances and observation noise. Numerical examples for control problems for the Burgers equation validate the proposed methodology.

Acknowledgment. We would like to thank Prof. Stefan Volkwein for providing us with the code of his open loop optimal control routine for the Burgers equation.

COMMON POLYNOMIAL LYAPUNOV FUNCTIONS FOR LINEAR SWITCHED SYSTEMS*

PAOLO MASON†, UGO BOSCAIN†, AND YACINE CHITOUR‡

Abstract. In this paper, we consider linear switched systems $\dot{x}(t) = A_{u(t)}x(t)$, $x \in \mathbb{R}^n$, $u \in U$, $\{A_u : \ u \in U\}$ compact, and the problem of asymptotic stability for arbitrary switching functions, uniform with respect to switching (UAS). Given a UAS system, it is always possible to build a common polynomial Lyapunov function. Our main result is that the degree of that common polynomial Lyapunov function is not uniformly bounded over all the UAS systems. This result answers a question raised by Dayawansa and Martin. A generalization to a class of piecewise-polynomial Lyapunov functions is given.

Key words. switched systems, stability, polynomial Lyapunov functions, uncertain systems

AMS subject classifications. 93D20, 37N35

DOI. 10.1137/040613147

1. Introduction.

In recent years, the problem of stability and stabilizability of switched systems has attracted increasing attention (see, for instance, [1, 4, 5, 8, 11, 13, 14, 20]), and still many questions remain unsolved.

In this paper, we address the problem of existence of common polynomial Lyapunov functions for linear switched systems.

By a switched system, we mean a family of continuous-time dynamical systems and a rule that determines at each time which dynamical system is responsible of the time evolution. More precisely, let $\{f_u : \ u \in U\}$ (where U is a subset of $\mathbb{R}^m$, $m \in \mathbb{N}$) be a finite or infinite set of sufficiently regular vector fields on a manifold M, and consider the family of dynamical systems:

$$\dot{x} = f_u(x), \quad x \in M. \tag{1}$$

The rule is given by assigning the so-called switching function, i.e., a function $u(.) : [0, \infty[\to U \subset \mathbb{R}^m$. Here, we consider the situation in which the switching function is not known a priori and represents some phenomenon (e.g., a disturbance) that is not possible to control. Therefore, the dynamics defined in (1) also fit into the framework of uncertain systems (cf., for instance, [9]).

In what follows, we use the notation $u \in U$ to label a fixed individual system and $u(.)$ to indicate the switching function.

These kinds of systems are sometimes called n-modal systems, dynamical polysystems, polysystems, or input systems. The term "switched system" is often reserved for situations in which the switching function $u(.)$ is piecewise continuous or the set U is finite. For the purpose of this paper, we only require $u(.)$ to be a measurable function and U to be a measurable set.

For a discussion of various issues related to switched systems, see [5, 13, 14].

A typical problem for switched systems goes as follows. Assume that for every $u \in U$, the dynamical system $\dot{x} = f_u(x)$ satisfies a given property (P). Then one can

investigate conditions under which property (P) still holds for $\dot{x} = f_{u(t)}(x)$, where $u(.)$ is an arbitrary switching function.

In [1, 8, 11, 12], the case of linear switched systems was considered:

$$\dot{x}(t) = A_{u(t)}x(t), \quad x \in \mathbb{R}^n, \quad A_u \in \mathbb{R}^{n\times n}, \tag{2}$$

where n is a positive integer and $u(.) : [0, \infty[\to U$ is a (measurable) switching function. For these systems, the problem of asymptotic stability of the origin, uniformly with respect to switching functions, was investigated.

Next, we set $\mathbf{A} := \{A_u \ : \ u \in \ U\}$ and, to simplify the notation, we still call *switching function* the measurable matrix-valued map $A(.) := A_{u(.)}$. In this way, the switching system (2) reads

$$\dot{x}(t) = A(t)x(t) \text{ with } x \in \mathbb{R}^n \text{ and } A(.) : [0, \infty[\to \mathbf{A} \text{ a measurable map.} \tag{3}$$

In the following, we assume that

(HO) the set $\mathbf{A}$ is a compact subset of the set of $n \times n$ real matrices.

Moreover, the set of switching functions, denoted by $\boldsymbol{\mathcal{A}}$, is the set of measurable functions $A(.) : [0, \infty[\to \mathbf{A}$. With our assumptions, for every switching function $A(.)$ and initial condition $x_0 \in \mathbb{R}^n$, the corresponding (Carathéodory) solution of (3) is defined for every $t \geq 0$. We use $\phi_t^{A(.)}(x_0)$ to denote the flow of (3) at time $t \geq 0$ corresponding to the switching function $A(.)$ and starting from x_0.

Let us recall the usual notions of stability used for the system (3).

DEFINITION 1. *Consider the switched system* (3). *We say that the origin is*

(S) *stable if for every* $A(.) \in \boldsymbol{\mathcal{A}}$ *and* $\varepsilon > 0$, *there exists* $\delta > 0$ *such that (s.t.)* $\|\phi_t^{A(.)}(x_0)\| \leq \varepsilon$ *for every* $t \geq 0$, $\|x_0\| \leq \delta$;

(US) *uniformly stable if it is stable with* δ *not depending on* $A(.)$;

(U) *unstable if it is not stable (i.e., if there exists* $A(.) \in \boldsymbol{\mathcal{A}}$ *s.t. the system* $\dot{x}(t) = A(t)x(t)$ *is unstable as a linear time-varying system);*

(AS) *asymptotically stable, if it is stable and attractive (i.e., there exists* $\delta' > 0$ *so that we have* $\lim_{t\to\infty} \|\phi_t^{A(.)}(x_0)\| = 0$ *for every* $A(.) \in \boldsymbol{\mathcal{A}}$ *and* $x_0 \in \mathbb{R}^n$ *with* $\|x_0\| \leq \delta'$);

(UAS) *uniformly asymptotically stable if it is uniformly stable and if for every* $\varepsilon' > 0$ *and* $\delta' > 0$ *there exists* $T > 0$ *such that, for every switching function* $A(.) \in \boldsymbol{\mathcal{A}}$, $t \geq T$, *and* $\|x_0\| \leq \delta'$, *we have* $\|\phi_t^{A(.)}(x_0)\| \leq \varepsilon'$;

(GUES) *globally uniformly exponentially stable if there exist positive constants* M, λ *such that:* $\|\phi_t^{A(.)}(x_0)\| \leq M\ e^{-\lambda t}\|x_0\|$ *for every* $x_0 \in \mathbb{R}^n$, $t > 0$, $A(.) \in \boldsymbol{\mathcal{A}}$.

Because the dynamics are linear in the state variable, the local and global notions of stability are equivalent. More precisely, it was proved in [3] that, for system (3) subject to HO, the three notions AS, UAS, GUES and the notion of attractivity are all equivalent (see also the bibliographical note in [14]). In addition, if the system is unstable, then there exists a switching function $A(.) \in \boldsymbol{\mathcal{A}}$ and an initial condition x_0 such that $\lim_{t\to\infty} \|\phi_t^{A(.)}(x_0)\| \to \infty$. In the following, we just refer to the notions of stability, instability, and GUES.

Remark 1. Since for the stability issue, a system of type (3), subject to HO, is uniquely determined by a compact set $\mathbf{A}$ of $n \times n$ real matrices, we identify $\mathbf{A}$ with the corresponding system for the rest of the paper. For instance, when we say that $\mathbf{A}$ is GUES, we mean that the corresponding system of type (3) is GUES.

We will often consider the problem of determining whether a system, belonging to a certain class C of systems of type (3) subject to HO, is GUES or not. Notice

that fixing such a class of systems means to fix a set of compact subsets of $\mathbb{R}^{n\times n}$, i.e., C can be identified with a subset of $\{\mathbf{A} \subset \mathbb{R}^{n\times n} : \ \mathbf{A} \text{ compact}\}$.

For a system (3) subject to HO, it is well known that the GUES property is a consequence of the existence of a common Lyapunov function.

DEFINITION 2. *A common Lyapunov function $V : \mathbb{R}^n \longrightarrow \mathbb{R}^+$, for a switched system (S) of type* (3)*, is a continuous function such that V is positive definite (i.e., $V(x) > 0\ \forall x \neq 0$, $V(0) = 0$) and V is strictly decreasing along nonconstant trajectories of (S).*

Vice versa, it is known that, given a GUES system of the type (3) subject to (HO), it is always possible to build a $\mathcal{C}^\infty$ common Lyapunov function (see, for instance, [11, 15, 16, 17] and the bibliographical note in [14]).

Anyway, the problem of finding a Lyapunov function or proving the nonexistence of a Lyapunov function is in general a difficult task. Sometimes, it is even easier to prove directly that a system is GUES or unstable. An example is provided below by bidimensional switched systems.

1.1. Single-input bidimensional switched systems. Consider a bidimensional system with *single input* of the type

$$\dot{x}(t) = u(t)Ax(t) + (1 - u(t))Bx(t), \tag{4}$$

where $x \in \mathbb{R}^2$, A and B are two 2×2 real Hurwitz matrices, and $u(.)$ is a measurable function defined on $\mathbb{R}^+$ and taking values in U equal either to $[0, 1]$ or $\{0, 1\}$. In what follows, we call Ξ the class of bidimensional systems of the above form. This class is parameterized by couples of 2×2 real Hurwitz matrices.

Remark 2. Whether systems of type (4) are GUES or not is independent on the specific choice $U = [0, 1]$ or $U = \{0, 1\}$. In fact, this is a particular instance of a more general result stating that the stability properties of systems (3) subject to HO depend only on the convex hull of the set $\mathbf{A}$; see Proposition 1, Remark 6, and Appendix B.

In [19], the authors provide a necessary and sufficient condition on the pair (A, B) to share a *quadratic* Lyapunov function, but it is known (see for instance [11, 18, 10, 21]) that there exist GUES linear bidimensional systems not admitting a quadratic Lyapunov function.

In [11], Dayawansa and Martin posed the problem of finding the minimal degree of a *polynomial* Lyapunov function. More precisely, the problem posed by Dayawansa and Martin is the following.

Problem P. Define $\Xi_{\text{GUES}} \subset \Xi$ as the set of GUES systems of the type (4). Find the minimal integer m such that every system of Ξ_{GUES} admits a polynomial Lyapunov function of degree less than or equal to m.

Remark 3. In the problem posed by Dayawansa and Martin, it is implicitly assumed that a GUES system always admits a polynomial common Lyapunov function. This fact was first proved by Molchanov and Pyatnitskii in [15, 16] under the assumption that the set $\mathbf{A}$ is of the form $\mathbf{A}= \{(a_{ij})_{i,j=1,\dots,n} \ : \ a_{ij}^- \leq a_{ij} \leq a_{ij}^+\}$. In [17] the authors state the result, with no further details, under the more general hypothesis $\mathbf{A}$ just compact. In the case in which the convex hull of $\mathbf{A}$ is finitely generated, the existence of a polynomial common Lyapunov function for GUES systems was proved by Blanchini and Miani [6, 7] in the context of uncertain systems.

Since the proofs of Molchanov, Pyatnitskii, Blanchini, and Miani need nontrivial intermediate results, in this paper we provide a self-contained proof, based on a more

direct argument, for a set **A** satisfying the weaker hypothesis that its convex hull is compact (see Theorem 1 and Remark 6).

As for the GUES issue, it was completely resolved in [8], where a necessary and sufficient condition for a system of type (4) to be GUES was found directly, without looking for a Lyapunov function. (See section 3 and Appendix A for more details.) This is a typical example in which it is easier to directly study the stability rather than look for a Lyapunov function.

1.2. Sets of functions sufficient to check GUES. The concept of Lyapunov function is useful for practical purposes when one can prove that, for a certain class of systems, if a Lyapunov function exists, then it is possible to find one of a certain type and possibly as simple as possible (e.g., polynomial with a bound on the degree, piecewise quadratic, etc.).

More precisely, consider a class C of systems of type (3) in $\mathbb{R}^n$ subject to HO, in the sense of Remark 1. One would like to find a class of functions $\mathcal{S}_C$, identified by a finite number of parameters, which is sufficient to check GUES for systems belonging to C i.e., if a system of C admits a Lyapunov function, then it admits one in $\mathcal{S}_C$. Once such a class of functions is identified, then in order to verify GUES, one could use numerical algorithms to check (by varying the parameters) whether a Lyapunov function exists (in which case the system is GUES) or not (meaning that the system is not GUES).

For instance, a remarkable result for a given class C of systems in $\mathbb{R}^n$ could be the following.

Claim. There exists a positive integer m (depending on n) such that whenever a system of C admits a Lyapunov function, then it admits one that is polynomial of degree less than or equal to m. In other words, the class of polynomials of degree at most m is sufficient to check GUES for the class C.

If this result were true, one could use a numerical algorithm to check, among all polynomial of degree m (varying the coefficients), if there is one that is a Lyapunov function. Unfortunately, *this claim is not true*, even for the simplest nontrivial case of class of systems in $\mathbb{R}^2$, namely, systems of type Ξ (cf. (4)).

The next definition formalizes the idea of class of functions sufficient to check GUES.

DEFINITION 3. *We say that a subset $\mathcal{S}$ of $\mathcal{C}^0(\mathbb{R}^n, \mathbb{R})$ is finitely (or q-finitely) parameterized if there exist $\Omega \subset \mathbb{R}^q$ for a positive integer q and a bijective map $\Psi : \Omega \subseteq \mathbb{R}^q \to \mathcal{S} \subset \mathcal{C}^0(\mathbb{R}^n, \mathbb{R})$. A subset $\mathcal{S}$ of $\mathcal{C}^0(\mathbb{R}^n, \mathbb{R})$ is said to be sufficient to check GUES for a class C of systems of type* (3) *in $\mathbb{R}^n$ (SSF) if every GUES system of C admits a Lyapunov function in $\mathcal{S}$. A subset $\mathcal{S}$ of $\mathcal{C}^0(\mathbb{R}^n, \mathbb{R})$ is said to be a (q-parameters) finite set of functions sufficient to check GUES for a class C of systems of type* (3) *in $\mathbb{R}^n$ (finite-SSF) if $\mathcal{S}$ is q-finitely parameterized and is an SSF for C.*

If a subset $\mathcal{S}$ of $\mathcal{C}^0(\mathbb{R}^n, \mathbb{R})$ is not finitely parameterizable but is an SSF for a class of systems C, we call $\mathcal{S}$ an ∞-SSF.

Remark 4. In [7], a concept similar to those introduced in the previous definition was provided and it was called "universal class of Lyapunov functions."

Using the previous definitions, the results and the problem formulated in [11] can be rephrased in the following way:

R1 for systems (3) subject to HO, the set $\mathcal{C}^\infty(\mathbb{R}^n, \mathbb{R})$ is an ∞-SSF;

R2 for linear bidimensional systems of the class Ξ (cf. (4)), the set of quadratic functions is not an SSF;

P let $\mathcal{P}^m$ be the set of polynomial functions of two variables with degree at most m. What is the minimal m such that $\mathcal{P}^m$ is a finite-SSF for the linear bidimensional systems of the class Ξ?

Remark 5. Notice that to check numerically the existence of a Lyapunov function using the concept of finite-SSF, one needs some regularity properties of the functions of the family, with respect to the parameters (at least continuity). This discussion is outside the purpose of this paper.

1.3. Main results. We first provide a proof that the implicit assumption of Dayawansa and Martin (i.e., that a linear GUES switched system always admits a polynomial Lyapunov function; cf. Remark 3) is correct for a set **A** just compact.

THEOREM 1. *If the origin is a GUES equilibrium for the switched system* (3) *subject to HO, then there exists a polynomial Lyapunov function.*

The above result can be stated equivalently as follows.

THEOREM 1BIS. *The set of polynomials from $\mathbb{R}^n$ to $\mathbb{R}$ is an ∞-SSF for linear switched systems* (3) *subject to HO.*

The proof of Theorem 1 is given in section 2 and the starting point is the construction of a homogeneous and convex Lyapunov function W, following the corresponding argument of [11]. The main idea is then to seek for a (homogeneous) polynomial $\tilde{W}$ whose level sets approximate, in some suitable sense, those of W and, finally, to show that $\tilde{W}$ is also a Lyapunov function. A similar argument was used in [7], where the authors used an intermediate approximation with polyhedral Lyapunov functions.

Remark 6. In Appendix B, it is proved that the GUES property of (3) depends only on the convex hull of **A** (proof of Proposition 1). The claim of Appendix B can be applied to a compact set **A** being the convex hull of a set not necessarily compact. For this reason Proposition 1 and Theorem 1 hold under the weaker hypothesis:

(HO-weak) the set **A** is a measurable subset of the set of $n \times n$ real matrices, whose convex hull is compact.

The core of the paper consists of showing that problem P does not have a solution, i.e., the minimum degree of a polynomial Lyapunov function cannot be uniformly bounded over the set of all GUES systems of the form (4). More precisely, we have the following.

THEOREM 2. *Let $\Xi_{\mathrm{GUES}} \subset \Xi$ be the set of all GUES systems of the type* (4). *If (A, B) is a pair of 2×2 real matrices giving rise to a system of Ξ_{GUES}, let $m(A, B)$ be the minimum value of the degree of any polynomial LF associated to that system. Then $m(A, B)$ cannot be bounded uniformly over Ξ_{GUES}.*

The above result can be stated equivalently as follows.

THEOREM 2BIS. *Let $\mathcal{P}^m$ the set of polynomial functions from $\mathbb{R}^2$ to $\mathbb{R}$ of degree at most m. Then $\mathcal{P}^m$ is not a finite-SSF for Ξ.*

The proof, given in section 4, is based on ideas developed in [8], where necessary and sufficient conditions for GUES of systems (4) are provided. We build a sequence of GUES systems corresponding to a sequence of pairs of matrices (A_i, B_i), $i \geq 1$. The sequence of systems is chosen in such a way that the limit system is uniformly stable but not attractive. In particular, that limit system admits a nontrivial periodic trajectory whose support Γ is a $\mathcal{C}^1$ but not a $\mathcal{C}^2$ submanifold of the plane. To each GUES system of the sequence, one considers any polynomial LF $V_{\bar{A}_i, \bar{B}_i}$ whose degree is at most m. We prove that a subsequence of $(V_{\bar{A}_i, \bar{B}_i})$ converges to a nonzero polynomial function V (of degree at most m) which admits Γ as a level set. Since Γ is not analytic, a contradiction is reached.

Remark 7. The result given by Theorem 2 generalizes to dimensions higher than 2 as follows. Let (A_i, B_i), $i \geq 1$, be a sequence of 2×2 matrices such that (i) the corresponding systems of type (4) are GUES, (ii) the limit is uniformly stable but not attractive. As explained above, for this sequence of systems it is not possible to build a sequence of polynomial Lyapunov function of uniformly bounded degree. Consider now the sequence of systems in $\mathbb{R}^n$, $n \geq 2$, of the form $\dot{\bar{x}} = u\bar{A}_i\bar{x} + (1-u)\bar{B}_i\bar{x}$ corresponding to the matrices

$$\bar{A}_i = \left(\begin{array}{c|ccc} A_i & 0 & \cdots & \vdots \\ \hline & -1 & \cdots & \vdots \\ 0 & 0 & -1 & \vdots \\ & \vdots & \ddots & \vdots \\ & 0 & \cdots & -1 \end{array}\right), \quad \bar{B}_i = \left(\begin{array}{c|ccc} B_i & 0 & \cdots & \vdots \\ \hline & -1 & \cdots & \vdots \\ 0 & 0 & -1 & \vdots \\ & \vdots & \ddots & \vdots \\ & 0 & \cdots & -1 \end{array}\right). \tag{5}$$

Each system of the sequence is GUES but the limit system is not (it is just uniformly stable). Now, if $V_{\bar{A}_i,\bar{B}_i}$, $i \geq 1$, are the corresponding polynomial Lyapunov functions, then they cannot be polynomials of uniformly bounded degree since this is not true for the restriction of $V_{\bar{A}_i,\bar{B}_i}$ to the first two variables.

Remark 8 (extension to piecewise polynomial functions). Another class of functions commonly used to check GUES is that of piecewise quadratic functions or more generally piecewise polynomial functions (PPF). Here, by a PPF, we mean a continuous function $V \in \mathcal{C}^0(\mathbb{R}^n, \mathbb{R})$ together with a finite number q of cones K_j, $1 \leq j \leq q$, based at zero and partitioning $\mathbb{R}^n$ so that V is a polynomial function of degree d_j on K_j, $1 \leq j \leq q$. We refer to $m(V) := \max\{q, d_1, \ldots, d_q\}$ as the *total degree* of V.

It is tempting to state a version of problem P by replacing polynomial functions of degree at most m with PPFs of total degree at most m.

Again, the PPF version of problem P does not have a solution for $n = 2$, i.e., the minimum total degree of a piecewise polynomial Lyapunov function cannot be uniformly bounded over the set of all GUES system of the form (4). The argument is a simple extension of the proof of Theorem 2 and it is briefly mentioned in Remark 14.

The last results of the paper concern the existence and the characterization of a finite-SSF for systems of the type (3) subject to HO.

Let us define the *convex semicone* generated by a set $D \subset \mathbb{R}^n$ as the set of points λx with $\lambda > 0$ and $x \in co(D)$, where $co(D)$ denotes the convex hull of the set D. With this definition, the point $x = 0$ does not belong to the convex semicone generated by a set D if $0 \notin co(D)$.

First, we prove the following. (See Appendix B for the argument.)

PROPOSITION 1. *For every compact subset* $\mathbf{A}$ *of* $\mathbb{R}^{n\times n}$ *(i.e., verifying HO), let* $S_{\mathbf{A}}$ *be the system of the type* (3) *associated to* $\mathbf{A}$. *Then, for* $\mathbf{A}$ *and* $\mathbf{A}'$ *verifying HO and generating the same convex semicone,* $S_{\mathbf{A}}$ *is GUES (resp., uniformly stable) if and only if* $S_{\mathbf{A}'}$ *is GUES (resp., uniformly stable).*

Based on converse Lyapunov theorems, one can deduce some trivial existence results for finite-SSFs. For instance, consider a class C of systems of type (3) in $\mathbb{R}^n$ subject to HO and satisfying the following property: for every $\mathbf{A} \in C$, the convex hull of $\mathbf{A}$ is generated by at most k matrices $n \times n$, where k is a positive integer. One can build a finite-SSF for the class C as follows.

First, it follows directly from Definition 3 that we may simply assume that C is made of GUES systems. Thanks to Proposition 1, the class C can be parameterized by k-tuples of $n\times n$ matrices, defined up to their norm. In this way, a $k(n^2-1)$-parameters

finite-SSF is provided for the class C. For instance, the class Ξ of two-dimensional systems of type (4) admits a 6-parameter finite-SSF.

The above construction is not explicit and therefore is not useful to check GUES. Similarly to Lyapunov functions, it is then clear that the real challenge for finite-SSFs concerns their *explicit* characterization. For classes of systems of type (3) in $\mathbb{R}^n$ with $n \geq 3$, that issue is completely open in general. In dimension two *we provide an explicit* 5*-parameter finite-SSF for* Ξ, using the necessary and sufficient conditions for GUES given in [8]. This is the content of section 5.

Clearly, Ξ can be parameterized by the pairs (A, B) of 2×2 real Hurwitz matrices, where both A and B are defined up to their norm. The construction of the explicit finite-SSF goes as follows. As done previously, we may assume that the pair (A, B) gives rise to a GUES system. By taking advantage of the complete characterization of GUES systems of the class Ξ given in [8], one can explicitly associate to every GUES pair (A, B) a Lyapunov function as explained next. We start by defining, from (A, B), a pair $(\tilde{A}, \tilde{B})$ giving rise to a system of Ξ which is uniformly stable but not attractive. Such a system admits a closed trajectory whose support Γ is a simple Jordan closed curve (cf. sections 3, 4). We then construct a homogeneous positive definite function V whose level set 1 is Γ. We finally show that V is a Lyapunov function for (A, B). Since the set of $(\tilde{A}, \tilde{B})$ built from the GUES pairs (A, B) can be parameterized by using five parameters, we end up with a 5-parameter finite-SSF.

1.4. Structure of the paper. Section 2 contains the proof of Theorem 1. In section 3, we recall the main ideas from [8] needed for the rest of the paper. For completeness, we provide in Appendix A the full statement of the main result of [8]. The proof of Theorem 2 is given in section 4 and the explicit construction of a 5-parameter finite-SSF for systems of type (4) is provided in section 5. Finally, in Appendix B, we prove Proposition 1.

2. Existence of common polynomial Lyapunov functions. In this section, we prove Theorem 1. The starting point of the argument follows the first part of the proof of an analogous result in [11].

We define the function $V : \mathbb{R}^n \to \mathbb{R}^+$ by

$$V(x) = \sup_{A(.)\in \boldsymbol{\mathcal{A}}} \int_0^{+\infty} \|\phi_t^{A(.)}(x)\|^2 \mathrm{d}t.$$

The function V is well defined since there exist positive constants C, μ such that for all $t \geq 0$ and $x \in \mathbb{R}^n$,

$$\|\phi_t^{A(.)}(x)\| \leq C\, e^{-\mu t}\|x\|.$$

Note that V is homogeneous of degree 2 and continuous. In addition, we next show that V is strictly convex. That fact will be crucial later in the argument. Fix $x, y \in \mathbb{R}^n$ and $x \neq y$. Let $A(.)$ be a switching function. The function $x \mapsto \|\phi_t^{A(.)}(x)\|^2$ is strictly convex. Moreover, for every $\lambda \in]0, 1[$, by compactness of $\mathbf{A}$, the expression

$$\lambda\, \|\phi_t^{A(.)}(x)\|^2 + (1-\lambda)\, \|\phi_t^{A(.)}(y)\|^2 - \|\phi_t^{A(.)}(\lambda x + (1-\lambda)y)\|^2$$

is nonnegative for every $t \geq 0$ and is bounded from below by a positive constant on some interval $[0, \bar{t}]$, uniformly with respect to $A(.)$.

Therefore, dividing the integration interval into the two intervals $[0, \bar{t}]$ and $[\bar{t}, +\infty]$ and taking a maximizing sequence of switching functions for $V(\lambda\, x + (1-\lambda)\, y)$, we

have

$$V(\lambda x + (1-\lambda) y) < \lambda V(x) + (1-\lambda) V(y) \quad \forall \lambda \in]0,1[, \quad \forall x, y \in \mathbb{R}^n.$$

It is shown in [11] that V is a LF. Nevertheless, we need to consider at least $\mathcal{C}^1$ Lyapunov functions; therefore we define

$$\tilde{V}(x) = \int_{SO(n)} f(R)\, V(Rx)\, \mathrm{d}R$$

where $f : SO(n) \longrightarrow [0, +\infty[$ is a smooth function with support on a small neighborhood of the identity matrix and $\int_{SO(n)} f(R)\, \mathrm{d}R = 1$.

In [11], it is also shown that $\tilde{V}$ is a smooth Lyapunov function except at the origin. Moreover, since V is homogeneous of degree 2 and strictly convex, it follows that $\tilde{V}$ also satisfies such properties.

We consider now the function $W(x) = \sqrt{\tilde{V}(x)}$, which is a continuous, positively homogeneous Lyapunov function. Therefore, $W^{-1}(1)$ is a compact set. Using the fact that the set $\{x : W(x) < 1\}$ is strictly convex, we construct a polynomial Lyapunov function $\tilde{W}$ by approximating the level sets of W. For this purpose, we need the following preliminary result, which describes a continuity property of the function $\nabla W(y) \cdot Dx$ with respect to x, y, D.

LEMMA 1. *Let us set*

$$M := \min_{x \in W^{-1}(1)} \min_{D \in \mathbf{A}} \big[-\nabla W(x) \cdot Dx \big].$$

Then, for every $\varepsilon \in (0, M)$, there exists $\delta \in (0,1)$ such that for every $x, y \in W^{-1}(1)$ with $\nabla W(y) \cdot x > 1 - \delta$ and every $D \in \mathbf{A}$, one has

$$\nabla W(y) \cdot Dx < -\varepsilon.$$

Proof of the Lemma. First, notice that M is well defined since it is the infimum of a continuous function over a compact set. Moreover, $M > 0$ because W is a Lyapunov function.

Since, by homogeneity, $\nabla W(y) \cdot y = W(y) = 1$, we have

$$\nabla W(y) \cdot x = 1 - \nabla W(y) \cdot (y - x),$$

and then the hypothesis is equivalent to $\nabla W(y) \cdot (y - x) < \delta$.

Reasoning by contradiction, assume that there exists a sequence (x_j, y_j, D_j) such that $\nabla W(y_j) \cdot D_j x_j \geq -\varepsilon$ and $\nabla W(y_j) \cdot (y_j - x_j)$ converges to 0 as j goes to infinity. By compactness, we can find a subsequence of (x_j, y_j, D_j) converging to $(\bar{x}, \bar{y}, \bar{D})$ and therefore, by continuity, $\nabla W(\bar{y}) \cdot \bar{D}\bar{x} \geq -\varepsilon$ and $\nabla W(\bar{y}) \cdot (\bar{y} - \bar{x}) = 0$.

Therefore $\bar{y} - \bar{x}$ belongs to the tangent space at $\bar{y}$ of the strictly convex set $W^{-1}([0,1])$. Since $\bar{x}$ also belongs to the boundary of that set, it must be $\bar{y} = \bar{x}$. It implies $\nabla W(\bar{y}) \cdot \bar{D}\bar{x} = \nabla W(\bar{x}) \cdot \bar{D}\bar{x} \leq -M$ and we reach a contradiction. ∎

Remark 9. Taking $-x$ instead of x, one obtains that for every $x, y \in W^{-1}(1)$ and every $D \in \mathbf{A}$, then $\nabla W(y) \cdot x < -1 + \delta \Longrightarrow \nabla W(y) \cdot Dx > \varepsilon$.

To conclude the proof of the theorem, we take $\delta \in (0,1)$ corresponding to some ε as in the lemma above, and for every $y \in W^{-1}(1)$ we consider the open sets $B_y = \big\{x \in \mathbb{R}^n : \nabla W(y) \cdot x > 1 - \delta/2\big\}$. Since $y \in B_y$, we have that $\{B_y\}_{y \in W^{-1}(1)}$ is an open covering of the compact set $W^{-1}(1)$, and therefore we can find $y_1, \ldots, y_N$ points of $W^{-1}(1)$ such that the union of B_{y_k}, $k = 1, \ldots, N$, covers $W^{-1}(1)$.

Let us define

$$\tilde{W}(x) := \sum_{k=1}^{N} (\nabla W(y_k) \cdot x)^{2p}.$$

We claim that for an integer p large enough, $\tilde{W}$ is a polynomial Lyapunov function. For $D \in \mathbf{A}$ and $x \in \mathbb{R}^n$, $x \neq 0$, we have

$$\nabla \tilde{W}(x) \cdot Dx = 2p \sum_{k=1}^{N} \big(\nabla W(y_k) \cdot x\big)^{2p-1} \nabla W(y_k) \cdot Dx, \tag{6}$$

and we want to show that $\nabla \tilde{W}(x) \cdot Dx < 0$. By homogeneity, it is enough to do it for $x \in W^{-1}(1)$. Set

$$K := \max_{x,y \in W^{-1}(1),\, D \in \mathbf{A}} \nabla W(y) \cdot Dx.$$

If, for some index k in $\{1, \dots, N\}$, one has $|\nabla W(y_k) \cdot x| \leq 1 - \delta$, then

$$|\big(\nabla W(y_k) \cdot x\big)^{2p-1} \nabla W(y_k) \cdot Dx| \leq (1-\delta)^{2p-1} K.$$

Otherwise, if the inequalities $1 - \delta/2 \geq |\nabla W(y_k) \cdot x| > 1 - \delta$ hold, then, by the previous lemma and remark, one has that the corresponding term in the summation must be negative.

Finally, since by the definition of the points y_k, there exist at least two distinct indices k_1 and k_2 such that $x \in B_{y_{k_1}}$ and $-x \in B_{y_{k_2}}$ we have that

$$\big(\nabla W(y_{k_i}) \cdot x\big)^{2p-1} \nabla W(y_{k_i}) \cdot Dx < -(1-\delta/2)^{2p-1} \varepsilon.$$

Summing up, we deduce that

$$\begin{aligned} \nabla \tilde{W}(x) \cdot Dx &< 2p\Big(-2(1-\delta/2)^{2p-1}\varepsilon + (N-2)(1-\delta)^{2p-1} K \Big) \\ &= -4p(1-\delta/2)^{2p-1}\varepsilon \left(1 - \frac{K(N-2)}{2\varepsilon} \left(\frac{1-\delta}{1-\delta/2} \right)^{2p-1} \right). \end{aligned}$$

For p large enough, the right-hand side of previous expression is negative, uniformly with respect to $D \in \mathbf{A}$ and $x \in W^{-1}(1)$. The theorem is proved.

Remark 10. One can also check that the level set $\tilde{W}^{-1}(1)$ approximates, as p tends to $+\infty$, the corresponding level set of the function $\max_{k=1,\dots,N} |\nabla W(y_k) \cdot x|$ (which is a polytope) and, therefore, the latter is a Lyapunov function as well (cf. [7]).

3. Necessary and sufficient conditions for GUES of bidimensional systems. Consider the following property:

($\mathcal{P}$) the bidimensional switched system given by

$$\dot{x}(t) = u(t)Ax(t) + (1-u(t))Bx(t), \text{ where } u(.) : [0, \infty[\to [0,1], \tag{7}$$

is GUES at the origin.

In this section, together with Appendix A, we recall the main ideas from [8], to get a necessary and sufficient condition on A and B under which $(\mathcal{P})$ holds, or under which we have at least uniform stability. The full statement of the theorem is reported in Appendix A.1.

Remark 11. Recall that by Proposition 1 (proved in Appendix B), the necessary and sufficient condition for stability of the system (7) are the same if we assume $u(.)$ taking values in $\{0,1\}$ or in $[0,1]$, or if we multiply A and B by two arbitrary positive constants.

Set $M(u) := uA + (1-u)B$, $u \in [0,1]$. In the class of constant functions the asymptotic stability of the origin of the system (7) occurs if and only if the matrix $M(u)$ has eigenvalues with strictly negative real part for each $u \in [0,1]$. So this is a necessary condition for GUES. On the other hand it is known that if $[A,B]=0$, then the system (7) is GUES. So, in what follows, we always assume the following conditions:

H1. Let λ_1, λ_2 (resp., λ_3, λ_4) be the eigenvalues of A (resp., B). Then $\mathrm{Re}(\lambda_1)$, $\mathrm{Re}(\lambda_2)$, $\mathrm{Re}(\lambda_3)$, $\mathrm{Re}(\lambda_4) < 0$.

H2. $[A,B] \neq 0$ (that implies that neither A nor B is proportional to the identity).

For simplicity we will also assume the following:

H3. A and B are diagonalizable in $\mathbb{C}$. (Notice that if H2 and H3 hold, then $\lambda_1 \neq \lambda_2$, $\lambda_3 \neq \lambda_4$.)

H4. Let $\mathbf{V}_1, \mathbf{V}_2 \in \mathbb{C}P^1$ (resp., $\mathbf{V}_3, \mathbf{V}_4 \in \mathbb{C}P^1$) be the eigenvectors of A (resp., B). Then $\mathbf{V}_i \neq \mathbf{V}_j$ for $i \in \{1,2\}$, $j \in \{3,4\}$. (Notice that, from H2 and H3, the V_i are uniquely defined, $\mathbf{V}_1 \neq \mathbf{V}_2$ and $\mathbf{V}_3 \neq \mathbf{V}_4$, and H4 can be violated only when both A and B have real eigenvalues.)

All the other cases in which H1 and H2 hold are the following:

- A or B are not diagonalizable. This case (in which $(\mathcal{P})$ can be true or false) can be treated with techniques entirely similar to the ones of [8].
- A or B are diagonalizable, but one eigenvector of A coincides with one eigenvector of B. In this case, using arguments similar to those of [8], it possible to conclude that $(\mathcal{P})$ is true.

We will call, respectively, (CC) the case where both matrices have nonreal eigenvalues, (RR) the case where both matrices have real eigenvalues, and (RC) the case where one matrix has real eigenvalues and the other nonreal eigenvalues.

Theorem 3, reported in Appendix A.1, gives necessary and sufficient conditions for the stability of the system (7) in terms of three (coordinates invariant) parameters given in Definition 4. The first two parameters, ρ_A and ρ_B, depend on the eigenvalues of A and B, respectively, and the third parameter $\mathcal{K}$ depends on $Tr(AB)$, which is a Killing-type pseudoscalar product in the space of 2×2 matrices. As explained in [8], the parameter $\mathcal{K}$ contains the interrelation between the two systems $\dot{x} = Ax$ and $\dot{x} = Bx$, and it has a precise geometric meaning. It is in $1:1$ correspondence with the cross ratio of the four points in the projective line $\mathbb{C}P^1$ that corresponds to the four eigenvectors of A and B.

Definition 4. *Let A and B be two 2×2 real matrices and suppose that H1, H2, H3, and H4 hold. Moreover, choose the labels $(_1)$ and $(_2)$ (resp., $(_3)$ and $(_4)$) so that $|\lambda_2| > |\lambda_1|$ (resp., $|\lambda_4| > |\lambda_3|$) if they are real or $\mathrm{Im}(\lambda_2) < 0$ (resp., $\mathrm{Im}(\lambda_4) < 0$) if they are complex. Define*

$$\rho_A := -i\frac{\lambda_1+\lambda_2}{\lambda_1-\lambda_2}; \qquad \rho_B := -i\frac{\lambda_3+\lambda_4}{\lambda_3-\lambda_4}; \qquad \mathcal{K} := 2\frac{Tr(AB)-\frac{1}{2}Tr(A)Tr(B)}{(\lambda_1-\lambda_2)(\lambda_3-\lambda_4)}.$$

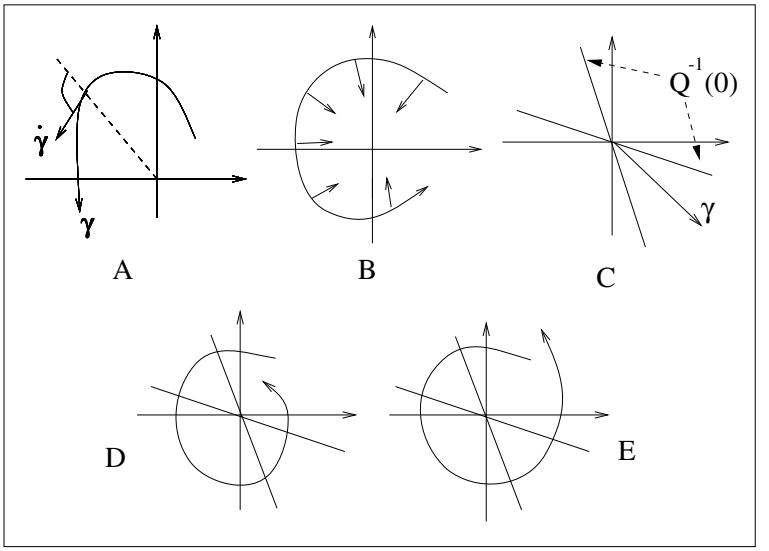

FIG. 1. *Proof of the stability conditions.*

Moreover, define the following function of $\rho_A, \rho_B, \mathcal{K}$*:*

$$\mathcal{D} := \mathcal{K}^2 + 2\rho_A\rho_B\mathcal{K} - (1 + \rho_A^2 + \rho_B^2). \tag{8}$$

Notice that ρ_A is a positive real number if and only if A has nonreal eigenvalues and $\rho_A \in i\mathbb{R}$, $\rho_A/i > 1$ if and only if A has real eigenvalues. The same holds for B. Moreover, $\mathcal{D} \in \mathbb{R}$.

Remark 12. Under hypotheses H1 to H4, using a suitable 3-parameter changes of coordinates, it is always possible to put the matrices A and B, up the their norm (cf. Remark 11), in the normal forms given in Appendix A.2, where $\rho_A, \rho_B, \mathcal{K}$ appear explicitly. (See [8] for more details.)

The parameter $\mathcal{K}$ contains important information about the matrices A and B. They are stated in the following proposition, which can be easily proved using the normal forms given in Appendix A.2.

PROPOSITION 2. *Let* A *and* B *be as in Definition* 4. *Then* (i) *if* A *and* B *have both complex eigenvalues, then* $\mathcal{K} \in \mathbb{R}$ *and* $|\mathcal{K}| > 1$*;* (ii) *if* A *and* B *have both real eigenvalues, then* $\mathcal{K} \in \mathbb{R} \setminus \{\pm 1\}$*;* (iii) A *and* B *have one complex and the other real eigenvalues if and only if* $\mathcal{K} \in i\mathbb{R}$.

Theorem 3, stated in Appendix A.1, is the main result of [8] and gives necessary and sufficient conditions for $(\mathcal{P})$ holding true. We next describe the main idea of the proof. All details can be found in [8].

DEFINITION 5. *The worst trajectory* γ_{x_0} *is the trajectory (based at* x_0*) having the following property. At each time* t, $\dot\gamma_{x_0}(t)$ *forms the smallest angle (in absolute value) with the (exiting) radial direction (Figure* 1A*).*

Then the system (7) is GUES if and only if, for each $x_0 \in \mathbb{R}^2$, the worst trajectory γ_{x_0} tends to the origin. The worst trajectory is constructed as follows. We study the locus $Q^{-1}(0)$ (where $Q(x) := \det(Ax, Bx)$) where the two vector fields Ax and Bx are collinear. The quantity $\mathcal{D}$, defined in Definition 4, is proportional to the discriminant of the quadratic form Q. We have several cases:

- If $Q^{-1}(0)$ contains only the origin, then, in the (CC) and (RC) case, one vector field points always on the same side of the other and the worst trajectory is a trajectory of a fixed vector field (either Ax or Bx). In that case, the system is GUES (case (CC.1) and (RC.1) of Theorem 3); see Figure 1, case B. The situation is similar in case (RR.1) (the worst trajectory tends to the origin).
- If $Q^{-1}(0)$ does not contain only the origin then it is the union of two lines passing through the origin (since Q is a quadratic form). If at each point of $Q^{-1}(0)$, the two vector fields have opposite direction, then there exists a trajectory going to infinity corresponding to a constant switching function (see Figure 1, case C). This correspond to cases (CC.2.1), (RC.2.1) and (RR.2.1) of Theorem 3. In that situation, there exists $u \in [0,1]$ such that the matrix $M(u) := uA+(1-u)B$, $u \in [0,1]$ admits an eigenvalue with positive real part. If at each point of $Q^{-1}(0)$, the two vector fields have the same direction, then the system is GUES if and only if the worst trajectory turns around the origin and after one turn the distance from the origin is decreased (see Figure 1, cases D and E). The quantities $\rho_{CC}, \rho_{RC}, \rho_{RR}$ defined in Theorem 3 (for the three cases (CC), (RC), (RR), resp.) represent the distance from the origin of the worst trajectory (that at time zero is at distance 1), after one half turn. This correspond to cases (CC.2.2), (RC.2.2), and (RR.2.2) of Theorem 3.
- Finally (CC.3), (RC.3), and (RR.3) are the degenerate cases in which the two straight lines coincide.

4. Nonexistence of a uniform bound on the minimal degree of polynomial Lyapunov functions. In this section, we prove Theorem 2. The starting point of the argument is to consider a pair of matrices A and B having both nonreal eigenvalues ((CC) case) and satisfying

$$\mathcal{D} > 0, \quad \mathcal{K} > 1, \quad \rho_{CC} = 1. \tag{9}$$

Such a pair exists. Indeed, Figure 2 translates graphically the contents of Theorem 3 for a fixed $\mathcal{K} > 1$, in the region of the (ρ_A, ρ_B)-plane where $\rho_A, \rho_B > 0$. The open shadowed region corresponds to values of the parameters ρ_A, ρ_B for which the system is GUES. We denote by S^+ the open subset of the shadowed region where $\mathcal{D} > 0$. The curve C represents the limit case where $\rho_{CC} = 1$. To each internal point of that curve, it is associated a system verifying (9), since $\mathcal{D} > 0$. A system corresponding to such a limit case is not asymptotically stable but just stable. Moreover, the worst trajectory (see Definition 5, and its construction in section 3) is a periodic curve, whose support is of class $\mathcal{C}^1$ but not of class $\mathcal{C}^2$ (recall that the switchings occur on $Q^{-1}(0)$, i.e., when the linear vector fields corresponding to A and B are parallel).

Fix a point $(\rho_A, \rho_B) \in C$ corresponding to (A, B). Since C is a subset of the boundary of the open set S^+ in the space of parameters (see Figure 2), there exists a sequence of points $(\rho_{A_k}, \rho_{B_k}) \in S^+$, for $k \geq 1$, converging to (ρ_A, ρ_B). This exactly means that there exists a sequence of GUES pairs (A_k, B_k), $k \geq 1$, such that (A_k, B_k) tends to (A, B) as k goes to ∞.

Let $x = (x_1, x_2)$. For every $k \geq 1$, consider a polynomial Lyapunov function V_k of degree at most m_k, i.e., $V_k = \sum_{1 \leq i+j \leq m_k} a_{ij}^{(k)} x_1^i x_2^j$. Arguing by contradiction, we assume that the sequence (m_k) is bounded by a positive integer m. Up to multiplication by a constant, we can choose $\sum_{1 \leq i+j \leq m_k} |a_{ij}^{(k)}| = 1$. By compactness, there exists a subsequence of (V_k) (still denoted by (V_k)) which converges (uniformly on compact subsets of $\mathbb{R}^2$) to some nonzero polynomial V with degree at most m. Note that $V(0) = 0$ since the V_k are Lyapunov functions.

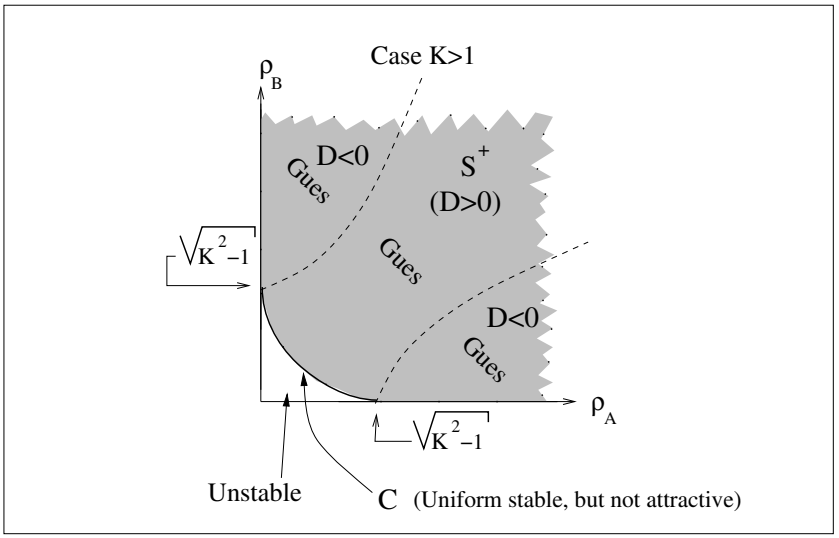

FIG. 2. *GUES property in the space of parameters and explicit construction of a* 5*-parameter SSF for systems of type* (4). S^+ *is the region in the* (ρ_A, ρ_B)*-plane in which the system is GUES and* $\mathcal{D} > 0$.

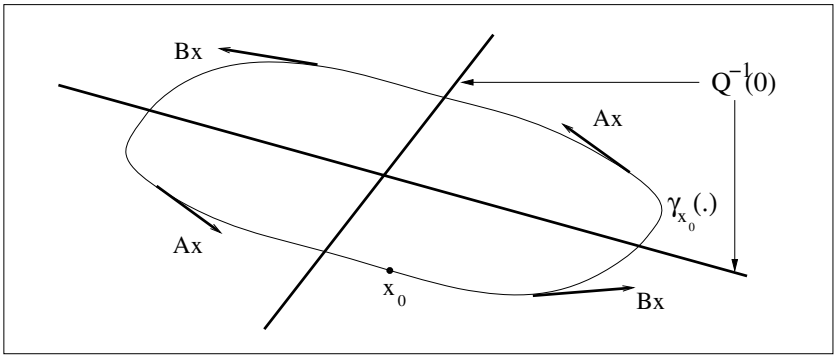

FIG. 3. *The worst trajectory.*

Fix $x_0 \in \mathbb{R}^2$, $x_0 \neq 0$. Let $T > 0$ be the period of the worst trajectory γ_{x_0} corresponding to the pair (A, B) and starting at x_0. Note that T is independent of x_0. The curve $\gamma_{x_0} : [0, T] \to \mathbb{R}^2$ can be seen as the concatenation of at most five arcs of integral curves of $\dot{x} = A\,x$ and $\dot{x} = B\,x$ (see Figure 3) and satisfies the Cauchy problem:

$$\begin{cases} \dot{x} = C(t)\,x, \\ x(0) = x_0, \end{cases}$$

where $C(t)$ is equal to A or B on subintervals of $[0, T]$.

For $k \geq 1$, consider the Cauchy problem:

$$\begin{cases} \dot{x} = C_k(t)\,x, \\ x(0) = x_0, \end{cases}$$

where $C_k(t) = A_k$ if $C(t) = A$ and $C_k(t) = B_k$ if $C(t) = B$. Then, γ_k is a trajectory of the switched system of the type (4) associated to (A_k, B_k). Since, the right-hand side of the previous equation is Lipschitz continuous in x and piecewise continuous in t, then the solutions γ_k converge uniformly to γ_{x_0} on $[0, T]$.

We next show that V remains constant on γ_{x_0}. For $k \geq 1$ and $t \in [0, T]$, one has

$$\|V_k \circ \gamma_k(t) - V \circ \gamma_{x_0}(t)\| \leq \|V_k \circ \gamma_k(t) - V \circ \gamma_k(t)\| + \|V \circ \gamma_k(t) - V \circ \gamma_{x_0}(t)\|.$$

By uniform convergence of V_k to V and of γ_k to γ_{x_0}, and by continuity of V, we deduce that $V_k \circ \gamma_k(t)$ converges to $V \circ \gamma_{x_0}(t)$ for every fixed t.

Since for every $k \geq 1$, V_k is a Lyapunov function for the switched system of the type (4) associated to (A_k, B_k), then $V_k \circ \gamma_k$ is a decreasing function and, hence, $V \circ \gamma_{x_0}$ is nonincreasing. Moreover, $V \circ \gamma_{x_0}(T) = V \circ \gamma_{x_0}(0)$. Therefore, $V \circ \gamma_{x_0}$ must be constant. It implies that there exists $t_1 > 0$ such that either $V(e^{At}x_0)$ or $V(e^{Bt}x_0)$ is constant on $[0, t_1]$. With no loss of generality, assume the first alternative. Since the map $t \mapsto V(e^{At}x_0)$ is real analytic, it follows that $V(e^{At}x_0)$ is constant over the whole real line. By letting t go to $+\infty$, since $e^{At}x_0 \to 0$, we deduce that $V(x_0) = V(0) = 0$. Since x_0 is an arbitrary non zero point of $\mathbb{R}^2$, we get that $V \equiv 0$, which is not possible.

Remark 13. The construction of the sequence (A_i, B_i) with unbounded degree for polynomial Lyapunov function was performed for matrices having both non real eigenvalues (that corresponds to the (CC) case). The same construction can be reproduced for the (RC) and (RR) cases.

Remark 14. For the PPF case (see Remark 8), the above argument can be easily modified to get that the minimum total degree of a piecewise polynomial Lyapunov function cannot be uniformly bounded over the set of all GUES systems of the form Ξ (cf. (4)). Indeed, let V_k be the sequence of PPFs taking the value $V_k^l(x) = \sum_{1 \leq i+j \leq m} a_{ijl}^{(k)} x_1^i x_2^j$ in the cone K_k^l, for $1 \leq l \leq m$. Here, to simplify the notation, we assume without loss of generality that for each element of the sequence, the number of cones and the degree of $V_k^l(x)$ is always m.

Each cone can be identified by a couple of angles with the x_1-direction. Therefore to each function V_k we can associate a m-uple of angles $(\alpha_1^k, \ldots, \alpha_m^k)$ such that the cone K_k^l coincides with the region between the lines corresponding to α_k^l and α_k^{l+1}. In particular, up to subsequences, we can assume that the numbers α_k^l converge to α^l. Similarly to the case above, we can normalize the coefficients of the Lyapunov functions V_k by $\sum_{l=1}^m \sum_{1 \leq i+j \leq m} |a_{ijl}^{(k)}| = 1$ and consider a subsequence of the coefficients converging to a_{ijl}. Then, if we define V as the PPF such that $V(x) = V^l(x) = \sum_{1 \leq i+j \leq m} a_{ijl} x_1^i x_2^j$ on the cone K^l defined by the angles α^l and α^{l+1}, it is easy to verify that $V_k(x)$ converges uniformly on compact subsets of $\mathbb{R}^2$ to $V(x)$. We can conclude the proof as before showing that $V^l(x_0) = V(0) = 0$ for arbitrary x_0, which leads to a contradiction.

5. Explicit construction of a finite-SSF for systems of type (4). In this section, we provide a 5-parameter finite-SSF for the class Ξ of bidimensional systems of type (4). Recall that for what concern the stability issue, Ξ can be parameterized by the 6-parameter family provided by the pairs (A, B) (of 2×2 matrices) defined up to their norm.

As explained in the introduction, it is enough to construct a Lyapunov function for a pair (A, B) giving rise to a GUES system of Ξ. We treat only the (CC.2.2) case since, in all the other cases, the construction is entirely similar.

In the (CC) case, after a 3-parameter change of coordinates, the normal form for the pair (A, B) is given by (cf. Appendix A.2)

$$A = \begin{pmatrix} -\rho_A & -1/E \\ E & -\rho_A \end{pmatrix}, \qquad B = \begin{pmatrix} -\rho_B & -1 \\ 1 & -\rho_B \end{pmatrix}, \qquad E > 0.$$

Moreover, in the (CC.2.2) case, we have $\mathcal{K} > 1$, $\mathcal{D} > 0$, and $\rho_{CC} < 1$, where $\mathcal{K} := 1/2(E + 1/E)$, $\mathcal{D}$ and ρ_{CC} being respectively defined in (4) and (11). Recall that for fixed $\mathcal{K} > 1$ (i.e., fixed $E > 1$), Figure 2 describes, in the (ρ_A, ρ_B)-plane, the status of each point with respect to the GUES issue.

We now associate, to every GUES pair (A, B), a pair $(\tilde{A}, \tilde{B})$ corresponding to a system of the type (4) uniformly stable but not attractive. Consider in Figure 2 the line segment joining the point $(0, 0)$ to (ρ_A, ρ_B) in the S^+ region. That segment intersects the curve C in a point $(\tilde{\rho}_A, \tilde{\rho}_B)$. That results from the Jordan separation theorem and the fact that C connects the points $(\sqrt{\mathcal{K}^2 - 1}, 0)$ and $(0, \sqrt{\mathcal{K}^2 - 1})$. Therefore, there exists a $\zeta \in (0, 1)$ such that, for the system given by

$$\tilde{A} = \begin{pmatrix} -\tilde{\rho}_A & -1/E \\ E & -\tilde{\rho}_A \end{pmatrix}, \qquad \tilde{B} = \begin{pmatrix} -\tilde{\rho}_B & -1 \\ 1 & -\tilde{\rho}_B \end{pmatrix}, \qquad \tilde{\rho}_A = \rho_A \zeta, \qquad \tilde{\rho}_B = \rho_B \zeta,$$

the worst trajectories γ_{x_0} are closed curves, i.e., $\rho_{CC} = 1$.

Moreover, one can easily compute

$$\det(\tilde{A}x, Ax) = \rho_A(1 - \zeta)\left({x_1}^2 E + \frac{{x_2}^2}{E}\right) > 0,$$
$$\det(\tilde{B}x, Bx) = \rho_B(1 - \zeta)|x|^2 > 0.$$

Therefore, the vector fields Ax, Bx point inside the area delimited by a fixed worst trajectory (that is, closed curve) of the modified switched system and so, passing to angular coordinates, the function

$$V(r, \alpha) = \frac{r}{\tilde{r}(\alpha)}, \tag{10}$$

where $\tilde{r}(\alpha)$ is a parameterization of the fixed worst trajectory, is a Lyapunov function for the system defined by (A, B).

Hence, we have provided a 5-parameter SSF in the (CC.2.2) case. The five parameters are $\mathcal{K}$, the ratio ρ_B/ρ_A, and the three parameters involved in the change of coordinates to get the normal forms (14).

Remark 15. Notice that in the cases (CC.1) and (CC.2.1) (cf. section 3 and Theorem 3 in Appendix A.1), one can choose as SSF the set of quadratic polynomials, which actually is parameterized by two parameters.

Remark 16. Let us come back to the general system (3), subject to HO. Notice that the question of finding the smallest m such that there exists an m-parameters finite-SSF, for a certain class C of systems, has no real meaning if one does not require suitable conditions on the map Ψ in Definition 3. Indeed, it is always possible to build a countable SSF for the class of systems of type (3) in $\mathbb{R}^n$ subject to HO.

Appendix A. Stability conditions for bidimensional systems.

A.1. Statement of the stability conditions.

THEOREM 3. *Let A and B be two real matrices such that* H1, H2, H3, *and* H4, *given in section* 3, *hold and define $\rho_A, \rho_B, \mathcal{K}, \mathcal{D}$ as in Definition* 4. *We have the following stability conditions.*

Case (CC) *If A and B have both complex eigenvalues, then*

Case (CC.1). *if $\mathcal{D} < 0$, then $(\mathcal{P})$ is true;*

Case (CC.2). *if $\mathcal{D} > 0$, then*

Case (CC.2.1). *if $\mathcal{K} < -1$, then $(\mathcal{P})$ is false;*

Case (CC.2.2). *if $\mathcal{K} > 1$, then $(\mathcal{P})$ is true if and only if it holds the following condition:*

$$\rho_{CC} := \exp\left[-\rho_A \arctan\left(\frac{-\rho_A\mathcal{K}+\rho_B}{\sqrt{\mathcal{D}}}\right) - \rho_B \arctan\left(\frac{\rho_A-\rho_B\mathcal{K}}{\sqrt{\mathcal{D}}}\right) - \frac{\pi}{2}(\rho_A+\rho_B)\right] \times \sqrt{\frac{(\rho_A\rho_B+\mathcal{K})+\sqrt{\mathcal{D}}}{(\rho_A\rho_B+\mathcal{K})-\sqrt{\mathcal{D}}}} < 1. \tag{11}$$

Case (CC.3). *If $\mathcal{D} = 0$, then $(\mathcal{P})$ holds true or false whether $\mathcal{K} > 1$ or $\mathcal{K} < -1$.*

Case (RC). *If A and B have one of them complex and the other real eigenvalues, define $\chi := \rho_A\mathcal{K} - \rho_B$, where ρ_A and ρ_B are chosen in such a way $\rho_A \in i\mathbb{R}$, $\rho_B \in \mathbb{R}$. Then*

Case (RC.1). *if $\mathcal{D} > 0$, then $(\mathcal{P})$ is true;*

Case (RC.2). *if $\mathcal{D} < 0$, then $\chi \neq 0$ and we have:*

Case (RC.2.1). *if $\chi > 0$, then (P) is false. Moreover, in this case $\mathcal{K}/i < 0$;*

Case (RC.2.2). *if $\chi < 0$, then*

Case (RC2.2.A). *if $\mathcal{K}/i \leq 0$, then $(\mathcal{P})$ is true;*

Case (RC2.2.B). *if $\mathcal{K}/i > 0$, then $(\mathcal{P})$ is true if and only if it holds the following condition:*

$$\rho_{RC} := \left(\frac{m^+}{m^-}\right)^{-\frac{1}{2}(\rho_A/i-1)} e^{-\rho_B\bar{t}} \times \left(\sqrt{1-\mathcal{K}^2}\, m^- \sin\bar{t} - \left(\cos\bar{t} - \frac{\mathcal{K}}{i}\sin\bar{t}\right)\right) < 1, \tag{12}$$

where

$$m^{\pm} := \frac{-\chi \pm \sqrt{-\mathcal{D}}}{(-\rho_A/i-1)\mathcal{K}/i},$$

$$\bar{t} = \arccos\frac{-\rho_A/i + \rho_B\mathcal{K}/i}{\sqrt{(1-\mathcal{K}^2)(1+\rho_B^2)}}.$$

Case (RC.3). *If $\mathcal{D} = 0$, then $(\mathcal{P})$ holds true whether $\chi < 0$ or $\chi > 0$.*

Case (RR). *If A and B have both real eigenvalues, then*

Case (RR.1). *if $\mathcal{D} < 0$, then $(\mathcal{P})$ is true; moreover we have $|\mathcal{K}| > 1$;*

Case (RR.2). *if $\mathcal{D} > 0$, then $\mathcal{K} \neq -\rho_A\rho_B$ (notice that $-\rho_A\rho_B > 1$) and*

Case (RR.2.1). *if $\mathcal{K} > -\rho_A\rho_B$, then (P) is false;*

Case (RR.2.2). *if $\mathcal{K} < -\rho_A\rho_B$, then*

Case (RR.2.2.A). *if $\mathcal{K} > -1$, then (P) is true;*

Case (RR.2.2.B). *if $\mathcal{K} < -1$, then (P) is true if and only if the following condition holds:*

$$\rho_{RR} := -f^{sym}(\rho_A, \rho_B, \mathcal{K}) f^{asym}(\rho_A, \rho_B, \mathcal{K}) \times f^{asym}(\rho_B, \rho_A, \mathcal{K}) < 1, \tag{13}$$

where

$$f^{sym}(\rho_A, \rho_B, \mathcal{K}) := \frac{1 + \rho_A/i + \rho_B/i + \mathcal{K} - \sqrt{\mathcal{D}}}{1 + \rho_A/i + \rho_B/i + \mathcal{K} + \sqrt{\mathcal{D}}};$$

$$f^{aym}(\rho_A, \rho_B, \mathcal{K}) := \left(\frac{\rho_B/i - \mathcal{K}\rho_A/i - \sqrt{\mathcal{D}}}{\rho_B/i - \mathcal{K}\rho_A/i + \sqrt{\mathcal{D}}} \right)^{\frac{1}{2}(\rho_A/i - 1)}.$$

Case (RR.3). *If $\mathcal{D} = 0$, then $(\mathcal{P})$ holds true or false whether $\mathcal{K} < -\rho_A\rho_B$ or $\mathcal{K} > -\rho_A\rho_B$.*

Finally, if $(\mathcal{P})$ is not true, then in case CC.2.2 *with $\rho_{CC} = 1$, case* (RC.2.2.B)*, with $\rho_{RC} = 1$, case* (RR.2.2.B)*, with $\rho_{RR} = 1$, case* (CC.3) *with $\mathcal{K} < -1$, case* (RC.3) *with $\chi > 0$ and case* (RR.3) *with $\mathcal{K} > -\rho_A\rho_B$, the origin is just stable. In the other cases, the system is unstable.*

Remark 17. Formula (13) is a corrected version of Formula (6), p. 93, of [8] and it is proved in Appendix A.3.

A.2. Normal forms of 2×2 matrices.

PROPOSITION 3. *Let A, B be two 2×2 real matrices satisfying conditions* H1*,* H2*,* H3*, and* H4 *given in section* 3*. In the case in which one of the two matrices has real and the other nonreal eigenvalues (i.e., the* (RC) *case), assume that A is the one having real eigenvalues. Then there exists a* 3*-parameter change of coordinates and two constant $\alpha_A, \alpha_B > 0$ such that the matrices A/α_A and B/α_B (still denoted below by A and B) are in the following normal forms*

Case in which A and B have both nonreal eigenvalues ((CC) case):

$$A = \begin{pmatrix} -\rho_A & -1/E \\ E & -\rho_A \end{pmatrix}, \qquad B = \begin{pmatrix} -\rho_B & -1 \\ 1 & -\rho_B \end{pmatrix}, \tag{14}$$

where $\rho_A, \rho_B > 0$, $|E| > 1$. In this case, $\mathcal{K} = \frac{1}{2}(E + \frac{1}{E})$. Moreover, the eigenvalues of A and B are, respectively, $-\rho_A \pm i$ and $-\rho_B \pm i$.

Case in which A has real and B nonreal eigenvalues ((RC) case):

$$A = \begin{pmatrix} -\rho_A/i + 1 & 0 \\ 0 & -\rho_A/i - 1 \end{pmatrix}, \tag{15}$$

$$B = \begin{pmatrix} -\rho_B - \mathcal{K}/i & -\sqrt{1 - \mathcal{K}^2} \\ \sqrt{1 - \mathcal{K}^2} & -\rho_B + \mathcal{K}/i \end{pmatrix}, \tag{16}$$

where $\rho_B > 0$, $\rho_A/i > 1$, $\mathcal{K} \in i\mathbb{R}$. In this case, the eigenvalues of A and B are, respectively, $-\rho_A/i \pm 1$ and $-\rho_B \pm i$.

Case in which A and B have both real eigenvalues ((RR) case):

$$A = \begin{pmatrix} -\rho_A/i + 1 & 0 \\ 0 & -\rho_A/i - 1 \end{pmatrix}, \tag{17}$$

$$B = \begin{pmatrix} \mathcal{K} - \rho_B/i & 1 - \mathcal{K} \\ 1 + \mathcal{K} & -\mathcal{K} - \rho_B/i \end{pmatrix}, \tag{18}$$

where $\rho_A/i, \rho_B/i > 1$ and $\mathcal{K} \in \mathbb{R} \setminus \{\pm 1\}$. In this case, the eigenvalues of A and B are, respectively, $-\rho_A/i \pm 1$ and $-\rho_B/i \pm 1$.

A.3. Proof of formula (12). In this paragraph, we prove formula (12), i.e., in the (RC.2.2.B) case, we determine an inequality defining the set of parameters ρ_A, ρ_B, $\mathcal{K}$ such that the property $(\mathcal{P})$, stated in section 3, holds.

Thanks to Proposition 3 (see also [8, Appendix B, p. 110]), we can find a coordinate transformation such that (up to a rescaling of the matrices) A and B are given by equations (15), (16). In the case (RC.2.2.B), we have $\mathcal{D} := \mathcal{K}^2 + 2\rho_A\rho_B\mathcal{K} - (1 + \rho_A^2 + \rho_B^2) < 0$, $\chi := \rho_A\mathcal{K} - \rho_B < 0$, $\mathcal{K}/i > 0$. Moreover, the set $Q^{-1}(0)$ is the union of two lines passing from the origin and, at each point of $Q^{-1}(0)$, the two vector fields point in the same direction. One easily checks that the slope of the two lines defining $Q^{-1}(0)$ is

$$m^{\pm} = \frac{-\chi \pm \sqrt{-\mathcal{D}}}{(-\rho_A/i - 1)\sqrt{1-\mathcal{K}^2}}.$$

Notice that in our case we have $m^{\pm} < 0$ and $m^+ < m^-$.

In this case, the worst trajectories are concatenations of arcs of integral curves of the vector fields Ax, Bx and rotate counterclockwise around the origin. More precisely, they are integral curves of Ax from the line $x_2 = m^+x_1$ to the line $x_2 = m^-x_1$ and integral curves of Bx otherwise.

Therefore, starting from the point $\binom{1}{m^+}$ (with the field Ax), we follow the worst trajectory until it touches again the line $x_2 = m^+x_1$. Property $(\mathcal{P})$ is then satisfied if and only if $\rho_{RC} < 1$, where ρ_{RC} is the absolute value of the first coordinate of the final point.

One can easily compute that the first switching time is $t_1 = \frac{1}{2}\log\frac{m^+}{m^-}$, which is positive since $\frac{m^+}{m^-} > 1$. Moreover, the integral curve of Bx starting from the point $\binom{1}{m^-}$ is

$$e^{-\rho_B t}\begin{pmatrix} -\sqrt{1-\mathcal{K}^2}\, m^- \sin t + (\cos t - \frac{\mathcal{K}}{i}\sin t) \\ \sqrt{1-\mathcal{K}^2}\sin t + m^-(\cos t + \frac{\mathcal{K}}{i}\sin t)\end{pmatrix},$$

and, setting the ratio between the second coordinate and the first one equal to m^+, one obtains that the second switching time is $t_2 = \arccos\frac{-\rho_A/i + \rho_B\mathcal{K}/i}{\sqrt{(1-\mathcal{K}^2)(1+\rho_B^2)}}$. Notice that t_2 is well defined if and only if $\mathcal{D} < 0$ (condition which is satisfied in our case). Moreover, t_2 is positive and less than π. Finally, the inequality we was seeking for is

$$\rho_{RC} = \left(\frac{m^+}{m^-}\right)^{-\frac{1}{2}(\rho_A/i-1)} e^{-\rho_B t_2}\left(\sqrt{1-\mathcal{K}^2}\, m^- \sin t_2 - \left(\cos t_2 - \frac{\mathcal{K}}{i}\sin t_2\right)\right) < 1\,.$$

Appendix B. The stability properties of (3) depend only on the convex hull of A. We provide here the proof of Proposition 1. First, let us show the following.

Claim. Consider the switched system (3), under HO, and let $\mathbf{A}'$ be a measurable subset of $\mathbf{A}$ such that the convex hull of $\mathbf{A}'$ contains $\mathbf{A}$. Then the following two conditions are equivalent:

(i) the system is GUES (resp., uniformly stable), with $A(.)$ measurable, taking values in $\mathbf{A}$;

(ii) the system is GUES (resp., uniformly stable), with $A(.)$ measurable, taking values in $\mathbf{A}'$.

Proof of the Claim. Let $\boldsymbol{\mathcal{A}}$ (resp., $\boldsymbol{\mathcal{A}}'$) be the set of measurable functions $A(.) : [0,\infty[\to \mathbf{A}$ (resp., $A(.) : [0,\infty[\to \mathbf{A}'$). Since $\mathbf{A}'$ is contained in $\mathbf{A}$, then the implication (i) $\Rightarrow$ (ii) is obvious.

Let us prove the other implication (which is strictly related to the classical approximability theorems in control theory). We start considering uniform stability. By contradiction, assume that we can find $\epsilon > 0$ satisfying the following. There exists a sequence of points (x_l) tending to zero and a sequence of controls $A_l(.) \in \boldsymbol{\mathcal{A}}$ such that the corresponding trajectory γ_l starting at x_l exits the interior of the ball of radius ϵ for some time t_l. Using classical approximability results (see, for instance, [2]), the trajectory γ_l can be approximated in the L^∞-norm on $[0, t_l]$ by a trajectory γ'_l corresponding to a switching function $A'_l(.) \in \boldsymbol{\mathcal{A}}'$ and starting at x_l. Hence γ'_l exits the interior of the ball of radius $\epsilon/2$ at time t_l. We reached a contradiction.

Now we want to prove that GUES holds in the case $A(.) \in \boldsymbol{\mathcal{A}}'$ implies GUES holds in the case $A(.) \in \boldsymbol{\mathcal{A}}$. Since $\mathbf{A}$ is compact, we know (see Definition 1 and below) that attractivity and GUES are equivalent for the corresponding switched system. Therefore, proceeding by contradiction, we can assume that there is a trajectory $\gamma(.)$ of the switched system corresponding to $A(.) \in \boldsymbol{\mathcal{A}}$ not converging to zero. That means that there exist $\epsilon > 0$ and a sequence t_n of times tending to infinity such that $|\gamma(t_n)| > \epsilon$. As before, we can approximate $\gamma(.)$ on the interval $[0, t_n]$ with a trajectory $\gamma_n(.)$ corresponding to controls taking values in $\mathbf{A}'$, in such a way that $|\gamma_n(t_n)| > \epsilon/2$. But this is impossible since we have assumed GUES for the switched system with $A(.) \in \boldsymbol{\mathcal{A}}'$. □

Notice that one can provide an alternative argument for the GUES part of Proposition 1, by using Lyapunov functions.

Then one immediately extends to semicones, observing that the stability properties of the system (3), subject to the compactness hypothesis HO, depend only on the shape of the trajectories and not on the way in which they are parameterized.

AN EVOLUTION EQUATION APPROACH TO NONAUTONOMOUS LINEAR SYSTEMS WITH STATE, INPUT, AND OUTPUT DELAYS*

SAID HADD†

Abstract. We propose a new approach which brings nonautonomous linear systems with state, input, and output delays in the line with the standard theory of nonautonomous linear systems. To this purpose, we establish, using the concept of Lebesgue extensions, a new variation of constants formula for nonhomogenous delay equations. From this we deduce another new one for nonautonomous linear systems with state and input delays. Inspiriting from this formula we show that a given delay system determines a nonautonomous absolutely regular linear system with the same input and output spaces as of the delay system. Our abstract results will be applied to investigate the existence and the uniqueness of the solutions for a class of nonautonomous neutral equations in Banach spaces.

Key words. nonautonomous delay equations, delay systems, nonautonomous regular systems, Lebesgue extension, representation, neutral equations

1. Introduction.

The delay systems (also called hereditary or systems with aftereffects) represent a class of infinite-dimensional systems largely used to describe propagation phenomena or population dynamics. Roughly speaking, the reaction of real-world systems to exogenous signals is never "instantaneous" and it needs some time, time which can be translated into a mathematical language by some delay terms. A distinguished feature of this class of systems is that their evolution rate is described by differential equations which include information on the past history. Into a mathematical framework, such systems may be described in several ways, and we mention, for example, differential equations on abstract spaces, over rings of operators or functional differential equations. We note that the delay effects on the stability and control of dynamical systems (delays in the state and/or in the input) are problems of recurring interest since the delay presence may induce complex behaviors (oscillations, instability, bad performances) for the (closed-loop) schemes.

The purpose of the current paper is to introduce an evolution equation approach which brings nonautonomous linear systems with delays in the state, control, and observation variables in line with the standard theory of nonautonomous systems developed recently by Schnaubelt [26], a nonautonomous version of the known abstract linear systems theory introduced mainly by Salamon [25] and Weiss [32]. We note that the results in [26] extend those obtained in the works by Hinrichsen and Pritchard [14], Jacob [16, 17], and Jacob, Dragan, and Pritchard [18].

In this paper we give conditions on delay operators so as to reformulate the delay systems as absolutely regular nonautonomous systems. In particular, this serves to establish a new representation of the state, as well as of the output function for delay systems in terms of some extensions of the delay operators. We show how this approach leads also to introduce a new definition of the solution of input delay equations.

A quite complete theory of representation for autonomous delay systems exists. We quote the classical work by Ichikawa [15] and Pritchard and Salamon [23] as well as the early papers by Delfour [7], Vinter and Kwong [29] and the books by Bensoussan et al. [3, Chap. 4] and Curtain and Zwart [6, Chap. 4.2]. In [23], the authors showed that autonomous delay systems are represented as Pritchard–Salamon systems (see, e.g., [5]), a strict subclass of that of Salamon and Weiss. Likewise we note that in [10, 11] we introduced a large class of autonomous delay systems which can be reformulated as Salamon–Weiss systems.

In the nonautonomous case, we have already started the investigation of delay systems; see [12]. There, we studied the robustness of the (absolute) regularity of a nonautonomous system under perturbation by appropriate state and input delay operators.

In the current paper a representation of nonautonomous linear systems with state, input, and output delay is considered. Our approach is based on a study of absolutely regular systems.

Before summarizing precisely our results, we first fix some notation which will be used throughout the paper. The state space X, the control space U, and the observation space Y are supposed to be Banach spaces, and $r > 0$ is a real number. For a Banach space Z, if $z : [-r, \infty) \to Z$, then its history is the function $z_t : [-r, 0] \to Z$ defined by $z_t(\theta) = z(t + \theta),\ t \geq 0$. We denote by $C([-r, 0], Z)$, the space of Z-valued continuous functions on $[-r, 0]$, $L^2([-r, 0], Z)$ the customary Lebesgue space of square integrable Z-valued functions on $[-r, 0]$, $W^{1,2}([-r, 0], Z)$ the Sobolev space, and $L^2_{loc}(J, Z)$ is the space of all functions $\phi : J \to Z$ locally 2-integrable endowed with the usual Fréchet topology, where $J \subset \mathbb{R}$ is a closed interval. Hereafter, the function $f \in L^2_{loc}([s, \infty), X)$ for $s \geq 0$ will denote the nonhomogenous term for evolution equations. If $(S_Z(t))_{t\geq 0}$ is the left shift semigroup on $L^2([-r, 0], Z)$ (see section 3), then $\mathcal{S}_Z := (\mathcal{S}_Z(t, s))_{t\geq s}$ is a strongly continuous evolution family on this space, where we set $\mathcal{S}_Z(t, s) = S_Z(t - s),\ t \geq s$.

Let us consider the nonhomogenous (state) delay equation

$$\dot{x}(t) = A(t)x(t) + L(t)x_t + f(t), \quad x(s) = \eta, \quad x_s = \varphi, \quad t \geq s \geq 0. \tag{1.1}$$

If $A(t)$ are linear operators on X which satisfy Aquistapace and Terreni assumptions (see [2] and the comments on evolution equations in section 4), then generate a strongly continuous evolution family $T := (T(t, s))_{t\geq s}$ on X; see [1]. Moreover, $L(t)$ are bounded linear operators from $C([-r, 0], X)$ into X, expressed in terms of a kernel $\ell(\cdot, \cdot) : [-r, 0] \times \mathbb{R}_+ \to \mathcal{L}(X),\ t \geq 0$, satisfying the assumption (H); see section 3. In [12], it is shown that (H) implies that $L(t)$ are nonautonomous observation operators for $\mathcal{S}_X$. We denote by $\tilde{L}(t)$ the *Lebesgue extensions* of $L(t)$ with respect to $\mathcal{S}_X$ (see (2.5)). We shall see that for initial conditions $\eta \in X$ and $\varphi \in L^2([-r, 0], X)$, the equation (1.1) has a solution $x : [s - r, \infty) \to X$ satisfying $x_t \in D(\tilde{L}(t))$ for almost everywhere (a.e.) $t \geq s \geq 0,\ \tilde{L}(\cdot)x_\cdot \in L^2_{loc}([s, \infty), X)$, and

$$x(t) = T(t, s)\eta + \int_s^t T(t, \tau)[\tilde{L}(\tau)x_\tau + f(\tau)]\, d\tau, \quad t \geq s. \tag{1.2}$$

What seems surprising is that if $x : [s - r, \infty) \to X$ is the solution of (1.1) corresponding to the initial conditions $\eta \in X$ and $\varphi \in C([-r, 0], X)$ such that $\eta = \varphi(0)$, then the formula (1.2) coincides with the usual one in the C-setting (see, e.g., [9]). In fact, as we shall see in section 4, in this case we have $\tilde{L}(t)x_t = L(t)x_t$ for almost every $t \geq s$. This motivates us to call (1.2) the *mild solution* of (1.1). In what follows we

will indicate the importance of the formula (1.2) when we study the solution of input delay equations.

Let us consider a control function $u \in L^2([s-r,\infty),U)$ such that $u_s = \zeta$ for initial time $s \geq 0$. We now consider the following delay system:

$$\begin{aligned} &\dot{x}(t) = A(t)x(t) + L(t)x_t + K(t)u_t, \quad t \geq s \geq 0, \\ &x(s) = \eta, \quad x(t) = \varphi, \quad u(t) = \zeta, \quad t \leq s, \end{aligned} \tag{1.3}$$

$$y(t) = G(t)x_t + D(t)u_t. \tag{1.4}$$

Here the delay operators $K(t) : C([-r,0],U) \to X$, $G(t) : C([-r,0],X) \to Y$ and $D(t) : C([-r,0],U) \to Y$ are defined by kernels $k(\cdot,\cdot)$, $g(\cdot,\cdot)$, and $d(\cdot,\cdot)$ satisfying the condition (H).

If one regards (1.3) as a nonhomogenous equation of the form (1.1), then to use the abstract framework cited above it is necessary that the X-valued function $f(t) := K(t)u_t$, $t \geq s \geq 0$, be locally 2-integrable. This is not clear since $K(t)$ are not bounded on $L^2([-r,0],U)$. However, for *smooth input,* i.e., $u \in W^{1,2}_{loc}([s-r,\infty),U)$ with $u(s) = 0$, we have proved, in fact, that f is well defined and belongs to $L^2_{loc}([s,\infty),X)$ (see section 3). Thus, due to the aforementioned result, the input delay equation (1.3) has a mild solution satisfying (1.2).

Analyzing in profile what happens when the input u is not smooth, one has to make sense to "$K(t)u_t$" for a.e. $t \geq s \geq 0$. Observe that $v(t,\cdot) := u_t$ is the state trajectory of the boundary control system $\frac{\partial}{\partial t}v(t,\cdot) = \frac{\partial}{\partial \theta}v(t,\cdot)$, $v(t,0) = u(t)$ for $t \geq s \geq 0$. Now, due to the rich existing theory of (absolutely) regular nonautonomous systems (see section 2), one considers $f(t) = K(t)u_t$, $t \geq s$, as the observation equation associated with this boundary control system, where we denote the obtained system by (BS). In section 3, we have proved that the hypothesis (H) on $K(t)$ implies that (BS) determines an absolutely regular nonautonomous system on the state space $L^2([-r,0],U)$, the control space U, and the observation space X. Now due to Theorem 2.3, we have $u_t \in D(\tilde{K}(t))$ for a.e. $t \geq s$ and $\tilde{f}(t) := \tilde{K}(t)u_t$ (as we shall see, this is the extension of f) belongs to $L^2_{loc}([s,\infty),X)$, where $\tilde{K}(t)$ are the Lebesgue extensions of $K(t)$ with respect to the evolution family $\mathcal{S}_U$. We thus apply formula (1.2) to $\tilde{f}$ and we get a new solution $x : [s-r,\infty) \to X$ satisfying $x_t \in D(\tilde{L}(t))$ for a.e. $t \geq s$, $\tilde{L}(\cdot)x_\cdot \in L^2_{loc}([s,\infty),X)$ and

$$x(t) = T(t,s)\eta + \int_s^t T(t,\tau)[\tilde{L}(\tau)x_\tau + \tilde{K}(\tau)u_\tau]\,d\tau, \quad t \geq s. \tag{1.5}$$

If we restrict ourselves to the initial condition $\varphi \in C([-r,0],X)$ such that $\eta = \varphi(0)$ and the smooth input u, then we have established that $\tilde{L}(t)x_t = L(t)x_t$ and $\tilde{K}(t)u_t = K(t)u_t$ for almost every $t \geq s$. This suggests that we call the function x satisfying (1.5) a *generalized solution* of (1.3). By density, every input u can approximated by a sequence of smooth inputs u^n. Now if x^n is the mild solution of (1.3) corresponding to u^n, then we shall see that the generalized solution of (1.3) corresponding to u satisfies $x^n \to x$ in $L^2_{loc}([s-r,\infty),X)$.

However, the formula for the generalized (and then the mild) solution still contains a delay term. In order to obtain a delay-free representation for the input delay equation (1.3), we have transformed (1.3) into a nonautonomous control system without delay $(\mathcal{T}_{L,K},\Phi_{L,K})$ on the new state space $\mathcal{X} := X \times L^2([-r,0],X) \times L^2([-r,0],U)$ and the control space U, by adding the history of the control to the dynamics of the system. Moreover, the state trajectory and the control function of the new system

are $z(t) = (x(t), x_t, u_t)$ and $u(t)$ for $t \geq s \geq 0$, respectively, where x is the generalized solution of (1.3). We thus see that there is a natural connection between the state z and the delayed observation equation (1.4). This suggests to regard y as the observation equation associated with the new control system. Typically, we have transformed the delay system (1.3)–(1.4) into an absolutely regular nonautonomous system $\Sigma_{L,K}$ on the state space $\mathcal{X}$, the control space U, and the observation space Y. This transformation allows us to prove that the output equation (1.4) is represented as $y(t) = \tilde{G}(t)x_t + \tilde{D}(t)u_t$ for almost every $t \geq s$, where $\tilde{G}(t)$ (resp., $\tilde{D}(t)$) are the Lebesgue extensions of $G(t)$ (resp., $D(t)$) with respect to $\mathcal{S}_X$ (resp., $\mathcal{S}_U$).

If in (1.3)–(1.4) we take $L(t) = 0$, $G(t) = \delta_0$, $X = Y = U$ and invoking the feedback law '$u(t) = y(t)$', then the delay system corresponds to the usual nonautonomous neutral equations (see, e.g., [13, Chap. 9]). Our representation theory allows us to introduce a kind of solutions for such neutral equations (see Definition 6.1). On the other hand, we show that the condition (H) implies that $\Delta(t) = I_X$ are admissible feedback operators for $\Sigma_{0,K}$, which give sense to the aforementioned feedback law. In view of our representation theorem (see Theorem 5.8) for nonautonomous delay systems and the feedback theory for nonautonomous systems (see section 2) we prove that the nonautonomous neutral equation has a unique (generalized) solution (see Theorem 6.3).

Section 2 is devoted to preliminaries from (absolutely) regular nonautonomous systems. Section 3 is on the study of the absolute regularity of a boundary nonautonomous system closely related to the left shift semigroup. In section 4 we investigate mild and generalized solutions of nonhomogenous delay evolution equations. In section 5 we prove that the delay system (1.3)–(1.4) determines an absolutely regular nonautonomous system. The last section is concerned with the study of a class of parabolic nonautonomous neutral equations.

2. Background on regular nonautonomous systems. Since our results are based on the theory of (absolutely) regular nonautonomous systems, we review the relevant theory from Schnaubelt [26]. We note that the results in [26] extend those obtained in the works by Hinrichsen and Pritchard [14], Jacob [16, 17], and Jacob, Dragan, and Pritchard [18]. We equally mention that the paper [26] can be regarded as the nonautonomous version of the Weiss works [30, 31, 32] and the Staffans book [28, Chaps. 5 and 7] on well-posed linear systems.

A *(strongly continuous) evolution family* on X is a set $T = (T(t,s))_{t \geq s \geq 0} \subset \mathcal{L}(X)$ (the space of bounded linear operators on X) such that

(i) $T(t,s) = T(t,\rho)T(\rho,s)$, $T(s,s) = Id$,

(ii) for each $x \in X$ the map $(t,s) \mapsto T(t,s)x$ is continuous for all $t \geq s \geq 0$, and

(iii) $\|T(t,s)\| \leq Me^{\omega(t-s)}$

for all $t \geq \rho \geq s \geq 0$ and constants $M \geq 1$ and $\omega \in \mathbb{R}$.

This notion of evolution families arises naturally from the theory of evolution equations which are well posed (see, e.g., [4, Chap. 2], [8, sect. VI.9], [22], [27]). That is, the evolution family arises as the solution operator of the well-posed nonautonomous evolution equation $\dot{x}(t) = A(t)x(t)$, $x(s) = \eta \in X$, for $t \geq s \geq 0$, where $A(t)$ is (in general) an unbounded linear operator for every fixed t. We mention that generally, the function $T(t,s)\eta$, as a function of t, is not differential. However, the differentiability of such a function is guaranteed if $A(t)$ satisfy additional conditions. (See section 4 for some comments and further references.) Moreover, we are concerned here with the notion of evolution families rather than that of evolution equations involving concrete differential operators.

For an evolution family T, we set

$$(\mathbb{K}_s^T f)(t) := \int_s^t T(t,\tau) f(\tau)\, d\tau$$

for all $t \geq s \geq 0$ and $f \in L^2_{loc}([s,\infty), X)$.

The pair $(T,\Phi) := (T, \{\Phi(t,s) : t \geq s \geq 0\})$ is called a *nonautonomous control system* (on X, U) if $\Phi(t,s) : L^2_{loc}([s,\infty), U) \to X,\ t \geq s \geq 0$, are linear operators such that

$$\begin{aligned} &\Phi(t,s)u = \Phi(t,\rho)(u \mid [\rho,\infty)) + T(t,\rho)\Phi(\rho,s)u, \quad t \geq \rho \geq s \geq 0, \\ &\|\Phi(t,s)u\|_X \leq \beta \|u\|_{L^2([s,t],U)}, \quad 0 \leq t-s \leq t_0, \end{aligned} \tag{2.1}$$

for $u \in L^2_{loc}([s,\infty), U),\ t_0 > 0$, and constant $\beta = \beta(t_0) > 0$.

Let $s \geq 0,\ u \in L^2_{loc}([s,\infty), U)$. Then the function $x : [s,\infty) \to X$ defined by $x(s) = \eta$ and

$$x(t) = T(t,s)\eta + \Phi(t,s)u, \quad t \geq s, \tag{2.2}$$

is called the *state trajectory* of the control system (T,Φ).

Let $\Psi(s) : X \longrightarrow L^2_{loc}([s,\infty), Y),\ s \geq 0$, be linear operators satisfying

$$\Psi(s)\eta = \Psi(t)T(t,s)\eta \quad \text{on} \quad [t,\infty) \quad \text{and} \quad \int_s^{s+t_0} \|(\Psi(s)\eta)(t)\|^2\, dt \leq \gamma^2 \|\eta\|^2 \tag{2.3}$$

for $t \geq s \geq 0$, $\eta \in X$, $t_0 > 0$, and constant $\gamma = \gamma(t_0) > 0$. In this case we say that $(T,\Psi) := (T, \{\Psi(s),\ s \geq 0\})$ is a *nonautonomous observation system* (on X, Y).

For linear operators $C(s) : D(C(s)) \subseteq X \to Y,\ s \geq 0$, we define the set

$$\begin{aligned} \mathcal{D}_s(C(\cdot)) := \{f \in L^2_{loc}([s,\infty), X) : f(t) \in D(C(t)) \ \text{ for a.e. } \ t \geq s, \\ C(\cdot)f(\cdot) \in L^2_{loc}([s,\infty), Y)\}. \end{aligned}$$

Let $C(s) : D(C(s)) \subseteq X \longrightarrow Y,\ s \geq 0$, be densely defined linear operators such that $T(\cdot,s)\eta \in D_s(C(\cdot))$ and

$$\int_s^{s+t_0} \|C(t)T(t,s)\eta\|^2\, dt \leq \gamma^2 \|\eta\|^2$$

for $s \geq 0$, $t_0 > 0$, $\eta \in D(C(s))$, and a constant $\gamma = \gamma(t_0) > 0$. Then we say that $C(s),\ s \geq 0$, are *admissible observation operators* for T. Note that the admissibility of $C(t)$ for T implies that the mapping

$$\Psi(s) : D(C(s)) \to L^2_{loc}([s,\infty), Y), \quad \Psi(s)\eta := C(\cdot)T(\cdot,s)\eta, \quad s \geq 0, \tag{2.4}$$

possess unique extensions (again denoted by $\Psi(s)$) to linear continuous operators from X to $L^2_{loc}([s,\infty), Y)$ which yield a nonautonomous observation system; see [26, Lem. 2.5].

Conversely, let (T,Ψ) be a nonautonomous observation system and $s \geq 0$. We define the operators

$$\begin{aligned} D(\tilde{C}(s)) &:= \Big\{\eta \in X : \lim_{\tau \searrow 0} \frac{1}{\tau} \int_s^{s+\tau} (\Psi(s)\eta)(\sigma)\, d\sigma \quad \text{exists in Y}\Big\}, \\ \tilde{C}(s)\eta &:= \lim_{\tau \searrow 0} \frac{1}{\tau} \int_s^{s+\tau} (\Psi(s)\eta)(\sigma)\, d\sigma. \end{aligned} \tag{2.5}$$

We say that $\tilde{C}(\cdot)$ *represent* (T,Ψ) or that $\tilde{C}(t)$ are the *Lebesgue extensions* of $C(t)$ with respect to T if $\Psi(s)$ is given by (2.4).

The following result, due to Schnaubelt [26, Thm. 2.7], can be regarded as a nonautonomous version of the well-known Weiss representation theorem [30].

THEOREM 2.1. *Let (T,Ψ) be a nonautonomous observation system on X,Y. Let $\tilde{C}(t)$, $t\geq 0$, be defined as in (2.5). Then $T(\cdot,s)\eta\in\mathcal{D}_s(\tilde{C}(\cdot))$ and $\Psi(s)\eta=\tilde{C}(\cdot)T(\cdot,s)\eta$ for $s\geq 0$ and $\eta\in X$.*

The following proposition will be used constantly throughout this paper (see [26, Prop. 2.11] and its proof).

PROPOSITION 2.2. *Let (T,Ψ) be a nonautonomous observation system represented by $\tilde{C}(t)$. Then $\mathbb{K}_s^T f\in\mathcal{D}_s(\tilde{C}(\cdot))$ and*

$$\|\tilde{C}(\cdot)\mathbb{K}_s^T f\|_{L^2([s,s+t_0],Y)}\leq c\ t_0^{\frac{1}{2}}\ \|f\|_{L^2([s,s+t_0],X)}$$

for $s\geq 0$, $0<t_0\leq t_1$, $f\in L^2_{loc}(\mathbb{R}_+,X)$, and a constant $c=c(t_1)>0$.

Let (T,Φ) and (T,Ψ) be nonautonomous control and observation systems. If there are linear operators $\mathbb{F}(s):L^2_{loc}([s,\infty),U)\to L^2_{loc}([s,\infty),Y)$ satisfying

$$\mathbb{F}(s)u=\Psi(t)\Phi(t,s)u+\mathbb{F}(t)(u\mid[t,\infty)) \quad \text{on } [t,\infty), \tag{2.6}$$

$$\|\mathbb{F}(s)u\|_{L^2([s,s+t_0],Y)}\leq\kappa\|u\|_{L^2([s,s+t_0],U)} \tag{2.7}$$

for $u\in L^2_{loc}([s,\infty),U)$, $t\geq s\geq 0$, $t_0>0$, and a constant $\kappa=\kappa(t_0)>0$, then $\Sigma=(T,\Phi,\Psi,\mathbb{F})$ is called a *well-posed nonautonomous system* (on X,U,Y) with *input-output operators* $\mathbb{F}(s)$. We note that $\mathbb{F}(s)u=0$ on $[s,t]$ and $\mathbb{F}(s)u=\mathbb{F}(t)(u|[t,\infty))$ on $[t,\infty)$ is u vanishes on $[s,t]$. Then one defines the following restrictions:

$$\mathbb{F}(s)|[s,t]=:\mathbb{F}(t,s):L^2([s,t],U)\to L^2([s,t],Y),\qquad t\geq s\geq 0.$$

Let $\Sigma=(T,\Phi,\Psi,\mathbb{F})$ be a well-posed nonautonomous system with state trajectory $x:[s,\infty)\to X$ (see (2.2)) and control function $u\in L^2([s,\infty),U)$ for initial time $s\geq 0$. In the rest of this section we assume that Ψ is given by nonautonomous admissible observation operators $C(t)$ as in (2.4), so we denote by $\tilde{C}(t)$ the Lebesgue extensions of $C(t)$ with respect to T. We now consider the system

$$\text{(CS)}\quad\begin{cases}x(t)=T(t,s)\eta+\Phi(t,s)u, & t\geq s\geq 0,\\ y(t)=C(t)x(t).\end{cases}$$

We say that y is the *observation function* of (CS) (or Σ). When $\eta=0$, the operators $\mathbb{F}(s)$ relate the input u to the output y (i.e., $u\to y$). Since $C(t)$ are unbounded operators, then $y(t)$ has a sense only if $\mathbb{F}(t)$ satisfy additional regularity properties.

A well-posed nonautonomous linear system $(T,\Phi,\Psi,\mathbb{F})$ is called *regular* (with feedthrough $D=0$) if

$$Y-\lim_{\tau\searrow 0}\frac{1}{\tau}\int_t^{t+\tau}(\mathbb{F}(t)u_z)(\sigma)\,d\sigma=0$$

and *absolutely regular* if

$$\lim_{\tau\searrow 0}\frac{1}{\tau}\int_t^{t+\tau}\|(\mathbb{F}(t)u_z)(\sigma)\|_Y^2\,d\sigma=0$$

for $t\geq 0$ and $z\in U$, where $u_z(s):=z$ for $s\geq 0$. We note that the absolute regularity implies the regularity of Σ.

The following result is a consequence of Theorem 2.1 and [26, Thm. 3.11].

THEOREM 2.3. *Let $\Sigma = (T, \Phi, \Psi, \mathbb{F})$ be a regular nonautonomous system, with state trajectory x, control function u, and observation function y. The following assertions hold:*

(i) $\Phi(\cdot, s)u \in \mathcal{D}_s(\tilde{C}(\cdot))$ *for* $s \geq 0$.
(ii) $x(t) \in D(\tilde{C}(t))$ *for a.e.* $t \geq s \geq 0$.
(iii) $y = \Psi(s)\eta + \mathbb{F}(s)u$ *for* $s \geq 0$.
(iv) $y(t) = \tilde{C}(t)x(t)$ *for a.e.* $t \geq s \geq 0$.

We end this section by recalling the concept of admissible feedback operators for nonautonomous linear systems.

DEFINITION 2.4. *Let $\Sigma = (T, \Phi, \Psi, \mathbb{F})$ be a well-posed nonautonomous system. We call $\Delta(\cdot) \in L^\infty(\mathbb{R}_+, \mathcal{L}_s(Y, U))$ (the space of essentially bounded and strongly measurable operator functions) an* admissible feedback *for Σ if there exists $t_0 > 0$ such that the operators $I_Y - \mathbb{F}(s + t_0, s)\Delta(\cdot)$, $s \geq 0$, have uniformly bounded inverses on $L^2([s, s + t_0], Y)$.*

If Σ is absolutely regular and $\Delta(t)$ are admissible feedback operators for Σ, then the closed-loop system Σ^Δ for Σ and $\Delta(\cdot)$ exists, and it is also absolutely regular. Moreover, we have several formulas relating the open-loop and closed-loop systems. To put the formulas in a concise form, we define the operators $\Psi(t, s)x := (\Psi_s x)_{|[s,t]}$ and

$$\Sigma(t, s) := \begin{pmatrix} T(t, s) & \Phi(t, s) \\ \Psi(t, s) & \mathbb{F}(t, s) \end{pmatrix} : \ X \times L^p([s, t], U) \longrightarrow X \times L^p([s, t], Y) \tag{2.8}$$

for $t \geq s \geq 0$. Then it holds

$$\Sigma^\Delta(t, s) - \Sigma(t, s) = \Sigma(t, s) \begin{pmatrix} 0 & 0 \\ 0 & \Delta(\cdot) \end{pmatrix} \Sigma^\Delta(t, s) = \Sigma^\Delta(t, s) \begin{pmatrix} 0 & 0 \\ 0 & \Delta(\cdot) \end{pmatrix} \Sigma(t, s). \tag{2.9}$$

These facts are shown in Theorem 4.4 and Proposition 5.1 of [26], where one can find further results on the relations ship between Σ and Σ^Δ.

3. A boundary control nonautonomous system. Let us first introduce some basic facts about bounded variation functions. For a Banach space Z, we shall denote by $BV([-r, 0], Z)$ the space of all functions $\nu : [-r, 0] \to Z$ of bounded variation, i.e., the total variation of ν

$$Var(\nu)_{-r}^0 := \sup \left\{ \sum_{j=1}^N \|\nu(\theta_j) - \nu(\theta_{j-1})\| : 0 = \theta_0 > \theta_1 \cdots > \theta_N = -r, \ N \in \mathbb{N} \right\}$$

is finite. Elements of $BV([-r, 0], Z)$ are normalized throughout this paper by the requirements $\nu(-r) = 0$ and that $\nu(\cdot)$ is left-continuous on $[-r, 0]$. Hence, extending $\nu \in BV([-r, 0], Z)$ by 0 to $(-\infty, 0]$, $\nu(\cdot)$ can also be considered as an element of $BV((-\infty, 0], Z)$. (This space is defined as $BV([-r, 0], Z)$.)

Throughout E and F are supposed to be Banach spaces. We shall study a boundary control system closely related to the left shift semigroup $S_E := (S_E(t))_{t \geq 0}$ on $L^2([-r, 0], E)$, where

$$(S_E(t)\psi)(\theta) := \mathbb{I}_{[-r,0]}(t + \theta)\psi(t + \theta), \quad \psi \in L^2([-r, 0], E), \ t \geq 0, \ \theta \in [-r, 0].$$

Here the symbol $\mathbb{I}_J$ denotes the constant function equal to one in the interval $J \subset \mathbb{R}$ and zero otherwise. It can be verified that the generator of S_E is given by

$$Q_E\psi := \psi' \quad \text{for} \quad \psi \in D(Q_E) := \{\psi \in W^{1,2}([-r, 0], E) : \psi(0) = 0\}.$$

Let $\mathcal{S}_E := (\mathcal{S}_E(t,s))_{t\geq s\geq 0}$ be the family defined by $\mathcal{S}_E(t,s) := S_E(t-s)$ for $t \geq s \geq 0$. Then $\mathcal{S}_E$ is a strongly continuous evolution family on $L^2([-r,0],E)$.

Observe that for $s \geq 0$, $\zeta \in L^2([-r,0],E)$ and $u \in L^2_{loc}([s-r,\infty),E)$ such that $u_s = \zeta$ we have

$$u_t = \mathcal{S}_E(t,s)\zeta + \Phi(t,s)u, \qquad t \geq s, \tag{3.1}$$

where $\Phi(t,s) : L^2([s,\infty),E) \to L^2([-r,0],E)$ are the linear operators defined by

$$(\Phi(t,s)u)(\theta) := \begin{cases} u(t+\theta), & \theta > s-t, \\ 0, & \theta \leq s-t, \end{cases} \tag{3.2}$$

for $t \geq s \geq 0,\ u \in L^2([s,\infty),E)$, and $\theta \in [-r,0]$. Clearly, these operators satisfy

$$\|\Phi(t,s)u\|_{L^2([-r,0],E)} = \|u\|_{L^2([s,t],E)}$$

for all $t \geq s \geq 0$ and $u \in L^2_{loc}([s,\infty),E)$. Moreover, one can see that $(\mathcal{S}_E,\Phi)$ satisfies the first identity in (2.1). Thus we have the following lemma.

LEMMA 3.1. *Let $\Phi(t,s)$, $t \geq s \geq 0$, be the operators defined by* (3.2). *Then $(\mathcal{S}_E,\Phi)$ is a nonautonomous control system on $L^2([-r,0],E),E$. Let now $u(t)$ and $v(t,\theta)$ for $t \geq s \geq 0,\ \theta \in [-r,0]$, be the control function and the state trajectory of this system, respectively, such that $v(s,\cdot) = \zeta$ is the initial state. Then $v(t,\cdot) = u_t$ for $t \geq s$.*

Proof. The proof follows immediately by (3.1). □

We note that the system $(\mathcal{S}_E,\Phi)$ is represented by the boundary control equation

$$\begin{aligned} &\frac{\partial}{\partial t}v(t,\theta) = \frac{\partial}{\partial \theta}v(t,\theta), \quad v(s,\theta) = \zeta(\theta), \quad t \geq s \geq 0, \ -r \leq \theta \leq 0, \\ &v(t,0) = u(t), \end{aligned} \tag{3.3}$$

which has the input segment $u_t,\ t \geq s$, as the state trajectory. Next, we couple (3.3) with the following observation equation:

$$y(t) = P(t)u_t, \qquad t \geq s \geq 0. \tag{3.4}$$

Here the operators $P(t) : C([-r,0],E) \to F$ are defined by

$$P(t)\psi = \int_{-r}^{0} dp(t,\theta)\psi(\theta), \qquad \psi \in C([-r,0],E), \quad t \geq 0, \tag{3.5}$$

where the kernel $p(\cdot,\cdot) : \mathbb{R}_+ \times [-r,0] \to \mathcal{L}(E,F)$ satisfies the following assumption:

(**H**) The function $\mathbb{R}_+ \times [-r,0] \ni (t,\theta) \mapsto p(t,\theta) \in \mathcal{L}(E,F)$ is strongly measurable in θ and strongly continuous in t such that $p(t,\cdot) \in BV([-r,0],\mathcal{L}(E,F))$ with total variation $\mu_p(t,\cdot) := Var(p(t,\cdot))_0^{-r} \leq c_p < +\infty$ for all $t \geq 0$ and $\sup_t \mu_p(t,[-\sigma,0]) \to 0$ as $\sigma \to 0$. Moreover,

$$\int_0^{\alpha} \|p(s+t,\theta'-t) - p(s+t,\theta-t)\|\,dt \leq c'_p|\theta'-\theta|,$$

where $c'_p = c'_p(\alpha_0),\ 0 < \alpha \leq \alpha_0,\ \theta',\theta \in [-r,0]$, and $s \geq 0$.

We already showed (see [12]) that there are examples of $p(\cdot,\cdot)$ for which condition (H) holds. For the sake of completeness we recall the following example.

EXAMPLE 3.2. *Let $q(\cdot,\cdot):\mathbb{R}_+\times[-r,0]\to\mathcal{L}(E,F)$ be strongly continuous in $t\geq 0$ such that $q(t,\cdot):[-r,0]\to\mathcal{L}(E,F)$ is Lipschitzien, $q(t,-r)=0$, and $\|q(t,\cdot)\|_{Lip}\leq c$ for all $t\geq 0$, where $\|\cdot\|_{Lip}$ is the Lipschitzien norm. We set*

$$p(t,\theta):=q(t,\theta)\varrho(\theta),\quad (t,\theta)\in\mathbb{R}_+\times[-r,0],$$

where $\varrho(\cdot)\in BV([-r,0],\mathcal{L}(E,F))$ is such that $Var(\varrho)_{-\tau}^{0}\to 0$ as $\tau\to 0$. Then the kernel $p(\cdot,\cdot)$ satisfies (H).

Since $W^{1,2}([-r,0],E)$ is continuously embedded in $C([-r,0],E)$, then $P(t)\in\mathcal{L}(W^{1,2}([-r,0],E),E)$. Next, we set

$$C_0([-r,0],E):=\{\psi\in C([-r,0],E):\psi(0)=0\}.$$

The following result shows that the linear operators with kernels satisfying the assumption (H) are nonautonomous admissible observation operators for the evolution family $\mathcal{S}_E$. For the proof see [12] (see also the proof of Lemma 3.5 below).

LEMMA 3.3. *Assume that the kernel $p(\cdot,\cdot)$ satisfies* (H). *Then*

$$\int_s^{s+\alpha}\|P(t)\mathcal{S}_X(t,s)\psi\|^2\,dt\leq\gamma\,\|\psi\|_2^2$$

for $0<\alpha\leq r$, $s\geq 0$, $\psi\in C_0([-r,0],E)$, and a constant $\gamma>0$.

Now Lemma 3.3 implies that the maps

$$\Psi(s):C_0([-r,0],E)\to L^2_{loc}([s,\infty),F),\quad \psi\mapsto P(\cdot)\mathcal{S}_E(\cdot,s)\psi,\quad s\geq 0, \tag{3.6}$$

admit unique continuous extensions to $L^2([-r,0],E)$ (which we denote again by $\Psi(s)$). Moreover one can see that $(\mathcal{S}_E,\Psi)$ is a nonautonomous observation system on $L^2([-r,0],E)$, F. Throughout we denote by $\tilde{P}(t)$ the Lebesgue extensions of $P(t)$ with respect to $\mathcal{S}_E$.

Now we are interested in studying the absolute regularity of the boundary linear system formed by (3.3) and (3.4). Before that, we shall give some preliminaries.

LEMMA 3.4. *Let $v:[s-r,\infty)\longrightarrow E$. The following three properties are equivalent:*

(i) $v\in W^{1,2}_{loc}([s-r,\infty),E)$,
(ii) $v_\cdot\in C^1([s,\infty),L^2([-r,0],E))$,
(iii) $v_\cdot\in C([s,\infty),W^{1,2}([-r,0],E))$.

Proof. The proof of this lemma is similar to that given in [3, p. 226], where $E=\mathbb{R}^n$, $n\geq 1$, was considered. □

We will frequently use the following dense spaces in $L^2_{loc}([s,\infty),E)$:

$$\mathcal{C}_s([s,\infty),X):=\{u\in C([s,\infty),E):u(s)=0\},$$
$$W^{1,2}_{s,loc}([s,\infty),E):=\{u\in W^{1,2}_{loc}([s,\infty),E):u(s)=0\}.$$

LEMMA 3.5. *Assume that the kernel $p(\cdot,\cdot)$ satisfies* (H) *and let $s\geq 0$. Then*

(a) *$\Phi(\cdot,s)u\in C([s,\infty),W^{1,2}([-r,0],E))$ for all $u\in W^{1,2}_{s,loc}([s,\infty),E)$.*
(b) *For $u\in\mathcal{C}_s([s,\infty),E)$ we have $\Phi(t,s)u\in C([-r,0],E)$ and*

$$\int_s^{s+\alpha}\|P(t)\Phi(t,s)u\|^2\,dt\leq\kappa\,\|u\|^2_{L^2([s,s+\alpha],E)} \tag{3.7}$$

for $t\geq s$, $0<\alpha<r$, a constant $\kappa>0$.

Proof. We show (a). Let $u \in W^{1,2}_{s,loc}([s,\infty),E)$ and take $\zeta \in D(Q_E)$. Now we define the function $v : [s-r,\infty) \longrightarrow E$ by

$$v(t) = \begin{cases} u(t), & t \geq s, \\ \zeta(t-s), & s-r \leq t < s. \end{cases}$$

Then we have $v \in W^{1,2}_{loc}([s-r,\infty),X)$ and $v_t = \mathcal{S}_E(t,s)\zeta + \Phi(t,s)u$ for $t \geq s$. So that $\Phi(\cdot,s)u \in C([s,\infty),W^{1,2}([-r,0],X))$, due to Lemma 3.4(iii).

We show (b), so we will proceed as in [12]. To this purpose, let $u \in \mathcal{C}_s([s,\infty),E)$ and $0 < \alpha < r$. Clearly, by (3.2), we have $\Phi(t,s)u \in C([-r,0],E)$ for $t \geq s$. Now we have

$$\int_s^{s+\alpha} \|P(t)\Phi(t,s)u\|^2\,dt = \int_0^\alpha \Big\| \int_{-t}^0 dp(t+s,\theta)u(t+s+\theta)\Big\|^2 dt. \tag{3.8}$$

Now we define $\theta_m := -mr/n,\ m = 0,1,\dots,n$, a subdivision of the interval $[-r,0]$. For a fixed $t \in [0,\alpha]$, $D_{\sigma,n} = \{-\theta_0 - t,\dots,-\theta_n - t\}$ is a subdivision of the interval $[-t,-t+\alpha]$, since we have extended $p(t,.)$ by $p(t,0)$, the extra terms on $[0,-t+r]$ are all equal to 0. So, for each fixed σ, we have

$$\int_{-t}^0 dp(s+t,\theta)u(t+s+\theta) = \lim_{n\to\infty} \sum_{m=0}^n \Delta_m(t,s)u(s-\theta_m), \tag{3.9}$$

where we set $\Delta_m(t,s) := p(t+s,-\theta_m - t) - p(t+s,-\theta_{m-1}-t)$. Observe that (H) implies $\sum_{m=0}^n \|\Delta_m(t,s)\| \leq c_p$. Now, due to (3.8), (3.9), Fatou's lemma, and the Cauchy–Schwartz inequality, we get

$$\begin{aligned}
&\int_s^{s+\alpha} \|P(t)\Phi(t,s)u\|^2\,dt \\
&\quad\leq \liminf_{n\to\infty} \int_0^\alpha \left(\sum_{m=0}^n \|\Delta_m(t,s)\|^{\frac12} \|\Delta_m(t,s)\|^{\frac12} \|u(s-\theta_m)\| \right)^2 dt \\
&\quad\leq c_p \liminf_{n\to\infty} \int_0^\alpha \sum_{m=0}^n \|\Delta_m(t,s)\| \|u(s-\theta_m)\|^2\,dt \\
&\quad\leq c_p \liminf_{n\to\infty} \sum_{m=0}^n \|u(s-\theta_m)\|^2 \int_0^\alpha \|\Delta_m(t,s)\|\,dt \\
&\quad\leq c_p\ c_p' \liminf_{n\to\infty} \sum_{m=0}^n \|u(s-\theta_m)\|^2\ |\theta_m - \theta_{m-1}| \\
&\quad\leq c_p c_p' \|u\|^2_{L^2([s,s+\alpha],E)}. \qquad (3.10)
\end{aligned}$$

Thus the lemma follows. □

According to Lemma 3.5 we can now define the following linear operators:

$$\mathbb{F}(s) : \mathcal{C}_s([s,\infty),E) \to L^2_{loc}([s,\infty),F), \quad \mathbb{F}(s)u = P(\cdot)\Phi(\cdot,s)u, \quad s \geq 0. \tag{3.11}$$

Further, by density and (3.7), we extend $\mathbb{F}(s)$ to bounded operators (denoted again by $\mathbb{F}(s)$) from $L^2_{loc}([s,\infty),E)$ to $L^2_{loc}([s,\infty),E)$. Moreover, we have the following main result of this section.

THEOREM 3.6. *Assume that $p(\cdot,\cdot)$ satisfies* (H). *Then $\Sigma = (\mathcal{S}_E, \Phi, \Psi, \mathbb{F})$ is an absolutely regular nonautonomous system on $L^2([-r,0],E), E, F$. Furthermore, if u is the control function of Σ, then the input segment u_t is the state trajectory of Σ which satisfies $u_\bullet \in \mathcal{D}_s(\tilde{P}(\cdot))$ for $s \geq 0$. Moreover, the output function of Σ satisfies the representation $y(t) = \tilde{P}(t)u_t$ for almost every $t \geq s \geq 0$.*

Proof. Let us first show that $\mathbb{F}(s)$ satisfy (2.6). For this let $0 \leq s \leq t \leq \rho$, $u^0 \in \mathcal{C}([s,\infty),E)$, and $u^1 \in \mathcal{C}([t,\infty),E)$ such that $u^0(s) = u^0(t) = u^1(t) = 0$. We now define the function

$$u(\tau) = \begin{cases} u^1(\tau), & t \leq \tau \leq \rho, \\ u^0(\tau), & s \leq \tau \leq t, \end{cases}$$

so that $u \in \mathcal{C}_s([s,\infty),E)$. Now Lemma 3.5 implies that $\Phi(t,s)u^0 \in C_0([-r,0],E)$ and $\Phi(\rho,t)u^1 \in C([-r,0],E)$. Now, by (2.1), (3.6), and (3.11), we obtain

$$\begin{aligned} (\mathbb{F}(s)u)(\rho) &= P(\rho)\Phi(\rho,s)u \\ &= P(\rho)\mathcal{S}_E(\rho,t)\Phi(t,s)u^0 + P(\rho)\Phi(\rho,t)u^1 \\ &= (\Psi(t)\Phi(t,s)u^0)(\rho) + (\mathbb{F}(t)u^1)(\rho). \end{aligned}$$

Then, by density, Σ is a well-posed nonautonomous system on $L^2([-r,0],E), E, F$. Next, we show that Σ is an absolutely regular nonautonomous system. For this we set $u_z(s) = z$ for $z \in E$ and $s \geq 0$. Moreover, let $\varepsilon_n \in C([s,\infty))$ such that $0 \leq \varepsilon_n \leq 1$, $\varepsilon_n(s) = 0$, and $\varepsilon_n(t) = 1$ for $t \geq s + 1/n$, $n \in \mathbb{N}\backslash\{0\}$. We now set $v^n = \varepsilon_n u_z$ for $n \in \mathbb{N}\backslash\{0\}$, so we have $v^n \in \mathcal{C}_s([s,\infty),U)$ and $v^n \to u_z$ in $L^2_{loc}([s,\infty),E)$. Let $0 < t < \inf\{1,r\}$ and $s \geq 0$. Due to (3.11) we get

$$\begin{aligned} \frac{1}{t}\int_s^{s+t} \|(\mathbb{F}(s)u_z)(\tau)\|^2\,d\tau &= \lim_{n\to\infty}\frac{1}{t}\int_s^{s+t}\|(\mathbb{F}(s)v^n)(\tau)\|^2\,d\tau \\ &= \lim_{n\to\infty}\frac{1}{t}\int_s^{s+t}\|P(\tau)\Phi(\tau,s)v^n\|^2\,d\tau \\ &\leq \frac{1}{t}\int_s^{s+t}\left(\int_{s-\tau}^0 d\mu_p(\tau,\theta)\right)^2 d\tau\,\|z\|^2 \\ &\leq \frac{1}{t}\int_s^{s+t}\Big(\mu_p(\tau,[-t,0])\Big)^2 d\tau\,\|z\|^2 \\ &\leq \|z\|^2\left(\sup_{s\leq\tau\leq s+r}\mu_p(\tau,[-t,0])\right)^2. \end{aligned}$$

Consequently, we have the absolute regularity of Σ, due to (H). Finally, the rest of the proof follows by Lemma 3.1 and Theorem 2.3(ii) and (iv). □

COROLLARY 3.7. *Assume that $p(\cdot,\cdot)$ satisfies* (H) *and let $\Sigma = (\mathcal{S}_E, \Phi, \Psi, \mathbb{F})$ be the absolutely regular nonautonomous system obtained in Theorem* 3.6. *If the initial condition $\zeta \in D(Q_E)$ and the control function $u \in W^{1,2}_{s,loc}([s,\infty),E)$, then the output function of Σ satisfies $y(t) = P(t)u_t$ for $t \geq s \geq 0$.*

Proof. Let $\zeta \in D(Q_E)$ and $u \in W^{1,2}_{s,loc}([s,\infty),E)$. Then, by Theorem 2.3(iii), (3.1), (3.6), and (3.11), we get

$$y(t) = (\Psi(s)\zeta)(t) + (\mathbb{F}(s)u)(t) = P(t)(\mathcal{S}_E(t,s)\zeta + \Phi(t,s)u) = P(t)u_t$$

for almost every $t \geq s \geq 0$. □

4. Nonhomogenous delay equations. Let us introduce some basic facts on the existence and regularity of the evolution equations,

$$\text{(CP)} \quad \begin{cases} \dot{x}(t) = A(t)x(t) + f(t), & t > s \geq 0, \\ x(s) = \eta, \end{cases}$$

for linear operators $A(t)$, $t \geq s \geq 0$, on a Banach space X, where $\eta \in X$ and $f \in L^2_{loc}([s,\infty), X)$. The homogenous problem with $f = 0$ is denoted by $(\text{CP})_0$.

Among various types of solutions x of (CP) we consider the following one.

DEFINITION 4.1. *A classical solution of* (CP) *is a function* $x \in W^{1,2}_{loc}([s,\infty), X)$ *such that* $x(t) \in D(A(t))$ *for* $t > s$ *and* (CP) *holds.*

Contrary to the autonomous case, the solvability of (CP) in the classical sense requires additional conditions on $A(t)$ (see, e.g., [2], [20], [24], [27] and the references therein). Here in the current paper we restrict ourselves to a class of parabolic equations, namely, those introduced by Aquistapace and Terreni [2]. We assume that

(AT1) $A(t)$, $t \geq 0$, are linear operators on a Banach space X with dense domains $D(A(t))$ and there are constants $\beta \geq 0$, $w \in \mathbb{R}$, and $\phi \in (\pi/2, \pi)$ such that $\lambda \in \rho(A(t))$ and $\|R(\lambda, A(t))\| \leq \beta(1+|\lambda - w|)^{-1}$ for $\lambda \in \Sigma(\phi, w)$ and $t \geq s \geq 0$.

(AT2) There are constants $\kappa \geq 0$ and $\mu, \nu \in (0,1]$ with $\mu + \nu > 1$ such that

$$|\lambda|^\nu \|A_w(t)R(\lambda, A_w(t))(A_w(t)^{-1} - A_w(t')^{-1})\| \leq \kappa |t - t'|^\mu$$

for $A_w(t) := A(t) - w$, $t, t' \geq s \geq 0$, and $|\arg \lambda| \leq \phi$.

Here we set $\Sigma(\phi, w) = \{w\} \cup \{\lambda \in \mathbb{C} \backslash \{w\} : |\arg(\lambda - w)| \leq \phi\}$. If (AT1) and (AT2) hold, then we say that (AT) is satisfied and (CP) is a *parabolic equation.*

Let us recall (see, e.g., Tanabe [24]) that if $D(A(t))$ do not depend on t, it suffices to suppose that $A(\cdot) : [0, t_0] \to \mathcal{L}(Z, X)$ is Hölder continuous, where $Y := D(A(0))$ is endowed with the graph norm.

THEOREM 4.2. *Assume that* (AT) *holds. Then there is a strongly continuous evolution family* $T := (T(t,s))_{t \geq s \geq 0}$ *on* X *such that* $T(t,s)X \subseteq D(A(t))$ *for* $t > s$.

If $A(t)$ satisfy (AT), the $(\text{CP})_0$ has a unique classical solution $x = T(\cdot, s)\eta$ for $\eta \in X$. We say that T solves $(\text{CP})_0$ or $A(t)$ generate T.

Let (AT) be satisfied. According to [1, Props. 3.2, 5.1], if x is a classical solution of (CP), then it is given by

$$x(t) = T(t,s)\eta + \int_s^t T(t,\sigma) f(\sigma)\, d\sigma, \qquad t \geq s \geq 0. \tag{4.1}$$

A function $x : [s,\infty) \to X$ satisfying (4.1) is called the *mild solution* of (CP).

Finally, we mention the important case of the *hyperbolic equations* studied by Kato [19], that is, if $A(t)$ are the generators of contraction semigroups satisfying $D(A(t)) \equiv Z$ and $A(\cdot)\eta \in C^1(\mathbb{R}_+, X)$ for $\eta \in X$. Then $(\text{CP})_0$ is well posed. (See also [20] for a more general version.)

The perturbation problem of $(\text{CP})_0$ by nonautonomous bounded perturbations is studied in [22, p. 129]. We note that the well-posedness of $(\text{CP})_0$ is not persisted even by bounded perturbations $B(\cdot) \in C_b(\mathbb{R}_+, \mathcal{L}(X))$ (see [21, Ex. 4.1.7]).

In what follows, we are concerned with the notion of perturbed evolution families rather than that of perturbed evolution equations involving concrete differential operators.

PROPOSITION 4.3. *Let* $B(t) : D(B(t)) \to X$ *be nonautonomous admissible observation operators for the strongly continuous evolution family* T *on* X. *Let* $\tilde{B}(t)$ *be the Lebesgue extensions of* $B(t)$ *with respect to* T. *The following assertions hold:*

(i) *There is a unique evolution family V on X such that $V(\cdot,s)\eta \in \mathcal{D}_s(\tilde{B}(\cdot))$, and*

$$\begin{aligned} &\|\tilde{B}(\cdot)V(\cdot,s)x\|_{L^2([s,s+t_0],X)} \le \gamma\,\|\eta\|, \\ &V(\cdot,s)\eta = T(\cdot,s)\eta + \mathbb{K}_s^T\tilde{B}(\cdot)V(\cdot,s)\eta \end{aligned} \tag{4.2}$$

for $s \ge 0,\ t_0 > 0,\ \eta \in X$ and a constant $\gamma = \gamma(t_0) > 0$.

(ii) *Let $C(t) : D(C(t)) \to Y$ be nonautonomous admissible observation operators for T. For any $s \ge 0,\ \eta \in X$, and $f \in L^2_{loc}([s,\infty),X)$ we have*

$$V(\cdot,s)\eta,\ \mathbb{K}_s^V f \in \mathcal{D}_s(\tilde{C}(\cdot)), \tag{4.3}$$

$$\|\tilde{C}(\cdot)\mathbb{K}_s^V f\|_{L^2([s,s+t_0],Y)} \le c t_0^{1/2}\|f\|_{L^2([s,s+t_0],X)} \tag{4.4}$$

for some constants $t_0 > 0$ and $c = c(t_0) > 0$ independent of f and s.

Proof. The assertion (i) can be obtained by [26, Rem. 4.6(a)]. Now we prove (ii). Let $s \ge 0,\ \eta \in X$, and $f \in L^2_{loc}([s,\infty),X)$. The fact that $V(\cdot,s)\eta \in \mathcal{D}_s(\tilde{C}(\cdot))$ is due to Theorem 2.1, Proposition 2.2, and (4.2). Due to (i) above, the function $[s,s+t_0]\times[s,s+t_0] \ni (t,\sigma) \mapsto \tilde{B}(\tau)V(\tau,\sigma)f(\sigma)$ is measurable for f in the subspaces

$$\mathfrak{F}_s = \operatorname{span}\{\xi(\cdot)V(\cdot,\sigma)x : x \in X,\ \sigma \ge s,\ \xi \in C_c(\mathbb{R}_+),\ \xi(t) = 0 \text{ for } s \le t \le \sigma\}.$$

Thus, by density it is measurable for $f \in L^2_{loc}([s,\infty),X)$ (the density of $\mathfrak{F}_s$ is proved in [4, Thm. 3.12]), where $C_c(\mathbb{R}_+)$ is the space of continuous functions with compact support in $[0,\infty)$. Fubini–Tonelli's theorem and (4.2) imply that

$$\begin{aligned} \int_s^{s+t_0}\int_s^t \|\tilde{B}(t)V(t,\sigma)f(\sigma)\|^2 d\sigma\,dt &= \int_s^{s+t_0}\int_\sigma^{s+t_0} \|\tilde{B}(t)V(t,\sigma)f(\sigma)\|^2 dt\,d\sigma \\ &\le \gamma^2\|f\|^2_{L^p([s,s+t_0],X)}. \end{aligned} \tag{4.5}$$

Now we define the function $g_s(t) := \int_s^t \tilde{B}(t)V(t,\sigma)f(\sigma)\,d\sigma$ for $t \ge s \ge 0$. Using Hölder's inequality, Fubini's theorem, and (4.5) we get

$$\begin{aligned} \int_s^{s+t_0} \|g_s(\tau)\|^2\,d\tau &\le t_0\int_s^{s+t_0}\int_s^\tau \|\tilde{B}(\tau)V(\tau,\sigma)f(\sigma)\|^2\,d\sigma\,dt \\ &\le t_0\gamma^2\|f\|^2_{L^2([s,s+t_0],X)}. \end{aligned} \tag{4.6}$$

On the other hand, by (4.2) and Fubini's theorem, we obtain

$$\begin{aligned} (\mathbb{K}_s^V f)(t) &= (\mathbb{K}_s^T f)(t) + \int_s^t\int_\sigma^t T(t,\tau)\tilde{B}(\tau)V(\tau,\sigma)f(\sigma)\,d\tau\,d\sigma \\ &= (\mathbb{K}_s^T f)(t) + \int_s^t T(t,\tau)\int_s^\tau \tilde{B}(\tau)V(\tau,\sigma)f(\sigma)\,d\sigma\,d\tau \\ &= (\mathbb{K}_s^T(f+g_s))(t) \end{aligned}$$

for $t \ge s \ge 0$. Thus, the rest of the proof now follows from (4.6) and Proposition 2.2. □

Let V be the evolution family obtained in Proposition 4.3. Let $s \ge 0$ and $f \in L^2_{loc}([s,\infty),X)$. We are looking for functions $x : [s,\infty) \to X$ satisfying

$$x(t) = V(t,s)\eta + \int_s^t V(t,\sigma)f(\sigma)\,d\sigma, \qquad t \ge s. \tag{4.7}$$

We need the following lemma.

LEMMA 4.4. *Let T be a strongly continuous evolution family on X. Let $B(t) : D(B(t)) \subseteq X \to X$ be nonautonomous admissible observation operators for T. Let $\tilde{B}(t)$ be the Lebesgue extensions of $B(t)$ with respect to T. Then*

$$\tilde{B}(t)(\mathbb{K}_s^V f)(t) = \int_s^t \tilde{B}(t)V(t,\sigma)f(\sigma)\,d\sigma$$

for a.e. $t \geq s$ and all $f \in \mathcal{C}_s([s,\infty),X)$, where V is the strongly continuous evolution family satisfying (4.2).

Proof. Due to Proposition 4.3(i) one defines $\Psi'(s)\eta = \tilde{B}(\cdot)V(\cdot,s)\eta$ for $\eta \in X$ and $s \geq 0$. Then (V,Ψ') is a nonautonomous observation system. Now we define

$$\tilde{B}_n(s)\eta = n\int_s^{s+\frac{1}{n}} (\Psi'(s)\eta)(\sigma)\,d\sigma$$

for $\eta \in X$, $s \geq 0$, and $n \in \mathbb{N}\backslash\{0\}$, so we have $B_n(s) \in \mathcal{L}(X)$. Next we take $f \in \mathcal{C}_s([s,\infty),X)$ for $s \geq 0$. The function $\rho \ni [0,t_0] \mapsto B_n(\cdot)V(\cdot,\rho)f(\rho) - \Psi'(\rho)f(\rho)$ is measurable, due to [26, Lem. 2.8]. On the other hand, for $t_0 > 0$ and $s \geq 0$, we have

$$\begin{aligned}
&\left\| B_n(\cdot)\mathbb{K}_s^V f - \int_s^{\cdot} [\Psi'(\rho)f(\rho)](\cdot)\,d\rho \right\|^2_{L^2([s,s+t_0],X)} \\
&\qquad \leq \int_s^{s+t_0} \left(\int_s^{\sigma} \|B_n(\sigma)V(\sigma,\rho)f(\rho) - [\Psi'(\rho)f(\rho)](\sigma)\| d\rho \right)^2 d\sigma \\
&\qquad \leq t_0^{\frac{1}{2}} \int_s^{s+t_0} \int_\rho^{\rho+t_0} \|B_n(\sigma)V(\sigma,\rho)f(\rho) - [\Psi'(\rho)f(\rho)](\sigma)\|^2 d\sigma d\rho \\
&\qquad := t_0^{\frac{1}{2}} \int_s^{s+t_0} h_{n,f}(\rho)\,d\rho, \qquad (4.8)
\end{aligned}$$

due to Hölder's inequality and Fubini's theorem, where we set

$$h_{n,f}(\rho) := \int_\rho^{\rho+t_0} \|B_n(\sigma)V(\sigma,\rho)f(\rho) - [\Psi'(\rho)f(\rho)](\sigma)\|^2 d\sigma, \quad s+t_0 \geq \rho \geq s,\ n \geq 1.$$

It can be verified (see the proof of [26, Lem. 2.9]) that $h_{n,f}(\rho) \leq c\|f(\rho)\|$ for $s \leq \rho \leq s+t_0$, $n \geq 1$, and a constant $c = c(t_0) > 0$, so $h_{n,f} \in L^2_{loc}([s,\infty))$. Now, for $f \in \mathfrak{F}_s$ one can see that $h_{n,f}(\rho) \to 0$ as $n \to \infty$ for $s \leq \rho \leq s+t_0$, due to [26, Lem. 2.9]. We now approximate f by $f_m \in \mathfrak{F}_s$ in $L^2_{loc}([s,\infty),X)$, so we have $f_{\phi(m)}(\rho) \to f(\rho)$ in X as $m \to \infty$ for a.e. $\rho \geq s$. Then

$$\begin{aligned}
h_{n,f}(\rho) &\leq \|B_n(\cdot)V(\cdot,\rho)(f(\rho) - f_{\phi(m)}(\rho))\|^2_{L^2([\rho,\rho+t_0],X)} \\
&\qquad + h_{n,f_{\phi(m)}} + \|\Psi'(\rho)(f(\rho) - f_{\phi(m)}(\rho))\|^2_{L^2([\rho,\rho+t_0])} \\
&\leq \delta\,\|f(\rho) - f_{\phi(m)}(\rho)\|^2_X + h_{n,f_{\phi(m)}}
\end{aligned}$$

for a.e. $s \leq \rho \leq s+t_0$ and a constant $\delta = \delta(t_0) > 0$, due to the proof of [26, Lem. 2.9]. Then

$$\lim_{n\to\infty} h_{n,f}(\rho) \leq \delta\,\|f(\rho) - f_{\phi(m)}(\rho)\|^2_X$$

for a.e. $s \leq \rho \leq s+t_0$. Now by letting $m \to \infty$ in the estimate above we obtain that $h_{n,f}(\rho) \to 0$ as $n \to \infty$. Lebesgue's dominated convergence theorem and (4.8) now

imply

$$\int_s^t [\Psi'(\sigma)f(\sigma)](t)\,d\sigma = \lim_{n\to\infty} B_{\phi(n)}(t)\mathbb{K}_s^V f = \tilde{B}(t)(\mathbb{K}^V f)(t)$$

for a.e. $t \geq s$, due to [26, Lem. 2.10]. □

THEOREM 4.5. *Assume that* (AT) *holds. Let T be the strongly continuous evolution family generated by $A(t)$. Let $B(t) : D(B(t)) \to X$ be nonautonomous admissible observation operators for T. Let $\tilde{B}(t)$ the Lebesgue extensions of $B(t)$ with respect to T. Finally, let $f \in L^2_{loc}([s,\infty), X)$, $s \geq 0$. Then the function x given by* (4.7) *satisfies $x \in \mathcal{D}_s(\tilde{B}(\cdot))$ and*

$$x(t) = T(t,s)\eta + \int_s^t T(t,\sigma)\Big[\tilde{B}(\sigma)x(\sigma) + f(\sigma)\Big]\,d\sigma, \qquad t \geq 0. \tag{4.9}$$

Proof. Let $x : [s,\infty) \to X$ be the function given by (4.7) corresponding to $\eta \in X$ and $f \in L^2_{loc}([s,\infty), X)$. Then $x \in \mathcal{D}_s(\tilde{B}(\cdot))$, due to (4.3). We now approximate f by a sequence f^n in $\mathcal{C}_s([s,\infty), X)$ and let $x^n : [s,\infty) \to X$ be the solution of (4.7) corresponding to η and f^n. Then, due to Hölder's inequality and (4.7), we obtain $x^n \to x$ in $L^2_{loc}([s,\infty), X)$. Moreover, by (4.2), (4.7), Fubini's theorem, and Lemma 4.4, we have

$$\begin{aligned}
x^n(t) &= T(t,s)\eta + \int_s^t T(t,\sigma)f(\sigma)\,d\sigma + \int_s^t T(t,\sigma)\tilde{B}(\sigma)V(\sigma,s)\eta\,d\sigma \\
&\qquad + \int_s^t \int_\sigma^t T(t,\tau)\tilde{B}(\tau)V(\tau,\sigma)f^n(\sigma)\,d\tau\,d\sigma \\
&= T(t,s)\eta + \int_s^t T(t,\sigma)f^n(\sigma)\,d\sigma + \int_s^t T(t,\sigma)\tilde{B}(\sigma)V(\sigma,s)\eta\,d\sigma \\
&\qquad + \int_s^t T(t,\tau)\int_s^\tau \tilde{B}(\tau)V(\tau,\sigma)f^n(\sigma)\,d\sigma\,d\tau \\
&= T(t,s)\eta + \int_s^t T(t,\sigma)\Big[\tilde{B}(\sigma)x^n(\sigma) + f^n(\sigma)\Big]\,d\sigma \qquad (4.10)
\end{aligned}$$

for $t \geq s \geq 0$. Let us denote by $v(t)$ the right-hand side of (4.9), so using again Hölder's inequality and (4.10) we get $x^n \to v$. Thus $x = v$ by uniqueness and continuity. □

In the remainder of this section we study mild solutions of the nonhomogenous delay equation (1.1). We assume that the state delay operators $L(t) : C([-r,0], X) \to X$ are defined by

$$L(t)f = \int_{-r}^0 d\ell(t,\theta)f(\theta), \quad f \in C([-r,0], X),\ t \geq 0, \tag{4.11}$$

where the kernel $\ell(\cdot,\cdot)$ satisfies (H).

At first we assume that the initial conditions $\eta \in X$ and $\varphi \in C([-r,0], X)$ are such that $\eta = \varphi(0)$. In this case, a *mild solution* of (1.1) is a function $x \in C([s-r,\infty), X)$ such that

$$\begin{aligned}
x(t) &= T(t,s)\eta + \int_s^t T(t,\sigma)\Big[L(\sigma)x_\sigma + f(\sigma)\Big]\,d\sigma, \quad t \geq s \geq 0, \\
x(s+\theta) &= \varphi(\theta), \quad -r \leq \theta \leq 0.
\end{aligned} \tag{4.12}$$

Next, we want to solve (1.1) for the initial condition $\binom{\eta}{\varphi}$ in the Banach space $\mathcal{X}_0 := X \times L^2([-r,0],X)$ endowed with the norm $\|\binom{\eta}{\varphi}\| = \|x\| + \|\varphi\|_2$. To this purpose, we consider the family $\mathcal{T} := (\mathcal{T}(t,s))_{t\geq 0}$ of bounded linear operators on $\mathcal{X}_0$ defined by

$$\mathcal{T}(t,s) := \begin{pmatrix} T(t,s) & 0 \\ T_{t,s} & \mathcal{S}_X(t,s) \end{pmatrix}, \quad t \geq s \geq 0, \tag{4.13}$$

where $(T_{t,s}\eta)(\theta) := T(t+\theta,s)\eta$ for $t+\theta \geq s$ and zero if not, for $\eta \in X$, $t \geq s \geq 0$, $\theta \in [-r,0]$. Clearly, $\mathcal{T}$ is a strongly continuous evolution family on $\mathcal{X}_0$.

In the sequel we need the subspace

$$\mathfrak{D} := \Big\{ \binom{\eta}{\varphi} \in X \times C([-r,0],X) : \varphi(0) = \eta \Big\},$$

which is dense in $\mathcal{X}_0$. Moreover, we consider the linear operators

$$\mathfrak{B}(t) := \begin{pmatrix} 0 & L(t) \\ 0 & 0 \end{pmatrix}, \qquad D(\mathfrak{B}(t)) := \mathfrak{D}, \quad t \geq 0.$$

As shown in [12], Lemma 3.3 implies that $\mathfrak{B}(t)$ are nonautonomous admissible observation operators for $\mathcal{T}$. Throughout we denote by $\tilde{\mathfrak{B}}(t)$ the Lebesgue extensions of $\mathfrak{B}(t)$ with respect to $\mathcal{T}$. So, due to Proposition 4.3, there exists a unique strongly continuous evolution family $\mathcal{T}_L := (\mathcal{T}_L(t,s))_{t\geq s\geq 0}$ on $\mathcal{X}_0$ satisfying

$$\mathcal{T}_L(\cdot,s)\binom{\eta}{\varphi} \in \mathcal{D}_s(\tilde{\mathfrak{B}}(\cdot)), \tag{4.14}$$

$$\mathcal{T}_L(\cdot,s)\binom{\eta}{\varphi} = \mathcal{T}(\cdot,s)\binom{\eta}{\varphi} + \mathbb{K}_s^{\mathcal{T}}\tilde{\mathfrak{B}}(\cdot)\mathcal{T}_L(\cdot,s)\binom{\eta}{\varphi} \tag{4.15}$$

for $\binom{\eta}{\varphi} \in \mathcal{X}_0$ and $s \geq 0$. We note that $\mathcal{T}_L$ solves the homogenous delay equation associated to (1.1) (i.e., when $f = 0$); see [12] for more details.

Next, we are looking for functions $w : [s,\infty) \to \mathcal{X}_0$ satisfying

$$w(t) = \mathcal{T}_L(t,s)\binom{\eta}{\varphi} + \int_s^t \mathcal{T}_L(t,\sigma)\binom{f(\sigma)}{0}\,d\sigma \tag{4.16}$$

for $t \geq s \geq 0$, $\binom{\eta}{\varphi} \in \mathcal{X}_0$, and $f \in L^2_{loc}([s,\infty),X)$.

Due to Theorem 4.5, the function w given by (4.16) satisfies $w \in \mathcal{D}_s(\tilde{\mathfrak{B}}(\cdot))$ and

$$w(t) = \mathcal{T}(t)\binom{\eta}{\varphi} + \int_s^t \mathcal{T}(t,\sigma)\Big[\tilde{\mathfrak{B}}(\sigma)w(\sigma) + \binom{f(\sigma)}{0}\Big]\,d\sigma \tag{4.17}$$

for $t \geq s \geq 0$ and $\binom{\eta}{\varphi} \in \mathcal{X}_0$.

In view of (4.13) and (4.17), the function w can be computed explicitly if we know the expressions of the Lebesgue extensions $\tilde{\mathfrak{B}}(t)$. In what follows, we will see that the expression of $\tilde{\mathfrak{B}}(t)$ depends on $\tilde{L}(t)$, the Lebesgue extension of $L(t)$ with respect to $\mathcal{S}_X$. Before showing this we have to prove the following lemma.

LEMMA 4.6. *Assume that the kernel $\ell(\cdot,\cdot)$ satisfies* (H). *Let $\eta \in X$ and set $\psi(\theta) := \eta$ for all $\theta \in [-r,0]$. Then $\psi \in D(\tilde{L}(s))$ and $\tilde{L}(s)\psi = L(s)\psi$ for all $s \geq 0$.*

Proof. Let $s \geq 0$, $\eta \in X$, and let $(\mathcal{S}_X, \Psi_L)$ be the nonautonomous observation system associated to $L(t)$. Let the sequence $\alpha_n \in C([-r,0])$ such that $0 \leq \alpha_n \leq 1$, $\alpha_n(0) = 0$ and $\alpha_n(\theta) = 1$ for $-r \leq \theta \leq -\frac{r}{n}$. Now we set $\psi^n = \alpha_n\psi$, so that $\psi^n \to \psi$

in $L^2([-r,0],X)$ as $n\to\infty$, $\psi^n\in C_0([-r,0],X)$ and $\Psi_L(s)\psi^n = L(\cdot)\mathcal{S}_X(\cdot,s)\psi^n$. Next, we take $0<\frac{r}{n}\le t\le\frac{r}{2}$ for $n\ge 3$. Then

$$\begin{aligned}\frac{1}{t}\int_s^{s+t}(\Psi_L(s)\psi)(\tau)\,d\tau - L(s)\psi \\ = \frac{1}{t}\int_s^{s+t}[\Psi_L(s)(\psi-\psi^n)](\tau)\,d\tau + \frac{1}{t}\int_s^{s+t}L(\tau)(\mathcal{S}_X(\tau,s)\psi^n-\psi)\,d\tau \\ + \frac{1}{t}\int_s^{s+t}[L(\tau)\psi - L(s)\psi]\,d\tau. \qquad (4.18)\end{aligned}$$

First, by Hölder's inequality,

$$\Big\|\frac{1}{t}\int_s^{s+t}[\Psi_L(s)\psi-\psi^n](\tau)\,d\tau\Big\| \le \frac{\gamma}{\sqrt{t}}\|\psi^n-\psi\|_2 \underset{n\to\infty}{\longrightarrow} 0.$$

Second, by the strong continuity of $(L(\tau))_{\tau\ge s}$,

$$\lim_{t\searrow 0}\frac{1}{t}\int_s^{s+t}[L(\tau)\psi - L(s)\psi]\,d\tau = 0.$$

Further,

$$\begin{aligned}\frac{1}{t}\int_s^{s+t}L(\tau)[\mathcal{S}_X(\tau,s)\psi^n-\psi]\,d\tau &= \frac{1}{t}\int_0^t\int_{-r}^{-\sigma}d\ell(s+\sigma,\theta)[\psi^n(\sigma+\theta)-\psi(\theta)]]\,d\sigma \\ &= \frac{1}{t}\int_0^t\int_{-\frac{r}{n}-\sigma}^{-\sigma}d\ell(s+\sigma,\theta)[\psi^n(\sigma+\theta)-\psi(\theta)]\,d\sigma,\end{aligned}$$

which implies that

$$\begin{aligned}\Big\|\frac{1}{t}\int_s^{s+t}L(\tau)[\mathcal{S}_X(\tau,s)\psi^n-\psi]\,d\tau\Big\| &\le 2\|\eta\|\frac{1}{t}\int_0^t\mu_\ell\Big(s+\sigma,\Big[-\frac{r}{n}-\sigma,-\sigma\Big]\Big)\,d\sigma \\ &\le 2\|\eta\|\sup_{0\le\sigma\le r}\mu_\ell(s+\sigma,[-2t,0])\to 0;\ (\text{as } t\searrow 0),\end{aligned}$$

due to (H). Thus the lemma now follows by taking the limits, first $n\to\infty$ and second $t\searrow 0$, in both sides of (4.18). □

Let us define $\Psi_{\mathfrak{B}}(s)\binom{\eta}{\varphi} = \mathfrak{B}(\cdot)\mathcal{T}(\cdot,s)\binom{\eta}{\varphi}$ for $\binom{\eta}{\varphi}\in\mathfrak{D}$ and $s\ge 0$. Then $(\mathcal{T},\Psi_{\mathfrak{B}})$ is a nonautonomous observation system. Moreover, by density of $\mathfrak{D}$ in $\mathcal{X}_0$, Hölder's inequality, and (4.13) one can see that

$$\begin{aligned}\frac{1}{t}\int_s^{s+t}\Big[\Psi_{\mathfrak{B}}(s)\binom{\eta}{\varphi}\Big](\tau)\,d\tau = \frac{1}{t}\int_s^{s+t}\binom{(\Psi_L(s)\varphi)(\tau)}{0}d\tau - \frac{1}{t}\int_s^{s+t}\binom{(\Psi_L(s)\psi)(\tau)}{0}d\tau \\ + \frac{1}{t}\int_s^{s+t}[\Psi_{\mathfrak{B}}(s)\binom{\eta}{\psi}](\tau)\,d\tau \qquad (4.19)\end{aligned}$$

for all $\binom{\eta}{\varphi}\in\mathcal{X}_0$, where we set $\psi(\theta)=\eta$.

LEMMA 4.7. *Let* (AT) *be holds and the kernel* $\ell(\cdot,\cdot)$ *satisfies* (H). *Then*

$$D(\tilde{\mathfrak{B}}(s)) = X\times D(\tilde{L}(s)) \quad \textit{and} \quad \tilde{\mathfrak{B}}(s) = \begin{pmatrix}0 & \tilde{L}(s)\\ 0 & 0\end{pmatrix}, \qquad s\ge 0.$$

Proof. The proof follows immediately by Lemma 4.6, (4.19), and the strong continuity of $\mathfrak{B}(t)$. □

The following theorem follows by (4.17) and Lemma 4.7.

THEOREM 4.8. *Assume that* (AT) *holds and* $\ell(\cdot,\cdot)$ *satisfies* (H). *Then the function* $w:[s,\infty)\to\mathcal{X}_0$ *given by* (4.16) *satisfies*

$$\begin{pmatrix} x(t)\\ x_t\end{pmatrix}=\mathcal{T}_L(t,s)\begin{pmatrix}\eta\\ \varphi\end{pmatrix}+\int_s^t\mathcal{T}_L(t,\sigma)\begin{pmatrix} f(\sigma)\\ 0\end{pmatrix}d\sigma \tag{4.20}$$

for $t\ge s\ge 0$ *and* $\begin{pmatrix}\eta\\ \varphi\end{pmatrix}\in\mathcal{X}_0$, *where the function* $x:[s-r,\infty)\to X$ *satisfies* $x_\cdot\in\mathcal{D}_s(\tilde{L}(\cdot))$ *and* (1.2).

The following result shows the relationship between the formulas (1.2) and (4.12).

PROPOSITION 4.9. *Assume that* (AT) *holds and* $\ell(\cdot,\cdot)$ *satisfies* (H). *Let the initial condition* $\begin{pmatrix}\eta\\ \varphi\end{pmatrix}\in\mathfrak{D}$. *Then the formulas given by* (1.2) *and* (4.12) *coincide.*

Proof. We first take $h\in C([-r,0],X)$ and $s\ge 0$. Due to the strong continuity of the family $(\mathfrak{B}(t))_{t\ge 0}$ one can see that $\tilde{\mathfrak{B}}(s)(h(0),h)^\top=\mathfrak{B}(s)(h(0),h)^\top$. Thus by Lemma 4.7, we obtain

$$L(s)h=\tilde{L}(s)h\quad\text{for}\quad h\in C([-r,0],X)\cap D(\tilde{L}(s)). \tag{4.21}$$

Let now the initial condition $\begin{pmatrix}\eta\\ \varphi\end{pmatrix}\in\mathfrak{D}$ and let x be the corresponding mild solution of (1.1). Then $(x(t),x_t)\in\mathfrak{D}$ for $t\ge s\ge 0$. Since by Theorem 4.8 we have $x_t\in D(\tilde{L}(t))$ for a.e. $t\ge s$, then $L(t)x_t=\tilde{L}(t)x_t$ for a.e. $t\ge 0$, due to (4.21). The proposition now follows by (1.2). □

In view of Theorem 4.8 and Proposition 4.9 we introduce the following definition.

DEFINITION 4.10. *Let* $s\ge 0$, $\begin{pmatrix}x\\ \varphi\end{pmatrix}\in\mathcal{X}_0$ *and* $f\in L^2_{loc}([s,\infty),X)$. *A continuous function* $x(\cdot):[s-r,\infty)\to X$ *is called a mild solution of* (1.1) *if* $x_\cdot\in\mathcal{D}_s(\tilde{L}(\cdot))$ *and satisfies* (1.2).

5. Nonautonomous linear systems with delays in the state, control, and observation variables. In this section we want to reformulate the delay system formed by (1.3) and (1.4) as an absolutely regular nonautonomous system.

Let us first prove the existence of a variation of constants formula for the delayed control equation (1.3). This formula will helps us to prove that (1.3) determines a nonautonomous control system.

As the kernel $k(\cdot,\cdot)$ satisfies (H), then $K(t)$ are nonautonomous admissible observation operators for $\mathcal{S}_U$. We then denote by $\tilde{K}(t)$ the Lebesgue extensions of $K(t)$ with respect to $\mathcal{S}_U$. Moreover, due to Theorem 3.6, $K(t)$ define an absolutely regular nonautonomous system on $L^2([-r,0],U),U,X$, which we denote throughout by $\Sigma_K:=(\mathcal{S}_U,\Phi,\Psi_K,\mathbb{F}_K)$. Note that the input segment u_t is the state trajectory of Σ_K. Then we have $u_\cdot\in\mathcal{D}_s(\tilde{K}(\cdot))$, due to Theorem 3.6.

The following proposition shows the existence of the mild solution of (1.3) in the case of smooth input u.

PROPOSITION 5.1. *Let* (AT) *be verified and assume that the kernels* $\ell(\cdot,\cdot)$ *and* $k(\cdot,\cdot)$ *satisfy* (H). *Let the initial condition* $\begin{pmatrix}\eta\\ \varphi\end{pmatrix}\in\mathcal{X}_0$. *If the input* u *is smooth, i.e.,* $u\in W^{1,2}_{loc}([s-r,\infty),U)$ *is such that* $u(s)=0$, *then* $u_t\in W^{1,2}([-r,0],U)$, $t\ge s\ge 0$, *and the function* $t\mapsto K(t)u_t$ *belongs to* $L^2_{loc}([s,\infty),U)$. *In particular, the equation* (1.3) *has a mild solution given by*

$$x(t)=T(t,s)\eta+\int_s^t T(t,\tau)[\tilde{L}(\tau)x_\tau+K(\tau)u_\tau]\,d\tau,\quad t\ge s. \tag{5.1}$$

If in addition $\binom{\eta}{\varphi} \in \mathfrak{D}$, *then this mild solution also satisfies*

$$\begin{aligned} x(t) &= T(t,s)\eta + \int_s^t T(t,\tau)\Big[L(\tau)x_\tau + K(\tau)u_\tau\Big]\,d\tau, \quad t \geq s \geq 0, \\ x(s+\theta) &= \varphi(\theta), \quad -r \leq \theta \leq 0. \end{aligned} \tag{5.2}$$

Proof. Let $\binom{\eta}{\varphi} \in \mathcal{X}_0$ and u be a smooth input, so $u_s = \zeta \in D(Q_U)$. Since $u_t = \mathcal{S}_U(t,s)\zeta + \Phi(t,s)u$ for $t \geq s \geq 0$, then by Lemma 3.5(a) we have $u_t \in W^{1,2}([-r,0],U)$, $t \geq s$. Now due to Corollary 3.7 we have $f(t) := K(t)u_t = \tilde{K}(t)u_t$ for a.e. $t \geq s$, which belongs to $L^2_{loc}([s,\infty),U)$. Thus the rest of the proof follows by Theorem 4.8 and Proposition 4.9. □

Let us now deal with with the solution of (1.3) for general input u.

THEOREM 5.2. *Let* (AT) *be verified and assume that the kernels* $\ell(\cdot,\cdot)$ *and* $k(\cdot,\cdot)$ *satisfy* (H). *Let the initial conditions* $\binom{\eta}{\varphi} \in \mathcal{X}_0$ *and* $\zeta \in L^2([-r,0],U)$. *For* $u \in L^2_{loc}[s-r,\infty),U)$ *there exists a squence of mild solutions* $x^n : [s-r,\infty) \to X$ *of* (1.3) *such that* $x^n \to x$ *in* $L^2_{loc}([s-r,\infty),X)$, *as* $n \to \infty$, *where* $x : [s-r,\infty) \to X$ *is the function satisfying* $x_\cdot \in \mathcal{D}_s(\tilde{L}(\cdot))$ *and*

$$\begin{aligned} x(t) &= T(t,s)\eta + \int_s^t T(t,\tau)[\tilde{L}(\tau)x_\tau + \tilde{K}(\tau)u_\tau]\,d\tau, \qquad t \geq s \geq 0. \\ x(t) &= \varphi(t-s), \qquad \text{a.e.} \quad t \leq s. \end{aligned} \tag{5.3}$$

Proof. Let $\binom{\eta}{\varphi} \in \mathcal{X}_0$ and $\zeta \in L^2([-r,0],U)$. Let us approximate the input $u \in L^2_{loc}[s-r,\infty),U)$ by a sequence of smooth inputs $u^n \in W^{1,2}_{loc}([s-r,\infty),U)$ such that $u^n(s) = 0$, so $\zeta^n := u^n_s \to \zeta$ in $L^2([-r,0],U)$ as $n \to \infty$. We set $f^n(t) := K(t)u^n_t$ for $t \geq s$ and let $x^n : [s-r,\infty) \to X$ with $x^n(s) = \eta$ and $x^n_s = \varphi$ be the mild solution of (1.3) corresponding to u^n and f^n, due to Proposition 5.1. By Theorem 4.8, the function $w^n(t) = (x^n(t), x^n_t)$ satisfies (4.20). Next, we set $f(t) := \tilde{K}(t)u_t$ for a.e. $t \geq s$, (which belongs to $L^2_{loc}([s,\infty),U)$) and let x be the function defined by (5.3). Thus, by Theorem 4.8, the function $w(t) = (x(t), x_t)^\top$ satisfies (4.20). We now claim that $x^n \to x$ in $L^2_{loc}([s,\infty),X)$ as $n \to \infty$. By using Theorem 2.3(iii), Theorem 3.6, and Corollary 3.7, we obtain $f^n \to f$ in $L^2_{loc}([s,\infty),U)$. Thus, Hölder's inequality and (4.20) imply that $w^n \to w$ in $L^2_{loc}([s,\infty),\mathcal{X}_0)$. In particular, $x^n \to x$ in $L^2_{loc}([s,\infty),X)$ and $x^{\phi(n)}_t \to x_t$ in $L^2([-r,0],X)$ for a.e. $t \in [s,s+t_0]$ as $n \to \infty$. □

Now let us introduce the following definition.

DEFINITION 5.3. *Assume that* (AT) *holds, and* $\ell(\cdot,\cdot)$ *and* $k(\cdot,\cdot)$ *satisfy* (H). *Let* (1.3) *with initial condition* $\binom{\eta}{\varphi} \in \mathcal{X}_0$, $\zeta \in L^2([-r,0],U)$ *and* $s \geq 0$. *Let the control function* $u \in L^2_{loc}([s,\infty),U)$ *such that* $u_s = \zeta$. *A function* $x : [s-r,\infty) \to X$ *is called the* generalized solution *of* (1.3) *if* $x_\cdot \in \mathcal{D}_s(\tilde{L}(\cdot))$ *and it satisfies* (5.3).

The following result follows immediately by Proposition 5.1, which motives Definition (5.3).

COROLLARY 5.4. *Assume that* (AT) *holds and the kernels* $\ell(\cdot,\cdot)$ *and* $k(\cdot,\cdot)$ *satisfy* (H). *Let the initial conditions* $s \geq 0$, $\binom{\eta}{\varphi} \in \mathfrak{D}$, *and* $\zeta \in D(Q_U)$ *and assume that* $u \in W^{1,2}_{loc}([s-r,\infty),U)$. *Then the generalized and mild solutions of* (1.3) *coincide.*

The following proposition is a consequence of Theorems 4.8 and 5.2, which will help us, later, to show that (1.3) determines a certain control system.

PROPOSITION 5.5. *Assume that* (AT) *holds and* $\ell(\cdot,\cdot)$ *and* $k(\cdot,\cdot)$ *satisfy* (H). *Let the initial conditions* $\binom{\eta}{\varphi} \in \mathcal{X}_0$, $\zeta \in L^2([-r,0],U)$, $s \geq 0$, *and* $u \in L^2_{loc}([s-r,\infty),U)$ *such that* $u_s = \zeta$. *Then* (1.3) *has a generalized solution* $x : [s-r,\infty) \to X$ *satisfying*

$x_\cdot \in \mathcal{D}_s(\tilde{L}(\cdot))$ and (1.5)*. Moreover, we have*

$$\begin{pmatrix} x(t) \\ x_t \end{pmatrix} = \mathcal{T}_L(t,s)\begin{pmatrix} \eta \\ \varphi \end{pmatrix} + \int_s^t \mathcal{T}_L(t,\sigma)\begin{pmatrix} \tilde{K}(\sigma)u_\sigma \\ 0 \end{pmatrix} d\sigma, \qquad t \geq s \geq 0. \tag{5.4}$$

In what follows, we endowed the Banach space $\mathcal{X} := \mathcal{X}_0 \times L^2([-r,0],U)$ with the norm $\|(\eta,\varphi,\zeta)\| = \|\eta\| + \|\varphi\|_2 + \|\zeta\|_2$. Further we define the linear operators

$$\mathcal{W}(t,s) : L^2([-r,0],U) \to \mathcal{X}_0, \quad \mathcal{W}(t,s)\zeta = \int_s^t \mathcal{T}_L(t,\sigma)\begin{pmatrix} (\Psi_K(s)\zeta)(\sigma) \\ 0 \end{pmatrix} d\sigma, \quad t \geq s \geq 0.$$

Using Hölder's inequality it can be verified that $\mathcal{W}(t,s)$, $t \geq s$, are bounded from $L^2([-r,0],U)$ to $\mathcal{X}_0$. Next, let us define the linear operators

$$\mathfrak{R}(t,s) : L^2_{loc}([s,\infty),U) \to \mathcal{X}_0, \quad \mathfrak{R}(t,s)u = \int_s^t \mathcal{T}_L(t,\sigma)\begin{pmatrix} (\mathbb{F}_K(s)u)(\sigma) \\ 0 \end{pmatrix} d\sigma, \quad t \geq s \geq 0.$$

Clearly, $\mathfrak{R}(t,s)$ are bounded linear operators from $L^2_{loc}([s,\infty,U)$ to $\mathcal{X}_0$.

Due to Theorem 2.3(iii) and Proposition 5.5 one can see that

$$(x(t), x_t, u_t)^\top = \mathcal{T}_{L,K}(t,s)(\eta,\varphi,\zeta) + \Phi_{L,K}(t,s)u \tag{5.5}$$

for $(\eta,\varphi,\zeta)^\top \in \mathcal{X}, t \geq s \geq 0$, and $u \in L^2_{loc}([s,\infty),U)$, where x is given by (1.5),

$$\mathcal{T}_{L,K}(t,s) := \left(\begin{array}{c|c} \mathcal{T}_L(t,s) & \mathcal{W}(t,s) \\ \hline 0 & \mathcal{S}_U(t,s) \end{array}\right), \tag{5.6}$$

and

$$\Phi_{L,K}(t,s)u := \begin{pmatrix} \mathfrak{R}(t,s)u \\ \Phi(t,s)u \end{pmatrix}. \tag{5.7}$$

It is not difficult to prove that $\mathcal{T}_{L,K} := (\mathcal{T}_{L,K}(t,s))_{t\geq s\geq 0}$ is a strongly continuous evolution family on $\mathcal{X}$. Moreover, using the regularity of the system Σ_K one can see that $(\mathcal{T}_{L,K}, \Phi_{L,K})$ is a nonautonomous control system on $\mathcal{X}, U$ (see [12] for a similar situation). Now due to (5.5) we have the following result.

PROPOSITION 5.6. *Assume that* (AT) *holds and $\ell(\cdot,\cdot)$ and $k(\cdot,\cdot)$ satisfy* (H). *Then $(\mathcal{T}_{L,K}, \Phi_{L,K})$ is a nonautonomous control system on $\mathcal{X}, U$, with control function $u \in L^2([s,\infty),U)$, $s \geq 0$, and state trajectory $z(t) = (x(t), x_t, u_t)$, $t \geq s \geq 0$, where x is given by* (5.3).

Next, we are interested in studying the output function given by (1.4). By assumption the delay operators $G(t)$ and $D(t)$ are given by the kernel $g(\cdot,\cdot)$ and $d(\cdot,\cdot)$ satisfying (H), so there are nonautonomous admissible observation operators for $\mathcal{S}_X$ and $\mathcal{S}_U$, respectively. Throughout we denote by $\tilde{G}(t)$ (resp., $\tilde{D}(t)$) the Lebesgue extensions of $G(t)$ (resp., $D(t)$) with respect to $\mathcal{S}_X$ (resp., $\mathcal{S}_U$). Further, by Theorem 3.6, the operators $D(t)$ are issued from an absolutely regular nonautonomous system which we denote by $\Sigma_D := (\mathcal{S}_U, \Phi, \Psi_D, \mathbb{F}_D)$.

According to Corollary 5.4 and Proposition 5.6, the control delay equation (1.3) determines the nonautonomous control system $(\mathcal{T}_{L,K}, \Phi_{L,K})$. It is then interesting to regard (1.4) as an observation equation for this latter.

Let us first consider the operators

$$\mathcal{G}(t) := [0\ G(t)] : \mathfrak{D} \longrightarrow Y, \qquad t \geq 0.$$

It is not difficult to show that $\mathcal{G}(t)$ are admissible observation operators for $\mathcal{T}$, so we denote by $\tilde{\mathcal{G}}(t)$ the Lebesgue extensions of $\mathcal{G}(t)$ with respect to $\mathcal{T}$. Arguing as in the proof of Lemma 4.7 we get

$$D(\tilde{\mathcal{G}}(t)) = X \times D(\tilde{G}(t)) \quad \text{and} \quad \tilde{\mathcal{G}}(t) = [0\ \tilde{G}(t)], \qquad t \geq 0. \tag{5.8}$$

Moreover, Proposition 4.3 and (4.15) imply that $\mathcal{T}_L(\cdot, s)\left(\begin{smallmatrix}\eta\\ \varphi\end{smallmatrix}\right) \in \mathcal{D}_s(\tilde{\mathfrak{B}}(\cdot)) \cap \mathcal{D}_s(\tilde{\mathcal{G}}(\cdot))$ for all $\left(\begin{smallmatrix}\eta\\ \varphi\end{smallmatrix}\right) \in \mathcal{X}_0$.

We set $\Omega_t := X \times D(\tilde{G}(t)) \times D(\tilde{D}(t))$ for $t \geq s \geq 0$ and we define the operators

$$\mathfrak{C}(t) := [0\ \tilde{G}(t)\ \tilde{D}(t)] : \Omega_t \longrightarrow Y, \qquad t \geq s. \tag{5.9}$$

Further, we consider

$$\begin{gathered}\Psi_{L,K}(s) : \mathcal{X} \longrightarrow L^2_{loc}([s,\infty), Y),\\ \Psi_{L,K}(s)(\eta,\varphi,\zeta) := \mathfrak{C}(\cdot)\mathcal{T}_{L,K}(\cdot, s)(\eta,\varphi,\zeta), \quad s \geq 0.\end{gathered} \tag{5.10}$$

Due to Theorem 2.1 and Proposition 4.3, $\Psi_{L,K}(s)$ are well-defined, bounded linear operators from $\mathcal{X}$ to $L^2_{loc}([s,\infty), Y)$. Moreover, we have the following proposition.

Proposition 5.7. *Assume that* (AT) *holds and the kernels* $\ell(\cdot,\cdot)$, $k(\cdot,\cdot)$, $g(\cdot,\cdot)$, *and* $d(\cdot,\cdot)$ *satisfy* (H). *Let* $\Psi_{L,K}(t)$, $t \geq 0$, *be the operators defined by* (5.10). *Then* $(\mathcal{T}_{L,K}, \Psi_{L,K})$ *is a nonautonomous observation system on* $\mathcal{X}, Y$. *Let then* $\mathcal{C}(t)$ *be the operators representing this system as in* (2.5). *Then for* $\tau \geq s$,

$$\Omega_\tau \subset D(\mathcal{C}(\tau)) \quad \textit{and} \quad \mathcal{C}(\tau) = \mathfrak{C}(\tau) \quad \textit{on} \quad \Omega_\tau. \tag{5.11}$$

Proof. As we mentioned above, the operators $\Psi_{L,K}(s)$ are linear bounded from $\mathcal{X}$ to $L^2_{loc}([s,\infty), Y)$. Now, clearly we have

$$[\Psi_{L,K}(t)\mathcal{T}_{L,K}(t,s)(\eta,\varphi,\zeta)](\rho) = [\Psi_{L,K}(s)(\eta,\varphi,\zeta)](\rho)$$

for $(\eta,\varphi,\zeta)^\top \in \mathcal{X}$ and $\rho \geq t \geq s \geq 0$. This shows that $(\mathcal{T}_{L,K}, \Psi_{L,K})$ is a nonautonomous observation system on $\mathcal{X}, Y$. Let now $\mathcal{C}(t)$ be the operators representing this system as in (2.5). Let us take $\tau \geq s \geq 0$, $t \in (0,1]$ and $(\eta,\varphi,\zeta)^\top \in \Omega_\tau$. Then, by combining (4.15), (5.6), (5.8), and (5.10), we have

$$\begin{aligned}\Psi_{L,K}(\tau)(\eta,\varphi,\zeta) = \tilde{\mathcal{G}}(\cdot)\mathcal{T}(\cdot,\tau)\left(\begin{smallmatrix}\eta\\ \varphi\end{smallmatrix}\right) + \tilde{\mathcal{G}}(\cdot)\mathbb{K}^{\mathcal{T}}_\tau\tilde{\mathfrak{B}}(\cdot)\mathcal{T}_L(\cdot,\tau)\left(\begin{smallmatrix}\eta\\ \varphi\end{smallmatrix}\right)\\ + \tilde{\mathcal{G}}(\cdot)\mathbb{K}^{\mathcal{T}_L}_\tau\left(\begin{smallmatrix}\Psi_K(s)\zeta\\ 0\end{smallmatrix}\right) + \Psi_D(\tau)\zeta.\end{aligned}$$

Since $\left(\begin{smallmatrix}\eta\\ \varphi\end{smallmatrix}\right) \in D(\tilde{\mathcal{G}}(\tau))$, then

$$\lim_{t\searrow 0}\frac{1}{t}\int_\tau^{\tau+t}\tilde{\mathcal{G}}(\sigma)\mathcal{T}(\sigma,\tau)\left(\begin{smallmatrix}\eta\\ \varphi\end{smallmatrix}\right)d\sigma = \tilde{\mathcal{G}}(\tau)\left(\begin{smallmatrix}x\\ \varphi\end{smallmatrix}\right).$$

On the other hand, due to (4.14), Hölder's inequality, and Proposition 2.2, we have

$$\left\| \frac{1}{t} \int_\tau^{\tau+t} \tilde{\mathcal{G}}(\sigma)[\mathbb{K}_\tau^{\mathcal{T}} \tilde{\mathfrak{B}}(\cdot)\mathcal{T}_L(\cdot,\sigma)\left(\begin{smallmatrix}\eta\\ \varphi\end{smallmatrix}\right)](\sigma)\, d\sigma \right\| \le c\|\tilde{\mathfrak{B}}(\cdot)\mathcal{T}_L(\cdot,\tau)\left(\begin{smallmatrix}\eta\\ \varphi\end{smallmatrix}\right)\|_{L^2([\tau,\tau+t],\mathcal{X}_0)} \underset{t\searrow 0}{\longrightarrow} 0.$$

Similarly, by Hölder's inequality and Proposition (4.3)(ii), we get

$$\lim_{t\searrow 0} \frac{1}{t} \int_\tau^{\tau+t} \tilde{\mathcal{G}}(\sigma)\left[\mathbb{K}_\tau^{\mathcal{T}_L}\left(\begin{smallmatrix}\Psi_K(\tau)\zeta\\ 0\end{smallmatrix}\right)\right](\sigma)\, d\sigma = 0.$$

Consequently,

$$\lim_{t\searrow 0} \frac{1}{t} \int_\tau^{\tau+t} [\Psi_{L,K}(\tau)(\eta,\varphi,\zeta)](\sigma) = \tilde{\mathcal{G}}(\tau)\left(\begin{smallmatrix}\eta\\ \varphi\end{smallmatrix}\right) + \tilde{D}(\tau)\zeta = \mathfrak{C}(\tau)(\eta,\varphi,\zeta),$$

so (5.11) is now verified. □

We note that the semigroup $\mathcal{T}_{L,K}$ corresponds to (1.3) in the case when $u(t) = 0$ for $t \ge s$. Thus Proposition 5.7 shows that the uncontrolled system associated with (1.3)–(1.4) is well posed.

Now we want to construct the operators which associate with every input function u the corresponding output function y defined by (1.4). We first remark, by Theorem 2.3(i), (5.7), Proposition 4.3(ii), and (5.8) that $\Phi_{L,K}(t,s)u \in \Omega_t$ for all $t \ge s \ge 0$ and $u \in L^2_{loc}([s,\infty),U)$. This allows us to introduce the following operators:

$$\mathbb{F}_{L,K}(s) : L^2_{loc}([s,\infty),U) \to L^2_{loc}([s,\infty),Y), \quad \mathbb{F}_{L,K}(s)u := \mathfrak{C}(\cdot)\Phi_{L,K}(\cdot,s)u, \quad s \ge 0.$$

Using Hölder's inequality, (5.7), and Proposition 4.3(ii) one can see that $\mathbb{F}_{L,K}(s)$ are linear bounded operators.

THEOREM 5.8. *Assume that* (AT) *holds and the kernels* $\ell(\cdot,\cdot)$, $k(\cdot,\cdot)$, $g(\cdot,\cdot)$, *and* $d(\cdot,\cdot)$ *satisfy* (H). *Let* $s \ge 0$, $(\eta,\varphi,\zeta)^\top \in \mathcal{X}$, *and* $u \in L^2_{loc}([s,\infty),U)$ *such that* $u_s = \zeta$. *Then the quadruple* $\Sigma_{L,K} := (\mathcal{T}_{L,K}, \Phi_{L,K}, \Psi_{L,K}, \mathbb{F}_{L,K})$ *is an absolutely regular nonautonomous system on* $\mathcal{X}, U, Y$ *having* $u(t)$ *as control function,* $z(t) = (x(t), x_t, u_t)$ *as state trajectory and output function* $y(t)$ *satisfying the representation*

$$y(t) = \tilde{G}(t)x_t + \tilde{D}(t)u_t \tag{5.12}$$

for almost every $t \ge s \ge 0$, *where* x *is the function given by* (1.5).

Proof. Let $0 \le s \le t \le \rho$ and $u \in L^2_{loc}([s,\infty),U)$ such that $u^0 := u_{|[s,t]}$ and $u^1 := u_{|[t,\rho]}$. Since $\Phi_{L,K}(t)$ satisfy (2.1), then by (5.10) we get

$$\begin{aligned}(\mathbb{F}_{L,K}(s)u)(\rho) &= \mathfrak{C}(\rho)[\Phi_{L,K}(\rho,t)u^1 + \mathcal{T}_{L,K}(\rho,t)\Phi_{L,K}(t,s)u^0] \\ &= (\mathbb{F}_{L,K}(t)u^1)(\rho) + (\Psi_{L,K}(t)\Phi(t,s)u^0)(\rho).\end{aligned}$$

Hence $\Sigma_{L,K}$ is a well-posed nonautonomous system on $\mathcal{X}, U, Y$. Now to prove the absolute regularity of $\Sigma_{L,K}$, let us consider the step $u_z(s) = z$, $s \ge 0$, $z \in U$, and $t \in (0,1]$. We have

$$\mathbb{F}_{L,K}(s)u_z = \tilde{\mathcal{G}}(\cdot)\mathbb{K}_s^{\mathcal{T}_L}\left(\begin{smallmatrix}\mathbb{F}_K(s)u_z\\ 0\end{smallmatrix}\right) + \mathbb{F}_D(s)u_z, \quad s \ge 0.$$

Then, by Proposition 4.3(ii), there exists a constant c independents of t such that

$$\frac{1}{t}\int_s^{s+t}\left\|\tilde{\mathcal{G}}(\tau)\left[\mathbb{K}_s^{\mathcal{T}_L}\begin{pmatrix}\mathbb{F}_K(s)u_z\\0\end{pmatrix}\right](\tau)\right\|^2 d\tau \le c\int_s^{s+t}\|[\mathbb{F}_K(s)u_z](\tau)\|^2\,d\tau \;\to\; 0 \text{ (as } t\searrow 0).$$

Thus our claim now follows by the absolute regularity of Σ_D (see Theorem 3.6). Now Proposition 5.6 shows that $u(t)$ and $z(t)=(x(t),x_t,u_t)$, $t\ge 0$, are the control function and the state trajectory of $\Sigma_{L,K}$, respectively, where $x(t)$ is given by (5.3). Due to Theorem 3.6 we have $z(t)\in\Omega_t$ for a.e. $t\ge s$. Let now $y(t)$ be the output function of $\Sigma_{L,K}$ and let $\mathcal{C}(t)$ be the operators representing the system $(\mathcal{T}_{L,K},\Psi_{L,K})$. Then, by (5.11), we have

$$y(t)=\mathcal{C}(t)z(t)=\mathfrak{C}(t)z(t)=\tilde{G}(t)x_t+\tilde{D}(t)u_t$$

for a.e. $t\ge s$. □

The following corollary shows, in fact, that the delay system (1.3)–(1.4) is completely determined by the absolutely regular nonautonomous system $\Sigma_{L,K}$ obtained in Theorem 5.8.

COROLLARY 5.9. *Assume that* (AT) *holds and the kernels* $\ell(\cdot,\cdot)$, $k(\cdot,\cdot)$, $g(\cdot,\cdot)$, *and* $d(\cdot,\cdot)$ *satisfy* (H). *Let the initial conditions* $s\ge 0$, $(\eta,\varphi,\zeta)^\top\in\mathfrak{D}\times D(Q_U)$. *Let the control function* $u\in W^{1,2}_{loc}([s-r,\infty),U)$ *such that* $u_s=\zeta$. *Let* $\Sigma_{L,K}$ *be the absolutely regular nonautonomous system obtained in Theorem* 5.8. *Then the state trajectory of this system is* $z(t)=(x(t),x_t,u_t)$ *for* $t\ge s$, *where* $x(t)$ *is the function given by* (5.2). *Further, the output function of* $\Sigma_{L,K}$ *satisfies* $y(t)=G(t)x_t+D(t)u_t$ *for a.e.* $t\ge s$.

Proof. The first statement of the corollary follows by Corollary 5.4 and Proposition 5.6. For the second, we know that $x_t\in C([-r,0],X)$, $t\ge s$, for initial condition $\binom{\eta}{\varphi}\in\mathfrak{D}$. Moreover, $x_t\in D(\tilde{G}(t))$ for a.e. $t\ge s$, due to Theorem 3.6. Thus $\tilde{G}(t)x_t=G(t)x_t$ for a.e. $t\ge s$, due to (4.21). Further, Corollary 3.7 implies that $\tilde{D}(t)u_t=D(t)u_t$ for a.e. $t\ge s$. Thus the last statement of the corollary follows. □

6. Application to a parabolic nonautonomous neutral equation. In this section we investigate a class of parabolic nonautonomous neutral equations on Banach space. Our abstract results obtained in section 5 allow as to introduce a new definition of the solutions of nonautonomous neutral equations and to prove the existence and uniqueness of those solutions.

Let $\mathcal{O}$ be a bounded domain in $\mathbb{R}^n$ such that the boundary $\partial\mathcal{O}$ is of class C^2. We set

$$A(t,\xi,\partial)=\sum_{i,j=1}^n a_{ij}(t,\xi)\partial_i\partial_j+\sum_{i=1}^n a_j(t,\xi)\partial_j+a_0(t,\xi),\qquad t\ge 0,\ \xi\in\mathcal{O},$$

where the functions $a_{ij},a_i,a_0:\mathbb{R}_+\times\overline{\mathcal{O}}$, $i,j=1,\dots,n$, are bounded and uniformly Hölder continuous and satisfying

$$\sum_{i,j=1}^n a_{ij}(t,\xi)\vartheta_i\vartheta_j\ge\gamma|\vartheta|^2$$

for a constant $\gamma>0$ and all $\vartheta\in\mathbb{R}^n$, $t\ge 0$, and $\xi\in\overline{\mathcal{O}}$.

We consider the nonautonomous neutral equation

$$\text{(nEq)}\quad \begin{cases} \dfrac{d}{dt}\Big[u(t,\xi) - \displaystyle\int_{-r}^{0} d\mathfrak{d}(t,\theta,\xi)u(t+\theta,\xi)\Big] \\ \qquad\qquad = A(t,\xi,\partial)\Big[u(t,\xi) - \displaystyle\int_{-r}^{0} d\mathfrak{d}(t,\theta,\xi)u(t+\theta,\xi)\Big] \\ \qquad\qquad\qquad + \displaystyle\int_{-r}^{0} dk(t,\theta,\xi)u(t+\theta,\xi), \qquad t \geq s \geq 0,\ \xi \in \overline{\mathcal{O}}, \\ \lim\limits_{t\to s}\Big[u(t,\xi) - \displaystyle\int_{-r}^{0} d\mathfrak{d}(t,\theta,\xi)u(t+\theta,\xi)\Big] = \eta(\xi), \qquad \xi \in \mathcal{O}, \\ u(t,\xi) = \zeta(t-s,\xi), \qquad \xi \in \mathcal{O},\ t \leq s, \\ u(t,\xi) = \displaystyle\int_{-r}^{0} d\mathfrak{d}(t,\theta,\xi)u(t+\theta,\xi), \qquad \xi \in \partial\mathcal{O},\ t \geq s, \end{cases}$$

for $\eta \in C_0(\mathcal{O})$ and $\zeta \in L^2([-r,0]\times\mathcal{O})$, where $\mathfrak{d}(\cdot,\cdot,\cdot), k(\cdot,\cdot,\cdot) : \mathbb{R}_+ \times [-r,0]\times\overline{\mathcal{O}} \to \mathbb{R}$ are some appropriate kernels.

Let us now introduce the auxiliary function

$$x(t,\xi) = u(t,\xi) - \int_{-r}^{0} d\mathfrak{d}(t,\theta,\xi)u(t+\theta,\xi), \quad t \geq s,\ \xi \in \overline{\mathcal{O}}.$$

Then (nEq) becomes

$$\text{(6.1)}\quad \begin{cases} \dfrac{d}{dt}x(t,\xi) = A(t,\xi,\partial)x(t,\xi) + \displaystyle\int_{-r}^{0} dk(t,\theta,\xi)u(t+\theta,\xi), & t \geq s \geq 0,\ \xi \in \overline{\mathcal{O}}, \\ x(s,\xi) = \eta(\xi), \quad u(t,\xi) = \zeta(t-s,\xi), & \xi \in \mathcal{O},\ t \leq s, \\ x(t,\xi) = 0, & t \geq s,\ \xi \in \partial\mathcal{O}, \\ u(t,\xi) = x(t,\xi) + \displaystyle\int_{-r}^{0} d\mathfrak{d}(t,\theta,\xi)u(t+\theta,\xi), & \xi \in \overline{\mathcal{O}},\ t \geq s. \end{cases}$$

On $X = L^2(\mathcal{O})$ we introduce the realizations $A(t)$ of the differential operator $A(t,\xi,\partial)$ with domains

$$\mathcal{D}(A(t)) = \Big\{h \in W^{2,2}(\mathcal{O}) : h = 0 \text{ on } \partial\mathcal{O}\Big\}.$$

In order to be in the setting of the previous section we set

$$D(t)u_t = \int_{-r}^{0} d\mathfrak{d}(t,\theta,\cdot)u(t+\theta,\cdot) \quad \text{and} \quad K(t)u_t = \int_{-r}^{0} dk(t,\theta,\cdot)u(t+\theta,\cdot).$$

On X we rewrite (6.1) in the following abstract form:

$$\text{(6.2)}\quad \begin{cases} \dfrac{d}{dt}x(t) = A(t)x(t) + K(t)u_t, & t \geq s \geq 0, \\ x(s) = \eta, \quad u_s = \zeta, & \\ u(t) = x(t) + D(t)u_t, & t \geq s. \end{cases}$$

It is known that $A(t)$ satisfy (AT) (see, e.g., [27]). Thus $A(t)$ generate the evolution family $T := (T(t,s))_{t\geq s\geq 0}$ on X, where

$$T(t,s)\eta = \int_{\mathcal{O}} \mathfrak{b}(t,s,\cdot,\xi)\eta(\xi)\,d\xi$$

for $t \geq s \geq 0$, $\eta \in X$, and a continuous kernel $\mathfrak{b}(t,s,\sigma,\xi)$, $t \geq s \geq 0$, $\sigma \in \overline{\mathcal{O}}$, $\xi \in \mathcal{O}$, satisfying the Gaussian estimate

$$|\mathfrak{b}(t,s,\sigma,\xi)| \leq M(t-s)^{-\frac{n}{2}} \exp\Big(-\frac{w|\sigma-\xi|^2}{t-s} + \tilde{w}(t-s)\Big)$$

for $0 < t-s \leq t_0$ and constants $M, w > 0$, and $\tilde{w} \in \mathbb{R}$ (see [26, sect. 6] and the references therein).

Next, we shall assume that the kernels $\mathfrak{d}(t,\cdot,\cdot,), k(t,\cdot,\cdot) \in BV([-r,0],\mathcal{L}(X))$, $t \geq 0$, satisfy the condition (H).

Observe that (6.2) corresponds to the delay system (1.3)–(1.4) with $L(t) = 0$, $G(t) = \delta_0$, $X = U = Y$, and the feedback law $y(t) = u(t)$. Thus to solve (nEq) it suffices to study the existence of the closed-loop system associated to (1.3)–(1.4) with respect to an appropriate feedback law.

The framework obtained in section 5 justifies the following definition of the solution of (nEq).

Definition 6.1. *A generalized solution of the initial value problem* (nEq) *is a pair* (x,u) *of functions* $x : [s,\infty) \to X$ *and* $u : [s-r,\infty) \to X$ *such that*

(i) x *is continuous,* $u_\bullet \in \mathcal{D}_s(\tilde{D}(\cdot)) \cap \mathcal{D}_s(\tilde{K}(\cdot))$,

(ii) $u_s = \zeta$ *a.e. on* $[-r,0]$,

(iii) *the pair* (x,u) *satisfies the following equations:*

$$x(t) = T(t,s)\eta + \int_s^t T(t,\tau)\tilde{K}(\tau)u_\tau \, d\tau, \tag{6.3}$$

$$x(t) = u(t) - \tilde{D}(t)u_t \tag{6.4}$$

for $\eta \in X$ *and a.e.* $t \geq s \geq 0$.

In the rest of this section, we are interested in studying the existence of the generalized solutions of the nonautonomous neutral equation (nEq). To this purpose, we denote by $\mathcal{T}_{0,K}$ and $\Phi_{0,K}$ the operators families given by (5.6) and (5.7), respectively, with $L(t) = 0$, $\mathcal{T}_0 = T$,

$$\mathcal{W}(t,s)\zeta = \int_s^t T(t,\sigma)(\Psi_K(s)\zeta)(\sigma)\, d\sigma \quad \text{and} \quad \mathfrak{R}(t,s)u = \int_s^t T(t,\sigma)(\mathbb{F}_K(s)u)(\sigma)\, d\sigma$$

for $t \geq s \geq 0$, $\zeta \in L^2([-r,0],X)$ and $u \in L^2_{loc}([s,\infty),X)$. Then, as in section 5, $(\mathcal{T}_{0,L}, \Phi_{0,L})$ is a nonautonomous control system on $\mathcal{X}_0, X$.

Let us now rewrite the operators $\mathfrak{C}(t)$ given by (5.9) as

$$\mathfrak{C}(t) := [I \ \tilde{D}(t)] : \Omega_t \longrightarrow X, \qquad t \geq s, \tag{6.5}$$

where $\Omega_t = X \times \mathcal{D}(\tilde{D}(t))$ for $t \geq s \geq 0$. So we denote by $\Psi_{0,K}(s)$, $s \geq 0$, the operators given by (5.10) with $L(t) = 0$, $Y = X$, so that $(\mathcal{T}_{0,K}, \Psi_{0,K})$ is a nonautonomous observation system on $\mathcal{X}_0, X$. Finally, we set

$$\mathbb{F}_{0,K}(s) : L^2_{loc}([s,\infty),X) \to L^2_{loc}([s,\infty),X), \quad \mathbb{F}_{0,K}(s)u := \mathfrak{C}(\cdot)\Phi_{0,K}(\cdot,s)u, \quad s \geq 0.$$

Lemma 6.2. *Let the kernels* $\mathfrak{d}(\cdot,\cdot,\cdot,)$ *and* $k(\cdot,\cdot,\cdot)$ *satisfy* (H) *and assume that* $\sup_t Var(\mathfrak{d}(t,\cdot,\cdot))^0_{-r}$ *is small enough. Then* $\Sigma_{0,K} := (\mathcal{T}_{0,K}, \Phi_{0,K}, \Psi_{0,K}, \mathbb{F}_{0,K})$ *is an absolutely regular nonautonomous system on* $\mathcal{X}_0, X, X$ *with admissible feedback operators* $\Delta(t) = I_X$, $t \geq 0$.

Proof. Theorem 5.8 shows that $\Sigma_{0,K} := (\mathcal{T}_{0,K}, \Phi_{0,K}, \Psi_{0,K}, \mathbb{F}_{0,K})$ is an absolutely regular nonautonomous system on $\mathcal{X}_0, X, X$. Now (5.7) and (6.5) imply

$$I_X - \mathbf{F}_K(s) = I_X - \mathbb{F}_D(s) - \mathfrak{R}(\cdot, s), \qquad s \geq 0, \tag{6.6}$$

where $\mathbb{F}_D(s)$ are the input-output operators of the absolutely regular nonautonomous system on $L^2([-r,0],X), X, X$ associated with the delay operators $D(t)$, $t \geq 0$, (see Theorem 3.6). We claim that $\Delta(t) = I_X$, $t \geq 0$, are admissible feedback operators for Σ_D. For this let $t_0 > 0$ and $v \in L^2_{loc}([s,\infty), X)$. Due to (3.10) we have

$$\int_s^{s+t_0} \|(\mathbb{F}_D(s)v)(t)\|^2 \, dt \leq c \sup_t Var(\mathfrak{d}(t,\cdot))^0_{-r} \|v\|_{L^2([s,s+t_0],X)}. \tag{6.7}$$

According to (6.7) and the fact that $\sup_t Var(\mathfrak{d}(t,\cdot))^0_{-r}$ is small enough, the operators $I_X - \mathbb{F}_D(s+t_0, s)$, $s \geq 0$, have uniformly bounded inverses on $L^2([s, s+t_0], X)$ for some $t_0 > 0$. Then, due to (6.6), $I_X - \mathbf{F}_K(s+t_1, s)$, $s \geq 0$, have uniformly bounded inverses on $L^2([s, s+t_1], X)$ for some $t_1 > 0$ as well. This ends the proof. ∎

THEOREM 6.3. *Let the kernels* $\mathfrak{d}(\cdot,\cdot,\cdot,)$ *and* $k(\cdot,\cdot,\cdot)$ *satisfy* (H) *and assume that* $\sup_t Var(\mathfrak{d}(t,\cdot,\cdot))^0_{-r}$ *is small enough. Then the nonautonomous neutral equation* (nEq) *has a unique generalized solution.*

Proof. We are looking for a pair of functions (x,u) satisfying Definition 6.1. For this we let v and y denote the control and the observation functions, respectively, of the absolutely regular nonautonomous system $\Sigma_{0,K}$. Due to Lemma 6.2, the closed-loop system $\Sigma^I_{0,K}$ associated with $\Sigma_{0,K}$ and $\Delta(t) = I_X$ exists. Now if we consider the feedback law $v = y + v_c$ for a suitable input v_c then, by (2.9) and Theorem 2.3(iii), the state trajectory of $\Sigma^I_{0,K}$ is given by $z(t) = \mathcal{T}_{0,K}(t,s)(\eta,\zeta) + \Phi_{0,K}(t,s)(v_c + y)$ for $t \geq s \geq 0$ and $(\eta,\zeta)^\top \in \mathcal{X}_0$. We now choose $v_c = 0$ and $u = y$ with $u_s = \zeta$. Then $z(t) = (x(t), u_t)$ for $t \geq s \geq 0$, where x satisfies (6.3) (see Theorem 5.8). Again by Theorem 5.8 we have $u(t) = y(t) = \mathfrak{C}(t)z(t) = x(t) + \tilde{D}(t)u_t$ for a.e. $t \geq s \geq 0$. Thus x satisfies (6.4). This ends the proof. ∎

Acknowledgments. I would like to thank the associate editor and the two referees whose detailed comments helped me to improve the organization and the content of the paper.

EXPONENTIAL STABILIZATION OF WELL-POSED SYSTEMS BY COLOCATED FEEDBACK*

RUTH F. CURTAIN† AND GEORGE WEISS‡

Abstract. We consider well-posed linear systems whose state trajectories satisfy $\dot{x} = Ax + Bu$, where u is the input and A is an essentially skew-adjoint and dissipative operator on the Hilbert space X. This means that the domains of A^* and A are equal and $A^* + A = -Q$, where $Q \geq 0$ is bounded on X. The control operator B is possibly unbounded, but admissible and the observation operator of the system is B^*. Such a description fits many wave and beam equations with colocated sensors and actuators, and it has been shown for many particular cases that the feedback $u = -\kappa y + v$, with $\kappa > 0$, stabilizes the system, strongly or even exponentially. Here, y is the output of the system and v is the new input. We show, by means of a counterexample, that if B is sufficiently unbounded, then such a feedback may be unsuitable: the closed-loop semigroup may even grow exponentially. (Our counterexample is a simple regular system with feedthrough operator zero.) However, we prove that if the original system is exactly controllable and observable and if κ is sufficiently small, then the closed-loop system is exponentially stable.

Key words. well-posed linear system, regular linear system, positive-real transfer function, output feedback, exact controllability and observability, skew-adjoint operator, colocated sensors and actuators, exponential stability

1. Introduction and the main result.

In this paper, we consider the stabilization of a special class of well-posed linear systems, as described below. To specify our terminology and notation, we recall that for any well-posed linear system Σ with input space U, state space X and output space Y, all Hilbert spaces, the state trajectories $z \in C([0,\infty), X)$ are described by the differential equation

$$\dot{z}(t) = Az(t) + Bu(t), \tag{1.1}$$

where $u \in L^2_{loc}([0,\infty), U)$ is the input function. The operator $A : \mathcal{D}(A) \to X$ is the generator of a strongly continuous semigroup of operators $\mathbb{T}$ on X and the (possibly unbounded) operator B is an admissible control operator for $\mathbb{T}$. In general, the output function y is in $L^2_{loc}([0,\infty), Y)$. If $u = 0$ and $z(0) \in \mathcal{D}(A)$, then y is given by

$$y(t) = Cz(t) \qquad \forall\, t \geq 0,$$

where $C : \mathcal{D}(A) \to Y$ is an admissible observation operator for $\mathbb{T}$. B is called the control operator of Σ and C is called the observation operator of Σ. If $z(0) = 0$, then the input and output functions u and y are related by the formula

$$\hat{y}(s) = \mathbf{G}(s)\hat{u}(s), \tag{1.2}$$

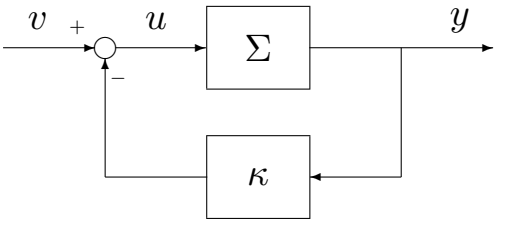

FIG. 1. *The open-loop system Σ with negative output feedback via κ. If the number $\kappa > 0$ is sufficiently small, then this is a new well-posed linear system Σ^κ, called the closed-loop system, which is input-output stable. If Σ is exactly controllable and exactly observable, then Σ^κ is exponentially stable.*

where a hat denotes the Laplace transform and $\mathbf{G}$ is the transfer function of Σ. The formula (1.2) holds for all $s \in \mathbb{C}$ with $\operatorname{Re} s$ sufficiently large. We refer to sections 3 and 4 for more details and references on admissibility and on well-posed linear systems. Now we specify the special class of systems studied in this paper.

Assumption ESAD. The operator A is *essentially skew-adjoint and dissipative*, which means that $\mathcal{D}(A) = \mathcal{D}(A^*)$ and there exists a $Q \in \mathcal{L}(X)$ with $Q \geq 0$ such that

$$Ax + A^*x = -Qx \qquad \forall\, x \in \mathcal{D}(A). \tag{1.3}$$

This implies that $\mathbb{T}$ is a contraction semigroup. Note that A is a bounded perturbation of the skew-adjoint operator $A + \frac{1}{2}Q$. Such a model is often used to describe the dynamics of oscillating systems, such as waves or flexible structures (often $Q = 0$, so that $\mathbb{T}$ is unitary); for a literature survey see section 2.

Assumption COL. $Y = U$ and $C = B^*$.

In the literature on the stabilization of flexible structures, a very popular way of implementing actuators and sensors is through colocated pairs, i.e., an actuator and sensor pair act at the same physical position. This often leads to assumption COL being satisfied, often with a finite-dimensional U.

Our aim is to show that for certain numbers $\kappa > 0$, the static output feedback law $u = -\kappa y + v$ stabilizes the system, where v is the new input function. The closed-loop system Σ^κ is shown as a block diagram in Figure 1 (see section 4 for some background on output feedback). The system Σ^κ is called *input-output stable* if its transfer function $\mathbf{G}^\kappa = \mathbf{G}(I + \kappa\mathbf{G})^{-1}$ is uniformly bounded on the open right half-plane where $\operatorname{Re} s > 0$. It is called *exponentially stable* if the growth bound of its semigroup is negative. Our main result is the following theorem.

THEOREM 1.1. *Suppose that Σ is a well-posed linear system which is exactly controllable, exactly observable and satisfies assumptions* ESAD *and* COL. *Then there exists a $\kappa_0 > 0$ (possibly $\kappa_0 = \infty$) such that for all $\kappa \in (0, \kappa_0)$, the feedback law $u = -\kappa y + v$ (where u and y are the input and the output of Σ) leads to a closed-loop system Σ^κ which is well-posed and exponentially stable.*

In fact, this result is only a corollary of Theorem 5.8, in which the assumptions are weaker than exact controllability and exact observability. We also give a formula for κ_0 based on the transfer function $\mathbf{G}$, see Theorem 5.8.

In all the published examples that we are aware of, the feedback $u = -\kappa y + v$ is stabilizing for all $\kappa > 0$, at least in the input-output sense, and often strongly or exponentially. In section 5 we give an example of a simple open-loop system Σ which fits into our framework, and it is regular with feedthrough operator zero (see section 4 for definitions), but for which the feedback $u = -\kappa y + v$ is only exponentially stabilizing for sufficiently small $\kappa > 0$. For too large a κ, the closed-loop semigroup $\mathbb{T}^\kappa$ will have a positive growth rate.

In section 6 we introduce the theoretical framework for discussing colocated feedback for systems described by second order differential equations in time, with a suitable version of Theorem 1.1. As an illustration, we outline the problem of stabilizing a Rayleigh beam with two sensors located in one point, which fits into the theory developed in this section. With the actuators designed such that $B = C^*$ and with proportional output feedback with not too high feedback gain, the closed-loop system is exponentially stable, for any position of the two sensors.

Exact controllability and exact observability are very restrictive conditions, especially if U is finite-dimensional, see, for example, the discussion in Rebarber and Weiss [29]. There is a rich literature dealing with various specific linear systems or classes of systems that satisfy ESAD and COL and that are approximately controllable and observable (or satisfy other related assumptions). In these papers, the main conclusion is usually the weak or strong stability of the closed-loop system (and various nonexponential decay rates of the energy). This area will be examined in a sequel to this paper, which will contain a unified theory of the strong stabilization of systems satisfying ESAD and COL.

2. Comments on the literature and a self-contained presentation of the finite-dimensional case. Many models of controlled flexible structures satisfy assumptions ESAD and COL. The feedback $u = -\kappa y + v$ is very simple to implement and it is often used in the stabilization of these structures. Our results may be regarded as an abstract unifying theory for colocated exponential stabilization of flexible structures. However, it must be pointed out that not all such examples in the literature satisfy all our assumptions. In particular, the open-loop system is not always well posed.

Much of the early work on the stabilization of flexible structures concerned finite-dimensional systems, see, for example, Benhabib et al. [9] and Joshi [18] and the references therein. They used the feedback $u = -\kappa B^* z + v$ because of its simplicity and its nice robustness properties. Indeed, it works for all systems with a positive-real transfer function, as we shall explain below (see also Desoer and Vidyasagar [12]). A valuable recent source for the finite-dimensional theory is Gawronski [13]. For a survey on the stabilization of finite-dimensional linear systems by static output feedback we refer to Syrmos et al. [39] (see also Zeheb and Hertz [54]).

We think that it will be instructive to give here a short self-contained presentation of the finite-dimensional version of our main result (Theorem 1.1), as well as of some related results, without any claims to novelty. Our infinite-dimensional arguments will go along the same lines, but with many more technicalities.

Recall that a square matrix-valued transfer function $\mathbf{G}$, analytic on the open right half-plane $\mathbb{C}_0$, is called *positive-real* if $\overline{\mathbf{G}(s)} = \mathbf{G}(\overline{s})$ and

$$\mathbf{G}(s)^* + \mathbf{G}(s) \geq 0 \qquad \forall\, s \in \mathbb{C}_0. \tag{2.1}$$

Positive-real transfer functions were introduced in electrical network theory, but they have strong connections with systems theory formulated in state space, see Anderson and Vongpanitlerd [3]. In particular, if the real square matrix A is dissipative, then for any real matrix B of appropriate dimensions, $\mathbf{G}(s) = B^*(sI - A)^{-1}B$ is positive-real. Such transfer functions often occur as models of flexible structures with colocated actuators and sensors, see [9, 13].

Now consider an arbitrary (but square) $m \times m$ matrix-valued transfer function $\mathbf{G}$. If the closed-loop system with transfer function $\mathbf{G}^\kappa$ is obtained from the open-loop system with transfer function $\mathbf{G}$ via the feedback $u = -\kappa y + v$, as in Figure 1, then

$\mathbf{G}^\kappa = \mathbf{G}(I + \kappa\mathbf{G})^{-1}$. The following lemma gives a simple sufficient condition for $\mathbf{G}^\kappa$ to be bounded on $\mathbb{C}_0$, a fact which is written as $\mathbf{G}^\kappa \in H^\infty$.

PROPOSITION 2.1. *Suppose that $cI + \mathbf{G}$ is positive-real for some $c \geq 0$, and denote $\kappa_0 = \frac{1}{c}$ (for $c = 0$, take $\kappa_0 = \infty$). Then for any $\kappa \in (0, \kappa_0)$, $\mathbf{G}^\kappa \in H^\infty$.*

Proof. Denoting $a = \frac{1}{\kappa}$ and $T(s) = aI + \frac{1}{2}(\mathbf{G}(s)^* + \mathbf{G}(s))$, we have $T(s) \geq (a - c)I > 0$. Hence, for every $\mathrm{v} \in \mathbb{C}^m$ with $\|\mathrm{v}\| = 1$ and for all $s \in \mathbb{C}_0$,

$$\|(aI + \mathbf{G}(s))\mathrm{v}\| \geq \mathrm{Re}\,\langle (aI + \mathbf{G}(s))\mathrm{v}, \mathrm{v}\rangle = \langle T(s)\mathrm{v}, \mathrm{v}\rangle \geq a - c,$$

hence

$$\left\|(aI + \mathbf{G}(s))^{-1}\right\| \leq \frac{1}{a - c} \tag{2.2}$$

so that $(aI + \mathbf{G})^{-1} \in H^\infty$. We rewrite $\mathbf{G}^\kappa$ in the form

$$\mathbf{G}^\kappa = a\left[I - a(aI + \mathbf{G})^{-1}\right],$$

which shows that $\mathbf{G}^\kappa \in H^\infty$ (a bound will be given below). □

PROPOSITION 2.2. *With the assumptions of Proposition 2.1, denote $c^\kappa = \frac{c}{1 - \kappa c}$ so that $c^\kappa \geq 0$. Then $c^\kappa I + \mathbf{G}^\kappa$ is positive-real.*

Proof. Notice that $\kappa c \in [0, 1)$. Introduce the transfer function

$$\mathbf{H} = \frac{\kappa}{1 - \kappa c}(cI + \mathbf{G})$$

so that clearly $\mathbf{H}$ is positive-real. It is readily verified that

$$c^\kappa I + \mathbf{G}^\kappa = \frac{1}{\kappa(1 - \kappa c)}\,\mathbf{H}(I + \mathbf{H})^{-1}. \tag{2.3}$$

This implies that for all $s \in \mathbb{C}_0$,

$$\begin{aligned}\kappa(1 - \kappa c)&\left[(c^\kappa I + \mathbf{G}^\kappa(s))^* + (c^\kappa I + \mathbf{G}^\kappa(s))\right] \\ &= (I + \mathbf{H}(s)^*)^{-1}\left[\mathbf{H}(s)^* + \mathbf{H}(s) + 2\mathbf{H}(s)^*\mathbf{H}(s)\right](I + \mathbf{H}(s))^{-1}.\end{aligned}$$

It is easy to see that the right-hand side of the above equation is nonnegative. Since clearly $\overline{\mathbf{G}^\kappa(s)} = \mathbf{G}^\kappa(\overline{s})$, it follows that $c^\kappa I + \mathbf{G}^\kappa$ is positive-real. □

LEMMA 2.3. *If H is an $m \times m$ matrix such that $\mathrm{Re}\,\langle H\mathrm{v}, \mathrm{v}\rangle \geq 0$ for all $\mathrm{v} \in \mathbb{C}^m$, then $I + H$ is invertible and $\|H(I + H)^{-1}\| \leq 1$.*

Proof. The invertibility is clear. Denote $T = H(I + H)^{-1}$; then it is easy to see that $H(I - T) = T$. If in $\mathrm{Re}\,\langle H\mathrm{v}, \mathrm{v}\rangle \geq 0$ we choose $\mathrm{v} = (I - T)z$, then we get

$$0 \leq \mathrm{Re}\,\langle Tz, (I - T)z\rangle = \mathrm{Re}\,\langle Tz, z\rangle - \|Tz\|^2$$

so that $\|Tz\|^2 \leq \mathrm{Re}\,\langle Tz, z\rangle$. Taking $\|z\| = 1$ and using the Cauchy inequality, we obtain $\|Tz\|^2 \leq \|Tz\|$, which implies that $\|Tz\| \leq 1$ for all z with $\|z\| = 1$. □

It is easy to see that, with the above notation, we also have $\|(I + H)^{-1}\| \leq 1$.

PROPOSITION 2.4. *With the assumptions of Proposition 2.1, we have*

$$\|c^\kappa I + \mathbf{G}^\kappa(s)\| \leq \frac{1}{\kappa(1 - \kappa c)} \qquad \forall\, s \in \mathbb{C}_0. \tag{2.4}$$

Proof. Since $\mathbf{H}$ is positive-real, the last lemma implies that

$$\|\mathbf{H}(s)(I+\mathbf{H}(s))^{-1}\| \le 1 \qquad \forall\, s \in \mathbb{C}_0.$$

Now (2.4) follows from this estimate and (2.3). □

The bound (2.4) is quite sharp: in the scalar case, as s approaches a pole of $\mathbf{G}$ on the imaginary axis, (2.4) tends to an equality. Note that in Propositions 2.1–2.4, $\mathbf{G}$ was not assumed to be rational.

Now consider a finite-dimensional system Σ described by the equations

$$\begin{cases} \dot z(t) &= Az(t)+Bu(t), \\ y(t) &= B^*z(t)+Du(t), \end{cases}$$

where A, B and D are real matrices of appropriate dimensions and $A^*+A = -Q \le 0$ so that assumptions ESAD and COL are satisfied. If the number κ is such that $I+\kappa D$ is invertible, then the feedback $u = -\kappa y + v$ leads to the closed-loop system Σ^κ described by the equations

$$\begin{cases} \dot z(t) &= \big(A - B\kappa(I+\kappa D)^{-1}B^*\big)\, z(t) + B(I+\kappa D)^{-1}v(t), \\ y(t) &= (I+\kappa D)^{-1}B^*z(t) + D(I+\kappa D)^{-1}v(t). \end{cases} \tag{2.5}$$

We are interested in conditions that guarantee that the matrix

$$A^\kappa = A - B\kappa(I+\kappa D)^{-1}B^*$$

appearing in (2.5) is stable, i.e., its eigenvalues are in the open left half-plane. The finite-dimensional version of Theorem 1.1 reads as follows.

PROPOSITION 2.5. *With the above notation, if (A,B) is controllable and (A,B^*) is observable, then there exists a $\kappa_0 > 0$ such that for all $\kappa \in (0,\kappa_0)$, A^κ is stable.*

Like Theorem 1.1, this is only a corollary of a stronger result (Proposition 2.6 below) which is a little more complicated to state. This stronger result is the finite-dimensional counterpart of Theorem 5.8. To state it, we introduce the notation

$$\kappa_0 = \frac{1}{c}, \quad \text{where} \quad c = \|E^+\|, \quad E = -\frac{1}{2}(D^*+D). \tag{2.6}$$

Here, E^+ denotes the positive part of E, i.e., $E^+ = EP^+$ where P^+ is the spectral projector corresponding to all the positive eigenvalues of E (hence $E^+ \ge E$ but $\|E^+\| \le \|E\|$). Note that if $E \le 0$, then $c = 0$, and then we put $\kappa_0 = \infty$.

PROPOSITION 2.6. *With the above notation, if (A,B) is stabilizable and (A,B^*) is detectable, then for all $\kappa \in (0,\kappa_0)$, A^κ is stable.*

Proof. The transfer function of Σ is $\mathbf{G}(s) = B^*(sI-A)^{-1}B + D$ and we have

$$\mathbf{G}(s)^* + \mathbf{G}(s) \ge D^* + D \qquad \forall\, s \in \mathbb{C}_0.$$

This implies that, denoting $E = -\frac{1}{2}(D^*+D)$, $\mathbf{G}+E$ is positive-real, and hence $\mathbf{G}+E^+$ is positive-real. Then for $c = \|E^+\|$, $cI+\mathbf{G}$ is positive-real. (A simpler but more restrictive choice would be $c = \|E\|$.) The transfer function of the closed-loop system Σ^κ from (2.5) is $\mathbf{G}^\kappa$. By Proposition 2.1, we have $\mathbf{G}^\kappa \in H^\infty$ for all $\kappa \in (0,\kappa_0)$. It is easy to show that Σ^κ is stabilizable and detectable (because these properties are preserved by output feedback). It is well known that if a finite-dimensional system is stabilizable, detectable and input-output stable, then it is stable. □

We now return to the discussion of the infinite-dimensional case. In this paper we replace the concept of positive-real transfer function with the more general concept of a positive transfer function. An analytic $\mathcal{L}(U)$-valued function on $\mathbb{C}_0$ is called a *positive transfer function* if (2.1) holds. Note that for simplicity we have dropped the condition concerning complex conjugates, since it is not needed in our arguments: in particular, it is not needed in Proposition 2.1. (Defining the complex conjugate of an operator is a bit awkward and not necessary.) In the finite-dimensional case, this slight generalization amounts to dropping the requirement that the system matrices should be real. Note that if the generator A is dissipative and $B \in \mathcal{L}(U, X)$ (i.e., B is bounded), then $\mathbf{G}(s) = B^*(sI - A)^{-1}B$ is a positive transfer function. This is not always true for unbounded B, as we shall show.

The first PDE examples fitting into our framework assumed that A is dissipative, B is bounded and the open-loop transfer function is $\mathbf{G}(s) = B^*(sI - A)^{-1}B$ (i.e., $D = 0$); see Bailey and Hubbard [5], Balakrishnan [6, 7], Russell [30], and Slemrod [33, 34]. In this case, $\mathbf{G}$ is positive and (by Proposition 2.1) the feedback $u = -\kappa y + v$ stabilizes in an input-output sense. Of course, the most desirable type of stability is exponential stability and for this, in the special case $A^* + A = 0$, we need the system to be exactly controllable (or equivalently, exactly observable). This is the setup studied in Haraux [15], Liu [24] and others.

Many examples of flexible beams, plates and hybrid structures with colocated control and observation have been shown to be exponentially stabilizable by static output feedback; see, for example, Chen [10, 11], Rebarber [27], Triggiani [40], Tucsnak and Weiss [41], Luo, Guo and Morgul [25], Guo and Luo [14], and Ammari and Tucsnak [2]. In many of these examples the approach is a classical Lyapunov one, with the key step being the appropriate PDE formulation so that the energy of the system can play the role of a Lyapunov functional. If one examines these examples carefully, one can recognize that they fit into our framework (the assumptions ESAD and COL are satisfied) and they use the feedback $u = -\kappa y + v$ for stabilization. There are also examples in the literature where the open-loop system is not well posed, but application of the static feedback results in a well-posed exponentially stable closed-loop system, see Rebarber [27], Rebarber and Townley [28], Weiss [49], Lasiecka and Triggiani [20]. These examples are not covered by the theory in this paper (except for some partial results in Remarks 5.3 and 5.4).

The recent paper [20] is interesting because it also gives an abstract framework for treating exponential stabilization by colocated feedback. The assumptions are ESAD (with $Q = 0$), COL, $0 \in \rho(A)$ and $A^{-\frac{1}{2}}B \in \mathcal{L}(U, X)$. The last two assumptions (and also the fact that $Q = 0$) are more restrictive than in our framework, but on the other hand, they do not require the open-loop system to be well posed. We note that our examples in sections 5 and 6 are not covered by the theory in [20], because they do not satisfy $A^{-\frac{1}{2}}B \in \mathcal{L}(U, X)$. The main thrust of [20] is to give examples of non-well-posed systems satisfying the assumptions mentioned earlier, for which $A - BB^*$ is exponentially stable. (See also the corrections to [20] in [21].)

As mentioned at the end of section 1, there is also a rich literature dealing with weak or strong stabilization by colocated feedback, which we shall discuss elsewhere.

3. Admissible control and observation operators. In this section we gather, for easy reference, some basic facts about admissible control and observation operators and various controllability and observability concepts. For proofs and for more details we refer to the literature.

We assume that X is a Hilbert space and $A : \mathcal{D}(A) \to X$ is the generator of a strongly continuous semigroup $\mathbb{T}$ on X. We define the Hilbert space X_1 as $\mathcal{D}(A)$ with the norm $\|z\|_1 = \|(\beta I - A)z\|$, where $\beta \in \rho(A)$ is fixed (this norm is equivalent to the graph norm). The Hilbert space X_{-1} is the completion of X with respect to the norm $\|z\|_{-1} = \|(\beta I - A)^{-1}z\|$. This space is isomorphic to $\mathcal{D}(A^*)^*$, the dual of $\mathcal{D}(A^*)$ with respect to the pivot space X, and we have the continuous embeddings

$$X_1 \subset X \subset X_{-1}. \tag{3.1}$$

$\mathbb{T}$ extends to a semigroup on X_{-1}, denoted by the same symbol. The generator of this extended semigroup is an extension of A, whose domain is X, so that $A : X \to X_{-1}$, see Weiss [42]. We denote by $\omega(\mathbb{T})$ the growth bound of $\mathbb{T}$. The semigroup $\mathbb{T}$ is called *exponentially stable* if $\omega(\mathbb{T}) < 0$.

We assume that U is a Hilbert space and $B \in \mathcal{L}(U, X_{-1})$ is an *admissible control operator* for $\mathbb{T}$, defined as in [42]. This means that if z is the solution of $\dot{z}(t) = Az(t) + Bu(t)$, as in (1.1), which is an equation in X_{-1}, with $z(0) = z_0 \in X$ and $u \in L^2([0,\infty), U)$, then $z(t) \in X$ for all $t \geq 0$. In this case, z is a continuous X-valued function of t. We have that for all $t \geq 0$,

$$z(t) = \mathbb{T}_t z_0 + \Phi_t u, \tag{3.2}$$

where $\Phi_t \in \mathcal{L}(L^2([0,\infty), U), X)$ is defined by

$$\Phi_t u = \int_0^t \mathbb{T}_{t-\sigma} B u(\sigma) d\sigma. \tag{3.3}$$

The above integration is done in X_{-1}, but the result is in X. The Laplace transform of z is

$$\hat{z}(s) = (sI - A)^{-1} \left[z_0 + B\hat{u}(s) \right].$$

B is called *bounded* if $B \in \mathcal{L}(U, X)$ (and unbounded otherwise). If B is an admissible control operator for $\mathbb{T}$, then for every $\omega > \omega(\mathbb{T})$ there exists a positive constant δ such that

$$\|(sI - A)^{-1} B\|_{\mathcal{L}(U,X)} \leq \frac{\delta}{\sqrt{\operatorname{Re} s}} \qquad \forall \operatorname{Re} s > \omega. \tag{3.4}$$

If $\dim U < \infty$ and $\mathbb{T}$ is normal or contractive, then (3.4) implies the admissibility of B, see Jacob and Partington [16] and Weiss [47, 48]. Similarly, if $\mathbb{T}$ is left-invertible, then again (3.4) implies the admissibility of B, see [47]. If $\mathbb{T}$ is invertible and $\tilde{\mathbb{T}}$ is the inverse semigroup (i.e., $\tilde{\mathbb{T}}_t = (\mathbb{T}_t)^{-1}$), then B is admissible for $\tilde{\mathbb{T}}$ if and only if it is admissible for $\mathbb{T}$, see, for example, [42].

The *degree of unboundedness* of an operator $B \in \mathcal{L}(U, X_{-1})$, denoted $\alpha(B)$, is the infimum of those $\alpha \geq 0$ for which there exist positive constants δ, ω such that

$$\|(\lambda I - A)^{-1} B\|_{\mathcal{L}(U,X)} \leq \frac{\delta}{\lambda^{1-\alpha}} \qquad \forall \lambda \in (\omega, \infty). \tag{3.5}$$

It is clear from (3.4) that for any admissible $B \in \mathcal{L}(U, X_{-1})$ we have $\alpha(B) \leq \frac{1}{2}$, and if B is bounded then $\alpha(B) = 0$ (see [29] for further comments on $\alpha(B)$).

We assume that Y is another Hilbert space and $C \in \mathcal{L}(X_1, Y)$ is an *admissible observation operator* for $\mathbb{T}$, defined as in Weiss [43]. This means that for every $T > 0$ there exists a $K_T \geq 0$ such that

$$\int_0^T \|C\mathbb{T}_t z_0\|^2 dt \leq K_T^2 \|z_0\|^2 \qquad \forall\, z_0 \in \mathcal{D}(A). \tag{3.6}$$

C is called *bounded* if it can be extended such that $C \in \mathcal{L}(X, Y)$.

We regard $L^2_{loc}([0,\infty), Y)$ as a Fréchet space with the seminorms being the L^2 norms on the intervals $[0, n]$, $n \in \mathbb{N}$. Then the admissibility of C means that there is a continuous operator $\Psi : X \to L^2_{loc}([0,\infty), Y)$ such that

$$(\Psi z_0)(t) = C\mathbb{T}_t z_0 \qquad \forall\, z_0 \in \mathcal{D}(A). \tag{3.7}$$

The operator Ψ is completely determined by (3.7), because $\mathcal{D}(A)$ is dense in X. We introduce an extension of C, called the Λ-extension of C, defined by

$$C_\Lambda z_0 = \lim_{\lambda \to +\infty} C\lambda(\lambda I - A)^{-1} z_0, \tag{3.8}$$

whose domain $\mathcal{D}(C_\Lambda)$ consists of all $z_0 \in X$ for which the limit exists. We shall also use the *weak Λ-extension* of C, $C_{\Lambda w}$. It is defined as in (3.8), but replacing the strong limit by the weak limit. Thus, $C_{\Lambda w}$ is an extension of C_Λ to an even larger subspace of X, denoted by $\mathcal{D}(C_{\Lambda w})$. If we replace C by C_Λ, formula (3.7) becomes true for all $z_0 \in X$ and for almost every $t \geq 0$. If $y = \Psi z_0$, then its Laplace transform is

$$\hat{y}(s) = C(sI - A)^{-1} z_0. \tag{3.9}$$

The following duality result holds: if $\mathbb{T}$ is a semigroup on X with generator A, then $B \in \mathcal{L}(U, X_{-1})$ is an admissible control operator for $\mathbb{T}$ if and only if $B^* : \mathcal{D}(A^*) \to U$ is an admissible observation operator for the dual semigroup $\mathbb{T}^*$.

The dual version of (3.4) is as follows: if C is an admissible observation operator for $\mathbb{T}$, then for every $\omega > \omega(\mathbb{T})$ there exists a positive constant δ such that

$$\|C(sI - A)^{-1}\|_{\mathcal{L}(X,Y)} \leq \frac{\delta}{\sqrt{\operatorname{Re} s}} \qquad \forall\, \operatorname{Re} s > \omega. \tag{3.10}$$

The *degree of unboundedness* of C, denoted $\alpha(C)$, is defined similarly as $\alpha(B)$. We have $\alpha(C) = \alpha(C^*)$, where C^* is regarded as a control operator for $\mathbb{T}^*$.

DEFINITION 3.1. *Let A be the generator of a strongly continuous semigroup $\mathbb{T}$ on X and let $B \in \mathcal{L}(U, X_{-1})$ be an admissible control operator for $\mathbb{T}$. The pair (A, B) is exactly controllable in time $T > 0$, if for every $x_0 \in X$ there exists a $u \in L^2([0, T], U)$ such that*

$$\Phi_T u = \int_0^T \mathbb{T}_{T-\sigma} B u(\sigma) d\sigma = x_0.$$

(A, B) is exactly controllable if it is exactly controllable in some finite time $T > 0$.

It will be useful to note that if A is the generator of a strongly continuous group (i.e., $-A$ is also a semigroup generator), then (A, B) is exactly controllable in time T if and only if $(-A, B)$ is exactly controllable in time T.

We introduce observability concepts via duality. Suppose that A is the generator of the strongly continuous semigroup $\mathbb{T}$ on X and $C \in \mathcal{L}(X_1, Y)$ is an admissible

observation operator for $\mathbb{T}$. Of course, this is equivalent to C^* being an admissible control operator for the dual semigroup $\mathbb{T}^*$. We say that (A, C) is *exactly observable* (*in time* T) if (A^*, C^*) is exactly controllable (in time T).

For more details on exact controllability in an operator-theoretic setting we refer also to Avdonin and Ivanov [4], Guo and Luo [14], Jacob and Zwart [17], Miller [26], Rebarber and Weiss [29], Russell and Weiss [31] and the references therein. In the PDE setting, the relevant literature on controllability is overwhelming, and we mention the books of Lions [23], Lagnese and Lions [22] and Komornik [19] and the paper of Bardos, Lebeau and Rauch [8].

4. Some background on well-posed linear systems. In this section we collect some basic facts about well-posed and regular linear systems, their transfer functions, output feedback and closed-loop systems. Only one result (Proposition 4.1) is new, and of course its proof is included.

By a *well-posed linear system* we mean a linear time-invariant system such that on any finite time interval, the operator from the initial state and the input function to the final state and the output function is bounded. The input, state and output spaces are Hilbert spaces, and the input and output functions are of class $L^2_{\rm loc}$. To express this more clearly, let us denote by U the input space, by X the state space and by Y the output space of a well-posed linear system Σ. The input and output functions u and y are locally L^2 functions with values in U and in Y. The state trajectory z is an X-valued function. The boundedness property mentioned earlier means that for every $\tau > 0$ there is a $c_\tau \geq 0$ such that

$$\|z(\tau)\|^2 + \int_0^\tau \|y(t)\|^2 \, dt \leq c_\tau^2 \left(\|z(0)\|^2 + \int_0^\tau \|u(t)\|^2 \, dt \right) \tag{4.1}$$

(with c_τ independent of $z(0)$ and of u). For the detailed definition, background and examples we refer to Salamon [32], Staffans [35, 36, 37], Weiss [45, 46], Weiss and Rebarber [51] and Weiss, Staffans and Tucsnak [52].

We recall some necessary facts about well-posed linear systems. Let Σ be such a system, with input space U, state space X and output space Y. Then there are operators A, B, C satisfying the assumptions in the previous section, which are related to Σ in the following way. First of all, the state trajectories of Σ satisfy the equation (1.1), so that they are given by (3.2). $\mathbb{T}$ is called the *semigroup* of Σ, A is called its *semigroup generator*, the family $\Phi = (\Phi_t)_{t \geq 0}$ is called the *input maps* of Σ, and B is called the *control operator* of Σ. If u is the input function of Σ, z_0 is its initial state, and y is the corresponding output function, then

$$y = \Psi z_0 + \mathbb{F} u. \tag{4.2}$$

Here, Ψ is an operator as in (3.7), called the (extended) *output map* of Σ and C is called the *observation operator* of Σ. $\mathbb{F}$ is a continuous linear operator from $L^2_{loc}([0, \infty), U)$ to $L^2_{loc}([0, \infty), Y)$, called the (extended) *input-output map* of Σ. The formal definition of Σ in [44, 45] is via $\mathbb{T}, \Phi, \Psi$ and $\mathbb{F}$ so that $\Sigma = (\mathbb{T}, \Phi, \Psi, \mathbb{F})$.

The operator $\mathbb{F}$ appearing above is easiest to represent using Laplace transforms. To state this in precise terms, we introduce the notation $\mathbb{C}_\alpha$ for the open right half-plane consisting of those $s \in \mathbb{C}$ for which $\operatorname{Re} s > \alpha$. An operator-valued analytic function $\mathbf{G}$ is called *well posed* (or proper) if there exists $\alpha \in \mathbb{R}$ such that the domain of $\mathbf{G}$ contains $\mathbb{C}_\alpha$ and $\mathbf{G}$ is uniformly bounded on $\mathbb{C}_\alpha$. We do not distinguish between two well-posed functions if one is a restriction of the other (to a smaller domain in

$\mathbb{C}$). If $\mathbb{F}$ is the input-output map of a well-posed system, then there exists a unique $\mathcal{L}(U,Y)$-valued well-posed function $\mathbf{G}$, called the *transfer function* of Σ, which determines $\mathbb{F}$ as follows. If $u \in L^2([0,\infty),U)$ and $y = \mathbb{F}u$, then y has a Laplace transform $\hat{y}$ and, for $\operatorname{Re} s > \max\{\omega(\mathbb{T}),0\}$ (recall that $\omega(\mathbb{T})$ is the growth bound of $\mathbb{T}$),

$$\hat{y}(s) = \mathbf{G}(s)\hat{u}(s).$$

This determines $\mathbb{F}$, since $L^2([0,\infty),U)$ is dense in $L^2_{loc}([0,\infty),U)$. $\mathbf{G}$ is uniformly bounded on every half-plane $\mathbb{C}_\omega$ with $\omega > \omega(\mathbb{T})$. Because of the identification of well-posed functions mentioned earlier, by a transfer function we mean in fact an equivalence class of analytic functions. For all $s,\beta \in \mathbb{C}_{\omega(\mathbb{T})}$ we have

$$\mathbf{G}(s) - \mathbf{G}(\beta) = C\left[(sI-A)^{-1} - (\beta I - A)^{-1}\right]B. \tag{4.3}$$

This shows that $\mathbf{G}$ is determined by A, B and C up to an additive constant operator. We call (A,B,C) the *generating triple* of Σ. In the time domain, the output function y corresponding to the input function u and state trajectory z is given by

$$y(t) = C_\Lambda\left[z(t) - (\beta I - A)^{-1}Bu(t)\right] + \mathbf{G}(\beta)u(t), \tag{4.4}$$

valid for almost every $t \geq 0$, if $\beta \in \mathbb{C}_{\omega(\mathbb{T})}$. Thus, the system Σ is completely determined (via (1.1) and (4.4)) by its generating triple (A,B,C) and by the value of its transfer function at one point.

The well-posed linear system Σ is called *regular* if the limit

$$\lim_{\lambda \to +\infty} \mathbf{G}(\lambda)\mathrm{v} = D\mathrm{v} \tag{4.5}$$

exists for every $\mathrm{v} \in U$, where λ is real (see [44, 45]). In this case, the operator $D \in \mathcal{L}(U,Y)$ is called the *feedthrough operator* of Σ. Regularity is equivalent to the fact that the product $C_\Lambda(sI-A)^{-1}B$ makes sense, for some (hence, for every) $s \in \rho(A)$. In this case, the formula for $\mathbf{G}$ looks like the finite-dimensional one:

$$\mathbf{G}(s) = C_\Lambda(sI-A)^{-1}B + D. \tag{4.6}$$

Moreover, the function y from (4.2) satisfies, for almost every $t \geq 0$,

$$y(t) = C_\Lambda z(t) + Du(t), \tag{4.7}$$

where z is the state trajectory of the system (compare this with (4.4)). The operators A,B,C,D are called the *generating operators* of Σ, because they determine Σ via (1.1) and (4.7). In particular, if A is a generator, one of B and C is admissible and the other is bounded, then for any $D \in \mathcal{L}(U,Y)$, the operators A,B,C and D are the generating operators of a regular linear system.

The well-posed linear system Σ is called *weakly regular* if the limit in (4.5) exists in the weak sense, see [37]. In this case, the weak limit still defines an operator $D \in \mathcal{L}(U,Y)$, called the *feedthrough operator* of Σ. Weak regularity is equivalent to the fact that the product $C_{\Lambda w}(sI-A)^{-1}B$ makes sense, for some (hence, for every) $s \in \rho(A)$. In this case, the formulas (4.6) and (4.7) become valid after we replace C_Λ by $C_{\Lambda w}$. This slight generalization of regular systems (to weakly regular ones) is sometimes needed because the dual of a regular linear system is not regular, in general, but it is weakly regular. Note that if Y is finite-dimensional, then the regularity of Σ is equivalent to its weak regularity.

PROPOSITION 4.1. *Let Σ be a well-posed linear system with control operator B, observation operator C and transfer function $\mathbf{G}$. If*

$$\alpha(B) + \alpha(C) < 1, \tag{4.8}$$

then Σ is regular. In fact, $\lim_{\lambda\to+\infty} \mathbf{G}(\lambda)$ exists in the operator norm.

Proof. From (4.3) it follows that $\mathbf{G}'(s) = C(sI - A)^{-2}B$ for all $s \in \mathbb{C}_{\omega(\mathbb{T})}$. So for all $\lambda > 0$ sufficiently large, we have

$$\|\mathbf{G}'(\lambda)\|_{\mathcal{L}(U,Y)} \le \|C(\lambda I - A)^{-1}\|_{\mathcal{L}(X,Y)} \cdot \|(\lambda I - A)^{-1}B\|_{\mathcal{L}(U,X)}.$$

Hence, for every $\alpha_1 > \alpha(C)$ and $\alpha_2 > \alpha(B)$ we can find $\delta_1, \delta_2 > 0$ such that, for all $\lambda > 0$ sufficiently large,

$$\|\mathbf{G}'(\lambda)\|_{\mathcal{L}(U,Y)} \le \frac{\delta_1}{\lambda^{1-\alpha_1}} \cdot \frac{\delta_2}{\lambda^{1-\alpha_2}}.$$

If (4.8) holds, then α_1 and α_2 can be chosen such that $\alpha_1 + \alpha_2 = 1 - \varepsilon$, with $\varepsilon > 0$. Denoting $\delta = \delta_1\delta_2$, we obtain that for all sufficiently large $\lambda > 0$,

$$\|\mathbf{G}'(\lambda)\|_{\mathcal{L}(U,Y)} \le \frac{\delta}{\lambda^{1+\varepsilon}}, \qquad \varepsilon > 0.$$

By integration we obtain that for $\lambda_1 < \lambda_2$ sufficiently large,

$$\|\mathbf{G}(\lambda_1) - \mathbf{G}(\lambda_2)\| \le \int_{\lambda_1}^{\lambda_2} \|\mathbf{G}'(\lambda)\| d\lambda \;\le\; \frac{\delta}{\varepsilon} \left| \frac{1}{\lambda_1^{\varepsilon}} - \frac{1}{\lambda_2^{\varepsilon}} \right|$$

so that $\lim_{\lambda\to+\infty} \mathbf{G}(\lambda)$ exists (which is stronger than (4.5)). ∎

It is often useful to introduce the space

$$Z = X_1 + (\beta I - A)^{-1}BU, \tag{4.9}$$

where $\beta \in \rho(A)$ (the space Z does not depend on the choice of β). Z is a Hilbert space with the following factor space norm:

$$\|z\|_Z = \inf_{z=x+(\beta I-A)^{-1}Bv} \left(\|x\|_1^2 + \|v\|_U^2\right)^{\frac{1}{2}}.$$

It is easy to see that $X_1 \subset Z \subset X$ with continuous embeddings, but X_1 need not be dense in Z. It was shown in [37, section 3] that for any well-posed system, C can be extended to an operator $\overline{C} \in \mathcal{L}(Z;Y)$ (this extension may be nonunique). For every $s \in \rho(A)$, the product $\overline{C}(sI - A)^{-1}B$ exists. For every such extension $\overline{C}$ there exists a unique $D \in \mathcal{L}(U,Y)$ such that $\mathbf{G}(s) = \overline{C}(sI - A)^{-1}B + D$. (For regular systems, we may take $\overline{C} = C_\Lambda$ and then D becomes the feedthrough operator of the system.) If $u \in \mathcal{H}^1_{loc}(0,\infty;U)$ and $Az(0) + Bu(0) \in X$, then for all $t \ge 0$ we have $z(t) \in Z$, the equation $\dot{z}(t) = Az(t) + Bu(t)$ holds for every $t \ge 0$, the output function y is continuous, and it is given for all $t \ge 0$ by

$$y(t) = \overline{C}z(t) + Du(t). \tag{4.10}$$

Let Σ be a well-posed linear system with generating triple (A, B, C) and transfer function $\mathbf{G}$. An operator $K \in \mathcal{L}(Y,U)$ is called an *admissible feedback operator* for Σ

(or for $\mathbf{G}$) if $I - \mathbf{G}K$ has a well-posed inverse (equivalently, if $I - K\mathbf{G}$ has a well-posed inverse). If this is the case, then the system with output feedback $u = Ky + v$ (see Figure 1, but with $-K$ in place of κ) is well posed (its input is v, its state and output are the same as for Σ), see [46]. This new system is called the *closed-loop system* corresponding to Σ and K, and it is denoted by Σ^K. Its transfer function is $\mathbf{G}^K = \mathbf{G}(I - K\mathbf{G})^{-1} = (I - \mathbf{G}K)^{-1}\mathbf{G}$. We have that $-K$ is an admissible feedback operator for Σ^K and the corresponding closed-loop system is Σ. Let us denote by (A^K, B^K, C^K) the generating triple of Σ^K. Then for every $x_0 \in \mathcal{D}(A^K)$ and for every $z_0 \in \mathcal{D}(A)$,

$$A^K x_0 = \left(A + BKC^K\right) x_0, \qquad Az_0 = \left(A^K - B^K KC\right) z_0. \tag{4.11}$$

Note that $B^K \in \mathcal{L}(U, X_{-1}^K)$ and $C^K \in \mathcal{L}(X_1^K, Y)$, where X_{-1}^K and X_1^K are the counterparts of X_{-1} and X_1 for Σ^K. Any interconnection of finitely many well-posed linear systems can be thought of as a closed-loop system in the above sense.

The following invariance result is taken from [46, section 6].

PROPOSITION 4.2. *Let Σ be a well-posed linear system, let K be an admissible feedback operator for Σ, and let Σ^K be the corresponding closed-loop system. We denote by (A, B, C) the generating triple of Σ and by (A^K, B^K, C^K) the generating triple of Σ^K. Then the following holds:*

(a) *(A, B) is exactly controllable if and only if (A^K, B^K) has the same property,*

(b) *(A, C) is exactly observable if and only if (A^K, C^K) has the same property.*

We recall some concepts that are used in the optimal control literature (under different names), following the formulation in Weiss and Rebarber [51].

DEFINITION 4.3. *Let A be the generator of a strongly continuous semigroup $\mathbb{T}$ on X and suppose that $B \in \mathcal{L}(U, X_{-1})$ is an admissible control operator for $\mathbb{T}$. Then (A, B) is optimizable if for every $z_0 \in X$ there exists a $u \in L^2([0, \infty), U)$ such that the state trajectory z defined in (3.2) is in $L^2([0, \infty), X)$.*

Let $C \in \mathcal{L}(X_1, Y)$ be an admissible observation operator for $\mathbb{T}$. Then (A, C) is estimatable if (A^*, C^*) is optimizable.

Estimatability can be formulated also directly, without using adjoints, see [51]. Optimizability is one possible generalization of the concept of stabilizability from finite-dimensional systems to infinite-dimensional ones. Similarly, estimatability is one possible generalization of detectability. It is clear that exact controllability implies optimizability, and exact observability implies estimatability. It was shown in [51] that optimizability and estimatability are invariant under output feedback (just like exact controllability and exact observability).

PROPOSITION 4.4. *With the notation from Proposition 4.2, (A, B) is optimizable if and only if (A^K, B^K) is optimizable and (A, C) is estimatable if and only if (A^K, C^K) is estimatable.*

We quote from [51] the following characterization of exponential stability.

THEOREM 4.5. *A well-posed linear system is exponentially stable if and only if it is optimizable, estimatable and input-output stable.*

It follows from this theorem that a well-posed linear system is exponentially stable if it is exactly controllable, exactly observable, and input-output stable.

5. Positivity and exponential stabilization. In this section we prove a rather technical result (Theorem 5.2) about the positivity of the transfer function $\mathbf{G} + E$, where $\mathbf{G}$ is the transfer function of the system Σ satisfying ESAD and COL, and E is given by a certain limit, see (5.4). If B is not too unbounded (more precisely, if

$\alpha(B) < \frac{1}{2}$), then Σ is regular and

$$E = -\frac{1}{2}(D^* + D), \tag{5.1}$$

where D is the feedthrough operator of Σ. Formula (5.1) may hold even if $\alpha(B) = \frac{1}{2}$, but we show by a counterexample that (5.1) may fail if $\alpha(B) = \frac{1}{2}$. If $0 \in \rho(A)$ and $Q = 0$, then it turns out that E is related to the direct current (DC)-gain of the system, $\mathbf{G}(0)$:

$$E = -\frac{1}{2}\left[\mathbf{G}(0)^* + \mathbf{G}(0)\right],$$

see (5.5). For this formula to hold, Σ does not need to be regular.

We also prove a result (Proposition 5.7) about the stabilization of systems whose transfer function $\mathbf{G}$ is such that for some $c \geq 0$, $cI + \mathbf{G}$ is a positive transfer function. These two results imply our main result about exponential stabilization, Theorem 5.8 (which is stronger than Theorem 1.1). We consider the general class of well-posed linear systems, but we also explain some consequences for the smaller but simpler class of weakly regular linear systems.

Notation and assumptions. We consider a well-posed system Σ with input and output space U, state space X, semigroup $\mathbb{T}$, and transfer function $\mathbf{G}$. Σ satisfies the assumptions ESAD and COL from section 1, and the operators A, Q and B are as in section 1. The space X_{-1} is defined as in section 3.

It follows from ESAD that the growth bound of $\mathbb{T}$ satisfies $\omega(\mathbb{T}) \leq 0$ so that $\mathbf{G}$ is defined on $\mathbb{C}_0$. Assumption ESAD also implies that $\mathbb{T}$ is invertible, so that $\sigma(A)$ is contained in a vertical strip in the closed left half-plane. Thus, $\rho(A)$ includes a left half-plane. We now introduce a natural extension of $\mathbf{G}$ to $\rho(A)$.

LEMMA 5.1. *With the above notation and assumptions, there exists a unique extension of* $\mathbf{G}$ *to* $\rho(A)$ *which satisfies*

$$\mathbf{G}(s) - \mathbf{G}(\beta) = B^*\left[(sI - A)^{-1} - (\beta I - A)^{-1}\right]B \qquad \forall\, s, \beta \in \rho(A). \tag{5.2}$$

This extension is analytic, and it is bounded on any right half-plane $\mathbb{C}_\varepsilon$ *with* $\varepsilon > 0$, *as well as on some left half-plane.*

Note that if $\rho(A)$ is connected, then the above extension of $\mathbf{G}$ coincides with its analytic continuation to $\rho(A)$.

Proof. It is clear that the original $\mathbf{G}$ satisfies (5.2) on $\mathbb{C}_0$, because (5.2) is just (4.3) with $C = B^*$. This implies that $\mathbf{G}(s)$ can be defined for $s \in \rho(A)$ by (5.2) with $\beta \in \mathbb{C}_0$, and the definition is independent of the choice of β. It is also clear that the extended $\mathbf{G}$ is analytic, and it satisfies (5.2) if at least one of the numbers s, β is in $\mathbb{C}_0$. We have to check that (5.2) also holds if neither s nor β is in $\mathbb{C}_0$. To show this, we choose $z \in \mathbb{C}_0$ and we decompose

$$\mathbf{G}(s) - \mathbf{G}(\beta) = [\mathbf{G}(s) - \mathbf{G}(z)] + [\mathbf{G}(z) - \mathbf{G}(\beta)].$$

Now (5.2) follows from the fact that it holds for each of the two terms. It follows from the theory in section 4 that $\mathbf{G}$ is bounded on $\mathbb{C}_\varepsilon$ for any $\varepsilon > 0$, since $\omega(\mathbb{T}) \leq 0$.

Finally, we have to show that the extended $\mathbf{G}$ is bounded on some left half-plane. Choose $\mu > 0$ such that $\sigma(A)$ is contained in the vertical strip, where $-\mu \leq \operatorname{Re} s \leq 0$. Then for $\operatorname{Re} s > \mu$, (5.2) with the resolvent identity implies that

$$\mathbf{G}(s) - \mathbf{G}(-\overline{s}) = 2(\operatorname{Re} s)B^*(sI - A)^{-1}(\overline{s}I + A)^{-1}B.$$

B is an admissible control operator for the inverse semigroup $\tilde{\mathbb{T}}_t = (\mathbb{T}_t)^{-1}$ (see section 3, after (3.4)). It follows from (3.4) rewritten for $\tilde{\mathbb{T}}$ that for some $\delta^1, \omega^1 > 0$,

$$\|(sI + A)^{-1}B\|_{\mathcal{L}(U,X)} \leq \frac{\delta^1}{\sqrt{\operatorname{Re} s}} \qquad \forall \operatorname{Re} s > \omega^1.$$

Applying this estimate and (3.10), we obtain that for $\operatorname{Re} s$ sufficiently large,

$$\|\mathbf{G}(s) - \mathbf{G}(-\overline{s})\| \leq 2\delta\delta^1.$$

Since $\mathbf{G}$ is bounded on $\mathbb{C}_\varepsilon$ (for any $\varepsilon > 0$), this estimate shows that it is also bounded on some left half-plane. □

The last lemma can be derived also as a consequence of the theory of time-invertible systems in Staffans and Weiss [38].

THEOREM 5.2. *With the above notation and assumptions, there exist operators $E = E^* \in \mathcal{L}(U)$ such that $\mathbf{G} + E$ is a positive transfer function, i.e.,*

$$\mathbf{G}(s)^* + \mathbf{G}(s) + 2E \geq 0 \qquad \forall\, s \in \mathbb{C}_0. \tag{5.3}$$

One such operator E is given by

$$E = -\frac{1}{2} \lim_{\lambda \to +\infty} \left[\mathbf{G}(\lambda)^* + \mathbf{G}(-\lambda)\right]. \tag{5.4}$$

If $0 \in \rho(A)$, then the same E is also given by

$$E = -\frac{1}{2}\left[\mathbf{G}(0)^* + \mathbf{G}(0)\right] + B^*(A^*)^{-1}QA^{-1}B. \tag{5.5}$$

If Σ is weakly regular, with feedthrough operator D, then E is also given by

$$\langle E\mathrm{v}, \mathrm{v}\rangle = -\frac{1}{2}\langle (D^* + D)\mathrm{v}, \mathrm{v}\rangle + \lim_{\lambda \to +\infty} \lambda \|(\lambda I - A)^{-1}B\mathrm{v}\|^2 \qquad \forall\, \mathrm{v} \in U. \tag{5.6}$$

Note that the limit in (5.4) exists in the operator norm, even if Σ is not regular.

Proof. We shall use the following identity (a consequence of ESAD):

$$(\overline{s}I - A^*)^{-1} + (sI - A)^{-1} = (\overline{s}I - A^*)^{-1}\big[2(\operatorname{Re} s)I + Q\big](sI - A)^{-1}. \tag{5.7}$$

Using the formulas (4.3) and (5.7), we calculate

$$\begin{aligned}
&[\mathbf{G}(s)^* + \mathbf{G}(s)] - [\mathbf{G}(\beta)^* + \mathbf{G}(\beta)] \\
&= B^*[(sI - A)^{-1} - (\beta I - A)^{-1}]B + B^*[(\overline{s}I - A^*)^{-1} - (\overline{\beta}I - A^*)^{-1}]B \\
&= B^*[(\overline{s}I - A^*)^{-1} + (sI - A)^{-1}]B - B^*[(\overline{\beta}I - A^*)^{-1} + (\beta I - A)^{-1}]B \\
&= B^*(\overline{s}I - A^*)^{-1}[2(\operatorname{Re} s)I + Q](sI - A)^{-1}B \\
&\qquad -B^*(\overline{\beta}I - A^*)^{-1}[2(\operatorname{Re}\beta)I + Q](\beta I - A)^{-1}B,
\end{aligned}$$

for all $s, \beta \in \mathbb{C}_0$. Rearranging the above formula, we obtain

$$\begin{aligned}
&[\mathbf{G}(s)^* + \mathbf{G}(s)] - B^*(\overline{s}I - A^*)^{-1}[2(\operatorname{Re} s)I + Q](sI - A)^{-1}B \\
=&[\mathbf{G}(\beta)^* + \mathbf{G}(\beta)] - B^*(\overline{\beta}I - A^*)^{-1}[2(\operatorname{Re}\beta)I + Q](\beta I - A)^{-1}B.
\end{aligned}$$

Thus, both sides are equal to a bounded, self-adjoint operator on U, which depends neither on s nor on β. We denote this operator by $-2E$. Now since

$$B^*(\overline{s}I - A^*)^{-1}[2(\operatorname{Re} s)I + Q](sI - A)^{-1}B \geq 0 \qquad \forall\, s \in \mathbb{C}_0,$$

we deduce that (5.3) holds. For all $\lambda > 0$ we have

$$2E = -[\mathbf{G}(\lambda)^* + \mathbf{G}(\lambda)] + B^*(\lambda I - A^*)^{-1}[2\lambda I + Q](\lambda I - A)^{-1}B. \tag{5.8}$$

Since $-A^* = A + Q$, we have

$$(\lambda I - A^*)^{-1} = (\lambda I + A)^{-1} - (\lambda I - A^*)^{-1}Q(\lambda I + A)^{-1}.$$

Substituting this into (5.8), we obtain

$$\begin{aligned} 2E = &-[\mathbf{G}(\lambda)^* + \mathbf{G}(\lambda)] + 2\lambda B^*(\lambda I + A)^{-1}(\lambda I - A)^{-1}B \\ &+ B^*(\lambda I + A)^{-1}Q(\lambda I - A)^{-1}B - B^*(\lambda I - A^*)^{-1}Q(\lambda I + A)^{-1}[2\lambda I + Q](\lambda I - A)^{-1}B. \end{aligned}$$

We want to examine what happens in this rather long formula when $\lambda \to +\infty$. Since B^* is an admissible observation operator for the inverse semigroup generated by $-A$, by (3.10) $\|B^*(\lambda I + A)^{-1}\|$ decays like $1/\sqrt{\lambda}$ for large λ. Similarly, by (3.4), the factors $\|(\lambda I - A)^{-1}B\| = \|B^*(\lambda I - A^*)^{-1}\|$ decay like $1/\sqrt{\lambda}$ for large λ. The factor $(\lambda I + A)^{-1}[2\lambda I + Q]$ remains bounded as $\lambda \to +\infty$. It follows from these considerations that the last two terms in the long formula (the ones containing a factor Q) tend to zero as $\lambda \to +\infty$. Hence,

$$2E = \lim_{\lambda \to +\infty} \left[-\mathbf{G}(\lambda)^* - \mathbf{G}(\lambda) + 2\lambda B^*(\lambda I + A)^{-1}(\lambda I - A)^{-1}B \right].$$

On the other hand, we know from (5.2) and the resolvent identity that for $\lambda > 0$ sufficiently large, using the extension of $\mathbf{G}$ to $\rho(A)$, the following holds:

$$\mathbf{G}(\lambda) - \mathbf{G}(-\lambda) = 2\lambda B^*(\lambda I + A)^{-1}(\lambda I - A)^{-1}B.$$

Substituting this into the previous formula, we get (5.4).

To prove (5.5), assume that $0 \in \rho(A)$. Taking $\lambda \to 0$ in (5.8), we obtain (5.5).

To prove (5.6), suppose now that Σ is weakly regular with feedthrough operator D. Then, applying (5.8) to $\mathrm{v} \in U$, taking the scalar product with v and taking limits as $\lambda \to +\infty$, we obtain

$$\begin{aligned} 2\langle E\mathrm{v}, \mathrm{v}\rangle &= -\lim_{\lambda \to +\infty} \langle (\mathbf{G}(\lambda)^* + \mathbf{G}(\lambda))\mathrm{v}, \mathrm{v}\rangle + \lim_{\lambda \to +\infty} 2\lambda \|(\lambda I - A)^{-1}B\mathrm{v}\|^2 \\ &\quad + \lim_{\lambda \to +\infty} \langle Q(\lambda I - A)^{-1}B\mathrm{v}, (\lambda I - A)^{-1}B\mathrm{v}\rangle \\ &= -\langle (D + D^*)\mathrm{v}, \mathrm{v}\rangle + 2 \lim_{\lambda \to +\infty} \lambda \|(\lambda I - A)^{-1}B\mathrm{v}\|^2, \end{aligned}$$

since the inequality (3.4) shows that the limit containing Q is zero. □

Remark 5.3. It follows from the last theorem that $cI + \mathbf{G}$ is a positive transfer function for $c = \|E^+\|$, where E^+ is the positive part of the self-adjoint operator E from (5.4). Indeed, this follows from $cI \geq E^+ \geq E$ (for finite-dimensional systems this was in the proof of Proposition 2.6). Note that the proof of (5.3), (5.4) and (5.5) did not use the well posedness of Σ, but only the admissibility of B. Thus, if A satisfies ESAD, B is an admissible control operator for the semigroup generated by A, and $C = B^*$, then for any function $\mathbf{G}$ satisfying (4.3) there exists a $c \geq 0$ such that $cI + \mathbf{G}$ is a positive transfer function. This $\mathbf{G}$ need not be well posed.

Remark 5.4. In the case that $Q = 0$, the conclusions of the previous remark remain valid without assuming that B is admissible; we only need the fact that

$B \in \mathcal{L}(U, X_{-1})$. Thus, in this case, (5.3), (5.4) and (5.5) still hold without assuming well posedness or admissibility. Moreover, (5.4) and (5.5) can be replaced by

$$E = -\frac{1}{2}[\mathbf{G}(\lambda)^* + \mathbf{G}(-\lambda)] \qquad \forall\, \lambda > 0.$$

Recall that $\alpha(B)$ denotes the degree of unboundedness of B, introduced in (3.5). In the following proposition we discuss the consequences of B being less than maximally unbounded, i.e., $\alpha(B) < \frac{1}{2}$, in the context of Theorem 5.2.

PROPOSITION 5.5. *With the notation and assumptions of this section, suppose that* $\alpha(B) < \frac{1}{2}$. *Then* Σ *is regular and* E *from* (5.4) *is given by* (5.1). *Moreover, in this case,* E *given by* (5.1) *is the smallest self-adjoint operator in* $\mathcal{L}(U)$ *satisfying* (5.3).

By the minimality of E we mean the following: If $F = F^* \in \mathcal{L}(U)$ is such that $\mathbf{G} + F$ is a positive transfer function, then $E \leq F$.

Proof. First we note that the regularity of Σ follows from Proposition 4.1 (since $\alpha(B^*) \leq \frac{1}{2}$). The formula (5.1) follows from (5.6), where the second term is now zero. Let $F = F^*$ be such that $\mathbf{G} + F$ is a positive transfer function so that

$$2F + [\mathbf{G}(\lambda)^* + \mathbf{G}(\lambda)] \geq 0 \qquad \forall\, \lambda > 0.$$

Taking limits as $\lambda \to +\infty$, we obtain that $2F + D + D^* \geq 0$. From here, using (5.1) we obtain $2F - 2E \geq 0$, i.e., E is minimal. ∎

By Theorem 5.2 $\mathbf{G} + E$ is a positive transfer function. If Σ is regular and (5.1) holds, then this implies that $\mathbf{G} - D$ is also a positive transfer function. From (4.6) with $C = B^*$ we then obtain that $B_\Lambda^*(sI - A)^{-1}B$ is a positive transfer function.

The following example is a regular linear system satisfying ESAD and COL, with feedthrough operator $D = 0$, for which the operator E from (5.4) or (5.6) is nonzero. For this example, $B_\Lambda^*(sI - A)^{-1}B$ is *not* a positive transfer function and the feedback $u = -\kappa y + v$ is exponentially destabilizing if κ is too large.

Example 5.6. Consider the usual realization of a delay line of length h, $h > 0$, as given, e.g., on p. 831 of [45]. The state space of this system Σ_0 is $X = L^2[-h, 0]$, the semigroup is the left shift operator with zero entering from the right, with the generator

$$A_0 = \frac{\mathrm{d}}{\mathrm{d}x}, \qquad \mathcal{D}(A_0) = \{z_0 \in \mathcal{H}^1(-h, 0) \mid z_0(0) = 0\}.$$

The control operator is $B = \delta_0$ and the observation operator is $C = \delta_{-h}^*$, which means that $Cz_0 = z_0(-h)$ for $z_0 \in \mathcal{D}(A_0)$. The feedthrough operator is zero and the transfer function of this system is $\mathbf{G}_0(s) = e^{-hs}$. We call the input w and the output y. (For an isomorphic system described by the wave equation we refer to [53, section 7]. We close a positive unity feedback loop around this delay line, meaning that $w = y + u$, where u is the new input function. This leads to a new well-posed linear system Σ with the transfer function

$$\mathbf{G}(s) = \frac{e^{-hs}}{1 - e^{-hs}}. \tag{5.9}$$

The semigroup $\mathbb{T}$ of this new system is the periodic left shift semigroup on X, which is unitary. The generating operators of Σ can be computed directly, or using the formulas from [46, section 7]. The generator of $\mathbb{T}$ is again $A = \frac{\mathrm{d}}{\mathrm{d}x}$, but now the domain is

$$\mathcal{D}(A) = \{z_0 \in \mathcal{H}^1(-h, 0) \mid z_0(0) = z_0(-h)\}.$$

It is easy to see that this A is skew-adjoint. The operators B and C remain basically the same, but of course the new C is defined on the new $\mathcal{D}(A)$ and this results in $C = B^*$. Thus, the system Σ fits into the framework of this paper (it satisfies ESAD and COL). Moreover, Σ is regular and its feedthrough operator is zero. It is not difficult to check that B is maximally unbounded, i.e., $\alpha(B) = \frac{1}{2}$.

We remark that the space Z from (4.9) is now $Z = \mathcal{H}^1(-h, 0)$ and for every $z_0 \in Z$ we have $C_\Lambda z_0 = z_0(-h)$. It follows from what we said at (4.10) that if $u \in \mathcal{H}^1(0, \infty)$ and if z_0, the initial state of Σ satisfies $z_0 \in \mathcal{H}^1(-h, 0)$ and $z_0(0) = z_0(-h) + u(0)$ (equivalently, $Az_0 + Bu(0) \in X$), then for all $t \geq 0$ we have

$$z(\cdot, t) \in \mathcal{H}^1(-h, 0), \qquad z(0, t) = z(-h, t) + u(t),$$

and the output function y is given by $y(t) = z(-h, t)$.

The spectrum $\sigma(A)$ now consists of the poles of $\mathbf{G}$, so that $\rho(A)$ is a connected set. The extension of $\mathbf{G}$ to $\rho(A)$, as introduced in Lemma 5.1, is the analytic continuation of $\mathbf{G}$, still given by (5.9). Formula (5.4) gives $E = \frac{1}{2}$. It is not difficult to verify that

$$\mathbf{G}(i\omega)^* + \mathbf{G}(i\omega) = -1 \qquad \forall\, \omega \in \mathbb{R}$$

so that $\mathbf{G}$ is not positive-real, but of course $\mathbf{G} + E = \mathbf{G} + \frac{1}{2}$ is positive-real. Note that E is minimal in the sense of Proposition 5.5, even though $\alpha(B) = \frac{1}{2}$.

If we close a negative feedback loop around Σ by putting $u = -\kappa y + v$, where v is the new input, then we get the closed-loop transfer function

$$\mathbf{G}^\kappa(s) = \frac{e^{-hs}}{1 - (1 - \kappa)e^{-hs}}.$$

This transfer function is bounded on some right half-plane, since

$$|\mathbf{G}^\kappa(s)| \leq e^{-h\sigma}/|1 - (1 - \kappa)e^{-h\sigma}|, \qquad \sigma = \operatorname{Re} s,$$

and so the closed-loop system is well posed. $\mathbf{G}^\kappa$ is stable for $0 < \kappa < 2$, but for $\kappa \geq 2$ the transfer function has unstable poles. This shows that the closed-loop semigroup becomes unstable. Moreover, the larger κ becomes, the more unstable the closed-loop system becomes (its poles move to the right).

If a system with transfer function $\mathbf{G}$ is such that $cI + \mathbf{G}$ is positive, we show that sufficiently small output feedbacks stabilize the system in an input-output sense. If the system is optimizable and estimatable (for example, if it is exactly controllable and exactly observable), then we can conclude exponential stability. During the following proposition (and its proof) we suspend the standing notation and assumptions introduced at the beginning of this section. Thus, for example, the system Σ is not required to satisfy assumptions ESAD and COL.

PROPOSITION 5.7. *Suppose that Σ is a well-posed linear system with input and output space U. Assume that its transfer function $\mathbf{G}$ is such that for some $c \geq 0$, $cI + \mathbf{G}$ is a positive transfer function. Denote $\kappa_0 = \frac{1}{c}$ (for $c = 0$, take $\kappa_0 = \infty$). Then for every $\kappa \in (0, \kappa_0)$ the operator $K = -\kappa I$ is an admissible feedback operator for Σ, and the corresponding closed-loop system Σ^κ is input-output stable, i.e., $\mathbf{G}^\kappa = \mathbf{G}(I + \kappa\mathbf{G})^{-1} \in H^\infty(\mathcal{L}(U))$. Moreover, if Σ is optimizable and estimatable, then the closed-loop system is exponentially stable.*

Proof. Denote $a = \frac{1}{\kappa}$. The proof of the fact that for all $\mathrm{v} \in U$ with $\|\mathrm{v}\| = 1$,

$$\|(aI + \mathbf{G}(s))\mathrm{v}\| \geq a - c \qquad \forall\, s \in \mathbb{C}_0, \tag{5.10}$$

is exactly like in the proof of Proposition 2.1. However, since U may now be infinite-dimensional, boundedness from below is not enough to conclude the invertibility of $aI + \mathbf{G}(s)$. By a similar argument, we have that $\|(aI + \mathbf{G}(s))^*\mathrm{v}\| \geq a - c$, and this together with (5.10) implies the desired invertibility and also that (2.2) holds. From here we easily get $\mathbf{G}^\kappa \in H^\infty$, as in the proof of Proposition 2.1.

Now applying Theorem 4.5, we can conclude exponential stability if Σ^κ is optimizable and estimatable. If Σ is optimizable and estimatable, then Σ^κ inherits these properties, according to Proposition 4.4. □

The above proof appears to be short and simple, but it relies on Proposition 4.4 and Theorem 4.5, and the proof of the latter (in [51]) is rather involved.

THEOREM 5.8. *With the notation and assumptions from the beginning of this section, let $c = \|E^+\|$, where E^+ is the positive part of E from* (5.4) *and denote $\kappa_0 = \frac{1}{c}$ (for $c = 0$, take $\kappa_0 = \infty$). Then for every $\kappa \in (0, \kappa_0)$, $K = -\kappa I$ is an admissible feedback operator for Σ, leading to the closed-loop system Σ^κ which is input-output stable. If Σ is optimizable and estimatable, then Σ^κ is exponentially stable.*

Proof. According to Remark 5.3, $cI + \mathbf{G}$ is a positive transfer function for $c = \|E^+\|$. Now the theorem follows from Proposition 5.7 using this c. □

The following proposition may be useful for checking if a specific system fits into the framework used in this paper.

PROPOSITION 5.9. *Suppose that A satisfies* ESAD *and $B \in \mathcal{L}(U, X_{-1})$. Then B is an admissible control operator for $\mathbb{T}$ if and only if B^* is an admissible observation operator for $\mathbb{T}$. Moreover, we have $\alpha(B) = \alpha(B^*)$.*

Proof. Denote $A_0 = A + \frac{1}{2}Q$ so that A_0 is skew-adjoint. Take $s \in \mathbb{C}_0$. From

$$(sI - A_0)^{-1} - (sI - A)^{-1} = \frac{1}{2}(sI - A_0)^{-1}Q(sI - A)^{-1}, \tag{5.11}$$

we see that the norms $\|x\|_{-1} = \|(sI - A)^{-1}x\|$ and $\|x\|^0_{-1} = \|(sI - A_0)^{-1}x\|$ are equivalent. Hence, the space X_{-1} for A and for A_0 is the same. Multiplying the last identity with B from the right and taking norms, we can see that $\alpha(B)$ with respect to A and A_0 is the same. We denote by $\mathbb{S}$ the (unitary) semigroup generated by A_0, and by $\mathbb{S}^*$ its adjoint (or inverse) semigroup, generated by $-A_0$. It is easy to see that B is an admissible control operator for $\mathbb{T}$ if and only if it is for $\mathbb{S}$ (because the perturbation $\frac{1}{2}Q$ is bounded). Similarly, we can show that $\alpha(B^*)$ with respect to A and A_0 is the same and B^* is an admissible observation operator for $\mathbb{T}$ if and only if it is for $\mathbb{S}$. Thus, so far we have shown that for our purposes, there is no difference between A and A_0 (i.e., between $\mathbb{T}$ and $\mathbb{S}$).

It is easy to see that the admissibility of B for $\mathbb{S}$ and for $\mathbb{S}^*$ are equivalent (see the text after (3.4)). On the other hand, the admissibility of B for $\mathbb{S}^*$ is equivalent to the admissibility of B^* for $\mathbb{S}$ (see section 3). Hence, B is an admissible control operator for $\mathbb{S}$ if and only if B^* is an admissible observation operator for $\mathbb{S}$. It remains to prove that $\alpha(B) = \alpha(B^*)$. This follows from

$$\begin{aligned}\|(\lambda I - A_0)^{-1}B\|^2 &= \|B^*(\lambda I + A_0)^{-1}(\lambda I - A_0)^{-1}B\| \\ &= \|B^*(\lambda I - A_0)^{-1}(\lambda I + A_0)^{-1}B\| = \|B^*(\lambda I - A_0)^{-1}\|^2. \qquad \square\end{aligned}$$

6. A class of undamped second order systems. In this section we introduce a class of undamped second order systems satisfying ESAD and COL. For these systems we derive an explicit expression for E from (5.4) that shows clearly that E^+ is not always zero. Hence, as we have seen in section 5, the range of exponentially stabilizing feedback gains is bounded in general.

Let U_0, U_1 and H be Hilbert spaces and let $A_0 : \mathcal{D}(A_0) \to H$ be positive and boundedly invertible on H. Consider the system described by the following second order differential equation and two output equations:

$$\left\{ \begin{array}{rcll} \ddot{q} + A_0 q & = & C_0^* u_0 + A_0^{-1} C_1^* \dot{u}_1, & \\ y_0 & = & \overline{C_0}\dot{q}, & y_1 = \overline{C_1} q, \end{array} \right. \tag{6.1}$$

for sufficiently smooth signals u_0, u_1 and compatible initial conditions $q(0)$ and $\dot{q}(0)$. The input signals u_0, u_1 and the output signals y_0, y_1 are such that $u_0(t) \in U_0$, $u_1(t) \in U_1$, $y_0(t) \in U_0$, $y_1(t) \in U_1$. To formulate these equations in the form (1.1) and (4.10), which describe a well-posed linear system for sufficiently smooth u and compatible $z(0)$, we need to introduce various spaces and operators, and to make some assumptions. For every $\mu > 0$, we define $H_\mu = \mathcal{D}(A_0^\mu)$, with the norm $\|\varphi\|_\mu = \|A_0^\mu \varphi\|_H$, and we define $H_{-\mu} = H_\mu^*$ (duality with respect to the pivot space H). We denote $H_0 = H$ and $\|\varphi\|_0 = \|\varphi\|_H$. We assume that

$$C_0 \in \mathcal{L}(H_{\frac{1}{2}}, U_0), \qquad C_1 \in \mathcal{L}(H_1, U_1).$$

We identify U_0 and U_1 with their duals so that $C_0^* \in \mathcal{L}(U_0, H_{-\frac{1}{2}})$, $C_1^* \in \mathcal{L}(U_1, H_{-1})$. We assume that C_0 and C_1 have extensions $\overline{C_0}$ and $\overline{C_1}$ such that the operators

$$D_0 = \overline{C_0} A_0^{-1} C_1^* \in \mathcal{L}(U_1, U_0), \qquad D_1 = \overline{C_1} A_0^{-1} C_0^* \in \mathcal{L}(U_0, U_1)$$

exist. We introduce the input (and output) space U and the state space X:

$$U = U_0 \times U_1, \qquad X = H_{\frac{1}{2}} \times H. \tag{6.2}$$

Now the equations of the system Σ from (6.1) can be rewritten in the form

$$\left\{ \begin{array}{rcl} \dot{z} & = & Az + Bu, \\ y & = & \overline{C} z + Du, \end{array} \right. \tag{6.3}$$

where

$$z = \left[\begin{array}{c} q \\ w \end{array} \right] \in X, \quad u = \left[\begin{array}{c} u_0 \\ u_1 \end{array} \right] \in U, \quad y = \left[\begin{array}{c} y_0 \\ y_1 \end{array} \right] \in U, \tag{6.4}$$

$$A : \mathcal{D}(A) \to X, \quad A = \left[\begin{array}{cc} 0 & I \\ -A_0 & 0 \end{array} \right], \tag{6.5}$$

$$X_1 = \mathcal{D}(A) = H_1 \times H_{\frac{1}{2}}, \quad X_{-1} = H \times H_{-\frac{1}{2}}, \quad A^* = -A,$$

$$B = \left[\begin{array}{cc} 0 & A_0^{-1} C_1^* \\ C_0^* & 0 \end{array} \right] \in \mathcal{L}(U, X_{-1}), \quad C = B^* = \left[\begin{array}{cc} 0 & C_0 \\ C_1 & 0 \end{array} \right] \in \mathcal{L}(X_1, U), \tag{6.6}$$

$$\overline{C} = \left[\begin{array}{cc} 0 & \overline{C_0} \\ \overline{C_1} & 0 \end{array} \right], \qquad D = \left[\begin{array}{cc} 0 & D_0 \\ 0 & 0 \end{array} \right]. \tag{6.7}$$

We shall now prove that for sufficiently smooth u, (6.1) is equivalent to (6.3). We also show how the condition of "compatible initial conditions," $Az(0) + Bu(0) \in X$, can be expressed in terms of the functions and operators appearing in (6.1). The significance of this condition was explained in section 4 (around (4.10)).

PROPOSITION 6.1. *For $u \in \mathcal{H}^1_{loc}(0,\infty;U)$, the equations* (6.1) *(for a specific $t \geq 0$) are equivalent to* (6.3) *(for the same t) with z, u, y as in* (6.4) *and with*

$$w(t) = \dot{q}(t) - A_0^{-1}C_1^* u_1(t).$$

The first part of (6.1) *is regarded as an equation in $H_{-\frac{1}{2}}$, and the first part of* (6.3) *is regarded as an equation in X_{-1}. Moreover, for any $t \geq 0$, the conditions*

$$A_0 q(t) - C_0^* u_0(t) \in H, \qquad \dot{q}(t) \in H_{\frac{1}{2}} \tag{6.8}$$

are equivalent to $Az(t) + Bu(t) \in X$.

Proof. We rewrite the first part of (6.3):

$$\frac{\mathrm{d}}{\mathrm{d}t}\begin{bmatrix} q(t) \\ w(t) \end{bmatrix} = \begin{bmatrix} 0 & I \\ -A_0 & 0 \end{bmatrix}\begin{bmatrix} q(t) \\ w(t) \end{bmatrix} + \begin{bmatrix} 0 & A_0^{-1}C_1^* \\ C_0^* & 0 \end{bmatrix}\begin{bmatrix} u_0(t) \\ u_1(t) \end{bmatrix},$$

or, equivalently,

$$\dot{q}(t) = w(t) + A_0^{-1}C_1^* u_1(t), \qquad \dot{w}(t) = -A_0 q(t) + C_0^* u_0(t).$$

By differentiating the first formula, we obtain the first equation in (6.1). To derive the last two equations in (6.1), we compute, starting from (6.3),

$$\begin{aligned}\begin{bmatrix} y_0(t) \\ y_1(t) \end{bmatrix} &= \begin{bmatrix} 0 & \overline{C_0} \\ \overline{C_1} & 0 \end{bmatrix}\begin{bmatrix} q(t) \\ w(t) \end{bmatrix} + \begin{bmatrix} 0 & \overline{C_0}A_0^{-1}C_1^* \\ 0 & 0 \end{bmatrix}\begin{bmatrix} u_0(t) \\ u_1(t) \end{bmatrix} \\ &= \begin{bmatrix} \overline{C_0}(\dot{q}(t) - A_0^{-1}C_1^* u_1(t)) + \overline{C_0}A_0^{-1}C_1^* u_1(t) \\ \overline{C_1}q(t) \end{bmatrix} = \begin{bmatrix} \overline{C_0}\dot{q}(t) \\ \overline{C_1}q(t) \end{bmatrix}.\end{aligned}$$

To obtain (6.3) from (6.1), we just reverse the order of the computations. It is easy to verify that the conditions (6.8) are equivalent to $Az(t) + Bu(t) \in X$. ∎

Clearly, Σ satisfies ESAD and COL, but it need not be well posed. The optimal control of systems of this type, but with $C_1 = 0$, has been studied in [49] without assuming well posedness. Here, *we do assume that our system Σ is well posed* (but not necessarily regular). Then, the equations (6.3) correspond to the representation of well-posed systems via (1.1) and (4.10).

As explained in section 4 (before (4.10)), the transfer function of Σ is given by $\mathbf{G}(s) = \overline{C}(sI - A)^{-1}B + D$, which is easy to compute in terms of A_0, C_0 and C_1: for $-s^2 \in \rho(A_0)$,

$$\mathbf{G}(s) = \begin{bmatrix} C_0 s \\ \overline{C_1} \end{bmatrix}(s^2 I + A_0)^{-1}\begin{bmatrix} C_0^* & A_0^{-1}C_1^* s \end{bmatrix}. \tag{6.9}$$

Note the curious fact that $\mathbf{G}$ does not depend on the extended operator $\overline{C_0}$. This extended operator appears in the representation (6.3) of Σ, but (6.9) shows that the system Σ is in fact independent of the choice of the extension $\overline{C_0}$.

In particular, we see from (6.9) that

$$\mathbf{G}(0) = \begin{bmatrix} 0 & 0 \\ D_1 & 0 \end{bmatrix}.$$

According to Theorem 5.2, we have $E = -\frac{1}{2}[\mathbf{G}(0)^* + \mathbf{G}(0)] + B^*(A^*)^{-1}QA^{-1}B$ so that (since $Q = 0$)

$$E = -\frac{1}{2}\begin{bmatrix} 0 & D_1^* \\ D_1 & 0 \end{bmatrix}. \tag{6.10}$$

Such systems, but with $C_1 = 0$, have been considered in [2, 14, 49].

PROPOSITION 6.2. *Suppose that the well-posed system* Σ *from* (6.3) *is exactly controllable (or equivalently, exactly observable). Let* $E \in \mathcal{L}(U)$ *be the operator from* (6.10)*, let* E^+ *be the positive part of* E*, and put* $c = \|E^+\|$, $\kappa_0 = \frac{1}{c}$. *Then for every* $\kappa \in (0, \kappa_0)$, $K = -\kappa I$ *is an admissible feedback operator for* Σ *and the resulting closed-loop system* Σ^κ *is exponentially stable.*

Proof. The equivalence of exact controllability and exact observability follows by duality, since $A^* = -A$ (see the comments after Definition 3.1). It is clear that exact controllability implies optimizability, and (by duality) exact observability implies estimatability. Thus, we can apply Theorem 5.8 to obtain this proposition. □

Example 6.3. We describe a well-posed system which fits into the above framework, so that proportional output feedback can exponentially stabilize it. Since the computations are rather long, they are the subject of a separate paper [50].

The physical system that we are modeling consists of a hinged elastic beam with two sensors: one measures the angular velocity of the beam at a point ξ and the other measures the bending (curvature) of the beam at the same point. These two measurements are advantageous because they make the open-loop system exactly observable. Our aim is to design the actuators and the feedback law in order to exponentially stabilize this system. Using Proposition 6.2, we shall design the actuators such that they are colocated, meaning that $B = C^*$, and then the open-loop system is described by equations of the form (6.1). Here, C_0 will be the operator corresponding to the measurement of the angular velocity at ξ, and C_1 will be the operator corresponding to the measurement of the bending at ξ. It turns out that the actuators cause a discontinuity of the bending exactly at ξ. As in the preceding theory, we are forced to use an extension of the operator C_1, which means that we have to decide if the corresponding sensor measures the left or the right limit of the bending at ξ, or a combination of the lateral limits.

We model the open-loop system as a homogenous Rayleigh beam situated along the interval $[0, \pi]$, with the two sensors located at $\xi \in (0, \pi)$. This is an extension of an example discussed in [1] and [52], and these papers contain further references to Rayleigh beam models. The equations describing the open-loop system are

$$\ddot{q}(x,t) - \alpha \frac{\partial^2 \ddot{q}}{\partial x^2}(x,t) + \frac{\partial^4 q}{\partial x^4}(x,t) = \mathcal{U}(x,t), \tag{6.11}$$

$$q(0,t) = q(\pi,t) = 0, \qquad \frac{\partial^2 q}{\partial x^2}(0,t) = \frac{\partial^2 q}{\partial x^2}(\pi,t) = 0, \quad t \geq 0, \tag{6.12}$$

$$y_0(t) = \frac{\partial \dot{q}}{\partial x}(\xi,t), \qquad y_1(t) = \frac{\partial^2 q}{\partial x^2}(\xi,t). \tag{6.13}$$

Here $q(x,t)$ represents the transverse displacement of the beam ($x \in [0,\pi]$ and $t \geq 0$), and $\alpha > 0$ is a constant, proportional to the moment of inertia of the cross section of the beam. In (6.11), $\mathcal{U}$ denotes the control terms which are to be designed.

In order to fit this system into the framework of (6.1), (6.2), we denote $H = \mathcal{H}_0^1(0,\pi)$, $V = \mathcal{H}^2(0,\pi) \cap \mathcal{H}_0^1(0,\pi)$. On H we define the inner product such that

$$\langle \varphi, \psi \rangle_H = \left\langle \left(I - \alpha \frac{\mathrm{d}^2}{\mathrm{d}x^2} \right) \varphi, \psi \right\rangle_{L^2} \qquad \forall\, \varphi, \psi \in V.$$

We introduce the operator $\mathcal{R} : L^2(0,\pi) \to V$ defined by

$$\mathcal{R} = \left(I - \alpha \frac{\mathrm{d}^2}{\mathrm{d}x^2} \right)^{-1}.$$

It is easy to see that $\mathcal{R} > 0$ when regarded as an operator from $L^2(0,\pi)$ to $L^2(0,\pi)$. We also define the linear operator $A_0 : \mathcal{D}(A_0) \to H$ by

$$\mathcal{D}(A_0) = \left\{ \varphi \in \mathcal{H}^3(0,\pi) \,\middle|\, \varphi(0) = \varphi(\pi) = 0,\ \frac{\mathrm{d}^2\varphi}{\mathrm{d}x^2}(0) = \frac{\mathrm{d}^2\varphi}{\mathrm{d}x^2}(\pi) = 0 \right\},$$

$$A_0\varphi = \frac{\mathrm{d}^4}{\mathrm{d}x^4}(\mathcal{R}\varphi) \qquad \forall\ \varphi \in \mathcal{D}(A_0).$$

The set $\{\varphi_k \,|\, k \in \mathbb{N}\}$ with

$$\varphi_k(x) = \frac{1}{\sqrt{1+\alpha k^2}} \cdot \sqrt{\frac{2}{\pi}} \sin kx \qquad \forall\ x \in [0,\pi]$$

is an orthonormal basis in H, and we have

$$A_0\varphi_k = \frac{k^4}{1+\alpha k^2}\,\varphi_k, \qquad \mathcal{R}\varphi_k = \frac{1}{1+\alpha k^2}\,\varphi_k$$

so that, in particular, A_0 is self-adjoint, strictly positive and it commutes with $\mathcal{R}$. Defining H_μ and $\|\varphi\|_\mu$ for $\mu \in \mathbb{R}$ by fractional powers of A_0 and duality, as explained after (6.1), we have $H_0 = H = \mathcal{H}_0^1(0,\pi)$ and

$$H_1 = \mathcal{D}(A_0), \quad H_{\frac{1}{2}} = V, \quad H_{-\frac{1}{2}} = L^2(0,\pi), \quad H_{-1} = \mathcal{H}^{-1}(0,\pi), \quad H_{-1.5} = V',$$

the norm $\|\cdot\|_{-\frac{1}{2}}$ being equivalent to the L^2-norm. Here, V' denotes the dual of V with respect to the pivot space $L^2(0,\pi)$. For every $\mu \in \mathbb{R}$, A_0 and $\mathcal{R}$ have extensions (or restrictions) to H_μ and we have $A_0 \in \mathcal{L}(H_\mu, H_{\mu-1})$, $\mathcal{R} \in \mathcal{L}(H_\mu, H_{\mu+1})$.

The spaces U_0 and U_1 from (6.2) are $U_0 = U_1 = \mathbb{C}$, so that $U = \mathbb{C}^2$. Corresponding to the two measurements in (6.13), we define the operators $C_0 \in \mathcal{L}(H_{\frac{1}{2}}, \mathbb{C})$ and $C_1 \in \mathcal{L}(H_1, \mathbb{C})$ by

$$C_0\varphi = \frac{\mathrm{d}\varphi}{\mathrm{d}x}(\xi), \qquad C_1\varphi = \frac{\mathrm{d}^2\varphi}{\mathrm{d}x^2}(\xi).$$

Then $C_0^* \in H_{-\frac{1}{2}}$ and $C_1^* \in H_{-1}$ (the adjoints of C_0 and C_1 with respect to the pivot space H) are

$$C_0^* = -\mathcal{R}\frac{\mathrm{d}}{\mathrm{d}x}\delta_\xi, \qquad C_1^* = \mathcal{R}\frac{\mathrm{d}^2}{\mathrm{d}x^2}\delta_\xi,$$

where δ_ξ is the Dirac mass at the point ξ.

We remark that according to (6.2), the state space of our system is $X = \mathcal{H}^2(0,\pi) \cap \mathcal{H}_0^1(0,\pi) \times \mathcal{H}_0^1(0,\pi)$ with the norm

$$\left\| \begin{bmatrix} q \\ w \end{bmatrix} \right\|^2 = \int_0^\pi \left| \frac{\mathrm{d}^2 q(x)}{\mathrm{d}x^2} \right|^2 \mathrm{d}x + \int_0^\pi |w(x)|^2 \mathrm{d}x + \alpha \int_0^\pi \left| \frac{\mathrm{d}\,w(x)}{\mathrm{d}x} \right|^2 \mathrm{d}x.$$

Assuming that the terms of (6.11) are in $H_{-1.5} = V'$ and applying $\mathcal{R}$ to these terms, we obtain

$$\ddot{q} + A_0 q = \mathcal{R}\mathcal{U} \qquad \text{in } H_{-\frac{1}{2}} = L^2(0,\pi). \tag{6.14}$$

Now the first equation in (6.1) shows that the control terms, represented above by $\mathcal{RU}$, should be

$$\mathcal{RU} = C_0^* u_0 + A_0^{-1} C_1^* \dot{u}_1 = -u_0 \mathcal{R} \frac{\mathrm{d}}{\mathrm{d}x} \delta_\xi - \dot{u}_1 b, \tag{6.15}$$

where $b = -A_0^{-1} C_1^* \in H$ is given by

$$b(x) = \begin{cases} \frac{ax}{\xi} & \text{for } x \le \xi, \\ \frac{a\pi - ax}{\pi - \xi} & \text{for } x > \xi, \end{cases} \qquad \text{where } \frac{1}{a} = \frac{1}{\xi} + \frac{1}{\pi - \xi}.$$

The graph of b consists of two straight lines, with a peak at $x = \xi$. If we apply $\mathcal{R}^{-1}$ to the terms of (6.14), with $\mathcal{RU}$ as in (6.15), we obtain that in $H_{-1.5}$,

$$\ddot{q} - \alpha \frac{\partial^2 \ddot{q}}{\partial x^2} + \frac{\partial^4 q}{\partial x^4} = -u_0 \frac{\mathrm{d}}{\mathrm{d}x} \delta_\xi - \dot{u}_1 [\alpha \delta_\xi + b]. \tag{6.16}$$

This equation must also hold in the sense of distributions on $(0, \pi)$. Together with (6.12) and (6.13), it defines our open-loop system with the "designed" actuators. However, since in general $\frac{\partial^2 q}{\partial x^2}$ will have a discontinuity at ξ, the second part of (6.13) has to be replaced by $y_1(t) = \overline{C}_1 q$, where $\overline{C}_1$ is an extension of C_1 given by

$$\overline{C}_1 \chi = \gamma \chi''(\xi-) + (1 - \gamma) \chi''(\xi+).$$

PROPOSITION 6.4. *For $u \in \mathcal{H}^1_{loc}(0, \infty; \mathbb{C}^2)$, the equations* (6.16) *(in $H_{-1.5}$) and* (6.13) *(with C_1 extended as above) are equivalent to*

$$\dot{z} = Az + Bu \quad (\text{in } X_{-1}), \qquad y = \overline{C} z + Du,$$

with z, u, y as in (6.4) *and with $w = \dot{q} - A_0^{-1} C_1^* u_1 = \dot{q} + b u_1$. Here, A is as in* (6.5), *B is as in* (6.6), *and $\overline{C}$, D are as in* (6.7). *These equations determine a well-posed linear system Σ with input and output space $U = \mathbb{C}^2$ and state space $X = H_{\frac{1}{2}} \times H$. This system is exactly controllable and exactly observable.*

For the proof of this proposition we refer to our paper [50].

PROPOSITION 6.5. *Let Σ be the system from Proposition* 6.4. *Denote*

$$D_1 = \overline{C_1} A_0^{-1} C_0^*, \qquad \kappa_0 = \frac{2}{|D_1|}.$$

Then for every $\kappa \in (0, \kappa_0)$, $K = -\kappa I$ is an admissible feedback operator for Σ and the resulting closed-loop system Σ^κ is exponentially stable.

Proof. We know from Proposition 6.4 that the system Σ is well posed, exactly controllable, and exactly observable. Let $E \in \mathcal{L}(\mathbb{C}^2)$ be the 2×2 matrix from (6.10). Its eigenvalues are $\pm \frac{1}{2} |D_1|$ so that E^+ (the positive part of E) is a matrix of rank one with the eigenvalues $\frac{1}{2}|D_1|$ and 0. Hence, $c = \|E^+\| = \frac{1}{2}|D_1|$, $\kappa_0 = \frac{1}{c} = \frac{2}{|D_1|}$. According to Proposition 6.2, for every $\kappa \in (0, \kappa_0)$, $K = -\kappa I$ is an admissible feedback operator for Σ and Σ^κ is exponentially stable. □

In [50] we derive a simple formula for the number D_1 appearing in the last proposition: $D_1 = \frac{\xi}{\pi} - \gamma$. Note that choosing $\gamma = \frac{\xi}{\pi}$ leads to $\kappa_0 = \infty$.

TWO-TIME-SCALE HYBRID FILTERS: NEAR OPTIMALITY*

J. W. WANG†, Q. ZHANG‡, AND G. YIN§

Abstract. This work develops a filtering scheme for hybrid systems. The process dictating the configuration or regimes is a continuous-time Markov chain with a finite state space. Exploiting hierarchical structure of the underlying system, the states of the Markov chain are divided into a number of groups so that it jumps rapidly within each group and slowly among different groups. Focusing on reduction of computational complexity, the filtering scheme includes the following steps: (1) partition the state space of the Markov chain into subspaces, (2) derive a limit system in which the states are averaged out with respect to the invariant distributions of the Markov chain, (3) use the limit system to design quadratic variation test statistics, and (4) use the test statistics to identify which ergodic class the aggregated process belongs to and to construct near-optimal filter. For demonstration, a numerical example is presented.

Key words. hybrid filter, near optimality, Kalman filter, Markov chain, weak convergence, quadratic variation test

1. Introduction.

This paper is concerned with filtering problems of hybrid dynamic systems, in which continuous dynamics and discrete events coexist. Let $(\Omega, \mathcal{F}, P)$ be the underlying probability space and $(x(t), \alpha(t))$ with $t \geq 0$ be a pair of signal processes that is not observable. Here $x(t)$ represents the continuous dynamics part and $\alpha(t)$ describes the discrete events. More specifically, the unknown or hidden process $\alpha(t)$ is a continuous-time Markov chain with a finite state space $\mathcal{M}$. Denote the observation process by $y(t)$ depending on $(x(s), \alpha(s),\ s \leq t)$ together with a Gaussian noise. Throughout the paper, we assume both $x(\cdot)$ and $y(\cdot)$ to be $\mathbb{R}^p$-valued stochastic processes satisfying the system of equations

$$\begin{cases} dx(t) = A(\alpha(t))x(t)dt + \sigma(\alpha(t))dw(t), & x(0) = x_0, \\ dy(t) = H(\alpha(t))x(t)dt + \delta dv(t), & y(0) = 0, \end{cases} \tag{1.1}$$

for $0 \leq t \leq T$, where T is a finite number, x_0 is a given random variable, $w(\cdot)$ and $v(\cdot)$ are independent standard Brownian motions, for $\alpha \in \mathcal{M}$, $A(\alpha)$, $H(\alpha)$, and $\sigma(\alpha)$ are matrices of appropriate dimensions, and $\delta > 0$ is a small parameter representing the intensity of the observation noise.

In the literature, when $\alpha(t) = \alpha_0$ is an unobservable constant, the optimal filtering problem was solved by Hijab [12] and Caines and Chen [3], assuming an a priori distribution of α_0. However, in many practical situations, a priori knowledge of α_0 is not available. To deal with such scenarios, Haussmann and Zhang [11] used two

statistical hypothesis tests, namely, the quadratic variation test (QVT) and the likelihood ratio test (LRT), to estimate the value of α_0 and to choose among competing filters on successive time intervals. The QVT and LRT were introduced by Fleming and Pardoux [6] to identify the sign of the state variable $x(t)$ in a partially observed system; see also Fleming and Zhang [8, 9] and Fleming et al. [5] for the corresponding discrete-time models and related numerical results along this line. These results are generalized to the case when $\alpha(\cdot)$ is an unknown Markov chain in Zhang [20]. The basic idea of these tests is to examine which state $\alpha(t)$ is more likely to belong to statistically. Then run a number of Kalman filters simultaneously and choose the one that associates with the current estimate of $\alpha(t)$. Therefore, a necessary condition for validating the tests is that $\alpha(t)$ must stay at the current state for some time before jumping to another state. If $\alpha(t)$ jumps too frequently, it is virtually impossible to obtain a meaningful estimate of $x(t)$.

In recent years, hybrid systems of the form (1.1), involving both continuous dynamics and discrete events, have attracted much attention due to their wide range of applicability in financial engineering, wireless communication, and network modeling and optimization. In these applications, the hidden Markov chain represents the random influence due to structural or regime changes in environmental, social, economical, or other factors. Denote the cardinality of the state space of the hidden Markov chain by $|\mathcal{M}|$. For the aforementioned applications, considerations of various factors frequently make $|\mathcal{M}|$ very large resulting in a difficult computational task. The main focus of this paper is to reduce the computational complexity. Within a large-scale system, not all state variables vary at the same speed. We may naturally subdivide the entire system into smaller pieces so that within each subsystem the participating state variables vary rapidly and among different subgroups the jumps take place at a slower pace. Noting the different transition rates of the Markov chain $\alpha(t)$ leads to a two-time-scale formulation involving states having weak and strong interactions. To highlight the contrast of the fast and slow motions, we introduce a small parameter $\varepsilon > 0$ and aim to design near-optimal filters. Our filtering procedure proceeds as follows. First, using weak convergence methods, we obtain certain limit filtering problem as $\varepsilon \to 0$. With the stipulation that the Markov chain varies slowly among different recurrent groups, we then develop quadratic variation test and use it in the process of filtering.

Concerning nonlinear filtering of a hybrid system, much effort has been devoted to finite dimensional approximations. In Blom and Bar-Shalom [2], a discrete-time version of the corresponding filtering problem was considered. They proposed a numerical algorithm to compute the conditional expectation of $(\alpha(t), x(t))$ given observation up to time t. The algorithm seems to perform well numerically. However, there is no theoretical justification for optimality (or near optimality) of these filters; see Li [15] for further discussions. There is substantial literature on related models and problems. For hybrid filter with non-Gaussian noise, see Zhang [22] for a continuous-time model, Zhang [21] for a discrete-time version, and Liu and Zhang [17] for numerical experiments. For a survey of results on nonlinear filtering, we refer to the books by Kallianpur [13] and Liptser and Shiryayev [16]. For recent developments and review of the literature on partially observed systems, see the books by Bensoussan [1], Elliott, Aggoun, and Moore [4], and Kushner [14] and references therein.

The rest of the paper is organized as follows. In the next section, we set up the problem by using a two-time-scale formulation. Preliminary results concerning two-time-scale Markov chains and limit filtering problem are also presented. Section 3 is devoted to an averaged filtering scheme, in which an intermediate filter is developed

for approximation purpose. First, a weak convergence method is used to establish the convergence of the original system to a limit system. Then we construct an averaged filter and show that its output approximates the state process. More specifically, we partition the state space of the Markov chain into subspaces, derive a limit system in which the states are averaged out with respect to the invariant distributions of the Markov chain, design quadratic variation test statistics using the limit system, design associated test statistics for the original process to identify which ergodic class that the aggregated process belongs to, and construct a near-optimal filter. In section 4, we demonstrate the near optimality of the filter by a simple example. Section 5 extends the results to the case, where some transient states are included in the Markov chain. Final remarks are made in section 6. To proceed, a word about the notation is in order. For simplicity, throughout the paper, we use K to denote a generic positive constant, whose values may change for different appearances. Given a matrix A, its transpose is denoted by A' and its trace by $\mathrm{tr}(A)$.

2. Preliminary results. In this section, we present results on two-time-scale Markov chains. In addition, a statistical test for the filtering is also given.

2.1. Two-time-scale Markov chains. To characterize the weak and strong interaction of $\alpha(t)$, we introduce a small parameter $\varepsilon > 0$ and assume $\alpha(\cdot) = \alpha^\varepsilon(\cdot)$, generated by Q^ε, where Q^ε has the form

$$Q^\varepsilon = \frac{1}{\varepsilon}\,\mathrm{diag}(\widetilde{Q}^1, \dots, \widetilde{Q}^l) = \frac{1}{\varepsilon}\begin{pmatrix} \widetilde{Q}^1 & & \\ & \ddots & \\ & & \widetilde{Q}^l \end{pmatrix} + \widehat{Q}, \tag{2.1}$$

where, for each $k = 1, \dots, l$, $\widetilde{Q}^k$ is a generator matrix with dimension $m_k \times m_k$, and $m_1 + \cdots + m_l = m$. Suppose that for $k = 1, \dots, l$, $\widetilde{Q}^k$ are irreducible. The state space of $\alpha^\varepsilon(\cdot)$ is given by

$$\mathcal{M} = \mathcal{M}_1 \cup \cdots \cup \mathcal{M}_l = \{s_{11}, \dots, s_{1m_1}\} \cup \cdots \cup \{s_{l1}, \dots, s_{lm_l}\},$$

where for $k = 1, \dots, l$, $\mathcal{M}_k = \{s_{k1}, \dots, s_{km_k}\}$ are the subspaces corresponding to the recurrent states. Let $\nu^k = (\nu^k_1, \dots, \nu^k_{m_k})$ denote the stationary distribution of $\widetilde{Q}^k$, i.e., ν^k is the only solution to

$$\nu^k \widetilde{Q}^k = 0 \text{ and } \nu^k 1_{m_k} = 1.$$

Let

$$\overline{Q} = \mathrm{diag}(\nu^1, \dots, \nu^l)\widehat{Q}\,\widetilde{1}, \tag{2.2}$$

where

$$\widetilde{1} = \begin{pmatrix} 1_{m_1} & & \\ & \ddots & \\ & & 1_{m_l} \end{pmatrix} \quad \text{and} \quad 1_{m_k} = (1, \dots, 1)' \in \mathbb{R}^{m_k \times 1}.$$

Noting the dominating force in Q^ε, namely, $\mathrm{diag}(\widetilde{Q}^1, \dots, \widetilde{Q}^l)$, the generator Q^ε is almost decomposable. The rationale is that we can take advantage of this structure and use a single state to represent each of the subspaces $\mathcal{M}_k$ (for $k = 1, \dots, l$). The

resulting process will have a much smaller state space. This leads to the following definition of aggregated process.

Let $\overline{\alpha}^\varepsilon(\cdot)$ be defined by $\overline{\alpha}^\varepsilon(t) = k$ if $\alpha^\varepsilon(t) \in \mathcal{M}_k$. Then as shown in Yin and Zhang [18, Thm. 7.4, p. 172] that $\overline{\alpha}^\varepsilon(\cdot)$ converges weakly to $\overline{\alpha}(\cdot)$, a continuous-time Markov chain with generator $\overline{Q}$ and state space $\overline{\mathcal{M}} = \{1, \ldots, l\}$. Moreover, for any deterministic test function $\beta_{kj}(t)$ with $k = 1, \ldots, l$ and $j = 1, \ldots, m_k$, the corresponding occupation measures satisfy

$$E\left(\int_0^T \left(I_{\{\alpha^\varepsilon(t)=s_{kj}\}} - \nu_j^k I_{\{\overline{\alpha}^\varepsilon(t)=k\}}\right)\beta_{kj}(t)dt\right)^2 = O(\varepsilon). \tag{2.3}$$

These estimates may be regarded as functional version of the law of large numbers if one discretizes the above integrals using step size ε.

These results suggest the following two-stage approximation of $\alpha^\varepsilon(\cdot)$ by $\overline{\alpha}(\cdot)$: (i) approximate $\alpha^\varepsilon(\cdot)$ by $\overline{\alpha}^\varepsilon(\cdot)$ under the weak topology in $L^2[0,T]$; (ii) approximate $\overline{\alpha}^\varepsilon(\cdot)$ by its limit $\overline{\alpha}(\cdot)$ in distribution.

2.2. Limit filter. Let $(x^\varepsilon(\cdot), y^\varepsilon(\cdot))$ be the actual state and observation satisfying (1.1) with $\alpha(\cdot)$ replaced by $\alpha^\varepsilon(\cdot)$, i.e.,

$$\begin{cases} dx^\varepsilon(t) = A(\alpha^\varepsilon(t))x^\varepsilon(t)dt + \sigma(\alpha^\varepsilon(t))dw(t), & x^\varepsilon(0) = x_0, \\ dy^\varepsilon(t) = H(\alpha^\varepsilon(t))x^\varepsilon(t)dt + \delta dv(t), & y^\varepsilon(0) = 0. \end{cases} \tag{2.4}$$

We will show that

$$(x^\varepsilon(\cdot), y^\varepsilon(\cdot), \overline{\alpha}^\varepsilon(\cdot)) \to (\overline{x}(\cdot), \overline{y}(\cdot), \overline{\alpha}(\cdot)) \text{ as } \varepsilon \to 0,$$

in distribution, where $(\overline{x}(\cdot), \overline{y}(\cdot))$ satisfies the limit system of equations

$$\begin{cases} d\overline{x}(t) = \overline{A}(\overline{\alpha}(t))\overline{x}(t)dt + \overline{\sigma}(\overline{\alpha}(t))dw(t), & \overline{x}(0) = x_0, \\ d\overline{y}(t) = \overline{H}(\overline{\alpha}(t))\overline{x}(t)dt + \delta dv(t), & \overline{y}(0) = 0, \end{cases} \tag{2.5}$$

with

$$\begin{cases} \overline{A}(k) = \displaystyle\sum_{j=1}^{m_k} \nu_j^k A(s_{kj}), \\ \overline{H}(k) = \displaystyle\sum_{j=1}^{m_k} \nu_j^k H(s_{kj}), \\ \overline{\Sigma}(k) = \overline{\sigma}(k)\overline{\sigma}'(k) = \displaystyle\sum_{j=1}^{m_k} \nu_j^k \sigma(s_{kj})\sigma'(s_{kj}) \end{cases} \tag{2.6}$$

for $k = 1, \ldots, l$.

In what follows, we briefly summarize related filtering results obtained in Zhang [20] for the limit system (2.5). We make the following assumptions:

- (**A1**) $\overline{H}(k)$ is invertible for $k \in \overline{\mathcal{M}}$.
- (**A2**) $\overline{\sigma}(k) = F(k)\overline{H}'(k)$ for symmetric matrices $F(k) \geq cI > 0$, for some $c > 0$.
- (**A3**) $\left|\mathrm{tr}\big(\overline{H}(k)F(k)\overline{H}'(k)\big)^2 - \mathrm{tr}\big(\overline{H}(k_1)F(k_1)\overline{H}'(k_1)\big)^2\right| \geq c > 0$ for $k \neq k_1$, for some $c > 0$.
- (**A4**) The initial value x_0 is a Gaussian random vector and $E|x_0 - Ex_0|^4 = O(\delta^2)$. Moreover, x_0, $\alpha^\varepsilon(\cdot)$, $w(\cdot)$, and $v(\cdot)$ are independent.

Remark 2.1. The form assumed for $\overline{\sigma}(k)$ in (A2) is not as restrictive as it appears. In fact, in the one-dimensional case, it is equivalent to the condition $\overline{\sigma}(k) \neq 0$. If $F(k) = 1$, then (A3) is equivalent to the condition $|\overline{H}(k)| \neq |\overline{H}(k_1)|$, for $k \neq k_1$. For higher dimensional cases, we refer to the papers by Haussmann and Zhang [10, 11] for related discussions. For notational simplicity, we use the Gaussian initial conditions in (A4). This requirement can be relaxed as in Haussmann and Zhang [10] to non-Gaussian initial cases. We next give an example to further illustrate these conditions in a one-dimensional ($p = 1$) system.

EXAMPLE 2.2. *Let* $\mathcal{M} = \mathcal{M}_1 \cup \mathcal{M}_2 = \{s_{11}, s_{12}\} \cup \{s_{21}, s_{22}\}$ *and the generator*

$$Q^\varepsilon = \frac{1}{\varepsilon}\begin{pmatrix} -1 & 1 & 0 & 0 \\ 1 & -1 & 0 & 0 \\ 0 & 0 & -1 & 1 \\ 0 & 0 & 1 & -1 \end{pmatrix} + \begin{pmatrix} -1 & 0 & 1 & 0 \\ 0 & -1 & 0 & 1 \\ 1 & 0 & -1 & 0 \\ 0 & 1 & 0 & -1 \end{pmatrix}.$$

Then the corresponding stationary distributions $\nu^1 = \nu^2 = (1/2, 1/2)$. *Consider the case when*

$$\sigma(s_{11}) = \sigma(s_{12}) = \sigma(s_{21}) = \sigma(s_{22}) = 1,$$

$$H(s_{11}) = H(s_{12}) = 1,\ H(s_{21}) = H(s_{22}) = 2.$$

Then

$$\overline{\sigma}(1) = \overline{\sigma}(2) = 1,\ \overline{H}(1) = 1,\ \overline{H}(2) = 2,\ \textit{and}\ F(1) = 1,\ F(2) = 1/2.$$

It can be seen that the conditions (A1)–(A3) *are satisfied.*

The parameter δ represents the observation noise level. In practice, the observation noise mainly depends on the sensor measurement characteristics. The development of new technology (such as the use of infrared technology) makes possible fairly small disturbances in observation. Thus it is not only reasonable but practical to consider the models with small observation noise.

If $\overline{\alpha}(t)$ is observable, then the corresponding limit Kalman filter has the form

$$\text{(2.7)}\qquad \begin{cases} d\widehat{x}(t) = \overline{A}(\overline{\alpha}(t))\widehat{x}(t)dt + \dfrac{1}{\delta^2}\overline{R}(t)\overline{H}'(\overline{\alpha}(t))\left(d\overline{y}(t) - \overline{H}(\overline{\alpha}(t))\widehat{x}(t)dt\right), \\ \dot{\overline{R}}(t) = \overline{A}(\overline{\alpha}(t))\overline{R}(t) + \overline{R}(t)\overline{A}'(\overline{\alpha}(t)) \\ \qquad\qquad + \overline{\sigma}(\overline{\alpha}(t))\overline{\sigma}'(\overline{\alpha}(t)) - \dfrac{1}{\delta^2}\overline{R}(t)\overline{H}'(\overline{\alpha}(t))\overline{H}(\overline{\alpha}(t))\overline{R}(t) \end{cases}$$

with $\widehat{x}(0) = Ex_0 \in \mathbb{R}^p$ and $\overline{R}(0) = \mathrm{Cov}(x_0) \in \mathbb{R}^{p\times p}$, where $\mathrm{Cov}(x_0)$ is the covariance matrix $E[(x_0 - Ex_0)(x_0 - Ex_0)']$.

It is important to estimate the value of $\overline{\alpha}(\cdot)$ in the filtering problem under consideration because if an estimate of $\overline{\alpha}(\cdot)$ is given, one can use such estimate to feed to the corresponding Kalman filter. In this paper, we use the QVT to identify the value of the unknown parameter process $\overline{\alpha}(\cdot)$ at a given time t.

For $j = 0, 1, \ldots,$ let

$$\zeta(j) = \frac{1}{\delta}\left(\overline{y}(\delta(j+2)) - 2\overline{y}(\delta(j+1)) + \overline{y}(\delta j)\right).$$

For $n_0, n = 0, 1, \ldots, n > n_0$, we define test statistics

$$\Lambda^{n_0,n} = \frac{1}{\delta(n-n_0)} \sum_{j=n_0}^{n-1} |\zeta(j)|^2. \tag{2.8}$$

Let

$$\mu_k^{n_0,n} = \left(\frac{1}{\delta(n-n_0)} \int_{\delta n_0}^{\delta(n+1)} \rho^{n_0,n}(s) ds \right) \mathrm{tr}(\overline{H}(k) F(k) \overline{H}'(k))^2 + 2p,$$

where

$$\rho^{n_0,n}(s) = \begin{cases} \phi^2(s) I_{[\delta n_0, \delta n]} + \phi^2(s-\delta) I_{[\delta(n_0+1), \delta n]} & \text{if } (n-n_0) \text{ even}, \\ \phi^2(s) I_{[\delta n_0, \delta(n+1)]} + \phi^2(s-\delta) I_{[\delta(n_0+1), \delta(n+1)]} & \text{if } (n-n_0) \text{ odd}, \end{cases}$$

and $\phi(s)$ is a "sawtooth" function on $[0, T]$ such that for any even integer $j = 0, 2, 4, \ldots,$

$$\phi(s) = \begin{cases} \dfrac{s - j\delta}{\delta} & \text{if } j\delta \le s < (j+1)\delta, \\ \dfrac{(j+2)\delta - s}{\delta} & \text{if } (j+1)\delta \le s < (j+2)\delta. \end{cases}$$

(See Haussmann and Zhang [11] for interpretation of these functions.)

Given $\overline{\alpha}(t) = k$, $\delta n_0 \le t < \delta n$, it can be shown as in [11] that for large $(n - n_0)$, $\Lambda^{n_0,n}/\mu_k^{n_0,n}$ is close to 1 by the law of large numbers. Under (A3), it follows that $\mu_{k_1}^{n_0,n} \ne \mu_{k_2}^{n_0,n}$ for $k_1 \ne k_2$. The quadratic variation test is given as follows. Let $\overline{\alpha}^{n_0,n}$ denote a random variable such that $\overline{\alpha}^{n_0,n} = k_0$ if

$$\left| \frac{\Lambda^{n_0,n}}{\mu_{k_0}^{n_0,n}} - 1 \right| = \min \left\{ \left| \frac{\Lambda^{n_0,n}}{\mu_k^{n_0,n}} - 1 \right|, \ k = 1, \ldots, l \right\}. \tag{2.9}$$

Let

$$l_0 = c_0 (\log \delta)^2 + 1 \ \text{ for some } \ c_0 \ge 0. \tag{2.10}$$

Then, for $\delta n \le t < \delta(n+1)$, $n = 0, 1, \ldots,$ we define

$$\widetilde{\alpha}(t) = \begin{cases} 1 & \text{if } t \in [0, \delta), \\ \overline{\alpha}^{0,n} & \text{if } n \le l_0, \\ \overline{\alpha}^{n-l_0,n} & \text{if } n \ge l_0. \end{cases} \tag{2.11}$$

Given $\widetilde{\alpha}(t)$, the corresponding filter is

$$\begin{cases} d\widetilde{x}(t) = \overline{A}(\widetilde{\alpha}(t))\widetilde{x}(t)dt + \dfrac{1}{\delta^2} \widetilde{R}(t) \overline{H}'(\widetilde{\alpha}(t)) \left(d\overline{y}(t) - \overline{H}(\widetilde{\alpha}(t))\widetilde{x}(t)dt \right), \\ \dot{\widetilde{R}}(t) = \overline{A}(\widetilde{\alpha}(t))\widetilde{R}(t) + \widetilde{R}(t)\overline{A}'(\widetilde{\alpha}(t)) \\ \qquad\qquad + \overline{\sigma}(\widetilde{\alpha}(t))\overline{\sigma}'(\widetilde{\alpha}(t)) - \dfrac{1}{\delta^2} \widetilde{R}(t) \overline{H}'(\widetilde{\alpha}(t)) \overline{H}(\widetilde{\alpha}(t)) \widetilde{R}(t) \end{cases} \tag{2.12}$$

with $\widetilde{x}(0) = Ex_0 \in \mathbb{R}^p$ and $\widetilde{R}(0) = \mathrm{Cov}(x_0) \in \mathbb{R}^{p\times p}$. For any given stochastic process $\xi(t)$, $t \geq 0$, we define the norm of $\xi(\cdot)$ as follows:

$$|\xi(\cdot)|_T = \int_0^T \left(E|\xi(t)|^2\right)^{\frac{1}{2}} dt.$$

Using this norm, it can be shown as in Zhang [20] that, under (A1)–(A4), there exist $c_0 > 0$ and $\delta_0 > 0$ such that for $0 < \delta < \delta_0$,

$$|\overline{\alpha}(\cdot) - \widetilde{\alpha}(\cdot)|_T = O(\sqrt{\delta}).$$

3. Near-optimal filter. Note that $\overline{y}(\cdot)$, the weak limit of $y^\varepsilon(\cdot)$, is not available. In order to have a feasible filter, one needs to feed the filter in (2.12) with the actual observation $y^\varepsilon(\cdot)$. Thus, we need to replace $\overline{y}(\cdot)$ by $y^\varepsilon(\cdot)$ in (2.12) and modify the test statistics Λ in (2.8) as follows. For $j = 0, 1, \ldots$, let

$$\zeta^\varepsilon(j) = \frac{1}{\delta}\left(y^\varepsilon(\delta(j+2)) - 2y^\varepsilon(\delta(j+1)) + y^\varepsilon(\delta j)\right).$$

Define

$$\Lambda^{\varepsilon,n_0,n} = \frac{1}{\delta(n-n_0)} \sum_{j=n_0}^{n-1} |\zeta^\varepsilon(j)|^2. \tag{3.1}$$

Let $\alpha^{\varepsilon,n_0,n}$ denote a random variable such that $\alpha^{\varepsilon,n_0,n} = k_0$ if

$$\left|\frac{\Lambda^{\varepsilon,n_0,n}}{\mu_{k_0}^{n_0,n}} - 1\right| = \min\left\{\left|\frac{\Lambda^{\varepsilon,n_0,n}}{\mu_k^{n_0,n}} - 1\right|,\ k = 1, \ldots, l\right\}. \tag{3.2}$$

Then, for $\delta n \leq t < \delta(n+1)$, $n = 0, 1, \ldots$, we define

$$\widetilde{\alpha}^\varepsilon(t) = \begin{cases} 1 & \text{if } t \in [0, \delta), \\ \alpha^{\varepsilon,0,n} & \text{if } n \leq l_0, \\ \alpha^{\varepsilon,n-l_0,n} & \text{if } n \geq l_0, \end{cases} \tag{3.3}$$

where l_0 is defined in (2.10).

Given $\widetilde{\alpha}^\varepsilon(t)$, the averaged filter is

$$\begin{cases} d\widetilde{x}^\varepsilon(t) = \overline{A}(\widetilde{\alpha}^\varepsilon(t))\widetilde{x}^\varepsilon(t)dt + \dfrac{1}{\delta^2}R^\varepsilon(t)\overline{H}'(\widetilde{\alpha}^\varepsilon(t))\left(dy^\varepsilon(t) - \overline{H}(\widetilde{\alpha}^\varepsilon(t))\widetilde{x}^\varepsilon(t)dt\right), \\ \dot{R}^\varepsilon(t) = \overline{A}(\widetilde{\alpha}^\varepsilon(t))R^\varepsilon(t) + R^\varepsilon(t)\overline{A}'(\widetilde{\alpha}^\varepsilon(t)) \\ \qquad\qquad + \overline{\sigma}(\widetilde{\alpha}^\varepsilon(t))\overline{\sigma}'(\widetilde{\alpha}^\varepsilon(t)) - \dfrac{1}{\delta^2}R^\varepsilon(t)\overline{H}'(\widetilde{\alpha}^\varepsilon(t))\overline{H}(\widetilde{\alpha}^\varepsilon(t))R^\varepsilon(t), \end{cases} \tag{3.4}$$

with $\widetilde{x}^\varepsilon(0) = Ex_0 \in \mathbb{R}^p$ and $R^\varepsilon(0) = \mathrm{Cov}(x_0) \in \mathbb{R}^{p\times p}$.

We will show that $\widetilde{x}^\varepsilon(\cdot)$ is an approximation to $x^\varepsilon(\cdot)$. To proceed, we first establish a couple of lemmas. They include the boundedness of the solution of Riccati equations and the moment bounds of the original and averaged processes.

LEMMA 3.1. *The solution of the system of Riccati equations $R^\varepsilon(t)$ in (3.4) is nonnegative definite and satisfies $\sup_{t\leq T}|R^\varepsilon(t)| \leq K$ for all $\omega \in \Omega$.*

Proof. First it is easy to see that $R^\varepsilon(t)$ is symmetric and nonnegative definite. We use the matrix norm $|A| = \sqrt{\mathrm{tr}(AA')}$. It follows that $\mathrm{tr}(AB) \le |A| \cdot |B|$ for any square matrices A and B of same dimension. Under this norm, for any symmetric nonnegative definite matrix R, we have

$$|R| = (\mathrm{tr}(R^2))^{\frac{1}{2}} = (\lambda_1^2 + \cdots + \lambda_n^2)^{\frac{1}{2}} \le (\lambda_1 + \cdots + \lambda_n) = \mathrm{tr}(R),$$

where $\lambda_1 \ge 0, \ldots, \lambda_n \ge 0$ are the eigenvalues of R. Therefore, it suffices to show that $\mathrm{tr}(R^\varepsilon(t))$ is bounded. Let $\phi(t) = \mathrm{tr}(R^\varepsilon(t))$. Take trace on both sides of the Riccati equation in (3.4) to obtain

$$\dot\phi(t) \le \mathrm{tr}(\overline{A}(\alpha^\varepsilon(t))R^\varepsilon(t) + R^\varepsilon(t)\overline{A}'(\alpha^\varepsilon(t))) + \mathrm{tr}(\overline{\sigma}(\alpha^\varepsilon(t))\overline{\sigma}'(\alpha^\varepsilon(t))).$$

Let $\{e_1(t), \ldots, e_p(t)\}$ be a base in $\mathbb{R}^p$ with $e_i(t)$ being eigenvector of $R^\varepsilon(t)$. Then, it follows that

$$\begin{aligned}
&\mathrm{tr}(\overline{A}(\alpha^\varepsilon(t))R^\varepsilon(t) + R^\varepsilon(t)\overline{A}'(\alpha^\varepsilon(t))) \\
&\quad = \sum_{i=1}^p e_i'(t)(\overline{A}(\alpha^\varepsilon(t))R^\varepsilon(t) + R^\varepsilon(t)\overline{A}'(\alpha^\varepsilon(t)))e_i(t) \\
&\quad = \sum_{i=1}^p \lambda_i e_i'(t)\left(\frac{\overline{A}(\alpha^\varepsilon(t)) + \overline{A}'(\alpha^\varepsilon(t))}{2}\right)e_i(t) \\
&\quad \le K_1 \mathrm{tr}(R^\varepsilon(t))
\end{aligned}$$

for some constant K_1. Therefore,

$$\dot\phi(t) \le K_0 + K_1\phi(t).$$

This implies, by Gronwall's inequality, that $\phi(t) \le K$ for some $K < \infty$. □

LEMMA 3.2.

$$\sup_{t\le T}(E|x^\varepsilon(t)|^4 + E|\overline{x}(t)|^4 + E|\widetilde{x}^\varepsilon(t)|^4 + E|\widetilde{x}(t)|^4) < \infty.$$

Proof. We shall verify this for each of the terms above. First, by the classical result on stochastic integration (for example, Fleming and Rishel [7] and Liptser and Shiryayev [16]),

$$\sup_{0\le t\le T} E|x^\varepsilon(t)|^4 \le K(1 + E|x_0|^4) < \infty, \qquad \sup_{0\le t\le T} E|\overline{x}(t)|^4 < \infty.$$

Similar estimates for the observation processes $y^\varepsilon(\cdot)$ and $\overline{y}(\cdot)$ yield that

$$\sup_{0\le t\le T} E|y^\varepsilon(t)|^4 < \infty, \qquad \sup_{0\le t\le T} E|\overline{y}(t)|^4 < \infty.$$

Next, consider $\widetilde{x}^\varepsilon(t)$. We obtain

$$\begin{aligned}
\widetilde{x}^\varepsilon(t) = \ & \widetilde{x}^\varepsilon(0) + \int_0^t \overline{A}(\widetilde{\alpha}^\varepsilon(s))\widetilde{x}^\varepsilon(s)ds + \frac{1}{\delta^2}\int_0^t R^\varepsilon(s)\overline{H}'(\widetilde{\alpha}^\varepsilon(s))H(\alpha^\varepsilon(s))x^\varepsilon(s)ds \\
& + \frac{1}{\delta}\int_0^t R^\varepsilon(s)\overline{H}'(\widetilde{\alpha}^\varepsilon(s))dv(s) - \frac{1}{\delta^2}\int_0^t R^\varepsilon(s)\overline{H}'(\widetilde{\alpha}^\varepsilon(s))\overline{H}(\widetilde{\alpha}^\varepsilon(s))R^\varepsilon(s)ds.
\end{aligned}$$

Taking norms and using the boundedness of

$$\overline{A}(i),\ \overline{H}(i),\ \sup_{0\le t\le T}|R^\varepsilon(t)|,\ \sup_{0\le t\le T}E|x^\varepsilon(t)|^4$$

and

$$E\Big|\int_0^t R^\varepsilon(s)\overline{H}'(\widetilde{\alpha}^\varepsilon(s))dv(s)\Big|^4<\infty$$

yield

$$E|\widetilde{x}^\varepsilon(t)|^4\le K+K\int_0^t E|\widetilde{x}^\varepsilon(s)|^4ds.$$

An application of Gronwall's inequality leads to $E|\widetilde{x}^\varepsilon(t)|^4<\infty$. Furthermore, the bound holds uniformly for $t\in[0,T]$. Similarly, we can establish the upper bound for $\widetilde{x}(t)$. The lemma is concluded. □

We next establish tightness of several pairs of processes. The result is stated in the following lemma.

LEMMA 3.3. *Both $(x^\varepsilon(\cdot),\overline{\alpha}^\varepsilon(\cdot))$ and $(y^\varepsilon(\cdot),\overline{\alpha}^\varepsilon(\cdot))$ are tight in $D([0,T];\mathbb{R}^p\times\overline{\mathcal{M}})$, where $D([0,T];G)$ denotes the space of functions defined on $[0,T]$ taking values in G that are right continuous have left limits endowed with the Skorohod topology.*

Proof. Let us begin with $(x^\varepsilon(\cdot),\overline{\alpha}^\varepsilon(\cdot))$. For any $\Delta>0$, $0<t$ with $0\le s\le\Delta$, we have

$$\begin{aligned}
&\lim_{\Delta\to0}\limsup_{\varepsilon\to0}E[E[|x^\varepsilon(t+s)-x^\varepsilon(t)|^2|\mathcal{F}_t^\varepsilon]]\\
&\quad\le\lim_{\Delta\to0}\limsup_{\varepsilon\to0}E\left[E\left[\left|\sum_{k=1}^{l}\sum_{j=1}^{m_k}\int_t^{t+s}A(s_{kj})x^\varepsilon(\tau)I_{\{\alpha^\varepsilon(\tau)=s_{kj}\}}d\tau\right|^2\Big|\mathcal{F}_t^\varepsilon\right]\right]\\
&\qquad+K\lim_{\Delta\to0}\limsup_{\varepsilon\to0}E\left[E\left[\left|\sum_{k=1}^{l}\sum_{j=1}^{m_k}\int_t^{t+s}\sigma(s_{kj})I_{\{\alpha^\varepsilon(\tau)=s_{kj}\}}dw(\tau)\right|^2\Big|\mathcal{F}_t^\varepsilon\right]\right]=0.
\end{aligned}$$

In addition, in view of Yin and Zhang [18, Thm. 7.4], $\overline{\alpha}^\varepsilon(\cdot)$ is tight. Then it follows from the tightness criterion (see Kushner [14], Yin and Zhang [18, Appendix], and the references therein), $(x^\varepsilon(\cdot),\overline{\alpha}^\varepsilon(\cdot))$ is tight in $D([0,T];\mathbb{R}^p\times\overline{\mathcal{M}})$. Likewise, $(y^\varepsilon(\cdot),\overline{\alpha}^\varepsilon(\cdot))$ is tight in $D([0,T];\mathbb{R}^p\times\overline{\mathcal{M}})$. □

We are now in a position to prove the weak convergence of $(x^\varepsilon(\cdot),\overline{\alpha}^\varepsilon(\cdot))$ and $(y^\varepsilon(\cdot),\overline{\alpha}^\varepsilon(\cdot))$. The proof will be furnished by using a martingale problem formulation.

Denote the class of real-valued functions that are twice continuously differentiable with compact support by C_0^2. For each $\alpha\in\mathcal{M}$ and $\psi(\cdot,\alpha)\in C_0^2$, define the operator $\mathcal{L}^\varepsilon$ by

(3.5)
$$\mathcal{L}^\varepsilon\psi(x,\alpha)=\psi_x'(x,\alpha)A(\alpha)x+\frac{1}{2}\mathrm{tr}[\psi_{xx}(x,\alpha)\sigma(\alpha)\sigma'(\alpha)]+Q^\varepsilon\psi(x,\cdot)(\alpha),\ \alpha\in\mathcal{M},$$

where $\psi_x(\cdot,\alpha)$ and $\psi_{xx}(\cdot,\alpha)$ denote the gradient and the Hessian of $\psi(\cdot,\alpha)$, respectively. For each $k\in\overline{\mathcal{M}}$, let $f(\cdot,k)\in C_0^2$ and define

(3.6)
$$\overline{f}(x,\alpha)=\sum_{k=1}^{l}f(x,k)I_{\{\alpha\in\mathcal{M}_k\}}.$$

Corresponding to (3.5), we also define

$$\mathcal{L}f(x,\overline{\alpha}) = f'_x(x,\overline{\alpha})\overline{A}(\overline{\alpha})x + \frac{1}{2}\mathrm{tr}[f_{xx}(x,\alpha)\overline{\sigma}(\overline{\alpha})\overline{\sigma}'(\overline{\alpha})] + \overline{Q}f(x,\cdot)(\overline{\alpha}) \tag{3.7}$$

for $\overline{\alpha} \in \overline{\mathcal{M}} = \{1,\dots,l\}$, where $\overline{A}(k)$ and $\overline{\sigma}(k)$ are defined in (2.6), and $\overline{Q}$ is defined in (2.2).

LEMMA 3.4. *Suppose that $(\overline{x}(\cdot),\overline{\alpha}(\cdot))$ is a solution of a martingale problem associated with the operator $\mathcal{L}$. Then it is unique (in the sense of distribution).*

Proof. The proof is a modification of Yin and Zhang [18, Lem. 7.18]. □

THEOREM 3.5. *Assume* (A1)–(A4). *Then as $\varepsilon \to 0$,*

$$(x^\varepsilon(\cdot),\overline{\alpha}^\varepsilon(\cdot)) \Rightarrow (\overline{x}(\cdot),\overline{\alpha}(\cdot)) \quad \textit{and} \quad (y^\varepsilon(\cdot),\overline{\alpha}^\varepsilon(\cdot)) \Rightarrow (\overline{y}(\cdot),\overline{\alpha}(\cdot)),$$

where $\overline{x}(\cdot)$ and $\overline{y}(\cdot)$ are solutions of (2.5) *and the symbol $\Rightarrow$ denotes convergence in distribution.*

Proof. Let $f(\cdot,k) \in C_0^2$ and $\overline{f}(\cdot,\alpha)$ as defined in (3.6) for each $k \in \overline{\mathcal{M}}$ and each $\alpha \in \mathcal{M}$. Since the joint pair of processes $(x^\varepsilon(\cdot),\alpha^\varepsilon(\cdot))$ is Markov, for any $t,s \geq 0$ with $t+s \leq T$,

$$\overline{f}(x^\varepsilon(t+s),\alpha^\varepsilon(t+s)) - \overline{f}(x^\varepsilon(t),\alpha^\varepsilon(t)) - \int_0^t \mathcal{L}^\varepsilon \overline{f}(x^\varepsilon(u),\alpha^\varepsilon(u))du$$

is a continuous-time martingale. Thus, for any positive integer κ, any bounded and continuous functions $h_i(\cdot,\alpha)$ for $i \leq \kappa$, and any $t_i \leq t$,

$$E\prod_{i=1}^{\kappa} h_i(x^\varepsilon(t_i),\alpha^\varepsilon(t_i))\Bigg[\overline{f}(x^\varepsilon(t+s),\alpha^\varepsilon(t+s)) - \overline{f}(x^\varepsilon(t),\alpha^\varepsilon(t)) - \int_t^{t+s} \mathcal{L}^\varepsilon \overline{f}(x^\varepsilon(u),\alpha^\varepsilon(u))du\Bigg] = 0,$$

and as a result,

$$\begin{aligned} &E\prod_{i=1}^{\kappa} h_i(x^\varepsilon(t_i),\overline{\alpha}^\varepsilon(t_i))\Bigg[\overline{f}(x^\varepsilon(t+s),\alpha^\varepsilon(t+s)) - \overline{f}(x^\varepsilon(t),\alpha^\varepsilon(t)) - \int_t^{t+s} \mathcal{L}^\varepsilon \overline{f}(x^\varepsilon(u),\alpha^\varepsilon(u))du\Bigg] \\ &= E\prod_{i=1}^{\kappa} h_i(x^\varepsilon(t_i),\overline{\alpha}^\varepsilon(t_i))\Bigg[f(x^\varepsilon(t+s),\overline{\alpha}^\varepsilon(t+s)) - f(x^\varepsilon(t),\overline{\alpha}^\varepsilon(t)) - \int_t^{t+s} \mathcal{L}^\varepsilon f(x^\varepsilon(u),\overline{\alpha}^\varepsilon(u))du\Bigg] = 0. \end{aligned} \tag{3.8}$$

By virtue of Lemma 3.3, $(x^\varepsilon(\cdot),\overline{\alpha}^\varepsilon(\cdot))$ is tight. Using Prohorov's theorem, we may extract weakly convergent subsequences. Select such a sequence and still index it by ε for notational simplicity. By the Skorohod representation, $(x^\varepsilon(\cdot),\overline{\alpha}^\varepsilon(\cdot))$ converges to $(\overline{x}(\cdot),\overline{\alpha}(\cdot))$ almost surely (a.s). It follows that

$$\begin{aligned} &E\prod_{i=1}^{\kappa} h_i(x^\varepsilon(t_i),\overline{\alpha}^\varepsilon(t_i))[f(x^\varepsilon(t+s),\overline{\alpha}^\varepsilon(t+s)) - f(x^\varepsilon(t),\overline{\alpha}^\varepsilon(t))] \\ &\to E\prod_{i=1}^{\kappa} h_i(\overline{x}(t_i),\overline{\alpha}(t_i))[f(\overline{x}(t+s),\overline{\alpha}(t+s)) - f(\overline{x}(t),\overline{\alpha}(t))]. \end{aligned} \tag{3.9}$$

Detailed calculation shows that

$$
\begin{aligned}
&\int_t^{t+s} \mathcal{L}^\varepsilon f(x^\varepsilon(u), \overline{\alpha}^\varepsilon(u))du \\
&\quad = \sum_{k=1}^{l}\sum_{j=1}^{m_k} \int_t^{t+s} \overline{f}'_x(x^\varepsilon(u), s_{kj})A(s_{kj})x^\varepsilon(u) I_{\{\alpha^\varepsilon(u)=s_{kj}\}}du \\
&\quad + \sum_{k=1}^{l}\sum_{j=1}^{m_k} \int_t^{t+s} \mathrm{tr}[\overline{f}_{xx}(x^\varepsilon(u), s_{kj})\sigma(s_{kj})\sigma'(s_{kj})] I_{\{\alpha^\varepsilon(u)=s_{kj}\}}du \\
&\quad + \sum_{k=1}^{l}\sum_{j=1}^{m_k} \int_t^{t+s} Q^\varepsilon \overline{f}(x^\varepsilon(u), \cdot)(s_{kj}) I_{\{\alpha^\varepsilon(u)=s_{kj}\}}du.
\end{aligned} \tag{3.10}
$$

Let us examine each of the above terms in (3.10). First,

$$
\begin{aligned}
&\int_t^{t+s} \overline{f}'_x(x^\varepsilon(u), s_{kj})A(s_{kj})x^\varepsilon(u) I_{\{\alpha^\varepsilon(u)=s_{kj}\}}du \\
&\quad = \int_t^{t+s} \overline{f}'_x(x^\varepsilon(u), s_{kj})A(s_{kj})x^\varepsilon(u)\nu_j^k I_{\{\alpha^\varepsilon(u)\in\mathcal{M}_k\}}du \\
&\qquad + \int_t^{t+s} \overline{f}'_x(x^\varepsilon(u), s_{kj})A(s_{kj})x^\varepsilon(u)[I_{\{\alpha^\varepsilon(u)=s_{kj}\}} - \nu_j^k I_{\{\alpha^\varepsilon(u)\in\overline{\mathcal{M}}\}}]du.
\end{aligned}
$$

Applying (2.3) to the last term above and recalling that $f(\cdot,\alpha)$ is a C^2-function with compact support,

$$
\begin{aligned}
&E\left|\int_t^{t+s} \overline{f}'_x(x^\varepsilon(u), s_{kj})A(s_{kj})x^\varepsilon(u)[I_{\{\alpha^\varepsilon(u)=s_{kj}\}} - \nu_j^k I_{\{\alpha^\varepsilon(u)\in\overline{\mathcal{M}}\}}]du\right|^2 \\
&\quad = O(\varepsilon) \to 0 \ \text{ as } \varepsilon \to 0.
\end{aligned}
$$

By the weak convergence of $(x^\varepsilon(\cdot), \overline{\alpha}^\varepsilon(\cdot))$, the Skorohod representation, and the continuity of $x^\varepsilon(\cdot)$ and $\overline{x}(\cdot)$, as $\varepsilon \to 0$, $I_{\{\alpha^\varepsilon(u)\in\mathcal{M}_k\}} = I_{\{\overline{\alpha}^\varepsilon(u)=k\}} \to I_{\{\overline{\alpha}(u)=k\}}$, and

$$
\begin{aligned}
&E\prod_{i=1}^{\kappa} h_i(x^\varepsilon(t_i), \overline{\alpha}^\varepsilon(t_i)) \sum_{k=1}^{l}\sum_{j=1}^{m_k} \int_t^{t+s} \overline{f}'_x(x^\varepsilon(u), s_{kj})A(s_{kj})x^\varepsilon(u)\nu_j^k I_{\{\alpha^\varepsilon(u)\in\mathcal{M}_k\}}du \\
&\quad \to E\prod_{i=1}^{\kappa} h_i(\overline{x}(t_i), \overline{\alpha}(t_i)) \sum_{k=1}^{l}\sum_{j=1}^{m_k} \int_t^{t+s} f'_x(\overline{x}(u), s_{kj})A(s_{kj})\overline{x}(u)\nu_j^k I_{\{\overline{\alpha}(u)=k\}}du \\
&\quad = E\prod_{i=1}^{\kappa} h_i(\overline{x}(t_i), \overline{\alpha}(t_i)) \int_t^{t+s} f'_x(\overline{x}(u), \overline{\alpha}(u))du.
\end{aligned} \tag{3.11}
$$

Likewise,

$$
\begin{aligned}
&E\prod_{i=1}^{\kappa} h_i(x^\varepsilon(t_i), \overline{\alpha}^\varepsilon(t_i)) \sum_{k=1}^{l}\sum_{j=1}^{m_k} \mathrm{tr}[\overline{f}_{xx}(x^\varepsilon(u), s_{kj})\sigma(s_{kj})\sigma'(s_{kj})] I_{\{\alpha^\varepsilon(u)=s_{kj}\}}du \\
&\quad \to E\prod_{i=1}^{\kappa} h_i(\overline{x}(t_i), \overline{\alpha}(t_i)) \int_t^{t+s} \mathrm{tr}[f_{xx}(\overline{x}(u), \overline{\alpha}(u))\overline{\Sigma}(\overline{\alpha}(u))]du,
\end{aligned} \tag{3.12}
$$

where $\overline{\Sigma}(k)$ is defined in (2.6).

Next note that the definition of $\overline{f}(x,\alpha)$ in (3.6) implies that $Q^\varepsilon \overline{f}(x,\cdot)(\alpha) = \widehat{Q} f(x,\cdot)(\alpha)$. Using the same averaging argument above with the help of (2.3), we also have

$$\begin{aligned} &E\prod_{i=1}^{\kappa} h_i(x^\varepsilon(t_i),\overline{\alpha}^\varepsilon(t_i))\int_t^{t+s} Q^\varepsilon \overline{f}(x^\varepsilon(u),s_{kj})I_{\{\alpha^\varepsilon(u)=s_{kj}\}}du \\ &\to E\prod_{i=1}^{\kappa} h_i(\overline{x}(t_i),\overline{\alpha}(t_i))\int_t^{t+s} \overline{Q} f(\overline{x}(u),\overline{\alpha}(u))du. \end{aligned} \tag{3.13}$$

Combining (3.9), (3.11), (3.12), and (3.13) leads to the convergence of $(x^\varepsilon(\cdot),\overline{\alpha}^\varepsilon(\cdot))$ to $(\overline{x}(\cdot),\overline{\alpha}(\cdot))$ with the desired operator $\mathcal{L}$, which is unique by virtue of Lemma 3.4. Using exactly the same arguments, we also obtain that $(y^\varepsilon(\cdot),\overline{\alpha}^\varepsilon(\cdot)) \Rightarrow (\overline{y}(\cdot),\overline{\alpha}(\cdot))$. The theorem is thus proved. □

COROLLARY 3.6. *Under the conditions of Theorem* 3.5 (*with the use of the Skorohod representation and without changing notation*), *for any* $t\in[0,T]$, $\widetilde{\alpha}^\varepsilon(t)\to\widetilde{\alpha}(t)$, $R^\varepsilon(t)\to R(t)$, *and* $\widetilde{x}^\varepsilon(t)\to\widetilde{x}(t)$ *a.s.*

Proof. In view of the weak convergence $y^\varepsilon(\cdot)\to y(\cdot)$, the Skorohod representation, and the definitions of $\zeta^\varepsilon(j)$ and $\zeta(j)$, $\zeta^\varepsilon(j)\to\zeta(j)$ a.s. as $\varepsilon\to 0$. Recall assumption (A3), which implies that $\mu_{k_1}\neq\mu_{k_2}$ for $k_1\neq k_2$. Owing to the definition of $\Lambda^{\varepsilon,n_0,n}$ in (3.1) and $\widetilde{\alpha}^\varepsilon(\cdot)$ in (3.3), $\Lambda^{\varepsilon,n_0,n}\to\Lambda^{n_0,n}$ a.s. Let

$$G_n=\left\{\left|\frac{\Lambda^{\varepsilon,n_0,n}}{\mu_{k_0}^{n_0,n}}-1\right|=\min\left\{\left|\frac{\Lambda^{\varepsilon,n_0,n}}{\mu_{k}^{n_0,n}}-1\right|,\ k=1,\dots,l\right\}\right\}.$$

It then follows that as $\varepsilon\to 0$,

$$\alpha^{\varepsilon,n_0,n}=\sum_{k_0=1}^{l} k_0 I_{G_n}\to\sum_{k_0=1}^{l} k_0 I_{G_n}=\overline{\alpha}^{n_0,n}\ \text{ a.s.}$$

As a result, $\widetilde{\alpha}^\varepsilon(t)\to\widetilde{\alpha}(t)$ a.s. for each $t\in[0,T]$. The convergence, in fact, is uniform in $[0,T]$.

Since $\overline{A}(k)$, $\overline{\sigma}(k)$, and $\overline{H}(k)$ take values in the finite set $\overline{\mathcal{M}}=\{1,\dots,l\}$,

$$\overline{A}(\widetilde{\alpha}^\varepsilon(t))\to\overline{A}(\widetilde{\alpha}(t)),\ \overline{\sigma}(\widetilde{\alpha}^\varepsilon(t))\to\overline{\sigma}(\widetilde{\alpha}(t)),\ \text{ and }\ \overline{H}(\widetilde{\alpha}^\varepsilon(t))\to\overline{H}(\widetilde{\alpha}(t)).$$

Since $R^\varepsilon(t)$ is uniformly bounded by Lemma 3.1, so is $\dot{R}^\varepsilon(t)$ on $[0,T]$. We may extract a convergent subsequence and still index it by ε for notational simplicity. Writing $R^\varepsilon(t)$ in its integral form leads to

$$\begin{aligned} R^\varepsilon(t) =\ & \mathrm{Cov}(x_0)+\int_0^t \overline{A}(\widetilde{\alpha}^\varepsilon(u))R^\varepsilon(u)du+\int_0^t R^\varepsilon(u)\overline{A}'(\widetilde{\alpha}^\varepsilon(u))du \\ &+\int_0^t \overline{\sigma}(\widetilde{\alpha}^\varepsilon(u))\overline{\sigma}'(\widetilde{\alpha}^\varepsilon(u))du-\frac{1}{\delta^2}\int_0^t R^\varepsilon(u)\overline{H}'(\widetilde{\alpha}^\varepsilon(u))R^\varepsilon(u))du \\ \to\ & \mathrm{Cov}(x_0)+\int_0^t \overline{A}(\widetilde{\alpha}(u))\widetilde{R}(u)du+\int_0^t \widetilde{R}(u)\overline{A}'(\widetilde{\alpha}(u))du \\ &+\int_0^t \overline{\sigma}(\widetilde{\alpha}(u))\overline{\sigma}'(\widetilde{\alpha}(u))du-\frac{1}{\delta^2}\int_0^t \widetilde{R}(u)\overline{H}'(\widetilde{\alpha}(u))\widetilde{R}(u))du \\ =\ & \widetilde{R}(t). \end{aligned}$$

The convergence of $R^\varepsilon(t) \to \widetilde{R}(t)$ is established. Furthermore, the limit does not depend on the chosen subsequence. Likewise, we can show that $\widetilde{x}^\varepsilon(\cdot)$ is tight as in Lemma 3.3. By a similar approach, we obtain $\widetilde{x}^\varepsilon(t) \to \widetilde{x}(t)$ a.s. □

THEOREM 3.7. *For each fixed $\delta > 0$, as $\varepsilon \to 0$,*

$$|x^\varepsilon(\cdot) - \widetilde{x}^\varepsilon(\cdot)|_T \to |\overline{x}(\cdot) - \widetilde{x}(\cdot)|_T = O(\sqrt{\delta}).$$

This, in particular, implies that

$$\lim_{\delta\to 0}\lim_{\varepsilon\to 0} |x^\varepsilon(\cdot) - \widetilde{x}^\varepsilon(\cdot)|_T = 0.$$

Proof. First of all, in view of Corollary 3.6 and Lemma 3.2, as $\varepsilon \to 0$,

$$|\widetilde{x}^\varepsilon(\cdot) - \widetilde{x}(\cdot)|_T \to 0.$$

Moreover, in view of Lemma 3.2 and the weak convergence of $x^\varepsilon(\cdot)$ to $\overline{x}(\cdot)$, we have that as $\varepsilon \to 0$,

$$|x^\varepsilon(\cdot) - \overline{x}(\cdot)|_T \to 0.$$

Therefore, it follows that

$$\Big||x^\varepsilon(\cdot) - \widetilde{x}^\varepsilon(\cdot)|_T - |\overline{x}(\cdot) - \widetilde{x}(\cdot)|_T\Big| \le |x^\varepsilon(\cdot) - \overline{x}(\cdot)|_T + |\widetilde{x}^\varepsilon(\cdot) - \widetilde{x}(\cdot)|_T \to 0.$$

Next, we show the error bound of $\widetilde{x}(\cdot) - \overline{x}(\cdot)$ in terms of $\sqrt{\delta}$. It can be shown as in Haussmann and Zhang [10] that

$$|\widehat{x}(\cdot) - \overline{x}(\cdot)|_T = O(\sqrt{\delta}).$$

It suffices to show

$$|\widetilde{x}(\cdot) - \widehat{x}(\cdot)|_T = O(\sqrt{\delta}).$$

Given $\theta = \theta(\cdot) \in D([0,T] : \overline{\mathcal{M}})$ and a, b being the multiples of δ such that $0 \le a < b$, let

$$F^\theta_{a,b} = \Big\{\alpha(\cdot) = \theta(\cdot) \text{ on } [a,b)\Big\}.$$

That is, $F^\theta_{a,b} = \{\alpha(t) = \theta(t) \text{ for all } t \in [a,b)\}$. Let $E^\theta_{a,b}$ denote the conditional expectation given $F^\theta_{a,b}$. We show that for given $0 < \eta < 1$,

$$E^\theta_{a,b}|\widetilde{x}(t) - \overline{x}(t)| = O\left(\delta^{1-\eta} + \exp\left(-\frac{\kappa(t-a-l_0\delta)}{\delta}\right)\right)$$

uniformly for $t \in [a + l_0\delta, b]$, here $l_0 = c_0(\log\delta)^2 + 1$.

Consider the differentials of $\overline{H}(k_0)(\widetilde{x}(t) - \widehat{x}(t))$ and $|\overline{H}(k_0)(\widetilde{x}(t) - \widehat{x}(t))|^2$ on the interval when $\overline{\alpha}(t) = k_0$, we obtain

$$\begin{aligned} d(\overline{H}(k_0)(\widetilde{x}(t) - \widehat{x}(t))) \ = \overline{H}(k_0)\Big\{ & (\overline{A}(\widetilde{\alpha}(t))\widetilde{x}(t) - \overline{A}(k_0)\widehat{x}(t))dt \\ & - \frac{1}{\delta^2}\widetilde{R}(t)\overline{H}'(\widetilde{\alpha}(t))(\overline{H}(\widetilde{\alpha}(t))\widetilde{x}(t) - \overline{H}(k_0)\widehat{x}(t))dt \\ & + \frac{1}{\delta^2}\left(\widetilde{R}(t)\overline{H}'(\widetilde{\alpha}(t)) - \overline{R}(t)\overline{H}'(k_0)\right)\overline{\eta}(t)dt \\ & + \frac{1}{\delta}\left(\widetilde{R}(t)\overline{H}'(\widetilde{\alpha}(t)) - \overline{R}(t)\overline{H}'(k_0)\right)d\widehat{v}(t)\Big\} \end{aligned}$$

and

$$\begin{aligned} d|\overline{H}(k_0)(\widetilde{x}(t)-\widehat{x}(t))|^2 &= 2(\widetilde{x}(t)-\widehat{x}(t))'\overline{H}'(k_0)d(\overline{H}(k_0)(\widetilde{x}(t)-\widehat{x}(t))) \\ &\quad + \frac{1}{\delta^2}\mathrm{tr}\left(\left(\widetilde{R}(t)\overline{H}'(\widetilde{\alpha}(t))-\overline{R}(t)\overline{H}'(k_0)\right)\left(\widetilde{R}(t)\overline{H}'(\widetilde{\alpha}(t))-\overline{R}(t)\overline{H}'(k_0)\right)'\right) \\ &\quad = A(t)dt + B(t)d\widehat{v}(t), \end{aligned}$$

where $\widehat{v}(t)$ is an innovation process given by $d\widehat{v}(t) = dy(t) - E(\overline{H}(\overline{\alpha}(t))x(t)|\mathcal{Y}_t)dt$, $\overline{\eta}(t) = E(\overline{H}(\overline{\alpha}(t))x(t)|\mathcal{Y}_t) - \overline{H}(\overline{\alpha}(t))\widehat{x}(t)$,

$$\begin{aligned} A(t) = 2(\widetilde{x}(t)-\widehat{x}(t))'\overline{H}'(k_0)\overline{H}(k_0)\Big\{ & (\overline{A}(\widetilde{\alpha}(t))\widetilde{x}(t)-\overline{A}(k_0)\widehat{x}(t)) \\ & - \frac{1}{\delta^2}\widetilde{R}(t)\overline{H}'(\widetilde{\alpha}(t))(H(t,\widetilde{\alpha}(t))\widetilde{x}(t)-\overline{H}(k_0)\widehat{x}(t)) \\ & + \frac{1}{\delta^2}\left(\widetilde{R}(t)\overline{H}'(\widetilde{\alpha}(t))-\overline{R}(t)\overline{H}'(k_0)\right)\overline{\eta}(t)\Big\} \\ & + \frac{1}{\delta^2}\mathrm{tr}\left(\left(\widetilde{R}(t)\overline{H}'(\widetilde{\alpha}(t))-\overline{R}(t)\overline{H}'(k_0)\right)\left(\widetilde{R}(t)\overline{H}'(\widetilde{\alpha}(t))-\overline{R}(t)\overline{H}'(k_0)\right)'\right) \end{aligned}$$

and

$$B(t) = \frac{2}{\delta}(\widetilde{x}(t)-\widehat{x}(t))'\overline{H}'(k_0)\left(\widetilde{R}(t)\overline{H}'(\widetilde{\alpha}(t))-\overline{R}(t)\overline{H}'(k_0)\right).$$

Let $\phi(t) = |\overline{H}(k_0)(\widetilde{x}(t)-\widehat{x}(t))|^2$. Then,

$$\phi(t) = \phi(a+l_0\delta) + \int_{a+l_0\delta}^{t} A(s)ds + \int_{a+l_0\delta}^{t} B(s)d\widehat{v}(s).$$

Write

$$A(t) = A(t)I_{\{\widetilde{\alpha}(\cdot)=k_0 \text{ on } [a+l_0\delta,b]\}} + A(t)I_{\{\widetilde{\alpha}(\cdot)=k_0 \text{ on } [a+l_0\delta,b]\}^c}.$$

As in Lemma 7.1 in the appendix, we can show that $(E^\theta_{a,b}|A(t)|^n)^{1/n} = O(1/\delta)$, for $n = 1, 2, \ldots$ In view of Lemma 7.2, it follows that

$$\begin{aligned} & E^\theta_{a,b}\left|A(t)I_{\{\widetilde{\alpha}(\cdot)=k_0 \text{ on } [a+l_0\delta,b]\}^c}\right| \\ & \quad \le (E^\theta_{a,b}|A(t)|^n)^{\frac{1}{n}}(E^\theta_{a,b}I_{\{\widetilde{\alpha}(\cdot)=k_0 \text{ on } [a+l_0\delta,b]\}^c})^{\frac{n-1}{n}} \\ & \quad \le \frac{K}{\delta}(P(\widetilde{\alpha}(t)\neq k_0 \text{ for some } t\in[a+l_0\delta,b]|F^\theta_{a,b}))^{\frac{n-1}{n}} \\ & \quad \le K\delta^{(2(n-1)/n)-1} \le K\delta^{1-\eta} \text{ for } n \text{ large enough.} \end{aligned} \tag{3.14}$$

Given $\{\widetilde{\alpha}(\cdot) = k_0 \text{ on } [a+l_0\delta, b]\}$, we have

$$\begin{aligned} A(t) = 2(\widetilde{x}(t)-\widehat{x}(t))'\overline{H}'(k_0)\overline{H}(k_0)\Big\{ & (\overline{A}(k_0)\widetilde{x}(t)-\overline{A}(k_0)\widehat{x}(t)) \\ & - \frac{1}{\delta^2}\widetilde{R}(t)\overline{H}'(k_0)(\overline{H}(k_0)(\widetilde{x}(t)-\widehat{x}(t)) \\ & + \frac{1}{\delta^2}\left(\widetilde{R}(t)-\overline{R}(t))\overline{H}'(k_0)\right)\overline{\eta}(t)\Big\} \\ & + \frac{1}{\delta^2}\mathrm{tr}\left((\widetilde{R}(t)-\overline{R}(t))\overline{H}'(k_0)\overline{H}(k_0)(\widetilde{R}(t)-\overline{R}(t))\right). \end{aligned}$$

Recall that $\overline{H}(k_0)$ is invertible and both $\widetilde{R}(t)/\delta$ and $\overline{R}(t)/\delta$ are uniformly bounded. Moreover, in view of Lemma 7.3 (appendix), we have

$$\frac{\widetilde{R}(t)-\overline{R}(t)}{\delta}=O\left(\delta+\exp\left(-\frac{\kappa(t-a-l_0\delta)}{\delta}\right)\right).$$

Given $\{\widetilde{\alpha}(\cdot)=k_0 \text{ on } [a+l_0\delta,b]\}$, it follows that

$$A(t)\le K_0\phi(t)-\frac{\kappa_0}{\delta}\phi(t)+K\left(\delta+\frac{|\overline{\eta}(t)|^2}{\delta^2}+\exp\left(-\frac{\kappa(t-a-l_0\delta)}{\delta}\right)\right).$$

Hence,

$$\begin{aligned}E^\theta_{a,b}A(t)\ &\le\left(K_0-\frac{\kappa}{\delta}\right)E^\theta_{a,b}\phi(t)\\ &\quad+K\left(\delta^{1-\eta}+\frac{E^\theta_{a,b}|\overline{\eta}(t)|^2}{\delta^2}+\exp\left(-\frac{\kappa(t-a-l_0\delta)}{\delta}\right)\right).\end{aligned}\tag{3.15}$$

Next, we claim that

$$E^\theta_{a,b}\int_{a+l_0\delta}^t B(s)d\widehat{v}(s)=0.$$

In fact, if we let $\mathcal{F}^\alpha_{a,b}=\sigma\{\alpha(r):\ a\le r<b\}$ and $\zeta(t)=\int_{a+l_0\delta}^t B(s)d\widehat{v}(s)$, then for $0\le t<b$, $E[\zeta(t)|\mathcal{F}^\alpha_{0,b}]=0$ because $\widehat{v}(\cdot)$ is a Brownian motion given $\alpha(\cdot)$. Note that $E[\zeta(t)|\mathcal{F}^\alpha_{a,b}]=E[E[\zeta(t)|\mathcal{F}^\alpha_{0,b}]|\mathcal{F}^\alpha_{a,b}]$. It follows that $E[\zeta(t)|\mathcal{F}^\alpha_{a,b}]=0$, a.s. Thus,

$$E^\theta_{a,b}\int_{a+l_0\delta}^t B(s)d\widehat{v}(s)=0,\ \text{a.s. with respect to } \widehat{P}(d\theta)=P(\alpha(\cdot)\in d\theta).$$

Using this claim, we have

$$E^\theta_{a,b}\phi(t)=E^\theta_{a,b}\phi(a+l_0\delta)+E^\theta_{a,b}\int_{a+l_0\delta}^t A(s)ds.$$

Thus, in view of (3.15),

$$\begin{aligned}\frac{dE^\theta_{a,b}\phi(t)}{dt}&=E^\theta_{a,b}A(t)\le\left(K_0-\frac{\kappa}{\delta}\right)E^\theta_{a,b}\phi(t)\\ &\quad+K\left(\delta^{1-\eta}+\frac{E^\theta_{a,b}|\overline{\eta}(t)|^2}{\delta^2}+\exp\left(-\frac{\kappa(t-a-l_0\delta)}{\delta}\right)\right).\end{aligned}$$

Using Gronwall's inequality, the uniform boundedness of $E^\theta_{a,b}\phi(a+l_0\delta)$, and integration by parts, we obtain

$$E^\theta_{a,b}\phi(t)\le K\left(\delta^{2-\eta}+\exp\left(-\frac{\kappa(t-a-l_0\delta)}{\delta}\right)\right)$$

for some $\kappa>0$. Therefore,

$$(E^\theta_{a,b}\phi(t))^{\frac{1}{2}}\le K\left(\delta^{1-\eta/2}+\exp\left(-\frac{\kappa(t-a-l_0\delta)}{\delta}\right)\right).$$

Given a fixed number $0 < \eta < 1$, let

$$\Theta_\eta^\varepsilon = \Big\{\theta(\cdot) \in D([0,T] : \overline{\mathcal{M}}) : \quad \text{the number of jumps of } \theta(\cdot) \le [1/\varepsilon^\eta]\Big\}.$$

Let $\gamma_0 > 0$ be a constant and define

$$\Theta_{\eta,\gamma_0}^\varepsilon = \Big\{\theta = \theta(\cdot) \in \Theta_\eta^\varepsilon : \quad \text{the duration between any two jumps of } \theta(\cdot) \ge \gamma_0\varepsilon\Big\}.$$

If we let $0 = t_0 < t_1 < \cdots < t_n < T$ denote the jump times of $\theta(\cdot)$, then $\theta(\cdot) \in \Theta_{\eta,\gamma_0}^\varepsilon$ implies that $n \le [1/\varepsilon^\eta]$ and $t_{j+1} - t_j \ge \gamma_0\varepsilon$.

Next, we show that

$$\int_0^T E|\widetilde{x}(t) - \widehat{x}(t)| I_{\{\alpha(\cdot)\in\Theta_{\eta,\gamma_0}^\varepsilon\}} dt = O(\delta^{1-\eta}). \tag{3.16}$$

Let $\xi(t) = |\widetilde{x}(t) - \widehat{x}(t)| I_{\{\alpha(\cdot)\in\Theta_{\eta,\gamma_0}^\varepsilon\}}$. Note that

$$E\int_0^T \xi(t)dt \le \sum_{j=0}^{[1/\delta^\eta]} E\int_0^T \xi(t) I_{[\tau_j,\tau_{j+1})}.$$

It suffices to show

$$E\int_0^T \xi(t) I_{[\tau_j,\tau_{j+1})} \le O(\delta^{1-\eta})$$

because

$$E\int_0^T \xi(t)dt \le \sum_{j=0}^{[1/\delta^\eta]} K\delta^{1-\eta} \le O(\delta^{1-2\eta}) = O(\delta^{1-\eta})$$

when $2\eta < \delta$.

For $j = 0$,

$$E\int_0^T \xi(t) I_{[0,\tau_1)} dt = \int_0^\infty E\left[\int_0^{s\wedge T} \xi(t)dt \Big| \tau_1 = s\right] p_1(s)ds,$$

where $p_1(s)$ is the density function of τ_1.

It can be seen that

$$E\left[\int_0^{l_0\delta} \xi(t)dt \Big| \tau_1 = s\right] = O(l_0\delta) = O(\varepsilon(\log\varepsilon)^2).$$

Moreover, we have

$$E\left[\int_{l_0\delta}^{s\wedge T} \xi(t)dt \Big| \tau_1 = s\right] = O\left(\delta^{1-\eta} + \exp\left(-\frac{\kappa(s - l_0\delta)}{\delta}\right)\right).$$

Thus,

$$E\int_0^T \xi(t) I_{[0,\tau_1)} dt = O(\delta^{1-\eta}).$$

For $j \geq 1$, we have

$$E\int_0^T \xi(t)I_{[\tau_j,\tau_{j+1})}dt = \int_0^\infty E\left[\int_r^T \xi(t)dt\Big|\tau_j = r\right]p_j(r)dr$$
$$= \int_0^\infty \int_r^T E\left[\xi(t)dtI_{[r,\tau_{j+1})}\Big|\tau_j = r\right]p_j(r)dr.$$

Similarly as in the case for $j = 0$, we can show

$$\int_r^T E\left[\xi(t)dtI_{[r,\tau_{j+1})}\Big|\tau_j = r\right] = O(\delta^{1-\eta}).$$

It follows that

$$E\int_0^T \xi(t)I_{[\tau_j,\tau_{j+1})}dt = O(\delta^{1-\eta}).$$

Taking $\eta = 1/2$ completes the proof. □

4. A numerical example. In this section we present a simple example to demonstrate the use of the near optimal filter. We consider the following one-dimensional model:

$$\text{(4.1)}\qquad \begin{cases} dx^\varepsilon(t) = A(\alpha^\varepsilon(t))x^\varepsilon(t)dt + \sigma(\alpha^\varepsilon(t))dw(t), & x(0) = x_0, \\ dy^\varepsilon(t) = H(\alpha^\varepsilon(t))x^\varepsilon(t)dt + \delta dv(t), & y(0) = 0, \end{cases}$$

where $\alpha^\varepsilon(t) \in \mathcal{M} = \{1, 2\}$, $t \geq 0$, is a Markov chain generated by

$$Q^\varepsilon = \frac{1}{\varepsilon}Q, \quad \text{with } Q = \begin{pmatrix} -\lambda & \lambda \\ \mu & -\mu \end{pmatrix}.$$

Computational experiments and numerical results are reported next.

In this example, it is readily seen that the stationary distribution is

$$\nu = (\nu_1, \nu_2) = \left(\frac{\mu}{\lambda+\mu}, \frac{\lambda}{\lambda+\mu}\right),$$

and

$$\overline{A} = \nu_1 A(1) + \nu_2 A(2),$$
$$\overline{H} = \nu_1 H(1) + \nu_2 H(2),$$
$$\overline{\Sigma} = \overline{\sigma}^2 = \nu_1\sigma^2(1) + \nu_2\sigma^2(2).$$

We use time discretization step size 0.0001. The time horizons in the continuous-time model is $T = 10$. All our results are based on computations with 100 sample paths.

We consider the model with the following specifications:

$$A(1) = -0.01, A(2) = -0.02, H(1) = 1, H(2) = 2, \sigma(1) = \sigma(2) = 1,$$

$$\lambda = \mu = 0.02.$$

TABLE 4.1
Convergence of J^ε to J^0.

ε	0.1	0.05	0.01	0.005	0.001	0.0001
$\lvert J^\varepsilon - J^0\rvert$	6.517	5.295	3.769	3.235	1.745	0.305

TABLE 4.2
Error bound of J^0.

δ	1	0.5	0.1	0.05	0.01	0.005	0.001	0.005
$J^0/\sqrt{\delta}$	8.046	8.071	8.111	8.126	8.170	8.202	8.475	8.450

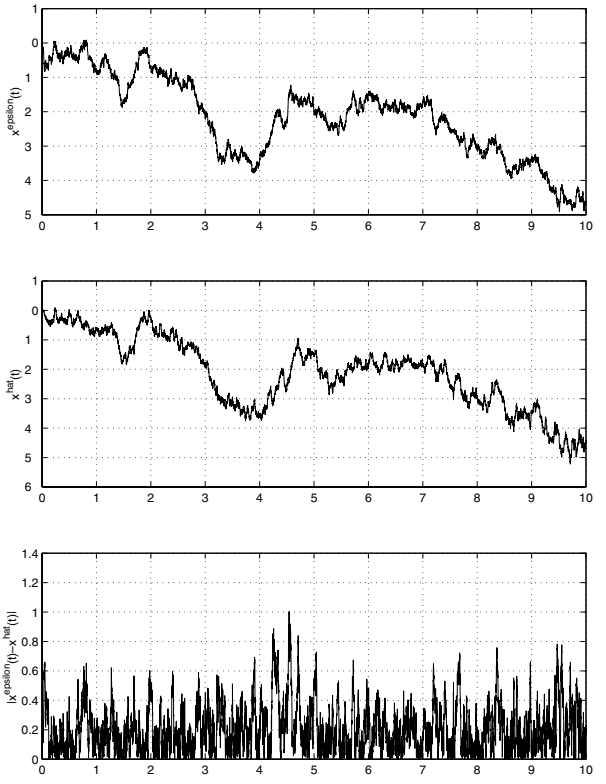

FIG. 4.1. *Sample paths of $x^\varepsilon(\cdot)$, $\widetilde{x}^\varepsilon(\cdot)$ and their difference.*

To demonstrate the convergence of

$$J^\varepsilon = \int_0^T (E|x^\varepsilon(t) - \widetilde{x}^\varepsilon(t)|^2)^{\frac{1}{2}} \quad \text{to} \quad J^0 = \int_0^T (E|\overline{x}(t) - \widetilde{x}(t)|^2)^{\frac{1}{2}},$$

we fix $\delta = 0.1$ and vary ε. In this case, the values of $|J^\varepsilon - J^0|$ are given in Table 4.1. The convergence of $|J^\varepsilon - J^0| \to 0$ can be seen from Table 4.1.

Then to demonstrate the error bound of $J^0 = O(\sqrt{\delta})$, we take $\varepsilon = 0.05$ and vary δ. The results are summarized in Table 4.2. It follows that $|J^0| \le 8.475\sqrt{\delta}$ at these points. Sample paths of $x^\varepsilon(\cdot), -\widetilde{x}^\varepsilon(\cdot)$, and $|x^\varepsilon(\cdot) - \widetilde{x}^\varepsilon(\cdot)|$ are plotted in Figure 4.1.

This example focuses exclusively on approximation of $\widetilde{x}^\varepsilon(\cdot)$ to $x^\varepsilon(\cdot)$ without involving the QVT. There are extensive numerical experiments on QVT in the literature; see, for example, Zhang [20] and references therein.

5. Extensions to Markov chains with transient states. Recall that a finite state Markov chain has at least one recurrent state and either all states are recurrent or there is a class of transient states. In this section, we consider extensions of results obtained in the previous sections to such chains that in addition to recurrent states, there is attached to them a number of transient states. The main idea is still aggregation of states, but we only lump the states in each recurrent class and leave the transient states alone. In fact, these transient states are asymptotically unimportant. Let $\alpha^\varepsilon(\cdot)$ be a finite-state Markov chain with its generator having the following decomposition form:

$$Q^\varepsilon = \frac{1}{\varepsilon}\begin{pmatrix} \widetilde{Q}^1 & & & \\ & \ddots & & \\ & & \widetilde{Q}^l & \\ \widetilde{Q}^1_* & \cdots & \widetilde{Q}^l_* & \widetilde{Q}_* \end{pmatrix} + \widehat{Q}, \tag{5.1}$$

where for each $k = 1, \ldots, l$, $\widetilde{Q}^k$ is a generator with dimension $m_k \times m_k$, $\widetilde{Q}_* \in \mathbb{R}^{m_* \times m_*}$, $\widetilde{Q}^k_* \in \mathbb{R}^{m_* \times m_k}$, and $m_1 + \cdots + m_l + m_* = m$. The state space of $\alpha^\varepsilon(\cdot)$ is given by

$$\mathcal{M} = \mathcal{M}_1 \cup \cdots \cup \mathcal{M}_l \cup \mathcal{M}_* = \{s_{11}, \ldots, s_{1m_1}\} \cup \cdots \cup \{s_{l1}, \ldots, s_{lm_l}\} \cup \{s_{*1}, \ldots, s_{*m_*}\},$$

where $\mathcal{M}_k = \{s_{k1}, \ldots, s_{km_k}\}$, $k = 1, \ldots, l$, are the subspaces corresponding to the recurrent states and $\mathcal{M}_* = \{s_{*1}, \ldots, s_{*m_*}\}$ consists of the transient states.

Suppose that, for $k = 1, \ldots, l$, $\widetilde{Q}^k$ are irreducible and $\widetilde{Q}_*$ is Hurwitz (i.e., all its eigenvalues have negative real parts). Let $a_{m_i} = -\widetilde{Q}_*^{-1}\widetilde{Q}^i_* 1_{m_i}$ for $i = 1, \ldots, l$. The jth component $a_{m_i,j}$ is the probability of $\alpha^\varepsilon(t)$ jumping from s_{*j} to $\mathcal{M}_i$ for small ε. Now define the aggregated process $\overline{\alpha}^\varepsilon(\cdot)$ by

$$\overline{\alpha}^\varepsilon(t) = \begin{cases} i & \text{if } \alpha^\varepsilon(t) \in \mathcal{M}_i, \\ \xi_j & \text{if } \alpha^\varepsilon(t) = s_{*j}, \end{cases}$$

where, for $j = 1, \ldots, m_*$,

$$\xi_j = I_{\{0 \le \xi \le a_{m_1,j}\}} + 2I_{\{a_{m_1,j} < \xi \le a_{m_1,j} + a_{m_2,j}\}} + \cdots + lI_{\{a_{m_1,j} + \cdots + a_{m_{l-1},j} < \xi \le 1\}},$$

and ξ is a random variable with uniform distribution on $[0, 1]$. Let

$$\overline{Q} = \operatorname{diag}(\nu^1, \ldots, \nu^l, 0_{m_* \times m_*})\widehat{Q}\,\widetilde{1}_* = \begin{pmatrix} \overline{Q}_* & \\ & 0_{m_* \times m_*} \end{pmatrix}, \tag{5.2}$$

where

$$\widetilde{1}_* = \begin{pmatrix} 1_{m_1} & & & \\ & \ddots & & \\ & & 1_{m_l} & \\ a_{m_1} & \cdots & a_{m_l} & 0_{m_* \times m_*} \end{pmatrix},$$

and 1_{m_k} is as defined before.

Then it can be shown as in Yin, Zhang, and Badowski [19] that $\overline{\alpha}^\varepsilon(\cdot)$ converges weakly to $\overline{\alpha}(\cdot)$ that is a continuous-time Markov chain with state space $\overline{\mathcal{M}}$ and generator $\overline{Q}_*$ defined in (5.2). Moreover, for any deterministic test functions $\beta_{kj}(t)$, the corresponding occupation measures satisfy

$$\begin{aligned} &E\left(\int_0^T \left(I_{\{\alpha^\varepsilon(t)=s_{kj}\}} - \nu_j^k I_{\{\overline{\alpha}^\varepsilon(t)=k\}}\right)\beta_{kj}(t)dt\right)^2 = O(\varepsilon), \\ &E\left(\int_0^T I_{\{\alpha^\varepsilon(t)=s_{*j}\}}\beta_{*j}(t)dt\right)^2 = O(\varepsilon^2). \end{aligned} \tag{5.3}$$

Recall that $\alpha^\varepsilon(\cdot)$ is a Markov chain generated by Q^ε defined in (5.1) and $\overline{\alpha}(\cdot)$ is a Markov chain generated by $\overline{Q}_*$. Let $(x^\varepsilon(\cdot), y^\varepsilon(\cdot))$ be the actual state and observation satisfying

$$\begin{cases} dx^\varepsilon(t) = A(\alpha^\varepsilon(t))x^\varepsilon(t)dt + \sigma(\alpha^\varepsilon(t))dw(t), & x^\varepsilon(0) = x_0, \\ dy^\varepsilon(t) = H(\alpha^\varepsilon(t))x^\varepsilon(t)dt + \delta dv(t), & y^\varepsilon(0) = 0. \end{cases}$$

The corresponding limit system is given by

$$\begin{cases} d\overline{x}(t) = \overline{A}(\overline{\alpha}(t))\overline{x}(t)dt + \overline{\sigma}(\overline{\alpha}(t))dw(t), & \overline{x}(0) = x_0, \\ d\overline{y}(t) = \overline{H}(\overline{\alpha}(t))\overline{x}(t)dt + \delta dv(t), & \overline{y}(0) = 0, \end{cases}$$

with $\overline{A}$, $\overline{\sigma}$, and $\overline{H}$ defined in (2.6). Let $\widetilde{x}(\cdot)$ and $\widetilde{x}^\varepsilon(\cdot)$ be defined in (2.12) and (3.4), respectively. Then we can prove the following theorem as in the proof of Theorem 3.7.

THEOREM 5.1. *For each fixed $\delta > 0$, we have*

$$|x^\varepsilon(\cdot) - \widetilde{x}^\varepsilon(\cdot)|_T \to |\overline{x}(\cdot) - \widetilde{x}(\cdot)|_T = O(\sqrt{\delta})$$

as $\varepsilon \to 0$, This, in particular, implies that

$$\lim_{\delta\to 0}\lim_{\varepsilon\to 0} |x^\varepsilon(\cdot) - \widetilde{x}^\varepsilon(\cdot)|_T = 0.$$

6. Conclusions. This paper develops a hybrid filter involving a hidden Markov chain with weak and strong interactions. An averaged filter is constructed based on a quadratic variation test. Such a filter is shown to be near optimal as the observation noise goes to zero. The scheme is easily implementable. Its advantage is significant savings of computational effort, which leads to computable filters for many applications arising in emerging applications of financial engineering and communication networks.

7. Appendix. In this appendix, we present several technical lemmas. The proof of Lemma 7.1 is similar to that of [11, Theorem 4.1]. Providing the error probability of the QVT, Lemma 7.2 can be proved similar to that of [11, Lem. 3.1]. The order of magnitude estimate in Lemma 7.3 may be derived as in [20].

LEMMA 7.1. *Let $x(t)$, $\widehat{x}(t)$, and $\widetilde{x}(t)$, $t \geq 0$, denote the processes defined in* (1.1), (2.7), *and* (2.12), *respectively. Then, for each $n = 1, 2, \ldots$, there exists a constant K such that*

$$E\left(|x(t)|^n + |\widehat{x}(t)|^n + |\widetilde{x}(t)|^n\right) \leq K.$$

LEMMA 7.2. *Assume* (A1)–(A5). *Then for each* $j = 1, 2, \ldots$, *there exist* $k_0 > 0$, $K > 0, \varepsilon_0 > 0$, *such that for* $0 < \varepsilon < \varepsilon_0$, $n - n_0 \geq l_0 := [k_0(\log \varepsilon)^2] + 1$,

$$P(\alpha^{n_0,n} \neq k_0 | \alpha(t) = k_0,\ t \in [\varepsilon n_0, \varepsilon n]) \leq K\varepsilon^2. \tag{7.1}$$

It follows that

$$P(\{\alpha^{n_0,n} \neq k_0\} \cap \{\alpha(t) = k_0,\ t \in [\varepsilon n_0, \varepsilon n]\}) \leq K\varepsilon^2. \tag{7.2}$$

LEMMA 7.3. *Assume* (A1)–(A4). *For each* $\theta \in D([0,T] : \overline{\mathcal{M}})$, *let* $R^\theta(t)$ *denote the solution to the Riccati equation* (3.4) *with* $\widetilde{\alpha}(t)$ *replaced by* $\theta(t)$. *Then the following hold:*

(a) *There exist positive constants* c_1 *and* c_2, *independent of* $0 < \eta < 1$, $\theta \in D([0,T] : \overline{\mathcal{M}})$, *and* $t \in [0,T]$ *such that*

$$c_1 I \leq \frac{R^\theta(t)}{\varepsilon} \leq c_2 I.$$

(b) *There exist* γ_0, K, *and* $\kappa > 0$ *such that, for each* $0 < \eta < 1$ *and* $\theta \in \Theta^\varepsilon_{\eta,\gamma_0}$, *we have*

$$\left| \frac{R^\theta(t)}{\varepsilon} - F(\theta(t)) \right| \leq K \left(\exp\left(-\frac{\kappa(t - t_j)}{\varepsilon} \right) + \varepsilon \right) \tag{7.3}$$

for $t \in [t_j, t_{j+1})$, *where* $\{t_j\}$ *is the set of jump times of* θ *and* $F(k)$ *is given in assumption* (A2).

FINITE-TIME GLOBAL STABILIZATION BY MEANS OF TIME-VARYING DISTRIBUTED DELAY FEEDBACK*

IASSON KARAFYLLIS†

Abstract. The paper contains certain results concerning the finite-time global stabilization for triangular control systems described by retarded functional differential equations by means of time-varying distributed delay feedback. These results enable us to present solutions to feedback stabilization problems for systems with delayed input. The results are obtained by using the backstepping technique.

Key words. nonlinear time delay systems, global feedback stabilization

AMS subject classifications. 93D15, 93C23, 93C10

DOI. 10.1137/040616383

1. Introduction.

It is known that for finite-dimensional continuous-time control systems with locally Lipschitz dynamics (e.g., $\dot{x} = f(x,u)$, where f is locally Lipschitz with respect to $(x,u) \in \Re^n \times \Re^m$), finite-time global stabilization cannot be achieved by means of a locally Lipschitz feedback law. However, it has been shown that finite-time global stabilization is possible by means of continuous (see [2, 3, 4, 6, 8] as well as the reported results in [1]) or discontinuous feedback laws (see [14]).

Recently, the option of using feedback with delays has been considered for the stabilization of continuous-time systems in various problems. The closed-loop system may be considered as a system of time-varying retarded functional differential equations (RFDEs). For example, in [20] analytic driftless control systems of the following form are considered:

$$\dot{x}(t) = f(x(t),\ u(t)) := \sum_{i=1}^{m} f_i(x(t))u_i(t)$$
$$x(t) \in \Re^n,\ u(t) := (u_1(t), \dots, u_m(t))' \in \Re^m.$$

The authors in [20] provide strategies for the construction of control laws of the form $u(t) = k(t, x(t), x(lT))$ for $t \in [lT, (l+1)T)$, where l is a nonnegative integer and $T > 0$ denotes the updating time-period of the control. Notice that this type of feedback is a time-varying feedback with delays of the form $u(t) = k(t, x(t), x([t/T]T))$, where $[t/T]$ denotes the integer part of t/T, which is time-varying even if k is independent of time, i.e., $k(t,x,\xi) = k(x,\xi)$. The same comments apply for the synchronous controller switching strategies proposed in [22]. The possibility of switching control laws using distributed delays was recently exploited in [17]. Observers that make use of past values of the state estimate and guarantee convergence in finite-time were considered in [5, 19]. The ability of output discrete delay feedback to stabilize minimum phase linear systems was studied in [9]. Recently, there has been an increasing interest in the feedback stabilization problems of systems with delayed input (see [15, 18]) as well as the application of the backstepping technique for the stabilization of nonlinear

time-delay systems (see [10, 16]). An account of the use of delays in linear feedback design is given in [21].

In the present work it is shown that finite-time global stabilization can be achieved by time-varying locally Lipschitz distributed delay feedback. It is known that systems described by time-varying RFDEs admit solutions that converge to the equilibrium point in finite time (e.g., Property 5.1 in Chapter 3 in [7]). Using the backstepping technique (see [13, 24]), the problem of finite-time global stabilization for nonlinear triangular systems is studied and solved. Moreover, the approach proposed in this paper is not limited to triangular finite-dimensional continuous-time control systems but can be directly applied to nonlinear triangular systems described by RFDEs. The case of delayed inputs is also considered. Among other cases, we address the finite-time global stabilization problems for the following cases:

- The case of triangular control systems with no delays,

$$\begin{aligned} &\dot{x}_i(t) = f_i(t, x_1(t), \dots, x_i(t)) + x_{i+1}(t), \quad i = 1, \dots, n-1; \\ &\dot{x}_n(t) = f_n(t, x(t)) + u(t), \\ &x(t) := (x_1(t), \dots, x_n(t)) \in \Re^n,\ u(t) \in \Re,\ t \geq 0. \end{aligned} \tag{1.1}$$

- The case of a chain of delayed integrators with no limitation on the size of the delays,

$$\dot{x}_i(t) = x_{i+1}(t - \tau_i), i = 1, \dots, n-1; \quad \dot{x}_n(t) = u(t - \tau_n), \tag{1.2}$$

  where $x(t) = (x_1(t), \dots, x_n(t)) \in \Re^n, u(t) \in \Re$ and $\tau_i \geq 0$ $i = 1, \dots, n$ are the delays.
- The case of triangular control systems with delayed drift terms:

$$\begin{aligned} &\dot{x}_i(t) = f_i(t, x_1(t - \tau_{i,1}), \dots, x_i(t - \tau_{i,i})) + x_{i+1}(t), \quad i = 1, \dots, n-1, \\ &\dot{x}_n(t) = f_n(t, x_1(t - \tau_{n,1}), \dots, x_n(t - \tau_{n,n})) + u(t), \\ &x(t) := (x_1(t), \dots, x_n(t)) \in \Re^n, u(t) \in \Re, t \geq 0, \end{aligned} \tag{1.3}$$

  where $\min_{i=1,\dots,n-1} \quad \min_{j=1,\dots,i} \tau_{i,j} > 0$.

The construction of the proposed distributed delay feedback control is based on a backstepping method, which is applicable to systems with delays. Roughly speaking, the main idea that lies behind the integrator backstepping lemma is described next (here $(T_r(t)x = \{x(t+\theta); \theta \in [-r, 0]\}$ denotes the *r-history* of the state):

> Suppose that the feedback $y(t) = k(t, T_r(t)x)$ leads the state of the system $\dot{x}(t) = f(t, x(t), y(t))$ to zero in finite time (say $T > 0$) and that the feedback $u(t) = \widetilde{k}(t, T_r(t)x, T_r(t)y)$ guarantees the equality $y(t) = k(t, T_r(t)x)$ in finite time (say $T' > 0$) for the augmented system $\dot{x}(t) = f(t, x(t), y(t)); \dot{y}(t) = u(t)$. Then the feedback $u(t) = \widetilde{k}(t, T_r(t)x, T_r(t)y)$ leads the state of the augmented system to zero in finite time.

The explanation of the conclusion is simple: the first T' time units are used in order to achieve $y(t) = k(t, T_r(t)x)$; the next T time units are used in order to achieve $x(t) = 0$ and finally the last r time units are used in order to achieve $x(t + \theta) = 0; \theta \in [-r, 0]$, which directly implies $y(t) = 0$. The idea above can be applied for the design of controllers using a step-by-step procedure (backstepping method).

The structure of the paper is as follows. In section 2, the reader can find definitions and technical results that will be used in later sections of this work. Section 2 is divided

into two subsections. In the first subsection (section 2.1) we present differentiability notions for functionals. In the second subsection (section 2.2) we give the notion of finite-time stabilizability of control systems as well as some preliminary results for the scalar case. Section 3 contains the statement and the proofs of the main results of the paper. Examples are presented in section 4, where the main results of the paper can be directly applied. The conclusions of the paper are given in section 5.

Notation. Throughout this paper we adopt the following notation:

- For a vector $x \in \Re^n$ we denote by $|x|$ its Euclidean norm. For $x \in C^0([-r,0];\Re^n)$ we define $\|x\|_r := \max_{\theta\in[-r,0]} |x(\theta)|$.
- By $C^j(A)(C^j(A;\Omega))$, where $j \geq 0$ is a nonnegative integer, we denote the class of functions (taking values in Ω) that have continuous derivatives of order j on A.
- We denote by K^+ the class of positive C^∞ functions defined on $\Re^+$. We say that an increasing and continuous function $\rho : \Re^+ \to \Re^+$ with $\rho(0) = 0$ is of class K_∞ if $\lim_{s\to+\infty} \rho(s) = +\infty$.
- Z^+ denotes the set of positive integers and $\Re^+$ the set of nonnegative real numbers. For every real number R, $[R]$ denotes its integer part, i.e., $[R] := \max\{x; x \leq R, x\, integer\}$.
- A continuous mapping $f : I \times C^0([-r,0];\Re^n) \times U \to \Re^k$, where $\Re^+ \subseteq I \subseteq \Re, U \subseteq \Re^m$, is said to be completely locally Lipschitz with respect to $(x,u) \in C^0([-r,0];\Re^n) \times U$ if for every bounded set $S \subset I \times C^0([-r,0];\Re^n) \times U$ there exists $L \geq 0$ such that $|f(t,x,u) - f(t,y,v)| \leq L\|x-y\|_r + L|u-v|$ for all $(t,x,u) \in S, (t,y,v) \in S$. Notice that a mapping $f : I \times C^0([-r,0];\Re^n) \times U \to \Re^k$, where $\Re^+ \subseteq I \subseteq \Re, U \subseteq \Re^m$, which is completely locally Lipschitz with respect to $(x,u) \in C^0([-r,0];\Re^n) \times U$, is also defined on $I \times C^0([-r-\sigma,0];\Re^n) \times U$, for every $\sigma \geq 0$, and is completely locally Lipschitz with respect to $(x,u) \in C^0([-r-\sigma,0];\Re^n) \times U$, for every $\sigma \geq 0$.
- Let $x : [a-r, b) \to \Re^n$ with $b > a \geq 0$ and $r \geq 0$. By $T_r(t)x$ we denote the "history" of x from $t-r$ to t, i.e., $T_r(t)x := \{x(t+\theta); \theta \in [-r,0]\}$, for $t \in [a,b)$.

2. Definitions and technical results. Consider the following control system described by retarded functional differential equations (RFDEs):

$$\dot{x}(t) = f(t, T_r(t)x, u(t-\tau(t))); \quad x(t) \in \Re^n, u(t) \in U, t \geq 0, \tag{2.1}$$

where $0 \in U \subseteq \Re^m$, $f : \Re^+ \times C^0([-r,0];\Re^n) \times U \to \Re^n$ is completely locally Lipschitz with respect to $(x,u) \in C^0([-r,0];\Re^n) \times U$ with $f(t,0,0) = 0$ for all $t \geq 0$ and $\tau : \Re^+ \to \Re^+$ is a bounded continuous function. We denote by $x(t) = x(t,t_0,x_0,u) \in \Re^n$ the solution of (2.1) initiated from $t_0 \geq 0$ with initial condition $T_r(t_0)x = x_0 \in C^0([-r,0];\Re^n)$ and corresponding to $u \in C^0(\Re;U)$. By virtue of Theorem 3.2 in [7], for every $(t_0,x_0,u) \in \Re^+ \times C^0([-r,0];\Re^n) \times C^0(\Re;U)$ there exists $t_{\max}(t_0,x_0,u) > t_0$ (called the maximal existence time) such that the solution $x(t) = x(t,t_0,x_0,u) \in \Re^n$ of (2.1) initiated from $t_0 \geq 0$ with initial condition $T_r(t_0)x = x_0$ and corresponding to $u \in C^0(\Re;U)$, is defined on $[t_0-r, t_{\max})$, is continuous on $[t_0-r, t_{\max})$ and continuously differentiable on $[t_0, t_{\max})$ and cannot be further continued, i.e., if $t_{\max} < +\infty$, then $\limsup_{t\to t^-_{\max}} |x(t)| = +\infty$. When $r = 0$ we identify the space $C^0([-r,0];\Re^n)$ with the finite-dimensional space $\Re^n$ and we obtain the familiar finite-dimensional continuous-time case. Consequently, all of the following definitions and results hold also for finite-dimensional continuous-time systems.

This section is divided into two subsections. In the first subsection (section 2.1) we present the differentiability notions for functionals used in the present paper. In the second subsection (section 2.2) we give the notion of finite-time stabilizability of control systems as well as some preliminary results for the scalar case.

2.1. Differentiability notions. In order to study the properties of control system (2.1), we must clarify the differentiability properties of functionals along the solutions of (2.1). The following definition provides the notions of ultimate differentiability and differentiability of functionals along the solutions of (2.1).

DEFINITION 2.1. *Let a functional $\varphi : I \times C^0([-r,0];\Re^n) \to \Re$, where $\Re^+ \subseteq I \subseteq \Re$, $\varphi(t,x)$ being completely locally Lipschitz with respect to $x \in C^0([-r,0];\Re^n)$, with $\varphi(t,0) = 0$ for all $t \in I$. We say that*

- *φ is ultimately differentiable along the solutions of (2.1) with time constant $T \geq 0$, if there exists a constant $T \geq 0$ and a functional $D\varphi : I \times C^0([-r,0];\Re^n) \times U \to \Re$ (called the derivative of φ along the solutions of (2.1) with $D\varphi(t,x,u)$ being completely locally Lipschitz with respect to $(x,u) \in C^0([-r,0];\Re^n) \times U$ and $D\varphi(t,0,0) = 0$ for all $t \in I$, such that for every $(t_0,x_0,u) \in \Re^+ \times C^0([-r,0];\Re^n) \times C^0(\Re;U)$ for which $t_0 + T < t_{\max}(t_0,x_0,u)$, the mapping $t \to \varphi(t,T_r(t)x)$ is of class C^1 on $[t_0+T, t_{\max})$ and it holds that*

$$\frac{d}{dt}\varphi(t,T_r(t)x) = D\varphi(t,T_r(t)x,u(t-\tau(t))) \quad \forall t \in [t_0+T, t_{\max}).$$

- *φ is differentiable along the solutions of (2.1), if φ is ultimately differentiable along the solutions of (2.1) with time constant $T = 0$.*

If $\varphi(t,x) = q(t,x(0))$, where $q \in C^1(\Re^+ \times \Re^n;\Re)$ is a function with locally Lipschitz derivatives and $q(t,0) = 0$ for all $t \geq 0$, then φ is differentiable along the solutions of (2.1) with $D\varphi(t,x,u) := \frac{\partial q}{\partial t}(t,x(0)) + \frac{\partial q}{\partial x}(t,x(0))f(t,x,u)$ for all $(t,x,u) \in \Re^+ \times C^0([-r,0];\Re^n) \times U$. This remark holds particularly for the case $r = 0$, where the functional $\varphi(t,x)$ is an ordinary function $\varphi : \Re^+ \times \Re^n \to \Re$ with $\varphi(t,0) = 0$ for all $t \geq 0$. However, when delays are involved, the notion of ultimate differentiability of a functional is useful. The following example illustrates this point.

Example 2.2. Consider the following system:

$$\begin{aligned} &\dot{x}_1(t) = x_2(t); \qquad \dot{x}_2(t) = u(t) \\ &(x_1(t),x_2(t)) \in \Re^2, \quad u(t) \in \Re. \end{aligned} \tag{2.2}$$

Let $r > 0$ and consider the functional $\varphi(t,x) := x_1(-r)$ defined on $\Re^+ \times C^0([-r,0];\Re^2)$. It can be shown that φ is ultimately differentiable along the solutions of (2.2) with time constant $T = r > 0$ but φ is *not differentiable* along the solutions of (2.2). Moreover, we have $D\varphi(t,x,u) := x_2(-r)$, since $\dot{x}_1(t-r) = x_2(t-r)$ for all $t \geq t_0 + r$. A *more demanding* notion of differentiability of functionals along the solutions of (2.1) is given next.

DEFINITION 2.3. *Let $0 \leq \mu \leq r$. A functional p defined on $I \times C^0([-(r-\mu),0];\Re^n)$, where $\Re^+ \subseteq I \subseteq \Re$, $p(t,x)$ being completely locally Lipschitz with respect to $x \in C^0([-(r-\mu),0];\Re^n)$, with $p(t,0) = 0$ for all $t \in I$, is called l-differentiable along the solutions of (2.1) with delay μ, if there exist functionals $D^i p$, $i = 1,2,\dots,l$, called the ith derivatives of p, defined on $I \times C^0([-(r-\mu),0];\Re^n)$, each $D^i p(t,x)$ being completely locally Lipschitz with respect to $x \in C^0([-(r-\mu),0];\Re^n)$ with $D^i p(t,0) = 0$ for all $t \in I$, such that for every $(t_0,x_0,u) \in \Re^+ \times C^0([-r,0];\Re^n) \times C^0(\Re;U)$, the*

mapping $t \to p(t, T_{r-\mu}(t-\mu)x)$ *is of class* C^l *on* $[t_0, t_{\max}+\mu)$ *and it holds that*

$$\frac{d^i}{dt^i}p(t, T_{r-\mu}(t-\mu)x) = D^i p(t, T_{r-\mu}(t-\mu)x) \quad \forall t \in [t_0, t_{\max}+\mu), i = 1, 2, \dots, l.$$

Remark 2.4. (i) If $p : I \times C^0([-(r-\mu), 0]; \Re^n) \to \Re$, where $\Re^+ \subseteq I \subseteq \Re$, $0 \leq \mu \leq r$, is l-differentiable along the solutions of (2.1) with delay μ, then its derivatives $D^i p : I \times C^0([-(r-\mu), 0]; \Re^n) \to \Re$, $i = 1, 2, \dots, l-1$, are functionals which are $(l-i)$-differentiable along the solutions of (2.1) with delay μ.

(ii) If $p : I \times C^0([-(r-\mu), 0]; \Re^n) \to \Re$, where $\Re^+ \subseteq I \subseteq \Re$, $0 \leq \mu \leq r$, is l-differentiable along the solutions of (2.1) with delay μ, then for every $\tau \in [0, \mu]$ the functional $k(t, x) := p(t+\tau, x)$ is l-differentiable along the solutions of (2.1) with delay $\mu - \tau$ with derivatives $D^i k(t, x) = D^i p(t+\tau, x)$. Moreover, the functional $k(t, x) := p(t+\tau, T_{r'}(\tau-\mu)x)$, where $r' \geq r+\tau-\mu$ is differentiable along the solutions of (2.1) with derivative $Dk(t, x) = Dp(t+\tau, T_{r'}(\tau-\mu)x)$.

The following definition clarifies the notion of a periodic functional.

Definition 2.5. *Let a functional* $\varphi : I \times C^0([-r, 0]; \Re^n) \to \Re$, *where* $\Re^+ \subseteq I \subseteq \Re$, $\varphi(t, x)$ *being completely locally Lipschitz with respect to* $x \in C^0([-r, 0]; \Re^n)$, *with* $\varphi(t, 0) = 0$ *for all* $t \in I$. *We say that* φ *is* T*-periodic if there exists* $T > 0$ *such that* $\varphi(t+T, x) = \varphi(t, x)$ *for all* $(t, x) \in I \times C^0([-r, 0]; \Re^n)$.

The following lemma provides classes of functionals, which are l-differentiable with delay μ along the solutions of (2.1) and are going to be used extensively in the next section.

Lemma 2.6. *The following statements hold:*

(i) *The functional*

$$k(t, x) := \int_{-2\mu}^{-\mu} \mu^{-1} h\left(\frac{s}{\mu}\right) \varphi(t+s, T_R(s+\mu)x) ds \tag{2.3}$$

defined on $\Re \times C^0([-R-\mu, 0]; \Re^n)$, *where* $\mu > 0$, $R \geq 0$, $h \in C^l(\Re; \Re^+)$ *with* $h(s) = 0$ *for all* $s \notin (-2, -1)$ *and* $\varphi : \Re \times C^0([-R, 0]; \Re^n) \to \Re$, $\varphi(t, x)$ *being completely locally Lipschitz with respect to* $x \in C^0([-R, 0]; \Re^n)$, *with* $\varphi(t, 0) = 0$ *for all* $t \in \Re$, *is* l*-differentiable along the solutions of* (2.1) *with delay* μ, *with derivatives for* $i = 1, 2, \dots, l$*:*

$$D^i k(t, x) := \frac{(-1)^i}{\mu^{i+1}} \int_{-2\mu}^{-\mu} \frac{d^i h}{dt^i}\left(\frac{s}{\mu}\right) \varphi(t+s, T_R(s+\mu)x) dw \tag{2.4}$$

Moreover, if φ *is* T*-periodic (or linear), then* k *and its derivatives* $D^i k$ $(i = 1, \dots, l)$ *are* T*-periodic (or linear).*

(ii) *Let* $a \in C^l(\Re; \Re)$ *and* $p : \Re \times C^0([-R-\mu, 0]; \Re^n) \to \Re$ *a* $(l+i)$*-differentiable functional along the solutions of* (2.1) *with delay* μ. *The functional*

$$k(t, x) := D^i p(t, x) + a(t) \int_{-2\mu}^{-\mu} \mu^{-1} h\left(\frac{s}{\mu}\right) \varphi(t+s, T_R(s+\mu)x) ds \tag{2.5}$$

defined on $\Re \times C^0([-R-\mu, 0]; \Re^n)$, *where* $\mu > 0$, $R \geq 0$, $h \in C^l(\Re; \Re^+)$ *with* $h(s) = 0$ *for all* $s \notin (-2, -1)$, $D^i p$ *is the* i*th derivative of* p *and* $\varphi : \Re \times C^0([-R, 0]; \Re^n) \to \Re$, $\varphi(t, x)$ *being completely locally Lipschitz with respect to* $x \in C^0([-R, 0]; \Re^n)$, *with* $\varphi(t, 0) = 0$ *for all* $t \in \Re$, *is* l*-differentiable along*

the solutions of (2.1) *with delay* μ. *Moreover, if* $a \in C^l(\Re;\Re^+)$, φ, p, *and its derivatives* $D^j p$ $(j = 1,\dots,l+i)$ *are* T*-periodic, then it follows that* k *and its derivatives* $D^j k$ $(j = 1,\dots,l)$ *are* T*-periodic. Finally, if* φ, p, *and its derivatives* $D^j p$ $(j = 1,\dots,l+i)$ *are linear, then it follows that* k *and its derivatives* $D^j k$ $(j = 1,\dots,l)$ *are linear.*

The proof of statement (i) of Lemma 2.6 is an immediate consequence of the following equalities:

$$k(t, T_{R+\mu}(t-\mu)x) = \int_{t-2\mu}^{t-\mu} \mu^{-1} h\left(\frac{w-t}{\mu}\right) \varphi(w, T_R(w)x)dw$$

$$\frac{d^i}{dt^i} k(t, T_{R+\mu}(t-\mu)x) = D^i k(t, T_{R+\mu}(t-\mu)x)$$
$$= \frac{(-1)^i}{\mu^{i+1}} \int_{t-2\mu}^{t-\mu} \frac{d^i h}{dt^i}\left(\frac{w-t}{\mu}\right) \varphi(w, T_R(w)x)dw.$$

The proof of statement (ii) of Lemma 2.6 is an immediate consequence of statement (i) of Lemma 2.6 and is omitted.

2.2. Finite-time stabilizability. Having clarified the notions of differentiability of functionals along the solutions of a control system, we next proceed to the notion of finite-time stabilizability of a control system.

DEFINITION 2.7. *Let* $b := \sup_{t\geq 0} \tau(t)$. *We say that system* (2.1) *is finite-time stabilizable if there exists constant* $T \geq 0$ *and a functional* $k : [-b, +\infty) \times C^0([-R, 0];\Re^n) \to U$, $k(t, x)$ *being completely locally Lipschitz with respect to* $x \in C^0([-R, 0];\Re^n)$ *with* $k(t, 0) = 0$ *for all* $t \geq -b$ *such that*

(P1) *for every* $(t_0, x_0) \in \Re^+ \times C^0([-\widetilde{r}, 0];\Re^n)$, *where* $\widetilde{r} := \max(r, R + b)$, *the solution* $x(t) = x(t, t_0, x_0) \in \Re^n$ *of the closed-loop system* (2.1) *with* $u(t) = k(t, T_R(t)x)$ *initiated from* $t_0 \geq 0$ *with initial condition* $T_{\widetilde{r}}(t_0)x = x_0 \in C^0([-\widetilde{r}, 0];\Re^n)$ *exists for all* $t \geq t_0$ *and satisfies* $x(t) = 0$ *for all* $t \geq t_0 + T$

(P2) $\sup\{|x(t_0 + h, t_0, x_0)|;\ h \in [-\widetilde{r}, s], \|x_0\|_{\widetilde{r}} \leq s, t_0 \in [0, s]\} < +\infty\ \forall s \geq 0$.

Particularly, if system (2.1) *is finite-time stabilizable, then we say that the closed-loop system* (2.1) *with* $u(t) = k(t, T_R(t)x)$ *satisfies the dead-beat property of order* T.

Remark 2.8. Using Lemma 3.3 in [12] it can be shown that if the closed-loop system (2.1) with $u(t) = k(t, T_R(t)x)$ satisfies the dead-beat property of order T, then the equilibrium point $0 \in C^0([-\widetilde{r}, 0];\Re^n)$ is nonuniformly in time globally asymptotically stable for the closed-loop system (2.1) with $u(t) = k(t, T_R(t)x)$. The notion of nonuniform in time robust global asymptotic stability was introduced in [11] for finite-dimensional continuous-time systems and was extended to a wide class of systems in [12], including systems described by RFDEs.

As already remarked in the introduction, it is generally known that for finite-dimensional continuous-time control systems with locally Lipschitz dynamics, finite-time global stabilization cannot be achieved by means of locally Lipschitz feedback. The following lemma studies the scalar case and shows that this is no longer true if time-varying distributed delay feedback is used.

LEMMA 2.9. *Consider the one-dimensional control system:*

$$\dot{x}(t) = u(t-\tau) + v(t); \quad x(t) \in \Re, u(t) \in \Re, v(t) \in \Re, t \geq 0, \tag{2.6}$$

where $\tau \geq 0$ *is a constant. Then for every* $\mu > \tau$, *the solutions of the closed-loop system* (2.6) *with*

$$u(t) = -p_\mu(t + \tau, T_\mu(t + \tau - \mu)x), \tag{2.7}$$

where $p_\mu : \Re \times C^0([-\mu, 0]; \Re) \to \Re$ *is the linear* 3μ*-periodic functional defined by*

$$p_\mu(t, x) := \mu^{-1} a\left(\frac{t}{\mu}\right) \int_{-2\mu}^{-\mu} \mu^{-1} h\left(\frac{s}{\mu}\right) x(s+\mu) ds \tag{2.8}$$

for certain $a \in C^0(\Re; \Re^+)$ *being a periodic function with period* 3 *with* $a(t) = 0$ *for* $t \in [0, 2]$ *and* $\int_2^3 a(t)dt = 1$ *and* $h \in C^0(\Re; \Re^+)$ *with* $\int_{-2}^{-1} h(s)ds = \int_{-2\mu}^{-\mu} \mu^{-1} h(\frac{s}{\mu})ds = 1$*, initiated from arbitrary* $t_0 \geq 0$ *with arbitrary initial condition* $T_{2\mu}(t_0)x = x_0 \in C^0([-2\mu, 0]; \Re)$ *and corresponding to arbitrary input* $v \in C^0(\Re^+; \Re)$ *satisfy*

(2.9)

$$|x(t)| \leq \exp(3L)\sigma\left(\frac{t - t_0}{\mu}\right) \|x_0\|_{2\mu} + 10\mu \exp(3L) \sup_{\max(t_0, t-6\mu) \leq s \leq t} |v(s)| \quad \forall t \geq t_0,$$

where $\sigma(t) := \left\{ \begin{smallmatrix} 1 & if & t < 6 \\ 0 & if & t \geq 6 \end{smallmatrix} \right.$ *and* $L := \max_{t \in [0,3]} a(t)$.

Proof. The closed-loop system (2.6) with (2.7) is described by the differential equation

$$\dot{x}(t) = -\mu^{-1} a\left(\frac{t}{\mu}\right) \int_{-2\mu}^{-\mu} \mu^{-1} h\left(\frac{s}{\mu}\right) x(t+s) ds + v(t). \tag{2.10}$$

As in the proof of Theorem 1.1, Chapter 6, page 168 in [7] it can be shown that for every initial condition $x_0 \in C^0([-2\mu, 0]; \Re)$ the solution of the closed-loop system (2.6) with (2.7) exists for all $t \geq t_0$ and satisfies

$$|x(t)| \leq \exp(L\mu^{-1}(t - t_0)) \left(\|x_0\|_{2\mu} + (t - t_0) \sup_{t_0 \leq \tau \leq t} |v(\tau)| \right) \quad \forall t \geq t_0. \tag{2.11}$$

Define the time sequence $t_i = 3\mu([\frac{t_0}{3\mu}] + i)$, $i \in Z^+$. We next prove the following claim.

Claim. For the solution of the closed-loop system (2.6) with (2.7), the following inequalities hold for all $i \in Z^+$:

$$\begin{gathered} |x(t)| \leq |x(t_i)| + 5\mu \sup_{t_i \leq \tau \leq t} |v(\tau)| \quad \forall t \in [t_i, t_{i+1}] \quad \text{and} \\ |x(t_{i+1})| \leq 5\mu \sup_{t_i \leq \tau \leq t_{i+1}} |v(\tau)|. \end{gathered} \tag{2.12}$$

Proof of Claim. Let arbitrary $i \in Z^+$. Indeed, since $a \in C^0(\Re; \Re^+)$ is a periodic function with period 3, with $a(t) = 0$ for $t \in [0, 2]$, we have $a(\frac{t}{\mu}) = 0$ for $t \in [t_i, t_i + 2\mu]$. Consequently, it follows that

$$x(t) = x(t_i) + \int_{t_i}^{t} v(\tau) d\tau \quad \forall t \in [t_i, t_i + 2\mu]. \tag{2.13}$$

For $t \in [t_i + 2\mu, t_{i+1}]$ we have

$$x(t) = x(t_i + 2\mu) + \int_{t_i + 2\mu}^{t} v(\tau) d\tau - \mu^{-1} \int_{t_i + 2\mu}^{t} a\left(\frac{\tau}{\mu}\right) \int_{-2\mu}^{-\mu} \mu^{-1} h\left(\frac{s}{\mu}\right) x(\tau + s) ds \, d\tau.$$

The latter relation in conjunction with (2.13) implies that

$$x(t) = x(t_i)\left[1 - \int_{-2\mu}^{-\mu} \mu^{-1} h\left(\frac{s}{\mu}\right) ds \int_{t_i+2\mu}^{t} \mu^{-1} a\left(\frac{\tau}{\mu}\right) d\tau\right] + \int_{t_i}^{t} v(\tau) d\tau$$
$$- \mu^{-1} \int_{t_i+2\mu}^{t} a\left(\frac{\tau}{\mu}\right) \int_{-2\mu}^{-\mu} \left(\mu^{-1} h\left(\frac{s}{\mu}\right) \left(\int_{t_i}^{\tau+s} v(w) dw\right)\right) ds \; d\tau$$
$$\forall t \in [t_i + 2\mu, t_{i+1}]. \tag{2.14}$$

Since $h \in C^0(\Re; \Re^+)$ with $\int_{-2}^{-1} h(s)ds = \int_{-2\mu}^{-\mu} \mu^{-1} h(\frac{s}{\mu})ds = 1$ and $a \in C^0(\Re; \Re^+)$ is a periodic function with period 3 with $\int_2^3 a(t)dt = 1$, it follows from (2.13), (2.14) that inequalities (2.12) hold. Thus the claim made above holds.

An immediate consequence of the previous claim is the following estimate for the solution of closed-loop system (2.6) with (2.7):

$$|x(t)| \le 10\mu \sup_{t_i \le \tau \le t} |v(\tau)| \quad \forall t \in [t_{i+1}, t_{i+2}]. \tag{2.15}$$

Combining estimates (2.11) (for the interval $[t_0, t_1]$), (2.12) (for the interval $[t_1, t_2]$) and (2.15) (for the interval $[t_2, +\infty)$) we obtain the desired estimate (2.9). The proof is complete. □

Remark 2.10. (a) Although the input of system (2.6) is delayed, when the state of the closed-loop system (2.6) with (2.7) and $v(t) \equiv 0$ hits zero, then the control action is indeed zero. Notice that the control action is given by the following formulae:

$$u(t) = -\mu^{-1} a\left(\frac{t+\tau}{\mu}\right) \int_{-2\mu}^{-\mu} \mu^{-1} h\left(\frac{s}{\mu}\right) x(t+\tau+s) ds;$$
$$u(t-\tau) = -\mu^{-1} a\left(\frac{t}{\mu}\right) \int_{-2\mu}^{-\mu} \mu^{-1} h\left(\frac{s}{\mu}\right) x(t+s) ds.$$

The reader can verify that under the hypotheses of Lemma 2.9, if $v(t) \equiv 0$ and t_0 is a multiple of 3μ, then we have

$$a\left(\frac{t}{\mu}\right) = 0, u(t-\tau) = 0, x(t) = x(t_0) \quad \forall t \in [t_0, t_0 + 2\mu] \quad \text{and}$$
$$x(t) = x(t_0)\left(1 - \mu^{-1} \int_{t_0+2\mu}^{t} a\left(\frac{\tau}{\mu}\right) d\tau\right),$$
$$u(t-\tau) = -\mu^{-1} a\left(\frac{t}{\mu}\right) x(t_0) \quad \forall t \in [t_0 + 2\mu, t_0 + 3\mu].$$

For $t = t_0 + 3\mu$ both state and input become zero (and thus the control cannot push the system away from zero). The same analysis repeated for the next interval $t \in [t_0 + 3\mu, t_0 + 6\mu]$ (with $x(t_0 + 3\mu) = 0$) shows that $x(t) = 0$, $u(t-\tau) = 0$, for all $t \in [t_0 + 3\mu, t_0 + 6\mu]$. Thus we have $x(t) = 0$, $u(t-\tau) = 0$ for all $t \ge t_0 + 3\mu$.

(b) The functions $a \in C^0(\Re; \Re^+)$ and $h \in C^0(\Re; \Re^+)$ are, in a generalized sense, *time-varying gains* of the linear feedback law $u(t) = -\mu^{-1} a(\frac{t+\tau}{\mu}) \int_{-2\mu}^{-\mu} \mu^{-1} h(\frac{s}{\mu}) x(t + \tau + s) ds$. Clearly, we have $|u(t)| \le \frac{L}{\mu} \|T_{2\mu}(t)x\|_{2\mu}$ for all $t \ge 0$, where $L := \max_{t \in [0,3]} a(t)$.

3. Main results. In the present paper we consider triangular time-varying systems described by RFDEs:

$$\begin{aligned} &\dot{x}_i(t) = f_i(t, T_r(t)x_1, \dots, T_r(t)x_i) + x_{i+1}(t-\tau_i), \quad i = 1, \dots, n-1, \\ &\dot{x}_n(t) = f_n(t, T_r(t)x) + u(t-\tau_n), \\ &x(t) := (x_1(t), \dots, x_n(t)) \in \Re^n, \ u(t) \in \Re, t \geq 0, \end{aligned} \tag{3.1}$$

where $r \geq \tau_i \geq 0, i = 1, \dots, n$, the mappings $f_i : \Re^+ \times C^0([-r, 0]; \Re^i) \to \Re \, i = 1, \dots, n$ are completely locally Lipschitz with respect to $x \in C^0([-r, 0]; \Re^n)$ with $f_i(t, 0) = 0$ for all $t \geq 0$ and satisfy one of the following assumptions:

(A1) *There exist mappings* $\varphi_i : \Re \times C^0([-r+\tau_i, 0]; \Re^i) \to \Re, i = 1, \dots, n$, *which are differentiable along the solutions of* (3.1) *and satisfy the following identities for all* $t \geq 0$ *and* $x \in C^0([-r, 0]; \Re^n)$*:*

$$\varphi_1(t - \tau_1, T_{r-\tau_1}(-\tau_1)x_1) := f_1(t, x_1) \tag{3.2a}$$

$$\begin{aligned} &\varphi_{i+1}(t - \tau_{i+1}, T_{r-\tau_{i+1}}(-\tau_{i+1})x_1, \dots, T_{r-\tau_{i+1}}(-\tau_{i+1})x_i, T_{r-\tau_{i+1}}(-\tau_{i+1})x_{i+1}) \\ &:= D\varphi_i(t, x_1, \dots, x_i, x_{i+1}(-\tau_i)) + f_{i+1}(t, x_1, \dots, x_i, x_{i+1}) \quad i = 1, \dots, n-1. \end{aligned} \tag{3.2b}$$

(A2) *There exist mappings* $\varphi_i : \Re \times C^0([-r+\tau_i, 0]; \Re^i) \to \Re, i = 1, \dots, n$, *which are ultimately differentiable along the solutions of* (3.1) *with time constant* $T > 0$ *and satisfy identities* (3.2). *Moreover, there exists a constant* $R \in (0, r]$ *and a continuous function* $L : \Re^+ \times \Re^+ \to \Re^+$ *such that*

$$\begin{aligned} &\sum_{i=1}^{n-1} x_i(0) f_i(t, x_1, \dots, x_i) - x_n(0) D\varphi_{n-1}(t, x) \\ &\quad \leq L\left(t, \sup_{-r \leq \theta \leq -R} |x(\theta)|\right)(|x(0)|^2 + 1), \\ &\quad \forall (t, x) \in \Re^+ \times C^0([-r, 0]; R^n). \end{aligned} \tag{3.3}$$

Our first main result states that system (3.1) is finite-time stabilizable under assumption (A1). Particularly, we have the following theorem.

THEOREM 3.1. *Consider system* (3.1) *and suppose that assumption* (A1) *holds. Let* $b_{i,m} := \sum_{k=i}^{m} \tau_k$. *Then for every* $\mu > b_{1,n}$ *and* $l \in Z^+$, *there exist functions* $\gamma \in K^+$, $\rho \in K_\infty$, *functionals* $p_i : \Re \times C^0([-r_n + \mu, 0]; \Re^i) \to \Re, i = 1, \dots, n$, *where* $r_n := r + 2n\mu$, *which are* l*-differentiable along the solutions of* (3.1) *with delay* $\mu > 0$ *and a constant* $T > 0$, *such that*

(i) *the closed-loop system* (3.1) *with* $u(t) = k(t, T_{r_n-\mu}(t)x)$ *satisfies the dead-beat property of order* T, *where* $k : \Re \times C^0([-r_n + \mu, 0]; \Re^n) \to \Re$ *is completely locally Lipschitz with respect to* $x \in C^0([-r_n + \mu, 0]; \Re^n)$ *with* $k(\cdot, 0) = 0$ *and is defined by*

$$k(t, x) := -\varphi_n(t, x) - \sum_{i=1}^{n} p_i(t + b_{i,n}, T_{r_n-\mu}(b_{i,n} - \mu)x_1, \dots, T_{r_n-\mu}(b_{i,n} - \mu)x_i), \tag{3.4}$$

(ii) *for every* $(t_0, x_0, v) \in \Re^+ \times C^0([-r_n, 0]; \Re^n) \times C^0(\Re; \Re)$ *the solution of the closed-loop system* (3.1) *with* $u(t) = k(t, T_{r_n-\mu}(t)x) + v(t)$ *satisfies the estimate*

$$|x(t)| \le \gamma(t)\rho\left(\|x_0\|_{r_n} + \sup_{t_0-\tau_n \le s \le t} |v(s)|\right) \quad \forall t \ge t_0. \tag{3.5}$$

Moreover, if the mappings $\varphi_i : \Re \times C^0([-r+\tau_i, 0]; \Re^i) \to \Re$, $i = 1, \dots, n$, *are independent of* t, *then the functionals* p_i $i = 1, \dots, n$ *and* k *as defined by* (3.4) *can be chosen to be* 3μ*-periodic. Finally, if the mappings* $\varphi_i : \Re \times C^0([-r+\tau_i, 0]; \Re^i) \to \Re$, $i = 1, \dots, n$, *are linear, then the functionals* p_i $i = 1, \dots, n$ *and* k *as defined by* (3.4) *can be chosen to be linear.*

The proof of Theorem 3.1 relies on the following technical lemma.

LEMMA 3.2 (adding a delayed integrator). *Consider the system*

$$\dot{x}(t) = f(t, T_r(t)x, y(t-\tau)), \tag{3.6a}$$

$$\begin{aligned} &\dot{y}(t) = g(t, T_r(t)x, T_r(t)y) + u(t-\tau'), \\ &x(t) \in \Re^n, y(t) \in \Re, u(t) \in \Re, t \ge 0, \end{aligned} \tag{3.6b}$$

where $r \ge \tau \ge 0$, $\tau' \ge 0$ *are constants and the mappings* $f : \Re^+ \times C^0([-r, 0]; \Re^n) \times \Re \to \Re^n$, $g : \Re^+ \times C^0([-r, 0]; \Re^n) \times C^0([-r, 0]; \Re) \to \Re$ *are completely locally Lipschitz with respect to* $(x, y) \in C^0([-r, 0]; \Re^n) \times C^0([-r, 0]; \Re)$ *with* $f(t, 0, 0) = 0, g(t, 0, 0) = 0$ *for all* $t \ge 0$. *Suppose there exists a functional* $k : \Re \times C^0([-r+\tau, 0]; \Re^n) \to \Re$, *with* $k(\cdot, 0) = 0$, *which is differentiable along the solutions of* (3.6a) *such that*

(H1) *The closed-loop system* (3.6a) *with* $y(t) = k(t, T_{r-\tau}(t)x)$ *satisfies the dead-beat property of order* $T > 0$.

(H2) *There exist functions* $\gamma \in K^+$ *and* $\rho \in K_\infty$ *such that for every* $(t_0, x_0, z) \in \Re^+ \times C^0([-r, 0]; \Re^n) \times C^0(\Re; \Re)$ *the solution of the closed-loop system* (3.6a) *with* $y(t) = k(t, T_{r-\tau}(t)x) + z(t)$, *initiated from* $t_0 \ge 0$ *with initial condition* $T_r(t_0)x = x_0 \in C^0([-r, 0]; \Re^n)$ *and corresponding to* $z \in C^0(\Re; \Re)$ *satisfies the estimate*

$$|x(t)| \le \gamma(t)\rho\left(\|x_0\|_r + \sup_{t_0-\tau \le s \le t} |z(s)|\right) \quad \forall t \ge t_0. \tag{3.7}$$

(H3) *There exists a functional* $\varphi : \Re \times C^0([-r+\tau', 0]; \Re^{n+1}) \to \Re$, $\varphi(t, x, y)$ *being completely locally Lipschitz with respect to* $(x, y) \in C^0([-r+\tau', 0]; \Re^n) \times C^0([-r-\tau', 0]; \Re)$ *with* $\varphi(t, 0, 0) = 0$ *for all* $t \in \Re$ *and such that the following identity holds for all* $t \ge 0$ *and* $(x, y) \in C^0([-r, 0]; \Re^n) \times C^0([-r, 0]; \Re)$*:*

$$\varphi(t-\tau', T_{r-\tau'}(-\tau')x, T_{r-\tau'}(-\tau')y) := -g(t, x, y) + Dk(t, x, y(-\tau)), \tag{3.8}$$

where $Dk : \Re \times C^0([-r, 0]; \Re^n) \times \Re \to \Re$ *denotes the derivative of* k *along the solutions of* (3.6a).

Then for every $\mu > \tau'$, *there exist functions* $\widetilde{\gamma} \in K^+$, $\widetilde{\rho} \in K_\infty$ *and a functional* $\widetilde{k} : \Re \times C^0([-r-2\mu+\tau', 0]; \Re^{n+1}) \to \Re$, *which is completely locally Lipschitz with respect to* $(x, y) \in C^0([-r-2\mu+\tau', 0]; \Re^{n+1})$ *with* $\widetilde{k}(t, 0, 0) = 0$ *for all* $t \in \Re$ *and is defined by*

$$\begin{aligned} \widetilde{k}(t, x, y) := \varphi(t, x, y) - \mu^{-1} a\left(\frac{t+\tau'}{\mu}\right) \int_{-2\mu}^{-\mu} \mu^{-1} h\left(\frac{s}{\mu}\right) (y(\tau'+s) \\ - k(t+\tau'+s, T_{r-\tau}(\tau'+s)x))ds, \end{aligned} \tag{3.9}$$

where $a \in C^0(\Re;\Re^+)$ *is a periodic function with period* 3, *with* $a(t) = 0$ *for* $t \in [0,2]$ *and* $\int_2^3 a(t)dt = 1$, $h \in C^0(\Re;\Re^+)$ *with* $\int_{-2}^{-1} h(s)ds = \int_{-2\mu}^{-\mu} \mu^{-1}h(\frac{s}{\mu})ds = 1$, *such that the closed-loop system* (3.6) *with* $u(t) = \widetilde{k}(t, T_{r+2\mu-\tau'}(t)x, T_{r+2\mu-\tau'}(t)y)$ *satisfies the dead-beat property of order* $T + r + 6\mu$ *and for every* $(t_0, x_0, y_0, v) \in \Re^+ \times C^0([-r-2\mu, 0];\Re^{n+1}) \times C^0(\Re;\Re)$ *the solution of the closed-loop system* (3.6) *with* $u(t) = \widetilde{k}(t, T_{r+2\mu-\tau'}(t)x, T_{r+2\mu-\tau'}(t)y) + v(t)$ *satisfies the estimate*

$$|(x(t), y(t))| \leq \widetilde{\gamma}(t)\widetilde{\rho}\left(\|(x_0, y_0)\|_{r+2\mu} + \sup_{t_0-\tau' \leq s \leq t} |v(s)|\right) \quad \forall t \geq t_0. \tag{3.10}$$

Remark 3.3. Notice that the stabilizing feedback is given by

$$u(t) = \varphi(t, T_r(t)x, T_r(t)y) - \mu^{-1}a\left(\frac{t+\tau'}{\mu}\right)\int_{-2\mu}^{-\mu} \mu^{-1}h\left(\frac{s}{\mu}\right) z(t+\tau'+s)ds,$$

where $z(t) := y(t) - k(t, T_{r-\tau}(t)x)$.

Proof of Lemma 3.2. Let arbitrary $(t_0, x_0, y_0, v) \in \Re^+ \times C^0([-r-2\mu, 0];\Re^{n+1}) \times C^0(\Re;\Re)$ and define

$$z(t) := y(t) - k(t, T_{r-\tau}(t)x). \tag{3.11}$$

By virtue of definitions (3.9), (3.11), and identity (3.8), we guarantee that as long as the solution of the closed-loop system (3.6) with $u(t) = \widetilde{k}(t, T_{r+2\mu-\tau'}(t)x, T_{r+2\mu-\tau'}(t)y) + v(t)$ and $T_{r+2\mu}(t_0)x = x_0$, $T_{r+2\mu}(t_0)y = y_0$ exists, it coincides with the solution of the following system:

$$\begin{aligned} \dot{x}(t) &= f(t, T_r(t)x, k(t-\tau, T_{r-\tau}(t-\tau)x) + z(t-\tau)) \\ \dot{z}(t) &= -\mu^{-1}a\left(\frac{t}{\mu}\right)\int_{-2\mu}^{-\mu} \mu^{-1}h\left(\frac{s}{\mu}\right) z(t+s)ds + v(t-\tau') \\ x(t) &\in \Re^n,\ z(t) \in \Re,\ v(t) \in \Re,\ t \geq 0 \end{aligned} \tag{3.12}$$

corresponding to the same input $v \in C^0(\Re;\Re)$ with $y(t) = z(t) + k(t, T_{r-\tau}(t)x)$ and $T_{r+2\mu}(t_0)x = x_0$, $z(t_0+\theta) = y_0(\theta) - k(t_0+\theta, T_{r-\tau}(t_0+\theta)x); \theta \in [-\widetilde{\tau}, 0]$, where $\widetilde{\tau} := \max(\tau, 2\mu)$. The solution of (3.12) exists for all $t \geq t_0$, since by virtue of Lemma 2.9, we obtain

$$\begin{aligned} |z(t)| \leq \exp(3L)\sigma\left(\frac{t-t_0}{\mu}\right)\|T_{\widetilde{\tau}}(t_0)z\|_{\widetilde{\tau}} \\ + 10\mu\exp(3L)\sup_{\max(t_0, t-6\mu) \leq s \leq t} |v(s-\tau')| \\ \forall t \geq t_0 - \widetilde{\tau}, \end{aligned} \tag{3.13}$$

where $\sigma(t) := \left\{ \begin{smallmatrix} 1 & if & t < 6 \\ 0 & if & t \geq 6 \end{smallmatrix} \right.$ and $L := \max_{t\in[0,3]} a(t)$ and inequality (3.13) in conjunction with estimate (3.7) implies the following estimate:

$$|x(t)| \leq \gamma(t)\bar{a}\left(\|T_r(t_0)x\|_r + \|T_{\widetilde{\tau}}(t_0)z\|_{\widetilde{\tau}} + \sup_{t_0-\tau' \leq s \leq t} |v(s)|\right) \quad \forall t \geq t_0, \tag{3.14}$$

where $\bar{a}(s) := \rho(\exp(3L)(1+10\mu)s) \in K_\infty$. We next prove the following claim.

CLAIM. There exist functions $\widetilde{\gamma} \in K^+$, $\widetilde{\rho} \in K_\infty$ such that for every $(t_0, x_0, y_0, v) \in \Re^+ \times C^0([-r-2\mu, 0]; \Re^{n+1}) \times C^0(\Re; \Re)$ the solution of (3.12) corresponding to $v \in C^0(\Re; \Re)$ with $y(t) = z(t) + k(t, T_{r-\tau}(t)x)$, $T_{r+2\mu}(t_0)x = x_0$, $z(t_0+\theta) = y_0(\theta) - k(t_0+\theta, T_{r-\tau}(t_0+\theta)x); \theta \in [-\widetilde{\tau}, 0]$ satisfies estimate (3.10).

Proof of Claim. Since $k : [-2\mu, +\infty) \times C^0([-r+\tau, 0]; \Re^n) \to \Re$ is completely locally Lipschitz with respect to $x \in C^0([-r+\tau, 0]; \Re^n)$ with $k(t, 0) = 0$ for all $t \geq -2\mu$, it follows from Lemma 3.2 in [12] that there exist functions $\delta \in K^+$, being nondecreasing and $q \in K_\infty$ such that

$$|k(t,x)| \leq q(\delta(t)\|x\|_{r-\tau}) \quad \forall (t,x) \in [-2\mu, +\infty) \times C^0([-r+\tau, 0]; \Re^n). \tag{3.15}$$

Notice that definition (3.11) in conjunction with (3.15) implies

$$\|T_{\widetilde{\tau}}(t_0)z\|_{\widetilde{\tau}} \leq \|y_0\|_{\widetilde{\tau}} + q(\delta(t)\|x_0\|_{r+2\mu}) \quad \forall t \geq t_0. \tag{3.16}$$

Using Corollary 10 and Remark 11 in [23] we may find a function $\kappa \in K_\infty$ such that

$$q(rs) + \overline{a}(rs) + \exp(3L)(1+10\mu)rs \leq \kappa(r)\kappa(s) \quad \forall r, s \geq 0. \tag{3.17}$$

Without loss of generality we may assume that the function $\gamma \in K^+$ involved in (3.14) is nondecreasing. Thus, using estimate (3.14), we obtain the following estimate for the solution of (3.12):

$$\|T_r(t)x\|_r \leq \gamma(t)\overline{a}\left(\|x_0\|_r + \|T_{\widetilde{\tau}}(t_0)z\|_{\widetilde{\tau}} + \sup_{t_0-\tau' \leq s \leq t} |v(s)|\right) \quad \forall t \geq t_0. \tag{3.18}$$

Combining (3.15), (3.16), (3.17), and (3.18) we obtain for the solution of (3.12),

$$|k(t, T_{r-\tau}(t)x)| \leq p(t)\zeta\left(\|(x_0, y_0)\|_{r+2\mu} + \sup_{t_0-\tau' \leq s \leq t} |v(s)|\right) \quad \forall t \geq t_0, \tag{3.19}$$

where $p(t) := \kappa(\delta(t)\gamma(t)\kappa(1+\kappa(\delta(t))))$ and $\zeta(s) := \kappa(\kappa(2s+\kappa(s)))$. Estimates (3.13), (3.14), (3.19) in conjunction with inequalities (3.16), (3.17) and the trivial inequality $|y(t)| \leq |z(t)| + |k(t, T_{r-\tau}(t)x)|$, show that the solutions of (3.12) satisfy estimate (3.10) for $\widetilde{\gamma}(t) := (1+\gamma(t))\kappa(1+\kappa(\delta(t))) + p(t)$ and $\widetilde{a}(s) := \kappa(2s+\kappa(s)) + \zeta(s)$. Thus the claim is proved.

Since for every $(t_0, x_0, y_0, v) \in \Re^+ \times C^0([-r-2\mu, 0]; \Re^{n+1}) \times C^0(\Re; \Re)$ the solution of the closed-loop system (3.6) with $u(t) = \widetilde{k}(t, T_{r+2\mu-\tau'}(t)x, T_{r+2\mu-\tau'}(t)y) + v(t)$ and $T_{r+2\mu}(t_0)x = x_0$, $T_{r+2\mu}(t_0)y = y_0$ coincides with the solution of (3.12) corresponding to the same input $v \in C^0(\Re; \Re)$ with $y(t) = z(t) + k(t, T_{r-\tau}(t)x)$ and $T_{r+2\mu}(t_0)x = x_0$, $z(t_0+\theta) = y_0(\theta) - k(t_0+\theta, T_{r-\tau}(t_0+\theta)x); \theta \in [-\widetilde{\tau}, 0]$, where $\widetilde{\tau} := \max(\tau, 2\mu)$, we conclude that for every $(t_0, x_0, y_0, v) \in \Re^+ \times C^0([-r-2\mu, 0]; \Re^{n+1}) \times C^0(\Re; \Re)$ the solution of the closed-loop system (3.6) with $u(t) = \widetilde{k}(t, T_{r+2\mu-\tau'}(t)x, T_{r+2\mu-\tau'}(t)y) + v(t)$ and $T_{r+2\mu}(t_0)x = x_0$, $T_{r+2\mu}(t_0)y = y_0$ exists for all $t \geq t_0$ and satisfies estimate (3.10). Finally, the fact that the closed-loop system (3.6) with $u(t) = \widetilde{k}(t, T_{r+2\mu-\tau'}(t)x, T_{r+2\mu-\tau'}(t)y)$ satisfies the dead-beat property of order $T + r + 6\mu$ follows from the observation that $z(t) = 0$ for all $t \geq t_0 + 6\mu$ (recall (3.13) with $v(t) \equiv 0$), which implies $y(t) = k(t, T_{r-\tau}(t)x)$ for all $t \geq t_0 + 6\mu$ (recall definition (3.11)). Thus for all $t \geq t_0 + 6\mu$ the solution of the closed-loop system (3.6) with $u(t) = \widetilde{k}(t, T_{r+2\mu-\tau'}(t)x, T_{r+2\mu-\tau'}(t)y)$ coincides with the solution of (3.6a) with $y(t) = k(t, T_{r-\tau}(t)x)$ initiated from $T_r(t_0+6\mu)x$. It follows that $x(t) = 0$ for all

$t \geq t_0 + T + 6\mu$, which implies $y(t) = k(t, T_{r-\tau}(t)x) = 0$ for all $t \geq t_0 + T + r + 6\mu$. The proof is complete. □

We are now in position to prove Theorem 3.1.

Proof of Theorem 3.1. The proof is made by induction.

Step 1: We show that the statement of Theorem 3.1 holds for $n = 1$. Let $l \in Z^+$ and $\mu > b_{1,n} = \tau_1$. The statement of Theorem 3.1 for $n = 1$ is an immediate consequence of Lemma 2.9, identity (3.2a), (3.4), and the definition

$$p_1(t, x_1) := -\mu^{-1} a\left(\frac{t}{\mu}\right) \int_{-2\mu}^{-\mu} \mu^{-1} h\left(\frac{s}{\mu}\right) x_1(s+\mu) ds, \tag{3.20}$$

where $a \in C^l(\Re; \Re^+)$ is a periodic function with period 3 with $a(t) = 0$ for $t \in [0, 2]$ and $\int_2^3 a(t)dt = 1$ and $h \in C^l(\Re; \Re^+)$ with $h(s) = 0$ for all $s \notin (-2, -1)$, $\int_{-2}^{-1} h(s)ds = \int_{-2\mu}^{-\mu} \mu^{-1} h(\frac{s}{\mu})ds = 1$. Notice that the fact that $p_1(t, x_1)$, as defined by (3.11), is l-differentiable with delay μ follows directly from Lemma 2.6. Moreover, if $\varphi_1 : \Re \times C^0([-r + \tau_1, 0]; \Re) \to \Re$ is independent of t, then the functionals p_1 and k (defined by (3.4)) are 3μ-periodic. Finally, if $\varphi_1 : \Re \times C^0([-r + \tau_1, 0]; \Re) \to \Re$ is linear, then the functionals p_1 and k (defined by (3.4)) are linear.

Induction step: Suppose that the statement of Theorem 3.1 holds for $n - 1$. We show that the statement of Theorem 3.1 holds for n. By assumption for every $\mu > b_{1,n-1}, l \in Z^+$, there exist functions $\gamma \in K^+, \rho \in K_\infty$, functionals $p_i : \Re \times C^0([-r_{n-1} + \mu, 0]; \Re^i) \to \Re$, $i = 1, \dots, n-1$, where $r_{n-1} := r + 2(n-1)\mu$, which are $(l+1)$-differentiable along the solutions of the following system:

$$\begin{aligned} &\dot{x}_i(t) = f_i(t, T_r(t)x_1, \dots, T_r(t)x_i) + x_{i+1}(t - \tau_i), \quad i = 1, \dots, n-1, \\ &\xi(t) := (x_1(t), \dots, x_{n-1}(t)) \in \Re^{n-1}, x_n(t) \in \Re, t \geq 0 \end{aligned} \tag{3.21}$$

with delay $\mu > 0$ and a constant $T > 0$, such that

(a) the closed-loop system (3.21) with $x_n(t) = k(t, T_{r_{n-1}-\mu}(t)\xi)$ satisfies the deadbeat property of order T, where

$$\begin{aligned} k(t, \xi) := &- \varphi_{n-1}(t, \xi) \\ &- \sum_{i=1}^{n-1} p_i(t + b_{i,n-1}, T_{r_{n-1}-\mu}(b_{i,n-1} - \mu)x_1, \dots, T_{r_{n-1}-\mu}(b_{i,n-1} - \mu)x_i), \end{aligned} \tag{3.22}$$

(ii) for every $(t_0, \xi_0, z) \in \Re^+ \times C^0([-r_{n-1}, 0]; \Re^n) \times C^0(\Re; \Re)$ the solution of the closed-loop system (3.21) with $x_n(t) = k(t, T_{r_{n-1}-\mu}(t)\xi) + z(t)$ satisfies the estimate

$$|\xi(t)| \leq \gamma(t)\rho\left(\|\xi_0\|_{r_{n-1}} + \sup_{t_0 - \tau_{n-1} \leq s \leq t} |z(s)|\right) \quad \forall t \geq t_0. \tag{3.23}$$

Remark 2.4(ii) and hypothesis (A1) show that k as defined by (3.22) is differentiable along the solutions of (3.21) with derivative

$$\begin{aligned} Dk(t, \xi, x_n(-\tau_{n-1})) := &- D\varphi_{n-1}(t, \xi, x_n(-\tau_{n-1})) \\ &- \sum_{i=1}^{n-1} Dp_i(t + b_{i,n-1}, T_{r_{n-1}-\mu}(b_{i,n-1} - \mu)x_1, \dots, \\ &\quad T_{r_{n-1}-\mu}(b_{i,n-1} - \mu)x_i). \end{aligned}$$

Clearly, hypotheses (H1) and (H2) of Lemma 3.2 hold for system (3.1). Next we show that hypothesis (H3) of Lemma 3.2 also holds for system (3.1). Notice that

$$\begin{aligned}&-f_n(t,x)+Dk(t,\xi,x_n(-\tau_{n-1})),\\&=-f_n(t,x)-D\varphi_{n-1}(t,\xi,x_n(-\tau_{n-1}))\\&\quad-\sum_{i=1}^{n-1}Dp_i(t+b_{i,n-1},T_{r_{n-1}-\mu}(b_{i,n-1}-\mu)x_1,\dots,T_{r_{n-1}-\mu}(b_{i,n-1}-\mu)x_i).\end{aligned}$$

Hypothesis (A1) implies that there exists a mapping $\varphi_n : \Re \times C^0([-r+\tau_n,0];\Re^n)\to\Re$, which is differentiable along the solutions of (3.1) and satisfies $\varphi_n(t-\tau_n, T_{r-\tau_n}(-\tau_n)x) := D\varphi_{n-1}(t,\xi,x_n(-\tau_{n-1}))+f_n(t,x)$ for all $t\ge 0$ and $x\in C^0([-r,0];\Re^n)$. Thus we obtain

$$-f_n(t,x)+Dk(t,\xi,x_n(-\tau_{n-1}))=\varphi(t-\tau_n,T_{r_{n-1}-\tau_n}(-\tau_n)x), \tag{3.24}$$

where $\varphi(t,x) := -\varphi_n(t,x)-\sum_{i=1}^{n-1}Dp_i(t+\tau_n+b_{i,n-1},T_{r_{n-1}-\mu}(b_{i,n-1}+\tau_n-\mu)x_1,\dots,T_{r_{n-1}-\mu}(b_{i,n-1}+\tau_n-\mu)x_i)$. Since $b_{i,n-1}+\tau_n=b_{i,n}$ we have

$$\varphi(t,x) := -\varphi_n(t,x)-\sum_{i=1}^{n-1}Dp_i(t+b_{i,n},T_{r_{n-1}-\mu}(b_{i,n}-\mu)x_1,\dots,T_{r_{n-1}-\mu}(b_{i,n}-\mu)x_i). \tag{3.25}$$

Notice that the mapping $\varphi:\Re\times C^0([-r_{n-1}+\tau_n,0];\Re^n)\to\Re$ defined by (3.25) is well defined for all $\mu > b_{1,n}$, with $\varphi(t,x)$ being completely locally Lipschitz with respect to $x\in C^0([-r+\tau_n,0];\Re^n)$ and $\varphi(t,0)=0$ for all $t\in\Re$.

Lemma 3.2 shows that there exist functions $\widetilde{\gamma}\in K^+$, $\widetilde{\rho}\in K_\infty$ and a functional $\widetilde{k}:\Re\times C^0([-r_{n-1}-2\mu,0];\Re^n)\to\Re$, which is completely locally Lipschitz with respect to $x\in C^0([-r_{n-1}-2\mu,0];\Re^n)$ with $\widetilde{k}(t,0)=0$ for all $t\in\Re$ and is defined by

$$\begin{aligned}&\widetilde{k}(t,x) := \varphi(t,x)-p_n(t+\tau_n,T_{r_n-\mu}(\tau_n-\mu)x),\\&p_n(t,x) := \mu^{-1}a\left(\frac{t}{\mu}\right)\int_{-2\mu}^{-\mu}\mu^{-1}h\left(\frac{s}{\mu}\right)(x_n(s+\mu)-k(t+s,T_{r_{n-1}}(s+\mu)\xi))ds,\end{aligned} \tag{3.26}$$

where $a\in C^l(\Re;\Re^+)$ is a periodic function with period 3, with $a(t)=0$ for $t\in[0,2]$ and $\int_2^3 a(t)dt=1$, $h\in C^l(\Re;\Re^+)$ with $h(s)=0$ for all $s\notin(-2,-1)$, $\int_{-2}^{-1}h(s)ds=\int_{-2\mu}^{-\mu}\mu^{-1}h(\frac{s}{\mu})ds=1$, such that the closed-loop system (3.1) with $u(t)=\widetilde{k}(t,T_{r_n-\mu}(t)x)$ satisfies the dead-beat property of order $T+r_{n-1}+6\mu$ and for every $(t_0,x_0,v)\in\Re^+\times C^0([-r_n,0];\Re^n)\times C^0(\Re;\Re)$ the solution of the closed-loop system (3.1) with $u(t)=\widetilde{k}(t,T_{r_n-\mu}(t)x)+v(t)$ satisfies estimate (3.5) with $\widetilde{\gamma}\in K^+$ and $\widetilde{\rho}\in K_\infty$ in place of $\gamma\in K^+$ and $\rho\in K_\infty$, respectively. Lemma 2.6 implies that the functional p_n is l-differentiable along the solutions of (3.1) with delay $\mu>0$. Moreover, if φ_n is independent of t and k is 3μ-periodic then the functionals p_n and $\widetilde{k}$ are 3μ-periodic. Finally, if φ_n and k are linear functionals, then the functionals p_n and $\widetilde{k}$ are linear. □

Our second main result states that system (3.1) is finite-time stabilizable under assumption (A2).

THEOREM 3.4. *Consider system* (3.1) *and suppose that assumption* (A2) *holds. Then for every* $\mu \geq R + \sum_{i=1}^{n} \tau_i$, *where* $R > 0$ *is the constant involved in assumption* (A2), *there exists a functional* $k : \Re \times C^0([-\widetilde{r}, 0]; \Re^n) \to \Re$, *where* $\widetilde{r} := 2r + 2n\mu$, *which is completely locally Lipschitz with respect to* $x \in C^0([-\widetilde{r}, 0]; \Re^n)$ *and a constant* $T' > T$ *(where* $T \geq 0$ *is the time constant involved in assumption* (A2)*, such that the closed-loop system* (3.1) *with* $u(t) = k(t, T_{\widetilde{r}}(t)x)$ *satisfies the dead-beat property of order* T'. *Moreover, if the mappings* $\varphi_i : \Re \times C^0([-r + \tau_i, 0]; \Re^i) \to \Re$, $i = 1, \ldots, n$ *are independent of* t, *then the functional* k *can be chosen to be* 3μ*-periodic. Finally, if the mappings* $\varphi_i : \Re \times C^0([-r + \tau_i, 0]; \Re^i) \to \Re$, $i = 1, \ldots, n$ *are linear, then the functional* k *can be chosen to be linear.*

Proof. Consider the system

$$\begin{aligned} &\dot{z}_i(t) = z_{i+1}(t - \tau_i), i = 1, \ldots, n-1;\ \dot{z}_n(t) = v(t - \tau_n) \\ &z(t) = (z_1(t), \ldots, z_n(t)) \in \Re^n, v(t) = \Re, \end{aligned} \tag{3.27}$$

where $\tau_i \geq 0$ are exactly the delays appearing in (3.1). Since assumption (A1) holds for system (3.27) with $\varphi_i \equiv 0$ for $i = 1, \ldots, n$, by virtue of Theorem 3.1 we conclude that for every $\mu \geq \sum_{i=1}^{n} \tau_i + R$ there exists a linear 3μ-periodic time-varying distributed delay feedback $v(t) = \widetilde{k}(t, T_{\widetilde{r-r-R}}(t - R)z)$ and a constant $T' > 0$ such that the closed-loop system (3.27) with $v(t) = \widetilde{k}(t, T_{\widetilde{r-r-R}}(t - R)z)$ satisfies the dead-beat property of order T'.

Consider the mapping $(t, x) \in \Re \times C^0([-\widetilde{r}, 0]; \Re^n) \to P(t, x) = y \in C^0([-(\widetilde{r} - r), 0]; \Re^n)$ defined by

$$\begin{aligned} &y_1(\theta) := x_1(\theta), \quad \theta \in [-(\widetilde{r} - r), 0], \\ &y_i(\theta) := x_i(\theta) + \varphi_{i-1}(t + \theta, T_r(\theta)x_1, \ldots, T_r(\theta)x_{i-1}), \quad i = 2, \ldots, n, \theta \in [-(\widetilde{r} - r), 0]. \end{aligned} \tag{3.28}$$

Notice that since the mappings $\varphi_i : \Re \times C^0([-r + \tau_i, 0]; \Re^i) \to \Re$, $i = 1, \ldots, n$, are all completely locally Lipschitz with respect to $x \in C^0([-r, 0]; \Re^n)$, it follows that for every bounded set $S \subset \Re \times C^0([-\widetilde{r}, 0]; \Re^n)$ there exists $L \geq 0$ such that $\|P(t, x) - P(t, y)\|_{\widetilde{r-r}} \leq L\|x - y\|_{\widetilde{r}}$ for all $(t, x) \in S$, $(t, y) \in S$. Moreover, notice that $P(t, 0) = 0$ for all $t \in \Re$. We next prove that the time-varying distributed delay feedback that induces the dead-beat property for the corresponding closed-loop system is defined by

$$k(t, x) := -\varphi_n(t, T_r(0)x) + \widetilde{k}(t, P(t - R, T_{\widetilde{r}}(-R)x)). \tag{3.29}$$

Notice that if the mappings $\varphi_i : \Re \times C^0([-r + \tau_i, 0]; \Re^i) \to \Re$, $i = 1, \ldots, n$ are independent of t (linear), then the functional k as defined by (3.29) is 3μ-periodic (linear). Let the solution $x(t)$ of the closed-loop system (3.1) with $u(t) = k(t, T_{\widetilde{r+R}}(t)x)$ with arbitrary initial condition $T_{\widetilde{r+R+\tau_n}}(t_0)x = x_0$.

We make the following claim.

CLAIM. *The solution* $x(t)$ *of the closed-loop system* (3.1) *with* $u(t) = k(t, T_{\widetilde{r+R}}(t)x)$ *exists for all* $t \geq t_0$ *and satisfies Property* (P2) *of Definition* 2.7.

Proof of Claim. Since

- $P(t, 0) = 0$ for all $t \in \Re$ and for every bounded set $S \subset \Re \times C^0([-\widetilde{r}, 0]; \Re^n)$ there exists $L \geq 0$ such that $\|P(t, x) - P(t, y)\|_{\widetilde{r-r}} \leq L\|x - y\|_{\widetilde{r}}$ for all $(t, x) \in S$, $(t, y) \in S$.
- $\widetilde{k}(t, z)$ is a linear 3μ-periodic time-varying functional

it follows from Lemma 3.2 in [12] that there exist functions $\delta \in K^+$, being nondecreasing and $q \in K_\infty$ such that

$$|\widetilde{k}(t-\tau_n, P(t-\tau_n-R, T_{\widetilde{r}}(-\tau_n-R)x))| \le q(\delta(t)\|T_{\widetilde{r}}(-\tau_n-R)x\|_{\widetilde{r}}) \quad \forall (t,x) \in \Re^+ \times C^0([-\widetilde{R},0];\Re^n) \tag{3.30}$$

with $\widetilde{R} := \widetilde{r} + \tau_n + R$. In order to prove the claim it suffices to show that if there exists an integer N such that

$$\sup\{|x(t_0+h,t_0,x_0)|;\ h \in [-\widetilde{R}, NR], \|x_0\|_{\widetilde{R}} \le s, t_0 \in [0,s]\} < +\infty \quad \forall s \ge 0, \tag{3.31}$$

then we have

$$\sup\{|x(t_0+h,t_0,x_0)|;\ h \in [-\widetilde{R}, (N+1)R], \|x_0\|_{\widetilde{R}} \le s, t_0 \in [0,s]\} < +\infty \quad \forall s \ge 0, \tag{3.32}$$

where $x(t,t_0,x_0)$ denotes the solution of the closed-loop system (3.1) with $u(t) = k(t, T_{\widetilde{r}}(t)x)$ with initial condition $T_{\widetilde{R}}(t_0)x = x_0$. Indeed, since (3.31) holds for $N = 0$, it will follow by induction that (3.31) holds for all nonnegative integers N.

Suppose that (3.31) holds for some nonnegative integer N. Let arbitrary $s \ge 0$ and define $V(t) := \frac{1}{2}|x(t)|^2$, where $x(t)$ denotes the solution of the closed-loop system (3.1) with $u(t) = k(t, T_{\widetilde{r}}(t)x)$ with arbitrary initial condition $T_{\widetilde{R}}(t_0)x = x_0$ such that $\|x_0\|_{\widetilde{R}} \le s$, $t_0 \in [0,s]$. Using identity (3.2b) for $i = n-1$, inequality (3.3) in conjunction with (3.30) imply that as long as the solution of the closed-loop system (3.1) with $u(t) = k(t, T_{\widetilde{r}}(t)x)$ exists, it holds that

$$\dot{V}(t) \le L\Big(t, \sup_{-r\le\theta\le -R} |x(t+\theta)|\Big)(2V(t)+1) + V(t) + q^2\Big(\delta(t) \sup_{-r\le\theta\le -R} |x(t+\theta)|\Big). \tag{3.33}$$

Let $a := \sup\{|x(t_0+h,t_0,x_0)|;\ h \in [-\widetilde{R}, NR], \|x_0\|_{\widetilde{R}} \le s, t_0 \in [0,s]\} < +\infty$. Clearly, for all $t \in [NR, (N+1)R]$ for which the solution of the closed-loop system (3.1) with $u(t) = k(t, T_{\widetilde{r}}(t)x)$ exists, we have

$$\dot{V}(t) \le \left(1 + q^2(\delta((N+1)R)a) + \max_{\substack{0\le t\le (N+1)R \\ 0\le s\le a}} 2L(t,s)\right)(V(t)+1).$$

The previous differential inequality implies that the solution of the closed-loop system (3.1) with $u(t) = k(t, T_{\widetilde{r}}(t)x)$ exists for all $t \in [NR, (N+1)R]$ and satisfies

$$|x(t)|^2 \le 2V(t) \le \exp(M(N,R,a))(a^2+2) \quad \forall t \in [NR, (N+1)R],$$

where $M(N,R,a) := R(1+q^2(\delta((N+1)R)a) + \max_{\substack{0\le t\le (N+1)R \\ 0\le s\le a}} 2L(t,a))$. The previous property shows that inequality (3.32) holds. Thus the claim is proved.

We continue the proof of Theorem 3.4 by considering the following variables defined by

$$z_1(t) := x_1(t); \quad z_i(t) := x_i(t) + \varphi_{i-1}(t, T_r(t)x_1, \dots, T_r(t)x_{i-1}), \quad i = 2, \dots, n. \tag{3.34}$$

Clearly, by virtue of definitions (3.28) and (3.34) we obtain $T_{r-r}(t-R)z = P(t-R, T_r(t-R)x)$ for all $t \geq t_0$. Moreover, by virtue of (3.34), identities (3.2), and the definition of the notion of ultimate differentiability along the solutions of (3.1) with time constant $T \geq 0$ (Definition 2.1), $z(t)$ as defined by (3.34) for the solution of the closed-loop system (3.1) with $u(t) = k(t, T_{r+R}(t)x)$, coincides for all $t \geq t_0 + T$ with the solution of the closed-loop system (3.27) with $v(t) = \widetilde{k}(t, T_{r-r-R}(t-R)z)$ with initial condition $T_{r-r}(t_0+T)z = P(t_0+T, T_r(t_0+T)x)$. Thus we obtain $z(t) = 0$ for all $t \geq t_0 + T + T'$. It follows from definition (3.34) that $x(t) = 0$ for all $t \geq t_0+T+T'+(n-1)r$. Thus the closed-loop system (3.1) with $u(t) = k(t, T_r(t)x)$ satisfies the dead-beat property of order $\widetilde{T} := T + T' + (n-1)r$. The proof is complete. □

4. Examples. The following examples present systems, which satisfy assumption (A1) and consequently, by virtue of Theorem 3.1, can be finite-time stabilized by means of time-varying distributed delay feedback. Our first example is concerned with finite-dimensional control systems.

Example 4.1. Consider the two-dimensional control system

$$\begin{aligned} &\dot{x}_1(t) = f_1(t, x_1(t)) + x_2(t); \quad \dot{x}_2(t) = f_2(t, x_1(t), x_2(t)) + u(t), \\ &(x_1(t), x_2(t)) \in \Re^2, u(t) \in \Re, t \geq 0, \end{aligned} \tag{4.1}$$

where $f_1 \in C^2(\Re \times \Re; \Re)$ and $f_2 \in C^1(\Re \times \Re^2; \Re)$ with $f_1(t,0) = f_2(t,0,0) = 0$ for all $t \in \Re$. For system (4.1) finite-time global stabilization cannot be achieved by means of a locally Lipschitz feedback law $u(t) = k(t, x_1(t), x_2(t))$. On the other hand Theorem 3.1 guarantees that there exists a time-varying distributed delay feedback law that achieves finite-time stabilization for the closed-loop system. Indeed, system (4.1) satisfies hypothesis (A1) and thus Theorem 3.1 can be applied. Following the proof of Theorem 3.1, it can be shown that for every $\mu > 0$, $l \in Z^+ \cup \{+\infty\}$, there exist functions $\gamma \in K^+$ and $\rho \in K_\infty$ such that the feedback law

$$\begin{aligned} u(t) = v(t) &- f_2(t, x_1(t), x_2(t)) - \frac{\partial f_1}{\partial t}(t, x_1(t)) - \frac{\partial f_1}{\partial x_1}(t, x_1(t)) f_1(t, x_1(t)) \\ &- \frac{\partial f_1}{\partial x_1}(t, x_1(t)) x_2(t) - \mu^{-2} \dot{a}\left(\frac{t}{\mu}\right) \int_{-2\mu}^{-\mu} \mu^{-1} h\left(\frac{s}{\mu}\right) x_1(t+s) ds \\ &+ \mu^{-1} a\left(\frac{t}{\mu}\right) \int_{-2\mu}^{-\mu} \mu^{-2} h'\left(\frac{s}{\mu}\right) x_1(t+s) ds \\ &- \mu^{-1} a\left(\frac{t}{\mu}\right) \int_{-2\mu}^{-\mu} \mu^{-1} h\left(\frac{s}{\mu}\right) \Big[x_2(t+s) + f_1(t+s, x_1(t+s)) \\ &+ \mu^{-1} a\left(\frac{t+s}{\mu}\right) \int_{-2\mu}^{-\mu} \mu^{-1} h\left(\frac{w}{\mu}\right) x_1(t+s+w) dw \Big] ds, \end{aligned} \tag{4.2}$$

where $a \in C^l(\Re; \Re^+)$ is a periodic function with period 3, with $a(t) = 0$ for $t \in [0, 2]$ and $\int_2^3 a(t)dt = 1$, $h \in C^l(\Re; \Re^+)$ with $h(s) = 0$ for all $s \notin (-2, -1)$, $\int_{-2}^{-1} h(s)ds = \int_{-2\mu}^{-\mu} \mu^{-1} h(\frac{s}{\mu}) ds = 1$

(i) achieves the dead-beat property of order $T = 14\mu$ for the corresponding closed-loop system with $v(t) \equiv 0$ and

(ii) for every $(t_0, x_0, v) \in \Re^+ \times C^0([-4\mu, 0]; \Re^2) \times C^0(\Re; \Re)$ the solution of the closed-loop system (4.1) with (4.2) satisfies estimate (3.5).

In order to estimate the functions $\gamma \in K^+$ and $\rho \in K_\infty$ we consider the coordinate transformation

$$z_1(t) = x_1(t); z_2(t) = f_1(t, x_1(t)) + \mu^{-1} a\left(\frac{t}{\mu}\right) \int_{t-2\mu}^{t-\mu} \mu^{-1} h\left(\frac{w-t}{\mu}\right) x_1(w)dw + x_2(t). \tag{4.3}$$

The closed-loop system (4.1) with (4.2) is described in z-coordinates by the following set of retarded functional differential equations:

$$\dot{z}_1(t) = -\mu^{-1} a\left(\frac{t}{\mu}\right) \int_{-2\mu}^{-\mu} \mu^{-1} h\left(\frac{s}{\mu}\right) z_1(t+s)dw + z_2(t);$$
$$\dot{z}_2(t) = -\mu^{-1} a\left(\frac{t}{\mu}\right) \int_{-2\mu}^{-\mu} \mu^{-1} h\left(\frac{s}{\mu}\right) z_2(t+s)dw + v(t).$$

Repeated application of Lemma 2.9 for the above system provides the following estimate:

$$|z(t)| \le 2(1+5\mu)\exp(9L)\sigma\left(\frac{t-t_0}{\mu} - 12\right) \|T_{2\mu}(t_0)z\|_{2\mu} + 100\mu(1+2\mu)\exp(9L) \sup_{t_0 \le s \le t} |v(s)| \quad \forall t \ge t_0, \tag{4.4}$$

where $z := (z_1, z_2)', \sigma(t) := \left\{ \begin{smallmatrix} 1 & if & t < 0 \\ 0 & if & t \ge 0 \end{smallmatrix} \right.$ and $L := \max_{t\in[0,3]} a(t)$. The functions $\gamma \in K^+$ and $\rho \in K_\infty$ can be determined directly from estimate (4.4). For example, consider the case that there exists $b \in K_\infty$ such that $|f_1(t, x_1)| \le b(|x_1|)$ for all $(t, x_1) \in \Re \times \Re$ (this requirement is automatically satisfied if f_1 is independent of time). In this case transformation (4.3) implies the inequalities $|x(t)| \le \beta(\|T_{2\mu}(t)z\|_{2\mu})$ and $|z(t)| \le \beta(\|T_{2\mu}(t)x\|_{2\mu})$, where $\beta(s) := (2 + \mu^{-1}L)s + b(s)$. Using estimate (4.4) and previous inequalities $\|T_{2\mu}(t_0)z\|_{2\mu} \le \beta(\|T_{4\mu}(t_0)x\|_{4\mu})$ (which directly imply the inequality $\|T_{2\mu}(t_0)z\|_{2\mu} \le \beta(\|T_{4\mu}(t_0)x\|_{4\mu})$), we obtain

$$|x(t)| \le \beta\Bigg(2(1+5\mu)\exp(9L)\sigma\left(\frac{t-t_0}{\mu} - 14\right)\beta(\|T_{4\mu}(t_0)x\|_{4\mu}) + 100\mu(1+2\mu)\exp(9L) \sup_{t_0 \le s \le t} |v(s)|\Bigg) \quad \forall t \ge t_0.$$

We conclude that estimate (3.5) holds for the closed-loop system (4.1), (4.2) with $\gamma(t) \equiv 1$ and $\rho(s) := \beta(M(s + \beta(s)))$, where $M := 100(1+5\mu)(1+\mu)\exp(9L)$.

Similarly, we can address the finite-time stabilization problem for the general triangular case (1.1) with no delays, where $f_i \in C^{n-i+1}(\Re \times \Re^i; \Re)$ with $f_i(t, 0, \dots, 0) = 0$ for all $t \in \Re, i = 1, \dots, n$. Proceeding exactly as in the 2-dimensional case, it can be shown that if (1.1) is autonomous then the proposed distributed delay feedback guarantees that estimate (3.5) holds for the corresponding closed-loop system with $\gamma(t) \equiv 1$.

The following example is a triangular autonomous control system with discrete delays.

Example 4.2. Consider the control system:

$$\begin{aligned} &\dot{x}_1(t) = x_1^2(t-\tau_1) + x_2(t-\tau_1); \\ &\dot{x}_2(t) = -2x_1(t)x_1^2(t-\tau_1) - 2x_1(t)x_2(t-\tau_1) + x_2(t-2\tau_2) + u(t-\tau_2), \\ &(x_1(t), x_2(t)) \in \Re^2, u(t) \in \Re. \end{aligned} \tag{4.5}$$

It can be verified that assumption (A1) holds for (4.5) with $\varphi_1(t, x_1) := x_1^2(0)$ and $\varphi_2(t, x_1, x_2) := x_2(-\tau_2)$. Thus Theorem 3.1 guarantees that for every $\mu > \tau_1 + \tau_2$, there exists a 3μ-periodic time-varying distributed delay feedback such that the corresponding closed-loop system satisfies the dead-beat property. The following feedback law:

$$\begin{aligned} u(t) = &-x_2(t-\tau_2) - \mu^{-2}\dot{a}\left(\frac{t+\tau_1+\tau_2}{\mu}\right)\int_{-2\mu}^{-\mu}\mu^{-1}h\left(\frac{s}{\mu}\right)x_1(t+\tau_1+\tau_2+s)ds \\ &+ \mu^{-1}a\left(\frac{t+\tau_1+\tau_2}{\mu}\right)\int_{-2\mu}^{-\mu}\mu^{-2}\dot{h}\left(\frac{s}{\mu}\right)x_1(t+\tau_1+\tau_2+s)ds \\ &- \mu^{-1}a\left(\frac{t+\tau_2}{\mu}\right)\int_{-2\mu}^{-\mu}\mu^{-1}h\left(\frac{s}{\mu}\right)\Big[x_2(t+\tau_2+s) + x_1^2(t+\tau_2+s) \\ &+ \mu^{-1}a\left(\frac{t+\tau_1+\tau_2+s}{\mu}\right)\int_{-2\mu}^{-\mu}\mu^{-1}h\left(\frac{w}{\mu}\right)x_1(t+\tau_1+\tau_2+s+w)dw\Big]ds, \end{aligned}$$

where $a \in C^l(\Re; \Re^+)$ is a periodic function with period 3, with $a(t) = 0$ for $t \in [0, 2]$ and $\int_2^3 a(t)dt = 1$, $h \in C^l(\Re; \Re^+)$ with $h(s) = 0$ for all $s \notin (-2, -1)$, $\int_{-2}^{-1} h(s)ds = \int_{-2\mu}^{-\mu} \mu^{-1}h(\frac{s}{\mu})ds = 1$, achieves the dead-beat property of order $T = 14\mu$ for the corresponding closed-loop system.

Example 4.3. The chain of delayed integrators (1.2), where $\tau_i \geq 0$, has been considered in the literature for the particular case of $\tau_1 = \cdots = \tau_{n-1} = 0$ in [15] with the additional requirement that the stabilizing feedback must be bounded. Here we consider the general case and demand finite-time stabilization of the corresponding closed-loop system. Since assumption (A1) holds with $\varphi_i \equiv 0$ for $i = 1, \ldots, n$, by virtue of Theorem 3.1 we conclude that for every $\mu > \sum_{i=1}^n \tau_i$ there exists a linear 3μ-periodic time-varying distributed delay feedback such that the closed-loop system satisfies the dead-beat property. Notice that there is no limitation on the size of the delays. Specifically, for the case $n = 2$ we obtain the following feedback, which guarantees the dead-beat property of order $T = 14\mu$:

(4.6)

$$\begin{aligned} u(t) = &-\mu^{-2}\dot{a}\left(\frac{t+\tau_1+\tau_2}{\mu}\right)\int_{-2\mu}^{-\mu}\mu^{-1}h\left(\frac{s}{\mu}\right)x_1(t+\tau_1+\tau_2+s)ds \\ &+ \mu^{-1}a\left(\frac{t+\tau_1+\tau_2}{\mu}\right)\int_{-2\mu}^{-\mu}\mu^{-2}h'\left(\frac{s}{\mu}\right)x_1(t+\tau_1+\tau_2+s)ds \\ &- \mu^{-1}a\left(\frac{t+\tau_2}{\mu}\right)\int_{-2\mu}^{-\mu}\mu^{-1}h\left(\frac{s}{\mu}\right)\Big[x_2(t+\tau_2+s) \\ &+ \mu^{-1}a\left(\frac{t+\tau_1+\tau_2+s}{\mu}\right)\int_{-2\mu}^{-\mu}\mu^{-1}h\left(\frac{w}{\mu}\right)x_1(t+\tau_1+\tau_2+s+w)dw\Big]ds, \end{aligned}$$

where $a \in C^l(\Re; \Re^+)$ is a periodic function with period 3, with $a(t) = 0$ for $t \in [0, 2]$ and $\int_2^3 a(t)dt = 1$, $h \in C^l(\Re; \Re^+)$ with $h(s) = 0$ for all $s \notin (-2, -1)$, $\int_{-2}^{-1} h(s)ds = \int_{-2\mu}^{-\mu} \mu^{-1}h(\frac{s}{\mu})ds = 1$. Figures 1–3 show the evolution of the state and the input for the C^2 selection:

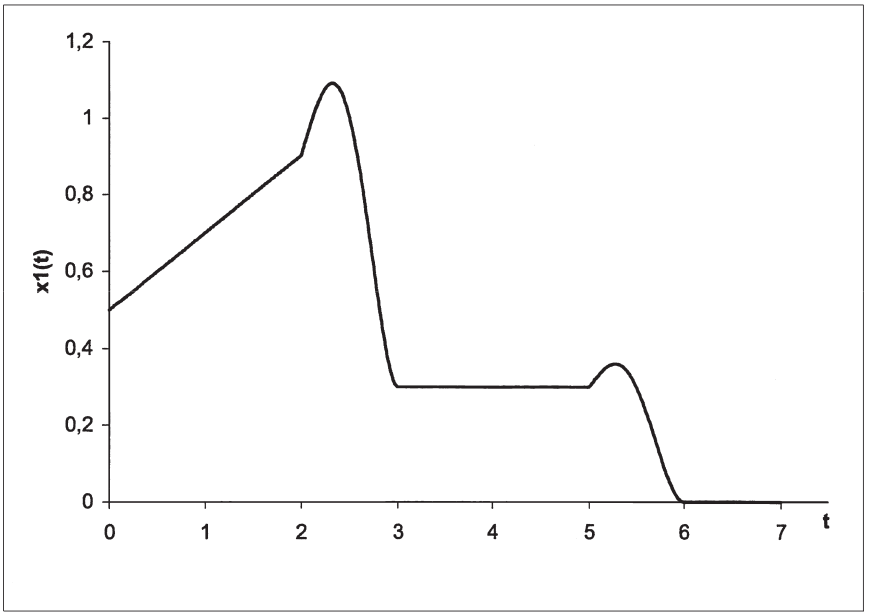

FIG. 1. *Evolution of* $x_1(t)$ *for the case* (1.2) *with* $n = 2$ *and* $\tau_1 = \tau_2 = 0$ *under the feedback law* (4.6), (4.7).

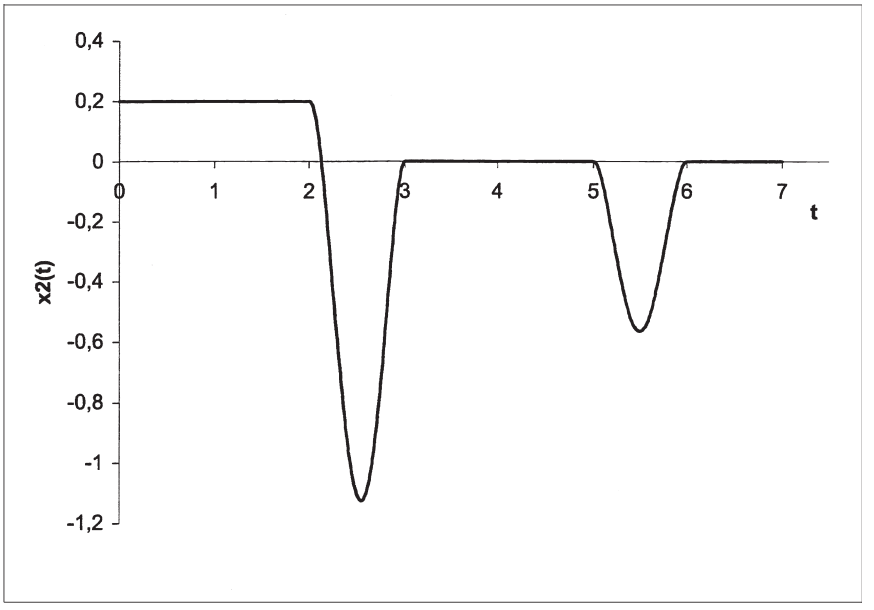

FIG. 2. *Evolution of* $x_2(t)$ *for the case* (1.2) *with* $n = 2$ *and* $\tau_1 = \tau_2 = 0$ *under the feedback law* (4.6), (4.7).

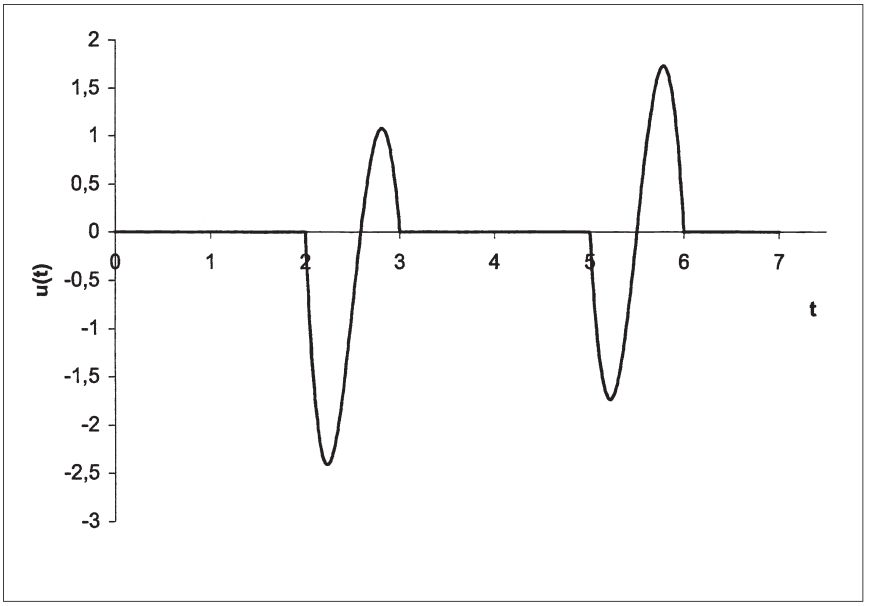

FIG. 3. *Evolution of* $u(t)$ *for the case* (1.2) *with* $n = 2$ *and* $\tau_1 = \tau_2 = 0$ *under the feedback law* (4.6), (4.7).

$$
\begin{aligned}
&a(t) := p\left(t - 3\left[\frac{t}{3}\right]\right) \quad \text{and} \quad h(s) := a(s+4), \text{ where}\\
&p(x) := \begin{cases} 30(x-2)^2(3-x)^2 & \text{if } x \geq 2\\ 0 & \text{if } x < 2 \end{cases}
\end{aligned} \tag{4.7}
$$

for the case (1.2) with $n = 2$ and $\tau_1 = \tau_2 = 0$ with initial condition $x_1(0) = 0.5$ and $x_2(0) = 0.2$.

The case of triangular control systems with delayed drift terms is considered in the following example.

Example 4.4. Consider the planar system

$$
\begin{aligned}
\dot{x}_1(t) &= f_1(t, x_1(t-\tau_{1,1})) + x_2(t);\\
\dot{x}_2(t) &= f_2(t, x_1(t-\tau_{2,1}), x_2(t-\tau_{2,2})) + u(t),\\
&\qquad (x_1(t), x_2(t)) \in \Re^2, u(t) \in \Re, t \geq 0,
\end{aligned} \tag{4.8}
$$

where $\tau_{1,1} > 0, \tau_{2,1} \geq 0, \tau_{2,2} \geq 0$, and $f_1 \in C^2(\Re^+ \times \Re; \Re)$ and $f_2 \in C^1(\Re^+ \times \Re^2; \Re)$ with $f_1(t,0) = f_2(t,0,0) = 0$ for all $t \geq 0$. Clearly, assumption (A2) holds for this system with $R := \tau_{1,1}$, since we have

$$
\begin{aligned}
&x_1(0) f_1(t, x_1(-\tau_{1,1})) - x_2(0)\left(\frac{\partial f_1}{\partial t}(t, x_1(-\tau_{1,1}))\right.\\
&\quad \left. + \frac{\partial f_1}{\partial x_1}(t, x_1(-\tau_{1,1})) f_1(t-\tau_{1,1}, x_1(-2\tau_{1,1})) + \frac{\partial f_1}{\partial x_1}(t, x_1(-\tau_{1,1})) x_2(-\tau_{1,1})\right)\\
&\quad \leq \frac{1}{2}x_1^2(0) + \frac{1}{2}x_2^2(0) + L\left(t, \sup_{-2\tau_{1,1} \leq \theta \leq -\tau_{1,1}} |x(\theta)|\right),
\end{aligned}
$$

where $L(t,s) := \frac{1}{2}\max_{|\xi|\le s}[(f_1(t,\xi_1))^2 + (\frac{\partial f_1}{\partial t}(t,\xi_1) + \frac{\partial f_1}{\partial x_1}(t,\xi_1)f_1(t-\tau_{1,1},\xi_2) + \frac{\partial f_1}{\partial x_1}(t,\xi_1)\xi_3)^2]$. Following the proof of Theorem 3.4, it can be shown that for every $\mu > \tau_{1,1}$ the feedback law

$$\begin{aligned}
u(t) = &-\frac{\partial f_1}{\partial t}(t, x_1(t-\tau_{1,1})) - \frac{\partial f_1}{\partial x_1}(t, x_1(t-\tau_{1,1}))f_1(t-\tau_{1,1}, x_1(t-2\tau_{1,1})) \\
&- \frac{\partial f_1}{\partial x_1}(t, x_1(t-\tau_{1,1}))x_2(t-\tau_{1,1}) - f_2(t, x_1(t-\tau_{2,1}), x_2(t-\tau_{2,2})) \\
&- \mu^{-2}\dot{a}\left(\frac{t}{\mu}\right)\int_{-2\mu}^{-\mu}\mu^{-1}h\left(\frac{s}{\mu}\right)x_1(t+s)ds \\
&+ \mu^{-1}a\left(\frac{t}{\mu}\right)\int_{-2\mu}^{-\mu}\mu^{-2}h'\left(\frac{s}{\mu}\right)x_1(t+s)ds \\
&- \mu^{-1}a\left(\frac{t}{\mu}\right)\int_{-2\mu}^{-\mu}\mu^{-1}h\left(\frac{s}{\mu}\right)\Big[x_2(t+s) + f_1(t+s, x_1(t-\tau_{1,1}+s)) \\
&+ \mu^{-1}a\left(\frac{t+s}{\mu}\right)\int_{-2\mu}^{-\mu}\mu^{-1}h\left(\frac{w}{\mu}\right)x_1(t+s+w)dw\Big]ds
\end{aligned}$$

guarantees the dead-beat property of order $14\mu + 2\tau_{1,1}$. Similarly, we can address the finite-time stabilization problem for the general triangular case with delayed drift terms (1.3), where $\min_{i=1,\dots,n-1}\ \min_{j=1,\dots,i}\tau_{i,j} > 0,\ f_i \in C^{n-i+1}(\Re^+ \times \Re^i; \Re)$ with $f_i(t,0,\dots,0) = 0$ for all $t \ge 0,\ i = 1,\dots,n$.

5. Conclusions. In this paper it is shown that finite-time stabilization by means of time-varying distributed delay feedback is possible for specific classes of systems described by RFDEs. Based on our main results (Theorems 3.1 and 3.4) we have been able to construct locally Lipschitz feedback laws that guarantee the dead-beat property for the corresponding closed-loop systems for important cases such as the general triangular case with no delays, the case of a chain of delayed integrators with no limitation on the size of the delays and the general triangular case with delayed drift terms.

VELOCITY EXTENSION FOR THE LEVEL-SET METHOD AND MULTIPLE EIGENVALUES IN SHAPE OPTIMIZATION*

FRÉDÉRIC DE GOURNAY†

Abstract. In the context of structural optimization by the level-set method, we propose an extension of the velocity of the underlying Hamilton–Jacobi equation. The gradient method is endowed with a Hilbertian structure based on the H^1 Sobolev space. Numerical results for compliance minimization and mechanism design show a strong improvement of the rate of convergence of the level-set method. Another important application is the optimization of multiple eigenvalues.

Key words. multiple eigenvalues, shape optimization, sensitivity analysis, shape derivative, level-set method, regularization

1. Introduction.

Optimal design of elastic structures has been widely studied and many different numerical methods are used to solve this problem. Most of the existing methods can be divided into two main classes: topology optimization which optimizes a density of material in each cell and geometric optimization which moves the boundary of the domain.

The most recent topology method, the homogenization method and its variants (power-law method or solid isotropic microstructure with penalization (SIMP) method), may be considered quite classical in view of the number of publications (see, e.g., [1], [2], [6], [8], [7], [12]). The homogenization method seems the most promising because it is independent with respect to initialization and because it gives a strong mathematical result of the existence of solution. Sadly this method bears the difficulty of handling quite badly eigenvalue problems where apparitions of so-called fictitious-material modes prevent stable numerical computation. Another problem is that topology methods give optimal shapes that are composite. Penalization methods allow one to project the composite shape on a classical shape (a black-and-white design).

The problem of fictitious modes is naturally solved with the geometric methods where the shape is clearly identified and the void cannot generate fictitious modes.

The major drawback of geometric methods is their dependency with respect to initialization. Even the most recent level-set method ([4], [5], [34]) is very sensitive to initialization although the topology can change. In order to avoid this problem, a method of topology optimization, the bubble method (or topological gradient method [16], [17], [31], [32]), has been recently coupled with geometric optimization (see [3], [11]). The most recent method of geometric optimization is developed in [23]. But this method has not been numerically implemented yet.

We wish here to correct the so-called void problem that arises when using the level-set algorithm. This problem is generated by the weak material approximation

*Received by the editors February 9, 2005; accepted for publication (in revised form) October 21, 2005; published electronically March 15, 2006.

†Centre de Mathématiques Appliquées (UMR 7641), Ecole Polytechnique, 91128 Palaiseau, France (degourna@cmapx.polytechnique.fr).

that gives rise to a negative velocity for advecting the shape in the void. The void problem slows down the algorithm when the mesh is refined.

The void problem is presented in section 3, and the chosen solution is presented in section 4. The method mainly consists of applying the Δ^{-1} operator to the velocity which is costless. This method allows one to regularize and to extend and gives a local Hilbertian structure (see the discussion in section 4.2). Numerical results are presented in sections 4.3–4.7; they compare the new method with the previous one and show strong improvements of the level-set algorithm.

The method also has made it possible to deal with the problem of optimizing an eigenvalue when its multiplicity is greater than 1. Theoretical differentiation of the eigenvalue is made in section 5. As can be expected from theory on eigenvalue differentiation, the first eigenvalue is directionally differentiable with respect to shape variation, even when this eigenvalue is multiple. The algorithm that optimizes the first eigenvalue is detailed in section 5.3. It strongly relies on the local Hilbertian structure given by velocity regularization. Indeed, because of this local Hilbertian structure, the differential gives rize to a gradient and therefore to a steepest descent. We show that the choice of the steepest descent is a semidefinite program in low dimension that is easily solved. Some numerical results are presented in section 6.

The method used for optimizing multiple eigenvalues can be extended to other criteria that are not differentiable as the robust compliance criterion in the sense of [13]. The method of velocity regularization presented here is an adaptation of [10], [26], [21]. It is a standard issue in numerical computation.

2. The level-set method in shape optimization.

2.1. Eigenvalue maximization. We set our model problem in linearized elasticity. Let $\Omega \subset \mathbb{R}^d$ ($d = 2$ or 3) be a bounded open set occupied by a linear isotropic elastic material with Hooke's law A_0. Recall that, for any symmetric matrix ξ, A_0 is defined by

$$A_0\xi = 2\mu\xi + \lambda\big(\mathrm{Tr}\xi\big)Id,$$

where μ and λ are the Lamé coefficients of the material. The boundary of Ω is made of two disjoint parts

$$\partial\Omega = \Gamma_N \cup \Gamma_D, \tag{1}$$

with Dirichlet boundary conditions on Γ_D and Neumann boundary conditions on Γ_N. The spectral problem is to find an eigenvalue γ and an eigenvector $u \neq 0$ such that

$$\left\{\begin{array}{rcll} -\mathrm{div}\,(\mathrm{A}\,\mathrm{e}(\mathrm{u})) & = & \gamma\rho u & \text{in } \Omega, \\ u & = & 0 & \text{on } \Gamma_D, \\ \big(A\,e(u)\big)n & = & 0 & \text{on } \Gamma_N, \end{array}\right. \tag{2}$$

where ρ is a scalar field on Ω that represents the material density (typically ρ is equal to 1 on Ω).

It is well known that $\mathrm{Sp}(\Omega)$ the set of eigenvalues is a countable set of positive numbers that tends to infinity. The smallest eigenvalue $\gamma_1(\Omega) = \min \mathrm{Sp}(\Omega)$ can then be defined.

A classical way of improving the rigidity of a structure is to maximize the first eigenfrequency. Thus, a natural objective function to be minimized is

$$\mathcal{L}(\Omega) = -\gamma_1(\Omega) + \eta|\Omega|, \tag{3}$$

where η is a given Lagrange multiplier for a volume constraint. We want to minimize $\mathcal{L}$ with respect to Ω with a constraint that $\Omega \subset D$, where D is a given domain of $\mathbb{R}^d$.

2.2. Classical algorithm. The works [24], [29], or [5] give an extensive explanation of the level-set method. Only the main ideas are to be reviewed in this section.

As described in [4], when the dimension of the eigenspace associated to γ_1 is equal to 1, the above functional $\mathcal{L}(\Omega)$ is differentiable with respect to variation of the domain and the geometrical shape optimization method can be applied. It reads, as follows:

1. **Calculation of the gradient.** Let Ω_k be the domain at iteration k. Assuming that $\gamma_1(\Omega_k)$ is simple, for a given $\theta \in W^{1,\infty}(D;D)$ define

$$(Id+\theta)\circ\Omega_k = \{x+\theta(x) \text{ with } x \in \Omega_k\}.$$

Prove that $\mathcal{L}((Id+\theta)\circ\Omega_k)$ is differentiable with respect to θ at the point $\theta = 0$. The value of $\mathcal{L}'$, the differential at the point 0 is given by

$$\mathcal{L}'(\theta) = \int_{\partial\Omega_k} (\theta\cdot n)(-v+\eta) \tag{4}$$

$$\text{with} \quad \begin{cases} v &= Ae(u)\colon e(u) - \gamma_1 \rho u\cdot u & \text{on} \quad \Gamma_N^k, \\ v &= -Ae(u)\colon e(u) & \text{on} \quad \Gamma_D^k, \end{cases} \tag{5}$$

where u is an eigenvector normalized by $\int_{\Omega_k} \rho u\cdot u = 1$ which is, up to a change of sign, by assumption, unique and where n is the outer normal of Ω_k.

2. **Calculation of a descent direction.** Choose θ_k such that $\mathcal{L}'(\theta_k) < 0$, and let $\Omega_{k+1} = (Id + t\theta_k)\circ\Omega_k$, where t is the step of the gradient method.

The level-set method is a geometrical shape optimization method where the domains Ω_k are represented through functions ϕ_k defined on D in the following way: $x \in \Omega_k \Longleftrightarrow \phi_k(x) < 0$. Such a ϕ_k is said to be "a level set function of Ω_k." Of course for a given domain, the associated level-set functions are not unique.

The changes of topology are then handled in a very simple way (see [5] for extensive explanations of numerical advantages). The method relies on the following lemma.

LEMMA 2.1. *If ϕ_k is a level-set function of Ω_k, define ϕ_{k+1} as*

$$\phi_{k+1} - \phi_k + t(\theta_k\cdot n)|\nabla\phi_k| = 0.$$

Then there exists an $O(t^2)$ such that $\phi_{k+1} + O(t^2)$ is a level-set function for the domains $\Omega_{k+1} = (Id + t\theta_k)\circ\Omega_k$.

Thus, the following scheme for choosing ϕ_{k+1} is the most commonly used:

$$\begin{aligned} \phi(0) &= \phi_k, \\ \frac{\partial\phi}{\partial t} + V^*|\nabla\phi| &= 0, \\ \phi_{k+1} &= \phi(T), \end{aligned} \tag{6}$$

where $T > 0$ is the step of the gradient method and V^* is the descent direction chosen according to the calculation (4) of the differential of J. Defining $V^* = v - \eta$ (v being defined in (4)) is the most commonly used choice; we will call this choice the natural extension method. The goal of this paper is to find a different way of defining V^*.

Remark 2.2. In order to avoid multiple definitions of V^*in the natural extension method, it is supposed that the Dirichlet part of the boundary is fixed and that the v used everywhere in the domain is the one defined for Γ_N.

3. The weak material approximation. The stiffness matrix that corresponds to the linear operator of elasticity is not defined on the nodes that does not belong to Ω, i.e., on $x \in D$ such that $\phi(x) > 0$. In other words, this matrix is not invertible. In order to avoid this problem, the so-called weak material (or ersatz material) approximation consists of fixing Hooke's law A and the material density ρ as

$$\begin{array}{rclcrcll} A & = & A_0 & \text{and} & \rho & = & 1 & \text{in} \quad \Omega \\ A & = & \varepsilon A_0 & \text{and} & \rho & = & \varepsilon^\alpha & \text{outside} \quad \Omega \end{array}$$

with a small parameter ε and $\alpha \geq 1$. The fictitious modes are avoided by setting $\alpha = \infty$. In the continuous case, it has been proven (see [28]) that the eigenvector $\tilde{u}$ calculated by using the ersatz material approximation is equal (at first order in ε) to the desired eigenvector u introduced in (2). In $D \setminus \Omega$ $\tilde{u}$ is the lifting of the Dirichlet condition $\tilde{u} = u$ on $\partial\Omega$ (at first order in ε).

Recalling that the Dirichlet part of the boundary of $\partial\Omega$ has been fixed (see Remark 2.2), $v - \eta = Ae(u) : e(u) - \gamma_1 \rho u \cdot u - \eta$ is defined everywhere on D, and the natural extension method consists of defining $V^* = Ae(u) : e(u) - \gamma_1 \rho u \cdot u - \eta$ on every cell.

This nevertheless raises a problem: since u is everywhere of order ε^0, then $Ae(u) : e(u)$ is of order ε outside Ω which means that the velocity extension is almost equal to $-\eta$ outside the domain and makes it very difficult for the shape to increase its volume. Even if the descent step T is increased in order to speed up the method, the parts of the shape where there is a need to decrease the volume will move faster than the parts of the shape where there is a demand on increasing the volume.

In numerical result, it can be seen that between each computation of the eigenvalue, the level-set method cannot move $\partial\Omega$ of more than one cell away from the original boundary when it wants to improve the volume. This leads to a drastically increasing computational time with mesh-refinement.

This remark is true, of course, for every objective function and not only for the minimization of the first eigenvalue.

4. Velocity regularization by the Hilbertian method.

4.1. Definition of the Hilbertian method. We will suppose that the domain Ω has enough regularity so that $v(\cdot, \cdot)$ defined in (4) belongs to $H^{-1/2}(\partial\Omega)$. Even if the optimal domain may possibly be irregular, physical and numerical intelligence tells that throughout optimization $v(\cdot, \cdot)$ has the required regularity but mathematical proof of this fact is still lacking. Let us first define a scalar product.

DEFINITION 4.1. *For $a \in \mathbb{R}^{*+}$, define the following scalar product on $H^1(D)$:*

$$(u, w)_{H^1} = \int_D a \nabla u \cdot \nabla w + uw$$

with the associated norm $\| \cdot \|_{H^1}$.

The velocity V^* in the Hamilton–Jacobi equation (6) is chosen as the unique solution to

$$\int_{\partial\Omega} V^*(-v + \eta) = \min_{\substack{V \in H^1(D) \\ \|V\|_{H^1} = 1}} \int_{\partial\Omega} V(-v + \eta), \tag{7}$$

where v is the differential defined in (4) and Ω is the actual working domain.

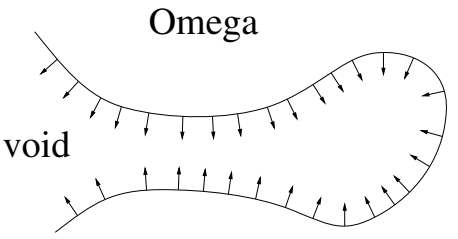

FIG. 1. *Two merging parts of the boundary leads to a nonregular vector field as seen as a distribution on D.*

4.2. Advantages of the method.

Scalar versus vector. We choose to extend the normal velocity which is a scalar field, i.e., if θ is the vector field that advects the domain, its normal velocity is equal to $\theta \cdot n$ on the boundary of the domain. Seen as a distribution over D, the normal velocity is more regular than the vector velocity. A good example is when two parts of the boundary want to merge: $\theta \cdot n$ is positive on the two parts and θ changes orientation. This situation gets worse at the next step of the algorithm (see Figure 1). That is why the normal velocity is extended and not the vector velocity.

How to compute V^*. The problem of finding V^* is not difficult. Let $\bar{V}$ be the unique solution to

$$(\bar{V}, X)_{H^1} = \int_{\partial\Omega} X(-v+\eta) \quad \forall X \in H^1(D),$$

where $(\cdot,\cdot)_{H^1}$ is the scalar product of Definition 4.1. Then $V^* = -\frac{\bar{V}}{\|\bar{V}\|_{H^1}}$ and the inversion of the matrix that corresponds to the scalar product $(\cdot,\cdot)_{H^1}$ has to be done only once in the optimization process.

Extension, regularization, and Hilbertian structure. Three different goals are sought in the Hilbertian extension of the velocity.

First, the formula for the differential of $\mathcal{L}$ gives a velocity that makes sense only on the boundary of the domain, and the Hamilton–Jacobi equation (6) needs a speed defined everywhere on the domain or else the algorithm cannot move the boundary of more than one cell during optimization. This is the extension issue.

Secondly, the velocity is regularized by being diffused with the scalar product defined in Definition 4.1. This is the regularization issue. It is expected to increase the accuracy of the algorithm and is a standard issue in optimization problems (see, e.g., [26], [10], [21]).

Thirdly, the problem is endowed with a Hilbertian structure, and we work with gradient-type methods. This issue will be developed later in section 5.

Hilbertian extension versus other extensions. The most natural way to extend the velocity outside $\partial\Omega$ would have been to extend $v - \eta$ according to the normal of $\partial\Omega$ by a front-propagating-type method such as the fast-marching method described in [25]. This method does not endow the space with a Hilbertian structure. Neither does it regularize the velocity.

V^* is indeed an extension. Because the scalar product diffuses the source term, the velocity is now defined everywhere on D, and the typical problem of null velocity in the void that raises with the natural extension method is now cured.

V^* is indeed a regularization. V^*, the speed used in the Hilbertian extension method, is more regular than $v - \eta$, the speed used in the natural extension method as can be seen in the following formal derivation.

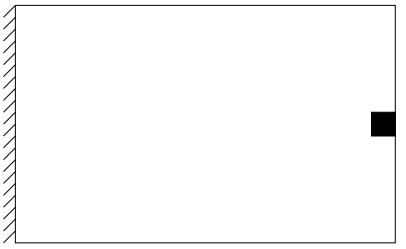

FIG. 2. *Boundary conditions for a two-dimensional (2d) cantilever (the black zone is heavier and not subject to optimization).*

If v belongs to an $H^s(D)$, then $X \mapsto \int_{\partial\Omega} X(-v+\eta)$ is a linear form on $H^{-s+1/2}(D)$, and V^* belongs to an $H^{s+3/2}(D)$ by elliptic regularity on the very smooth domain D. Indeed V^* is obtained by operating an inverse Laplacian on the distribution (on D) $X \mapsto \int_{\partial\Omega} X(-v+\eta)$ and so gains two derivatives.

Consistency of the extension. This algorithm could be seen as a gradient-type algorithm if there were a vector field $\theta^* \in W^{1,\infty}(D;D)$ such that $\theta^* \cdot n = V^*$ on $\partial\Omega$. Two hypotheses would then be needed: a certain regularity on V^* and a certain regularity of the domain Ω itself.

In order to ensure regularity of V^*, a scalar product on H^p, $p \geq 1$, could have been used instead of a scalar product on H^1. In this case, formally, V^* would have $2p - 1/2$ more derivatives in L^2 than v. But numerical computation of V^* may be quite difficult. Indeed, the computation of the matrix of the scalar product of H^p needs finite elements that are chosen according to p.

The extension parameters. The coefficient a characterizes the diffusion of $v-\eta$ in the sense that setting it small compared to 1 will lead to a solution V^* which is pointwise almost equal to $v-\eta$ on $\partial\Omega$ and equal to 0 outside $\partial\Omega$. It must be set small enough so that a big value of $|v-\eta|$ on one part of the boundary does not interfere too much with the values of $v-\eta$ on the other parts of the boundary. But it must be set big enough in order to diffuse the value of $v-\eta$ outside the boundary of Ω.

4.3. Numerical example: Eigenvalues of a cantilever. We study a medium-cantilever problem. The working domain is a 2×1 rectangle, with zero displacement condition on the left side and a small square region at the middle of the right side (see Figure 2) which is 500 times heavier and not subject to optimization. This heavier mass allows one to avoid trivial shapes. Figure 3 is a display of the initialization (left) and the optimal shape at the end of the optimization process (right). The Young modulus of the material is set to 1, the Poisson ratio ν to 0.3, and the Lagrange multiplier to 7×10^{-2}. In the void, the ersatz material has a Young modulus set to 10^{-5} and a density ρ set to 0. The mesh is refined alternatively in each direction by a factor of 2, and the number of transport iterations is adequately increased at each mesh refinement (see the table below).

Explanation of Table 1. Table 1 lists, for different meshes, the number of transport iterations used for each optimization step in the Hamilton–Jacobi equation, the average computed time used per iteration step of the gradient method, and the global computing time. The number of transport iterations is shown for the Hilbertian method only. The number of transport iterations for the natural method is 16 times the number of transport iterations of the Hilbertian method. This explains why the average time per iteration of the gradient algorithm is bigger for the natural method than for the Hilbertian. The last column is the global computing time for obtaining

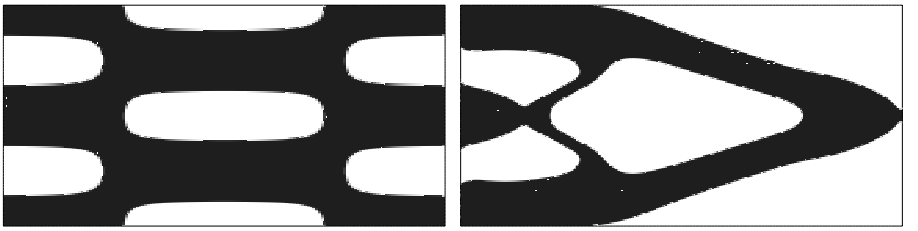

FIG. 3. *Initialization and optimal shape for the first eigenvalue of a cantilever.*

TABLE 1
Data of the numerical test.

Mesh	N^o of transport	Time per iteration Hilbertian / natural	Global time Hilbertian / natural
81×41	16	1.46 / 1.62	30.68 / 50.13
161×81	32	9.35 / 11.37	233.87 / 330.01
321×161	64	72.17 / 94.91	2237.2 / 2657.63
41×41	14	0.74 / 0.84	13.26 / 22.6
81×81	28	4.46 / 6.19	120.62 / 136.1
161×161	56	38.50 / 46.61	1116.57 / 1771.44

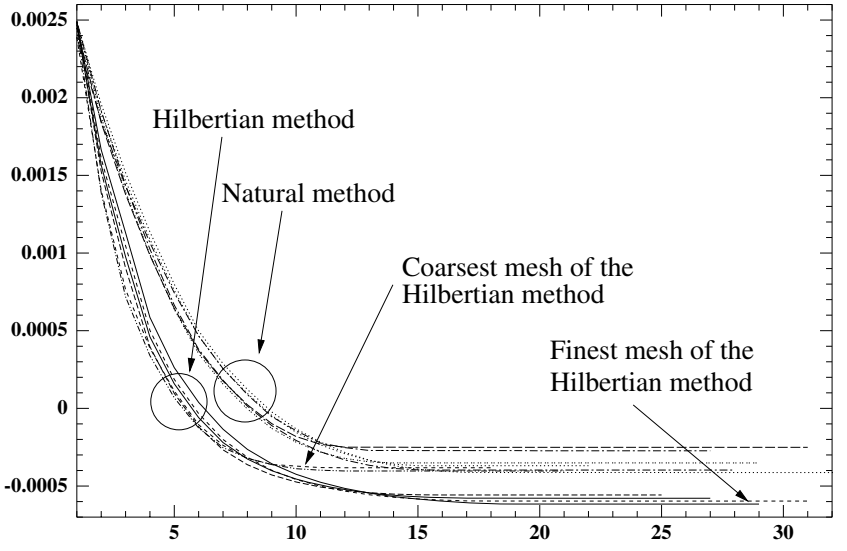

FIG. 4. *Mesh-refinement influence on the velocity for the natural extension (left) and the Hilbertian extension (right).*

the optimal shape. The Hilbertian method takes the same amount of time as the natural method to obtain the optimal shape but only because it is more accurate. As can be seen in Figure 4, the convergence curves of the Hilbertian method are indeed better than the convergence curves of the natural method. Time is given in seconds.

Explanation of Figure 4. There is two sets of curves in Figure 4. The better ones are obtained with the Hilbertian method. It appears that the more the mesh is refined, the better the optimal shape is, even if, when the mesh is refined, the

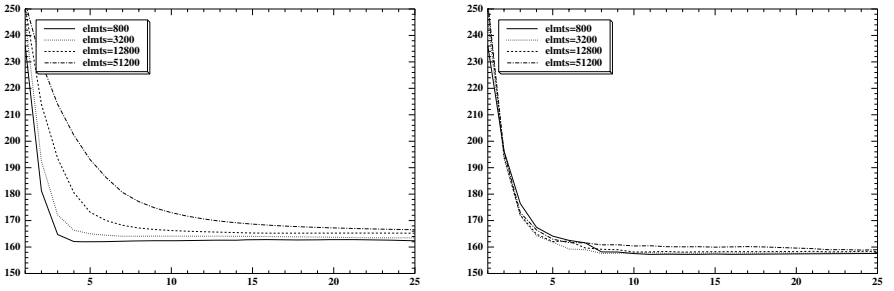

FIG. 5. *Mesh-refinement influence on the natural extension (left) and the Hilbertian extension (right).*

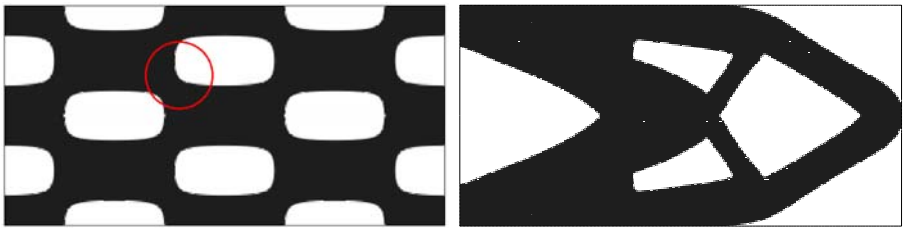

FIG. 6. *Initialization and optimal shape of the cantilever.*

decreasing of the smallest eigenvalue leads to an increase of the criterion. This is easily explained by a better accuracy on the optimal shape itself.

Remark 4.2. In order to prove mesh-consistency of the algorithm and to have comparable curves in Figure 4, the optimal shape has to be the same when the mesh is changed. Thus those examples are chosen so that there is no possibility for the algorithm to create thin structures when the mesh is refined. This explains why there are a very few holes in the initialization. It is well known that the level-set algorithm can produce more complicated structures.

4.4. Numerical example: The compliance of the cantilever. We performed our new velocity extension method on the well-known cantilever problem which is fixed on the left wall and supports a unit vertical point load in the middle of the right wall. The compliance is here optimized. The working domain size is 2×1. The Young modulus is set to 1, and the Poisson ratio to 0.3. The Lagrange multiplier is set to $\eta = 100$.

Optimization is performed for several finer meshes, and the number of transport iterations is multiplied by 2 as each square of the mesh is cut into 4 squares. For the finest mesh (321×161) that corresponds to 51200 elements; the number of transport iterations is equal to 128 for the natural extension and to 16 for the Hilbertian. As a result, the Hilbertian extension is really quicker.

Mesh-refinement influence. The curves in Figure 5 show that the Hilbertian method is less sensitive to mesh-refinement than the natural method. Because there are parts of the boundary that have to increase the volume (one of them is circled in Figure 6) and the natural extension method has problems to improve these parts as was said in section 3, the natural extension method is sensitive to mesh-refinement. In Figure 4 there was no such demand on improving the volume and the mesh-independence of the Hilbertian method was less obvious.

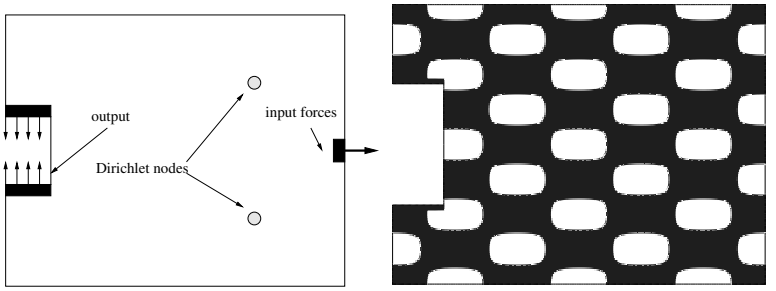

FIG. 7. *The definition of the* 2*d gripping mechanism and its initialization.*

4.5. Numerical example: A two-dimensional (2d) gripping-mechanism. On a 1.2×3.2 rectangle meshed with 241×641 nodes, we give a numerical example for minimizing the least square of a prescribed displacement. This example was given by the Comissariat à l'Energie Atomique for the design of a grip (see [9]). The objective function is

$$\mathcal{J}_{lse}(\Omega) = \int_{\Omega} k(x)|u(x) - u_0(x)|^2, \tag{8}$$

where u is the displacement obtained by a given set of forces, u_0 is a prescribed given displacement, and k is a scalar field that characterizes the zone of interest.

The ponderation k is equal to 10 on the left black box in Figure 7 (left), is equal to 1 on the right black box, and is equal to 0 elsewhere. The prescribed displacement u_0 is equal to $(0, \pm 1)$ on the left black box, and $(0, 0)$ on the right box. Enforcing u to be close to 0 where the force is input allows one to ensure the stiffness and the connectivity of the structure. These black boxes are not subject to optimization.

A force of modulus 1 N is applied in the x-direction on the middle of the left, and a uniform pressure which represents a total force of modulus 5×10^{-2} N is applied between the jaws of the mechanism in order to force the mechanism to hold objects. The prescribed displacement is located on the black box on the left as shown in Figure 7. The Young modulus is set to 1, the Poisson ratio to 0.3, and there is a small Lagrange multiplier of a volume constraint of value 0.05. This Lagrange multiplier helps remove parts of the boundary that are useless.

This is a typical problem where an adjoint is needed. For some reason that is not completely understood, the ratio of the weak material (the factor ε in section 3) cannot be set too low (typically it must be at least 1 percent of the strong material) or the algorithm will not work. One of the explanations that may be given is the tendency of the shape to create hinges. The algorithm then concentrates on the hinges only, ignoring the rest of the shape, and it is believed it is then stuck in a local minimum. If the ratio of the weak material is high, hinges are less efficient and the previous problem is avoided.

Optimization must then be made in two steps. First the shape is optimized with a ratio of the weak material equal to 1 percent. The optimal shape is then reoptimized with a smaller ratio (10^{-5} in this numerical case). In the second optimization procedure, the displacement and the adjoint state are calculated with a more accurate precision which leads to a better precision of the shape-derivative.

In Figure 8 (left), it may seem that the Hilbertian method is less efficient than the natural method. This is explained by the lack of precision in the computation of the

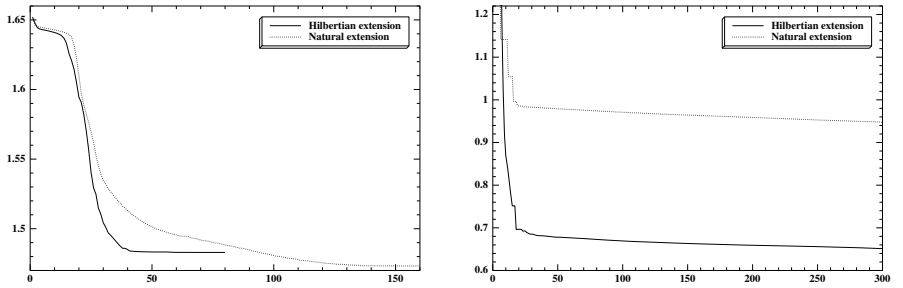

FIG. 8. *Evolution of the objective function for the first step (left) with a ratio for the weak material equal to* 0.01 *and the second step with a ratio of* 10^{-5} *(right).*

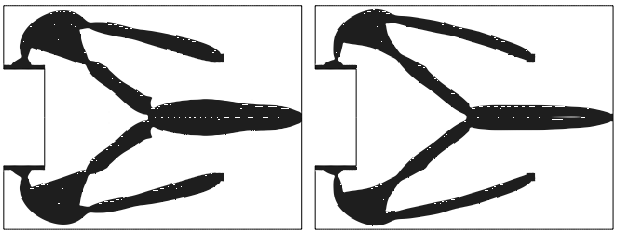

FIG. 9. *Optimal shape for the Hilbertian method (left) and the natural method (right) at the end of the first step of optimization.*

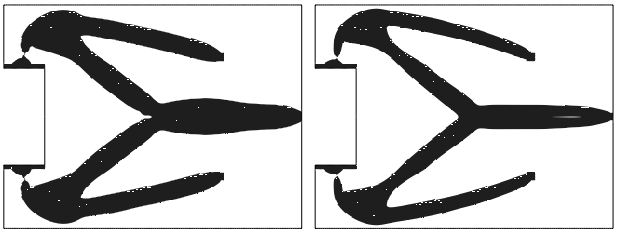

FIG. 10. *Optimal shape for the Hilbertian method (left) and the natural method (right) at the end of the second step of optimization.*

shape-derivative in the first step of the algorithm. But it is also explained by the lack of precision of the computation of the criterion during the first step of the algorithm. Indeed when the two shapes of Figure 9 (obtained with $\varepsilon = 10^{-2}$) are computed using $\varepsilon = 10^{-5}$, the Hilbertian shape is the better one. Figure 10 displays the optimal shape for the two different methods and Figure 11 show how the grip works.

Remark 4.3. The optimal shape for the natural extension method has less volume than the one for the Hilbertian extension (see Figure 10) it is a numerical validation of the problem raised in section 3.

4.6. Numerical example: More 2d mechanisms. We briefly present here some more 2d mechanisms: namely, a negative Poisson modulus cell (Figures 12 to 14) and a force inverter (Figures 15 to 17). These examples are standards of shape optimization problems, and their description can be found in [8]. In order to ensure stiffness of the structures, a small pressure load is applied where the displacement is optimized (on the right black box of Figure 15 for the force inverter and at the

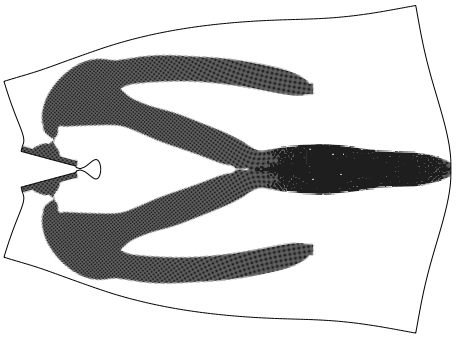

FIG. 11. *Optimal shape displacement.*

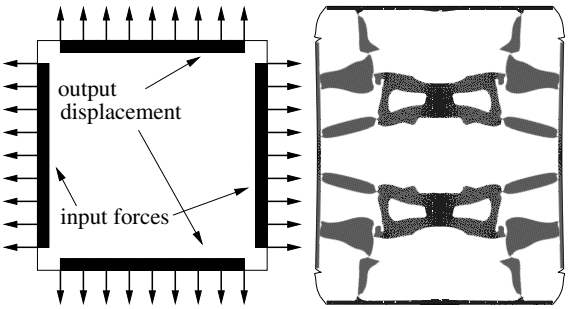

FIG. 12. *The Negative Poisson modulus problem and its deformed solution.*

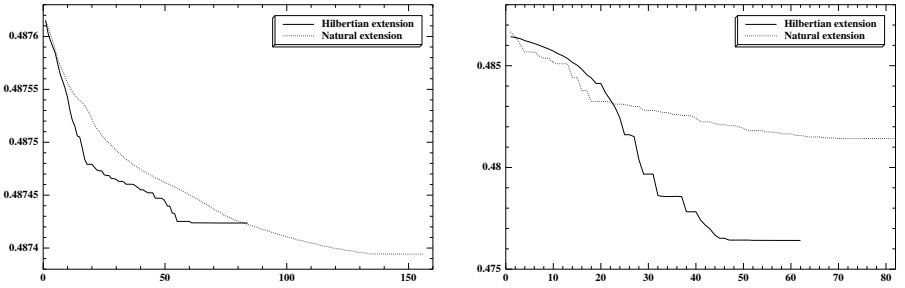

FIG. 13. *Negative Poisson modulus's evolution of the objective function at the first step (left) with a ratio for the weak material equal to* 0.01 *and the second step with a ratio of* 10^{-5} *(right).*

top and bottom of Figure 12 for the negative Poisson modulus mechanism). At the location of the input forces (left black box for the force inverter or the left and right walls for the negative Poisson modulus mechanism), the displacement is enforced to be close to zero in order to ensure connectivity of the shapes. Optimization is made in two steps like the 2d grip of section 4.5, and the behavior of the Hilbertian extension with respect to the natural extension is comparable.

4.7. Numerical example: A three-dimensional (3d) gripping mechanism. The objective function is defined by (8) in section 4.5. The working domain is a $3 \times 2 \times 6$ rectangle. A uniform pressure load is applied on the plane $x = 3$, and the

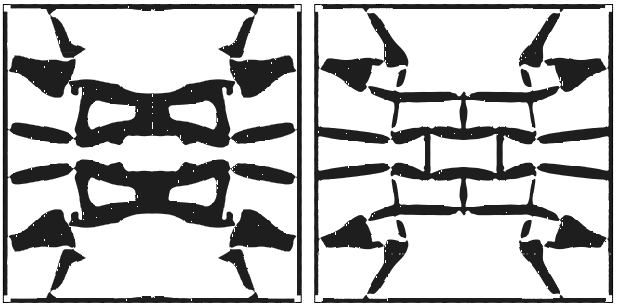

FIG. 14. *Negative Poisson modulus's optimal shape for the Hilbertian method (left) and the natural method (right) at the end of optimization.*

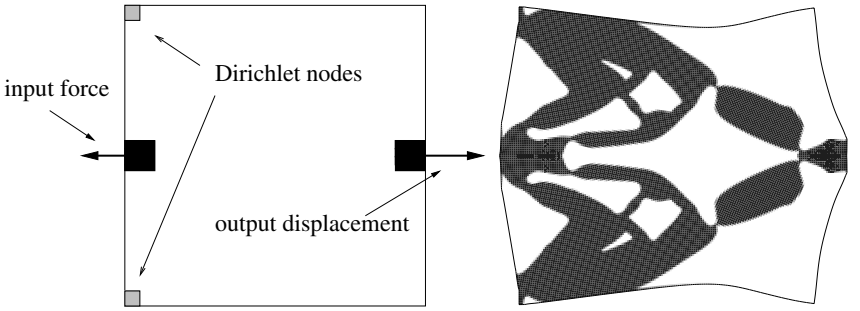

FIG. 15. *The force inverter problem and its deformed solution.*

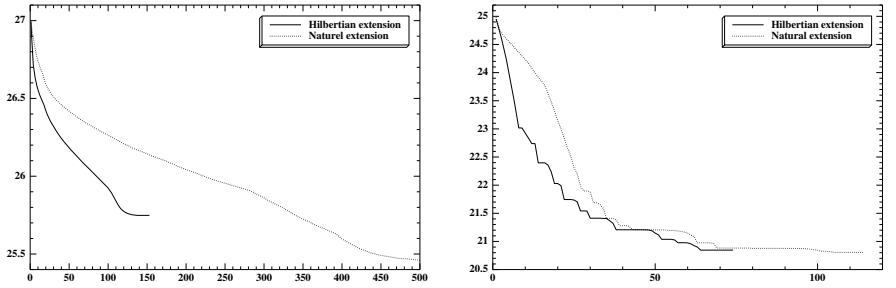

FIG. 16. *Force inverter's evolution of the objective function for the first step (left) with a ratio for the weak material equal to* 0.01 *and the second step with a ratio of* 10^{-5} *(right).*

prescribed displacement is localized on a box at the opposite side (see Figure 18 where a cross-section at $y = 0$ is shown). A uniform pressure load (of order 60 percent of the one on the plane $x = 3$) is also imposed between the jaws of the mechanism so that this mechanism is designed to hold and grip. The Poisson ratio is 0.3, and the Young modulus is 1. The Lagrange multiplier is set to 3, and the mesh used is $31 \times 21 \times 61$. The ratio of the weak material is set to 10^{-5}. There is no need here to perform the 2-step optimization of section 4.5. The reason why things seems to be simpler in 3d is that the changes of topology and the hinges are not of the same nature as in 2d; consequently, it is believed that throughout the process of optimization, the objective

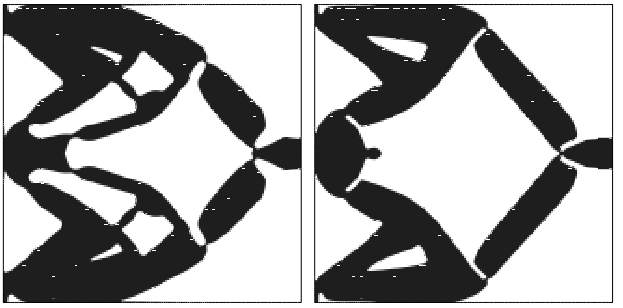

FIG. 17. *Force inverter's optimal shape for the Hilbertian method (left) and the natural method (right) at the end of optimization.*

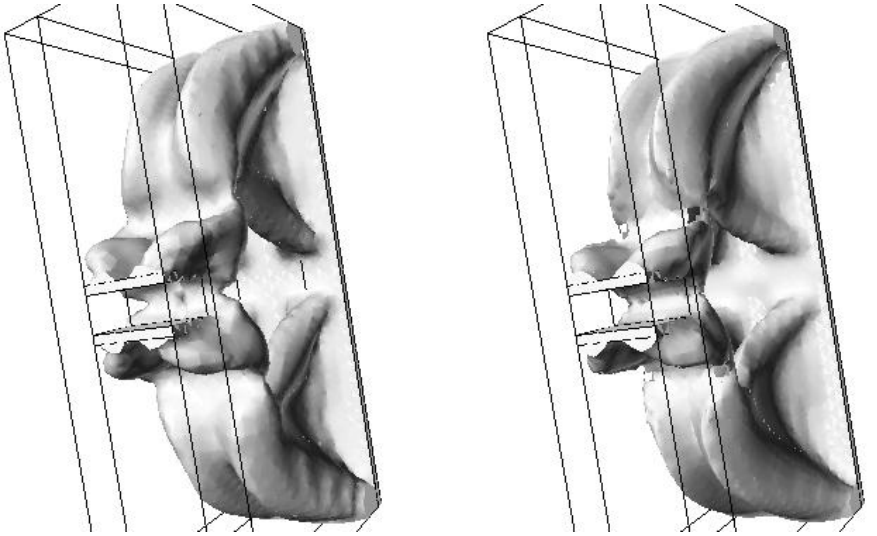

FIG. 19. *Optimal shape for the Hilbertian method (left) and the natural method (right) (isovalue* 0 *of the level-set is shown).*

function is more regular in 3d. Figure 19 displays the resulting optimal shape for the two different methods, as Figure 20 shows the convergence history for both method (left) and how the grip actually works (right).

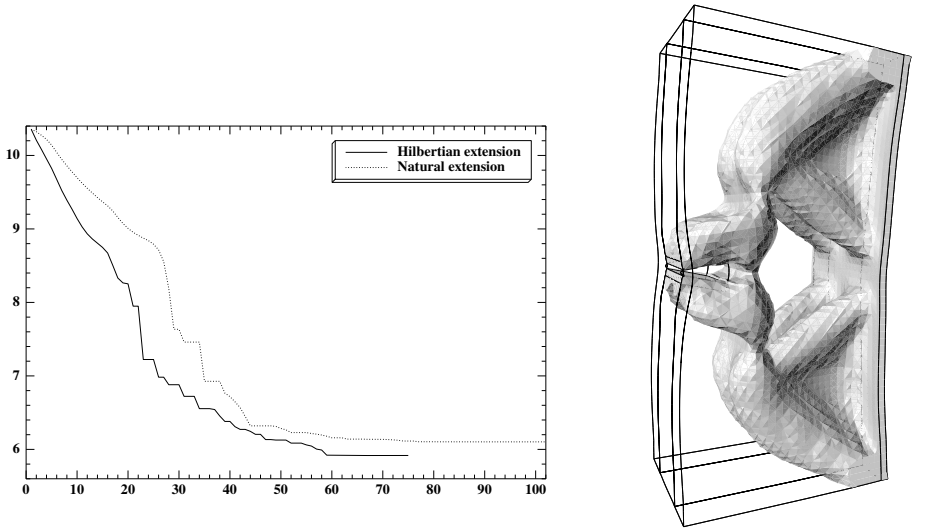

FIG. 20. *Objective function (left) and displacement of the Hilbertian shape (right) (density of material* ≥ 0.3 *is shown).*

5. Optimizing multiple eigenvalues. The development above for optimizing the first eigenvalue stands only when this eigenvalue is of multiplicity equal to 1. When this is not the case, there is no more differentiability of the first eigenvalue with respect to θ, and the above method cannot be applied. Nevertheless it has been proven that $\mathcal{L}$ is directionally differentiable. The velocity extension which endows the space with a Hilbertian structure allows one to find a direction of descent. The algorithm used is now a subgradient-type algorithm. The goal of this section is two-fold:

1. Calculate $\mathcal{L}'(\theta) : W^{1,\infty}(D;D) \to \mathbb{R}$ the nonlinear collection of directional derivative of $\mathcal{L}$. Show that according to Hadamard's structure theorem $\mathcal{L}'(\theta)$ depends only on the value of $\theta \cdot n$ on $\partial\Omega$. Let us denote $j(\theta \cdot n) = \mathcal{L}'(\theta)$.

2. Compute V^* such that $j(V^*) = \min_{\|V\|=1} j(V)$, and advance the domain according to V^*. It is in the computation of V^* that the Hilbertian structure is compulsorily needed.

5.1. A general theorem about eigenvalue differentiation. Differentiating eigenvalues when they are multiple is nowadays quite standard. Two different approaches exist: the one of [19] for the foundations or [27] and [20], or the one of [15] or [18] using the subgradient theory of Clarke [14]. We shall only state their result here.

DEFINITION 5.1. *Define* Ω_0 *as the actual working domain.*

$\diamond$ *Let* $\alpha > 0$, $\beta_1 > 0$ *be constants and* $\mathbb{L}$ *be the space of linear unbounded auto-adjoint operators from* $L^2(\Omega_0) \to L^2(\Omega_0)$ *such that*

$$\forall L \in \mathbb{L}, \quad \forall u \in H^1_D(\Omega_0) \quad \beta_1 \|u\|^2_{H^1_D(\Omega_0)} \geq (Lu,u)_{L^2} \geq \alpha \|u\|^2_{H^1_D(\Omega_0)},$$

i.e., $\mathbb{L}$ *is made of operators "uniformly" coercive with constant* α *and uniformly continuous with constant* β_1

$\diamond$ *Let* $\beta_2 > 0$ *be a constant and* $\mathbb{M}$ *be the space of continuous linear auto-adjoint operators from* $L^2(\Omega_0) \to L^2(\Omega_0)$ *uniformly continuous with constant* β_2*, i.e.,*

$$\forall M \in \mathbb{M}, \quad \forall u \in L^2(\Omega_0) \quad \beta_2 \|u\|^2_{L^2(\Omega_0)} \geq (Mu,u)_{L^2}.$$

◇ *Define the norm in those two spaces as follows: If* $N \in \mathbb{L}$ *or* $N \in \mathbb{M}$*, then*

$$\|N\| = \max_{u \in H^1_D} \frac{(Nu,u)_{L^2}}{\|u\|^2_{H^1_D}},$$

i.e., we endow $\mathbb{M}$ *with the natural norm of* $\mathbb{L}$*.*

◇ *Let*

$$\begin{array}{ccc} U \subset W^{1,\infty}(D;D) & \to & \mathbb{L} \times \mathbb{M} \\ \theta & \mapsto & (L(\theta), M(\theta)) \end{array}$$

be a Fréchet differentiable mapping with respect to the norm just defined. Define $L'(\theta_0)$ *(resp.* $M'(\theta_0)$*) the differential of* $L(\theta)$ *(resp.* $M(\theta)$*) with respect to* θ *at the point* $\theta = 0$ *applied to* θ_0*.*

THEOREM 5.2. *Define* $\gamma_1(\theta)$ *the smallest eigenvalue of the generalized eigenproblem* $L(\theta)u = \gamma M(\theta)u$ *and* E_θ *its eigenspace,* $E_\theta = Ker(L(\theta) - \gamma_1 M(\theta))$*. Then, for all* $\theta_0 \in W^{1,\infty}(D;D)$*,* $\gamma_1(\theta)$ *is directionally differentiable at the point* $\theta = 0$ *in the direction* θ_0 *and the value of the directional derivative is*

$$\gamma_1'(\theta_0) = \min_{\substack{u \in E_0 \\ (M(0)u,u)=1}} \big(L'(\theta_0)u,u\big) - \gamma_1(0)\big(M'(\theta_0)u,u\big).$$

5.2. Calculus of the directional derivative of $\mathcal{L}$. We want to apply the general Theorem 5.2 in the shape sensitivity setting. We want to derivate $\tilde{\mathcal{L}}(\theta)$ defined as below.

DEFINITION 5.3.

◇ *Let* $T = Id + \theta$ *and* $\Omega_\theta = T \circ \Omega_0$*.*

◇ *Let* $\tilde{M}(\theta)$ *and* $\tilde{L}(\theta)$ *be defined as for all* u, v *in* $H^1_D(\Omega_\theta)$*,*

$$(\tilde{M}(\theta)u, v) = \int_{\Omega_\theta} \rho u \cdot v$$
$$(\tilde{L}(\theta)u, v) = \int_{\Omega_\theta} Ae(u) : e(v).$$

◇ *Let* $\tilde{\gamma}_1(\theta)$ *be the smallest eigenvalue associated to the problem*

$$\tilde{L}(\theta)u = \tilde{\gamma}_1(\theta)\tilde{M}(\theta)u.$$

◇ *Let* $\tilde{\mathcal{L}}(\theta) = -\tilde{\gamma}_1(\theta) + \eta|\Omega_\theta|$*.*

The $\tilde{\mathcal{L}}(\theta)$ (resp. $\tilde{\gamma}_1(\theta)$) just defined corresponds to what has been denoted $\mathcal{L}(\Omega_\theta)$ (resp. $\gamma_1(\Omega_\theta)$) in section 2.1.

Theorem 5.2 cannot be applied to $\tilde{\gamma}_1(\theta)$ because the spaces where the operators $\tilde{L}(\theta)$ and $\tilde{M}(\theta)$ are defined changes with θ. That is why we consider the following definition.

DEFINITION 5.4.

◇ *Let* $M(\theta) \in \mathbb{M}$ *and* $L(\theta) \in \mathbb{L}$ *be defined as*

$$(M(\theta)u, v) = (\tilde{M}(\theta)u \circ T^{-1}, v \circ T^{-1})$$
$$(L(\theta)u, v) = (\tilde{L}(\theta)u \circ T^{-1}, v \circ T^{-1}).$$

◇ *Let* $\bar{\gamma}(\theta)$ *be the smallest eigenvalue associated to the problem*

$$L(\theta)u = \bar{\gamma}(\theta)M(\theta)u.$$

We shall work with those operators instead of the classical one. They are defined on a domain independent of θ so that the first eigenvalue can be derivated in the sense of Theorem 5.2. First it must be proven that the introduced eigenvalue $\bar{\gamma}$ is the same as γ_1 the first eigenvalue of the elasticity problem.

LEMMA 5.5.

$\diamond$ *$L(\theta)$ and $M(\theta)$ indeed belongs to $\mathbb{L}$ and $\mathbb{M}$.*

$\diamond$ *$\bar{\gamma}(\theta)$ and $\tilde{\gamma}_1(\theta)$ coincide, where $\tilde{\gamma}_1$ is defined in Definition* 5.3.

Proof of Lemma 5.5.

$\diamond$ Let us first prove that $\tilde{\gamma}_1(\theta) = \bar{\gamma}(\theta)$. Using $u \in H^1(\Omega_\theta) \Longleftrightarrow v = u \circ T^{-1} \in H^1(\Omega_0)$, we have

$$\begin{aligned}\tilde{\gamma}_1(\theta)^{-1} &= \max_{u\in H^1(\Omega_\theta)} \frac{\left(\tilde{M}(\theta)u,u\right)}{\left(\tilde{L}(\theta)u,u\right)} = \max_{u\in H^1(\Omega_\theta)} \frac{\left(M(\theta)u\circ T,u\circ T\right)}{\left(L(\theta)u\circ T,u\circ T\right)}\\ &= \max_{v\in H^1(\Omega_0)} \frac{\left(M(\theta)v,v\right)}{\left(L(\theta)v,v\right)} = \bar{\gamma}(\theta)^{-1}.\end{aligned}$$

$\diamond$ Let us now prove that $L(\theta)$ belongs to $\mathbb{L}$. The fact that $L(\theta)$ is coercive and bounded with respect to the $H^1_D(\Omega_0)$ norm comes from the fact that $\tilde{L}(\theta)$ is coercive and bounded in the $H^1_D(\Omega_\theta)$ norm. We have to show that these constants of coercivity and boundedness are uniform in θ. Let's introduce the tensor A which has the symmetries of the elasticity:

$$A^{ijkl} = A^{jikl} = A^{ijlk} = A^{klij}$$

such that $A^{ijkl}(\partial_j u^i)(\partial_l v^k) = Ae(u)\colon e(v)$. We use the standard tool of shape sensitivity, namely a change of variable:

$$\begin{aligned}(L(\theta)u,v) &= \int_{\Omega_\theta} A^{ijkl}\partial_j(u\circ T^{-1})^i\partial_l(v\circ T^{-1})^k\\ &= \int_{\Omega_0} |\det\nabla T|A^{ijkl}(\partial_s u^i)\left(\partial_j(T^{-1})^s\right)(\partial_m v^k)\left(\partial_l(T^{-1})^m\right) \qquad (9)\\ &= \int_{\Omega_0} l(\theta)^{iskm}(\partial_s u^i)(\partial_m v^k)\end{aligned}$$

with

$$l(\theta)^{iskm} = A^{iskm} + (\partial_l\theta^l)A^{iskm} - A^{ijkm}(\partial_j\theta^s) - A^{iskl}(\partial_l\theta^m) + o(\|\theta\|_{W^{1,\infty}}).$$

Given α and β the coercivity and continuity constant of $L(0)$, there exist $\eta > 0$ such that (s.t.) for every θ with $\|\theta\|_{W^{1,\infty}} < \eta$, we have

$$\forall u \in H^1_D(\Omega_0) \quad 2\beta_0\|u\|^2_{H^1_D(\Omega_0)} \geq (L(\theta)u,u)_{L^2} \geq \frac{\alpha_0}{2}\|u\|^2_{H^1_D(\Omega_0)}.$$

We then verify the hypothesis of Definition 5.1 with $\alpha_1 = \alpha/2$, $\beta_1 = 2\beta$, and $U = \{\theta \text{ s.t. } \|\theta\|_{W^{1,\infty}} < \eta\}$. An analog development stands for M. □

We can now apply Theorem 5.2 to $\bar{\gamma}(\theta) = \tilde{\gamma}_1(\theta)$ and end with the following result.

THEOREM 5.6. *Recalling Definition* 5.3, *$\tilde{\mathcal{L}}(\theta) = -\tilde{\gamma}_1(\theta) + \eta|\Omega_\theta|$ is directionally differentiable with respect to θ, and its directionally derivative at $\theta = 0$ in the direction θ_0 is given by*

$$\mathcal{L}'(\theta_0) = \max_{\substack{u\in E_0\\ \int_{\Omega_0}\rho u\cdot u=1}} \int_{\partial\Omega_0} (\theta_0\cdot n)\left(-v(u,u)+\eta\right),$$

where $v(\cdot,\cdot)$ is a bilinear functional defined by

$$v(u,w) = Ae(u)\colon e(w) - \gamma_1\rho(\Omega_0)u\cdot w \quad \text{on } \Gamma_N,$$
$$v(u,w) = -Ae(u)\colon e(w) \quad \text{on } \Gamma_D,$$

and where E_0 is the first eigenspace associated to $\gamma_1(\Omega_0) = \tilde{\gamma}(0)$ the smallest eigenvalue for $\theta = 0$.

One can of course verify that the formula when the dimension of the eigenspace is greater than 1 is the same as the formula when the dimension is equal to 1.

Proof of Theorem 5.6. We apply Theorem 5.2 to $\tilde{\gamma}_1(\theta) = \bar{\gamma}(\theta)$ in order to calculate $\mathcal{L}'(\theta_0)$. The calculus above for L (and the same for M) shows that

$$\begin{aligned}(L'(\theta)u,v) &= \int_{\Omega_0} \left((\partial_l\theta^l)A^{iskm} - A^{ijkm}(\partial_j\theta^s) - A^{iskl}(\partial_l\theta^m)\right)(\partial_s u^i)(\partial_m v^k)\\ &= \int_{\Omega_0} A^{iskm}(\partial_l\theta^l)(\partial_s u^i)(\partial_m v^k) - A^{iskm}(\partial_s\theta^l)(\partial_l u^i)(\partial_m v^k)\\ &\quad -A^{iskm}(\partial_m\theta^l)(\partial_s u^i)(\partial_l v^k),\\ (M'(\theta)u,v) &= \int_{\Omega_0} (\partial_l\theta^l)\rho u^i v^i.\end{aligned}$$

Applying Theorem 5.2 gives

$$\begin{aligned}\mathcal{L}' = \max_{\substack{u\in E_0\\ \int_{\Omega_0}\rho u\cdot u=1}} &-\int_{\Omega_0} A^{iskm}(\partial_l\theta^l)(\partial_s u^i)(\partial_m v^k) + A^{iskm}(\partial_s\theta^l)(\partial_l u^i)(\partial_m v^k)\\ &+\int_{\Omega_0} A^{iskm}(\partial_m\theta^l)(\partial_s u^i)(\partial_l v^k) + (\partial_l\theta^l)\rho u^i v^i + \eta(\partial_l\theta^l).\end{aligned} \tag{10}$$

We perform an integration by part on θ; the term in $\int_{\Omega_0}$ is equal to

$$\theta^l A^{iskm}\left[\partial_l(\partial_s u^i\partial_m u^k) - \partial_s(\partial_l u^i\partial_m u^k) - \partial_m(\partial_s u^i\partial_l u^k)\right] - \theta^l\gamma_1\rho\partial_l(u^i u^i). \tag{11}$$

Some algebra used in coordination with $\gamma_1\rho u = -\mathrm{divAe(u)}$ allows us to conclude that this term is equal to 0. The remaining term is then equal to

$$\begin{aligned}\mathcal{L}'(\theta) = \max &\int_{\partial\Omega_0} (\theta\cdot n)[-A^{iskm}(\partial_s u^i)(\partial_m u^k) + \gamma_1\rho u\cdot u + \eta]\\ &+\int_{\partial\Omega_0} A^{iskm}\theta^l n^m(\partial_s u^i)(\partial_l u^k) + A^{iskm}\theta^l n^s(\partial_l u^i)(\partial_m u^k).\end{aligned} \tag{12}$$

On the Neumann part of the boundary we use $Ae(u)\cdot n = 0$ and the definition of C to conclude that

$$A^{iskm}(\partial_s u^i)n^m = 0 = A^{iskm}(\partial_m u^k)n^s.$$

On the Dirichlet part of the boundary we use $u = 0$ so that $\nabla u = \frac{\partial u}{\partial n}\otimes n$ to conclude that

$$(\theta\cdot n)(\partial_m u^k) = \theta^l n^m(\partial_l u^k) \text{ and } (\theta\cdot n)(\partial_s u^i) = \theta^l n^s(\partial_l u^i)$$

so that

$$\mathcal{L}'(\theta) = \max\int_{\partial\Omega_0}(\theta\cdot n)[-Ae(u)\colon e(u) + \gamma_1 u\cdot u + \eta] + 2\int_{\Gamma_D}(\theta\cdot n)Ae(u)\colon e(u). \qquad \square$$

Remark 5.7 (*Assumed regularity of* Ω_0). We need regularity on the domain Ω_0 in two occurrences. The first one is when we perform a change of variable ((9) in the demonstration of Lemma 5.5), and the second one is when we perform an integration by part ((11) in the demonstration of Theorem 5.6).

The change of variable is compulsory in order to prove the derivability. It is sufficient to suppose Ω_0 Lipschitz in order to be able to perform it.

The integration by part is used only in order to express the directional derivative (10) as an integral over $\partial\Omega_0$ (see (12)). Performing this integration by part is asking a lot of regularity on Ω_0 because the eigenvector u must be regular enough, i.e., $u \in H^1(\partial\Omega_0)$. But this integration by part is not needed if the only goal is to prove the directional derivability.

5.3. Calculating V^*. The goal of this subsection is to calculate V^* the minimizer to

$$\min_{\|V\|=1} \max_{\substack{u\in E_0 \\ \int_{\Omega_0} u\cdot u=1}} \int_{\partial\Omega_0} V\left(-v(u,u)+\eta\right), \tag{13}$$

where $v(\cdot,\cdot)$ is defined in Theorem 5.6. We will prove in this section that this is a semidefinite programming (SDP) problem in low dimension that is easily solved. The use of SDP for eigenvalue optimization is classical; the goal of this section is to show that solving this SDP problem is a very easy task thanks to the Hilbertian structure endowed by the velocity regularization. A good introduction to SDP is [33] and the references therein. Only some basic facts about SDP problems have been recalled here.

Definition 5.8.

$\diamond$ *Let Y be an unknown vector. Give Y_0 a vector and $E(Y)$ a matrix whose coefficients depend linearly on Y. Let ≥ 0 stand for "symmetric positive." An SDP problem is of the form*

$$\min_{E(Y)\geq 0} Y^T Y_0.$$

$\diamond$ *SDP problems are efficiently solvable by duality methods. In order to ensure that there is no gap of duality, a sufficient condition is to find Y_1 a strictly primal feasible point, i.e., such that $E(Y_1) > 0$ (definite positive).*

We now need to introduce the semidefinite programming problem we will work on.

Definition 5.9. *Recall Definition* 4.1 *of the scalar product $(\cdot,\cdot)_{H^1}$.*

$\diamond$ *Define $(e_i)_{i=1,\dots,d}$ an orthonormal basis of E_0 for the scalar product*

$$(u,w) = \int_{\Omega_0} \rho u\cdot v.$$

$\diamond$ *Define $(a_{ij})_{i,j=1,\dots,d}$ and c as*

$$(a_{ij},X)_{H^1} = \int_{\partial\Omega_0} -Xv(e_i,e_j) \quad \textit{and} \quad (c,X)_{H^1} = \int_{\partial\Omega_0} X\eta.$$

$\diamond$ *Define h_k an orthonormalized basis of $Span(a_{ij},c)_{i,j}$ for the scalar product $(,)_{H^1}$. Let m be the dimension of this space, and let $(a_{ij}^k)_{k=1,\dots,m}$ (resp. $(c^k)_{k=1,\dots,m}$) be the coordinates of a_{ij} (resp. c) on the basis $(h_k)_{k=1,\dots,m}$.*

◇ *For any* $X = (X_1, \dots, X_m)$ *and* $(z, w) \in \mathbb{R}^2$, *let* $Y = [X, w, z]$.
◇ *Let* $A(X)$ *be the* $d \times d$ *matrix* $A(X)_{ij} = a_{ij}^k X_k$, *let* $C(X) = c^k X_k$, *and let*

$$D(Y) = \begin{bmatrix} -A(X) + zId & 0 \\ 0 & -C(X) - z + w \end{bmatrix}, \quad E(Y) = \begin{bmatrix} D(Y) & 0 & 0 \\ 0 & Id & X \\ 0 & X^T & 1 \end{bmatrix}.$$

The coefficients of E *depends linearly on* $Y = [X, w, z]$.
◇ *Let* $Y^* = [X^*, w^*, z^*]$ *be the solution of the following SDP problem:*

$$\min_{E(Y) \geq 0} w \tag{14}$$

THEOREM 5.10. V^*, *the minimizer of the problem* (13), *is given by*

$$V^* = \sum_{k=1}^{m} V_k h_k,$$

where the vector $X^* = [V_1, \dots, V_k]$ *is defined as a solution of the semidefinite problem* (14).
◇ *The problem* $\min_{E(Y) \geq 0} w$ *is strictly feasible; SDP programming can be applied.*
◇ V^* *(or equivalently* X^**) is attained.*

Proof. We transform the problem (13) into (14) by using the fact that $v(\cdot, \cdot)$ is bilinear (see Theorem 5.6 for the definition of v)

$$\begin{aligned} &\min_{\|V\|_{H^1}=1} \max_{\substack{u \in E_0 \\ \int_{\Omega_0} \rho u \cdot u = 1}} \int_{\partial\Omega_0} V[-v(u,u) + \eta] \\ &= \min_{\|V\|_{H^1}=1} \max_{\sum_{i=1}^d \lambda_i^2 = 1} \int_{\partial\Omega_0} V[-\lambda_i \lambda_j v(e_i, e_j) + \eta] \\ &= \min_{\|V\|_{H^1}=1} \max_{\sum_{i=1}^d \lambda_i^2 = 1} \lambda_i \lambda_j (V, a_{ij})_{H^1} + (V, c)_{H^1} \\ &= \min_{\|V\|_{H^1}=1} \max_{\sum_{i=1}^d \lambda_i^2 = 1} (V, h_k)_{H^1} (\lambda_i \lambda_j a_{ij}^k + c^k) \end{aligned}$$

so that V^* is a minimizer of (13) if and only if $X_k^* = (V^*, h_k)_{H^1}$ are minimizers of the following problem:

$$\min_{\sum X_k^2 \leq 1} \max_{\sum_{i=1}^d \lambda_i^2 = 1} \lambda_i \lambda_j a_{ij}^k X_k + c^k X_k. \tag{15}$$

◇ Showing that (15) is equivalent to (14) is a standard issue of SDP: The condition $E([X, w, z]) \geq 0$ is equivalent to $(X, X) \leq 1$ and $D([X, w, z]) \geq 0$. The condition $D([X, w, z]) \geq 0$ is equivalent to $zId \geq A(X)$ and $w \geq z + C(X)$. So

$$E([X, w, z]) \geq 0 \Longleftrightarrow \sum_k X_k^2 \leq 1 \text{ and } w \geq z + X_k c^k \text{ and } z \geq \max_{\sum_{i=1}^d \lambda_i^2 = 1} \lambda_i \lambda_j a_{ij}^k X_k$$

so that minimizing w with the above condition is equivalent to finding X in the problem (15).

◇ Choosing $X = 0$, $z > 0$, and $w > z$ gives a $[X, w, z]$ for which $F([X, w, z]) > 0$. The problem is then strictly feasible, an extended Slater's condition holds, and the dual problem (in terms of semidefinite duality) has the same extremal value.

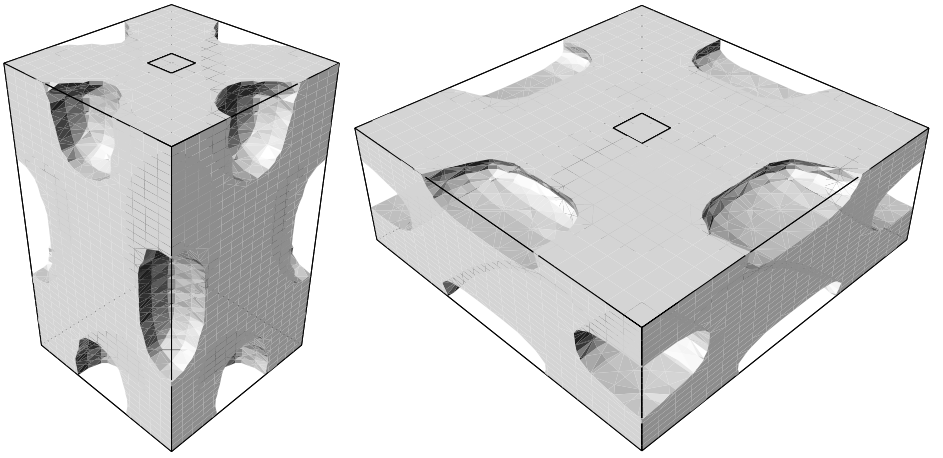

FIG. 21. *Initialization for the narrow domain (left) and for the big domain (right).*

$\diamond$ The condition $\sum_k X_k^2 \leq 1$ ensures that X is bounded and that every minimizing sequence converges up to a subsequence. The maximum is indeed attained. $\square$

Remark 5.11. The SDP problem is not difficult to solve. Recall that d is the dimension of the first eigenspace, then $[X, w, z]$ is of dimension lower or equal to $\frac{d(d+1)}{2} + 3$ and the matrix E is a $\frac{d(d+3)}{2} + 3$ square matrix.

6. Numerical results.

6.1. The 3d eigenvalue of a beam. We naturally set our problem in 3d with symmetries, where we are sure to obtain a multiplicity of the first eigenvalue greater than 1. The first example which will be called the "big domain" problem is a $3 \times 3 \times 1$ rectangle discretized with a $21 \times 21 \times 23$ mesh. A zero displacement boundary condition is imposed on the plane $z = 0$, and four cells on the middle of the plane $z = 1$ are not subject to optimization and are 50 times heavier (see Figure 21). Since the domain is symmetric, the shapes are expected to keep a first eigenvalue of dimension at least 2 along the iterations. The Young's modulus is set to 1 and the Poisson ratio to 0.3. In the void, the density ρ is set to 0 and the parameter ε is equal to 10^{-5}. The second problem is the same as the first except that the rectangle is of dimension $0.6 \times 0.6 \times 1$ (discretized by a $15 \times 15 \times 43$ mesh) with a mass tip that is 200 times heavier. The second problem will be called in this section the "narrow domain" problem.

Discussion about the big domain problem. The Lagrange multiplier being set to 5.3×10^{-8}, Figure 22 is a display of the optimal shape and Figure 23 displays the three smallest eigenvalues. There is one eigenvalue that is always (except on iterations 22 to 28) of multiplicity two and one which is of multiplicity one. The eigenvalue of multiplicity one corresponds to an eigenvector which is localized on the heavy cells and that interferes in the optimization process. The panel on the left-hand side of Figure 23 shows the evolution of the eigenvalues. On each iteration, the value of d the dimension of the subspace of the first eigenvalue is shown. The expected behavior of the algorithm can be verified.

Discussion about the narrow domain problem. Figure 24 shows the optimal shape and Figure 25 shows the convergence history of the narrow domain problem. As can be seen in Figure 25 (left), the global evolution of the algorithm is as follows:

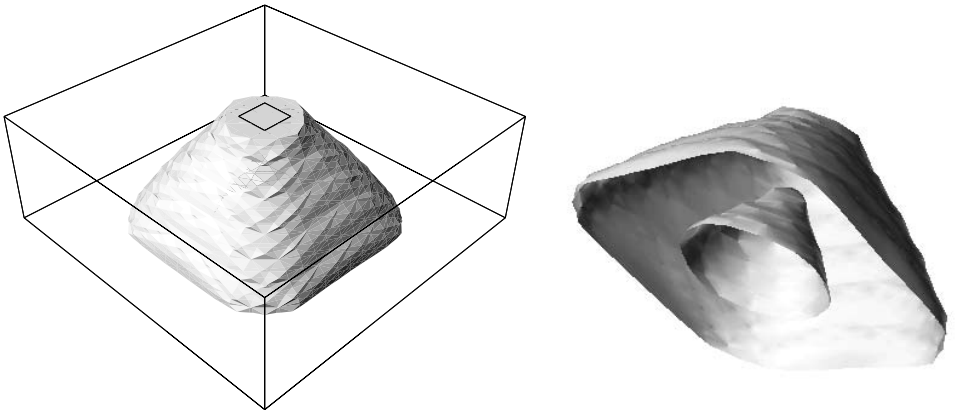

FIG. 22. *The optimal shape for the first eigenvalue in a big domain (left) and its boundary (right).*

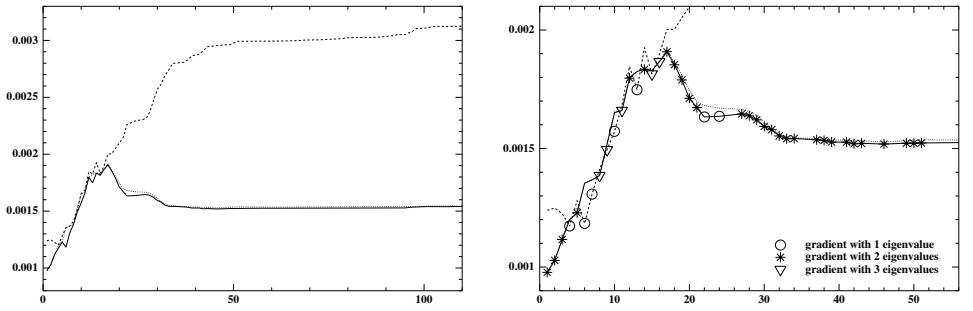

FIG. 23. *Evolution of the three smallest eigenvalues (left) and an interpretation (right) for the big domain.*

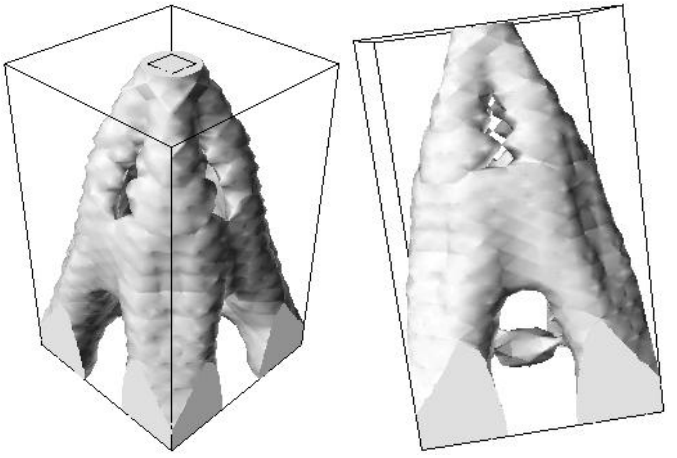

FIG. 24. *The optimal shape for the first eigenvalue in a narrow domain (isovalue* 0.2 *of the density is drawn).*

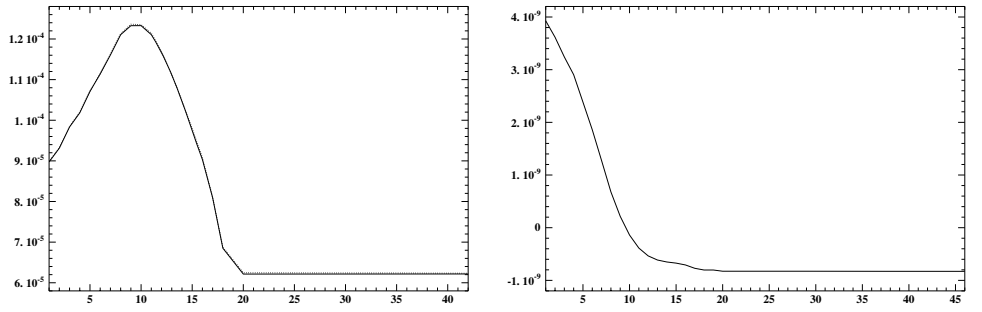

FIG. 25. *Evolution of the two smallest eigenvalues (left) and the objective function (right) for the narrow domain.*

First reinforce the structure so that the first eigenvalue raises, and then optimize the weight of the structure. The Lagrange multiplier is set to 10^{-8} for this example.

Discussion about the symmetries. Neither of the two problems give rise to radially symmetrical shapes. For the narrow-domain problem it can be easily understood by the fact that the shape is constrained into a box. For the big-domain problem one can advance an explanation based on a mesh-effect. But it is known that there exist symmetric problems whose solutions do not respect the symmetries. We still do not know if the optimal shape is or is not radially symmetric for this problem.

6.2. The short cantilever. We run our algorithm on a vibrating cantilever that is the same test case as the one of section 4.3 except that the working domain is of size 1×2 discretized with a regular 80×160 mesh. The other parameters that have changed are the Lagrange multiplier which is set to 0.3 and the heavier mass which has a density 80 times heavier. This test case was introduced in [4] where the authors pointed out the appearance of multiple eigenvalues. It is not the exact same test because when the test of [4] has been run, the improvement of the multiple eigenvalue method is not as obvious as in the test presented here.

The test is run with the standard single eigenvalue optimization (only one eigenvalue is taken into account during optimization) and the multiple eigenvalue optimization processes. Figure 26 (left) is the initializing shape which is the same for the two process and Figure 26 (right) is the optimal shape for the multiple eigenvalue optimization process. Figure 27 shows the evolution of the objectives functions for the two different processes.

At iteration n, the algorithm considers an eigenvalue to be of multiplicity d if and only if the relative differences $\gamma_d/\gamma_1 - 1 \leq \epsilon_0 < \gamma_{d+1}/\gamma_1 - 1$, where ε_0 is a user-defined criterion. If the shape computed at iteration $n+1$ is not better than the shape computed at iteration n and if the eigenvalue at iteration n is multiple, then the parameter ε_0 is decreased. The parameter ε_0 is set to 10 percent at the beginning of the optimization process. This explains the behavior of the algorithm in Figure 28 (right).

It can be seen in Figure 28 (left) that when the first eigenvalue is considered to be always of multiplicity one, the two first eigenvalues have a tendency to merge and the algorithm cannot improve the shape. If we follow the branches of eigenvalues according to the modes, we would see that the smallest eigenvalue does not correspond to the same modes during optimization, i.e., the algorithm optimizes one mode at iteration

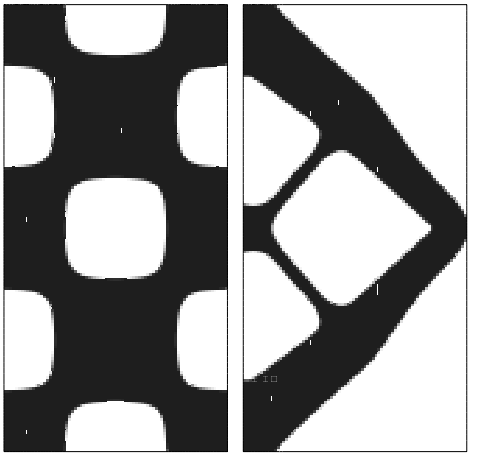

FIG. 26. *Initialization and optimal shape for the first eigenvalue of a short cantilever.*

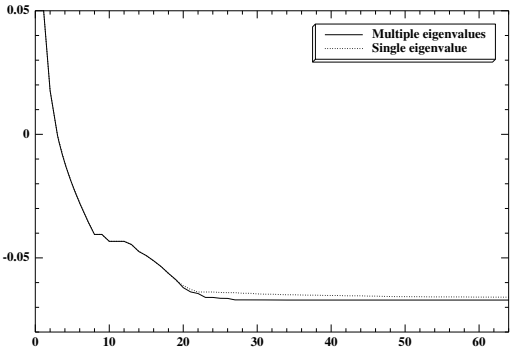

FIG. 27. *Evolution of the objective function for the two different methods.*

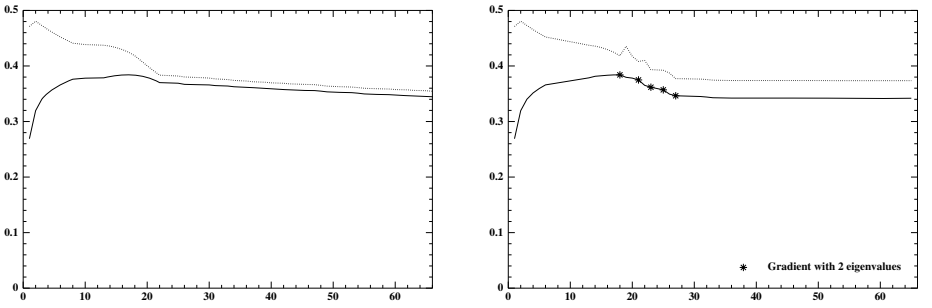

FIG. 28. *Evolution of the two smallest eigenvalues for the single eigenvalue optimization (left) and for the multiple eigenvalue optimization (right).*

n and another one at iteration $n+1$. This is standard of optimization with respect to a maximum of a function when the maximum is multiple and it is well known to slow down the algorithm.

7. Conclusion. The velocity-regularization method presented here improves the speed and accuracy of the level-set method and extends it to new problems. Thanks to the Hilbertian method, three issues can be dealt with: the extension, the regularization, and the endowment of a Hilbertian structure (see the discussion in section 4.2).

The extension issue (i.e., extending everywhere a velocity which is only defined on the boundary) is related only to the speed of the algorithm. The 2d compliant cantilever of section 4.4 which shows the mesh-independence of the Hilbertian method is a good example of the improvements this new method brings to the level-set algorithm.

The regularization issue is about dealing with more regular velocities. It is indeed an improvement as can be seen in the mechanism examples because it allows one to improve the accuracy of the optimal shape. It allows one to also improve the speed of the algorithm by diffusing the peaks of the velocity in the vicinity of the peak. The only test for which velocity regularization is not as efficient in terms of accuracy as the natural extension is the first step of the optimization procedure of the 2d mechanism of section 4.5 (see Figure 8 (left)). This can be explained by the fact that the adjoint is not computed with a precision that is accurate enough when the ratio of the weak material is too high. Sadly for 2d tests which need the computation of an adjoint, it still seems compulsory to perform the 2-steps optimization procedure. It was seen in section 4.7 that this trick is not needed in 3d.

Because the velocity regularization endows the problem with a Hilbertian structure, it allows one to apply the level-set method of optimization for several problems that are not differentiable but whose directional derivative exists. The computation of the descent direction relies on an SDP problem. The transformation of the steepest descent algorithm into an SDP problem can be made because the directional derivative of the problem is a maximum of quadratic functions over a sphere. This is the case for the eigenvalue problem, for the robust compliance problem, and for the buckling load problem which are all based on the generalized eigenvalues problem. The investigation of the two latest problems and application of the Hilbertian method to those issues is in progress.

Acknowledgments. I deeply thank Grégoire Allaire for his advise on this work, for his useful and always pertinent comments and suggestions, and François Jouve for his programming skills and useful critics. Every figure was obtained by using François Jouve's personal software.

ROBUST MATRIX ROOT-CLUSTERING ANALYSIS THROUGH EXTENDED KYP LEMMA*

OLIVIER BACHELIER† AND DRISS MEHDI†

Abstract. This paper is dedicated to robust matrix eigenvalue clustering in a subregion $\mathcal{D}$ of the complex plane. A norm-bounded uncertainty is considered. $\mathcal{D}$ is any intersection and/or union of half planes, discs, and outsides of discs. This work aims at computing the associated complex $\mathcal{D}$-stability radius. This challenge was already tackled in a recent paper but the technique therein may fail or lead to conservative results when the subregions overlap. The present paper proposes to circumvent those limits thanks to an extended version of the Kalman–Yakubovich–Popov (KYP) lemma which is deduced from the so-called generalized S-procedure.

Key words. matrix $\mathcal{D}$-stability, $\partial\mathcal{D}$-regularity, KYP lemma, generalized S-procedure

AMS subject classifications. 93D09, 34D20, 15A39

DOI. 10.1137/S036301290444349X

1. Introduction.

Matrix $\mathcal{D}$-stability appears to be a discerning tool to appreciate the transient performances of a linear model (a matrix is said to be $\mathcal{D}$-stable when its spectrum lies in a region $\mathcal{D}$ of the complex plane). Many contributions propose necessary and sufficient conditions for matrix $\mathcal{D}$-stability such as paper [12], its generalized Lyapunov equations and its Ω-regions, based on the pioneer work of [14], or [9] and its LMI regions (LMI stands for linear matrix inequality: see [8]).

In the presence of uncertainties, the necessity of the above-mentioned conditions cannot be preserved in most cases. Thus, it is important to check robust $\mathcal{D}$-stability through sufficient conditions. The Hurwitz-stability case was tackled in [19, 29, 27, 11]. Ω-regions were considered in [28, 6]. For polytopic uncertainty, LMI conditions given in [9, 20] prove to be very effective. The special case of norm-bounded uncertainty [21] is of interest since the complex $\mathcal{D}$-stability radius can be reached owing to the bounded real lemma when $\mathcal{D}$ is either a disc or a half plane [17, 18, 10] (the complex stability radius corresponds to the largest radius of the ball of complex uncertainties that preserve stability). For the real stability radius, see [13, 22].

Quite few results exist concerning nonconnected regions, especially combinations of several subregions, although it helps to handle the compromise between robustness and satisfactory transient behavior. Since the first contribution [2], other works were presented in [5, 4, 7]. For structured uncertainty, see the work of [25] on the original good ride quality region particularly convenient for aircraft models. One of the most recent contributions dealing with norm-bounded uncertainty is [3] in which the reader can find details and discussions about the above-mentioned papers. Starting from the notion of $\partial\mathcal{D}$-regularity (nonintersection between the matrix spectrum and some curve $\partial\mathcal{D}$), the approach presented in [3] is efficient and often leads to the complex $\mathcal{D}$-stability radius, except when the various subregions of $\mathcal{D}$ overlap. The present paper must be seen as an extension of [3] that circumvents the mentioned limits. It relies on

an extended version of the Kalman–Yakubovich–Popov (KYP) lemma deduced from the insightful paper [16] and its generalized S-procedure.

The present paper is organized as follows: section 2 emphasizes the limits of [3] and states the problem under a new and more precise formulation. In section 3, once some background is recalled, an extended version of the KYP lemma is proposed. Section 4 is devoted to numerical examples. Section 5 concludes the paper.

Notation. M' denotes the transpose conjugate of matrix M. Hence, $s' \in \mathbb{C}$ is the conjugate of s. M^H equals matrix $M + M'$. The 2-norm of M (maximal singular value) is denoted by $||M||_2$. $\mathbf{I}$ and 0 are the identity matrix and the null matrix of appropriate dimensions, respectively. In matrix inequalities, > 0 and < 0 mean positive definite and negative definite, respectively; ≥ 0 and ≤ 0 mean positive semidefinite and negative semidefinite, respectively. Symbol $\mathbf{i}$ denotes the imaginary unit. $\lambda(M)$ and $\mathrm{tr}(M)$ are the spectrum and the trace of square matrix M, respectively. Symbol $\otimes$ stands for the matrix Kronecker product. Finally, given a couple of complex matrices (X,Y) and a matrix

$$T = T' = \begin{bmatrix} t_{00} & t_{10} \\ t'_{10} & t_{11} \end{bmatrix} \in \mathbb{C}^{2\times 2},$$

the expressions $\mathcal{F}_T(X,Y)$ and $\mathcal{G}_T(X,Y)$ are defined by

$$\begin{cases} \mathcal{F}_T(X,Y) = t_{00}XX' + (t_{10}YX')^H + t_{11}YY' \\ \mathcal{G}_T(X,Y) = t_{00}X'X + (t_{10}X'Y)^H + t_{11}Y'Y. \end{cases}$$

2. Motivation. In this section, some results proposed in [3] are first recalled. However, the limits inherent to those techniques are highlighted. That is why the problem initially stated in [3] is presented under a new and more complete formulation.

Consider an uncertain matrix that reads:

$$A_c = A + B\Delta C \in \mathbb{C}^{n\times n}. \tag{1}$$

Matrix Δ is constant, unknown, and assumed to belong to the ball $\mathcal{B}(\rho)$ of all matrices $\Delta \in \mathbb{C}^{q\times r}$ satisfying $||\Delta||_2 \leq \rho$. Matrices $A \in \mathbb{C}^{n\times n}$, $B \in \mathbb{C}^{n\times q}$, and $C \in \mathbb{C}^{r\times n}$ are given. Such a description is referred to as norm-bounded uncertainty [21].

Now consider the next Hermitian matrices:

$$R_k = R'_k = \begin{bmatrix} r_{k_{00}} & r_{k_{10}} \\ r'_{k_{10}} & r_{k_{11}} \end{bmatrix} \in \mathbb{C}^{2\times 2} \quad \forall k \in \{1,\ldots,m\}, \tag{2}$$

from which the following geometric curves are defined:

$$\partial\mathcal{D}_k = \{s \in \mathbb{C} | f_k(s) = \mathcal{F}_{R_k}(1,s) = \mathcal{G}_{R_k}(1,s) = 0\} \quad \forall k \in \{1,\ldots,m\}. \tag{3}$$

Relevant curves are lines or circles which can be nonsymmetric with respect to the real axis. Each curve $\partial\mathcal{D}_k$ enables one to define an associated region:

$$\mathcal{D}_k = \{s \in \mathbb{C} \,|\, f_k(s) < 0\} \quad \forall k \in \{1,\ldots,m\}. \tag{4}$$

Clearly, $\mathcal{D}_k$ denotes either one side or the other side of the boundary $\partial\mathcal{D}_k$. Then it can be a half plane, a disc, or the outside of a disc. It is an open region (i.e., not including $\partial\mathcal{D}_k$) in order to encompass the concept of asymptotic stability for linear time-invariant (LTI) systems.

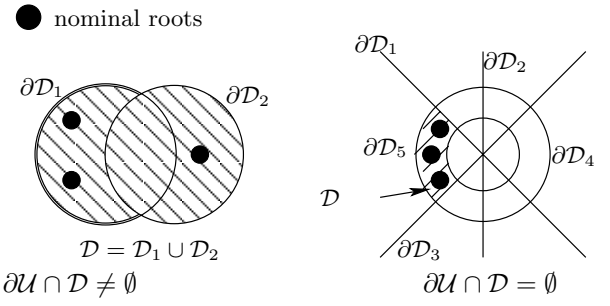

FIG. 1. $\varrho_{\partial\mathcal{U}} = r_{\mathcal{D}}$.

Also define the region $\mathcal{D}$ as a combination, i.e., any union and/or intersection of the various subregions $\mathcal{D}_k$. Such a formulation of $\mathcal{D}$ clearly enables a very large choice of regions.

This contribution aims at computing the complex $\mathcal{D}$-stability radius $r_{\mathcal{D}}$, i.e., the largest value of ρ—the radius of $\mathcal{B}(\rho)$—so that, A being $\mathcal{D}$-stable, A_c defined in (1) remains also $\mathcal{D}$-stable for any $\Delta \in \mathcal{B}(\rho)$. In [3] a technique to derive a lower bound $\rho^\star$ was proposed. This bound may equal the $\mathcal{D}$-stability radius, but it is sometimes conservative. The main result of [3] is now recalled.

THEOREM 1 (see [3]). *Let A_c, $\mathcal{D}$, $\partial\mathcal{D}$ be an uncertain matrix as defined in* (1)*, a clustering region as defined above and its boundary, respectively. Then A_c is robustly $\partial\mathcal{D}$-regular against $\mathcal{B}(\rho)$ if there exist m Hermitian matrices P_k, $k = 1, \ldots, m$, such that*

(5)
$$\mathcal{Q}_k(P_k, \gamma) = \begin{bmatrix} \mathcal{G}_{R_k}(P_k^{1/2}, P_k^{1/2}A) + C'C & r_{k_{10}} P_k B + r_{k_{11}} A' P_k B \\ r'_{k_{10}} B' P_k + r_{k_{11}} B' P_k A & r_{k_{11}} B' P_k B - \gamma \mathbf{I} \end{bmatrix} < 0 \quad \forall k \in \{1, \ldots, m\},$$

where $\gamma = \rho^{-2}$.

In this event, A_c keeps the same number of eigenvalues inside $\mathcal{D}$ for any $\Delta \in \mathcal{B}(\rho)$.

Moreover, if $\partial\mathcal{D}$ can be identified with $\partial\mathcal{U} = \bigcup_{k=1}^{m} \partial\mathcal{D}_k$, then condition (5) *is also necessary.*

To roughly sum up the above theorem and paper [3] in general, one can write that the uncertain matrix A_c defined in (1) is robustly $\mathcal{D}$-stable if the nominal matrix A is $\mathcal{D}$-stable and if A_c is robustly $\partial\mathcal{D}$-regular. The $\partial\mathcal{D}$-regularity of a matrix is simply the nonintersection between its spectrum and the set $\partial\mathcal{D}$. In [3], there are also considerations on the relation between the inertias of matrices P_k and the dispatching of the eigenvalues of A or A_c with respect to the various $\mathcal{D}_k$. But these notions do not need to be developed here. Note that Theorem 1 is deduced from the KYP lemma [26, 23].

The value $\rho^\star$ of ρ, obtained by minimizing γ while satisfying (5), equals $\varrho_{\partial\mathcal{U}}$ (the so-called complex $\partial\mathcal{U}$-regularity radius) which is itself a lower bound of $\varrho_{\partial\mathcal{D}}$ (the complex $\partial\mathcal{D}$-regularity radius). It is shown in [3] that if A is $\mathcal{D}$-stable and if $\partial\mathcal{U} \cap \mathcal{D} = \emptyset$, then $\varrho_{\partial\mathcal{U}}$ actually equals $r_{\mathcal{D}}$, the complex $\mathcal{D}$-stability radius. The $\mathcal{D}$-stability of A is obviously necessary to check the $\mathcal{D}$-stability of A_c but assumption $\partial\mathcal{U} \cap \mathcal{D} = \emptyset$ is not always satisfied; hence the possible conservativeness of Theorem 1. To highlight it, Figure 1 shows both cases: the left side corresponds to $\partial\mathcal{U} \cap \mathcal{D} \neq \emptyset$ so $\varrho_{\partial\mathcal{U}} \leq r_{\mathcal{D}}$, whereas the right side corresponds to $\partial\mathcal{U} \cap \mathcal{D} = \emptyset$ so $\varrho_{\partial\mathcal{U}} = r_{\mathcal{D}}$.

The drawback of Theorem 1 is that no rigorous description of the actual set $\partial\mathcal{D}$ is provided when $\partial\mathcal{U} \cap \mathcal{D} = \emptyset$. For example, on the left side of Figure 1, the parts

of the circles $\partial\mathcal{D}_1$ and $\partial\mathcal{D}_2$ that belong to $\mathcal{D}$ should not be taken into account. This selection of points in $\partial\mathcal{D}_k$ is not made. To remedy this, a new description of $\partial\mathcal{D}$ is now proposed.

Let m curves $\partial\mathcal{D}_k$ be described as in (3). Let the matrices $\Phi_{k,l}$ be defined by

$$\Phi_{k,l} = \begin{bmatrix} \phi_{k,l_{00}} & \phi_{k,l_{10}} \\ \phi'_{k,l_{10}} & \phi_{k,l_{11}} \end{bmatrix} = \Phi'_{k,l} \in \mathbb{C}^{2\times 2}, \quad k = 1,\dots,m,\ l = 1,\dots,p_k. \tag{6}$$

Define m subregions $\bar{\mathcal{E}}_k$ by

$$\bar{\mathcal{E}}_k = \left\{ s \in \mathbb{C} | \mathcal{F}_{\Phi_{k,l}}(1,s) = \mathcal{G}_{\Phi_{k,l}}(1,s) \geq 0 \ \forall l \in \{1,\dots,p_k\} \right\} \ \ \forall k \in \{1,\dots,m\}. \tag{7}$$

Each region $\bar{\mathcal{E}}_k$ is actually the intersection of various closed subregions $\bar{\mathcal{E}}_{k,l}$ characterized by inequalities $\mathcal{G}_{\Phi_{k,l}}(1,s) \geq 0$. Subregions $\bar{\mathcal{E}}_{k,l}$ are half planes, discs, or outsides of discs, not necessarily symmetric. Consider the sets $\partial\Gamma_k$ defined by

$$\partial\Gamma_k = \partial\mathcal{D}_k \cap \bar{\mathcal{E}}_k = \left\{ s \in \mathbb{C} | \mathcal{G}_{R_k}(1,s) = 0, \mathcal{F}_{\Phi_{k,l}}(1,s) \geq 0 \forall l \in \{1,\dots,p_k\} \right\} \tag{8}$$

for all $k \in \{1,\dots,m\}$. Each set $\partial\Gamma_k$ is the intersection of a line or a circle with p_k closed half planes, discs, or outsides of discs. In other words, it is a line or a circle from which only some points are selected through the choice of various $\Phi_{k,l}$. Furthermore, define the set $\partial\mathcal{D}$ as

$$\partial\mathcal{D} = \bigcup_{k=1}^{m} \partial\Gamma_k. \tag{9}$$

If one considers any combination (intersection and/or union) of half planes, discs, and outsides of discs, then its boundary can read formulation (9). For $\mathcal{D}$ as pictured on Figure 1 (left side), the circles $\partial\mathcal{D}_1$ and $\partial\mathcal{D}_2$ can be restricted to the subsets that are not in $\mathcal{D}$, thanks to an appropriate choice of $\Phi_{1,1}$ and $\Phi_{2,1}$ (the first example in section 4 will highlight this assertion). With the description given in (9), the computation of the complex $\mathcal{D}$-stability radius $r_{\mathcal{D}}$ becomes equivalent to that of the complex $\partial\mathcal{D}$-regularity radius $\varrho_{\partial\mathcal{D}}$.

3. Extended KYP lemma and complex $\mathcal{D}$-stability radius. This section is devoted to the computation of $r_{\mathcal{D}}$ through an LMI approach. First, some technical preliminaries are needed. Then, some sort of extended KYP lemma is deduced. Finally, it is shown that this lemma can be directly exploited to solve the stated problem.

3.1. Background and preliminary lemmas. A key point in the present reasoning is that each LMI condition of Theorem 1 enables testing of the robust $\partial\mathcal{D}_k$-regularity of a matrix, whereas it should test the robust $\partial\Gamma_k$-regularity ($\partial\Gamma_k \subset \partial\mathcal{D}_k$, $\forall k$). It is similar to the problem encountered while applying the finite frequency KYP lemma. Such a lemma is proposed in [16] and is proven with the help of the so-called generalized S-procedure. The present paper largely exploits the results provided in [16]. The reader is strongly invited to refer to this paper from which Definition 1 is extracted.

DEFINITION 1 (see [16]). *A subset $\mathcal{S}$ of $n \times n$ Hermitian matrices is said lossless if*

(a) *$\mathcal{S}$ is convex;*

(b) *$S \in \mathcal{S} \Rightarrow \tau S \in \mathcal{S}\ \ \forall \tau > 0$;*

(c) *For each nonzero matrix* $H \in \mathbb{C}^{n\times n}$ *of rank* r *such that*

$$H = H' \geq 0, \quad \mathrm{tr}(SH) \leq 0 \quad \forall S \in \mathcal{S},$$

there exist vectors $\xi_i \in \mathbb{C}^n$, $i = 1, \ldots, r$, *such that*

$$H = \sum_{i=1}^{r} \xi_i \xi_i' \quad \textit{and} \quad \xi_i' S \xi_i \leq 0 \quad \forall S \in \mathcal{S}.$$

The above definition is necessary to apply the so-called generalized S-procedure [16, Theorem 1] implicitly used in forthcoming Theorem 2. This definition and this procedure are not the only borrowings from [16]. Other insights of this discerning paper are exploited in what follows.

LEMMA 1. *Let* W *and* Z *be complex matrices of the same size and* $R \in \mathbb{C}^{2\times 2}$ *be defined by*

$$R = R' = \begin{bmatrix} r_{00} & r_{10} \\ r_{10}' & r_{11} \end{bmatrix}.$$

Then the following statements are equivalent.

(i)

$$\mathcal{F}_R(W, Z) = 0. \tag{10}$$

(ii) *There exists a matrix* E *such that* $Z = WE$ *and*

$$\mathcal{F}_R(\mathbf{I}, E) = 0. \tag{11}$$

Proof. (i)⇒(ii): First assume that $r_{11} = 0$; then from (10)

$$\begin{aligned} r_{00}WW' + r_{10}'WZ' + r_{10}ZW' &= W\left(\frac{1}{2}r_{00}W + r_{10}Z\right)' + \left(\frac{1}{2}r_{00}W + r_{10}Z\right)W' \\ &= WY' + YW' = 0 \end{aligned}$$

with $Y = (\frac{1}{2}r_{00}W + r_{10}Z)$. By virtue of [23, Lemma 3, statement (iii)], this implies the existence of U such that $UU' = \mathbf{I}$ and $Y = W(\mathbf{I} - U)(\mathbf{I} + U)^{-1} = W\bar{U}$. Hence

$$\bar{U} + \bar{U}' = (\mathbf{I} + U')^{-1}\left\{(\mathbf{I} + U')(\mathbf{I} - U) + (\mathbf{I} - U')(\mathbf{I} + U)\right\}(\mathbf{I} + U)^{-1}$$

$$= (\mathbf{I} + U')^{-1}\left\{\mathbf{I} + U' - U - U'U + \mathbf{I} - U' + U - U'U\right\}(\mathbf{I} + U)^{-1} = 0.$$

From $Y = W\bar{U}$, it can be deduced that W and Z comply with

$$W\left(\bar{U} - \frac{1}{2}r_{00}\mathbf{I}\right) = r_{10}Z,$$

which can be written as $Z = WE$ with

$$E = \frac{1}{r_{10}}\left(\bar{U} - \frac{1}{2}r_{00}\mathbf{I}\right) \tag{12}$$

(note that $r_{10} \neq 0$ otherwise W and Z equal 0). Since $\bar{U} + \bar{U}' = 0$,

$$r_{00}\mathbf{I} + r_{10}'E' + r_{10}E = 0 \Leftrightarrow \mathcal{F}_R(\mathbf{I}, E) = 0.$$

Now assume that $r_{11} \neq 0$, then (10) becomes

$$\hat{r}_{00} WW' + \hat{r}'_{10} WZ' + \hat{r}_{10} ZW' + ZZ' = 0$$

with $\hat{r}_{i0} = \dfrac{r_{i0}}{r_{11}}$ for $i = 0, 1$. The previous equation can be rewritten as

$$(Z + \hat{r}'_{10} W)\,(Z + \hat{r}'_{10} W)' = (\hat{r}_{10}\hat{r}'_{10} - \hat{r}_{00})\, WW'$$

from which, by virtue of lemma [23, Lemma 3, statement (i)], one gets

$$Z + \hat{r}'_{10} W = \sqrt{(\hat{r}_{10}\hat{r}'_{10} - \hat{r}_{00})}\, WU$$

for some U such that $UU' = \mathbf{I}$. Finally it leads to $Z = WE$ with

$$E = \left(-\hat{r}'_{10}\mathbf{I} + \sqrt{(\hat{r}_{10}\hat{r}'_{10} - \hat{r}_{00})}\, U \right). \tag{13}$$

It is obvious that E satisfies

$$E + \hat{r}'_{10}\mathbf{I} = \sqrt{(\hat{r}_{10}\hat{r}'_{10} - \hat{r}_{00})}\, U$$

which yields

$$(E + \hat{r}'_{10}\mathbf{I})\,(E + \hat{r}'_{10}\mathbf{I})' = (\hat{r}_{10}\hat{r}'_{10} - \hat{r}_{00})\,\mathbf{I}$$

$$\Leftrightarrow \mathcal{F}_R(\mathbf{I}, E) = 0.$$

To prove (ii)⇒(i), just left- and right-multiply (11) by W and W', respectively, to recover (10). □

An extension of [16, Lemma 2] is now presented.

LEMMA 2. *Let two complex vectors f and $g \neq 0$ be given. Also let $\partial\mathcal{D}$ be defined by* (8) *with $k = m = 1$ (so the dependence of R, P, Φ_l and Q_l on k is omitted). The following statements are equivalent.*

(i) $\exists s \in \partial\mathcal{D} = \partial\Gamma_1 \,|\, f = sg$.

(ii) $$\mathcal{Z} = \begin{bmatrix} g \\ f \end{bmatrix}' \left(R \otimes P - \sum_{l=1}^{p} (\Phi_l \otimes Q_l) \right) \begin{bmatrix} g \\ f \end{bmatrix} \leq 0$$
$$\forall P = P' \text{ and } \forall Q_l = Q'_l > 0,\ l = 1, \ldots, p.$$

Proof.

$$\text{(i)} \Rightarrow \mathcal{Z} = \mathcal{F}_R(1, s) g' P g - \sum_{l=1}^{p} (\mathcal{F}_{\Phi_l}(1, s) g' Q_l g).$$

Since $s \in \partial\Gamma_1$, relations

$$-\sum_{l=1}^{p} (\mathcal{F}_{\Phi_l}(1, s)) \leq 0 \quad \text{and} \quad \mathcal{F}_R(1, s) = 0$$

are satisfied. Besides, since $Q_l > 0\, \forall l \in \{1, \ldots, p\}$, one gets $\mathcal{Z} \leq 0$ and then (ii) is true.

Reciprocally, (ii) $\Rightarrow$

$$\operatorname{tr}\left(\begin{bmatrix} g \\ f \end{bmatrix}\begin{bmatrix} g' & f' \end{bmatrix}\left(R\otimes P-\sum_{l=1}^{p}(\Phi_l\otimes Q_l)\right)\right)\leq 0$$

$$\Leftrightarrow \operatorname{tr}\left(\begin{bmatrix} g \\ f \end{bmatrix}\begin{bmatrix} g' & f' \end{bmatrix}\left[\begin{array}{c|c} r_{00}P-\sum_{l=1}^{p}(\phi_{l_{00}}Q_l) & r_{10}P-\sum_{l=1}^{p}(\phi_{l_{10}}Q_l) \\ \hline r'_{10}P-\sum_{l=1}^{p}(\phi'_{l_{10}}Q_l) & r_{11}P-\sum_{l=1}^{p}(\phi_{l_{11}}Q_l) \end{array}\right]\right)\leq 0$$

$$\Leftrightarrow \operatorname{tr}(\mathcal{F}_R(g,f)P)-\operatorname{tr}\left(\sum_{l=1}^{p}(\mathcal{F}_{\Phi_l}(g,f)Q_l)\right)\leq 0. \tag{14}$$

Clearly, since (14) is true for all $P=P'$ and $Q_l=Q'_l>0$, it holds for any choice $Q_l=w_lI$, $w_l>0$, $l=1,\ldots,p$, and $P=\alpha\mathbf{I}$ with $\alpha>0$ possibly very large. Hence

$$\begin{cases} \mathcal{F}_R(g,f)=0 \\ \displaystyle\sum_{l=1}^{p}(w_l\mathcal{F}_{\Phi_l}(g,f))\geq 0 \quad \forall w_l>0,\ l=1,\ldots,p. \end{cases} \tag{15}$$

From the equality in (15) and Lemma 1, a scalar $s^\bullet\in\partial\mathcal{D}_1$ verfies $f=s^\bullet g$.

Now consider the inequality in (15). Since $f=s^\bullet g$, it comes:

$$\sum_{l=1}^{p}(w_l\mathcal{F}_{\Phi_l}(1,s^\bullet))\geq 0 \quad \forall w_l>0, l=1,\ldots,p.$$

The above inequality holds for any set of $w_l>0$ if and only if $\mathcal{F}_{\Phi_l}(1,s^\bullet)\geq 0$ for all l in $\{1,\ldots,p\}$. Thus, $s^\bullet$ belongs to $\partial\Gamma_1$. □

Now, still inspired from [16], the next lemma is proposed.

LEMMA 3. *Let some matrix R defined in* (2)*, some matrices Φ_l defined in* (6) *(with $k=1$) and a matrix $F\in\mathbb{C}^{2n\times q}$ be given. Also let a subset of Hermitian matrices $\mathcal{S}$ be defined by*

$$\mathcal{S}:=\left\{F'\left(R\otimes P-\sum_{l}^{p}(\Phi_l\otimes Q_l)\right)F\ :\ P=P', Q_l=Q'_l>0, l=1,\ldots,p\right\}. \tag{16}$$

Then $\mathcal{S}$ is lossless.

Proof. Refering to Definition 1, properties (a) and (b) are obvious. For property (c), consider a matrix $H=H'\geq 0$ such that $\operatorname{tr}(HS)\leq 0\,\forall S\in\mathcal{S}$ and $H=GG'$, where $G\in\mathbb{C}^{q\times r}$ is of rank r. One gets:

$$\operatorname{tr}\left(GG'F'\left(R\otimes P-\sum_{l}^{p}(\Phi_l\otimes Q_l)\right)F\right)\leq 0 \quad \forall\, P=P', Q_l=Q'_l>0$$

$$\Leftrightarrow \operatorname{tr}\left(FGG'F'\left(R\otimes P-\sum_{l=1}^{p}(\Phi_l\otimes Q_l)\right)\right)\leq 0 \quad \forall\, P=P', Q_l=Q'_l>0. \tag{17}$$

Define matrices W and Z by

$$\begin{bmatrix} W \\ Z \end{bmatrix} = FG. \tag{18}$$

Thus, inequality (17) can be written

$$\begin{aligned} &\operatorname{tr}\left(\begin{bmatrix} W \\ Z \end{bmatrix}\begin{bmatrix} W \\ Z \end{bmatrix}'\left(R\otimes P - \sum_{l=1}^{p}(\Phi_l\otimes Q_l)\right)\right) \\ &= \operatorname{tr}\left(\begin{bmatrix} WW' & WZ' \\ ZW & ZZ' \end{bmatrix}'\left(R\otimes P - \sum_{l=1}^{p}(\Phi_l\otimes Q_l)\right)\right) \\ &= \operatorname{tr}\left(\begin{bmatrix} WW' & WZ' \\ ZW' & ZZ' \end{bmatrix}(R\otimes P)\right) - \operatorname{tr}\left(\sum_{l=1}^{p}\left(\begin{bmatrix} WW' & WZ' \\ ZW' & ZZ' \end{bmatrix}(\Phi_l\otimes Q_l)\right)\right) \le 0 \end{aligned}$$

$\forall\, P = P', Q_l = Q_l' > 0.$

As in the proof of Lemma 2, it can be deduced that

$$\begin{cases} \mathcal{F}_R(W,Z) = 0 \\ \displaystyle\sum_{l=1}^{p}(w_l\mathcal{F}_{\Phi_l}(W,Z)) \ge 0 \quad \forall w_l > 0,\ \ l = 1,\dots,p. \end{cases} \tag{19}$$

From Lemma 1 and from the equality in (19), there exists some matrix E such that

$$Z = WE \tag{20}$$

and

$$\mathcal{F}_R(\mathbf{I}, E) = 0. \tag{21}$$

Such a matrix E is given by either (12) and (13). Since U satisfies $UU' = \mathbf{I}$, it is easy to check that it has no eigenvalue with geometric multiplicity greater than 1. Then it can be written

$$U = V\Lambda_U V^{-1},$$

where V is a modal matrix and Λ_U is diagonal. Matrix $\bar{U}$ involved in (12) complies with

$$\bar{U} = V(\mathbf{I} - \Lambda_U)(\mathbf{I} + \Lambda_U)^{-1}V^{-1}$$

so it has a similar diagonal form. Expressions (12) and (13) enable one to check that E has also a similar diagonal form with V as a modal matrix. Thus let r vectors v_i, $i = 1,\dots,r$, be the columns of V; one can write the definition of the right eingenstructure of E as follows:

$$Ev_i = \lambda_i v_i,\ \lambda_i \in \mathbb{C} \quad \forall i \in \{1,\dots,r\}.$$

The eigenvectors v_i can be chosen as the orthonormal basis of a subspace of dimension r so that $\sum_{i=1}^{r}(v_i v_i') = \mathbf{I}$. Then, inequality (21) yields

$$v_i'\mathcal{F}_R(I,E)v_i = \mathcal{F}_R(1,\lambda_i)v_i'v_i = 0 \quad \forall i \in \{1,\dots,r\}. \tag{22}$$

The above equality proves that each λ_i belongs to $\partial\mathcal{D}_1$ characterized by R.

Besides, from the inequality given in (19), relation (20) enables one to write:

$$v_i' \left(\sum_{l=1}^{p} (w_l \mathcal{F}_{\Phi_l}(W, WE)) \right) v_i$$

$$= \left(\sum_{l=1}^{p} (w_l \mathcal{F}_{\Phi_l}(1, \lambda_i)) \right) (v_i' W W' v_i) \geq 0 \quad \forall i \in \{1, \dots, r\},\ \forall w_l > 0,\, l = 1, \dots p$$

$$\Rightarrow \sum_{l=1}^{p} (w_l \mathcal{F}_{\Phi_l}(1, \lambda_i)) \geq 0 \quad \forall i \in \{1, \dots, r\},\ \forall w_l > 0,\, l = 1, \dots p$$

$$\Rightarrow \mathcal{F}_{\Phi_l}(1, \lambda_i) \geq 0 \quad \forall l = 1, \dots p. \tag{23}$$

The above inequality proves that each $\lambda_i \in \partial\mathcal{D}_1$ belongs to $\bar{\mathcal{E}}_1$ and therefore to $\partial\Gamma_1$.

The remaining part of the proof is analogous to the one in [16, Lemma 3]. The sum and the Kronecker product in the expressions of $\mathcal{F}_R$ and $\mathcal{F}_{\Phi_l}$ are no real obstacles and bring only slight modifications. ∎

3.2. Extended KYP lemma. Now that the set $\mathcal{S}$ is proved to be lossless, an appropriate application of the generalized S-procedure [16, Theorem 1] enables us to state the next theorem which might be considered as the main result of the paper.

THEOREM 2. *Let $\partial\mathcal{D} = \partial\Gamma_1$ be defined by (8) ($k = m = 1$ so the dependence of R, P, Φ_l and Q_l on k is still omitted). Also let matrices $A \in \mathbb{C}^{n\times n}$, $B \in \mathbb{C}^{n\times q}$ and $\Theta = \Theta' \in \mathbb{C}^{(n+m)\times(n+m)}$ be given. Assume that A is $\partial\mathcal{D}$-regular. Then the following statements are equivalent.*

(i)

$$\begin{bmatrix} (s\mathbf{I} - A)^{-1} B \\ \mathbf{I} \end{bmatrix}' \Theta \begin{bmatrix} (s\mathbf{I} - A)^{-1} B \\ \mathbf{I} \end{bmatrix} < 0 \quad \forall s \in \partial\mathcal{D}. \tag{24}$$

(ii) *There exist $n \times n$ complex Hermitian matrices P and $Q_l = Q_l > 0$, $l = 1, \dots, p$, such that*

$$\begin{bmatrix} \mathbf{I} & 0 \\ A & B \end{bmatrix}' \left(R \otimes P + \sum_{l=1}^{p} (\Phi_l \otimes Q_l) \right) \begin{bmatrix} \mathbf{I} & 0 \\ A & B \end{bmatrix} + \Theta < 0. \tag{25}$$

Proof. The proof is similar to the one of the finite frequency KYP lemma proposed in [16]. However, an outline is proposed for clarity.

Statement (i) is equivalent to $\zeta'\Theta\zeta < 0\ \forall \zeta \in \mathcal{G}$, where

$$\mathcal{G} = \left\{ \zeta = \begin{bmatrix} x \\ y \end{bmatrix} \in \mathbb{C}^{n+m} \,|\, y \neq 0, sx = Ax + By \text{ for some } s \in \partial\mathcal{D} \right\}.$$

Note that with $F = \begin{bmatrix} \mathbf{I} & 0 \\ A & B \end{bmatrix}$ and by virtue of Lemma 2, the set $\mathcal{G}$ complies with

$$\mathcal{G} = \left\{ \zeta \in \mathbb{C}^{n+m} \,|\, \zeta \neq 0,\ \zeta' S \zeta \leq 0\ \forall S \in \mathcal{S} \right\},$$

where $\mathcal{S}$ is defined in (16). Since it is lossless from Lemma 3, the generalized S-procedure [16] can be applied to prove that there exists $S \in \mathcal{S}$ such that $\Theta < S$ which is equivalent to (ii). ∎

Remark 1. The assumption of $\partial\mathcal{D}$-regularity of A is necessary to ensure that $(sI - A)^{-1}$ exists. However, by virtue of the results of [3] related to the inertia of P, this assumption can be omitted when applying the theorem for the implication (ii) ⇒ (i).

For special applications of this theorem, the following cases can be considered:

(a) $p=1$, $R=\begin{bmatrix} 0 & 1 \\ 1 & 0 \end{bmatrix}$, $\Phi_1=0$;

(b) $p=1$, $R=\begin{bmatrix} -1 & 0 \\ 0 & 1 \end{bmatrix}$, $\Phi_1=0$;

(c) $p=1$, $R=\begin{bmatrix} 0 & 1 \\ 1 & 0 \end{bmatrix}$, $\Phi_1=\begin{bmatrix} -1 & 0 \\ 0 & \omega_0^2 \end{bmatrix}$.

Cases (a) and (b) correspond to the continuous-time and discrete-time versions of the well-known KYP lemma [26, 23]. Case (c) corresponds to the so-called finite frequency KYP lemma proposed in [16]. It is not surprising since, as already mentioned, a part of this paper is based on ideas borrowed from [16]. Note that a recent paper [15] generalizes the results in [16]. The reader is strongly advised to refer to this article. In comparison with [16, 15], the present contribution is mostly the involvement of the sum in (25), i.e., the possibility to consider several sets $\bar{\mathcal{E}}_{k,l}$ (i.e., $p>1$).

3.3. Application to the computation of $r_{\mathcal{D}}$. Theorem 2 is now exploited to solve the stated problem.

THEOREM 3. *Let A_c, $\mathcal{D}$, $\partial\mathcal{D}$ be an uncertain matrix as defined in* (1)*, a clustering region and its boundary that reads definition* (9)*, respectively. Assume that A is $\partial\mathcal{D}$-regular. Then A_c is robustly $\partial\mathcal{D}$-regular against $\mathcal{B}(\rho)$ if there exist m Hermitian matrices P_k and positive definite Hermitian matrices $Q_{k,l}$, $k=1,\dots,m$ and $l=1,\dots,p_k$, such that*

(26)
$$\begin{bmatrix} \mathbf{I} & 0 \\ A & B \end{bmatrix}' \left(R_k \otimes P_k + \sum_{l=1}^{p_k} (\Phi_{k,l} \otimes Q_{k,l}) \right) \begin{bmatrix} \mathbf{I} & 0 \\ A & B \end{bmatrix} + \begin{bmatrix} C'C & 0 \\ 0 & -\gamma\mathbf{I} \end{bmatrix} < 0 \ \forall k \in \{1,\dots,m\},$$

where $\gamma=\rho^{-2}$.

Moreover, if A is assumed to be $\mathcal{D}$-stable then A_c remains $\mathcal{D}$-stable over $\mathcal{B}(\rho)$.

Proof. Inequality (26) corresponds to statement (ii) in Theorem 2 with some special choice of Θ and with respect to all sub-boundaries $\partial\Gamma_k$, $k=1,\dots,m$. Equivalent statement (i) holds, i.e.,

$$\Leftrightarrow ||C(s\mathbf{I}-A)^{-1}B||_2 < \sqrt{\gamma} = \rho^{-1} \quad \forall s \in \partial\Gamma_k.$$

At this stage, arguments similar to those in [22, 3] conclude the proof. ∎

Any LMI solver can reach $\rho^\star$, the maximum value of $\rho=(\sqrt{\gamma})^{-1}$ under LMI constraint (26), and then

$$\rho^\star = \varrho_{\partial\mathcal{D}} = \min_{k=1,\dots,m} \varrho_{\partial\Gamma_k}. \tag{27}$$

Furthermore, if A is $\mathcal{D}$-stable, then one gets $\rho^\star = r_{\mathcal{D}}$.

4. Examples.

4.1. First example. This simple example highlights the improvement in comparison with [3]. Consider (1) with

$$A=\begin{bmatrix} -1.1388 & 1.8993 \\ -2.5882 & -2.8612 \end{bmatrix}, \quad B=C=\mathbf{I}.$$

The nominal spectrum is $\lambda(A)=\{-2.5;-1.5\}$. Region $\mathcal{D}$ is the union of two intersecting open discs $\mathcal{D}_1$ and $\mathcal{D}_2$ centered around the eigenvalues of A and both of

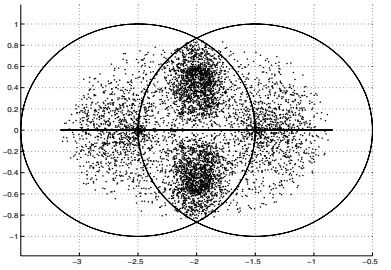

FIG. 2. *Root-locus perturbed with acceptable uncertainties.*

radius 1. Thus, A is $\mathcal{D}$-stable but is both $\partial\mathcal{D}_1$-singular and $\partial\mathcal{D}_2$-singular. That is why LMI condition (5) is found *infeasible*. The reason is that the parts of $\partial\mathcal{D}_1$ and $\partial\mathcal{D}_2$ that belong to $\mathcal{D}$ cannot be excluded before the $\partial\mathcal{D}$-regularity test is achieved. In the present work, one can consider, firstly, $\partial\mathcal{D}_1$ intersecting the outside of $\mathcal{D}_2$ and, secondly, $\partial\mathcal{D}_2$ intersecting the outside of $\mathcal{D}_1$. Then one can apply Theorem 3. It leads to the actual value of the complex $\mathcal{D}$-stability radius:

$$\rho^\star = \varrho_{\partial\mathcal{D}} = r_{\mathcal{D}} = 0.39212.$$

Five hundred instances of uncertainties Δ checking $||\Delta||_2 \leq r_{\mathcal{D}}$ are generated using standard Matlab function `rand`. The associated uncertain root-locus is plotted in Figure 2.

4.2. Second example. Before this example is detailed, it is important to notice that Theorem 2 can be used for various purposes different from pole placement analysis. For instance, assume that A is Hurwitz-stable and that matrix Θ involved in Theorem 2 is

$$\Theta = \begin{bmatrix} C'C & D'C \\ D'C & D'D - \gamma\mathbf{I} \end{bmatrix}.$$

Then, Theorem 2 becomes an extension of the well-known LMI version of the bounded real lemma [1] dedicated to the computation of the $\mathcal{H}_\infty$-norm of a linear model. Indeed, this $\mathcal{H}_\infty$-norm is nothing else than $\sqrt{\gamma}$. In this case, since A is Hurwitz-stable, P is positive definite.

To illustrate the possibilities offered by Theorem 2, a simple SISO model is considered:

$$A = \begin{bmatrix} -1.5000 & -1.0100\times10^4 & -1.50050\times10^4 & -1.0000\times10^6 \\ 1.0000 & 0.0000 & 0.0000 & 0.0000 \\ 0.0000 & 1.0000 & 0.0000 & 0.0000 \\ 0.0000 & 0.0000 & 1.0000 & 0.0000 \end{bmatrix}; \quad B = \begin{bmatrix} 1 \\ 0 \\ 0 \\ 0 \end{bmatrix};$$

$$C = \begin{bmatrix} 0 & 0 & 0 & 10^6 \end{bmatrix}.$$

This realization actually corresponds to the transfer function

$$G(s) = \frac{1}{(1+0.01s+0.01s^2)(1+5\times10^{-5}s+10^{-4}s^2)},$$

which shows that there are two peaks of magnitude in the frequency response, one at $\omega_1 = 10rad/s$ and the other one at $\omega_2 = 100rad/s$. Theorem 2 will be used to analyze

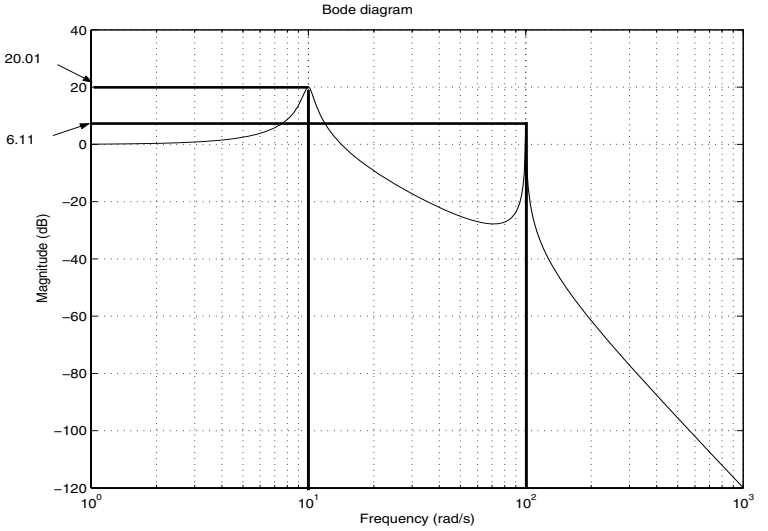

FIG. 3. *Bode diagram of the model.*

the magnitude of $G(s)$ in low frequencies, and around the peaks. The principle consists of considering the imaginary axis as the only curve $\partial\mathcal{D}_1$. To select frequencies, one can make a discerning choice of subregions $\bar{\mathcal{E}}_k$. Several tests are achieved.

(a) The static gain is obtained by considering only one region $\bar{\mathcal{E}}_1$ which is the disc centered around the origin with a radius 0.0001. Then, Theorem 2 corresponds to the finite frequency KYP lemma [16] and here yields

$$\gamma \simeq 1.0000 \Rightarrow T = 20\log(\sqrt{\gamma}) = 3.4375 \times 10^{-6} dB.$$

(b) The magnitude of the first peak is found by considering $\bar{\mathcal{E}}_1$ as the disc centered around $10\mathbf{i}$ with a radius 1. The result is

$$\gamma = 1.0228 \times 10^2 \Rightarrow T = 20\log(\sqrt{\gamma}) = 20.098 dB.$$

The same value is reached when no region $\bar{\mathcal{E}}_k$ is considered since in that case Theorem 2 is reduced to the classical bounded real lemma and the $\mathcal{H}_\infty$-norm is $\sqrt{\gamma} = 10.11$.

(c) The magnitude of the second peak is analyzed with the disc $\bar{\mathcal{E}}_1$ centered around $100\mathbf{i}$ with a radius 10. It leads to

$$\gamma = 4.0881 \Rightarrow T = 20\log(\sqrt{\gamma}) = 6.1077 dB.$$

(d) Both peaks can be analyzed together. One can consider $\bar{\mathcal{E}}_1$ as the intersection of two subregions $\bar{\mathcal{E}}_{1,1}$ and $\bar{\mathcal{E}}_{1,2}$. Here, $\bar{\mathcal{E}}_{1,1}$ is chosen as the disc centered around $55\mathbf{i}$ with a radius 47 while $\bar{\mathcal{E}}_{1,2}$ is chosen as the outside of the disc centered around $55\mathbf{i}$ with a radius 43. Of course the highest magnitude due to the first peak is recovered, i.e., $20.098dB$.

To check the above results, the Bode diagram is given in Figure 3.

5. Conclusions. In this paper, a technique is proposed to compute the complex $\mathcal{D}$-stability radius when $\mathcal{D}$ is a combination (intersection and/or union) of open half planes, discs, and outsides of discs. This point was already addressed in [3] but

an overlap of various subregions could lead to a conservative value. In the present contribution, the inconvenient is circumvented. This is made possible by the use of some extension of the KYP lemma. Such a lemma was deduced by considering insightful results of [16], particularly its generalized S-procedure. This procedure appears to be a catalyst for many future works. The reading of [16] and the more recent paper [15] is highly recommended.

As possible further investigations, the case where A, B and C are affected by polytopic uncertainty could be tackled using the matrix elimination lemma [24, Theorem 2.3.12]. Both the application of this approach in a design context and its possible exploitation for model reduction are a challenge.

ERRATA: ELIMINATION OF STRICT CONVERGENCE IN OPTIMIZATION*

DUŠAN BEDNAŘÍK† AND KAREL PASTOR‡

Abstract. We revise our previous paper [*SIAM J. Control Optim.*, 43 (2004), pp. 1063–1077]. We supply an assumption missing in the first part of the assertion of Corollary 4.6, and we prove that the second part of this corollary remains true also under conditions given in the previous paper. Finally, we comment on new contributions and pose the open question in the topic.

Key words. generalized second-order directional derivative, second-order optimality conditions, minimal cusco mapping

AMS subject classifications. 49K35, 26B02, 54C60

DOI. 10.1137/050636309

1. Introduction and preliminaries. In [BP1] we studied the generalized second-order directional derivatives to obtain sufficient and necessary optimality conditions, which we compare with the previous results.

Let X be a real Banach space with the norm $\|\cdot\|$, let X^* be the topological dual space of X, and let $\langle x^*, x\rangle$ be a canonical pair, where $x^* \in X^*$, $x \in X$. S_X denotes the set $\{x \in X : \|x\| = 1\}$.

For a function $f : X \to \mathbb{R}$, we denote the first-order directional derivative of f at $x \in X$ in the direction $v \in X$ by

$$f'(x; v) = \lim_{t \downarrow 0} \frac{f(x + tv) - f(x)}{t}$$

and the lower and upper Clarke directional derivatives of f at $x \in X$ in the direction $v \in X$, respectively, by

$$f_\circ(x; v) = \liminf_{y \to x, t \downarrow 0} \frac{f(y + tv) - f(y)}{t},$$

$$f^\circ(x; v) = \limsup_{y \to x, t \downarrow 0} \frac{f(y + tv) - f(y)}{t}.$$

The Cominetti–Correa [CC] lower and upper generalized second-order directional derivatives of f at x in the direction $(u, v) \in X \times X$ are defined, respectively, by

$$f_\infty(x; u, v) = \liminf_{y \to x,\ s,t \downarrow 0} \frac{f(y + tu + sv) - f(y + tu) - f(y + sv) + f(y)}{st},$$

$$f^\infty(x; u, v) = \limsup_{y \to x,\ s,t \downarrow 0} \frac{f(y + tu + sv) - f(y + tu) - f(y + sv) + f(y)}{st}.$$

We note that for a set-valued mapping $F : \mathbb{R} \rightsquigarrow \mathbb{R}$, it is a natural to denote

$$\liminf_{t\downarrow 0} F(t) = \liminf_{t\downarrow 0} \inf\{a : a \in F(t)\},$$

etc. Then, we define

$$f'^{L}(x;u,v) = \liminf_{t\downarrow 0} \frac{\langle \partial_c f(x+tu) - \partial_c f(x), v\rangle}{t},$$
$$f'^{U}(x;u,v) = \limsup_{t\downarrow 0} \frac{\langle \partial_c f(x+tu) - \partial_c f(x), v\rangle}{t},$$

where f is Lipschitz near $x \in X$, $(u,v) \in X \times X$ and $\partial_c f(x)$ stands for the Clarke subdifferential [Cl] at x defined by

$$\partial_c f(x) = \{x^* \in X^* : \langle x^*, v\rangle \le f^\circ(x;v) \quad \forall v \in X\}.$$

Finally, for a function which is directonally differentiable, we denote

$$f'^{l}(x;u,v) = \liminf_{t\downarrow 0} \frac{f'(x+tu;v) - f'(x;v)}{t},$$
$$f'^{u}(x;u,v) = \limsup_{t\downarrow 0} \frac{f'(x+tu;v) - f'(x;v)}{t}.$$

Let us recall that a locally Lipschitz function $f : X \mapsto \mathbb{R}$ is said to be regular at $x \in X$ provided that $f'(x;v) = f^\circ(x;v)$ for every $v \in X$. If we say that f is regularly locally Lipschitz function on a subset $A \subset X$, we mean that f is locally Lipschitz on A and regular at every point $x \in A$. Further f is said to be regularly locally Lipschitz near $x \in X$ if f is regularly locally Lipschitz function on some neighborhood of x. If f is assumed to be regularly locally Lipschitz on the whole space X, we simply say that f is regularly locally Lipschitz function.

PROPOSITION 1.1 (see [BP1, Proposition 4.4]). *Let $f : X \mapsto \mathbb{R}$ be a regularly locally Lipschitz function, $x, h \in X$. Then*

$$f'^{L}(x;h,h) = f'^{l}(x;h,h).$$

Because it holds [CC] for f to be directionally differentiable,

$$f_\infty(x;u,v) = \liminf_{y\to x, t\downarrow 0} \frac{f'(y+tu;v) - f'(y;v)}{t},$$

and

$$f^\infty(x;u,v) = \limsup_{y\to x, t\downarrow 0} \frac{f'(y+tu;v) - f'(y;v)}{t},$$

Proposition 1.1 implies the following corollary.

COROLLARY 1.2 (see [BP1, Corollary 4.5]). *Let $f : X \mapsto \mathbb{R}$ be a regularly locally Lipschitz function, $x, h \in X$. Then*

$$f_\infty(x;h,h) \le f'^{L}(x;h,h).$$

Since f can be a regularly locally Lipschitz function, but $(-f)$ cannot, we cannot derive (as we unfortunately did in [BP1, Corollary 4.6]) from Proposition 1.1 by using

lim inf and lim sup calculus that $f'^U(x;h,h) = f'^u(x;h,h)$ and that $f^\infty(x;h,h) \geq f'^U(x;h,h)$. By this way, we can state only the next corollary.

COROLLARY 1.3. *Let $f : X \mapsto \mathbb{R}$ be such function that $(-f)$ is regularly locally Lipschitz, and let $x, h \in X$. Then*

$$f'^U(x;h,h) = f'^u(x;h,h),$$

$$f^\infty(x;h,h) \geq f'^U(x;h,h). \tag{1.1}$$

It follows from definitions that for regularly locally Lipschitz functions we have $f'^u(x;h,h) \leq f'^U(x;h,h)$, but the equality is not true—for example, considering a function $f : \mathbb{R} \mapsto \mathbb{R} : f(x) = |x|$; then $f'^u(0;1,1) = 0 < +\infty = f'^U(0;1,1)$.

Our mistake in [BP1] mentioned above and [BP1, Theorem 6.4] lead to the conclusion that the condition $f'^u(x;h,h) \geq 0$ for every $h \in S_X$ is necessary for x to be a local minimum of a regularly locally Lipschitz function f. As we show by the following example, this conclusion is false.

Example 1.4. Let $f : \mathbb{R} \mapsto \mathbb{R}$ be a function defined as follows:

$$f(x) = \begin{cases} lnx & \text{for } x \geq 1, \\ 0 & \text{for } x < 1. \end{cases}$$

Then f attains a local minimum at 1, and f is regularly locally Lipschitz. On the other hand, because $f'(x;1) = \frac{1}{x}$ for every $x \geq 1$, it holds

$$f'^u(1;1,1) = \limsup_{t \downarrow 0} \frac{\frac{1}{1+t} - 1}{t} = -1.$$

2. Main result. The main aim of this paper is to show that inequality (1.1) from Corollary 1.3 is really true also for regularly locally Lipschitz functions.

For the proof we use some properties of minimal cusco mappings. A set-valued mapping F from a topological space A into nonempty subsets of a Hausdorff locally convex space Y is called cusco if $F(t)$ is compact and convex for each $t \in A$ and F is upper-semicontinuous (i.e., $\{t \in A : F(t) \subset U\}$ is an open subset for each open subset U of Y).

Furthermore, F is said to be *minimal cusco* on A if its graph does not contain the graph of any other cusco on A. The Clarke subdifferential of a regularly locally Lipchitz function [Mo] or maximal monotone operator (see, e.g., [Ph]) are the well-known examples of minimal cusco mappings.

The following lemma is a particular case of a more general result given in [J, Corollary 4.1].

LEMMA 2.1. *Let $D \subset \mathbb{R}$ be an open set, and let $F : D \rightsquigarrow \mathbb{R}$ be minimal cusco. Then the set $\{x \in D : F$ is single-valued at $x\}$ is dense in D.*

LEMMA 2.2 (see [BM, Theorem 3.7]). *For a cusco mapping Φ, from a topological space A into subsets of a separated locally convex topological space X, the following conditions are equivalent:*

(i) *Φ is a minimal cusco on A.*

(ii) *For any densely defined selection σ of Φ, $CSC(\sigma) = \Phi$,*

$$CSC(\sigma)(x) = \bigcap \{\overline{co}\ \sigma(V) : V \text{ is open neighborhood of } x\}.$$

By the analogous way as in the lemma near 2.3.7 in [Cl], we can obtain the following.

LEMMA 2.3. *Let $f : X \mapsto \mathbb{R}$ be a regularly locally Lipschitz function on an open subset containing the line segment $[x, y]$. Then the function $g : [0, 1] \mapsto \mathbb{R}$ defined by $g(t) = f(x + t(y - x))$ is regularly locally Lipschitz on $(0, 1)$, and we have*

$$\partial_c g(t) = \langle \partial_c f(x + t(y - x)), y - x \rangle.$$

THEOREM 2.4. *Let $f : X \mapsto \mathbb{R}$ be a regularly locally Lipschitz function near $x \in X$ and let $h \in S_X$. Then*

$$f'^U(x; h, h) \le f^\infty(x; h, h).$$

Proof. Since

$$f^\circ(x; v) = \max\{\langle x^*, v\rangle; x^* \in \partial_c f(x)\}, \quad f_\circ(x; v) = \min\{\langle x^*, v\rangle, x^* \in \partial_c f(x)\},$$

it holds

$$f'^U(x; h, h) = \limsup_{t \downarrow 0} \frac{f^\circ(x + th; h) - f_\circ(x; h)}{t}.$$

Let $\lambda \in \mathbb{R}$ be such that

$$\lambda < f'^U(x; h, h).$$

Then there exists a sequence $\{t_n\}_{n=1}^{+\infty}$, $t_n > 0$, $\lim_{n\to+\infty} t_n = 0$, with the property

$$\lambda < \frac{f^\circ(x + t_n h; h) - f_\circ(x; h)}{t_n} \quad \forall n \in \mathbb{N}. \tag{2.1}$$

Due to Lemma 2.3, the graph of multivalued mapping $F : \{x + th; t \in \mathbb{R}\} \rightsquigarrow \mathbb{R} : z \rightsquigarrow \langle \partial_c f(z), h\rangle$ is the same as the graph of multivalued mapping $\partial_c g$, where $g : \mathbb{R} \mapsto \mathbb{R} : g(t) = f(x + th)$ is regularly locally Lipschitz function.

Since multivalued mapping $\partial_c g$ is minimal cusco, Lemma 2.1 implies that multivalued mapping F is single-valued on the dense subset of $\{x + th; t \in \mathbb{R}\}$. Thus we can take a densely defined selection σ of F with the property

$$\sigma(z) = f^\circ(z; h) = f_\circ(z; h), \quad z \in D(\sigma), \tag{2.2}$$

where $D(\sigma)$ denotes the domain of σ. Now, for every $n \in \mathbb{N}$, there exists a sequence $\{t_n^k\}_{k=1}^{+\infty}$ such that $F(x + t_n^k h) = \sigma(x + t_n^k h)$, $\lim_{k\to+\infty} t_n^k = t_n$ and $\lim_{k\to+\infty} f^\circ(x + t_n^k h) = f^\circ(x + t_n h)$, because considering a densely defined selection σ_n of F, where

$$\sigma_n(z) = \begin{cases} \sigma(z) & \text{for every } z \in D(\sigma), \\ f^\circ(x + t_n h) & \text{for } z = x + t_n h, \end{cases}$$

it suffices to use Lemma 2.2.

Following inequality (2.1), we can find $k(n) \in \mathbb{N}$ for every $n \in \mathbb{N}$ such that

$$\lambda < \frac{f^\circ(x + t_n^{k(n)} h; h) - f_\circ(x; h)}{t_n^{k(n)}}. \tag{2.3}$$

Using (2.2), it holds

$$f^\circ(x + t_n^{k(n)} h; h) = \lim_{y \to x, s \downarrow 0} \frac{f(y + t_n^{k(n)} h + sh) - f(y + t_n^{k(n)} h)}{s}. \tag{2.4}$$

There exist sequences $\{y_l\}_{l=1}^{+\infty}$ and $\{s_l\}_{l=1}^{+\infty}$, $\lim_{l\to+\infty} y_l = x$, $s_l > 0$, $\lim_{l\to+\infty} s_l = 0$, with the property

$$f_\circ(x;h) = \liminf_{y\to x, s\downarrow 0} \frac{f(y+sh)-f(y)}{s} = \lim_{l\to+\infty} \frac{f(y_l+s_l h)-f(y_l)}{s_l}. \tag{2.5}$$

From formulas (2.3), (2.4), and (2.5), we obtain for every $n \in \mathbb{N}$

$$\lambda < \frac{\lim_{l\to+\infty} \frac{f(y_l+t_n^{k(n)}h+s_l h)-f(y_l+t_n^{k(n)}h)}{s_l} - \lim_{l\to+\infty} \frac{f(y_l+s_l h)-f(y_l)}{s_l}}{t_n^{k(n)}}.$$

Hence,

$$\lambda < \frac{\lim_{l\to+\infty} \frac{f(y_l+t_n^{k(n)}h+s_l h)-f(y_l+t_n^{k(n)}h)-f(y_l+s_l h)+f(y_l)}{s_l}}{t_n^{k(n)}} \quad \forall n \in \mathbb{N}.$$

Thus, for every $n \in \mathbb{N}$, we can find $y_{l(n)} \in X$ and $s_{l(n)} > 0$ such that it holds

$$\lambda < \frac{f(y_{l(n)}+t_n^{k(n)}h+s_{l(n)}h)-f(y_{l(n)}+t_n^{k(n)}h)-f(y_{l(n)}+s_{l(n)}h)+f(y_{l(n)})}{s_{l(n)}t_n^{k(n)}}.$$

Setting $t_n = t_n^{k(n)}$, $y_n = y_{l(n)}$, and $s_n = s_{l(n)}$, for every $n \in \mathbb{N}$, we have

$$\lambda < \frac{f(y_n+t_n h+s_n h)-f(y_n+t_n h)-f(y_n+s_n h)+f(y_n)}{s_n t_n}.$$

Limiting $n \to +\infty$, we obtain

$$\lambda \le \limsup_{n\to+\infty} \frac{f(y_n+t_n h+s_n h)-f(y_n+t_n h)-f(y_n+s_n h)+f(y_n)}{s_n t_n} \le f^\infty(x;h,h).$$

Because λ was arbitrary with the property $\lambda < f'^U(x;h,h)$, it holds

$$f'^U(x;h,h) \le f^\infty(x;h,h). \qquad \square$$

3. Final remarks and open question. In this section, we mention the progress in this topic since the paper [BP1] and set an open question.

Motivated by [GGR], in [BP2] we have generalized the second-order sufficient unconstrained optimality conditions [BZ, Theorem 3.2], [GGR, Theorem 2], [BP1, Theorem 3.2], and [CC, Proposition 5.2] by the following way.

THEOREM 3.1 (see [BP2, Theorem 7]). *Let $f : \mathbb{R}^N \mapsto \mathbb{R}$ be continuous near $x \in \mathbb{R}^N$ and let be ℓ-stable at x. If $f^\ell(x;h) = 0$ for every $h \in S_{\mathbb{R}^N}$, and*

$$\underline{f}'^l_P(x;h) > 0 \quad \forall h \in S_{\mathbb{R}^N},$$

then x is an isolated minimizer of order 2 for f.

In the previous theorem,

$$f^l(x;h) = \liminf_{t\downarrow 0} \frac{f(x+th)-f(x)}{t},$$
$$\underline{f}'^l_P(x;h) = \liminf_{t\downarrow 0} \frac{f(x+th)-f(x)-tf^\ell(x;h)}{t^2/2}.$$

By ℓ-stability of f at x we mean that for some neighborhood U of x and $K > 0$ it holds

$$|f^\ell(y;h) - f^\ell(x;h)| \le K\|y - x\| \quad \forall y \in U, \forall h \in S_X. \tag{3.1}$$

Finally, recall that $x \in X$ is an isolated minimizer of order k ($k \in \mathbb{N}$) for a function $f : X \mapsto \mathbb{R}$ if there are a neighborhood V of x and $A > 0$ satisfying $f(y) \ge f(x)+A\|y-x\|^k$ for every $y \in V$.

Open question. Let $\overline{\ell}$-stability of f at x means that for some neighborhood U of x and $K > 0$ it holds

$$|f^\ell(z; z-y) - f^\ell(y; z-y)| \le K\|z-y\|^2 \quad \forall y, z \in U.$$

It seems that the notions of ℓ-stability and $\overline{\ell}$-stability are quite different (really?) and there arises the question whether we can replace the condition to be ℓ-stable by the condition to be $\overline{\ell}$-stable in Theorem 3.1.

ON THE GEOMETRY OF THE SOLUTIONS OF THE COVER PROBLEM*

F. PUERTA†, X. PUERTA†, AND I. ZABALLA‡

Abstract. For a given system $\Sigma(A, B)$ and a subspace $\mathcal{S}$, the cover problem consists of finding all (A, B)-invariant subspaces containing $\mathcal{S}$. For controllable systems, the set of these subspaces can be suitably stratified. In this paper, necessary and sufficient conditions are given for the cover problem to have a solution on a given strata. Then the geometry of these solutions is studied. In particular, the set of the solutions is provided with a differentiable structure and a parameterization of all solutions is obtained through a coordinate atlas of the corresponding smooth manifold.

Key words. cover problem, controlled invariant subspace, smooth manifold, coordinate chart, Brunovsky indices

1. Introduction.

Given a time-invariant linear system

$$\dot{x}(t) = Ax(t) + Bu(t)$$

with A, B, $n \times n$, and $n \times m$ matrices, respectively, a subspace $\mathcal{V}$ of $\mathbb{K}^n$ ($\mathbb{K}$ is both the field of real or complex numbers) is said to be controlled invariant with respect to (A, B) or, simply, (A, B)-invariant, if $A\mathcal{V} \subset \mathcal{V} + \operatorname{Im} B$ (see, for example, [3]).

For a given subspace $\mathcal{S}$ of $\mathbb{K}^n$, the cover problem associated to the above system consists of finding all (A, B)-invariant subspaces $\mathcal{V}$ such that $\mathcal{S} \subset \mathcal{V}$. A number of important problems are related to the cover problem. For instance, the *disturbance decoupling problem* (DDP) calls for a state feedback transformation such that an output $y(t) = Cx(t)$ of the closed-loop system does not depend on an input disturbance given by $Qv(t)$. As shown in, for example, [11, Th. 4.2] this is possible if and only if $\operatorname{Im} Q \subset \mathcal{V}^* = \max \mathcal{V}(A, B, \ker C)$, the maximal (A, B)-invariant subspace contained in $\operatorname{Ker} C$. Very nice and efficient algorithms are known in order to compute subspace $\mathcal{V}^*$ (see, for example, [11, 3]). In this paper we are interested in computing not only $\mathcal{V}^*$ but all (A, B)-invariant subspaces containing a given subspace. In fact, important questions concerning this kind of subspace, as, for example, robustness with regard to matrix Q, lead us to the problem of parameterizing the set of solutions of this cover problem. Moreover, some other important problems, like the *observer* and *model-matching* problems, are related to the cover problem (see [1]) as well. Actually, as said by Antoulas in that paper, "The cover problems provide a unifying framework for the solution of a number of important feedforward as well as feedback problems in linear system theory."

Antoulas' paper is one of the main contributions to the solution of the cover problem. Antoulas links together the cover problem and the nice partial realization problem providing, through the last one, a parameterization of the solutions. Our approach is based on considering the dual problem. We recall that $\mathcal{V}$ is a conditioned invariant subspace with regard to (C, A) or, simply, a (C, A)-invariant subspace, if $A(\mathcal{V} \cap \operatorname{Ker} C) \subset \mathcal{V}$. By dualilty, $\mathcal{V}$ is (A, B)-invariant if and only if $\mathcal{V}^{\perp}$ is (B^t, A^t)-invariant. Therefore, the map $\mathcal{V} \mapsto \mathcal{V}^{\perp}$ defines a bijection between the solutions of the cover problem of dimension d, with respect to a pair (A, B) and a subspace $\mathcal{S}$, and the set of (B^t, A^t)-invariant subspaces of $\mathcal{S}^{\perp}$ of codimension d. For a give pair (C, A), the problem of parameterizing the set of δ-dimensional (C, A)-invariant subspaces will be called the *dual cover problem*. Of course, the cover problem and the dual one are equivalent. In this note we focus on the last one due to the following interpretation of its solutions. We denote by $Gr_{\delta}(\mathcal{S})$ the Grassmann manifold formed by the δ-dimensional subspaces of $\mathcal{S}$. Then, the set of solutions of the dual cover problem is just the intersection of $Gr_{\delta}(\mathcal{S})$ with the set of δ-dimensional (C, A)-invariant subspaces, which is an stratified manifold as shown in [5]. Our goal here is to gain insight into the parameterization of the solutions of the (dual) cover problem, through the parameterization of the strata of the set of δ-dimensional (C, A)-invariant subspaces given in [6].

A natural requirement in many problems for which the cover problem is a generalization is that of stability. Different approaches can be taken to this issue. For example, for the DDP with stability, the approaches in [11] and [3] are different. In the first one, the solution is connected to the maximal internally stabilizable (A, B)-invariant subspace, while in the second one the minimal (A, B)-invariant subspace self-bounded with respect to $\operatorname{Ker} C$ is considered. Even more general situations can be considered, like, for example, the DDP with pole placement. It is shown in [10] that a necessary and sufficient condition for this problem to be solvable is that (A, B) be controllable and $\operatorname{Im} Q \subset \mathcal{R}^*$, where $\mathcal{R}^*$ is the maximal (A, B)-controllability subspace contained in $\operatorname{Ker} C$. Among other, possibly better known, characterizations, the controllability subspaces can be defined as those (A, B)-invariant subspaces for which the restriction of (A, B) to the subspace is completely controllable (see [6]). The set of controllability susbspaces is also a stratified manifold [6] and for each strata a coordinate atlas that locally parameterizes them has been obtained [8]. This parameterization eventually could be used to study the geometry of the cover problem with pole placement, but it must be said that the differentiable structure of the (A, B)-controllability subspaces is more complicated than that of the (C, A)-invariant ones.

Throughout this note, $\mathcal{M}_{m,n}$ denotes the set of $m \times n$ matrices with elements in $\mathbb{K}$, $\mathcal{M}_n$, the set of the $n \times n$-square ones and $\mathcal{M}^*_{m,n}$, the subset of the full column rank $m \times n$ matrices. If $X \in \mathcal{M}^*_{m,n}$, then $[X]$ denotes the subspace spanned by the columns of X. Finally, if $X \in \mathcal{M}_{m,n}$, $X^* \in \mathcal{M}_{n,m}$ is its conjugate transpose.

The structure of this paper is as follows. In section 2 we recall the parameterization of the set of (C, A)-invariant subspaces given in [7]. In section 3 we describe the solutions of the (dual) cover problem in terms of the solution of a set of algebraic linear equations on the parameters of the mentioned parameterization. From this description we derive explicit necessary and sufficient conditions for the (dual) cover problem to have a solution with given observability indices (Theorem 3.4). In section 4 we prove a simple necessary and sufficient condition in order to ensure that the above conditions are satisfied *generically* (Theorem 4.9). In addition, for the generic case and if the observability indices of the restriction are not required, we give an easy-to-check necessary and sufficient condition for the (dual) cover problem to have

a solution. In section 5 we provide an example of application of the previous results: we propose an algorithm which implements these results to parameterize the output matrices C for which $y = Cx$ can be made insensitive to the input disturbance. In section 6 we show that the set of solutions of the cover problem is a stratified smooth manifold with an orbit space structure similar to the set of (C, A)-invariant subspaces and we compute its dimension (Theorem 6.1). Finally we parameterize this manifold by means of coordinate charts (Theorem 6.9) and we prove that it is connected.

2. Preliminaries. Throughout this note (C, A) is an observable pair of matrices of $\mathcal{M}_{m,n} \times \mathcal{M}_n$ with observability indices $\underline{k} = (k_1, \ldots, k_r)$ which, without loss of generality, we can assume is in the dual Brunovsky canonical form (see [2, Lem. 4.4]).

In this section we recall the results on the differentiable structure and parameterization of the strata of the set of (C, A)-invariant subspaces that we use in the next sections. These strata are defined by fixing specific Brunovsky form for the restriction of (C, A) to the (C, A)-invariant subspaces (see [5] and [7] for more details and proofs). More precisely, we fix a set of indices $\underline{h} = (h_1, \ldots, h_s)$ of a possible restriction of (C, A) (we call $\underline{h}$ *compatible* with $\underline{k}$), which is any finite set of integers with the condition $h_i \leq k_i$ for $i = 1, 2, \ldots, s$. The parameterization of the set of (C, A)-invariant subspaces for which the restriction of (C, A) to them has indices $\underline{h}$ is simpler if it is refered to the dual partitions. So, let the conjugate partitions of $\underline{k}$ and $\underline{h}$ be $\underline{r} = (r_1, \ldots, r_k)$ and $\underline{s} = (s_1, \ldots, s_h)$, respectively, with $r = r_1 \geq \cdots \geq r_k > 0$ and $s = s_1 \geq \cdots \geq s_h > 0$. (Recall that if $\underline{k} = (k_1, k_2, \ldots)$, then $\underline{r} = (r_1, r_2, \ldots)$ is its conjugate partition if and only if $r_j = \#\{i : k_i \geq j\}$, where # stands for cardinality.) From now on we will assume that $s_i := 0$ for $i > h$, $r_i := 0$ for $i > k$, $h_i := 0$ for $i > s$, and $k_i := 0$ for $i > r$. If $(k_1, \ldots, k_r)$ are the observability indices of (C, A), then $(r_1, \ldots, r_k)$ are called the *Brunovsky indices* of (C, A) (see [4]).

Notice that $k_i \geq h_i$ for $i = 1, 2, \ldots, r$ if and only if $r_i \geq s_i$ for $i = 1, 2, \ldots, k$. In other words, $\underline{h}$ and $\underline{k}$ are compatible if and only if $\underline{s}$ and $\underline{r}$ are compatible. In what follows we also assume that $\underline{s}$ and $\underline{r}$ are compatible partitions and we denote by $\mathrm{Inv}\,(\underline{r}, \underline{s})$ the set of (C, A)-conditioned invariant subspaces for which the restriction of (C, A) to each one of them has Brunovsky indices $\underline{s}$.

DEFINITION 2.1. *Let $\mathcal{M}(\underline{r}, \underline{s})$ denote the set of matrices $X \in \mathcal{M}_{n,d}$ which are partitioned into blocks $X = (X_{ij})$, $1 \leq i \leq k$, $1 \leq j \leq h$, such that*

(a) $X_{ij} \in \mathcal{M}_{r_i, s_j}$.

(b) $X_{ij} = 0$ *if* $i < j$.

(c) *If $i \geq j$, X_{ij} can be partitioned into blocks $X_{ij} = (Z_{i\alpha}^{i-j+1})$, $1 \leq \alpha \leq h - j + 1$, where*

$$Z_{i\alpha}^{i-j+1} = \begin{pmatrix} Y_{i\alpha}^{i-j+1} \\ 0 \end{pmatrix}$$

with $Y_{i\alpha}^{i-j+1}$ having size $r_{h-\alpha+i-j+1} \times (s_{h-\alpha+1} - s_{h-\alpha+2})$. That is to say, X_{ij} is a block upper triangular matrix with blocks of sizes $(r_i - r_{i+1}) \times (s_i - s_{i+1})$ (if $r_i = r_{i+1}$ or $s_i = s_{i+1}$, the correspondig block vanishes). We call this block decomposition the standard *block decomposition of X_{ij}.*

(d) *$X_{i+1,j+1}$ is obtained from X_{ij} by removing the last $s_j - s_{j+1}$ columns and the last $r_i - r_{i+1}$ rows (the last column and row blocks) for $1 \leq i \leq k$, $1 \leq j \leq h$.*

(e) $\operatorname{rank} X_{ii} = s_i$, $1 \leq i \leq k$.

We denote by $\mathcal{G}(\underline{s})$ the set $\mathcal{M}(\underline{s}, \underline{s})$, which turns out to be a subgroup of $\mathrm{Gl}(n)$.

Example 2.2. If $k = 4$ and $h = 3$, the elements of $\mathcal{M}(\underline{r}, \underline{s})$ and $\mathcal{G}(\underline{s})$ are, respectively, matrices having the form displayed in the following matrices:

$$\begin{array}{l} r_4 \\ r_3 - r_4 \\ r_2 - r_3 \\ r_1 - r_2 \\ r_4 \\ r_3 - r_4 \\ r_2 - r_3 \\ r_4 \\ r_3 - r_4 \\ r_4 \end{array} \left(\begin{array}{ccc|cc|c} X_{11}^1 & X_{12}^1 & X_{13}^1 & & & \\ X_{21}^1 & X_{22}^1 & X_{23}^1 & & & \\ 0 & X_{32}^1 & X_{33}^1 & \multicolumn{2}{c|}{\mathbf{0}} & \mathbf{0} \\ 0 & 0 & X_{43}^1 & & & \\ \hline X_{11}^2 & X_{12}^2 & X_{13}^2 & X_{11}^1 & X_{12}^1 & \\ 0 & X_{22}^2 & X_{23}^2 & X_{21}^1 & X_{22}^1 & \mathbf{0} \\ 0 & 0 & X_{33}^2 & 0 & X_{32}^1 & \\ \hline 0 & X_{12}^3 & X_{13}^3 & X_{11}^2 & X_{12}^2 & X_{11}^1 \\ 0 & 0 & X_{23}^3 & 0 & X_{22}^2 & X_{21}^1 \\ \hline 0 & 0 & X_{13}^4 & 0 & X_{12}^3 & X_{11}^2 \end{array}\right),$$

$$\begin{array}{l} s_3 \\ s_2 - s_3 \\ s_1 - s_2 \\ s_3 \\ s_2 - s_3 \\ s_3 \end{array} \left(\begin{array}{ccc|cc|c} T_{11}^1 & T_{12}^1 & T_{13}^1 & & & \\ 0 & T_{22}^1 & T_{23}^1 & \multicolumn{2}{c|}{\mathbf{0}} & \mathbf{0} \\ 0 & 0 & T_{33}^1 & & & \\ \hline 0 & T_{12}^2 & T_{13}^2 & T_{11}^1 & T_{12}^1 & \\ 0 & 0 & T_{23}^2 & 0 & T_{22}^1 & \mathbf{0} \\ \hline 0 & 0 & T_{13}^3 & 0 & T_{12}^2 & T_{11}^1 \end{array}\right).$$

Notice that $\operatorname{rank} X_{ii} = s_i$ if and only if $\operatorname{rank} X_{11} = s_1$.

The description of Inv $(\underline{r}, \underline{s})$ as a smooth manifold is given in the next theorem, whose items are proved in [5] and [6].

THEOREM 2.3. *With the notation of Definition* 2.1,

1. $\mathcal{G}(\underline{s})$ *is a subgroup of* $\mathrm{Gl}(\mathbb{K}^d)$.
2. $\mathcal{G}(\underline{s})$ *acts freely on* $\mathcal{M}(\underline{r}, \underline{s})$ *on the right by matrix multiplication.*
3. *If* $X \in \mathcal{M}(\underline{r}, \underline{s})$, $T \in \mathrm{Gl}(\mathbb{K}^d)$, *and* $XT \in \mathcal{M}(\underline{r}, \underline{s})$, *then* $T \in \mathcal{G}(\underline{s})$.
4. *The orbit space* $\mathcal{M}(\underline{r}, \underline{s})/\mathcal{G}(\underline{s})$ *has a differentiable structure such that the natural projection of* $\mathcal{M}(\underline{r}, \underline{s})$ *on it is a submersion.*

There is a natural bijection between Inv $(\underline{r}, \underline{s})$ and $\mathcal{M}(\underline{r}, \underline{s})/\mathcal{G}(\underline{s})$ given by

$$\begin{array}{ccc} \mathcal{M}(\underline{r}, \underline{s})/\mathcal{G}(\underline{s}) & \longrightarrow & \text{Inv } (\underline{r}, \underline{s}), \\ \{XP | X \in \mathcal{M}(\underline{r}, \underline{s}), P \in \mathcal{G}(\underline{s})\} & \rightsquigarrow & [X]. \end{array}$$

(In other words, every (C, A)-conditioned invariant subspace with $\underline{s}$ as Brunovsky indices for the restriction is spanned by the columns of a matrix in $\mathcal{M}(\underline{r}, \underline{s})$ and vice versa.) We consider in Inv $(\underline{r}; \underline{s})$ the differentiable structure defined through this bijection.

COROLLARY 2.4. *If for* $j = 1, \ldots, h$, $m_j = s_j - s_{j+1}$, *then*

$$\dim \text{Inv } (\underline{r}, \underline{s}) = \sum_{i=1}^{h} \sum_{j=1}^{k} m_i (r_{i+j-1} - s_{i+j-1}).$$

The parameterization of Inv $(\underline{r}, \underline{s})$ is based on the construction of a canonical element of each orbit of $\mathcal{M}(\underline{r}, \underline{s})/\mathcal{G}(\underline{s})$. The following definition and proposition deal with such canonical form.

DEFINITION 2.5. *A matrix* $Y \in \mathcal{M}(\underline{r}, \underline{s})$ *is said to be in* reduced *form if there exists a set of pairwise different positive integers* $\underline{n} = \{n_{ij}, 1 \le i \le h, 1 \le j \le m_{h-i+1}\}$ *such that for* $i = 1, 2, \ldots, h$

$$1 \le n_{i1} < n_{i2} < \cdots < n_{im_{h-i+1}} \le r_{h-i+1}$$

and Y can be partitioned into blocks $Y = (Y_{ij})$, $1 \le i \le k$, $1 \le j \le h$, satisfying the following conditions:

1. $Y_{ij} \in \mathcal{M}_{r_i, s_j}$.
2. $Y_{ij} = 0$ *if* $i < j$.
3. *For $i = 1, 2, \dots, h$, Y_{ii} can be partitioned into blocks $Y_{ii} = (L^1_{i\beta})$, $1 \le \beta \le h - i + 1$, in such a way that for $\beta = 1, 2, \dots, h - i + 1$, $L^1_{i\beta} \in \mathcal{M}_{r_i, m_{h-\beta+1}}$ is a matrix whose last $r_i - r_{h-\beta+1}$ rows are zero, the rows n_{ij}, $1 \le i \le \beta - 1$, $1 \le j \le m_{h-i+1}$ are also zero, and the rows $n_{\beta 1}, n_{\beta 2}, \dots, n_{\beta m_{h-\beta+1}}$ are unit vectors $e^\beta_1, e^\beta_2, \dots, e^\beta_{m_{h-\beta+1}}$:*

$$e^\beta_j = (0 \dots 0 \overset{(j}{1} 0 \dots 0) \in \mathbb{K}^{m_{h-\beta+1}}.$$

4. *For $i > j$, Y_{ij} can be partitioned into blocks $Y_{ij} = (L^{i-j+1}_{i\beta})$, $1 \le \beta \le h - j + 1$, in such a way that $L^{i-j+1}_{i\beta} \in \mathcal{M}_{r_i, m_{h-\beta+1}}$ is a matrix whose last $r_i - r_{h-\beta+i-j+1}$ rows are zero and for $\beta \ge i-j+1$, the rows n_{pq}, $1 \le p \le \beta - i + j$, $1 \le q \le m_{h-p+1}$ are also zero. (Note that the entries of Y_{ij} are prescribed by the entries of $Y_{i-j+1,1}$).*
5. *The number of parameters of Y coincide with the dimension of* Inv $(\underline{r}, \underline{s})$.

PROPOSITION 2.6. *For every $X \in \mathcal{M}(\underline{r}, \underline{s})$ there exists a matrix $P \in \mathcal{G}(\underline{s})$ such that XP is a matrix in reduced form. Then, the set of integers $\underline{n}$ is called an* admissible set of indices *for X and XP a* reduced form *of X.*

Example 2.7. Let $k = 4$, $h = 3$, $\underline{r} = (5, 3, 2, 1)$ and $\underline{s} = (3, 3, 1)$. A matrix $X \in \mathcal{M}(\underline{r}, \underline{s})$ has the form

$$\left(\begin{array}{ccc|ccc|c} x_1 & y_1 & y_2 & & & & \\ x_2 & y_3 & y_4 & & & & \\ 0 & y_5 & y_6 & & \mathbf{0} & & \mathbf{0} \\ 0 & 0 & 0 & & & & \\ 0 & 0 & 0 & & & & \\ \hline z_1 & t_1 & t_2 & x_1 & y_1 & y_2 & \\ 0 & t_3 & t_4 & x_2 & y_3 & y_4 & \mathbf{0} \\ 0 & 0 & 0 & 0 & y_5 & y_6 & \\ \hline 0 & u_1 & u_2 & z_1 & t_1 & t_2 & x_1 \\ 0 & 0 & 0 & 0 & t_3 & t_4 & x_2 \\ \hline 0 & 0 & 0 & 0 & u_1 & u_2 & z_1 \end{array}\right).$$

Then, the only possible reduced forms are

$$\left(\begin{array}{ccc|ccc|c} 1 & 0 & 0 & & & & \\ x & 1 & 0 & & \mathbf{0} & & \mathbf{0} \\ 0 & 0 & 1 & & & & \\ 0 & 0 & 0 & & & & \\ 0 & 0 & 0 & & & & \\ \hline y & 0 & 0 & 1 & 0 & 0 & \\ 0 & z & t & x & 1 & 0 & \mathbf{0} \\ 0 & 0 & 0 & 0 & 0 & 1 & \\ \hline 0 & u & v & y & 0 & 0 & 1 \\ 0 & 0 & 0 & 0 & z & t & x \\ \hline 0 & 0 & 0 & 0 & u & v & y \end{array}\right) \text{ and } \left(\begin{array}{ccc|ccc|c} 1 & 0 & 0 & & & & \\ x & 1 & 0 & & \mathbf{0} & & \mathbf{0} \\ 0 & 0 & 1 & & & & \\ 0 & 0 & 0 & & & & \\ 0 & 0 & 0 & & & & \\ \hline y & 0 & 0 & 1 & 0 & 0 & \\ 0 & z & t & x & 1 & 0 & \mathbf{0} \\ 0 & 0 & 0 & 0 & 0 & 1 & \\ \hline 0 & u & v & y & 0 & 0 & 1 \\ 0 & 0 & 0 & 0 & z & t & x \\ \hline 0 & 0 & 0 & 0 & u & v & y \end{array}\right),$$

corresponding to the indices $n_{11} = 1$, $n_{21} = 2$, $n_{22} = 3$ (if $x_1 \neq 0$) and $n_{11} = 2$, $n_{21} = 1$, $n_{22} = 3$ (if $x_2 \neq 0$), respectively.

The admissible set of indices for X depends only on the block X_{11} and completely determines the structure of the reduced form Y. However, they are not uniquely determined by X_{11}; that is to say, several sets may be admissible for the same matrix. In fact, $1 \leq n_{11} < n_{12} < \cdots < n_{1s_h} \leq r_h$ are s_h linearly independent rows of the matrix

$$\begin{pmatrix} X^1_{11} \\ X^1_{21} \\ \vdots \\ X^1_{k-h+1,1} \end{pmatrix},$$

$1 \leq n_{11} < n_{12} < \cdots < n_{1s_h} \leq r_h$, $1 \leq n_{21} < n_{22} < \cdots < n_{2s_{h-1}-s_h} \leq r_{h-1}$ are s_{h-1} linearly independent rows of

$$\begin{pmatrix} X^1_{11} & X^1_{12} \\ X^1_{21} & X^1_{22} \\ \vdots & \vdots \\ X^1_{k-h+1,1} & X^1_{k-h+1,2} \\ 0 & X^1_{k-h+2,2} \end{pmatrix},$$

and so on. Of course, there may be several different ways of choosing these linear independent rows.

PROPOSITION 2.8. (i) *Let $X \in \mathcal{M}(\underline{r}, \underline{s})$ and $Q \in \mathcal{G}(\underline{s})$. If $\underline{n}$ is an admissible set of indices for X, it is also an admissible set of indices for XQ.*

(ii) *Let Y and $\overline{Y}$ be matrices of $\mathcal{M}(\underline{r}, \underline{s})$ in reduced form with the same set of indices $\underline{n}$. If there is a matrix $P \in \mathcal{G}(\underline{s})$ such that $\overline{Y} = YP$, then $Y = \overline{Y}$.*

In other words, once an admissible set of indices (i.e., linearly independent rows in the (1,1)-block) of $X \in \mathcal{M}(\underline{r}, \underline{s})$ has been fixed, the reduced form, Y, of X is unique and the free parameters of Y completely parameterizes the (C, A)-invariant subspace $[X]$. This parameterization can be used to provide the differentiable manifold Inv $(\underline{r}, \underline{s})$ with a coordinate atlas (for details see [7]).

The above proposition shows that all bases of the same (C, A)-invariant subspace have the same admissible set of indices.

DEFINITION 2.9. *Given a (C, A)-invariant subspace $\mathcal{V}$, a multi-index of $\mathcal{V}$ is any admissible set of indices for any matrix $X \in \mathcal{M}(\underline{r}, \underline{s})$ such that $\mathcal{V} = [X]$.*

3. The set of solutions of the (dual) cover problem. Let $\mathcal{S}$ be a subspace of $\mathbb{K}^n$ of codimension $d \leq n$, which is fixed along this note. Let $F \in \mathcal{M}^*_{d,n}$ such that $\mathcal{S} = \text{Ker}F$ or, equivalently, $[F^*] = \mathcal{S}^\perp$. Given $\delta \leq d$ and $X \in \mathcal{M}^*_{n,\delta}$, $[X] \subset \mathcal{S}$ if and only if $FX = 0$. So, the solutions of the (dual) cover problem are given by the set of matrices $X \in \mathcal{M}(\underline{r}, \underline{s})$ such that $FX = 0$ for each partition $\underline{s}$ compatible with $\underline{r}$. The rest of this section is devoted to study the compatibility of these linear algebraic systems.

Let $X \in \mathcal{M}(\underline{r}, \underline{s})$ and put $X^j = (X_{ij})_{1 \leq i \leq k}$, $j = 1, \ldots, h$. For $i = 1, 2, \ldots, h$ let X_i denote the submatrix of X whose jth column block is the ith column block of X^j.

For example, for the matrix in Example 2.2 we would have

$$X_1 = \left(\begin{array}{c|c|c} X_{11}^1 & & \\ X_{21}^1 & \mathbf{0} & \mathbf{0} \\ 0 & & \\ 0 & & \\ \hline X_{11}^2 & X_{11}^1 & \\ 0 & X_{21}^1 & \mathbf{0} \\ 0 & 0 & \\ \hline 0 & X_{11}^2 & X_{11}^1 \\ 0 & 0 & X_{21}^1 \\ \hline 0 & 0 & X_{11}^2 \end{array}\right), \quad X_2 = \left(\begin{array}{c|c} X_{12}^1 & \\ X_{22}^1 & \mathbf{0} \\ X_{32}^1 & \\ 0 & \\ \hline X_{12}^2 & X_{12}^1 \\ X_{22}^2 & X_{22}^1 \\ 0 & X_{32}^1 \\ \hline X_{12}^3 & X_{12}^2 \\ 0 & X_{22}^2 \\ \hline 0 & X_{12}^3 \end{array}\right), \quad X_3 = \left(\begin{array}{c} X_{13}^1 \\ X_{23}^1 \\ X_{33}^1 \\ X_{43}^1 \\ \hline X_{13}^2 \\ X_{23}^2 \\ X_{33}^2 \\ \hline X_{13}^3 \\ X_{23}^3 \\ \hline X_{13}^4 \end{array}\right).$$

Also put

$$R_j^i = \begin{pmatrix} X_{1j}^i \\ X_{2j}^i \\ \vdots \\ X_{k-h-i+j+1,j}^i \end{pmatrix}, \quad j = 1, \ldots, h, \quad i = 1, \ldots, k-h+j,$$

and

$$R_j = \begin{pmatrix} R_j^1 \\ R_j^2 \\ \vdots \\ R_j^{k-h+j} \end{pmatrix}, \quad j = 1, \ldots, h.$$

R_j is of size $(r_{h-j+1}+\cdots+r_k)\times(s_{h-j+1}-s_{h-j+2})$ and will be said to be the *condensed form* of X_j, $j = 1, \ldots, h$. Also the sequence of all these matrices $(R_1, \ldots, R_h)$ will be called the *condensed form* of X. Notice that by knowing the condensed form of X we can easily reconstruct $X \in \mathcal{M}(\underline{r}, \underline{s})$. (The information about $\underline{r}$ and $\underline{s}$ is contained in the condensed form).

In the previous example,

$$R_1^1 = \begin{pmatrix} X_{11}^1 \\ X_{21}^1 \end{pmatrix}, \quad R_1^2 = X_{11}^2, \quad R_1 = \begin{pmatrix} R_1^1 \\ R_1^2 \end{pmatrix} = \left(\begin{array}{c} X_{11}^1 \\ X_{21}^1 \\ \hline X_{11}^2 \end{array}\right),$$

$$R_2^1 = \begin{pmatrix} X_{12}^1 \\ X_{22}^1 \\ X_{32}^1 \end{pmatrix}, \quad R_2^2 = \begin{pmatrix} X_{12}^2 \\ X_{22}^2 \end{pmatrix}, \quad R_2^3 = X_{12}^3, \quad R_2 = \left(\begin{array}{c} X_{12}^1 \\ X_{22}^1 \\ X_{32}^1 \\ \hline X_{12}^2 \\ X_{22}^2 \\ \hline X_{12}^3 \end{array}\right),$$

etc.

The (1,1)-block of X, X_{11} will be also denoted by R:

$$R := \left(\begin{array}{c|c|c|c} R_1^1 & R_2^1 & \cdots & R_h^1 \\ \hline \mathbf{0} & \mathbf{0} & & \end{array}\right) = \left(\begin{array}{c|c|c|c} X_{11}^1 & X_{12}^1 & & X_{1h}^1 \\ X_{21}^1 & X_{22}^1 & & X_{2h}^1 \\ \vdots & \vdots & & \vdots \\ X_{k-h+1,1}^1 & X_{k-h+1,2}^1 & \cdots & X_{k-h+1,h}^1 \\ \hline \mathbf{0} & X_{k-h+2,2}^1 & & X_{k-h+2,h}^1 \\ & \mathbf{0} & & \vdots \\ & & & \vdots \\ & & & X_{k,h}^1 \end{array}\right). \tag{3.1}$$

Now we split the columns of F according to the sizes of the row blocks of X:

$$F = \left(\begin{array}{c|c|c|c|c} F_{11} \quad F_{12} \quad \cdots \quad F_{1k} & F_{21} \quad F_{22} \quad \cdots \quad F_{2,k-1} & \cdots & F_{k-1,1} \quad F_{k-1,2} & F_{k1} \end{array}\right)$$

with F_{ij} of size $d \times (r_{k-j+1} - r_{k-j+2})$, $i = 1, \ldots, k$, $j = 1, \ldots k-i+1$.

Now, $FX = 0$ if and only if $FX_j = 0$ for $j = 1, \ldots, h$. In these homogeneous linear equations the unknown matrix X_j has some repeated entries and other ones must be compulsory zero. However, with the help of the matrices R_j we can avoid these inconveniences. We introduce the following notation. For $\alpha = 1, \ldots, k$ and $\beta = 1, \ldots k-\alpha+1$ let

$$H(\alpha, \beta) = \left(\begin{array}{c} F_{\alpha,1} \; F_{\alpha,2} \; \cdots \; F_{\alpha,\beta} \end{array}\right) \in \mathcal{M}_{d, r_{k-\beta+1}},$$

and for $j = 1, \ldots, h$ let

$$H_j = \begin{pmatrix} H(1, k-j+1) & H(2, k-j) & \cdots & H(k-j+1, 1) \\ H(2, k-j+1) & H(3, k-j) & \cdots & H(k-j+2, 1) \\ \vdots & \vdots & \cdots & \vdots \\ H(j, k-j+1) & H(j+1, k-j) & \cdots & H(k, 1) \end{pmatrix}.$$

Thus H_j is of size $jd \times (r_j + r_{j+1} + \cdots + r_k)$. Notice that this matrix is a kind of truncated block Hankel matrix. In fact

$$H(2, k-j+1) = \left(\begin{array}{c} H(2, k-j) \; F_{2,k-j+1} \end{array}\right),$$
$$H(3, k-j) = \left(\begin{array}{c} H(3, k-j-1) \; F_{3,k-j} \end{array}\right),$$

and so on.

Matrices $H_1, \ldots, H_h$ depend only on the selected basis for $\mathcal{S}^\perp$ and the Brunovsky structure of (C, A). We say that $(H_1, \ldots, H_h)$ is the *block-Hankel structure* associated to F, or *a* block-Hankel structure of $\mathcal{S}$, with regard to (C, A). (Notice that $H_1 = F$).

Now it is easily computed that $FX_j = 0$ for $j = 1, \ldots, h$ if and only if

$$H_{h-j+1} R_j = 0, \quad j = 1, \ldots, h.$$

As said above, the advantage of this expression is that all elements of R_j can be seen as arbitrary unknowns in the open set defined by the condition $\operatorname{rank} R = s_1$.

Following with our example we have that

$$F = \left(\begin{array}{c|c|c|c|c} F_{11} \quad F_{12} \quad F_{13} \quad F_{14} & F_{21} \quad F_{22} \quad F_{23} & F_{31} \quad F_{32} & F_{41} \end{array}\right)$$

and $FX = 0$ if and only if

$$H_3R_1 = \left(\begin{array}{ccc|c} F_{11} & F_{12} & F_{21} & \\ F_{21} & F_{22} & F_{31} & \\ F_{31} & F_{32} & F_{41} & \end{array}\right) \left(\begin{array}{c} X_{11}^1 \\ X_{21}^1 \\ \hline X_{11}^2 \end{array}\right) = 0,$$

$$H_2R_2 = \left(\begin{array}{ccc|cc|c} F_{11} & F_{12} & F_{13} & F_{21} & F_{22} & F_{31} \\ F_{21} & F_{22} & F_{23} & F_{31} & F_{32} & F_{41} \end{array}\right) \left(\begin{array}{c} X_{12}^1 \\ X_{22}^1 \\ X_{32}^1 \\ \hline X_{12}^2 \\ X_{22}^2 \\ \hline X_{12}^3 \end{array}\right) = 0,$$

$$H_1R_3 = \left(\begin{array}{cccc|ccc|ccc|c} F_{11} & F_{12} & F_{13} & F_{14} & F_{21} & F_{22} & F_{23} & F_{31} & F_{32} & F_{41} \end{array}\right) \left(\begin{array}{c} X_{13}^1 \\ X_{23}^1 \\ X_{33}^1 \\ X_{43}^1 \\ \hline X_{13}^2 \\ X_{23}^2 \\ X_{33}^2 \\ \hline X_{13}^3 \\ X_{23}^3 \\ \hline X_{13}^4 \end{array}\right) = 0.$$

As a conclusion we have the following result, whose proof is immediate.

PROPOSITION 3.1. *With the above notation there is a matrix $X \in \mathcal{M}(\underline{r}, \underline{s})$ such that $FX = 0$ if and only if there are matrices $R_1, \ldots, R_h$ such that $H_{h-j+1}R_j = 0$, $j = 1, \ldots, h$, and* $\operatorname{rank} R = s_1$.

Thus the existence of solutions for the cover problem is reduced to the compatibility of a finite number of homogeneous linear equations with the additional restriction $\operatorname{rank} R = s_1$. In what follows we aim to give a more explicit condition with the help of the reduced form introduced in Definition 2.5.

First we pay attention to matrices H_j that form a block-Hankel structure of the subspace $\mathcal{S}$. Let $t_j = \operatorname{rank} H_j$, $j = 1, \ldots, h$. In particular $t_1 = \operatorname{rank} H_1 = \operatorname{rank} F = d$.

DEFINITION 3.2. *An increasing sequence of positive integers $1 \le \ell_1^j < \cdots < \ell_{t_j}^j \le r_j + \cdots + r_k$ is said to be a multi-index for H_j if columns $\ell_1^j, \ldots, \ell_{t_j}^j$ are linearly independent.*

PROPOSITION 3.3. *Let $F, G \in \mathcal{M}_{d,n}^*$ be matrices such that $[F^*] = [G^*] = \mathcal{S}^\perp$. Let $(H_1, \ldots, H_h)$ and $(G_1, \ldots, G_h)$ be two block-Hankel structures associated to F and G (with regard to (C, A)), respectively. Then* $\operatorname{rank} H_j = \operatorname{rank} G_j$ *and $(\ell_1^j, \ldots, \ell_{t_j}^j)$ is a multi-index for H_j if and only if it is a multi-index for G_j, $j = 1, \ldots, h$.*

Proof. In fact $[F^*] = [G^*] = \mathcal{S}^\perp$ if and only if there is an invertible matrix $P \in \mathcal{M}_d^*$ such that $G = PF$. Thus $G_j = \operatorname{Diag}(P, \ldots, P)H_j$ and the proposition follows. □

Then, the following definition makes sense. Let $F \in \mathcal{M}_{d,n}^*$ be such that $[F^*] = \mathcal{S}^\perp$ and $(H_1, \ldots, H_h)$ the block-Hankel structure associated to F. Let $\underline{\ell}^j = (\ell_1^j, \ldots, \ell_{t_j}^j)$ with $1 \le \ell_1^j < \cdots < \ell_{t_j}^j \le r_j + \cdots + r_k$ a multi-index for H_j. Then, we call $\underline{\ell} = (\underline{\ell}^1, \ldots, \underline{\ell}^h)$ a *multi-index of* $\mathcal{S}$ with respect to (C, A).

Similarly we introduce a notation for the multi-indices of a (C, A)-invariant subspace. If $\{(1 \le n_{i1} < n_{i2} < \cdots < n_{im_{h-i+1}} \le r_{h-i+1}) | 1 \le i \le h\}$ (recall that $m_{h-i+1} = s_{h-i+1} - s_{h-i+2}$) is a multi-index of a (C, A)-invariant subspace (Defini-

tion 2.9), then we will write $\underline{n}^i = (n_{i1}, \dots, n_{im_{h-i+1}})$ and $\underline{n} = (\underline{n}^1, \dots, \underline{n}^h)$ denotes a multi-index of that subspace.

In the sequel we will use the same symbol to denote $\underline{\ell}^j$ and $\underline{n}^j$ as tuples and as sets of positive integers. Thus, for example, we will say that that multi-index $\underline{\ell} = (\underline{\ell}^1, \dots, \underline{\ell}^h)$ is either the d-tuple formed by the t_i-tuples $\underline{\ell}^i$, one behind the other, or $\underline{\ell} = \underline{\ell}^1 \cup \underline{\ell}^2 \cup \cdots \cup \underline{\ell}^h$ is the union set of all multi-indices of $\mathcal{S}$. The same applies to $\underline{n}$.

We will also use the following notation: if $\underline{i} = (i_1, \dots, i_r)$ and $\underline{j} = (j_1, \dots . j_s)$ are sequences of positive integers such that $1 \le i_1 < \cdots < i_r \le m$ and $1 \le j_1 < \cdots < j_s \le n$, then $A(\underline{i}, \underline{j})$ will denote the $r \times s$ submatrix of $A \in \mathcal{M}_{m,n}$ formed with rows $i_1, \dots, i_r$ and columns $j_1, \dots, j_s$; and $A[\underline{i}, \underline{j}]$ is the submatrix of A obtained by removing rows $i_1, \dots, i_r$ and columns $j_1, \dots, j_s$. In particular, if $\underline{j} = (1, \dots, n)$, then $A(\underline{i}, \ )$ is the submatrix formed by rows $i_1, \dots, i_r$ and all the columns of A and $A[\underline{i}, \ ]$ is the submatrix obtained by deleting from A rows $i_1, \dots, i_r$ and no columns. Similarly if $\underline{i} = (1, \dots, m)$.

Now we can prove an explicit condition for the cover problem to have a solution

THEOREM 3.4. *Let $\mathcal{S} \in Gr_{n-d}(\mathbb{K}^n)$, (C, A) an observable pair with $r_1 \ge \cdots \ge r_k > 0$ as positive Brunovsky indices and let $s_1 \ge \cdots \ge s_h > 0$ be a partition compatible with $(r_1, \dots, r_k)$. Then, there exists a (C, A)-invariant subspace $\mathcal{V}$ contained in $\mathcal{S}$ such that the restriction of (C, A) to $\mathcal{V}$ has $(s_1, \dots, s_h)$ as positive Brunovsky indices if and only if there are multi-indices $\underline{\ell} = (\underline{\ell}^1, \dots, \underline{\ell}^h)$ and $\underline{n} = (\underline{n}^1, \dots, \underline{n}^h)$ for $\mathcal{S}$ and $\mathcal{V}$, respectively, such that $\underline{\ell}^j \cap \underline{n}^{h-j+1} = \emptyset$ for $j = 1, \dots, h$.*

Proof. Assume first that there is a (C, A)-invariant subspace $\mathcal{V} \in Gr_\delta(\mathbb{K}^n)$ such that $\mathcal{S} \supset \mathcal{V}$ and let $[F^*] = \mathcal{S}^\perp$. For any matrix $X \in \mathcal{M}(\underline{r}, \underline{s})$ (whose columns span $\mathcal{V}$) we have that $FX = 0$. By Proposition 2.6 we can assume that X is in reduced form given by Definition 2.5.

Let $\underline{n} = (\underline{n}^1, \dots, \underline{n}^h)$ be a multi-index of $\mathcal{V}$ and then for X. Since X is in reduced form we have that

$$R_j^1(\underline{n}^j, \ ) = I_{m_{h-j+1}}, \quad j = 1, \dots, h.$$

Thus $\operatorname{rank} R = s_1$ independent of the remaining elements of R_i^1, $i = 1, \dots, h$. We only have to analyze under what conditions equations $H_{h-j+1} R_j = 0$, $j = 1, 2, \dots, h$, are solvable.

Let us consider the equations $H_{h-j+1} R_j = 0$. As $R_j(\underline{n}^j, \ ) = R_j^1(\underline{n}^j, \ ) = I_{m_{h-j+1}}$, if $H_{h-j+1} R_j = 0$, then

$$H_{h-j+1}[\ , \underline{n}^j] R_j[\underline{n}^j, \ ] = -H_{h-j+1}(\ , \underline{n}^j),$$

i.e., the columns of H_{h-j+1} in $\underline{n}^j$ are linearly dependent on the remaining columns of H_{h-j+1}. Since $\operatorname{rank} H_{h-j+1} = t_{h-j+1}$, there must be a multi-index for H_{h-j+1}, $\underline{\ell}^{h-j+1} = (\ell_1^{h-j+1}, \dots, \ell_{t_{h-j+1}}^{h-j+1})$ such that $\underline{\ell}^{h-j+1} \cap \underline{n}^j = \emptyset$, as we wanted to prove.

Conversely, if $\underline{\ell}^{h-j+1} \cap \underline{n}^j = \emptyset$ for $j = 1, \dots, h$, then there are matrices $Z_1, \dots, Z_h$ such that

$$H_{h-j+1}[\ , \underline{n}^j] Z_j = -H_{h-j+1}(\ , \underline{n}^j), \quad j = 1, \dots, h.$$

For $j = 1, \dots, h$ we construct a matrix R_j as follows:

$$\begin{aligned} R_j[\underline{n}^j, \ ] &= Z_j, \\ R_j(\underline{n}^j, \ ) &= I_{m_{h-j+1}}. \end{aligned}$$

Thus $H_{h-j+1}R_j = 0$ and by defining R as in (3.1) we have that $\operatorname{rank} R = s_1$. Now the theorem follows from Proposition 3.1. □

It is worth noticing that in the proof of the above theorem we have not used the whole reduced form of X, just the fact that the rows in $\underline{n}^j$ are canonical vectors. Actually, there are some hidden properties of the admissible multi-indices of H_j behind the block-Hankel structure of these matrices. The following one is relevant.

LEMMA 3.5. *If for some $j = 1, \dots, h$ there is a positive integer α, $1 \le \alpha \le r_j$, such that column α of H_j is a linear combination of the remaining columns of H_j, then for $i = 1, \dots, j-1$ columns α, $r_i + \alpha, \dots, r_i + \cdots + r_{j-1} + \alpha$ of H_i are also linear combinations of the remaining columns of H_i.*

Proof. The proof is straightforward, bearing in mind the block-Hankel structure of matrices H_j. □

A consequence of this lemma is the following necessary condition for the cover problem to have a solution. In fact, this condition is also sufficient generically, as we will show in the next section.

THEOREM 3.6. *Under the assumptions of Theorem* 3.4 *let $(H_1, \dots, H_h)$ be any block-Hankel structure of $\mathcal{S}$ with regard to (C, A). If there exists a (C, A)-invariant subspace $\mathcal{V}$ contained in $\mathcal{S}$, such that the restriction of (C, A) to $\mathcal{V}$ has $(s_1, \dots, s_h)$ as positive Brunovsky indices, then*

$$\operatorname{rank} H_j \le \sum_{i=j}^{k} (r_i - s_i), \quad j = 1, \dots, h. \tag{3.2}$$

Proof. We have seen in the proof of Theorem 3.4 that if $\underline{n} = (\underline{n}^1, \dots, \underline{n}^h)$ is a multi-index for $\mathcal{V}$, then the columns of H_j in $\underline{n}^{h-j+1}$ are a linear combination of the remaining columns of H_j. Thus, if we define that for a positive integer a, $a + \underline{n}^j = \{a + n_{j,1}, a + n_{j,2}, \dots, a + n_{j,m_j}\}$, then, according to Lemma 3.5, the columns of H_j in

$$\begin{aligned}
&\underline{n}^{h-j+1} \cup \\
&\underline{n}^{h-j} \cup (r_j + \underline{n}^{h-j}) \cup \\
&\underline{n}^{h-j-1} \cup (r_j + \underline{n}^{h-j-1}) \cup (r_j + r_{j+1} + \underline{n}^{h-j-1}) \cup \\
&\cdots \\
&\underline{n}^1 \cup (r_j + \underline{n}^1) \cup \cdots (r_j + \cdots + r_{h-1} + \underline{n}^1)
\end{aligned}$$

are linear combination of the remaining columns of H_j. But all these sets of indices are pairwise disjoint (thanks to the relations $n_{i,m_{h-i+1}} \le r_{h-i+1}$) and

$$\begin{aligned}
&\#(\underline{n}^1 \cup \underline{n}^2 \cup \cdots \cup \underline{n}^{h-j+1}) = s_h + m_{h-1} + \cdots + m_j = s_j, \\
&\#(r_j + \underline{n}^1 \cup r_j + \underline{n}^2 \cup \cdots \cup r_j + \underline{n}^{h-j}) = s_h + m_{h-1} + \cdots + m_{j+1} = s_{j+1}, \\
&\qquad\qquad\qquad\qquad\qquad\qquad \vdots \\
&\#(r_1 + \cdots + r_{h-1} + \underline{n}^1) = s_h.
\end{aligned}$$

As the number of columns of H_j is $r_j + \cdots + r_k$ we conclude that

$$\operatorname{rank} H_j \le (r_j + \cdots + r_k) - (s_j + \cdots + s_h), \quad j = 1, \dots, k,$$

as we wanted to prove. □

Condition (3.2) is not sufficient in general because not only is the number of linearly independent columns of H_j inportant but also their positions. For example, assume that $\underline{r} = (5,3,2,1)$ and $\underline{s} = (3,3,1)$ as in Example 2.7, and let $\mathcal{S}$ such that $\mathcal{S}^\perp$ is the subspace of $\mathbb{R}^{11}$ generated by the matrix F^*, where $F = \left(\begin{array}{cccccccccccc} 1 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 \end{array}\right)$. Then

$$H_1 = F = \left(\begin{array}{ccccc|ccc|c|c} 1 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 \end{array}\right),$$

$$H_2 = \left(\begin{array}{ccc|cc|c} 1 & 0 & 0 & 0 & 0 & 0 \\ 0 & 0 & 0 & 0 & 0 & 0 \end{array}\right),$$

$$H_3 = \left(\begin{array}{cc|c} 1 & 0 & 0 \\ 0 & 0 & 0 \\ 0 & 0 & 0 \end{array}\right).$$

On one hand, $\operatorname{rank} H_1 = 1 \leq r_1 + r_2 + r_3 + r_4 - s_1 - s_2 - s_3 = 4$, $\operatorname{rank} H_2 = 1 \leq r_2 + r_3 + r_4 - s_2 - s_3 = 2$, and $\operatorname{rank} H_3 = 1 \leq r_3 + r_4 - s_3 = 2$. Thus condition (3.2) holds. However, we have seen in Example 2.7 that the only possible multi-indices for all invariant subspaces are $((1),(2,3))$ and $((2),(1,3))$. (Notice that in this case $\underline{n}^3 = \emptyset$.) But $\ell^1 = \ell^2 = \ell^3 = (1)$; and so either $\ell^3 \cap \underline{n}^1 \neq \emptyset$ or $\ell^2 \cap \underline{n}^2 \neq \emptyset$. That is to say, there is not any (C,A)-invariant subspace $\mathcal{V}$ such that the restriction of (C,A) to $\mathcal{V}$ has Brunovsky indices $\underline{s} = (3,3,1)$ and $\mathcal{V} \subset \mathcal{S}$. This does not mean that there is no (C,A)-invariant subspaces of dimension 7 contained in $\mathcal{S}$. In fact, many other partitions $\underline{s}$ are compatible with $\underline{r} = (5,3,2,1)$. For example, $\underline{s} = (4,2,1)$ is compatible with $\underline{r}$ and a possible multi-index may be $\underline{n} = ((2),(3),(4,5))$. Since $\ell^{3-j+1} \cap \underline{n}^j = \emptyset$ for $j = 1,2,3$ we conclude that there is at least one (C,A)-invariant subspace of dimension 7 contained in $\mathcal{S}$. This subspace is generated by a matrix $Y \in \mathcal{M}(\underline{r},\underline{s})$ in the reduced form given in Definition 2.5. In particular, the subspace spanned by

$$Y(y_1,\ldots,y_9) = \left(\begin{array}{cccc|cc|c} 0 & 0 & 0 & 0 & 0 & 0 & 0 \\ 1 & 0 & 0 & 0 & 0 & 0 & 0 \\ 0 & 1 & 0 & 0 & 0 & 0 & 0 \\ 0 & 0 & 1 & 0 & 0 & 0 & 0 \\ 0 & 0 & 0 & 1 & 0 & 0 & 0 \\ \hline y_1 & y_2 & y_3 & y_4 & 0 & 0 & 0 \\ 0 & 0 & 0 & 0 & 1 & 0 & 0 \\ 0 & 0 & 0 & 0 & 0 & 1 & 0 \\ \hline 0 & y_5 & y_6 & y_7 & y_1 & y_2 & 0 \\ 0 & 0 & 0 & 0 & 0 & 0 & 1 \\ \hline 0 & 0 & y_8 & y_9 & 0 & y_5 & y_1 \end{array}\right)$$

has dimension 7, it is (C,A)-invariant, and it is contained in $\mathcal{S}$. Notice that there are nine free parameters in Y. So, there are many other different choices for matrices Y in reduced form with the same properties; i.e., each one of them spans a (C,A)-invariant subspace of dimension 7 with Brunovsky indices for the restriction $\underline{s} = (4,2,1)$ contained in $\mathcal{S}$. We will see in a later section that the set of all (C,A)-invariant subspace with fixed Brunovsky indices for the restriction contained in a given subspace can be provided with a differentiable structure. As we will prove, the number of free parameters in Y is just the dimension of the corresponding manifold.

4. The generic case. The aim of this section is to show that, generically, that is to say, for $\mathcal{S}$ belonging to an open and dense subset $\mathfrak{S}$ of $\operatorname{Gr}_{n-d}(\mathbb{K}^n)$, condition

(3.2) in Theorem 3.6 is a sufficient condition for the (dual) cover problem to have a solution. We would like to emphasize that genericity is an interesting property from a practical point of view. In fact, it means that if $\mathcal{S} \notin \mathfrak{S}$ we can obtain by a slight modification of $\mathcal{S}$ a subspace $\mathcal{S}' \in \mathfrak{S}$ and that if $\mathcal{S} \in \mathfrak{S}$ the small perturbations of $\mathcal{S}$ remain in $\mathfrak{S}$.

We begin by recalling the definition of genericity. Given a property (P) concerning the elements of a topological space T, (P) is said to be a *generic property* with respect to T if there exists an open and dense subset O of T such that every element of O satisfies this property. Then, we also say that the set O satisfies property (P) *generically*. For example, being invertible is a generic property with respect to the set of square matrices. The following property will play an important role in the achievement of our objective.

(P). We say that a matrix A satisfies property (P) if A has full rank, say r, and all $r \times r$ submatrices of A are invertible.

It is clear that (P) is a generic property with respect to $\mathcal{M}_{m,n}$. However, what we will need is that this property keeps being generic with respect to a smaller set: the set of all block-Hankel structures $(H_1, \ldots, H_h)$ associated to F. The following particular case is essential to this end.

Let $\mathcal{H}_{p,q}$ be the set of $p \times q$ Hankel matrices and ν the number of perpendiculars to the main diagonal. From a topological point of view we identify $\mathcal{H}_{p,q}$ with $\mathbb{K}^\nu$. Let $H(x)$ be the Hankel matrix

$$H(x) = \begin{pmatrix} x_1 & x_2 & x_3 & \ldots & x_q \\ x_2 & x_3 & \ldots & \ldots & \ldots \\ x_3 & \ldots & \ldots & \ldots & \ldots \\ \ldots & \ldots & \ldots & \ldots & \ldots \\ x_p & \ldots & \ldots & \ldots & x_\nu \end{pmatrix} = (x_{i+j-2}),$$

where $x_1, \ldots, x_\nu$ are indeterminates. We will also say that $x_1 \ldots, x_\nu$ are the *parameters* of $H(x)$ and that $H(x)$ is a *parametric* Hankel matrix. A particular Hankel matrix $H(a)$ is obtained by giving to the parameters the values $x_i = a_i$, $i = 1, \ldots, \nu$. We will show that (P) is generic with respect to $\mathcal{H}_{p,q}$. For this we need the following result.

LEMMA 4.1. *Let $H(x)$ be a parametric Hankel matrix with $p \leq q$. Let $I = (i_1, \ldots, i_p)$ be a given sequence of indices, $1 \leq i_1 < \cdots < i_p \leq q$, and let $\Delta_I(x)$ be the determinant formed with the columns in I. Then $\Delta_I(x)$ is not the zero polynomial of $\mathbb{K}[x]$.*

Proof. The proof is by recurrence on the number of rows p. If $p = 1$, the lemma is obvious. Assume now that the lemma is also true for $p - 1 \geq 2$. Then, if p is the number of rows of $H(x)$, we compute $\Delta_I(x)$ by its first column cofactor expansion:

$$\Delta_I(x) = x_{i_1}\Delta_{1,i_1}(x) + \cdots + x_{i_1+p-1}\Delta_{p,i_1}(x).$$

Notice that if we eliminate the first row of a Hankel matrix, the remaining matrix is still a Hankel matrix. Hence, by applying the induction hypothesis we conclude that $\Delta_{1,i_1}(x) \neq 0$. Then taking into account that the indeterminate x_{i_1} does not appear in any of the remaining summands we obtain that $\Delta_I(x) \neq 0$, as we wanted. □

Let $\mathcal{V}_I$ denote the set of matrices $H(a) \in \mathcal{H}_{p,q}$ such that $\Delta_I(a) \neq 0$. The above lemma shows that $\mathcal{V}_I$ is a Zariski open (and hence dense) subset of $\mathcal{H}_{p,q}$. When I runs over all $i_1, \ldots, i_p$ such that $1 \leq i_1 < \cdots < i_p \leq q$, $\bigcap_I \mathcal{V}_I$ is still open and dense.

Since $H \in \mathcal{H}_{p,q}$ satisfies (P) if and only if H^t satisfies the same property, the next lemma follows.

LEMMA 4.2. (P) *is a generic property with respect to* $\mathcal{H}_{p,q}$.

We will have to deal with matrices formed by a finite number of parametric Hankel matrices, one each other with different parameters. For convenience we introduce the following definition.

DEFINITION 4.3. *Let* $\mathcal{H}_{ij}(x_{i,j})$ *be a parametric Hankel matrices with different parameters (that is to say,* $x_{i,j} \neq x_{k,l}$ *if* $(i,j) \neq (k,l)$*). A matrix of the form*

$$\mathcal{H}(x) = \begin{pmatrix} \mathcal{H}_{11}(x_{11}) & \mathcal{H}_{12}(x_{12}) & \cdots & H_{1n}(x_{1n}) \\ \mathcal{H}_{21}(x_{21}) & \mathcal{H}_{22}(x_{22}) & \cdots & H_{2n}(x_{2n}) \\ \vdots & \vdots & \cdots & \vdots \\ \mathcal{H}_{m1}(x_{m1}) & \mathcal{H}_{m2}(x_{m2}) & \cdots & H_{mn}(x_{mn}) \end{pmatrix}$$

will be called an $\mathcal{H}$*-matrix.*

For example,

$$\begin{pmatrix} x_1 & x_2 & x_3 & y_1 & y_2 & v_1 & v_2 & v_3 & v_4 \\ x_2 & x_3 & x_4 & y_2 & y_3 & v_2 & v_3 & v_4 & v_5 \\ \\ z_1 & z_2 & z_3 & u_1 & u_2 & t_1 & t_2 & t_3 & t_4 \\ z_2 & z_3 & z_4 & u_2 & u_3 & t_2 & t_3 & t_4 & t_5 \\ z_3 & z_4 & z_5 & u_3 & u_4 & t_3 & t_4 & t_5 & t_6 \end{pmatrix}$$

is an $\mathcal{H}$-matrix. (For simplicity we have written $x_{11}^i = x_i, x_{12}^j = y_j, \ldots$)

LEMMA 4.4. (P) *is a generic property with respect to the set of* $\mathcal{H}$*-matrices.*

Proof. Let $(x_{ij}^1, \ldots, x_{ij}^{n_{ij}})$ be the parameters of $\mathcal{H}_{ij}(x_{ij})$. Since $x_{ij}^\alpha \neq x_{k\ell}^\alpha$ for $(i,j) \neq (k,\ell)$ we can obtain from $\mathcal{H}(x)$ a Hankel matrix as follows. In the first row block

$$\begin{pmatrix} \mathcal{H}_{11}(x_{11}) & \mathcal{H}_{12}(x_{12}) & \cdots & \mathcal{H}_{1n}(x_{1n}) \end{pmatrix}$$

we modify the parameters of the first column of each one of the blocks $\mathcal{H}_{12}(x_{12})$, $\mathcal{H}_{13}(x_{13}), \ldots$, so that the first row block becomes a Hankel matrix with different parameters. We illustrate this through the example above. Replace y_1 by x_4 and v_1 by y_3:

$$\begin{pmatrix} x_1 & x_2 & x_3 & x_4 & y_2 & y_3 & v_2 & v_3 & v_4 \\ x_2 & x_3 & x_4 & y_2 & y_3 & v_2 & v_3 & v_4 & v_5 \end{pmatrix}.$$

Next we modify conveniently the parameters of the second row block

$$\begin{pmatrix} \mathcal{H}_{21}(x_{21}) & \mathcal{H}_{22}(x_{22}) & \cdots & \mathcal{H}_{2n}(x_{2n}) \end{pmatrix}$$

so that the resulting matrix formed by the two modified row blocks is a Hankel matrix with different parameters. Again, we illustrate this procedure through the previous example:

$$\begin{pmatrix} x_1 & x_2 & x_3 & x_4 & y_2 & y_3 & v_2 & v_3 & v_4 \\ x_2 & x_3 & x_4 & y_2 & y_3 & v_2 & v_3 & v_4 & v_5 \\ \\ x_3 & x_4 & y_2 & y_3 & v_2 & v_3 & v_4 & v_5 & t_4 \\ x_4 & y_2 & y_3 & v_2 & v_3 & v_4 & v_5 & t_4 & t_5 \\ y_2 & y_3 & v_2 & v_3 & v_4 & v_5 & t_4 & t_5 & t_6 \end{pmatrix}.$$

Following this way we will obtain from $\mathcal{H}(x)$ a Hankel matrix, $H(x) \in \mathcal{H}_{p,q}$. From the same argument as in the proof of Lemma 4.2, (P) is generic with respect to $\mathcal{H}_{p,q}$, and so it is with respect to the $\mathcal{H}$-matrices. □

Finally, let $\mathcal{O}_j$ be the set of all matrices $F \in \mathcal{M}_{d,n}$ such that if $(H_1 \ \dots \ H_h)$ is the block Hankel structure associated to F, H_j satisfies (P) and set $\mathcal{O} = \cap_j \mathcal{O}_j$.

PROPOSITION 4.5. *$\mathcal{O}_j$ is an open and dense subset of $\mathcal{M}_{d,n}$.*

Proof. Recall that matrices H_j, as defined in section 3, are almost block Hankel matrices. Actually, we can permute the blocks in H_j in order to obtain a matrix with the form

$$H_j P = \begin{pmatrix} H_j^1 & H_j^2 & \cdots & H_j^{k_j} \end{pmatrix}$$

(P a permutation matrix) such that each submatrix H_j^i is a block Hankel matrix for $i = 1, \dots, k_j$.

Following our example in section 3 we would have

$$H_1^1 = \begin{pmatrix} F_{11} & F_{21} & F_{31} & F_{41} \end{pmatrix} \quad H_1^2 = \begin{pmatrix} F_{12} & F_{22} & F_{32} \end{pmatrix} \quad H_1^3 = \begin{pmatrix} F_{13} & F_{23} \end{pmatrix}$$
$$H_1^4 = F_{14}$$
$$H_2^1 = \begin{pmatrix} F_{11} & F_{21} & F_{31} \\ F_{21} & F_{31} & F_{41} \end{pmatrix} \qquad H_2^2 = \begin{pmatrix} F_{12} & F_{22} \\ F_{22} & F_{32} \end{pmatrix} \qquad H_2^3 = \begin{pmatrix} F_{13} \\ F_{23} \end{pmatrix}$$
$$H_3^1 = \begin{pmatrix} F_{11} & F_{21} \\ F_{21} & F_{31} \\ F_{31} & F_{41} \end{pmatrix} \qquad H_3^2 = \begin{pmatrix} F_{12} \\ F_{22} \\ F_{32} \end{pmatrix}.$$

Now, by a suitable permutation of the rows and columns of $H_j P$ we can obtain an $\mathcal{H}$-matrix. The proposition follows from Lemma 4.4, taking into account that the parameters of F not being in H_j are free. □

COROLLARY 4.6. *$\mathcal{O}$ is an open and dense subset of $\mathcal{M}_{d,n}$.*

From this corollary we derive the following result, which is basic to attain our objective.

PROPOSITION 4.7. *Let $\mathfrak{S}$ be the set of subspaces $\mathcal{S} \in Gr_{n-d}(\mathbb{K}^n)$ such that $\mathcal{S}^\perp = [F^*]$ with $F \in \mathcal{O}$. Then $\mathfrak{S}$ is an open and dense subset of $Gr_{n-d}(\mathbb{K}^n)$.*

Proof. Let $F, G \in \mathcal{M}_{d,n}$ be matrices such that $[F^*] = [G^*] = \mathcal{S}^\perp$, and let $(H_1, \dots, H_h)$, $(K_1, \dots, K_h)$ be the block Hankel structures associated to F and G, respectively. From Proposition 3.3 one has that $F \in \mathcal{O}$ if and only if $G \in \mathcal{O}$. Then the proposition follows from the above corollary and the fact that in the description of $\mathrm{Gr}_{n-d}(\mathbb{K}^n)$ as the orbit space $\mathcal{M}^*_{n-d,n}/\operatorname{Gl}(\mathbb{K}^{n-d})$, the natural projection $\mathcal{M}^*_{n-d,n} \longrightarrow \mathcal{M}^*_{n-d,n}/\operatorname{Gl}(\mathbb{K}^{n-d})$ is an open map. □

LEMMA 4.8. *If $\mathcal{S} \in \mathfrak{S}$ and $H_1, \dots, H_h$ is a block Hankel structure of $\mathcal{S}$ satisfying condition* (3.2) *in Theorem* 3.6*, then*

$$\operatorname{rank} H_j = jd.$$

Proof. Since $\mathcal{S} \in \mathfrak{S}$, H_j has full rank. Therefore,

$$\operatorname{rank} H_j = \min\{jd,\, r_j + \cdots + r_k\}$$

and from condition (3.2) we have

$$\min\{jd,\, r_j + \cdots + r_k\} \leq \sum_{i=j}^{k} (r_i - s_i)\,.$$

Hence, $\operatorname{rank} H_j = jd$. □

We are now in position to show the main result of this section.

THEOREM 4.9. *Under the assumptions of Theorem* 3.4 *and with the above notation, for every* $\mathcal{S} \in \mathfrak{S}$ *there is a* (C, A)*-invariant subspace* $\mathcal{V}$ *contained in* $\mathcal{S}$ *such that the restriction of* (C, A) *to* $\mathcal{V}$ *has* $(s_1, \ldots, s_h)$ *as positive Brunovsky indices if and only if*

$$0 \leq \sum_{j=h}^{k} r_j - s_h - hd. \tag{4.1}$$

Proof. (if) Condition (4.1) can be written as

$$hd \leq \sum_{i=h}^{k} (r_i - s_i)$$

and from this relation and bearing in mind that $r_i \geq s_i$, we conclude that for $j = 1, \ldots, h$

$$jd \leq hd \leq \sum_{i=h}^{k} (r_i - s_i) \leq \sum_{i=j}^{k} (r_i - s_i)\,. \tag{4.2}$$

But $jd = \operatorname{rank} H_j = t_j$, because $H_j = \min\{jd, r_1 + \cdots + r_k\}$. Hence,

$$t_j + m_j = jd + s_j - s_{j+1} \leq r_j + \cdots + r_k\,, \qquad j = 1, \ldots, h. \tag{4.3}$$

Since $\mathcal{S} \in \mathfrak{S}$, if $(H_1, \ldots, H_h)$ is a block-Hankel structure of $\mathcal{S}$, for $j = 1, \ldots, h$ any set of t_j columns of H_j is linearly independent. Thus any multi-index is available to be chosen, and, in order to apply Theorem 3.4, we only have to check that $t_j + \#\underline{n}^{h-j+1}$ is less than or equal to the number of columns of H_j. And this is just what relation (4.3) shows.

(only if). From Theorem 3.6 we know that condition (3.2) is satisfied, so that for $j = h$ we have

$$t_h \leq \sum_{j=h}^{k} r_j - s_h$$

and from Lemma 4.8 $\operatorname{rank} H_h = hd$. Hence, condition (4.1) is satisfied. ∎

Remark 4.10. Given $\mathcal{S} \in \operatorname{Gr}_{n-d}(\mathbb{K}^n)$, the existence of a (C, A)-invariant subspace $\mathcal{V}$ contained in $\mathcal{S}$, such that the restriction of (C, A) to $\mathcal{V}$ has $(s_1, \ldots, s_h)$ as positive Brunovsky indices can be stated geometrically as

$$\operatorname{Gr}_\delta(\mathcal{S}) \cap \operatorname{Inv}\,(r, s) \neq \emptyset\,. \tag{4.4}$$

According to the Thom transversality theorem [12, Th. 3.2] we have that for generic submanifolds $\mathcal{T}_1, \mathcal{T}_2$ of $\operatorname{Gr}_\delta(\mathbb{K}^n)$

$$\mathcal{T}_1 \cap \mathcal{T}_2 \neq \emptyset \Rightarrow \dim \mathcal{T}_1 + \dim \mathcal{T}_2 \geq \dim \operatorname{Gr}_\delta(\mathbb{K}^n).$$

So, by analogy, one is tempted to check whether

$$\dim \operatorname{Gr}_\delta(\mathcal{S}) + \dim \operatorname{Inv}\,(r, s) \geq \dim \operatorname{Gr}_\delta(\mathbb{K}^n). \tag{4.5}$$

provided that condition (4.4) holds. We are going to see that this is so in the generic case.

In fact, if $\eta = \dim \mathrm{Inv}\ (r,s)$, inequality (4.5) is equivalent to

$$\delta(n-d-\delta)+\eta \geq \delta(n-\delta)$$

or

$$\delta d \leq \eta. \tag{4.6}$$

We know that $\delta = s_1 + \cdots + s_h$ and

$$\eta = \sum_{i=1}^{h} \left[(s_i - s_{i+1}) \sum_{j=1}^{k} (r_{i+j-1} - s_{i+j-1}) \right]$$

(see Corollary 2.4).

Hence relation (4.6) is equivalent to

$$d\left(\sum_{i=1}^{h} s_i\right) \leq \sum_{i=1}^{h} \left[(s_i - s_{i+1}) \sum_{j=i}^{k} (r_j - s_j) \right].$$

But

$$\sum_{i=1}^{h} s_i = \sum_{i=1}^{h} i(s_i - s_{i+1})$$

so that, finally, (4.6) is equivalent to

$$\sum_{i=1}^{h} \left[(s_i - s_{i+1}) \left(id - \sum_{j=i}^{k} (r_j - s_j) \right) \right] \leq 0. \tag{4.7}$$

Since (4.7) is implied by (4.2) and this is equivalent to (4.1), we conclude that (4.5) follows from (4.1).

Now, by Theorem 4.9, if $S \in \mathfrak{S}$ (i.e., $\mathcal{S}$ is generic), condition (4.1) is necessary and sufficient for $\mathrm{Gr}_\delta(\mathcal{S}) \cap \mathrm{Inv}\ (r,s) \neq \emptyset$. In conclusion, if $S \in \mathfrak{S}$ we have that

$$\mathrm{Gr}_\delta(\mathcal{S}) \cap \mathrm{Inv}\ (r,s) \neq \emptyset \Rightarrow \dim \mathrm{Gr}_\delta(\mathcal{S}) + \dim \mathrm{Inv}\ (r,s) \geq \dim \mathrm{Gr}_\delta(\mathbb{K}^n),$$

i.e., for S generic the submanifolds $\mathrm{Gr}_\delta(\mathcal{S})$ and $\mathrm{Inv}\ (r,s)$ either do not intersect or they intersect transversaly. Following with the analogy with the Thom transversality theorem we can expect that if $\mathrm{Gr}_\delta(\mathcal{S}) \cap \mathrm{Inv}\ (r,s) \neq \emptyset$, then this intersection is a differentiable manifold whose dimension is

$$\dim \mathrm{Gr}_\delta(\mathbb{K}^n) - \dim \mathrm{Gr}_\delta(\mathcal{S}) - \dim \mathrm{Inv}\ (r,s) = \eta - \delta d.$$

We will prove by direct methods in section 6 that $\mathrm{Gr}_\delta(\mathcal{S}) \cap \mathrm{Inv}\ (r,s)$ is a submanifold of $\mathrm{Gr}_\delta(\mathbb{K}^n)$ whose dimension is $\eta - \delta d$, and we will do it not only for generic subspaces but in general.

Theorem 4.9 can be used to provide a solution, in the generic case, to the original (dual) cover problem, that is to say, without prescribing the Brunovsky indices of

the restriction, s. This is stated in the corollary below, whose proof follows from the following observation. Assume that $\underline{s}' = (s'_1, \ldots, s'_{h'})$ is such that $h' < h$. Then,

$$\sum_{j=h}^{k} r_j - s_h - hd < \sum_{j=h'+1}^{k} r_j - h'd < \sum_{j=h'}^{k} r_j - s'_{h'} - h'd.$$

COROLLARY 4.11. *With the notation of the above theorem, for every $\mathcal{S} \in \mathfrak{S}$ there is an (C, A)-invariant subspace $\mathcal{V}$ contained in $\mathcal{S}$ if and only if*

$$0 \leq \sum_{j=h}^{k} r_j - s_h - hd \tag{4.8}$$

for the unique $\underline{s}$ compatible with $\underline{r}$ having minimal h.

We will give an example applying this result. First notice that the unique partition $\underline{s}$ compatible with $\underline{r}$ (i.e., $s_i \leq r_i$ for all i) having minimal h can be explicitly constructed as follows (recall that $s_1 + \cdots + s_h = \delta$):

(i) $s_1 = \min\{r_1, \delta\}$,
(ii) for $j = 2, 3 \ldots$, $s_1 + \cdots + s_j = \min\{r_1 + \cdots + r_j, \delta\}$,

and $h = \min\{j : r_1 + \cdots r_j \geq \delta\}$.

Example 4.12. Let $\underline{r} = (3, 3, 2)$ and $d = 3$. We are going to determine when the cover problem has a generic solution for the possible values of δ. Since $n = 8$, we have $1 \leq \delta \leq 5$. We examine the inequality of formula (4.8) for the partitions $\underline{s}$ compatible with $\underline{r}$ having minimal h, that is to say, for $\delta = 1$, $\underline{s} = (1)$, for $\delta = 2$, $\underline{s} = (2)$, for $\delta = 3$, $\underline{s} = (3)$, for $\delta = 4$, $\underline{s} = (3, 1)$, and for $\delta = 5$, $\underline{s} = (3, 2)$. We conclude that for $\delta = 1, 2, 3$ the cover problem has a generic solution and for $\delta = 4, 5$, it does not.

5. The cover algorithm. In this section we present an application to the disturbance decoupling problem based on the parameterization of the solutions of the dual cover problem given in the previous sections. More precisely, given $\dot{x} = Ax + Bu + Qv$ with Q a full rank $n \times d$ matrix, we aim to parameterize the output matrices C for which Cx can be decoupled from v by state feedback. This is the case if and only if there is an (A, B)-invariant subspace, $\mathcal{V}$, such that $\operatorname{Im} Q \subseteq \mathcal{V} \subseteq \operatorname{Ker} C$. Equivalently, if and only if there is an (A^t, B^t)-invariant subspace, $\mathcal{S}$, such that $(\operatorname{Ker} C)^\perp \subseteq \mathcal{S} \subset (\operatorname{Im} Q)^\perp$. But if $[X]$ is a (B^t, A^t)-invariant subspace contained in $\operatorname{Im} Q^\perp$, then the matrices C such that $[X]^\perp \subset \operatorname{Ker} C$ are those of the form PX^*, where P is any $p \times \delta$ matrix. Thus, the following algorithm provides a paramaterization of the output matrices C for which the output of the system is insensitive to the input disturbance:

Step 1 (data capture)
- compute the controllability indices of (A, B),
- form the corresponding conjugate partition $\underline{r}$,
- form the Young diagram of $\underline{r}$, and
- list the partitions $\underline{s}$ compatible with $\underline{r}$.

Step 2 (robustness with regard to Q)
- for each δ, $1 \leq \delta \leq n - d$ do
  - find $\underline{s}$ compatible with $\underline{r}$ such that $s_1 + \cdots + s_h = \delta$ with h minimal,
  - check the condition $0 \leq \sum_{j=h}^{k} r_j - s_h - hd$,
  - if the condition is not fulfilled, then

- for almost all matrices in any open neighborhood of Q, there is not any (maximal) full rank $(n-\delta)\times n$ matrix C for which the decoupling problem has solution. There is not robustness with respect to Q. End or go to step 3 (you can try anyway).
- else
  - for almost all matrices in an open neighborhood of Q, the decoupling problem has solution with a full rank matrix $(n-\delta)\times n$. The problem will be almost surely solvable, and we have robustness with regard to Q. Go to step 3.
- end if
- end for

Step 3 (data from the particular Q)

- compute S such that $(S^{-1}AS+S^{-1}BF, S^{-1}BT)$ is in the dual Brunovsky canonical form,
- compute $F := (S^{-1}Q)^*$,
- form the block-Hankel sequence associated to F, $H = (H_1, \ldots, H_h)$,
- compute all the possible multi-indices $\underline{l}$ of H.

Step 4 (output matrix parameterization)

- for each δ, $1 \leq \delta \leq n-d$ do
  - for each $\underline{s}$ compatible with $\underline{r}$ such that $s_1+\cdots+s_h = \delta$ do (if we are only interested in a dense set of solutions we can take only $\underline{s}$ having minimal h).
    - for each $\underline{n}$ corresponding to $\underline{s}$ do
      - if $\underline{\ell}^j \cap \underline{n}^{h-j+1} = \emptyset$ for $j = 1, \ldots, h$, then
        - form the parametric matrix $X \in \mathcal{M}(\underline{r}, \underline{s})$ in the standard reduced form with indices $\underline{n}$,
        - solve $FX = 0$,
        - the output matrices C for which the decoupling problem has solution are PX^*S^{-1} where P is any $p \times \delta$ matrix and S the matrix in step 3.
      - end if
    - end for
  - end for
- end for

6. The differentiable structure of the solutions. Along this section we are given a subspace $\mathcal{S} \in Gr_{n-d}(\mathbb{K}^n)$ for which there is at least one $\mathcal{V} \in \text{Inv}\ (\underline{r}, \underline{s})$ such that $\mathcal{V} \subset \mathcal{S}$. A necessary and sufficient condition for such a property to hold was given in Theorem 3.4. Our aim in this section is to show that for a subspace $\mathcal{S}$, the set $\text{Inv}\ (\underline{r}, \underline{s}, \mathcal{S}) = \{\mathcal{V} \in \text{Inv}\ (\underline{r}, \underline{s}) | \mathcal{V} \subset \mathcal{S}\}$ can be provided with a differentiable structure, to compute its dimension and to find an atlas of coordinate charts. This will allow us to parameterize the solutions of the (dual) cover problem.

To begin, let $F \in \mathcal{M}^*_{d,n}$ be a matrix such that $\mathcal{S}^\perp = [F^*]$ and let $X \in \mathcal{M}(\underline{r}, \underline{s})$ be such that $\mathcal{V} = [X]$ with $\mathcal{V} \in \text{Inv}\ (\underline{r}, \underline{s}, \mathcal{S})$. Then $FX = 0$. Let

$$\mathcal{N}(\underline{r}, \underline{s}, \mathcal{S}) := \{X \in \mathcal{M}(\underline{r}, \underline{s}) | FX = 0\},$$

which is an open set of a linear manifold. Notice that if $F, G \in \mathcal{M}^*_{d,n}$ such that $\mathcal{S}^\perp = [F^*] = [G^*]$, then $\{X \in \mathcal{M}(\underline{r}, \underline{s}) | FX = 0\} = \{X \in \mathcal{M}(\underline{r}, \underline{s}) | GX = 0\}$. For notational simplicity we will write $\mathcal{N} := \mathcal{N}(\underline{r}, \underline{s}, \mathcal{S})$ and $\mathcal{M} := \mathcal{M}(\underline{r}, \underline{s})$. Let $\mathcal{G} := \mathcal{G}(\underline{s})$ be the group defined in Definition 2.1. By Theorem 2.3 this group acts freely on $\mathcal{M}$

on the right by matrix multiplication as well as on $\mathcal{N}$. In addition we can identify Inv $(\underline{r}, \underline{s}, \mathcal{S})$ with $\mathcal{N}/\mathcal{G}$ by means of the bijection

$$\begin{array}{ccc} \mathcal{N}/\mathcal{G} & \longrightarrow & \text{Inv } (\underline{r}, \underline{s}, \mathcal{S}), \\ \{XP | X \in \mathcal{N}, P \in \mathcal{G}(\underline{s})\} & \rightsquigarrow & [X]. \end{array}$$

Through this bijection a differentiable structure on Inv $(\underline{r}, \underline{s}, \mathcal{S})$ can be defined.

THEOREM 6.1. (i) *The orbit space $\mathcal{N}/\mathcal{G}$ has a differentiable stucture such that the natural projection $\pi : \mathcal{N} \to \mathcal{N}/\mathcal{G}$ is a submersion.*

(ii) $\dim(\mathcal{N}/\mathcal{G}) = \dim \mathcal{N} - \dim \mathcal{G}$.

Proof. (i) According to [9, Th. 2.9.10] we have to prove

(a) $\Gamma = \{(X, X') \in \mathcal{N} \times \mathcal{N} | X' = XP, P \in \mathcal{G}\}$ is closed in $\mathcal{N} \times \mathcal{N}$, and

(b) the map $\gamma : \mathcal{N} \times \mathcal{G} \to \Gamma$ defined by $\gamma(X, P) = (X, XP)$ is a homeomorphism.

In order to prove (a) notice that if $\Gamma_1 = \{(X, X') \in \mathcal{M} \times \mathcal{M} | X' = XP, P \in \mathcal{G}\}$, then $\Gamma = \Gamma_1 \cap (\mathcal{N} \times \mathcal{N})$. As Γ_1 is closed in $\mathcal{M} \times \mathcal{M}$ (see [5]), Γ is closed in $\mathcal{N} \times \mathcal{N}$.

On the other hand, γ is clearly bijective due to the free action of $\mathcal{G}$ on $\mathcal{N}$, and it continues because it is the restriction of the homeomorphism $\gamma_1 : \mathcal{M} \times \mathcal{G} \to \Gamma_1$ defined by $\gamma_1(X, P) = (X, XP)$ (again see [5]). Its inverse is also to continue for the same reason.

(ii) The dimension formula follows from (i) as in [5]. □

Now we compute the dimension of $\mathcal{N}/\mathcal{G}$. On one hand (see [7]),

$$\dim \mathcal{G} = \sum_{i=1}^{k} \sum_{j=1}^{h} (s_i - s_{i+1}) s_{i+j-1}.$$

On the other hand, $X \in \mathcal{N}$ if and only if $X \in \mathcal{M}$ and $FX = 0$. As shown in the previous section this is equivalent to

$$H_{h-j+1} R_j = 0, \quad j = 1, \ldots, h,$$

where $(R_1, \ldots, R_h)$ is the condensed form of X and $(H_1, \ldots, H_h)$ is a block-Hankel structure of $\mathcal{S}$ with respect to (C, A). This is equivalent, in turns, to

$$H_{h-j+1} R_j(\ , i) = 0, \quad j = 1, \ldots, h, i = 1, \ldots, s_{h-j+1} - s_{h-j+2},$$

where, as in section 3, $R_j(\ , i)$ is the ith column of R_j. The set of solutions of this linear homogeneous system is a vector space of dimension $(r_{h-j+1} + \cdots + r_k) - \operatorname{rank} H_{h-j+1}$; i.e., the solutions depend on $(r_{h-j+1} + \cdots + r_k) - \operatorname{rank} H_{h-j+1}$ parameters. Thus the solutions of $H_{h-j+1} R_j = 0$ depend on $(s_{h-j+1} - s_{h-j+2})\left(\sum_{i=h-j+1}^{k} r_i - \operatorname{rank} H_{h-j+1}\right)$ parameters. Since we have h of these equations,

$$\dim \mathcal{N} = \sum_{j=1}^{h} (s_j - s_{j+1}) \left(\sum_{i=j}^{k} r_i - \operatorname{rank} H_j \right) = \sum_{j=1}^{h} (s_j - s_{j+1}) \left(\sum_{i=1}^{k} r_{i+j-1} - \operatorname{rank} H_j \right).$$

Hence we have proved the following.

PROPOSITION 6.2.

$$\dim \mathcal{N}/\mathcal{G} = \sum_{j=1}^{h}(s_j - s_{j+1})\left(\sum_{i=1}^{k}(r_{i+j-1} - s_{i+j-1}) - \operatorname{rank} H_j\right).$$

Recall that (see [7])

$$\dim \mathcal{M}/\mathcal{G} = \sum_{j=1}^{h}\sum_{i=1}^{k}(s_j - s_{j+1})(r_{i+j-1} - s_{i+j-1}).$$

Hence

$$\dim \mathcal{N}/\mathcal{G} = \dim \mathcal{M}/\mathcal{G} - \sum_{j=1}^{h}(s_j - s_{j+1}) \operatorname{rank} H_j.$$

Notice that, in the generic case, by Lemma 4.8 $\operatorname{rank} H_j = jd$, and so $\sum_{j=1}^{h}(s_j - s_{j+1}) \operatorname{rank} H_j = d\sum_{j=1}^{h} j(s_j - s_{j+1}) = d\sum_{j=1}^{h} s_j = d\delta$. Since $\eta = \dim \operatorname{Inv}(\underline{r}, \underline{s}) = \dim \mathcal{M}/\mathcal{G}$, we recover the result in Remark 4.10.

Since $\mathcal{N}/\mathcal{G} \subset \mathcal{M}/\mathcal{G}$ and the topology of $\mathcal{N}/\mathcal{G}$ is the induced one by that of $\mathcal{M}/\mathcal{G}$ ($\mathcal{N}$ is a submanifold of $\mathcal{M}$ and the projection $\mathcal{M} \to \mathcal{M}/\mathcal{G}$ is an open map), we have the following.

PROPOSITION 6.3. *$\mathcal{N}/\mathcal{G}$ is a regular submanifold of $\mathcal{M}/\mathcal{G}$.*

We are going now to parameterize $\mathcal{N}/\mathcal{G}$ by means of a coordinate atlas.

First we recall an elementary fact from linear algebra. If the homogeneous linear system $Ax = 0$ has a solution, $\{a_{i_1}, \dots, a_{i_r}\}$ is a basis of the column span of A and $\{j_1, \dots, j_{n-r}\} = \{1, \dots, n\} \backslash \{i_1, \dots, i_r\}$, then

$$a_{j_k} = \sum_{t=1}^{r} \alpha_{kt} a_{i_t}, \quad k = 1, \dots, n-r,$$

if and only if

$$x_{i_t} = -\sum_{k=1}^{n-r} \alpha_{tk} x_{j_k}, \quad t = 1, \dots, r.$$

Consider now a matrix $X \in \mathcal{M}(\underline{r}, \underline{s})$ in reduced form (Definition 2.5) such that $FX = 0$, and for $j = 1, \dots, h$ let $(R_1, \dots, R_h)$ be the condensed form of X. Let $\underline{\ell} = (\underline{\ell}^1, \dots, \underline{\ell}^k)$ and $\underline{n} = (\underline{n}^1, \dots, \underline{n}^h)$ be compatible multi-indices of $\mathcal{S}$ and X, respectively; i.e.,

$$\underline{\ell}^j \cap \underline{n}^{h-j+1} = \emptyset, \quad j = 1, \dots, h.$$

If $\underline{\ell}^j = (\underline{\ell}^j_1, \dots, \underline{\ell}^j_{t_j})$, $t_j = \operatorname{rank} H_j$, then $\ell^j_1, \dots, \ell^j_{t_j}$ are linearly independent columns of H_j, $(H_1, \dots, H_h)$ being a block-Hankel structure of $\mathcal{S}$ with respect to (C, A).

Since X is in reduced form, the rows of R_{h-j+1} in $\underline{n}^{h-j+1}$ are canonical vectors; i.e., $R_{h-j+1}(\underline{n}^{h-j+1}, \ ) = I_{m_j}$. And the rows of R_{h-j+1} in the set of indices $\underline{p}^{h-j+1} = \underline{n}^1 \cup \cdots \cup \underline{n}^{h-j} \cup (r_j + \underline{n}^1) \cup \cdots \cup (r_j + \underline{n}^{h-j}) \cup (r_{j+1} + r_j + \underline{n}^1) \cup \cdots \cup (r_{j+1} + r_j + \underline{n}^{h-j-1}) \cup \cdots \cup (r_k + \cdots + r_j + \underline{n}^1)$ are zero rows; i.e., $R_{h-j+1}(\underline{p}^{h-j+1}, \ ) = 0$. (Compare with

the indices in the proof of Theorem 3.6.) But $FX = 0$ is equivalent to $H_j R_{h-j+1} = 0$, $j = 1, \dots, h$. So, if $s^j = \#\underline{p}^{h-j+1} = 2s_{j+1} + s_{j+2} + \cdots + s_h$, $r^j = r_j + \cdots + r_k$ and

$$\{g_1^j, \dots, g_{r^j - t_j - s^j}^j\} = \{1, \dots, r^j\} \backslash (\underline{\ell}^j \cup \underline{p}^{h-j+1}),$$

then columns $H_j(\ , g_i^j)$ are linear combinations of the columns $\ell_1^j, \dots, \ell_{t_j}^j$ of H_j. We can write

$$H_j(\ , g_i^j) = \sum_{q=1}^{t_j} \alpha_{iq} H_j(\ , \ell_q^j), \quad i = 1, \dots, r^j - t_j - s^j, \tag{6.1}$$

and so

$$R_{h-j+1}(\ell_i^j, \ ) = - \sum_{q=1}^{r^j - t_j - s^j} \alpha_{qi} R_{h-j+1}(g_q^j, \ ), \quad i = 1, \dots, t_j. \tag{6.2}$$

This proves the following.

THEOREM 6.4. *For any matrix $X \in \mathcal{N}(\underline{r}, \underline{s}, \mathcal{S})$ there are multi-indices $\underline{\ell} = (\underline{\ell}^1, \dots, \underline{\ell}^h)$ of $\mathcal{S}$ and $\underline{n} = (\underline{n}^1, \dots, \underline{n}^h)$ of X such that*

(i) $\ell^j \cap \underline{n}^{h-j+1} = \emptyset, \quad j = 1, \dots, h.$

(ii) *$Y = XP$ is in reduced form, as give by Definition 2.5, for some $P \in \mathcal{G}(\underline{s})$.*

(iii) *if $(H_1, \dots, H_h)$ is a block-Hankel structure of $\mathcal{S}$, $(R_1, \dots, R_h)$ the condensed form of Y, $\{g_1^j, \dots, g_{r^j - t_j - s^j}^j\} = \{1, \dots, r^j\} \backslash (\underline{\ell}^j \cup \underline{p}^{h-j+1})$ for $j = 1, \dots, h$ and $H_j(\ , g_i^j)$ is given by (6.1), then matrix $R_{h-j+1}(\ell_i^j, \ )$ is given by (6.2).*

DEFINITION 6.5. *With the notation of the above theorem we will say that Y is a reduced form of $X \in \mathcal{N}(\underline{r}, \underline{s}, \mathcal{S})$ with respect to $\underline{n}$ and $\underline{\ell}$.*

Let us compute now the number of free parameters in a reduced form of $X \in \mathcal{N}(\underline{r}, \underline{s}, \mathcal{S})$. We will show that this is the dimension of $\mathcal{N}/\mathcal{G}$. In fact, the number of free parameters of any reduced form is the same as the number of free parameters in its condensed form. And this is the number of free parameters in the condensed form of the reduced form of $X \in \mathcal{M}(\underline{r}, \underline{s})$ minus the number of elements in $R_{h-j+1}(\ell_i^j, \ )$, $j = 1, \dots, h$, $i = 1, \dots, t_j$. Bearing in mind that the number of free parameters in any reduced form $Y \in \mathcal{M}(\underline{r}, \underline{s})$ is $\dim \mathcal{M}/\mathcal{G}$ (see [7]), we conclude that the number of free parameters in $Y \in \mathcal{N}(\underline{r}, \underline{s}, \mathcal{S})$ is (recall that the number of columns of R_{h-j+1} is $s_j - s_{j+1}$)

$$\dim \mathcal{M}/\mathcal{G} - \sum_{j=1}^{h} t_j (s_j - s_{j+1}) = \dim \mathcal{N}/\mathcal{G}.$$

DEFINITION 6.6. *A multi-index $\underline{n} = (\underline{n}^1, \dots, \underline{n}^h)$ for $X \in \mathcal{M}(\underline{r}, \underline{s})$ will be said an admissible set of indices (or a multi-index) for $X \in \mathcal{N}(\underline{r}, \underline{s}, \mathcal{S})$ if there is a multi-index $\underline{\ell} = (\underline{\ell}^1, \dots, \underline{\ell}^h)$ of $\mathcal{S}$ such that $\underline{\ell}^j \cap \underline{n}^{h-j+1} = \emptyset$, $j = 1, \dots, h$.*

The following lemmas follow immediately from Lemmas 3 and 4 of [7] (see Proposition 2.8).

LEMMA 6.7. *Let $X \in \mathcal{N}$ and $Q \in \mathcal{G}$. If $\underline{n}$ is an admissible set of indices for X it is also an admissible set of indices for XQ.*

LEMMA 6.8. *Let Y and $\tilde{Y}$ be matrices of $\mathcal{N}(\underline{r}, \underline{s}, \mathcal{S})$ in reduced form with the same multi-index $\underline{n}$. If there is a matrix $P \in \mathcal{G}$ such that $\tilde{Y} = YP$, then P is the identity matrix.*

In order to define the coordinate charts of $\mathcal{N}/\mathcal{G}$ we start as in [7]. Let Λ be the set of multi-indices $\underline{n} = (\underline{n}^1, \ldots, \underline{n}^h)$ for which there is a multi-index, $\underline{\ell} = (\underline{\ell}^1, \ldots, \underline{\ell}^k)$, of $\mathcal{S}$ with respect to (C, A) such that $\underline{\ell}^j \cap \underline{n}^{h-j+1} = \emptyset$, $j = 1, \ldots, h$, i.e., compatible with $\underline{n}$. For $\underline{n} \in \Lambda$ let $\mathcal{U}_{\underline{n}}$ denote the set of matrices $X \in \mathcal{N}(\underline{r}, \underline{s}, \mathcal{S})$ with $\underline{n}$ as a set of admissible indices. Since all matrices in $\mathcal{N}(\underline{r}, \underline{s}, \mathcal{S})$ close enough to X have $\underline{n}$ as a set of admissible indices (because these are just linear independent rows), we have that $\{\mathcal{U}_{\underline{n}} | \underline{n} \in \Lambda\}$ is an open covering of $\mathcal{N}(\underline{r}, \underline{s}, \mathcal{S})$. If $\pi : \mathcal{N} \to \mathcal{N}/\mathcal{G}$ is the natural projection, then π is open and $\{\tilde{\mathcal{U}}_{\underline{n}} = \pi(\mathcal{U}_{\underline{n}}) | \underline{n} \in \Lambda\}$ is an open covering of $\mathcal{N}/\mathcal{G}$.

We must notice that for a multi-index $\underline{n} \in \Lambda$, there may be several multi-indices $\underline{\ell}$ compatible with it. To define the coordinate charts we aim to find a differentiable onto mapping $\phi_{\underline{n}} : \mathcal{U}_{\underline{n}} \to \mathbb{K}^N$, $N = \dim \mathcal{N}/\mathcal{G}$, for each $\underline{n} \in \Lambda$. We proceed as follows. If $\underline{n} \in \Lambda$ admits several compatible multi-indices $\underline{\ell} = (\underline{\ell}^1, \ldots, \underline{\ell}^h)$ we take the one such that for $i = 1, \ldots, h$, $\underline{\ell}^i$ is the smallest in the lexicographical order. In other words, as the elements of $\underline{\ell}^i$ are linearly independent columns of H_i, we are taking its first t_i linearly independent columns compatible with $\underline{n}$. Then for $X \in \mathcal{U}_{\underline{n}}$ we define $\phi_{\underline{n}}(X)$ as the point of $\mathbb{K}^N$ defined by the free parameters of the reduced form of X corresponding to $\underline{n}$ and $\underline{\ell}$, Y, in a certain order. For example, if $(R_1, \ldots, R_h)$ is the condensed form of Y, then the free parameters of Y are in the rows $\{f_1^j, \ldots, f_{r^j - t_j - s'^j}^j\} = \{1, \ldots, r^j\} \backslash (\underline{\ell}^j \cup \underline{p}^{h-j+1} \cup \underline{n}^{h-j+1})$ $(s'^j = s_j + s_{j+1} + \cdots + s_h)$ of R_{h-j+1}, $j = 1, \ldots, h$. Thus we may define

$$\begin{aligned}\phi_{\underline{n}}(X) = (&R_1(f_1^1, \,)\, R_1(f_2^1, \,) \cdots R_1(f_{r^j - t_1 - s'^1}^1, \,) \\ &R_2(f_1^2, \,) \cdots R_2(f_{r^j - t_2 - s'^2}^2, \,) \cdots R_h(f_{r^j - t_h - s'^h}^h, \,)).\end{aligned}$$

In this way $\phi_{\underline{n}}$ is well defined and onto. The differentiability follows from the fact that $Y_{\underline{n}}$ is obtained form X by means of rational operations. This mapping induces the mapping $\theta_{\underline{n}} : \tilde{\mathcal{U}}_{\underline{n}} \to \mathbb{K}^N$.

THEOREM 6.9. *With the above notation $\theta_{\underline{n}}$ is a diffeomorphism and $\{\tilde{\mathcal{U}}_{\underline{n}}; \underline{n} \in \Lambda\}$ is a coordinate atlas of $\mathcal{N}/\mathcal{G}$.*

Proof. The proof is in [7]. □

Example 6.10. Consider a slight modification of the example at the end of the section 3: $\underline{r} = (5, 3, 2, 1)$, $\underline{s} = (3, 3, 1)$, and $\mathcal{S}$ such that $\mathcal{S}^\perp = [F^*]$, where $F = \begin{pmatrix} 1 & 0 & 0 & 0 & 0 & 2 & 0 & 0 & 0 & 0 & 0 \end{pmatrix}$. Then

$$H_1 = F = \left(\begin{array}{ccccc|ccc|cc|c} 1 & 0 & 0 & 0 & 0 & 2 & 0 & 0 & 0 & 0 & 0 \end{array}\right),$$

$$H_2 = \left(\begin{array}{ccc|cc|c} 1 & 0 & 0 & 2 & 0 & 0 \\ 2 & 0 & 0 & 0 & 0 & 0 \end{array}\right),$$

$$H_3 = \left(\begin{array}{cc|c} 1 & 0 & 2 \\ 2 & 0 & 0 \\ 0 & 0 & 0 \end{array}\right).$$

An admissible multi-index in $\mathcal{M}(\underline{r}, \underline{s})$ is $\underline{n} = ((2), (3), (4, 5))$. But now this multi-index is compatible with two multi-indices $\underline{\ell}$: $\underline{\ell}_1 = ((1), (1, 4), (1, 3))$ and $\underline{\ell}_2 = ((6), (1, 4), (1, 3))$. The one to be chosen to construct the coordinate chart is $\underline{\ell}_1$. The reduced form cor-

responding to $\underline{n}$ and $\underline{\ell}_1$ is

$$Y = \left(\begin{array}{cccc|cc|c} 0 & 0 & -2a_2 & -2a_3 & 0 & 0 & 0 \\ 1 & 0 & 0 & 0 & 0 & 0 & 0 \\ 0 & 1 & 0 & 0 & 0 & 0 & 0 \\ 0 & 0 & 1 & 0 & 0 & 0 & 0 \\ 0 & 0 & 0 & 1 & 0 & 0 & 0 \\ \hline 0 & 0 & a_2 & a_3 & 0 & 0 & 0 \\ 0 & 0 & 0 & 0 & 1 & 0 & 0 \\ 0 & 0 & 0 & 0 & 0 & 1 & 0 \\ \hline 0 & a_1 & a_4 & a_5 & 0 & 0 & 0 \\ 0 & 0 & 0 & 0 & 0 & 0 & 1 \\ \hline 0 & 0 & a_6 & a_7 & a_4 & a_5 & 0 \end{array}\right),$$

and so $\phi_{\underline{n}}(\tilde{\mathcal{U}}_{\underline{n}}) = \{(a_1, a_2, a_3, a_4, a_5, a_6, a_7) \in \mathbb{R}^7\} = \mathbb{R}^7$.

Our last result is about the connection of the manifold $\mathcal{N}/\mathcal{G}$.

THEOREM 6.11. *If $\mathbb{K} = \mathbb{C}$, the manifold $\mathcal{N}/\mathcal{G}$ is connected.*

Proof. It is sufficient to prove that $\mathcal{N}$ is connected.

Assume, on the contrary, that there are open sets $U_1, U_2 \in \mathcal{N}$ such that $U_1 \cup U_2 = \mathcal{N}$ and $U_1 \cap U_2 = \emptyset$. Let $X_1 \in U_1$ and $X_2 \in U_2$ and let $\underline{n}$ be an admissible multi-index for X_1. For a given matrix $X \in \mathcal{N}$, let $M_{\underline{n}}(X)$ denote the submatrix of X formed by the rows in $\underline{n}$ and the first s_1 columns. As $\underline{n}$ is a multi-index admissible for X_1 we have that $\det M_{\underline{n}}(X_1) \neq 0$.

For $z \in \mathbb{C}$ define $p(z) = \det M_{\underline{n}}(X_1 + z(X_2 - X_1))$. Since $p(0) = \det M_{\underline{n}}(X_1) \neq 0$, $p(z)$ is not the zero polynomial, and so $p(z)$ has finitely many zeros. This allows us to define a trajectory $z(t) : [0, 1] \to \mathbb{C}$ such that $z(0) = 0$, $z(1) = 1$ and $p(z(t)) \neq 0$ for all $t \in [0, 1)$. In other words, if $X(t) = X_1 + z(t)(X_2 - X_1)$, then $\det M_{\underline{n}}(X(t)) \neq 0$ for all $t \in [0, 1)$. Notice that for $t \in [0, 1)$, $X(t) \in \mathcal{N} = U_1 \cup U_2$. Furthermore, since $X_1 \in U_1$, $\{X(t) \mid t \in [0, 1)\}$ is connected (because it is the image of a connected set by a continuous map) and $U_1 \cap U_2 = \emptyset$ we conclude that $\{X(t) \mid t \in [0, 1)\} \subset U_1$.

Now as $X_2 \in U_2$ and U_2 is open there is a neighborhood of X_2 contained in U_2. But X_2 is the limit of a sequence of matrices in $\{X(t) \mid t \in [0, 1)\}$. This means that in that neighborhood of X_2 there are matrices of this set. Thus $U_1 \cap U_2 \neq \emptyset$, a contradiction. ∎

7. Conclusions. In this paper the solutions of the cover problem have been studied by taking a geometric approach. The main tool is the parameterization of the set of (C, A)-invariant subspaces according to the Brunovsky indices of the restriction, each strata being a differentiable manifold. The structure of the matrices whose columns form a basis of such (C, A)-invariant subspaces (with respect to the dual Brunovsky basis of $\mathbb{K}^n$ and $\mathbb{K}^{n+m}$) was used to produce a necessary and sufficient condition for the cover problem to have a solution in each strata. This condition was used to provide the set of solutions with a differentiable structure in such a way that this set is a regular submanifold of the previous one. Then, an atlas of coordinate charts for the set of solution was given, obtaining a parameterization of all solutions of the cover problem on each strata. The generic case was also considered. In this case a simple and very easily computable condition for the cover problem to have a solution has been shown to hold.

Acknowledgment. We want to thank the referees for their suggestions and comments, which were very useful to improve the paper.

A TURNPIKE THEOREM FOR A RISK-SENSITIVE MARKOV DECISION PROCESS WITH STOPPING*

ERIC V. DENARDO† AND URIEL G. ROTHBLUM‡

Abstract. This paper concerns a Markov decision problem with an infinite planning horizon, stationary data, an exponential utility function, and no discounting, but also with the possibility of voluntary or involuntary termination (stopping). This paper establishes conditions under which the expected utility of the income received by repeated use of a well-chosen stationary control equals the limit, as n becomes large, of the optimal expected utility for the n-period problem. Tests for these (turnpike) conditions are provided, as is a linear program whose optimal solution determines such a control.

Key words. Markov control process, risk-sensitive dynamic programming, stopping, turnpike theorem, overtaking optimality

1. Introduction.

Howard and Matheson [1972] were the first to analyze a Markov decision problem with a (risk-sensitive) exponential utility function. As a performance criterion, they focused on the "gain rate"—the improvement in certain monetary equivalent (CME) per epoch under steady-state conditions. Their work kindled substantial interest in gain-rate maximization with an exponential utility function: for example, see Jacobson [1972, 1977], Hernández Lerma [1989], Whittle [1990], Fleming and Hernández-Hernández [1997, 1999], Di Masi and Stettner [2000], Cavazos-Cadena and Montes-de-Oca [2003], Cavazos-Cadena and Hernández-Hernández [2004], and the papers they cite. Each of these papers studies gain-rate maximization in a risk-sensitive model with an infinite planning horizon, no discounting, and no possibility of stopping.

Howard and Matheson [1972] rest their analysis on the hypothesis that all states communicate under every control. They demonstrate the equivalence of maximizing the CME and optimizing the spectral radius of the corresponding (positive) transition matrix. This links their work to earlier papers on maximizing the spectral radii of controlled branching systems by Bellman [1957], Mandl [1967], and Mandl and Seneta [1969] and to later work by Sladky [1980], Zijm [1980, 1987], Rothblum and Whittle [1982], Rothblum [1984], and Rothblum and Veinott [forthcoming].

Here, we study a somewhat different model of a Markov decision process with exponential utility with stopping. This model was introduced in Denardo and Rothblum (DR) [1979a]. In it, voluntary or involuntary stopping serves to place an upper bound on the net income that can be earned prior to termination, and the decision maker's goal is to maximize the expected utility of the net income that is earned before stopping occurs. In the context of this model, the widely used gain-rate criterion is unselective: *every* control whose expected net income prior to termination is finite has

zero as its gain rate. In DR [1979a] the best of the stationary controls were found, but no comparisons were attempted between stationary controls and more general decision procedures. Here, we establish a *turnpike theorem* by showing that the expected utility of the income received by repeated use of any one of the best stationary controls equals the limit, as n becomes large, of the optimal expected utility for the n-period problem. Turnpike theorems like this one are a prime justification for repeated use of a stationary control when the planning horizon is long and possibly of uncertain length. A corollary (presented in section 4) is that each (stationary) turnpike control overtakes (is overtaking optimal over) all randomized history-remembering decision procedures.

The hypothesis on which this turnpike theorem rests avoids assumptions on the chain structure. In their place are conditions guaranteeing that no control has aggregate payoff that approaches plus infinity but allowing poorly chosen controls to have aggregate payoff that approaches minus infinity. This turnpike theorem sets a proper foundation for the analysis of the multiarmed bandit problem with exponential utility in Denardo, Park, and Rothblum [2004]. This analysis also relates to work by Denardo, Rothblum, and Van der Heyden [2004] on index policies for a search problem with exponential utility and to work by DR [2005] on multiplicative systems.

The model on which this paper is focused is now presented. A system is observed sequentially at epochs labeled $1, 2, \ldots$, while termination has not occurred. At each epoch prior to termination, the system is observed to be in one of N states that are labeled 1 through N. If the system is observed to occupy state i at epoch t, the decision maker must choose some action k in the finite set D_i, with these consequences:

(i) With probability of $P_{iu}^k \geq 0$, the decision maker will earn (possibly negative) reward w_{iu}^k and will observe the system to be in state u at epoch $t+1$.

(ii) With probability of $T_i^k = 1 - \sum_{u=1}^N P_{iu}^k \geq 0$, the decision maker will earn (possibly negative) reward w_i^k, and termination (stopping) will occur.

After termination occurs, the decision maker observes no state, selects no action, and earns no further reward.

The utility $u(x)$ that the decision maker places on x units of income has an exponential form whose shape is determined by a parameter (constant) λ: in the *risk-averse* case, λ is positive and $u(x) = -e^{-\lambda x}$, while in the *risk-seeking* case, λ is negative and $u(x) = e^{-\lambda x}$. To consolidate these cases, we designate $\alpha = \text{sign}(\lambda)$ and write $u(x) = -\alpha e^{-\lambda x}$. The decision maker has no time-preference for money, so the utility $U(w_1, \ldots, w_n)$ of receiving (possibly negative) income $w_1, \ldots, w_n$ in epochs $1, \ldots, n$, respectively, is given by

$$U(w_1, \ldots, w_n) = -\alpha e^{-\lambda(w_1 + \cdots + w_n)} = e^{-\lambda w_1} U(w_2, \ldots, w_n). \tag{1}$$

Equation (1) reflects the multiplicative property of the exponential utility function, and the fact that $e^{-\lambda w_1}$ is nonnegative ensures that the monotonicity property of dynamic programming will be satisfied.

The decision maker's goal is to maximize the expectation of the utility earned until termination. Denote as $f(n)$ the $N \times 1$ vector whose ith element $f(n)_i$ equals the supremum over all randomized history-remembering decision procedures of the expected utility for starting at state i and continuing for n transitions or until termination occurs, whichever comes first. With R_i^k and Q_{iu}^k defined by

$$R_i^k = -T_i^k \alpha e^{-\lambda w_i^k}, \quad Q_{iu}^k = P_{iu}^k e^{-\lambda w_{iu}^k} \qquad \forall\, i,\ \forall\, u, \tag{2}$$

the fact that the Q_{iu}^k are nonnegative and the multiplicative property in (1) lead to the recursion,

$$f(0)_i = -\alpha \qquad \forall\, i, \tag{3}$$

$$f(n)_i = \max_{k \in D_i} \left\{ R_i^k + \sum_u Q_{iu}^k f(n-1)_u \right\} \qquad \forall\, i,\ \forall\, n \geq 1. \tag{4}$$

To relate (4) to a sequential decision problem having a linear utility function, interpret Q_{iu}^k as a *rate* (of transition) and R_i^k as a *reward*. Note from (2) that the rewards (the R_i^k) are nonpositive in the risk-averse case and are nonnegative in the risk-seeking case. Note from (3) that the natural "terminal reward" for this model is $-\alpha$, and not 0 as would be the case for a linear utility function.

This paper is focused on the limiting behavior of $f(n)$ as n becomes large. The $N \times 1$ vector ϕ is specified by

$$\phi_i = \limsup_{n \to \infty} f(n)_i \qquad \forall\, i. \tag{5}$$

Interpret ϕ_i as the least upper bound, as n becomes large, on the expected utility for starting at state i and operating the system for n periods or until termination, whichever comes first. In the risk-averse case, ϕ_i can be as large as zero and as small as $-\infty$. In the risk-seeking case, ϕ_i can be as large as $+\infty$ and as small as 0. This paper establishes conditions under which ϕ is finite and is attained by repeated use of a stationary nonrandomized decision procedure that will be called a "turnpike control."

Throughout, "control" is shorthand for a stationary nonrandomized decision procedure, one whose actions are functions only of the observed state. By contrast, "strategy" is short for a possibly randomized decision procedure whose action can depend on the current state and the prior history of the process. Formally, a *control* δ is an $N \times 1$ vector whose ith element $\delta(i)$ is in D_i for $i = 1, \ldots, N$. To *use* control δ is to select decision $\delta(i)$ at each epoch at which state i is observed. The set D of all such controls is given by $D = D_1 \times \cdots \times D_N = \prod_{i=1}^N D_i$, where $\prod$ denotes the Cartesian product. Each control δ has an $N \times 1$ *reward vector* R^δ and an $N \times N$ *rate* matrix Q^δ whose entries are given by

$$\left[R^\delta\right]_i = R_i^{\delta(i)}, \qquad \left[Q^\delta\right]_{iu} = Q_{iu}^{\delta(i)} \qquad \forall\, i,\ \forall\, u. \tag{6}$$

We designate as $v^\delta(n)$ the $N \times 1$ vector whose ith entry $v^\delta(n)_i$ equals the expected utility for using (stationary) control δ for n epochs given initial state i. Conditioning this expectation on the first transition and using the multiplicative property in (1) leads to the recursion,

$$\begin{aligned} v^\delta(n) &= R^\delta + Q^\delta v^\delta(n-1) \\ &= [1 + Q^\delta + \cdots + (Q^\delta)^{n-1}]R^\delta - (Q^\delta)^n e\alpha, \end{aligned} \tag{7}$$

where e denotes the $N \times 1$ vector of 1's.

A (stationary) control π is now said to be a *turnpike control* if

$$\lim_{n \to \infty} v^\pi(n) = \phi, \tag{8}$$

if each entry in ϕ is finite, and, in the risk-averse case, if no entry in ϕ equals zero. This paper provides conditions under which a turnpike control exists. It provides tests

for those conditions, and it shows how to find the turnpike control (or controls) from the optimal solution to a linear program. Evidently, a (stationary) turnpike control performs well when the actual planning horizon n is long and perhaps of uncertain length.

Before introducing conditions that ensure the existence of a turnpike control, we review some standard nomenclature. If B is an $N \times N$ matrix and S and T are subsets of $\{1, 2, \ldots, N\}$, then B_{ST} denotes the submatrix of B whose rows are indexed by the entries in S and whose columns are indexed by the entries in T. Similar notation applies to subvectors. If J is a subset of $\{1, 2 \ldots, N\}$, then J' denotes the set $\{1, 2, \ldots, N\} \setminus J$. With B as a square matrix, $\rho(B)$ denotes the *spectral radius* of B, namely, the largest absolute value of B's eigenvalues. A square matrix B is called *transient* if $\rho(B) < 1$. A standard result is that a square matrix B is transient if and only if $B^n \to 0$ as $n \to \infty$, and moreover, that if B is transient, then $I - B$ is invertible, with

$$(1 - B)^{-1} = \sum_{n=0}^{\infty} B^n. \tag{9}$$

A nonempty subset J of $\{1, 2, \ldots, N\}$ is said to be *closed* under control δ if

$$0 = T_i^{\delta(i)} + \sum_{u \notin J} P_{iu}^{\delta(i)} \qquad \forall\, i \in J. \tag{10}$$

Evidently, if J is closed under a control, then "escape" from J cannot occur when that control is used repeatedly. For the risk-averse case, the hypothesis that suffices for the existence of a turnpike control includes the following.

Condition I. $\rho[(Q^\pi)_{JJ}] > 1$ for each control π and set J such that J is closed under π.

Two different linear programs test for Condition I; one of them appears in section 2 and the other in section 3.

To explore Condition I, we consider a control π that has a closed set J. Equations (10) and (2) imply $[R^\pi]_J = 0$ and $[Q^\pi]_{JJ'} = 0$, and it follows from (7) that

$$[v^\pi(n)]_J = -[(Q^\pi)_{JJ}]^n e_J \alpha. \tag{11}$$

The risk-averse case has $\alpha = 1$, so Condition I and (11) guarantee that starting in at least one state i in J using control π repeatedly earns expected utility of $-\infty$, in which sense control π is to be avoided, if possible.

In the hypotheses that appear below, RA stands for risk-averse, RS for risk-seeking.

Hypothesis RA. At least one control δ has rate matrix Q^δ that is transient, and Condition I holds.

Hypothesis RS. Each control δ has rate matrix Q^δ that is transient.

The central result in this paper is the following theorem.

THEOREM 1. *Suppose either that* $\lambda > 0$ *and Hypothesis* RA *is satisfied or that* $\lambda < 0$ *and Hypothesis* RS *is satisfied. Then there exists a (stationary) turnpike control.*

In concert, this paper and DR [1979a] demonstrate the existence of a turnpike control, provide tests for Hypotheses RA and RS, and use the optimal solution to a linear program to construct the turnpike control (or controls). In particular, equation

(19) constructs a set D^* of controls from the optimal solution to a linear program, and Theorem 1a (in section 4) shows that D^* is the set of turnpike controls.

That $f(n)$ converges geometrically to ϕ is a theme of discounted dynamic programming. For proofs, see Shapley [1953], Blackwell [1965], Denardo [1967], Veinott [1969, 1971] , and Schweitzer and Federgruen [1978, 1979]. The aforementioned proofs rely, explicitly or implicitly, on monotone contractions. For the risk-averse case, we were unable to obtain a contraction from Hypothesis RA. Our search for a proof for the risk-averse case led us to the linear-algebraic result in Theorem 2, which is presented in section 3. By contrast, for the risk-seeking case, Hypothesis RS allows for the construction of a monotone contraction using an idea of Alan Hoffman that was reported by Veinott [1969] and is reviewed in section 4.

Theorem 1 is reminiscent of work by Blackwell [1967] and Strauch [1966] on positive and negative dynamic programming, respectively. In the risk-averse case, the rewards (the R_i^k) are nonpositive, so the one-stage optimization operation A satisfies $A(0) < 0$, as it does in negative dynamic programming. Similarly, in the risk-seeking case, the rewards are nonnegative, and A satisfies $A(0) > 0$, as it does in positive dynamic programming. There is, however, a key difference. In our model, the terminal reward is $-\alpha e$, not 0; for us, $f(n) = A^n(-\alpha e)$. We require neither $A(-\alpha e) \geq -\alpha e$ nor $A(-\alpha e) \leq -\alpha e$, so the methodologies in Blackwell and Strauch do not seem to be helpful.

Section 2 reviews the material in DR [1979a] about stationary controls that will be needed here. Section 3 develops a test for Condition I. Section 4 uses the results in sections 2 and 3 to prove Theorem 1, along with ancillary results.

2. Stationary controls. When comparing vectors or matrices, $\geq$ refers to elementwise weak inequality, $\gg$ refers to elementwise strict inequality, and $>$ refers to $\geq$ together with $\neq$. The vector x is said to be *semipositive* if $x > 0$. Also, e denotes the vector all of whose elements are 1 (always of appropriate size).

If B is a $K \times K$ nonnegative matrix, the classic *Perron–Frobenius theorem* shows that the spectral radius $\rho(B)$ of B is an eigenvalue of B with semipositive right and left eigenvectors; furthermore, these eigenvectors are strictly positive if B is *irreducible*, that is, if $(\sum_{n=0}^{K} B^n)_{uv} > 0$ for $u, v = 1, 2, \ldots, K$. Condition I can be sharpened to the following equivalent form.

Condition I′. $\rho[(Q^\pi)_{JJ}] > 1$ for each control π and set J such that J is closed under π and $(Q^\pi)_{JJ}$ is irreducible.

To show that Condition I′ suffices, we note that if control π has a closed set J, then it has a closed set $\tilde{J} \subseteq J$ with $(Q^\pi)_{\tilde{J}\tilde{J}}$ irreducible and $\rho[(Q^\pi)_{JJ}] \geq \rho[(Q^\pi)_{\tilde{J}\tilde{J}}]$. Thus, if the latter exceeds 1, so must the former.

Designate as f the $N \times 1$ vector whose ith entry f_i is given by

$$f_i = \max_{\delta \in D} \left\{ \limsup_{n \to \infty} v^\delta(n)_i \right\} \qquad \forall\, i. \tag{12}$$

From $v^\delta(n) \leq f(n)$ and equation (5), it is evident that $f \leq \phi$. Also, for each control δ whose rate matrix Q^δ is transient, the $N \times 1$ vector v^δ is now defined by

$$v^\delta = (1 - Q^\delta)^{-1} R^\delta \qquad \text{if } Q^\delta \text{ is transient.} \tag{13}$$

Letting n approach infinity in (7) and using (9) gives

$$\lim_{n \to \infty} v^\delta(n) = (1 - Q^\delta)^{-1} R^\delta = v^\delta \qquad \text{if } Q^\delta \text{ is transient.} \tag{14}$$

The $N \times 1$ vector v^* is now defined by

$$v_i^* = \max \{[v^\delta]_i : Q^\delta \text{ is transient}\} \qquad \forall i. \tag{15}$$

Interpret v_i^* as the largest infinite-horizon expected utility obtainable by starting in state i and using any (stationary) control δ whose rate matrix Q^δ is transient. A central role is played by the following linear program.

Program 1. Minimize $\sum_i v_i$, subject to the constraints

$$v_i \geq R_i^k + \sum_u Q_{iu}^k v_u \qquad \forall i, k. \tag{16}$$

The use of linear programs to solve Markov decision problems has a long history. We mention the papers that relate most directly to Program 1. D'Epenoux [1960] showed that the correspondent of Program 1 finds the optimal control for a Markov decision process with a linear utility function and discounting. Denardo [1967] generalized this to discounted dynamic programs. Veinott [1968] extended the applicability of Program 1 to identify optimal solutions to Leontief substitution systems. In the context of Markov decision chains with exponential utility, Program 1 is due to DR [1979a], where Proposition 1 is established.

PROPOSITION 1. *Suppose $\lambda > 0$ and at least one control δ has Q^δ transient or that $\lambda < 0$ and every control δ has Q^δ transient. Then Program* 1 *is feasible and bounded, and its unique optimal solution is v^*. Moreover, v^* is a solution to the equation*

$$v_i = \max_k \left\{ R_i^k + \sum_u Q_{iu}^k v_u \right\} \qquad \forall i. \tag{17}$$

Proof. This theorem is an amalgam of Theorems 1 through 3 of DR [1979a]. □

The sets D_i^* and D^* are now defined in terms of v^* by

$$D_i^* = \left\{ k \in D_i : v_i^* = R_i^k + \sum_u Q_{iu}^k v_u^* \right\} \qquad \forall i, \tag{18}$$

$$D^* = \prod_{i=1}^N D_i^*. \tag{19}$$

Proposition 1 shows that v^* satisfies (17), hence that D^* is nonempty. In section 4, Hypotheses RA and RS are shown to imply that D^* is the set of turnpike controls.

For the risk-averse case, the hypothesis of Proposition 1 excludes Condition I, and we pause to indicate what Proposition 1 fails to demonstrate without Condition I. First, it does not conclude that $v^* = f$ because it does not compare v^* with the infinite-horizon utility of any control π whose rate matrix fails to be transient. Second, while it does show that v^* is a solution to (functional equation) (17), it does not guarantee that v^* is the unique solution to this functional equation. Third, while it shows that at least one control π in D^* has Q^π transient and $v^\pi = v^*$, it does not conclude that every control π in D^* has these properties. The following example demonstrates that none of these results can be obtained without strengthening the hypothesis of Proposition 1.

Example 1. There are two states. State 1 has a single decision. State 2 has two decisions, which are a and b. There are only two controls, δ and π, with $\delta(2) = a$ and $\pi(2) = b$. Their rate matrices and reward vectors are

$$(20) \quad Q^\delta = \begin{bmatrix} 1/2 & 0 \\ 2/3 & 0 \end{bmatrix}, R^\delta = \begin{bmatrix} -1 \\ -1 \end{bmatrix}, \quad Q^\pi = \begin{bmatrix} 1/2 & 0 \\ 0 & 1 \end{bmatrix}, \quad R^\pi = \begin{bmatrix} -1 \\ 0 \end{bmatrix}.$$

The matrix Q^δ is transient and (14) indicates that $v^\delta = [-2, -7/3]^T$. (The superscript T denoting transpose.) By contrast, Q^π is not transient (it has 1 as an eigenvalue), and (7) indicates that $v^\pi(n) \to [-2, 0]^T + [0, -1]^T = [-2, -1]^T$ as n becomes large. Evidently, $v^* = [-2, -7/3]^T < f = [-2, -1]^T$. It is easy to check that both v^* and f satisfy functional (17), and moreover, that $D_2^* = \{a, b\}$. For the risk-averse case (in which $\lambda > 0$), it is easy to construct a model whose rates and rewards satisfy (20). □

The risk-averse case. Example 1 violates Condition I because the set $J = \{2\}$ is closed under control π and $\rho[(Q^\pi)_{JJ}] = 1$. For the risk-averse case, Condition I rules out Example 1 and others like it.

DR [1979a] provided a test for Condition I. To review it, we define the sets $S^*(0)$ through $S^*(N)$ from this recursion: $S^*(0) = \{1, 2, \ldots, N\}$ and

$$(21) \qquad S^*(n+1) = \left\{ i \in S^*(n) : 1 = \max_{k \in D_i^*} \sum_{u \in S^*(n)} P_{iu}^k \right\} \qquad \forall\, n \geq 0.$$

Evidently, $S^*(N)$ consists of those states from which it is possible to survive with probability 1 for N transitions using only the decisions in D_1^* through D_N^* that are given in terms of v^* by (18). Consider the following proposition.

PROPOSITION 2. *Suppose $\lambda > 0$ and that at least one control δ has Q^δ transient. Then Condition* I *is satisfied if and only if the set $S^*(N)$ is empty. Furthermore, if Condition* I *is satisfied, then*

(a) $v^* = f \ll 0$.
(b) *f is the unique solution to* (17) *and $v \ll 0$.*
(c) *The set D^* is nonempty, each control π in D^* has Q^π transient, and* $[\pi \in D^*] \Leftrightarrow [f = \lim_{n\to\infty} \{v^\pi(n)\}]$.

Proof. This is an amalgam of Theorems 4 and 5 of DR [1979a]. □

Let us summarize the risk-averse case. Proposition 1 shows that solving Program 1 determined v^*, which makes it easy to compute D_1^* through D_N^* from (18) and then $S^*(0)$ through $S^*(N)$ from (21). If $S^*(N)$ is empty, then Proposition 2 shows that Condition I is satisfied, that $v^* = f \ll 0$, that f is the unique strictly negative solution to (17), and that every control in D^* has $v^\pi = f$. Since f is finite and negative, f is the expected utility of an income stream whose total is bounded, and maximizing expected utility is an appropriate criterion.

The risk-seeking case. For the risk-seeking case, the analogue of Proposition 2 is the following.

PROPOSITION 3. *Suppose $\lambda < 0$ and that every control δ has Q^δ transient. Then*
(a) $v^* = f \geq 0$.
(b) *f is the unique solution to* (17).
(c) *The set D^* is nonempty, and* $[\pi \in D^*] \Leftrightarrow [f = \lim_{n\to\infty} \{v^\pi(n)\}]$.

Proof. This is an amalgam of Theorems 6 and 7 of DR [1979a]. □

The conclusions of Proposition 3 are similar to those for the risk-averse case. One difference is that, for the risk-seeking case, it can occur that some state i has $f_i = 0$. Should $f_i = 0$, it is the expected utility of an income stream whose total approaches $-\infty$ with positive probability, in which case maximizing expected utility would be insensitive to the rate at which costs accrue.

To complete the discussion, we note how Program 1 provides tests for transient matrices. Theorem 3 of DR [1979a] shows that Program 1 is bounded if and only if there exists a control δ for which Q^δ is transient. Theorem 6 of DR [1979a] shows that every control δ has matrix Q^δ that is transient if and only if the variant of Program 1 in which 1 replaces each R_i^k is feasible and bounded.

3. A second test for Condition I. To prove Theorem 1 for the risk-averse case, we will employ a different test for Condition I. Condition I will be shown to hold if and only if a particular set of linear inequalities has a solution. These inequalities will be described in terms of the original decision sets D_1 through D_N, rather than D_1^* through D_N^*.

To prepare, we specify the sets $S(0)$ through $S(N)$ by the recursion: $S(0) = \{1, 2, \ldots, N\}$ and

$$S(n+1) = \left\{ i \in S(n) : 1 = \max_{k \in D_i} \sum_{u \in S(n)} P_{iu}^k \right\}. \tag{22}$$

Evidently, $S(n)$ consists of those states from which it is possible to survive with probability 1 for n transitions. We recall that N is the number of states. The sets C, E_i, and E are now defined in terms of $S(N)$ by

$$C = S(N), \tag{23}$$

$$E_i = \left\{ k \in D_i : 1 = \sum_{u \in C} P_{iu}^k \right\} \qquad \forall\, i \in C, \tag{24}$$

$$E = \prod_{i \in C} E_i. \tag{25}$$

Each element π of E is a *control* for the restricted Markov decision problem whose state space is C and whose decision set for each state j in C is E_j. To *use* a control π in E is to begin at some state i in C and, at each epoch at which state j is observed, select decision $\pi(j)$. The set E contains those controls whose use avoids termination. For each control π in E, the symbol Q^π denotes the $|C| \times |C|$ rate matrix whose rows and columns appear in their natural order, e.g., if state 6 is the lowest-numbered state in C, then the top row of Q^π contains the entries $Q_{6u}^{\pi(6)}$ for $u \in C$, listed in their natural order. We begin with the following lemma.

LEMMA 1. *Suppose $S(N) = C$ is nonempty. Then the following are equivalent:*

(a) *There exists a control π in E and a row vector x such that*

$$x \geq 0 \quad \text{and} \quad x\,Q^\pi < x. \tag{26}$$

(b) *There exists a solution to*

$$\sum_{i \in C} \sum_{k \in E_i} x_i^k Q_{iu}^k - \sum_{k \in E_u} x_u^k + \alpha_u = 0 \qquad \forall\, u \in C\ , \tag{27}$$

$$\sum_{i\in C} \alpha_i = 1 \ , \tag{28}$$

$$x_i^k \geq 0 \ \text{ and } \ \alpha_i \geq 0 \qquad \forall\, i \in C, \quad \forall\, k \in E_i. \tag{29}$$

Proof. First, consider a control π in E and a row vector x that satisfy (26). Rewrite $x\,Q^\pi < x$ as $x\,Q^\pi + \alpha = x$ with $\alpha > 0$, and then normalize the variables x and α, if necessary, so that $\alpha\, e = 1$. Finally, for each i in C, set $x_i^k = 0$ for each $k \neq \pi(i)$ and set $x_i^k = x_i$ for $k = \pi(i)$ to obtain a solution to (27)–(29), thereby proving that (a) implies (b).

To see that (b) implies (a), consider a solution to (27)–(29). Since this system has a solution, it has a solution $(\bar{x},\, \bar{\alpha})$ with minimal support, that is, no other solution has a smaller set of positive variables. For this minimal-support solution, set

$$J = \left\{ u \in C : 0 < \sum_{k\in E_u} \bar{x}_u^k \right\}. \tag{30}$$

All data and decision variables in (27)–(29) are nonnegative. Thus, from (27), we see that each state u in $C \setminus J$ has $\bar{\alpha}_u = 0$ and therefore, from (28), that J is nonempty. Further, by construction, $(\bar{x},\, \bar{\alpha})$ satisfies

$$\sum_{i\in J} \sum_{k\in E_i} \bar{x}_i^k Q_{iu}^k - \sum_{k\in E_u} \bar{x}_u^k + \bar{\alpha}_u = 0 \qquad \forall\, u \in J \ , \tag{31}$$

$$\sum_{i\in J} \bar{\alpha}_i = 1 \ , \tag{32}$$

$$\bar{x}_i^k \geq 0 \ \text{ and } \ \bar{\alpha}_i \geq 0 \qquad \forall\, i \in J, \quad \forall\, k \in E_i. \tag{33}$$

Also, since $(\bar{x},\, \bar{\alpha})$ satisfies (27)–(29), we see that $Q_{iu}^k = 0$ for each triplet (u, i, k) having $u \in C \setminus J$ and $\bar{x}_i^k > 0$. Consequently, each solution of (31)–(33) whose positive variables are a subset of the positive variables in $(\bar{x},\, \bar{\alpha})$ also satisfies (27)–(29). Hence, $(\bar{x},\, \bar{\alpha})$ is also a minimal support solution to system (31)–(33). This system contains $|J|+1$ linear equations. Thus, a standard result is that $(\bar{x},\, \bar{\alpha})$ contains at most $|J|+1$ positive variables.

By construction, for each i in J, at least one of the $\bar{x}_i^k$ is positive. Also, at least one of the $\bar{\alpha}_i$ is positive. We conclude that for each $i \in J$, we have $\bar{x}_i^k > 0$ for exactly one $k \in E_i$, and we have $\bar{\alpha}_i > 0$ for exactly one $i \in J$. These positive variables are now used to specify a control π and a vector x. For each $i \in J$, select the decision $k \in E_i$ having $\bar{x}_i^k > 0$ and set $\pi(i) = k$ and $x_i = \bar{x}_i^k$. For each $i \in C \setminus J$, set $\pi(i) = k$ for any $k \in E_i$ and set $x_i = 0$. These definitions combine with (31)–(33) to give $x\,Q^\pi - x < 0$ and $x > 0$, so that (26) is satisfied. Thus, (b) implies (a), which completes the proof. □

The main result of this section is the next theorem.

THEOREM 2. *Condition* I *holds if and only if there exists a vector w such that*

$$\sum_{u\in C} Q_{iu}^k w_u > w_i \qquad \forall\, i \in C, \ \forall\, k \in E_i, \tag{34}$$

$$w_i > 0 \qquad \forall\, i \in C. \tag{35}$$

Proof. In the case $S(N) = C = \emptyset$ (the empty set), Condition I holds vacuously, and (34)–(35) are vacuous, so the theorem is true. We focus on the remaining case, for which $S(N) = C$ is not empty.

To prove the "if" part, we suppose that w satisfies (34) and (35). Consider any control π for the original decision problem and any nonempty set J of states that is closed under control π. It suffices to prove that the spectral radius of $(Q^\pi)_{JJ}$ exceeds 1. Necessarily, and has $(Q^\pi)_{JJ}$ irreducible J is a subset of C. Further, since $Q^\pi_{ij} = 0$ for each pair (i, j) having $i \in J$ and $j \notin J$, we have that $\pi(i) \in E_i$ for each $i \in J$ and inequalities (35) and (34) give

$$0 \ll w_J \ll (Q^\pi w)_J = (Q^\pi)_{JJ}\, w_J. \tag{36}$$

The Perron–Frobenius theorem guarantees the existence of a row vector $x > 0$ such that $x(Q^\pi)_{JJ} = \mu x$, where μ equals the spectral radius of $(Q^\pi)_{JJ}$. Premultiply (36) by x to obtain $0 < x\, w_J < x(Q^\pi)_{JJ}\, w_J = \mu x\, w_J$, implying $\mu > 1$, which verifies Condition I. This concludes the "if" portion of the proof.

To prove the "only if" part, we assume that Condition I is satisfied. The first step in our proof will be to arrange to use Lemma 1: we assert that there can exist no vector x and control $\hat\pi$ whose restriction π to C is in E and satisfies (26). Suppose there existed such an x and $\hat\pi$. By hypothesis, $\hat\pi_i = \pi_i$ for each $i \in C$. Equations (24)–(25) guarantee that C is closed under control π and thus is closed under $\hat\pi$. Set $J = \{i \in C : x_i > 0\}$. Inequality (26) guarantees that J is nonempty. Applying (26) to $C \setminus J$ gives $0 = x_{C\setminus J} \geq (xQ^\pi)_J = x_J(Q^\pi)_{J,C\setminus J}$, guaranteeing $(Q^\pi)_{J,C\setminus J} = 0$ and, consequently, that J is closed under π. Since $\hat\pi_i = \pi_i$ for each $i \in J$, the set J is closed under $\hat\pi$. By construction, $(Q^\pi)_{JJ} = (Q^{\hat\pi})_{JJ}$. Set $\mu = \rho[(Q^\pi)_{JJ}] = \rho[(Q^{\hat\pi})_{JJ}]$. Condition I guarantees $\mu > 1$. The Perron–Frobenius theorem guarantees the existence of a semipositive right eigenvector v of $(Q^\pi)_{JJ}$ having $(Q^\pi)_{JJ}v = \mu v$. On the other hand, application of (26) to J gives

$$x_J \geq (xQ^\pi)_J = x_J(Q^\pi)_{JJ}, \tag{37}$$

and postmultiplying (37) by v produces $x_J v \geq x_J(Q^\pi)_{JJ}v = \mu x_J v$. Since $x_J \gg 0$ and $v > 0$, we have $x_J v > 0$, and hence that $\mu \leq 1$, which contradicts $\mu > 1$.

Thus, with states restricted to C and controls restricted to E, there can exist no control π and vector x that satisfy (26). Hence Lemma 1 shows that no solution can exist to (27), (28), and (29). Let us consider the linear program whose decision variables are x and α, whose objective is to maximize $\sum_{i\in C} \alpha_i$, and whose constraints are (27) and (29) but not (28). This linear program has 0 as its optimal value. The duality theorem of linear programming shows that its dual also has 0 as its optimal value; as the objective function of the dual program is identically 0, this means that a solution exists to

$$\sum_{u\in C} Q^k_{iu} w_u - w_i \geq 0 \qquad \forall\, i \in C, \quad \forall\, k \in E_i, \tag{38}$$

$$w_i \geq 1 \qquad \forall\, i \in C. \tag{39}$$

With ε as a small positive number, consider the perturbed model in which each datum Q^k_{iu} is replaced by $Q^k_{iu}/(1+\varepsilon)$. This perturbation preserves all eigenvectors and multiplies each eigenvalue by $1/(1+\varepsilon)$. For ε sufficiently close to zero, Condition I is preserved, so the argument in the prior paragraph applied to the model with perturbed data. Hence, there exists a vector w that satisfies (39) and

$$\sum_{u\in C} \frac{Q^k_{iu}}{1+\varepsilon}\, w_u \geq w_i \qquad \forall\, i \in C, \quad \forall\, k \in E_i. \tag{40}$$

Multiply (40) by $(1+\varepsilon)$ to see that w satisfies (34), completing the proof. □

The thrust of (34)–(35) is to provide a lower bound on the growth rate of any state for a system of matrices in product form. Upper bounds are classic, as are least upper bounds. Surprisingly, lower bounds seem to be novel; related results are developed in DR [2005].

4. The turnpike theorem and a corollary. We now state and prove a strengthened form of Theorem 1.

THEOREM 1a. *Suppose either that* $\lambda > 0$ *and Hypothesis* RA *is satisfied or that* $\lambda < 0$ *and Hypothesis* RS *is satisfied. Then the set* D^* *that is defined by* (19) *is nonempty and is the set of turnpike controls.*

The proof of Theorem 1a is parsed into a series of lemmas, for which some nomenclature is necessary. Each control δ has a rate matrix Q^δ that has been defined by (6). Similarly, each control δ has a *transition probability* matrix P^δ that is defined by

$$[P^\delta]_{iu} = P_{iu}^{\delta(i)} \qquad \forall\, i, \quad \forall\, u. \tag{41}$$

Note that P^δ is substochastic, not stochastic; its ith row sums to $1 - T_i^{\delta(i)}$.

Before treating the full class of (randomized, history-remembering) strategies, we focus on "transition-counting" controls, namely, on nonrandomized decision procedures whose decision when state u is observed can depend on the number n of periods that has elapsed since the planning began. Thus, each *transition-counting control* σ is a sequence $\sigma = (\sigma^1, \sigma^2, \ldots)$, where $\sigma^1, \sigma^2, \ldots$ are (stationary) controls and where action $\sigma^t(u)$ is taken if state u is observed at epoch t. With $\sigma = (\sigma^1, \sigma^2, \ldots)$ as any transition-counting control, we now designate $\sigma(t)$ by $\sigma(t) = (\sigma^1, \ldots, \sigma^t)$. For each transition-counting control σ, the matrices $P^{\sigma(t)}$ and $Q^{\sigma(t)}$ are defined by

$$P^{\sigma(t)} = P^{\sigma^1} P^{\sigma^2} \ldots P^{\sigma^t} \qquad \text{for } t = 1, 2, \ldots, \tag{42}$$

$$Q^{\sigma(t)} = Q^{\sigma^1} Q^{\sigma^2} \ldots Q^{\sigma^t} \qquad \text{for } t = 1, 2, \ldots \tag{43}$$

with $P^{\sigma(0)} = Q^{\sigma(0)} = I$. Evidently, $P^{\sigma(t)}$ and $Q^{\sigma(t)}$ are the transition probability matrix and the rate matrix that correspond to using transition-counting control σ for the first t epochs. For $n = 0, 1, \ldots$, designate as $v^{\sigma(n)}$ the $N \times 1$ vector whose ith entry equals the expected utility obtained by using transition-counting control σ for epochs 1 through n, given that state i is observed initially. We have this analogue of (7):

$$v^{\sigma(n)} = R^{\sigma^1} + Q^{\sigma(1)} R^{\sigma^2} + \cdots + Q^{\sigma(n-1)} R^{\sigma^n} - Q^{\sigma(n)} e\alpha. \tag{44}$$

The total (random) reward during the first n periods is bounded, and the exponential utility function guarantees

$$\alpha \left[v^{\sigma(n)} \right]_i < 0 \qquad \forall\, i. \tag{45}$$

Observations about the signs of certain addends in (44) appear in the next lemma.

LEMMA 2. *Consider a state* i *and a transition-counting control* σ *that satisfy* $\sum_u [P^{\sigma(n)}]_{iu} < 1$ *for some positive integer* n*, and let* s *be the smallest integer having* $\sum_u [P^{\sigma(s)}]_{iu} < 1$*. Then*

$$\alpha \sum_u \left[Q^{\sigma(s-1)} \right]_{iu} R_u^{\sigma^s(u)} < 0. \tag{46}$$

Proof. We recall that P_{iu}^k, Q_{iu}^k, and T_i^k are nonnegative numbers. It is immediate from (2) that

$$\left\{P_{iu}^k > 0\right\} \Leftrightarrow \left\{Q_{iu}^k > 0\right\} \quad \text{and} \quad \left\{T_i^k > 0\right\} \Leftrightarrow \left\{\alpha R_i^k < 0\right\}. \tag{47}$$

It follows that

$$\left\{\left[P^{\sigma(t)}\right]_{iu} > 0\right\} \Leftrightarrow \left\{\left[Q^{\sigma(t)}\right]_{iu} > 0\right\}. \tag{48}$$

Aiming to verify (46), note that the selection of s assures that $1 = \sum_v [P^{\sigma(s-1)}]_{iv}$ and that

$$\begin{aligned} 1 > \sum_u \left[P^{\sigma(s)}\right]_{iu} &= \sum_v \left\{\left[P^{\sigma(s-1)}\right]_{iv} \sum_u P_{vu}^{\sigma^s(v)}\right\} = \sum_v \left\{\left[P^{\sigma(s-1)}\right]_{iv} \left[1 - T_v^{\sigma^s(v)}\right]\right\} \\ &= 1 - \sum_v \left[P^{\sigma(s-1)}\right]_{iv} T_v^{\sigma^s(v)}, \end{aligned}$$

which gives $\sum_v [P^{\sigma(s-1)}]_{iv} T_v^{\sigma^s(v)} > 0$, which couples with (48) and (47) to verify (46). □

For the risk-averse case, inequality (45) shows that starting in any state i and using any transition-counting control σ for x periods earns expected utility $[v^{\sigma(x)}]_i$ that is negative. For the risk-averse case, our proof of Theorem 1 requires the *uniform* negative bound in the next lemma.

LEMMA 3. *Suppose $\lambda > 0$, and that Hypothesis* RA *is satisfied. Then there exists a positive number ε such that every transition-counting control σ has*

$$\left[v^{\sigma(x)}\right]_i \le -\varepsilon \qquad \forall\, i,\ \forall\, x \ge 1. \tag{49}$$

Proof. The proof begins by establishing two preliminary claims. □

Claim 1. For each positive integer n, there exists a negative number $A(n)$ such that

$$\left[v^{\sigma(x)}\right]_i \le A(n) \tag{50}$$

for each state i, each transition-counting control σ, and each integer x having $1 \le x \le n + N$.

Proof of Claim 1. Pick any positive integer n. There are finitely many triplets $\{i, x \text{ and } \sigma(n+N)\}$ for which i is a state, x is an integer satisfying $1 \le x \le n + N$, and $\sigma(n+N)$ is a sequence of $n + N$ controls. Inequality (45) implies that each such triplet has $[v^{\sigma(x)}]_i < 0$. Designate as $A(n)$ the largest (least negative) value of $[v^{\sigma(x)}]_i$ over all such triplets. Evidently, (50) is satisfied, which proves Claim 1. □

The next claim applies to states i and transition-counting controls σ whose first n controls $\sigma(n) = (\sigma^1, \ldots, \sigma^n)$ violate

$$\sum_{u \in C} \left[P^{\sigma(t)}\right]_{iu} = 1 \qquad \text{for } t = 0, 1, \ldots, n, \tag{51}$$

where C is (we recall) the set of states from which it is possible to survive with probability of 1 for N transions. Violations of (51) occur if $i \notin C$ or if $i \in C$ and there is a positive probability of "escape" from C within n transitions.

Claim 2. For each positive integer n there exists a negative number $B(n) \geq A(n)$ such that each state i and transition-counting control σ that violate (51) have

$$\left[v^{\sigma(x)}\right]_i \leq B(n) \qquad \forall\, x \geq 1. \tag{52}$$

Proof of Claim 2. Consider any state i and control sequence $\sigma(n)$ that violate (51). Thus, some integer $t \leq n$ satisfies $\sum_{u\in C}[P^{\sigma(t)}]_{iu} < 1$, which assures us that termination occurs with positive probability by epoch $t+N$. Designate as s the first (lowest-numbered) epoch at which termination occurs with positive probability when starting in state i and using control sequence $\sigma(n)$. We have seen that $s \leq N+n$. In addition, Lemma 2 and (44) give

$$0 > \left[Q^{\sigma(s-1)}R^{\sigma^s}\right]_i \geq \left[v^{\sigma(x)}\right]_i \qquad \forall\, x \geq N+n. \tag{53}$$

Over all trios i, $\sigma(n)$ and $s \leq N+n$ for which $[Q^{\sigma(s-1)}R^{\sigma^s}]_i$ is negative, let $C(n)$ be the largest (least negative) value of $[Q^{\sigma(s-1)}R^{\sigma^s}]_i$. Set $B(n) = \max\{A(n), C(n)\}$. Claim 1 and (53) verify (52), which completes the proof of Claim 2.

We are now prepared to prove that (49) holds. If C is empty, Claim 2 with $n=1$ ensures that (52) applies to each state i and transition-counting control σ, so (49) holds with $\varepsilon = -B(1)$.

It remains to establish (49) for the case in which C is nonempty. Applying Theorem 2 to the model with state space C and action set E_i for each $i \in C$ shows that there exists a $|C| \times 1$ vector w and a positive number A such that

$$0 < w_i \leq 1 \qquad \forall\, i \in C, \tag{54}$$

$$w_i(1+A) \leq \sum_{u\in C} Q^k_{iu} w_u \qquad \forall\, i \in C,\ k \in E_i. \tag{55}$$

Having selected w and A that satisfy (54)–(55), we pick any positive integer n large enough that

$$1 \leq w_i(1+A)^n \qquad \forall\, i \in C. \tag{56}$$

With this value of n, we take $A(n)$ and $B(n)$ as negative numbers that satisfy Claims 1 and 2, respectively. We shall establish (49) with $\varepsilon = -B(n)$.

Aiming for a contradiction, consider a triplet (i, s, σ) with $[v^{\sigma(s)}]_i > B(n)$. Among such triplets, we take one that minimizes s. From Claim 1 and $B(n) \geq A(n)$, we have $s > n+N$. From Claim 2, we have that i, n, and $\sigma(n)$ satisfy (51), which guarantees $i \in C$. Equation (51) also ensures that if $u \in C$ and $t \leq n$ and $[P^{\sigma(t-1)}]_{iu} > 0$, then $u \in C$ and $\sigma^t(u) \in E_u$. On the other hand, if $u \in C$ and $t \leq n$ and $[P^{\sigma(t-1)}]_{iu} = 0$, then replacing $\sigma^t(u)$ by any decision in E_u preserves $[v^{\sigma(s)}]_i$. Thus, we can assume that i and $\sigma(n)$ satisfy (51), that $[v^{\sigma(s)}]_i > B(n)$, and, in addition, that

$$\sigma^t(u) \in E_u \qquad \forall\, t \leq n,\ \forall\, u \in C. \tag{57}$$

The set C is closed under every control π having $\pi(u) \in E_u$ for each $u \in C$. Hence, repeated application of (55), coupled with (56) and (54), shows that

$$1 \leq w_i(1+A)^n \leq \sum_{u\in C} \left[Q^{\sigma(n)}\right]_{iu} \qquad \forall\, i \in C. \tag{58}$$

Next, designate transition-counting control γ by $\gamma^x = \sigma^{n+x}$ for $x = 1, 2, \ldots$. From (51), (47), and (48), we have

$$\left[Q^{\sigma(x-1)} R^{\sigma^s}\right]_u = 0 \qquad \text{for } x = 1, \ldots, n,$$

and therefore from $s > n + N$ and (44),

$$\left[v^{\sigma(s)}\right]_i = \sum_{u \in C} \left[Q^{\sigma(n)}\right]_{iu} \left[v^{\gamma(s-n)}\right]_u. \tag{59}$$

The selection of s guarantees

$$\left[v^{\gamma(s-n)}\right]_u \le B(n) \qquad \forall\, u \in C. \tag{60}$$

By hypothesis, $0 > [v^{\sigma(s)}]_i > B(n)$, which combines with (59) and (60) and then (58) to establish the contradiction,

$$\begin{aligned} B(n) < \left[v^{\sigma(s)}\right]_i &= \sum_{u \in C} \left[Q^{\sigma(n)}\right]_{iu} \left[v^{\gamma(s-n)}\right]_u \\ &\le \sum_{u \in C} \left[Q^{\sigma(n)}\right]_{iu} B(n) \le B(n), \end{aligned}$$

which completes the proof. □

The next step in our proof is to study the $N \times 1$ vector ϕ that is defined by (5). Lemma 3 is central to the next lemma.

LEMMA 4. *Suppose $\lambda > 0$ and that Hypothesis* RA *is satisfied. Then,*

$$\phi \ll 0 \qquad \textit{and} \qquad f \le \phi \le \max_{\delta \in D} \left\{R^\delta + Q^\delta \phi\right\}. \tag{61}$$

Proof. Lemma 3 implies that some positive number ε has $f(n) \le -\varepsilon e$, so that $\phi \le -\varepsilon e \ll 0$ is immediate from (5), that $f \le \phi$ is immediate from (12) and (5), and that $\phi \le \max_{\delta \in D}\{R^\delta + Q^\delta \phi\}$ follows directly from the recursion in (3) and from the nonnegativity of the Q^k_{iu}. □

LEMMA 5. *Suppose $\lambda > 0$, and that Hypothesis* RA *is satisfied. Any vector ϕ that satisfies* (61) *has $\phi = f$.*

Proof. From (61), we have $\phi \ll 0$, as well as the existence of a control π such that

$$\phi \le R^\pi + Q^\pi \phi. \tag{62}$$

Set $\mu = \rho(Q^\pi)$, the spectral radius of Q^π. The Perron–Frobenius theorem guarantees the existence of a row vector $x > 0$ such that $x\mu = xQ^\pi$. Set $J = \{j : x_j > 0\}$. Note that J is nonempty, that $x_J \gg 0$, that $x_{J'} = 0$, that $x_J \mu = (xQ^\pi)_J = x_J (Q^\pi)_{JJ}$, and that $0 = x_{J'}\mu = (xQ^\pi)_{J'} = x_J (Q^\pi)_{JJ'}$, which shows that $(Q^\pi)_{JJ'} = 0$. Hence, from (62), we get $\phi_J \le (R^\pi)_J + (Q^\pi)_{JJ}\phi_J$. Premultiply by x_J to get

$$x_J \phi_J (1 - \mu) \le x_J (R^\pi)_J. \tag{63}$$

The hypothesis, $\phi \ll 0$, guarantees $x_J \phi_J < 0$. Since $x_J \gg 0$ and $R^\pi \le 0$, we have $x_J (R^\pi)_J \le 0$. Aiming for a contradiction, suppose $(R^\pi)_J = 0$. In this case, J is closed under control π, so Condition I guarantees $\mu = \rho(Q^\pi) \ge \rho[(Q^\pi)_{JJ}] > 1$, and

(63) establishes the desired contradiction. Thus, $(R^\pi)_J < 0$, ensuring $x_J(R^\pi)_J < 0$, and (63) guarantees $\mu < 1$. Thus, Q^π is transient, and premultiplying (62) by the nonnegative matrix $(I - Q^\pi)^{-1}$ verifies the first inequality in $\phi \leq (I - Q^\pi)^{-1}R^\pi = v^\pi \leq v^*$. Since Proposition 2 and Lemma 4 give $v^* = f \leq \phi$, we have obtained $\phi \leq v^* = f \leq \phi$, so equality holds throughout, completing the proof. □

For the risk-averse case, we are now poised to prove Theorem 1a, which was formulated at the beginning of this section.

Proof of Theorem 1a *under Hypothesis* RA. Lemmas 4 and 5 show that

$$f_i = \phi_i = \limsup_{n\to\infty} \{f(n)_i\} \qquad \forall\, i. \tag{64}$$

Proposition 2 shows that D^* is nonempty and that every control δ in D^* has Q^δ transient and $v^\delta = f$.

Pick any control δ in D^*. From $v^\delta(n) \leq f(n)$, from $v^\delta(n) \to v^\delta = f$, and from (64), we get

$$f_i = (v^\delta)_i = \lim_{n\to\infty} \left\{v^\delta(n)_i\right\} \leq \limsup_{n\to\infty}\{f(n)_i\} = \phi_i = f_i. \tag{65}$$

Thus, equality holds in (65), proving that every control δ in D^* is a turnpike control.

Since $f = \phi$, Proposition 2 implies that no control that is not in D^* can be a turnpike control. This completes the proof. □

The risk-seeking case. For the risk-seeking case, the hypothesis of Theorem 1 is that each control δ has rate matrix Q^δ that is transient. This facilitates an analysis that Veinott [1969] attributed to Alan Hoffman. The idea is so brief and so lovely that we review it. It is to rescale the rate matrices and the rewards in a way that preserves optimizers and converts the model to a discounted Markov decision process. The key lies in equation (66), below.

LEMMA 6. *Suppose* $\lambda < 0$ *and that Hypothesis* RS *is satisfied. Then* $\phi = f$.

Proof. By hypothesis, each control δ has rate matrix Q^δ that is transient. To verify that the equation

$$w_i = \max_k \left\{1 + \sum_j Q^k_{ij} w_j\right\} \qquad \forall\, i \tag{66}$$

has a unique solution, do any one of the following: adapt the control improvement method of Howard [1960], apply Theorem 4 of Denardo [1967], or use a result of Veinott [1969]. It is clear from (66) that $w_i \geq 1$ for each i. The w_i in (66) *rescale* the transition rates and rewards as is indicated by the hats in

$$\hat{Q}^k_{ij} = (1/w_i)Q^k_{ij}w_j, \qquad \hat{R}^k_i = (1/w_i)R^k_i \tag{67}$$

and *rescale* the utility for terminating at state j from $-\alpha$ to $-\hat{\alpha}$, with $\hat{\alpha} = \alpha/w_j$. Thus, the rescaled problem has a state-dependent terminal reward.

It is clear from (44) that the rescaled utility vector $\hat{v}^{\sigma(n)}$ for using transition-counting control σ for n periods satisfies

$$\left[\hat{v}^{\sigma(n)}\right]_i = (1/w_i)\left[v^{\sigma(n)}\right]_i \qquad \forall\, i, \tag{68}$$

so that optimizers for the rescaled problem are identical to those for the original problem. In particular, (68) gives $\hat{f}(n)_i = (1/w_i)f(n)_i$ and $\hat{f}_i = (1/w_i)f_i$ for each i.

Multiply (66) by $(1/w_i)$ and use (67) to obtain $\sum_j \hat{Q}_{ij}^k \leq 1 - 1/w_i$ for each i and k. With $c = \max_i\{1 - 1/w_i\}$, we conclude that

$$\sum_j \hat{Q}_{ij}^k \leq c < 1 \qquad \forall\, i, k. \tag{69}$$

Expression (69) shows that the rescaled problem is a discounted Markov decision process to which the standard theory (see Blackwell [1965] or Denardo [1967]) applies. In particular, $\hat{f}(n)$ converges geometrically to $\hat{f}$, so $f(n)$ converges geometrically to f, implying that $f = \phi$. □

Proof of Theorem 1a *under Hypothesis* RS. The argument of the proof of Theorem 1 under Hypothesis RA applies, with Lemma 6 replacing Lemmas 4 and 5 and with Proposition 3 replacing Proposition 2. □

Overtaking optimality. Now, let σ^* denote a strategy, i.e., a decision procedure in which the decision selected when state i is observed at a particular period can be randomized and can depend on the number n of periods that have elapsed and on the entire history of the process. Designate as $v^{\sigma^*(n)}$ as the $N \times 1$ vector whose ith entry equals the expected utility obtained by starting at state i and using σ^* for periods 1 through n. By a standard argument (cf. section 7 (symmetries) in Denardo [1967]),

$$[v^{\sigma^*(n)}]_i \leq f(n)_i. \tag{70}$$

A (stationary) control π is now said to be *overtaking optimal* if

$$\liminf_{n\to\infty}\{v^\pi(n)_i - v_i^{\sigma^*(n)}\} \geq 0 \qquad \forall\, \sigma,\ \forall\, i. \tag{71}$$

This optimality criterion was introduced by Von Weizsäcker [1965] and Gale [1967].

For the risk-averse case, we now adapt the proof of Theorem 1a to show that D^* is the set of overtaking optimal controls. Evidently, a control π for which Q^π is transient will be overtaking optimal if and only if

$$v^\pi \geq \limsup_{n\to\infty} v^{\sigma^*(n)} \qquad \forall\, \sigma. \tag{72}$$

We designate as g the $N \times 1$ vector whose entries are given by

$$g_i = \sup_{\sigma^*}\left\{\limsup_{n\to\infty}[v^{\sigma^*(n)}]_i\right\} \qquad \forall\, i. \tag{73}$$

In (73), the supremum is taken over all strategies. In the risk-averse case, g_i can be as low as $-\infty$ and as high as 0. Similarly, in the risk-seeking case, g_i lies between 0 and $+\infty$, inclusive. That there is no economic benefit to using a history-remembering control is the thrust of the following corollary.

COROLLARY 1. *Suppose either that* $\lambda > 0$ *and Hypothesis* RA *holds or that* $\lambda < 0$ *and Hypothesis* RS *holds. Then* $f = g$ *and* D^* *is the set of overtaking optimal controls.*

Proof. From (12) and (73), we have $f \leq g$. Next, using (70), we have that every strategy σ^* and state i has

$$\limsup_{n\to\infty}\left[v^{\sigma^*(n)}\right]_i \leq \limsup_{n\to\infty} f(n)_i = \phi_i = f_i, \tag{74}$$

the last from Lemmas 4 through 6. Inequality (74) and (73) give $g \leq f$. Thus, $g = f = \phi$. That D^* is the set of overtaking optimal controls now follows from the proof of Theorem 1. □

To see that there is a difference between turnpike controls and overtaking-optimal controls, consider the undiscounted Markov decision process. DR [1979b] shows that this model has an (average) overtaking-optimal control. But income earned at the end of the planning interval is not attenuated, so this model has no turnpike control, that is, no (stationary) control π having $v^\pi(n) - f(n) \to 0$.

ON THE EXISTENCE OF A KAZANTZIS–KRAVARIS/LUENBERGER OBSERVER*

VINCENT ANDRIEU† AND LAURENT PRALY‡

Abstract. We state sufficient conditions for the existence, on a given open set, of the extension, to nonlinear systems, of the Luenberger observer as it has been proposed by Kazantzis and Kravaris. We prove it is sufficient to choose the dimension of the system, giving the observer, less than or equal to 2 + twice the dimension of the state to be observed. We show that it is sufficient to know only an approximation of the solution of a PDE, needed for the implementation. We establish a link with high gain observers. Finally we extend our results to systems satisfying an unboundedness observability property.

Key words. nonlinear osbservers, Luenberger observers, high gain observers

1. Introduction.

We consider the system

$$\dot{x} = f(x), \qquad y = h(x) \tag{1}$$

with state x in $\mathbb{R}^n$ and output y in $\mathbb{R}^p$ and where the functions f and h are sufficiently smooth. We are concerned with the problem of existence of an observer for x from the measurement y.

In a seminal paper [13], Kazantzis and Kravaris have proposed to extend to the nonlinear case the primary observer introduced by Luenberger in [17] for linear systems. Following this suggestion, the estimate $\widehat{x}$ of x is obtained as the output of the dynamical system

$$\dot{z} = A\,z + B(y), \qquad \widehat{x} = T^*(z), \tag{2}$$

with state z (a complex matrix) in $\mathbb{C}^{m\times p}$ and where A is a Hurwitz complex matrix and B and T^* are sufficiently smooth functions.

In the following we state sufficient conditions on f and h such that we can find (A, B, m) for which there exists T^* guaranteeing the convergence of $\widehat{x}$ to x.

To ease readability, we have divided the paper into two parts. In the first part, we introduce and state our main results, which are proved in the second part. Our first result gives a sufficient condition on f, h, A, and B implying the existence of T^* providing an appropriate observer. This condition involves a partial differential equation whose solution should be injective. In our second result, we propose a set of assumptions guaranteeing the existence of a solution for this equation. Our third and fourth results give two sufficient conditions implying the injectivity property of this solution. Our fifth result shows that an observer can already be obtained if we know only an appropriate approximation of this solution. This latter result allows

us to propose a new insight in the standard high gain observer. Finally we claim that all these statements can be extended to the case where the system satisfies an unboundedness observability property.

Some notations. We assume the functions f and h in (1) are at least locally Lipschitz. So, for each x in $\mathbb{R}^n$, there exists a unique solution $X(x,t)$ to (1), with x as initial condition.

Given an open set $\mathcal{O}$ of $\mathbb{R}^n$, for each x in $\mathcal{O}$, we denote by $(\sigma^-_{\mathcal{O}}(x), \sigma^+_{\mathcal{O}}(x))$ the maximal interval of definition of the solution $X(x,t)$ conditioned to take values in $\mathcal{O}$.

For a set S, we denote by $\mathtt{cl}(S)$ its closure and by $S+\delta$ the open set

$$S+\delta \;=\; \{x \in \mathbb{R}^n : \exists\, \varkappa \in S :\; |x-\varkappa| < \delta\} = \bigcup_{x\in S} \mathcal{B}_\delta(x),$$

where $\mathcal{B}_\delta(x)$ denotes the open ball with center x and radius δ.

By $L_f V$ we denote the Lie derivative of V when it makes sense, i.e.,

$$L_f V(x) \;=\; \lim_{h\to 0} \frac{V(X(x,h)) - V(x)}{h}.$$

Finally, B_{1m} denotes the following vector in $\mathbb{R}^m$:

$$B_{1m} \;=\; (\;1 \quad \dots \quad 1\;)^T. \tag{3}$$

2. Results and comments.

2.1. Existence of a Kazantzis–Kravaris/Luenberger observer. In [13], m, the row dimension of z, is chosen equal to n, the dimension of x, and T^* is the inverse T^{-1} of a function T, solution of the following partial differential equation:

$$\frac{\partial T}{\partial x}(x)\, f(x) \;=\; A\, T(x) \;+\; B(h(x)). \tag{4}$$

The rationale for this equation, as emphasized more in [15] (see also [18]), is that, if T is a diffeomorphism satisfying (4), then the change of coordinates

$$\zeta \;=\; T(x) \tag{5}$$

allows us to rewrite the dynamics (1) equivalently as

$$\dot\zeta \;=\; A\,\zeta \;+\; B(h(T^{-1}(\zeta))), \qquad y \;=\; h(T^{-1}(\zeta)).$$

We then have

$$\dot{\widehat{z-\zeta}} \;=\; A\,(z-\zeta).$$

A being Hurwitz, z in (2) is the state of an asymptotically convergent observer of $\zeta = T(x)$. Then, if the function $T^* = T^{-1}$ is uniformly continuous, $\widehat{x} = T^*(z)$ is an asymptotically convergent observer of $x = T^*(\zeta) = T^*(T(x))$.

This way of finding the function T^* has motivated active research on the problem of the existence of an analytic and invertible solution to (4) (see [13, 15], for instance). But it turns out that having a (weak) solution to (4) which is only continuous and uniformly injective is already sufficient. By sufficiency we mean, here, that an observer is appropriate if we have convergence to zero of the observation error associated to any solution which remains in a given open set $\mathcal{O}$. For the latter, we need the following.

DEFINITION 1 (completeness within $\mathcal{O}$). *The system* (1) *is forward (resp., backward) complete within* $\mathcal{O}$ *if we have the implication, for each* x *in* $\mathcal{O}$,

$$\sigma^+_{\mathcal{O}}(x) \ < \ +\infty \qquad \Longrightarrow \qquad \sigma^+_{\mathcal{O}}(x) \ < \ \sigma^+_{\mathbb{R}^n}(x). \tag{6}$$

In other words, completeness within $\mathcal{O}$ says that any solution $X(x,t)$ which exits $\mathcal{O}$ in finite time must cross the boundary of $\mathcal{O}$ (at a finite distance). An usual case where this property holds is when f has an at most linear growth within $\mathcal{O}$.

THEOREM 1 (sufficient condition of existence of an observer). *Assume the system* (1) *is forward complete within* $\mathcal{O}$ *and there exist an integer* m, *a Hurwitz complex* $m \times m$ *matrix* A, *and functions* $T : \mathtt{cl}(\mathcal{O}) \to \mathbb{C}^{m\times p}$, *continuous,* $B : \mathbb{R}^p \to \mathbb{C}^{m\times p}$, *continuous, and* ρ, *of class* $\mathcal{K}_\infty$, *satisfying*

$$L_f T(x) = AT(x) + B(h(x)) \qquad \forall x \in \mathcal{O}, \tag{7}$$

$$|x_1 - x_2| \le \rho(|T(x_1) - T(x_2)|) \qquad \forall (x_1, x_2) \in \mathtt{cl}(\mathcal{O})^2. \tag{8}$$

Under these conditions, there exists a continuous function $T^* : \mathbb{C}^{m\times p} \to \mathtt{cl}(\mathcal{O})$ *such that for each* x *in* $\mathcal{O}$ *and* z *in* $\mathbb{C}^{m\times p}$ *the (unique) solution* $(X(x,t), Z(x,z,t))$ *of*

$$\dot{x} \ = \ f(x), \qquad \dot{z} \ = \ Az + B(h(x)) \tag{9}$$

is right maximally defined on $[0, \sigma^+_{\mathbb{R}^n}(x))$. *Moreover, we have the implication*

$$\sigma^+_{\mathcal{O}}(x) \ = \ \sigma^+_{\mathbb{R}^n}(x) \qquad \Longrightarrow \qquad \lim_{t\to\sigma^+_{\mathbb{R}^n}(x)} |T^*(Z(x,z,t)) - X(x,t)| \ = \ 0. \tag{10}$$

Remark 1. 1. With the forward completeness within $\mathcal{O}$ (6), the condition on the left in (10) implies that the solution $X(x,t)$ never exits $\mathcal{O}$ and so

$$\sigma^+_{\mathcal{O}}(x) \ = \ \sigma^+_{\mathbb{R}^n}(x) \ = \ +\infty. \tag{11}$$

2. Theorem 1 extends readily to the case where (a) y is a scalar, (b) the state x can be decomposed in $x = (\xi_1, \xi_2)$ and satisfies

$$\dot{\xi}_1 \ = \ f_1(\xi_1, u) \ + \ h(\xi_2), \qquad \dot{\xi}_2 \ = \ f_2(\xi_2), \qquad y \ = \ \xi_1,$$

and (c) the function B can be chosen linear. In this case the observer is implemented as the reduced order observer:

$$\dot{\widehat{z - By}} \ = \ Az \ + \ Bf_1(y,u), \qquad \widehat{\xi}_2 \ = \ T^*(z).$$

Assuming we have a continuous function T satisfying (7), to implement the observer, we have to find a function T^* satisfying

$$|T^*(z) - x| \ \le \ \rho^*(|z - T(x)|) \qquad \forall (x,z) \in \mathcal{O} \times \mathbb{C}^{m\times p}$$

for some function ρ^* of class $\mathcal{K}_\infty$. As shown by Kreisselmeier and Engel in [14], such a function T^* exists if T is continuous and uniformly injective as prescribed by (8).

In conclusion, a Kazantzis–Kravaris/Luenberger observer exists mainly if we can find a continuous function T solving (7) and uniformly injective in the sense of (8).

2.2. Existence of T solving (7). To exhibit conditions guaranteeing the existence of a function T solution of (7), we abandon the interpretation above of a change of coordinates (see (5)) and come back to the original idea in [17] (see also [13] and [4]) of dynamic extension. Namely, we consider the augmented system (9). Because of its triangular structure and the fact that A is Hurwitz, we may expect this system to have, at least maybe only locally, an exponentially attractive invariant manifold in the augmented (x, z) space which could even be described as the graph of a function as

$$\left\{(x,z) \in \mathbb{R}^n \times \mathbb{C}^{m\times p} \,:\, z = T(x)\right\}.$$

In this case, the function T would satisfy the following identity, for all t in the domain of definition of the solution $(X(x,t), Z((x,z),t))$ of (9) issued from (x,z) (compare with [18, Definition 5]),

$$T(X(x,t)) \;=\; Z((x,T(x)),t),$$

or equivalently,

$$T(X(x,t)) \;=\; \exp(At)\,T(x) \;+\; \int_0^t \exp(As)B(h(X(x,s)))ds. \tag{12}$$

From this identity, (7) is obtained by derivation with respect to t. But since we need (7) to hold only on $\mathcal{O}$, from (12), it is sufficient that T satisfies

$$T(x) \;=\; \exp(-At)\,T(\breve{X}(x,t)) \;-\; \int_0^t \exp(-As)B(h(\breve{X}(x,s)))ds,$$

where $\breve{X}(x,s)$ is a solution of the modified system

$$\dot{x} \;=\; \breve{f}(x) \;=\; \chi(x)\,f(x), \tag{13}$$

where $\chi : \mathbb{R}^n \to \mathbb{R}$ is an arbitrary locally Lipschitz function satisfying

$$\chi(x) \;=\; 1 \quad \text{if} \quad x \in \mathcal{O}, \qquad \chi(x) \;=\; 0 \quad \text{if} \quad x \notin \mathcal{O} + \delta_u, \tag{14}$$

for some positive real number δ_u. So, as standard in the literature on invariant manifolds, by letting t go to $-\infty$, we get the following candidate expression for T:

$$T(x) \;=\; \int_{-\infty}^0 \exp(-As)B(h(\breve{X}(x,s)))ds. \tag{15}$$

The above nonrigorous reasoning can be made correct as follows

THEOREM 2 (existence of T). *Assume the existence of a strictly positive real number δ_u such that the system* (1) *is backward complete within $\mathcal{O} + \delta_u$. Then, for each Hurwitz complex $m\times m$ matrix A, we can find a C^1 function $B : \mathbb{R}^p \to \mathbb{C}^{m\times p}$ such that the function $T : \mathtt{cl}(\mathcal{O}) \to \mathbb{C}^{m\times p}$, given by* (15)*, is continuous and satisfies* (7).

Remark 2. All that is needed here about the function B is that it guarantees that the function $t \mapsto |\exp(-At)B(h(\breve{X}(x,t)))|$ is exponentially decaying with t going to $-\infty$. So in particular (see Remark 6) when $\mathtt{cl}(\mathcal{O})$ is bounded, B can be chosen simply as a linear function.

Approaching the problem from another perspective, Kreisselmeier and Engel have introduced in [14] this same expression (15) (but with X instead of $\breve{X}$ and B the identity function). Another link between [13] and [14] has been established in [16].

2.3. T injective. Assuming now we have at our disposal the continuous function T, we need to make sure that it is injective, if not uniformly injective as specified by (8). Here is where observability enters the game. Following [17], in [13, 15], when $m = n$, observability of the first order approximation at an equilibrium together with an appropriate choice of A and B is shown to imply injectivity of the solution T of (4) in a neighborhood of this equilibrium. In [14], uniform injectivity of T is obtained under the following two assumptions:

1. The past output path $t \mapsto h(X(x,t))$ is uniformly injective in x with the set of past output paths equipped with an exponentially weighted L^2-norm.

2. The system (1) has finite complexity, i.e., there exists a (finite) number M of piecewise continuous function ϕ_i in $L^2(\mathbb{R}_-;\mathbb{R}^p)$ and a strictly positive real number δ such that we have, for each pair (x_1,x_2) in $\mathcal{O}^2$,

$$\sum_{i=1}^{M}\left[\int_{-\infty}^{0}\exp(-\ell s)\phi_i(s)^T[h(X(x_1,s))-h(X(x_2,s))]ds\right]^2 \geq \delta\int_{-\infty}^{0}\exp(-2\ell s)|h(X(x_1,s))-h(X(x_2,s))|^2ds.$$

Our next result states that with the only assumption that the past output path $t \mapsto h(X(x,t))$ is injective in x, it is sufficient to choose $m = n+1$ generic complex eigenvalues for A to get T injective. The specific injectivity condition we need is as follows.

DEFINITION 2 (backward $\mathcal{O}$-distinguishability). *There exist two strictly positive real numbers $\delta_\Upsilon < \delta_d$ such that for each pair of distinct points x_1 and x_2 in $\mathcal{O}+\delta_\Upsilon$, there exists a time t, in $(\max\{\sigma^-_{\mathcal{O}+\delta_d}(x_1),\sigma^-_{\mathcal{O}+\delta_d}(x_2)\},0]$, such that we have*

$$h(X(x_1,t)) \neq h(X(x_2,t)).$$

This distinguishability assumption says that the present state x can be distinguished from other states in $\mathcal{O}+\delta_\Upsilon$ by looking at the past output path restricted to the negative time interval where the solution $X(x,t)$ is in $\mathcal{O}+\delta_d$.

THEOREM 3 (injectivity). *Assume the system (1) is backward complete within $\mathcal{O}+\delta_u$ and backward $\mathcal{O}$-distinguishable with the corresponding δ_d in $(0,\delta_u)$. Assume also the existence of an injective C^1 function $b:\mathbb{R}^p\to\mathbb{C}^p$, a continuous function $M:\mathcal{O}+\delta_\Upsilon\to\mathbb{R}^+$, and a negative real number ℓ such that, for each x in $\mathcal{O}+\delta_\Upsilon$, the two functions $t\mapsto\exp(-\ell t)b(h(\breve{X}(x,t)))$ and $t\mapsto\exp(-\ell t)\frac{\partial b\circ h\circ\breve{X}}{\partial x}(x,t)$ satisfy, for each t in $(\breve{\sigma}^-_{\mathbb{R}^n}(x),0]$,*

$$|\exp(-\ell t)b(h(\breve{X}(x,t)))| + \left|\exp(-\ell t)\frac{\partial b\circ h\circ\breve{X}}{\partial x}(x,t)\right| \leq M(x), \tag{16}$$

where again $\breve{X}$ is a solution of (13), but this time with the function χ satisfying

$$\chi(x) = 1 \quad \text{if} \quad x\in\mathcal{O}+\delta_d, \qquad \chi(x) = 0 \quad \text{if} \quad x\notin\mathcal{O}+\delta_u. \tag{17}$$

Under these conditions, there exists a subset S of $\mathbb{C}^{n+1}$ of zero Lebesgue measure such that the function $T:\mathtt{cl}(\mathcal{O})\to\mathbb{C}^{(n+1)\times p}$ defined, with the notation (3), by

$$T(x) = \int_{-\infty}^{0}\exp(-As)B_{1m}\,b(h(\breve{X}(x,s)))ds \tag{18}$$

is injective provided A is a diagonal matrix with $n+1$ complex eigenvalues λ_i arbitrarily chosen in $\mathbb{C}^{n+1}\setminus S$ and with real part strictly smaller than ℓ.

Remark 3. 1. Condition (16) holds, for instance, if f, h, and b have bounded derivative on $\mathtt{cl}(\mathcal{O} + \delta_\Upsilon)$ (see [16]).

2. Theorem 3 gives injectivity, not uniform injectivity. As already mentioned, if $\mathcal{O}$ is bounded, continuity and the former imply the latter.

Following Theorem 3, for any generic choice of $n+1$ complex eigenvalues for the matrix A, the function T given by (18) (or, equivalently, (15)) is injective. This says that the (real) row dimension of z is $m = 2n+2$. It is a well-known fact in observer theory that it is generically sufficient to extract $m = 2n+1$ pieces of information from the output path (with h generically chosen) to observe a state of dimension n (see, for instance, [1, 23, 10, 7, 22]). It can be understood from the adage that the relation $T(x_1) = T(x_2)$ between the two states x_1 and x_2 in $\mathbb{R}^n$, i.e., for $2n$ unknowns, has generically the unique trivial solution $x_1 = x_2$ if we have strictly more than $2n$ equations, i.e., $T(x)$ has strictly more than $2n$ components.

2.4. Injectivity in the case of complete observability. Another setup where injectivity can be obtained is when we have complete observability. Namely, we can find a row dimension m and a function $b : y \in \mathbb{R}^p \mapsto b(y) = (b_1(y), \dots, b_p(y)) \in \mathbb{R}^p$ so that the following function $H : \mathbb{R}^n \to \mathbb{R}^{m\times p}$ is injective when restricted to $\mathtt{cl}(\mathcal{O})$:

$$H(x) = \begin{pmatrix} b_1(h(x)) & \dots & b_p(h(x)) \\ L_f b_1(h(x)) & \dots & L_f b_p(h(x)) \\ \vdots & \vdots & \vdots \\ L_f^{m-1} b_1(h(x)) & \dots & L_f^{m-1} b_p(h(x)) \end{pmatrix}. \tag{19}$$

Here $L_f^i h$ denotes the ith iterate Lie derivative, i.e., $L_f^{i+1} h = L_f(L_f^i h)$. Of course, for this to make sense, the functions b, f, and h must be sufficiently smooth. This setup has been popularized and studied in detail by Gauthier and his coworkers (see [11] and the references therein; see also [18]). In particular, it is established in [10] that when $p = 1$, for any generic pair (f, h) in (1), it is sufficient to pick $m = 2n+1$.

With a Taylor expansion of the output path at $t = 0$, we see that the injectivity of H implies that the function which associates the initial condition x to the output path, restricted to a very small time interval, is injective. This property is nicely exploited by observers with very fast dynamics as high gain observers (see [11]). Specifically, we have the next theorem.

THEOREM 4 (injectivity in the case of complete observability). *Assume the existence of a sufficiently smooth function $b : \mathbb{R}^p \to \mathbb{C}^p$ such that for the function H defined in* (19)*, there exist a positive real number L and a class $\mathcal{K}_\infty$ function ρ such that we have*

$$|L_f^m b(h(x_1) - L_f^m b(h(x_2))| \le L|H(x_1) - H(x_2)| \quad \forall (x_1, x_2) \in \mathtt{cl}(\mathcal{O})^2, \tag{20}$$

$$|x_1 - x_2| \le \rho(|H(x_1) - H(x_2)|) \quad \forall (x_1, x_2) \in \mathtt{cl}(\mathcal{O})^2. \tag{21}$$

Then, for any diagonal Hurwitz complex $m \times m$ matrix A, with m the row dimension of H, there exists a real number k^* such that for any k strictly larger than k^*, there exists a function $T : \mathtt{cl}(\mathcal{O}) \to \mathbb{C}^{m\times p}$ which is continuous, uniformly injective, and satisfies (see (3)*)*

$$L_f T(x) \;=\; kAT(x) + B_{1m} b(h(x)) \qquad \forall x \in \mathcal{O}. \tag{22}$$

2.5. Approximation. Fortunately for the implementation of the observer, knowing a function T satisfying (7) only approximately is sufficient. But, in this case, we have to modify the observer dynamics.

THEOREM 5 (approximation). *Assume the system* (1) *is forward complete within* $\mathcal{O}$. *Assume also the existence of an integer* m, *a Hurwitz complex* $m \times m$ *matrix* A, *and functions* $T_a : \mathtt{cl}(\mathcal{O}) \to \mathbb{C}^{m\times p}$, *continuous,* $B : \mathbb{R}^p \to \mathbb{C}^{m\times p}$, *continuous, and* ρ *of class* $\mathcal{K}_\infty$, *such that*

$$|x_1 - x_2| \;\le\; \rho(|T_a(x_1) - T_a(x_2)|) \qquad \forall (x_1, x_2) \in \mathtt{cl}(\mathcal{O})^2, \tag{23}$$

the function $L_f T_a$ *is well defined on* $\mathcal{O}$, *and the function* $\mathfrak{E} : \mathtt{cl}(\mathcal{O}) \to \mathbb{C}^{m\times p}$ *defined as*

$$\mathfrak{E}(x) = L_f T_a(x) - [AT_a(x) + B(h(x))] \qquad \forall x \in \mathcal{O} \tag{24}$$

satisfies

$$|\mathfrak{E}(x_1) - \mathfrak{E}(x_2)| \;\le\; N\,|T_a(x_1) - T_a(x_2)| \qquad \forall (x_1, x_2) \in \mathtt{cl}(\mathcal{O})^2, \tag{25}$$

where N *is a positive real number satisfying*

$$2N\,\lambda_{\max}(P) \;<\; 1 \tag{26}$$

with $\lambda_{\max}(P)$ *the largest eigenvalue of the Hermitian matrix* P *solution of*

$$\overline{A}^{\top} P + PA = -I. \tag{27}$$

Under these conditions, there exists a function $T_a^* : \mathbb{C}^{m\times p} \to \mathtt{cl}(\mathcal{O})$ *and a locally Lipschitz function* $\mathfrak{F} : \mathbb{C}^{m\times p} \to \mathbb{C}^{m\times p}$ *such that for each* x *in* $\mathcal{O}$ *and* z *in* $\mathbb{C}^{m\times p}$ *each solution* $(X(x,t), Z(x,z,t))$ *of*

$$\dot{x} \;=\; f(x), \qquad \dot{z} \;=\; Az + \mathfrak{F}(z) + B(h(x)) \tag{28}$$

is right maximally defined on $[0, \sigma^+_{\mathbb{R}^n}(x))$. *Moreover, we have the implication*

$$\sigma^+_{\mathcal{O}}(x) \;=\; \sigma^+_{\mathbb{R}^n}(x) \qquad \Longrightarrow \qquad \lim_{t\to\sigma^+_{\mathbb{R}^n}(x)} |T_a^*(Z(x,z,t)) - X(x,t)| \;=\; 0. \tag{29}$$

Remark 4. 1. In (24), $\mathfrak{E}$ represents the error in (7) given by the approximation T_a of T. This error should not be too large in an incremental sense as specified by (25) and (26). This indicates that one way to approximate T is to look for T_a in a set of functions minimizing the L^∞ norm on $\mathtt{cl}(\mathcal{O})$ of the gradient of the associated error $\mathfrak{E}$. In particular, in the case where $\mathcal{O}$ is bounded, it follows from the Weierstrass approximation theorem that we can always choose a Hurwitz complex matrix A and a linear function B so that the constraint (26) can be satisfied by restricting ourself to choose the function T_a as a polynomial in x.

2. The function $\mathfrak{F}$ in the observer (28) can be chosen as any Lipschitz extension of $\mathfrak{E} \circ T_a^*$ outside $T_a(\mathtt{cl}(\mathcal{O}))$. This is very similar to what is done in [18] where a constructive procedure for this extension is proposed. Fortunately, this Lipschitz extension is not needed in the case where the function $\mathfrak{E}$ satisfies

$$|\mathfrak{E}(x_1) - \mathfrak{E}(x_2)| \le \frac{N}{4}\,\rho^{-1}(|x_1 - x_2|) \quad \forall (x_1, x_2) \in \mathtt{cl}(\mathcal{O})^2,$$

where ρ is the function satisfying (23). In this case we take simply (see (67))

$$\mathfrak{F}(z) = \mathfrak{E}(T_a^*(z)) \quad \forall z \in \mathbb{C}^{m\times p}.$$

The combination of Theorems 4 and 5 gives us a new insight in the classical high gain observer of order m as studied in [10] or [18], for instance. Specifically, we have the following.

COROLLARY 1 (high gain observer). *Assume the system* (1) *is forward complete within* $\mathcal{O}$ *and there exist a sufficiently smooth function* $b : \mathbb{R}^p \to \mathbb{C}^p$, *a class* $\mathcal{K}_\infty$ *function* ρ, *and a positive real number* L *such that* (20) *and* (21) *hold with* H *and* m *given by* (19). *Under these conditions, for any diagonal Hurwitz complex* $m \times m$ *matrix* A, *there exists a real number* k^* *such that for any real number* k *strictly larger than* k^*, *there exist a function* $T_a^* : \mathbb{C}^{m\times p} \to \mathtt{cl}(\mathcal{O})$, *left inverse on* $T_a(\mathtt{cl}(\mathcal{O}))$ *of the function* $T_a : \mathtt{cl}(\mathcal{O}) \to \mathbb{C}^{m\times p}$ *defined as*

$$T_a(x) \;=\; -\sum_{i=1}^{m} (kA)^{-i} B_{1m} L_f^{i-1} b(h(x)) \tag{30}$$

and a function $\mathfrak{F} : \mathbb{R}^{m\times p} \to \mathbb{R}^{m\times p}$ *such that for each* x *in* $\mathcal{O}$ *and* z *in* $\mathbb{R}^{m\times p}$ *each solution* $(X(x,t), Z(x,z,t))$ *of*

$$\dot{x} \;=\; f(x), \qquad \dot{z} \;=\; kAz \;+\; \mathfrak{F}(z) \;+\; B_{1m}\, b(h(x)) \tag{31}$$

is right maximally defined on $[0, \sigma^+_{\mathbb{R}^n}(x))$. *Moreover, we have the implication*

$$\sigma^+_{\mathcal{O}}(x) \;=\; \sigma^+_{\mathbb{R}^n}(x) \qquad \Longrightarrow \qquad \lim_{t\to\sigma^+_{\mathbb{R}^n}(x)} |T_a^*(Z(x,z,t)) - X(x,t)| \;=\; 0. \tag{32}$$

Remark 5. When $\mathcal{O}$ is bounded and H is injective, uniform injectivity (21) and forward completeness within $\mathcal{O}$ hold necessarily. Thus, in this case, we recover [18, Lemma 1].

2.6. Extension to boundedness observability. Completeness is a severe restriction. Instead, it is proved in [4] that a necessary condition for the existence of an observer providing the convergence to zero of the observation error within the domain of definition of the solutions is the forward unboundedness observability property.

DEFINITION 3 (unboundedness observable within $\mathcal{O}$). *The system* (1) *is forward (resp., backward) unboundedness observable within* $\mathcal{O}$ *if there exists a proper and* C^1 *function* $V_{\mathfrak{f}} : \mathbb{R}^n \to \mathbb{R}_+$ *(resp.,* $V_{\mathfrak{b}} : \mathbb{R}^n \to \mathbb{R}_+$*) and a continuous function* $\gamma_{\mathfrak{f}} : \mathbb{R}^p \to \mathbb{R}_+$ *(resp.,* $\gamma_{\mathfrak{b}} : \mathbb{R}^p \to \mathbb{R}_+$*) such that*

$$L_f V_{\mathfrak{f}}(x) \le V_{\mathfrak{f}}(x) \;+\; \gamma_{\mathfrak{f}}(h(x)) \qquad \forall x \in \mathcal{O}, \tag{33}$$

$$(\text{ resp. } L_f V_{\mathfrak{b}}(x) \ge -V_{\mathfrak{b}}(x) \;-\; \gamma_{\mathfrak{b}}(h(x)) \qquad \forall x \in \mathcal{O}).$$

Fortunately, all our previous results still hold if completeness is replaced by unboundedness observability but provided[1]

1. the observer is modified in

$$\dot{z} \;=\; \gamma(y)\,[Az + B(y)]\,, \qquad \widehat{x} \;=\; T^*(z),$$

[1]The interested reader will find in [3] the precise statements of the corresponding results.

where γ is a C^1 function satisfying

$$\gamma(h(x)) \geq 1 + \gamma_{\mathfrak{f}}(h(x)) \quad \text{(resp., and } \gamma(h(x)) \geq 1 + \gamma_{\mathfrak{b}}(h(x))) \quad \forall x \in \mathtt{cl}(\mathcal{O}). \tag{34}$$

As suggested in [4], the introduction of γ takes care of possible finite escape time. This has nothing in common with the objective of error dynamics linearization as considered in [19].

2. In most occurrences, e.g., (7), (13), (19), (22), (24), ..., f is replaced by f_γ defined as

$$f_\gamma(x) \;=\; \frac{f(x)}{\gamma(h(x))}.$$

3. Proofs.

3.1. Proof of Theorem 1. Because of the triangular structure of the system (9), for each x in $\mathcal{O}$ and z in $\mathbb{C}^{m\times p}$, the component $Z(x,z,t)$ of the corresponding solution of this system is defined as long as $h(X(x,t))$ is defined. So this solution $(X(x,t), Z(x,z,t))$ is right maximally defined on the same interval $[0, \sigma^+_{\mathbb{R}^n}(x))$ as $X(x,t)$, solution of (1).

Let us now restrict our attention to points x in $\mathcal{O}$ satisfying the condition on the left in (10). In this case, with the forward completeness within $\mathcal{O}$, we have (11). On the other hand, from (7) and (9), we obtain, for each x in $\mathcal{O}$, z in $\mathbb{C}^{m\times p}$ and t in $[0, \sigma^+_{\mathbb{R}^n}(x))$,

$$T(X(x,t)) - Z(x,z,t) \;=\; \exp(At)\,(T(x) - z). \tag{35}$$

As A is a Hurwitz matrix, this and (11) yield

$$\lim_{t\to\sigma^+_{\mathbb{R}^n}(x)} |Z(x,z,t) - T(X(x,t))| \;=\; 0.$$

From this, the implication (10) follows readily if there exist a continuous function $T^* : \mathbb{C}^{m\times p} \to \mathtt{cl}(\mathcal{O})$ and a class $\mathcal{K}_\infty$ function $\rho^* : \mathbb{R}_+ \to \mathbb{R}_+$ satisfying

$$|T^*(z) - x| \;\leq\; \rho^*(z - T(x)) \qquad \forall z \in \mathbb{C}^{m\times p}\,,\ \forall x \in \mathtt{cl}(\mathcal{O}). \tag{36}$$

To find such functions, we first remark, as in [14], that (8) and completeness of $\mathbb{C}^{m\times p}$ and $\mathbb{R}^n$ imply that $T(\mathtt{cl}(\mathcal{O}))$ is a closed subset of $\mathbb{C}^{m\times p}$. It follows that for each z in $\mathbb{C}^{m\times p}$, the infimum, in x in $\mathtt{cl}(\mathcal{O})$, of $|T(x) - z|$ is achieved by at least one point, denoted $T^*_p(z)$ (in $\mathtt{cl}(\mathcal{O})$). This defines a function $T^*_p : \mathbb{C}^{m\times p} \to \mathtt{cl}(\mathcal{O})$ satisfying

$$T(T^*_p(z)) \;=\; z \qquad \forall z \in T(\mathtt{cl}(\mathcal{O})), \tag{37}$$

$$|T(T^*_p(z)) - z| \;\leq\; |T(x) - z| \qquad \forall z \in \mathbb{C}^{m\times p}\,,\ \forall x \in \mathtt{cl}(\mathcal{O}). \tag{38}$$

With (8), (37) implies that the restriction T^*_p to $T(\mathtt{cl}(\mathcal{O}))$ is continuous. Also, with the triangle inequality, (38) gives, for each z in $\mathbb{C}^{m\times p}$ and each x in $\mathtt{cl}(\mathcal{O})$,

$$|x - T^*_p(z)| \;\leq\; \rho(|T(x) - z| + |z - T(T^*_p(z))|) \;\leq\; \rho(2|T(x) - z|). \tag{39}$$

Now we build the function T^* by smoothing out T^*_p. For each z in $\mathbb{C}^{m\times p}$, let

$$\epsilon(z) \;=\; \frac{1}{2} \inf_{x\in\mathtt{cl}(\mathcal{O})} |T(x) - z|.$$

$\big(\mathcal{B}_{\epsilon(z)}(z)\big)_{z\in\mathbb{C}^{m\times p}\setminus T(\mathtt{cl}(\mathcal{O}))}$ is a covering of the open set $\mathbb{C}^{m\times p}\setminus T(\mathtt{cl}(\mathcal{O}))$ by open subsets. From the Lindelöf theorem (see [6, Lemma 4.1], for instance), there exists a sequence $\{z_i\}_{i\in\mathbb{N}}$ such that $\big\{\mathcal{B}_{\epsilon(z_i)}(z_i)\big\}_{i\in\mathbb{N}}$ is a countable and locally finite covering by open subsets of $\mathbb{C}^{m\times p}\setminus T(\mathtt{cl}(\mathcal{O}))$.

For each x in $\mathtt{cl}(\mathcal{O})$, each z_i in $\{z_i\}_{i\in\mathbb{N}}$ and each z in $\mathcal{B}_{\epsilon(z_i)}(z_i)$, we have

$$|z_i - z| \;<\; \epsilon(z_i) \;\le\; \frac{1}{2}\,|T(x) - z_i| \;\le\; \frac{1}{2}\,[|T(x) - z| + |z - z_i|] \;\le\; |T(x) - z|.$$

With (39), this gives

$$|x - T_p^*(z_i)| \;\le\; \rho(2|T(x) - z_i|) \;\le\; \rho(2(|T(x) - z| + |z - z_i|)) \;\le\; \rho(4|T(x) - z|).$$

From [6, Theorem IV.4.4], we know that there exists a countable set of C^∞ functions $\{\phi_i\}_{i\in\mathbb{N}} : \mathbb{C}^{m\times p}\setminus T(\mathtt{cl}(\mathcal{O})) \to [0,1]$ satisfying, for each z in $\mathbb{C}^{m\times p}\setminus T(\mathtt{cl}(\mathcal{O}))$,

$$\sum_i \phi_i(z) \;=\; 1, \qquad\qquad \phi_i(z) \;=\; 0 \quad \forall z \notin \mathcal{B}_{\epsilon(z_i)}(z_i).$$

We define the function $T^* : \mathbb{C}^{m\times p} \to T(\mathtt{cl}(\mathcal{O}))$ as

$$\begin{aligned} T^*(z) &= \sum_i \phi_i(z) T_p^*(z_i) \quad \text{if } z \in \mathbb{C}^{m\times p}\setminus T(\mathtt{cl}(\mathcal{O})),\\ &= T_p^*(z) \qquad\qquad\quad \text{if } z \in T(\mathtt{cl}(\mathcal{O})). \end{aligned}$$

It is continuous when restricted to the open set $\mathbb{C}^{m\times p}\setminus T(\mathtt{cl}(\mathcal{O}))$ and to the closed set $T(\mathtt{cl}(\mathcal{O}))$. Also, for each z in $\mathbb{C}^{m\times p}\setminus T(\mathtt{cl}(\mathcal{O}))$ and each x in $\mathtt{cl}(\mathcal{O})$, we get

$$\begin{aligned} |T^*(z) - x| \;&=\; \left|\sum_i \phi_i(z) T_p^*(z_i) - x\right| \le \sum_i \phi_i(z)|T_p^*(z_i) - x|,\\ &\le \sum_i \phi_i(z)\rho(4|z - T(x)|) \;\le\; \rho(4|z - T(x)|). \end{aligned} \tag{40}$$

And, for each z in $T(\mathtt{cl}(\mathcal{O}))$ and each x in $\mathtt{cl}(\mathcal{O})$, we get readily from (8) and (37)

$$|T^*(z) - x| \;=\; |T_p^*(z) - x| \;\le\; \rho(|T(T_p^*(z)) - T(x)|) \;=\; \rho(|z - T(x)|). \tag{41}$$

With (40) and (41), (36) is established. This proves also that T^* is continuous on whole $\mathbb{C}^{m\times p}$.

3.1.1. Proof of Theorem 2. With [12, Corollary I.4.7], we know there exists a locally Lipschitz function $\chi : \mathbb{R}^n \to \mathbb{R}$ satisfying (14). It follows that the function $\breve{f}$ in (13) is locally Lipschitz. Thus, for each x in $\mathbb{R}^n$ there exists a unique solution $\breve{X}(x,t)$ of (13), with initial condition x, maximally defined on $(\breve{\sigma}^-_{\mathbb{R}^n}(x), \breve{\sigma}^+_{\mathbb{R}^n}(x))$. Moreover, backward completeness within $\mathcal{O} + \delta_u$ of (1) implies backward completeness of (13), i.e., $\breve{\sigma}^-_{\mathbb{R}^n}(x) = -\infty$. Following [2], this implies the existence of a proper and C^1 function $V_{\mathfrak{b}} : \mathbb{R}^n \to \mathbb{R}_+$ and a continuous function $\gamma_{\mathfrak{b}} : \mathbb{R}^p \to \mathbb{R}_+$ satisfying

$$L_{\breve{f}} V_{\mathfrak{b}}(x) \;\ge\; -V_{\mathfrak{b}}(x) \;-\; 1 \qquad \forall x \in \mathbb{R}^n. \tag{42}$$

Let α be a strictly positive real number so that $A + \alpha I$ is a Hurwitz matrix. We define the function $W_{\mathfrak{b}} : \mathbb{R}^n \to \mathbb{R}$ as

$$W_{\mathfrak{b}}(x) \;=\; (V_{\mathfrak{b}}(x) \;+\; 1)^\alpha.$$

With the help of Gronwall's lemma, (42) yields

$$W_{\mathfrak{b}}(\breve{X}(x,t)) \leq W_{\mathfrak{b}}(x)\exp(-\alpha t) \qquad \forall x \in \mathbb{R}^n,\ \forall t \in (-\infty, 0]. \tag{43}$$

Since $W_{\mathfrak{b}}$ is a proper function and h is continuous, we can find a C^1 function $\beta : \mathbb{R}_+ \to \mathbb{R}_+$ of class $\mathcal{K}_\infty$ and a real number β_0 such that for each component h_i of h, we have

$$|h_i(x)| \ \leq\ \beta(W_{\mathfrak{b}}(x)) + \beta_0 \qquad \forall x \in \mathbb{R}^n.$$

Let $\breve{\beta} : \mathbb{R}_+ \to \mathbb{R}_+$ be the function defined as

$$\breve{\beta}(w) \ =\ \sqrt{w} \ +\ \beta(w) \ +\ \beta_0.$$

This function is strictly increasing, C^1 on $(0, +\infty)$ and its derivative $\breve{\beta}'$ satisfies

$$\lim_{x \to 0} \breve{\beta}'(x) \ =\ +\infty.$$

It admits an inverse $\breve{\beta}^{-1} : \mathbb{R}_+ \to \mathbb{R}_+$ which satisfies

$$\breve{\beta}^{-1}(|h_i(x)|) \ \leq\ W_{\mathfrak{b}}(x) \qquad \forall x \in \mathbb{R}^n. \tag{44}$$

Moreover the function $\eta \mapsto \frac{\eta \breve{\beta}^{-1}(|\eta|)}{|\eta|}$ is C^1 on $\mathbb{R}\backslash\{0\}$ and can be extended by continuity on $\mathbb{R}$ as a C^1 injective function. So, with p arbitrary vectors b_j in $\mathbb{R}^m$, we define the function $B : \mathbb{R}^p \to \mathbb{R}^{m \times p}$ as

$$B(h) = \left(\begin{array}{ccc} \frac{h_1 \breve{\beta}^{-1}(|h_1|)}{|h_1|} b_1 & \dots & \frac{h_p \breve{\beta}^{-1}(|h_p|)}{|h_p|} b_p \end{array} \right).$$

Since $A + \alpha I$ is a Hurwitz matrix, (43), (44), and the backward completeness imply

1. The existence of strictly positive real numbers c_0, c_1, and ε such that we have

$$|\exp(-As)B(h(\breve{X}(x,s)))| \leq c_0\, |\exp(-As)|\, W_{\mathfrak{b}}(\breve{X}(x,s)), \tag{45}$$

$$\leq c_1\, W_{\mathfrak{b}}(x)\, \exp(\varepsilon s) \qquad \forall (s,x) \in \mathbb{R}_- \times \mathbb{R}^n. \tag{46}$$

2. For each fixed s in $\mathbb{R}_-$, the function $x \mapsto \exp(-As)B(h(\breve{X}(x,s)))$ is continuous.

So the Lebesgue dominated convergence Theorem (see [8, Théorème (3.149)], for instance) implies that the following expression defines properly a continuous function $T : \mathbb{R}^n \to \mathbb{C}^{m \times p}$:

$$T(x) \ =\ \int_{-\infty}^{0} \exp(-As)\, B(h(\breve{X}(x,s)))ds. \tag{47}$$

Then, for each x in $\mathbb{R}^n$ and for each t in $(-\infty, \breve{\sigma}^{+}_{\mathbb{R}^n}(x))$, we get

$$\begin{aligned} T(\breve{X}(x,t)) - T(x) &= \int_{-\infty}^{0} \exp(-As)\, B(h(\breve{X}(\breve{X}(x,t),s)))ds \ -\ T(x), \\ &= \exp(At) \int_{-\infty}^{t} \exp(-Au)\, B(h(\breve{X}(x,u)))du \ -\ T(x), \\ &= (\exp(At) - I)\, T(x) \ +\ \exp(At) \int_{0}^{t} \exp(-Au) B(h(\breve{X}(x,u)))du. \end{aligned}$$

Thus, we obtain, for all x in $\mathbb{R}^n$,

$$\chi(x)\, L_f T(x) = L_{\breve{f}} T(x) = \lim_{t\to 0} \frac{T(\breve{X}(x,t)) - T(x)}{t} = AT(x) + B(h(x)). \tag{48}$$

With (14), this implies (7) is satisfied. □

Remark 6. 1. For the case where A is diagonalizable, with eigenvalue λ_i, and where the vectors b_j are chosen so that the p pairs (A, b_j) are controllable, our expression for T gives for its ith component in the diagonalizing coordinates:

$$T_i(x) \;=\; \int_{-\infty}^{0} \exp(-\lambda_i s) B_i(h(\breve{X}(x,s)))ds \tag{49}$$

with

$$B_i(h) \;=\; \left(\begin{array}{ccc} \frac{h_1 \breve{\beta}^{-1}(|h_1|)}{|h_1|} b_{i1} & \dots & \frac{h_p \breve{\beta}^{-1}(|h_p|)}{|h_p|} b_{ip} \end{array} \right),$$

where each b_{ij} is nonzero. Note that each of the m rows of the function B is an injective function from $\mathbb{R}^p$ to $\mathbb{R}^p$.

2. If $\mathcal{O}$ is bounded, the function $s \in \mathbb{R}_- \mapsto h(\breve{X}(x,s)) \in \mathbb{R}^p$ is a bounded function, uniformly in x in $\mathtt{cl}(\mathcal{O})$. It follows that the inequality (46) holds by choosing the function $\breve{\beta}^{-1}$ simply as the identity function. This says that, in this case, the function B is linear.

3.2. Proof of Theorem 3. We first remark that backward $\mathcal{O}$-distinguishability property of the original system (1) implies the same property for the modified system (13). Then we need the following lemma.

LEMMA 1 (due to Coron). *Let Ω and Υ be open subsets of $\mathbb{C}$ and $\mathbb{R}^{2n}$, respectively. Let $g : \Upsilon \times \Omega \to \mathbb{C}^p$ be a function which is holomorphic in λ for each x in Υ and C^1 in x for each λ in Ω. If for each pair (x,λ) in $\Upsilon \times \Omega$ for which $g(x,\lambda)$ is zero we can find, for at least one of the p components g_j of g, an integer k satisfying*

$$\frac{\partial^i g_j}{\partial \lambda^i}(x,\lambda) \;=\; 0 \qquad \forall i \in \{0,\dots,k-1\}, \qquad\qquad \frac{\partial^k g_j}{\partial \lambda^k}(x,\lambda) \;\neq\; 0, \tag{50}$$

then the following set has zero Lebesgue measure in $\mathbb{C}^{n+1}$:

$$S \;=\; \bigcup_{x\in\Upsilon} \left\{ (\lambda_1,\dots,\lambda_{n+1}) \in \Omega^{n+1} :\; g(x,\lambda_1) = \cdots = g(x,\lambda_{n+1}) = 0 \right\}. \tag{51}$$

This result has been established by Coron in [7, Lemma 3.2] in a stronger form except for the very minor point that, here, g is not C^∞ in both x and λ. To make sure that this difference has no bad consequence and for the sake of completeness, we give an ad hoc proof in the appendix.

To complete the proof of Theorem 3 all we have to do is to generate an appropriate function g satisfying all the required assumptions of this Lemma 1.

Let Ω and Υ be the following open subsets of $\mathbb{C}$ and $\mathbb{R}^{2n}$, respectively:

$$\Omega \;=\; \{\lambda \in \mathbb{C} :\, \mathtt{Re}(\lambda) < \ell\}, \qquad \Upsilon \;=\; \left\{ x = (x_1, x_2) \in (\mathcal{O} + \delta_\Upsilon)^2 :\, x_1 \neq x_2 \right\}.$$

By following the same arguments as in the proof of Theorem 2, the backward completeness allows us to conclude

$$\breve{\sigma}^{-}_{\mathbb{R}^n}(x) = -\infty \qquad \forall x \in \mathcal{O} + \delta_\Upsilon.$$

Then, with (16), we get, for each (x,λ,t) in $(\mathcal{O}+\delta_\Upsilon)\times\Omega\times(-\infty,0]$,

$$\begin{aligned}|\exp(-\lambda t)\, b(h(\breve{X}(x,t)))| &\leq \exp([\ell-\mathtt{Re}(\lambda)]t)|\exp(-\ell t) b(h(\breve{X}(x,t)))|,\\ &\leq \exp([\ell-\mathtt{Re}(\lambda)]t)\, M(x).\end{aligned}$$

So the Lebesgue dominated convergence theorem implies that for each fixed λ in Ω, the expression

$$T_\lambda(x) \;=\; \int_{-\infty}^{0} \exp(-\lambda s)\, b(h(\breve{X}(x,s)))ds$$

defines properly a continuous function $T_\lambda : \mathcal{O}+\delta_\Upsilon \to \mathbb{C}^p$. With similar arguments (see [8, Théorème (3.150)], for instance), with (16), we can establish that this function is actually C^1.

Now, let $\mathcal{D}T : (\mathcal{O}+\delta_\Upsilon)^2\times\Omega\to\mathbb{C}^p$ be the function defined as

$$\begin{aligned}\mathcal{D}T(x,\lambda) &= T_\lambda(x_1)-T_\lambda(x_2),\\ &= \int_{-\infty}^{0}\exp(-\lambda s)[b(h(\breve{X}(x_1,s)))-b(h(\breve{X}(x_2,s)))]ds\end{aligned} \tag{52}$$

with $x=(x_1,x_2)$. It is C^1 in x in $(\mathcal{O}+\delta_\Upsilon)^2$ for each λ in Ω. Also, as proved in [21, chapter 19, p. 367] with the help of the Morera and Fubini theorems, it is holomorphic in λ in Ω for each x in $(\mathcal{O}+\delta_\Upsilon)^2$. Moreover, since we have for each a in $(-\infty,\ell)$

$$\int_{-\infty}^{0}\exp(-2as)|b(h(\breve{X}(x_1,s)))-b(h(\breve{X}(x_2,s)))|^2\,ds \;\leq\; \frac{M(x_1)^2+M(x_2)^2}{2(\ell-a)} \;<\; +\infty,$$

we can apply the Plancherel theorem to obtain, for each a in $(-\infty,\ell)$ and each x in $(\mathcal{O}+\delta_\Upsilon)^2$,

$$\begin{aligned}&\frac{1}{2\pi}\int_{-\infty}^{+\infty}|\mathcal{D}T(x,a+is)|^2\,ds\\ &\qquad=\int_{-\infty}^{0}\exp(-2as)|b(h(\breve{X}(x_1,s)))-b(h(\breve{X}(x_2,s)))|^2\,ds.\end{aligned} \tag{53}$$

Now, for x in Υ, with the distinguishability property, continuity with respect to time and injectivity of b imply the existence of an open time interval (t_0,t_1) such that

$$|b(h(\breve{X}(x_1,s)))-b(h(\breve{X}(x_2,s)))| \;>\; 0 \qquad \forall s\in(t_0,t_1).$$

It follows with (53) that we have

$$\int_{-\infty}^{+\infty}|\mathcal{D}T(x,a+is)|^2\,ds \;>\; 0.$$

This says that for each x in Υ, the function $\lambda\mapsto\mathcal{D}T(x,\lambda)$ is not identically equal zero on Ω. Since it is holomorphic, this implies that for each (x,λ) in $\Upsilon\times\Omega$, we can find, for at least one of the p components $\mathcal{D}T_j$ of $\mathcal{D}T$, an integer k satisfying

$$\frac{\partial^i\mathcal{D}T_j}{\partial\lambda^i}(x,\lambda) \;=\; 0 \qquad \forall i\in\{0,\dots,k-1\}, \qquad\qquad \frac{\partial^k\mathcal{D}T_j}{\partial\lambda^k}(x,\lambda) \;\neq\; 0.$$

Thus we can invoke Lemma 1 with $\mathcal{D}$ as function g. With (52), it allows us to conclude that the following set S has zero Lebesgue measure in $\mathbb{C}^{n+1}$:

$$S \;=\; \bigcup_{(x_1,x_2)\in\Upsilon}\left\{(\lambda_1,\dots,\lambda_{n+1})\in\Omega^{n+1}:\quad T_{\lambda_i}(x_1)=T_{\lambda_i}(x_2)\quad \forall i\in\{1,\dots,n+1\}\right\}.$$

3.3. Proof of Theorem 4. Our first step consists in proposing a function T solution of (22). The definition (19) of H and the inequality (20), give, for each pair (x_1, x_2) in $\mathtt{cl}(\mathcal{O})^2$,

$$\begin{aligned}|L_f H(x_1) - L_f H(x_2)| &\leq |H(x_1) - H(x_2)| + |L_f^m b(h(x_1)) - L_f^m b(h(x_2))|,\\ &\leq (1+L)|H(x_1) - H(x_2)|.\end{aligned}$$

Also (21) implies that for each Y in $H(\mathtt{cl}(\mathcal{O}))$, there exists a unique x in $\mathtt{cl}(\mathcal{O})$ solution of $Y = H(x)$. Hence we can define a Lipschitz function $F : H(\mathtt{cl}(\mathcal{O})) \to \mathbb{R}^{m\times p}$ satisfying

$$F(H(x)) \;=\; L_f H(x) \qquad \forall x \in \mathtt{cl}(\mathcal{O}). \tag{54}$$

Furthermore, as in the proof of Theorem 1, continuity and uniform injectivity of the function H on $\mathtt{cl}(\mathcal{O})$ as given by (21) imply that $H(\mathtt{cl}(\mathcal{O}))$ is closed. Then it follows from Kirszbraun's Lipschitz extension theorem (see [9, Theorem 2.10.43], for instance) that F can be extended as a function $\breve{F} : \mathbb{R}^{m\times p} \to \mathbb{R}^{m\times p}$ satisfying

$$|\breve{F}(Y_1) - \breve{F}(Y_2)| \leq (1+L)\,|Y_1 - Y_2| \qquad \forall (Y_1, Y_2) \in \mathbb{R}^{m\times p} \times \mathbb{R}^{m\times p}, \tag{55}$$

$$\breve{F}(Y) = F(Y) \qquad \forall Y \in H(\mathtt{cl}(\mathcal{O})). \tag{56}$$

Let $\mathfrak{Y}(Y,t)$ denote a solution of the following system on $\mathbb{R}^{m\times p}$:

$$\dot{Y} = \breve{F}(Y).$$

With (55), such a solution is unique for each Y in $\mathbb{R}^{m\times p}$ defined on $(-\infty, +\infty)$ and satisfies, for some fixed matrix Y_0 in $\mathbb{R}^{m\times p}$ and for each pair (Y_1, Y_2) in $\mathbb{R}^{m\times p} \times \mathbb{R}^{m\times p}$,

$$\begin{aligned}|\mathfrak{Y}(Y_1,t) - Y_0| &\leq |Y_1 - Y_0| \;+\; \int_t^0 |\breve{F}(\mathfrak{Y}(Y_1,s)) - \breve{F}(Y_0)|ds \;-\; |\breve{F}(Y_0)|\,t,\\ &\leq |Y - Y_0| \;+\; (1+L)\int_t^0 |\mathfrak{Y}(Y,s) - Y_0|ds \;-\; |\breve{F}(Y_0)|\,t,\\ |\mathfrak{Y}(Y_1,t) - \mathfrak{Y}(Y_2,t)| &\leq (1+L)\int_t^0 |\mathfrak{Y}(Y_1,s) - \mathfrak{Y}(Y_2,t)|ds.\end{aligned}$$

With Gronwall's inequality, this gives for all $t \leq 0$,

$$|\mathfrak{Y}(Y,t) - Y_0| \leq \exp(-(1+L)t)\left[|Y - Y_0| + \frac{|\breve{F}(Y_0)|}{1+L}\right] \;-\; \frac{\breve{F}(Y_0)}{1+L}, \tag{57}$$

$$|\mathfrak{Y}(Y_1,t) - \mathfrak{Y}(Y_2,t)| \leq \exp(-(1+L)t)\,|Y_1 - Y_2|. \tag{58}$$

So, in particular, we have, for each $t \leq 0$ and Y in $\mathbb{R}^{m\times p}$,

$$|\breve{F}(\mathfrak{Y}(Y,t))| \;\leq\; (1+L)\left(\exp(-(1+L)t)\left[|Y - Y_0| + \frac{|\breve{F}(Y_0)|}{1+L}\right]\right). \tag{59}$$

Hence, given any diagonal Hurwitz $m \times m$ matrix A, with eigenvalue λ_i, for each real number $k \geq \frac{1+L}{-\max_i\{\mathtt{Re}(\lambda_i)\}}$, we can properly define a continuous function $\mathfrak{R} : \mathbb{R}^{m\times p} \to \mathbb{C}^m$ as

$$\mathfrak{R}(Y) \;=\; \int_{-\infty}^0 \exp(-skA)\,B_{1m}\,\breve{F}(\mathfrak{Y}(Y,s))_m ds \tag{60}$$

with the notation (3), and where $\breve{F}(Y)_m$ denotes the mth row of $\breve{F}(Y)$. As for (48), we can prove that we have

$$L_{\breve{F}}\mathfrak{R}(Y) \;=\; kA\,\mathfrak{R}(Y) \;+\; B_{1m}\,\breve{F}(Y)_m \qquad \forall Y \in \mathbb{R}^{m\times m}.$$

But with (19), (54), and (56), this yields

$$L_F\mathfrak{R}(H(x)) \;=\; kA\,\mathfrak{R}(H(x)) \;+\; B_{1m}\,L_f^m b(h(x)) \qquad \forall x \in \mathtt{cl}(\mathcal{O}). \tag{61}$$

Let now $T : \mathtt{cl}(\mathcal{O}) \to \mathbb{R}^n$ be the continuous function defined as

$$T(x) \;=\; (kA)^{-m}\mathfrak{R}(H(x)) - K^{-1}SH(x) \tag{62}$$

with the notations:

$$S \;=\; \begin{pmatrix} \lambda_1^{-1} & \dots & \lambda_1^{-m} \\ \vdots & \vdots & \vdots \\ \lambda_m^{-1} & \dots & \lambda_m^{-m} \end{pmatrix}, \qquad K \;=\; \mathrm{diag}\,(k,\dots,k^m). \tag{63}$$

We want to show that T is a solution of (22). We have

$$K^{-1}SH(x) = \begin{pmatrix} \sum_{i=1}^m (k\lambda_1)^{-i} L_f^{i-1} b(h(x)) \\ \vdots \\ \sum_{i=1}^m (k\lambda_m)^{-i} L_f^{i-1} b(h(x)) \end{pmatrix}.$$

Thus, for each x in $\mathbb{R}^n$, we get

$$K^{-1}SL_fH(x) \;=\; kAK^{-1}SH(x) \;-\; B_{1m}b(h(x)) \;+\; (kA)^{-m}B_{1m}L_f^m b(h(x)). \tag{64}$$

In view of (62), it remains to compute the Lie derivatives of $(kA)^{-m}\mathfrak{R}(H(x))$. From (14), (19), (54), and (56), we get the identity

$$\mathfrak{Y}(H(x),t) \;=\; H(\breve{X}(x,t)) \qquad \forall t \in (\breve{\sigma}^{\,-}_{\mathcal{O}}(x), \breve{\sigma}^{\,+}_{\mathcal{O}}(x)) \qquad \forall x \in \mathcal{O}.$$

This gives readily for all t in $(\breve{\sigma}^{\,-}_{\mathcal{O}}(x), \breve{\sigma}^{\,+}_{\mathcal{O}}(x))$ and x in $\mathcal{O}$,

$$\mathfrak{R}(\mathfrak{Y}(H(x),t)) \;-\; \mathfrak{R}(H(x)) \;=\; \mathfrak{R}(H(\breve{X}(x,t)) \;-\; \mathfrak{R}(H(x))$$

and therefore

$$L_F\mathfrak{R}(H(x)) \;=\; L_f\mathfrak{R}(H(x)) \qquad \forall x \in \mathcal{O}.$$

By continuity this identity extends to $\mathtt{cl}(\mathcal{O})$. So, with (61), we get

$$L_f\mathfrak{R}(H(x)) \;=\; kA\,\mathfrak{R}(H(x)) \;+\; B_{1m}\,L_f^m(b(h(x))) \qquad \forall x \in \mathtt{cl}(\mathcal{O}).$$

Consequently, with (62) and (64), we finally obtain, for each x in $\mathtt{cl}(\mathcal{O})$,

$$\begin{aligned} L_fT(x) &= (kA)^{-m}L_f\mathfrak{R}(H(x)) - K^{-1}SL_fH(x), \\ &= kA\left[(kA)^{-m}\,\mathfrak{R}(H(x)) - K^{-1}SH(x)\right] + B_{1m}b(h(x)), \\ &= kAT(x) + B_{1m}b(h(x)). \end{aligned}$$

This proves that the function T defined by (62) is a solution of (22).

Our second step in this proof is to show that by picking k large enough, the function T given by (62) is uniformly injective. To simplify the following notation, to a function f, we associate the function Δf as follows:

$$\Delta f(x_1, x_2) \;=\; f(x_1) \;-\; f(x_2).$$

So, for instance, for each pair (x_1, x_2) in $\mathcal{O}^2$, we have

$$T(x_1) - T(x_2) \;=\; (kA)^{-m} \Delta(\mathfrak{R} \circ H)(x_1, x_2)) \;+\; K^{-1} S \Delta H(x_1, x_2).$$

With (55), (60), and (58), we get, for each (Y_1, Y_2) in $\mathbb{R}^{m\times p} \times \mathbb{R}^{m\times p}$,

$$\begin{aligned}
|\Delta\mathfrak{R}(Y_1, Y_2)| &\leq \int_{-\infty}^{0} \left|\exp(-skA)\, B_{1m} \,\left[\breve{F}(\mathfrak{Y}(Y_1, s))_m - \breve{F}(\mathfrak{Y}(Y_2, s))_m\right]\right| ds \\
&\leq (1+L) \int_{-\infty}^{0} |\exp(-skA)|\, |B_{1m}|\, [\mathfrak{Y}(Y_1, s) - \mathfrak{Y}(Y_2, s)|\, ds \\
&\leq (1+L)\, |B_{1m}|\, |Y_1 - Y_2| \int_{-\infty}^{0} \exp\left(-s\left[1 + L + k \max_i\{\mathtt{Re}(\lambda_i)\}\right]\right) ds \\
&\leq \frac{(1+L)|B_{1m}|}{-\left[1 + L + k \max_i\{\mathtt{Re}(\lambda_i)\}\right]}\, |Y_1 - Y_2|.
\end{aligned}$$

This yields, for each pair (x_1, x_2) in $\mathtt{cl}(\mathcal{O})^2$,

$$\begin{aligned}
|T(x_1) - T(x_2)| &\geq |K^{-1} S \Delta H(x_1, x_2)| \;-\; |(kA)^{-m} \Delta(\mathfrak{R} \circ H)(x_1, x_2)|, \\
&\geq \frac{|\Delta H(x_1, x_2)|}{|K|\, |S^{-1}|} \;-\; \frac{|(kA)^{-m}|\, (1+L)|B_{1m}|}{-\left[1 + L + k \max_i\{\mathtt{Re}(\lambda_i)\}\right]}\, |\Delta H(x_1, x_2)|, \\
&\geq k^{-m} \left(\frac{1}{|S^{-1}|} - \frac{|A|^{-m}(1+L)|B_{1m}|}{-\left[1 + L + k \max_i\{\mathtt{Re}(\lambda_i)\}\right]}\right) |H(x_1 - H(x_2)|.
\end{aligned}$$

So, with (21), the function T is uniformly injectivity on $\mathtt{cl}(\mathcal{O})$ for all k large enough.

3.4. Proof of Theorem 5. Following the same arguments as in the proof of Theorem 1, continuity and uniform injectivity (23) of the function T_a on $\mathtt{cl}(\mathcal{O})$ imply that $T_a(\mathtt{cl}(\mathcal{O}))$ is closed and we can construct a continuous function $T_a^* : \mathbb{C}^{m\times p} \to \mathtt{cl}(\mathcal{O})$ satisfying

$$|T_a^*(z) - x| \;\leq\; \rho(4|z - T_a(x)|) \qquad\qquad \forall (x, z) \in \mathtt{cl}(\mathcal{O}) \times \mathbb{C}^{m\times p}. \tag{65}$$

This implies

$$T_a^*(T_a(x)) \;=\; x \qquad \forall x \in \mathtt{cl}(\mathcal{O}). \tag{66}$$

Now, let us assume for the time being there exists a function $\mathfrak{F} : \mathbb{C}^{m\times p} \to \mathbb{C}^{m\times p}$ to be used in (28) and satisfying

$$|\mathfrak{E}(x) - \mathfrak{F}(z)| \;\leq\; N\, |T_a(x) - z| \qquad \forall (x, z) \in \mathtt{cl}(\mathcal{O}) \times \mathbb{C}^{m\times p}. \tag{67}$$

As a direct consequence, we get the inequality

$$|\mathfrak{F}(z)| \;\leq\; N\, |z| \;+\; M \qquad z \in \mathbb{C}^{m\times p}$$

for some real number M $(= |\mathfrak{E}(x_0)| + N|T_a(x_0)|$, with some arbitrarily fixed x_0 in $\mathtt{cl}(\mathcal{O}))$. It follows that the z dynamics in the system (28) satisfy

$$|\dot{z}| \;\leq\; (|A| + N)\,|z| \;+\; (M \;+\; |B(h(x))|).$$

Hence, for each x in $\mathcal{O}$ and z in $\mathbb{C}^{m\times p}$, the component $Z(x,z,t)$ of a solution $(X(x,t), Z(x,z,t))$ of (28) is defined as long as $h(X(x,t))$ is defined. So this solution is right maximally defined on the same interval $[0, \sigma^+_{\mathbb{R}^n}(x))$ as $X(x,t)$ solution of (1).

With (65), (29) holds if we have

$$\lim_{t\to\sigma^+_{\mathbb{R}^n}(x)} T_a(X(x,t)) - Z(x,z,t) \;=\; 0 \qquad\qquad \forall (x,z)\in\mathcal{O}\times\mathbb{C}^{m\times p}. \tag{68}$$

To establish this limit, we associate to each pair (x,z) in $\mathcal{O}\times\mathbb{C}^{m\times p}$ the matrix e in $\mathbb{C}^{m\times p}$:

$$e \;=\; T_a(x) - z.$$

With (24) and (28), we get

$$\dot{e} \;=\; Ae + \mathfrak{E}(x) - \mathfrak{F}(z).$$

Let $U : \mathbb{C}^{m\times p} \to \mathbb{R}_+$ be the positive definite and proper function defined as

$$U(e) \;=\; \sum_{i=1}^{p} \overline{e}_i^{\top} P e_i,$$

where e_i denotes the ith column of e, $\overline{e_i}$ denotes its complex conjugate and P is given by (27). Using (67) and completing the squares, we get

$$\begin{aligned}\dot{\overline{U(e)}} \;=\; \sum_{i=1}^{p} \left[-|e_i|^2 \;+\; 2\overline{e_i}^{\top} P\left(\mathfrak{E}(x) - \mathfrak{F}((z))_i\right]\right. &\leq -[1 - 2N\lambda_{\max}(P)]\,|e|^2,\\ &\leq -\frac{1 - 2N\lambda_{\max}(P)}{\lambda_{\min}(P)}\,U(e).\end{aligned}$$

So, with (26), we have established the existence of a strictly positive real number ε such that we have

$$\dot{\overline{U(e)}} \;\leq\; -\varepsilon\, U(e) \qquad \forall (x,z)\in\mathcal{O}\times\mathbb{C}^{m\times p}. \tag{69}$$

This implies for all t in $[0, \sigma^+_{\mathcal{O}}(x))$ and (x,z) in $\mathcal{O}\times\mathbb{C}^{m\times p}$,

$$\exp(-\varepsilon t)\; U(e) \;\geq\; U(E(x,z,t)) \qquad (\;=\; U\left(T_a(X(x,t)) - Z(x,z,t)\right)). \tag{70}$$

With forward completeness within $\mathcal{O}$ and the condition in the left of (29) (see (11)), this implies (68) holds.

It remains to establish the existence of a function $\mathfrak{F} : \mathbb{C}^{m\times p} \to \mathbb{C}^{m\times p}$ satisfying (67). With (66), we see that (25) becomes

$$|\mathfrak{E}(T_a^*(z_1)) - \mathfrak{E}(T_a^*(z_2))| \;\leq\; N\,|z_1 - z_2| \qquad \forall (z_1,z_2)\in T_a(\mathtt{cl}(\mathcal{O}))^2.$$

Thus, $\mathfrak{E}\circ T_a^*$ is a Lipschitz function on the closed subset $T_a(\mathtt{cl}(\mathcal{O}))$. From Kirszbraun's Lipschitz extension theorem, $\mathfrak{E}\circ T_a^*$ can be extended as a function $\mathfrak{F} : \mathbb{C}^{m\times p} \to \mathbb{C}^{m\times p}$ satisfying

$$|\mathfrak{F}(z_1) \;-\; \mathfrak{F}(z_2)| \leq N\,|z_1 \;-\; z_2| \quad \forall (z_1,z_2)\in(\mathbb{C}^{m\times p})^2,$$

$$\mathfrak{F}(z) = \mathfrak{E}(T^*(z)) \quad \forall z \in T_a(\mathtt{cl}(\mathcal{O})).$$

So, in particular, we get (67).

3.5. Proof of Corollary 1. Let λ_i be the eigenvalues of a given diagonal Hurwitz complex $m \times m$ matrix A. With the notation (63), the function $T_a : \mathtt{cl}(\mathcal{O}) \to \mathbb{R}^{m\times p}$ defined in (30) can be rewritten as

$$T_a(x) \;=\; -K^{-1}SH(x). \tag{71}$$

In the following we show that we can find a real number $k^* \geq 1$ such that if k is strictly larger than k^*, then the triple (kA, T_a, B_{1m}) satisfies all the assumptions of Theorem 5:

1. The forward completeness within $\mathcal{O}$ is satisfied by assumption.

2. (23) is satisfied since, using (21) and the definition of T_a in (71), we get, for each pair (x_1, x_2) in $\mathtt{cl}(\mathcal{O})^2$,

$$\begin{aligned} |x_1 - x_2| &\leq \rho(|S^{-1}K|\,|K^{-1}SH(x_1) - K^{-1}SH(x_2)|), \\ &\leq \rho(|S^{-1}K|\,|T_a(x_1) - T_a(x_2)|). \end{aligned}$$

3. Let the function $\mathfrak{E} : \mathtt{cl}(\mathcal{O}) \to \mathbb{R}^{m\times p}$ be defined as

$$\mathfrak{E}(x) \;=\; -(kA)^{-m}B_{1m}L_f^m b(h(x)).$$

We have to show that this function satisfies (24) and (25). Using (64), we get, for each x in $\mathcal{O}$,

$$\mathfrak{E}(x) + B_{1m}b(h(x)) = -K^{-1}SL_fH(x) + kAK^{-1}SH(x) = L_fT_a(x) - kAT_a(x).$$

So, (24) does hold. Also, with (20) and $k^{-m}|K| \leq 1$, which holds for $k \geq 1$, we get, for each (x_1, x_2) in $\mathtt{cl}(\mathcal{O})^2$,

$$\begin{aligned} |\mathfrak{E}(x_1) \;-\; \mathfrak{E}(x_2)| &= |(kA)^{-m}(B_{1m}(L_f^m(h(x_1)) \;-\; L_f^m(h(x_2))))|, \\ &\leq |(kA)^{-m}|\,|B_{1m}|\,L\,|H(x_1) - H(x_2)|, \\ &\leq \frac{1}{\min_i |\lambda_i|^m}\,|B_{1m}|\,L\,|S^{-1}|\,|T_a(x_1) - T_a(x_2)|. \end{aligned}$$

Hence, (25) is satisfied with $N = \frac{1}{\min_i |\lambda_i|^m}\,|B_{1m}|\,L\,|S^{-1}|$, which does not depend on k.

4. It remains to show that by choosing k sufficiently large, the constraint (26) is satisfied. As kA is a diagonal complex matrix, the inequality (26) is simply

$$\frac{1}{\min_i |\lambda_i|^m}\,|B_{1m}|\,L\,|S^{-1}|\,\frac{1}{k\,(-\max_i \mathtt{Re}(\lambda_i))} \;<\; 1.$$

Clearly this inequality holds for all k large enough.

3.6. Technical comments on section 2.6. Due to space limitations, we give here only some hints on how the results established for the case of completeness can be extended to the case of boundedness observability.

The introduction of γ in the observer has mainly two consequences:

1. For the error convergence, t, in $\exp(At)$ in (35) or $\exp(-\varepsilon t)$ in (70), is replaced by the integral $\int_0^t \gamma(h(X(x,s)))ds$. If $\sigma^+_{\mathbb{R}^n}(x) = +\infty$, then,$\gamma$ being larger than 1, this integral goes to $+\infty$ as t goes to $\sigma^+_{\mathbb{R}^n}(x)$. If, instead, $\sigma^+_{\mathbb{R}^n}(x)$ is finite, then $V_{\mathfrak{f}}(X(x,t))$ goes to $+\infty$ as t goes to $\sigma^+_{\mathbb{R}^n}(x)$. From (33) this is possible only if the above integral tends again to $+\infty$.

2. The function T given in (18) is defined in terms of the solutions $\breve{X}(x,t)$ of the modified system (13) with f_γ instead of f. So we must show that this latter system shares the backward $\mathcal{O}$-distinguishability property of the original system (1). This can be done by associating, to each x in $\mathcal{O}+\delta_d$, the function $\tau_x : (\sigma^-_{\mathcal{O}+\delta_d}(x), \sigma^+_{\mathcal{O}+\delta_d}(x)) \to \mathbb{R}$ defined as

$$\tau_x(t) \;=\; \int_0^t \gamma(h(X(x,s)))ds.$$

It admits an inverse τ^{-1} which is such that we have

$$X(x, \tau_x^{-1}(t)) \;=\; \breve{X}(x,t) \qquad \forall x \in \mathcal{O}+\delta_d \;,\; \forall t \in \tau_x(\sigma^-_{\mathcal{O}+\delta_d}(x), \sigma^+_{\mathcal{O}+\delta_d}(x)).$$

Then it is possible to prove that, if for some pair (x_1, x_2) in $\mathcal{O}^2$ we have

$$h(\breve{X}(x_1,t)) \;=\; h(\breve{X}(x_2,t)) \qquad \forall t \;\in\; (\breve{\sigma}\,{}^-_{\mathcal{O}+\delta_d}(x_1), 0] \cap (\breve{\sigma}\,{}^-_{\mathcal{O}+\delta_d}(x_2), 0],$$

then we have also

$$\tau_{x_1}^{-1}(t) \;=\; \tau_{x_2}^{-1}(t) \qquad \forall t \;\in\; (\breve{\sigma}\,{}^-_{\mathcal{O}+\delta_d}(x_1), 0] \cap (\breve{\sigma}\,{}^-_{\mathcal{O}+\delta_d}(x_2), 0].$$

4. Conclusion. We have stated sufficient conditions under which the extension to nonlinear systems of the Luenberger observer, as it has been proposed by Kazantzis and Kravaris in [13], can be used as long as the state to be observed remains in a given open set. In doing so, we have exploited the fact, already mentioned in [4, 16], that the observer proposed by Kreisselmeier and Engel in [14] is a possible way of implementing the Kazantzis–Kravaris/Luenberger observer.

We have established that a sufficient (row) dimension of the dynamic system giving the observer is 2 + twice the dimension of the state to be observed. This is in agreement with many other results known on the generic number of pieces of information to be extracted from the output paths to be able to reconstruct the state.

We have also shown that it is sufficient to know only an approximation of a solution of a partial differential equation which we need to solve to implement the observer. In this way, we have been able to make a connection with high gains observers.

Finally, to get less restrictive sufficient conditions, we have found it useful to modify the observer in a way which induces a time rescaling as already suggested in [4].

At this stage, our results are mainly theoretical. They are concerned with existence. Several problems of prime importance for practice remain to be addressed, like type and speed of convergence. In these regards, the contribution of Rapaport and Maloum in [18] is an important starting point.

Even for the purpose of showing the existence, we have to note that the conditions we have given can be strongly relaxed if an estimation of the norm of the state is available. This idea has been exploited in [4], where a truly global observer has been proposed under the assumption of global complete observability and unboundedness observability.

Appendix. Proof of Coron's Lemma 1. The idea of the proof is to show that the set

$$S \;=\; \bigcup_{x\in\Upsilon} \big\{\Lambda = (\lambda_1, \ldots, \lambda_{n+1}) \in \Omega^{n+1} : \quad g(x,\lambda_\ell) = 0 \quad \forall \ell \in \{1, \ldots, n+1\}\big\}$$

defined in (51) is contained in a countable union of sets which have zero Lebesgue measure.

Given $(\underline{x}, \underline{\Lambda}, \epsilon)$ in $\Upsilon \times \Omega^{n+1} \times \mathbb{R}_{+*}$, we denote by $S_{\epsilon,\underline{x},\underline{\Lambda}}$ the set

$$S_{\epsilon,\underline{x},\underline{\Lambda}} \;=\; \bigcup_{x \in \mathcal{B}_\epsilon(\underline{x})} \{\Lambda \in \mathcal{B}_\epsilon(\underline{\Lambda}) : \quad g(x,\lambda_\ell) = 0 \quad \forall \ell \in \{1,\ldots,n+1\}\}\,. \tag{72}$$

Assume for the time being that for each pair $(\underline{x}, \underline{\Lambda})$ in $\Upsilon \times \Omega^{n+1}$, we can find a strictly positive real number ϵ and a countable family of C^1 functions $\sigma_i : \mathcal{B}_\epsilon(\underline{x}) \to \Omega^{n+1}$, such that we have

$$S_{\epsilon,\underline{x},\underline{\Lambda}} \subset \bigcup_{i \in \mathbb{N}} \sigma_i(\mathcal{B}_\epsilon(\underline{x})). \tag{73}$$

The family $(\mathcal{B}_\epsilon(\underline{x}) \times \mathcal{B}_\epsilon(\underline{\Lambda}))_{(\underline{x},\underline{\Lambda}) \in \Upsilon \times \Omega^{n+1}}$ is a covering of $\Upsilon \times \Omega^{n+1}$ by open subsets. From the Lindelöf theorem (see [6, Lemma 4.1], for instance), there exists a countable family $\left\{(\underline{x}_j, \underline{\Lambda}_j)\right\}_{j \in \mathbb{N}}$ such that we have

$$\Upsilon \times \Omega^{n+1} \;\subset\; \bigcup_{j \in \mathbb{N}} \mathcal{B}_{\epsilon_j}(\underline{x}_j) \times \mathcal{B}_{\epsilon_j}(\underline{\Lambda}_j),$$

where ϵ_j denotes the ϵ associated to the pair $(\underline{x}_j, \underline{\Lambda}_j)$. With (73), it follows that we have

$$S \;\subset\; \bigcup_{j \in \mathbb{N}} \bigcup_{i \in \mathbb{N}} \sigma_{i,j}(\mathcal{B}_{\epsilon_j}(\underline{x}_j)),$$

where $\sigma_{i,j}$ denotes the ith function σ associated with the pair $(\underline{x}_j, \underline{\Lambda}_j)$. The set $\sigma_{i,j}(\mathcal{B}_{\epsilon_j}(\underline{x}_j))$ is the image, contained in $\mathbb{C}^{n+1}$, a real manifold of dimension $2(n+1)$, by a C^1 function of $\mathcal{B}_{\epsilon_j}(\underline{x}_j)$, a real manifold of dimension $2n$. From a variation on Sard's theorem (see [20, Theorem 3, paragraph 3], for instance), this image $\sigma_{i,j}(\mathcal{B}_{\epsilon_j}(\underline{x}_j))$ has zero Lebesgue measure in $\mathbb{C}^{n+1}$. So S, being a countable union of such zero Lebesgue measure subsets, has zero Lebesgue measure.

So all we have to do to establish Lemma 1 is to prove the existence of ε and the functions σ_i satisfying (73) for each pair $(\underline{x}, \underline{\Lambda})$in $\Upsilon \times \Omega^{n+1}$. For ε, we consider two cases:

1. Consider a pair $(\underline{x}, \underline{\Lambda})$ such that $g_j(\underline{x}, \underline{\lambda}_\ell)$ is nonzero for some component λ_ℓ of $\underline{\Lambda}$ and g_j of g. By continuity of g_j, we can find a strictly positive real number ϵ such that $g(x, \lambda_\ell)$ is also nonzero for all x in $\mathcal{B}_\epsilon(\underline{x})$ and Λ in $\mathcal{B}_\epsilon(\underline{\lambda})$. In this case, the set $S_{\epsilon,\underline{x},\underline{\Lambda}}$ is empty.

2. Consider a pair $(\underline{x}, \underline{\Lambda})$ such that $g(\underline{x}, \underline{\lambda}_\ell)$ is zero for each of the $n+1$ components of $\underline{\lambda}_\ell$ of $\underline{\Lambda}$. From the assumption (50), for each ℓ, we can find a component g_{j_ℓ} of g and an integer k_ℓ satisfying

$$\frac{\partial^i g_{j_\ell}}{\partial \lambda^i}(\underline{x}, \underline{\lambda}_\ell) \;=\; 0 \qquad \forall i \in \{0,\ldots,k_\ell - 1\}, \qquad\qquad \frac{\partial^{k_\ell} g_{j_\ell}}{\partial \lambda^{k_\ell}}(\underline{x}, \underline{\lambda}_\ell) \;\neq\; 0.$$

In this case, following the Weierstrass preparation theorem (see [12, Theorem IV.1.1],[2] for instance), for each ℓ in $\{1,\ldots,n+1\}$, we know the existence of a strictly positive

[2]In [12, Theorem IV.1.1], this theorem is stated with the assumption that g_j is holomorphic in both x and λ. However, as far as x is concerned, it can be seen in the proof of this theorem that we need only the implicit function theorem to apply. So continuous differentiability in x for each λ is enough.

real number ϵ_ℓ, a function $q_\ell : \mathcal{B}_{\epsilon_\ell}(\underline{x}) \times \mathcal{B}_{\epsilon_\ell}(\underline{\lambda}_\ell) \to \mathbb{C}$, and k_ℓ C^1 functions $a_j^\ell : \mathbb{R}^{2n} \to \mathbb{C}$ satisfying for all (x, λ) in $\mathcal{B}_{\epsilon_\ell}(\underline{x}) \times B_{\epsilon_\ell}(\underline{\lambda}_\ell)$

$$q_\ell(x,\lambda)\, g_{j_\ell}(x,\lambda) \;=\; (\lambda - \underline{\lambda}_\ell)^{k_\ell} \;+\; \sum_{j=0}^{k_\ell - 1} a_j^\ell(x)(\lambda - \underline{\lambda}_\ell)^j. \tag{74}$$

We choose the real number ϵ, to be associated to $(\underline{x}, \underline{\Lambda})$ in the definition of $S_{\epsilon,\underline{x},\underline{\Lambda}}$, as

$$\epsilon \;=\; \inf_{\ell \in \{1,\ldots,n+1\}} \epsilon_\ell.$$

In the following $P_\ell : \mathcal{B}_\epsilon(\underline{x}) \times \mathbb{C} \to \mathbb{C}$ and $a^\ell(x) : \mathcal{B}_\epsilon(\underline{x}) \to \mathbb{C}^{k_\ell}$ denote

$$P_\ell(x,\lambda) \;=\; (\lambda - \underline{\lambda}_\ell)^{k_\ell} \;+\; \sum_{j=0}^{k_\ell - 1} a_j^\ell(x)(\lambda - \underline{\lambda}_\ell)^j, \qquad a^\ell(x) \;=\; (a_0^\ell(x), \ldots, a_{k_\ell - 1}^\ell(x)).$$

With this definition of ε, we have the following implication for Λ in $\mathcal{B}_\epsilon(\underline{\Lambda})$ and x in $\mathcal{B}_\epsilon(\underline{x})$:

$$g(x,\lambda_\ell) = 0 \quad \forall \ell \in \{1,\ldots,n+1\} \quad \Rightarrow \quad (\lambda_\ell, a^\ell(x)) \in M^\ell \quad \forall \ell \in \{1,\ldots,n+1\}, \tag{75}$$

where M^ℓ is the set

$$M^\ell \;=\; \left\{ (\lambda, (b_0, \ldots, b_{k_\ell - 1})) \in \mathbb{C} \times \mathbb{C}^{k_\ell} \;:\; (\lambda - \underline{\lambda}_\ell)^{k_\ell} + \sum_{j=0}^{k_\ell - 1} b_j (\lambda - \underline{\lambda}_\ell)^j = 0 \right\}. \tag{76}$$

Our interest in this set follows from the following lemma, which we prove later on.

LEMMA 2. *Let M be the set defined as*

$$M \;=\; \left\{ (\lambda, b_0, \ldots, b_{k-1}) \in \mathbb{C} \times \mathbb{C}^k \;:\; \lambda^k + \sum_{j=0}^{k-1} b_j \lambda^j = 0 \right\}.$$

There exists a countable family $\{M_m\}_{m \in \mathbb{N}}$ of regular submanifolds of $\mathbb{C}^k$ and a countable family of C^1 functions $\rho_m : M_m \to \mathbb{C}$ such that we have the inclusion

$$M \;\subset\; \bigcup_{m \in \mathbb{N}} \bigcup_{b \in M_m} \{(\rho_m(b), b)\}. \tag{77}$$

So, for each ℓ in $\{1,\ldots,n+1\}$ we have a countable family $\{M_{m_\ell}^\ell\}_{m_\ell \in \mathbb{N}}$ of regular submanifolds of $\mathbb{C}^{k_\ell}$ and a countable family of C^1 functions $\rho_{m_\ell}^\ell : M_{m_\ell}^\ell \to \mathbb{C}$ such that for each x in $\mathcal{B}_\epsilon(\underline{x})$, if $P_\ell(x, \lambda_\ell)$ is zero, then there exists an integer m_ℓ such that we have

$$a^\ell(x) \;\in\; M_{m_\ell}^\ell, \qquad \lambda_\ell \;=\; \rho_{m_\ell}^\ell(a^\ell(x)). \tag{78}$$

Hence, with (75), if

$$g(x,\lambda_\ell) \;=\; 0 \qquad \forall \ell \in \{1,\ldots,n+1\},$$

then there exists an $(n+1)$-tuple $\mu = (m_1, \ldots, m_{n+1})$ of integers satisfying

$$a^\ell(x) \;\in\; M_{m_\ell}^\ell, \quad \lambda_\ell \;=\; \rho_{m_\ell}^\ell(a^\ell(x)) \qquad \forall \ell \in \{1,\ldots,n+1\}.$$

So, by letting

$$S^{\mu}_{\epsilon,\underline{x},\underline{\Lambda}} = \bigcup_{\left\{x\in\mathcal{B}_\epsilon(\underline{x}):\ a^\ell(x)\in M^\ell_{m_\ell}\ \forall \ell\in\{1,\ldots,n+1\}\right\}} \left\{(\rho^1_{m_1}(a^1(x)),\ldots,\rho^{n+1}_{m_{n+1}}(a^{n+1}(x))\right\} \tag{79}$$

we have established

$$S_{\epsilon,\underline{x},\underline{\Lambda}} \subset \bigcup_{\mu\in\mathbb{N}^{n+1}} S^{\mu}_{\epsilon,\underline{x},\underline{\Lambda}}. \tag{80}$$

Comparing (73) with (80) and using the definition (79), we see that a candidate for the function σ_i is

$$\sigma_i(x) = \left(\rho^\ell_{m_\ell}\left(R_{M^\ell_{m_\ell}}(a^\ell(x))\right)\right)_{\ell\in\{1,\ldots,n+1\}},$$

where i happens to be the $(n+1)$-tuple μ and $R_{M^\ell_{m_\ell}} : \mathbb{C}^{k_\ell} \to M^\ell_{m_\ell}$ is a "restriction" to $M^\ell_{m_\ell}$ since we have to consider only those $a^\ell(x)$ which are in $M^\ell_{m_\ell}$. Finding such functions $R_{M^\ell_{m_\ell}}$ such that σ_i is C^1 may not be possible. But, following [7, Lemma 3.3], we know the existence, for each ℓ, of a countable family of C^1 functions $R^\ell_\nu : \mathbb{C}^{k_\ell} \to M^\ell_{m_\ell}$ such that we get

$$S^{\mu}_{\epsilon,\underline{x},\underline{\Lambda}} \subset \bigcup_{\nu\in\mathbb{N}} \left\{\left(\rho^\ell_{m_\ell}\left(R^\ell_\nu(a^\ell(\mathcal{B}_\epsilon(\underline{x})))\right)\right)_{\ell\in\{1,\ldots,n+1\}}\right\}.$$

In other words, the family of functions σ_i is actually given by the family

$$\sigma_{\mu,\nu} = \left(\rho^\ell_{m_\ell}\circ R^\ell_\nu \circ a_\ell\right)_{\ell\in\{1,\ldots,n+1\}},$$

i.e., we have

$$S_{\epsilon,\underline{x},\underline{\Lambda}} \subset \bigcup_{\mu\in\mathbb{N}^{n+1}} \bigcup_{\nu\in\mathbb{N}} \sigma_{\mu,\nu}(\mathcal{B}_\epsilon(\underline{x})). \qquad \square$$

Proof of Lemma 2: The inclusion (77) says that we are looking for a covering of the set M with some special structure. A covering easily found, but not having this special structure, is obtained by choosing a first complex number λ, denoted λ_1, as well as $k-1$ other complex numbers λ_j. Then the b_j are given by the identity

$$\prod_{j=1}^{k}(\lambda-\lambda_j) = \lambda^k + \sum_{j=0}^{k-1} b_j\lambda^j, \quad \lambda\in\mathbb{C}. \tag{81}$$

In other words, if we denote by $\eta : \mathbb{C}^k \to \mathbb{C}^k$ the function which gives the b_j from the λ_j, we have

$$\bigcup_{(\lambda_1,\ldots,\lambda_k)\in\mathbb{C}^k} \{(\lambda_1,\eta(\lambda_1,\ldots,\lambda_k))\} \subseteq M.$$

Specifically, given the elementary symmetric functions s_i, sum of all the products of i distinct λ_j,

$$s_i = \lambda_1\ldots\lambda_{i-1}\lambda_i + \lambda_1\ldots\lambda_{i-1}\lambda_{i+1} + \cdots + \lambda_{k-i+1}\lambda_{k-i+2}\ldots\lambda_k,$$

the b_j are obtained as

$$b_j \;=\; (-1)^{k-j} s_{k-j} \qquad \forall j \in \{1, \dots, k-1\}.$$

Also, the elementary symmetric functions are related to the sum of similar powers σ_p,

$$\sigma_p \;=\; \sum_{j=1}^{k} \lambda_j^p,$$

via the Newton equations:

$$\sigma_i \;-\; \sigma_{i-1} s_1 \;+\; \sigma_{i-2} s_2 \;+\; \cdots \;+\; (-1)^{i-1} \sigma_1 s_{k-1} \;+\; (-1)^i i s_i \;=\; 0.$$

The corresponding functions $(\sigma_p) \mapsto (s_i)$ and $(s_i) \mapsto (b_j)$ are C^∞ diffeomorphisms.

To obtain the result stated in the lemma, we need to invert the function $\eta : (\lambda_\ell) \mapsto (b_j)$. This function is known to be a homeomorphism if the λ_j are defined up to permutations (see [5, Proposition 1.5.5], for instance). But unfortunately we cannot go beyond continuity of the inverse because of possible multiple roots. To round this problem, we choose the multiplicity c_ℓ of the root λ_ℓ so that the sum of the c_ℓ is k. So, except if they are all 1, some of them must be 0. Maybe after reordering, we can assume that each c_1 to c_q is nonzero and satisfies

$$c_1 \;+\; \cdots \;+\; c_q \;=\; k.$$

Then we choose q different complex numbers ϖ_ℓ and we let

$$\lambda_1 = \cdots = \lambda_{c_1} = \varpi_1,\ \lambda_{c_0+1} = \cdots = \lambda_{c_1+c_2} = \varpi_2,\ \dots \\ \dots\ ,\ \lambda_{c_1+\cdots+c_{q-1}+1} = \ldots = \lambda_{c_1+\cdots+c_q} = \varpi_q.$$

This yields

$$\sigma_p \;=\; \sum_{\ell=1}^{q} c_\ell \varpi_\ell^p. \tag{82}$$

We stress at this point that to any k-tuple of λ_ℓ in $\mathbb{C}^k$, we can associate, maybe after a permutation θ of its components, such q-tuples of $c = (c_r)$ and $\varpi = (\varpi_r)$, with $\varpi_i \neq \varpi_j$ if $i \neq j$. It follows that the function η can be decomposed as follows:

$$(\lambda_\ell) \underbrace{\;\mapsto\; \theta(\lambda_\ell) \;\mapsto\; (c, \varpi) \;\mapsto\; (\sigma_p) \;\mapsto\; (s_i) \;\mapsto\;}_{\eta} (b_j).$$

This way, given a permutation θ and a root multiplicity vector c, with no zero component, we have defined a function $\gamma : \mathbb{C}^q \setminus \{\varpi_i = \varpi_j\} \to \mathbb{C}^k$ which maps the ϖ_r into the b_j:

$$\gamma : \varpi \;\mapsto\; (\sigma_p) \;\mapsto\; (s_i) \;\mapsto\; (b_j).$$

This function has rank q. Indeed, we know that the last two functions above are diffeomorphisms and, for the first one, we get from (82)

$$\frac{\partial \sigma_p}{\partial \varpi_r} \;=\; p\, c_r\, \varpi_r^{p-1}.$$

Since the p and c_r are not zero, we see that the matrix $(\frac{\partial \sigma_p}{\partial \varpi_r})$ has full rank since it has a Vandermonde structure and the ϖ_r are different. Consequently, the jacobian matrix $(\frac{\partial b_j}{\partial \varpi_r})$ of the function γ has full rank $q \leq k$. It follows from [6, Theorem III, 4.12, Theorem III, 5.5] that for each q-tuple ϖ in $\mathbb{C}^q \setminus \{\varpi_i = \varpi_j\}$, there exists a strictly positive real number $\epsilon(\varpi)$ such that

- $\mathcal{B}_{\epsilon(\varpi)}(\varpi)$ is a subset of $\mathbb{C}^q \setminus \{\varpi_i = \varpi_j\}$,
- $\gamma\left(\mathcal{B}_{\epsilon(\varpi))}(\varpi)\right)$ is a regular submanifold of (the real manifold) $\mathbb{C}^k$,
- the restriction of $\gamma : \mathcal{B}_{\epsilon(\varpi)}(\varpi) \to \gamma\left(\mathcal{B}_{\epsilon(\varpi)}(\varpi)\right)$ is a diffeomorphism.

We denote by γ^{-1} the "inverse" function.

The family $\left\{\mathcal{B}_{\epsilon(\varpi)}(\varpi)\right\}_{\varpi \in \mathbb{C}^q \setminus \{\varpi_i = \varpi_j\}}$ is a covering by open subsets of $\mathbb{C}^q \setminus \{\varpi_i = \varpi_j\}$. So there exists a countable family $(\varpi^i)_{i \in \mathbb{N}}$ such that the family $\left\{\mathcal{B}_{\epsilon(\varpi^i)}(\varpi^i)\right\}_{i \in \mathbb{N}}$ is covering by open subsets of $\mathbb{C}^q \setminus \{\varpi_i = \varpi_j\}$. Moreover, since to each k-tuple (b_j) in $\mathbb{C}^k$ we can associate a pair (c, ϖ) with $\varpi_i \neq \varpi_j$ if $i \neq j$, any such k-tuple (b_j) is in at least one set $\gamma\left(\mathcal{B}_{\epsilon(\varpi^i)}(\varpi^i)\right)$. So, since the number of permutations θ in $\mathbb{C}^k$ and multiplicity vectors c is finite, with varying i and q, we get a countable family $\{M_m\}_{m \in \mathbb{N}}$ of regular submanifold of $\mathbb{C}^k$ defined as

$$M_m \ := \ \gamma\left(\mathcal{B}_{\epsilon(\varpi^i)}(\varpi^i)\right)$$

and a countable family of C^1 functions ρ_m defined as

$$\begin{array}{ccccccc} & & \gamma^{-1} & & & (c,\theta) & \\ \rho_m \ : \ (b_0, \ldots, b_{k-1}) \in M_m & \mapsto & \varpi \in \mathcal{B}_{\epsilon(\varpi^i)}(\varpi^i) & \mapsto & (\lambda_1, \ldots, \lambda_k) \in \mathbb{C}^k \ . & & \end{array}$$

Each $b = (b_0, \ldots, b_{k-1})$ in $\mathbb{C}^k$ is in least one M_m and we have

$$\eta(\rho_m(b)) = b.$$

Our result follows then from

$$\mathbb{C}^k \ = \ \bigcup_{m \in \mathbb{N}} \bigcup_{b \in M_m} \{\rho_m(b)\}.$$

Acknowledgments. This paper was initiated by many discussions with Alessandro Astolfi about the gap between the Kazantzis–Kravaris/Luenberger observer, introduced as a local object in [13], and the global observer in [4]. We are also very grateful to Jean-Michel Coron, who was our guide all along our way in the quite involved technicalities needed in the proof of most of our results.

DUBINS' PROBLEM ON SURFACES II: NONPOSITIVE CURVATURE*

MARIO SIGALOTTI† AND YACINE CHITOUR‡

Abstract. Let M be a complete, connected, two-dimensional Riemannian manifold with nonpositive Gaussian curvature K. We say that M satisfies the *unrestricted complete controllability* (UCC) property for the Dubins problem if the following holds: given any (p_1, v_1) and (p_2, v_2) in TM, there exists, for every $\varepsilon > 0$, a curve γ in M, with geodesic curvature smaller than ε, such that γ connects p_1 to p_2 and, for $i = 1, 2$, $\dot\gamma$ is equal to v_i at p_i. Property UCC is equivalent to the complete controllability of a family of control systems of Dubins' type, parameterized by ε. It is well known that the Poincaré half-plane does not verify property UCC. In this paper, we provide a complete characterization of the two-dimensional nonpositively curved manifolds M, with either uniformly negative or bounded curvature, that satisfy property UCC. More precisely, if $\sup_M K < 0$ or $\inf_M K > -\infty$, we show that UCC holds if and only if (i) M is of the first kind or (ii) the curvature satisfies a suitable integral decay condition at infinity.

Key words. controllability, geometric control, geodesic curvature, nonpositive curvature

1. Introduction.

Let (M, m) be a connected, oriented, complete Riemannian manifold and let $N = UM$ be its unit tangent bundle. Points of N are pairs (p, v), where $p \in M$, $v \in T_pM$, and $m(v, v) = 1$. Given $\varepsilon > 0$, Dubins' problem consists of finding, for every $(p_1, v_1), (p_2, v_2) \in N$, a curve $\gamma : [0, T] \to M$, parameterized by arc-length and whose geodesic curvature is bounded by ε, such that $\gamma(0) = p_1$, $\dot\gamma(0) = v_1$, $\gamma(T) = p_2$, $\dot\gamma(T) = v_2$, and which minimizes T. Although Dubins' problem makes sense in any dimension, the present paper deals only with the two-dimensional case, which can be seen as the time-optimal control problem for the following control system:

$$(D_\varepsilon): \qquad \dot q = f(q) + ug(q),\ q \in N,\ u \in [-\varepsilon, \varepsilon],$$

where f is the geodesic spray on N (i.e., the infinitesimal generator of the geodesic flow on M), g is the smooth vector field generating the fiberwise rotation with angular velocity equal to one, and the admissible controls are measurable functions $u : [0, T] \to [-\varepsilon, \varepsilon]$.

In the robotics literature (cf. [20]), the dynamics defined by (D_ε) when M is the Euclidean plane represent the motion of a unicycle (or a rolling penny) and the projections of the trajectories of (D_ε) on the plane are planar curves parameterized by arc-length with curvature bounded by ε. In 1957, Dubins [9] determined the global structure of the corresponding time-optimal trajectories: he showed that they are concatenations of at most three pieces made of circles of radius $1/\varepsilon$ or straight lines. Further restrictions on the length of the arcs of an optimal concatenation have been obtained by Sussmann and Tang [30].

Dubins'-like problems have been proposed by considering more general manifolds M. For instance, the case where M is a two-dimensional manifold of constant Gaussian curvature was investigated in [5, 6, 12, 17], and the case where $M = \mathbf{R}^n, S^n$, $n \geq 3$, was studied in [18, 19, 29]. The controllability issue is not difficult to solve, because Dubins' problem can be reformulated as a control system (left-)invariant under the action of a Lie group. Let us mention another line of generalization, which consists of considering the distributional version of (D_ε), whose best-known example is the so-called Reeds–Shepp car [22]. In dimension two, the distributional dynamics can be represented by the two-input control system $(DD_\varepsilon) : \dot{q} = uf(q) + vg(q)$ with $|u|, |v| \leq \varepsilon$. The controllability of (DD_ε) simply results from the fact that the distribution (f, g) is strong bracket generating, i.e., for every $q \in N$, the triple $(f(q), g(q), [f, g](q))$ spans T_qN.

A motivation for the present work is the remark that when generalizing Dubins' problem from the Euclidean plane to a general Riemannian surface M, the complete controllability of (D_ε) stops to be a trivial issue. Indeed, when M has no particular symmetry, it is not clear how to design a trajectory starting from and ending at the fiber of a given point $p \in M$, with "small" geodesic curvature. We are naturally faced with an intrinsic property of M, independent of global rescaling of its metric m, that is, whether (D_ε) is completely controllable for every $\varepsilon > 0$. We refer to such property as the *unrestricted complete controllability* (UCC) of Dubins' problem on M. The present paper primarily focuses on the controllability of Dubins' problem, and our main scope is to find geometric or topological conditions on M characterizing UCC.

The Lie algebraic structure of (D_ε) reveals quickly that the Gaussian curvature K plays a crucial role in the characterization of controllable Dubins' problems. Indeed, as it follows from the structural equations satisfied by Cartan's connections (cf. Spivak [28, Volume II]),

$$[f, [f, g]](q) = -K(\pi(q))g(q) \tag{1}$$

for every $q \in N$, where $\pi : N \to M$ denotes the bundle projection. Notice that the bracket relation (1) identifies K uniquely. A generalized version of it was proposed by Agrachev and Sachkov ([1]; see also [26]) in order to introduce a notion of curvature for two-dimensional optimal control systems.

The role of K in the study of UCC of Dubins' problem is further suggested by the following standard example of noncontrollability: if M is the Poincaré half-plane H^2, then (D_ε) is completely controllable if and only if $\varepsilon > 1$ (cf. [6, 17]). Roughly speaking, the negativeness of K is an obstacle for the controlled turning action (modeled by g) to overcome the spreading of the geodesics. When $|u| \leq \varepsilon \leq 1$, the effect of ug is not strong enough and complete controllability fails to hold.

In a previous paper [7], we proposed some geometric and topological conditions on M, which ensure that the UCC property holds true. In particular, it was proved that any compact M satisfies the UCC property. In the unbounded case, the same conclusion was obtained when M is *asymptotically flat*, i.e., K tends to zero at infinity. The control strategy goes as follows. It is first shown that the controllability of (D_ε) is equivalent to the fact that every $q = (p, v) \in N$ can be steered to $q^- = (p, -v)$ by an admissible trajectory of (D_ε). The latter property, called *weak controllability* of (D_ε), is proved by tracking a teardrop loop (see Figure 1) in a covering domain over a piece of M at infinity. A suitable covering manifold can be globally described by a single appropriate geodesic chart.

If one keeps in mind the noncontrollability of Dubins' problem on H^2, it is reasonable to consider the situation where $K \geq 0$. Indeed, in that case, no local spreading

effect due to the drift term has to be compensated. Moreover, if M is an open manifold with nonnegative curvature, then the theorems of Cohn-Vossen [8] and Huber [11] imply that

$$\int_M K dA < \infty, \tag{2}$$

where dA is the surface element in M (see [7] for details). The integral decay of K to zero at infinity can be interpreted as a sort of asymptotic flatness condition and it suggests that (D_ε) should be completely controllable for every $\varepsilon > 0$. In [7], we were able to confirm that intuition under the additional assumption that K is bounded over M, i.e., $\sup_M K$ is finite, and also to extend that result to the case where $K \geq 0$ outside a compact set. The strategy of the proof still consists in tracking a teardrop loop in a covering domain D but the construction of D becomes much more delicate than that of the asymptotic flat case.

Recently, Pansu pointed out how the existence of a closed geodesic on a surface M with constant negative curvature implies that for every point $p \in M$ and every $\varepsilon > 0$, there exists a noncontractible admissible trajectory of (D_ε) which steers some point $q \in U_p M$ to the point q^-. Such a feature is particularly interesting, taking into account that UCC does not hold for the Poincaré half-plane H^2. An immediate question is whether UCC can be recovered for a quotient manifold $M = H^2/\Gamma$, provided that we add enough topology to H^2 (i.e., provided that the group Γ is large enough), or if, on the contrary, Dubins' problem on any quotient of H^2 is not UCC. It turns out that the answer can be easily stated: $M = H^2/\Gamma$ has the UCC property if and only if it is of the first kind, i.e., its limit set (see Definition 3.1) is the entire boundary at infinity of H^2.

In the present work, we investigate the more general case of Riemannian surfaces with nonpositive curvature. It is well known that a surface M of such kind can be identified with the quotient space X/Γ, where X is a Hadamard surface (i.e., a simply connected, complete Riemannian manifold of nonpositive curvature) and Γ is a group of orientation-preserving isometries which acts freely and discontinuously on X. (For all the definitions, see section 3.) We provide conditions on M, sufficient for UCC to hold. The first one generalizes the hyperbolic case. It says that (i) $M = X/\Gamma$ is of the first kind, i.e., its limit set $\mathcal{L}(\Gamma)$ is equal to the ideal boundary $X(\infty)$ of X. The second condition is reminiscent of the nonnegative curvature case, namely, it states that (ii) for every $r > 0$ and every sector S in X, $\sup_{p \in S} \int_{B_X(p,r)} K dA = 0$, where $B_X(p, r)$ denotes the ball of center p and radius r. Then, we present necessary conditions on M for property UCC to hold. A quite surprising result is the following. Under the assumption that either K is bounded or $\sup_M K < 0$, if M verifies property UCC, then either condition (i) or condition (ii) must hold true. In that way, we exactly characterize the surfaces M, with nonpositive curvature K either bounded or such that $\sup_M K < 0$, verifying property UCC. In addition, some controllability and noncontrollability results in the case where K is nonpositive outside a compact subset of M are given. We also provide sufficient conditions ensuring that M has the UCC property, with no sign assumption on K, namely, (a) M has finite area, (b) the geodesic flow on M is topologically transitive. We conclude with some remarks on the structure of time-optimal trajectories for (D_ε). If $\sup_M K \leq -\varepsilon$, we show that they follow Dubins' pattern, namely, that they are concatenation of a bang, a singular, and a bang arc (where some arc can possibly have zero length), with the (possible) singular arc being a geodesic of the surface.

The paper is organized as follows. In section 2, we formulate the control problem at hand and describe its basic features. In section 3, general facts on Riemannian surfaces of nonpositive curvature are recalled. The main results of the paper are stated in section 4 and their proofs are provided in section 5. Finally, section 6 contains some remarks on time-optimal trajectories.

2. Formulation of the problem. Let (M, m) be a two-dimensional Riemannian manifold, or, as we will equivalently call it, a *Riemannian surface*. Notice that M is not required to be embedded nor immersed in $\mathbf{R}^3$. Assume that M is oriented and that its metric m is complete. Denote by N the unit tangent bundle $UM = \{q \in TM |\ m(q,q) = 1\}$ and by $\pi : N \to M$ the canonical bundle projection of N onto M. Let K be the Gaussian curvature on M. We will use the symbol K also for the trivial extension (constant on fibers) of K on N. The distance on M induced by m is denoted by $d_M(\cdot,\cdot)$ (or $d(\cdot,\cdot)$ when no confusion is possible), and, for every $p \in M$ and $r > 0$, $B_M(p, r)$ stands for the ball of center p and radius r.

Let f be the *geodesic spray* on TM, whose restriction to N (still denoted by f) is a well-defined vector field on N. Recall that f is characterized by the following property: $p(\cdot)$ is a geodesic on M if and only if $(p(\cdot), \dot{p}(\cdot))$ is an integral curve of f. In particular, f satisfies the relation

$$\pi_\star(f(q)) = q \tag{3}$$

for every $q \in N$. The *exponential map on* M is defined by

$$\exp(t, q) = \pi(e^{tf}(q)), \tag{4}$$

where $e^{tf} : N \to N$ denotes the flow of the vector field f at time t.

Let g be the smooth vector field on N, whose corresponding flow at time t is the fiberwise rotation of angle t. For every $q \in N$, we set $q^- = e^{\pi g}(q)$ and $\mathcal{R}q = e^{-\frac{\pi}{2}g}(q)$.

For $\varepsilon > 0$, let $(\mathcal{D}_\varepsilon^M)$ be the control system

$$(\mathcal{D}_\varepsilon^M): \qquad \dot{q} = f(q) + ug(q), \quad q \in N, \quad u \in [-\varepsilon, \varepsilon].$$

An *admissible control* is a measurable function $u(\cdot)$, defined on some interval of $\mathbf{R}$, with values in $[-\varepsilon, \varepsilon]$. The solutions of $(\mathcal{D}_\varepsilon^M)$ corresponding to admissible controls are called *admissible trajectories*. (Sometimes, to prevent any confusion, we will speak also of *ε-admissible controls* and *ε-admissible trajectories*).

For every $q \in N$ and $T > 0$, the *attainable set from q up to time T* is the set $A_q^T = A_q^T(M, \varepsilon)$ consisting of the endpoints of all admissible trajectories for $(\mathcal{D}_\varepsilon^M)$, starting from q, of length smaller than or equal to T. We also write

$$A_q = A_q(M, \varepsilon) = \cup_{T>0} A_q^T(M, \varepsilon).$$

The control system $(\mathcal{D}_\varepsilon^M)$ is called *completely controllable* if $A_q = N$ for every $q \in N$.

Definition 2.1. *We say that the Dubins problem on M has the* unrestricted complete controllability (UCC) property *(or, equivalently, that it is* UCC*) if, for every $\varepsilon > 0$, $(\mathcal{D}_\varepsilon^M)$ is completely controllable.*

We stress that the UCC notion corresponds to the property of existence of solutions to the original, control-free Dubins problem on M: UCC holds if and only if, for every $\varepsilon > 0$ and every (p_1, v_1), (p_2, v_2) in TM, there exists a curve $\gamma : [0, T] \to M$ with geodesic curvature smaller than ε such that $\gamma(0) = p_1$, $\gamma(T) = p_2$ and $\dot{\gamma}(0) = v_1$,

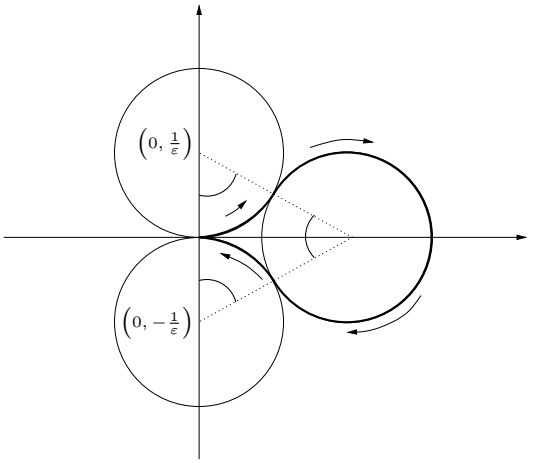

FIG. 1. *The teardrop trajectory of size* $1/\varepsilon$.

$\dot\gamma(T) = v_2$. Up to a reparameterization by arc-length, $(\gamma, \dot\gamma)$ is an ε-admissible trajectory in N, whose corresponding control $u(t)$ is equal, at almost every $t \in [0, T]$, to the geodesic curvature of γ at the point $\gamma(t)$.

It is easy to check that the distribution $\{f, g\}$ is *bracket generating*, i.e., that, for every $q \in N$, $T_qM = \text{span}\{X(q) |\ X \in \text{Lie}(f, g)\}$, where $\text{Lie}(f, g)$ denotes the Lie algebra of vector fields on N generated by f and g. Indeed, for every $q \in N$, we have that $\pi_*([f, g](q)) = \pi_*(f(\mathcal{R}q))$. Therefore, f, g, and $[f, g]$ span T_qM at every $q \in N$, proving not only that $\{f, g\}$ is bracket generating but also that it is a *contact distribution* on N. As a consequence, for every $0 < t < T$ and every $q \in N$,

$$e^{tf}(q) \in \text{Int}(A_q^T), \tag{5}$$

where $\text{Int}(A_q^T)$ denotes the interior of A_q^T. This follows, for instance, from the description of small-time attainable sets for single-input nondegenerate three-dimensional control systems given by Lobry in [15].

Since f, g, and $[f, g]$ are linearly independent at every point, they can be used to introduce a metric on N, requiring $(f(q), g(q), [f, g](q))$ to be an orthonormal basis of T_qN, for every $q \in N$. Such metric endows N with a complete Riemannian structure (see, for instance, [23]). In accordance with the notations introduced above, we will denote by $d_N(\cdot, \cdot)$ the induced distance on N and, for every $q \in N$ and $\rho > 0$, by $B_N(q, \rho)$ the ball of center q and radius ρ.

Remark 2.2. In [7] we noticed that, since (D_ε^M) has the property of being bracket generating, Dubins' problem on M is UCC if and only if for every $\varepsilon > 0$ and every $q \in N$, there exists $\hat q \in A_q(M, \varepsilon)$ such that $\hat q^- \in A_{\hat q}(M, \varepsilon)$. In order to prove this last property, we will often mimic on M the behavior of a teardrop trajectory on the Euclidean plane. We call teardrop trajectory of size $1/\varepsilon$ (see Figure 1) the bang-bang trajectory of $(D_\varepsilon^{\mathbf{R}^2})$ whose control u, defined by

$$u(t) = \begin{cases} \varepsilon & \text{if} \quad 0 \le t \le \frac{\pi}{3\varepsilon}, \\ -\varepsilon & \text{if} \quad \frac{\pi}{3\varepsilon} < t \le \frac{2\pi}{\varepsilon}, \\ \varepsilon & \text{if} \quad \frac{2\pi}{\varepsilon} < t \le \frac{7\pi}{3\varepsilon}, \end{cases}$$

steers $(1, 0) \in U_{(0,0)}\mathbf{R}^2$ to $(-1, 0) \in U_{(0,0)}\mathbf{R}^2$.

Remark 2.3. If M_1, M_2 are two Riemannian manifolds and $P : M_1 \to M_2$ is a local isometry at every point of M_1, then every admissible trajectory for $(D_\varepsilon^{M_1})$ is transformed by $P_* : UM_1 \to UM_2$ in an admissible trajectory for $(D_\varepsilon^{M_2})$. In particular, if P is onto and the Dubins problem on M_1 is UCC, then the same is true for the Dubins problem on M_2.

3. General facts on Riemannian surfaces of nonpositive curvature. Of special interest for the present study are Riemannian surfaces of nonpositive curvature. We collect in this section some definitions and known results about them, which will be used in what follows. When no explicit source is given, see [4].

A simply connected, complete Riemannian manifold of nonpositive sectional curvature is called a *Hadamard manifold*. If M is a complete, connected, oriented Riemannian manifold of nonpositive sectional curvature, then M can be described as X/Γ, where X is a Hadamard manifold and Γ is a group of orientation-preserving isometries which acts freely and discontinuously on X. We will denote by $\Pi : X \to M$ the canonical projection of X onto M. When the sectional curvature is constant on M, then M is said a *hyperbolic manifold* and X a *hyperbolic space*.

3.1. Hadamard surfaces. From now on, X will denote a Hadamard surface, that is, a Hadamard two-dimensional manifold. If $M = X/\Gamma$ is a complete Riemannian surface, then we will denote by the same letters f, g, K, m, and π the corresponding objects on X and M. This is motivated by the fact that $\Pi : X \to M$, being a local isometry, identifies such objects, at least at a local level.

It is well known that X is diffemorphic to $\mathbf{R}^2$. Any geodesic segment in X is the unique length-minimizing trajectory between its extremes. In particular, all complete geodesics are simple.

A *ray* is a half-geodesic on X. A *sector* is a region of X bounded by two distinct rays starting at the same point, which is called the *vertex of* S.

The *ideal boundary* of X, denoted by $X(\infty)$, is defined as the quotient of the set of all rays parameterized by arc-length by the equivalence relation

$$c_1 \sim c_2 \iff \limsup_{t\to\infty} d_X(c_1(t), c_2(t)) < \infty.$$

The equivalence class of a parameterized ray c is denoted by $c(+\infty)$ and it is called the *endpoint of* c. If $c : \mathbf{R} \to X$ is a parameterized complete geodesic, then $c(-\infty)$ denotes the equivalence class of $[0, \infty) \ni t \mapsto c(-t)$.

For a given point $p \in X$ there is a one-to-one correspondence ψ_p between U_pX and $X(\infty)$, which assigns to $v \in U_pX$ the equivalence class of $[0, \infty) \ni t \mapsto \exp(t, v)$. The correspondence defines a topology on $X(\infty)$, which is called the *sphere topology*. The sphere topology extends to the so-called cone topology on $\overline{X} = X \cup X(\infty)$. The cone topology is generated by the open sets of X and the sets

$$\psi_p(U) \cup (\cup_{t>0} \exp(t, U)),$$

where $p \in X$ and U is an open set of U_pX. Notice that the action on X of an element of Γ has a natural continuous extension on $\overline{X}$.

Given a set Ω in X, we write $\partial\Omega$ for the boundary of Ω in X, while $\Omega(\infty)$ will denote the intersection between $X(\infty)$ and the closure of Ω in $\overline{X}$.

The isometric transformations of X can be classified in terms of the so-called *displacement function* $X \ni p \mapsto d_X(p, \gamma(p))$. An isometry $\gamma : X \to X$ is called *elliptic* if it has at least one fixed point in X; *hyperbolic* if the displacement function attains its minimum in X, and such minimum is strictly positive; *parabolic* otherwise.

3.2. Closed geodesics and limit sets. If $M = X/\Gamma$ is a complete Riemannian surface, then the only elliptic element of Γ is the identity. Let G be a closed geodesic in M. Fix one of its lifts $\widetilde{G}$ in X and let $c : \mathbf{R} \to X$ be a parameterization of $\widetilde{G}$ by arc-length. There is one isometry $\gamma \in \Gamma$ such that $\gamma(c(0)) = c(T)$, where T is the length of G. Then $c(t+T) = c(t)$ for every $t \in \mathbf{R}$. (The proof goes as in the hyperbolic case; see [21, Theorem 9.6.2].) The isometry γ is hyperbolic (see [4, section 6]) and $\widetilde{G}$ is called an *axis* of γ. Actually, every hyperbolic isometry γ has at least one axis. (Given any point p at which the displacement function attains its minimum, the geodesic line between p and $\gamma(p)$ is indeed an axis.) If none of the half-planes bounded by $\widetilde{G}$ is flat, then, given a neighborhood U of $c(-\infty)$ and a neighborhood V of $c(+\infty)$ in $\overline{X}$, there exists $\bar{n} \in \mathbf{N}$ such that

$$\gamma^n\left(\overline{X} \setminus U\right) \subset V, \qquad \gamma^{-n}\left(\overline{X} \setminus V\right) \subset U, \tag{6}$$

for every $n \geq \bar{n}$, as proved by Ballmann in [3].

The existence of a closed geodesic on Riemannian surfaces is established by some classical results under very general assumptions. Lyusternik and Fet [16] proved that all complete compact Riemannian surfaces contain at least one closed geodesic. After that, Thorbergsson [31] extended the result to all complete, connected Riemannian surfaces neither homeomorphic to the plane nor to the cylinder. As a consequence, if Γ is not cyclic, then $M = X/\Gamma$ contains a closed geodesic.

DEFINITION 3.1. *Let Γ be a group of isometries of X. Fix $p \in X$ and consider $\overline{\Gamma(p)}$, the closure in $\overline{X}$ of the Γ-orbit of p. The set $\mathcal{L}(\Gamma) = \overline{\Gamma(p)} \cap X(\infty)$ is called the limit set of Γ.*

The definition of $\mathcal{L}(\Gamma)$ is actually independent of the choice of the point p. Fix, indeed, p, p' in X, and let $\gamma_n(p) \to z \in X(\infty)$ as $n \to \infty$, with $\{\gamma_n\}_{n\in\mathbf{N}} \subset \Gamma$. Notice that for every $n \in \mathbf{N}$, $d(\gamma_n(p), \gamma_n(p')) = d(p, p')$. Moreover, every sector S of X such that $z \in S(\infty)$ contains a subsector S' such that $z \in S'(\infty)$ and whose distance from the boundary of S is larger than $d(p, p')$. Therefore, in the cone topology of $\overline{X}$, $\gamma_n(p') \to z$ as $n \to \infty$.

DEFINITION 3.2. *Let X be a Hadamard surface and $M = X/\Gamma$ be a complete Riemannian surface. We say that M is of the first kind if $\mathcal{L}(\Gamma) = X(\infty)$; otherwise we say that M is of the second kind.*

Remark 3.3. If Γ is cyclic, then M is of the second kind. Indeed, if $\Gamma = \{\mathrm{Id}\}$, then $\mathcal{L}(\Gamma)$ is empty. If Γ is nontrivial, then it is generated by a hyperbolic or a parabolic isometry, denoted by γ. If γ is hyperbolic, then it translates at least one geodesic, hence $\mathcal{L}(\Gamma)$ is made of the two endpoints of such geodesic (just consider the orbit of a point on the geodesic). If γ, instead, is parabolic, then there exists a point $z \in X(\infty)$ which is invariant under the action of γ, together with the horospheres centered at z (see [4, Lemma 6.6]). Fix any point $x \in X$ and consider a horosphere U centered at z which contains x. Then $\mathcal{L}(\Gamma)$ is contained in $U(\infty)$. In both cases, M is not of the first kind. Therefore, if M is of the first kind, then it contains a closed geodesic.

DEFINITION 3.4. *Let M be a Riemannian surface. We say that its Gaussian curvature K is uniformly negative if* $\sup_M K < 0$.

If K is uniformly negative on X, then, for every two elements x, y of $X(\infty)$, there exists a parameterized geodesic $c : \mathbf{R} \to X$ such that $c(+\infty) = x$ and $c(-\infty) = y$. That is, using the terminology introduced by Eberlein and O'Neill in [10], X is a *visibility manifold*.

3.3. Geodesic coordinates. Geodesic coordinates can be globally defined on X. They depend on the choice of an element q of UX and are defined through the map

$$\begin{array}{rccl} \phi_q : & \mathbf{R}^2 & \longrightarrow & X, \\ & (x,y) & \longmapsto & \pi(e^{yf} \circ e^{\frac{\pi}{2} g} \circ e^{xf}(q)). \end{array} \tag{7}$$

Let $B : \mathbf{R}^2 \to \mathbf{R}$ be the solution of the system

$$\begin{cases} B_{yy} + KB = 0, \\ B(x,0) \equiv 1, \\ B_y(x,0) \equiv 0, \end{cases} \tag{8}$$

in which the index y appearing in B_y, B_{yy} stands for the partial differentiation with respect to y. Notice that since $K \leq 0$, B is globally defined and

$$B(x,y) \geq 1, \tag{9}$$

$$yB_y(x,y) \geq 0 \tag{10}$$

for every $(x,y) \in \mathbf{R}^2$. The coordinate expression for the metric m on X is given by

$$m(x,y) = B^2(x,y)dx^2 + dy^2.$$

(See, for instance, [13].) The unit bundle UX can be identified with

$$\left\{ \left(x, y, \frac{\cos\theta}{B(x,y)}, \sin\theta \right) \in \mathbf{R}^4 \,\middle|\, (x,y) \in \mathbf{R}^2,\ \theta \in \mathcal{S}^1 \right\}.$$

In the coordinates (x,y,θ), f and g are given by

$$f(x,y,\theta) = \left(\frac{\cos\theta}{B(x,y)}, \sin\theta, F(x,y)\cos\theta \right)^T, \qquad g(x,y,\theta) = (0,0,1)^T, \tag{11}$$

where

$$F(x,y) = \frac{B_y(x,y)}{B(x,y)}. \tag{12}$$

Equivalently, (D_ε^X) can be written as follows:

$$\dot{x} = \frac{\cos\theta}{B}, \tag{13}$$

$$\dot{y} = \sin\theta, \tag{14}$$

$$\dot{\theta} = u + F\cos\theta. \tag{15}$$

Notice that, as it can be easily deduced from (8), F satisfies the Cauchy problem

$$F_y = -K - F^2, \qquad F(x,0) \equiv 0. \tag{16}$$

If $M = X/\Gamma$ is a complete Riemannian surface, then, for any fixed $q \in N$, the map ϕ_q, defined as in (7), is a local diffeomorphism at every point of $\mathbf{R}^2$. The pullback of

the metric m through ϕ_q endows $\mathbf{R}^2$ with a Riemannian structure, which renders $\mathbf{R}^2$ isomorphic to X.

Remark 3.5. The previous formulation of Dubins' problem in coordinates still makes sense when only local, instead of global, geodesic coordinates are defined. Consider the case of a Riemannian surface M with possibly sign-varying curvature. Recall that a *half-plane* of M is a simply connected open subset of M bounded by a simple open complete geodesic. If M contains a half-plane H and if K is nonpositive on H, then H admits a system of geodesic coordinates. Indeed, for any $q \in N$ such that $\phi_q(\mathbf{R}\times[0,\infty)) = H$, $\mathbf{R}\times[0,\infty)$ can be endowed with the metric $\phi_q^* m$, and Dubins' problem on H can be described by equations (13)–(15). Similarly, if $q = (p, v) \in N$ and $a, b, r > 0$ are such that $K \leq 0$ on $B_M(p, r)$ and $a + b < r$, then the rectangle $[-a, a] \times [-b, b] \subset \mathbf{R}^2$, endowed with $\phi_q^* m$, is a nonpositively curved covering domain of a neighborhood of p. Again, system (13)–(15) describes Dubins' problem on such nonflat rectangle.

4. Statement of the results. We collect here the statements of the main results proved in the next section, in order to stress the interrelations between the proposed necessary and sufficient conditions for the UCC property to hold.

PROPOSITION 4.1. *Let M be a complete, connected Riemannian surface. The Dubins problem on M has the* UCC *property if at least one of the following conditions is satisfied:* (*a*) *M has finite area or* (*b*) *the geodesic flow on M is topologically transitive.*

THEOREM 4.2. *Let M be a complete, connected Riemannian surface with nonpositive Gaussian curvature K. Denote by X the universal covering of M. The Dubins problem on M has the* UCC *property if at least one of the following conditions is satisfied:* (i) *M is of the first kind or* (ii) *for every $r > 0$ and every sector S in X, $\sup_{p\in S} \int_{B_X(p,r)} K dA = 0$.*

Conditions which are both sufficient and necessary for UCC can be formulated under more restrictive hypotheses on K.

THEOREM 4.3. *Let M be a complete, connected Riemannian surface and assume that its Gaussian curvature K is uniformly negative. Then the Dubins problem on M has the* UCC *property if and only if M is of the first kind.*

THEOREM 4.4. *Let M be a complete, connected Riemannian surface and assume that its Gaussian curvature K is nonpositive and bounded. Assume, moreover, that M is of the second kind and denote by X its universal covering. The Dubins problem on M has the* UCC *property if and only if, for every $r > 0$, for every sector S in X, $\sup_{p\in S} \int_{B_X(p,r)} K dA = 0$.*

The results stated in Theorem 4.2 are proved in Propositions 5.9 and 5.10. For what concerns Theorem 4.3, it is a combination of Proposition 5.9 and Corollary 5.15. Finally, the proof of Theorem 4.4 is split into the ones of Proposition 5.10 and Corollary 5.18. For results concerning manifolds with possibly sign-varying curvature, we refer to the detail of sections 5.2, 5.3, and 5.4.

5. Proofs of the results.

5.1. Additional properties of Riemannian surfaces of nonpositive curvature. In this paragraph, we prove some geometric properties of Riemannian surfaces of nonpositive curvature, which are at the heart of the arguments of the theorems stated above. In particular, we show how certain properties of limit sets which hold in the hyperbolic case can be recovered in the nonconstant curvature case, under suitable nonflatness assumptions. To this extent we propose the following definition.

DEFINITION 5.1. *A sector S of a Hadamard surface X is said to be heavy if, for every sector S' contained in S, $\int_{S'} KdA = -\infty$.*

For example, as we will often use, if $r, \delta > 0$ exist such that $\int_{B_X(p,r)} KdA \leq -\delta$ for every $p \in S$, then S is heavy. Heavy sectors enjoy the following visibility-type property.

LEMMA 5.2. *Let S be a heavy sector of a Hadamard surface X. Then, for every z_1 in the interior of $S(\infty)$ and every $z_2 \in X(\infty)$ different from z_1, there exists a geodesic $c : \mathbf{R} \to X$ such that $c(-\infty) = z_1$ and $c(+\infty) = z_2$.*

The lemma is basically a reformulation of [4, Exercise (i), p. 57]. For sake of completeness, let us provide its proof. Consider a convex sector S' bounded by two rays having z_1 and z_2 as endpoints. Since z_1 belongs to the interior of $S(\infty)$, then S' contains a subsector which is a included in S. Therefore, by definition of heavy sector, $\int_{S'} KdA = -\infty$. Denote by x the vertex of S' and let p_n, q_n be two sequences of points in $\partial S'$, tending, respectively, to z_1, z_2, as n tends to infinity. Denote by T_n the geodesic triangle with vertices x, p_n, and q_n. The Gauss–Bonnet theorem implies that $\int_{T_n} KdA > -\pi$ for every n. Therefore, there exists a compact subset C of S' such that, possibly passing to a subsequence, the geodesic segment between p_n and q_n intersects C for every n. By compactness of $UC = \{q \in UX |\ \pi(q) \in C\}$, there exists $q \in UC$ such that the geodesic $s \mapsto \exp(s, q)$ connects, as required, z_1 and z_2.

Given a Hadamard surface X and a group Γ of isometries of X, let us denote by $\mathcal{A}(\Gamma)$ the closure in $X(\infty)$ of the set of endpoints of axis of hyperbolic isometries contained in Γ.

LEMMA 5.3. *Let X be a Hadamard surface and Γ a group of isometries of X. If $\mathcal{A}(\Gamma)$ is nonempty, then, for every heavy sector S of X, $\mathcal{L}(\Gamma) \cap S(\infty) = \mathcal{A}(\Gamma) \cap S(\infty)$.*

Proof. Clearly $\mathcal{A}(\Gamma) \subset \mathcal{L}(\Gamma)$. Fix an axis G of a hyperbolic transformation of Γ, a point z in $S(\infty)$, and assume that there exists a neighborhood J of z which does not contain any endpoint of complete geodesics of the type $\gamma(G)$, $\gamma \in \Gamma$. Let H be a half-plane of X such that $z \in H(\infty) \subset J$, whose existence is guaranteed by Lemma 5.2. Then, the entire Γ-orbit of G is contained in $X \setminus H$. Therefore, z is not a density point of the Γ-orbit of any point of G, i.e., $z \notin \mathcal{L}(\Gamma)$. □

The following lemma concerns the existence of half-planes in nonpositively curved Riemannian surfaces. Its role will be crucial while proving the noncontrollability results contained in section 5.3.

LEMMA 5.4. *Let M be a complete, connected Riemannian surface with nonpositive curvature and let X be its universal covering. Assume that M is of the second kind and that X contains a heavy sector S. Then the canonical projection $\Pi : X \to M$ embeds in M a half-plane of X, contained in S.*

Proof. We start the proof by noticing that if there exists an open, nonempty, connected subset U of $S(\infty) \setminus \mathcal{L}(\Gamma)$ such that $\gamma(U) \cap U = \emptyset$ for every $\gamma \in \Gamma \setminus \{\mathrm{Id}\}$, then every half-plane H bounded by U and a geodesic with endpoints in U is embedded by Π in M. Indeed, $H \cap \gamma(H) \neq \emptyset$ implies that $H(\infty) \cap (\gamma(H))(\infty) = H(\infty) \cap \gamma(H(\infty)) \neq \emptyset$ and γ must therefore be the identity. The existence of a geodesic with endpoints in U follows from Lemma 5.2.

We distinguish two cases, depending on whether Γ contains a hyperbolic isometry.

Assume first that $\Gamma \setminus \{\mathrm{Id}\}$ is made of parabolic isometries only. In particular, Γ is cyclic, since M contains no closed geodesic. Denote by γ a generator of Γ. The set of fixed points of γ on $X(\infty)$ is closed and nonempty. If it does not contain $S(\infty)$, then there exists an open, nonempty, connected subset U of $S(\infty)$ such that $\gamma^j(U) \cap U = \emptyset$ for every $j \in \mathbf{Z} \setminus \{0\}$. Then the lemma follows from the above remark. We are

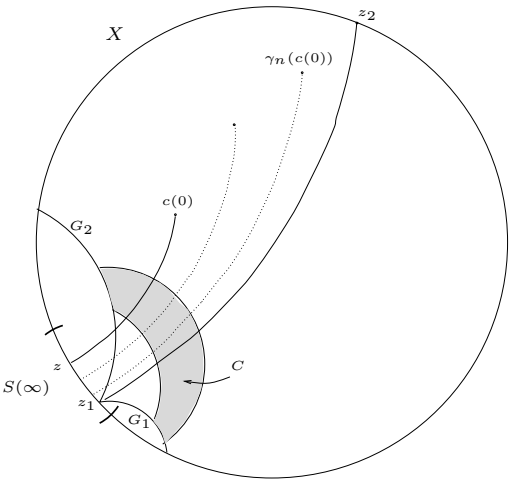

FIG. 2.

left to deal with the case in which every point of $S(\infty)$ is fixed by γ. Consider a parameterized geodesic $c : \mathbf{R} \to X$ such that $c(+\infty)$ and $c(-\infty)$ are both in $S(\infty)$. Since γ fixes the endpoints of c, then P_c, the set spanned by all the geodesics parallel to c, is invariant under the action of γ. The set P_c is isometric to $\mathbf{R} \times \Sigma$, where Σ is a closed geodesic line in X (see [4, Lemma 2.4]). By hypothesis, c bounds no flat half-plane; therefore Σ is bounded. Since γ induces a continuous transformation of Σ, there must exist at least one complete geodesic of X fixed by γ. Thus γ, which is a nonhyperbolic isometry of P_c, is the identity transformation, and the statement of the lemma is trivially true. (Notice that the argument, which follows the proof of Lemma 6.8 in [4], shows that γ has at most one fixed point in the interior of $S(\infty)$, unless $\Gamma = \{\mathrm{Id}\}$.)

Assume now that Γ contains at least one hyperbolic isometry. According to Lemma 5.3, then, $\mathcal{L}(\Gamma) \cap S(\infty) = \mathcal{A}(\Gamma) \cap S(\infty)$. Notice that by definition of heavy sector, for every complete geodesic G with at least one endpoint in the interior of $S(\infty)$, the half-planes bounded by G are not flat. Therefore, $\mathcal{L}(\Gamma) \cap S(\infty)$ has a nonempty interior, since otherwise (6) would imply that M is of the first kind. In particular, $S(\infty)$ is not contained in $\mathcal{L}(\Gamma)$. Fix $z \in S(\infty) \setminus \mathcal{L}(\Gamma)$. According to the remark at the beginning of the proof, it is enough to prove that z is an isolated point of the Γ-orbit of z in $X(\infty)$. To this extent, let us show that the Γ-orbit of z in $X(\infty)$ has no density point in the interior of $S(\infty) \setminus \mathcal{L}(\Gamma)$. Assume, by contradiction, that there exist z_1 in the interior of $S(\infty) \setminus \mathcal{L}(\Gamma)$ and a sequence γ_n of isometries in Γ such that $\gamma_n(z)$ tends to z_1 as n goes to infinity. Let $c : [0, \infty) \to X$ be a ray with $c(+\infty) = z$. Passing possibly to a subsequence, $\gamma_n(c(0))$ converges to a point z_2 of $\mathcal{L}(\Gamma)$. According to Lemma 5.2, there exist two geodesics G_1 and G_2, each of them having one endpoint in z_1, such that the region of X bounded by G_1 and G_2 contains $\gamma_n(c(0))$ for every n. Thus, there exists a compact subset C of X which intersects each ray $c_n(\cdot) = \gamma_n(c(\cdot))$, $n \in \mathbf{N}$ (see Figure 2). Therefore, we can fix a sequence t_n of positive real numbers such that for every $x \in X$, $c_n(t_n)$ has distance from x uniformly bounded with respect to n. Fix $x \in X$ and notice that

$$t_n = d(c_n(0), c_n(t_n)) \geq d(c_n(0), x) - d(x, c_n(t_n)),$$

which implies that t_n tends to infinity with n. Thus, $c(t_n)$ tends to z as n goes to infinity. On the other hand, $\gamma_n^{-1}(x)$ has distance from $c(t_n)$ uniformly bounded with respect to n. It follows that as n goes to infinity, $\gamma_n^{-1}(x)$ converges to z, which contradicts the fact that z does not belong to $\mathcal{L}(\Gamma)$. ∎

5.2. Controllability results. Let us begin the section with the following elementary remark. Consider a complete Riemannian surface M, with no restriction on the sign of its curvature K. Setting $t = 1$ and $T = 2$ in (5), we have that for every $q \in N$ and $\varepsilon > 0$, $e^f(q) \in \mathrm{Int}(A_q^2(M, \varepsilon))$. Fix q and let q' vary in $B_N(q, 2)$, which is a relatively compact neighborhood of q. The continuous dependence of $A_{q'}^2(M, \varepsilon)$ on q' implies that there exists $\rho(\varepsilon, q) \in (0, 1)$ such that for every $q' \in B_N(q, 2)$,

$$B_N(e^f(q'), \rho(\varepsilon, q)) \subset A_{q'}(M, \varepsilon).$$

Therefore,

$$q \in \mathrm{Int}(A_{q'}(M, \varepsilon)) \quad \text{if} \quad e^f(q') \in B(q, \rho(\varepsilon, q)). \tag{17}$$

Indeed, for every $q' \in N$ such that $e^f(q') \in B(q, \rho(\varepsilon, q))$, we have

$$d_N(q, q') \le d_N(q, e^f(q')) + d_N(q', e^f(q')) < 2.$$

LEMMA 5.5. *Let M be a complete, connected Riemannian surface. If $q \in N$ and $\varepsilon > 0$ exist such that $A_q(M, \varepsilon)$ has finite volume, then M has finite area and $A_q(M, \varepsilon) = N$.*

Proof. Fix $q \in N$ and $\varepsilon > 0$ such that $A_q = A_q(M, \varepsilon)$ has finite volume. We want to prove that ∂A_q is empty. Let, by contradiction, $\bar{q} \in \partial A_q$, and define $\bar{\rho} = \rho(\varepsilon, \bar{q}) > 0$, where the function ρ satisfies (17). A well-known theorem by Krener [14] states that any attainable set of a bracket-generating system is contained in the closure of its interior. Therefore, $V = A_q \cap B_N(\bar{q}, \bar{\rho})$ has a nonempty interior and, in particular, positive volume. Since e^f is a volume-preserving diffeomorphism of N (see, for instance, [23]) and A_q has finite volume, then the sets $e^{nf}(V)$, for $n \in \mathbf{N}$, cannot be pairwise disjoint, being $e^{nf}(V) \subset A_q$ for every $n \in \mathbf{N}$. Therefore, there exist $n_1 < n_2$ such that $e^{n_1 f}(V) \cap e^{n_2 f}(V)$ is nonempty. Equivalently, there exists a point q' in $e^{(n_2 - n_1 - 1)f}(V)$ whose image by e^f lies in V. Due to (17), the contradiction is reached. ∎

COROLLARY 5.6. *Let M be a complete, connected Riemannian surface with finite area. Then the Dubins problem on M has the* UCC *property.*

Notice that in the nonpositive curvature case, if M has finite area, then it is of the first kind (see, for instance, [3]). The converse, clearly, is not true in general. It is, however, when M is a finitely connected hyperbolic surface (see, for instance, [21]). In particular, we proved that the Dubins problem on a finitely connected hyperbolic surface of the first kind is UCC. Actually, first kind implies UCC in complete generality, as will be shown in Proposition 5.9.

Let us now prove the second part of Proposition 4.1. Recall that the geodesic flow on M is said to be *topologically transitive* if there exists $q \in N$ such that the orbit of q for the geodesic flow is dense in N.

PROPOSITION 5.7. *Let M be a complete, connected Riemannian surface such that the geodesic flow on M is topologically transitive. Then the Dubins problem on M has the* UCC *property.*

Proof. Fix $q_0 \in N$ such that

$$\mathcal{O}_{q_0} = \{e^{tf}(q_0) \mid t \in \mathbf{R}\}$$

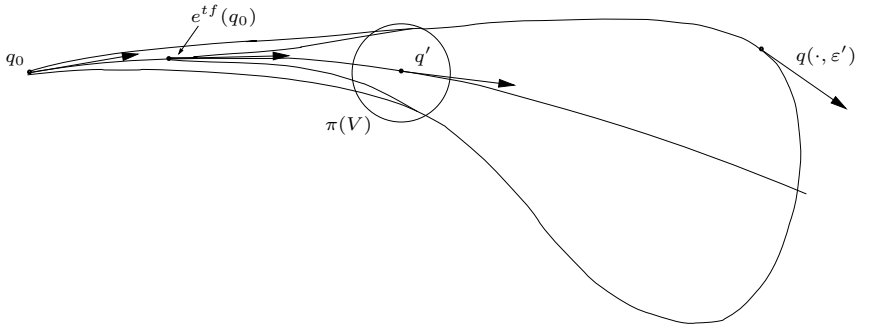

FIG. 3. *Construction of a teardrop trajectory from* $e^{tf}(q_0)$.

is dense in N. The property formulated in (17) implies that for every $\varepsilon > 0$,

$$N = A_{q_0}(M,\varepsilon) \cup \left(A_{q_0^-}(M,\varepsilon)\right)^-,$$

where $(A_{q_0^-}(M,\varepsilon))^-$ denotes the image of $A_{q_0^-}(M,\varepsilon)$ through the involutive diffeomorphism $q \mapsto q^-$. Hence, there exists a decreasing sequence ε_n, converging to zero as n tends to infinity, such that

$$q_0^- \in A_{q_0}(M,\varepsilon_n) \quad \text{for every } n \geq 1 \tag{18}$$

or

$$q_0 \in A_{q_0^-}(M,\varepsilon_n) \quad \text{for every } n \geq 1. \tag{19}$$

Without loss of generality, we can assume that (18) holds, since

$$\mathcal{O}_{q_0^-} = (\mathcal{O}_{q_0})^-$$

is dense in N, which means that the roles of q_0 and q_0^- are symmetric.

Since $\varepsilon \mapsto A_{q_0}(M,\varepsilon)$ is monotone with respect to the inclusion, then q_0 belongs to the set

$$W = \{q \in N \mid q^- \in A_q(M,\varepsilon) \text{ for every } \varepsilon > 0\}.$$

The UCC property for Dubins' problem on M is equivalent to the equality $N = W$ (see Remark 2.2). It is enough to show that $\mathcal{O}_{q_0} \subset W$, due to (5) and to the density of $\mathcal{O}_{q_0}$ in N.

This is trivial for what concerns the negative orbit of q_0. Fix now $\varepsilon, t > 0$. We have to show that there exists an ε-admissible trajectory connecting $e^{tf}(q_0)$ and $(e^{tf}(q_0))^-$. Notice that $A_{e^{tf}(q_0)}(M,\varepsilon)$ contains a neighborhood V of $q' = e^{(t+1)f}(q_0)$. For every $\varepsilon' > 0$, let $q(\cdot,\varepsilon') : [0, T_{\varepsilon'}] \to N$ be an ε'-admissible trajectory such that $q(0,\varepsilon') = q_0$ and $q(T_{\varepsilon'},\varepsilon') = q_0^-$. Then, as ε' goes to zero, we have that $T_{\varepsilon'}$ goes to infinity, while, for every $L > 0$, the restriction of $q(\cdot,\varepsilon')$ on $[0,L]$ (respectively, $[T_{\varepsilon'} - L, T_{\varepsilon'}]$) converges uniformly to $[0,L] \ni s \mapsto e^{sf}(q_0)$ (respectively, $[T_{\varepsilon'} - L, T_{\varepsilon'}] \ni s \mapsto e^{(s-T_{\varepsilon'})f}(q_0^-)$). In particular, for ε' small enough, $q(t+1,\varepsilon')$ and $q(T_{\varepsilon'} - t - 1,\varepsilon')^-$ belong to V (see Figure 3). Provided that $\varepsilon' \leq \varepsilon$, an ε-admissible trajectory steering $e^{tf}(q_0)$ to $(e^{tf}(q_0))^-$ can be obtained by gluing three ε-admissible subtrajectories, the first

going from $e^{tf}(q_0)$ to $q(t+1,\varepsilon')$, the second coinciding with the restriction of $q(\cdot,\varepsilon')$ on $[t+1, T_{\varepsilon'}-t-1]$, and the last connecting $q(T_{\varepsilon'}-t-1,\varepsilon')$ and $(e^{tf}(q_0))^-$. □

Recall that the *injectivity radius at a point p of a Riemannian manifold M* is defined as the least upper bound $i_p(M)$ of all $r>0$ such that the map $(t,q)\mapsto \exp(t,q)$, restricted to the punctured disk $(0,r)\times U_pM$, is injective. Before stating sufficient conditions for UCC on nonpositively curved Riemannian surfaces, we prove the following technical result.

LEMMA 5.8. *Let M be a Riemannian surface, $q=(p,v)\in N$, and $\varepsilon, R, \delta>0$. Assume that $R<i_p(M)$, that $K\le 0$ on $B_M(p,R)$, and that $\int_{B_M(p,R)}(-K)dA\le\delta$. There exist $R(\varepsilon),\delta(\varepsilon)>0$, depending only on ε, such that if $R\ge R(\varepsilon)$ and $\delta\le\delta(\varepsilon)$, then there exists an ε-admissible trajectory going from q to q^- and contained in $UB_M(p,R)$.*

Proof. Notice that it is enough to prove the existence of $\delta(\varepsilon)$ and $R(\varepsilon)$ in the case $\varepsilon=1$. Indeed, given $\varepsilon>0$, denote by M^ε the Riemannian surface $(M,\varepsilon m)$. Let, moreover, K^ε and dA^ε be, respectively, the curvature and the surface form on M^ε. Then $K^\varepsilon=\varepsilon K$, $dA=\varepsilon dA^\varepsilon$, and, for every $p\in M$ and $r>0$, $B_M(p,\varepsilon r)=B_{M^\varepsilon}(p,r)$. Thus,

$$\int_{B_M(p,\varepsilon r)}(-K)dA=\int_{B_{M^\varepsilon}(p,r)}(-K^\varepsilon)dA^\varepsilon.$$

The reduction to the case $\varepsilon=1$ is proved (with $\varepsilon R(\varepsilon)=R(1)$ and $\delta(\varepsilon)=\varepsilon\delta(1)$), since an ε-admissible trajectory in M is a 1-admissible trajectory in M^ε and $i_p(M)=\varepsilon i_p(M^\varepsilon)$.

Let $q=(p,v)$ and R be, respectively, a point of N and a positive constant such that $R<i_p(M)$ and $K\le 0$ on $B_M(p,R)$. Denote by Q the square $[-R/2,R/2]\times[-R/2,R/2]\subset\mathbf{R}^2$, endowed with the metric ϕ_q^*m. Recall that Dubins' problem on Q is described by (13)–(15).

Let $u:[0,T]\to[-1,1]$ be a 1-admissible control, and denote by $(x(\cdot),y(\cdot),\theta(\cdot))$ the coordinates of the corresponding trajectory starting from a given $(x_0,y_0,\theta_0)\in UQ$.

Assume that $(x(t),y(t),\theta(t))\in UQ$ and $\dot x(t)>0$ for every $t\in(0,T)$. We can define a map $\tau:[x_0,x(T)]\to[0,T]$ by means of the relation $x(\tau(\xi))=\xi$. Notice that τ is continuous, as well as the function $\eta:[x_0,x(T)]\to\mathbf{R}$ which maps ξ to $\eta(\xi)=y(\tau(\xi))$. Let Ω be the open region of Q defined by

$$\Omega=\cup_{\xi\in(x_0,x(T))}I(\eta(\xi)),$$

where, for every $l\in\mathbf{R}$, $I(l)$ denotes the open interval with 0 and l as boundary points.

Let (X,Y,Θ) be the solution of

$$\begin{cases}\dot X=\cos\Theta,\\ \dot Y=\sin\Theta,\\ \dot\Theta=u\end{cases}$$

with initial condition $(X(0),Y(0),\Theta(0))=(x_0,y_0,\theta_0)$. For every $t\in[0,T]$,

$$\begin{aligned}|\theta(t)-\Theta(t)|=\left|\int_0^t\cos(\theta(s))\frac{B_y(x(s),y(s))}{B(x(s),y(s))}ds\right| &= \left|\int_{x_0}^{x(t)}B_y(\xi,\eta(\xi))d\xi\right|\\ \le\int_{x_0}^{x(t)}d\xi\left(\int_{I(\eta(\xi))}B_{yy}(\xi,v)dv\right) &= \int_{x_0}^{x(t)}\int_{I(\eta(\xi))}-K(\xi,v)B(\xi,v)dv\,d\xi,\end{aligned}$$

where the last equality follows from (8). Since the surface element dA of Q is equal to $B(\xi, v)dv\,d\xi$, we have

$$|\theta(t) - \Theta(t)| \leq \int_Q (-K)dA. \tag{20}$$

Integrating the equations satisfied by $y(\cdot)$ and $Y(\cdot)$, we get, for every $t \in [0, T]$,

$$|y(t) - Y(t)| \leq \int_0^t |\theta(s) - \Theta(s)|ds \leq t \int_Q (-K)dA. \tag{21}$$

Similarly, we obtain

$$\begin{aligned}
|x(t) - X(t)| &= \left| \int_0^t \left(\frac{\cos(\theta(t))}{B(x(t), y(t))} - \cos(\Theta(t)) \right) dt \right| \\
&\leq \left| \int_0^t (\cos(\theta(t)) - \cos(\Theta(t)))\, dt \right| + \left| \int_{x_0}^{x(t)} (1 - B(\xi, \eta(\xi)))\, d\xi \right| \\
&\leq t \int_Q (-K)dA + \int_{x_0}^{x(t)} \left(\int_{I(\eta(\xi))} B_y(\xi, v)dv \right) d\xi \\
&= t \int_Q (-K)dA + \int_{x_0}^{x(t)} \left(\int_{I(\eta(\xi))} \left(\int_{I(v)} (-K(\xi, l)B(\xi, l))dl \right) dv \right) d\xi \\
&= t \int_Q (-K)dA + \int_{x_0}^{x(t)} \left(\int_{I(\eta(\xi))} |\eta(\xi) - l|(-K(\xi, l)B(\xi, l))dl \right) d\xi \\
&\leq \left(t + (x(t) - x_0)\frac{R}{2} \right) \int_Q (-K)dA \\
&\leq t \left(1 + \frac{R}{2} \right) \int_Q (-K)dA. \qquad (22)
\end{aligned}$$

Let

$$\delta = \int_Q (-K)dA. \tag{23}$$

Our aim is to show that under suitable assumptions on R and δ, there exists a 1-admissible trajectory contained in UQ which steers $(0, 0, 0)$ to $(0, 0, -\pi)$. As a model we consider the teardrop in the plane of size 1, whose projection is contained in a square of center $(0, 0)$ and side length 6.

Let $\alpha \in (0, \pi/2)$ and consider the trajectory $(x^+(\cdot, \alpha), y^+(\cdot, \alpha), \theta^+(\cdot, \alpha))$ in UQ with initial condition $(x^+(0, \alpha), y^+(0, \alpha), \theta^+(0, \alpha)) = (0, 0, 0)$ corresponding to the control

$$u^+(s, \alpha) = \begin{cases} 1 & \text{if} \quad 0 \leq s \leq \alpha, \\ -1 & \text{if} \quad s > \alpha. \end{cases}$$

Let $t^+(\alpha)$ be the first time t at which $\theta^+(t, \alpha) = -\pi/2$. The fact that a finite $t^+(\alpha)$ with such property exists, for δ and $1/R$ small enough, depends on the following considerations. First, notice that the trajectory is defined as long as its projection on the plane (x, y) stays in Q; thus, for a time $T_{\max}$ larger than $R/2$. If $\dot{x}^+(s, \alpha) > 0$ for

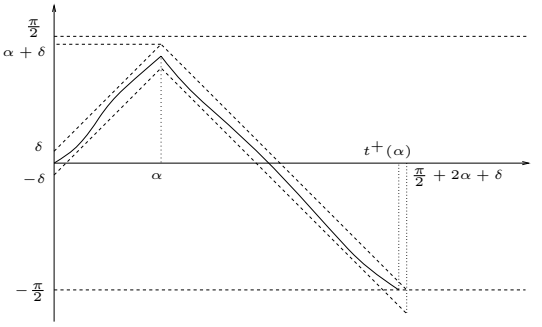

FIG. 4. *The graph of* $\theta^+(\cdot, \alpha)$.

every $s \in [0, t]$, then $|\theta^+(t, \alpha) - \int_0^t u^+(s, \alpha) ds| \leq \delta$, as it follows from (20). Assume that

$$\delta < \pi/2 - \alpha. \tag{24}$$

In particular, $\dot{x}^+(t, \alpha) > 0$ until $\theta^+(\cdot, \alpha)$ assumes the value $-\pi/2$ or up to time $T_{\max}$. If, moreover,

$$R \geq 2\pi + 2\alpha, \tag{25}$$

then $T_{\max} \geq R/2 > \pi/2 + 2\alpha + \delta$ and, since $\int_0^{\pi/2+2\alpha} u^+(s, \alpha) ds = -\pi/2$, $t^+(\alpha)$ is well defined and satisfies

$$\left| t^+(\alpha) - \frac{\pi}{2} - 2\alpha \right| \leq \delta. \tag{26}$$

(See Figure 4.) Let $u^-(\cdot, \alpha) = -u^+(\cdot, \alpha)$, define $(x^-(\cdot, \alpha), y^-(\cdot, \alpha), \theta^-(\cdot, \alpha))$ as the trajectory in UQ corresponding to the control $u^-(\cdot, \alpha)$ with initial condition

$$(x^-(0, \alpha), y^-(0, \alpha), \theta^-(0, \alpha)) = (0, 0, 0).$$

As above, if δ and R satisfy (24) and (25), then $t^-(\alpha)$, the first time t for which $\theta^-(t, \alpha) = \pi/2$, is well defined and the estimate

$$\left| t^-(\alpha) - \frac{\pi}{2} - 2\alpha \right| \leq \delta \tag{27}$$

holds true.

Fix $R = 3\pi$ and notice that, as a consequence, (25) is always satisfied. Let U be a neighborhood of $(\pi/3, \pi/3)$ compactly contained in $(0, \pi/2) \times (0, \pi/2)$. Thus there exists $\delta_0 > 0$ such that if $\delta \leq \delta_0$, then

$$\mathcal{F}(\alpha_0, \alpha_1) = (x^+(t^+(\alpha_0), \alpha_0), y^+(t^+(\alpha_0), \alpha_0)) - (x^-(t^-(\alpha_1), \alpha_1), y^-(t^-(\alpha_1), \alpha_1))$$

is well defined for every (α_0, α_1) in U, and

$$t^+(\alpha_0), t^-(\alpha_1) \leq \frac{3}{2}\pi.$$

Notice that δ_0 depends only on the choice of U. The quantity $|\mathcal{F}(\alpha_0, \alpha_1)|$ measures how far the two trajectories corresponding to the controls $u^+(\cdot, \alpha_0)$ and $u^-(\cdot, \alpha_1)$ are

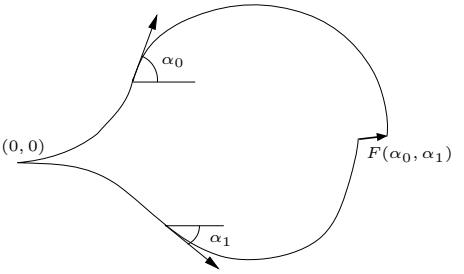

FIG. 5.

from matching their ends (see Figure 5). The lemma is proved if we show that the minimum of $|\mathcal{F}|$ on U is equal to zero.

For every $\alpha \in (0,\pi/2)$, let $(X^{\pm}(\cdot,\alpha), Y^{\pm}(\cdot,\alpha), \Theta^{\pm}(\cdot,\alpha))$ be the trajectories in $U\mathbf{R}^2 \cong \mathbf{R}^2 \times \mathcal{S}^1$ corresponding to the controls $u^{\pm}(\cdot,\alpha)$ and to the initial conditions $(X^{\pm}(0,\alpha), Y^{\pm}(0,\alpha), \Theta^{\pm}(0,\alpha)) = (0,0,0)$. For every (α_0,α_1) in U, let

$$\begin{aligned}\mathcal{G}(\alpha_0,\alpha_1) &= \left(X^{+}\left(\frac{\pi}{2}+2\alpha_0,\alpha_0\right), Y^{+}\left(\frac{\pi}{2}+2\alpha_0,\alpha_0\right)\right)\\ &\quad - \left(X^{-}\left(\frac{\pi}{2}+2\alpha_1,\alpha_1\right), Y^{-}\left(\frac{\pi}{2}+2\alpha_1,\alpha_1\right)\right)\\ &= 2(\sin\alpha_0 - \sin\alpha_1, -\cos\alpha_0 - \cos\alpha_1),\end{aligned}$$

which is the flat counterpart of $\mathcal{F}$. Note that, by construction, $\mathcal{G}(\pi/3,\pi/3) = (0,0)$. Moreover,

$$\det D\mathcal{G}(\pi/3,\pi/3) = \det\begin{pmatrix} \cos\dfrac{\pi}{3} & -\cos\dfrac{\pi}{3} \\ \sin\dfrac{\pi}{3} & \sin\dfrac{\pi}{3} \end{pmatrix} = \frac{\sqrt{3}}{2},$$

and so if $\mathcal{S}^1 \ni s \mapsto (\alpha_0(s),\alpha_1(s)) \in U$ is a simple closed loop encircling $(\pi/3,\pi/3)$ and being close enough to $(\pi/3,\pi/3)$, then $s \mapsto \mathcal{G}(\alpha_0(s),\alpha_1(s))$ encircles $(0,0)$. Fix a loop $(\alpha_0(\cdot),\alpha_1(\cdot))$ of such kind and let

$$r = \min_{s\in\mathcal{S}^1} d_{\mathbf{R}^2}((0,0),\mathcal{G}(\alpha_0(s),\alpha_1(s))) > 0.$$

We stress that r, by construction, is independent of the specific point p and of the manifold M. In fact, it depends only on the dynamics of the flat Dubins problem.

According to (21) and (22), we get, for every $(\alpha_0,\alpha_1) \in U$ and for $j = 0,1$,

$$\begin{aligned}|x^{\pm}(t^{\pm}(\alpha_j),\alpha_j) - X^{\pm}(t^{\pm}(\alpha_j),\alpha_j)| &\le t^{\pm}(\alpha_j)\left(1+\frac{R}{2}\right)\delta \quad \le \quad \frac{3}{2}\pi\left(1+\frac{3}{2}\pi\right)\delta,\\ |y^{\pm}(t^{\pm}(\alpha_j),\alpha_j) - Y^{\pm}(t^{\pm}(\alpha_j),\alpha_j)| &\le t^{\pm}(\alpha_j)\delta \quad \le \quad \frac{3}{2}\pi\delta.\end{aligned}$$

On the other hand, for for every $(\alpha_0,\alpha_1) \in U$ and $j = 0,1$,

$$\begin{aligned}|X^{\pm}(t^{\pm}(\alpha_j),\alpha_j) - X^{\pm}(\pi/2+2\alpha_j,\alpha_j)| &\le \delta,\\ |Y^{\pm}(t^{\pm}(\alpha_j),\alpha_j) - Y^{\pm}(\pi/2+2\alpha_j,\alpha_j)| &\le \delta,\end{aligned}$$

as it follows from (26) and (27). Therefore, by triangle inequality,

$$|\mathcal{F}(\alpha_0, \alpha_1) - \mathcal{G}(\alpha_0, \alpha_1)| \leq c_0 \delta$$

for every $(\alpha_0, \alpha_1) \in U$, where c_0 is a universal positive constant. If

$$\delta \leq \min\left\{\delta_0, \frac{r}{c_0}\right\}, \tag{28}$$

then it follows from standard degree theory considerations that there exists (α_0, α_1) in U such that $\mathcal{F}(\alpha_0, \alpha_1) = (0, 0)$. The lemma is proved, with $R(1) = 3\pi$ and $\delta(1)$ equal to the right-hand side of (28). □

From now on, let, for every complete Riemannian surface M, for every $p \in M$ and $r > 0$,

$$\Phi(p, r) = \int_{B_M(p,r)} K dA.$$

PROPOSITION 5.9. *Let M be of the first kind. Then the Dubins problem on M is* UCC.

Proof. Fix $q \in N$ and $\varepsilon > 0$. Motivated by Remark 2.2, we are going to prove the so-called weak controllability from q, i.e., that there exists $\hat{q} \in A(q, \varepsilon)$ such that $\hat{q}^- \in A(\hat{q}, \varepsilon)$.

Let $\tilde{q} \in UX$ be such that $\Pi_*(\tilde{q}) = q$ and define $\tilde{q}_1 = e^f(\tilde{q})$. Recall that, due to (5), $\tilde{q}_1$ belongs to the interior of $A_{\tilde{q}}(X, \varepsilon)$. Therefore, there exists $\rho > 0$ such that for every $\theta \in [-\rho, \rho]$, the ray $[0, \infty) \ni s \mapsto \exp(s, e^{\theta g}(\tilde{q}_1))$ is projected by Π in the interior of $\pi(A_q)$. Denote by S the sector of X spanned by all rays $\exp(\cdot, e^{\theta g}(\tilde{q}_1))$, $\theta \in [-\rho, \rho]$.

Consider the case in which there exists $p \in S$ such that $\Phi(p, R(\varepsilon)) \geq -\delta(\varepsilon)$, where $R(\cdot)$ and $\delta(\cdot)$ are the functions whose existence was established by Lemma 5.8. Notice that $i_p(X) = \infty$. Then, for every $\hat{q} \in U_pX$, we would have $\hat{q}^- \in A_{\hat{q}}(X, \varepsilon)$. Since $U_pX \cap A_{\tilde{q}}(X, \varepsilon) \neq \emptyset$, then the weak controllability from q would follow. Thus, we can assume that S is heavy.

Recall that M contains at least one closed geodesic G (see Remark 3.3). The set $\Pi^{-1}(G)$ is the union of infinitely many complete geodesics. Let $\widetilde{G}$ be one of these lifts of G. Fix one endpoint of $\widetilde{G}$ and denote it by z.

Lemma 5.3 implies that, without loss of generality, $z \in S(\infty)$ and $\widetilde{G}$ is not the boundary of a flat half-plane. Since $\widetilde{G}$ is the axis of a hyperbolic isometry contained in Γ, it follows from (6) that there exist components of $\Pi^{-1}(G)$ which are entirely contained in S. Thus, we can assume that $\widetilde{G} \subset S$ (see Figure 6).

Choose a parameterization $c : \mathbf{R} \to X$ of $\widetilde{G}$. A standard application of Topogonov theorem to the triangle $(\pi(\tilde{q}_1), c(t), c(0))$ shows that the angle between $\widetilde{G}$ and the segment from $\pi(\tilde{q}_1)$ to $c(t)$ goes to zero as t goes to plus or minus infinity (see [4, p. 34]).

Fix $p \in G$ and let $\sigma > 0$ be such that for every $q' \in U_pM$, $B_N(q', \sigma) \subset A^2_{e^{-f}(q')}(M, \varepsilon)$. There exists a ray from $\pi(\tilde{q})$, contained in S, which intersects $\widetilde{G}$ at a point which projects to p, with an angle smaller than σ, and at a distance from $\pi(\tilde{q})$ larger than one.

Therefore, there exists an admissible curve for $(\mathcal{D}^M_\varepsilon)$ which starts from the point-with-direction q and arrives tangentially on G. Moreover, the same procedure can be applied in order to arrive tangentially on G with the opposite orientation. Gluing

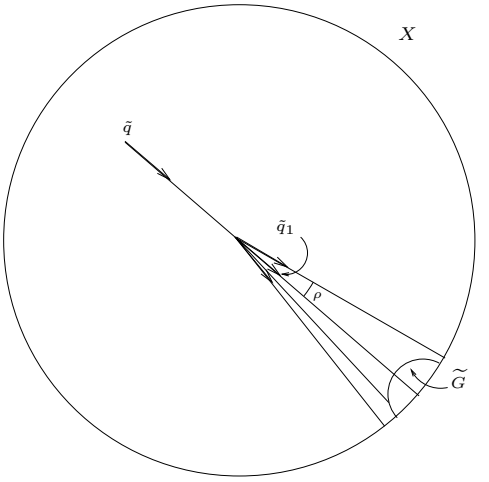

FIG. 6.

pieces of admissible trajectories, one obtains an admissible strategy which connects q with q^-. □

In the above proof we additionally gave an argument for the following proposition.

PROPOSITION 5.10. *Let M be a connected complete nonpositively curved Riemannian surface and denote by X its universal covering. If for every $r > 0$ and every sector S of X, $\sup_{p\in S} \Phi(p, r) = 0$, then the Dubins problem on M is* UCC.

Remark 5.11. If $\lim_{p\to\infty,\, p\in M} K(p) = 0$, then $\lim_{p\to\infty,\, p\in X} \Phi(p, r) = 0$ for every $r > 0$, and therefore the Dubins problem on M is UCC. This does not come unexpected. Indeed, it is a special case of [6, Theorem 5.14], where unrestricted complete controllability was proved for all complete, connected Riemannian surfaces whose curvature tends to zero at infinity.

COROLLARY 5.12. *If $K \leq 0$ and $\int_M K dA$ is finite, then the Dubins problem on M is* UCC.

Proof. Assume that the UCC property does not hold. In particular, M is of the second kind and, according to Proposition 5.10, there exist $r > 0$ and a sector S in X such that

$$\sup_{p\in S} \Phi(p, r) < 0, \tag{29}$$

where X denotes the universal covering of M. Then S is heavy and Lemma 5.4 guarantees the existence of a half-plane $H \subset S$ embedded by Π in M. Finally, $\int_M K dA = \int_H K dA = -\infty$. □

Remark 5.13. Let M be a complete, connected unbounded Riemannian surface and assume that $K \leq 0$ outside a compact subset C of M. Then, for every $p \in M \setminus C$, for every $q \in U_p M$, the square $[-d(p, C)/2, d(p, C)/2] \times [-d(p, C)/2, d(p, C)/2]$ can be endowed with the metric $\phi_q^* m$. Therefore, for every $r > 0$, on a complement of a compact subset of M, which depends on r, it is possible to define

$$\widetilde{\Phi}(p, r) = \int_{\tilde{B}(p,r)} K dA,$$

where $\tilde{B}(p, r)$ is the ball of center $(0, 0)$ and radius r contained in a sufficiently large square of the type $[-\rho, \rho] \times [-\rho, \rho]$ endowed with $\phi_q^* m$, for some $q \in U_p M$. The

definition makes sense, since the value of $\int_{\tilde{B}(p,r)} K dA$ does not depend on the choice of q. Clearly, if $i_p(M) \geq r$, then $\widetilde{\Phi}(p,r) = \Phi(p,r)$.

If $\lim_{p\to\infty} \widetilde{\Phi}(p,r) = 0$, then the Dubins problem on M is UCC. Indeed, it is a general fact that on an unbounded surface M every attainable set is unbounded (see Lemma 5.5). Then, for every $\varepsilon > 0$ and every $q \in N$, there exists $\hat{q} \in A_q(M,\varepsilon)$ such that $\widetilde{\Phi}(\pi(\hat{q}), R(\varepsilon))$ is well defined and it is larger than $-\delta(\varepsilon)$. Applying Lemma 5.8 to $(-R(\varepsilon), R(\varepsilon)) \times (-R(\varepsilon), R(\varepsilon))$, endowed with $\phi_{\hat{q}}^* m$, we obtain the desired weak controllability from q.

5.3. Noncontrollability results.

LEMMA 5.14. *Let M be a complete Riemannian surface. If a half-plane H in M exists, such that $\sup_H K < 0$, then the Dubins problem on M is not* UCC.

Proof. Let $a = |\sup_H K| > 0$. Fix a system of geodesic coordinates (x,y) on H such that H is parameterized by $\{(x,y) |\ x \in \mathbf{R}, y \geq 0\}$. Let us compare $F(x,y)$, defined as in (12), with

$$G(y) = \sqrt{a} \tanh\left(\sqrt{a} y\right),$$

the solution of (16) corresponding to $K \equiv -a$. If $(x,y) \in H$ and $F(x,y) = G(y)$, then $F_y(x,y) - G_y(y) = -K(x,y) - a \geq 0$. Therefore

$$F(x,y) \geq \sqrt{a} \tanh\left(\sqrt{a} y\right). \tag{30}$$

Let $q = (0,1,\pi/2) \in UH$. We claim that for ε small enough, the attainable set $A_q(M,\varepsilon)$ is contained in the interior of UH. Indeed, let $\varepsilon \in (0, \sqrt{a}\tanh(\sqrt{a}))$ and consider any admissible control $u : [0,\infty) \to [-\varepsilon,\varepsilon]$. Denote by $(x(\cdot), y(\cdot), \theta(\cdot))$ its corresponding trajectory such that $(x(0), y(0), \theta(0)) = q$. Define $\theta_0 \in (0, \pi/2)$ through the relation

$$\sqrt{a} \tanh\left(\sqrt{a}\right) \cos\theta_0 = \varepsilon \tag{31}$$

and let

$$T = \sup\{\tau > 0 \,|\, \pi - \theta_0 \leq \theta(\tau) \leq \theta_0\}.$$

Notice that $y(t) \geq 1$ for every $t \in [0,T)$. It follows from (30) that $F(x(t), y(t)) \geq \sqrt{a}\tanh(\sqrt{a})$ for every $t \in [0,T)$. Therefore, if T were finite, then

$$F(x(T), y(T)) \cos\theta_0 > \varepsilon,$$
$$F(x(T), y(T)) \cos(\pi - \theta_0) < -\varepsilon.$$

This would not be compatible with (15), the equation satisfied by $\theta(\cdot)$, and the definition of T. ∎

COROLLARY 5.15. *If K is uniformly negative and M is of the second kind, then the Dubins problem is not* UCC. *More precisely, if $0 < \varepsilon < |\sup_M K|$, then (D_ε^M) is not completely controllable.*

Proof. The first part of the statement follows from Lemma 5.4, which ensures that Π embeds a half-plane of X in M. The quantitative assertion is easily derived from the proof proposed for Lemma 5.14, where the point $q_1 = (0,1,\pi/2)$ can be replaced by $(0,y,\pi/2)$, with y arbitrarily large. ∎

LEMMA 5.16. *Let M be a complete Riemannian surface. Let $H \subset M$ be a half-plane such that K is nonpositive and bounded on H. Assume that there exists $r > 0$ such that $\sup_{p\in H} \Phi(p,r) < 0$. Then the Dubins problem on M is not* UCC.

Proof. Parameterize H over $\{(x,y)|\ x \in \mathbf{R}, y \geq 0\}$ with a system of geodesic coordinates. By contradiction, let us assume that the Dubins problem on M is UCC. Therefore, for every $\varepsilon > 0$, there exists a curve leaving from $(0,0)$ in the direction $(0,0,\pi/2)$ and coming back to ∂H in finite time, having geodesic curvature bounded by ε. In particular, there exists an ε-admissible trajectory $q = (x,y,\theta) : [0,T] \to N$ such that $q(0) = (0,0,\pi/2)$ and $q(T) = (x(T), y(T), k\pi)$, with $x(T) \in \mathbf{R}$, $y(T) > 0$, and $k \in \{0,1\}$.

Without loss of generality, $\theta(t) \in (0,\pi)$ for every $t \in [0,T)$. Hence, $t \mapsto y(t)$ is nonnegative and strictly increasing on $[0,T]$. Notice that T tends to infinity as ε goes to zero, since otherwise the Ascoli theorem would immediately lead to a contradiction.

The following claim will be repeatedly applied.

CLAIM 5.17. *For every $\rho, \tau > 0$, there exists $\varepsilon(\rho,\tau) > 0$ with the following property: let $\gamma : [0,\tau] \to H$ be a curve with geodesic curvature bounded by $\varepsilon(\rho,\tau)$, parameterized by arc-length and such that $\phi_{\dot\gamma(0)}([0,\tau] \times [-\rho,\rho])$ is contained in H; then, for every $t \in [0,\tau]$, $\operatorname{dist}(\gamma(t), \exp(t,\dot\gamma(0))) < \rho$.*

The claim can be obtained by a standard perturbation argument, as ε approaches zero, applied to the system (13)–(15). The use of geodesic coordinates is justified by the hypothesis that $\phi_{\dot\gamma(0)}([0,\tau] \times [-\rho,\rho]) \subset H$. Notice that ε can be chosen only depending on τ and ρ, because K is uniformly bounded from below.

Up to a global rescaling of M, as performed in the proof of Lemma 5.8, we can assume that $r = 1/4$. Assume from now on that $\varepsilon < \varepsilon(1/4, 1)$ and $T > 2$.

Let T_1 be the largest number between $T-2$ and the maximal time $t \in [0,T)$ such that $\theta(t) = \pi/2$. Let, moreover,

$$\Omega = \cup_{t \in (T_1,T)} \{x(t)\} \times (0, y(t)),$$

and D be the disk of center $p = \exp(1/2, \mathcal{R}q(T-1))$ and radius $1/4$. Assume that $\theta(T) = 0$ (symmetric arguments hold when $\theta(T) = \pi$). The Gauss–Bonnet theorem, applied to Ω, implies that

$$\theta(T_1) + \int_\Omega (-K) dA = -\int_{T_1}^T u(t) dt.$$

Since both $\theta(T_1)$ and $\int_\Omega (-K) dA$ are nonnegative, then

$$\max\left\{\theta(T_1), \int_\Omega (-K) dA\right\} \leq \left|\int_{T_1}^T u(t) dt\right| \leq 2\varepsilon. \tag{32}$$

A contradiction is reached if we show that for ε small enough, D is contained in Ω. It follows from (32) and the definition of T_1 that for $\varepsilon < \pi/4$, $T_1 = T-2$. Claim 5.17 implies that $y(1) \geq 3/4$. Thus, the y-component of p is larger than $y(T-1) - 1/2 > y(1) - 1/2 \geq 1/4$. Therefore, D does not intersect the line $\{(x,0)|\ x \in \mathbf{R}\}$. If D contained a point of the type $\pi(q(\tau))$, for $\tau \in [T-2, T]$, then the distance from p to the geodesic $s \mapsto \exp(s, q(T-1))$ would be smaller than

$$d(p, \pi(q(\tau))) + d(\pi(q(\tau)), \exp(\tau - T + 1, q(T-1))) < \frac{1}{2}.$$

(See Figure 7.) Therefore, drawing the minimizing segment from p to the considered geodesic, we would construct a triangle (having p and $\pi(q(T-1))$ as two of its vertices) with two orthogonal angles. This is impossible, due to the Gauss–Bonnet theorem.

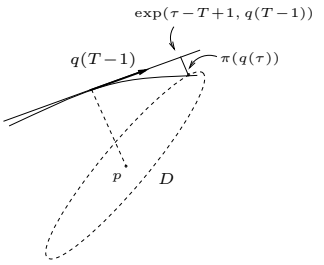

FIG. 7.

Assume now that $y \in [0, y(T)]$ exists such that $(x(T), y)$ belongs to D. Then the distance from $\exp(-1, q(T))$ to the geodesic $s \mapsto (x(T), s)$ is strictly smaller than one. Again, this leads to a contradiction.

The same argument shows that D does not intersect $\Sigma = \{\exp(s, \mathcal{R}q(T-2))|\ s \in J\}$, where J is the maximal interval containing zero such that $\exp(s, \mathcal{R}q(T-2)) \in H$ for every $s \in J$. Since $\theta(T-2)$ is contained in $(0, \pi/2)$, and Σ cannot intersect $\{(x(T-2), y)|\ y \geq 0\}$ twice, then the stated inclusion of D in Ω follows. □

From Lemma 5.4, one easily obtains the next corollary.

COROLLARY 5.18. *Let M be a complete, connected Riemannian surface. Assume that K is nonpositive and bounded on M and that M is of the second kind. Let X be the universal covering of M. Assume that $\sup_{p\in S} \Phi(p, r) < 0$ for some sector S of X and some $r > 0$. Then the Dubins problem on M is not* UCC.

5.4. Riemannian surfaces with nonpositive curvature outside a compact set. In this section, let us focus on Riemannian surfaces with sign-varying curvature, allowing K to be positive on a bounded set. Recall that a subset U of a finitely connected complete Riemannian surface M is called a *Riemannian half-cylinder* if it is diffeomorphic to $\mathcal{S}^1 \times [0, \infty)$. With a Riemannian half-cylinder U, we can associate its curvature at infinity $K_\infty(U) = -\int_U K dA - k(\partial U)$, where $k(\partial U)$ denotes the integral of the geodesic curvature of ∂U. The Cohn-Vossen theorem [8, 27] guarantees that $K_\infty(U) \geq 0$. When $K_\infty(U)$ is strictly positive, U is called a *strict Riemannian half-cylinder*. Notice that if U' is a Riemannian half-cylinder homotopic to U, then $K_\infty(U) = K_\infty(U')$. In particular, U' is strict if and only if U is.

We can prove the following.

PROPOSITION 5.19. *Let M be a finitely connected complete Riemannian surface such that K is bounded and nonpositive outside a compact set. Assume, moreover, that every Riemannian half-cylinder in M is strict. Then the Dubins problem on M is* UCC *if and only if, for every half-plane H contained in M and every $r > 0$, $\sup_{p\in H} \Phi(p, r) = 0$. In particular, the Dubins problem on M is* (i) UCC *if $\int_M K dA > -\infty$;* (ii) *not* UCC *if there exists a strict Riemannian half-cylinder $U \subset M$ such that $\sup_{p\in U} \Phi(p, r) < 0$ for some $r > 0$.*

We do not provide a complete argument, since Proposition 5.19 basically follows from what precedes and from the results of Shioya [27]. Let us just sketch the main points of the proof.

Shioya proved that if U is a strict Riemannian half-cylinder, then, through every point of U far enough from ∂U, passes a complete geodesic $c : \mathbf{R} \to M$, contained in U and which has a finite number $n(U)$ of self-intersections (only depending on U). In addition, $n(U) = 0$ if $\int_U K dA = -\infty$, which means that U contains a half-plane of M. When $n(U) \geq 1$, the self-intersections of c are *regular* in the sense defined in

Chapter 1 of [27]. Such notion of regularity guarantees that up to reorientation of c, the restriction of $\phi_{\dot c(0)}$ to $\mathbf{R}\times[0,+\infty)$ takes values in U and each of its preimages is finite, with cardinality bounded by $n(U)+1$. Therefore, $\phi_{\dot c(0)}(\mathbf{R}\times[0,+\infty))$ lifts to a nonpositively curved half-plane.

If there exist $r>0$ and a half-plane H contained in M such that $\sup_{p\in H}\Phi(p,r)<0$, then the Dubins problem on M is not UCC (Proposition 5.16).

Fix $q\in N$ and $\varepsilon>0$ and assume that, for every half-plane H contained in M and every $r>0$, $\sup_{p\in H}\Phi(p,r)=0$. Recall that $A_q(M,\varepsilon)$ is unbounded. If $\int_U KdA>-\infty$ for some Riemannian half-cylinder U, then, for every $r>0$, $\lim_{p\in U,p\to\infty}\widetilde{\Phi}(p,r)=0$. (For the definition of $\widetilde{\Phi}$, see Remark 5.13.) If $A_q(M,\varepsilon)$ contains a point $\hat q$ such that $\widetilde{\Phi}(\pi(\hat q),R(\varepsilon))=0$, then the weak controllability from q is proved. Otherwise, there must exist a Riemannian half-cylinder U such that $\int_U KdA=-\infty$ and $\pi(A_q(M,\varepsilon))\cap U$ is unbounded. Thus, there exist a parameterized complete geodesic $c(\cdot)$ of the type described above and $\hat q\in\pi^{-1}(c(0))\cap A(q,\varepsilon)$ pointing inside the half-plane $\phi_{\dot c(0)}(\mathbf{R}\times[0,+\infty))$. From the usual reasoning based on (5), $\phi_{\dot c(0)}(\mathbf{R}\times[0,+\infty))\cap\pi(A_q(M,\varepsilon))$ contains a sector S. If $\lim_{p\in S,\,p\to\infty}\Phi(p,R(\varepsilon))=0$, then the weak controllability from q follows. Otherwise, $\int_S KdA=-\infty$. From a visibility property analogous to Lemma 5.2, it follows that S contains a half-plane of M. The weak controllability from q follows.

Remark 5.20. The argument above shows that when $\sup_{p\in H}\Phi(p,r)=0$ for every half-plane H contained in M and every $r>0$, UCC holds even in the case in which K is unbounded. Analogously, Lemma 5.14 implies that, if K is uniformly negative (possibly unbounded) on a strict Riemannian half-cylinder, then the Dubins problem on M is not UCC.

6. Remarks on optimal control. Let M be any complete oriented Riemannian surface, with no assumption on the sign of K. Denote by $\langle\lambda,\cdot\rangle$ the action of a covector $\lambda\in T_q^*N$ on T_qN.

Fix $q_1=(p_1,v_1)$, $q_2=(p_2,v_2)\in N$ and assume that $q_2\in A_{q_1}(M,\varepsilon)$. Then, there exists an ε-admissible curve $q:[0,T]\to N$ such that $q(0)=q_1$, $q(T)=q_2$, and for which T is minimal. According to the Pontryagin maximum principle, the time-optimality of $q(\cdot)$ implies that there exist an absolutely continuous curve $\lambda:[0,T]\to T^*N$ and a constant $c\geq 0$ such that for almost every $t\in[0,T]$, $\lambda(t)\in T^*_{q(t)}N\setminus\{0\}$ and the function

$$H_w(\lambda)=\langle\lambda,f(q)\rangle+w\,\langle\lambda,g(q)\rangle\,,\quad \lambda\in T_q^\star N,\quad q\in N,\quad w\in[-\varepsilon,\varepsilon],$$

verifies

$$H_{u(t)}(\lambda(t))=\max_{w\in[-\varepsilon,\varepsilon]}H_w(\lambda(t))\;=\;\langle\lambda,f(q)\rangle+\varepsilon|\langle\lambda(t),g(q(t))\rangle|\;\equiv\;c, \tag{33}$$

$$\dot\lambda(t)=\overrightarrow{H_{u(t)}}(\lambda(t)), \tag{34}$$

where, for every $w\in[-\varepsilon,\varepsilon]$, $\overrightarrow{H_w}$ denotes the Hamiltonian vector field associated with $H_w:T^*N\to\mathbf{R}$.

A simple computation shows that

$$[f\pm g,[f,g]]=-K\,g\pm f.$$

In particular, $(f,g,[f,g])$, $(g,[f,g],[f+g,[f,g]])$, and $(g,[f,g],[f-g,[f,g]])$ are three moving frames in N. Therefore, the results by Schättler [24, 25] (see also [2])

imply that $q(\cdot)$ is piecewise smooth. A subinterval I of $[0,T]$ is called a *bang arc* if, up to a modification on a set of measure zero, u is constant and equal to ε or $-\varepsilon$ along I, while it is called a *singular arc* if $u|_I$ is smooth (again, up to a modification on a set of measure zero) but $|u|$ is not constantly equal to ε on I. Schättler's results give restrictions on the structure of time-optimal controls, stating that for every $q \in N$, there exists a neighborhood U of q such that every time-optimal trajectory of (D_ε) contained in U is the concatenation of three bang arcs or of a bang, a singular, and a bang arc (where some arc possibly has zero length).

In order to show that every time-optimal trajectory follows locally Dubins' pattern, let us prove that every singular arc corresponds to a geodesic of M, i.e., that $u = 0$ almost everywhere along singular arcs.

The covector lift $\lambda(\cdot)$ of a time-optimal trajectory $q : [0,t] \to N$ can be represented through the three real-valued functions:

$$\begin{aligned}\varphi_1(t) &= \langle \lambda(t), f(q(t)) \rangle ,\\ \varphi_2(t) &= \langle \lambda(t), g(q(t)) \rangle ,\\ \varphi_3(t) &= \langle \lambda(t), [f,g](q(t)) \rangle .\end{aligned}$$

Note that, according to (33),

$$u(t) = \operatorname{sign}(\varphi_2(t))\, \varepsilon \tag{35}$$

for almost every t such that $\varphi_2(t) \neq 0$ and that

$$|\varphi_1(t)| + |\varphi_2(t)| + |\varphi_3(t)| \neq 0 \tag{36}$$

for every t, since $\lambda(t) \neq 0$ and $f,\ g$, and $[f,g]$ are everywhere linearly independent.

Equation (34) implies that φ_1, φ_2, φ_3 satisfy the system of differential equations

$$\dot\varphi_1(t) = -u(t)\varphi_3(t), \tag{37}$$

$$\dot\varphi_2(t) = \varphi_3(t), \tag{38}$$

$$\dot\varphi_3(t) = u(t)\varphi_1(t) - K(q(t))\varphi_2(t). \tag{39}$$

Let $I \subset [0,T]$ be a singular arc. Modify, if necessary, u on a set of measure zero in order to render it smooth on I. By definition of singular arc, $\varphi_2|_{I'} \equiv 0$ on some subinterval I' of I. From (38), we have that $\varphi_3 = 0$ on I'. Plugging the information in (37) and (39), we get that φ_1 is constant and that $\varphi_1(t)u(t) = 0$ for every $t \in I'$. Due to (36), $\varphi_1 \neq 0$, and thus $u = 0$ along I'. Since u is smooth on I, it follows that $\varphi_2 = u = 0$ on I.

We proved that every singular arc of a time-optimal trajectory of (D_ε) (independently of the sign of K) corresponds to a geodesic segment and that time-optimal trajectories follow locally Dubins' pattern. The following proposition provides further restrictions on the structure of time-optimal trajectories under the hypothesis that K is uniformly negative.

PROPOSITION 6.1. *If K is uniformly negative and ε is small enough, then every time-optimal trajectory $q : [0,T] \to N$ of (D_ε) is the concatenation of a bang, a singular, and a bang arc (some of which possibly having zero length). In particular, $q(\cdot)$ follows Dubins' pattern.*

Proof. Assume that

$$K \leq -\varepsilon^2. \tag{40}$$

From (33) and (35), we get that $u\,\varphi_1 = \operatorname{sign}(\varphi_2)\,\varepsilon\,c - \varepsilon^2\varphi_2$ and so, for almost every $t \in [0,T]$,

$$\ddot{\varphi}_2(t) = -(K(q(t)) + \varepsilon^2)\varphi_2(t) + \operatorname{sign}(\varphi_2(t))\,\varepsilon\,c. \tag{41}$$

Therefore, $\ddot{\varphi}_2\varphi_2 \geq 0$ almost everywhere. If τ is such that $\varphi_2(\tau) = 0$ and $\varphi_2 > 0$ on a left neighborhood of τ, then $\varphi_2 > 0$ on $(\tau, T]$. Symmetric arguments show that the set $\{t \in [0,T] \mid \varphi_2(t) \neq 0\}$ has at most two connected components and that $q(\cdot)$ is the concatenation of a bang, a singular, and a bang arc. □

OPTIMAL CONTROL OF FAVORABLE GAMES WITH EXPECTED LOSS CONSTRAINT*

JOHANNES LEITNER†

Abstract. Using a forward-backward iterative method, we maximize the expected profit of a gambling strategy for an arbitrary finite sequence of independent favorable gambles with payoffs in L^1 under an expected loss constraint. The solution is explicit up to solving a finite sequence of (deterministic) optimization problems over $\mathbf{R}^2_+$.

Key words. stochastic control, constraint portfolio optimization, gambling theory, favorable games, inequalities for stochastic processes, gain-loss ratio

1. Introduction.

Discrete gambling theory and stochastic games have been studied intensively for a long time. See the classic book [9] or, e.g., [20] for a modern introduction. A special case of stochastic games are the so-called favorable games; see [9] (see [24] for unfavorable games). Optimal gambling strategies (optimal with respect to expected wealth or the probability of reaching a goal) for favorable games were found in [6]. Kulldorff [18] also considers discrete time favorable games with a finite time limit and obtains the corresponding continuous time result as a limiting case. For the discrete time model, Kelly [17] found optimal growth rate strategies. The corresponding continuous time equivalent was solved by Heath et al. [15]. Furthermore, they found expected time optimal strategies with which to reach a goal for the continuous time model.

We consider the problem of maximizing the expected profit, i.e., expected change of wealth relative to some initial capital, in a sequence of independent gambles with return $V \in L^1$ under an expected loss (EL) constraint on $E[V_-]$. Maximizing the probability of reaching a certain wealth goal in a stochastic game is a good strategy for "how to gamble if you must" [9]. In contrast to this, the approach we are considering provides a good strategy for a gambler who is tempted by a favorable game but is risk-aware enough to impose a risk constraint by means of a bound on the EL relative to the initial capital. Clearly, depending on the type of gamble, in general that does not exclude arbitrarily high losses.

The EL is a special case of the so-called lower partial nth-moment ($LPM_n, n \geq 0$) risk measures studied, e.g., in [1], [3], [4], [11], [16], [23]. However, it is crucial in our approach to use the EL rather than the expected shortfall below some other wealth level or performance bound. The idea of measuring utility with respect to relative changes of wealth rather than absolute wealth goes back to [21].

Note also that EL is positively homogeneous, monotone, and convex, but not translation invariant, and hence is not a coherent risk measure; see [2]. It is rather a

loss measure than a risk measure. However, it satisfies convexity, a generally accepted property of a risk measure, which should encourage risk mitigation by diversification. See [12] for the notion of convex risk measures.

Trivially, the problem of maximizing expected return under an EL constraint is equivalent to the problem of minimizing EL under an expected return constraint. There is a third way to solve these constrained problems: Equivalently we can also consider the problem of maximizing the ratio of expected returns over EL! Our objective is to demonstrate that this latter, now *unconstrained* optimization problem can be solved *explicitly* in our restricted discrete time gambling framework. Unlike in the case of the discrete time unconstrained expected return (utility) optimization problem, the solution cannot be found by a backward iteration, which would lead to a discrete time Bellman-type equation. The problem does not decouple completely and a combined forward-backward iteration method has to be applied. Unfortunately, so far we did not succeed in applying our method to a more general model, such as a finite state Markovian gambling model. However, see [19] for an abstract duality result that allows one to determine the lowest upper bound of the ratio of expected returns over EL as the optimal value of a dual optimization problem over the set of all corresponding equivalent martingale measures for a general market model.

Optimal strategies for the expected profit over the EL ratio can in general, be unique at best up to a strictly positive scaling factor. This can actually be very convenient: While the ratio captures the trade-off, a gambler has to make between upside chances, measured by expected profits, and downside risk, measured by EL, the scaling factor allows the gambler to introduce an additional constraint, e.g., for bounded gambles a maximal loss constraint, a bound on the probability of wealth falling below a certain level, or a bound on the expected shortfall below some benchmark. This could be used to compensate for the fact that ruin is a priori not possible in our model. Considering that small or moderate losses are painful but qualitatively different from high losses causing irreversible bankruptcy, this feature of the proposed ratio might help a gambler (investor) to decide on a strategy.

For example, consider a coin-tossing game: Let $(S_i)_{1\le i\le N}$ be an i.i.d. sequence of random variables with $P(S_i=1)=1-P(S_i=-1)>\frac{1}{2}$ for all $1\le i\le N, N\ge 2$. Let S_i describe the payoff of a game at time i after having bet one currency unit. Denote by $V_i, 1\le i\le N$, the total change of wealth relative to some initial capital at time i after having bet on $S_j, 1\le j\le i$, according to some (nonanticipating) strategy. We are going to show that the following strategy leads to an optimal expected profit over the EL ratio $\frac{E[V_N]}{E[(V_N)_-]}$: Betting, say, one currency unit on S_1, V_1 equals S_1. It is then optimal to bet $|V_1|$ currency units on S_2 so that $V_2=0$ if $S_1\ne S_2$ and $V_2=2S_1$ if $S_1=S_2$. Interestingly, it is optimal to stop gambling (and not optimal to continue gambling) if $V_2=0$ holds; even so, S_3 is again a favorable game for $N\ge 3$. After having won twice or lost twice, it is optimal to keep doubling the bet on S_i to $|V_{i-1}|=2^{i-2}$ at each time $2<i\le N$ until either $S_i\ne S_1$ and we stop there (in which case $V_i=\cdots=V_N=0$) or $i=N$ and $S_1=\cdots=S_N$, in which case $V_N=2^{N-1}S_1$ holds. By a simple calculation, we find $\frac{E[V_N]}{E[(V_N)_-]}=(\frac{P(S_1=1)}{P(S_1=-1)})^N-1$ for the optimal ratio. By appropriate scaling of the initial bet, a bound on the maximal loss can be guaranteed.

In section 2 the model is specified and a stopping result is shown, which will allow us to split up the optimization problem into local backward-iterative optimization problems. This local problem is considered in section 3. Optimal values and gambling strategies are given in section 4. In section 5 we will give some easy examples, e.g., tossing of a coin. In section 6 we give some results for the multidimensional case.

2. Independent gambles. Let $\mathbf{\Omega} = (\Omega, (\mathcal{F}_t)_{0\le t\le T}, \mathcal{F}, P), 0 < T < \infty$, be a filtered probability space in discrete time. Let $S = (S_t)_{0\le t\le T}$ be an adapted $\mathbf{R}$-valued process on $\mathbf{\Omega}$ with $S_0 = 0$ and such that $S_t \in L^1$ is independent of $\mathcal{F}_{t-1}$ for all $1 \le t \le T$. Write $H \in \mathcal{F}_t$ if H is a random variable measurable with respect to $\mathcal{F}_t$.

Define $\mathbf{V}$ as the set of all adapted $\mathbf{R}$-valued processes $V = (V_t)_{0\le t\le T}$ on $\mathbf{\Omega}$ which are of the following form: $V_0 = 0$ and $V_t = \sum_{s=0}^{t-1} H_s S_{s+1}, 0 < t \le T$, where $H_s \in \mathcal{F}_s$ is such that $H_s S_{s+1} \in L^1, 0 \le s < T$. For $0 \le t \le T$, define $\mathbf{V}^t := \{V^t | V \in \mathbf{V}\}$, where $V^t = (V_u^t)_{0\le u\le T}$ is the process V stopped at t: $V_u^t := V_{u\wedge t}, 0 \le u \le T$. Set $\mathcal{V}^t := \{V_t | V \in \mathbf{V}^t\} \subseteq L^1$. $\mathcal{V}^t$ is to be interpreted as the set of all attainable wealth changes relative to some initial capital. $\mathcal{V}^t$ is called *arbitrage-free* if $P(V < 0) = 0$ for $V \in \mathcal{V}^t$ implies $V = 0$. It is well known that $\mathcal{V}^t$ is arbitrage-free for all $0 < t \le T$ iff $S_t \ne 0$ implies $P(S_t < 0), P(S_t > 0) > 0$ for all $0 < t \le T$; see [7] (and [8] for a general version of this result). In particular, $E[V_-] = 0$ then implies $V = 0$ for all $V \in \mathcal{V}^t$. By replacing S_t with $-S_t$ if $E[S_t] < 0$, we can assume $E[S_t] \ge 0$ for all $0 < t \le T$. For simplicity (but essentially without loss of generality), we can assume $S_t \ne 0$ for all $0 < t \le T$.

We always assume that $\mathcal{V} := \mathcal{V}^T$ is arbitrage-free. $\mathcal{V}$ is called *favorable* if there exists a $V \in \mathcal{V}$ with $E[V] > 0$. Set $\alpha(V) := \frac{E[V]}{E[V_-]}$ for $V \in \mathcal{V} \setminus \{0\}$ and $\alpha(0) = 0$. Consider the following optimization problems:

$$\bar{\alpha}^t := \sup_{V\in\mathcal{V}^t} \alpha(V), \quad 0 < t \le T. \tag{2.1}$$

We have $\bar{\alpha}^t \ge 0$ and $\bar{\alpha}^t = 0$ iff for all $V \in \mathcal{V}^t$, $E[V] = 0$ holds. Clearly, $\bar{\alpha}^t \le \bar{\alpha}^{\bar{t}}$ for all $0 < t \le \bar{t} \le T$. The optimization problem (2.1) will be solved by a forward-backward iterative method. The case $T = 1$ is trivial and we assume from now on that $1 < T < \infty$. Set also $S := S_T$.

The proofs of our main results, Theorem 4.1 and Theorem 4.2, are based on three steps. Not being in a Hamilton–Jacobi–Bellman setting, we cannot directly solve the optimization problem (2.1) by a backward-iterative method; i.e., we cannot apply the *dynamic programming principle*.

The first step is to transform problem (2.1) into a nested optimization problem over $V \in \mathcal{V}^{T-1}$ and a local optimization problem at time $T-1$ given V with optimal value α_V. This is done in the next subsection. The trick is to observe that an optimal strategy that returns to zero can be stopped and remains optimal.

The second step is to solve the local problem. This is quite technical but elementary and is done in section 3. The trick here is to observe that an optimal strategy can be chosen to assume only two values, depending on the sign of the value process at time $0 < t < T$. These two values are determined as the solution of a deterministic problem over $\mathbf{R}_+^2$. We also have to handle some marginal cases, e.g., if $E[S_T] = 0$. Moreover, it is possible that even if the games $S_t, 1 \le t < \tilde{t}$, are all favorable up to time $\tilde{t} \le T$, it is still optimal not to start gambling before time $\tilde{t}$ (this is where the dynamic programming principle breaks down).

The last step is to observe that the optimal value α_V of the local problem depends only on $\alpha(V)$. This allows us to then iterate the local optimization backwards in time. This is done in the proof of Theorem 4.1.

2.1. Stopping at zero. Let us start with a very simple result that will be used repeatedly without further mention.

LEMMA 2.1. *Let a, A, b, B be real numbers with $A, A + B > 0$ and $B \ne 0$; then $\frac{a+b}{A+B} \ge \frac{a}{A}$ iff $\frac{b}{B} \ge \frac{a}{A}$ and $B > 0$, or $\frac{b}{B} \le \frac{a}{A}$ and $B < 0$.*

The following result means that an optimal strategy can be stopped when the process of wealth changes returns to 0 at time $T-1$ and remains optimal.

PROPOSITION 2.2. *The following assertion holds:*

$$\bar{\alpha}^T = \max\left(\sup_{V\in\mathcal{V}^{T-1}} \sup_{\substack{HS\in L^1, H\in\mathcal{F}_{T-1}\\ HS=HS\mathbf{1}_{\{V\neq 0\}}}} \alpha(V+HS), \alpha(S)\right). \tag{2.2}$$

Proof. Let $V\in\mathcal{V}^{T-1}$ and $H\in\mathcal{F}_{T-1}$ such that $HS\in L^1$. Note that $\bar{V} := V + \mathbf{1}_{\{V\neq 0\}}HS \in \mathcal{V}^T$ and $W := \mathbf{1}_{\{V=0\}}HS \in \mathcal{V}^T$. Hence for all $x,y\in\mathbf{R}_+$, $x\bar{V}+yW\in\mathcal{V}^T$ holds and we have $\alpha(x\bar{V}+yW) = \frac{xE[\bar{V}]+yE[W]}{xE[\bar{V}_-]+yE[W_-]}$. Considering this as a function of (x,y) and by partial differentiation with respect to x and y at $x=y=1$, one checks that $\alpha(\bar{V})\neq\alpha(W)$ implies either $\alpha(\bar{V})>\alpha(\bar{V}+W)$ or $\alpha(W)>\alpha(\bar{V}+W)$. Since S is independent of $\mathcal{F}_{T-1}$, we have $\alpha(W)=\alpha(S)$ for $\mathbf{1}_{\{V=0\}}H\geq 0$ and $\mathbf{1}_{\{V=0\}}H\neq 0$, implying the assertion. ∎

Instead of solving the nested optimization problem in Proposition 2.2, it is more convenient to solve the following related problem: Fix a $V\in\mathcal{V}^{T-1}\setminus\{0\}$ and denote by $\mathcal{H}_V$ the set of $\mathcal{F}_{T-1}$-measurable random variables H on $\mathbf{\Omega}$ such that $VHS\in L^1$. For $\lambda\in\mathbf{R}$ and $H\in\mathcal{H}_V$, set $V_{\lambda,H} := V(\lambda+HS)$. Note that $V_{\lambda,H}\in\mathcal{V}$ for all $(\lambda,H)\in\mathbf{R}\times\mathcal{H}_V$ and consider the optimization problem

$$\alpha_V := \sup_{\lambda\in\mathbf{R}, H\in\mathcal{H}_V} \alpha(V_{\lambda,H}). \tag{2.3}$$

We have $\alpha_V=0$ iff $E[S]=E[V]=0$. Set $\alpha_V := \alpha(S)$ for $V=0$ and note that $\alpha_V\geq\alpha(S)$ for all $V\in\mathcal{V}^{T-1}$: For $V\in\mathcal{V}^{T-1}\setminus\{0\}$ we have $H := V^{-1}\mathbf{1}_{\{V\neq 0\}}\in\mathcal{H}_V$, $V_{0,H}\in\mathcal{V}$, since H is $\mathcal{F}_{T-1}$-measurable, and $\alpha(V_{0,H}) = \frac{E[S\mathbf{1}_{\{V\neq 0\}}]}{E[S_-\mathbf{1}_{\{V\neq 0\}}]} = \alpha(S)$ since S is independent of $\mathcal{F}_{T-1}$.

LEMMA 2.3. $\bar{\alpha}^T = \sup_{V\in\mathcal{V}^{T-1}}\alpha_V$.

Proof. Note first that $\alpha_V\leq\bar{\alpha}^T$ holds since $\alpha_V=\alpha(S)$ for $V=0$ and for $V\in\mathcal{V}^{T-1}\setminus\{0\}$, $V_{\lambda,H}\in\mathcal{V}$ for all $(\lambda,H)\in\mathbf{R}\times\mathcal{H}_V$. Since $\alpha_V\geq\sup_{\substack{HS\in L^1, H\in\mathcal{F}_{T-1}\\ HS=HS\mathbf{1}_{\{V\neq 0\}}}}\alpha(V+HS)$ and $\alpha_V\geq\alpha(S)$, the assertion now follows from Proposition 2.2. ∎

3. The local problem. The local optimization problem (2.3) will be solved using a necessary and sufficient 1st order condition for optimality of the ratio α.

3.1. The 1st order optimality condition. Let $u:\mathbf{R}\to\mathbf{R}$ be a function such that $U(V) := E[u(V)]\in\mathbf{R}$ for all $V\in L^1$. For $V,Z\in L^1$, the right directional derivative in direction Z at V of U is defined as $\partial_Z^+U(V) := \lim_{\epsilon\searrow 0}\frac{U(V+\epsilon Z)-U(V)}{\epsilon}$ if the limit exists; e.g., for convex u the limit always exists in $[-\infty,\infty)$.

LEMMA 3.1. *For $V,Z\in L^1$ we have $\partial_Z^+E[V_-] = E[\mathbf{1}_{\{V=0\}}Z_-] - E[\mathbf{1}_{\{V<0\}}Z]$, and for $E[V_-]>0$,*

$$\partial_Z^+\alpha(V) = \frac{E[Z]-\alpha(V)(E[\mathbf{1}_{\{V=0\}}Z_-]-E[\mathbf{1}_{\{V<0\}}Z])}{E[V_-]}$$

holds.

Proof. Note that $\frac{(x+\epsilon y)_- - x_-}{\epsilon}$ decreases to, resp., $-y$, y_-, 0 for $x<0$, $x=0$, $x>0$, as $\epsilon\searrow 0$. The first assertion follows from the monotone convergence theorem. The remaining assertions follow from the chain rule. ∎

The ratio α is in general not concave, but shares same of the properties of concave functionals.

PROPOSITION 3.2. *Let $\mathcal{V}$ be a linear subspace of L^1 such that $E[V_-] > 0$ for all $V \in \mathcal{V} \setminus \{0\}$; i.e., $\mathcal{V}$ is arbitrage-free. Then $\hat{V} \in \mathcal{V} \setminus \{0\}$ is a global maximum for α, i.e., $\alpha(V) \le \alpha(\hat{V})$ for all $V \in \mathcal{V}$, iff $E[\hat{V}] \ge 0$ and the local 1st order optimality condition $\partial_Z^+ \alpha(\hat{V}) \le 0$ holds for all $Z \in \mathcal{V}$.*

Proof. The clearly necessary condition $E[\hat{V}] \ge 0$ and $\partial_Z^+ \alpha(\hat{V}) \le 0$ for all $Z \in \mathcal{V}$ holds iff $E[\hat{V}] \ge 0$ and $E[Z] \le \alpha(\hat{V}) \partial_Z^+ E[\hat{V}_-]$. If $E[\hat{V}] = 0$, this implies $E[Z] = 0 = \alpha(Z)$ for all $Z \in \mathcal{V}$. If $E[\hat{V}] > 0$, this condition, together with convexity of $E[(\cdot)_-]$, implies $\alpha(\hat{V} + \epsilon Z) \le \frac{E[\hat{V}] + \epsilon E[Z]}{E[\hat{V}_-] + \epsilon \partial_Z^+ E[\hat{V}_-]} \le \alpha(\hat{V})$ for all $\epsilon \ge 0$ if $\partial_Z^+ E[\hat{V}_-] \ge 0$, resp., for all $0 \le \epsilon < -\frac{E[\hat{V}]}{E[Z]} \le -\frac{E[\hat{V}_-]}{\partial_Z^+ E[\hat{V}_-]}$ otherwise, and hence $\hat{V}$ is a local maximum for α. Assume $\alpha(\tilde{V}) > \alpha(\hat{V})$ for a $\tilde{V} \in \mathcal{V}$. We can also assume $E[\tilde{V}] = E[\hat{V}]$. From $\partial_Z^+ \alpha(\hat{V}) \le 0$ for $Z = \tilde{V} - \hat{V}$ it follows that $\partial_Z^+ E[\hat{V}_-] \ge 0$, and hence $\alpha(\hat{V} + \epsilon Z) \le \alpha(\hat{V})$ for all $\epsilon \ge 0$, a contradiction. □

3.2. Simple strategies. The scaling properties of α suggest that we look for solutions (λ, H) of (2.3), where $H = \hat{f}\mathbf{1}_{\{V>0\}} - \hat{g}\mathbf{1}_{\{V<0\}}$ for $\hat{f}, \hat{g} \in \mathbf{R}$. Note that then

$$\alpha(V_{1,H}) = \frac{E[V_+](1 + \hat{f}E[S]) + E[V_-](-1 + \hat{g}E[S])}{E[V_+]F(\hat{f}) + E[V_-]G(\hat{g})}, \tag{3.1}$$

where F, G are defined for $h \in \mathbf{R}$ by $F(h) := E[(1+hS)_-]$ and $G(h) := E[(-1+hS)_-]$.

Define $u^+(h) := \lim_{\epsilon \searrow 0} \frac{u(h+\epsilon)-u(h)}{\epsilon}$ and $u^-(h) := \lim_{\epsilon \searrow 0} \frac{u(h)-u(h-\epsilon)}{\epsilon}$ for a convex function u defined in a neighborhood of $h \in \mathbf{R}$. Set $\bar{S} := \operatorname{esssup} S \in (0, \infty]$ and $\underline{S} := \operatorname{essinf} S \in [-\infty, 0)$. F and G play a crucial role in solving problems (2.1) and (2.3). We collect some of their simple properties for later reference.

LEMMA 3.3. *The following assertions hold:*

1. *F and G are convex nonnegative functions on $\mathbf{R}$, G is strictly positive, $F^{\pm}, G^{\pm}$ are nondecreasing, F^+, G^+ are right-continuous, F^-, G^- are left-continuous, and $\lim_{\epsilon \searrow 0} F^+(h-\epsilon) = F^-(h) \le F^+(h)$, $\lim_{\epsilon \searrow 0} G^+(h-\epsilon) = G^-(h) \le G^+(h)$ holds for all $h \in \mathbf{R}$.*
2. *For all $h \in [0, \infty)$, $F^+(h) = -E[\mathbf{1}_{\{1+hS \le 0\}} S]$, $F^-(h) = -E[\mathbf{1}_{\{1+hS<0\}} S]$ and $G^+(h) = -E[\mathbf{1}_{\{-1+hS<0\}} S]$, $G^-(h) = -E[\mathbf{1}_{\{-1+hS \le 0\}} S]$ holds.*
3. *For all $h \in (-\infty, 0]$, $F^+(h) = -E[\mathbf{1}_{\{1+hS<0\}} S]$, $F^-(h) = -E[\mathbf{1}_{\{1+hS \le 0\}} S]$ and $G^+(h) = -E[\mathbf{1}_{\{-1+hS \le 0\}} S]$, $G^-(h) = -E[\mathbf{1}_{\{-1+hS<0\}} S]$ holds.*
4. *We have $\lim_{h \to \infty} F^+(h) = E[S_-]$, $\lim_{h \to -\infty} F^+(h) = -E[S_+]$, $F^+(h) = 0$ if $h \in [-\bar{S}^{-1}, -\underline{S}^{-1}) \cup \{0\}$ and $F^+(h) \ne 0$ if $h \notin F^{-1}(0) = [-\bar{S}^{-1}, -\underline{S}^{-1}]$ ($\frac{1}{\pm\infty} := 0$).*
5. *We have $\lim_{h \to \infty} G^+(h) = E[S_-]$, $\lim_{h \to -\infty} G^+(h) = -E[S_+]$, $G^+(h) = -E[S]$ if $h \in [\underline{S}^{-1}, \bar{S}^{-1}) \cup \{0\}$ and $G^+(h) \ne -E[S]$ if $h \notin G^{-1}(1) = [\underline{S}^{-1}, \bar{S}^{-1}]$.*

Proof. The assertions easily follow from the convexity of the function $x \mapsto x_-$. Monotonous convergence of difference quotients for convex functions, together with the monotonous convergence theorem, allows us to calculate the one-sided derivatives of F, G. □

The following key auxiliary result will allow us to replace general strategies $(\lambda, H) \in \mathbf{R} \times \mathcal{H}_V$ in the optimization problem (2.3) with simpler ones which assume only two values.

LEMMA 3.4. *For all $V \in \mathcal{V}^{T-1} \setminus \{0\}$, the optimization problem (2.3) admits a solution $(\hat\lambda, \hat H)$, where $\hat\lambda \in \{-1,0,1\}$ and $\hat H = \hat f \mathbf{1}_{\{V>0\}} - \hat g \mathbf{1}_{\{V<0\}}$ for constants $\hat f, \hat g \in \mathbf{R}$.*

Proof. The trick of the proof is to apply 1st order optimality conditions to finite-dimensional approximations of the original optimization problem. Let $(\lambda^n, H^n)_{n\geq 1}$ be a sequence in $\mathbf{R}\times\mathcal{H}_V$ such that $\lim_{n\to\infty}\alpha(V_{\lambda^n,H^n}) = \alpha_V$. Approximating each H^n by a sequence $(H^n_k)_{k\geq 1}$ of finite step functions in $\mathbf{R}\times\mathcal{H}_V$, we easily find, using continuity of α on $\mathbf{R}\times\mathcal{H}_V\setminus\{0\}$, a sequence $(H^n_{k_n})_{n\geq 1}$ with $\lim_{n\to\infty}\alpha(V_{\lambda^n,H^n_{k_n}}) = \alpha_V$. Note that we can assume $H^n_{k_n} = \mathbf{1}_{\{V\neq 0\}}H^n_{k_n}$. Setting $\mathcal{F}^n := \sigma(\mathbf{1}_{\{V=0\}}, \mathbf{1}_{\{V>0\}}, H^i_{k_i}, 1\leq i\leq n)$, we have constructed an increasing sequence of finite σ-algebras $\mathcal{F}^n \subseteq \mathcal{F}_{T-1}$ such that $\{V=0\}$ is an atom in $\mathcal{F}^n$ and with $\{V<0\}, \{V>0\} \in \mathcal{F}^n$ for all $n\geq 1$. Denote by $\mathcal{H}^n$ the $\mathcal{F}^n$-measurable elements of L^∞. Since for $n\geq 1$, $\alpha(V_{\lambda^n,H^n}) = \alpha(V_{x\lambda^n,xH^n})$ for all $x\in(0,\infty)$, the finite-dimensional optimization problem $\sup_{\lambda\in\mathbf{R},H\in\mathcal{H}^n}\alpha(V_{\lambda,H})$ admits, by continuity of α on $\mathbf{R}\times\mathcal{H}^n\setminus\{0\}$, a solution on a compact sphere. Therefore, by scaling,

$$\alpha^n_V := \sup_{\lambda\in\{-1,0,1\},H\in\mathcal{H}^n}\alpha(V_{\lambda,H}) \tag{3.2}$$

admits for all $n\geq 1$ a solution $(\hat\lambda,\hat H)\in\{-1,0,1\}\times\mathcal{H}^n$ with $\alpha(V_{\hat\lambda,\hat H}) =: \alpha^n_V \geq 0$ and such that $\lim_{n\to\infty}\alpha^n_V = \alpha_V$. We are going to show that $\hat H$ can be chosen to be constant on $\{V>0\}$ and on $\{V<0\}$ and to vanish on $\{V=0\}$. This implies that $\alpha_V = \alpha^n_V = \alpha(V_{\hat\lambda,\hat H})$ holds for all $n\geq 1$, and the assertion will be proved.

If $\alpha_V = 0$, then $\alpha^n_V = 0$ for all $n\geq 1$ is equivalent to $E[S] = E[V] = 0 = \alpha_V$, and we can choose $(\hat\lambda,\hat H) = (0,0)$ for all $n\geq 1$. Assume $\alpha_V > 0$ and $N\in\mathbf{N}$ such that $\alpha^n_V > 0$ for all $n\geq N$. Fix $n\geq N$. We have to distinguish two cases. First, assume $\hat\lambda = 0$. We then have

$$\alpha(V_{\hat\lambda,\hat H}) = \frac{(E[(V\hat H)_+] - E[(V\hat H)_-])E[S]}{E[(V\hat H)_+]E[S_-] + E[(V\hat H)_-]E[S_+]} \leq \frac{E[S]}{E[S_-]},$$

and hence we can choose $\hat H = \mathbf{1}_{\{V>0\}} - \mathbf{1}_{\{V<0\}}$ so that $\alpha(V_{0,\hat H}) = \frac{E[S]}{E[S_-]}$. Assume now $\hat\lambda\in\{-1,1\}$. Let $(A_m)_{0\leq m\leq M}$ be the sequence of nonempty atoms in $\mathcal{F}^n$; i.e., for $0\leq m,\tilde m\leq M$, $P(A_m)>0$ and $A_m\cap A_{\tilde m} = \emptyset$ iff $m\neq\tilde m$ and $\mathcal{F}^n = \sigma(A_m, 1\leq m\leq M)$. By assumption, $M\geq 2$ and, without loss of generality, we can assume that $A_0 = \{V=0\}$ and that there exists a $1\leq\tilde M<M$ such that $\bigcup_{m=1}^{\tilde M}A_m = \{\hat V>0\}$ and $\bigcup_{m=\tilde M+1}^{M}A_m = \{\hat V<0\}$, where $\hat V := \hat\lambda V$. Note that $V_{\lambda,H} = (\lambda V)_{1,\lambda H}$ for $\lambda\in\{-1,1\}$. Hence for $\hat\lambda\hat H = \sum_{i=1}^{\tilde M}\mathbf{1}_{A_i}h_i - \sum_{i=\tilde M+1}^{M}\mathbf{1}_{A_i}h_i$, where $h_i\in\mathbf{R}, 1\leq i\leq M$, we have

$$\alpha(V_{\hat\lambda,\hat H}) = \frac{\sum_{i=1}^{\tilde M}E[\hat V_+\mathbf{1}_{A_i}](1+h_iE[S]) + \sum_{i=\tilde M+1}^{M}E[\hat V_-\mathbf{1}_{A_i}](-1+h_iE[S])}{\sum_{i=1}^{\tilde M}E[\hat V_+\mathbf{1}_{A_i}]F(h_i) + \sum_{i=\tilde M+1}^{M}E[\hat V_-\mathbf{1}_{A_i}]G(h_i)}.$$

The necessary 1st order optimality conditions, $\frac{\partial^+}{\partial h_i}\alpha(V_{\hat\lambda,\hat H})\leq 0$ and $\frac{\partial^-}{\partial h_i}\alpha(V_{\hat\lambda,\hat H})\leq 0$ for $1\leq i\leq M$, imply $\alpha^n_V F^-(h_i)\leq E[S]\leq\alpha^n_V F^+(h_i)$ for all $1\leq i\leq\tilde M$ and $\alpha^n_V G^-(h_i)\leq E[S]\leq\alpha^n_V G^+(h_i)$ for all $\tilde M<i\leq M$. Define $I := \{h\in\mathbf{R}|\ \alpha^n_V F^-(h)\leq E[S]\leq\alpha^n_V F^+(h)\}$ and $\tilde I := \{h\in\mathbf{R}|\ \alpha^n_V G^-(h)\leq E[S]\leq\alpha^n_V G^+(h)\}$. By Lemma 3.3, we have $I = [\underline f,\bar f]$ and $\tilde I = [\underline g,\bar g]$ for constants $-\infty<\underline f\leq\bar f\leq\infty$ and $-\infty<\underline g\leq$

$\bar{g} \leq \infty$, where "∞]" is to be interpreted as "∞)" for $\bar{f} = \infty$, resp., $\bar{g} = \infty$. Clearly, if $\underline{f} = \bar{f}$, resp., if $\underline{g} = \bar{g}$, then $\hat{H}$ is constant on $\{\hat{V} > 0\}$, resp., on $\{\hat{V} < 0\}$. It follows from straightforward calculations, that for $\underline{f} < \bar{f}$, resp., $\underline{g} < \bar{g}$, $h_i \in I, 1 \leq i \leq \tilde{M}$, resp., $h_i \in \tilde{I}, \tilde{M} + 1 \leq i \leq M$, can be chosen to be equal to $\hat{f} \in I$, resp., $\hat{g} \in \tilde{I}$. □

We can now give a first characterization of solutions (λ, H) of problem (2.3) in the case $\lambda \in \{-1, 1\}$. Note, however, that at this point it is not clear under which conditions there exists such a solution. We will see in Proposition 3.8 that such solutions do not exist in all cases.

PROPOSITION 3.5. *Let $V \in \mathcal{V}^{T-1} \setminus \{0\}$. $(\hat{\lambda}, \hat{\lambda}\hat{H}) \in \{-1, 1\} \times \mathcal{H}_V$ solves (2.3) iff $E[\hat{V}] \geq 0$ for $\hat{V} := \hat{\lambda} V$ and the following inequalities hold:*

$$\alpha_V F^-(\hat{H}) \leq E[S] \leq \alpha_V F^+(\hat{H}) \quad \text{a.s. on } \{\hat{V} > 0\}, \tag{3.3}$$

$$\alpha_V G^-(\hat{H}) \leq E[S] \leq \alpha_V G^+(\hat{H}) \quad \text{a.s. on } \{\hat{V} < 0\}. \tag{3.4}$$

Proof. Note that the assertion holds if $\alpha_V = 0$. Assume $\alpha_V > 0$. From the proof of Lemma 3.4, we know that $(\hat{\lambda}, \hat{\lambda}\hat{H}) \in \{-1, 1\} \times \mathcal{H}_V$ solves (2.3) if (3.3) and (3.4) hold. Conversely , given a solution $(\hat{\lambda}, \hat{\lambda}\hat{H}) \in \{-1, 1\} \times \mathcal{H}_V$ for (2.3), it is not difficult to show that (3.3) and (3.4) hold by calculating right-derivatives at $\hat{H}$ in directions $\mathbf{1}_A$ for measurable sets A, where (3.3) or (3.4) does not hold, and applying the 1st order optimality conditions from Proposition 3.2.

It remains to show that $E[\hat{V}] \geq 0$. This is clearly the case if $E[S] = 0$. Assume $E[S] > 0$. From the proof of Lemma 3.4 and by Lemma 3.3(4), (5), we know that if $(\hat{\lambda}, \hat{\lambda}\hat{H})$ solves (2.3); then we can find $\hat{f}, \hat{g} > 0$ such that $(1, \hat{f}\mathbf{1}_{\{\hat{V}>0\}} - \hat{g}\mathbf{1}_{\{\hat{V}<0\}})$ solves (2.3) for $\hat{V}$ and $F(\hat{f}) > 0$. Since

$$\frac{1 + \hat{f}E[S]}{F(\hat{f})} = \frac{\hat{f}^{-1} + E[S]}{F(\hat{f})\hat{f}^{-1}} \geq \frac{\hat{f}^{-1} + E[S]}{F^-(\hat{f})} > \frac{E[S]}{F^-(\bar{f})} \geq \alpha_V$$

by convexity of F, we find $\frac{-1+\hat{g}E[S]}{G(\hat{g})} < \alpha_V$, and, for $x, y > 0$,

$$\frac{x(1 + \hat{f}E[S]) + y(-1 + \hat{g}E[S])}{xF(\hat{f}) + yG(\hat{g})} \geq \frac{y(1 + \hat{f}E[S]) + x(-1 + \hat{g}E[S])}{yF(\hat{f}) + xG(\hat{g})}$$

iff $x \geq y$, and hence $E[\hat{V}_+] \geq E[\hat{V}_-]$. □

In order to study the existence of solutions (λ, H) of problem (2.3) with $\lambda \in \{-1, 1\}$, we must study several marginal cases which require separate analysis. This will be performed in the following two subsections before we consider the generic case.

3.3. Marginal cases. For $V \in \mathcal{V}^{T-1} \setminus \{0\}$, denote by $\hat{\mathcal{V}}_V$ the set of all $(\lambda, H) \in \{-1, 0, 1\} \times L^\infty(\mathcal{F}_{T-1})$ such that $\alpha_V = \alpha(V_{\lambda,H})$.

Let us first deal with the case $E[S] = 0$. The following result essentially means that one cannot improve a strategy by gambling if $E[S] = 0$.

PROPOSITION 3.6. *Let $V \in \mathcal{V}^{T-1} \setminus \{0\}$ and let $(\lambda, H) \in \{-1, 0, 1\} \times L^\infty(\mathcal{F}_{T-1})$. The following assertions hold:*

1. $\alpha_V = 0 \Leftrightarrow E[S] = E[V] = 0 \Leftrightarrow \hat{\mathcal{V}}_V = \{-1, 0, 1\} \times L^\infty(\mathcal{F}_{T-1})$.
2. $\alpha_V = \max(\alpha(V), \alpha(-V))$ *iff* $E[S] = 0$. *If* $\alpha_V > 0$ *and* $E[S] = 0$, *then* $(\lambda, H) \in \hat{\mathcal{V}}_V$ *iff* $\lambda \in \{-1, 1\}$, $E[\lambda V] > 0$ *and* $F(H) = 0$ *a.s. on* $\{\lambda V > 0\}$, *and* $G(H) = 1$ *a.s. on* $\{\lambda V < 0\}$. *Furthermore,* $(\mathrm{sgn}E[V], 0) \in \hat{\mathcal{V}}_V$.

Proof. Assertion (1) is easy to see, and, clearly, (2) holds if $\alpha_V = 0$. Assume $\alpha_V > 0$. $E[S] = 0$ implies $G \geq 1$ since G is convex, $G(0) = 1$, and, by Lemma 3.3,

$G^{\pm}(0) = 0$ holds. Hence, for all $H \in L^\infty(\mathcal{F}_{T-1})$ we have $\alpha(V_{0,H}) = 0$. Thus $\max(\alpha(V_{1,H}), \alpha(V_{-1,H})) \le \max(\alpha(V), \alpha(-V)) = \max(\alpha(V_{1,0}), \alpha(V_{-1,0}))$, and $\alpha_V = \max(\alpha(V), \alpha(-V))$ follows. Conversely, without loss of generality we can assume $E[V] > 0$ and $\alpha_V = \alpha(V) > 0$. $E[S] > 0$ implies $G^+(0) < 0$, and hence we have $G(h) < 1$ for small $h > 0$ and $\alpha(V(1 - h\mathbf{1}_{\{V<0\}}S)) > \alpha(V)$. This contradiction proves the first part of assertion (2). The second part follows directly from Proposition 3.5 and Lemma 3.3(4), (5). □

3.4. Waiting for a good chance. It might happen that α_V for $V \in \mathcal{V}^{T-1} \setminus \{0\}$ equals $\alpha(S)$. This means that gambling up to time $T-1$ with return V is as good as waiting until time $T-1$ and gambling just once on S. The following results characterize this situation.

LEMMA 3.7. *Let $V \in \mathcal{V}^{T-1} \setminus \{0\}$ and set $V_H := V + HS$ for $H \in \mathcal{F}_{T-1}$ such that $HS \in L^1$. We have*

$$\partial^+_{V_H}\alpha(S) = \frac{E[V] - \alpha(S)\big(P(S=0)E[V_-] - P(S<0)E[V]\big)}{E[S_-]}. \tag{3.5}$$

Furthermore, $\partial^+_{V_H}\alpha(S) \le 0$ for all $H \in \mathcal{F}_{T-1}$ with $HS \in L^1$ iff the following condition is satisfied:

$$\alpha(V) \le \frac{\alpha(S)P(S=0)}{1 + \alpha(S)P(S<0)}. \tag{3.6}$$

Proof. By Lemma 3.1, (3.5) follows from

$$\begin{aligned}\partial^+_{V_H}E[S_-] &= E[\mathbf{1}_{\{S=0\}}V_-] - E[\mathbf{1}_{\{S<0\}}(V + HS)] \\ &= P(S=0)E[V_-] - P(S<0)E[V] + E[H]E[S_-].\end{aligned}$$

We find $\partial^+_{V_H}\alpha(S) \le 0$ iff $\alpha(V) - \alpha(S)\big(P(S=0) - P(S<0)\alpha(V)\big) \le 0$, which is equivalent to $\alpha(V) \le \frac{\alpha(S)P(S=0)}{1+\alpha(S)P(S<0)}$. □

PROPOSITION 3.8. *Let $V \in \mathcal{V}^{T-1} \setminus \{0\}$. $\alpha_V = \alpha(S)$ is equivalent to the inequality*

$$\max(\alpha(V), \alpha(-V)) \le \frac{\alpha(S)P(S=0)}{1 + \alpha(S)P(S<0)}. \tag{3.7}$$

If $\alpha_V = \alpha(S) > 0$, then the following assertions hold:

1. *$(0, H)$ with $H \in \mathcal{H}_V$ solves problem (2.3) iff $H \ge 0$ a.s. on $\{V > 0\}$, $H \le 0$ a.s. on $\{V < 0\}$, and $H\mathbf{1}_{\{V \ne 0\}} \ne 0$.*
2. *$(\hat\lambda, \hat\lambda\hat H) \in \{-1, 1\} \times \mathcal{H}_V$ solves problem (2.3) iff the following conditions hold:*
   (a) *Equality holds in (3.7).*
   (b) *$\bar s_0 := \sup\{h | P(0 < S < h) = 0\} > 0$ and $\underline{s}_0 := \inf\{h | P(h < S < 0) = 0\} < 0$. If $E[V] = 0$, then S is bounded away from 0.*
   (c) *$E[\hat V] \ge 0$ for $\hat V := \hat\lambda V$ and a.s. $\hat H \in [-\underline{s}_0^{-1}, \infty)$ a.s. on $\{\hat V > 0\}$, resp., $\hat H \in [\bar s_0^{-1}, \infty)$ a.s. on $\{\hat V < 0\}$.*

   In particular, if (a) and (b) are satisfied, then there exists a solution $(\hat\lambda, \hat\lambda\hat H) \in \{-1, 1\} \times \mathcal{H}_V$ to problem (2.3).

Proof. The equivalence of $\alpha_V = \alpha(S)$ and (3.7) follows from Proposition 3.2 and Lemma 3.7. Assume $\alpha_V = \alpha(S) > 0$. For $H \in \mathcal{H}_V$ we have

$$\alpha(V_{0,H}) = \frac{(E[(VH)_+] - E[(VH)_-])E[S]}{E[(VH)_+]E[S_-] + E[(VH)_-]E[S_+]} \le \alpha(S)$$

and equality holds iff $(VH)_- = 0$ and $(VH)_+ \neq 0$, proving assertion (1). In order to prove assertion (2), assume now $(\hat\lambda, \hat\lambda\hat H) \in \{-1,1\}\times\mathcal{H}_V$ to solve (2.3). By Proposition 3.5 and inequalities (3.3) and (3.4), we find $E[\hat V] \geq 0$, $F^-(\hat H) \leq E[S_-] \leq F^+(\hat H)$ a.s. on $\{\hat V > 0\}$, and $G^-(\hat H) \leq E[S_-] \leq G^+(\hat H)$ a.s. on $\{\hat V < 0\}$. In particular by Lemma 3.3, F^+, resp., G^+, assumes their maximum $E[S_-]$ on $\mathbf{R}$. Condition (c) and the first part of condition (b) follow now since $F^+(h) = E[\mathbf{1}_{\{1+hS<0\}}S_-] = E[S_-]$ iff $P(-h^{-1} < S < 0) = 0$, and $G^+(h) = E[\mathbf{1}_{\{-1+hS<0\}}S_-] = E[S_-]$ iff $P(0 < S < h^{-1}) = 0$. For $f \in (-\underline{s}_0^{-1}, \infty)$ and $g \in (\bar s_0^{-1}, \infty)$, we find $F(f) = fE[S_-] - P(S<0)$, resp., $G(g) = P(S \leq 0) + gE[S_-]$, and calculate for $\bar V := \hat V(1+(f\mathbf{1}_{\{\hat V>0\}} + g\mathbf{1}_{\{\hat V>0\}})S)$

$$\alpha(S) = \alpha_V = \alpha(\bar V) = \frac{E[\hat V] + (E[\hat V_+]f + E[\hat V_-]g)E[S]}{E[\hat V_+]F(f) + E[\hat V_-]G(g)}$$

$$= \frac{E[\hat V] + (E[\hat V_+]f + E[\hat V_-]g)E[S]}{(E[\hat V_+]f + E[\hat V_-])E[S_-] - E[\hat V]P(S<0) + E[\hat V_-]P(S=0)},$$

which is equivalent to $\alpha(\hat V) = \frac{\alpha(S)P(S=0)}{1+\alpha(S)P(S<0)}$, proving (a). $E[V] = 0$ now implies $P(S=0) = 0$, and hence the second part of (b) holds. The converse implication easily follows by again using Proposition 3.5. □

3.5. The generic case. We can now deal with the generic case.

PROPOSITION 3.9. *Let $V \in \mathcal{V}^{T-1}\setminus\{0\}$. If $\alpha_V > \alpha(S)$, then $(\hat\lambda, \hat\lambda\hat H) \in \{-1,0,1\}\times\mathcal{H}_V$ solves problem* (2.3) *iff $\hat\lambda \in \{-1,1\}$, $E[\hat\lambda V] > 0$, and inequalities* (3.3) *and* (3.4) *hold with $\hat V := \hat\lambda V$. Furthermore, problem* (2.3) *admits a solution.*

Proof. By Lemma 3.4 we know that there exists a solution to problem (2.3), and, from the proof of Proposition 3.8(1), we know that necessarily $\hat\lambda \in \{-1,1\}$. The assertion follows now from Proposition 3.5. □

4. Optimal gambling. We can now solve problem (2.1). Denote by $\hat{\mathcal{V}}^t$ the set of solutions for problem (2.1) for $0 < t \leq T$. We introduce the following auxiliary function $R = R_S$:

$$R(x,f,g) := \frac{(x+1)(1+fE[S]) + (-1+gE[S])}{(x+1)F(f) + G(g)}, \quad x,f,g \in \mathbf{R}_+. \tag{4.1}$$

We summarize our results in the following two theorems.

THEOREM 4.1. *The optimization problem* (2.1) *admits a solution for all $0 < T < \infty$. There exists a $V \in \mathcal{V}^{T-1}$ such that $\alpha_V = \bar\alpha^T$ and $\alpha_V = \bar\alpha^T$ holds for $V \in \mathcal{V}^{T-1}$ iff $\alpha(V) = \bar\alpha^{T-1}$. Furthermore, for $1 < T < \infty$, $\bar\alpha^T$ is characterized by the following statements:*

1. *$\bar\alpha^T = 0$ iff $\bar\alpha^{T-1} = 0$ and $E[S] = 0$.*
2. *$\bar\alpha^T \geq \bar\alpha^{T-1}$, and equality holds iff $E[S] = 0$.*
3. *$\bar\alpha^T \geq \alpha(S)$, and equality holds iff $\bar\alpha^{T-1} \leq \frac{\alpha(S)P(S=0)}{1+\alpha(S)P(S<0)}$.*
4. *$\bar\alpha^T = \sup_{f,g\geq 0} R(\bar\alpha^{T-1}, f, g)$. Furthermore, $R(\bar\alpha^{T-1},\cdot,\cdot)$ assumes its maximum on $\mathbf{R}_+^2$ iff one of the following statements holds:*
   (a) *$\bar\alpha^{T-1} > \frac{\alpha(S)P(S=0)}{1+\alpha(S)P(S<0)}$.*
   (b) *$\bar\alpha^{T-1} = \frac{\alpha(S)P(S=0)}{1+\alpha(S)P(S<0)}$ and if $E[S] > 0$, then in addition, $\underline{s}_0 < 0 < \bar s_0$.*

   Under this condition, $\bar\alpha^T = R(\bar\alpha^{T-1}, \hat f, \hat g)$ for $\hat f, \hat g \geq 0$ iff the following inequalities hold:

$$\bar\alpha^T F^-(\hat f) \leq E[S] \leq \bar\alpha^T F^+(\hat f), \tag{4.2}$$

$$\bar\alpha^T G^-(\hat g) \leq E[S] \leq \bar\alpha^T G^+(\hat g). \tag{4.3}$$

Proof. Existence of a solution $V_{\lambda,H}$, $(\lambda,H)\in\{-1,0,1\}\times\mathcal{H}_V$, where $V\in\mathcal{V}^{T-1}$, to problem (2.1) will be proved by induction. Clearly, there exists such a solution for $T=1$. Let $T>1$ and assume existence of solutions for all $1\le t<T$. In particular $\bar\alpha^{T-1}<\infty$. The assertion follows now from Lemma 2.3 and Lemma 3.4.

Assertion (1) and $\bar\alpha^T\ge\bar\alpha^{T-1}$ are easy to see. If $\bar\alpha^T=\bar\alpha^{T-1}>0$, then by the first part of the proof there exists a $V\in\mathcal{V}^{T-1}$ such that $\alpha_V=\bar\alpha^T=\alpha(V)$. By Proposition 3.6(2), we find $E[S]=0$, and, conversely, $E[S]=0$ implies $\alpha_V=\alpha(V)$ for all $V\in\mathcal{V}^{T-1}$ with $E[V]\ge0$, and hence $\bar\alpha^T=\sup_{V\in\mathcal{V}^{T-1}}\alpha_V=\sup_{V\in\mathcal{V}^{T-1}}\alpha(V)=\bar\alpha^{T-1}$. Clearly, $\bar\alpha^T\ge\alpha(S)$, and assertion (3) follows from Proposition 3.8. For the proof of assertion (4), we have to distinguish three cases. First, assume $\bar\alpha^{T-1}>\frac{\alpha(S)P(S=0)}{1+\alpha(S)P(S<0)}$. Then there exists a $V\in\mathcal{V}^{T-1}$ with $E[V]>0$, and, for all such V, there exist constants $f_V,g_V\ge0$ such that

$$\begin{aligned}\alpha_V&=\frac{E[V_+](1+f_VE[S])+E[V_-](-1+g_VE[S])}{E[V_+]F(f_V)+E[V_-]G(g_V)}\\&=\frac{(\alpha(V)+1)(1+f_VE[S])+(-1+g_VE[S])}{(\alpha(V)+1)F(f_V)+G(g_V)}\\&=R(\alpha(V),f_V,g_V)=\max_{f,g\ge0}R(\alpha(V),f,g);\end{aligned}$$

i.e., α_V and f_V,g_V depend only on $\alpha(V)$. We write $\hat f\big(\alpha(V)\big)$, resp., $\hat g\big(\alpha(V)\big)$ for f_V, resp., g_V. As we have seen at the end of the proof of Proposition 3.5, $\frac{1+f_VE[S]}{F(f_V)}>\alpha_V$, which implies $R(x,\hat f(\alpha(V)),\hat g(\alpha(V)))$ to be increasing in $x>0$, and hence $\bar\alpha^T=\sup_{V\in\mathcal{V}^{T-1}}\alpha_V=\sup_{V\in\hat{\mathcal{V}}^{T-1}}\alpha_V=R(\bar\alpha^{T-1},\hat f,\hat g)$, where $\hat f,\hat g\ge0$ are such that $\bar V:=V(1+(\hat f\mathbf{1}_{\{V>0\}}-\hat g\mathbf{1}_{\{V<0\}})S)$ solves problems (2.3) and (2.1) for $V\in\hat{\mathcal{V}}^{T-1}$, i.e., $\alpha(V)=\bar\alpha^{T-1}$.

For the second case, assume $\bar\alpha^{T-1}=\frac{\alpha(S)P(S=0)}{1+\alpha(S)P(S<0)}$. Then $\bar\alpha^T=\alpha(S)$, and the first part of assertion (4) follows since $\lim_{h\to\infty}\frac{F(h)}{h}=\lim_{h\to\infty}\frac{G(h)}{h}=E[S_-]$ implies $\lim_{h\to\infty}R(x,h,h)=\alpha(S)$ for all $x\ge0$ and $R(\bar\alpha^{T-1},f,g)\le\bar\alpha^T$ for all $h_+,h_-\ge0$. By Proposition 3.8(2), existence of optimal $\hat f,\hat g\ge0$ follows for $\alpha(S)>0$. For $\alpha(S)=0$, we have $\bar\alpha^T=\bar\alpha^{T-1}=0$, and the assertion is easy to see. Finally, for $\bar\alpha^{T-1}<\frac{\alpha(S)P(S=0)}{1+\alpha(S)P(S<0)}$, we clearly have $\alpha(S)>0$, and, again by Proposition 3.8(2a), there cannot exist an optimal pair $\hat f,\hat g$. The last part of assertion (4) follows from inequalities (3.3) and (3.4). ∎

Set for $E[S]>0$, ${}_{T-1}\hat{\mathcal{V}}^T:=\{HS\in L^1\setminus\{0\}|\,H\in\mathcal{F}_{T-1},H\ge0\}$, resp., ${}_{T-1}\hat{\mathcal{V}}^T:=\{HS\in L^1|\,H\in\mathcal{F}_{T-1}\}$ for $E[S]=0$. Concerning the set of solutions for problem (2.1), we have the following result.

THEOREM 4.2. *For $1<T<\infty$, $\hat{\mathcal{V}}^T$ is characterized by the following statements:*

1. *If $\bar\alpha^{T-1}=0$ and $E[S]=0$, then $\hat{\mathcal{V}}^T=\mathcal{V}^T$.*
2. *If $\bar\alpha^{T-1}=0$, $E[S]>0$, and S is not bounded away from 0, then $\hat{\mathcal{V}}^T={}_{T-1}\hat{\mathcal{V}}^T$.*
3. *If $\bar\alpha^{T-1}=0$, $E[S]>0$, and S is bounded away from 0, then*

$$\begin{aligned}\hat{\mathcal{V}}^T=\Big\{&V(1+HS)+HS\mathbf{1}_{\{V=0\}}\big|V\in\mathcal{V}^{T-1},H\in[-\underline{s}_0^{-1},\infty)\ \text{a.s. on}\ \{V>0\},\\&H\in[\bar s_0^{-1},\infty)\ \text{a.s. on}\ \{V<0\},HS\mathbf{1}_{\{V=0\}}\in{}_{T-1}\hat{\mathcal{V}}^T\Big\}.\end{aligned}\tag{4.4}$$

4. *If $\bar\alpha^{T-1}=\frac{\alpha(S)P(S=0)}{1+\alpha(S)P(S<0)}>0$ and $\bar s_0\underline{s}_0=0$, then $\hat{\mathcal{V}}^T={}_{T-1}\hat{\mathcal{V}}^T$.*

5. *If* $\bar{\alpha}^{T-1} = \frac{\alpha(S)P(S=0)}{1+\alpha(S)P(S<0)} > 0$ *and* $\underline{s}_0 < 0 < \bar{s}_0$, *then*

$$\hat{\mathcal{V}}^T = \Big\{ V(1+HS) + HS\mathbf{1}_{\{V=0\}} \big| V \in \hat{\mathcal{V}}^{T-1}, H \in [-\underline{s}_0^{-1}, \infty) \text{ a.s. on } \{V>0\},$$

$$H \in [\bar{s}_0^{-1}, \infty) \text{ a.s. on } \{V<0\}, HS\mathbf{1}_{\{V=0\}} \in {}_{T-1}\hat{\mathcal{V}}^T \cup \{0\} \Big\} \cup {}_{T-1}\hat{\mathcal{V}}^T. \tag{4.5}$$

6. *If* $0 < \bar{\alpha}^{T-1} < \frac{\alpha(S)P(S=0)}{1+\alpha(S)P(S<0)}$, *then* $\hat{\mathcal{V}}^T = {}_{T-1}\hat{\mathcal{V}}^T$.
7. *If* $\bar{\alpha}^{T-1} > \frac{\alpha(S)P(S=0)}{1+\alpha(S)P(S<0)}$ *and* $E[S] > 0$, *then*

$$\hat{\mathcal{V}}^T = \Big\{ V(1+HS) \big| V \in \hat{\mathcal{V}}^{T-1}, \bar{\alpha}^T F^-(H) \le E[S] \le \bar{\alpha}^T F^+(H) \text{ a.s. on } \{V>0\},$$

$$\bar{\alpha}^T G^-(H) \le E[S] \le \bar{\alpha}^T G^+(H) \text{ a.s. on } \{V<0\} \Big\}. \tag{4.6}$$

In particular, $H \ge \underline{S}^{-1} \ge 0$ *a.s. on* $\{V>0\}$ *and* $H \ge \bar{S}^{-1} \ge 0$ *a.s. on* $\{V<0\}$ *for* $V(1+HS) \in \hat{\mathcal{V}}^T$.

8. *If* $\bar{\alpha}^{T-1} > 0$ *and* $E[S] = 0$, *then*

$$\hat{\mathcal{V}}^T = \Big\{ V(1+HS) \big| V \in \hat{\mathcal{V}}^{T-1}, H \in [-\bar{S}^{-1}, -\underline{S}^{-1}] \text{ a.s. on } \{V>0\},$$

$$H \in [\underline{S}^{-1}, \bar{S}^{-1}] \text{ a.s. on } \{V<0\} \Big\}. \tag{4.7}$$

Proof. The proof is an immediate consequence of our considerations. First, note that the eight cases above are mutually exclusive and form a complete list of all possible cases. Assertion (1) follows from Proposition 3.6. Assertions (2)–(6) follow from Proposition 3.8 and Theorem 4.1. Assertions (7) and (8) follow from Proposition 3.9 and Theorem 4.1. □

5. Examples. Note that inequalities (4.2) and (4.3) are in general not easily solved explicitly since $\bar{\alpha}^T$ is part of the solution to be found.

The following result is an easy consequence of Theorem 4.1 and Theorem 4.2.

COROLLARY 5.1. *Assume* $(S_t)_{1\le t\le T}, T < \infty$, *is an i.i.d. sequence of random variables* $S_t \sim S$ *with* $E[S] > 0$ *and* $P(S<0) > 0$. *Then the following statements hold:*

1. $\bar{\alpha}^1 = \alpha(S)$, *and* $\bar{\alpha}^t$ *strictly increases in* $1 \le t \le T$.
2. *For* $1 < t \le T$, $\bar{\alpha}^t = \max_{f,g\ge 0} R(\bar{\alpha}^{t-1}, f, g)$ *and* $\hat{f}_t, \hat{g}_t \ge 0$ *are optimal iff the following inequalities hold:*

$$\bar{\alpha}^t F^-(\hat{f}_t) \le E[S] \le \bar{\alpha}^t F^+(\hat{f}_t), \tag{5.1}$$

$$\bar{\alpha}^t G^-(\hat{g}_t) \le E[S] \le \bar{\alpha}^t G^+(\hat{g}_t). \tag{5.2}$$

3. *The sequence* $(\hat{f}_t, \hat{g}_t)_{1<t\le T}$ *of optimal pairs can be chosen to be nonincreasing in* $1 < t \le T$. *If* S *admits a density with respect to the Lebesgue-measure on* $\mathbf{R}$, *then* $\hat{f}_t, \hat{g}_t$ *are strictly decreasing and satisfy the following equation:*

$$F'(\hat{f}_t) = G'(\hat{g}_t) = \frac{E[S]}{\bar{\alpha}^t}. \tag{5.3}$$

4. *For* $1 < t \le T$,

$$\hat{\mathcal{V}}^t = \Big\{ V(1+HS) \big| V \in \hat{\mathcal{V}}^{t-1}, \bar{\alpha}^t F^-(H) \le E[S] \le \bar{\alpha}^t F^+(H) \text{ a.s. on } \{V>0\},$$

$$\bar{\alpha}^t G^-(H) \le E[S] \le \bar{\alpha}^t G^+(H) \text{ a.s. on } \{V<0\} \Big\}. \tag{5.4}$$

Note. If S admits a density f_S, then it is easy to check that $F'(f) = G'(g)$ iff $\int_{-\frac{1}{f}}^{\frac{1}{g}} u f_S(u)du = 0$. This can facilitate the problem of solving (5.3) considerably.

5.1. Optimization for random walks. Assume that S satisfies $S \in \{\underline{S}, 0, \bar{S}\}$ almost surely, where $-\infty < \underline{S} < 0 < \bar{S} < \infty$, $P(S = \underline{S}), P(S = \bar{S}) > 0$, and $E[S] > 0$. Note that in this case we have $F^+(h) = F^-(h) = 0$ for all $0 \le h < -\underline{S}^{-1}$ and $F^+(h) = E[S_-]$ for all $h \ge -\underline{S}^{-1}$. Furthermore, $G^+(h) = G^-(h) = -E[S]$ for all $0 \le h < \bar{S}^{-1}$ and $G^+(h) = E[S_-]$ for all $h \ge \bar{S}^{-1}$. Since $\bar{\alpha}^T \ge \alpha(S)$, we find $(\hat{f}, \hat{g}) := (-\underline{S}^{-1}, \bar{S}^{-1})$ to solve $R_S(\alpha, \hat{f}, \hat{g}) = \sup_{f,g\ge 0} R_S(\alpha, f, g)$ for all $\alpha \ge 0$. By Corollary 5.1, we find the optimal strategy described in the introduction. Note also that $F(\hat{f}) = 0$ and $G(\hat{g}) = 1 - \hat{g}E[S]$ so that $R_S(\alpha, \hat{f}, \hat{g}) + 1 = (\alpha + 1)\frac{1+\hat{f}E[S]}{1-\hat{g}E[S]}$ follows by a simple calculation. We find for $T > 1$, $\bar{\alpha}^T = (\bar{\alpha}^{T-1} + 1)\frac{1+\hat{f}E[S]}{1-\hat{g}E[S]} - 1$. In the i.i.d. case ($S_t \sim S$ for all $1 \le t \le T$), we find $\bar{\alpha}^T = (\frac{1+\hat{f}E[S]}{1-\hat{g}E[S]})^T - 1$ for all $T \ge 1$. For $P(S \in \{-1, 1\}) = 1$, this simplifies to $\bar{\alpha}^T = (\frac{P(S=1)}{P(S=-1)})^T - 1$, as claimed in the introduction. It easily follows from Proposition 2.2 and Corollary 5.1(1) that it is not optimal to continue gambling after reaching a zero wealth change. It is easy to check that the corresponding $\bar{\alpha}$ diverges to infinity when we try to approximate Brownian motion by a sequence of such random walk models.

6. Some remarks on the multidimensional case. For a random variable X with c.d.f. F_X, define the right-continuous inverse q_X of F_X by $q_X(s) := \inf\{t \in \mathbf{R} |\, F_X(t) > s\}$, $s \in (0, 1)$. For random variables $X, Y \in L^\infty$, we say X stochastically dominates Y in 2nd order ($Y \preceq^2 X$) if

$$\int_{-\infty}^{t} F_X(s)ds \le \int_{-\infty}^{t} F_Y(s)ds \ \forall\, t \in \mathbf{R}. \tag{6.1}$$

Recall the following result; see, e.g., [12, Thm. 2.58].

THEOREM 6.1. *For $X, Y \in L^\infty$, the following conditions are equivalent:*

1. $Y \preceq^2 X$.
2. $E[U(Y)] \le E[U(X)]$ *for all nondecreasing concave functions U defined on* $\mathbf{R}$.
3. *For all* $c \in \mathbf{R}$, $E[(c + X)_-] \le E[(c + Y)_-]$.

LEMMA 6.2. *Assume $E[S] = E[\tilde{S}]$ and $\tilde{S} \preceq^2 S$ for an $\mathcal{F}_T$-measurable $\tilde{S} \in L^1$, independent of $\mathcal{F}_{T-1}$. Then $R_S(\alpha, f, g) \ge R_{\tilde{S}}(\alpha, f, g)$ for all $\alpha, f, g \ge 0$. In particular, α_V calculated with respect to S is greater than or equal to α_V calculated with respect to $\tilde{S}$ for all $V \in \mathcal{V}^{T-1}$.*

Proof. The result follows from Theorem 6.1, which implies $E[(\pm 1 + hS)_-] = hE[(\frac{\pm 1}{h} + S)_-] \le hE[(\frac{\pm 1}{h} + \tilde{S})_-] = E[(\pm 1 + h\tilde{S})_-]$ for all $h > 0$. □

Let at time $T - 1$ gambles $S^i, i \in I \ne \emptyset$ be available, where $S^i \in L^1(\mathcal{F}_T)$ is independent of $\mathcal{F}_{T-1}$ and $E[S^i] \ge 0$ for all $i \in I$. Without loss of generality, we can assume $E[S^i] \in \{0, 1\}$ for all $i \in I$. Assume that there exist $\preceq^2$-maximal elements in $\{S_i |\, i \in I\}$; i.e., assume that there exists an $\bar{I} \subseteq I$ such that for all $i \in I$ with $E[S^i] > 0$, there exists an $\bar{i} \in \bar{I}$ such that $S^i \preceq^2 S^{\bar{i}}$.

Lemma 6.2 immediately implies the following result.

PROPOSITION 6.3. *In the above setting, we have*

$$\alpha_I := \sup_{i\in I} \sup_{f,g\ge 0} R_{S^i}(\alpha, f, g) = \sup_{i\in \bar{I}} \sup_{f,g\ge 0} R_{S^i}(\alpha, f, g). \tag{6.2}$$

In particular, if there exists an $\bar{i} \in I$ such that $E[S^{\bar{i}}] > 0$ and $S^i \preceq^2 S^{\bar{i}}$ for all $i \in I$ with $E[S^i] > 0$, then $\alpha_I = \sup_{f,g\ge 0} R_{S^{\bar{i}}}(\alpha, f, g)$.

This result allows us, e.g., to deal with the classical CAPM (capital asset pricing model; see [22]) or its (symmetric) α-stable generalizations ($1 < \alpha \leq 2$; see [10]) by reducing the multidimensional case to the one-dimensional case.

Acknowledgments. I am grateful to the anonymous referees for their helpful comments. I sincerely thank Walter Schachermayer for his hospitality.

MIXED ZERO-SUM STOCHASTIC DIFFERENTIAL GAME AND AMERICAN GAME OPTIONS*

S. HAMADÈNE†

Abstract. In this paper we solve the mixed zero-sum stochastic differential game problem in the general case. The main tool is the notion of a local solution of backward stochastic differential equations (BSDEs) with two reflecting barriers. As an application we deal with the American game options.

Key words. mixed zero-sum stochastic differential game, reflected backward SDEs, Dynkin games, American game options

1. Introduction.

Suppose the dynamics of a stochastic system is described by a functional differential equation of the form

$$dx_t = f(t, x., u_t, v_t)dt + \Sigma(t, x.)dB_t,\ t \leq T, \text{ and } x_0 = \bar{x}_0 \in R^m.$$

Here the stochastic processes $(u_t)_{t\leq T}$ and $(v_t)_{t\leq T}$ are adapted and stand for, respectively, the intervention functions of two agents c_1 and c_2 on that system. Additionally, the agents are allowed to exit from the control of the system when they decide, i.e., c_1 (resp., c_2) can stop controlling at a stopping time τ (resp., σ). The actions of the agents are not free and their advantages are antagonistic, which means that between c_1 and c_2 there is a payoff $J(u, \tau; v, \sigma)$ which is a cost for c_1 and a reward for c_2.

The problem we are interested in is finding a saddle-point for the payoff functional $J(u, \tau; v, \sigma)$, i.e., a quadruple $(u^*, \tau^*; v^*, \sigma^*)$ which satisfies that for any (u, τ) and (v, σ), we have

$$J(u^*, \tau^*; v, \sigma) \leq J(u^*, \tau^*; v^*, \sigma^*) \leq J(u, \tau; v^*, \sigma^*).$$

This property of $(u^*, \tau^*; v^*, \sigma^*)$ means that when the agents c_1 and c_2 control with (u^*, τ^*) and (v^*, σ^*), respectively, it is advantageous for both to keep the same control. Otherwise, if one of them decides unilaterally to change a strategy, it is penalized if the other keeps its initial one. Actually, when c_1 chooses (u^*, τ^*) as a control action and keeps it, then the best choice for c_2 is to act with (v^*, σ^*). If c_2 deviates, it would get a lesser amount (than what it would obtain if it acts with (v^*, σ^*)). Conversely if c_2 chooses to control with (v^*, σ^*), then the best choice for c_1 is to act with (u^*, τ^*); otherwise c_1 will pay a greater amount.

This problem is a zero-sum game of mixed type because it combines control and stopping.

Mixed game problems are linked to backward stochastic differential equations (BSDEs) with two reflecting barriers, which were first introduced by Cvitanic and Karatzas in [6] (see also [19] and [16]). In [16], Hamadène and Lepeltier showed that if the BSDE with two reflecting barriers associated with the mixed game has a

†Laboratoire de Statistique et Processus, Université du Maine, 72085 Le Mans Cedex 9, France (hamadene@univ-lemans.fr).

solution, then the game has a value and a saddle-point. The expression of the saddle-point is given explicitly. However, solutions for BSDEs with two reflecting barriers are obtained mainly under two conditions. The first one is the well-known Mokobodski's hypothesis, which requires the existence of a difference of two nonnegative supermartingales between the barriers [6], [16]. The second one is a regularity assumption on one of the barriers which, roughly speaking, should be a semimartingale [6], [19]. For general barriers the solution may not exist. Therefore the mixed game problem remains open in the general case, i.e., without assuming either Mokobodski's hypothesis or regularity of one of the barriers.

Thus the main objective of this paper is to solve this problem in its general setting. We show that, in order to solve the mixed game problem, it is enough to solve locally its associated double obstacle reflected BSDE. Therefore we prove that the game has a saddle-point and a value function which is also continuous.

A particular case of the mixed game problem is the well-known Dynkin game. Actually the latter corresponds to the case when the agents have no control actions but just stopping. The Dynkin game has been widely studied in the past [1, 2, 4, 5, 10, 23, 25, 26, 29]. However, to our knowledge, the most general paper on this subject is the one by Lepeltier and Maingueneau [25]. They proved, without assuming Mokobodski's hypothesis, the existence of the value function for the game which is a right continuous with left limits process. So as a by-product of our result on mixed games, we deduce that, in the case of Brownian filtration, the value function of the Dynkin game is continuous. Additionally, we give a convenient characterization of the saddle-point.

Another setting of Dynkin games that deserves to be mentioned is the one with mixed strategies. This consists of the relaxation of the stopping times. They are replaced by either nondecreasing processes or processes whose sections are stopping times. For more details on this setting see, e.g., the paper by Touzi and Vieille [30] for the case of finite duration T and the one by Laraki and Solan [24] for the case when $T = \infty$. In this framework the required properties for the processes that define the payoff of the game are somehow less stringent than in the usual setting.

Finally, let us point out that when the controllers are not allowed to stop the game (i.e., $\sigma = \tau = T$), this problem turns into the well-known zero-sum stochastic differential game, which was studied by many authors, e.g., Elliott [11], Davis and Elliott [8], and Hamadène and Lepeltier [17], [18].

In the second part of this paper we deal with American game options, which we briefly introduce. In a financial market let us assume we have two agents, a broker c_1 and a trader c_2. The trader pays a premium to the broker and has the right to ask for a payment (a "contingent claim" in the usual language of financial markets), provided by the broker, when he decides to exercise within a period of time $[0, T]$. Thus when c_2 decides to exercise at time σ, she gets an amount equal to L_σ. The difference with the standard American options is that the broker is allowed to cancel the contract which binds her to the trader. In that case he pays a money penalty. Indeed, if c_1 decides to cancel the contract at time τ, she pays c_2 an amount equal to $L_\tau + \alpha_\tau$ (α_τ stands for the money penalty). If c_1 and c_2 agree to stop the option at τ, then the reward for c_2 is equal to $L_\tau + \alpha'_\tau$ with $0 \leq \alpha'_t \leq \alpha_t$.

This problem is typically a Dynkin game. As usual, the main issues are as follows:

(i) What is the fair price of the option at $t \in [0, T]$?

(ii) Does a hedging strategy for the broker exist?

(iii) When it is optimal for the broker (resp., trader) to cancel (resp., exercise) the option?

Cvitanic and Ma [7] and Kifer [20] dealt with American game options. Both papers showed that the value of the option is given by Y_0, where $(Y_t)_{t\leq T}$ is the value function of the associated Dynkin game. In addition, in [20], the author showed the existence of a hedge which replicates the option for the broker in a complete financial market. However, Kifer, whose work is based heavily on the results of [25], dealt with a less general setting than ours. Additionally, in our work we obtain more regularity properties for the model. In [7] the authors make use of BSDEs but consider only specific processes $(L_t)_{t\leq T}$ and $(\alpha_t)_{t\leq T}$, namely, Itô processes.

In this paper we show that the value of the option at any $t \in [0,T]$ is given by $e^{rt}Y_t$, where r is the credit rate of the nonrisky asset and $(Y_t)_{t\leq T}$ is the continuous *local* solution for a specific BSDE with two reflecting barriers. Moreover a hedging strategy after t for the broker, against the game option, exists. We do not require any restriction on the processes $(L_t)_{t\leq T}$ and $(\alpha_t)_{t\leq T}$.

This paper is organized as follows. In section 2, we present the mixed game problem, while section 3 is related to BSDEs with two reflecting barriers. We give the main theorem, which allows us to solve the mixed zero-sum stochastic differential game problem. The proof is given in the appendix. In section 4, we deal with the mixed game problem and show the existence of the value and of a saddle-point for the game. The expression of the latter is given. Moreover we consider an example for which we give a numerical result. Finally, in the last section we study the American game options in a complete financial market. We give the fair price of the option at any time $t \in [0,T]$ and show the existence of a hedging strategy after t. Once again we deal with an example and give some numerical results.

2. Setting of the mixed zero-sum stochastic differential game problem. Throughout this paper $(\Omega, \mathcal{F}, P)$ is a fixed probability space on which is defined a standard m-dimensional Brownian motion $B = (B_t)_{t\leq T}$, whose natural filtration is $(F_t^0 := \sigma\{B_s, s \leq t\})_{t\leq T}$. We denote by $(F_t)_{t\leq T}$ the completed filtration of $(F_t^0)_{t\leq T}$ with the P-null sets of $\mathcal{F}$; therefore $(F_t)_{t\leq T}$ satisfies the usual conditions, i.e., it is right continuous and complete. Moreover

- $\mathcal{P}$ is the σ-algebra on $[0,T]\times\Omega$ of F_t-progressively measurable sets;
- for any stopping time ν, $\mathcal{T}_\nu$ is the set of F_t-measurable stopping times τ such that P-a.s. $\nu \leq \tau \leq T$; $\mathcal{T}_0$ will be simply denoted $\mathcal{T}$;
- $\mathcal{H}^{2,k}$ is the set of $\mathcal{P}$-measurable processes $w = (w_t)_{t\leq T}$, R^k-valued and square integrable w.r.t. $dt \otimes dP$;
- $\mathcal{S}^2$ is the set of $\mathcal{P}$-measurable and continuous processes $w' = (\omega'_t)_{t\leq T}$ such that $E[\sup_{t\leq T} |w'_t|^2] < \infty$.

We now introduce the mixed stochastic differential game problem.

Let $\mathcal{C}$ be the space of continuous functions $\bar{x}$ from $[0,T]$ into R^m and let $\bar{\mathcal{F}}_t$ be the σ-field of $\mathcal{C}$ generated by $\{\Pi_s : \bar{x} \in \mathcal{C} \mapsto \bar{x}_s,\ s \leq t\}$. By $\mathcal{D}$ we denote the σ-field of $[0,T]\times\mathcal{C}$ consisting of all the subsets D, which have the property that the section of D at time t is in $\bar{\mathcal{F}}_t$ and the section of D at $\bar{x}$ is Lebesgue measurable for any $\bar{x}$ (see, e.g., [11] for more details).

Let us consider a mapping $\Sigma :\ (t,\bar{x}) \in [0,T]\times\mathcal{C} \mapsto \Sigma(t,\bar{x}) \in R^{m\times m}$ satisfying the following:

$$\begin{cases} \text{(1.1) } \Sigma \text{ is } \mathcal{D}\text{-measurable.} \\ \text{(1.2) There exists a constant } C \text{ such that } |\Sigma(t,\bar{x}) - \Sigma(t,\bar{x}')| \leq C\|\bar{x} - \bar{x}'\|_t \text{ and} \\ \qquad |\Sigma(t,\bar{x})| \leq C(1 + \|\bar{x}\|_t), \text{ where for any } \bar{x} \in \mathcal{C} \text{ and } t \leq T, \|\bar{x}\|_t = \sup_{s\leq t} |\bar{x}_s|. \\ \text{(1.3) For any } (t,\bar{x}) \in [0,T]\times\mathcal{C}, \text{ the matrix } \Sigma(t,\bar{x}) \text{ is invertible and } |\Sigma^{-1}(t,\bar{x})| \leq \\ \qquad C(1 + \|\bar{x}\|_t^m) \text{ for some constants } C \text{ and } m \geq 0. \end{cases}$$

Let $x_0 \in R^m$ and let $x = (x_t)_{t\le T}$ be the solution of the following standard functional differential equation:

$$x_t = x_0 + \int_0^t \Sigma(s, x.)dB_s,\ t \le T; \tag{1}$$

here we emphasize that Σ depends not only on x_t but also on the path of the process x up to time t. The process $(x_t)_{t\le T}$ exists, since Σ satisfies (1.1)–(1.3) (see, e.g., [28, p. 375]).

Let A (resp., B) be a compact metric space and $\mathcal{U}$ (resp., $\mathcal{V}$) be the space of $\mathcal{P}$-measurable processes $u := (u_t)_{t\le T}$ (resp., $v := (v_t)_{t\le T}$) with values in A (resp., B). Let $f : [0,T] \times \mathcal{C} \times A \times B \to R^m$ be such that

$$\begin{cases} \text{(1.4) there exists a constant } C \text{ such that } |f(t,\bar{x},\tilde{u},\tilde{v})| \le C(1 + \|\bar{x}\|_t) \text{ for any} \\ \qquad t, \bar{x}, \tilde{u}, \text{ and } \tilde{v}; \\ \text{(1.5) for any } (t,\bar{x}) \in [0,T] \times \mathcal{C},\ \text{the mapping } (\tilde{u},\tilde{v}) \mapsto f(t,\bar{x},\tilde{u},\tilde{v}) \text{ is continuous;} \\ \text{(1.6) for any } (\tilde{u},\tilde{v}) \in A \times B,\ \text{the function } (t,\bar{x}) \mapsto f(t,\bar{x},\tilde{u},\tilde{v}) \text{ is } \mathcal{D}\text{-measurable.} \end{cases}$$

For $(u,v) \in \mathcal{U} \times \mathcal{V}$, let $\Gamma^{u,v} := (\Gamma_t^{u,v})_{t\le T}$ be the local martingale defined by

$$d\Gamma_t^{u,v} = \Gamma_t^{u,v}\Sigma^{-1}(t,x.)f(t,x.,u_t,v_t)dB_t, t \le T,\ \text{and } \Gamma_0^{u,v} = 1.$$

As Σ and f verify (1.1), (1.3), (1.4), and (1.6), the measure $P^{u,v}$ defined by $P^{u,v}(A) = E[\Gamma_T^{u,v} 1_A]$ for $A \in \mathcal{F}$ is actually a probability on $(\Omega, \mathcal{F})$ (see, e.g., [13]). Additionally, thanks to Girsanov's theorem (see, e.g., [21, p. 191] or [28, p. 331]), under the probability $P^{u,v}$, the process $dB_t^{u,v} = dB_t - \Sigma^{-1}(t,x.)f(t,x.,u_t,v_t)dt$, $t \le T$, is a Brownian motion and $(x_t)_{t\le T}$ satisfies

$$x_t = x_0 + \int_0^t f(s,x.,u_s,v_s)ds + \int_0^t \Sigma(s,x.)dB_s^{u,v},\ t \le T, \tag{2}$$

which means that $(x_t)_{t\le T}$ is a weak solution for the stochastic functional differential equation (2).

The process $x = (x_t)_{t\le T}$ stands for the dynamics of the system when it is not controlled. On that system, two agents c_1 and c_2 intervene. A control action for c_1 (resp., c_2) is a process $u = (u_t)_{t\le T}$ (resp., $v = (v_t)_{t\le T}$) which belongs to $\mathcal{U}$ (resp., $\mathcal{V}$). Thereby $\mathcal{U}$ (resp., $\mathcal{V}$) is called *the set of admissible controls* for c_1 (resp., c_2). When c_1 and c_2 act with, respectively, u and v, the law of the dynamics of the system is the same as the one of x under $P^{u,v}$. It turns out that the interventions of the agents give rise to a drift $f(t,x.,u_t,v_t)$ in the dynamics.

As previously mentioned, an intervention strategy for an agent combines control and stopping. Therefore a strategy for c_1 (resp., c_2) is a pair (u,τ) (resp., (v,σ)), where u (resp., v) is an admissible control and τ (resp., σ) a stopping time. It implies that the agents keep controlling until one of them decides to stop and the system is actually stopped at $\tau \wedge \sigma$. So assume that c_1 (resp., c_2) chooses (u,τ) (resp., (v,σ)) as a strategy of intervention which is not free and generates a payoff, which is a cost for c_1 and a reward for c_2. The expression of that payoff is given by

$$J(u,\tau;v,\sigma) = E^{u,v}\left[\int_0^{\tau\wedge\sigma} h(s,x.,u_s,v_s)ds + U_\tau 1_{[\tau<\sigma]} + L_\sigma 1_{[\sigma<\tau<T]} + Q_\tau 1_{[\tau=\sigma<T]} + \xi 1_{[\tau=\nu=T]}\right], \tag{3}$$

where

$$\begin{cases} (1.7)\ h : [0,T]\times\mathcal{C}\times A\times B \to R^+ \text{ is } \mathcal{D}\otimes\mathcal{B}(A\times B)/\mathcal{B}(R^+)\text{-measurable and for any } (t,\bar{x})\in[0,T]\times\mathcal{C},\ \text{the mapping } h(t,\bar{x},.,.):\ (\tilde{u},\tilde{v})\in A\times B\mapsto h(t,\bar{x},\tilde{u},\tilde{v}) \text{ is continuous. In addition there exists a constant } C \text{ such that for any } (t,\bar{x},\tilde{u},\tilde{v})\in[0,T]\times\mathcal{C}\times A\times B, |h(t,\bar{x},\tilde{u},\tilde{v})|\le C(1+\|\bar{x}\|_t). \text{ The process } (h(t,x.(\omega),u_t,v_t))_{t\le T} \text{ stands for the instantaneous payoff between } c_1 \text{ and } c_2,\\ (1.8)\ U=(U_t)_{t\le T}, Q=(Q_t)_{t\le T},\ \text{and } L=(L_t)_{t\le T} \text{ are processes of } \mathcal{S}^2 \text{ such that } L_t\le Q_t\le U_t, \forall\, t\le T,\\ (1.9)\ \xi\in L^2(\Omega,F_T,dP;R) \text{ and satisfies P-}a.s.\ L_T\le\xi\le U_T. \end{cases}$$

The meaning of $J(u,\tau;v,\sigma)$ is as follows:

(i) When the two agents decide to stop at the same time $\tau=\sigma<T$, c_2 obtains from c_1 an amount equal to $\int_0^\tau h(s,x,u_s,v_s)ds+Q_\tau 1_{[\tau=\sigma<T]}+\xi 1_{[\tau=\sigma=T]}$.

(ii) If c_1 is the first to decide to stop controlling at $\tau<T$, he pays c_2 the amount $\int_0^\tau h(s,x,u_s,v_s)ds+U_\tau$.

(iii) If c_2 is the first to decide to stop controlling at $\sigma<T$, he gets from c_1 the amount $\int_0^\sigma h(s,x,u_s,v_s)ds+L_\sigma$.

The difference U_t-L_t is the money penalty that c_1 pays for the unilateral decision to exit from the system, while Q_t-L_t is a money penalty for c_1, which corresponds to the situation when both agree to stop controlling before T.

The problem we are interested in is finding two intervention strategies (u^*,τ^*) and (v^*,σ^*), respectively, for c_1 and c_2 such that for any (u,τ) and (v,σ), we have

$$J(u^*,\tau^*;v,\sigma)\le J(u^*,\tau^*;v^*,\sigma^*)\le J(u,\tau;v^*,\sigma^*).$$

The quadruple $(u^*,\tau^*;v^*,\sigma^*)$ is called a *saddle-point* for the zero-sum mixed stochastic differential game.

The particular case when $h\equiv 0$ and $f\equiv 0$ corresponds to the well-known Dynkin game studied by many authors; see, e.g., [1, 2, 4, 5, 6, 10, 23, 25, 26, 29].

3. Connection with BSDEs with two reflecting barriers. Let $\varphi:[0,T]\times\Omega\times R^{1+m}\to R$ satisfy the following conditions:

$$\begin{cases} (2.1)\ \forall (y,z)\in R^{1+m},\ \text{the process } (\varphi(t,\omega,y,z))_{t\le T} \text{ is } \mathcal{P}\text{-measurable and the process } (\varphi(t,\omega,0,0))_{t\le T} \text{ belongs to } \mathcal{H}^{2,1}.\\ (2.2)\ \varphi \text{ is uniformly Lipschitz with respect to } (y,z);\ \text{i.e., there exists a constant } C \text{ such that } |\varphi(t,\omega,y,z)-\varphi(t,\omega,y',z')|\le C(|y-y'|+|z-z'|)\ \forall t,y,y',z, \text{ and } z'. \end{cases}$$

A solution for the double obstacle reflected BSDE, whose coefficient (resp., terminal value; resp., lower and upper barriers) is φ (resp., ξ; resp., L and U), is a quadruple $(\bar{Y}_t,\bar{Z}_t,\bar{K}_t^+,\bar{K}_t^-)_{t\le T}$ of $\mathcal{P}$-measurable processes with values in $R^{1+m+1+1}$ such that

$$(4)\quad \begin{cases} \bar{Y},\bar{K}^\pm\in\mathcal{S}^2,\ \bar{Z}\in\mathcal{H}^{2,m};\ \bar{K}^\pm \text{ are nondecreasing processes } (\bar{K}_0^\pm=0);\\ \bar{Y}_t=\xi+\displaystyle\int_t^T\varphi(s,\bar{Y}_s,\bar{Z}_s)ds+(\bar{K}_T^+-\bar{K}_t^+)-(\bar{K}_T^--\bar{K}_t^-)-\int_t^T\bar{Z}_s dB_s\ \forall t\le T;\\ L_t\le\bar{Y}_t\le U_t\ \forall t\le T\ \text{ and }\ \displaystyle\int_0^T(U_s-\bar{Y}_s)d\bar{K}_s^-=\int_0^T(L_s-\bar{Y}_s)d\bar{K}_s^+=0. \end{cases}$$

For general processes L and U, (4) may not have a solution. Actually if $L\equiv U$, and L is not a semimartingale, then obviously there is no solution. As shown in

[16], in order to solve the mixed game problem, it is sufficient to solve its associated BSDE with two reflecting barriers, which is of type (4) with a specific drift φ. Indeed, φ is just the minmax of the *Hamiltonian* function of the game. However, a careful examination of the proof of Theorem 4 in [16] shows that it is unnecessary to solve the associated BSDE in $[0,T]$, but just in $[0,\theta]$, where θ is an appropriate stopping time. In a way, we need to solve (4) *locally* and not globally. This observation is the key point of this work. Theorem 3.1 below provides a local solution for the above reflected BSDE, which enables us to solve the mixed game problem in its general setting, i.e., without assuming either Mokobodski's hypothesis or regularity of the barriers. The proof of this theorem, given in the appendix, is based on a penalization scheme of a BSDE with one reflecting barrier and concatenation.

THEOREM 3.1. *There exists a $\mathcal{P}$-measurable lower semicontinuous process $(Y_t)_{t\le T}$ such that*

(i) $Y_T = \xi$;

(ii) *for any stopping time ν, there exist another stopping time $\theta_\nu \ge \nu$, a process $(Z_s^\nu)_{s\ge 0} \in \mathcal{H}^{2,m}$, and two nondecreasing processes $(K^{\nu,\pm})_{s\ge 0} \in \mathcal{S}^2$ $(K_\nu^{\nu,\pm} = 0)$ such that the quadruple $(Y, Z^\nu, K^{\nu,\pm})$ satisfies P-a.s.*

$$
(5)\quad \begin{cases} \forall s \in [\nu,\theta_\nu], Y_s = Y_{\theta_\nu} + \displaystyle\int_s^{\theta_\nu} \varphi(s,Y_s,Z_s^\nu)ds + (K_{\theta_\nu}^{\nu,+} - K_s^{\nu,+}) \\ \qquad\qquad - (K_{\theta_\nu}^{\nu,-} - K_s^{\nu,-}) - \displaystyle\int_s^{\theta_\nu} Z_s^\nu dB_s; \\ \forall s \in [\nu,\theta_\nu], L_s \le Y_s \le U_s \text{ and } \displaystyle\int_\nu^{\theta_\nu} (Y_s - L_s)dK_s^{\nu,+} = \int_\nu^{\theta_\nu} (Y_s - U_s)dK_s^{\nu,-} = 0; \\ Y \text{ is continuous on } [\nu,\theta_\nu]; \end{cases}
$$

(iii) *if $\tau_\nu^* := \inf\{s \ge \nu, Y_s = U_s\} \wedge T$ and $\sigma_\nu^* := \inf\{s \ge 0, Y_s = L_s\} \wedge T$, then $\tau_\nu^* \vee \sigma_\nu^* \le \theta_\nu$.*

4. Resolution of the mixed zero-sum stochastic differential game. We focus once again on the mixed zero-sum stochastic differential game introduced in section 2. We show it has a value and a saddle-point; the expression of the latter is given. To do so we use the notion of local solutions for BSDEs with two reflecting barriers introduced by Theorem 3.1.

Thus let us set $H(t,\bar{x},z,u,v) = z\Sigma^{-1}(t,\bar{x})f(t,\bar{x},u,v) + h(t,\bar{x},u,v)$ for any $(t,\bar{x},z,u,v) \in [0,T]\times\mathcal{C}\times R^m \times A \times B$. The function H is called the *Hamiltonian* associated with the game. We now make the following assumption:

[H] We assume that

$$
\begin{cases} \text{(i)} & \text{the function } \Sigma^{-1}.f \text{ is bounded;} \\ \text{(ii)} & \inf_{u\in A}\sup_{v\in B} H(t,\bar{x},z,u,v) = \sup_{v\in B}\inf_{u\in A} H(t,\bar{x},z,u,v) \text{ for any } (t,\bar{x},z) \in \\ & [0,T]\times\mathcal{C}\times R^m. \end{cases}
$$

Assumption [H](ii), called the *Isaacs condition*, is quite natural in zero-sum differential games (see, e.g., [8, 11, 16]). We have the following result.

PROPOSITION 4.1. *There exist two $\mathcal{D}\otimes\mathcal{B}(R^m)$-measurable functions u^* and v^* from $[0,T]\times\mathcal{C}\times R^m$ into A and B, respectively, such that*

(i) *$(u^*(t,\bar{x},z),v^*(t,\bar{x},z))$ is a saddle-point for H, i.e., for any $t,\bar{x},z,u,v$ we have*

$$H(t,\bar{x},z,u^*(t,\bar{x},z),v)\le H(t,\bar{x},z,(u^*,v^*)(t,\bar{x},z))\le H(t,\bar{x},z,u,v^*(t,\bar{x},z));$$

(ii) *the function $z\mapsto H(t,\bar{x},z,(u^*,v^*)(t,\bar{x},z))$ is uniformly Lipschitz.*

Proof. The function $(t,\bar{x},u,v)\mapsto\Sigma^{-1}(t,\bar{x}).f(t,\bar{x},u,v)$ (resp., $h(t,\bar{x},u,v)$) is $\mathcal{D}\otimes\mathcal{B}(A\times B)$-measurable. In addition, the functions f and h are continuous w.r.t. (u,v) and the sets A and B are compact. Therefore, according to Benes' selection theorem [3], there exist two $\mathcal{D}\otimes\mathcal{B}(R^m)$-measurable functions u^* and v^* from $[0,T]\times\mathcal{C}\times R^m$ into A and B, respectively, such that

$$\inf_{u\in A}\sup_{v\in B}H(t,\bar{x},z,u,v)=\sup_{v\in B}H(t,\bar{x},z,u^*(t,\bar{x},z),v)$$

and

$$\sup_{v\in B}\inf_{u\in A}H(t,\bar{x},z,u,v)=\inf_{u\in A}H(t,\bar{x},z,u,v^*(t,\bar{x},z)).$$

It follows that

$$\inf_{u\in A}H(t,\bar{x},z,u,v^*(t,\bar{x},z))\le H(t,\bar{x},z,(u^*,v^*)(t,\bar{x},z))\le\sup_{v\in B}H(t,\bar{x},z,u^*(t,\bar{x},z),v).$$

Then taking into account [H](ii), we obtain

$$\inf_{u\in A}H(t,\bar{x},z,u,v^*(t,\bar{x},z))=H(t,\bar{x},z,(u^*,v^*)(t,\bar{x},z))=\sup_{v\in B}H(t,\bar{x},z,u^*(t,\bar{x},z),v).$$

Henceforth $(u^*,v^*)(t,\bar{x},z)$ is a saddle-point for the function $(u,v)\longmapsto H(t,\bar{x},z,u,v)$.

Next, for any $z,z'\in R^m$ we have

$$\begin{aligned}&\left|\inf_{u\in A}\sup_{v\in B}H(t,\bar{x},z,u,v)-\inf_{u\in A}\sup_{v\in B}H(t,\bar{x},z',u,v)\right|\\&\le\sup_{u\in A}\sup_{v\in B}|H(t,\bar{x},z,u,v)-H(t,\bar{x},z',u,v)|\le\|\Sigma^{-1}.f\|.|z-z'|.\end{aligned}$$

The result follows because of the boundedness of $\Sigma^{-1}.f$. □

For $(t,\omega,z)\in[0,T]\times\Omega\times R^m$, let us set

$$H^*(t,\omega,z)=H(t,x.(\omega),z,(u^*,v^*)(t,x.(\omega),z)),$$

where x is the solution of (1). Let $(Y_t)_{t\le T}$ be the process constructed as in Theorem 3.1, but associated with (H^*,ξ,L,U) (note that H^* does not depend on y). Using once again Theorem 3.1 with $\nu=0$, let $(Z_t,K_t^+,K_t^-)_{t\le T}$ be the triple of processes and θ the stopping time such that

$$(6)\quad\begin{cases}\text{(i) } Z\in\mathcal{H}^{2,m},K^\pm\in\mathcal{S}^2\text{ nondecreasing }(K_0^\pm=0);\\ \text{(ii) }\forall t\le\theta,Y_t=Y_\theta+\displaystyle\int_t^\theta H^*(s,\omega,Z_s)ds+(K_\theta^+-K_t^+)\\ \qquad\qquad-(K_\theta^--K_t^-)-\displaystyle\int_t^\theta Z_sdB_s\,;\,Y_T=\xi;\\ \text{(iii) }\forall t\le\theta,L_t\le Y_t\le U_t\text{ and }\displaystyle\int_0^\theta(Y_s-L_s)dK_s^+=\int_0^\theta(Y_s-U_s)dK_s^-=0;\\ \text{(iv) }Y\text{ is continuous on }[0,\theta].\end{cases}$$

Let $\tau^* := \inf\{s \geq 0, Y_s = U_s\} \wedge T$ and $\sigma^* := \inf\{s \geq 0, Y_s = L_s\} \wedge T$; then we know that $\tau^* \vee \sigma^* \leq \theta$. On the other hand, if $u^* := (u^*(t,x,Z_t))_{t\leq T}$ and $v^* := (v^*(t,x,Z_t))_{t\leq T}$, then the controls u^* and v^* belong to $\mathcal{U}$ and $\mathcal{V}$, respectively, since $u^*(t,\bar{x},z)$ and $v^*(t,\bar{x},z)$ are $\mathcal{D}\otimes\mathcal{B}(R^m)$-measurable. We are ready to give the main result of this paper.

THEOREM 4.2. *The strategy $(\tau^*,u^*;\sigma^*,v^*)$ is a saddle-point for the mixed zero-sum stochastic differential game; i.e., it satisfies*

$$J(u^*,\tau^*;v,\sigma) \leq J(u^*,\tau^*;v^*,\sigma^*) = Y_0 \leq J(u,\tau;v^*,\sigma^*)\ \forall\,(v,\sigma)\ \textit{and}\ (u,\tau).$$

Additionally, Y_0 is the value of the game, i.e.,

$$Y_0 = \inf_{u\in\mathcal{U};\tau\in\mathcal{T}}\sup_{v\in\mathcal{V};\sigma\in\mathcal{T}} J(u,\tau;v,\sigma) = \sup_{v\in\mathcal{V};\sigma\in\mathcal{T}}\inf_{u\in\mathcal{U};\tau\in\mathcal{T}} J(u,\tau;v,\sigma).$$

Proof. Let us show that $Y_0 = J(\tau^*,u^*;\sigma^*,v^*)$. First recall that $\tau^*\vee\sigma^* \leq \theta$ and that Y is continuous on $[0,\theta]$. In addition K^+ and K^- are continuous on $[0,\theta]$ and move only when Y reaches either L or U; thus $K^+_{\tau^*\wedge\sigma^*} = K^-_{\tau^*\wedge\sigma^*} = 0$. It follows that

$$\begin{aligned} Y_0 &= Y_{\tau^*_\wedge\sigma^*} + K^+_{\tau^*\wedge\sigma^*} - K^-_{\tau^*\wedge\sigma^*} + \int_0^{\tau^*\wedge\sigma^*} H(r,x,Z_r,(u^*,v^*)(r,x,Z_r))dr \\ &\qquad - \int_0^{\tau^*\wedge\sigma^*} Z_r dB_r \\ &= Y_{\tau^*_\wedge\sigma^*} + \int_0^{\tau^*\wedge\sigma^*} h(r,x,(u^*,v^*)(r,x,Z_r))dr - \int_0^{\tau^*\wedge\sigma^*} Z_r dB_r^{u^*,v^*}. \end{aligned}$$

As $(\int_0^t Z_r dB_r^{u^*,v^*})_{s\leq T}$ is an (F_t,P^{u^*,v^*})-martingale, taking expectation we get

$$Y_0 = E^{u^*,v^*}[Y_0] = E^{u^*,v^*}\left[Y_{\tau^*_\wedge\sigma^*} + \int_0^{\tau^*\wedge\sigma^*} h(r,x(\omega),Z_r,(u^*,v^*)(r,x(\omega),Z_r))dr\right]$$

because Y_0 is F_0-measurable, and hence deterministic. Now P-a.s., and also P^{u^*,v^*}-a.s. (since they are equivalent probabilities); we have

$$Y_{\tau^*\wedge\sigma^*} = Y_{\tau^*}1_{[\tau^*<\sigma^*]} + Y_{\sigma^*}1_{[\sigma^*<\tau^*]} + Y_{\sigma^*}1_{[\sigma^*=\tau^*<T]} + \xi 1_{[\tau^*=\sigma^*=T]}.$$

But $Y_{\tau^*}1_{[\tau^*<\sigma^*]} = Y_{\tau^*}1_{[\tau^*<\sigma^*]}.1_{[\theta<T]} + Y_{\tau^*}1_{[\tau^*<\sigma^*]}.1_{[\theta=T]}$. On $[\theta<T]$, $\tau^*\leq\theta<T$, and Y is continuous on $[0,\theta]$; therefore $Y_{\tau^*} = U_{\tau^*}$. On the other hand, on $[\theta=T]$, Y is continuous on $[0,T]$ and $Y_{\tau^*}1_{[\tau^*<\sigma^*]} = U_{\tau^*}1_{[\tau^*<\sigma^*]}$, since in this case $\tau^*<\sigma^*$ implies $\tau^*<T$. It follows that $Y_{\tau^*}1_{[\tau^*<\sigma^*]} = U_{\tau^*}1_{[\tau^*<\sigma^*]}$. In the same way we have $Y_{\sigma^*}1_{[\sigma^*<\tau^*]} = L_{\sigma^*}1_{[\sigma^*<\tau^*]}$. Finally, $Y_{\sigma^*}1_{[\sigma^*=\tau^*<T]} = L_{\sigma^*}1_{[\sigma^*=\tau^*<T]} = U_{\tau^*}1_{[\sigma^*=\tau^*<T]} = Q_{\tau^*}1_{[\sigma^*=\tau^*<T]}$ due to $L\leq Q\leq U$. Thus we have

$$Y_{\tau^*\wedge\sigma^*} = U_{\tau^*}1_{[\tau^*<\sigma^*]} + L_{\sigma^*}1_{[\sigma^*<\tau^*]} + Q_{\sigma^*}1_{[\sigma^*=\tau^*<T]} + \xi 1_{[\tau^*=\sigma^*=T]}\ \ P\text{- and } P^{u^*,v^*}\text{-a.s.},$$

and then

$$\begin{aligned} Y_0 &= E^{u^*,v^*}\left[\int_0^{\tau^*\wedge\sigma^*} h(r,x,(u^*,v^*)(r,x,Z_r))dr + U_{\tau^*}1_{[\tau^*<\sigma^*]} + L_{\sigma^*}1_{[\sigma^*<\tau^*]}\right. \\ &\qquad\qquad \left. + Q_{\sigma^*}1_{[\sigma^*=\tau^*<T]} + \xi 1_{[\tau^*=\sigma^*=T]}\right] \\ &= J(u^*,\tau^*;v^*,\sigma^*). \end{aligned}$$

Next let $v=(v_t)_{t\leq T}$ be an admissible control for c_2 and let $\sigma\in\mathcal{T}$. Let us show that $Y_0\geq J(u^*,\tau^*;v,\sigma)$. Once again since $\tau^*\wedge\sigma\leq\theta$ (thanks to $\tau^*\leq\theta$), we have

$$\begin{aligned}Y_0 &= Y_{\tau^*\wedge\sigma}+K^+_{\tau^*\wedge\sigma}+\int_0^{\tau^*\wedge\sigma}H(r,x,Z_r,(u^*,v^*)(r,x,Z_r))dr-\int_0^{\tau^*\wedge\sigma}Z_rdB_r\\ &= Y_{\tau^*\wedge\sigma}+\int_0^{\tau^*\wedge\sigma}\{H(r,x,Z_r,(u^*,v^*)(r,x,Z_r))-H(r,x,Z_r,u^*(r,x,Z_r),v_r)\}dr\\ &\quad+\int_0^{\tau^*\wedge\sigma}h(r,x,u^*(r,x,Z_r),v_r)dr-\int_0^{\tau^*\wedge\sigma}Z_rdB^{u^*,v}_r+K^+_{\tau^*\wedge\sigma}.\end{aligned}$$

Here, without $\tau^*\leq\theta$ we would not have been able to write this equality since in that case we were not sure whether $\tau^*\wedge\sigma\leq\theta$. As $K^+_{\tau^*\wedge\sigma}\geq 0$ and $H(r,x,Z_r,(u^*,v^*)(r,x,Z_r))-H(r,x,Z_r,u^*(r,x,Z_r),v_r)\geq 0$, then

$$Y_0\geq Y_{\tau^*\wedge\sigma}+\int_0^{\tau^*\wedge\sigma}h(r,x,Z_r,u^*(r,x,Z_r),v_r)dr-\int_0^{\tau^*\wedge\sigma}Z_rdB^{u^*,v}_r.$$

Once more $(\int_0^s Z_rdB^{u^*,v}_r)_{s\leq T}$ is an $(F_s,P^{u^*,v})$-martingale; then taking the expectation with respect to $P^{u^*,v}$ and taking into account the fact that Y_0 is deterministic, we obtain

$$Y_0=E^{u^*,v}[Y_0]\geq E^{u^*,v}\left[Y_{\tau^*\wedge\sigma}+\int_0^{\tau^*\wedge\sigma}h(r,x,u^*(r,x,Z_s),v_r)dr\right].$$

But once again

$$Y_{\tau^*\wedge\sigma}\quad=Y_{\tau^*}1_{[\tau^*<\sigma]}+Y_\sigma 1_{[\sigma<\tau^*]}+Y_{\tau^*}1_{[\tau^*=\sigma<T]}+\xi 1_{[\tau^*=\sigma=T]},$$

and $Y_\sigma 1_{[\sigma<\tau^*]}\geq L_\sigma 1_{[\sigma<\tau^*]}$, $Y_{\tau^*}1_{[\tau^*<\sigma]}=U_{\tau^*}1_{[\tau^*<\sigma]}$. Additionally, $Y_{\tau^*}1_{[\tau^*=\sigma<T]}=U_{\tau^*}1_{[\tau^*=\sigma<T]}\geq Q_{\tau^*}1_{[\tau^*=\sigma<T]}$. Therefore we have

$$\begin{aligned}Y_0 &\geq E^{u^*,v}\left[\int_0^{\tau^*\wedge\sigma}h(r,x,u^*(r,x,Z_r),v_r)dr+U_{\tau^*}1_{[\tau^*<\sigma]}+L_\sigma 1_{[\sigma<\tau^*]}\right.\\ &\qquad\left.+Q_{\tau^*}1_{[\tau^*=\sigma<T]}+\xi 1_{[\tau^*=\sigma=T]}\right]\\ &= J(\tau^*,u^*;\sigma,v)\end{aligned}$$

and $Y_0=J(u^*,\tau^*;v^*,\sigma^*)\geq J(u^*,\tau^*;v,\sigma)$. In the same way we can show that $Y_0=J(u^*,\tau^*;v^*,\sigma^*)\leq J(u,\tau;v^*,\sigma^*)$ for any $\tau\in\mathcal{T}$ and u an admissible control for c_1. It follows that $(u^*,\tau^*;v^*,\sigma^*)$ is a saddle-point for the game.

Finally, let us show that the value of the game is Y_0. We proved that

$$J(u^*,\tau^*;v,\sigma)\leq Y_0=J(u^*,\tau^*;v^*,\sigma^*)\leq J(u,\tau;v^*,\sigma^*)$$

for any $(u,v)\in\mathcal{U}\times\mathcal{V}$ and $\tau,\sigma\in\mathcal{T}$. Thereby

$$Y_0\leq\inf_{u\in\mathcal{U},\tau\in\mathcal{T}}J(u,\tau;v^*,\sigma^*)\leq\sup_{v\in\mathcal{V},\sigma\in\mathcal{T}}\inf_{u\in\mathcal{U},\tau\in\mathcal{T}}J(u,\tau;v,\sigma).$$

On the other hand

$$Y_0 \geq \sup_{v\in\mathcal{V},\sigma\in\mathcal{T}} J(u^*,\tau^*;v,\sigma) \geq \inf_{u\in\mathcal{U},\tau\in\mathcal{T}} \sup_{v\in\mathcal{V},\sigma\in\mathcal{T}} J(u,\tau;v,\sigma).$$

Now due to the inequality

$$\inf_{u\in\mathcal{U},\tau\in\mathcal{T}} \sup_{v\in\mathcal{V},\sigma\in\mathcal{T}} J(u,\tau;v,\sigma) \geq \sup_{v\in\mathcal{V},\sigma\in\mathcal{T}} \inf_{u\in\mathcal{U},\tau\in\mathcal{T}} J(u,\tau;v,\sigma)$$

we have

$$Y_0 = \inf_{u\in\mathcal{U},\tau\in\mathcal{T}} \sup_{v\in\mathcal{V},\sigma\in\mathcal{T}} J(u,\tau;v,\sigma) = \sup_{v\in\mathcal{V},\sigma\in\mathcal{T}} \inf_{u\in\mathcal{U},\tau\in\mathcal{T}} J(u,\tau;v,\sigma).$$

The proof is now complete. □

Let $t\in[0,T]$ be fixed; for τ, $\sigma\in\mathcal{T}_t$, and $(u,v)\in\mathcal{U}\times\mathcal{V}$, we define the conditional payoff after t as follows:

$$J_t(u,\tau;v,\sigma) := E^{u,v}\left[\int_t^{\tau\wedge\sigma} h(s,x,u_s,v_s)ds + U_\tau 1_{[\tau<\sigma]} + L_\sigma 1_{[\sigma<\tau<T]} + Q_\tau 1_{[\tau=\sigma<T]} + \xi 1_{[\tau=\nu=T]}|F_t\right].$$

In the previous result we characterized Y_0 as the value of the game. However, more can be said about the process $(Y_t)_{t\leq T}$. Actually we have the following proposition.

PROPOSITION 4.3. *The process $(Y_t)_{t\leq T}$ is continuous, and for any stopping time ν we have*

$$\begin{aligned} Y_\nu &= \operatorname{ess\,inf} f_{u\in\mathcal{U};\tau\in\mathcal{T}_\nu} \operatorname{ess\,sup}_{v\in\mathcal{V};\sigma\in\mathcal{T}_\nu} J_\nu(u,\tau;v,\sigma) \\ &= \operatorname{ess\,sup}_{v\in\mathcal{V};\sigma\in\mathcal{T}_\nu} \operatorname{ess\,inf} f_{u\in\mathcal{U};\tau\in\mathcal{T}_\nu} J_\nu(u,\tau;v,\sigma); \end{aligned} \tag{7}$$

i.e., the process $(Y_t)_{t\leq T}$ is the value function of the game.

Proof. Let ν be a stopping time. Let θ_ν ($\geq\nu$) be the stopping time with which $(Z_s^\nu)_{s\in[0,T]}\in\mathcal{H}^{2,m}$ and $(K_s^{\nu,\pm})_{s\in[0,T]}\in\mathcal{S}^2$ nondecreasing ($K_\nu^{\nu,\pm}=0$) are such that

$$\begin{cases} \forall s\in[\nu,\theta_\nu], Y_s = Y_{\theta_\nu} + \displaystyle\int_s^{\theta_\nu} H^*(r,Z_r^\nu)dr + (K_{\theta_\nu}^{\nu,+} - K_s^{\nu,+}) \\ \qquad\qquad - (K_{\theta_\nu}^{\nu,-} - K_s^{\nu,-}) - \displaystyle\int_s^{\theta_\nu} Z_r^\nu dB_r,\ Y_T=\xi, \\ \forall s\in[\nu,\theta_\nu], L_s\leq Y_s\leq U_s \ \text{ and } \displaystyle\int_\nu^{\theta_\nu}(Y_r-L_r)dK_r^{\nu,+} = \int_\nu^{\theta_\nu}(Y_r-U_r)dK_r^{\nu,-}=0, \\ Y \text{ is continuous on } [\nu,\theta_\nu]. \end{cases} \tag{8}$$

The existence of θ_ν, Z^ν, and $K^{\nu,\pm}$ stems from Theorem 3.1. If $\tau_\nu^* = \inf\{s\geq\nu, Y_s=U_s\}\wedge T$ and $\sigma_\nu^* = \inf\{s\geq\nu, Y_s=L_s\}\wedge T$, then P-a.s., $\tau_\nu^*\vee\sigma_\nu^*\leq\theta_\nu$. For $s\geq 0$, let $u_s^* = u^*(s,x,Z_s^\nu)$ and $v_s^* = v^*(s,x,Z_s^\nu)$; then u^* and v^* are admissible controls for c_1 and c_2, respectively. Along the same lines as in the proof of Theorem 4.2 we can show that $Y_\nu = J_\nu(u^*,\tau_\nu^*;v^*,\sigma_\nu^*)$. On the other hand if τ, $\sigma\in\mathcal{T}_\nu$ and $(u,v)\in\mathcal{U}\times\mathcal{V}$, then

$$P\text{-a.s. } Y_\nu\leq J_\nu(u,\tau;v^*,\sigma_\nu^*) \text{ and } Y_\nu\geq J_\nu(u^*,\tau_\nu^*;v,\sigma),$$

from which we can infer relation (7). We now focus on the continuity of $(Y_t)_{t\leq T}$. In the construction of Y we used an increasing scheme, but it is possible to use a

decreasing scheme by making the penalization at (11) on the barrier U. Therefore there exists an upper semicontinuous process $\tilde{Y}$ such that for any stopping time ν equality (7) is satisfied with $\tilde{Y}_\nu$ instead of Y_ν. It follows that $Y_\nu = \tilde{Y}_\nu$, P-a.s. for any stopping time ν. The optional section theorem (see [9, p. 220]) implies that P-a.s. for any $t \leq T$, $Y_t = \tilde{Y}_t$. Therefore the process Y is both upper and lower semicontinuous; i.e., it is continuous. □

Remark 4.4. (i) The value function of the zero-sum mixed game does not depend on the values $Q_s, s < T$, of the process Q.

(ii) In the case when $h \equiv 0$ and $f \equiv 0$, the problem is just the well-known zero-sum Dynkin game. Our results, Theorem 4.2 and Proposition 4.3, imply the game has a value function and a saddle-point when L and U are merely continuous processes. We do not require further conditions of Mokobodski type or regularity of the barriers. In addition, the value function is continuous and the saddle-point τ^*, σ^* is characterized as the first times when we have $Y = U$ and $Y = L$, respectively. Those properties of Dynkin games were not known. Actually in [25], for example, the authors show just that the value function is right continuous with left limits and that a saddle-point exists for bounded processes L and U and when $Q = L$. Additionally, a characterization such as ours of the saddle-point is not obtained.

Example 4.5. Let us consider the following example:

$$\begin{aligned} &dx_t = x_t dB_t,\ t \leq 1,\ \text{and } x_0 = 1;\\ &A = [0,1],\ B = [-1,1],\ f(t,x,u,v) = x_t(u-v),\\ &\text{and } h(t,x,u,v) = \min\{|x_t|, 2\} + \frac{1}{2}(u^2+v^2). \end{aligned}$$

Therefore $H(t,x,p,u,v) = p(u-v)+\min\{|x_t|,2\}+\frac{1}{2}(u^2+v^2)$, and obviously the Isaacs condition is satisfied with $u^*(p) = 1_{[p<-1]} - p1_{[-1\leq p\leq 0]}$ and $v^*(p) = 1_{[p<0]} - 1_{[p\geq 0]}$ for any $p \in R$. It follows that

$$\begin{aligned} H^*(t,x,p) := H(t,x,p,u^*(p),v^*(p)) &= pu^*(p) - pv^*(p) + \min\{|x_t|,2\}\\ &\quad + \tfrac{1}{2}(u^*(p)^2 + v^*(p)^2)\\ &= p1_{[p<-1]} - p^2 1_{[-1\leq p\leq 0]} + |p| + \min\{|x_t|,2\}\\ &\quad + \tfrac{1}{2}\{1 + 1_{[p<-1]} + p^2 1_{[-1\leq p\leq 0]}\}. \end{aligned}$$

Assume that for $t \leq 1$, $U_t = \min(2, x_t)$, $L_t = \min(1, \frac{1}{3}x_t)$, $\xi = \min(2, x_1)$, and let $(Y_t)_{t\leq 1}$ be the value function of the associated mixed stochastic differential game. Figure 1 shows a simulation of a path of the process Y and an evaluation of Y_0.

5. Application in finance. Let $\mathcal{M}$ be a financial market where, for the sake of simplicity, we have a bond $(C_t)_{t\leq T}$ whose evolution is

$$dC_t = rC_t dt, \quad t \leq T, \quad C_0 > 0,$$

and one risky asset, whose price $(S_t)_{t\leq T}$ is given by

$$dS_t = S_t(\mu dt + \nu dB_t), \quad t \leq T, \quad S_0 > 0.$$

Let $t \in [0,T]$ be fixed and let X be a nonnegative F_t-measurable random variable. A self-financing portfolio after t, whose endowment at t is X, is a $\mathcal{P}$-measurable process $\pi = (\beta_s, \gamma_s)_{s\in[t,T]}$ with values in R^2 such that, P-a.s.,

(i) $\displaystyle\int_t^T \{|\beta_s| + (\gamma_s S_s)^2\} ds < \infty,$

(ii) if $A_s^{\pi,X} = \beta_s.C_s + \gamma_s.S_s$, then $A_s^{\pi,X} = X + \displaystyle\int_t^s \beta_u dC_u + \int_t^s \gamma_u dS_u \ \ \forall s \in [t,T].$

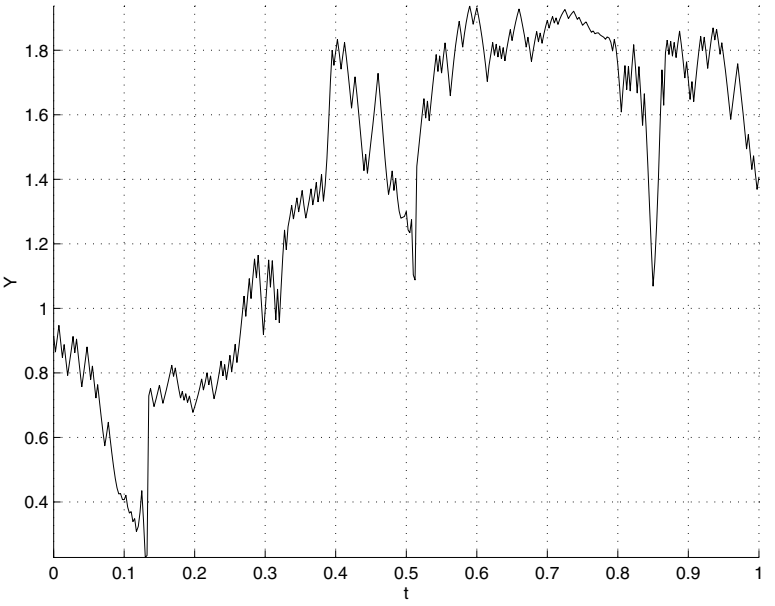

FIG. 1. *Trajectory of the value function* $(Y_t)_{t\leq 1}$ $(Y_0 = 0.9142)$.

Let P^* be the unique probability on $(\Omega, \mathcal{F})$ under which the actualized price of the risky asset is a martingale, i.e.,

$$\frac{dP^*}{dP} := \exp\left\{-\nu^{-1}(\mu - r)B_T - \frac{1}{2}(\nu^{-1}(\mu - r))^2 T\right\}.$$

Therefore under P^*, by Girsanov's theorem (see [21, p. 191] or [28, p. 331]), the process $(W_t = B_t + \nu^{-1}(\mu - r)t)_{t\leq T}$ is an (F_t, P^*)-Brownian motion.

An American game or Israeli option is a contract between a broker c_1 and a trader c_2 who are, respectively, the seller and the buyer of the option. The trader pays an initial amount (the price of the option) which guarantees a payment of $(L_t)_{t\leq T}$ (a "contingent claim" in the usual language of financial markets). The trader can exercise whenever he decides before the maturity T of the option. Thus, if the trader decides to exercise at τ, he gets the amount L_τ. On the other hand, the broker is allowed to cancel the contract which binds him to c_2. Therefore if he chooses σ as the contract cancellation time, he pays the amount U_σ equal to at least the one that would earn c_2 if he decided to exercise at σ, i.e., $U_\sigma \geq L_\sigma$. The difference $U_\sigma - L_\sigma$ is the premium that the broker pays for his decision to cancel the contract. If c_1 and c_2 decide together to stop the contract at the same time τ, then c_2 gets a reward equal to $Q_\tau 1_{[\tau<T]} + \xi 1_{[\tau=T]}$.

In [7], the authors consider this problem, but with payoffs L and U as Itô processes (they also suppose that $Q \equiv L$). Additionally, in [20] Kifer studied this problem in detail. However, since his work is based on the paper by Lepeltier and Maingueneau [25], he was able to consider only the case when $Q = U$. Our framework is more general and we have deduced more properties of the solution of the problem (e.g., continuity of the fair price, characterization of the optimal strategy) than Kifer did.

Let us now consider the probability space $(\Omega, \mathcal{F}, P^*)$ endowed with the Brownian motion $(W_t)_{t\leq T}$. Let $(\tilde{Y})_{t\leq T}$ be the continuous process (through Proposition 4.3) such

that for any $t \le T$, there exist a stopping time $\theta_t \ge t$ and a process $(\tilde{Z}_s)_{s\in[t,T]}$ of $\mathcal{H}^{2,m}$ and $(\tilde{K}_s^+, \tilde{K}_s^-)_{s\in[t,T]}$, which are a pair of nondecreasing processes of $\mathcal{S}^2$ $((\tilde{K}_t^+, \tilde{K}_t^-) = (0,0))$, such that

$$\begin{cases} \forall s \le T, e^{-rs}L_s \le \tilde{Y}_s \le e^{-rs}U_s \text{ and } \tilde{Y}_T = e^{-rT}\xi; \\ \tilde{Y}_s = \tilde{Y}_{\theta_t} + (\tilde{K}_{\theta_t}^+ - \tilde{K}_s^+) - (\tilde{K}_{\theta_t}^- - \tilde{K}_s^-) - \displaystyle\int_s^{\theta_t} \tilde{Z}_r dW_r \ \forall s \in [t, \theta_t], \\ \displaystyle\int_t^{\theta_t} (e^{-ru}U_u - \tilde{Y}_u) d\tilde{K}_u^- = \int_t^{\theta_t} (e^{-ru}L_u - \tilde{Y}_u) d\tilde{K}_u^+ = 0. \end{cases}$$

According to Proposition 4.3, if we set $\tau_t^* := \inf\{s \ge t, \tilde{Y}_s = e^{-rs}U_s\} \wedge T$ and $\sigma_t^* := \inf\{s \ge t, \tilde{Y}_s = e^{-rs}L_s\} \wedge T$, then we have

$$\forall\ \tau, \sigma \in \mathcal{T}_t,\ \bar{\Gamma}_t(\tau_t^*, \sigma) \le \tilde{Y}_t = \bar{\Gamma}_t(\tau_t^*, \sigma_t^*) \le \bar{\Gamma}_t(\tau, \sigma_t^*), \tag{9}$$

where $\bar{\Gamma}_t(\tau,\sigma) = E^*[e^{-r\tau}U_\tau 1_{[\tau<\sigma]} + e^{-r\sigma}L_\sigma 1_{[\sigma<\tau]} + e^{-r\tau}Q_\tau 1_{[\tau=\sigma<T]} + e^{-rT}\xi 1_{[\tau=\sigma=T]}|F_t]$.

A hedge for the broker against the game option after t is a pair (π, τ), where π is a self-financing portfolio after t, whose endowment at t is X and τ is a stopping time $\ge t$, satisfying

$$A_{s\wedge\tau}^{\pi,X} \ge R(s,\tau) := U_\tau 1_{[\tau<s]} + L_s 1_{[s<\tau]} + Q_s 1_{[s=\tau<T]} + \xi 1_{[s=\tau=T]}\ \forall s \in [t,T] P\text{-a.s.}$$

Since the broker is allowed to cancel the option he does not need to hedge with a portfolio up to maturity T but only up to its cancellation time. This is the main reason why a hedging strategy for the broker has two components, a portfolio and a stopping time. The quantity $R(s,\tau)$ is the amount that the broker has to pay if the option is exercised at s or cancelled at τ.

In [20], Kifer showed that the value (the fair price) of the option at $t = 0$ is $\tilde{Y}_0$ and a hedge exists. We show that the fair price of the option at time t is $e^{rt}\tilde{Y}_t$ and a hedge after t exists also.

First, as usual (see, e.g., [14], [22]), we define the value of the option at t by V_t, where $(V_t)_{t\le T}$ is an *rcll* (right continuous with left limits) process which satisfies $\forall t \le T$, P-a.s.

$V_t :=$ ess inf$\{X \ge 0,\ F_t$-measurable such that there exists a hedge (π,τ) after t against the game option, where π is a self-financing portfolio after t whose endowment at t is $X\}$.

Then we have the following theorem.

THEOREM 5.1. *P-a.s., for any $t \le T$, $V_t = e^{rt}\tilde{Y}_t$. Moreover a hedge after t against the option exists.*

Proof. Let $t \le T$ be fixed and let (π,τ) be a hedge after t against the game option. Therefore $\tau \ge t$, and $\pi = (\beta_s, \gamma_s)_{s\in[t,T]}$ is a self-financing portfolio whose value at t is X, satisfying $A_{s\wedge\tau}^{\pi,X} \ge R(s,\tau)\ \forall s \in [t,T]$. But

$$e^{-rs\wedge\tau}A_{s\wedge\tau}^{\pi,X} = e^{-rt}X + \nu\int_t^{s\wedge\tau} \gamma_u S_u e^{-ru} dW_u \ge e^{-rs\wedge\tau}R(s,\tau)\ \forall s \in [t,T]. \tag{10}$$

Let σ be a stopping time $\ge t$. Putting $s = \sigma$ and taking the conditional expectation in (10) we have

$$e^{-rt}X \ge E^*[e^{-r\tau\wedge\sigma}R(\sigma,\tau)|F_t].$$

Therefore

$$\begin{aligned} e^{-rt}X &\geq \text{ess sup}_{\sigma\geq t}E^*[e^{-r\tau\wedge\sigma}R(\sigma,\tau)|F_t] \\ &\geq \text{ess inf}_{\tau\geq t}\text{ess sup}_{\sigma\geq t}E^*[e^{-r\tau\wedge\sigma}R(\sigma,\tau)|F_t] = \tilde{Y}_t \end{aligned}$$

because of (9) and Proposition 4.3. It follows that $V_t \geq e^{rt}\tilde{Y}_t$. Let us now show the reverse inequality. Since $\tau_t^* \leq \theta_t$, then for any $s \geq t$ we have

$$\tilde{Y}_{s\wedge\tau_t^*} = \tilde{Y}_t - \tilde{K}^+_{s\wedge\tau_t^*} + \int_t^{s\wedge\tau_t^*} \tilde{Z}_u dW_u.$$

On the other hand, since $\tilde{Y}_{\tau_t^*}1_{[\tau_t^*<T]} = e^{-r\tau_t^*}U_{\tau_t^*}1_{[\tau_t^*<T]} \geq e^{-r\tau_t^*}Q_{\tau_t^*}1_{[\tau_t^*<T]}$, then

$$\begin{aligned} \tilde{Y}_{s\wedge\tau_t^*} &= \tilde{Y}_s 1_{[s<\tau_t^*]} + \tilde{Y}_{\tau_t^*}1_{[\tau_t^*<s]} + \tilde{Y}_{\tau_t^*}1_{[s=\tau_t^*<T]} + \xi 1_{[s=\tau_t^*=T]} \\ &\geq e^{-rs}L_s 1_{[s<\tau_t^*]} + e^{-r\tau_t^*}U_{\tau_t^*}1_{[\tau_t^*<s]} + e^{-r\tau_t^*}Q_{\tau_t^*}1_{[s=\tau_t^*<T]} + \xi 1_{[s=\tau_t^*=T]} \\ &= e^{-rs\wedge\tau_t^*}R(s,\tau_t^*). \end{aligned}$$

Henceforth we have

$$\tilde{Y}_t + \int_t^{s\wedge\tau_t^*} \tilde{Z}_u dW_u \geq e^{-rs\wedge\tau_t^*}R(s,\tau_t^*)\ \forall s \in [t,T].$$

Next for $s \in [t,T]$ let us set $\tilde{M}_s := e^{rs}(\tilde{Y}_t + \int_t^{s\wedge\tau_t^*} \tilde{Z}_u dW_u)$, $\gamma_s = e^{rs}\tilde{Z}_s(\nu S_s)^{-1}1_{[s\leq\tau_t^*]}$, and $\beta_s = (\tilde{M}_s - \gamma_s S_s)C_s^{-1}$. Therefore for any $s \in [t,T]$ we obviously have $\tilde{M}_s =$

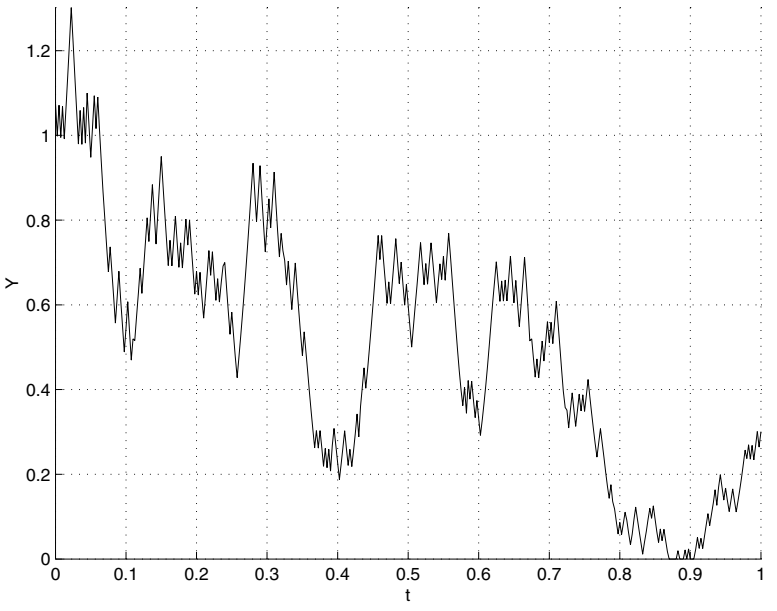

FIG. 2. $S_0 = 2$, $r = \mu = \nu = 1$, $T = 1$, $L_t = (S_t - 1)^+$, $U_t = 1.1(S_t - 1)^+$, *and* $\xi = 1.05(S_1 - 1)^+$.

$\beta_s C_s + \gamma_s S_s$. Additionally, using Itô's formula we obtain

$$\forall s \in [t,T],\ \tilde{M}_s = e^{rt}\tilde{Y}_t + \int_t^s e^{ru}\tilde{Z}_u 1_{[u\le\tau_t^*]}dW_u + \int_t^s r\tilde{M}_u du$$
$$= e^{rt}\tilde{Y}_t + \int_t^s \beta_u dC_u + \int_t^s \gamma_u dS_u.$$

It follows that $(\beta_s,\gamma_s)_{s\in[t,T]}$ is a self-financing portfolio whose value at t is $e^{rt}\tilde{Y}_t$. Since $\tilde{M}_{s\wedge\tau_t^*} \ge R(s,\tau_t^*)$ for any $s\in[t,T]$, then $((\beta_s,\gamma_s)_{s\in[t,T]},\tau_t^*)$ is a hedge against the game option. It implies that $e^{rt}\tilde{Y}_t \ge V_t$ and then $e^{rt}\tilde{Y}_t = V_t$ P-a.s. As $\tilde{Y}$ is continuous and V is $rcll$, those processes are undistinguishable, i.e., P-a.s. for any $t\le T$, $V_t = e^{rt}\tilde{Y}_t$. This ends the proof. □

We finally present a numerical result of an example. Let us take $S_0 = 2$, $r = \mu = \nu = 1$, $T = 1$, $L_t = (S_t - 1)^+$, $U_t = 1.1(S_t-1)^+$, and finally $\xi = 1.05(S_1-1)^+$. Figure 2 shows a simulation of a path of the process $(\tilde{Y}_t = V_t e^{-t})_{t\le 1}$ ($V_0 = 1.0746$).

Appendix. The proof of Theorem 3.1, divided into five steps, is given for the case when $\nu = 0$. If ν is not equal to 0, it just needs a slight modification.

For $n\ge 0$, let $\varphi_n : [0,T]\times\Omega\times R^{1+m}\to R$ such that $\varphi_n(t,\omega,y,z) = \varphi(t,\omega,y,z) + n(L_t - y)^+$. The function φ_n is uniformly Lipschitz with respect to (y,z). According to the result of El-Karoui et al. [12, Theorem 5.2], there exists a process $(Y^n, Z^n, K^{-,n})$ solution of the BSDE with one reflecting barrier associated with (φ_n,ξ,U), i.e.,

(11)
$$\begin{cases} Y^n \in \mathcal{S}^2,\ Z^n\in\mathcal{H}^{2,m};\ K^{-,n} \text{ is a continuous nondecreasing process with } K_0^{-,n} = 0;\\ Y_t^n = \xi + \displaystyle\int_t^T \varphi(s,Y_s^n,Z_s^n)ds + n\int_t^T (L_s - Y_s^n)^+ds - (K_T^{-,n} - K_t^{-,n}) - \int_t^T Z_s^n dB_s;\\ Y_t^n \le U_t\ \forall t\le T \ \text{ and } \displaystyle\int_0^T (U_s - Y_s^n)dK_s^{-,n} = 0. \end{cases}$$

As $\varphi^n \le \varphi^{n+1}$, thus a comparison theorem (see, e.g., [12, Theorem 4.1]) implies that for any $n\ge 0$, $Y^n \le Y^{n+1} \le U$. Let ν be a stopping time, let $n\ge 0$, and $\delta_\nu^n = \inf\{s\ge\nu, Y_s^n = U_s\}\wedge T$. Since $Y^n\le Y^{n+1}$ we have $\delta_\nu^{n+1}\le\delta_\nu^n$ and the sequence of stopping times $(\delta_\nu^n)_{n\ge0}$ converges to another stopping time $\delta_\nu := \lim_{n\to\infty}\delta_\nu^n$. In what follows, δ_0^n (resp., δ_0) will be simply denoted δ^n (resp., δ).

First let us give the following result.

PROPOSITION A.1. *There exists a process $Y := (Y_t)_{t\le T}$ such that P-a.s. for any $t\le T$, $Y_t^n\to Y_t$ as $n\to\infty$ and $(Y^n)_{n\ge0}\to Y$ in $\mathcal{H}^{2,1}$. Moreover Y is lower semicontinuous and satisfies*

$$\text{P-a.s. } \forall t\le T, L_t\le Y_t\le U_t, \text{ and } Y_T = \xi.$$

Proof. Since P-a.s. for any $n\ge0$ we have $Y^n\le Y^{n+1}\le U$ and Y^n is continuous, there exists a $\mathcal{P}$-measurable lower semicontinuous process $(Y_t)_{t\le T}$ such that P-a.s. for any $t\le T$, $Y_t^n\to Y_t$ as $n\to\infty$, $Y_t\le U_t$, and $Y_T = \xi$. On the other hand, the dominated convergence theorem implies that $(Y^n)_{n\ge0}\to Y$ in $\mathcal{H}^{2,1}$.

We want to show that P-a.s. for any $t\le T$, $Y_t\ge L_t$. It is enough to show that P-a.s., $Y_\nu\ge L_\nu$ (ν is a "whatever" stopping time); then the result follows from the optional section theorem [9, p. 220].

For any $n \geq 0$, the process Y^n satisfies (see, e.g., [12])

$$Y_\nu^n = \operatorname{ess\,inf}_{\tau \in \mathcal{T}_\nu} E\left[\int_\nu^\tau \varphi(s, Y_s^n, Z_s^n)ds + n\int_\nu^\tau (L_s - Y_s^n)^+ ds + U_\tau 1_{[\tau<T]} + \xi 1_{[\tau=T]} | F_\nu\right]$$

and

$$Y_\nu^n = E\left[\int_\nu^{\delta_\nu^n} \varphi(s, Y_s^n, Z_s^n)ds + n\int_\nu^{\delta_\nu^n} (L_s - Y_s^n)^+ ds + U_{\delta_\nu^n} 1_{[\delta_\nu^n<T]} + \xi 1_{[\delta_\nu^n=T]} | F_\nu\right].$$

Therefore we have

(12)
$$Y_\nu^n \geq E\left[-\int_\nu^{\delta_\nu^n} |\varphi(s, Y_s^n, Z_s^n)|ds + n\int_\nu^{\delta_\nu^n} (L_s - Y_s^n)^+ ds + U_{\delta_\nu^n} 1_{[\delta_\nu^n<T]} + \xi 1_{[\delta_\nu^n=T]} | F_\nu\right].$$

Since the process $K^{-,n}$ moves only when Y^n reaches the barrier U, then for any $s \leq T$ from (11) we have

$$Y_{(s\vee\nu)\wedge\delta_\nu^n}^n = Y_{\delta_\nu^n}^n + \int_{(s\vee\nu)\wedge\delta_\nu^n}^{\delta_\nu^n} \varphi(r, Y_r^n, Z_r^n)dr + n\int_{(s\vee\nu)\wedge\delta_\nu^n}^{\delta_\nu^n} (L_r - Y_r^n)^+ dr - \int_{(s\vee\nu)\wedge\delta_\nu^n}^{\delta_\nu^n} Z_r^n dB_r.$$

Therefore basic calculations (see, e.g., [12]) imply the existence of a constant C, which does not depend on n, such that

$$E\left[\int_\nu^{\delta_\nu^n} |Z_r^n|^2 dr\right] \leq C \ \forall n \geq 0, \tag{13}$$

since $Y_{\delta_\nu^n}^n$ is uniformly bounded in $L^2(\Omega, F, P)$. As $Y^0 \leq Y^n \leq U$, φ is Lipschitz, and taking into account (13), we deduce from (12) that

$$\int_\nu^{\delta_\nu} (L_r - Y_r)^+ dr = 0, \text{P-a.s.} \tag{14}$$

On the other hand, for any $s \leq T$ we have, due to $\delta_\nu \leq \delta_\nu^n$,

$$Y_{(s\vee\nu)\wedge\delta_\nu}^n = Y_{\delta_\nu}^n + \int_{(s\vee\nu)\wedge\delta_\nu}^{\delta_\nu} \varphi(r, Y_r^n, Z_r^n)dr + n\int_{(s\vee\nu)\wedge\delta_\nu}^{\delta_\nu} (L_r - Y_r^n)^+ dr - \int_{(s\vee\nu)\wedge\delta_\nu}^{\delta_\nu} Z_r^n dB_r,$$

which implies

$$Y_{(s\vee\nu)\wedge\delta_\nu}^n = Y_\nu^n - \int_\nu^{(s\vee\nu)\wedge\delta_\nu} \varphi(r, Y_r^n, Z_r^n)dr - n\int_\nu^{(s\vee\nu)\wedge\delta_\nu} (L_r - Y_r^n)^+ dr + \int_\nu^{(s\vee\nu)\wedge\delta_\nu} Z_r^n dB_r \ \forall s \leq T.$$

From $Y^n \leq Y^{n+1}$ and (13), using a result of Peng [27, Theorem 2.1] we deduce that the process $(Y_{(s\vee\nu)\wedge\delta_\nu})_{s\leq T}$ is right continuous, and hence Y is right continuous on

$[\nu,\delta_\nu]$. Therefore on the set $\{\nu<\delta_\nu\}$, we obtain from (14) that $Y_s\geq L_s$ for $s\in[\nu,\delta_\nu[$ and $Y_\nu\geq L_\nu$. The set $\{\nu=\delta_\nu\}$ is F_ν-measurable, and thus from (12) we have

(15)
$$1_{\{\nu=\delta_\nu\}}Y^n_\nu\geq E\left[1_{\{\nu=\delta_\nu\}}\left\{-\int_\nu^{\delta^n_\nu}|\varphi(s,Y^n_s,Z^n_s)|ds+U_{\delta^n_\nu}1_{[\delta^n_\nu<T]}+\xi 1_{[\delta^n_\nu=T]}\right\}|F_\nu\right].$$

But

$$E\left[1_{\{\nu=\delta_\nu\}}\int_\nu^{\delta^n_\nu}|\varphi(s,Y^n_s,Z^n_s)|ds\right]\to 0 \text{ as } n\to\infty.$$

Then taking the limit in (15), if necessary extracting a subsequence, we obtain

$$1_{\{\nu=\delta_\nu\}}(Y_\nu-U_{\delta_\nu}1_{[\delta_\nu<T]}-\xi 1_{[\delta_\nu=T]})\geq 0$$

which implies $1_{\{\nu=\delta_\nu\}}(Y_\nu-L_\nu)\geq 0$. It follows that P-*a.s.* $Y_\nu\geq L_\nu$ and the optional section theorem yields the desired result. □

On $[0,\delta]$ the process Y satisfies a BSDE with one reflecting lower barrier. Actually we have the following lemma.

LEMMA A.2. *There exist two $\mathcal{P}$-measurable processes $(\tilde K^+_s)_{s\leq T}$ and $(\tilde Z_s)_{s\leq T}$ with values, respectively, in R^+ and R^m such that P-a.s.*

$$(16)\quad\begin{cases}E\left[\int_0^T|\tilde Z_s|^2ds\right]<\infty;\ \tilde K^+ \text{ is continuous nondecreasing and } \tilde K^+_0=0;\\ Y_s=Y_\delta+\int_s^\delta\varphi(u,Y_u,\tilde Z_u)du+(\tilde K^+_\delta-\tilde K^+_s)-\int_s^\delta\tilde Z_u dB_u\ \forall s\in[0,\delta];\\ \int_0^\delta(Y_s-L_s)d\tilde K^+_s=0.\end{cases}$$

Proof. We know that the process $K^{-,n}$ of (11) moves only when Y^n reaches the barrier U; therefore for any $n\geq 0$ and $s\in[0,\delta]$ we have

$$Y^n_s=Y^n_\delta+\int_s^\delta\varphi(u,Y^n_u,Z^n_u)du+n\int_s^\delta(L_u-Y^n_u)^+du-\int_s^\delta Z^n_u dB_u$$

since $\delta\leq\delta^n$. As $\lim_{n\to\infty}E[|Y^n_\delta-Y_\delta|^2]=0$ and $Y_\delta\geq L_\delta$, the sequences

$$((Z^n_s1_{[s\leq\delta]})_{s\leq T})_{n\geq 0}\text{ and }\left(\left(n\int_0^{s\wedge\delta}(L_u-Y^n_u)^+dr\right)_{s\leq T}\right)_{n\geq 0}$$

converge, respectively, in $\mathcal{H}^{2,m}$ and $\mathcal{S}^2$ to $\tilde Z$ and $\tilde K^+$. In addition we have $\int_0^\delta(Y_u-L_u)d\tilde K^+_u=0$. The proof of those claims is the same as the proof of Theorem 5.2 in [12] in the part related to the penalization method (6th paragraph). The minor changes are that the terminal time is a bounded stopping time and that the terminal value Y^n_δ depends on n. But we have $\lim_n\to\infty Y^n_\delta=Y_\delta\geq L_\delta$. Therefore those changes are irrelevant. It follows that $(Y,\tilde Z,\tilde K^+)$ satisfies (16). □

Next for $n\geq 0$ and ν a stopping time let $\theta^n_\nu=\inf\{s\geq\delta_\nu,Y^n_s\leq L_s\}\wedge T$. Since $Y^n\leq Y^{n+1}$, then $\theta^n_\nu\leq\theta^{n+1}_\nu$; therefore $\theta^n_\nu\to\theta_\nu$ as $n\to\infty$ and θ_ν is also a stopping time. In what follows, θ_0 will be simply denoted θ.

Let us deal with the convergence of $Y^n_{t\wedge\theta^n}$ for $t \in [\delta, \theta]$.

PROPOSITION A.3. *P-a.s. we have*

(i) *for any* $t \in [\delta, \theta[$, $Y^n_{t\wedge\theta^n} \to Y_t$ *as* $n \to \infty$;

(ii) *on the set* $[Y_\delta = L_\delta]$ *(resp.,* $[Y_\delta > L_\delta]$*),* $Y^n_{\theta^n} \to Y_\theta$ *(resp.,* $L_\theta 1_{[\theta<T]} + \xi 1_{[\theta=T]}$*) as* $n \to \infty$.

Proof. (i) Let ω be fixed. If $t \in [\delta(\omega), \theta(\omega)[$, then there exists an $n_0(\omega)$ such that for $n \geq n_0$ we have $\theta^n \geq t$ and $Y^n_{t\wedge\theta^n} = Y^n_t \to Y_t$. Let us focus on (ii). If $\omega \in [Y_\delta = L_\delta]$, one has $\theta^n(\omega) = \delta(\omega)$ and $\theta(\omega) = \delta(\omega)$, since $Y^n \leq Y$. It follows that $Y^n_{\theta^n}(\omega) = Y^n_\delta(\omega) = Y^n_\theta(\omega) \to Y_\theta(\omega) = Y_\delta(\omega)$. Assume instead $\omega \in [Y_\delta > L_\delta]$. As $Y^n \nearrow Y$, there exists $n_1(\omega)$ such that for $n \geq n_1(\omega)$ we have $Y^n_\delta(\omega) > L_\delta(\omega)$. The continuity of Y^n and L implies that for $n \geq n_1$, $\theta^n(\omega) > \delta(\omega)$. Let us now write

$$Y^n_{\theta^n} = Y^n_{\theta^n} 1_{[\theta<T]} + Y^n_{\theta^n} 1_{[\theta=T]}.$$

We note that for $n \geq n_1$, $Y^n_{\theta^n} 1_{[\theta<T]} = L_{\theta^n} 1_{[\theta<T]} \to L_\theta 1_{[\theta<T]}$, while $Y^n_{\theta^n} 1_{[\theta=T]} \to \xi 1_{[\theta=T]}$ as $n \to \infty$. To see the latter, suppose there exists $k(\omega)$ such that $Y^k(\omega)$ does not reach $L(\omega)$ after $\delta(\omega)$. Then for $n \geq k$, we have $\theta_n(\omega) = T$ since $Y^k \leq Y^n$; therefore $Y^n_{\theta^n} 1_{[\theta=T]} \to \xi 1_{[\theta=T]}$. Otherwise, for any $n \geq 0$, $Y^n(\omega)$ reaches $L(\omega)$ after $\delta(\omega)$; this implies $\theta(\omega) = T$ and necessarily $L_T(\omega) = \xi(\omega)$, and thus at least for $n \geq n_1$, $Y^n_{\theta^n} 1_{[\theta=T]} = L_{\theta^n} 1_{[\theta=T]} \to \xi 1_{[\theta=T]}$.

It follows that for $\omega \in [Y_\delta > L_\delta]$, $Y^n_{\theta^n} \to L_\theta 1_{[\theta<T]} + \xi 1_{[\theta=T]}$, as $n \to \infty$. □

On $[\delta, \theta]$, the process Y satisfies a BSDE with one upper reflecting barrier. Specifically we have the following proposition.

PROPOSITION A.4.

(i) *P-a.s.* $Y_\theta 1_{[\theta<T]} = L_\theta 1_{[\theta<T]}$.

(ii) *There exist two processes* $\tilde{Z}^1 \in \mathcal{H}^{2,m}$ *and a nondecreasing* $\tilde{K}^{1-} \in \mathcal{S}^2$ *with* $\tilde{K}^{1-}_\delta = 0$ *such that*

$$\text{(17)} \quad \begin{cases} \forall t \in [\delta, \theta],\ Y_t = Y_\theta + \displaystyle\int_t^\theta \varphi(s, Y_s, \tilde{Z}^1_s) ds - (\tilde{K}^{1-}_\theta - \tilde{K}^{1-}_t) - \int_t^\theta \tilde{Z}^1_s dB_s; \\ \displaystyle\int_\delta^\theta (Y_s - U_s) d\tilde{K}^{1-}_s = 0. \end{cases}$$

(iii) *P-a.s.* $Y_\delta 1_{[\delta<T]} = U_\delta 1_{[\delta<T]}$.

Proof. Let us set $\zeta := \lim_{n\to\infty} Y^n_{\theta^n} = Y_\theta 1_{[Y_\delta = L_\delta]} + (L_\theta 1_{[\theta<T]} + \xi 1_{[\theta=T]}) 1_{[Y_\delta > L_\delta]}$ and let us consider a $(Y', \tilde{Z}', \tilde{K}'^-)$ solution of the BSDE with one upper barrier U on $[0, \theta]$, i.e.,

$$\text{(18)} \quad \begin{cases} Y',\ \tilde{K}'^- \in \mathcal{S}^2, \tilde{Z}' \in \mathcal{H}^{2,m}; \tilde{K}'^- \text{ is nondecreasing and } \tilde{K}'^-_0 = 0; \\ \forall t \leq \theta,\ Y'_t = \zeta + \displaystyle\int_t^\theta \varphi(s, Y_s, \tilde{Z}'_s) ds - (\tilde{K}'^-_\theta - \tilde{K}'^-_t) - \int_t^\theta \tilde{Z}'_s dB_s; \\ \forall t \leq \theta, Y'_t \leq U_t \text{ and } \displaystyle\int_0^\theta (Y'_s - U_s) d\tilde{K}'^-_s = 0. \end{cases}$$

Let us emphasize that in the arguments of φ we have Y and not Y'.

To begin, we show that P-a.s. $\forall t \leq T, Y^n_{(t\vee\delta)\wedge\theta^n} \to Y'_{(t\vee\delta)\wedge\theta}$ as $n \to \infty$. From (11), for $n \geq 0$ and $t \in [\delta, \theta]$ we have

$$Y^n_{t\wedge\theta^n} = Y^n_{\theta^n} + \int_t^\theta 1_{[s\leq\theta^n]} \varphi(s, Y^n_s, Z^n_s) ds - (K^{-,n}_{\theta^n} - K^{-,n}_{t\wedge\theta^n}) - \int_t^\theta 1_{[s\leq\theta^n]} Z^n_s dB_s$$

since either $\theta^n = \delta$ or $Y_t^n \geq L_t$ for $t \in [\delta, \theta^n]$. Using Itô's formula for $t \in [\delta, \theta]$ we get

$$\begin{aligned}
&(Y_{t\wedge\theta^n}^n - Y_t')^2 + \int_t^\theta |Z_s^n 1_{[s\leq\theta^n]} - \tilde{Z}_s'|^2 ds = (Y_{\theta^n}^n - \zeta)^2 \\
&+ 2\int_t^\theta (Y_{s\wedge\theta^n}^n - Y_s')\{1_{[s\leq\theta^n]}\varphi(s, Y_s^n, Z_s^n) \\
&- \varphi(s, Y_s, \tilde{Z}_s')\}ds - 2\int_t^\theta (Y_{s\wedge\theta^n}^n - Y_s')(dK_{s\wedge\theta^n}^{-,n} - d\tilde{K}_s'^{-}) \\
&- 2\int_t^\theta (Y_{s\wedge\theta^n}^n - Y_s')(1_{[s\leq\theta^n]}Z_s^n - \tilde{Z}_s')dB_s.
\end{aligned}$$

But for $t \in [\delta, \theta^n]$,

$$\begin{aligned}
&\int_t^\theta (Y_{s\wedge\theta^n}^n - Y_s')(dK_{s\wedge\theta^n}^{-,n} - d\tilde{K}_s'^{-}) \\
&= \int_t^{\theta^n} (Y_s^n - Y_s')(dK_s^{-,n} - d\tilde{K}_s'^{-}) - \int_{\theta^n}^\theta (Y_{\theta^n}^n - Y_s')d\tilde{K}_s'^{-} \\
&\geq -\int_{\theta^n}^\theta (Y_{\theta^n}^n - Y_s')d\tilde{K}_s'^{-} \geq -2\sup_{s\leq\theta}|U_s|(\tilde{K}_\theta'^{-} - \tilde{K}_{\theta^n}'^{-})
\end{aligned}$$

due to $\int_t^{\theta^n}(Y_s^n - Y_s')(dK_s^{-,n} - d\tilde{K}_s'^{-}) \geq 0$. On the other hand, for $t \in [\theta^n, \theta]$,

$$\int_t^\theta (Y_{s\wedge\theta^n}^n - Y_s')(dK_{s\wedge\theta^n}^{-,n} - d\tilde{K}_s'^{-}) = -\int_t^\theta (Y_{\theta^n}^n - Y_s')d\tilde{K}_s'^{-} \geq -2\sup_{s\leq\theta}|U_s|(\tilde{K}_\theta'^{-} - \tilde{K}_{\theta^n}'^{-}).$$

Therefore for any $t \in [\delta, \theta]$ we have

$$\begin{aligned}
&(Y_{t\wedge\theta^n}^n - Y_t')^2 + \int_t^\theta |Z_s^n 1_{[s\leq\theta^n]} - \tilde{Z}_s'|^2 ds \leq (Y_{\theta^n}^n - \zeta)^2 + 4\sup_{s\leq\theta}|U_s|(\tilde{K}_\theta'^{-} - \tilde{K}_{\theta^n}'^{-}) \\
&+ 2\int_t^\theta (Y_{s\wedge\theta^n}^n - Y_s')(1_{[s\leq\theta^n]}\varphi(s, Y_s^n, Z_s^n) - \varphi(s, Y_s, \tilde{Z}_s'))ds \qquad (19) \\
&- 2\int_t^\theta (Y_{s\wedge\theta^n}^n - Y_s')(1_{[s\leq\theta^n]}Z_s^n - \tilde{Z}_s')dB_s.
\end{aligned}$$

For $t \in [\delta, \theta]$, the following estimate holds true:

$$\begin{aligned}
&\int_t^\theta (Y_{s\wedge\theta^n}^n - Y_s')(1_{[s\leq\theta^n]}\varphi(s, Y_s^n, Z_s^n) - \varphi(s, Y_s, \tilde{Z}_s'))ds \\
&= \int_t^\theta (Y_{s\wedge\theta^n}^n - Y_s')[1_{[s\leq\theta^n]}(\varphi(s, Y_s^n, Z_s^n) - \varphi(s, Y_s, \tilde{Z}_s')) + (1_{[s\leq\theta^n]} - 1)\varphi(s, Y_s, \tilde{Z}_s')]ds \\
&\leq \int_t^\theta \{C1_{[s\leq\theta^n]}|Y_{s\wedge\theta^n}^n - Y_s'|(|Y_s^n - Y_s| + |Z_s^n - \tilde{Z}_s'|) \\
&\qquad + |1_{[s\leq\theta^n]} - 1||\varphi(s, Y_s, \tilde{Z}_s')||Y_{s\wedge\theta^n}^n - Y_s'|\}ds \\
&\leq \int_t^\theta \left\{C|Y_{s\wedge\theta^n}^n - Y_s'|^2 + C|Y_{s\wedge\theta^n}^n - Y_s|^2 + \frac{1}{4}|Z_s^n 1_{[s\leq\theta^n]} - \tilde{Z}_s'|^2\right\} ds \\
&\qquad + \int_t^\theta |1_{[s\leq\theta^n]} - 1||\varphi(s, Y_s, \tilde{Z}_s')||Y_{s\wedge\theta^n}^n - Y_s'|ds,
\end{aligned}$$

where C is a constant independent of n, which may change from one line to another. Substituting in (19) and replacing t by $(t \vee \delta) \wedge \theta$ for $t \in [0,T]$, we obtain

$$
\begin{aligned}
&(Y^n_{(t\vee\delta)\wedge\theta^n} - Y'_{(t\vee\delta)\wedge\theta})^2 + \frac{3}{4}\int_{(t\vee\delta)\wedge\theta}^{\theta} |Z^n_s 1_{[s\le\theta^n]} - \tilde{Z}'_s|^2 ds \\
&\le (Y^n_{\theta^n} - \zeta)^2 + 4\sup_{s\le\theta}|U_s|(\tilde{K}'^-_\theta - \tilde{K}'^-_{\theta^n}) \\
&+ \int_{(t\vee\delta)\wedge\theta}^{\theta} \{C|Y^n_{s\wedge\theta^n} - Y'_s|^2 + C|Y^n_{s\wedge\theta^n} - Y_s|^2\} ds \\
&+ \int_{\delta}^{\theta} |1_{[s\le\theta^n]} - 1||\varphi(s, Y_s, \tilde{Z}'_s)||Y^n_{s\wedge\theta^n} - Y'_s| ds \\
&\quad -2\int_{(t\vee\delta)\wedge\theta}^{\theta} (Y^n_{s\wedge\theta^n} - Y'_s)(1_{[s\le\theta^n]} Z^n_s - \tilde{Z}'_s) dB_s.
\end{aligned} \tag{20}
$$

Taking expectations in *bhs* (both hand sides) and using Gronwall's inequality [15, p. 195] we obtain

$$\forall t \le T,\ E[(Y^n_{(t\vee\delta)\wedge\theta^n} - Y'_{(t\vee\delta)\wedge\theta})^2] \to 0 \text{ as } n \to \infty,$$

since

$$E[(Y^n_{\theta^n}-\zeta)^2 + 2\sup_{s\le\theta}|U_s|(\tilde{K}'^-_\theta - \tilde{K}'^-_{\theta^n}) + \int_\delta^\theta |Y^n_{s\wedge\theta^n} - Y_s|^2 + |1_{[s\le\theta^n]} - 1||\varphi(s, Y_s, \tilde{Z}'_s)|^2 ds] \to 0$$

as $n \to \infty$. Finally in (20), taking the supremum in t, expectations in *bhs*, and using first the Burkholder–Davis–Gundy inequality (see [21, p. 166] or [28, p. 160]) and then the inequality $|a.b| \le \epsilon|a|^2 + \frac{1}{\epsilon}|b|^2$ for any $a, b \in R^k$ and $\epsilon > 0$, we get

$$E\left[\sup_{t\le T} |Y^n_{(t\vee\delta)\wedge\theta^n} - Y'_{(t\vee\delta)\wedge\theta}|^2\right] \to 0 \text{ as } n \to \infty.$$

According to Proposition A.3, for any $t \le T$, $\lim_n \to \infty Y^n_{(t\vee\delta)\wedge\theta^n} = Y_{(t\vee\delta)} 1_{[t<\theta]} + \zeta 1_{[t\ge\theta]}$; therefore uniform convergence implies that the process $(Y_{(t\vee\delta)} 1_{[t<\theta]} + \zeta 1_{[t\ge\theta]})_{t\le T}$ is continuous, and for any $t \le T$ we have $Y'_{(t\vee\delta)\wedge\theta} = Y_{(t\vee\delta)} 1_{[t<\theta]} + \zeta 1_{[t\ge\theta]}$. It follows that for any $t \in [\delta, \theta]$, $Y'_t = Y_t 1_{[t<\theta]} + \zeta 1_{[t=\theta]}$.

Let us show (i). If $\delta = \theta < T$, then for any $n \ge 0$, $\delta = \theta^n = \theta$ and $Y^n_{\theta^n} = Y^n_\delta \le L_\delta$; therefore taking the limit we obtain $Y_\theta = L_\theta$ since $Y_\theta \ge L_\theta$ (Proposition A.1).

Next, suppose that $\delta < \theta < T$ (then $L_\delta < Y_\delta$), and let $(t_n)_{n\ge0}$ be a sequence of real numbers which converges increasingly to θ. Then $\lim_n \to \infty Y_{t_n} = \zeta = L_\theta$ since $\theta < T$ (thanks to A.3(ii)), but the process Y is lower semicontinuous, and thus $Y_\theta \le \lim_n \to \infty Y_{t_n} = L_\theta$. Henceforth we have also $Y_\theta = L_\theta$.

We now focus on (ii). Since $Y_\theta 1_{[\theta<T]} = L_\theta 1_{[\theta<T]}$, then $\zeta = Y_\theta$, and for any $t \in [\delta, \theta]$, $Y'_t = Y_t$. For $t \le T$, let us set $\tilde{Z}^1_t = \tilde{Z}'_t 1_{[\delta\le t\le\theta]}$ and $\tilde{K}^{1-}_t = \tilde{K}'^-_{(t\vee\delta)\wedge\theta} - \tilde{K}'^-_\delta$; therefore the triple $(Y, \tilde{Z}^1, \tilde{K}^{1-})$ satisfies (17). As a by-product we have also the continuity of Y on $[\delta, \theta]$.

Finally, it remains to show that $Y_\delta 1_{[\delta<T]} = U_\delta 1_{[\delta<T]}$. For $\omega \in [Y_\delta > L_\delta] \cap [\delta < T]$ we have $\theta(\omega) > \delta(\omega)$, and since Y is continuous on $[\delta, \theta]$ then $Y_\delta(\omega) =$

$\lim_{n\to\infty} Y_{\delta^n}(\omega) \geq \limsup_{n\to\infty} Y^n_{\delta^n}(\omega) = \lim_{n\to\infty} U_{\delta^n}(\omega) = U_\delta(\omega)$ which implies $Y_\delta(\omega) = U_\delta(\omega)$.

Let us now show that $Y_\delta = U_\delta$ on $[Y_\delta = L_\delta] \cap [\delta < T]$.

For $n \geq 0$, let $\nu^n = \inf\{s \geq \delta, Y^n_s = L_s\} \wedge T$. On $[Y_\delta = L_\delta]$, $\delta \leq \nu^n \leq \delta^n$ for any $n \geq 0$; therefore $\lim_{n\to\infty} \nu^n = \delta$. From (11), for any $n \geq 0$ we have

$$\begin{aligned} 1_{[Y_\delta = L_\delta]} Y^n_{\nu^n} &\geq \left(Y^n_{\delta^n} + \int_{\nu^n}^{\delta^n} \varphi(u, Y^n_u, Z^n_u)du - \int_{\nu^n}^{\delta^n} Z^n_u dB_u \right) 1_{[Y_\delta = L_\delta]} \\ &\geq Y^n_{\delta^n} 1_{[Y_\delta = L_\delta]} + \int_{\nu^n}^{\delta^n} 1_{[Y_\delta = L_\delta]} \varphi(u, Y^n_u, Z^n_u)du - \int_{\nu^n}^{\delta^n} 1_{[Y_\delta = L_\delta]} Z^n_u dB_u \end{aligned}$$

since $n(L_u - Y^n_u)^+ \geq 0$ and $K^{-,n}_{\delta^n} = K^{-,n}_{\nu^n}$ on $[Y_\delta = L_\delta]$. Using (13), we deduce that $E[\int_{\nu^n}^{\delta^n} 1_{[Y_\delta = L_\delta]} \varphi(u, Y^n_u, Z^n_u)du] \to 0$ as $n \to \infty$ since on $[Y_\delta = L_\delta]$, the sequence $(\nu^n - \delta^n)_{n\geq 0} \to 0$, and thus $\liminf_{n\to\infty} E[1_{[Y_\delta = L_\delta]}(Y^n_{\nu^n} - Y^n_{\delta^n})] \geq 0$. But P-a.s. we have

$$1_{[Y_\delta = L_\delta]}(Y^n_{\nu^n} - Y^n_{\delta^n}) = 1_{[Y_\delta = L_\delta]}(Y^n_{\nu^n} - Y^n_{\delta^n}) 1_{[\delta < T]} \to 1_{[Y_\delta = L_\delta]}(L_\delta - U_\delta) 1_{[\delta < T]},$$

and hence using the dominated convergence theorem we obtain

$$\begin{aligned} \liminf_{n\to\infty} E[1_{[Y_\delta = L_\delta]}(Y^n_{\nu^n} - Y^n_{\delta^n})] &= \lim_{n\to\infty} E[1_{[Y_\delta = L_\delta]}(Y^n_{\nu^n} - Y^n_{\delta^n})] \\ &= E[1_{[Y_\delta = L_\delta]}(L_\delta - U_\delta) 1_{[\delta < T]}] \geq 0. \end{aligned}$$

It follows that $1_{[Y_\delta = L_\delta]}(L_\delta - U_\delta) 1_{[\delta < T]} = 0$. □

Remark A.5. The motivation of (iii) is related to the mixed zero-sum stochastic differential game. Loosely speaking, we need to affirm that the process Y reaches U before θ.

We finally give the main result of this section.

For $t \leq T$, let us set $Z_t = \tilde{Z}_t 1_{[t\leq\delta]} + \tilde{Z}^1_t 1_{[\delta<t\leq\theta]}$, $K^+_t = \tilde{K}^+_{t\wedge\delta}$, and $K^-_t = \tilde{K}^{1-}_t$. We can easily see that $Z \in \mathcal{H}^{2,m}$ and that $K^\pm$ are nondecreasing processes belonging to $\mathcal{S}^2$ and verify $K^\pm_0 = 0$. Additionally, we have the following theorem.

THEOREM A.6. *The processes Y, Z, and $K^\pm$ satisfy*

$$(21) \quad \begin{cases} \text{(i) } \forall t \leq \theta, Y_t = Y_\theta + \displaystyle\int_t^\theta \varphi(s, Y_s, Z_s)ds + (K^+_\theta - K^+_t) - (K^-_\theta - K^-_t) \\ \qquad\qquad - \displaystyle\int_t^\theta Z_s dB_s \,;\, Y_T = \xi; \\ \text{(ii) } \forall t \leq \theta, L_t \leq Y_t \leq U_t \;\; \textit{and} \;\; \displaystyle\int_0^\theta (Y_s - L_s)dK^+_s = \int_0^\theta (Y_s - U_s)dK^-_s = 0; \\ \text{(iii) } Y \textit{ is continuous on } [0, \theta]. \end{cases}$$

In addition if $\tau^* = \inf\{s \geq 0, Y_s = U_s\} \wedge T$ and $\sigma^* = \inf\{s \geq 0, Y_s = L_s\} \wedge T$, then P-a.s. $\tau^* \vee \sigma^* \leq \theta$.

Proof. (ii) For any $t \leq T$ we know that $L_t \leq Y_t \leq U_t$ and $Y_T = \xi$. By Lemma A.2, $\int_0^\theta (Y_s - L_s)dK^+_s = \int_0^\delta (Y_s - L_s)dK^+_s = 0$. On the other hand, $\int_0^\theta (Y_s - U_s)dK^-_s = \int_\delta^\theta (Y_s - U_s)dK^-_s = 0$, because of A.4(ii) and the definition of K^-.

(i) If $t \in [\delta, \theta]$, then the equation is satisfied because of A.4(ii) being $K^+_\theta - K^+_t = 0$. Hence for $t \in [0, \delta]$,

$$Y_t = Y_\delta + \int_t^\delta \varphi(s, Y_s, \tilde{Z}_s)ds + (\tilde{K}^+_\delta - \tilde{K}^+_t) - \int_t^\delta \tilde{Z}_s dB_s.$$

On the other hand thanks to A.4(ii) we have

$$Y_\delta = Y_\theta + \int_\delta^\theta \varphi(s, Y_s, \tilde{Z}_s^1)ds - (\tilde{K}_\theta^{1-} - \tilde{K}_\delta^{1-}) - \int_\delta^\theta \tilde{Z}_s^1 dB_s.$$

We plug the latter into the previous one to prove (i), since $K_\delta^+ = K_\theta^+$ and $\tilde{K}_\delta^{1-} = \tilde{K}_t^{1-} = 0$ for any $t \leq \delta$.

Point (iii) is an immediate consequence of (ii).

Finally, let us deal with the last point. If $\theta < T$, the inequality stems from the continuity of Y on $[0, \theta]$ and A.4(i),(iii). If $\theta = T$, this is obvious. □

The proof of Theorem 3.1 for $\nu = 0$ is a direct consequence of the results established in Propositions A.1, A.3, and A.4, Lemma A.2, Remark A.5, and Theorem A.6. When $\nu \neq 0$, in the same way as before, we can construct a solution on the interval $[\nu, \theta_\nu]$, where θ_ν is a stopping time $\geq \nu$, which makes the claim of Theorem 3.1 valid.

Acknowledgments. The author thanks the referees for their helpful comments.

OPTIMAL MEASUREMENT STRATEGY FOR NONLINEAR FILTERING*

N. U. AHMED† AND C. D. CHARALAMBOUS‡

Abstract. In this paper we consider the question of an optimal measurement strategy for nonlinear filtering. Given a set of measurement and observation options, the problem faced by a designer is to choose the option that gives the best nonlinear filter. We develop the necessary conditions of optimality whereby one can determine the best filter.

Key words. nonlinear filtering, conditional density, optimization

1. Introduction.

Throughout this paper, we use the filtered probability space $(\Omega, \mathcal{F}, \mathcal{F}_t, P)$, where the filtration $\mathcal{F}_t, t \geq 0$, is an increasing family of subsigma algebras of the sigma algebra $\mathcal{F}$, which are right continuous having left limits. All the random processes appearing in the equations are assumed to be $\mathcal{F}_t$ adapted.

Consider the system governed by stochastic differential equations of the form

$$\begin{aligned} dx(t) &= f(t, x(t))dt + \sigma(t, x(t))dW(t), \qquad x(0) = \xi, \qquad t \geq 0, \\ dy(t) &= h(t, x(t))dt + \sigma_0(t)dV(t), \qquad\quad y(0) = 0, \qquad t \geq 0, \end{aligned} \tag{1}$$

where the state $x(t) \in R^n$ is the (unobserved) process to be estimated and $y(t) \in R^m$ is the (measurement or) observation process. The processes $\{W, V\}$ are $\{R^d, R^m\}$ valued independent standard Brownian motions; $f : R_0 \times R^n \equiv [0, \infty) \times R^n \to R^n$ and $\sigma : R_0 \times R^n \to M(n \times d)$; the class of $n \times d$ matrices (with entries real) and $h : R_0 \times R^n \to R^m$ and σ_0 is an $m \times m$ matrix valued function; and x_0 is an $\mathcal{F}_0$ measurable vector independent of the Wiener processes W and V.

Let φ be any bounded measurable function on R^n with values in R. The classical problem of nonlinear filtering [8] is to estimate $\varphi(x(t))$ given the history of y up to time t. It is well known that the best (unbiased minimum variance) filter is given by the conditional expectation. That is,

$$\hat{\varphi}(t) = E\{\varphi(x(t))|\mathcal{F}_t^y\} = \int_{R^n} \varphi(\xi) Q_t^y(d\xi), \tag{2}$$

where $\mathcal{F}_t^y \subset \mathcal{F}_t$ denotes the smallest sigma algebra induced by the history of the process y up to time t and Q_t^y is the conditional probability measure of $x(t)$ given this history. In other words, for any Borel measurable set $\Gamma \subset R^n$,

$$Q_t^y(\Gamma) = Prob.\{x(t) \in \Gamma|\mathcal{F}_t^y\}.$$

For any given measurement strategy determined by the function h, it is well known that the probability measure valued process $Q_t^y(\cdot) \equiv Q_t^h(\cdot)$ is governed by the Kushner–Stratonovich equation, which is a nonlinear stochastic partial differential equation [7].

Thus, expression (2) can be written equivalently as

$$\hat{\varphi}^h(t) = E\{\varphi(x(t))|\mathcal{F}_t^y\} = \int_{R^n} \varphi(\xi) Q_t^h(d\xi), \tag{3}$$

emphasizing the dependence of the estimate on the measurement operator. In other words, the estimate strongly depends on the measurement strategy, or measurement devices and techniques, chosen entirely by h that appears in the observation equation. Thus, one may have the option of choosing this from a set of feasible strategies. Let $M \equiv B(R_0 \times R^n, R^m)$ denote the space of bounded Borel measurable maps. Furnished with the sup norm topology, we have

$$\| h \|_0 \equiv \sup\{\| h(t,x) \|, (t,x) \in R_0 \times R^n\},$$

which is a Banach space. Note that the inclusion map $M \hookrightarrow L_\infty(I \times R^n, R^m)$ is continuous. Let M_0 be a closed convex possibly bounded subset of M.

Problem. Our basic problem is to find a measurement strategy $h^o \in M_0$ that produces the best estimate out of all the estimates $\{\hat{\varphi}^h(t), h \in M_0\}$.

This requires a quantitative measure that distinguishes one from the rest. The most suitable measure for this is the entropy. Thus if we can find an admissible h^o that minimizes the entropy associated with the conditional probability measure $Q_t^h, t \geq 0$, we have the best estimator (out of all the best unbiased minimum variance estimates). Entropy measures have been employed in many applications of information theory, an anthology of which is found in [1]. In addition, entropy measures are used in control systems (see, for example, [2]). An application of entropy in estimation and tracking problems is found in [3, 4], while minimax control problems using relative entropy as a payoff are found in [13, 14]. Alternative methods addressing similar problems are found in [11, 12].

Some notation. Let H denote the Hilbert space $L_2(R^n)$ and $\mathcal{H} \equiv H^m$ the Cartesian product of m copies of the Hilbert space H, equipped with the natural inner product and norm. For any pair of Hilbert spaces $\{X, Y\}$, we use $\mathcal{L}(X, Y)$ to denote the Banach space of bounded linear operators from X to Y. In the case when $X = Y$, $\mathcal{L}(X, X) \equiv \mathcal{L}(X)$.

The rest of the paper is organized as follows. In section 2 we present the mathematical formulation of a general optimization problem, which we specialize to our original problem, which motivated this paper in the first place. We develop the necessary conditions of optimality. In section 3 we deal with the original problem. We conclude the paper with some comments and an elementary (one-dimensional) example for illustration.

2. Formulation of the optimization problem. In this section we formulate a general optimization problem and present the necessary conditions of optimality.

If one is willing to work with unnormalized bounded positive measures, one has the unnormalized conditional density equation [5, 6, 9], which is linear. This equation is given by

$$d\mu_t = A^*(t)\mu_t dt + B(h\mu_t) \cdot dy, \quad t \geq 0, \quad \mu_0 = \nu, \tag{4}$$

where A^* is the adjoint of the infinitesimal generator A of the Markov process x, B is simply the multiplicative linear operator

$$B(h\mu) = (\Gamma(t)h)\mu, \quad \text{with} \quad \Gamma(t) = (\sigma_0(t)\sigma_0^*(t))^{-1},$$

and $x \cdot y = (x, y)$ for $x, y \in R^m$. The relationship between Q and μ is simply the normalization factor $\mu_t(1) = \mu_t(R^n)$ which means $Q_t = \mu_t/\mu_t(1)$. Given the initial measure μ_0, one can prove the existence and uniqueness of the solution of this equation in the space of countably additive bounded positive measures [10]. However, if $\mu_0 = \nu$ is absolutely continuous with respect to the Lebesgue measure, with density $q_0 \in H \equiv L_2(R^n)$, then the measure equation (4) is equivalent to the density equation

$$d\rho_t = A^*(t)\rho_t dt + B(h\rho_t) \,.\, dy, \quad t \geq 0, \quad \rho_0 = q_0, \tag{5}$$

and, further, under certain assumptions on the coefficients of the operator A and h, one can prove that, for any finite interval $I = [0, T]$, the evolution equation (5) has a unique solution ρ which belongs to $C(I, H) \cap L_2(I, V) \cap L_\infty(I, H)$ with probability one, where $V = H^1$ is the standard Sobolev space. For more details see [5]. In view of the Girsanov theorem used in the original derivation of (5), it is known that one can replace the observation with a Brownian motion $\hat{W}$ which, without loss of generality, we assume to be a standard Brownian motion. Thus from now on we write (5) as

$$d\rho_t = A^*(t)\rho_t dt + B(h\rho_t) \,.\, d\hat{W}, \quad t \geq 0, \quad \rho_0 = q_0, \tag{6}$$

and formulate the optimization problem using this equation. Let $(\hat{\mathcal{F}}_t, \uparrow, t \geq 0)$ denote the smallest family of increasing subsigma algebras of the sigma algebra $(\mathcal{F}_t, \uparrow, t \geq 0)$ with respect to which $\{\hat{W}(s), 0 \leq s \leq t\}$ is measurable for all $t \geq 0$. Let X denote any Hilbert space and $L_2^e(I, X)$ the Hilbert space of $\hat{\mathcal{F}}_t$ adapted X valued random processes defined on I having square integrable second moments. Let $\bar{R}_0 \equiv [0, \infty]$, $\ell : I \times H \to \bar{R}_0$, and $\Psi : H \to \bar{R}_0$. The objective functional is given by

$$J(h) \equiv E\left\{ \int_0^T \ell(t, \rho_t)dt + \Psi(\rho_T) \right\}. \tag{7}$$

The problem involves finding an $h^o \in M_0$ that minimizes the functional (7) subject to the dynamic constraint (6). In order to develop necessary conditions of optimality for this problem, we need some basic results.

In particular, we present the following lemma which proves the continuous dependence and differentiability of the solution with respect to $h \in M$.

Without loss of generality, we assume that the operator A, and hence A^*, is time invariant. For the time varying case, the semigroup is replaced with the transition operator.

LEMMA 1. *Consider the system* (6) *with initial condition* $\rho_0 = q_0 \in H$. *Suppose* A^* *generates a* C_0 *semigroup* $S(t), t \geq 0$, *in* H *and the operator* B *is the mutiplication operator mapping* H *to* $\mathcal{H} \equiv H^m$, *and let* M_0 *be a closed bounded subset of* M. *Then the solution* ρ *is continuously dependent on* $h \in M_0$ *and once Gâteaux differentiable. Further, the Gâteaux differential of* ρ *at* h^o *in the direction* $h - h^o$, *denoted by* p^o, *has the following properties:* $p^o \in L_2^e(I, H)$, *with sample paths belonging to* $C(I, H)$ *almost surely, and it satisfies the evolution equation*

$$dp^o = A^*p^o dt + B(h^o p^o) \cdot d\hat{W}(t) + B((h - h^o)\rho^o) \cdot d\hat{W}(t), \quad t \in I, \quad p_0^o = 0. \tag{8}$$

Proof. Since $S(t)$ is a semigroup in H, it is clear that there exists a number $K > 0$, possibly dependent on T, such that

$$\sup\{\| S(t) \| \equiv \| S(t) \|_{\mathcal{L}(H)}, t \in I\} \leq K.$$

Let $h^n \in M_0$, and let ρ^n be the corresponding solution of (6). Suppose $h^n \xrightarrow{s} h^o$ in the Banach space M and ρ^o is the solution corresponding to h^0. We show that $\rho^n \xrightarrow{s} \rho^o$ in $L_2^e(I, H)$. Clearly the solutions $\{\rho^n, \rho^0\}$ are mild and given by the solutions of the integral equations

$$\rho^n(t) = S(t)\rho_0 + \int_0^t S(t-s)B(h^n\rho^n) \cdot d\hat{W},$$
$$\rho^o(t) = S(t)\rho_0 + \int_0^t S(t-s)B(h^o\rho^o) \cdot d\hat{W}, \qquad t \in I.$$

Subtracting the second equation from the first, we obtain

$$\rho^n(t) - \rho^o(t) = \int_0^t S(t-r)B(h^n(\rho^n - \rho^o)) \cdot d\hat{W} + \int_0^t S(t-r)B((h^n - h^o)\rho^o) \cdot d\hat{W}, \qquad t \in I. \tag{9}$$

Since $\Gamma(t)$ is bounded and M_0 is a bounded subset of M, there exist constants $c_0, c_1 > 0$ such that

$$E \| \rho^n(t) - \rho^o(t) \|_H^2 \leq 2K^2c_o^2 \int_0^t E \| \rho^n(r) - \rho^o(r) \|_H^2 \, dr + 2K^2c_1^2 \int_0^t E \| (h^n - h^o)\rho^o(r) \|_{\mathcal{H}}^2 \, dr. \tag{10}$$

Since the set M_0 is a bounded subset of M, there exists a number $0 < m_0 < \infty$ such that

$$\sup\{\| h \|_{B(I \times R^n, R^m)}, h \in M_0\} \leq m_0.$$

Hence $c_0 = c_1 m_0$. Using the Gronwall inequality, it follows from inequality (10) that

$$E \| \rho^n(t) - \rho^o(t) \|_H^2 \leq c_3 \int_0^T E \| (h^n - h^o)\rho^o(r) \|_{\mathcal{H}}^2 \, dr \quad \forall \, t \in I, \tag{11}$$

where

$$c_3 = 2K^2c_1^2 \exp\{2K^2c_0^2T\}.$$

Now by virtue of the Lebesgue dominated convergence theorem, it follows from (11) that

$$\rho^n \xrightarrow{s} \rho^o \quad \text{in} \quad L_2^e(I, H).$$

This proves continuous dependence. Next, we prove Gâteaux differentiability. Let $h, h^o \in M_0$. Since M_0 is a closed convex set, the function $h^\varepsilon \equiv h^o + \varepsilon(h - h^o) \in M_0$

also for $\varepsilon \in [0,1]$. Let ρ^o denote the solution of (6) corresponding to h^o and ρ^ε the solution corresponding to h^ε. Define

$$p^\varepsilon \equiv \{(\rho^\varepsilon - \rho^o)/\varepsilon\}.$$

Then one can easily verify that p^ε satisfies the evolution equation (in the mild sense)

$$dp^\varepsilon = A^* p^\varepsilon dt + B(h^o p^\varepsilon) \cdot d\hat{W} + B((h-h^o)\rho^\varepsilon) \cdot d\hat{W}, \qquad p^\varepsilon(0) = 0. \tag{12}$$

Using the (Markov) semigroup, we observe that p^ε must be the solution of the integral equation

$$\begin{aligned} p^\varepsilon(t) = &\int_0^t S(t-r)B(h^o p^\varepsilon(r)) \cdot d\hat{W}(r) \\ &+ \int_0^t S(t-r)B((h-h^o)\rho^\varepsilon(r)) \cdot d\hat{W}(r), \qquad t \in I. \end{aligned} \tag{13}$$

It follows from continuous dependence of solution with respect to h, as proved in the first part of this lemma, that $\rho^\varepsilon \xrightarrow{s} \rho^o$ in $L_2^e(I,H)$ as $\varepsilon \to 0$. This implies that the second integral on the right side of (13) also converges strongly. Thus letting $\varepsilon \downarrow 0$, it follows from the above equation that

$$p^\varepsilon \xrightarrow{s} p^o \quad \text{in} \quad L_2^e(I,H).$$

In other words, p^o is the mild solution of the evolution equation

$$dp^o = A^* p^o dt + B(h^o p^o) \cdot d\hat{W}(t) + B((h-h^o)\rho^o) \cdot d\hat{W}(t), \quad p^o(0) = 0, \quad t \in I, \tag{14}$$

which uniquely defines the Gâteaux differential of ρ at h^o in the direction $(h-h^o)$. This completes the proof. □

Remark 1. Since $H \equiv L_2(R^n)$ is a Hilbert space, both $T(t)$ and its adjoint $S(t) = T^*(t)$ are strongly continuous bounded linear operators on H. See [6] or any other book on semigroup theory.

Remark 2. Note that the semigroup $S(t), t \geq 0$, is the adjoint of the Markov semigroup $T(t), t \geq 0$, defined by

$$(T(t)\varphi)(\xi) \equiv \int_{R^n} P_t(\xi, dy)\varphi(y),$$

where $P_t(\xi, dy)$ denotes the transition probability measure. Strictly speaking, these semigroups are the continuous extensions of the Markov semigroups from the space of bounded measurable functions $B(R^n)$ to H. Further, they are positive semigroups in the sense that $(T(t)\phi)(\xi) \geq 0$ given that $\phi(\xi) \geq 0$. Since a Markov semigroup is a contraction semigroup, the number K used in Lemmas 1 and 2 can be taken as 1.

Now we are prepared to consider the optimization problem (6)–(7) with the constraints as specified there. Since we are going to consider entropy functionals later and these functionals are concave, we shall not impose any convexity condition on our objective functional. This is compensated by assuming that M_0 is a closed bounded subset of the Banach space $M = B(I \times R^n, R^m)$, implying the boundedness of the solution set as proved in the following lemma.

LEMMA 2. *Suppose A^* and the set $M_0 \subset M$ satisfy the assumptions of Lemma 1. Then, for any $q_0 \in H$ and for every $h \in M_0$, (6) has a unique mild solution*

$\rho^h \in L_2^e(I,H)$. *Further, the solution set* $\mathcal{S} \equiv \{\rho^h, h \in M_0\}$ *is a bounded subset of* $L_2^e(I,H) \cap L_\infty^e(I,H)$.

Proof. Recall that by definition, a mild solution ρ^h must satisfy the integral equation

$$\rho^h(t) = S(t)q_0 + \int_0^t S(t-r)B((h\rho^h)(r)) \cdot d\hat{W}(r), \quad t \in I. \tag{15}$$

We will see that existence and uniqueness of a solution of this integral equation follow from the fact that, for any given $h \in M_0$, $\rho \longrightarrow B(h\rho)$ is a bounded linear (hence Lipschitz) map in H. Indeed, since $q_0 \in H$ and $h \in M_0$, it is easy to verify that the operator G, defined by

$$(G\rho)(t) \equiv S(t)q_0 + \int_0^t S(t-r)(B(h\rho))(r) \cdot d\hat{W}(r), \quad t \in I,$$

maps $L_2^e(I,H)$ into itself. This follows from the inequality

$$\| G\rho \|^2_{L_2^e(I,H)} \leq 2K^2 \big\{ T|q_0|_H^2 + \beta_h^2 \, \| \rho \|^2_{L_2^e(I,H)} \big\},$$

where $\beta_h \equiv \sup\{|\Gamma(t)h(t,x)|_{R^m}, (t,x) \in I \times R^n\}$ and $K \equiv \sup\{\| S(t) \|_{\mathcal{L}(H)}, t \in I\}$. On $L_2^e(I,H)$, we can introduce the metric d given by

$$d^2(\rho,q) \equiv \sup\{E|\rho(s) - q(s)|_H^2, s \in I\}.$$

Clearly, with respect to this metric topology, $L_2^e(I,H)$ is a complete metric space. For $t \in I$, define $d_t^2(\rho,q) \equiv \sup\{E|\rho(r) - q(r)|_H^2, 0 \leq r \leq t\}$. Then using the operator G as defined above, it is easy to verify that

$$d_t^2(G\rho, Gq) \leq K^2\beta_h^2 \int_0^t d_s^2(\rho,q)ds, \quad t \in I. \tag{16}$$

By successive substitution of (16) into itself, after n iterations we obtain

$$d_t^2(G^n\rho, G^nq) \leq ((K^2\beta_h^2 t)^n/n!)d_t^2(\rho,q), \quad t \in I.$$

Since $t \longrightarrow d_t$ is a nondecreasing function, it follows from this that

$$d^2(G^n\rho, G^nq) \leq ((K^2\beta_h^2 T)^n/n!)d^2(\rho,q).$$

Thus for n sufficiently large, the nth iterate G^n of the operator G is a contraction on the metric space $(L_2^e(I,H), d)$, and hence by Banach fixed point theorem, G^n, and hence G itself, has a unique fixed point which we denote by ρ^h. Thus $\rho^h \in L_2^e(I,H)$ is the unique solution of the integral equation (15), and hence, by definition, this is the unique mild solution of (6). Next we verify that the solution set is bounded. Taking the H-norm, it follows from (15) that

$$E \, \| \rho^h(t) \|^2 \leq 2K^2 E \, \| q_0 \|^2 + 2K^2 \int_0^t E \, \| B(h\rho^h) \|^2_{\mathcal{H}} \, dr, \quad t \in I.$$

Since the set $M_0 \subset B(I \times R^n, R^m)$ is bounded, $c_0 \equiv \{\beta_h, h \in M_0\} < \infty$. Thus it follows from this that

$$E \, \| \rho^h(t) \|^2 \leq 2K^2 E \, \| \rho_0 \|^2 + 2K^2 c_0^2 \int_0^t E \, \| \rho^h(r) \|^2 \, dr, \quad t \in I. \tag{17}$$

Applying the Gronwall lemma, we arrive at the estimate

$$E\,\|\,\rho^h(t)\,\|^2 \le \big(2K^2\exp\big(2K^2c_0^2T\big)\big)E\,\|\,\rho_0\,\|^2, \quad t\in I, \quad \forall\ h\in M_0. \tag{18}$$

Since this is true for all $t\in I$, and for all $h\in M_0$, the solution set $\mathcal{S}$, corresponding to the measurement constraints M_0, is a bounded subset of $L_2^e(I,H)\cap L_\infty^e(I,H)$. This completes the proof. □

Remark 3. It is not clear to us at this time if the solution set $\mathcal{S}$ is closed in $L_2^e(I,H)$. Our conjecture is based on Mazur's theorem which states that a convex set in a locally convex topological space is closed if and only if it is weakly closed, and the fact that the space $B(I\times R^n,R^m)$ is continuously embedded in $L_\infty(I\times R^n,R^m)$ and hence M_0, considered as a subset of $L_\infty(I\times R^n,R^m)$, is a weak star compact subset of the space $L_\infty(I\times R^n,R^m)$.

Here we are interested only in the optimality conditions. Now we are prepared to present the necessary conditions of optimality. This is the main result of this paper.

THEOREM 3. *Suppose the cost integrand ℓ and the terminal cost Ψ of the objective functional* (7) *are once Gâteaux differentiable on H, ℓ is measurable in t on I, and the set of admissible measurement strategies M_0 is a closed bounded convex subset of $M\equiv B(I\times R^n,R^m)$. Then, for a pair $\{h^o,\rho^o\}$, satisfying the evolution equation*

$$d\rho_t^o = A^*\rho_t^o dt + B(h^o\rho_t^o)\,.\,d\hat{W}, \quad t\ge 0, \quad \rho_0 = q_0, \tag{19}$$

to be optimal, it is necessary that there exists a $\psi\in L_2^e(I,H)$ satisfying the adjoint equation

$$d\psi = -A\psi dt + |B(h^o)|^2\psi dt + \ell_\rho(t,\rho^o(t))dt - B(h^o\psi)\cdot d\hat{W}, \tag{20}$$

$$\psi(T) = -\Psi_\rho(\rho_T^o) \tag{21}$$

and the inequality

$$E\int_I (B((h-h^o)\rho^o), B(h^o\psi))_{\mathcal{H}}\ dt \ge 0 \quad \forall\ h\in M_0. \tag{22}$$

Proof. The proof is based on variational arguments. Let $h^o\in M_0$ be the optimal strategy and ρ^0 the solution of the evolution equation (6) corresponding to $h=h^o$. Let $h\in M_0$ be any other element. Since M_0 is a closed convex set, it is evident that

$$h^\varepsilon \equiv h^o + \varepsilon(h-h^o)\in M_0 \quad \forall\ \varepsilon\in[0,1].$$

Let $\rho^\varepsilon\in L_2^e(I,H)$, having sample paths in $C(I,H)$ almost surely, be the solution of (6) corresponding to h^ε replacing h. By optimality of h^o, it is clear that

$$J(h^\varepsilon)\ge J(h^o) \quad \forall\ \varepsilon\in[0,1]. \tag{23}$$

By our assumption, both ℓ and Ψ are Gâteaux differentiable on H and it follows from Lemma 1 that the solutions are once Gâteaux differentiable. Thus the objective functional J is also once Gâteaux differentiable. Denote the Gâteaux differential of J at h^o in the direction $h-h^o$ by $dJ(h^o,h-h^o)$. By letting $\varepsilon\downarrow 0$ to the difference quotient

$$(1/\varepsilon)[J(h^\varepsilon)-J(h^o)]$$

and using Lemma 1, inequality (23), and Fubini's theorem, we arrive at

$$dJ(h^o, h-h^o) = E\left\{\int_I \langle p^o(t), \ell_\rho(t,\rho^o(t))\rangle_H + \langle p^o(T), \Psi_\rho(\rho^o_T)\rangle_H\right\} \geq 0, \tag{24}$$

where we have used ℓ_ρ, Ψ_ρ to denote the first Fréchet derivatives of ℓ and Ψ on H. For h^o to be optimal, it is necessary that this inequality hold for all $h \in M_0$. Recall that p^o is the solution of the variational equation

$$dp^o = A^*p^o dt + B(h^o p^o)\cdot d\hat{W}(t) + B((h-h^o)\rho^o)\cdot d\hat{W}(t), \qquad p^o(0)=0, \quad t\in I. \tag{25}$$

Since p^o has continuous sample paths with probability one, the terminal values are well defined random variables with values in H and have finite second moments. Clearly the map

$$p^o \to dJ(h^o, h-h^o)$$

is a continuous linear map from $L_2^e(I,H)$ to R. Further, it is also clear from the variational equation (25) that the map

$$B((h-h^o)\rho^o) \to p^o$$

is a continuous linear map from $L_2^e(I,H)$ to itself. More precisely, this is a map from the martingale

$$\int_0^t B((h-h^o)\rho^o)\cdot d\hat{W} \to p^o.$$

Hence the composition map

$$B((h-h^o)\rho^o) \to dJ(h^o, h-h^o)$$

is a continuous linear map. Thus by the standard representation theorem for continuous functionals on Hilbert spaces and classical martingale representation theory, there exists a $\psi \in L_2^e(I,H)$ (having almost surely continuous sample paths) determining the intensity of the martingale, $M_t \equiv \int_0^t B(h^o\psi)d\hat{W}, t\geq 0$, dual to the first martingale term of the variational equation (14), such that

$$\begin{aligned} dJ(h^o, h-h^o) &\equiv E\left\{\int_I \langle p^o(t), \ell_\rho(t,\rho^o(t))\rangle_H dt + \langle p^o(T), \Psi_\rho(\rho^o_T)\rangle_H\right\} \\ &= E\int_0^T (B((h-h^o)\rho^o), B(h^o\psi))_{\mathcal{H}}\, dt. \end{aligned} \tag{26}$$

It follows from (24) and (26) that inequality (22) is necessary for h^o to be optimal. It remains to characterize the element ψ. Using the Itô differential of the functional (p^o,ψ) and the variational equation (14), we obtain

$$\begin{aligned} d(p^o,\psi) &= (dp^o,\psi) + (p^o, d\psi) + \langle dp^o, d\psi\rangle \\ &= (A^*p^o + B(h^op^o)\cdot d\hat{W} + B((h-h^o)\rho^o)\cdot d\hat{W}, \psi) + (p^o, d\psi) + \langle dp^o, d\psi\rangle \\ &= (p^o, d\psi + A\psi dt - |B(h^o)|^2\psi dt + B(h^o\psi)\cdot d\hat{W}) \\ &\quad - (B((h-h^o)\rho^o\psi)\cdot d\hat{W}) - (B((h-h^o)\rho^o), B(h^o\psi))_{\mathcal{H}}\, dt, \end{aligned} \tag{27}$$

where we have used the bracket $\langle \cdot, \cdot \rangle$ to denote the quadratic variation term. The formal application of the Itô differential rule can be justified rigorously by Yosida approximation of the unbounded operator A^* by a sequence of bounded operators $A_n^* \equiv nA^*R(n, A^*)$, where $R(\lambda, A^*)$ denotes the resolvent of the operator A^* for $\lambda \in \rho(A^*)$, the resolvent set of A^*. This off course requires some limiting arguments in the process. This is a standard technique used in infinite-dimensional problems with unbounded operators. We do not go into detail here; the interested reader may consult any book on semigroup theory (e.g., [2]). Returning to our problem, by integrating (27) over the interval $I = [0, T]$ and taking the expectation, we obtain

$$E(p^0(T), \psi(T)) = E\Big\{ \int_I (p^o(t), d\psi + A\psi dt - |B(h^o)|^2 \psi dt + B(h^o\psi) \cdot d\hat{W}(t)) \\ - \int (B((h-h^o)\rho^o), B(h^o\psi))_{\mathcal{H}}\, dt \Big\}. \tag{28}$$

Choosing ψ, existence of which is already proved, as any solution of the equation

$$d\psi + A\psi dt - |B(h^o)|^2 \psi dt + B(h^o\psi) \cdot d\hat{W}(t) = \ell_\rho(t, \rho^o(t))dt, \quad t \in I, \tag{29}$$

we find that (28) reduces to

$$-E(p^0(T), \psi(T)) + E\int_I (p^o(t), \ell_\rho(t, \rho^o(t)))\, dt = E\int_I (B((h-h^o)\rho^o), B(h^o\psi))_{\mathcal{H}}\, dt. \tag{30}$$

As it stands, no initial or boundary conditions have been specified so far for (29). Choosing the boundary condition as

$$\psi(T) = -\Psi_\rho(\rho_T^o), \tag{31}$$

(29) determines ψ uniquely. As a result of this choice, (30) takes the form

$$E(p^0(T), \Psi_\rho(\rho^o(T))) + E\int_I (p^o(t), \ell_\rho(t, \rho^o(t)))dt \\ = E\int_I (B((h-h^o)\rho^o), B(h^o\psi))_{\mathcal{H}}\, dt, \tag{32}$$

which coincides with expression (26) as required. In other words, ψ characterized by the adjoint equation (29) with the boundary condition (31) satisfies the identity (26). Combining (24) and (32), we obtain the inequality

$$dJ(h^0, h-h^o) = E\int_0^T (B((h-h^o)\rho^o), B(h^o\psi))_{\mathcal{H}}\, dt \geq 0. \tag{33}$$

Observe that we have now derived all the necessary conditions. Equations (29) and (31) give the adjoint equations (20), (21) as stated in the theorem. Since inequality (33) holds for any $h \in M_0$, we have the necessary inequality (22). This completes the proof. □

Implementation of the necessary conditions. The necessary conditions given by (19)–(22), like the celebrated Pontryagin minimum principle, help to isolate candidates from the set M_0 which contain the optimal. Thus these conditions can be used to construct an optimal measurement strategy h for the measurement channel (see (1)). Necessary conditions for a risk-sensitive payoff in which (6) includes a potential can be derived as well [15].

3. Application to observer design. In this section we apply some results of the previous section to design problems. For illustration we conclude with an elementary example. Our objective is to determine the best observer from a given family of options. The fundamental question is, What should be the appropriate measure that distinguishes one or more members being the best from the given family of options? Before we state the criteria, recall that the mutual information, associated with the random element $x(t)$ and the history of observation $\mathcal{Y}_0^t$ (dependent on the history of x), denoted by $I(x(t), \mathcal{Y}_0^t)$, is given by

$$I(x(t), \mathcal{Y}_0^t) = H(x(t)) - H(x(t)|\mathcal{Y}_0^t), \quad t \geq 0,$$

where $H(x(t))$ denotes the entropy of the random element $x(t)$, and $H(x(t)|\mathcal{Y}_0^t)$ is the conditional entropy of $x(t)$ given the measurement history $\mathcal{Y}_0^t$ up to time t. Since the measurement history depends on the unknown process x, it is natural to choose a measurement strategy that maximizes the mutual information. But since in the filtering or estimation problem considered here nothing can be done to modify the source x, this is equivalent to minimizing the conditional entropy $H(x(t)|\mathcal{Y}_0^t)$. This argument suggests the first of two possible criteria as described below. A related, although alternative formulation, is found in [13].

Entropy functional. In order to reduce uncertainty in our estimates, it seems to be appropriate to minimize the weighted entropy functional given by

$$\Psi(q) = -\int_{R^n} \{q(x) \log q(x)\} \phi(x) dx, \tag{34}$$

where ϕ is a nonnegative continuous bounded function having compact support in R^n. By setting $\phi \equiv 1$, we obtain the classical entropy. In any case, the running cost here is zero, that is, $\ell \equiv 0$. Thus the cost functional is given by

$$J(h) \equiv E\{\Psi(\rho_T^h)\}, \tag{35}$$

where ρ^h denotes the solution of the filtering equation (6) corresponding to the choice of $h \in M_0$. In this case, the adjoint equation is given by

$$\begin{aligned} -d\psi &= A\psi dt - |B(h^o)|^2 \psi dt + B(h^o\psi) \cdot d\hat{W}(t), \qquad t \in I, \\ \psi(T) &= -(1 + \log \rho_T^o)\phi. \end{aligned} \tag{36}$$

Remark 4. In some communication problems, the entropy functional may have to be maximized. Applications requiring source coding, those requiring the jamming of opponents' information exchange capabilities, etc. are some examples in which one wants to maximize uncertainty (information). In this situation, the necessary conditions of optimality (19), (20), (21) remain valid and the inequality (22) is reversed.

Relative entropy. Another possible measure is given by the relative entropy, relative to a given density ν, similar to [14]. Suppose an ideal measure or density $\nu(x), x \in R^n$, is given. Then the objective functional may be taken to be one that measures the closeness of the chosen ρ^h from the desired one. This requires that the elements of the solution set $\mathcal{S} \equiv \{\rho^h, h \in M_0\}$, or a closed subset of this, be absolutely continuous with respect to the desired density ν. Thus we may consider the relative entropy

$$\begin{aligned} J(h) \equiv H(\rho_T^h|\nu) &= \int_{R^n} \log\big(\rho_T^h(x)/\nu(x)\big) \rho_T^h(x) dx \\ &= \int_{R^n} \big\{\rho_T^h(x)/\nu(x)\big\} \big\{\log\big(\rho_T^h(x)/\nu(x)\big)\big\} \nu(x) dx \end{aligned} \tag{37}$$

as the objective functional. The problem involves choosing an $h^o \in M_0$ that minimizes the relative entropy

$$J(h) \equiv H(\rho_T^h|\nu)$$

over the admissible set M_0. Again the adjoint system is given by (36) with the terminal condition given by

$$\psi(T) = -(1 + \log(\rho_T^h/\nu)).$$

Remark 5. Often engineers have a very specific and physically implementable and relatively inexpensive family of measurement options that determine the set $M_{00} \subset M_0$. For example, M_{00} may be described by a family of neural networks

$$M_{00} \equiv \left\{ h \in M_0 : h(t,x) = \sum_{k=1}^{p} \alpha_k(t)\varphi_k(x), x \in R^n \right\},$$

where $\{\varphi_k : R^n \longrightarrow R^m\}$ are the basis functions of the neural network. Note that currently, neural networks are built by the use of a whole class of continuous as well as discontinuous elementary functions, and therefore are able to generate a wide variety of bounded measurable functions. Once a structure is put in, all that the engineer needs to do is choose the weights $\{\alpha_k, k = 1, 2, \ldots, p\}$ optimally. Clearly this set is determined only by a finite number of time dependent functions taking values from a given set $\Lambda \subset R^p$. In fact, one may wish to simplify further and choose constant weights. This can be done relatively easily by the use of the general algorithm given in the previous section. Implementation of an element from M_0 may be expensive and technically difficult. Let $h^* \in M_0$ be an ideal choice and ρ^* the corresponding ideal density. Falling back to the inexpensive and physically implementable class M_{00}, one wishes to make a choice that comes as close as possible to the ideal. Here, one may use the relative entropy $H(\rho^h|\rho^*)$ as the objective functional and choose an h from the set M_{00} that minimizes the objective functional

$$J(h) \equiv H(\rho^h|\rho^*).$$

This is precisely the problem stated above.

Remark 6. Note that we have used unnormalized densities, and thus the entropies and the relative entropies are not the true entropies according to strict definition. In any case, they are related to the normalized densities as follows. Let $e_n(\rho)$ denote the normalized entropy and $e(\rho)$ the unnormalized entropy corresponding to any density ρ. One can easily verify that they are related by the identity

$$e(\rho) = \|\rho\| \, (e_n(\rho) - \log \|\rho\|).$$

Similarly one can verify that the unnormalized relative entropy is related to the normalized by the identity

$$H(\rho|\nu) = H_n(\rho|\nu) + \|\rho\| \log(\|\rho\| \, / \, \|\nu\|),$$

where $\|\rho\| \equiv \int_{R^n} \rho(x)dx$.

An elementary example. Here we present an elementary example to illustrate the basic procedure. Consider a noisy signal $\{x(t), t \geq 0\}$ (vector or scalar valued) which is a Markov diffusion process, in particular an Itô process, with the corresponding infinitesimal generator A. Then there exist a pair of functions $\{b, a\}$ such that the differential generator A and its formal adjoint A^* are given by

$$(A\varphi)(x) \equiv (1/2)a(x)(\partial^2/\partial x^2)\varphi + b(x)(\partial/\partial x)\varphi, \quad x \in R,$$
$$(A^*\varphi)(x) \equiv (1/2)(\partial^2/\partial x^2)(a\varphi) - (\partial/\partial x)(b\varphi), \quad x \in R.$$

Let the measurement process be given by the scalar valued signal $\{y(t), t \in I\}$ generated by a noisy measurement device given by

$$dy = \beta \tanh(F(t)x(t))dt + \sigma_0 dV, \quad \sigma_0 \not\equiv 0.$$

The function $\{F(t), t \geq 0\}$ represents an on-off sampler given by

$$F(t) = \begin{cases} 1 & \text{for } t \in I_i, \quad i = 0, 2, 4, 6, \ldots, \\ 0 & \text{for } t \in I_i, \quad i = 1, 3, 5, \ldots, \end{cases}$$

where the intervals $\{I_i\}$ are mutually disjoint, each having a fixed length with the union covering the positive half of the real line, $\cup_{i=0}^{\infty} I_i = R_+ = [0, \infty)$. The hyperbolic tangent is used to represent a nonlinear (saturating) amplifier and β is the amplifier gain with admissible values $\beta \in [0, \alpha] \equiv \Lambda$. The objective is to find the best amplifier gain $\beta^* \in \Lambda$ that minimizes the terminal entropy given by expression (35). One possible way to compute the optimal solution is by the following algorithm. We start with any arbitrary element $\beta^0 \in \Lambda$ and solve for ρ^0 the density equation

$$d\rho = A^*\rho dt + (1/\sigma_0^2)(h^0\rho) \cdot d\hat{W}, \quad \rho(0) = q_0,$$
$$h^0(t, x) = \beta^0 \tanh(F(t)x).$$

Using the pair (β^0, ρ^0) in the adjoint system

$$-d\psi = A\psi dt - (1/\sigma^0)^4(h^0)^2\psi dt + (1/\sigma^0)^2(h^0\psi) \cdot d\hat{W}$$
$$\psi(T) = -(1 + \log \rho_T^0),$$

we obtain ψ^0. The triple $\{\beta^0, \rho^0, \psi^0\}$ is then used to compute the gradient $\tilde{D}J(\beta^0)$ as follows:

$$\tilde{D}J(\beta^0) \equiv \int_{I \times R} \{E(\rho^0\psi^0)(1/\sigma^0)^4\beta^0(\tanh^2(F(t)x)\}dxdt.$$

Using this gradient, define the next best value for β as follows:

$$\beta^1 = \beta^0 - \varepsilon\tilde{D}J(\beta^0) \quad \text{for } \varepsilon > 0 \quad \text{so that } \beta^1 \in \Lambda,$$

giving

$$h^1(t, x) = \beta^1 \tanh(F(t)x).$$

Using this new value, the iteration starts all over again from step one, giving ρ^1 leading to the pair $\{\beta^1, \rho^1\}$. This is then used for solving the adjoint system yielding ψ^1. The triple $\{\beta^1, \rho^1, \psi^1\}$ is used to compute the gradient $\tilde{D}J(\beta^1)$. These steps produce two sequences $\{\beta^k, J(\beta^k) = J(h^k)\}$. Comparing the difference $|J(\beta^{k+1}) - J(\beta^k)|$ with the specified tolerance, we see that the iteration is stopped if satisfied or continued if not.

Acknowledgments. The authors would like to express their thanks to the anonymous reviewers for their valuable comments.

SHAPE OPTIMIZATION OF AN ELLIPTIC EQUATION IN AN EXTERIOR DOMAIN*

GENGSHENG WANG†, LIJUAN WANG‡, AND DONGHUI YANG†

Abstract. This work concerns the shape optimization problem governed by some elliptic equations in exterior domains. The existence of optimal solutions is obtained and the so-called $\overset{\wedge}{\Gamma}$-property for a family $\mathcal{O}$ of open subsets is established; i.e., if $\Omega_m, \Omega \in \mathcal{O}$ are such that $\Omega_m \to \Omega$ in the Hausdorff metric, then for any $K \subset\subset R^N \setminus \overline{\Omega}$, there exists $m(K) > 0$ such that for all $m \geq m(K), K \subset\subset R^N \setminus \overline{\Omega}_m$.

Key words. shape optimization, exterior domain, elliptic equation

1. Introduction.

Let $D \subset R^N, N \geq 1$, be a given bounded and open subset. We shall study the existence of the following shape optimization problem:

$$(P) \qquad \text{Min}_{\Omega \in \mathcal{O}} \int_{R^N \setminus \overline{\Omega}} J(x, u_\Omega, \ldots, D^l u_\Omega)\, dx$$

subject to

$$(1.1) \qquad \begin{cases} Au_\Omega = f \quad \text{in } R^N \setminus \overline{\Omega}, \\ u_\Omega \in W_0^{l,p}(R^N \setminus \overline{\Omega}). \end{cases}$$

Here $f \in L^q(R^N)$ is a given function with $\frac{1}{p} + \frac{1}{q} = 1$, $1 < p, q < \infty$; $l \geq 1$ is an integer; $\mathcal{O}$ is a certain family of open subsets contained in D, which will be defined in section 2; J is a functional; and A is a nonlinear elliptic operator, which will be made precise in section 3.

There have been many works on the existence theory for shape optimization problems governed by elliptic equations (cf. [3], [4], [5], [7], [9], [10], [11], [13], [14], and [15]). In all these works, the domains in which the elliptic equations are defined are bounded. To the best of our knowledge, the shape optimization problems governed by elliptic equations defined on unbounded domains have not yet been studied. The problem (P) studied in this work is a shape optimization problem governed by elliptic equations on exterior domains. This work is inspired by [14], where the following shape optimization problem was studied:

$$(P_1) \qquad \text{Min}_{\Omega \in \mathcal{O}} \int_{\Omega} J(x, u_\Omega, \ldots, D^l u_\Omega)\, dx$$

subject to

$$\begin{cases} Au_\Omega = f \quad \text{in } \Omega, \\ u_\Omega \in W_0^{l,p}(\Omega). \end{cases}$$

Like most shape optimization problems governed by elliptic equations defined on bounded domains, the existence of optimal shapes for problem (P_1) can be implied by the following (cf. [14], [11]):

(i) If $\{\Omega_m\}_{m=1}^\infty \subset \mathcal{O}$, then there is a subsequence $\{\Omega_{m_k}\}_{k=1}^\infty$ of $\{\Omega_m\}_{m=1}^\infty$ such that $\Omega_{m_k} \to \Omega$ in the Hausdorff metric and $\Omega \in \mathcal{O}$.

(ii) If $\{\Omega_m\}_{m=1}^\infty \subset \mathcal{O}$ and $\Omega \in \mathcal{O}$ are such that $\Omega_m \to \Omega$ in the Hausdorff metric, then for any open subset K with $K \subset\subset \Omega$, i.e., $\overline{K} \subset \Omega$, there is an integer $m(K) > 0$ such that for all $m \geq m(K), K \subset\subset \Omega_m$ (this property is called the Γ-property for $\mathcal{O}$).

(iii) If $\{\Omega_m\}_{m=1}^\infty \subset \mathcal{O}$ and $\Omega \in \mathcal{O}$ are such that $\Omega_m \to \Omega$ in the Hausdorff metric, then $\chi_{\Omega_m} \to \chi_\Omega$ a.e. in R^N.

(iv) If $u \in W^{l,p}(R^N)$ and $u = 0$ a.e. in $R^N \setminus \Omega$ for some $\Omega \in \mathcal{O}$, then $u \in W_0^{l,p}(\Omega)$.

However, conditions (i)–(iv) cannot guarantee the existence of the optimal solutions for problem (P) since the equations in problem (P) are defined on the exterior domains. In this paper, we observe that the existence of the optimal solutions for problem (P) can be implied by (i), (ii), (iv) and the following:

(iii)′ If $\{\Omega_m\}_{m=1}^\infty \subset \mathcal{O}$ and $\Omega \in \mathcal{O}$ are such that $\Omega_m \to \Omega$ in the Hausdorff metric, then for any open subset K with $K \subset\subset R^N \setminus \overline{\Omega}$, there exists an integer $m(K) > 0$ such that for all $m \geq m(K), K \subset\subset R^N \setminus \overline{\Omega}_m$. (This property is called the $\overset{\wedge}{\Gamma}$-property for $\mathcal{O}$.)

Moreover, we establish the $\overset{\wedge}{\Gamma}$-property for $\mathcal{O}$. We must mention that the Γ-property holds for any family of open subsets contained in D, but the $\overset{\wedge}{\Gamma}$-property holds only for certain families of open subsets contained in D, which will be shown in section 2.

2. $\overset{\wedge}{\Gamma}$-property for $\mathcal{O}$. In this section, we shall introduce the family $\mathcal{O}$, which is the same as that in [14], and prove the $\overset{\wedge}{\Gamma}$-property for $\mathcal{O}$.

Let $\Omega \subset R^N$ be a bounded and open subset. We say that Ω is of class $\mathcal{C}$ if the following conditions (2.1), (2.2), and (2.3) are fulfilled. There is a family $\mathcal{F}_\Omega$ of real valued continuous functions g defined on $\overline{S(0, k_\Omega)}$, where $S(0, k_\Omega) \subset R^{N-1}$ is the open ball centered at 0 and is of radius $k_\Omega > 0$ such that

$$\partial\Omega = \bigcup_{g \in \mathcal{F}_\Omega} \{R_g(s, 0) + o_g + g(s)y_g; s \in S(0, k_\Omega)\}. \tag{2.1}$$

Here $o_g \in \partial\Omega$ is a certain point, which gives the center of the local system of axes, and $R_g : R^N \to R^N$ is a certain unitary rotation operator such that $R_g(0, 0, \ldots, 0, 1) = y_g$, where the unit vector y_g gives the local vertical direction. Moreover, for $g \in \mathcal{F}_\Omega$, there is $a_\Omega > 0$ such that

$$R_g(s, 0) + o_g + (g(s) - t)y_g \in \Omega \text{ for all } t \in (0, a_\Omega), \quad s \in S(0, k_\Omega), \tag{2.2}$$

and

$$R_g(s, 0) + o_g + (g(s) + t)y_g \in R^N \setminus \overline{\Omega} \text{ for all } t \in (0, a_\Omega), \quad s \in S(0, k_\Omega). \tag{2.3}$$

Roughly speaking, $\partial\Omega$ is locally the graph of a continuous function satisfying the segment property, and Ω is under the graph.

By the Lebesgue lemma, it follows from (2.1) that there is an $r_\Omega \in (0, k_\Omega)$ such that the restricted local charts defined on $\overline{S(0, r_\Omega)}$ also give a covering of $\partial\Omega$:

$$\partial\Omega = \bigcup_{g\in\mathcal{F}_\Omega} \{R_g(s,0) + o_g + g(s)y_g; s \in \overline{S(0,r_\Omega)}\}. \tag{2.4}$$

Let k_0, r_0, a_0 be positive constants with $r_0 < k_0$. We define $\mathcal{O}(k_0, r_0, a_0)$ to be the family of all open subsets Ω contained in D such that every $\Omega \in \mathcal{O}(k_0, r_0, a_0)$ is of class $\mathcal{C}$ with $k_\Omega \geq k_0, a_\Omega \geq a_0, r_\Omega \leq r_0$, where k_Ω, a_Ω, and r_Ω are given as in (2.1)–(2.4). In what follows, we will write $\mathcal{O}$ for $\mathcal{O}(k_0, r_0, a_0)$ for simplicity of notation. Moreover, we require that the family of functions $\mathcal{F} = \cup_{\Omega\in\mathcal{O}}\mathcal{F}_\Omega$ be equicontinuous and equibounded on $\overline{S(0,k_0)}$.

We define the usual topology on $\mathcal{O}$ by the Hausdorff–Pompeiu distance between the complementary sets, i.e.,

(2.5)
$$\rho(\Omega_1,\Omega_2) = \max\{\sup_{x\in\overline{D}\setminus\Omega_1} d(x, \overline{D}\setminus\Omega_2), \sup_{y\in\overline{D}\setminus\Omega_2} d(\overline{D}\setminus\Omega_1, y)\} \quad \text{for all } \Omega_1,\Omega_2\in\mathcal{O},$$

where $d(\cdot,\cdot)$ denotes the Euclidean metric in R^N. We denote by Hlim the limit in terms of (2.5).

By Theorem 1 of Chapter 3 in [11] and Theorem 2.1 in [14], the following result follows immediately.

LEMMA 2.1. *For any sequence $\{\Omega_n\}_{n=1}^\infty \subset \mathcal{O}$, there are subsequences $\{\Omega_{n_k}\}_{k=1}^\infty$ of $\{\Omega_n\}_{n=1}^\infty$ and $\Omega^* \in \mathcal{O}$ such that $\mathrm{Hlim}_{k\to\infty}\Omega_{n_k} = \Omega^*$.*

In [6] and [8], the Γ-property for $\mathcal{O}$ (indeed for any family of open subsets $\Omega \subset D$) was established.

LEMMA 2.2 (Γ-property for $\mathcal{O}$). *Assume that $\{\Omega_n\}_{n=1}^\infty \subset \mathcal{O}, \Omega_0 \in \mathcal{O}$, and $\Omega_0 = \mathrm{Hlim}\Omega_n$. Then for each open subset K satisfying $\overline{K} \subset \Omega_0$, there exists a positive integer n_K (depending on K) such that $\overline{K} \subset \Omega_n$ for all $n \geq n_K$.*

The next lemma plays a key role in this paper.

LEMMA 2.3 ($\overset{\wedge}{\Gamma}$-property for $\mathcal{O}$). *Assume that $\{\Omega_n\}_{n=1}^\infty \subset \mathcal{O}, \Omega_0 \in \mathcal{O}$, and $\Omega_0 = \mathrm{Hlim}\Omega_n$. Then for any open subset K satisfying $\overline{K} \subset R^N \setminus \overline{\Omega}_0$, there exists a positive integer n_K such that $\overline{K} \subset R^N \setminus \overline{\Omega}_n$ for $n \geq n_K$.*

Proof. Throughout the proof of Lemma 2.3, we shall use $B(x,r)$ and $S(y,r)$ to denote the closed ball with center at x and radius r in R^N and the open ball with center at y and radius r in R^{N-1}, respectively.

Let K be an open subset such that $\overline{K} \subset R^N \setminus \overline{\Omega}_0$. It suffices to prove that there is a neighborhood U_{Ω_0} of $\overline{\Omega_0}$ such that $U_{\Omega_0} \cap \overline{K} = \emptyset$ and $\overline{\Omega}_n \subset U_{\Omega_0}$ for n large enough.

We observe first that

$$\inf_{x\in\overline{K}, y\in\overline{\Omega}_0} d(x,y) \equiv c_0 > 0 \tag{2.6}$$

and there are $\varepsilon_0 > 0$ and a positive integer n_0 such that

$$\left\{x \in \Omega_n : d(x, \partial\Omega_n) \geq \frac{\varepsilon_0}{2}\right\} \neq \emptyset \text{ for } n \geq n_0. \tag{2.7}$$

Indeed, since $\Omega_0 \in \mathcal{O}, \Omega_0 \neq \emptyset$, there exist $x_0 \in \Omega_0$ and $\varepsilon_0 > 0$ such that $B(x_0, \varepsilon_0) \subset \Omega_0$. Hence by Lemma 2.2, there is a positive integer n_0 such that for all $n \geq n_0$, $B(x_0, \varepsilon_0) \subset \Omega_n$. Hence $x_0 \in \{x \in \Omega_n : d(x, \partial\Omega_n) \geq \frac{\varepsilon_0}{2}\}$, and thus (2.7) holds.

Now we take $\varepsilon > 0$ such that $\varepsilon < \frac{1}{2}\min\{\varepsilon_0, a_0, k_0 - r_0, \frac{c_0}{12}\}$. By the equicontinuity of the family $\cup_{\Omega\in\mathcal{O}}\mathcal{F}_\Omega$, there is $0 < \delta(\varepsilon) < \frac{\varepsilon}{2}$ such that

$$|g(s) - g(\widetilde{s})| < \frac{\varepsilon}{2} \quad \text{for all } g \in \mathcal{F}_\Omega \text{ and } \Omega \in \mathcal{O}, \tag{2.8}$$
$$\text{for all } s, \widetilde{s} \in S(0, k_0) \text{ and } |s - \widetilde{s}\,|_{R^{N-1}} \le \delta(\varepsilon).$$

Let $\Omega_n^1 = \{x \in \Omega_n : d(x, \partial\Omega_n) \ge \frac{\delta(\varepsilon)}{2}\}$ and $\Omega_n^2 = \{x \in \Omega_n : d(x, \partial\Omega_n) < \frac{\delta(\varepsilon)}{2}\}$. It is clear that by (2.7), $\Omega_n^1 \ne \emptyset$ for all $n \ge n_0$.

First we claim that

$$\Omega_n^1 \subset \overline{\Omega}_0 \subset \left\{x \in R^N : d(x, \overline{\Omega}_0) \le \frac{c_0}{12}\right\}. \tag{2.9}$$

In order to prove (2.9), we observe that

$$R^N \Big\backslash \left((\overline{D} \setminus \Omega_n) + \frac{\delta(\varepsilon)}{4}B(0,1)\right) \subset R^N \setminus (\overline{D} \setminus \Omega_0) \subset (R^N \setminus \overline{D}) \cup \overline{\Omega}_0. \tag{2.10}$$

Indeed, since $\Omega_0 = \mathrm{Hlim}\Omega_n$, we have that (see page 48 of [12])

$$\inf\{\lambda \ge 0 | \overline{D} \setminus \Omega_n \subset (\overline{D} \setminus \Omega_0) + \lambda B(0,1), \overline{D} \setminus \Omega_0 \subset (\overline{D} \setminus \Omega_n) + \lambda B(0,1)\} \to 0 \text{ as } n \to \infty.$$

Thus there is a positive integer $n_0(\varepsilon) \ge n_0$ such that for all $n \ge n_0(\varepsilon)$,

$$\inf\{\lambda \ge 0 | \overline{D} \setminus \Omega_n \subset (\overline{D} \setminus \Omega_0) + \lambda B(0,1), \overline{D} \setminus \Omega_0 \subset (\overline{D} \setminus \Omega_n) + \lambda B(0,1)\} \le \frac{\delta(\varepsilon)}{8},$$

and then for each $n \ge n_0(\varepsilon)$, there is a λ_n with $0 \le \lambda_n \le \frac{\delta(\varepsilon)}{4}$ such that

$$\overline{D} \setminus \Omega_0 \subset (\overline{D} \setminus \Omega_n) + \lambda_n B(0,1) \subset (\overline{D} \setminus \Omega_n) + \frac{\delta(\varepsilon)}{4}B(0,1),$$

from which the first inclusion in (2.10) follows. The second inclusion in (2.10) is obvious.

Then we prove that

$$\Omega_n^1 \subset R^N \Big\backslash \left((\overline{D} \setminus \Omega_n) + \frac{\delta(\varepsilon)}{4}B(0,1)\right) \text{ for all } n \ge n_0(\varepsilon). \tag{2.11}$$

By contradiction, we assume that there exists $x_n \in \Omega_n^1$ and $x_n \in (\overline{D}\setminus\Omega_n) + \frac{\delta(\varepsilon)}{4}B(0,1)$. It follows from the latter that

$$x_n = y_n + \frac{\delta(\varepsilon)}{4}z_n \text{ for some } y_n \in \overline{D} \setminus \Omega_n \text{ and } z_n \in B(0,1).$$

Hence $d(x_n, y_n) \le \frac{\delta(\varepsilon)}{4}$. By Lemma A in the appendix, there exists $w_n \in \partial\Omega_n$ satisfying $d(x_n, w_n) \le d(x_n, y_n) \le \frac{\delta(\varepsilon)}{4}$, which leads to a contradiction and implies (2.11) as desired.

Notice that $\Omega_n \subset D$ for all $n \ge 1$. Equation (2.9) follows immediately from (2.10) and (2.11).

Next we claim that

$$\Omega_n^2 \subset \left\{x \in R^N : \ d(x, \overline{\Omega}_0) \le \frac{c_0}{12}\right\}. \tag{2.12}$$

Let $n \geq n_0(\varepsilon)$ be arbitrary but fixed and let $x \in \Omega_n^2$. It suffices to find $z \in \overline{\Omega}_0$ such that $d(x,z) \leq \frac{c_0}{12}$.

To this end, we notice that there exists $y \in \partial\Omega_n$ such that

$$d(x,y) = d(x,\partial\Omega_n) < \frac{\delta(\varepsilon)}{2}. \tag{2.13}$$

By (2.4), there is a $g \in \mathcal{F}_{\Omega_n}$ and an $s_n \in \overline{S(0,r_n)}$ such that

$$y = R_g(s_n,0) + o_g + g(s_n)y_g.$$

By (2.8), we get that

$$-\frac{\varepsilon}{2} < g(s) - g(s_n) < \frac{\varepsilon}{2} \quad \text{for all } s \in S(0,k_0) \cap \overline{S\left(s_n, \frac{\delta(\varepsilon)}{2}\right)},$$

which, together with (2.2), implies that

$$\begin{aligned}
&\left\{R_g(s,0) + o_g + (g(s_n) - t)y_g \in R^N : \ s \in S(0,k_0) \cap \overline{S\left(s_n, \frac{\delta(\varepsilon)}{2}\right)}, \right. \\
&\qquad\qquad \left. t \in \left[\frac{\varepsilon}{2}, a_0 - \frac{\varepsilon}{2}\right]\right\} \\
&= \left\{R_g(s,0) + o_g + g(s)y_g - (g(s) - g(s_n) + t)y_g \in R^N : \right. \\
&\qquad\qquad \left. s \in S(0,k_0) \cap \overline{S\left(s_n, \frac{\delta(\varepsilon)}{2}\right)}, \ t \in \left[\frac{\varepsilon}{2}, a_0 - \frac{\varepsilon}{2}\right]\right\} \\
&\subset \left\{R_g(s,0) + o_g + (g(s) - t)y_g \in R^N : \ s \in S(0,k_0) \cap \overline{S\left(s_n, \frac{\delta(\varepsilon)}{2}\right)}, t \in (0,a_0)\right\} \\
&\subset \Omega_n.
\end{aligned} \tag{2.14}$$

Since $s_n \in \overline{S(0,r_n)}$, $r_n \leq r_0 < k_0$, and $0 < 2\delta(\varepsilon) < \varepsilon < \frac{k_0 - r_0}{2}$, we get

$$\overline{S\left(s_n, \frac{\delta(\varepsilon)}{2}\right)} \subset S(0,k_0).$$

Then by (2.14), we have that

$$\left\{R_g(s,0) + o_g + (g(s_n) - t)y_g \in R^N : \ s \in \overline{S\left(s_n, \frac{\delta(\varepsilon)}{2}\right)}, t \in \left[\frac{\varepsilon}{2}, a_0 - \frac{\varepsilon}{2}\right]\right\} \subset \Omega_n. \tag{2.15}$$

Now we take $z = R_g(s_n,0) + o_g + (g(s_n) - \varepsilon)y_g$. Since $0 < 2\delta(\varepsilon) < \varepsilon < \frac{a_0}{2}$, it follows from (2.15) that

$$z \in \Omega_n, \ \ d(z,\partial\Omega_n) \geq \min\left\{\frac{\delta(\varepsilon)}{2}, \frac{\varepsilon}{2}, a_0 - \frac{3\varepsilon}{2}\right\} = \frac{\delta(\varepsilon)}{2} \tag{2.16}$$

and

$$d(y,z) = \varepsilon. \tag{2.17}$$

By (2.13) and (2.17), we have that

$$d(x,z) \le d(x,y) + d(y,z) \le 2\varepsilon \le \frac{c_0}{12}.$$

By (2.9) and (2.16), we get $z \in \overline{\Omega}_0$. Thus we have proved (2.12).

By (2.9) and (2.12), we get that

$$\overline{\Omega}_n \subset \left\{ x \in R^N : d(x, \overline{\Omega}_0) \le \frac{c_0}{12} \right\}.$$

Take $U_{\Omega_0} = \left\{ x \in R^N : d(x, \overline{\Omega}_0) < \frac{c_0}{6} \right\}$. Then by (2.6), we have that

$$U_{\Omega_0} \cap \overline{K} = \emptyset \text{ and } \overline{\Omega}_n \subset U_{\Omega_0}.$$

This completes the proof. □

Finally, we shall show by a counterexample that the $\overset{\wedge}{\Gamma}$-property may not hold for some family $\widetilde{O}$ of open subsets $\Omega \subset D$, even though each Ω in $\widetilde{O}$ is of class $\mathcal{C}$.

Example. Let

$$D = \{(x,y) \in R^2 : |x| < 2, |y| < 2\}, \quad \widetilde{\mathcal{O}} = \{\Omega \subset D : \Omega \text{ is open and of class } \mathcal{C}\},$$

$$\Omega_0 = \left\{ (x,y) \in R^2 : 0 < y < 1 - |x|, \frac{1}{2} < |x| < 1 \right\} \cup \left\{ (x,y) \in R^2 : |x| \le \frac{1}{2}, 0 < y < \frac{1}{2} \right\},$$

$$\Omega_n = \Omega_0 \cup \left\{ (x,y) \in R^2 : \frac{1}{2} \le y < 1 - n|x|, |x| < \frac{1}{2n} \right\}, \qquad n \ge 1,$$

and

$$K = \left\{ (x,y) \in R^2 : |x| < \frac{3}{2}, |y| < 1 \right\} \Big\backslash \left\{ (x,y) \in R^2 : |x| \le \frac{5}{4}, |y| \le \frac{3}{4} \right\}.$$

One can easily check that

(i) $\Omega_0 \in \widetilde{\mathcal{O}}$ and $\Omega_n \in \widetilde{\mathcal{O}}, n = 1, 2, \ldots$;

(ii) $\Omega_0 = \text{Hlim}\Omega_n$;

(iii) $\overline{K} \subset R^N \setminus \overline{\Omega}_0$, but $\overline{K} \cap \overline{\Omega}_n \ne \emptyset$ for any $n \ge 1$.

Thus $\widetilde{\mathcal{O}}$ has no $\overset{\wedge}{\Gamma}$-property.

Figures 1–3 show the regions Ω_0, Ω_n, and $\overline{K}$.

3. Existence of optimal shape for problem (*P*). In this section, we shall first introduce the elliptic operator A and cost functional J in problem (P) given in section 1, and then prove the existence of an optimal shape for problem (P).

Let A be a differential operator from $W^{l,p}(R^N)$ to $W^{-l,q}(R^N)$ defined by

$$Az = \sum_{|\alpha| \le l} (-1)^{|\alpha|} D^\alpha A_\alpha(x, z, \ldots, D^l z), \quad x \in R^N. \tag{3.1}$$

Here α is a multi-index such that $|\alpha| \le l$ and $A_\alpha : R^N \times R^T \to R$ (T is the number of all partial derivatives in R^N from the order 0 to the order l) satisfies the following:

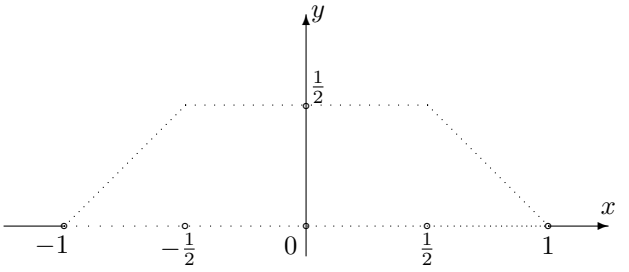

FIG. 1. Ω_0 *is the region surrounded by imaginary lines.*

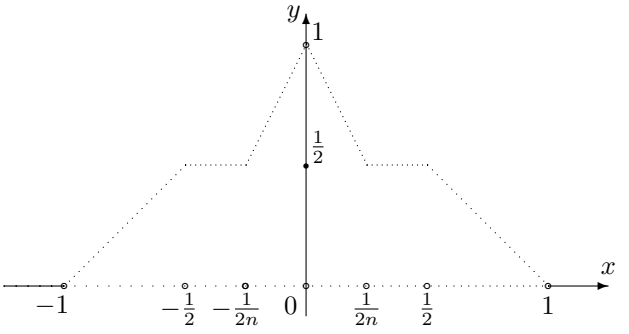

FIG. 2. Ω_n *is the region surrounded by imaginary lines.*

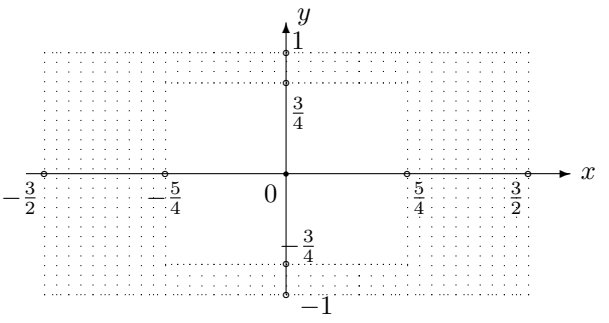

FIG. 3. K *is the region occupied by imaginary lines.*

(H_1) For each multi-index α, A_α is measurable in $x \in R^N$ and continuous in the other variables (denoted by $\xi \in R^T$) as follows:

$$|A_\alpha(x,\xi)| \le c_1(|\xi|_{R^T}^{p-1} + \mu(x)), \quad x \in R^N, \quad \xi \in R^T,$$

where $\mu \in L^q(R^N)$ is a given function, $\xi = (\xi_\alpha)_{|\alpha|\le l}$, and c_1 is a positive constant independent of α.

(H_2) There exists a positive constant c_2 such that for almost all $x \in R^N$ and all $\xi, \eta \in R^T$,

$$\sum_{|\alpha|\le l} (A_\alpha(x,\xi) - A_\alpha(x,\eta))(\xi_\alpha - \eta_\alpha) \ge c_2|\xi - \eta|_{R^T}^p.$$

(H_3) There exists a positive constant c_3 such that for almost all $x \in R^N$ and all $\xi \in R^T$,

$$\sum_{|\alpha|\le l} A_\alpha(x,\xi)\xi_\alpha \ge c_3\Big(\sum_{|\alpha|=l} |\xi_\alpha|^p + |\xi_0|^p\Big),$$

where $\xi_0 \equiv \xi_\alpha$ with $\alpha = 0$ is the component of ξ corresponding to the 0 order partial derivative, and $\xi_\alpha, |\alpha| = l$, are the components of ξ corresponding to the highest order partial derivatives.

Let $\mathcal{O}$ be given as in section 2 and let $\Omega \in \mathcal{O}$. We say $u_\Omega \in W_0^{l,p}(R^N \setminus \overline{\Omega})$ is a weak solution of (1.1) if

$$\sum_{|\alpha|\le l} \int_{R^N\setminus\overline{\Omega}} A_\alpha(x, u_\Omega, \dots, D^l u_\Omega)\cdot D^\alpha v\, dx = \int_{R^N\setminus\overline{\Omega}} f\cdot v\, dx \tag{3.2}$$

for all $v \in W_0^{l,p}(R^N \setminus \overline{\Omega})$.

THEOREM 3.1. *Under assumptions* $(H_1)-(H_3)$, (1.1) *has a unique weak solution for each open and bounded subset* $\Omega \subset R^N$.

Proof. It follows from (H_2) that for almost all $x \in R^N$ and all $\xi, \eta \in R^T$,

$$\sum_{|\alpha|\le l} (A_\alpha(x,\xi) - A_\alpha(x,\eta))(\xi_\alpha - \eta_\alpha) \ge 0. \tag{3.3}$$

Now we shall show that

$$A : W_0^{l,p}(R^N \setminus \overline{\Omega}) \to W^{-l,q}(R^N \setminus \overline{\Omega}) \text{ is coercive.} \tag{3.4}$$

Indeed, it follows from (H_3) that

$$\begin{aligned}
&\frac{\langle Au, u\rangle_{W_0^{l,p}(R^N\setminus\overline{\Omega}),W^{-l,q}(R^N\setminus\overline{\Omega})}}{\|u\|_{W_0^{l,p}(R^N\setminus\overline{\Omega})}}\\
&\ge \frac{c_3\Big(\sum_{|\alpha|=l}\|D^\alpha u\|^p_{L^p(R^N\setminus\overline{\Omega})} + \|u\|^p_{L^p(R^N\setminus\overline{\Omega})}\Big)}{\|u\|_{W_0^{l,p}(R^N\setminus\overline{\Omega})}}\\
&\ge C\|u\|^{p-1}_{W_0^{l,p}(R^N\setminus\overline{\Omega})} \to +\infty \qquad \text{as } \|u\|_{W_0^{l,p}(R^N\setminus\overline{\Omega})} \to +\infty,
\end{aligned}$$

which implies (3.4). Here and throughout the proof of Theorem 3.1, C denotes several positive constants.

Then by (H_1), (3.3), (3.4), and using the same arguments as those in Proposition 1.2 of Chapter 2 in [1], we infer that (1.1) has at least one weak solution.

Next, we prove the uniqueness. Suppose that u_1 and u_2 are two weak solutions of (1.1); then by (H_2) and (3.2), we obtain that

$$\begin{aligned}
0 &= \sum_{|\alpha|\le l} \int_{R^N\setminus\overline{\Omega}} [A_\alpha(x, u_1, \dots, D^l u_1) - A_\alpha(x, u_2, \dots, D^l u_2)]\cdot[D^\alpha u_1 - D^\alpha u_2]\, dx\\
&\ge C\|u_1 - u_2\|^p_{W_0^{l,p}(R^N\setminus\overline{\Omega})},
\end{aligned}$$

which indicates that $u_1 = u_2$. This completes the proof. □

Next we suppose that the function $J(x,\xi): R^N \times R^T \to R$ satisfies the following:
(H_4) J is measurable in $x \in R^N$ and continuous in $\xi \in R^T$,

$$0 \le J(x,\xi) \le c_4(|\xi|^p_{R^T} + \eta(x)), \quad x \in R^N, \ \ \xi \in R^T,$$

with $c_4 > 0$ and $\eta \in L^1(R^N)$.

The following lemma, which was provided in [14], will be used in our proof of the existence of problem (P).

LEMMA 3.2. *Let Ω be a bounded domain of class $\mathcal{C}$. If $z \in W^{l,p}(R^N)$ and $z = 0$ a.e. in $R^N \setminus \Omega$, then $z \in W^{l,p}_0(\Omega)$.*

The main result of the paper is as follows.

THEOREM 3.3. *The shape optimization problem (P) has at least one solution.*

Proof. Throughout the proof of Theorem 3.3, we shall use spt$u$ and $U(x,r)$ to denote the support of u and the open ball in R^N with center at x and radius r, respectively.

Let $d = \mathrm{Min}_{\Omega\in\mathcal{O}} \int_{R^N\setminus\overline{\Omega}} J(x, u_\Omega, \dots, D^l u_\Omega)\, dx$. It is obvious that $d > -\infty$. Then there exists a sequence $\{\Omega_n\}_{n=1}^\infty \subset \mathcal{O}$ such that

$$d = \lim_{n\to\infty} \int_{R^N\setminus\overline{\Omega}_n} J(x, u_n, \dots, D^l u_n)\, dx, \tag{3.5}$$

where $u_n \equiv u_{\Omega_n}$ is the weak solution of (1.1) in $R^N \setminus \overline{\Omega}_n$. By Lemma 2.1, there exist a subsequence of $\{\Omega_n\}_{n=1}^\infty$, still denoted by itself, and $\Omega^* \in \mathcal{O}$, such that $\Omega^* = \mathrm{Hlim}\Omega_n$.

By taking $v = u_n, \Omega = \Omega_n$ in (3.2) and by (H_3), we get that

$$\sum_{|\alpha|=l} \|D^\alpha u_n\|^p_{L^p(R^N\setminus\overline{\Omega}_n)} + \|u_n\|^p_{L^p(R^N\setminus\overline{\Omega}_n)} \le \frac{1}{2}\|u_n\|^p_{L^p(R^N\setminus\overline{\Omega}_n)} + C\|f\|^q_{L^q(R^N)},$$

which implies that

$$\|u_n\|_{W^{l,p}_0(R^N\setminus\overline{\Omega}_n)} \le C;$$

here and throughout the proof of Theorem 3.3, C denotes several positive constants independent of n. Let

$$\hat{u}_n(x) = \begin{cases} u_n(x) & \text{in } R^N \setminus \overline{\Omega}_n, \\ 0 & \text{in } \overline{\Omega}_n; \end{cases} \tag{3.6}$$

then $\{\hat{u}_n\}_{n=1}^\infty$ is bounded in $W^{l,p}(R^N)$. Hence there exists a subsequence of $\{\hat{u}_n\}$, still denoted by itself, such that

$$\hat{u}_n \to \hat{u} \ \text{ weakly in } W^{l,p}(R^N) \text{ and strongly in } L^p(\overline{D}) \tag{3.7}$$

for some $\hat{u} \in W^{l,p}(R^N)$.

We observe that

$$\hat{u}\,(x) = 0 \text{ a.e. in } \Omega^*. \tag{3.8}$$

Indeed, for any open subset K satisfying $\overline{K} \subset \Omega^*$, by Lemma 2.2, there is a positive integer n_K, such that $\overline{K} \subset \Omega_n \subset D$ for all $n \ge n_K$. Thus

$$\int_K |\,\hat{u}\,(x)|^p\, dx = \lim_{n\to\infty} \int_K |\hat{u}_n(x)|^p\, dx \le \overline{\lim_{n\to\infty}} \int_{\Omega_n} |\hat{u}_n(x)|^p\, dx = 0,$$

which implies that $\hat{u}(x) = 0$ a.e. in K. Since $K \subset \overline{K} \subset \Omega^*$ is arbitrary, (3.8) follows.

We claim first that

$$\hat{u}(x) \in W_0^{l,p}(R^N \setminus \overline{\Omega}^*). \tag{3.9}$$

It suffices to construct a sequence of functions in $W_0^{l,p}(R^N \setminus \overline{\Omega}^*)$ converging to $\hat{u}$ in the $W^{l,p}(R^N \setminus \overline{\Omega}^*)$-norm.

To this end, we let $\eta_{\frac{1}{4}}(x) = 4^N \eta(4x)$, where $\eta : R^N \to R$ is defined by

$$\eta(x) = \begin{cases} c \cdot \exp\left(\frac{1}{|x|^2 - 1}\right) & \text{if } |x| < 1, \\ 0 & \text{if } |x| \geq 1 \end{cases}$$

with the constant c satisfying $\int_{R^N} \eta(x)\, dx = 1$, and let

$$\varphi_r(x) = \left(\eta_{\frac{1}{4}} * \chi_{U(0, r+\frac{1}{2})}\right)(x) = \int_{R^N} \eta_{\frac{1}{4}}(x - y) \chi_{U(0, r+\frac{1}{2})}(y)\, dy.$$

One can easily check that $\varphi_r(x) \in C_0^\infty(R^N)$,

(3.10)

$$|D^\alpha \varphi_r(x)| \leq C \text{ for all } |\alpha| \leq l \text{ and } x \in R^N, \quad \varphi_r(x) = \begin{cases} 1 & \text{in } \overline{U(0, r)}, \\ 0 & \text{in } R^N \setminus U(0, r + \frac{7}{8}); \end{cases}$$

here and throughout the proof of Theorem 3.3, C denotes several positive constants independent of r. Thus we have that

$$(\varphi_r \hat{u})(x) \in W^{l,p}(R^N).$$

Let $\widetilde{r}_0 > 0$ be such that $\overline{\Omega}^* \subset U(0, \frac{\widetilde{r}_0}{2})$. Then for all $r \geq \widetilde{r}_0$, the set $\widetilde{\Omega}_r = U(0, r + 1) \setminus \overline{\Omega}^*$ is of class $\mathcal{C}$ and $R^N \setminus \widetilde{\Omega}_r = \overline{\Omega}^* \cup (R^N \setminus U(0, r + 1))$.

By (3.8) and (3.10), we obtain that

$$(\varphi_r \hat{u})(x) = 0 \text{ a.e. in } R^N \setminus \widetilde{\Omega}_r \quad \text{for all } r \geq \widetilde{r}_0;$$

then by Lemma 3.2, $\varphi_r \hat{u} \in W_0^{l,p}(\widetilde{\Omega}_r)$, and thus

$$\varphi_r \hat{u} \in W_0^{l,p}(R^N \setminus \overline{\Omega}^*).$$

It is clear that $\varphi_r \hat{u} \to \hat{u}$ in $W^{l,p}(R^N \setminus \overline{\Omega}^*)$. Thus (3.9) holds.

Then we claim that

$$\begin{aligned} &\sum_{|\alpha| \leq l} \int_{R^N \setminus \overline{\Omega}^*} A_\alpha(x, \hat{u}, \ldots, D^l \hat{u}) \cdot D^\alpha v\, dx \\ &\quad = \int_{R^N \setminus \overline{\Omega}^*} f(x) \cdot v(x)\, dx \text{ for all } v(x) \in W_0^{l,p}(R^N \setminus \overline{\Omega}^*). \end{aligned} \tag{3.11}$$

It suffices to prove that

$$\sum_{|\alpha|\le l}\int_{R^N\setminus\overline{\Omega}^*} A_\alpha(x,\hat{u},\dots,D^l\,\hat{u})\cdot D^\alpha v\,dx$$
$$=\int_{R^N\setminus\overline{\Omega}^*} f(x)\cdot v(x)\,dx \quad \text{for all } v(x)\in C_0^\infty(R^N\setminus\overline{\Omega}^*),$$

i.e., for each $v(x)\in C_0^\infty(R^N\setminus\overline{\Omega}^*)$,

$$\sum_{|\alpha|\le l}\int_{\mathrm{spt}v} A_\alpha(x,\hat{u},\dots,D^l\,\hat{u})\cdot D^\alpha v\,dx=\int_{\mathrm{spt}v} f(x)\cdot v(x)\,dx. \tag{3.12}$$

We observe that

$$\sum_{|\alpha|\le l}\int_{\mathrm{spt}v} A_\alpha(x,\hat{u}_n,\dots,D^l\hat{u}_n)\cdot D^\alpha v\,dx=\int_{\mathrm{spt}v} f(x)\cdot v(x)\,dx. \tag{3.13}$$

Indeed, we set

$$\hat{v}=\begin{cases} v & \text{in } \mathrm{spt}v,\\ 0 & \text{in } R^N\setminus \mathrm{spt}v.\end{cases} \tag{3.14}$$

By Lemma 2.3, there exists a positive integer $n_0(v)$ such that

$$\mathrm{spt}\,\hat{v}=\mathrm{spt}v\subset R^N\setminus\overline{\Omega}_n \quad \text{for all } n\ge n_0(v). \tag{3.15}$$

Then for each $n\ge n_0(v)$, $\hat{v}\in C_0^\infty(R^N\setminus\overline{\Omega}_n)$. Thus by (3.2), we have that

$$\sum_{|\alpha|\le l}\int_{R^N\setminus\overline{\Omega}_n} A_\alpha(x,\hat{u}_n,\dots,D^l\hat{u}_n)\cdot D^\alpha\,\hat{v}\,dx=\int_{R^N\setminus\overline{\Omega}_n} f(x)\cdot\hat{v}\,dx,$$

which, together with (3.14) and (3.15), implies (3.13).

Now we shall prove that

$$A_\alpha(x,\hat{u}_n,\dots,D^l\hat{u}_n)\to A_\alpha(x,\hat{u},\dots,D^l\,\hat{u}) \text{ weakly in } L^q(\mathrm{spt}v) \text{ for } |\alpha|\le l. \tag{3.16}$$

Let $\varphi\in C_0^\infty(R^N\setminus\overline{\Omega}^*)$ be a positive function such that

$$\varphi=1 \quad \text{in } \mathrm{spt}v. \tag{3.17}$$

By Lemma 2.3, there exists a positive integer $n_1\ge n_0(v)$ such that

$$\mathrm{spt}\varphi\subset R^N\setminus\overline{\Omega}_n \quad \text{for all } n\ge n_1. \tag{3.18}$$

We set

$$\hat{\varphi}=\begin{cases}\varphi & \text{in } R^N\setminus\overline{\Omega}^*,\\ 0 & \text{in } \overline{\Omega}^*\end{cases} \tag{3.19}$$

and

(3.20)
$$\begin{aligned} I_n &\equiv \int_{R^N} \hat{\varphi} \sum_{|\alpha|\le l} (A_\alpha(x, \hat{u}_n, \dots, D^l \hat{u}_n) - A_\alpha(x, \hat{u}, \dots, D^l \hat{u})) \cdot (D^\alpha \hat{u}_n - D^\alpha \hat{u})\, dx \\ &= \int_{\mathrm{spt}\hat{\varphi}} \hat{\varphi} \sum_{|\alpha|\le l} (A_\alpha(x, \hat{u}_n, \dots, D^l \hat{u}_n) - A_\alpha(x, \hat{u}, \dots, D^l \hat{u})) \cdot (D^\alpha \hat{u}_n - D^\alpha \hat{u})\, dx \\ &\equiv I_n^1 + I_n^2 + I_n^3, \end{aligned}$$

where

$$I_n^1 \equiv \int_{\mathrm{spt}\hat{\varphi}} \sum_{|\alpha|\le l} A_\alpha(x, \hat{u}_n, \dots, D^l \hat{u}_n) \cdot D^\alpha [\hat{\varphi}\, (\hat{u}_n - \hat{u})]\, dx,$$

$$I_n^2 \equiv - \int_{\mathrm{spt}\hat{\varphi}} \hat{\varphi} \sum_{|\alpha|\le l} A_\alpha(x, \hat{u}, \dots, D^l \hat{u}) \cdot (D^\alpha \hat{u}_n - D^\alpha \hat{u})\, dx,$$

and

$$I_n^3 \equiv - \int_{\mathrm{spt}\hat{\varphi}} \sum_{|\alpha|\le l} A_\alpha(x, \hat{u}_n, \dots, D^l \hat{u}_n) \cdot [D^\alpha (\hat{\varphi}\, (\hat{u}_n - \hat{u})) - \hat{\varphi}\, (D^\alpha \hat{u}_n - D^\alpha \hat{u})]\, dx.$$

We claim that

$$I_n \to 0 \text{ as } n \to \infty. \tag{3.21}$$

Indeed, it follows from (3.2), (3.6), (3.7), (3.18), and (3.19) that

$$\begin{aligned} I_n^1 &= \int_{R^N \setminus \overline{\Omega}_n} \sum_{|\alpha|\le l} A_\alpha(x, \hat{u}_n, \dots, D^l \hat{u}_n) \cdot D^\alpha [\hat{\varphi}\, (\hat{u}_n - \hat{u})]\, dx \\ &= \int_{R^N \setminus \overline{\Omega}_n} f \cdot \hat{\varphi}\, (\hat{u}_n - \hat{u})\, dx = \int_{\mathrm{spt}\varphi} f \cdot \varphi (\hat{u}_n - \hat{u})\, dx \to 0 \ \text{ as } n \to \infty. \end{aligned} \tag{3.22}$$

Then by (H_1) and (3.7), we get that

$$\sum_{|\alpha|\le l} (\|A_\alpha(x, \hat{u}_n, \dots, D^l \hat{u}_n)\|_{L^q(R^N)} + \|A_\alpha(x, \hat{u}, \dots, D^l \hat{u})\|_{L^q(R^N)}) \le C, \tag{3.23}$$

which implies

$$I_n^2 \to 0 \ \text{ as } n \to \infty. \tag{3.24}$$

Now we deal with the term I_n^3. Since the term $D^\alpha(\hat{\varphi}\, (\hat{u}_n - \hat{u})) - \hat{\varphi}\, (D^\alpha \hat{u}_n - D^\alpha \hat{u})$ does not contain any derivative of order l of $\hat{u}_n - \hat{u}$ for any multi-index α with $|\alpha| \le l$, there exists a subsequence of $\{\hat{u}_n\}$, still denoted by itself, such that for all multi-indices α with $|\alpha| \le l$,

$$D^\alpha(\hat{\varphi}\, (\hat{u}_n - \hat{u})) - \hat{\varphi}\, (D^\alpha \hat{u}_n - D^\alpha \hat{u}) \to 0 \ \text{ strongly in } L^p(\mathrm{spt}\, \hat{\varphi}),$$

which, combined with (3.23), implies

$$I_n^3 \to 0 \ \text{ as } n \to \infty.$$

This together with (3.20), (3.22), and (3.24) proves (3.21).

By (H_2), (3.17), (3.19), and (3.21), we get that

$$\int_{\mathrm{spt}v} \sum_{|\alpha|\le l} |D^\alpha \hat{u}_n - D^\alpha \hat{u}|^p \, dx \le \int_{R^N} \hat{\varphi} \sum_{|\alpha|\le l} |D^\alpha \hat{u}_n - D^\alpha \hat{u}|^p \, dx \le C I_n \to 0.$$

Hence there exists a subsequence of $\{\hat{u}_n\}$, still denoted by itself, such that

$$D^\alpha \hat{u}_n \to D^\alpha \hat{u} \ \text{ a.e. in } \mathrm{spt}v \text{ for } |\alpha| \le l,$$

which, combined with (H_1), implies

$$A_\alpha(x, \hat{u}_n, \dots, D^l \hat{u}_n) \to A_\alpha(x, \hat{u}, \dots, D^l \hat{u}) \ \text{ a.e. in } \mathrm{spt}v \text{ for } |\alpha| \le l.$$

This together with (3.23) immediately shows (3.16).

Then by (3.16) we may pass to the limit for $n \to \infty$ in (3.13) to get (3.12).

Next we claim that

$$d \ge \int_{R^N \setminus \overline{\Omega}^*} J(x, \hat{u}, \dots, D^l \hat{u}) \, dx. \tag{3.25}$$

Let $R^N \setminus \overline{\Omega}^* = \cup_{j=1}^\infty G_j$, where $G_j, j = 1, \dots,$ are open and bounded subsets in $R^N \setminus \overline{\Omega}^*$ such that $\overline{G}_j \subset G_{j+1}$. By Lemma 2.3, for each j, there exists a positive integer n_j such that

$$\overline{G}_j \subset R^N \setminus \overline{\Omega}_n \text{ for all } n \ge n_j.$$

Thus

$$\underline{\lim}_{n\to\infty} \int_{R^N \setminus \overline{\Omega}_n} J(x, \hat{u}_n, \dots, D^l \hat{u}_n) \, dx \ge \underline{\lim}_{n\to\infty} \int_{G_j} J(x, \hat{u}_n, \dots, D^l \hat{u}_n) \, dx. \tag{3.26}$$

By the same arguments as above, we may prove that there exists a subsequence of $\{\hat{u}_n\}$, still denoted by itself, such that

$$J(x, \hat{u}_n, \dots, D^l \hat{u}_n) \to J(x, \hat{u}, \dots, D^l \hat{u}) \ \text{ a.e. in } G_j.$$

Then by (3.5) and (3.26) and using the Fatou lemma, we get that for each j,

$$d \ge \int_{G_j} J(x, \hat{u}, \dots, D^l \hat{u}) \, dx. \tag{3.27}$$

It is clear that

$$\lim_{j\to\infty} \chi_{G_j}(x) = \chi_{R^N \setminus \overline{\Omega}^*}(x), \tag{3.28}$$

where χ_{G_j} and $\chi_{R^N \setminus \overline{\Omega}^*}$ are the characteristic functions of G_j and $R^N \setminus \overline{\Omega}^*$, respectively.

Thus by (3.27) and (3.28) and using the Fatou lemma again, we get that

$$d \geq \underline{\lim}_{j\to\infty} \int_{G_j} J(x, \hat{u}, \ldots, D^l \hat{u})\, dx = \underline{\lim}_{j\to\infty} \int_{R^N \setminus \overline{\Omega}^*} \chi_{G_j} J(x, \hat{u}, \ldots, D^l \hat{u})\, dx$$
$$\geq \int_{R^N \setminus \overline{\Omega}^*} J(x, \hat{u}, \ldots, D^l \hat{u})\, dx.$$

This proves (3.25).

Finally, it follows from (3.9), (3.11), and (3.25) that Ω^* is a solution of problem (P), and this completes the proof. □

4. Application. In this section, we shall give some examples which are under the framework of problem (P).

Let $\Omega \subset R^N, N \geq 1$, be an open and bounded subset, let $\mathcal{O}$ be the family defined in section 2, and let $u_0 \in L^p(R^N)$ be a given observation function, where $p \geq 2$.

Example 4.1. Consider the following p-Laplace elliptic equation in exterior domain $R^N \setminus \overline{\Omega}$:

$$\begin{cases} -\mathrm{div}(|\nabla u|^{p-2}\nabla u) + k^2|u|^{p-2}u = f \quad \text{in } R^N \setminus \overline{\Omega}, \\ u \in W_0^{1,p}(R^N \setminus \overline{\Omega}), \end{cases} \tag{4.1}$$

where $k \neq 0$ is a constant and $f \in L^{\frac{p}{p-1}}(R^N)$ is a given function. By the definition of weak solution in section 3, $u_\Omega \in W_0^{1,p}(R^N \setminus \overline{\Omega})$ is a weak solution of (4.1) if

$$\int_{R^N \setminus \overline{\Omega}} |\nabla u_\Omega|^{p-2}\nabla u_\Omega \cdot \nabla v\, dx + k^2 \int_{R^N \setminus \overline{\Omega}} |u_\Omega|^{p-2}u_\Omega \cdot v\, dx = \int_{R^N \setminus \overline{\Omega}} f \cdot v\, dx \tag{4.2}$$

for all $v \in W_0^{1,p}(R^N \setminus \overline{\Omega})$.

Consider the following shape optimization problem:

$$\mathrm{Min}_{\Omega \in \mathcal{O}} \int_{R^N \setminus \overline{\Omega}} |u_\Omega - u_0|^p\, dx, \tag{P_2}$$

where u_Ω is the weak solution to (4.1). One can check that problem (P_2) is a special case of problem (P). As $p = 2$, in quantum mechanics, (4.1) is known as the Schrödinger equation and describes the steady state of a particle outside of a domain shaped by Ω (cf. [2]), and thus problem (P_2) may be understood to ask for the shape Ω from among the family $\mathcal{O}$ such that the corresponding steady state u of the particle distributed outside of Ω is "as close as possible" to a given state u_0.

Example 4.2. Consider the following semilinear elliptic equation in exterior domain $R^N \setminus \overline{\Omega}$:

$$\begin{cases} -\triangle u + g(u) = f \quad \text{in } R^N \setminus \overline{\Omega}, \\ u \in W_0^{1,2}(R^N \setminus \overline{\Omega}), \end{cases} \tag{4.3}$$

where $f \in L^2(R^N)$ is a given function and $g : R \to R$ satisfies the following hypotheses:

(i) $g : R \to R$ is continuous;

(ii) there are a positive constant c and a function $\mu \in L^2(R^N)$ such that for almost all $x \in R^N$ and all $y \in R$,

$$|g(y)| \leq c(|y| + \mu(x));$$

(iii) for all $y, z \in R, (g(y) - g(z))(y - z) \geq 0$;

(iv) there is a positive constant $\widetilde{c}$ such that for all $y \in R, g(y) \cdot y \geq \widetilde{c}\, y^2$.

By the definition of weak solution in section 3, $u_\Omega \in W_0^{1,2}(R^N \setminus \overline{\Omega})$ is a weak solution of (4.3) if

$$\int_{R^N \setminus \overline{\Omega}} \nabla u_\Omega \cdot \nabla v \, dx + \int_{R^N \setminus \overline{\Omega}} g(u_\Omega) \cdot v \, dx = \int_{R^N \setminus \overline{\Omega}} f \cdot v \, dx \tag{4.4}$$

for all $v \in W_0^{1,2}(R^N \setminus \overline{\Omega})$.

We consider the following shape optimization problem:

$$\text{Min}_{\Omega \in \mathcal{O}} \int_{R^N \setminus \overline{\Omega}} |u_\Omega - u_0|^2 \, dx, \tag{P_3}$$

where u_Ω is the weak solution of (4.3). It is clear that problem (P_3) is still under framework (P) after some simple modification.

Appendix.

LEMMA A. *Let $U \subset R^N, N \geq 1$, be an open subset. For any $x \in U$ and $y \in R^N \setminus \overline{U}$, there exists a constant t with $0 < t < 1$ such that $x + t(y - x) \in \partial U$.*

Proof. Since $x \in U$ and U is an open subset of R^N, there exists a constant $t_0 \in (0, 1)$ such that

$$x + t_0(y - x) \in U.$$

Let

$$t^* = \sup\{0 \leq t \leq 1 : \ x + t(y - x) \in U\}.$$

Then $t_0 \leq t^* \leq 1$.

Now we claim that

$$t^* \neq 1.$$

By contradiction, we assume that $t^* = 1$. Then there exists a sequence $\{t_n\}_{n=1}^{\infty}$ with $0 \leq t_n \leq 1$ and $x + t_n(y - x) \in U$ such that $t_n \to 1$ as $n \to \infty$. Thus $x + t_n(y - x) \to y \in \overline{U}$, which leads to a contradiction.

Next we claim that

$$x + t^*(y - x) \in \partial U.$$

By contradiction, we assume that $x + t^*(y - x) \notin \partial U$. Then

$$x + t^*(y - x) \in U$$

or

$$x + t^*(y - x) \in R^N \setminus \overline{U}.$$

If $x + t^*(y - x) \in U$, then there exists a positive constant $0 < \delta < 1 - t^*$ such that

$$x + (t^* + \delta)(y - x) \in U,$$

which contradicts the fact that $t^* = \sup\{0 \leq t \leq 1 : \ x + t(y - x) \in U\}$.

If $x + t^*(y - x) \in R^N \setminus \overline{U}$, then there exists a positive constant $0 < \widetilde{\delta} < t^*$ such that

$$x + t(y - x) \in R^N \setminus \overline{U} \text{ for all } \widetilde{\delta} \leq t \leq t^*,$$

which contradicts the fact that $t^* = \sup\{0 \leq t \leq 1 : x + t(y - x) \in U\}$.

This completes the proof. □

EXISTENCE OF REGULAR LAGRANGE MULTIPLIERS FOR A NONLINEAR ELLIPTIC OPTIMAL CONTROL PROBLEM WITH POINTWISE CONTROL-STATE CONSTRAINTS*

A. RÖSCH† AND F. TRÖLTZSCH‡

Abstract. A class of optimal control problems for semilinear elliptic equations with mixed control-state constraints is considered. The existence of bounded and measurable Lagrange multipliers is proven. As a particular application, the Lavrentiev-type regularization of pointwise state constraints is discussed. Here, the existence of associated regular multipliers is shown, too.

Key words. nonlinear programming, function space, optimal control, Lagrange multiplier, semilinear elliptic equation, mixed control-state constraint, pointwise state constraint, Lavrentiev-type regularization

1. Introduction.

In this paper, we consider the optimal control problem

$$\min J(y,u) := \int_\Omega \psi(x,y(x),u(x))\,dx + \int_\Gamma \varphi(x,y(x))\,ds(x) \tag{1.1}$$

subject to the semilinear boundary value problem

$$\begin{aligned} (Ay)(x) + d(x,y(x)) &= \beta(x)u(x) && \text{in } \Omega,\\ \partial_\nu y(x) + b(x,y(x)) &= 0 && \text{on } \Gamma \end{aligned} \tag{1.2}$$

and to the mixed control-state constraints

$$\begin{aligned} 0 \le u(x) &\le c(x) + \gamma(x)y(x) && \text{a.e. in } \Omega,\\ u(x) &\le e(x) && \text{a.e. in } \Omega. \end{aligned} \tag{1.3}$$

We will investigate also another type of constraint that might be useful for applications. In this setting, A is a uniformly elliptic differential operator and Ω is a bounded domain of $\mathbb{R}^N$, $N \ge 2$, with boundary Γ and outward unit normal ν. Precise assumptions on and definitions of the quantities introduced above are formulated at the end of this section.

The investigation of optimal control problems of this type is interesting for different reasons. First of all, they exhibit nice theoretical properties. As we shall prove in this paper, the Lagrange multipliers associated with optimal solutions are quite regular functions, while they are measures for pure state constraints. This higher regularity allows for a better numerical analysis. For instance, second-order sufficient optimality conditions have been discussed in a fairly complete way [15], [14]. For pointwise state constraints, the associated theory is still partially open (cf. Casas et al. [7]) since it works only for a small dimension of Ω if the constraints are imposed

on the whole domain. Moreover, we mention the application of mixed constraints in the numerical analysis that is briefly addressed in section 7.

Constraints of this type are also interesting for problems in which the difference between control and state has to be bounded (problems of bottleneck type). An application to optimal heating has been given in [19].

Our main issue is the existence of bounded and measurable Lagrange multipliers associated with constraints (1.3). We shall consider the control u in $L^\infty(\Omega)$—this is the natural space obtained from the constraints. Therefore, the multipliers should belong to the dual space $L^\infty(\Omega)^*$, a space of Radon measures.

However, it is known from similar problems for linear and nonlinear parabolic problems that the Lagrange multipliers are more regular under natural assumptions [3], [4], [5], [18]. In fact, they can be constructed as functions of $L^2(\Omega)$ or even of $L^\infty(\Omega)$. Recently, the same result has been obtained for linear-quadratic elliptic problems by the convex duality theory [17]. The elliptic case is more difficult than the parabolic one due to the appearance of eigenvalues.

In principle, two ways are known for proving regularity. In [4], [5], the problems are linearized at the optimal solution and the Lagrange multipliers are obtained by the associated linear dual problem. Another technique was suggested later in [3]: An application of a Kuhn–Tucker theorem in Banach spaces delivers existence of Lagrange multipliers in $L^\infty(\Omega)^*$. In a second step, these multipliers are shown to be bounded functions. This step is fairly technical.

Here, we follow again the idea of linearization and application of duality theory. We think that this approach is more elementary, although not simple as well. Moreover, linearization and working with different norms and spaces seem to be interesting on their own. Therefore, we devote a section to this issue. Later, we shall embed problem (1.1)–(1.3) into a more general class of problems in function spaces and prove the regularity of Lagrange multipliers for this general class. The result for (1.1)–(1.3) is obtained as a conclusion.

Assumptions. $\Omega \subset \mathbb{R}^N$, $N \geq 2$, is a bounded Lipschitz domain. The functions $\psi = \psi(x, y, u) : \Omega \times \mathbb{R}^2 \to \mathbb{R}$, $d = d(x, y) : \Omega \times \mathbb{R} \to \mathbb{R}$, and $\varphi, b : \Gamma \times \mathbb{R} \to \mathbb{R}$ are measurable with respect to x for all fixed pairs (y, u) and differentiable with respect to y and u for all fixed x. They satisfy the following conditions on boundedness and Lipschitz continuity: There is a constant $K > 0$ and, for all $M > 0$, a constant $L(M) > 0$ exists such that

$$\left|\psi(x,0,0) + \frac{\partial\psi}{\partial y}(x,0,0) + \frac{\partial\psi}{\partial u}(x,0,0)\right| \leq K$$

$$|\psi(x,y_1,u_1) - \psi(x,y_2,u_2)| + \left|\frac{\partial\psi}{\partial y}(x,y_1,u_1) - \frac{\partial\psi}{\partial y}(x,y_2,u_2)\right|$$

$$+ \left|\frac{\partial\psi}{\partial u}(x,y_1,u_1) - \frac{\partial\psi}{\partial u}(x,y_2,u_2)\right| \leq L(M)\left\{|y_1 - y_2| + |u_1 - u_2|\right\}$$

for all u_i, y_i with $|u_i| + |y_i| \leq M$, $i = 1, 2$, and for a.a. $x \in \Omega$. The functions d, φ, b satisfy the same assumptions with respect to $x \in \Omega$ or $x \in \Gamma$.

The functions $\beta, \gamma, c, e : \Omega \to \mathbb{R}$ are bounded, measurable, and nonnegative. To avoid a trivial problem, we assume that $\beta \not\equiv 0$. A is the uniformly elliptic differential operator defined by

$$(Ay)(x) = -\sum_{i,j=1}^{N} \frac{\partial}{\partial x_i}\left(a_{ij}(x)\frac{\partial}{\partial x_j}y(x)\right) + c_0(x)y(x)$$

with functions a_{ij} that belong to $C^{0,1}(\bar{\Omega})$, satisfy the condition $a_{ij}(x) = a_{ji}(x)$, and satisfy the condition of uniform ellipticity

$$\sum_{i,j=1}^{N} a_{ij}(x)\xi_i\xi_j \geq \delta_0|\xi|^2 \qquad \text{a.e. on } \Omega$$

with some $\delta_0 > 0$ for all $\xi \in \mathbb{R}^N$. We assume $c_0(x) \geq 0$ a.e. on Ω and $\|c_0\|_{L^2(\Omega)} > 0$. It holds that $(\partial d/\partial y)(x, y) \geq 0$ and $(\partial b/\partial y)(x, y) \geq 0$ for all $y \in \mathbb{R}$ and almost all $x \in \Omega$ and Γ, respectively.

2. Lagrange multipliers and linearization. In (1.1)–(1.3), the state y is associated with u by a differentiable mapping G, $y = G(u)$, and thus y can be eliminated from the problem. Then $J(y, u) = J(G(u), u) = f(u)$, and the state y can also be eliminated in (1.3). Details are worked out in the next section. Finally, we arrive at a differentiable mathematical programming problem in Banach spaces that admits the following form:

$$\min f(u), \qquad g(u) \leq_K 0, \quad u \in C. \tag{2.1}$$

Here, $f : U \to \mathbb{R}$, $g : U \to Z$ are continuously Fréchet differentiable mappings defined in real Banach spaces U, Z. Moreover, $C \subset U$ is a convex set and $K \subset Z$ is a convex closed cone that defines a partial ordering $\leq_K$ in Z by $z \leq_K 0 \Leftrightarrow -z \in K$. In this sense, K can be considered as the nonnegative cone of Z, although the concrete meaning can be quite different.

Assume that $\bar{u}$ is a *local solution* of (2.1); i.e., for some $r > 0$ it holds that $f(\bar{u}) \leq f(u)$ for all $u \in U$ with $\|u - \bar{u}\|_U \leq r$, $g(u) \leq_K 0$, and $u \in C$. A Lagrange multiplier is an element of the dual cone K_+ of K,

$$K_+ = \{\mu \in Z^* : \mu(z) \geq 0 \quad \forall z \in K\},$$

where Z^* is the dual space of Z, the Banach space of all linear and continuous functionals on Z.

DEFINITION 2.1. *A* Lagrange multiplier *associated with $\bar{u}$ is an element $\mu \in K_+$ such that the* variational inequality

$$f'(\bar{u})(u - \bar{u}) + \mu(g'(\bar{u})(u - \bar{u})) \geq 0 \quad \forall u \in C \tag{2.2}$$

and the complementary slackness condition

$$\mu(g(\bar{u})) = 0 \tag{2.3}$$

hold true.

Remark. Equation (2.2) might be written as

$$\langle f'(\bar{u}) + g'(\bar{u})^*\mu, u - \bar{u}\rangle \geq 0 \quad \forall u \in C$$

with the adjoint operator $g'(\bar{u})^*$ and the pairing $\langle\cdot,\cdot\rangle$ between Z^* and Z. We avoid $g'(\bar{u})^*$ since it might be fairly complicated to find its concrete form in applications. Moreover, we aim at finding μ in a more "regular" subspace of Z^*.

In our applications, Z is of type $L^\infty(\Omega)$ and K is the associated nonnegative cone. It has a nonempty interior int K. Therefore, we are justified in requiring the following *constraint qualification* (regularity of $\bar{u}$):

There is a $u_0 \in C$ such that

$$-[g(\bar{u}) + g'(\bar{u})(u_0 - \bar{u})] \in \operatorname{int} K. \tag{2.4}$$

Under this assumption, a Lagrange multiplier $\mu \in Z^*$ exists, since (2.4) is equivalent to the well-known regularity condition of Zowe and Kurcyusz [23]; see also [13] and [20].

The condition of Zowe and Kurcyusz is sufficient for the existence of $\mu \in Z^*$ [23]. However, we shall apply another conclusion of (2.4) that was used in [23] as an auxiliary result: (2.4) permits us to view $\bar{u}$ as the solution of the linearized problem.

DEFINITION 2.2 (linearizing cone). *Let $\bar{z} \in K$ and $\bar{u} \in C$.*

$$C(\bar{u}) = \{v \in U : v = \lambda\,(u - \bar{u}),\ \lambda \geq 0,\ u \in C\},$$
$$K(\bar{z}) = \{w \in Z : w = \lambda\,(z - \bar{z}),\ \lambda \geq 0,\ z \in K\}.$$

The set

$$L(\bar{u}) = \{v \in U : v \in C(\bar{u}),\ g'(\bar{u})v \in -K(-g(\bar{u}))\}$$

is said to be the linearizing cone *of the feasible set at $\bar{u}$.*

LEMMA 2.3. *Under the regularity assumption* (2.4)*, it holds that*

$$f'(\bar{u})\,v \geq 0 \quad \forall v \in L(\bar{u}). \tag{2.5}$$

For this result of [23], we refer to [20, Theorem 1.2.1] and condition (2.2) of [20]. The reason for (2.5) is that (2.4) ensures $L(\bar{u}) \subset T(\bar{u})$, where $T(\bar{u})$ is the so-called tangent cone.

We rewrite (2.5) in a more convenient form. Obviously,

$$L(\bar{u}) = \{v \in U : v = \alpha\,(u - \bar{u}),\ g'(\bar{u})\,v + \beta\,g(\bar{u}) \leq_K 0,\ u \in C,\ \alpha \geq 0,\ \beta \geq 0\}.$$

Taking $\alpha = \beta = 1$, we obtain from (2.5)

$$f'(\bar{u})(u - \bar{u}) \geq 0 \tag{2.6}$$

for all $u \in C$ with

$$g(\bar{u}) + g'(\bar{u})(u - \bar{u}) \leq_K 0. \tag{2.7}$$

THEOREM 2.4. *If $\bar{u}$ is a local solution of problem* (2.1) *that satisfies the constraint qualification* (2.4)*, then $\bar{u}$ is a (global) solution of the* linearized programming problem

$$\min f'(\bar{u})\,u, \quad g(\bar{u}) + g'(\bar{u})(u - \bar{u}) \leq_K 0, \quad u \in C. \tag{2.8}$$

Proof. This follows from rewriting (2.6) in the form $f'(\bar{u})u \geq f'(\bar{u})\bar{u}$, together with (2.7). □

THEOREM 2.5. *Let the assumptions of Theorem* 2.4 *be satisfied. Then a Lagrange multiplier $\mu \in K_+$ associated with $\bar{u}$ exists. It is also a Lagrange multiplier for $\bar{u}$, considered as the solution of* (2.8)*. Conversely, let $\bar{u}$ solve* (2.8) *and let μ be any Lagrange multiplier for $\bar{u}$ in* (2.8)*. Then $\bar{u}$ and μ together satisfy the first-order necessary conditions for problem* (2.1)*.*

Proof. Define $\tilde{f}(u) = f'(\bar{u})u$, $\tilde{g}(u) = g(\bar{u}) + g'(\bar{u})(u - \bar{u})$. Then we have for all u,

$$\tilde{f}'(u) \equiv f'(\bar{u}), \quad \tilde{g}'(u) \equiv g'(\bar{u}), \quad \tilde{g}(\bar{u}) = g(\bar{u}).$$

The first statement of the theorem follows from [23], since the regularity condition (2.4) implies the one of Zowe and Kurcyusz. The converse is shown as follows: Let μ be any Lagrange multiplier associated with $\bar{u}$ as a solution of (2.8). By the associated complementarity condition and the relations above, we get $\mu(g(\bar{u})) = \mu(\tilde{g}(\bar{u})) = 0$. Moreover,

$$f'(\bar{u})(u-\bar{u}) + \mu(g'(\bar{u})(u-\bar{u})) = \tilde{f}'(\bar{u})(u-\bar{u}) + \mu(\tilde{g}'(\bar{u})(u-\bar{u})) \geq 0 \quad \forall u \in C.$$

Therefore, (2.2) and (2.3) are satisfied, and thus μ is a Lagrange multiplier for (2.1). □

In view of this, we may concentrate on the linearized problem (2.8) to find a Lagrange multiplier. Why is this helpful? There are two reasons: (2.8) can be considered in a space with coarser topology, where f and g are *not* differentiable. Moreover, we shall be able to use cones of nonnegative functions with empty interior such as $(L^2(\Omega))_+$.

3. Transformation and linearization of the control problem. In this section, we convert the elliptic optimal control problem (1.1)–(1.3) into a mathematical programming problem and consider its linearization, together with an associated dual problem.

THEOREM 3.1. *Under the general assumptions, for all $u \in L^p(\Omega)$, $p > N/2$, (1.2) has a unique solution $y = y(u) \in H^1(\Omega) \cap C(\bar{\Omega}) =: Y$. The associated control-to-state mapping $G : u \mapsto y$ is continuously Fréchet differentiable. Its derivative $G'(\bar{u})$ at $\bar{u} \in L^p(\Omega)$ is given by $G'(\bar{u})u = v$, where v solves the linearized equation*

$$\begin{aligned} (A\,v)(x) + d_y(x,\bar{y}(x))v(x) &= \beta(x)u(x) && \text{in } \Omega, \\ \partial_\nu v(x) + b_y(x,\bar{y}(x))v(x) &= 0 && \text{on } \Gamma, \end{aligned} \tag{3.1}$$

and $\bar{y} = G(\bar{u})$.

This result is standard. Existence of $y \in L^\infty(\Omega)$ follows for Lipschitz domains by a truncation technique and the Stampacchia method, as in Casas [6] (see also Alibert and Raymond [1]). In [6], the continuity of y was still shown for $C^{1,1}$-domains. In [1], continuity has been deduced from a result by Murthy and Stampacchia [12] that holds in Lipschitz domains. The reader might also consult the monograph [21], where these ideas are presented in detail in sections 4.1.3 and 7.1.2.

In what follows, we consider G and $G'(\bar{u})$ as operators with a range in $C(\bar{\Omega})$, although their range is actually contained also in $H^1(\Omega)$. Inserting $y = G(u)$ into J, the elliptic problem (1.1)–(1.3) is transformed into

$$\min f(u) := J(G(u), u) \tag{3.2}$$

subject to

$$\begin{aligned} 0 \;\leq\; u(x) &\leq c(x) + \gamma(x)(G(u))(x), \\ u(x) &\leq e(x) \end{aligned} \tag{3.3}$$

for almost all $x \in \Omega$. If we consider u as a function of $L^p(\Omega)$, then $0 \leq u(x) \leq e(x)$, and the assumption $e \in L^\infty(\Omega)$ guarantees $u \in L^\infty(\Omega)$. Therefore, from now on, we fix $U = L^\infty(\Omega)$, $Z = (L^\infty(\Omega))^2$, $K = (L^\infty(\Omega)_+)^2$, and we define $g : U \to Z$ by

$$(g(u))(x) = \begin{pmatrix} u(x) - c(x) - \gamma(x)(G(u))(x) \\ u(x) - e(x) \end{pmatrix}.$$

Moreover, we define $C = L^\infty(\Omega)_+$. Then (1.1)–(1.3) is equivalent to

$$\min f(u), \quad g(u) \leq_K 0, \quad u \in C. \tag{3.4}$$

Let $\bar{u}$ be a local solution of (3.4). "Local" is related to the topology of $L^\infty(\Omega)$. To satisfy the regularity condition, we must assume the existence of $u_0 \in L^\infty(\Omega)$ such that (2.4) is fulfilled. We require here a stronger condition and assume that $u_0 = 0$ satisfies (2.4). This means that $\varepsilon > 0$ exists such that

$$\begin{aligned} &\varepsilon \leq c(x) + \gamma(x)\bar{y}(x) - \gamma(x)(G'(\bar{u})\bar{u})(x), \\ &\varepsilon \leq e(x) \end{aligned} \tag{3.5}$$

is satisfied almost everywhere in Ω. This assumption appears to be natural in some sense: the smallest function—namely $u_0(x)$—should satisfy the upper bounds strictly. Since some monotonicity follows from the maximum principle for elliptic equations, this is reasonable. The next result is obtained as a direct conclusion of Theorem 2.4.

LEMMA 3.2. *If $\bar{u} \in L^\infty(\Omega)$ is a local solution of the optimal control problem* (1.1)–(1.3)*, and the regularity condition* (3.5) *is satisfied with some $\varepsilon > 0$, then $\bar{u}$ is also a solution of the linear optimal control problem*

$$\min f'(\bar{u})u$$

subject to $u \in L^\infty(\Omega)$ and

$$\begin{aligned} &u(x) \leq c(x) + \gamma(x)(G(\bar{u}))(x) + \gamma(x)(G'(\bar{u})(u - \bar{u}))(x), \\ &u(x) \leq e(x), \\ &u(x) \geq 0. \end{aligned} \tag{3.6}$$

Transforming this problem into an elliptic control problem, we arrive at

$$\begin{aligned} \min \Bigg\{ &\int_\Omega \psi_y(x, \bar{y}(x), \bar{u}(x))y(x)\,dx + \int_\Gamma \varphi_y(x, \bar{y}(x))y(x)\,ds(x) \\ &+ \int_\Omega \psi_u(x, \bar{y}(x), \bar{u}(x))u(x)\,dx \Bigg\} \end{aligned} \tag{3.7}$$

subject to the linearized equation (3.1) and

$$\begin{array}{rcccl} 0 & \leq & u(x) & \leq & c(x) + \gamma(x)\bar{y}(x) + \gamma(x)y(x) - \gamma(x)(G'(\bar{u})\bar{u})(x), \\ & & u(x) & \leq & e(x). \end{array} \tag{3.8}$$

We introduce the fixed part of the right-hand side by

$$\bar{c}(x) = c(x) + \gamma(x)\bar{y}(x) - \gamma(x)(G'(\bar{u})\bar{u})(x).$$

Moreover, we introduce an adjoint state $\hat{p} \in H^1(\Omega) \cap C(\bar{\Omega})$ by

$$\begin{array}{rcll} (A\hat{p})(x) + d_y(x, \bar{y}(x))\hat{p}(x) & = & \psi_y(x, \bar{y}(x), \bar{u}(x)) & \text{in } \Omega, \\ \partial_\nu \hat{p}(x) + b_y(x, \bar{y}(x))\hat{p}(x) & = & \varphi_y(x, \bar{y}(x)) & \text{on } \Gamma. \end{array} \tag{3.9}$$

Then it holds that

$$\int_\Omega \psi_y(x, \bar{y}(x), \bar{u}(x))y(x)\,dx + \int_\Gamma \varphi_y(x, \bar{y}(x))y(x)\,ds(x) = \int_\Omega \beta(x)\hat{p}(x)u(x)\,dx.$$

This well-known relation is easily obtained from the weak formulation of (3.1) and (3.9), respectively. With these notations, the linear programming problem (3.6) becomes equivalent to the *primal problem*

$$\min \int_\Omega a(x)u(x)\,dx \tag{3.10}$$

subject to

$$\begin{aligned} &u(x) \le \bar c(x) + (Su)(x),\\ &u(x) \le e(x),\\ &u(x) \ge 0 \end{aligned} \tag{3.11}$$

with

$$\begin{aligned} a &= \beta\,\hat p + \psi_u(\cdot, \bar y, \bar u),\\ Su &= \gamma\, G'(\bar u)\, u. \end{aligned}$$

By our assumptions, it holds that $a \in L^\infty(\Omega)$, and S is a linear continuous operator in $L^\infty(\Omega)$. The unknown function is $u \in L^\infty(\Omega)$. However, we also know that $\|Su\|_{L^2(\Omega)} \le c\|u\|_{L^2(\Omega)}$, and thus we can consider S as a linear continuous operator in $L^2(\Omega)$. Let us view S in this way and consider the linear programming problem (3.10)–(3.11) for $u \in L^2(\Omega)$ with all inequalities defined in $L^2(\Omega)$ as well. Notice that this does not change the feasible set, since $0 \le u \le e$ implies $u \in L^\infty(\Omega)$. Therefore, $\bar u$ solves the linear problem (3.11) in $L^2(\Omega)$.

4. The dual linear problem. Let us now establish the dual problem associated with the primal problem (3.10)–(3.11). In what follows, we denote by $(\cdot\,,\,\cdot)$ the inner product in $L^2(\Omega)$, and $S^* : L^2(\Omega) \to L^2(\Omega)$ denotes the adjoint operator to S. By Lagrange duality, the dual problem is obtained as follows: (3.10)–(3.11) is equivalent to

$$\min_{u\in L^2(\Omega)} \left\{ \max_{\mu\in(L^2(\Omega)_+)^3} \{(a,u) - (u,\mu_1) + (u - Su - \bar c, \mu_2) + (u - e, \mu_3)\} \right\},$$

where $\mu = (\mu_1, \mu_2, \mu_3)$. The dual problem is obtained by reversing the order of min and max,

$$\max_{\mu\in(L^2(\Omega)_+)^3} \left\{ (-\bar c, \mu_2) - (e, \mu_3) + \min_{u\in L^2(\Omega)} \{(a - \mu_1 + \mu_2 - S^*\mu_2 + \mu_3, u)\} \right\}.$$

The minimum is $-\infty$ if $0 \ne a - \mu_1 + \mu_2 - S^*\mu_2 + \mu_3$. This is meaningless for maximization, and hence we obtain the dual problem as

$$\left.\begin{aligned} &\max \quad -\int_\Omega (\bar c(x)\mu_2(x) + e(x)\mu_3(x))\,dx\\ &\text{subject to}\\ &\mu_2 + \mu_3 = -a + \mu_1 + S^*\mu_2\\ &\mu_i \ge 0, \quad i = 1,2,3. \end{aligned}\right\} \tag{4.1}$$

We show that (4.1) is solvable. Moreover, the problems (3.10)–(3.11) and (4.1) turn out to be in duality—they have the same optimal values. Preparing this discussion, we finish this section by computing S^*. This operator is defined by $(v\,,\,Su) = (S^*v\,,\,u)$

for all $u, v \in L^2(\Omega)$. We recall that $Su = \gamma G'(\bar{u})u = \gamma y$, where y is the solution of (3.1). Therefore,

$$(v\,,\,Su) = (v\,,\,\gamma y) = (\gamma v\,,\,y) = (\beta q\,,\,u),$$

where q is the solution of the adjoint equation

$$\begin{array}{rcll} (A\,q)(x) + d_y(x,\bar{y}(x))q(x) & = & \gamma(x)v(x) & \text{in } \Omega, \\ \partial_\nu q(x) + b_y(x,\bar{y}(x))q(x) & = & 0 & \text{on } \Gamma. \end{array} \tag{4.2}$$

This follows again in a standard way from the weak formulation of (3.1), (4.2). In view of this, S^* is given by

$$(S^*v)(x) = \beta(x)q(x), \tag{4.3}$$

where $q \in H^1(\Omega)$ is the solution of (4.2).

5. The duality relation. Here, we discuss the equality of the optimal values for the primal problem (3.10)–(3.11) and its dual (4.1).

THEOREM 5.1. *If $\bar{c}(x) \geq 0$ and $e(x) \geq 0$ hold a.e. in Ω, then the minimum of* (3.10)–(3.11) *is equal to the supremum of* (4.1).

Proof. We sketch the proof for convenience, since it is standard for continuous linear programming problems. We refer, for instance, to [8], [10], [22], [9], to the monograph [2] and—in the context of elliptic PDEs—to the recent paper [17].

(i) Define the convex cone E,

$$E = \{(\alpha, d_1, d_2) \in \mathbb{R} \times L^2(\Omega)^2 |\, \exists u \in L^2(\Omega), u \geq 0, u \leq d_1 + Su, u \leq d_2, (a,u) \leq \alpha\}.$$

We show that E is closed. In fact, if $(\alpha_n, d_{1,n}, d_{2,n}) \to (\alpha, d_1, d_2)$ in $\mathbb{R} \times L^2(\Omega)^2$ for $n \to \infty$, then there are $u_n \in L^2(\Omega)$ such that

$$0 \leq u_n \leq d_{2,n} \quad \forall n = 1, 2, \ldots .$$

Therefore, the sequence $(u_n)_{n=1}^\infty$ is bounded in $L^2(\Omega)$. By weak compactness, we can assume $u_n \rightharpoonup u$ in $L^2(\Omega)$. The weak continuity of S yields $Su_n \rightharpoonup Su$ in $L^2(\Omega)$. Finally, convexity ensures weak closedness, and hence it holds in the limit that

$$0 \leq u \leq d_2, \quad u \leq d_1 + Su, \quad (a,u) \leq \alpha.$$

This means that (α, d_1, d_2) is in E.

(ii) Let $\bar{\alpha}$ denote the minimum for (3.10)–(3.11). Clearly, the primal problem (3.10)–(3.11) has a solution; i.e., its infimum is attained. This follows from weak compactness, since $0 \leq u \leq e$ gives boundedness of the feasible set. By definition, $(\bar{\alpha} - \frac{1}{n}, \bar{c}, e) \notin E$ for all $n \in \mathbb{N}$. Therefore, the element $(\bar{\alpha} - \frac{1}{n}, \bar{c}, e)$ can be separated from the set E by a closed hyperplane in $\mathbb{R} \times L^2(\Omega)^2$: There are $(\beta_n, c_n^*, e_n^*) \in \mathbb{R} \times L^2(\Omega)^2$ such that $(\beta_n, c_n^*, e_n^*) \neq (0,0,0)$, and

$$\beta_n \left(\bar{\alpha} - \frac{1}{n}\right) + (\bar{c}, c_n^*) + (e, e_n^*) < \beta_n \alpha + (d_1, c_n^*) + (d_2, e_n^*) \tag{5.1}$$

holds for all $(\alpha, d_1, d_2) \in E$. Inserting $(\bar{\alpha}, \bar{c}, e)$ in the right-hand side, it follows that $\beta_n > 0$ and w.l.o.g. $\beta_n = 1$. We deduce that $\mu_{2,n} := c_n^*$ and $\mu_{3,n} := e_n^*$ satisfy the constraints

$$\begin{array}{c} \mu_2 + \mu_3 \geq -a + S^*\mu_2, \\ \mu_i \geq 0, \quad i = 2, 3. \end{array} \tag{5.2}$$

To confirm this insert, for arbitrary $u \geq 0$, $d_1 = u - Su$, $d_2 = u$, and $\alpha = (a\,,\, u)$ in the right-hand side of (5.1). Denote its (fixed) left-hand side by γ_n. Then

$$\gamma_n < (a + \mu_{2,n} + \mu_{3,n} - S^*\mu_{2,n}\,,\, u)$$

must hold for all $u \geq 0$. This implies $a + \mu_{2,n} + \mu_{3,n} - S^*\mu_{2,n} \geq 0$, i.e., the upper inequality of (5.2). Inserting $\alpha = 0$, $u = 0$, $d_2 = 0$, and arbitrary $d_1 \geq 0$, we obtain

$$\gamma_n < (d_1\,,\, \mu_{2,n}) \qquad \forall\, d_1 \geq 0,$$

and hence $\mu_{2,n} \geq 0$. In the same way, $\mu_{3,n} \geq 0$ is shown.

Setting $\mu_1 = \mu_2 + \mu_3 + a - S^*\mu_2$, (5.2) becomes equivalent to the constraints of (4.1). Moreover, inserting above $(\alpha, d_1, d_2) = (0, 0, 0) \in E$,

$$-\int_\Omega (\bar{c}(x)\mu_{2,n}(x) + e(x)\mu_{3,n}(x))\,dx > \bar{\alpha} - \frac{1}{n}$$

is obtained for every $n \in \mathbb{N}$. It is true in general that the dual supremum $\bar{\sigma}$ is less than or equal to the primal minimum $\bar{\alpha}$ (cf. (6.13)), and hence

$$\bar{\alpha} \geq \bar{\sigma} > \bar{\alpha} - \frac{1}{n}.$$

Now, $n \to \infty$ yields $\bar{\alpha} = \bar{\sigma}$, the statement of the theorem. □

Remark. The main point in the proof was the closedness of E. It was deduced from the boundedness of the sets $\{u \in L^2(\Omega) |\, 0 \leq u \leq d_{2,n}\}$.

6. Solvability of the dual problem. To prove existence for the dual problem, we rely on the nonnegativity and certain smoothing properties of S and S^*.

LEMMA 6.1. *S and S^* are nonnegative, i.e.,*

$$u \geq 0 \;\Rightarrow\; Su \geq 0 \quad \textit{a.e. in } \Omega.$$

This follows from $G'(\bar{u}) \geq 0$, a consequence of comparison principles for linear elliptic equations: For $u \geq 0$, we consider v^-, the negative part of the solution $v = G'(\bar{u})u$ of (3.1). By using v^- as a test function in (3.1), we see that v^- vanishes. Here, $\beta \geq 0$, $\gamma \geq 0$ are used.

By their definitions, S and S^* are linear and continuous operators in $L^2(\Omega)$. We shall estimate them in different L^p-norms for $1 \leq p \leq \infty$. To match their domain $L^2(\Omega)$, we have to consider the intersection of $L^p(\Omega)$ with $L^2(\Omega)$ in the estimates below. For instance, we know from Theorem 3.1 that

$$\|Su\|_{L^\infty(\Omega)} \leq c_S\, \|u\|_{L^p(\Omega)} \qquad \forall u \in L^p(\Omega) \cap L^2(\Omega), \quad p \geq N/2.$$

LEMMA 6.2. *With constants c_S, $\delta > 0$, the following estimates are fulfilled:*

$$\|S^*v\|_{L^\infty(\Omega)} \leq c_S\, \|v\|_{L^p(\Omega)} \qquad \forall v \in L^p(\Omega) \cap L^2(\Omega), \quad p > N/2. \tag{6.1}$$

$$\|S^*v\|_{L^{p+\delta}(\Omega)} \leq c_S\, \|v\|_{L^p(\Omega)} \qquad \forall v \in L^p(\Omega) \cap L^2(\Omega), \quad 1 \leq p \leq N/2. \tag{6.2}$$

Proof. (i) *First estimate.* S^*v is given by formula (4.3), where q is obtained as the solution of the adjoint elliptic equation (4.2). The mapping $v \mapsto q$ is continuous from $L^p(\Omega)$ to $L^\infty(\Omega)$. This follows from Theorem 3.1 with γ substituted for β. Therefore, the estimate $\|S^*v\|_{L^\infty(\Omega)} = \|\beta\, q\|_{L^\infty(\Omega)} \leq c_S\, \|v\|_{L^p(\Omega)}$ follows immediately.

(ii) *Some continuity properties.* To avoid confusion of operators and their associated spaces, let us first mention that the solution mapping $u \mapsto v$ for (3.1) is linear and continuous from $(H^1(\Omega))^*$ to $H^1(\Omega)$. We denote this operator by $\mathbf{S}$. In this sense, S is the restriction of $\mathbf{S}$ to $L^2(\Omega)$ considered with a range in $L^2(\Omega)$. Define, for $p > N/2$, $S_p : L^p(\Omega) \to L^\infty(\Omega)$ as the restriction of $\mathbf{S}$ to $L^p(\Omega)$. By Theorem 3.1, this operator is continuous. For arbitrary $v \in L^1(\Omega)$, the mapping

$$u \mapsto \int_\Omega v\,(S_p\,u)\,dx$$

defines a functional $\varphi \in L^p(\Omega)^* = L^{p'}(\Omega)$. The mapping $v \mapsto \varphi$ is obviously continuous from $L^1(\Omega)$ to $L^{p'}(\Omega)$. We denote this mapping by $S_p^\otimes$. It is the restriction of S_p^* to $L^1(\Omega)$, and hence we have

$$\|S_p^\otimes v\|_{L^{p'}(\Omega)} \le c_1\,\|v\|_{L^1(\Omega)} \qquad \forall v \in L^1(\Omega).$$

This estimate holds in particular for all $v \in L^2(\Omega)$. For such functions we have $S_p^\otimes v = S^* v$. In fact, we find for all $u \in L^\infty(\Omega)$ and $v \in L^2(\Omega)$,

$$\int_\Omega (S_p^\otimes v)\,u\,dx = \int_\Omega v\,(S_p\,u)\,dx = (v, S_p u) = (v, Su) = (S^* v, u).$$

Since this is true for all $u \in L^\infty(\Omega)$, it must hold that $S_p^\otimes v = S^* v$ for all $v \in L^2(\Omega)$. Therefore, the boundedness of $S_p^\otimes$ extends to S^*:

$$\|S^* v\|_{L^{p'}(\Omega)} \le c_1 \|v\|_{L^1(\Omega)} \qquad \forall v \in L^2(\Omega).$$

This shows that S^* can be extended to a continuous linear operator from $L^1(\Omega)$ to $L^{p'}(\Omega)$. In fact, it is known from Alibert and Raymond [1] and Casas [6] that the solution operator of the adjoint equation (4.2) is linear and continuous from $L^1(\Omega)$ to $W^{1,\sigma}(\Omega)$ for all $\sigma < N/(N-1)$. However, we do not rely on this deep result. We just use the available following information.

We know in particular that S^* is continuous from $L^{p_0}(\Omega)$ to $L^{p_1}(\Omega)$ and from $L^{q_0}(\Omega)$ to $L^{q_1}(\Omega)$ for $p_0 = N$, $p_1 = 2N$, $q_0 = 1$, $q_1 = p' > 1$, where p' is associated with the arbitrary but fixed $p \in (N/2, \infty)$ chosen at the beginning. It is now fairly clear that the second estimate can be obtained by interpolation.

(iii) *Second estimate.* Define, for $\theta \in [0,1]$, $r_j = r_j(\theta)$ by

$$\frac{1}{r_j} = \frac{1-\theta}{p_j} + \frac{\theta}{q_j}, \quad j = 0, 1.$$

Then the classical interpolation theorem in Triebel [16, §1.18.7, Thm. 1] ensures that S^* is continuous from $L^{r_0}(\Omega)$ to $L^{r_1}(\Omega)$. From now on, we need only simple calculations. Inserting the concrete values for p_j, q_j, we find

$$\frac{1}{r_0(\theta)} = \frac{1-\theta}{N} + \theta, \qquad \frac{1}{r_1(\theta)} = \frac{1-\theta}{2N} + \frac{\theta}{p'}.$$

Therefore,

$$\frac{1}{r_0(\theta)} - \frac{1}{r_1(\theta)} = \frac{1-\theta}{N} + \theta - \frac{1-\theta}{2N} - \frac{\theta}{p'} = \frac{1}{2N} + \theta\left(1 - \frac{1}{2N} - \frac{1}{p'}\right).$$

The difference $1/r_0(\theta) - 1/r_1(\theta)$ is a linear function of θ. It admits the values $1/2N$ and $1 - 1/p' > 0$ for $\theta = 0$ and $\theta = 1$, respectively, and thus

$$\frac{1}{r_0(\theta)} - \frac{1}{r_1(\theta)} \geq \delta > 0$$

holds with $\delta = \min(1/2N, 1 - 1/p')$. After multiplication with $r_0 r_1 > 1$, we get $r_1(\theta) - r_0(\theta) \geq \delta r_0 r_1 \geq \delta$ for all $\theta \in [0,1]$, and hence $r_1 \geq r_0 + \delta$. Therefore, the second estimate holds for all $r_0 = p \in [1, N]$, in particular for $p \in [1, N/2]$. □

THEOREM 6.3. *If the regularity condition* (3.5) *is satisfied, then the dual problem* (4.1) *has a solution* $\bar\mu \in (L^\infty(\Omega))^3$.

Proof. (i) *Boundedness in* L^1. We know that the supremum $\bar\alpha$ in (4.1) is finite. Let $(\mu_{i,n})_{n=1}^\infty \in L^2(\Omega)$, $i = 1,2,3$, be sequences such that the constraints of (4.1) are satisfied and

$$-(\bar c\,,\, \mu_{2,n}) - (e\,,\, \mu_{3,n}) \to \bar\alpha$$

for $n \to \infty$. The regularity condition (3.5) gives $\bar c \geq \varepsilon$ and $e \geq \varepsilon$ a.e. on Ω, and hence

$$-(\bar c, \mu_{2,n}) - (e, \mu_{3,n}) \leq -\varepsilon\,(\|\mu_{2,n}\|_{L^1(\Omega)} + \|\mu_{3,n}\|_{L^1(\Omega)}).$$

Therefore, the L^1-norm of $\mu_{2,n}$ and $\mu_{3,n}$ is bounded. The boundedness of $\mu_{1,n}$ in $L^1(\Omega)$ can now be obtained from the constraints of (4.1).

(ii) *Boundedness in* $L^{1+\delta}$. The constraints of (4.1) are equivalent to the constraints (5.2), i.e., $\mu_2 \geq 0$, $\mu_3 \geq 0$, and

$$\mu_2 + \mu_3 \geq -a + S^*\mu_2.$$

In view of this, we have

$$\mu_{2,n} + \mu_{3,n} \geq -a + S^*\mu_{2,n}. \tag{6.3}$$

By Lemma 6.2 and the L^1-boundedness of the sequence $\mu_{2,n}$, the sequence $(S^*\mu_{2,n})$ is bounded in the reflexive Banach space $L^{1+\delta}(\Omega)$, and hence the right-hand side of (6.3) is bounded in $L^{1+\delta}(\Omega)$. Now, we redefine $\mu_{2,n}$, $\mu_{3,n}$ as follows: We take

(6.4)
$$\hat\mu_{2,n}(x) + \hat\mu_{3,n}(x) = \begin{cases} 0, & \text{where } -a(x) + (S^*\mu_{2,n})(x) \leq 0, \\ -a(x) + (S^*\mu_{2,n})(x), & \text{where } -a(x) + (S^*\mu_{2,n}(x)) > 0 \end{cases}$$

and require $0 \leq \hat\mu_{2,n} \leq \mu_{2,n}$ and $0 \leq \hat\mu_{3,n} \leq \mu_{3,n}$. Certainly, this is possible. Then,

$$|\hat\mu_{2,n}(x)| + |\hat\mu_{3,n}(x)| \leq |a| + |(S^*\mu_{2,n})(x)| \text{ a.e. on } \Omega,$$

and hence these new sequences are bounded in $L^{1+\delta}(\Omega)$. Moreover, $\hat\mu_{2,n}, \hat\mu_{3,n} \geq 0$ and $\hat\mu_{2,n} \leq \mu_{2,n}$, together with $S^* \geq 0$, show

$$\hat\mu_{2,n} + \hat\mu_{3,n} \geq -a + S^*\mu_{2,n} \geq -a + S^*\hat\mu_{2,n},$$

and thus the new functions are feasible. They have an objective value greater than or equal to the pair $\mu_{2,n}, \mu_{3,n}$ since $\bar c \geq 0$ and $e \geq 0$. In this way, we have found a sequence with a better objective value that is bounded in the reflexive Banach space $L^{1+\delta}(\Omega)$. By selecting weakly convergent subsequences we can assume that

$$\hat\mu_{2,n} \rightharpoonup \mu_2, \quad \hat\mu_{3,n} \rightharpoonup \mu_3, \quad n \to \infty$$

hold in $L^{1+\delta}(\Omega)$, where $\mu_2, \mu_3 \in L^{1+\delta}(\Omega)$ satisfy all constraints of the dual problem. Moreover, the functions are optimal, and

$$\mu_1 := \mu_2 + \mu_3 + a - S^*\mu_2$$

is the associated optimal μ_1.

(iii) *Solution in* $(L^\infty(\Omega))^3$. We have found an optimal triplet in $(L^{1+\delta}(\Omega))^3$ that satisfies the nonnegativity constraints and

$$\mu_2 + \mu_3 \geq -a + S^*\mu_2. \tag{6.5}$$

By the smoothing property (6.2) of S^*, the function $S^*\mu_2$ belongs to $L^{1+2\delta}(\Omega)$. Applying the technique of (ii), we find $\hat{\mu}_2 \geq 0$, $\hat{\mu}_3 \geq 0$, which satisfy all constraints. Moreover, they belong to $L^{1+2\delta}(\Omega)$ and have the same objective value (clearly, the value cannot be improved further). Applying this bootstrapping technique, we arrive after finitely many steps at the case when $1 + k\delta > N/2$. In the next step, $S^* : L^{1+k\delta}(\Omega) \to L^\infty(\Omega)$ is used to obtain $\hat{\mu}_i \in L^\infty(\Omega)$, $i = 1, 2, 3$. □

THEOREM 6.4. *Suppose that $\bar{u}$ is a local solution of the optimal control problem* (1.1)–(1.3) *that satisfies the regularity condition* (3.5). *Then there exist Lagrange multipliers $\mu_i \in L^\infty(\Omega)$, $i = 1, 2, 3$, satisfying with $\bar{u}$, $\bar{y}$, $\bar{p}$ the optimality system that consists of constraints* (1.2)–(1.3), *the adjoint equation*

$$\begin{array}{rcll} (Ap)(x) + d_y(x, \bar{y}(x))p(x) & = & \psi_y(x, \bar{y}(x), \bar{u}(x)) - \gamma(x)\mu_2(x) & \text{in } \Omega, \\ \partial_\nu p(x) + b_y(x, \bar{y}(x))p(x) & = & \varphi_y(x, \bar{y}(x)) & \text{on } \Gamma, \end{array} \tag{6.6}$$

and, for almost all $x \in \Omega$, the conditions

$$\psi_u(x, \bar{y}(x), \bar{u}(x)) + \beta(x)p(x) + \mu_3(x) + \mu_2(x) - \mu_1(x) = 0, \tag{6.7}$$

$$\mu_i(x) \geq 0, \tag{6.8}$$

$$(\bar{u}(x) - e(x))\mu_3(x) = 0, \tag{6.9}$$

$$(\bar{u}(x) - \gamma(x)\bar{y}(x) - c(x))\mu_2(x) = 0, \tag{6.10}$$

$$\bar{u}(x)\mu_1(x) = 0. \tag{6.11}$$

Proof. We consider the optimal solutions $\mu_i \in L^\infty(\Omega)$ of the dual problem (4.1) and show that they fulfill the required properties. First, we mention

$$\begin{aligned} (a\,,\,\bar{u}) &\geq (a\,,\,\bar{u}) + (\bar{u} - \bar{c} - S\bar{u}\,,\,\mu_2) + (\bar{u} - e\,,\,\mu_3) \\ &= (a + \mu_2 + \mu_3 - S^*\mu_2\,,\,\bar{u}) - (\bar{c}\,,\,\mu_2) - (e\,,\,\mu_3) \end{aligned} \tag{6.12}$$

$$\geq -(\bar{c}\,,\,\mu_2) - (e\,,\,\mu_3), \tag{6.13}$$

since $\bar{u}, \mu_2, \mu_3 \geq 0$ and the inequalities (3.11), (6.5) hold true. From the duality relation of Theorem 5.1,

$$(a\,,\,\bar{u}) = -(\bar{c}\,,\,\mu_2) - (e\,,\,\mu_3),$$

we deduce that the inequalities (6.12), (6.13) must hold as equations, and hence

$$0 = (\bar{u} - \bar{c} - S\bar{u}\,,\,\mu_2) = (\bar{u} - e\,,\,\mu_3) = (a + \mu_2 + \mu_3 - S^*\mu_2\,,\,\bar{u}). \tag{6.14}$$

By definition, $\bar{c} = c + \gamma\,\bar{y} - S\bar{u}$, and hence (6.14) yields

$$\int_\Omega (\bar{u} - c - \gamma\,\bar{y})\mu_2\,dx = \int_\Omega (\bar{u} - e)\mu_3\,dx = 0.$$

Thanks to $\bar u - c - \gamma\bar y \le 0$, $\bar u \le e$, and to the nonnegativity of μ_2, μ_3, this is equivalent to (6.9)–(6.10). Inserting $\mu_1 = a + \mu_2 + \mu_3 - S^*\mu_2$, we obtain from (6.14)

$$\int_\Omega \bar u\, \mu_1\, dx = 0.$$

The nonnegativity of $\bar u$ and μ_1 implies (6.11). By definition, it holds that

$$a + \mu_2 + \mu_3 - \mu_1 - S^*\mu_2 = 0. \tag{6.15}$$

The representation (4.3) for S^* permits us to write

$$S^*\mu_2 = \beta\, q, \tag{6.16}$$

where q solves the adjoint equation (4.2) with right-hand side $\gamma\mu_2$. Moreover,

$$a = \psi_u(\bar y, \bar u) + \beta\, \hat p, \tag{6.17}$$

where $\hat p$ is the solution of (3.9). Obviously, (6.15)–(6.17) are equivalent to (6.6)–(6.7). The complete system of necessary conditions is shown. □

7. An application to pointwise state constraints. Consider the optimal control problem (1.1)–(1.2) subject to the pointwise constraints

$$0 \le u(x), \tag{7.1}$$

$$0 \le c(x) + y(x). \tag{7.2}$$

We know $y \in C(\bar\Omega)$, and hence a Lagrange multiplier μ_2 associated with (7.2) is in general a regular Borel measure, provided that $c \in C(\bar\Omega)$ (cf. Casas [6]). One way to deal with (7.2) numerically by the Lavrentiev-type regularization

$$-\lambda\, u(x) \le c(x) + y(x) \tag{7.3}$$

with $\lambda > 0$ being small [11].

For the results of this section, we assume that the control problem (1.1), (1.2), (7.1), (7.3) has a locally optimal solution $\bar u \in L^\infty(\Omega)$. Notice that this boundedness does not follow from the constraints (7.1), (7.3).

We do not consider here the pass to the limit $\lambda \downarrow 0$. However, we are able to show that, for $\lambda > 0$ fixed, the associated Lagrange multiplier μ_2 can be taken as a function from $L^\infty(\Omega)$ again. For this result, the theory of the preceding sections needs a few modifications. To simplify the notation, we write $\mu := \mu_2$ below. Recall that now $\gamma(x) = 1$, $S = G'(\bar u)$ and therefore $\bar c = c + \bar y - S\,\bar u$.

The state constraints in (7.2) are meaningful only if $c \not\ge 0$, since otherwise $u \ge 0$ would imply $c + y \ge 0$. Therefore, now we cannot assume $\bar c \ge 0$ if we are interested in taking λ small (consider, for instance, the linear case, where $\bar y = S\bar u$, and hence $c = \bar c$).

Our approach is based on linearization and needs the regularity condition (2.4). For the case of the constraints (7.1), (7.3), this condition amounts to the existence of $u_0 \in L^\infty(\Omega)$ and $\varepsilon > 0$ such that

$$\varepsilon \le u_0(x), \quad \varepsilon - \lambda\, u_0(x) \le \bar c(x) + S\, u_0(x) \tag{7.4}$$

for almost all $x \in \Omega$. It is easy to see that this condition is satisfied for the function $u_0(x) \equiv c_0$ if c_0 is taken sufficiently large. Indeed, for $c_0 \to \infty$, the term $-\lambda\, c_0$ in (7.4)

tends to $-\infty$, while $S\,c_0$ remains nonnegative. Moreover, $\bar{c}$ is bounded. Therefore, (7.4) is satisfied for sufficiently large c_0, and we are justified to linearize at any $\bar{u}$.

The associated linear programming problem for a local solution of the problem (1.1), (1.2), (7.2), (7.3) that replaces (3.10)–(3.11) is now

$$\begin{aligned} &\min \quad (a\,,\,u),\\ &-\lambda\,u \le \bar{c} + Su,\\ &\quad u \ge 0,\ u \in L^\infty(\Omega). \end{aligned} \tag{7.5}$$

We know that $\bar{u}$ is a solution of that problem, since $\bar{u}$ is supposed to be a local solution of the optimal control problem in $L^\infty(\Omega)$ and the regularity condition is satisfied. However, this information is related to the space $L^\infty(\Omega)$ that is not suitable for obtaining regular Lagrange multipliers. Therefore, we show that the optimal value of problem (7.5) does not increase if the feasible set is extended from $L^\infty(\Omega)$ to $L^p(\Omega)$ with $p > N/2$.

LEMMA 7.1. *The optimal value of problem* (7.5) *does not change if its feasible set is extended to all* $u \in L^p(\Omega)$, $p > \max\{2, N/2\}$, *satisfying the associated constraints.*

Proof. Let an arbitrary $u \in L^p(\Omega)$ be given such that $u \ge 0$ and

$$-\lambda\,u \le \bar{c} + S\,u \quad \text{a.e. in } \Omega. \tag{7.6}$$

We construct a sequence of functions $u_n \in L^\infty(\Omega)$ such that u_n satisfies (7.6) and $u_n \to u$ in $L^p(\Omega)$ as $n \to \infty$. This implies the statement of the lemma.

By the smoothing property (6.2) of S, we know that $\bar{c} + S\,u \in C(\bar{\Omega})$. Define

$$K = \frac{1}{\lambda}\|\bar{c} + S\,u\|_{L^\infty(\Omega)}$$

and introduce the "cut-off" function

$$v_n(x) = \begin{cases} n, & u(x) > n,\\ u(x), & u(x) \le n. \end{cases}$$

This function is bounded, measurable, and nonnegative. It holds that $v_n \to u$ in $L^p(\Omega)$ as $n \to \infty$. For all $n \ge K$ we have

$$-\lambda\,v_n \le \bar{c} + S\,u \quad \text{a.e. in } \Omega.$$

This inequality is trivial for all x with $u(x) \le n$, since $v_n(x) = u(x)$ is satisfied there. In the remaining points, it holds that

$$-\lambda\,v_n(x) = -\lambda\,n \le -\lambda\,K = -\|\bar{c} + S\,u\|_{L^\infty(\Omega)} \le \bar{c}(x) + (S\,u)(x).$$

In view of $v_n \to u$, the continuity of S from $L^p(\Omega)$ to $C(\bar{\Omega})$ yields

$$-\lambda\,v_n \le \bar{c} + S\,v_n + \varepsilon_n$$

with $\varepsilon_n \downarrow 0$ as $n \to \infty$. For sufficiently large constant $c_0 > 0$, we have

$$-\lambda\,c_0 \le \bar{c} + S\,c_0 - 1.$$

For all $t \in [0,1]$, the convex combination $u_n := (1-t)\,v_n + t\,c_0$ is nonnegative and satisfies

$$-\lambda u_n \le \bar{c} + S\,u_n + (1-t)\,\varepsilon_n - t.$$

We take $t = t_n = \varepsilon_n/(1+\varepsilon_n)$. Then $(1-t_n)\,\varepsilon_n - t_n = \varepsilon_n - t_n\,(1+\varepsilon_n) = 0$, thus

$$-\lambda u_n \le \bar{c} + S\,u_n,$$

and hence u_n fulfills the linearized constraints. Moreover, we have $u_n \to u$, $n \to \infty$. □

Lemma 7.1 ensures that $\bar{u}$ is also a solution of the extended primal problem

$$\begin{aligned} &\min \quad (a\,,\,u),\\ &-\lambda\,u \le \bar{c} + Su,\\ &\quad u \ge 0,\ u \in L^p(\Omega). \end{aligned} \tag{7.7}$$

The dual problem to (7.7) is

$$\begin{aligned} &\max \quad (-\bar{c}\,,\,\mu),\\ &\quad a \ge \lambda\,\mu + S^*\mu,\\ &\quad \mu \ge 0,\ \mu \in L^{p'}(\Omega), \end{aligned} \tag{7.8}$$

where a function $\mu \in L^{p'}(\Omega)$ is to be found. We have already discussed that $S_p^{\otimes}$ maps $L^1(\Omega)$ to $L^{p'}(\Omega)$, and hence S^* can be extended to a continuous operator in $L^{p'}(\Omega)$. Moreover, S^* is nonnegative. We shall see that the constraints above imply $\mu \in L^\infty(\Omega)$, and hence $\mu \in L^2(\Omega)$ so that the notation S^* in (7.8) is justified.

We show that both problems admit the same optimal values and that (7.8) has a solution.

LEMMA 7.2. *The function a is nonnegative a.e. on Ω.*

Proof. As the regularity condition is always satisfied here, Theorem 2.4 shows that $\bar{u}$ solves the linearized problem (7.5). Moreover, Lemma 7.1 ensures that $\bar{u}$ is a solution of the extended problem (7.7), too. Therefore, (7.7) must have at least the optimal solution $\bar{u}$. For all $u \ge 0$, $\bar{u} + u$ satisfies the constraints of (7.5): obviously, we have $\bar{u} + u \ge 0$. Moreover,

$$-\bar{c} \le \lambda\,\bar{u} + S\bar{u} \le \lambda(\bar{u}+u) + S(\bar{u}+u)$$

follows from $\lambda \ge 0$ and $S \ge 0$. Assume that $a(x) < 0$ on $M \subset \Omega$, where M has a positive measure. Take

$$u(x) = \begin{cases} 1 & \text{on } M,\\ 0 & \text{on } \Omega \setminus M. \end{cases}$$

Then $\bar{u} + u$ is feasible, but $(a\,,\,\bar{u}+u) < (a\,,\,\bar{u})$ would hold in contradiction to the optimality of $\bar{u}$. □

THEOREM 7.3. *The dual problem* (7.8) *admits a solution. Moreover, the maximum of the primal problem* (7.5) *is equal to the minimum of* (7.8). *The solution of* (7.8) *is bounded and measurable and is a Lagrange multiplier associated with* (7.2).

Proof. (i) *Solvability of* (7.8). We know from Lemma 7.2 that a is nonnegative. Therefore, $\mu = 0$ is feasible for (7.8). The feasible set is bounded in $L^\infty(\Omega)$, since $\mu \ge 0$ implies $S^*\mu \ge 0$, and hence

$$a \ge \lambda\,\mu + S^*\mu \ge \lambda\mu \ge 0.$$

Now the existence of an optimal solution of (7.8) follows by weak*-compactness.

(ii) *Equality of optimal values.* Rewrite (7.8) in the form of a primal problem, namely,

$$\begin{aligned} &\min \quad (\bar{c}\,,\,\mu),\\ &\lambda\,\mu + S^*\mu \le a,\\ &\mu \ge 0. \end{aligned} \tag{7.9}$$

Its dual admits the form

$$\begin{aligned} &\max \quad (-a\,,\,u),\\ &\lambda\,u + Su \ge -\bar{c},\\ &u \ge 0. \end{aligned} \tag{7.10}$$

(If B is a linear continuous operator, then the general rule for establishing dual problems is as follows: If the primal problem is to minimize $(c\,,\,u)$ subject to $B\,u \le a$ and $u \ge 0$, then its dual is to maximize $(-a\,,\,\mu)$ subject to $B^*\,\mu \ge -c$ and $\mu \ge 0$.)

The optimal values of (7.9) and (7.10) are equal. To show this, we follow the same steps as in the proof of Theorem 5.1. We introduce the cone

$$E := \{(\alpha, d) \in \mathbb{R} \times L^{p'}(\Omega) |\, \exists \mu \ge 0 :\ \lambda\mu + S^*\mu \le d,\ (\bar{c}, \mu) \le \alpha\}.$$

Again, E is closed (boundedness of a sequence $\{\alpha_n, d_n\}$ in $\mathbb{R} \times L^{p'}(\Omega)$ implies that the associated sequence $\{\mu_n\}$ is bounded). Moreover, the element $(\bar{\alpha} - \frac{1}{k}, \bar{c})$ does not belong to E for all $k \in \mathbb{N}$. This element can be separated from E by a closed hyperplane. Continuing as in the proof of Theorem 5.1 (here, the term e does not occur), the equality of the optimal values of (7.9) and (7.10) is obtained. By changing the signs, the same holds for problems (7.8) and (7.7). Lemma 7.1 completes the proof. It follows as in section 6 that the solution $\mu \in L^\infty(\Omega)$ of (7.8) is a Lagrange multiplier associated with the mixed pointwise control-state constraint (7.2). ∎

ON AN OPTIMAL STOPPING PROBLEM OF TIME INHOMOGENEOUS DIFFUSION PROCESSES*

YOICHI OSHIMA†

Abstract. For given quasi-continuous (q.c.) functions g, h with $g \leq h$ and diffusion process $\mathbf{M}$ determined by stochastic differential equations or symmetric Dirichlet forms, characterizations of the value functions $\widetilde{e}_g(s,x) = \sup_\sigma J_{(s,x)}(\sigma)$ and $\bar{w}(s,x) = \inf_\tau \sup_\sigma J_{(s,x)}(\sigma,\tau)$ have been well studied. In this paper, by using the time-dependent Dirichlet forms, we generalize these results to time inhomogeneous diffusion processes. The difficulty of our case arises from the existence of essential semipolar sets [Y. Oshima, *Tohoku Math. J.* (2), 54 (2002), pp. 443–449]. In particular, excessive functions are not necessarily continuous along the sample paths. We get the result by showing such a continuity of the value functions.

Key words. time inhomogeneous diffusion processes, optimal stopping, Dirichlet forms, quasi-variational inequality

1. Introduction and preliminaries.

Let $\mathbf{M} = (X_t, P_{(s,x)})$ be a not necessarily time homogeneous diffusion process on a locally compact separable metric space X. For given (quasi-) continuous functions g, h on $[0,\infty) \times X$ and stopping times σ and τ, let

$$J_{(s,x)}(\sigma) = E_{(s,x)}\left(e^{-\sigma} g(s+\sigma, X_\sigma)\right), \tag{1.1}$$

$$J_{(s,x)}(\sigma,\tau) = E_{(s,x)}\left(e^{-\sigma\wedge\tau}\left(g(s+\sigma,X_\sigma)I_{\{\sigma\leq\tau\}} + h(s+\tau,X_\tau)I_{\{\tau<\sigma\}}\right)\right). \tag{1.2}$$

The main purpose of this paper is to characterize $\widetilde{e}_g(s,x) = \sup_\sigma J_{(s,x)}(\sigma)$ and $\bar{w}(s,x) = \sup_\sigma \inf_\tau J_{(s,x)}(\sigma,\tau)$.

Usually, such a problem is considered for

$$J^f_{(s,x)}(\sigma,\tau) = E_{(s,x)}\left(\int_0^{\sigma\wedge\tau} e^{-t} f(s+t,X_t)dt\right) + J_{(s,x)}(\sigma,\tau) \tag{1.3}$$

instead of $J_{(s,x)}(\sigma,\tau)$. But we use $J_{(s,x)}(\sigma,\tau)$ because (1.3) is essentially reduced to (1.2) by taking $g + R_1 f$ and $h + R_1 f$ instead of g and h, respectively, in (1.3), where $R_\alpha f$ is the resolvent of $\mathbf{M}$.

There are many works related to our problem. In particular, when $\mathbf{M}$ is a diffusion process determined by a stochastic differential equation with Lipschitz continuous coefficients, the detailed results related to $\widetilde{e}_g$ can be found in [1], [7] and references therein. In the time homogeneous case, Nagai [10], [11] and Zabczyk [19] used (symmetric) Dirichlet form theory to solve the problem. The diffusion process $\mathbf{M}$ corresponding to the generator on R^d determined by

$$A\varphi(x) = \sum_{i,j=1}^d \frac{1}{\rho(x)}\frac{\partial}{\partial x_i}\left(a_{ij}(x)\rho(x)\frac{\partial\varphi}{\partial x_j}\right) \tag{1.4}$$

†Department of Mathematics, Faculty of Engineering, Kumamoto University, Kumamoto, 860-8555, Japan (oshima@gpo.kumamoto-u.ac.jp).

for uniformly elliptic functions $(a_{ij}(x))_{i,j=1,2,\dots,d}$ and a function $\rho(x) > 0$ belonging to a Sobolev space on R^d is contained in their framework. See also [5] and [8] for related results.

The purpose of this paper is to generalize those results to time inhomogeneous diffusion processes including the case that (a_{ij}) in (1.4) admits to dependence on a time parameter. In this case, the generator for each t is given by

$$A^{(t)}\varphi(x) = \sum_{i,j=1}^{d} \frac{1}{\rho(x)} \frac{\partial}{\partial x_i} \left(a_{ij}(t,x)\rho(x) \frac{\partial \varphi}{\partial x_j} \right) \tag{1.5}$$

and the coresponding Dirichlet form on $L^2(R^d; \rho(x)dx)$ is an extension of

$$E^{(t)}(\varphi, \psi) = \sum_{i,j=1}^{d} \int_{R^d} a_{ij}(t,x) \frac{\partial \varphi}{\partial x_i} \frac{\partial \psi}{\partial x_j} \rho(x) dx. \tag{1.6}$$

In the Lipschitz continuous and time homogeneous cases stated above, the (quasi-) continuity of the value functions $\widetilde{e}_g$ and $\bar{w}$ follows naturally. The essential step in this paper is to prove the fine and cofine continuities of the value functions.

The organization of this paper is as follows. In the rest of this section, the notions of time-dependent Dirichlet forms and the basic properties of the associated time inhomogeneous Markov processes are stated. In section 2, under the separability condition, quasi-variational inequalities and their solutions are given. In section 3, the optimal stopping problem is solved and is divided into three cases: (I) one obstacle cases, (II) two obstacles cases under the separability condition, and (III) general two obstacles cases.

Now we shall start with our settings. Let X be a locally compact separable metric space and m a positive Radon measure on X with full support. We assume that we are given a family $(E^{(t)}, F)_{t \geq 0}$ of Dirichlet forms on $H = L^2(X; m)$ satisfying the following conditions [4]:

(i) For each $t \geq 0$, $(E^{(t)}, F)$ is an m-symmetric Dirichlet form on H.

(ii) For any $\varphi \in F$, $E^{(t)}(\varphi, \varphi)$ is a measurable function of $t \geq 0$ and satisfies

$$\lambda^{-1} \|\psi\|_F^2 \leq E_1^{(t)}(\psi, \psi) \leq \lambda \|\psi\|_F^2 \tag{1.7}$$

for some positive constant λ, where $E_\alpha^{(t)}(\psi, \psi) = E^{(t)}(\psi, \psi) + \alpha(\psi, \psi)_m$ and $\|\psi\|_F^2 = E_1^{(0)}(\psi, \psi)$.

(iii) F is regular; that is, $C_0(X) \cap F$ is uniformly dense in $C_0(X)$ and $\|\cdot\|_F$-dense in F, where $C_0(X)$ is the family of continuous functions on X with compact support.

(iv) For any $t \geq 0$, $(E^{(t)}, F)$ is local; that is, for any $\varphi, \psi \in F \cap C_0(X)$ such that $\varphi \cdot \psi = 0$, $E^{(t)}(\varphi, \psi) = 0$.

For simplicity, we put $E^{(t)} = E^{(0)}$ for $t < 0$. For each t, there exists an operator $A^{(t)}$ from F to F' such that

$$-\langle A^{(t)}\varphi, \psi \rangle = E^{(t)}(\varphi, \psi) \tag{1.8}$$

for any $\varphi, \psi \in F$. To consider an optimal stopping problem related to the time inhomogeneous diffusion process X_t with generator $A^{(t)}$, we shall introduce the space-time process $Z_t = (\tau(t), X_t)$ on $Z = R^1 \times X$ with uniform motion $\tau(t)$. Formally, the resolvent $R_\alpha f$ of Z_t satisfies

$$\left(\alpha - \frac{\partial}{\partial t} - A^{(t)} \right) R_\alpha f(t,x) = f(t,x). \tag{1.9}$$

To define Z_t more rigorously, let us introduce the spaces $\mathcal{H}$, $\mathcal{F}$, and $\mathcal{W}$. Put $\mathcal{H} = \{u(t,x) : u(t,\cdot) \in H, \|u\|_{\mathcal{H}} < \infty\}$, where

$$\|u\|_{\mathcal{H}}^2 = \int_{R^1} \|u(t,\cdot)\|_H^2 dt.$$

The space $\mathcal{F}$ is a family of measurable functions $u \in \mathcal{H}$ such that $u(t,\cdot) \in F$ for all t and $\|u\|_{\mathcal{F}} < \infty$, where

$$\|u\|_{\mathcal{F}}^2 = \int_{R^1} \|u(t,\cdot)\|_F^2 \, dt.$$

The dual space $\mathcal{F}'$ is defined similarly by taking F' instead of F in the definition of $\mathcal{F}$. For any function $f \in \mathcal{F}$, considering f as a function of $t \in R^1$ with value in F', the distribution derivative $\partial f/\partial t$ is defined as a function $g(t,\cdot)$ on R^1 with value in F' such that

$$\int_{R^1} g(t,\cdot)\xi(t)dt = \int f(t,\cdot)\xi'(t)dt$$

for any $\xi \in C_0^\infty(R^1)$. Using this derivative, define the space $(\mathcal{W}, \|\cdot\|_{\mathcal{W}})$ by

$$\mathcal{W} = \left\{ u \in \mathcal{F} : \frac{\partial u}{\partial t} \in \mathcal{F}', \ \|u\|_{\mathcal{W}} < \infty \right\},$$
$$\|u\|_{\mathcal{W}}^2 = \left\| \frac{\partial u}{\partial t} \right\|_{\mathcal{F}'}^2 + \|u\|_{\mathcal{F}}^2 .$$

Further, define the bilinear form $\mathcal{E}$ by

$$\mathcal{E}(u,v) = \begin{cases} -\int_{R^1} \left(\frac{\partial u}{\partial t}, v \right) dt + \int_{R^1} E^{(t)}(u(t,\cdot), v(t,\cdot))dt, & u \in \mathcal{W}, v \in \mathcal{F}, \\ \int_{R^1} \left(\frac{\partial v}{\partial t}, u \right) dt + \int_{R^1} E^{(t)}(u(t,\cdot), v(t,\cdot))dt, & u \in \mathcal{F}, v \in \mathcal{W}. \end{cases}$$

Then for $f \in \mathcal{H}$, $R_\alpha f$ in (1.9) is considered as a version of $G_\alpha f \in \mathcal{W}$ of the solution of

$$\mathcal{E}_\alpha(G_\alpha f, v) = (f, v)_\nu$$

for any $v \in \mathcal{F}$, where $\mathcal{E}_\alpha(\ ,\ ) = \mathcal{E}(\ ,\ ) + \alpha(\ ,\ )_\nu$ and $d\nu(t,x) = dtdm(x)$. This equation is equivalent to

$$-\left(\frac{\partial}{\partial t} G_\alpha f(t,\cdot), \varphi \right) + E_\alpha^{(t)} \left(G_\alpha f(t,\cdot), \varphi \right) = (f(t,\cdot), \varphi)$$

for any $t \geq 0$ and $\varphi \in F$. The dual resolvent $\widehat{G}_\alpha f \in \mathcal{W}$ is defined as a solution of

$$\left(\frac{\partial}{\partial t} \widehat{G}_\alpha f(t,\cdot), \varphi \right) + E_\alpha^{(t)} \left(\varphi, \widehat{G}_\alpha f(t,\cdot) \right) = (f(t,\cdot), \varphi)$$

for any $t \geq 0$ and $\varphi \in F$. Then, for any $f \in \mathcal{F}$ (resp., $f \in \mathcal{H}$), $\|\alpha G_\alpha f\|_{\mathcal{F}} \leq C_1 \|f\|_{\mathcal{F}}$ (resp., $\|\alpha G_\alpha f\| \leq \|f\|_{\mathcal{H}}$) for some constant C_1 and $\lim_{\alpha\to\infty} \alpha G_\alpha f = f$ in $\mathcal{F}$ (resp.,

$\mathcal{H}$) (see [14, Lemma 2.1], [16, I.3, I.4]). Similar results also hold for the dual resolvent $\widehat{G}_\alpha$.

To choose a version $R_\alpha f$ of $G_\alpha f$, we need to define a capacity. A function $u \in \mathcal{F}$ is called *α-excessive* if $\mathcal{E}_\alpha(u, w) \geq 0$ for any nonnegative function $w \in \mathcal{W}$. Then $u \in \mathcal{F}$ is α-excessive if and only if $u \geq 0$ and $\beta G_{\beta+\alpha} u \leq u$ a.e. for all $\beta > 0$ (see [14]). We denote by $\mathcal{P}_\alpha$ the family of all α-excessive functions. In particular, put $\mathcal{P} = \mathcal{P}_1$.

For any function $h \in \mathcal{H}$, let

$$\mathcal{L}_h = \{u \in \mathcal{F} : u \geq h \ \nu \ a.e.\}$$

and $\mathcal{L}_A = \mathcal{L}_{I_A}$. Then the following results hold (see [9] and [15]).

LEMMA 1.1. *For any $\varepsilon > 0$ and $\alpha > 0$, there exists a unique function $h_\varepsilon^\alpha \in \mathcal{W}$ such that*

$$-\left(\frac{\partial h_\varepsilon^\alpha}{\partial t}, \varphi\right) + E_\alpha^{(t)}\left(h_\varepsilon^\alpha(t,\cdot), \varphi\right) = \frac{1}{\varepsilon}\left(\left(h_\varepsilon^\alpha(t,\cdot) - h(t,\cdot)\right)^-, \varphi\right) \tag{1.10}$$

for any $\varphi \in F$.

THEOREM 1.2. *Suppose that $\mathcal{L}_h \cap \mathcal{W} \neq \emptyset$. Then $e_h^\alpha = \lim_{\varepsilon \downarrow 0} h_\varepsilon^\alpha$ converges increasingly, strongly in $\mathcal{H}$ and weakly in $\mathcal{F}$. Furthermore, e_h^α is the minimal function of $\mathcal{P}_\alpha \cap \mathcal{L}_h$ and satisfies*

$$\mathcal{A}_\alpha\left(e_h^\alpha, e_h^\alpha\right) \leq \mathcal{E}_\alpha\left(e_h^\alpha, w\right) \tag{1.11}$$

for any $w \in \mathcal{L}_h \cap \mathcal{W}$.

If $u \in \mathcal{P}_\alpha$, then there exists a positive Radon measure μ_u^α on Z such that

$$\mathcal{E}_\alpha(u, w) = \int_Z w(z) d\mu_u^\alpha(z) \quad \text{for any } w \in C_0(Z) \cap \mathcal{W}. \tag{1.12}$$

We omit the superfix α in e_h^α and μ_u^α if $\alpha = 1$. For any open set A of Z such that $\mathcal{L}_A \cap \mathcal{W} \neq \emptyset$, put $e_A = e_{I_A}$ and $\mu_A = \mu_{e_A}$. Then μ_A is supported by the closure $\bar{A}$ of A. The *capacity* $\mathrm{Cap}(A)$ of A is defined by

$$\mathrm{Cap}(A) = \mu_A(\bar{A}).$$

If there exists $w \in \mathcal{W}$ such that $w = 1$ a.e. on A, then

$$\mathrm{Cap}(A) = \mathcal{E}_\alpha(e_A^\alpha, w). \tag{1.13}$$

The notion of the capacity is extended to any Borel set by the usual manner. A set is called *exceptional* if it is of zero capacity. If a statement holds everywhere except on an exceptional set, then we say the statement holds quasi-everywhere (q.e.).

An increasing sequence of closed sets $\{F_n\}$ is called a *nest* if $\lim_{n\to\infty} \mathrm{Cap}(Z \backslash F_n) = 0$. A function u is called *quasi-continuous* (q.c.) if there exists a nest $\{F_n\}$ of closed sets such that u is continuous on each F_n. The *quasi-lower semicontinuity* is defined similarly. Any function $u \in \mathcal{W}$ has a q.c. modification $\widetilde{u}$. In particular, for any $f \in \mathcal{H}$ and $\alpha > 0$, $G_\alpha f$ and $\widehat{G}_\alpha f$ have q.c. modifications. The relation (1.12) can be extended to $w \in \mathcal{W}$ by taking the q.c. modification. For any α-excessive function $u \in \mathcal{F}$, define its α-excessive modification $\widetilde{u}$ by $\widetilde{u} = \lim_{n\to\infty} nR_{n+\alpha} u$. Since $\widetilde{u}$ is an increasing limit of q.c. functions, $\widetilde{u}$ is quasi-lower semicontinuous. The following theorem and the properties of the associated diffusion process can be found in [12], [14], [16], [17], and [18].

THEOREM 1.3. *There exist diffusion processes* $\mathbf{M} = (Z_t, P_z)$ *and* $\widehat{\mathbf{M}} = (\widehat{Z}_t, \widehat{P}_z)$ *on* Z *satisfying the following conditions:*

(i) *The resolvents* $R_\alpha f$ *and* $\widehat{R}_\alpha f$ *of* $\mathbf{M}$ *and* $\widehat{\mathbf{M}}$ *are q.c. modifications of* $G_\alpha f$ *and* $\widehat{G}_\alpha f$*, respectively.*

(ii) *Let* $Z_t = (\tau(t), X_t)$ *and* $\widehat{Z}_t = (\widehat{\tau}(t), \widehat{X}_t)$ *be the decompositions of* Z_t *and* $\widehat{Z}_t$ *into the processes on* R^1 *and* X*, respectively. Then* $\tau(t) = \tau(0)+t$ *and* $\widehat{\tau}(t) = \widehat{\tau}(0)-t$.

(iii) *For any open set* A *of* Z, $E.(e^{-\alpha\sigma_A})$ *is a quasi-lower semicontinuous modification of* e_A^α*, where* σ_A *is the hitting time of* A.

For later use, we present two lemmas. The proof of Lemma 1.4 can be found in [12, Lemma 3.7].

LEMMA 1.4. *For any* α*-excessive function* $u \in \mathcal{F}$, $\mu_u^{(\alpha)}$ *does not charge any Borel set of zero capacity.*

LEMMA 1.5. *Suppose that a sequence of* 1*-excessive functions* $\{u_n\}$ *converges to zero in* $\mathcal{H}$*. Then there exists a subsequence* $\{u_{n_k}\}$ *such that* $\lim_{k\to\infty} \widetilde{u}_{n_k} = 0$ *quasi-uniformly; that is, there exists a nest* $\{F_n\}$ *such that* $\lim_{k\to\infty} \widetilde{u}_{n_k} = 0$ *uniformly on each* F_n.

Proof. Since $\widetilde{u}_n$ is quasi-lower semicontinuous, there exists an open set N_k such that $\mathrm{Cap}(N_k) < 1/2^k$ and $\widetilde{u}_n$ is lower semicontinuous on $Z \setminus N_k$ for all n. Put $B_k^n = \{z \in Z \setminus N_k : \widetilde{u}_n(z) > 1/2^k\}$ and $D_k^n = B_k^n \cup N_k$. Then D_k^n is open and, noting that $(e_{N_k}, p) = \langle \mu_{N_k}, \widehat{R}_1 p\rangle \le ||p||_\infty \mathrm{Cap}(N_k) < ||p||_\infty/2^k$ for any nonnegative bounded continuous function $p \in \mathcal{H}$, it holds that

$$\begin{aligned}(e_{D_k^n}, p) &\le (e_{B_k^n}, p) + (e_{N_k}, p) \le 2^k (u_n, p) + \|p\|_\infty \mathrm{Cap}(N_k)\\ &\le 2^k \|u_n\|_{\mathcal{H}} \cdot \|p\|_{\mathcal{H}} + \frac{\|p\|_\infty}{2^k}.\end{aligned}$$

For each k, take n_k such that $\|u_n\|_{\mathcal{H}} \le 1/2^{2k}$ for any $n \ge n_k$. Then $F_m = Z \setminus \cup_{k=m}^\infty D_{n_k}^k$ is a closed set. Since $\{Z \setminus F_m\}$ is a decreasing sequence of open sets such that

$$\langle \mu_{Z\setminus F_m}, \widehat{R}_1 p\rangle = \left(e_{Z\setminus F_m}, p\right) \le \frac{1}{2^{m-1}} \left(\|p\|_{\mathcal{H}} + \|p\|_\infty\right)$$

for any p satisfying the stated conditions, $\lim_{m\to\infty} \mathrm{Cap}(Z\setminus F_m) = \lim_{m\to\infty} \mu_{Z\setminus F_m}(Z) = 0$. Furthermore, $\lim_{k\to\infty} u_{n_k} = 0$ uniformly on each F_m. □

2. Quasi-variational inequalities. In this section, we assume that we are given two *obstacles* $g, h \in \mathcal{F}$ which are q.-c. and $g \le h$ q.e. We say that the pair (g, h) satisfies the *separability condition* if there exist $\varphi, \psi \in \mathcal{P}$ such that

$$g \le \widetilde{\varphi} - \widetilde{\psi} \le h \text{ q.e.} \tag{2.1}$$

Define the sequences of 1-excessive functions $\{u_n\}$ and $\{v_n\}$ inductively by

$$u_0 = 0,\ v_n = e_{u_{n-1}-h},\ u_n = e_{v_n+g}.$$

For any $\phi \in \mathcal{P}$, let L_ϕ be a continuous linear functional on $\mathcal{F}$ defined by $L_\phi(w) = \mathcal{A}_1(\phi, w)$. In the proof of Lemma 5.2 in [14], one can see that $2\widehat{G}_1 L_\phi - \phi$ is 1-coexcessive, and thus in particular nonnegative. Hence

$$\phi \le 2\widehat{G}_1 L_\phi \in \mathcal{W}. \tag{2.2}$$

LEMMA 2.1. *Suppose that the separability condition* (2.1) *holds. Then*

(i) u_n, v_n *are well defined.*

(ii) $\lim_{n\to\infty} u_n = \bar{u}$ *and* $\lim_{n\to\infty} v_n = \bar{v}$ *converge increasingly, strongly in* $\mathcal{H}$, *and weakly in* $\mathcal{F}$.

(iii) $\bar{u} \le \varphi$, $\bar{v} \le \psi$, *and* $g \le \bar{u} - \bar{v} \le h$ *a.e.*

Proof. Clearly $u_0 = 0 \le \varphi$. Suppose that u_{n-1} is defined and satisfies $u_{n-1} \le \varphi$. Then by the separability condition, $u_{n-1} - h \le \varphi - h \le \psi$. Thus $u_{n-1} - h \le 2\widehat{G}_1 L_\psi \in \mathcal{W}$ by (2.2). Hence $v_n := e_{u_{n-1}-h}$ is well defined and $v_n \le \psi$ by Theorem 1.2. Again, by (2.2) and the separability condition, $v_n + g = e_{u_{n-1}-h} + g \le \psi + g \le \varphi \le 2\widehat{G}_1 L_\varphi \in \mathcal{W}$. Therefore $u_n := e_{v_n+g}$ is well defined and dominated by φ.

If $u_{n-1} \le u_n$, then $v_n = e_{u_{n-1}-h} \le e_{u_n-h} = v_{n+1}$ and $u_n = e_{v_n+g} \le e_{v_{n+1}+g} = u_{n+1}$. Thus u_n and v_n are well defined and increasing relative to n. By virtue of (2.2),

$$\mathcal{A}_1(u_n.u_n) \le 2\mathcal{E}_1(u_n, \widehat{G}_1 L_\varphi) \le 2\|u_n\|_{\mathcal{F}} \|\widehat{G}_1 L_\varphi\|_{\mathcal{W}}.$$

Hence $\{\|u_n\|_{\mathcal{F}}\}$ is bounded. Similarly, $\{\|v_n\|_{\mathcal{F}}\}$ is bounded and the assertion (ii) holds by Lemma I.2.12 in [6].

Since $u_n \le \varphi$ and $v_n \le \psi$, the first assertion of (iii) holds. Furthermore, from the definition, $u_{n-1} - h \le v_n$ and $v_n + g \le u_n$. This implies the second assertion of (iii). □

THEOREM 2.2. *Under the separability condition,* $\bar{u} = e_{\bar{v}+g}$ *and* $\bar{v} = e_{\bar{u}-h}$. *In particular,*

$$\mathcal{A}_1(\bar{u}, \bar{u}) \le \mathcal{E}_1(\bar{u}, w) \quad \forall w \in \mathcal{L}_{\bar{v}+g} \cap \mathcal{W},$$
$$\mathcal{A}_1(\bar{v}, \bar{v}) \le \mathcal{E}_1(\bar{v}, w) \quad \forall w \in \mathcal{L}_{\bar{u}-h} \cap \mathcal{W}.$$

Moreover, if a pair of 1*-excessive functions* (u, v) *satisfies* $g \le u - v \le h$, *then* $\bar{u} \le u$ *and* $\bar{v} \le v$.

Proof. Since $\bar{u}$ is a 1-excessive function in $\mathcal{L}_{\bar{v}+g}$, clearly $e_{\bar{v}+g} \le \bar{u}$. Conversely, $\bar{u} = \lim_{n\to\infty} u_n = \lim_{n\to\infty} e_{v_n+g} \le e_{\bar{v}+g}$ by Lemma 2.1. Similarly, $\bar{v} = e_{\bar{u}-h}$. The quasi-variational inequalities are already stated in Theorem 1.2. By Lemma 2.1, if g, h satisfy the separability condition with $(u, v) \in \mathcal{P} \times \mathcal{P}$, then $u_n \le u, v_n \le v$ for any n. Since $\lim_{n\to\infty} u_n = \bar{u}, \lim_{n\to\infty} v_n = \bar{v}$, we obtain $\bar{u} \le u, \bar{v} \le v$. □

A similar quasi-variational inequality for $\bar{u} - \bar{v}$ also holds. But it will be given in the next section because we use a probabilistic argument for the proof.

LEMMA 2.3. *For any* $g \in \mathcal{W}$, $\lim_{k\to\infty} e_{g-g^{(k)}} = 0$ *in* $\mathcal{F}$.

Proof. Since $g - g^{(k)} \in \mathcal{L}_{g-g^{(k)}} \cap \mathcal{W}$,

$$\begin{aligned}
\mathcal{A}_1\left(e_{g-g^{(k)}}, e_{g-g^{(k)}}\right) &\le \mathcal{E}_1\left(e_{g-g^{(k)}}, g - g^{(k)}\right) \\
&= -\mathcal{E}_1\left(g - g^{(k)}, e_{g-g^{(k)}}\right) + 2\mathcal{A}_1\left(e_{g-g^{(k)}}, g - g^{(k)}\right) \\
&= -\mathcal{E}_1\left(g, e_{g-g^{(k)}} - k\widehat{G}_k e_{g-g^{(k)}}\right) + 2\mathcal{A}_1\left(e_{g-g^{(k)}}, g - g^{(k)}\right) \qquad (2.3) \\
&\le 2\|g\|_{\mathcal{W}} \|e_{g-g^{(k)}} - k\widehat{G}_k e_{g-g^{(k)}}\|_{\mathcal{F}} + 2\|g - g^{(k)}\|_{\mathcal{F}} \|e_{g-g^{(k)}}\|_{\mathcal{F}} \\
&\le 4\|g\|_{\mathcal{W}}(C_1 + 1)\|e_{g-g^{(k)}}\|_{\mathcal{F}}.
\end{aligned}$$

Hence $\mathcal{A}_1(e_{g-g^{(k)}}, e_{g-g^{(k)}})$ is bounded. By virtue of [16, III.Lemma 2.2], $e_{g-g^{(k)}}$ converges to 0 strongly in $\mathcal{H}$, and hence weakly in $\mathcal{F}$ from [6, Lemma I.2.12]. Since $\|k\widehat{G}_k e_{g-g^{(k)}}\|_{\mathcal{F}} \le C_1 \|e_{g-g^{(k)}}\|_{\mathcal{F}}$, by the same argument, $\lim_{k\to\infty} k\widehat{G}_k e_{g-g^{(k)}} = 0$ strongly in $\mathcal{H}$ and weakly in $\mathcal{F}$. Hence from (2.3), $\lim_{k\to\infty} \mathcal{A}_1(e_{g-g^{(k)}}, e_{g-g^{(k)}}) = 0$. □

3. An optimal stopping problem. Let $\mathbf{M}$ and $\widehat{\mathbf{M}}$ be the diffusion processes given by Theorem 1.3. Denote by R_α and $\widehat{R}_\alpha$ their associated resolvents. For any stopping time σ, define $H_\sigma u$ by $H_\sigma u(z) = E_z\left(e^{-\sigma}u(Z_\sigma)\right)$. In particular, put $H_B = H_{\sigma_B}$ for the hitting time σ_B of the nearly Borel set B.

(I) One obstacle case:

Let g be a q.c. function of $\mathcal{F}$ such that $\mathcal{L}_g \cap \mathcal{W} \neq \emptyset$. As in the previous section, denote by e_g the minimal 1-excessive function of $\mathcal{L}_g$. Then it is the minimal function of $\mathcal{L}_g$ satisfying the quasi-variational inequality (1.11). The following result is a time inhomogeneous version of Nagai's result [10].

THEOREM 3.1. *Suppose that $g \in \mathcal{F}$ is q.c. and $\mathcal{L}_g \cap \mathcal{W} \neq \emptyset$. Then*

$$\widetilde{e}_g(z) = \sup_\sigma J_z(\sigma) = E_z\left(e^{-\sigma_B}g(Z_{\sigma_B})\right) \text{ q.e.}, \tag{3.1}$$

where the supremum is taken over all stopping times σ and $B = \{z : \widetilde{e}_g(z) = g(z)\}$.

Proof. Noting that $\widetilde{e}_g$ is the smallest 1-excessive function dominating g q.e., we have for any stopping time σ,

$$E_z\left(e^{-\sigma}g(Z_\sigma)\right) \le E_z\left(e^{-\sigma}\widetilde{e}_g(Z_\sigma)\right) \le \widetilde{e}_g(z) \text{ q.e.}$$

Hence it is enough to show

$$\widetilde{e}_g(z) = E_z\left(e^{-\sigma_B}g(Z_{\sigma_B})\right). \tag{3.2}$$

This is essentially shown in [14, Lemma 6.2], but we shall give the outline of the proof for completeness. For $\varepsilon_n \downarrow 0$, let g_n be a q.c. version of the solution of $g_n = (1/\varepsilon_n)G_1\left((g_n - g)^-\right)$ determined by Lemma 1.1. Let $B_n = \{z : g_n(z) \le g(z)\}$ and $\dot{\sigma}_n = \dot{\sigma}_{B_n}$, where $\dot{\sigma}_A$ is the first entry time of A defined by $\dot{\sigma}_A = \inf\{t \ge 0 : Z_t \in A\}$. Then

$$\begin{aligned} g_n(z) &= \frac{1}{\varepsilon_n}E_z\left(\int_{\dot{\sigma}_n}^\infty e^{-t}(g_n - g)^-(Z_t)dt\right) \\ &= E_z\left(e^{-\dot{\sigma}_n}g_n(Z_{\dot{\sigma}_n})\right) \le E_z\left(e^{-\dot{\sigma}_n}g(Z_{\dot{\sigma}_n})\right) \\ &\le E_z\left(e^{-\dot{\sigma}_n}\widetilde{e}_g(Z_{\dot{\sigma}_n})\right). \end{aligned}$$

Put $\dot{\sigma} = \lim_{n\to\infty}\dot{\sigma}_n$. Then $\dot{\sigma} \le \dot{\sigma}_B$. By virtue of Theorem 1.2, since $g_n \uparrow e_g$ a.e., we then have, for any nonnegative function $f \in \mathcal{H}$,

$$\begin{aligned} (f, \widetilde{e}_g) &= \lim_{n\to\infty}(f, g_n) = \lim_{n\to\infty} E_{f\cdot\nu}\left(e^{-\dot{\sigma}_n}g_n(Z_{\dot{\sigma}_n})\right) \le \lim_{n\to\infty} E_{f\cdot\nu}\left(e^{-\dot{\sigma}_n}g(Z_{\dot{\sigma}_n})\right) \\ &= E_{f\cdot\nu}\left(e^{-\dot{\sigma}}g(Z_{\dot{\sigma}})\right) \le E_{f\cdot\nu}\left(e^{-\dot{\sigma}}\widetilde{e}_g(Z_{\dot{\sigma}})\right) \le (f, \widetilde{e}_g). \end{aligned}$$

Hence $\widetilde{e}_g(z) = E_z\left(e^{-\dot{\sigma}}g(Z_{\dot{\sigma}})\right)$ for a.e. z. Since $g \le \widetilde{e}_g$ q.e., we also have $g(Z_{\dot{\sigma}}) = \widetilde{e}_g(Z_{\dot{\sigma}})$, and hence $\dot{\sigma}_B \le \dot{\sigma}$ a.s. P_z for a.e. z. Therefore $\dot{\sigma} = \dot{\sigma}_B$ a.s. P_z and $\widetilde{e}_g(z) = E_z\left(e^{-\dot{\sigma}_B}g(Z_{\dot{\sigma}_B})\right)$ for a.e. z. By taking the 1-excessive regularization, we get the result. □

Remark. Since $\dot{\sigma}_B \le \sigma_B$, it holds that

$$\widetilde{e}_g \ge H_{\dot{\sigma}_B}\widetilde{e}_g \ge H_B\widetilde{e}_g \ge H_Bg \quad \text{q.e.}$$

Hence Theorem 3.1 implies that $H_{\dot{\sigma}_B}\widetilde{e}_g = H_B\widetilde{e}_g$ q.e. z. In particular, the set of irregular points of B is exceptional.

(II) Two obstacles case under the separability condition:

We assume that we are given two q.c. functions $g, h \in \mathcal{F}$ such that $g \leq h$ q.e. If the separability condition (2.1) is satisfied, then there exists the minimal pair of finely continuous functions $(\bar{u}, \bar{v})$ given by Theorem 2.2. They are given by $\bar{u} = \lim_{k\to\infty} \bar{u}_k$ and $\bar{v} = \lim_{k\to\infty} \bar{v}_k$ with the solutions $\bar{u}_k, \bar{v}_k \in \mathcal{W}$ of $\bar{u}_k = (1/\varepsilon_k)G_\alpha\left((\bar{u}_k - \bar{v} - g)^-\right)$ and $\bar{v}_k = (1/\varepsilon_k)G_\alpha\left((\bar{v}_k - \bar{u} + h)^-\right)$, respectively. Define the sets C_k and D_k by

$$C_k = \{z : \bar{u}_k(z) \leq (g + \bar{v})(z)\}, \quad D_k = \{z : \bar{v}_k(z) \leq (\bar{u} - h)(z)\}. \tag{3.3}$$

Then $C_k \supset C$ and $D_k \supset D$ for

$$C = \{z : \bar{u}(z) = (g + \bar{v})(z)\}, \quad D = \{z : \bar{v}(z) = (\bar{u} - h)(z)\}. \tag{3.4}$$

As we remarked before (2.2), $\bar{u}$ can be represented as a difference of a function of $\mathcal{W}$ and a coexcessive function. In particular, $\bar{u}$ has a q.e. cofinely continuous modification $\widehat{u}$ given by $\widehat{u} = \lim_{n\to\infty} n\widehat{R}_{n+1}\bar{u}$. Since $\bar{u}$ is q.e. lower semicontinuous, $\widehat{u}(z) = \lim_{t\to 0} \widehat{E}_z\left(\bar{u}(Z_t)\right) \geq \underline{\lim}_{y\to z} \bar{u}(y) \geq \bar{u}(z)$ q.e. Similarly, a q.e. cofinely continuous modification $\widehat{v}$ of $\bar{v}$ exists and satisfies $\widehat{v} \geq \bar{v}$ q.e.

Since $\bar{v}$ is 1-excessive, there exists a positive Radon measure $\mu_{\bar{v}}$ charging no exceptional set such that $\mathcal{E}_1(\bar{v}, w) = \langle \mu_{\bar{v}}, \widetilde{w} \rangle$ for any $w \in \mathcal{W}$. In the following two lemmas, we use the notation $\mu_{\bar{v},F} = \mu_{\bar{v}}|_F, \mu_{\bar{v},F^c} = \mu_{\bar{v}}|_{F^c}, \bar{v}_F = \widetilde{U}_1\mu_{\bar{v},F}$, $\bar{v}_{F^c} = \widetilde{U}_1\mu_{\bar{v},F^c}$, and $\widehat{v}_{F^c} = \lim_{n\to\infty} n\widehat{R}_{n+1}\bar{v}_{F^c}$.

LEMMA 3.2. *Assume that there exists a nonexceptional compact set F such that $F \subset \{z : (\widehat{v} - \bar{v})(z) \geq \delta\}$ for some $\delta > 0$. Then $\widehat{v}_{F^c}(z) = \bar{v}_{F^c}(z)$ for q.e. $z \in F$.*

Proof. For simplicity of the notation, put $\mu_1 = \mu_{\bar{v},F}$, $\mu_2 = \mu_{\bar{v},F^c}$, $\bar{v}_2 = \widetilde{U}_1\mu_2$, and $\widehat{v}_2$ the cofinely continuous modification of $\bar{v}_2$. Assume that there exists a nonexceptional compact subset K of F such that $\bar{v}_2(z) < \widehat{v}_2(z)$ for q.e. $z \in K$. For a decreasing sequence of open sets G_n such that $\bar{G}_{n+1} \subset G_n$ and $\cap_n G_n = K$, since σ_{G_n} increases strictly to σ_K a.s. P_z for q.e. $z \notin K$, the left continuity of $\widehat{v}_2(Z_t)$ implies that

$$\lim_{n\to\infty} H_{G_n}\bar{v}_2(z) = \lim_{n\to\infty} E_z\left(e^{-\sigma_{G_n}}\bar{v}_2(Z_{\sigma_{G_n}})\right) = E_z\left(e^{-\sigma_K}\widehat{v}_2(Z_{\sigma_K})\right) = H_K\widehat{v}_2(z).$$

On the other hand, since $\mu_2(K) = 0$, for any $f \in L^2_+(Z)$, we have from [14, Corollary 5.1] and [2, Theorem I.11.2],

$$\begin{aligned}
\lim_{n\to\infty} (H_{G_n}\bar{v}_2, f) &= \lim_{n\to\infty} \mathcal{E}_1(H_{G_n}\bar{v}_2, \widehat{R}_1 f) = \lim_{n\to\infty} \mathcal{E}_1(U_1\mu_2, \widehat{H}_{G_n}\widehat{R}_1 f) \\
&= \lim_{n\to\infty} \langle \mu_2, \widehat{H}_{G_n}\widehat{R}_1 f\rangle = \langle \mu_2, \widehat{H}_K\widehat{R}_1 f\rangle \\
&= (H_K\bar{v}_2, f).
\end{aligned}$$

Hence $H_K\widehat{v}_2 = H_K\bar{v}_2$ a.e., which contradicts the assumption. □

LEMMA 3.3. *$\widehat{u} = \bar{u}$ and $\widehat{v} = \bar{v}$ q.e.*

Proof. We shall divide the proof into three steps.

Step 1. The sets $\{z : \widehat{v}(z) > \bar{v}(z), \widehat{v}(z) > (\widehat{u} - h)(z)\}$ and $\{z : \widehat{u}(z) > \bar{u}(z), \widehat{u}(z) > (\widehat{v} + g)(z)\}$ are exceptional.

To prove that any compact subset set of $\{z : \widehat{v}(z) > \bar{v}(z), \widehat{v}(z) > (\widehat{u} - h)(z)\}$ is exceptional, assume that there exists a compact nonexceptional subset F of $\{z : \widehat{v}(z) \geq \bar{v}(z) + \delta, \widehat{v}(z) \geq (\widehat{u} - h)(z) + \delta\}$ for some $\delta > 0$. For any cofinely open neighborhood A of F, since $H_A\bar{v}_F = \widetilde{U}_1(\widehat{H}_A\mu_{\bar{v},F}) = \widetilde{U}_1\mu_{\bar{v},F} = \bar{v}_F$, $\bar{v}_F$ takes its supremum on the cofine closure ${}^rF$ of F. Put $\gamma =$ q.e. sup $\bar{v}_F =$ q.e. sup $\widehat{v}_F$ and

$F_\gamma = \{z : \widehat{v}_F(z) = \gamma\} \subset {}^rF$. Then any cofine neighborhood of F_γ has positive capacity. Suppose that q.e. $\sup(\bar{u} - h - \bar{v}_{F^c}) = \gamma$; then q.e. $\sup(\widehat{u} - h - \widehat{v}_{F^c}) = \gamma$. Since $\widehat{u} - h - \widehat{v}_{F^c} \le \widehat{v}_F$, the q.e. supremum of $\widehat{u} - h - \widehat{v}_{F^c}$ is attained on $F_\gamma \subset {}^rF \subset F$. But this is absurd, because $\widehat{u} - h - \widehat{v}_{F^c}$ is a cofinely continuous function dominated by $\widehat{v}_F - \delta$ on F. Therefore $\bar{u} - h - \bar{v}_{F^c} \le \eta$ q.e. for some $\eta < \gamma$. In particular, $\bar{u} - h \le \bar{v}_F \wedge \eta + \bar{v}_{F^c}$. Since $\bar{v}_F \wedge \eta + v_{F^c}$ is an excessive function satisfying

$$g \le \bar{u} - \bar{v} \le \bar{u} - (v_F \wedge \eta + v_{F^c}) \le h,$$

this contradicts the minimality of $\bar{v}$. Now we have shown that the set $\{z : \widehat{v}(z) > \bar{v}(z), \widehat{v}(z) > (\widehat{u} - h)(z)\}$ is exceptional. The exceptionality of $\{z : \widehat{u}(z) > \bar{u}(z), \widehat{v}(u) > (\widehat{v} + g)(z)\}$ follows similarly.

Step 2. $\widehat{u} - \widehat{v} = \bar{u} - \bar{v}$ q.e.

If $(\widehat{u} - \bar{u})(z) < (\widehat{v} - \bar{v})(z)$, then $\widehat{v}(z) > \bar{v}(z)$ and $\widehat{v}(z) > (\widehat{u} - h)(z)$, because $(\widehat{u} - h)(z) < (\bar{u} + \widehat{v} - \bar{v} - h)(z) \le \widehat{v}(z)$. Hence $\{z : (\widehat{u} - \bar{u})(z) < (\widehat{v} - \bar{v})(z)\}$ is exceptional from Step 1. Similarly, $\{z : (\widehat{u} - \bar{u})(z) > (\widehat{v} - \bar{v})(z)\}$ is exceptional.

Step 3. $\widehat{u} = \bar{u}$ and $\widehat{v} = \bar{v}$ q.e.

Note that $\mu_{\bar{u}}$ and $\mu_{\bar{v}}$ are mutually singular. In fact, if we can write $\mu_{\bar{u}} = \mu_{\bar{u}}^{(s)} + f \cdot \mu_{\bar{v}}$ for some nonnegative measure $\mu_{\bar{u}}^{(s)}$ and nonnegative function f such that $\langle \mu_{\bar{v}}, f \rangle > 0$, then

$$\bar{u} - \bar{v} = \widetilde{U}_1 \mu_{\bar{u}} - \widetilde{U}_1 \mu_{\bar{v}} = \widetilde{U}_1 \left(\mu_{\bar{u}}^{(s)} + (f - f \wedge 1) \cdot \mu_{\bar{v}} \right) - \widetilde{U}_1 \left((1 - f \wedge 1) \cdot \mu_{\bar{v}} \right),$$

which contradicts the minimality of $\bar{u}$ and $\bar{v}$ in Theorem 2.2. Hence there exists a Borel set B such that $\mu_{\bar{u}}(\cdot) = \mu_{\bar{u}}(B \cap \cdot)$ and $\mu_{\bar{v}}(\cdot) = \mu_{\bar{v}}(B^c \cap \cdot)$. By virtue of Lemma 3.2, if $\{z : \widehat{v}(z) \ne \bar{v}(z)\}$ is not exceptional, then there exists a compact nonexceptional set $F \subset \{z : \widehat{v}(z) > \bar{v}(z)\}$. Since $\widehat{v}_{F^c} = \bar{v}_{F^c}$ q.e. on F by Lemma 3.2, $\widehat{v}_F > \bar{v}_F$ q.e. on F and, in particular, $\mu_{\bar{v}}(F) = \mu_{\bar{v}}(B^c \cap F) > 0$. We may assume that $F \subset B^c$. Then $\mu_{\bar{u}}(F) = 0$, and hence $\widehat{u} = \bar{u}$ q.e. on F. In fact, if $\widehat{u} > \bar{u}$ on a nonexceptional set $K \subset F$, then $\widehat{u}_{K^c} = \bar{u}_{K^c}$ q.e. on K, and hence $\widehat{u}_K > \bar{u}_K$ q.e. on K. This implies $\mu_{\bar{u}}(K) > 0$, which is impossible because $\mu_{\bar{u}}(F) = 0$. Therefore

$$(\widehat{u} - \widehat{v}) - (\bar{u} - \bar{v}) = -(\widehat{v} - \bar{v}) < 0$$

q.e. on F which contradicts the assertion of Step 2. □

Since $\bar{u}$ is finely continuous, $\bar{u}(Z_t)$ is right continuous a.s. P_z for q.e. z. Similarly, $\widehat{u}(\widehat{Z}_t)$ is right continuous a.s. $\widehat{P}_z$ for q.e. z. Since $\bar{u} = \widehat{u}$, it becomes continuous along the sample paths. In fact, for any $f, g \ge 0$, and $t > 0$,

$$\begin{aligned} &E_{f \cdot \nu} \left(g(Z_t) : \bar{u}(Z_s)_- \ne \bar{u}(Z_s), \exists s \in (0, t) \right) \\ &= \widehat{E}_{g \cdot \nu} \left(f(\widehat{Z}_t) : \bar{u}(\widehat{Z}_s)_+ \ne \bar{u}(\widehat{Z}_s), \exists s \in (0, t) \right) \\ &= \widehat{E}_{g \cdot \nu} \left(f(\widehat{Z}_t) : \widehat{u}(\widehat{Z}_s)_+ \ne \widehat{u}(\widehat{Z}_s), \exists s \in (0, t) \right) = 0. \end{aligned}$$

The similar result also holds for $\bar{v}$. Hence

$$P_z \left(\bar{u}(Z_t) \text{ and } \bar{v}(Z_t) \text{ are continuous for } t > 0 \right) = 1 \tag{3.5}$$

for a.e. z. By operating the transition function p_s and letting $s \to 0$, (3.5) holds for q.e. z.

Let $\mathcal{J} = \{u = u_1 - u_2 + w; u_i \in \mathcal{P}, w \in \mathcal{W}\}$. As in [14, section 5], $\mathcal{E}$ can be extended to $\mathcal{J} \times \mathcal{J}$ by $\mathcal{E}(u,v) = \lim_{\alpha\to\infty} \mathcal{E}(\alpha G_\alpha u, v)$ for $u, v \in \mathcal{J}$.

LEMMA 3.4. *The function $\bar{w} := \bar{u} - \bar{v}$ is the unique function of $\mathcal{J}$ such that $\bar{w} = \widehat{w}$, $g \le \bar{w} \le h$, and, for any $w \in \mathcal{J}$ satisfying $g \le w \le h$,*

$$\mathcal{A}_1(\bar{w}, \bar{w}) \le \mathcal{E}_1(\bar{w}, w). \tag{3.6}$$

Proof. For any $w \in \mathcal{J}$ such that $g \le w$, since

$$\mathcal{E}_1(\bar{u}_n, \bar{u}_n - \bar{v} - w) = \frac{1}{\varepsilon_n}\left((\bar{u}_n - \bar{v} - g)^-, \bar{u}_n - \bar{v} - w\right) \le 0,$$

it holds that

$$\mathcal{A}_1(\bar{u}, \bar{u}) \le \lim_{n\to\infty} \mathcal{E}_1(\bar{u}_n.\bar{u}_n) \le \lim_{n\to\infty} \left(\mathcal{E}_1(\bar{u}_n, \bar{v}) + \mathcal{E}_1(\bar{u}_n, w)\right). \tag{3.7}$$

For any $p \in \mathcal{P}$, since $\mathcal{E}_1(\bar{u}_n, p) = -\mathcal{E}_1(p, \bar{u}_n) + 2\mathcal{A}_1(\bar{u}_n, p)$ and $\alpha G_{\alpha+1}\bar{u}_n$ is increasing relative to α and n, we have

$$\begin{aligned}
\lim_{n\to\infty} \mathcal{E}_1(\bar{u}_n, p) &= -\lim_{n\to\infty}\lim_{\alpha\to\infty} \mathcal{E}_1(p, \alpha G_{\alpha+1}\bar{u}_n) + 2\mathcal{A}_1(\bar{u}, p) \\
&= -\lim_{\alpha\to\infty} \mathcal{E}_1(p, \alpha G_{\alpha+1}\bar{u}) + 2\lim_{\alpha\to\infty} \mathcal{A}_1(\alpha G_{\alpha+1}\bar{u}, p) \\
&= \lim_{\alpha\to\infty} \mathcal{E}_1(\alpha G_{\alpha+1}\bar{u}, p) = \mathcal{E}_1(\bar{u}, p).
\end{aligned}$$

This relation can be extended to all $p \in \mathcal{J}$, and hence by (3.7),

$$\mathcal{A}_1(\bar{u}, \bar{u}) \le \mathcal{E}_1(\bar{u}, \bar{v}) + \mathcal{E}_1(\bar{u}, w).$$

Furthermore, since $\widehat{v} = \bar{v}$ q.e. from Lemma 3.3,

$$\begin{aligned}
\mathcal{E}_1(\bar{u}, \bar{v}) &= \lim_{\alpha\to\infty} \mathcal{E}_1(\alpha G_{\alpha+1}\bar{u}, \bar{v}) = \lim_{\alpha\to\infty} \mathcal{E}_1\left(\bar{u}, \alpha\widehat{G}_{\alpha+1}\bar{v}\right) \\
&= \int \widehat{v} d\mu_{\bar{u}} = \int \bar{v} d\mu_{\bar{u}} \\
&= \lim_{\alpha\to\infty} \mathcal{E}_1(\bar{u}, \alpha G_{\alpha+1}\bar{v}).
\end{aligned} \tag{3.8}$$

Thus we get that

$$\mathcal{A}_1(\bar{u}, \bar{u}) \le \lim_{\alpha\to\infty} \mathcal{E}_1(\bar{u}, \alpha G_{\alpha+1}\bar{v}) + \mathcal{E}_1(\bar{u}, w).$$

Similarly, for any $w \in \mathcal{J}$ such that $w \le h$,

$$\mathcal{A}_1(\bar{v}, \bar{v}) \le \lim_{\alpha\to\infty} \mathcal{E}_1(\alpha G_{\alpha+1}\bar{v}, \bar{u}) - \mathcal{E}_1(\bar{v}, w).$$

Therefore, for any $w \in \mathcal{J}$ such that $g \le w \le h$,

$$\begin{aligned}
\mathcal{E}_1(\bar{u} - \bar{v}, w) &\ge \mathcal{A}_1(\bar{u}, \bar{u}) + \mathcal{A}_1(\bar{v}, \bar{v}) - \lim_{\alpha\to\infty} \{\mathcal{E}_1(\bar{u}, \alpha G_{\alpha+1}\bar{v}) + \mathcal{E}_1(\alpha G_{\alpha+1}\bar{v}, \bar{u})\} \\
&= \mathcal{A}_1(\bar{u}, \bar{u}) + \mathcal{A}_1(\bar{v}, \bar{v}) - 2\lim_{\alpha\to\infty} \mathcal{A}_1(\bar{u}, \alpha G_{\alpha+1}\bar{v}) \\
&= \mathcal{A}_1(\bar{u} - \bar{v}, \bar{u} - \bar{v}),
\end{aligned}$$

that is, (3.6) holds. To prove the uniqueness of the solution, suppose that $w_1, w_2 \in \mathcal{J}$ satisfy the properties of the lemma. Since (3.8) holds for w_1 and w_2 instead of $\bar{u}$ and $\bar{v}$, respectively,

$$\begin{aligned}\mathcal{A}_1(w_1, w_2) + \mathcal{A}_1(w_2.w_1) &= \lim_{\alpha\to\infty} \left(\mathcal{A}_1(w_1, \alpha G_{\alpha+1} w_2) + \mathcal{A}_1(\alpha G_{\alpha+1} w_2, w_1)\right) \\ &= \lim_{\alpha\to\infty} \left(\mathcal{E}_1(w_1, \alpha G_{\alpha+1} w_2) + \mathcal{E}_1(\alpha G_{\alpha+1} w_2, w_1)\right) \\ &= \mathcal{E}_1(w_1, w_2) + \mathcal{E}_1(w_2, w_1).\end{aligned}$$

Hence, from (3.6),

$$\begin{aligned}\mathcal{A}_1(w_1 - w_2, w_1 - w_2) &= \mathcal{A}_1(w_1, w_1) + \mathcal{A}_1(w_2, w_2) - \mathcal{A}_1(w_1, w_2) - \mathcal{A}_1(w_2, w_1) \\ &= \mathcal{A}_1(w_1, w_1) + \mathcal{A}_1(w_2, w_2) - \mathcal{E}_1(w_1, w_2) - \mathcal{E}_1(w_2, w_1) \le 0,\end{aligned}$$

which implies $w_1 = w_2$ a.e. □

Put $\dot{\sigma}_k = \dot{\sigma}_{C_k}$ and $\dot{\tau}_k = \dot{\sigma}_{D_k}$. Since C_k and D_k are decreasing, $\dot{\sigma} = \lim_{k\to\infty} \sigma_k$ and $\dot{\tau} = \lim_{k\to\infty} \tau_k$ exist as increasing limits. Clearly $\dot{\sigma} \le \dot{\sigma}_C$ and $\dot{\tau} \le \dot{\sigma}_D$.

LEMMA 3.5. *For q.e. $z \in Z$, $\dot{\sigma}_C = \dot{\sigma}$ and $\dot{\sigma}_D = \dot{\tau}$ a.s. P_z.*

Proof. We shall prove only the assertion for $\dot{\sigma}_C$. For any $\ell \le k$,

$$\bar{u}_\ell(Z_{\dot{\sigma}_k}) \le \bar{u}_k(Z_{\dot{\sigma}_k}) \le (g + \bar{v})(Z_{\dot{\sigma}_k}).$$

Hence by letting $k \uparrow \infty$ and then $\ell \uparrow \infty$, we get from (3.5) that $\bar{u}(Z_{\dot{\sigma}}) \le (g + \bar{v})(Z_{\dot{\sigma}})$. Hence $\dot{\sigma}_C \le \dot{\sigma}$. □

Since $\bar{u}$ and $\bar{v}$ are 1-excessive,

$$\bar{u}(z) \ge E_z\left(e^{-\sigma}\bar{u}(Z_\sigma)\right), \tag{3.9}$$

$$\bar{v}(z) \ge E_z\left(e^{-\tau}\bar{v}(Z_\tau)\right) \tag{3.10}$$

for any stopping times σ and τ. From the definition, $\bar{u}_k = \frac{1}{\varepsilon_k} R_1\left((\bar{u}_k - g - \bar{v})^-\right)$ q.e. Hence for any stopping time σ such that $\sigma \le \dot{\sigma_k}$,

$$\begin{aligned}\bar{u}_k(z) &= \frac{1}{\varepsilon_k} E_z\left(\int_0^\infty e^{-t}(\bar{u}_k - g - \bar{v})^-(Z_t)dt\right) \\ &= \frac{1}{\varepsilon_k} E_z\left(\int_\sigma^\infty e^{-t}(\bar{u}_k - g - \bar{v})^-(Z_t)dt\right) \\ &= E_z\left(e^{-\sigma}\bar{u}_k(Z_\sigma)\right) \quad \text{q.e. } z. \qquad (3.11)\end{aligned}$$

Similarly, if $\tau \le \dot{\tau}_k$, then

$$\bar{v}_k(z) = E_z\left(e^{-\tau}\bar{v}_k(Z_\tau)\right). \tag{3.12}$$

THEOREM 3.6. *Suppose that g and h are q.c. functions of $\mathcal{F}$ satisfying the separability condition. Then*

$$\bar{u}(z) - \bar{v}(z) = \sup_\sigma \inf_\tau J_z(\sigma, \tau) = \inf_\tau \sup_\sigma J_z(\sigma, \tau) \quad \text{q.e.} \tag{3.13}$$

Furthermore, $(\dot{\sigma}_C, \dot{\sigma}_D)$ is the saddle point of $J_z(\sigma, \tau)$, and $\bar{u} - \bar{v}$ is the unique solution of the quasi-variational inequality (3.6).

Proof. For any stopping time τ, applying (3.10) and (3.11) for $\dot{\sigma}_k \wedge \tau \leq \dot{\sigma}_k$, we have

$$\begin{aligned}\bar{u}_k(z) - \bar{v}(z) &\leq E_z\left(e^{-\dot{\sigma}_k \wedge \tau}(\bar{u}_k - \bar{v})(Z_{\dot{\sigma}_k \wedge \tau})\right) \\ &= E_z\left(e^{-\dot{\sigma}_k}(\bar{u}_k - \bar{v})(Z_{\dot{\sigma}_k}) : \dot{\sigma}_k \leq \tau\right) + E_z\left(e^{-\tau}(\bar{u}_k - \bar{v})(Z_\tau) : \tau < \dot{\sigma}_k\right) \\ &\leq E_z\left(e^{-\dot{\sigma}_k} g(Z_{\dot{\sigma}_k}) : \dot{\sigma}_k \leq \tau\right) + E_z\left(e^{-\tau} h(Z_\tau) : \tau < \dot{\sigma}_k\right).\end{aligned}$$

Then by letting $k \to \infty$, we have

$$\bar{u}(z) - \bar{v}(z) \leq E_z\left(e^{-\dot{\sigma}} g(Z_{\dot{\sigma}}) : \dot{\sigma} \leq \tau\right) + E_z\left(e^{-\tau} h(Z_\tau) : \tau < \dot{\sigma}\right).$$

Similarly, for any stopping time σ, by considering $\sigma \wedge \dot{\tau}_k$, it holds that

$$E_z\left(e^{-\sigma} g(Z_\sigma) : \sigma < \dot{\tau}\right) + E_z\left(e^{-\dot{\tau}} h(Z_{\dot{\tau}}) : \dot{\tau} \leq \sigma\right) \leq \bar{u}(z) - \bar{v}(z).$$

Since $\dot{\sigma} = \dot{\sigma}_C$ and $\dot{\tau} = \dot{\sigma}_D$ from Lemma 3.5, the assertion of the theorem follows. ∎

(III) General two obstacles case:

In this case, we assume that g and h are q.c. functions of $\mathcal{W}$. As in the preceding section, put $g^{(k)} = kR_k g$ and $h^{(k)} = kR_k h$. Then the separability condition holds for the obstacles $(g^{(k)}, h^{(k)})$. For any stopping times σ and τ, put

$$J_z^{(k)}(\sigma, \tau) = E_z\left(e^{-\sigma \wedge \tau}\left(g^{(k)}(Z_\sigma) I_{\{\sigma \leq \tau\}} + h^{(k)}(Z_\tau) I_{\{\tau < \sigma\}}\right)\right). \tag{3.14}$$

Let $(\bar{u}^{(k)}, \bar{v}^{(k)})$ be the 1-excessive modifications of the minimal pair of functions determined by Theorem 2.2 for $(g^{(k)}, h^{(k)})$ and put $\bar{w}^{(k)} = \bar{u}^{(k)} - \bar{v}^{(k)}$. Then $\widehat{w}^{(k)} = \bar{w}^{(k)}$ q.e. and satisfies

$$\bar{w}^{(k)}(z) = \sup_\sigma \inf_\tau J_z^{(k)}(\sigma, \tau) = \inf_\tau \sup_\sigma J_z^{(k)}(\sigma, \tau), \tag{3.15}$$

where $\widehat{w}^{(k)} = \lim_{n \to \infty} n\widehat{R}_n \bar{w}^{(k)}$. By virtue of (3.5), $\bar{w}^{(k)}$ is continuous along the sample paths a.s.

THEOREM 3.7. *Suppose that g, h are q.c. functions of $\mathcal{W}$. Then*

$$\bar{w}(z) := \sup_\sigma \inf_\tau J_z(\sigma, \tau) = \inf_\tau \sup_\sigma J_z(\sigma, \tau) \tag{3.16}$$

belongs to $\mathcal{F}$ and satisfies, for any $w \in \mathcal{W}$ such that $g \leq w \leq h$,

$$\mathcal{A}_1(\bar{w}, \bar{w}) \leq \mathcal{E}_1(\bar{w}, w). \tag{3.17}$$

Moreover, the pair of the entry times $(\dot{\sigma}_C, \dot{\sigma}_D)$ is a saddle point of $J_z(\sigma, \tau)$.

Proof. For any stopping times σ, τ, and q.e. z,

$$E_z\left(e^{-\sigma}|g^{(k)} - g|(Z_\sigma) I_{\{\sigma \leq \tau\}}\right) \leq E_z\left(e^{-\sigma} \widetilde{e}_{|g^{(k)} - g|}(Z_\sigma)\right) \leq \widetilde{e}_{|g^{(k)} - g|}(z) \tag{3.18}$$

and

$$E_z\left(e^{-\tau}|h^{(k)} - h|(Z_\tau) I_{\{\tau < \sigma\}}\right) \leq E_z\left(e^{-\tau} \widetilde{e}_{|h^{(k)} - h|}(Z_\tau)\right) \leq \widetilde{e}_{|h^{(k)} - h|}(z). \tag{3.19}$$

Hence

$$|J_z^{(k)}(\sigma, \tau) - J_z(\sigma, \tau)| \leq \widetilde{e}_{|g^{(k)} - g|}(z) + \widetilde{e}_{|h^{(k)} - h|}(z) \text{ q.e.}$$

By virtue of Lemmas 1.5 and 2.3, there exists an increasing sequence of closed sets $\{F_n\}$ and a subsequence $n_k \uparrow \infty$ such that $\mathrm{Cap}(Z\backslash F_n) \to 0$ and $\lim_{k\to\infty} \widetilde{e}_{|g^{(n_k)}-g|} = 0$, $\lim_{k\to\infty} \widetilde{e}_{|h^{(n_k)}-h|} = 0$ in $\mathcal{F}$ and uniformly on each set F_n. Hence

$$\lim_{k\to\infty} \inf_{\tau} \sup_{\sigma} J_z^{(n_k)}(\sigma,\tau) = \inf_{\tau} \sup_{\sigma} J_z(\sigma,\tau) \quad \text{on } F_n.$$

Equation (3.15) combined with (3.18) and (3.19) implies that

$$|\bar{w}^{(k)} - \bar{w}^{(l)}| \le \widetilde{e}_{|g^{(k)}-g|} + \widetilde{e}_{|g^{(l)}-g|} + \widetilde{e}_{|h^{(k)}-h|} + \widetilde{e}_{|h^{(l)}-h|} \text{ q.e.}$$

Therefore $\lim_{k\to\infty} \bar{w}^{(k)} = \bar{w}^{(\infty)}$ exists in $\mathcal{H}$ and a subsequence converges quasi-uniformly on each F_n and satisfies

$$\bar{w}^{(\infty)} = \sup_{\sigma} \inf_{\tau} J_z(\sigma,\tau) = \inf_{\tau} \sup_{\sigma} J_z(\sigma,\tau) \quad \text{q.e. } z \in F_n.$$

Letting $n \to \infty$, we get that $\bar{w}^{(\infty)} = \bar{w}$ q.e. By virtue of the quasi-variational inequality (3.6) applied for $\bar{w}^{(k)}$,

$$\begin{aligned}\mathcal{A}_1(\bar{w}^{(k)},\bar{w}^{(k)}) &\le \mathcal{E}_1(\bar{w}^{(k)},g^{(k)}) = \mathcal{E}_1(k\widehat{G}_k\bar{w}^{(k)},g)\\ &\le \|g\|_{\mathcal{W}}\|k\widehat{G}_k\bar{w}^{(k)}\|_{\mathcal{F}} \le C_1\|g\|_{\mathcal{W}}\|\bar{w}^{(k)}\|_{\mathcal{F}}.\end{aligned}$$

Hence $\|\bar{w}^{(k)}\|_{\mathcal{F}}$ and $\|k\widehat{G}_k\bar{w}^{(k)}\|_{\mathcal{F}}$ are uniformly bounded relative to k. This combined with $\lim_{k\to\infty} \bar{w}^{(k)} = \lim_{k\to\infty} k\widehat{G}_k\bar{w}^{(k)} = \bar{w}$ in $\mathcal{H}$ implies that $\lim_{k\to\infty} \bar{w}^{(k)} = \lim_{k\to\infty} k\widehat{G}_k\bar{w}^{(k)} = \bar{w}$ weakly in $\mathcal{F}$. Therefore, for any $w \in \mathcal{W}$ such that $g \le w \le h$,

$$\mathcal{A}_1(\bar{w}^{(k)},\bar{w}^{(k)}) \le \mathcal{E}_1(\bar{w}^{(k)}, kG_kw) = \mathcal{E}_1(k\widehat{G}_k\bar{w}^{(k)},w).$$

By letting $k \to \infty$, the quasi-variational inequality (3.17) follows.

The proof of the last part of the theorem is similar to [19]. It suffices to prove the following inequalities for any stopping times σ and τ such that $\tau \le \dot{\sigma}_C$ and $\sigma \le \dot{\sigma}_D$:

$$\bar{w}(z) \le E_z\left(e^{-\tau}\bar{w}(Z_\tau)\right) \quad \text{q.e.} \tag{3.20}$$

$$\bar{w}(z) \ge E_z\left(e^{-\sigma}\bar{w}(Z_\sigma)\right) \quad \text{q.e.} \tag{3.21}$$

In fact, if these hold, by noting $\bar{w}(Z_{\dot{\sigma}_C}) = g(Z_{\dot{\sigma}_C})$, we have for any stopping time τ,

$$\begin{aligned}J_z(\dot{\sigma}_C,\tau) &= E_z\left(e^{-\dot{\sigma}_C}g(Z_{\dot{\sigma}_C})I_{\{\dot{\sigma}_C\le\tau\}} + e^{-\tau}h(Z_\tau)I_{\{\tau<\dot{\sigma}_C\}}\right)\\ &\ge E_z\left(e^{-\dot{\sigma}_C}\bar{w}(Z_{\dot{\sigma}_C})I_{\{\dot{\sigma}_C\le\tau\}} + e^{-\tau}\bar{w}(Z_\tau)I_{\{\tau<\dot{\sigma}_C\}}\right)\\ &= E_z\left(e^{-\dot{\sigma}_C\wedge\tau}\left(\bar{w}(Z_{\dot{\sigma}_C\wedge\tau})\right)\right) \ge \bar{w}(z).\end{aligned}$$

Similarly, $J_z(\sigma,\dot{\sigma}_D) \le \bar{w}$ q.e. for any stopping time σ.

Let $C^{(k)} = \{z : \bar{w}^{(k)}(z) \le g^{(k)}(z)\}$, $D^{(k)} = \{z : h^{(k)}(z) \le \bar{w}^{(k)}(z)\}$, $\dot{\sigma}^{(k)} = \dot{\sigma}_{C^{(k)}}$, and $\dot{\tau}^{(k)} = \dot{\sigma}_{D^{(k)}}$. Further, for each positive number γ, let $\eta_\gamma = \inf\{t \ge 0 : \bar{w}(Z_t)+\gamma \ge h(Z_t)\}$. If $t < \eta_\gamma(\omega)$, then $\bar{w}(Z_t(\omega)) + \gamma < h(Z_t(\omega))$. Noting that $\lim_{k\to\infty} \bar{w}^{(k)} = \bar{w}$ and $\lim_{k\to\infty} h^{(k)} = h$ uniformly on each F_n, we can find k_0 such that $|\bar{w}^{(k)} - \bar{w}| \le \gamma/2$ and $|h^{(k)} - h| < \gamma/2$ on F_n for any $k \ge k_0$. Therefore $t < \dot{\tau}^{(k)}$, and hence $\eta_\gamma \wedge \dot{\sigma}_{F_n} \le \dot{\tau}^{(k)}$. In view of (3.9) and (3.12), since (3.21) holds for $\bar{w}^{(k)}$ and $\dot{\tau}^{(k)}$ instead of $\bar{w}$ and $\dot{\sigma}_D$, respectively, it then holds that

$$\bar{w}^{(k)}(z) \ge E_z\left(e^{-(\eta_\gamma\wedge\tau_{F_n}\wedge\sigma)}w^{(k)}(Z_{\eta_\gamma\wedge\tau_{F_n}\wedge\sigma})\right) \quad \text{q.e.}$$

Letting $k \to \infty$ and then $n \to \infty$, we have

$$\bar{w}(z) \geq E_z\left(e^{-(\eta_\gamma \wedge \sigma)}\bar{w}(Z_{\eta_\gamma \wedge \sigma})\right) \quad \text{q.e.}$$

Since $\bar{w}(Z_{\eta_\gamma}) + \gamma \geq h(Z_{\eta_\gamma})$ and η_γ is increasing as $\gamma \downarrow 0$, $\widehat{w}(Z_{\eta_0}) = \bar{w}(Z_{\eta_0}) \geq h(Z_{\eta_0})$ for $\eta_0 = \lim_{\gamma \to 0} \eta_\gamma$. This yields that $\dot{\sigma}_D \leq \eta_0$, and hence

$$\bar{w}(z) \geq E_z\left(e^{-\sigma}\bar{w}(Z_\sigma)\right)$$

for any stopping time σ such that $\sigma \leq \dot{\sigma}_D$. The proof of (3.20) is similar. □

Example. Let (Z_t, P_z) be the space-time diffusion process corresponding to the generator $A^{(t)}\varphi(x) = \frac{d^2\varphi}{dx^2}$ for $t < 1$ and $A^{(t)}\varphi(x) = \frac{1}{2}\frac{d^2\varphi}{dx^2}$ for $t \geq 1$. Denote by q_t and K_α the transition function and resolvent of a one-dimensional Brownian motion, respectively. Taking a nonnegative, nonzero continuous function ϕ on R^1 with compact support, let $\varphi(x) = K_2\phi(x)$,

$$g(s,x) = \begin{cases} e^{-(3-2s)}q_{2(1-s)}\varphi(x), & s < 1, \\ e^{-s}\varphi(x), & s \geq 1, \end{cases}$$

and

$$h(s,x) = \begin{cases} 2e^{-(3-s)/2}q_{2(1-s)}\varphi(x), & s < 1, \\ 2e^{-s}\varphi(x), & s \geq 1. \end{cases}$$

Furthermore, let $\bar{v} = 0$ and

$$\bar{u}(s,x) = \begin{cases} e^{-(2-s)}q_{2(1-s)}\varphi(x), & s < 1, \\ e^{-s}\varphi(x), & s \geq 1. \end{cases}$$

Then $g \leq \bar{u} - \bar{v} \leq h$. Since $\bar{u}(s,x) = E_{(s,x)}\left(\int_0^\infty e^{-t}\xi \otimes \phi(Z_t)dt\right)$, for $\xi(t) = e^{-t}I_{\{t \geq 1\}}$, $\bar{u}$ is 1-excessive function of Z_t and satisfies

$$\mathcal{A}_1(\bar{u}, \bar{u}) = \frac{1}{2}e^{-2}\int_{-\infty}^{\infty} \varphi(x)\phi(x)dx.$$

Further, for any $w \in \mathcal{J}$ such that $g \leq w \leq h$,

$$\mathcal{E}_1(\bar{u}, w) = \int_1^\infty \int_{-\infty}^\infty e^{-s}\phi(x)w(s,x)dxds \geq \int_1^\infty \int_{-\infty}^\infty e^{-s}\phi(x)g(s,x)dxds = \mathcal{A}_1(\bar{u}, \bar{u}).$$

Therefore $\bar{u} - \bar{v} = \bar{u}$ is a solution of (3.6), and the saddle point $(\dot{\sigma}_C, \dot{\sigma}_D)$ of $J_z(\sigma, \tau)$ in Theorem 3.6 is given by $\dot{\sigma}_C = (1 - \tau(0)) \vee 0$ and $\dot{\sigma}_D = \infty$.

Acknowledgments. The author wishes to thank the anonymous referees for their valuable suggestions by which the proofs are improved and the results are generalized.

A VARIATIONAL INEQUALITY SUFFICIENT CONDITION FOR OPTIMAL STOPPING WITH APPLICATION TO AN OPTIMAL STOCK SELLING PROBLEM*

RAYMOND RISHEL† AND KURT HELMES‡

Abstract. We give a variational inequality sufficient condition for optimal stopping problems. This result is illustrated by computing solutions to an optimal stock selling problem. The stock selling problem has a model for the stock price, which initially has a "hot" growth rate and then "tanks." Solution of the conditions allows for computation of both the value function and the optimal stopping times. Optimal stock selling times are computed for two utility functions and a variety of realistic parameter values.

Key words. stock selling times, optimal stopping, variational inequalities

DOI. 10.1137/050622699

1. Introduction. Variational inequalities for solving optimal stopping problems were first introduced by Bensoussan and Lions [1], [2]. Many variational inequality sufficient conditions have since been given. Some examples of these are Bensoussan [1, p. 301], Krylov [7, Thm. 7, p. 41], and Oksendal [9, p. 225].

The sufficiency condition we give is an extremely simple extension of that of [1]. However, it points out the apparently previously overlooked requirement of a boundedness condition on the gradient of the value function in determining the correct solution from the possibly many solutions of the variational inequality. The use of this property is illustrated in our solution of the stock selling problem.

A number of different stock selling problems have been considered. For instance, in [9, pp. 219, 227], Oksendal considers a stock selling problem whose stock price is given by a geometric Brownian motion with constant coefficients. In [12], Zhang considers a stock selling problem whose stock price is given by a diffusion process whose coefficients are unobservable finite state jump Markov processes. In [3], Beibel and Lerche consider an optimal stock selling problem for a model which is basically the same as the partially observed model we consider below. We discuss comparison of Zhang's results and Beibel and Lerche's results with ours in section 9.

The problem we consider is motivated by the past behavior of "bubble stocks" such as Enron. The problem is to decide when to sell a stock which has a rapid growth rate and then a rapid rate of decline but, because of randomness in the stock price, it is difficult for the investor to know when the stock price is really in decline. We consider an idealized model of such a situation in which the stock price is given by a geometric Brownian motion, which has an initial positive growth rate, and after a random time, jumps to and remains at a negative growth rate. The investor observes the stock prices but cannot observe the growth rates. Deciding when to sell is based

only on past stock prices. Thus this is a partially observed optimal stopping problem. Converting it to a completely observed optimal stopping problem is done similarly to the methods used by Shiryayev [10, p. 200] in his quickest detection of a disorder problem.

We consider the problem with two different utility functions $U(S) = \ln(S)$ and $U(S) = S$. For the utility function $U(S) = \ln(S)$, there are solutions of the variational inequality with the appropriate boundedness, and optimal stopping times are calculated. For the utility function $U(S) = S$, it appears to be difficult to find solutions of the variational inequality with the appropriate boundedness for the problem in its original form. We use two changes of probability measure to convert the problem into one for which these boundedness conditions are determined and calculations of the optimal stopping time can be carried out.

2. A variational inequality sufficient condition for optimal stopping. We begin by stating an optimal stopping problem and giving variational inequality sufficient conditions for it. Let $g(z)$ and $h(z)$ denote, respectively, an n-dimensional vector valued function and an $(n \times m)$-dimensional matrix valued function of the n-dimensional vector z. Let $W(t)$ denote an m-dimensional Wiener process. Assume $g(z)$ and $h(z)$ are regular enough so that solutions of the stochastic differential equation and initial condition

$$dz(t) = g(z(t))\,dt + h(z(t))\,dW(t), \quad z(0) = z, \tag{2.1}$$

exist and are unique. Let $\mathcal{F}_t$ denote the σ-fields

$$\mathcal{F}_t = \sigma[z(r) : \ 0 \le r \le t] \tag{2.2}$$

generated by the past of $z(t)$. Let $\beta(z)$ be a continuous scalar function and $U(z)$ a twice continuously differentiable utility function. Let $\mathcal{A}$ denote a class of $\mathcal{F}_t$ stopping times. For each stopping time $\tau \in \mathcal{A}$, consider the expected discounted utility

$$E\Big[e^{\int_0^\tau \beta(z(t))\,dt} U(z(\tau))\Big]. \tag{2.3}$$

The optimal stopping problem is as follows: Find τ in $\mathcal{A}$ which achieves the maximum of (2.3).

The following theorem gives variational inequality sufficient conditions for optimality for this problem.

THEOREM 2.1. *Let R be a region in E^n. Assume for each z in R that the solution of* (2.1) *with initial condition z is contained in R. Let $V(z)$ be a scalar valued function defined on R. Let $V(z)$ be regular enough so that Itô's stochastic differential rule holds for $V(z(t))$. Define the differential operator $A[V](z)$ by*

$$A[V](z) = \beta(z)V(z) + V_z(z)g(z) + \frac{1}{2}\,\text{trace}\,(h(z)h(z)'V_{zz}(z)). \tag{2.4}$$

Let $V(z)$ be a solution of the variational inequality

$$\begin{aligned} &A[V](z) \le 0, \quad V(z) \ge U(z), \\ &(V(z) - U(z))\ A[V](z) = 0, \end{aligned} \tag{2.5}$$

and let the condition

$$E\int_0^\tau e^{2\int_0^t \beta(z(r))\,dr} \|V_z(z(t))h(z(t))\|^2\,dt < \infty \tag{2.6}$$

hold for each stopping time τ in $\mathcal{A}$. For $z(t)$ the solution of (2.1) *with initial condition z, let*

$$\tau(z) = \textit{ first time } z(t) \textit{ hits } \{q:\ V(q) = U(q)\}. \tag{2.7}$$

Let

$$\tau(z) \in \mathcal{A} \textit{ for each } z \in R. \tag{2.8}$$

Then

$$V(z) = E\Big[e^{\int_0^{\tau(z)} \beta(z(r))\,dr} U(z(\tau(z)))\Big] = \max_{\tau\in\mathcal{A}} E\Big[e^{\int_0^{\tau} \beta(z(r))\,dr}\, U(z(\tau))\Big]. \tag{2.9}$$

That is, $\tau(z)$ is an optimal stopping time in $\mathcal{A}$ and $V(z)$ is the value function for the optimal stopping problem.

Theorem 2.1 should be known. Its simple proof uses that condition (2.6) implies that the expected value of the stochastic integral term in the Itô differential of $e^{\int_0^t \beta(z(r))\,dr}\, V(z(t))$ is zero. Then standard variational inequality arguments such as in Bensoussan [1, p. 201] give the conclusion. For completeness we give the short proof in an appendix. However, the importance of conditions (2.6) and (2.8) holding along with the variational inequality conditions (2.5) does not appear to have been pointed out. Conditions (2.6) and (2.8) make the correct selection of the possibly many solutions of conditions (2.5).

Remark 2.2. Notice that if

$$\beta(z) \le 0 \text{ and } \|V_z(z)h(z)\|^2 \le K, \tag{2.10}$$

then

$$E\left[\int_0^{\tau} e^{2\int_0^t \beta(z(r))\,dr}\, \|V_z(z(t))h(z(t))\|^2\,dt\right] \le KE(\tau). \tag{2.11}$$

Thus if the boundedness condition (2.10) holds, (2.6) holds for stopping times with finite expectations.

Remark 2.2 motivates looking for solutions of (2.5) for which the boundedness condition (2.10) holds.

3. The stock price model. Consider a stock whose price $S(t)$ satisfies the stochastic differential equation and initial condition

$$dS(t) = S(t)(a(t)dt + \sigma dW(t)), \quad S(0) = S. \tag{3.1}$$

In (3.1) S and σ are positive constants, $W(t)$ is a Wiener process, and $a(t)$ is a random process which jumps from $a > 0$ to $b < 0$ at a random time J, which satisfies

$$Pr[J = 0] = 1 - x, \quad Pr[J > t | J > 0] = e^{-ct}, \tag{3.2}$$

where x and c are constants satisfying $0 \le x \le 1$ and $c > 0$.

Let $U(S)$ be a utility function. Let

$$\mathcal{F}_t = \sigma\{S(r):\ 0 \le r \le t\} \tag{3.3}$$

denote the σ-fields generated by the past of the process $S(\cdot)$ up to times t.

Consider finding, in a class $\mathcal{A}$ of $\mathcal{F}_t$ stopping times τ, a stopping time which maximizes the expected utility

$$E[U(S(\tau))]. \tag{3.4}$$

4. Reduction to a completely observed problem. It is well known that the solution of the stock price equation (3.1) is given by

$$S(t) = Se^{\int_0^t a(s)ds + \sigma W(t) - \frac{1}{2}\sigma^2 t}. \tag{4.1}$$

This can be checked using Itô's differential rule.

Equation (4.1) implies

$$\ln(S(t)) - \ln(S) + \frac{1}{2}\sigma^2 t = \int_0^t a(s)ds + \sigma W(t). \tag{4.2}$$

This implies that observing the process $S(t)$ is equivalent to observing the process $y(t)$, where

$$y(t) = \int_0^t a(s)ds + \sigma W(t), \tag{4.3}$$

and that the σ-fields

$$\sigma\{S(r) :\ 0 \le r \le t\} \quad \text{and} \quad \sigma\{y(r) :\ 0 \le r \le t\} \tag{4.4}$$

are equal.

Our assumptions about $a(t)$ imply it is a jump Markov process with two states a and b and the process jumps once from a to b.

Nonlinear filtering results, for instance, Davis and Marcus [4], Liptser and Shiryayev [8], govern conditional probabilities of states of a jump Markov process given measurements of the type (4.3). In particular, if

$$x(t) = Pr[a(t) = a | y(r),\ 0 \le r \le t], \tag{4.5}$$

then $x(t)$ is a solution of

$$dx(t) = -cx(t)dt + \frac{1}{\sigma}(a-b)(1-x(t))\ x(t)d\nu(t),\ x(0) = x. \tag{4.6}$$

In (4.6) $\nu(t)$ is a Wiener process called the innovations process. It satisfies

$$d\nu(t) = \frac{1}{\sigma}(a(t) - (ax(t) + b(1-x(t))))dt + dW(t). \tag{4.7}$$

The relationship (4.7) between the innovations Wiener process $\nu(t)$ and the original Wiener process $W(t)$ implies

$$a(t)dt + \sigma dW(t) = (ax(t) + b(1-x(t)))dt + \sigma d\nu(t). \tag{4.8}$$

Thus we may rewrite the stock price equation (3.1) in terms of the conditional probabilities $x(t)$ and the innovations Wiener process $\nu(t)$ as

$$dS(t) = S(t)[(ax(t) + b(1-x(t)))dt + \sigma d\nu(t)],\quad S(0) = S. \tag{4.9}$$

Since

$$\mathcal{F}(t) = \sigma\{S(r) :\ 0 \le r \le t\} = \sigma\{y(r) :\ 0 \le r \le t\}, \tag{4.10}$$

and $x(t)$ is defined by (4.5), $x(t)$ is $\mathcal{F}_t$ adapted. Thus the optimization problem given in (3.1)–(3.4) is equivalent to the completely observed optimization problem of choosing the $\mathcal{F}_t$ stopping time τ in our class $\mathcal{A}$ of stopping times to maximize

$$E[U(S(\tau))] \tag{4.11}$$

subject to

$$\begin{aligned} dS(t) &= S(t)[(ax(t) + b(1 - x(t)))dt + \sigma d\nu(t)],\ S(0) = S, \\ dx(t) &= -cx(t)dt + \frac{1}{\sigma}(a - b)(1 - x(t))x(t)d\nu(t),\ x(0) = x. \end{aligned} \tag{4.12}$$

LEMMA 4.1. *For q in $(0, 1)$, let*

$$T(q) = \textit{ first time } x(t) \textit{ hits } [0, q]. \tag{4.13}$$

Then

$$E[T(q)] < \infty. \tag{4.14}$$

We give the proof of Lemma 4.1 in the appendix. We remark that (4.14) is false if the interval is replaced by $[q, 1]$.

5. The logarithmic utility problem. Consider the problem (4.11)–(4.12) with utility function

$$U(S) = \ln(S) \tag{5.1}$$

and class of admissible $\mathcal{F}_t$ stopping times τ given by

$$\mathcal{A} = \{\tau : E(\tau) < \infty\}. \tag{5.2}$$

For this problem, in the notation of Theorem 2.1,

$$z = \begin{pmatrix} S \\ x \end{pmatrix}, \quad \beta(z) = 0, \quad h(z) = \begin{pmatrix} S\sigma \\ \frac{1}{\sigma}(a - b)x(1 - x) \end{pmatrix}. \tag{5.3}$$

The region R is

$$R = \{(S, x) :\ 0 \le S < \infty, \quad 0 \le x \le 1\}. \tag{5.4}$$

The operator $A[V](S, x)$ is

$$\begin{aligned} A[V](S, x) &= S(ax + b(1 - x))V_s(S, x) - cxV_x(S, x) \\ &\quad + \frac{1}{2}S^2\sigma^2 V_{ss}(S, x) + (a - b)(1 - x)xSV_{sx}(S, x) \\ &\quad + \frac{1}{2}\left(\frac{a - b}{\sigma}\right)^2 (1 - x)^2 x^2 V_{xx}(S, x), \end{aligned} \tag{5.5}$$

and

$$V_z(z)h(z) = S\sigma V_s(S, x) + \frac{a - b}{\sigma}(1 - x)xV_x(S, x), \tag{5.6}$$

where z and (S, x) are related by (5.3).

Let us begin the discussion by asking if there are conditions for which it is optimal to always sell the stock immediately. Since $a(t)$ takes on values a and b, and b is negative, $a(t) \leq a$. Thus (4.2) implies

$$E[\ln(S(t))] \leq \ln(S) + \left(a - \frac{1}{2}\sigma^2\right)t. \tag{5.7}$$

If $2a \leq \sigma^2$, then $E[\ln(S(t))] \leq \ln(S)$, so $\tau = 0$ is the optimal selling time.

Let us assume $2a > \sigma^2$ and find optimal stopping times in the class $\mathcal{A}$ under this condition. We shall see that under this condition for an appropriate $f(x)$,

$$V(S,x) = \ln(S) + f(x) \tag{5.8}$$

gives a solution of Theorem 2.1.

Using (5.5),

$$\begin{aligned} A[\ln(S) + f(x)](S,x) \\ = ax + b(1-x) - cxf'(x) - \frac{1}{2}\sigma^2 + \frac{1}{2}\left(\frac{a-b}{\sigma}\right)^2 (1-x)^2x^2f''(x). \end{aligned} \tag{5.9}$$

Calling the righthand side of (5.9) $B[f](x)$, the variational inequality (2.5) reduces to

$$B[f](x) \leq 0, \ f(x) \geq 0, \text{ and } f(x)B[f](x) = 0. \tag{5.10}$$

We also see that

$$S\sigma V_s(S,x) + \frac{a-b}{\sigma}(1-x)xV_x(S,x) = \sigma + \frac{a-b}{\sigma}(1-x)xf'(x). \tag{5.11}$$

Since $0 \leq x \leq 1$, this will be bounded if $f'(x)$ is bounded. Thus (2.10) of Remark 2.2 will be satisfied if $f'(x)$ is bounded.

For Itô's differential rule to hold for $\ln(S(t)) + f(x(t))$, $f(x)$ must be at least once continuously differentiable. This continuous differentiability implies: If $q \in (0,1)$, and if q is a boundary point of an interval on which $f(x) = 0$, then $f'(q) = 0$.

Thus we look for a continuously differentiable solution $f(x)$ of (5.10) for which $f'(x)$ is bounded and $f'(q) = 0$ at boundary points q of intervals on which $f(x) = 0$.

Conditions (5.10) imply that if $f(x) \neq 0$, then $B[f](x) = 0$. From (5.9) this equation is

$$ax + b(1-x) - cxf'(x) - \frac{1}{2}\sigma^2 + \frac{1}{2}\left(\frac{a-b}{\sigma}\right)^2 (1-x)^2x^2f''(x) = 0. \tag{5.12}$$

Since we are interested in conditions on $f'(x)$, we will set $r(x) = f'(x)$ in (5.12) and solve

$$ax + b(1-x) - cxr(x) - \frac{1}{2}\sigma^2 + \frac{1}{2}\left(\frac{a-b}{\sigma}\right)^2 x^2(1-x)^2r'(x) = 0 \tag{5.13}$$

for $r(x)$. The general solution of (5.13) is given by

$$\begin{aligned} r(x) = (1-x)^{-h}x^h e^{\frac{h}{1-x}} \\ \cdot \left[\int \frac{h}{2c}x^{-(2+h)}(1-x)^{(h-2)}e^{\frac{-h}{1-x}}(\sigma^2 - 2b - 2(a-b)x)dx + C\right] \end{aligned} \tag{5.14}$$

in which C is an arbitrary constant and h is given by

$$h = \frac{2c\sigma^2}{(a-b)^2}. \tag{5.15}$$

Since $h > 0$,

$$\lim_{x\to 1}(1-x)^{-h}x^h e^{h/(1-x)} = +\infty. \tag{5.16}$$

Thus for $r(x)$ to be bounded at $x = 1$, we must have

$$\lim_{x\to 1}\left[\int \frac{h}{2c}x^{-(2+h)}(1-x)^{(h-2)}e^{\frac{-h}{1-x}}(\sigma^2 - 2b - 2(a-b)x)\,dx + C\right] = 0. \tag{5.17}$$

Define $g(x)$ by

$$g(x) = \int_x^1 \frac{-h}{2c}y^{-(2+h)}(1-y)^{(h-2)}e^{-h/(1-y)}(\sigma^2 - 2b - 2(a-b)y)\,dy. \tag{5.18}$$

For (5.17) to hold, the quantity in brackets in (5.17) must equal $g(x)$. This follows because both quantities have the same derivative and the same limit at $x = 1$. Thus let

$$r(x) = (1-x)^{-h}x^h e^{h/(1-x)}g(x). \tag{5.19}$$

A calculation using L'Hospital's rule shows that

$$\lim_{x\to 1} r(x) \;=\; \frac{2a-\sigma^2}{2c}. \tag{5.20}$$

LEMMA 5.1. *$r(x)$ has a unique root x^* in $(0,1)$ which satisfies*

$$0 < x^* < \frac{\sigma^2 - 2b}{2(a-b)}, \tag{5.21}$$

and $r(x)$ is positive on $(x^*, 1]$.

Proof. Since on the interval $(0,1)$ the function $r(x)$ is given by positive quantities times $g(x)$, its roots will be the same as those of $g(x)$. The integrand of $g(x)$ is given by positive quantities times the linear term

$$2(a-b)y - \sigma^2 + 2b. \tag{5.22}$$

Since $2a > \sigma^2$, (5.22) is positive near $y = 1$. Since $b < 0$, (5.22) is clearly negative near $y = 0$.

Now (5.22) will be positive on

$$\frac{\sigma^2 - 2b}{2a - 2b} < y \le 1. \tag{5.23}$$

Thus

$$g(x) > 0 \quad \text{if} \quad \frac{\sigma^2 - 2b}{2a-2b} < x < 1. \tag{5.24}$$

The term $y^{-(2+h)}$ with $h > 0$ in the integrand of $g(x)$ and the negativity of (5.22) near $y = 0$ imply

$$\lim_{x\to 0} g(x) = -\infty. \tag{5.25}$$

Thus $g(x)$, and hence $r(x)$ must have a root x^* in $\left(0, \frac{\sigma^2-2b}{2a-2b}\right)$. Since $g(x)$ is monotone increasing on this interval, x^* is unique. This implies $r(x)$ is positive on $(x^*, 1]$. □

THEOREM 5.2. *For $f(x)$ defined by*

$$f(x) = \begin{cases} 0 & \text{if } 0 \le x \le x^*, \\ \displaystyle\int_{x^*}^{x} r(x)\,dx & \text{if } x^* \le x \le 1, \end{cases} \tag{5.26}$$

the function $V(S, x) = \ln(S) + f(x)$ satisfies the conditions of Theorem 2.1*, and*

$$T(x^*) = 1st \text{ time } x(t) \text{ hits } [0, x^*] \tag{5.27}$$

is an optimal stopping time in the class $\mathcal{A}$.

Proof. Since $r(x^*) = 0$, $f(x)$ is continuously differentiable and is twice continuously differentiable, except at x^*. Thus Itô's differential rule holds for $\ln(S) + f(x)$. Lemma 5.1 implies that $f(x) \ge 0$. Using (5.9),

$$B[f](x) = \begin{cases} ax + b(1-x) - \frac{1}{2}\sigma^2 & \text{if } 0 \le x \le x^*, \\ 0 & \text{if } x^* \le x \le 1, \end{cases} \tag{5.28}$$

and since

$$x^* < \frac{\sigma^2 - 2b}{2(a-b)}, \tag{5.29}$$

we have that

$$B[f](x) \le 0. \tag{5.30}$$

Since $f(x) = 0$ if $0 \le x \le x^*$ and $B[f](x) = 0$ if $x^* < x \le 1$, $f(x)B[f](x) = 0$. Thus all the conditions of (5.10) are satisfied. The conditions of (5.10) imply the conditions (2.5) for the function (5.8).

Since $r(x)$ is continuous on $[0, 1)$ and has a finite limit at $x = 1$, it is bounded. Thus $f'(x)$ is bounded, which together with (5.11) and Remark 2.2 implies that condition (2.6) holds for stopping times in $\mathcal{A}$. Condition (2.8) follows from Lemma 4.1. Thus the conditions of Theorem 2.1 are satisfied and $T(x^*)$ given by (5.27) is an optimal stopping time in the class $\mathcal{A}$. □

6. The problem with utility function $U(S) = S$. Consider the problem of maximizing

$$E[S(\tau)], \tag{6.1}$$

subject to (4.12) holding, over a class of stopping times $\mathcal{A}$. As mentioned in the introduction, we shall use changes of probability measure to convert this problem into one for which we can verify the conditions of Theorem 2.1.

The solution of the stock price equation is given by

$$S(t) = Se^{\int_0^t (ax(r)+b(1-x(r)))\,dr+\sigma\nu(t)-\frac{\sigma^2}{2}t}. \tag{6.2}$$

Again this can be checked by using Itô's differential rule. Let $\tilde{P}$ be a probability measure which is locally absolutely continuous with respect to P through the following: For each t and $A \in \mathcal{F}_t$,

$$\tilde{P}(A) = \int_A e^{\sigma\nu(t)-\frac{\sigma^2}{2}t}\,dP. \tag{6.3}$$

Let $\tilde{E}$ denote taking expectation with respect to $\tilde{P}$. It follows from [6, Thm. 3.4, p. 153] that for each finite stopping time τ, $\tilde{P}$ is absolutely continuous with respect to P on $\mathcal{F}_\tau$, and for each $A \in \mathcal{F}_\tau$,

$$\tilde{P}(A) = \int_A e^{\sigma\nu(\tau)-\frac{\sigma^2}{2}\tau}\,dP. \tag{6.4}$$

Thus since (6.2) also holds with t replaced by a finite stopping time τ, we have

$$E[S(\tau)] = \tilde{E}\Big[Se^{\int_0^\tau (ax(r)+b(1-x(r)))\,dr}\Big]. \tag{6.5}$$

Now Girsanov's theorem implies that under $\tilde{P}$, $\tilde{\nu}(t)$ defined by

$$\tilde{\nu}(t) = \nu(t) - \sigma t \tag{6.6}$$

is a Wiener process. Thus $x(t)$ is a solution of

$$\begin{aligned} &dx(t) = (-cx(t) + (a-b)(1-x(t))x(t))\,dt + \frac{a-b}{\sigma}(1-x(t))\,x(t)d\tilde{\nu}(t), \\ &x(0) = x. \end{aligned} \tag{6.7}$$

Thus our original problem is equivalent to the following problem: Find a stopping time τ in $\mathcal{A}$ to maximize

$$\tilde{E}\Big[Se^{\int_0^\tau (ax(r)+b(1-x(r)))\,dr}\Big], \tag{6.8}$$

where $x(t)$ is the solution of (6.7).

We shall convert this problem into yet another equivalent problem. Notice that the solution of (6.7) satisfies the integral equation

$$x(t) = xe^{\int_0^t (-c+(a-b)(1-x(r))-\frac{1}{2}(\frac{a-b}{\sigma})^2(1-x(r))^2)\,dr+\int_0^t \frac{a-b}{\sigma}(1-x(r))\,d\tilde{\nu}(r)}. \tag{6.9}$$

Again this may be checked using Itô's differential rule. Formula (6.9) may be rearranged to give

$$\begin{aligned} &e^{\int_0^t (ax(r)+b(1-x(r)))\,dr} \\ &\quad = \frac{xe^{(a-c)t}}{x(t)}\, e^{\int_0^t \frac{a-b}{\sigma}(1-x(r))\,d\tilde{\nu}(r)-\int_0^t \frac{1}{2}(\frac{a-b}{\sigma})^2(1-x(r))^2\,dr}. \end{aligned} \tag{6.10}$$

This suggests making the change of measures defined through the following: For each t and $A \in \mathcal{F}_t$,

$$\tilde{\tilde{P}}(A) = \int_A e^{\int_0^t \frac{a-b}{\sigma}(1-x(r))\,d\tilde{\nu}(r)-\int_0^t \frac{1}{2}(\frac{a-b}{\sigma})^2(1-x(r))^2\,dr}\,d\tilde{P}. \tag{6.11}$$

Then by setting $y(t) = \frac{1}{x(t)}$, again using Theorem 3.4 of [6], and denoting expectation with respect to $\tilde{\tilde{P}}$ by $\tilde{\tilde{E}}$, (6.10) with t replaced by a finite stopping time τ implies

$$E[S(\tau)] = \tilde{E}\Big[Se^{\int_0^\tau (ax(r)+b(1-x(r)))\,dr}\Big] = \tilde{\tilde{E}}[Sxe^{(a-c)\tau}\, y(\tau)]. \tag{6.12}$$

Girsanov's theorem implies that under $\tilde{\tilde{P}}$,

$$\tilde{\tilde{\nu}}(t) = \tilde{\nu}(t) - \int_0^t \frac{a-b}{\sigma}(1-x(r))\,dr \tag{6.13}$$

is a Wiener process.

A calculation using Itô's rule, (6.7), and (6.13) gives that $y(t)$ is the solution of

$$dy(t) = ((c-a+b)y(t) + a - b)\,dt + \frac{a-b}{\sigma}(y(t)-1)\,d\tilde{\tilde{\nu}}(t),\ y(0) = \frac{1}{x}. \tag{6.14}$$

Thus we arrive at the problem of choosing $\tau \in \mathcal{A}$ to maximize

$$\tilde{\tilde{E}}[Sxe^{(a-c)\tau}y(\tau)], \tag{6.15}$$

where $y(t)$ is the solution of (6.14).

7. Solution of the third equivalent problem. Since S and x are positive constants, we consider the problem of choosing $\tau \in \mathcal{A}$ to maximize

$$\tilde{\tilde{E}}[e^{(a-c)\tau}\, y(\tau)], \tag{7.1}$$

where $y(t)$ is the solution of

$$dy(t) = ((c-a+b)y(t) + a - b)\,dt + \left(\frac{a-b}{\sigma}\right)(y(t)-1)\,d\tilde{\tilde{\nu}}(t),\ y(0) = \frac{1}{x}. \tag{7.2}$$

Define

$$T(q) = \text{ first time } y(t) \in [q, \infty). \tag{7.3}$$

In order to utilize Theorem 2.1, we shall first consider maximizing (7.1) over the set of stopping times $\mathcal{A}$ defined by

$$\mathcal{A} = \{\tau :\ \tau \le T(q) \text{ for some } q\} \tag{7.4}$$

and then show that an optimal stopping time in $\mathcal{A}$ is also optimal in the class $\mathcal{B}$ of all finite stopping times.

Notice that if $a \ge c$ and q_n is a sequence approaching infinity, then

$$\tilde{\tilde{E}}[e^{(a-c)T(q_n)}y(T(q_n))] \ge q_n. \tag{7.5}$$

This leads to the very counterintuitive conclusion that no matter how negative the rate of decline b is, if $a \ge c$, then arbitrarily large expected returns can be obtained by using the stopping times $T(q_n)$.

Let us assume $a < c$ and solve the problem given in terms of (7.1), (7.2), and (7.4). The quantity $A[V](y)$ for this problem is given by

$$\begin{aligned} A[V](y) = (a-c)V(y) + ((c-a+b)y + (a-b))V'(y) \\ + \frac{1}{2}\left(\frac{a-b}{\sigma}\right)^2 (y-1)^2 V''(y). \end{aligned} \tag{7.6}$$

The general solution of $A[V](y) = 0$ is given by

$$V(y) = C_1\, W_{k,m}\left(\frac{h}{y-1}\right) e^{\frac{h}{2(y-1)}}(y-1)^k + C_2\, M_{k,m}\left(\frac{h}{y-1}\right) e^{\frac{h}{2(y-1)}}(y-1)^k, \tag{7.7}$$

where

$$k = 1 + \frac{\sigma^2(a-b-c)}{(a-b)^2}, \quad h = \frac{2c\sigma^2}{(a-b)^2}, \quad m = \left[\left(k-\frac{1}{2}\right)^2 + h\frac{(c-a)}{c}\right]^{\frac{1}{2}}, \tag{7.8}$$

and $W_{k,m}(\cdot)$ and $M_{k,m}(\cdot)$ are the classical Whittaker functions.

LEMMA 7.1. *The condition $c > a$ implies that the following conditions* (a) *and* (b) *hold:*

$$\text{(a)} \quad m + k - \frac{3}{2} > 0, \qquad \text{(b)} \quad \frac{h}{(m-k+\frac{1}{2})(m+k-\frac{1}{2})} > 1.$$

The proof of Lemma 7.1 is given in the appendix.

Let

$$g(y) = W_{k,m}\left(\frac{h}{y-1}\right) e^{\frac{h}{2(y-1)}}(y-1)^k, \tag{7.9}$$

and let us see if we can construct a solution to the conditions of Theorem 2.1 from the function $C_1 g(y)$.

The $W_{k,m}(\cdot)$ function [11, p. 122] has integral representation given by

$$W_{k,m}\left(\frac{h}{y-1}\right) = \left[\int_0^\infty e^{-x} x^{m-k-\frac{1}{2}}\left(1 + \frac{x(y-1)}{h}\right)^{m+k-\frac{1}{2}} dx\right] \cdot \left[\frac{1}{\Gamma(m-k+\frac{1}{2})}\left(\frac{h}{y-1}\right)^k e^{\frac{-h}{2(y-1)}}\right]. \tag{7.10}$$

Thus $g(y)$ given by (7.9) has the representation

$$g(y) = \frac{h^k}{\Gamma(m-k+\frac{1}{2})} \int_0^\infty e^{-x} x^{m-k-\frac{1}{2}}\left(1 + \frac{x(y-1)}{h}\right)^{m+k-\frac{1}{2}} dx. \tag{7.11}$$

Differentiating (7.11) under the integral sign gives

$$g'(y) = \frac{h^{k-1}(m+k-\frac{1}{2})}{\Gamma(m-k+\frac{1}{2})} \int_0^\infty e^{-x} x^{m-k+\frac{1}{2}}\left(1 + \frac{x(y-1)}{h}\right)^{m+k-\frac{3}{2}} dx \tag{7.12}$$

and

$$g''(y) = \left[\int_0^\infty e^{-x} x^{m-k+\frac{3}{2}}\left(1 + \frac{x(y-1)}{h}\right)^{m+k-\frac{5}{2}} dx\right] \cdot \left[\frac{(m+k-\frac{1}{2})(m+k-\frac{3}{2})h^{k-2}}{\Gamma(m-k+\frac{1}{2})}\right]. \tag{7.13}$$

It follows from (a) of Lemma 7.1 that for $1 \le y < \infty$, (7.12) and (7.13) are greater than 0. This implies $g(y)$ is increasing and strictly convex on $1 \le y < \infty$.

In order for

$$V(y) = \begin{cases} C_1 g(y) & \text{if } 1 \le y < y^*, \\ y & \text{if } y^* \le y < \infty \end{cases} \tag{7.14}$$

to satisfy the conditions of Theorem 2.1, it must be at least once continuously differentiable. For this to happen, C_1 and y^* must be a solution of

$$C_1 g(y^*) = y^*, \quad C_1 g'(y^*) = 1. \tag{7.15}$$

If y^* is a solution of

$$\frac{g(y)}{g'(y)} = y, \tag{7.16}$$

(7.15) will hold with $C_1 = \frac{1}{g'(y^*)}$.

LEMMA 7.2. *There is a solution $y^* > 1$ of* (7.16).

Proof.

$$\frac{g(y)}{g'(y)} = \frac{h}{m+k-\frac{1}{2}} \frac{\int_0^\infty e^{-x} x^{m-k-\frac{1}{2}} (1 + \frac{x(y-1)}{h})^{m+k-\frac{1}{2}}\, dx}{\int_0^\infty e^{-x} x^{m-k+\frac{1}{2}} (1 + \frac{x(y-1)}{h})^{m+k-\frac{3}{2}}\, dx}. \tag{7.17}$$

Thus

$$\frac{g(1)}{g'(1)} = \frac{h}{m+k-\frac{1}{2}} \frac{\int_0^\infty e^{-x} x^{m-k-\frac{1}{2}}\, dx}{\int_0^\infty e^{-x} x^{m-k+\frac{1}{2}}\, dx}. \tag{7.18}$$

An integration by parts gives

$$\int_0^\infty e^{-x} x^{m-k+\frac{1}{2}}\, dx = \left(m - k + \frac{1}{2}\right) \int_0^\infty e^{-x} x^{m-k-\frac{1}{2}}\, dx, \tag{7.19}$$

and thus by (7.18) and (b) of Lemma 7.1,

$$\frac{g(1)}{g'(1)} = \frac{h}{(m-k+\frac{1}{2})(m+k-\frac{1}{2})} > 1. \tag{7.20}$$

Dividing both numerator and denominator of (7.17) by $(y-1)^{(m+k-\frac{1}{2})}$ gives

$$\frac{g(y)}{g'(y)} = \frac{h(y-1)}{m+k-\frac{1}{2}} \frac{\int_0^\infty e^{-x} x^{m-k-\frac{1}{2}} (\frac{1}{(y-1)} + \frac{x}{h})^{m+k-\frac{1}{2}}\, dx}{\int_0^\infty e^{-x} x^{m-k+\frac{1}{2}} (\frac{1}{(y-1)} + \frac{x}{h})^{m+k-\frac{3}{2}}\, dx}. \tag{7.21}$$

Now

$$\lim_{y\to\infty} \frac{\int_0^\infty e^{-x} x^{m-k-\frac{1}{2}} (\frac{1}{y-1} + \frac{x}{h})^{m+k-\frac{1}{2}}\, dx}{\int_0^\infty e^{-x} x^{m-k+\frac{1}{2}} (\frac{1}{y-1} + \frac{x}{h})^{m+k-\frac{3}{2}}\, dx} = \frac{1}{h}. \tag{7.22}$$

Thus asymptotically as $y \to \infty$,

$$\frac{g(y)}{g'(y)} \sim \frac{y-1}{m+k-\frac{1}{2}}. \tag{7.23}$$

Since $m + k - \frac{1}{2} > 1$, $\frac{g(y)}{g'(y)}$ asymptotically has slope less than one. Since its value at one is bigger than one, and it has asymptotic slope less than one, $\frac{g(y)}{g'(y)}$ must cross the line given by y at some $y^* > 1$. □

THEOREM 7.3. *For y^* the solution of* (7.16)*, the function*

$$V(y) = \begin{cases} \frac{1}{g'(y^*)} g(y) & \text{if } 1 \le y \le y^*, \\ y & \text{if } y^* \le y < \infty \end{cases} \tag{7.24}$$

satisfies the conditions of Theorem 2.1 *for the problem given by* (7.1)*,* (7.2)*, and* (7.4)*. The stopping time $T(y^*)$ is an optimal stopping time in the class $\mathcal{A}$.*

Proof. Since $g'(y) > 0$, and $g(y)$ is strictly convex, the conditions

$$\frac{1}{g'(y^*)}\, g(y^*) = y^*, \quad \frac{1}{g'(y^*)}\, g'(y^*) = 1 \tag{7.25}$$

imply y is a line of support of $\frac{1}{g'(y^*)}\, g(y)$ at y^*. Thus

$$\frac{1}{g'(y^*)}\, g(y) \ge y, \tag{7.26}$$

which implies

$$V(y) \ge y. \tag{7.27}$$

Since $A[\frac{1}{g'(y^*)}\, g(\cdot)](y) = 0$, for $V(y)$ given by (7.24),

$$A[V](y) = \begin{cases} 0 & \text{if } 1 \le y < y^*, \\ by + (a - b) & \text{if } y^* < y < \infty. \end{cases} \tag{7.28}$$

Evaluating $A[\frac{1}{g'(y^*)}\, g(\cdot)](y) = 0$ at y^*, and using (7.6) and the conditions of (7.25), give

$$(a - c)y^* + (cy^* - (a - b)(y^* - 1)) + \frac{1}{2}\left(\frac{a - b}{\sigma}\right)^2 (y^* - 1)^2\, \frac{g''(y^*)}{g'(y^*)} = 0. \tag{7.29}$$

Since $g(y)$ is increasing and strictly convex, the last term in (7.29) is positive. Thus (7.29) implies

$$by^* + a - b < 0. \tag{7.30}$$

Since b is negative,

$$by + (a - b) < 0 \quad \text{if } \ y^* \le y < \infty, \tag{7.31}$$

or, from (7.28), then $A[V](y) \le 0$ for $V(y)$ given by (7.24). That $(V(y) - y)A[V](y) = 0$ follows immediately from (7.24) and (7.28).

To verify condition (2.6), we see

$$V'(y) = \begin{cases} \frac{1}{g'(y^*)}\, g'(y) & \text{if } 1 \le y \le y^*, \\ 1 & \text{if } y^* < y < \infty. \end{cases} \tag{7.32}$$

From (7.12) and (a) of Lemma 7.1, $g'(1) > 0$. Since $g'(y)$ is increasing, (7.32) implies

$$0 \le V'(y) \le 1. \tag{7.33}$$

The quantity in (2.6) for this problem is

$$\tilde{\tilde{E}}\left[\int_0^\tau e^{2(a-c)t}\left(V'(y(t))^2\left(\frac{a-b}{\sigma}\right)^2(y(t)-1)\right)^2 dt\right]. \tag{7.34}$$

Since $\tau \le T(q)$ for some q and (7.33) holds, (7.34) is bounded by

$$\int_0^\infty e^{2(a-c)t}\left(\frac{a-b}{\sigma}\right)^2(q-1)^2\,dt = \frac{(q-1)^2}{2(c-a)}\left(\frac{a-b}{\sigma}\right)^2. \tag{7.35}$$

Thus condition (2.6) holds. Condition (2.8) follows from Lemma 4.1 and the definition of $T(y^*)$. Thus the conditions of Theorem 2.1 are satisfied and $T(y^*)$ is an optimal stopping time in the class $\mathcal{A}$. □

THEOREM 7.4. *The stopping time $T(y^*)$ is optimal in the class $\mathcal{B}$ of all finite stopping times.*

Proof. If τ is a finite stopping time and q_n is a sequence approaching ∞, satisfying $q_n > 1/x$, the definition of $T(q_n)$ implies

$$y(\tau \wedge T(q_n)) = \begin{cases} y(\tau) & \text{if } \tau < T(q_n), \\ q_n & \text{if } \tau \ge T(q_n). \end{cases} \tag{7.36}$$

It can be shown that $\lim_{n\to\infty} T(q_n) = +\infty$ with probability one.

Hence

$$\lim_{n\to\infty} e^{(a-c)\tau\wedge T(q_n)} y(\tau \wedge T(q_n)) = e^{(a-c)\tau} y(\tau). \tag{7.37}$$

Theorem 7.3 implies

$$\tilde{\tilde{E}}[e^{(a-c)\tau\wedge T(q_n)} y(\tau \wedge T(q_n))] \le \tilde{\tilde{E}}[e^{(a-c)T(y^*)} y(T(y^*))]. \tag{7.38}$$

Fatou's Lemma and (7.37) imply

$$\tilde{\tilde{E}}[e^{(a-c)\tau} y(\tau)] \le \liminf_{n\to\infty} \tilde{\tilde{E}}[e^{(a-c)\tau\wedge T(q_n)} y(\tau \wedge T(q_n))]. \tag{7.39}$$

Thus (7.38) and (7.39) imply

$$\tilde{\tilde{E}}[e^{(a-c)\tau} y(\tau)] \le \tilde{\tilde{E}}[e^{(a-c)T(y^*)} y(T(y^*))], \tag{7.40}$$

which gives the optimality of $T(y^*)$ in the class $\mathcal{B}$ of all finite stopping times. □

8. Computations. In Table 8.1 we give results of computing optimal selling regions for a variety of conditions. To explain the coefficients used in Table 8.1, we note that (4.1) implies the following: If the growth rate $a(t)$ has the constant value a, the expected stock price is

$$E[S(t)] = Se^{at}, \tag{8.1}$$

and similarly, if $a(t)$ has the constant value b, the expected stock price is

$$E[S(t)] = Se^{bt}. \tag{8.2}$$

TABLE 8.1
Optimal selling regions for both criteria and different parameter values.

Problem coefficients				$U(S) = \ln(S)$	$U(S) = S$
Growth	Decline	Mean years	σ	Selling region	Selling region
10%	60%	2	.3	$0 \le x \le .911$	$0 \le x \le .766$
10%	60%	2	.4	$0 \le x \le .978$	$0 \le x \le .831$
10%	60%	2	.5	$0 \le x \le 1.00$	$0 \le x \le .857$
10%	80%	2	.3	$0 \le x \le .927$	$0 \le x \le .760$
10%	80%	2	.4	$0 \le x \le .986$	$0 \le x \le .856$
10%	80%	2	.5	$0 \le x \le 1.00$	$0 \le x \le .891$
20%	60%	2	.3	$0 \le x \le .678$	$0 \le x \le .441$
20%	60%	2	.4	$0 \le x \le .849$	$0 \le x \le .601$

20%	80%	2	.5	$0 \le x \le .953$	$0 \le x \le .709$
20%	80%	6	.4	$0 \le x \le .659$	For the sequence of selling regions $0 \le x \le a_n$ where $a_n \downarrow 0$, the problem is unbounded

TABLE 8.2
Correspondence of parameter values and approximate percents of growth and decline per year.

a	.1	.18	b	−.92	−1.6
% growth	10	20	% decline	60	80

The value $a = .1$ gives $e^{.1} \approx 1.105$, or a growth rate of approximately 10% per year. The value $b = -.92$ gives $e^{-.92} \approx .398$, or a rate of decline of approximately 60% per year. Table 8.1 was computed in terms of values of a, b, c, σ but is displayed in terms of approximate percents of growth and decline to aid intuitive understanding of the results. The relationships between the values of a and b used in the computation of Table 8.1 and the approximate percents of growth and decline per year are listed in Table 8.2.

Except in the last case in Table 8.1, the mean of the jump time was taken to be two years, or $c = \frac{1}{2}$. In literature using actual stock data, values for the stock variance σ near .3 or .4 are common. We use those and also the value $\sigma = .5$ to illustrate a case with large variance.

Table 8.1 shows that the optimal stock selling regions for $U(S) = \ln(S)$ and $U(S) = S$ are quite different. The optimal selling regions for $\ln(S)$ are uniformly larger than those of S. In some cases these differences are large. If the growth rate equals 10% and $\sigma = .5$, the inequality

$$2a = .2 < .25 = \sigma^2$$

holds, and thus selling immediately always occurs for the $ln(S)$ criteria, while for the S criteria selling immediately does not occur if x is large enough. If the growth rate is approximately 20% for an exponentially distributed length of time with mean six years, then

$$a = .18 > \frac{1}{6} = c.$$

This implies that there is a sequence of values of x approaching zero so that stopping

at these values gives unbounded expected return for the criteria S. For this case, the criteria $\ln(S)$ is finite and its optimal selling region is $0 \le x \le .659$.

9. Comparison with Zhang [12] and Beibel and Lerche [3]. In [12] Zhang considers a stock selling problem in which the stock price is given by a geometric Brownian motion whose drift and diffusion coefficients are given by unobservable, finite state, jump Markov processes. This model is more general than that of the current paper, whose a drift coefficient is a one jump Markov process, and where a diffusion coefficient is constant. However, the classes of stopping times optimized over are different. In [12] the stopping times are first times that the stock price leaves a given interval. In the present paper they are stopping times adapted to the past measurements of the stock price. These include the first times the stock price leaves an interval, so there should be a larger optimal expected return in the present case. There is an advantage to using the stopping times of [12] in that they are easier to implement.

The difference between the two problems is especially clear in the case in which the initial probability x of being in the increasing state a is less than one. (Some people assert this is "always" the case by the time a small investor invests in a stock.) The stopping times of [12] do not depend on x. If x is small enough to be in the optimal selling region for the current problem, the investor should sell the stock immediately. If he/she is using stopping times of [12], he/she holds the stock until its price leaves an interval.

In [3] Beibel and Lerche consider an optimal stock selling problem with utility function $U(S) = S$, which is roughly the same as our second equivalent problem. Their methods applied to this problem would be roughly the following. Let $x(t)$ be the solution of (6.7) with initial condition $x(0) = 1$. Let $0 < x < 1$ and

$$T(x) = \text{ first time } x(t) = x. \tag{9.1}$$

Then, using elegant probabilistic arguments, they show

$$E\left[e^{\int_0^{T(x)} a(x(r))+b(1-x(r))\,dr}\right] \tag{9.2}$$

has a maximum attained at some x^* and for the problem with $x(t)$ given by (6.7), with initial condition γ, for which $x^* \le \gamma \le 1$ that

$$T(x^*) = \text{ first time } x(t) = x^* \tag{9.3}$$

maximizes the criteria (6.8).

However, they do not carry out any computations. It appears that computing (9.2) would encounter similar difficulties to those we encountered in solving the variational inequalities for this case.

Appendix. In this appendix we provide the proofs of Theorem 2.1, Lemma 4.1, and Lemma 7.1.

Proof of Theorem 2.1. Itô's differential rule implies that

$$\begin{aligned} de^{\int_0^t \beta(z(r))dr}V(z(t)) &= \beta(z(t))e^{\int_0^t \beta(z(r))dr}V(z(t))dt \\ &+ e^{\int_0^t \beta(z(r))dr}\Big[V_z(z(t))g(z(t)) \\ &\qquad + \frac{1}{2}\operatorname{trace}\left(h(z(t))h'(z(t))V_{zz}(z(t))\right)\Big]dt \\ &+ e^{\int_0^t \beta(z(r))dr}V_z(z(t))h(z(t))dW(t), \end{aligned} \tag{A.1}$$

or, expressed in integrated form and using (2.4), that

$$e^{\int_0^t \beta(z(r))dr}V(z(t)) - V(z) = \int_0^t e^{\int_0^s \beta(z(r))dr}A[V](z(s))ds + \int_0^t e^{\int_0^s \beta(z(r))dr}V_z(z(s))h(z(s))dW(s). \tag{A.2}$$

Since (A.2) holds for each sample function, it also holds with t replaced by a finite stopping time τ.

It follows from Remark 1 on page 29 of Gihman and Skorohod [5] that condition (2.6) implies for each stopping time τ in $\mathcal{A}$ that

$$E\left[\int_0^\tau e^{\int_0^s \beta(z(r))\,dr}\,V_z(z(s))h(z(s))\,dW(s)\right] = 0. \tag{A.3}$$

Thus for each τ in $\mathcal{A}$,

$$E\left[e^{\int_0^\tau \beta(z(r))\,dr}\,V(z(\tau))\right] = V(z) + E\left[\int_0^\tau\ e^{\int_0^s \beta(z(r))\,dr}\,A[V](z(s))\,ds\right]. \tag{A.4}$$

Now from (2.5),

$$V(z) \geq U(z) \quad \text{and} \quad A[V](z) \leq 0,$$

and thus for each τ in $\mathcal{A}$,

$$E\left[e^{\int_0^\tau \beta(z(r))\,dr}U(z(\tau))\right] \leq V(z). \tag{A.5}$$

From (2.5) for

$$\tau(z) = \text{ first time } z(t) \text{ hits } \{y:\ U(y) = V(y)\},$$

it follows that

$$A[V](z(s)) = 0 \quad \text{on } 0 \leq s < \tau(z) \tag{A.6}$$

and

$$U(z(\tau(z))) = V(z(\tau(z))). \tag{A.7}$$

Thus (A.4) implies

$$E\left[e^{\int_0^{\tau(z)}\ \beta(z(r))\,dr}\,U(z(\tau(z)))\right] = V(z). \tag{A.8}$$

Since condition (2.8) requires $\tau(z)$ to belong to $\mathcal{A}$, (A.5) and (A.8) imply $\tau(z)$ is an optimal stopping time in the class $\mathcal{A}$. □

Proof of Lemma 4.1. We may assume $x > q$; otherwise $T(q) = 0$ and $E[T(q)] = 0$. For $x(t)$ given by (4.8), from Theorem 2 on page 149 of [5], appropriately modified, it follows that for $t > 0$,

$$P[x(t) < 1] = 1. \tag{A.9}$$

A solution $K(x)$ of the differential equation

$$-cxK'(x) + \frac{1}{2}r^2(1-x)^2x^2K''(x) + 1 = 0 \tag{A.10}$$

on $[0,1]$ satisfying $K(q) = 0$ and $K'(x)$ bounded on $[q,1]$ is given by

(A.11)

$$K(x) = \int_q^x \left[\frac{2}{r^2} e^{\frac{2c}{r^2(1-z)}} z^{\frac{2c}{r^2}} (1-z)^{-\frac{2c}{r^2}} \int_z^1 (1-y)^{\frac{-2(r^2-c)}{r^2}} y^{\frac{-2(r^2+c)}{r^2}} e^{\frac{-2c}{r^2(1-y)}} dy\right] dz.$$

To see that $K'(x)$ is bounded, a L'Hospital's rule argument implies that

$$\lim_{x\to 1} K'(x) = \frac{r^4}{2c}, \tag{A.12}$$

and from this and the form of $K'(x)$, boundedness follows. Notice that $K(x) \geq 0$ for $x \geq q$.

Set

$$T(q) = \inf\{t : x(t) = q\}, \tag{A.13}$$

and for a fixed time T greater than 0,

$$\tau_T = \min(T, T(q)). \tag{A.14}$$

From (A.9) and (A.13), it follows for $s < \tau_T$ that $x(s)$ is contained in $[q,1]$ over which $K(x)$ is defined. Itô's formula implies that

$$\begin{aligned} &K(x(\tau_T)) - K(x) \\ &\quad = \frac{a-b}{\sigma}\int_0^{\tau_T} (1-x(s))x(s)K'(x(s))\, dW(s) \\ &\qquad + \int_0^{\tau_T} \left[-cx(s)K'(x(s)) + \frac{1}{2}\left(\frac{a-b}{\sigma}\right)^2 (1-x(s))^2x(s)^2K''(x(s))\right] ds. \end{aligned} \tag{A.15}$$

For $K(x)$ the solution of (A.10) with $r = \frac{a-b}{\sigma}$, (A.15) implies

$$K(x(\tau_T)) - K(x) = -\tau_T + \frac{a-b}{\sigma}\int_0^{\tau_T} (1-x(s))x(s)K'(x(s))\, dW(s). \tag{A.16}$$

Since the integrand in the stochastic integral is bounded and τ_T is bounded, the expected value of the stochastic integral is zero, giving

$$E[\tau_T] = K(x) - E[K(x(\tau_T))]. \tag{A.17}$$

Now τ_T increases monotonically to $T(q)$ as T approaches infinity. This and the positivity of $K(x(\tau_T))$ imply

$$E[T(q)] \leq K(x). \qquad \square \tag{A.18}$$

Proof of Lemma 7.1. (a) Since $m \geq 0$, if $k - \frac{3}{2} > 0$ there is nothing to prove. Thus consider $k - \frac{3}{2} \leq 0$. A calculation using (7.8) shows

$$m^2 - \left(\frac{3}{2} - k\right)^2 = \frac{2\sigma^2(-b)}{(a-b)^2} > 0. \tag{A.19}$$

Thus $m^2 > (\frac{3}{2} - k)^2$, and since both m and $\frac{3}{2} - k$ are ≥ 0,

$$m > \frac{3}{2} - k \quad \text{or} \quad m + k - \frac{3}{2} > 0, \tag{A.20}$$

giving (a).

(b) Using (7.8),

$$\begin{aligned} \frac{h}{(m-k+\frac{1}{2})(m+k-\frac{1}{2})} &= \frac{h}{m^2-(k-\frac{1}{2})^2} \\ &= \frac{\frac{2c\sigma^2}{(a-b)^2}}{(k-\frac{1}{2})^2 + \frac{2\sigma^2(c-a)}{(a-b)^2} - (k-\frac{1}{2})^2} \\ &= \frac{c}{c-a} \ > \ 1. \qquad \square \end{aligned} \tag{A.21}$$

APPROXIMATION OF NONLINEAR FILTERS FOR MARKOV SYSTEMS WITH DELAYED OBSERVATIONS*

ANTONELLA CALZOLARI†, PATRICK FLORCHINGER‡, AND GIOVANNA NAPPO§

Abstract. The aim of this paper is to give some approximation results for a class of nonlinear filtering problems with delay in the observation. First, we point out some general results on the approximation problem for the filter in nonlinear filtering. In particular, we give a general procedure for obtaining some upper bounds for the different approximations we consider. This procedure is then applied in the case of nonlinear filtering problems with delay (X, Y), which can be represented by means of a Markov system $(X, \hat{Y})$, in the sense that $Y_t = \hat{Y}_{a(t)}$. Finally, these upper bounds are computed explicitly in the particular case of Markov jump process with counting observations.

Key words. nonlinear filtering, jump processes, Markov processes, approximation of stochastic processes

1. Introduction.

Consider a partially observed stochastic system $(\boldsymbol{X}, \boldsymbol{Y}) = (X_t, Y_t)_{t\geq 0}$, that is, a *state process* $\boldsymbol{X} = (X_t)_{t\geq 0}$, which cannot be directly observed, and a completely observable process $\boldsymbol{Y} = (Y_t)_{t\geq 0}$, which is referred to as the *observation process*. The aim of stochastic nonlinear filtering is to compute the conditional law π_t of the state process at time t, given the observation process up to time t, i.e., the computation of the so-called filter

$$\pi_t(\varphi) = E\big[\varphi(X_t)/\mathcal{F}_t^Y\big], \tag{1}$$

for all functions φ belonging to a determining class, i.e., the best estimate of $\varphi(X_t)$ given the σ-algebra of the observations up to time t, $\mathcal{F}_t^Y = \sigma\{Y_s,\, s \leq t\}$.

A classical model of partially observed systems arises when both the state and the observation are diffusion processes. In this case it has been shown that the filter solves a stochastic partial differential equation known as the Kushner–Stratonovich equation (see, e.g., Pardoux [20] and the references therein).

Filtering problems involving jump-diffusion processes have been studied by many authors. In particular, the jump system

$$\begin{aligned} x_t = x_0 &+ \int_0^t \int_{D_0(x_{s^-}, y_{s^-})} K_0(x_{s^-}, y_{s^-}; \zeta)\mathcal{N}(ds, d\zeta) \\ &+ \int_0^t \int_{D_1(x_{s^-}, y_{s^-})} K_1(x_{s^-}, y_{s^-}; \zeta)\mathcal{N}(ds, d\zeta), \end{aligned} \tag{2}$$

§Dipartimento di Matematica, Università di Roma "La Sapienza," piazzale A. Moro 2, I 00185 Roma, Italy (nappo@mat.uniroma1.it).

$$y_t = \int_0^t \int_{D_1(x_{s^-}, y_{s^-})} \mathcal{N}(ds, d\zeta), \tag{3}$$

where

- $\mathcal{N}(ds, d\zeta)$ is a Poisson measure on $\mathbb{R} \times \Sigma$ with mean measure $ds \times \nu(d\zeta)$,
- the random variable x_0 has values in $\mathbb{R}^k$ and probability distribution μ_0^x,
- the random variable x_0 and the Poisson random measure $\mathcal{N}(ds, d\zeta)$ are independent,
- the sets $D_0(x, y)$ and $D_1(x, y)$ are disjoint,

enters in the more general framework studied by Kliemann, Koch, and Marchetti [15]. Under suitable hypotheses (see [15]), the above system has a unique solution $(x_t, y_t)_{t \geq 0}$, which is a Markov process with formal generator $\boldsymbol{L}$ given by

$$\begin{aligned} \boldsymbol{L} f(x, y) = &\int_{D_0(x,y)} [f(x + K_0(x, y; \zeta), y) - f(x, y)] \, \nu(d\zeta) \\ &+ \int_{D_1(x,y)} [f(x + K_1(x, y; \zeta), y + 1) - f(x, y)] \, \nu(d\zeta). \end{aligned} \tag{4}$$

Then the filter $\pi_t^x(\varphi) = E[\varphi(x_t)/\mathcal{F}_t^y]$ can be obtained via the following normalization procedure:

- Let $\boldsymbol{s} = \{s_i\}_{i \geq 0}$ be an increasing sequence of times such that $s_0 = 0$;
- define

$$B^y \varphi(x) = \int_{D_0(x,y)} [\varphi(x + K_0(x, y; \zeta)) - \varphi(x)] \, \nu(d\zeta) \tag{5}$$

and

$$R^y \varphi(x) = \int_{D_1(x,y)} [\varphi(x + K_1(x, y; \zeta)) - \varphi(x)] \, \nu(d\zeta); \tag{6}$$

- define $\hat{\rho}_t(dx|\boldsymbol{s})$ by the following self-contained procedure:

(7)

$$\hat{\rho}_t(\varphi|\boldsymbol{s}) = E\left[\varphi(X^i_{t-s_i}(\boldsymbol{s})) \exp\left\{-\int_0^{t-s_i} \lambda_1(X^i_u(\boldsymbol{s}), i) du\right\}\right], \qquad s_i \leq t < s_{i+1},$$

where $\lambda_1(x, i) = \nu(D_1(x, i))$, and $\{X_t^i(\boldsymbol{s}); t \geq 0\}$ is a Markov process with generator B^i and initial distribution $\hat{\rho}_{s_i}(dx|\boldsymbol{s})$ defined inductively by

$$\hat{\rho}_{s_0}(\varphi|\boldsymbol{s}) = \mu_0^x(\varphi), \qquad \hat{\rho}_{s_{i+1}}(\varphi|\boldsymbol{s}) = \frac{\hat{\rho}_{s_{i+1}^-}(Q^i \varphi|\boldsymbol{s})}{\hat{\rho}_{s_{i+1}^-}(\lambda_1(\cdot, i)|\boldsymbol{s})} \tag{8}$$

with $Q^i \varphi(x) = R^i \varphi(x) + \lambda_1(x, i)\varphi(x) = \int_{D_1(x,i)} \varphi(x + K_1(x, i; \zeta)) \, \nu(d\zeta)$.

Setting

$$\hat{\Pi}_t(\varphi|\boldsymbol{s}) := \frac{\hat{\rho}_t(\varphi|\boldsymbol{s})}{\hat{\rho}_t(\mathbf{1}|\boldsymbol{s})}, \tag{9}$$

we have

$$\pi_t^x(\varphi) = E[\varphi(x_t)/\mathcal{F}_t^y] = \hat{\Pi}_t(\varphi|\boldsymbol{s})\Big|_{\boldsymbol{s} = \{T_i\}_{i \geq 0}}, \tag{10}$$

where T_i are the observed jump times.

Different approximation procedures and numerical schemes have been studied by many authors in the past years (see, for example, Kushner [17], Di Masi, Pratelli, and Runggaldier [12], Le Gland [18], Elliott and Glowinski [13], Lototsky, Mikulevicius, and Rozovskii [19], Del Moral [11], Calzolari and Nappo [8], or Ceci, Gerardi, and Tardelli [9] and the references therein).

In this paper we are interested in the approximation of the filter when dealing with the following nonlinear filtering problem with delay in the observation: $(\boldsymbol{X}, \hat{\boldsymbol{Y}})$ is a Markov process with generator $\boldsymbol{L}$, and the observation process $\boldsymbol{Y}$ satisfies

$$Y_t = \hat{Y}_{a(t)},$$

where $a(\cdot)$ is a nondecreasing continuous function such that $a(0) = 0$, $a(t) \le t$ for all $t \ge 0$.

For this system the following result has been proved by the authors in [4].

THEOREM 1.1. *The filter π_t associated with the system $(\boldsymbol{X}, \boldsymbol{Y})$ described above can be represented as*

$$\pi_t(\varphi) = E\big[\big(\exp\{\boldsymbol{L}(t - a(t))\}\phi\big)(X_{a(t)}, \hat{Y}_{a(t)})/\mathcal{F}^{\hat{Y}}_{a(t)}\big],$$

where $\phi(x, y) = \varphi(x)$.

Moreover, if the conditional law of X_s given $\mathcal{F}^{\hat{Y}}_s$ is known and denoted by $\hat{\pi}_s$, then

$$\pi_t(\varphi) = \hat{\pi}_{a(t)}\big((\exp\{\boldsymbol{L}(t - a(t))\}\phi)(\cdot, \hat{Y}_{a(t)})\big). \tag{11}$$

Remark 1.2. As an example we can take $(\boldsymbol{X}, \hat{\boldsymbol{Y}}) = (x_t, y_t)_{t \ge 0}$, with x_t and y_t defined as in (2) and (3), respectively. In this case the generator $\boldsymbol{L}$ coincides with the one given in (4).

Remark 1.3. The case when the state process solves the stochastic differential equation

$$X_t = X_0 + \int_0^t b(X_s)ds + \int_0^t \sigma(X_s)dB_s, \qquad t \ge 0,$$

and the observation is given by

$$\begin{cases} Y_t = 0, & 0 \le t \le \tau, \\ Y_t = \int_\tau^t h(X_{s-\tau})ds + W_t - W_\tau, & t \ge \tau, \end{cases} \tag{12}$$

corresponds to $a(t) = (t - \tau)^+$ and to the system $(\boldsymbol{X}, \hat{\boldsymbol{Y}})$ with the generator

$$\boldsymbol{L}f(x, y) = b(x)\nabla_x f(x, y) + h(x)\nabla_y f(x, y) + \frac{1}{2}\mathrm{tr}\{\sigma(x)\sigma^*(x)\nabla_x^2 f(x, y)\} + \frac{1}{2}\Delta_y f(x, y)$$

in the above theorem. On the other hand, by applying a shift in time of size τ to the system $(\boldsymbol{X}, \boldsymbol{Y})$, we get a stochastic delay system: indeed, setting $X_{(\tau)}(s) := X_{s+\tau}$ and $Y_{(\tau)}(s) := Y_{s+\tau}$, we have

$$dX_{(\tau)}(s) = b\big(X_{(\tau)}(s)\big)ds + \sigma\big(X_{(\tau)}(s)\big)d\tilde{B}_s, \quad s \ge 0, \qquad X_{(\tau)}(s) = \xi(s), \quad -\tau \le s \le 0, \tag{13}$$

$$Y_{(\tau)}(t) = \int_0^t h\big(X_{(\tau)}(s-\tau)\big)ds + \hat{W}_t, \qquad t \geq 0, \tag{14}$$

where $\tilde{B}_s = B_{s+\tau}$, and $\xi(s)$ is the solution of the stochastic differential equation

$$d\xi(s) = b(\xi(s))ds + \sigma(\xi(s))d\tilde{B}_s \quad \text{for } -\tau \leq s \leq 0 \quad \text{with } \xi(-\tau) = X(0).$$

Clearly, in the above system the delay is present only in the observation.

The approximation problem we consider is interesting due to the fact that partially observed systems with delay in the observations appear in stochastic finance. For instance, in [21] Schweizer has given an example of information with delay for a financial model. From [21] one can easily deduce that when the market is incomplete the risk minimization criterion leads to a filtering problem with delayed observation. The risk minimization criterion corresponds to a quadratic loss function, and this is criticized, as it implies the minimization of both earnings and losses. This leads to the use of different loss functions and to the consideration of the hedging problem as an optimal control problem. Then, from a Bayesian point of view, filtering may appear in the case of partial observations, and in this direction diffusion-type models are mainly studied in the literature. More recently, in [14] Kirch and Runggaldier have studied a control problem with partial observation when the stock price evolves as

$$S_t = s_0\, e^{aN_t^+ - bN_t^-},$$

where a, $b > 0$ are constants, and N^+ and N^- are counting processes with random unobservable intensities Λ^+ and Λ^-.

The observation of the stock price is equivalent to the observation of the couple of counting processes N^+ and N^-.

In [14], N^+ and N^- are assumed to be conditionally independent Poisson processes given their random time constant intensities Λ^+ and Λ^-, which are independent and with prior distribution gamma. In this case the filter of (Λ^+, Λ^-) given N^+ and N^- up to time t can be reduced to a couple of filtering problems, each with one counting observation process, and can be computed explicitly.

If the time constant assumption on the intensities were dropped, then the explicit computation of the filter would no longer be feasible, and a filtering approximation problem would naturally arise. Considering also a delay in the information would then lead to an example fitting the framework of section 4. Another related situation fitting the same framework could arise if the interest were focused on a fixed strike lookback call option, that is,

$$\left(\max_{t\in[0,T]} S_t - K\right)^+.$$

In this situation, instead of observing the price, it could be natural to observe the process of the running maximum of the price $\max_{u\in[0,t]} S_u$, and this amounts to observing one counting process.

This paper is divided into four sections and an appendix and is organized as follows. In section 2, we introduce different kinds of approximation for the filter that we will use throughout. These approximation schemes rely on the trajectories actually observed, and upper bounds for these approximations are obtained in Theorem 2.3. A relation between these upper bounds and weak convergence of the sequence of filters is presented in Theorem 2.6. In section 3, we consider the approximation of filters for Markov models with delayed observations for which we obtain upper bounds depending on the trajectory actually observed (see Proposition 3.1). In section 4, the

approximation results obtained in section 2, together with the representation for the filter in Theorem 1.1, will be applied to obtain some explicit upper bounds in the counting observation case, as in Remark 1.2 (see Theorem 4.5).

Some approximation results can be obtained for different systems and by making use of different techniques. As an example we can consider the simple stochastic delay system of Remark 1.3. Taking into account this remark, the computation of the filter is equivalent to the computation of the filter of the stochastic delay system (13), (14), for which the convergence result obtained in [5] can be applied. To our knowledge there are only two other papers dealing with the approximation of nonlinear filtering for delayed diffusion systems: Chang [10] and Twardowska, Marnik, and Pasławaska-Połuniak [22].

2. General considerations on approximation for filters.

2.1. Different kinds of approximation. Suppose that a sequence of stochastic systems $(\boldsymbol{X^n}, \boldsymbol{Y^n})$ with values in $\mathbb{R}^k \times \mathbb{R}^d$ converges to a system $(\boldsymbol{X}, \boldsymbol{Y})$. Then a natural question is whether the corresponding sequence of filters π^n converges to the filter of the limit system π.

Different kinds of convergence can be considered for both the systems and the filters. Convergence of their distributions is the first one, and, moreover, the only one that can be considered when the systems $(\boldsymbol{X^n}, \boldsymbol{Y^n})$ are defined on different probability spaces. The most frequently used is weak convergence of their distributions. Furthermore, in this case one can distinguish between convergence of π_t^n to π_t as random probability measures on $\mathbb{R}^k$, for each t, and convergence of the processes $\boldsymbol{\pi^n} = (\pi_t^n; t \geq 0)$ to $\boldsymbol{\pi} = (\pi_t; t \geq 0)$, as *càdlàg* measure-valued processes. Finally, one can consider different metrics $dist(\nu_1, \nu_2)$ on the space $\mathcal{P} = \mathcal{P}(\mathbb{R}^k)$, which is the space of probability measures on $\mathbb{R}^k$, such as the total variation, i.e.,

$$\|\nu_1 - \nu_2\|_{TV} = \sup\left\{\frac{|\nu_1(\varphi) - \nu_2(\varphi)|}{\|\varphi\|}; \varphi \text{ bounded}\right\},$$

the Kantorovitch metric, i.e.,

$$\boldsymbol{\kappa}(\nu_1, \nu_2) = \sup\left\{\frac{|\nu_1(\varphi) - \nu_2(\varphi)|}{L_\varphi}; \varphi \text{ Lipschitz}\right\},$$

or the bounded-Lipschitz metric, i.e.,

$$d_{BL}(\nu_1, \nu_2) = \sup\left\{\frac{|\nu_1(\varphi) - \nu_2(\varphi)|}{\|\varphi\| \vee L_\varphi}; \varphi \text{ bounded and Lipschitz}\right\},$$

where $\|\varphi\|$ denotes the sup-norm, and L_φ is the Lipschitz constant of φ. We recall that the bounded-Lipschitz metric induces the weak convergence topology on the space of probability measures $\mathcal{P}$.

In the following we will consider $\mathcal{P}$ endowed with one of the above metrics.

When instead all the processes are defined on the same probability space $(\Omega, \mathcal{F}, P)$, then one can also consider other kinds of convergence such as convergence in probability, convergence in $L^p([0,T] \times \Omega, dt \otimes dP)$, and so on.

This situation arises typically when one is interested in the limit system, and the sequence $(\boldsymbol{X^n}, \boldsymbol{Y^n})$ is constructed pathwise starting from the path $(\boldsymbol{X}, \boldsymbol{Y})$ such as, for instance, in the Euler approximations of diffusive systems.

When the filters $\boldsymbol{\pi^n}$ and $\boldsymbol{\pi}$ have a robust version, that is, when for suitable deterministic measure-valued functionals U^n and U, with paths in the Skorohod space $D_{\mathcal{P}}([0,T])$,

$$U^n,\, U:\ [0,T]\times D_{\mathbb{R}^d}([0,T])\mapsto \mathcal{P}$$

such that

$$U^n(t,\boldsymbol{y}) = U^n(t, y(\cdot\wedge t)) \text{ and } U(t,\boldsymbol{y}) = U(t, y(\cdot\wedge t)),$$

$$\pi^n_t(dx) = U^n(t,\boldsymbol{Y^n}; dx) \text{ and } \pi_t(dx) = U(t,\boldsymbol{Y}; dx),$$

then, in order to consider convergence in probability, one has to assume that the processes $\boldsymbol{Y^n}$ and $\boldsymbol{Y}$ are defined on the same probability space. Such deterministic functionals U^n and U satisfying the above properties always exist under very general conditions (see Kurtz and Ocone [16]). Note that the functionals U^n and U depend on the joint distribution of $(\boldsymbol{X^n},\boldsymbol{Y^n})$ and $(\boldsymbol{X},\boldsymbol{Y})$, respectively, and are defined in $D_{\mathbb{R}^d}([0,T])$ almost surely with respect to $P_{\boldsymbol{Y^n}}$, the law of $\boldsymbol{Y^n}$, and with respect to $P_{\boldsymbol{Y}}$, the law of $\boldsymbol{Y}$, respectively.

As an example one can consider approximating and limit models such as the jump model with counting observations, as given by (2) and (3), for which the functionals U and U^n can be computed as in (9), or such as the classical diffusive model, for which the functionals U and U^n are also computable as shown in [16], for example.

A different approach to the problem of the approximation of the filter takes into account that a realistic approximation depends on the trajectory actually observed and uses the robust representation described above. Two different types of situations can arise as follows:

1. The *true* model is $(\boldsymbol{X},\boldsymbol{Y})$, and therefore we observe $\boldsymbol{Y}$, while the models $(\boldsymbol{X^n},\boldsymbol{Y^n})$ are *more manageable* approximations.
2. The *true* model is $(\boldsymbol{X^n},\boldsymbol{Y^n})$, depending on a large parameter n, and therefore we observe $\boldsymbol{Y^n}$, while $(\boldsymbol{X},\boldsymbol{Y})$ is a *more manageable* limit model.

In these situations,

1. the *true* filter is π_t, and it is natural to consider

$$\tilde{\pi}^n_t = U^n(t,\boldsymbol{Y}) \tag{15}$$

   as an approximation of π_t, depending on the trajectory actually observed.
2. the *true* filter is π^n_t, and it is natural to consider

$$\overline{\pi}^n_t = U(t,\boldsymbol{Y^n}) \tag{16}$$

   as an approximation of π^n_t, depending on the trajectory actually observed.

The functional U^n is defined $P_{\boldsymbol{Y^n}}$-almost surely; therefore, in order to define $\tilde{\boldsymbol{\pi}}^{\boldsymbol{n}} = \{\tilde{\pi}^n_t; t\ge 0\}$ almost surely it is natural to assume that $P_{\boldsymbol{Y}}$ is absolutely continuous with respect to $P_{\boldsymbol{Y^n}}$. Indeed, when the functional U^n is defined $P_{\boldsymbol{Y^n}}$-almost surely, there exists a set $D^n\subset D_{\mathbb{R}^d}([0,T])$ with $P_{\boldsymbol{Y^n}}(D^n)=1$ such that the filter π^n_t is almost surely equal to $\mathbf{1}_{D^n}(\boldsymbol{Y^n})U^n(t,\boldsymbol{Y^n}) + (1-\mathbf{1}_{D^n}(\boldsymbol{Y^n}))\delta_{\{x_0\}}$ for any fixed point x_0, and one could always define

$$\tilde{\pi}^n_t = \mathbf{1}_{D^n}(\boldsymbol{Y})U^n(t,\boldsymbol{Y}) + (1-\mathbf{1}_{D^n}(\boldsymbol{Y}))\delta_{\{x_0\}}.$$

Furthermore if $P_{\boldsymbol{Y}}(D^n) = 0$, as an extreme example, then the chosen approximation would be clearly useless: indeed, in this case $\tilde{\pi}_t^n = \delta_{\{x_0\}}$ almost surely, and this is clearly not a good approximation, while if $P_{\boldsymbol{Y}}(D^n) = 1$, then the approximation coincides almost surely with $U^n(t, \boldsymbol{Y})$.

In analogy, the functional U is defined $P_{\boldsymbol{Y}}$-almost surely, and to define $\overline{\boldsymbol{\pi}}^{\boldsymbol{n}} = \{\overline{\pi}_t^n; t \geq 0\}$ almost surely, it is natural to assume that $P_{\boldsymbol{Y}^{\boldsymbol{n}}}$ is absolutely continuous with respect to $P_{\boldsymbol{Y}}$.

When using these kinds of approximations one is interested in evaluating

$$dist(\pi_t, \tilde{\pi}_t^n) = dist(U(t, \boldsymbol{Y}), U^n(t, \boldsymbol{Y})), \tag{17}$$

when we observe $\boldsymbol{Y}$ (situation 1), or

$$dist(\pi_t^n, \overline{\pi}_t^n) = dist(U^n(t, \boldsymbol{Y}^{\boldsymbol{n}}), U(t, \boldsymbol{Y}^{\boldsymbol{n}})), \tag{18}$$

when we observe $\boldsymbol{Y}^{\boldsymbol{n}}$ (situation 2). Here the $dist(\nu_1, \nu_2)$ can be, for example, the total variation, the Kantorovitch metric, or the bounded-Lipschitz metric.

Note that, in contrast to the approximations previously considered, neither $\tilde{\pi}_t^n$ nor $\overline{\pi}_t^n$ are conditional laws. Moreover, with this kind of approximation it is not even necessary that the sequence of processes $\{\boldsymbol{Y}^{\boldsymbol{n}}\}$ and $\boldsymbol{Y}$ be defined on the same probability space, and both the almost sure convergence and the convergence in probability can be considered.

For instance, in situation 1, the convergence in probability is implied by the convergence to zero of

$$\begin{aligned} E[dist(\pi_t, \tilde{\pi}_t^n)] &= E[dist(U(t, \boldsymbol{Y}), U^n(t, \boldsymbol{Y}))] \\ &= \int_{D_{\mathbb{R}^d}([0,T])} dist(U(t, \boldsymbol{y}), U^n(t, \boldsymbol{y})) dP_{\boldsymbol{Y}}(\boldsymbol{y}), \end{aligned} \tag{19}$$

while, in situation 2, the convergence in probability is implied by the convergence to zero of

$$\begin{aligned} E[dist(\pi_t^n, \bar{\pi}_t^n)] &= E[dist(U^n(t, \boldsymbol{Y}^{\boldsymbol{n}}), U(t, \boldsymbol{Y}^{\boldsymbol{n}}))] \\ &= \int_{D_{\mathbb{R}^d}([0,T])} dist(U^n(t, \boldsymbol{y}), U(t, \boldsymbol{y})) dP_{\boldsymbol{Y}^{\boldsymbol{n}}}(\boldsymbol{y}). \end{aligned} \tag{20}$$

Finally, note that when the distance between π_t and $\tilde{\pi}_t^n$ is given in terms of one of the integral metrics quoted at the beginning of this section, then

$$E[dist(\pi_t, \tilde{\pi}_t^n)] = E\left[\sup_{\varphi \in \mathcal{K}} |\pi_t(\varphi) - \tilde{\pi}_t^n(\varphi)|\right] \tag{21}$$

and

$$E[dist(\pi_t^n, \overline{\pi}_t^n)] = E\left[\sup_{\varphi \in \mathcal{K}} |\pi_t^n(\varphi) - \overline{\pi}_t^n(\varphi)|\right], \tag{22}$$

where $\mathcal{K}$ is a suitable class of functions: the class $\mathcal{K}_{TV}$ of functions φ with $\|\varphi\| \leq 1$ for the total variation, the class $\mathcal{K}_{BL}$ of functions φ with $\|\varphi\| \vee L_\varphi \leq 1$ for the bounded-Lipschitz metric, and the class $\mathcal{K}_K$ of functions φ with $L_\varphi \leq 1$ for the Kantorovitch metric.

2.2. General upper bounds for the approximations of the filters. In the following, we study the approximation problem for the filter by using a general procedure leading to a partial result, which is summarized in Theorem 2.3. Moreover, in the following we also consider the connections with weak convergence of the filters (cf. Theorem 2.6 and Remark 2.7). However, as will become clear in section 3, since these results are not sufficient for application to the models with delayed observations, we conclude this section with two results (cf. Theorem 2.9 and Proposition 2.11). These results will be applied to the Markov jump models with delayed counting observations in section 4.

Assume that it is possible to construct copies $(\tilde{\boldsymbol{X}}^{\boldsymbol{n}}, \tilde{\boldsymbol{Y}}^{\boldsymbol{n}})$ and $(\tilde{\boldsymbol{X}}, \tilde{\boldsymbol{Y}})$ of the pairs $(\boldsymbol{X}^{\boldsymbol{n}}, \boldsymbol{Y}^{\boldsymbol{n}})$ and $(\boldsymbol{X}, \boldsymbol{Y})$ on the same measurable space $(\Omega, \mathcal{F})$, equipped with different probability measures $\mathbb{P}$ and $\mathbb{P}^n$ and with the property that $\tilde{\boldsymbol{Y}}^{\boldsymbol{n}} = \tilde{\boldsymbol{Y}}$, i.e.,

(a) on $(\Omega, \mathcal{F}, \mathbb{P})$ the model $(\tilde{\boldsymbol{X}}, \tilde{\boldsymbol{Y}})$ has the same law as the model $(\boldsymbol{X}, \boldsymbol{Y})$,

($\mathrm{a_n}$) on $(\Omega, \mathcal{F}, \mathbb{P}^n)$ the model $(\tilde{\boldsymbol{X}}^{\boldsymbol{n}}, \tilde{\boldsymbol{Y}}^{\boldsymbol{n}}) = (\tilde{\boldsymbol{X}}^{\boldsymbol{n}}, \tilde{\boldsymbol{Y}})$ has the same law as the model $(\boldsymbol{X}^{\boldsymbol{n}}, \boldsymbol{Y}^{\boldsymbol{n}})$.

Remark 2.1. In particular, when the systems $(\boldsymbol{X}, \boldsymbol{Y})$ and $(\boldsymbol{X}^{\boldsymbol{n}}, \boldsymbol{Y}^{\boldsymbol{n}})$ are Markovian, condition (a) means that under $\mathbb{P}$ the pair $(\tilde{\boldsymbol{X}}, \tilde{\boldsymbol{Y}})$ has the generator $\boldsymbol{L}$ of $(\boldsymbol{X}, \boldsymbol{Y})$, and the initial condition $\mu = \mu_0^{X,Y}$, while condition ($\mathrm{a_n}$) means that under $\mathbb{P}^n$ the pair $(\tilde{\boldsymbol{X}}^{\boldsymbol{n}}, \tilde{\boldsymbol{Y}})$ has the generator $\boldsymbol{L}^n$ of $(\boldsymbol{X}^{\boldsymbol{n}}, \boldsymbol{Y}^{\boldsymbol{n}})$, and the initial condition $\mu^n = \mu_0^{X^n,Y^n}$. Moreover, if the systems are Markov with generators $\boldsymbol{L}$ and $\boldsymbol{L}^{\boldsymbol{n}}$ and initial conditions $\mu_0^{X,Y} = \delta_{\{x,y\}}$ and $\mu_0^{X^n,Y^n} = \delta_{\{x,y\}}$, then the semigroups can be represented, respectively, as

$$\exp\{\boldsymbol{L}t\}\phi(x,y) = \mathbb{E}\big[\phi(\tilde{X}_t, \tilde{Y}_t)\big] \quad \text{and} \quad \exp\{\boldsymbol{L}^{\boldsymbol{n}}t\}\phi(x,y) = \mathbb{E}^n\big[\phi(\tilde{X}_t^n, \tilde{Y}_t)\big].$$

As will become clear in the application to the jump models in section 4, it is natural to construct the probability spaces $(\Omega, \mathcal{F}, \mathbb{P})$ and $(\Omega, \mathcal{F}, \mathbb{P}^n)$ starting from a given probability space $(\Omega, \mathcal{F}, \mathbb{Q})$ in such a way that

(b1) $\mathbb{P}$ and $\mathbb{P}^n$ are absolutely continuous with respect to $\mathbb{Q}$ on $\tilde{\mathcal{F}}_t = \mathcal{F}_t^{\tilde{X},\tilde{X}^n,\tilde{Y}}$ for all $t \geq 0$.

The above condition implies that $\mathbb{P}$ and $\mathbb{P}^n$ are absolutely continuous with respect to $\mathbb{Q}$ on $\mathcal{F}_t^{\tilde{Y}}$. For technical reasons, it is more convenient to assume the further condition that

(b2) the probability measures $\mathbb{Q}$, $\mathbb{P}$, and $\mathbb{P}^n$ are equivalent on $\mathcal{F}_t^{\tilde{Y}}$ for all $t \geq 0$.

Indeed, if conditions (a), ($\mathrm{a_n}$), and (b2) hold, then

$$U(t, \tilde{\boldsymbol{Y}}; \varphi) = \mathbb{E}[\varphi(\tilde{X}_t)/\mathcal{F}_t^{\tilde{Y}}],\ \mathbb{P}\text{-}a.s. \quad \text{(and therefore also } \mathbb{Q}\text{-a.s. and } \mathbb{P}^n\text{-a.s.)},$$

and analogously,

$$U^n(t, \tilde{\boldsymbol{Y}}; \varphi) = \mathbb{E}^n[\varphi(\tilde{X}_t^n)/\mathcal{F}_t^{\tilde{Y}}],\ \mathbb{P}^n\text{-}a.s. \quad \text{(and therefore also } \mathbb{Q}\text{-a.s. and } \mathbb{P}\text{-a.s.)}.$$

Therefore,

$$E[dist(\pi_t, \tilde{\pi}_t^n)] = E\left[\sup_{\varphi\in\mathcal{K}} |\pi_t(\varphi) - \tilde{\pi}_t^n(\varphi)|\right] \tag{23}$$

$$= E\left[\sup_{\varphi\in\mathcal{K}} |U(t, \boldsymbol{Y}; \varphi) - U^n(t, \boldsymbol{Y}; \varphi)|\right] \tag{24}$$

$$= \mathbb{E}\left[\sup_{\varphi\in\mathcal{K}} |U(t, \tilde{\boldsymbol{Y}}; \varphi) - U^n(t, \tilde{\boldsymbol{Y}}; \varphi)|\right]$$

$$= \mathbb{E}\left[\sup_{\varphi\in\mathcal{K}} |\mathbb{E}[\varphi(\tilde{X}_t)/\mathcal{F}_t^{\tilde{Y}}] - \mathbb{E}^n[\varphi(\tilde{X}_t^n)/\mathcal{F}_t^{\tilde{Y}}]|\right],$$

where we stress that, under $\mathbb{P}$, the law of $U^n(t,\tilde{\boldsymbol{Y}};\varphi)=\mathbb{E}^n[\varphi(\tilde{X}_t^n)/\mathcal{F}_t^{\tilde{Y}}]$ is the same as the law of $\tilde{\pi}_t^n(\varphi)$, and therefore not the law of $\pi_t^n(\varphi)$, the filter of the approximating system, evaluated at φ. Analogously,

$$
\begin{aligned}
(25)\qquad E[dist(\pi_t^n,\overline{\pi}_t^n) &= E\left[\sup_{\varphi\in\mathcal{K}}|\pi_t^n(\varphi)-\overline{\pi}_t^n(\varphi)|\right]\\
&= E\left[\sup_{\varphi\in\mathcal{K}}|U^n(t,\boldsymbol{Y^n};\varphi)-U(t,\boldsymbol{Y^n};\varphi)|\right]\\
&= \mathbb{E}^n\left[\sup_{\varphi\in\mathcal{K}}|U^n(t,\tilde{\boldsymbol{Y}};\varphi)-U(t,\tilde{\boldsymbol{Y}};\varphi)|\right]\\
&= \mathbb{E}^n\left[\sup_{\varphi\in\mathcal{K}}|\mathbb{E}^n[\varphi(\tilde{X}_t^n)/\mathcal{F}_t^{\tilde{Y}}]-\mathbb{E}[\varphi(\tilde{X}_t)/\mathcal{F}_t^{\tilde{Y}}]|\right].
\end{aligned}
$$

Thus our aim is equivalent to proving the convergence to zero of either

$$\mathbb{E}[dist(U^n(t,\tilde{\boldsymbol{Y}}),U(t,\tilde{\boldsymbol{Y}}))]$$

or

$$\mathbb{E}^n[dist(U^n(t,\tilde{\boldsymbol{Y}}),U(t,\tilde{\boldsymbol{Y}}))],$$

depending on which metric and situation we are interested in. In any case it is natural to start by looking for $\mathbb{Q}$-a.s. upper bounds of

$$\sup_{\varphi\in\mathcal{K}}\left|\mathbb{E}\left[\varphi(\tilde{X}_t)/\mathcal{F}_t^{\tilde{Y}}\right]-\mathbb{E}^n\left[\varphi(\tilde{X}_t^n)/\mathcal{F}_t^{\tilde{Y}}\right]\right|,$$

with $\mathcal{K}$ depending on the metric, and then to take the expectation with respect to either $\mathbb{E}$ or $\mathbb{E}^n$, depending on the situation we are interested in.

Furthermore, if condition (b1) holds, it can be shown (e.g., by Lemma 4.1 of [8]) that, for any bounded function φ,

$$
(26)\qquad \left|\mathbb{E}\left[\varphi(\tilde{X}_t)/\mathcal{F}_t^{\tilde{Y}}\right]-\mathbb{E}^n\left[\varphi(\tilde{X}_t^n)/\mathcal{F}_t^{\tilde{Y}}\right]\right|
$$

is bounded above either by

$$
2\|\varphi\|\,\frac{\mathbb{E}_{\mathbb{Q}}\left[|(d\mathbb{P}^n/d\mathbb{Q})|_{\widetilde{\mathcal{F}}_t}-(d\mathbb{P}/d\mathbb{Q})|_{\widetilde{\mathcal{F}}_t}|/\mathcal{F}_t^{\tilde{Y}}\right]}{\mathbb{E}_{\mathbb{Q}}\left[(d\mathbb{P}^n/d\mathbb{Q})|_{\widetilde{\mathcal{F}}_t}/\mathcal{F}_t^{\tilde{Y}}\right]}+\mathbb{E}^n\left[|\varphi(\tilde{X}_t)-\varphi(\tilde{X}_t^n)|/\mathcal{F}_t^{\tilde{Y}}\right],
$$

$\mathbb{Q}$-a.s., and therefore also $\mathbb{P}$-a.s. and $\mathbb{P}^n$-a.s., or by

$$
2\|\varphi\|\,\frac{\mathbb{E}_{\mathbb{Q}}\left[|(d\mathbb{P}/d\mathbb{Q})|_{\widetilde{\mathcal{F}}_t}-(d\mathbb{P}^n/d\mathbb{Q})|_{\widetilde{\mathcal{F}}_t}|/\mathcal{F}_t^{\tilde{Y}}\right]}{\mathbb{E}_{\mathbb{Q}}\left[(d\mathbb{P}/d\mathbb{Q})|_{\widetilde{\mathcal{F}}_t}/\mathcal{F}_t^{\tilde{Y}}\right]}+\mathbb{E}\left[|\varphi(\tilde{X}_t)-\varphi(\tilde{X}_t^n)|/\mathcal{F}_t^{\tilde{Y}}\right],
$$

$\mathbb{Q}$-a.s., and therefore also $\mathbb{P}$-a.s. and $\mathbb{P}^n$-a.s. Again we use the first or the second upper bound, depending on which situation we are interested in.

Taking into account that

$$|\varphi(\tilde{X}_t)-\varphi(\tilde{X}_t^n)|\le 2\|\varphi\|\,\mathbb{I}_{\{\tilde{X}_t\neq\tilde{X}_t^n\}},$$

or that, if φ is also a Lipschitz function,

$$|\varphi(\tilde{X}_t)-\varphi(\tilde{X}_t^n)|\le L_\varphi\left|\tilde{X}_t-\tilde{X}_t^n\right|,$$

the previous observations can be used to get upper bounds for $E[dist(\pi_t, \tilde{\pi}_t^n)]$ and for $E[dist(\pi_t^n, \overline{\pi}_t^n)]$ when using the total variation or the bounded-Lipschitz metric. Indeed, if one is interested in total variation, one has the following upper bounds, depending on the trajectories actually observed: either

$$\sup_{\varphi\in\mathcal{K}_{TV}} \left|\mathbb{E}\left[\varphi(\tilde{X}_t)/\mathcal{F}_t^{\tilde{Y}}\right] - \mathbb{E}^n\left[\varphi(\tilde{X}_t^n)/\mathcal{F}_t^{\tilde{Y}}\right]\right| \le 2\,\mathcal{Z}_t^n + 2\,\mathbb{P}^n\left(\{\tilde{X}_t \neq \tilde{X}_t^n\}/\mathcal{F}_t^{\tilde{Y}}\right)$$

or

$$\sup_{\varphi\in\mathcal{K}_{TV}} \left|\mathbb{E}\left[\varphi(\tilde{X}_t)/\mathcal{F}_t^{\tilde{Y}}\right] - \mathbb{E}^n\left[\varphi(\tilde{X}_t^n)/\mathcal{F}_t^{\tilde{Y}}\right]\right| \le 2\,\mathcal{Z}_t + 2\,\mathbb{P}\left(\{\tilde{X}_t \neq \tilde{X}_t^n\}/\mathcal{F}_t^{\tilde{Y}}\right),$$

where, as in the rest of this paper, the following notation is used:

$$\mathcal{Z}_t^n = \frac{\mathbb{E}_{\mathbb{Q}}\left[\left|(d\mathbb{P}^n/d\mathbb{Q})|_{\tilde{\mathcal{F}}_t} - (d\mathbb{P}/d\mathbb{Q})|_{\tilde{\mathcal{F}}_t}\right|/\mathcal{F}_t^{\tilde{Y}}\right]}{\mathbb{E}_{\mathbb{Q}}\left[(d\mathbb{P}^n/d\mathbb{Q})|_{\tilde{\mathcal{F}}_t}/\mathcal{F}_t^{\tilde{Y}}\right]} \tag{27}$$

and

$$\mathcal{Z}_t = \frac{\mathbb{E}_{\mathbb{Q}}\left[\left|(d\mathbb{P}^n/d\mathbb{Q})|_{\tilde{\mathcal{F}}_t} - (d\mathbb{P}/d\mathbb{Q})|_{\tilde{\mathcal{F}}_t}\right|/\mathcal{F}_t^{\tilde{Y}}\right]}{\mathbb{E}_{\mathbb{Q}}\left[(d\mathbb{P}/d\mathbb{Q})|_{\tilde{\mathcal{F}}_t}/\mathcal{F}_t^{\tilde{Y}}\right]}. \tag{28}$$

If one is interested in the bounded-Lipschitz metric, one has either

$$\sup_{\varphi\in\mathcal{K}_{BL}} \left|\mathbb{E}\left[\varphi(\tilde{X}_t)/\mathcal{F}_t^{\tilde{Y}}\right] - \mathbb{E}^n\left[\varphi(\tilde{X}_t^n)/\mathcal{F}_t^{\tilde{Y}}\right]\right| \le 2\,\mathcal{Z}_t^n + \mathbb{E}^n\left[\left|\tilde{X}_t - \tilde{X}_t^n\right|/\mathcal{F}_t^{\tilde{Y}}\right]$$

or

$$\sup_{\varphi\in\mathcal{K}_{BL}} \left|\mathbb{E}\left[\varphi(\tilde{X}_t)/\mathcal{F}_t^{\tilde{Y}}\right] - \mathbb{E}^n\left[\varphi(\tilde{X}_t^n)/\mathcal{F}_t^{\tilde{Y}}\right]\right| \le 2\,\mathcal{Z}_t + \mathbb{E}\left[\left|\tilde{X}_t - \tilde{X}_t^n\right|/\mathcal{F}_t^{\tilde{Y}}\right].$$

Remark 2.2. Considering that

$$\begin{aligned}|\varphi(\tilde{X}_t) - \varphi(\tilde{X}_t^n)| &\le \max(2\|\varphi\|, L_\varphi)\left(\left|\tilde{X}_t - \tilde{X}_t^n\right| \wedge 1\right)\\ &\le 2\max(\|\varphi\|, L_\varphi)\left(\left|\tilde{X}_t - \tilde{X}_t^n\right| \wedge 1\right),\end{aligned}$$

one can also have the bounds with either

$$\sup_{\varphi\in\mathcal{K}_{BL}} \left|\mathbb{E}\left[\varphi(\tilde{X}_t)/\mathcal{F}_t^{\tilde{Y}}\right] - \mathbb{E}^n\left[\varphi(\tilde{X}_t^n)/\mathcal{F}_t^{\tilde{Y}}\right]\right| \le 2\,\mathcal{Z}_t^n + 2\,\mathbb{E}^n\left[\left|\tilde{X}_t - \tilde{X}_t^n\right| \wedge 1/\mathcal{F}_t^{\tilde{Y}}\right]$$

or

$$\sup_{\varphi\in\mathcal{K}_{BL}} \left|\mathbb{E}\left[\varphi(\tilde{X}_t)/\mathcal{F}_t^{\tilde{Y}}\right] - \mathbb{E}^n\left[\varphi(\tilde{X}_t^n)/\mathcal{F}_t^{\tilde{Y}}\right]\right| \le 2\,\mathcal{Z}_t + 2\,\mathbb{E}\left[\left|\tilde{X}_t - \tilde{X}_t^n\right| \wedge 1/\mathcal{F}_t^{\tilde{Y}}\right].$$

Moreover, an easy computation gives

$$\mathbb{E}^n\left[\mathcal{Z}_t^n\right] = \mathbb{E}\left[\mathcal{Z}_t\right] = \mathbb{E}_{\mathbb{Q}}\left[\left|(d\mathbb{P}^n/d\mathbb{Q})|_{\tilde{\mathcal{F}}_t} - (d\mathbb{P}/d\mathbb{Q})|_{\tilde{\mathcal{F}}_t}\right|\right].$$

Indeed,

$$\begin{aligned}\mathbb{E}^n\left[\mathcal{Z}_t^n\right] &= \mathbb{E}_{\mathbb{Q}}\left[(d\mathbb{P}^n/d\mathbb{Q})|_{\mathcal{F}_t^{\tilde{Y}}} \frac{\mathbb{E}_{\mathbb{Q}}\left[\left|(d\mathbb{P}^n/d\mathbb{Q})|_{\tilde{\mathcal{F}}_t} - (d\mathbb{P}/d\mathbb{Q})|_{\tilde{\mathcal{F}}_t}\right|/\mathcal{F}_t^{\tilde{Y}}\right]}{\mathbb{E}_{\mathbb{Q}}\left[(d\mathbb{P}^n/d\mathbb{Q})|_{\tilde{\mathcal{F}}_t}/\mathcal{F}_t^{\tilde{Y}}\right]}\right]\\ &= \mathbb{E}_{\mathbb{Q}}\left[\mathbb{I}_{\{(d\mathbb{P}^n/d\mathbb{Q})|_{\mathcal{F}_t^{\tilde{Y}}}\neq 0\}}\mathbb{E}_{\mathbb{Q}}\left[\left|(d\mathbb{P}^n/d\mathbb{Q})|_{\tilde{\mathcal{F}}_t} - (d\mathbb{P}/d\mathbb{Q})|_{\tilde{\mathcal{F}}_t}\right|/\mathcal{F}_t^{\tilde{Y}}\right]\right]\\ &= \mathbb{E}_{\mathbb{Q}}\left[\left|(d\mathbb{P}^n/d\mathbb{Q})|_{\tilde{\mathcal{F}}_t} - (d\mathbb{P}/d\mathbb{Q})|_{\tilde{\mathcal{F}}_t}\right|\right], \qquad (29)\end{aligned}$$

where in the last equality we have used condition (b2), and analogously we get

$$\mathbb{E}\big[\mathcal{Z}_t\big] = \mathbb{E}_{\mathbb{Q}}\big[\big|(d\mathbb{P}^n/d\mathbb{Q})|_{\tilde{\mathcal{F}}_t} - (d\mathbb{P}/d\mathbb{Q})|_{\tilde{\mathcal{F}}_t}\big|\big].$$

As a consequence of the above analysis, by taking (23) and (25) into account, we get the following upper bounds.

THEOREM 2.3. *Under conditions* (a), (a_n), (b1), *and* (b2),

$$E\big[\|\pi_t - \tilde{\pi}_t^n\|_{TV}\big] \le 2\mathbb{E}_{\mathbb{Q}}\big[\big|(d\mathbb{P}^n/d\mathbb{Q})|_{\tilde{\mathcal{F}}_t} - (d\mathbb{P}/d\mathbb{Q})|_{\tilde{\mathcal{F}}_t}\big|\big] + 2\mathbb{P}\big(\{\tilde{X}_t \neq \tilde{X}_t^n\}\big) \tag{30}$$

or

$$E\big[\|\pi_t^n - \overline{\pi}_t^n\|_{TV}\big] \le 2\mathbb{E}_{\mathbb{Q}}\big[\big|(d\mathbb{P}^n/d\mathbb{Q})|_{\tilde{\mathcal{F}}_t} - (d\mathbb{P}/d\mathbb{Q})|_{\tilde{\mathcal{F}}_t}\big|\big] + 2\mathbb{P}^n\big(\{\tilde{X}_t \neq \tilde{X}_t^n\}\big), \tag{31}$$

and

$$E\big[d_{BL}(\pi_t, \tilde{\pi}_t^n)\big] \le 2\mathbb{E}_{\mathbb{Q}}\big[\big|(d\mathbb{P}^n/d\mathbb{Q})|_{\tilde{\mathcal{F}}_t} - (d\mathbb{P}/d\mathbb{Q})|_{\tilde{\mathcal{F}}_t}\big|\big] + \mathbb{E}\big[\big|\tilde{X}_t - \tilde{X}_t^n\big|\big] \tag{32}$$

or

$$E\big[d_{BL}(\pi_t^n, \overline{\pi}_t^n)\big] \le 2\mathbb{E}_{\mathbb{Q}}\big[\big|(d\mathbb{P}^n/d\mathbb{Q})|_{\tilde{\mathcal{F}}_t} - (d\mathbb{P}/d\mathbb{Q})|_{\tilde{\mathcal{F}}_t}\big|\big] + \mathbb{E}^n\big[\big|\tilde{X}_t - \tilde{X}_t^n\big|\big]. \tag{33}$$

Remark 2.4. It is clear from the proof that we can rewrite the above inequalities (30)–(33) by substituting $\mathbb{E}^n[\mathcal{Z}_t^n]$ or $\mathbb{E}[\mathcal{Z}_t]$ in the first addend. Moreover, when in addition $\mathbb{P}$ is absolutely continuous with respect to $\mathbb{P}^n$ on $\tilde{\mathcal{F}}_t$, we can substitute

$$\mathbb{E}\left[\left|\frac{d\mathbb{P}^n}{d\mathbb{P}}\big|_{\tilde{\mathcal{F}}_t} - 1\right|\right]$$

in the first addend, since

$$\mathbb{E}^n\left[\left|1 - \frac{d\mathbb{P}}{d\mathbb{P}^n}\big|_{\tilde{\mathcal{F}}_t}\right|\right] = \mathbb{E}_{\mathbb{Q}}\left[\big|(d\mathbb{P}^n/d\mathbb{Q})|_{\tilde{\mathcal{F}}_t} - (d\mathbb{P}/d\mathbb{Q})|_{\tilde{\mathcal{F}}_t}\big|\right].$$

An analogous substitution can be done when, in addition, $\mathbb{P}$ is absolutely continuous with respect to $\mathbb{P}^n$ on $\tilde{\mathcal{F}}_t$, since

$$\mathbb{E}_{\mathbb{Q}}\big[\big|(d\mathbb{P}^n/d\mathbb{Q})|_{\tilde{\mathcal{F}}_t} - (d\mathbb{P}/d\mathbb{Q})|_{\tilde{\mathcal{F}}_t}\big|\big] = \mathbb{E}\left[\left|\frac{d\mathbb{P}^n}{d\mathbb{P}}\big|_{\tilde{\mathcal{F}}_t} - 1\right|\right].$$

Remark 2.5. By taking into account the estimates obtained in Remark 2.2 one can substitute in (32) and (33) the expectations of $\big|\tilde{X}_t - \tilde{X}_t^n\big|$ with the corresponding expectations of $2\big|\tilde{X}_t - \tilde{X}_t^n\big| \wedge 1$.

In the following theorem and remark we highlight the connections of the above considerations with the weak convergence of the sequence of filters π_t^n to π_t (see [1] and [2] for similar considerations).

THEOREM 2.6. *Assume that*

1. (a), (a_n), *and* (b2) *are satisfied;*
2. *the sequence* $U^n(t, \tilde{\boldsymbol{Y}})$ *converges in* $\mathbb{Q}$*-probability to* $U(t, \tilde{\boldsymbol{Y}})$ *as random variables with values in* $\mathcal{P}$, *the space of probability measures endowed with the metric dist, that is, for all* $\varepsilon > 0$,

$$\lim_{n\to\infty} \mathbb{Q}\big(A_\varepsilon^n\big) = 0, \quad \textit{where } A_\varepsilon^n := \big\{dist\big(U^n(t, \tilde{\boldsymbol{Y}}), U(t, \tilde{\boldsymbol{Y}})\big) \ge \varepsilon\big\};$$

3. $\lim_{n\to\infty} \mathbb{E}_{\mathbb{Q}}\big[\big|(d\mathbb{P}/d\mathbb{Q})|_{\mathcal{F}_t^{\tilde{Y}}} - (d\mathbb{P}^n/d\mathbb{Q})|_{\mathcal{F}_t^{\tilde{Y}}}\big|\big] = 0.$

Then, the filters converge in distribution for each t as random variables with values in $\mathcal{P}$, i.e.,

$$\pi_t^n \Rightarrow \pi_t.$$

Remark 2.7. (I) It is important to stress the connection of the above results to the convergence in probability of (17) and (18). Indeed, conditions 2 and (b2) imply that $\mathbb{P}\big(A_\varepsilon^n\big)$ converge to zero, and thus by condition (a),

$$P\big(dist\big(\tilde{\pi}_t^n;\pi_t\big)\geq\varepsilon\big) = P\big(dist\big(U^n(t,\boldsymbol{Y}),U(t,\boldsymbol{Y})\big)\geq\varepsilon\big) = \mathbb{P}\big(A_\varepsilon^n\big)\to 0.$$

Similarly, by condition ($\mathrm{a_n}$),

$$P\big(dist\big(\pi_t^n;\overline{\pi}_t^n\big)\geq\varepsilon\big) = P\big(dist\big(U^n(t,\boldsymbol{Y^n}),U(t,\boldsymbol{Y^n})\big)\geq\varepsilon\big) = \mathbb{P}^n\big(A_\varepsilon^n\big),$$

and, by conditions 2, 3, and (b2), $\mathbb{P}^n(A_\varepsilon^n)$ converge to zero: the set

$$A_\varepsilon^n = \big\{dist\big(U^n(t,\tilde{\boldsymbol{Y}}),U(t,\tilde{\boldsymbol{Y}})\big)\geq\varepsilon\big\}$$

is $\mathcal{F}_t^{\tilde{Y}}$-measurable, and by condition (b2),

$$\begin{aligned}\mathbb{P}^n(A_\varepsilon^n) &= \mathbb{E}_{\mathbb{Q}}\big[\ (d\mathbb{P}^n/d\mathbb{Q})|_{\mathcal{F}_t^{\tilde{Y}}}\,\mathbb{I}_{A_\varepsilon^n}\big]\\ &= \mathbb{E}_{\mathbb{Q}}\big[(d\mathbb{P}/d\mathbb{Q})|_{\mathcal{F}_t^{\tilde{Y}}}\mathbb{I}_{A_\varepsilon^n}\big] + \mathbb{E}_{\mathbb{Q}}\big[\big[(d\mathbb{P}^n/d\mathbb{Q})|_{\mathcal{F}_t^{\tilde{Y}}} - (d\mathbb{P}/d\mathbb{Q})|_{\mathcal{F}_t^{\tilde{Y}}}\big]\mathbb{I}_{A_\varepsilon^n}\big]\\ &\leq \mathbb{E}_{\mathbb{Q}}\big[(d\mathbb{P}/d\mathbb{Q})|_{\mathcal{F}_t^{\tilde{Y}}}\mathbb{I}_{A_\varepsilon^n}\big] + \mathbb{E}_{\mathbb{Q}}\big[\big|(d\mathbb{P}^n/d\mathbb{Q})|_{\mathcal{F}_t^{\tilde{Y}}} - (d\mathbb{P}/d\mathbb{Q})|_{\mathcal{F}_t^{\tilde{Y}}}\big|\big].\end{aligned}$$

The first addend in the last line, i.e., $\mathbb{E}_{\mathbb{Q}}[(d\mathbb{P}/d\mathbb{Q})|_{\mathcal{F}_t^{\tilde{Y}}}\mathbb{I}_{A_\varepsilon^n}] = \mathbb{P}(A_\varepsilon^n)$, converges to zero by conditions 2 and (b2), while condition 3 asserts that the second addend converges to zero.

(II) Note that if condition (b1) also holds, then condition 3 is implied by the stronger condition

$$3'\ \lim_{n\to\infty} \mathbb{E}_{\mathbb{Q}}\big[|\ (d\mathbb{P}/d\mathbb{Q})|_{\tilde{\mathcal{F}}_t} - \ (d\mathbb{P}^n/d\mathbb{Q})|_{\tilde{\mathcal{F}}_t}\ |\big] = 0,$$

that is, the convergence to zero of the first addend in all the upper bounds (30)–(33).

Therefore, if we can prove that the second addend in upper bound (30) or (32), depending on the chosen metric, also converges to zero, we get the convergence to zero of $\mathbb{P}(A_\varepsilon^n)$. As a consequence condition 2 is automatically satisfied and, provided condition 1 is enforced, we get the weak convergence of the filters. The convergence to zero in condition $3'$ can also be used to get the upper bounds for the second addends, as in section 4 for the counting observation case.

An analogous result holds for the convergence to zero of $\mathbb{P}^n(A_\varepsilon^n)$, when assuming that the second addend in the upper bound (31) or (33), depending on the chosen metric, also converges to zero, since one can prove that $\mathbb{P}(A_\varepsilon^n)$ converge to zero.

Proof of Theorem 2.6. For any bounded function $G:\ \mathcal{P}\to\mathbb{R}$, continuous with respect to *dist*,

$$\begin{aligned}E[G(\pi_t^n)] \ &= \ \mathbb{E}^n\big[G\big(U^n(t,\tilde{Y})\big)\big] = \mathbb{E}_{\mathbb{Q}}\big[(d\mathbb{P}^n/d\mathbb{Q})|_{\mathcal{F}_t^{\tilde{Y}}}G\big(U^n(t,\tilde{Y})\big)\big]\\ &\to \mathbb{E}_{\mathbb{Q}}\big[(d\mathbb{P}/d\mathbb{Q})|_{\mathcal{F}_t^{\tilde{Y}}}G\big(U(t,\tilde{Y})\big)\big] = \mathbb{E}\big[G\big(U(t,\tilde{Y})\big)\big] = E[G(\pi_t)].\end{aligned}$$

All the equalities in the above relations are obvious; we need only prove the convergence result.

We can restrict to G uniformly continuous, with modulus of continuity $\boldsymbol{w}_G(\varepsilon)$:

$$\begin{aligned}
&\left|\mathbb{E}_{\mathbb{Q}}\left[(d\mathbb{P}^n/d\mathbb{Q})|_{\mathcal{F}_t^{\tilde{Y}}} G\big(U^n(t,\tilde{Y})\big)\right] - \mathbb{E}_{\mathbb{Q}}\left[(d\mathbb{P}/d\mathbb{Q})|_{\mathcal{F}_t^{\tilde{Y}}} G\big(U(t,\tilde{Y})\big)\right]\right| \\
&\quad \le \mathbb{E}_{\mathbb{Q}}\left[|(d\mathbb{P}^n/d\mathbb{Q})|_{\mathcal{F}_t^{\tilde{Y}}} - (d\mathbb{P}/d\mathbb{Q})|_{\mathcal{F}_t^{\tilde{Y}}}|\,|G\big(U^n(t,\tilde{Y})\big)|\right] \\
&\qquad + \mathbb{E}_{\mathbb{Q}}\left[(d\mathbb{P}/d\mathbb{Q})|_{\mathcal{F}_t^{\tilde{Y}}} |G\big(U^n(t,\tilde{Y})\big) - G\big(U(t,\tilde{Y})\big)|\right] \\
&\quad \le \|G\|\,\mathbb{E}_{\mathbb{Q}}\left[|(d\mathbb{P}^n/d\mathbb{Q})|_{\mathcal{F}_t^{\tilde{Y}}} - (d\mathbb{P}/d\mathbb{Q})|_{\mathcal{F}_t^{\tilde{Y}}}|\right] \\
&\quad + \mathbb{E}_{\mathbb{Q}}\Big[(d\mathbb{P}/d\mathbb{Q})|_{\mathcal{F}_t^{\tilde{Y}}} \Big(2\|G\|\,\mathbf{1}_{\{dist(U^n(t,\tilde{Y}),U(t,\tilde{Y}))\ge\varepsilon\}} + \boldsymbol{w}_G(\varepsilon)\Big)\Big].
\end{aligned}$$

The first addend converges to zero by condition 3. The second addend is equal to

$$2\|G\|\mathbb{P}(A_\varepsilon^n) + \boldsymbol{w}_G(\varepsilon)$$

and converges to zero by conditions 2 and (b2) and the arbitrariness of ε. □

This result has been obtained by using the same kind of techniques as in [1]. In the latter paper the context is more general in the sense that the state space $\mathcal{S}$ is a complete separable metric space, and the filters converge weakly as measure-valued processes in $D_{\mathcal{P}(\mathcal{S})}([0,T])$. However, in [1] the space $\mathcal{P}(\mathcal{S})$ is always endowed with the Prokhorov topology, while in this paper we consider different kinds of metrics.

Remark 2.8. If one is interested in weak convergence of the filters $\boldsymbol{\pi^n}$ to $\boldsymbol{\pi}$ as random processes in $\mathcal{D}_{\mathcal{P}}[0,T]$, then condition 2 can be replaced by

$2'$ $\lim_{n\to\infty} \mathbb{Q}(\sup_{t\in[0,T]} dist(U^n(t,\tilde{\boldsymbol{Y}}),U(t,\tilde{\boldsymbol{Y}})) \ge \varepsilon) = 0$,

and condition 3 must be satisfied for $t = T$:

$$\lim_{n\to\infty} \mathbb{E}_{\mathbb{Q}}\left[|\ (d\mathbb{P}/d\mathbb{Q})|_{\mathcal{F}_T^{\tilde{Y}}} - (d\mathbb{P}^n/d\mathbb{Q})|_{\mathcal{F}_T^{\tilde{Y}}}\ |\right] = 0.$$

Indeed, for any bounded function $G : \mathcal{D}_{\mathcal{P}}[0,T] \to \mathbb{R}$, continuous with respect to ***Dist***, the Skorokhod metric, we have

$$\begin{aligned}
E[G(\boldsymbol{\pi^n})] &= \mathbb{E}^n\left[G\big(U^n(\cdot,\tilde{Y})\big)\right] = \mathbb{E}_{\mathbb{Q}}\left[\ (d\mathbb{P}^n/d\mathbb{Q})|_{\mathcal{F}_T^{\tilde{Y}}}\, G\big(U^n(\cdot,\tilde{Y})\big)\right] \\
&\to \mathbb{E}_{\mathbb{Q}}\left[\ (d\mathbb{P}/d\mathbb{Q})|_{\mathcal{F}_T^{\tilde{Y}}}\, G\big(U(\cdot,\tilde{Y})\big)\right] = \mathbb{E}\left[G\big(U(\cdot,\tilde{Y})\big)\right] = E[G(\boldsymbol{\pi})].
\end{aligned}$$

All the equalities in the above relations are obvious; we need only prove the convergence result.

We can restrict to G uniformly continuous, with modulus of continuity $\boldsymbol{w}_G^{\mathcal{S}}(\varepsilon)$ with respect to the Skorokhod metric:

$$\begin{aligned}
&\left|\mathbb{E}_{\mathbb{Q}}\left[(d\mathbb{P}^n/d\mathbb{Q})|_{\mathcal{F}_T^{\tilde{Y}}} G\big(U^n(\cdot,\tilde{Y})\big)\right] - \mathbb{E}_{\mathbb{Q}}\left[(d\mathbb{P}/d\mathbb{Q})|_{\mathcal{F}_T^{\tilde{Y}}} G\big(U(\cdot,\tilde{Y})\big)\right]\right| \\
&\quad \le \mathbb{E}_{\mathbb{Q}}\left[|(d\mathbb{P}^n/d\mathbb{Q})|_{\mathcal{F}_T^{\tilde{Y}}} - (d\mathbb{P}/d\mathbb{Q})|_{\mathcal{F}_T^{\tilde{Y}}}|\,|G\big(U^n(\cdot,\tilde{Y})\big)|\right] \\
&\qquad + \mathbb{E}_{\mathbb{Q}}\left[(d\mathbb{P}/d\mathbb{Q})|_{\mathcal{F}_T^{\tilde{Y}}} |G\big(U^n(\cdot,\tilde{Y})\big) - G\big(U(\cdot,\tilde{Y})\big)|\right] \\
&\quad \le \|G\|\,\mathbb{E}_{\mathbb{Q}}\left[|(d\mathbb{P}^n/d\mathbb{Q})|_{\mathcal{F}_T^{\tilde{Y}}} - (d\mathbb{P}/d\mathbb{Q})|_{\mathcal{F}_T^{\tilde{Y}}}|\right] \\
&\qquad + \mathbb{E}_{\mathbb{Q}}\Big[(d\mathbb{P}/d\mathbb{Q})|_{\mathcal{F}_T^{\tilde{Y}}} \Big(2\|G\|\,\mathbf{1}_{\{\boldsymbol{Dist}(U^n(\cdot,\tilde{Y}),U(\cdot,\tilde{Y}))\ge\varepsilon\}} + \boldsymbol{w}_G^{\mathcal{S}}(\varepsilon)\Big)\Big].
\end{aligned}$$

The first addend converges to zero by condition 3 for $t = T$. The second addend is

equal to

$$2\|G\|\mathbb{P}(\boldsymbol{Dist}\big(U^n(\cdot,\tilde{Y}),U(\cdot,\tilde{Y})\big)\geq\varepsilon)+\boldsymbol{w}_G^{\mathcal{S}}(\varepsilon)$$
$$\leq 2\|G\|\mathbb{P}\bigg(\sup_{[0,T]} dist\big(U^n(t,\tilde{Y}),U(t,\tilde{Y})\big)\geq\varepsilon\bigg)+\boldsymbol{w}_G^{\mathcal{S}}(\varepsilon)$$

and converges to zero by conditions $2'$ and (b2) and the arbitrariness of ε.

2.3. Further upper bounds. In the next section we will use a slight modification of the above procedure, taking into account the delay structure of the model we are dealing with in order to prove our approximation results. Indeed, for technical reasons we will need the obvious observation

$$\sup_{\varphi\in\mathcal{K}}\big|\mathbb{E}\big[\varphi(\tilde{X}_t)/\mathcal{F}_t^{\tilde{Y}}\big]-\mathbb{E}^n\big[\varphi(\tilde{X}_t^n)/\mathcal{F}_t^{\tilde{Y}}\big]\big|\leq\sup_{\phi\in\mathcal{K}'}\big|\mathbb{E}\big[\phi(\tilde{X}_t,\tilde{Y}_t)/\mathcal{F}_t^{\tilde{Y}}\big]-\mathbb{E}^n\big[\phi(\tilde{X}_t^n,\tilde{Y}_t)/\mathcal{F}_t^{\tilde{Y}}\big]\big|$$

whenever $\mathcal{K}'$ contains all functions $\phi(x,y)$ such that $\phi(x,y)=\varphi(x)$, with $\varphi\in\mathcal{K}$. The r.h.s. of the last inequality is equal to

$$\sup_{\phi\in\mathcal{K}'}|U(t,\tilde{\boldsymbol{Y}};\phi(\cdot,\tilde{Y}_t))-U^n(t,\tilde{\boldsymbol{Y}};\phi(\cdot,\tilde{Y}_t))|,$$

which coincides with

$$\sup_{\phi\in\mathcal{K}'}|\pi_t(\phi(\cdot,\tilde{Y}_t))-\tilde{\pi}_t^n(\phi(\cdot,\tilde{Y}_t))|,\qquad\mathbb{P}\text{-a.s.},$$

and with

$$\sup_{\phi\in\mathcal{K}'}|\bar{\pi}_t^n(\phi(\cdot,\tilde{Y}_t))-\pi_t^n(\phi(\cdot,\tilde{Y}_t))|,\qquad\mathbb{P}^n\text{-a.s.},$$

and hence, our aim will be accomplished once we prove the convergence to zero of the expectation of the latter quantity for a suitable choice of $\mathcal{K}'$, with the expectation taken with respect to $\mathbb{P}$ or $\mathbb{P}^n$, depending on which situation we are interested in. With this aim, denote by $\mathcal{K}_{TV}(\alpha)$ the class of measurable functions $\varphi(x)$ bounded above by α, and denote by $\mathcal{K}_{BL}(\alpha,\Lambda)$ the class of measurable functions $\varphi(x)$ bounded above by α, such that for all x, x',

$$|\varphi(x)-\varphi(x')|\leq\Lambda|x-x'|,$$

and thus $\mathcal{K}_{TV}=\mathcal{K}_{TV}(1)$ and $\mathcal{K}_{BL}=\mathcal{K}_{BL}(1,1)$. $\mathcal{K}'_{TV}(\alpha)$ is the class of measurable functions $\phi(x,y)$ bounded above by α, and $\mathcal{K}'_{BL}(\alpha,\Lambda)$ is the class of measurable functions $\phi(x,y)$ bounded above by α, such that for all x, x', and y,

$$|\phi(x,y)-\phi(x',y)|\leq\Lambda|x-x'|.$$

Note that $\mathcal{K}'_{TV}(\alpha)$ contains all functions $\phi(x,y)=\varphi(x)$, with $\varphi\in\mathcal{K}_{TV}(\alpha)$, and that, analogously, $\mathcal{K}'_{BL}(\alpha,\Lambda)$ contains all functions $\phi(x,y)=\varphi(x)$, with $\varphi\in\mathcal{K}_{BL}(\alpha,\Lambda)$.

THEOREM 2.9. *Assume that conditions* (a), (a_n), (b1), *and* (b2) *are satisfied; then the following inequalities hold:*

$$\mathbb{E}^n\bigg[\sup_{\phi\in\mathcal{K}'_{TV}(\alpha)}|U(t,\tilde{\boldsymbol{Y}};\phi(\cdot,\tilde{Y}_t))-U^n(t,\tilde{\boldsymbol{Y}};\phi(\cdot,\tilde{Y}_t))|\bigg]\leq 2\alpha\,\mathbb{E}^n\big[\mathcal{Z}_t^n\big]+2\alpha\,\mathbb{P}^n\big(\{\tilde{X}_t\neq\tilde{X}_t^n\}\big),$$

$$\mathbb{E}\Big[\sup_{\phi\in\mathcal{K}'_{TV}(\alpha)}|U(t,\tilde{\boldsymbol{Y}};\phi(\cdot,\tilde{Y}_t))-U^n(t,\tilde{\boldsymbol{Y}};\phi(\cdot,\tilde{Y}_t))|\Big]\leq 2\alpha\,\mathbb{E}\big[\mathcal{Z}_t\big]+2\alpha\,\mathbb{P}\big(\{\tilde{X}_t\neq\tilde{X}_t^n\}\big),$$

$$\mathbb{E}^n\Big[\sup_{\phi\in\mathcal{K}'_{BL}(\alpha,\Lambda)}|U(t,\tilde{\boldsymbol{Y}};\phi(\cdot,\tilde{Y}_t))-U^n(t,\tilde{\boldsymbol{Y}};\phi(\cdot,\tilde{Y}_t))|\Big]\leq 2\alpha\,\mathbb{E}^n\big[\mathcal{Z}_t^n\big]+\Lambda\,\mathbb{E}^n\big[\big|\tilde{X}_t-\tilde{X}_t^n\big|\big],$$

$$\mathbb{E}\Big[\sup_{\phi\in\mathcal{K}'_{BL}(\alpha,\Lambda)}|U(t,\tilde{\boldsymbol{Y}};\phi(\cdot,\tilde{Y}_t))-U^n(t,\tilde{\boldsymbol{Y}};\phi(\cdot,\tilde{Y}_t))|\Big]\leq 2\alpha\,\mathbb{E}\big[\mathcal{Z}_t\big]+\Lambda\,\mathbb{E}\big[\big|\tilde{X}_t-\tilde{X}_t^n\big|\big],$$

where $\mathcal{Z}_t^n$ and $\mathcal{Z}_t$ are defined as in (27) *and* (28)*, respectively.*

Proof. It can be shown (e.g., by Lemma 4.1 of [8]) that, for any bounded function ϕ, the following inequalities hold $\mathbb{Q}$-a.s., and therefore also $\mathbb{P}$-a.s. and $\mathbb{P}^n$-a.s.:

$$\big|\mathbb{E}\big[\phi(\tilde{X}_t,\tilde{Y}_t)/\mathcal{F}_t^{\tilde{Y}}\big]-\mathbb{E}^n\big[\phi(\tilde{X}_t^n,\tilde{Y}_t)/\mathcal{F}_t^{\tilde{Y}}\big]\big|\leq 2\|\phi\|\,\mathcal{Z}_t^n+\mathbb{E}^n\big[|\phi(\tilde{X}_t,\tilde{Y}_t)-\phi(\tilde{X}_t^n,\tilde{Y}_t)|/\mathcal{F}_t^{\tilde{Y}}\big]$$

and

$$\big|\mathbb{E}\big[\phi(\tilde{X}_t,\tilde{Y}_t)/\mathcal{F}_t^{\tilde{Y}}\big]-\mathbb{E}^n\big[\phi(\tilde{X}_t^n,\tilde{Y}_t)/\mathcal{F}_t^{\tilde{Y}}\big]\big|\leq 2\|\phi\|\,\mathcal{Z}_t+\mathbb{E}\big[|\phi(\tilde{X}_t,\tilde{Y}_t)-\phi(\tilde{X}_t^n,\tilde{Y}_t)|/\mathcal{F}_t^{\tilde{Y}}\big].$$

Taking into account that, if $\phi\in\mathcal{K}'_{TV}(\alpha)$, we have

$$|\phi(\tilde{X}_t,\tilde{Y}_t)-\phi(\tilde{X}_t^n,\tilde{Y}_t)|\leq 2\alpha\,\mathbb{I}_{\{\tilde{X}_t\neq\tilde{X}_t^n\}},$$

or that, if $\phi\in\mathcal{K}'_{BL}(\alpha;\Lambda)$, we have

$$|\phi(\tilde{X}_t,\tilde{Y}_t)-\phi(\tilde{X}_t^n,\tilde{Y}_t)|\leq\Lambda\,\big|\tilde{X}_t-\tilde{X}_t^n\big|,$$

the previous observations can be used to get upper bounds for $E\big[dist(\pi_t,\tilde{\pi}_t^n)\big]$ and $E\big[dist(\pi_t^n,\overline{\pi}_t^n)\big]$ when using the total variation or the bounded-Lipschitz metric. Indeed, if we are interested in total variation, one has either

$$\sup_{\phi\in\mathcal{K}'_{TV}(\alpha)}|U(t,\tilde{\boldsymbol{Y}};\phi(\cdot,\tilde{Y}_t))-U^n(t,\tilde{\boldsymbol{Y}};\phi(\cdot,\tilde{Y}_t))|\leq 2\alpha\,\mathcal{Z}_t^n+2\alpha\,\mathbb{P}^n\big(\{\tilde{X}_t\neq\tilde{X}_t^n\}/\mathcal{F}_t^{\tilde{Y}}\big)$$

or

$$\sup_{\phi\in\mathcal{K}'_{TV}(\alpha)}|U(t,\tilde{\boldsymbol{Y}};\phi(\cdot,\tilde{Y}_t))-U^n(t,\tilde{\boldsymbol{Y}};\phi(\cdot,\tilde{Y}_t))|\leq 2\alpha\,\mathcal{Z}_t+2\alpha\,\mathbb{P}\big(\{\tilde{X}_t\neq\tilde{X}_t^n\}/\mathcal{F}_t^{\tilde{Y}}\big),$$

and, if we are interested in the bounded-Lipschitz metric, one has either

$$\sup_{\phi\in\mathcal{K}'_{BL}(\alpha,\Lambda)}|U(t,\tilde{\boldsymbol{Y}};\phi(\cdot,\tilde{Y}_t))-U^n(t,\tilde{\boldsymbol{Y}};\phi(\cdot,\tilde{Y}_t))|\leq 2\alpha\,\mathcal{Z}_t^n+\Lambda\,\mathbb{E}^n\big[\big|\tilde{X}_t-\tilde{X}_t^n\big|/\mathcal{F}_t^{\tilde{Y}}\big]$$

or

$$\sup_{\phi\in\mathcal{K}'_{BL}(\alpha,\Lambda)}|U(t,\tilde{\boldsymbol{Y}};\phi(\cdot,\tilde{Y}_t))-U^n(t,\tilde{\boldsymbol{Y}};\phi(\cdot,\tilde{Y}_t))|\leq 2\alpha\,\mathcal{Z}_t+\Lambda\,\mathbb{E}\big[\big|\tilde{X}_t-\tilde{X}_t^n\big|/\mathcal{F}_t^{\tilde{Y}}\big].$$

Taking the expectation we get the stated inequalities. □

Remark 2.10. Noting that $\mathcal{K}'_{BL}(\alpha,\Lambda)$ is contained in $\mathcal{K}'_{TV}(\alpha)$ from the upper bounds in the last two inequalities in the above Theorem 2.9 we get

$$\mathbb{E}^n\Big[\sup_{\phi\in\mathcal{K}'_{BL}(\alpha,\Lambda)}|U(t,\tilde{\boldsymbol{Y}};\phi(\cdot,\tilde{Y}_t))-U^n(t,\tilde{\boldsymbol{Y}};\phi(\cdot,\tilde{Y}_t))|\Big]$$
$$\leq 2\alpha\,\mathbb{E}^n\big[\mathcal{Z}^n_t\big]+\min\Big(2\alpha\,\mathbb{P}^n\big(\{\tilde{X}_t\neq\tilde{X}^n_t\}\big);\,\Lambda\,\mathbb{E}^n\big[\big|\tilde{X}_t-\tilde{X}^n_t\big|\big]\Big),$$

$$\mathbb{E}\Big[\sup_{\phi\in\mathcal{K}'_{BL}(\alpha,\Lambda)}|U(t,\tilde{\boldsymbol{Y}};\phi(\cdot,\tilde{Y}_t))-U^n(t,\tilde{\boldsymbol{Y}};\phi(\cdot,\tilde{Y}_t))|\Big]$$
$$\leq 2\alpha\,\mathbb{E}\big[\mathcal{Z}_t\big]+\min\Big(2\alpha\,\mathbb{P}\big(\{\tilde{X}_t\neq\tilde{X}^n_t\}\big);\,\Lambda\,\mathbb{E}\big[\big|\tilde{X}_t-\tilde{X}^n_t\big|\big]\Big).$$

Furthermore, observing that for any $\phi\in\mathcal{K}'_{BL}(\alpha,\Lambda)$,

$$|\phi(x,y)-\phi(x',y)|\leq\max(2\alpha;\,\Lambda)\big(|x-x'|\wedge 1\big),$$

by arguments similar to the proof of Theorem 2.9, we get

$$\mathbb{E}^n\Big[\sup_{\phi\in\mathcal{K}'_{BL}(\alpha,\Lambda)}|U(t,\tilde{\boldsymbol{Y}};\phi(\cdot,\tilde{Y}_t))-U^n(t,\tilde{\boldsymbol{Y}};\phi(\cdot,\tilde{Y}_t))|\Big]$$
$$\leq 2\alpha\,\mathbb{E}^n\big[\mathcal{Z}^n_t\big]+\max(2\alpha;\,\Lambda)\,\mathbb{E}^n\big[\big|\tilde{X}_t-\tilde{X}^n_t\big|\wedge 1\big],$$

$$\mathbb{E}\Big[\sup_{\phi\in\mathcal{K}'_{BL}(\alpha,\Lambda)}|U(t,\tilde{\boldsymbol{Y}};\phi(\cdot,\tilde{Y}_t))-U^n(t,\tilde{\boldsymbol{Y}};\phi(\cdot,\tilde{Y}_t))|\Big]$$
$$\leq 2\alpha\,\mathbb{E}\big[\mathcal{Z}_t\big]+\max(2\alpha;\,\Lambda)\,\mathbb{E}\big[\big|\tilde{X}_t-\tilde{X}^n_t\big|\wedge 1\big].$$

Moreover, in the next section we will also use the following result.

PROPOSITION 2.11. *Assume that conditions* (a), ($\mathrm{a_n}$), (b1), *and* (b2) *are satisfied; then the following inequalities hold:*

$$\sup_{\phi\in\mathcal{K}'_{TV}(\alpha)}\big|\mathbb{E}\big[\phi(\tilde{X}_t,\tilde{Y}_t)\big]-\mathbb{E}^n\big[\phi(\tilde{X}^n_t,\tilde{Y}_t)\big]\big|\leq\alpha\,\mathbb{E}^n\big[\mathcal{Z}^n_t\big]+2\alpha\,\mathbb{P}^n\big(\{\tilde{X}_t\neq\tilde{X}^n_t\}\big),$$

$$\sup_{\phi\in\mathcal{K}'_{TV}(\alpha)}\big|\mathbb{E}\big[\phi(\tilde{X}_t,\tilde{Y}_t)\big]-\mathbb{E}^n\big[\phi(\tilde{X}^n_t,\tilde{Y}_t)\big]\big|\leq\alpha\,\mathbb{E}\big[\mathcal{Z}_t\big]+2\alpha\,\mathbb{P}\big(\{\tilde{X}_t\neq\tilde{X}^n_t\}\big),$$

$$\sup_{\phi\in\mathcal{K}'_{BL}(\alpha,\Lambda)}\big|\mathbb{E}\big[\phi(\tilde{X}_t,\tilde{Y}_t)\big]-\mathbb{E}^n\big[\phi(\tilde{X}^n_t,\tilde{Y}_t)\big]\big|\leq\alpha\,\mathbb{E}^n\big[\mathcal{Z}^n_t\big]+\Lambda\,\mathbb{E}^n\big[\big|\tilde{X}_t-\tilde{X}^n_t\big|\big],$$

$$\sup_{\phi\in\mathcal{K}'_{BL}(\alpha,\Lambda)}\big|\mathbb{E}\big[\phi(\tilde{X}_t,\tilde{Y}_t)\big]-\mathbb{E}^n\big[\phi(\tilde{X}^n_t,\tilde{Y}_t)\big]\big|\leq\alpha\,\mathbb{E}\big[\mathcal{Z}_t\big]+\Lambda\,\mathbb{E}\big[\big|\tilde{X}_t-\tilde{X}^n_t\big|\big],$$

where $\mathcal{Z}^n_t$ *and* $\mathcal{Z}_t$ *are defined as in* (27) *and* (28), *respectively.*

Proof. For any $\phi\in\mathcal{K}'_{TV}(\alpha)$,

$$\begin{aligned}&|\mathbb{E}[\phi(\tilde{X}_t,\tilde{Y}_t)]-\mathbb{E}^n[\phi(\tilde{X}^n_t,\tilde{Y}_t)]|\\&\leq|\mathbb{E}[\phi(\tilde{X}_t,\tilde{Y}_t)]-\mathbb{E}[\phi(\tilde{X}^n_t,\tilde{Y}_t)]|\\&\qquad+|\mathbb{E}[\phi(\tilde{X}^n_t,\tilde{Y}_t)]-\mathbb{E}_{\mathbb{Q}}[(d\mathbb{P}^n/d\mathbb{Q})|_{\mathcal{F}^{\tilde{X}^n,\tilde{Y}}_t}\phi(\tilde{X}^n_t,\tilde{Y}_t)]|\\&\leq|\mathbb{E}[\phi(\tilde{X}_t,\tilde{Y}_t)]-\mathbb{E}[\phi(\tilde{X}^n_t,\tilde{Y}_t)]|+\alpha\mathbb{E}_{\mathbb{Q}}[|(d\mathbb{P}/d\mathbb{Q})|_{\mathcal{F}^{\tilde{X}^n,\tilde{Y}}_t}-(d\mathbb{P}^n/d\mathbb{Q})|_{\mathcal{F}^{\tilde{X}^n,\tilde{Y}}_t}|].\end{aligned}$$

Since, by the Jensen inequality, $|E(Z/\mathcal{G})| = |E(E(Z/\mathcal{H})/\mathcal{G})| \le E(|E(Z/\mathcal{H})|/\mathcal{G})$ for any integrable random variable Z and σ-algebras $\mathcal{G} \subseteq \mathcal{H} \subseteq \mathcal{F}$, we have

$$\mathbb{E}_{\mathbb{Q}}[|(d\mathbb{P}/d\mathbb{Q})|_{\mathcal{F}_t^{\tilde{X}^n,\tilde{Y}}} - (d\mathbb{P}^n/d\mathbb{Q})|_{\mathcal{F}_t^{\tilde{X}^n,\tilde{Y}}}|] \le \mathbb{E}_{\mathbb{Q}}[|(d\mathbb{P}/d\mathbb{Q})|_{\tilde{\mathcal{F}}_t} - (d\mathbb{P}^n/d\mathbb{Q})|_{\tilde{\mathcal{F}}_t}|],$$

and therefore

$$\begin{aligned}&|\mathbb{E}[\phi(\tilde{X}_t,\tilde{Y}_t)] - \mathbb{E}^n[\phi(\tilde{X}_t^n,\tilde{Y}_t)]|\\ &\quad\le |\mathbb{E}[\phi(\tilde{X}_t,\tilde{Y}_t)] - \mathbb{E}[\phi(\tilde{X}_t^n,\tilde{Y}_t)]| + \alpha\mathbb{E}_{\mathbb{Q}}[|(d\mathbb{P}/d\mathbb{Q})|_{\tilde{\mathcal{F}}_t} - (d\mathbb{P}^n/d\mathbb{Q})|_{\tilde{\mathcal{F}}_t}|].\end{aligned}$$

As a consequence,

$$\begin{aligned}&\sup_{\phi\in\mathcal{K}'_{TV}(\alpha)} |\mathbb{E}[\phi(\tilde{X}_t,\tilde{Y}_t)] - \mathbb{E}^n[\phi(\tilde{X}_t^n,\tilde{Y}_t)]|\\ &\quad\le \alpha\mathbb{E}_{\mathbb{Q}}[|(d\mathbb{P}/d\mathbb{Q})|_{\tilde{\mathcal{F}}_t} - (d\mathbb{P}^n/d\mathbb{Q})|_{\tilde{\mathcal{F}}_t}|] + 2\,\alpha\,\mathbb{P}(\{\tilde{X}_t \ne \tilde{X}_t^n\}).\end{aligned}$$

Interchanging the role of $\mathbb{P}$ and $\mathbb{P}^n$, we get

$$\begin{aligned}&\sup_{\phi\in\mathcal{K}'_{TV}(\alpha)} |\mathbb{E}[\phi(\tilde{X}_t,\tilde{Y}_t)] - \mathbb{E}^n[\phi(\tilde{X}_t^n,\tilde{Y}_t)]|\\ &\quad\le \alpha\mathbb{E}_{\mathbb{Q}}[|(d\mathbb{P}/d\mathbb{Q})|_{\tilde{\mathcal{F}}_t} - (d\mathbb{P}^n/d\mathbb{Q})|_{\tilde{\mathcal{F}}_t}|] + 2\,\alpha\,\mathbb{P}^n(\{\tilde{X}_t \ne \tilde{X}_t^n\}).\end{aligned}$$

By using similar arguments, it is easy to get

$$\begin{aligned}&\sup_{\phi\in\mathcal{K}'_{BL}(\alpha,\Lambda)} |\mathbb{E}[\phi(\tilde{X}_t,\tilde{Y}_t)] - \mathbb{E}^n[\phi(\tilde{X}_t^n,\tilde{Y}_t)]|\\ &\quad\le \alpha\mathbb{E}_{\mathbb{Q}}[|(d\mathbb{P}/d\mathbb{Q})|_{\tilde{\mathcal{F}}_t} - (d\mathbb{P}^n/d\mathbb{Q})|_{\tilde{\mathcal{F}}_t}|] + \Lambda\,\mathbb{E}[|\tilde{X}_t - \tilde{X}_t^n|]\end{aligned}$$

and

$$\begin{aligned}&\sup_{\phi\in\mathcal{K}'_{BL}(\alpha,\Lambda)} |\mathbb{E}[\phi(\tilde{X}_t,\tilde{Y}_t)] - \mathbb{E}^n[\phi(\tilde{X}_t^n,\tilde{Y}_t)]|\\ &\quad\le \alpha\mathbb{E}_{\mathbb{Q}}[|(d\mathbb{P}/d\mathbb{Q})|_{\tilde{\mathcal{F}}_t} - (d\mathbb{P}^n/d\mathbb{Q})|_{\tilde{\mathcal{F}}_t}|] + \Lambda\,\mathbb{E}^n[|\tilde{X}_t - \tilde{X}_t^n|]. \qquad \square\end{aligned}$$

Remark 2.12. As in Remark 2.10, by arguments similar to the proof of Theorem 2.9, we also get

$$\begin{aligned}&\sup_{\phi\in\mathcal{K}'_{BL}(\alpha,\Lambda)} |\mathbb{E}[\phi(\tilde{X}_t,\tilde{Y}_t)] - \mathbb{E}^n[\phi(\tilde{X}_t^n,\tilde{Y}_t)]|\\ &\quad\le \alpha\mathbb{E}_{\mathbb{Q}}[|(d\mathbb{P}/d\mathbb{Q})|_{\tilde{\mathcal{F}}_t} - (d\mathbb{P}^n/d\mathbb{Q})|_{\tilde{\mathcal{F}}_t}|]\\ &\qquad\qquad + \max(2\alpha;\Lambda)\,\min(\mathbb{E}^n[|\tilde{X}_t - \tilde{X}_t^n| \wedge 1];\ \mathbb{E}[|\tilde{X}_t - \tilde{X}_t^n| \wedge 1]).\end{aligned}$$

3. Approximation in filtering for Markov models with delayed observations. In this section we show how to use the approximations $\tilde{\pi}_t^n$ and $\overline{\pi}_t^n$ introduced in section 2 for the filter in the case of Markov models with delayed observations, in order to obtain upper bounds for the expectations in (19) and (20) when dealing with the bounded-Lipschitz distance or the total variation distance. For this purpose, we give some general upper bounds, depending on the trajectories actually observed (see (35) and (38) below) which lead to the main results of this section stated in Propositions 3.1 and 3.2. In the next section we use these bounds, and we exploit the results

about the sensitivity of the filter for Markov jump processes with counting observations given in [6], [7], and [8]. As we have already noticed at the end of section 1, some approximation results hold also for different systems and can be obtained with different techniques.

Consider the systems $(\boldsymbol{X^n}, \boldsymbol{Y^n})$ and $(\boldsymbol{X}, \boldsymbol{Y})$ such that

$$(\boldsymbol{X^n}, \hat{\boldsymbol{Y}}^{\boldsymbol{n}}) \text{ is a Markov system with generator } \boldsymbol{L^n}$$

and

$$Y_t^n = \hat{Y}_{a(t)}^n;$$

analogously,

$$(\boldsymbol{X}, \hat{\boldsymbol{Y}}) \text{ is a Markov system with generator } \boldsymbol{L}$$

and

$$Y_t = \hat{Y}_{a(t)},$$

where $a(\cdot)$ has the same properties as in Theorem 1.1.

As explained in Theorem 1.1 the filters π_t^n and π_t can be expressed in terms of the filters $\hat{\pi}_t^n$ and $\hat{\pi}_t$ and the semigroups $\exp\{\boldsymbol{L^n}s\}$ and $\exp\{\boldsymbol{L}s\}$ of the corresponding Markovian systems. More precisely (see (11))

$$\pi_t^n(\varphi) = \hat{\pi}_{a(t)}^n\big(\exp\{\boldsymbol{L^n}(t-a(t))\}\phi(\cdot, \hat{Y}_{a(t)}^n)\big)$$

and

$$\pi_t(\varphi) = \hat{\pi}_{a(t)}\big(\exp\{\boldsymbol{L}(t-a(t))\}\phi(\cdot, \hat{Y}_{a(t)})\big),$$

where $\phi(x,y) = \varphi(x)$, as in Theorem 1.1 and section 2.3.

Therefore, on the one hand, the convergence of the filters may be investigated in terms of the convergence of $\hat{\pi}_t^n$ to $\hat{\pi}_t$ and of $\exp\{\boldsymbol{L^n}s\}$ to $\exp\{\boldsymbol{L}s\}$. On the other hand, we are interested in the approximations (15) and (16) of the filter, and therefore we need a representation formula for the functionals U^n and U. These functionals can be expressed in terms of the corresponding functionals $\hat{U}^n$ and $\hat{U}$ of the underlying Markov systems, i.e., the functionals such that

$$\hat{\pi}_t^n = \hat{U}^n\big(t, \hat{\boldsymbol{Y}}^{\boldsymbol{n}}\big) \text{ and } \hat{\pi}_t = \hat{U}\big(t, \hat{\boldsymbol{Y}}\big),$$

where the functionals $\hat{U}^n$ and $\hat{U}$ depend on the initial distributions and the generators of the corresponding Markov systems.

As a consequence,

$$\pi_t^n(\varphi) = \int_{\mathbb{R}^k} \hat{U}^n\big(a(t), \boldsymbol{Y^n} \circ \boldsymbol{\mathcal{A}^{-1}}; dx\big) \exp\{\boldsymbol{L^n}(t-a(t))\}\phi(x, Y_t^n)$$

and

$$\pi_t(\varphi) = \int_{\mathbb{R}^k} \hat{U}\big(a(t), \boldsymbol{Y} \circ \boldsymbol{\mathcal{A}^{-1}}; dx\big) \exp\{\boldsymbol{L}(t-a(t))\}\phi(x, Y_t),$$

where again $\phi(x,y) = \varphi(x)$ and hence, the r.h.s.'s of the previous equalities define implicitly the functionals U^n and U, respectively.

Recalling that

$$(Y \circ \mathcal{A}^{-1})_s = Y_{a^{-1}(s)} = \hat{Y}_{a(a^{-1}(s))} = \hat{Y}_s, \tag{34}$$

since $a(a^{-1}(s)) = s$, $Y_t = \hat{Y}_{a(t)}$, and $Y_t^n = \hat{Y}_{a(t)}^n$, we can rewrite the above formulas as

$$\begin{aligned}\pi_t^n(\varphi) &= \int_{\mathbb{R}^k} \hat{U}^n\big(a(t), \hat{\boldsymbol{Y}}^{\boldsymbol{n}}; dx\big) \exp\{\boldsymbol{L}^{\boldsymbol{n}}(t - a(t))\}\phi(x, \hat{Y}_{a(t)}^n) \\ &= \hat{U}^n\big(r, \boldsymbol{y}; \exp\{\boldsymbol{L}^{\boldsymbol{n}}(t-r)\}\phi(\cdot, y_r)\big)\big|_{r=a(t), \boldsymbol{y}=\hat{\boldsymbol{Y}}^{\boldsymbol{n}}}\end{aligned}$$

and

$$\begin{aligned}\pi_t(\varphi) &= \int_{\mathbb{R}^k} \hat{U}\big(a(t), \hat{\boldsymbol{Y}}; dx\big) \exp\{\boldsymbol{L}(t - a(t))\}\phi(x, \hat{Y}_{a(t)}) \\ &= \hat{U}\big(r, \boldsymbol{y}; \exp\{\boldsymbol{L}(t-r)\}\phi(\cdot, y_r)\big)\big|_{r=a(t), \boldsymbol{y}=\hat{\boldsymbol{Y}}}.\end{aligned}$$

Therefore, when we observe $\boldsymbol{Y}$ (situation 1 of section 2), either the total variation distance or the bounded-Lipschitz distance between π_t and $\tilde{\pi}_t^n$ can be evaluated in terms of the supremum of

$$\begin{aligned}|\pi_t(\varphi) - \tilde{\pi}_t^n(\varphi)| &= \big|U\big(t, \boldsymbol{Y}; \varphi\big) - U^n\big(t, \boldsymbol{Y}; \varphi\big)\big| \\ &= \big|\hat{U}\big(r, \boldsymbol{y}; \exp\{\boldsymbol{L}(t-r)\}\phi(\cdot, y_r)\big) - \hat{U}^n\big(r, \boldsymbol{y}; \exp\{\boldsymbol{L}^{\boldsymbol{n}}(t-r)\}\phi(\cdot, y_r)\big)\big|_{r=a(t), \boldsymbol{y}=\hat{\boldsymbol{Y}}}\end{aligned}$$

over φ in the class of functions $\mathcal{K}_{TV}$ or $\mathcal{K}_{BL}$, respectively. When instead we observe $\boldsymbol{Y}^{\boldsymbol{n}}$ (situation 2 of section 2), the distance between π_t^n and $\bar{\pi}_t^n$ can be evaluated in terms of the supremum of

$$\begin{aligned}|\pi_t^n(\varphi) - \bar{\pi}_t^n(\varphi)| &= \big|U^n\big(t, \boldsymbol{Y}^{\boldsymbol{n}}; \varphi\big) - U\big(t, \boldsymbol{Y}^{\boldsymbol{n}}; \varphi\big)\big| \\ &= \big|\hat{U}^n\big(r, \boldsymbol{y}; \exp\{\boldsymbol{L}^{\boldsymbol{n}}(t-r)\}\phi(\cdot, y_r)\big) - \hat{U}\big(r, \boldsymbol{y}; \exp\{\boldsymbol{L}(t-r)\}\phi(\cdot, y_r)\big)\big|_{r=a(t), \boldsymbol{y}=\hat{\boldsymbol{Y}}^{\boldsymbol{n}}}\end{aligned}$$

over φ in the class of functions $\mathcal{K}_{TV}$ or $\mathcal{K}_{BL}$, respectively.

In situation 1 we have

$$\begin{aligned}&|\pi_t(\varphi) - \tilde{\pi}_t^n(\varphi)| \qquad (35)\\ &\le |\hat{U}(r, \boldsymbol{y}; \exp\{\boldsymbol{L}(t-r)\}\phi(\cdot, y_r)) - \hat{U}^n(r, \boldsymbol{y}; \exp\{\boldsymbol{L}(t-r)\}\phi(\cdot, y_r))|_{r=a(t), \boldsymbol{y}=\hat{\boldsymbol{Y}}} \qquad (36)\\ &+ |\hat{U}^n(r, \boldsymbol{y}; \exp\{\boldsymbol{L}(t-r)\}\phi(\cdot, y_r)) - \hat{U}^n(r, \boldsymbol{y}; \exp\{\boldsymbol{L}^{\boldsymbol{n}}(t-r)\}\phi(\cdot, y_r))|_{r=a(t), \boldsymbol{y}=\hat{\boldsymbol{Y}}}, \qquad (37)\end{aligned}$$

and in situation 2,

$$\begin{aligned}&|\pi_t^n(\varphi) - \bar{\pi}_t^n(\varphi)| \qquad (38)\\ &\le |\hat{U}^n(r, \boldsymbol{y}; \exp\{\boldsymbol{L}^{\boldsymbol{n}}(t-r)\}\phi(\cdot, y_r)) - \hat{U}^n(r, \boldsymbol{y}; \exp\{\boldsymbol{L}(t-r)\}\phi(\cdot, y_r))|_{r=a(t), \boldsymbol{y}=\hat{\boldsymbol{Y}}^{\boldsymbol{n}}} \qquad (39)\\ &+ |\hat{U}^n(r, \boldsymbol{y}; \exp\{\boldsymbol{L}(t-r)\}\phi(\cdot, y_r)) - \hat{U}(r, \boldsymbol{y}; \exp\{\boldsymbol{L}(t-r)\}\phi(\cdot, y_r))|_{r=a(t), \boldsymbol{y}=\hat{\boldsymbol{Y}}^{\boldsymbol{n}}}. \qquad (40)\end{aligned}$$

Note that the two previous upper bounds differ only by the fact that they are evaluated on $\boldsymbol{y} = \hat{\boldsymbol{Y}}$ and $\boldsymbol{y} = \hat{\boldsymbol{Y}}^{\boldsymbol{n}}$. Moreover, natural upper bounds for (37) are

$$\begin{aligned}&\sup_x |\exp\{\boldsymbol{L}(t-r)\}\phi(x, y_r) - \exp\{\boldsymbol{L}^{\boldsymbol{n}}(t-r)\}\phi(x, y_r)|_{r=a(t), \boldsymbol{y}=\hat{\boldsymbol{Y}}} \qquad (41)\\ &\quad \le \sup_{x,y} |\exp\{\boldsymbol{L}(t-r)\}\phi(x, y) - \exp\{\boldsymbol{L}^{\boldsymbol{n}}(t-r)\}\phi(x, y)|_{r=a(t)}. \qquad (42)\end{aligned}$$

The same bounds are valid for (39) when substituting $\boldsymbol{y} = \hat{\boldsymbol{Y}}$ with $\boldsymbol{y} = \hat{\boldsymbol{Y}}^{\boldsymbol{n}}$.

Then in both situations the distance between the filter and the approximation can be expressed by means of the distance between $\hat{U}^n$ and $\hat{U}$ and the distance between the semigroups $\exp\{\boldsymbol{L^n}s\}$ and $\exp\{\boldsymbol{L}s\}$, as can be deduced by the following results.

PROPOSITION 3.1. *For the system with delayed observations described at the beginning of this section we have*

(43)
$$\sup_{\varphi\in\mathcal{K}_{TV}(\alpha)} |\pi_t(\varphi) - \tilde{\pi}_t^n(\varphi)| \le \sup_{\psi\in\mathcal{K}'_{TV}(\alpha)} |\hat{U}(r,\boldsymbol{y};\psi(\cdot,y_r)) - \hat{U}^n(r,\boldsymbol{y};\psi(\cdot,y_r))|_{r=a(t),\boldsymbol{y}=\hat{\boldsymbol{Y}}}$$

$$+ \sup_{\phi\in\mathcal{K}'_{TV}(\alpha)} \sup_{x,y} |\exp\{\boldsymbol{L}(t-r)\}\phi(x,y) - \exp\{\boldsymbol{L^n}(t-r)\}\phi(x,y)|_{r=a(t)}, \tag{44}$$

where $\mathcal{K}_{TV}(\alpha)$ and $\mathcal{K}'_{TV}(\alpha)$ are defined as in section 2.3.

Furthermore, if for all $u \ge 0$ there exists a constant $\Lambda'(u,\Lambda)$ such that

$$\exp\{\boldsymbol{L}u\}\big(\mathcal{K}'_{BL}(\alpha,\Lambda)\big) \subseteq \mathcal{K}'_{BL}(\alpha,\Lambda'(u,\Lambda)), \tag{45}$$

then we have

$$\sup_{\varphi\in\mathcal{K}_{BL}(\alpha,\Lambda)} |\pi_t(\varphi) - \tilde{\pi}_t^n(\varphi)|$$

$$\le \sup_{\psi\in\mathcal{K}'_{BL}(\alpha,\Lambda'(t-r,\Lambda))} |\hat{U}(r,\boldsymbol{y};\psi(\cdot,y_r)) - \hat{U}^n(r,\boldsymbol{y};\psi(\cdot,y_r))|_{r=a(t),\boldsymbol{y}=\hat{\boldsymbol{Y}}} \tag{46}$$

$$+ \sup_{\phi\in\mathcal{K}'_{BL}(\alpha,\Lambda)} \sup_{x,y} |\exp\{\boldsymbol{L}(t-r)\}\phi(x,y) - \exp\{\boldsymbol{L^n}(t-r)\}\phi(x,y)|_{r=a(t)}, \tag{47}$$

where $\mathcal{K}_{BL}(\alpha,\Lambda)$ and $\mathcal{K}'_{BL}(\alpha,\Lambda)$ are defined as in section 2.3.

Proof. Taking into account (35)–(37) we get

$$\begin{aligned}
\sup_{\varphi\in\mathcal{K}_{TV}(\alpha)} |\pi_t(\varphi) - \tilde{\pi}_t^n(\varphi)| &\le \sup_{\phi\in\mathcal{K}'_{TV}(\alpha)} |\hat{U}\big(r,\boldsymbol{y};\exp\{\boldsymbol{L}(t-r)\}\phi(\cdot,y_r)\big) \\
&\quad - \hat{U}^n\big(r,\boldsymbol{y};\exp\{\boldsymbol{L}(t-r)\}\phi(\cdot,y_r)\big)|_{r=a(t),\boldsymbol{y}=\hat{\boldsymbol{Y}}} \\
&\quad + \sup_{\phi\in\mathcal{K}'_{TV}(\alpha)} \sup_{x,y} |\exp\{\boldsymbol{L}(t-r)\}\phi(x,y) - \exp\{\boldsymbol{L^n}(t-r)\}\phi(x,y)|_{r=a(t)} \\
&\le \sup_{\psi\in\mathcal{K}'_{TV}(\alpha)} |\hat{U}\big(r,\boldsymbol{y};\psi(\cdot,y_r)\big) - \hat{U}^n\big(r,\boldsymbol{y};\psi(\cdot,y_r)\big)|_{r=a(t),\boldsymbol{y}=\hat{\boldsymbol{Y}}} \\
&\quad + \sup_{\phi\in\mathcal{K}'_{TV}(\alpha)} \sup_{x,y} |\exp\{\boldsymbol{L}(t-r)\}\phi(x,y) - \exp\{\boldsymbol{L^n}(t-r)\}\phi(x,y)|_{r=a(t)}.
\end{aligned}$$

Moreover, we also have

$$\begin{aligned}
\sup_{\varphi\in\mathcal{K}_{BL}(\alpha,\Lambda)} |\pi_t(\varphi) - \tilde{\pi}_t^n(\varphi)| &\le \sup_{\phi\in\mathcal{K}'_{BL}(\alpha,\Lambda)} |\hat{U}\big(r,\boldsymbol{y};\exp\{\boldsymbol{L}(t-r)\}\phi(\cdot,y_r)\big) \\
&\quad - \hat{U}^n\big(r,\boldsymbol{y};\exp\{\boldsymbol{L}(t-r)\}\phi(\cdot,y_r)\big)|_{r=a(t),\boldsymbol{y}=\hat{\boldsymbol{Y}}} \\
&\quad + \sup_{\phi\in\mathcal{K}'_{BL}(\alpha,\Lambda)} \sup_{x,y} |\exp\{\boldsymbol{L}(t-r)\}\phi(x,y) - \exp\{\boldsymbol{L^n}(t-r)\}\phi(x,y)|_{r=a(t)} \\
&\le \sup_{\psi\in\exp\{\boldsymbol{L}(t-r)\}\mathcal{K}'_{BL}(\alpha,\Lambda)} |\hat{U}\big(r,\boldsymbol{y};\psi(\cdot,y_r)\big) - \hat{U}^n\big(r,\boldsymbol{y};\psi(\cdot,y_r)\big)|_{r=a(t),\boldsymbol{y}=\hat{\boldsymbol{Y}}} \\
&\quad + \sup_{\phi\in\mathcal{K}'_{BL}(\alpha,\Lambda)} \sup_{x,y} |\exp\{\boldsymbol{L}(t-r)\}\phi(x,y) - \exp\{\boldsymbol{L^n}(t-r)\}\phi(x,y)|_{r=a(t)},
\end{aligned}$$

and invoking (45) we get (46) by noticing that the supremum over

$$\exp\{\boldsymbol{L}(t-r)\}\big(\mathcal{K}'_{BL}(\alpha,\Lambda)\big)$$

in the bound given above can be replaced by the supremum over $\mathcal{K}'_{BL}(\alpha,\Lambda'(t-r,\Lambda))$. □

Taking into account (38)–(40) and changing $\hat{\boldsymbol{Y}}$ into $\hat{\boldsymbol{Y}}^{\boldsymbol{n}}$ we have the following result.

PROPOSITION 3.2. *For the system with delayed observations described at the beginning of this section we have*

$$\sup_{\varphi\in\mathcal{K}_{TV}(\alpha)}|\pi_t^n(\varphi)-\overline{\pi}_t^n(\varphi)|$$

$$\leq \sup_{\psi\in\mathcal{K}'_{TV}(\alpha)}\big|\hat{U}\big(r,\boldsymbol{y};\psi(\cdot,y_r)\big)-\hat{U}^n\big(r,\boldsymbol{y};\psi(\cdot,y_r)\big)\big|_{r=a(t),\boldsymbol{y}=\hat{\boldsymbol{Y}}^{\boldsymbol{n}}} \tag{48}$$

$$+\sup_{\phi\in\mathcal{K}'_{TV}(\alpha)}\sup_{x,y}|\exp\{\boldsymbol{L}(t-r)\}\phi(x,y)-\exp\{\boldsymbol{L}^{\boldsymbol{n}}(t-r)\}\phi(x,y)|_{r=a(t)}\,. \tag{49}$$

Furthermore, if condition (45) *holds, then we have*

$$\sup_{\varphi\in\mathcal{K}_{BL}(\alpha,\Lambda)}|\pi_t^n(\varphi)-\overline{\pi}_t^n(\varphi)|$$

$$\leq \sup_{\psi\in\mathcal{K}'_{BL}(\alpha,\Lambda'(t-r,\Lambda))}|\hat{U}(r,\boldsymbol{y};\psi(\cdot,y_r))-\hat{U}^n(r,\boldsymbol{y};\psi(\cdot,y_r))|_{r=a(t),\boldsymbol{y}=\hat{\boldsymbol{Y}}^{\boldsymbol{n}}} \tag{50}$$

$$+\sup_{\phi\in\mathcal{K}'_{BL}(\alpha,\Lambda)}\sup_{x,y}|\exp\{\boldsymbol{L}(t-r)\}\phi(x,y)-\exp\{\boldsymbol{L}^{\boldsymbol{n}}(t-r)\}\phi(x,y)|_{r=a(t)}. \tag{51}$$

The above upper bounds will be evaluated when studying filtering systems with counting observations in the following section. In particular, upper bounds for the expectations of the r.h.s. of (43) and (46) will be obtained by a slight modification of the arguments used in the previous section (see Theorem 2.9). The same kind of consideration holds for the expectations of (44) and (47) (see Proposition 2.11).

4. Counting processes observations.

4.1. Main results. In this section, we accomplish the above-mentioned general program in the case of a Markov jump process with counting delayed observations. More precisely we assume that the pairs $(\boldsymbol{X},\hat{\boldsymbol{Y}})$ and $(\boldsymbol{X}^{\boldsymbol{n}},\hat{\boldsymbol{Y}}^{\boldsymbol{n}})$ are Markov systems in $\mathbb{R}\times\mathbb{N}$, with respective initial conditions $\mu_0^X\otimes\delta_{\{y\}}$ and $\mu_0^{X^n}\otimes\delta_{\{y\}}$, and with respective generators $\boldsymbol{L}$ and $\boldsymbol{L}^{\boldsymbol{n}}$, where

$$\begin{aligned}\boldsymbol{L}\phi(x,y)&=\lambda_0(x,y)\int\big(\phi(x',y)-\phi(x,y)\big)\mu_0(x,y;dx')\\&\quad+\lambda_1(x,y)\int\big(\phi(x',y+1)-\phi(x,y)\big)\mu_1(x,y;dx')\end{aligned}$$

and

$$\begin{aligned}\boldsymbol{L}^{\boldsymbol{n}}\phi(x,y)&=\lambda_0^n(x,y)\int\big(\phi(x',y)-\phi(x,y)\big)\mu_0^n(x,y;dx')\\&\quad+\lambda_1^n(x,y)\int\big(\phi(x',y+1)-\phi(x,y)\big)\mu_1^n(x,y;dx'),\end{aligned}$$

and thus the predictable intensities of $\hat{\boldsymbol{Y}}$ and $\hat{\boldsymbol{Y}}^{\boldsymbol{n}}$ are $\lambda_1(X_{t^-}, \hat{Y}_{t^-})$ and $\lambda_1^n(X^n_{t^-}, \hat{Y}^n_{t^-})$, respectively. Furthermore we assume such that the following hypotheses are satisfied:
(H$_0$) $0 \le \underline{\lambda}_i \le \lambda_i(x,y), \lambda_i^n(x,y) \le \overline{\lambda}_i \quad$ for $i = 0, 1$;
(H$_1$) $0 < \lambda_1(x,y), \lambda_1^n(x,y)$;
(H$_2$) $\Delta_i^n := \sup_{x,y} \boldsymbol{\kappa}(\mu_i(x,y;\cdot), \mu_i^n(x,y;\cdot)) < \infty \quad$ for $i = 0, 1$.

Note that the operator $\boldsymbol{L}$ given above can be expressed in the same form as the one defined by (4) and vice versa.

From now on we will say that the operator $\boldsymbol{L}$ is *bL-regular* when it satisfies the following conditions:
(R$_0$) For every z the function $x \mapsto \lambda_i(x,z)$, $i = 0, 1$, is bounded-Lipschitz continuous and the Lipschitz constant is bounded from above by L_{λ_i}.
(R$_1$) $\sup_y \boldsymbol{\kappa}(\mu_i(x,y;\cdot), \mu_i(x',y;\cdot)) \le \Gamma_{\mu_i}|x - x'|$ for $i = 0, 1$.
(R$_2$) $\sup_{x,y} \int |z - x| \mu_0(x,y;dz) \le b_0, \qquad \int |z - x| \mu_1(x,y;dz) \le a_1(|x| + y) + b_1$.

It is important to stress that, if $\boldsymbol{L}$ is bL-regular, then $\exp\{\boldsymbol{L}u\}(\mathcal{K}'_{BL}(\alpha, \Lambda)) \subseteq \mathcal{K}'_{BL}(\alpha, \Lambda e^{Mu})$ (see Corollary 4.9) for a suitable constant M (given in (67)), and thus condition (45) is satisfied with

$$\Lambda'(u, \Lambda) = \Lambda e^{Mu}. \tag{52}$$

Finally, we will denote by $\|\cdot\|_\infty$ the norm defined by $\|\mu\|_\infty = \sup_{x,y} \|\mu(x,y,\cdot)\|_{TV}$ for any regular nucleus $\mu(x,y;dz)$.

The central tool for the proofs of our bounds (see Theorem 4.5 below) is a particular construction of the pairs $(\boldsymbol{X}^{\boldsymbol{n}}, \hat{\boldsymbol{Y}}^{\boldsymbol{n}})$ and $(\boldsymbol{X}, \hat{\boldsymbol{Y}})$ on the same measurable space $(\Omega, \mathcal{F})$, equipped with three different probability measures $\mathbb{Q}$, $\mathbb{P}$, and $\mathbb{P}^n$, in a similar way to that used in section 2, and such that
(â) under $\mathbb{P}$ the pair $(\boldsymbol{X}, \hat{\boldsymbol{Y}})$ has generator $\boldsymbol{L}$ and initial condition $\mu = \mu_0^X \otimes \delta_{\{y\}}$,
(â$_n$) under $\mathbb{P}^n$ the pair $(\boldsymbol{X}^{\boldsymbol{n}}, \hat{\boldsymbol{Y}})$ has generator $\boldsymbol{L}^n$ and initial condition $\mu^n = \mu_0^{X^n} \otimes \delta_{\{y\}}$,
(b̂) the probability measures $\mathbb{Q}$, $\mathbb{P}$, and $\mathbb{P}^n$ are equivalent on $= \mathcal{F}_t^{X, X^n, \hat{Y}}$.

Note that the use of $(\boldsymbol{X}^{\boldsymbol{n}}, \hat{\boldsymbol{Y}}^{\boldsymbol{n}})$ and $(\boldsymbol{X}, \hat{\boldsymbol{Y}})$ is a slight abuse of notation: as at the end of the previous section we should write instead $(\tilde{\boldsymbol{X}}^{\boldsymbol{n}}, \tilde{\hat{\boldsymbol{Y}}}^{\boldsymbol{n}})$ and $(\tilde{\boldsymbol{X}}, \tilde{\hat{\boldsymbol{Y}}})$. Nevertheless we prefer the slight abuse of notation, in order to avoid the notation $\tilde{\hat{Y}}$.

Therefore, when dealing with the triplet $(\boldsymbol{X}, \boldsymbol{X}^{\boldsymbol{n}}, \hat{\boldsymbol{Y}})$ instead of $(\tilde{\boldsymbol{X}}, \tilde{\boldsymbol{X}}^{\boldsymbol{n}}, \tilde{\boldsymbol{Y}})$, conditions (a), (a$_n$), (b1), and (b2) are satisfied. Then, in this framework, Theorem 2.9 applies with $(\boldsymbol{X}, \boldsymbol{X}^{\boldsymbol{n}}, \hat{\boldsymbol{Y}})$ instead of $(\tilde{\boldsymbol{X}}, \tilde{\boldsymbol{X}}^{\boldsymbol{n}}, \tilde{\boldsymbol{Y}})$ and with $\hat{U}$ and $\hat{U}^n$ instead of U and U^n, respectively; the same considerations are valid for Proposition 2.11. The explicit expression of $\hat{U}$ is given by

$$\hat{U}(t, \boldsymbol{y}; \varphi) = \begin{cases} \hat{\Pi}_t(\varphi | \boldsymbol{s}) & \text{for } y(t) = \sum_{i=1}^\infty \mathbb{I}_{[0,s_i]}(t), \\ \varphi(x_0) & \text{otherwise} \end{cases}$$

(see (9) and (10)). Obviously the definition of the probability measure $\hat{U}(t, \boldsymbol{y}; dx)$ on the complement of the set $\{\boldsymbol{y}$ such that $y(t) = \sum_{i=1}^\infty \mathbb{I}_{[0,s_i]}(t)\}$ is not unique. An analogous representation holds for $\hat{U}^n$.

Basically the above conditions coincide with Condition A of [8], and the construction we use is the same as the one in section 3 of [8]; the only difference is that in [8] we assume $\hat{Y}_0 = 0$. By this construction the model $(\boldsymbol{X}, \boldsymbol{Y})$ is defined on $(\Omega, \mathcal{F}, \mathbb{P})$ taking $Y_t = \hat{Y}_{a(t)}$, and the model $(\boldsymbol{X}^{\boldsymbol{n}}, \boldsymbol{Y}^{\boldsymbol{n}})$ is defined on $(\Omega, \mathcal{F}, \mathbb{P}^n)$ taking $\hat{\boldsymbol{Y}}^{\boldsymbol{n}} = \hat{\boldsymbol{Y}}$ and $Y_t^n = \hat{Y}^n_{a(t)}$ and thus $(\boldsymbol{X}^{\boldsymbol{n}}, \boldsymbol{Y}^{\boldsymbol{n}})$ coincides with $(\boldsymbol{X}^{\boldsymbol{n}}, \boldsymbol{Y})$ on $(\Omega, \mathcal{F}, \mathbb{P}^n)$. Moreover,

if $\mu_0^X = \delta_{\{x\}}$ and $\mu_0^{X^n} = \delta_{\{x\}}$, then the semigroups can be represented, respectively, as

$$\exp\{\boldsymbol{L}t\}\phi(x,y) = \mathbb{E}\big[\phi(X_t, \hat{Y}_t)\big] \tag{53}$$

and

$$\exp\{\boldsymbol{L^n}t\}\phi(x,y) = \mathbb{E}^n\big[\phi(X_t^n, \hat{Y}_t)\big]. \tag{54}$$

The construction of the triplet $(\boldsymbol{X}, \boldsymbol{X^n}, \hat{\boldsymbol{Y}})$ is possible under the assumptions (H_0) and (H_1).

The space $(\Omega, \mathcal{F}, \mathbb{Q})$ is a probability space on which two independent Poisson random measures are defined: $\mathcal{N}_0(ds, d\zeta)$ on $[0,T] \times [0, \bar{\lambda}_0]$, with intensity measure $ds\, d\zeta$, and $\mathcal{N}_1(ds, d\zeta)$ on $[0,T] \times [0,1]$, with intensity measure $ds\, d\zeta$. Then for suitable functions K_0, K_1, K_0^n, K_1^n, the triplet $(\boldsymbol{X}, \boldsymbol{X^n}, \hat{\boldsymbol{Y}})$ is

$$\begin{aligned} X_t = X_0 &+ \int_0^t \int_0^{\bar{\lambda}_0} K_0(X_{s^-}, X^n_{s^-}, \hat{Y}_{s^-}; \zeta)\mathcal{N}_0(ds, d\zeta) \\ &+ \int_0^t \int_0^1 K_1(X_{s^-}, X^n_{s^-}, \hat{Y}_{s^-}; \zeta)\mathcal{N}_1(ds, d\zeta), \end{aligned} \tag{55}$$

$$\begin{aligned} X^n_t = X^n_0 &+ \int_0^t \int_0^{\bar{\lambda}_0} K^n_0(X_{s^-}, X^n_{s^-}, \hat{Y}_{s^-}; \zeta)\mathcal{N}_0(ds, d\zeta) \\ &+ \int_0^t \int_0^1 K^n_1(X_{s^-}, X^n_{s^-}, \hat{Y}_{s^-}; \zeta)\mathcal{N}_1(ds, d\zeta), \end{aligned} \tag{56}$$

$$\hat{Y}_t = y + \int_0^t \int_0^1 \mathcal{N}_1(ds, d\zeta) = y + \mathcal{N}_1((0,t] \times [0,1]), \tag{57}$$

with initial conditions (X_0, X_0^n) independent of $\mathcal{N}_0$ and $\mathcal{N}_1$, and

$$\left.\frac{d\mathbb{P}}{d\mathbb{Q}}\right|_{\mathcal{F}_t^{X, X^n, \hat{Y}}} = \exp\left\{\int_0^t \log\big(\lambda_1(X_{s^-}, \hat{Y}_{s^-})\big) d\hat{Y}_s - \int_0^t \big(\lambda_1(X_{s^-}, \hat{Y}_{s^-}) - 1\big) ds\right\},$$

$$\left.\frac{d\mathbb{P}^n}{d\mathbb{Q}}\right|_{\mathcal{F}_t^{X, X^n, \hat{Y}}} = \exp\left\{\int_0^t \log\big(\lambda_1^n(X^n_{s^-}, \hat{Y}_{s^-})\big) d\hat{Y}_s - \int_0^t \big(\lambda_1^n(X^n_{s^-}, \hat{Y}_{s^-}) - 1\big) ds\right\}.$$

Remark 4.1. By using Lemma 3.7 in [8], explicit expressions for the functions K_0, K_1, K_0^n, K_1^n can be given. In particular, $K_0(x, \tilde{x}, y)$ and $K_0^n(x, \tilde{x}, y)$ are constructed using $\lambda(x) = \lambda_0(x,y)$, $\tilde{\lambda}(\tilde{x}) = \lambda_0^n(\tilde{x}, y)$, $\bar{\lambda} = \bar{\lambda}_0$, $\mu(x; dz) = \mu_0(x, y; dz)$, and $\tilde{\mu}(\tilde{x}; dz) = \mu_0^n(\tilde{x}, y; dz)$, while $K_1(x, \tilde{x}, y)$ and $K_1^n(x, \tilde{x}, y)$ are constructed using $\lambda(x) = \tilde{\lambda}(\tilde{x}) = \bar{\lambda} = 1$, $\mu(x; dz) = \mu_1(x, y; dz)$, and $\tilde{\mu}(\tilde{x}; dz) = \mu_1^n(\tilde{x}, y; dz)$.

Note that this construction relies on the fact that the state space is one-dimensional. Similar expressions could be obtained in higher dimensions.

First, we deduce from the above Radon–Nikodym derivatives some upper bounds which will play a key role in what follows. By using Lemma 4.7 in [8], we have

$$\mathbb{E}^n\left[\left|\left.\frac{d\mathbb{P}}{d\mathbb{P}^n}\right|_{\mathcal{F}_t^{X,X^n,\hat{Y}}}-1\right|\right]=\mathbb{E}\left[\left|\left.\frac{d\mathbb{P}^n}{d\mathbb{P}}\right|_{\mathcal{F}_t^{X,X^n,\hat{Y}}}-1\right|\right]$$

$$\leq 2\mathbb{E}\wedge\mathbb{E}^n\left[\int_0^t\left|\lambda_1(X_s,\hat{Y}_s)-\lambda_1^n(X_s^n,\hat{Y}_s)\right|ds\right] \tag{58}$$

$$\leq 2\int_0^t\mathbb{E}\vee\mathbb{E}^n\left[\left|\lambda_1(X_s,\hat{Y}_s)-\lambda_1^n(X_s^n,\hat{Y}_s)\right|\right]ds, \tag{59}$$

where $\mathbb{E}\wedge\mathbb{E}^n[Z]=\min\{\mathbb{E}[Z],\mathbb{E}^n[Z]\}$, and $\mathbb{E}\vee\mathbb{E}^n[Z]=\max\{\mathbb{E}[Z],\mathbb{E}^n[Z]\}$, for any random variable Z.

Second, note that since in our construction $\hat{\boldsymbol{Y}}^{\boldsymbol{n}}=\hat{\boldsymbol{Y}}$, the r.h.s. of (43) and (48) coincide, and thus the first upper bounds in Propositions 3.1 and 3.2 also coincide. The same holds for (46) and (50) and consequently for the last upper bounds. Then, taking $r=a(t)$, the following result can be used to obtain upper bounds for the expectations of the r.h.s. of (43) and (46).

PROPOSITION 4.2. *Under the hypotheses* (H_0) *and* (H_1),

$$\mathbb{E}\vee\mathbb{E}^n\left[\sup_{\psi\in\mathcal{K}'_{TV}(\alpha)}\left|\hat{U}\big(r,\boldsymbol{y};\psi(\cdot,y_r)\big)-\hat{U}^n\big(r,\boldsymbol{y};\psi(\cdot,y_r)\big)\right|_{\boldsymbol{y}=\hat{\boldsymbol{Y}}}\right] \tag{60}$$

$$\leq\alpha\Big[4\|\lambda_1-\lambda_1^n\|r$$

$$+\exp\{(\bar{\lambda}_1-\underline{\lambda}_1)\,r\}\left(\|\mu_0^X-\mu_0^{X^n}\|_{TV}\left(\frac{2\bar{\lambda}_1}{\bar{\lambda}_1-\underline{\lambda}_1}+1\right)+(\bar{\lambda}_0+\bar{\lambda}_1)J^n\,A(r)\right)\Big],$$

where

$$A(r)=2r+4\bar{\lambda}_1\frac{\exp\{-(\bar{\lambda}_1-\underline{\lambda}_1)\,r\}+(\bar{\lambda}_1-\underline{\lambda}_1)r-1}{(\bar{\lambda}_1-\underline{\lambda}_1)^2} \tag{61}$$

and

$$J^n=\max(\|p_0-p_0^n\|_\infty,\|\mu_1-\mu_1^n\|_\infty)/2, \tag{62}$$

with

$$p_0(x,y;dx')=\big(1-(\lambda_0(x,y)/\bar{\lambda}_0)\big)\delta_x(dx')+\big(\lambda_0(x,y)/\bar{\lambda}_0\big)\;\mu_0(x,y;dx'), \tag{63}$$

$$p_0^n(x,y;dx')=\big(1-(\lambda_0^n(x,y)/\bar{\lambda}_0)\big)\delta_x(dx')+\big(\lambda_0^n(x,y)/\bar{\lambda}_0\big)\;\mu_0^n(x,y;dx'). \tag{64}$$

If furthermore the operator $\boldsymbol{L}$ *is bL-regular, assumption* (H_2) *holds, and the initial distributions* μ_0^X *and* $\mu_0^{X^n}$ *have finite first moments, then*

$$\mathbb{E}\vee\mathbb{E}^n\left[\sup_{\psi\in\mathcal{K}'_{BL}(\alpha,\Lambda')}\left|\hat{U}\big(r,\boldsymbol{y};\psi(\cdot,y_r)\big)-\hat{U}^n\big(r,\boldsymbol{y};\psi(\cdot,y_r)\big)\right|_{\boldsymbol{y}=\hat{\boldsymbol{Y}}}\right] \tag{65}$$

$$\leq 4\alpha\big[\|\lambda_1-\lambda_1^n\|r+L_{\lambda_1}H^n\,\boldsymbol{\mathcal{E}}_2^M(r)\big]+\Lambda' H^n\,\boldsymbol{\mathcal{E}}_1^M(r)$$

$$+\boldsymbol{\kappa}\big(\mu_0^X,\mu_0^{X^n}\big)\big(4\alpha L_{\lambda_1}\boldsymbol{\mathcal{E}}_1^M(r)+\Lambda'\boldsymbol{\mathcal{E}}_0^M(r)\big),$$

where

$$H^n = \bar{\lambda}_0 \Delta_0^n + b_0 \, \|\lambda_0 - \lambda_0^n\| + \bar{\lambda}_1 \Delta_1^n, \tag{66}$$

$$M = \bar{\lambda}_0 (\Gamma_{\mu_0} - 1)^+ - \underline{\lambda}_0 (1 - \Gamma_{\mu_0})^+ + b_0 L_{\lambda_0} + \bar{\lambda}_1 (\Gamma_{\mu_1} - 1)^+ - \underline{\lambda}_1 (1 - \Gamma_{\mu_1})^+, \tag{67}$$

and

$$\boldsymbol{\mathcal{E}}_k^M(t) := \frac{1}{M^k} \sum_{h=k}^{\infty} \frac{(tM)^h}{h!} = \frac{1}{M^k} \left(\exp\{tM\} - \sum_{h=0}^{k-1} \frac{(tM)^h}{h!} \right). \tag{68}$$

The proof of the above result is given in the next subsection.

Remark 4.3. As a consequence, taking $\alpha = 1$, we can obtain

(69)

$$\begin{aligned} &\mathbb{E} \vee \mathbb{E}^n \left[\|\hat{U}(r, \boldsymbol{y}) - \hat{U}^n(r, \boldsymbol{y})\|_{TV} \big|_{\boldsymbol{y}=\hat{\boldsymbol{Y}}} \right] \\ &\quad \le \Bigg[4 \|\lambda_1 - \lambda_1^n\| r \\ &\qquad + \exp\{(\bar{\lambda}_1 - \underline{\lambda}_1)\, r\} \left(\|\mu_0^X - \mu_0^{X^n}\|_{TV} \left(\frac{2\bar{\lambda}_1}{\bar{\lambda}_1 - \underline{\lambda}_1} + 1 \right) + (\bar{\lambda}_0 + \bar{\lambda}_1) J^n \, A(r) \right) \Bigg], \end{aligned}$$

and similarly, taking $\Lambda' = 1$,

(70)

$$\begin{aligned} &\mathbb{E} \vee \mathbb{E}^n \left[d_{BL}\big(\hat{U}(r, \boldsymbol{y}), \hat{U}^n(r, \boldsymbol{y})\big) \big|_{\boldsymbol{y}=\hat{\boldsymbol{Y}}} \right] \\ &\quad \le 4 \Big[\|\lambda_1 - \lambda_1^n\| r + L_{\lambda_1} H^n \, \boldsymbol{\mathcal{E}}_2^M(r) \Big] + H^n \, \boldsymbol{\mathcal{E}}_1^M(r) \\ &\qquad + \boldsymbol{\kappa}\big(\mu_0^X, \mu_0^{X^n}\big) \big(4 L_{\lambda_1} \boldsymbol{\mathcal{E}}_1^M(r) + \boldsymbol{\mathcal{E}}_0^M(r) \big). \end{aligned}$$

The above upper bounds are interesting by themselves, since they correspond to upper bounds for the approximations of the system without delay. The last bound was essentially obtained in [8, Remark 2.7]. However, in that bound there was an imprecision, and (70) corrects it.

Note that the upper bound for (69) grows exponentially fast in r, and therefore is valid only in a finite interval of time, namely, when the l.h.s. is less than or equal to 2. A similar consideration holds for the upper bound for (60). Moreover, note that we have used implicitly $\bar{\lambda}_1 - \underline{\lambda}_1 > 0$. The upper bound (69) grows exponentially fast also when $\boldsymbol{L} = \boldsymbol{L^n}$, i.e., when the approximating system and the limit system differ only in the distribution of the initial condition, but it simplifies to

$$\begin{aligned} &\mathbb{E} \vee \mathbb{E}^n \left[\|\hat{U}(r, \boldsymbol{y}) - \hat{U}^n(r, \boldsymbol{y})\|_{TV} \big|_{\boldsymbol{y}=\hat{\boldsymbol{Y}}} \right] \\ &\quad \le \exp\{(\bar{\lambda}_1 - \underline{\lambda}_1)\, r\} \left(\frac{2\bar{\lambda}_1}{\bar{\lambda}_1 - \underline{\lambda}_1} + 1 \right) \|\mu_0^X - \mu_0^{X^n}\|_{TV}, \end{aligned} \tag{71}$$

since in this case $\|\lambda_1 - \lambda_1^n\| = 0$ and $J^n = 0$.

As far as the bounds (70) and (65) are concerned, note that if $\boldsymbol{L} = \boldsymbol{L^n}$, then the bound (70) simplifies to

$$\mathbb{E} \vee \mathbb{E}^n \left[d_{BL}\big(\hat{U}(r, \boldsymbol{y}), \hat{U}^n(r, \boldsymbol{y})\big) \big|_{\boldsymbol{y}=\hat{\boldsymbol{Y}}} \right] \le \boldsymbol{\kappa}\big(\mu_0^X, \mu_0^{X^n}\big) \big(4 L_{\lambda_1} \boldsymbol{\mathcal{E}}_1^M(r) + \boldsymbol{\mathcal{E}}_0^M(r) \big), \tag{72}$$

since in this case $\|\lambda_1 - \lambda_1^n\| = 0$ and $H^n = 0$.

Moreover, note that the constants H^n and M correspond to the constants defined in (2.9) and (2.10) of Theorem 2.1 in [8], respectively, and that the constant M can be either positive or negative; for instance, if $\Gamma_{\mu_1} < 1$, then for any $\lambda_0(x,y)$ and $\mu_0(x,y;dx')$, $M = \bar{\lambda}_0(\Gamma_{\mu_0} - 1)^+ - \underline{\lambda}_0(1 - \Gamma_{\mu_0})^+ + b_0 L_{\lambda_0} - \underline{\lambda}_1(1 - \Gamma_{\mu_1})$, and thus for $\underline{\lambda}_1$ sufficiently large, the constant M is negative. The condition that the value of $\underline{\lambda}_1$ is sufficiently large can be interpreted as the condition that the times of observation are sufficiently frequent. In this case the error evaluated in the bounded-Lipschitz metric is of the same order as the error at time zero, evaluated in the Kantorovitch metric. If instead of $\Gamma_{\mu_1} < 1$ we have $\Gamma_{\mu_1} \geq 1$ and $\Gamma_{\mu_0} < 1$, then $M = -\underline{\lambda}_0(1 - \Gamma_{\mu_0})^+ + b_0 L_{\lambda_0} + \bar{\lambda}_1(\Gamma_{\mu_1} - 1)$, and thus for $\underline{\lambda}_0$ sufficiently large, M is again negative.

Furthermore it is interesting to note that in the case of the observation of a fixed parameter, i.e., $X_t = X_0$ and $X_t^n = X_0^n$, observed at times which form a standard Poisson process independent of $\boldsymbol{X}$, we have $M = 0$ since in this case $\lambda_0(x) = \lambda_0^n(x) = 0$, $L_{\lambda_0} = 0$, $\lambda_1(x) = \lambda_1^n(x) = 1$, and $\Gamma_{\mu_1} = 1$.

Finally, note that for any $k \geq 0$ and for positive M, $\boldsymbol{\mathcal{E}}_k^M(t)$ increases to infinity exponentially fast, with $\boldsymbol{\mathcal{E}}_k^M(t) \leq \frac{t^k \exp\{tM\}}{k!}$. Hence the bounds (65) and (70) are meaningful only in a finite interval of time. When M is negative, we have that

$$\lim_{t\to\infty} \boldsymbol{\mathcal{E}}_k^M(t) = \infty \qquad \text{for } k \geq 2,$$

but the rate of convergence is polynomial (indeed, $\lim_{t\to\infty} \boldsymbol{\mathcal{E}}_k^M(t)/t^{k-1} = (k-1)!/|M|$), while

$$\lim_{t\to\infty} \boldsymbol{\mathcal{E}}_0^M(t) = \lim_{t\to\infty} e^{Mt} = 0$$

and

$$\lim_{t\to\infty} \boldsymbol{\mathcal{E}}_1^M(t) = \lim_{t\to\infty} \frac{e^{Mt} - 1}{M} = \frac{1}{|M|}.$$

Hence for negative M, though the general bounds (65) and (70) are meaningful only in a finite interval of time, when the systems differ only for the initial conditions, i.e., when $\boldsymbol{L} = \boldsymbol{L^n}$, we can use (72) and get that

$$\lim_{r\to\infty} \mathbb{E} \vee \mathbb{E}^n \Big[d_{BL}\big(\hat{U}(r,\boldsymbol{y}), \hat{U}^n(r,\boldsymbol{y})\big)\big|_{\boldsymbol{y}=\hat{\boldsymbol{Y}}} \Big] \leq \boldsymbol{\kappa}\big(\mu_0^X, \mu_0^{X^n}\big) \frac{4L_{\lambda_1}}{|M|}. \tag{73}$$

The latter result can be interpreted as a kind of stability property for the filter with respect to its initial condition. Asymptotic stability properties with respect to the Hilbert projective metric have been studied by Budhiraja and Kushner [3] in the case when $\boldsymbol{X}$ is an ergodic Markov process with generator $\boldsymbol{A}$, and the system $(\boldsymbol{X}, \boldsymbol{Y})$ is described by $\boldsymbol{L}\phi(x,y) = (\boldsymbol{A}\phi(\cdot,y))(x) + \lambda_1(x,y)[\phi(x,y+1) - \phi(x,y)]$. Their result does not require $\boldsymbol{X}$ to be a jump process; however, when this is the case simultaneous jump times of $\boldsymbol{X}$ and $\boldsymbol{Y}$ are not allowed. In order to compare their result with (73), note that on the one hand we need $\boldsymbol{X}$ to be a jump process, while on the other hand simultaneous jump times are not prohibited and we do not need $\boldsymbol{X}$ to be Markov.

The same kind of considerations hold for the next upper bounds and can be used to give upper bounds for (44) and (47).

PROPOSITION 4.4. *Under the assumptions* $(H_0), (H_1)$ *and the notation of Proposition* 4.2,

$$\begin{aligned}&\sup_{\phi\in\mathcal{K}'_{TV}(\alpha)}\sup_{x,y}|\exp\{\boldsymbol{L}t\}\phi(x,y)-\exp\{\boldsymbol{L^n}t\}\phi(x,y)|\\&\le\alpha\big(2\|\lambda_1-\lambda_1^n\|\,t+\exp\{(\bar\lambda_1-\underline{\lambda}_1)t\}(\bar\lambda_0+\bar\lambda_1)\,J^n\,B(t)\big),\end{aligned}\tag{74}$$

where

$$B(t)=2t+2\bar\lambda_1\frac{\exp\{-(\bar\lambda_1-\underline{\lambda}_1)\,t\}+(\bar\lambda_1-\underline{\lambda}_1)t-1}{(\bar\lambda_1-\underline{\lambda}_1)^2}=t+\frac{A(t)}{2}.\tag{75}$$

If furthermore the operator $\boldsymbol{L}$ *is bL-regular, assumption* (H_2) *holds, and the initial distributions* μ_0^X *and* $\mu_0^{X^n}$ *have finite first moments, then*

$$\begin{aligned}&\sup_{\phi\in\mathcal{K}'_{BL}(\alpha,\Lambda)}\sup_{x,y}|\exp\{\boldsymbol{L}t\}\phi(x,y)-\exp\{\boldsymbol{L^n}t\}\phi(x,y)|\\&\le2\alpha\big[\|\lambda_1-\lambda_1^n\|t+L_{\lambda_1}H^n\,\boldsymbol{\mathcal{E}}_2^M(t)\big]+\Lambda H^n\,\boldsymbol{\mathcal{E}}_1^M(t).\end{aligned}\tag{76}$$

The proof of the above result is given in the next subsection.

Using the results and the notation of Propositions 3.1 and 3.2, with $\alpha=1$, $\Lambda=1$, and $\Lambda'(t-r,1)=e^{M(t-r)}$ (see (52)), then using Proposition 4.2 with $\Lambda'=\Lambda'(t-r,1)$ and Proposition 4.4, we get immediately the main result of this section.

THEOREM 4.5. *Under the assumptions* (H_0) *and* (H_1)*, and the notation introduced in Propositions* 4.2 *and* 4.4,

$$\begin{aligned}&E\big[\|\pi_t-\tilde\pi_t^n\|_{TV}\big]\vee E\big[\|\pi_t^n-\overline{\pi}_t^n\|_{TV}\big]\\&\le\Big[2\|\lambda_1-\lambda_1^n\|(t+r)+\|\mu_0^X-\mu_0^{X^n}\|_{TV}\exp\{(\bar\lambda_1-\underline{\lambda}_1)\,r\}\Big(\frac{2\bar\lambda_1}{\bar\lambda_1-\underline{\lambda}_1}+1\Big)\\&\quad+(\bar\lambda_0+\bar\lambda_1)J^n\big(\exp\{(\bar\lambda_1-\underline{\lambda}_1)\,r\}A(r)+\exp\{(\bar\lambda_1-\underline{\lambda}_1)\,(t-r)\}B(t-r)\big)\Big]_{r=a(t)}.\end{aligned}\tag{77}$$

Furthermore assume (H_2)*, the bL-regularity of* $\boldsymbol{L}$*, and that the initial distributions* μ_0^X *and* $\mu_0^{X^n}$ *have finite first moments. Then*

$$\begin{aligned}&E\big[d_{BL}(\pi_t,\tilde\pi_t^n)\big]\vee E\big[d_{BL}(\pi_t^n,\overline{\pi}_t^n)\big]\\&\le4\big[\|\lambda_1-\lambda_1^n\|r+L_{\lambda_1}H^n\,\boldsymbol{\mathcal{E}}_2^M(r)\big]+\exp\{M(t-r)\}H^n\,\boldsymbol{\mathcal{E}}_1^M(r)\\&\qquad+\boldsymbol{\kappa}\big(\mu_0^X,\mu_0^{X^n}\big)\big(4L_{\lambda_1}\boldsymbol{\mathcal{E}}_1^M(r)+\boldsymbol{\mathcal{E}}_0^M(t)\big)\\&\qquad+2\big(\|\lambda_1-\lambda_1^n\|(t-r)+L_{\lambda_1}H^n\,\boldsymbol{\mathcal{E}}_2^M(t-r)\big)+H^n\,\boldsymbol{\mathcal{E}}_1^M(t-r)\big|_{r=a(t)}.\end{aligned}\tag{78}$$

To conclude this section we work out an example highlighting the bounds in (78) by using a particular case of the model considered in Remark 2.5 in [8].

Example. Assume that the measures $\mu_i(x,y,\cdot)$ are Gaussian with mean $m_i(x,y)$ and variance $\sigma_i^2(x,y)$, and that the functions $\lambda_i(z,y)$, $m_i(z,y)$, and $\sigma_i(z,y)$ are Lipschitz in z, uniformly in y, with Lipschitz constant L_{λ_i}, L_{m_i} and L_{σ_i}, respectively. We assume also that the functions $\lambda_i(z,y)$, $\sigma_0(z,y)$, and $\mathsf{m}_0(z,y):=m_0(z,y)-z$ are uniformly bounded by $\overline{\lambda}_i$, $\overline{\sigma}_0$, and $\overline{\mathsf{m}}_0$, respectively, and that $\sigma_1(0,y)\le\mathsf{K}_1^\sigma(y+1)$ and $|m_1(0,y)|\le\mathsf{K}_1^m(y+1)$.

Then conditions (R_0), (R_1), and (R_2) are satisfied with

$$\Gamma_{\mu_i}=\sqrt{\tfrac{2}{\pi}}\,L_{\sigma_i}+L_{m_i},$$

$$b_0 = \overline{\sigma}_0 + \overline{\mathsf{m}}_0,\ b_1 = \mathsf{K}_1^{\sigma} + \mathsf{K}_1^{m},\ \text{and } a_1 = (L_{\sigma_1} + L_{m_1}) \vee b_1,$$

as can be easily deduced by the assumptions, the upper bound

$$\begin{aligned}\boldsymbol{\kappa}\big(\mu_i(x,y;\cdot),\mu_i(x',y;\cdot)\big) &\le \sqrt{\tfrac{2}{\pi}}\,|\sigma_i(x,y)-\sigma_i(x',y)| + |m_i(x,y)-m_i(x',y)| \\ &\le \left(\sqrt{\tfrac{2}{\pi}}\,L_{\sigma_i} + L_{m_i}\right)|x-x'|,\end{aligned}$$

and the bound

$$\begin{aligned}\int_{\mathbb{R}} |z-x|\,\mu_i(x,y;dz) &\le \int_{\mathbb{R}} |z-m_i(x,y)|\,\mu_i(x,y;dz) + \int_{\mathbb{R}} |m_i(x,y)-x|\,\mu_i(x,y;dz) \\ &\le \sigma_i(x,y) + |m_i(x,y)-x|.\end{aligned}$$

As far as the approximating process is concerned, we define

$$\lambda_i^n(x,y) = \lambda\left(\tfrac{\lfloor nx\rfloor}{n}, y\right), \quad \mu_i^n(x,y;A) := \mathcal{T}^n\mu_i\left(\tfrac{\lfloor nx\rfloor}{n}, y; A\right), \quad \text{and} \quad \pi_0^n(A) = \mathcal{T}^n\pi_0(A),$$

where, for any probability measure ν,

$$\mathcal{T}^n\nu(A) = \sum_k \nu\left(\left[\tfrac{k}{n}, \tfrac{k+1}{n}\right)\right)\,\delta_{\{\frac{k}{n}\}}(A).$$

Then condition (H_0) is obviously satisfied, condition (H_1) is satisfied if we assume furthermore that $\lambda_1(x,y)$ is strictly positive, and finally, condition (H_2) is satisfied with

$$\Delta_i^n = \left(\sqrt{\tfrac{2}{\pi}}\,L_{\sigma_i} + L_{m_i} + 1\right)\tfrac{1}{n}$$

since $\boldsymbol{\kappa}(\nu, \mathcal{T}^n\nu) \le \frac{1}{n}$, and thus

$$\begin{aligned}\boldsymbol{\kappa}(\mu_i(x,y;\cdot),\mu_i^n(x,y;\cdot)) &\le \boldsymbol{\kappa}\left(\mu_i(x,y;\cdot),\mu_i\left(\tfrac{\lfloor nx\rfloor}{n},y;\cdot\right)\right) \\ &\quad + \boldsymbol{\kappa}\left(\mu_i\left(\tfrac{\lfloor nx\rfloor}{n},y;\cdot\right),\mathcal{T}^n\mu_i\left(\tfrac{\lfloor nx\rfloor}{n},y;\cdot\right)\right) \\ &\le \left(\sqrt{\tfrac{2}{\pi}}\,L_{\sigma_i} + L_{m_i} + 1\right)\tfrac{1}{n}.\end{aligned}$$

Then $E\big[d_{BL}(\pi_t,\tilde{\pi}_t^n)\big]$ and $E\big[d_{BL}(\pi_t^n,\overline{\pi}_t^n)\big]$ are of order $\frac{1}{n}$, since the quantities involved in the upper bound (78) are of order $\frac{1}{n}$. Indeed,

$$\|\lambda_i - \lambda_i^n\| \le L_{\lambda_i}\,\tfrac{1}{n}, \quad \boldsymbol{\kappa}(\pi_0,\pi_0^n) \le \tfrac{1}{n},$$

and finally, recalling (66) and the previously obtained upper bounds,

$$H^n \le \left[\bar{\lambda}_0\left(\sqrt{\tfrac{2}{\pi}}\,L_{\sigma_0} + L_{m_0} + 1\right) + (\overline{\sigma}_0 + \overline{\mathsf{m}}_0)\,L_{\lambda_0} + \bar{\lambda}_1\left(\sqrt{\tfrac{2}{\pi}}\,L_{\sigma_1} + L_{m_1} + 1\right)\right]\,\tfrac{1}{n}.$$

4.2. Proofs of Propositions 4.2 and 4.4. Using the construction of the triplet $(\boldsymbol{X}, \boldsymbol{X^n}, \hat{\boldsymbol{Y}})$, it is easy to prove the following auxiliary results. In the first two results we need the processes

$$N_0(t) = \mathcal{N}_0\big((0,t] \times [0, \bar{\lambda}_0]\big), \quad N_1(t) = \mathcal{N}_1\big((0,t] \times [0,1]\big),$$

which are independent Poisson processes under $\mathbb{Q}$, with parameter $\bar{\lambda}_0$ and 1, respectively.

PROPOSITION 4.6. *If the assumptions* $(\mathrm{H}_0), (\mathrm{H}_1)$ *hold and if the initial conditions* (X_0, X_0^n) *in* (55) *and* (56) *are coupled in such a way that* $\mathbb{Q}(X_0 \neq X_0^n) = \|\mu_0^X - \mu_0^{X^n}\|_{TV}/2$ *(see, e.g.,* [8]*), then*

$$\mathbb{P} \vee \mathbb{P}^n\big(X_t \neq X_t^n\big) \leq \exp\{(\bar{\lambda}_1 - \underline{\lambda}_1)\, t\}\big(\|\mu_0^X - \mu_0^{X^n}\|_{TV}/2 + (\bar{\lambda}_0 + \bar{\lambda}_1)\, t J^n\big),$$

where the constant J^n *has been introduced in* (62) *of Proposition* 4.2.

Proof. To get a bound for $\mathbb{P} \vee \mathbb{P}^n(X_t \neq X_t^n)$, observe that

$$\mathbb{P}\big(X_t \neq X_t^n\big) = \mathbb{E}^{\mathbb{Q}}\big[(d\mathbb{P}/d\mathbb{Q})|_{\mathcal{F}_t^{X, X^n, \hat{Y}}}\, \mathbb{I}_{\{X_t \neq X_t^n\}}\big]$$

and that

$$\begin{aligned}
(d\mathbb{P}/d\mathbb{Q})|_{\mathcal{F}_t^{X,X^n,\hat{Y}}} &= \exp\left\{\int_0^t \log\big(\lambda_1(X_{s^-}, \hat{Y}_{s^-})\big) d\hat{Y}_s - \int_0^t \big(\lambda_1(X_{s^-}, \hat{Y}_{s^-}) - 1\big) ds\right\} \\
&= \exp\left\{\int_0^t \log\big(\lambda_1(X_{s^-}, \hat{Y}_{s^-})\big) dN_1(s) - \int_0^t \big(\lambda_1(X_{s^-}, \hat{Y}_{s^-}) - 1\big) ds\right\} \\
&\leq \big(\bar{\lambda}_1\big)^{N_1(t)} \exp\{-(\underline{\lambda}_1 - 1)t\}.
\end{aligned}$$

As a consequence,

$$\mathbb{P}\big(X_t \neq X_t^n\big) \leq \mathbb{E}^{\mathbb{Q}}\big[\,\big(\bar{\lambda}_1\big)^{N_1(t)}\, \mathbb{I}_{\{X_t \neq X_t^n\}}\big] \exp\{-(\underline{\lambda}_1 - 1)t\}. \tag{79}$$

In a similar way we prove that

$$\mathbb{P}^n\big(X_t \neq X_t^n\big) \leq \mathbb{E}^{\mathbb{Q}}\big[\,\big(\bar{\lambda}_1\big)^{N_1(t)}\, \mathbb{I}_{\{X_t \neq X_t^n\}}\big] \exp\{-(\underline{\lambda}_1 - 1)t\}. \tag{80}$$

The result then follows immediately from the next lemma, which is proved in the appendix. □

LEMMA 4.7. *Under the hypotheses and notation of Proposition* 4.6*,*

$$\mathbb{E}^{\mathbb{Q}}\big[\,\big(\bar{\lambda}_1\big)^{N_1(t)}\, \mathbb{I}_{\{X_t \neq X_t^n\}}\big] \leq \exp\{(\bar{\lambda}_1 - 1)\, t\}\big(\|\mu_0^X - \mu_0^{X^n}\|_{TV}/2 + (\bar{\lambda}_0 + \bar{\lambda}_1)\, t J^n\big). \tag{81}$$

The following result plays a key role in our analysis in order to get the upper bounds when dealing with the bounded-Lipschitz metric.

PROPOSITION 4.8. *If the operator* $\boldsymbol{L}$ *is bL-regular, the hypotheses* (H_0)–(H_2) *hold, and if the initial conditions* (X_0, X_0^n) *in* (55) *and* (56) *have finite first moments and are coupled in such a way that* $\mathbb{E}_Q\big[\big|X_0 - X_0^n\big|\big] = \boldsymbol{\kappa}(\mu_0^X, \mu_0^{X^n})$ *(see, e.g.,* [8]*), then*

$$\mathbb{E} \vee \mathbb{E}^n\big[\,|X_t - X_t^n|\,\big] \leq \boldsymbol{\kappa}\big(\mu_0^X, \mu_0^{X^n}\big)\boldsymbol{\mathcal{E}}_0^M(t) + H^n \boldsymbol{\mathcal{E}}_1^M(t)$$

where the constants H^n*,* M *and the functions* $\boldsymbol{\mathcal{E}}_k^M$ *are as introduced in Proposition* 4.2.

Proof. The proof of this result is the same as the proof of Lemma 5.1 in [8], with obvious changes in the notation; in particular we have to substitute $\tilde{X}$ with X^n. Indeed, as in that proof, one can show

$$\mathbb{E}\big[|X_t - X_t^n|\big] \le \mathbb{E}\big[|X_0 - X_0^n|\big] + \int_0^t \mathbb{E}\big[H + M|X_s - X_s^n|\big]ds$$

and a similar inequality with respect to $\mathbb{E}^n$. Then the statement follows by the Gronwall inequality. We note also that there was a mistake in the statement of Lemma 5.1 of [8], and this result corrects it. □

As a consequence of Proposition 4.8 we get immediately that the class of bounded functions ψ, which are Lipschitz in x for all y, uniformly in y, is invariant under the action of the semigroup $\exp\{\boldsymbol{L}t\}$.

COROLLARY 4.9. *Let $\boldsymbol{L}$ be a bL-regular operator, with λ_i, $i = 0, 1$, satisfying hypotheses* (H_0) *and* (H_1)*, and let ψ be a measurable bounded function such that, for all x, x', y, $|\psi(x,y) - \psi(x',y)| \le L_\psi|x - x'|$.*

Then

$$|\exp\{\boldsymbol{L}t\}\psi(x,y) - \exp\{\boldsymbol{L}t\}\psi(x',y)| \le e^{Mt}L_\psi|x - x'| \qquad \textit{for all } x, x', y,$$

and

$$\exp\{\boldsymbol{L}t\}\big(K'(\alpha,\Lambda)\big) \subseteq K'(\alpha, e^{Mt}\Lambda).$$

Proof. Assume that $\boldsymbol{L^n} = \boldsymbol{L}$, and thus $H^n = 0$, and assume that $\mu_0^X = \delta_{\{x\}}$, $\mu_0^{X^n} = \delta_{\{x'\}}$, and thus $\boldsymbol{\kappa}(\mu_0^X, \mu_0^{X^n}) = |x - x'|$. Then

$$\begin{aligned}|\exp\{\boldsymbol{L}t\}\psi(x,y) - \exp\{\boldsymbol{L}t\}\psi(x',y)| &= \Big|\mathbb{E}\big[\psi(X_t, \hat{Y}_t)\big] - \mathbb{E}\big[\psi(X_t^n, \hat{Y}_t)\big]\Big| \\ &\le L_\psi\mathbb{E}[|X_t - X_t^n|],\end{aligned}$$

and, observing that (H_2) is trivially satisfied and that $\boldsymbol{\mathcal{E}}_0^M(t) = e^{Mt}$, Proposition 4.8 implies the result.

The second statement is an immediate consequence of the first one. □

Remark 4.10. We note that the boundedness condition on the function ψ is not necessary and that we could ask for a bound of the kind $|\psi(x,y)| \le A(|x| + y) + B$; indeed, under the conditions of Corollary 4.9, $\exp(\boldsymbol{L}t)\psi(x,y)$ is finite for any ψ Lipschitz in x uniformly in y. In Proposition 4.8 the condition on the first moments of (X_0, X_0^n) guarantees the integrability of (X_t, X_t^n) for all $t \ge 0$, and when $(X_0, X_0^n) = (x, x')$ this condition is obviously satisfied and implies that $\exp(\boldsymbol{L}t)\psi(x,y) = \mathbb{E}\big[\psi(X_t, \hat{Y}_t)\big]$ is finite for all such functions which are Lipschitz in x uniformly in y.

Proof of Proposition 4.2. In order to get the first estimate, we can use the first part of Theorem 2.9, with $(\boldsymbol{X}, \boldsymbol{X^n}, \hat{\boldsymbol{Y}})$ and r instead of $(\tilde{\boldsymbol{X}}, \tilde{\boldsymbol{X}}^{\boldsymbol{n}}, \tilde{\boldsymbol{Y}})$ and t, and get that (60) is bounded above by

$$2\alpha \max\big(\mathbb{E}[\hat{\mathcal{Z}}_r] + \mathbb{P}(X_r \ne X_r^n)\,;\, \mathbb{E}^n[\hat{\mathcal{Z}}_r^n] + \mathbb{P}^n(X_r \ne X_r^n)\big),$$

where $\hat{\mathcal{Z}}_r$ and $\hat{\mathcal{Z}}_r^n$ are defined as $\mathcal{Z}_r$ and $\mathcal{Z}_r^n$, with obvious changes. Using Remark 2.4 we get that $\mathbb{E}[\hat{\mathcal{Z}}_r]$ and $\mathbb{E}^n[\hat{\mathcal{Z}}_r^n]$ are equal to

$$\mathbb{E}^n\left[\left|\frac{d\mathbb{P}}{d\mathbb{P}^n}\Big|_{\mathcal{F}_t^{X,X^n,\hat{Y}}} - 1\right|\right] = \mathbb{E}\left[\left|\frac{d\mathbb{P}^n}{d\mathbb{P}}\Big|_{\mathcal{F}_t^{X,X^n,\hat{Y}}} - 1\right|\right].$$

Therefore, by (59), (60) is bounded above by

$$2\alpha\Big(2\int_0^r \mathbb{E}\vee\mathbb{E}^n\left[\left|\lambda_1(X_s,\hat{Y}_s)-\lambda_1^n(X_s^n,\hat{Y}_s)\right|\right]ds+\mathbb{P}\vee\mathbb{P}^n(X_r\neq X_r^n)\Big)$$
$$\leq 4\alpha\int_0^r\left(\|\lambda_1-\lambda_1^n\|+\bar{\lambda}_1\mathbb{P}\vee\mathbb{P}^n\left(X_s\neq X_s^n\right)\right)ds+2\alpha\,\mathbb{P}\vee\mathbb{P}^n\left(X_r\neq X_r^n\right).$$

The thesis is achieved by applying Proposition 4.6.

To obtain the second estimate, we can use the second part of Theorem 2.9, again with $(\boldsymbol{X},\boldsymbol{X^n},\hat{\boldsymbol{Y}})$ and r instead of $(\tilde{\boldsymbol{X}},\tilde{\boldsymbol{X}}^{\boldsymbol{n}},\tilde{\boldsymbol{Y}})$ and t, and get that (65) is bounded above by

$$\max\left(2\alpha\,\mathbb{E}[\hat{\mathcal{Z}}_r]+\Lambda\mathbb{E}(|X_r-X_r^n|)\,;\,2\alpha\,\mathbb{E}^n[\hat{\mathcal{Z}}_r^n]+\Lambda\,\mathbb{E}^n(|X_r-X_r^n|)\right).$$

Therefore, by (59), (65) is bounded above by

$$4\alpha\int_0^r \mathbb{E}\vee\mathbb{E}^n\left[\left|\lambda_1(X_s,\hat{Y}_s)-\lambda_1^n(X_s^n,\hat{Y}_s)\right|\right]ds+\Lambda\,\mathbb{E}\vee\mathbb{E}^n[|X_r-X_r^n|]$$
$$\leq 4\alpha\int_0^r\left(\|\lambda_1-\lambda_1^n\|+L_{\lambda_1}\mathbb{E}\vee\mathbb{E}^n\left[|X_s-X_s^n|\right]\right)ds+\Lambda\,\mathbb{E}\vee\mathbb{E}^n\left[|X_r-X_r^n|\right].$$

The thesis is achieved by applying Proposition 4.8 and using the fact that $\boldsymbol{\mathcal{E}}_{k+1}^M(r)=\int_0^r\boldsymbol{\mathcal{E}}_k^M(s)\,ds$. □

The upper bounds in Proposition 4.4 are similar to the upper bounds in Proposition 4.2, and the last fact is due to the similarity in the proof: the main changes from the proof of Proposition 4.2 consist in using Proposition 2.11 instead of Theorem 2.9 and in taking initial distributions $\mu_0^X=\mu_0^{X^n}=\delta_x$.

Remark 4.11. When the first moments are not finite the result of Proposition 4.8 cannot be used. However, we can prove that

$$\mathbb{E}\vee\mathbb{E}^n\left[\,|X_t-X_t^n|\wedge 1\right]\leq d_{BL}\big(\mu_0^X,\mu_0^{X^n}\big)\boldsymbol{\mathcal{E}}_0^{\bar{M}}(t)+\bar{H}^n\boldsymbol{\mathcal{E}}_1^{\bar{M}}(t), \tag{82}$$

where $\bar{M}=(M_0)^+ + \bar{\lambda}_1(\Gamma_{\mu_1}-1)^+$ and $\bar{H}^n=H_0^n\wedge\bar{\lambda}_0+\bar{\lambda}_1(\Delta_1^n\wedge 1)$, with $H_0^n=\bar{\lambda}_0\Delta_0^n+\|\lambda_0-\lambda_0^n\|b_0$ and $M_0=\bar{\lambda}_0(\Gamma_{\mu_0}-1)^+-\underline{\lambda}_0(1-\Gamma_{\mu_0})^+ + b_0L_{\lambda_0}$. Indeed, using the same techniques as in the proofs of Lemma 5.1 in [8] and Lemma 4.3 in [7] when setting $g_1(x,x')=|x-x'|\wedge 1$ we get

$$\begin{aligned}\mathbb{L}g_1(x,x')\leq{}&\big(H_0^n+M_0|x-x'|+\bar{\lambda}_0|x-x'|\big)\wedge\bar{\lambda}_0-\bar{\lambda}_0(|x-x'|\wedge 1)\\&+\lambda_1(x,y)\left[(\Delta_1^n+\Gamma_{\mu_1}|x-x'|)\wedge 1-|x-x'|\wedge 1\right].\end{aligned}$$

Then taking into account that $M_0+\bar{\lambda}_0\geq 0$, and that if $a,b,\lambda\geq 0$, then $(a+b)\wedge\lambda\leq a\wedge\lambda+b\wedge\lambda$ and $(ab)\wedge\lambda\leq(a\vee\lambda)(b\wedge 1)$, we have

$$\begin{aligned}\mathbb{L}g_1(x,x')&\leq H_0^n\wedge\bar{\lambda}_0+\big((M_0+\bar{\lambda}_0)\vee\bar{\lambda}_0\big)(|x-x'|\wedge 1)-\bar{\lambda}_0(|x-x'|\wedge 1)\\&\quad+\lambda_1(x,y)\big[\Delta_1^n\wedge 1+(\Gamma_{\mu_1}\vee 1)(|x-x'|\wedge 1)-(|x-x'|\wedge 1)\big]\\&=H_0^n\wedge\bar{\lambda}_0+\lambda_1(x,y)(\Delta_1^n\wedge 1)+\big((M_0)^+ +\lambda_1(x,y)(\Gamma_{\mu_1}-1)^+\big)(|x-x'|\wedge 1)\\&\leq\bar{H}^n+\bar{M}(|x-x'|\wedge 1).\end{aligned}$$

Therefore, when the hypothesis on the first moments does not hold, taking into account (82) and the estimates in Remarks 2.5, 2.10, and 2.12, the upper bound (78) of Theorem 4.5 remains valid with minor changes in the constants and by substituting M and H^n with $\bar{M}$ and $\bar{H}^n$, respectively.

Appendix: Proof of Lemma 4.7. In order to prove (81) it is sufficient to prove that

$$\mathbb{E}^{\mathbb{Q}}\big[\,(\bar\lambda_1)^{N_1(t)}\,\mathbb{I}_{\{X_t\neq X_t^n\}}\big] \le \mathbb{E}^{\mathbb{Q}}\big[\,(\bar\lambda_1)^{N_1(t)}\,\big]\|\mu_0^X-\mu_0^{X^n}\|_{TV}/2 + \mathbb{E}^{\mathbb{Q}}\big[\big(N_0(t)+N_1(t)\big)\,(\bar\lambda_1)^{N_1(t)}\,\big]\,J^n. \tag{83}$$

Indeed the r.h.s. of (83) is equal to the r.h.s. of (81), since $\boldsymbol{N_0}$ and $\boldsymbol{N_1}$ are independent under $\mathbb{Q}$ and for any Poisson process $M(t)$ of parameter ρ, and for any $a>0$, it holds that $\mathbb{E}[M(t)]=\rho\,t$, $\mathbb{E}\big[a^{M(t)}\big]=\exp\{\rho(a-1)t\}$, $\mathbb{E}\big[M(t)\,a^{M(t)}\big]=\rho a\,t\exp\{\rho(a-1)t\}$.

Let T_k denote the jump times of the Poisson process $N(t)=N_0(t)+N_1(t)$, where we recall that $N_0(t)=\mathcal{N}_0\big([0,\bar\lambda_0]\times(0,t]\big)$ and $N_1(t)=\mathcal{N}_1\big([0,1]\times(0,t]\big)$. Then the processes defined by (55), (56), and (57), i.e.,

$$\big(X_t,X_t^n,\hat Y_t\big)=\big(X_t,X_t^n,y+N_1(t)\big),$$

are obtained as a Markov chain $(\eta_k,\eta_k^n,\hat y_k)$ evaluated at time $k=N(t)$, and thus $(\eta_k,\eta_k^n,\hat y_k)=(X_{T_k},X^n_{T_k},\hat Y_{T_k})$. Moreover, the Markov chain and the Poisson process $\{N(t),t>0\}$ are independent.

Let $S\in\{T_h,\,h\ge0\}$ be the first time when $\{X_t\neq X_t^n\}$; then

$$\begin{aligned}
&\mathbb{E}^{\mathbb{Q}}\big[(\bar\lambda_1)^{N_1(t)}\mathbb{I}_{\{X_t\neq X_t^n\}}\big] \le \mathbb{E}^{\mathbb{Q}}\big[(\bar\lambda_1)^{N_1(t)}\mathbb{I}_{\{S\le t\}}\big]\\
&\quad=\mathbb{E}^{\mathbb{Q}}\big[(\bar\lambda_1)^{N_1(t)}\mathbb{I}_{\{X_0\neq X_0^n\}}\big]+\sum_{k=1}^{\infty}\mathbb{E}^{\mathbb{Q}}\left[\mathbb{I}_{\{N(t)=k\}}\sum_{h=1}^{k}(\bar\lambda_1)^{\hat Y_t-y}\mathbb{I}_{\{S=T_h\}}\right]\\
&\quad=\mathbb{E}^{\mathbb{Q}}\big[(\bar\lambda_1)^{N_1(t)}\big]\mathbb{Q}(X_0\neq X_0^n)+\sum_{k=1}^{\infty}\sum_{h=1}^{k}\mathbb{E}^{\mathbb{Q}}\big[\mathbb{I}_{\{N(t)=k\}}(\bar\lambda_1)^{\hat y_k-y}\mathbb{I}_{\{\eta_h\neq\eta_h^n,\,\eta_l=\eta_l^n,\,l\le h-1\}}\big].
\end{aligned} \tag{84}$$

The first addend is equal to the first addend in the r.h.s. of inequality (83), since $\mathbb{Q}(X_0\neq X_0^n)=\|\mu_0^X-\mu_0^{X^n}\|_{TV}/2$. Moreover, for any k and $1\le h\le k$, we have

$$\begin{aligned}
&\mathbb{E}^{\mathbb{Q}}\big[\mathbb{I}_{\{N(t)=k\}}\big(\bar\lambda_1\big)^{\hat y_k-y}\mathbb{I}_{\{\eta_h\neq\eta_h^n,\,\eta_l=\eta_l^n,\,l\le h-1\}}\big]\\
&\quad=\mathbb{Q}(N(t)=k)\,\mathbb{E}^{\mathbb{Q}}\big[\big(\bar\lambda_1\big)^{\hat y_k-y}\mathbb{I}_{\{\eta_h\neq\eta_h^n,\,\eta_l=\eta_l^n,\,l\le h-1\}}\big],
\end{aligned}$$

since under $\mathbb{Q}$ the Poisson process $N(t)$ and the Markov chain $(\eta_k,\eta_k^n,\hat y_k)$ are independent.

Therefore, according to Lemma A.1 below, the second addend in the last line of (84) is bounded above by

$$\begin{aligned}
&\sum_{k=1}^{\infty}\mathbb{Q}(N(t)=k)\,k\,\mathbb{E}^{\mathbb{Q}}\big[\big(\bar\lambda_1\big)^{\hat y_k-y}\big]\;J^n\\
&=\sum_{k=1}^{\infty}\mathbb{E}^{\mathbb{Q}}\big[\mathbb{I}_{\{N(t)=k\}}\,k\,\big(\bar\lambda_1\big)^{\hat y_k-y}\,\big]\;J^n=\mathbb{E}^{\mathbb{Q}}\big[N(t)\,\big(\bar\lambda_1\big)^{N_1(t)}\,\big]\;J^n,
\end{aligned}$$

and this ends the proof of inequality (83).

LEMMA A.1. *For any $k\ge1$ and $1\le h\le k$,*

$$\mathbb{E}^{\mathbb{Q}}\big[\,\big(\bar\lambda_1\big)^{\hat y_k-y}\,\mathbb{I}_{\{\eta_h\neq\eta_h^n,\,\eta_l=\eta_l^n,\,l\le h-1\}}\,\big]\le\mathbb{E}^{\mathbb{Q}}\big[\,\big(\bar\lambda_1\big)^{\hat y_k-y}\,\big]\;J^n. \tag{85}$$

To prove this inequality we need the following technical result.

LEMMA A.2. *Under the hypotheses and notation of Proposition* 4.6, *the following upper bound holds for any* $a > 0$*:*

$$\begin{aligned}
&\mathbb{E}^{\mathbb{Q}}\big[a^{\hat{y}_{k+1}-\hat{y}_k}\mathbb{I}_{\{\eta_{k+1}\neq\eta^n_{k+1}\}}|\eta_k = z, \eta^n_k = z, \hat{y}_k = w\big] \\
&\quad = a^1\,\frac{1}{1+\bar{\lambda}_0}\|\mu_1(z,w,\cdot) - \mu^n_1(z,w,\cdot)\|_{TV}/2 \qquad (86)\\
&\qquad\quad + a^0\,\frac{\bar{\lambda}_0}{1+\bar{\lambda}_0}\|p_0(z,w,\cdot) - p^n_0(z,w,\cdot)\|_{TV}/2 \\
&\quad \le \mathbb{E}^{\mathbb{Q}}\big[a^{\hat{y}_{k+1}-\hat{y}_k}\big]\max(\|p_0 - p^n_0\|_\infty, \|\mu_1 - \mu^n_1\|_\infty)/2. \qquad (87)
\end{aligned}$$

Proof. Without loss of generality, we can assume that $\mathcal{N}_0 = \{(T^0_k, \zeta^0_k), k \ge 1\}$ is the restriction to $(0,\infty)\times(0,\bar{\lambda}_0]$ of a Poisson measure $\mathcal{N} = \{(T_k,\zeta_k), k \ge 1\}$ on $(0,\infty)\times(-1,\bar{\lambda}_0]$. Moreover, if $\overline{\mathcal{N}}_1 = \{(\bar{T}^1_k, \bar{\zeta}^1_k), k \ge 1\}$ is the restriction of $\mathcal{N}$ to $(0,\infty)\times(-1,0]$, we can assume that $\mathcal{N}_1 = \{(T^1_k,\zeta^1_k), k \ge 1\}$ is obtained by taking $(T^1_k,\zeta^1_k) = (\bar{T}^1_k, -\bar{\zeta}^1_k)$.

We recall that under $\mathbb{Q}$ the processes

$$\big(X_t, X^n_t, \hat{Y}_t\big) = \big(X_t, X^n_t, y + N_1(t)\big)$$

are constructed by defining K_0, K^n_0, K_1, and K^n_1 as explained in Definition 3.8 of [8]; that is, K_0 and K^n_0 are defined by means of Lemma 3.7 of [8] using the measures $p_0(x,y;dx')$ and $p^n_0(x,y;dx')$ defined by (63) and (64), respectively, while K_1 and K^n_1 are defined using the measures $\mu_1(x,y;dz)$ and $\mu^n_1(x,y;dz)$.

Equality (86) can be derived as follows:

$$\begin{aligned}
&\mathbb{E}^{\mathbb{Q}}\big[a^{\hat{y}_{k+1}-\hat{y}_k}\mathbb{I}_{\{\eta_{k+1}\neq\eta^n_{k+1}\}}|\ \eta_k = z, \eta^n_k = z, \hat{y}_k = w\big] \\
&\quad = \mathbb{E}^{\mathbb{Q}}\big[a^1\,\mathbb{I}_{\{\zeta_{k+1}\in(-1,0]\}}\,\mathbb{I}_{\{K_1(z,z,w;-\zeta_{k+1})\neq K^n_1(z,z,w;-\zeta_{k+1})\}}\big] \\
&\qquad + \mathbb{E}^{\mathbb{Q}}\big[a^0\,\mathbb{I}_{\{\zeta_{k+1}\in(0,\bar{\lambda}_0]\}}\,\mathbb{I}_{\{K_0(z,z,w;\zeta_{k+1})\neq K^n_0(z,z,w;\zeta_{k+1})\}}\big] \\
&\quad = a^1\mathbb{Q}(\zeta_{k+1}\in(-1,0], K_1(z,z,w;-\zeta_{k+1}) \neq K^n_1(z,z,w;-\zeta_{k+1})) \\
&\qquad + a^0\mathbb{Q}(\zeta_{k+1}\in(0,\bar{\lambda}_0], K_0(z,z,w;\zeta_{k+1}) \neq K^n_0(z,z,w;\zeta_{k+1})) \\
&\quad = a^1\,\frac{1}{1+\bar{\lambda}_0}\int_0^1 \mathbb{I}_{\{u:\,K_1(z,z,w;u)\neq K^n_1(z,z,w;u)\}}(v)\,dv \\
&\qquad + a^0\,\frac{\bar{\lambda}_0}{1+\bar{\lambda}_0}\int_0^{\bar{\lambda}_0} \mathbb{I}_{\{u:\,K_0(z,z,w;u)\neq K^n_0(z,z,w;u)\}}(v)\,\frac{dv}{\bar{\lambda}_0} \\
&\quad = a^1\,\frac{1}{1+\bar{\lambda}_0}\|\mu_1(z,w,\cdot) - \mu^n_1(z,w,\cdot)\|_{TV}/2 \\
&\qquad + a^0\,\frac{\bar{\lambda}_0}{1+\bar{\lambda}_0}\|p_0(z,w,\cdot) - p^n_0(z,w,\cdot)\|_{TV}/2,
\end{aligned}$$

where the last equality is due to the specific choice of K_0, K^n_0, K_1, and K^n_1. Observing that

$$a^1\,\frac{1}{1+\bar{\lambda}_0} + a^0\,\frac{\bar{\lambda}_0}{1+\bar{\lambda}_0} = \mathbb{E}^{\mathbb{Q}}\big[a^{\hat{y}_{k+1}-\hat{y}_k}\big],$$

we see that inequality (87) is an immediate consequence of (86). ∎

Proof of Lemma A.1. We observe that

$$\begin{aligned}
&\mathbb{E}^{\mathbb{Q}}\big[\,\big(\bar\lambda_1\big)^{\hat y_k - y}\,\mathbb{I}_{\{\eta_h\neq\eta_h^n,\,\eta_l=\eta_l^n,\,l\le h-1\}}\big]\\
&=\mathbb{E}^{\mathbb{Q}}\big[\,\big(\bar\lambda_1\big)^{\hat y_h - y}\;\mathbb{I}_{\{\eta_h\neq\eta_h^n,\,\eta_l=\eta_l^n,\,l\le h-1\}}\;\mathbb{E}^{\mathbb{Q}}\big[\,\big(\bar\lambda_1\big)^{\hat y_k-\hat y_h}\;\big|\mathcal{F}_h^{\eta,\eta^n,\hat y}\big]\big]\\
&=\mathbb{E}^{\mathbb{Q}}\big[\,\big(\bar\lambda_1\big)^{\hat y_h - y}\;\mathbb{I}_{\{\eta_h\neq\eta_h^n,\,\eta_l=\eta_l^n,\,l\le h-1\}}\;\big]\mathbb{E}^{\mathbb{Q}}\big[\,\big(\bar\lambda_1\big)^{\hat y_k-\hat y_h}\,\big]\\
&\le\mathbb{E}^{\mathbb{Q}}\big[\,\big(\bar\lambda_1\big)^{\hat y_h - y}\;\mathbb{I}_{\{\eta_h\neq\eta_h^n,\,\eta_{h-1}=\eta_{h-1}^n\}}\;\big]\mathbb{E}^{\mathbb{Q}}\big[\,\big(\bar\lambda_1\big)^{\hat y_k-\hat y_h}\,\big].
\end{aligned}$$

Then (85) follows, taking into account that

$$\begin{aligned}
&\mathbb{E}^{\mathbb{Q}}\big[\,\big(\bar\lambda_1\big)^{\hat y_h - y}\;\mathbb{I}_{\{\eta_h\neq\eta_h^n,\,\eta_{h-1}=\eta_{h-1}^n\}}\,\big]\\
&=\mathbb{E}^{\mathbb{Q}}\big[\mathbb{I}_{\{\eta_{h-1}=\eta_{h-1}^n\}}\;\big(\bar\lambda_1\big)^{\hat y_{h-1} - y}\,\mathbb{E}^{\mathbb{Q}}\big[\,\big(\bar\lambda_1\big)^{\hat y_h-\hat y_{h-1}}\;\mathbb{I}_{\{\eta_h\neq\eta_h^n\}}\;\big|\mathcal{F}_{h-1}^{\eta,\eta^n,\hat y}\big]\big]\\
&=\mathbb{E}^{\mathbb{Q}}\big[\,\big(\bar\lambda_1\big)^{\hat y_{h-1} - y}\,\mathbb{I}_{\{\eta_{h-1}=\eta_{h-1}^n\}}\;\mathbb{E}^{\mathbb{Q}}\big[\,\big(\bar\lambda_1\big)^{\hat y_h-\hat y_{h-1}}\;\mathbb{I}_{\{\eta_h\neq\eta_h^n\}}\;\big|\eta_{h-1},\eta_{h-1}^n,\hat y_{h-1}\big]\big],
\end{aligned}$$

and that, using inequality (87) of Lemma A.2, with $a=\bar\lambda_1$, the above quantity is bounded above by

$$\begin{aligned}
&\mathbb{E}^{\mathbb{Q}}\big[(\bar\lambda_1)^{\hat y_{h-1}-y}\mathbb{I}_{\{\eta_{h-1}=\eta_{h-1}^n\}}\;\mathbb{E}^{\mathbb{Q}}\big[\,\big(\bar\lambda_1\big)^{\hat y_h-\hat y_{h-1}}\,\big]\max(\|p_0-p_0^n\|_\infty,\|\mu_1-\mu_1^n\|_\infty)/2\big]\\
&\le\mathbb{E}^{\mathbb{Q}}\big[\,\big(\bar\lambda_1\big)^{\hat y_{h-1}-y}\,\big]\mathbb{E}^{\mathbb{Q}}\big[\,\big(\bar\lambda_1\big)^{\hat y_h-\hat y_{h-1}}\,\big]J^n=\mathbb{E}^{\mathbb{Q}}\big[\,\big(\bar\lambda_1\big)^{\hat y_h-y}\,\big]\;J^n,
\end{aligned}$$

where in the last equality we have used the independence of the increments $\hat y_{h-1}-y$ and $\hat y_h-\hat y_{h-1}$ under $\mathbb{Q}$. □

THE VERIFICATION AND CONTROL OF INTERACTING SIMILAR DISCRETE-EVENT SYSTEMS*

KURT ROHLOFF† AND STÉPHANE LAFORTUNE‡

Abstract. This paper explore issues related to the control and verification of similar module systems in the discrete-event systems framework. Similar module systems are distributed systems comprised of subsystem modules that exhibit isomorphic local behavior coordinated on global event occurrences. When given a global model of these systems, it is shown how to decompose the global model into the component subsystems in polynomial time. It is also shown how to perform various verification tasks for these interacting systems while mitigating common state explosion difficulties by taking advantage of the special similar module system structure. Control properties of the similar module systems are also discussed. It is assumed that the local modules are supervised by exactly one local controller and the controllers enforce the same local control policy. Necessary and sufficient conditions for achieving local and global control specifications in this setting are identified.

Key words. control, discrete-event systems, isomorphic behavior, distributed systems

1. Introduction.

Many significant, real-world systems are comprised of concurrent processes that are most conveniently modeled in a distributed manner. The current standard methods for solving many important verification and control problems for these distributed systems typically involve converting the distributed system models into equivalent monolithic system models. Unfortunately, these monolithic system conversions are generally computationally expensive. This has prompted researchers to investigate solution methods for distributed system problems that avoid these procedures. However, it has been found that many of these important verification and control problems for distributed systems are still computationally intractable despite the avoidance of the monolithic conversions [8, 9, 14, 26, 28, 30].

This paper expands on prior investigations into the control of distributed systems by exploring the properties of these systems that can be modeled as a set of interacting discrete-event system modules, where the system module behaviors are identical with respect to a relabeling of local behavior. This class of distributed systems is referred to as the class of *similar module systems* and is formally defined below. For these systems, the behaviors of the modules are represented as languages over a set of events partitioned into private and global events generated by finite-state automata. All modules must coordinate their behavior on the occurrence of global events, while private events represent behavior that is relevant to only one module.

The similar module system model used in this paper is designed to be as general as possible in order for it to have wide applicability, yet still have computationally

reasonable solution methods for otherwise difficult verification and control problems. Consequently, many important real-world processes are included in the class of similar module systems that can be modeled in the framework discussed in this paper. Aspects of the behavior of systems such as communication networks, where the nodes are all running the same communication protocol, distributed sensor networks, and platoons of similar unmanned aerial vehicles, can all be effectively represented by similar module systems for the purpose of verification and control with respect to logical specifications. A number of biological processes can also be effectively represented by similar module systems [1, 21].

The work in this paper is presented using the framework of discrete-event systems and supervisory control theory surveyed in the seminal work [25]. The interested reader may consult the text [2] for a general introduction to this framework. The finite automaton modeling formalism used in this paper is generally considered to be the simplest one for discrete-event systems that is expressive enough to model the behavior of real-world systems in a reasonable manner. Furthermore, as the behavior of the similar module systems is coordinated on the occurrence of global events, an equivalent monolithic global system model of a set of interacting similar module systems is constructed by composing the similar module systems using the parallel composition operation. The parallel composition operation is currently the standard method for modeling the coordination of behavior of distributed discrete-event systems.

Because similar module systems exhibit behavior that is distinctly local and global, specifications on the behavior of similar modular systems can be made at both the global and local levels. Global specifications describe the desired behavior of a system when the modules in the similar module system interact. Local specifications describe the desired locally relevant behavior of a system module when it interacts with other modules. The global and local behavioral specifications used in the paper are specified as the languages marked by finite-state automata.

Properties related to the control of similar modular systems for both local and global specifications given as regular languages are explored when the desired behavior of the controlled similar module system should match the given specification. It is assumed that when the modules are controlled, they are controlled locally with exactly one controller per module such that the controllers make local observations of the behavior of a module and enforce local control actions. As with the system modules, the controllers are similar in that all controllers enforce the same control policy at each of their respective subsystems with respect to a renaming of the relevant local events. It is also assumed that there is no communication between controllers besides the implicit communication due to the occurrence of observable global events.

Beyond the introduction of the similar module systems, the main contributions of this paper include

- a polynomial time decomposition operation for converting a monolithic similar module system model into a more efficiently encoded distributed similar module system model.
- a quotient machine construction for more efficiently testing state reachability and other important properties of composed similar module systems that avoids expensive parallel composition operations.
- a polynomial time method for verifying local behavior specifications and a set of necessary and sufficient conditions for achieving local control objectives in similar module systems.

- a set of necessary and sufficient conditions for achieving global control objectives in similar module systems that implies a polynomial time method for synthesizing similar module systems which satisfy global control specifications.

The work in this paper generalizes and extends that in [27], which contains preliminary versions of some of the results presented herein. The extensions in this paper beyond those shown in [27] include the improved method for performing the verification of important system properties such as state reachability in similar module systems and the polynomial time decomposition operation for composed similar module systems.

The next section gives a survey of the literature relevant to the work presented in this paper. Section 3 introduces the system model along with the notation and basic system properties used in this paper. The quotient automaton is introduced in section 4 for decreasing the computational difficulty of testing state reachability, global nonblockingness, and deadlock-freeness in similar module systems. In section 5 the properties related to the verification of similar module systems for specifications made at local sites are discussed. Section 6 shows the computationally efficient method of decomposing global models of similar module systems into distributed models. The control formalisms used in this paper are presented section 7. Section 8 discusses properties related to the control of similar module systems for specifications made at the local sites, and the control of similar module systems for the satisfaction of global specifications is discussed in section 9. This paper concludes with a discussion of the results and possible avenues for future work in section 10.

2. Related literature survey. The supervision of modular discrete-event systems is currently receiving much attention in the control community; see, e.g., [3, 12, 13, 15, 16, 17, 19, 20, 22, 23, 31, 32, 33]. Some of the earlier results related to modular supervision are shown in [17, 19, 23, 31, 33]. Properties of modular discrete-event systems in which the modules have disjoint event sets are investigated in [22, 23]. Various local specification and concurrent supervision problems, respectively, are investigated in [12, 13]. Properties related to the supervision of modular systems using specific architectures are explored in [15, 16]. A form of modular control in which each controller has a different objective is discussed in [3], and situations when local nonblocking behavior implies global nonblocking behavior are discussed in [20].

Excluding [7, 27], there has been little work in the supervisory control community that exploits system symmetry when controlling discrete-event systems. Group-theoretic methods are used in [7] to define classes of states and transitions in monolithic system that are equivalent under predefined group-theoretic permutation operations. These classes of equivalent states and transitions are used to construct a quotient automaton that has a state space smaller than that of the original system, which is used to perform various centralized controller synthesis operations for the original system. Similar module systems are briefly discussed in [7] and the predefined quotient structure is extended to this setting. However, centralized control is discussed exclusively in [7]. A similar quotient automaton with predefined state equivalence classes is also discussed in [27] for similar module systems and is likewise based on state permutation equivalences.

A type of quotient automaton is presented below to test properties such as state reachability, nonblockingness, and deadlock-freeness that uses a much more efficient predefined state aggregation method for defining state equivalence classes than seen in [7, 27]. This results in a quotient automaton with a much smaller state space than the previously discussed quotient automata with predefined state equivalence classes.

Furthermore, necessary and sufficient conditions are discussed for the existence of decentralized controllers for these systems using both local and global specifications. This control setting is not discussed in [7].

The work in [7, 27] and this paper is inspired by an extensive literature from the formal methods community based on the uses of symmetry for performing model checking over large symmetric systems. Most of the current work in the formal methods community related to symmetry is based on methods presented in [5, 6]. Some of this work is also summarized in the text [4]. Due to the natural similarity of the supervisory control theory models used in this paper and the Kripke structure models used in the formal methods literature, results related to the verification of symmetric systems as presented in this literature are briefly discussed.

Group-theoretic methods and the quotient automaton structures for Kripke structures are presented in [5, 6]. These references present how various temporal logic properties can hold in the original system if and only if those properties hold in the quotient automaton. Defining effective state equivalence classes is computationally at least as difficult as the graph isomorphism problem [10]. This has induced several authors to attempt to design distributed systems with special architectures so that symmetry is guaranteed to occur a priori, as in [6, 7, 27] and this paper. Even when used with distributed systems, the symmetry reductions due to the construction of the quotient automata presented in [5, 6] do not alleviate the state-explosion problem in the worst case. However, several real-world examples are presented in [11], where the quotient models allow for an 80%–90% reduction in computation time and space for several important temporal logic verification problems.

There has also been work in the formal methods community on the use of partial order reductions for the verification of concurrent systems [4]. Although the reduction methods appear similar, partial order reduction methods are fundamentally different from the symmetry reduction methods discussed herein.

3. Similar module systems. As was stated in the introduction, the similar module systems are modeled as a set of finite automata $\{G_1, \ldots, G_n\}$ that interact on the occurrence of common global events. Furthermore, all of the modules in $\{G_1, \ldots, G_n\}$ are exact copies of one another with respect to a renaming of private events.

Let the automaton $G_i = (X, x_0, \Sigma_i, \delta_i, X_m)$ be the ith module in the system, where $i \in \{1, \ldots, n\}$. The module event set Σ_i is partitioned into the distinct subsets Σ_g and Σ_{pi}, the (unique) global event set and the private event set for module i, respectively. The private event sets $\Sigma_{p1}, \ldots, \Sigma_{pn}$ are copies of one another for $G_1, \ldots, G_n$, respectively, such that for all $i, j, i \neq j$, $\Sigma_{pi} \cap \Sigma_{pj} = \emptyset$. It is assumed that $\Sigma_g \cap \Sigma_{pi} = \emptyset$ and Σ denotes $\Sigma_1 \cup \cdots \cup \Sigma_n$.

For any local event $\sigma_i \in \Sigma_{pi}$ there are corresponding local events $\Psi_{i1}(\sigma_i) \in \Sigma_{p1}, \ldots, \Psi_{in}(\sigma_i) \in \Sigma_{pn}$ in the other private event sets. The one-to-one mapping $\Psi_{ij}(\cdot)$ is extended for notational simplicity in this setting to $\Psi_{ij} : \Sigma \to \Sigma$ so that the private event set of module i is mapped to the jth private event set, the private event set of module j is mapped to the ith private event set, and all other events are mapped to themselves. The function $\Psi_{ij}(\cdot)$ is extended in the usual manner to map between strings of events and languages. Note that $\Psi_{ii}(\cdot)$ is the identity function and $\Psi_{ii}(\cdot) = \Psi_{ij}(\Psi_{ij}(\cdot))$. As an example of the operation of the $\Psi_{ij}(\cdot)$ function, suppose there are system event sets $\Sigma_i = \{a_i, b_i, d, g\}$ and $\Sigma_j = \{a_j, b_j, d, g\}$. In this case $\Sigma_g = \{d, g\}$, $\Sigma_{p1} = \{a_i, b_i\}$, and $\Sigma_{p2} = \{a_j, b_j\}$. Then, $\Psi_{ij}(dga_ia_jb_jgb_i) = dga_ja_ib_igb_j$.

With the above framework, similar module systems can now be formally defined.

DEFINITION 1. *The set of modules* $\{G_1, \ldots, G_n\}$ *as described above is a similar module system if for all* $i, j \in \{1, \ldots, n\}$*, for all* $x \in X$ *and* $\gamma \in \Sigma_i$*,* $\delta_i(x, \gamma) = \delta_j(x, \Psi_{ij}(\gamma))$ *if it is defined.*

Example 1 shows a simple example of the systems discussed in this paper.

Example 1. Consider the 2 module similar module system composed of G_1 and G_2 seen in Figure 1. The relevant event sets are $\Sigma_g = \{\gamma, \lambda\}$, $\Sigma_{p1} = \{\alpha_1, \beta_1\}$, and $\Sigma_{p2} = \{\alpha_2, \beta_2\}$. Note that G_1 and G_2 are both locally nonblocking and deadlock free.

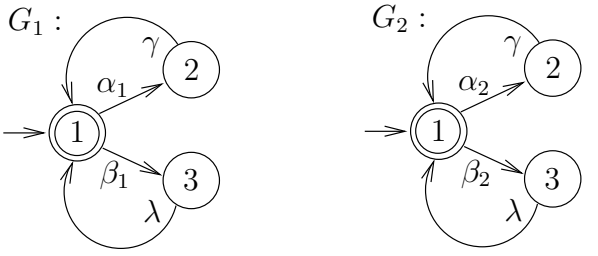

FIG. 1. *The automata* G_1 *and* G_2.

The natural projection $P_i : \Sigma^* \to \Sigma_i^*$ is defined such that $P_i(s)$ is the string s with events in $\Sigma \setminus \Sigma_i$ erased. Similarly, let $P_{pi} : \Sigma^* \to \Sigma_{pi}^*$ be the natural projection that erases events in $\Sigma \setminus \Sigma_{pi}$, and let $P_g : \Sigma^* \to \Sigma_g^*$ be the natural projection that erases events in $\Sigma \setminus \Sigma_g$.

The automata $\{G_1, \ldots, G_n\}$ model the private behaviors of the modules of the similar module system, but the parallel composition $G_1 \| \cdots \| G_n$ is used to model the global behavior of all the interacting subsystems. The behavior of the composed automaton $G_1 \| \cdots \| G_n$ is equivalent to the concurrent behavior of the modules $\{G_1, \ldots, G_n\}$, where the local behaviors of $\{G_1, \ldots, G_n\}$ are coordinated on the occurrence of common global events in Σ_g.

To review the parallel composition operation, suppose the automata G_1 and G_2 are given. The parallel composition of G_1 and G_2, denoted by $G_1 \| G_2$, is defined as follows:

$$G_1 \| G_2 := ((X \times X), (x_o, x_o), \Sigma_1 \cup \Sigma_2, \delta^{G_1 \| G_2}, (X_m \times X_m)),$$

where

(1)

$$\delta^{G_1 \| G_2}((x^{G_1}, x^{G_2}), \sigma) = \begin{cases} (\delta_1(x^{G_1}, \sigma), \delta_2(x^{G_2}, \sigma)) & \text{if } \delta_1(x^{G_1}, \sigma)! \wedge \delta_2(x^{G_2}, \sigma)! \\ (\delta_1(x^{G_1}, \sigma), x^{G_2}) & \text{if } \delta_1(x^{G_1}, \sigma)! \wedge (\sigma \notin \Sigma_2) \\ (x^{G_1}, \delta_2(x^{G_2}, \sigma)) & \text{if } \delta_2(x^{G_2}, \sigma)! \wedge (\sigma \notin \Sigma_1) \\ \text{undefined} & \text{otherwise} \end{cases}.$$

Note that the unary operator ! is used such that $f(\alpha)!$ returns true if $f(\cdot)$ is defined for input α, but false otherwise. The parallel composition $G_1 \| G_2$ is also defined in [2] for the case where G_1 and G_2 are not similar module systems.

Example 2 shows the automaton $G_1 \| G_2$ constructed from the automata in Example 1.

Example 2. Consider the composed system $G_1 \| G_2$ as seen in Figure 2.

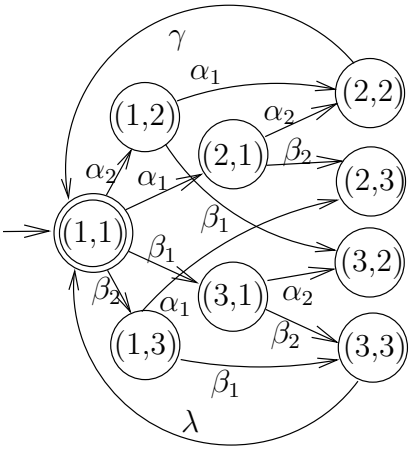

FIG. 2. *The automaton* $G_1 \| G_2$.

The automaton $G_1 \| G_2$ has a large degree of state-based symmetry due to the similarity of the component automata G_1 and G_2. Consider for instance the states $(1,2)$ and $(2,1)$; these states are reached by the occurrence of α_2 and α_1 events, respectively.

Now consider the states $(2,3)$ and $(3,2)$. The state $(2,3)$ can be reached from $(1,1)$ on the occurrence of either $\alpha_1\beta_2$ or $\beta_2\alpha_1$. The state $(3,2)$ can be reached from $(1,1)$ on the occurrence of either $\alpha_2\beta_1$ or $\beta_1\alpha_2$. Notice that if the subscript labels of the events in the strings leading to state $(2,3)$ are swapped, then the resulting string leads to state $(3,2)$.

This is a symptom of properties inherent to similar module systems such that many properties of state $(2,3)$ are also held in a sense by state $(3,2)$. For this similar module system the swapping of event subscript labels is equivalent to reordering the parallel composition of the component automata by swapping state locations. This operation is valid because the parallel composition operation is commutative and therefore the order of parallel composition is arbitrary. The various similar modules are identical with respect to a renaming of private events.

For $G_1 \| G_2$ there are six classes of states that could be considered equivalent with respect to a reordering of the component states. The six sets of equivalent state classes are

$$\{(1,1)\}, \{(1,2),(2,1)\}, \{(1,3),(3,1)\}, \{(2,2)\}, \{(2,3),(3,2)\}, \{(3,3)\}.$$

It is now shown that $P_i\left(\mathcal{L}_m(G_1 \| \cdots \| G_n)\right)$, the local behavior relevant to module i of the interacting modules, is language equivalent to the local behavior of module i when the modules operate in isolation (i.e., $\mathcal{L}_m(G_i)$).

THEOREM 1. *For a similar module system* $\{G_1, \ldots, G_n\}$ *as introduced above with respective local projection operations* $\{P_1, \ldots, P_n\}$ *and for* $i \in \{1, \ldots, n\}$,

$$P_i\left(\mathcal{L}_m(G_1 \| \cdots \| G_n)\right) = \mathcal{L}_m(G_i).$$

Proof. It is known that

$$\mathcal{L}_m(G_1 \| \cdots \| G_n) = \left[P_1^{-1}(\mathcal{L}_m(G_1)) \cap \cdots \cap P_n^{-1}(\mathcal{L}_m(G_n))\right],$$

and thus it is sufficient to show that $\left[P_i\left[P_1^{-1}(\mathcal{L}_m(G_1)) \cap \cdots \cap P_n^{-1}(\mathcal{L}_m(G_n))\right] = \mathcal{L}_m(G_i)\right]$.

This proof is composed of two parts.
It is known that $P_1^{-1}(\mathcal{L}_m(G_1)) \cap \cdots \cap P_n^{-1}(\mathcal{L}_m(G_n)) \subseteq P_i^{-1}(\mathcal{L}_m(G_i))$.
This implies that $P_i\left[P_1^{-1}(\mathcal{L}_m(G_1)) \cap \cdots \cap P_n^{-1}(\mathcal{L}_m(G_n))\right] \subseteq P_i\left[P_i^{-1}(\mathcal{L}_m(G_i))\right]$.
For any language K it is known that $P_i\left[P_i^{-1}(K)\right] = K$, and thus
$P_i\left[P_1^{-1}(\mathcal{L}_m(G_1)) \cap \cdots \cap P_n^{-1}(\mathcal{L}_m(G_n))\right] \subseteq \mathcal{L}_m(G_i)$
$\Rightarrow P_i(\mathcal{L}_m(G_1 \| \cdots \| G_n)) \subseteq \mathcal{L}_m(G_i)$.
The other direction is proved by showing
$(t_i \in \mathcal{L}_m(G_i)) \Rightarrow \left(t_i \in P_i\left[\cap_{j=1}^n P_j^{-1}(\mathcal{L}_m(G_j))\right]\right)$.

Let $t_i \in \mathcal{L}_m(G_i)$. This implies that $t_i \in P_i(P_i^{-1}(\mathcal{L}_m(G_i)))$. Let the string $t_{\{1,\ldots,n\}}$ be a copy of t_i except that occurrences of all private events $\sigma_{pi} \in \Sigma_{pi}$ in t_i are replaced with the string of events $\sigma_{p1}\Psi_{12}(\sigma_{p1}), \ldots, \Psi_{1n}(\sigma_{p1})$. Due to the construction of $\{G_1, \ldots, G_n\}$, $t_{\{1,\ldots,n\}} \in P_j^{-1}(\mathcal{L}_m(G_j))$ for all $j \in \{1, \ldots, n\}$. Thus,

$\forall j \in \{1, \ldots, n\}\ t_{\{1,\ldots,n\}} \in P_j^{-1}(\mathcal{L}_m(G_j))$
$\Rightarrow t_{\{1,\ldots,n\}} \in \left(\cap_{j=1}^n P_j^{-1}(\mathcal{L}_m(G_j))\right)$.
$\Rightarrow t_i \in P_i\left[\cap_{j=1}^n P_j^{-1}(\mathcal{L}_m(G_j))\right]$.
Therefore, $\mathcal{L}_m(G_i) \subseteq P_i\left[\cap_{j=1}^n P_j^{-1}(\mathcal{L}_m(G_j))\right]$ which implies

$$\mathcal{L}_m(G_i) \subseteq P_i\left(\mathcal{L}_m(G_1 \| \cdots \| G_n)\right). \qquad \square$$

It is a simple matter to extend the result in Theorem 1 to the case of languages generated instead of languages marked, i.e.,

$$P_i\left[P_1^{-1}(\mathcal{L}(G_1)) \cap \cdots \cap P_n^{-1}(\mathcal{L}(G_n))\right] = \mathcal{L}(G_i).$$

Some basic properties of distributed discrete-event systems are now presented.

DEFINITION 2 (see [31]). *A language $K \subseteq \Sigma^*$ is* separable *with respect to the projections $\{P_1, \ldots, P_n\}$ if $K = P_1^{-1}(P_1(K)) \cap \cdots \cap P_n^{-1}(P_n(K))$.*

According to the above definition, a language is separable if, with distributed local knowledge of K at all modules, i.e., $P_1(K), \ldots, P_n(K)$, the language K can be recovered exactly through combining all local knowledge as follows: $P_1^{-1}(P_1(K)) \cap \cdots \cap P_n^{-1}(P_n(K))$. Note that in [29] a concept similar to separability, called decomposability, is defined where a language $K \subseteq \Sigma^*$ is decomposable with respect to the set of projections $\{P_1, \ldots, P_n\}$ and the automaton G if $K = P_1^{-1}(P_1(K)) \cap \cdots \cap P_n^{-1}(P_n(K)) \cap \mathcal{L}(G)$.

In general the current known methods for testing a language for separability take exponential time. These methods compute automata $\{B_1, \ldots, B_n\}$ such that for all $i \in \{1, \ldots, n\}$, $\mathcal{L}(B_i) = P_i^{-1}(P_i(K))$ and then test to see if $K = \mathcal{L}(B_1 \| \cdots \| B_n)$.

DEFINITION 3 (see [33]). *The languages in the set $\{L_1, \ldots, L_n\}$ are called* nonconflicting *if*

$$\overline{L_1 \cap \cdots \cap L_n} = \overline{L_1} \cap \cdots \cap \overline{L_n}.$$

It is known that the parallel composition of a set of nonblocking automata need not be nonblocking unless the respective languages marked by the automata are nonconflicting.

DEFINITION 4. *A language $K \subseteq \Sigma^*$ is* symmetric *with respect to the mappings $\Psi_{11}, \ldots, \Psi_{1n}$ if for all $i \in \{1, \ldots, n\}$, $\Psi_{1i}(K) = K$.*

A language marked by a deterministic automaton B can be generally tested for symmetry in linear time. To do this, for all $i \in \{1, \ldots, n\}$, construct B_{1i} such that $\mathcal{L}(B_{1i}) = \Psi_{1i}(\mathcal{L}(B))$. This can be done by replacing the event labels on the state

transitions in B according to the $\Psi_{1i}(\cdot)$ function and can be performed in linear time. Then, if for all $i \in \{1, \ldots, n\}$, $\mathcal{L}(B_{1i}) = \mathcal{L}(B)$, then by definition $\mathcal{L}(B)$ is symmetric. Note that the language equivalence of deterministic automata can be tested in linear time using standard methods.

The symmetry definition is used to convey the intuition that K is identical with respect to a relabeling of private events for the similar module system $\{G_1, \ldots, G_n\}$. This prompts the following lemmas, whose proofs are straightforward and therefore omitted.
